ADSP-SC57x Register List

Preface

Thank you for purchasing and developing systems using an ADSP-SC57x SHARC+® processor from Analog Devices, Inc.

Purpose of This Manual

The ***ADSP-SC57x SHARC Processor Hardware Reference*** provides architectural information about the ADSP-SC57x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support. For information about programming the ARM core in the ADSP-SC57x processor, visit the ARM Information Center at:

http://infocenter.arm.com.

For timing, electrical, and package specifications, see the processor data sheet.

Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices processors. The manual assumes the audience has a working knowledge of the appropriate processor architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as programming reference books and data sheets, that describe their target architecture.

What's New in This Manual

This revision (1.1) of the *ADSP-SC57x SHARC+ Processor Hardware Reference* has the following changes from the previous version:

- Removed the SMC chapter and all corresponding references
- DMA - updated the Memory DMA and Triggering topic
- SCB - corrected Group A and Group C text and QOS Register table in the SCB Programming Concepts topic.
- Made the SWU_CTL.LCMPEN bit private
- Updated the maximum window size in the IIR Programming Model topic
- Updated SPI Master Boot BCODE Descriptions in the SPI Master Boot Mode topic
- Updated *Pin Buffer as Input* figure in the Pin Buffers as Signal Input topic
- Added TMU Calibration topic

- Updated CGU_PLLCTL bit descriptions

Technical or Customer Support

You can reach customer and technical support for processors from Analog Devices in the following ways:

- Post your questions in the processors and DSP support community at ***EngineerZone***®:

  http://ez.analog.com/community/dsp
- Submit your questions to technical support at ***Connect with ADI Specialists***:

  http://www.analog.com/support
- E-mail your questions about software/hardware development tools to:

  processor.tools.support@analog.com
- E-mail your questions about processors and DSPs to:

  processor.support@analog.com (world wide support)

  processor.china@analog.com (China support)
- Contact your Analog Devices sales office or authorized distributor. Locate one at:

  http://www.analog.com/adi-sales
- Send questions by mail to:

  Analog Devices, Inc.

  Three Technology Way

  P.O. Box 9106

  Norwood, MA 02062-9106 USA

Product Information

Product information can be obtained from the Analog Devices Web site and CrossCore Embedded Studio® (CCES) online Help system.

Analog Devices Web Site

The Analog Devices Web site, http://www.analog.com, provides information about a broad range of products—analog integrated circuits, amplifiers, converters, and digital signal processors.

To access a complete technical library for each processor family, go to: http://www.analog.com/processors/technical_library The manuals selection opens a list of current manuals related to the product as well as a link to the previous revisions of the manuals. When locating your manual title, note a possible errata check mark next to the title that leads to the current correction report against the manual.

Also note, MyAnalog.com is a free feature of the Analog Devices Web site that allows customization of a Web page to display only the latest information about products you are interested in. You can choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. MyAnalog.com provides access to books, application notes, data sheets, code examples, and more.

Visit MyAnalog.com to sign up. If you are a registered user, just log on. Your user name is your e-mail address.

EngineerZone

EngineerZone is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your embedded processing and DSP design questions.

Use EngineerZone to connect with other DSP developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit http://ez.analog.com to sign up.

Supported Processors

The following is the list of Analog Devices, Inc. processors supported by the CCES development tools suite.

Blackfin+® (ADSP-BF7xx) Processors

The name *Blackfin+* refers to the enhanced fixed-point Blackfin core architecture featured by the ADSP-BF70x processor product line, which is a family of 16-bit embedded processors.

Blackfin® (ADSP-BF6xx/BF5xx) Processors

The name *Blackfin* refers to the fixed-point core architecture featured on the following processors: ADSP-BF5xx and ADSP-BF6xx.

SHARC® (ADSP-21xxx) Processors

The name *SHARC* refers to the high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-2116x, ADSP-2126x, ADSP-213xx, and ADSP-214xx. These processors can be used in speech, sound, graphics, and imaging applications.

SHARC+® (ADSP-SC5xx, ADSP-215xx) Processors

The name *SHARC+* refers to the enhanced high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-215xx/ADSP-SC5xx. The connected SHARC+ ADSP-SC5xx processors

also contain an ARM® Cortex®-A5 core. These products can be used in speech, sound, graphics, and imaging applications.

The following is the list of Analog Devices, Inc. processors supported by the IAR Embedded WorkBench® development tools. For information about the IAR Embedded WorkBench product and software download, go to http://www.iar.com/en/Products/IAR-Embedded-Workbench .

Mixed-Signal Control Processors

The ADSP-CM40x processors are based on the ARM Cortex-M4 core and are designed for motor control and industrial applications.

The ADSP-CM41x processors are based on the ARM Cortex-M4 and ARM Cortex-M0 cores and are designed for motor control and industrial applications.

Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

Example	Description
File > ***Close***	Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the ***Close*** command appears on the ***File*** menu).
`{this | that}`	Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as `this` or `that`. One or the other is required.
`[this | that]`	Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional `this` or `that`.
`[this, …]`	Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of `this`.
`.SECTION`	Commands, directives, keywords, and feature names are in text with `Letter Gothic` font.
`filename`	Non-keyword placeholders appear in text with italic style format.
NOTE:	***NOTE:*** For correct operation, ... A note provides supplementary information on a related topic. In the online version of this book, the word ***NOTE:*** appears instead of this symbol.

Example	Description
CAUTION:	*CAUTION:* Incorrect device operation may result if ... *CAUTION:* Device damage may result if ... A caution identifies conditions or inappropriate usage of the product that could lead to undesirable results or product damage. In the online version of this book, the word *CAUTION:* appears instead of this symbol.
ATTENTION:	*ATTENTION:* Injury to device users may result if ... A warning identifies conditions or inappropriate usage of the product that could lead to conditions that are potentially hazardous for devices users. In the online version of this book, the word *ATTENTION:* appears instead of this symbol.
Registers/Bits	All registers and bits in this manual are linked (clickable) to their respective descriptions in the "Register Descriptions" of each chapter.
Miscellaneous Conventions	Interrupt and internal signals are shown in all caps with no other formatting. For example the SPDIFn_RX or SCLK signal or the PKTE0_IRQ interrupt. An overbar denotes an active-low signal as in $\overline{\text{SYS\_FAULT}}$.

Register Documentation Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.
- Bits marked *X* have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved

NOTE: To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

Register description tables use the following conventions:

- Each bit's or bit field's access type appears beneath the bit number in the table in the form (read-access/write-access). The access types include:
  - R = read, RC = read clear, RS = read set, R0 = read zero, R1 = read one, Rx = read undefined
  - W = write, NW = no write, W1C = write one to clear, W1S = write one to set, W0C = write zero to clear, W0S = write zero to set, WS = write to set, WC = write to clear, W1A = write one action
- Many bit and bit field descriptions include enumerations, identifying bit values and related functionality. Unless otherwise indicated (with a prefix), these enumerations are decimal values.

1 ARM Cortex-A5 Sub-System

The ADSP-SC57x processor includes an ARM® Cortex-A5® core. The ARM Cortex-A5 processor is the smallest, lowest cost and lowest power ARMv7 application processor. The A5 sub-system in the ADSP-SC57xprocessor includes a Floating-Point Unit, NEON Media Processing Engine, Generic Interrupt Controller and a Level 2 Cache Controller. The A5 also includes support for a L1-Cache sub-system and a full-fledged Memory Management Unit. The A5 implements the ARMv7 architecture and runs 32-bit ARM instructions, 16-bit and 32-bit Thumb instructions, and 8-bit Java byte-codes in Jazelle state.

This document describes the ARM Cortex-A5 core and memory architecture used on the ADSP-SC57x processor, but does not provide detailed programming information for the ARM processor. For more information about programming the ARM processor, visit the ARM Information Center:

- http://infocenter.arm.com.

The applicable documentation for programming the ARM Cortex-A5 processor include:

- Cortex-A5 Technical Reference Manual, Revision: r0p1
- Cortex-A Series Programmer's Guide, Revision: r0p1
- Cortex-A5 NEON Media Processing Engine Technical Reference Manual, Revision: r0p1
- Cortex-A5 Floating-Point Unit Technical Reference Manual, Revision: r0p1
- CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision: r3p3
- PrimeCell Generic Interrupt Controller (PL390) Technical Reference Manual, Revision: r0p0

Cortex A5 Features

The Cortex-A5 Sub-system has the following features.

- Thumb / ARM Instruction support
- L1- Instruction Cache and L1-Data Cache
- Floating Point Unit (FPU)
- NEON Media Processing Engine (NEON)

- Generic Interrupt Controller (GIC)
- Level 2 Cache Controller (L2CC)
- Memory Management Unit (MMU)

Functional Description

The following sections provide information on the function of the sub-system.

A5 Block Diagram

The following figure shows the primary blocks of the Cortex A5 sub-system. The performance increases with accesses to lower levels of memory as follows:

1. Level 1 – cache on-chip, separate data/code (highest)
2. Level 2 – cache on-chip, unified
3. Level 3 – memory external, (lowest)

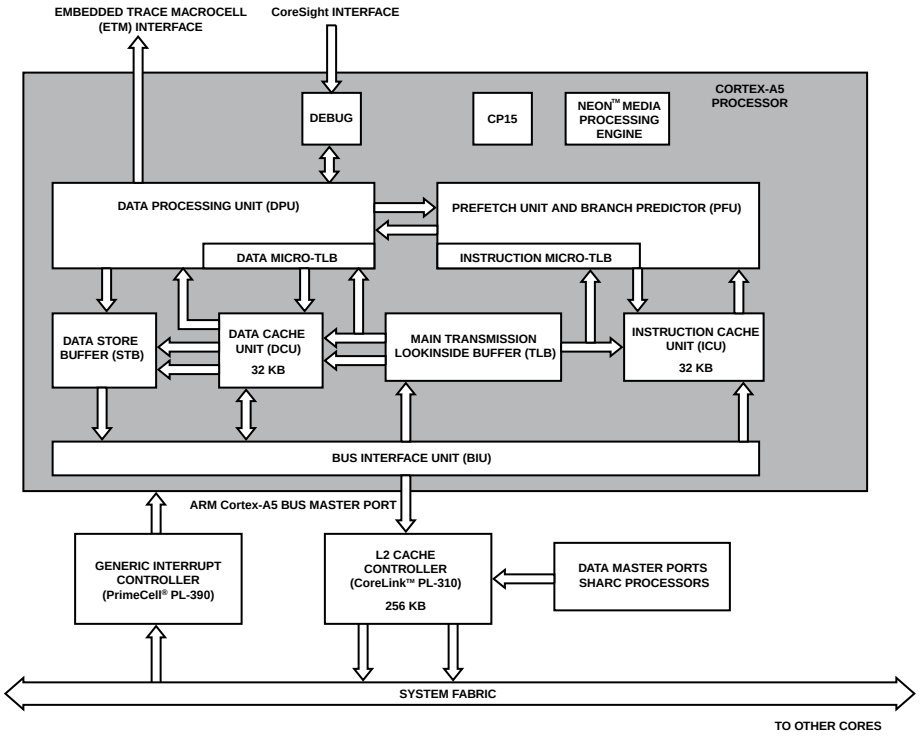

Figure 1-1: A5 Sub-System Block Diagram

Control Co-Processor (CP15)

The system control co-processor, CP15, controls and provides status information for the functions implemented in the processor. The main functions of the system control co processor are:

- Overall system control and configuration
- MMU configuration and management
- Cache configuration and management
- System performance monitoring

All system architecture functions are controlled by reading or writing a general purpose processor register (Rt) from or to a set of registers (CRn) located within co-processor 15. The Op1, Op2, and CRm fields of the instruction can also be used to select registers or operations.

- MRC p15, Op1, Rt, CRn, CRm, Op2; read a CP15 register into an ARM register
- MCR p15, Op1, Rt, CRn, CRm, Op2; write a CP15 register from an ARM register

L1 Cache

The Cortex-A5 processor has separate instruction and data caches that run at ARM Core clock speed. The caches have the following features:

- L1-Data Cache size 32 KB
- L1-Instruction Cache size 32 KB
- Each cache can be disabled independently, using the system control coprocessor
- Cache replacement policy is pseudo random
- Data cache is 4-way set-associative
- Instruction cache is 2-way set-associative
- The cache line length is eight words.
- On a cache miss, critical word first filling of the cache is performed.

Prefetch Unit (PFU)

The PFU implements a two-level prediction mechanism, comprising the following:

- A 256 entry branch pattern history table
- A four-entry BTAC
- A four-entry return stack

Memory-Management Unit (MMU)

The ARM MMU is responsible for translating addresses of code and data from the virtual view of memory to the physical addresses in the real system. The translation is carried out by the MMU hardware and is transparent to the application. In addition, the MMU controls such things as memory access permissions, memory ordering and cache policies for each region of memory.

The MMU enables tasks or applications to be written in a way that requires them to have no knowledge of the physical memory map of the system, or about other programs that might be running simultaneously. This enables you to use the same virtual memory address space for each program. It also lets you work with a contiguous virtual memory map, even if the physical memory is fragmented. This virtual address space is separate from the actual physical map of memory in the system. Applications are written, compiled and linked to run in the virtual memory space. Virtual addresses are those used by you, and the compiler and linker, when placing code in memory. Physical addresses are those used by the actual hardware system.

The first level MMU uses a Harvard design with separate micro TLB structures in the PFU for instruction fetches and in the DPU for data read and write requests. A miss in the micro TLB results in a request to the main unified TLB shared between the data and instruction sides of the memory system. The TLB consists of a 128-entry two-way set-associative RAM based structure. The TLB page-walk mechanism supports page descriptors held in the L1 data cache. The caching of page descriptors is configured globally for each translation table base register, TTBRx, in the system coprocessor, CP15.

Page table entries support:

- 16 MB super sections
- 1 MB sections
- 64 KB large pages
- 4 KB small pages

NOTE: Virtual Memory translation tables are typically created by operating systems, and are often dynamically managed by the memory management layer. However, even a bare metal system can enable the MMU. For this, a flat mapping technique is used, where all virtual memory addresses shall be programmed exactly same as the physical memory addresses in the system.

NOTE: In order to utilize L1-Data Cache, application has to enable the MMU, via Co-Processor 15 in the ARM Core. After MMU and L1-Data Cache are enabled via CP15: SCTLR, application can disable / enable cache for individual pages / sections.

L2 Cache

The Level 2 Cache Controller in the ADSP-SC589 is a CoreLink Level 2 Cache Controller (L2C-310) from ARM and is clocked at SYSCLK speed. The addition of an on-chip secondary cache, also referred to as a Level 2 or L2 cache, is a recognized method of improving the performance of ARM-based systems when significant memory traffic is generated by the processor. By definition a secondary cache assumes the presence of a Level 1 or primary cache, closely coupled or internal to the processor. The cache controller is a unified, physically addressed, physically tagged cache. It includes the following features:

- 256 KB total size
- Lockdown by Line / Way / Master
- Fixed line length of 32 bytes, eight words or 256 bits

- Direct mapped to 8-way associativity (fixed)
- Prefetching capability
- Event monitoring
- Software option to enable exclusive cache configuration
- Additional Buffers:
  - Line Fill Buffers (LFBs)
  - Line Read Buffers (LRBs)
  - Eviction Buffers (EBs)
  - Store Buffers (STBs)
- TrustZone support, with the following features:
  - Non-Secure (NS) tag bit added in tag RAM and used for lookup in the same way as an address bit. The NS-tag bit is added in all buffers.
  - NS bit in Tag RAM used to determine security level of evictions to L3.
  - Restrictions for NS accesses for control, configuration, and maintenance registers to restrict access to secure data.
- Parity Support

NOTE: The L2CC Address Filtering registers should not be programmed by user. Not retaining the reset values can give unpredictable results.

Sharing L2 Cache with SHARC+ Cores

The L2CC (PL310) supports two master and two slave ports. The SHARC+ core can access the L2-Cache without bank conflict versus the Cortex A5 core by programming the L2CC registers. The cache access is restricted to the address range: from `CMMR_L2CC_START` [31:0] to `CMMR_L2CC_END` [31:0]. For more information, see the SHARC+ Core Programming Reference.

NOTE: There is no guarantee for the data coherency between A5 and SHARC+ cores.

NOTE: Programs should perform L2 cache write-back invalidation before changing the value of `CMMR_L2CC_START` and `CMMR_L2CC_END`.

Floating-Point Unit (FPU)

The Cortex-A5 FPU is a VFPv4-D16 implementation of the ARMv7 floating-point architecture. It provides low-cost high performance floating-point computation. The FPU supports all addressing modes and operations described in the *ARM Architecture Reference Manual*.

The features in the FPU are as follows.

- Support for single-precision and double-precision floating-point formats
- Support for conversion between half-precision and single-precision
- Support for Fused Multiply Accumulate (FMA) operations
- Normalized and de-normalized data are all handled in hardware
- Trap-less operation enabling fast execution

NeON

The Cortex-A5 NEON MPE extends the Cortex-A5 functionality to provide support for the ARM v7 Advanced SIMD v2 and Vector Floating-Point v4 (VFPv4) instruction sets. The Cortex-A5 NEON MPE supports all addressing modes and data-processing operations described in the *ARM Architecture Reference Manual*.

The Cortex-A5 NEON MPE features are:

- SIMD and scalar single-precision floating-point computation
- scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- SIMD 8, 16, 32, and 64-bit signed and unsigned integer computation
- 8 or 16-bit polynomial computation for single-bit coefficients
- structured data load capabilities
- Large, shared register file, addressable as:
    - 32 32-bit S (single) registers
    - 32 64-bit D (double) registers
    - 16 128-bit Q (quad) registers
- The operations include:
    - Addition and subtraction
    - Multiplication with optional accumulation
    - Maximum or minimum value driven lane selection operations
    - Inverse square-root approximation
    - Comprehensive data-structure load instructions, including register-bank-resident table lookup

See the *ARM Architecture Reference Manual* for details of the extension register set.

Generic Interrupt Controller (GIC)

The GIC is an ARM Architecture compliant System-on-Chip (SoC) peripheral. It is a high-performance, area-optimized interrupt controller. The GIC implements the ARM Generic Interrupt Controller Architecture. The GIC takes interrupts asserted at the system level and signals them to each connected processor as appropriate. The GIC has the following features.

- Registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors
- Support for the ARM architecture Security Extensions
- Support for enabling, disabling, and generating processor interrupts from hardware (peripheral) interrupt sources
- Support for generating software interrupts
- Support for interrupt masking and prioritization

Refer to GIC Overview for more information on the ADSP-SC57x specific configuration of GIC.

A5 Configurations

The following are the Cortex A5 and ADSP-SC57x configurations.

A5 Configurations

Table 1-1: A5 Core Configuration

Core Feature	Comment
JAZELLE Support	Implemented
NEON Engine	Implemented
FPU	Implemented
Instruction cache size	32 KB
Data cache size	32 KB

A5 Configuration Signals

Table 1-2: A5 Configuration Signals

Configuration	A5 TRM Signal Name	Comment
Default Exception Handler Endianness	CFGEND	Little Endian
CPU ID field	CLUSTERID[3:0]	4'b0000
Disable Write access to some CP15 registers	CP15SDISABLE	Not Enabled
Default exception handling state	TEINIT	ARM Mode
Exception vectors' location at reset	VINITHI	start exception vectors at address 0x00000000

Table 1-2: A5 Configuration Signals (Continued)

Configuration	A5 TRM Signal Name	Comment
Disable invalidate entire data cache, instruction cache and TLB at reset	L1RSTDISABLE	Disabled
Enable the RAM interface clamps	CPURAMCLAMP	clamps not active

A5 Power Modes

Table 1-3: ARM Core Power Modes

Mode	Comment
Run mode	Supported
Standby mode	Supported
Dormant mode	Not Supported
Shutdown mode	Not Supported

L2CC Configuration Signals

Table 1-4: L2CC Configuration Signals

Configuration	L2CC TRM Signal Name	Comment
Associativity	ASSOCIATIVITY	8-Way
Cache controller cache ID	CACHEID[5:0]	0
Address filtering Enable out of reset	CFGADDRFILTEN	Enabled
Address filtering End Address out of reset	CFGADDRFILTEND[11:0]	0xFFF
Address filtering Start Address out of reset	CFGADDRFILTSTART[11:0]	0x201
Endian mode for accessing configuration registers out of reset	CFGBIGEND	Little-endian
Base address for accessing configuration registers	REGFILEBASE[19:0]	0x10000
Size of ways	WAYSIZE[2:0]	32 KB

L2CC Power Down Modes

Table 1-5: L2CC Power Down Modes

Mode	Comment
Run mode	Supported
Dynamic Clock Gating	Supported
Standby mode	Not Supported
Dormant mode	Not Supported

Table 1-5: L2CC Power Down Modes (Continued)

Mode	Comment
Shutdown mode	Not Supported

L2CC Configuration

Table 1-6: L2CC Configuration

Feature	Comment
Cache way size	32 KB
Associativity	8 Ways
Default RAM latencies	2 cycles
DATA RAM banking	Disabled
Slave port 1 present	Enabled
Master port 1 present	Enabled
Parity logic	Enabled
Lock down by master	Enabled
Lock down by line	Enabled
Address filtering	Enabled
Speculative reading	Disabled

2 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a master clock that runs at a frequency that is a multiple of the CLKIN input clock frequency. The PCU divides down the master clock to generate various system clocks and synchronization signals.

CGU Features

The CGU module supports the following features:

- Provides smooth transitions from the current clock condition to a new condition with PLL logic and executes the changes to clocks due to register programming.
- Provides PLL and clock domain status reporting for event management.
- Supports the capability to bypass the PLL for power savings.
- Software controlled dynamic power management allows control of the core clock frequency (f_{CCLK}).
- Controls clock gating of the core and system clocks.

NOTE: For more information about processor-specific CGU features, see the processor data sheet.

CGU Functional Description

The CGU generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers. The CGU provides the following functionality.

Change the PLL Clock Frequency

The CGU allows programs to change the PLL clock frequency by writing new values to bits in the control register. Any time the PLL relocks, the CGU aligns all core and system clocks.

Change Other Clock Frequencies

The CGU allows programs to change the CCLKn, SYSCLK, SCLKn, DCLK, and OCLK frequencies by writing values to the CGU_DIV register. Any time the clock frequency is changed, the OCLK, CCLKn, SYSCLK, DCLK, and SCLKn clocks exit the frequency change sequence aligned.

Perform Clock Alignment

The CGU can align all clocks by writing to the CGU_DIV register. This function aligns all PLL-based clocks.

For more information on these functions, see the CGU Programming Model section.

ADSP-SC57x CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

Table 2-1: ADSP-SC57x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

ADSP-SC57x CGU Interrupt List

Table 2-2: ADSP-SC57x CGU Interrupt List

Trigger ID	Name	Description	Sensitivity
None			

CGU Definitions

DPM

The Dynamic Power Management module (DPM) works with the CGU to provide flexible power dissipation modes for the processor.

PCU

The PLL control unit (PCU) in the CGU controls PLL operations. The MMR registers of the CGU are implemented in the PCU.

PLL

The phase-locked loop (PLL) operates within the CGU.

RCU

The reset control unit (RCU) provides input to the CGU to manage clocks during processor reset.

CDU

The clock distribution unit distributes the clocks from the CGU to different clock domains

CGU

The clock generation unit (CGU) is comprised of the PLL and PCU. The CGU generates the clocks listed in the ***Clock Descriptions*** table.

Table 2-5: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK1_1	CCLK1 derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1

CGU PLL Block Diagram

The ***CGU PLL Block Diagram*** provides a top-level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase/frequency detector (PFD), the charge pump, the loop filter and the voltage controlled oscillator (VCO). The VCO multiplies the `SYS_CLKIN0` input to a higher frequency.

Additional configuration options are configured using the Clock Distribution Unit.

NOTE: The processor supports two PLLs (CGU1–0), see the ***CDU Block Diagram*** figure in the Clock Distribution (CDU) chapter. Configuring CGU0 is mandatory as it provides the SYSCLK to the system fabric and SCLK0–1 to various peripherals.

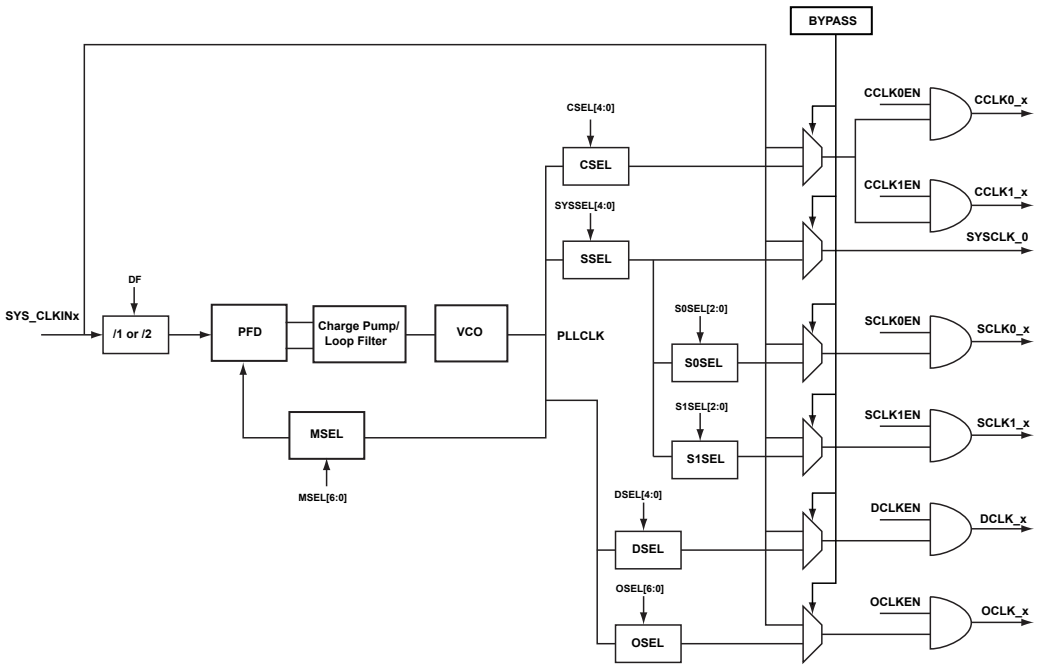

Figure 2-1: CGU0 PLL Block Diagram

CGU Operating Modes

The CGU does not have configurable operating modes, but CGU operations affect the operating modes of other modules. Some CGU operation issues that affect operation of other modules include the following:

- The PLL of the CGU operates in either normal mode (CGU clock divisors applied) or bypass mode (CGU PLL is bypassed and clock divisors ignored).
- The SCB uses the CGU for clock synchronization across clock domains. For more information, see System Crossbars (SCB).
- The DPM uses the CGU for clock management as power state transitions occur. For more information, see the Dynamic Power Management (DPM) chapter.
- The CGU uses clock gating control to obtain flexible low-power modes.

CGU Power-up Sequence

See the product data sheet for exact power-up requirements. The processor is configured to come up in clock bypass mode. The programs is required to configure full speed clocks and safety monitors. CLKIN0 and all supplies should be stable before the $\overline{\texttt{SYS\_HWRST}}$ signal is deasserted.

CGU Event Control

The CGU generates an event or error for several different reasons. Events and errors are described in the following sections.

Events

After a frequency change, a CGU event indicates that the PLL has locked and clocks are synchronized. If a core was idled while changing frequencies, the CGU can use an event interrupt to break the core idle. While in active mode, a CGU event indicates that the PLL has locked.

CGU Errors

A CGU error occurs under following conditions:

- A write access to the CGU_DIV register triggers an alignment sequence while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV register.

- A change to the CGU_DIV register occurs while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV register.

- A write access to the CGU_CTL.DF bit field occurs or a write access to the CGU_CTL.MSEL bit field occurs while the PLL is locking.

  The CGU_STAT.WDFMSERR bit state indicates this error. If this error occurs, wait until the PLL has finished locking, clear the error, and rewrite the desired value change.

- A clock divisor value error occurs when the *CCLK* divisor is greater than the *SYSCLK* divisor. For example, the CGU_DIV.CSEL bit field value is greater than the CGU_DIV.SYSSEL bit field value.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear it. The CGU writes a new value to the CGU_DIV.CSEL bit field, so that it is less than or equal to the CGU_DIV.SYSSEL bit field value.

The CGU monitors changes to the following fields:

- CCLK Divisor – CGU_DIV.CSEL
- SYSCLK Divisor – CGU_DIV.SYSSEL

CGU Generated Bus Errors

The CGU generates a bus error when a read or write transaction to an unused address within the CGU address range is attempted. It also generates a bus error when a misaligned access is made to a CGU register. In addition to

the bus error, the CGU_STAT.ADDRERR bit is set. If a write to a write-protected CGU register is attempted, the CGU generates a bus error. In addition, the CGU_STAT.LWERR bit is set.

Oscillator Watchdog

The oscillator watchdog detects the absence of input clock transitions and provides a fault warning through the SYS_FAULT pin. To detect harmonic or subharmonic crystal oscillator behavior, the watchdog (under programmable control) also detects and reports input oscillator frequencies above and below the specified limits. Use an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters for this detection. Set the CGU_OSCWDCTL.MONDIS bit and clear the CGU_OSCWDCTL.FAULTEN bit to optionally disable all the input clock monitor and fault detection functions.

Set the CGU_OSCWDCTL.HODEN bit to enable harmonic oscillation detection. The CGU uses the CGU_OSCWDCTL.HODF bit field to indicate the desired lower fail limit (in MHz) for the harmonic oscillation detection. The upper limit is always twice the lower limit.

The ***HODF Settings for Different Input Clock Frequencies*** table shows an example of the CGU_OSCWDCTL.HODF bit settings for different input clock frequencies.

Table 2-6: HODF Settings for Different Input Clock Frequencies

CGU_OSCWDCTL.HODF[5:0]	Subharmonic Frequency (MHz)	Nom. Lower Fail Limit (MHz)	Input Clock Frequency (MHz)	Nom. Upper Fail Limit (MHz)	Second Harmonic Frequency (MHz)
14	10	14	20	28	40
21	15	21	30	42	60

The CGU uses the CGU_OSCWDCTL.BOUF (Bad Oscillator Upper Frequency limit) asynchronous control bit field to indicate the desired upper fail limit for the bad oscillation detection. Set the CGU_OSCWDCTL.BOUEN bit to enable upper-limit bad oscillation detection. A bad oscillation detection condition signals a fault before any processor operations occur. This detection occurs (even in bypass mode) whenever a clock frequency exceeds the specifications.

The CGU_OSCWDCTL.BOUF =0 operation starts with a target of 32 MHz and each additional LSB increases the frequency test limit by 2 MHz. For example:

Target Upper Frequency Limit = CGU_OSCWDCTL.BOUF × 2 MHz + 32 MHz

The CGU_STAT.OSCWDSTATFC status bits indicate the nature of the fault.

The ***Fault Map*** table shows the fault values.

Table 2-7: Fault Map

CGU_STAT.OSCWDSTATFC Bitfield Values	Fault Type
0	No Fault
1	No Input Clock

Table 2-7: Fault Map (Continued)

CGU_STAT.OSCWDSTATFC Bitfield Values	Fault Type
2	Subharmonic CLKIN
3	Harmonic CLKIN
4	No AUX_CLK
5	CLKIN > Upper Freq Limit (BOUF)
6	Reserved
7	Multiple Limit Faults

There is a priority to the faults given in the case of multiple fault errors. The highest priority is given to No Input clock followed by No AUX_CLK. The other three fault cases share the lowest priority. Multiple limit faults are asserted if more than one type of subharmonic CLKIN, harmonic CLKIN, or BOUF faults are observed.

NOTE: All the CGU_STAT.OSCWDSTATFC faults other than the absence of AUX_CLK (for example, CGU_STAT.OSCWDSTATFC =4) are not reliable and used for debug only.

Program and enable the OSCWDOG to match the actual crystal, before bringing the PLL out of bypass.

CGU Programming Model

The programming model for the CGU involves the various mode configuration techniques.

Configuring CGU Modes

Use the following procedures to configure the clocks and PLL.

NOTE: The program needs to clear the CGU_STAT.CLKSALGN bit before changing clocks. The following sequence is executed once, inside the application, after coming out of reset.

```
*pREG_CGU0_PLLCTL |= BITM_CGU_PLLCTL_PLLBPCL; // come out of bypass and enter
Full ON
while( (pADI_CGU0 ->STAT & 0xF) != 0x5 ) { } // poll
// now clocks are running with hardware default divisors.
// now program can change frequencies If desired the program can put the PLL
again into bypass.
```

Changing the Clock Frequencies

Applications change clock frequencies in two ways. The first way is modifying the PLL multiplication value by writing to the CGU_CTL register and the second is modifying the clock dividers by writing to the CGU_DIV register. Both actions have different implications even if the frequencies of the final clock are the same. Write accesses to change the CGU_CTL.DF or CGU_CTL.MSEL bit fields while the PLL is locking set the CGU_STAT.WDFMSERR error bit. The CGU_STAT.WDIVERR error bit is set when one of following accesses is attempted while the PLL is locked, but still aligning the clocks:

- A write access to the CGU_DIV to trigger an alignment sequence.
- A write access to the CGU_DIV to change the CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL bits.

Read-after-write accesses to these registers return the new value, even if the frequency of the clock change is still in-progress.

Modifying the PLL multiplier requires the PLL to relock. Once the PLL locks, the CGU synchronizes the clocks. Changes to the CGU_CTL.DF or CGU_CTL.MSEL bit field result in bypassing the PLL. By setting the CGU_CTL.WFI bit, programs force the PLL to wait for all the cores to return to their idle or reset states before the frequency changes . If necessary, clear the CGU_DIV.UPDT bit to avoid multiple clock alignment sequences. If the CGU_DIV register is not updated, the CGU uses the current values to determine the frequencies of the clock. It is the programs responsibility to guarantee that the new CGU_CTL.DF or CGU_CTL.MSEL and CGU_DIV combinations are legal.

Changing the PLL Clock Frequency

To change the phase-locked loop clock (*PLLCLK*) frequency, write new values to the CGU_CTL.MSEL field or CGU_CTL.DF field. Any time the PLL relocks, all core and system clocks are aligned.

1. Read CGU_STAT register and verify that:
   a. The CGU_STAT.PLLEN bit =1 (PLL enabled)
   b. The CGU_STAT.PLOCK bit =1 (PLL is not locking)
   c. The CGU_STAT.CLKSALGN bit =0 (clocks aligned)
2. Write the desired values to the clock divisor select fields of the CGU_DIV register with the CGU_DIV.UPDT bit =0.
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL fields.
   a. To change the PLL frequency while the cores are idle, write to the CGU_CTL register with the CGU_CTL.WFI bit =1.
   b. To change the PLL frequency while the cores are active, write to the CGU_CTL register with the CGU_CTL.WFI bit =0.

This sequence performs these actions:

1. Updates the corresponding CGU registers.
2. Bypasses the PLL.
3. Makes the PLL lock to the new values in the CGU_CTL.MSEL or CGU_CTL.DF fields.
4. Changes the clock frequencies.
5. Exits the PLL bypass with all clocks aligned.

When exiting the PLL bypass state, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.PLLEN bit =1, the CGU_STAT.PLOCK bit =1, the CGU_STAT.PLLBP bit =0, and the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.PLOCK bit, CGU_STAT.PLLBP bit, and CGU_STAT.CLKSALGN bit to discover when the PLL is locked and the clocks are aligned.

Changing the frequency of the PLL is allowed while the PLL is bypassed. In this case the new PLLCLK frequency is not used until the PLL is no longer bypassed.

Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies, write new values to CGU_DIV.CSEL or CGU_DIV.SYSSEL bits. The frequency change occurs only when the PLL is not bypassed. Any time the CCLKn or SYSCLK clock frequencies are changed, they exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.CSEL, CGU_DIV.SYSSEL, and CGU_DIV.OSEL bitfield values with the CGU_DIV.UPDT bit = 1. This write updates the CGU_DIV register, changes the SCLKn and SYSCLK frequencies, and aligns the clocks. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.S0SEL or CGU_DIV.S1SEL bit fields while CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIV register is not modified.

Programming the SYSCLK frequency to a higher value than CCLKn also triggers an MMR access bus error and the CGU_DIV register is not modified.

Writing to the CGU_DIV register is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the SYSCLK frequency is not supported and can have unpredictable results.

Changing the OCLK Frequency

To change the OCLK clock frequency, write a new CGU_DIV.OSEL bit value. Any time the OCLK clock frequency is changed, the OCLK, CCLKn, SYSCLK, and SCLKn clocks exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.OSEL value with the CGU_DIV.UPDT bit =1. This write updates the CGU_DIV register, changes the OCLK frequency, and aligns all clocks except OCLK.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.DSEL field while the CGU_STAT.CLKSALGN bit =1 (clock alignment in progress) triggers an MMR access bus error and the CGU_DIV is not modified. When the clocks are aligned, a CGU event occurs.

Writing to the CGU_DIV.OSEL bit field is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Aligning All Clocks

To align the clocks, write 1 to the CGU_DIV.ALGN bit. The frequency can also be changed, if necessary. The clocks aligned include:

- CCLKn
- SYSCLK
- SCLKn
- DCLK
- OCLK

1. Read the CGU_STAT register to verify that CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write 1 to the CGU_DIV.ALGN bit. All other fields can change.

   ADDITIONAL INFORMATION: This write does not alter the CGU_DIV register unless one of the clock-select fields is modified. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write to the CGU_DIV register intended to align clocks or to change a clock select field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error. In this case, the CGU_DIV register is not modified.

Writing 1 to the CGU_DIV.ALGN bit has no effect while the processor is in active (PLL bypassed) mode.

The CGU does not support accessing the DDR memory while changing the SYSCLK or DCLK frequencies. This type of access can have unpredictable results.

Shutting Off CCLKn from Another Master

CCLKn can be shut off to save power when it is not in use.

1. Disable interrupts to core n.
2. Set the RCU_SIDIS.SI[n] bit to disable the interfaces of core n in order to:
   a. Stop DMA accesses to its L1.

b. Stop memory accesses to core 0.

c. Stop accesses to MMRs.

3. Test the RCU_SISTAT.SI[n] bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
4. Set the CGU_CCBF_DIS.CCBF0 bit to disable the CCLKn buffer.
5. Check the CGU_CCBF_STAT.CCBF0 bit.

If the CGU_CCBF_STAT.CCBF0 bit is set, continue.

Reenable CCLKn From Another Master

1. Clear the CGU_CCBF_DIS.CCBF0 to enable CCLKn.
2. Check the CGU_CCBF_STAT.CCBF0 bit.
   a. If the CGU_CCBF_DIS.CCBF0 bit is cleared, continue.
3. Clear the RCU_SIDIS.SI[n] bit. The core deasserts its acknowledge signal in response to the RCU_SYSRST0signal. This operation clears the RCU_SISTAT.SI[n] bit.

Valid Clock Multiplier Settings

Processor operations depend on valid settings in the CGU_CTL and CGU_DIV registers. These registers control the clock multiplier and divisor values. Set these registers such that the minimum and maximum clocks specified in the data sheet are not violated. All other clock specifications in the data sheet must also be adhered to for correct operation of the processor.

NOTE: The frequency of any processor core clock to the *SYSCLK* is either 1:1 or 2:1 only.

PLL Bypass and PLL Disable

Writing 1 to the CGU_PLLCTL.PLLBPST bit tells the PLL to apply OSC_CLKIN clock to CCLK, SYSCLK, SCLK0, SCLK1, DCLK (PLL Bypass), and OCLK outputs. Writing 1 to the CGU_PLLCTL.PLLBPCL bit tells the PLL to exit its PLL Bypass state and make all output clocks align and transition to their programmed frequencies.

The PLL can be disabled by clearing the CGU_PLLCTL.PLLEN bit while in the bypass state. If necessary, clock buffers can be disabled.

CCLK0 and CCLK1 clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_CCBF_DIS register. To know which core clock buffers are enabled or disabled, software reads the CGU_CCBF_STAT register.

To determine which core clock buffers were disabled since the last read, software reads the CGU_CCBF_STAT register. The SCLK0, SCLK1, DCLK and OCLK clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_SCBF_DIS register. Software cannot disable SYSCLK.

ADSP-SC5xx Specific Information

The processor has two system crystal oscillators and two system CGU units to provide the clocks to the system. Both of the CGUs come up in bypass mode out of reset.

CGU0 is the main CGU which provides SYSCLK (SYSCLK_0), SCLK0 (SCLK0_0), and SCLK1 (SCKL1_0) to the system buses, infrastructure, and most of the peripherals. The rest of the clock outputs from the two CGUs can be routed to a specific peripheral and the cores in the system. For more details, refer to the Clock Distribution Unit (CDU).

NOTE: Frequency ratios of the core clock to SYSCLK are either 2:1 or 1:1.

The processor does not support any other frequency ratio. Program the divider/CDU values for the CLKO0, CLKO1, and CLKO2 in relation with the divider programming for the SYSCLK.

ADSP-SC57x CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

Table 2-8: ADSP-SC57x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

Core Clock Buffer Disable Register

The CGU_CCBF_DIS register controls each core's clock buffer to determine if the CCLK is enabled.

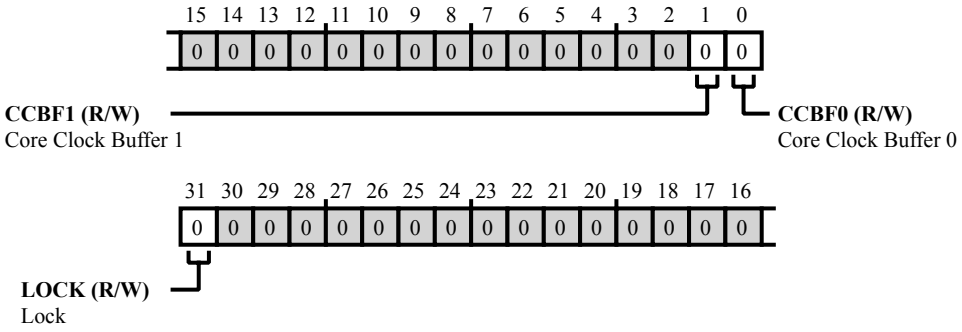

Figure 2-2: CGU_CCBF_DIS Register Diagram

Table 2-9: CGU_CCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If set (=1) the CGU_CCBF_DIS.LOCK bit locks the CGU_CCBF_DIS register.	
		0	Unlock register
		1	Lock register
1 (R/W)	CCBF1	Core Clock Buffer 1. The CGU_CCBF_DIS.CCBF1 bit enables (=0) or disables (=1) CCLK1s buffer.	
0 (R/W)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_DIS.CCBF0 bit enables (=0) or disables (=1) CCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

Core Clock Buffer Status Register

The CGU_CCBF_STAT register shows which core clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_CCBF_STAT.CCBF0 bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

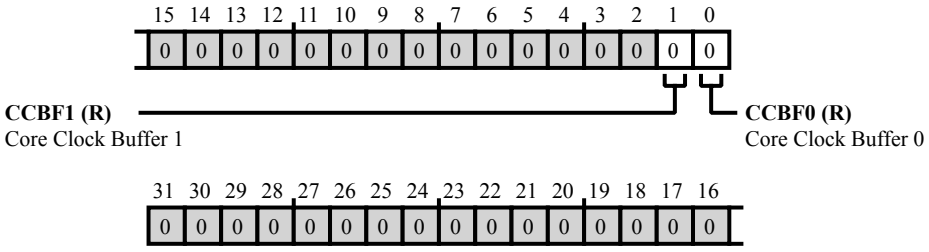

Figure 2-3: CGU_CCBF_STAT Register Diagram

Table 2-10: CGU_CCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	CCBF1	Core Clock Buffer 1. The CGU_CCBF_STAT.CCBF1 bit reports the status of the CGU_CCBF_DIS.CCBF1 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
0 (R/NW)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_STAT.CCBF0 bit reports the status of the CGU_CCBF_DIS.CCBF0 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

CLKOUT Select Register

The CGU_CLKOUTSEL selects the signal that the CGU drives through the CLKOUT multiplexer. Also, this register selects the divisor for the USBCLK output.

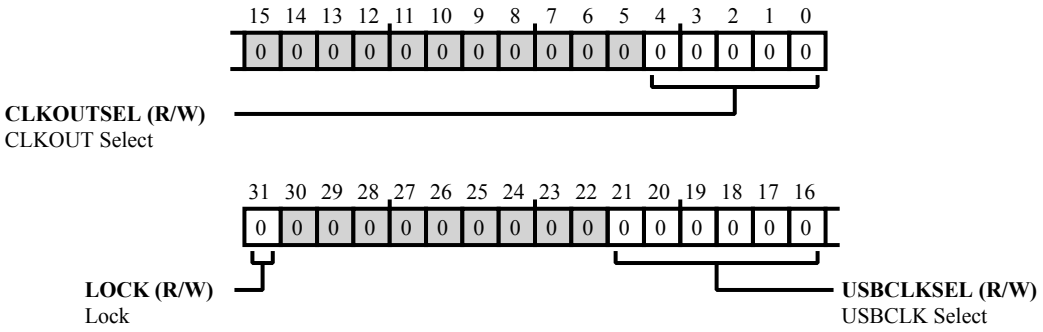

Figure 2-4: CGU_CLKOUTSEL Register Diagram

Table 2-11: CGU_CLKOUTSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CLKOUTSEL.LOCK bit is set, the CGU_CLKOUTSEL register is read only (locked).	
		0	Unlock
		1	Lock
21:16 (R/W)	USBCLKSEL	USBCLK Select. The CGU_CLKOUTSEL.USBCLKSEL selects the divisor in the USBCLK equation: USBCLK frequency = (USB PLL frequency) / (CGU_CLKOUTSEL.USBCLKSEL +1) Where the value of CGU_CLKOUTSEL.USBCLKSEL is between 0 and 63.	
		0	USBCLKSEL = 0
		63	USBCLKSEL = 63
4:0 (R/W)	CLKOUTSEL	CLKOUT Select. The CGU_CLKOUTSEL.CLKOUTSEL selects the signal that the CGU drives through the CLKOUT pin multiplexer.	
		0	CLKIN0
		1	CLKIN1
		2	CGU_0.SYSCLK
		3	CLKO0

Table 2-11: CGU_CLKOUTSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	CLKO2
		5	CLKO3
		6	CLKO5
		7	CLKO7
		8	CLKO8
		9	Reserved
		10	Reserved
		11	Reserved
		12	Reserved
		13	Reserved
		14	SCLK1_0
		15	Reserved
		16	SCLK0_0
		17	Reserved
		18	Reserved
		19-31	GND

Control Register

The CGU_CTL controls the clock generation divisors for SYS_CLKIN and the PLL. Read after write accesses to the CGU_CTL register returns the new value even if the clock's frequency change is still in progress.

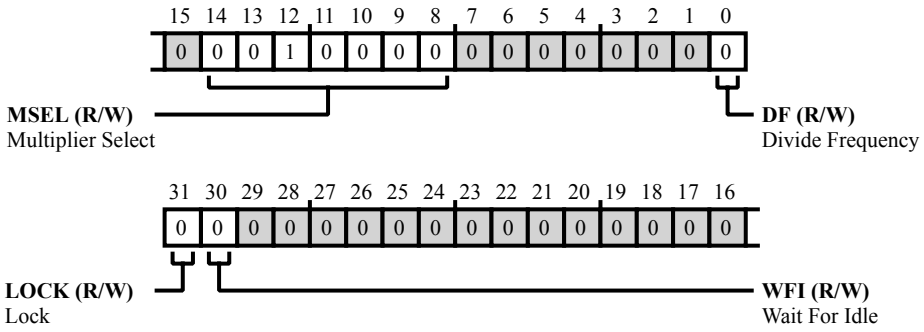

Figure 2-5: CGU_CTL Register Diagram

Table 2-12: CGU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CTL.LOCK bit is set, the CGU_CTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	WFI	Wait For Idle. Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the CGU_CTL.MSEL and the CGU_CTL.DF bit values results in bypassing the PLL. The CGU_CTL.WFI bit forces the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of changes to the CGU_CTL.MSEL or CGU_CTL.DF bits. Write accesses to the CGU_CTL to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking sets the CGU_STAT.WDFMSERR bit.	
		0	Update Immediately
		1	Wait for Idle

Table 2-12: CGU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:8 (R/W)	MSEL	Multiplier Select. The `CGU_CTL.MSEL` bit field selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL Where the value of MSEL is between 1 and 127.	
		0	MSEL = 128
		1-127	MSEL = 1 to 127
0 (R/W)	DF	Divide Frequency. The `CGU_CTL.DF` bit selects whether or not the CLKIN input is divided by two before being passed to the PLL.	
		0	Pass OSC_CLKIN to PLL
		1	Pass OSC_CLKIN/2 to PLL

Clocks Divisor Register

The CGU_DIV register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the CGU_DIV register returns the new value even if the clock's frequency change is still in progress.

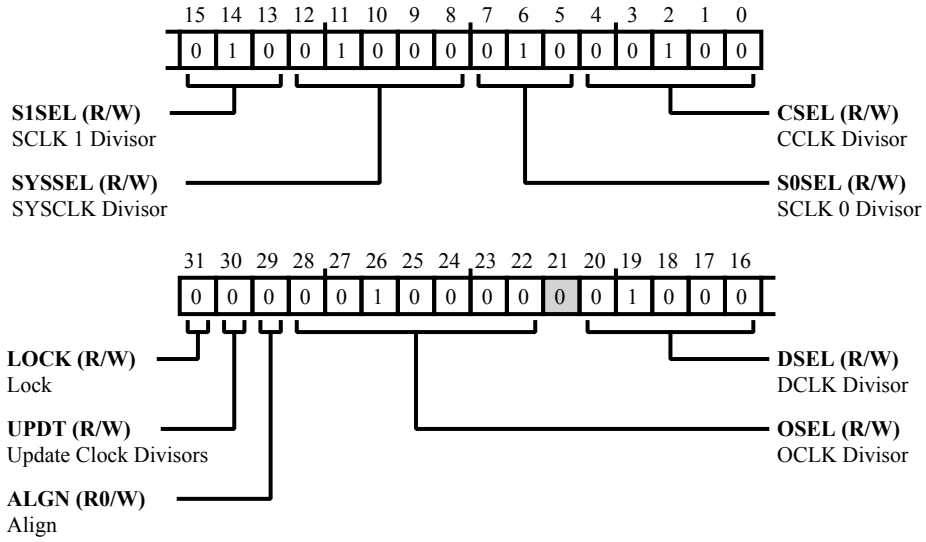

Figure 2-6: CGU_DIV Register Diagram

Table 2-13: CGU_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_DIV.LOCK bit is set, the CGU_DIV register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	UPDT	Update Clock Divisors. The CGU_DIV.UPDT controls whether the CGU drives new CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and CGU_DIV.OSEL values to PLL after CGU_DIV register update.	
		0	No PLL Update
		1	Drive Updated SEL Values to PLL

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R0/W)	ALGN	Align. The CGU_DIV.ALGN directs the CGU to align the PLL-based clocks. The divisor selections (CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and/or CGU_DIV.OSEL) do not have to change.	
		0	No Action
		1	Align PLL Clocks
28:22 (R/W)	OSEL	OCLK Divisor. The CGU_DIV.OSEL selects the divisor in the OCLK equation: OCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.OSEL Where the value of CGU_DIV.OSEL is between 1 and 127.	
		0	OSEL = 128
		1-127	OSEL = 1 to 127
20:16 (R/W)	DSEL	DCLK Divisor. The CGU_DIV.DSEL selects the divisor in the DCLK equation: DCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.DSEL Where the value of CGU_DIV.DSEL is between 1 and 31.	
		0	DSEL = 32
		1-31	DSEL = 1 to 31
15:13 (R/W)	S1SEL	SCLK 1 Divisor. The CGU_DIV.S1SEL selects the divisor in the SCLK1 equation: SCLK1 frequency = (SYSCLK frequency) / CGU_DIV.S1SEL Where the value of CGU_DIV.S1SEL is between 1 and 7.	
		0	S1SEL = 8
		1-7	S1SEL = 1 to 7
12:8 (R/W)	SYSSEL	SYSCLK Divisor. The CGU_DIV.SYSSEL selects the divisor in the SYSCLK equation: SYSCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.SYSSEL Where the value of CGU_DIV.SYSSEL is between 1 and 31.	
		0	SYSSEL = 32
		1-31	SYSSEL = 1 to 31

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:5 (R/W)	S0SEL	SCLK 0 Divisor. The CGU_DIV.S0SEL selects the divisor in the SCLK0 equation: SCLK0 frequency = (SYSCLK frequency) / CGU_DIV.S0SEL Where the value of CGU_DIV.S0SEL is between 1 and 7.	
		0	S0SEL = 8
		1-7	S0SEL = 1 to 7
4:0 (R/W)	CSEL	CCLK Divisor. The CGU_DIV.CSEL selects the divisor in the CCLK equation: CCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.CSEL Where the value of CGU_DIV.CSEL is between 1 and 31.	
		0	CSEL = 32
		1-31	CSEL= 1 to 31

Oscillator Watchdog Register

The CGU_OSCWDCTL register configures the CGU to allow the detection of the absence of input clock transitions and provides a fault warning via the SYS_FAULT pin. The CGU_OSCWDCTL register also detects and reports input oscillator frequencies above and below specified limits, in order to specifically detect harmonic or sub-harmonic crystal oscillator behavior. This detection is achieved by using an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters.

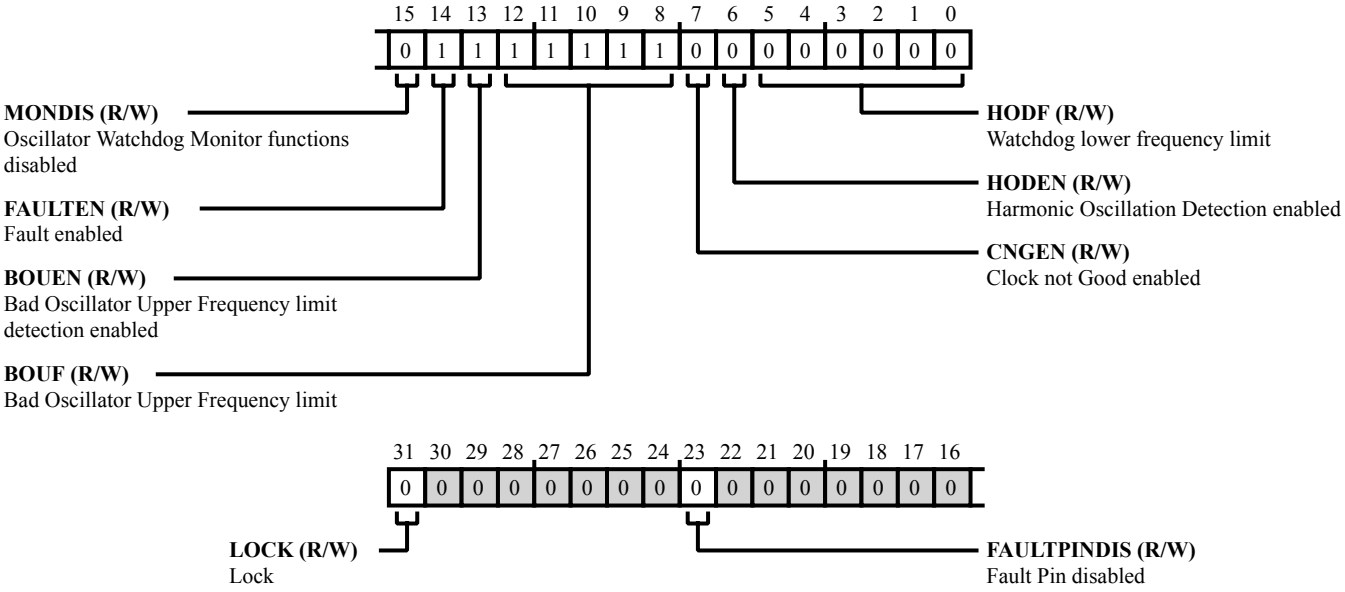

Figure 2-7: CGU_OSCWDCTL Register Diagram

Table 2-14: CGU_OSCWDCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	LOCK	Lock.
23 (R/W)	FAULTPINDIS	Fault Pin disabled. The CGU_OSCWDCTL.FAULTPINDIS bit disables pin fault detection.
15 (R/W)	MONDIS	Oscillator Watchdog Monitor functions disabled. The CGU_OSCWDCTL.MONDIS bit disables all the input clock monitor and fault detection functions.
14 (R/W)	FAULTEN	Fault enabled. The CGU_OSCWDCTL.FAULTEN bit enables fault detection.
13 (R/W)	BOUEN	Bad Oscillator Upper Frequency limit detection enabled. The CGU_OSCWDCTL.BOUEN bit enables upper limit bad oscillation detection.

Table 2-14: CGU_OSCWDCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12:8 (R/W)	BOUF	Bad Oscillator Upper Frequency limit. The `CGU_OSCWDCTL.BOUF` bits indicate the desired upper fail limit for the bad oscillation detection.	
		0	Enable buffer
		1	Disable buffer
7 (R/W)	CNGEN	Clock not Good enabled. The `CGU_OSCWDCTL.CNGEN` bit enables the detection of an oscillator watchdog clock fault.	
6 (R/W)	HODEN	Harmonic Oscillation Detection enabled. The `CGU_OSCWDCTL.HODEN` bit enables harmonic oscillation detection.	
5:0 (R/W)	HODF	Watchdog lower frequency limit. The `CGU_OSCWDCTL.HODF` bit field is used to indicate the desired lower fail limit for the harmonic oscillation detection in MHz.	

PLL Control Register

The CGU_PLLCTL register contains bits that enable and disable the PLL as well as control its function.

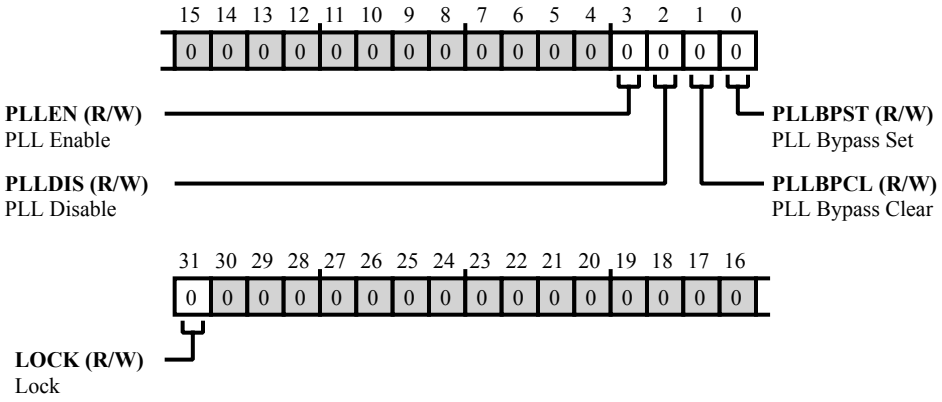

Figure 2-8: CGU_PLLCTL Register Diagram

Table 2-15: CGU_PLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting (=1) the CGU_PLLCTL.LOCK bit locks access to the CGU_PLLCTL register.	
		0	Unlock register
		1	Lock register
3 (R/W)	PLLEN	PLL Enable. Setting (=1) the CGU_PLLCTL.PLLEN bit enables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Enable PLL
2 (R/W)	PLLDIS	PLL Disable. Setting (=1) the CGU_PLLCTL.PLLDIS bit disables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Disable PLL
1 (R/W)	PLLBPCL	PLL Bypass Clear. Setting (=1) the CGU_PLLCTL.PLLBPCL bit takes the PLL out of bypass mode. Check the CGU_STAT.PLLBP bit to verify that the action is complete.	
		0	No action
		1	Exit bypass mode

Table 2-15: CGU_PLLCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PLLBPST	PLL Bypass Set. Setting (=1) the `CGU_PLLCTL.PLLBPST` bit bypasses the PLL and all the clocks run on CLKIN. Check the `CGU_STAT.PLLBP` bit to verify that the action is complete.	
		0	Use PLL
		1	Bypass PLL

Revision ID Register

The CGU_REVID register reports the version of the CGU.

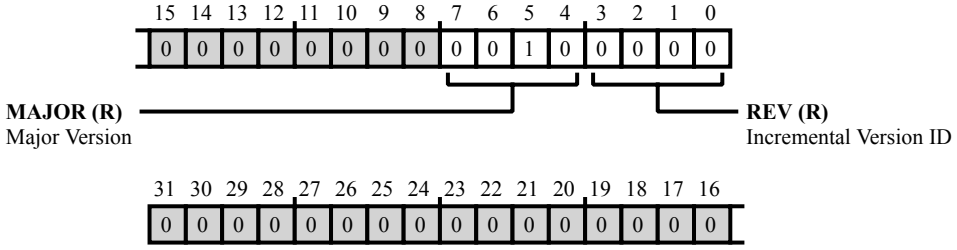

Figure 2-9: CGU_REVID Register Diagram

Table 2-16: CGU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version.
3:0 (R/NW)	REV	Incremental Version ID.

System Clock Buffer Disable Register

The CGU_SCBF_DIS register controls each system's clock buffer to determine if the SCLKn buffer is enabled.

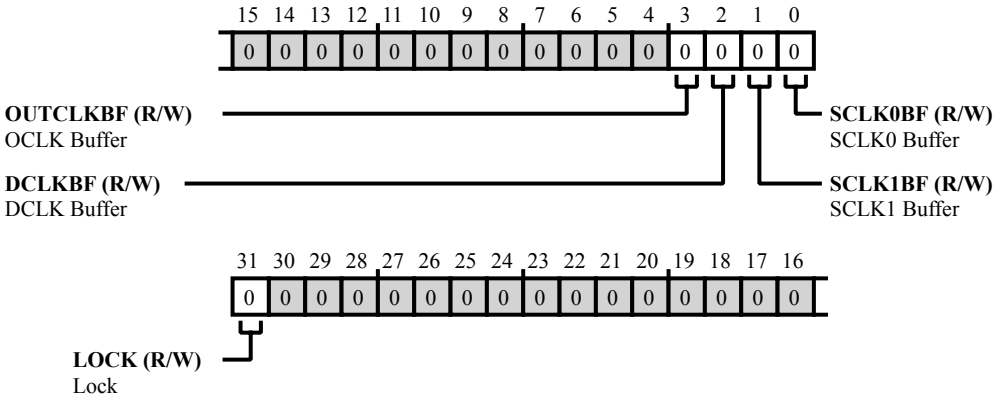

Figure 2-10: CGU_SCBF_DIS Register Diagram

Table 2-17: CGU_SCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. The CGU_SCBF_DIS.LOCK bit allows writes to the CGU_SCBF_DIS register when cleared (=0) or blocks writes if set (=1) and the SPU_CTL.GLCK bit is set.	
		0	Unlock register
		1	Lock register
3 (R/W)	OUTCLKBF	OCLK Buffer. The CGU_SCBF_DIS.OUTCLKBF bit enables (=0, default) or disables (=1) OCLKs buffer.	
		0	Enable buffer
		1	Disable buffer
2 (R/W)	DCLKBF	DCLK Buffer. The CGU_SCBF_DIS.DCLKBF bit enables (=0, default) or disables (=1) DCLKs buffer.	
		0	Enable buffer
		1	Disable buffer

Table 2-17: CGU_SCBF_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SCLK1BF	SCLK1 Buffer. The `CGU_SCBF_DIS.SCLK1BF` bit enables (=0, default) or disables (=1) SCLK1s buffer.	
		0	Enable buffer
		1	Disable buffer
0 (R/W)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_DIS.SCLK0BF` bit enables (=0, default) or disables (=1) SCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

System Clock Buffer Status Register

The CGU_SCBF_STAT register shows which system clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_SCBF_STAT.SCLK0BF bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

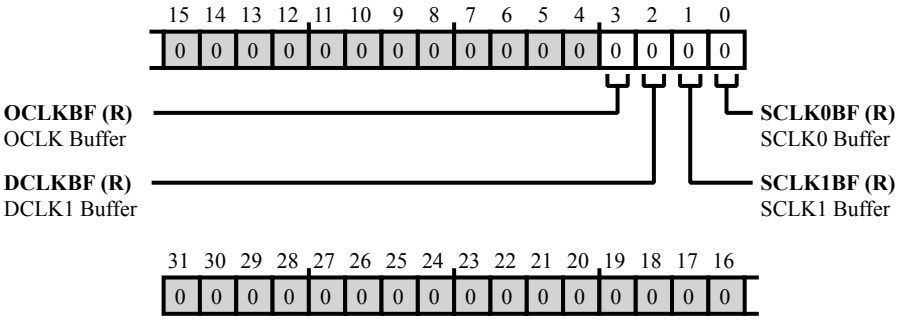

Figure 2-11: CGU_SCBF_STAT Register Diagram

Table 2-18: CGU_SCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	OCLKBF	OCLK Buffer. The CGU_SCBF_STAT.OCLKBF bit reports the status of the CGU_SCBF_DIS.OUTCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
2 (R/NW)	DCLKBF	DCLK1 Buffer. The CGU_SCBF_STAT.DCLKBF bit reports the status of the CGU_SCBF_DIS.DCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
1 (R/NW)	SCLK1BF	SCLK1 Buffer. The CGU_SCBF_STAT.SCLK1BF bit reports the status of the CGU_SCBF_DIS.SCLK1BF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Table 2-18: CGU_SCBF_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_STAT.SCLK0BF` bit reports the status of the `CGU_SCBF_DIS.SCLK0BF` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Status Register

The CGU_STAT register reflects the PLL status and errors detected during the PLL configuration. This register may be cleared asynchronously by a reset signal from the RCU module. All bits---except those defined as W1C (write-1-to-clear)---are read only.

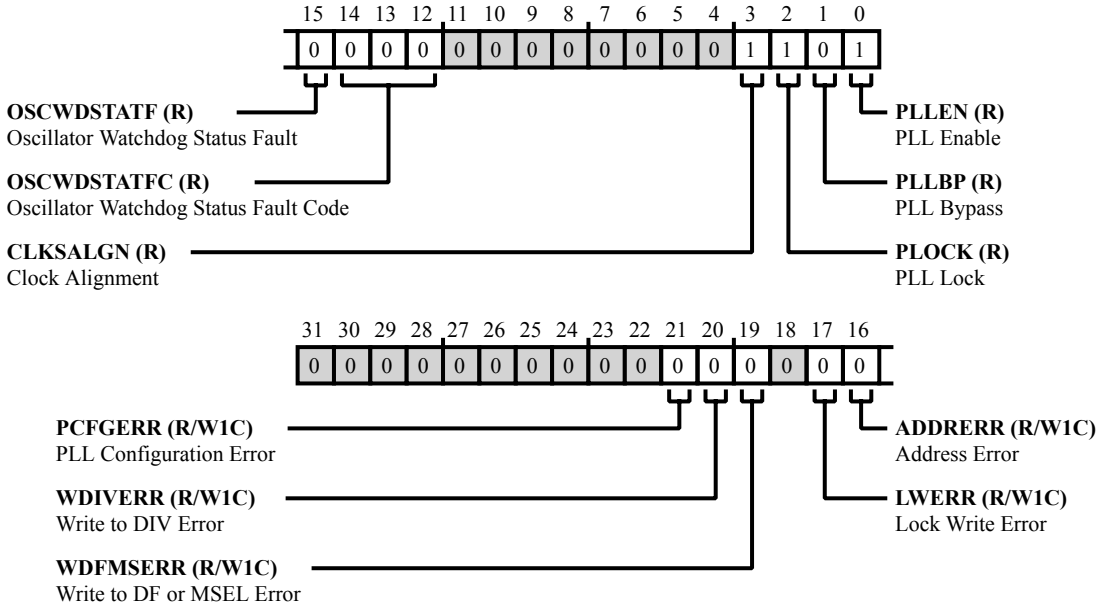

Figure 2-12: CGU_STAT Register Diagram

Table 2-19: CGU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PCFGERR	PLL Configuration Error. If the CGU_PLLCTL.PLLBPST and the CGU_PLLCTL.PLLBPCL bits are set (=1) simultaneously or the CGU_PLLCTL.PLLDIS bit was set (=1) in full-on mode or while trying to enter full-on mode (CGU_PLLCTL.PLLBPCL =1), the CGU_STAT.PCFGERR bit triggers the bus error.	
		0	No Error
		1	Configuration Error

Table 2-19: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W1C)	WDIVERR	Write to DIV Error. The CGU_STAT.WDIVERR bit indicates a write access to the CGU_DIV register (to trigger an alignment sequence or to change the CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL bit values) while the PLL is locked, but still aligning the clocks. Read after write accesses to the CGU_STAT and CGU_DIV registers return the new value even if the clock frequency change is still in progress.	
		0	No Error
		1	Write DIV Error
19 (R/W1C)	WDFMSERR	Write to DF or MSEL Error. The CGU_STAT.WDFMSERR bit indicates a write access to the CGU_CTL register to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking.	
		0	No Error
		1	Write DF/MSEL Error
17 (R/W1C)	LWERR	Lock Write Error. The CGU_STAT.LWERR bit indicates an attempt to write to write-protected (locked) CGU registers. The CGU issues a bus error for this condition.	
		0	No Error
		1	Lock Write Error
16 (R/W1C)	ADDRERR	Address Error. The CGU_STAT.ADDRERR bit indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The CGU issues a bus error for this condition.	
		0	No Error
		1	Address Error
15 (R/NW)	OSCWDSTATF	Oscillator Watchdog Status Fault. The CGU_STAT.OSCWDSTATF bit indicates a fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	Fault
14:12 (R/NW)	OSCWDSTATFC	Oscillator Watchdog Status Fault Code. The CGU_STAT.OSCWDSTATFC bit field indicates the nature of the fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	No Input Clock

Table 2-19: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Subharmonic CLKIN
		3	Harmonic CLKIN
		4	No AUX_CLK
		5	CLKIN > Upper Frequency Limit (BOUF)
		6	Reserved
		7	Multiple Limit Faults
3 (R/NW)	CLKSALGN	Clock Alignment. The CGU_STAT.CLKSALGN bit indicates whether a clock alignment sequence is in progress. This bit is set when clocks alignment is required by changes to CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, or CGU_DIV.OSEL. The CGU_STAT.CLKSALGN bit is cleared when clocks are aligned. Note that (after a PLL frequency change in active state) the CGU_STAT.CLKSALGN bit may indicate that clocks are not aligned even though the clocks are aligned (all clocks are aligned and running at CLKIN frequency).	
		0	Clocks are Aligned
		1	Clocks not Aligned (alignment in progress)
2 (R/NW)	PLOCK	PLL Lock. The CGU_STAT.PLOCK bit indicates whether the PLL is locked. This bit is set when the PLL locks (PLL lock counter end-of-count). The CGU_STAT.PLOCK bit is cleared when requested PLL frequency change (for PLL reset, PLL disable-to-enable transition, or a change to the CGU_CTL.MSEL or CGU_CTL.DF values) is in progress.	
		0	PLL not Locked (PLL frequency change in progress)
		1	PLL Locked
1 (R/NW)	PLLBP	PLL Bypass. The CGU_STAT.PLLBP bit indicates whether the PLL is bypassed. The default value for the CGU_STAT.PLLBP bit is determined by the bypass strap pin.	
		0	PLL not Bypassed
		1	PLL Bypassed
0 (R/NW)	PLLEN	PLL Enable. The CGU_STAT.PLLEN bit indicates whether the PLL is enabled.	
		0	Disabled
		1	Enabled

Time Stamp Counter 32 LSB Register

The CGU_TSCOUNT0 register address is used to read the CoreSight time stamp counter LSB 32-bit (bits [31:0]) value.

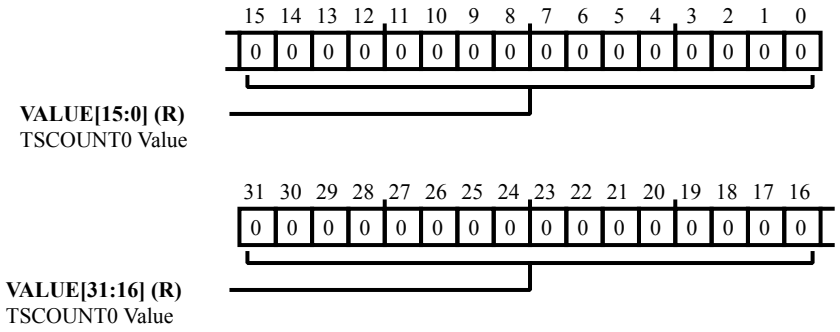

Figure 2-13: CGU_TSCOUNT0 Register Diagram

Table 2-20: CGU_TSCOUNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	TSCOUNT0 Value. The CGU_TSCOUNT0.VALUE bit field holds the time stamp counter 32 LSBs.

Time Stamp Counter 32 MSB Register

The CGU_TSCOUNT1 register address is used to read the CoreSight time stamp counter MSB 32-bit (bits [63:32]) value.

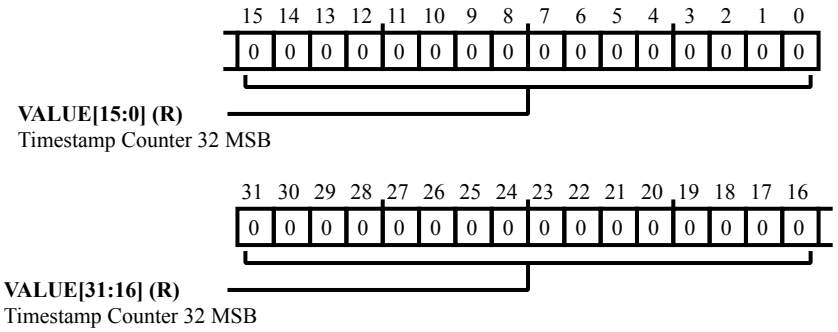

Figure 2-14: CGU_TSCOUNT1 Register Diagram

Table 2-21: CGU_TSCOUNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Timestamp Counter 32 MSB. The CGU_TSCOUNT1.VALUE bit field holds the time stamp counter 32 MSBs.

Time Stamp Control Register

The CGU_TSCTL register controls the operation of the CoreSight time stamp counter.

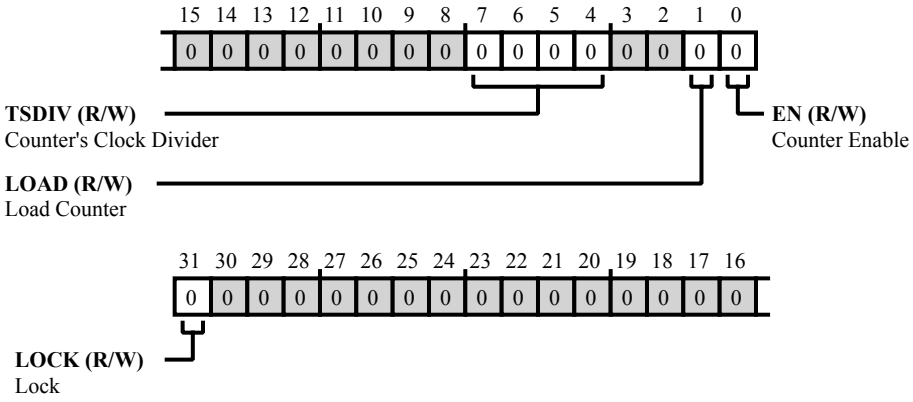

Figure 2-15: CGU_TSCTL Register Diagram

Table 2-22: CGU_TSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting the CGU_TSCTL.LOCK bit locks this register.	
		0	Unlock
		1	Lock
7:4 (R/W)	TSDIV	Counter's Clock Divider. The CGU_TSCTL.TSDIV bit field divides SYSCLK by 2^{TSDIV}.	
		0-15	Divides SYSCLK by 2^{TSDIV}
1 (R/W)	LOAD	Load Counter. Writing one to the CGU_TSCTL.LOAD bit causes CoreSight time stamp counter to be loaded from the CGU_TSVALUE0 and CGU_TSVALUE1 registers.	
		0	Always read as "0"
0 (R/W)	EN	Counter Enable. The CGU_TSCTL.EN bit enables or disables the CoreSight time stamp counter.	
		0	Counter Disabled
		1	Counter Enabled

Time Stamp Counter Initial 32 LSB Value Register

The CGU_TSVALUE0 register holds the least significant bits (bits [31:0]) value that is initially loaded to the Core-Sight time stamp counter.

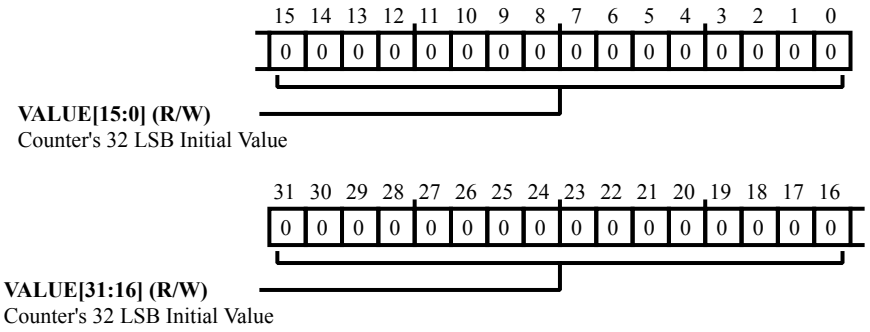

Figure 2-16: CGU_TSVALUE0 Register Diagram

Table 2-23: CGU_TSVALUE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's 32 LSB Initial Value. The CGU_TSVALUE0.VALUE bit field holds the LSBs value that is initially loaded to the CoreSight time stamp counter.

Time Stamp Counter Initial MSB Value Register

The CGU_TSVALUE1 register holds the most significant bits (bits [63:32]) value that is initially loaded to the CoreSight time stamp counter.

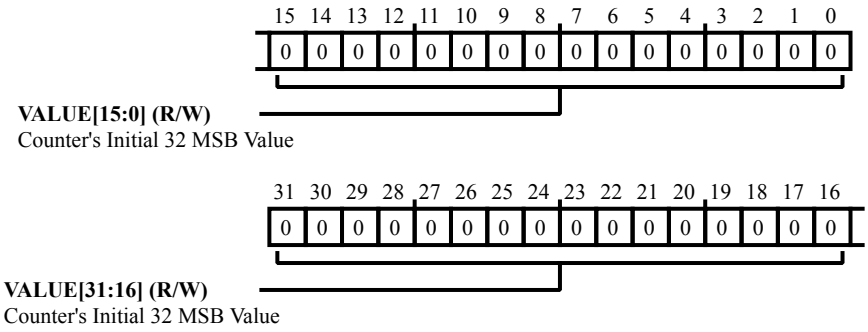

Figure 2-17: CGU_TSVALUE1 Register Diagram

Table 2-24: CGU_TSVALUE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's Initial 32 MSB Value. The CGU_TSVALUE1.VALUE bit field holds the MSBs value that is initially loaded to the CoreSight time stamp counter.

3 Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of multiplexors that select clocks originated from up to four different clock sources. These sources are different clocks that are generated from the CGUs. The multiplexors are configured by software. All clocks multiplexors have up to four different sources. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor.

CDU Features

The CDU modules supports the following features:

- Generation of up to 10 output clocks
- Output clock buffers that can be disabled by software
- Each multiplexor has four input clocks
- Multiplexors that are configured by writing to configuration registers (`CDU_CFG[n]`)
- Clocks originated in CGU0 that are selected by default
- A CDU status register (`CDU_STAT`) that indicates a configuration change is in-progress

CDU Functional Description

The CDU functions as a set of software-configurable multiplexors that select clocks from different sources.

CDU Block Diagram

The ***CDU Block Diagram*** figure shows the functional blocks within the CDU. As shown in the figure, the CDU takes different clocks generated by the CGU blocks and provides flexibility to route any clock from possible options to the output CDU clocks. The output clocks from the CDU are connected to specific targets such as the DDR module. These targets are clocked though the CDU output clocks rather than being directly clocked by CGU clocks.

This configuration provides the flexibility to meet the specific clock requirements of the different modules in the system (such as the core, DDR, or SPI module) without compromising the clocking of other modules. Such a flexibility is not possible with a single CGU in the system. With two CGUs:

- Each CGU has its own set of clock multipliers and dividers, providing a greater number of orthogonal clocks than possible with a single CGU.
- Each CGU can be clocked from a different CLKIN source, providing additional flexibility.
- CGU0 is always clocked by CLKIN0, whereas CGU1 can be clocked either by CLKIN0 or CLKIN1.

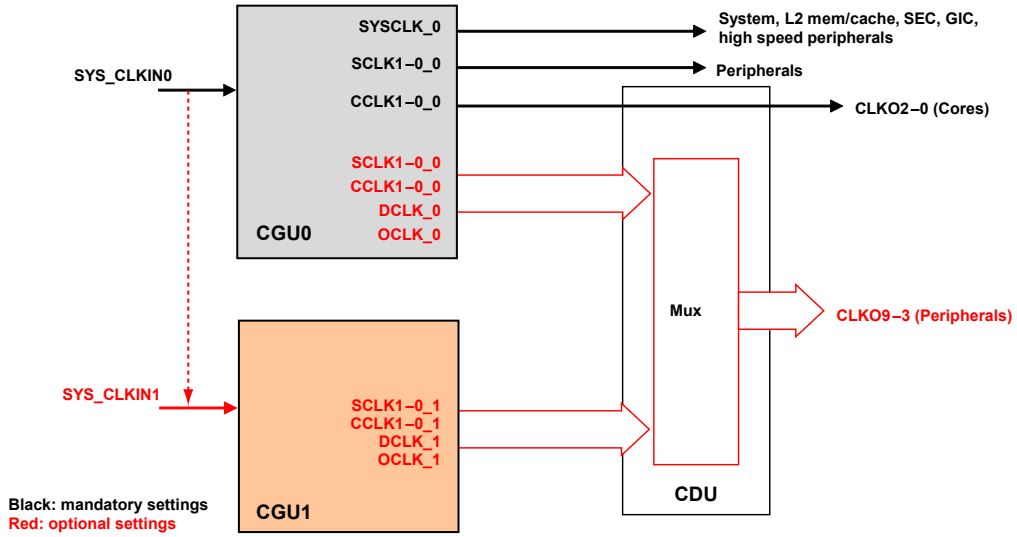

Figure 3-1: CGU/CDU Block Diagram

CDU Definitions

The ***Clock Descriptions*** table provides a brief description of the clocks supported by the processor.

Table 3-1: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK1_1	CCLK1 derived from CGU1

Table 3-1: Clock Descriptions (Continued)

Clock	Description
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CDU_CLKOn	Clocks that come out of the CDU and goes to different blocks

CDU Clock Configuration Options

Table 3-2: CDU Targets

CDU0 Input				CDU0 Output	Target
CCLK0_0	SYSCLK_0	N/A	N/A	CDU_CLKO0	Core1 (SHARC1)
CCLK0_0	SYSCLK_0	N/A	N/A	CDU_CLKO1	Core2 (SHARC2)
CCLK1_0	SYSCLK_0	N/A	N/A	CDU_CLKO2	Core0 (ARM A5)
DCLK_0	DCLK_1	N/A	N/A	CDU_CLKO3	DDR1/2/3
OCLK_0	OCLK_1	DCLK_1	OCLK_0/2	CDU_CLKO4	CAN
OCLK_0	OCLK_1	DCLK_1	DCLK_0	CDU_CLKO5	S/PDIF-RX
N/A	N/A	N/A	N/A	CDU_CLKO6	N/A
SCLK1_0	SCLK1_1	CCLK0_1	OCLK_0	CDU_CLKO7	GigE/RGMII
N/A	N/A	N/A	N/A	CDU_CLKO8	N/A
OCLK_0/2	CCLK1_1/2	CCLK1_1	DCLK_1	CDU_CLKO9	SDIO

Table 3-3: Peripheral Clock Domains

Peripheral	Clock Source
TIMER, CRC0, CRC1, TWI, SPORT, UART, PORT, PINT, WDT, CNT, EMAC0, TMU, HADC, ACM, EMDMA, MDMA, DAI, CRYPTO ACCELERATOR (SPE), EPPI	SCLK0_0
QSPI, SPI	SCLK1_0
L2_CTL, SEC, TRU, RCU, SPU, SMPU, CDU, DPM, EMDMA, MAX BW MDMA, MLB, CRYPTO ACCELERATOR (PKA), ROM, CGU	SYSCLK_0

To further illustrate clocking options, the ***CDU Core Clock Options*** figure shows the conceptual routing of different clock sources to each target. Note that all three cores can be clocked by the clocks originating from CGU0. Select SYS_CLKIN accordingly to get the best match for the core clock frequency.

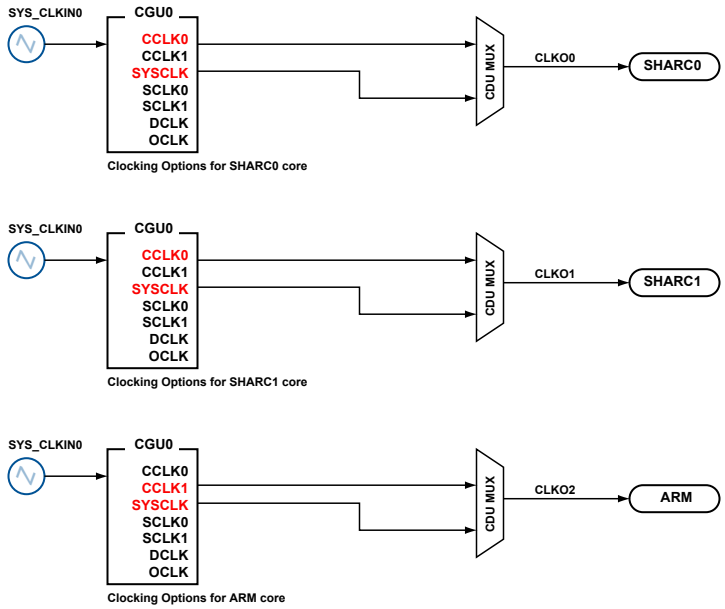

Figure 3-2: CDU Core Clock Options

In the ***CDU Clock Options - DDR*** figure, DDR is clocked from the DCLK from CGU0 or CGU1. This configuration provides the flexibility to program the DDR with frequencies orthogonal to the core clock frequencies.

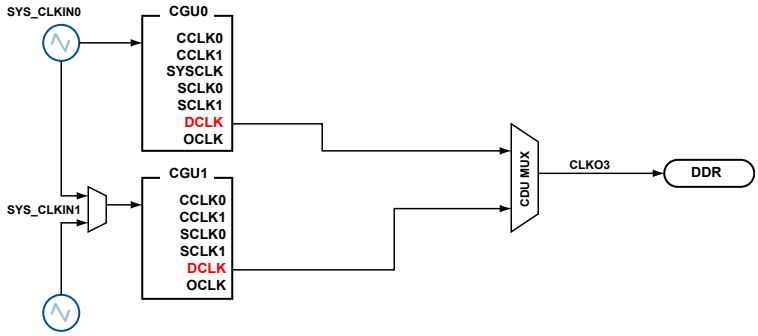

Figure 3-3: CDU Clock Options - DDR

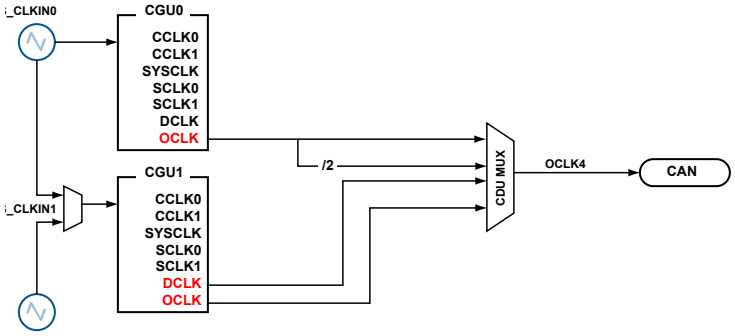

Figure 3-4: CDU Clock Options - CAN

The S/PDIF clock is ideally programmed to operate at 225 MHz (out of the four options).

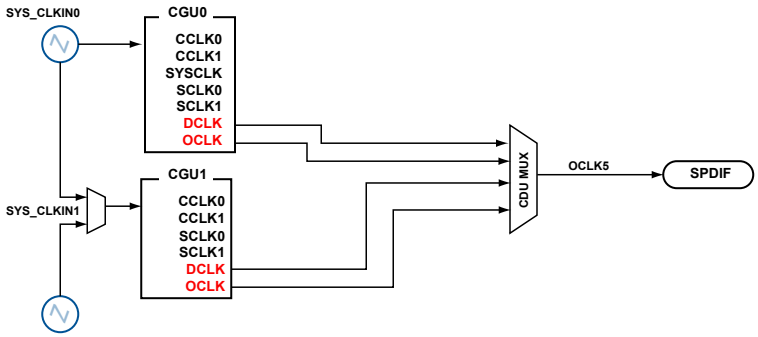

Figure 3-5: CDU Clock Options - S/PDIF

The Gigabit Ethernet clock should always be 125 MHz if GigE/RGMII is used. Program the CDU depending on which CGU can provide 125 MHz.

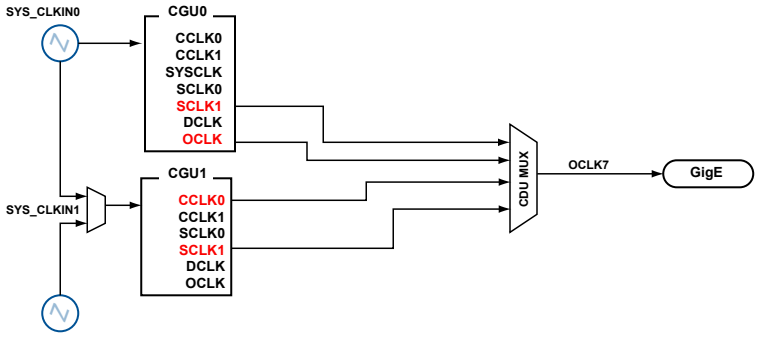

Figure 3-6: CDU Clock Options Gigabit Ethernet

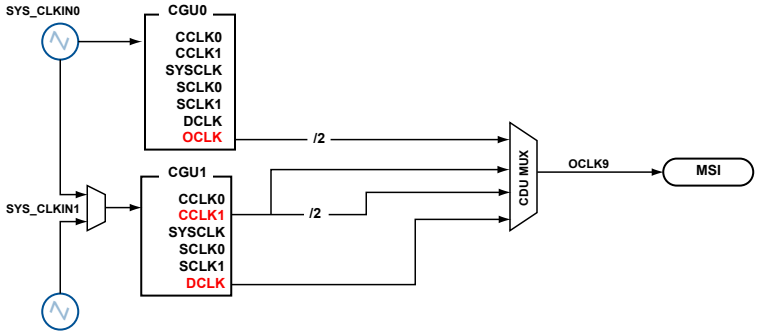

Figure 3-7: CDU Clock Options MSI

CDU Programming Model

The `CDU_CFG[n]` registers are a system configuration resource. These registers are accessed by a system configuration routine that also handles the configuration of other system modules. Writes to a `CDU_CFG[n]` register must occur when there is not a CDU_CLKOn configuration change in progress. If a CGUn inputs are selected, that CGUn configuration must be completed first.

Changing the PLL and Clock Frequency

1. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN =1 (enabled)
   - CGU_STAT.PLOCK =1 (PLL is not locking)
   - CGU_STAT.CLKSALGN =0 (clocks aligned)
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit cleared (= 0).
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL bits.
   - To change the PLL frequency while all cores are idle, set the CGU_CTL.WFI bit (=1).
   - To change the PLL frequency while the cores are active, clear the CGU_CTL.WFI bit (=0).
4. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN = 1 (enabled)
   - CGU_STAT.PLOCK = 1 (not locking)
   - CGU_STAT.CLKSALGN = 0 (clocks aligned)
5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register. Verify that the CDU_STAT.CLKO0 (no CLKOn configuration change in progress).
7. Write to the CDU_CLKINSEL register to select the CGU's CLKIN input clock.
8. Write to the CDU_CFG[n].SEL bit to select the clock source (the CDU_CFG[n].EN bit should =1.)
9. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.

CLKOn is reconfigured.

Changing the Clock Frequency

Use the following procedure to change a clock frequency.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit = 1.

3. Read the CGU_DIV registers to verify that the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bit values are correct.
4. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN = 0 (clocks aligned).
5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register. Verify that the CDU_STAT.CLKO5 through CDU_STAT.CLKO9 bits =0 (No CLKOn configuration change in progress).
7. Write to the CDU_CFG[n].SEL bit to select the clock source (CDU_CFG[n].EN = 1).
8. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.
9. Verify that the CDU_STAT.CLKO0 through CDU_STAT.CLKO9 = 0.

ADSP-SC57x CDU Register Descriptions

Clock Distribution Unit (CDU) contains the following registers.

Table 3-4: ADSP-SC57x CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_CLKINSEL	CLKIN Select
CDU_REVID	CDU Revision ID
CDU_STAT	CDU Status

CDU Configuration

The CDU_CFG[n] registers control the configuration of the clock multiplexors. CDU0_CFG[n] corresponds to output clock CDU_CLKO[n].

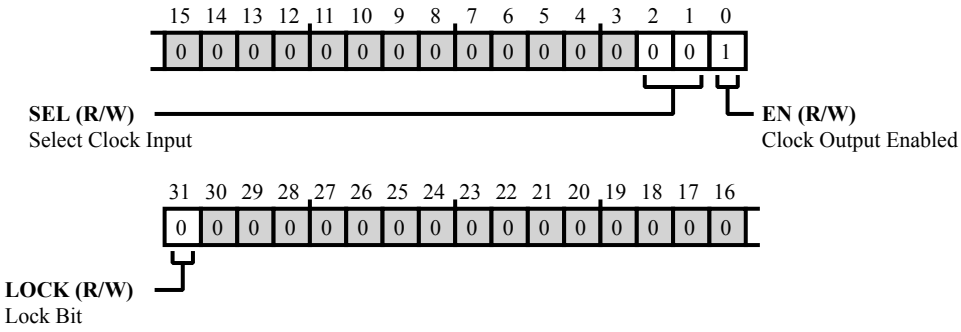

Figure 3-8: CDU_CFG[n] Register Diagram

Table 3-5: CDU_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
2:1 (R/W)	SEL	Select Clock Input.	
		0	IN0_CLKOn Selected
		1	IN1_CLKOn Selected
		2	IN2_CLKOn Selected
		3	IN3_CLKOn Selected
0 (R/W)	EN	Clock Output Enabled. The CDU_CFG[n].EN bit enables clock output.	

CLKIN Select

The CDU_CLKINSEL register controls the configuration of the CLKIN multiplexors. One bit is assigned to each CGU in the system. This bit selects either CLKIN0 or CLKINn CGUn inputs.

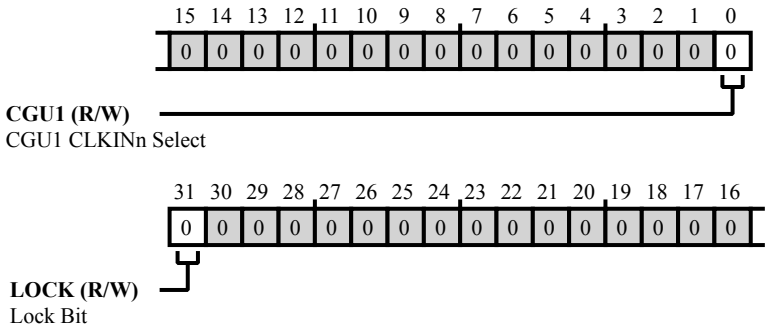

Figure 3-9: CDU_CLKINSEL Register Diagram

Table 3-6: CDU_CLKINSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
0 (R/W)	CGU1	CGU1 CLKINn Select. The CDU_CLKINSEL.CGU1 bit drives CDU_CLKIN_SEL[0] to CGU1.	
		0	Selects CLKIN0
		1	Selects CLKIN1

CDU Revision ID

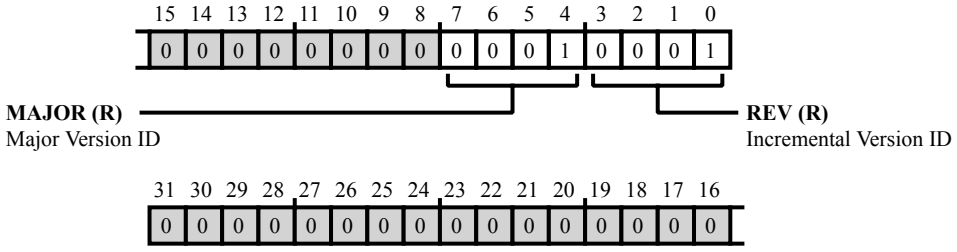

Figure 3-10: CDU_REVID Register Diagram

Table 3-7: CDU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

CDU Status

The CDU_STAT register reflects the status a change in the configuration of the clock muxes.

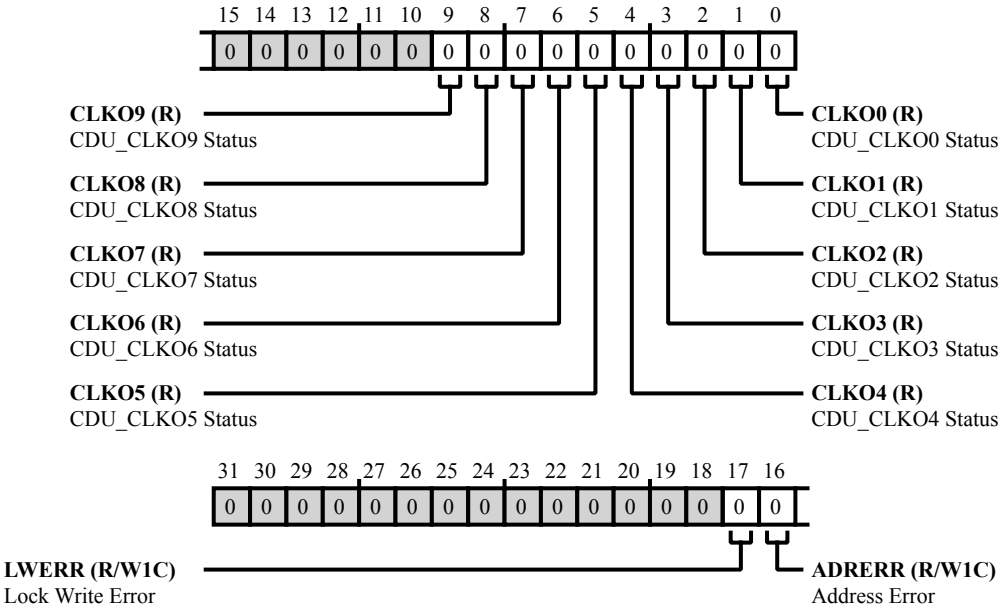

Figure 3-11: CDU_STAT Register Diagram

Table 3-8: CDU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The CDU_STAT.LWERR bit indicates a lock error where write transactions try to access write protected registers.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The CDU_STAT.ADRERR bit indicates an address error where read or write transactions try to access unimplemented addresses or accesses are non-aligned.	
		0	No Address Error
		1	Address Error
9 (R/NW)	CLKO9	CDU_CLKO9 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress

Table 3-8: CDU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	CLKO8	CDU_CLKO8 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
7 (R/NW)	CLKO7	CDU_CLKO7 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
6 (R/NW)	CLKO6	CDU_CLKO6 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
5 (R/NW)	CLKO5	CDU_CLKO5 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
4 (R/NW)	CLKO4	CDU_CLKO4 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
3 (R/NW)	CLKO3	CDU_CLKO3 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
2 (R/NW)	CLKO2	CDU_CLKO2 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
1 (R/NW)	CLKO1	CDU_CLKO1 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
0 (R/NW)	CLKO0	CDU_CLKO0 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress

4 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power-saving modes.

DPM Features

The DPM allows programs to control the power mode of the processor as follows.

- Permits operation of multiple, external wake-up sources

DPM Functional Description

The DPM can be programmed to transition between power modes.

ADSP-SC57x DPM Register List

A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

Table 4-1: ADSP-SC57x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

CGU

Acronym for the clock generation unit (CGU), which is comprised of the PLL and PCU

DPM

Acronym for the dynamic power management (DPM) controller.

Full-on mode

The normal operating mode in which all clock domains are derived from the PLL.

PCU

Acronym for the PLL control unit (PCU).

PLL

Acronym for the phase-locked loop (PLL).

RCU

Acronym for the reset control unit (RCU).

DPM Operating Modes

The DPM includes several operating modes. The modes are:

- Reset
- Full-on

Reset State

Reset is the initial state of the processor and is the result of a hardware or software triggered event. The DPM itself does not trigger entering reset. The external `SYS_HWRST` pin or the RCU triggers entering reset. The DPM responds to reset by transitioning to its default state.

From Reset, the DPM always transitions to PLL Bypassed state.

Full-on Mode

Full-on mode is the default state of the DPM after Reset.

In full-on mode, the processor can reach its maximum clock rate and power dissipation can be at its highest.

DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. The DPM generates bus errors when a misaligned access to a register occurs. It also generates errors when an attempt is made to access unused DPM address space or a write-protected register.

DPM Events

The DPM event interrupt is triggered when any bit in the DPM_STAT register is set, indicating that an enabled wake-up was asserted. The DPM event interrupt stays active until the user clears any bits that are set in the DPM_STAT register.

DPM Errors

The DPM generates a bus error when a read or write transaction is attempted to an unused address within the DPM address range. It also generates a bus error when a misaligned access is made to a DPM register. In addition to the bus error, the DPM sets the DPM_STAT.ADDRERR bit.

If a write to a write-protected DPM register is attempted, the DPM generates a bus error. In addition, the DPM sets the DPM_STAT.LWERR bit.

DPM Programming Model

The ***DPM_PER_DIS0 Register Mapping*** table shows the module clocks and the corresponding peripheral. The DPM_PER_DIS0 register is used to shut off the clock to each peripheral if it is not required by the application.

NOTE: In the table, SMPU-L2CTL-CL2_x and SMPU-L2CTL-DL2_x correspond to the SMPU modules associated with the core and the DMA ports of L2, respectively.

Table 4-2: DPM0_PER_DIS0 Register Mapping

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
FIR0	sclk0	Single Flop	2	0
IIR0	sclk0	Single Flop	2	1
DAI0	sclk0 clk05 sysclk	Single Flop Async Not Required	2 4 1	5
MLB0	sys_clk	Not Required	1	9
EMAC0 (GigE)	clko7 sclk0	Async Single Flop	4 2	10

Table 4-2: DPM0_PER_DIS0 Register Mapping (Continued)

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
MSI0	clko9 sclk0	Async Single Flop	4 1	12
EMDMA0	sclk0	Single Flop	2	13
EMDMA1	sclk0	Single Flop	2	14
CRYPTO ACCELERA-TOR-0 (EIP-150/PKP)	sysclk	Not Required	1	16
CRYPTO ACCELERA-TOR-1 (EIP-93/SPE)	sclk0	Single Flop	2	17
SMPU-L2CTL-CL2-0	sysclk	Not Required	1	20
SMPU-L2CTL-DL2-0	sysclk	Not Required	1	21
SMPU-DMC0	sysclk	Not Required	1	27
CAN0	clko4	Async	4	29
CAN1	clko4	Async	4	30

Table 4-3: DPM0_PER_DIS1 Register Mapping

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
TWI0	sclk0	Single Flop	2	0
TWI1	sclk0	Single Flop	2	1
TWI2	sclk0	Single Flop	2	2
USB0	sclk0	Single Flop	2	3
C1_L1CBTB[*1]	clko0	Not Required	1	5
C1_L1BK0[*1]	clko0	Not Required	1	6
C1_L1BK1[*1]	clko0	Not Required	1	7
C1_L1BK2[*1]	clko0	Not Required	1	8
C1_L1BK3[*1]	clko0	Not Required	1	9
C2_L1CBTB[*1]	clko1	Not Required	1	10
C2_L1BK0[*1]	clko1	Not Required	1	11
C2_L1BK1[*1]	clko1	Not Required	1	12
C2_L1BK2[*1]	clko1	Not Required	1	13

Table 4-3: DPM0_PER_DIS1 Register Mapping (Continued)

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
C2_L1BK3*1	clko1	Not Required	1	14
C0*1	clko2	Not Required	1	15

*1 This bit is used only for light sleep connection to memory and not for clock gating.

ADSP-SC57x DPM Register Descriptions

Dynamic Power Management (DPM) contains the following registers.

Table 4-4: ADSP-SC57x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

Control Register

The DPM_CTL register controls sleep modes selections and PLL operations of the DPM. A write protect feature permits locking out changes to this register.

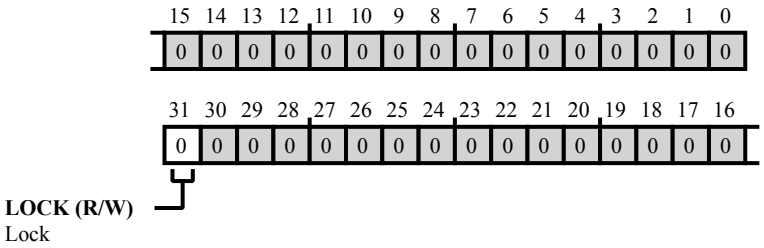

Figure 4-1: DPM_CTL Register Diagram

Table 4-5: DPM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the DPM_CTL.LOCK bit is set, the DPM_CTL register is read only (locked).	
		0	Unlock
		1	Lock

Peripherals Disable Register 0

The DPM_PER_DIS0 register is used to shut off the clocks to peripherals that are not used in an application in order to save clock switching power.

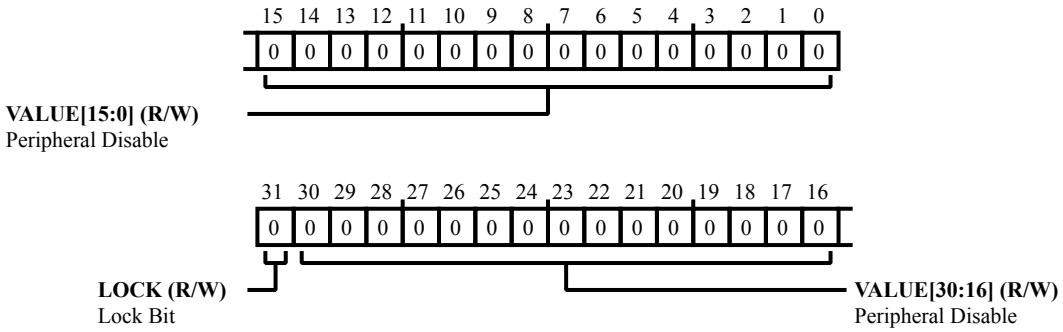

Figure 4-2: DPM_PER_DIS0 Register Diagram

Table 4-6: DPM_PER_DIS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
30:0 (R/W)	VALUE	Peripheral Disable. The DPM_PER_DIS0.VALUE bits are used to shut of clocks in individual peripherals.

		28	Reserved
		29	Reserved
		30	Reserved

Peripherals Disable Register 1

The DPM_PER_DIS1 register is used to shut off the clocks to peripherals that are not used in an application to save clock switching power. Bits 5 to 15 are used only for light sleep connection to memory and not for clock gating.

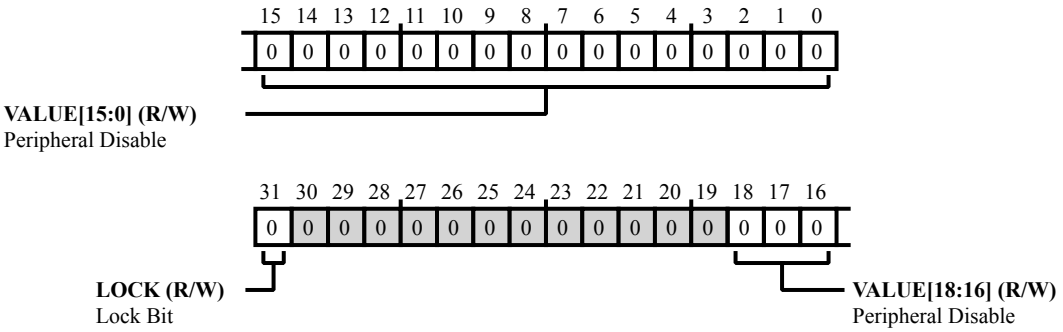

Figure 4-3: DPM_PER_DIS1 Register Diagram

Table 4-7: DPM_PER_DIS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
18:0 (R/W)	VALUE	Peripheral Disable. The DPM_PER_DIS1.VALUE bits are used to shut of clocks in individual peripherals. Bits 5 to 15 are used only for light sleep connection to memory and not for clock gating.

Revision ID

The DPM_REVID register provides the revision of the DPM module.

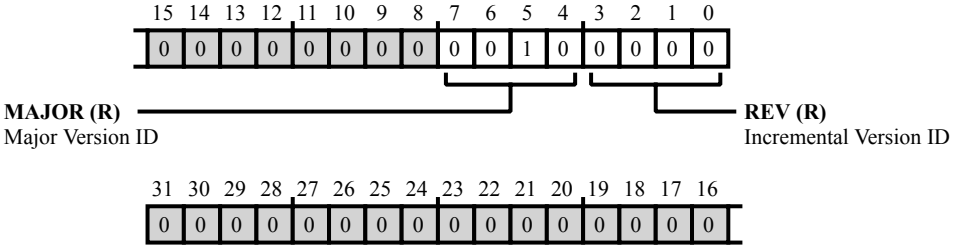

Figure 4-4: DPM_REVID Register Diagram

Table 4-8: DPM_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Status Register

The DPM_STAT register contains bits that report the state of the module and various errors.

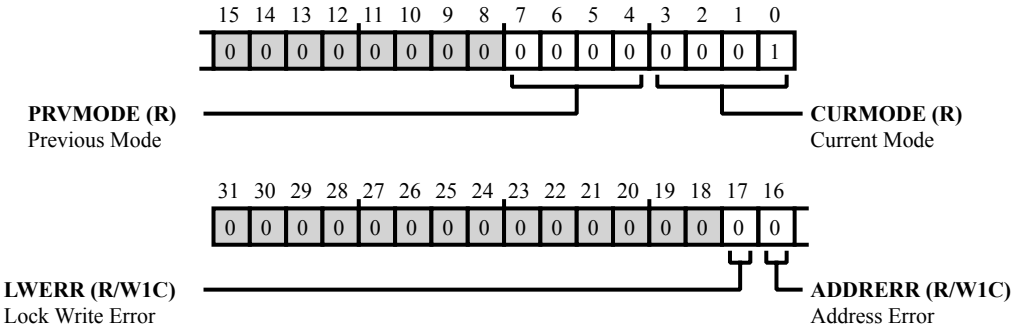

Figure 4-5: DPM_STAT Register Diagram

Table 4-9: DPM_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The DPM_STAT.LWERR bit indicates that a write transaction attempted an access to a write protected register. Triggers the DPMLV_PSLVERR interrupt.	
		0	Inactive
		1	Active
16 (R/W1C)	ADDRERR	Address Error. The DPM_STAT.ADDRERR bit indicates that a read or write transaction attempted an access to an unimplemented address or a write transaction attempted an access to a read only register or accesses are non aligned. Triggers the DPMLV_PSLVERR interrupt.	
		0	Inactive
		1	Active
7:4 (R/NW)	PRVMODE	Previous Mode. The DPM_STAT.PRVMODE bit field indicates the previous mode of the the module.	
		0	Reset
		1	Full-On
		2	Reserved
		3	Reserved
		4	Reserved
		5-15	Reserved

Table 4-9: DPM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	CURMODE	Current Mode. The `DPM_STAT.CURMODE` bit field indicates the current mode of the the module.	
		0	Reserved
		1	Full-On
		2	Reserved
		3	Reserved
		4-15	Reserved

5 Reset Control Unit (RCU)

Reset is the initial state of the processor at power-on or the run-time state of any core, as controlled by another core in the device via the RCU or as a a result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system hardware reset results with only the host core being released from reset and ready to boot (Core 0 on the ADSP-SC57x devices, Core 1 on the ADSP-215xx devices).

The following table shows the cores that are released from reset. Exiting a Core n only reset starts with this Core n being ready to execute the code from the software vector registers (`RCU_SVECT0` , `RCU_SVECT2`).

Additional information on reset and booting can be found in the *Boot ROM and Booting the Processor* chapter.

Product	Core Released from Reset by RCU
ADSP-SC57x	Core 0
ADSP-2157x	Core 1

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset). While core resets and software system resets are controlled directly in the RCU, hardware resets can come from the TRU, SEC, or CGU Oscillator Watchdog.

RCU Features

The RCU module supports the following features:

- Hardware reset through the $\overline{\texttt{SYS\_HWRST}}$ pin
- Software system reset through the RCU control (`RCU_CTL`) register
- Hardware system reset through:
  - TRU module
  - SEC module (System Fault Unit)

- A clock not good reset state (safe state of chip under reset) from the Oscillator Watchdog.
- Core reset through RCU Core Reset Output (RCU_CRCTL) register

RCU Functional Description

This section provides information on the function of RCU module.

NOTE: In 2156x series of processors, there is only one core. The terminology *n* when describing number of cores (for example, core[n]) must be considered always as 0 (core 0).

Hardware reset using SYS_HWRST pin

Asserting the $\overline{\text{SYS\_HWRST}}$ pin resets all functional units, except the real time clock (RTC) (if present).

Hardware reset through RCU

The RCU can perform a full system reset which can be initiated through hardware blocks like the SEC, the TRU, and the oscillator watchdog.

Software reset using RCU registers

Setting the RCU_STAT.SWRST bit issues a software reset for all system units except the RTC module and RCU_BCODE, RCU_CRCTL and RCU_STAT registers.

Core reset RCU registers

A core can be individually reset by software, or by setting the RCU_CRCTL.CR[n] bit.

ADSP-SC57x RCU Register List

The Reset Control Unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints exist (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way), and these differences define how reset signals are generated. Reset signals propagate through all functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

Table 5-1: ADSP-SC57x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register

Table 5-1: ADSP-SC57x RCU Register List (Continued)

Name	Description
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register

RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

ADSP-SC57x RCU Trigger List

Table 5-2: ADSP-SC57x RCU Trigger List Masters

Trigger ID	Name	Description	Sensitivity
None			

Table 5-3: ADSP-SC57x RCU Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
34	RCU0_SYSRST0	RCU0 System Reset 0	Pulse
35	RCU0_SYSRST1	RCU0 System Reset 1	Pulse

RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The target or source defines the following are types of resets.

Hardware Reset (by target)

All functional units except a small subsection of debug interfaces are set to their default states. State is lost in all non-volatile storage.

System Reset (by target)

All functional units except the RCU, flash interface, and debug are set to their default states.

Core n Only Reset (by target)

Affects Core n only. The system software must guarantee that a bus master cannot access the core in reset state.

Hardware Reset (by source)

The $\overline{\texttt{SYS\_HWRST}}$ input signal is asserted active (pulled low).

System Reset (by source)

Software can trigger the reset by writing to the RCU_CTL register or by another functional unit such as the TRU or any of the generic reset inputs.

RCU Architectural Concepts

To understand the architecture of the RCU, it is important to consider the reset sources and how differing resets affect the functional units of the processor.

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. For example, units in different clock domains must enter reset asynchronously but exit reset in a deterministic way.

The program must guarantee that none of the reset functions put the system in an undefined state or cause resources to stall. This functionality is important when only one of the cores is reset. The program must guarantee that there is no pending system activity involving Core n before it is reset. For example, there must be no pending transactions to core 0 when the core 0 is reset and vice-versa.

The ***RCU Reset Sources*** table defines how reset sources affect the different functional units.

Table 5-4: RCU Reset Sources

Reset Source	Reset Type	Affected Functional Units
$\overline{\texttt{SYS\_HWRST}}$ pin assertion	Hardware Reset	All functional units, except RTC (if present)
SYSCLK clock domain system reset by the Fault Unit (FMU) or TRU slave	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
RCU_CTL.SYSRST bit set (software triggered reset)	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain

Table 5-4: RCU Reset Sources (Continued)

Reset Source	Reset Type	Affected Functional Units
RCU_CRCTL.CR[n] bit set (software triggered reset)	Core Only Reset	Core n only , for (2 ≥ n ≥ 0)

RCU Status and Error Signals

The RCU_STAT register reflects status and error information. There are three kinds of errors that can occur in the RCU. The reset out error is triggered when RSTOUT is both asserted and deasserted at the same time. The lock write error occurs if an attempt is made to write a lock RCU register. The address error occurs if a read-only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

ADSP-SC57x RCU Register Descriptions

Reset Control Unit (RCU) contains the following registers.

Table 5-5: ADSP-SC57x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

Boot Code Register

The RCU_BCODE register can be used to determine if and how core boots. This register is set to its default values by RESET.

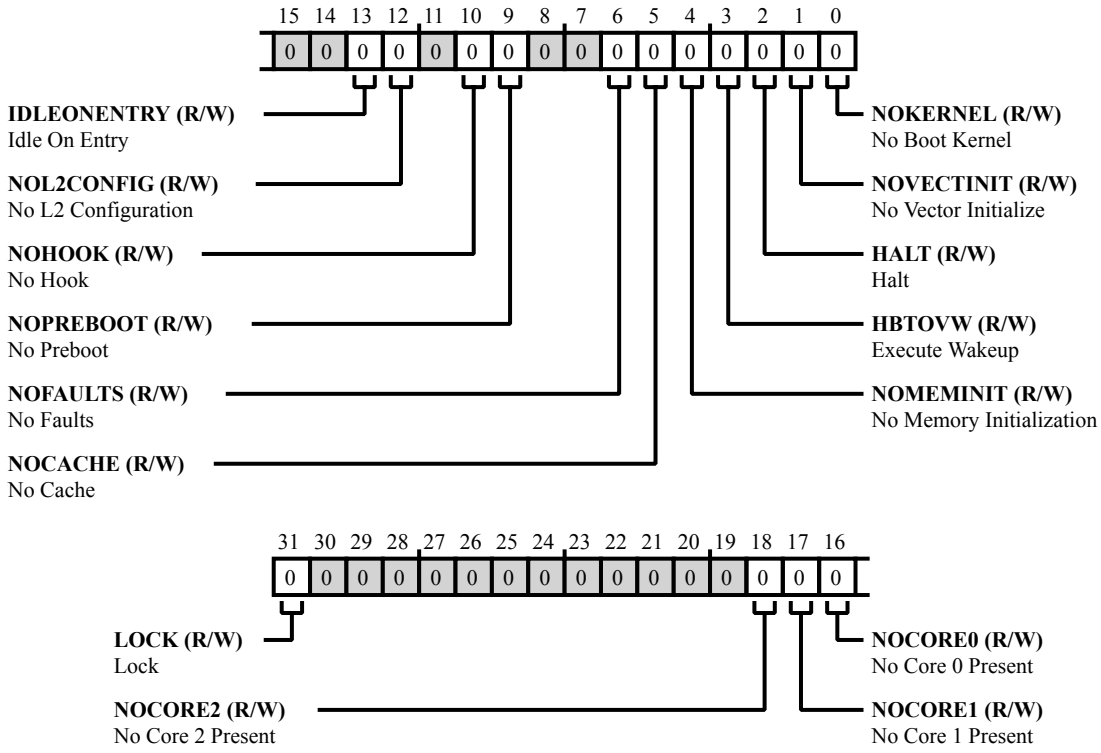

Figure 5-1: RCU_BCODE Register Diagram

Table 5-6: RCU_BCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_BCODE.LOCK bit is set, the RCU_BCODE register is read only (locked).	
		0	Unlock
		1	Lock
18 (R/W)	NOCORE2	No Core 2 Present. The RCU_BCODE.NOCORE2 bit indicates the presence of core 2.	
		0	Core does not exist
		1	Core exists

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	NOCORE1	No Core 1 Present. The `RCU_BCODE.NOCORE1` bit indicates the presence of core 1.	
		0	Core does not exist
		1	Core exists
16 (R/W)	NOCORE0	No Core 0 Present. The `RCU_BCODE.NOCORE0` bit indicates the presence of core 0.	
		0	Core does not exist
		1	Core exists
13 (R/W)	IDLEONENTRY	Idle On Entry. The `RCU_BCODE.IDLEONENTRY` bit configures the RCU to enter the idle state at startup.	
		0	Do not enter idle state
		1	Enter idle state
12 (R/W)	NOL2CONFIG	No L2 Configuration. The `RCU_BCODE.NOL2CONFIG` bit configures the RCU to not perform the L2 memory configuration.	
		0	Configure L2 memory
		1	Do not configure L2 memory
10 (R/W)	NOHOOK	No Hook. The `RCU_BCODE.NOHOOK` bit configures the RCU to not perform the hook routine.	
		0	Perform hook routine
		1	Do not perform hook routine
9 (R/W)	NOPREBOOT	No Preboot. The `RCU_BCODE.NOPREBOOT` bit configures the RCU to not perform the customer preboot routine.	
		0	Perform preboot
		1	Do not perform preboot
6 (R/W)	NOFAULTS	No Faults. The `RCU_BCODE.NOFAULTS` bit configures the RCU to not perform fault initialization.	
		0	Perform fault initialization
		1	Do not perform fault initialization

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	NOCACHE	No Cache. The RCU_BCODE.NOCACHE bit configures the RCU to not perform a cache initialization and to not enable the cache.	
		0	Enable and initialize cache
		1	Do not initialize or enable cache
4 (R/W)	NOMEMINIT	No Memory Initialization. The RCU_BCODE.NOMEMINIT bit configures the RCU to not perform a memory initialization.	
		0	Perform memory initialization
		1	Do not perform memory initialization
3 (R/W)	HBTOVW	Execute Wakeup. The RCU_BCODE.HBTOVW bit configures the RCU to execute a wakeup.	
		0	Do not wakeup
		1	Execute wakeup
2 (R/W)	HALT	Halt. The RCU_BCODE.HALT bit configures the RCU to execute the no boot routine.	
		0	Do not execute routine
		1	Execute routine
1 (R/W)	NOVECTINIT	No Vector Initialize. The RCU_BCODE.NOVECTINIT bit configures the RCU to not vector to the application.	
		0	Vector
		1	Do not vector
0 (R/W)	NOKERNEL	No Boot Kernel. The RCU_BCODE.NOKERNEL bit configures the RCU to not execute the boot kernel.	
		0	Execute boot kernel
		1	Do not execute boot kernel

Core Reset Outputs Control Register

The RCU core reset control n registers (RCU_CRCTL) include a lock bit (RCU_CRCTL.LOCK) and a core reset bit (RCU_CRCTL.CR[n]) for each core reset signal on the product.

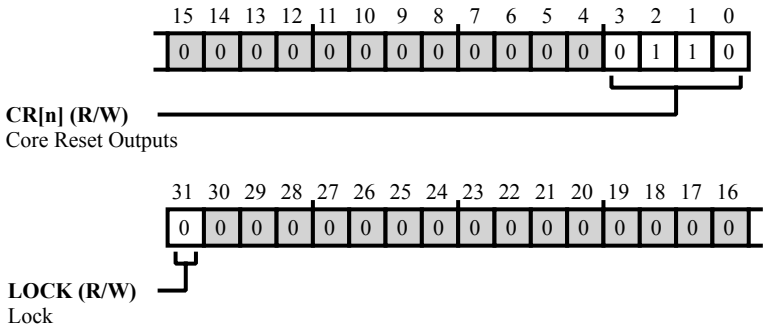

Figure 5-2: RCU_CRCTL Register Diagram

Table 5-7: RCU_CRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CRCTL.LOCK bit is set, the RCU_CRCTL register is read only (locked).	
		0	Unlock
		1	Lock
3:0 (R/W)	CR[n]	Core Reset Outputs. The RCU_CRCTL.CR[n] bits control CRES[1:0] core reset signals. The RCU_CRES[n] signals can be individually controlled. They are reset to their default value by a hard reset or a system reset. For each RCU_CRES[n], the selected RCU0_CRMSKi[n] bit is cleared.	
		0	RCU_CRES[3:0] Deasserted
		15	RCU_CRES[3:0] Asserted

Core Reset Outputs Status Register

The RCU core reset status register (RCU_CRSTAT) contains status bits, indicating which core reset signals have been asserted.

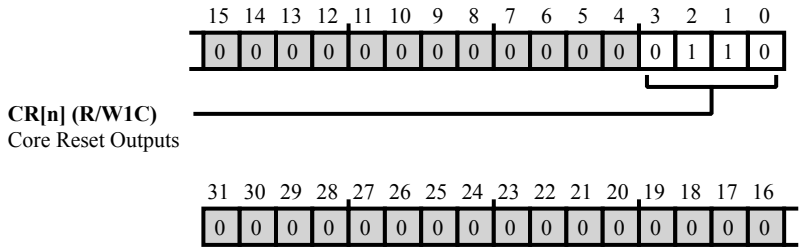

Figure 5-3: RCU_CRSTAT Register Diagram

Table 5-8: RCU_CRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W1C)	CR[n]	Core Reset Outputs. The `RCU_CRSTAT.CR[n]` bits indicate which cores have been reset since the last time the bit was cleared. Bits masked by CORE_DISABLE_MASK[15:0] are permanently disabled and the corresponding CR bits set. CR bits are sticky, they need to be cleared by software.	
		0	RCU_CRES[1:0] deasserted. CR[n] corresponds to RCU_CRES[n].
		15	RCU_CRES[3:0] were asserted since the last time bits were cleared. CR[n] corresponds to RCU_CRES[n].

Control Register

The RCU control register (RCU_CTL) provides a register lock, enables for the core and system reset requests inputs and control for the Reset Output pin.

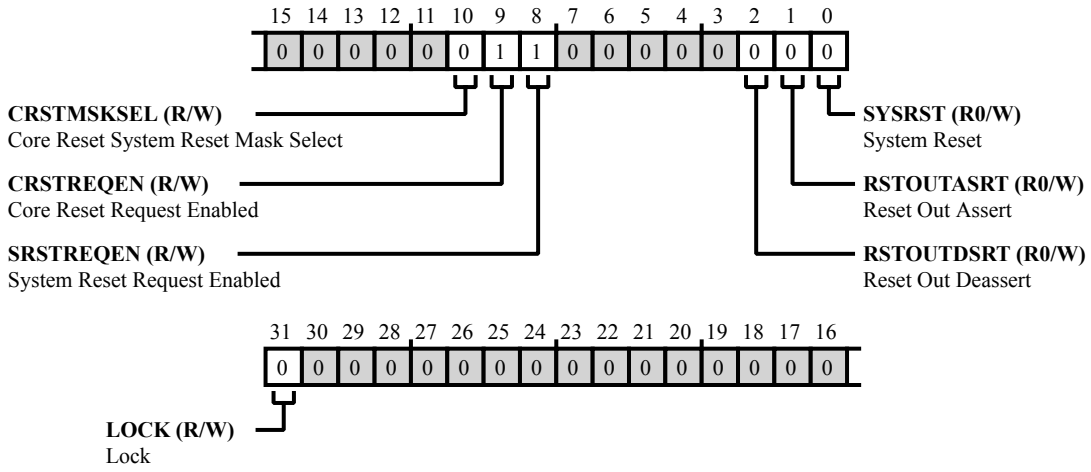

Figure 5-4: RCU_CTL Register Diagram

Table 5-9: RCU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CTL.LOCK bit is set, the RCU_CTL register is read only (locked). This bit is cleared by a hard reset or any system reset event.	
		0	Unlock
		1	Lock
10 (R/W)	CRSTMSKSEL	Core Reset System Reset Mask Select. The RCU_CTL.CRSTMSKSEL bit selects the core reset system reset mask. This bit is cleared by a hard reset.	
9 (R/W)	CRSTREQEN	Core Reset Request Enabled. The RCU_CTL.CRSTREQEN bit controls whether the SYSCLK domain source(s) of reset is/are enabled to reset the core(s) when asserted. This bit is cleared by hard reset or any system reset event.	
		0	Disabled
		1	Enabled

Table 5-9: RCU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SRSTREQEN	System Reset Request Enabled. The `RCU_CTL.SRSTREQEN` bit controls whether the SYSCLK domain sources of reset are enabled to do a system reset when asserted. This bit is cleared by a hard reset.	
		0	Disabled
		1	Enabled
2 (R0/W)	RSTOUTDSRT	Reset Out Deassert. The `RCU_CTL.RSTOUTDSRT` bit controls the deassertion of the system reset pin.	
		0	No Action
		1	Deassert RSTOUT
1 (R0/W)	RSTOUTASRT	Reset Out Assert. The `RCU_CTL.RSTOUTASRT` bit controls assertion of the system reset pin.	
		0	No Action
		1	Assert RSTOUT
0 (R0/W)	SYSRST	System Reset. The `RCU_CTL.SYSRST` bit provides reset for all system units.	
		0	No Action
		1	System Reset

Message Register

The RCU_MSG is a general-purpose register. It is intended to provide flexibility for Boot ROM code and to pass predefined variables to the debugger. Please see the Booting chapter for product-specific details.

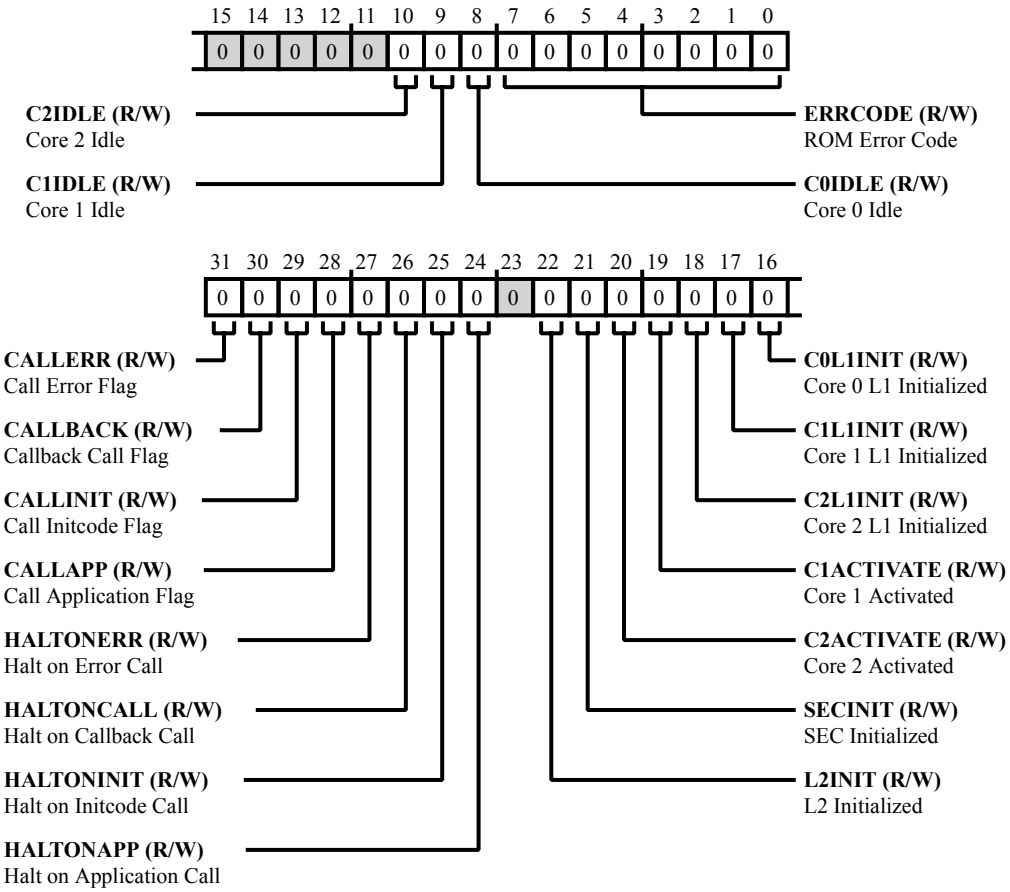

Figure 5-5: RCU_MSG Register Diagram

Table 5-10: RCU_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CALLERR	Call Error Flag. The RCU_MSG.CALLERR bit indicates that a flag has been set by the boot code prior to an error call.	
		0	Flag not set
		1	Flag set

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	CALLBACK	Callback Call Flag. The RCU_MSG.CALLBACK bit indicates that a flag has been set by the boot code prior to a callback call.	
		0	Flag not set
		1	Flag set
29 (R/W)	CALLINIT	Call Initcode Flag. The RCU_MSG.CALLINIT bit indicates that a flag has been set by the boot code prior to an initcode call.	
		0	Flag not set
		1	Flag set
28 (R/W)	CALLAPP	Call Application Flag. The RCU_MSG.CALLAPP bit indicates that a flag has been set by the boot code prior to an application call.	
		0	Flag not set
		1	Flag set
27 (R/W)	HALTONERR	Halt on Error Call. The RCU_MSG.HALTONERR bit generates an emulation exception prior to an error call.	
		0	Do not generate exception
		1	Generate exception
26 (R/W)	HALTONCALL	Halt on Callback Call. The RCU_MSG.HALTONCALL bit generates an emulation exception prior to a callback call.	
		0	Do not generate exception
		1	Generate exception
25 (R/W)	HALTONINIT	Halt on Initcode Call. The RCU_MSG.HALTONINIT bit generates an emulation exception prior to an initcode call.	
		0	Do not generate exception
		1	Generate exception

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	HALTONAPP	Halt on Application Call. The RCU_MSG.HALTONAPP bit generates an emulation exception prior to an application call.	
		0	Do not generate exception
		1	Generate exception
22 (R/W)	L2INIT	L2 Initialized. The RCU_MSG.L2INIT bit indicates that the L2 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
21 (R/W)	SECINIT	SEC Initialized. The RCU_MSG.SECINIT bit is used by tools for initialization of the SEC.	
20 (R/W)	C2ACTIVATE	Core 2 Activated. The RCU_MSG.C2ACTIVATE bit is used by tools for activation of Core 2.	
19 (R/W)	C1ACTIVATE	Core 1 Activated. The RCU_MSG.C1ACTIVATE bit is used by tools for activation of Core 1.	
18 (R/W)	C2L1INIT	Core 2 L1 Initialized. The RCU_MSG.C2L1INIT bit indicates that the core 2 L1 resource is initialized.	
17 (R/W)	C1L1INIT	Core 1 L1 Initialized. The RCU_MSG.C1L1INIT bit indicates that the core 1 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
16 (R/W)	C0L1INIT	Core 0 L1 Initialized. The RCU_MSG.C0L1INIT bit indicates that the core 0 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
10 (R/W)	C2IDLE	Core 2 Idle. The RCU_MSG.C2IDLE bit indicates that core 2 is in a safe idle state in ROM.	
9 (R/W)	C1IDLE	Core 1 Idle. The RCU_MSG.C1IDLE bit indicates that core 1 is in a safe idle state in ROM.	
8 (R/W)	C0IDLE	Core 0 Idle. The RCU_MSG.C0IDLE bit indicates that core 0 is in a safe idle state in ROM.	

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ERRCODE	ROM Error Code. The `RCU_MSG.ERRCODE` bit indicates the error code of the ROM. It is valid only when in the error handler.

Message Clear Bits Register

The RCU_MSG_CLR register is used to clear bits in RCU_MSG register. Reading this register returns 0x00000000.

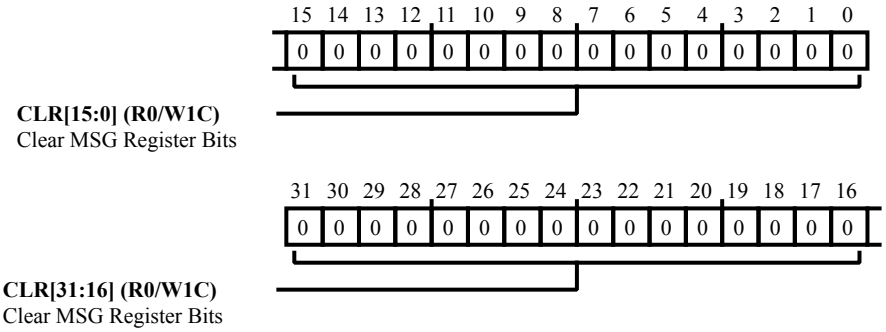

Figure 5-6: RCU_MSG_CLR Register Diagram

Table 5-11: RCU_MSG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1C)	CLR	Clear MSG Register Bits. The RCU_MSG_CLR.CLR bit resets MSG bit n.

Message Set Bits Register

The RCU_MSG_SET register is used to set bits in RCU_MSG register. Reading this register returns 0x00000000.

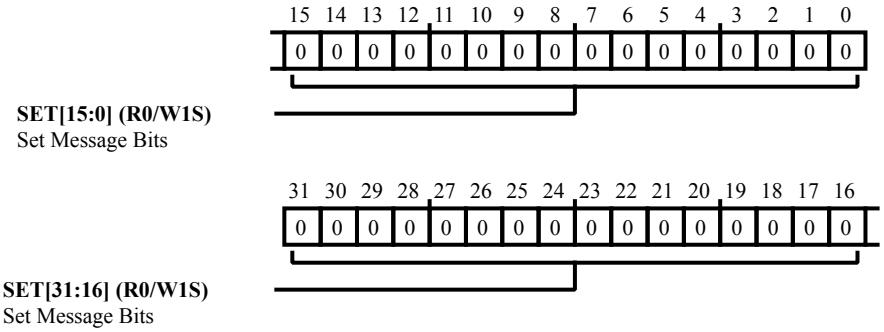

Figure 5-7: RCU_MSG_SET Register Diagram

Table 5-12: RCU_MSG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1S)	SET	Set Message Bits. The RCU_MSG_SET.SET bit sets MSG bit n.

System Interface Disable Register

The RCU system interface disable register (RCU_SIDIS) lets the RCU assert a system interface disable request to functional units in the processor. This register is set to its default values by a hard reset or any system reset event. For information on mapping between RCU_SIDIS bits and functional units, see the RCU functional description.

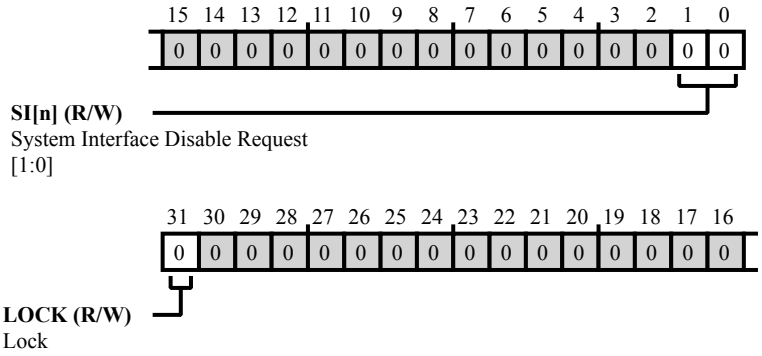

Figure 5-8: RCU_SIDIS Register Diagram

Table 5-13: RCU_SIDIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SIDIS.LOCK bit is set, the RCU_SIDIS register is read only (locked).	
		0	Unlock
		1	Lock
1:0 (R/W)	SI[n]	System Interface Disable Request [1:0]. Each RCU_SIDIS.SI[n] bit corresponds to a functional unit in the processor that supports the system interface disable request-acknowledge protocol.	
		0	RCU_SI_DISABLE_REQ[1:0] deasserted
		3	RCU_SI_DISABLE_REQ[1:0] asserted

System Interface Status Register

The RCU system interface status register (RCU_SISTAT) indicates whether a functional unit has or has not acknowledged an RCU unit disable request.

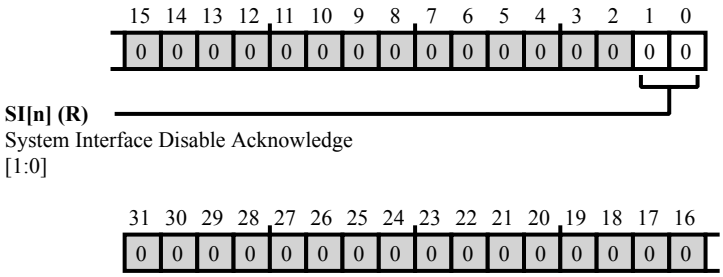

Figure 5-9: RCU_SISTAT Register Diagram

Table 5-14: RCU_SISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	SI[n]	System Interface Disable Acknowledge [1:0]. The RCU_SISTAT.SI[n] bit indicates whether a functional unit has or has not acknowledged an RCU unit disable request.	
		0	No Acknowledge
		3	SI_DISABLE_ACK[1:0] asserted

System Reset Request Status Register

The RCU system reset request status register (RCU_SRRQSTAT) contains status bits, indicating which system reset request input triggered a system reset. This register is set to its default values by a hard reset.

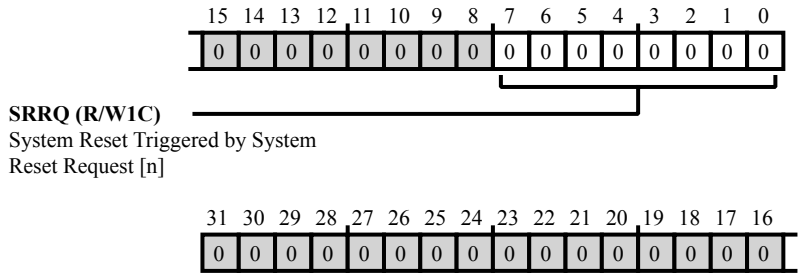

Figure 5-10: RCU_SRRQSTAT Register Diagram

Table 5-15: RCU_SRRQSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	SRRQ	System Reset Triggered by System Reset Request [n]. The RCU_SRRQSTAT.SRRQ bits are set by the assertion of the corresponding system reset request input and deasserted by writing "1" to the bit. The RCU_SRRQSTAT register is cleared by a hard reset.

Status Register

The RCU status register (RCU_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can cleared by software. Error status bits are cleared by any reset event.

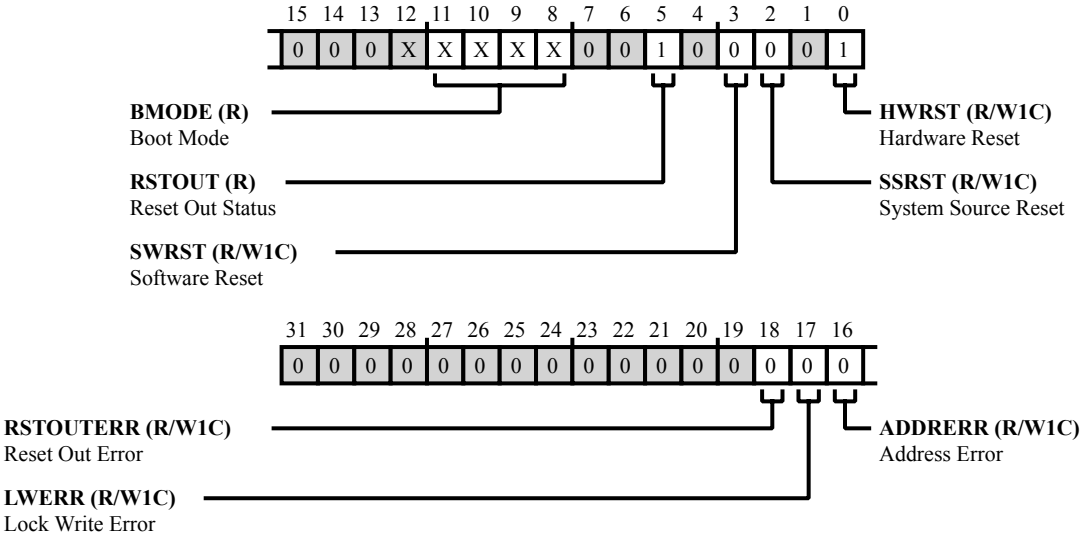

Figure 5-11: RCU_STAT Register Diagram

Table 5-16: RCU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	RSTOUTERR	Reset Out Error. The RCU_STAT.RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL.RSTOUTASRT and RCU_CTL.RSTOUTDSRT simultaneously. This condition triggers a bus error.	
		0	No Error
		1	Error Occurred
17 (R/W1C)	LWERR	Lock Write Error. The RCU_STAT.LWERR bit indicates (when set) there was an attempted write to an RCU register while the RCU_CTL.LOCK bit was set and the global lock bit is enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear	
		0	No Error
		1	Error Occurred

Table 5-16: RCU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ADDRERR	Address Error. The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
11:8 (R/NW)	BMODE	Boot Mode. The RCU_STAT.BMODE bits indicate the input on the boot mode pins.	
5 (R/NW)	RSTOUT	Reset Out Status. The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.	
		0	RSTOUT Deasserted
		1	RSTOUT Asserted
3 (R/W1C)	SWRST	Software Reset. The RCU_STAT.SWRST bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the RCU_STAT.SWRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
2 (R/W1C)	SSRST	System Source Reset. The RCU_STAT.SSRST bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the RCU_STAT.SSRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
0 (R/W1C)	HWRST	Hardware Reset. The RCU_STAT.HWRST bit indicates that a hardware reset has occurred.	
		0	Inactive
		1	Reset Occurred

Software Vector Register 0

The RCU_SVECT0 register contains the default location of the first instruction to execute after a reset.

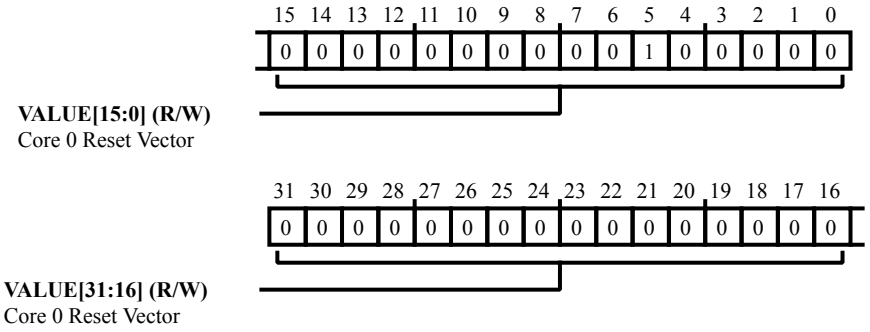

Figure 5-12: RCU_SVECT0 Register Diagram

Table 5-17: RCU_SVECT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Core 0 Reset Vector. The RCU_SVECT0.VALUE bit field contains the default location of the first instruction to execute after a reset.

Software Vector Register 1

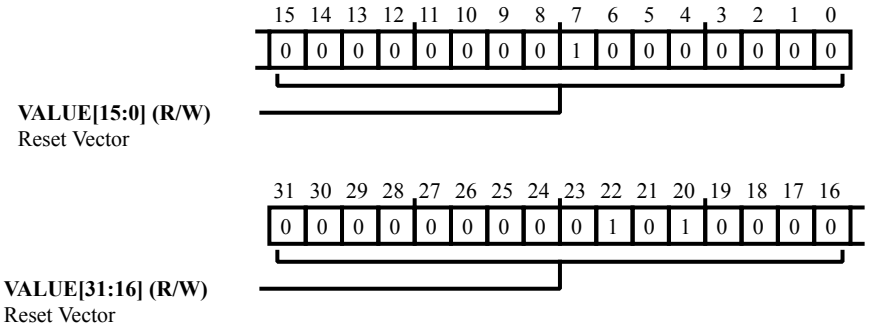

Figure 5-13: RCU_SVECT1 Register Diagram

Table 5-18: RCU_SVECT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector.

Software Vector Register 2

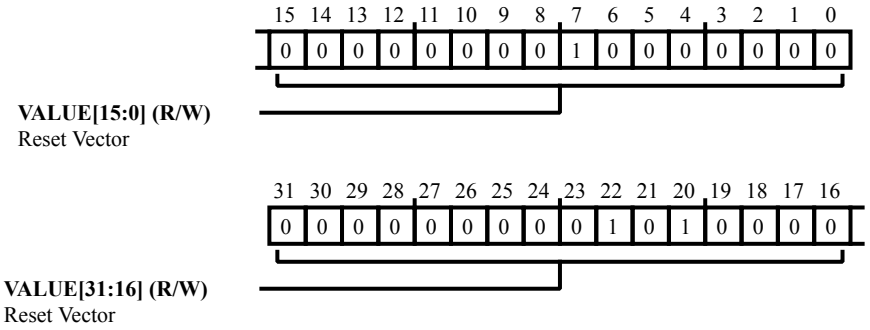

Figure 5-14: RCU_SVECT2 Register Diagram

Table 5-19: RCU_SVECT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector.

SVECT Lock Register

The RCU software vector lock register (RCU_SVECT_LCK) provides a register lock and software vector n enable bits for each processor core on the product. This register is set to its default values by a hard reset or any system reset event.

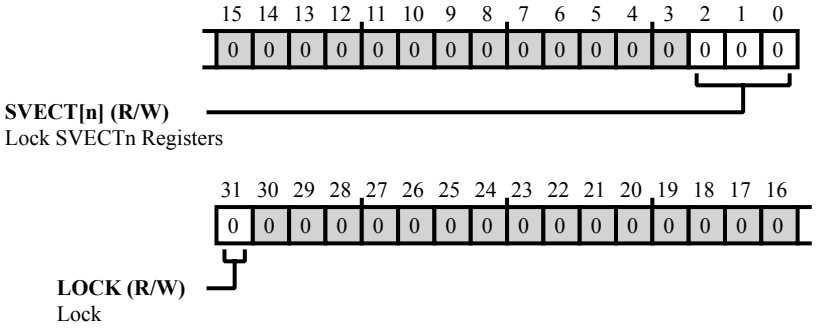

Figure 5-15: RCU_SVECT_LCK Register Diagram

Table 5-20: RCU_SVECT_LCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.LOCK bit is set, the RCU_SVECT_LCK register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SVECT[n]	Lock SVECTn Registers. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.SVECT[n] bit is set, the SVECT registers are read only (locked).	

6 System Event Controller (SEC) and Generic Interrupt Controller (GIC)

There are two interrupt controllers—a generic interrupt controller (GIC) for the ARM core and the system event controller (SEC) for the SHARC cores.

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources. The SEC also manages the propagation of system events to all connected cores and the system fault interface.

All of the peripheral interrupts are routed using a single SEC interrupt to the desired core. The SEC allows programmability of the peripheral interrupt's priority, supporting up to 256 priority levels that are arbitrated within the SEC itself. The SEC also allows these interrupts to be grouped and masked by priority level and provides the flexibility to choose which core(s) the interrupt is routed to.

The SEC also supports self-nesting of interrupts, which is required when sharing a single interrupt request to an individual core, as this allows for a higher-priority peripheral interrupt to be passed to the core while it is currently servicing a lower-priority peripheral interrupt. For more information, refer to "Self-Nesting Mode for System Event Controller Interrupt (SECI)" in the *SHARC+ Core Programming Reference*.

For more information about the ARM GIC, visit the ARM Information Center.

SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, priority, core mapping, and source grouping.
- Fault management including fault action configuration, timeout, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are independent of all others.

- Slave control port which provides access to all SEC registers for configuration, status, and interrupt or fault service model.
- Global locking supports a register level protection model to prevent writes to “locked” registers.

SEC Functional Description

The following sections provide a functional description of the SEC.

The *SEC/GIC Interrupt Signal Flow* figure shows an overview of the interrupt systems.

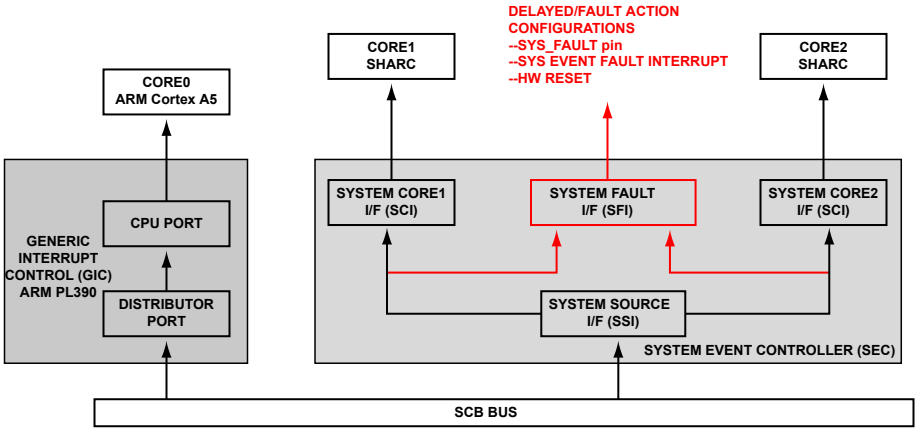

Figure 6-1: SEC/GIC Interrupt Signal Flow

ADSP-SC57x SEC Register List

The System Event Controller (SEC) manages the system fault sources, including control features such as enable/disable, priority, and active/pending source status. For more information on SEC functionality, see the SEC register descriptions.

Table 6-1: ADSP-SC57x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n

Combined SEC and GIC Interrupt List

The ***Combined SEC and GIC Interrupt List*** table provides a complete list of the processor and Cortex interrupts. Note that the DAI has its own system interrupt controllers. For more information see the DAI System Interrupt Controller (SIC). Note in the table below many interrupts are supported by all cores. In the cases were an interrupt is not supported its ID number (GIC_ID for ARM Cortex-A5 or SEC_ID for SHARC+) is reserved.

Table 6-5: ADSP-SC57x Combined SEC and GIC Interrupt List

Module	Event/Interrupt	SEC ID	GIC ID	SEC/GIC Interrupt Name
GIC	Software Interrupt 0	N/A	0	GIC0_SOFT00

SEC Definitions

The event controller uses the following definitions.

System Events

System source indications including interrupts and faults.

System Source

Point of origin of system event.

SID (Identification, unique)

Source numeric identifier for each system source connected to the SEC.

SSI

SEC source interface, system event source control, and status subblock of the SEC.

SCI

SEC core interface, core interface subblock of the SEC

SPR

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt. The SPR provides these interrupts in the appropriate registers of the SCI for the priority and nesting model of the SCI.

SFI

SEC Fault Interface, fault management subblock of the SEC.

SEC Block Diagram

The *SEC Block Diagram* shows the event management architecture.

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

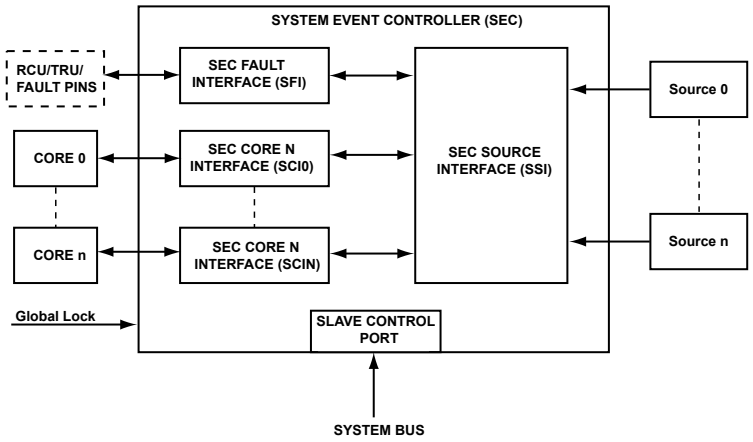

Figure 6-2: SEC Block Diagram

As shown in the figure, the SEC has three blocks for event management. The SFI monitors and manages any fault event triggered from various fault input sources. System interrupt sources are routed to the SFI through SEC source interface (SSI).

SEC Fault Interface (SFI)

The SFI manages fault events and associated actions. The fault management support provided in the SEC helps satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown, and once the countdown expires, takes the prescribed action.

Fault actions which can be configured, as shown in *SFI Block Diagram*, include

- Trigger Output
- System Reset
- Fault Output
    - Computer Operating Properly (COP) mode
    - Fault Mode

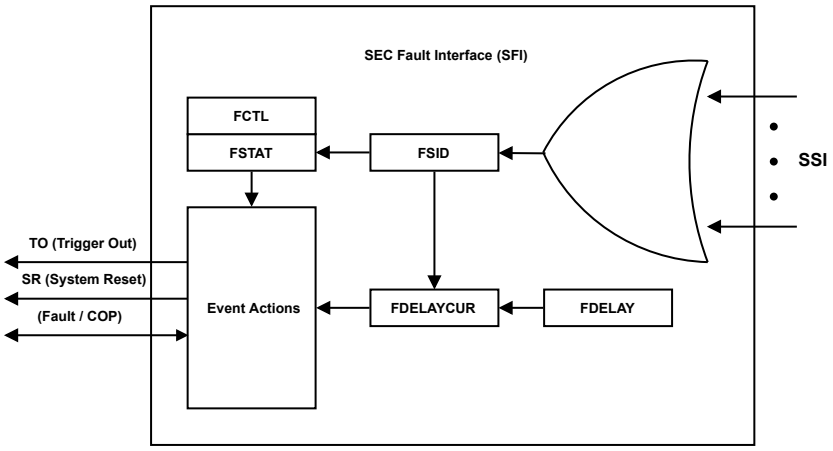

Figure 6-3: SFI Block Diagram

Fault Management

System sources can be enabled as fault sources in the SEC_SCTL[n] register. When a source enabled as a fault moves to pending, it is forwarded to the SFI as a fault indication. The pending bit (SEC_FSTAT.PND) indicates a source has signaled a fault assertion but it has not yet triggered the event actions (if delay is enabled). The SEC fault interface sets the SEC_FSTAT.PND bit when the fault source ID register (SEC_FSID) is updated on assertion of a fault source input. The system source pending triggers a fault pending and after a programmable delay the fault moves to active. Event actions then execute if appropriate action is not taken by the core. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the delay has expired, and the fault actions are enabled.

The SEC_FSTAT.NPND bit indicates if one or more sources have signaled a fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.

A fault indication from an external device can also be detected on sampling the fault signals. When a fault is detected the SEC_FSTAT.ACT and SEC_FSID.FEXT bits are set. The assertion of either signal results in a fault input detection.

The SEC_FEND register receives a fault end indication from the core. The core writes the SID of the fault to the SEC_FEND register. If the SID matches the value in the SEC_FSID register, the SEC_FSTAT.PND and SEC_FSTAT.ACT bits are cleared.

SEC Core Interface (SCI)

The SCI manages communication between the corresponding core and the SEC. The SEC prioritizer (SPR) of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest-priority pending system event and the SCI determines whether it propagates to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

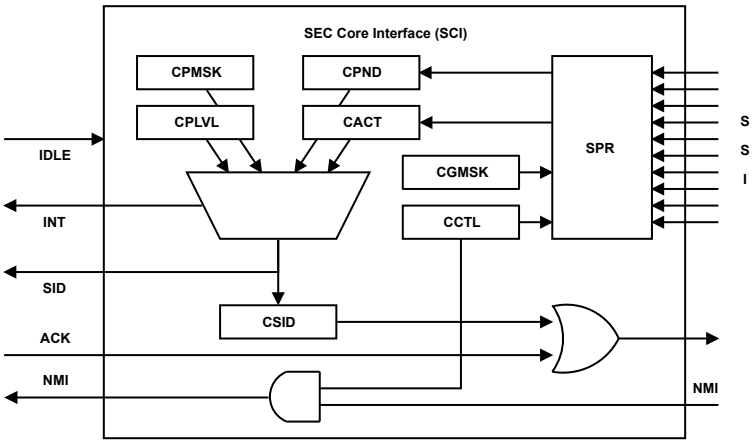

Figure 6-4: SCI Overview Block Diagram

SEC Source Interface (SSI)

The SSI manages all of the system event sources. It maintains the status of each source in the corresponding `SEC_SSTAT[n]` register. The corresponding `SEC_SCTL[n]` register manages the control of each source. A pending and enabled event passes its indication and priority to the SCI to which it is assigned for further processing.

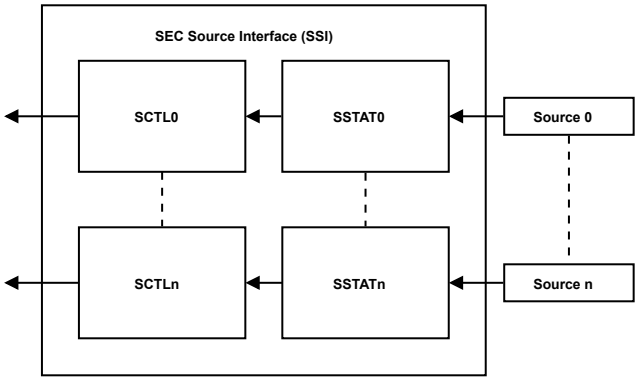

Figure 6-5: SSI Overview Block Diagram

SEC Architectural Concepts

The following sections describe SEC architectural features.

System Interrupt Acknowledge

A system interrupt acknowledge occurs when the core provides an indication that it has acquired the SID of the interrupt last issued by the SEC. The SEC core interface option allows generation by:

- A slave port write to the `SEC_CSID[n]` register.
- The assertion of an input acknowledge signal (the connected core generates the signal).

System Interrupt Groups

System sources can be assigned to groups using the SEC_SCTL[n].GRP bit field. Source groups allow fast context switching for system interrupts at each SCI. The SEC_CGMSK[n] register allows quick masking of interrupt groups of unlimited size with a single write operation.

System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the core target select (SEC_SCTL[n].CTG) bit field setting. The SEC priority ordering determines the highest priority pending system interrupt and the SCI updates the SEC_CPND[n].SID and SEC_CACT[n].PRIO bit field values. The SCI compares the SEC_CPND[n] register value against the highest priority active source in the SEC_CACT[n] register).

The priority level register (SEC_CPLVL[n]) determines how many of the MSBs the SEC uses in the comparison. The priority mask register (SEC_CPMSK[n]) and the group mask register (SEC_CGMSK[n]) determines which pending interrupt sources participate. If the SEC_CPND[n] register value is a higher priority (lower value) than the priority of the SEC_CACT[n] register from the comparison based on the SEC_CPLVL[n] register, the system interrupt output is asserted. The source ID register (SEC_CSID[n]) is updated with the SEC_CPND[n].SID bit field value and forwarded to the connected core.

After the core provides an interrupt acknowledgment, the interrupt source is active, until the SEC completes interrupt service with a write to the SEC_END.SID bit field with the same value. Note the following:

- Interrupt acknowledgement occurs with an MMR write of the SEC_CSID[n] register or the core version of the SEC_CSID[n] register.
- Interrupt active status indication is SEC_SSTAT[n].ACT==1.

The following sequence shows the example flow for a single interrupt.

1. The SEC compares the SEC_CPND[n] register value to the SEC_CACT[n] register value. If the interrupt in the SEC_CPND[n] register is higher priority, continue.
2. The SEC copies the SEC_CPND[n] register value to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the interrupt signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source going active.
6. The core writes the SEC_CSID[n] of the active interrupt to the SEC_END register.
7. The SEC clears theSEC_SSTAT[n].ACT bit of the source being ended.

The following sequence shows the example flow for interrupt nesting where interrupt A is a lower priority and occurs earlier than interrupt B.

1. The SEC compares the SEC_CPND[n] (A) register value to the SEC_CACT[n] register and if the interrupt in the SEC_CPND[n] register is a higher priority, continue.
2. The SEC copies SEC_CPND[n] (A) register to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] (A) register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (A) going active.
6. The SEC compares the SEC_CPND[n] (B) register value to the SEC_CACT[n] (A) register value. If the SEC_CACT[n] (B) register value is a higher priority, continue.
7. The SEC copies the SEC_CPND[n] (B) register value to SEC_CSID[n] register and asserts the interrupt signal.
8. The core reads the SEC_CSID[n] (B) register (or core version).
9. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
10. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (B) going active.
11. The core writes the SEC_CSID[n] of the active interrupt (B) to the SEC_END register.
12. The SEC clears the SEC_SSTAT[n].ACT bit of the source (B) being ended.
13. The core writes the SEC_CSID[n] of the active interrupt (A) to the SEC_END register.
14. The SEC clears the SEC_SSTAT[n].ACT bit of the source (A) being ended.

System Interrupt Priorities

Each system interrupt source has its own programmable priority level which is configured using the SEC_SCTL[n].PRIO bit field. The SCI evaluates the priority of all pending sources to determine the source of the highest-priority pending system interrupt for forwarding to the attached core. If more than one source of the pending system interrupt has the same priority setting, the SCI chooses the one with the lowest SID. For example, if SID 0, SID 1, and SID 2 are all pending and have the same priority setting, the SCI chooses SID 0 as the highest-priority source.

SEC Error

The processor includes an SEC error (SEC_GSTAT.ERR) as a source input to the SEC to allow for handling the error as an interrupt or fault.

SEC Programming Model

Implementing a system interrupt service model using the SEC requires, at a minimum:

- Proper configuration of a system interrupt source (for example a peripheral or DMA)
- A core interrupt or event service model

The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, the processor can use software triggering for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the SEC_RAISE register.

Programming Concepts

The following list provides the basic programming concepts necessary for configuring the SEC.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core (See Configuring a System Source to Interrupt a Core).
- Configuring an SSI as a system fault (See Configuring a System Source as a Fault).
- Configuring the SFI to manage system faults.

Programming Examples

This section provides example programming tasks that are typical for SEC usage.

Fault Management Interface Programming Model

The SFI interface can be programmed to manage fault events from system sources and associated actions such as issuing a system reset when watchdog expiration event occurs.

1. Set the SEC_GCTL.EN bit to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
    - Trigger Output. Set the SEC_FCTL.TOEN bit for the SEC to produce trigger outputs when a fault becomes active. The SEC_FCTL.TES bit can be programmed to select the event that directs the SEC to assert trigger output when a fault is pending or active. Configure slaves for SEC fault trigger master output.

      NOTE: If the SEC_FCTL.TOEN and or the SEC_FCTL.TES bits =1 (Trigger Output Enabled and Trigger on Fault Pending), an external fault (if enabled by the SEC_FCTL.FIEN bit) will not issue a trigger since Fault Pending is bypassed for external faults.
    - System Reset. The Reset Control Unit (RCU) controls how the functional units enter and exit reset. Configure the RCU_CTL.SRSTREQEN bit. This bit controls whether the sources of reset are enabled to perform a system reset. To issue a system reset request when a fault becomes active, set the SEC_FCTL.SREN bit. The SEC fault system reset delay register (SEC_FSRDLY) can be programmed for the delay, if required, from a fault becoming active to system reset request assertion.

- Fault Output. This configuration alows the SEC to indicate the fault status based on the SEC_FCTL.CMS bit configuration.
  - Computer Operating Normally (COP) mode. To configure fault output for COP mode, set the SEC_FCTL.FOEN bit to enable fault output. Set the SEC_FCTL.CMS bit to select COP mode to toggle the fault pin when no fault is active. Program the SEC_FCOPP period register with a desired width value for the COP toggled output pin.
  - Fault mode. Set the SEC_FCTL.FOEN bit to enable fault output. The SEC_FCTL.CMS bit should be set to Fault mode to toggle the fault pin when a fault is active.

3. If required, program the Fault Input to sample fault inputs from external devices on fault pins. Configure the SEC_FCTL.FIEN bit to enable the SEC to sample a fault input from an external device.

   ADDITIONAL INFORMATION: The SEC_FCTL.FIEN bit should be set only while the SEC_FCTL.EN bit is low. If the SEC_FCTL.EN bit is already high and the SEC_FCTL.FIEN bit needs to be set, the SEC_FCTL.EN bit should be cleared first. Fault input can only be enabled when Fault mode is selected by the SEC_FCTL.CMS bit.

4. Program the required fault delay to the SEC_FDLY.COUNT bit field if a delay between fault source assertion and the fault response is required.

5. Configure the SEC_FCTL register to enable the SEC.

   ADDITIONAL INFORMATION: The SEC_FCTL.EN bit should be set only while the SEC_FSTAT.ACT bit is low.

6. Write to the control register of a specific source register using the SEC_SCTL[n] register to enable the source as a fault.

Configuring a System Source to Interrupt a Core

To configure a system source to interrupt a core, the SEC itself must be enabled with the source interface (SSI) and core interface (SCI) properly initialized. Specifically, the SCI must be set up to accept interrupt signaling from the SEC and pass them to the specified core, and the SSI must properly enable each of the peripheral interrupt sources to generate interrupt signals and optionally define a priority scheme that overrides the default priority settings. In summary:

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the appropriate SCI SEC_CCTL[n] register to enable SEC interrupts to be sent to that core.
3. Write to the appropriate SSI SEC_SCTL[n] register to enable that peripheral as an interrupt source and to set the core target field to map the source to the desired SCI.
4. (Optional) By default, all the SEC interrupts are grouped as a single priority level, so passing of peripheral interrupt requests from the SEC is based solely on the default enumerated source ID. By programming the SEC_CPLVL[n].PLVL register, interrupt sources can be grouped into priority levels within the SEC such that arbitration is first performed by source ID within a grouped priority level before proceeding to the next

priority level, thus providing the flexibility to have lower-priority interrupt sources considered before higher-priority sources.

ADDITIONAL INFORMATION: The SEC_CPMSK[n] and SEC_CGMSK[n] registers must also can be programmed to mask the interrupts based on the customized levels and grouping.

Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling

A specific handshake with the SEC is required to handle interrupts associated with an individual core. The handshake ensures that nested interrupts are properly tracked and that new peripheral interrupts being raised within the SEC are either passed immediately to the core or held off and queued within the SEC for later servicing.

Use the following procedure to write a custom dispatcher inside the Interrupt Service Routine. Note that the core needs to read and acknowledge the SEC_CSID[n] register by writing the same value. The core must also write to the SEC_END register after the ISR execution completes.

1. Read the SEC_CSID[n] register to obtain the source ID of the peripheral interrupt request.
2. Write the read value back to the SEC_CSID[n] register to send the acknowledge signal to the SEC that the core has accepted and begun processing the interrupt request.
3. Execute the actual ISR (typically a call to a specific handler function from a look-up table based on the peripheral source ID). Write to the SEC_GCTL register to enable the SEC.
4. Write the value of the SEC_CSID[n] register of the active interrupt (read in step 1 above) to the SEC_END register to signal to the SEC that the interrupt has now been serviced.
5. Return from interrupt.

This procedure allows a higher-priority interrupt raised by the SEC to be serviced by the core after step 2. The SEC knows what it passed to the core because of the write to the SEC_CSID[n] register. After the core acknowledges that write, the SEC knows whether or not newly raised peripheral interrupts are a higher priority than the highest-priority interrupt currently being processed by the core.

- If higher priority, the SEC pushes the current SEC_CSID[n] value to an internal stack, writes the new SEC_CSID[n] value, and asserts a new SEC interrupt request.
- If lower priority, the SEC queues the interrupt until the core writes to the SEC_END register with the source ID of the higher-priority interrupt, confirming that it was fully processed.

At this point the SEC_CSID[n] value is popped from the internal stack and any pending peripheral interrupt requests are arbitrated before the SEC writes the new SEC_CSID[n] value and asserts a new interrupt request. At the same time the core self-nests the latched SEC interrupt requests as needed. When a higher-priority interrupt is presented to the core the write to the SEC_END register in the SEC handler epilog code guarantees that each nested level has the required handshake to signal to the SEC block that each individual source ID interrupt request is fully serviced. See the *SHARC+ Core Programming Reference* for more details about SEC handler code.

Configuring a System Source as a Fault

Use the following procedure configure a system source as a fault.

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
3. Write to the SEC_FDLY bit field to specify fault delay.
4. Write to the control register of a specific source to enable the source as a fault.

Configuring the WDOG Expiry Event to Issue a System Reset

Use the following procedure to configure the WDOG timer to issue a system reset.

1. Configure the SEC_GCTL register to enable the SEC.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_GCTL = BITM_SEC_GCTL_EN;
   ```

2. Configure the SEC_FCTL register to choose the Fault response mode. In the following code example, the system reset is issued.

   ADDITIONAL INFORMATION:

   ```
   *pREG_RCU0_CTL |= BITM_RCU_CTL_SRSTREQEN;
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_SREN;
   ```

   ADDITIONAL INFORMATION: Similarly, the program can also choose to signal the fault pin or choose to issue a trigger via the TRU as a response to the fault source (WDOG expiry is the fault source in this example) by programming the relevant bit fields in the SEC_FCTL register.

3. Configure the SEC_SCTL[n].SEN and SEC_SCTL[n].FEN bits in the Source Control 3 (n=3) register registers to determine how the fault source is handled. To configure the WDOG as the fault source, program the register. The program can configure any interrupt as the fault source by programming the corresponding register.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_SCTL3 = BITM_SEC_SCTL_FEN|BITM_SEC_SCTL_SEN;
   ```

   ADDITIONAL INFORMATION: The SEC ID corresponding to WDOG0 is 3, as indicated in Table 6-5 ADSP-SC57x Combined SEC and GIC Interrupt List .

4. Write to the enable bit.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_EN;
   ```

SEC Programming Restrictions

Setting the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is high can result in unpredictable behavior. To avoid this issue, set the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is low. The SEC_FSTAT.ACT bit is only set when the SEC_FCTL.EN bit is high. Therefore, the problem can only occur if the SEC_FCTL.EN bit transitions from 1 to 0 and then to 1 again.

Writing to SEC_FEND to end a fault with both the SEC_FCTL.FOEN bit and the SEC_FCTL.FIEN bit set can result in erroneous external fault detection. If this operation (ending a fault) and configuration (fault input and fault output enabled) are required by the application, clear the SEC_FCTL.FOEN bit prior to writing to SEC_FEND. The recommended sequence for ending a fault with the SEC_FCTL.FIEN or SEC_FCTL.FOEN==1 is as follows:

1. Clear the SEC_FCTL.FOEN bit.
2. Write to the SEC_FEND register.
3. Set the SEC_FCTL.FOEN bit.

ADSP-SC57x SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

Table 6-6: ADSP-SC57x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register
SEC_FCOPP	Fault COP Period Register
SEC_FCOPP_CUR	Fault COP Period Current Register
SEC_FCTL	Fault Control Register
SEC_FDLY	Fault Delay Register
SEC_FDLY_CUR	Fault Delay Current Register
SEC_FEND	Fault End Register

Table 6-6: ADSP-SC57x SEC Register List (Continued)

Name	Description
SEC_FSID	Fault Source ID Register
SEC_FSRDLY	Fault System Reset Delay Register
SEC_FSRDLY_CUR	Fault System Reset Delay Current Register
SEC_FSTAT	Fault Status Register
SEC_GCTL	Global Control Register
SEC_GSTAT	Global Status Register
SEC_RAISE	Global Raise Register
SEC_SCTL[n]	Source Control Register n
SEC_SSTAT[n]	Source Status Register n

SCI Active Register n

The SEC SCI active interrupt register (SEC_CACT[n]) contains the source ID and priority of the highest priority active interrupt detected by the SEC prioritizer.

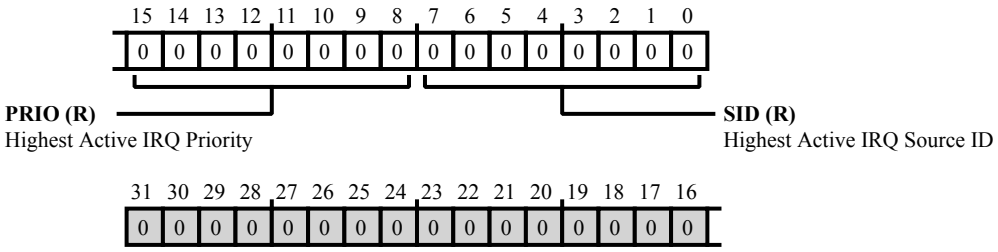

Figure 6-6: SEC_CACT[n] Register Diagram

Table 6-7: SEC_CACT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Active IRQ Priority. The SEC_CACT[n].PRIO indicates the priority value of the highest priority active interrupt for core n.
7:0 (R/NW)	SID	Highest Active IRQ Source ID. The SEC_CACT[n].SID identifies the source ID value of the highest priority active interrupt for core n.

SCI Control Register n

The SEC control register (SEC_CCTL[n]) contains SCI control bits for all system sources.

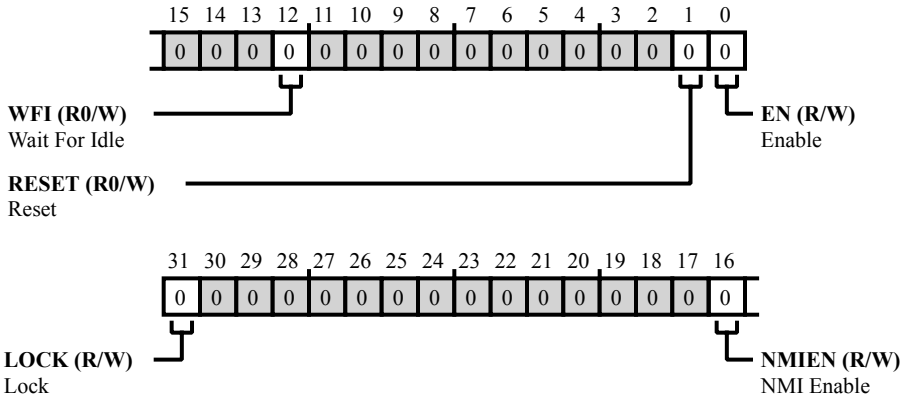

Figure 6-7: SEC_CCTL[n] Register Diagram

Table 6-8: SEC_CCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CCTL[n].LOCK bit is enabled, the SEC_CCTL[n] register is read only.	
		0	Unlock
		1	Lock
16 (R/W)	NMIEN	NMI Enable. The SEC_CCTL[n].NMIEN bit controls NMI propagation to the core. When the SEC_CCTL[n].NMIEN bit is enabled, the SCI allows NMIs to propagate to the core for servicing.	
		0	Disable
		1	Enable
12 (R0/W)	WFI	Wait For Idle. When set, the SEC_CCTL[n].WFI bit forces the SCI to wait for indication of core idle before the SCI resumes activity.	
		0	No Action
		1	Wait for Idle

Table 6-8: SEC_CCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RESET	Reset. When set, the `SEC_CCTL[n].RESET` bit resets all SCI registers to their default values.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The `SEC_CCTL[n].EN` bit controls operation of the SCI. Clearing the `SEC_CCTL[n].EN` bit halts the execution of the SCI without resetting status registers. (The INT signal to a core is not affected.) Setting the `SEC_CCTL[n].EN` bit enables the SCI to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

SCI Group Mask Register n

The SEC SCI group mask register (SEC_CGMSK[n]) contains selections for a group mask, an ungroup mask, and a register lock. This register contains the system interrupt group masks for the connected core. The core uses the SEC_CGMSK[n].UGRP and SEC_CGMSK[n].GRP fields to mask (disable) interrupts from the specified groups.

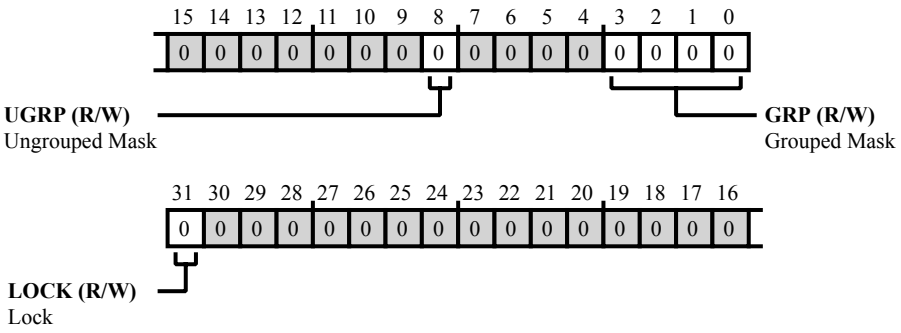

Figure 6-8: SEC_CGMSK[n] Register Diagram

Table 6-9: SEC_CGMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CGMSK[n].LOCK bit is enabled, the SEC_CGMSK[n] register is read only.	
		0	Unlock
		1	Lock
8 (R/W)	UGRP	Ungrouped Mask. The SEC_CGMSK[n].UGRP bit masks interrupts (if set) for the ungrouped interrupt sources for core n.	
		0	Unmask Ungrouped Sources
		1	Mask Ungrouped Sources
3:0 (R/W)	GRP	Grouped Mask. The SEC_CGMSK[n].GRP field selects a group of interrupt sources to mask for core n. (For more information about interrupt source groups, see the SEC_SCTL[n] register description.)	
		0	No groups masked
		1	Mask group 0
		2	Mask group 1
		3	Mask groups 0, 1

Table 6-9: SEC_CGMSK[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Mask group 2
		5	Mask groups 0, 2
		6	Mask groups 1, 2
		7	Mask groups 0, 1, 2
		8	Mask group 3
		9	Mask groups 0, 3
		10	Mask groups 1, 3
		11	Mask groups 0, 1, 3
		12	Mask groups 2, 3
		13	Mask groups 0, 2, 3
		14	Mask groups 1, 2, 3
		15	Mask groups 0, 1, 2, 3

SCI Priority Level Register n

The SEC SCI priority level register (SEC_CPLVL[n]) contains selections for priority levels and a register lock. This register is used to divide the total number of priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same level.

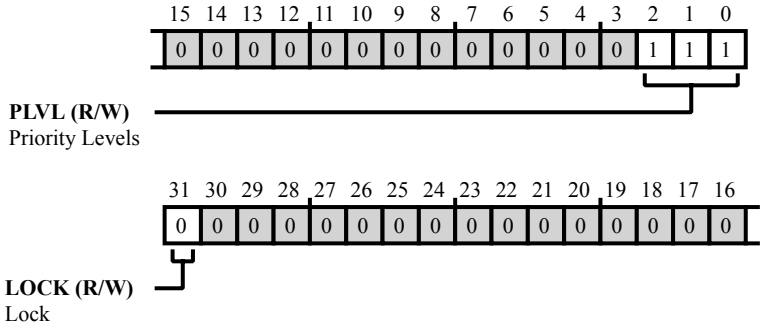

Figure 6-9: SEC_CPLVL[n] Register Diagram

Table 6-10: SEC_CPLVL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPLVL[n].LOCK bit is enabled, the SEC_CPLVL[n] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	PLVL	Priority Levels. The SEC_CPLVL[n].PLVL field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the SEC_CPLVL[n].PLVL field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.	
		0	1 MSBs (2 priority levels)
		1	2 MSBs (4 priority levels)
		2	3 MSBs (8 priority levels)
		3	4 MSBs (16 priority levels)
		4	5 MSBs (32 priority levels)
		5	6 MSBs (64 priority levels)

Table 6-10: SEC_CPLVL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 MSBs (128 priority levels)
		7	8 MSBs (256 priority levels)

SCI Priority Mask Register n

The SEC SCI priority mask register (SEC_CPMSK[n]) contains the SCI priority mask for core n and includes a register lock.

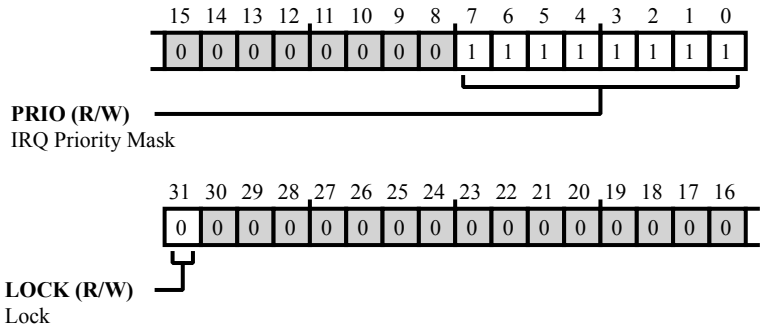

Figure 6-10: SEC_CPMSK[n] Register Diagram

Table 6-11: SEC_CPMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPMSK[n].LOCK bit is enabled, the SEC_CPMSK[n] register is read only.	
		0	Unlock
		1	Lock
7:0 (R/W)	PRIO	IRQ Priority Mask. The SEC_CPMSK[n].PRIO contains the system interrupt priority mask for core n. The core uses the SEC_CPMSK[n].PRIO field to mask (block) interrupts below the specified level.	
		0	Priority level 0 (highest)
		1-254	
		255	Priority level 255 (lowest)

Core Pending Register n

The SCI pending interrupt register (SEC_CPND[n]) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.

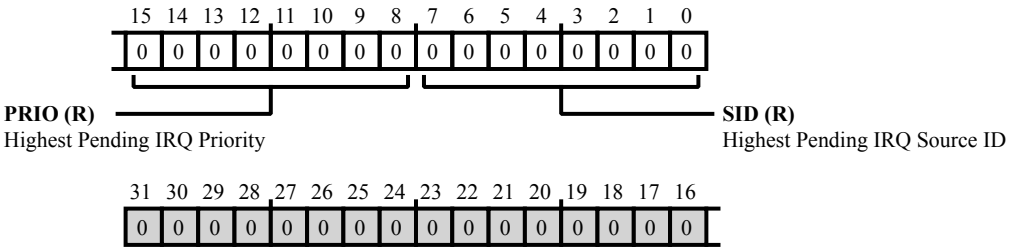

Figure 6-11: SEC_CPND[n] Register Diagram

Table 6-12: SEC_CPND[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Pending IRQ Priority. The SEC_CPND[n].PRIO indicates the priority value of the highest priority pending interrupt for core n.
7:0 (R/NW)	SID	Highest Pending IRQ Source ID. The SEC_CPND[n].SID identifies the source ID value of the highest priority pending interrupt for core n.

SCI Source ID Register n

The SCI source ID register (SEC_CSID[n]) contains the source ID of the interrupt last issued to core n. The SEC_CSID[n] register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the SEC_CSID[n] until after the interface receives an interrupt acknowledge from core n. Writing to the SEC_CSID[n] register generates an interrupt acknowledge, but does not update the value in the register.

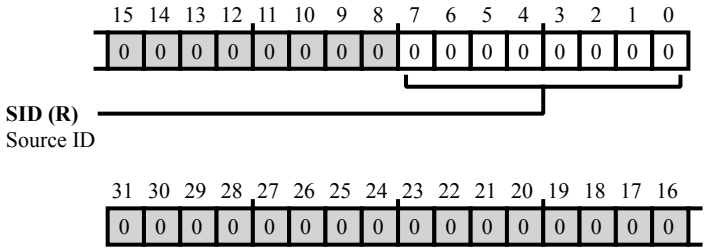

Figure 6-12: SEC_CSID[n] Register Diagram

Table 6-13: SEC_CSID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	SID	Source ID. The SEC_CSID[n].SID bit is the source ID of the interrupt last issued to core n.

SCI Status Register n

The SCI status register (SEC_CSTAT[n]) contains status bits, indicating the operational status of the SCI.

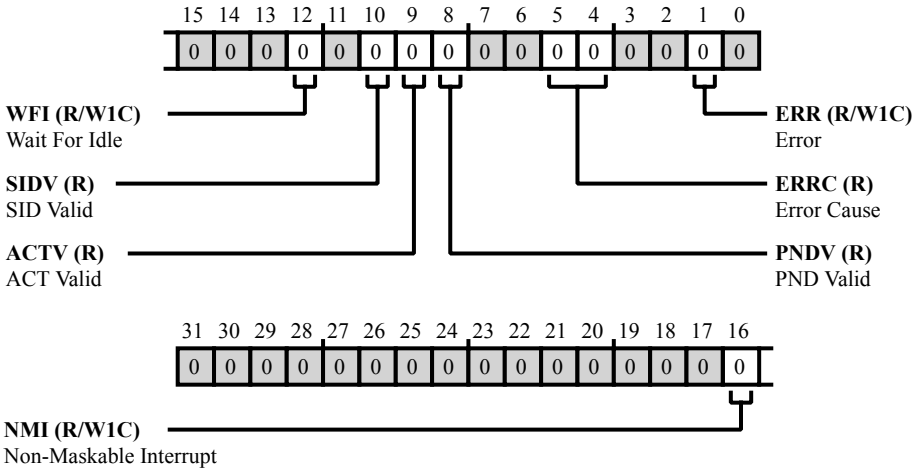

Figure 6-13: SEC_CSTAT[n] Register Diagram

Table 6-14: SEC_CSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	NMI	Non-Maskable Interrupt. The SEC_CSTAT[n].NMI bit indicates whether an NMI has occurred since the bit was last cleared.	
		0	No NMI Occurred
		1	NMI Occurred
12 (R/W1C)	WFI	Wait For Idle. The SEC_CSTAT[n].WFI bit indicates (if set) that the SCI is temporarily disabled, pending a core idle indication. This bit is set when SEC_CCTL[n].WFI is set.	
		0	Not Waiting
		1	Waiting
10 (R/NW)	SIDV	SID Valid. The SEC_CSTAT[n].SIDV bit indicates (if set) that the current value in the SEC_CSID[n] register is valid. The SCI sets the SEC_CSTAT[n].SIDV bit when the updating the SEC_CSID[n] register with a new value. The SEC_CSTAT[n].SIDV bit is cleared when the SEC_CSID[n] register is written. This status indication may be used to extract all pending interrupts in a single interrupt service routine.	
		0	Invalid
		1	Valid

Table 6-14: SEC_CSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	ACTV	ACT Valid. The SEC_CSTAT[n].ACTV bit indicates (if set) that the current value in the SEC_CACT[n] register is valid. The SCI sets the SEC_CSTAT[n].ACTV bit when updating the SEC_CACT[n] registers with a new value. The SEC_CSTAT[n].ACTV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
8 (R/NW)	PNDV	PND Valid. The SEC_CSTAT[n].PNDV bit indicates (if set) that the current value in the SEC_CPND[n] register is valid. The SCI sets the SEC_CSTAT[n].PNDV bit when updating the SEC_CPND[n] register with a new value. The SEC_CSTAT[n].PNDV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
5:4 (R/NW)	ERRC	Error Cause. The SEC_CSTAT[n].ERRC bits are updated on assertion of the SEC_CSTAT[n].ERR bit to indicate the SCI error type. SEC_CSTAT[n].ERRC is only updated on the assertion of SEC_CSTAT[n].ERR. Subsequent errors while SEC_CSTAT[n].ERR is asserted do not update SEC_CSTAT[n].ERRC.	
		0	Reserved
		1	Acknowledge Error. SCI has received an acknowledge without a pending, unacknowledged interrupt present.
		2	Reserved
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_CSTAT[n].ERR bit indicates that an error has occurred in the SCI. When SEC_CSTAT[n].ERR is set, the SCI updates the SEC_CSTAT[n].ERRC field to the value of the corresponding error cause.	
		0	No Error
		1	Error Occurred

Global End Register

The SEC global end register (SEC_END) contains a source ID interrupt service end field (SEC_END.SID). When a core has finished servicing an interrupt, the core writes the SEC_END.SID field in the SEC_END register. This write causes the SEC to clear the SEC_SSTAT[n].ACT bit in the SEC_SSTAT[n] register of the corresponding interrupt.

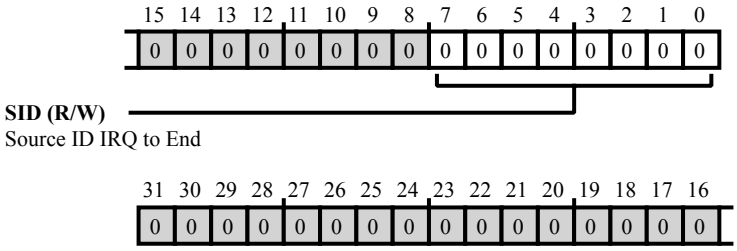

Figure 6-14: SEC_END Register Diagram

Table 6-15: SEC_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID IRQ to End. The SEC_END.SID bit field contains the source ID interrupt service end value.

Fault COP Period Register

The SEC fault COP period register (SEC_FCOPP) contains the width value (count in (SEC) clock cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase value is the SEC_FCOPP.COUNT programmed value plus 1.

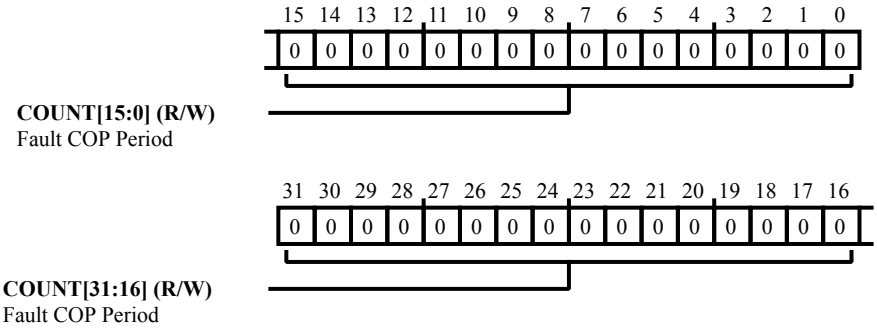

Figure 6-15: SEC_FCOPP Register Diagram

Table 6-16: SEC_FCOPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault COP Period. The SEC_FCOPP.COUNT bit field is the width value for the high and low phase of the computer operating properly (COP) toggled output on the COP pin.

Fault COP Period Current Register

The SEC fault COP period current register (SEC_FCOPP_CUR) contains the active count (in (SEC) clock periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC_FCOPP_CUR register from the SEC_FCOPP register when the SEC_FCOPP_CUR.COUNT field is cleared and the SEC is in COP mode (SEC_FCTL.CMS bit =1). The SEC decrements the SEC_FCOPP_CUR count each (SEC) clock cycle while SEC_FCTL.CMS is set and the SEC_FSTAT.ACT bit is not set.

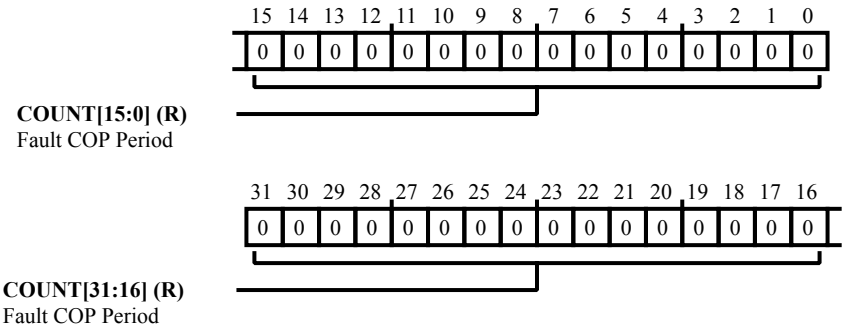

Figure 6-16: SEC_FCOPP_CUR Register Diagram

Table 6-17: SEC_FCOPP_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault COP Period. The SEC_FCOPP_CUR.COUNT bit field is the active count for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin.

Fault Control Register

The SEC fault control register (SEC_FCTL) contains fault control bits for all SEC channels. This register controls the operation of the System Fault Management Interface (SFI).

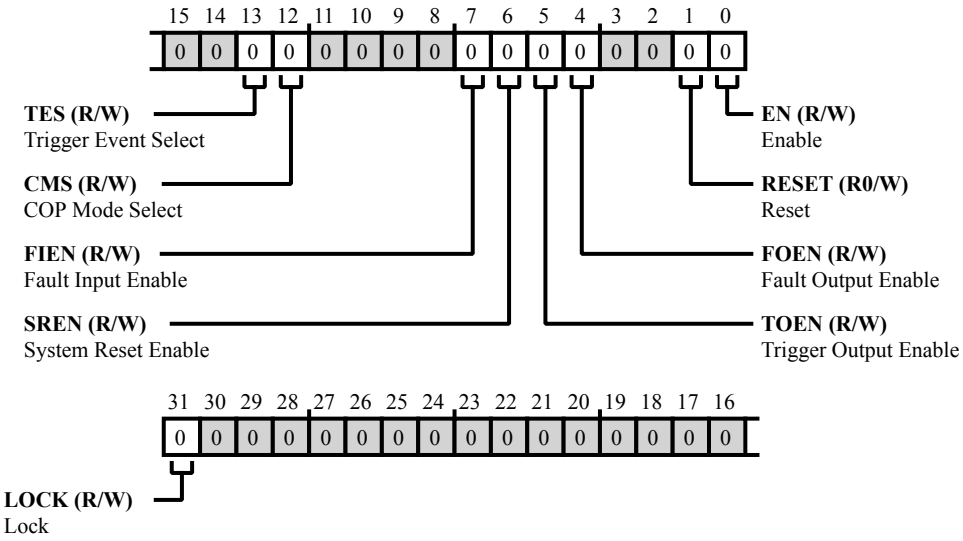

Figure 6-17: SEC_FCTL Register Diagram

Table 6-18: SEC_FCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_FCTL.LOCK bit is enabled, the SEC_FCTL register is read only.	
		0	UnLock
		1	Lock
13 (R/W)	TES	Trigger Event Select. The SEC_FCTL.TES bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.	
		0	Fault Active Mode
		1	Fault Pending Mode

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	CMS	COP Mode Select. The SEC_FCTL.CMS selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. Not all processors feature both the fault and fault_b pins. Refer to the product data sheet for details.	
		0	Fault Mode
		1	COP Mode
7 (R/W)	FIEN	Fault Input Enable. The SEC_FCTL.FIEN bit enables the SEC to sample fault input. If SEC_FCTL.FIEN is set (=1), a fault indication from an external device sets the SEC_FSTAT.ACT bit and SEC_FSID.FEXT bit.	
		0	Disable
		1	Enable
6 (R/W)	SREN	System Reset Enable. The SEC_FCTL.SREN bit enables the SEC to issue a system reset request when a fault becomes active.	
		0	Disable
		1	Enable
5 (R/W)	TOEN	Trigger Output Enable. The SEC_FCTL.TOEN bit enables the SEC to produce trigger output when a fault becomes active.	
		0	Disable
		1	Enable
4 (R/W)	FOEN	Fault Output Enable. The SEC_FCTL.FOEN bit enables the SEC to indicate fault status, according to the SEC_FCTL.CMS bit configuration.	
		0	Disable
		1	Enable
1 (R0/W)	RESET	Reset. Setting the SEC_FCTL.RESET bit resets ALL SEC registers to their default values.	
		0	No Action
		1	Reset

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The SEC_FCTL.EN bit controls the operational state of the SEC. Clearing the SEC_FCTL.EN bit halts the execution of the SEC without resetting status registers. Setting the SEC_FCTL.EN bit enables the SEC to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Fault Delay Register

The SEC fault delay register (SEC_FDLY) contains the number (SEC_FDLY.COUNT field) of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

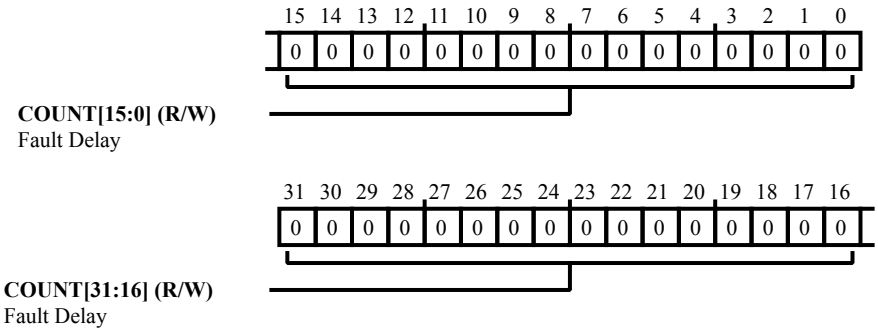

Figure 6-18: SEC_FDLY Register Diagram

Table 6-19: SEC_FDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault Delay. The SEC_FDLY.COUNT bit field is the number of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

Fault Delay Current Register

The SEC fault delay current register (SEC_FDLY_CUR) contains the active count (SEC_FDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the SEC_FDLY register when a fault becomes pending (SEC_FSTAT.PND bit is set). The SEC decrements the value in SEC_FDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.PND bit is set.

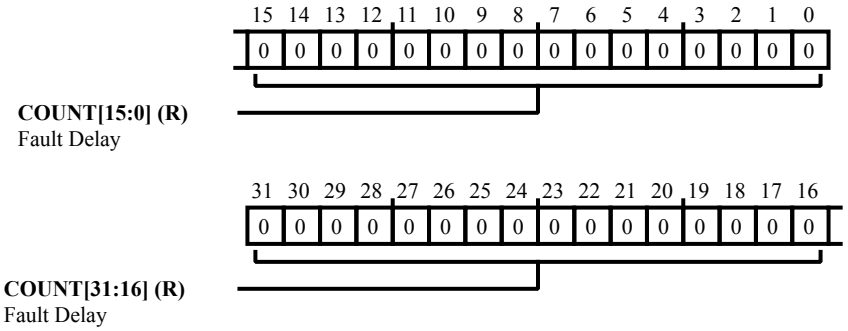

Figure 6-19: SEC_FDLY_CUR Register Diagram

Table 6-20: SEC_FDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault Delay. The SEC_FDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled.

Fault End Register

The SEC fault end register (SEC_FEND) contains fault source ID and internal/external fields. This register receives fault end indication from a core.

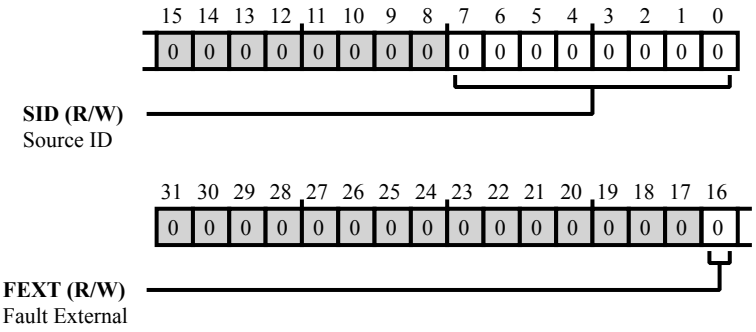

Figure 6-20: SEC_FEND Register Diagram

Table 6-21: SEC_FEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	FEXT	Fault External. Setting the SEC_FEND.FEXT bit, when the SEC_FEND.SID field is cleared, clears an active fault from an external source.	
		0	Fault Internal
		1	Fault External
7:0 (R/W)	SID	Source ID. The SEC_FEND.SID identifies a fault to be ended as indicated to the SEC by the core. The core loads the SEC_FEND.SID field value. If the SEC_FEND.SID value matches the SEC_FSID.SID value, the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit are cleared.	

Fault Source ID Register

The SEC fault source ID register (SEC_FSID) contains a fault source ID and internal/external fields.

NOTE:These bits are not reset by system reset so that a fault that automatically triggers a system reset to avoid a fault may be analyzed after the reset occurs.

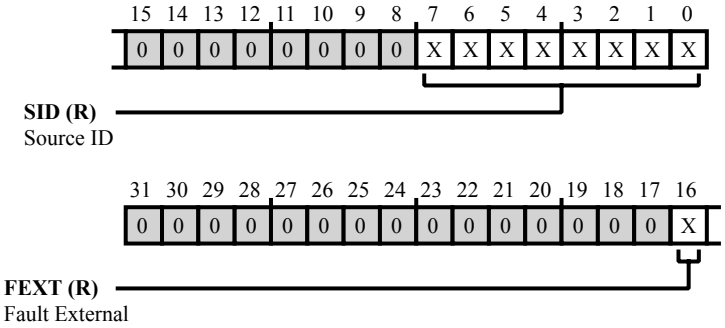

Figure 6-21: SEC_FSID Register Diagram

Table 6-22: SEC_FSID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	FEXT	Fault External. The SEC_FSID.FEXT bit indicates that the last active fault was asserted by an external device. The SEC sets the SEC_FSID.FEXT bit when the SEC_FSTAT.ACT bit is set by the fault input pins. The SEC_FSID.FEXT bit is cleared when the SEC_FSTAT.ACT bit is set by an internal fault or when the external fault is ended. When the SEC_FSID.FEXT bit is set, the SEC_FSID.SID is cleared.	
		0	Fault Internal
		1	Fault External
7:0 (R/NW)	SID	Source ID. The SEC_FSID.SID identifies the fault assertion detected by the SEC fault interface. The SEC loads the SEC_FSID.SID field value when a system fault indication is asserted. The SEC fault interface does not change the SEC_FSID.SID value until the fault is no longer pending or active, as indicated by the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit being cleared in the SEC_FSTAT register.	

Fault System Reset Delay Register

The SEC fault system reset delay register (SEC_FSRDLY) contains the number (SEC_FSRDLY.COUNT field) of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion, if enabled.

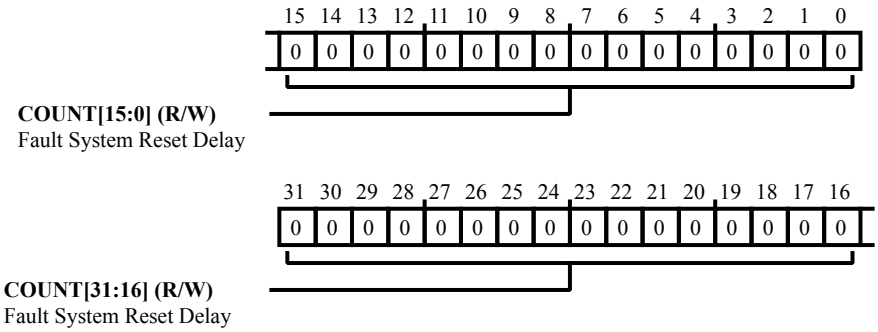

Figure 6-22: SEC_FSRDLY Register Diagram

Table 6-23: SEC_FSRDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault System Reset Delay. The SEC_FSRDLY.COUNT bit field is the number of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion.

Fault System Reset Delay Current Register

The SEC fault system reset delay current register (SEC_FSRDLY_CUR) contains the active count (SEC_FSRDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the SEC_FSRDLY register when a fault becomes active (SEC_FSTAT.ACT bit is set). The SEC decrements the value in SEC_FSRDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.ACT bit is set.

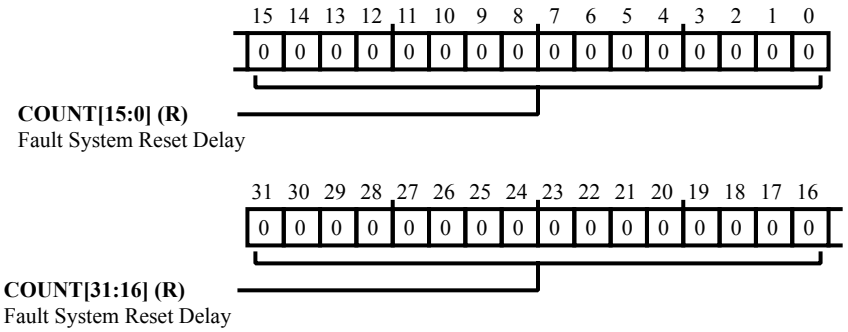

Figure 6-23: SEC_FSRDLY_CUR Register Diagram

Table 6-24: SEC_FSRDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault System Reset Delay. The SEC_FSRDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault active to system reset assertion.

Fault Status Register

The SEC fault status register (SEC_FSTAT) indicates the operational status of the SFI.

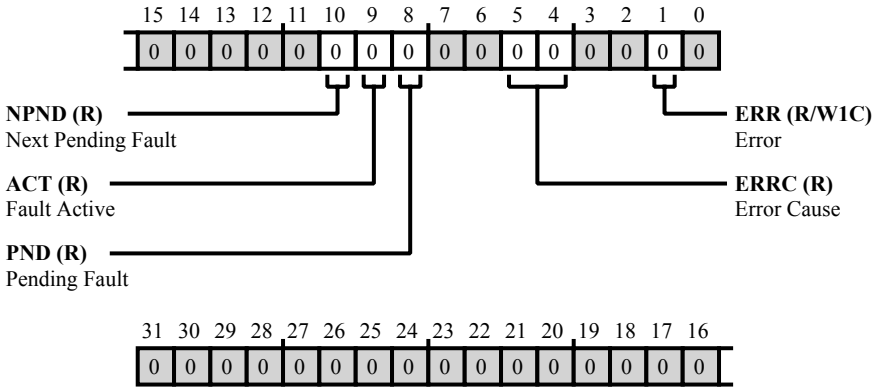

Figure 6-24: SEC_FSTAT Register Diagram

Table 6-25: SEC_FSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	NPND	Next Pending Fault. The SEC_FSTAT.NPND bit indicates that one or more sources have signaled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.	
		0	Not Pending
		1	Pending
9 (R/NW)	ACT	Fault Active. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the ID value of the asserted fault from SEC_FSID register to the SEC_FEND register.	
		0	No Fault
		1	Active Fault

Table 6-25: SEC_FSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	PND	Pending Fault. The SEC_FSTAT.PND bit indicates a fault source has signaled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to the delay selected with the SEC_FDLY register. The SEC fault interface sets the SEC_FSTAT.PND bit when the SEC_FSID is updated on assertion of a fault source input. The SEC_FSTAT.PND bit is only set when the SEC_FSTAT.ACT bit is cleared. The SEC updates the SEC_FSID register with the SID value when the SEC_FSTAT.PND bit is set. The SEC_FSTAT.PND bit is cleared *either* by the SEC fault interface when the current delay count in the SEC_FDLY_CUR register expires *or* by writing the SEC_FSID.SID field value (which indicates the ID of the asserted fault) to the SEC_FEND register.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_FSTAT.ERR bit is asserted, the SEC updates SEC_FSTAT.ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_FSTAT.ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_FSTAT.ERR bit indicates an SEC fault interface error. When SEC_FSTAT.ERR is set, the SEC updates the SEC_FSTAT.ERRC field to indicate the corresponding error cause. When multiple errors occur, the SEC_FSTAT register captures the status for the first error and does not capture subsequent errors until the status is cleared.	
		0	No Error
		1	Error Occurred

Global Control Register

The SEC global control register (SEC_GCTL) provides register locking, reset, and enable for the SEC module.

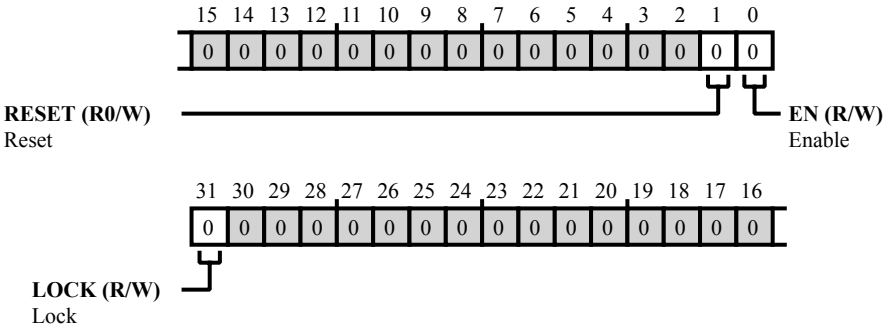

Figure 6-25: SEC_GCTL Register Diagram

Table 6-26: SEC_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_GCTL.LOCK bit is enabled, the SEC_GCTL register is read only.	
		0	Unlock
		1	Lock
1 (R0/W)	RESET	Reset. The SEC_GCTL.RESET bit is write-1-action and triggers a soft reset to all SEC registers.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The SEC_GCTL.EN bit is read/write and must be set for the SEC to begin/resume SEC operation with the current configuration and status. Clearing the SEC_GCTL.EN bit halts the execution of the SFI and all SCIs. All SSIs remain active, along with all error detection, without resetting status registers.	
		0	Disable
		1	Enable

Global Status Register

The SEC global status register (SEC_GSTAT) contains global status bits for the SEC.

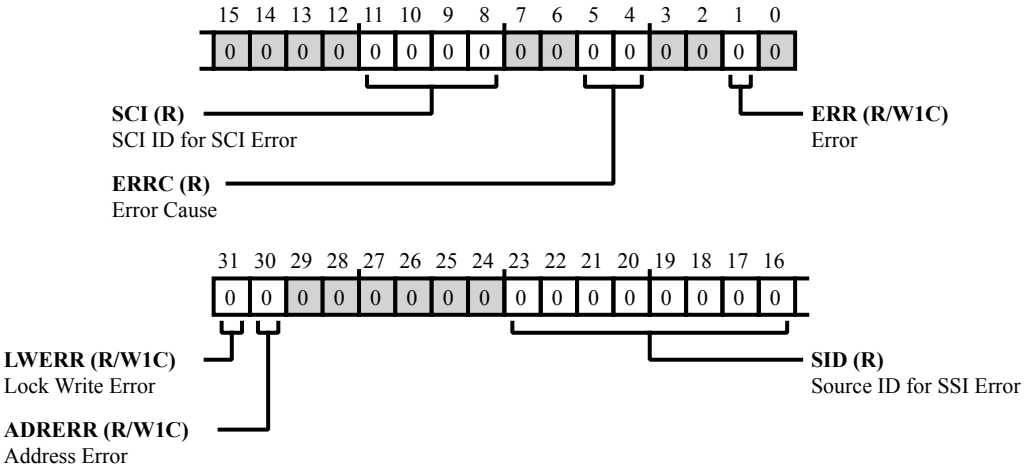

Figure 6-26: SEC_GSTAT Register Diagram

Table 6-27: SEC_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SEC_GSTAT.LWERR bit indicates (when set) there was an attempted write to an SEC register while the SEC_GCTL.LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30 (R/W1C)	ADRERR	Address Error. The SEC_GSTAT.ADRERR bit indicates that the SEC generated and address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
23:16 (R/NW)	SID	Source ID for SSI Error. The SEC_GSTAT.SID bits indicate the source ID that generated the last SSI error conveyed in the SEC_GSTAT.ERRC field.	
11:8 (R/NW)	SCI	SCI ID for SCI Error. The SEC_GSTAT.SCI bits indicate the number for the specific SCI that generated the last SCI error conveyed in the SEC_GSTAT.ERRC field.	

Table 6-27: SEC_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	ERRC	Error Cause. When the SEC updates the `SEC_GSTAT.ERR` bit, the SEC updates the `SEC_GSTAT.ERRC` bits to indicate the error type. Note that for SCI errors, the error status represents an OR of all the errors from each SCI. Note that for SSI errors, the error status indicates an error is active for any SSI input. This error is an OR of all the interrupt source errors.	
		0	SFI Error
		1	SCI Error
		2	SSI Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_GSTAT.ERR` bit indicates an error has occurred in the SEC. When the SEC asserts this bit (=1), the SEC updates the `SEC_GSTAT.ERRC` field to indicate the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of this bit. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred

Global Raise Register

The SEC global raise register (SEC_RAISE) contains a source ID event set-to-pending field (SEC_RAISE.SID). When a source ID value is written to this field, the SEC raises the source's event status to pending.

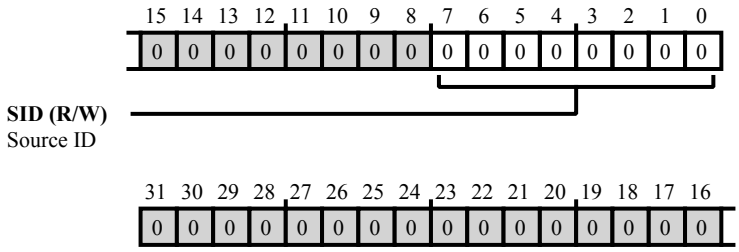

Figure 6-27: SEC_RAISE Register Diagram

Table 6-28: SEC_RAISE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID. The SEC_RAISE.SID bit field is the source ID of event that is set to pending status.

Source Control Register n

The SEC source control register (SEC_SCTL[n]) contains control bits to configure the SEC event sources. This register controls the configuration of the corresponding SEC event source.

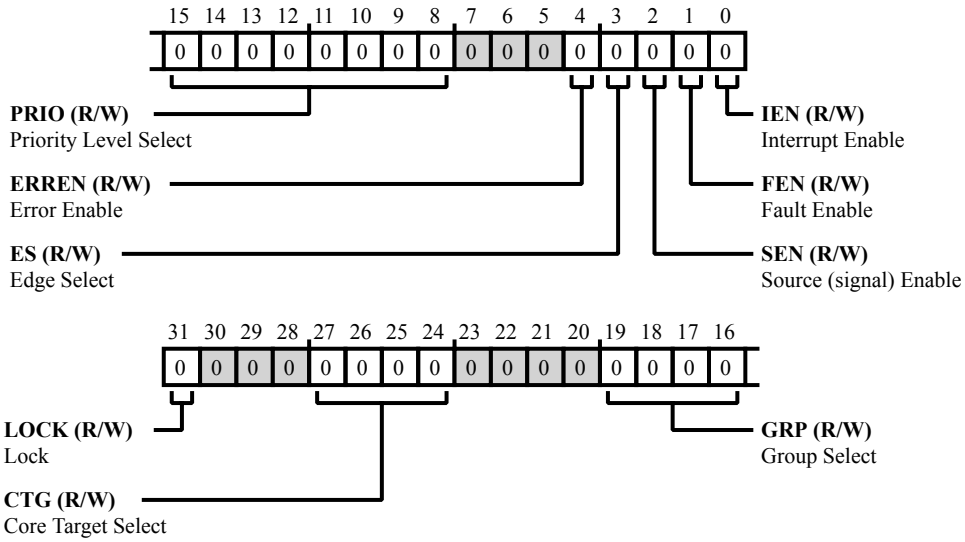

Figure 6-28: SEC_SCTL[n] Register Diagram

Table 6-29: SEC_SCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_SCTL[n].LOCK bit is enabled, the SEC_SCTL[n] register is read only.	
		0	Unlock
		1	Lock
27:24 (R/W)	CTG	Core Target Select. The SEC_SCTL[n].CTG bits selects the specific SEC core interface to which the interrupt is mapped. Each system interrupt is mapped uniquely to one specific SEC core interface and (as a result) to a specific core.	

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	GRP	Group Select. The SEC_SCTL[n].GRP bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the SEC_SCTL[n].GRP field. For example, consider the situation where SEC_SCTL[n].GRP0 represents interrupt group 0, SEC_SCTL[n].GRP1 represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset. Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all SEC_SCTL[n].GRP bits = 0) places the interrupt source in the category of "ungrouped".	
15:8 (R/W)	PRIO	Priority Level Select. The SEC_SCTL[n].PRIO bits sets the relative priority for an interrupt request. A pending interrupt request forwards its SEC_SCTL[n].PRIO value to the SEC core interface.	
4 (R/W)	ERREN	Error Enable. The SEC_SCTL[n].ERREN bit permits the SEC_SSTAT[n].ERR status bit to be set on error detection. If SEC_SCTL[n].ERREN is cleared, no errors are detected.	
		0	Disable
		1	Enable
3 (R/W)	ES	Edge Select. The SEC_SCTL[n].ES bit selects the operational and sensitivity mode of the SEC source interface input.	
		0	Level Sensitive
		1	Edge Sensitive
2 (R/W)	SEN	Source (signal) Enable. The SEC_SCTL[n].SEN bit controls whether the system event source input signal may affect the pending status of the source. Clearing the SEC_SCTL[n].SEN bit disables the source input signal from affecting the pending status. Setting SEC_SCTL[n].SEN enables the source input signal to affect the pending status.	
		0	Disable
		1	Enable

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FEN	Fault Enable. The `SEC_SCTL[n].FEN` bit controls whether the SEC may forward an interrupt request to the SEC fault interface as a fault source. This bit does not affect the ability of an interrupt source to set an interrupt as pending. The `SEC_SCTL[n].FEN` bit only affects whether the pending request may be forwarded to the SEC fault interface.	
		0	Disable
		1	Enable
0 (R/W)	IEN	Interrupt Enable. The `SEC_SCTL[n].IEN` bit controls whether the SEC may forward an interrupt request to a core for servicing. This bit does not affect the ability of an interrupt source to set an interrupt as pending.	
		0	Disable
		1	Enable

Source Status Register n

The SEC event source status register (SEC_SSTAT[n]) contains bits indicating the status of the corresponding event source n. An event source may be: pending, active, active and pending, or neither pending nor active.

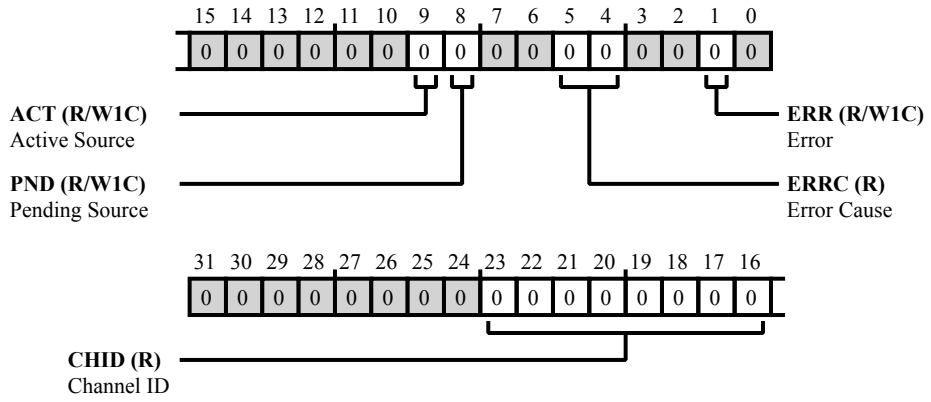

Figure 6-29: SEC_SSTAT[n] Register Diagram

Table 6-30: SEC_SSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/NW)	CHID	Channel ID. The SEC_SSTAT[n].CHID bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The SEC_SSTAT[n].CHID field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The SEC_SSTAT[n].CHID is captured when the SEC source interface input is acknowledged.	
9 (R/W1C)	ACT	Active Source. The SEC_SSTAT[n].ACT bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An SEC_SSTAT[n].ACT bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An SEC_SSTAT[n].ACT bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.	
		0	Not Active
		1	Active

Table 6-30: SEC_SSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	PND	Pending Source. The SEC_SSTAT[n].PND bit indicates the source has signaled an event request, but the event request has not been (or is not currently being) serviced. A SEC_SSTAT[n].PND bit is set by the SEC on detection of an assertion of the corresponding system source input. A SEC_SSTAT[n].PND bit is cleared by the SEC when the specific system event is acknowledged by the core through the SEC core interface or by a W1C operation.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_SSTAT[n].ERR bit is asserted, the SEC updates SEC_SSTAT[n].ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_SSTAT[n].ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_SSTAT[n].ERR bit indicates an error for a specific system interrupt source. When the SEC_SSTAT[n].ERR bit is set, the SEC updates the SEC_SSTAT[n].ERRC field to the value of the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of the SEC_SSTAT[n].ERR bit.	
		0	No Error
		1	Error Occurred

GIC Overview

The generic interrupt controller (GIC) provides an interface to the uniprocessor Cortex A5 core in the processor and collects up to 270 interrupt requests from all processor system sources. In addition, the GIC also supports eight software generated interrupts that are internal to the Cortex A5 core and not connected to the SECs. All GIC interrupts are also connected to the SEC in the same order.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The "Register Descriptions" section in this chapter provide brief descriptions of these ARM-based registers. For complete information refer to the *ARM® Generic Interrupt Controller Architecture version 1.0 Architecture Specification*.

GIC Functional Description

The GIC splits logically into a GICPORT0 (distributor block) and one GICPORT1 (CPU interface blocks).

General Interrupt Controller Port0 (GIC Distributer)

The distributor block provides a programming interface to perform the following tasks.

- Globally enable the forwarding of interrupts to the CPU interfaces
- Enable or disable each interrupt
- Set the priority level of each interrupt
- Set the target processor list of each interrupt
- Set each peripheral interrupt to be level-sensitive or edge-triggered
- Set each interrupt as either Group 0 or Group 1
- Forward an SGI to one or more target processors

In addition, the Distributor provides:

- Visibility of the state of each interrupt
- A mechanism for software to set or clear the pending state of a peripheral interrupt.

General Interrupt Controller Port1 (GIC CPU)

GICPORT1 (CPU interface) block performs priority masking and preemption handling for a connected processor in the system. GICPORT1 supports 8 SGIs (software generated interrupts) and 262 SPIs (shared peripheral interrupts).

Each CPU interface provides a programming interface to perform the following tasks.

- Enable signaling of interrupt requests to the processor
- Acknowledge interrupts
- Indicate that interrupt processing is complete
- Set interrupt priority masks for the processor
- Define the preemption policy for the processor
- Determine the highest priority pending interrupt for the processor

GIC Block Diagram

The *GIC Block Diagram* shows the event management architecture.

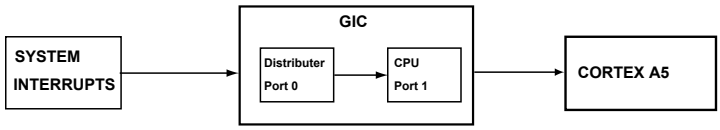

Figure 6-30: GIC Block Diagram

ADSP-SC57x GICDST Register Descriptions

GIC Distributor Port (GICDST) contains the following registers.

Table 6-31: ADSP-SC57x GICDST Register List

Name	Description
GICDST_EN	GIC Port 0 Enable
GICDST_SGI_PRIO[n]	Software Generated Interrupt Priority Register
GICDST_SPI_PRIO[n]	Shared Peripheral Interrupt Priority Register
GICDST_SGI_ACTIVE	Software Generated Interrupt Active Register
GICDST_SGI_CTL	Software Generated Interrupt Control Register
GICDST_SGI_PND_CLR	Software Generated Interrupt Clear-Pending Register
GICDST_SGI_PND_SET	Software Generated Interrupt Pending Set Register
GICDST_SGI_SECURITY	Software Generated Interrupt Security Register
GICDST_SPI[n]	Shared Peripheral Interrupt Register
GICDST_SPI_ACTIVE[n]	Shared Peripheral Interrupt Active Register
GICDST_SPI_CFG[n]	Shared Peripheral Interrupt Configuration Register
GICDST_SPI_EN_CLR[n]	Shared Peripheral Interrupt Enable Clear Register
GICDST_SPI_EN_SET[n]	Shared Peripheral Interrupt Enable Set Register
GICDST_SPI_PND_CLR[n]	Shared Peripheral Interrupt Pending Clear Register
GICDST_SPI_PND_SET[n]	Shared Peripheral Interrupt Pending Set Register
GICDST_SPI_SECURITY[n]	Shared Peripheral Interrupt Security Register
GICDST_SPI_TRGT[n]	Shared Peripheral Interrupt Processor Targets Register

GIC Port 0 Enable

The GICDST_EN register enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

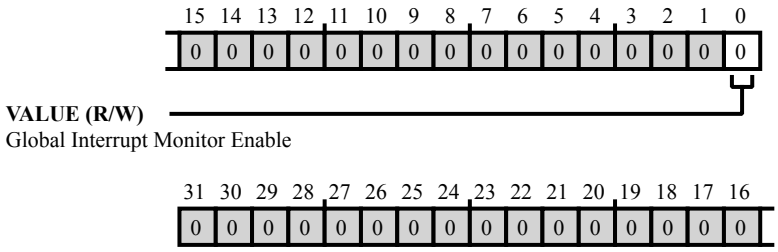

Figure 6-31: GICDST_EN Register Diagram

Table 6-32: GICDST_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Global Interrupt Monitor Enable. The GICDST_EN.VALUE bit field enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

Software Generated Interrupt Priority Register

The `GICDST_SGI_PRIO[n]` register provides the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

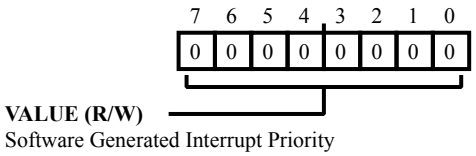

Figure 6-32: GICDST_SGI_PRIO[n] Register Diagram

Table 6-33: GICDST_SGI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Software Generated Interrupt Priority. The `GICDST_SGI_PRIO[n].VALUE` bit field contains the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

Shared Peripheral Interrupt Priority Register

The GICDST_SPI_PRIO[n] registers provide an 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

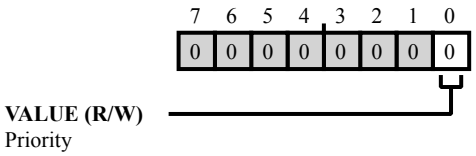

Figure 6-33: GICDST_SPI_PRIO[n] Register Diagram

Table 6-34: GICDST_SPI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Priority. The GICDST_SPI_PRIO[n].VALUE bit field stores the priority of the corresponding interrupt (byte offset 3 to Byte offset 0).

Software Generated Interrupt Active Register

The GICDST_SGI_ACTIVE registers provide a Set-active bit for each interrupt that the GIC supports. Writing to a Set-active bit Activates the corresponding interrupt. These registers are used when preserving and restoring GIC state.

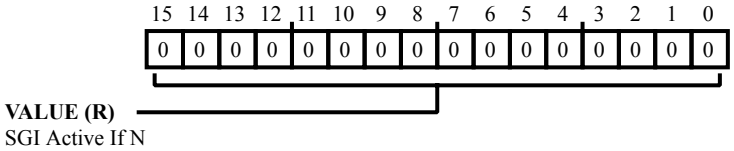

Figure 6-34: GICDST_SGI_ACTIVE Register Diagram

Table 6-35: GICDST_SGI_ACTIVE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	SGI Active If N. The GICDST_SGI_ACTIVE.VALUE bit field provides a Set-active bit for each interrupt that the GIC supports.

Software Generated Interrupt Control Register

The GICDST_SGI_CTL register controls the generation of SGIs.It is implementation defined whether this register has any effect when the forwarding of interrupts by Distributor is disabled by the GICD_CTLR settings.

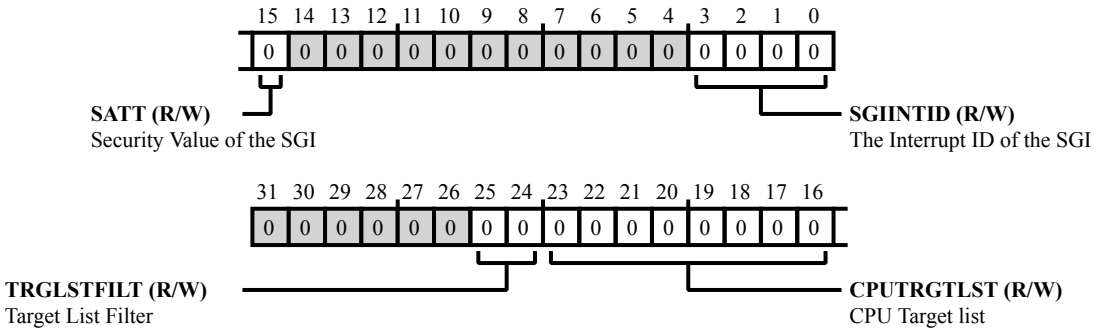

Figure 6-35: GICDST_SGI_CTL Register Diagram

Table 6-36: GICDST_SGI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRGLSTFILT	Target List Filter. The GICDST_SGI_CTL.TRGLSTFILT bit field determines how the distributor must process the requested SGI.	
		0	Forward the interrupt to the CPU interfaces specified in the CPUTargetList field
		1	Forward the interrupt to all CPU interfaces except that of the processor that requested the interrupt
		2	Forward the interrupt only to the CPU interface of the processor that requested the interrupt
		3	Reserved
23:16 (R/W)	CPUTRGTLST	CPU Target list. When the GICDST_SGI_CTL.CPUTRGTLST bit field TargetList Filter = 0b00, defines the CPU interfaces to which the Distributor must forward the interrupt. Each bit of the GICDST_SGI_CTL.CPUTRGTLST bit field refers to the corresponding CPU interface, for example CPUTargetList[0] corresponds to CPU interface 0. Setting a bit to 1 indicates that the interrupt must be forwarded to the corresponding interface. If this field is 0x00 when TargetListFilter is 0b00, the Distributor does not forward the interrupt to any CPU interface.	

Table 6-36: GICDST_SGI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SATT	Security Value of the SGI. The `GICDST_SGI_CTL.SATT` bit is implemented only if the GIC includes the Security Extensions. This field is writable only by a Secure access. Any Non-secure write to the GICD_SGIR generates an SGI only if the specified SGI is programmed as Group 1, regardless of the value of bit[15] of the write.	
		0	Forward the SGI specified in the SGIINTID field to a specified CPU interface only if the SGI is configured as Group 0 on that interface.
		1	Forward the SGI specified in the SGIINTID field to a specified CPU interfaces only if the SGI is configured as Group 1 on that interface.
3:0 (R/W)	SGIINTID	The Interrupt ID of the SGI.	

Software Generated Interrupt Clear-Pending Register

The GICDST_SGI_PND_CLR register provides a clear pending bit for each interrupt supported by the GIC. Writing 1 to a clear-pending bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

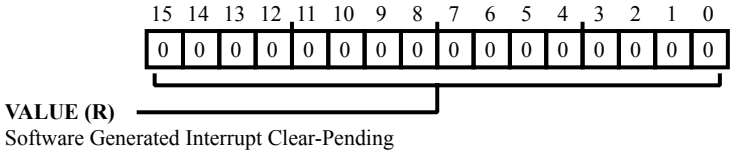

Figure 6-36: GICDST_SGI_PND_CLR Register Diagram

Table 6-37: GICDST_SGI_PND_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Software Generated Interrupt Clear-Pending. Writing 1 to a clear-pending bit in the GICDST_SGI_PND_CLR.VALUE bit field clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Pending Set Register

The GICDST_SGI_PND_SET register provides a set-pending bit for each interrupt supported by the GIC.

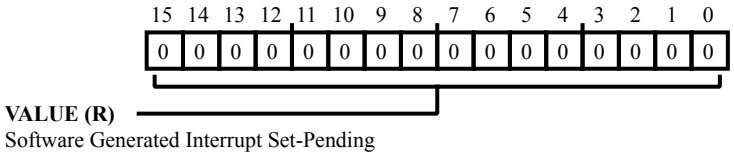

Figure 6-37: GICDST_SGI_PND_SET Register Diagram

Table 6-38: GICDST_SGI_PND_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Software Generated Interrupt Set-Pending. Writing 1 to a Set-pending bit in the GICDST_SGI_PND_SET.VALUE bit field sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Security Register

The GICDST_SGI_SECURITY registers provide a status bit for each interrupt supported by the GIC. Each bit controls whether the corresponding interrupt is in Group 0 or Group 1. Typically, when used with a processor that implements the ARM Security Extensions, Group 0 interrupts are Secure interrupts, and Group 1 interrupts are Non-secure interrupts,

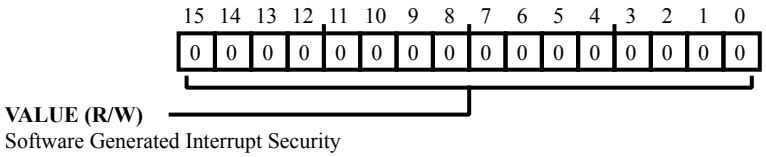

Figure 6-38: GICDST_SGI_SECURITY Register Diagram

Table 6-39: GICDST_SGI_SECURITY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Software Generated Interrupt Security. Each bit in the GICDST_SGI_SECURITY.VALUE bit field controls whether the corresponding interrupt is in Group 0 or Group 1.

Shared Peripheral Interrupt Register

The `GICDST_SPI[n]` register contains bits that provide the status of the SPI[987:0] inputs.

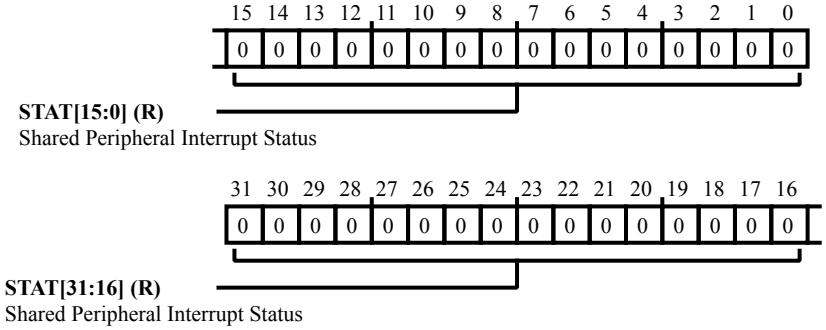

Figure 6-39: GICDST_SPI[n] Register Diagram

Table 6-40: GICDST_SPI[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	STAT	Shared Peripheral Interrupt Status. The `GICDST_SPI[n].STAT` bit field returns the status of the SPI[987:0] inputs on the distributor where bit [x] = 0 SPI[x] is low and bit [x] = 1 SPI[x] is high.

Shared Peripheral Interrupt Active Register

The GICDST_SPI_ACTIVE[n] register provides an active bit for each interrupt supported by the GIC.

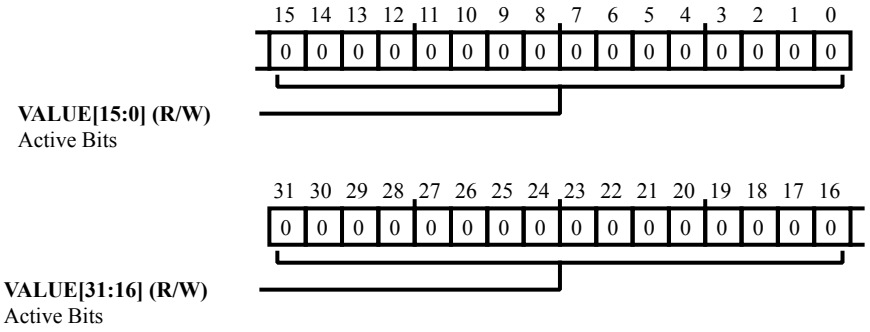

Figure 6-40: GICDST_SPI_ACTIVE[n] Register Diagram

Table 6-41: GICDST_SPI_ACTIVE[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Active Bits. The GICDST_SPI_ACTIVE[n].VALUE bit field contains an Active bit for each interrupt supported by the GIC. Reading an active bit identifies whether the corresponding interrupt is active (=1) or not active (=0).

Shared Peripheral Interrupt Configuration Register

The `GICDST_SPI_CFG[n]` register provides a 2-bit Int_config field for each interrupt supported by the GIC.

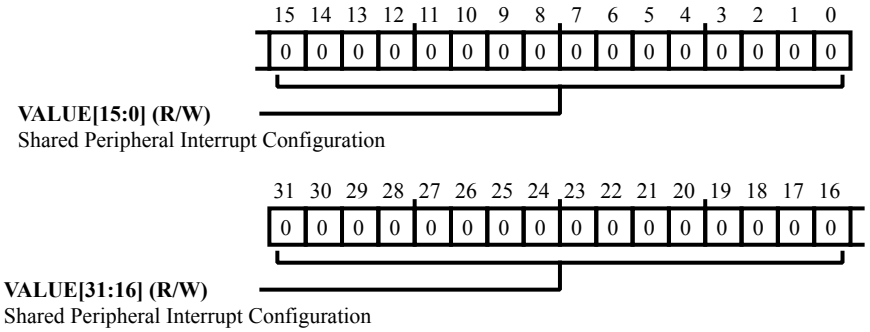

Figure 6-41: GICDST_SPI_CFG[n] Register Diagram

Table 6-42: GICDST_SPI_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Configuration. The `GICDST_SPI_CFG[n].VALUE` bit field identifies whether the corresponding interrupt is: edge-triggered or level-sensitive handled using the 1-N model or using the N-N model

Shared Peripheral Interrupt Enable Clear Register

The GICDST_SPI_EN_CLR[n] register provides a clear-enable bit for each interrupt supported by the GIC.

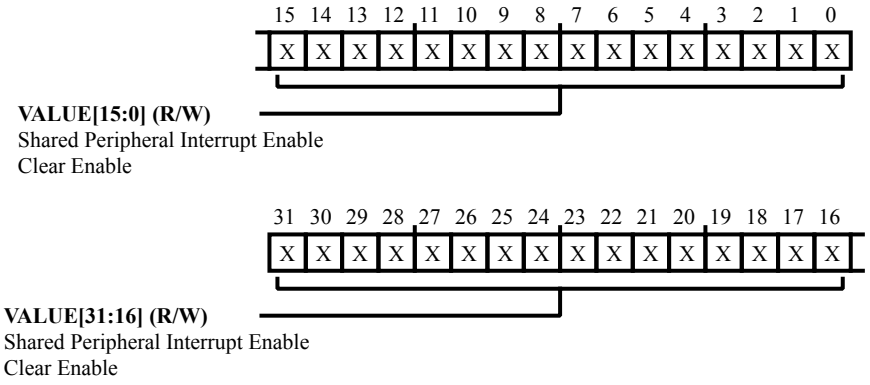

Figure 6-42: GICDST_SPI_EN_CLR[n] Register Diagram

Table 6-43: GICDST_SPI_EN_CLR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Enable Clear Enable. Writing 1 to a GICDST_SPI_EN_CLR[n].VALUE bit disables forwarding of the corresponding interrupt to the CPU interfaces. Reading a bit identifies whether the interrupt is enabled.

Shared Peripheral Interrupt Enable Set Register

The `GICDST_SPI_EN_SET[n]` register provides a set-enable bit for each interrupt supported by the GIC.

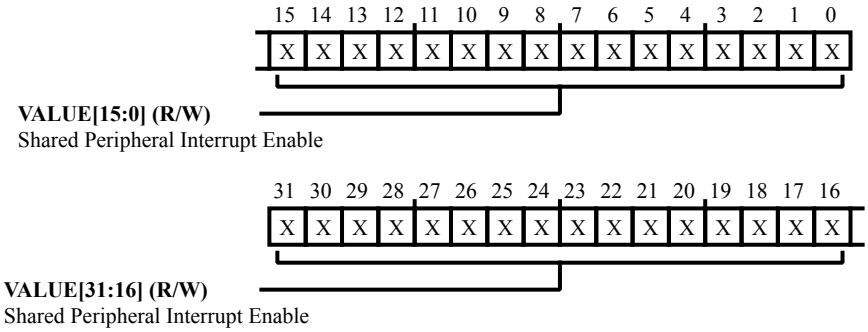

Figure 6-43: GICDST_SPI_EN_SET[n] Register Diagram

Table 6-44: GICDST_SPI_EN_SET[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Enable. Writing 1 to a `GICDST_SPI_EN_SET[n].VALUE` bit enables forwarding of the corresponding interrupt to the CPU interfaces. Reading a bit identifies whether the interrupt is enabled.

Shared Peripheral Interrupt Pending Clear Register

The GICDST_SPI_PND_CLR[n] register provides a clear-pending bit for each interrupt supported by the GIC.

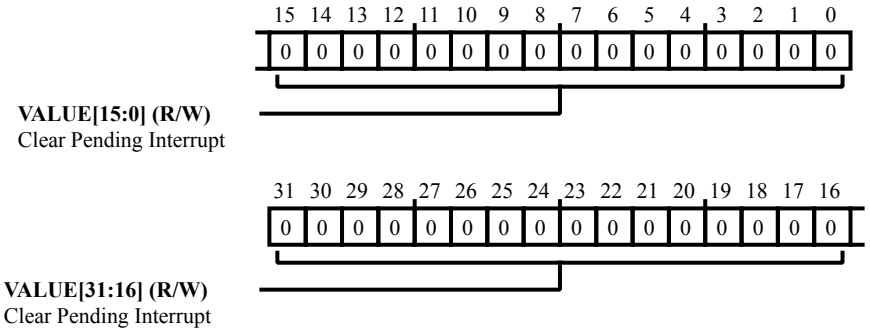

Figure 6-44: GICDST_SPI_PND_CLR[n] Register Diagram

Table 6-45: GICDST_SPI_PND_CLR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Clear Pending Interrupt. Writing 1 to a GICDST_SPI_PND_CLR[n].VALUE bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

Shared Peripheral Interrupt Pending Set Register

The GICDST_SPI_PND_SET[n] register provides a set-pending bit for each interrupt supported by the GIC.

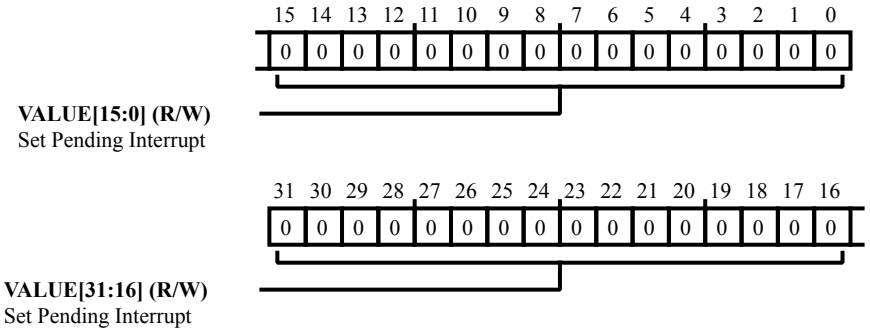

Figure 6-45: GICDST_SPI_PND_SET[n] Register Diagram

Table 6-46: GICDST_SPI_PND_SET[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Set Pending Interrupt. Writing 1 to a GICDST_SPI_PND_SET[n].VALUE bit sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Shared Peripheral Interrupt Security Register

The GICDST_SPI_SECURITY[n] register provides a security status bit for each interrupt supported by the GIC.

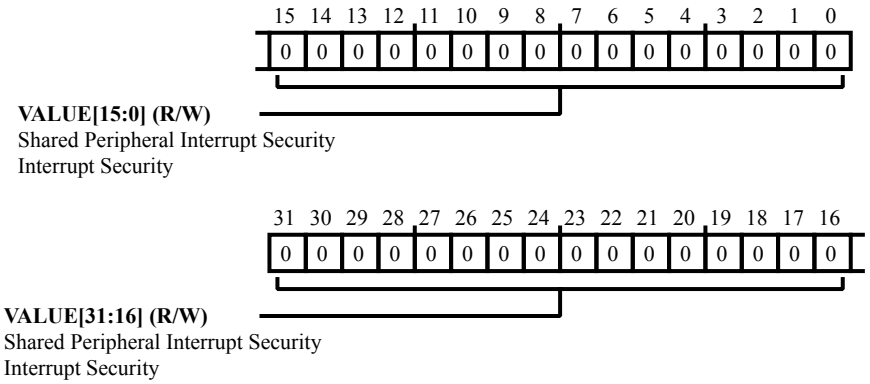

Figure 6-46: GICDST_SPI_SECURITY[n] Register Diagram

Table 6-47: GICDST_SPI_SECURITY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Security Interrupt Security. The GICDST_SPI_SECURITY[n].VALUE bits control the security status of the corresponding interrupt.

Shared Peripheral Interrupt Processor Targets Register

The GICDST_SPI_TRGT[n] register provides an 8-bit CPU targets field for each interrupt supported by the GIC.

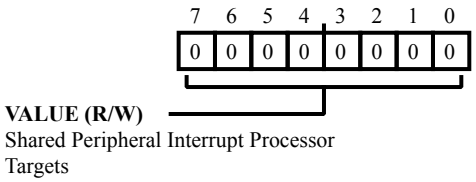

Figure 6-47: GICDST_SPI_TRGT[n] Register Diagram

Table 6-48: GICDST_SPI_TRGT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Shared Peripheral Interrupt Processor Targets. The GICDST_SPI_TRGT[n].VALUE bit field stores the list of processors that the interrupt is sent to if it is asserted.

ADSP-SC57x GICCPU Register Descriptions

GIC CPU Port (GICCPU) contains the following registers.

Table 6-49: ADSP-SC57x GICCPU Register List

Name	Description
GICCPU_BIN_PT_ALIAS	Aliased Binary Point Register (ICCABPR)
GICCPU_BIN_PT	Binary Point Register (ICCBPR)
GICCPU_CTL	CPU Interface Control Register (ICCICR)
GICCPU_EOI	End of Interrupt Register (ICCEOIR)
GICCPU_PND_HI	Highest Pending Interrupt Register (ICCHPIR)
GICCPU_INT_ACK	Interrupt Acknowledge Register (ICCIAR)
GICCPU_PRIO_MSK	Priority Mask Register (ICCIPMR)
GICCPU_RUN_PRIO	Running Priority Register (ICCRPR)

Aliased Binary Point Register (ICCABPR)

The GICCPU_BIN_PT_ALIAS register Provides an alias for the non secure GICCPU_BIN_PT register.

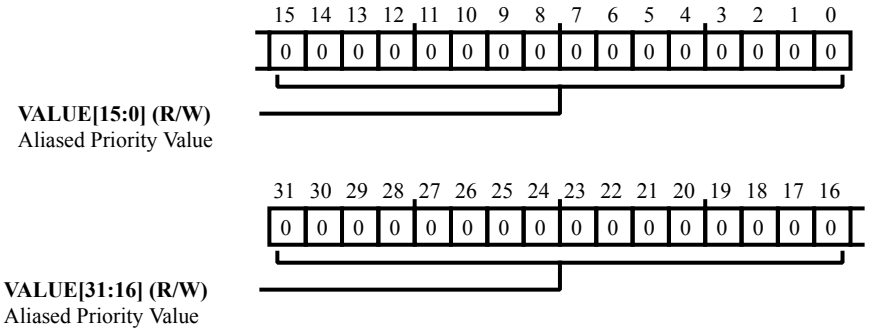

Figure 6-48: GICCPU_BIN_PT_ALIAS Register Diagram

Table 6-50: GICCPU_BIN_PT_ALIAS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Aliased Priority Value.

Binary Point Register (ICCBPR)

The GICCPU_BIN_PT register defines the point at which the priority value fields split into two parts, the group priority field and the sub-priority field. The group priority field is used to determine interrupt preemption.

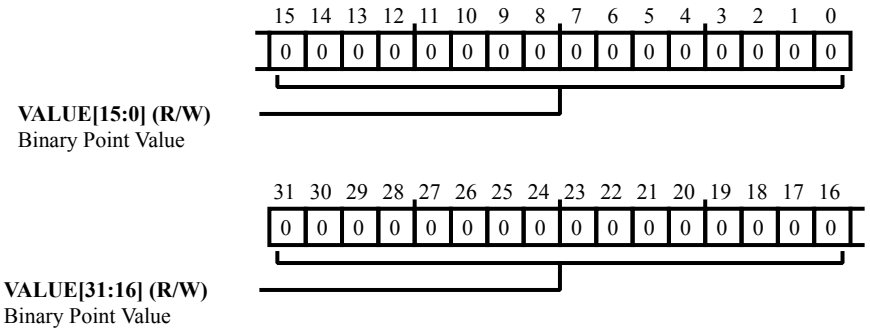

Figure 6-49: GICCPU_BIN_PT Register Diagram

Table 6-51: GICCPU_BIN_PT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Binary Point Value. The GICCPU_BIN_PT.VALUE bit field defines the point at which the priority value fields split into two parts.

CPU Interface Control Register (ICCICR)

The GICCPU_CTL register enables the signaling of interrupts to the target processors. In a GIC that implements the Security Extensions, provides additional global controls for handling Secure interrupts.

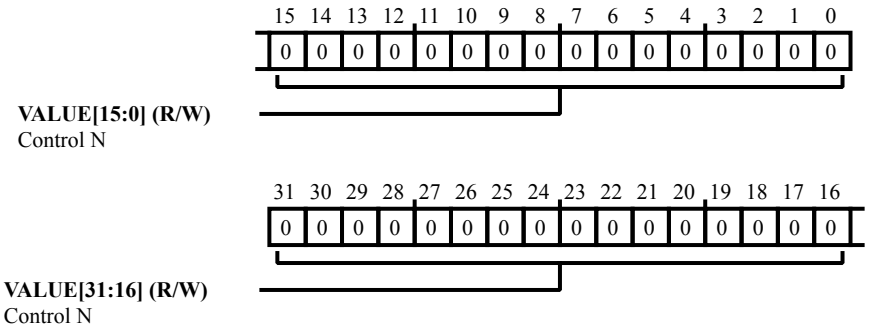

Figure 6-50: GICCPU_CTL Register Diagram

Table 6-52: GICCPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Control N.

End of Interrupt Register (ICCEOIR)

A processor writes to the GICCPU_EOI register to inform the CPU interface that it has completed its interrupt service routine for the specified interrupt.

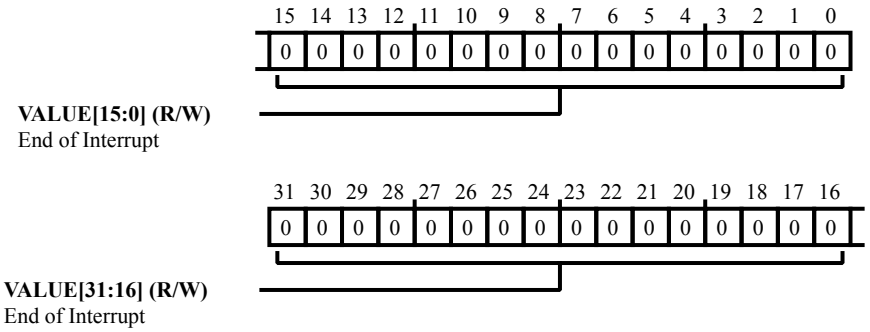

Figure 6-51: GICCPU_EOI Register Diagram

Table 6-53: GICCPU_EOI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	End of Interrupt. The GICCPU_EOI.VALUE bit field indicates to the CPU interface that it has completed its interrupt service routine for the specified interrupt.

Highest Pending Interrupt Register (ICCHPIR)

The GICCPU_PND_HI register indicates the Interrupt ID, and processor ID if appropriate, of the pending interrupt with the highest priority on the CPU interface.

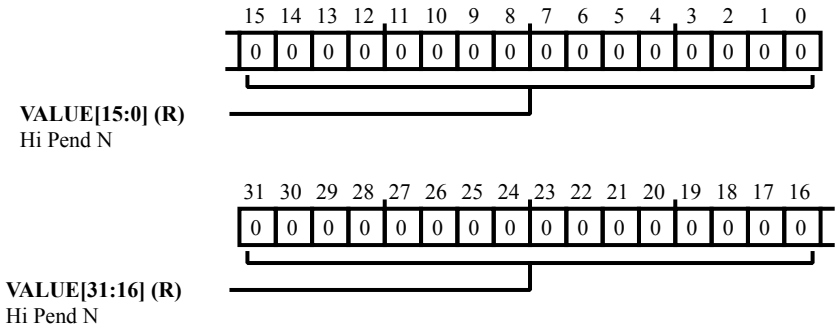

Figure 6-52: GICCPU_PND_HI Register Diagram

Table 6-54: GICCPU_PND_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Hi Pend N. Highest Pending Interrupt Register (ICCHPIR)

Interrupt Acknowledge Register (ICCIAR)

The processor reads the GICCPU_INT_ACK register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.

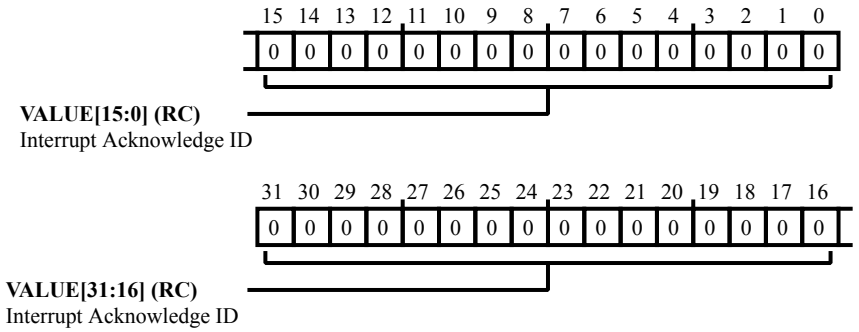

Figure 6-53: GICCPU_INT_ACK Register Diagram

Table 6-55: GICCPU_INT_ACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RC/NW)	VALUE	Interrupt Acknowledge ID. The GICCPU_INT_ACK.VALUE bit field contains the interrupt ID of the signaled interrupt.

Priority Mask Register (ICCIPMR)

The GICCPU_PRIO_MSK register provides an interrupt priority filter. Only interrupts with higher priority than the value in this register can be signaled to the processor.

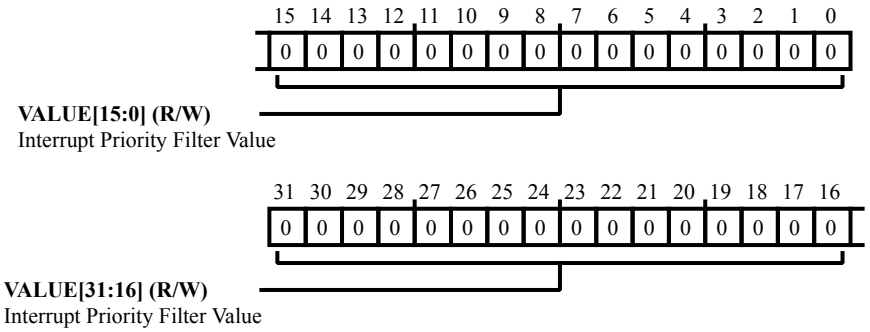

Figure 6-54: GICCPU_PRIO_MSK Register Diagram

Table 6-56: GICCPU_PRIO_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Interrupt Priority Filter Value. The GICCPU_PRIO_MSK.VALUE bit field contains the interrupt priority filter value.

Running Priority Register (ICCRPR)

The GICCPU_RUN_PRIO register indicates the priority of the highest priority interrupt that is active on the CPU interface.

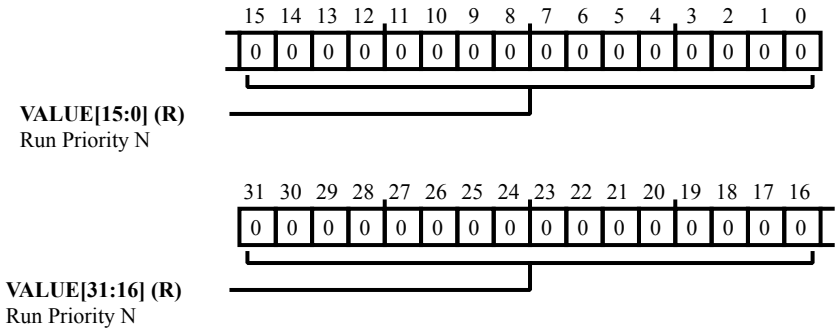

Figure 6-55: GICCPU_RUN_PRIO Register Diagram

Table 6-57: GICCPU_RUN_PRIO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Run Priority N. The GICCPU_RUN_PRIO.VALUE bit field contains the priority value of the highest priority interrupt that is active on the CPU interface. If there is no active interrupt on the CPU interface, and the GIC implements 8-bit priority fields, a read of this register returns the value 0xFF, corresponding to the lowest possible interrupt priority. If the GIC implements priority fields of less than 8 bits, the read might return the register reset value of 0xFF, or might return a value corresponding to the lowest possible interrupt priority. Software cannot determine the number of implemented priority bits from a read of this register.

7 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger masters (generators of triggers) to trigger slaves (receivers of triggers). Slave endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

TRU Features

The TRU supports the following features:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes. Once a DMA channel completes data transfer, it can act as a Trigger Master and signal an internal trigger pulse to the programmed Trigger Slave which can also be another DMA channel. The Slave Trigger connected to the DMA channel kicks off the DMA transfer automatically. None of this requires core intervention once the initialization is done.
- Software triggers. The best use of triggers is to minimize core intervention. It is also possible to initiate a trigger pulse to a Trigger Slave, in the software.
- Synchronization of concurrent activities. A single Trigger Master can initiate a trigger pulse to multiple Trigger Slaves so that several system level activities can be synchronized on an internally or externally generated event.
- Configuration protection through register-level lock bits and global lock indication

TRU Functional Description

The following sections provide a description of the TRU.

ADSP-SC57x TRU Register List

The Trigger Routing Unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU receives trigger inputs from all master trigger inputs (MTI) and the TRU master trigger register (TRU_MTR). Based on these inputs, the TRU logic generates trigger outputs that initiate slave operations in the processor core and peripherals. A set of registers governs TRU operations. For more information on TRU functionality, see the TRU register descriptions.

Table 7-1: ADSP-SC57x TRU Register List

Name	Description
TRU_ERRADDR	Error Address Register
TRU_GCTL	Global Control Register
TRU_MTR	Master Trigger Register
TRU_SSR[n]	Slave Select Register
TRU_STAT	Status Information Register

ADSP-SC57x TRU Interrupt List

Table 7-2: ADSP-SC57x TRU Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
126	TRU0_SLV4	TRU0 Interrupt 4 -- Core 1 only	Edge	
127	TRU0_SLV5	TRU0 Interrupt 5 -- Core 1 only	Edge	
128	TRU0_SLV6	TRU0 Interrupt 6 -- Core 1 only	Edge	
129	TRU0_SLV7	TRU0 Interrupt 7 -- Core 1 only	Edge	
130	TRU0_SLV8	TRU0 Interrupt 8 -- Core 2 only	Edge	
131	TRU0_SLV9	TRU0 Interrupt 9 -- Core 2 only	Edge	
132	TRU0_SLV10	TRU0 Interrupt 10 -- Core 2 only	Edge	
133	TRU0_SLV11	TRU0 Interrupt 11 -- Core 2 only	Edge

204	TRU0_SLV1	TRU0 Interrupt 1 -- Core 0 only	Edge	
205	TRU0_SLV2	TRU0 Interrupt 2 -- Core 0 only	Edge	
206	TRU0_SLV3	TRU0 Interrupt 3 -- Core 0 only	Edge	

ADSP-SC57x TRU Trigger List

Table 7-3: ADSP-SC57x TRU Trigger List Masters

Trigger ID	Name	Description	Sensitivity
None			

Table 7-4: ADSP-SC57x TRU Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
68	TRU0_SLV0	TRU0 Interrupt Request 0	Pulse
69	TRU0_SLV1	TRU0 Interrupt Request 1	Pulse
70	TRU0_SLV2	TRU0 Interrupt Request 2	Pulse
71	TRU0_SLV3	TRU0 Interrupt Request 3	Pulse
72	TRU0_SLV4	TRU0 Interrupt Request 4	Pulse
73	TRU0_SLV5	TRU0 Interrupt Request 5	Pulse
74	TRU0_SLV6	TRU0 Interrupt Request 6	Pulse
75	TRU0_SLV7	TRU0 Interrupt Request 7	Pulse
76	TRU0_SLV8	TRU0 Interrupt Request 8	Pulse
77	TRU0_SLV9	TRU0 Interrupt Request 9	Pulse
78	TRU0_SLV10	TRU0 Interrupt Request 10	Pulse
79	TRU0_SLV11	TRU0 Interrupt Request 11	Pulse

TRU Definitions

The following definitions are helpful when using the TRU module.

Trigger Master

A trigger master is any system module that provides trigger event indication to the TRU. Trigger master modules define trigger events and conditions for assertion.

Trigger Master ID

Trigger masters are assigned a unique numeric ID according to their physical connection to the TRU. Trigger master ID 0 is reserved and defined as null.

Trigger Slave

A trigger slave is any system module that receives a trigger event indication from the TRU. Trigger slave modules define a trigger event response.

TRU Block Diagram

Trigger masters and the Master Trigger Register (MTR) generate trigger assertions. Each trigger slave has a dedicated Slave Select Register (SSR) that specifies the unique trigger master from which it receives the trigger indication.

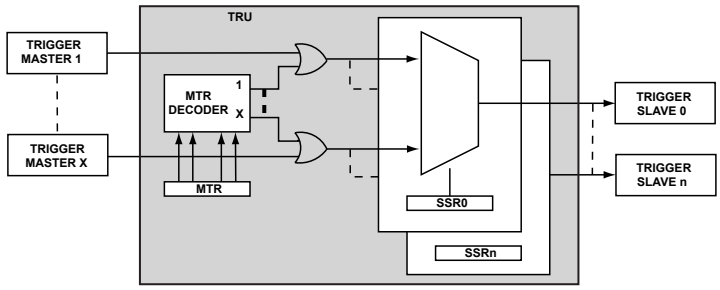

Figure 7-1: TRU Block Diagram

TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger masters are mapped to trigger inputs of trigger slaves through a set of programmable registers (`TRU_SSR[n]`).

System modules are trigger master only, trigger slave only, or trigger master and trigger slave.

All of the trigger input and output signals are connected to a trigger routing unit (TRU) which manages the connections of triggers between modules.

In multi-processor systems, multiple TRU units are provided. These TRUs are networked together. Generic Trigger Ports (GTPs) are provided to forward trigger events from one TRU unit to another, forming a pathway from trigger masters to trigger slaves wherever they might lie in the system.

TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger slave, a trigger master, and the TRU module itself. The only requirement for the configuration procedure is that the trigger master is configured and enabled as the last step.

Complete the following other steps:

- Configure the trigger slave for response to triggers.
- Configure the TRU to map the trigger master to the trigger slave through the `TRU_SSR[n]` registers.
- Configure the trigger master to generate trigger assertions.
- Alternatively, use software triggering for trigger assertion. Writing the trigger master ID to the MTR register generates software triggers.

Programming Concepts

The following concepts aid in programming the TRU.

- ***Trigger Sequence Configuration.*** A simple sequence consists of one trigger master and one trigger slave. More complex trigger sequences consist of several trigger slaves functioning as trigger slave and trigger master. Additionally, trigger sequences can loopback to the original master forming a perpetual sequence.
- ***Software Triggering.*** Writing a trigger master ID to the MTR generates a trigger within the TRU from the trigger master ID specified.
- ***Synchronization.*** The TRU can be used to coarsely synchronize events by mapping multiple trigger slaves to the same trigger master or by generating multiple trigger master assertions simultaneously through the MTR.
- ***Configuration Protection.*** The `TRU_SSR[n].LOCK` bit and the `TRU_GCTL.LOCK` bit enable register level write-protection when the global lock is asserted in the SPU.

Programming Examples

The following examples shows the steps to create a single trigger.

Configuring a Simple Trigger Sequence

The following example shows the steps to create a simple trigger.

1. Write to the `TRU_GCTL` register to enable the TRU.
2. Write to the `TRU_SSR[n]` register of a specific trigger slave to assign it to a specific trigger master.
3. Enable the trigger slave to wait for and accept a trigger.
4. Enable the trigger master to generate a trigger.

TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and can extend to support the interrupt and fault management models as well.

TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Slave errors are reported to the master over the standard peripheral bus protocol.

ADSP-SC57x TRU Register Descriptions

Trigger Routing Unit (TRU) contains the following registers.

Table 7-5: ADSP-SC57x TRU Register List

Name	Description
TRU_ERRADDR	Error Address Register
TRU_GCTL	Global Control Register
TRU_MTR	Master Trigger Register
TRU_SSR[n]	Slave Select Register
TRU_STAT	Status Information Register

Error Address Register

The TRU error address register (TRU_ERRADDR) holds the address from the memory-mapped register access generating an access error of TRU registers.

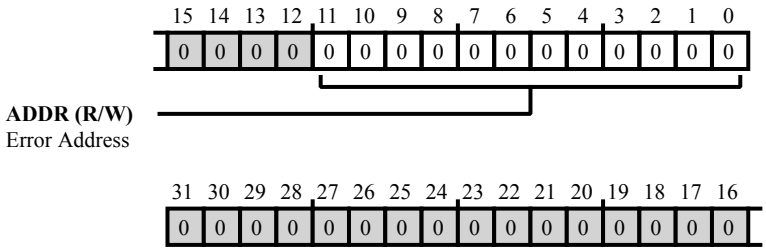

Figure 7-2: TRU_ERRADDR Register Diagram

Table 7-6: TRU_ERRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ADDR	Error Address. The TRU_ERRADDR.ADDR holds the address from the memory-mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_SSR[n] or TRU_MTR registers when these registers are locked or on access to an invalid address. See the TRU_SSR[n] and TRU_MTR register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of multiple errors occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared.

Global Control Register

The TRU global control register (TRU_GCTL) provides register locking, TRU reset, and TRU enable.

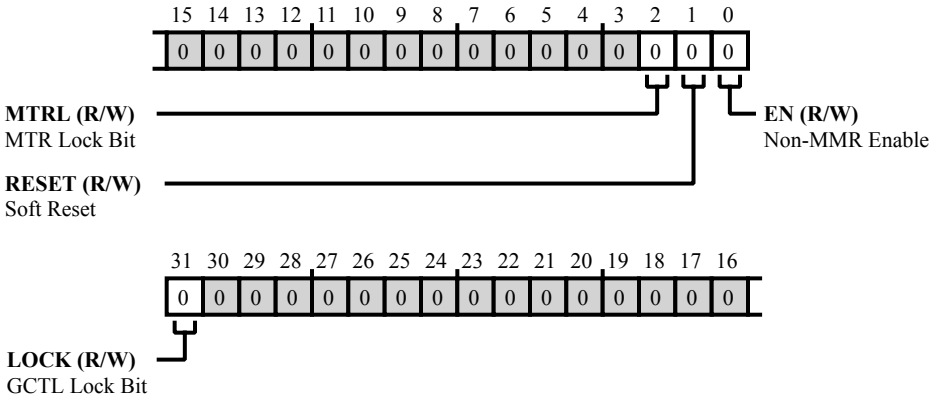

Figure 7-3: TRU_GCTL Register Diagram

Table 7-7: TRU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	GCTL Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is enabled, the TRU_GCTL register is read only.	
		0	Read write
		1	Read only
2 (R/W)	MTRL	MTR Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.MTRL bit is enabled, the TRU_MTR register is read only.	
		0	Read write
		1	Read only
1 (R/W)	RESET	Soft Reset. The TRU_GCTL.RESET bit is write-1-action and triggers a soft reset to all TRU registers.	
		0	No action
		1	Soft reset

Table 7-7: TRU_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Non-MMR Enable. The `TRU_GCTL.EN` bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the `TRU_GCTL.EN` bit.	
		0	No trigger events
		1	Propagate trigger events

Master Trigger Register

The TRU master trigger register (TRU_MTR) permits trigger generation through software by writing a trigger master ID value to one of the four fields in the TRU_MTR register. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is set, the TRU_MTR register is read only. Note this register is primarily used for debug to trigger a TRU output

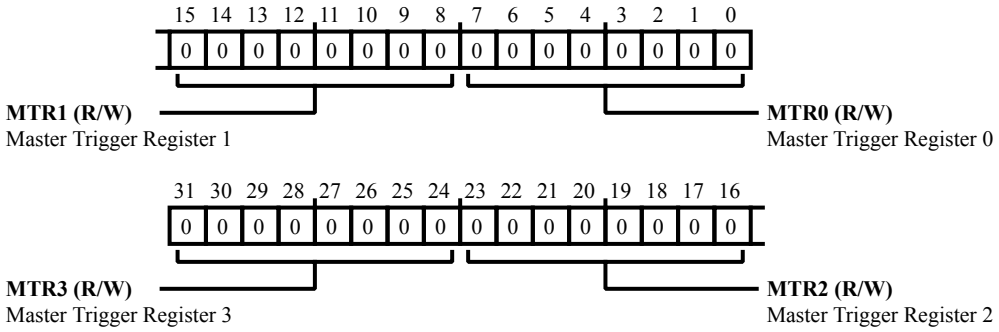

Figure 7-4: TRU_MTR Register Diagram

Table 7-8: TRU_MTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	MTR3	Master Trigger Register 3. The TRU_MTR.MTR3 bit field is the trigger master ID value for master 3.	
		0	No master specified
		1-255	Range of valid masters
23:16 (R/W)	MTR2	Master Trigger Register 2. The TRU_MTR.MTR2 bit field is the trigger master ID value for master 2.	
		0	No master specified
		1-255	Range of valid masters
15:8 (R/W)	MTR1	Master Trigger Register 1. The TRU_MTR.MTR1 bit field is the trigger master ID value for master 1.	
		0	No master specified
		1-255	Range of valid masters
7:0 (R/W)	MTR0	Master Trigger Register 0. The TRU_MTR.MTR0 bit field is the trigger master ID value for master 0.	
		0	No master specified
		1-255	Range of valid masters

Slave Select Register

The TRU slave select registers (`TRU_SSR[n]`) each provide slave selection and register locking.

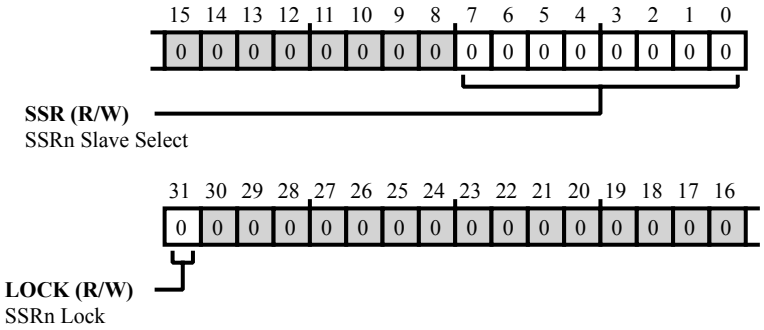

Figure 7-5: TRU_SSR[n] Register Diagram

Table 7-9: TRU_SSR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	SSRn Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `TRU_SSR[n].LOCK` bit is enabled, the `TRU_SSR[n]` register is read only.	
		0	Unlock register
		1	Lock register
7:0 (R/W)	SSR	SSRn Slave Select. The `TRU_SSR[n]` register selects the trigger master ID to which the trigger slave responds. For example, when a `TRU_SSR[n]` register is set to respond to trigger master ID n, a trigger that is generated by trigger master ID n results in a trigger out to the slave.	
		0	No master specified
		1-255	Range of valid masters

Status Information Register

The TRU status register (TRU_STAT) contains the status of TRU_MTR and TRU_SSR[n] register writes and status of bus read/write errors.

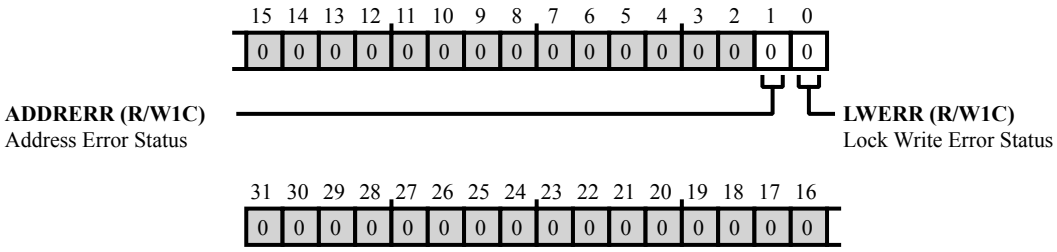

Figure 7-6: TRU_STAT Register Diagram

Table 7-10: TRU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ADDRERR	Address Error Status. The TRU_STAT.ADDRERR bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected.	
		0	No error
		1	Error occurred
0 (R/W1C)	LWERR	Lock Write Error Status. If TRU_STAT.LWERR is set, a lock write error has occurred. Writing a one to this bit clears the error indication.	
		0	No error
		1	Error occurred

8 L2 System Memory

L2 system memories have significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

L2 System Memory Features

The L2 system memory features include:

- Operation at SCLK frequency
- ECC protection of SRAM area
- ECC memory refresh

There is one instance of L2 system memory: L2CTL0.

- L2CTL0 contains 1M byte of RAM grouped into eight banks, 128K bytes each and 96K bytes of boot ROM.
- All instances supports exclusive access through SMPU.
- SHARC core data ports can access L2 memory through direct path as well as through ARM L2 cache.

L2 System Memory Functional Description

The L2 system memory manages all of the L2 SRAM and ROM memory banks. The system memory interface arbitrates competing accesses, write protection, and ensures SRAM data integrity. The L2 system memory domain is a unified instruction and data memory. It can hold any mixture of code and data required by the system design.

The following sections provide a functional description of the L2 system memory.

ADSP-SC57x L2CTL Register List

L2 System Memory Block Diagram

The ***L2 System Block Diagram*** shows the complete L2 system memory, including the memory block instance L2CTL0. The L2CTL0 block contains boot ROM code for ARM and three banks of L2 RAM containing 32 Kbytes each. ARM's 0x00000000 location (reset ISR) is mapped to this block.

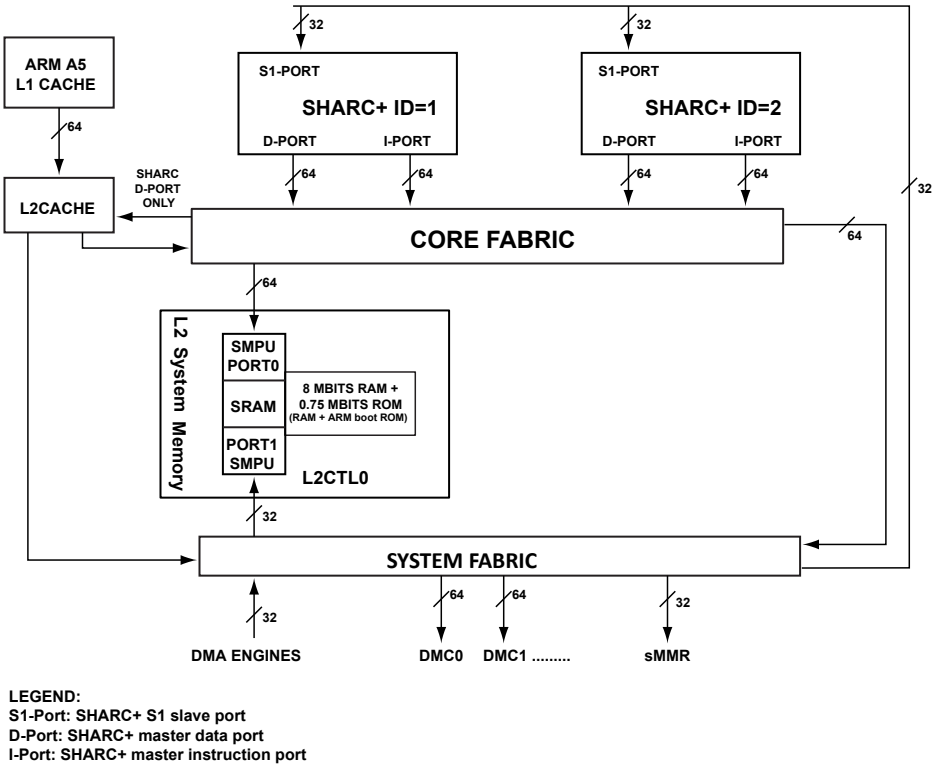

Figure 8-1: L2 System Block Diagram

L2 System Memory Architectural Concepts

The following sections describe architecture features of the L2 system memory.

- Read/Write Latency and Throughput

- Arbitration and Priority

Access Characteristics

The L2 system memory interface converts all 8-bit, 16-bit, and 32-bit accesses to 64-bit accesses. Additionally, it converts 8-bit, 16-bit, and 32-bit bursts to an equivalent internal 64-bit access. For example, the L2 system memory interface converts a 64-bit address-aligned burst of 8-bit accesses of burst length 8 to a single 64-bit access.

Read/Write Latency and Throughput

The L2 memory design is optimized for burst accesses at the crossbar interface. The L2 system memory buffers and converts write data of 8/16/32-bit to an equivalent 64-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8-bit or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an extra latency of two SCLK cycles. No extra latency is seen if the ECC is disabled.

NOTE: Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

L2 Memory Controller Block Diagram (Instance)

As shown in the ***L2 System Memory Block Diagram***, the L2 controller has two ports that interface to system crossbars. Port 0 is a 64-bit interface that is dedicated to core and MDMA3 traffic, and port 1 is a 32-bit interface that connects through the rest of the DMA access. For L2 SRAM both ports (0/1) have a read channel and a write channel, for L2 ROM both ports (0/1) have read channels only. The SRAM is organized in multiple banks, and each bank has 128K Bytes. The 96KB ROM is divided into three banks of 32KB.

Within each bank, data is organized into 16384 words, with each word comprising 64 bits of data and 14 bits of ECC checksum. ROM memory is not protected by the ECC scheme. When the L2 controller accesses RAM and ROM cells, it always reads and writes whole 64-bit words. Despite this, the L2 controller supports 8-, 16-, and 32-bit reads and writes from cores and system by applying respective data masks.

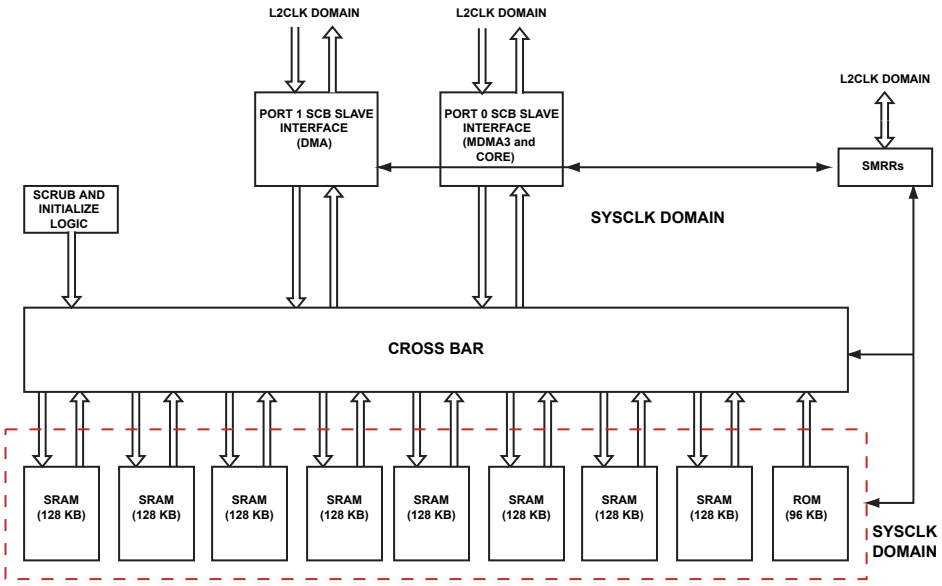

Figure 8-2: L2 System Memory Block Diagram

Arbitration and Priority

Each bank of L2 RAM or ROM has an arbiter which receives requests from the two crossbar ports.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through urgent priority requests.

NOTE: Attempting a write access to both L2 ROM spaces returns an error.

The ***Fixed Priority*** table shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

If two cores (or the 64-bit Max BW DMA) simultaneously try to access L2 for the same instance (both read or both write), even to different banks, software allows only one master access at a time. One access port can support one read and write at the same time. However, if one core issues a write and the other issues a read, then access can proceed simultaneously. There is no extra latency inside L2, as long as the accesses are to different banks (assuming pending DMA traffic is also to a non-conflicting bank).

When a core and DMA both access the same bank via the same port (both read or both writes), the best access rate that DMA can achieve is one 64-bit access in every three SCLK cycles during the conflict period. This access rate is achieved by programming the read priority count register (`L2CTL_RPCR.RPC0`) bit and the write priority count register (`L2CTL_WPCR.WPC0`) bit to 0, while programming the `L2CTL_RPCR.RPC1` and the `L2CTL_WPCR.WPC1` bits to 1.

The arbiters also support priority elevation for a particular channel that has been starved of grants for many SCLK cycles. If a channel does not get a grant for *N* cycles after its request, then that channel can elevate the priority of its request by issuing an urgent priority request. This request causes that particular channel to become the highest priority master for the next grant cycle (pipelined arbitration for urgent priority). The number of cycles *N*, after which

the priority is elevated, can be programmed for each channel separately using the L2CTL_RPCR and L2CTL_WPCR registers.

Programming the bits in the L2CTL_RPCR and L2CTL_WPCR registers appropriately achieves the best grant rate for DMA. This grant rate of one in three SCLK cycles during the conflict period is achievable under the following conflict conditions:

- An access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme with core activity always prioritized over DMA activity
- An access conflict within the pipelined implementation of urgent priority

To disable urgent priority requests, set the L2CTL_CTL.DISURP bit. This bit disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

The ***Fixed Priority With Priority Elevation*** table provides the various priority levels for the L2 system memory.

Table 8-5: Fixed Priority With Priority Elevation

Channel	Priority Level
L2 Refresh Request	9 (highest)
Port 0 Read Channel Urgent Request	8
Port 0 Write Channel Urgent Request	7
Port 1 Read Channel Urgent Request	6
Port 1 Write Channel Urgent Request	5
Port 0 Read Channel Normal Request	4
Port 0 Write Channel Normal Request	3
Port 1 Read Channel Normal Request	2
Port 1 Write Channel Normal Request	1 (lowest)

Data Integrity

The following sections provide information on how the L2 system memory ensures data integrity.

ECC Algorithm

Hsaio encoding calculates the ECC syndrome. A 7-bit syndrome is generated during write operation and stored as a 7-bit parity field along with the 32 data bits. Each data bit contributes to three parity bits according. Each parity bit represents the XOR value of 13 or 14 data bits according to the following mapping:

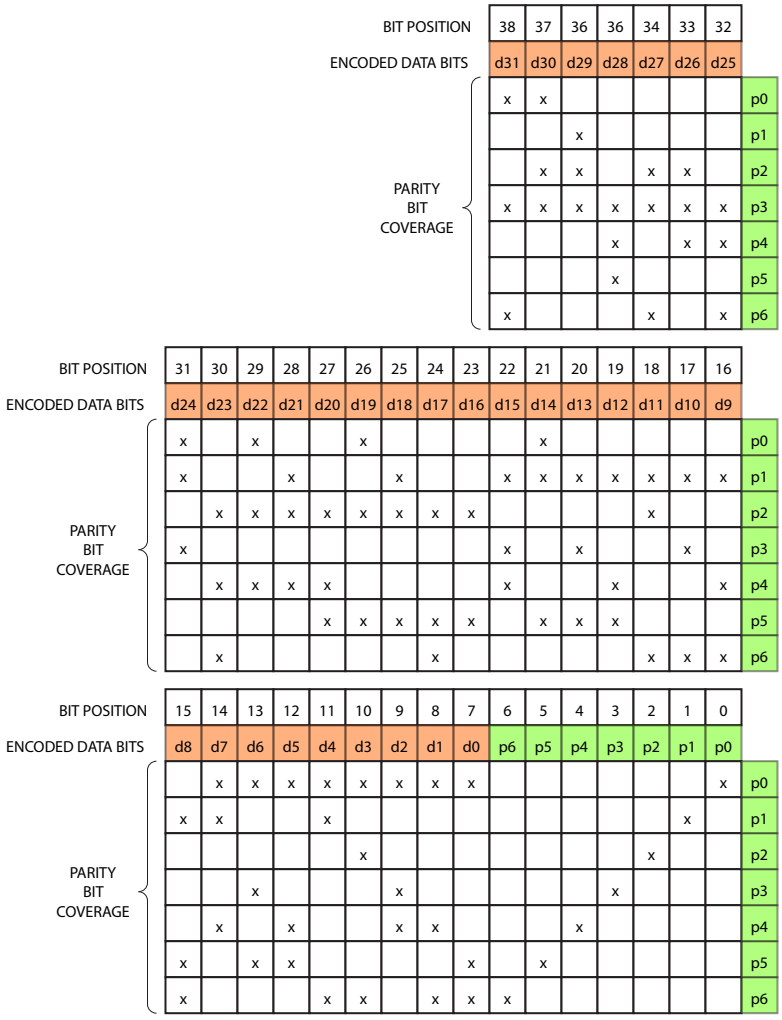

Figure 8-3: Hsaio Parity Bit Mapping

During read operation, the parity bits become part of the syndrome equation. The new syndrome bits are now the XOR values of the 13 or 14 data bits plus the respective stored parity bit. If any of the seven syndrome bits is set, an error situation is detected. An OR gate cross of the 7 bits reports the error, without specifying the type of the error.

If a single parity bit failed, the new 7-bit syndrome has 1 bit that is set. If a single data bit failed, the new syndrome has 3 bits that are set, because all three related parity bits fail. So, an XOR gate cross of all seven syndrome bits detects a single-bit error, indicating that an odd number of syndrome bits is set.

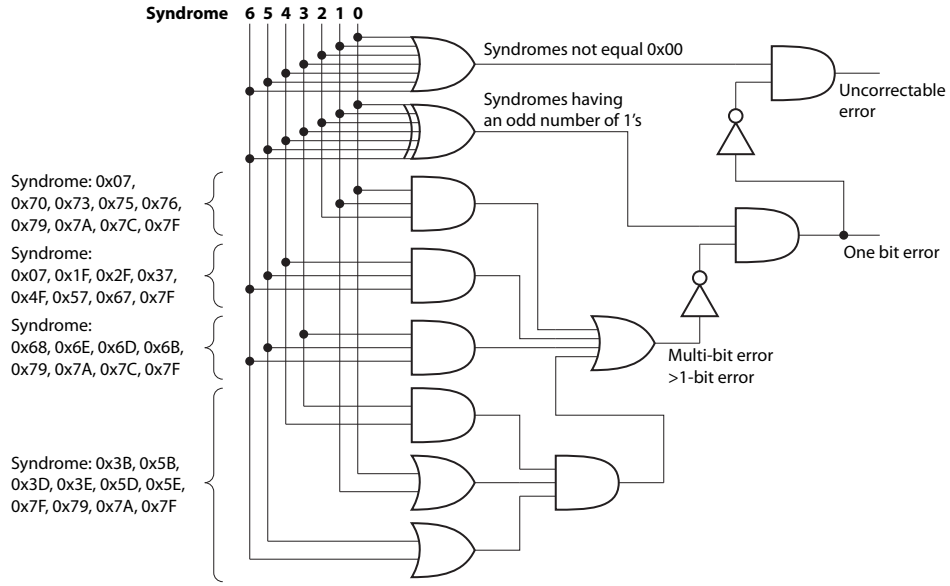

Figure 8-4: Hsiao Error Reports

The XOR gate detects single-bit errors and does not flag any dual-bit error. But, the gate does flag 50% of the other multi-bit errors undesirably. Extra logic is implemented to increase the detection rate of multi-bit errors to 68.7% as shown in the figure.

If a single-bit error is detected, the failing bit can be localized and corrected. If all three syndrome bits corresponding to a specific data bit are 1, a data error is assumed. The respective data bit is toggled on its way to the system bus.

ECC Hardware Control

After reset, ECC protection is enabled. The boot code initializes all L2 SRAM data and checksum cells. ECC protection adds some cycle penalty when 8-bit and 16-bit values write L2 memory. Disable ECC protection for individual SRAM banks by setting the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits. Due to caching mechanisms of the processor cores and data bursting of the DMA channels, 8-bit and 16-bit write accesses are rather uncommon. Typically, only two-dimensional DMA operations or uncached 8-bit and 16-bit store instruction can trigger these writes.

ECC Error Management

The L2 system memory flags 2-bit and multi-bit errors to the system by:

- Raising the ECC_ERR interrupt
- Reporting a read error to the system bus
- Setting the sticky `L2CTL_STAT.ECCERR7-L2CTL_STAT.ECCERR0` status flag
- Latching the address of the failing operation into the respective `L2CTL_ERRADDR7-L2CTL_ERRADDR0` register.

There is one error status bit and one error address register per L2 SRAM bank.

Typically, ECC_ERR events are declared as system faults in the system event controller (SEC). Whether these faults are reported, the interrupt service routine can consult the L2CTL_STAT register and the L2CTL_ERRADDR0 through L2CTL_ERRADDR7 registers to determine whether:

- The data at the failing L2 address was critical enough to require an immediate reboot of the system
- The data at the failing L2 address was less critical or can be restored

The L2CTL_STAT.ECCERR0 through L2CTL_STAT.ECCERR7 flags are cleared with a W1C operation.

Memory Refresh

If data in L2 SRAM contains single-bit errors, the data is corrected on its way to the system buses. The corrected value is not written back to the SRAM location. To prevent any risk of accumulation of single-bit errors over time and to minimize likelihood of multi-bit errors, the L2 system memory provides a special memory refresh mechanism.

If there are dual-bit or multi-bit errors, the ECC_ERR interrupt is raised, and data is not written back to memory.

Program the memory refresh or scrub using:

- TheL2CTL_SADR register with the start address of the scrub
- The L2CTL_SCNT register with the total number of 64-bit addresses to be scrubbed starting from the L2CTL_SADR address

Program the number of cycles between each scrub using the L2CTL_SCTL register. During the scrub, the L2 system memory issues a read, followed by a write-back operation if there is a single-bit ECC error. Once the L2 system memory completes scrubbing the programmed memory region, it generates an interrupt and starts again from the L2CTL_SADR address unless the L2CTL_SCTL.SEN bit is disabled. If the L2CTL_SCTL.SEN bit is cleared before completing the programmed address range, the scrub stops after completing any already issued scrub access. The scrub read/writes always start from the full 64-bit equivalent of the address written into the L2CTL_SADR register. A 64-bit value is always read, and the 64-bit value is written back. The scrub access has the highest priority. Programs can configure 8-bit, 16-bit, or 32-bit addresses in the L2CTL_SADR register. The lower 3 bits of this register are treated as *do-not-care* values because the internal memory array is always accessed when using 64 bits.

Memory refresh operation is meaningless when the L2CTL_CTL.BK0EDIS through L2CTL_CTL.BK7EDIS disable bits are set.

L2 System Memory Event Control

The following sections describe event control features of the L2 system memory, such as error response.

ECC Error Interrupt

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space

- An ECC multi-bit error in an ECC-enabled bank. A non-modulo, 32-bit write to an ECC-enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This response is because the L2 system memory implements a 32-bit ECC, and therefore a non-modulo, 32-bit write results in a read. This read can create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the L2CTL_STAT register, and the addresses that generated the error on a given port are stored in the L2CTL_EADDR0/L2CTL_EADDR1 register of that port. The details of the error are stored in the L2CTL_ET0/L2CTL_ET1 register of the port.

NOTE: The ECC error interrupt can be routed to different cores using the MEC. For more information, refer to the MEPU chapter.

ADSP-SC57x L2CTL Register Descriptions

Some description. (L2CTL) contains the following registers.

Table 8-6: ADSP-SC57x L2CTL Register List

Name	Description
L2CTL_CTL	Control Register
L2CTL_EADDR0	Error Type 0 Address Register
L2CTL_EADDR1	Error Type 1 Address Register
L2CTL_ERRADDR0	ECC Error Address 0 Register
L2CTL_ERRADDR1	ECC Error Address 1 Register
L2CTL_ERRADDR2	ECC Error Address 2 Register
L2CTL_ERRADDR3	ECC Error Address 3 Register
L2CTL_ERRADDR4	ECC Error Address 4 Register
L2CTL_ERRADDR5	ECC Error Address 5 Register
L2CTL_ERRADDR6	ECC Error Address 6 Register
L2CTL_ERRADDR7	ECC Error Address 7 Register
L2CTL_ERRADDR8	ECC Error Address 8 Register
L2CTL_ET0	Error Type 0 Register
L2CTL_ET1	Error Type 1 Register
L2CTL_INIT	Initialization Register
L2CTL_ISTAT	Initialization Status Register
L2CTL_REVID	Revision ID Register
L2CTL_RPCR	Read Priority Count Register
L2CTL_SADR	Scrub Start Address Register

Table 8-6: ADSP-SC57x L2CTL Register List (Continued)

Name	Description
L2CTL_SCNT	Scrub Count Register
L2CTL_SCTL	Scrub Control Register
L2CTL_STAT	Status Register
L2CTL_WPCR	Write Priority Count Register

Control Register

The L2CTL_CTL register includes a write protection bit, enables L2 banks, and selects mapping of banks (as ECC RAM or data RAM).

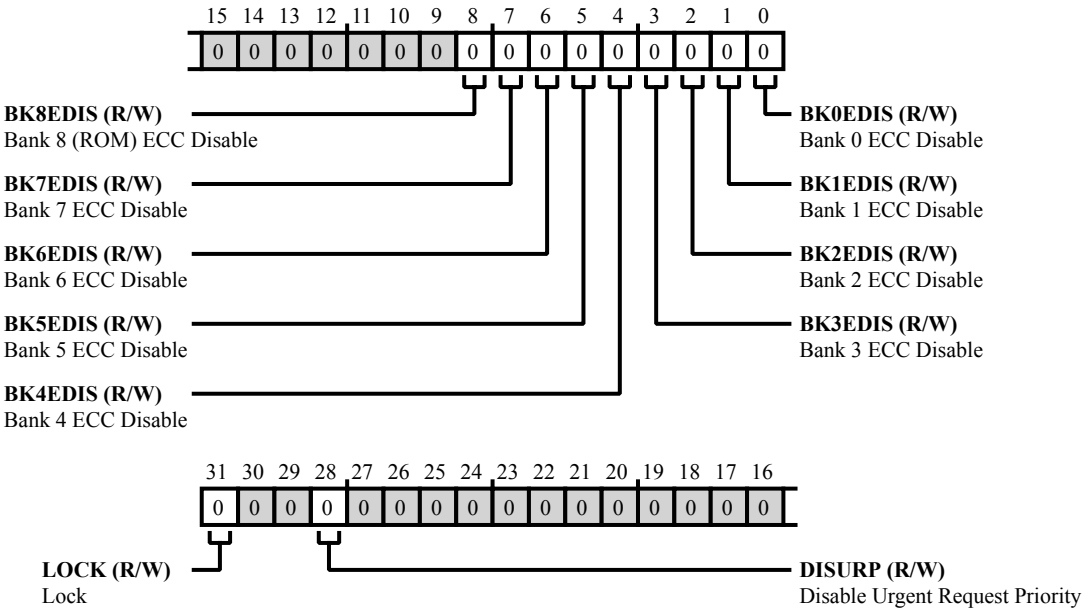

Figure 8-5: L2CTL_CTL Register Diagram

Table 8-7: L2CTL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_CTL.LOCK bit is set, the L2CTL_CTL register is read only (locked).	
		0	Unlock
		1	Lock
28 (R/W)	DISURP	Disable Urgent Request Priority. The L2CTL_CTL.DISURP disables urgent request priority mode for all L2 banks.	
		0	Enable URP
		1	Disable URP
8 (R/W)	BK8EDIS	Bank 8 (ROM) ECC Disable. The L2CTL_CTL.BK8EDIS bit disables L2 bank 8 (ROM) ECC operation.	
		0	Enable ECC
		1	Disable ECC

Table 8-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	BK7EDIS	Bank 7 ECC Disable. The `L2CTL_CTL.BK7EDIS` bit disables L2 bank 7 ECC operation.	
		0	Enable ECC
		1	Disable ECC
6 (R/W)	BK6EDIS	Bank 6 ECC Disable. The `L2CTL_CTL.BK6EDIS` bit disables L2 bank 6 ECC operation.	
		0	Enable ECC
		1	Disable ECC
5 (R/W)	BK5EDIS	Bank 5 ECC Disable. The `L2CTL_CTL.BK5EDIS` bit disables L2 bank 5 ECC operation.	
		0	Enable ECC
		1	Disable ECC
4 (R/W)	BK4EDIS	Bank 4 ECC Disable. The `L2CTL_CTL.BK4EDIS` bit disables L2 bank 4 ECC operation.	
		0	Enable ECC
		1	Disable ECC
3 (R/W)	BK3EDIS	Bank 3 ECC Disable. The `L2CTL_CTL.BK3EDIS` bit disables L2 bank 3 ECC operation.	
		0	Enable ECC
		1	Disable ECC
2 (R/W)	BK2EDIS	Bank 2 ECC Disable. The `L2CTL_CTL.BK2EDIS` bit disables L2 bank 2 ECC operation.	
		0	Enable ECC
		1	Disable ECC
1 (R/W)	BK1EDIS	Bank 1 ECC Disable. The `L2CTL_CTL.BK1EDIS` bit disables L2 bank 1 ECC operation.	
		0	Enable ECC
		1	Disable ECC

Table 8-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration

		0	Enable ECC
		1	Disable ECC

Error Type 0 Address Register

The L2CTL_EADDR0 register holds the address that created an access error on the L2 port 0 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR0) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

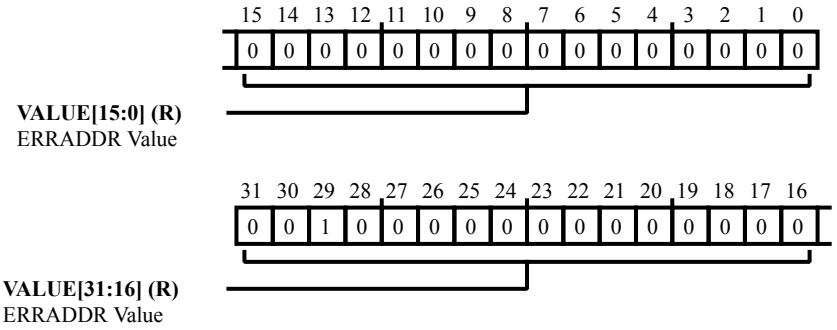

Figure 8-6: L2CTL_EADDR0 Register Diagram

Table 8-8: L2CTL_EADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR0.VALUE bits hold the address causing the bus error.

Error Type 1 Address Register

The L2CTL_EADDR1 register holds the address that created an access error on the L2 port 1 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR1) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

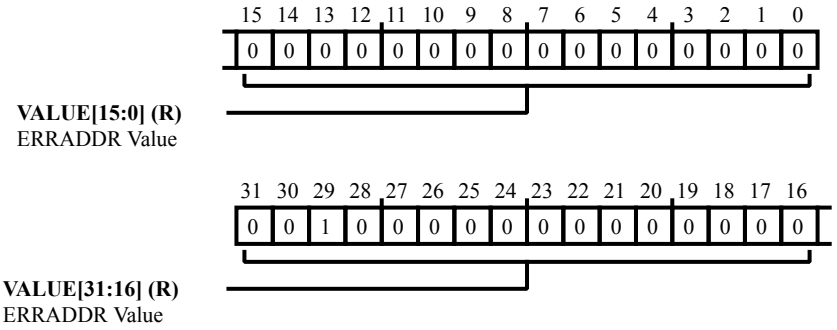

Figure 8-7: L2CTL_EADDR1 Register Diagram

Table 8-9: L2CTL_EADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR1.VALUE bits hold the address causing the bus error.

ECC Error Address 0 Register

The L2CTL_ERRADDR0 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR0) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

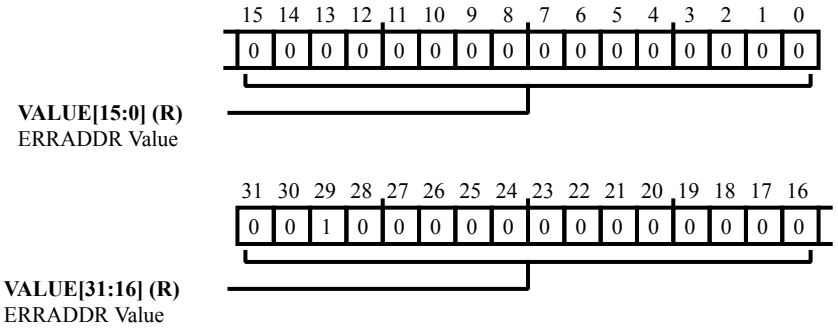

Figure 8-8: L2CTL_ERRADDR0 Register Diagram

Table 8-10: L2CTL_ERRADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR0.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 1 Register

The L2CTL_ERRADDR1 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR1) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

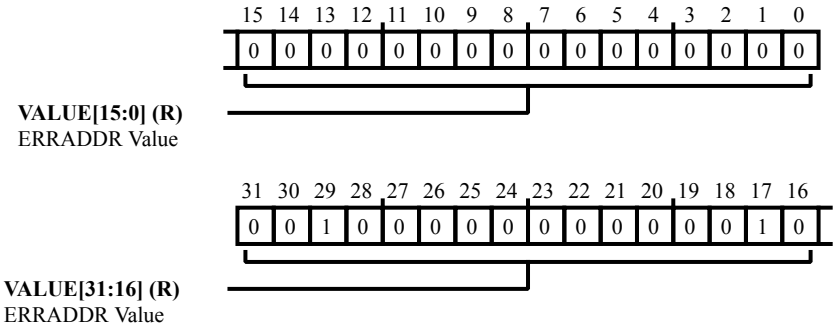

Figure 8-9: L2CTL_ERRADDR1 Register Diagram

Table 8-11: L2CTL_ERRADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR1.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 2 Register

The L2CTL_ERRADDR2 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR2) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

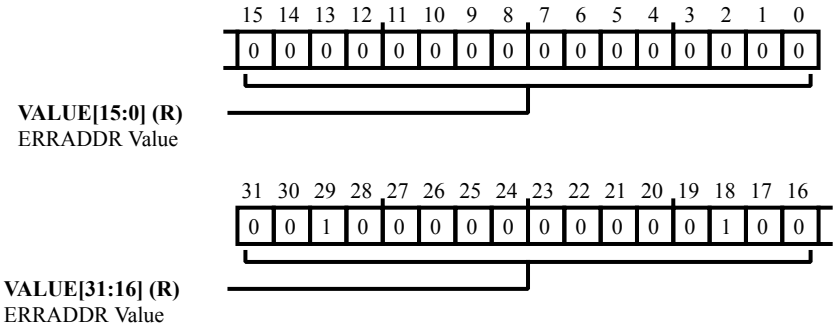

Figure 8-10: L2CTL_ERRADDR2 Register Diagram

Table 8-12: L2CTL_ERRADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR2.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 3 Register

The L2CTL_ERRADDR3 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR3) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

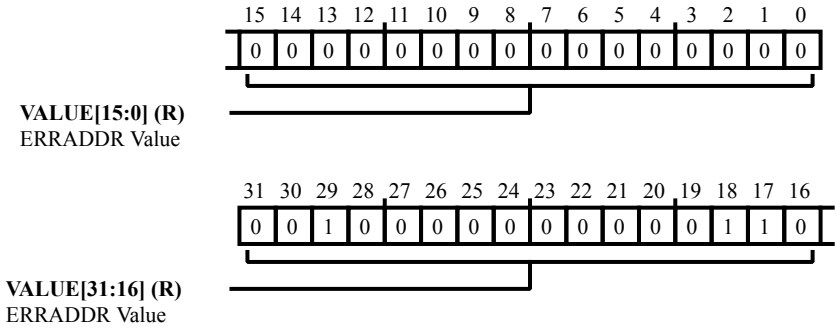

Figure 8-11: L2CTL_ERRADDR3 Register Diagram

Table 8-13: L2CTL_ERRADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR3.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 4 Register

The L2CTL_ERRADDR4 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR4) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

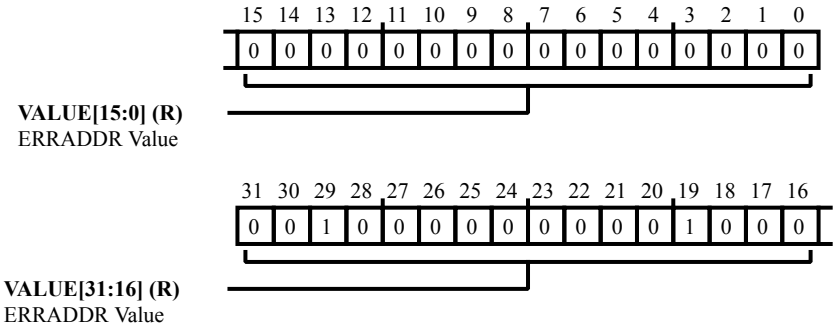

Figure 8-12: L2CTL_ERRADDR4 Register Diagram

Table 8-14: L2CTL_ERRADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR4.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 5 Register

The L2CTL_ERRADDR5 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR5) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

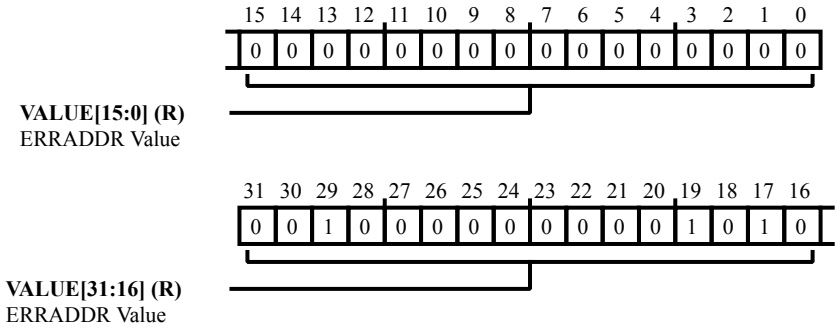

Figure 8-13: L2CTL_ERRADDR5 Register Diagram

Table 8-15: L2CTL_ERRADDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR5.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 6 Register

The L2CTL_ERRADDR6 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR6) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

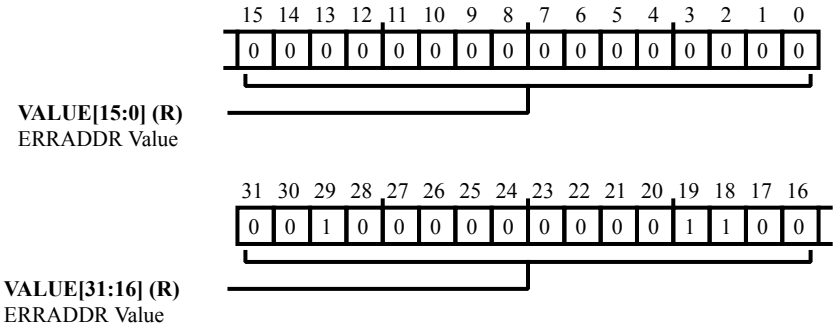

Figure 8-14: L2CTL_ERRADDR6 Register Diagram

Table 8-16: L2CTL_ERRADDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR6.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 7 Register

The L2CTL_ERRADDR7 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR7) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

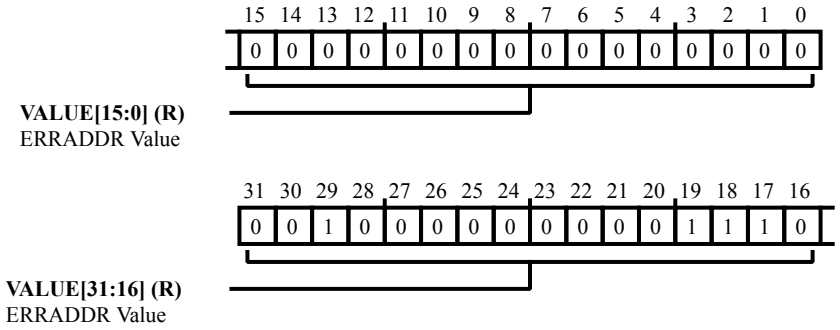

Figure 8-15: L2CTL_ERRADDR7 Register Diagram

Table 8-17: L2CTL_ERRADDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR7.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 8 Register

The L2CTL_ERRADDR8 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR8) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

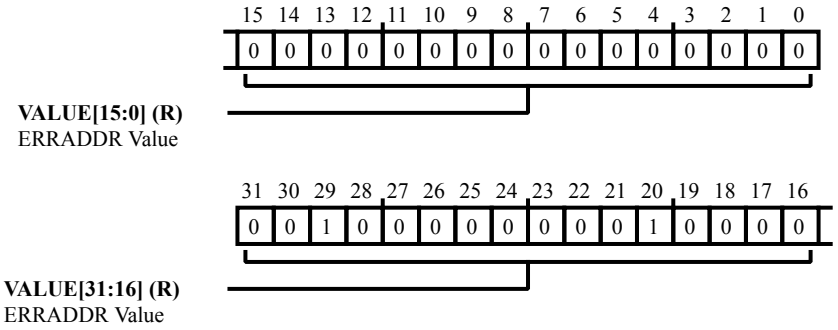

Figure 8-16: L2CTL_ERRADDR8 Register Diagram

Table 8-18: L2CTL_ERRADDR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR8.VALUE bits hold the address containing the ECC double-bit error.

Error Type 0 Register

The L2CTL_ET0 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 0. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR0 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET0 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR0).

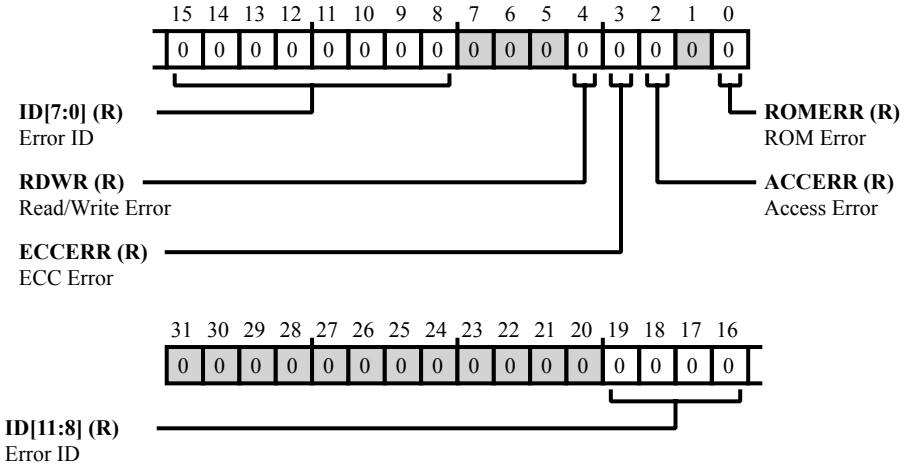

Figure 8-17: L2CTL_ET0 Register Diagram

Table 8-19: L2CTL_ET0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:8 (R/NW)	ID	Error ID. The L2CTL_ET0.ID bits hold the bus master ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET0.RDWR bit indicates whether a read or write access caused an error.	
		0	Read Access created Error
		1	Write Access created Error
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET0.ECCERR bit indicates whether the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. The L2CTL_ET0.ACCERR bit indicates whether the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. The L2CTL_ET0.ROMERR bit indicates whether a write access went to a ROM area.	

Error Type 1 Register

The L2CTL_ET1 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 1. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR1 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET1 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR1).

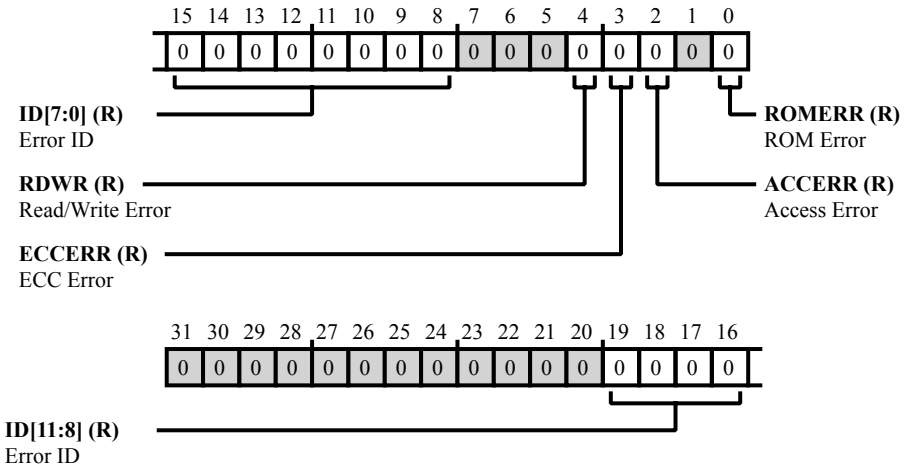

Figure 8-18: L2CTL_ET1 Register Diagram

Table 8-20: L2CTL_ET1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:8 (R/NW)	ID	Error ID. The L2CTL_ET1.ID bits hold the bus master ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET1.RDWR bit indicates whether a read or write access caused an error.	
		0	Read access created error
		1	Write access created error
3 (R/NW)	ECCERR	ECC Error. If the L2CTL_ET1.ECCERR bit =1, the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET1.ACCERR bit =1, the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET1.ROMERR bit =1, a write access went to a ROM area.	

Initialization Register

The L2CTL_INIT register initializes memory banks with 64'b0 and ECC bits corresponding to 64'b0. Any writes to the bits in this register while initialization is occurring to any of the banks is ignored. All bits are W1A (Write 1 for Action).

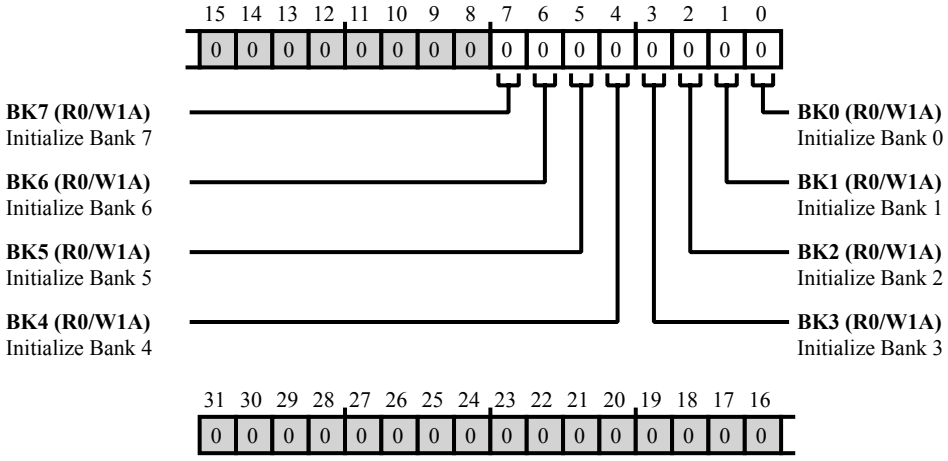

Figure 8-19: L2CTL_INIT Register Diagram

Table 8-21: L2CTL_INIT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R0/W1A)	BK7	Initialize Bank 7. The write-1 to the L2CTL_INIT.BK7 bit initializes bank 7 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
6 (R0/W1A)	BK6	Initialize Bank 6. The write-1 to the L2CTL_INIT.BK6 bit initializes bank 6 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
5 (R0/W1A)	BK5	Initialize Bank 5. The write -1 to the L2CTL_INIT.BK5 bit initializes bank 5 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
4 (R0/W1A)	BK4	Initialize Bank 4. The write-1 to the L2CTL_INIT.BK4 bit initializes bank 4 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.

Table 8-21: L2CTL_INIT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W1A)	BK3	Initialize Bank 3. The write-1 to the `L2CTL_INIT.BK3` bit initializes bank 3 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
2 (R0/W1A)	BK2	Initialize Bank 2. The write-1 to the `L2CTL_INIT.BK2` bit initializes bank 2 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
1 (R0/W1A)	BK1	Initialize Bank 1. The write-1 to the `L2CTL_INIT.BK1` bit initializes bank 1 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.
0 (R0/W1A)	BK0	Initialize Bank 0. The write-1 to the `L2CTL_INIT.BK0` bit initializes bank 0 with 64b0 and ECC bits corresponding to 64b0. Any write to this bit during the initialization of the banks is ignored.

Initialization Status Register

The L2CTL_ISTAT register holds the status of the RAM bank initialization. If set, the corresponding bank is initialized.

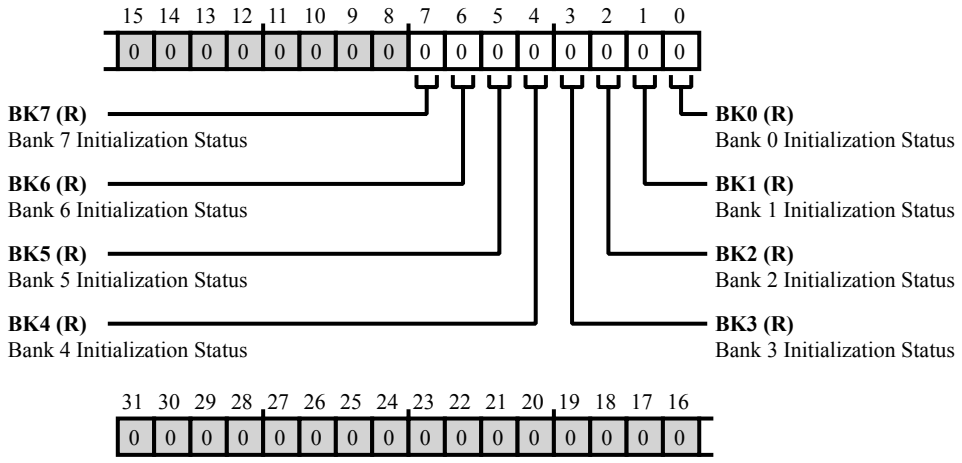

Figure 8-20: L2CTL_ISTAT Register Diagram

Table 8-22: L2CTL_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	BK7	Bank 7 Initialization Status. The L2CTL_ISTAT.BK7 bits hold the bank 7 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
6 (R/NW)	BK6	Bank 6 Initialization Status. The L2CTL_ISTAT.BK6 bits hold the bank 6 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
5 (R/NW)	BK5	Bank 5 Initialization Status. The L2CTL_ISTAT.BK5 bits hold the bank 5 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
4 (R/NW)	BK4	Bank 4 Initialization Status. The L2CTL_ISTAT.BK4 bits hold the bank 4 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
3 (R/NW)	BK3	Bank 3 Initialization Status. The L2CTL_ISTAT.BK3 bits hold the bank 3 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
2 (R/NW)	BK2	Bank 2 Initialization Status. The L2CTL_ISTAT.BK2 bits hold the bank 2 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Table 8-22: L2CTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BK1	Bank 1 Initialization Status. The `L2CTL_ISTAT.BK1` bits hold the bank 1 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
0 (R/NW)	BK0	Bank 0 Initialization Status. The `L2CTL_ISTAT.BK0` bits hold the bank 0 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Revision ID Register

The L2CTL_REVID register provides the L2 Revision ID.

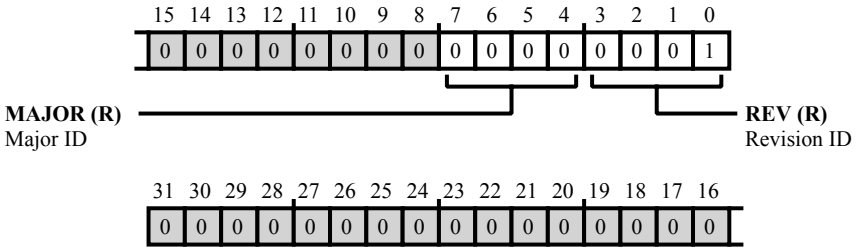

Figure 8-21: L2CTL_REVID Register Diagram

Table 8-23: L2CTL_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major ID. The L2CTL_REVID.MAJOR bit indicates L2 Major ID.
3:0 (R/NW)	REV	Revision ID. The L2CTL_REVID.REV bit indicates the L2 Revision ID.

Read Priority Count Register

The L2CTL_RPCR register stores the count value to be used for priority elevation for bus read channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

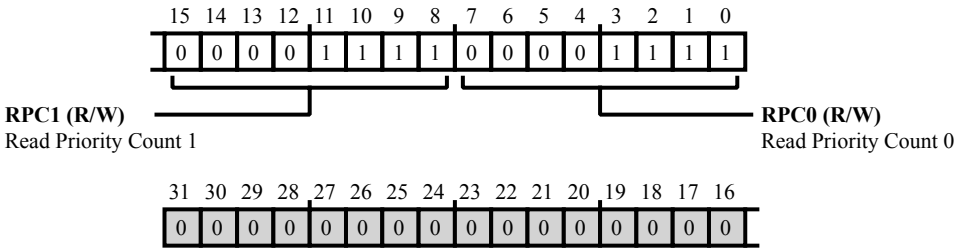

Figure 8-22: L2CTL_RPCR Register Diagram

Table 8-24: L2CTL_RPCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	RPC1	Read Priority Count 1. The L2CTL_RPCR.RPC1 bits hold the priority count for L2 bus read channel 1.
7:0 (R/W)	RPC0	Read Priority Count 0. The L2CTL_RPCR.RPC0 bits hold the priority count for L2 bus read channel 0.

Scrub Start Address Register

The L2CTL_SADR register stores the scrub start address value. Writes to this register can be prevented by setting the L2CTL_SCTL.LOCK bit and the global lock.

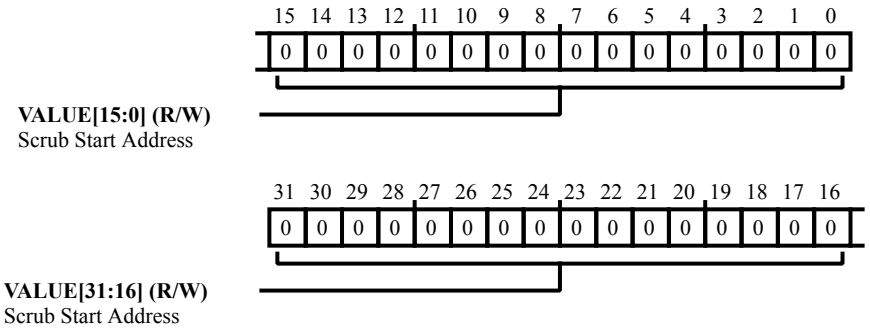

Figure 8-23: L2CTL_SADR Register Diagram

Table 8-25: L2CTL_SADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Scrub Start Address. The L2CTL_SADR.VALUE bits hold the scrub start address. The writes to this register can be prevented by setting the L2_SCTL.LOCK and the global lock.

Scrub Count Register

The L2CTL_SCNT register determines the number of 64-bit locations scrubbed starting from the start address (L2CTL_SADR register). Writes to the L2CTL_SCNT register can be prevented by setting the L2CTL_CTL.LOCK bit and the global lock.

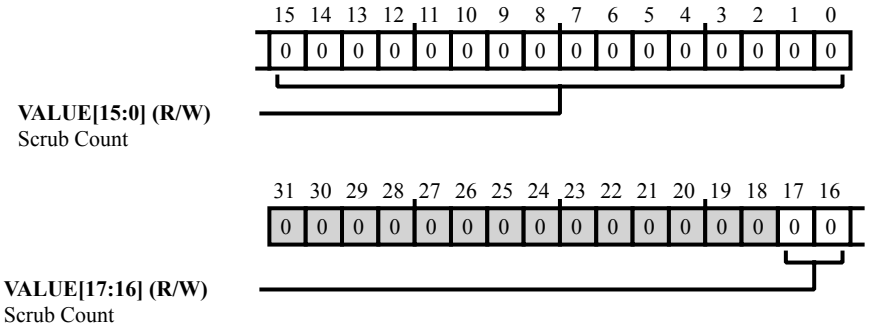

Figure 8-24: L2CTL_SCNT Register Diagram

Table 8-26: L2CTL_SCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:0 (R/W)	VALUE	Scrub Count. The L2CTL_SCNT.VALUE bits determines the number of 64-bit locations scrubbed starting from the start address. Ensure value programmed is less than the total addressable 64-bit L2 RAM locations available.

Scrub Control Register

The L2CTL_SCTL register holds the automatic scrub related controls. This is a read/write register. Memory scrub can be performed by programming the L2CTL_SADR (scrub start address) register with the start address of the scrub and the L2CTL_SCNT register with the total number of 64-bit addresses to be scrubbed starting from the L2CTL_SADR register. The number of cycles between each scrub can be programmed with the L2CTL_SCTL.SRT bit.

During the scrub the controller issues a read followed by write back if there is a single bit ECC error. Once the L2 controller completes scrubbing the memory region mentioned using the L2CTL_SADR and the L2CTL_SCNT registers, an interrupt is generated and scrubbing re-starts from the start unless the scrub enable bit is disabled in the control register. If scrub enable is cleared before completing the address range used in the L2CTL_SADR and L2CTL_SCNT registers, the scrub stops after completing any already issued scrub access.

The scrub read/writes always start from the full 64-bit equivalent of the address written into the L2CTL_SADR register. A 64-bit value is always read and the 64-bit value is written back. The scrub access has the highest priority. Programs can configure 8-, 16-, or 32-bit addresses in the L2CTL_SADR register but the lower 3 bits are treated as don't care because the internal memory array is always accessed in a 64-bit mode.

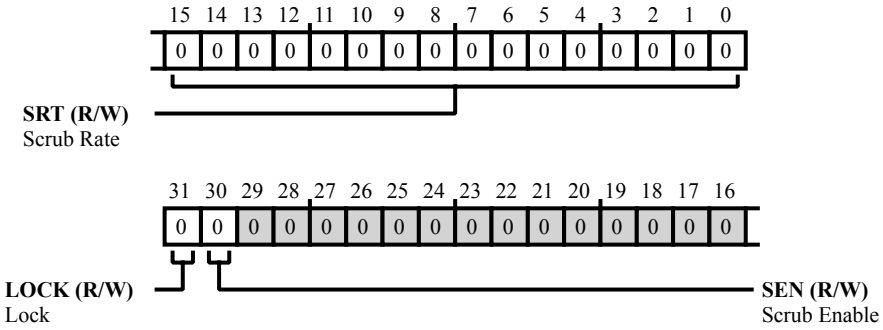

Figure 8-25: L2CTL_SCTL Register Diagram

Table 8-27: L2CTL_SCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_SCTL.LOCK bit is set, the L2CTL_SCTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	SEN	Scrub Enable. The L2CTL_SCTL.SEN bits enable automatic scrub.	

Table 8-27: L2CTL_SCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SRT	Scrub Rate. The `L2CTL_SCTL.SRT` bits determines the number of clock cycles that elapsed between two automatic scrubs.

Status Register

The L2CTL_STAT register indicates ECC error status, refresh register status, and bus error status of Port0 and Port1.

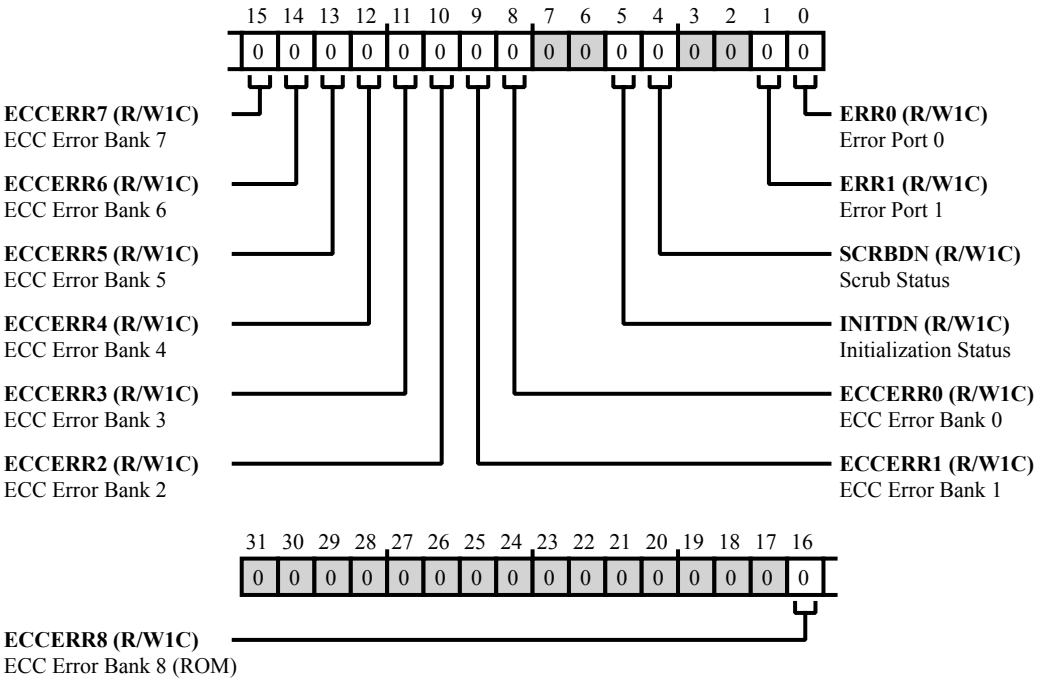

Figure 8-26: L2CTL_STAT Register Diagram

Table 8-28: L2CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ECCERR8	ECC Error Bank 8 (ROM). The L2CTL_STAT.ECCERR8 bit indicates that an ECC double-bit error occurred inside L2 bank 8 (ROM).	
		0	No Status
		1	ECC Double Bit Error
15 (R/W1C)	ECCERR7	ECC Error Bank 7. The L2CTL_STAT.ECCERR7 bit indicates that an ECC double-bit error occurred inside L2 bank 7.	
		0	No Status
		1	ECC Double Bit Error

Table 8-28: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ECCERR6	ECC Error Bank 6. The `L2CTL_STAT.ECCERR6` bit indicates that an ECC double-bit error occurred inside L2 bank 6.	
		0	No Status
		1	ECC Double Bit Error
13 (R/W1C)	ECCERR5	ECC Error Bank 5. The `L2CTL_STAT.ECCERR5` bit indicates that an ECC double-bit error occurred inside L2 bank 5.	
		0	No Status
		1	ECC Double Bit Error
12 (R/W1C)	ECCERR4	ECC Error Bank 4. The `L2CTL_STAT.ECCERR4` bit indicates that an ECC double-bit error occurred inside L2 bank 4.	
		0	No Status
		1	ECC Double Bit Error
11 (R/W1C)	ECCERR3	ECC Error Bank 3. The `L2CTL_STAT.ECCERR3` bit indicates that an ECC double-bit error occurred inside L2 bank 3.	
		0	No Status
		1	ECC Double Bit Error
10 (R/W1C)	ECCERR2	ECC Error Bank 2. The `L2CTL_STAT.ECCERR2` bit indicates that an ECC double-bit error occurred inside L2 bank 2.	
		0	No Status
		1	ECC Double Bit Error
9 (R/W1C)	ECCERR1	ECC Error Bank 1. The `L2CTL_STAT.ECCERR1` bit indicates that an ECC double-bit error occurred inside L2 bank 1.	
		0	No Status
		1	ECC Double Bit Error

Table 8-28: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	ECCERR0	ECC Error Bank 0. The `L2CTL_STAT.ECCERR0` bit indicates that an ECC double-bit error occurred inside L2 bank 0.	
		0	No Status
		1	ECC Double Bit Error
5 (R/W1C)	INITDN	Initialization Status. The `L2CTL_STAT.INITDN` bit indicates whether initialization has been completed.	
		0	Initialization Not Complete
		1	Initialization Completed
4 (R/W1C)	SCRBDN	Scrub Status. The `L2CTL_STAT.SCRBDN` bit indicates whether a round of memory scrub has completed.	
		0	Scrub Not Complete
		1	Scrub Completed
1 (R/W1C)	ERR1	Error Port 1. The `L2CTL_STAT.ERR1` indicates whether the L2CTL has detected a bus access error on L2s bus port 1.	
		0	No Error
		1	Bus Access Error
0 (R/W1C)	ERR0	Error Port 0. The `L2CTL_STAT.ERR0` indicates whether the L2CTL has detected a bus access error on L2s bus port 0.	
		0	No Error
		1	Bus Access Error

Write Priority Count Register

The L2CTL_WPCR register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

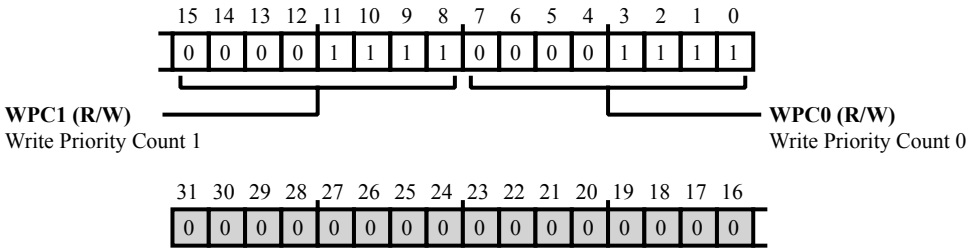

Figure 8-27: L2CTL_WPCR Register Diagram

Table 8-29: L2CTL_WPCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	WPC1	Write Priority Count 1. The L2CTL_WPCR.WPC1 bits hold the priority count for L2 bus write channel 1.
7:0 (R/W)	WPC0	Write Priority Count 0. The L2CTL_WPCR.WPC0 bits hold the priority count for L2 bus write channel 0.

9 Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glueless interface between DDR3/DDR2/LPDDR SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR3, DDR2 SDRAM or LPDDR SDRAM respectively.

NOTE: The terms DDR2, DDR3, and LPDDR SDRAM are referred to generically as DDR SDRAM in the rest of this chapter unless otherwise noted.

NOTE: According to JEDEC STD specification (JESD79-3-1A.01) DDR3L marked devices (1.35 V) can also be connected to the ADSP-SC57x processors, as these devices also meet 1.5 V voltage level specifications of DDR3 marked devices.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the *protocol controller*. An access and operation reordering mechanism is incorporated as an *efficiency controller*. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient slave implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC can be accessed using the MMR access bus.

The DMC supports access to the external memory by core and DMA accesses.

DMC Features

The DMC includes a protocol controller that supports:

- JESD79-3E compatible double data rate DDR3 SDRAM devices
- JESD79-2E compatible DDR2 SDRAM devices
- JESD209A low-power DDR (LPDDR) SDRAM devices

The features of the dynamic memory controller are:

- Provides 16-bit data only interface to SDRAM devices
- Supports a single external rank (one chip select)
- Supports various burst lengths

- Provides page hit detection that supports multiple column accesses to the same row
- User-specified active, precharge, and refresh commands.
- Programmable SDRAM access timing parameters
- Enables automatic refresh generation with programmable refresh intervals
- Self-refresh mode to reduce system power consumption
- Efficient transaction processing to improve throughput and bandwidth using:
    - Software programmable SCB IDs to allow SCB ID-based priority
    - The ability to postpone up to eight auto-refresh commands
    - Software selectable closed page scheme on a per bank basis
    - Simple transaction scheduling mechanism to reduce read write turnaround frequency on the memory bus
    - Accesses with the same SCB ID are scheduled back-to-back to take advantage of same page access in SDRAM
    - Caching of SDRAM read data burst for specific masters to reduce the latency for same burst accesses.

The DDR2 features are:

- 256M bit to 4G-bit device sizes
- Burst length BL = 4 or 8
- Support for additive latency
- Support for programmable ODT and drive impedance from memory end
- Support for programmable (and ZQ calibration) ODT and drive impedance from the processor end

The DDR3 features are:

- 512 Mb to 8 Gb device sizes
- Burst length BL = 8
- Support for additive latency
- Support for programmable (and ZQ calibration) ODT and drive impedance

The LPDDR features are:

- 64M bit to 2G-bit device sizes
- Burst length BL = 4 or 8
- Support for deep power-down mode

Feature Exclusions

The DMC exclusions are as follows:

For DDR2:

- 4-bit and 8-bit wide DDR2 DRAM memories are not supported
- OCD is not supported
- Burst interleaved accesses are not supported
- Single-ended signaling mode not supported

For DDR3:

- 4-bit and 8-bit wide DDR3 DRAM memories are not supported
- Burst interleaved accesses are not supported
- Both burst chop-BC4 and BC4-on-the-fly are not supported
- Auto refresh pull-in is not supported
- Write leveling is not supported
- DLL off mode is not supported

For LPDDR:

- 32-bit wide LPDDR memory devices are not supported
- Status register read (SRR) is not supported
- Sampling the optional temperature output (TQ) signal is not supported
- Clock stop mode is not supported
- Bursts of 2 and 16 words are not supported
- No support for BURST_TERMINATE command
- Dual-die, two CS# and two CKE packages are not supported

DMC Functional Description

The dynamic memory controller consists of master and slave interfaces, a protocol controller, and an efficiency controller. The following sections describe the function of these interfaces and controllers.

ADSP-SC57x DMC Register List

The Dynamic Memory Controller module (DMC) provides an interface to external double-data-rate SDRAM. This interface supports various DDR standards (see chapter descriptions). A set of registers governs DMC controller operations. For more information on DMC controller functionality, see the DMC Controller Register Descriptions.

Table 9-1: ADSP-SC57x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CPHY_CTL	Controller to PHY Interface Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR1	Shadow EMR1 DDR2 Register
DMC_EMR2	Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR)
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register
DMC_TR1	Timing 1 Register
DMC_TR2	Timing 2 Register

Protocol Controller

The DDR SDRAM protocol controller translates memory access requests from the SCB (system crossbar) interface to JEDEC protocol-specific transactions used by DDR SDRAM devices.

The protocol controller ensures that the various timing parameters are met before reading and writing the SDRAM. The controller also performs the SDRAM initialization sequence as mandated by the standard. The protocol controller can:

- Issue reads and writes
- Precharge a row in a bank
- Activate a row in a bank
- Put the SDRAM devices in self-refresh and power-down modes

The protocol controller takes mode register writes from the MMR interface and translates them into mode register writes to SDRAM. Writing into the mode register is restricted through a mask register.

Efficiency Controller

The efficiency controller controls the ordering of transfers buffered in the read and write command buffers. It attempts to order transfers to optimize the available memory bandwidth. The DMC uses a number of schemes, described in the following sections, to increase the throughput.

Page-Based Scheduling

The DMC parses each write and read transaction that it buffered and gets the information of the row (page) and bank address. The protocol controller maintains the information about the pages that are opened in each bank. The efficiency controller uses the information about the opened pages while scheduling the buffered transactions. The transactions to the opened pages are given higher priority than the other outstanding transactions.

Same Master Transaction Scheduling

The DMC also stores the ID of each transaction that it buffered. In most of the cases, the transactions related to a master result in page hits from the locality of reference rule. The efficiency controller uses the ID information of the transactions while scheduling. When the page-based scheduling of the buffered transactions is complete, same master transaction scheduling is triggered. If multiple transactions from a master are received, the efficiency controller schedules the transactions back-to-back.

DMC Read Data Buffer

The DMC read data buffer contains a data buffer and an address buffer. The depth of the data buffer is equal to the burst length that is programmed in SDRAM. The address buffer holds the corresponding SDRAM burst address. When an SDRAM write address from any master matches an address in the DMC read data buffer, the DMC invalidates the related data in the read buffer. When the DMC_RDDATABUFMSK1 or DMC_RDDATABUFMSK2 register is programmed with a value other than zero, the DMC read data buffer operation is enabled. The set of masters whose data is buffered and retrieved are programmed in the DMC_RDDATABUFID1 or DMC_RDDATABUFID2 registers. The DMC can use the DMC_RDDATABUFMSK1 and DMC_RDDATABUFMSK2 ID registers to select a set of masters similar to the programming of the DMC_PRIOMSK and DMC_PRIOMSK2 registers.

See the SCB ID-Based Priority section for details.

Closed Page Per Bank

The DMC_EFFCTL register provides per-bank granularity for closing pages. The software can determine that most accesses to a given bank in memory always result in a missed page. In this case, set the PREC_BANK bit corresponding to the required bank to close the row after every transfer. This proactive step can result in reduced thrashing and increases memory throughput.

SCB ID-Based Priority

The primary goal of the dynamic memory controller is to improve sustainable memory system bandwidth so that the service time for the average request can be reduced. However, to service critical requests from any master in the system, the DMC provides a mechanism to elevate priority of a given access. The DMC priority ID registers (DMC_PRIO and DMC_PRIO2) can be programmed with up to two SCB IDs with elevated priority.

After every access in a snapshot, the command buffers are searched to determine whether an ID of a command matches with the ID programmed in the DMC_PRIO and DMC_PRIO2 registers. The priority SCB ID access is sent before the subsequent access in the snapshot if:

- A match occurs, and
- The direction of the access (for example write) is the same as the direction of the snapshot (write)

There is an alternative to providing priority to a specific SCB ID. If a number of IDs from the same master require priority, program the DMC priority mask ID registers (DMC_PRIOMSK and DMC_PRIOMSK2) so that the corresponding bits are 0. The DMC uses a combination of the DMC_PRIO and DMC_PRIO2 registers and the DMC_PRIOMSK/DMC_PRIOMSK2 registers to elevate the priority of a select few or all IDs that belong to a master. By default, none of the IDs are prioritized. The following are a few possibilities:

- The DMC_PRIOMSK field is set to 0x00000000. If a single ID (7234) needs priority, set the DMC_PRIOMSK field to 0xFFFFFFFF and set the DMC_PRIO field to 7234.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFE, the SCB IDs 7234 and 7235 are given priority.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFC, the SCB IDs 7234, 7235, 7236, and 7237 are given priority.
- If two transactions with priority, one read and the other a write, are outstanding, the priority transaction that does not change the direction of the DMC access gets priority. The other priority transaction is handled at the beginning of the next snapshot. For example, if a write snapshot is in-progress, the write priority transaction is sent. The read priority transaction is sent at the beginning of the next read snapshot.

NOTE: Use SCB ID-based priority judiciously because it can significantly reduce the throughput of the DMC.

Delaying up to Eight Auto-Refresh Commands

The DMC uses this method to ensure that auto-refresh does not interfere with any critical data transfers. Up to eight auto-refresh commands can accumulate in the DMC. The exact number of auto-refresh commands can be programmed using the DMC_EFFCTL.NUMREF bit.

After the first refresh command is accumulated, the DMC constantly looks for an opportunity to schedule a refresh command. When the SCB read and write command buffers become empty for the programmed number of clock cycles (DMC_EFFCTL.IDLECYC bit field), the accumulated number of refresh commands are sent back-to-back to the DRAM. (The empty state of the SCB command buffers implies that no access is outstanding.)

After every refresh, the SCB command buffers are checked to ensure that they stay empty. If the SCB command buffers are always full, once the programmed number of refresh commands accumulates, the refresh operation is elevated to urgent priority. One refresh command is sent immediately. After this process, the DMC continues to wait for an opportunity to send out refresh commands. If self-refresh mode is enabled, all pending refresh commands are given out only after that DMC enters into self-refresh mode.

Page and Bank Interleaving

Page and bank interleaving allow consecutive row accesses to fall into the same bank (bank interleaving) or into a different bank (page interleaving). The DMC uses bank interleaving by default (DMC_CTL.ADDRMODE bit =0). If the DMC_CTL.ADDRMODE bit =1, the DMC uses page interleaving. Page misses in one addressing mode result in hits in the other addressing mode.

System Crossbar Slave Interface

The DMC uses the system crossbar slave interface to move all data. The system crossbar interface accepts interleaved write transactions and sends out-of-order responses. The read and write interfaces consist of buffers for address, data, and control information transferred to or from the system crossbar bus.

The system crossbar interface transactions are sent to the SDRAM only after the SDRAM has been initialized. However, if transactions arrive before or during initialization, they accumulate in the system crossbar interface and are sent out to the protocol controller once the initialization completes.

To increase throughput, the system crossbar write-response is sent out as soon as the final DDR burst is scheduled for transfer into the SDRAM. However, if an auto-refresh is needed, the scheduled write data is sent only after the auto-refresh. A delay can occur. The delay is a maximum of 64 clock cycles from the moment the write response is sent on the SCB to the write operation of the data into SDRAM.

The system crossbar interface performs the following operations:

- Buffers read and write command requests from the system crossbar bus
- Processes the requests by converting them to protocol controller user-interface transfers
- Sends and receives data to or from the protocol controller
- Creates a suitable read/write response and sends read data back to the system crossbar bus

The system crossbar slave interface supports the following:

- All burst lengths (1–16)
- Incremental and wrap bursts
- Data transfer sizes of 8-bit, 16-bit, or 32-bit

- Arrival of write data before write address
- Generation of error responses which include:
  - Any access to an unimplemented region of the external memory space
  - Any access when the SDRAM is in self-refresh mode/power-down mode/deep power-down mode (in case of LPDDR)
  - Any access when the direct command interface is in operation

Read/Write Command and Data Buffers

The system crossbar interface consists of a four-deep read command buffer and a four-deep write command buffer. Up to four write commands and four read commands can be waiting for access to the SDRAM. The system crossbar write buffer is 32 deep. It can support write data interleaving of two. The system crossbar read buffer is 32 deep.

Peripheral Bus Slave Interface

The peripheral bus slave interface connects the dynamic memory controller to the peripheral bus and provides a host controller with access to the registers. The peripheral bus slave interface supports the following features:

- Read and write word accesses
- 32-bit data bus

Architectural Concepts

The following sections provide information on the architecture of the interface.

Controller On Die Termination (ODT)

The controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers. Controller ODT involves extra overhead in terms of power consumption during reads.

The DMC implements dynamic on die termination at processor pads. When controller ODT is enabled, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller writes to the DRAM.

Mode Register Set and Extended Mode Register Set Command

The load mode register command initializes the SDRAM operation parameters. The DMC supports the mode register set and extended mode register set commands. The controller automatically issues the mode register set command during power-on initialization and also when the DMC_MR register is written with the DMC_MSK.MR bit. The mode register set command is sent after the ongoing data transfer completes.

The DMC automatically issues the mode register set command when the shadow MR/EMR1/EMR2 registers are written. The corresponding DMC_MSK.MR1/DMC_MSK.MR2/DMC_MSK.EMR3 bits must be enabled.

DDR3 Reset Functionality

DDR3 contains an additional pin corresponding to reset functionality. Reset is part of the initialization sequence but it can be performed asynchronously when needed. The reset procedure is similar to the steps involved in the initialization except the initial part of power-up.

To perform reset on the DDR3 module:

1. Check to ensure the module is in the idle state by polling the `DMC_STAT.IDLE` bit (0x0008).
2. Set the `DMC_CTL.RESET` bit (0x0004).
3. Monitor the `DMC_STAT.RESETDONE` bit for the completion of the reset function.

Do not perform any transactions during a module reset. Wait for the `DMC_STAT.RESETDONE` signal.

DDR3 SDRAM Organization

The DMC supports DDR3 SDRAM memory modules ranging from 512 Mb to 8 Gb. The following tables list the address translation mechanism from the user interface to DDR3 memory interface. The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE` =1) and page interleaving (`DMC_CTL.ADDRMODE` =0).

Bank Interleaving

The ***DDR3 Bank Interleaving*** table shows DDR3 bank interleaving.

Table 9-2: DDR3 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
512 Mb	25:24	23:11	10:1
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1
4 Gb	28:26	25:11	10:1
8 Gb	29:27	26:11	10:1

Page Interleaving

The ***DDR3 Page Interleaving*** table shows DDR3 page interleaving.

Table 9-3: DDR3 Page Interleaving

SDRAM size	Row address bits	Bank address bits	Column address bits
512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10:1
4 Gb	28:14	13:11	10.1

Table 9-3: DDR3 Page Interleaving (Continued)

SDRAM size	Row address bits	Bank address bits	Column address bits
8 Gb	29:14	13:11	10.1

DDR2 SDRAM Organization

The DMC supports DDR2 SDRAM memory modules ranging from 256 Md to 4 Gb. The following tables list the address translation mechanism from the user interface to DDR2 memory interface. The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE` =1) and page interleaving (`DMC_CTL.ADDRMODE` =0).

Bank Interleaving

The ***DDR2 Bank Interleaving*** table shows DDR2 bank interleaving.

Table 9-4: DDR2 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
256 Mb	24:23	22:10	9:1
512 Mb	25:24	23:11	10:1
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1

Page Interleaving

The ***DDR2 Page Interleaving*** table shows DDR2 page interleaving.

Table 9-5: DDR2 Page Interleaving

SDRAM size	Row address bits	Bank address bits	Column address bits
256 Mb	24:12	11:10	9.1
512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10:1

LPDDR SDRAM Organization

The DMC supports LPDDR SDRAM memory modules ranging from 64M bit to 2G bit. The following tables list the address translation mechanism from the user interface to LPDDR memory interface.

Bank Interleaving

The ***LPDDR Bank Interleaving*** table shows LPDDR bank interleaving.

Table 9-6: LPDDR Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
64 Mb	22:21	20:9	8:1
128 Mb	23:22	21:10	9:1
256 Mb	24:23	22:10	9:1
512 Mb	25:24	23:11	10:1

2 Gb	27:26	25:12	11:1

Page Interleaving

The ***LPDDR Page Interleaving*** table shows LPDDR page interleaving.

Table 9-7: LPDDR Page Interleaving

SDRAM size	Row address bits	Bank address bits	Column address bits
64 Mb	22:11	10:9	8.1
128 Mb	23:12	11:10	9:1
256 Mb	24:12	11:10	9:1
512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10.1

DMC Clocking

The DMC uses a divided-down version of the *PLLCLK* (PLL clock) to generate an internal clock for clocking the DMC block and interface. The specific value of the *DCLK* frequency is programmed in the `CGU_DIV` register. The section Initializing the DMC describes the procedure.

For information on the maximum clock frequency supported for specific modes, refer to the processor data sheet.

NOTE: For the processor variants that have two DMC blocks, both blocks run on the same DCLK frequency.

NOTE: In some cases, it might be required to generate a DCLK frequency asynchronous to CCLK (for example, CCLK=450 MHz and DCLK=400 MHz). For these cases, one CGU can be used to generate CCLK and another can be used to generate DCLK. For more details, refer to the CGU chapter.

DMC DMA

The DMC supports DMA-based transfers to and from external DDR SDRAM memory and internal memory.

The DMC DMA controller, part of the distributed DMA engines (DDE) that are dispersed through the infrastructure, connects to the system crossbar fabric.

The DMC uses two DDEs for memory-to-memory DMA (MDMA). One channel is the source channel, and the second, the destination channel.

DMA transfers on the processor are descriptor-based or register-based. Register-based DMA allows the processor to program DMA control registers directly to initiate a DMA transfer. On completion, the control registers can be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. This transfer allows the chaining together of multiple DMA sequences. In descriptor-based DMA operations, a DMA channel can be programmed to set up and start another DMA transfer automatically after the current sequence completes.

Enhanced DMA operations (such as delay line DMA, scatter or gather DMA) are also supported to or from the DMC module.

DMC Operating Modes

By default, the DMC is in DDR2 mode. To enable DDR3 or LPDDR mode, the corresponding bits in the DMC_CTL and DMC_PHY_CTL4 register must be configured.

DDR2 Mode

This mode is the default mode of the DMC module and supports JESD79-2E compatible DDR2 SDRAM. In this mode, the DMC_CTL.DDR3EN bit =0, the DMC_CTL.LPDDR bit =0, and the DMC_PHY_CTL4.DDRMODE bit field is 0b'01.

DDR3 Mode

The DMC module supports JESD79-3E compatible double data rate DDR3 SDRAM. To configure this mode of operation, first set (=1) the DMC_CTL.DDR3EN bit and set the DMC_PHY_CTL4.DDRMODE bit field to 0b'00.

LPDDR Mode

The DMC module supports JESD209A low-power DDR (LPDDR) SDRAM. To configure this mode of operation, set (=1) the DMC_CTL.LPDDR bit and set the DMC_PHY_CTL4.DDRMODE bit field to 0b'11.

Deep Power-Down Mode

The DMC module supports JESD209A low-power DDR (LPDDR) SDRAM. To configure this mode of operation, set (=1) the DMC_CTL.LPDDR bit and set the DMC_PHY_CTL4.DDRMODE bit field to 0b'11.

When the processor does not require the data stored in SDRAM (assume reset state of SDRAM), the DMC can put the SDRAM in deep power-down mode. When the DMC is in deep power-down, any data accesses cause the DMC to generate a bus error. To configure this mode, set (=1) the DMC_CTL.DPDREQ bit when low-power DMC operation is enabled (DMC_CTL.LPDDR =1).

The DMC_STAT.IDLE bit indicates the activity in the DMC. If this bit is set, there is no activity all through the DMC. Deep power can be entered by setting the DMC_CTL.DPDREQ bit. The DMC_STAT.DPDACK bit is asserted when the SDRAM enters deep power-down mode. The DMC stays in deep power-down mode as long as the DMC_CTL.DPDREQ bit is asserted.

Clearing (=0) the DMC_CTL.DPDREQ bit causes the DMC to exit deep power-down mode. Also, when exiting deep power-down mode, the controller clears the DMC_STAT.DPDACK bit. The user must re-initialize the DMC after it comes out of deep power-down mode.

Self-Refresh Mode

For low-power consumption, the SDRAM can be put in self-refresh mode. When no data activity occurs, the DMC can put the SDRAM in self refresh to save power. The DMC_STAT.IDLE bit indicates the activity on the DMC. If this bit is set, there is no activity in the DMC.

Enable self-refresh mode by writing the DMC_CTL.SRREQ bit. The DMC stays in a self-refresh state as long as this bit is asserted. The DMC_STAT.SRACK bit indicates when the SDRAM enters self-refresh mode.

When the DMC is in self-refresh mode, the DMC generates an SCB error when any data accesses (read or write requests) is requested.

The DMC can be brought out of self-refresh mode by clearing the DMC_CTL.SRREQ bit again. The controller clears the DMC_STAT.SRACK bit after the self-refresh operation completes.

DMC Event Control

The DMC has no related interrupt or trigger event information.

DMC Programming Model

The dynamic memory controller contains five groups of memory-mapped registers. The DMC uses the MMR access bus to connect to these registers.

- Control and status registers. These registers control the various operation modes of the dynamic memory controller and provide status.
- Timing parameter registers. The value programmed in these registers depends on the speed grade of the SDRAM device used.
- Mode register mirror registers. These shadow registers are copies of the mode registers residing in the SDRAM device.
- PHY control and status registers. The DMC uses these registers to control the operation of the PHY.
- PAD control registers. The DMC uses these registers to control the various aspects of the I/O pads.

The DMC control registers contain sensitive timing parameters and settings for the DDR SDRAM. These registers are programmed with values that are in the operating range of the DDR used.

Writing to reserved fields or writing any reserved values in register bits can cause the dynamic memory controller to function erroneously.

Programming Considerations for DDR2, DDR3, and LPDDR Memory

The ***DDR2, DDR3, and LPDDR Programming*** table shows important programming considerations and differences across DDR2, DDR3, and LPDDR memory technologies. The table serves as a quick reference when configuring the DMC and PHY registers.

Table 9-8: DDR2, DDR3, and LPDDR Programming

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
PHY	Enabling DDR3/ DDR2/LPDDR modes	DMC_PHY_CTL4	Select DDR3 mode by setting the DMC_PHY_CTL4.DDRMODE bit field to 00.	Select DDR2 mode by setting the DMC_PHY_CTL4.DDRMODE bit field to 01.	Select LPDDR mode by setting the DMC_PHY_CTL4.DDRMODE bit field to 11.
PHY	ODT and drive impedance calibration	DMC_CAL_PADCTL0, DMC_CAL_PADCTL2	The DMC supports ODT and drive impedance calibration. Configure the DMC_CAL_PADCTL0 and DMC_CAL_PADCTL2 registers accordingly. For details, refer PAD Calibration for Driver Impedance and On Die Termination (ODT) section. Programming driver impedance is required. Programming ODT is optional. To disable ODT, set the DMC_PHY_CTL1.BYPODTEN bit.	The DMC supports OCD calibration. Configure the DMC_CAL_PADCTL0 register accordingly.	The DMC does not support ODT and drive impedance calibration. No need to program the DMC_CAL_PADCTL0 and DMC_CAL_PADCTL2 registers. Ensure that the DMC_PHY_CTL1.BYPODEN bit is set to bypass the processor ODT settings.
Controller	Enabling DDR3/ DDR2/LPDDR modes	DMC_CTL.DDR3EN, DMC_CTL.LPDDR	Select DDR3 mode by setting the DMC_CTL.DDR3EN bit. Make sure that the bit DMC_CTL.LPDDR is cleared.	Default is DDR2 mode. Make sure that both the bits DMC_CTL.LPDDR and DMC_CTL.DDR3EN are cleared.	Select LPDDR mode by setting the DMC_CTL.LPDDR bit. Make sure that the bit DMC_CTL.DDR3EN is cleared.

Table 9-8: DDR2, DDR3, and LPDDR Programming (Continued)

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
Controller	Configuring DMC_CTL.RDTOWR bit field	DMC_CTL.RDTOWR	Make sure that the DMC_CTL.RDTOWR bit field is always set to 010 (=2 in decimal).		
Controller	Configuring DMC_CFG register fields	DMC_CFG	Make sure that the DMC_CFG.IFWID and DMC_CFG.SDRWID bit fields are always set to 0010 (=2 in decimal) as the DMC only supports 16-bit wide interface and SDRAM widths. Make sure that the bit field DMC_CFG.EXTBANK is always set to 0000 as the DMC only supports one external bank. Select the DMC_CFG.SDRSIZE as per the SDRAM size. Supported sizes are 64 Mb to 2 Gb for LPDDR, 256 Mb to 4 Gb for DDR2, and 512 Mb to 8 Gb for DDR3.		
Controller	Configuring controller timing parameter registers	DMC_TR0, DMC_TR2	Configure the parameters t_{RCD}, t_{WTR}, t_{RP}, t_{RAS}, t_{MRD}, t_{REF}, t_{RFC}, t_{RRD}, t_{WR}, t_{XP}, t_{CKE} (DDR3/DDR2/LPDDR), and t_{FAW}, t_{RTP} (DDR3/DDR2) in terms of DCLK cycles.		
Controller	Configuring burst length	DMC_MR.BLEN (for DDR2 and LPDDR), DMC_MR0.BLEN for DDR3	The DMC only supports burst length of 8. Configure the DMC_MR0.BLEN field to 00 only.	The DMC supports both burst length of 4 and 8. Configure DMC_MR.BLEN field to 10 for burst length of 4 and to 11 for burst length of 8 words.	The DMC supports both burst length of 4 and 8. Configure DMC_MR.BLEN field to 10 for burst length of 4 and to 11 for burst length of 8 words.
Controller	Configuring CAS latency	DMC_MR.CL (for DDR2 and LPDDR), DMC_MR0.CL0, and DMC_MR0.CL (for DDR3)	The DMC supports CAS latencies of 5 to14. Refer to the DMC_MR.CL register description for more details.	The DMC supports CAS latencies of 3 to 6. Refer to the DMC_MR register description for more details.	The DMC supports CAS latency of 3. Refer to the DMC_MR register description for more details.
Controller	Configuring the DMC_MR.DLLRST bit (DDR2/LPDDR) or DMC_MR0(DDR3)	DMC_MR.DLLRST/ DMC_MR0.DLLRST	Set this bit while performing the initialization	Setting of this bit is optional for DDR2.	Reserved
Controller	Write recovery timing	DMC_MR.WRRECOV and DMC_MR0.WRRECOV	The DMC supports WR values of 5 to 16. Refer to the DMC_MR0 register description for more details.	The DMC supports WR values of 2 to 8. Refer to the DMC_MR register description for more details.	Reserved
Controller	Configuring DMC_MR1(DDR3) or DMC_EMR1 (DDR2) register	DMC_MR1(DDR3) or DMC_EMR1 (DDR2)	The DMC can use this register to configure memory drive impedance, ODT, and additive latency parameters. Refer to the corresponding register descriptions for more details.		This register is not used for LPDDR programming.

Table 9-8: DDR2, DDR3, and LPDDR Programming (Continued)

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
Controller	Configuring DMC_MR2(DDR3) or DMC_EMR2 (DDR2) or DMC_EMR (LPDDR) register	DMC_MR2(DDR3) or DMC_EMR2(DDR2) or DMC_EMR (LPDDR)	Configure the write latency field (CWL) to the required value. The DMC can also use this register to enable Auto Self-Refresh (ASR) and to select Self-Refresh Temperature (SRT) functionalities in the memory device. For more details on these functionalities, refer to the DDR3 memory device data sheets.	The DMC can use this register to configure the Partial Array Self-Refresh (PASR) and High Temperature Self-Refresh Rate Enable (SRF) functionalities of DDR2 memory device. For more details on these functionalities, refer to the DDR2 memory device data sheet.	The DMC can use this register to configure the Partial Array Self-Refresh (PASR), Temperature compensated self-refresh (TCSR), and drive strength (DS) functionalities of the memory device. For more details on these functionalities, refer to the LPDDR memory device data sheet.
Controller	Configuring the DMC_DLLCTL register	DMC_DLLCTL	Always configure the DMC_DLLCTL.DLLCALRDCNT field to 0x48 and DMC_DLLCTL.DATACYC field to 0x9.		

PHY DLL Calibration

The PHY DLL calibration is performed as part of the SDRAM power-up initialization. It calibrates data against the DQS and CLK signal. However, running DLL calibration after self-refresh or at an arbitrary time is required in certain cases.

The DMC allows PHY DLL calibration to start by setting the DMC_CTL.DLLCAL bit. The DMC_STAT.DLLCALDONE bit can be used to monitor the progress of the calibration. Once calibration is over, this bit is set. Once the calibration procedure is started by writing to the DMC_CAL_PADCTL0.CALSTRT bit, the full calibration takes 300 DCLK cycles to complete.

NOTE: DLL calibration can be initiated only when the DMC is idle (DMC_STAT.IDLE= 1).

DDR2 OCD Calibration

OCD calibration is not supported by the ADSP-SC57x processors.

DDR3 ZQ Calibration Short CMD

The ZQ calibration short command is generally used to correct small variations in ZQ (~0.5%). To perform ZQ calibration, the controller is first checked for its idle state. Once the idle bit is obtained, a ZQCS command can be issued by setting the DMC_STAT.ZQCSDONE bit (0x0004). The DMC_STAT.ZQCSDONE bit (0x0008) can be used to monitor the calibration sequence. When this bit is 0, it indicates that the calibration is ongoing. When it is

1, it indicates that the calibration is done. As an example, a GP timer can be used to periodically trigger a ZQCS command to address tiny variations.

NOTE: The ZQ calibration function is essential for normal operation of DDR3. With the reference of the external resistance (240 Ω ± 1%) connected to the DMC_RZQ pin, DDR3 calibrates the R_{on} and R_{tt} values of the ZQ pin against temperature and voltage variations.

DDR3 ZQ Calibration Long CMD

Several DDR3 impedance calibrations are implemented for optimal signal integrity. The long ZQ calibration is used after power-up and the short ZQ calibration is used periodically during normal operation to compensate for voltage and temperature drift. These calibration sequences improve connectivity between the SDRAM pads and the PCB trace. The DMC_RZQ pin on the SDRAM is connected to an external precision resistor that adjusts the output driver impedance Rtt and ODT values to match the trace impedance. The connection reduces impedance discontinuity and minimizes signal reflections.

The command has two variants named as ZQ calibration long (ZQCL) and ZQ calibration short (ZQCS). The ZQCL command is issued during initialization and after self-refresh exit command. It can be issued later depending on the system environment.

The DMC pads can be autocalibrated to the required driver impedance Rtt using an external resistance RZQ and the On Die Termination (ODT) value using the corresponding bits (`DMC_CAL_PADCTL2`). The autocalibration logic translates these values into a corresponding drive strength control inside the PHY and then routed to the PADS. Autocalibration starts as soon as the bit is programmed (set the DCLK at the required frequency before setting this `DMC_CAL_PADCTL0.CALSTRT` bit). Autocalibration expects the program to select two different member sets of pads (address/command pads versus CLK/Data/DQS/DM pads).

On Die Termination (DDR2/DDR3)

The DMC supports dynamic On Die Termination (ODT) at the pads. When the controller ODT is set, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller is writing to the DRAM. Controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers.

ODT resistance Rtt is selectable in the same way as DDR2 SDRAM ([A9, A6, A2] in MR1, [A10, A9] in MR2).

DDR3 SDRAM inherits the ODT function provided for DDR2 SDRAM, and provides extended ODT mode.

- *Synchronous ODT*: ODT timing is the same as that of DDR2 SDRAM
- *Asynchronous ODT*: ODT timing in the slow exit power-down mode
- *Dynamic ODT*: Function that can dynamically switch the ODT resistance during a write operation without an MRS command. It improves signal quality during a write operation.

Output Driver Impedance

Output driver impedance (Rtt) of DQ, DQS, $\overline{\text{DQS}}$/DM is selectable in the same way as DDR2 SDRAM ([A5, A1] in MR1). Rtt can fluctuate with the process, voltage, and temperature (PVT). DDR2 SDRAM can calibrate Rtt fluctuation due to PVT using the optional OCD (off-chip driver calibration) function. DDR3 SDRAM uses the ZQ calibration function instead of the OCD function.

In addition to the driver impedance, the bidirectional pads (Data and DQS) also require the initialization sequence to program the termination impedance by writing to the field `DMC_CAL_PADCTL2.IMPRTT`. The DMC pads use parallel termination, one branch goes from the pad to the I/O supply. The other branch goes to the I/O ground. The value programmed to this 8-bit field is the value to be used for each branch. There is a correction factor involved while programming this register. The value of this correction factor is 0.8. For example, suppose that a termination of 50 Ω is required on the data pads to match with the board trace. The value is programmed to 100 × 0.8 = 80, as the two parallel paths lead to an effective impedance of 50 Ω.

Initializing the DMC

To initialize the DMC, use the following steps. If it is not the first time that the DMC initializes, check to first ensure that the DMC is idle and not in the midst of any activity.

If DMC initialization occurs for the first time after power-up, PHY and PAD initialization is a requirement. The initialization occurs with the following steps:

For LPDDR mode, set the `DMC_PHY_CTL4.DDRMODE` bits to 0b'11 (3 in decimal) and set the `DMC_PHY_CTL1.BYPODTEN` bit.

For DDR2/DDR3 modes, follow these steps to perform pad impedance calibration:

1. Set the device mode in the `DMC_PHY_CTL4.DDRMODE` to DDR2 or DD3.
2. Configure the required values in the `DMC_CAL_PADCTL0` and `DMC_CAL_PADCTL2` registers without setting

   the `DMC_CAL_PADCTL0.CALSTRT` bit.
3. Set the `DMC_CAL_PADCTL0.CALSTRT` bit.
4. Wait for 300 DCLK cycles for the PAD calibration to complete.

NOTE: The bits 0, 1, 2, 3 of the `DMC_PHY_CTL0` register and the bits 31:26 of the `DMC_PHY_CTL2` register are timing trim bits. Always set these bits for DDR2 and DDR3 modes. For example, set these bits during first-time DMC initialization. Then, software does not need to touch or clear these bits.

Use the following C code to set these bits for the first time DMC initialization:

```
*pREG_DMC0_PHY_CTL0 |= 0x0000000F;
*pREG_DMC0_PHY_CTL2 |= 0xFC000000;
```

For DDR3 mode, set bit 1 and configure bits [5:2] of the PHY control register with WL= CWL + AL in DCLK cycles. For example, in case of DMC0, if CWL =6 and AL =0, the DMC_PHY_CTL0 register should be programmed with the value 0x0000001A.

Bits 6, 7, 25 and 27 of the DMC_PHY_CTL3 register should be always set for all the DDR modes (DDR3/DDR2/LPDDR). One can set these bits during first-time DMC initialization. Then, software need not touch or clear these bits. Use the following C code to set these bits for the first time DMC initialization:

```
*pREG_DMC0_PHY_CTL3=0xA0000C0;
```

Use the following steps for first-time DMC initialization and reinitialization:

1. Perform first-time DMC initialization, as needed.

   ADDITIONAL INFORMATION: Perform this step only for the first time DMC initialization after power-up or reset. Skip this step if reinitializing the DMC.

   a. Set the DMC_PHY_CTL0.RESETDLL bit

   b. Initialize the CGU to change the DCLK frequency.

   a. Clear the DMC_PHY_CTL0.RESETDLL bit.

2. Reinitialize the DMC with a DCLK change

   a. Place the DMC in self-refresh mode.

   b. Set the DMC_PHY_CTL0.RESETDLL bit.

   c. Initialize the CGU to change the DCLK frequency.

   d. Clear the DMC_PHY_CTL0.RESETDLL bit

   e. Bring the DMC out of self-refresh mode.

3. If not already done, wait 9000 DCLK cycles to ensure that the DLL locked.

4. Program the DMC_CFG, DMC_CTL, DMC_TR0, and DMC_TR2 registers to the appropriate values to set proper SDRAM cycle timing options.

   ADDITIONAL INFORMATION: For example, t_{RAS}, t_{RC}, t_{RP}, t_{RCD}, t_{WR}, t_{FAW} are some of the parameters.

5. Program the shadow registers DMC_MR (DDR2/DDR3/LPDDR), DMC_EMR1 (DDR2)/DMC_EMR1(DDR3), DMC_EMR1 (DDR2)/DMC_EMR1 (LPDDR) DMC_EMR1 (DDR3), with the needed burst length, CAS latency, additive latency, and other parameters.

6. Finally, after programming these registers, write the DMC_CTL.INIT bit to the DMC control register to begin the power-up initialization sequence.

7. Wait for the SDRAM initialization sequence to complete by making sure that the DMC_STAT.INITDONE bit is set.

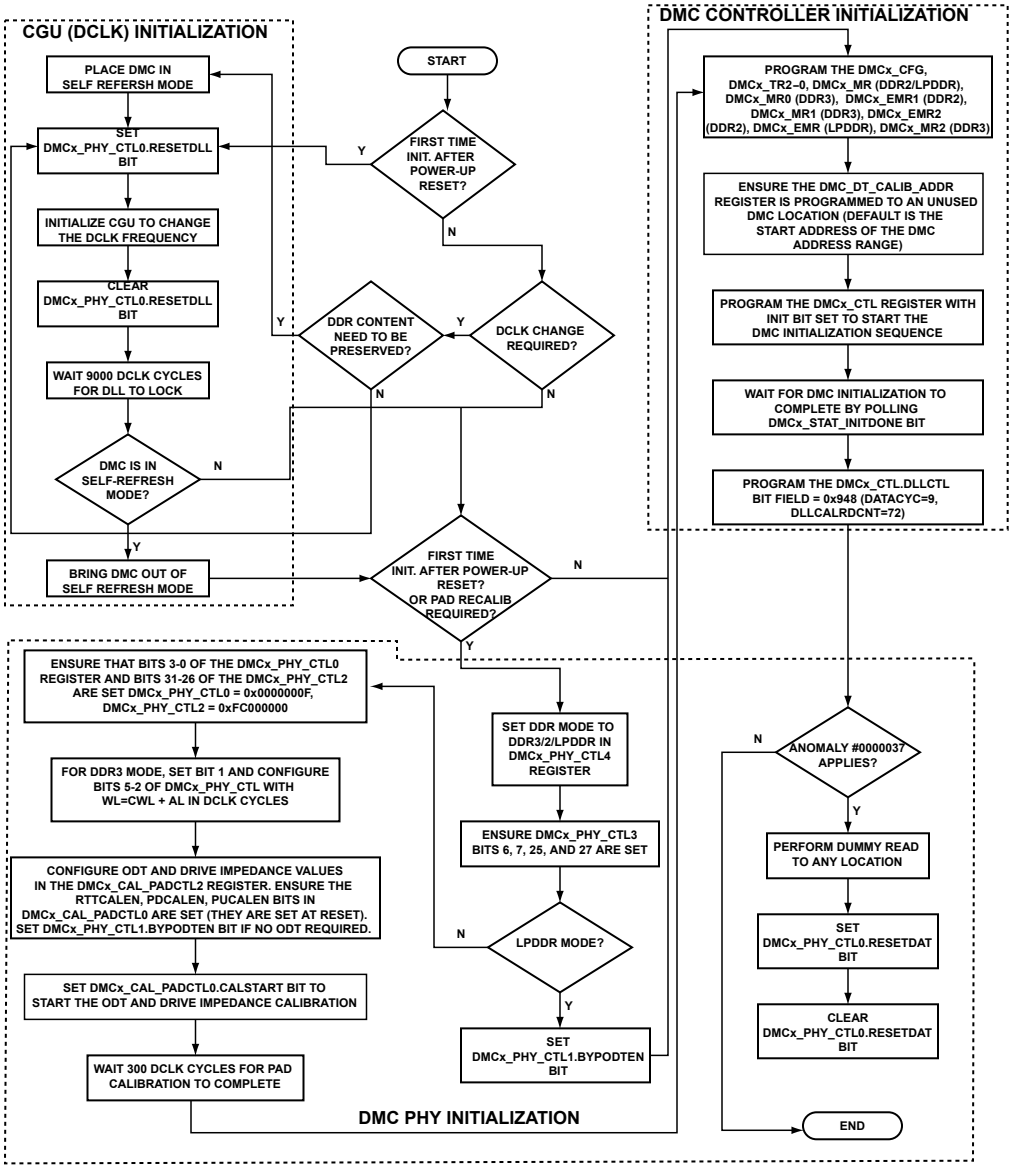

Figure 9-1: DMC Initialization Flow

The DMC accumulates system crossbar transactions that occur during or before initialization and sends them to SDRAM once the SDRAM initialization or DLL calibration is complete.

NOTE: During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written followed immediately by a series of reads. The DMC PHY needs information about the data to be read during the PHY DLL calibration prior to the operation. The controller performs one burst write operation to the address programmed in the DMC_DT_CALIB_ADDR register. The exact address chosen does not matter during memory initialization. If calibration of the PHY is performed when the DRAM contains valid data, ensure that this address points to an unused address. Otherwise, this operation modifies application data stored at the address selected. The DLL calibration modifies all 16 bytes corresponding to the 16-byte aligned address, even if the address programmed is not 16-byte aligned. For example, it updates all the

locations 0x80000000 to 0x8000000F regardless of whether the address is programmed as 0x80000000 or 0x80000004.

The program performs second-time initialization for cases where the DMC has already been initialized. The initialization can be through a preload during a debug session, or through code executed during the booting process.

ADSP-SC57x DMC Register Descriptions

Dynamic Memory Controller (DMC) contains the following registers.

Table 9-9: ADSP-SC57x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CPHY_CTL	Controller to PHY Interface Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR1	Shadow EMR1 DDR2 Register
DMC_EMR2	Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR)
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register

Table 9-9: ADSP-SC57x DMC Register List (Continued)

Name	Description
DMC_TR1	Timing 1 Register
DMC_TR2	Timing 2 Register

Configuration Register

The DMC_CFG register selects SDRAM device specific parameters and selects the SDRAM interface width.

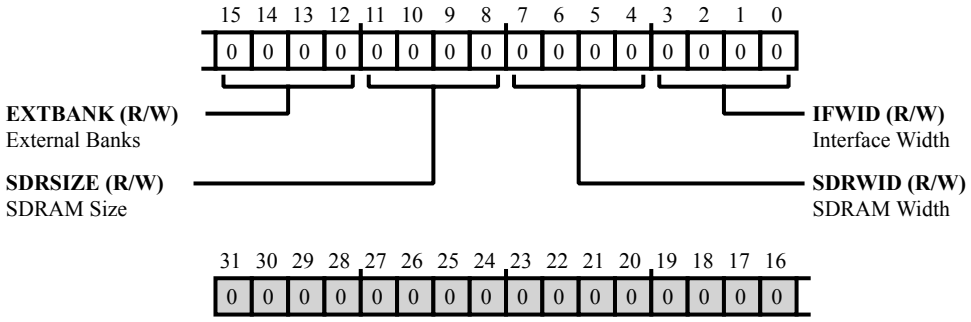

Figure 9-2: DMC_CFG Register Diagram

Table 9-10: DMC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	EXTBANK	External Banks. The DMC_CFG.EXTBANK bits select the number of external banks connected to the DMC. Note that all values other than those shown are reserved.	
		0	1 External Bank
		1-15	Reserved
11:8 (R/W)	SDRSIZE	SDRAM Size. The DMC_CFG.SDRSIZE bits select the size of individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		0	64M Bit SDRAM (LPDDR Only)
		1	128M Bit SDRAM (LPDDR Only)
		2	256M Bit SDRAM
		3	512M Bit SDRAM
		4	1G Bit SDRAM
		5	2G Bit SDRAM
		6	4G Bit SDRAM
		7	8G Bit SDRAM

Table 9-10: DMC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/W)	SDRWID	SDRAM Width. The `DMC_CFG.SDRWID` bits select the width of the individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide SDRAM
		3-15	Reserved
3:0 (R/W)	IFWID	Interface Width. The `DMC_CFG.IFWID` bits select the width of the interface between the DMC and SDRAM. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide Interface. All other values are reserved. This field specifies the interface width between the controller and the SDRAM.
		3-15	Reserved

Controller to PHY Interface Register

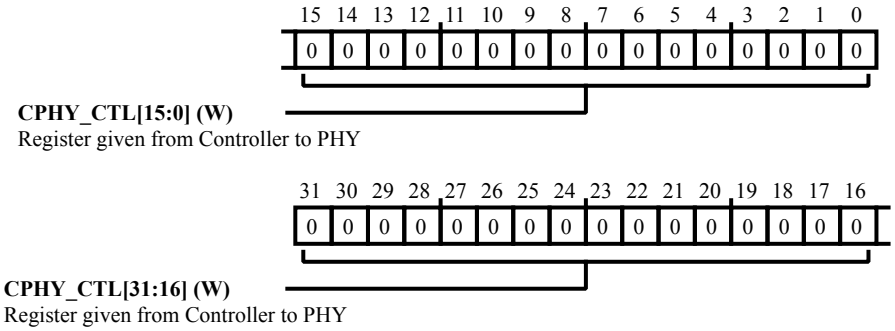

Figure 9-3: DMC_CPHY_CTL Register Diagram

Table 9-11: DMC_CPHY_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	CPHY_CTL	Register given from Controller to PHY.

Control Register

The DMC_CTL register controls DMC modes, DLL calibration, and DRAM initialization.

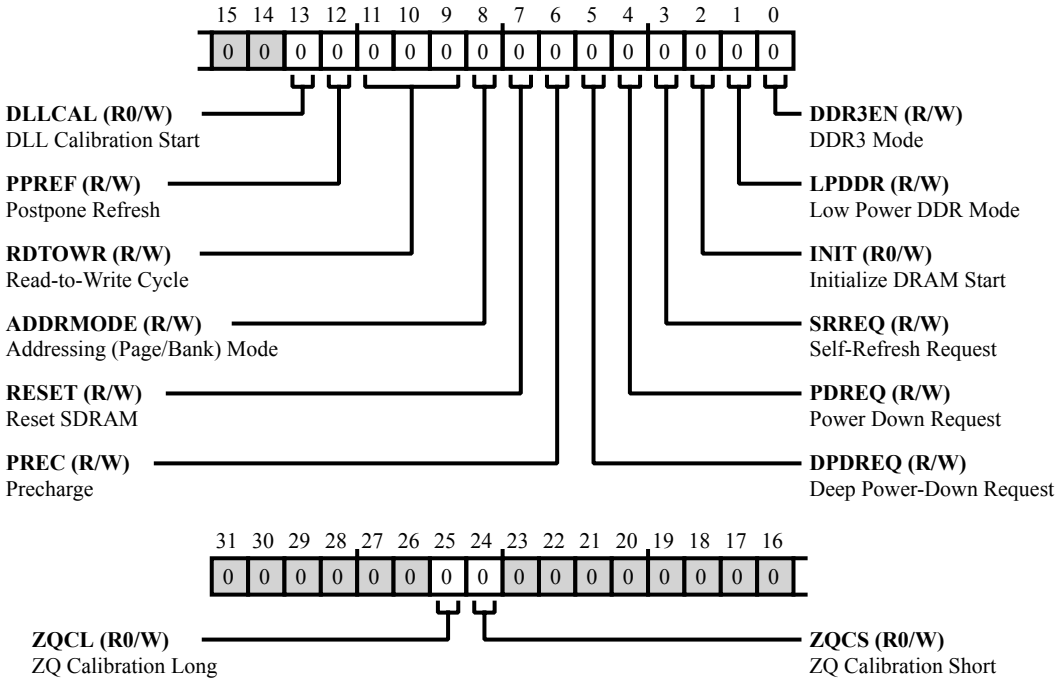

Figure 9-4: DMC_CTL Register Diagram

Table 9-12: DMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R0/W)	ZQCL	ZQ Calibration Long. The DMC_CTL.ZQCL bit starts the ZQ calibration long sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration long sequence
24 (R0/W)	ZQCS	ZQ Calibration Short. The DMC_CTL.ZQCS bit starts the ZQ calibration short sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration short sequence

Table 9-12: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R0/W)	DLLCAL	DLL Calibration Start. The DMC_CTL.DLLCAL bit starts the PHY DLL calibration sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Start PHY DLL calibration
12 (R/W)	PPREF	Postpone Refresh. The DMC_CTL.PPREF bit enables postponing the DMCs sending of auto-refresh commands. When enabled, the DMC accumulates refresh commands. The DMC_EFFCTL.NUMREF field selects the number of refresh commands that the DMC may accumulate. When disabled, the DMC_TR1.TREF field selects the interval for auto-refresh command distribution. A maximum of eight auto-refresh commands can be accumulated in DDR3 mode.	
		0	Disable Postpone Refresh
		1	Enable Postpone Refresh
11:9 (R/W)	RDTOWR	Read-to-Write Cycle. The DMC_CTL.RDTOWR bits select the number of cycles that the DMC adds when a write operation follows a read operation. For proper operation, it should be programmed with the value of 010.	
		0	1 Cycle Added from JEDEC Spec Value
		1	2 Cycles Added from JEDEC Spec Value
		2	3 Cycles Added from JEDEC Spec Value
		3	4 Cycles Added from JEDEC Spec Value
		4	5 Cycles Added from JEDEC Spec Value
		5	6 Cycles Added from JEDEC Spec Value
		6	7 Cycles Added from JEDEC Spec Value
		7	8 Cycles Added from JEDEC Spec Value
8 (R/W)	ADDRMODE	Addressing (Page/Bank) Mode. The DMC_CTL.ADDRMODE bit selects whether the DMC uses page or bank interleaving for addressing. When using page interleaving, the bank address bits follow the most significant column address bits. When using bank interleaving, the bank address bits follow the most significant row address bits.	
		0	Bank Interleaving
		1	Page Interleaving

Table 9-12: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	RESET	Reset SDRAM. The DMC_CTL.RESET bit starts the reset sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Starts reset sequence
6 (R/W)	PREC	Precharge. The DMC_CTL.PREC bit enables precharge, which closes DRAM rows immediately after access. When disabled, all accesses result in the respective DRAM rows remaining open, until the DMC needs to close them.	
		0	No Effect
		1	Enable Precharge
5 (R/W)	DPDREQ	Deep Power-Down Request. The DMC_CTL.DPDREQ bit enables deep power-down mode if low power DMC operation is enabled (DMC_CTL.LPDDR =1). When the processor does not require the data stored in SDRAM (assume reset state of SDRAM), the DMC may put the SDRAM in deep power-down mode. When the DMC is in deep power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in deep power-down mode as along as this bit is 1.	
		0	Disable Deep Power-Down
		1	Enable Deep Power-Down
4 (R/W)	PDREQ	Power Down Request. The DMC_CTL.PDREQ bit enables power-down mode. When the DMC is in power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in power-down mode as along as this bit is 1.	
		0	Disable Power-Down
		1	Enable Power-Down
3 (R/W)	SRREQ	Self-Refresh Request. The DMC_CTL.SRREQ bit enables self-refresh mode. When the DMC is in self-refresh mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in self-refresh mode as along as this bit is 1.	
		0	Disable Self-Refresh
		1	Enable Self-Refresh

Table 9-12: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R0/W)	INIT	Initialize DRAM Start. The `DMC_CTL.INIT` bit starts the power up DRAM initialization sequence and DLL calibration sequence. Note that this bit always reads as 0.	
		0	No Effect
		1	Start DRAM Initialization
1 (R/W)	LPDDR	Low Power DDR Mode. The `DMC_CTL.LPDDR` bit selects whether the DMC operates in low power DDR mode or DDR2 mode.	
		0	DDR2 mode
		1	LPDDR mode
0 (R/W)	DDR3EN	DDR3 Mode. The `DMC_CTL.DDR3EN` bit selects whether the DMC operates in DDR3 mode.	
		0	Reserved
		1	Enable DDR3 mode

DLL Control Register

The DMC_DLLCTL register holds the programmable parameters associated with the DLLs within the DMC PHY.

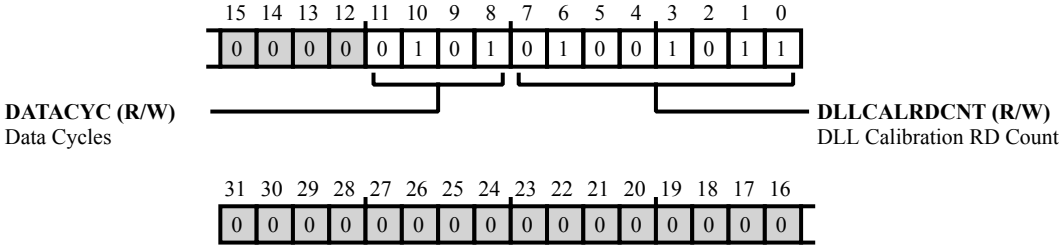

Figure 9-5: DMC_DLLCTL Register Diagram

Table 9-13: DMC_DLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:8 (R/W)	DATACYC	Data Cycles. The DMC_DLLCTL.DATACYC bits select the latency after which the DMC reads data from the PHY. This field must be written with the value (9). All other values are reserved. Taking round trip delay into account, the DLL indicates whether a latency of 2 cycles is supported by means of status bits.
7:0 (R/W)	DLLCALRDCNT	DLL Calibration RD Count. The DMC_DLLCTL.DLLCALRDCNT field selects the number of read operations that the PHY uses for DLL calibration.

Data Calibration Address Register

The DMC_DT_CALIB_ADDR register provides the address used for the data calibration for read and write. During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written and a series of reads are performed back to back to calibrate the PHY. The DMC PHY needs prior information about the data that would be read during the PHY DLL calibration. The controller performs one burst write operation to the address programmed in DMC_DT_CALIB_ADDR (0x0090).

Note: While the exact address chosen does not matter much during memory initialization, if calibration of the PHY is performed when the DRAM contains valid data, care needs to be taken to ensure that this address points to an unused address. Else, this operation will modify application data stored at the address selected.

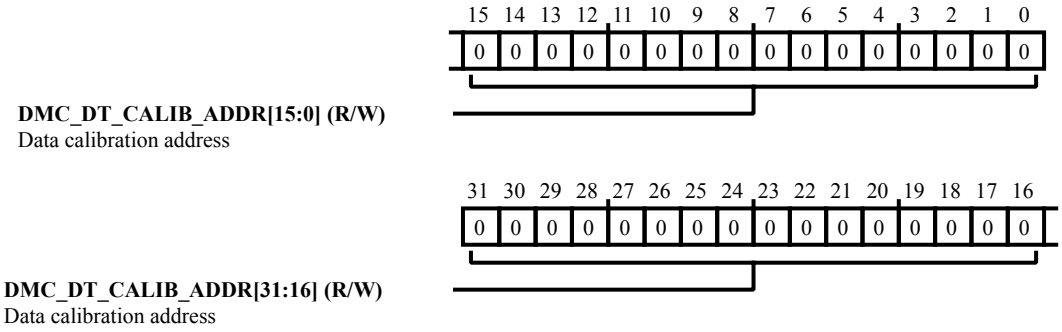

Figure 9-6: DMC_DT_CALIB_ADDR Register Diagram

Table 9-14: DMC_DT_CALIB_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_CALIB_ADDR	Data calibration address. The DMC_DT_CALIB_ADDR.DMC_DT_CALIB_ADDR bit field contains the address to be programmed for the data calibration for read and write.

Data Calibration Data 0 Register

The DMC_DT_DATA_CALIB_DATA0 register contains the first 32-bit data used for the write during the data calibration.

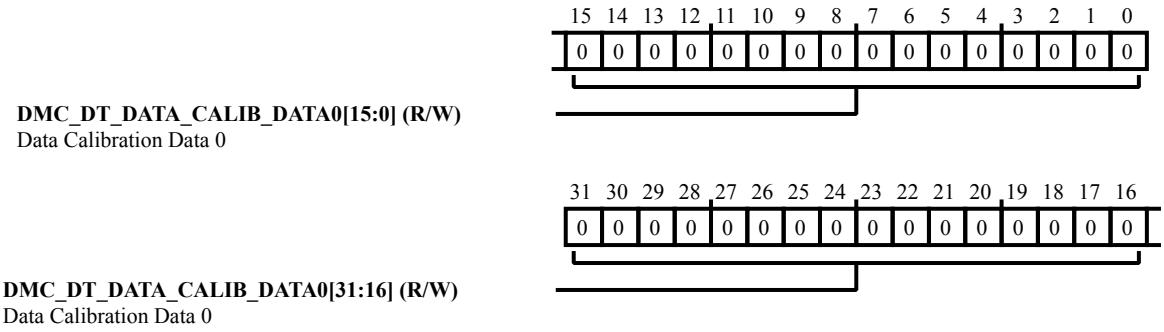

Figure 9-7: DMC_DT_DATA_CALIB_DATA0 Register Diagram

Table 9-15: DMC_DT_DATA_CALIB_DATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0. The DMC_DT_DATA_CALIB_DATA0.DMC_DT_DATA_CALIB_DATA0 bit field contains the first 32 bit data used for the write during the data calibration.

Data Calibration Data 1 Register

The DMC_DT_DATA_CALIB_DATA1 register contains the second 32-bit data used for the write during the data calibration.

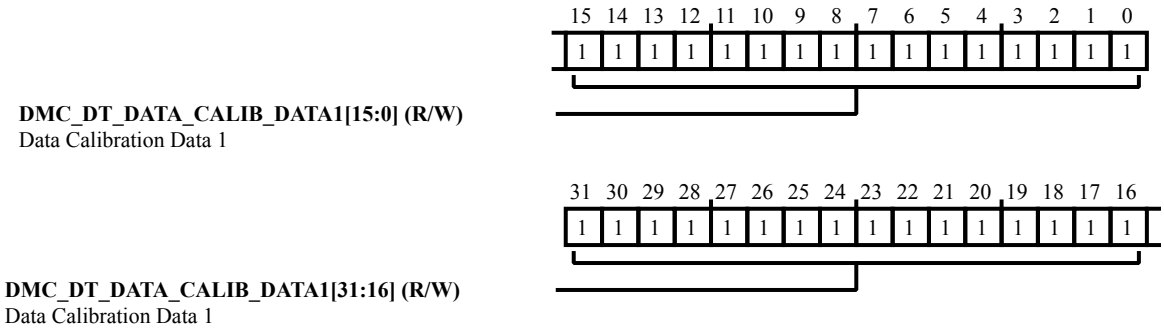

Figure 9-8: DMC_DT_DATA_CALIB_DATA1 Register Diagram

Table 9-16: DMC_DT_DATA_CALIB_DATA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1. The DMC_DT_DATA_CALIB_DATA1.DMC_DT_DATA_CALIB_DATA1 bit field contains the second 32 bit data used for the write during the data calibration.

Efficiency Control Register

The DMC_EFFCTL register control DMC features that improve throughput efficiency. These include features such as auto-refresh management, precharge options, and write data options.

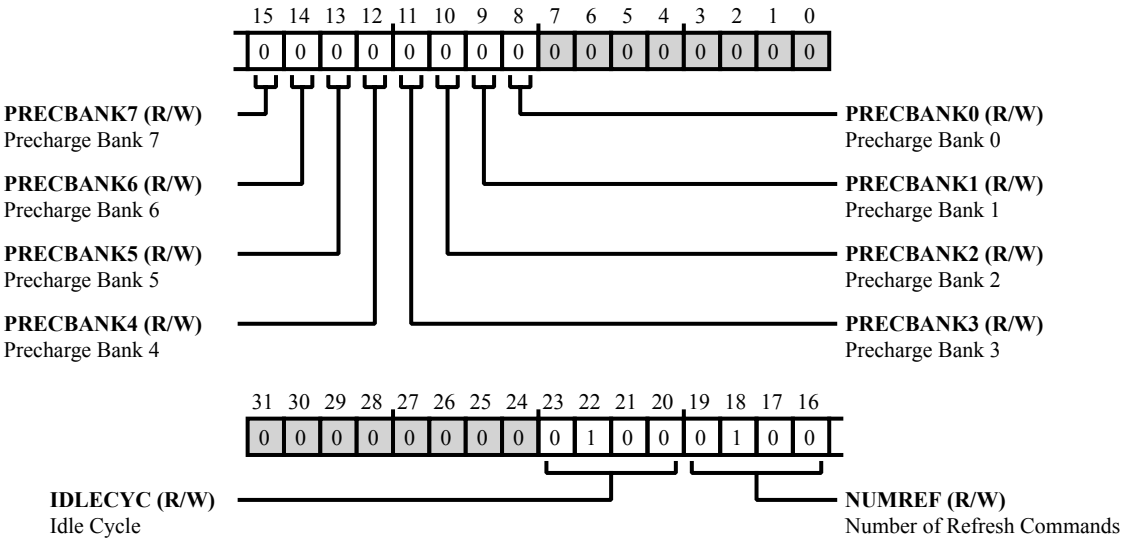

Figure 9-9: DMC_EFFCTL Register Diagram

Table 9-17: DMC_EFFCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	IDLECYC	Idle Cycle. The DMC_EFFCTL.IDLECYC bits select the number of cycles after which the DMC issues any accumulated auto-refresh commands if postpone refresh is enabled (DMC_CTL.PPREF =1). When DMC_EFFCTL.IDLECYC is set to 0, the DMC ignores the DMC_CTL.PPREF selection and does not accumulate/postpone periodic auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set. Note 3: Setting this value to 0000 overrides the "postpone refresh" feature and does not accumulate/postpone periodic auto refreshes.	
		0-15	0 to 15 Idle Cycles to Postpone Refresh Commands

Table 9-17: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	NUMREF	Number of Refresh Commands. The DMC_EFFCTL.NUMREF bits select the number of auto-refresh commands that the DMC can accumulate if postpone refresh is enabled (DMC_CTL.PPREF =1). In DDR3 mode, the DMC may accumulate up to eight auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set.	
		0	No Refresh Commands Accumulate
		1	1 Refresh Command May Accumulate
		2	2 Refresh Commands May Accumulate
		3	3 Refresh Commands May Accumulate
		4	4 Refresh Commands May Accumulate
		5	5 Refresh Commands May Accumulate
		6	6 Refresh Commands May Accumulate
		7	7 Refresh Commands May Accumulate
		8	8 Refresh Commands May Accumulate
15 (R/W)	PRECBANK7	Precharge Bank 7. The DMC_EFFCTL.PRECBANK7 bit enables precharge (closes the page) of bank 7 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 7
		1	Enable Precharge Bank 7
14 (R/W)	PRECBANK6	Precharge Bank 6. The DMC_EFFCTL.PRECBANK6 bit enables precharge (closes the page) of bank 6 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 6
		1	Enable Precharge Bank 6

Table 9-17: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PRECBANK5	Precharge Bank 5. The DMC_EFFCTL.PRECBANK5 bit enables precharge (closes the page) of bank 5 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 5
		1	Enable Precharge Bank 5
12 (R/W)	PRECBANK4	Precharge Bank 4. The DMC_EFFCTL.PRECBANK4 bit enables precharge (closes the page) of bank 4 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 4
		1	Enable Precharge Bank 4
11 (R/W)	PRECBANK3	Precharge Bank 3. The DMC_EFFCTL.PRECBANK3 bit enables precharge (closes the page) of bank 3 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 3
		1	Enable Precharge Bank 3
10 (R/W)	PRECBANK2	Precharge Bank 2. The DMC_EFFCTL.PRECBANK2 bit enables precharge (closes the page) of bank 2 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 2
		1	Enable Precharge Bank 2
9 (R/W)	PRECBANK1	Precharge Bank 1. The DMC_EFFCTL.PRECBANK1 bit enables precharge (closes the page) of bank 1 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 1
		1	Enable Precharge Bank 1

Table 9-17: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PRECBANK0	Precharge Bank 0. The DMC_EFFCTL.PRECBANK0 bit enables precharge (closes the page) of bank 0 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 0
		1	Enable Precharge Bank 0

Shadow EMR1 DDR2 Register

The DMC_EMR1 register in the DMC shadows the EMR1 register in the SDRAM when the DMC is in DDR2 mode (DMC_CTL.LPDDR =0). This register is used only when the DMC is operating in DDR2 mode.

If unmasked by the corresponding bit in the shadow mask register, a write to DMC_EMR1 triggers an extended "mode register set" command on the memory interface. If masked, a write to DMC_EMR1 only updates the register in the DMC, not the register in the SDRAM.

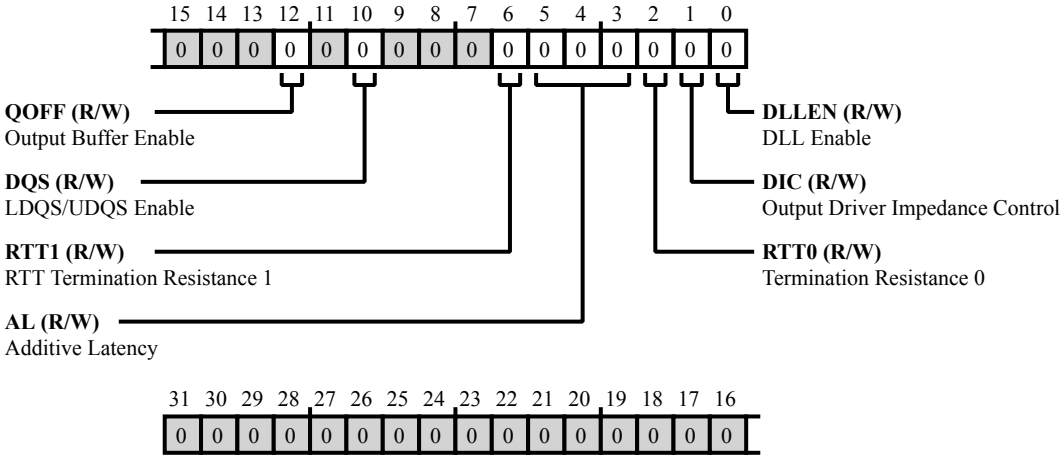

Figure 9-10: DMC_EMR1 Register Diagram

Table 9-18: DMC_EMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	QOFF	Output Buffer Enable. The DMC_EMR1.QOFF bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable
		1	Disable
10 (R/W)	DQS	LDQS/UDQS Enable. The DMC_EMR1.DQS bit enables the single ended operation of the DMC_LDQS/DMC_LDQS or DMC_UDQS/DMC_UDQS pin. For more information about this operation, see the data sheet for the SDRAM being used in your system. The DDR Controller enables differential signaling mode (EMR1) by default. Because the controller supports differential signaling mode only, setting this bit is not allowed.	
6 (R/W)	RTT1	RTT Termination Resistance 1. The DMC_EMR1.RTT1 bit combines with the DMC_EMR1.RTT0 bit to set the termination resistance. See the DMC_EMR1.RTT0 bit description for more information.	

Table 9-18: DMC_EMR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:3 (R/W)	AL	Additive Latency. The DMC_EMR1.AL bits select a number of added latency time for CAS operations in terms of clock cycles (t_{CK}). For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	0 Clock Cycles Added
		1	1 Clock Cycle Added
		2	2 Clock Cycles Added
		3	3 Clock Cycles Added
		4	4 Clock Cycles Added
		5	5 Clock Cycles Added
2 (R/W)	RTT0	Termination Resistance 0. The DMC_EMR1.RTT0 bit and the DMC_EMR1.RTT1 bits select the SDRAM termination resistance. RTT1=0, RTT0=0: No ODT at memory device RTT1=0, RTT0=1: 75 Ohm ODT at memory device RTT1=1, RTT0=0: 150 Ohm ODT at memory device RTT1=1, RTT0=1: 50 Ohm ODT at memory device For more information about this operation, see the data sheet for the SDRAM being used in your system.	
1 (R/W)	DIC	Output Driver Impedance Control. The DMC_EMR1.DIC bit selects the drive strength mode for the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system. It must be kept at 0 if the SDRAM does not support this bit.	
		0	Full Strength
		1	Reduced Strength
0 (R/W)	DLLEN	DLL Enable. The DMC_EMR1.DLLEN bit enables the DLL in the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable DLL (Normal Operation)
		1	Disable DLL (Test/Debug Operation)

Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR)

The DMC_EMR2 register in the DMC shadows the EMR2 register in the SDRAM when the DMC is in DDR2 mode (DMC_CTL.LPDDR =0) and shadows the EMR register in the SDRAM when the DMC is in LPDDR mode (DMC_CTL.LPDDR =1). If unmasked by the corresponding bit in the shadow mask register, a write to DMC_EMR2 triggers an extended "mode register set" command on the memory interface. If masked, a write to DMC_EMR2 only updates the register in the DMC, not the register in the SDRAM.

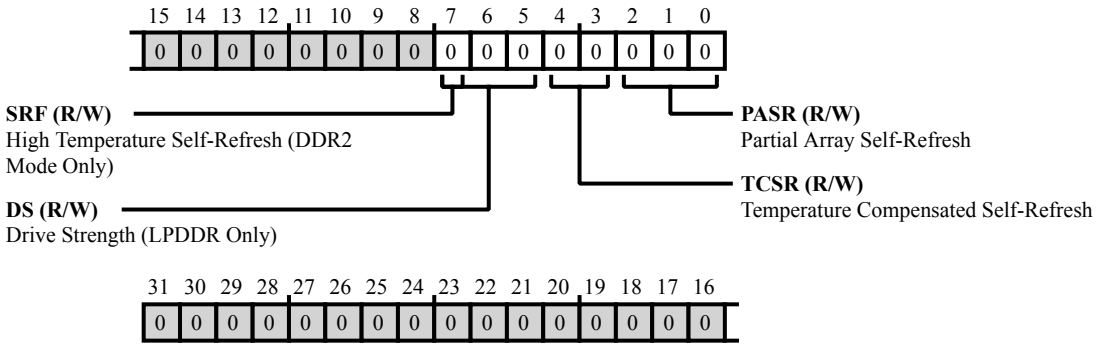

Figure 9-11: DMC_EMR2 Register Diagram

Table 9-19: DMC_EMR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SRF	High Temperature Self-Refresh (DDR2 Mode Only). The DMC_EMR2.SRF bit enables the high temperature self-refresh rate feature of the SDRAM when the DMC is not in LPDDR mode. For more, see the SDRAM data sheet.	
		0	Disable
		1	Enable
7:5 (R/W)	DS	Drive Strength (LPDDR Only). The DMC_EMR2.DS fields select the drive strength of the DMC pins when the DMC is in LPDDR mode.When in non-LPDDR modes, bit 7 functions as DMC_EMR2.SRF, and the remaining bits are reserved. For more information, see the SDRAM data sheet.	
		0	Full Strength Driver
		1	Half Strength Driver
		2	Reserved
		3	Reserved
		4	Three-Quarters Strength Driver
		5	Reserved

Table 9-19: DMC_EMR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Quarter Strength Driver
		7	Octant Strength Driver
4:3 (R/W)	TCSR	Temperature Compensated Self-Refresh. The DMC_EMR2.TCSR bits select the temperature for applying temperature compensated self-refresh when the DMC is in LPDDR mode. (These bits are reserved when the DMC is in DDR2 mode.) For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	70 degree C (in LPDDR Mode)
		1	45 degree C
		2	15 degree C
		3	85 degree C
2:0 (R/W)	PASR	Partial Array Self-Refresh. The DMC_EMR2.PASR bits select the amount of memory to be refreshed during self-refresh. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Full Array for DDR2 and LPDDR Modes. Applies to both 4 and 8 bank devices.
		1	1/2 Array for DDR2 and LPDDR Modes. For 4 bank devices, BA[1:0] =00 and 01. For 8 bank devices, BA[2:0] = 000, 001, 010, 011
		2	1/4 Array for DDR2 and LPDDR Modes. For 4 bank devices, BA[1:0] = 00. For 8 bank devices, BA[2:0] = 000 and 001.
		3	1/8 Array for 8 DDR2 Banks Only. Reserved for LPDDR. For 4 bank devices, not defined. For 8 bank devices, BA[2:0] = 000.
		4	3/4 Array for DDR2. Reserved for LPDDR. For 4 bank devices, BA[1:0]=01, 10 and 11. For 8 bank devices, BA[2:0] = 010, 011, 100, 101, 110, and 111.
		5	1/2 Array for DDR2. 1/8 Array for LPDDR. For 4 bank devices, BA[1:0]=10 and 11. For 8 bank devices, BA[2:0] = 100, 101, 110, and 111.
		6	1/4 Array for DDR2. 1/16 Array for LPDDR. For 4 bank devices, BA[1:0]=11. For 8 bank devices, BA[2:0] =110 and 111.
		7	1/8 array (for DDR2 Banks only); Reserved (LPDDR)

Shadow MR0 Register (DDR3)

The DMC_MR register in the DMC shadows the MR register in the SDRAM when the DMC is DDR3 mode (DMC_CTL.DDR3EN =1). If unmasked by the corresponding bit in the shadow mask register (DMC_MSK.MR =1), a write to DMC_MR triggers a “mode register set” command on the memory interface. If masked, a write to DMC_MR only updates the register in the DMC, not the register in the SDRAM.

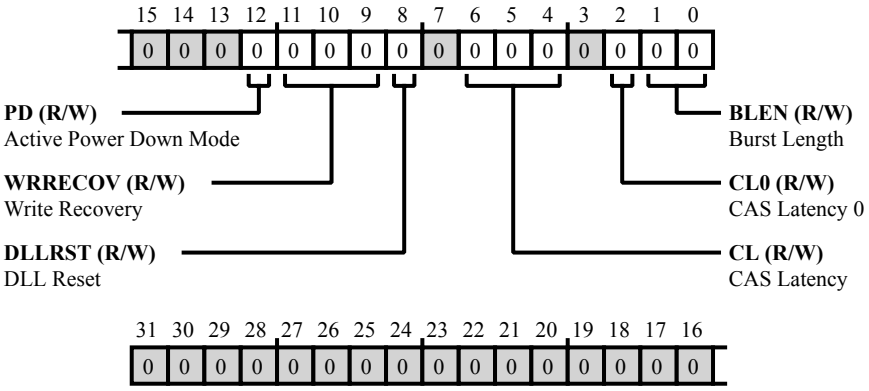

Figure 9-12: DMC_MR Register Diagram

Table 9-20: DMC_MR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PD	Active Power Down Mode. The DMC_MR.PD bit selects the active power-down mode. Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	Fast Exit (normal)
		1	Slow Exit (low power)
11:9 (R/W)	WRRECOV	Write Recovery. The DMC_MR.WRRECOV bit selects the write recovery time in terms of clock cycles (t_{CK}). Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	16 clock cycles for DDR3
		1	5 clock cycles for DDR3
		2	6 clock cycles for DDR3
		3	7 clock cycles for DDR3
		4	8 clock cycles for DDR3
		5	10 clock cycles for DDR3
		6	12 clock cycles for DDR3

Table 9-20: DMC_MR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	14 clock cycles for DDR3
8 (R/W)	DLLRST	DLL Reset. The DMC_MR.DLLRST bit initiates a DLL reset on the SDRAM. Note that this parameter applies only for DDR3 mode. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Normal Operation
		1	Reset DLL
6:4 (R/W)	CL	CAS Latency. The DMC_MR.CL bit field select latency from the assertion of a read/write signal to the SDRAM until the first valid data on the output from the SDRAM in terms of clock cycles. For more information about this operation, see the data sheet for the SDRAM being used in your system. For DDR3 only, Bit[2] of this register must be used along with [6:4]. Following CAS values are seen. "0010": 5 "0100": 6 "0110": 7 "1000": 8 "1010": 9 "1100": 10 "1110": 11 "0001": 12 "0011": 13 "0101": 14 All other combinations are reserved.	
2 (R/W)	CL0	CAS Latency 0. The DMC_MR.CL0 bit is applicable for DDR3 only and is used in conjunction with the DMC_MR.CL bits.	
1:0 (R/W)	BLEN	Burst Length. The DMC_MR.BLEN bits select burst length for transfers. For more information about this operation, see the data sheet for the SDRAM being used in your system. Note that values other than those shown are not supported.	
		0	8-Bit Burst Length - DDR3 only
		2	4-Bit Burst Length -LPDDR/DDR2 only
		3	8-Bit Burst Length - LPDDR/DDR2 only

Shadow MR1 Register (DDR3)

The DMC_MR1 register is a mirror of the DDR3 SDRAM Mode register 1. This register is used only when the DMC is operating in DDR3 mode. A write to this register triggers an extended "mode register 1 set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

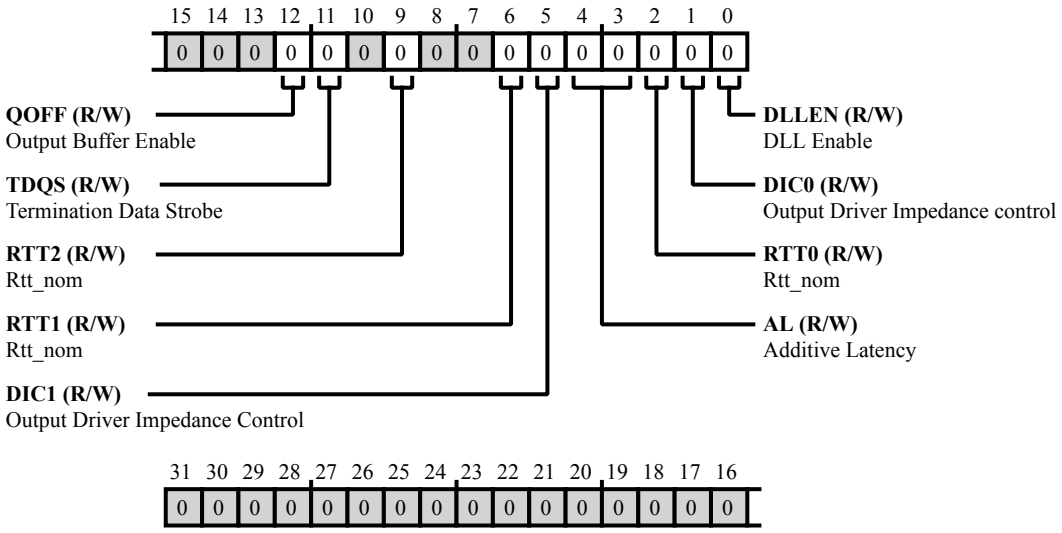

Figure 9-13: DMC_MR1 Register Diagram

Table 9-21: DMC_MR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	QOFF	Output Buffer Enable. The DMC_MR1.QOFF bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Output buffer enabled
		1	Output buffer disabled
11 (R/W)	TDQS	Termination Data Strobe. The DMC_MR1.TDQS bit provides additional termination resistance outputs that may be useful in some system configurations. The DMC_MR1.TDQS bit is not supported in x4 or x16 configurations. When enabled via the mode register, the same termination resistance function is applied to the TDQS/TDQS# pins that is applied to the DQS/DQS# pins.	
		0	Enable
		1	Disable

Table 9-21: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RTT2	Rtt_nom. The DMC_MR1.RTT2 bit is used in conjunction with the DMC_MR1.RTT0 and DMC_MR1.RTT1 bits. (9 6 2) 0 0 0 Rtt_Nom disabled 0 0 1 RZQ/4 0 1 0 RZQ/2 0 1 1 RZQ/6 1 0 0 RZQ/12 (reserved if Rtt_Nom is used during writes) 1 0 1 RZQ/8 (reserved if Rtt_Nom is used during writes) 1 1 0 Reserved 1 1 1 Reserved	
6 (R/W)	RTT1	Rtt_nom. The DMC_MR1.RTT1 bit combines with the DMC_MR1.RTT0 bit to set the termination resistance. See the DMC_MR1.RTT2 and DMC_MR1.RTT0 bit description for more information.	
5 (R/W)	DIC1	Output Driver Impedance Control. The DMC_MR1.DIC1 bit is used in conjunction with the DMC_MR1.DIC0 bit. (5, 1) 0 0 RZQ/6 0 1 RZQ/7 1 0 Reserved 1 1 Reserved	
4:3 (R/W)	AL	Additive Latency. The DMC_MR1.AL bits select a number of added latency time for CAS operations in terms of clock cycles (t_{CK}). For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	AL disabled
		1	CL-1
		2	CL-2
		3	Reserved
2 (R/W)	RTT0	Rtt_nom. The DMC_MR1.RTT0 bit combines with the DMC_MR1.RTT1 and DMC_MR1.RTT1 bits to set the termination resistance. See the DMC_MR1.RTT1 and DMC_MR1.RTT2 bit descriptions for more information.	

Table 9-21: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	DIC0	Output Driver Impedance control. The `DMC_MR1.DIC0` bit is used with the `DMC_MR1.DIC1` bit.	
0 (R/W)	DLLEN	DLL Enable. The `DMC_MR1.DLLEN` bit enables the DLL in the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable
		1	Disable

Shadow MR2 Register (DDR3)

The DMC_MR2 register mirrors DDR3 SDRAM device Mode register 2 when the controller is operating in DDR3 mode. A write to this register triggers an extended "mode register set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

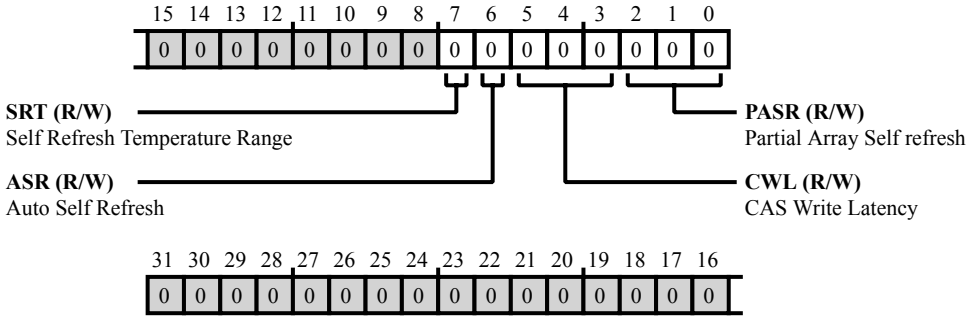

Figure 9-14: DMC_MR2 Register Diagram

Table 9-22: DMC_MR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SRT	Self Refresh Temperature Range. The DMC_MR2.SRT bit enables high temperature self-refresh rate.	
		0	Disable
		1	Enable
6 (R/W)	ASR	Auto Self Refresh.	
		0	Manual SR Reference (SRT)
		1	ASR enable (Optional)
5:3 (R/W)	CWL	CAS Write Latency.	
		0	5 clock cycles
		1	6 clock cycles
		2	7 clock cycles
		3	8 clock cycles
		4	9 clock cycles
		5	10 clock cycles
		6	11 clock cycles
		7	12 clock cycles

Table 9-22: DMC_MR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	PASR	Partial Array Self refresh. The `DMC_MR2.PASR` bits select the amount of memory to be refreshed during self refresh. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	4 banks: full array, 8 banks: full array
		1	4 banks: Half Array (BA[1:0]=00&01), 8 banks: Half Array (BA[2:0] = 000, 001, 010, &011)
		2	4 banks: Quarter Array (BA[1:0]=00), 8 banks: Quarter Array (BA[2:0] = 000&001)
		3	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 000)
		4	4 banks: 3/4 Array (BA[1:0]=01, 10&11), 8 banks: 3/4 Array (BA[2:0] = 010, 011, 100, 101, 110, &111)
		5	4 banks: Half Array (BA[1:0]=10&11), 8 banks: Half Array (BA[2:0] = 100, 101, 110, &111)
		6	4 banks: Quarter Array (BA[1:0]=11), 8 banks: Quarter Array (BA[2:0] =110 & 111)
		7	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 111)

Mask (Mode Register Shadow) Register

The DMC_MSK register permits masking (disabling) writes to the MR and EMRn registers in the SDRAM in DDR3 Mode. When masked, writes to these registers go instead to shadow copies of these registers (DMC_MR, DMC_MR1, DMC_MR2), which are maintained within the DMC. When a shadow register's corresponding bit is unmasked (enabled), the DMC generates the MRS or EMRS command to transfer the contents of the shadow register (in the DMC) to the actual register (in the SDRAM).

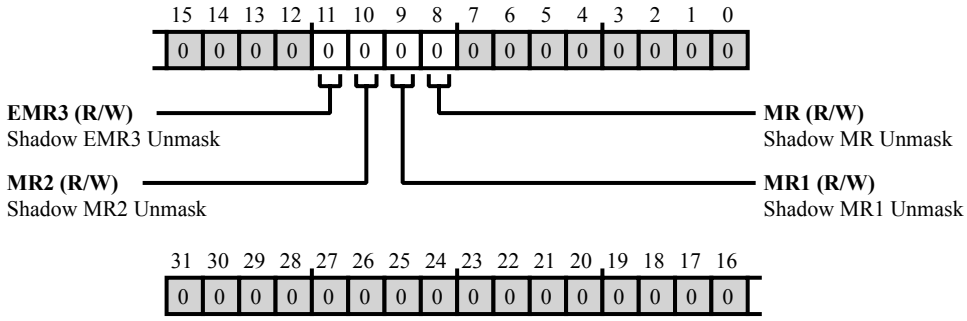

Figure 9-15: DMC_MSK Register Diagram

Table 9-23: DMC_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EMR3	Shadow EMR3 Unmask. The DMC_MSK.EMR3 bit masks or unmasks writes to the EMR3 register in the SDRAM. When masked, writes to this register instead go to the EMR3 register. When unmasked, the DMC writes the EMR3 value to the EMR3 register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR3
		1	Unmask (Enable) Write to EMR3
10 (R/W)	MR2	Shadow MR2 Unmask. The DMC_MSK.MR2 bit masks or unmasks writes to the MR2 register (in DDR3 mode) in the SDRAM. When masked, writes to this register instead go to the DMC_MR2 register. When unmasked, the DMC writes the DMC_MR2 value to the MR2 register (in DDR3 mode) in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR2
		1	Unmask (Enable) Write to EMR2

Table 9-23: DMC_MSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	MR1	Shadow MR1 Unmask. The DMC_MSK.MR1 bit masks or unmasks writes to the MR1 register in the DDR3 SDRAM. When masked, writes to this register instead go to the DMC_MR1 register. When unmasked, the DMC writes the DMC_MR1 value to the MR1 register in the SDRAM. After completing the write, the DMC clears this bit. Note that this bit is valid only for DDR3 Mode of operation.	
		0	Mask (Disable) Write to EMR1
		1	Unmask (Enable) Write to EMR1
8 (R/W)	MR	Shadow MR Unmask. The DMC_MSK.MR bit masks or unmasks writes to the MR register in the SDRAM. When masked, writes to this register instead go to the DMC_MR register. When unmasked, the DMC writes the DMC_MR value to the MR register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to MR
		1	Unmask (Enable) Write to MR

Priority ID Register 1

The DMC_PRIO register allows transactions from selected masters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK register to obtain a single SCB ID or a range of IDs that get elevated priority.

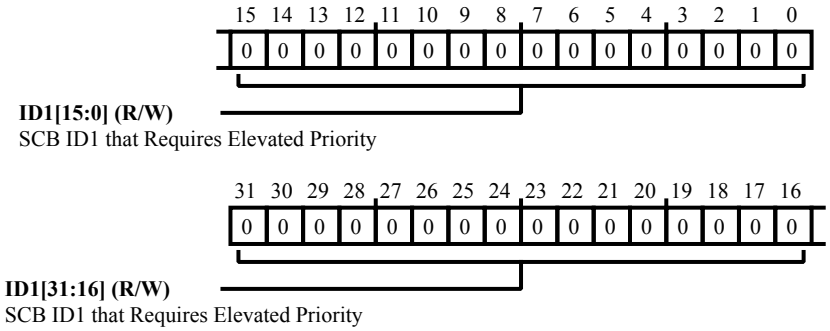

Figure 9-16: DMC_PRIO Register Diagram

Table 9-24: DMC_PRIO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1	SCB ID1 that Requires Elevated Priority.

Priority ID Register 2

The DMC_PRIO2 register is another register which allows transactions from selected masters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

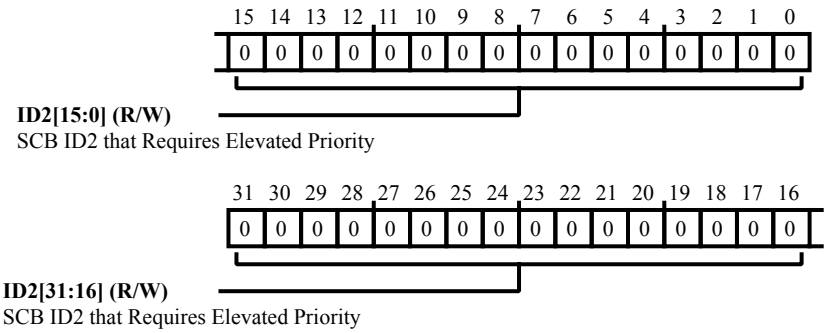

Figure 9-17: DMC_PRIO2 Register Diagram

Table 9-25: DMC_PRIO2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2	SCB ID2 that Requires Elevated Priority.

Priority ID Mask Register 1

The DMC_PRIOMSK register masks the respective ID bits in the DMC_PRIOMSK register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

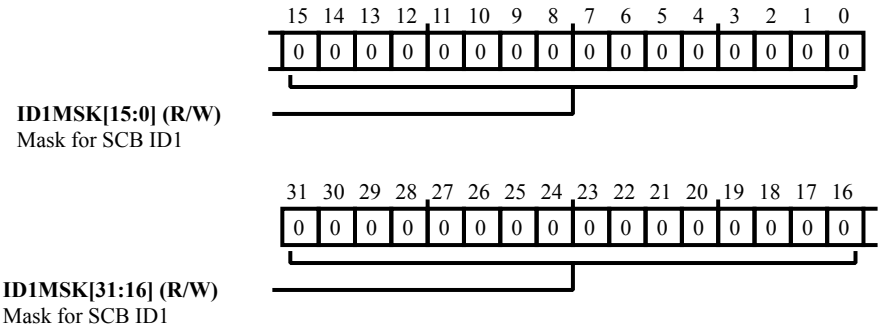

Figure 9-18: DMC_PRIOMSK Register Diagram

Table 9-26: DMC_PRIOMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1MSK	Mask for SCB ID1.

Priority ID Mask Register 2

The DMC_PRIOMSK2 register bits mask the respective ID bits in the DMC_PRIO2 register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

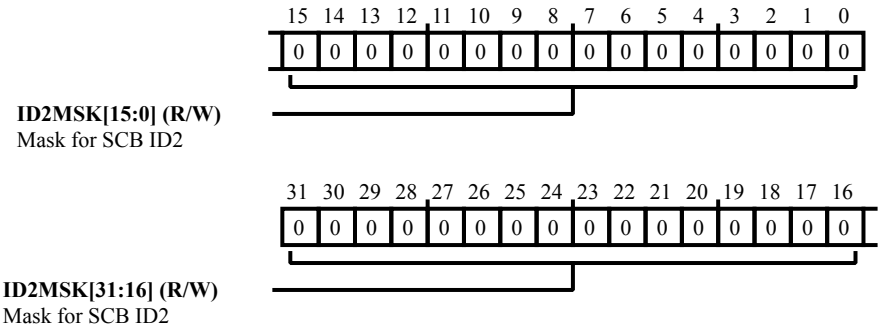

Figure 9-19: DMC_PRIOMSK2 Register Diagram

Table 9-27: DMC_PRIOMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2MSK	Mask for SCB ID2.

DMC Read Data Buffer ID Register 1

The DMC_RDDATABUFID1 register allows read transactions from selected masters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK1 register to obtain a single SCB ID or a range of IDs that get elevated priority.

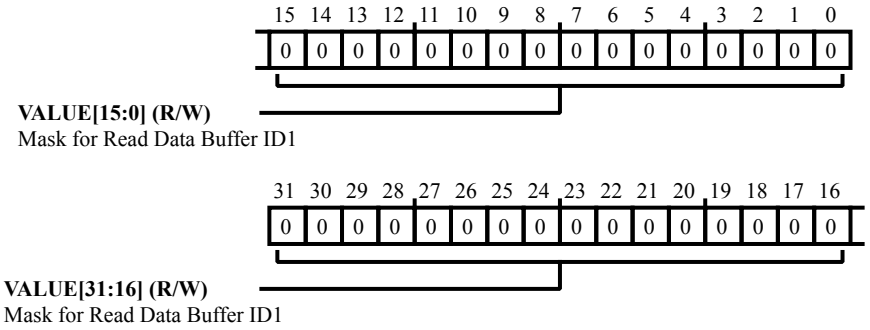

Figure 9-20: DMC_RDDATABUFID1 Register Diagram

Table 9-28: DMC_RDDATABUFID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer ID Register 2

The DMC_RDDATABUFID2 register allows read transactions from selected masters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

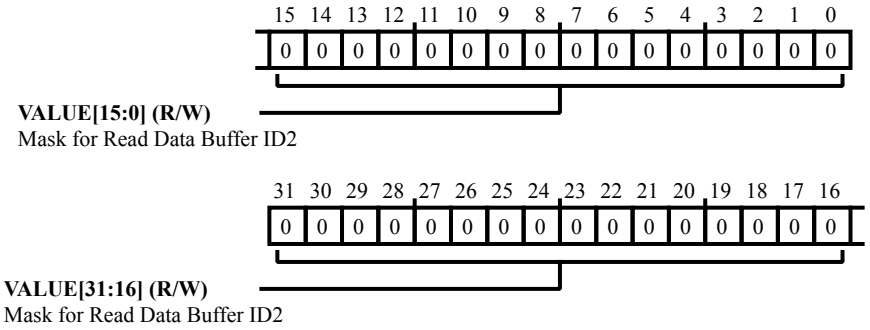

Figure 9-21: DMC_RDDATABUFID2 Register Diagram

Table 9-29: DMC_RDDATABUFID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

DMC Read Data Buffer Mask Register 1

The DMC_RDDATABUFMSK1 register bits mask the respective ID bits in the DMC Priority Mask ID register.

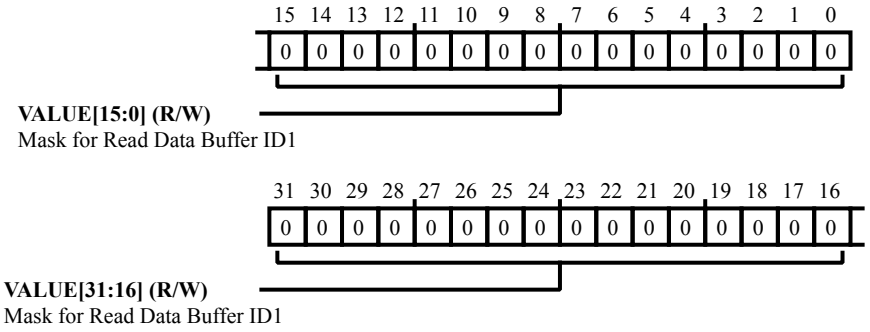

Figure 9-22: DMC_RDDATABUFMSK1 Register Diagram

Table 9-30: DMC_RDDATABUFMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer Mask Register 2

The DMC_RDDATABUFMSK2 register bits mask the respective ID bits in the DMC Priority Mask ID register.

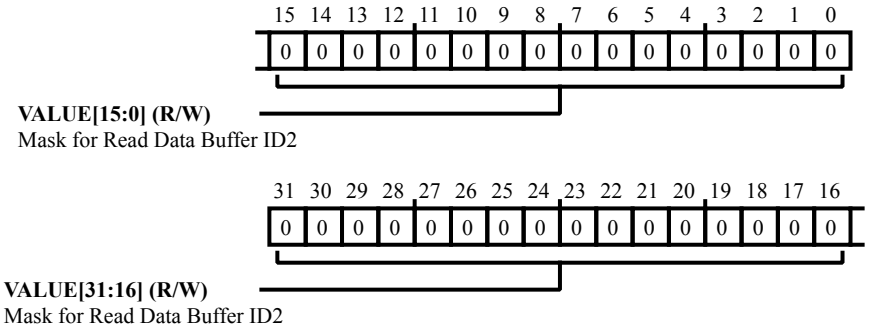

Figure 9-23: DMC_RDDATABUFMSK2 Register Diagram

Table 9-31: DMC_RDDATABUFMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

Status Register

The DMC_STAT register indicates status for modes selected with the DMC_CTL register and indicates status DMC operations.

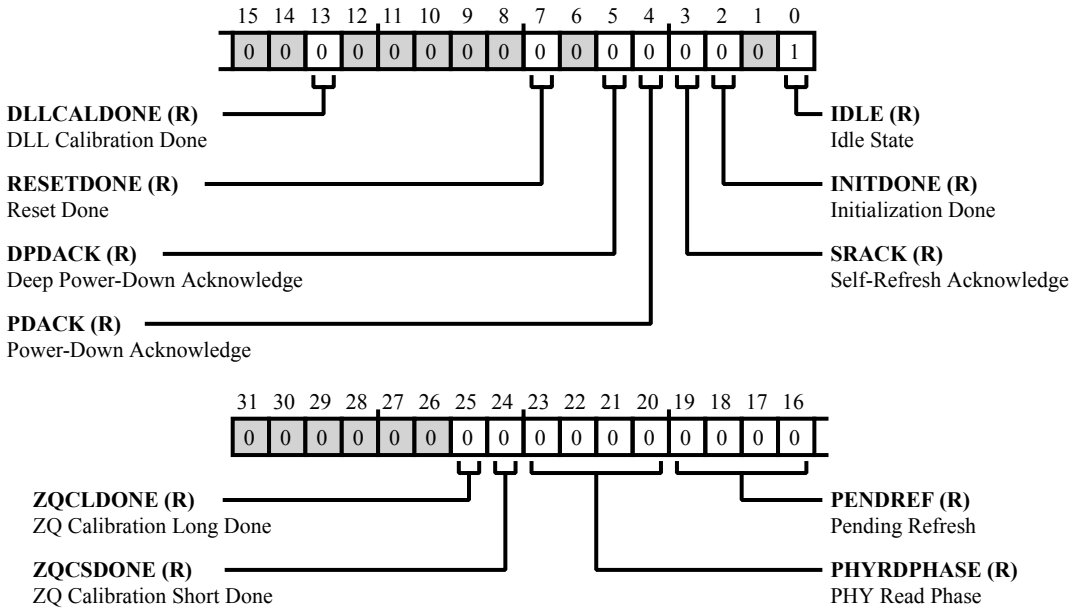

Figure 9-24: DMC_STAT Register Diagram

Table 9-32: DMC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	ZQCLDONE	ZQ Calibration Long Done. The DMC_STAT.ZQCLDONE bit checks if the ZQ calibration long sub routine is done.	
		0	ZQ Calibration long is ongoing
		1	ZQ Calibration long is done
24 (R/NW)	ZQCSDONE	ZQ Calibration Short Done. The DMC_STAT.ZQCSDONE bit checks if the ZQ calibration short sub routine is done.	
		0	ZQ Calibration short is ongoing
		1	ZQ Calibration Short is done
23:20 (R/NW)	PHYRDPHASE	PHY Read Phase. The DMC_STAT.PHYRDPHASE bits indicate the latency after which the DMC may read from the PHY. Taking round trip delay into account, the DLL indicates the exact number of clock cycles after which the controller needs to read data. Values other than those shown are reserved.	

Table 9-32: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	2 Clock Cycles Latency
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7Clock Cycles Latency
19:16 (R/NW)	PENDREF	Pending Refresh. The DMC_STAT.PENDREF bits indicate the number of pending auto-refresh commands whose value can be from "0000" to "0111".	
13 (R/NW)	DLLCALDONE	DLL Calibration Done. The DMC_STAT.DLLCALDONE indicates that the PHY DLL calibration sequence is complete.	
		0	No Status
		1	Completed PHY DLL Calibration
7 (R/NW)	RESETDONE	Reset Done. The DMC_STAT.RESETDONE bit indicates that the reset sequence is complete.	
		0	SDRAM Reset is ongoing
		1	SDRAM Reset is done
5 (R/NW)	DPDACK	Deep Power-Down Acknowledge. The DMC_STAT.DPDACK bit indicates that deep power-down mode is active. Note that this status is available in low power DDR mode (DMC_CTL.LPDDR =1) only.	
		0	Not in Deep Power-Down Mode
		1	Deep Power-Down Mode Active
4 (R/NW)	PDACK	Power-Down Acknowledge. The DMC_STAT.PDACK bit indicates that power-down mode is active.	
		0	Not in Power-Down Mode
		1	Power-Down Mode Active
3 (R/NW)	SRACK	Self-Refresh Acknowledge. The DMC_STAT.SRACK bit indicates that self-refresh mode is active.	
		0	Not in Self-Refresh Mode
		1	Self-Refresh Mode Active

Table 9-32: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	INITDONE	Initialization Done. The `DMC_STAT.INITDONE` bit indicates that the initialization sequence is complete.	
		0	No Status
		1	Initialize Done
0 (R/NW)	IDLE	Idle State. The `DMC_STAT.IDLE` bit indicates whether the DMC is idle or busy.	
		0	Busy
		1	Idle

Timing 0 Register

The DMC_TR0 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR0 are in increments of clock cycle time (t_{CK}).

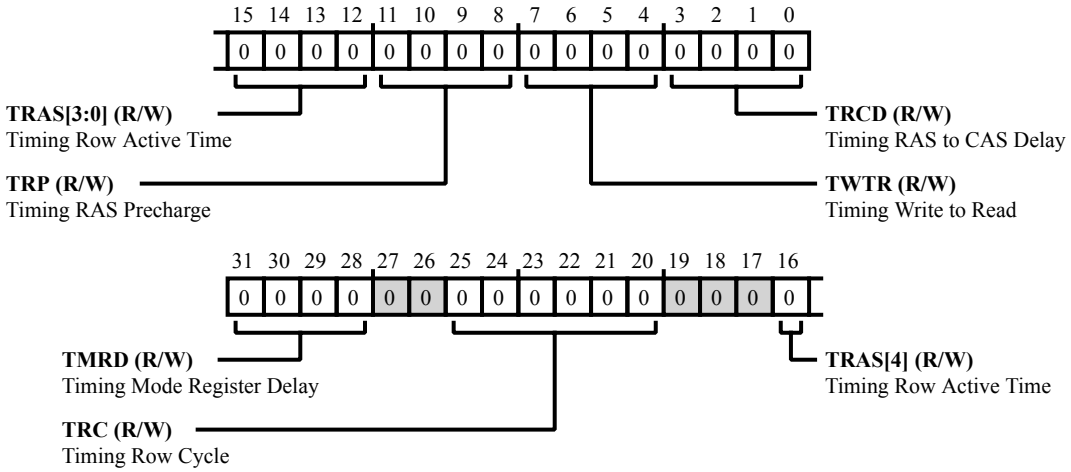

Figure 9-25: DMC_TR0 Register Diagram

Table 9-33: DMC_TR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	TMRD	Timing Mode Register Delay. The DMC_TR0.TMRD field selects the set-to-active timing parameter (t_{MRD}), which is the number of clock cycles that occur after the mode registers in the SDRAM are set and before the next command is issued.
25:20 (R/W)	TRC	Timing Row Cycle. The DMC_TR0.TRC field selects the active-to-active time (t_{RC}), which is the minimum number of clock cycles that occur from an active command to the next active command in the same bank.
16:12 (R/W)	TRAS	Timing Row Active Time. The DMC_TR0.TRAS field selects the active-to-precharge time (t_{RAS}), which is the number of clock cycles that occur from an active command until a precharge command is allowed.
11:8 (R/W)	TRP	Timing RAS Precharge. The DMC_TR0.TRP field selects the precharge-to-active time (t_{RP}), which is the number of clock cycles that occur while the SDRAM recovers from a precharge command and becomes ready to accept the next active command.

Table 9-33: DMC_TR0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	TWTR	Timing Write to Read. The `DMC_TR0.TWTR` field selects the write-to-read delay time (t_{WTR}), which is the number of clock cycles that occur from the last write data to the next read command.
3:0 (R/W)	TRCD	Timing RAS to CAS Delay. The `DMC_TR0.TRCD` field selects the RAS to CAS delay time (t_{RCD}), which is the number of clock cycles that occur from an active command to a read/write assertion.

Timing 1 Register

The DMC_TR1 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR1 are in increments of clock cycle time (t_{CK}).

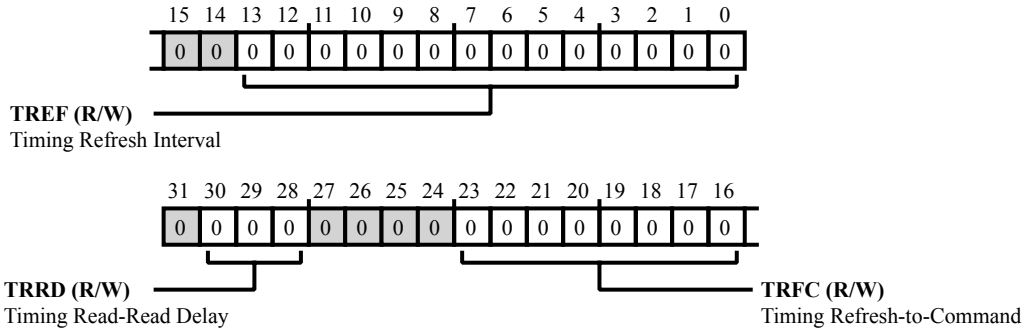

Figure 9-26: DMC_TR1 Register Diagram

Table 9-34: DMC_TR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	TRRD	Timing Read-Read Delay. The DMC_TR1.TRRD field selects the active-to-active time (t_{RRD}), which is the minimum number of clock cycles occurring from a bank x active command to a bank y active command.
23:16 (R/W)	TRFC	Timing Refresh-to-Command. The DMC_TR1.TRFC field selects the refresh-to-active command delay (t_{RFC}), which is the number of clock cycles required for the SDRAM to recover from a refresh signal to be ready to take the next command. It is also the number of clock cycles needed for the SDRAM to recover from executing one active command and ready to accept the next active command.
13:0 (R/W)	TREF	Timing Refresh Interval. The DMC_TR1.TREF field selects the refresh interval time (t_{REF}), which is the number of clock cycles occurring from one refresh command to the next refresh command. The actual timing of issuing a precharge command may be delayed by if the SDRAM is processing a normal access. However, the delay is not accumulative so there is no need to shorten the refresh interval to account for the memory access time. The non-accumulative refresh delay typically increases memory bandwidth by a few percentage points.

Timing 2 Register

The DMC_TR2 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and before initializing the SDRAM.

Note that all values for bit fields in DMC_TR2 are in increments of clock cycle time (t_{CK}).

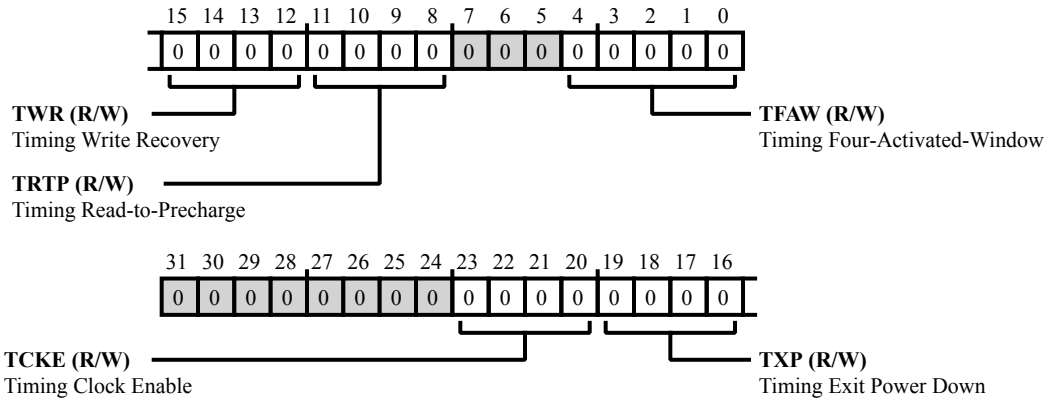

Figure 9-27: DMC_TR2 Register Diagram

Table 9-35: DMC_TR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:20 (R/W)	TCKE	Timing Clock Enable. The DMC_TR2.TCKE field selects the CKE minimum pulsewidth (t_{CKE}).
19:16 (R/W)	TXP	Timing Exit Power Down. The DMC_TR2.TXP field selects the exit power down to next valid command time (t_{XP}).
15:12 (R/W)	TWR	Timing Write Recovery. The DMC_TR2.TWR field selects the write recovery time (t_{WR}). Note that this parameter applies to LPDDR only.
11:8 (R/W)	TRTP	Timing Read-to-Precharge. The DMC_TR2.TRTP field selects the internal read to precharge time (t_{RTP}). If the resulting value is less than 2, the register needs to be programmed with two. Note: Minimum tRTP that needs to be programmed is 2.
4:0 (R/W)	TFAW	Timing Four-Activated-Window. The DMC_TR2.TFAW field selects the four-banks-activated window time (t_{FAW}). No more than four SDRAM banks should be activated within this window.

ADSP-SC57x DMC Register Descriptions

DMCPHY (DMC) contains the following registers.

Table 9-36: ADSP-SC57x DMC Register List

Name	Description
DMC_CAL_PADCTL0	Calibration PAD Control 0 Register
DMC_CAL_PADCTL2	Calibration PAD Control 2 Register
DMC_PHY_CTL0	PHY Control 0 Register
DMC_PHY_CTL1	PHY Control 1 Register
DMC_PHY_CTL2	PHY Control 2 Register
DMC_PHY_CTL3	PHY Control 3 Register
DMC_PHY_CTL4	PHY Control 4 Register

Calibration PAD Control 0 Register

The DMC_CAL_PADCTL0 register sets the pad calibration controls.

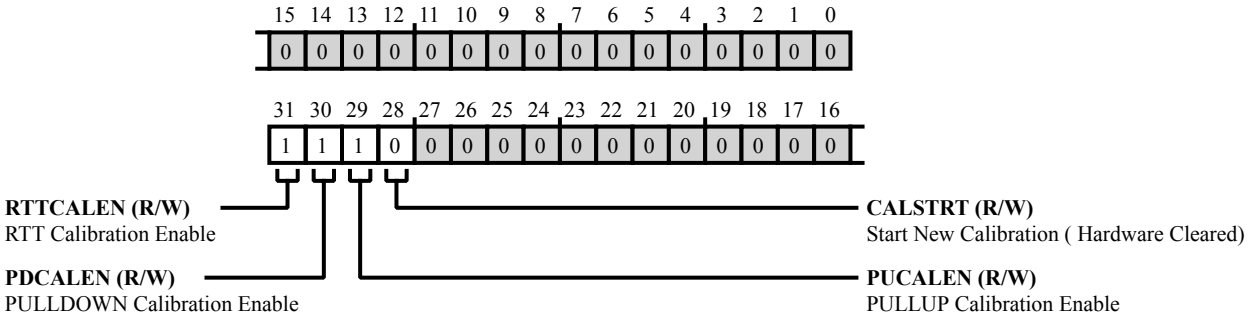

Figure 9-28: DMC_CAL_PADCTL0 Register Diagram

Table 9-37: DMC_CAL_PADCTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	RTTCALEN	RTT Calibration Enable. The DMC_CAL_PADCTL0.RTTCALEN bit is set to 1 at reset. Programming this bit to 0 is not allowed.
30 (R/W)	PDCALEN	PULLDOWN Calibration Enable. The DMC_CAL_PADCTL0.PDCALEN bit is set to 1 at reset. Programming this bit to 0 is not allowed.
29 (R/W)	PUCALEN	PULLUP Calibration Enable. The DMC_CAL_PADCTL0.PUCALEN bit is set to 1 at reset. Programming this bit to 0 is not allowed.
28 (R/W)	CALSTRT	Start New Calibration (Hardware Cleared).

Calibration PAD Control 2 Register

The DMC_CAL_PADCTL2 register sets the pad calibration controls. The DMC pads can be auto-calibrated to the required driver impedance and the On Die Termination (ODT) value using the corresponding bits in this register. These values are translated by the auto calibration logic into a corresponding drive strength control inside the PHY and then routed to the PADS. Auto-calibration starts as soon as the DMC_CAL_PADCTL0.CALSTRT bit is programmed. The DCLK needs to be set at the required frequency before setting the DMC_CAL_PADCTL0.CALSTRT bit.

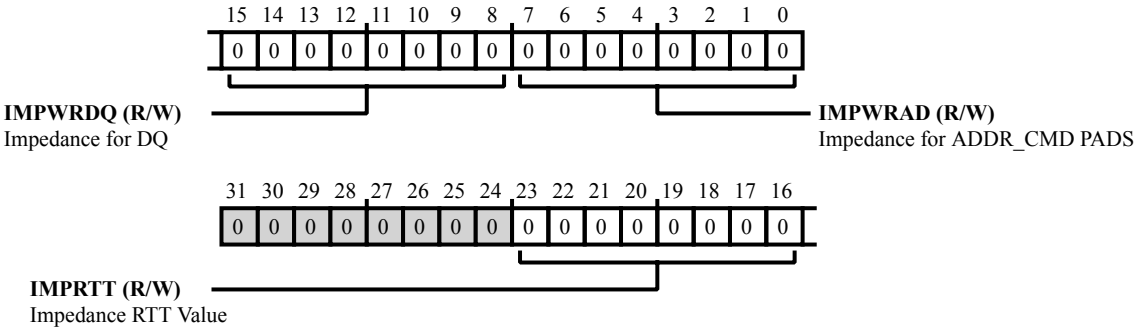

Figure 9-29: DMC_CAL_PADCTL2 Register Diagram

Table 9-38: DMC_CAL_PADCTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	IMPRTT	Impedance RTT Value. Writing to the DMC_CAL_PADCTL2.IMPRTT bit field sets the required initialization sequence to program the termination impedance for the data PADS and the DQS PADS.
15:8 (R/W)	IMPWRDQ	Impedance for DQ. The DMC_CAL_PADCTL2.IMPWRDQ bit field sets the drive impedance for DQ DQS CLK and DM pads. Data pads (DDR_DQ[NN]), DQS pads (DDR_LDQS, /DDR_LDQS, DDR_UDQS, /DDR_UDQS), Clock pads (DDR_CK, /DDR_CK), DM pads (DDR_UDM, DDR_LDM)
7:0 (R/W)	IMPWRAD	Impedance for ADDR_CMD PADS. The DMC_CAL_PADCTL2.IMPWRAD bit field sets the desired drive for address pads (DDR_A[NN]), Command pads (DDR_RAS, DDR_CAS, DDR_CKE, DDR_WE, DDR_CS[N], DDR_ODT).

PHY Control 0 Register

The DMC_PHY_CTL0 register controls programmable PHY features.

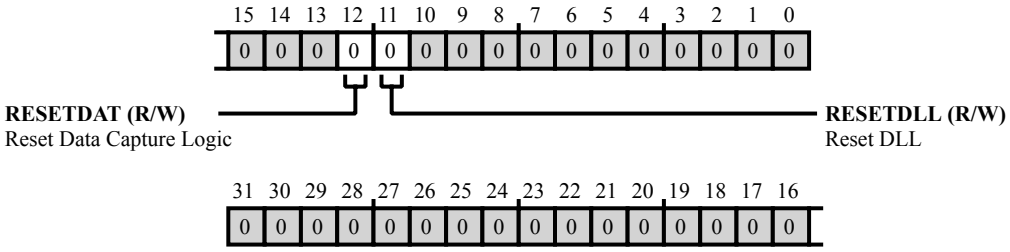

Figure 9-30: DMC_PHY_CTL0 Register Diagram

Table 9-39: DMC_PHY_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	RESETDAT	Reset Data Capture Logic. The DMC_PHY_CTL0.RESETDAT bit resets the data capture logic only, including P and N buffers. If Quickboot is used, this bit does not have any effect. The DMC_PHY_CTL0.RESETDAT bit is reset by the hardware. A read of this bit returns zero.
11 (R/W)	RESETDLL	Reset DLL. The DMC_PHY_CTL0.RESETDLL bit resets DLL control logic only, including the 90 degree DQS shifters. If Quickboot is used, this bit does not have any effect. The DMC_PHY_CTL0.RESETDLL bit is reset by the hardware a read of this bit returns zero.

PHY Control 1 Register

The DMC_PHY_CTL1 register controls programmable PHY features.

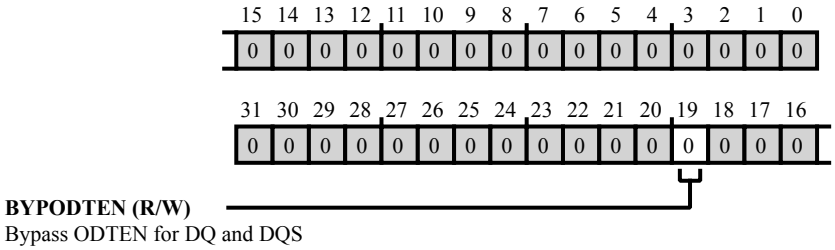

Figure 9-31: DMC_PHY_CTL1 Register Diagram

Table 9-40: DMC_PHY_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	BYPODTEN	Bypass ODTEN for DQ and DQS.	
		0	Reserved
		1	Reserved

PHY Control 2 Register

The DMC_PHY_CTL2 register controls programmable PHY features. Program this register as per the programming guidelines for proper operation of the DMC.

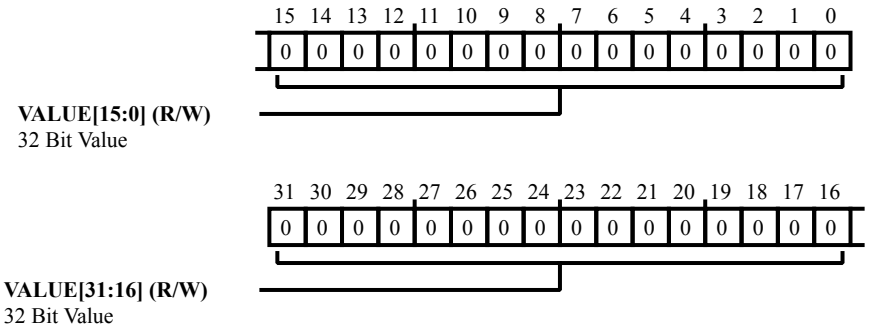

Figure 9-32: DMC_PHY_CTL2 Register Diagram

Table 9-41: DMC_PHY_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	32 Bit Value.

PHY Control 3 Register

The DMC_PHY_CTL3 register controls programmable PHY features. Program this register as per the programming guidelines for proper operation of DMC.

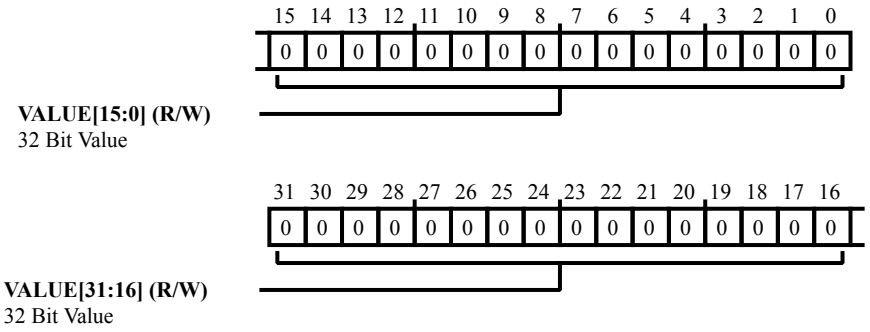

Figure 9-33: DMC_PHY_CTL3 Register Diagram

Table 9-42: DMC_PHY_CTL3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	32 Bit Value.

PHY Control 4 Register

The DMC_PHY_CTL4 register controls programmable PHY features.

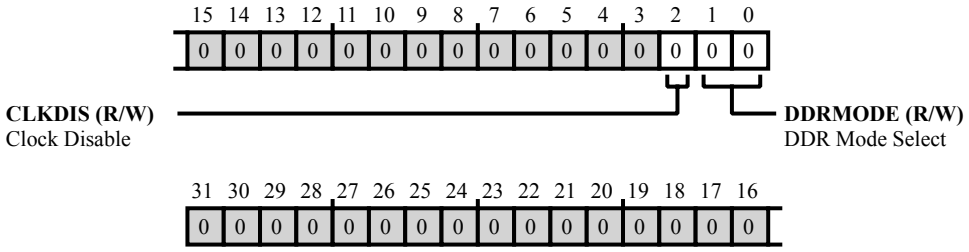

Figure 9-34: DMC_PHY_CTL4 Register Diagram

Table 9-43: DMC_PHY_CTL4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CLKDIS	Clock Disable. The DMC_PHY_CTL4.CLKDIS bit enables and disables the DDR clock.	
		0	Enable Clock
		1	Disable Clock
1:0 (R/W)	DDRMODE	DDR Mode Select. The DMC_PHY_CTL4.DDRMODE bit field selects between the various DDR modes. Not all modes are available on all processors.	
		0	DDR3 Mode
		1	DDR2 Mode
		2	Reserved
		3	LPDDR Mode

10 One-Time Programmable Memory Controller (OTPC)

This chapter describes the operation of the OTP controller. The OTP module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

OTP memory access is through the OTP API Overview provided by the ROM.

CAUTION: OTP memory does not support burst transfers, which are required to support cache line fills. As such, OTP memory should not be made cacheable. If it is, the OTP controller returns an error when a read access is attempted.

OTPC Features

The OTP memory and controller have the following features:

- Built-in redundant read mode
- Built-in integrated power supply
- Built-in Hamming Code Error Correction (ECC)
- Full word serial (single bit at a time) programming with internal VPP

OTPC Functional Description

ADSP-SC57x OTPC Register List

The One-Time-Programmable Memory controller (OTPC) supports programming the OTP memory. A set of registers governs OTPC operations. For more information on OTPC functionality, see the OTPC register descriptions.

Table 10-1: ADSP-SC57x OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register

Table 10-1: ADSP-SC57x OTPC Register List (Continued)

Name	Description
OTPC_STAT	OTP Status Register

ADSP-SC57x OTPC Interrupt List

Table 10-2: ADSP-SC57x OTPC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
6	OTPC0_ERR	OTPC0 Dual-bit error	Level	

Error Correction

The OTP memory features a Hamming error correction implementation. Signal bit errors are automatically corrected, and dual-bit errors are detected. Refer to OTPC Interrupt Signals.

ECC is always enabled. ECC applies to each 16-bit segment. Because of this functionality, each 16-bit location can only be written to once. Writing to a 16-bit location a second time results in unexpected behavior.

OTP Layout

This section details the memory layout of the OTP memory.

Table 10-3: OTP Layout

Name	Byte Address	Size (bits)	Description
Customer OTP Area - 896 bytes			
huk	0x0 + 0 - 0x1c	256	Hardware unique key
pvt_128key0	0x168 + 0 - 0x174	128	Customer private key 0 128bits
pvt_128key1	0x178 + 0 - 0x184	128	Customer private key 1 128bits
pvt_128key2	0x188 + 0 - 0x194	128	Customer private key 2 128bits
pvt_128key3	0x198 + 0 - 0x1a4	128	Customer private key 3 128bits
ek	0x1a8 + 0 - 0x1c4	256	Endorsement key
secure_emu_key	0x1c8 + 0 - 0x1d4	128	Secure emulation key
Reserved	0x1d8 + 0 - 0x1fc	320	Reserved
public_key0	0x200 + 0 - 0x23c	512	Customer public key 0
public_key1	0x240 + 0 - 0x27c	512	Customer public key 1
boot_info	0x280 + 0 - 0x2bc	512	Customer programmable boot information

Table 10-3: OTP Layout (Continued)

Name	Byte Address	Size (bits)	Description
antiroll_nv_cntr	0x2c0 + 0 - 0x2fc	512	AntiRollback NV counter
gp1	0x300 + 0 - 0x33c	512	General purpose 1
Reserved	0x340 + 0 - 0x340	24	Reserved
bootModeDisable	0x343 + 24 - 0x343	8	Boot mode disable bits
preboot_ddr_cfg	0x344 + 0 - 0x370	384	User preboot DDR configuration
stageID	0x374 + 0 - 0x376	48	Stage ID
Reserved	0x37a + 16 - 0x37a	16	Reserved
Reserved	0x37c + 0 - 0x37c	32	Reserved
Overlaid Fields in Customer OTP Area			
otpTiming	0x2be + 16 - 0x2be	16	OTP read timing override
Overlaid Fields in ADI BOOT			
Customer BOOT - 116 Bytes			
lock	0x48c + 0 - 0x48c	1	Lockbit
Reserved	0x48c + 1 - 0x4fc	927	Reserved

OTPC Event Control

The following sections provide information on OTP events and error management.

OTPC Interrupt Signals

When making 32-bit accesses to OTP memory, a double-bit error in any 16-bit segment triggers the OTPC_INT interrupt. The OTPC also has the OTPC dual bit error (OTPC0_ERR) with the SEC ID of 5 and the GIC ID of 37. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for more information.

OTPC Status and Error Signals

The OTP controller does not produce error signals.

OTP API Overview

The ROM provides a set of functions to facilitate OTP field access. The OTP memory is broken up into a set of specialized fields that are described in this section. The API removes the requirement of understanding the details of the layout or OTP access procedures.

All OTP accesses are made through the provided API.

OTP Programming

The OTP programming API provides a simple access, abstracting particulars of the OTP controller.

Any fields that contain zero or null pointers are skipped.

All addresses are assumed to be byte addresses unless otherwise noted.

A list of APIs follows:

`bool adi_rom_otp_pgm(otp_data* data);`	OTP Program
`bool adi_rom_lock();`	Lock API

OTP Program

Program OTP memory using a struct containing the following predefined data fields.

Name	OTP Program	-
PP Define	`FUNC_ROM_OTPPGM`	
Prototype	`bool adi_rom_otp_pgm(otp_data* data);`	-
Argument	data	struct containing data to program OTP with
Return Value	bool	true for programming success
Stack Requirements	valid stack	-

```
bool res = adi_rom_otp_pgm(data);
```

The following type of struct is available for programming. Refer to the ROM header file for the exact definition

```
typedef struct {
    uint32_t (*huk)[8];
    uint32_t (*pvt_128key1)[4];
    uint32_t (*pvt_128key2)[4];
    uint32_t (*pvt_128key3)[4];
    uint32_t (*pvt_128key4)[4];
    uint32_t (*pvt_192key1)[6];
    uint32_t (*pvt_192key2)[6];
    uint32_t (*public_key0)[16];
    uint32_t (*public_key1)[16];
    uint32_t (*ek)[8];
    uint32_t (*secure_emu_key)[4];
    uint8_t  bootModeDisable;
    uint32_t (*boot_info)[16];
    uint32_t (*gp0)[16];
    uint32_t antiroll_nv_cntr;
    uint8_t  stageID;
    uint32_t (*preboot_ddr_cfg)[11];
} otp_data;
```

NOTE: Make OTP memory a non-cacheable region if the core needs access to it.

OTP Reading

This API provides a unified source for retrieving OTP data fields.

All addresses are assumed to be byte addresses, unless otherwise noted.

A list of APIs follow:

`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	OTP Get Field

OTP Get Field

Retrieves indicated data from OTP memory.

Name	OTP Get Field	
Prototype	`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	
Argument	cmd	Indicates what data to fetch, based on the`OTPCMD` enum.
Argument	data	memory location to write the data to
Return Value	bool	true for a successful read
Stack Requirements	valid stack	

```
bool res = adi_rom_otp_get(otpcmd_info,data);
```

The data specified by the `OTPCMD` enum parameter is fetched from OTP memory and placed in the location specified by data. The `OTPCMD` enum contains entries for each field defined in OTP memory, for the most current list, refer to the OTP header file.

An example of the enum style follows:

```
                /*  Field Name                Description                 No of
Bits */
                typedef enum {
                  /* add msi bits */
                  otpcmd_reserved0 = 0,
                  otpcmd_pvt_128key1,      /* Private 128-bit Key 1
[128] */
                  otpcmd_pvt_128key2,      /* Private 128-bit Key 2
[128] */
                  otpcmd_pvt_128key3,      /* Private 128-bit Key 3
[128] */
                  otpcmd_pvt_128key4,      /* Private 128-bit Key 4
[128] */
                  otpcmd_pvt_192key1,      /* Private 192-bit Key 1
```

```
[192] */
                otpcmd_pvt_192key2,      /* Private 192-bit Key 2
[192] */
                otpcmd_huk,              /* Hardware Unique Key
[256] */
                otpcmd_ek,               /* Endorsement Key (EK)
[256] */
                otpcmd_secure_emu_key,   /* Secure Emulation Key
[128] */
                otpcmd_public_key1,      /* Customer Public Key 1
[512] */
                otpcmd_public_key2,      /* Customer Public Key 2
[512] */
                otpcmd_antiroll_nv_cntr, /* Anti-Rollback NV Counter
[32] */
                otpcmd_nonvolatile_cntr, /* NV Counter
[32] */
                otpcmd_bootModeDisable,  /* Boot Mode disable
field            [8] */
                otpcmd_stageID,          /* Stage
ID                          [8] */
                otpcmd_gp0,              /* General Purpose
[512] */
                otpcmd_boot_info,        /* Customer Programmable Boot info
[384] */
                otpcmd_preboot_ddr_cfg,  /* User Preboot DDR configuration
[352] */
                otpcmd_reserved1        /* invalid */
              } OTPCMD;
```

OTP Counters

The OTPC module implements a counter API to allow easy reading or writing of the counter without dealing with the complexities of rewriting OTP memory sections that are ECC protected.

The OTPC module provides two functional APIs for counters. These APIs are not extra; the module uses the same `get` and `pgm` APIs. The APIs are functionally unique in the way that they set and retrieve data as counters in OTP memory.

The API uses a different method to count bits because each bit in OTP memory can only be set =1 once, and the ECC protects each 16-bit unit. This functionality essentially means that each 16-bit unit can only be written to once. Therefore, a counter that can count 0–31 requires 32 × 16 bits of memory.

The API receives and returns the value of the counter as a `uint8_t` binary number. Writing a value less than the current value of the counter or greater than the maximum value results in an error.

To implement this functionality, the driver counts by shifting 1's from the left, treating each block as 1 bit. A three-bit counter is encoded as follows.

bit 2	bit 1	bit 0	Value
0000	0000	0000	0
0001	0000	0000	1
0001	0001	0000	2
0001	0001	0001	3

Lock API

This API locks the device.

Name	Lock API	-
PP Define	`FUNC_ROM_LOCK`	-
Prototype	`bool adi_rom_lock();`	-
Return Value	bool	true for success
Stack Requirements	valid stack	-

```
bool res = adi_rom_lock();
```

Calling this function locks the device, making it a secure. Once locked, the `OTPC_SECU_STATE` register indicates that the part is locked, and access is limited. For more information, refer to the security documentation regarding a locked device.

NOTE: Locked Status. The `OTPC_SECU_STATE` register is updated only after the part is rebooted. After calling the lock function, the register still indicates that the part is open.

ADSP-SC57x OTPC Register Descriptions

OTP Memory Controller (OTPC) contains the following registers.

Table 10-4: ADSP-SC57x OTPC Register List

Name	Description
`OTPC_SECU_STATE`	OTP Security State Register
`OTPC_STAT`	OTP Status Register

OTP Security State Register

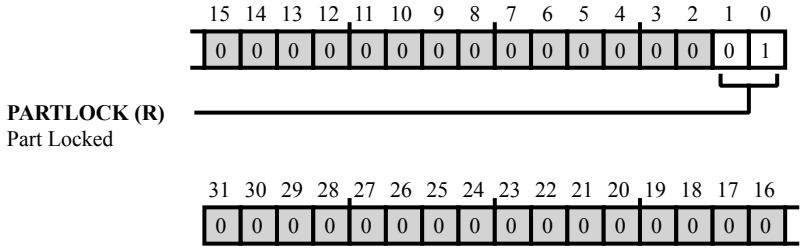

Figure 10-1: OTPC_SECU_STATE Register Diagram

Table 10-5: OTPC_SECU_STATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PARTLOCK	Part Locked. The `OTPC_SECU_STATE.PARTLOCK` bit indicates a locked part.	
		0	OPEN part
		1	Locked part
		2	Reserved

OTP Status Register

The OTPC_STAT register bits indicate errors and flag status and control the protection bits.

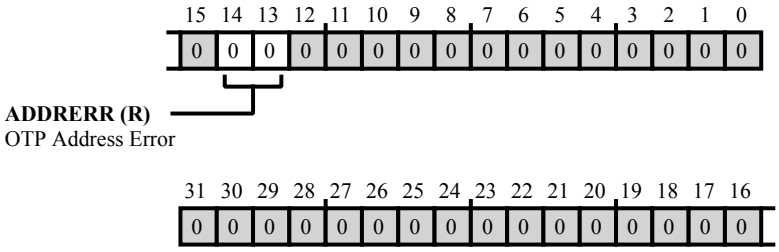

Figure 10-2: OTPC_STAT Register Diagram

Table 10-6: OTPC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/NW)	ADDRERR	OTP Address Error. The OTPC_STAT.ADDRERR bit field indicates errors which occur when the OTP programming address is out of range or tries to access protected space.	
		0	No error - proper OTP address
		1	OTP address out of range
		2	8-bit OTP address
		3	Protected OTP address

11 System Memory Protection Unit (SMPU)

The SMPU provides a flexible way of protecting memory regions against read or write access from any or all masters in the system. In addition, it can guard against memory access depending on security privileges of the system master.

SMPU Features

The system memory protection unit has the following features.

- After reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces by any master.
- Each SMPU instance can be configured to monitor multiple regions. Each can be individually enabled.
- Each region can be configured with its own protection settings.
- Provides general read or write protection.
- Read and write transactions are restricted or allowed depending on the transaction ID.

On the ADSP-SC57x, four SMPU instances are available to protect the L2, external memory (DMC) interface.

Table 11-1: SMPU Instances

Module	SMPU Instance
Core_L2	2
DMA_L2	3
DMC0	9

All the SMPU instances can be configured up to eight regions.

- Up to eight outstanding read or write transactions supported on SMPU instances for Core_L2 and DMC0. Up to four outstanding read or write transactions supported on the SMPU instances for DMA_L2.
- Exclusive access enabled by hardware for the SMPU instances of Core_L2 and DMC0. Up to four exclusive-access-capable masters can be supported.

SMPU Functional Description

The following sections provide details on the function of the SMPU module. If the region security settings allow transactions to go through, the ID in the ID-based region protection settings can still filter the transactions.

For the memory that an SMPU protects, programs can configure region-based settings with the SMPU_RCTL[n] registers. (There can be multiple SMPUs in a system.) The SMPU_RCTL[n] registers define the ID-based protection for memory regions.

If the target address does not reside in any configured memory region, the transaction permission resorts back to the global configuration setting.

Protection Units

Each SMPU provides two protection units, A and B for ID-based matching in the region-based memory protection. This feature provides a degree of flexibility for the user to match against multiple IDs.

Instruction Fetches

When the core executes instructions from memory, this operation is also considered a memory transaction. If the SMPU is configured to protect a memory region from read accesses that contain instructions, the core cannot fetch and execute these instructions.

Speculative Reads

If speculative reads are enabled (SMPU_CTL.RSDIS =0), the SMPU forwards the read transaction directly to the memory before checking the protection setting corresponding to the addressed memory region. This functionality saves one clock cycle in the clock domain of the SMPU. The SMPU checks the protection setting while the read transaction occurs with the memory. If the protection setting dictates that the target memory address is blocked, the SMPU blocks the read to the master.

If speculative reads are disabled (SMPU_CTL.RSDIS =1), the SMPU checks the protection settings first and forwards the transaction to memory only if it passes the configured protection settings. This functionality incurs a one-cycle latency per read.

NOTE: Reads affect certain memory operations such as automatic clearing of the memory (that is, FIFOs). When the SMPU protects this type of memory, disable read speculation since the blocking can occur without the read transaction reaching the target memory.

ADSP-SC57x SMPU Register List

The System Memory Protection Unit (SMPU) provides selective protection of the processor's memory resources. The SMPU includes a set of processor events that can be monitored during program execution. A set of registers governs SMPU operations. For more information on SMPU functionality, see the SMPU register descriptions.

Table 11-2: ADSP-SC57x SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

ADSP-SC57x SMPU Interrupts

The SMPU has one interrupt with the SEC ID = 201. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for complete information on interrupt generation and use.

Memory Writes

A write transaction to address n is prevented when the following is true.

Address n is in memory region m and memory region m is write-protected (SMPU_RCTL[n].WPROTEN =1) and ID is not a match. (See ID Comparison). The block occurs because the memory region is configured for write-protection and the ID comparison does not result in a match. If an ID comparison results in a match, the write transaction is allowed through.

Memory Reads

A read transaction from address n is prevented when the following is true:

- Address n is in memory region and memory region m is read-protected (SMPU_RCTL[n].RPROTEN =1) and

- ID is not a match

The block occurs because the memory region is configured for read-protection and the ID comparison does not result in a match. If the ID comparison results in a match, the read transaction is permitted. (See ID Comparison).

ID Comparison

ID comparison automatically occurs during region-based memory protection. ID matches allow the transaction to bypass the configured memory protection for that region. The following sections describe the calculation of a write ID match and read ID match.

Write Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming write transaction:

- The `SMPU_RCTL[n].WIDCINV` bit
- The `SMPU_RIDA[n].ID` and `SMPU_RIDB[n].ID` bit fields
- The `SMPU_RIDMSKA[n].MSK` and `SMPU_RIDMSKB[n].MSK` bit fields

Write IDA match = ((ID of incoming write transaction AND `SMPU_RIDMSKA[n].MSK`) == (`SMPU_RIDA[n].ID` AND `SMPU_RIDMSKA[n].MSK`))

Write IDB match = ((ID of incoming write transaction AND `SMPU_RIDMSKB[n].MSK`) == (`SMPU_RIDB[n].ID` AND `SMPU_RIDMSKB[n].MSK`))

Write ID match = (Write IDA match OR Write IDB match) XOR `SMPU_RCTL[n].WIDCINV` bit

Read Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming read transaction:

- The `SMPU_RCTL[n].RIDCINV` bit
- The `SMPU_RIDA[n].ID` and `SMPU_RIDB[n].ID` bit fields
- The `SMPU_RIDMSKA[n].MSK` and `SMPU_RIDMSKB[n].MSK` bit fields

Read IDA match = ((ID of incoming read transaction AND `SMPU_RIDMSKA[n].MSK`) == (`SMPU_RIDA[n].ID` AND `SMPU_RIDMSKA[n].MSK`))

Read IDB match = ((ID of incoming read transaction AND `SMPU_RIDMSKB[n].MSK`) == (`SMPU_RIDB[n].ID` AND `SMPU_RIDMSKB[n].MSK`))

Read ID match = (Read IDA match OR Read IDB match) XOR `SMPU_RCTL[n].RIDCINV`

In the two cases described above, the incoming transaction (either write or read) ID is AND'ed with the configured mask value in protection unit A. It is then compared to the value of the configured ID value which is also AND'ed

with the configured mask value in protection unit A. The mask provides a method to allow a group of IDs to match. This process is also performed for protection unit B. The two outcomes (from A and B) are then OR'ed together.

Depending on the setting of the SMPU_RCTL[n].RIDCINV or the SMPU_RCTL[n].WIDCINV bits, the ID match comparison is inverted or not. The final result after applying the inversion, SMPU_RCTL[n].RIDCINV, or SMPU_RCTL[n].WIDCINV, determines whether the transaction bypasses the protection.

Usage

The masks, SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n], are AND'ed with both the incoming transaction ID and the configured ID in SMPU_RIDA[n].ID and SMPU_RIDB[n].ID, respectively. By default the masks are zero. If ID-based region protection is enabled by setting the SMPU_RCTL[n].WPROTEN or SMPU_RCTL[n].RPROTEN bit fields and the masks are not set, the ID comparison essentially compares zeros. The comparison allows all transactions to bypass (if the region-based security setting is also configured in a way to allow transactions to go through for the region). To have the ID-based region protection to function, the mask registers and ID registers must also be set.

System IDs

The ***System Master IDs*** table provides the IDs for the system masters. An x means that the bit can be a 0 or a 1. There are multiple IDs associated with that particular system master.

Table 11-3: System Master IDs

ASIB Name	IID	SIID	ID
SP0A	0	0	12'b00000000x000
SP0B	0	1	12'b00000000x001
SP1A	0	2	12'b00000000x010
SP1B	0	3	12'b00000000x011
SP2A	0	4	12'b00000000x100
SP2B	0	5	12'b00000000x101
SP3A	0	6	12'b00000000x110
SP3B	0	7	12'b00000000x111
CRC0_CH0	1	6	12'b00010000x110
CRC0_CH1	1	7	12'b00010000x111

Memory Region

Memory regions can start at address 0x00000000 or at any address that is a multiple of its size. The ***Supported Memory Region Size and Alignment*** table shows the memory region sizes that the processor supports and the alignment of the memory region. (X values are do-not-care).

SMPU0 and SMPU2 support a maximum of four regions. SMPU1 supports a maximum of eight regions.

Table 11-4: Supported Memory Region Size and Alignment

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
4KB	0b00000	0xXXXXX000	-
8KB	0b00001	0xXXXXN000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
16KB	0b00010	0xXXXXN000	0x0, 0x4, 0x8, 0xC
32KB	0b00011	0xXXXXN000	0x0, 0x8
64KB	0b00100	0xXXXX0000	-
128KB	0b00101	0xXXXN0000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
256KB	0b00110	0xXXXN0000	0x0, 0x4, 0x8, 0xC
512KB	0b00111	0xXXXN0000	0x0, 0x8
1MB	0b01000	0xXXX00000	-
2MB	0b01001	0xXXN00000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
4MB	0b01010	0xXXN00000	0x0, 0x4, 0x8, 0xC
8MB	0b01011	0xXXN00000	0x0, 0x8
16MB	0b01100	0xXX000000	-
32MB	0b01101	0xXN000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
64MB	0b01110	0xXN000000	0x0, 0x4, 0x8, 0xC

Table 11-4: Supported Memory Region Size and Alignment (Continued)

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
128MB	0b01111	0xXN000000	0x0, 0x8
256MB	0b10000	0xX0000000	-
512MB	0b10001	0xN0000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
1GB	0b10010	0xN0000000	0x0, 0x4, 0x8, 0xC
2GB	0b10011	0xN0000000	0x0, 0x8
4GB	0b10100	0x00000000	-

For the case where the region size is selected as 4 GB, the region address must be at address 0x00000000.

NOTE: If a memory region address is not aligned to its size, the memory region start address protected by the SMPU is the configured address with the corresponding least significant bits masked. For example, if the size is configured for 16 KB (`SMPU_RCTL[n].SIZE` =0b00010), and the base address is configured for `SMPU_RADDR[n].BADDR`=0x00005018, the actual base address used by the SMPU is 0x00004000. When `SMPU_RADDR[n].BADDR` is read back, the program reads 0x00005000. This functionality is because only bits [11:0] are reserved as 0's. Programs must use care when setting the base address as it is not always the true base address.

SMPU Definitions

To make the best use of the SMPU, it is useful to understand the terms in this section.

Global Protection

Guarding of the entire memory space for the particular SMPU instantiation.

Region-Based Protection

Guarding individual segments of memory inside the memory space for the particular SMPU instantiation.

ID Match

A successful comparison of the ID associated with the incoming transaction and the ID and MASK configured in the SMPU.

SMPU Block Diagram

The ***SMPU Top-Level Block Diagram*** shows the SMPU block.

As seen in the diagram, the SMPU sits between the memory port (SCB master port) and the SCB fabric (SCB slave port). It acts as a gateway analyzing the transaction requests. It either rejects the transaction request or allows access based on the user-programmed configuration of the SMPU.

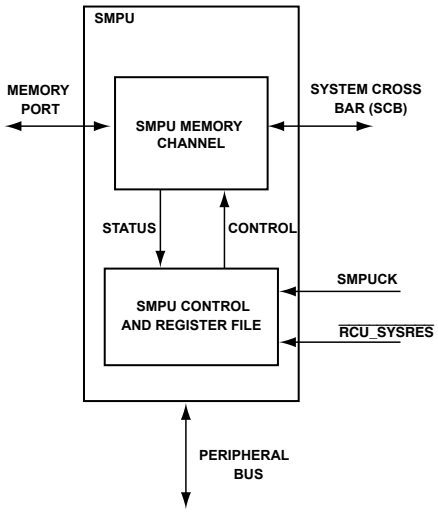

Figure 11-1: SMPU Top-Level Block Diagram

SMPU Architectural Concepts

The following sections provide brief descriptions of the architecture of the SMPU module.

Default Setting

At reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces.

Latency

The SMPU adds latency to all the transactions to the memory except reads when read speculation is enabled (`SMPU_CTL.RSDIS` =0). In this case, read accesses are always forwarded to the memory and read responses are generated according to the SMPU settings. If read speculation is disabled (`SMPU_CTL.RSDIS` =1), reads are blocked if they cause a security or protection violation. The SMPU generates the SCB read response that corresponds to a blocked transaction.

If read speculation is enabled, the SMPU adds 1 clock cycle latency to the read transaction. If read speculation is disabled, the SMPU adds 2 clock cycles latency to the read transaction.

SMPU Operating Modes

The SMPU does not have any strict modes of operation. However, it can be configured for region-based protection where a master with a particular ID can be blocked or allowed based on settings in the `SMPU_RCTL[n]` register.

Region-based protection is programmed with registers:

- `SMPU_RCTL[n]`
- `SMPU_RADDR[n]`
- `SMPU_RIDA[n]`

- SMPU_RIDMSKA[n]
- SMPU_RIDB[n]
- SMPU_RIDMSKB[n]

Exclusive Accesses. On the ADSP-SC57x processors, the hardware supports the exclusive accesses. The exclusive accesses are supported for the SMPU instances that correspond to DMC 0, and Core_L2_0. The exclusive accesses are automatically enabled when one of the cores (SHARC Core 0, SHARC Core 1, and ARM core) executes the exclusive access instruction. Refer to the Programming Reference manual for more details on how the exclusive access works.

SMPU Interrupt Signals

There is one interrupt signal associated with the SMPU. If interrupts are enabled, the SMPU_STAT.IRQ bit is set. The SMPU_IRQ signal is asserted when the SMPU detects a memory access violation. The target address triggering the interrupt is found in the SMPU_IADDR register. The SMPU_IDTLS register provides further details about the cause of the interrupt.

Write errors are prioritized over read errors.

Protection violations (an ID-based violation) can trigger the SMPU interrupt, and can be enabled independently. The protection violation interrupt is enabled by setting the SMPU_CTL.PINTEN bit.

The SMPU interrupt is asserted for any of the following conditions:

If a second memory access violation occurs while the SMPU_STAT.IRQ bit is set, the SMPU_STAT.IOVR (interrupt overrun) bit is set. The SMPU_IADDR and the SMPU_IDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. Any information on the subsequent interrupt is lost. Once the SMPU_STAT.IRQ bit and the SMPU_STAT.IOVR bit are cleared, any new memory access violations can trigger an interrupt and its details can be captured.

NOTE: When a blocked access occurs, the SMPU triggers an interrupt when interrupt generation is enabled. The SMPU can also be configured to generate a bus error that propagates back to the system master. The system master can also trigger an interrupt due to this bus error.

NOTE: On the processor, each SMPU instance has an interrupt. All of the SMPU interrupts are OR'ed and mapped to a single SMPU interrupt on the SEC/GIC. While servicing the SMPU interrupt, check all of the SMPU_STAT registers to determine which triggered the interrupt. The interrupt service routine clears the SMPU_STAT.IRQ bit of the all of the SMPU_STAT registers for which the interrupt is triggered.

SMPU Status and Error Signals

If bus errors are enabled (SMPU_CTL.PBEDIS =0), the SMPU generates and returns a bus error to the master initiating the blocked access. This bit also sets the SMPU_STAT.BERR bit. The SMPU_BADDR and

SMPU_BDTLS registers can be read to get the address and details of the transaction that caused the SMPU to generate the error.

Write errors are prioritized over read errors.

A bus error status is returned to the system master if:

- an ID-based violation happened and the SMPU_CTL.PBEDIS bit =0

If a second memory access violation occurs while the SMPU_STAT.BERR bit is set, the SMPU_STAT.BEOVR bit (bus error overrun) is set. The SMPU_BADDR and the SMPU_BDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. The information about the transaction that caused the SMPU_STAT.BEOVR bit to be set is lost.

NOTE: If both the protection violation interrupt is not enabled (SMPU_CTL.PINTEN =0) and the protection bus error is disabled (SMPU_CTL.PBEDIS =1), the SMPU blocks invalid transactions. However, it does not provide any status or interrupt information indicating that a transaction is blocked.

ADSP-SC57x SMPU Register Descriptions

The System Memory Protection Unit (SMPU) contains the following registers.

Table 11-5: ADSP-SC57x SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register

Table 11-5: ADSP-SC57x SMPU Register List (Continued)

Name	Description
SMPU_STAT	SMPU Status Register

Bus Error Address Register

Programs read the SMPU_BADDR and the SMPU_BDTLS registers to determine the cause of a bus error. Write errors are prioritized over read errors.

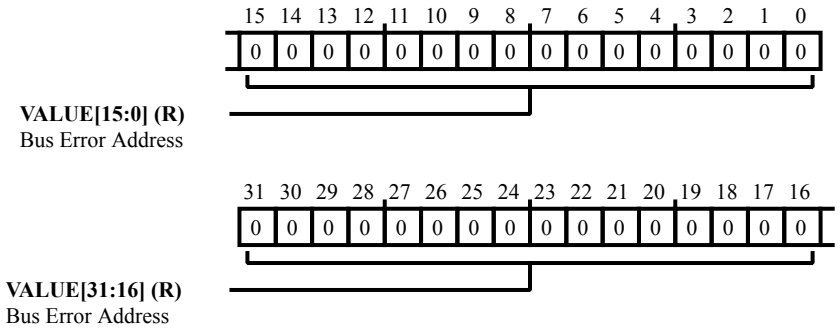

Figure 11-2: SMPU_BADDR Register Diagram

Table 11-6: SMPU_BADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bus Error Address. The SMPU_BADDR.VALUE bit field contains the address of the bus error.

Bus Error Details Register

The SMPU_BDTLS register indicates the ID of the bus error transaction, whether the transaction that caused the last bus error was a read, a write, secure or non-secure.

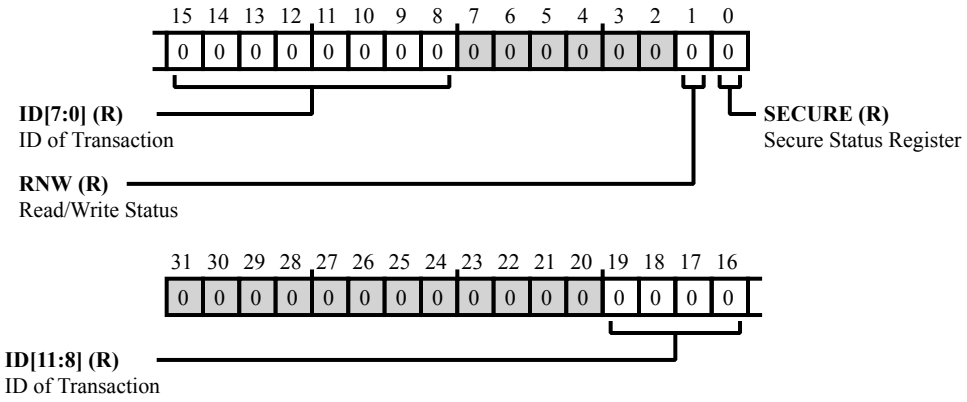

Figure 11-3: SMPU_BDTLS Register Diagram

Table 11-7: SMPU_BDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:8 (R/NW)	ID	ID of Transaction. The SMPU_BDTLS.ID bit field provides the ID of the transaction that caused the bad address error.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_BDTLS.RNW bit indicates whether the last transaction that caused the bad address error was a read or write.	
		0	Transaction that caused last bus error was a write
		1	Transaction that caused last bus error was a read
0 (R/NW)	SECURE	Secure Status Register. The SMPU_BDTLS.SECURE bit indicates whether the last transaction that caused the bad address error was secure or non-secure.	
		0	Transaction that caused last bus error was non-secure
		1	Transaction that caused last bus error was secure

SMPU Control Register

The SMPU_CTL register provides access to the locking control, error interrupts and SMPU violations.

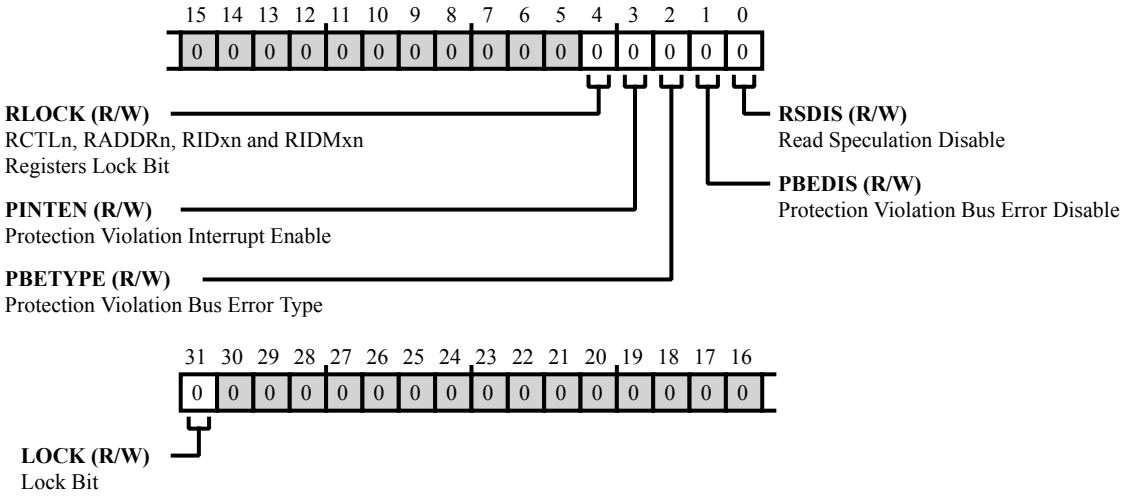

Figure 11-4: SMPU_CTL Register Diagram

Table 11-8: SMPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_CTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_CTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	CTL Global Lock Disable. The SMPU_CTL register is not write-protected.
		1	CTL Global Lock Enable. The SMPU_CTL register is write-protected.
4 (R/W)	RLOCK	RCTLn, RADDRn, RIDxn and RIDMxn Registers Lock Bit. When the SMPU_CTL.RLOCK bit is set, all the registers associated with region-based control (SMPU_RCTL[n], SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n]) are write-protected when the global lock signal is active from the SPU. Write access is allowed again when the global lock signal is deasserted.	
		0	Region Registers Write-Protect Enable. All region registers are not write-protected.
		1	Region Registers Write-Protect Disable. All region registers are write-protected.

Table 11-8: SMPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PINTEN	Protection Violation Interrupt Enable. The SMPU_CTL.PINTEN bit controls whether or not an interrupt is generated when a protection violation occurs.	
		0	Protection Violation IRQ Disable. The protection violation interrupt is disabled.
		1	Protection Violation IRQ Enable. The protection violation interrupt is enabled.
2 (R/W)	PBETYPE	Protection Violation Bus Error Type. The SMPU_CTL.PBETYPE bit controls whether a protection violation produces a decode error or a slave error.	
		0	Decode Error Type. Decode error for transactions that violate the configured protection.
		1	Save Error Type. Slave Error for transactions which violate the configured protection
1 (R/W)	PBEDIS	Protection Violation Bus Error Disable. If set, the SMPU_CTL.PBEDIS bit blocks protection violations, but does not cause a bus error.	
		0	Bus Error Generation Enable. Transactions which violate the configured protection are blocked and cause a bus error.
		1	Bus Error Generation Disable. Transactions which violate the configured protection are blocked but do not cause a bus error.
0 (R/W)	RSDIS	Read Speculation Disable. The SMPU_CTL.RSDIS bit controls whether or not the read addresses are checked before being sent to the slave.	
		0	Read Speculation Enable. Read addresses are sent to the slave without checking.
		1	Read Speculation Disable. Read addresses are checked before being sent to the slave.

Exclusive Access IDn Address

The SMPU_EXACADD[n] register provides the address ID of an exclusive access.

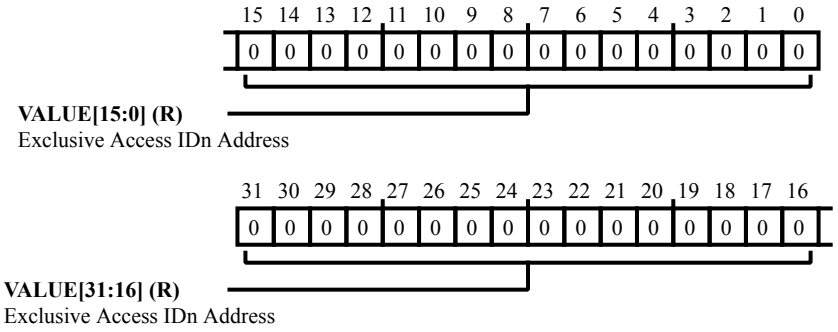

Figure 11-5: SMPU_EXACADD[n] Register Diagram

Table 11-9: SMPU_EXACADD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Exclusive Access IDn Address.

Exclusive Access Status

The SMPU_EXACSTAT[n] register provides the exclusive access ID, read size and read length as well as the indication that the access was valid.

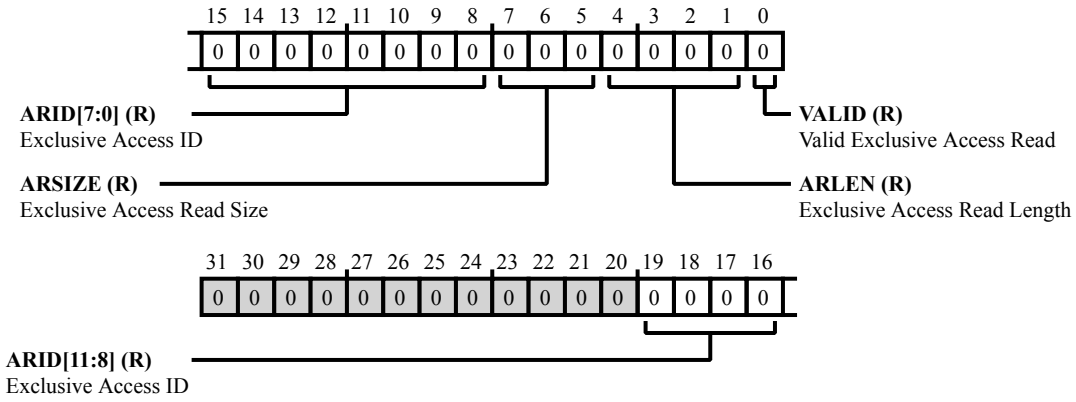

Figure 11-6: SMPU_EXACSTAT[n] Register Diagram

Table 11-10: SMPU_EXACSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:8 (R/NW)	ARID	Exclusive Access ID.
7:5 (R/NW)	ARSIZE	Exclusive Access Read Size.
4:1 (R/NW)	ARLEN	Exclusive Access Read Length.
0 (R/NW)	VALID	Valid Exclusive Access Read.

Interrupt Address Register

The SMPU_IADDR register indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The SMPU issues a bus error for this condition.

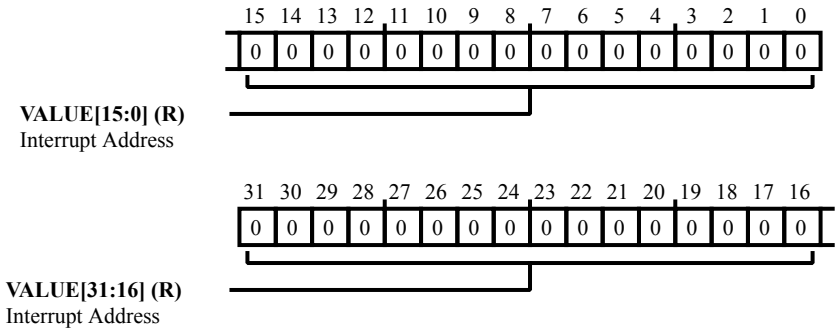

Figure 11-7: SMPU_IADDR Register Diagram

Table 11-11: SMPU_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Interrupt Address. The SMPU_IADDR.VALUE bit field is the address where an attempt to access an unimplemented address or a non-aligned access has occurred.

Interrupt Details Register

The SMPU_IDTLS register provides the ID of the last signaled interrupt, whether the interrupt was caused by a read or write, and whether the transaction that caused the last signaled interrupt was secure.

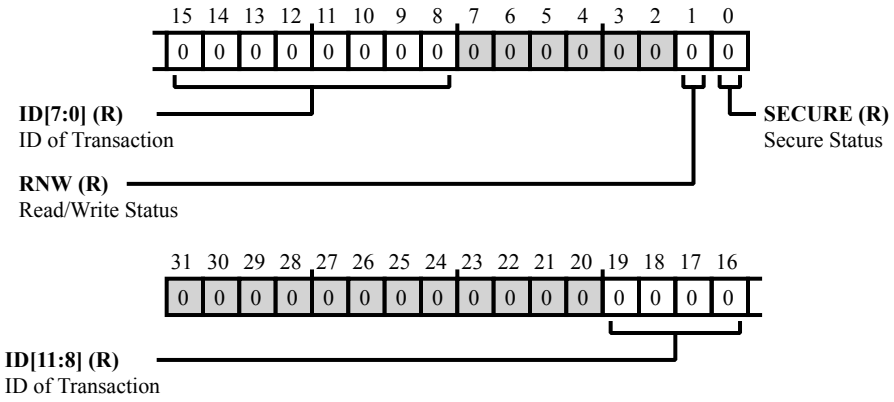

Figure 11-8: SMPU_IDTLS Register Diagram

Table 11-12: SMPU_IDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:8 (R/NW)	ID	ID of Transaction. The SMPU_IDTLS.ID bit field provides the ID of the transaction that caused the interrupt.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_IDTLS.RNW bit indicates whether the last transaction that caused the interrupt was a read or write.	
		0	Transaction that caused last signaled interrupt was a write
		1	Transaction that caused last signaled interrupt was a read
0 (R/NW)	SECURE	Secure Status. The SMPU_IDTLS.SECURE bit indicates whether the last transaction that caused the interrupt was secure or non-secure.	
		0	Transaction that caused last signaled interrupt was non-secure
		1	Transaction that caused last signaled interrupt was secure

Region n Address Register

The SMPU_RADDR[n] register is used to define the base address for a memory region to be protected.

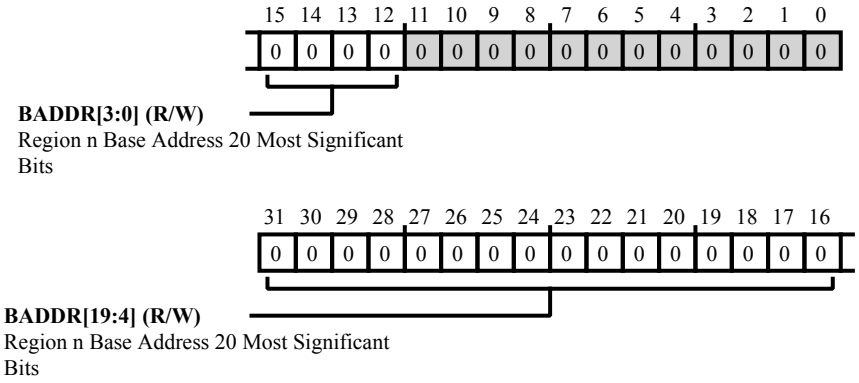

Figure 11-9: SMPU_RADDR[n] Register Diagram

Table 11-13: SMPU_RADDR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/W)	BADDR	Region n Base Address 20 Most Significant Bits. The SMPU_RADDR[n].BADDR bit field defines the base address for a memory region to be protected.

Region n Control Register

The SMPU_RCTL[n] register is used to define the level of protection for a region of memory. The protection of a region is controlled and defined by this register and the SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n], and SMPU_RIDMSKB[n] registers.

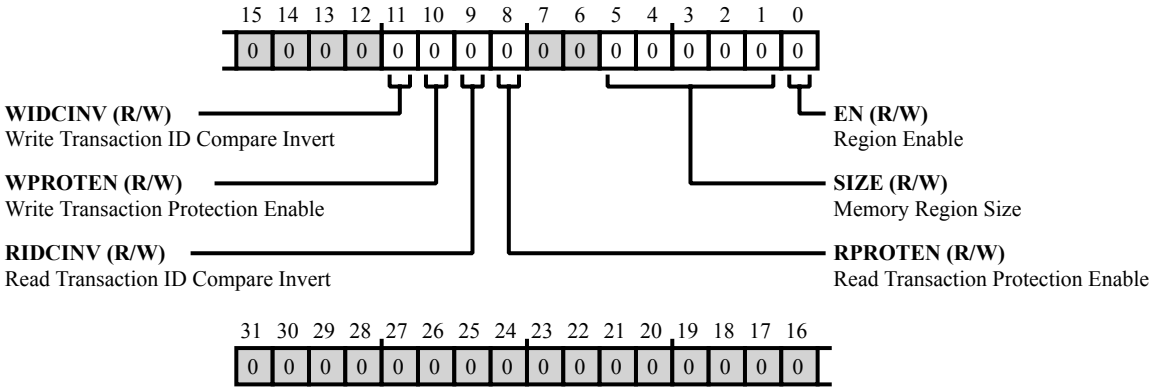

Figure 11-10: SMPU_RCTL[n] Register Diagram

Table 11-14: SMPU_RCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	WIDCINV	Write Transaction ID Compare Invert. The SMPU_RCTL[n].WIDCINV bit inverts the write ID match result.	
		0	Write transaction ID comparison result not inverted
		1	Write transaction ID comparison result inverted
10 (R/W)	WPROTEN	Write Transaction Protection Enable. The SMPU_RCTL[n].WPROTEN bit enables protection against ID-based write transactions for the memory region.	
		0	Write transaction ID-based protection disabled
		1	Write transaction ID-based protection enabled
9 (R/W)	RIDCINV	Read Transaction ID Compare Invert. When the SMPU_RCTL[n].RIDCINV bit is set, the read ID match result is inverted.	
		0	Read transaction ID comparison result not inverted
		1	Read transaction ID comparison result inverted

Table 11-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RPROTEN	Read Transaction Protection Enable. The `SMPU_RCTL[n].RPROTEN` bit enable bit to turn on protection against ID-based read transactions for the memory region.	
		0	Read transaction ID-based protection disabled
		1	Read transaction ID-based protection enabled
5:1 (R/W)	SIZE	Memory Region Size. The `SMPU_RCTL[n].SIZE` bit defines the size of the memory region to be protected.	
		0	4 KB
		1	8 KB
		2	16 KB
		3	32 KB
		4	64 KB
		5	128 KB
		6	256 KB

		18	1 GB
		19	2 GB
		20	4 GB
		21-31	Reserved

Table 11-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Region Enable. The `SMPU_RCTL[n].EN` bit enables the protection of a region.	
		0	Disabled
		1	Enabled

SMPU Revision ID Register

The SMPU_REVID register provides the major and minor revision numbers of this module.

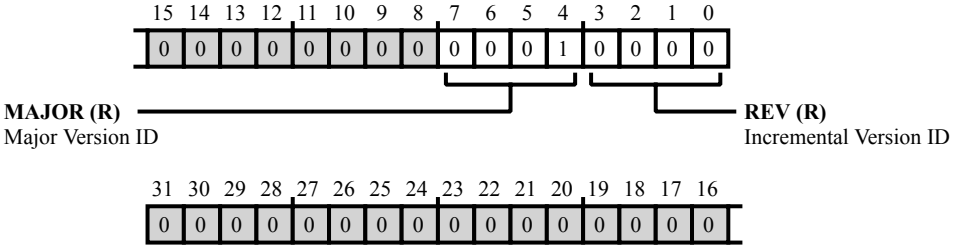

Figure 11-11: SMPU_REVID Register Diagram

Table 11-15: SMPU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Region n ID A Register

The SMPU_RIDA[n] register is used for ID comparison 'A'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more detail, refer to the ID Comparison section.

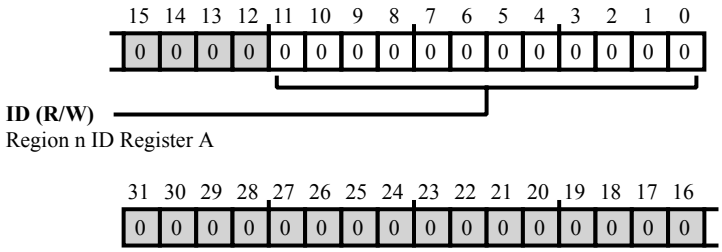

Figure 11-12: SMPU_RIDA[n] Register Diagram

Table 11-16: SMPU_RIDA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ID	Region n ID Register A. The SMPU_RIDA[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID B Register

The SMPU_RIDB[n] register is used for ID comparison 'B'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more details, refer to the ID Comparison section.

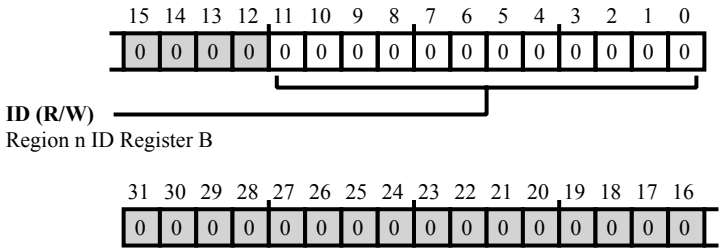

Figure 11-13: SMPU_RIDB[n] Register Diagram

Table 11-17: SMPU_RIDB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ID	Region n ID Register B. The SMPU_RIDB[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID Mask A Register

The SMPU_RIDMSKA[n] register is used for ID comparison 'A'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

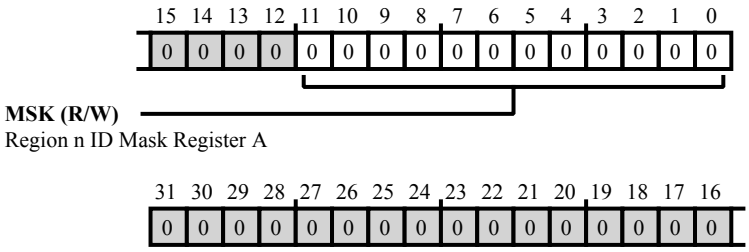

Figure 11-14: SMPU_RIDMSKA[n] Register Diagram

Table 11-18: SMPU_RIDMSKA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	MSK	Region n ID Mask Register A. The SMPU_RIDMSKA[n].MSK bit field, combined with the incoming transaction, provides the means to bypass the configured memory protection for a region.

Region n ID Mask B Register

The SMPU_RIDMSKB[n] register is used for ID comparison 'B'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

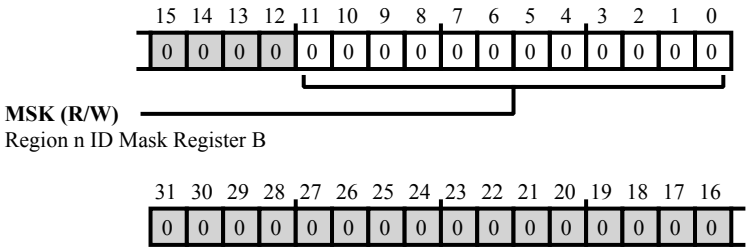

Figure 11-15: SMPU_RIDMSKB[n] Register Diagram

Table 11-19: SMPU_RIDMSKB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	MSK	Region n ID Mask Register B. The SMPU_RIDMSKB[n].MSK bit field, combined with the incoming transaction provides the means to bypass the configured memory protection for a region.

SMPU Control Secure Accesses Register

The SMPU_SECURECTL register provides the bits required to set up the security settings for the processor. These settings includes error generation and read/write security.

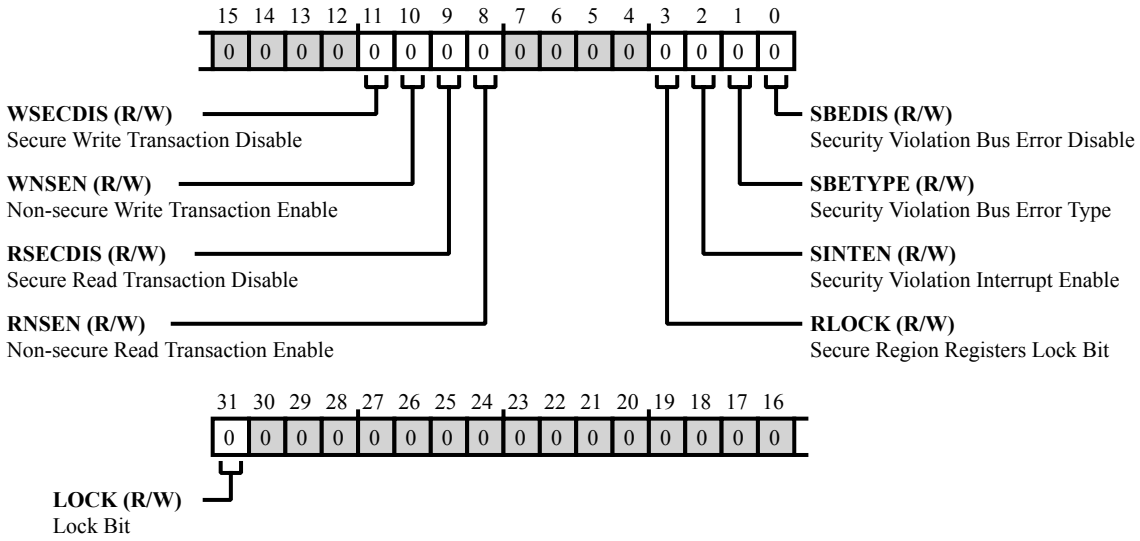

Figure 11-16: SMPU_SECURECTL Register Diagram

Table 11-20: SMPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_SECURECTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_SECURECTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	SMPU_SECURECTL is not write-protected
		1	SMPU_SECURECTL is write-protected
11 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURECTL.WSECDIS bit disables secure write transactions.	
		0	Enable secure write transactions
		1	Disable secure write transactions
10 (R/W)	WNSEN	Non-secure Write Transaction Enable. The SMPU_SECURECTL.WNSEN bit enables non-secure write transactions.	
		0	Disable non-secure writes
		1	Enable non-secure writes

Table 11-20: SMPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURECTL.RSECDIS bit disables secure read transactions.	
		0	Enable secure read transactions
		1	Disable secure read transactions
8 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURECTL.RNSEN bit enables non-secure read transactions.	
		0	Disable non-secure read transactions
		1	Enable non-secure read transactions
3 (R/W)	RLOCK	Secure Region Registers Lock Bit. When the SMPU_SECURECTL.RLOCK bit is set, the secure region control registers, SMPU_SECURERCTL[n], are write-protected when the global lock signal is active from the SPU. When the global lock signal is deasserted, write access is allowed again.	
		0	Disable write-protection on secure region registers
		1	Enable write-protection on secure region registers
2 (R/W)	SINTEN	Security Violation Interrupt Enable. The SMPU_SECURECTL.SINTEN bit enables interrupt generation when a security violation occurs.	
		0	Disable security settings violation interrupt
		1	Enable security settings violation interrupt
1 (R/W)	SBETYPE	Security Violation Bus Error Type. The SMPU_SECURECTL.SBETYPE bit controls whether a decode error or a slave error is returned when a security violation occurs.	
		0	Return a decode error error which violates the security settings
		1	Return a slave error which violates the security settings
0 (R/W)	SBEDIS	Security Violation Bus Error Disable. The SMPU_SECURECTL.SBEDIS bit controls whether or not a bus error is caused when a security violation occurs.	
		0	Enable bus error
		1	Disable bus error

Region n Control Secure Accesses Register

The SMPU_SECURERCTL[n] register contains bits that configure read/write security for a specific region.

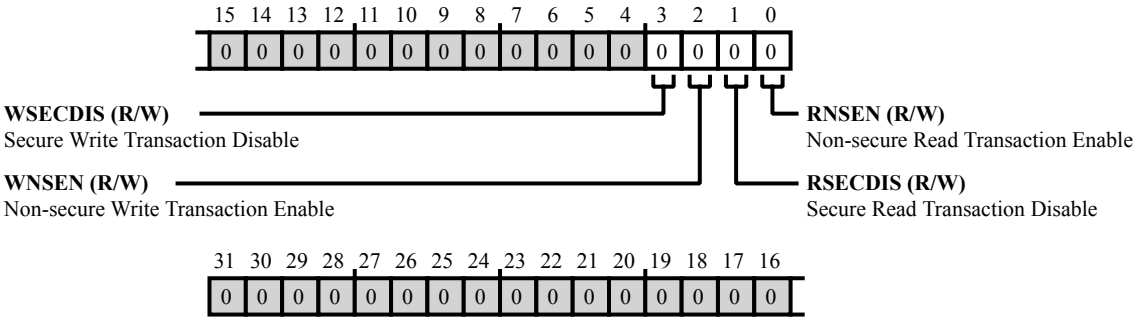

Figure 11-17: SMPU_SECURERCTL[n] Register Diagram

Table 11-21: SMPU_SECURERCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURERCTL[n].WSECDIS bit disables secure write transactions for the memory region.	
		0	Enable secure write transactions to this region
		1	Disable secure write transactions to this region
2 (R/W)	WNSEN	Non-secure Write Transaction Enable. This SMPU_SECURERCTL[n].WNSEN bit enables non-secure write transactions for the memory region.	
		0	Disable non-secure write transactions to this region
		1	Enable non-secure write transactions to this region
1 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURERCTL[n].RSECDIS bit disables secure read transactions for the memory region.	
		0	Enable secure read transactions to this region
		1	Disable secure read transactions to this region
0 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURERCTL[n].RNSEN bit enables non-secure read transactions for the memory region.	
		0	Disable non-secure read transactions to this region
		1	Enable non-secure read transactions to this region

SMPU Status Register

The SMPU_STAT register provides the state of the SMPU and indicates various errors. All bits in this register are write 1 to clear.

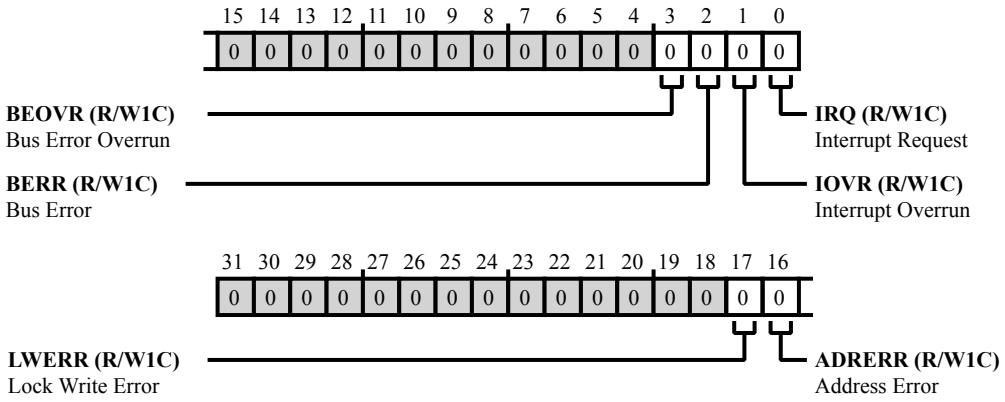

Figure 11-18: SMPU_STAT Register Diagram

Table 11-22: SMPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The SMPU_STAT.LWERR bit is set when SMPU_CTL.LOCK bit =1, the global lock signal is asserted from the SPU and a read or write attempt was made to the SMPU_CTL MMR.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The SMPU_STAT.ADRERR bit is set when the SMPU MMR is accessed as an un-aligned address, or when a read-only MMR is written to.	
		0	No Address Error
		1	Address Error
3 (R/W1C)	BEOVR	Bus Error Overrun. The SMPU_STAT.BEOVR bit indicates that another bus error had occurred. Any new information about the most recent violation which caused the bus error is not captured.	
		0	No Bus Error overrun
		1	Bus Error overrun has occurred

Table 11-22: SMPU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	BERR	Bus Error. This SMPU_STAT.BERR bit indicates if a bus error was generated.	
		0	No Bus Error since this bit has been cleared
		1	Bus Error has been generated
1 (R/W1C)	IOVR	Interrupt Overrun. The SMPU_STAT.IOVR bit indicates if another violation occurred while the previous violation interrupt was not finished being serviced. Information about the most recent violation is then not captured.	
		0	No Interrupt overrun
		1	Interrupt overrun has occurred
0 (R/W1C)	IRQ	Interrupt Request. The SMPU_STAT.IRQ bit provides an indication that an interrupt has been generated.	
		0	No Interrupt since this bit has been cleared
		1	Interrupt has been generated

12 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts. The general-purpose ports provide the following three functions:

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupt requests

NOTE: In this chapter, the naming convention for registers and bits omits the alphabetic group enumeration to refer to any and all of the ports. For example, `PORT_FER` represents registers `PORTA_FER`, `PORTB_FER`, and so on. Likewise `PORT_FER.PX1` represents bits PA1, PB1, and so on.

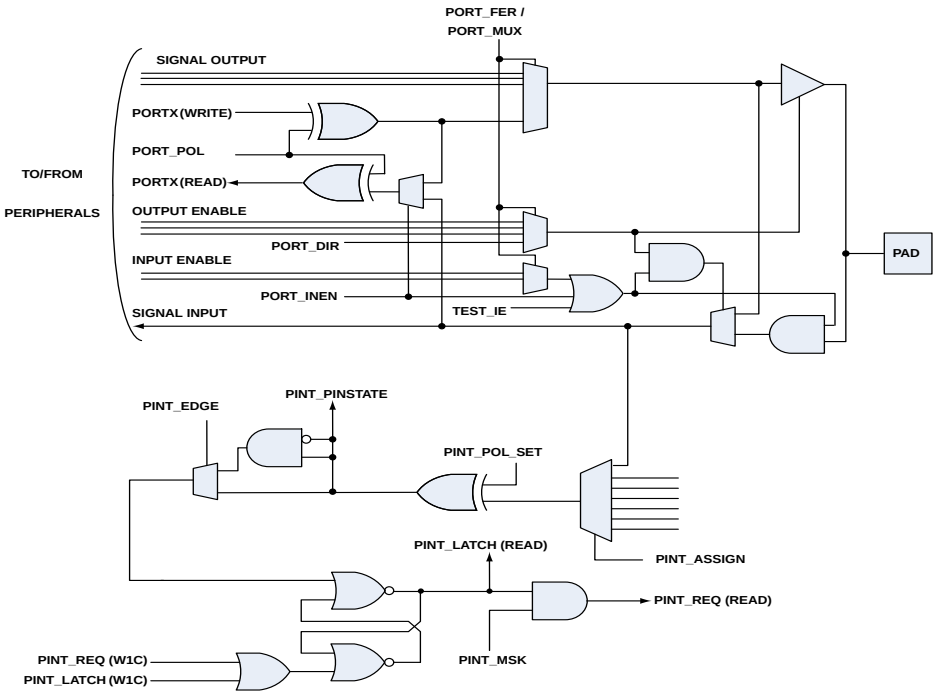

Figure 12-1: Simplified GPIO and Pin Interrupt Signal Flow

PORT Features

The PORTs include the following features:

- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled on a pin-by-pin basis
- No external glue hardware required for unused pins
- All port pins provide interrupt request functionality
- Byte-wide pin-to-interrupt request assignment

PORT Functional Description

The number of ports and each's composition are defined in the processor datasheet. Each port has a dedicated set of MMR registers that control pin functions and operates in general-purpose I/O (GPIO) mode by default, as controlled by the port-specific PORT_FER register. Each bit in this register, as well as the other PORT MMRs, represents a specific GPIO pin on the specified port.

Input Mode, Output Mode, and Open-Drain Mode of GPIO Operation

At reset, every GPIO pin defaults to input mode with the input drivers disabled. To enable any GPIO input driver, set the bits corresponding to the individual pins in the appropriate input enable register (PORT_INEN).

The GPIO output drivers are enabled by setting the corresponding bits in the direction registers (PORT_DIR).

The PORT can use every GPIO in open-drain mode by clearing the respective bit in the PORT_DATA register or setting the respective bit in the PORT_DATA_CLR register. Then, set the corresponding bit in the PORT_INEN register. Read from the PORT_DATA register to obtain the status from the pin.

Port Multiplexing Controlled on Pin-by-Pin Basis

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

All Port Pins Provide Interrupt Functionality

Pin interrupts are completely decoupled from GPIO functionality. Pins are connected to the system event controller (SEC) via the PINTx modules, each of which is configurable in terms of which port pins are sensed for interrupt generation.

ADSP-SC57x PORT Register List

The PORT module (PORT) regulates the use of the multiplexable processor pins. Every port pin can operate in general-purpose I/O (GPIO) mode or as an alternate function. This GPIO operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

Table 12-1: ADSP-SC57x PORT Register List

Name	Description

ADSP-SC57x PINT Register List

The Pin Interrupt module (PINT) controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control. For more information, see the PINT register descriptions.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

Table 12-4: ADSP-SC57x PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register

PADS_PORT[n]_PUD	PORTx Pull-Up Disable
PADS_PORT[n]_PUE	PORTx Pull-Up Enable

PORT Architectural Concepts

These sections describe in more detail how the PORT module connects externally to pins and internally to the MMR bus. Ports are named alphabetically beginning with A.

- Internal Interfaces
- External Interfaces
- GPIO Pin Function
- Port Multiplexing Control

Internal Interfaces

All of the pin multiplexing, GPIO, and pin interrupt control block MMRs can be accessed through the MMR bus. There is no DMA support. Each of the pin interrupt (PINTx) modules has its own dedicated interrupt request output signal that connects directly to the system event controller (SEC).

External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the silicon pads connecting to the physical pins/balls or the package, as controlled by the PORT unit.

GPIO Pin Function

By default, the PORT sets every GPIO pin to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and external termination resistors on unused pins.

Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the bits corresponding to the PORT pins in the appropriate input enable register (PORT_INEN). When enabled, a read from the PORT_DATA register returns the logical state of the input pins. However, the input signal does not overwrite the state of the internal flip-flop used for providing output to the same pin. Only software can alter the state. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the flip-flop, but the change cannot be read back.

Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the bits corresponding to the PORT pins in the appropriate direction register. The PORT implements direction registers as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs called PORT_DIR_SET and PORT_DIR_CLR, respectively. As such, software can alter the direction of the signal flow on individual GPIO pins without impacting other GPIOs on the same port.

Both the PORT_DIR_SET and PORT_DIR_CLR registers return the same value when read, and a logical 1 indicates an enabled output. The PORT_DATA registers control the state of output pins. A logical 0 drives the output low while a logical 1 drives the output high.

While writes to the PORT_DATA register can alter all of the GPIOs on a specific port at once, there are also a pair of W1S and W1C MMRs called PORT_DATA_SET and PORT_DATA_CLR, respectively. These registers enable

the manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the PORT_DATA registers. Because the state of the GPIO output can be controlled before the output driver is enabled, set or clear the internal flip-flop first by programming this register to avoid volatile levels on the output pin.

Trigger Toggle Mode

Any GPIO pin that has been configured for output mode can be toggled using a trigger input from the Trigger Routing Unit (TRU). To enable this functionality for a particular GPIO, set the appropriate bit in the PORT_TRIG_TGL register. Any subsequent trigger for the designated port causes all GPIO outputs set in the PORT_TRIG_TGL register to toggle.

To avoid unpredictable behavior, do not set, clear, or toggle the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, or PORT_DATA_TGL registers when the GPIO output has the corresponding PORT_TRIG_TGL bit set. To change the state of the GPIO output using one of these registers, first clear the corresponding bit in the PORT_TRIG_TGL register.

Open-Drain Mode

Every GPIO can also be used in open-drain mode. First, either clear the respective bit in the PORT_DATA register or set the respective bit in the PORT_DATA_CLR register. Then, set the appropriate bit in the PORT_INEN register. Read from the PORT_DATA register to return the status from the pin rather than the state of the internal flip-flop.

By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated, as required. The polarity of the driven signal can be inverted when the internal flip-flop is set. When using a GPIO port in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pins.

Port Multiplexing Control

To configure pins properly, consult the processor datasheet to determine which bits in the PORT_FER and PORT_MUX register map to the pin of interest, and then set these registers appropriately for the desired function.

After reset, all port pins default to GPIO input mode with their output and input drivers disabled. As a result, all unused port pins can be left unconnected. Disabled pins appear as high-impedance to external circuits.

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

The function enable register specifies whether the pin is used as a GPIO pin or allocated for use by a specific peripheral, but it does not specify what the peripheral function is. Each bit in the 16-bit PORT_FER register corresponds to an individual port pin. For example, if bit 1 (PA1) of the PORTA_FER register is cleared, the PA_01 pin is configured as a GPIO. When set, one of the available peripheral functions becomes active on the PA_01 pin instead.

Pairs of bits in the PORT_MUX register control the multiplexing between the peripheral functions available to an individual pin, as some PORT pins provide up to four possible peripheral functions.

Refer to the Signal Muxing table in the datasheet for the specific PORT_MUX settings.

PORT Event Control

The following sections describe event generation in the PORT module.

PORT Interrupt Signals

The pin interrupts are decoupled from GPIO functionality, providing the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.
- Interrupt requests work on input and output pins regardless of whether the pin is functioning as a GPIO or a peripheral.

The processor has a number of interrupt channels dedicated to pin interrupts, managed by a set of pin interrupt (PINTx) blocks. Each PINTx block can sense up to 32 GPIO pins, as described in the following list and figure.

- PINT0 can sense pin activity on PORTA and PORTB
- PINT1 can sense pin activity on PORTB and PORTC
- PINT2 can sense pin activity on PORTC and PORTD
- PINT3 can sense pin activity on PORTD and PORTE
- PINT4 can sense pin activity on PORTE and PORTF
- PINT5 can sense pin activity on PORTF and PORTG. Note that PORTF and PORTG are not available on the low pin count package.

The processor supports both 32-bit and 16-bit peripheral bus accesses to PINTx registers.

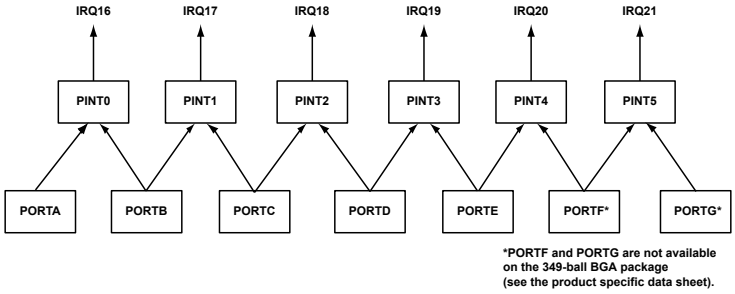

Figure 12-2: GPIO to PINTx Assignment

Pins connect to the PINTx module and then to the system event controller (SEC), as shown in the ***PINTx Block Diagram***.

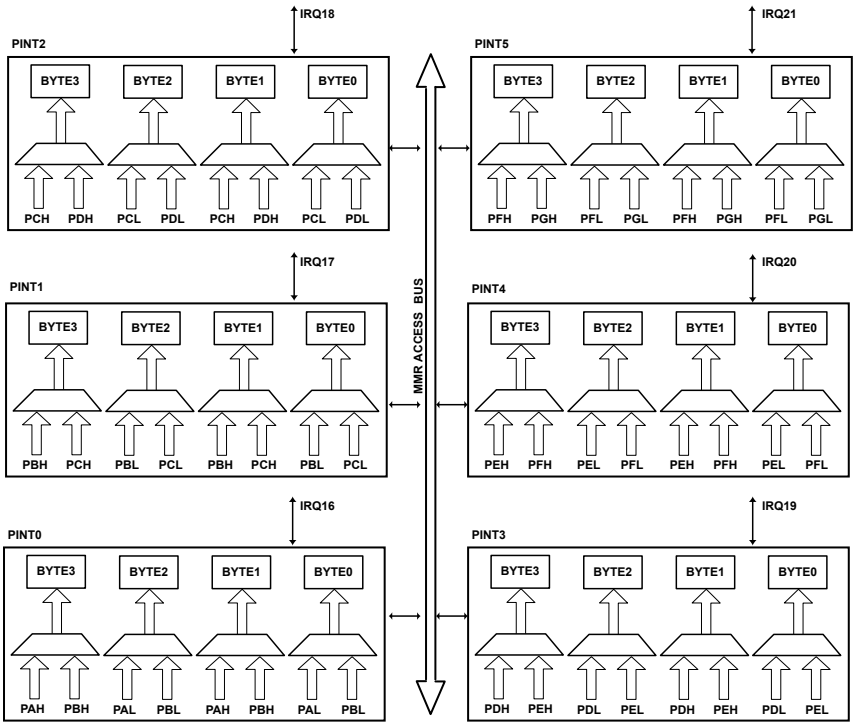

Figure 12-3: PINTx Block Diagram

As shown in the ***PINTx Block Diagram***, each port is subdivided into two 8-pin half ports, upper (PxH) and lower (PxL). The PINT_ASSIGN registers control the 8-bit multiplexers associated with these half ports, where the lower half units (eight pins) can be forwarded to either byte 0 or byte 2 of the PINTx blocks, and the upper half units (eight pins) can be forwarded to either byte 1 or byte 3 of the PINTx blocks.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins appears in the PINT_PINSTATE register, regardless of whether the pin is enabled for GPIO or peripheral functions (input or output). When neither the input nor output drivers of the pin are enabled, the pin state is read as zero. The PINT_PINSTATE register reports the inverted state of the pin when the PINT_INV_SET register activates the signal inverter. The inverter can be enabled on an individual bit-by-bit basis. Each bit in the PINT_INV_SET/ PINT_INV_CLR register pair represents a pin signal.

By default, PORT interrupt request generation is level-sensitive, and an interrupt request occurs when the enabled pin is sensed as active high. Use the PINT_EDGE_SET register to change the interrupt request genearion scheme to instead be edge-sensitive (rising edge generates the interrupt request). Use the PINT_INV_SET register to invert the polarity such that the PINTx block generates the interrupt request on active-low signals or falling edges.

The PINTx modules also assist when both signal edges must generate unique interrupt requests. If two different interrupt requests are required, the PINT_ASSIGN registers can route a single input signal to two different PINTx blocks, where one block inverts the signal in the PINT_INV_SET register and the other one does not. In this fashion, a unique software routine is associated with the hardware PINTx block that is generating the unique interrupt request for each signal edge. When both signal edges can be serviced by the same interrupt request, each half port can be routed to two separate bytes within a single PINTx block using the PINT_ASSIGN register, and then one of

the half ports needs to have the inversion enabled in the PINT_INV_SET register. The servicing software routine can then detect from the PINT_LATCH register whether a falling, rising, or both edges have occurred.

Regardless of whether level-sensitive or edge-sensitive mode is used, the hardware always latches an interrupt request. Latched signals can be read from the PINT_LATCH registers. Only a software or hardware reset clears the latches. To clear the latch, a W1C operation must be performed to the PINT_REQ or PINT_LATCH register. When in level-sensitive mode, the interrupt request remains asserted if the pin state does not change by the time the interrupt service routine exits.

Because every PINTx block groups up to 32 pin signals, the PINT_MSK_SET/ PINT_MSK_CLR register pair can control which of the signals can request an interrupt at the system level. Software can interrogate the PINT_REQ register for signaling pins. The PINT_REQ bits represent a logical AND between the mask and the latch. When any of these bits is set, the block output interrupt request is asserted.

PORT Programming Model

The ***GPIO Programming Model Flow (Part 1)***, ***GPIO Programming Model Flow (Part 2)***, and ***GPIO Programming Model Flow (Part 3)*** figures show the programming model for the general-purpose ports. This programming includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

NOTE: These process flow diagrams connect where call-out letters appear. For example, call-out A in the ***GPIO Programming Model Flow (Part 1)*** diagram connects to call-out A in the ***GPIO Programming Model Flow (Part 2)*** diagram.

The following flowcharts describe the processes for setting up pins for various functions. Begin the process from the start label in the ***GPIO Programming Model Flow (Part 1)*** figure. The first decision (GPIO or peripheral) determines how to program the PORT_FER register. Set the bit(s) corresponding to the pin(s) to 1 to enable peripheral functionality or to 0 to enable GPIO mode. For more information on setting up for peripheral functions, refer to Port Multiplexing Control.

If the pin is to be a GPIO pin, a subsequent series of decisions must be made that will impact how the PORT_DATA, PORT_POL, PORT_DIR, and PORT_INEN configuration registers must be programmed. Depending on the type of GPIO pin desired, some configurations do not apply and can have different meanings. The following paragraphs briefly describe the function of the different settings for each of the pin functions in the input, output, and open-drain GPIO modes. It is a best practice to use the SET or CLR versions of the PORT registers, where applicable, to effect changes on a pin-by-pin basis rather than on the full port.

For output mode, first clear the PORT_DATA register to set all the pins low. Then write the PORT_DIR register to define the direction of each pin (set the bits associated with the desired output pins to 1). In output mode, the other registers are not significant. The ***GPIO Programming Model Flow (Part 1)*** chart shows this flow starting at label 2.

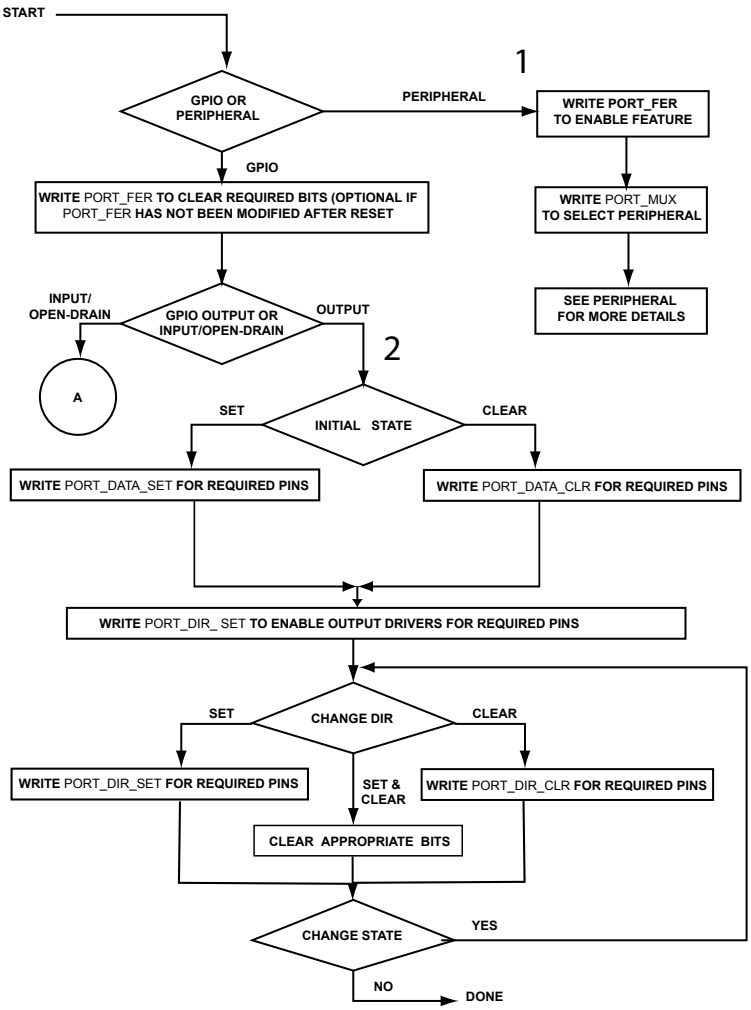

Figure 12-4: GPIO Programming Model Flow (Part 1)

For input mode, first decide the polarity for each pin using the PORT_POL register. Program the PORT_DIR register to define the appropriate pins as inputs (write a 0 to the bit location associated with the pin). If interrupt requests are desired, configure the PINT module as shown in the ***GPIO Programming Model Flow (Part 3)*** figure starting at label B. Finally, write the PORT_INEN register to enable the associated input drivers. The ***GPIO Programming Model Flow (Part 2)*** chart shows this entire flow starting at label 3.

For open-drain mode, set all pins low by clearing the PORT_DATA register. Then, use the PORT_INEN register to enable the appropriate input drivers. Set the PORT_DIR register in this mode to indicate whether the pin is in an active state or not (active being 0). The ***GPIO Programming Model Flow (Part 2)*** chart shows this flow starting at label 4.

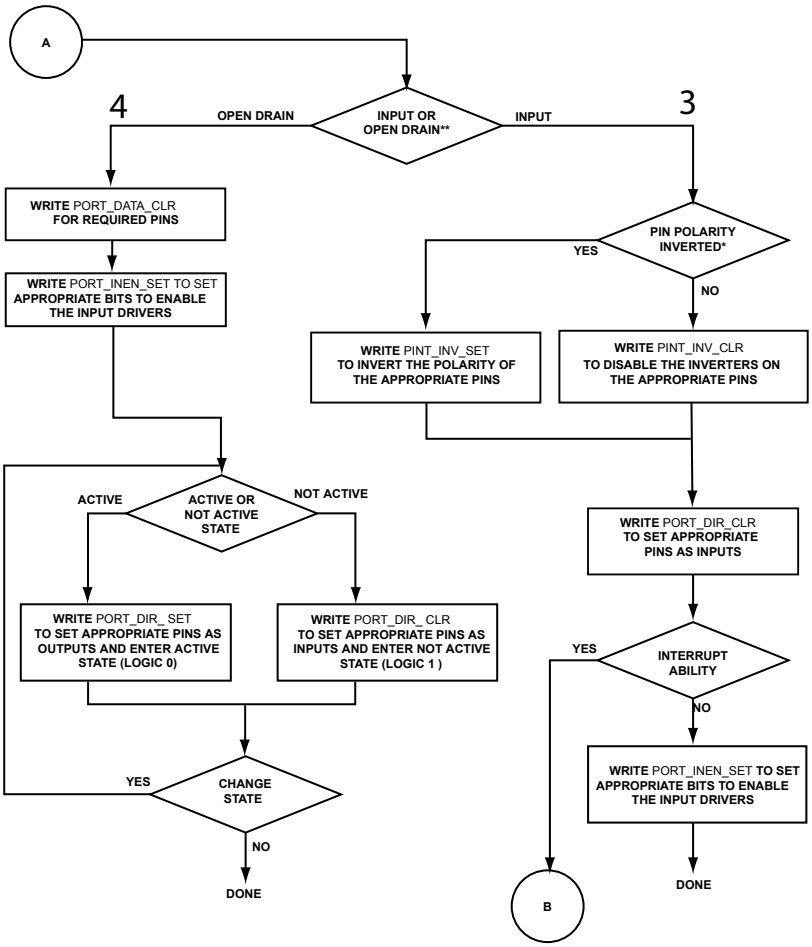

Figure 12-5: GPIO Programming Model Flow (Part 2)

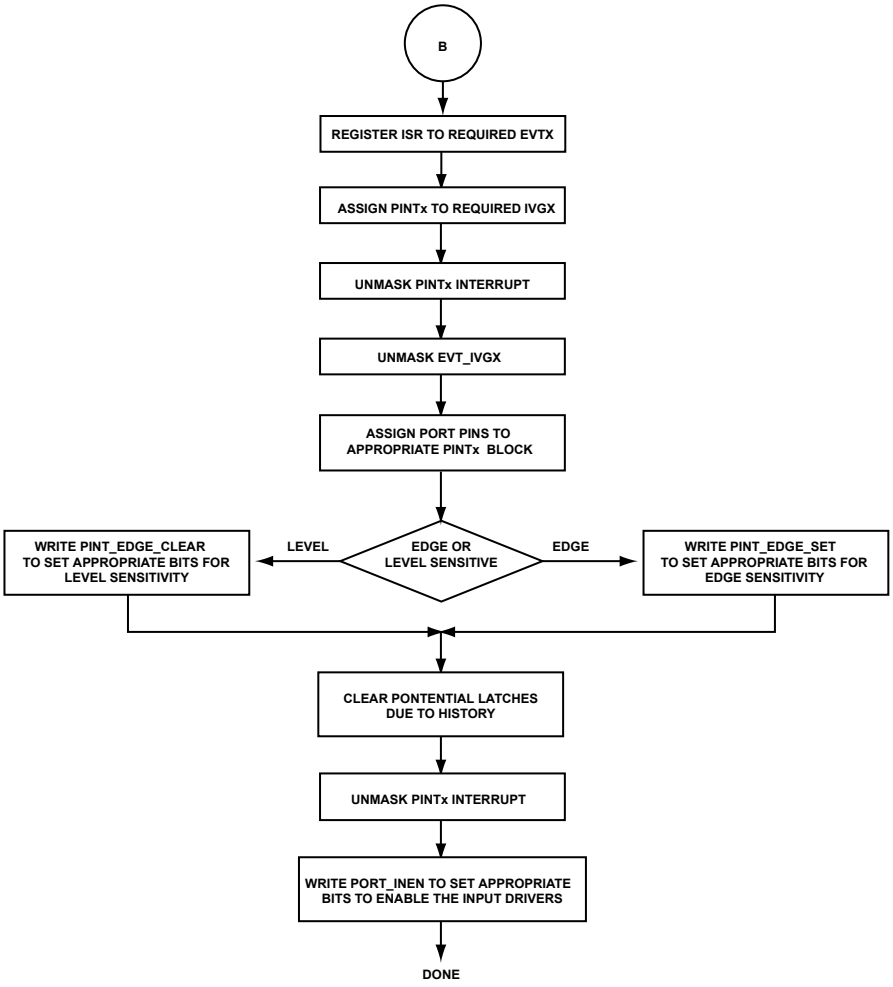

Figure 12-6: GPIO Programming Model Flow (Part 3)

Programmable Pull-up Resistors for PORT and DAI

There are programmable weak pull-up resistors for DAI and PORT pins. These resistors can be enabled or disabled by configuring the `PADS_DAI[n]_PUE`, `PADS_PORT[n]_PUE`, `PADS_DAI[n]_PUD`, and `PADS_PORT[n]_PUD` registers.

For DAI pins, if both the `PADS_DAI[n]_PUD` and `PADS_DAI[n]_PUE` registers are set (=1) for the same pin, then the `PADS_DAI[n]_PUD` register takes priority over `PADS_DAI[n]_PUE` register.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

Refer to the ***DAI Pull-up Resistor States*** table. To enable the pull-up on a DAI pin, the `PADS_DAI[n]_PUD.PUD` bit must be cleared (=0) ***AND*** the `PADS_DAI[n]_PUE.PUE` bit must be set (=1). To disable the pull-up on a DAI pin, the `PADS_DAI[n]_PUD.PUD` bit must be set (=1) and `PADS_DAI[n]_PUE.PUE` bit can be any value.

Table 12-9: DAI Pull-up Resistor States

PADS_DAI[n]_PUE.PUE	PADS_DAI[n]_PUD.PUD	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

Similarly, for PORT pins, if both PADS_PORT[n]_PUD and PADS_PORT[n]_PUE registers are set (=1) for the same pin, then the PADS_PORT[n]_PUD register takes priority over PADS_PORT[n]_PUE register.

Refer to the ***PORT Pull-up Resistor States*** table. To enable the pull-up on a PORT pin, the PADS_PORT[n]_PUD.PUD bit must be cleared (=0) ***AND*** the PADS_PORT[n]_PUE.PUE bit must be set (=1). To disable the pull-up on a PORT pin, PADS_PORT[n]_PUD.PUD bit must be set (=1) and PADS_PORT[n]_PUE.PUE bit can be any value.

Table 12-10: PORT Pull-up Resistor States

PADS_PORT[n]_PUE.PUE	PADS_PORT[n]_PUD.PUD	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

NOTE: Refer to the ***Designer Quick Reference*** section of the datasheet for handling unused PORT and DAI pins.

NOTE: The internal pull-up on GPIO pins are very weak. These pins hold a defined logic level when pins are left floating. The internal pull-up resistance varies over a wide range. If an application needs a specified pull-up on the pin, use an external resistor.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

ADSP-SC57x PORT Register Descriptions

The General-Purpose Input/Output Port (PORT) contains the following registers.

Table 12-11: ADSP-SC57x PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register
PORT_DATA_CLR	Port x GPIO Data Clear Register
PORT_DATA_SET	Port x GPIO Data Set Register

Table 12-11: ADSP-SC57x PORT Register List (Continued)

Name	Description
PORT_DATA_TGL	Port x GPIO Output Toggle Register
PORT_DIR	Port x GPIO Direction Register
PORT_DIR_CLR	Port x GPIO Direction Clear Register
PORT_DIR_SET	Port x GPIO Direction Set Register
PORT_FER	Port x Function Enable Register
PORT_FER_CLR	Port x Function Enable Clear Register
PORT_FER_SET	Port x Function Enable Set Register
PORT_INEN	Port x GPIO Input Enable Register
PORT_INEN_CLR	Port x GPIO Input Enable Clear Register
PORT_INEN_SET	Port x GPIO Input Enable Set Register
PORT_LOCK	Port x GPIO Lock Register
PORT_MUX	Port x Multiplexer Control Register
PORT_POL	Port x GPIO Polarity Invert Register
PORT_POL_CLR	Port x GPIO Polarity Invert Clear Register
PORT_POL_SET	Port x GPIO Polarity Invert Set Register
PORT_TRIG_TGL	Port x GPIO Trigger Toggle Register

Port x GPIO Data Register

The operation of the PORT_DATA register depends on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the PORT_DATA register corresponds to a signal high on a GPIO pin. A cleared bit in the PORT_DATA register corresponds to a signal low on a GPIO pin.

The PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the PORT_DIR_SET and PORT_DIR_CLR registers.

Writes to the PORT_DATA register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the PORT_DATA_SET and PORT_DATA_CLR registers.

When the GPIO pins are in input mode (input driver is enabled with the PORT_INEN register), reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the value previously written to the registers.

		0	Signal Low
		1	Signal High
0 (R/W)	PX0	Port x Bit 0 Data. The `PORT_DATA.PX0` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Port x GPIO Data Clear Register

The PORT_DATA_CLR register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

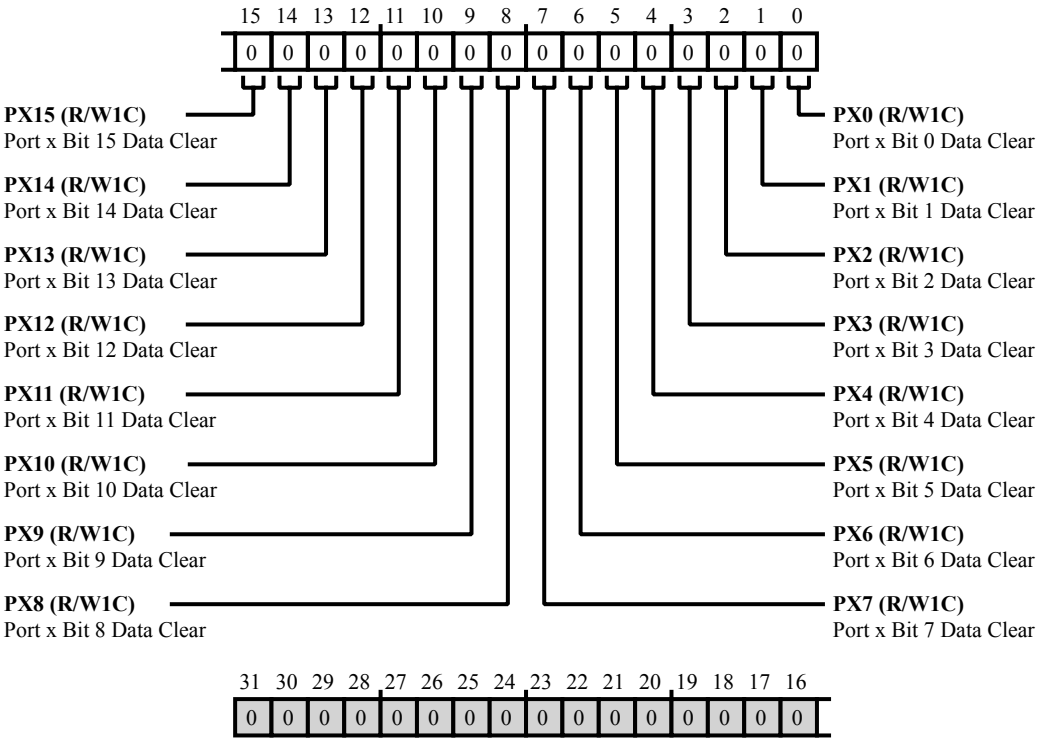

Figure 12-8: PORT_DATA_CLR Register Diagram

Table 12-13: PORT_DATA_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Data Clear. The PORT_DATA_CLR.PX15 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
14 (R/W1C)	PX14	Port x Bit 14 Data Clear. The PORT_DATA_CLR.PX14 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1C)	PX13	Port x Bit 13 Data Clear. The `PORT_DATA_CLR.PX13` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
12 (R/W1C)	PX12	Port x Bit 12 Data Clear. The `PORT_DATA_CLR.PX12` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
11 (R/W1C)	PX11	Port x Bit 11 Data Clear. The `PORT_DATA_CLR.PX11` bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
10 (R/W1C)	PX10	Port x Bit 10 Data Clear. The `PORT_DATA_CLR.PX10` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
9 (R/W1C)	PX9	Port x Bit 9 Data Clear. The `PORT_DATA_CLR.PX9` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
8 (R/W1C)	PX8	Port x Bit 8 Data Clear. The `PORT_DATA_CLR.PX8` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	PX7	Port x Bit 7 Data Clear. The PORT_DATA_CLR.PX7 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
6 (R/W1C)	PX6	Port x Bit 6 Data Clear. The PORT_DATA_CLR.PX6 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
5 (R/W1C)	PX5	Port x Bit 5 Data Clear. The PORT_DATA_CLR.PX5 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
4 (R/W1C)	PX4	Port x Bit 4 Data Clear. The PORT_DATA_CLR.PX4 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
3 (R/W1C)	PX3	Port x Bit 3 Data Clear. The PORT_DATA_CLR.PX3 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
2 (R/W1C)	PX2	Port x Bit 2 Data Clear. The PORT_DATA_CLR.PX2 bit clears the pin without impacting other pins of the port.	
		0	No Effect Write 0 has no effect in output mode.
		1	Clear Bit Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	PX1	Port x Bit 1 Data Clear. The `PORT_DATA_CLR.PX1` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
0 (R/W1C)	PX0	Port x Bit 0 Data Clear. The `PORT_DATA_CLR.PX0` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Port x GPIO Data Set Register

The PORT_DATA_SET register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

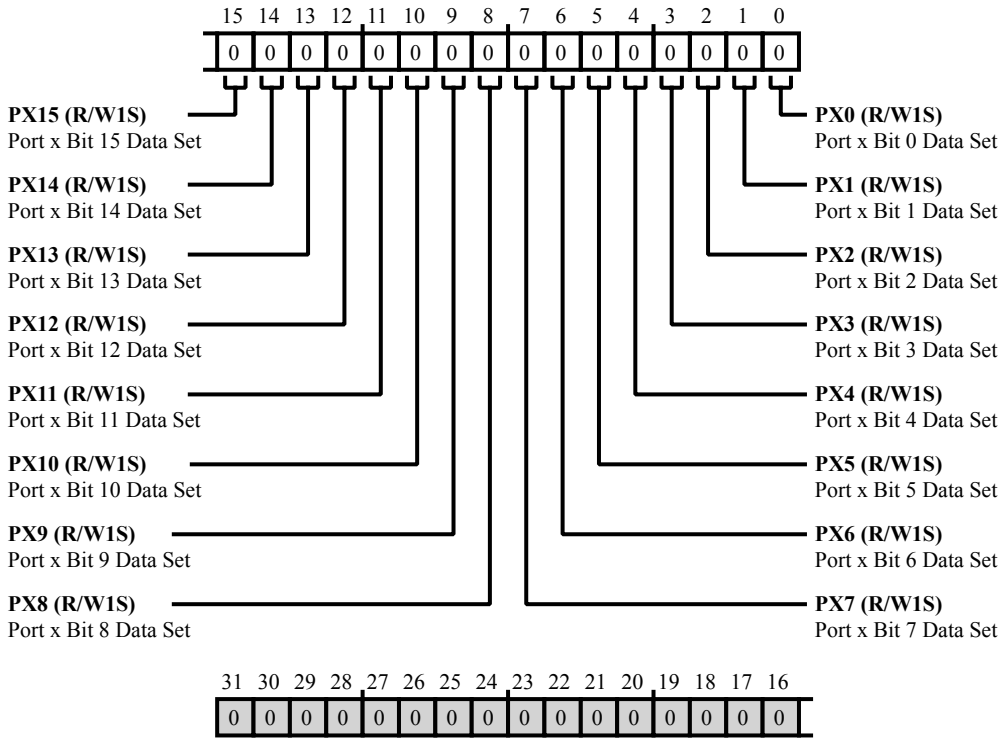

Figure 12-9: PORT_DATA_SET Register Diagram

Table 12-14: PORT_DATA_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
14 (R/W1S)	PX14	Port x Bit 14 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
13 (R/W1S)	PX13	Port x Bit 13 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1S)	PX12	Port x Bit 12 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
11 (R/W1S)	PX11	Port x Bit 11 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit.
10 (R/W1S)	PX10	Port x Bit 10 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
9 (R/W1S)	PX9	Port x Bit 9 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
8 (R/W1S)	PX8	Port x Bit 8 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
7 (R/W1S)	PX7	Port x Bit 7 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
6 (R/W1S)	PX6	Port x Bit 6 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
5 (R/W1S)	PX5	Port x Bit 5 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
4 (R/W1S)	PX4	Port x Bit 4 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
3 (R/W1S)	PX3	Port x Bit 3 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 12-14: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1S)	PX2	Port x Bit 2 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
1 (R/W1S)	PX1	Port x Bit 1 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
0 (R/W1S)	PX0	Port x Bit 0 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Port x GPIO Output Toggle Register

The PORT_DATA_TGL register permits toggling the state of output GPIO pins. Setting bits in the PORT_DATA_TGL register affects the state of specific pins without impacting other pins of the port.

Reading the PORT_DATA_TGL returns the state of the PORT_DATA register output pin state, but does not return the input pin/signal state.

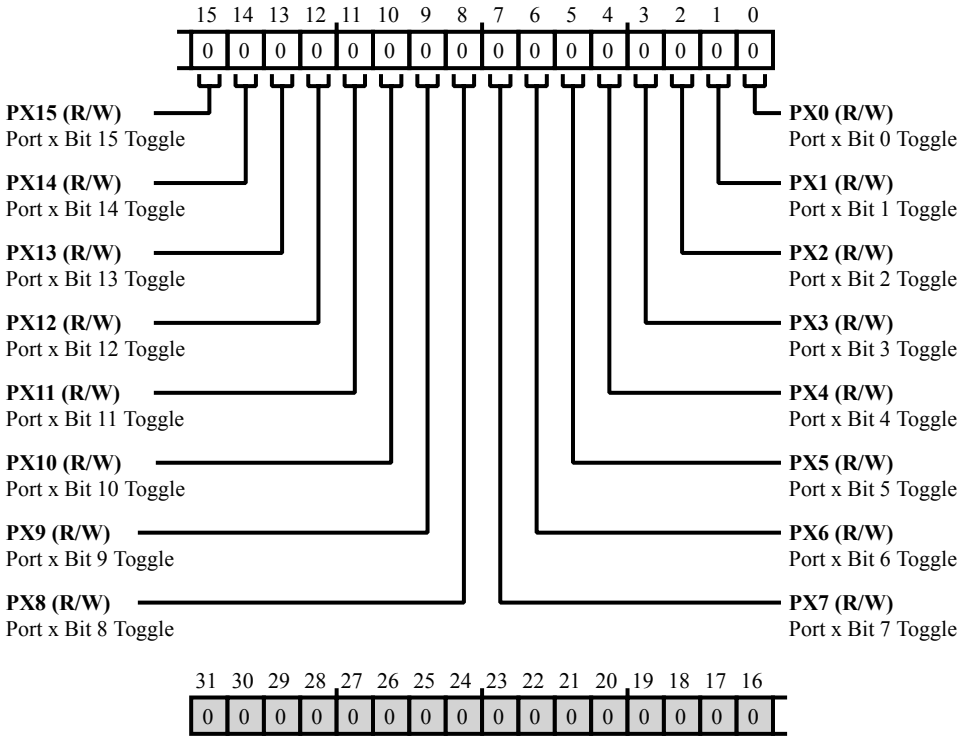

Figure 12-10: PORT_DATA_TGL Register Diagram

Table 12-15: PORT_DATA_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Toggle. The PORT_DATA_TGL.PX15 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit.
14 (R/W)	PX14	Port x Bit 14 Toggle. The PORT_DATA_TGL.PX14 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PX13	Port x Bit 13 Toggle. The PORT_DATA_TGL.PX13 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
12 (R/W)	PX12	Port x Bit 12 Toggle. The PORT_DATA_TGL.PX12 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
11 (R/W)	PX11	Port x Bit 11 Toggle. The PORT_DATA_TGL.PX11 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
10 (R/W)	PX10	Port x Bit 10 Toggle. The PORT_DATA_TGL.PX10 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
9 (R/W)	PX9	Port x Bit 9 Toggle. The PORT_DATA_TGL.PX9 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
8 (R/W)	PX8	Port x Bit 8 Toggle. The PORT_DATA_TGL.PX8 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
7 (R/W)	PX7	Port x Bit 7 Toggle. The PORT_DATA_TGL.PX7 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Table 12-15: PORT_DATA_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	PX6	Port x Bit 6 Toggle. The PORT_DATA_TGL.PX6 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
5 (R/W)	PX5	Port x Bit 5 Toggle. The PORT_DATA_TGL.PX5 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
4 (R/W)	PX4	Port x Bit 4 Toggle. The PORT_DATA_TGL.PX4 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
3 (R/W)	PX3	Port x Bit 3 Toggle. The PORT_DATA_TGL.PX3 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
2 (R/W)	PX2	Port x Bit 2 Toggle. The PORT_DATA_TGL.PX2 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
1 (R/W)	PX1	Port x Bit 1 Toggle. The PORT_DATA_TGL.PX1 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
0 (R/W)	PX0	Port x Bit 0 Toggle. The PORT_DATA_TGL.PX0 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Port x GPIO Direction Register

The PORT_DIR, PORT_DIR_SET, and PORT_DIR_CLR registers select output or input mode for GPIO pins and enable output drivers. Use the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers to enable or disable input drivers.

Writes to the PORT_DIR register affect the state of all pins of the port. To select a direction for specific pins without impacting other pins of the port, use the PORT_DIR_SET and PORT_DIR_CLR registers.

Setting a bit in the PORT_DIR register enables output mode on the corresponding a GPIO pin. Clearing a bit in the PORT_DIR register disables output mode on the corresponding GPIO pin.

Input Mode - The default mode of every GPIO pin after reset is the input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the corresponding bits in the PORT_INEN register. When enabled, a read from the PORT_DATA register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the bit, but the change cannot be read back.

Output Mode - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the PORT_DIR, PORT_DIR_SET, or PORT_DIR_CLR registers. By using the PORT_DIR_SET and PORT_DIR_CLR registers, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers) to avoid any volatile levels on the output.

Open-Drain Mode - Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the PORT_DATA or PORT_DATA_CLR register. Then, set the one bit in the PORT_INEN register. Reads from the PORT_DATA register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pin.

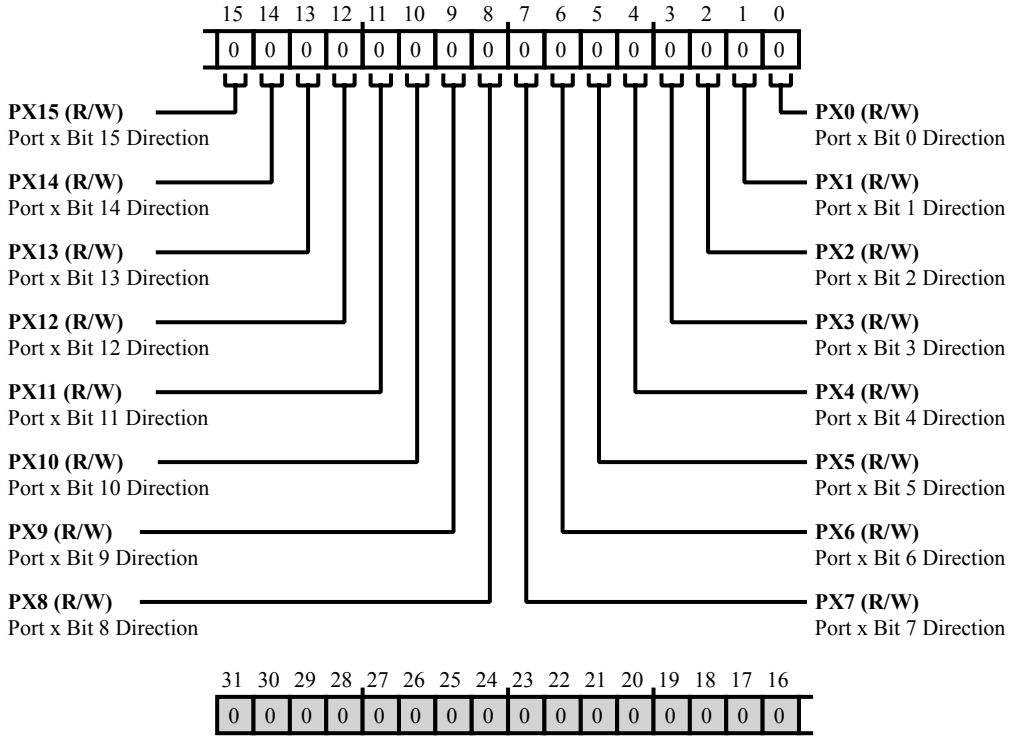

Figure 12-11: PORT_DIR Register Diagram

Table 12-16: PORT_DIR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
14 (R/W)	PX14	Port x Bit 14 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
13 (R/W)	PX13	Port x Bit 13 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
12 (R/W)	PX12	Port x Bit 12 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 12-16: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	PX11	Port x Bit 11 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
10 (R/W)	PX10	Port x Bit 10 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
9 (R/W)	PX9	Port x Bit 9 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
8 (R/W)	PX8	Port x Bit 8 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
7 (R/W)	PX7	Port x Bit 7 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
6 (R/W)	PX6	Port x Bit 6 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
5 (R/W)	PX5	Port x Bit 5 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Direction Set. The PORT_DIR_SET.PX15 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
14 (R/W1S)	PX14	Port x Bit 14 Direction Set. The PORT_DIR_SET.PX14 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Table 12-18: PORT_DIR_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Direction Set. The PORT_DIR_SET.PX13 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
12 (R/W1S)	PX12	Port x Bit 12 Direction Set. The PORT_DIR_SET.PX12 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
11 (R/W1S)	PX11	Port x Bit 11 Direction Set. The PORT_DIR_SET.PX11 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
10 (R/W1S)	PX10	Port x Bit 10 Direction Set. The PORT_DIR_SET.PX10 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
9 (R/W1S)	PX9	Port x Bit 9 Direction Set. The PORT_DIR_SET.PX9 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
8 (R/W1S)	PX8	Port x Bit 8 Direction Set. The PORT_DIR_SET.PX8 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
7 (R/W1S)	PX7	Port x Bit 7 Direction Set. The PORT_DIR_SET.PX7 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Table 12-18: PORT_DIR_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Direction Set. The PORT_DIR_SET.PX6 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
5 (R/W1S)	PX5	Port x Bit 5 Direction Set. The PORT_DIR_SET.PX5 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
4 (R/W1S)	PX4	Port x Bit 4 Direction Set. The PORT_DIR_SET.PX4 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
3 (R/W1S)	PX3	Port x Bit 3 Direction Set. The PORT_DIR_SET.PX3 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
2 (R/W1S)	PX2	Port x Bit 2 Direction Set. The PORT_DIR_SET.PX2 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
1 (R/W1S)	PX1	Port x Bit 1 Direction Set. The PORT_DIR_SET.PX1 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
0 (R/W1S)	PX0	Port x Bit 0 Direction Set. The PORT_DIR_SET.PX0 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Port x Function Enable Register

The PORT_FER register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the PORT_FER registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the PORT_MUX registers as to which peripheral takes control.

0 (R/W1S)	PX0	Port x Bit 0 Mode Set. The PORT_FER_SET.PX0 bit enables peripheral mode.	
		0	No Effect
		1	Set Bit for Peripheral Mode

Port x GPIO Input Enable Register

The PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the PORT_INEN register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the PORT_INEN_SET and PORT_INEN_CLR registers.

If the input is enabled, reads from the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information, see the PORT_DATA register description and the PORT_DIR register description.

		0	No Effect
		1	Set Bit. Set to enable the input driver.

Port x GPIO Lock Register

The PORT_LOCK register enables (unlocks) or disables (locks) write access selectively for the PORT control registers.

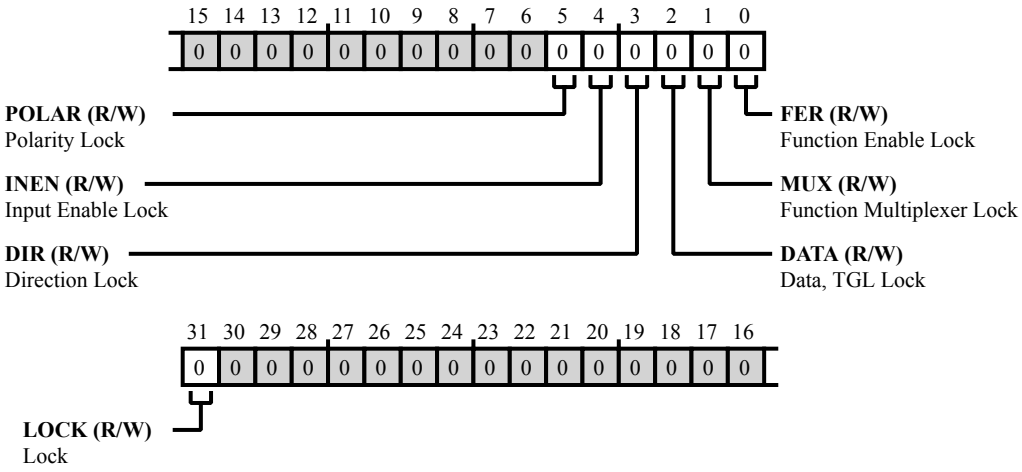

Figure 12-20: PORT_LOCK Register Diagram

Table 12-25: PORT_LOCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the PORT_LOCK.LOCK bit is set, the PORT_LOCK register is read only (locked).	
		0	Unlock
		1	Lock
5 (R/W)	POLAR	Polarity Lock. The PORT_LOCK.POLAR disables write access to the PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers.	
		0	Unlock POL
		1	Lock POL
4 (R/W)	INEN	Input Enable Lock. The PORT_LOCK.INEN disables write access to the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers.	
		0	Unlock INEN
		1	Lock INEN

Table 12-25: PORT_LOCK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIR	Direction Lock. The PORT_LOCK.DIR disables write access to the PORT_DIR, PORT_DIR_SET, PORT_DIR_CLR registers.	
		0	Unlock DIR
		1	Lock DIR
2 (R/W)	DATA	Data, TGL Lock. The PORT_LOCK.DATA disables write access to the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, and PORT_DATA_TGL registers.	
		0	Unlock DATA
		1	Lock DATA
1 (R/W)	MUX	Function Multiplexer Lock. The PORT_LOCK.MUX disables write accesses to the PORT_MUX register.	
		0	Unlock MUX
		1	Lock MUX
0 (R/W)	FER	Function Enable Lock. The PORT_LOCK.FER disables write access to the PORT_FER, PORT_FER_SET, and PORT_FER_CLR registers.	
		0	Unlock FER
		1	Lock FER

Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the PORT_MUX register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, bit 0 and bit 1 of the PORT_MUX register control the multiplexer of pin 0, bit 2 and bit 3 of PORT_MUX control the multiplexer of pin 1, and so on. The value of any PORT_MUX bit has no effect on the port pins when the associated bit in the PORT_FER register is 0 (selects GPIO mode). Even if a port has only one function, the PORT_MUX register is still present. For single function ports (no multiplexing is needed), leave the PORT_MUX bits at 0 (default). For all PORT_MUX bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

See the processor data sheet for details regarding the peripheral options associated with each port.

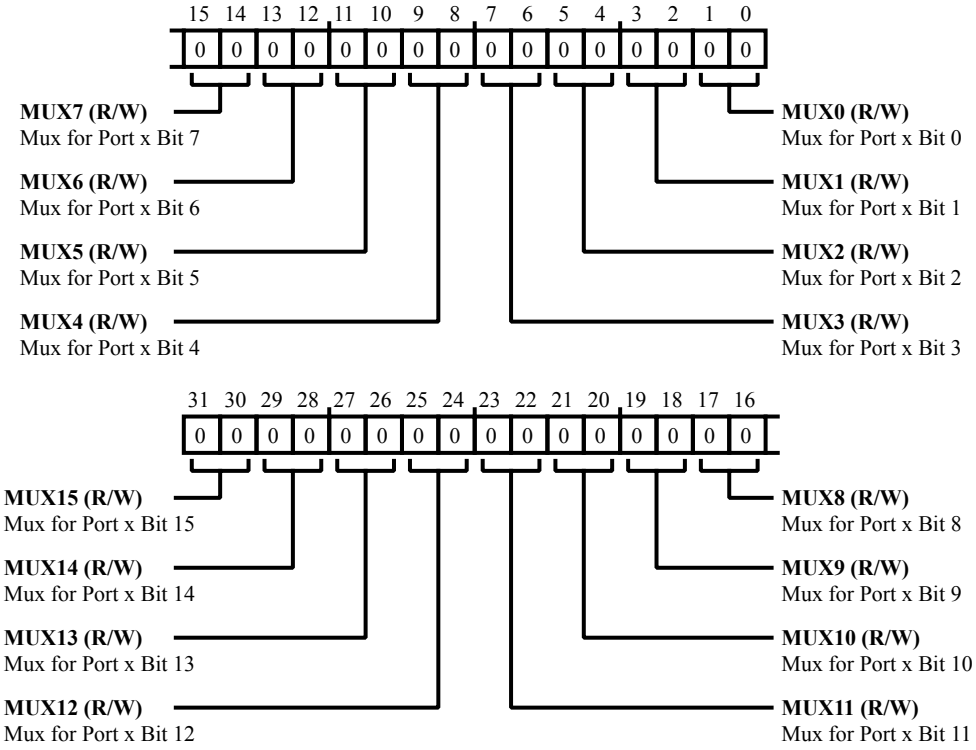

Figure 12-21: PORT_MUX Register Diagram

Table 12-26: PORT_MUX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	MUX15	Mux for Port x Bit 15. The PORT_MUX.MUX15 bit provides multiplexer control for port x bit 15.

Table 12-26: PORT_MUX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:28 (R/W)	MUX14	Mux for Port x Bit 14. The PORT_MUX.MUX14 bit provides multiplexer control for port x bit 14.
27:26 (R/W)	MUX13	Mux for Port x Bit 13. The PORT_MUX.MUX13 bit provides multiplexer control for port x bit 13.
25:24 (R/W)	MUX12	Mux for Port x Bit 12. The PORT_MUX.MUX12 bit provides multiplexer control for port x bit 12.
23:22 (R/W)	MUX11	Mux for Port x Bit 11. The PORT_MUX.MUX11 bit provides multiplexer control for port x bit 11.
21:20 (R/W)	MUX10	Mux for Port x Bit 10. The PORT_MUX.MUX10 bit provides multiplexer control for port x bit 10.
19:18 (R/W)	MUX9	Mux for Port x Bit 9. The PORT_MUX.MUX9 bit provides multiplexer control for port x bit 9.
17:16 (R/W)	MUX8	Mux for Port x Bit 8. The PORT_MUX.MUX8 bit provides multiplexer control for port x bit 8.
15:14 (R/W)	MUX7	Mux for Port x Bit 7. The PORT_MUX.MUX7 bit provides multiplexer control for port x bit 7.
13:12 (R/W)	MUX6	Mux for Port x Bit 6. The PORT_MUX.MUX6 bit provides multiplexer control for port x bit 6.
11:10 (R/W)	MUX5	Mux for Port x Bit 5. The PORT_MUX.MUX5 bit provides multiplexer control for port x bit 5.
9:8 (R/W)	MUX4	Mux for Port x Bit 4. The PORT_MUX.MUX4 bit provides multiplexer control for port x bit 4.
7:6 (R/W)	MUX3	Mux for Port x Bit 3. The PORT_MUX.MUX3 bit provides multiplexer control for port x bit 3.
5:4 (R/W)	MUX2	Mux for Port x Bit 2. The PORT_MUX.MUX2 bit provides multiplexer control for port x bit 2.
3:2 (R/W)	MUX1	Mux for Port x Bit 1. The PORT_MUX.MUX1 bit provides multiplexer control for port x bit 1.
1:0 (R/W)	MUX0	Mux for Port x Bit 0. The PORT_MUX.MUX0 bit provides multiplexer control for port x bit 0.

Port x GPIO Polarity Invert Register

The PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the PORT_POL register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the PORT_POL_SET and PORT_POL_CLR registers.

Setting a bit in the PORT_POL register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the PORT_POL register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

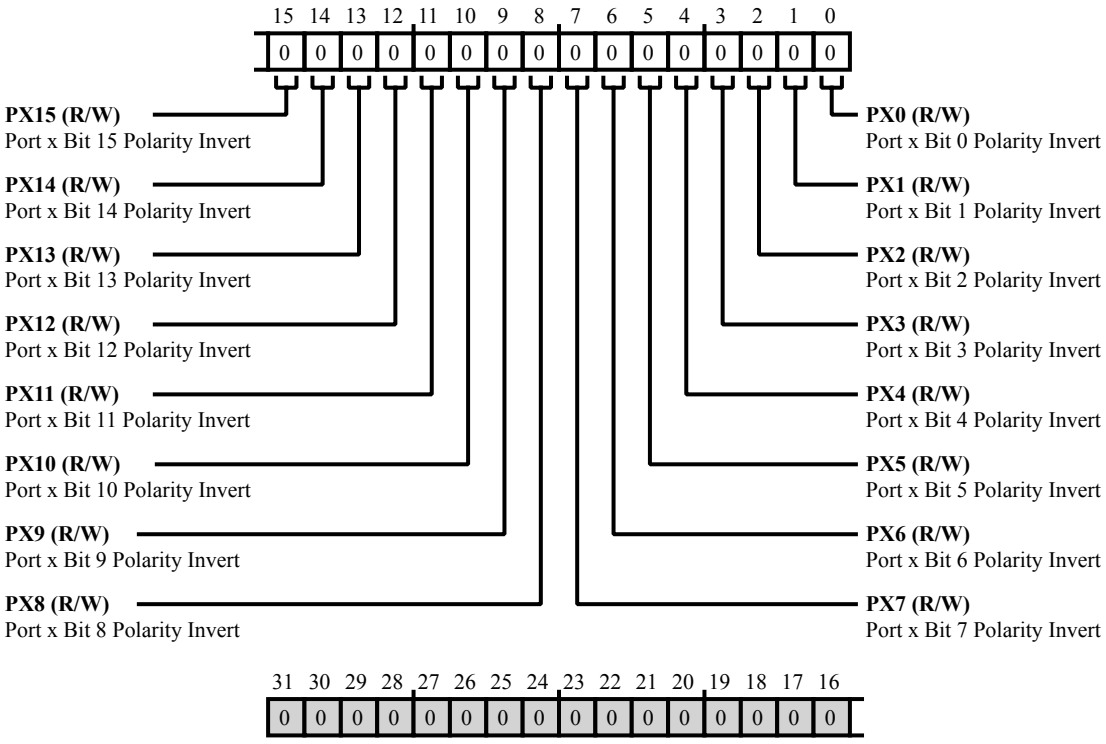

Figure 12-22: PORT_POL Register Diagram

Table 12-27: PORT_POL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Polarity Invert. The PORT_POL.PX15 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	PX14	Port x Bit 14 Polarity Invert. The PORT_POL.PX14 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
13 (R/W)	PX13	Port x Bit 13 Polarity Invert. The PORT_POL.PX13 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
12 (R/W)	PX12	Port x Bit 12 Polarity Invert. The PORT_POL.PX12 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
11 (R/W)	PX11	Port x Bit 11 Polarity Invert. The PORT_POL.PX11 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
10 (R/W)	PX10	Port x Bit 10 Polarity Invert. The PORT_POL.PX10 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
9 (R/W)	PX9	Port x Bit 9 Polarity Invert. The PORT_POL.PX9 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
8 (R/W)	PX8	Port x Bit 8 Polarity Invert. The PORT_POL.PX8 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PX7	Port x Bit 7 Polarity Invert. The PORT_POL.PX7 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
6 (R/W)	PX6	Port x Bit 6 Polarity Invert. The PORT_POL.PX6 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
5 (R/W)	PX5	Port x Bit 5 Polarity Invert. The PORT_POL.PX5 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
4 (R/W)	PX4	Port x Bit 4 Polarity Invert. The PORT_POL.PX4 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
3 (R/W)	PX3	Port x Bit 3 Polarity Invert. The PORT_POL.PX3 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
2 (R/W)	PX2	Port x Bit 2 Polarity Invert. The PORT_POL.PX2 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
1 (R/W)	PX1	Port x Bit 1 Polarity Invert. The PORT_POL.PX1 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PX0	Port x Bit 0 Polarity Invert. The `PORT_POL.PX0` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Port x GPIO Polarity Invert Clear Register

The PORT_POL_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

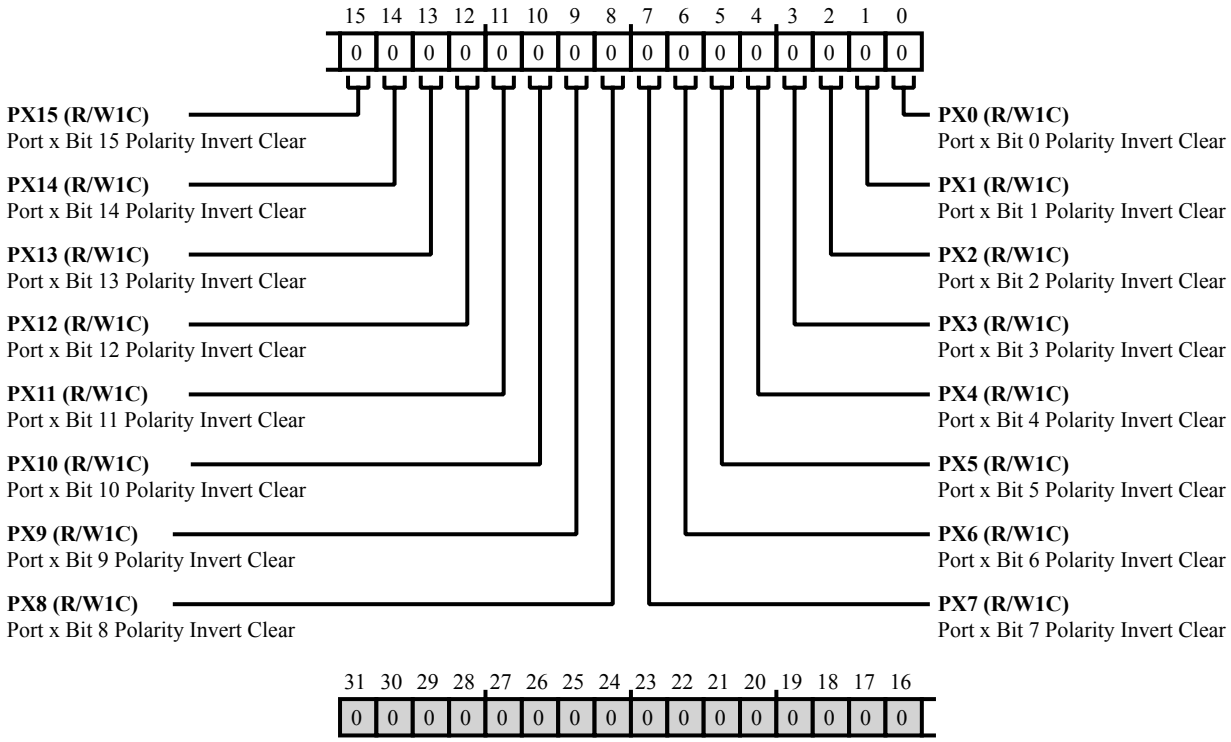

Figure 12-23: PORT_POL_CLR Register Diagram

Table 12-28: PORT_POL_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
14 (R/W1C)	PX14	Port x Bit 14 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
13 (R/W1C)	PX13	Port x Bit 13 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 12-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	PX12	Port x Bit 12 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
11 (R/W1C)	PX11	Port x Bit 11 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
10 (R/W1C)	PX10	Port x Bit 10 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
9 (R/W1C)	PX9	Port x Bit 9 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
8 (R/W1C)	PX8	Port x Bit 8 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
7 (R/W1C)	PX7	Port x Bit 7 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
6 (R/W1C)	PX6	Port x Bit 6 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
5 (R/W1C)	PX5	Port x Bit 5 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
4 (R/W1C)	PX4	Port x Bit 4 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
3 (R/W1C)	PX3	Port x Bit 3 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 12-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	PX2	Port x Bit 2 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
1 (R/W1C)	PX1	Port x Bit 1 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
0 (R/W1C)	PX0	Port x Bit 0 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Port x GPIO Polarity Invert Set Register

The PORT_POL_SET register enables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

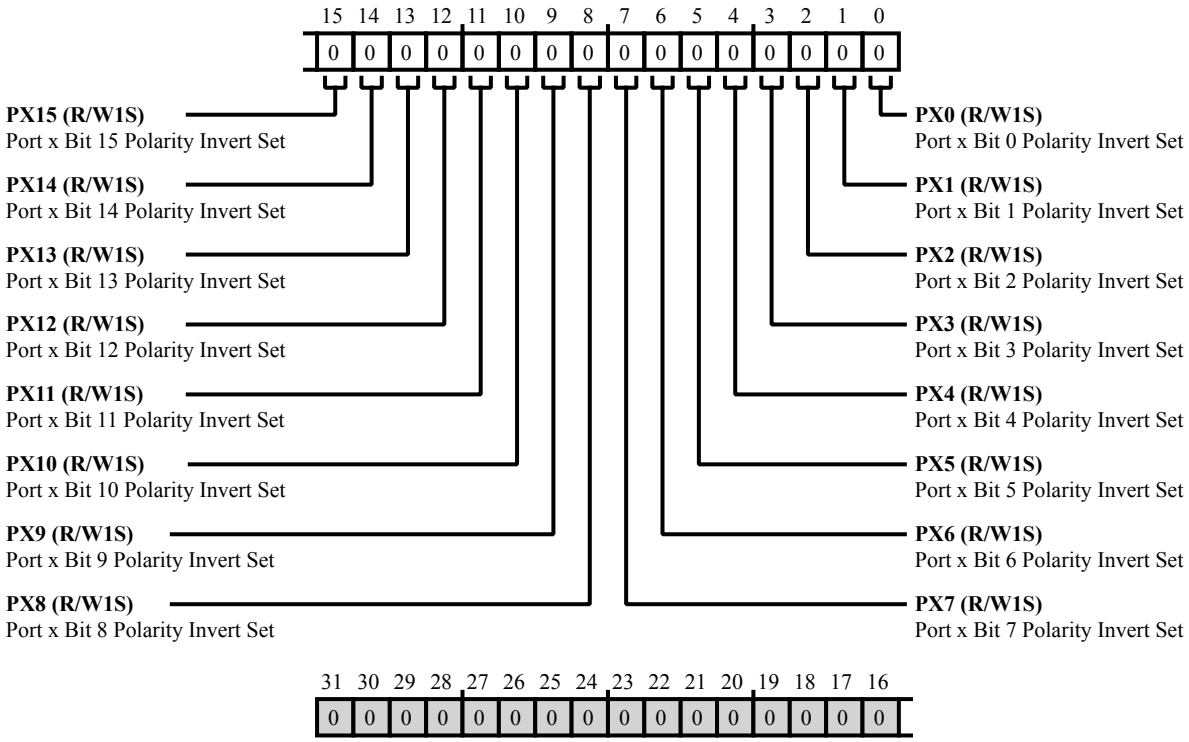

Figure 12-24: PORT_POL_SET Register Diagram

Table 12-29: PORT_POL_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Polarity Invert Set. The PORT_POL_SET.PX15 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
14 (R/W1S)	PX14	Port x Bit 14 Polarity Invert Set. The PORT_POL_SET.PX14 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 12-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Polarity Invert Set. The PORT_POL_SET.PX13 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
12 (R/W1S)	PX12	Port x Bit 12 Polarity Invert Set. The PORT_POL_SET.PX12 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
11 (R/W1S)	PX11	Port x Bit 11 Polarity Invert Set. The PORT_POL_SET.PX11 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
10 (R/W1S)	PX10	Port x Bit 10 Polarity Invert Set. The PORT_POL_SET.PX10 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
9 (R/W1S)	PX9	Port x Bit 9 Polarity Invert Set. The PORT_POL_SET.PX9 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
8 (R/W1S)	PX8	Port x Bit 8 Polarity Invert Set. The PORT_POL_SET.PX8 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
7 (R/W1S)	PX7	Port x Bit 7 Polarity Invert Set. The PORT_POL_SET.PX7 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 12-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Polarity Invert Set. The PORT_POL_SET.PX6 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
5 (R/W1S)	PX5	Port x Bit 5 Polarity Invert Set. The PORT_POL_SET.PX5 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
4 (R/W1S)	PX4	Port x Bit 4 Polarity Invert Set. The PORT_POL_SET.PX4 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
3 (R/W1S)	PX3	Port x Bit 3 Polarity Invert Set. The PORT_POL_SET.PX3 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
2 (R/W1S)	PX2	Port x Bit 2 Polarity Invert Set. The PORT_POL_SET.PX2 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
1 (R/W1S)	PX1	Port x Bit 1 Polarity Invert Set. The PORT_POL_SET.PX1 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
0 (R/W1S)	PX0	Port x Bit 0 Polarity Invert Set. The PORT_POL_SET.PX0 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Port x GPIO Trigger Toggle Register

The PORT_TRIG_TGL register permits toggling the state of output GPIO pins in response to a trigger from the TRU for the corresponding port. Setting bits in the PORT_TRIG_TGL register enables triggers to toggle the state of those specific pins without impacting other pins of the port.

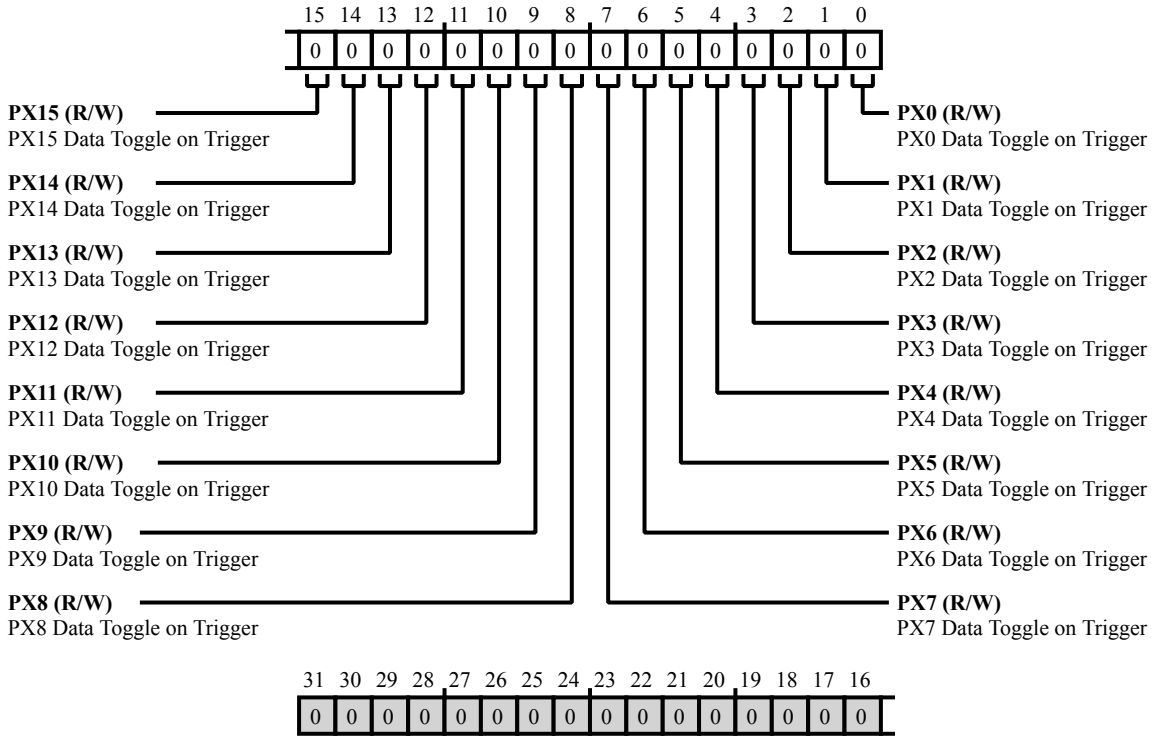

Figure 12-25: PORT_TRIG_TGL Register Diagram

Table 12-30: PORT_TRIG_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PX15	PX15 Data Toggle on Trigger. The PORT_TRIG_TGL.PX15 bit enables triggers to toggle the state of the pin.
14 (R/W)	PX14	PX14 Data Toggle on Trigger. The PORT_TRIG_TGL.PX14 bit enables triggers to toggle the state of the pin.
13 (R/W)	PX13	PX13 Data Toggle on Trigger. The PORT_TRIG_TGL.PX13 bit enables triggers to toggle the state of the pin.
12 (R/W)	PX12	PX12 Data Toggle on Trigger. The PORT_TRIG_TGL.PX12 bit enables triggers to toggle the state of the pin.
11 (R/W)	PX11	PX11 Data Toggle on Trigger. The PORT_TRIG_TGL.PX11 bit enables triggers to toggle the state of the pin.

Table 12-30: PORT_TRIG_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	PX10	PX10 Data Toggle on Trigger. The PORT_TRIG_TGL.PX10 bit enables triggers to toggle the state of the pin.
9 (R/W)	PX9	PX9 Data Toggle on Trigger. The PORT_TRIG_TGL.PX9 bit enables triggers to toggle the state of the pin.
8 (R/W)	PX8	PX8 Data Toggle on Trigger. The PORT_TRIG_TGL.PX8 bit enables triggers to toggle the state of the pin.
7 (R/W)	PX7	PX7 Data Toggle on Trigger. The PORT_TRIG_TGL.PX7 bit enables triggers to toggle the state of the pin.
6 (R/W)	PX6	PX6 Data Toggle on Trigger. The PORT_TRIG_TGL.PX6 bit enables triggers to toggle the state of the pin.
5 (R/W)	PX5	PX5 Data Toggle on Trigger. The PORT_TRIG_TGL.PX5 bit enables triggers to toggle the state of the pin.
4 (R/W)	PX4	PX4 Data Toggle on Trigger. The PORT_TRIG_TGL.PX4 bit enables triggers to toggle the state of the pin.
3 (R/W)	PX3	PX3 Data Toggle on Trigger. The PORT_TRIG_TGL.PX3 bit enables triggers to toggle the state of the pin.
2 (R/W)	PX2	PX2 Data Toggle on Trigger. The PORT_TRIG_TGL.PX2 bit enables triggers to toggle the state of the pin.
1 (R/W)	PX1	PX1 Data Toggle on Trigger. The PORT_TRIG_TGL.PX1 bit enables triggers to toggle the state of the pin.
0 (R/W)	PX0	PX0 Data Toggle on Trigger. The PORT_TRIG_TGL.PX0 bit enables triggers to toggle the state of the pin.

ADSP-SC57x PINT Register Descriptions

The Pin Interrupt module (PINT) contains the following registers.

Table 12-31: ADSP-SC57x PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register

Table 12-31: ADSP-SC57x PINT Register List (Continued)

Name	Description
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

PINT Assign Register

The PINT_ASSIGN register controls the pin-to-interrupt request assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block. The upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

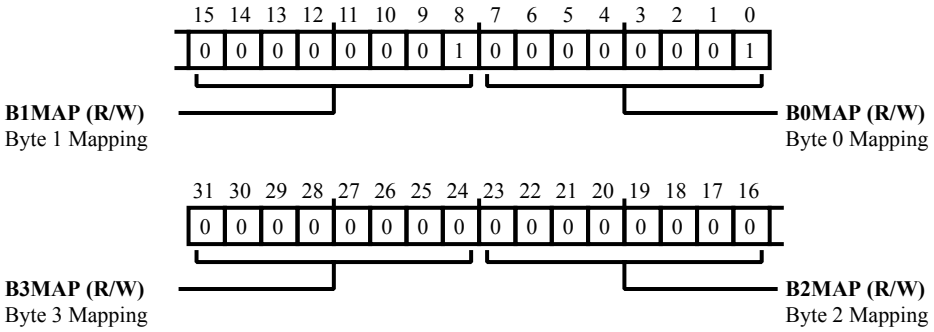

Figure 12-26: PINT_ASSIGN Register Diagram

Table 12-32: PINT_ASSIGN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	B3MAP	Byte 3 Mapping.	
		0	B3MAP_PAH. Byte 3 = PA.H
		1	B3MAP_PBH. Byte 3 = PB.H
23:16 (R/W)	B2MAP	Byte 2 Mapping.	
		0	B2MAP_PAL. Byte 2 = PA.L
		1	B2MAP_PBL. Byte 2 = PB.L
15:8 (R/W)	B1MAP	Byte 1 Mapping.	
		0	B1MAP_PAH. Byte 1 = PA.H
		1	B1MAP_PBH. Byte 1 = PB.H
7:0 (R/W)	B0MAP	Byte 0 Mapping.	
		0	B0MAP_PAL. Byte 0 = PA.L
		1	B0MAP_PBL. Byte 0 = PB.L

PINT Edge Clear Register

The PINT_EDGE_CLR register permits selecting level-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_CLR enables level sensitivity for the corresponding pin interrupt.

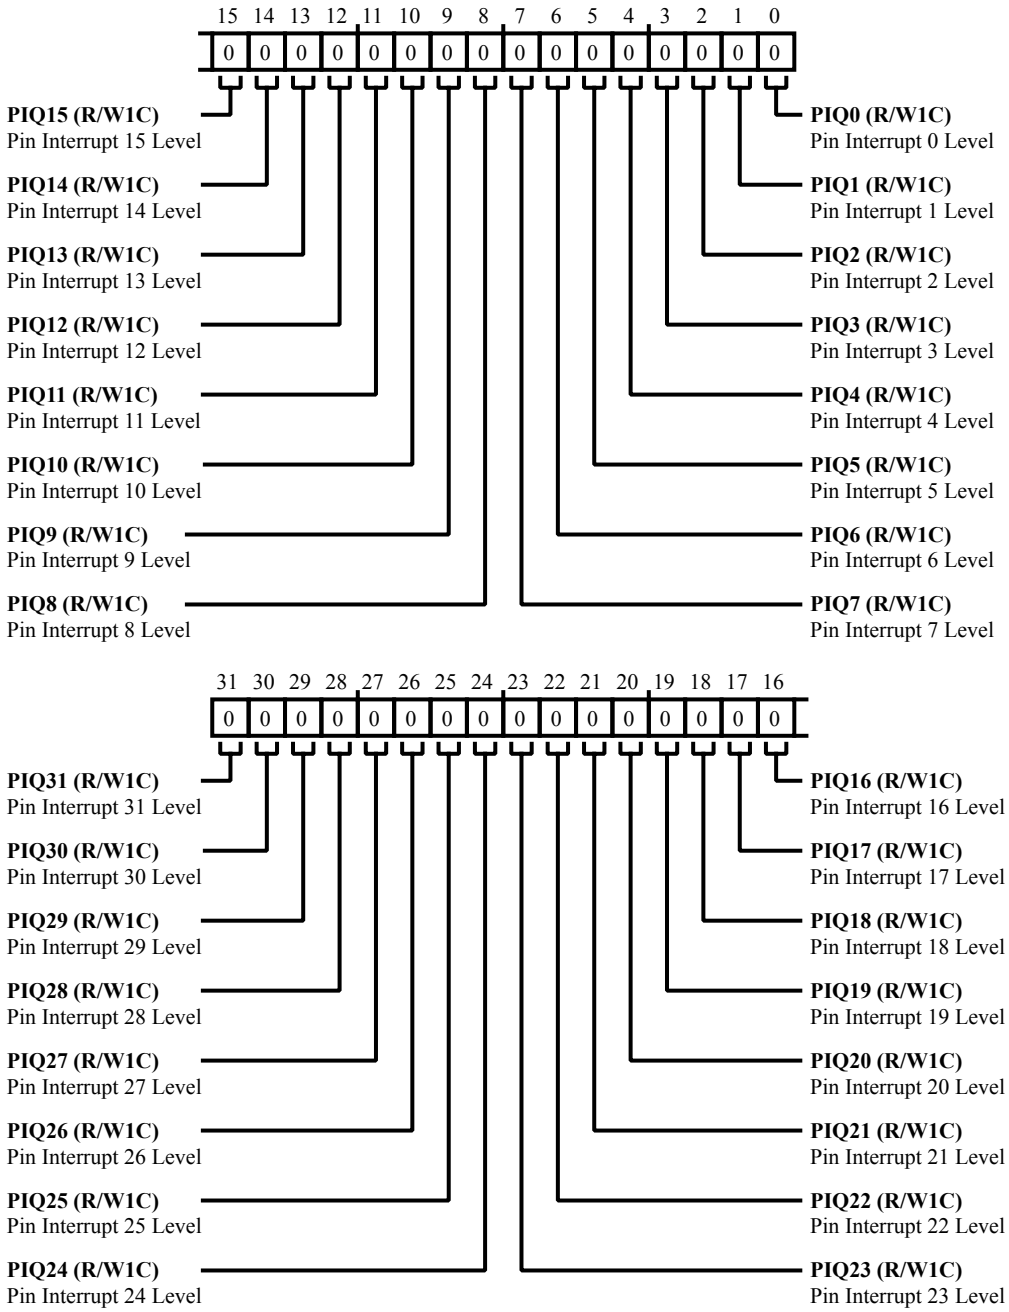

Figure 12-27: PINT_EDGE_CLR Register Diagram

Table 12-33: PINT_EDGE_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Level. Set the PINT_EDGE_CLR.PIQ31 bit to enable level sensitivity.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Level. Set the PINT_EDGE_CLR.PIQ30 bit to enable level sensitivity.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Level. Set the PINT_EDGE_CLR.PIQ29 bit to enable level sensitivity.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Level. Set the PINT_EDGE_CLR.PIQ28 bit to enable level sensitivity.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Level. Set the PINT_EDGE_CLR.PIQ27 bit to enable level sensitivity.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Level. Set the PINT_EDGE_CLR.PIQ26 bit to enable level sensitivity.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Level. Set the PINT_EDGE_CLR.PIQ25 bit to enable level sensitivity.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Level. Set the PINT_EDGE_CLR.PIQ24 bit to enable level sensitivity.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Level. Set the PINT_EDGE_CLR.PIQ23 bit to enable level sensitivity.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Level. Set the PINT_EDGE_CLR.PIQ22 bit to enable level sensitivity.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Level. Set the PINT_EDGE_CLR.PIQ21 bit to enable level sensitivity.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Level. Set the PINT_EDGE_CLR.PIQ20 bit to enable level sensitivity.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Level. Set the PINT_EDGE_CLR.PIQ19 bit to enable level sensitivity.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Level. Set the PINT_EDGE_CLR.PIQ18 bit to enable level sensitivity.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Level. Set the PINT_EDGE_CLR.PIQ17 bit to enable level sensitivity.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Level. Set the PINT_EDGE_CLR.PIQ16 bit to enable level sensitivity.

Table 12-33: PINT_EDGE_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Level. Set the PINT_EDGE_CLR.PIQ15 bit to enable level sensitivity.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Level. Set the PINT_EDGE_CLR.PIQ14 bit to enable level sensitivity.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Level. Set the PINT_EDGE_CLR.PIQ13 bit to enable level sensitivity.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Level. Set the PINT_EDGE_CLR.PIQ12 bit to enable level sensitivity.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Level. Set the PINT_EDGE_CLR.PIQ11 bit to enable level sensitivity.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Level. Set the PINT_EDGE_CLR.PIQ10 bit to enable level sensitivity.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Level. Set the PINT_EDGE_CLR.PIQ9 bit to enable level sensitivity.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Level. Set the PINT_EDGE_CLR.PIQ8 bit to enable level sensitivity.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Level. Set the PINT_EDGE_CLR.PIQ7 bit to enable level sensitivity.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Level. Set the PINT_EDGE_CLR.PIQ6 bit to enable level sensitivity.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Level. Set the PINT_EDGE_CLR.PIQ5 bit to enable level sensitivity.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Level. Set the PINT_EDGE_CLR.PIQ4 bit to enable level sensitivity.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Level. Set the PINT_EDGE_CLR.PIQ3 bit to enable level sensitivity.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Level. Set the PINT_EDGE_CLR.PIQ2 bit to enable level sensitivity.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Level. Set the PINT_EDGE_CLR.PIQ1 bit to enable level sensitivity.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Level. Set the PINT_EDGE_CLR.PIQ0 bit to enable level sensitivity.

PINT Edge Set Register

The PINT_EDGE_SET register permits selecting edge-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_SET enables edge sensitivity for the corresponding pin interrupt.

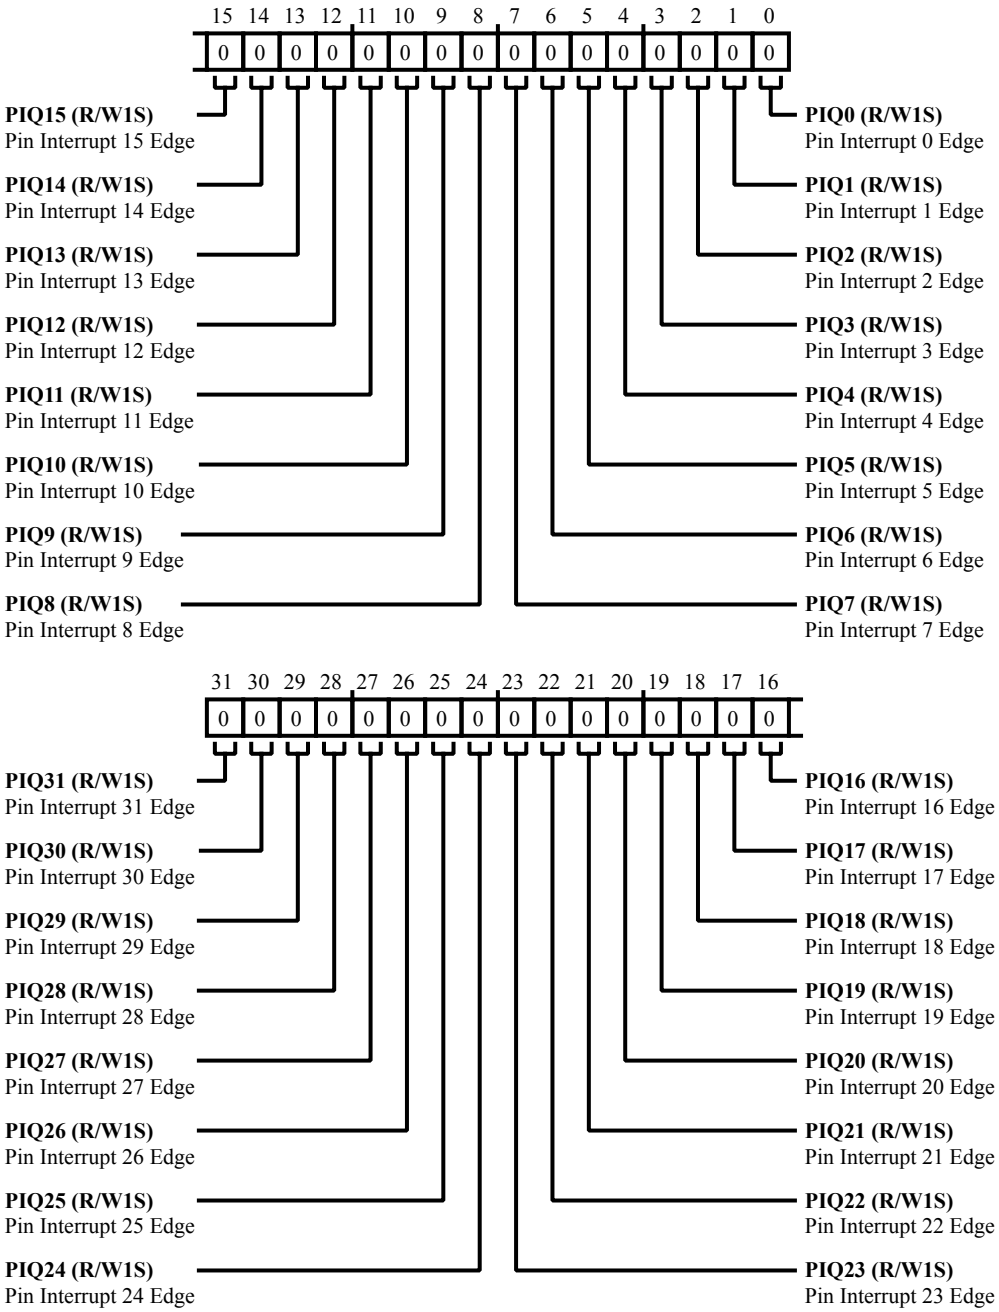

Figure 12-28: PINT_EDGE_SET Register Diagram

Table 12-34: PINT_EDGE_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Edge. Set the PINT_EDGE_SET.PIQ31 bit to enable edge sensitivity.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Edge. Set the PINT_EDGE_SET.PIQ30 bit to enable edge sensitivity.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Edge. Set the PINT_EDGE_SET.PIQ29 bit to enable edge sensitivity.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Edge. Set the PINT_EDGE_SET.PIQ28 bit to enable edge sensitivity.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Edge. Set the PINT_EDGE_SET.PIQ27 bit to enable edge sensitivity.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Edge. Set the PINT_EDGE_SET.PIQ26 bit to enable edge sensitivity.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Edge. Set the PINT_EDGE_SET.PIQ25 bit to enable edge sensitivity.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Edge. Set the PINT_EDGE_SET.PIQ24 bit to enable edge sensitivity.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Edge. Set the PINT_EDGE_SET.PIQ23 bit to enable edge sensitivity.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Edge. Set the PINT_EDGE_SET.PIQ22 bit to enable edge sensitivity.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Edge. Set the PINT_EDGE_SET.PIQ21 bit to enable edge sensitivity.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Edge. Set the PINT_EDGE_SET.PIQ20 bit to enable edge sensitivity.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Edge. Set the PINT_EDGE_SET.PIQ19 bit to enable edge sensitivity.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Edge. Set the PINT_EDGE_SET.PIQ18 bit to enable edge sensitivity.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Edge. Set the PINT_EDGE_SET.PIQ17 bit to enable edge sensitivity.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Edge. Set the PINT_EDGE_SET.PIQ16 bit to enable edge sensitivity.

Table 12-34: PINT_EDGE_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Edge. Set the PINT_EDGE_SET.PIQ15 bit to enable edge sensitivity.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Edge. Set the PINT_EDGE_SET.PIQ14 bit to enable edge sensitivity.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Edge. Set the PINT_EDGE_SET.PIQ13 bit to enable edge sensitivity.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Edge. Set the PINT_EDGE_SET.PIQ12 bit to enable edge sensitivity.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Edge. Set the PINT_EDGE_SET.PIQ11 bit to enable edge sensitivity.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Edge. Set the PINT_EDGE_SET.PIQ10 bit to enable edge sensitivity.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Edge. Set the PINT_EDGE_SET.PIQ9 bit to enable edge sensitivity.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Edge. Set the PINT_EDGE_SET.PIQ8 bit to enable edge sensitivity.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Edge. Set the PINT_EDGE_SET.PIQ7 bit to enable edge sensitivity.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Edge. Set the PINT_EDGE_SET.PIQ6 bit to enable edge sensitivity.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Edge. Set the PINT_EDGE_SET.PIQ5 bit to enable edge sensitivity.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Edge. Set the PINT_EDGE_SET.PIQ4 bit to enable edge sensitivity.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Edge. Set the PINT_EDGE_SET.PIQ3 bit to enable edge sensitivity.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Edge. Set the PINT_EDGE_SET.PIQ2 bit to enable edge sensitivity.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Edge. Set the PINT_EDGE_SET.PIQ1 bit to enable edge sensitivity.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Edge. Set the PINT_EDGE_SET.PIQ0 bit to enable edge sensitivity.

PINT Invert Clear Register

The PINT_INV_CLR register disables inverting input polarity. Writing 1 to a bit in PINT_INV_CLR disables an inverter for input on the corresponding pin.

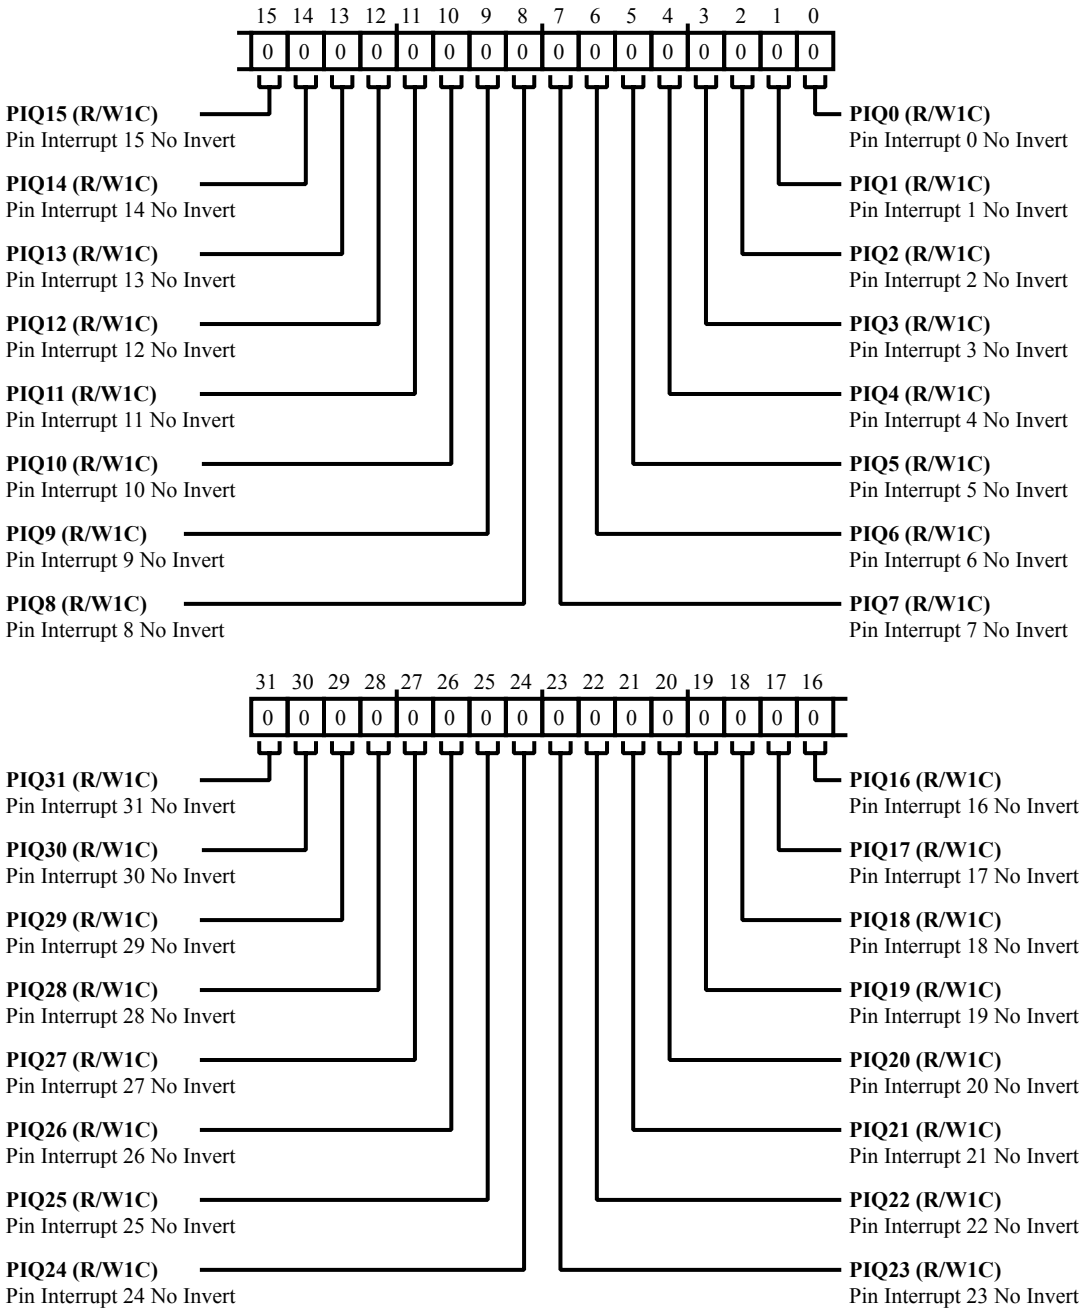

Figure 12-29: PINT_INV_CLR Register Diagram

Table 12-35: PINT_INV_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 No Invert. Set the PINT_INV_CLR.PIQ31 bit to disable inverted input.
30 (R/W1C)	PIQ30	Pin Interrupt 30 No Invert. Set the PINT_INV_CLR.PIQ30 bit to disable inverted input.
29 (R/W1C)	PIQ29	Pin Interrupt 29 No Invert. Set the PINT_INV_CLR.PIQ29 bit to disable inverted input.
28 (R/W1C)	PIQ28	Pin Interrupt 28 No Invert. Set the PINT_INV_CLR.PIQ28 bit to disable inverted input.
27 (R/W1C)	PIQ27	Pin Interrupt 27 No Invert. Set the PINT_INV_CLR.PIQ27 bit to disable inverted input.
26 (R/W1C)	PIQ26	Pin Interrupt 26 No Invert. Set the PINT_INV_CLR.PIQ26 bit to disable inverted input.
25 (R/W1C)	PIQ25	Pin Interrupt 25 No Invert. Set the PINT_INV_CLR.PIQ25 bit to disable inverted input.
24 (R/W1C)	PIQ24	Pin Interrupt 24 No Invert. Set the PINT_INV_CLR.PIQ24 bit to disable inverted input.
23 (R/W1C)	PIQ23	Pin Interrupt 23 No Invert. Set the PINT_INV_CLR.PIQ23 bit to disable inverted input.
22 (R/W1C)	PIQ22	Pin Interrupt 22 No Invert. Set the PINT_INV_CLR.PIQ22 bit to disable inverted input.
21 (R/W1C)	PIQ21	Pin Interrupt 21 No Invert. Set the PINT_INV_CLR.PIQ21 bit to disable inverted input.
20 (R/W1C)	PIQ20	Pin Interrupt 20 No Invert. Set the PINT_INV_CLR.PIQ20 bit to disable inverted input.
19 (R/W1C)	PIQ19	Pin Interrupt 19 No Invert. Set the PINT_INV_CLR.PIQ19 bit to disable inverted input.
18 (R/W1C)	PIQ18	Pin Interrupt 18 No Invert. Set the PINT_INV_CLR.PIQ18 bit to disable inverted input.
17 (R/W1C)	PIQ17	Pin Interrupt 17 No Invert. Set the PINT_INV_CLR.PIQ17 bit to disable inverted input.
16 (R/W1C)	PIQ16	Pin Interrupt 16 No Invert. Set the PINT_INV_CLR.PIQ16 bit to disable inverted input.

Table 12-35: PINT_INV_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 No Invert. Set the PINT_INV_CLR.PIQ15 bit to disable inverted input.
14 (R/W1C)	PIQ14	Pin Interrupt 14 No Invert. Set the PINT_INV_CLR.PIQ14 bit to disable inverted input.
13 (R/W1C)	PIQ13	Pin Interrupt 13 No Invert. Set the PINT_INV_CLR.PIQ13 bit to disable inverted input.
12 (R/W1C)	PIQ12	Pin Interrupt 12 No Invert. Set the PINT_INV_CLR.PIQ12 bit to disable inverted input.
11 (R/W1C)	PIQ11	Pin Interrupt 11 No Invert. Set the PINT_INV_CLR.PIQ11 bit to disable inverted input.
10 (R/W1C)	PIQ10	Pin Interrupt 10 No Invert. Set the PINT_INV_CLR.PIQ10 bit to disable inverted input.
9 (R/W1C)	PIQ9	Pin Interrupt 9 No Invert. Set the PINT_INV_CLR.PIQ9 bit to disable inverted input.
8 (R/W1C)	PIQ8	Pin Interrupt 8 No Invert. Set the PINT_INV_CLR.PIQ8 bit to disable inverted input.
7 (R/W1C)	PIQ7	Pin Interrupt 7 No Invert. Set the PINT_INV_CLR.PIQ7 bit to disable inverted input.
6 (R/W1C)	PIQ6	Pin Interrupt 6 No Invert. Set the PINT_INV_CLR.PIQ6 bit to disable inverted input.
5 (R/W1C)	PIQ5	Pin Interrupt 5 No Invert. Set the PINT_INV_CLR.PIQ5 bit to disable inverted input.
4 (R/W1C)	PIQ4	Pin Interrupt 4 No Invert. Set the PINT_INV_CLR.PIQ4 bit to disable inverted input.
3 (R/W1C)	PIQ3	Pin Interrupt 3 No Invert. Set the PINT_INV_CLR.PIQ3 bit to disable inverted input.
2 (R/W1C)	PIQ2	Pin Interrupt 2 No Invert. Set the PINT_INV_CLR.PIQ2 bit to disable inverted input.
1 (R/W1C)	PIQ1	Pin Interrupt 1 No Invert. Set the PINT_INV_CLR.PIQ1 bit to disable inverted input.
0 (R/W1C)	PIQ0	Pin Interrupt 0 No Invert. Set the PINT_INV_CLR.PIQ0 bit to disable inverted input.

PINT Invert Set Register

The PINT_INV_SET register enables inverting input polarity. Writing 1 to a bit in PINT_INV_SET enables an inverter for input on the corresponding pin.

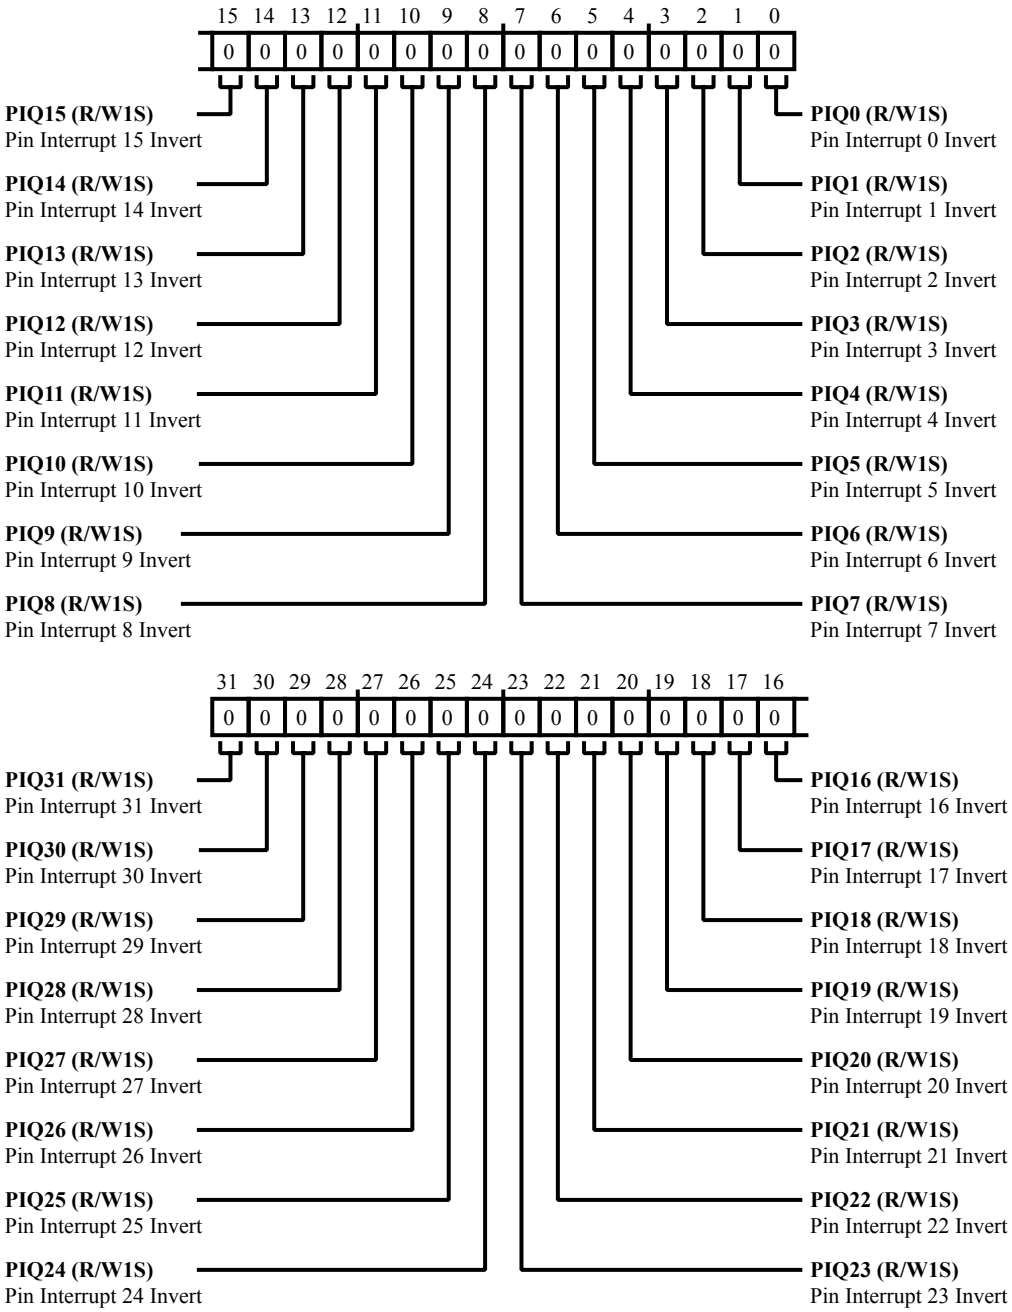

Figure 12-30: PINT_INV_SET Register Diagram

Table 12-36: PINT_INV_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Invert. Set the PINT_INV_SET.PIQ31 bit to enable inverted input.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Invert. Set the PINT_INV_SET.PIQ30 bit to enable inverted input.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Invert. Set the PINT_INV_SET.PIQ29 bit to enable inverted input.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Invert. Set the PINT_INV_SET.PIQ28 bit to enable inverted input.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Invert. Set the PINT_INV_SET.PIQ27 bit to enable inverted input.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Invert. Set the PINT_INV_SET.PIQ26 bit to enable inverted input.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Invert. Set the PINT_INV_SET.PIQ25 bit to enable inverted input.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Invert. Set the PINT_INV_SET.PIQ24 bit to enable inverted input.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Invert. Set the PINT_INV_SET.PIQ23 bit to enable inverted input.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Invert. Set the PINT_INV_SET.PIQ22 bit to enable inverted input.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Invert. Set the PINT_INV_SET.PIQ21 bit to enable inverted input.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Invert. Set the PINT_INV_SET.PIQ20 bit to enable inverted input.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Invert. Set the PINT_INV_SET.PIQ19 bit to enable inverted input.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Invert. Set the PINT_INV_SET.PIQ18 bit to enable inverted input.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Invert. Set the PINT_INV_SET.PIQ17 bit to enable inverted input.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Invert. Set the PINT_INV_SET.PIQ16 bit to enable inverted input.

Table 12-36: PINT_INV_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Invert. Set the PINT_INV_SET.PIQ15 bit to enable inverted input.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Invert. Set the PINT_INV_SET.PIQ14 bit to enable inverted input.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Invert. Set the PINT_INV_SET.PIQ13 bit to enable inverted input.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Invert. Set the PINT_INV_SET.PIQ12 bit to enable inverted input.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Invert. Set the PINT_INV_SET.PIQ11 bit to enable inverted input.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Invert. Set the PINT_INV_SET.PIQ10 bit to enable inverted input.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Invert. Set the PINT_INV_SET.PIQ9 bit to enable inverted input.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Invert. Set the PINT_INV_SET.PIQ8 bit to enable inverted input.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Invert. Set the PINT_INV_SET.PIQ7 bit to enable inverted input.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Invert. Set the PINT_INV_SET.PIQ6 bit to enable inverted input.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Invert. Set the PINT_INV_SET.PIQ5 bit to enable inverted input.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Invert. Set the PINT_INV_SET.PIQ4 bit to enable inverted input.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Invert. Set the PINT_INV_SET.PIQ3 bit to enable inverted input.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Invert. Set the PINT_INV_SET.PIQ2 bit to enable inverted input.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Invert. Set the PINT_INV_SET.PIQ1 bit to enable inverted input.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Invert. Set the PINT_INV_SET.PIQ0 bit to enable inverted input.

PINT Latch Register

The PINT_LATCH register indicates the interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The PINT_LATCH registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either register clears the respective bits in both registers. For interrupt operation, the user may prefer to W1C the PINT_REQ register (address still loaded in Px pointer). In polling mode, it might be cleaner to W1C the PINT_LATCH register.

Whether in edge-sensitive mode or level-sensitive mode, PINT_LATCH bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the PINT_LATCH register functions as latch.

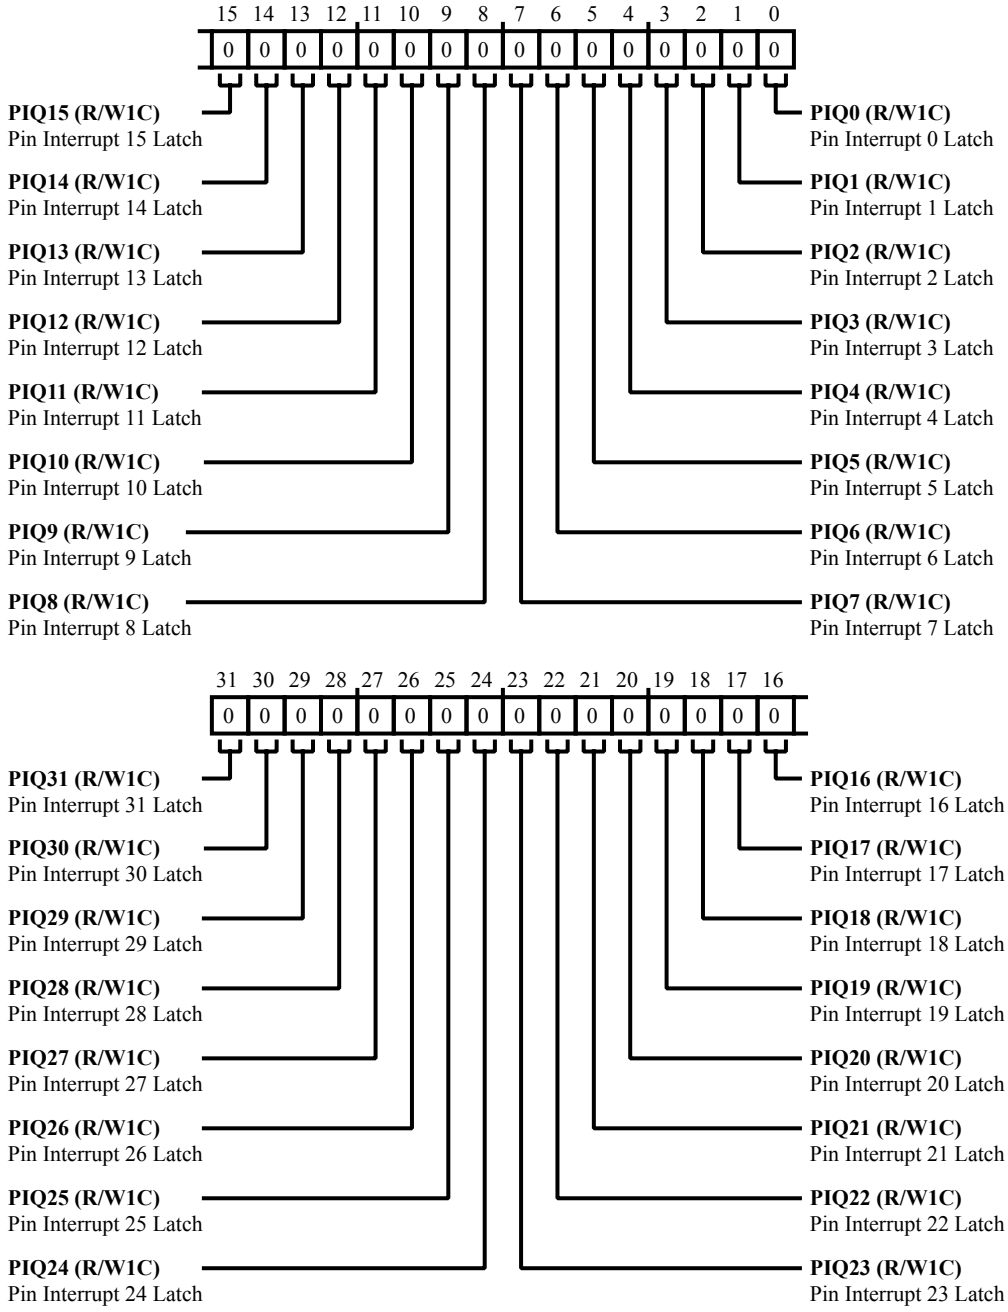

Figure 12-31: PINT_LATCH Register Diagram

Table 12-37: PINT_LATCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Latch. If the `PINT_LATCH.PIQ31` bit is set, the request is latched.

Table 12-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Latch. If the `PINT_LATCH.PIQ30` bit is set, the request is latched.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Latch. If the `PINT_LATCH.PIQ29` bit is set, the request is latched.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Latch. If the `PINT_LATCH.PIQ28` bit is set, the request is latched.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Latch. If the `PINT_LATCH.PIQ27` bit is set, the request is latched.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Latch. If the `PINT_LATCH.PIQ26` bit is set, the request is latched.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Latch. If the `PINT_LATCH.PIQ25` bit is set, the request is latched.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Latch. If the `PINT_LATCH.PIQ24` bit is set, the request is latched.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Latch. If the `PINT_LATCH.PIQ23` bit is set, the request is latched.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Latch. If the `PINT_LATCH.PIQ22` bit is set, the request is latched.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Latch. If the `PINT_LATCH.PIQ21` bit is set, the request is latched.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Latch. If the `PINT_LATCH.PIQ20` bit is set, the request is latched.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Latch. If the `PINT_LATCH.PIQ19` bit is set, the request is latched.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Latch. If the `PINT_LATCH.PIQ18` bit is set, the request is latched.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Latch. If the `PINT_LATCH.PIQ17` bit is set, the request is latched.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Latch. If the `PINT_LATCH.PIQ16` bit is set, the request is latched.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Latch. If the `PINT_LATCH.PIQ15` bit is set, the request is latched.

Table 12-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Latch. If the `PINT_LATCH.PIQ14` bit is set, the request is latched.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Latch. If the `PINT_LATCH.PIQ13` bit is set, the request is latched.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Latch. If the `PINT_LATCH.PIQ12` bit is set, the request is latched.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Latch. If the `PINT_LATCH.PIQ11` bit is set, the request is latched.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Latch. If the `PINT_LATCH.PIQ10` bit is set, the request is latched.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Latch. If the `PINT_LATCH.PIQ9` bit is set, the request is latched.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Latch. If the `PINT_LATCH.PIQ8` bit is set, the request is latched.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Latch. If the `PINT_LATCH.PIQ7` bit is set, the request is latched.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Latch. If the `PINT_LATCH.PIQ6` bit is set, the request is latched.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Latch. If the `PINT_LATCH.PIQ5` bit is set, the request is latched.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Latch. If the `PINT_LATCH.PIQ4` bit is set, the request is latched.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Latch. If the `PINT_LATCH.PIQ3` bit is set, the request is latched.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Latch. If the `PINT_LATCH.PIQ2` bit is set, the request is latched.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Latch. If the `PINT_LATCH.PIQ1` bit is set, the request is latched.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Latch. If the `PINT_LATCH.PIQ0` bit is set, the request is latched.

PINT Mask Clear Register

The PINT_MSK_CLR register permits masking (disabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_CLR masks the corresponding pin interrupt.

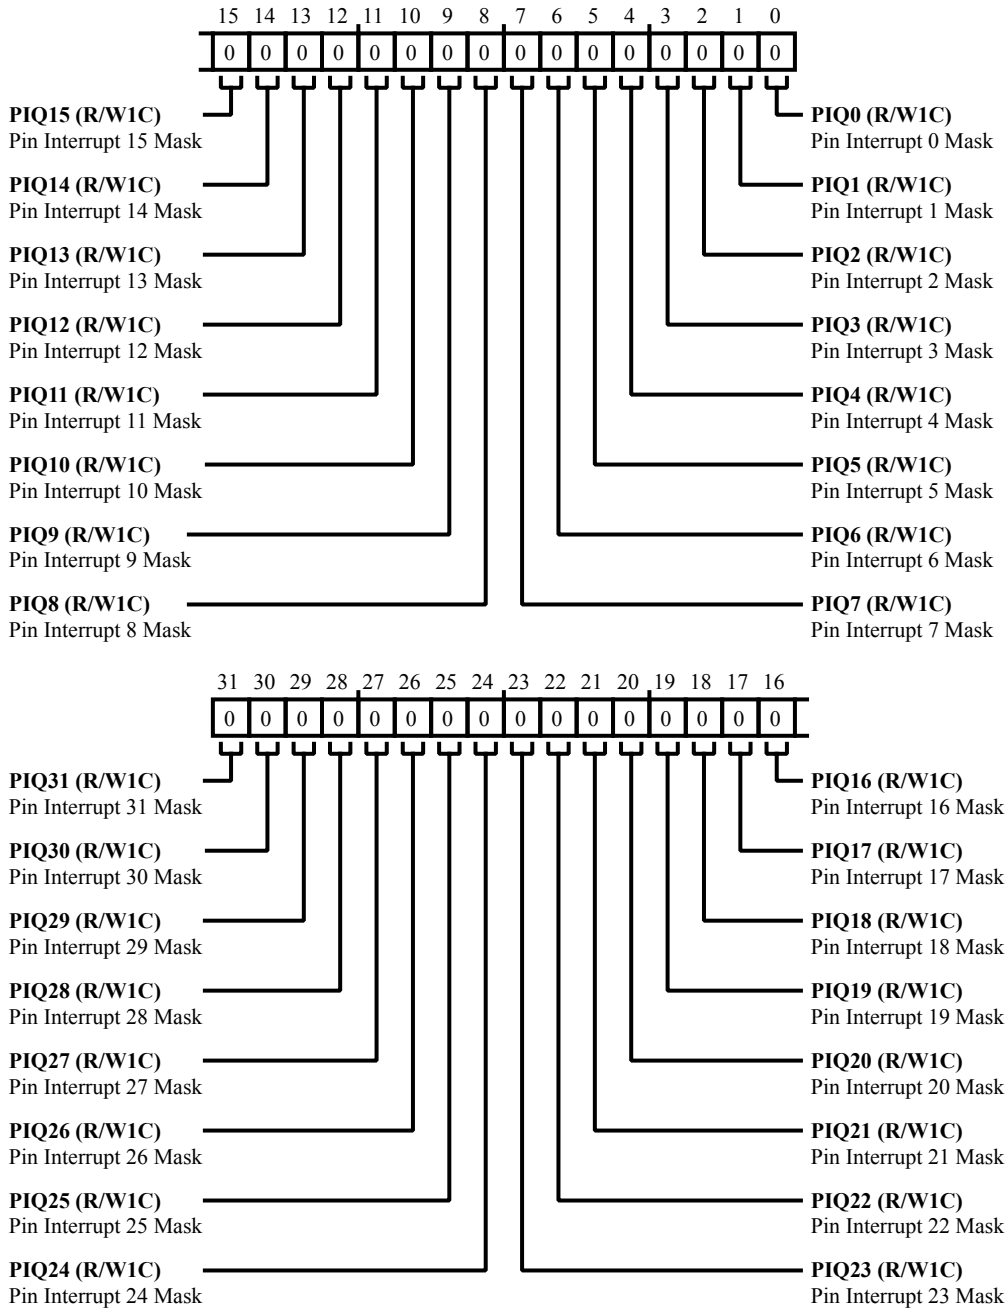

Figure 12-32: PINT_MSK_CLR Register Diagram

Table 12-38: PINT_MSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Mask. Set the PINT_MSK_CLR.PIQ31 bit to disable the interrupt.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Mask. Set the PINT_MSK_CLR.PIQ30 bit to disable the interrupt.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Mask. Set the PINT_MSK_CLR.PIQ29 bit to disable the interrupt.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Mask. Set the PINT_MSK_CLR.PIQ28 bit to disable the interrupt.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Mask. Set the PINT_MSK_CLR.PIQ27 bit to disable the interrupt.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Mask. Set the PINT_MSK_CLR.PIQ26 bit to disable the interrupt.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Mask. Set the PINT_MSK_CLR.PIQ25 bit to disable the interrupt.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Mask. Set the PINT_MSK_CLR.PIQ24 bit to disable the interrupt.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Mask. Set the PINT_MSK_CLR.PIQ23 bit to disable the interrupt.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Mask. Set the PINT_MSK_CLR.PIQ22 bit to disable the interrupt.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Mask. Set the PINT_MSK_CLR.PIQ21 bit to disable the interrupt.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Mask. Set the PINT_MSK_CLR.PIQ20 bit to disable the interrupt.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Mask. Set the PINT_MSK_CLR.PIQ19 bit to disable the interrupt.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Mask. Set the PINT_MSK_CLR.PIQ18 bit to disable the interrupt.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Mask. Set the PINT_MSK_CLR.PIQ17 bit to disable the interrupt.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Mask. Set the PINT_MSK_CLR.PIQ16 bit to disable the interrupt.

Table 12-38: PINT_MSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Mask. Set the PINT_MSK_CLR.PIQ15 bit to disable the interrupt.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Mask. Set the PINT_MSK_CLR.PIQ14 bit to disable the interrupt.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Mask. Set the PINT_MSK_CLR.PIQ13 bit to disable the interrupt.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Mask. Set the PINT_MSK_CLR.PIQ12 bit to disable the interrupt.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Mask. Set the PINT_MSK_CLR.PIQ11 bit to disable the interrupt.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Mask. Set the PINT_MSK_CLR.PIQ10 bit to disable the interrupt.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Mask. Set the PINT_MSK_CLR.PIQ9 bit to disable the interrupt.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Mask. Set the PINT_MSK_CLR.PIQ8 bit to disable the interrupt.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Mask. Set the PINT_MSK_CLR.PIQ7 bit to disable the interrupt.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Mask. Set the PINT_MSK_CLR.PIQ6 bit to disable the interrupt.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Mask. Set the PINT_MSK_CLR.PIQ5 bit to disable the interrupt.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Mask. Set the PINT_MSK_CLR.PIQ4 bit to disable the interrupt.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Mask. Set the PINT_MSK_CLR.PIQ3 bit to disable the interrupt.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Mask. Set the PINT_MSK_CLR.PIQ2 bit to disable the interrupt.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Mask. Set the PINT_MSK_CLR.PIQ1 bit to disable the interrupt.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Mask. Set the PINT_MSK_CLR.PIQ0 bit to disable the interrupt.

PINT Mask Set Register

The PINT_MSK_SET register permits unmasking (enabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_SET unmasks the corresponding pin interrupt.

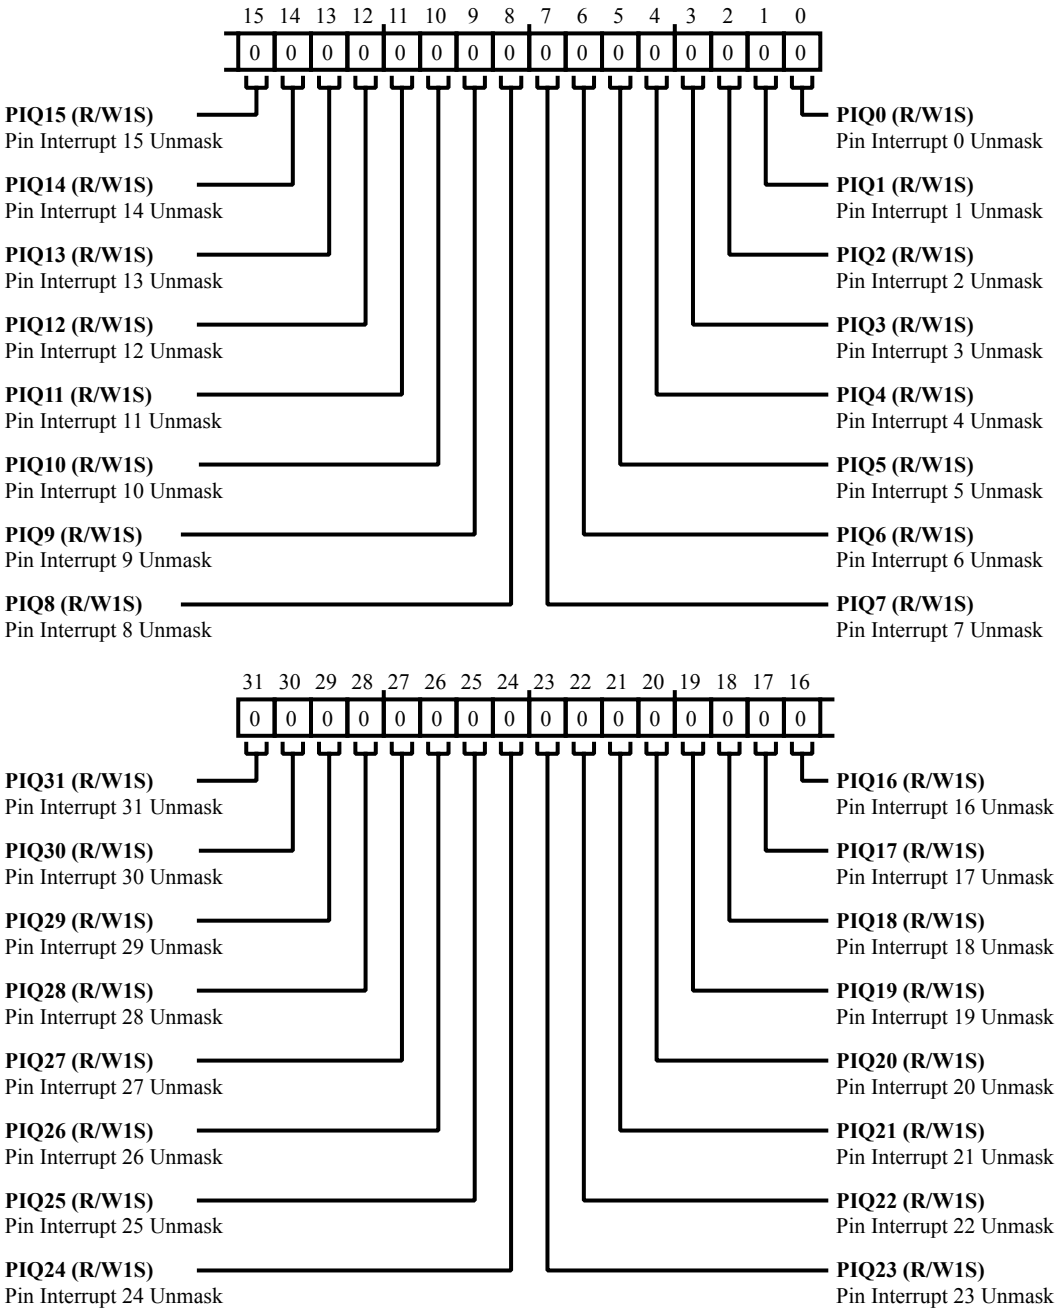

Figure 12-33: PINT_MSK_SET Register Diagram

Table 12-39: PINT_MSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Unmask. Set the PINT_MSK_SET.PIQ31 bit to enable the interrupt.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Unmask. Set the PINT_MSK_SET.PIQ30 bit to enable the interrupt.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Unmask. Set the PINT_MSK_SET.PIQ29 bit to enable the interrupt.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Unmask. Set the PINT_MSK_SET.PIQ28 bit to enable the interrupt.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Unmask. Set the PINT_MSK_SET.PIQ27 bit to enable the interrupt.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Unmask. Set the PINT_MSK_SET.PIQ26 bit to enable the interrupt.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Unmask. Set the PINT_MSK_SET.PIQ25 bit to enable the interrupt.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Unmask. Set the PINT_MSK_SET.PIQ24 bit to enable the interrupt.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Unmask. Set the PINT_MSK_SET.PIQ23 bit to enable the interrupt.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Unmask. Set the PINT_MSK_SET.PIQ22 bit to enable the interrupt.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Unmask. Set the PINT_MSK_SET.PIQ21 bit to enable the interrupt.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Unmask. Set the PINT_MSK_SET.PIQ20 bit to enable the interrupt.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Unmask. Set the PINT_MSK_SET.PIQ19 bit to enable the interrupt.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Unmask. Set the PINT_MSK_SET.PIQ18 bit to enable the interrupt.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Unmask. Set the PINT_MSK_SET.PIQ17 bit to enable the interrupt.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Unmask. Set the PINT_MSK_SET.PIQ16 bit to enable the interrupt.

Table 12-39: PINT_MSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Unmask. Set the PINT_MSK_SET.PIQ15 bit to enable the interrupt.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Unmask. Set the PINT_MSK_SET.PIQ14 bit to enable the interrupt.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Unmask. Set the PINT_MSK_SET.PIQ13 bit to enable the interrupt.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Unmask. Set the PINT_MSK_SET.PIQ12 bit to enable the interrupt.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Unmask. Set the PINT_MSK_SET.PIQ11 bit to enable the interrupt.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Unmask. Set the PINT_MSK_SET.PIQ10 bit to enable the interrupt.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Unmask. Set the PINT_MSK_SET.PIQ9 bit to enable the interrupt.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Unmask. Set the PINT_MSK_SET.PIQ8 bit to enable the interrupt.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Unmask. Set the PINT_MSK_SET.PIQ7 bit to enable the interrupt.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Unmask. Set the PINT_MSK_SET.PIQ6 bit to enable the interrupt.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Unmask. Set the PINT_MSK_SET.PIQ5 bit to enable the interrupt.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Unmask. Set the PINT_MSK_SET.PIQ4 bit to enable the interrupt.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Unmask. Set the PINT_MSK_SET.PIQ3 bit to enable the interrupt.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Unmask. Set the PINT_MSK_SET.PIQ2 bit to enable the interrupt.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Unmask. Set the PINT_MSK_SET.PIQ1 bit to enable the interrupt.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Unmask. Set the PINT_MSK_SET.PIQ0 bit to enable the interrupt.

PINT Pin State Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the PINT_PINSTATE register. While neither input nor output drivers of the pin are enabled, reads of the pin state in PINT_PINSTATE return zero. The PINT_PINSTATE register reports the inverted state of the pin if the signal inverter is activated by the PINT_INV_SET register. The inverter can be enabled on an individual bit-by-bit basis. Every bit in the PINT_INV_SET and PINT_INV_CLR register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

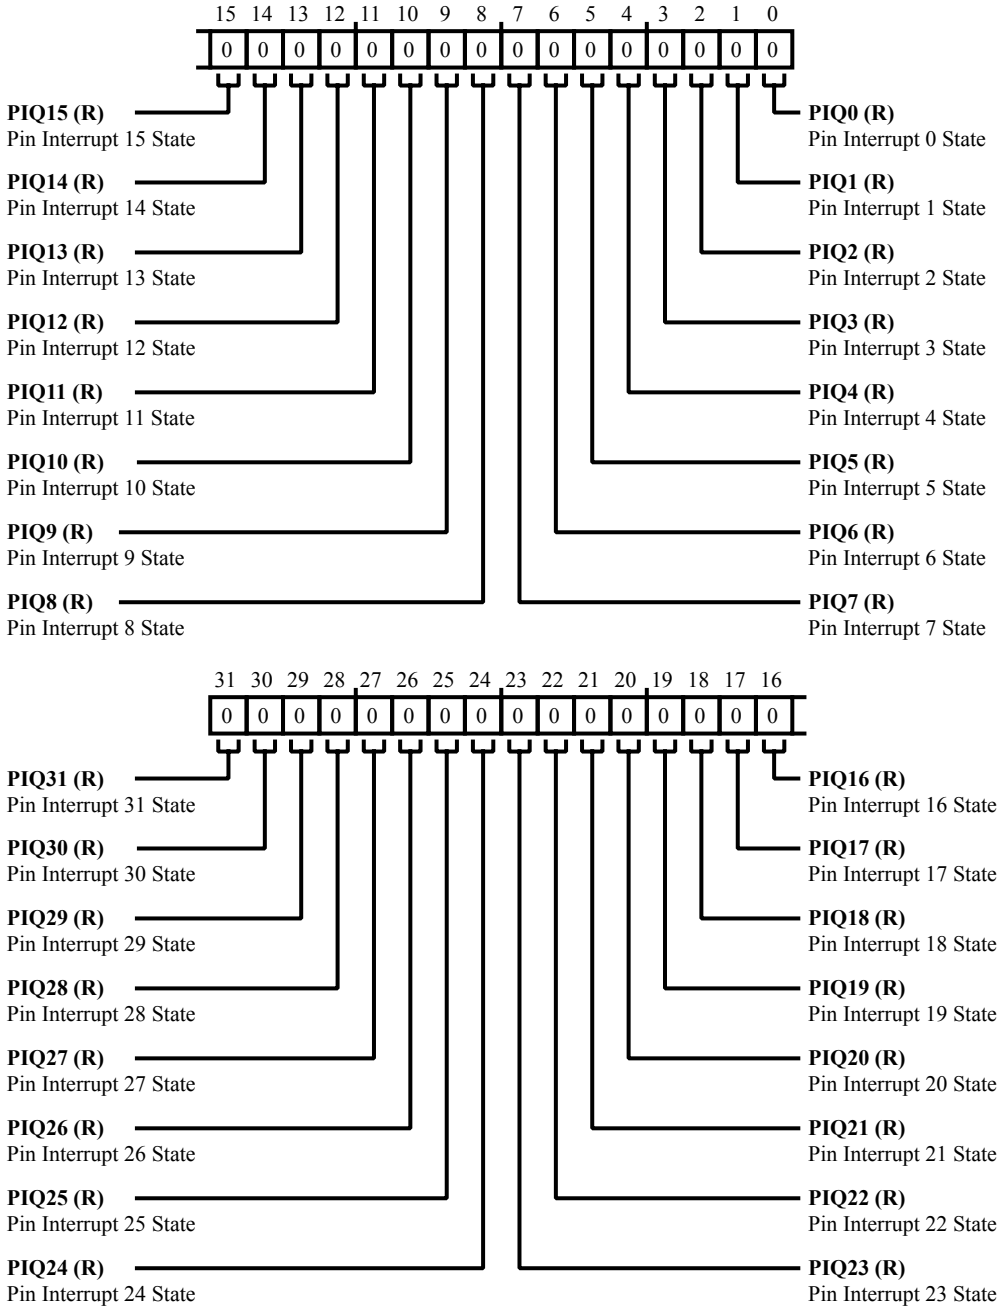

Figure 12-34: PINT_PINSTATE Register Diagram

Table 12-40: PINT_PINSTATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	PIQ31	Pin Interrupt 31 State. A read of the `PINT_PINSTATE.PIQ31` bit returns the pin state.

Table 12-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	PIQ30	Pin Interrupt 30 State. A read of the PINT_PINSTATE.PIQ30 bit returns the pin state.
29 (R/NW)	PIQ29	Pin Interrupt 29 State. A read of the PINT_PINSTATE.PIQ29 bit returns the pin state.
28 (R/NW)	PIQ28	Pin Interrupt 28 State. A read of the PINT_PINSTATE.PIQ28 bit returns the pin state.
27 (R/NW)	PIQ27	Pin Interrupt 27 State. A read of the PINT_PINSTATE.PIQ27 bit returns the pin state.
26 (R/NW)	PIQ26	Pin Interrupt 26 State. A read of the PINT_PINSTATE.PIQ26 bit returns the pin state.
25 (R/NW)	PIQ25	Pin Interrupt 25 State. A read of the PINT_PINSTATE.PIQ25 bit returns the pin state.
24 (R/NW)	PIQ24	Pin Interrupt 24 State. A read of the PINT_PINSTATE.PIQ24 bit returns the pin state.
23 (R/NW)	PIQ23	Pin Interrupt 23 State. A read of the PINT_PINSTATE.PIQ23 bit returns the pin state.
22 (R/NW)	PIQ22	Pin Interrupt 22 State. A read of the PINT_PINSTATE.PIQ22 bit returns the pin state.
21 (R/NW)	PIQ21	Pin Interrupt 21 State. A read of the PINT_PINSTATE.PIQ21 bit returns the pin state.
20 (R/NW)	PIQ20	Pin Interrupt 20 State. A read of the PINT_PINSTATE.PIQ20 bit returns the pin state.
19 (R/NW)	PIQ19	Pin Interrupt 19 State. A read of the PINT_PINSTATE.PIQ19 bit returns the pin state.
18 (R/NW)	PIQ18	Pin Interrupt 18 State. A read of the PINT_PINSTATE.PIQ18 bit returns the pin state.
17 (R/NW)	PIQ17	Pin Interrupt 17 State. A read of the PINT_PINSTATE.PIQ17 bit returns the pin state.
16 (R/NW)	PIQ16	Pin Interrupt 16 State. A read of the PINT_PINSTATE.PIQ16 bit returns the pin state.
15 (R/NW)	PIQ15	Pin Interrupt 15 State. A read of the PINT_PINSTATE.PIQ15 bit returns the pin state.

Table 12-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PIQ14	Pin Interrupt 14 State. A read of the PINT_PINSTATE.PIQ14 bit returns the pin state.
13 (R/NW)	PIQ13	Pin Interrupt 13 State. A read of the PINT_PINSTATE.PIQ13 bit returns the pin state.
12 (R/NW)	PIQ12	Pin Interrupt 12 State. A read of the PINT_PINSTATE.PIQ12 bit returns the pin state.
11 (R/NW)	PIQ11	Pin Interrupt 11 State. A read of the PINT_PINSTATE.PIQ11 bit returns the pin state.
10 (R/NW)	PIQ10	Pin Interrupt 10 State. A read of the PINT_PINSTATE.PIQ10 bit returns the pin state.
9 (R/NW)	PIQ9	Pin Interrupt 9 State. A read of the PINT_PINSTATE.PIQ9 bit returns the pin state.
8 (R/NW)	PIQ8	Pin Interrupt 8 State. A read of the PINT_PINSTATE.PIQ8 bit returns the pin state.
7 (R/NW)	PIQ7	Pin Interrupt 7 State. A read of the PINT_PINSTATE.PIQ7 bit returns the pin state.
6 (R/NW)	PIQ6	Pin Interrupt 6 State. A read of the PINT_PINSTATE.PIQ6 bit returns the pin state.
5 (R/NW)	PIQ5	Pin Interrupt 5 State. A read of the PINT_PINSTATE.PIQ5 bit returns the pin state.
4 (R/NW)	PIQ4	Pin Interrupt 4 State. A read of the PINT_PINSTATE.PIQ4 bit returns the pin state.
3 (R/NW)	PIQ3	Pin Interrupt 3 State. A read of the PINT_PINSTATE.PIQ3 bit returns the pin state.
2 (R/NW)	PIQ2	Pin Interrupt 2 State. A read of the PINT_PINSTATE.PIQ2 bit returns the pin state.
1 (R/NW)	PIQ1	Pin Interrupt 1 State. A read of the PINT_PINSTATE.PIQ1 bit returns the pin state.
0 (R/NW)	PIQ0	Pin Interrupt 0 State. A read of the PINT_PINSTATE.PIQ0 bit returns the pin state.

PINT Request Register

The PINT_REQ register indicates the interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

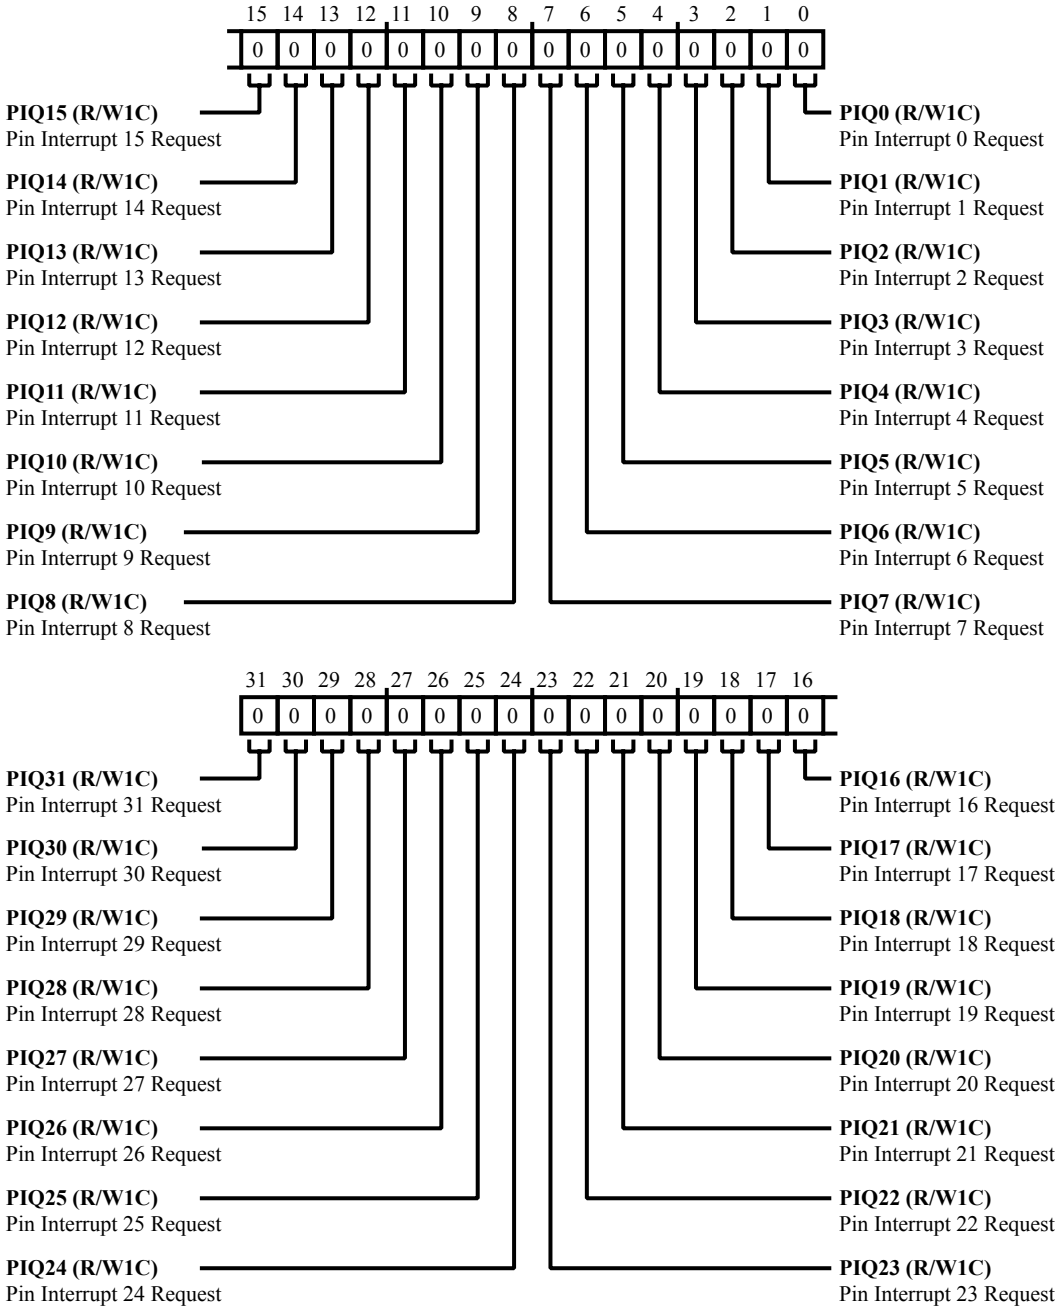

Figure 12-35: PINT_REQ Register Diagram

Table 12-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Request. If the PINT_REQ.PIQ30 bit is set, a request is pending.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Request. If the PINT_REQ.PIQ29 bit is set, a request is pending.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Request. If the PINT_REQ.PIQ28 bit is set, a request is pending.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Request. If the PINT_REQ.PIQ27 bit is set, a request is pending.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Request. If the PINT_REQ.PIQ26 bit is set, a request is pending.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Request. If the PINT_REQ.PIQ25 bit is set, a request is pending.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Request. If the PINT_REQ.PIQ24 bit is set, a request is pending.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Request. If the PINT_REQ.PIQ23 bit is set, a request is pending.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Request. If the PINT_REQ.PIQ22 bit is set, a request is pending.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Request. If the PINT_REQ.PIQ21 bit is set, a request is pending.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Request. If the PINT_REQ.PIQ20 bit is set, a request is pending.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Request. If the PINT_REQ.PIQ19 bit is set, a request is pending.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Request. If the PINT_REQ.PIQ18 bit is set, a request is pending.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Request. If the PINT_REQ.PIQ17 bit is set, a request is pending.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Request. If the PINT_REQ.PIQ16 bit is set, a request is pending.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Request. If the PINT_REQ.PIQ15 bit is set, a request is pending.

Table 12-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Request. If the `PINT_REQ.PIQ14` bit is set, a request is pending.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Request. If the `PINT_REQ.PIQ13` bit is set, a request is pending.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Request. If the `PINT_REQ.PIQ12` bit is set, a request is pending.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Request. If the `PINT_REQ.PIQ11` bit is set, a request is pending.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Request. If the `PINT_REQ.PIQ10` bit is set, a request is pending.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Request. If the `PINT_REQ.PIQ9` bit is set, a request is pending.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Request. If the `PINT_REQ.PIQ8` bit is set, a request is pending.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Request. If the `PINT_REQ.PIQ7` bit is set, a request is pending.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Request. If the `PINT_REQ.PIQ6` bit is set, a request is pending.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Request. If the `PINT_REQ.PIQ5` bit is set, a request is pending.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Request. If the `PINT_REQ.PIQ4` bit is set, a request is pending.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Request. If the `PINT_REQ.PIQ3` bit is set, a request is pending.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Request. If the `PINT_REQ.PIQ2` bit is set, a request is pending.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Request. If the `PINT_REQ.PIQ1` bit is set, a request is pending.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Request. If the `PINT_REQ.PIQ0` bit is set, a request is pending.

ADSP-SC57x PADS Register Descriptions

Pads Controller (PADS) contains the following registers.

Table 12-42: ADSP-SC57x PADS Register List

Name	Description
PADS_DAI[n]_PUD	DAIx Pull-Up Disable
PADS_DAI[n]_PUE	DAIx Pull-Up Enable
PADS_PCFG0	Peripheral PAD Configuration0 Register
PADS_PORTS_DS	Voltage Domain Control Register
PADS_PORT[n]_PUD	PORTx Pull-Up Disable
PADS_PORT[n]_PUE	PORTx Pull-Up Enable

DAIx Pull-Up Disable

The PADS_DAI[n]_PUD register disables the pull-up resistor for the DAI pins. If both the PADS_DAI[n]_PUD and PUE registers are set (=1) for the same pin then the PADS_DAI[n]_PUD register takes priority over the PUE register. To disable the pull-up on a pin, the PUD bit must be set (= 1) and the PUE bit can be of any value.

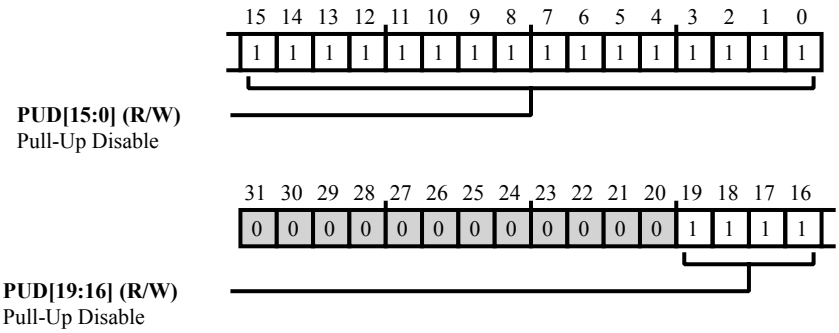

Figure 12-36: PADS_DAI[n]_PUD Register Diagram

Table 12-43: PADS_DAI[n]_PUD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PUD	Pull-Up Disable.

DAIx Pull-Up Enable

The PADS_DAI[n]_PUE register enables the pull-up resistor for DAI pins. If both the PADS_DAI[n]_PUE and PUD registers are set (= 1) for the same pin, then the PUD register takes priority over the PADS_DAI[n]_PUE register. To enable the pull-up on a pin, the PUD bit must be cleared (= 0) and the PUE bit must be set (=1).

Table 12-44: PADS_DAI[n]_PUE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PUE	Pull-Up Enable.

Peripheral PAD Configuration0 Register

The PADS_PCFG0 register provides several configuration options for the pads and multiplexing for peripherals.

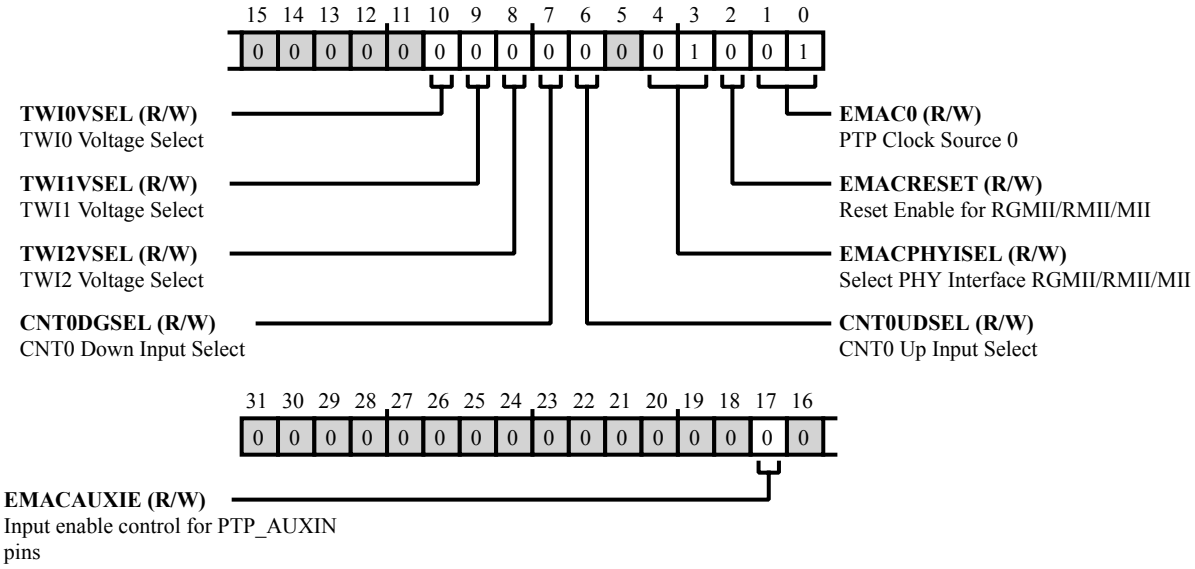

Figure 12-38: PADS_PCFG0 Register Diagram

Table 12-45: PADS_PCFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	EMACAUXIE	Input enable control for PTP_AUXIN pins.	
		0	Disable input
		1	Enable input
10 (R/W)	TWI0VSEL	TWI0 Voltage Select. The PADS_PCFG0.TWI0VSEL bit selects the drive/tolerate voltage for the TWI_SCL and TWI_SDA pins for TWI0. By default this bit is cleared (=0, 3.3V).	
		0	TWI0 voltage is 3.3V
		1	TWI0 voltage is 5.0V
9 (R/W)	TWI1VSEL	TWI1 Voltage Select. The PADS_PCFG0.TWI1VSEL bit selects the drive/tolerate voltage for the TWI_SCL and TWI_SDA pins for TWI1. By default this bit is cleared (=0, 3.3V).	
		0	TWI1 voltage is 3.3V
		1	TWI1 voltage is 5V

Table 12-45: PADS_PCFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	TWI2VSEL	TWI2 Voltage Select. The PADS_PCFG0.TWI2VSEL bit selects the drive/tolerate voltage for the TWI_SCL and TWI_SDA pins for TWI2. By default this bit is cleared (=0, 3.3V).	
		0	TWI2 voltage is 3.3V
		1	TWI2 voltage is 5V
7 (R/W)	CNT0DGSEL	CNT0 Down Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter down and gate.	
		0	GPIO port pins
		1	Trigger connection
6 (R/W)	CNT0UDSEL	CNT0 Up Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter up and direction.	
		0	GPIO port pins
		1	Trigger connection
4:3 (R/W)	EMACPHYISEL	Select PHY Interface RGMII/RMII/MII.	
		0	MII Interface
		1	RGMII Interface
		2	RMII Interface
		3	Reserved
2 (R/W)	EMACRESET	Reset Enable for RGMII/RMII/MII. The PADS_PCFG0.EMACRESET bit asserts the reset on the PHY interface. To select the PHY interface (RGMII/RMII/MII), set the EMACPHYISEL bit as required and then set PADS_PCFG0.EMACRESET.	
		0	Reset is asserted
		1	Reset reset is deasserted
1:0 (R/W)	EMAC0	PTP Clock Source 0. The PADS_PCFG0.EMAC0 selects the clock source for the PTP Block in EMAC0.	
		0	EMAC0_RMII CLK
		1	SCLK
		2	External Clock
		3	SCLK

Voltage Domain Control Register

The PADS_PORTS_DS register sets the drive strength for the PORT GPIO pins. The drive strength can be controlled only for pin groups. For more information about pin groups, see the PORT register definitions.

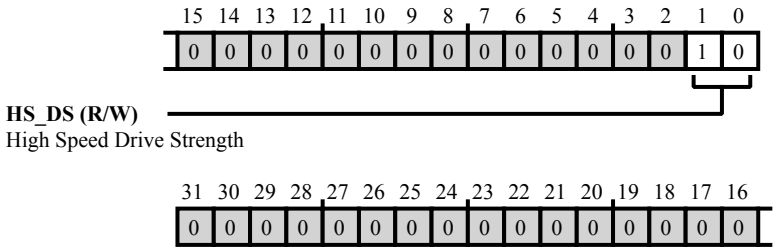

Figure 12-39: PADS_PORTS_DS Register Diagram

Table 12-46: PADS_PORTS_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	HS_DS	High Speed Drive Strength. The PADS_PORTS_DS.HS_DS bit field can be programmed with values 0, 1, 2, and 3. The value 0 corresponds to the highest drive strength. An increase in the value programmed in this field reduces the drive strength. Pins in this category include PB_03 to PB_14 and PE_02.

PORTx Pull-Up Disable

The PADS_PORT[n]_PUD register disables the pull-up resistor for the PORT pins. If both the PADS_PORT[n]_PUD and PUE registers are set (= 1) for the same pin then the PADS_PORT[n]_PUD register takes priority over the PUE register. To disable the pull-up on a pin, the PUD bit must be set (= 1) and the PUE bit can be of any value.

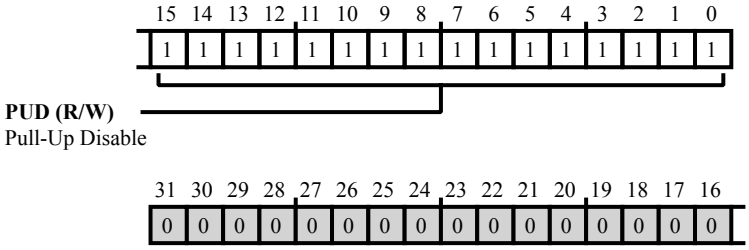

Figure 12-40: PADS_PORT[n]_PUD Register Diagram

Table 12-47: PADS_PORT[n]_PUD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	PUD	Pull-Up Disable.

PORTx Pull-Up Enable

The PADS_PORT[n]_PUE register enables the pull-up resistor for the PORT pins. If both PADS_PORT[n]_PUE and PUD registers are set (= 1) for the same pin, then the PUD register takes priority over the PADS_PORT[n]_PUE register. To enable the pull-up on a pin, the PUD bit must be cleared (= 0) and the PUE bit must be set (=1).

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	PUE	Pull-Up Enable.

13 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows various I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The link ports of the processor support 8-bit wide data transfers. The link port pins are multiplexed in the GPIO ports. For information on processor multiplexing, see the data sheet for the specific processor.

Link ports can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors.

NOTE: Reference to SCLK in this chapter can be considered as OCLK0_0.

LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with eight data signals (`LP0_D0` - `LP0_D7`), an acknowledge signal (`LP0_ACK`), and a clock signal (`LP0_CLK`).
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple processors.
- Pack data into 32-bit words. The processor can directly read this data or transfer it through DMA to or from on-chip memory.
- Support for data buffering through a 2-deep FIFO for transmit and a 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- A dedicated DMA channel.

LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

ADSP-SC57x LP Register List

The Link Port LP is an 8-bit wide parallel port that can connect to another processor's LP or another LP-compatible device. This port allows a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers governs LP operations. For more information on LP functionality, see the LP register descriptions.

Table 13-1: ADSP-SC57x LP Register List

Name	Description
LP_CTL	Control Register
LP_DIV	Clock Divider Value Register
LP_RX	Receive Buffer Register
LP_STAT	Status Register
LP_TX	Transmit Buffer Register
LP_TXIN_SHDW	Shadow Input Transmit Buffer Register
LP_TXOUT_SHDW	Shadow Output Transmit Buffer Register

Block Diagram

The ***Link Port Block Diagram*** shows the block diagram of a link port.

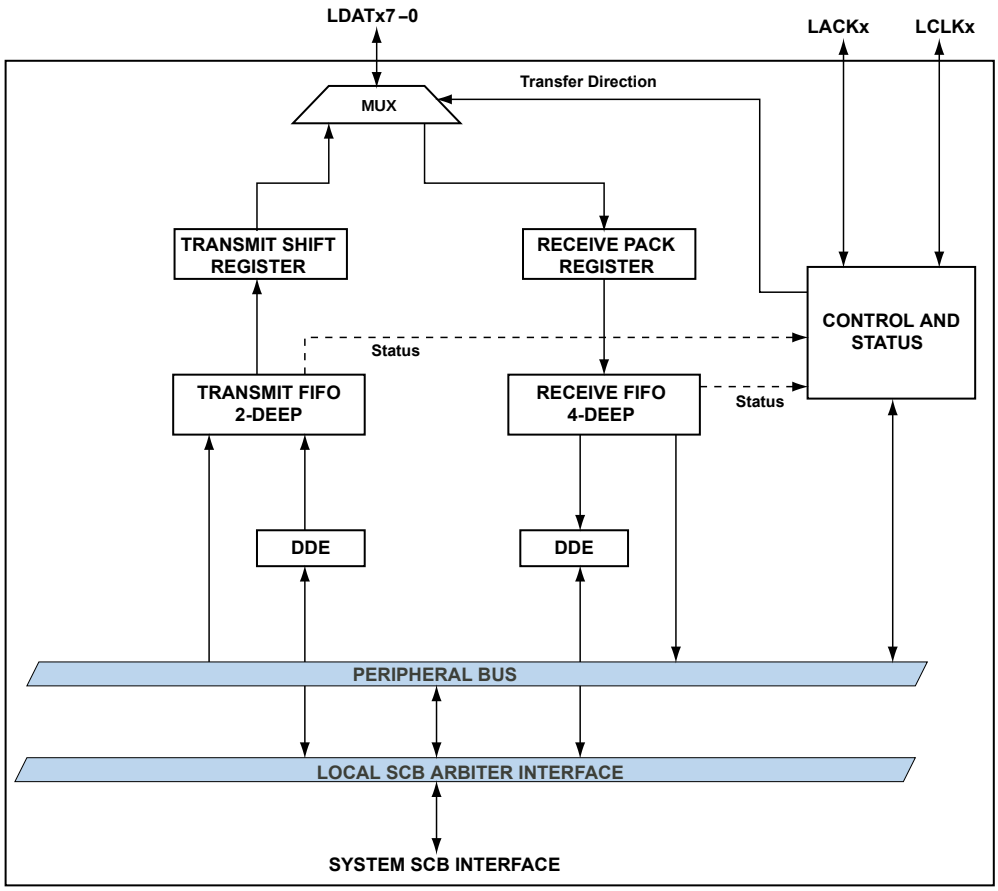

Figure 13-1: Link Port Block Diagram

External Connections

As shown in the ***Link Port Pin Connections*** figure, a link port has eight data lines (LP_D0 – LP_D7), a clock line (LP_CLK), and an acknowledge line (LP_ACK). A link port can act as either a transmitter or a receiver but not both at the same time.

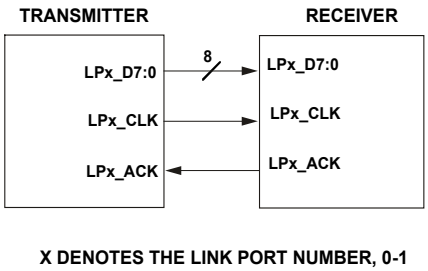

Figure 13-2: Link Port Pin Connections

Use external pull-downs for the LP_CLK and LP_ACK pins so that the link port can enable the transmitter and receiver, irrespective of the state of the other.

Internal Blocks

As shown in the block diagram, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. The core MMR access bus interfaces with these FIFOs. The distributed DMA engines (DDE) use the system cross bar (SCB) interface to access the FIFO. The link port uses the LP_CTL.TRAN bit to determine whether the module is enabled for transmit or receive operation.

Architectural Concepts

The following sections describe the architectural concepts of the link port.

- Link Port Protocol
- FIFO Buffers
- Handshake for Link Port Enable Process
- Clocking
- Multi-Processor Connectivity

Link Port Protocol

A link port transmitted word consists of 4 bytes and the communication proceeds as follows.

1. The transmitter asserts the link port clock (LP_CLK) with each byte of data. The receiver uses the falling edge of LP_CLK driven by the transmitter to latch the byte.
2. When the receiver is ready to accept another word in the receive buffer it asserts the acknowledge signal, LP_ACK.

3. The transmitter samples LP_ACK driven by the receiver at the beginning of each word transmission. If LP_ACK is deasserted, then the transmitter does not transmit the next word.
4. The transmitter leaves LP_CLK high and continues to drive the first byte of the next word until LP_ACK is asserted.
5. When this assertion occurs, the transmitter drives LP_CLK low. The transmission of the next word starts. If the transmit buffer is empty, LP_CLK remains low until the buffer refills, regardless of the state of LP_ACK.

The LP_ACK signal can deassert when it anticipates that the buffer could fill. The receiver reasserts the LP_ACK signal as soon as the internal DMA grant signal has occurred or the core reads the receive buffer. Either of these actions frees a buffer location.

NOTE: The LP_ACK signal inhibits transmission of the next word and not of the current byte.

The LP_ACK signal provides a handshake between the receiver and transmitter in the following configurations.

- When configured as a transmitter, the port drives both the data and the clock while LP_ACK is three-stated. In this mode, LP_CLK is always synchronous with SCLK.
- When configured as a receiver, the link port drives the acknowledge signal and the data and clock lines are three-stated. In this case, the external LP_CLK signal can either be synchronous or asynchronous with SCLK.
- When the link port is disabled, the data, clock, and acknowledge signals are three-stated.

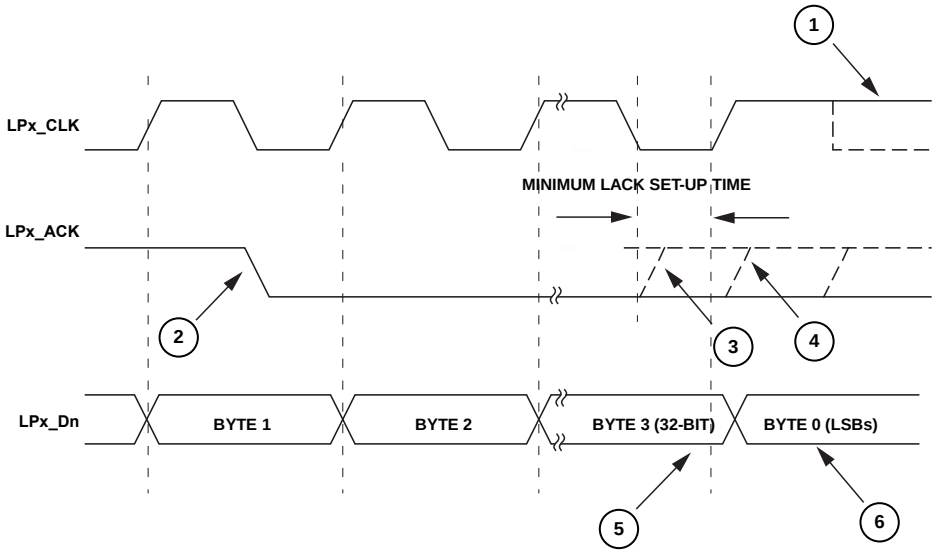

Figure 13-3: Link Port Communication and Handshake Waveform

The following list describes the stages shown in the ***Link Port Communication and Handshake Waveform*** figure.

1. LP_CLK stays high at byte 0 when LP_ACK is sampled low on the previous LP_CLK rising edge. LP_CLK high indicates a stall.
2. The LP_ACK signal can deassert after byte 0.

3. The LP_ACK signal reasserts as soon as the link buffer is not full (depending on Rx FIFO conditions).
4. The transmitter samples LP_ACK to determine whether to transmit the next word.
5. The receiver accepts the remaining word even if LP_ACK is deasserted. The transmitter does not send the following word.
6. Transmission of data for next word is held until LP_ACK is asserted.

The transmitter samples the LP_ACK signal. If the signal is high, the transmitter gives out the falling edges of LP_CLK for data sampling. The LP_ACK signal is first sampled at the rising edge of SCLK. One more SCLK stage synchronizes the signal further. This synchronized signal is given to the subsequent logic. The LP_CLK falling edge is aligned with SCLK falling edge in a 1:1 clock ratio mode and with the *SCLK* rising edge for the rest of the clock ratios. The following figures explain how the synchronization is maintained between the LP_ACK and LP_CLK signals.

In the following figure, synchronizing time is guaranteed to be 1.5 SCLK cycles.

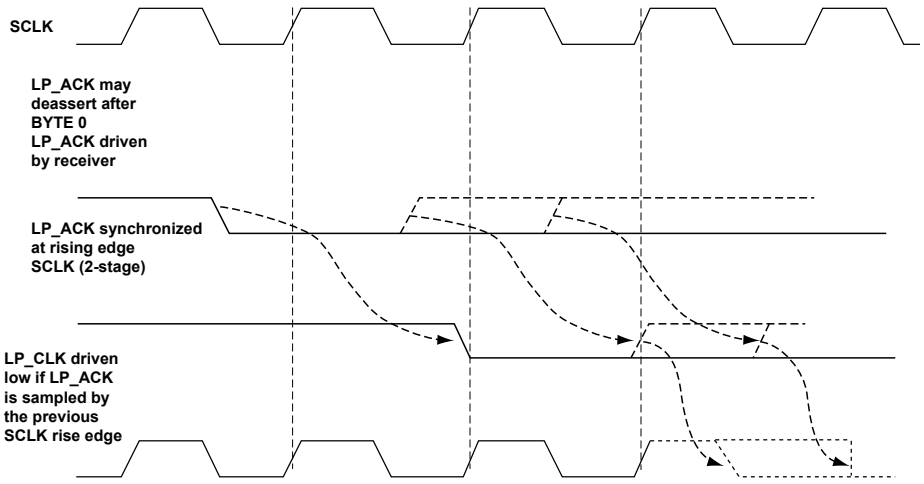

Figure 13-4: LP_ACK Synchronization for SCLK:LP_CLK=1:1

In the following figure, synchronizing time is guaranteed to be 2 SCLK cycles.

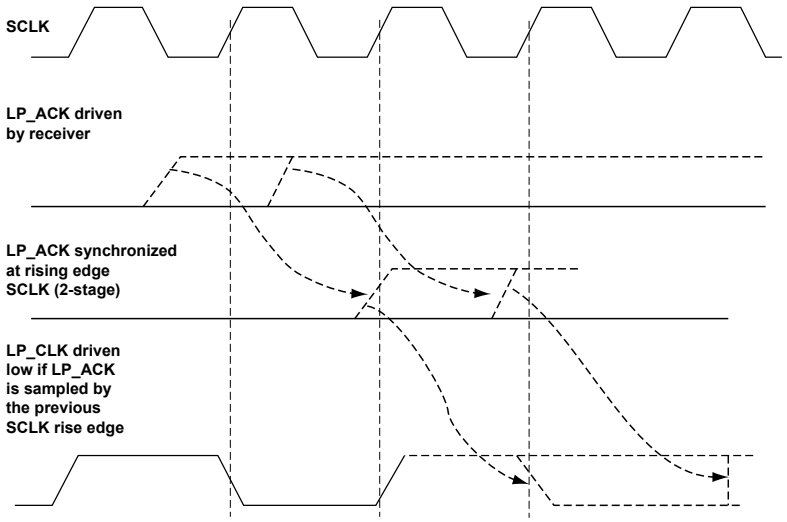

Figure 13-5: LP_ACK Synchronization for SCLK: LP_CLK=1:2, 1:4 and Up

The link port uses the value programmed in the LP_DIV register at the transmitter to determine the frequency of the link port clock (LP_CLK). However, the signal appearing on the LP_CLK pin is also dependent on the status of the LP_ACK pin driven by the receiver. The ***Relationship Between Internal Link Port Clock and Link Port Clock at the Pins*** figure shows this relationship.

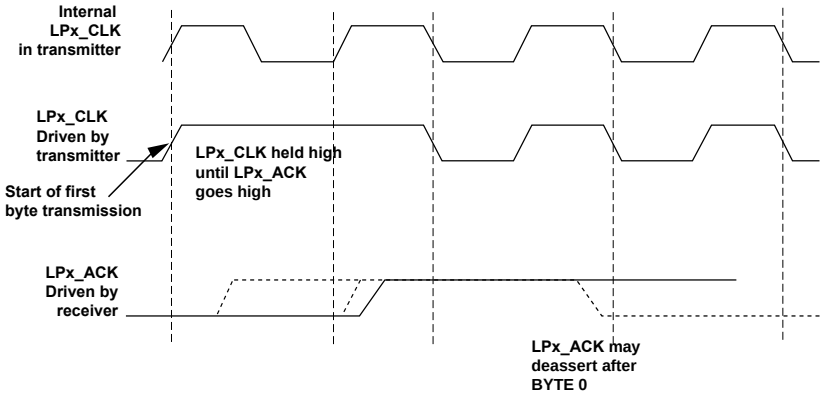

Figure 13-6: Relationship Between Internal Link Port Clock and Link Port Clock at the Pins

FIFO Buffers

When a link port is configured as transmitter, the link port uses a 2-deep FIFO buffer. A shift register unpacks the single 32-bit word to four 8-bit data bytes. As the FIFO has space for more data, the link port makes a new DMA request. If the FIFO becomes empty, the LP_CLK signal is deasserted. The core can access FIFO through the LP_TX register.

The core or DMA makes three writes (2-stage FIFO and 1 shift register) to the transmit buffer before it signals a full condition. The link port uses the LP_STAT.FFST bit field to reflect the status of the FIFO but not the shift register full or empty condition. However, the program can poll the LP_STAT.LPBS bit to discover whether the link

port is driving data from the shift register to the pins. The LP_STAT.LPBS bit is also set when receiver has held off transmission by driving LP_ACK low.

NOTE: When the 2-deep FIFO and the output shift-register overflow, any further write to the link port buffer overwrites the input stage of the FIFO.

NOTE: The core can also read the transmit FIFO through the data LP_TX register.

NOTE: If the transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition is signaled after two writes.

The transmit buffer registers have shadow registers. Using these shadow registers, both stages of the 2-deep FIFO can be read without updating the status registers. The LP_TXIN_SHDW register corresponds to the input stage of the FIFO. The LP_TXOUT_SHDW register corresponds to the output stage of the FIFO as shown in the ***Transmit FIFO path*** figure.

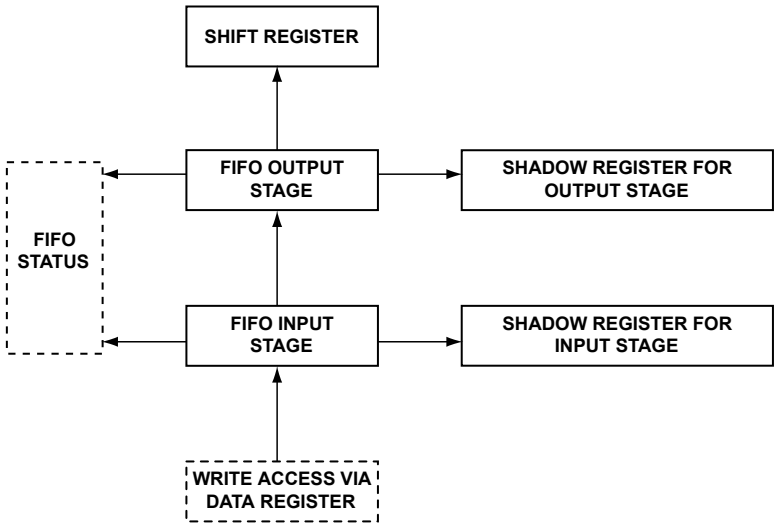

Figure 13-7: Transmit FIFO path

When a link port is configured as receiver, data transfers to the core or DMA from the full 4-deep receive FIFO. An internal packing register packs data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. The link port uses the LP_STAT.FFST bits to reflect the status of the 4-deep read buffer FIFO. The core can access this FIFO through the LP_RX register.

NOTE: When receive FIFO overflows (LP_STAT.ROVF bit=1), any further data from the transmitter is lost. Only the data retained in the receive FIFO can be retrieved further.

The receiver drives the LP_ACK output signal low, after the first byte of data for the next-to-last empty slot (in the 4-deep FIFO) is received. This functionality prevents data loss due to the transmitter starting transmission of the next word before the LP_ACK signal reaches the transmitter. (The timing is due to the larger delay in synchronization.) This functionality guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. The ***LACK Generation Based on Receive FIFO Status*** figure

shows how FIFO slots influence the acknowledge signal generation. The grayed sections show received data. The white sections show empty locations where the decision to pull LP_ACK high is taken.

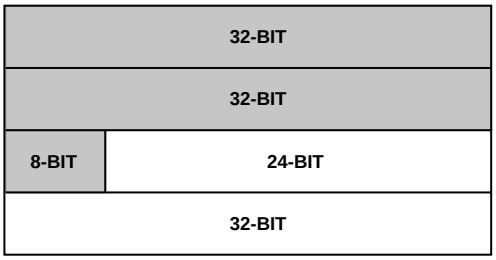

Figure 13-8: LACK Generation Based on Receive FIFO Status

NOTE: The link port uses a 4-deep receive FIFO only under a worst case situation, as mentioned. In all other cases, respond as if the FIFO has only a 3-deep stage. The LP_ACK signal is pulled high before the last stage of the FIFO.

The link port has memory-mapped buffers for both receive and transmit operations. A JTAG-based emulator can read the FIFO which can cause unexpected problems in data transfers. This activity can only happen during an emulation event (typically hitting a breakpoint or single-stepping). The emulator issues core reads through JTAG. To work around this issue, see the tools documentation for more information.

Handshake for Link Port Enable Process

In a link port-based system, the transmitter and the receiver can be enabled at different times. Use external pull-downs for the LP_CLK and LP_ACK signals.

If the receiver is enabled before the transmitter, the external pull-down holds the LP_CLK signal of the transmitter low. The receiver is held off. The receiver can wait for a rising edge on the LP_CLK signal to assert its receive service request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after the application enables it.

If the transmitter is enabled before the receiver, the external pull-down holds the LP_ACK signal of the receiver low. Transmission is held off. Refer to the ***Enable the Transmitter Before the Receiver*** figure. The transmitter can wait for a rising edge on the LP_ACK signal to assert its transmit service request interrupt. This rising edge is asserted as soon as the receiver is enabled after the hardware drives the LP_ACK high.

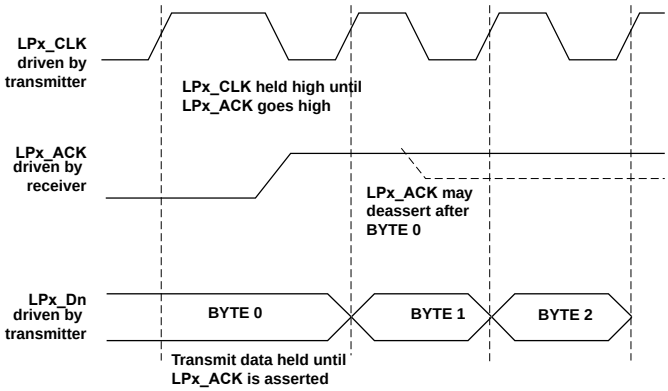

Figure 13-9: Enable the Transmitter Before the Receiver

NOTE: Service request interrupts or status are asserted only when the link port (receiver or transmitter) is disabled.

Clocking

The link port clock (LP_CLK) is derived from the internal system clock (SCLK). The link port clock to system clock ratio can be configured in the LP_DIV register. This value applies to the transmitter only. The receiver can operate at any asynchronous frequency up to the maximum frequency, independent of the ratio programmed. The following formula describes the relationship between the frequency of the link port clock, the SCLK frequency, and the LP_DIV value.

- $f_{LP\_CLK} = f_{SCLK} <$ or $= f_{LP\_CLK\text{-}MAX}$ if DIV = 0
- $f_{LP\_CLK} = f_{SCLK}/(2 \times DIV)$ if DIV > 0

Where: f_{LP_CLK} = link clock frequency, $f_{LP\_CLK\text{-}MAX}$ = link clock maximum frequency, and f_{SCLK} = system clock frequency.

While programming the LP_DIV register to select the clock ratio, ensure that the LP_CLK frequency does not exceed the maximum frequency supported for the device. The resulting LP_CLK frequency is less than or equal to 112.5 MHz. For supported frequencies, see the product-specific data sheet.

Multi-Processor Connectivity

Link ports can operate independently, allowing glueless connection with external processors. Link ports have dedicated DMA channels, allowing independent data transfers. The following group of figures shows some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

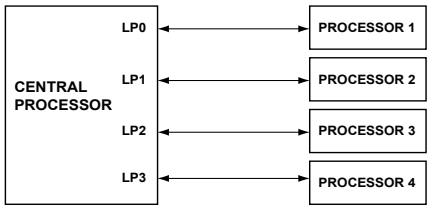

Figure 13-10: Central Processor-Based Model

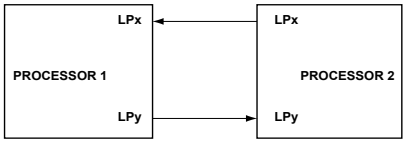

Figure 13-11: Link Port Full-Duplex Transfer Model

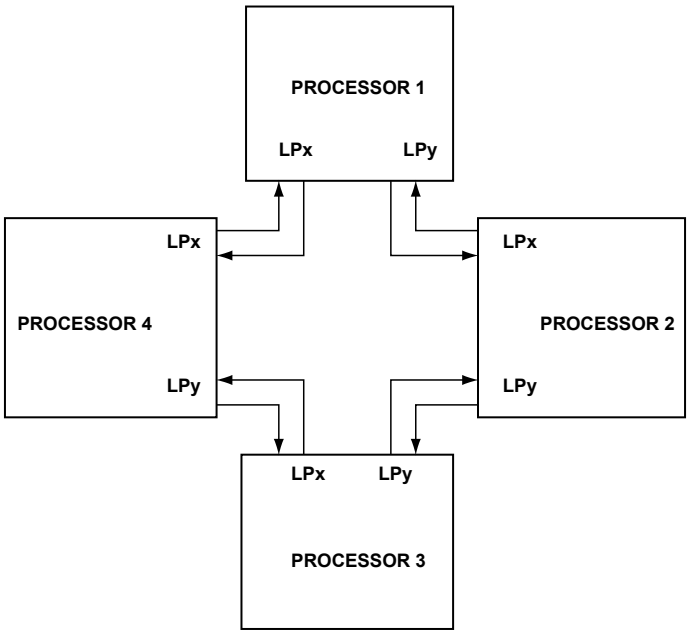

Figure 13-12: Link Port Ring Model

The link port protocol does not include built-in support for multiple masters. However, there can be situations where multiple devices try to become the bus master at the same time. Multi-master conflicts can be resolved using token passing. In token passing, the token is a software flag that passes between processors.

At reset, the token is set to reside in the link port of one device, making it the master and the transmitter. When a receiver (slave) wants to become the master, it can assert its `LP_ACK` signal to get the attention of the master. The master knows, through the software protocol, whether to respond with actual data or whether the token is requested. If the master wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag.

Simultaneously, the slave sets its token and can thereafter transmit. The token release word can be any user-defined value. Because the transmitter and receiver expect a code word, this word does not need to be exclusive of normal data transmission. If the master wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the slave examines the data sent back and if it is the token release word, the slave sets its token, and can thereafter transmit.

The link port protocol includes handshake mechanism to inform the other end of transfer (transmit or receive) of an enable instance. However, it does not support handshakes to inform a disable instance, while a chunk of data transfers. The application must assume the disabled state of the other end, and take appropriate action.

For example, in a multi-processing environment, a receiver did not read its full FIFO for an extended time due to internal bus arbitrations. The transmitter can require software or a peripheral timer-based timeout to inform the application that the LP_ACK signal is low for an extended time period.

LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The following sections explain the data transfer modes, using the core and using DMA.

- Core Data Transfers
- DMA Data Transfers

LP Data Transfer Modes

This section describes link port DMA and core data transfers.

Core Data Transfers

If DMA is disabled for a link port buffer, the processor core can write or read internal FIFO buffers as a memory-mapped register through the MMR access bus. In order to avoid FIFO overflow or underflow, the core can access the FIFO registers in one of the two following ways.

1. Access link port registers using an interrupt service routine (ISR) mapped to the data request interrupt of the link port. The interrupt request remains high only if the FIFO is accessible (if the FIFO is not full in transmit mode and not empty in receive mode).
2. Poll the FIFO status bits of the LP_STAT register. Write to the transmit FIFO if not full or read from the receive FIFO if not empty.

DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA-related activity is explained in the following steps.

1. Data Receive – Once the DMA channel and link port module are configured and enabled, the external device begins writing data to the FIFO through the data pins of the link port. The FIFO detects this activity and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. Data Transmit – Once the DMA channel and link port module are configured and enabled, setting the LP_CTL.EN bit automatically asserts a DMA request when the transmit FIFO is empty. After the request is granted, DMA fills the FIFO. The external device begins reading data from the FIFO through the data pins of the link port. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

LP Event Control

This section describes how the link port uses interrupts and status signals.

Interrupt Signals

Each link port has two dedicated interrupt lines registered with the system event controller—a data request interrupt and a status interrupt. Data request interrupts are asserted based on FIFO conditions for data transfer. Status interrupts are asserted when a service request status or an overflow status is set. The following list explains each of these interrupts.

- ***Data Request Interrupt.*** Asserted if the FIFO is not full in transmission mode and the FIFO is not empty in reception mode. This functionality serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is based on the `LP_STAT.FFST` (status bit of the link port buffer).
- ***Link Port Transmit Service Request Interrupt (LTRQ).*** Allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, the transmit service request interrupt is enabled by setting the `LP_CTL.TRQMSK` bit. When set, an external receiver can indicate to the disabled transmitter that it must receive data through the connected link port. The receiver does so by driving a high level on the `LP_ACK` line. When the `LP_ACK` of the disabled transmitter link port is detected high, a `LP_STAT.LTRQ` interrupt is generated. The transmitter can enable itself for data transfer with the receiver. The link port needs a pull-down on `LP_ACK` for this feature to function properly.
- ***Link Port Receive Service Request Interrupt (LRRQ).*** When a link port is configured as receiver, this interrupt is enabled by setting the `LP_CTL.RRQMSK` bit. When set, an external transmitter can indicate to the disabled receiver that it must receive data through the connected link port. The transmitter does so by driving out the first data. When the `LP_CLK` of the disabled receiver link port is detected high, a `LP_STAT.LRRQ` interrupt is generated. The receiver can further enable itself for data transfer with the transmitter. The link port needs a pull-down on the `LP_CLK` signal for this feature to function properly.
- ***Link Port Receive Overflow Interrupt (LPOVF).*** Generated when the receiver FIFO overflows and is enabled by setting the `LP_CTL.ROVFMSK` bit. This interrupt can happen if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` signal causing the receive FIFO to overflow.

Enabling Link Port Interrupts

A data request interrupt is fed to the system event controller directly and can be controlled separately from the application.

To mask the interrupt, set the mask bits in `LP_CTL` register corresponding to service interrupts and the overflow interrupt. These interrupts are OR'ed and fed to the SIC as a single `LP_STAT` interrupt. These interrupts are latched and stored in the associated bits of `LP_STAT` register. If an `LP_STAT` interrupt occurs, in the ISR, programs can read the `LP_STAT` register bits to determine the type of interrupt. These bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

Status and Error Signals

This section explains the various status signals in the `LP_STAT` register.

- *Transfer Status signals*. The link port uses the bus status bit (LP_STAT.LPBS) to give the status of the bus condition (busy or idle), when the link port is configured as transmitter. The LP_STAT.LPBS is high if the link port drives data into the link port pins. Programs can poll this bit after polling the LP_STAT.FFST bit to disable the link port safely.

  The link buffer status (LP_STAT.FFST) field directly indicates the status of the FIFO (including empty or full conditions) during data transfer. Software can poll this field in the LP_STAT register before writing to the FIFO (in case of transmission) or reading from the FIFO (in case of reception). The LP_STAT.FFST bit is automatically cleared when the link port is disabled.

- *Transfer Request Status signals*. The link port uses the receive request status (LP_STAT.LRRQ) bit to indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter). The link port uses the transmit request status (LP_STAT.LTRQ) bit to indicate that an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll these bits to enable the transmitter or receiver accordingly.

- *Error Status signals*. In receive mode 32-bit data is received in four chunks of 8-bit data. This data is then packed to a single 32-bit data before loading the FIFO. The link buffer error status (LP_STAT.LPACK) bit is high during this packing process and goes low after packing.

  The link port overflow status (LP_STAT.ROVF) bit is set when the receive FIFO overflows. This event can occur if the transmitter continues to transmit data even though the receiver has deasserted LP_ACK causing the receiver FIFO to overflow.

LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- Setting Up a DMA Transmit Operation
- Setting Up a DMA Receive Operation
- Setting Up a Core Transmit Operation
- Setting Up a Core Receive Operation

Setting Up a DMA Transmit Operation

This following procedure describes the typical steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port to transmit by setting the LP_CTL bit and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit.
4. Program the link port clock divider by writing a value to the LP_DIV register.

5. If using DMA stop mode or auto buffer mode, program the appropriate DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation and memory read).

6. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
7. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
8. Enable DMA by setting the DMA_CFG.EN bit.
9. Enable the link port by setting the LP_CTL.EN bit.
10. Wait for DMA to assert a transfer completion interrupt.
11. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit.

Setting Up a DMA Receive Operation

This section describes the typical steps for using the link ports in DMA receive mode.

1. Enable the link port pins in GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port for reception (clear the LP_CTL.TRAN bit) and enable the receive request interrupt mask by setting the LP_CTL.RRQMSK bit.
4. If using DMA stop mode or auto buffer mode, program the DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE=1, DMA_CFG.MSIZE=4, interrupt generation and memory write).

5. If using DMA array mode or list mode, create DMA configuration data structures filled with components.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation, memory write and fetch =4/5) and DMA_DSCPTR_NXT register (if list mode). Further, program DMA configuration register (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, Memory Write and Fetch =4/5) and program the DMA_DSCPTR_NXT register (if list mode).

6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for the receive service request interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
8. Enable DMA by setting the DMA_CFG.EN bit.
9. Enable the link port by setting the LP_CTL.EN bit.

10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit of the DMA status register.

Setting Up a Core Transmit Operation

This section describes the typical steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC.
3. Configure the link port for transmission by setting the LP_CTL.TRAN bit) and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit).
4. Program the link port clock divider by writing a value in to the LP_DIV register.
5. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
6. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
7. Enable the link port by setting the LP_CTL.EN bit.
8. The data request interrupt is asserted whenever there is free space in the FIFO. The application can write to the LP_TX register based on the FIFO conditions (half or empty) reflected in the LP_STAT.FFST bit field.

Setting Up a Core Receive Operation

This section describes the typical steps for using the link ports in processor core-based reception.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC).
3. Configure link port for reception (clear LP_CTL.TRAN bit). Enable the receive request interrupt mask bit (set LP_CTL.RRQMSK).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. The application can wait for receive service request interrupt to be asserted.
5. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
6. Enable the link port by setting the LP_CTL.EN bit.
7. The data request interrupt is asserted whenever there is free space in the FIFO. The application can read from the LP_RX register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the LP_STAT.FFST bit field.

ADSP-SC57x LP Register Descriptions

Link Port (LP) contains the following registers.

Table 13-6: ADSP-SC57x LP Register List

Name	Description
LP_CTL	Control Register
LP_DIV	Clock Divider Value Register
LP_RX	Receive Buffer Register
LP_STAT	Status Register
LP_TX	Transmit Buffer Register
LP_TXIN_SHDW	Shadow Input Transmit Buffer Register
LP_TXOUT_SHDW	Shadow Output Transmit Buffer Register

Control Register

The LP_CTL register provides LP interrupt masking, selection of transfer direction, and link port enable.

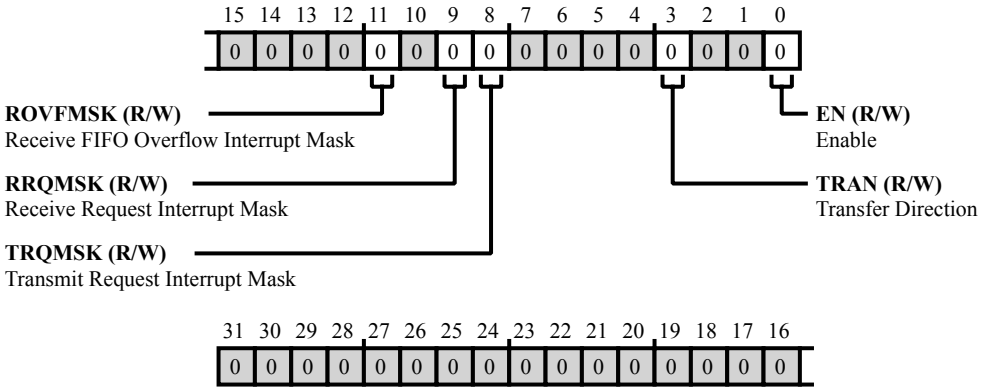

Figure 13-13: LP_CTL Register Diagram

Table 13-7: LP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ROVFMSK	Receive FIFO Overflow Interrupt Mask. Receive FIFO Overflow Interrupt Mask	
		0	Mask Disable Receive FIFO Overflow Interrupt
		1	Unmask Enable Receive FIFO Overflow Interrupt
9 (R/W)	RRQMSK	Receive Request Interrupt Mask. Link Port Receive Request Mask	
		0	Mask Disable Receive Request interrupt.
		1	Unmask Enable Receive Request interrupt.
8 (R/W)	TRQMSK	Transmit Request Interrupt Mask. Link Port Transmit Request Mask	
		0	Mask Disable Transmit Request interrupt.
		1	Unmask Enable Transmit Request interrupt.
3 (R/W)	TRAN	Transfer Direction. The LP_CTL.TRAN bit selects the transfer direction as transmit (if set) or receive (if cleared) for link buffer.	
		0	Receive Direction transfer is receive
		1	Transmit Direction transfer is transmit

Table 13-7: LP_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The `LP_CTL.EN` enables or disables the link port. When the processor disables the port (`LP_CTL.EN` transitions from high to low), the processor clears the corresponding `LP_STAT` bits.	
		0	Disable Disable linkport
		1	Enable linkport Enable linkport

Clock Divider Value Register

The LP_DIV register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (SCLK). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

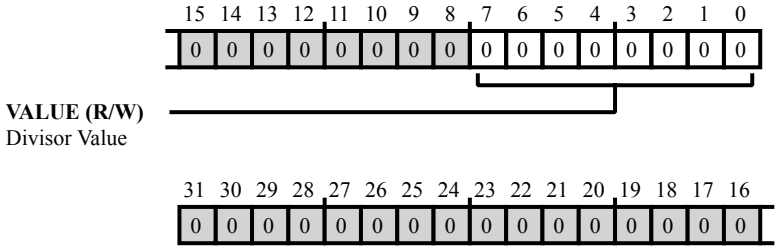

Figure 13-14: LP_DIV Register Diagram

Table 13-8: LP_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Divisor Value. The LP_DIV.VALUE bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (SCLK). The LP_DIV.VALUE should be programmed prior to LP enable. For LP_DIV.VALUE = 0, LCLK = SCLK For LP_DIV.VALUE = xxxxxxxx, LCLK = SCLK / (2 x DIV)

Receive Buffer Register

The LP_RX register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

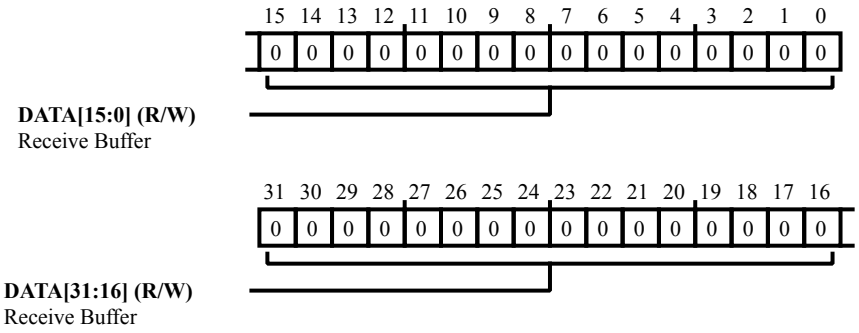

Figure 13-15: LP_RX Register Diagram

Table 13-9: LP_RX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Receive Buffer.

Status Register

The LP_STAT register provides status information on link port interrupts, FIFO, buses, and receive/transmit requests.

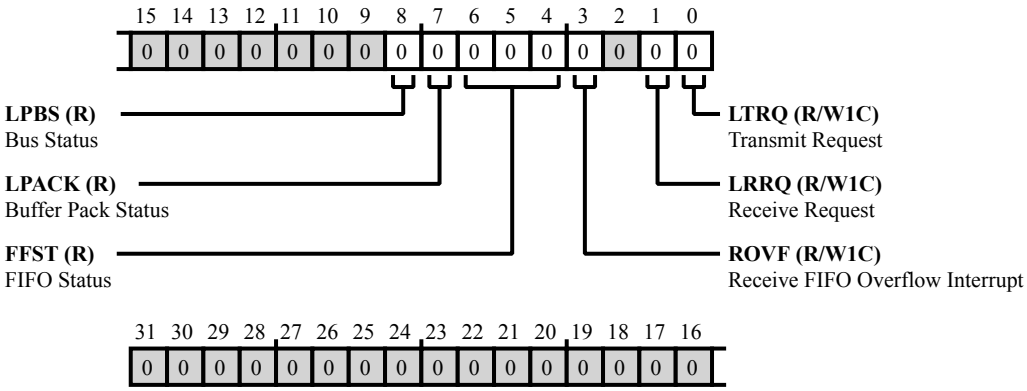

Figure 13-16: LP_STAT Register Diagram

Table 13-10: LP_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	LPBS	Bus Status. The LP_STAT.LPBS bit indicates the LPDAT bus status. LP_STAT.LPBS is kept high if data is being driven by the link port into the LP_D[n] pins.	
		0	Bus is Idle Link Port Bus is idle
		1	Bus Busy Link Port Bus is busy
7 (R/NW)	LPACK	Buffer Pack Status. The LP_STAT.LPACK bit indicates packing status. In receive mode, 32-bit data is received in 4 blocks of 8-bit data. Then, the data is packed to get a single 32-bit data before loading the FIFO. The LP_STAT.LPACK bit is high during this packing process and goes low after packing. In transmit mode, 32-bit data in the FIFO is unpacked to 4 blocks of 8-bit data before sending. The LP_STAT.LPACK is high during unpacking.	
		0	Packing Complete Packing done
		1	Packing Incomplete Packing is in progress
6:4 (R/NW)	FFST	FIFO Status. The LP_STAT.FFST bits indicate the FIFO status. These bits are cleared when the LP is disabled.	
		0	TX - Empty; RX - Empty Link buffer (TX OR RX) empty

Table 13-10: LP_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	TX - Reserved ; RX - Has 1 data word RX has 1 word of data. TX reserved
		2	TX - Reserved; RX - Has 2 data words RX has 2 word of data. TX reserved.
		3	TX - Reserved; RX - Has 3 data words RX has 3 word of data. TX reserved.
		4	TX - One Word; RX -Has 4 data words RX has 4 word of data. TX 1 word of data.
		5	Reserved
		6	TX - FIFO Full; RX - Reserved RX reserved. TX reserved.
		7	Reserved
3 (R/W1C)	ROVF	Receive FIFO Overflow Interrupt. This interrupt is generated when the receiver FIFO overflows. This overflow may happen if the transmitter continues to transmit data even though the receiver has de-asserted the LP_ACK pin.	
1 (R/W1C)	LRRQ	Receive Request. The LP generates this interrupt when the LP_CLK pin of a disabled link port (the receiver) is forced high by another link port (the transmitter).	
0 (R/W1C)	LTRQ	Transmit Request. The LP generates this interrupt when the LP_ACK pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).	

Transmit Buffer Register

The LP_TX register buffers the transmit data flow through the LP. The transmit buffer is two words deep. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the link port interface from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the LP_CLK signal. For more information on LP buffer features and operations, see the LP functional description.

14 Serial Peripheral Interface (SPI)

The serial peripheral interface is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

With a range of configurable options, the SPI ports provide a glueless hardware interface with other SPI-compatible devices in master mode, slave mode, and multimaster environments. The SPI peripheral includes programmable baud rates, clock phase, and clock polarity. The peripheral can operate in a multimaster environment by interfacing with several other devices, acting as either a master device or a slave device. In a multimaster environment, the SPI peripheral uses open-drain outputs to avoid data bus contention. The flow control features enable slow slave devices to interface with fast master devices by providing an SPI ready pin which flexibly controls the transfers.

NOTE: SPI peripherals (SPI0 and SPI1) on the processor operate in the SCLK0 domain. SPI2 operates in the SCLK1 domain. For more details on SCLK programming, refer the *Clock Generation Unit (CGU)* chapter.

SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- 8, 16-bit and 32-bit word sizes
- Programmable baud rate, clock phase, and polarity
- Programmable inter-frame latency
- Flow control
- Support for Fast and DIOM modes
- SPI2 supports quad and memory-mapped modes
- Independent receive and transmit DMA channels

- Burst transfer mode for non-DMA write accesses

SPI Functional Description

This section provides information on the function of the SPI module.

Shift register functionality

The SPI is essentially a shift register that serially transmits and receives data bits to or from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

Master slave functionality

During a data transfer, one SPI system acts as the link master which controls the data flow. The other system acts as the slave, which has data shifted into and out of it by the master. Different devices can take turn being masters, and one master can simultaneously shift data into multiple slaves (broadcast mode). However, only one slave can drive its output to write data back to the master at any given time. This rule must be enforced in the broadcast mode. Several slaves can be selected to receive data from the master in this mode. But only one slave can be enabled to send data back to the master.

Enhanced operating modes

SPI supports enhanced modes of operation like fast mode, DIOM, and Quad-SPI, and optional flow control. In fast mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both MOSI and MISO are configured as input or output pins, and 2 bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI_D3:0 are configured as input or output pins and 4 bits are shifted in or out on each receive or transmit edge. A slower slave can use flow control to stall a faster master device.

Single and multi-master use

The SPI can be used in a single master as well as multi-master environment. The `SPI_MOSI`, `SPI_MISO`, and the `SPI_CLK` signals are all tied together in both configurations. SPI transmission and reception can be enabled simultaneously or individually, depending on `SPI_RXCTL` and `SPI_TXCTL` settings. In broadcast mode, several slaves can be enabled to receive, but only one slave must be in transmit mode and driving the `SPI_MISO` line.

ADSP-SC57x SPI Register List

The Serial Peripheral Interface (SPI) provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments. The SPI's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers governs SPI operations. For more information on SPI functionality, see the SPI register descriptions.

Table 14-1: ADSP-SC57x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register

SPI Block Diagram

The ***SPI Controller Block Diagram*** illustrates the blocks of the SPI module. The module is comprised of three primary parts:

- SPI core contains the receive and transmit FIFOs and their associated shift registers
- Control blocks contain the synchronizer and logic to control the data flow through the data pipelines
- Register block

Transfer Protocol

The SPI module implements two channels that are independent of each other. The SPI module uses the SPI_RXCTL and SPI_TXCTL dedicated control registers to control these channels. Except in dual and quad modes, SPI can enable and use both channels simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the SPI_CTL.CPOL and SPI_CTL.CPHA bits.

The ***SPI Transfer Protocol*** figures demonstrate the two basic transfer formats as defined by the CPHA bit. Two waveforms are shown for SPI_CLK; one for SPI_CTL.CPOL=0 and the other for SPI_CTL.CPOL=1. The diagrams can be interpreted as master or slave timing diagrams since the SPI_CLK, SPI_MISO, and SPI_MOSI pins are directly connected between the master and the slave. The SPI_MISO signal is the output from the slave (slave transmission), and the SPI_MOSI signal is the output from the master (master transmission). The master generates the SPI_CLK signal. The SPI_SS signal is the slave device select input to the slave from the master. The

diagrams represent an 8-bit transfer (SPI_CTL.SIZE=0) with the MSB first (SPI_CTL.LSBF=0). Any combination of the SPI_CTL.SIZE and SPI_CTL.LSBF bits is permissible. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase could be identical for the master device and the slave device involved in the communication link. The transfer format from the master can be changed between transfers to adjust for various requirements of a slave device.

The SPI module uses the SPI_CTL.ASSEL bit to determine when the SPI hardware or software control the SPI_SEL[n] line. When SPI_CTL.ASSEL=1, the slave select line must be set to the polarity set in the SPI_CTL.SELST field between each serial transfer. The actual behavior of SPI_SEL[n] also depends on the parameters programmed into the SPI_DLY register. The SPI hardware logic automatically controls this functionality. When SPI_CTL.ASSEL=0, SPI_SEL[n] can either remain active between successive transfers or be inactive. The software must control this activity through manipulation of the SPI_SLVSEL register.

The ***SPI Transfer Protocol*** pair of figures illustrates the case when SPI_CTL.ASSEL = 1 and the $\overline{\text{SPI\_SEL[n]}}$ line is inactive between frames. If ASSEL = 0, the SPI_SEL[n] line can remain active between frames; however, the first bit is only driven when an active transition of SPI_CLK occurs.

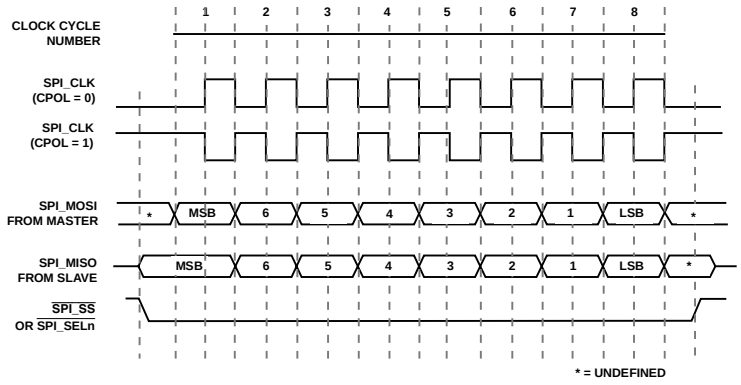

Figure 14-1: SPI Transfer Protocol for CPHA=0

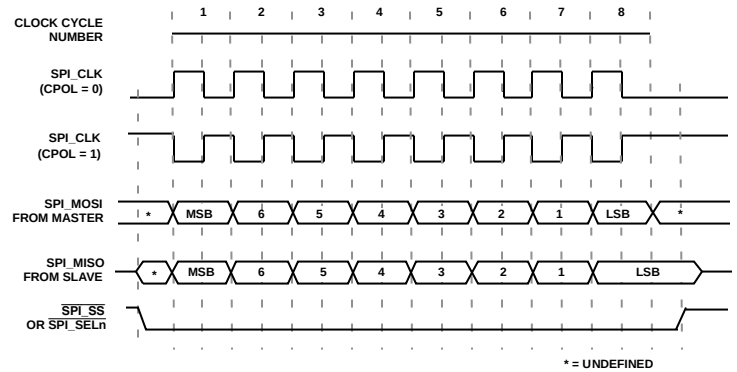

Figure 14-2: SPI Transfer Protocol for CPHA=1

Clock Considerations

The SPI_CLK signal is a gated clock that is only active during data transfers, for the time of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In dual-I/O mode, it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be derived using both even and odd dividers from SCLK.

For master devices, the SPI uses the SPI_CLK register value to determine the clock rate, whereas this value is ignored for slave devices.

When the SPI controller is a master, SPI_CLK is an output signal. Conversely, when the SPI controller is a slave, SPI_CLK is an input signal. Slave devices ignore the SPI clock when the slave select input is driven inactive. The SPI uses the SPI_CLK signal to shift out and shift in the data driven onto the SPI_MISO and SPI_MOSI lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the SPI_CTL register and define the transfer format.

Controlling Delay Between Frames

The ***SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing using the SPI_DLY.LEADX and SPI_DLY.LAGX programming. The SPI uses the SPI_DLY.LAGX bits to control the timing between the slave select (SPI_SS) signal assertion and the first SPI_CLK edge. The SPI uses the SPI_DLY.LEADX bits to control the timing between the last SPI_CLK edge and deassertion of the SPI_SS signal. The lead and lag timing can be extended by a 1 SPI_CLK duration to ease timing restrictions on the slave device.

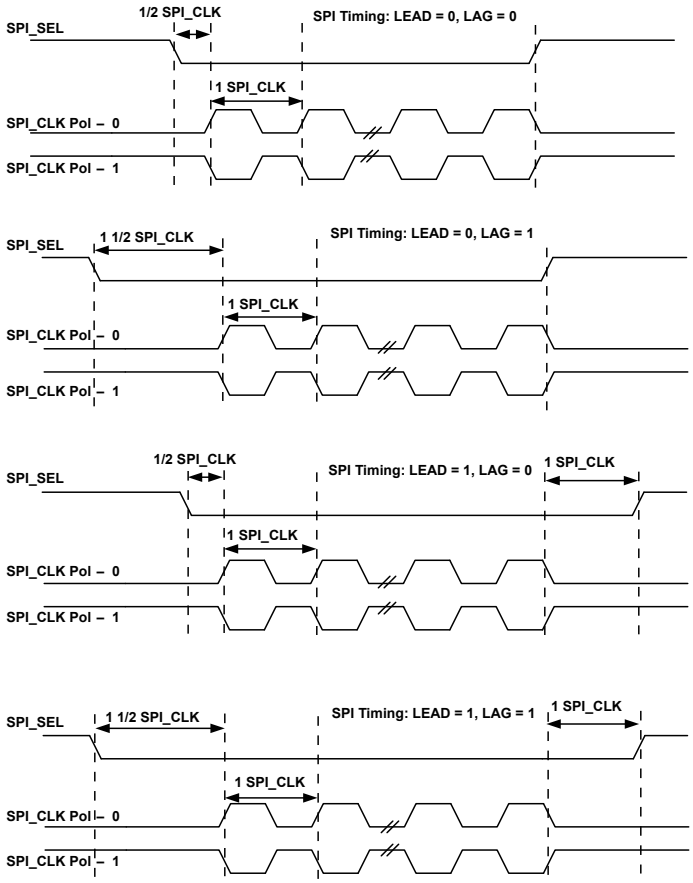

Figure 14-3: SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)

The ***SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing with STOP programming. The SPI module uses this timing to insert multiples of `SPI_CLK` period delays between transfers. The `SPI_SS` line is deasserted for the duration specified in the `SPI_DLY.STOP` bit field, assuming the `SPI_CTL.SELST` bit is configured for deassertion between transfers.

If the `SPI_DLY.STOP` bit =0, the master operates in a *continuous mode*. This mode causes an immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the slave select line is continuously asserted.

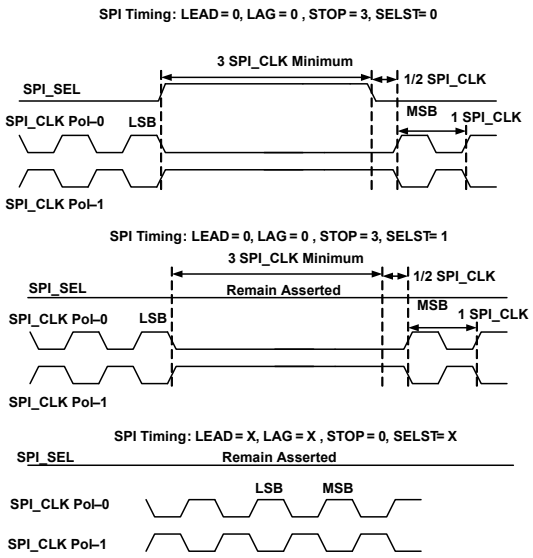

Figure 14-4: SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)

When the SPI_DLY.STOP bit =0 and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the SPI uses the SPI_CTL.SELST bit to determine the state of the slave select pin. The SPI uses the SPI_DLY.LEADX and SPI_DLY.LAGX bits to determine the timing between SPI_CLK edges and the slave select line.

Flow Control

In master mode, the slave device must drive the SPI_RDY pin. The pin acts as an input signal. The slave can deassert the SPI_RDY pin to stop the master from initiating any new transfer. If SPI_RDY is deasserted in the middle of a transfer, the current transfer continues, and the next transfer will not start unless the slave asserts the SPI_RDY signal. Whenever the slave deasserts SPI_RDY and stalls the master, the SPI controller goes into a waiting state, and the SPI_STAT.FCS bit is set. When the slave asserts SPI_RDY, the SPI controller resumes operation, and the SPI_STAT.FCS bit is cleared.

In slave mode, the SPI_RDY pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. The SPI uses the SPI_CTL.FCCH bit to control this configuration. If flow control is configured on the TX channel, as the SPI_TFIFO status nears the empty condition, the SPI_RDY pin is deasserted. If flow control is configured on the RX channel, as the SPI_RFIFO status nears the full condition, the SPI_RDY pin is deasserted. The SPI uses the SPI_CTL.FCWM bits to control the FIFO status at which SPI_RDY deassertion takes place. Flow control in slave mode is purely based on the FIFO status and does not depend on the word counters.

The ***SPI Flow Control Timing in Master Mode*** figure illustrates this timing.

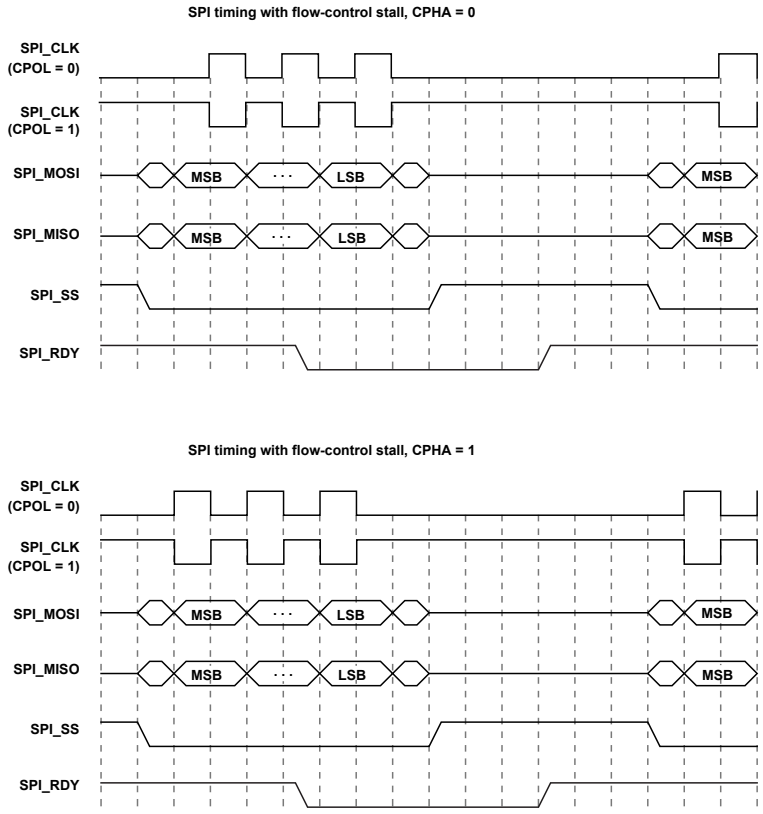

Figure 14-5: SPI Flow Control Timing in Master Mode.

Slave Select Operation

If the SPI is in slave mode, $\overline{\texttt{SPI\_SS}}$ acts as the slave select input. When SPI is enabled as a master, $\overline{\texttt{SPI\_SS}}$ can serve as an error detection input for the SPI in a multi-master environment. The `SPI_CTL.PSSE` bit enables this feature. When `SPI_CTL.PSSE`=1, the $\overline{\texttt{SPI\_SS}}$ input is the master mode error input. Otherwise, $\overline{\texttt{SPI\_SS}}$ is ignored.

The $\overline{\texttt{SPI\_SS}}$ signal is an active-low signal. The master asserts the signal during the transfer. The signal can be deasserted or remain asserted between transfers. When $\overline{\texttt{SPI\_SS}}$ is deasserted, `SPI_CLK` and inputs are ignored, and outputs are three-stated.

The slave select bits (`SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7`) are used in a multiple-slave SPI environment. For example, if there are eight SPI devices in the system including a processor master, the master processor can support the SPI mode transactions across the other seven devices. This configuration requires only one master processor in this multi-slave environment.

For example, assume that the SPI of the processor is the master. The `SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7` bits on the processor can be connected to the slave select pin of each slave device. In this configuration, the slave select bits can be used in three ways. In cases 1 and 2, the processor is the master and the seven microcontrollers or peripherals with SPI interfaces are slaves. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all slave select bits are set.

2. Receive and transmit from one SPI device by enabling only one slave SPI device at a time.
3. If all the slaves are also processors, then the requester can receive data from only one processor at a time. (The functionality is enabled by clearing the SPI_CTL.EMISO bit in the six other slave processors.) The requestor can transmit broadcast data to all seven at the same time. This MISO enabling feature is available in some other microcontrollers. Therefore, it is possible to use the MISO enabling feature with any other SPI device that includes this functionality.

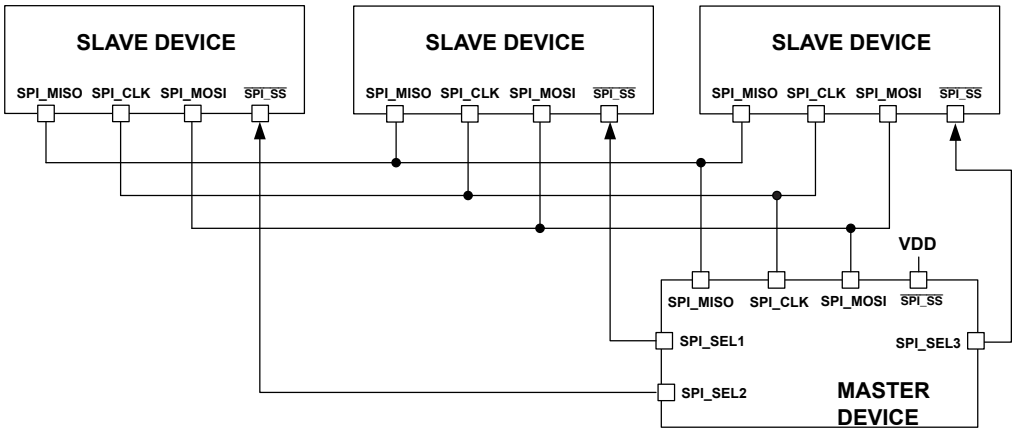

Figure 14-6: Single-Master, Multiple-Slave Configuration

Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a master or a slave.
2. The state of the SPI_CTL.ASSEL bit, which selects between hardware and software control over SPI_SLVSEL.

When SPI_CTL.CPHA=0, the enabled slave select outputs are driven active. However, the SPI_CLK signal remains inactive for the first half of the first cycle of SPI_CLK. For a slave with SPI_CTL.CPHA=0, the transfer starts as soon as the SPI_SS input goes low.

When SPI_CTL.CPHA=1, a transfer starts with the first active edge of SPI_CLK for both slave and master devices. For a master device, a transfer is complete after it sends the last data and simultaneously receives the last data bit. A transfer for a slave device ends after the last sampling edge of SPI_CLK. If SPI_CTL.ASSEL=0, the hardware maintains responsibility for toggling SPI_SS between frames. If SPI_CTL.ASSEL=1, software controls the SPI_SS line and can keep it active between frames.

The SPI_STAT.RFE bit defines when the receive buffer can be read, indicating that SPI_RFIFO is not empty. The SPI_STAT.TFF bit defines when the transmit buffer can be written, indicating that the SPI_TFIFO is not full. The end of a single word transfer occurs when the SPI_STAT.RFE bit is cleared. The status indicates that a new word has been received and written into the receive FIFO. The SPI_STAT.RFE bit remains cleared as long as the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the SPI_STAT.SPIF bit is also available for polling. This bit can have a slightly different behavior from other commercially available devices.

In master mode with the SPI_CTL.ASSEL bit cleared, software manually asserts the required slave select signal before starting the transaction. After all data transfers, software typically releases the slave select line.

When the receive or transmit word counters are enabled in the SPI_TXCTL or SPI_RXCTL registers, the SPI generates a finish interrupt at the end of the transfer. It signals the end of all transfers related to that transaction.

Transmit Operation in Non-DMA Mode

The transmit operation in non-DMA mode is enabled through the SPI_TXCTL.TEN bit. It can be enabled independently from the receive operation, and the transmit channel can become the initiating channel based on the SPI_TXCTL.TTI bit setting.

Transmit underrun is not possible in this mode, as no new transfer initiates unless the transmit FIFO is empty (in the case that SPI_TXCTL.TTI =1). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This event can occur if SPI_TXCTL.TTI =1 and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt request is signaled once the transmit channel has been enabled and the transmit FIFO is not full. The SPI uses the SPI_TXCTL.TDR bit setting to control the frequency of the interrupt request.

Receive Operation in Non-DMA Mode

The receive operation in non-DMA mode is enabled through the SPI_RXCTL.REN bit. It can be enabled independently from the transmit operation, and the receive channel can become the initiating channel based on the SPI_RXCTL.RTI bit setting.

Receive overflow is not possible in this mode, as no new transfer initiates when the receive FIFO is full (in the case of SPI_RXCTL.RTI =1). A transmit underrun can occur (SPI_TXCTL.TDU bit) when no valid data is in the SPI_TFIFO register when a transfer is initiated. This event can occur if SPI_RXCTL.RTI =1 and the transmit channel is enabled in a non-initiating capacity.

An SPI receive interrupt request is signaled once the receive channel has been enabled and there is data waiting to be read. The SPI uses the SPI_RXCTL.RDR bit setting to control the frequency of the interrupt request.

Dual I/O Mode

In Dual I/O mode, the SPI_MISO and SPI_MOSI pins are configured to operate in the same direction which doubles bandwidth. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends the first bit on the SPI_MOSI pin and the second bit on the SPI_MISO pin. If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt request generation is unaffected by dual I/O mode. However, the interrupt service interval is reduced, since the individual transfer latency is halved.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

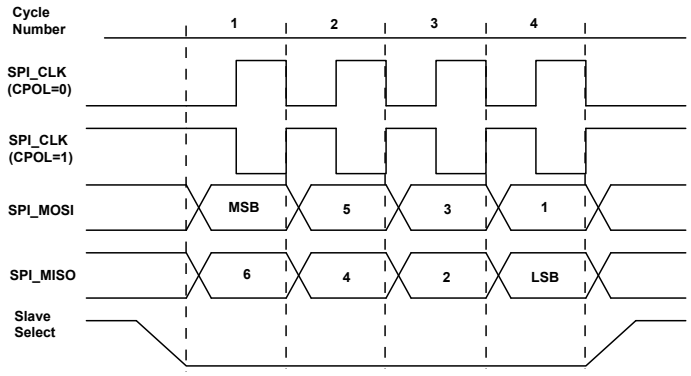

Figure 14-7: Dual I/O Mode Transfer Protocol for CPHA=0, SOSI=1, 8-Bit Transfer, LSBF=0.

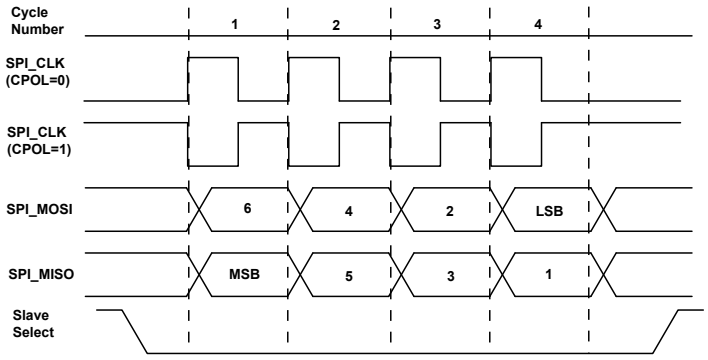

Figure 14-8: Dual I/O Mode Transfer Protocol for CPHA=1, SOSI=0, 8-Bit Transfer, LSBF=0.

Quad I/O Mode (SPI2 only)

In quad SPI mode, the SPI_MISO and SPI_MOSI pins, in tandem with the SPI_D2 and SPI_D3 pins, are configured to operate in the same direction. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends:

- The first bit on the SPI_MOSI pin
- The second bit on the SPI_MISO pin
- The third bit on the SPI_D2 pin
- The fourth bit on the SPI_D3 pin

If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled as either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt generation is unaffected by quad SPI mode.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

While using dual or quad I/O mode for communicating with flash devices, program the SPI_CTL.CPHA and the SPI_CTL.CPOL bits =1. This programming avoids bus contention during read operations, because the flash device starts driving out the bits immediately after dummy cycles in read header.

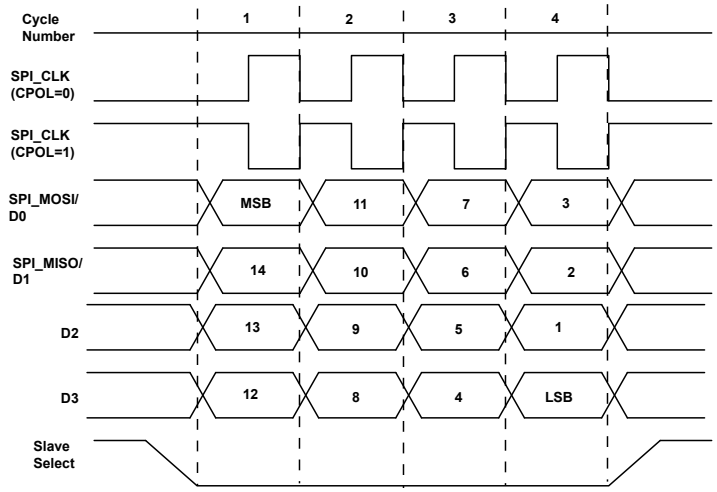

Figure 14-9: Quad Mode Timing for CPHA=0, SOSI=1, 16-Bit Transfer, LSBF=0.

NOTE: The SPI does support quad SPI 8-bit transfer in slave continuous mode of operation with an SCLK:`SPI_CLK` ratio of less than 1:2. A minimum of 2 SCLK cycles is required between transfers in 8-bit quad SPI slave mode with an SCLK:`SPI_CLK` ratio of less than 1:2.

Fast Mode

Fast mode is similar to the normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in master mode operation only. When the SPI operates in fast mode, the slave drives the data for one full cycle.

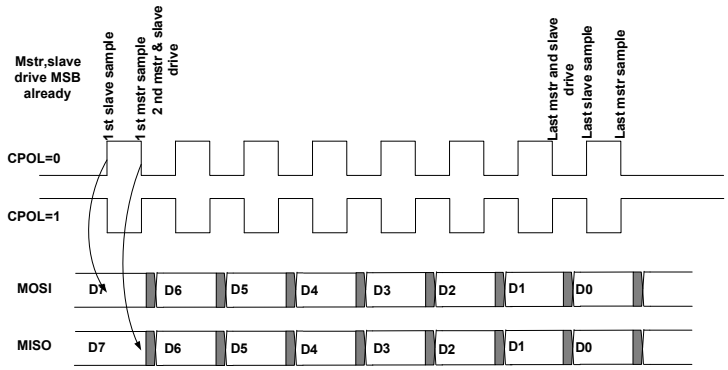

Figure 14-10: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 0

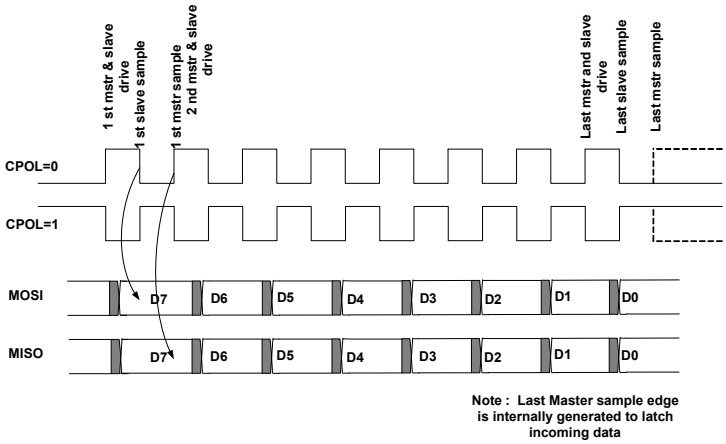

Figure 14-11: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 1

Memory-Mapped Mode (SPI2 only)

The SPI supports direct memory-mapped read accesses from a SPI memory device, enabled by setting the `SPI_CTL.MMSE` bit. This mode allows for direct execution of instructions from a SPI memory device without the need for a low-level software driver, as hardware handles all overhead tasks (for example, transmission of the read header, pin turnaround timing, and receive data sizing). The SPI features configurable options in the memory-mapped read header register (`SPI_MMRDH`) to provide compatibility with a wide range of SPI memory devices.

In non-memory-mapped mode, the software is responsible for providing the command and required dummy words for the read response, whereas this is all handled by hardware when the SPI is in memory-mapped mode. The memory of the SPI device is accessible directly through reads of the processor address space. The read accesses can be code or data accesses in core mode or when using memory DMA (MDMA). These accesses allow code to execute directly from SPI memory devices (true eXecute-In-Place operations), and the contents can be cached to improve performance. It is not necessary to access the SPI data buffer registers nor poll status bits; however, the hardware does not support peripheral DMA accesses nor write operations to the SPI memory space.

The ***Types of Operations*** table is a comparison of the permitted operations in the non-memory-mapped and memory-mapped modes supported by the SPI controller.

Table 14-6: Types of Operations

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
Core data write	Yes	No
Core data read	Yes	Yes
Code fetch: Execute-In-Place (XIP)	No	Yes
Read/Write accesses using SPI Peripheral DMA	Yes	No
Read/Write accesses by other peripheral DMA channels	No	No
MDMA read*	No	Yes

Table 14-6: Types of Operations (Continued)

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
MDMA write	No	No

NOTE: MDMA read* - Only standard bandwidth MDMA (MDMA0 and MDMA1) and Enhanced Bandwidth MDMA (MDMA2) can be used for accessing flash address space in memory mapped mode. The maximum bandwidth MDMA (MDMA3) cannot access flash address space.

Memory-Mapped Description of Operation

Memory-mapped mode is enabled by setting the SPI_CTL.MMSE bit. When enabled, the SPI (if ready) accepts the read requests through a dedicated on-chip slave interface. The memory subsystem master drives this dedicated interface through the SCB fabric.

In a typical scenario, the memory subsystem master issues read requests to the fabric, and the fabric routes these requests to the slave port of the SPI peripheral. The master describes the read access using a number of parameters such as starting address, transfer size, and burst type. The SPI responds to this read access request when it is ready for a new transfer. It loads the opcode, a specified number of address bytes, and an optional mode byte into the transmit FIFO. The SPI memory state machine begins when both the transmit and receive channels of the SPI are enabled with:

- the transmit transfer initiation bit is set (SPI_TXCTL.TTI=1), *and*
- the receive initiation bit is cleared (SPI_RXCTL.RTI=0)

The SPI memory read sequence starts with the assertion of $\overline{\text{SPI\_SEL1}}$. If the SPI memory state machine is in the reset state, it looks for a command. The SPI hardware then sends the specific 8-bit read command (which can be optionally skipped), followed by the SPI memory read address. After this, a dummy period is inserted, in which a mode byte is optionally sent and the pins are held or three-stated during the dummy clocking period.

NOTE: This read header is transmitted over the SPI standard protocol pins (SPI_CLK, SPI_MOSI, SPI_MISO, $\overline{\text{SPI\_SEL1}}$) or over the extended SPI protocol pins (SPI_CLK, SPI_MOSI, SPI_MISO, SPI_D2, SPI_D3, $\overline{\text{SPI\_SEL1}}$), based on the SPI_MMRDH.CMDPINS, SPI_MMRDH.ADRPINS, and SPI_CTL.MIOM bit settings. SPI memory devices usually support communication in MSB-first mode. In dual mode, the SPI typically uses SPI_MISO as IO1 and SPI_MOSI as IO0. In quad mode, the SPI typically uses SPI_D3 pin as IO3, SPI_D2 as IO2, SPI_MISO as IO1, and SPI_MOSI as IO0.

When all I/O data pins are three-stated, the SPI continues clocking the SPI memory device, which drives out the data bits at the addressed location, until all bytes are received. The SPI hardware reads the data as configured by the SPI_CTL.MIOM bit setting. Upon reception of the last byte, the SPI typically deasserts $\overline{\text{SPI\_SEL1}}$ to prepare for the next requested read header.

Application code must ensure that the opcode sent is consistent with multiple I/O programming and that the parameters specified in the memory-mapped read header register are consistent with flash read access timing.

The *SPI Memory-Mapped Register Operations Flow* diagram shows how the fields of the SPI_MMRDH register determine the read header while initiating transfers in memory-mapped mode.

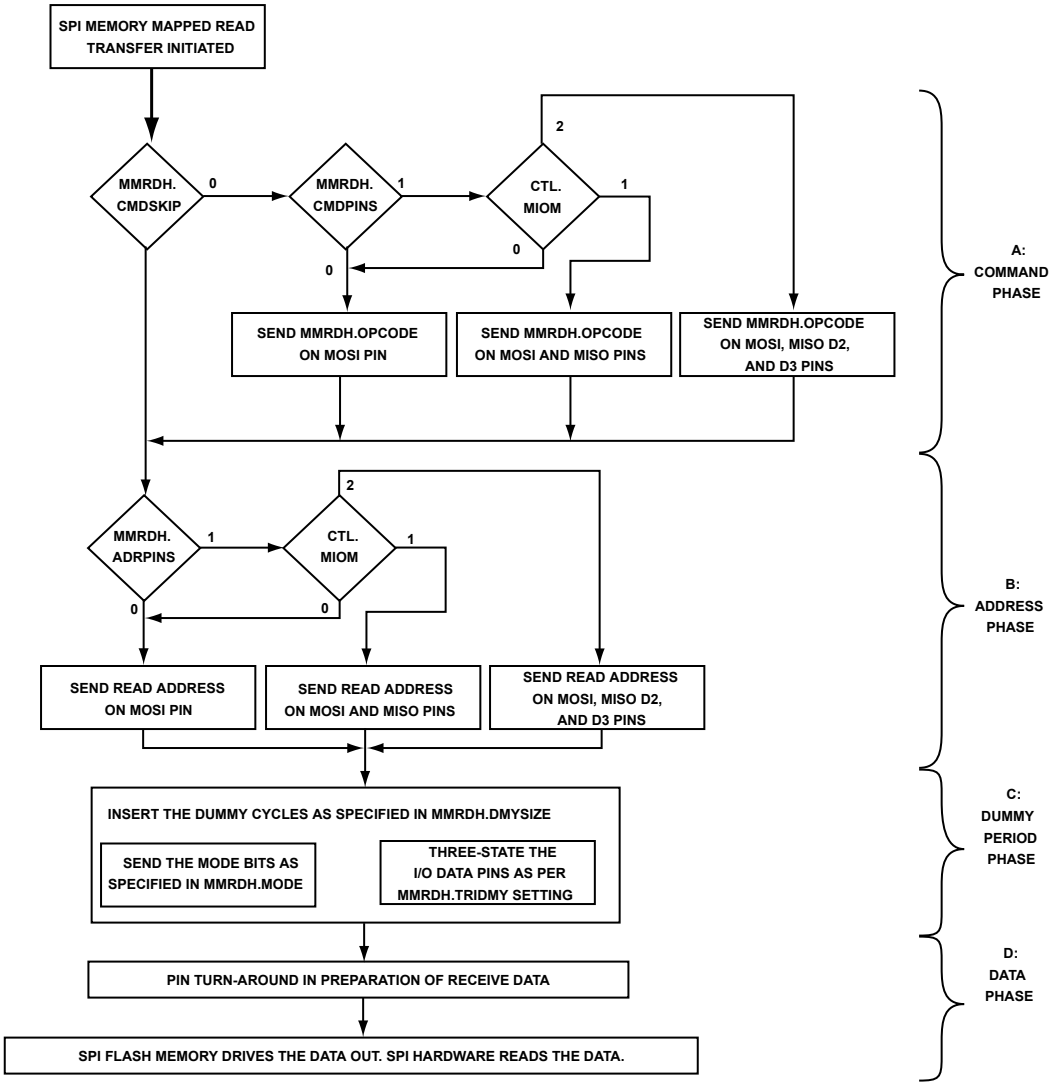

Figure 14-12: SPI Memory-Mapped Register Operations Flow

Memory-Mapped Architectural Concepts

In memory-mapped mode, the SPI accepts read requests through a dedicated on-chip slave interface. The SPI (if ready) accepts these requests and begins the process of assembling the read header based on access attributes described in both the SPI_MMRDH register and the internal bus request. After the read header transmission is complete, a pin turnaround period is timed and the receiver is enabled. The SPI continues clocking the SPI memory device until all bytes are received.

The SPI memory-mapped hardware accommodates various memory devices with different read timing. The capabilities include extra mode bits, flexible dummy period timing, and three-state control, as configured in the SPI_MMRDH register.

The *Memory-Mapped Protocol* figure shows the protocol for the SPI controller in memory-mapped mode.

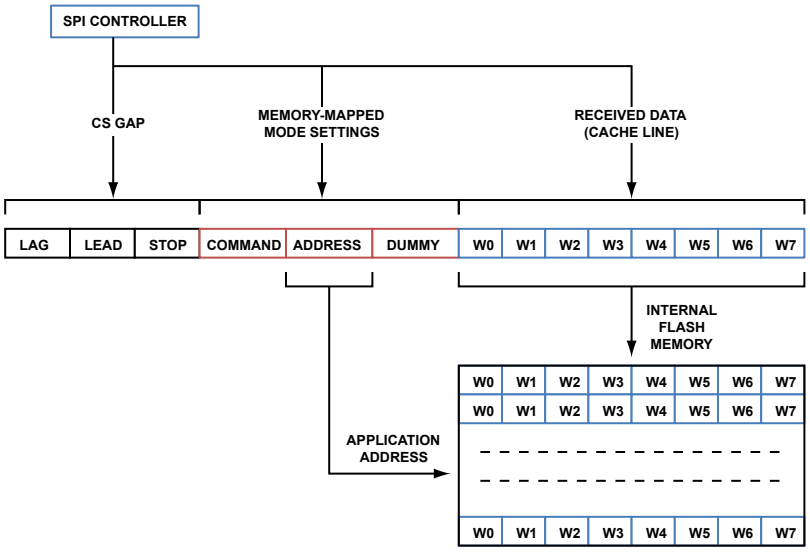

Figure 14-13: Memory-Mapped Protocol

As shown in the figure, the COMMAND field (`SPI_MMRDH.OPCODE`) is transmitted upon assertion of the `SPI_SEL[n]` signal. The SPI memory interprets this 8-bit value as a read command. Any 8-bit read opcode whose timing is compliant with the processor SPI and features provided by memory-mapped hardware is allowed, the most common being:

- Standard Read (0x03)
- Fast Read (0x0B)
- Fast Read Dual Output (0x3B)
- Fast Read Dual I/O (0x6B)
- Fast Read Quad Output (0xBB)
- Fast Read Quad I/O (0xEB)

NOTE: The SPI hardware does not validate the content of the `SPI_MMRDH.OPCODE` field prior to transmitting.

DMYSIZE (Number of Dummy Bytes)

When operating at a high clock frequency in multi-IO modes, most flash devices require some dummy clocks after the address bits. These dummy clock cycles allow the internal circuits of the device extra time for setting up the initial address. These bits specify the number of bytes separating address transmission and read data return.

The number of dummy cycles required varies per manufacturer, the read command used, and the SPI access time. The SPI hardware allows dummy cycles to be programmed in bytes in the `SPI_MMRDH.DMYSIZE` field, the value of which is a function of the number of pins used to transmit the address (`SPI_MMRDH.ADRPINS`), as shown in the *Pins Used to Transmit the Address (ADRPINS)* table.

Table 14-7: Pins Used to Transmit the Address (ADRPINS)

	Dummy clock cycles		
SPI_MMRDH.DMYSIZE	(**SPI_MMRDH.ADRPINS**=0, **SPI_CTL.MIOM**=x) Dummy bytes elapse over 1-pin	(**SPI_MMRDH.ADRPINS**=1, **SPI_CTL.MIOM**=1) Dummy bytes elapse over 2-pins	(**SPI_MMRDH.ADRPINS**=1, MIOM=2) Dummy bytes elapse over 4-pins
000	0	0	0
001	8	4	2
010	16	8	4
011	24	12	6
100	32	16	8
101	40	20	10
110	48	24	12
111	56	28	14

This dummy clocking period allows the mode bits to be sent, the pins to be three-stated, and the pins to be turned around in preparation for the receive data.

Memory-Mapped Read Accesses

The SPI hardware supports the most commonly used read operations.

- Two standard SPI reads (read and read fast), which use the unidirectional SPI_MOSI and SPI_MISO pins in addition to SPI_SEL[n] and SPI_CLK
- Four extended SPI multiple I/O reads: dual output, quad output, dual I/O, and quad I/O reads

The ***SPI Read Operations*** table and ***SPI Flash Fast Read Sequence*** figures summarize the types of read operations. Program each read operation in a way that is compatible with the description given in the SPI flash data sheet.

Table 14-8: SPI Read Operations

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Read	0x03	1	1	Zero	No	No	1
Fast Read	0x0B	1	1	Non-Zero	Yes	No	1
Dual Output Read	0x3B	1	1	Non-Zero	Yes	Yes(IO0-1)	2
Quad Output Read	0x6B	1	1	Non-Zero	Yes	Yes(IO0-3)	4
Dual I/O Read	0xBB	1, 2	2	Non-Zero	Yes	Yes (IO0-1)	2
Quad I/O Read	0xEB	1, 4	4	Non-Zero	Yes	Yes (IO0-3)	4

Some memory devices also support word quad I/O read (0xE7) and octal quad I/O read (0xE3) operations. These operations require fewer dummy cycles than normal quad I/O read operations.

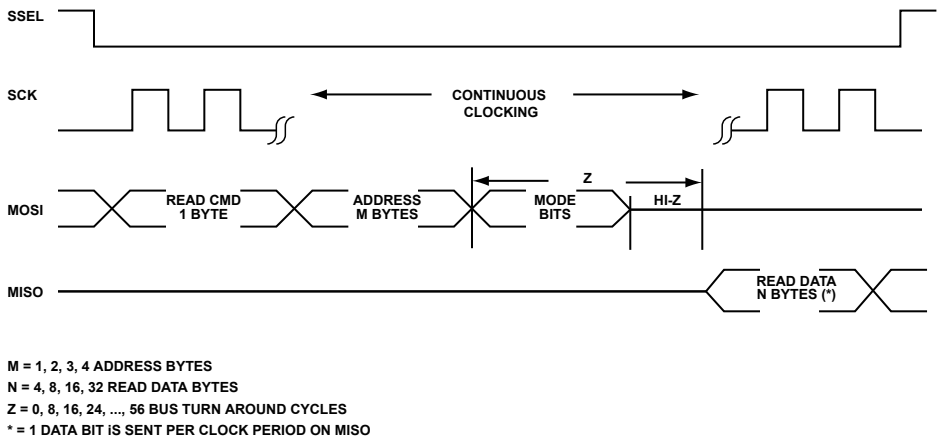

Figure 14-14: SPI Flash Fast Read Sequence

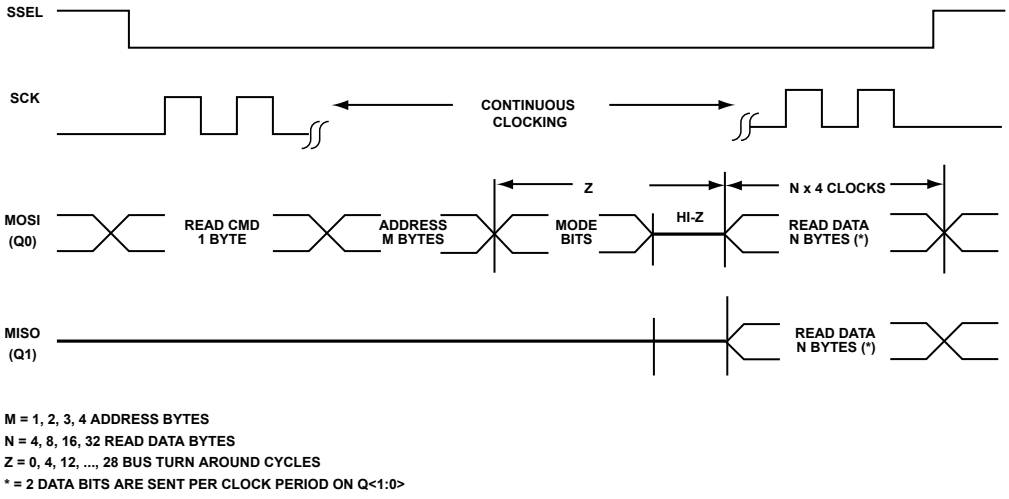

Figure 14-15: SPI Flash Fast Read (Dual Output) Sequence

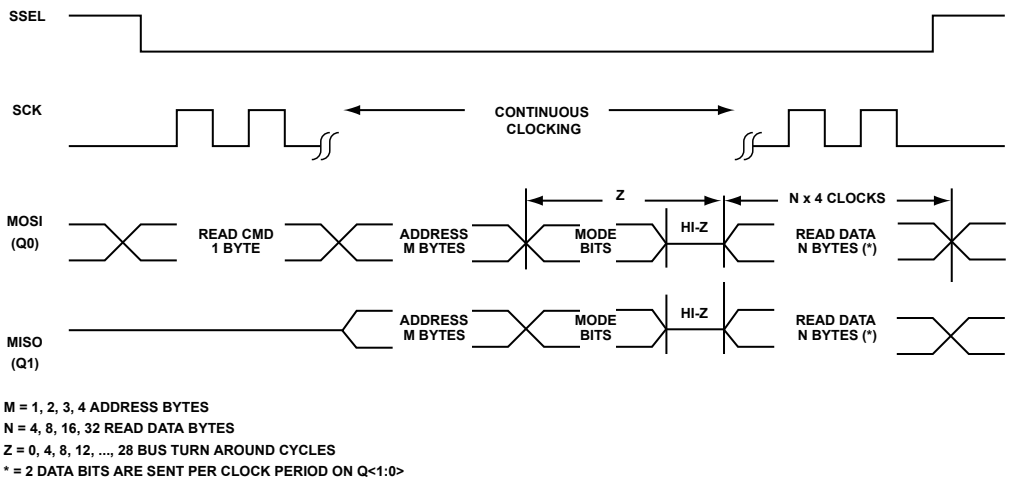

Figure 14-16: SPI Flash Fast Read (Dual I/O) Sequence

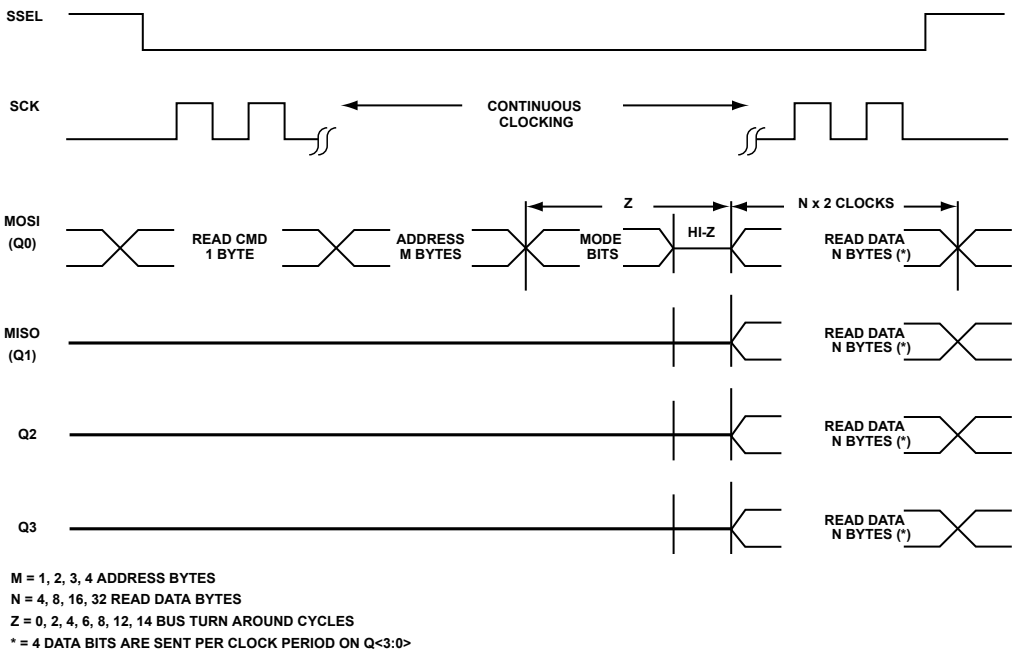

Figure 14-17: SPI Flash Quad Output Read Sequence

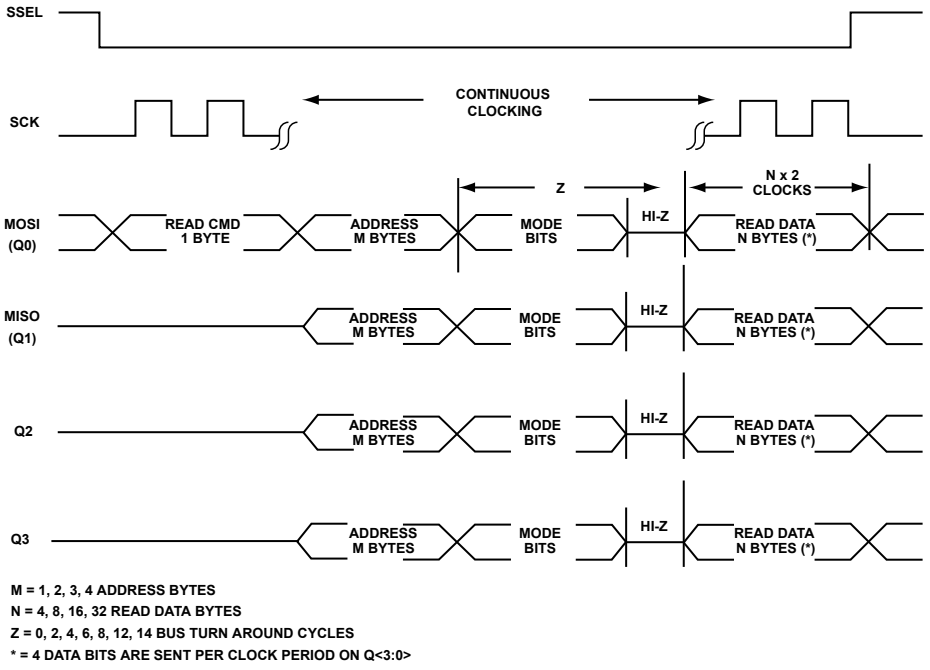

Figure 14-18: SPI Flash Quad I/O Read Sequence

SPI memory-mapped reads can be made cacheable in the core's internal memory by properly configuring the region as cacheable memory without bypass (see the related core's cache configuration documentation for details). In the figures, the number of read data bytes (N) is based on the following:

- For an instruction fetch by core (when in XIP mode); the number of instruction bytes to be fetched depends on the cache line size of the cache.

- For a data fetch by the core (data read), the number of data bytes to be fetched depends on the cache line size of the cache.

Although the minimum size of a memory-mapped data read transfer is 4 bytes, applications can fetch a single byte or a 2-byte data. (For example, it can fetch an unsigned char or short access in C code). In this case, only the required bytes are provided to the core and the other bytes are cached.

The on-chip memory subsystem master provides a starting address for the burst and the SPI hardware issues this address as part of the read header. The address provided is N-byte aligned. For example, to read the 30th byte from SPI memory, then the typical address to provide is:

- 28 (0x0000_001C) for a 32-bit cache line
- 24 (0x0000_0018) for a 64-bit cache line
- 16 (0x0000_0010) for a 128-bit cache line
- 0 (0x0000_0000) for a 256-bit cache line

The read data is returned to the memory subsystem in the order provided by the SPI memory. There can be considerable delay for the expected data provided to the master.

To minimize this delay, the wrap feature can be used where the memory subsystem provides the address of the critical word.

- For MDMA reads, the number of read data bytes (N) is always equal to 4 bytes. The MDMA read does not depend on the cache setting. For MDMA reads, limit the `DMA_CFG.MSIZE` field to 1, 2 or 4 bytes. The address provided by the memory subsystem master to the SPI hardware is always 4 byte-aligned.

Memory-Mapped High-Performance Features

In addition to automating the SPI memory read accesses, the memory-mapped hardware also provides some features to improve SPI memory fetches and increase the system performance. The following sections describe these features.

Merged Read Accesses

It is common for the memory subsystem to fetch two or more cache lines from consecutive addresses (the address sequencing is linear without any jumps). To take advantage of this situation, the SPI memory-mapped hardware provides a feature called merging. Enable merging by setting the `SPI_MMRDH.MERGE` bit.

When enabled, the hardware compares the address of an incoming read request to the address of a request the SPI memory is actively servicing. It can decide to merge two accesses when the address for the second access is incremental. For example, if the first address of a 32-byte cache line fetch is 0x0000_0000 and the second fetch is to address 0x0000_0020, then these two accesses can be merged. Merging increases efficiency and overall fetch bandwidth by eliminating the read header for those accesses which only require continuation of the SPI clock.

Wrap Around Accesses

Many SPI flash memory devices support wrapping which is used to enhance critical word fetching of cache lines. In this mode, the SPI device automatically wraps the read address to the base of a cache line once the end of the cache line is reached.

Wrap around accesses are enabled by setting the SPI_MMRDH.WRAP bit.

Some flash devices require programs to send a ***Set Wrap*** command to place the device in wrap mode. Other flash devices provide a configuration register which must be programmed to set the flash in wrap mode. Since the SPI memory-mapped hardware does not support any write operations to flash, perform this step in non-memory-mapped mode (SPI_CTL.MMSE=0) by accessing the SPI registers.

Table 14-9: Wrap Modes

Cache Line Size	Wrap Mode	Comments
4-byte	Not applicable	Usually flash does not support 4-byte wrapping.
8-byte	8 byte wrapping	Read data wraps within an aligned 8-byte boundary starting from the specified address.
16-byte	16 byte wrapping	Read data wraps within an aligned 16-byte boundary starting from the specified address.
32-byte	32 byte wrapping	Read data wraps within an aligned 32-byte boundary starting from the specified address.

Data access is limited to 8-byte, 16-byte, or 32-byte sections of flash page in wrap mode. The ARM core uses the Wrap 4 access (64-bit data) for L1 cache. The ARM core uses Wrap 4 and Wrap 8 accesses (64-bit data) for L2 cache. The cores use the Wrap 8 accesses for unaligned accesses. During the read request to the SPI memory-mapped hardware, the memory subsystem master of the processor provides the address of a critical word instead of the line base. The read-data starts at the address specified in the instruction. Once it reaches the end boundary of the 8, 16, or 32-byte section, the output automatically wraps around to the beginning boundary to the line base address. The data fetch continues. It is not necessary to deassert the SPI SPI_SEL[n] signal or resend the read header to wrap to the cache line base when servicing misaligned cache fill requests.

The ***Byte Sequence in Wrap Modes*** table shows byte sequences in various wrap modes.

Table 14-10: Byte Sequence in Wrap Modes

Starting Address	8-Byte Wrap (cache_line = 8 byte)
0	0-1-2- . . . -6-7
1	1-2- 3-. . . -7-0
7	7-0-1- . . . -5-6
15	15-8-9- . . . -13-14
31	31-24-25-. . . .-29-30

The burst with wrap feature allows applications to fetch a critical address quickly. Applications then fill the cache afterwards within a fixed length (8/16/32-byte) of data without issuing multiple read commands. Certain applications can benefit from this feature to improve cache fill efficiency and overall performance of system code execution.

NOTE: Do not use the merge and wrap feature together. Using wrap bursts can unintentionally disable merging (merging cannot occur for unaligned wrapping bursts). A wrap burst can start fetching data words in the middle of the cache line and cannot be merged with the next access.

Execute-In-Place (XIP, SPI2 only)

Execute-In-Place, most commonly known as XIP, allows software code to execute directly from an SPI flash device rather than downloading the code and executing it out of RAM. XIP, also known as Command Skip mode, is a general term and can be applied to fetching data as well.

There is a difference between XIP mode and standard mode. In XIP mode, after the SPI memory device is selected (CS# =LOW), the memory device does not decode the first input byte as command code. Instead, it expects the read header to directly start with address bytes. In standard mode, the memory decodes the first input byte it receives as a command code.

The XIP mode dramatically reduces random access time for applications that require fast code execution without shadowing the memory content on a RAM. The SPI memory-mapped hardware provides a control bit, `SPI_MMRDH.CMDSKIP` to skip the command from read header.

Some SPI memory devices require configuration of their control register to enable the XIP mode of operation, using the non-memory-mapped mode of the processor SPI. Typically, during the dummy cycle period, the mode bits are used to confirm the XIP operation and the `SPI_MMRDH.MODE` field must be set appropriately. A dummy memory-mapped access may be needed before setting the `SPI_MMRDH.CMDSKIP` bit in order to set the SPI memory device in Command Skip mode.

For more details about how to configure SPI memories into XIP mode, refer to the device data sheet.

NOTE: When configuring the flash to XIP mode from the SHARC+ core, ensure that the routine that configures flash to XIP is not routed through the L2CC. This is accomplished by first configuring the flash to XIP mode, then enabling the L2CC from the core.

Memory-Mapped Mode Error Status Bits

The SPI memory-mapped hardware provides bits in the `SPI_STAT` register to report errors. It provides these bits for notification only and their state has no effect on SPI operations. The status register bits are sticky. A W1C (write-1-to-clear) operation clears the bits.

- Memory-Mapped Write Error (`SPI_STAT.MMWE`). This bit is set (=1) if an attempt is made to write to address space that is reserved for memory-mapped SPI memory. The SPI memory-mapped hardware does not support automated write access to SPI memory space.
- Memory-Mapped Read Error (`SPI_STAT.MMRE`). This bit is set (=1) if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (`SPI_CTL.MMSE` =0).
- Memory-Mapped Access Error (`SPI_STAT.MMAE`). This bit is set (=1) if an attempt is made to access either the TX or RX FIFO while memory-mapped access of SPI memory is enabled. In this case, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric reports an error. Legacy methods include any direct access made to the TX and RX FIFOs, whether by DMA or processor MMR.

- Memory-Mapped Write Error Mask (SPI_CTL.MMWEM) bit specifies whether an error response is returned to the fabric on write attempts to address space that is reserved for memory-mapped SPI memory reads. Regardless of whether a write error response is masked using this bit, the memory-mapped write error (SPI_STAT.MMWE) sticky notification bit is still set.

  NOTE: Unlike other bits in the SPI_STAT register, these memory-mapped mode error bits do not have associated bits in the SPI interrupt mask (SPI_IMSK) and SPI interrupt condition (SPI_ILAT) registers.

The memory-mapped top register (SPI_MMTOP) is used to specify the upper limit of the SPI memory address. The memory-mapped accesses to SPI memory addresses equal to or above this range are considered illegal. The accesses are blocked and a bus error response is generated.

This register is useful to block the invalid SPI memory address accesses. Some SPI memory vendors do not clearly specify (guarantee) that overrange address bits are ignored (address spaces can be wrapped).

Memory-Mapped Programming Guidelines

Setting the SPI_CTL.MMSE bit enables SPI memory-mapped mode. When enabled, the SPI interface is forced to be consistent with SPI memory requirements regardless the settings of certain control bits. The following tables specify typical settings for configuring the SPI in memory-mapped mode:

Table 14-11: SPI Control (SPI_CTL) Register

Bits	Typical values to set	Description	Comments
SPI_CTL.MSTR	1	Master mode enable	
SPI_CTL.PSSE	0	Protected slave select enable	
SPI_CTL.ODM	0	Open-drain mode enable	
SPI_CTL.CPHASPI_CTL.CPOL	0–0 or 1–1	SPI mode of communication	Flash dependent, usually SPI flash supports mode-0 (CPHA=CPOL=0) and mode-3 (CPHA=CPOL=1)
SPI_CTL.ASSEL	1	Hardware slave select pin control	
SPI_CTL.SELST	1	Slave select asserted between transfers	
SPI_CTL.EMISO	1	MISO pin enable	
SPI_CTL.SIZE	2	32-bit transfer size	
SPI_CTL.LSBF	0	MSB bit first mode	Flash dependent, usually SPI flash communicates in MSB bit first mode

Table 14-11: SPI Control (SPI_CTL) Register (Continued)

Bits	Typical values to set	Description	Comments
SPI_CTL.FCEN SPI_CTL.FCCH SPI_CTL.FCPL SPI_CTL.FCWM	0	Hardware flow control related bits	
SPI_CTL.FMODE	1	Fast mode enable	Typically set to 1 for full cycle timing, 0 only works at low speed
SPI_CTL.SOSI	0	Treat SPI_MOSI pin as IO0 pin.	

Table 14-12: SPI Receive Control Register

Bits	Typical values to set	Description
SPI_RXCTL.REN	1	Receive channel enable
SPI_RXCTL.RTI	0	Receive transfer initiation disable
SPI_RXCTL.RWCEN	0	Receive word counter disable
SPI_RXCTL.RDR	0	Receive data request disable
SPI_RXCTL.RDO	0	Discard incoming data if RFIFO is full
SPI_RXCTL.RRWM	0	Receive FIFO regular watermark
SPI_RXCTL.RUWM	0	Receive FIFO urgent watermark disable

Table 14-13: SPI Transmit Control Register

Bits	Typical values to set	Description
SPI_TXCTL.TEN	1	Transmit channel enable
SPI_TXCTL.TTI	1	Transmit transfer initiation disable
SPI_TXCTL.TWCEN	0	Transmit word counter disable
SPI_TXCTL.TDR	0	Transmit data request disable
SPI_TXCTL.TDU	0	Send last word when TFIFO is empty
SPI_TXCTL.TRWM	0	Transmit FIFO regular watermark
SPI_TXCTL.TUWM	0	Transmit FIFO urgent watermark disable

Table 14-14: SPI DLY Control Register

Bits	Typical values to set	Description	Comments See Flash data sheet for CS (for example. SSEL) timing specs
SPI_DLY.LAGX	1	Extended lag timing	

Table 14-14: SPI DLY Control Register (Continued)

Bits	Typical values to set	Description	Comments See Flash data sheet for CS (for example. SSEL) timing specs
SPI_DLY.LEADX	1	Extended lead timing	
SPI_DLY.STOP	3	Stop bit between the transfers	Can be set to 1 at lower SPI clock frequencies.

The multiple I/O mode (SPI_CTL.MIOM) bits are partially ignored:

- The command (opcode) is transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.CMDPINS bit setting.
- The address is then transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.ADRPINS bit setting.
- The data is always read with the number of pins specified by the SPI_CTL.MIOM bits.

NOTE: Set the SPI module enable bits SPI_CTL.EN last after configuring all registers.

Use the following programming guidelines for memory-mapped mode:

- The SPI memory-mapped hardware does not check the flash status before initiating the access. It assumes that SPI memory is always able to respond to a read access. Befor enabling memory-mapped mode (for example, setting the SPI_CTL.MMSE bit) ensure that SPI flash is ready for a read access. When using non-memory-mapped mode, a write-complete status can be examined prior to enabling the SPI in memory-mapped mode. (See the write in progress bit in the SPI flash memory status register.) Also, immediately after initial power-up, SPI memory devices can be inaccessible for a vendor-specified period.
- When SPI is enabled in memory-mapped mode, attempts to communicate with the SPI device using legacy methods are blocked. Legacy methods include any direct access made to the transmit or receive FIFOs, whether initiated by DMA or by a processor MMR access.
- To use some of the features offered by SPI memory devices, programs can first configure the SPI memory device by setting its control word or sending some commands. Since SPI memory-mapped hardware does not allow any type of SPI write operations, configure the SPI in non-memory-mapped mode prior to enabling memory-mapped mode.
- The memory-mapped hardware does not interpret the opcode. It does not check the validity of the timing that is specified in the SPI_MMRDH register for a particular opcode. Programs must set the fields of the SPI_MMRDH register to be consistent with the read-type selected.
- When the core requests the data or code fetch, the memory-mapped transfer depends on cache settings. The cache configuration register in the SPI memory device must be appropriately configured before enabling memory-mapped mode. Some of the high performance modes like merge, wrap, and transfer size depend on cache parameters.

- SPI memory-mapped MDMA reads do not support wrapping. For MDMA reads, limit the DMA_CFG.MSIZE field to 1 byte, 2 bytes or 4 bytes.
- There is not always tool support to change the SPI memory-mapped hardware setting or cache settings on-the-fly. Changing these settings can optimize the performance of code that accesses SPI memory in memory-mapped mode. It is expected that the SPI memory, SPI peripheral, and cache are programmed to one specific set of control settings for the whole application. Profiling or benchmarking of the actual application can be done to find the setting that works best.

SPI Interrupt Signals

The SPI controller supports three types of interrupt request signals that correspond to data, status, and error conditions.

Data Interrupts

The SPI peripheral supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the peripheral interfaces with separate read and write interfaces with DMA, the read and write data interrupts are independent. When the DMA channels are not used, the interrupts are routed directly to the system event controller. The interrupts occupy the same vector locations as the corresponding DMA channels.

Each of the data interrupt requests can be individually controlled. Program the SPI_RXCTL.RDR and SPI_TXCTL.TDR bit fields for receive and transmit, respectively. When receive is enabled, the RX interrupt request is issued whenever there is data available in the receive datapath for reading. (The event occurs according to the SPI_RXCTL.RDR bit setting.) When transmit is enabled, the TX interrupt request is issued whenever the transmit datapath can be written. (The event occurs according to the SPI_TXCTL.TDR setting.) DMA data interrupts are compatible with second-generation DMA to incorporate urgent data requests and transfer finish interrupt requests apart from the usual data request interrupts. Transmit interrupt requests operate independently from the word counter-value in the SPI_TWC register.

Status Interrupts

The SPI controller supports several status interrupt requests to indicate different conditions of the receiver and transmitter. All status interrupt requests can be masked. Status interrupt requests are signaled directly through a single SPI status IRQ line. The line cannot be combined with the SPI error IRQ line for some processors. The ***SPI Status Interrupts*** table describes the status interrupt requests that are available for the SPI controller.

Table 14-15: SPI Status Interrupts

SPI_STAT Bit	Description
SPI_STAT.RUWM	Receive FIFO urgent watermark interrupt request. Issued when the level of the RFIFO breaches the watermark set in the SPI_RXCTL.RUWM field. It is cleared when the level of the RFIFO reaches the watermark set in the SPI_RXCTL.RRWM field. If the RX channel is configured in DMA mode, SPI_RXCTL.RUWM is multiplexed with the data request.

Table 14-15: SPI Status Interrupts (Continued)

SPI_STAT Bit	Description
SPI_STAT.TUWM	Transmit FIFO urgent watermark interrupt request. Issued when the level of the TFIFO breaches the watermark set using the SPI_TXCTL.TUWM bit. It is cleared when the level of the TFIFO reaches the watermark set in the SPI_TXCTL.TRWM field. If the TX channel is configured in DMA mode, SPI_STAT.TUWM is multiplexed with the data request.
SPI_STAT.TS	Transmit start interrupt request. Issued when the start of a transmit burst is detected by loading of the SPI_TWC register with the contents of the SPI_TWCR register.
SPI_STAT.RS	Receive start interrupt request. Issued when the start of a receive burst is detected by the loading of SPI_RWC with the contents of SPI_RWCR.
SPI_STAT.TF	Transmit finish interrupt request. Issued when a transmit burst completes (SPI_TWC decrements to zero).
SPI_STAT.RF	Receive finish interrupt request. Issued when a receive burst completes (SPI_RWC decrements to zero).

Error Conditions

The SPI controller supports interrupt requests upon several different error conditions. All interrupt requests are maskable. The individual error indications combine into a single SPI error IRQ signal, which can be multiplexed on some processors with the aggregated SPI status IRQ signal. The ***SPI Error Interrupts*** table details the possible error indications.

Error conditions arise depending on which of the channels (transmit or receive) are enabled. If a channel is disabled, all errors related to it are ignored. When both channels are enabled, errors from both channels are enabled.

Table 14-16: SPI Error Interrupts

Bit	Description
SPI_STAT.MF	Mode fault. Signaled when another device also tries to be a master in a multi-master system and drives the SPI_SS input low. This error is signaled in master mode operation.
SPI_STAT.TUR	Transmission error. Signaled when an underflow condition occurs on the transmit channel. This event occurs when a new transfer starts but SPI_TFIFO is empty. This error does not occur in master transmit initiating mode since SPI_TFIFO *Not Empty* is one of the conditions for transfer initiation.
SPI_STAT.ROR	Reception error. Signaled when an overflow condition occurs on the receive channel. This event occurs when a new data word is received, but the SPI_RFIFO is full. This error condition does not occur in master receive initiating mode since SPI_RFIFO *Not Full* is one of the conditions for transfer initiation.
SPI_STAT.TC	Transmit collision error. Signaled when loading data to the transmit shift register happens near the first transmitting edge of SPI_CLK. In slave mode of operation, the SPI controller is unaware of when the next transfer starts. Loading of data to the transmit shift register can happen just after the transmitting edge. This event results in the setup time not being met for the first bit transmitted. The transmitted data is corrupt. In SPI_CTL.CPHA 1 mode, the first SPI_CLK edge is taken as the first transmitting edge. If SPI_CTL.CPHA =0, then the last SPI_CLK edge of the last transmission (SPI_CTL.SELST =1) or slave select deassertion (SPI_CTL.SELST =0) is taken as the first transmitting edge. This error is signaled only in the slave mode of operation. In master mode of operation, loading of data happens before the first transmitting edge of SPI_CLK.

SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

Programming Guidelines

It is acceptable to program SPI_RXCTL and SPI_TXCTL registers after programming the SPI_CTL register. However, program the initiating mode register and its counter-register, if enabled, after the non-initiating mode register. For example, if transmit is the initiating mode and receive is the non-initiating mode, then program the SPI_RXCTL and SPI_RWC registers before the SPI_TXCTL and SPI_TWC registers. If enabling both transmit and receive in initiating mode, enable the SPI_CTL register after programming both the SPI_RXCTL and SPI_TXCTL registers.

These programming guidelines prevent SPI from starting a transfer when SPI registers are not fully programmed. Other ways of programming are also allowed as long as the initiating conditions prevent the start of communication until after programming of SPI registers is complete.

Avoid data corruption when changing the SPI module configuration. Do not change the configuration during a data transfer. Additionally, change the clock polarity only when no slave is selected. However, an exception to this rule exists. When an SPI communication link consists of a single master and slave, SPI_CTL.ASSEL = 0. The slave select input of the slave is permanently tied low. In this case, the slave is always selected. Avoid data corruption by enabling the slave only after both the master and slave devices are configured.

The module supports 8, 16-bit and 32-bit word sizes. To ensure correct operation, configure both the master and slave with the same word size.

Master Operation in Non-DMA Modes

This section describes the operation of the SPI as a master in non-DMA mode.

1. Write to the SPI_SLVSEL register, setting one or more of the SPI select enable bits. This operation ensures that the desired slaves are properly deselected while the master is configured.
2. The SPI_RXCTL.RTI and SPI_TXCTL.TTI bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the SPI_CLK, SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. This operation enables the device as a master and configures the SPI system. It specifies the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

   ADDITIONAL INFORMATION: If SPI_RXCTL.RTI is enabled and SPI_TXCTL.TTI is not, write to the SPI_RXCTL register after writing into SPI_CTL, SPI_TXCTL, and SPI_TFIFO registers to prevent a transmit underrun for the first transfer.
4. If SPI_CTL.ASSEL=0, activate the desired slaves by clearing one or more of the SPI_SLVSEL flag bits. Otherwise, the SPI hardware performs slave activation.

5. The SPI controller then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. Before a shift, the shift register is loaded with the contents of the SPI_TFIFO register. At the end of the transfer, the contents of the shift register are loaded into SPI_RFIFO.
6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows usage of available channel resources for receives or transmits simultaneously with the initiating channel.

Slave Operation in Non-DMA Modes

When a device is enabled as a slave in a non-DMA mode, a transition of the $\overline{\text{SPI\_SS}}$ select signal to the active state (low) triggers the the start of a transfer. Or, the first active edge of SPI_CLK triggers the start, depending on the state of SPI_CTL.CPHA bit. The interface operates in the following manner.

1. The core writes to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. The operation defines the mode of the serial link to be the same as the mode setup in the SPI master.
2. To prepare for the data transfer, the core writes data to be transmitted into SPI_TFIFO.
3. Once the $\overline{\text{SPI\_SS}}$ falling edge is detected, the slave starts sending data on active SPI_CLK edges and sampling data on inactive SPI_CLK edges.
4. Reception or transmission continues until $\overline{\text{SPI\_SS}}$ is released or until the slave has received the proper number of clock cycles.
5. The slave device continues to receive or transmit with each new falling edge transition on $\overline{\text{SPI\_SS}}$ or active SPI_CLK edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.

Configuring DMA Master Mode

The SPI interface supports a write DMA channel and a read DMA channel. It can use these functions individually or in a lock-step manner in duplex mode (SPI_TXCTL.TTI= SPI_RXCTL.RTI=1).

1. Write to the appropriate DMA registers to enable the SPI DMA channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_SLVSEL register, setting one or more of the SPI flag select bits.
3. Write to the SPI_CLK and SPI_CTL registers, enabling the device as a master and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, and so forth.
4. Write to SPI_RXCTL to configure SPI master receive mode, or write to SPI_TXCTL to configure SPI master transmit mode.

5. Finally, write to the SPI_RXCTL.REN bit to enable the receive channel, or write to SPI_TXCTL.TEN to enable the transmit channel.
6. If the SPI_RXCTL.RTI bit is enabled, a receive transfer is initiated upon enabling SPI_CTL.EN bit. If the receive word counter is enabled (SPI_RXCTL.RWCEN), then the SPI_RWC register must be non-zero for a transfer to initiate.

   ADDITIONAL INFORMATION: If enabling both receive and transmit DMA channels, but not enabling SPI_TXCTL.TTI, write to the SPI_RXCTL register after writing the SPI_CTL and SPI_TXCTL registers. In this way, a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the receive shift register and writes to the SPI receive FIFO. The SPI then requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the SPI receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, when SPI_RWC does not become zero while SPI_RXCTL.RWCEN=1.
7. If SPI_TXCTL.TTI is enabled, the SPI controller requests DMA reads from memory as long as there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the SPI_TWC register is non-zero when SPI_TXCTL.TWCEN=1, the SPI continues to initiate transfers until disabled.
8. If both the SPI_TXCTL.TTI and SPI_RXCTL.RTI bits are enabled, the SPI controller requests a DMA read from memory. However, there must be space for more data in the transmit pipe and the number of words written into the SPI must be less than SPI_TWC if SPI_TXCTL.TWCEN=1. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

   ADDITIONAL INFORMATION: As the SPI writes data from the transmit FIFO into the transmit shift register, it initiates a transfer on the SPI link. Data received from the transfer is moved from the SPI receive shift register to the receive FIFO. The SPI controller requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory. Transfer continues to be initiated as long as both receives and transmits can accommodate new data.
9. If the receive pipe fills up due to unavailability of DMA grants, the transmit pipe stalls until the pipe is drained. If the transmit pipe fills up, the SPI stops requesting for DMA writes. If the value in SPI_RWC expires, further write-requests to DMA stop. However, data already written into the transmit FIFO is sent, and read requests to DMA continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. For receive transfers, the value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer. For transmit transfers, the value in the SPI_TFIFO register is loaded into the shift register at the start of the transfer.

Configuring DMA Slave Mode Operation

This mode occurs when the SPI is enabled as a slave and the DMA engine is configured to transmit or receive data. A transition of the SPI_SS signal to the active-low state triggers the start of a transfer. Or, the first active edge of SPI_CLK triggers the start of a transfer, depending on the state of the SPI_CTL.CPHA bit. The following steps

illustrate the SPI receive or transmit DMA sequence in an SPI slave (in response to a master command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers to define the mode of the serial link to be the same as the mode configured in the SPI master.
3. If the receive channel is enabled (SPI_RXCTL.REN is asserted), the following actions occur:
    a. Once the slave select input is active, the slave starts receiving and transmitting data on active SPI_CLK edges.
    b. The value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer.
    c. Once SPI_RFIFO has valid data, it requests a write from DMA to memory.
    d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
    e. As long as there is data in the receive FIFO, the SPI slave continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory. The SPI slave continues receiving words on active SPI_CLK edges as long as the SPI_SS input is active.
    f. If the data collected in the receive pipe breaches the set level, and the DMA engine cannot keep up with the receive rate, the slave can deassert the SPI_RDY signal. This signaling throttles the master. The receive pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the SPI can use the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten into the receive FIFO (when SPI_CTL.FCEN is inactive).
4. If the transmit channel is enabled (SPI_TXCTL.TEN is asserted), the following actions occur:
    a. The SPI requests a DMA read from memory.
    b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.
    c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.
    d. Once the slave select input is active, the slave starts receiving and transmitting data on active SPI_CLK edges.
    e. As long as there is room in the transmit FIFO, the SPI slave continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO. The SPI slave continues transmitting words on active SPI_CLK edges as long as the SPI_SS input is active.
    f. If the number of outstanding data entries in the transmit pipe breaches the level set and the DMA cannot keep up with the transmit rate, the slave deasserts the SPI_RDY signal. This signaling throttles the master. The transmit pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA fills the transmit FIFO. Alternately, the SPI_TXCTL.TDU bit decides the state of the transmit data (when SPI_CTL.FCEN is deasserted).

5. If both receive and transmit channels are enabled, the following actions occur after the actions for each channel. Transfers continue as long as both receive and transmit channels can accommodate new data.
    a. If the receive pipe fills up due to the unavailability of DMA grant, the SPI interface stalls the master by asserting the SPI_RDY pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI uses the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten in the receive FIFO (when SPI_CTL.FCEN is deasserted).
    b. If the transmit pipe fills up, the SPI stops requesting DMA writes until the pipe clears.
    c. If there is an underflow problem in the transmit pipe, the slave stalls the master by deasserting SPI_RDY while the DMA fills the transmit FIFO. Alternately, the SPI uses the SPI_TXCTL.TDU bit to decide the state of the transmit data (when SPI_CTL.FCEN is deasserted).

ADSP-SC57x SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

Table 14-17: ADSP-SC57x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header (Only on SPI2)
SPI_MMTOP	SPI Memory Top Address (Only on SPI2)
SPI_RFIFO	Receive FIFO Data Register
SPI_RWC	Received Word Count Register
SPI_RWCR	Received Word Count Reload Register
SPI_RXCTL	Receive Control Register
SPI_SLVSEL	Slave Select Register
SPI_STAT	Status Register
SPI_TFIFO	Transmit FIFO Data Register
SPI_TWC	Transmitted Word Count Register

Table 14-17: ADSP-SC57x SPI Register List (Continued)

Name	Description
SPI_TWCR	Transmitted Word Count Reload Register
SPI_TXCTL	Transmit Control Register

Clock Rate Register

The SPI_CLK register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SPI clock) and the system clock (SCLK).

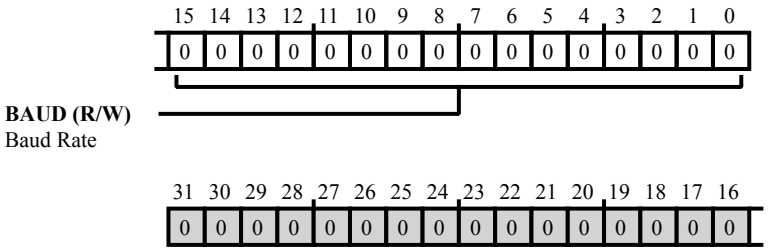

Figure 14-19: SPI_CLK Register Diagram

Table 14-18: SPI_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	BAUD	Baud Rate. The SPI_CLK.BAUD bits set the SPI baud rate according to the formula: BAUD = (SCLK / SPI Clock) - 1

Control Register

The SPI_CTL register enables the SPI and configures settings for operating modes, communication protocols, and buffer operations.

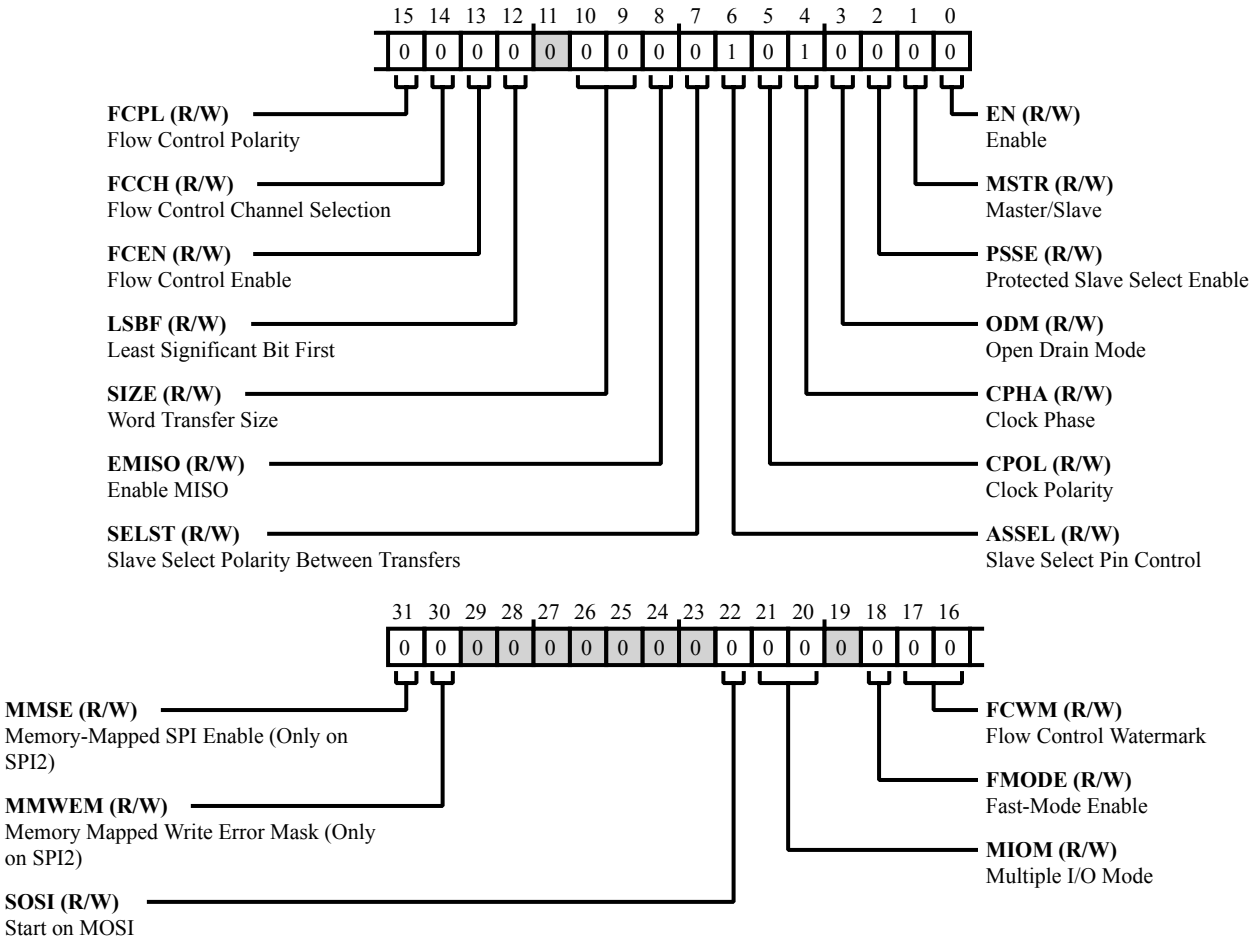

Figure 14-20: SPI_CTL Register Diagram

Table 14-19: SPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MMSE	Memory-Mapped SPI Enable (Only on SPI2). When the SPI_CTL.MMSE bit is asserted, communication to an SPI memory device is automated such that the memory it contains is accessible directly through the read of processor address space assigned to it. (As far as the SPI peripheral is concerned, this includes all read accesses received by the SPI peripherals system crossbar slave port.) Note that when memory-mapped access of SPI memory is enabled, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses are generated. Legacy methods include any direct access made to the Tx and Rx FIFOs, whether initiated by DMA or processor MMR access.	
		0	Hardware automated access of memory-mapped SPI memory disabled.
		1	Hardware-automated access of memory-mapped SPI memory enabled.
30 (R/W)	MMWEM	Memory Mapped Write Error Mask (Only on SPI2). The SPI_CTL.MMWEM bit specifies whether an error response is returned to the fabric upon write attempts to address space reserved for memory-mapped reads of SPI memory.	
		0	Write error response returned upon write attempts to memory-mapped SPI memory
		1	Write error response masked (not returned) upon write attempts to memory-mapped SPI memory
22 (R/W)	SOSI	Start on MOSI. The SPI_CTL.SOSI bit is valid only when SPI_CTL.MIOM is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes. In DIOM, by default, (SPI_CTL.SOSI =0) SPI sends the first bit on the SPI_MISO pin and the second bit on the SPI_MOSI pin. In QIOM, by default, the SPI sends the first bit on the SPI_D3 pin, the second bit on the SPI_D2 pin, the third bit on the SPI_MISO pin and the fourth bit on the SPI_MOSI pin. This order can be reversed by setting the SPI_CTL.SOSI bit. When this bit is set, the SPI sends the first bit on the SPI_MOSI pin. The first bit referred to here depends on the SPI_CTL.LSBF bit setting (MSB bit or LSB bit).	
		0	Start on MISO (DIOM) or start on SPI_D3
		1	Start on MOSI

Table 14-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	MIOM	Multiple I/O Mode. The SPI_CTL.MIOM bits enable SPI operation in dual I/O mode (DIOM) or quad I/O mode (QIOM). These bits can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	No MIOM (disabled)
		1	DIOM operation
		2	QIOM operation
		3	Reserved
18 (R/W)	FMODE	Fast-Mode Enable. The SPI_CTL.FMODE bit enables fast mode operation for SPI receive transfers. SPI transmit operations in fast mode are the same as normal mode.	
		0	Disable
		1	Enable
17:16 (R/W)	FCWM	Flow Control Watermark. The SPI_CTL.FCWM bits select the watermark level of the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer) that triggers flow control operation. These bits are applicable only when the SPI is a slave (SPI_CTL.MSTR = 0) and flow control is enabled (SPI_CTL.FCEN =1). When the watermark condition is met, the SPI slave deasserts the SPI_RDY pin.	
		0	TFIFO empty or RFIFO full
		1	TFIFO 75% or more empty, or RFIFO 75% or more full
		2	TFIFO 50% or more empty, or RFIFO 50% or more full
		3	Reserved
15 (R/W)	FCPL	Flow Control Polarity. The SPI_CTL.FCPL bit selects flow control polarity for the SPI_RDY pin when flow control is enabled. When the SPI_RDY pin is active, the SPI is indicating it is ready for data transfer.	
		0	Active-low RDY
		1	Active-high RDY

Table 14-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	FCCH	Flow Control Channel Selection. The SPI_CTL.FCCH bit selects whether the SPI applies flow control to the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer). This bit is applicable only when the SPI is a slave and flow control is enabled.	
		0	Flow control on RX buffer
		1	Flow control on TX buffer
13 (R/W)	FCEN	Flow Control Enable. The SPI_CTL.FCEN bit enables SPI flow control operation, which permits slow slave devices to interface with fast master devices. This bit controls the operation of the SPI_RDY pin. Note that options for flow control operation are available using the SPI_CTL.FCCH, SPI_CTL.FCPL, and SPI_CTL.FCWM bits.	
		0	Disable
		1	Enable
12 (R/W)	LSBF	Least Significant Bit First. The SPI_CTL.LSBF bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit can only be changed when the SPI is disabled.	
		0	MSB sent/received first (big endian)
		1	LSB sent/received first (little endian)
10:9 (R/W)	SIZE	Word Transfer Size. The SPI_CTL.SIZE bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the master and slave must be configured with the same word size. This bit can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	8-bit word
		1	16-bit word
		2	32-bit word
		3	Reserved
8 (R/W)	EMISO	Enable MISO. The SPI_CTL.EMISO bit enables master-in-slave-out (MISO) mode. This SPI mode is applicable only when the SPI is a slave.	
		0	Disable
		1	Enable

Table 14-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SELST	Slave Select Polarity Between Transfers. The SPI_CTL.SELST bit selects the state (polarity) for the $\overline{\text{SPI\_SEL[n]}}$ pin between SPI transfers when the SPI is a master and hardware slave select assertion is enabled (SPI_CTL.ASSEL =1). In slave mode, this bit affects the detection of both transmit collision (SPI_STAT.TC and underrun (SPI_STAT.TUR) errors.	
		0	Deassert slave select (high)
		1	Assert slave select (low)
6 (R/W)	ASSEL	Slave Select Pin Control. The SPI_CTL.ASSEL bit selects whether the SPI hardware sets the $\overline{\text{SPI\_SEL[n]}}$ pin output value (ignoring the slave select SPI_SLVSEL.SSEL1 - SPI_SLVSEL.SSEL7 bits) or whether software control of the slave select bits set the $\overline{\text{SPI\_SEL[n]}}$ pin output value. This feature is applicable only when the SPI is a master. When hardware control is enabled, the $\overline{\text{SPI\_SEL[n]}}$ pin output is asserted during the transfers, and the pin polarity between transfers is selected by the SPI_CTL.SELST bit. When software control is enabled, the $\overline{\text{SPI\_SEL[n]}}$ pin output value is set through software control of the slave select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers.	
		0	Software slave select control
		1	Hardware slave select control
5 (R/W)	CPOL	Clock Polarity. The SPI_CTL.CPOL bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (SPI_CLK). This bit works with the SPI_CTL.CPHA bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	Active-high SPI CLK
		1	Active-low SPI CLK
4 (R/W)	CPHA	Clock Phase. The SPI_CTL.CPHA bit selects whether the SPI starts toggling the signal for the SPI clock (SPI_CLK) from the start of the first data bit or from the middle of the first data bit. The SPI_CTL.CPHA bit works with the SPI_CTL.CPOL bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	SPI CLK toggles from middle
		1	SPI CLK toggles from start

Table 14-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ODM	Open Drain Mode. The SPI_CTL.ODM bit configures the data output pins (SPI_MOSI and SPI_MISO) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-master or multi-slave SPI systems. When SPI_CTL.ODM is enabled and the SPI is a master, the SPI three-states the SPI_MOSI pin when the data driven out on MOSI is a logic-high. The SPI does not three-state the SPI_MOSI pin when the driven data is a logic-low. When SPI_CTL.ODM is enabled and the SPI is a slave, the SPI three-states the SPI_MISO pin when the data driven out on SPI_MISO is a logic-high. Note that an external pull-up resistor is required on both the SPI_MOSI and SPI_MISO pins when SPI_CTL.ODM is enabled.	
		0	Disable
		1	Enable
2 (R/W)	PSSE	Protected Slave Select Enable. The SPI_CTL.PSSE bit enables the $\overline{\text{SPI\_SS}}$ pin to provide error detection input in a multi-master environment when the SPI is in master mode. If some other device in the system asserts the $\overline{\text{SPI\_SS}}$ pin while SPI is enabled as master (and SPI_CTL.PSSE is enabled), this condition causes a mode fault error.	
		0	Disable
		1	Enable
1 (R/W)	MSTR	Master/Slave. The SPI_CTL.MSTR bit toggles the SPI between master mode and slave mode. This bit can only be changed when the SPI is disabled.	
		0	Slave
		1	Master
0 (R/W)	EN	Enable. The SPI_CTL.EN bit enables SPI operation.	
		0	Disable SPI module
		1	Enable

Delay Register

The SPI_DLY register selects a transfer delay and the lead/lag timing between slave select signals and SPI clock edge assertion/deassertion.

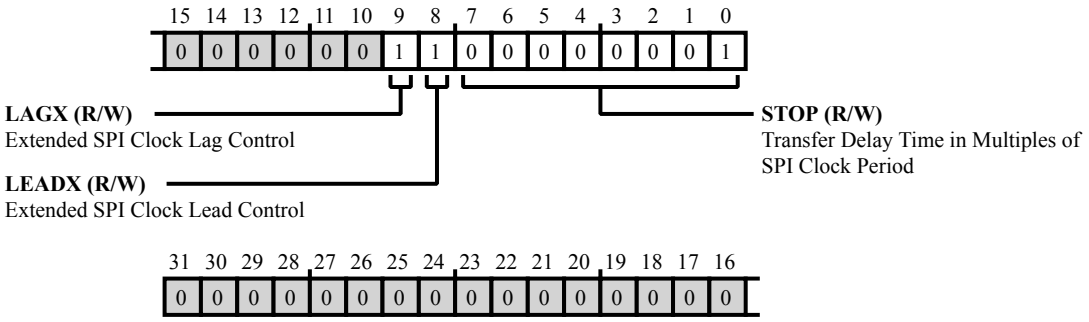

Figure 14-21: SPI_DLY Register Diagram

Table 14-20: SPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	LAGX	Extended SPI Clock Lag Control. The SPI_DLY.LAGX bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the slave select (SPI_SEL[n]) assertion and first SPI clock edge.	
		0	Disable
		1	Enable
8 (R/W)	LEADX	Extended SPI Clock Lead Control. The SPI_DLY.LEADX bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the slave select (SPI_SEL[n]) deassertion and last SPI clock edge.	
		0	Disable
		1	Enable
7:0 (R/W)	STOP	Transfer Delay Time in Multiples of SPI Clock Period. The SPI_DLY.STOP bits select a delay (number of stop bits in multiples of SPI clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The SPI_DLY.STOP bits can be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0).	

Masked Interrupt Condition Register

The SPI_ILAT register latches interrupts, queuing the interrupt requests for service. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in SPI_ILAT.

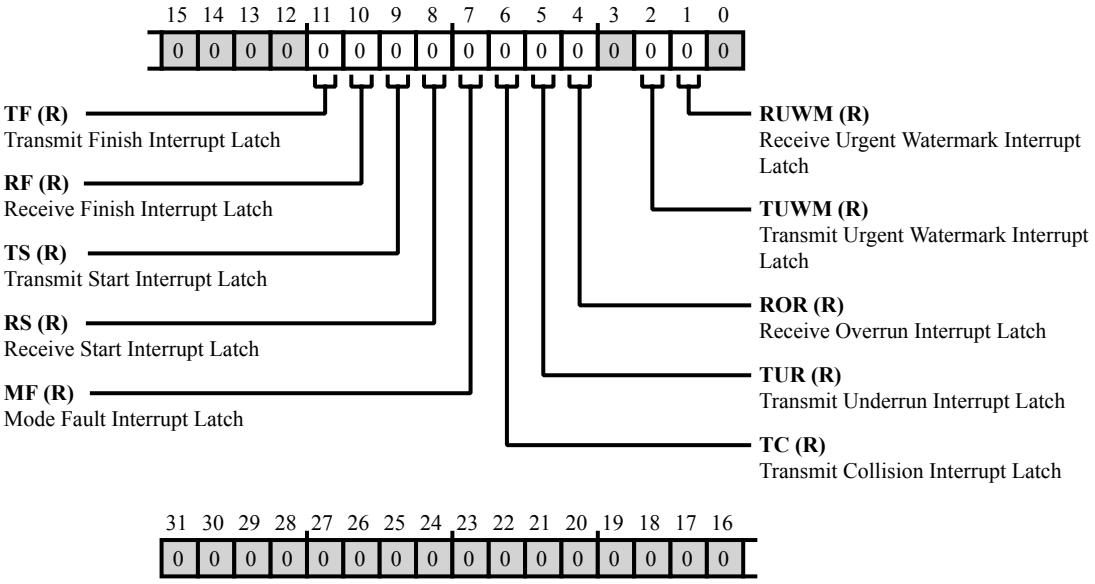

Figure 14-22: SPI_ILAT Register Diagram

Table 14-21: SPI_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
10 (R/NW)	RF	Receive Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
9 (R/NW)	TS	Transmit Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
8 (R/NW)	RS	Receive Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Table 14-21: SPI_ILAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	MF	Mode Fault Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
6 (R/NW)	TC	Transmit Collision Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
5 (R/NW)	TUR	Transmit Underrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
4 (R/NW)	ROR	Receive Overrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Masked Interrupt Clear Register

The SPI_ILAT_CLR register permits clearing individual mask bits in the SPI_ILAT register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_ILAT_CLR register to clear the corresponding bit in the SPI_ILAT register.

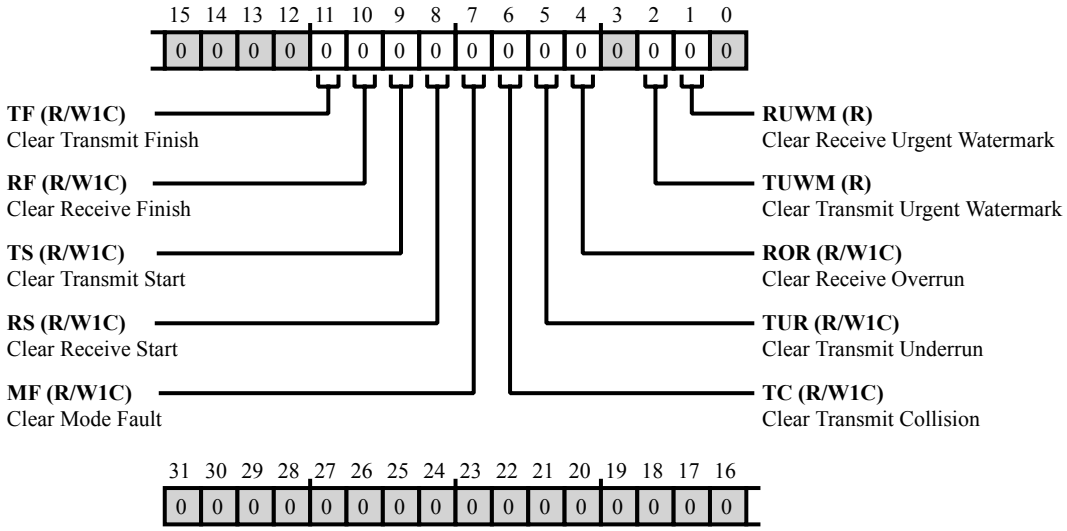

Figure 14-23: SPI_ILAT_CLR Register Diagram

Table 14-22: SPI_ILAT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_ILAT_CLR.TF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_ILAT_CLR.RF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_ILAT_CLR.TS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 14-22: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_ILAT_CLR.RS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_ILAT_CLR.MF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_ILAT_CLR.TC bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_ILAT_CLR.TUR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_ILAT_CLR.ROR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
2 (R/NW)	TUWM	Clear Transmit Urgent Watermark. The SPI_ILAT_CLR.TUWM bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 14-22: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	RUWM	Clear Receive Urgent Watermark. The `SPI_ILAT_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_ILAT` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Register

The SPI_IMSK register unmasks (enables) or masks (disables) SPI interrupt requests. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in the SPI_ILAT register, queuing the interrupt request for service.

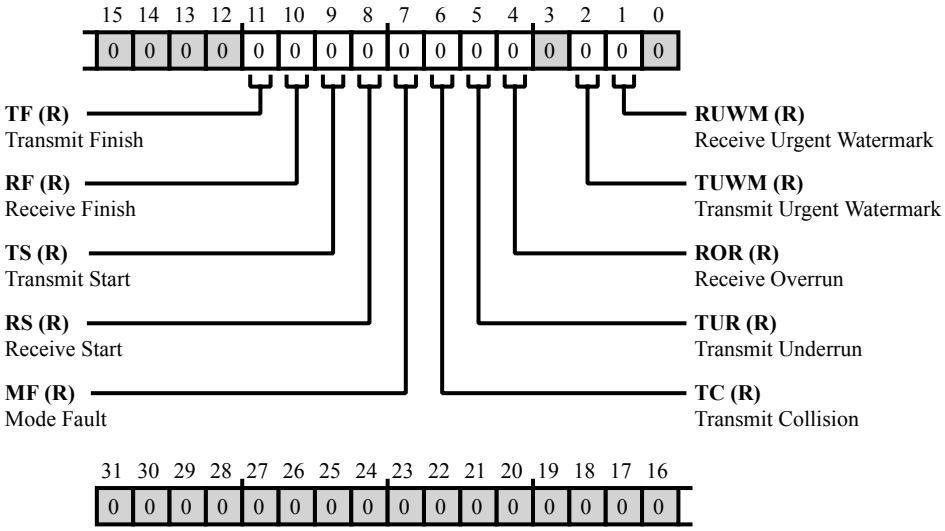

Figure 14-24: SPI_IMSK Register Diagram

Table 14-23: SPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish. The SPI_IMSK.TF bit unmasks (enables) or masks (disables) the TF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
10 (R/NW)	RF	Receive Finish. The SPI_IMSK.RF bit unmasks (enables) or masks (disables) the RF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
9 (R/NW)	TS	Transmit Start. The SPI_IMSK.TS bit unmasks (enables) or masks (disables) the TS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Table 14-23: SPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	RS	Receive Start. The SPI_IMSK.RS bit unmasks (enables) or masks (disables) the RS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
7 (R/NW)	MF	Mode Fault. The SPI_IMSK.MF bit unmasks (enables) or masks (disables) the MF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
6 (R/NW)	TC	Transmit Collision. The SPI_IMSK.TC bit unmasks (enables) or masks (disables) the TC interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
5 (R/NW)	TUR	Transmit Underrun. The SPI_IMSK.TUR bit unmasks (enables) or masks (disables) the TUR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
4 (R/NW)	ROR	Receive Overrun. The SPI_IMSK.ROR bit unmasks (enables) or masks (disables) the ROR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark. The SPI_IMSK.TUWM bit unmasks (enables) or masks (disables) the TUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark. The SPI_IMSK.RUWM bit unmasks (enables) or masks (disables) the RUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Interrupt Mask Clear Register

The SPI_IMSK_CLR register permits clearing individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_IMSK_CLR register to clear the corresponding bit in the SPI_IMSK register.

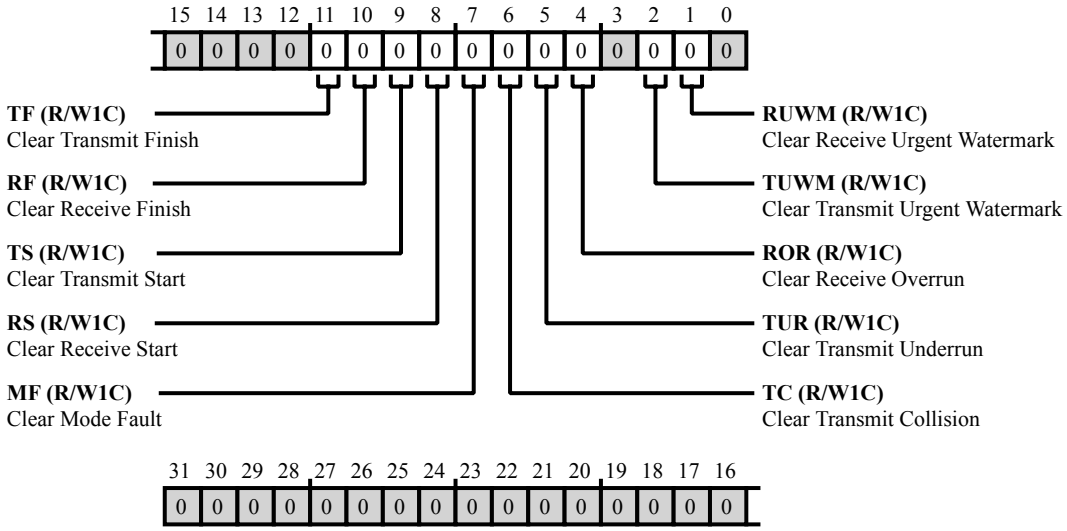

Figure 14-25: SPI_IMSK_CLR Register Diagram

Table 14-24: SPI_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_IMSK_CLR.TF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_IMSK_CLR.RF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_IMSK_CLR.TS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 14-24: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_IMSK_CLR.RS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_IMSK_CLR.MF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_IMSK_CLR.TC bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_IMSK_CLR.TUR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_IMSK_CLR.ROR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
2 (R/W1C)	TUWM	Clear Transmit Urgent Watermark. The SPI_IMSK_CLR.TUWM bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 14-24: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RUWM	Clear Receive Urgent Watermark. The `SPI_IMSK_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Set Register

The SPI_IMSK_SET register permits setting individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-set on a bit in the SPI_IMSK_SET register to set the corresponding bit in the SPI_IMSK register.

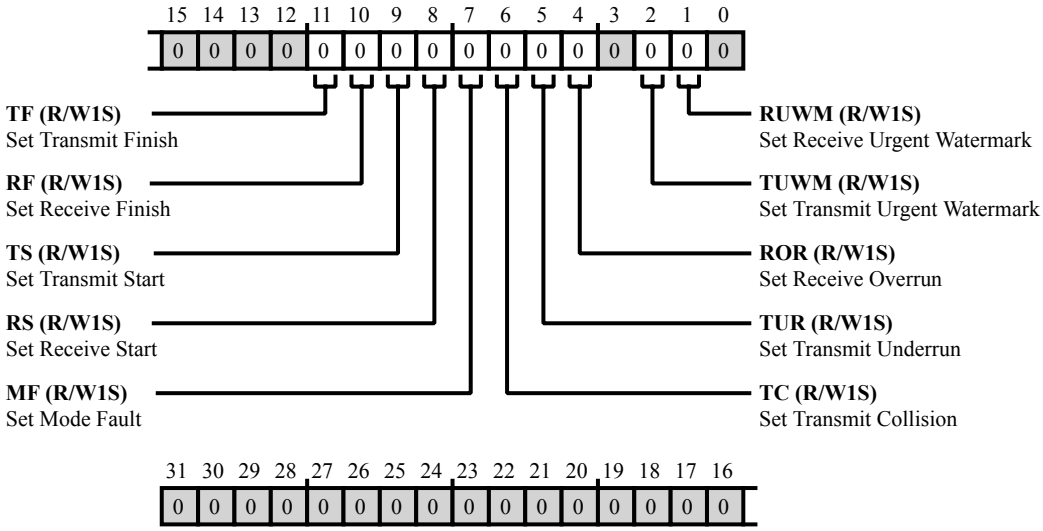

Figure 14-26: SPI_IMSK_SET Register Diagram

Table 14-25: SPI_IMSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1S)	TF	Set Transmit Finish. The SPI_IMSK_SET.TF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
10 (R/W1S)	RF	Set Receive Finish. The SPI_IMSK_SET.RF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
9 (R/W1S)	TS	Set Transmit Start. The SPI_IMSK_SET.TS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 14-25: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1S)	RS	Set Receive Start. The `SPI_IMSK_SET.RS` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit
7 (R/W1S)	MF	Set Mode Fault. The `SPI_IMSK_SET.MF` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit
6 (R/W1S)	TC	Set Transmit Collision. The `SPI_IMSK_SET.TC` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit
5 (R/W1S)	TUR	Set Transmit Underrun. The `SPI_IMSK_SET.TUR` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit
4 (R/W1S)	ROR	Set Receive Overrun. The `SPI_IMSK_SET.ROR` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit
2 (R/W1S)	TUWM	Set Transmit Urgent Watermark. The `SPI_IMSK_SET.TUWM` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit

Table 14-25: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	RUWM	Set Receive Urgent Watermark. The `SPI_IMSK_SET.RUWM` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit

Memory Mapped Read Header (Only on SPI2)

The SPI_MMRDH register enables the use of memory-mapped mode. This mode allows direct memory-mapped read accesses of an SPI memory device and is primarily used to directly execute instructions from an SPI FLASH memory without using a low-level software driver. All overhead tasks such as transmission of the read header, pin turnaround timing and receive data sizing are handled in hardware.

The memory-mapped access mode is enabled by setting the SPI_CTL.MMSE bit. The features within the SPI_MMRDH register include a command skip mode, variable length byte addressing, and independent multi-pin support for command transmission, address transmission and data reception. In addition, the command opcode and mode bytes are fully programmable.

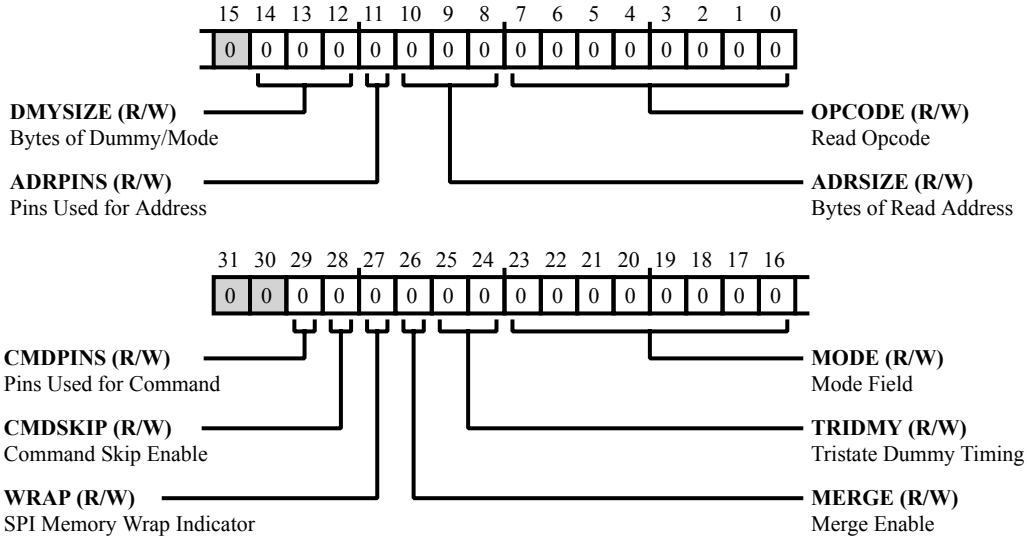

Figure 14-27: SPI_MMRDH Register Diagram

Table 14-26: SPI_MMRDH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CMDPINS	Pins Used for Command. The SPI_MMRDH.CMDPINS bit specifies the number of pins to be used for command transmission. This bit must be set consistent with the expectations established by the read opcode. Hardware does not interpret SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior. When cleared, it overrides the SPI_CTL.MIOM bits. When set, it uses bits specified by the SPI_CTL.MIOM bit setting.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits

Table 14-26: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMDSKIP	Command Skip Enable. The SPI_MMRDH.CMDSKIP bit enables command skip mode where the address is sent first and the OPCODE field is not sent (SPI_MMRDH.CMDSKIP bit =1). This mode is useful for supporting XIP (Execute-In-Place) operation where only the address is sent and the same read command is assumed. The SPI flash device must be primed with an initial read command, before the SPI_MMRDH.CMDSKIP bit is set.	
		0	OPCODE field is sent first followed by address
		1	OPCODE field is not sent; address is sent first
27 (R/W)	WRAP	SPI Memory Wrap Indicator. The SPI_MMRDH.WRAP bit must be set by software if software places a connected SPI memory device into a 8-byte, 16-byte or 32-byte wrap mode based on the ILINE and DLINE field setting of the cache configuration register address wrap mode. Software achieves this by transmitting a vendor specified command to the SPI memory device while the SPI_CTL.MMSE bit =0. If the SPI_MMRDH.WRAP bit =1, the SPI does not need to deassert the SPI slave select signal and resend the read header in order to wrap to the cache line base when servicing misaligned cache fill requests. Although this improves cache fill efficiency, it requires that the SPI deassert the SPI slave select pin and resend the read header whenever a DMA burst requests crosses 32 byte alignments. Setting this bit improves cache throughput but decreases DMA throughput.	
		0	SPI Memory auto increments address purely sequentially
		1	SPI Memory auto increments address but wraps within 32 Byte lines
26 (R/W)	MERGE	Merge Enable. When the SPI_MMRDH.MERGE bit is set, SPI hardware combines the two successive transfers. This increases the throughput rate when accessing a large number of sequential memory locations. For more information refer to the Merged Read Accesses section.	

Table 14-26: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRIDMY	Tristate Dummy Timing. The SPI_MMRDH.TRIDMY bits specify whether and when output pins are three-stated during the interval of time specified by the SPI_MMRDH.DMYSIZE bits. Output pins potentially three-stated include all pins which were used to transmit the address	
		0	Tristate outputs immediately
		1	Tristate outputs after 4 bits of dummy/mode are transmitted
		2	Tristate outputs after 8 bits of dummy/mode are transmitted
		3	Never tristate outputs (previously specified output state is held)
23:16 (R/W)	MODE	Mode Field. These bits specify up to a leading byte to be transmitted during the interval of time specified by the SPI_MMRDH.DMYSIZE bit field. This first byte, or a portion of it, is interpreted as mode bits when certain opcodes are used in conjunction with certain SPI memory devices. Mode bits are sent using the same number of pins which were used to transmit the address. Once sent, output pins will be held in their final resultant state until the conclusion of all dummy byte periods, unless three-stating the outputs is specified first by the SPI_MMRDH.TRIDMY bits.	
14:12 (R/W)	DMYSIZE	Bytes of Dummy/Mode. The SPI_MMRDH.DMYSIZE bit field specifies the number of bytes separating address transmission and read data return. Dummy bytes elapse assuming dummy bits are transmitted using the same number of pins which were used to transmit address.	
		0	0 Bytes
		1	1 Bytes
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
		5	5 Bytes
		6	6 Bytes
		7	7 Bytes

Table 14-26: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ADRPINS	Pins Used for Address. The SPI_MMRDH.ADRPINS bit specifies the number of pins to be used for address transmission. This bit must be set consistent with expectations established by read opcode. Hardware does not interpret the SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits
10:8 (R/W)	ADRSIZE	Bytes of Read Address. The SPI_MMRDH.ADRSIZE bit field defines the number of bytes used to specify the read address. The read address is sent immediately following the transmission of opcode. Unlike opcode bits, address bits may be sent using either one or multiple pins. The number of pins is selected using the SPI_MMRDH.ADRPINS bit. The address sent to a connected SPI memory device is an echo of the read address received by the SPI peripheral slave port. The least significant bytes of address are sent when the entire address is not sent.	
		0	1 Byte
		1	1 Byte
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
7:0 (R/W)	OPCODE	Read Opcode. The SPI_MMRDH.OPCODE bit field specifies the initial bits transmitted in response to a read request of SPI memory. Although any opcode may be sent, values 0x03, 0x0B, 0x3B, 0x6B, 0xBB, and 0xEB are likely to be the most commonly used. SPI_MMRDH.OPCODE is sent by the SPI without interpretation; the states of these bits have no effect beyond specifying what is initially shifted across the SPI interface.	

SPI Memory Top Address (Only on SPI2)

The SPI_MMTOP register specifies the top populated address of a connected SPI memory device.

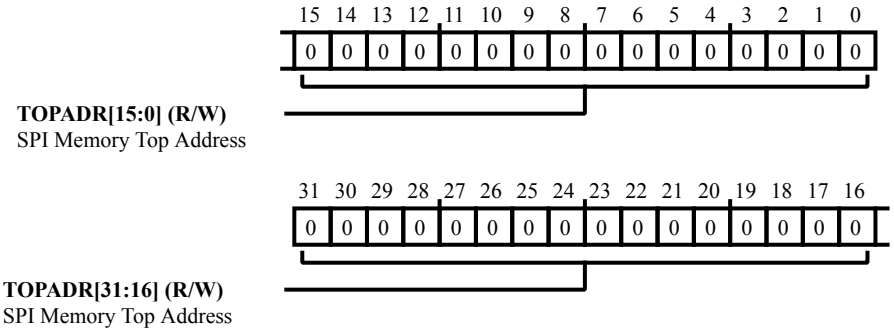

Figure 14-28: SPI_MMTOP Register Diagram

Table 14-27: SPI_MMTOP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TOPADR	SPI Memory Top Address. The SPI_MMTOP.TOPADR bit field specifies the top populated address of a connected SPI memory device. Attempts to access SPI memory are not blocked if this address is exceeded and an error is generated as part of the read response.

Receive FIFO Data Register

The SPI_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI master stops initiating new transfers on the SPI if SPI_RXCTL.RTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI_RFIFO is full, the data in the receive FIFO is invalid. The SPI indicates this condition with receive overrun (SPI_STAT.ROR) error. This condition is possible when SPI_RXCTL.RTI =0 and SPI_RXCTL.REN =1 for a master, or for a slave that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

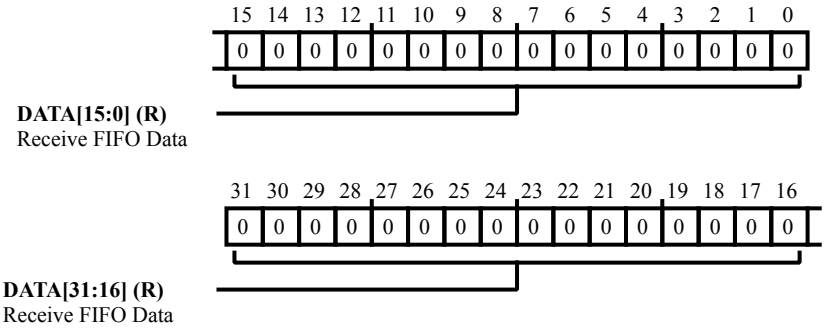

Figure 14-29: SPI_RFIFO Register Diagram

Table 14-28: SPI_RFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Receive FIFO Data. The SPI_RFIFO.DATA bit field contains the FIFO receive data.

Received Word Count Register

The SPI_RWC register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in SPI_RWC, enable the receive word counter (SPI_RXCTL.RWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (SPI_ILAT.RF). In DMA mode, the SPI uses the SPI_RWC register to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_RWC registers should match the word count in the DMA configuration. The SPI_RWC register maintains the number of frames to be received in a transfer. The SPI_RWC should only be changed when the counter is disabled.

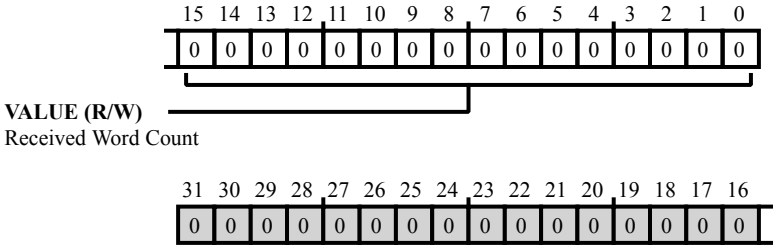

Figure 14-30: SPI_RWC Register Diagram

Table 14-29: SPI_RWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count. The SPI_RWC.VALUE bits hold the receive transfer word count.

Received Word Count Reload Register

The SPI_RWCR register holds the receive word count value that the SPI loads into the SPI_RWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_RWCR register should only be changed when the counter is disabled.

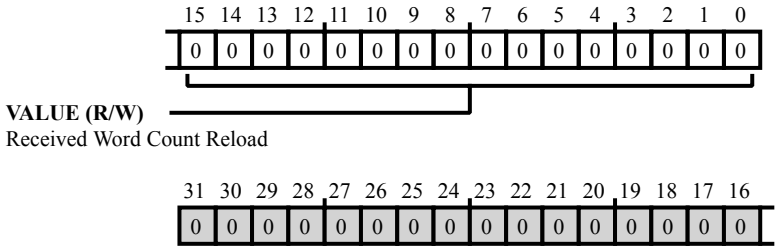

Figure 14-31: SPI_RWCR Register Diagram

Table 14-30: SPI_RWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count Reload. The SPI_RWCR.VALUE bits hold the receive transfer word count reload value.

Receive Control Register

The SPI_RXCTL register enables the SPI receive channel, initiates receive transfers, and configures SPI_RFIFO buffer watermark settings.

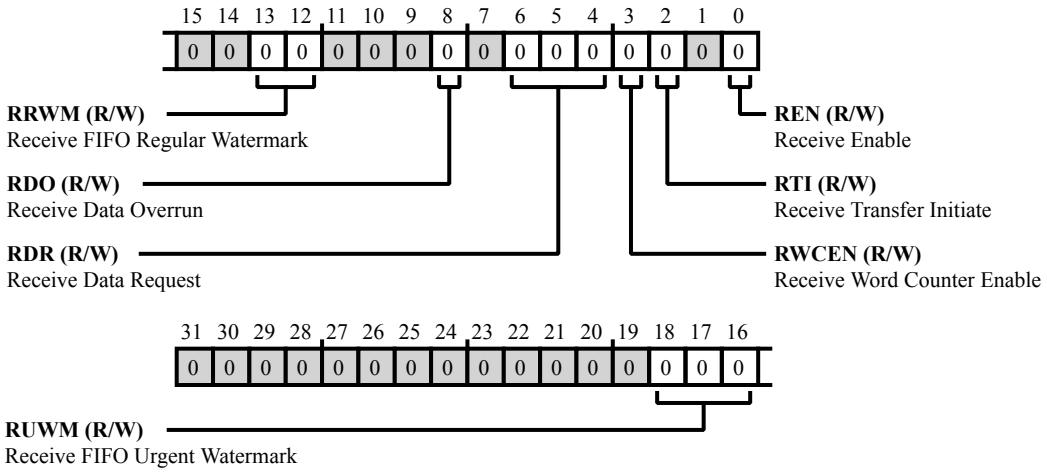

Figure 14-32: SPI_RXCTL Register Diagram

Table 14-31: SPI_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RUWM	Receive FIFO Urgent Watermark. The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Disabled
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
		5	Reserved
		6	Reserved
		7	Reserved

Table 14-31: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	RRWM	Receive FIFO Regular Watermark. The SPI_RXCTL.RRWM bits select the receive FIFO (SPI_RFIFO) watermark level for regular data bus requests. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Empty RFIFO
		1	RFIFO less than 25% full
		2	RFIFO less than 50% full
		3	RFIFO less than 75% full
8 (R/W)	RDO	Receive Data Overrun. The SPI_RXCTL.RDO bit selects handling for receive data requests when the receive buffer (SPI_RFIFO) is full. If enabled and SPI_RFIFO is full, the SPI overwrites old data in the buffer with incoming data. If disabled and SPI_RFIFO is full, the SPI keeps old data in the buffer and discards incoming data.	
		0	Discard incoming data if SPI_RFIFO is full
		1	Overwrite old data if SPI_RFIFO is full
6:4 (R/W)	RDR	Receive Data Request. The SPI_RXCTL.RDR bits select receive FIFO (SPI_RFIFO) watermark conditions that direct the SPI to generate a receive data request.	
		0	Disabled
		1	Not empty RFIFO
		2	25% full RFIFO
		3	50% full RFIFO
		4	75% full RFIFO
		5	Full RFIFO
		6	Reserved
		7	Reserved
3 (R/W)	RWCEN	Receive Word Counter Enable. The SPI_RXCTL.RWCEN bit enables the decrement of the SPI_RWC register when the count is not zero and SPI_RXCTL.RTI is enabled. Enabling SPI_RXCTL.RWCEN prevents receive overrun errors from occurring. The SPI_RXCTL.RWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 14-31: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RTI	Receive Transfer Initiate. The SPI_RXCTL.RTI bit enables initiation of receive transfers if the receive FIFO (SPI_RFIFO) is not full. The bit also enables this initiation if SPI_RWC is not zero when SPI_RXCTL.RWCEN is enabled. Enabling SPI_RXCTL.RTI prevents receive overrun errors from occurring. The SPI_RXCTL.RTI bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	REN	Receive Enable. The SPI_RXCTL.REN bit enables SPI receive channel operation.	
		0	Disable
		1	Enable

Slave Select Register

The SPI_SLVSEL register enables the SPI_SEL[n] pins for output and indicates the state (high or low) of these pins when enabled.

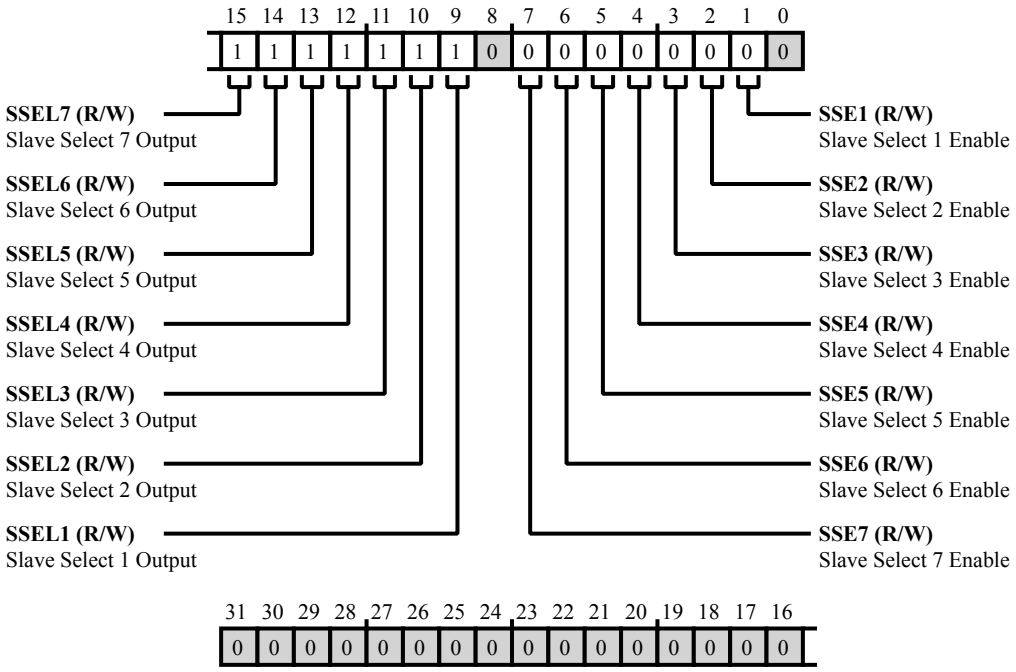

Figure 14-33: SPI_SLVSEL Register Diagram

Table 14-32: SPI_SLVSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SSEL7	Slave Select 7 Output. The SPI_SLVSEL.SSEL7 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
14 (R/W)	SSEL6	Slave Select 6 Output. The SPI_SLVSEL.SSEL6 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High

Table 14-32: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	SSEL5	Slave Select 5 Output. The SPI_SLVSEL.SSEL5 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
12 (R/W)	SSEL4	Slave Select 4 Output. The SPI_SLVSEL.SSEL4 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
11 (R/W)	SSEL3	Slave Select 3 Output. The SPI_SLVSEL.SSEL3 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
10 (R/W)	SSEL2	Slave Select 2 Output. The SPI_SLVSEL.SSEL2 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
9 (R/W)	SSEL1	Slave Select 1 Output. The SPI_SLVSEL.SSEL1 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
7 (R/W)	SSE7	Slave Select 7 Enable. The SPI_SLVSEL.SSE7 bit enables the related SPI_SEL[n] pin for output. If disabled, the SPI three-states the related SPI_SEL[n] pin.	
		0	Disable
		1	Enable

Table 14-32: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SSE6	Slave Select 6 Enable. The SPI_SLVSEL.SSE6 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
5 (R/W)	SSE5	Slave Select 5 Enable. The SPI_SLVSEL.SSE5 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
4 (R/W)	SSE4	Slave Select 4 Enable. The SPI_SLVSEL.SSE4 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
3 (R/W)	SSE3	Slave Select 3 Enable. The SPI_SLVSEL.SSE3 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
2 (R/W)	SSE2	Slave Select 2 Enable. The SPI_SLVSEL.SSE2 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
1 (R/W)	SSE1	Slave Select 1 Enable. The SPI_SLVSEL.SSE1 bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable

Status Register

The SPI_STAT register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the SPI_IMSK register, the interrupt request is latched into the corresponding bit in the SPI_ILAT register.

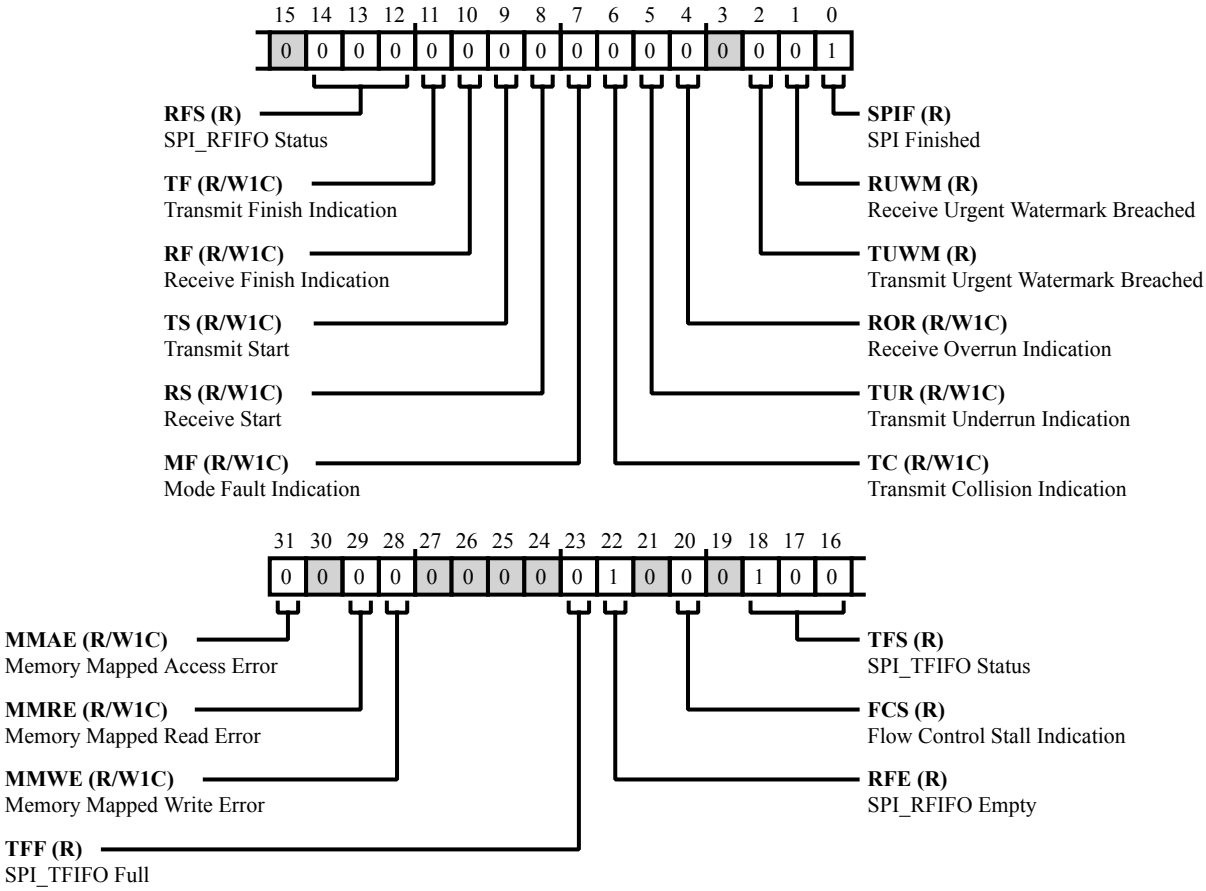

Figure 14-34: SPI_STAT Register Diagram

Table 14-33: SPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MMAE	Memory Mapped Access Error. The SPI_STAT.MMAE bit =1 if an attempt is made to access either the Tx or Rx FIFO while memory-mapped access of SPI memory is enabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMAE bit =0 when a 1 is written to it. The SPI_STAT.MMAE bit is provided for software notification only. Its state has no further effect.

Table 14-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W1C)	MMRE	Memory Mapped Read Error. The SPI_STAT.MMRE bit =1 if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMRE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
28 (R/W1C)	MMWE	Memory Mapped Write Error. The SPI_STAT.MMWE bit =1 if an attempt is made to write address space reserved for memory-mapped SPI memory. The SPI_STAT.MMWE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
23 (R/NW)	TFF	SPI_TFIFO Full. The SPI_STAT.TFF bit indicates whether the SPI_TFIFO is full or not full.	
		0	Not full Tx FIFO
		1	Full Tx FIFO
22 (R/NW)	RFE	SPI_RFIFO Empty. The SPI_STAT.RFE bit indicates whether the SPI_RFIFO is empty or not empty.	
		0	Rx FIFO not empty
		1	Rx FIFO empty
20 (R/NW)	FCS	Flow Control Stall Indication. The SPI_STAT.FCS bit indicates whether a slave has deasserted the SPI_RDY pin to stall the SPI master while the slave is unable to service the SPI masters request. This bit is valid only when the SPI is a master (SPI_CTL.MSTR =1) and flow control is enabled (SPI_CTL.FCEN =1).	
		0	No Stall (RDY pin asserted)
		1	Stall (RDY pin deasserted)
18:16 (R/NW)	TFS	SPI_TFIFO Status. The SPI_STAT.TFS bits indicate the status of the SPI_TFIFO. The SPI uses this status when evaluating transmit watermark conditions.	
		0	Full TFIFO
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 14-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/NW)	RFS	SPI_RFIFO Status. The SPI_STAT.RFS bits indicate the status of the SPI_RFIFO. The SPI uses this status when evaluating receive watermark conditions.	
		0	Empty RFIFO
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
11 (R/W1C)	TF	Transmit Finish Indication. The SPI_STAT.TF bit indicates that the SPI has detected the finish of a transmit burst transfer (the SPI_TWC count decrements to zero). This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit finish detected
10 (R/W1C)	RF	Receive Finish Indication. The SPI_STAT.RF bit indicates that the SPI has detected the finish of a receive burst transfer (the SPI_RWC count decrements to zero). This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive finish detected
9 (R/W1C)	TS	Transmit Start. The SPI_STAT.TS bit indicates that the SPI has detected the start of a transmit burst transfer. A transmit bursts starts with the load of SPI_TWC from the SPI_TWCR. This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit start detected
8 (R/W1C)	RS	Receive Start. The SPI_STAT.RS bit indicates that the SPI has detected the start of a receive burst transfer. A receive bursts starts with the load of SPI_RWC from the SPI_RWCR. This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive start detected

Table 14-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	MF	Mode Fault Indication. The SPI_STAT.MF bit, when SPI is a master and SPI_CTL.PSSE is enabled, indicates that multiple masters have asserted slave select inputs.	
		0	No status
		1	Mode fault occurred
6 (R/W1C)	TC	Transmit Collision Indication. The SPI_STAT.TC bit, when SPI is a slave, indicates that the load of data into the shift register has occurred too close to the first transmitting edge of the SPI clock.	
		0	No status
		1	Transmit collision occurred
5 (R/W1C)	TUR	Transmit Underrun Indication. The SPI_STAT.TUR bit, when the transmit FIFO (SPI_TFIFO) is empty, indicates that the last word in the transmit FIFO has been re-sent as transmit data. Alternately, it indicates that zero has been sent as transmit data.	
		0	No status
		1	Transmit underrun occurred
4 (R/W1C)	ROR	Receive Overrun Indication. The SPI_STAT.ROR bit, when the receive FIFO (SPI_RFIFO) is full, indicates that a word in the receive FIFO has been overwritten with incoming receive data. Alternately, it indicates that incoming receive data has been discarded.	
		0	No status
		1	Receive overrun occurred
2 (R/NW)	TUWM	Transmit Urgent Watermark Breached. The SPI_STAT.TUWM bit indicates that the transmit urgent watermark (SPI_TXCTL.TUWM) has been reached. This condition is cleared when the transmit FIFO fills enough to reach the transmit regular watermark (SPI_TXCTL.TRWM).	
		0	Tx regular watermark reached
		1	Tx urgent watermark breached
1 (R/NW)	RUWM	Receive Urgent Watermark Breached. The SPI_STAT.RUWM bit indicates that the receive urgent watermark (SPI_RXCTL.RUWM) has been reached. This condition is cleared when the receive FIFO empties enough to reach the receive regular watermark (SPI_RXCTL.RRWM).	
		0	Rx regular watermark reached
		1	Rx urgent watermark breached

Table 14-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SPIF	SPI Finished. The `SPI_STAT.SPIF` bit indicates that a single word transfer is complete.	
		0	No status
		1	Completed single word transfer

Transmit FIFO Data Register

The SPI_TFIFO register has an interface to the transmit shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_TFIFO register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI master stops initiating new transfers on the SPI if SPI_TXCTL.TTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after SPI_TFIFO is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (SPI_STAT.TUR). This condition is possible when SPI_TXCTL.TTI =0 and SPI_TXCTL.TEN =1 for a master, or for a slave that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

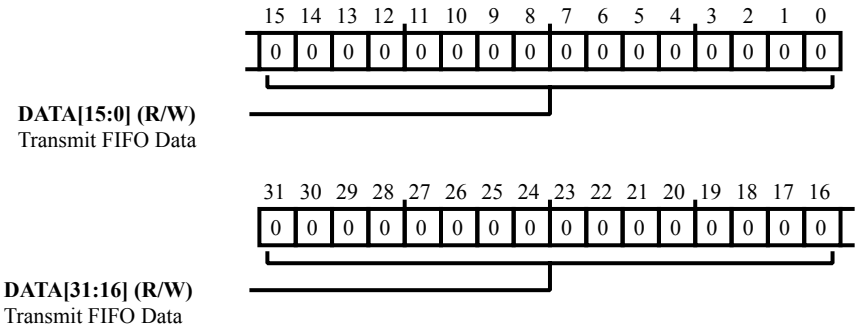

Figure 14-35: SPI_TFIFO Register Diagram

Table 14-34: SPI_TFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit FIFO Data. The SPI_TFIFO.DATA bit field contains the FIFO transmit data.

Transmitted Word Count Register

The SPI_TWC register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in SPI_TWC, enable the transmit word counter (SPI_TXCTL.TWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt request. In DMA mode, the SPI uses the SPI_TWC to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_TWC registers should match the word count in the DMA configuration. The SPI_TWC maintains the number of frames to be transmitted in a transfer. The SPI_TWC should only be changed when the counter is disabled.

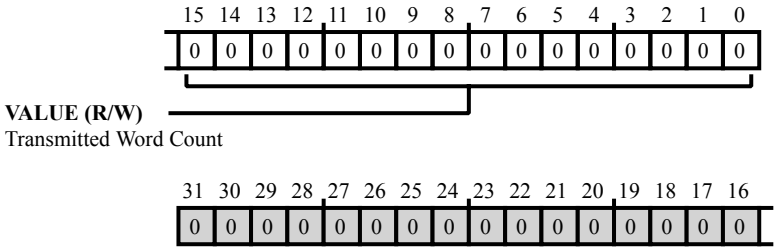

Figure 14-36: SPI_TWC Register Diagram

Table 14-35: SPI_TWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count. The SPI_TWC.VALUE bits hold the transmit transfer word count.

Transmitted Word Count Reload Register

The SPI_TWCR register holds the transmit word count value that the SPI loads into the SPI_TWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_TWCR should only be changed when the counter is disabled.

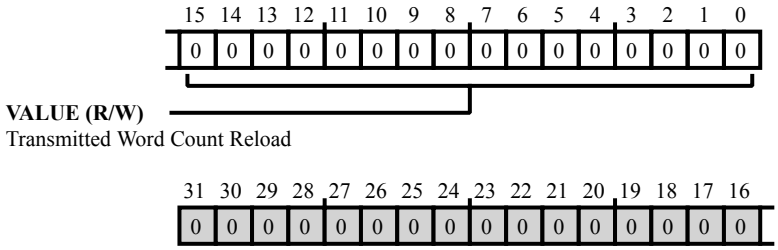

Figure 14-37: SPI_TWCR Register Diagram

Table 14-36: SPI_TWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count Reload. The SPI_TWCR.VALUE bits hold the transmit transfer word count reload value.

Transmit Control Register

The SPI_TXCTL register enables the SPI transmit channel, initiates transmit transfers, and configures SPI_TFIFO buffer watermark settings.

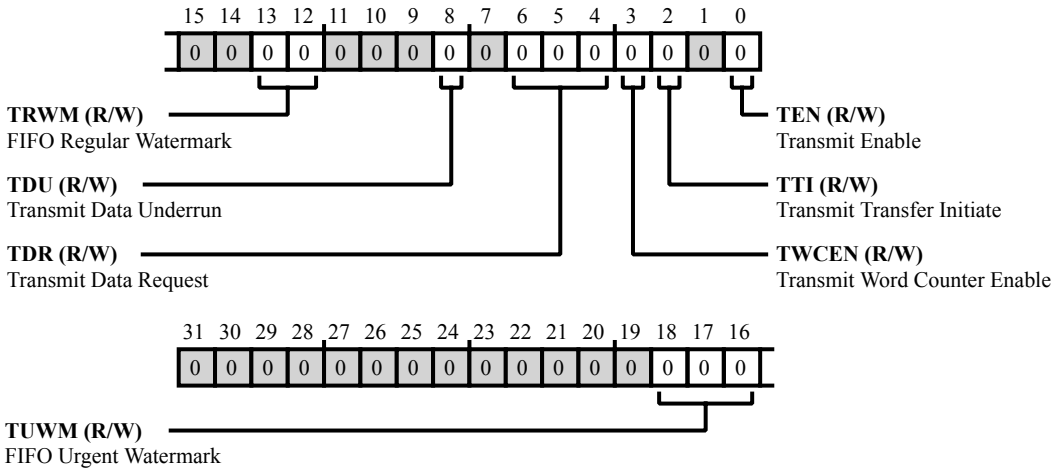

Figure 14-38: SPI_TXCTL Register Diagram

Table 14-37: SPI_TXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	TUWM	FIFO Urgent Watermark. The SPI_TXCTL.TUWM bits select the transmit FIFO (SPI_TFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.TUWM interrupt request. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Disabled
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 14-37: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	TRWM	FIFO Regular Watermark. The SPI_TXCTL.TRWM bits select the transmit FIFO (SPI_TFIFO) watermark level for regular data bus requests. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Full TFIFO
		1	TFIFO less than 25% empty
		2	TFIFO less than 50% empty
		3	TFIFO less than 75% empty
8 (R/W)	TDU	Transmit Data Underrun. The SPI_TXCTL.TDU bit selects handling for transmit data requests when the transmit buffer (SPI_TFIFO) is empty. If enabled and SPI_TFIFO is empty, the SPI transmits zero as data. If disabled and SPI_TFIFO is empty, the SPI transmits the last word in the buffer as data.	
		0	Send last word when SPI_TFIFO is empty
		1	Send zeros when SPI_TFIFO is empty
6:4 (R/W)	TDR	Transmit Data Request. The SPI_TXCTL.TDR bits select transmit FIFO (SPI_TFIFO) watermark conditions that direct the SPI to generate a transmit status interrupt request.	
		0	Disabled
		1	Not full TFIFO
		2	25% empty TFIFO
		3	50% empty TFIFO
		4	75% empty TFIFO
		5	Empty TFIFO
3 (R/W)	TWCEN	Transmit Word Counter Enable. The SPI_TXCTL.TWCEN bit enables the decrement of the transmit word count (SPI_TWC) register when the count is not zero and SPI_TXCTL.TTI is enabled. Enabling SPI_TXCTL.TWCEN prevents transmit underrun errors from occurring. The SPI_TXCTL.TWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 14-37: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	TTI	Transmit Transfer Initiate. The `SPI_TXCTL.TTI` bit enables initiation of transmit transfers if the transmit FIFO (`SPI_TFIFO`) is not empty. The bit also enables this initiation if `SPI_TWC` is not zero when `SPI_TXCTL.TWCEN` is enabled. Enabling `SPI_TXCTL.TTI` prevents transmit underrun errors from occurring. The `SPI_TXCTL.TTI` bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	TEN	Transmit Enable. The `SPI_TXCTL.TEN` bit enables SPI transmit channel operation.

15 Universal Asynchronous Receiver/Transmitter (UART)

The UART module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

The UART module supports partial modem status and control functionality to allow for hardware flow control.

The UART is a DMA-capable peripheral with separate transmit and receive DMA master channels. The use of DMA requires minimal software intervention as the DMA engine moves the data. The UART can also use a programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling.

The UART can use one of the peripheral timers for a hardware-assisted auto-baud detection mechanism. The timers are external to the UART.

UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Extra 8-stage receive FIFO with programmable threshold interrupt request
- Flexible transmit and receive interrupt request timing
- Three interrupt outputs for receive, transmit, and status

- Independent DMA operation for receive and transmit
- Programmable automatic request to send (RTS)/clear to send (CTS) hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loopback
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

Table 15-1: UART Specifications

Feature	Availability
Protocol	
Master-Capable	Yes
Slave-Capable	Yes
Transmission Simplex	Yes
Transmission Half-Duplex	Yes
Transmission Full-Duplex	Yes
Access Type	
Data Buffer	Yes
Core Data Access	Yes
DMA Data Access	Yes
DMA Channels	2 (per UART Port)
DMA Descriptor	Yes
Boot Capable	Yes (Slave Mode)
Local Memory	No
Clock Operation	SCLK/16

UART Functional Description

The following sections provide details on the UARTs functionality.

ADSP-SC57x UART Register List

The Universal Asynchronous Receiver/Transmitter module (UART) is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word length, stop bit, parity, and interrupt generation

options. A set of registers governs UART operations. For more information on UART functionality, see the UART register descriptions.

UART Block Diagram

The ***UART Block Diagram*** figure shows a simplified block diagram of one UART module and how it interconnects to the processor system.

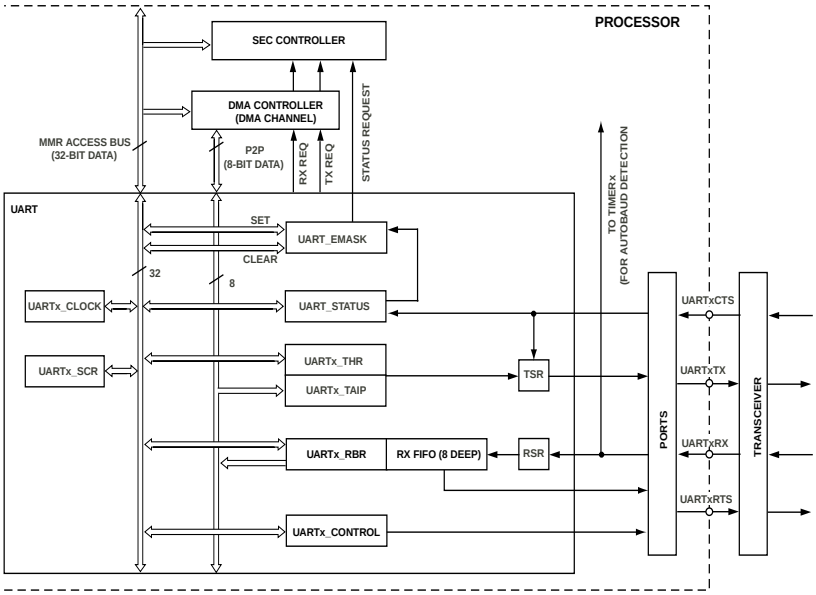

Figure 15-1: UART Block Diagram

UART Architectural Concepts

The following sections provide information about the UART architecture.

Internal Interface

The UART is a DMA-capable peripheral with support for separate transmit and receive DMA master channels. It operates in either DMA or programmed core modes. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data. The `UART_RBR` and `UART_THR` registers also connect to one of the peripheral DMA buses.

All UART registers are 32 bits wide and the registers connect to the peripheral MMR bus. Not all MMRs can be used and unused bits are zero-filled. The UART has three interrupt outputs described as follows.

- The transmit and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC).
- The status interrupt output connects directly to the SEC. On many processors, the alternative capture input (TIMER_ACI[n]) of one of the GP timers also senses the UART_RX pin. When configured in capture mode, the processor can then use the GP timer to detect the bit rate of the received signal.

External Interface

Each UART features a UART_RX (receive) pin and a UART_TX (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full-duplex or half-duplex standards. For example, EIA-232, EIA-422, 4-wire EIA-485 for full-duplex or 2-wire EIA-485, LIN for half-duplex. Additionally, the UART features a pair of clear-to-send, input pins (UART_CTS), and request-to-send, output pins (UART_RTS) for hardware flow control. UART signals are multiplexed with other functions at the pin level.

Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, the UART features a UART_RTS/UART_CTS hardware flow control mechanism. The UART_RTS signal is an output that connects to the UART_CTS input of the communication partner. If data transfer is bidirectional, the figure shows the ***UART Hardware Flow Control*** handshake.

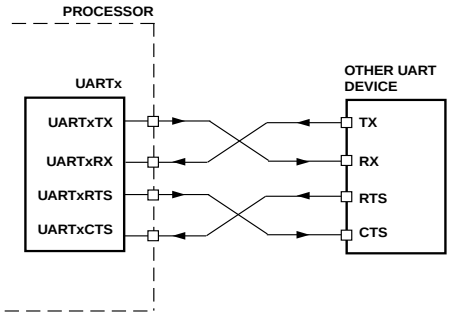

Figure 15-2: UART Hardware Flow Control

In both DMA and core mode, the receiver can deassert the UART_RTS signal to indicate that its receive buffer is almost full. Continued data transfers can cause an overrun error. The transmitter pauses when the UART_CTS input is in a deasserted state. In this state, the transmitter completes transmission of the data currently held in the transmit shift register (UART_TSR) but it does not continue with the data in the transmit hold register (UART_THR). If the UART_CTS pin is asserted again, the transmitter resumes and loads the content of UART_THR register into the UART_TSR register.

Bit Rate Generation

The peripheral clock (SCLK) and the 16-bit divisor in the UART_CLK register characterize the sample clock. The UART uses the UART_CTL.EN bit to enable the clock. By default, every serial bit is oversampled 16 times. The bit

clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the UART_CLK.EDBO bit is set, so that the following equation applies:

Bit Rate = SCLK/16 $^{(1\text{-EDBO})}$ × Divisor

The ***UART Bit Rate Examples with 100 MHz SCLK*** table provides example divide factors required to support standard baud rates at an SCLK of 100 MHz.

Table 15-7: UART Bit Rate Examples with 100 MHz SCLK

Bit Rate (bits/ sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
2400	2604	2400.15	0.006	41667	2399.98	0.001
4800	1302	4800.31	0.006	20833	4800.08	0.002
9600	651	9600.61	0.006	10417	9599.69	0.003
19200	326	19171.78	0.147	5208	19201.23	0.006
38400	163	38343.56	0.147	2604	38402.46	0.006
57600	109	57339.45	0.452	1736	57603.69	0.006
115200	54	115740.74	0.469	868	115207.37	0.006
921600	7	892857.14	3.119	109	917431.19	0.452
1500000	4	1562500	4.167	67	1492537.31	0.498
3000000	2	3125000	4.167	33	3030303.03	1.01
6250000	1	6250000	0	16	6250000	0

NOTE: Properly select the SCLK frequencies. Even multiples of bit rate decrease the error percentage.

Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. The disadvantage is that the power dissipation is higher and sample points are not always accurate. Therefore, use UART_CLK.EDBO mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode.

TheUART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.

Autobaud Detection

At the chip level, the $\overline{\text{UART\_RX}}$ pin is typically routed to an alternate capture input (TIMER_ACI[n]) of a general-purpose timer. When working in width capture mode, the processor uses this general-purpose timer to detect the bit rate applied to the $\overline{\text{UART\_RX}}$ pin automatically by an external device. It often uses the capture capabilities of the timer to supervise the bit rate at run time. If the UART communicates with any device supplied by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically, as required.

Often, the processor uses autobaud detection for initial bit rate negotiations where it is most likely a slave device waiting for the host to send a predefined autobaud character. This situation is common for UART booting. Do not enable the UART_CTL.EN bit while autobaud detection is in-process, to prevent the UART from starting a receive operation with incorrect bit rate matching. Alternatively, set the UART_CTL.LOOP_EN bit to disconnect the UART from its UART_RX pin.

A software routine can detect the pulse widths of serial stream bit cells. The sample base of the timer is synchronous with the UART operation (all derived from the same SCLK). The UART uses pulse widths to calculate the bit rate divider as follows:

Divisor = TIMER_TMR[n]_WID/$16^{(1-EDBO)}$ × Number of captured UART bits

To increase the number of timer counts and the resolution of the captured signal, do not measure just the pulse width of a single bit. Instead, enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown in the ***Autobaud Detection*** figure.

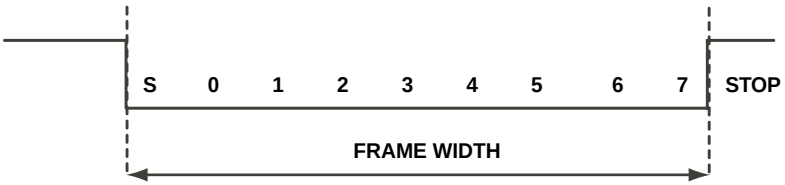

Figure 15-3: Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula:

Divisor = TIMER_TMR[n]_WID/$16^{(1-EDBO)}$ × 9

NOTE: For processor-specific mapping of timer alternate capture inputs to the UARTs of the processor, see "Width Capture (WIDCAP) Mode" in the "*General-Purpose Timer (TIMER)*" chapter.

Real receive signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection does not always return adequate results without extra conditioning of the analog signal. Measure signal periods to work around this issue.

For example, predefine the ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the ***Autobaud Detection Character 0x40*** figure, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula:

Divisor = TIMER_TMR[n]_PER/$16^{(1-EDBO)}$ × 8

or:

- Divisor = TIMER_TMR[n]_PER>> 7, if UART_CLK.EDBO=0
- Divisor = TIMER_TMR[n]_PER>> 3, if UART_CLK.EDBO=1

The ***Autobaud Detection Character 0x40*** figure shows the ASCII “@” (0x40) detection character.

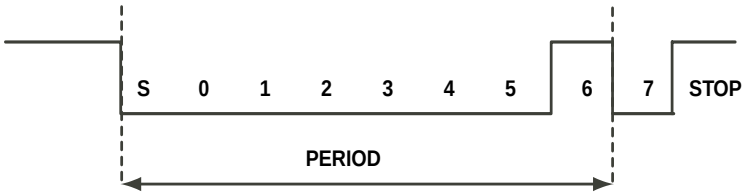

Figure 15-4: Autobaud Detection Character 0x40

UART Debug Features

The UART can automatically calculate and transmit a parity bit. The ***UART Parity*** table summarizes parity behavior assuming 8-bit data words (`UART_CTL.WLS`=b#11).

Table 15-8: UART Parity

PEN	STP	EPS	Data (hex)	Data (binary, LSB first)	Parity
0	x	x	x	x	None
1	0	0	0x60	0000 0110	1
1	0	0	0x57	1110 1010	0
1	0	1	0x60	0000 0110	0
1	0	1	0x57	1110 1010	1
1	1	0	x	x	1
1	1	1	x	x	0

The two force error bits, `UART_CTL.FPE` and `UART_CTL.FFE`, are intended for test purposes. They are useful for debugging software, especially in loopback mode.

The UART can be set to internal loopback mode (`UART_CTL.LOOP_EN`=1). Loopback mode disconnects the input of the receiver from the receive pin and internally redirects the transmit output to the receiver. The transmit pin remains active and continues to transmit data externally as well. Loopback mode also forces the `UART_RTS` pin to deassert, disconnects the `UART_STAT.CTS` bit from the `UART_CTS` input pin, and connects the internal version of `UART_RTS` to the `UART_STAT.CTS` bit.

Additionally, the `UART_TX` pin can be forced to zero asynchronously using the `UART_CTL.SB` bit.

UART Operating Modes

The following sections describe the main operating modes of the UART.

- UART Mode
- IrDA SIR Mode
- Multi-Drop Bus Mode

UART Mode

The UART mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5–8 data bits
- Address bit (available in MDB mode only)
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits valid only in 5-bit word length)

The UART_CTL register controls the format of received and transmitted character frames. Data is always transmitted and received with the least significant bit (LSB) first.

The ***Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)*** figure shows a typical physical bit stream measured on a UART_TX pin.

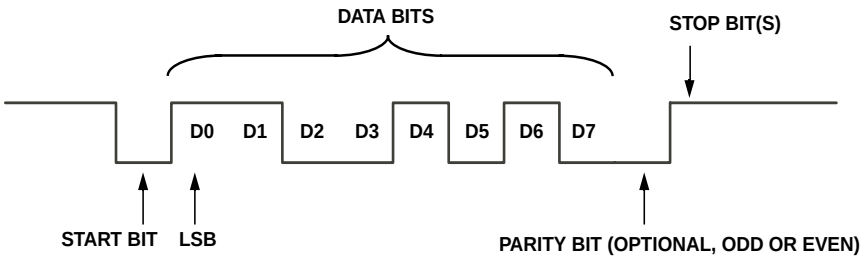

Figure 15-5: Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)

IrDA SIR Mode

The UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. The UART does not support pulse position modulation.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the UART uses a 16x clock to determine an IrDA pulse sample window, from which it recovers the RZI modulated NRZ code.

NOTE: The UART_CLK.EDBO bit is not valid in IrDA mode. Clear (=0) this bit in this mode.

Multi-Drop Bus Mode

The UART uses a protocol for point-to-point connections as well as in networks where the EIA-485 standard is representative of UART-based bus systems. The EIA-232 standard defines point-to-point connections. In such networks, node addressing is important.

In a multidrop bus (MDB) network, for example, an address bit enhances the UART frame. The address bit is inserted between the data bits and the optional parity bit. To configure the UART for MDB mode, set the mode of operation bits (UART_CTL.MOD [5:4]) to 01.

By convention, the address bit is transmitted low for regular data bytes. When set, it marks special address bytes that require the attention of all nodes on the network.

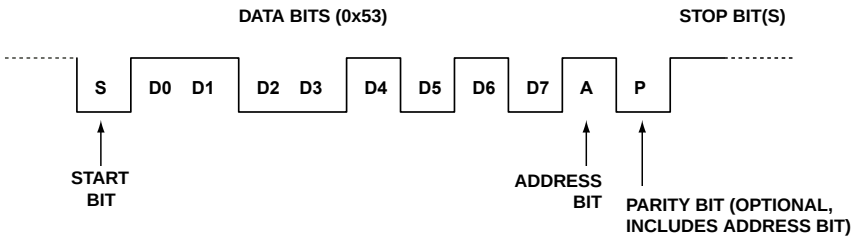

Figure 15-6: UART Frame with Address Bit

All transmit operations are processed through the transmit buffer register (UART_THR), so all DMA data transmissions clear the address bit. If data is written to the transmit address or insert pulse register (UART_TAIP) instead, the same transmit operation is initiated with the only exception that the address bit is sent high.

The UART uses the UART_STAT.ADDR bit of the receiver to signal whether the previously received frame had the address bit set or not. Hardware updates it every time a new frame is received. When the enable address word interrupt bit (UART_IMSK.EAWI) is set, the reception of an address byte triggers a special status interrupt request.

The address sticky bit (UART_STAT.ASTKY) is the sticky version of the UART_STAT.ADDR bit. Hardware sets it whenever the UART_STAT.ADDR bit is set. Software can clear the UART_STAT.ASTKY bit with a W1C operation.

In MDB mode, only address bytes progress to the receive FIFO by default. Data bytes are gated unless the UART_STAT.ASTKY bit is set. The receiver ignores all traffic on the UART bus. This way, the processor can go into low-power mode and interrupt activity does not load the processor every time a frame is transmitted on the UART bus. If, however, an address frame is transmitted, the receiver immediately samples all further traffic. A software routine can analyze the received data, decide whether it was of relevance for the local network node, and W1C the UART_STAT.ASTKY bit if it was not.

Software can overrule of the hardware address frame detection by setting the UART_STAT.ADDR bit and (indirectly) the UART_STAT.ASTKY bit with a W1S operation.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5–8 data bits
- Address bit
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits are valid only in 5-bit word length)

NOTE: If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

UART Data Transfer Modes

The UART can transfer data using both the core and DMA. Receive and transmit paths operate independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The UART_THR register buffers the transmit shift register (UART_TSR) and the UART_RBR register buffers the receive shift register (UART_RSR).

UART Mode Transmit Operation (Core)

In core mode, the processor core moves data to and from the UART. A write to the UART_THR register initiates the transmit operation. If no former operation is pending, the UART_THR register passes the data immediately to the UART_TSR register. There, it is shifted out at the bit rate characterized by the UART_CLK register, with start, stop, and parity bits appended as defined by the UART_CTL register.

The UART_THR register and the UART_TSR register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) always transmits first. This bit is bit 0 of the value written to the UART_THR register.

UART Mode LIN Break Command

Some UART-based protocols demand synchronization methods that are not native to standard UART implementations. For example, the Local Interconnect Network (LIN) protocol requires a low-pulse of well-defined transmit length as a prologue to every multi-byte message. Its length must be at least 13 bit-times.

With previous UARTs, there were two options to implement this protocol:

- A null byte is transmitted with a temporarily lowered bit rate, or
- A software counter generates the period and the asynchronous set break (SB) mechanisms pull the transmit pin low

Since both methods have their disadvantages, the newer UART introduces a new inter-frame gap technique.

The feature is not available in MDB or IrDA operating modes. However, in standard UART mode (bits UART_CTL.MOD [5:4] =00), a write to the UART_TAIP register initiates the transmission of an inter-frame pulse. If the transmit buffer is not empty, the UART first transmits all bytes in the queue. It only initiates with pulse generation after the last stop bit of the last byte has been shifted out.

The value written into the UART_TAIP register defines the nature and the duration of the transmitted pulse. Bits [6:0] control the duration in bit-times and bit [7] controls the value (duration = UART_TAIP[6:0] / UART_CLK[15:0]). If UART_TAIP[7] is set, and an active high pulse is issued, the number of stop bits is extended. If UART_TAIP[7] is cleared, a low pulse is generated. Invert the polarity using the UART_CTL.FCPOL bit. Writing a value of 13 into the UART_TAIP register generates the break command as required by the LIN protocol.

NOTE: If the UART_CTL.TPOLC bit is enabled, an inverted most-significant bit can be transmitted.

NOTE: If another transmission is pending (in the UART_TSR register), the UART_TAIP initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap precedes transmission of the number of stop bits as set in the UART_CTL.STB and UART_CTL.STBH bit fields.

The UART receiver can detect break commands through the break indicator (UART_STAT.BI) flag. This flag reports that an entire UART frame has been received in low state. It does not report whether the duration of the received low pulse was exact or at least 13 bit-times as LIN masters transmit. Typically, the break indicator meets LIN requirements. The processor can use GP timers to determine the pulse width more precisely, if necessary.

Each $\overline{\text{UART\_RX}}$ pin is also routed to a GP timer through its alternate capture input (TACI). This functionality is not only useful for bit rate detection (*autobaud*) but also helps to measure the pulse widths precisely on the $\overline{\text{UART\_RX}}$ input. Additionally, the GP timers can issue an interrupt request or a fault condition when the received pulse width is shorter than a bit time or longer than the worst-case break condition. The windowed watchdog width mode of the GP timers controls this functionality.

UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration except that one valid stop bit is always sufficient. The UART_CTL.STB and UART_CTL.STBH bits have no impact on the receiver.

The UART receiver senses the falling edges of the receive input. When it detects an edge, the receiver starts sampling the input according to settings in the UART_CLK register. The receiver samples the start bit (majority sampling) close to its midpoint. If sampled low, it assumes a valid start condition. Otherwise, it discards the detected falling edge.

After detection of the start bit, the received word is shifted into the UART_RSR register.

After the corresponding stop bit is received, the content of the UART_RSR register is transferred to the 8-deep receive FIFO and is accessible by reading the UART_RBR register.

The receive FIFOs and the UART_RBR register act as a 9-stage receive buffer. If the stop bit of the ninth word is received before software reads the UART_RBR register, an overrun error is reported. Overruns protect data in the UART_RBR register and the receive FIFO from being overwritten by further data until the software clears the UART_STAT.OE bit. However, the data in the UART_RSR register is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver oversamples every bit 16 times and makes a majority-decision based on the middle three samples. This functionality improves immunity against noise and hazards on the line. The receiver disregards spurious pulses of less than two times the sampling clock period.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set to 1, the receiver samples bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy as required at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception starts when the UART receiver detects a falling edge on the $\overline{\text{UART\_RX}}$ input pin. The receiver attempts to see a start bit. The data is shifted into the UART_RSR register. After the ninth sample of the first, the receiver processes the stop bit and copies the received data to the 8-stage receive FIFO. The UART_RSR recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is typically asynchronous to the data rate of the transmitter, the sampling point can drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the UART_CTL.RPOLC bit.

NOTE: The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately acts (status update). It then prepares for new falling edge detection (start detection).

IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the UART_CTL.TPOLC bit is configured for active-low operation. In this configuration, a zero is transmitted as a high pulse of 16 UART clock periods and a one is transmitted as a low pulse for 16 UART clock periods. Then, six UART clock periods delay the leading edge of the pulse. Similarly, eight UART clock periods truncate the trailing edge of the pulse. For a 16-cycle UART clock period, this operation results in the final representation of the original zero as a high pulse of only 3/16 clock periods. The ***IrDA Transmit Pulse*** figure shows how the pulse is centered around the middle of the bit time. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the ***IrDA Transmit Pulse*** figure, the error terms associated with the bit rate generator are small and well within the tolerance of most infrared transceiver specifications.

NOTE: In IrDA mode, writes to the UART_TAIP register are equivalent to writes to the UART_THR register.

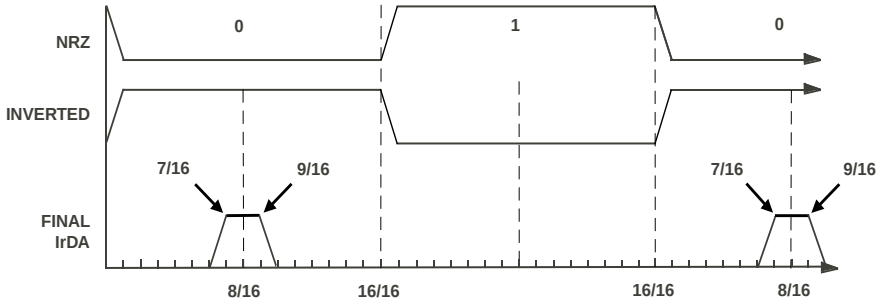

Figure 15-7: IrDA Transmit Pulse

IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. The receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time the receiver detects an initial pulse. If the pulse is absent when the counter expires, the receiver interprets it as a glitch. Otherwise, the receiver interprets it as a zero. This assessment is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK) period. Appropriate shielding avoids sources outside of the chip and not part of the transmitter. The only other source of a glitch is the transmitter itself. The processor

relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results can occur. The 4-bit counter adds an extra level of protection at a minimal cost.

NOTE: Because SCLK can change across systems, the longest glitch tolerated is inversely proportional to the SCLK frequency.

A counter that is clocked at the 16x bit-time sample clock determines the receive sampling window. The sampling window is resynchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the `UART_CTL.RPOLC` bit. The ***IrDA Receiver Pulse Detection*** figure provides examples of each polarity type.

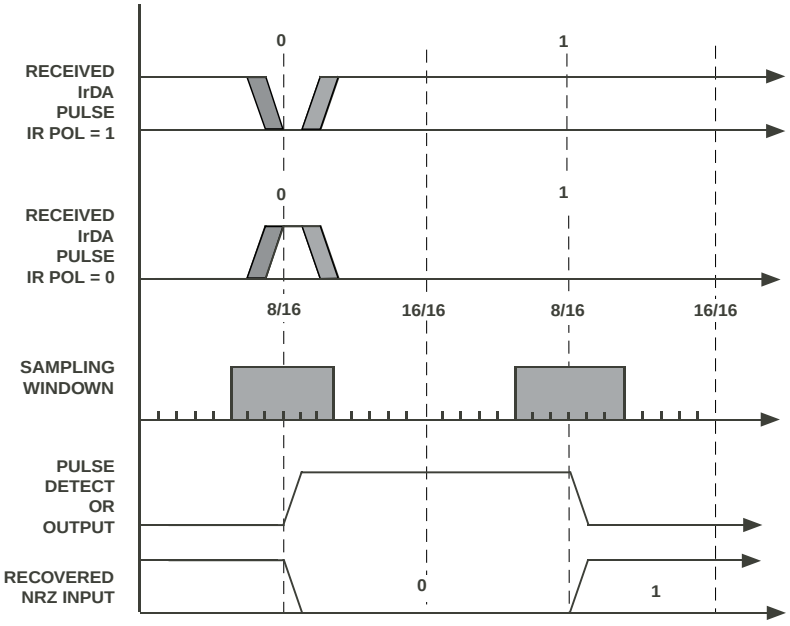

Figure 15-8: IrDA Receiver Pulse Detection

MDB Transmit Operation

In MDB mode, receive and transmit paths operate independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the `UART_THR` or `UART_TAIP` registers. A write to the `UART_THR` register transmits the written word with the appending address bit set low. A write to the `UART_TAIP` register transmits the written word with the appended address bit set high. The data is moved into the `UART_TSR` register, where it is shifted out at the bit rate programmed by the `UART_CLK` register, with start, stop, address, and parity bits appended, as required.

If DMA is enabled, the DMA engine always writes the data into the `UART_THR` register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the `UART_CTL.TPOLC` bit.

MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the UART_RSR register at the programmed bit.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set, the receiver samples the bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy needed at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the UART_RSR register is transferred to the receive FIFO and accessible through the UART_RBR register.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit.

DMA Mode

In DMA mode, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just has to set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the bus activity and arbitration mechanism determine the latency. The processor loading and interrupt priorities do not determine the latency.

To enable UART DMA, first set up the system DMA control registers. Then, enable the UART_IMSK.ERBFI or UART_IMSK.ETBEI interrupts. This sequence is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit. The status interrupt for the UART goes directly to the system event controller (SEC), bypassing the DMA unit completely.

For transmit DMA, programs must set the DMA_CFG.SYNC bit. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART transmit DMA interrupt service routine can disable the DMA or to clear the UART_IMSK.ETBEI control bit only when the DMA_CFG.SYNC bit is set. Otherwise, up to four data bytes can be lost.

When the UART_IMSK.ETBEI bit is set, an initial transmit DMA request is issued immediately. The program then clears the UART_IMSK.ETBEI bit through the DMA service routine.

In DMA transmit mode, the UART_IMSK.ETBEI bit enables the peripheral request to the DMA FIFO. The DMA_CFG.EN bit enables the strobe on the memory side. If the DMA count is less than the DMA FIFO depth, which is 4, then the DMA interrupt can be requested before the UART_IMSK.ETBEI bit is set. If this behavior is unwanted, set the DMA_CFG.SYNC bit.

Regardless of the DMA_CFG.SYNC setting, the DMA stream has not left the UART transmitter completely at the time the interrupt request is generated. Transmission can abort in the middle of the stream, causing data loss, when the UART clock was disabled without extra synchronization with the UART_STAT.TEMT bit.

The UART provides functionality to avoid resource-consuming polling of the UART_STAT.TEMT bit. The UART_IMSK_SET.EDTPTI bit enables the UART_STAT.TEMT bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the DMA_CFG.INT bit cleared and set the UART_IMSK_SET.EDTPTI bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the UART_STAT.TEMT event triggers a DMA interrupt after the last word of the DMA has left the UART transmit buffers. If DMA_CFG.INT and UART_IMSK.EDTPTI are set, when finishing STOP mode, the DMA requests two interrupts.

The DMA of the UART module supports 8-bit and 16-bit operation, but not 32-bit operation. It does not support sign-extension.

Mixing DMA and Core Modes

Switching from DMA mode to core operation dynamically requires some consideration, especially for transmit operations. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the transmit DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The transmit DMA interrupt service routine is not yet permitted to disable the DMA_CFG.EN bit. The interrupt is requested when the DMA_STAT.IRQDONE bit is set. The DMA_STAT.RUN bit, however, remains set until the data has completely left the transmit DMA FIFO.

When planning to switch from a DMA to core mode, set the DMA_CFG.SYNC bit in the word of the last descriptor or work unit before handing over control. Then, after the interrupt request occurs, software can write new data into the UART_THR register as soon as the UART_STAT.THRE bit permits. If the DMA_CFG.SYNC bit cannot be set, software can poll the DMA_STAT.RUN bit instead. Alternatively, using the UART_IMSK.EDTPTI bit can avoid expensive status bit polling.

When switching from core to DMA operation, ensure that the first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the UART_STAT.TEMT bit is high, pulse the UART_IMSK.ETBEI bit to initiate DMA transmission.

Setting Up Hardware Flow Control

The following steps show how to set up UART hardware flow control:

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART\_CTS}}$ and $\overline{\text{UART\_RTS}}$ polarity through the UART_CTL.FCPOL bit.

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the $\overline{\text{UART\_RTS}}$ pin is not driven. Some applications require a resistor pull the UART_RTS signal to either state during reset.

UART Event Control

Status flags in the UART_STAT register are available to signal data reception, parity, and error conditions, if necessary.

DMA and Interrupt Multiplexing

See the *Direct Memory Access (DMA)* chapter on for information on DMA multiplexing. Several interrupts and DMA channels in thr UART can be multiplexed.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Masks

Each UART features a set of interrupt mask registers: UART_IMSK, UART_IMSK_SET, and UART_IMSK_CLR. The UART_IMSK register supports read/write operations. Writing ones to the UART_IMSK_SET register enables interrupts, writing ones to the UART_IMSK_CLR register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupt requests independently and easily.

The UART module uses the UART_IMSK registers to enable requests for system handling of empty or full states of data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits in this register are normally set.

Each UART module has three interrupt outputs. It uses one for transmission, one for reception, and one for reporting status events. The UART module routes transmit and receive requests through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. A DMA channel must be associated with the UART module to enable transmit and receive interrupts. Otherwise, transmit and receive requests cannot be forwarded.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt request output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Servicing

Interrupt service routines (ISRs) perform UART writes and reads. Separate interrupt lines are provided for transmit, receive, and status. The UART_IMSK register group enables the independent interrupts individually. To enable UART transmit interrupts, set the UART_CTL.EN bit.

The ISRs evaluate the status bits in the UART_STAT register to determine the signaling interrupt source. The system event controller for the processor assigns and unmasks interrupts. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, use the UART_IMSK.ERFCI status interrupt as an alternative to the regular UART_IMSK.ERBFI receive interrupt. Hardware must ensure that at least two (if UART_CTL.RFIT=0) or four (if UART_CTL.RFIT=1) words are available in the receive buffer by the time the interrupt is requested.

Transmit Interrupts

The UART module uses the UART_IMSK_SET.ETBEI bit to enable transmit interrupt requests.

The UART_THR and UART_TAIP registers are the same physical register, and both affect the signaling of the UART_STAT.TEMT, UART_STAT.TFI, and UART_STAT.THRE bits similarly.

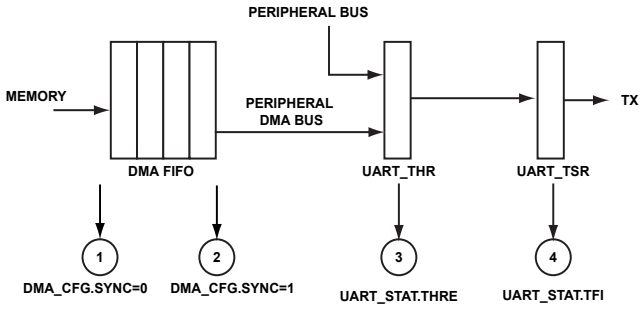

Figure 15-9: Transmit Interrupts

The UART module asserts the transmit request along with the UART_STAT.THRE bit, indicating that the transmit buffer is ready for new data. The UART_STAT.THRE bit resets to 1. When the UART_IMSK_SET.ETBEI bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Set the UART_IMSK_SET.ETBEI bit and let the interrupt service routine load the first character from memory and write it to the UART_THR register in the normal manner. ISRs can clear the UART_IMSK.ETBEI bit through the UART_IMSK_CLR register when the string transmission has completed.

Hardware clears the UART_STAT.THRE bit when new data is written to the UART_THR register. These write operations also clear the transmit interrupt request. However, they also initiate further transmission. If continued transmission is undesirable, the UART module can alternatively clear the transmit request through the UART_IMSK_CLR.ETBEI bit register. Transfers of data from the UART_THR register to the UART_TSR register reset this status flag in the UART_STAT register.

ISRs can interrogate the UART_STAT.TEMT bit to discover any ongoing transmission. The sticky counterpart of the UART_STAT.TEMT bit, UART_STAT.TFI, indicates when the transmit buffer has drained and can trigger a status interrupt. When data is pending in either one of these registers, the UART_STAT.TEMT flag is low. As soon as all data has left the UART_TSR register, the UART_STAT.TEMT bit goes high again and indicates that all pending transmit operations (including stop bits) have finished. Then, it is safe to disable the UART_CTL.EN bit or to three-state off-chip line drivers. Then, the UART module can generate an interrupt either through the status interrupt channel when the UART_IMSK.ETFI bit is set, or through the DMA controller when enabled by the UART_IMSK.EDTPTI bit.

When enabled by the UART_IMSK.ETBEI bit, the UART_STAT.THRE flag requests data along the peripheral command lines to the DMA controller (referred to as TXREQ). This signal is routed through the DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA

controller simply forwards it to the SEC. Alternatively the UART_IMSK.ETXS bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, the UART module can poll the status flags to determine when data is ready to move. Because polling is processor intensive, it is not typically used in real-time signal processing environments. Since read operations from UART_STAT registers have no side effects, different software threads can interrogate these registers without mutual impacts.

Polling the SEC_SSTAT[n] register without enabling the interrupts by the SEC_CCTL[n] register is an alternate method of operation to consider. Software can write up to two words into the UART_THR register before enabling the UART clock. As soon as the UART_CTL.EN bit is set, the UART module sends those two words.

Receive Interrupts

The UART module uses the UART_IMSK_SET.ERBFI bit to enable receive interrupt requests. If set, the UART_STAT.DR flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the UART_RBR register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the UART_IMSK.ERXS bit can redirect the receive interrupts to the UART status interrupt. When software reads the UART_RBR register, hardware clears the UART_STAT.DR bit again, which, in turn, clears the receive interrupt request.

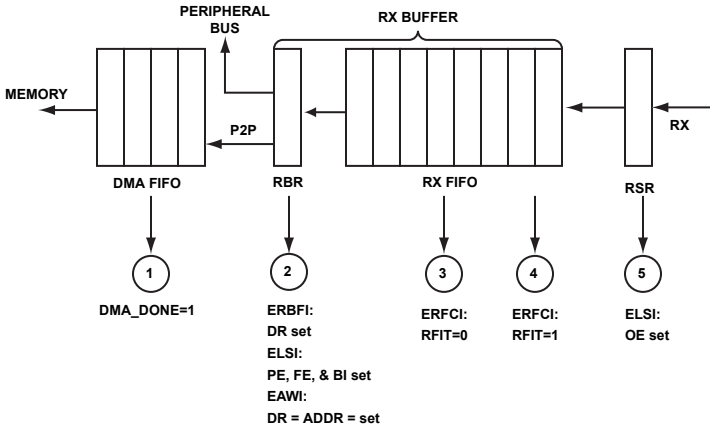

Figure 15-10: Receive Interrupts

Hardware updates the following:

- UART_STAT.DR bits
- UART_STAT.ADDR bits
- UART_STAT.ASTKY bits
- UART_STAT.PE bits
- UART_STAT.FE bits
- UART_STAT.BI bits

- UART_RBR register

The UART_STAT.OE bit is updated as soon as an overflow condition occurs (for example when a stop bit for a frame is received and the receive FIFO is full). When software does not read the UART_RBR register in time, the received data is protected from being overwritten by new data until software clears the UART_STAT.OE bit. Only the content of the UART_RSR register can be overwritten in the overrun case.

The UART module uses the UART_STAT.RFCS bit to monitor the state of the 8-deep receive FIFO. It uses the UART_CTL.RFIT bit to control the behavior of the buffer. If UART_CTL.RFIT is zero, the UART_STAT.RFCS bit is set when the receive buffer holds four or more words. If UART_CTL.RFIT is set, the UART_STAT.RFCS bit is set when the receive buffer holds seven or more words. Hardware clears the UART_STAT.RFCS bit when a core or DMA reads the UART_RBR register and when the buffer is flushed below the level of four (UART_CTL.RFIT=0) or seven (UART_CTL.RFIT=1). If the associated interrupt bit UART_IMSK.ERFCI is enabled, a status interrupt request is reported when the UART_STAT.RFCS bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. The bit enables status interrupt requests.

The controller detects the following error conditions, shown with their associated bits in the UART_STAT register.

- Overrun error (UART_STAT.OE bit)
- Parity error (UART_STAT.PE bit)
- Framing error or invalid stop bit (UART_STAT.FE bit)
- Break indicator (UART_STAT.BI bit)

Status Interrupts

The UART module uses status interrupt channels for the following purposes:

- Line status interrupt requests
- Flow control interrupt requests
- Receive FIFO threshold interrupt requests
- Transmission finished interrupt request

The UART module uses the UART_IMSK.ELSI bit to enable the line status interrupts. If set, the status interrupt request is asserted with one of the UART_STAT.BI, UART_STAT.FE, UART_STAT.PE, or UART_STAT.OE receive errors bits. A W1C operation to the UART_STAT register clears the error bits. Once all error conditions are cleared, the interrupt request deasserts.

The UART module uses the UART_IMSK_SET.ERFCI bit to enable the receive FIFO count interrupt. If set, a status interrupt request is generated when the UART_STAT.RFCS is active. The UART_STAT.RFCS bit indicates a receive buffer threshold level. If the UART_CTL.RFIT bit is cleared, software can safely read two words out of the UART_RBR register by the time the UART_STAT.RFCS interrupt occurs.

If the UART_CTL.RFIT bit is set, software can safely read four words. The interrupt request and the UART_STAT.RFCS bit are cleared when the UART_RBR is read enough of times, so that the receive buffer drains below the threshold of two (UART_CTL.RFIT=0) or four (UART_CTL.RFIT=1). Because in DMA mode a status service routine may not be permitted to read UART_RBR, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The UART module uses the UART_IMSK_SET.EDSSI bit to enable the flow control interrupts. If active, a status interrupt is generated when the sticky UART_STAT.SCTS bit register is set, indicating that the UART_CTS input of the transmitter been reasserted. A W1C operation to the UART_STAT.SCTS bit clears the interrupt request.

The UART module uses the UART_IMSK_SET.ETFI bit to enable the transmission finished interrupt. If active, a status interrupt request is asserted when the UART_STAT.TFI bit is set. The UART_STAT.TFI is the sticky version of the UART_STAT.TEMT bit, indicating that a byte that started transmission has finished. A W1C operation to the UART_STAT.TFI bit clears the interrupt request.

Multi-Drop Bus Events

Several status bits and interrupt features in the UART_STAT and UART_IMSK registers facilitate efficient data handling in multi-drop bus mode. These features include the address (UART_STAT.ADDR) bit, the address sticky (UART_STAT.ASTKY) bit and the enable address word interrupt (UART_IMSK.EAWI). One of the key features of the multi-drop bus protocol is its address bit. The address bit signifies to the slaves that the master is transmitting an address word (all read it) or a data word (only the addressed slave reads its). The UART hardware provides an efficient method of handling the situation described with the use of UART_STAT.ASTKY bit.

NOTE: The UART module uses the UART_STAT.ASTKY bit in multi-drop bus mode to indicate when an address operation for a peripheral is occurring. The UART_STAT.ASTKY bit is a sticky version of the UART_STAT.ADDR bit. Hardware sets the bit whenever the UART_STAT.ADDR bit is set. Only software clears it with a W1C operation. With the UART_STAT.ASTKY bit set, words are received irrespective of the mode bit or address bit setting. With the UART_STAT.ASTKY bit cleared, only address words (mode bit =1) are received and words with mode bit =0 are ignored in MDB mode. This bit does not affect reception in non-MDB modes. (Words with mode bit =0 are not moved from the UART_RSR register to the receive FIFO.)

UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

Detecting Autobaud

To detect Autobaud:

1. Ensure that the timer is disabled.
2. Configure the following bits: UART_CTL.MOD =00, UART_CTL.LOOP_EN =1, UART_CTL.WLS =11 (8-bit data), and UART_CTL.EN =1

3. Configure the following bits: TIMER_TMR[n]_CFG.TMODE =1101, TIMER_TMR[n]_CFG.OUTDIS =1, TIMER_TMR[n]_CFG.IRQMODE =10 and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.

   The bit rate can be derived from the timer period register value according to the formula provided in the Auto-baud Detection section.

Using Common Initialization Steps

When using the core or the DMA to execute transfers, the following steps are common to all UART modes.

1. All UART signals are multiplexed and compete with other functions at pin level. First, program the port registers according to the guidelines in the PORT chapter.
2. Program the UART_CLK register. Refer to Bit Rate Generation topic.
3. Program the UART_CTL register and enable the UART clock.

Using Core Transfers

Write data into the UART_THR register, when the UART_STAT.THRE bit is set, to initiate a core transmit operation. If the UART_STAT.DR bit is set, received data can be read from the UART_RBR register.

Using DMA Transfers

1. Make sure that the UART_IMSK.ETBEI or the UART_IMSK.ERBFI bits are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the UART_IMSK.ETBEI or UART_IMSK.ERBFI bits to start the transfer.

Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC).
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART\_CTS}}$ and $\overline{\text{UART\_RTS}}$ polarity through the UART_CTL.FCPOL bit.

ADSP-SC57x UART Register Descriptions

UART (UART) contains the following registers.

Table 15-9: ADSP-SC57x UART Register List

Name	Description
UART_CLK	Clock Rate Register
UART_CTL	Control Register
UART_IMSK	Interrupt Mask Register
UART_IMSK_CLR	Interrupt Mask Clear Register
UART_IMSK_SET	Interrupt Mask Set Register
UART_RBR	Receive Buffer Register
UART_RSR	Receive Shift Register
UART_RXCNT	Receive Counter Register
UART_SCR	Scratch Register
UART_STAT	Status Register
UART_TAIP	Transmit Address/Insert Pulse Register
UART_THR	Transmit Hold Register
UART_TSR	Transmit Shift Register
UART_TXCNT	Transmit Counter Register

Clock Rate Register

The UART_CLK register divides the system clock (SCLK) down to the bit clock.

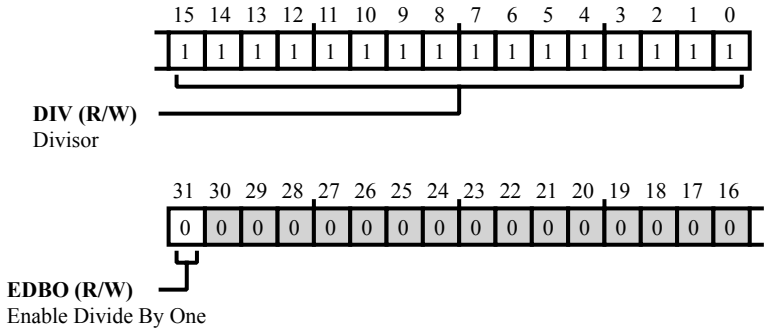

Figure 15-11: UART_CLK Register Diagram

Table 15-10: UART_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EDBO	Enable Divide By One. The UART_CLK.EDBO bit enables the bypassing of the divide-by-16 prescaler in bit clock generation. This functionality improves bit rate granularity, especially at high bit rates. Do not set this bit in IrDA mode. Note: Properly select the SCLK frequencies. Even multiples of bit rate decrease the error percentage. Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. The disadvantage is that the power dissipation is higher and sample points are not always accurate. Therefore, use UART_CLK.EDBO=1 mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode. The UART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.	
		0	Bit clock prescaler = 16
		1	Bit clock prescaler = 1
15:0 (R/W)	DIV	Divisor. The UART_CLK.DIV provides the divisor for the UART's clock bit rate calculation. The bit rate is defined by: Bit Rate = SCLK / ($16^{(1\text{-EDBo})}$ x UART_CLK.DIV)	

Control Register

The UART_CTL register provides enable and disable control for UART and IrDA mode of operation. It also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

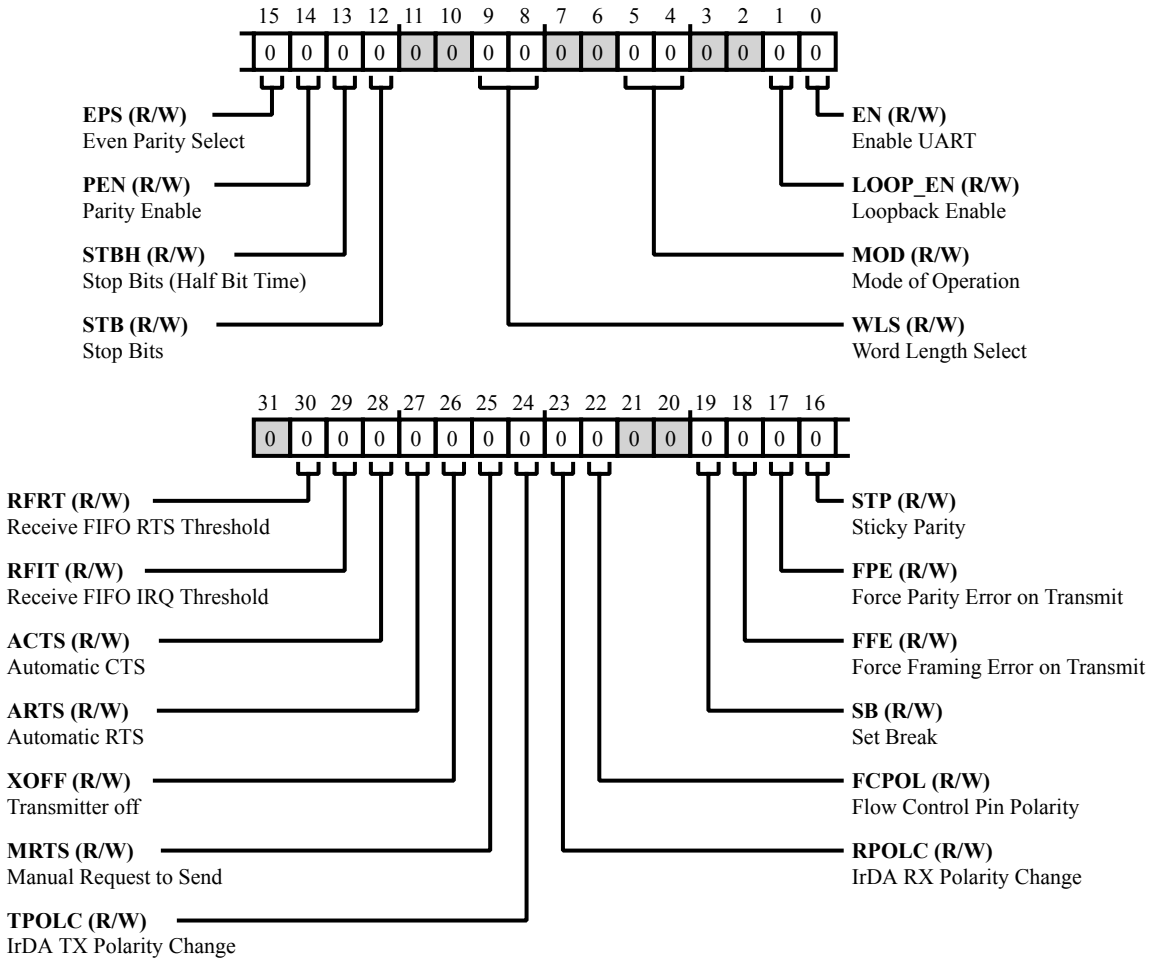

Figure 15-12: UART_CTL Register Diagram

Table 15-11: UART_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RFRT	Receive FIFO RTS Threshold. The UART_CTL.RFRT bit controls UART_RTS pin assertion and deassertion timing. This bit is ignored if UART_CTL.ARTS is cleared. If set, the UART_RTS pin is deasserted when the receive buffer already holds seven words and an eighth start bit is detected. It is reasserted when the FIFO contains seven words or less. If cleared, the UART_RTS pin is deasserted when the RX buffer already holds four words and a fifth start bit is detected. The UART_RTS pin is reasserted when the RX buffer contains no more than 4 words.	
		0	Deassert RTS if RX FIFO word count > 4; assert if <= 4
		1	Deassert RTS if RX FIFO word count > 7; assert if <= 7
29 (R/W)	RFIT	Receive FIFO IRQ Threshold. The UART_CTL.RFIT bit controls the timing of the UART_STAT.RFCS bit. If UART_CTL.RFIT is cleared, the receive threshold is two. If UART_CTL.RFIT is set, the threshold is four words in the receive buffer.	
		0	Set RFCS=1 if RX FIFO count >= 4
		1	Set RFCS=1 if RX FIFO count >= 7
28 (R/W)	ACTS	Automatic CTS. The UART_CTL.ACTS bit must be set to enable the UART_CTS input pin for UART_TX handshaking. If enabled, the UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL is set) or complement value (if UART_CTL.FCPOL is cleared) of the UART_CTS input pin. The UART_STAT.CTS bit can be used to determine whether the external device is ready to receive data (if UART_STAT.CTS is set) or whether it is busy (if UART_STAT.CTS is cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART_TX line transmits data whenever there is data to send, regardless of the value of UART_CTS. Software can pause ongoing transmission by setting the UART_CTL.XOFF bit.	
		0	Disable TX handshaking protocol
		1	Enable TX handshaking protocol
27 (R/W)	ARTS	Automatic RTS. The UART_CTL.ARTS bit must be set to enable the UART_RTS input pin for UART_TX handshaking. If set, the hardware guarantees a minimal UART_RTS pin deassertion pulse width of at least the number of data bits defined by the UART_CTL.WLS bit field. If cleared, the UART_RTS pin is not generated automatically by hardware. The UART_RTS pin can still be manually controlled by the UART_CTL.MRTS bit, and software is responsible for UART_RTS pulse width control (if needed).	
		0	Disable RX handshaking protocol.
		1	Enable RX handshaking protocol.

Table 15-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	XOFF	Transmitter off. The UART_CTL.XOFF bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the UART_CTL.XOFF bit is ignored if the UART_CTL.ACTS bit is set.	
		0	Transmission ON, if ACTS=0
		1	Transmission OFF, if ACTS=0
25 (R/W)	MRTS	Manual Request to Send. The UART_CTL.MRTS bit controls the state of the UART_RTS output pin when the UART_CTL.ARTS bit is cleared. When UART_CTL.MRTS is cleared, the UART deasserts the UART_RTS pin, signaling to the external device that the UART is not ready to receive. When UART_CTL.MRTS is set, the UART asserts the UART_RTS pin, signaling to the external device that the UART is ready to receive.	
		0	Deassert RTS pin when ARTS=0
		1	Assert RTS pin when ARTS=0
24 (R/W)	TPOLC	IrDA TX Polarity Change. The UART_CTL.TPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_TX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_TX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low TX polarity setting
		1	Active-high TX polarity setting
23 (R/W)	RPOLC	IrDA RX Polarity Change. The UART_CTL.RPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_RX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_RX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low RX polarity setting
		1	Active-high RX polarity setting

Table 15-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	FCPOL	Flow Control Pin Polarity. The UART_CTL.FCPOL bit selects the polarities of the UART_CTS and UART_RTS pins. When the UART_CTL.FCPOL bit is cleared, the UART_RTS and UART_CTS pins are active low, and the UART is halted when the UART_RTS and UART_CTS pin state is high. When UART_CTL.FCPOL bit is set, the UART_RTS and UART_CTS pins are active high, and the UART is halted when the UART_RTS and UART_CTS pin state is low.	
		0	Active low CTS/RTS
		1	Active high CTS/RTS
19 (R/W)	SB	Set Break. If set, the UART_CTL.SB bit forces the UART_TX pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the UART_TX pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if UART_CTL.TPOLC is cleared, drive UART_TX pin low; or if UART_CTL.TPOLC is set, drive UART_TX pin high.)	
		0	No force
		1	Force TX pin to 0
18 (R/W)	FFE	Force Framing Error on Transmit. The UART_CTL.FFE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force error
17 (R/W)	FPE	Force Parity Error on Transmit. The UART_CTL.FPE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force parity error

Table 15-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	STP	Sticky Parity. The UART_CTL.STP bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by UART_CTL.STP cleared and UART_CTL.EPS set. Then, the count of logical-1 bits must be a even value. If the UART_CTL.STP bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted UART_CTL.EPS bit.	
		0	No forced parity
		1	Force (Stick) parity to defined value (if PEN=1)
15 (R/W)	EPS	Even Parity Select.	
		0	Odd parity
		1	Even parity
14 (R/W)	PEN	Parity Enable. The UART_CTL.PEN bit enables parity transmission and parity check. The UART_CTL.PEN bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the UART_CTL.STP and UART_CTL.EPS control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they do not match. If the UART_CTL.PEN bit is cleared, the UART_CTL.STP and the UART_CTL.EPS bits are ignored.	
		0	Disable
		1	Enable parity transmit and check
13 (R/W)	STBH	Stop Bits (Half Bit Time).	
		0	0 half-bit-time stop bit
		1	1 half-bit-time stop bit
12 (R/W)	STB	Stop Bits. The UART_CTL.STB bit controls how many stop bits are appended to transmitted data.	
		0	1 stop bit
		1	2 stop bits

Table 15-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	WLS	Word Length Select. The UART_CTL.WLS field determines whether the transmitted and received UART word consists of 5, 6, 7, or 8 data bits.	
		0	5-bit word
		1	6-bit word
		2	7-bit word
		3	8-bit word
5:4 (R/W)	MOD	Mode of Operation. The UART_CTL.MOD selects the UART operation mode (UMOD).	
		0	UART mode
		1	MDB mode
		2	IrDA SIR mode
1 (R/W)	LOOP_EN	Loopback Enable. The UART_CTL.LOOP_EN bit enables UART loopback mode. When set, this bit disconnects the input of the receiver from the UART_RX pin, and internally redirects the transmit output to the receiver. The UART_TX pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to its deassertive state, disconnects the UART_CTS bit from the UART_CTS input pin, and directly connects the UART_CTL.MRTS bit to the UART_STAT.CTS bit. In loopback mode, setting the UART_CTL.MRTS bit sets the UART_STAT.CTS bit and enables the transmitter of the UART. Clearing the UART_CTL.MRTS bit clears the UART_STAT.CTS bit and disables the transmitter of the UART.	
		0	Disable
		1	Enable
0 (R/W)	EN	Enable UART. The UART_CTL.EN enables the UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.	
		0	Disable
		1	Enable

Interrupt Mask Register

The UART_IMSK register indicates the interrupt mask status (unmasked, if set, or masked, if cleared) of the UART status interrupt requests. This register is not a data register. Instead, it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to the UART_IMSK_SET register enables (unmasks) interrupt requests, and writing ones to the UART_IMSK_CLR register disables (masks) them. Reads from either register return the enabled bits.

The UART_IMSK register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of the data inventory state using interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle the data transmit, data receive, and line status events independently, regardless of whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the UART_IMSK.ELSI bit to reroute the transmit and receive interrupts to the status interrupt request output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available for receive and transmit operations. Line error handling can be configured independently from the receive or transmit setup.

The DMA of the UART is enabled by first setting up the system DMA control registers and then enabling the UART_IMSK.ERBFI and UART_IMSK.ETBEI interrupts. This configuration is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit(s). However, the error interrupt for the UART goes directly to the system interrupt handling unit(s), bypassing the DMA unit completely.

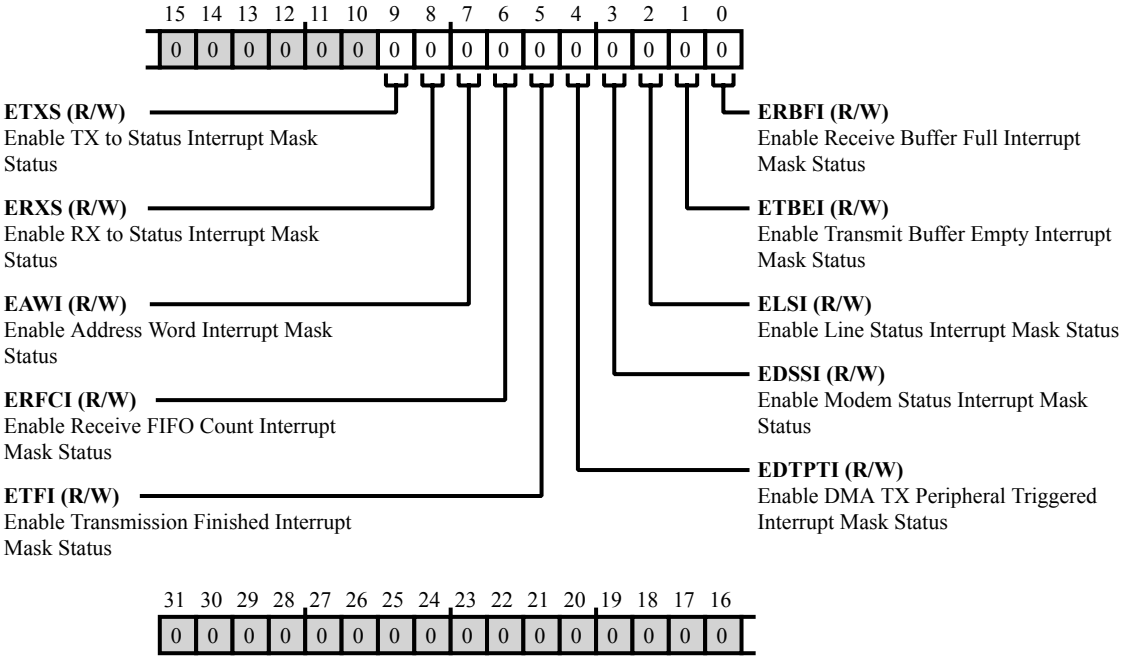

Figure 15-13: UART_IMSK Register Diagram

Table 15-12: UART_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ETXS	Enable TX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETXS` bit indicates re-direction of the TX interrupt requests to status interrupt output. If cleared, TX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
8 (R/W)	ERXS	Enable RX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERXS` bit indicates re-direction of RX interrupt requests to status interrupt output. If cleared, RX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 15-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EAWI	Enable Address Word Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EAWI bit indicates generation of a status interrupt request when an Address word in MDB-mode is present in the UART_RBR. A received word is an address word if the UART_STAT.ADDR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
6 (R/W)	ERFCI	Enable Receive FIFO Count Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERFCI bit indicates enabling of the receive buffer threshold interrupt request if signaled by the UART_STAT.RFCS bit. Read the UART_RBR register sufficient times to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
5 (R/W)	ETFI	Enable Transmission Finished Interrupt Mask Status. If set (interrupt unmasked) the UART_IMSK.ETFI bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the UART_STAT.TFI. The UART_IMSK.ETFI interrupt can be used to avoid expensive polling of the UART_STAT.TEMT bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the UART_STAT.TFI bit to clear the interrupt request. In DMA operation, the UART_IMSK.ETFI bits functionality might be preferred.	
		0	Interrupt is masked
		1	Interrupt is unmasked
4 (R/W)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDTPTI bit indicates enabling of the DMA completion interrupt request to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt request by the time the UART_STAT.TEMT bit goes high after the last DMA data word is transmitted. When UART_IMSK.EDTPTI is set, usually the DMA_CFG.INT field is cleared to 00 in a STOP mode DMA. This set up suppresses the normal completion interrupt request, and the UART_STAT.TEMT event is signaled through the DMA controller and triggers the DMA interrupt. If both (DMA_CFG.INT not 00 and UART_IMSK.EDTPTI set), two interrupts are requested at the end of a STOP mode DMA.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 15-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	EDSSI	Enable Modem Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDSSI bit indicates enabling of a modem status interrupt request on the same status interrupt channel when the UART_STAT.SCTS bit is set. This indicates UART_CTS pin re-assertion. Write-1-to-clear (W1C) the UART_STAT.SCTS bit to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
2 (R/W)	ELSI	Enable Line Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ELSI bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the UART_STAT.OE, UART_STAT.PE, UART_STAT.FE, and UART_STAT.BI interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling UART_IMSK.ELSI disables the RX/TX interrupt channels and negates the UART_IMSK.EDTPTI bit.	
		0	Interrupt is masked
		1	Interrupt is unmasked
1 (R/W)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ETBEI bit indicates generation of a TX interrupt request if the UART_STAT.THRE bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
0 (R/W)	ERBFI	Enable Receive Buffer Full Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERBFI indicates generation of an RX interrupt request if the UART_STAT.DR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Interrupt Mask Clear Register

The UART_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

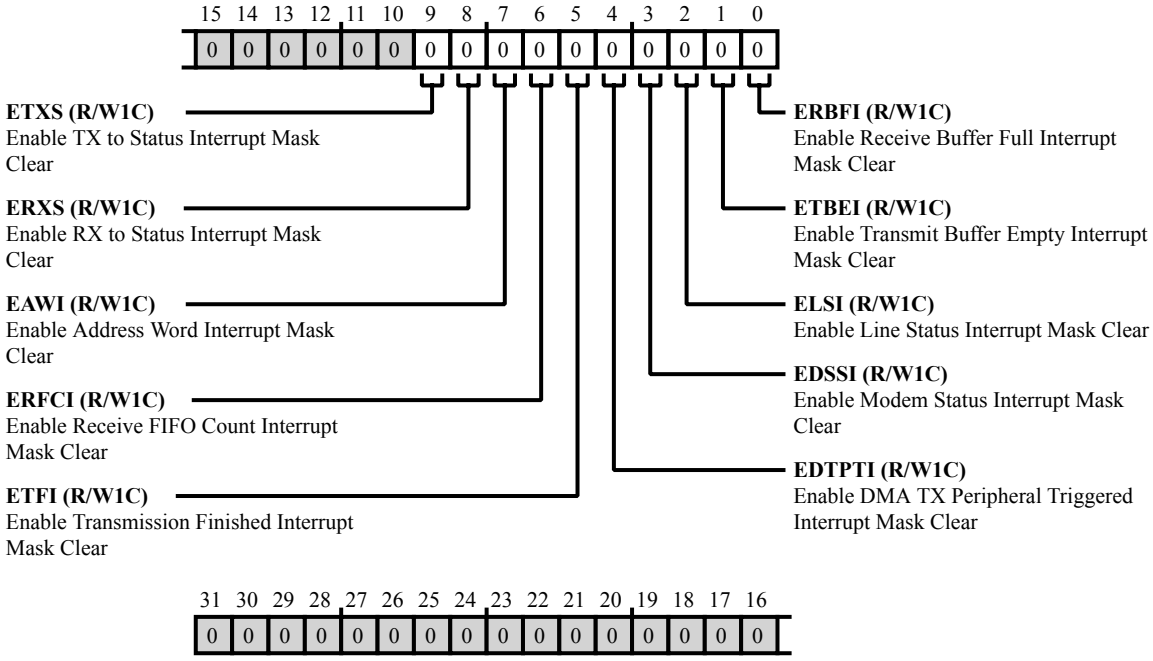

Figure 15-14: UART_IMSK_CLR Register Diagram

Table 15-13: UART_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ETXS	Enable TX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
8 (R/W1C)	ERXS	Enable RX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
7 (R/W1C)	EAWI	Enable Address Word Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Table 15-13: UART_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERFCI	Enable Receive FIFO Count Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
5 (R/W1C)	ETFI	Enable Transmission Finished Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
4 (R/W1C)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
3 (R/W1C)	EDSSI	Enable Modem Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
2 (R/W1C)	ELSI	Enable Line Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
1 (R/W1C)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
0 (R/W1C)	ERBFI	Enable Receive Buffer Full Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Interrupt Mask Set Register

The UART_IMSK indicates interrupt request mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

		0	No action
		1	Unmask interrupt
0 (R/W1S)	ERBFI	Enable Receive Buffer Full Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt

Receive Buffer Register

The read-only UART_RBR register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the UART_STAT.DR bit.

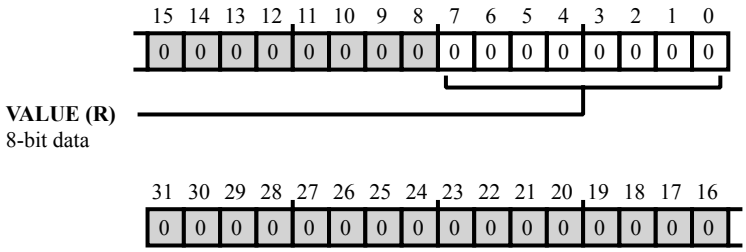

Figure 15-16: UART_RBR Register Diagram

Table 15-15: UART_RBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	8-bit data.

Receive Shift Register

The read only UART_RSR register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the UART_RSR contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

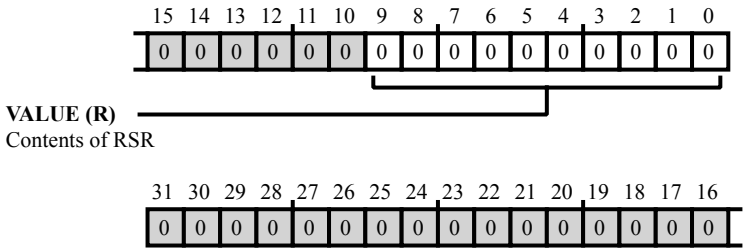

Figure 15-17: UART_RSR Register Diagram

Table 15-16: UART_RSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	VALUE	Contents of RSR.

Receive Counter Register

The UART_RXCNT register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

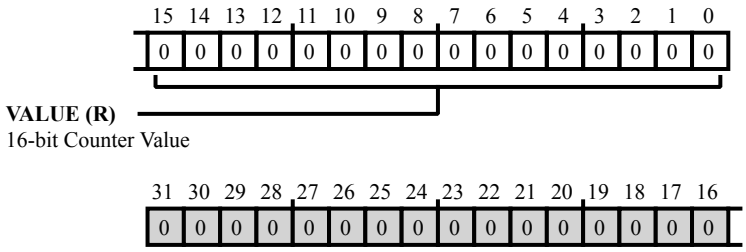

Figure 15-18: UART_RXCNT Register Diagram

Table 15-17: UART_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

Scratch Register

The UART_SCR registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

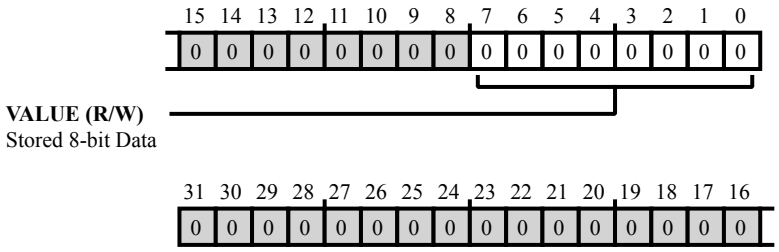

Figure 15-19: UART_SCR Register Diagram

Table 15-18: UART_SCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Stored 8-bit Data.

Status Register

The UART_STAT register contains the UART line status and UART modem status, as indicated by the current states of the UART's UART_CTS pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

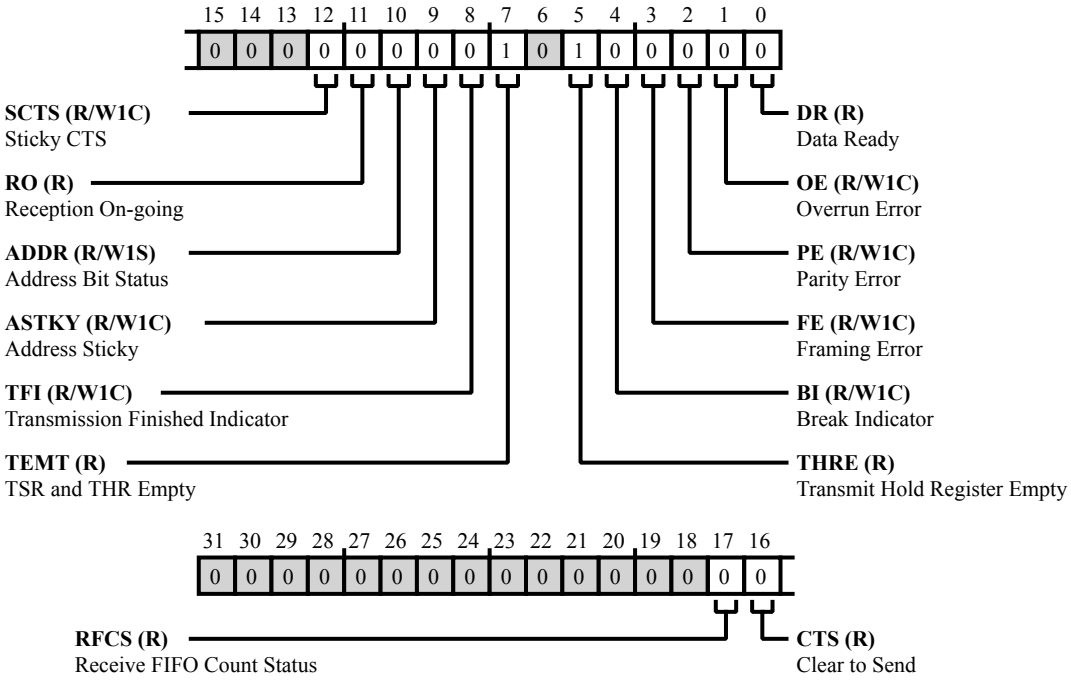

Figure 15-20: UART_STAT Register Diagram

Table 15-19: UART_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RFCS	Receive FIFO Count Status. The UART_STAT.RFCS bit is set when the receive buffer holds more or equal entries than a certain threshold. The threshold is controlled by the UART_CTL.RFIT bit. If UART_CTL.RFIT is cleared, the threshold is four entries. If UART_CTL.RFIT is set, the threshold is seven entries. The UART_STAT.RFCS bit is cleared when the UART_RBR register is read sufficient times until the buffer is drained below the threshold. The UART_STAT.RFCS bit can trigger a status interrupt request if enabled by the UART_IMSK_SET.ERFCI bit.	
		0	RX FIFO has less than 4 (7) entries when RFIT=0 (1)
		1	RX FIFO has at least 4 (7) entries when RFIT=0 (1)

Table 15-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CTS	Clear to Send. The UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL set) or the complement value (if UART_CTL.FCPOL cleared) of the UART_CTS input pin. The UART_CTL.ACTS bit must be set to enable this feature. The core can read the value of the UART_STAT.CTS bit to determine whether the external device is ready to receive (UART_STAT.CTS set) or if it is busy (UART_STAT.CTS cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of UART_STAT.CTS. When UART_CTL.ACTS is cleared, the software can pause transmission temporarily by setting the XOFF bit. Note that in loopback mode (UART_CTL.LOOP_EN set), the UART_STAT.CTS bit is disconnected from the UART_CTS input pin. Instead, the bit is directly connected to the UART_CTL.MRTS bit.	
		0	Not clear to send (External device not ready to receive)
		1	Clear to send (External device ready to receive)
12 (R/W1C)	SCTS	Sticky CTS. The UART_STAT.SCTS bit is a sticky bit that is set when UART_STAT.CTS transitions from 0 to 1. The UART_STAT.SCTS bit is cleared by software with a W1C operation. This bit can trigger a line status interrupt request if enabled by the UART_IMSK_SET.EDSSI bit.	
		0	CTS has not transitioned from low to high
		1	CTS has transitioned from low to high
11 (R/NW)	RO	Reception On-going.	
		0	No data reception in progress
		1	Data reception in progress
10 (R/W1S)	ADDR	Address Bit Status. The UART_STAT.ADDR bit is used to mirror the address bit of the word in UART_RBR in multi-drop bus protocol, and is enabled only in MDB mode. The UART_STAT.ADDR bit is updated by hardware upon detecting a received word with the address bit in UART_RBR set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.	
		0	Address bit is low
		1	Address bit is high

Table 15-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ASTKY	Address Sticky. The UART_STAT.ASTKY bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the UART_STAT.ADDR bit and is set by hardware when setting the UART_STAT.ADDR bit. The UART_STAT.ASTKY bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the UART_STAT.ASTKY bit set, words will be received irrespective of the UART_CTL.MOD bit or UART_STAT.ADDR bit selection. With the UART_STAT.ASTKY bit cleared, only address words (UART_CTL.MOD bit set) will be received and words with UART_CTL.MOD bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The UART_STAT.ASTKY bit does not affect reception in non-MDB modes.	
		0	ADDR bit has not been set
		1	ADDR bit has been set
8 (R/W1C)	TFI	Transmission Finished Indicator. The UART_STAT.TFI bit is a sticky version of the UART_STAT.TEMT bit. While UART_STAT.TEMT is automatically cleared by hardware when new data is written to the UART_THR register, the sticky UART_STAT.TFI bit remains set, until it is cleared by software (W1C). The UART_STAT.TFI bit enables more flexible transmit interrupt request timing.	
		0	TEMT did not transition from 0 to 1
		1	TEMT transition from 0 to 1
7 (R/NW)	TEMT	TSR and THR Empty. The UART_STAT.TEMT bit indicates that the UART_THR and UART_TAIP registers and the UART_TSR register are empty. In this case, the program is permitted to write to the UART_THR and UART_TAIP registers twice without losing data. The UART_STAT.TEMT bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the UART_CTL.EN bit or to three-state the off-chip line driver.	
		0	Not empty TSR/THR
		1	TSR/THR Empty

Table 15-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	THRE	Transmit Hold Register Empty. The UART_STAT.THRE bit indicates that the UART transmit channel is ready for new data and software can write to the UART_THR and UART_TAIP registers. Writes to the UART_THR and UART_TAIP registers clear the UART_STAT.THRE. The bit is set again when the UART_THR and UART_TAIP registers are empty and ready to accept data.	
		0	Not empty THR/TAIP
		1	Empty THR/TAIP
4 (R/W1C)	BI	Break Indicator. The UART_STAT.BI bit indicates that the first stop bit is sampled low and the entire data word, including parity bit, consists of low bits only. (This condition indicates that UART_RX was held low for more than the maximum word length.) The UART_STAT.BI bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The bit is sticky and can be cleared by W1C operations.	
		0	No break interrupt
		1	Break interrupt this indicates UARTxRX was held low(RPOLC=0) / high (RPOLC=1) for more than the maximum word length
3 (R/W1C)	FE	Framing Error. The UART_STAT.FE bit indicates that the first stop bit is sampled. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.FE bit is sticky and can be cleared by W1C operations. Note that invalid stop bits can be simulated by setting the UART_CTL.FFE bit.	
		0	No error
		1	Invalid stop bit error
2 (R/W1C)	PE	Parity Error. The UART_STAT.PE bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.PE bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the UART_CTL.FPE bit.	
		0	No parity error
		1	Parity error

Table 15-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	OE	Overrun Error. The UART_STAT.OE bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the UART_RBR register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the UART_RBR and receive FIFO are protected from being overwritten by new data until the UART_STAT.OE bit is cleared by software. The content of the UART_RSR register is lost as soon as the overrun occurs. The UART_STAT.OE bit is sticky and can be cleared by W1C operations.	
		0	No overrun
		1	Overrun error
0 (R/NW)	DR	Data Ready. The UART_STAT.DR bit indicates that data is available in the receiver and can be read from the UART_RBR register. The bit is set by hardware when the receiver detects the first valid stop bit. The bit is cleared by hardware when the UART_RBR register is read.	
		0	No new data
		1	New data in RBR

Transmit Address/Insert Pulse Register

The UART_TAIP register and the UART_THR register share the same physical register, but UART_TAIP has different effect than the UART_THR register when UART_TAIP is written to in MDB and UART modes.

In MDB mode, data written to the UART_TAIP register is transmitted as an address frame (as with the UART_CTL.MOD bit set).

In UART mode, a write to UART_TAIP causes a pulse of value UART_TAIP [7] for a duration of UART_TAIP [6:0] x bit time. (There is additional inversion if the UART_CTL.TPOLC bit is set).

Bit time is defined by the UART_CLK register. The transmission of the pulse is followed by stop bit transmission as specified by the UART_CTL.STB and UART_CTL.STBH bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to UART_TAIP is treated the same as writes to UART_THR.

Accesses to the UART_TAIP register have the same affects as the UART_THR register with respect to the UART_STAT.THRE, UART_STAT.TEMT, and UART_STAT.TFI flags.

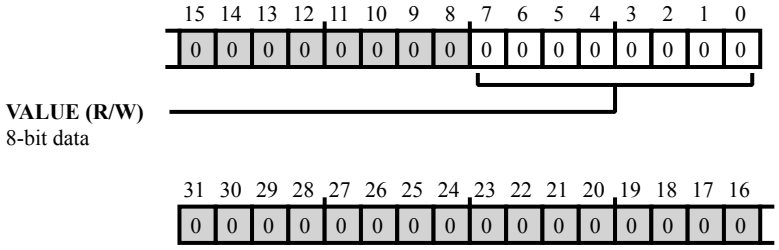

Figure 15-21: UART_TAIP Register Diagram

Table 15-20: UART_TAIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8-bit data.

Transmit Hold Register

The write-only UART_THR register is the UART's transmit buffer. The UART_STAT.THRE bit indicates whether data can be written to UART_THR. Writes to this register automatically propagate to the internal UART_TSR register as soon as UART_TSR is ready. Then, transmit operation is initiated immediately.

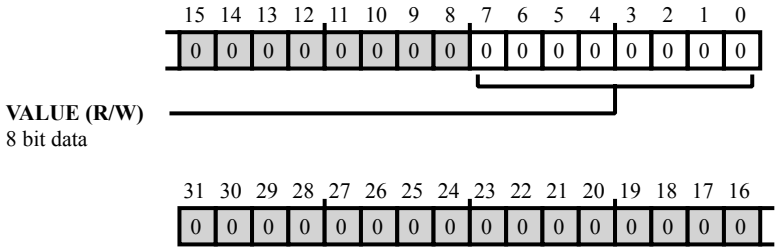

Figure 15-22: UART_THR Register Diagram

Table 15-21: UART_THR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8 bit data.

Transmit Shift Register

The read only UART_TSR register which returns the content of the UART's transmit shift register.

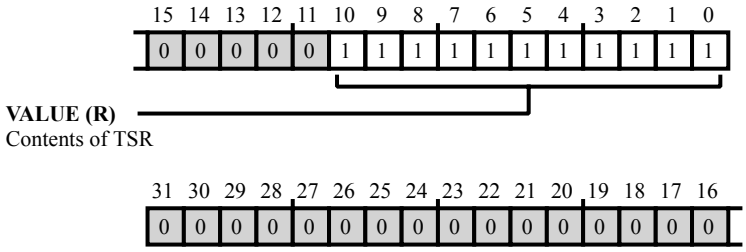

Figure 15-23: UART_TSR Register Diagram

Table 15-22: UART_TSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Contents of TSR.

Transmit Counter Register

The UART_TXCNT read only register returns the content of 16-bit counter in the UART transmitter. This count is used for baud rate clock generation (the lower [15:0] is the count data).

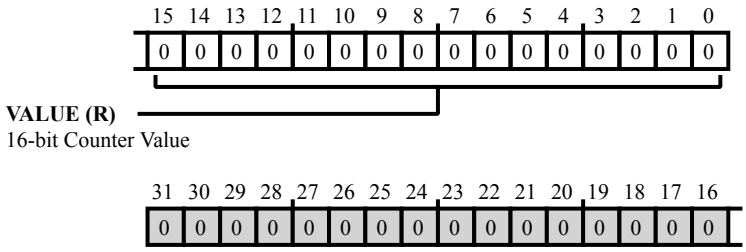

Figure 15-24: UART_TXCNT Register Diagram

Table 15-23: UART_TXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

16 Enhanced Parallel Peripheral Interface (EPPI)

The Enhanced Parallel Peripheral Interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCDs, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has two DMA channels associated with it. Moreover, in some modes, an EPPI can use an extra DMA channel.

EPPI Features

The EPPI module supports the following features.

- Programmable data length from 8 bits to up to 24 bits per clock cycle (depending on the product model)
- Bidirectional and half-duplex port
- Internal or external clock source
- Clock gating by an external device asserting the clock gating control signal
- Various framed and non-framed operating modes, as well as internal or external frame syncs
- Various general-purpose modes with 0, 1, 2, and 3 frame sync modes for both receive and transmit
- Ignores premature external frame syncs for data consistency
- SMPTE274M and SMPTE 296M high definition format support
- ITU-656, SMPTE 296M and SMPTE 274M status word error detection and correction for ITU-656 receive modes
- ITU-656, SMPTE 296M and SMPTE 274M receive modes – active video only, vertical blanking only, and entire field
- ITU-656, SMPTE 296M and SMPTE 274M preamble and status word decode
- Optional packing and unpacking of data to or from 32 bits from or to 8, 16 bits and 24 bits. If packing or unpacking is enabled, endianness can be altered to change the order of packing or unpacking of bytes/words
- Optional sign extension or zero-fill and alternate even or odd data sample filter for receive modes

- RGB888 to RGB666 or RGB565 conversion for transmit modes
- 4:2:2 YCrCb data Tx/Rx interleaving or de-interleaving modes
- Configurable LCD data enable (DEN) output available on frame sync 3
- Delayed start of PPI frame syncs
- Data clipping and mirroring
- Horizontal and vertical windowing for general purpose 2 and 3 frame sync modes
- Preamble, blanking and stripping support
- Multiplexing dual input

EPPI Functional Description

The EPPI has the following functionality.

RGB data formats

For transmit modes, the EPPI can convert RGB888 data in memory to either RGB565 or RGB666 at the output using bits in the Control register.

Data clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. This functionality is used for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes.

Data mirroring

A data mirroring feature is available which mirrors the EPPI data bits 15–0. This functionality is available in both transmit and receive modes.

Windowing

The EPPI supports windowing for general-purpose input modes.

Preamble, blanking and stripping support

The EPPI can embed blanking information and clip active data to be transmitted. This functionality is available for single channel data, interleaved data, and parallel data and supports data lengths equal to 16 bits, 20 bits or 24 bits.

ADSP-SC57x EPPI Register List

The EPPI is a half-duplex, bidirectional parallel port. It comprises a clock pin, 3 frame sync pins, and a set of data pins. For more information on EPPI functionality, see the EPPI register descriptions.

Table 16-1: ADSP-SC57x EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

ADSP-SC57x EPPI Interrupt List

Trigger ID	Name	Description	Sensitivity
30	EPPI0_CH0_DMA	EPPI0 Channel 0 DMA	Pulse
31	EPPI0_CH1_DMA	EPPI0 Channel 1 DMA	Pulse

RGB Data Formats

For transmit modes, the EPPI can convert RGB888 data in memory to RGB666 at the output when the EPPI_CTL.RGBFMTEN bit is set and the EPPI_CTL.DLEN value is equal to 18 bits. Similarly, the EPPI can convert RGB888 data in memory to RGB565 at the output when the EPPI_CTL.RGBFMTEN bit is set and EPPI_CTL.DLEN is equal to 16 bits.

This conversion is performed as follows:

- If EPPI_CTL.PACKEN =1, the EPPI first unpacks according to the EPPI_CTL.SWAPEN bit setting, and the three 32-bit data words from the DMA are broken into four 24-bit data words to be transmitted out, as described earlier.
- If EPPI_CTL.PACKEN =0, the EPPI takes the lower 24 bits of the 32-bit DMA as the data to be transmitted. Then, the EPPI truncates this 24-bit data word to the required data width. It removes the lower 2 bits of G and the lower 2 bits or 3 bits of R and B.

Data Clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. It uses these registers for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes. All data values for odd samples which are less than the value in the EPPI_ODDCLIP.LOWODD bit field are replaced with the value in the EPPI_ODDCLIP.LOWODD field. All data values for even samples which are less than the value in the EPPI_EVENCLIP.LOWEVEN field are replaced with the value in the EPPI_EVENCLIP.LOWEVEN field.

In the same manner, all data values for odd samples which are more than the value in the EPPI_ODDCLIP.HIGHODD bit field are replaced with the value in the EPPI_ODDCLIP.HIGHODD field. All data values for even samples which are more than the values in the EPPI_EVENCLIP.HIGHEVEN field are replaced with the values in the EPPI_EVENCLIP.HIGHEVEN field.

Depending on the programmed EPPI length, only the corresponding bits (least aligned) are considered for clipping. For example, if the EPPI is programmed in 10-bit mode, bits 9:0 and bits 25:16 constitute the clipping thresholds. The higher bits are ignored. The EPPI supports 8-bit, 10-bit, 12-bit, and 16-bit clipping thresholds.

For the 4:2:2 YCrCb color space, Luma and Chroma typically have different lower and upper thresholds. Separate thresholds can be required for even and odd data samples. For monochrome (Y only) or some non-video clipping applications, the value in the EPPI_ODDCLIP.LOWODD field can be the same as the value in the EPPI_EVENCLIP.LOWEVEN field. The value in the EPPI_ODDCLIP.HIGHODD field can be the same as the value in the EPPI_EVENCLIP.HIGHEVEN field.

In GP 0 FS mode with internal blanking generation, clipping is valid only for the active video part of the transmitted data. ITU-R 656 preambles, status words, and blanking data bypass the clipping logic.

If the EPPI is programmed in 16, 20-bit or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the YDATA (luma data) gets the clipping threshold levels of the EPPI_EVENCLIP register. The CDATA (chroma data) gets the clipping threshold levels of the EPPI_ODDCLIP register.

The clipping registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

Data Mirroring

To increase the pin multiplexing options for the EPPI data pins, a data mirroring feature is available which mirrors the EPPI data bits 15:0. This feature is available in both transmit and receive modes. It is enabled by setting the EPPI_CTL.DMIRR bit.

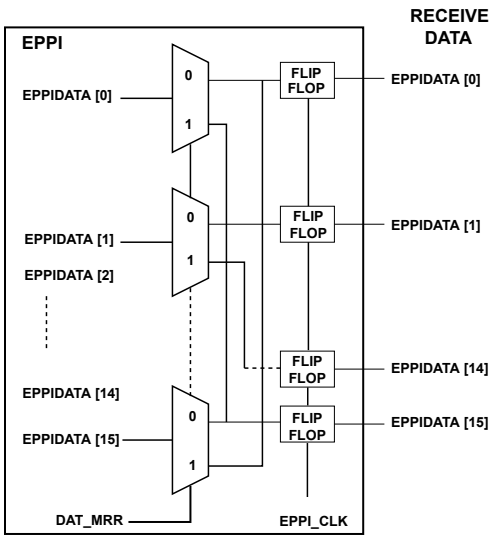

Figure 16-1: Data Mirroring Receive

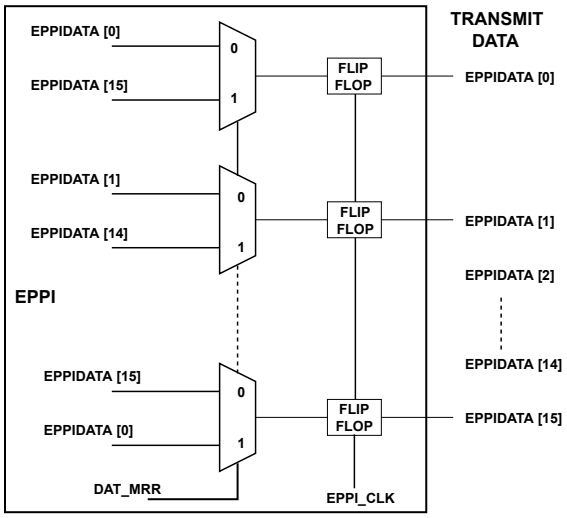

Figure 16-2: Data Mirroring Transmit

Windowing

The EPPI supports windowing for general-purpose input modes. The module can be configured to bring in a region of interest instead of the entire frame of data, which helps reduce bandwidth requirements.

Preamble, Blanking and Stripping Support

The EPPI supports embedding blanking information and clipping of active data for transmission. This functionality is available for single-channel data, interleaved data, and parallel data and supports a data length (`EPPI_CTL.DLEN`) of 16, 20 bits or 24 bits.

Support of preamble generation or detection and stripping of blanking information is also provided for ITU656 mode and the SMPTE 274M and 296M HD formats. The ***Video Mode Comparison*** table shows the SMPTE standards in comparison with the ITU656 modes. Preambles for SMPTE and ITU656 modes are identical. Extension of preamble to 12 bits is also supported.

Table 16-5: Video Mode Comparison

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
ITU656 (NTSC)	30	1716x525	720x480	27.02	Y-C interleaved
ITU656 (PAL)	25	1728x625	720x576	27.00	Y-C interleaved
SMPTE 296M	30	3300x750	1280x720	74.25	Y,C separate
	60	1650x750	1280x720	74.25	Y,C separate

Table 16-5: Video Mode Comparison (Continued)

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
SMPTE 274M	30	2200x1125	1920x1080	74.25	Y,C separate
	60	2200x1125	1920x1080	148.50	Y,C separate
	25	2640x1125	1920x1080	74.25	Y,C separate
	50	2640x1125	1920x1080	148.50	Y,C separate
	24	2750x1125	1920x1080	74.25	Y,C separate

See the clock operating conditions section of the data sheet for the maximum sampling frequency for this product.

EPPI Definitions

The following definitions are helpful when using the EPPI module.

ITU-R BT.-656

Description of a digital video protocol for interfaces and data stream format required to send uncompressed PAL or NTSC standard definition TV (525 or 625 lines) signals.

YUV422

YUV is a color space where luminance (Y) and chrominance (UV) components define the pixels. The suffix signifies how the chrominance components have been decimated and provide formatting information. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component is available. Typical YUV422 formatting interleaves the luminance and chrominance (for example, U1Y1V1Y2U2Y3V2Y4).

RGB888

RGB is a color space where three color values, one red (R), one green (G) and one blue (B), define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green, and blue value is 8 bits.

RGB565

RGB is a color space where three color values, one red (R), one green (G) and one blue (B) define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB565 means that the red (R) and blue (B) are 5 bits each while the green (G) is 6 bits. When packed together, each RGB565 pixel can be represented in a 16-bit data word. LCD display panels commonly use this format.

SMPTE 274M

An HD standard defining the spatial resolution (image sample structure) and frame rates for 1920x1080.

SMPTE 296M

An HD standard for defining the spatial resolution (image sample structure) and frame rates fro 1280x720.

EPPI Block Diagram

The ***EPPI Block Diagram*** figure shows the functional blocks within the EPPI.

EPPI Architectural Concepts

The following sections describe the architectural concepts.

- Reset Operation
- Frame Sync Polarity and Sampling Edge
- Direct Memory Access (DMA)
- EPPI Clock

Reset Operation

On a hardware reset, the entire EPPI is reset. All MMRs return to their default values. EPPI interrupt and DMA requests become inactive and internally generated `EPPI_CLK` and frame syncs are aborted.

In software, write 0 to the `EPPI_CTL.EN` bit to reset and reconfigure the EPPI. When disabled in this manner, only the `EPPI_STAT` register is cleared to its reset value. Interrupts and DMA requests become inactive and internally generated clock and frame syncs are aborted.

Frame Sync Polarity and Sampling Edge

The `EPPI_CTL.POLS` and `EPPI_CTL.POLC` bits provide a mechanism to select the active level of the frame syncs and the sampling or driving edge of the EPPI clock, respectively. This functionality allows the EPPI to connect to data sources and receivers with a wide array of control signal polarities. Often, the remote data source or receiver also offer configurable signal polarities. In these cases, the `EPPI_CTL.POLS` and `EPPI_CTL.POLC` bits add flexibility.

Table 16-6: Frame Sync Polarity Selections and Frame Sync Pin States

Bit Setting	Frame Sync 2	Frame Sync 1
POLS = b#00	Active high	Active high
POLS = b#01	Active high	Active low
POLS = b#10	Active low	Active high

Table 16-6: Frame Sync Polarity Selections and Frame Sync Pin States (Continued)

Bit Setting	Frame Sync 2	Frame Sync 1
POLS = b#11	Active low	Active low

Table 16-7: Clock Polarity Selections and Receive/Transmit Pin States

	Receive		Transmit	
Bit Setting	Sample Data	Sample/Drive Syncs	Drive Data	Sample/Drive Syncs
POLC = b#00	Falling edge	Falling edge	Rising edge	Rising edge
POLC = b#01	Falling edge	Rising edge	Rising edge	Falling edge
POLC = b#10	Rising edge	Falling edge	Falling edge	Rising edge
POLC = b#11	Rising edge	Rising edge	Falling edge	Falling edge

Direct Memory Access (DMA)

The EPPI has a native DMA controller with two channels. A local arbiter arbitrates between these channels and requests are forwarded to the system crossbar. The EPPI has one connection to the fabric.

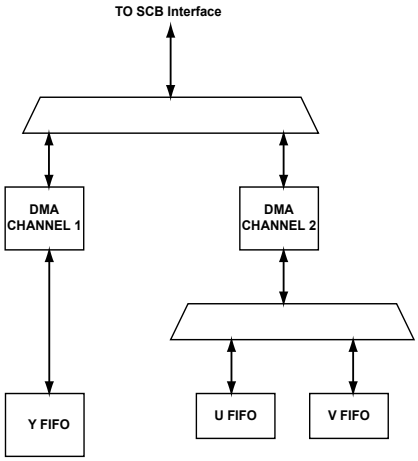

Figure 16-3: EPPI DMA Interface

The EPPI must be used with DMA. Configuring the EPPI DMA channels is a necessary step toward using the EPPI interface. The channels can be configured for either transmit or receive operation, and have a maximum throughput of (EPPI_CLK) x (32 bits/transfer). In modes where data lengths permit, packing can increase transfer bandwidth.

The DMA engine generates interrupts at the completion of a row, frame, or partial-frame transfer. The DMA engine also coordinates the source or destination point for the data that is transferred through the EPPI.

The 2D DMA capability allows the processor to be interrupted at the end of a line or after a frame of video is transferred, or if a DMA error occurs. The DMA_XCNT and DMA_YCNT registers allow for flexible data interrupt points. For example, assume the DMA_XMOD = DMA_YMOD =1. If a data frame contains 320 × 240 bytes (240 rows of 320 bytes each), the following conditions hold.

- Setting DMA_XCNT =320, DMA_YCNT = 240, and DMA_CFG.INT =1 interrupts on every row transferred, for the entire frame.
- Setting DMA_XCNT =320, DMA_YCNT =240, and DMA_CFG.INT =2 interrupts only on the completion of the frame (when 240 rows of 320 bytes have been transferred).
- Setting DMA_XCNT =38,400 (320 x 120), DMA_YCNT =2, and DMA_CFG.INT =1 causes an interrupt when half of the frame is transferred, and again when the whole frame is transferred.

The following is the general procedure for setting up DMA operation with the EPPI.

1. Configure the DMA registers as appropriate for the desired DMA operating mode.
2. Enable the DMA channel for operation.
3. Configure appropriate EPPI registers.
4. Enable the EPPI by writing 1 to the EPPI_CTL.EN bit.

EPPI Clock

The EPPI can be supplied with an external clock, or the clock can be generated internally and supplied to external devices. For information on the maximum PPI_CLK specification in internal and external clock modes, see the product-specific data sheet.

When using an external EPPI_CLK, there can be up to two cycles latency before valid data is received or transmitted.

The internal clock can be generated from SCLK when the EPPI_CTL.ICLKGEN bit is set. The value in the EPPI_CLKDIV register determines the generated clock frequency. The internally generated EPPI clock frequency is:

$f_{PCLK} = f_{SCLK0}/(EPPI\_CLKDIV + 1)$

where:

f_{PCLK} – frequency of internally generated EPPI clock

f_{SCLK} – frequency of SCLK

EPPI_CLKDIV – Clock division value programmed in the EPPI_CLKDIV register.

The ***Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock*** table gives a few examples.

Table 16-8: Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock

CLKDIV15–0	EPPI/SCLK0 Clock Ratio
0x0002	1:3
0x0003	1:4
0x0004	1:5

Table 16-8: Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock (Continued)

CLKDIV15–0	EPPI/SCLK0 Clock Ratio
0x0005	1:6
...	...

EPPI Operating Modes

The EPPI supports various receive and transmit modes of operation which include the detection and generation of preamble data. Specifically, the EPPI supports data formats described in the specifications ITU656, SMPTE 274M and SMPTE 296M. In addition to these modes, the EPPI also supports general-purpose receive and transmit using up to three frame syncs (FS).

The control register (`EPPI_CTL`) includes most of the bits used for configuring operating modes. The “Register Descriptions” section of this chapter provides complete descriptions of these bits.

ITU-R 656 Modes

The EPPI supports three input modes and one output mode for ITU-R 656 framed data. This section describes these modes.

ITU-R 656 Background

In ITU-R 656 mode, the horizontal (H), vertical (V), and field (F) signals are sent as an embedded part of the video data stream. The signals are sent in a series of bytes that form a control word. ITU-R 656 was formerly known as CCIR-656.

The letter H is used to distinguish between the *start of active video* (SAV) and *end of active video* (EAV) signals. These signals indicate the beginning and end of active video data in each line. The SAV occurs on a 1-to-0 transition of H, and EAV occurs on a 0-to-1 transition of H. The space between EAV and SAV is filled with horizontal blanking data. Therefore, H = 1 during the horizontal blanking portion of the data stream, and H = 0 during the active video portion of the data stream.

The letter V is used to denote the vertical blanking portion of the data stream. A transition in V can occur only in the EAV sequence. When V = 1, the data stream contains vertical blanking data, and when V = 0, the data stream contains active video data.

The letter F is used to distinguish Field 1 from Field 2. Interlaced video has two fields in a frame of data. It requires each field to be handled uniquely, and alternate rows of each field combined to create the actual video image.

For interlaced video, F = 0 represents Field 1 (*Odd Field*) and F = 1 represents Field 2 (*Even Field*). Progressive video makes no distinction between Field 1 and Field 2, and F is always 0 for progressive video. Interlaced video requires each field to be handled uniquely because alternate rows of each field combine to create the actual video image.

An entire field of video is comprised of active video plus horizontal blanking (the space between an EAV and SAV code) and vertical blanking (the space where V = 1). A field of video commences on a transition of the F bit.

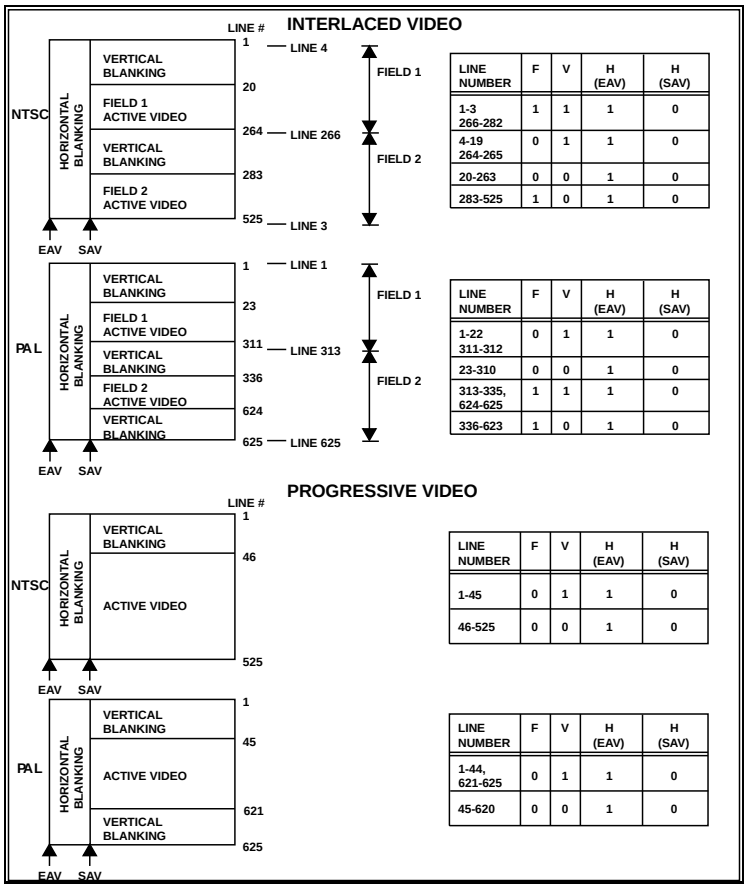

Figure 16-4: Typical Video Frame Partitioning for NTSC/PAL Systems in Interlaced and Progressive ITU-R BT.656 Systems

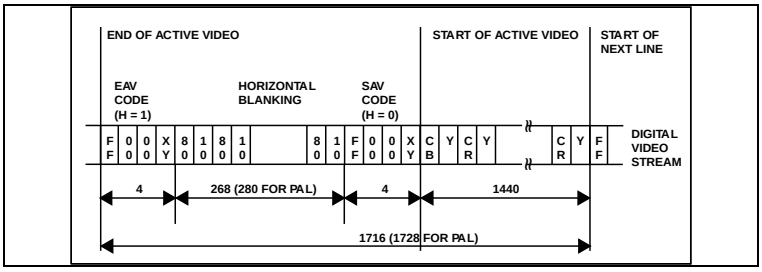

Figure 16-5: ITU-R 656 8-Bit Parallel Data Stream from NTSC (PAL) Systems

NOTE: Refer to the ***Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video*** table. There is a defined preamble of three data elements (for example, in the case of 8-bit video: 0xFF, 0x00, 0x00), followed by the XY status word. The status word contains four protection bits for error detection and correction excluding the F (field), V (vertical blanking), and H (horizontal blanking) bits. F and V are only allowed to change as part of EAV sequences (that is, transition from H = 0 to H = 1).

The bit definitions are as follows:

- F = 0 for field 1
- F = 1 for field 2

- V = 1 during vertical blanking
- V = 0 when not in vertical blanking
- H = 0 at SAV
- H = 1 at EAV
- P3 = V XOR H
- P2 = F XOR H
- P1 = F XOR V
- P0 = F XOR V XOR H

P3–P0 are protection bits that enable 1-bit and 2-bit error detection, and 1-bit error correction at the receiver. The EPPI corrects the error if it detects 1-bit errors in F, V, or H. Errors in the protection bits themselves are detected but not corrected.

Table 16-9: Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video

	8-Bit Data								10-Bit Data	
	D9 (MSB	D8	D7	D6	D5	D4	D3	D2	D1	D0
Preamble	1	1	1	1	1	1	1	1	1	1
	0	0	0	0	0	0	0	0	0	0
	0	0	0	0	0	0	0	0	0	0
Control Byte	1	F	V	H	P3	P2	P1	P0	0	0

The EPPI_STAT register contains 2 bits, EPPI_STAT.ERRDET and EPPI_STAT.ERRNCOR, that are used to report the status of error detected and error not corrected, respectively.

The EPPI_STAT.ERRDET bit is set whenever an error is detected in the status word. However, this bit does not generate an interrupt. The EPPI_STAT.ERRNCOR bit is set when more than a 1-bit error is detected in the status word. An interrupt is generated when the EPPI_STAT.ERRNCOR bit is set. It can be cleared by clearing the EPPI_STAT.ERRNCOR and EPPI_STAT.ERRDET bits. Both bits are sticky and W1C.

In many applications, video streams other than the standard NTSC/PAL formats (for example, CIF, QCIF) can be employed. The processor interface is flexible enough to accommodate different row and field lengths. In general, as long as the incoming video has the proper EAV/SAV codes, the EPPI can read it in. A CIF image could be formatted to be 656-compliant, where EAV and SAV values define the range of the image for each line. The V and F codes are used to delimit fields and frames.

The following sections provide descriptions of EPPI operations.

Table 16-10: Operating Modes and Generic EPPI Operation

		How to configure	Useful for	How to configure in ITU R 656 Tx Mode

	Rx	DIR = 0 XFRTYPE = b#11 FSCFG = b#11		

ITU-R 656 Input Modes

In the ITU-R 656 input modes, the video source provides the clock or the system supplies it externally.

As shown in the ***ITU-R 656 Input Submodes*** figure and described in the following sections, there are three submodes supported for ITU-R 656 inputs: entire field, active video only, and vertical blanking interval only.

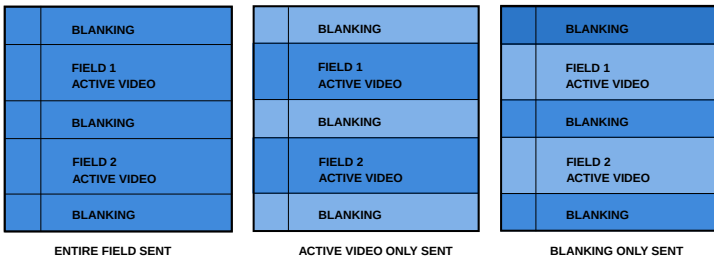

Figure 16-6: ITU-R 656 Input Submodes

Entire Field

In this mode, the EPPI reads the entire incoming bit stream. This stream includes active video as well as control byte sequences and ancillary data that can be embedded in horizontal and vertical blanking intervals.

Data transfer starts immediately after Field 1 synchronization occurs. The transfer does not include the first EAV code that contains the F = 0 assignment for interlaced video or the V = 0 assignment for progressive video.

Active Video

The EPPI uses this mode when only the active video portion of a field is of interest. The EPPI ignores (does not read in) all data between EAV and SAV, as well as all data present when V = 1. Furthermore, the control byte sequences are not stored to memory. The EPPI filters the sequences. After the start of Field 1 synchronizes, the EPPI ignores incoming samples until it sees an SAV.

In active video mode, programs must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. Programs must specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.

In this mode, any input data sequence that is considered part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appear in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually and not be tagged along with the preamble sequence FF, 00, 00. This functionality also applies to vertical blanking interval mode.

Vertical Blanking Interval (VBI)

In this mode, data transfer is only active while V = 1 is in the control byte sequence. This functionality indicates that the video source is in the midst of the vertical blanking interval (VBI), which is sometimes used for ancillary data transmission. The ITU-R 656 recommendation specifies the format for these ancillary data packets, but the EPPI is not equipped to decode the packets themselves. Software must handle this task. Horizontal blanking data is logged where it coincides with the rows of the VBI.

The VBI is split into two regions within each field. The EPPI considers these two separate regions as one contiguous space. However, frame synchronization begins at the start of Field 1, which does not necessarily correspond to the start of vertical blanking. For instance, in 525/60 systems, the start of Field 1 (F = 0) corresponds to line 4 of the VBI.

In VBI mode, the program must specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. The program must specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.

In this mode, any input data sequence that is considered as part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appears in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually, and not be tagged along with the preamble sequence FF, 00, 00. This functionality applies to active video mode too.

ITU-R 656 Output in General-Purpose Transmit Modes

In GP transmit mode, the EPPI frames an ITU-R 656 output stream with the proper preambles and blanking intervals by setting the EPPI_CTL.BLANKGEN bit. The EPPI fetches active data from memory through the DMA channel, saving DMA bandwidth. The EPPI generates and embeds the proper preamble, status word (EAV and SAV sequences), and blanking data along with the active video from memory. Program the EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF, and EPPI_FS1_WLHB registers to perform the desired functions. The EPPI can also drive out the frame syncs using the EPPI_CTL.FSCFG bit setting.

The ***16-Bit Transmit with Internal Blanking Generation*** figure shows the bit stream format in 16-bit transmit modes with blanking generation (EPPI_CTL.BLANKGEN enabled). Each 16-bit data sample consists of 8-bit luma (Y) and 8-bit chroma (Cr or Cb) components. During transmission, the chroma data and blanking bytes of value 0x80 are placed on the upper half (MSBs) of the data lines. The luma data and blacking bytes of value 0x10 are placed on the lower half (LSBs) of the data lines.

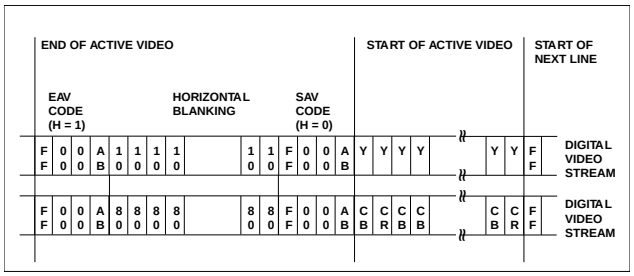

Figure 16-7: 16-Bit Transmit with Internal Blanking Generation

The ***Generated Blanking Preamble Sequence*** figure shows the data transmitted by the EPPI in this mode. After the EPPI is enabled, and if the EPPI FIFO is not empty, the transmission starts by sending out an EAV sequence for a vertical blanking line. For interlaced video, F starts at 1. For progressive video, F is always 0.

NOTE: Internal blanking generation functionality is valid only when the data length is 8, 10, or 16 bits and when the EPPI is in GP transmit modes. The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

The internal blanking generation functionality of the ITU-R 656 output mode can also be bypassed by clearing the EPPI_CTL.BLANKGEN bit. (For example, if sending ancillary data in the blanking interval). The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

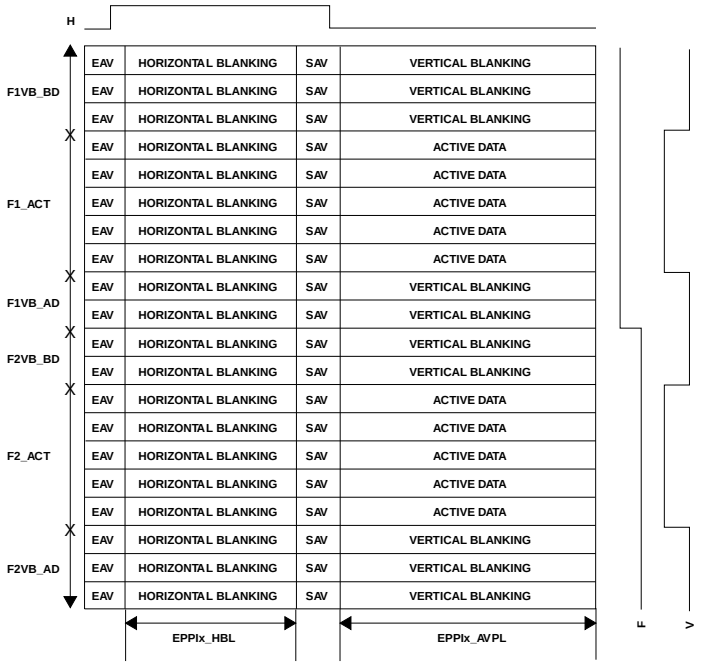

Figure 16-8: Generated Blanking Preamble Sequence

Frame Synchronization in ITU-R 656 Modes

For interlaced video, the start of frame synchronization occurs when a high-to-low transition is detected in F, the field indicator. For progressive video, the start of frame synchronization occurs when a high-to-low transition is detected in V, the vertical blanking indicator. These transitions in F and V can occur only in the EAV sequence. A start of line is detected on a low-to-high transition in H, the horizontal blanking indicator, which occurs in the EAV sequence as well.

For interlaced video, the start of frame corresponds to the start of field 1. Therefore, up to two fields can be ignored before the EPPI receives data. (For example, if field 1 started before the EPPI-to-camera channel was established). For progressive video, the start of frame corresponds to the start of active video.

Because all H and V signaling is embedded in the data stream in ITU-R 656 modes, the EPPI ignores the count registers (`EPPI_HCNT`, `EPPI_VCNT`). However, the EPPI still uses the `EPPI_FRAME` register to check for synchronization errors. Therefore, program this MMR with the number of lines expected in each frame of video.

The EPPI monitors the number of EAV-to-SAV transitions that occur from the start of a frame until it decodes the end of frame condition. (For example, a transition from F = 1 to F = 0 for interlaced video and a transition from V = 1 to V = 0 for progressive video).

At the end of frame condition, the actual number of lines processed is compared against the value in `EPPI_FRAME`. If there is a mismatch, a frame track error is asserted in the `EPPI_STAT` register. For example, if an SAV transition was missed, the current field only has NUM_ROWS – 1 rows. But, resynchronization occurs at the start of the next frame. When the EPPI receives the entire field, the field status bit is toggled in the `EPPI_STAT` register. This way, an interrupt service routine (ISR) can discern which field was previously read in.

General-Purpose EPPI Modes

The general-purpose (GP) EPPI modes accommodate a wide variety of data capture and transmission applications.

Each EPPI has three bidirectional frame sync pins. The EPPI internally generates frame syncs, or an external device communicating with the EPPI generates them.

GP modes differ based on the number of frame syncs used and the EPPI supports GP 0 FS—GP 3 FS modes.

All the GP modes, except 0 FS mode, support horizontal windowing. GP modes with 2 and 3 frame syncs also support vertical windowing.

For GP transmit modes with internal clock or frame syncs, the EPPI starts generating the clock or frame syncs only when the EPPI FIFO is full for the first time. For GP 0 FS transmit mode, the EPPI only starts transmitting when the EPPI FIFO is full for the first time.

General-Purpose 0 Frame Sync Mode

This mode is useful for applications where periodic frame syncs are not used to frame the data.

After the initial trigger, the EPPI receives or transmits data samples on every clock cycle. However, if the `EPPI_CTL.SKIPEN` bit is set for receive mode, the EPPI receives only alternate data samples.

The `EPPI_LINE`, `EPPI_FRAME`, `EPPI_HCNT`, `EPPI_HDLY`, `EPPI_VCNT`, and `EPPI_VDLY` registers are not valid for GP 0 FS mode. Therefore, windowing is not possible in this mode. Also, line and frame track errors are not applicable in this mode.

GP 0 FS receive mode is further divided into two submodes; internal trigger (`EPPI_CTL.FLDSEL` bit =0) and external trigger (`EPPI_CTL.FLDSEL` bit =1). The submodes are based on how the processor initiates data transmission or reception. GP 0 FS transmit mode is always internally triggered. DMA handles all subsequent data manipulation.

- ***Frame synchronization in GP 0 FS external trigger mode.*** When the EPPI is programmed in external trigger mode, it does not generate the `EPPI_FS1` signal and the external device must provide a trigger. The EPPI starts receiving the data as soon as an `EPPI_FS1` signal assertion is detected. After that, the DMA handles all subsequent data manipulation and any activity on `EPPI_FS1` is ignored.
- ***Frame synchronization in GP 0 FS internal trigger mode.*** When the EPPI is programmed in internal trigger mode, it starts receiving or transmitting data as soon as the EPPI clock is enabled and synchronized. There can be up to four PPI clock cycles of latency before valid data is received or transmitted.

General-Purpose 1 Frame Sync Mode

This mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

The `EPPI_FRAME`, `EPPI_VDLY`, and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not available.

General-Purpose 2 Frame Sync Mode

This mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC signal can be connected to EPPI_FS1 and the VSYNC signal can be connected to EPPI_FS2.

Data Enable in General-Purpose 2 Frame Sync Transmit Mode

The EPPI_FS3 pin functions as a data enable (DEN) pin, when EPPI is configured in GP 2 FS transmit mode and generating the frame sync internally. The bits EPPI_CTL.MUXSEL and EPPI_CTL.CLKGATEN are not enabled. The functionality of the DEN pin is described in the following two cases.

Case 1

Blanking generation is configured using the EPPI_CTL.BLANKGEN bit. EPPI data length (EPPI_CTL.DLEN bit) is configured for 8, 10, or 16-bit transfers. The EPPI_FS3 pin asserts during the *active data* regions, aligned with EPPI_CLK according to the clock polarity (EPPI_CTL.POLC bit) settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The pin EPPI_FS3 is driven out on the same EPPI clock edge that drives out data. The frame sync polarity (EPPI_CTL.POLS) setting does not apply here—EPPI_FS3 is always active high in this mode.

Case 2

Blanking generation (EPPI_CTL.BLANKGEN =0) is disabled. Or blanking generation is enabled, but the EPPI data length (EPPI_CTL.DLEN bit) is configured for a transfer size other than 8, 10, or 16 bits. The EPPI_FS3 pin asserts at the start of the active data region on each line, aligned with EPPI_CLK according to the EPPI_CTL.POLC bit settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The EPPI_FS3 signal is driven out on the same EPPI clock edge that drives out data.

The EPPI_CTL.POLS bit setting does not apply for case 2. The EPPI_FS3 signal is always active high in this mode. Once asserted, EPPI_FS3 stays asserted for the number of clock cycles per line configured in the EPPI_HCNT register, then it deasserts. This behavior on each line continues for the total number of lines programmed in the EPPI_VCNT register per frame. The behavior repeats at the start of subsequent video frames.

In case 2, if transmission of valid data is held off due to delays programmed in the EPPI_HDLY or EPPI_VDLY registers, the assertion of EPPI_FS3 is also held off. The delay is on a per-line or per-frame basis.

General-Purpose 3 Frame Sync Mode

This mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to the EPPI_FS1 pin, VSYNC connects to the EPPI_FS2 pin, and FIELD connects to the EPPI_FS3 pin.

GP 3 FS mode is similar in operation to GP 2 FS mode. However, the start of frame synchronization in GP 3 FS also considers the state of the EPPI_FS3 pin. All the windowing register settings (EPPI_FRAME, EPPI_LINE, EPPI_HDLY, EPPI_HCNT, EPPI_VDLY, and EPPI_VCNT registers), as well as data reception or transmission and error generation are the same as for GP 2 FS mode. In addition, for GP 3 FS mode with internal frame syncs, the EPPI_CTL.FLDSEL bit setting specifies the condition under which the transfer begins.

The EPPI generates the EPPI_FS3 signal and toggles during every assertion of EPPI_FS2 or a combination of EPPI_FS2 and EPPI_FS1. The toggle depends on the EPPI_CTL.FLDSEL bit setting. The EPPI skips an EPPI_FS2 signal when the EPPI_FS3 value is high. Because of this condition, program the EPPI_FS2 period value to half of the total number of pixels in the frame as in GP 3 FS mode. When in GP 2 FS mode, program the EPPI_FS2 period with the value equal to the number of pixels per frame.

Supported Data Formats

The following sections describe EPPI receive and transmit data formats.

Receive Data Formats

The ***EPPI Receive Data Formats*** table provides information about EPPI configuration for specific use models for receive data.

Table 16-11: EPPI Receive Data Formats

Input Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1 – Four EPPI words are packed to 32-bit DMA data. EPPI_CTL.PACKEN =0 – Each EPPI word is sent as 8-bit data on the 32-bit DMA bus. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Gives I (in phase) and Q (quadrature) components. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 16-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
10	NTSC/PAL data	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1. EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 10-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 SEPPI_CTL.SUBSPLTODD = 0 since there are only two components.
12	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 12-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.
14	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 16-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB565 sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are packed to a 32-bit DMA data. EPPI_CTL.RGBFMTEN is valid only in transmit modes. So, RGB565 cannot be byte aligned in memory. EPPI_CTL.PACKEN =0. Each EPPI word is sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 16-bit case with EPPI_CTL.PACKEN =1
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =0.
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =0.

Transmit Data Formats

The ***EPPI Transmit Data Formats*** table provides information about EPPI configuration for specific use models for transmit data.

Table 16-12: EPPI Transmit Data Formats

Output Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	Serial RGB for lower-resolution LCDs	No splitting possible. EPPI_CTL.PACKEN =1. The 32-bit DMA data is unpacked to drive four EPPI words. EPPI_CTL.PACKEN =0. The lowest 8 bits of the DMA data is driven on the EPPI data and the rest of the 24 bits are discarded. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1.
10	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.

Table 16-12: EPPI Transmit Data Formats (Continued)

Output Data Width	Use Model	Splitting/Packing Options
12	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
14	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	RGB565 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the LSBs from each component to drive out RGB565 data.
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD = 0
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1
18	RGB666 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the 2 LSBs from each component to drive out RGB666 data.

Data Transfer Modes

The following sections describe EPPI data transfer modes, including receive or transmit data packing, sign extension, zero fill, receive or transmit split modes, clock gating, delayed start, and data consistency management.

Data Packing for Receive Modes

For receive modes, if the EPPI_CTL.PACKEN bit =1 and the DMA is 32 bits, the EPPI packs the incoming data into 32-bit words based on the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings. When EPPI_CTL.SWAPEN =0, the EPPI puts the first data in the least significant bits and when EPPI_CTL.SWAPEN =1, the EPPI puts the first data in the most significant bits. The packing options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, four 8-bit words can be packed into one 32-bit word.
- When EPPI_CTL.DLEN =16, two 16-bit words can be packed into one 32-bit word.
- For EPPI_CTL.DLEN values that are more than 8 bits but less than 16 bits, two such words are either sign-extended or zero-filled to 16 bits, and packed into one 32-bit word.
- When EPPI_CTL.DLEN =18, the EPPI sign-extends or zero-fills the 18-bit data to 24 bits and packs four 24-bit words into three 32-bit words.

- When EPPI_CTL.DLEN =24, the EPPI packs four 24-bit words into three 32-bit words.

When EPPI_CTL.PACKEN =0, the EPPI receives the incoming data and sends it on the bus as-is. If EPPI_CTL.DLEN is less than or equal to 16 bits, the DMA is a 16-bit DMA; otherwise it is a 32-bit DMA.

Data Packing for Transmit Modes

For transmit modes, if the EPPI_CTL.DLEN bit =1 and the DMA is a 32-bit DMA, the EPPI unpacks the 32-bit word according to the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings.

If EPPI_CTL.SWAPEN =1, the EPPI transmits the most significant bits as the first data, and if EPPI_CTL.SWAPEN =0, the EPPI transmits the least significant bits as the first data. The unpacking options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, the EPPI transmits one 32-bit word from memory as four 8-bit data words.
- For EPPI_CTL.DLEN values greater than 8 bits but less than or equal to 16 bits, the EPPI transmits one 32-bit word from memory as two 16-bit data words.
- When EPPI_CTL.DLEN =18 or 24, the EPPI transmits three 32-bit words from memory as four data words.

Sign-Extended and Zero-Filled Data

The following list describes the bit settings and functionality for sign-extending and zero-filling data.

- For EPPI_CTL.DLEN equal to 10, 12 or 14, data is zero-filled or sign-extended to 16 bits.
- For EPPI_CTL.DLEN equal to 18 bits, data is zero-filled or sign-extended to 24 bits if packing is enabled, and zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 24 bits, data is zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 8 bits, data is zero-filled or sign-extended to 16 bits if packing is disabled.
- If EPPI_CTL.SIGNEXT =1, then the data is sign-extended, otherwise it is zero-filled.

Split Receive Modes

The control register has three control bits for split receive modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI splits the incoming data stream into two substreams, an even stream, and an odd stream, and packs them separately.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. When EPPI_CTL.SUBSPLTODD =1, the EPPI subsplits the odd substream, and packs the streams separately.
- The EPPI_CTL.DMACFG bit is also available only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Split Transmit Modes

The EPPI_CTL register has three control bits for split transmit modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. The DMA is always a 32-bit DMA. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI receives the Luma (Y3Y2Y1Y0) and interleaved Chroma (Cr1Cb1Cr0Cb0) data as 32 bits from the DMA channel. The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. In this case, if EPPI_CTL.SUBSPLTODD =1, the EPPI receives the Luma (Y3Y2Y1Y0) and deinterleaved Chroma (Cb3Cb2Cb1Cb0 and Cr3Cr2Cr1Cr0). The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit. (The EPPI does not decimate the chroma data when formatting it into 4:2:2.)
- The EPPI_CTL.DMACFG bit is also valid only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Clock Gating

In ITU-R BT.656 and GP 0/1/2 FS modes, EPPI_FS3 becomes a clock-gating input. This functionality is valid for both internally and externally sourced EPPI_CLK, in both receive and transmit modes. This clock gating signal must be synchronous with EPPI_CLK. The external device on the rising edge of EPPI_CLK must drive the clock gating signal. Its function is to hold the sync and data lines in their current state until EPPI_FS3 is driven low. There are no additional latency cycles upon coming out of clock gating mode.

If clock gating is not required, the EPPI_FS3 pin must either be tied to ground, or configured to operate as another of its multiplexed functions.

In GP 2 FS transmit mode with internally generated frame syncs, the EPPI_FS3 pin functions as a data enable signal.

Support for Delayed Start of EPPI Frame Syncs

The EPPI supports a delayed start of the EPPI_FS1 and EPPI_FS2 frame syncs. The EPPI_FS1_DLY and EPPI_FS2_DLY registers are programmable registers corresponding to EPPI_FS1 (HSYNC) and EPPI_FS2 (VSYNC).

The delay programmed in these registers applies to the first active edge of the internally generated frame sync. The delay starts from the first EPPI_CLK edge. The delay counter runs only for the first time and then shuts off until the EPPI is reenabled. (The delay counter is the period counter itself, since they do not run together.) Program the delay registers prior to the first EPPI_CLK edge (similar to the width and period registers). The ***EPPI Delayed Frame Sync Generation*** figure shows the functioning of EPPI_FS1 and EPPI_FS2.

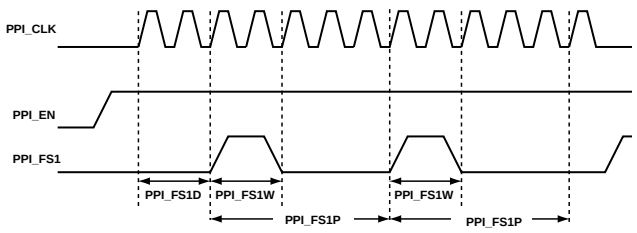

Figure 16-9: EPPI Delayed Frame Sync Generation

Ignoring Premature External Frame Syncs for Data Consistency

Once a frame has started with a VSYNC followed by an HSYNC (or both coming together), a line is tracked. When the count expires, the state machine waits at the end of line for an HSYNC to come. With the arrival of the HSYNC, the state machine starts tracking the next line, and so on.

The number of lines tracked is counted separately. Once the end of a frame is reached, the state machine waits there for the next VSYNC/HSYNC combination. The next frame starts once they are sampled. Unfortunately, every incoming FS (VSYNC or HSYNC) resets the respective counters and the tracking starts all over (even if the FS signals are premature). The result is incomplete data (or frames) to enter into memory through the PxP interface.

To correct this problem, the EPPI waits for a frame or line completion before considering any incoming FS as valid.

- Single FS mode and line tracking in dual FS mode – When a line is in progress, when HSYNC is detected prematurely, it is ignored. A line track underflow event is generated.
- Dual FS mode – If a VSYNC is received when a frame is in progress, it is ignored. A frame track underflow error (`EPPI_STAT.FTERRUNDR`) is generated.

Ignoring the FS ensures that once a frame starts, the amount of data that goes into the memory/PxP interface corresponds exactly to the programmed data size in a frame.

NOTE: Even if the premature FS is a valid FS, the state machine loses at most one frame and it recovers in the subsequent FS. The FS to number of data going into the memory relationship is always maintained as programmed.

When data underflow errors occur at the DMA interface, the EPPI does the following.

- If a premature line sync is detected, an LT underflow error is generated (`EPPI_STAT.LTERRUNDR` =1). All further line track errors are ignored until the EPPI detects the next valid line sync.
- If a premature frame sync is detected, an FT underflow error is generated (`EPPI_STAT.FTERRUNDR` =1). All further frame track and line track errors are ignored until the EPPI detects the next valid frame sync.

EPPI Event Control

The following sections describe how EPPI manages events.

EPPI Status, Error, and Interrupt Signals

The EPPI generates error interrupts (flagged in the EPPI_STAT register) when any one of the following error conditions occur.

- EPPI_STAT.YFIFOERR (YFIFO underflow or overflow)
- EPPI_STAT.CFIFOERR (CFIFO underflow or overflow)
- EPPI_STAT.LTERROVR (line track overflow error)
- EPPI_STAT.LTERRUNDR (line track underflow error)
- EPPI_STAT.FTERROVR (frame track overflow error)
- EPPI_STAT.FTERRUNDR (frame track underflow error)
- EPPI_STAT.ERRNCOR (ITU preamble error not corrected)

A W1C (write-1-to-clear) operation clears the error conditions. Each of the individual conditions which cause an EPPI error interrupt can be masked. The interrupt mask register (EPPI_IMSK) allows the masking of individual conditions which cause error interrupts.

There is only one interrupt line from each EPPI so all interrupts are internally OR'ed and sent as a single interrupt to the core. The EPPI_STAT register must then be read to discover specific errors. The following sections describe these errors in detail.

Frame and Line Track Errors

In external frame sync mode, the EPPI uses line track error (EPPI_STAT.LTERROVR and EPPI_STAT.LTERRUNDR) and frame track error (EPPI_STAT.FTERROVR and EPPI_STAT.FTERRUNDR) status bits to monitor the line and frame synchronization errors. The EPPI updates the bits when there is a mismatch detected in the HSYNC and VSYNC as compared to the programmed values in EPPI_LINE and EPPI_FRAME count registers.

Line Track Errors

The line track overflow (EPPI_STAT.LTERROVR) and underflow errors (EPPI_STAT.LTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them and not at the next frame sync.

- If the frame sync has not arrived when the EPPI_LINE counter expires, then the EPPI_STAT.LTERROVR error is generated.
- When the EPPI_LINE counter is running and a frame sync is detected, the EPPI_STAT.LTERRUNDR error is generated. A W1C operation clears boths interrupts.

Frame Track Errors

The frame track overflow (EPPI_STAT.FTERROVR) and underflow errors (EPPI_STAT.FTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them. When the EPPI_FRAME.VALUE counter expires, the EPPI_STAT.FTERROVR error is reported before the next frame sync arrives.

When the EPPI_FRAME counter is running and a frame sync is detected, then an EPPI_STAT.FTERRUNDR is reported.

Both errors generate an error interrupt. Perform a W1C operation to clear the interrupts at their respective locations in the status register.

A premature frame sync results in a frame track under run error. But, the error is logged (register bit set) only after the subsequent blanking period (if any) elapses.

Preamble Error Not Corrected Error

The EPPI supports data embedded frame syncs in ITU and SMPTE formats. In these formats, the module can receive an erroneous preamble which is not correctable. The EPPI_STAT.ERRNCOR error signals when this event occurs.

EPPI Programming Model

The following sections describe programming techniques, including receiving or transmitting ITU-R 656 frames; configuring transfers in GP0, GP1, GP2, and GP3 modes; and managing EPPI mode configurations.

Receiving ITU-R 656 Frames

The EPPI supports the reception of ITU-R 656 compliant frames.

1. Configure the EPPI to receive either full ITU-R 656 frame, active video, or blanking information by configuring the EPPI_CTL.XFRTYPE bits.
2. In both active video mode and in VBI (vertical blanking information) mode, specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. Specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.
3. Configure DMA descriptors to move the data to memory.
4. Enable DMA.
5. Enable the EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Depending on the EPPI configuration, either the full ITU-R 656 frame is moved to memory or only the active video or only the blanking information.

Transmitting ITU-R 656 Frames in GP Transmit Modes

The EPPI can take active video from memory and generate the proper preambles and blanking information to produce valid ITU-R 656 video frames for transmission.

1. Provide active data frame in memory.
2. Set the EPPI_CTL.BLANKGEN bit so the EPPI generates blanking information.
3. Configure the EPPI_FS1_WLHB, EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF registers accordingly.
4. Configure the rest of the EPPI settings.
5. Configure DMA to fetch active frame data from memory buffers.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The EPPI takes the active data from memory, generates the blanking information, and transmits an ITU-R 656 frame

Configuring Transfers in GP 0 FS Mode

The EPPI can be configured to not use periodic frame syncs to frame the data.

1. Configure the EPPI to operate in GP 0 FS mode by setting EPPI_CTL.XFRTYPE = b#11 and EPPI_CTL.FSCFG = b#00.
2. When receiving, configure the EPPI to trigger on internally or externally by setting the EPPI_CTL.FLDSEL field appropriately. When transmitting, the EPPI always generates a trigger internally.
3. Configure DMA to move the data to or from memory.
4. Enable DMA.
5. Enable EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The DMA descriptions control the amount of data transferred. The frame syncs from the EPPI do not control the amount.

Configuring Transfers in GP 1 FS Mode

The GP 1 FS mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

NOTE: The EPPI_FRAME, EPPI_VDLY, and EPPI_VCNT registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

1. Configure GP 1 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#01. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_LINE register to contain the number clock cycles expected between two assertions of the EPPI_FS1 signal to monitor the line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
3. Program the EPPI_HDLY register to contain the number of clock cycles to wait after the assertion of EPPI_FS1. For example, the start of frame.
4. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each frame.
5. Configure DMA to move the data to or from memory.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then, switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line.

Configuring Transfers in GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC connects to the EPPI_FS1 signal and VSYNC connects to the EPPI_FS2 signal.

1. Configure the EPPI to operate in GP 0 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#10. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_FRAME register to contain the number of expected lines per frame. The value can be equal to the number of EPPI_FS1 signal assertions expected between the start of each frame sync. The EPPI uses the value to monitor frame track errors. Program the EPPI_FRAME register before the EPPI_VCNT register.
3. Program the EPPI_LINE register to contain the number of clock cycles expected between two assertions of the EPPI_FS1 signal to monitor line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
4. Program the EPPI_HDLY register to configure the number of clock cycles to wait after the assertion of the EPPI_FS1 signal. (For example, the start of the line).
5. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each line.

6. Program the EPPI_VDLY register to contain the number of lines to wait after the start of frame is detected.
7. Program the EPPI_VCNT register to contain the number of lines to receive or transmit.
8. If setting up the EPPI for transmit, the data enable (DEN) pin behaves according to the enabling of the blanking generation and the data length setting (DLEN). See Data Enable in General-Purpose 2 Frame Sync Transmit Mode for more details.
9. Enable DMA.
10. Enable the EPPI.
11. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame.

Configuring Transfers in GP 3 FS Mode

GP 3 FS mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to EPPI_FS1, VSYNC connects to EPPI_FS2, and FIELD connects to EPPI_FS3.

1. Configure the EPPI to operate in GP 3 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#11. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Configure the windowing registers according to steps in GP 2 FS mode.
3. Enable DMA.
4. Enable the EPPI.
5. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame. Operation and result are similar to operation in GP 2 FS mode but the EPPI also uses the EPPI_FS3 signal.

Configuring the EPPI to Use the Windowing Feature

Windowing is a useful feature for applications where the region of interest is smaller than the active video stream (for example, sensor calibration, auto-focusing, and others). It can result in significant DMA bandwidth reduction. The EPPI supports windowing for GP input modes.

1. Program the EPPI_FRAME register with the number of lines the frame contains.

2. Program the EPPI_LINE register with the number of samples per line in the frame.
3. Program the EPPI_VDLY register with the number of lines to wait after the start of a new frame before starting to read or transmit data.
4. Program the EPPI_VCNT register with the number of lines to read in or write out after EPPI_VDLY number of lines from the start of the frame.
5. Program the EPPI_HDLY register with the number of clock cycles to delay after the assertion of EPPI_FS1 is detected for the start of a new line.
6. Program the EPPI_HCNT register with the number of samples to read in or write out after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1.

EPPI Mode Configuration

This section describes EPPI mode configurations, including support for all EPPI transmit and receive modes.

Configuring 8-Bit Receive Mode

For 8-bit non-split receive mode and if EPPI_CTL.PACKEN =1, the EPPI packs 4 bytes of incoming data into a 32-bit word. Alternate even or odd samples can be skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

Table 16-13: 8-Bit Receive Mode with Packing Enabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0x11						
0x22						
0x33						
0x44	0x4433 2211	0x1122 3344				
0x55						
0x66						
0x77			0x7755 3311		0x1133 5577	
0x88	0x8877 6655	0x5566 7788		0x8866 4422		0x2244 6688
0x99						
0xAA						
0xBB						

Table 16-13: 8-Bit Receive Mode with Packing Enabled (Continued)

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0xCC	0xCCBB AA99	0x99AA BBCC				
0xDD

0xFF			0xFFDD BB99		0x99BB DDFF	
0x00	0x00FF EEDD	0xDDE EFF00		0x00EE CCAA		0xAACC EE00

If `EPPI_CTL.PACKEN`=0, the DMA is a 16-bit DMA and the EPPI either sign-extends or zero-fills the bytes of incoming data into a 16-bit word. The `EPPI_CTL.SWAPEN` bit has no effect if `EPPI_CTL.PACKEN`=0.

Table 16-14: 8-Bit Receive Mode with Packing Disabled

0xBB	0x00BB	0xFFBB		0xFFBB

Configuring 10/12/14-Bit Receive Modes

For 10, 12, or 14-bit non-split receive modes, the EPPI first either zero-fills or sign-extends the incoming data into a 16-bit word. The action depends on the setting of the `EPPI_CTL.SIGNEXT` bit. If `EPPI_CTL.PACKEN` =1, the EPPI then packs two of these words into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Configuring 16-Bit Receive Mode

For 16-bit non-split receive mode, if `EPPI_CTL.PACKEN` =1, the EPPI packs two 16-bit incoming data into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and

EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

0x8888	0x8888		0x8888

Configuring 18-Bit Receive Mode

For 18-bit non-split receive mode, if EPPI_CTL.PACKEN =0, the EPPI zero-fills or sign-extends the incoming data into a 32-bit word. If EPPI_CTL.PACKEN =1, the EPPI first zero-fills or sign-extends the incoming data to 24 bits, and then packs four such 24-bit data words into three 32-bit words. Alternate even or odd samples can be

skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The EPPI_CTL.SWAPEN bit has no effect.

Table 16-21: 18-bit Receive Mode with Packing Disabled

When the bits settings are `EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =1 and `EPPI_CTL.DMACFG` =0, the EPPI packs the second Chroma component sent over the DMA bus completely before the Luma component. However, it is intentionally held until that previous word is moved out. This functionality allows the separation of Luma and Chroma values into individual buffers when using 2D-DMA. The second Chroma component is U0U1U2U3 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0*** and ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** tables. The Luma component is Y4Y5Y6Y7 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** table.

Configuring 10/12/14/16-Bit Split Receive Mode with SPLTWRD=0

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. For 10, 12, or 14-bit split receive modes, the EPPI first either sign-extends or zero-fills the incoming data into a 16-bit word. The EPPI then packs two of these words into one 32-bit word to send to the DMA.

Table 16-25: 16-bit Split Receive Mode with SPLTWRD = 0, SKIPEN = 0 and SWAPEN = 0

Configuring 8-Bit Transmit Mode

For 8-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into 4 bytes to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the lower 8 bits. The `EPPI_CTL.SWAPEN` bit has no effect when `EPPI_CTL.PACKEN` =0.

Table 16-28: 8-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x11223344	0x44	0x11
0x55667788	0x33	0x22
	0x22	0x33
	0x11	0x44
	0x88	0x55
	0x77	0x66
	0x66	0x77

Table 16-28: 8-bit Transmit Mode with Packing Enabled (Continued)

	0x55	0x88

Table 16-29: Data Sent in 8-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x34
0x2345	0x45
0x3456	0x56

Configuring 10/12/14-Bit Transmit Modes

For 10, 12, or 14-bit non-split transmit modes, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words. The EPPI then transmits the required LSBs from each data word. The EPPI transmits either the most significant word or the least significant word as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the required LSBs. The `EPPI_CTL.SWAPEN` bit has no effect when the `EPPI_CTL.PACKEN` bit =0.

Table 16-30: 10-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x222	0x111
0x3333 4444	0x111	0x222
	0x044	0x333
	0x333	0x044

Table 16-31: 10-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x234
0x2345	0x345
0x3456	0x056
0x4567	0x167

Configuring 16-Bit Transmit Mode

For 16-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If the `EPPI_CTL.PACKEN` bit =0, the DMA is a 16-bit DMA and the EPPI transmits the data as is. The `EPPI_CTL.SWAPEN` has no effect when `EPPI_CTL.PACKEN` bit =0.

Table 16-32: 16-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x2222	0x1111
0x3333 4444	0x1111	0x2222
	0x4444	0x3333
	0x3333	0x4444

Table 16-33: 16-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x1234
0x2345	0x2345
0x3456	0x3456

Configuring 18-Bit Transmit Mode

For 18-bit transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory. In this mode, when `EPPI_CTL.RGBFMTEN` is set, the least significant 2 bits of R, G, and B are dropped.

Table 16-34: 18-bit Transmit Mode with Packing Enabled

DMA Data	Pin Data (18-bits)	
	RGBFMTEN=0	RGBFMTEN=1
0x0123 4567	0x3 4567	0x0 8459

Configuring 10/12/14/16-Bit Transmit Mode with SPLTWRD=0

For 16-bit split transmit mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. For 10, 12, or 14-bit split transmit modes, the EPPI first unpacks the data in the same way as for 16-bit transmit mode. But, the EPPI transmits only the required number of LSBs.

Table 16-40: 16-bit Split Transmit Mode with SPLTEO = 1, SUBSPLTODD = 0, and SWAPEN = 0

DMACFG = 1			DMACFG = 0

EPPI Programming Concepts

This section provides information on SMPTE programming.

SMPTE Modes Programming

The programming model of SMPTE modes is similar to ITU Modes. All programming modes pertaining to ITU modes like XFRTYPE, FSCFG, FLDSEL, and BLANKGEN hold true for SMPTE modes as well. The only difference is that since ITU modes use Y-Cr/Cb interleaved data and SMPTE use parallel Y-Cr/Cb data, SPLTWRD could be set while operating in SMPTE modes. The ***Programming Modes for SMPTE Formats*** table describes the programming modes for different SMPTE formats.

Table 16-46: Programming Modes for SMPTE Formats

SMPTE Format	SMPTE Channel Width	EPPI Input Bit Width	EPPI Mode	Remarks
296M	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported
	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported

ADSP-SC57x EPPI Register Descriptions

Enhanced Parallel Peripheral Interface (EPPI) contains the following registers.

Table 16-47: ADSP-SC57x EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

Clock Divide Register

The EPPI_CLKDIV register provides the divisor for EPPI internal clock generation. The generated clock frequency is given by following formula:

EPPI_CLK = (SCLK) / (EPPI_CLKDIV + 1)

Note that a value of 0xFFFF is invalid for the EPPI_CLKDIV register.

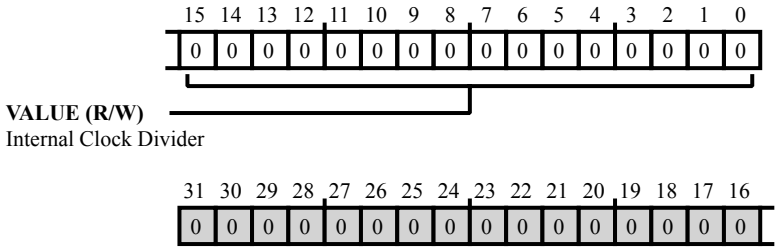

Figure 16-10: EPPI_CLKDIV Register Diagram

Table 16-48: EPPI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Internal Clock Divider.

Control Register

The EPPI_CTL register configures the EPPI for operating mode, control signal polarities, and data width of the port.

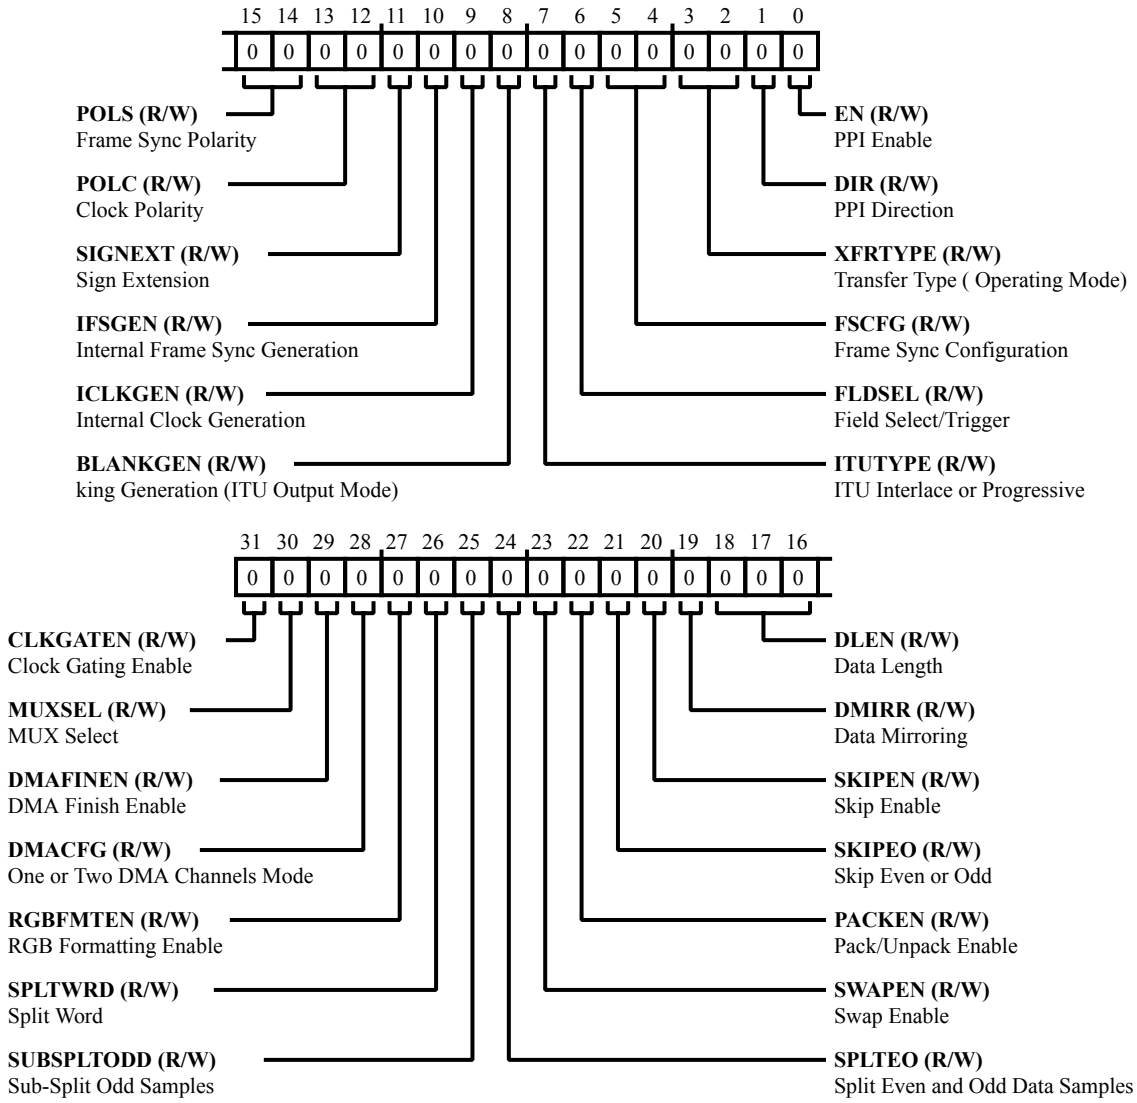

Figure 16-11: EPPI_CTL Register Diagram

Table 16-49: EPPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKGATEN	Clock Gating Enable. The EPPI_CTL.CLKGATEN bit enables using the EPPI_FS3 pin as a clock gating pin. When EPPI_CTL.CLKGATEN is set, the EPPI_FS3 pin acts as a clock gating signal, and both the internal and external clock are gated. Note that the EPPI_FS3 pin gating signal is active low, and the EPPI_CTL.CLKGATEN selection is ignored if EPPI_CTL.MUXSEL is set or EPPI_CTL.FSCFG equals 0x3.	
		0	Disable
		1	Enable
30 (R/W)	MUXSEL	MUX Select. The EPPI_CTL.MUXSEL bit enables multiplexing of a primary and alternate camera using the EPPI main data and clock lines. For more information on this feature, see the EPPI functional description.	
		0	Normal Operation
		1	Multiplexed Operation
29 (R/W)	DMAFINEN	DMA Finish Enable. The EPPI_CTL.DMAFINEN bit selects whether or not the EPPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.	
		0	No Finish Command
		1	Enable Send Finish Command
28 (R/W)	DMACFG	One or Two DMA Channels Mode. The EPPI_CTL.DMACFG bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.DMACFG is set, the EPPI uses two DMA channels. And, if EPPI_CTL.DMACFG is cleared, the EPPI uses only one DMA channel.	
		0	PPI Uses One DMA Channel
		1	PPI Uses Two DMA Channels
27 (R/W)	RGBFMTEN	RGB Formatting Enable. For 16- or 18-bit transmit modes only, the EPPI_CTL.RGBFMTEN bit enables conversion of RGB888 from memory into RGB666 output data (18-bit transmit) or enables conversion of RGB888 from memory into RGB565 output data (16-bit transmit). Note that EPPI_CTL.SPLTEO and EPPI_CTL.RGBFMTEN should never be set simultaneously.	
		0	Disable RGB Formatted Output
		1	Enable RGB Formatted Output

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	SPLTWRD	Split Word. The EPPI_CTL.SPLTWRD bit selects split word data placement when the data length (EPPI_CTL.DLEN) selects 16-, 20-, or 24-bit data words. For all other EPPI_CTL.SPLTWRD values, the set or clear selections for EPPI_CTL.SPLTWRD produce the same result (act as though EPPI_CTL.SPLTWRD is cleared). For EPPI_CTL.SPLTWRD set, the EPPI_CTL.DLEN values below result in the following combinations of split words: DLEN Cr/Cb data Y data 16 PPI_DATA[15:8] PPI_DATA[7:0] 20 PPI_DATA[19:10] PPI_DATA[9:0] 24 PPI_DATA[23:12] PPI_DATA[11:0]	
		0	PPI_DATA has (DLEN-1) bits of Y or Cr or Cb
		1	PPI_DATA Contains 2 Elements per Word
25 (R/W)	SUBSPLTODD	Sub-Split Odd Samples. The EPPI_CTL.SUBSPLTODD bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.SUBSPLTODD is set, the EPPI sub-splits the odd sub-stream, and packs them separately.	
		0	Disable
		1	Enable
24 (R/W)	SPLTEO	Split Even and Odd Data Samples. If EPPI_CTL.SPLTEO is set, the EPPI splits the incoming data stream into two sub-streams, an even stream and an odd stream, and packs them separately.	
		0	Do Not Split Samples
		1	Split Even/Odd Samples
23 (R/W)	SWAPEN	Swap Enable. The EPPI_CTL.SWAPEN selects whether or not to swap the order of the first data (most-significant bits versus least-significant bits) of the DMA word. For receive modes, the EPPI puts the first data in the most significant bits (if set) or puts the first data in the least significant bits (if cleared) of the DMA word. For transmit modes, the EPPI transmits the most significant bits in the DMA word as the first data (if set) or transmits the least significant bits in the DMA word as the first data (if cleared).	
		0	Disable
		1	Enable

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	PACKEN	Pack/Unpack Enable. The EPPI_CTL.PACKEN select whether or not packing is enabled (for receive modes) and unpacking is enabled (for transmit modes). When this bit is set, EPPI transfer DMA is 32-bits wide. When this bit is cleared and the EPPI_CTL.DLEN is less than or equal to 16 bits, EPPI transfer DMA is 16-bits wide. For receive modes, if this bit is set, then the EPPI packs the incoming data into 32-bit words. If this bit is cleared, then the EPPI does not do any packing. For transmit modes, if this bit is set, then the EPPI always unpacks the 32-bit data from DMA. If this bit is not set, the EPPI does not do any unpacking.	
		0	Disable
		1	Enable
21 (R/W)	SKIPEO	Skip Even or Odd. The EPPI_CTL.SKIPEO bit selects whether even (if set) or odd (if cleared) samples are skipped if sample skipping is enabled (EPPI_CTL.SKIPEN is set). This feature only is useful for receive modes.	
		0	Skip Odd Samples
		1	Skip Even Samples
20 (R/W)	SKIPEN	Skip Enable. The EPPI_CTL.SKIPEN bit enables skipping alternate samples. This feature only is useful for receive modes.	
		0	No Samples Skipping
		1	Skip Alternate Samples
19 (R/W)	DMIRR	Data Mirroring. The EPPI_CTL.DMIRR field enables mirroring (bit reversing) of the data coming in or going out on the EPPI data pins. Pin Data PPI Data (DAT_MRR=0) PPI Data (DAT_MRR=1) 15 15 0 14 14 1 .... 1 1 14 0 0 15	
		0	No Data Mirroring
		1	Data Mirroring
18:16 (R/W)	DLEN	Data Length. The EPPI_CTL.DLEN bits select the data length for the EPPI. Note that the 20 bits data length selection is valid only for SMPTE modes (EPPI_CTL.SPLTWRD set).	

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	8 bits
		1	10 bits
		2	12 bits
		3	14 bits
		4	16 bits
		5	18 bits
		6	20 bits
		7	24 bits
15:14 (R/W)	POLS	Frame Sync Polarity. The `EPPI_CTL.POLS` selects whether the frame syncs' polarity is active low versus active high.	
		0	FS1 and FS2 are active high
		1	FS1 is active low. FS2 is active high
		2	FS1 is active high. FS2 is active low
		3	FS1 and FS2 are active low
13:12 (R/W)	POLC	Clock Polarity. The `EPPI_CTL.POLC` selects the rising versus falling edge for sampling data and sampling/driving syncs.	
		0	Clock/Sync Polarity Mode 0. For receive mode: Sample data on falling edge and sample/drive syncs on falling edge. For transmit mode: Drive data on rising edge and sample/drive syncs on rising edge.
		1	Clock/Sync Polarity Mode 1. For receive mode: Sample data on falling edge and sample/drive syncs on rising edge. For transmit mode: Drive data on rising edge and sample/drive syncs on falling edge.
		2	Clock/Sync Polarity Mode 2. For receive mode: Sample data on rising edge and sample/drive syncs on falling edge. For transmit mode: Drive data on falling edge and sample/drive syncs on rising edge.
		3	Clock/Sync Polarity Mode 3. For receive mode: Sample data on rising edge and sample/drive syncs on rising edge. For transmit mode: Drive data on falling edge and sample/drive syncs on falling edge.

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SIGNEXT	Sign Extension. The EPPI_CTL.SIGNEXT select whether (for receive modes when EPPI_CTL.DLEN selecting 16 bit data length) the data is sign extended or zero filled. Not that EPPI_CTL.SPLTWRD is removed from this shared bit.	
		0	Zero Filled
		1	Sign Extended
10 (R/W)	IFSGEN	Internal Frame Sync Generation. The EPPI_CTL.IFSGEN bit selects whether the frame syncs are generated internally or are supplied by an external device.	
		0	External Frame Sync
		1	Internal Frame Sync
9 (R/W)	ICLKGEN	Internal Clock Generation. The EPPI_CTL.ICLKGEN bit selects whether the EPPI_CLK is generated internally or is supplied by an external device.	
		0	External Clock
		1	Internal Clock
8 (R/W)	BLANKGEN	king Generation (ITU Output Mode). The EPPI_CTL.BLANKGEN enables ITU output with internal blanking. In GP 8, 10 transmit bit modes (when EPPI_CTL.SPLTWRD is cleared) and 16-, 20-, and 24-bit transmit modes (when EPPI_CTL.SPLTWRD is set), EPPI_CTL.BLANKGEN selects whether or not the EPPI generates blanking and generates preamble and insertion with active data from memory.	
		0	Disable
		1	Enable
7 (R/W)	ITUTYPE	ITU Interlace or Progressive. The EPPI_CTL.ITUTYPE selects interlaced or progressive operation for ITU656 mode. This selection is valid for both TX and RX modes.	
		0	Interlaced
		1	Progressive

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	FLDSEL	Field Select/Trigger. The EPPI_CTL.FLDSEL bits configure the EPPI field and trigger selection. These are valid for GP modes (EPPI_CTL.XFRTYPE =0x3) and ITU656 active video mode (EPPI_CTL.XFRTYPE cleared).	
		0	Field Mode 0. Read field 1 (for ITU656 active video mode). Set internal trigger (for GP RX mode). FS3 is toggled on FS2 assertion followed by FS1 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
		1	Field Mode 1 Read field 1 and field 2 (ITU656 active video mode). Set external trigger (GP RX mode). FS3 is toggled on FS2 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
5:4 (R/W)	FSCFG	Frame Sync Configuration. The EPPI_CTL.FSCFG bits configure the EPPI frame syncs. These are valid only for GP modes (EPPI_CTL.XFRTYPE =0x3). The output of the frames syncs also depends on whether the EPPI transfer direction is transmit and the EPPI is in ITU output mode (EPPI_CTL.BLANKGEN is set).	
		0	Sync Mode 0. FS0 driven in GP mode. FS0 not driven in ITU output mode.
		1	Sync Mode 1. FS1 driven in GP mode. HSYNC driven on FS1 in ITU output mode.
		2	Sync Mode 2. FS2 driven in GP mode. HSYNC driven on FS1 and VSYNC driven on FS1 in ITU output mode.
		3	Sync Mode 3. FS3 driven in GP mode. HSYNC driven on FS1, VSYNC driven on FS2, and FIELD driven on FS3 in ITU output mode.

Table 16-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	XFRTYPE	Transfer Type (Operating Mode). The EPPI_CTL.XFRTYPE bits select the EPPI operating mode. In receive mode (EPPI_CTL.DIR cleared), the EPPI modes include ITU656 active video only mode, ITU656 entire field mode, ITU656 vertical blanking only mode, and non-ITU656 mode (GP mode). For transmit mode (EPPI_CTL.DIR set), the EPPI_CTL.XFRTYPE bits have no effect, and the EPPI (in transmit mode) is always in GP mode.	
		0	ITU656 Active Video Only Mode
		1	ITU656 Entire Field Mode
		2	ITU656 Vertical Blanking Only Mode
		3	Non-ITU656 Mode (GP Mode)
1 (R/W)	DIR	PPI Direction. The EPPI_CTL.DIR bit selects whether the EPPI is in receive mode (if cleared) or in transmit mode (if set).	
		0	Receive Mode
		1	Transmit Mode
0 (R/W)	EN	PPI Enable. The EPPI_CTL.EN bit enables or disables the EPPI.	
		0	Disable
		1	Enable

Control Register 2 Register

The EPPI_CTL2 register controls HSYNC finish signal generation.

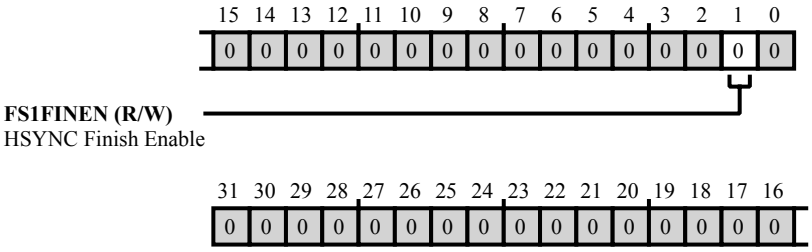

Figure 16-12: EPPI_CTL2 Register Diagram

Table 16-50: EPPI_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FS1FINEN	HSYNC Finish Enable. The EPPI_CTL2.FS1FINEN bit selects whether (if set) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a LINE is received completely or (if cleared) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely. Note that the EPPI_CTL.DMAFINEN bit must be set for the EPPI to generate either of the finish commands.	
		0	Finish sent after frame RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely
		1	Finish sent after frame/line RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.

Clipping Register for EVEN (Luma) Data Register

The EPPI_EVENCLIP register selects the clipping threshold for luma data, which provides clipping of individual video components.

The high even and low even spaces in EPPI_EVENCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

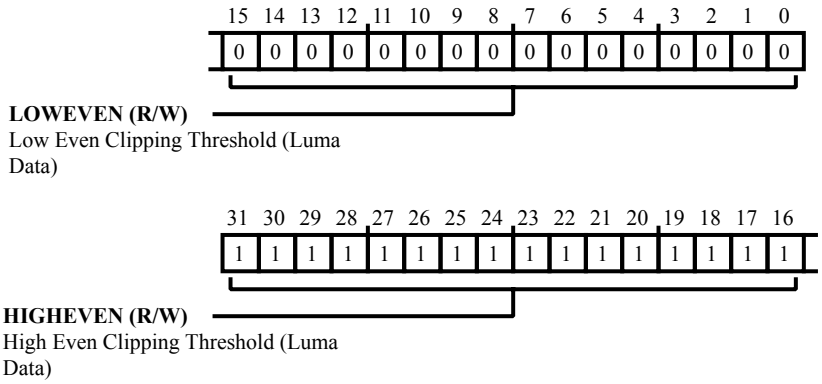

Figure 16-13: EPPI_EVENCLIP Register Diagram

Table 16-51: EPPI_EVENCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHEVEN	High Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.HIGHEVEN bit field selects the clipping threshold for luma data. The high even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWEVEN	Low Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.LOWEVEN bit field selects the clipping threshold for luma data. The low even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Lines Per Frame Register

The EPPI_FRAME register tracks the frame track overflow and underflow errors. This register should be programmed with the number of lines expected per frame. Any write to the EPPI_FRAME register will also write the same value to the EPPI_VCNT register. But, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_FRAME register should be programmed before the EPPI_VCNT register.

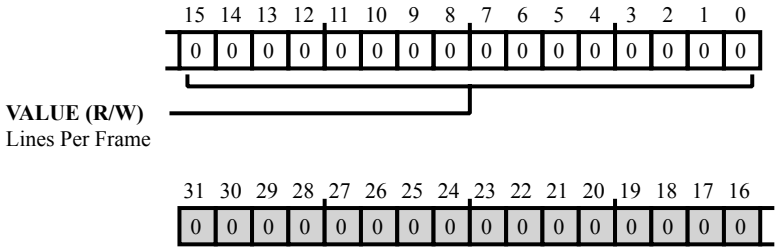

Figure 16-14: EPPI_FRAME Register Diagram

Table 16-52: EPPI_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Lines Per Frame. The EPPI_FRAME.VALUE holds the number of lines expected per frame of data.

Frame Sync 1 Delay Value Register

The EPPI_FS1_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after the EPPI is enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

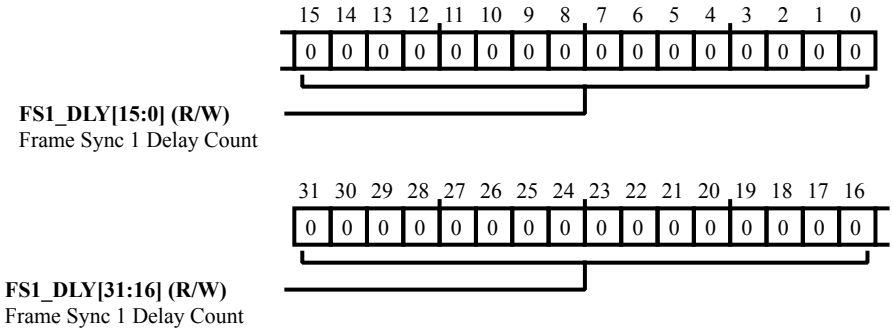

Figure 16-15: EPPI_FS1_DLY Register Diagram

Table 16-53: EPPI_FS1_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS1_DLY	Frame Sync 1 Delay Count. The EPPI_FS1_DLY.FS1_DLY bit field selects the delay count.

FS1 Period Register / EPPI Active Samples Per Line Register

The EPPI_FS1_PASPL register content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL register is used for the generation of frame sync 1. The register contains the period required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of active video or vertical blanking samples per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for this register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_PASPL register as containing 1.

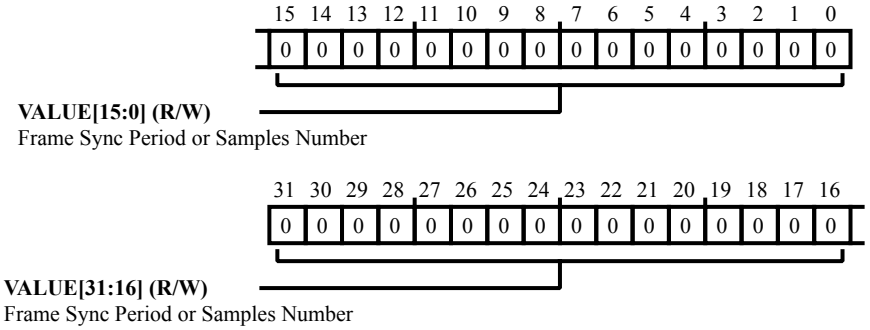

Figure 16-16: EPPI_FS1_PASPL Register Diagram

Table 16-54: EPPI_FS1_PASPL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Period or Samples Number. In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL.VALUE bit field is used for the generation of frame sync 1 and contains the period required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this bit field contains the number of samples of active video or vertical blanking samples per line.

FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register

The EPPI_FS1_WLHB register's content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2 or 3 FS modes, EPPI_FS1_WLHB is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of horizontal blanking per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for the EPPI_FS1_WLHB register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_WLHB register as containing 1.

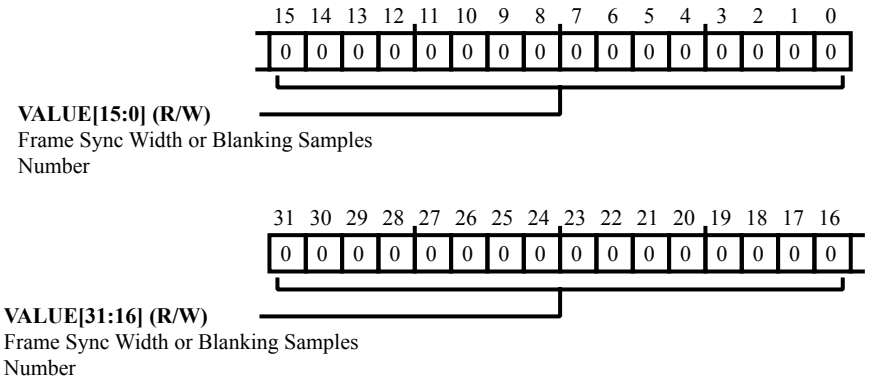

Figure 16-17: EPPI_FS1_WLHB Register Diagram

Table 16-55: EPPI_FS1_WLHB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Width or Blanking Samples Number. The EPPI_FS1_WLHB.VALUE bit field content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode. In GP 1, 2 or 3 FS modes, the EPPI_FS1_WLHB.VALUE bit field is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with EPPI_CTL.BLANKGEN set, this bit field contains the number of samples of horizontal blanking per line.

Frame Sync 2 Delay Value Register

The EPPI_FS2_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after EPPI enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with the value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

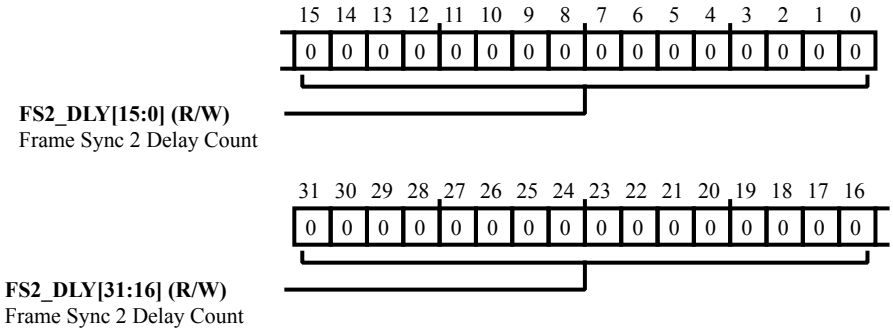

Figure 16-18: EPPI_FS2_DLY Register Diagram

Table 16-56: EPPI_FS2_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS2_DLY	Frame Sync 2 Delay Count. The EPPI_FS2_DLY.FS2_DLY bit field selects the delay count.

FS2 Period Register / EPPI Active Lines Per Field Register

The EPPI_FS2_PALPF register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, EPPI_FS2_PALPF is used for the generation of frame sync 2. This register contains the period required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of lines of active video per field.

Note that a value of 0 for the EPPI_FS2_PALPF.F1ACT or EPPI_FS2_PALPF.F2ACT bits is illegal. If either is programmed as 0, the EPPI regards the 0 value fields as containing 1.

Also, note that for progressive video, the EPPI_FS2_PALPF.F2ACT bit is ignored.

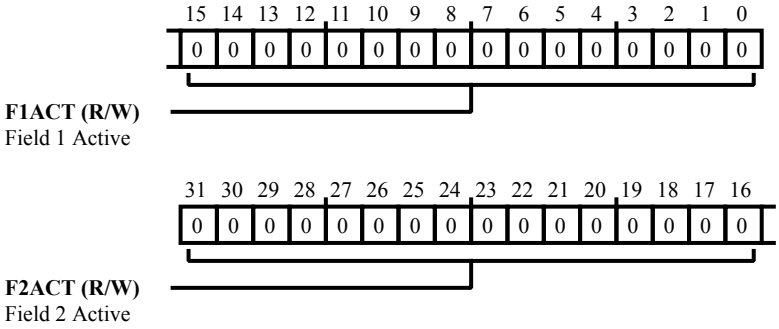

Figure 16-19: EPPI_FS2_PALPF Register Diagram

Table 16-57: EPPI_FS2_PALPF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	F2ACT	Field 2 Active. The EPPI_FS2_PALPF.F2ACT bit field contains the number of lines of active data in field 2.
15:0 (R/W)	F1ACT	Field 1 Active. The EPPI_FS2_PALPF.F1ACT bit field contains the number of lines of active data in field 1.

FS2 Width Register / EPPI Lines Of Vertical Blanking Register

The EPPI_FS2_WLVB register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, the EPPI_FS2_WLVB register is used for the generation of frame sync 2. The register contains the width required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number or lines of vertical blanking.

Note that for progressive video, the EPPI_FS2_WLVB.F2VBBD and EPPI_FS2_WLVB.F2VBAD bits are ignored.

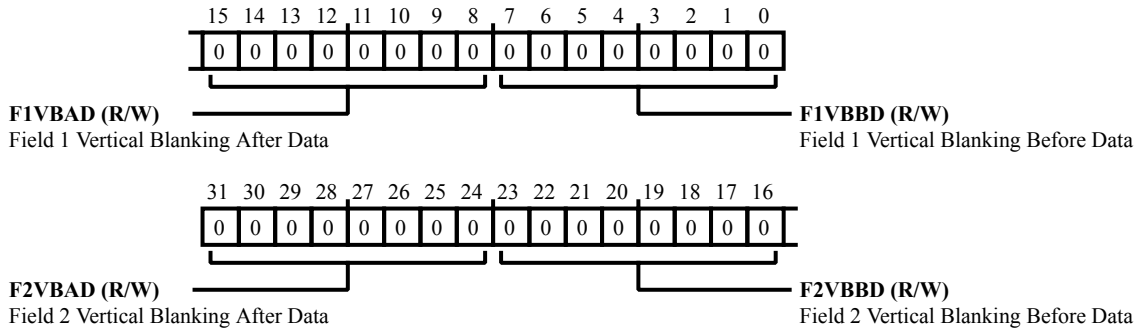

Figure 16-20: EPPI_FS2_WLVB Register Diagram

Table 16-58: EPPI_FS2_WLVB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	F2VBAD	Field 2 Vertical Blanking After Data. The EPPI_FS2_WLVB.F2VBAD bit field contains the number of lines of vertical blanking after field 2.
23:16 (R/W)	F2VBBD	Field 2 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F2VBBD bit field contains the number of lines of vertical blanking before field 2.
15:8 (R/W)	F1VBAD	Field 1 Vertical Blanking After Data. The EPPI_FS2_WLVB.F1VBAD bit field contains the number of lines of vertical blanking after field 1.
7:0 (R/W)	F1VBBD	Field 1 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F1VBBD bit field contains the number of lines of vertical blanking before field 1.

Horizontal Transfer Count Register

The EPPI_HCNT register holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1. Any write to the EPPI_LINE register modifies the EPPI_HCNT register. But, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_HCNT register should be programmed after the EPPI_LINE register.

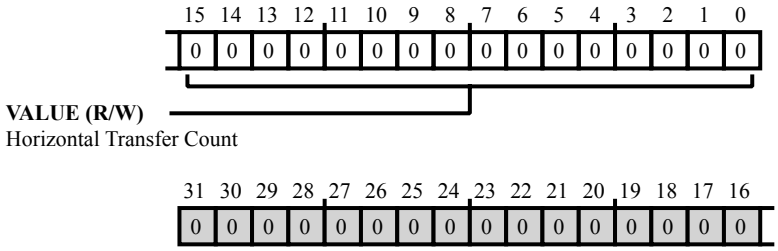

Figure 16-21: EPPI_HCNT Register Diagram

Table 16-59: EPPI_HCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Transfer Count. The EPPI_HCNT.VALUE holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the last assertion of EPPI_FS1.

Horizontal Delay Count Register

The EPPI_HDLY register contains the number of clock cycles to delay after the assertion of EPPI_FS1 is detected before starting to read or write data.

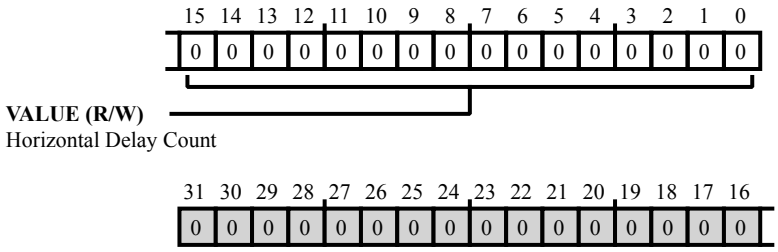

Figure 16-22: EPPI_HDLY Register Diagram

Table 16-60: EPPI_HDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Delay Count. The EPPI_HDLY.VALUE holds the number of EPPI_CLK cycles to delay after assertion of EPPI_FS1 before starting to read or write data.

Interrupt Mask Register

The EPPI_IMSK register permits the masking (if associated bit is set) of EPPI error interrupts for YFIFO underflow or overflow, CFIFO underflow or overflow, line track overflow error, line track underflow error, frame track overflow error, frame track underflow error, and ERR_NCOR (ITU preamble error not corrected. These conditions are flagged in the EPPI_STAT register and cleared by write-1-to-clear.

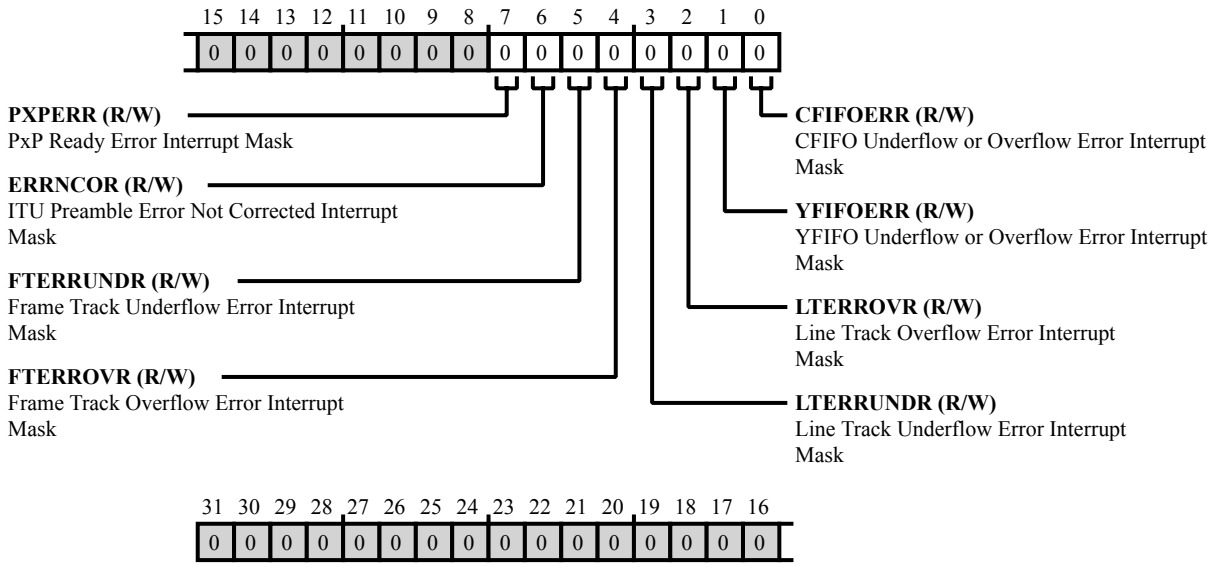

Figure 16-23: EPPI_IMSK Register Diagram

Table 16-61: EPPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PXPERR	PxP Ready Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
6 (R/W)	ERRNCOR	ITU Preamble Error Not Corrected Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
5 (R/W)	FTERRUNDR	Frame Track Underflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
4 (R/W)	FTERROVR	Frame Track Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt

Table 16-61: EPPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	LTERRUNDR	Line Track Underflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
2 (R/W)	LTERROVR	Line Track Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
1 (R/W)	YFIFOERR	YFIFO Underflow or Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
0 (R/W)	CFIFOERR	CFIFO Underflow or Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt

Samples Per Line Register

The EPPI_LINE register tracks the line track overflow and underflow errors. This register should be programmed with the number of samples expected per line. Any write to the EPPI_LINE register will also write the same value to the EPPI_HCNT register. However, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_LINE register should be programmed before the EPPI_HCNT register.

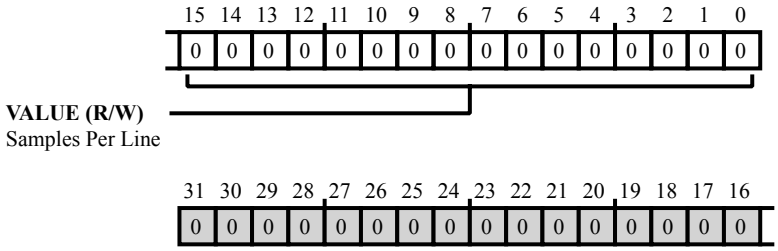

Figure 16-24: EPPI_LINE Register Diagram

Table 16-62: EPPI_LINE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Samples Per Line. The EPPI_LINE.VALUE holds the number of samples expected per line.

Clipping Register for ODD (Chroma) Data Register

The EPPI_ODDCLIP register selects the clipping threshold for chroma data, which provides clipping of individual video components.

The high odd and low odd spaces in EPPI_ODDCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

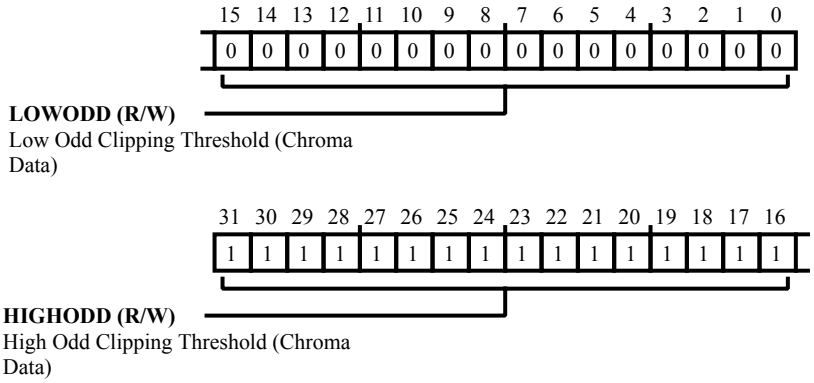

Figure 16-25: EPPI_ODDCLIP Register Diagram

Table 16-63: EPPI_ODDCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHODD	High Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.HIGHODD bit field selects the clipping threshold for luma data. The high odd spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWODD	Low Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.LOWODD bit field selects the clipping threshold for luma data. The low add spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Status Register

The EPPI_STAT register contains bits that provide information about the current operating state of the EPPI.

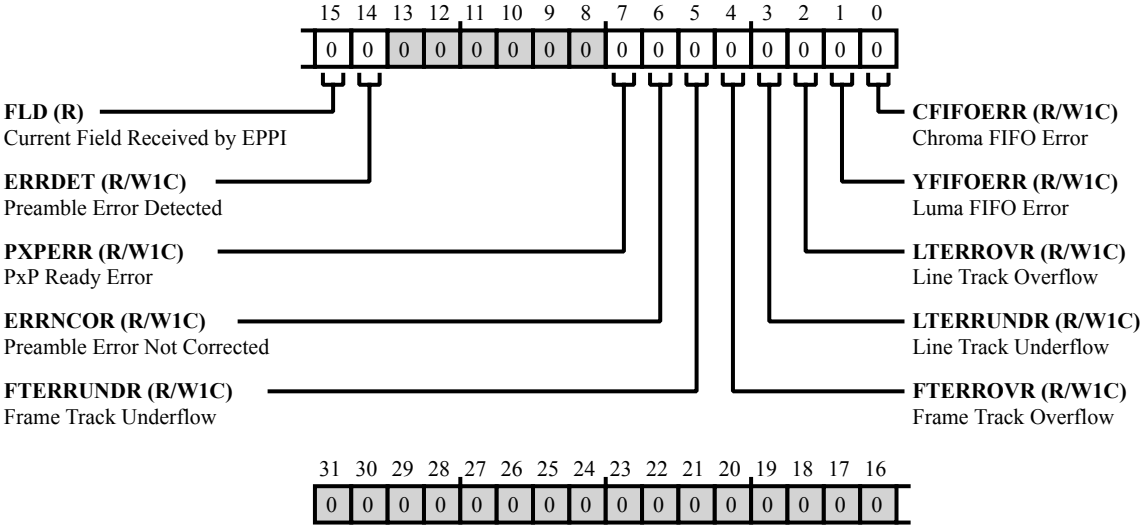

Figure 16-26: EPPI_STAT Register Diagram

Table 16-64: EPPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	FLD	Current Field Received by EPPI. The EPPI_STAT.FLD bit indicates whether the current field being received by the PPI is field 1 (if clear) or field 2 (if set).	
		0	Field 1
		1	Field 2
14 (R/W1C)	ERRDET	Preamble Error Detected. The EPPI_STAT.ERRDET bit is useful only in ITU receive modes and indicates if an error has been detected in the status word of EAV or SAV sequences (if set) or not (if clear).	
		0	No Preamble Error Detected
		1	Preamble Error Detected
7 (R/W1C)	PXPERR	PxP Ready Error. The EPPI_STAT.PXPERR bit is valid only in the RX mode. This bit indicates whether the incoming PPI data overflows the PxP interface (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	

Table 16-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERRNCOR	Preamble Error Not Corrected. The `EPPI_STAT.ERRNCOR` bit is useful only in the ITU receive modes and indicates if an error in the status word of EAV or SAV sequences can not be cleared (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No uncorrected preamble error has occurred
		1	Preamble error detected but not corrected
5 (R/W1C)	FTERRUNDR	Frame Track Underflow. The `EPPI_STAT.FTERRUNDR` bit indicates whether a frame track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
4 (R/W1C)	FTERROVR	Frame Track Overflow. The `EPPI_STAT.FTERROVR` bit indicates whether a frame track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
3 (R/W1C)	LTERRUNDR	Line Track Underflow. The `EPPI_STAT.LTERRUNDR` bit indicates whether a line track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
2 (R/W1C)	LTERROVR	Line Track Overflow. The `EPPI_STAT.LTERROVR` bit indicates whether a line track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Table 16-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	YFIFOERR	Luma FIFO Error. For RX modes, the `EPPI_STAT.YFIFOERR` bit indicates whether the Luma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the Luma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
0 (R/W1C)	CFIFOERR	Chroma FIFO Error. For RX modes, the `EPPI_STAT.CFIFOERR` bit indicates whether the chroma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the chroma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Vertical Transfer Count Register

The EPPI_VCNT register holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame. Any write to the EPPI_FRAME register modifies the EPPI_VCNT register. However, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_VCNT register should be programmed after the EPPI_FRAME register.

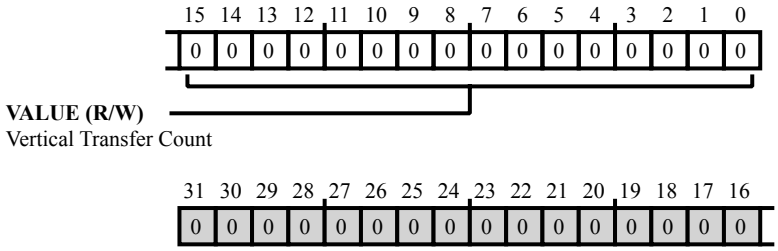

Figure 16-27: EPPI_VCNT Register Diagram

Table 16-65: EPPI_VCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Transfer Count. The EPPI_VCNT.VALUE holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame.

Vertical Delay Count Register

The EPPI_VDLY register contains the number of lines to wait after the start of a new frame before starting to read/transmit data.

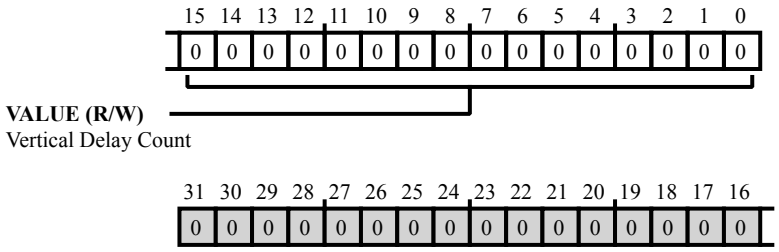

Figure 16-28: EPPI_VDLY Register Diagram

Table 16-66: EPPI_VDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Delay Count. The EPPI_VDLY.VALUE holds the number of lines to wait after the start of a new frame before starting to read/transmit data.

17 General-Purpose Timer (TIMER)

The general-purpose timer (GP Timer) module serves as a collection of system timers that support various system-level functions. These functions include:

- Synchronized PWM waveform output capability
- External signal capture
- External event count
- General time-base functionality

Additionally, interrupt requests can be generated upon completion of timer events. Moreover, GP timers can act both as trigger masters and trigger slaves.

GP Timer Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed watchdog mode
- Pulse-width count and capture (WDTH_CAP) mode
- External Event (EXT_CLK) mode
- Pulse-width modulation (PWM_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values

- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output

ADSP-SC57x TIMER Register List

The General-Purpose Timer block (TIMER) provides timers that may be used for external event capture and measurement, system timing, and PWM waveform generation. A set of registers governs TIMER operations. For more information on TIMER functionality, see the TIMER register descriptions.

Table 17-1: ADSP-SC57x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register

Timer Block Diagram

The Timer block diagram figure shows all of the possible clock sources.

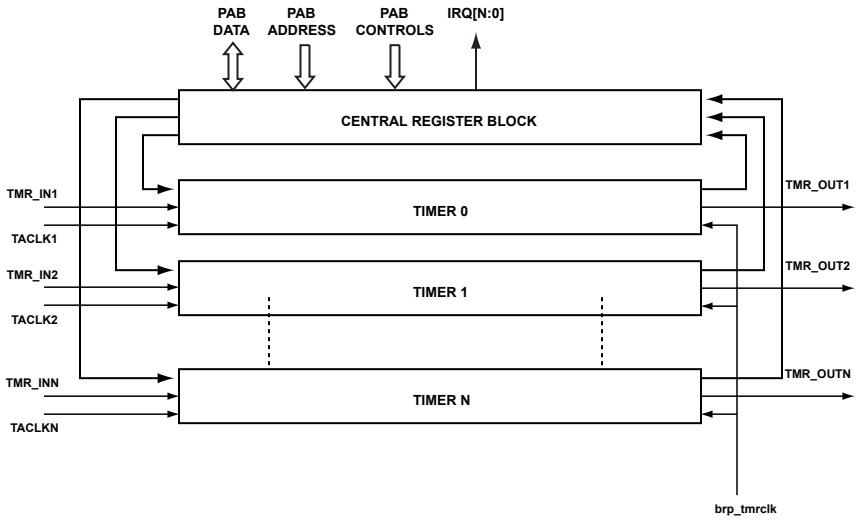

Figure 17-1: Timer Block Diagram

Internal Interface

The processor core always accesses the timer registers through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has a dedicated data interrupt request. There is also one common timer status and error interrupt request output that connects to the system event controller. Whenever a data interrupt request is generated, a data trigger master pulse is also driven out, if enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a trigger slave.

In total, the GP timer module can have up to (N + 1) interrupt request output lines and N data trigger lines.

Internal Timer Connections

The Timers support alternate inputs for the clock/capture (see External Interface). Some signals have internal default alternate connections according to the ***Timer Signal Routing*** table.

Table 17-5: Timer Signal Routing

Timer Signal	Connection
TM0_ACLK0	SYS_CLKIN1
TM0_ACI5	DAI0_CRS_PB04
TM0_ACLK5	DAI0_CRS_PB03
TM0_ACI6	DAI1_CRS_PB04
TM0_ACLK6	DAI1_CRS_PB03
TM0_ACI07	CNT0_TO signal
TM0_ACLK7	SYS_CLKIN0

External Interface

Each GP timer module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in the data sheet for the processor.

Every timer has one main input/output signal (`TIMER_TMR[n]`) and, usually, one auxiliary input pin, used as an alternate capture input (`TIMER_ACI[n]`). Each timer can either run with a time base of SCLK or can reference an external clock on one of two `TIMER_ACLK[n]` pins. The TMR_ALT_CLK0 signal maps to individual alternate clock (`TIMER_ACLK[n]`) pins for one or more timers. For instance, a TM_ACLK3 pin would provide an alternate site to supply an external signal that would serve as reference clock for TMR3. Likewise, the TMR_ALT_CLK1 signal from each timer unit connects together internally to provide a single global timer clock pin (`TIMER_CLK`) for the GP timer module. It is used as an additional time base.

GP Timer Operating Modes

The following sections provide information on the various operating modes of the GP timer.

General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only `TIMER_TMR[n]_CNT` register. Once the module enables a timer, it loads the timer `TIMER_TMR[n]_CNT` register with a starting value.

A timer can operate in one of several different modes, configured through the `TIMER_TMR[n]_CFG` register for that timer. These modes are: PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT, and IDLE. The ***Timer Mode Descriptions*** table summarizes the modes.

Table 17-6: Timer Mode Descriptions

Timer Mode	Description
PWMOUT	Generates single or continuous PWM waveforms with programmable pulse width, period, and delay
EXTCLK	Counts edges of an externally applied waveform
WIDCAP	Captures pulse width or period of an externally applied waveform
WATCHDOG	Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt when it falls inside or outside of that window
PININT	Can generate an interrupt request on an active edge applied to a timer pin
IDLE	Idle; no activity

Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the double-buffered period, pulse width, and delay registers. These values are then ready for use in the first timer period. When a timer is already running, software can write new values to the `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` registers. The written values are buffered and do not update into the registers until the end of the current period. (The update occurs when the value in the `TIMER_TMR[n]_CNT` register equals the value in the `TIMER_TMR[n]_PER` register.)

If new values are not written to these registers, the value from the previous period is reused. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. Values written to the period, pulse width, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width, or delay value. Written values are not readback until they become active.

The usage of the `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` registers varies, depending on the mode of the timer specified by the `TIMER_TMR[n]_CFG.TMODE` bits. See the ***Usage of the Period, Width, and Delay Registers in Different Timer Modes*** table for more information.

Table 17-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes

Timer Mode	`TIMER_TMR[n]_PER`	`TIMER_TMR[n]_WID`	`TIMER_TMR[n]_DLY`
IDLE	Not writable	Not writable	Not writable
WATCHDOG	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.	Read-only. Retains value of last measured width or period of the input signal.	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.
WIDCAP	Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.	Read-only. Width value captured at the appropriate time and updated from its buffer register simultaneously with the Period register.	Not used

Table 17-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes (Continued)

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
PWMOUT	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.
EXTCLK	Can be updated on-the-fly.	Not used	Not used
PININT	Not used	Not used	Not used

If any of the period, pulse width, and delay registers are not used, then programs cannot write into that register. For example, in WIDCAP mode, the delay registers are not used. So, the program is not allowed to write any value to the TIMER_TMR[n]_DLY register. To prevent undesired operation, program the TIMER_TMR[n]_CFG.TMODE bits before programming the period, width, or delay registers.

If a program changes the TIMER_TMR[n]_CFG.TMODE bits from a status register to writable register (for example in PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWMOUT mode with small periods, there may not be enough time between updates from the buffer registers to write these registers. The next period can use one old value and one new value. To prevent (width + pulse delay) > period errors, write the width and delay registers before the period register when decreasing the values. Write the period register before the width and delay registers when increasing the value.

Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TIMER_TMR[n] pin. This mode is frequently used to implement a precise delay, often with generating an output trigger. The timer module uses the value in the TIMER_TMR[n]_DLY register to control the assertion of a pulse. The value in the TIMER_TMR[n]_WID register defines the pulse width. The TIMER_TMR[n]_PER is not used and cannot be written in this mode. After completion of the pulse, the timer is automatically stopped, and optionally generates an interrupt. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control pulse polarity.

The timer can be configured to generate a data interrupt request after satisfying various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is not necessary to clear the relevant TIMER_RUN bit to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding TIMER_RUN bit is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate TIMER_RUN bit, and wait for the timer to stop. Then, write another 1 to the same TIMER_RUN bit.

Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates a repetitive pulse with a well-defined period, duty cycle, and pulse position. The TIMER_TMR[n]_DLY, TIMER_TMR[n]_PER, and TIMER_TMR[n]_WID registers are

programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in the TIMER_TMR[n]_PER register. Initially, the TIMER_TMR[n] pin remains in a deasserted state. The pin toggles to an asserted state when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_DLY register.

The timer can control the assertion sense of the TIMER_TMR[n] pin with the TIMER_TMR[n]_CFG.PULSEHI bit. The TIMER_TMR[n] pin holds this value for the number of clock cycles specified in the TIMER_TMR[n]_WID register. Then, the pin deasserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

The timer can be configured to generate a data interrupt request after satisfying any of various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is important to guarantee that the programmed period is greater than or equal to the sum of width and delay. Similarly, delay must be less than period. Violating either of these criteria results in an unpredictable waveform on the TIMER_TMR[n] pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TIMER_TMR[n] pin is achieved by setting TIMER_TMR[n]_PER to 2 and TIMER_TMR[n]_WID to 1. This operation makes the TIMER_TMR[n] pin toggle each SCLK clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%.

When the TIMER_STOP_CFG.TMR[nn] bit of a timer is 0, the timer treats a stop operation as a stop-is-pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This funtionality prevents truncation of the current pulse and unwanted PWM patterns at the TIMER_TMR[n] pin. The processor can determine when the timer stops running by polling the corresponding TIMER_RUN.TMR[nn] bit until it reads 0 or by waiting for the last interrupt (if enabled).

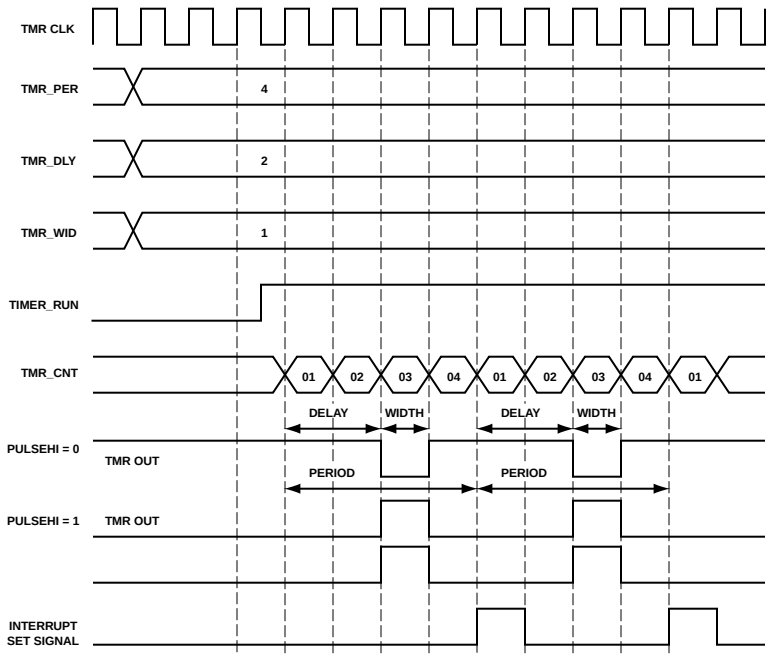

Figure 17-2: Signal Generation in Continuous PWMOUT Mode

The TIMER_TMR[n]_CFG register cannot be reconfigured until after the timer stops and the TIMER_RUN register reads 0.

Programs can force a timer to stop immediately in PWMOUT mode by writing a 1 to the TIMER_STOP_CFG register followed by writing a 1 to the TIMER_RUN_CLR register. (Or, a program can stop a timer by writing a 0 to the appropriate TIMER_RUN.TMR[nn] bit.) This operation stops the timer whether the pending stop is waiting for the end of the current period or the end of the current pulse width. The timer can use this feature to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, as it can corrupt the PWM pattern generated at the TIMER_TMR[n] pin, though after such a stop the pin deasserts automatically. Each timer samples its TIMER_RUN.TMR[nn] bit at the end of each period. It stops cleanly at the end of the first period after the TIMER_RUN.TMR[nn] bit is low. A timer that is disabled and then restarted (before the end of the current period), continues to run as if nothing happened. Typically, the program disables a PWMOUT timer and then waits for it to stop itself.

Width Capture (WIDCAP) Mode

The timer uses WIDCAP mode, often called capture mode, to measure pulse widths on the TIMER_TMR[n] or TIMER_ACI[n] inputs. The polarity (active high or low) of the input signal can be selected with the TIMER_TMR[n]_CFG.PULSEHI bit. The ***Timer Signal Flow in Width Capture Mode*** figure shows the control signal flow for WIDCAP_CAP mode.

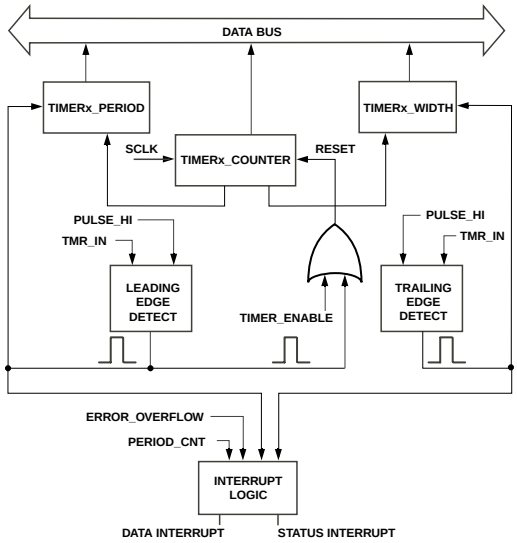

Figure 17-3: Timer Signal Flow in Width Capture Mode

NOTE: SCLK in the ***Timer Signal Flow in Width Capture Mode*** figure is SCLK.

In this mode, the timer uses the TIMER_TMR[n]_CFG.TINSEL bit to select between the TIMER_TMR[n] or TIMER_ACI[n] input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its TIMER_TMR[n]_CNT register to 0x0000 0001. It does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its TIMER_TMR[n]_CNT register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its TIMER_TMR[n]_CNT register into its period buffer register. The TIMER_TMR[n]_CNT register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, programs can measure both the pulse width and the pulse period of a waveform. The timer does not use the TIMER_TMR[n]_DLY register in this mode. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control the definition of leading edge and trailing edge of the TIMER_TMR[n]/TIMER_ACI[n] pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The TIMER_TMR[n]_PER register is updated from the period buffer register.
2. The TIMER_TMR[n]_WID register is updated from the width buffer register.
3. The TIMER_DATA_ILAT.TMR[nn] bit is set (if enabled).
4. A timer data trigger pulse is generated (if enabled).

The TIMER_TMR[n]_CFG.TMODE bit 0 controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The TIMER_STAT_ILAT register is not set at a measurement report. A measurement report occurs, at most, once per input signal period. The current TIMER_TMR[n]_CNT value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively. But, these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt request to signal that the TIMER_TMR[n]_PER and the TIMER_TMR[n]_WID registers are ready to be read.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1011, the measurement report occurs just after the width buffer register captures its value at a falling edge. Then, the TIMER_TMR[n]_WID register reports the pulse width measured in the pulse that has ended, but the TIMER_TMR[n]_PER register reports the pulse period measured at the end of the previous period. If only the first trailing edge has occurred, then the first period value has not yet been measured at the first measurement report. So, the period value is not valid. A read of the TIMER_TMR[n]_PER value in this case returns 0. See the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure for more information.

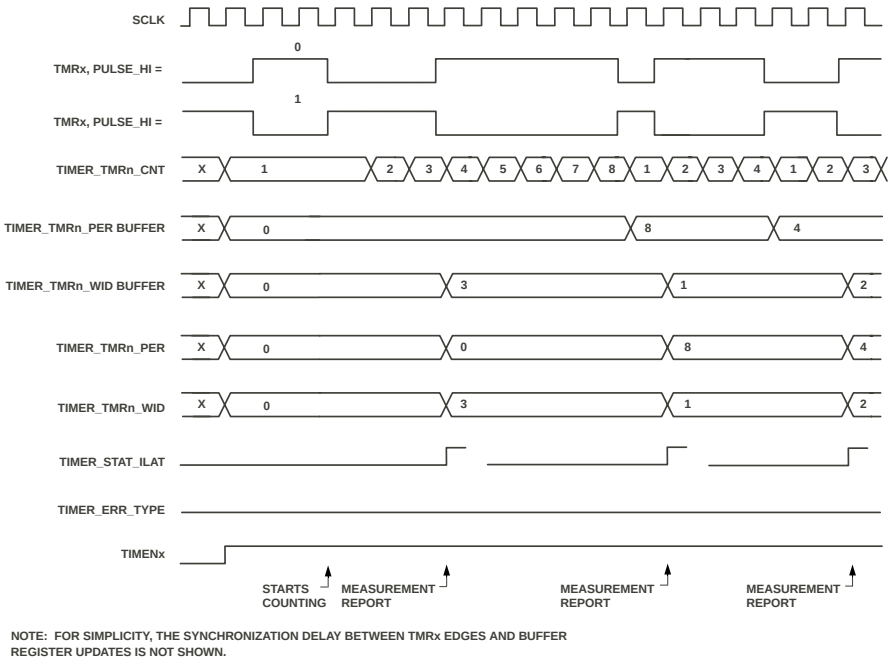

Figure 17-4: Example of Width Capture Deasserted Mode (TMODE=b#1011)

NOTE: SCLK in the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure is SCLK.

When the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the measurement report occurs just after the period buffer register captures its value at a leading edge. Then, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers report the pulse period and pulse width measured in the period that has ended. Refer to the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure for more information.

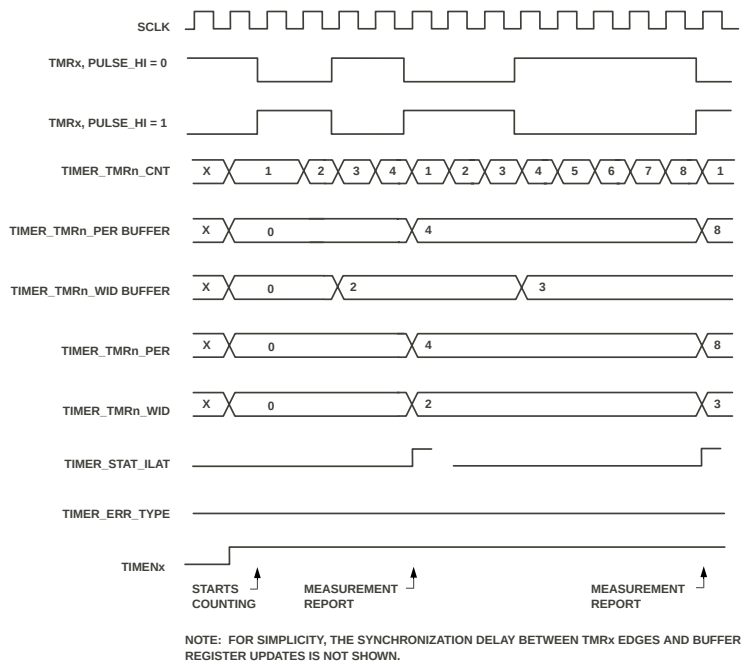

Figure 17-5: Example of Width Capture Asserted Mode (TMODE=b#1010)

NOTE: SCLK in the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure is SCLK.

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set `TIMER_TMR[n]_CFG.TMODE` = b#1011. If `TIMER_TMR[n]_CFG.TMODE` = b#1010 for this case, no period value is captured in the period buffer register. Instead, the timer genererates an error report interrupt request (if enabled) when the `TIMER_TMR[n]_CNT` range is exceeded and the counter wraps around. In this case, both the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers read 0 (because no measurement report occurred to copy the value captured in the width buffer register to the `TIMER_TMR[n]_WID` register).

If using the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010 mode to measure the width of a single pulse, programs can disable the timer after taking the interrupt that ends the measurement interval. If desired, restart the timer as appropriate in preparation for another measurement. This procedure prevents the timer from free-running after the width measurement and logging errors generated by the timer count overflowing.

Width Capture Mode Overflow

A timer status interrupt request (when enabled) is generated when the `TIMER_TMR[n]_CNT` register wraps around from 0xFFFF FFFF to 0 in the absence of a leading edge. At that point, the `TIMER_STAT_ILAT` bit is set and the `TIMER_ERR_TYPE` bits change to indicate a count overflow due to a period greater than the range of the counter. This indication is referred to as an error report. A data interrupt request in WIDCAP mode indicates that a new measurement is ready to be read (a measurement report). Similarly, an interrupt request on the timer status interrupt line (shared interrupt request for all timers) indicates an overflow error when generated in this mode.

The `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are never updated at the time an overflow error is signaled. If the timer overflows and the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are not updated. If the timer overflows and the

TIMER_TMR[n]_CFG.TMODE bit =b#1011, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers are updated only if a trailing edge is detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupt requests to measure input signal periods longer than 0xFFFF FFFF. Each error report interrupt request adds a full 2^{32}SCLK counts to the total for the period, but the width is ambiguous. Ensure that if software monitors only the status interrupt request, then status interrupt requests from all other timers are masked.

Refer to the ***Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)*** figure. The period is 0x1 0000 0004, but the pulse width could be either 0x0 0000 0002 or 0x1 0000 0002.

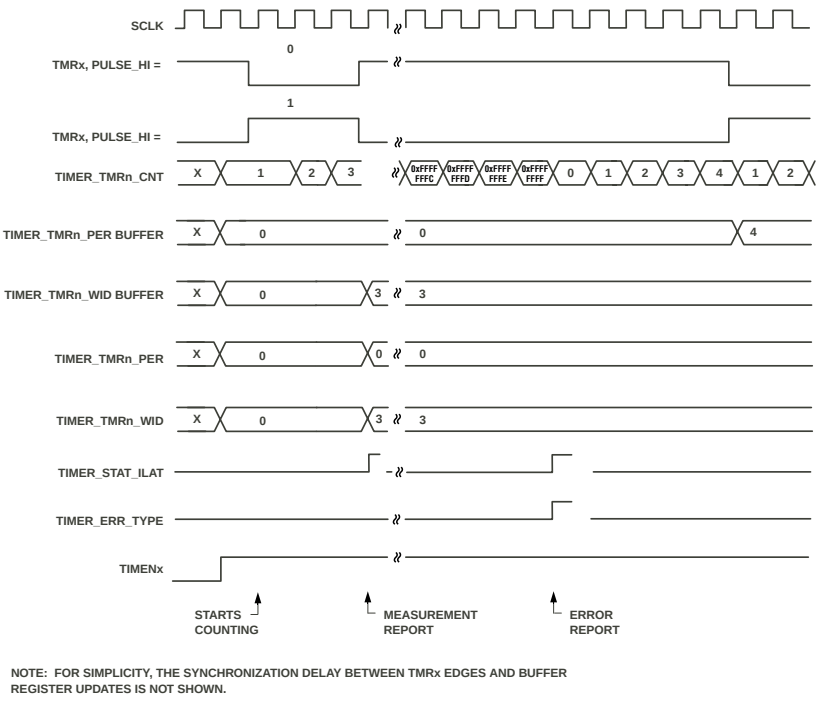

Figure 17-6: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK.

The waveform applied to the TIMER_TMR[n] (or TIMER_ACI[n]) pin is not required to have a 50% duty cycle. The minimum input low time is little more than one SCLK period. The minimum input high time is a little more than one SCLK period. (Refer to the product data sheet for details.) The maximum TIMER_TMR[n] input frequency is less than SCLK/2, with a 50% duty cycle. Under these conditions, the WIDCAP mode timer measures: period =2 and pulse width =1.

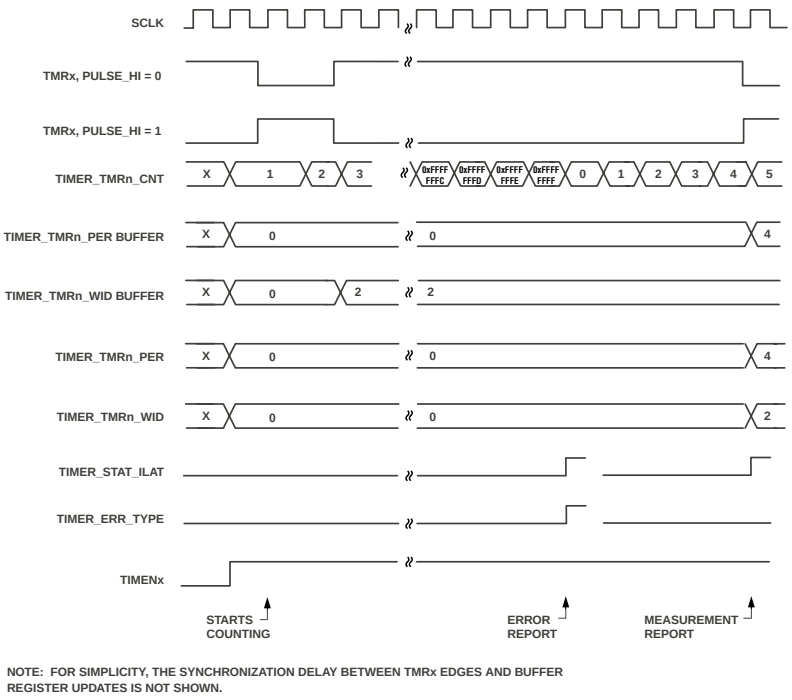

Figure 17-7: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1011)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK.

Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from either the `TIMER_TMR[n]` pin or the `TIMER_ACI[n]` pin. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt request appropriately. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to select polarity of the input signal.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet.

Windowed Watchdog Width Mode

In windowed watchdog width mode, the timer counter monitors the pulse width of an input signal on either the `TIMER_TMR[n]` pin or one of the alternate clock pins (`TIMER_ACLK[n]`). Program the minimum pulse width (p_{MIN}) in the `TIMER_TMR[n]_DLY` register and the maximum pulse width (p_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK or alternate clock). The timer can generate an interrupt if the deasserting pulse edge occurs:

- Inside the window (p_{MIN} < pulse width ≤ p_{MAX}), or
- Outside the window (pulse width ≤ p_{MIN} or pulse width > p_{MAX})

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. Any pulse that is already active when the timer is enabled is ignored.

With the TIMER_TMR[n]_CFG.IRQMODE bit =b#11, the timer generates an interrupt if the timed pulse width exceeds p_{MAX}, or if the pulse width is less than p_{MIN}. After attaining p_{MAX}, the pulse stays at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting TIMER_TMR[n]_CFG.IRQMODE =b#10.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the TIMER_TMR[n]_WID register. During the inactive portion of the input signal, the internal counter does not increment. The ***Watchdog Width Mode Timing*** figure shows the signal flow in this mode.

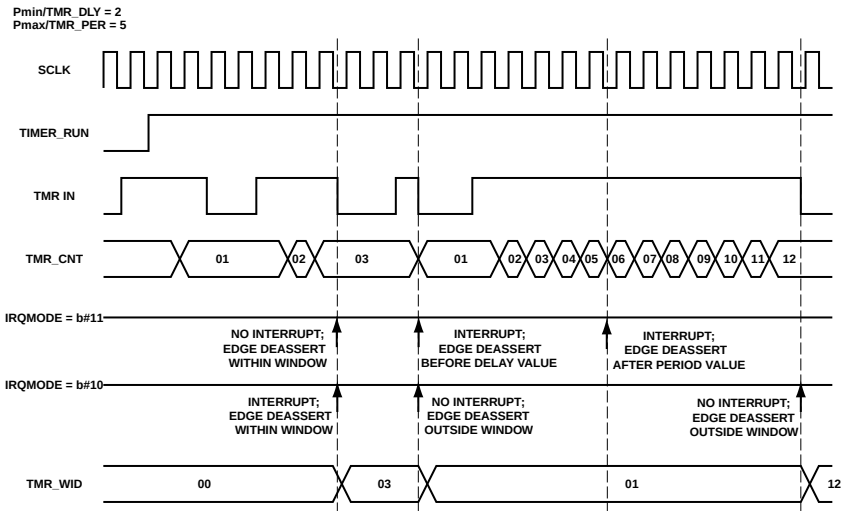

Figure 17-8: Watchdog Width Mode Timing

NOTE: SCLK in the ***Watchdog Width Mode Timing*** figure is SCLK.

To check only the upper limit on pulse width (p_{MAX} but not p_{MIN}), then program p_{MIN} as 0 or 1. In such a case, it is better to use TIMER_TMR[n]_CFG.IRQMODE =b#11. With TIMER_TMR[n]_CFG.IRQMODE = b#10, a pulse width of 1 clock cycle results in an interrupt. For details, see the ***Windowed Watchdog Width Mode Interpretation*** table.

Table 17-8: Windowed Watchdog Width Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE= b#10	IRQMODE= b#11	Error Interrupt?
0 or 1	Anything ≥ 1	PW = 1	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
> 1 but ≤ (Period -1)	Anything > 1	PW ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < PW≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
≥ Period	-	PW ≤ TMR_PER	Undefined	Undefined	No Error Interrupt
	-	PW > TMR_PER	Undefined	Undefined	b#11 Error Type
-	0	-	Undefined	Undefined	b#10 Error Type

Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising or falling edges of an input signal on either the `TIMER_TMR[n]` or `TIMER_ACI[n]` pin. Program the required minimum number of clock cycles (t_{MIN}) in the `TIMER_TMR[n]_DLY` register and the required maximum allowed number of clock cycles (t_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK) or alternate time clock (`TIMER_ACLK[n]`). The timer can generate an interrupt when two consecutive occurrences of an active edge are:

- Within a specified window (t_{MIN} < Pulse Period ≤ t_{MAX}), or
- Outside a specified window (pulse width ≤ (t_{MIN} or t_{MAX} < pulse width)

When the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11 and the pulse period > t_{MAX} or is ≤ t_{MIN}, the timer generates an interrupt (if unmasked). After attaining the t_{MAX} value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified

window condition, by setting `TIMER_TMR[n]_CFG.IRQMODE` =b#10. Refer to the ***Watchdog Period Mode Timing*** figure for timer functionality in period watchdog mode.

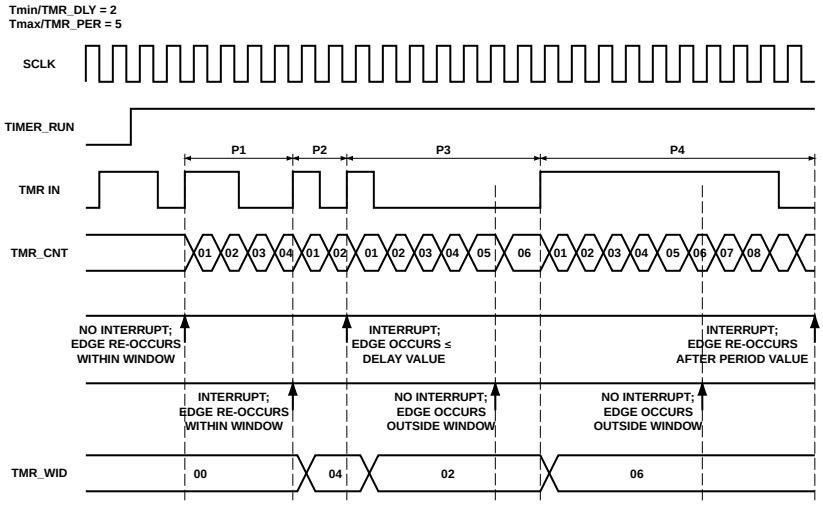

Figure 17-9: Watchdog Period Mode Timing

NOTE: SCLK in the ***Watchdog Period Mode Timing*** figure is SCLK.

To check only the upper limit on period (the t_{MAX} value, not the t_{MIN} value), program t_{MIN} as 0 or 1. For details, refer to the ***Windowed Watchdog Period Mode Interpretation*** table.

Table 17-9: Windowed Watchdog Period Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
0 or 1	Anything ≥ 2	Pulse Period ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse period crosses Pmax (Period Register) value	No Error Interrupt
> 1 but ≤ Period -1	Anything ≥ 2	Pulse Period ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < Pulse Period ≤TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) value	No Error Interrupt

Table 17-9: Windowed Watchdog Period Mode Interpretation (Continued)

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
≥ Period	-	Pulse Period < TMR_PER	Undefined	Undefined	No Error Interrupt
		Pulse Period ≥ TMR_PER	Undefined	Undefined	b#11 Error Type
-	0 or 1	-	Undefined	Undefined	b#10 Error Type

Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the `TIMER_TMR[n]` pin or the `TIMER_ACI[n]` pin can cause an edge-based interrupt, if enabled. (The timer uses the `TIMER_TMR[n]_CFG.TINSEL` register to select the pin). The event on the input pin can set the `TIMER_DATA_ILAT.TMR[nn]` bit and issue a system interrupt request. Program the `TIMER_TMR[n]_CFG.PULSEHI` bit to change active edge polarity.

Since the interrupt request is generated in the SCLK clock domain, the width of the input signal must be more than one SCLK period. Along with generating the interrupt request, the timer also generates a trigger pulse (configured using the `TIMER_TRG_MSK` register). Due to the configuration of polarity, glitches can cause the generation of an undesired interrupt request at the input. To avoid this problem, programs must ensure that interrupt requests are unmasked only after configuring the desired polarity.

External Clock (EXTCLK) Mode

The timer uses EXTCLK mode, sometimes referred to as the counter mode, to count external events (signal edges), on either the `TIMER_TMR[n]` or `TIMER_ACI[n]` input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to SCLK. The current count in the `TIMER_TMR[n]_CNT` register represents the number of leading-edge events detected. The `TIMER_TMR[n]_PER` register is programmed with the value of the maximum timer external count before stopping or issuing an interrupt request or trigger.

The `TIMER_TMR[n]_CFG.PULSEHI` bit determines the polarity of the leading edge on the input pin. The timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select whether the event is counted on the `TIMER_TMR[n]` or on the `TIMER_ACI[n]` pin. The `TIMER_STAT_ILAT.TMR[nn]` and `TIMER_ERR_TYPE` bits are set if *one* of these conditions is met:

- `TIMER_TMR[n]_CNT` wraps around from 0xFFFF FFFF to 0
- The period = 0 at startup
- `TIMER_TMR[n]_CNT` register rolls over (from count = period to count = 0x1)

The `TIMER_TMR[n]_WID` and `TIMER_TMR[n]_DLY` registers are unused in this mode and must not be written.

The ***EXTCLK Mode Control Flow*** figure shows a flow diagram for EXTCLK mode.

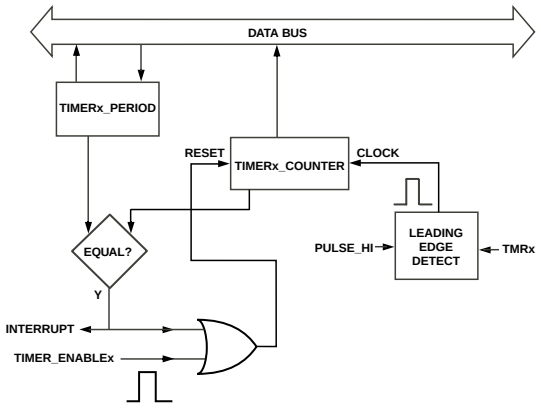

Figure 17-10: EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet. Program the period to any value from 1 to (2^{32} – 1), inclusive.

After the timer has started, it resets the `TIMER_TMR[n]_CNT` register to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TIMER_TMR[n]_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After the `TIMER_TMR[n]_CNT` register reaches the value programmed in the `TIMER_TMR[n]_PER` register, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading-edge reloads the `TIMER_TMR[n]_CNT` register with 0x1, and the timer continues counting until it is disabled.

GP Timer Programming Concepts

Using the features, operating modes, and event control for the GP timer to their greatest potential requires an understanding of some GP timer-related concepts.

Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and delay settings for each of the first three timer periods after the timer starts.

1. Program the first set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.
2. Enable the timer using the `TIMER_RUN` register.
3. Immediately program the second set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values, as needed.
4. Wait for the first timer interrupt request.
5. Program the third set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.

Each new setting is then programmed when the preceding timer interrupt request is received.

Configuring, Enabling, and Disabling One or More Timers

1. Configure the relevant timers for the operating mode and other properties using the TIMER_TMR[n]_CFG register.
2. Write a 1 to the representative TIMER_RUN.TMR[nn] bit. Or, use the TIMER_RUN_SET register to avoid disturbing the settings of other timers that are not going through configuration.

   The timer is enabled and operating.
3. To stop one or more timers, first program the TIMER_STOP_CFG register to determine whether to stop immediately or gracefully upon receiving a stop command.

   ADDITIONAL INFORMATION: PWMOUT modes are the only modes where a timer can be configured for graceful termination.
4. Write a 0 to the representative TIMER_RUN.TMR[nn] bits to stop the timer according to their TIMER_STOP_CFG settings. Alternately, write a 1 to the appropriate TIMER_RUN_CLR.TMR[nn] bits to avoid disturbing the settings of other timers that are not terminating.

   The timers stop.

Configuring Timer Data and Status Interrupts

1. Configure the TIMER_TMR[n]_CFG.IRQMODE bit field with the desired interrupt properties.
2. Unmask the interrupt source at the system event controller.
3. Set the TIMER_TMR[n]_CFG.IRQMODE field but leave the interrupt masked at the system level to poll the TIMER_DATA_ILAT.TMR[nn] bit of the timer without generating an interrupt.
4. Use the TIMER_STAT_IMSK register to generate interrupt requests by overflow or error conditions (incorrect programming values). The timer uses the TIMER_STAT_ILAT.TMR[nn] bits to report interrupt errors, when the timer status interrupt source is unmasked at the system event controller.
5. To poll the TIMER_STAT_ILAT.TMR[nn] bit of the timer without generating an interrupt, unmask the corresponding bit in the TIMER_STAT_IMSK register, but leave the interrupt masked at the system level.

Configuring the Timer as a Trigger Slave

The timer can be configured to either start or stop or toggle between these two states on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.SLAVETRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =1 then the trigger pulse starts timer, if it is stopped.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =0 then the trigger pulse stops timer, if it is running.
- When TIMER_TMR[n]_CFG.TGLTRIG bit =0, the trigger pulse has no effect when the timer is already in the requested state.

If TIMER_TMR[n]_CFG.TGLTRIG bit is 1, the trigger pulse starts the timer if it is stopped, or stops the timer if it is running. The TIMER_TMR[n]_CFG.SLAVETRIG bit has no effect on trigger mechanism. In continuous PWMOUT mode, the timer stops gracefully or abruptly depending on the stop mechanism programmed in the TIMER_STOP_CFG_CLR register. In other modes, the timer stops immediately.

Ordered Trigger Toggle Mode

The timer can be configured to either start or stop the timer on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.ORDTGLTRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 0, then the input trigger pulse on trigger slave 0 or trigger slave 1 starts the timer if it is stopped, or stops the timer if it is running.
- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 1, then the input trigger pulse on trigger slave 0 starts timer if it is stopped. If the timer is running, it stops when the input trigger pulse on trigger slave 1 is detected.

  Trigger slave 0 cannot toggle the timer from the run to halt state. Trigger slave 1 cannot toggle the timer from the halt to run state.

NOTE: The timer state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET, and TIMER_RUN_CLR registers in this mode.

Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width, and delay registers simultaneously across more than one timer.

Timer triggers TIMER_TMR[n]_SLV0 and TIMER_TMR[n]_SLV1 are logically OR'd so each individual timer can have two input triggers.

1. Enable the appropriate broadcast bits (TIMER_TMR[n]_CFG.BPEREN, TIMER_TMR[n]_CFG.BWIDEN are TIMER_TMR[n]_CFG.BDLYEN) for the timers involved in the broadcast. The use of these bits depends on which broadcast registers the timer uses (TIMER_BCAST_PER, TIMER_BCAST_WID, or TIMER_BCAST_DLY).
2. Program the TIMER_BCAST_PER register (for example), to broadcast the period setting across the multiple timers enabled.

   The enabled timers load their TIMER_TMR[n]_PER registers with the value specified in the TIMER_BCAST_PER register.

3. Repeat Step 2 as needed for the TIMER_BCAST_WID and TIMER_BCAST_DLY register settings.

Timer Illegal States

The following sections use these definitions:

- Startup. The first clock period during which the timer counter is running after the timer is started by writing the TIMER_RUN register.
- Rollover. The time when the current count in TIMER_TMR[n]_CNT matches the value in TIMER_TMR[n]_PER and the counter is reloaded with the value 1.
- Overflow. The timer counter was incremented instead of doing a rollover when it was holding the maximum count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so it erroneously loads a new value of 0x0000 0000.
- Unchanged. No new error.

When the TIMER_ERR_TYPE register is designated unchanged, it displays the previously reported error code orb# 00 when there has been no error since this timer was enabled.

When the TIMER_STAT_ILAT register is unchanged, it reads 0 when there has been no error or overflow since this timer was enabled. Or, it reads 0 if software has performed a W1C to clear any previous error. If software has not acknowledged a previous error, the TIMER_STAT_ILAT register reads 1. Software can read the TIMER_STAT_ILAT register to check for errors. If a particular bit of a timer is set in this register, software can then read the TIMER_ERR_TYPE register for more information. Once detected, software can W1C the appropriate TIMER_STAT_ILAT bit to acknowledge the error.

Read the following tables as:

- In mode __ at event __,
- if TIMER_TMR[n]_PER is __ and TIMER_TMR[n]_WID is __ and TIMER_TMR[n]_DLY is __,
- then TIMER_ERR_TYPE is __ and TIMER_STAT_ILAT is __.

Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases can cause unwanted behavior of the TIMER_TMR[n] pin.

NOTE: For PININT mode, the timer does not use error functionality.

Continuous PWMOUT Mode

Table 17-10: Startup Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≤ 1	Anything other than period[8]	Anything	Anything	b#10	Set

ADSP-SC57x TIMER Register Descriptions

General-Purpose Timer Block (TIMER) contains the following registers.

Table 17-22: ADSP-SC57x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register
TIMER_STAT_ILAT	Status Interrupt Latch Register
TIMER_STAT_IMSK	Status Interrupt Mask Register
TIMER_STOP_CFG	Stop Configuration Register
TIMER_STOP_CFG_CLR	Stop Configuration Clear Register
TIMER_STOP_CFG_SET	Stop Configuration Set Register
TIMER_TMR[n]_CFG	Timer n Configuration Register
TIMER_TMR[n]_CNT	Timer n Counter Register
TIMER_TMR[n]_DLY	Timer n Delay Register
TIMER_TMR[n]_PER	Timer n Period Register
TIMER_TMR[n]_WID	Timer n Width Register
TIMER_TRG_IE	Trigger Slave Enable Register
TIMER_TRG_MSK	Trigger Master Mask Register

Broadcast Delay Register

For timers with TIMER_TMR[n]_CFG.BDLYEN enabled, a write to the TIMER_BCAST_DLY register concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_DLY register.

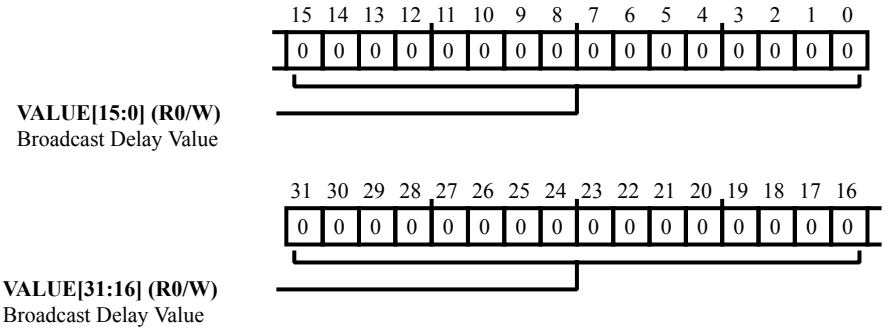

Figure 17-11: TIMER_BCAST_DLY Register Diagram

Table 17-23: TIMER_BCAST_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Delay Value. A write to the TIMER_BCAST_DLY.VALUE bit field concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Broadcast Period Register

For timers with TIMER_TMR[n]_CFG.BPEREN enabled, a write to the TIMER_BCAST_PER register concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of TIMER_BCAST_PER returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_PER register.

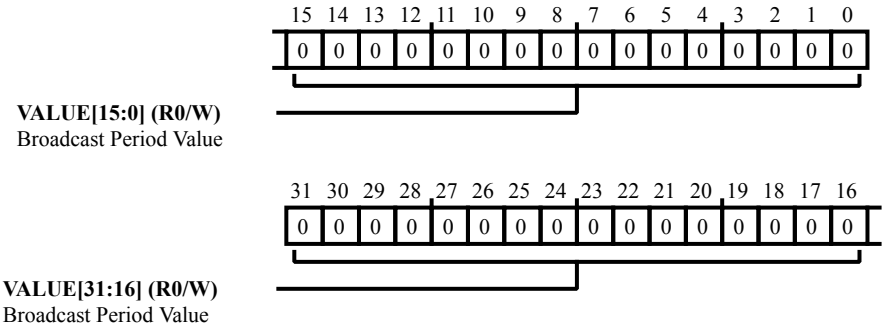

Figure 17-12: TIMER_BCAST_PER Register Diagram

Table 17-24: TIMER_BCAST_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Period Value. A write to the TIMER_BCAST_PER.VALUE bit field concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of the TIMER_BCAST_PER.VALUE bit fields returns 0x0000 0000, and no bus error is generated.

Broadcast Width Register

For timers with TIMER_TMR[n]_CFG.BWIDEN enabled, a write to the TIMER_BCAST_WID register concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_WID register.

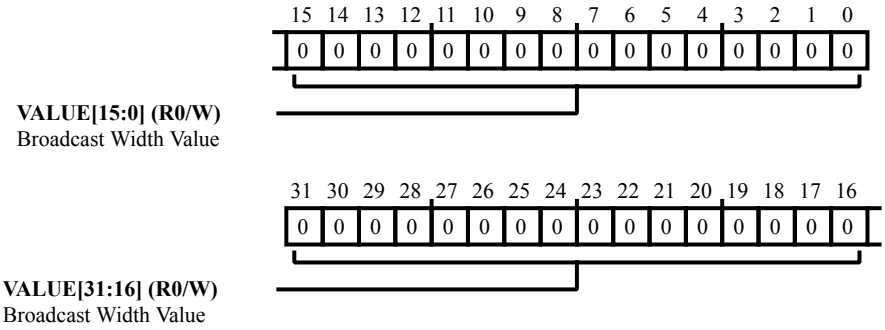

Figure 17-13: TIMER_BCAST_WID Register Diagram

Table 17-25: TIMER_BCAST_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Width Value. A write to the TIMER_BCAST_WID.VALUE bit field concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Data Interrupt Latch Register

The TIMER_DATA_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER_DATA_IMSK register and generated according to the conditions selected by the TIMER_TMR[n]_CFG.IRQMODE bits. If a bit in TIMER_DATA_ILAT is already set and the corresponding interrupt is masked in TIMER_DATA_IMSK, the latch holds its old value, leaving the interrupt request asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER_DATA_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

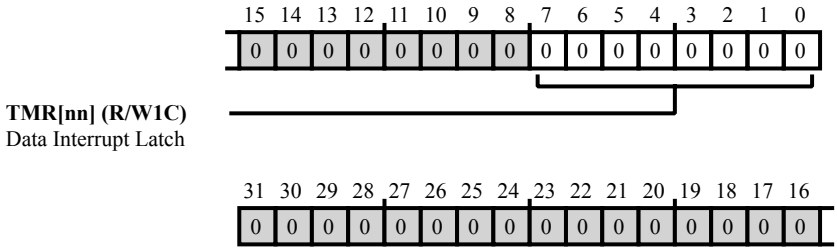

Figure 17-14: TIMER_DATA_ILAT Register Diagram

Table 17-26: TIMER_DATA_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	TMR[nn]	Data Interrupt Latch. For all TIMER_DATA_ILAT.TMR[nn] bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding TIMER_TMR[n]_CFG.IRQMODE bit has occurred).

Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The TIMER_DATA_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_DATA_IMSK register is 0xFFFF, masking these interrupts after reset.

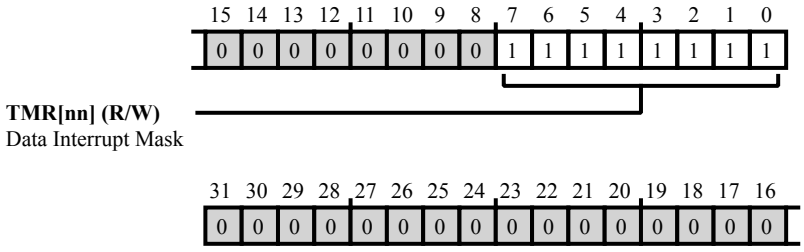

Figure 17-15: TIMER_DATA_IMSK Register Diagram

Table 17-27: TIMER_DATA_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Data Interrupt Mask. For all TIMER_DATA_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request.

Error Type Status Register

The TIMER_ERR_TYPE register contains error type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error request interrupt is latched in the TIMER_STAT_ILAT register, the corresponding TERRx bits in the TIMER_ERR_TYPE register are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on the TIMER_ERR_TYPE register.

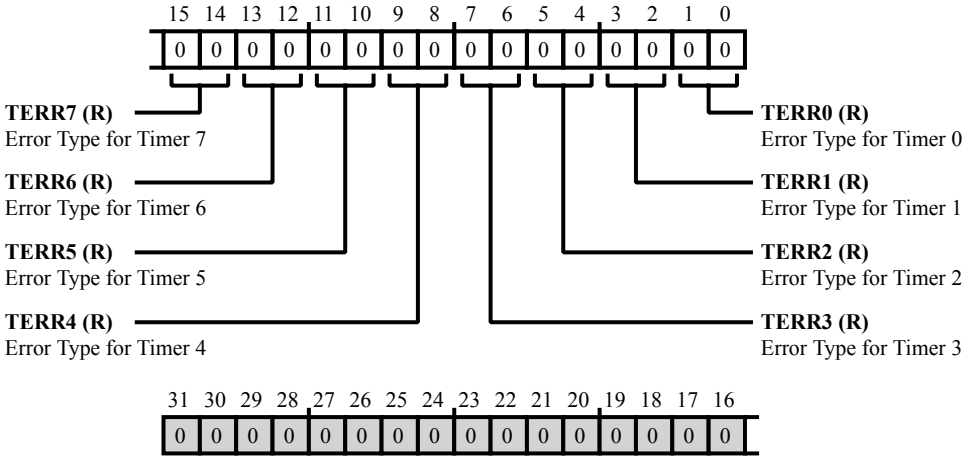

Figure 17-16: TIMER_ERR_TYPE Register Diagram

Run Register

The TIMER_RUN allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration TIMER_STOP_CFG register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the TIMER_RUN_CLR register.

Reading the TIMER_RUN register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the TIMER_RUN register is not used in PININT mode. PININT mode starts as soon as the TIMER_TMR[n]_CFG.TMODE bits are set to 111.

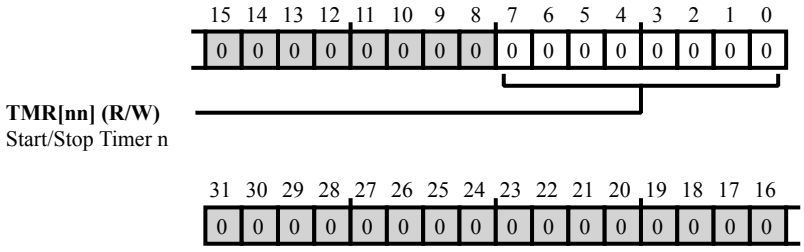

Figure 17-17: TIMER_RUN Register Diagram

Table 17-29: TIMER_RUN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Start/Stop Timer n. For all TIMER_RUN.TMR[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running.

Run Clear Register

The TIMER_RUN_CLR register is an alias register, providing a mechanism to clear a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To stop a particular timer, software must write a 1 into the corresponding TIMER_RUN_CLR bit. Writing a 0 has no effect. Because TIMER_RUN_CLR is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_CLR returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the TIMER_STOP_CFG register.

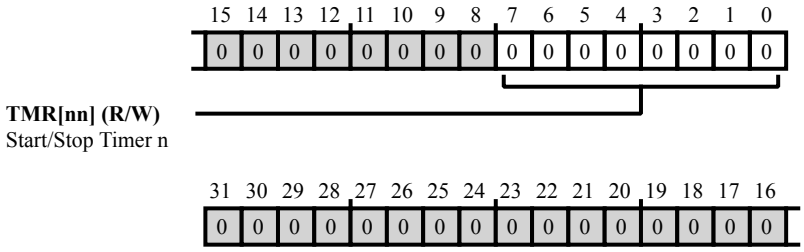

Figure 17-18: TIMER_RUN_CLR Register Diagram

Table 17-30: TIMER_RUN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1C)	TMR[nn]	RUN Clear Alias. For all TIMER_RUN_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the TIMER_RUN register). Using TIMER_RUN_CLR to clear start/stop bits permits stopping specific timers without influencing run status of other timers.

Run Set Register

The TIMER_RUN_SET register is an alias register, providing a mechanism to set a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To start a particular timer, software must write a 1 into the corresponding TIMER_RUN_SET bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into TIMER_RUN_SET. Because TIMER_RUN_SET is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_SET returns 0x0000.

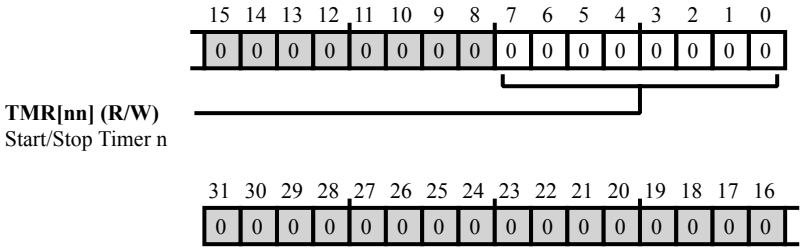

Figure 17-19: TIMER_RUN_SET Register Diagram

Table 17-31: TIMER_RUN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1S)	TMR[nn]	RUN Set Alias. For all TIMER_RUN_SET.TMR[nn] bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the TIMER_RUN register). Using TIMER_RUN_SET to set start/stop bits permits starting specific timers without influencing the run status of other timers.

Status Interrupt Latch Register

The TIMER_STAT_ILAT holds the latched interrupt status for error interrupt requests, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the TIMER_STAT_ILAT register provide information regarding each timer interrupt request source.

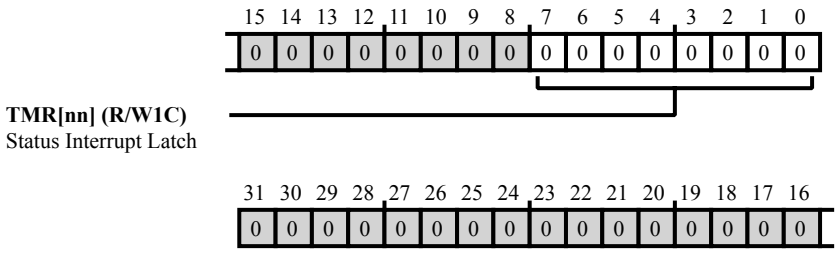

Figure 17-20: TIMER_STAT_ILAT Register Diagram

Table 17-32: TIMER_STAT_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	TMR[nn]	Status Interrupt Latch. For all TIMER_STAT_ILAT.TMR[nn] bits, status of 0 indicates no error interrupt request is latched, and status of 1 indicates a timer counter overflow or programming error interrupt request is latched.

Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the system event controller. The TIMER_STAT_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_STAT_IMSK register is 0xFFFF, masking these interrupts after reset.

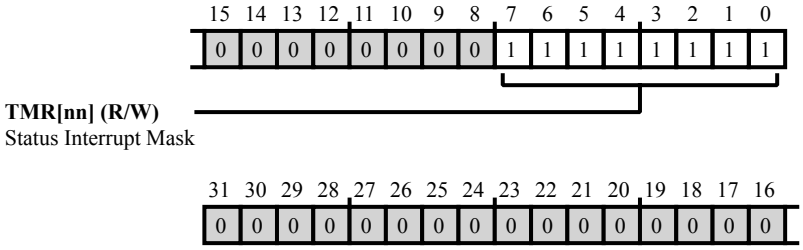

Figure 17-21: TIMER_STAT_IMSK Register Diagram

Table 17-33: TIMER_STAT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Status Interrupt Mask. For all TIMER_STAT_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request.

Stop Configuration Register

The TIMER_STOP_CFG register selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in TIMER_RUN or a write =1 to the corresponding bit in TIMER_RUN_CLR. A read of TIMER_STOP_CFG returns the last value written.

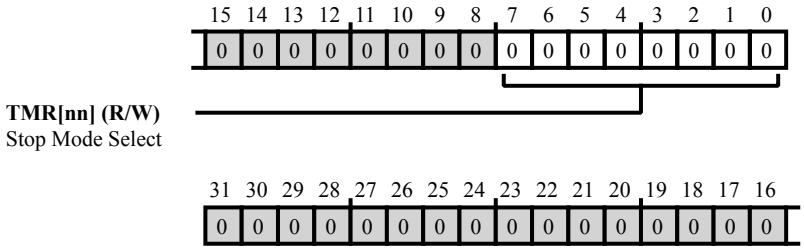

Figure 17-22: TIMER_STOP_CFG Register Diagram

Table 17-34: TIMER_STOP_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Stop Mode Select. For all TIMER_STOP_CFG.TMR[nn] bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop.

Stop Configuration Clear Register

This is an alias register, providing a mechanism to clear a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To clear a bit in TIMER_STOP_CFG, software must write a 1 to the corresponding bit of TIMER_STOP_CFG_CLR register. Writing a zero has no effect. Because the TIMER_STOP_CFG_CLR register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_CLR register returns 0x0000.

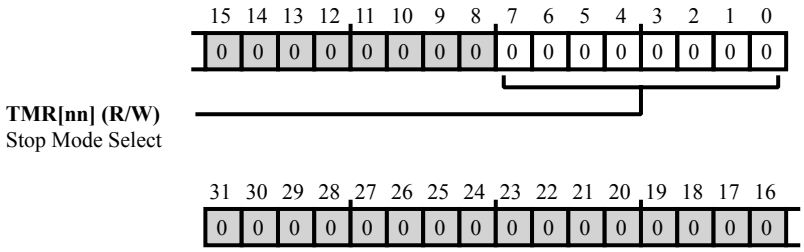

Figure 17-23: TIMER_STOP_CFG_CLR Register Diagram

Table 17-35: TIMER_STOP_CFG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1C)	TMR[nn]	STOP_CFG Clear Alias. For all TIMER_STOP_CFG_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To set a bit in the TIMER_STOP_CFG register, software must write a 1 to the corresponding bit of the TIMER_STOP_CFG_SET register. Writing a zero has no effect. Because the TIMER_STOP_CFG_SET register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_SET register returns 0x0000.

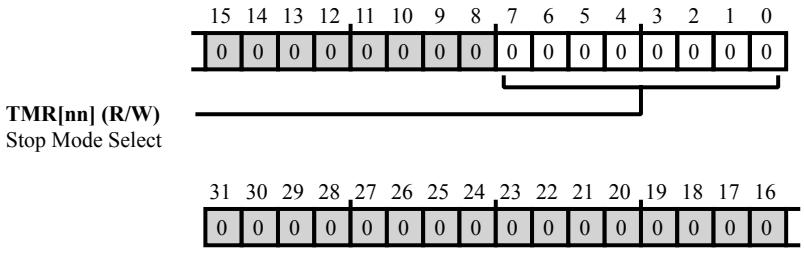

Figure 17-24: TIMER_STOP_CFG_SET Register Diagram

Table 17-36: TIMER_STOP_CFG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1S)	TMR[nn]	STOP_CFG Set Alias. For all TIMER_STOP_CFG_SET.TMR[nn] bits, write =0 has no effect, and write =1 for abrupt stop (setting the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_SET to set stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Timer n Configuration Register

Each timer has a TIMER_TMR[n]_CFG register that specifies its operating mode. Only write to a TIMER_TMR[n]_CFG register when the corresponding timer is not running.

After disabling a timer operating in PWMOUT mode, verify that the timer has stopped running by checking the start/stop status of the timer in the TIMER_RUN register before writing to the timer's TIMER_TMR[n]_CFG register.

Note that a timer's TIMER_TMR[n]_CFG register may be read at any time.

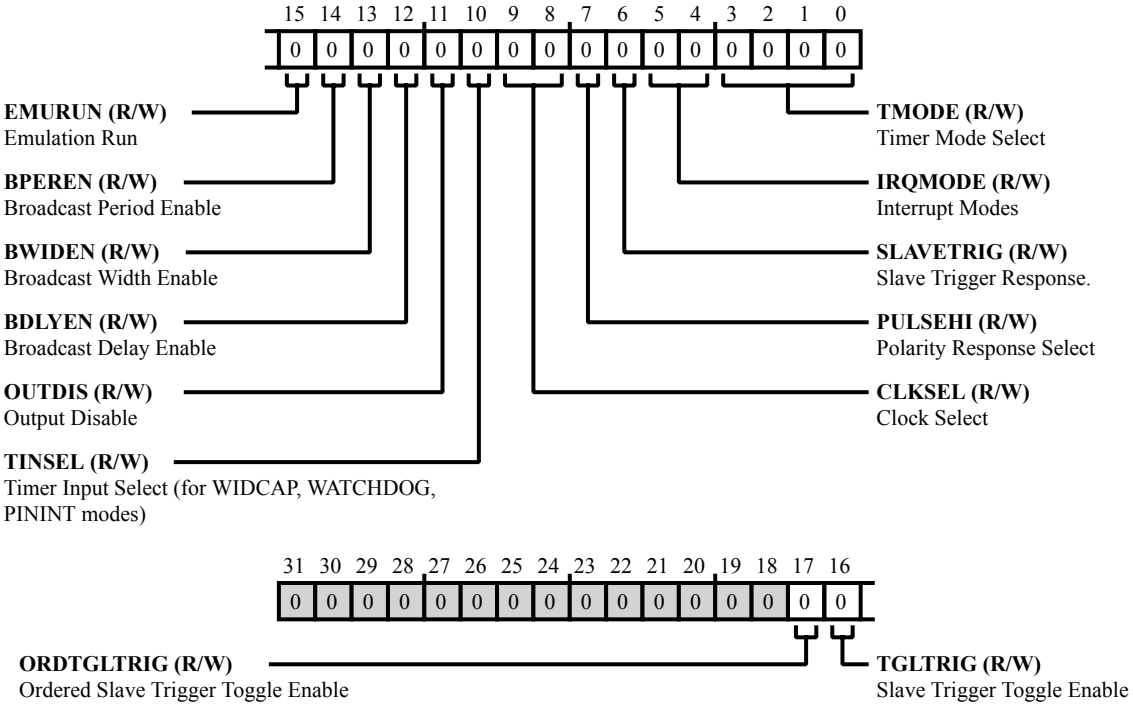

Figure 17-25: TIMER_TMR[n]_CFG Register Diagram

Table 17-37: TIMER_TMR[n]_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ORDTGLTRIG	Ordered Slave Trigger Toggle Enable. The TIMER_TMR[n]_CFG.ORDTGLTRIG bit controls ordered slave trigger toggle mode. The timer(slave) state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET and TIMER_RUN_CLR registers when this bit is enabled.	
		0	No effect
		1	Trigger pulse on Trigger Slave 0 starts the timer if it in halt state and trigger pulse in Trigger Slave 1 stops the timer if it is running
16 (R/W)	TGLTRIG	Slave Trigger Toggle Enable. The TIMER_TMR[n]_CFG.TGLTRIG bit stops the timer if it is running and starts the timer if it is halted (in the stop state). If the TIMER_TMR[n]_CFG.TGLTRIG bit is set, then the setting of the TIMER_TMR[n]_CFG.SLAVETRIG bit is ignored.	
		0	Slave Trigger Response Depends on SLAVETRIG Bit Setting
		1	Slave Trigger Toggles Timer State
15 (R/W)	EMURUN	Emulation Run. The TIMER_TMR[n]_CFG.EMURUN bit causes the timer to run (count) during emulation.	
		0	Stop Timer During Emulation
		1	Run Timer During Emulation
14 (R/W)	BPEREN	Broadcast Period Enable. The TIMER_TMR[n]_CFG.BPEREN bit enables updates to the TIMER_TMR[n]_PER register simultaneously across more than one timer.	
		0	Disable Broadcast to PER Register
		1	Enable Broadcast to PER Register
13 (R/W)	BWIDEN	Broadcast Width Enable. The TIMER_TMR[n]_CFG.BWIDEN bit enables updates to the TIMER_TMR[n]_WID register simultaneously across more than one timer.	
		0	Disable Broadcast to WID Register
		1	Enable Broadcast to WID Register

Table 17-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BDLYEN	Broadcast Delay Enable. The `TIMER_TMR[n]_CFG.BDLYEN` bit enables updates to the `TIMER_TMR[n]_DLY` register simultaneously across more than one timer.	
		0	Disable Broadcast to DLY Register
		1	Enable Broadcast to DLY Register
11 (R/W)	OUTDIS	Output Disable. The `TIMER_TMR[n]_CFG.OUTDIS` bit enables or disables the timer pin output buffer.	
		0	Enable TMR Pin Output Buffer
		1	Disable TMR Pin Output Buffer
10 (R/W)	TINSEL	Timer Input Select (for WIDCAP, WATCHDOG, PININT modes).	
		0	Use TMR Pin Input
		1	Use TMR Alternate Capture Input
9:8 (R/W)	CLKSEL	Clock Select. The `TIMER_TMR[n]_CFG.CLKSEL` bit field selects the TIMER clock to use.	
		0	Use SCLK
		1	Use TMR_ALT_CLK0 as TMR Clock
		3	Use TMR_ALT_CLK1 as TMR Clock
7 (R/W)	PULSEHI	Polarity Response Select. The `TIMER_TMR[n]_CFG.PULSEHI` bit defines specific behaviors of the timer based on the operating mode. For more information, see the specific operating mode in the Programming Concepts section.	
		0	Negative Response or Pulse. A Negative Edge Response or Negative Action Pulse on the TMR pin.
		1	Positive Response or Pulse. A Positive Edge Response or Positive Action Pulse on the TMR pin.
6 (R/W)	SLAVETRIG	Slave Trigger Response.. The `TIMER_TMR[n]_CFG.SLAVETRIG` bit controls the trigger response. The trigger pulse has no effect (to stop or start the timer) if the timer is already in the requested state.	
		0	Pulse Stops Timer if it is Running
		1	Pulse Starts Timer if it is Stopped

Table 17-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	IRQMODE	Interrupt Modes. The TIMER_TMR[n]_CFG.IRQMODE bit field selects the interrupt request mode. Note that any mismatched combination of the TIMER_TMR[n]_CFG.IRQMODE and the TIMER_TMR[n]_CFG.TMODE bits results in no interrupt being generated. In WIDCAP modes, the position of the interrupt is controlled with the TIMER_TMR[n]_CFG.TMODE bit, and the TIMER_TMR[n]_CFG.IRQMODE bit is ignored. Whenever an interrupt is generated, a trigger master pulse is also generated, if enabled in the TIMER_TRG_MSK register.	
		0	Active Edge Mode. The timer generates an interrupt at every active edge. The active edge polarity depends on the state of the TIMER_TMR[n]_CFG.PULSEHI bit. Valid for PININT mode only.
		1	Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_DLY register. This mode is valid for all PWMOUT modes.
		2	Width Plus Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_WID register plus the value in the TIMER_TMR[n]_DLY register. (PWMOUT modes only) The timer generates an interrupt if the deasserting edge is within the specified window. (WATCHDOG modes only)
		3	Period Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_PER register. (Continuous PWMOUT and EXTCLK modes only) The timer generates an interrupt if the deasserting edge is outside the specified window.(WATCHDOG modes only)
3:0 (R/W)	TMODE	Timer Mode Select. The TIMER_TMR[n]_CFG.TMODE bit field selects the operating mode of each timer.	
		0-7	Idle Mode
		8	Period Watchdog Mode
		9	Width Watchdog Mode

Table 17-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		10	Measurement Report at Asserting Edge of Waveform
		11	Measurement Report at Deasserting Edge of Waveform
		12	Continuous PWMOUT Mode
		13	Single Pulse PWMOUT Mode
		14	EXTCLK Mode
		15	PININT (pin interrupt) Mode

Timer n Counter Register

The TIMER_TMR[n]_CNT register holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The TIMER_TMR[n]_CNT register is read-only and may be read at any time (whether the timer is running or stopped). Reading the TIMER_TMR[n]_CNT register returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK, the TMR or alternate capture input pins, TIMER_ACLK[n]. The counter retains its value after the timer is disabled.

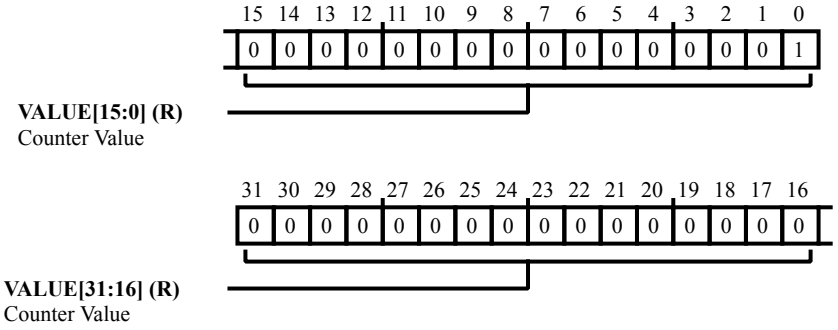

Figure 17-26: TIMER_TMR[n]_CNT Register Diagram

Table 17-38: TIMER_TMR[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Counter Value. The TIMER_TMR[n]_CNT.VALUE bit field holds the current timer count.

Timer n Delay Register

The TIMER_TMR[n]_DLY register holds the delay value for the corresponding timer. This register's use is based on the selected timer mode.

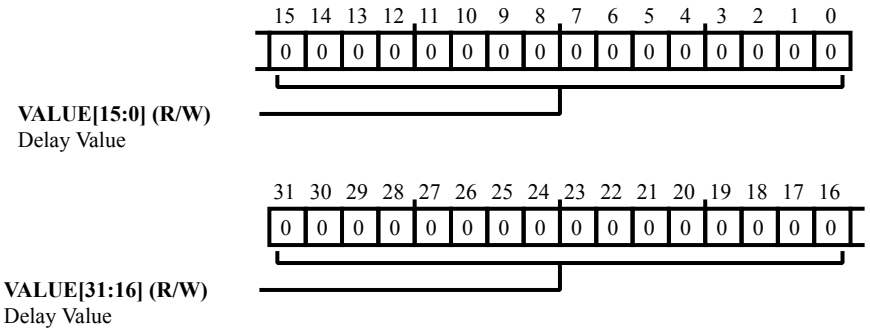

Figure 17-27: TIMER_TMR[n]_DLY Register Diagram

Table 17-39: TIMER_TMR[n]_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Value. The TIMER_TMR[n]_DLY.VALUE bit field holds the delay value for the corresponding timer.

Timer n Period Register

The TIMER_TMR[n]_PER register holds the period value for the corresponding timer. This register's use is based on the selected timer mode.

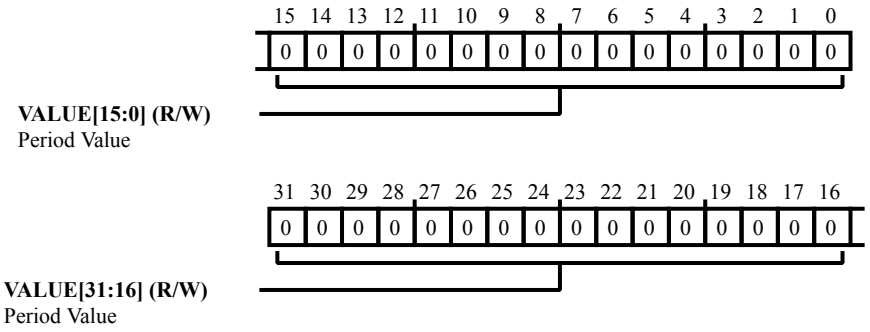

Figure 17-28: TIMER_TMR[n]_PER Register Diagram

Table 17-40: TIMER_TMR[n]_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Period Value. The TIMER_TMR[n]_PER.VALUE bit field holds the period value for the corresponding timer.

Timer n Width Register

The TIMER_TMR[n]_WID register holds the width value for the corresponding timer. This register's use is based on the selected timer mode.

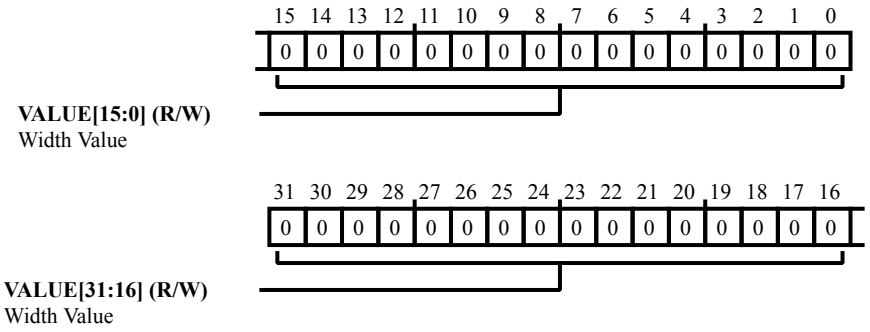

Figure 17-29: TIMER_TMR[n]_WID Register Diagram

Table 17-41: TIMER_TMR[n]_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Width Value. The TIMER_TMR[n]_WID.VALUE bit field holds the width value for the corresponding timer.

Trigger Slave Enable Register

As a trigger slave, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_IE contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the TIMER_TRG_IE register is 0xFFFF, masking these triggers after reset.

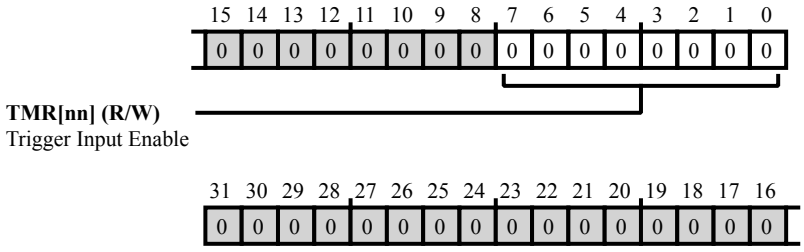

Figure 17-30: TIMER_TRG_IE Register Diagram

Table 17-42: TIMER_TRG_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Trigger Input Enable. For all TIMER_TRG_IE.TMR[nn] bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input.

Trigger Master Mask Register

As a trigger master, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_MSK` register contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the `TIMER_TRG_MSK` register is 0xFFFF, masking these triggers after reset.

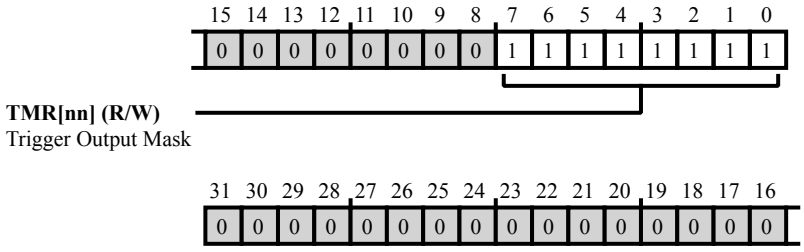

Figure 17-31: TIMER_TRG_MSK Register Diagram

Table 17-43: TIMER_TRG_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Trigger Output Mask. For all `TIMER_TRG_MSK.TMR[nn]` bits, write =0 unmasks (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output.

18 Watchdog Timer (WDOG)

The processor has a 32-bit watchdog timer that can be used to verify system reliability by generating an event to the processor core when the watchdog expires before software updates it.

WDOG Features

The watchdog timer has the following features:

- Programmable 32-bit watchdog count value
- 8-bit disable bit pattern
- General-purpose core event generation

The watchdog timer can supervise system software stability by periodically reloading it to prevent expiration of the downward-counting timer (such that the count never becomes 0). When used in this fashion, an expiring timer can indicate the system software is not running normally.

Expiration of the WDOG counter generates a general-purpose interrupt, which can be used in a variety of ways:

- as an interrupt vector sent through the System Event Controller (SEC) to the core to be serviced by a handler function, providing full software control of device resources (for example, GPIO management and reset control).
- as a fault condition through the SEC to provide hardware-automated:
    - signalling of the fault condition on external pins to the system,
    - system reset requests to the Reset Control Unit (RCU), and/or
    - trigger outputs (SEC0_FAULT trigger master) through the Trigger Routing Unit (TRU) to initiate activities in a variety of potential trigger slaves (for example, GPIO control).

To facilitate debugging, the watchdog timer does not decrement (even if enabled) when the processor is in emulation mode.

WDOG Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK0_0 cycle. If it reaches zero, the watchdog expiration event is generated, which can be used in many ways.

To start the watchdog timer:

1. Program the watchdog timeout period (in SCLK0_0 cycles) in the WDOG_CNT register. With the watchdog disabled, this write also preloads the WDOG_STAT register.
2. Enable the watchdog timer by writing any value other than 0xAD to the WDOG_CTL.WDEN field.

Once the watchdog is enabled, writes to the WDOG_CNT register are ignored. The counter begins decrementing, and the current counter value can be read from the 32-bit WDOG_STAT register at any time.

To prevent the counter from expiring, software must "kick" the watchdog by writing any value to the WDOG_STAT register while the current count is non-zero. While the value written is irrelevant and ignored, this action resets the current counter in the WDOG_STAT register to the programmed WDOG_CNT value, and decrementing continues. The internal counter continues decrementing until it reaches zero, at which point the expiration event is generated, and the WDOG_CTL.WDRO rollover bit is set.

Watchdog operation continues in this manner unless disabled by explicitly writing 0xAD to the WDOG_CTL.WDEN field.

The watchdog expiration event can be used in a variety of ways, as listed below.

- The watchdog expiration event itself is one of numerous interrupt sources that is managed by the System Event Controller. Like other peripheral sources, this event can be used to cause a vector to a handler function that executes based on interrupt priority.
- The watchdog expiration event can be used to initiate automated hardware response through the SEC Fault Interface (SFI).

For this, the WDOG expiry has to be configured as the fault source in the SEC. Then the response to the WDOG expiry can be set to any of the below:

- Signalling through the external fault pin.
- System reset
- Trigger outputs to numerous potential trigger slaves.

For further details on how watchdog expiration event can be used with the SFI, see Configuring the WDOG Expiry Event to Issue a System Reset.

ADSP-SC57x WDOG Register List

The Watchdog Timer unit (WDOG) provides a software-based watchdog timer that can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. A set of registers governs WDOG operations. For more information on WDOG functionality, see the WDOG register descriptions.

Table 18-1: ADSP-SC57x WDOG Register List

Name	Description
WDOG_CNT	Count Register
WDOG_CTL	Control Register
WDOG_STAT	Watchdog Timer Status Register
WDOG_WIN	Watchdog Timer Window Register

ADSP-SC57x WDOG Interrupt List

Table 18-2: ADSP-SC57x WDOG Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
3	WDOG0_EXP	WDOG0 Expiration	Level	
4	WDOG1_EXP	WDOG1 Expiration	Level	
5	WDOG2_EXP	WDOG2 Expiration	Level	

WDOG Block Diagram

The *Watchdog Timer Block Diagram* figure shows the detailed block diagram for the watchdog timer.

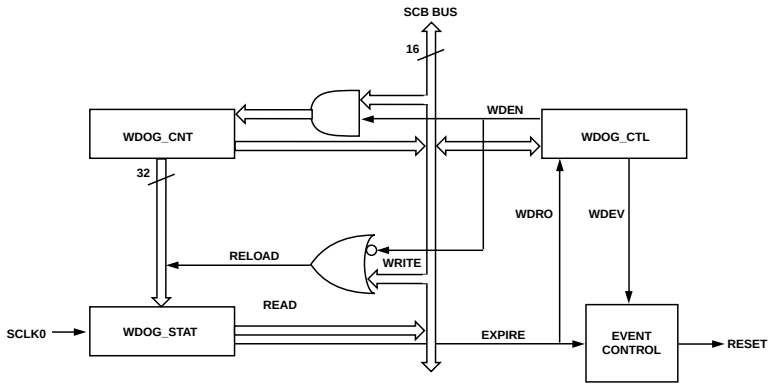

Figure 18-1: Watchdog Timer Block Diagram

Internal Interface

The system clock (SCLK) clocks the watchdog timer. The registers are accessed through the 16-bit peripheral MMR access bus. 32-bit read/write operations always access the 32-bit WDOG_CNT and WDOG_STAT registers. Hardware ensures that those accesses are atomic. When the counter expires, the WDOG expiration event is generated.

External Interface

The watchdog timer does not directly interact with any external pins.

ADSP-SC57x WDOG Register Descriptions

Watchdog Timer Unit (WDOG) contains the following registers.

Table 18-3: ADSP-SC57x WDOG Register List

Name	Description
WDOG_CNT	Count Register
WDOG_CTL	Control Register
WDOG_STAT	Watchdog Timer Status Register
WDOG_WIN	Watchdog Timer Window Register

Count Register

The WDOG_CNT register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the WDOG_CNT register can be updated only when the WDOG timer is disabled. A write to the WDOG_CNT register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

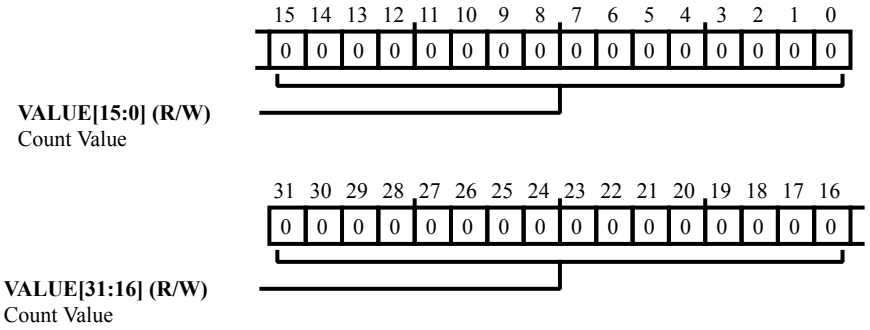

Figure 18-2: WDOG_CNT Register Diagram

Table 18-4: WDOG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Count Value. The WDOG_CNT.VALUE bit field holds the programmable, unsigned count value.

Control Register

The WDOG_CTL register controls the watchdog timer. This register supports enabling/disabling the watchdog timer and supports checking the timer rollover status. Note that when the processor is in emulation mode, the watchdog timer counter will not decrement even if it is enabled.

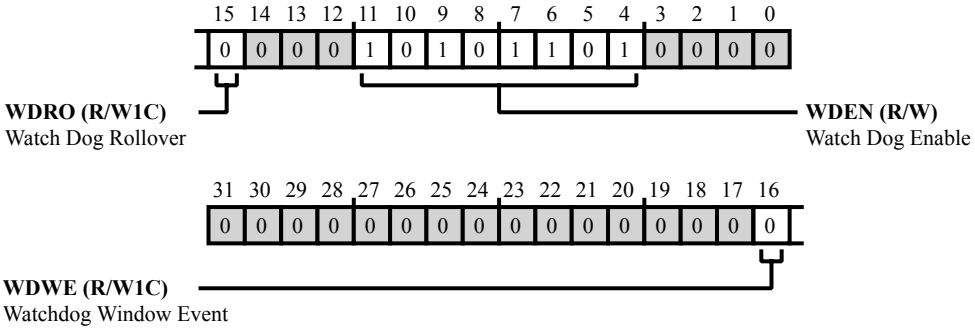

Figure 18-3: WDOG_CTL Register Diagram

Table 18-5: WDOG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	WDWE	Watchdog Window Event. Software can determine whether the timer has been serviced unexpectedly early by interrogating the WDOG_CTL.WDWE status bit. This is a sticky bit that is set whenever the watchdog is serviced and the WDOG_STAT value is greater than the WDOG_WIN value. It is cleared only by disabling the watchdog timer and by writing a 1 to the bit.	
		0	Window Event has not occurred
		1	Window Event has occurred
15 (R/W1C)	WDRO	Watch Dog Rollover. Software can determine whether the timer has rolled over by interrogating the WDOG_CTL.WDRO status bit. This is a sticky bit that is set whenever the watch dog timer count reaches 0 and cleared only by disabling the watch dog timer and then writing a 1 to the bit.	
		0	WDT Has Not Expired
		1	WDT Has Expired
11:4 (R/W)	WDEN	Watch Dog Enable. The WDOG_CTL.WDEN field is used to enable and disable the watchdog timer. Writing any value other than the disable value into this field enables the watchdog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watchdog timer.	
		173	Counter Disabled. All other values mean that the counter is enabled.

Watchdog Timer Status Register

The WDOG_STAT register contains the current count value of the watchdog timer. Reads of this register return the current count value. When the watchdog timer is enabled, the WDOG_STAT register is decremented by 1 on each SCLK cycle. When the count value reaches 0, the watchdog timer stops counting, and the expiry event is generated. The WDOG_STAT register is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in this register but are instead copied from the WDOG_CNT register. This copy process can happen in two ways:

- While the watchdog timer is disabled, writing the WDOG_CNT register pre-loads the WDOG_STAT register.
- While the watchdog timer is enabled, writing the WDOG_STAT register loads it with the value in the WDOG_CNT register.
- While the watchdog timer is disabled, writing to the WDOG_STAT register also reloads it with the value in the WDOG_CNT register.

When the processor executes a write (of an arbitrary value) to the WDOG_STAT register, the value in the WDOG_CNT register is copied into the WDOG_STAT register. Typically, software sets the value of WDOG_CNT at initialization, then periodically writes to the WDOG_STAT register before the watchdog timer expires. This reloads the watchdog timer with the value from WDOG_CNT and prevents generation of the expiry event.

If the program does not reload the counter before SCLK x count register cycles, an expiry event is generated, and the WDOG_CTL.WDRO bit is set. When this happens, the counter stops decrementing and remains at zero. If the counter is enabled with a zero loaded to the counter, the WDOG_CTL.WDRO bit is set immediately and the counter remains at zero and does not decrement.

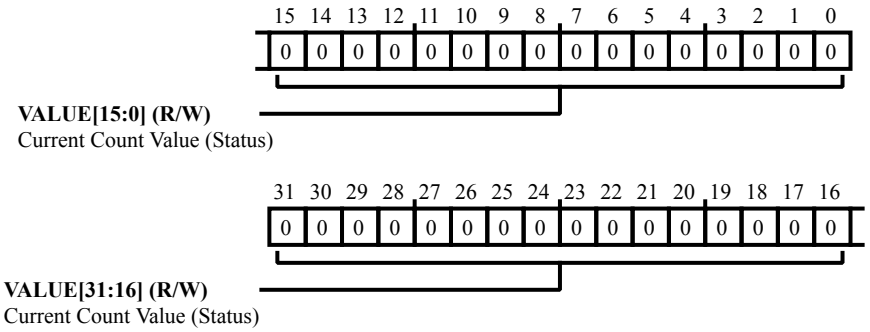

Figure 18-4: WDOG_STAT Register Diagram

Table 18-6: WDOG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Current Count Value (Status). The `WDOG_STAT.VALUE` bit field contains the current count value of the watchdog timer.

Watchdog Timer Window Register

Watchdog window register holds the unsigned window value programmed. The window register can be programmed while the WDOG is disabled; any write to the register when WDOG is enabled doesn't alter the contents of the register. When the WDOG is enabled and the core services the WDOG by doing a write to `WDOG_STAT` register while the `WDOG_STAT` value is greater than `WDOG_WIN`, the WDWE event is generated and also the counter stops decrementing.

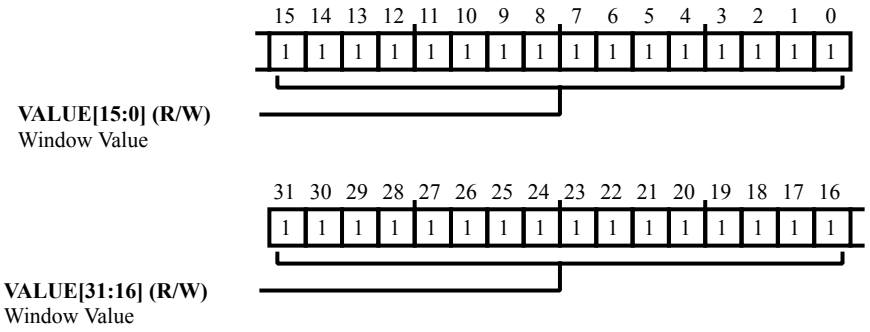

Figure 18-5: WDOG_WIN Register Diagram

Table 18-7: WDOG_WIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Window Value. The `WDOG_WIN.VALUE` bit field contains the unsigned window value.

19 General-Purpose Counter (CNT)

The GP counter converts pulses from incremental position encoders into data that is representative of the actual position of the pulse. This conversion is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero-position input (zero marker). The GP counter can use the zero position input feature to establish a reference point for verifying that the acquired position does not drift over time. In addition, the GP counter can use the incremental position information to determine speed, if the time intervals are measured.

The GP counter provides flexible ways to establish position information. When used with the GP timer block, the GP counter can allow for the acquisition of coherent position or time stamp information that enables speed calculation.

GP Counter Features

The GP counter includes the following features:

- 32-bit up or down counter
- Quadrature encode mode (Gray code)
- Binary encoder mode
- Alternative frequency-direction mode
- Timed direction and up or down counting modes
- Zero marker or push-button support
- Capture event timing in association with GP Timer
- Boundary comparison and boundary setting features

GP Counter Functional Description

The ***GP Counter Block Diagram*** shows a block diagram of the GP counter. The `CNT_UD` and `CNT_DG` pins accept various forms of incremental inputs. The 32-bit counter processes the inputs. The GP counter uses the `CNT_ZM` pin to sense the pressing of a push button.

NOTE: When enabled, the GP counter requires 3 SCLK cycles of initialization before recognizing valid toggles on its input pins.

The three input pins can be filtered (debounced) before the GP counter evaluates them.

The GP counter features a flexible boundary comparison. In all of the operating modes, the counter can be compared to an upper and lower limit. It takes various actions when reaching these limits.

The GP counter has a flexible input selection. Apart from accepting inputs from the CNT0_UD and CNT0_DG and PORT pins, the counter can be configured to accept trigger inputs by setting PADS_PCFG0.CNT0UDSEL and PADS_PCFG0.CNT0DGSEL bits. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

The module can optionally generate an interrupt request to the system through its IRQ line. On many processors, a GP timer module can use an output to generate time stamps on certain events.

ADSP-SC57x CNT Register List

The GP Counter (CNT) provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial encoders.

The CNT converts pulses from incremental position encoders into data that is representative of the actual position. To complete this task, the CNT integrates (counts) pulses on one or two inputs. Because integration provides relative position, a zero position input (zero marker) is usually provided that establishes a reference point, verifying that the acquired position does not drift over time. The incremental position information may also be used to determine speed, if the relevant time intervals are measured. The CNT provides flexible ways to establish position information. When used in conjunction with the General-purpose Timer (TIMER), the CNT allows acquisition of coherent position/time stamp information, enabling speed calculation.

A set of registers govern CNT operations. For more information on CNT functionality, see the CNT register descriptions.

Table 19-1: ADSP-SC57x CNT Register List

Name	Description

GP Counter Operating Modes

The GP counter has the following five modes of operation.

1. Quadrature Encoder
2. Binary Encoder
3. Up/Down Counter
4. Direction Counter
5. Timed Direction

With the exception of the timed direction mode, the GP counter can operate with the GP timer block to capture additional timing information (time stamps) associated with events detected by this block.

Quadrature Encoder Mode

In this mode, the CNT_UD and CNT_DG inputs expect a quadrature-encoded signal that is interpreted as a two-bit Gray code. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Quadrature Events and Counting Mechanism*** table. Optionally, an interrupt is generated when both inputs

change within one SCLK cycle. Gray coding prohibits such transitions. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 19-5: Quadrature Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG, CUD Inputs	00	01	11	10	00	01	11	10	00

It is possible to reverse the count direction of the Gray-coded signal by enabling the polarity inverter of either the CNT_UD pin or the CNT_DG pin. Inverting both pins does not alter the behavior. The GP counter can enable this feature with the CNT_CFG.CDGINV and CNT_CFG.CUDINV bits.

As an example, the CNT_DG and CNT_UD inputs are 00 and the next transition is to 01. These inputs normally change the counter in increments as shown in the table. If the CNT_UD polarity is inverted, this condition generates a received input of 01 followed by 00. The results is a decrement of the counter, altering the behavior of the connected hardware.

Binary Encoder Mode

This mode is almost identical to quadrature encoder mode, with the exception that the CNT_UD: CNT_DG inputs expect a binary-encoded signal. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Binary Events and Counting Mechanism*** table. Optionally, an interrupt is generated when the detected code steps by more than 1 (in binary arithmetic) within one SCLK cycle. Such transitions are erroneous. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 19-6: Binary Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG:CUD Inputs	00	01	10	11	00	01	10	11	00

Reversing the CNT_UD and CNT_DG pin polarity has a different effect in binary encoder mode than for the quadrature encoder mode. Inverting the polarity of the CNT_UD pin only, or inverting both the CNT_UD and CNT_DG pins, results in reversing the count direction.

Up/Down Counter Mode

In this mode, the counter increments or decrements at every active edge of the input pins. The GP counter uses the CNT_CFG.CUDINV bit to select an active edge and has the following results.

- If the GP counter module detects an active edge at the CNT_UD input, the counter increments.
- If the GP counter module detects an active edge at the CNT_DG input, the counter decrements.
- If simultaneous edges occur on the CNT_DG and CNT_UD pins, the counter remains unchanged, and both up-count and down-count events are signaled in the CNT_STAT register.

Direction Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the CNT_DG input pin. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity.

If the GP counter detects an active edge at the CNT_DG input, the counter value changes by one in the selected direction.

Timed Direction Mode

In this mode, the counter is incremented or decremented at each SCLK cycle. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity. The CNT_DG pin can be used to gate the clock. The GP counter uses the CNT_CFG.CDGINV bit to select the polarity.

GP Counter Programming Model

The following sections provide information for programming the interface.

GP Counter General Programming Flow

The following are general guidelines for configuring and enabling the GP counter.

1. Initialize (but do not enable) the GP counter for the desired mode and settings through the CNT_CFG register.
2. Usually, events of interest are processed using interrupts rather than by polling status bits. In this case, clear all status bits and activate the interrupt generation requests with the CNT_IMSK register.
3. Configure interrupts at the system level to insure desired interrupt signaling to the system.
4. If timing information is required, set up the relevant GP Timer in width capture mode.
5. Finally, enable interrupt requests and the GP Counter itself using the CNT_IMSK and CNT_CFG registers, respectively.

GP Counter Mode Configuration

The GP counter can use the CNT_ZM input pin to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes:

- Push-button mode
- Zero-marker-zeros-counter mode
- Zero-marker-error mode
- Zero-once mode

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

Configuring Zero-Marker-Zeros-Counter Mode

The following provides information on configuring zero-marker-zeros-counter mode for the GP counter.

1. Set CNT_IMSK.CZMZ to enable CNT_CNTR. The zero marker interrupt zeroes the counter.
2. Set CNT_CFG.ZMZC to enable ZMZC mode.
3. Select the active edge polarity through the CNT_CFG.CZMINV bit.
4. Proceed with any other desired configuration steps and enable the peripheral.

This configuration causes an active level at the CNT_ZM pin to clear the CNT_CNTR register and keep it cleared until the CNT_ZM pin is deactivated. In addition, the CNT_STAT.CZMZ bit is set.

Configuring Zero-Marker-Error Mode

The GP counter uses this mode to detect discrepancies between counter-value and the zero marker output of certain rotary encoder devices.

1. Set the CNT_STAT.CZME bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

When the GP counter detects an active edge at the CNT_ZM input pin, it compares the four LSBs of the CNT_CNTR register to zero. If they are not zero, the GP counter uses CNT_STAT.CZME bit to signal a mismatch.

Configuring Zero-Once Mode

The GP counter uses this mode to perform an initial reset of the counter-value when it detects an active zero marker. After that, the zero marker is ignored (the counter is no longer reset).

1. Set the CNT_CMD.W1ZMONCE bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Ensure that at least one of the following bits is enabled: CNT_IMSK.CZM, CNT_IMSK.CZME, CNT_IMSK.CZMZ.

4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_CNTR register and the CNT_CMD.W1ZMONCE bit are cleared on the next active edge of the CNT_ZM pin. Now the CNT_CMD.W1ZMONCE bit can be read to check whether the event has already occurred.

Configuring Boundary Auto-Extend Mode

In this mode, hardware modifies the boundary registers (CNT_MIN and CNT_MAX) whenever the CNT_CNTR value reaches either of them. The GP counter uses this mode to monitor the widest angle a thumb wheel even if the software did not generate interrupts.

1. Initialize CNT_CNTR with the desired value.
2. Set both CNT_MIN and CNT_MAX to this same value.
3. Configure the CNT_CFG.BNDMODE field for auto extend mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_MAX register is loaded with the current CNT_CNTR value when the latter increments beyond the CNT_MAX value. Similarly, the CNT_MIN register is loaded with the CNT_CNTR value when the latter decrements below the CNT_MIN value. The CNT_STAT.MAXC and CNT_STAT.MINC status bits are set when the CNT_CNTR value matches the respective boundary register value.

Configuring Boundary Capture Mode

In this mode, the CNT_CNTR value is latched into the CNT_MIN register at one detected edge of the CNT_ZM input pin, and latched into the CNT_MAX boundary register at the opposite edge.

1. To capture the CNT_ZM pin rising edge into CNT_MIN and the falling edge into CNT_MAX, program CNT_CFG.CZMINV for active high polarity. Conversely, to capture the CNT_ZM pin falling edge into CNT_MIN and the rising edge into CNT_MAX, program CNT_CFG.CZMINV for active low polarity.
2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary capture mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_STAT.MAXC and CNT_STAT.MINC status bits report the capture event, depending on how interrupt masks are configured.

Configuring Boundary Compare and Boundary Zero Modes

In these modes, the two boundary registers (CNT_MAX and CNT_MIN) are compared to the value in the CNT_CNTR register.

1. Program CNT_MAX and CNT_MIN registers with appropriate upper and lower range values.

2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary compare mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

If after incrementing, CNT_CNTR = CNT_MAX, then the CNT_STAT.MAXC bit is set. Similarly if after decrementing, CNT_CNTR = CNT_MIN, then the CNT_STAT.MINC bit is set.

Additionally, for boundary zero mode, the counter-value in CNT_CNTR is set to zero. The CNT_STAT.MAXC and CNT_STAT.MINC bits are not set when software updates the CNT_MAX or CNT_MIN registers.

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

GP Counter Programming Concepts

Using the features, operating modes, and event control for the GP counter to their greatest potential requires an understanding of some GP counter-related concepts. Some key aspects to consider are input noise filtering and capturing timing information.

CNT Input Noise Filtering

In all modes, the three input pins can be filtered to present clean signals to the GP counter logic. The GP counter uses the CNT_CFG.DEBEN bit to enable or disable this filtering. The ***Programmable Noise Filtering*** figure shows the filtering operation for the CNT_UD pin.

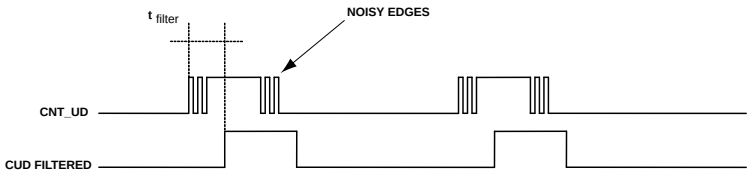

Figure 19-1: Programmable Noise Filtering

The CNT module implements the filtering mechanism using counters for each GP counter pin, where each counter is initialized from the CNT_DEBNCE.DPRESCALE field. When a transition is detected on a pin, the corresponding counter starts counting up to the programmed number of SCLK cycles. The state of the pin is latched after time t_{filter} and passed on to the GP counter logic.

The following formula determines the time t_{filter}, given SCLK and the CNT_DEBNCE.DPRESCALE value, where lower values of CNT_DEBNCE.DPRESCALE result in shorter debounce delays:

$t_{filter} = 128 \times (2^{DPRESCALE} \times SCLK)$

Capturing Counter Interval and CNT_CNTR Read Timing

When the count speed is low, it is often useful to capture the time elapsed since the last count event. Program the TIMER_TMR[n]_CFG register of the associated GP timer in a width capture mode with the following bit settings.

- TIMER_TMR[n]_CFG.PULSEHI = 0
- TIMER_TMR[n]_CFG.TMODE = b#1011
- TIMER_TMR[n]_CFG.TINSEL = 1

The ***Capture Intervals*** figure shows and the following list describe the operation of the GP counter and the GP timer in this mode.

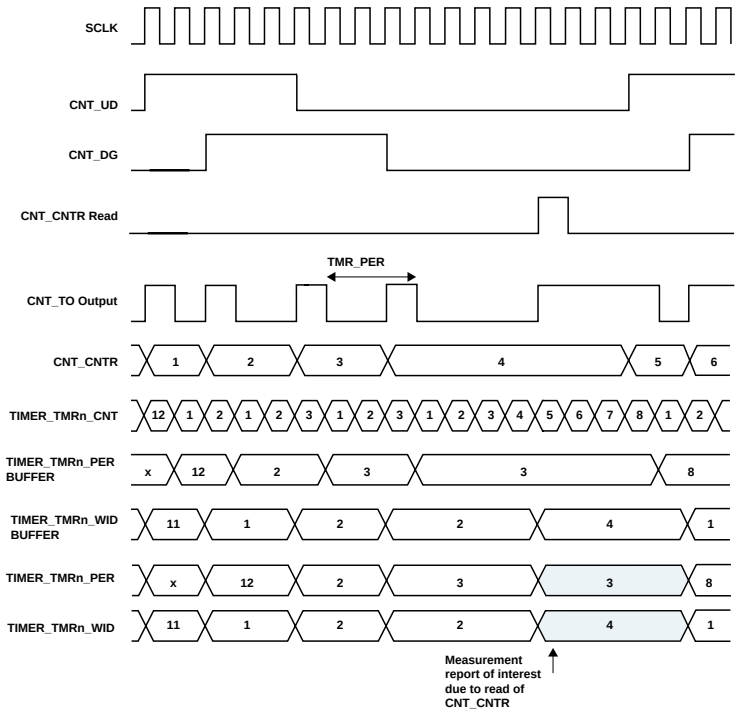

Figure 19-2: Capture Intervals

NOTE: SCLK in the ***Capture Intervals*** figure is SCLK.

1. The CNT_TO signal generates a pulse every time a count event occurs. In addition, when the processor reads the CNT_CNTR register, the CNT_TO signal presents a pulse which is extended (high) until the next count event.
2. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from falling edge to falling edge, because TIMER_TMR[n]_CFG.PULSEHI = 0) of the CNT_TO signal.

3. The TIMER_TMR[n]_WID register is updated with the pulse width (the portion where CNT_TO is low, again because TIMER_TMR[n]_CFG.PULSEHI = 0).
4. Both registers are updated at every rising edge of the CNT_TO signal (because TIMER_TMR[n]_CFG.TMODE= b#011).

The TIMER_TMR[n]_PER register contains the period between the last two count events. The TIMER_TMR[n]_WID register contains the time since the last count event and the read of the CNT_CNTR register, both measured in SCLK cycles.

Read the CNT_CNTR register to latch the two time measurements, providing a coherent triplet of information to calculate speed and position.

NOTE: Speed restrictions apply to the use of the CNT_TO signal. Therefore, programs must not operate at count event rates that are high. For instance, if CNT_CNTR is incremented or decremented every SCLK cycle (timed direction mode), the CNT_TO signal is not valid.

Capturing Time Interval Between Successive Counter Events

When the required timing information is the interval between successive count events, program the associated timer in a width capture mode. Set the TIMER_TMR[n]_CFG bit of TIMER_TMR[n]_CFG.PULSEHI = 1, TIMER_TMR[n]_CFG.TMODE = b#1010 and TIMER_TMR[n]_CFG.TINSEL = 1. Typically, this information is sufficient if the speed of GP counter events does not to reach low values.

The ***Period Register Timing*** figure shows the operation of the GP counter and the GP timer in this mode.

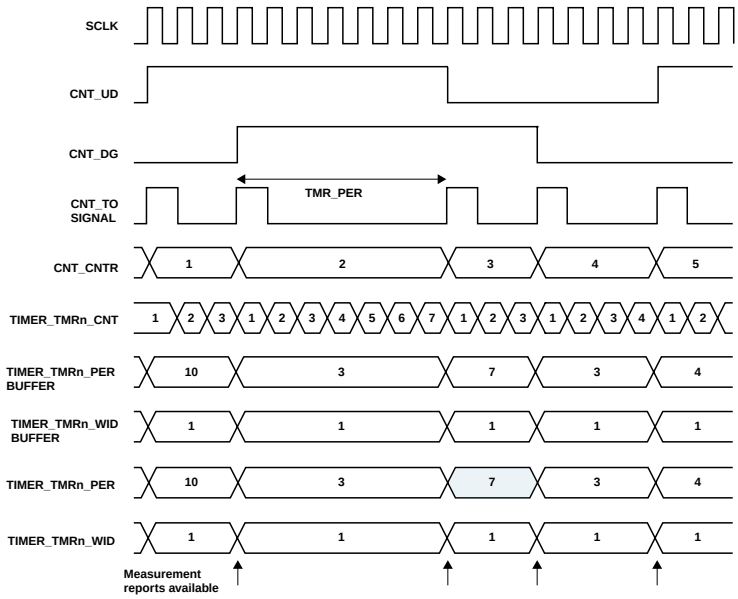

Figure 19-3: Period Register Timing

NOTE: SCLK in the ***Period Register Timing*** figure is SCLK.

The CNT_TO signal generates a pulse every time a count event occurs. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from rising edge to rising edge) of the CNT_TO signal. The TIMER_TMR[n]_PER register is updated at every rising edge of the CNT_TO signal and contains the number of SCLK cycles that have elapsed since the previous rising edge.

Incidentally, the TIMER_TMR[n]_WID register is also updated at the same time, but is generally of no interest in this mode of operation. If no reads of the CNT_CNTR register occur between counter events, the TIMER_TMR[n]_WID register only contains the width of the CNT_TO pulse. If a read of CNT_CNTR has occurred between events, the TIMER_TMR[n]_WID register contains the time between the read of CNT_CNTR and the next event.

This mode can also be used with TIMER_TMR[n]_CFG.PULSEHI = 0. In this case, the period of CNT_TO is measured between falling edges. It results in the same values as in the previous case, only the latching occurs one SCLK cycle later.

GP Counter Event Control

Eleven events can be signaled to the processor using status information and optional interrupt requests. The GP counter uses the respective bits in the CNT_IMSK register to enable the interrupt requests. It uses dedicated bits in the CNT_STAT register to report events. When an interrupt request from the GP counter is serviced, the application software is responsible for correct interpretation of the events. It is recommended to logically AND the content of the CNT_IMSK and CNT_STAT registers to identify pending interrupt requests.

Perform a write-one-to-clear (W1C) operation to the CNT_STAT register to clear the interrupt requests. Hardware does not clear the status bits automatically, unless the counter module is disabled.

The following sections describe the events associated with the GP counter.

Illegal Gray and Binary Code Events

When illegal transitions occur in quadrature encoder or binary encoder modes, the CNT_STAT.IC bit is set. If enabled by the CNT_STAT.IC bit, the counter module generates an interrupt request. Set the CNT_STAT.IC bit only in the quadrature encoder or binary encoder modes.

Up/Down Count Events

The GP counter uses the CNT_STAT.UC bit to indicate whether the counter has been incremented. Similarly, the CNT_STAT.DC bit reports decrements. The two events are independent. For instance, if the counter increments by one and then decrements by two, both bits remain set, even though the resulting counter-value shows a decrement by one.

In up/down counter mode, hardware can detect simultaneous active edges on the CNT_UD and CNT_DG inputs. In that case, the CNT_CNTR remains unchanged, but both the CNT_STAT.UC and CNT_STAT.DC bits are set. Interrupt requests for these events can be enabled through the CNT_IMSK.UC and CNT_IMSK.DC bits. Use this feature carefully when the counter is clocked at high rates. This suggestion is especially critical when the counter operates in DIR_TMR mode, as interrupts are generated every SCLK cycle.

These events can also be used for more push buttons, when GP counter features are unnecessary. When up/down counter mode is enabled, the GP counter can use these count events to report interrupts from push buttons that connect to the CNT_UD and CNT_DG inputs.

Zero-Count Events

The CNT_STAT.CZERO status bit indicates that the CNT_CNTR has reached a value equal to 0x0000 0000 after an increment or decrement. This bit is not set when the counter value is set to zero by a write to CNT_CNTR or by setting the CNT_CMD.W1LCNTZERO bit. If enabled by the CNT_IMSK.CZERO bit, the GP counter module generates an interrupt request.

Overflow Events

There are two status bits that indicate whether the signed counter-register has overflowed from a positive to a negative value or conversely. The CNT_STAT.COV31 bit reports that the 32-bit CNT_CNTR register has either incremented from 0x7FFF FFFF to 0x8000 0000, or decremented from 0x8000 0000 to 0x7FFF FFFF.

If enabled by the CNT_IMSK.COV31 bit, an interrupt request is generated. Similarly, in applications where only the lower 16 bits of the counter are of interest, the CNT_STAT.COV15 status bit reports counter transitions from 0xXXXX 7FFF to 0xXXXX 8000, or from 0xXXXX 8000 to 0xXXXX 7FFF. If enabled by the CNT_IMSK.COV15 bit, an interrupt request is generated.

Boundary Match Events

The CNT_STAT.MINC and CNT_STAT.MAXC status bits report boundary events as described in Configuring Boundary Capture Mode. These bits are not set if the software updates the CNT_CNTR, CNT_MAX, or CNT_MIN registers or writes to the CNT_CMD register. The CNT_IMSK.MINC and CNT_IMSK.MAXC bits enable interrupt request generation on boundary events.

Zero Marker Events

The CNT_STAT.CZM, CNT_STAT.CZME, and CNT_STAT.CZMZ bits are associated with zero marker events, as described in Configuring GP Counter Push-Button Operation. Each of these events can optionally generate an interrupt request, when enabled by the corresponding CNT_IMSK.CZM, CNT_IMSK.CZME and CNT_IMSK.CZMZ bits.

ADSP-SC57x CNT Register Descriptions

CNT (CNT) contains the following registers.

Table 19-7: ADSP-SC57x CNT Register List

Name	Description
CNT_CFG	Configuration Register
CNT_CMD	Command Register

Table 19-7: ADSP-SC57x CNT Register List (Continued)

Name	Description
CNT_CNTR	Counter Register
CNT_DEBNCE	Debounce Register
CNT_IMSK	Interrupt Mask Register
CNT_MAX	Maximum Count Register
CNT_MIN	Minimum Count Register
CNT_STAT	Status Register

Configuration Register

The CNT_CFG register configures counter modes, configures input pins, and enables the CNT.

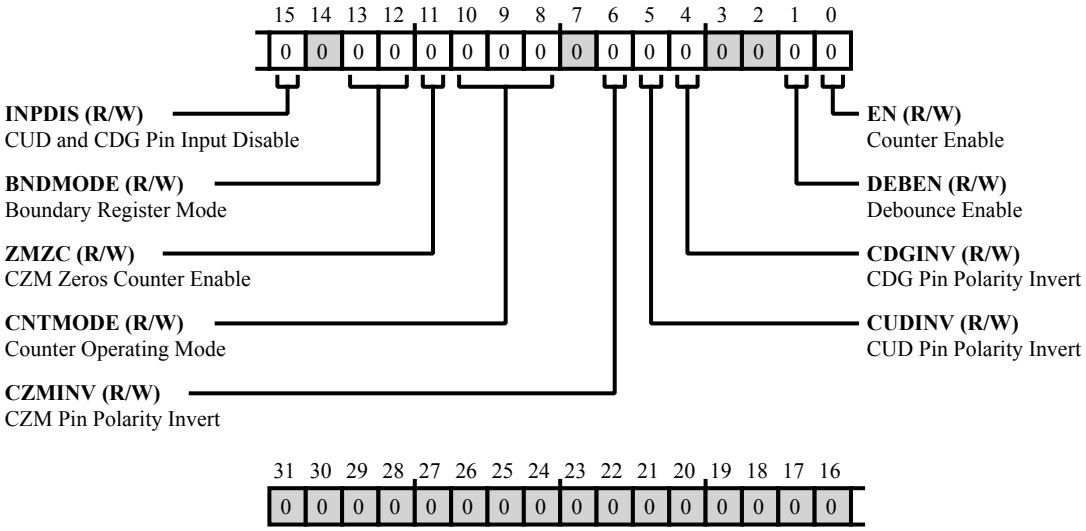

Figure 19-4: CNT_CFG Register Diagram

Table 19-8: CNT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	INPDIS	CUD and CDG Pin Input Disable. The CNT_CFG.INPDIS disables or enables the CNT_UD input pin and the CNT_DG pin.	
		0	Enable
		1	Pin Input Disable
13:12 (R/W)	BNDMODE	Boundary Register Mode. The CNT_CFG.BNDMODE bit field selects the mode for the CNT_MIN and CNT_MAX boundary registers.	
		0	BND_COMP. Boundary Compare Mode
		1	BND_ZERO. Boundary Zero Mode
		2	BND_CAPT. Boundary Capture Mode
		3	BND_AEXT. Boundary Auto-extend Mode

Table 19-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ZMZC	CZM Zeros Counter Enable. The CNT_CFG.ZMZC bit enables or disables level sensitive - active CNT_ZM pin operation to zero the CNT_CNTR register.	
		0	Disable
		1	Enable
10:8 (R/W)	CNTMODE	Counter Operating Mode. The CNT_CFG.CNTMODE bit field selects the operating mode for the CNT_UD input pin and the CNT_DG pin.	
		0	QUAD_ENC. Quadrature Encoder Mode
		1	BIN_ENC. Binary Encoder Mode
		2	UD_CNT. Rotary Counter Mode
		4	DIR_CNT. Direction Counter Mode
		5	DIR_TMR. Direction Timer Mode
6 (R/W)	CZMINV	CZM Pin Polarity Invert. The CNT_CFG.CZMINV bit selects the polarity for the CNT_ZM pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
5 (R/W)	CUDINV	CUD Pin Polarity Invert. The CNT_CFG.CUDINV bit selects the polarity for the CNT_UD pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
4 (R/W)	CDGINV	CDG Pin Polarity Invert. The CNT_CFG.CDGINV bit selects the polarity for the CNT_DG pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge

Table 19-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	DEBEN	Debounce Enable. The CNT_CFG.DEBEN bit enables or disables CNT input debounce filtering operation selected with the CNT_DEBNCE register.	
		0	Disable
		1	Enable
0 (R/W)	EN	Counter Enable. The CNT_CFG.EN bit enables or disables CNT operation.	
		0	Counter Disable
		1	Counter Enable

Command Register

The CNT_CMD register configures the CNT, enabling operations such as zeroing a counter register and copying or swapping boundary registers. These actions are taken by setting the appropriate bit.

Read operations from this register do not return meaningful values, with the exception of the CNT_CMD.W1ZMONCE bit, where a set bit indicates that the bit has been set by software before, but a zero marker event has not yet been detected on the CNT_ZM pin yet. For more information, see the CNT functional description.

The CNT_CNTR, CNT_MIN, and CNT_MAX registers can be initialized to zero by setting the CNT_CMD.W1LCNTZERO, CNT_CMD.W1LMINZERO, and CNT_CMD.W1LMAXZERO bits. In addition to clearing registers, the CNT_CMD register permits modifying the CNT_MIN and CNT_MAX boundary registers in a number of ways. The current counter value in the CNT_CNTR register can be captured and loaded into either of the two boundary registers to create new boundary limits. This operation is performed by setting the CNT_CMD.W1LMAXCNT and CNT_CMD.W1LMINCNT bits. Alternatively, the counter can be loaded from CNT_MAX or CNT_MIN using the CNT_CMD.W1LCNTMAX and CNT_CMD.W1LCNTMIN bits. It is also possible to transfer the current CNT_MAX value into CNT_MIN (or conversely) through the CNT_CMD.W1LMINMAX and CNT_CMD.W1LMAXMIN bits.

Another counter operation is the ability to only have the zero marker clear the CNT_CNTR register once. For more information, see the CNT functional description.

It is possible for multiple actions to be performed simultaneously by setting multiple bits in the CNT_CMD register. However, there are restrictions. The bits associated with each command have been grouped together such that all bits that involve a write to the CNT_CNTR, CNT_MAX, or CNT_MIN registers are located within bits 4-bit groups of the CNT_CMD register.

Note that a maximum of three commands can be issued at any one time, excluding the CNT_CMD.W1ZMONCE command. Also, note that CNT_CMD.W1LCNTMIN, CNT_CMD.W1LCNTMAX, and CNT_CMD.W1LCNTZERO bits have to be used exclusively. Never set more than one of them at the same time.

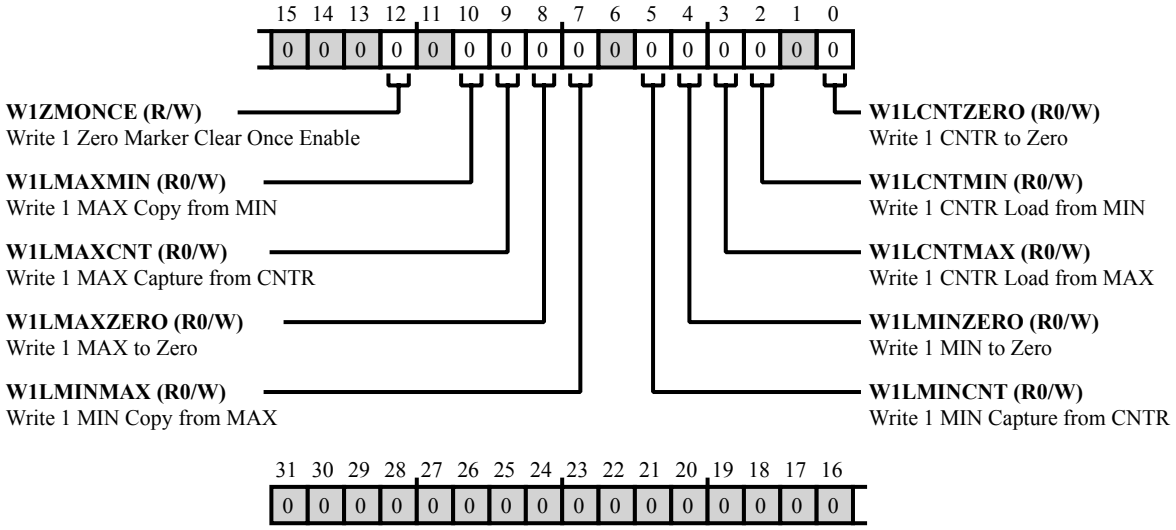

Figure 19-5: CNT_CMD Register Diagram

Table 19-9: CNT_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	W1ZMONCE	Write 1 Zero Marker Clear Once Enable. The CNT_CMD.W1ZMONCE enables a single zero marker clear of the CNT_CNTR register. Reading a 1 in this bit indicates that the bit has been set by software before, but no zero marker event has been detected on the CNT_ZM pin yet.
10 (R0/W)	W1LMAXMIN	Write 1 MAX Copy from MIN. The CNT_CMD.W1LMAXMIN bit transfers the current CNT_MIN register value into CNT_MAX register.
9 (R0/W)	W1LMAXCNT	Write 1 MAX Capture from CNTR. The CNT_CMD.W1LMAXCNT bit loads the current value in the CNT_CNTR register into the CNT_MAX register to create a new boundary limit.
8 (R0/W)	W1LMAXZERO	Write 1 MAX to Zero. Writing a 1 to the CNT_CMD.W1LMAXZERO bit clears the CNT_MAX register.
7 (R0/W)	W1LMINMAX	Write 1 MIN Copy from MAX. The CNT_CMD.W1LMINMAX bit transfers the current CNT_MAX register value into CNT_MIN register.
5 (R0/W)	W1LMINCNT	Write 1 MIN Capture from CNTR. The CNT_CMD.W1LMINCNT bit loads the current value in the CNT_CNTR register into the CNT_MIN register to create a new boundary limit.
4 (R0/W)	W1LMINZERO	Write 1 MIN to Zero. Writing a 1 to the CNT_CMD.W1LMINZERO bit clears the CNT_MIN register.

Table 19-9: CNT_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W)	W1LCNTMAX	Write 1 CNTR Load from MAX. The CNT_CMD.W1LCNTMAX bit loads the current value in the CNT_MAX register into the CNT_CNTR register to create a new boundary limit.
2 (R0/W)	W1LCNTMIN	Write 1 CNTR Load from MIN. The CNT_CMD.W1LCNTMIN bit loads the current value in the CNT_MIN register into the CNT_CNTR register to create a new boundary limit.
0 (R0/W)	W1LCNTZERO	Write 1 CNTR to Zero. Writing a 1 to the CNT_CMD.W1LCNTZERO bit clears the CNT_CNTR register.

Counter Register

The CNT_CNTR register holds the 32-bit, two's-complement count value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows use of the CNT as a 16-bit counter if sufficient for the application.

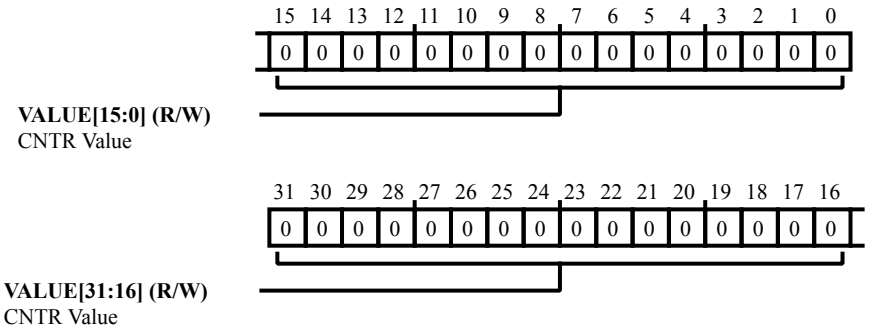

Figure 19-6: CNT_CNTR Register Diagram

Table 19-10: CNT_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CNTR Value. The CNT_CNTR.VALUE bit field holds the 32-bit, two's-complement count value.

Debounce Register

The CNT_DEBNCE register selects the noise filtering characteristic of the three input pins according to the formula:

t_{filter} = 128 x ($2^{DPRESCALE}$/ SCLK)

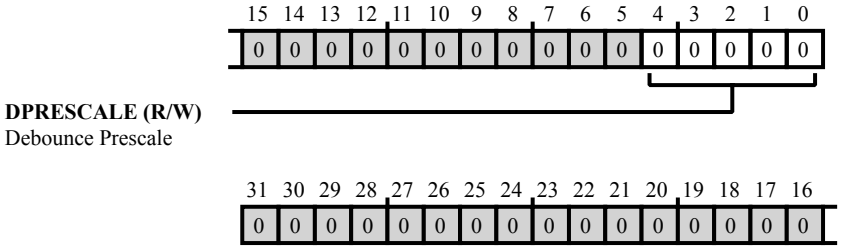

Figure 19-7: CNT_DEBNCE Register Diagram

Table 19-11: CNT_DEBNCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4:0 (R/W)	DPRESCALE	Debounce Prescale. The CNT_DEBNCE.DPRESCALE selects the desired number of input filtering cycles (and resulting input debounce time) in multiples of SCLK.	
		0	1x cycles = 128 SCLK cycles
		1	2x cycles
		2	4x cycles
		3	8x cycles
		4	16x cycles
		5	32x cycles
		6	64x cycles
		7	128x cycles
		8	256x cycles
		9	512x cycles
		10	1024x cycles
		11	2048x cycles
		12	4096x cycles
		13	8192x cycles
		14	16384x cycles
		15	32768x cycles
		16	65536x cycles

Table 19-11: CNT_DEBNCE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		17	131072x cycles
		18	Reserved from this value. The values 10010 - 11111 are reserved.
		31	Reserved until this value

Interrupt Mask Register

The CNT_IMSK register supports enabling (unmasking) interrupt request generation from each of the CNT events.

All bits in CNT_IMSK either disable/mask an interrupt request (if bit cleared) or enable/unmask an interrupt request (if bit set).

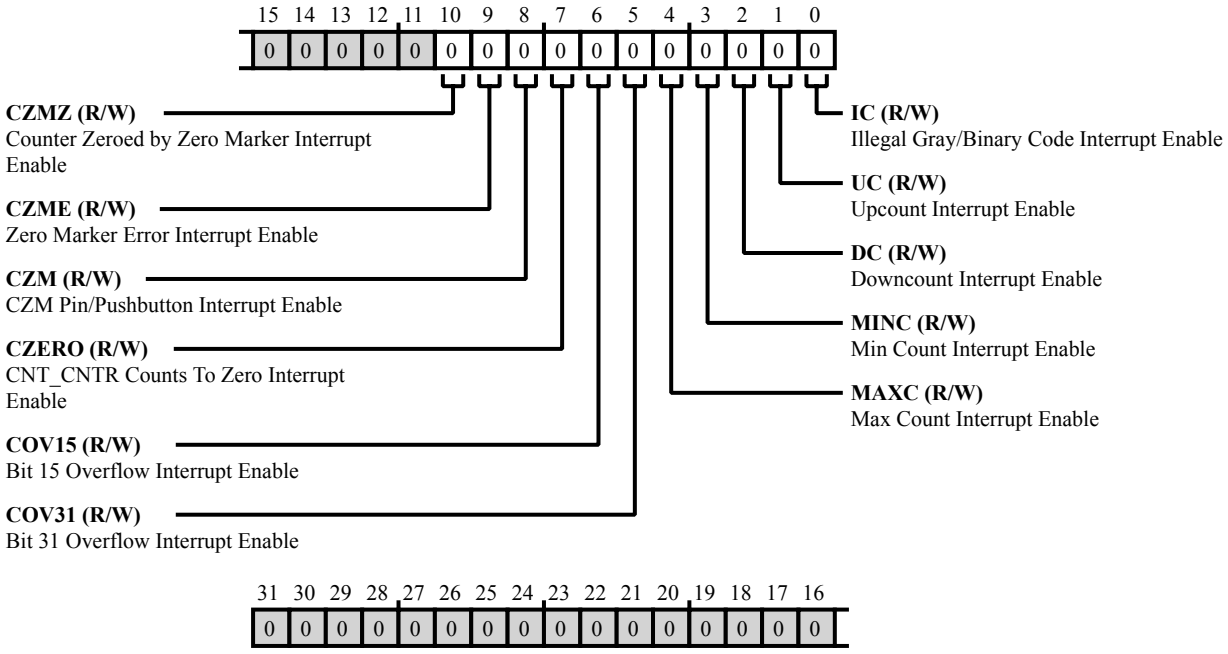

Figure 19-8: CNT_IMSK Register Diagram

Table 19-12: CNT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	CZMZ	Counter Zeroed by Zero Marker Interrupt Enable. The CNT_IMSK.CZMZ bit enables (unmasks) the counter zeroed by zero marker interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
9 (R/W)	CZME	Zero Marker Error Interrupt Enable. The CNT_IMSK.CZME bit enables (unmasks) the zero marker error interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt

Table 19-12: CNT_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	CZM	CZM Pin/Pushbutton Interrupt Enable. The CNT_IMSK.CZM bit enables (unmasks) the CZM pin/pushbutton interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
7 (R/W)	CZERO	CNT_CNTR Counts To Zero Interrupt Enable. The CNT_IMSK.CZERO bit enables (unmasks) the counts to zero interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
6 (R/W)	COV15	Bit 15 Overflow Interrupt Enable. The CNT_IMSK.COV15 bit enables (unmasks) the bit 15 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
5 (R/W)	COV31	Bit 31 Overflow Interrupt Enable. The CNT_IMSK.COV31 bit enables (unmasks) the bit 31 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
4 (R/W)	MAXC	Max Count Interrupt Enable. The CNT_IMSK.MAXC bit enables (unmasks) the max count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
3 (R/W)	MINC	Min Count Interrupt Enable. The CNT_IMSK.MINC bit enables (unmasks) the min count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
2 (R/W)	DC	Downcount Interrupt Enable. The CNT_IMSK.DC bit enables (unmasks) the down count interrupt request.

		1	Unmask Interrupt

Maximum Count Register

The CNT_MAX register holds the 32-bit, two's-complement, higher boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

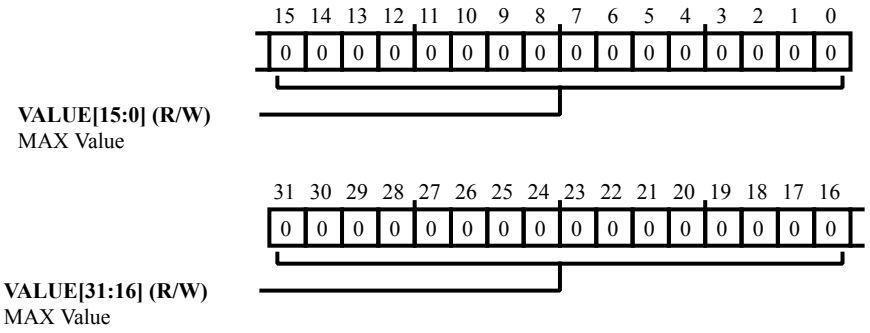

Figure 19-9: CNT_MAX Register Diagram

Table 19-13: CNT_MAX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MAX Value. The CNT_MAX.VALUE bit field holds the 32-bit, two's-complement, higher boundary value.

Minimum Count Register

The CNT_MIN register holds the 32-bit, two's-complement, lower boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

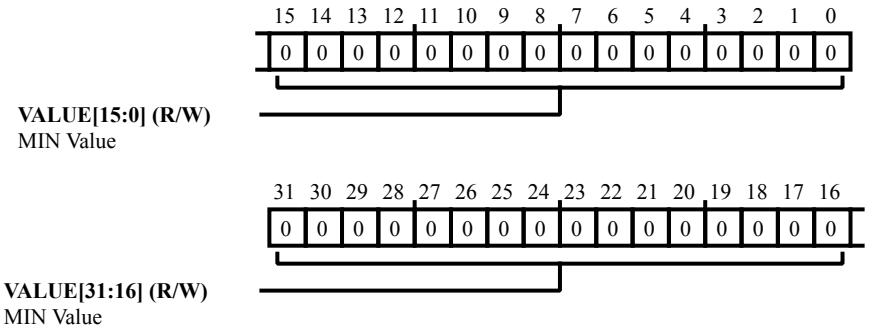

Figure 19-10: CNT_MIN Register Diagram

Table 19-14: CNT_MIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MIN Value. The CNT_MIN.VALUE bit field holds the 32-bit, two's-complement, lower boundary value.

Status Register

The CNT_STAT register provides status information for each of the CNT events as configured in the CNT_IMSK register. When a CNT event is detected, the corresponding bit in this register is set. It remains set until either software writes a 1 to the bit (write-1-to-clear) or the CNT is disabled.

All bits in the CNT_STAT register indicate either no interrupt request pending (if bit cleared) or an interrupt request pending (if bit set).

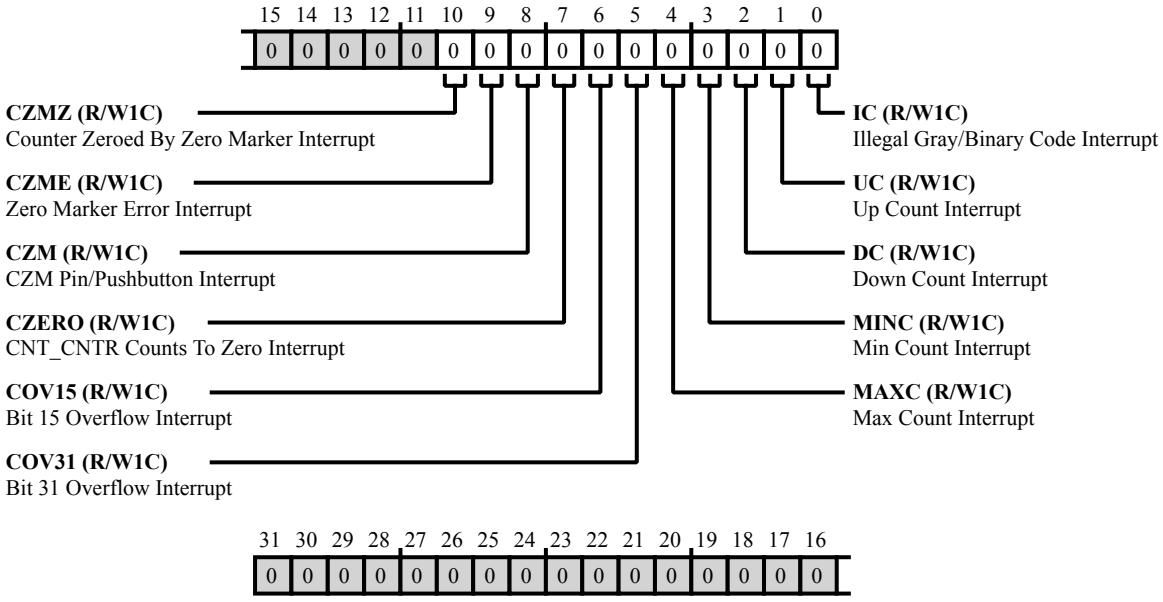

Figure 19-11: CNT_STAT Register Diagram

Table 19-15: CNT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	CZMZ	Counter Zeroed By Zero Marker Interrupt. The CNT_STAT.CZMZ bit indicates a zero marker error. If the CNT_CFG.ZMZC bit =1, this interrupt request is generated when the CZMII latch reports a significant edge on the CZM input. Once cleared by software the CNT_STAT.CZM bit is not set again when the CZM input remains active without pulsing.	
		0	No error
		1	Error occurred

Table 19-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	CZME	Zero Marker Error Interrupt. The CNT_STAT.CZME bit behaves similarly to the CNT_STAT.CZM bit, with the exception that CNT_STAT.CZME is not set on the CZM edge when the lower four bits of the CNT_CNTR are not zero. In many applications this indicates an error condition, as the zero marker might be out of sync with the counter.	
		0	No error
		1	Error occurred
8 (R/W1C)	CZM	CZM Pin/Pushbutton Interrupt. The CNT_STAT.CZM bit indicates a CZM pin/pushbutton error. This interrupt request is generated when a significant edge is seen on the CZM pin, regardless what mode the counter is operating in. This is often used to sense push buttons (especially with the debouncing circuit enabled).	
		0	No error
		1	Error occurred
7 (R/W1C)	CZERO	CNT_CNTR Counts To Zero Interrupt. The CNT_STAT.CZERO bit indicates a counts to zero error. This error is generated when the CNT_CNTR register has incremented or decremented toward 0x0000.0000. The latch is not set when software writes to the CNT_CNTR register directly or when the counter is zeroed by writes to the CNT_CMD register.	
		0	No error
		1	Error occurred
6 (R/W1C)	COV15	Bit 15 Overflow Interrupt. The CNT_STAT.COV15 bit indicates a bit 15 overflow error. This error is generated when the 16-bit twos-complement CNT_CNTR register has incremented from 0xxxxx.7FFF to 0xxxxx.8000 or decremented from 0xxxxx.8000 to 0xxxxx.7FFF.	
		0	No error
		1	Error occurred
5 (R/W1C)	COV31	Bit 31 Overflow Interrupt. The CNT_STAT.COV31 bit indicates a bit 31 overflow error. This error is generated when the 32-bit twos-complement CNT_CNTR register has incremented from 0x7FFF.FFFF to 0x8000.0000 or decremented from 0x8000.0000 to 0x7FFF.FFFF.	
		0	No error
		1	Error occurred

Table 19-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	MAXC	Max Count Interrupt. The CNT_STAT.MAXC bit indicates a max count error. This interrupt is used in boundary compare (BND_COMP) mode. If after incrementing the CNT_CNTR register equals CNT_MAX, the CNT_STAT.MAXC bit is set.	
		0	No error
		1	Error occurred
3 (R/W1C)	MINC	Min Count Interrupt. The CNT_STAT.MINC bit indicates a minimum count error. This interrupt is used in boundary compare (BND_COMP) mode. If, after decrementing, the CNT_CNTR register equals CNT_MIN, the CNT_STAT.MINC bit is set.	
		0	No error
		1	Error occurred
2 (R/W1C)	DC	Down Count Interrupt. The CNT_STAT.DC bit indicates a down count error. This interrupt is generated when the CNT_CNTR register decrements.	
		0	No error
		1	Error occurred
1 (R/W1C)	UC	Up Count Interrupt. The CNT_STAT.UC bit indicates an up count interrupt. This interrupt is generated when the CNT_CNTR register increments.	
0 (R/W1C)	IC	Illegal Gray/Binary Code Interrupt. The CNT_STAT.IC bit indicates a illegal Gray/Binary Code interrupt and should only be used in these modes. In normal operation those codes can increment or decrement the CNT_CNTR register by one at a time. If the sensed inputs instruct the counter to increment or decrement by two, the CNT_STAT.IC bit is set. Hardware sets the CNT_STAT.IC bit in QUAD_ENC and BIN_ENC encoder modes only.	
		0	No error
		1	Error occurred

20 ADC Control Module (ACM)

The processor includes an ADC control module (ACM) that provides an interface that synchronizes the controls between the processor and an analog-to-digital converter (ADC). The processor initiates analog-to-digital conversions, based on either external or internal events.

Traditionally, ADC sampling uses processor interrupts and the interrupt service routine programming of the appropriate peripheral for initiating the ADC conversion process. Events initiate the interrupts. The interrupt service routine usually programs the SPORT or SPI peripherals. This traditional approach has some limiting factors:

- The ADC sampling instances are not precisely controlled due to interrupt latencies (which can vary) or due to variable instruction execution cycles
- Consumption of processor instruction cycles can be prohibitive, especially for high frequency of conversion-related events.
- If the ADC requires control signals with specific set-up, hold, or zero time for sampling time, it is difficult to provide the signals with GP flags in the application. For example, channel select pins, ADC mode select, ADC range pin.

The ADC control module (ACM) provides dedicated hardware to work around these limitations. The module samples the events and provides sampling signals and timing to the ADC in real time. The ADC permits flexible scheduling of sampling instants and provides precise sampling signals to the ADC. The ACM saves processor bandwidth and provides precise control for ADC sampling time. Furthermore, the processor can be interfaced directly to multiple ADCs without any glue logic required.

The ACM synchronizes the ADC conversion process (by providing the ADC clock, the ADC conversion start signal, and related ADC controls). However, other peripherals such as SPORT acquire the actual data from the ADC. The processor does not support ACM operation with the SPI. The ***ADC/SPORT Interface*** figure shows how an external ADC can be interfaced using the ACM and SPORT0 peripherals of the processor.

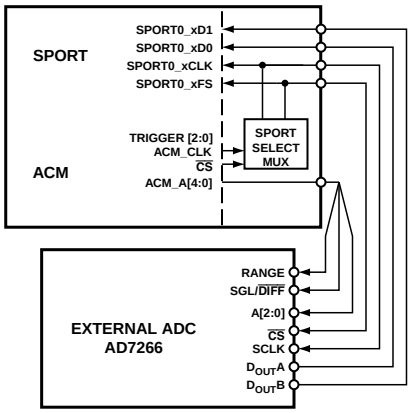

Figure 20-1: ADC/SPORT Interface

NOTE: The processor does not include an on-chip, internal ADC.

ACM Features

The ADC control module (ACM) offers the following features and capabilities:

- The ACM on the ADSP-SC57x/ADSP-2157xprocessors operate on the SCLK0_0 domain.
- The ACM can interface to the ADC at a maximum clock frequency of 30 MHz.
- It provides serial clock, chip select, and five general-purpose control lines capable of controlling the ADC operations. Internally routes serial clock and frame sync (chip select) signals to serial port 0.

  Only SPORT0 performs actual data acquisition from the ADC (no other SPORT instance). The `ACM_CLK` and `ACM_FS` signals are multiplexed with the SP0_CLK and SP0_FS signals. These signals are driven through the DAI0 and not through the GPIO port. The SPORT uses the `ACM_CTL.EN` bit to control the connection between SPORT0 and the ACM. By setting the `ACM_CTL.EN` bit, the ACM clock and FS are internally multiplexed to the SPORT0 SPORT0_CLK_O/SPORT0_FS_O outputs of the DAI0.
- The ACM can accept three trigger inputs (one from external on `ACM_T0` and two from the TRU) based on which it can precisely initiate the ADC sampling events. The trigger inputs can be internally generated or externally supplied. The polarity of trigger inputs is configurable.
- The ACM can handle 16 ADC sampling events per valid trigger received. Each event can be independently programmed to specify when to initiate ADC sampling for a trigger input.
- Two independent 32-bit ACM timers that can be used to divide 16 events into two groups of 8 events.
- Automatically stops the ACM timer after completion of associated events, saving power.
- Four-deep pending FIFO to queue the active events when the ACM is busy.
- The ACM can internally generate serial clock up to SCLK ÷ 2 rate. Improved granularity for internal clock generation, allowing both odd and even SCLK:ACLK ratios.

- The ACM clock can be gated (active only during enabled events) to interface it with SPI-compatible ADCs.
- When initiating an ADC sampling cycle, the width of chip select signal can be configured from 1 ACLK to 256 ACLKs. ADC can also use the width of chip select signal as start of conversion. Further the polarity of this signal can be configured as active-high or active-low signal.
- Auto ACLK adjustment at the time of $\overline{CS}$ assertion. After assertion of the $\overline{CS}$ signal, the first edge of ACLK can be configured to be either rising edge or falling edge.
- The ACM provides the five general-purpose control lines that can be programmed for required set-up and hold time based on the ADC sampling cycle. Additionally, zero time can be inserted between two successive sampling cycles.
- The ACM provides 16 event order registers (one per each event) which indicate the order in which events are handled. Optionally, the trigger input of the ACM can clear these registers automatically.
- The ACM hardware flags the appropriate event completion status bit on completion of an event. If an event is missed, the appropriate event missed status bit is flagged. Each event has separate bits. Optionally, the event completion interrupt and event missed interrupt can be triggered on these respective conditions.
- Predictable latency between the internal occurrence of an event and the assertion of a sampling event.
- The ACM can operate as trigger master to provide signal to TRU upon completion of events.

ACM Functional Description

The ADC control module uses internal ACM timers and the event time register to create events. Enable one of the timers (or both timers) for the ACM operation. Program the appropriate event control register and event time register values. After receiving a valid trigger on the selected trigger input, the timer starts counting. When the timer count matches the time specified in the event time register (`ACM_EVTIME[n]`), the comparators generate an active event signal to the timing generation unit. The signal starts the ADC access. The event must be enabled and the event must be associated with the timer. The counter continues counting, and for each match with enabled event time, the ACM gives an event signal to the timing generation unit.

ADSP-SC57x ACM Register List

The ADC control module (ACM) provides an interface that synchronizes the controls between the processor and an analog-to-digital converter (ADC). The analog-to-digital conversions are initiated by the processor, based on external or internal events. A set of registers govern ACM operations. For more information on ACM functionality, see the ACM register descriptions.

ACM Event Handling Latency

The ACM ensures a predictable latency between the internal occurrence of an event and the assertion of a sampling event by the timing generation unit (for example, the assertion of $\overline{CS}$ and other ACM signals). The internal occurrence of an event is when the event time value matches the ACM timer count value.

Latency between occurrence of an event to $\overline{CS}$ assertion = (t_S + t_{ED}) *SCLK* cycles, where:

- t_S= ADC control setup cycles programmed in the `ACM_TC0` register
- t_{ED} = 1 SCLK cycle latency

This predictable latency is applicable only when events are generated when the timing generation unit is idle. If this unit was processing a prior sampling event, the new event is held in the pending event FIFO. The duration that the new event is held in the pending event FIFO increases the latency.

If an external trigger input is selected as a trigger input, then synchronization to this signal leads to a 3 SCLK cycle fixed delay and 1 SCLK cycle variability. This result is due to delays in latching asynchronous external triggers. When the external trigger is synchronous to SCLK, the 1 SCLK cycle variability is eliminated. The latency from the external trigger to the start of the count of an ACM timer becomes fixed at 3 SCLK cycles. This latency is denoted as t_{TRIG}.

As a result, the total latency between an external trigger and the assertion of an ADC sampling event is:

Total latency = t_{TRIG} + t_{ED} + t_{PD} + t_S

The latency calculation assumes that the sampling event is not queued in the pending event FIFO. The ***Latency of External Triggers to Assertion of ADC Sampling Events*** figure shows latency details from the occurrence of external triggers to the assertion of ADC sampling events.

Observe the following timing definitions:

- t_{TRIG} = trigger to timer start delay (3–4 SCLK cycles)
- t_{PD} = event time (programmed in the `ACM_EVTIME[n]` register of the event)
- t_{ED} = internal event delay (1 SCLK cycle)
- t_S = setup time (programmed in the `ACM_TC0` register)
- t_{CSW} = $\overline{CS}$ width (programmed in the `ACM_TC1.CSW` bit field)
- t_H = hold time (programmed in the `ACM_TC1` register)

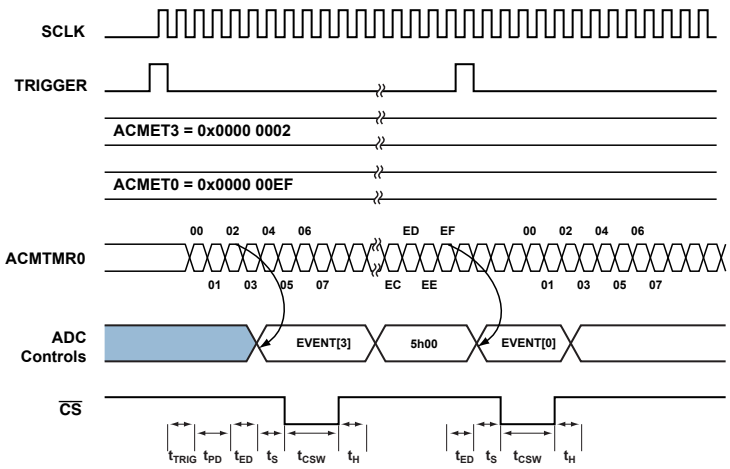

Figure 20-2: Latency of External Triggers to Assertion of ADC Sampling Events

ACM Timing Specifications

The AC timing of the ACM signals is specified in the product-specific data sheet. When trigger sources external to the processor are used for triggering the ACM, the minimum pulse width for the sources must be greater than one SCLK period. This pulse width is the minimum needed for the ACM trigger logic to detect the source as a valid trigger (for example, external signals on the GPIO, timer, or PWM sync pins).

- When the processor uses the ACM with the SPORTs, the requirements for the SPORT data signals vary. The setup and hold time requirements for the SPORT data signals for the `SPORT_ACLK` signal differ from those requirements for an internally-generated or externally-supplied SPORT clock. Consult the product-specific data sheet for information on these timing requirements.

When using gated clock mode (`ACM_CTL.CLKMOD` =1), configure the interfaced serial mode in gated clock mode (`SPORT_CTL_A.GCLKEN`, `SPORT_CTL_B.GCLKEN` =1). In this case, some conditions must be satisfied to set up the serial port in gated clock mode. These conditions are:

- The serial port needs at least 7 serial clock cycles between enabling the SPORT and first frame sync. If this requirement is not met, the SPORT may drop the first data. (For subsequent data, this requirement is not applicable.)
- Set the frame sync to the inactive (deasserted) state when the SPORT is enabled. Otherwise, one extra cycle (in addition to the cycle mentioned) is needed before the frame sync can be applied. If this requirement is not met, the SPORT may drop the first data.

ACM External Pin Timing

The ACM clock (`ACM_CLK`) is derived internally from SCLK using the `ACM_TC0.CKDIV` divider. The other output signals, such as the ADC control pins (`ACM_A0` through `ACM_A4`) and the chip select are driven on the rising edge of SCLK. As a result, these signals cannot be synchronous to the `ACM_CLK` signal.

The ACM uses timing configuration registers (`ACM_TC0` and `ACM_TC1`) to configure setup, hold, and other timing parameters of the ADC control signals, the width of the chip select signal, and the frequency of `ACM_CLK`. The

polarity of $\overline{CS}$ and the ACM_CLK signals can be configured in the ACM control register (ACM_CTL). The timing parameters of the ADC control pins cannot be individually specified.

The ***Timing Reference*** figure shows the inactive period of $\overline{CS}$ as t_{CSIW}. The inactive period of $\overline{CS}$ is the sum of the three timing parameters; Setup time (t_S), Zero time (t_Z) and the Hold time (t_H):

$t_{CSIW} = t_S + t_Z + t_H$.

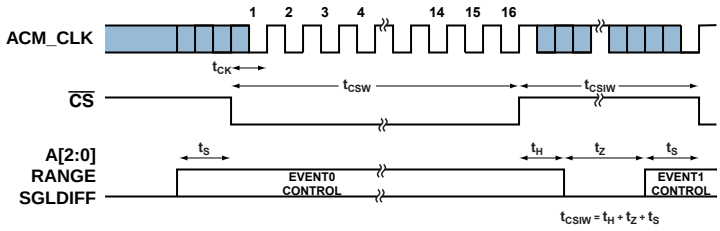

Figure 20-3: Timing Reference

Proper specification of the values of these three parameters yields the desired inactive period of $\overline{CS}$.

The ADC provides a predictable latency from the occurrence of an internal event to the assertion of an external ADC sampling event. The ADC controls and drives the $\overline{CS}$ signal on the rising edge of SCLK. Therefore, the setup time (T_s) of these signals is specified in terms of SCLK. However, the hold-time and zero-time are specified in terms of ACM_CLK cycles.

To achieve an accurate timing relationship between the $\overline{CS}$ and ACM_CLK (which is normally a free running clock) signals, the ACM_CLK signal is realigned with the active edge of $\overline{CS}$. This realignment of the ACM_CLK signal ensures that the setup time of the first active edge of ACM_CLK, relative to the active edge of $\overline{CS}$, is at least 1 ACM_CLK cycle.

The following set of figures in the cases show various scenarios of ACM_CLK realignment. All of these figures assume an *ACM_CLK:SCLK* ratio of 1:4.

- Case 1—Chip select asserted during the high phase of ACM_CLK
- Case 2—Chip select asserted during the low phase of ACM_CLK
- Case 3—Chip select asserted right before the falling edge of ACM_CLK
- Case 4—Chip select asserted right before the rising edge of ACM_CLK
- Case 5—ACM_CLK polarity set to 1 (ACM_CTL.CLKPOL =1)

Realignment of the ACM clock causes the suppression or extention of clock edges, leading to duty cycle variation. Ensure that systems interfacing with the ACM can tolerate such duty cycle variation.

The set of figures shows both the ACM-generated $\overline{CS}$ signal, which is output externally onto the appropriate ACM_FS pin, and the serial port receive frame sync signal. This internal signal is routed to the frame sync input of the appropriate SPORT.

The ACM clock polarity can be configured using the ACM_CTL.CLKPOL bit. After the $\overline{CS}$ signal is asserted, the first edge of ACM_CLK can be configured to be either rising edge or falling edge. Also, by default the clock is free running; it is possible to gate the ACM clock during an inactive $\overline{CS}$ period using the ACM_CTL.CLKMOD bit.

Case 1—Chip Select Asserted During the High Phase of ACM_CLK (ACM_CTL.CLKPOL =0)

The ***Chip Select Asserted During the High Phase of*** ACM_CLK figure shows the realignment of ACM_CLK when $\overline{CS}$ is asserted during the high phase of ACM_CLK. The first edge of ACM_CLK, after the assertion of $\overline{CS}$, is the falling edge.

The two reference clock signals (REF ACLK1 and REF ACLK2) illustrate how the ACM_CLK signal can be generated from a free running clock (REF ACLK1). This setup meets the timing requirements between the ACM_CLK and $\overline{CS}$ signals. The REF ACLK2 signal is based on the free running clock REF ACLK1. However, the REF ACLK2 signal is adjusted such that its period is immediately reset upon the assertion of $\overline{CS}$. In the resulting ACM_CLK signal, the time from the active edge of $\overline{CS}$ to the falling edge of ACM_CLK is constant at a period of 1 ACM_CLK cycle. See ACM_CLK in the ***Chip Select Asserted During the High Phase of*** ACM_CLK figure.

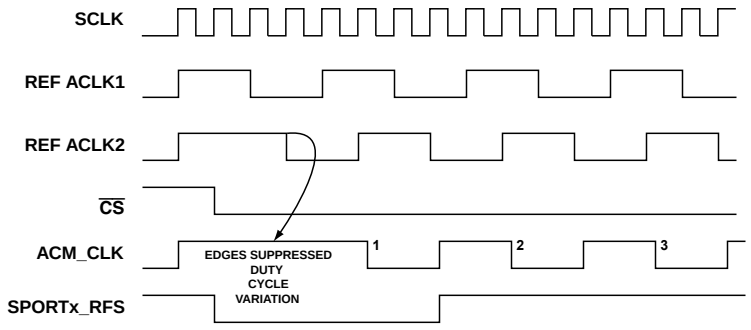

Figure 20-4: Chip Select Asserted During the High Phase of ACM_CLK

Case 2—Chip Select Asserted During the Low Phase of ACM_CLK (ACM_CTL.CLKPOL =0)

Refer to the ***Chip Select Asserted During the Low Phase of*** ACM_CLK figure. When the $\overline{CS}$ signal is asserted during the low phase of ACM_CLK, ACM_CLK is immediately pulled high which causes a duty cycle variation. In this case, (similar to Case 1), the time from the active edge of $\overline{CS}$ to the falling edge of ACM_CLK is 1 ACM_CLK period.

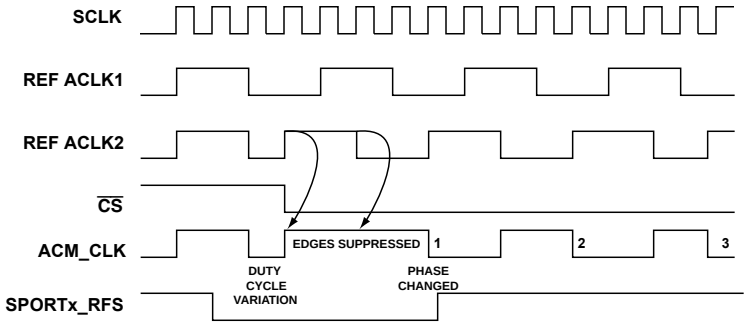

Figure 20-5: Chip Select Asserted During the Low Phase of ACM_CLK

Case 3—Chip Select Asserted Right Before the Falling Edge of ACM_CLK (ACM_CTL.CLKPOL =1)

Refer to the ***Chip Select Asserted Right Before the Falling Edge of*** ACM_CLK figure. When $\overline{CS}$ is asserted right before the falling edge of ACM_CLK, the falling edge of ACM_CLK is suppressed. This functionality ensures that the time from the active edge of $\overline{CS}$ to the falling edge of ACM_CLK is constant at a period of 1 ACM_CLK cycle.

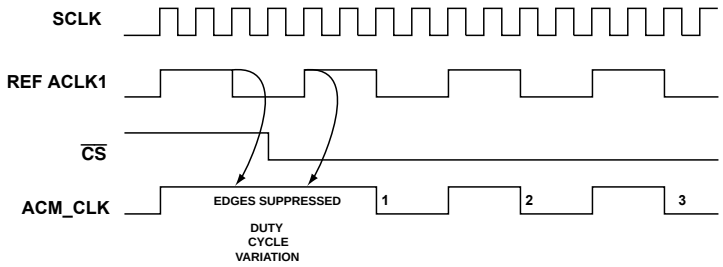

Figure 20-6: Chip Select Asserted Right Before the Falling Edge of ACM_CLK

Case 4—Chip Select Asserted Right Before the Rising Edge of ACM_CLK (ACM_CTL.CLKPOL =0)

Refer to the ***Chip Select Asserted Right Before the Rising Edge of*** ACM_CLK figure. When $\overline{CS}$ is asserted right before the rising edge of ACM_CLK, the high phase of ACM_CLK is extended. This extension ensures that the time from the active edge of $\overline{CS}$ to the falling edge of ACM_CLK is constant at a period of 1 ACM_CLK cycle.

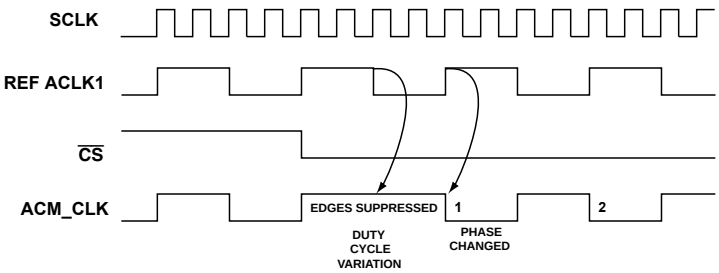

Figure 20-7: Chip Select Asserted Right Before the Rising Edge of ACM_CLK

Case 5— ACM_CLK Polarity Set to 1 (ACM_CTL.CLKPOL =1)

When the ACM_CLK polarity is set to 1 (the ACM_CTL.CLKPOL bit is set to 1), the first ACM_CLK edge after the assertion of $\overline{CS}$ is the rising edge. The ACM ensures that the time from the active edge of $\overline{CS}$ to the rising edge of ACM_CLK has a constant duration of 1 ACM_CLK cycle. The ***Polarity Set to 1*** figure shows an example diagram of the case where ACM_CTL.CLKPOL =1.

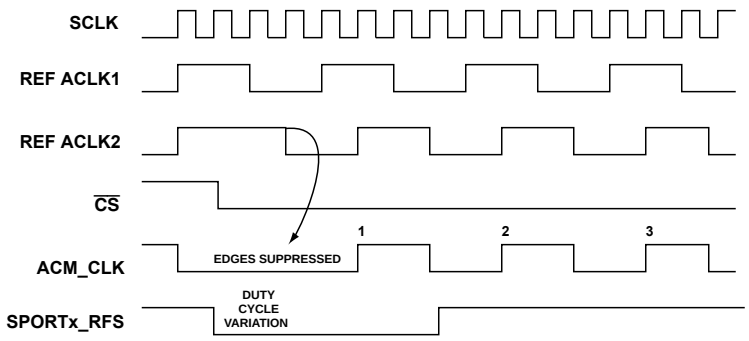

Figure 20-8: Polarity Set to 1

ACM Architectural Concepts

The following sections provide information on the architecture of the ACM module.

Clocking

The ACM on the ADSP-SC57x/ADSP-2157x processors operate on the SCLK domain. The term SCLK in this chapter is a generic reference to SCLK. For more details on SCLK programming refer to CDU Functional Description.

Block Diagram

The ADC Control Module (ACM) consists of two independent 32-bit ACM timers, 16 event register pairs, 16 event comparators and a timing generation unit.

The ACM can accept four trigger inputs (internal as well as external signals). On receiving a valid trigger on selected trigger input, the ACM timer/s start counting (based on the mode of the ACM). The trigger input can be independently selected for each timer.

Two sets of eight event register pairs (a total of 16 event register pairs) determine the ADC controls for each ADC sample. The registers also determine when the sample occurs. The event register pair consists of the event control register (`ACM_EVCTL[n]`) and the event time register (`ACM_EVTIME[n]`). The event comparators unit compares the timer of the ACM count with the event time of associated enabled events. When the count matches, the event comparators unit signals to the timing generation unit. The unit starts handling the events by driving the $\overline{CS}$ and `ACM_A4` to `ACM_A0` signals accordingly.

The ***ACM Block Diagram*** shows the structure of the ACM. The following sections discuss these blocks in detail.

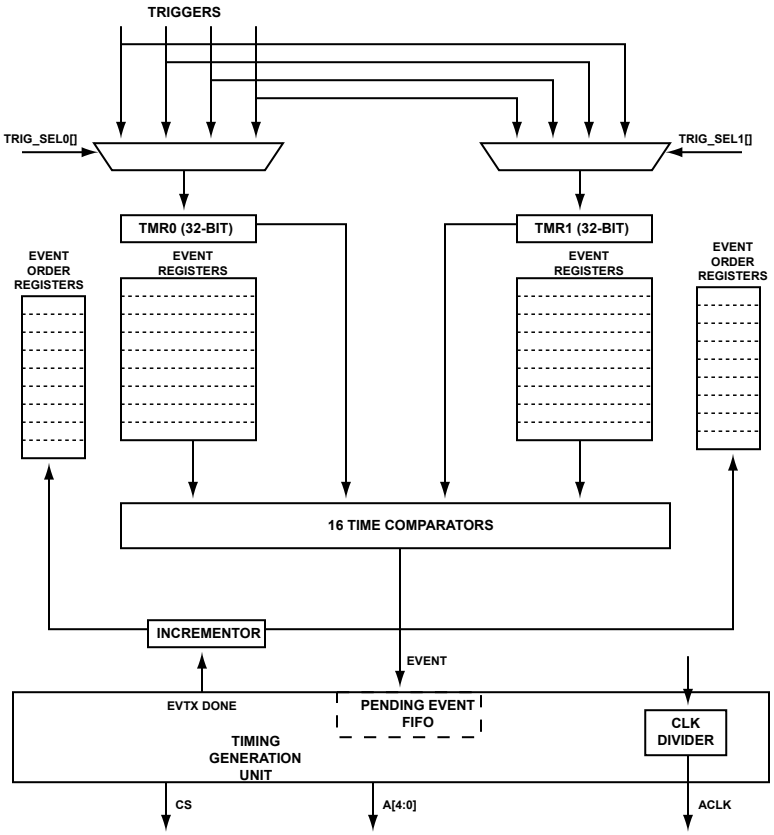

Figure 20-9: ACM Block Diagram

Trigger Inputs

The ACM can accept four trigger inputs, based on which the ACM timers start running at the SCLK rate. The ACM contains three 32-bit internal timers (timer 0, timer 2, and timer 3). Each timer can be independently configured to use one of these trigger inputs. The ACM uses `ACM_CTL.TRGSEL0` and `ACM_CTL.TRGSEL1` bit fields to select the trigger input for Timer0 and Timer1 respectively.

Out of the 4 trigger inputs to the ACM design:

- `ACM_T0` is driven from the chip I/O
- `ACM_T2` and `ACM_T3` are driven from the TRU

The ACM uses two trigger inputs when both ACM timers are enabled for different trigger inputs. However, it uses only one trigger if both ACM timers are enabled for same trigger input or if a single ACM timer is enabled. The non-selected trigger inputs are *do-not-care* for the ACM. At most two, and at least one selected trigger input must be active in the system for the ACM to start operation.

The following list briefly describes the possible trigger inputs:

- Trigger input 0 (`ACM_T0`) – PE8:

Trigger input 0 is sourced from the PE8 pin of the GPIO port E (sometimes also referred as GPIO[72]). When the ACM is enabled, the input tap on the PE8 pin is enabled. The ACM trigger input can be from any source (internal or external) depending on the PE8 pin configuration.

When the PE8 pin is configured in GPIO mode (PORT_FER =0), the source of the GPIO signal can be either internal or external. The source depends on the GPIO direction, configured in the E PORT_DIR register. When the PE8 pin is configured in function mode (PORT_FER =1), the trigger 0 input is sourced in from peripheral signals. The source is based on the PORT_MUX register setting for the PE8 pin.

Consider the source of the trigger input when programming the PORT_FER.PX8 and PORT_MUX.MUX8 bits for the PE8 pin. Enabling the input tap ensures that the ACM operation does not interfere with the module driving the PE8 pin.

- Trigger input 2 (ACM_T2) – (PG5) – ACM Slave TriggerID 135:

  The trigger routing unit (TRU) of the processor provides system-level sequence control without core intervention. When this trigger input mode is selected, the ACM acts as a trigger slave and accepts a trigger through the trigger slave ID-135. The slave-select (TRU_SSR[n].SSR) field of the SSR 135 register can be configured to receive triggers from a specific trigger master. In this way, ACM_T2 trigger input can accept triggers asserted by that particular trigger master or through software. The software writes the ID of that trigger master to one of the four fields in the TRU_MTR register. The trigger response from selected master is internally routed to ACM trigger input. This way, ACM slave trigger ID 135 can receive any one of the 86 internal triggers available.

- Trigger input 3 (ACM_T3) – ACM Slave TriggerID 136:

  Similar to the ACM_T2 input, the TRU of the processor provides the ACM trigger input 3 (ACM_T3) internally. When this trigger input mode is selected, the ACM acts as trigger slave and accepts a trigger through trigger slave ID 136. The slave-select (TRU_SSR[n].SSR) field of the SSR 136 register can be configured to receive triggers from a specific trigger master. In this way, the ACM slave trigger ID 136 can accept triggers asserted by that particular trigger master or through software. The software writes the ID of that trigger master to one of the four fields in the TRU_MTR register. The trigger response from selected master is internally routed to the ACM trigger input. This way, ACM slave trigger ID 136 can receive any one of the 86 internal triggers available.

  See the Trigger Routing Unit (TRU) chapter for more details about trigger slaves and trigger masters.

For all trigger input signals, the active edge of the trigger is programmable in the ACM control register as either rising edge or falling edge trigger.

The ***Detailed ACM Trigger Generation Logic*** figure shows the detailed ACM trigger generation logic.

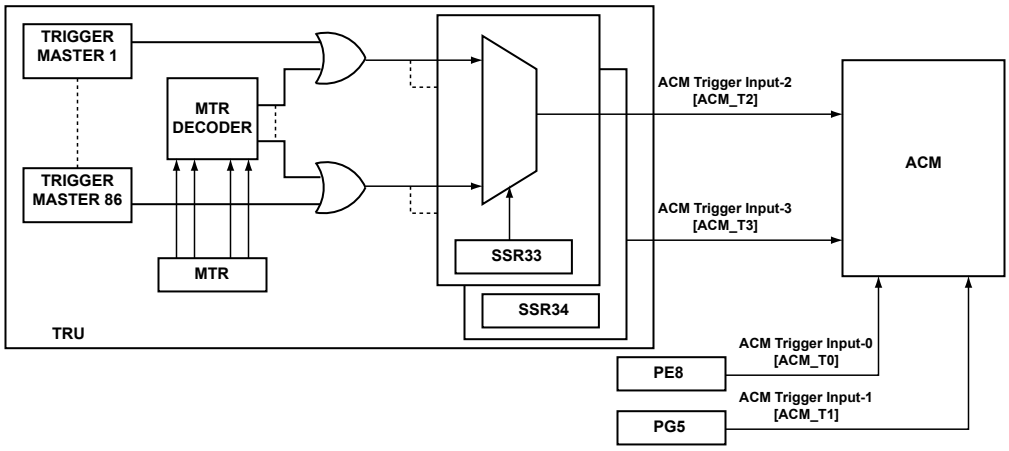

Figure 20-10: Detailed ACM Trigger Generation Logic

When the processor uses external trigger sources external for triggering the ACM timers, the minimum pulse width for these sources must be greater than one SCLK period. (For example, `ACM_T1:ACM_T0`).

NOTE: A latency of no more than four SCLK cycles exists between external trigger and ACM timer starts counting. Refer to the ACM Event Handling Latency section for further details.

Timers

The ACM module has two independent 32-bit timers (ACMTMR0 and ACMTMR1) which start counting at the system clock (SCLK) rate when a valid trigger is detected on a selected trigger input. The timers are independently enabled using the timer enable bits (`ACM_CTL.TMR0EN`, `ACM_CTL.TMR1EN`). The timers can be independently configured for one of the four trigger inputs with configurable polarity of the signal. Enable at least one ACM timer for proper ACM operation.

By default, each ACM timer has 8 events associated with it. If both timers are enabled, Event[7:0] are associated with ACMTMR0 while Event[15:8] are associated with ACMTMR1. However, if only one timer is enabled, all of the event registers are associated with that particular timer. For example, if only ACMTMR1 is enabled (if `ACM_CTL.TMR0EN` =0 and `ACM_CTL.TMR1EN` =1), ACMTMR1 handles all 16 events, Event[15:0].

The timers start counting when a trigger input occurs that is selected for that particular timer. The timer only stops counting under one of the following conditions:

1. A timer rollover occurs.
2. All the events associated with the trigger have completed.

A timer rollover cannot occur unless the event time register of an event is programmed at some point after the trigger occurs. This practice is contrary to ACM programming guidelines.

In the second case, the exact time at which the timer stops counting depends on the FIFO state when the last event occurred internally.

If a trigger occurs while the timer is counting, the time resets and starts counting again. In this case, some of the events can miss which results in flagging the appropriate status bit and optionally an event missed interrupt.

When an ACM timer is disabled or the ACM itself is disabled, the timer resets to zero.

Event Register Pairs

An event for the ACM is a point in time where ADC sampling occurs on a particular channel of the ADC with the specified control settings of the ADC.

The ACM can handle a total of 16 events which are grouped into two sets of 8 events. The 8 events can be assigned to each of the timers (if both timers are enabled) or all 16 events can be assigned to one particular timer. (Assignment happens when only one timer is enabled). See the Timers sections for details.

All events can be independently configured and enabled. The enabled events determine the ADC controls and timing for each ADC sampling interval. Each event consists of a register pair with an event control register (`ACM_EVCTL[n]`) and an event time register (`ACM_EVTIME[n]`). The `ACM_EVCTL[n]` register enables a particular event and determines settings for the ADC control lines (`ACM_A[4:0]`) for that particular ADC conversion. The ACM uses the `ACM_EVTIME[n]` register to determine the time offset from the corresponding ACM timer trigger input to the start of that particular event. (The time offset is when the event occurs based on trigger input.) This time offset can be specified in terms of the system clock of the processor.

Enable at least one event associated with an enabled ACM timer, for ACM to execute ADC sampling.

Event Comparators Unit

The event comparators block consists of 16 event time comparators which determine when an enabled event could happen. After detecting valid trigger on selected trigger input, ACM timer starts running at *SCLK* rate. The comparators compare the ACM timer count with the event time specified in the `ACM_EVTIME[n]` register of the enabled event. If the time value matches, the comparators indicate an active event signal to the timing generation unit.

If an event happens when another event is ongoing, the occurred event is stored in the pending event FIFO of timing generation unit. If more than one event associated with an ACM timer is active during the same SCLK cycle, only the highest priority event is processed. All other events are missed (even if there was space in the pending event FIFO). However, if both timers are enabled and if multiple events associated with both ACM timers are active at the same SCLK cycle, then two events are signaled. One highest priority active event for each timer is signaled.

The priority of events is fixed; the event with the lowest event ID has higher priority compared to other events.

When both ACM timers are enabled, Event0 has the highest priority and Event7 has the lowest priority in the Event[0:7] group associated with ACMTIMER0. Similarly, Event8 has the highest priority and Event15 has the lowest priority in the Event[8:15] group associated with ACMTIMER1. So if Event1 and Event5 occur simultaneously, then Event5 is missed, even if space exists in the pending FIFO. But between the Event[0:7] and Event[8:15] group, simultaneous events can be written into the FIFO.

For example, if Event0 and Event9 occur together, then both are written into the FIFO. The Event[0:7] group has higher priority. Therefore, the order of events in the FIFO is Event0 first and then Event9. If Event1, Event5, Event9, Event15 occurred together, then Event5, and Event15 are missed. Event1 and Event9 are put into the FIFO (Event1 first followed by Event9). When both timers trigger events simultaneously, the event triggered by ACMTMR0 is given higher priority.

When only a single ACM timer is enabled, then all 16 events, Event[0:15], are assigned to that timer. Event0 has highest priority; while Event15 has lowest priority. In this case, if Event1, Event5, Event9, Event15 happened together, then only Event1 is placed in forwarded. Event5, Event9, and Event15 are missed, even if space exists in the pending FIFO.

If an event is missed, the ACM_STAT.EMISS bit and the corresponding bit in the ACM event missed status register (ACM_MEVSTAT) are set.

Timing Generation Unit

After event signaling from event comparators, the timing generation unit initiates an ADC sampling interval as per settings of that particular event. It generates ADC control signals based on the ACM_EVCTL[n].EPF bit field setting. The ACM uses timing registers (ACM_TC0, ACM_TC1) to determine the timing of output signals (ACM_CLK, $\overline{\text{CS}}$, A[4:0]). These registers contains the fields for set-up time, hold time and zero time for the output signals and ACM clock divider.

The pending FIFO is part of the timing generation unit. If an event occurs when the ACM is busy with another event, the occurred event is stored in the pending event FIFO. This pending event is serviced (for example, the ACM starts an ADC conversion for the event that occurred), after completion of an ongoing event.

The pending event FIFO has a depth of 4, so it can hold up to four pending events. If an event occurs when the pending event FIFO is full, that event is missed. If an event is missed, the ACM_STAT.EMISS bit is set and the corresponding bit in the ACM_MEVSTAT register also is set.

When the ACM is disabled, all pending entries in the pending FIFO are flushed.

Status Flags and Interrupts

The ACM provides a read-only status register (ACM_STAT) to check the module activities. Activities include identifying which event is being serviced, whether any event has been missed, or whether all the events have been serviced for the current trigger.

In addition to this register, the ACM also provides two general-purpose status registers, the ACM event completion status register (ACM_EVSTAT) and the ACM missed event status register (ACM_MEVSTAT). The ACM_EVSTAT register specifies how to service a completed enabled event for a particular trigger cycle. The ACM_MEVSTAT register specifies which enabled event has been missed for that particular trigger cycle. This information is provided for all 16 events through individual bits.

Based on these status bits, the ACM can generate two interrupts, event-completed or event-missed, for each event. These interrupts can be selectively enabled for particular ACM events through the ACM completed event interrupt mask register (ACM_EVMSK) and the ACM missed event interrupt mask register (ACM_MEVMSK).

The event completion interrupt is generated only after the entire event completes externally. (For example, when the $\overline{\text{CS}}$ signal goes inactive, and the hold time (TH) and zero time (TZ) periods are completed for that particular event). The ACM uses the ACM_EVSTAT register to provide the status of each event indicating which event has caused the interrupt. It is also possible to generate this interrupt when all the events associated with an ACM timer are completed for an ACM trigger cycle. Write the relevant W1C (write 1 to clear) bit in the ACM_EVSTAT register to clear this interrupt.

The event missed interrupt is generated when an enabled event is missed for a trigger cycle and the corresponding mask bit in the ACM_MEVMSK register is set. The event comparators unit can miss the event when more than one event, related to the same timer, are active during the same SCLK cycle. The timing generation unit can miss when an event occurred and the event pending FIFO was full. The ACM uses the ACM_MEVSTAT register to provide the status of each missed event indicating which event-miss caused the interrupt. Write the relevant W1C bit in the ACM_MEVSTAT register to clear this interrupt.

NOTE: A status bit set either in the ACM_EVSTAT or ACM_MEVSTAT registers triggers an interrupt only if the corresponding bit in the ACM_EVMSK or ACM_MEVMSK registers is enabled.

The ACM provides an event completion interrupt upon completion of particular event or all events. The ACM can also provide a trigger output to the trigger routing unit (TRU) of the processor. Trigger slaves can use this trigger output for their operations without requiring core intervention.

Event Order Registers

For debugging purpose, ACM hardware includes 16 event order registers, one per each event. These registers indicate the order in which the events complete externally.

These registers are denoted as ACM_EVORD[n], where n stands for event ID, 0–15. The ACM module uses the 8-bit ACM_EVORD[n].ORD field of this register to indicate the order the ADC data has been captured for the event. This field accumulates the order count every trigger cycle, unless it is cleared in the software. At each trigger cycle, the values of the register are updated. The ACM must read the register at the end of each trigger cycle (as it writes the new order value of the event in the next trigger cycle). Thus, the 8-bit field can store the order of 256 data captures at a stretch, after which it starts the order count from zero again.

All the event registers can be reset in software by setting the ACM_CTL.ORST bit. When set, it clears all the register values to zero. This bit is auto-cleared to 0 after all ACM_EVORD[n] registers are cleared. The ACM can select trigger inputs of the timers to automatically clear these registers, when the ACM_CTL.AOREN bit is set. The ACM uses the ACM_CTL.OTSEL bit to determine which trigger input to select for this auto-clearing.

The event order functionality is demonstrated with an example where the ACM has only three events enabled (Event1, Event7, and Event13). The ***Event Order Timing*** figure shows the event order register value of these events at different stages.

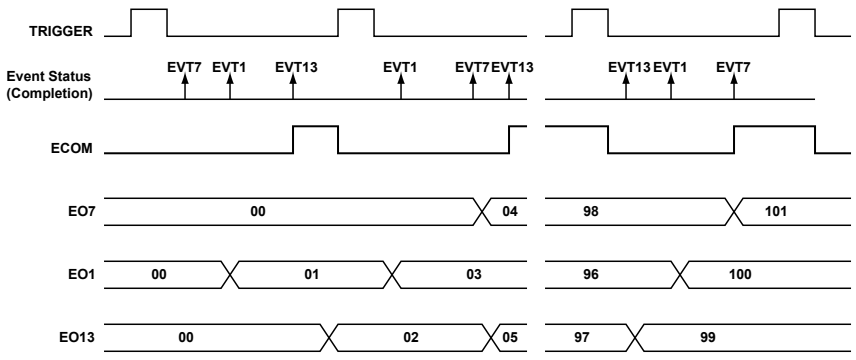

Figure 20-11: Event Order Timing

ACM Operation

The ***ACM Operation, Two Events*** figure shows the ACM operation where only two events (Event0 and Event3) are enabled. The line labeled “ADC Controls” depicts the timing of the ADC control signals: ACM_A4 through ACM_A0.

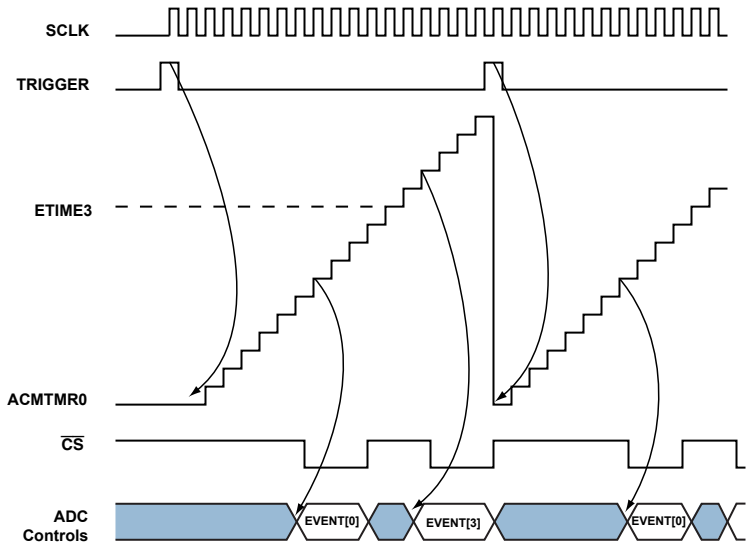

Figure 20-12: ACM Operation, Two Events

The ***ACM Operation, Two Events*** figure depicts a usage case. The ACM_EVTIME[n] 3 time register is programmed with a count value that is greater than the value programmed in Event0. So, Event3 occurs after Event0. There are, however, no restrictions on the order of the different events. Event0 time can be greater than, less than or equal to Event3 time.

If the value in Event0 time register is less than the value in Event3 time, Event3 occurs after Event0. If the value in Event0 is greater than the value in Event3, then Event3 occurs before Event0. If Event0 time is equal to the Event3 time, the events are processed according to their priorities. Only the highest priority event is processed. Other lower-priority events are missed (even if there is a space in pending event FIFO), as the same ACM timer handles both events. Event0 has the highest priority. So in this case, the timing generation unit processes Event0, while Event3 is missed. In this case, the Event3 missed status bit (ACM_MEVSTAT.EV3) is set and the event missed bit (ACM_STAT.EMISS) is set, indicating that an event has been missed.

If event times are not sufficiently spaced apart, an event could occur while a previous event is underway (while the chip select of the previous event is asserted). In this situation, the second event is queued in the pending event FIFO. If the pending event FIFO is full, the event is not queued and is missed. This situation happens most commonly when enabling both ACM timers with different trigger inputs and the sources of these triggers are not synchronized together. In this case, it is possible that the events controlled by the two timers overlap. It is therefore important to consider the possibility of events occurring either simultaneously or being missed when enabling events on two asynchronously triggered timers. It is the programs responsibility to ensure that the values in the event time registers do not lead to event misses. The bits corresponding to the missed event in the ACM_MEVSTAT and ACM_STAT registers are flagged on a missed event.

When both ACM timers are enabled and they triggered the events simultaneously, the event triggered by ACM_TMR0 has the higher priority. For example, when an ACM_TMR0 event (one of events 0 through 7) and ACM_TMR1 event (one of events 8 through 15) occur simultaneously:

- The timing generation unit processes the ACM_TMR0 event, or
- The ACM_TMR0 event is queued in the pending event FIFO before the processing or the queuing of the ACM_TMR1 event.

When all the events enabled for a given ACM timer are processed, the ACM timer stops incrementing. (This timer action is not reflected in the ***ACM Operation, Two Events*** figure). Also, the corresponding event completion bit (ACM_STAT.ECOM1, ACM_STAT.ECOM0) is flagged. The same bit is also reflected in the status register for event compilation (ACM_EVSTAT). This register can optionally generate the event completion interrupt when the corresponding bit in the event completion interrupt mask register (ACM_EVMSK) is set. Two separate bits are available, one for each ACM timer.

The processor can use the ACM to generate various sequences of ADC sampling events through appropriate programming of event time registers, event control registers, and triggers. For more information, see the use cases described in Emulation Mode Use Case.

ACM Programming Concepts

Since the ACM module is used with the SPORT, GP timer, and GPIO, the programming must comply with the following guidelines for reliable operation of the ACM.

- The ACM is a control module and provides clock and chip select and control signals with required timing. But for capturing the data from ADC, the ACM uses one of the halves of SPORT1.
- Enable the ACM before enabling the SPORT. The SPORT can be configured before enabling the ACM. Configure the SPORT in slave mode [external clock (SPORT_CTL_A.ICLK =0), external frame sync (SPORT_CTL_A.IFS =0)] as receiver.

  The timings of external ADC decide the settings of SPORT_CTL_A.LFS, SPORT_CTL_A.LAFS, SPORT_CTL_A.CKRE bits. Generally, the SPORT is configured in DSP serial mode to receive the ADC samples, but other operating modes (such as multichannel) are possible.

  If the ACM is programmed in gated clock mode (ACM_CTL.CLKMOD =1), set the serial port also in gated clock mode (SPORT_CTL_A.GCLKEN =1).
- DMA mode of SPORT operation is preferred, as it saves the processor MIPS when receiving chunks of data. However, receiving ADC samples in core mode is also possible. When using DMA mode, configure the DMA registers of the selected SPORT appropriately and enable DMA before enabling the SPORT. When using the primary and secondary channels of a SPORT to receive data from two ADC channels, use the 2D feature of DMA to de-interleave the data from two channels. When using core mode of SPORT operation, register the core handler to handle the data read requests from the SPORT receiver.

- In addition to SPORT register settings, first set the DAI registers to enable: SPORT data pins, the ACM clock, the $\overline{CS}$, and the data pins. Then, configure the PORT registers for the trigger and control pins. When using either of the ACM_T1/ACM_T0 trigger inputs for ACM timers, configure the PORT_FER and PORT_MUX bits of the corresponding pins (PE8 or PG5) according to source of trigger input.
- When using ACM_T[2:3] trigger inputs for ACM timers, the ACM can configure and enable the trigger routing unit (TRU) at this step. Program the corresponding slave trigger ID using the TRU_SSR[n] register to select the required master trigger. When using these trigger inputs, do not configure the TRU_SSR[n] register when the ACM is enabled. The default value of this register is zero and the master trigger ID 0 is system reserved.
- Before enabling the ACM (by setting the ACM_CTL.EN bit), program all the control bits of ACM control register. These control bits include ACM trigger selects (ACM_CTL.TRGSEL1/ACM_CTL.TRGSEL0), trigger input polarities (ACM_CTL.TRGPOL1/ACM_CTL.TRGPOL0), $\overline{CS}$ signal polarity (ACM_CTL.CSPOL), ACM clock polarity (ACM_CTL.CLKPOL), ACM clock mode (ACM_CTL.CLKMOD), and serial port unit selection and the ACM_EVORD[n] register settings.
- Configure the ACM timing control registers to define the ACM clock frequency and the setup, hold, and zero time of the ACM control signals.
- Program the timer enabled bits (ACM_CTL.TMR0EN/ACM_CTL.TMR1EN) together only after the ACM is enabled. Once the bits are programmed, do not change them. Modifying these enable bits in the ACM control register is not recommended while the ACM is in operation. Doing so can cause events to change dependency from one timer to the other and can cause the values in the ACM status registers (ACM_EVSTAT and ACM_STAT) to be inaccurate. If both timers are required for use, enable them together after the ACM is enabled. If one timer is already enabled, disable and then reenable the ACM and then program both timer enable bits together. Similarly, when both timers are running, disable them together.
- Once the peripherals have been configured, enable the ACM first and then the SPORT DMA and finally the SPORT module itself. Ideally, a trigger should not be active when enabling the ACM.
- After enabling the ACM, configure and enable the event register pairs (event control and event time registers) to create the required events.
- ACLK is an external clock relative to the SPORT peripheral. Observe any SPORT requirements around a minimum number of stable external clock cycles before the assertion of the first SPORT frame sync. The SPORT requires a minimum of 3 clock cycles before it is able to recognize a frame sync. When the SPORT is configured in gated clock mode, this requirement becomes a minimum of 7 SPORT clock cycles. The required number of ACLK cycles should elapse before first assertion of $\overline{CS}$. Use any of the following methods:
  - Ensure that ACM triggers are generated at least 3 ACLK cycles after the ACM is enabled.
  - Ensure that the event time value (ACM_EVTIME[n]) of the first active event is such that 3 ACLK cycles elapse before the event is processed.

- When the minimum number of ACLK cycles before the assertion of $\overline{CS}$ is not observed, the SPORT can miss the data of the first ADC sampling event. There is a software workaround for fulfilling this requirement. Program the `ACM_TC0.CKDIV` value after enabling the SPORT (subsequently after enabling the ACM) but before the trigger is applied. Since the default value of `ACM_TC0.CKDIV` is 1, the ACLK frequency is higher. Therefore, the SPORT can receive the required clock cycles within a short period (before the frame sync arrives).
- When using the `ACM_T2/ACM_T3` trigger inputs, the master can be enabled as a last step (if it is configured only to provide triggers to the ACM) to generate the triggers.
- While disabling the ACM system, disable the SPORT first, then the DMA. Finally, disable the ACM.

Emulation Mode Use Case

This section describes the usage modes of the ACM by illustrating how to implement various sequencing ADC sampling modes.

Single-Shot Sequencing Mode Emulation

In single-shot sequencing mode, all enabled events are sequentially issued one after the other on the occurrence of an ACM trigger. The sequence of events is fixed, starting with Event0 and ending with Event15.

The ***Single Shot Sequencing*** figure shows an example of single-shot sequencing mode where only Event0 and Event1 are enabled. The value ETIME0 is written into the ACM_ET0 register, and ACMTMR0 is enabled in this mode.

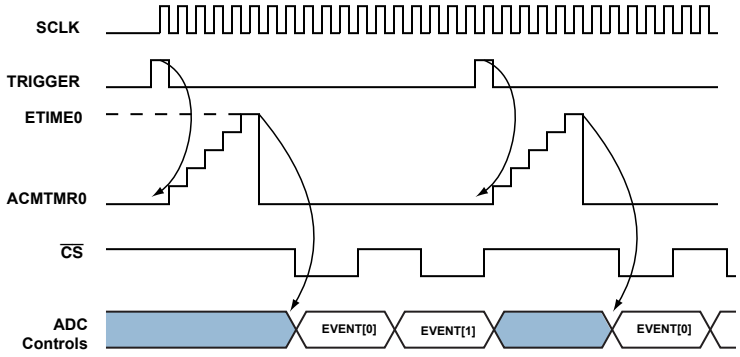

Figure 20-13: Single Shot Sequencing

To emulate this mode of operation using the ACM:

- Configure the appropriate trigger source for initiating ACM activity. Refer to ADC Control Module (ACM) for information on signals that can trigger the ACM counters.
- Enable only one ACM timer (ACMTMR0)
- Enable events and program the event time values as: Event0 time = X, Event1 time = X + Y, Event2 time = X + 2Y where:

  X = `ETIME0`, the initial time offset from trigger (if needed)

Y = t_H + t_{CSW} + t_S + t_Z, where t_H is the hold time, t_Z is the zero time, and t_S is the setup time for ACM control lines, as specified in ACM timing registers.

For more information, refer to the ACM External Pin Timing section.

NOTE: Y has to be slightly less than the calculated value to ensure that the next event occurs before the first event completes. Then, the next event is in the pending FIFO and enables the transitions between events without a break.

Continuous Sequencing Mode Emulation

Continuous sequencing mode is similar to single-shot sequencing mode, except in continuous sequencing the event sequencing continuously repeats. As in single-shot mode, the time offset is programmable in continuous mode. The trigger in continuous mode is relevant only for the first time. Therefore, any subsequent triggers after the first active edge of the trigger are neglected.

The ***Continuous Sequencing*** figure shows an example of continuous sequencing mode with only two events – Event0, Event1 enabled. To emulate continuous sequencing mode using ACM:

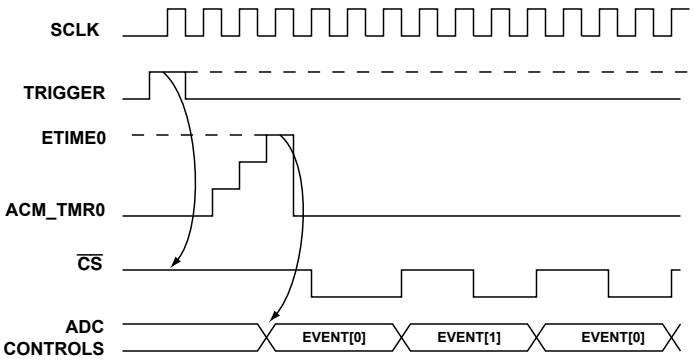

Figure 20-14: Continuous Sequencing

- Enable only one ACM timer (for example ACMTIMER0). Select a timer trigger input from the TRU (either of the `ACM_T[n]`[3:2].

  If `ACM_T2` is selected, program ACM slave trigger ID 33 to select ACM event completion (whose master trigger ID is 19) as trigger input. If `ACM_T3` is selected as trigger input, configure ACM slave trigger ID 34.

- Configure rest of the settings required by programming ACM control and timing registers.
- Enable ACM events with required ACM control lines settings.

  Program the event time registers as: Event0 time = X, Event1 time = X + Y, Event 2 time = X + 2Y where:

  X and Y values, in terms of SCLK, are as described in the single-shot case. (Y must be slightly less than t_H + t_{CSW} + t_S + t_Z to avoid any break between events.)

- Configure and enable system event controller (SEC).

Also configure, map, and enable the ACM event completion interrupt. This interrupt occurs on the completion of all enabled ACM events for the current trigger. That means that programs must only set the ACM_EVMSK.IECOM0 bit (or the ACM_EVMSK.IECOM1 bit, if using ACMTIMER1) register.

- Enable ACM, SPORT, and SPORT DMA as per the guidelines in the ACM Programming Concepts section.
- Since the ACM trigger input is configured as ACM event completion trigger output, the first trigger is necessary to start the ACM operation. We can provide this dummy trigger by writing master trigger ID into master trigger register (TRU_MTR).

  Write the ACM event completion trigger ID (19) into the TRU_MTR register. This action triggers the ACM timers and the ACM starts handling the events.
- After completing all events, the ACM provides an event completion trigger and the corresponding interrupt is generated. The ACM trigger output is provided to the ACM timers. The timers reset their counter and start running from zero. The ACM rehandles all the enabled ACM events. This sequence continues.

  However, in order to provide the trigger outputs properly, clear the interrupt latch in the ISR by clearing the ACM_EVSTAT.ECOM0S (or ACM_EVSTAT.ECOM1S, if using ACMTIMER1) bit.

ADSP-SC57x ACM Register Descriptions

ADC Control Module (ACM) contains the following registers.

Table 20-5: ADSP-SC57x ACM Register List

Name	Description
ACM_CTL	Control Register
ACM_EVCTL[n]	Event N Control Register
ACM_EVMSK	Event Complete Interrupt Mask Register
ACM_EVORD[n]	Event N Order Register
ACM_EVSTAT	Event Complete Status Register
ACM_EVTIME[n]	Event N Time Register
ACM_MEVMSK	Missed Event Interrupt Mask Register
ACM_MEVSTAT	Missed Event Status Register
ACM_STAT	Status Register
ACM_TC0	Timing Configuration 0 Register
ACM_TC1	Timing Configuration 1 Register
ACM_TMR0	Timer 0 Register
ACM_TMR1	Timer 1 Register

Control Register

The ACM_CTL register enables and selects the various modes of operation of the ACM.

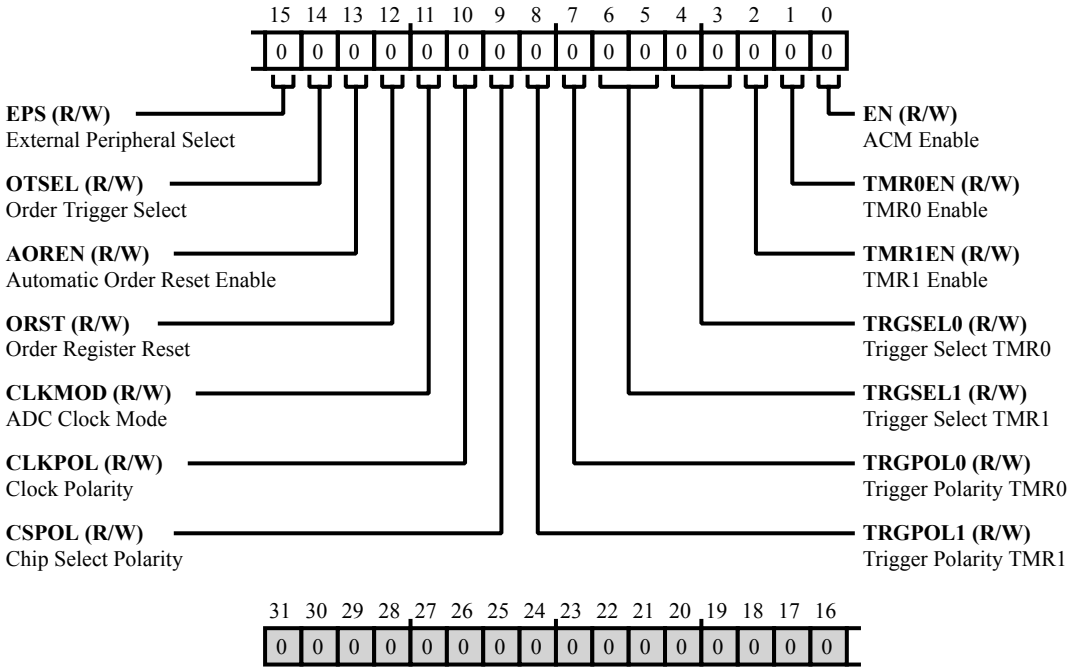

Figure 20-15: ACM_CTL Register Diagram

Table 20-6: ACM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EPS	External Peripheral Select. The ACM_CTL.EPS bit selects whether the ACM interfaces to half SPORT A or half SPORT B.	
		0	Half SPORT A Interfaces to ACM
		1	Half SPORT B Interfaces to ACM
14 (R/W)	OTSEL	Order Trigger Select. The ACM_CTL.OTSEL bit selects whether TMR0 or TMR1 triggers a reset of the event order (ACM_EVORD[n]) registers. This bit is applicable only if the ACM_CTL.AOREN bit is set.	
		0	ACM TMR0 Triggers Reset of Order Registers
		1	ACM TMR1 Triggers Reset of Order Registers

Table 20-6: ACM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	AOREN	Automatic Order Reset Enable. The ACM_CTL.AOREN bit enables automatic reset of the event order (ACM_EVORD[n]) registers, based on the selected timer trigger. The ACM_CTL.OTSEL bit selects the trigger.	
		0	Disable Automatic Order Reset
		1	Enable Automatic Order Reset
12 (R/W)	ORST	Order Register Reset. The ACM_CTL.ORST bit resets the event order (ACM_EVORD[n]) register value to 0. This bit auto-clears to 0 after the ACM_EVORD[n] registers clear.	
11 (R/W)	CLKMOD	ADC Clock Mode. The ACM_CTL.CLKMOD bit selects gated clock mode (ACM_CLK is gated when the ADC CS is inactive) or continuous (ACM generates continuous ACM_CLK).	
		0	Continuous Clock Mode
		1	Gated Clock Mode
10 (R/W)	CLKPOL	Clock Polarity. The ACM_CTL.CLKPOL bit selects whether the rising or falling edge of ACM_CLK comes after ADC CS becomes active.	
		0	Falling Edge of Clock After CS
		1	Rising Edge of Clock After CS
9 (R/W)	CSPOL	Chip Select Polarity. The ACM_CTL.CSPOL bit selects whether ADC CS is active high or low.	
		0	Active Low CS
		1	Active High CS
8 (R/W)	TRGPOL1	Trigger Polarity TMR1. The ACM_CTL.TRGPOL1 bit selects whether the trigger polarity for ACM TMR1 occurs on the falling or rising edge.	
		0	Rising Edge Trigger
		1	Falling Edge Trigger
7 (R/W)	TRGPOL0	Trigger Polarity TMR0. The ACM_CTL.TRGPOL0 bit selects whether the trigger polarity for ACM TMR0 occurs on the falling or rising edge.	
		0	Rising Edge Trigger
		1	Falling Edge Trigger

Table 20-6: ACM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	TRGSEL1	Trigger Select TMR1. The ACM_CTL.TRGSEL1 bits select the external trigger for ACM TMR1.	
		0	Trigger 0 (ACM_T0 Pin)
		1	Trigger 1 (ACM_T1 Pin)
		2	Trigger 2 (Trigger Input 2 - TRU Slave)
		3	Trigger 3 (Trigger Input 3 - TRU Slave)
4:3 (R/W)	TRGSEL0	Trigger Select TMR0. The ACM_CTL.TRGSEL0 bits select the external trigger for ACM TMR0.	
		0	Trigger 0 (ACM_T0 Pin)
		1	Trigger 1 (ACM_T1 Pin)
		2	Trigger 2 (Trigger Input 2 - TRU Slave)
		3	Trigger 3 (Trigger Input 3 - TRU Slave)
2 (R/W)	TMR1EN	TMR1 Enable. The ACM_CTL.TMR1EN bit enables ACM TMR1.	
		0	Disable ACM TMR1
		1	Enable ACM TMR1
1 (R/W)	TMR0EN	TMR0 Enable. The ACM_CTL.TMR0EN bit enables ACM TMR0.	
		0	Disable ACM TMR0
		1	Enable ACM TMR0
0 (R/W)	EN	ACM Enable. The ACM_CTL.EN bit enables ACM operation.	
		0	Disable ACM
		1	Enable ACM

Event N Control Register

The ACM_EVCTL[n] registers each hold the ADC control value corresponding to the event related to the register. These control registers each have an event enable bit, that permits a selective enable of a particular event.

Do not program the ACM_EVCTL[n] register when an event is active. Program this register before setting trigger and re-program this register after all the events are complete (ACM_STAT.ECOM1 or ACM_STAT.ECOM0 bit is set). If no events are enabled in this register (for example, all ACM_EVCTL[n].ENAEV bits =0, and the ACM_STAT.ECOM0 or ACM_STAT.ECOM1 bits are set) and an interrupt generates (if unmasked) a trigger is applied with the Timer enabled.

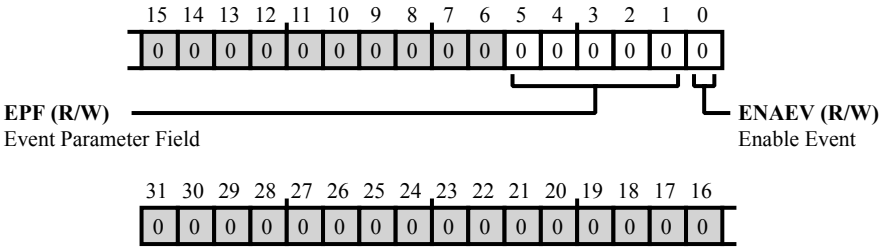

Figure 20-16: ACM_EVCTL[n] Register Diagram

Table 20-7: ACM_EVCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5:1 (R/W)	EPF	Event Parameter Field. The ACM_EVCTL[n].EPF bits select values for the ADC control pins (ACM_A[n]. These values are output when the enabled event occurs. Selection of ACM_EVCTL[n].EPF values are based on the type of ADC, usage mode, and other items. For more information, see the operating modes section. All ACM_EVCTL[n].EPF bits have the same external pin timing.	
0 (R/W)	ENAEV	Enable Event. The ACM_EVCTL[n].ENAEV bit causes a sampling event to occur based on the controls selected by the ACM_EVCTL[n].EPF bit field when an event (time comparison match or other external trigger) occurs. If disabled, the corresponding event has no significance, and the control values are not used.	
		0	Disable Event
		1	Enable Event

Event Complete Interrupt Mask Register

The ACM_EVMSK register enables interrupts corresponding to status bits in the ACM_EVSTAT register. When a bit in the ACM_EVMSK register is set (=1), an interrupt generates when the corresponding event complete bit in the ACM_EVSTAT register is set.

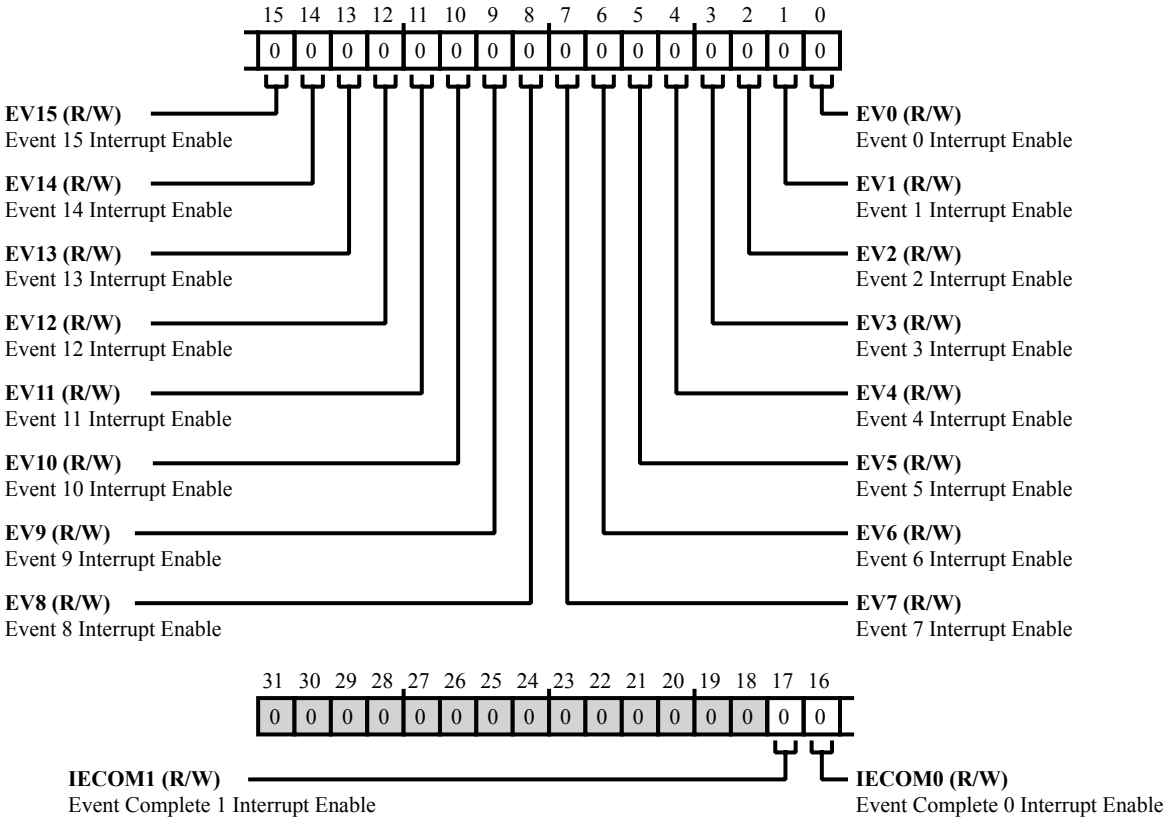

Figure 20-17: ACM_EVMSK Register Diagram

Table 20-8: ACM_EVMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	IECOM1	Event Complete 1 Interrupt Enable.	
		0	Disable (Mask) Interrupt
		1	Enable (Unmask) Interrupt
16 (R/W)	IECOM0	Event Complete 0 Interrupt Enable.	
		0	Disable (Mask) Interrupt
		1	Enable (Unmask) Interrupt

Table 20-8: ACM_EVMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EV15	Event 15 Interrupt Enable.	
		0	Disable (Mask) Interrupt
		1	Enable (Unmask) Interrupt
14 (R/W)	EV14	Event 14 Interrupt Enable.	
		0	Disable (Mask) Interrupt
		1	Enable (Unmask) Interrupt

Event N Order Register

The ACM_EVORD[n] registers hold the ADC data capture event order. These registers can store the order of 256 data captures at a stretch. The ACM_EVORD[n] registers also have status bits indicating whether an event misses or completes in the trigger cycle.

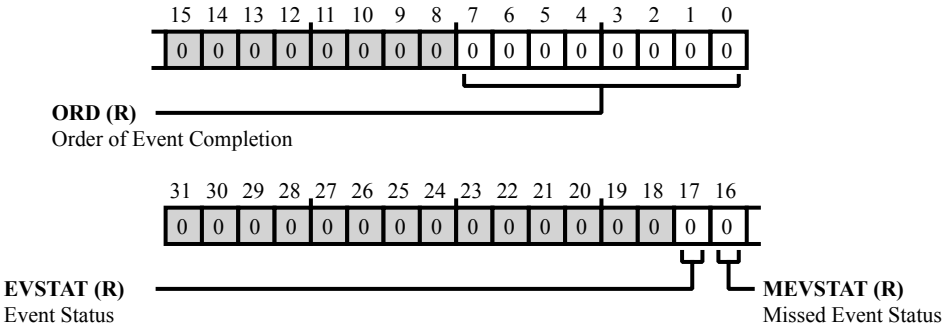

Figure 20-18: ACM_EVORD[n] Register Diagram

Table 20-9: ACM_EVORD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	EVSTAT	Event Status. The ACM_EVORD[n].EVSTAT bit reflects the state of the corresponding event bit in the ACM_EVSTAT register.	
16 (R/NW)	MEVSTAT	Missed Event Status. The ACM_EVORD[n].MEVSTAT bit reflects the state of the corresponding event bit in the ACM_MEVSTAT register.	
7:0 (R/NW)	ORD	Order of Event Completion. The ACM_EVORD[n].ORD bits indicate the order of event completion. Zero indicates the first event completed (after the ACM is enabled or after the ACM_CTL.ORST bit is set) and 255 indicates the 256th event completed.	
		0	1st Event Completed
		1	2nd Event Completed
		255	256th Event Completed

Event Complete Status Register

The ACM_EVSTAT register identifies which enabled event has occurred for a particular trigger cycle. When an ACM_EVSTAT bit is cleared (=0), this status indicates that the ACM has not begun or completed conversion for the corresponding event (conversion not done). When an ACM_EVSTAT bit is set (=1), this status indicates that the ACM has completed conversion for the corresponding event (conversion done).

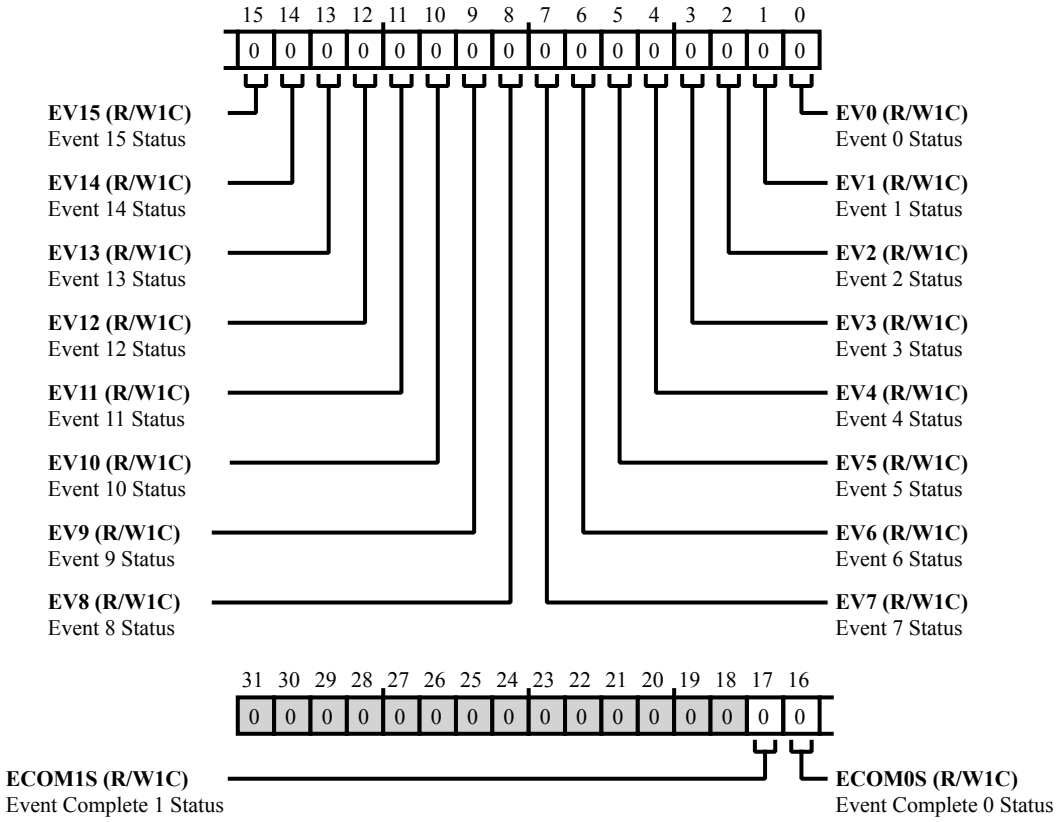

Figure 20-19: ACM_EVSTAT Register Diagram

Table 20-10: ACM_EVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	ECOM1S	Event Complete 1 Status. The ACM_EVSTAT.ECOM1S bit indicates the state of the ACM_STAT.ECOM1 bit. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C and is not cleared by a trigger.	
		0	No Status
		1	ACM_STAT.ECOM1 =1 Occurred

Table 20-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ECOM0S	Event Complete 0 Status. The ACM_EVSTAT.ECOM0S bit indicates the state of the ACM_STAT.ECOM0 bit. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C and is not cleared by a trigger.	
		0	No Status
		1	ACM_STAT.ECOM0 =1 Occurred
15 (R/W1C)	EV15	Event 15 Status. The ACM_EVSTAT.EV15 bit indicates when the ACM has completed the conversion for event 15. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 15 Conversion
		1	Event 15 Conversion Done
14 (R/W1C)	EV14	Event 14 Status. The ACM_EVSTAT.EV14 bit indicates when the ACM has completed the conversion for event 14. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 14 Conversion
		1	Event 14 Conversion Done
13 (R/W1C)	EV13	Event 13 Status. The ACM_EVSTAT.EV13 bit indicates when the ACM has completed the conversion for event 13. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 13 Conversion
		1	Event 13 Conversion Done
12 (R/W1C)	EV12	Event 12 Status. The ACM_EVSTAT.EV12 bit indicates when the ACM has completed the conversion for event 12. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 12 Conversion
		1	Event 12 Conversion Done

Table 20-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	EV11	Event 11 Status. The ACM_EVSTAT.EV11 bit indicates when the ACM has completed the conversion for event 11. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 11 Conversion
		1	Event 11 Conversion Done
10 (R/W1C)	EV10	Event 10 Status. The ACM_EVSTAT.EV10 bit indicates when the ACM has completed the conversion for event 10. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 10 Conversion
		1	Event 10 Conversion Done
9 (R/W1C)	EV9	Event 9 Status. The ACM_EVSTAT.EV9 bit indicates when the ACM has completed the conversion for event 9. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 9 Conversion
		1	Event 9 Conversion Done
8 (R/W1C)	EV8	Event 8 Status. The ACM_EVSTAT.EV8 bit indicates that the ACM has completed the conversion for event 8. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 8 Conversion
		1	Event 8 Conversion Done
7 (R/W1C)	EV7	Event 7 Status. The ACM_EVSTAT.EV7 bit indicates when the ACM has completed the conversion for event 7. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 7 Conversion
		1	Event 7 Conversion Done

Table 20-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	EV6	Event 6 Status. The ACM_EVSTAT.EV6 bit indicates when the ACM has completed the conversion for event 6. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 6 Conversion
		1	Event 6 Conversion Done
5 (R/W1C)	EV5	Event 5 Status. The ACM_EVSTAT.EV5 bit indicates when the ACM has completed the conversion for event 5. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 5 Conversion
		1	Event 5 Conversion Done
4 (R/W1C)	EV4	Event 4 Status. The ACM_EVSTAT.EV4 bit indicates when the ACM has completed the conversion for event 4. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 4 Conversion
		1	Event 4 Conversion Done
3 (R/W1C)	EV3	Event 3 Status. The ACM_EVSTAT.EV3 bit indicates when the ACM has completed the conversion for event 3. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 3 Conversion
		1	Event 3 Conversion Done
2 (R/W1C)	EV2	Event 2 Status. The ACM_EVSTAT.EV2 bit indicates when the ACM has completed the conversion for event 2. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 2 Conversion
		1	Event 2 Conversion Done

Table 20-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	EV1	Event 1 Status. The ACM_EVSTAT.EV1 bit indicates when the ACM has completed the conversion for event 1. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 1 Conversion
		1	Event 1 Conversion Done
0 (R/W1C)	EV0	Event 0 Status. The ACM_EVSTAT.EV0 bit indicates when the ACM has completed the conversion for event 0. If set and the corresponding bit in ACM_EVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 0 Conversion
		1	Event 0 Conversion Done

Event N Time Register

The ACM_EVTIME[n] registers each hold a 32-bit event time value. There are 16 event time registers, 8 for each ACM timer (when both timers are enabled). If only one timer is enabled, all 16 of the ACM_EVTIME[n] registers are assigned to the enabled timer.

Do not program the ACM_EVTIME[n] register when an event is active. Program this register before setting a trigger and re-program the register after all events are complete (ACM_STAT.ECOM1 or ACM_STAT.ECOM0 bits are set). If no events are enabled in this register (for example, the ACM_EVCTL[n].ENAEV bits =0 and the ACM_STAT.ECOM0 or ACM_STAT.ECOM1 bits =1) and an interrupt generates (if unmasked), a trigger is applied with the Timer enabled.

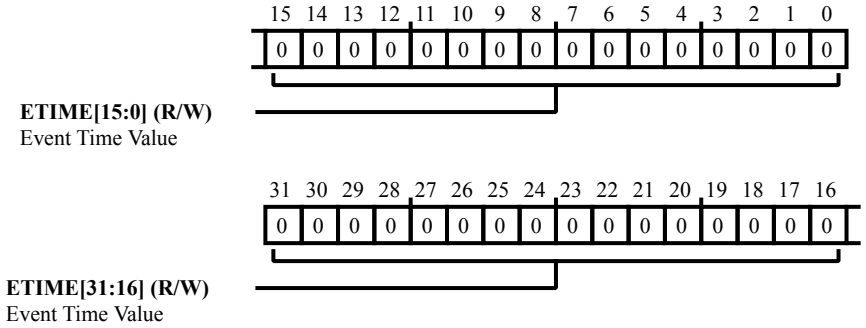

Figure 20-20: ACM_EVTIME[n] Register Diagram

Table 20-11: ACM_EVTIME[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ETIME	Event Time Value. The ACM_EVTIME[n].ETIME bit field contains a 32-bit event time value.

Missed Event Interrupt Mask Register

The ACM_MEVMSK register enables interrupts corresponding to status bits in the ACM_MEVSTAT register. When a bit is set in the ACM_MEVMSK register, an interrupt generates when the corresponding event missed bit in the ACM_MEVSTAT register is set.

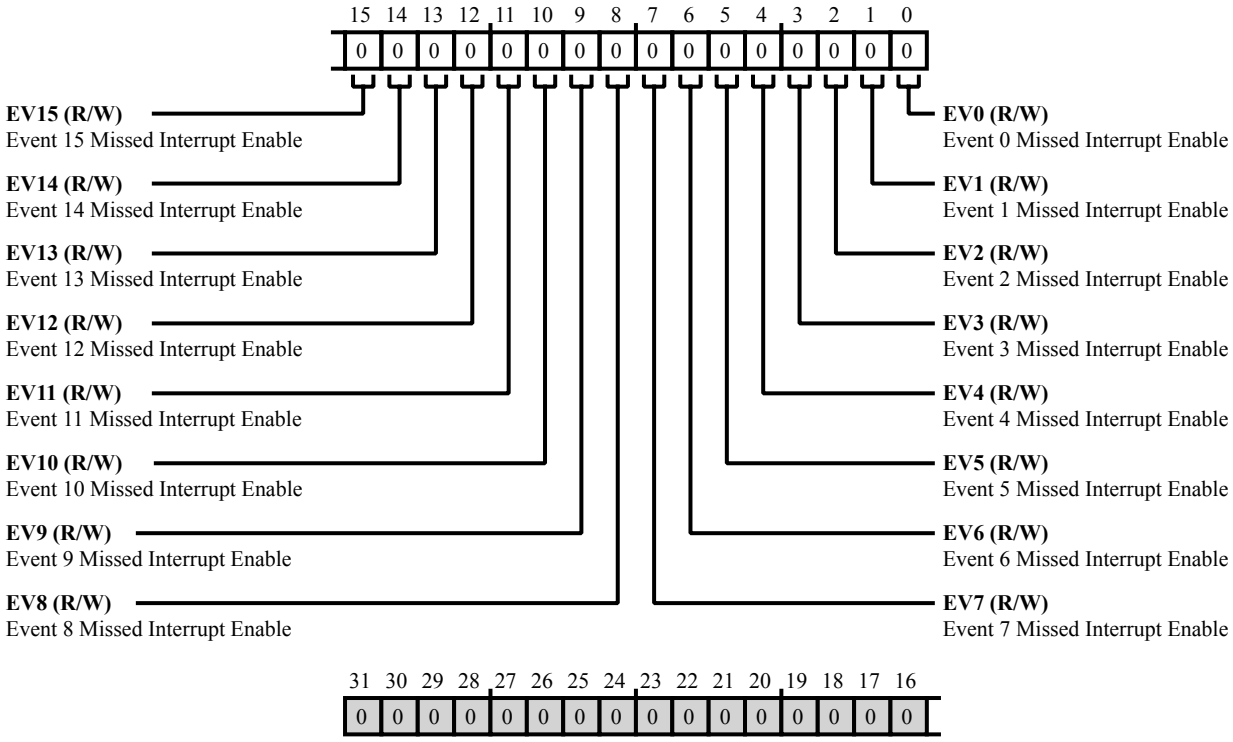

Figure 20-21: ACM_MEVMSK Register Diagram

		0	Disable (Mask) Interrupt
		1	Enable (Unmask) Interrupt

Missed Event Status Register

The ACM_MEVSTAT register indicates which enabled event is missed for a particular trigger cycle. When a ACM_MEVSTAT register bit is set (=1), this status indicates a miss of the corresponding event. This status generates an interrupt if the corresponding bit in the ACM_MEVMSK register is set.

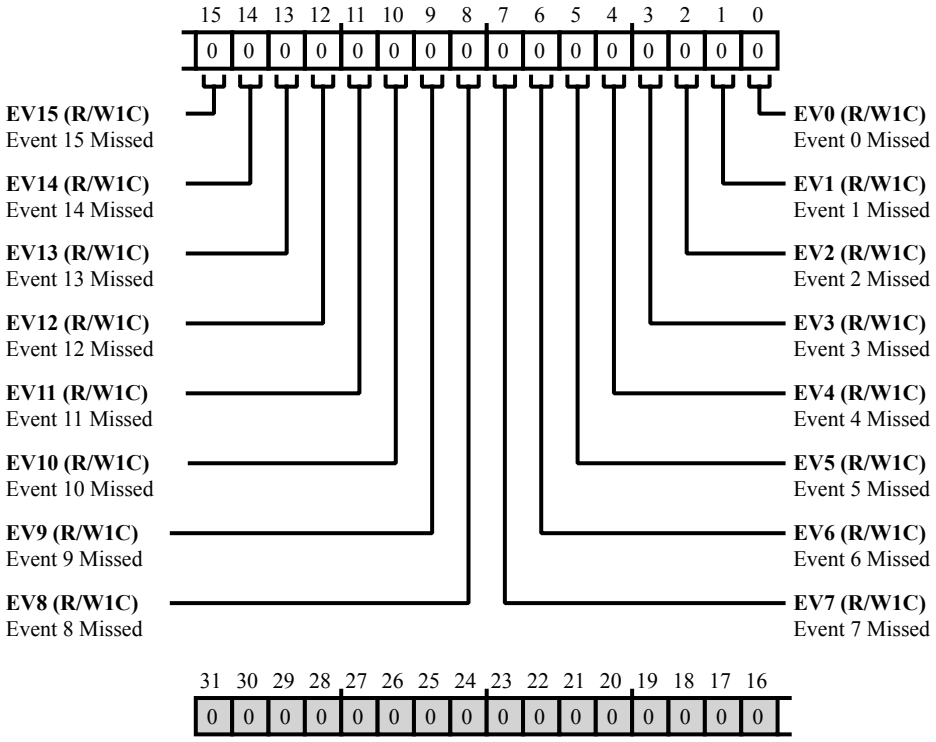

Figure 20-22: ACM_MEVSTAT Register Diagram

Table 20-13: ACM_MEVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	EV15	Event 15 Missed. The ACM_MEVSTAT.EV15 bit indicates a miss of event 15 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 15 Missed Status
		1	Event 15 Missed

Table 20-13: ACM_MEVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	EV14	Event 14 Missed. The ACM_MEVSTAT.EV14 bit indicates a miss of event 14 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 14 Missed Status
		1	Event 14 Missed
13 (R/W1C)	EV13	Event 13 Missed. The ACM_MEVSTAT.EV13 bit indicates a miss of event 13 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 13 Missed Status
		1	Event 13 Missed
12 (R/W1C)	EV12	Event 12 Missed. The ACM_MEVSTAT.EV12 bit indicates a miss of event 12 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 12 Missed Status
		1	Event 12 Missed
11 (R/W1C)	EV11	Event 11 Missed. The ACM_MEVSTAT.EV11 bit indicates a miss of event 11 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 11 Missed Status
		1	Event 11 Missed
10 (R/W1C)	EV10	Event 10 Missed. The ACM_MEVSTAT.EV10 bit indicates a miss of event 10 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 10 Missed Status
		1	Event 10 Missed

Table 20-13: ACM_MEVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	EV9	Event 9 Missed. The ACM_MEVSTAT.EV9 bit indicates when a miss of event 9 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 9 Missed Status
		1	Event 9 Missed
8 (R/W1C)	EV8	Event 8 Missed. The ACM_MEVSTAT.EV8 bit indicates a miss instance of event 8 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 8 Missed Status
		1	Event 8 Missed
7 (R/W1C)	EV7	Event 7 Missed. The ACM_MEVSTAT.EV7 bit indicates a miss of event 7 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 7 Missed Status
		1	Event 7 Missed
6 (R/W1C)	EV6	Event 6 Missed. The ACM_MEVSTAT.EV6 bit indicates a miss of event 6 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 6 Missed Status
		1	Event 6 Missed
5 (R/W1C)	EV5	Event 5 Missed. The ACM_MEVSTAT.EV5 bit indicates a miss of event 5 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 5 Missed Status
		1	Event 5 Missed

Table 20-13: ACM_MEVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	EV4	Event 4 Missed. The ACM_MEVSTAT.EV4 bit indicates a miss of event 4 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 4 Missed Status
		1	Event 4 Missed
3 (R/W1C)	EV3	Event 3 Missed. The ACM_MEVSTAT.EV3 bit indicates a miss of event 3 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 3 Missed Status
		1	Event 3 Missed
2 (R/W1C)	EV2	Event 2 Missed. The ACM_MEVSTAT.EV2 bit indicates a miss of event 2 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 2 Missed Status
		1	Event 2 Missed
1 (R/W1C)	EV1	Event 1 Missed. The ACM_MEVSTAT.EV1 bit indicates a miss of event 1 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 1 Missed Status
		1	Event 1 Missed
0 (R/W1C)	EV0	Event 0 Missed. The ACM_MEVSTAT.EV0 bit indicates a miss of event 0 since the last trigger. If set and the corresponding bit in ACM_MEVMSK is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 0 Missed Status
		1	Event 0 Missed

Status Register

The ACM_STAT register indicates the ACM event that is currently being serviced, pending events, missed events, and missed triggers.

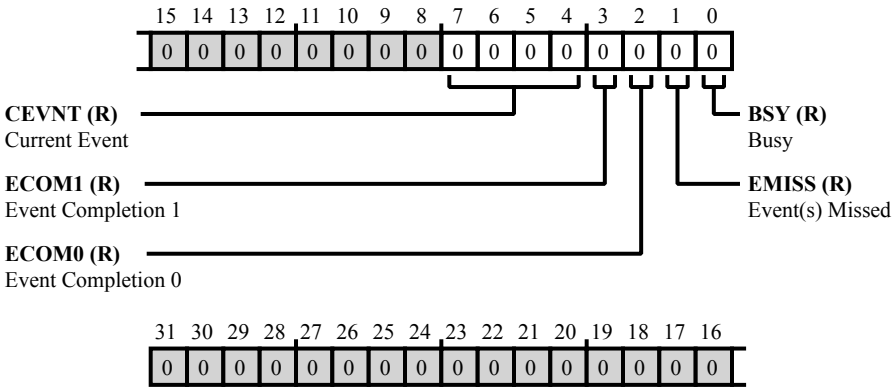

Figure 20-23: ACM_STAT Register Diagram

Table 20-14: ACM_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	CEVNT	Current Event. The ACM_STAT.CEVNT bits indicate to which event (0 through 15) the ongoing access (current event, if any) corresponds.	
		0	Current Event Correspond to Event 0
		1	Current Event Correspond to Event 1
		15	Current Event Correspond to Event 15
3 (R/NW)	ECOM1	Event Completion 1. The ACM_STAT.ECOM1 bit indicates TMR1 event completion for all enabled ACM TMR1 events and the current trigger. The ACM clears this bit with each trigger.	
		0	No Status
		1	ACM TMR1 Events Complete
2 (R/NW)	ECOM0	Event Completion 0. The ACM_STAT.ECOM0 bit indicates TMR0 event completion for all enabled ACM TMR0 events and the current trigger. The ACM clears this bit with each trigger.	
		0	No Status
		1	ACM TMR0 Events Complete

Table 20-14: ACM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	EMISS	Event(s) Missed. The ACM_STAT.EMISS bit indicates a missed event time (any bits in ACM_MEVSTAT set). This bit is cleared by writing into the ACM_MEVSTAT register.	
		0	No Missed Event(s)
		1	Missed Event(s)
0 (R/NW)	BSY	Busy. The ACM_STAT.BSY bit indicates when the ACM is busy (an external sampling event in progress; CS is active or about to go active).	
		0	Idle
		1	Busy

Timing Configuration 0 Register

The ACM_TC0 register determines the frequency of ACM_CLK (using the ACM_TC0.CKDIV field) and the setup cycles (using the ACM_TC0.SC field) for the ADC controls. Setup cycles are specified in terms of SCLK.

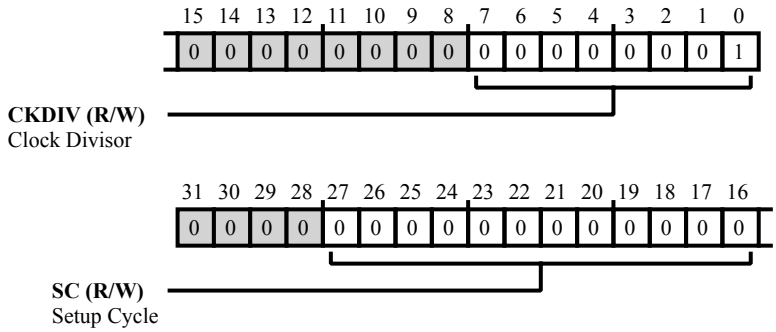

Figure 20-24: ACM_TC0 Register Diagram

Table 20-15: ACM_TC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27:16 (R/W)	SC	Setup Cycle. The ACM_TC0.SC bits select the ADC control pins and the setup time in SCLK cycles with respect to the ADC chip select active edge. The setup time may be calculated from: Setup Time = ACM_TC0.SC + 1. The maximum setup cycle time is 4096 * SCLK, and the minimum setup cycle time is 1 SCLK.	
		0	1 SCLK Cycle Setup Time
		1	2 SCLK Cycles Setup Time
		4095	4096 SCLK Cycles Setup Time
7:0 (R/W)	CKDIV	Clock Divisor. The ACM_TC0.CKDIV bits select the frequency of ACM_CLK as a function of the system clock frequency (SCLK) and the value of the CKDIV field according to the formula: ACM_CLK frequency = (SCLK frequency)/(ACM_TC0.CKDIV + 1) The maximum ACM_CLK frequency is SCLK/2, and the minimum ACM_CLK frequency is SCLK/256. For example, for a 100 MHz SCLK, the ACM_CLK frequency range is from 390 KHz to 50 MHz. The value ACM_TC0.CKDIV =0 is reserved.	

Timing Configuration 1 Register

The ACM_TC1 register provides programmability for the active duration of the following ADC controls: chip select (T_{CSW}), Hold Cycles (T_H), and Zero Cycles (T_Z).

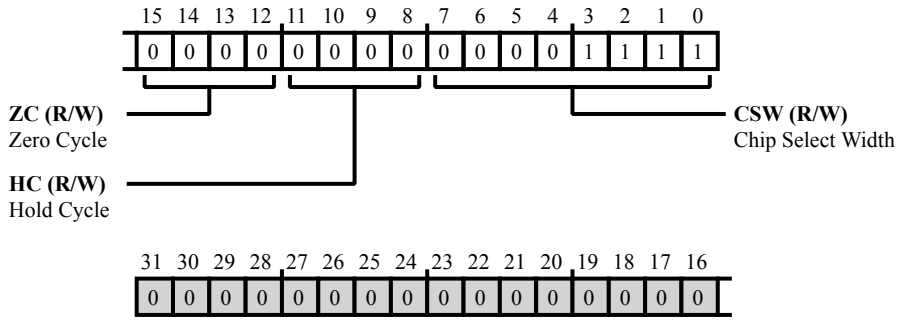

Figure 20-25: ACM_TC1 Register Diagram

Table 20-16: ACM_TC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	ZC	Zero Cycle. The ACM_TC1.ZC bits select the ADC control zero duration. All ADC controls drive low for ACM_TC1.ZC ACM_CLK cycles.	
		0	0 Zero Cycles
		1	1 Zero Cycle
		15	15 Zero Cycles
11:8 (R/W)	HC	Hold Cycle. The ACM_TC1.HC bits select the ADC control hold duration. All ADC controls are held after the inactive edge of CS for ACM_TC1.HC ACM_CLK cycles.	
		0	0 Hold Cycles
		1	1 Hold Cycle
		15	15 Hold Cycles
7:0 (R/W)	CSW	Chip Select Width. The ACM_TC1.CSW bits select the active duration of CS. The CS is active for ACM_TC1.CSW ACM_CLK +1 cycles.	
		0	1 Active CS Cycle
		1	2 Active CS Cycles
		15	16 Active CS Cycles
		255	256 Active CS Cycles

Timer 0 Register

The ACM_TMR0 register contains the active count value for ACM timer 0. Access this read-only value at any time.

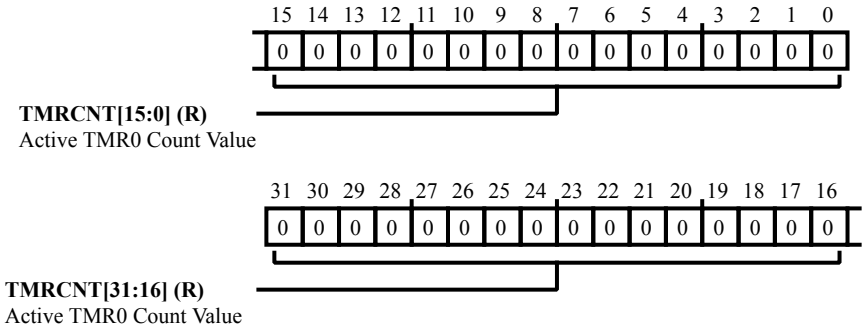

Figure 20-26: ACM_TMR0 Register Diagram

Table 20-17: ACM_TMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TMRCNT	Active TMR0 Count Value. The ACM_TMR0.TMRCNT bit field contains the active count value for ACM timer 0.

Timer 1 Register

The ACM_TMR1 register contains the active count value for ACM timer 1. Programs can access this read-only value at any time.

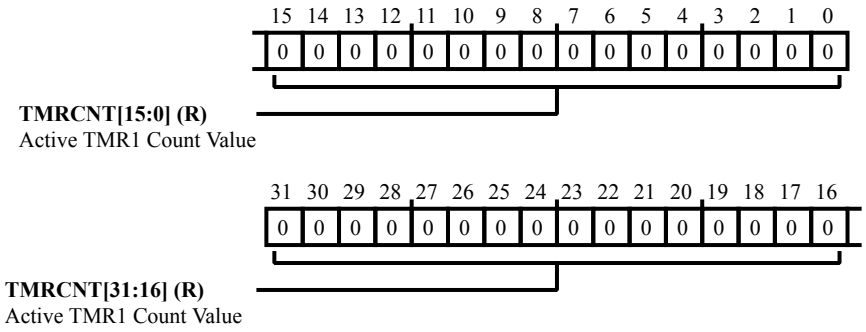

Figure 20-27: ACM_TMR1 Register Diagram

Table 20-18: ACM_TMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TMRCNT	Active TMR1 Count Value. The ACM_TMR1.TMRCNT bit field contains the active count value for ACM timer 1.

21 Controller Area Network (CAN)

The processor contains a Controller Area Network (CAN) module based on the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is compatible with the control applications. It can communicate reliably over a network and incorporates CRC checking, message error tracking, and fault node confinement.

NOTE: This document assumes familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN specification from Robert Bosch GmbH.

CAN Features

Key features of the CAN module include:

- Conformity to the CAN 2.0B (active) standard
- Dedicated acceptance mask for each mailbox
- Support for data rates of up to 1M bit/s
- Support for standard (11-bit) and extended (29-bit) identifiers
- 32 mailboxes (8 transmit, 8 receive, 16 configurable)
- Data filtering (first 2 bytes) for acceptance filtering (DeviceNet™ mode)
- Error status and warning registers
- Universal counter-module
- Readable receive and transmit pin values
- Support for remote frames
- Active or passive network support
- Interrupts, including transmit or receive complete, error, and global
- Clock derived from SCLK through a programmable divider, eliminating the need for an extra crystal

CAN Functional Description

The following sections provide information on the functional operation of the CAN module. This section also provides listings of the CAN registers and interrupts.

ADSP-SC57x CAN Register List

The controller area network (CAN) module implements the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. A set of registers govern CAN operations. For more information on CAN functionality, see the CAN register descriptions.

Table 21-1: ADSP-SC57x CAN Register List

Name	Description
CAN_AA1	Abort Acknowledge 1 Register
CAN_AA2	Abort Acknowledge 2 Register
CAN_AM[nn]H	Acceptance Mask (H) Register
CAN_AM[nn]L	Acceptance Mask (L) Register
CAN_CEC	Error Counter Register
CAN_CLK	Clock Register
CAN_CTL	CAN Master Control Register
CAN_DBG	Debug Register
CAN_ESR	Error Status Register
CAN_EWR	Error Counter Warning Level Register

External Interface

The interface to the CAN bus is a simple two-wire line. The ***Representation of CAN Transceiver Interconnection*** shows a symbolic representation of the CAN transceiver interconnection. Typically, the `CAN_TX` output and `CAN_RX` input pins of the processor connect to an external CAN `CAN_TX` and `CAN_RX` pins (respectively) of the tranceiver. The `CAN_TX` and `CAN_RX` pins operate with TTL levels and are appropriate for operation with CAN bus transceivers according to ISO/DIS 11898.

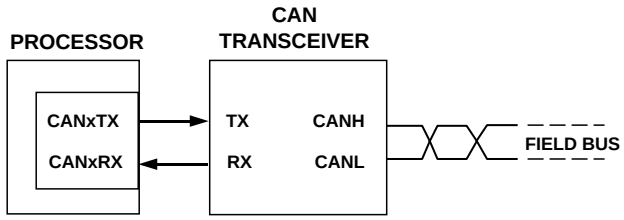

Figure 21-1: Representation of CAN Transceiver Interconnection

CAN data is either dominant (logic 0) or recessive (logic 1). The default state of the `CAN_TX` output is recessive.

Architectural Concepts

The full CAN controller features 32 message buffers called mailboxes. Eight mailboxes are dedicated for message transmission, eight are for reception, and 16 are programmable in direction.

The CAN module architecture is based around a 32-entry mailbox RAM. The CAN serial interface or the processor core accesses the mailbox sequentially. Each mailbox consists of eight 16-bit control and data registers and two optional 16-bit acceptance mask registers. Configure all of these registers before enabling the mailbox.

Since the mailbox area is implemented as RAM, the reset values of these registers are undefined. The ***CAN Mailbox Area*** figure shows the mailbox area. The data is divided into fields, which include a message identifier, a time stamp, a byte count, up to 8 bytes of data, and several control bits.

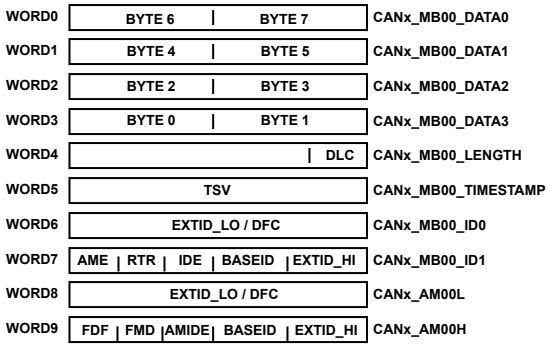

Figure 21-2: CAN Mailbox Area

The CAN mailbox identification register pair (CAN_MB[nn]_ID0/1) includes:

- The 29-bit identifier (base part CAN_AM[nn]H.BASEID plus the extended part CAN_AM[nn]L.EXTID/ CAN_AM[nn]H.EXTID)
- The acceptance mask enable bit (CAN_MB[nn]_ID1.AME)
- The remote transmission request bit (CAN_MB[nn]_ID1.RTR)
- The identifier extension bit (CAN_MB[nn]_ID1.IDE)

NOTE: Do not write to the identifier of a message object while the mailbox is enabled for the CAN module (the corresponding bit in CAN_MC1 is set).

The other mailbox area registers and bits are:

- The data length code bit (CAN_MB[nn]_LENGTH.DLC). The upper 12 bits of this register for each mailbox are marked as reserved. Always, set these 12 bits to zero.
- The mailbox word registers (CAN_MB[nn]_DATA0/1/2/3) supply up to 8 bytes for the data field. The data is sent MSB first based on the number of bytes defined in the CAN_MB[nn]_LENGTH.DLC bit. For example, if only one byte is transmitted or received (CAN_MB[nn]_LENGTH.DLC=1), then it is stored in the most significant byte of the CAN_MB[nn]_DATA3 register.
- The time stamp value bits (CAN_MB[nn]_TIMESTAMP.TSV)

The final registers in the mailbox area are the acceptance mask registers (CAN_AM[nn]H and CAN_AM[nn]L). The acceptance mask is enabled when the CAN_MB[nn]_ID1.AME bit is set.

Setting the CAN_CTL.DNM and CAN_AM[nn]H.FDF bits enables the *filtering on data field* option. When enabled, the CAN_MB[nn]_ID0.EXTID[15:0] bits are reused as acceptance code (DFC) for the data field filtering.

Block Diagram

The ***CAN Controller Block Diagram*** figure shows a block diagram of the CAN module.

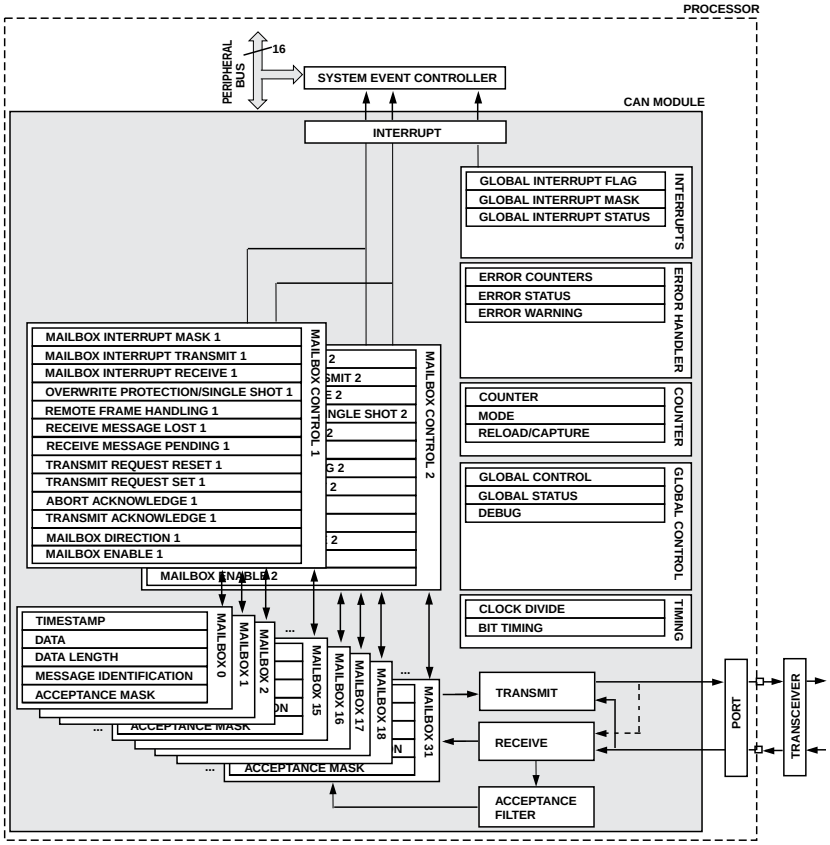

Figure 21-3: CAN Controller Block Diagram

Mailbox Control

Mailbox control memory-mapped registers (MMRs) function as control and status registers for the 32 mailboxes. Each bit in these registers represents one specific mailbox. Since CAN MMRs are all 16 bits wide, pairs of registers manage certain functionality for all 32 individual mailboxes. Mailboxes 0–15 are configured or monitored in registers with a suffix of 1. Similarly, mailboxes 16–31 use the same named register with a suffix of 2. For example, the CAN mailbox direction registers (`CAN_MD1` / `CAN_MD2`) control mailboxes. See the ***CAN Mailbox Register Pair*** figure. The ***CAN Register List*** table shows the mailbox control registers.

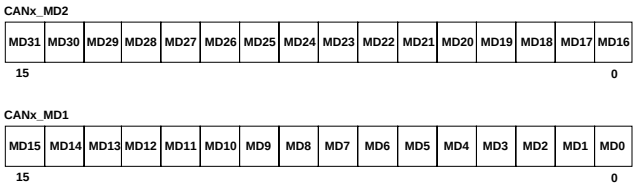

Figure 21-4: CAN Mailbox Register Pair

Mailboxes 24–31 support transmit operation only and mailboxes 0–7 are receive-only mailboxes. Therefore, the lower 8 bits in the 1 registers and the upper 8 bits in the 2 registers are sometimes reserved or are restricted in their use.

Protocol Fundamentals

Although the CAN_RX and CAN_TX pins are TTL-compliant signals, the CAN signals beyond the transceiver have asymmetric drivers. A low state on the CAN_TX pin activates strong drivers while a high state activates weak drivers. So, the active low state is the *dominant* state and the active high state is the *recessive* state. If the CAN module is passive, the CAN_TX pin is always high. If two CAN nodes transmit at the same time, dominant bits overwrite recessive bits.

The CAN protocol specifies that all nodes trying to send a message on the CAN bus attempt to send a frame once the bus is available. The ***Standard CAN Frame*** figure shows the frame. The Start of Frame (SOF) indicator signals the beginning of a new frame. Each CAN node then begins transmitting its message starting with the message ID.

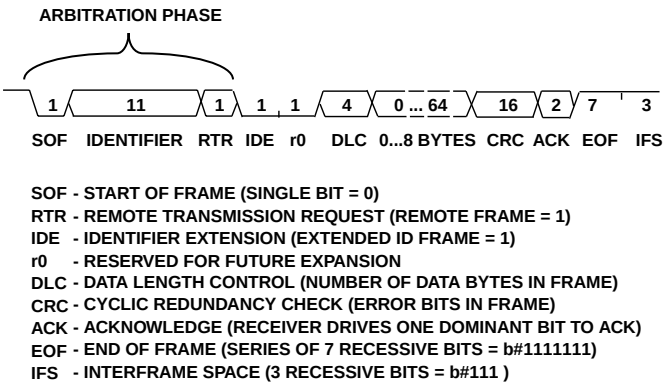

Figure 21-5: Standard CAN Frame

While transmitting, the CAN controller samples the CAN_RX pin to verify that the driven logic level is the value it placed on the CAN_TX pin. The names for the logic levels apply here. When a transmitting node places a recessive 1 on the CAN_TX pin and detects a dominant 0 on the CAN_RX pin, another node has placed a dominant bit on the bus. In this case, the dominant bit from from the other node has a higher priority.

Therefore, if the value sensed on the CAN_RX pin is the value driven on the CAN_TX pin, transmission continues. Otherwise, the CAN controller senses that it has lost arbitration. Module configuration determines the next course of action.

The ***Standard CAN Frame*** figure shows a basic 11-bit identifier frame. The CAN_MB[nn]_ID1.RTR bit follows the SOF and identifier. The CAN_MB[nn]_ID1.RTR bit indicates whether the frame contains data (data frame) or is a request for data associated with the message identifier in the frame sent (remote frame).

NOTE: In the CAN protocol, a dominant bit in the CAN_MB[nn]_ID1.RTR field wins arbitration against a remote frame request (CAN_MB[nn]_ID1.RTR=1) for the same message ID. This functionality allows a remote request to be a lower priority than a data frame.

The next field of interest in the frame is the CAN_MB[nn]_ID1.IDE bit. When set, it indicates that the message is an extended frame with a 29-bit identifier instead of an 11-bit identifier. In an extended frame, the first part of the message resembles the ***Extended CAN Frame*** figure.

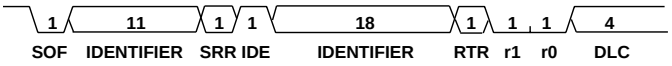

Figure 21-6: Extended CAN Frame

For the CAN_MB[nn]_ID1.RTR field, a dominant bit in the CAN_MB[nn]_ID1.IDE field wins arbitration against an extended frame with the same lower 11 bits. Standard frames have a higher priority than extended frames.

The internal logic automatically generates the Substitute Remote Request (SRR), the reserved bits r0 and r1, and the checksum (CRC). (The SRR is always sent as recessive; reserved bits r0 and r1 are always sent as dominant).

CAN Operating Modes

The CAN controller is in configuration mode when coming out of processor reset. Hardware behavior can be altered only when CAN is in configuration mode. Before initializing the mailboxes, configure the CAN bit timing to work on the CAN bus. The controller connect to the CAN bus.

Data Transfer Modes

The following sections provide information on the data transfer modes supported by the CAN controller.

Transmit Operations

The *CAN Transmit Operation Flowchart* shows the CAN transmit operation. Mailboxes 24–31 are dedicated transmitters. Configure mailboxes 8–23 as transmitters by writing 0 to the corresponding bit in the CAN_MD1 or CAN_MD2 registers. Enable mailbox n (CAN_MC1.MB=1). After writing the data and the identifier into the mailbox area, the message is sent. Then, the corresponding transmit request bit is set (CAN_TRS1.MB=1).

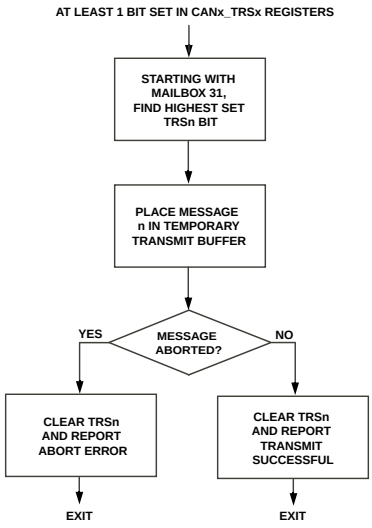

Figure 21-7: CAN Transmit Operation Flowchart

When a transmission completes, the corresponding bits in the CAN_TRS1 or CAN_TRS2 and CAN_TRR1 or CAN_TRR2 registers are cleared. If the transmission is successful, the corresponding bit in the CAN_TA1/CAN_TA2 register is set. If the transmission aborts due to lost arbitration or a CAN error, the corresponding bit in

the CAN_AA1/CAN_AA2 register is set. A requested transmission can also be manually aborted by setting the corresponding bit in the CAN_TRR1/CAN_TRR2 register.

Software sets multiple CAN_TRS1.MB bits simultaneously. These bits are reset after either a successful or an aborted transmission.

The CAN hardware sets these bits in the following cases:

- When using the auto-transmit mode of the universal counter
- When a message loses arbitration and the single-shot CAN_OPSS1.MB bit is not set
- When a remote frame request occurs (only possible for receive or transmit mailboxes if the feature for automatic remote frame handling is enabled (CAN_RFH1.MB=1)).

NOTE: Manage the mailbox area when a CAN_TRS1 or CAN_TRS2 bit is set. Write access to the mailbox is permissible with a bit set. But, changing data in such a mailbox can lead to unexpected data during transmission.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN_TRS1 or CAN_TRS2 bit associated with a disabled mailbox can result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN_TRS1 or CAN_TRS2 bit is reset by the internal logic can cause unpredictable results.

Retransmission

Normally, the current message object is resent after the loss of arbitration or error frame detection on the CAN bus line. If there is more than one transmit message object pending, the message object with the highest mailbox transmits first. See the ***Transmit Flow*** figure. The currently aborted transmission restarts after any messages with higher priority are sent.

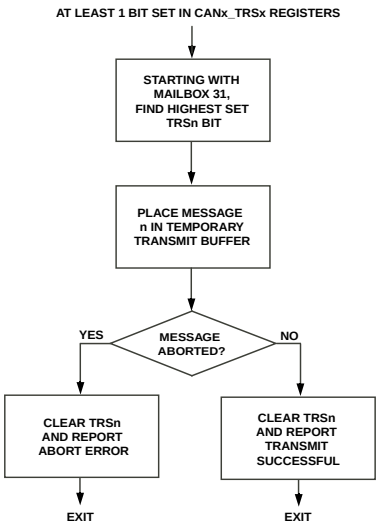

Figure 21-8: Transmit Flow

A message written into the mailbox does not replace a message under preparation. The message under preparation is copied into the temporary transmit buffer when the internal transmit request for the CAN core module is set. The message in the buffer is not replaced until:

- The message is sent successfully
- The arbitration on the CAN bus line is lost
- There is an error frame on the CAN bus line

Single-Shot Transmission

When using the single-shot transmission feature (CAN_OPSS1.MB=1), the corresponding CAN_TRS1 bit is cleared after the message is successfully sent. The bit is cleared even if the transmission aborts due to a lost arbitration or an error frame on the CAN bus line. Therefore, there is no further attempt to transmit the message again when the initial try failed, and the abort error is reported (CAN_AA1.MB=1).

Auto-Transmission

In auto-transmit mode, the message in mailbox 11 (MB11) can be sent periodically using the universal counter. This mode often broadcasts heartbeats to all CAN nodes. So, messages sent this way usually have a high priority.

The period value is written to the CAN_UCRC register. Auto-transmission mode is enabled by setting the CAN_UCCNF.UCCNF field to 0x03. When enabled, the counter CAN_UCCNT is loaded with the value in the CAN_UCRC register. The counter decrements to 0 at the CAN bit clock rate and is then reloaded from CAN_UCRC. Each time the counter reaches a value of 0, internal logic automatically sends the CAN_TRS1.MB bit. The corresponding message from mailbox 11 transfers.

For proper auto-transmit operation, configure mailbox 11 as a transmit mailbox. The mailbox must contain valid data (identifier, control bits, and data) before the counter expires and after this mode is enabled.

Receive Operation

The CAN hardware autonomously receives messages and discards invalid messages. Once a valid message is successfully received, the receive logic interrogates all enabled receive mailboxes. The logic interrogates sequentially, from mailbox 23 down to mailbox 0, whether the message is of interest to the local node or not.

Each incoming data frame is compared to all identifiers stored in the active receive and transmit mailboxes with the feature for remote frame handling enabled (=1). The active receive mailboxes indices of CAN_MD1 and CAN_MC1 registers are set to 1. The message identifier of the received message, along with the identifier extension (CAN_MB[nn]_ID1.IDE) and remote transmission request (CAN_MB[nn]_ID1.RTR) bits, are compared with the register settings of each mailbox. In standard mode, the message is compared with the content of the CAN_MB[nn]_ID1 register. In extended mode, the content of the CAN_MB[nn]_ID0 register must also match.

If the acceptance mask enable CAN_MB[nn]_ID1.AME bit is not set, a match is signaled only if CAN_MB[nn]_ID1.IDE, CAN_MB[nn]_ID1.RTR, and all (11 or 29) identifier bits are exact. If, however, the CAN_MB[nn]_ID1.AME bit is set, the acceptance mask registers (CAN_AM[nn]H/L) determine which of the CAN_MB[nn]_ID1.IDE and CAN_MB[nn]_ID1.RTR bits must match.

The following logic applies:

[(Received Message ID) XNOR (CAN_MB[nn]_ID0/1)] OR [(CAN_MB[nn]_ID1.AME) AND (CAN_AM[nn]H /L)].

This logic appears graphically in the ***CAN Message Receive Logic*** figure.

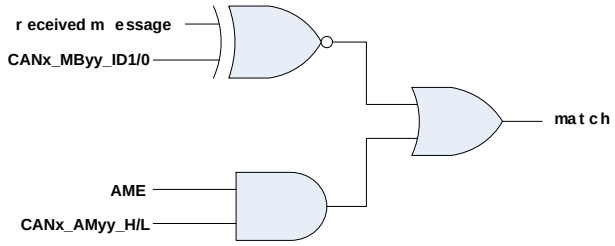

Figure 21-9: CAN Message Receive Logic

A one (1) at the respective bit position in the CAN_AM[nn]H/CAN_AM[nn]L mask registers means that the bit does not need to match when CAN_MB[nn]_ID1.AME=1. This way, a mailbox can accept a group of messages.

Table 21-3: Mailbox Used for Acceptance Filtering

MCn	MDn	RFHn	Mailbox n	Comment
0	X	X	Ignored	Mailbox n disabled
1	0	0	Ignored	Mailbox n enabled; Mailbox n configured for transmit; Remote frame handling disabled
1	0	1	Used	Mailbox n enabled; Mailbox n configured for transmit; Remote frame handling enabled
1	1	X	Used	Mailbox n enabled; Mailbox n configured for receive

If the acceptance filter finds a matching identifier, the content of the received data frame is stored in that mailbox. A received message is stored only once, even if multiple receive mailboxes match its identifier. If the current identifier does not match any mailbox, the message is not stored.

The ***CAN Receive Operation Flowchart*** illustrates the decision tree of the receive logic when processing the individual mailboxes.

If a message is received for a mailbox and that mailbox still contains unread data (CAN_RMP1.MB), then the program decides whether to overwrite the old message. If the CAN_OPSS1.MB bit is cleared, the corresponding CAN_RML1.MB bit is set, and the stored message is overwritten. The receive message lost interrupt request occurs (CAN_GIS.RMLIS is set). If, however, the CAN_OPSS1.MB bit is set, the next mailboxes are checked for another matching identifier. If no match is found, the message is discarded, and the next message is checked.

NOTE: If a receive mailbox is disabled, an ongoing receive message for that mailbox is lost even if a second mailbox is configured to receive the same identifier.

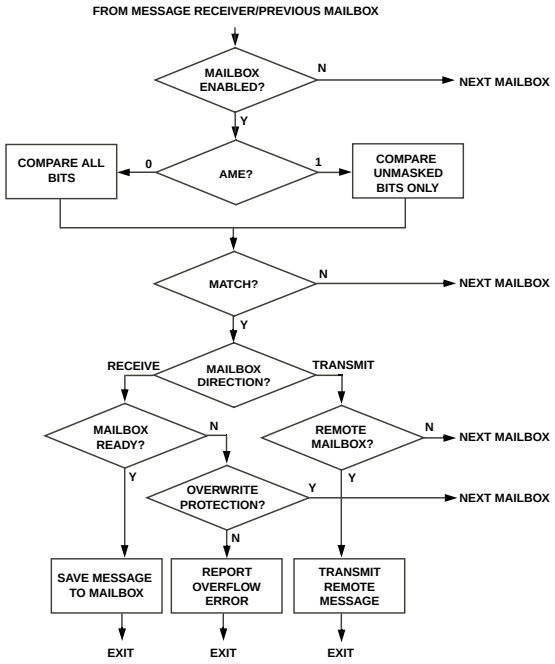

Figure 21-10: CAN Receive Operation Flowchart

Data Acceptance Filtering

If Device Net mode is enabled (`CAN_CTL.DNM` = 1) and the mailbox is set up for filtering on data field, the filtering occurs on the standard ID of the message and data fields. The data field filtering can be programmed for either the first byte only or the first 2 bytes, as shown the ***Data Field Filtering*** table.

If the `CAN_AM[nn]H.FDF` bit is set, the corresponding `CAN_AM[nn]L` register holds the data field mask (DFM bits 15:0]). If the `CAN_AM[nn]H.FDF` bit is cleared, the corresponding `CAN_AM[nn]L` register holds the extended identifier mask (`CAN_AM[nn]H.EXTID` bits 15:0).

Table 21-4: Data Field Filtering

FDF (Filter on Data Field)	FMD (Full Mask Data Field)	Description
0	0	Do not allow filtering on the data field
0	1	Not allowed. FMF must be 0 when FDF is 0
1	0	Filter on first data byte only
1	1	Filter on first two data bytes

Watchdog Mode

Watchdog mode ensures that messages are received periodically. It also observes whether a certain node on the network is alive and functioning properly. Watchdog mode detects and manages the failure cases, as needed.

Enable this mode by programming the universal counter to watchdog mode by setting the `CAN_UCCNF.UCCNF` to 0x2. Once enabled, the `CAN_UCCNT` register is loaded with the predefined value contained in `CAN_UCRC`. This counter decrements at the CAN bit rate.

If the CAN_UCCNF.UCCT and CAN_UCCNF.UCRC bits are set and a message is received in mailbox 4 before the counter counts down to 0, the counter is reloaded with the CAN_UCRC contents. If the counter has counted down to 0 without receiving a message in mailbox 4, then the CAN_GIS.UCEIS bit is set. The counter reloads automatically with the contents of the CAN_UCRC register. If an interrupt request is desired for this event, set the CAN_GIM.UCEIM bit. With the mask bit set, when a watchdog interrupt request occurs, the CAN_GIF.UCEIF bit is also set.

Write to the CAN_UCCNF register to reload the counter with the contents of CAN_UCRC or to disable the register.

The CAN_UCRC register controls the time period it takes for the watchdog interrupt request to occur.

Time Stamps

To get an indication of the time of the receive or transmit time for each message, program the CAN universal counter to time stamp mode. Enable this mode by setting the CAN_UCCNF.UCCNF field to 0x01.

If enabled, the value of the 16-bit free-running counter (CAN_UCCNT) is written into the CAN_MB[nn]_TIMESTAMP register of the corresponding mailbox. The operation occurs when a received message is stored or a message is transmitted.

The time stamp value is captured at the sample point of the Start of Frame (SOF) bit of each incoming or outgoing message. Afterwards, this time stamp value is copied to the CAN_MB[nn]_TIMESTAMP register of the corresponding mailbox.

If the mailbox is configured for automatic remote frame handling (CAN_RFH1.MB = 1), the time stamp value is written for transmission of a data frame or the reception of the requested data frame. The mailbox is configured for transmit or receive.

Clear the counter by setting the CAN_UCCNF.UCRC bit to 1. Or, disable the counter by clearing the CAN_UCCNF.UCE bit. Write to the CAN_UCCNT register to load the counter with a value.

It is also possible to clear the counter (CAN_UCCNT) by the reception of a message in mailbox number 4 (synchronization of all time stamp counters in the system). This operation is accomplished by setting the CAN_UCCNF.UCCT bit.

The CAN_GIS.UCEIS bit is set when the counter overflows. A global CAN interrupt request can optionally occur by unmasking the CAN_GIM.UCEIM bit. If the interrupt source is unmasked, the CAN_GIF.UCEIF bit is also set.

Remote Frame Handling

Automatic handling of remote frames for a transmit mailbox is enabled by setting the corresponding CAN_RFH1.MB bit.

Remote frames are data frames that have no data field and the CAN_MB[nn]_ID1.RTR bit is set. The data length code (DLC) of the requesting remote frame overrules the DLC of the responding data frame. A DLC can be programmed with values in the range of 0–15, but DLC values greater than 8 are considered as 8.

A remote frame contains:

- The identifier bits
- The control field CAN_MB[nn]_LENGTH.DLC (data length count)
- The remote transmission request (CAN_MB[nn]_ID1.RTR) bit

Only configurable mailboxes MB8–MB23 can process remote frames, but all mailboxes can receive and transmit remote frame requests. The CAN_OPSS1 register has no effect when configured for automatic remote frame handling. All content of a mailbox is always overwritten by an incoming message.

NOTE: If a remote frame is received, the DLC of the corresponding mailbox is overwritten with the received value.

Erroneous behavior can result when the CAN_RFH1.MB bit is changed while the corresponding mailbox is processing. To avoid the risk of inconsistent messages, programs must temporarily disable the mailbox while its data registers are updating.

Temporarily Disabling CAN Mailbox

If a mailbox is enabled and configured to transmit, monitor the write accesses to the data field to avoid transmitting inconsistent messages. Be careful if the mailbox is transmitting (or attempting to transmit) repeatedly. Also, if this mailbox is used for automatic remote frame handling, the data field must be updated without losing an incoming remote request frame and without sending inconsistent data. Therefore, the CAN controller allows for temporarily disabling the mailbox using the mailbox temporary disable register (CAN_MBTD).

The pointer to the requested mailbox to the CAN_MBTD.TDPTR field is written, and the CAN_MBTD.TDR bit is set. Internal logic then sets the corresponding CAN_MBTD.TDA flag.

If a mailbox is configured as transmit (CAN_MD1 = 0) and the CAN_MBTD.TDA bit is set, the content of the data field of that mailbox can be updated. If there is an incoming remote request frame while the mailbox is temporarily disabled,

- Internal logic sets the corresponding transmit request bit (CAN_TRS1.MB), and
- The data length code (DLC) of the incoming message is written to the corresponding mailbox.

However, the requested message is not sent until the CAN_MBTD.TDR bit is cleared. Similarly, all transmit requests for temporarily disabled mailboxes are ignored until the CAN_MBTD.TDR bit is cleared. Additionally, transmission of a message immediately aborts when the mailbox is temporarily disabled and the corresponding transmission request reset (CAN_TRR1.MB) bit for this mailbox is set.

If a mailbox is configured to receive (CAN_MD1 = 1), then after issuing a temporary disable request, the CAN_MBTD.TDA flag is set. The mailbox is not processed. If there is an incoming message for a temporarily disabled mailbox, the internal logic waits until reception is complete or there is an error on the CAN bus before setting CAN_MBTD.TDA. Once this flag is set, the mailbox can then be disabled (CAN_MC1 = 0) without the risk of losing an incoming frame. The CAN_MBTD.TDR bit must then be reset as soon as possible.

When the CAN_MBTD.TDA flag is set for a given mailbox, only the data field of that mailbox can be updated. Accesses to the control bits and the identifier are denied.

Bit Timing

The CAN controller does not have a dedicated clock. Instead, the CAN clock is derived from the system clock based on a configurable number of time quanta. The time quantum (TQ) is derived from the formula:

TQ = (BRP + 1)/SCLK

where BRP is the 10-bit bit rate prescaler field in the CAN_CLK register.

Although the CAN_CLK.BRP field can be set to any value, it is recommended that the value be greater than or equal to 4. Restrictions apply to the bit timing configuration when BRP is less than 4.

The CAN_CLK register defines the TQ value, and multiple time quanta make up the duration of a CAN bit on the bus. The CAN_TIMING register controls the nominal bit time and the sample point of the individual bits in the CAN protocol. The ***Three Phases of a CAN Bit*** figure shows the three phases of a CAN bit: the synchronization segment, the segment before the sample point, and the segment after the sample point.

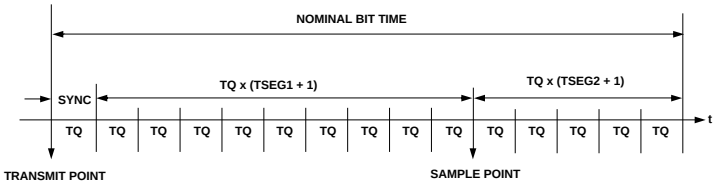

Figure 21-11: Three Phases of a CAN Bit

The synchronization segment is fixed to one TQ. Synchronize the nodes on the bus. All signal edges are expected to occur within this segment.

The CAN_TIMING.TSEG1 and CAN_TIMING.TSEG2 fields control how many TQs the CAN bits consist of, resulting in the CAN bit rate. The following formula gives the nominal bit time.

t_{BIT} = TQ × [1 + (1 + TSEG1) + (1 + TSEG2)]

For safe receive operations on given physical networks, the sample point is programmable by the CAN_TIMING.TSEG1 field. The CAN_TIMING.TSEG2 field holds the number of TQs to complete the bit time. Often, best sample reliability is achieved with sample points in the high 80% range of the bit time. Never use sample points lower than 50%. Therefore, CAN_TIMING.TSEG1 must always be greater than or equal to CAN_TIMING.TSEG2.

The CAN module does not distinguish between the propagation segment and the phase segment-1 as defined by the standard. The CAN_TIMING.TSEG1 value is intended to cover both of them. The CAN_TIMING.TSEG2 value represents the phase segment-2.

If the CAN module detects a recessive-to-dominant edge outside the synchronization segment, it can automatically move the sampling point such that the CAN bit is still handled properly. The synchronization jump width (CAN_TIMING.SJW) field specifies the maximum number of TQs, ranging from 1 to 4 (SJW + 1), allowed for such a resynchronization attempt. The SJW value must not exceed CAN_TIMING.TSEG2 or CAN_TIMING.TSEG1. Therefore, the fundamental rule for writing CAN_TIMING is:

SJW ≤ TSEG2 ≤ TSEG1

In addition to this fundamental rule, CAN_TIMING.TSEG2 must also be greater than or equal to the information processing time (IPT). IPT is the time required by the logic to sample the CAN_RX input, which is 3 system clock cycles.

Therefore, restrictions apply to the minimal value of CAN_TIMING.TSEG2 if CAN_CLK.BRP is less than 2. If CAN_CLK.BRP is set to 0, the CAN_TIMING.TSEG2 field must be greater than or equal to 2. If CAN_CLK.BRP is set to 1, the minimum CAN_TIMING.TSEG2 value is 1.

NOTE: Use the same nominal bit rate for all nodes on a CAN bus.

With all the timing parameters set, the final consideration is sampling performance. The default behavior of the CAN controller is to sample the CAN bit once. The controller samples at the point described by the CAN_TIMING register and controlled by the CAN_TIMING.SAM bit. If this bit is set, however, the input signal is oversampled three times at the system clock rate. The resulting value is generated by a majority decision of the three sample values. Always keep the CAN_TIMING.SAM bit cleared if the BRP value is less than 4.

Do not modify the CAN_CLK and CAN_TIMING registers during normal operation. Always enter configuration mode first. Writes to these registers have no effect when CAN is not in configuration or debug mode. If not coming out of processor reset, enter configuration mode by setting the CAN_CTL.CCR bit and poll the CAN_STAT register until CAN_STAT.CCA is set.

NOTE: If the CAN_TIMING.TSEG1 field is programmed to 0, the module does not leave the configuration mode.

During configuration mode, the module is not active on the CAN bus line. The CAN_TX output pin remains recessive and the module does not receive or transmit messages or error frames. After leaving the configuration mode, all CAN internal core registers and the CAN error counters are set to their initial values.

A soft reset does not change the values of CAN_CLK and CAN_TIMING. Therefore, an ongoing transfer through the CAN bus cannot be corrupted by changing the bit timing parameter or initiating the soft reset (by setting the CAN_CTL.SRS bit).

CAN Low Power Features

The CAN module includes built-in sleep and suspend modes to save power.

The following sections describe the behavior of the CAN module in these modes.

Built-In Suspend Mode

The most modest of power savings mode is the suspend mode. This mode is entered by setting the CAN_CTL.CSR bit. The module enters the suspend mode after the current operation of the CAN bus finishes. Then, the internal logic sets the CAN_STAT.CSA bit. Once CAN enters this mode, the module is no longer active on the CAN bus line, slightly reducing power consumption.

In suspend mode, the CAN_TX output pin remains in a recessive state, and the module does not receive or transmit messages or error frames. The content of the CAN_CEC register remains unchanged. Clear CAN_CTL.CSR to exit suspend mode.

The only difference between suspend mode and configuration mode is that the CAN_CTL and CAN_STAT registers are not reset when exiting suspend mode.

Built-In Sleep Mode

The next level of power savings can be realized by using the built-in sleep mode for the module. This mode is entered by setting the CAN_CTL.SMR bit. The module enters the sleep mode after the current operation of the CAN bus finishes. Once this mode is entered, many of the internal CAN module clocks are shut off, reducing power consumption, and the CAN_INT.SMACK bit is set.

When the CAN module is in sleep mode, all register reads return the contents of CAN_INT instead of the usual contents. All register writes, except to CAN_INT, are ignored in sleep mode. A small part of the module is clocked continuously to allow for waking up out of sleep mode.

A write to the CAN_INT register ends sleep mode. If the CAN_CTL.WBA bit is set before entering sleep mode, a dominant bit on the CAN_RX pin also ends sleep mode. When software sets the CAN_CTL.SMR bit, hardware sets the CAN_CTL.CSR bit as well, making sleep mode a super set of suspend mode. When the controller wakes up from sleep mode, hardware automatically clears CAN_CTL.SMR and CAN_CTL.CSR. If, however, the controller never enters sleep mode because the wake-up condition was met before CAN_INT.SMACK bit turns to 1, the CAN_CTL.SMR and CAN_CTL.CSR bits do not always automatically clear. Therefore, clear the two bits using software, when returning from sleep mode.

Soft Reset

The CAN controller features a build-in reset mechanism called soft reset. Soft reset is entered immediately after software has set the CAN_CTL.SRS bit. Soft reset brings all control registers to a defined state. Mailbox and error registers remain unaffected. Soft reset does not alter the CAN_TIMING and CAN_CLK registers and does not disturb the on-going transmission of a currently pending message, acknowledge bit or error frame. However, when recovering from soft reset, software can lose track of transmission or reception reports and interrupt requests.

CAN Event Control

The following section describe how the CAN module generates and controls events.

CAN Interrupt Signals

The CAN module provides three independent interrupt requests: two mailbox interrupt requests (mailbox receive interrupt request (MBRIRQ) and mailbox transmit interrupt request (MBTIRQ)) and a global CAN status interrupt request (GIRQ). The values of these three interrupt requests can also be read through the CAN_GIS register.

Mailbox Interrupts

Each of the 32 mailboxes in the CAN module can generate a receive or transmit interrupt request, depending on the mailbox configuration. To enable a mailbox to generate an interrupt request, set the corresponding CAN_MBIM1 bit.

If a mailbox is configured as a receive mailbox, the corresponding CAN_MBRIF1 bit and CAN_RMP1 bit are set after a received message is stored in mailbox n. When using the feature for automatic remote frame handling (CAN_RFH1=1), the receive interrupt flag is set after the requested data frame is stored in the mailbox.

If any CAN_MBRIF1 bits are set, the mailbox generates a CAN_INT.MBRIRQ interrupt request. To clear the CAN_INT.MBRIRQ interrupt request, software must clear all of the set CAN_MBRIF1 bits by writing a 1 to those bit locations in CAN_MBRIF1. Prior to this operation, software must clear the corresponding CAN_RMP1 bit.

If a mailbox is configured as a transmit mailbox, the corresponding CAN_MBTIF1 bit in the transmit interrupt flag is set after the message in mailbox n is sent correctly. The corresponding CAN_TA1 bit is also set. The CAN_TA1 bits maintain their state even after the corresponding mailbox n is disabled (CAN_MC1=0). When using the feature for automatic remote frame handling, the transmit interrupt flag is set after the requested data frame is sent from the mailbox.

If any CAN_MBTIF1.MB bits are set, the MBTIRQ interrupt output is raised in the CAN_INT register. To clear the MBTIRQ interrupt request, software must clear all of the bits that are set in the CAN_MBTIF1 register by writing a 1 to those bit locations. Additionally, software must clear the associated CAN_TA1 bit or set the associated CAN_TRS1 bit to clear the interrupt source that asserts the CAN_MBTIF1 bit.

Global Interrupt

The global CAN interrupt logic implements with three registers:

- The CAN_GIM register, where each interrupt source can be enabled or disabled separately
- The CAN_GIS register
- The CAN_GIF register

The interrupt mask bits only affect the content of the CAN_GIF register. If the mask bit is not set in the CAN_GIM register, the corresponding flag bit is not set when the event occurs. The interrupt status bits in the CAN_GIS register, however, are always set when the corresponding interrupt event occurs, independent of the mask bits. Thus, the interrupt status bits can be used to poll interrupt events.

The CAN_INT.GIRQ bit is only asserted if a bit in the CAN_GIF register is set. The read-only CAN_INT.GIRQ bit remains set as long as at least 1 bit in CAN_GIF is set. All bits in the interrupt status and interrupt flag registers remain set until cleared by software or a soft reset has occurred.

NOTE: The CAN_GIF register is read-only (RO). In the global CAN interrupt ISR, clear the interrupt latch by writing a 1 to the corresponding bit of the CAN_GIS register. The operations clear the related bits of the CAN_GIS and CAN_GIF registers, as well as the CAN_INT.GIRQ bit.

There are several interrupt events that can activate this GIRQ interrupt request:

- Access denied event interrupt (CAN_GIM.ADIM, CAN_GIS.ADIS, CAN_GIF.ADIF): At least one access to the mailbox RAM occurred during a data update by internal logic.

- Universal counter exceeded event interrupt (CAN_GIM.UCEIM, CAN_GIS.UCEIS, CAN_GIF.UCEIF): There is an overflow of the universal counter (in time stamp mode or event counter mode) or the counter has reached the value 0x0000 (in watchdog mode).
- Receive message lost event interrupt (CAN_GIM.RMLIM, CAN_GIS.RMLIS, CAN_GIF.RMLIF): A message is received for a mailbox that currently contains unread data. At least 1 bit in the CAN_RMLn register is set. If the bit in CAN_GIS and CAN_GIF registers is cleared and there is at least 1 bit in CAN_RML1 still set, then the bit in the CAN_GIS and CAN_GIF registers is not set again. The internal interrupt source signal is only active if a new bit in CAN_RML1 is set.
- Abort acknowledge event interrupt (CAN_GIM.AAIM, CAN_GIS.AAIS, CAN_GIF.AAIF): At least 1 CAN_AA1.MB bit in the CAN_AA1 registers is set. If the bit in the CAN_GIS and CAN_GIF registers is cleared and there is at least 1 bit in CAN_AA1 still set, then the bit in the CAN_GIS and CAN_GIF registers is not set again. The internal interrupt source signal is only active if a new bit in CAN_AA1 is set. The CAN_AA1.MB bits maintain state even after the corresponding mailbox n is disabled (CAN_MC1 = 0).
- Access to unimplemented address event interrupt (CAN_GIM.UIAIM, CAN_GIS.UIAIS, CAN_GIF.UIAIF): There was a CPU access to an address which is not implemented in the controller module.
- Wake-up event interrupt (CAN_GIM.WUIM, CAN_GIS.WUIS, CAN_GIF.WUIF): The CAN module has left the sleep mode because of detected activity on the CAN bus line.
- Bus-off event interrupt (CAN_GIM.BOIM, CAN_GIS.BOIS, CAN_GIF.BOIF): The CAN module has entered the bus-off state. This interrupt source is active if the status of the CAN core changes from normal operation mode to the bus-off mode. If the bit in the CAN_GIS and CAN_GIF registers is cleared and the bus-off mode is still active, then this bit is not set again. If the module leaves the bus-off mode, the bit in the CAN_GIS and CAN_GIF registers remains set, if not explicitly cleared.
- Error-passive event interrupt (CAN_GIM.EPIM, CAN_GIS.EPIS, CAN_GIF.EPIF): The CAN module has entered the error-passive state. This interrupt source is active if the status of the CAN module changes from the error-active mode to the error-passive mode. If the bit in the CAN_GIS and CAN_GIF registers is cleared and the error-passive mode is still active, then this bit is not set again. If the module leaves the error-passive mode, the bit in the CAN_GIS and CAN_GIF registers remains set, if not explicitly cleared.
- Error warning receive event interrupt (CAN_GIM.EWRIM, CAN_GIS.EWRIS, CAN_GIF.EWRIF): The CAN receive error counter (CAN_CEC.RXECNT) has reached the warning limit. If the bit in the CAN_GIS and CAN_GIF registers) is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in the CAN_GIS and CAN_GIF registers remains set, if not explicitly cleared.
- Error warning transmit interrupt (CAN_GIM.EWTIM, CAN_GIS.EWTIS, CAN_GIF.EWTIF): The CAN transmit error counter (CAN_CEC.TXECNT) has reached the warning limit. If the bit in the CAN_GIS and CAN_GIF registers is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in the CAN_GIS and CAN_GIF registers remains set, if not explicitly cleared.

Event Counter

For diagnostic functions, it is possible to use the universal counter as an event counter. The counter can be programmed in the CAN_UCCNF[3:0] field to increment on one of these conditions:

- 0x6 – CAN error frame. Counter increments if there is an error frame on the CAN bus line.
- 0x7 – CAN overload frame. Counter increments if there is an overload frame on the CAN bus line.
- 0x8 – Lost arbitration. Counter increments every time arbitration on the CAN line is lost during transmission.
- 0x9 – Transmission aborted. Counter increments every time arbitration is lost or a transmit request is canceled (CAN_AA1 is set).
- 0xA – Transmission succeeded. Counter increments every time a message sends without detected errors (CAN_TA1 is set).
- 0xB – Receive message rejected. Counter increments every time a message is received without detected errors but not stored in a mailbox because there is no matching identifier found.
- 0xC – Receive message lost. Counter increments every time a message is received without detected errors but not stored in a mailbox because the mailbox contains unread data (CAN_RML1 is set).
- 0xD – Message received. Counter increments every time a message is received without detected errors, whether the received message is rejected or stored in a mailbox.
- 0xE – Message stored. Counter increments every time a message is received without detected errors, has an identifier that matches an enabled receive mailbox, and is stored in the receive mailbox (CAN_RMP1 is set).
- 0xF – Valid message. Counter increments every time a valid transmit or receive message is detected on the CAN bus line.

CAN Warnings and Errors

The processor controls CAN warnings and errors using the error counter (CAN_CEC) register, the error status (CAN_ESR) register, and the error counter warning level (CAN_EWR) register. The following sections describe error handling.

Programmable Warning Limits

Programs can set the warning level for CAN_GIS.EWTIS and CAN_GIS.EWRIS separately by writing to the CAN_EWR.EWLREC and CAN_EWR.EWLTEC fields. After power-on reset, the CAN_EWR register is set to the default warning level of 96 for both error counters. After a soft reset, the contents of this register remain unchanged.

Error Handling

Error management is a part of the CAN standard. Several different kinds of bus errors can occur during transmissions:

- Bit error – Only the transmitting node detects this error. Whenever a node transmits, it continuously monitors its receive pin (CAN_RX) and compares the received bit with the transmitted bit. During the arbitration phase,

the node postpones the transmission if the received and transmitted bits do not match. However, after the arbitration phase, a bit error is signaled any time the value on CAN_RX does not equal what is transmitted on the CAN_TX pin. (The arbitration phase completes when the CAN_MB[nn]_ID1.RTR bit is sent successfully.)

- Form error. Occurs when a fixed-form bit position in the CAN frame contains one or more illegal bits. Occurs when a dominant bit is detected at a delimiter or end of frame bit position.
- Acknowledge error. Occurs whenever a message is sent and no receivers drive an acknowledge bit.
- CRC error. Occurs whenever a receiver calculates the CRC on the data it received and finds it different than the CRC that transmitted on the bus itself.
- Stuff error. The CAN specification requires the transmitter to insert an extra stuff bit of opposite value after 5 bits have transmitted with the same value. The receiver disregards the value of the stuff bits. However, it takes advantage of the signal edge to resynchronize itself. A stuff error occurs on receiving nodes whenever the sixth consecutive bit value is the same as the previous 5 bits.

Once the CAN module detects any of the errors, it updates the CAN_ESR and CAN_CEC registers. In addition to the standard errors, the CAN_ESR.SAO flag signals when the CAN_RX pin sticks at dominant level, indicating a possibility of shorted wires.

Error Frames

It is important that all nodes on the CAN bus ignore data frames that any single node failed to receive. Every node sends an error frame as soon as it has detected an error as shown in the ***CAN Error Example*** figure.

A device that has detected an error still completes the ongoing bit. It initiates an error frame by sending six dominant and eight recessive bits to the bus. Since this activity is a violation of the bit stuffing rule, all nodes are signaled to discard the ongoing frame. (All receivers that did not detect the transmission error in the first instance now detect a stuff bit error.)

The transmitter can detect a normal bit error sooner. It aborts the transmission of the ongoing frame and tries resending it later.

When all nodes on the bus have detected the error, they also send six dominant and eight recessive bits to the bus. The resulting error frame consists of two different fields. The first field is the superposition of error flags contributed from the different stations, which are a sequence of 6–12 dominant bits. The second field is the error delimiter and consists of eight recessive bits indicating the end of frame.

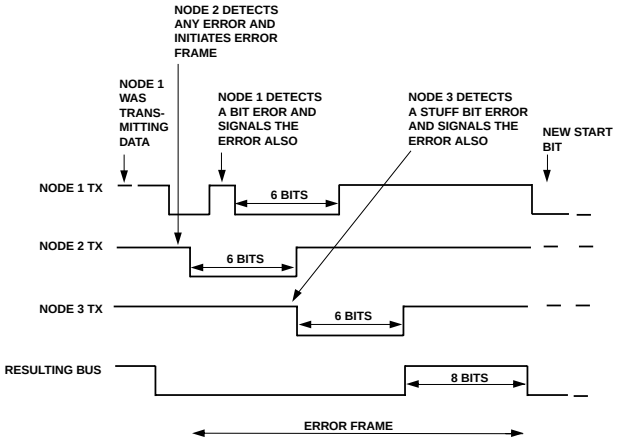

Figure 21-12: CAN Error Example

For CRC errors, the error frame initiates at the end of the frame, rather than immediately after the failing bit.

After having received eight recessive bits, every node knows that the error condition is resolved and, if messages are pending, starts transmission. The transmitter that had to abort its operation must win the new arbitration again; otherwise its message is delayed as determined by priority.

Because the transmission of an error frame destroys the frame under transmission, a faulty node erroneously detecting an error can block the bus. So, there are two node states which determine a nodes right to signal an error—error-active and error-passive.

- *Error-active* nodes have an error detection rate below a certain limit. These nodes drive an active error flag of six dominant bits.
- *Error-passive* nodes have a higher error detection rate and can have a local problem and therefore have a limited right to signal errors. These nodes drive a passive error flag consisting of six recessive bits. Therefore, an error-passive transmitting node is still able to inform the other nodes about the aborting of a self-transmitted frame. But, it is no longer able to destroy correctly received frames of other nodes.

Error Levels

The CAN specification requires each node in the system to operate at one of three levels. The ***CAN Error Level Description*** table describes the levels. This functionality prevents nodes with high error rates from blocking the entire network, as local hardware can cause the errors. The CAN module provides an error counter for transmit (TEC) and an error counter for receive (REC). The `CAN_CEC` register contains each of these 8-bit counters.

After initialization, both the TEC and the REC counters are 0. Each time a bus error occurs, one of the counters increments by either 1 or 8, depending on the error situation. Refer to version 2.0 of the CAN specification. Successful transmit or receive operations decrement the respective counter by 1.

If either of the error counters exceeds 127, the CAN module goes into an error-passive state and the `CAN_STAT.EP` bit is set. Once this state occurs, the module is not allowed to send any more active error frames. However, the module can still transmit messages and signal passive error frames in case the transmission fails due to bit errors.

If one of the counters exceeds 255 (that is, when an 8-bit counter overflows), the CAN module disconnects from the bus and it goes into bus-off mode. In this mode, the CAN_STAT.EBO bit is set. Software intervention is needed for recovery from this state, unless the CAN_CTL.ABO bit is enabled. The bit puts the module into active mode after the bus-off recovery sequence.

Table 21-5: CAN Error Level Description

Level	Condition	Description
Error active	Transmit and receive error counters <128	This level is the initial condition level. As long as errors stay below 128, the node drives active error flags during error frames.
Error passive	Transmit or receive error counter-value from 128 through 255, inclusive	Errors have accumulated to a level that requires the node to drive passive error flags during error frames
Bus off	Transmit or receive error counters greater than 255	CAN module goes into bus-off mode

In addition to the three levels in the table, the CAN module also generates separate transmit and receive warnings (CAN specification enhancement). By default, when one of the error counters exceeds 96, it signals and reports a warning in the CAN_STAT register. The CAN receive warning flag (CAN_STAT.WR) bit is set when CAN_CEC.RXECNT exceeds 96. The CAN transmit warning flag (CAN_STAT.WT) bit is set when CAN_CEC.TXECNT exceeds 96. The error warning level can be programmed using the error warning register (CAN_EWR).

Additionally, interrupt requests can occur for all of these levels by unmasking them in the global CAN interrupt mask register (CAN_GIM). These sources include: the bus-off interrupt (CAN_GIM.BOIM), the error-passive interrupt (CAN_GIM.EPIM), the error warning receive interrupt (CAN_GIM.EWRIM), and the error warning transmit interrupt (CAN_GIM.EWTIM).

During the bus-off recovery sequence, internal logic sets the configuration mode request CAN_CTL.CCR bit. The CAN core module does not automatically come out of the bus-off mode. The CAN_CTL.CCR bit cannot be reset until the bus-off recovery sequence completes.

NOTE: Set the CAN_CTL.ABO bit to override this behavior. After exiting the bus-off or configuration modes, the CAN error counters are reset.

CAN Debug and Test Modes

The CAN module contains test mode features that aid in the debugging of the CAN software and system.

NOTE: When using these features, the CAN module does not always comply to the CAN specification. Enable or disable all test modes only when the module is in configuration mode (CAN_STAT.CCA=1) or suspend mode (CAN_STAT.CSA=1).

The CAN_DBG.CDE bit provides access to all of the debug features. Set this bit to enable the test mode. Write to the bit first before writing to the CAN_DBG register. When the CAN_DBG.CDE bit is cleared, all debug features are disabled.

When the CAN_DBG.CDE bit is set, it enables writes to the other bits of the CAN_DBG register. It also enables these features, which are not compliant to the CAN standard:

- Bit timing registers can be changed anytime, not only during configuration mode. The group includes the CAN_CLK and CAN_TIMING registers.
- Write access is allowed to the normally read-only CAN_CEC register.

The following list describes other bits in the debug register.

- The CAN module uses the CAN_DBG.MRB bit to enable the read back mode. In this mode, a message transmitted on the CAN bus (or through an internal loopback mode) is received back directly to the internal receive buffer. After a correct transmission, the internal logic treats this transfer as a normal receive message. This feature allows testing of most of the CAN features without an external device.
- The CAN_DBG.MAA bit allows the CAN module to generate its own acknowledge during the ACK slot of the CAN frame. No external devices or connections are necessary to read back a transmit message. In this mode, the sent message is automatically stored in the internal receive buffer. In auto-acknowledge mode, the module itself transmits the acknowledge. This acknowledge can be programmed to appear on the CAN_TX pin, if CAN_DBG.DIL=1 and CAN_DBG.DTO= 0. If the acknowledge is only used internally, then set these test mode bits to CAN_DBG.DIL= 0 and CAN_DBG.DTO=1.
- The CAN module uses the CAN_DBG.DIL bit to internally enable the transmit output to be routed back to the receive input.
- The CAN module uses the CAN_DBG.DTO bit to disable the CAN_TX output pin. When this bit is set, the CAN_TX pin continuously drives recessive bits.
- The CAN module uses the CAN_DBG.DRI bit to disable the CAN_RX input. When set, the internal logic receives recessive bits or receives the internally-generated transmit value in the case of the internal loop enabled (CAN_DBG.DIL= 0). In either case, the value on the CAN_RX input pin is ignored.
- The CAN module uses the CAN_DBG.DEC bit to disable the transmit and receive error counters in the CAN_CEC register. When this bit is set, the CAN_CEC holds its current contents and is not allowed to increment or decrement the error counters. This mode does not conform to the CAN specification.

NOTE: Write to the error counter registers in debug mode only. Write-access during reception can lead to undefined values. The maximum value which can be written into the error counters is 255. Therefore, the error counter value of 256, which forces the module into the bus off state, cannot be written into the error counter registers.

Table 21-6: Common CAN Test Mode Bit Combinations

MRB	MAA	DIL	DTO	DRI	CDE	Functional Description
X	X	X	X	X	0	Normal mode, not debug mode
0	X	X	X	X	X	No readback of transmit message

Table 21-6: Common CAN Test Mode Bit Combinations (Continued)

MRB	MAA	DIL	DTO	DRI	CDE	Functional Description
1	0	1	0	0	1	Normal transmission on CAN bus line. Read back. External acknowledge from external device required.
1	1	1	0	0	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge are transmitted on CAN bus line. CAN_RX input is enabled.
1	1	0	0	0	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge transmit on CAN bus line. CAN_RX input and internal loop are enabled (internal OR of TX and RX)
1	1	0	0	1	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge are transmitted on CAN bus line. CAN_RX input is ignored. Internal loop is enabled.
1	1	0	1	1	1	No transmission on CAN bus line. Read back. No external acknowledge required. Nether transmit message nor acknowledge are transmitted on CAN_TX. CAN_RX input is ignored. Internal loop is enabled.

ADSP-SC57x CAN Register Descriptions

Controller Area Network (CAN) contains the following registers.

Table 21-7: ADSP-SC57x CAN Register List

Name	Description
CAN_AA1	Abort Acknowledge 1 Register

Table 21-7: ADSP-SC57x CAN Register List (Continued)

Name	Description
CAN_AA2	Abort Acknowledge 2 Register
CAN_AM[nn]H	Acceptance Mask (H) Register
CAN_AM[nn]L	Acceptance Mask (L) Register
CAN_CEC	Error Counter Register
CAN_CLK	Clock Register
CAN_CTL	CAN Master Control Register
CAN_DBG	Debug Register
CAN_ESR	Error Status Register
CAN_EWR	Error Counter Warning Level Register
CAN_GIF	Global CAN Interrupt Flag Register

CAN_UCCNT	Universal Counter Register
CAN_UCRC	Universal Counter Reload/Capture Register

Abort Acknowledge 1 Register

The CAN_AA1 register indicates a transmission abort (due to lost arbitration or a CAN error) for mailboxes 8 through 15. Each bit in this register indicates a transmission abort for the corresponding mailbox when set (=1). Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

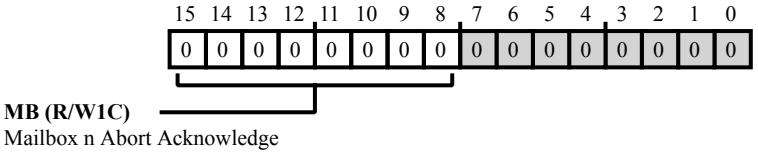

Figure 21-13: CAN_AA1 Register Diagram

Table 21-8: CAN_AA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W1C)	MB	Mailbox n Abort Acknowledge.

Abort Acknowledge 2 Register

The CAN_AA2 register indicates a transmission abort (due to lost arbitration or a CAN error) for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register indicates a transmission abort for the corresponding mailbox when set (=1).

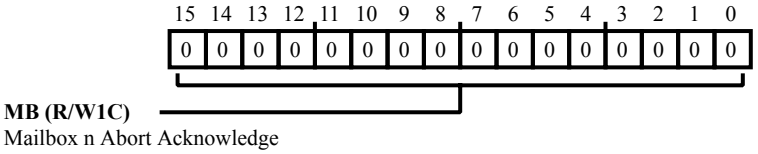

Figure 21-14: CAN_AA2 Register Diagram

Table 21-9: CAN_AA2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Abort Acknowledge.

Acceptance Mask (H) Register

The CAN_AM[nn]H register and CAN_AM[nn]L register manage acceptance mask operation. For information about acceptance mask operation, see the Receive Operation section.

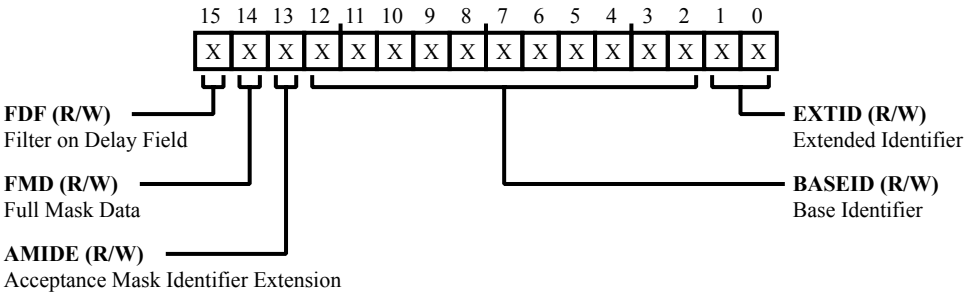

Figure 21-15: CAN_AM[nn]H Register Diagram

Table 21-10: CAN_AM[nn]H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	FDF	Filter on Delay Field. The CAN_AM[nn]H.FDF bit selects the operation of the CAN_AM[nn]H register and CAN_AM[nn]L register when the CAN_CTL.DNM bit is enabled. If the CAN_AM[nn]H.FDF bit is set, the corresponding CAN_AM[nn]L.EXTID bits hold the data field mask. If the CAN_AM[nn]H.FDF bit is cleared, the corresponding CAN_AM[nn]L.EXTID bits hold the high bits of the extended identifier mask.
14 (R/W)	FMD	Full Mask Data. The CAN_AM[nn]H.FMD bit works with the CAN_AM[nn]H.FDF bit to determine data field filtering. For information about data field filtering, see the Receive Operation section.
13 (R/W)	AMIDE	Acceptance Mask Identifier Extension. The CAN_AM[nn]H.AMIDE bit enables the comparison of the received message ID to the value in the CAN_AM[nn]H.EXTID and CAN_AM[nn]L.EXTID bits.
12:2 (R/W)	BASEID	Base Identifier. The CAN_AM[nn]H.BASEID bits hold the base ID for acceptance mask operations.
1:0 (R/W)	EXTID	Extended Identifier. The CAN_AM[nn]H.EXTID bits hold the extended ID (upper two bits) for acceptance mask operations.

Acceptance Mask (L) Register

The CAN_AM[nn]L register and CAN_AM[nn]H register manage acceptance mask operation. For information about acceptance mask operation, see the Receive Operation section.

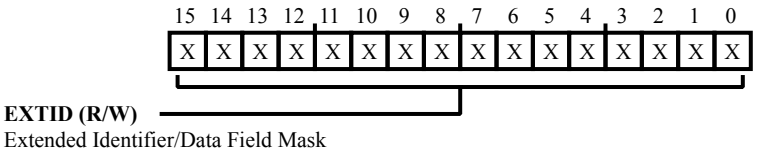

Figure 21-16: CAN_AM[nn]L Register Diagram

Table 21-11: CAN_AM[nn]L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	EXTID	Extended Identifier/Data Field Mask. The CAN_AM[nn]L.EXTID bits hold the extended ID (lower 16 bits) for data field mask in acceptance mask operations.

Error Counter Register

The CAN_CEC register, CAN_ESR register, and CAN_EWR register control CAN warnings and errors. For detailed information about error and warning operations, see the Event Control section.

The CAN_CEC register holds an error counter for transmit (CAN_CEC.TXECNT) and an error counter for receive (CAN_CEC.RXECNT). After initialization, both counters are 0. Each time a bus error occurs, one of the counters is incremented by either 1 or 8, depending on the error situation (documented in Version 2.0 of CAN Specification). Successful transmit and receive operations decrement the respective counter by 1.

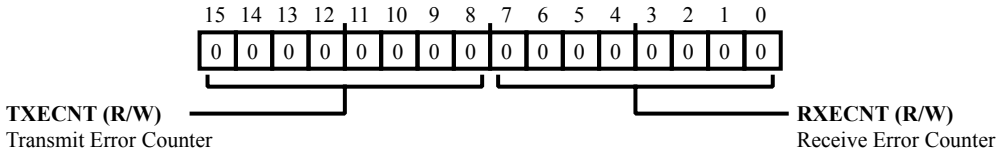

Figure 21-17: CAN_CEC Register Diagram

Table 21-12: CAN_CEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	TXECNT	Transmit Error Counter. The CAN_CEC.TXECNT bits hold the transmit error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful transmit operations.
7:0 (R/W)	RXECNT	Receive Error Counter. The CAN_CEC.RXECNT bits hold the receive error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful receive operations.

Clock Register

The CAN_CLK register selects the bit rate prescaler for calculating the time quantum (TQ), which is used to derive the CAN clock from the system clock (SCLK). For more information about bit timing and clock operation, see the CAN Operating Modes section.

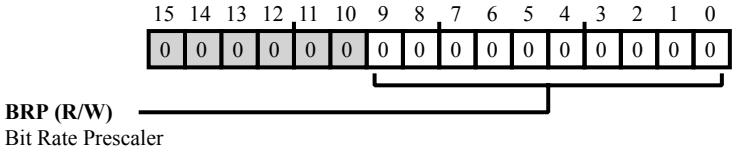

Figure 21-18: CAN_CLK Register Diagram

Table 21-13: CAN_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	BRP	Bit Rate Prescaler. The CAN_CLK.BRP bits select the bit rate prescaler value, which is used to calculate the time quantum for CAN bit timing. The formula using CAN_CLK.BRP to calculate the time quantum is: TQ = (BRP+1) / SCLK Note that it is recommended that the CAN_CLK.BRP value be greater than or equal to 4. For more information about bit timing, see the Operating Modes section.

CAN Master Control Register

The CAN_CTL register controls CAN mode requests, including soft reset.

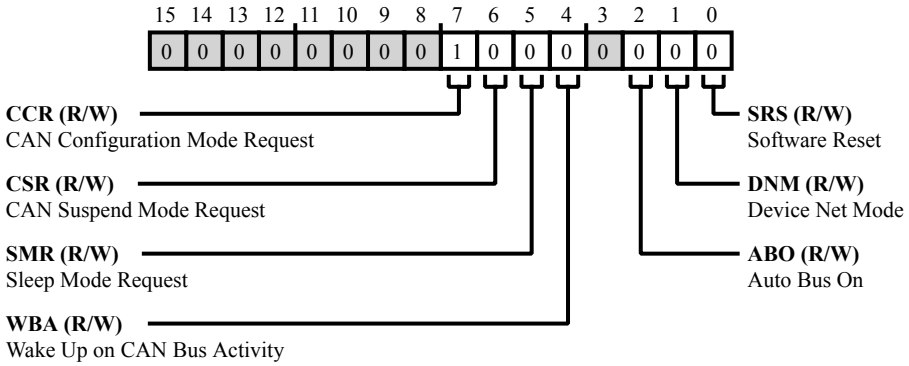

Figure 21-19: CAN_CTL Register Diagram

Table 21-14: CAN_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CCR	CAN Configuration Mode Request. The CAN_CTL.CCR bit requests that the CAN enter configuration mode. Note that the CAN should always be put in configuration mode before modifying the CAN_CLK or CAN_TIMING registers.	
		0	No Request (Exit Configuration Mode)
		1	Request Configuration Mode
6 (R/W)	CSR	CAN Suspend Mode Request. The CAN_CTL.CSR bit requests that the CAN enter suspend mode. The CAN enters suspend mode after the current operation of the CAN bus is finished.	
		0	No Request (Exit Suspend Mode)
		1	Request Suspend Mode
5 (R/W)	SMR	Sleep Mode Request. The CAN_CTL.SMR bit requests that the CAN enter sleep mode. The CAN enters sleep mode after the current operation of the CAN bus is finished.	
		0	No Request (Exit Sleep Mode)
		1	Request Sleep Mode

Table 21-14: CAN_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	WBA	Wake Up on CAN Bus Activity. The CAN_CTL.WBA bit enables wake on CAN bus activity. When enabled, a dominant bit on the CAN_RX pin ends sleep mode (also, the default wake up condition of a write to the CAN_INT register).	
		0	Disable Wake on Bus Activity
		1	Enable Wake on Bus Activity
2 (R/W)	ABO	Auto Bus On. The CAN_CTL.ABO bit selects whether (if enabled) the CAN enters active mode after the bus-off recovery sequence or (if disabled) the CAN enters configuration mode after the bus-off recovery sequence.	
		0	Disable Auto Bus On
		1	Enable Auto Bus On
1 (R/W)	DNM	Device Net Mode. The CAN_CTL.DNM bit enables mailbox filtering on a data field. The filtering is done on the standard ID of the message and data fields. For more information, see the CAN_AM[nn]H.FDF bit description.	
		0	Disable Device Net Mode
		1	Enable Device Net Mode
0 (R/W)	SRS	Software Reset. The CAN_CTL.SRS bit resets the CAN, bringing all control registers to a defined state. Soft reset is entered immediately after software has set the CAN_CTL.SRS bit.	
		0	No Action
		1	Reset CAN

Debug Register

The CAN_DBG register controls CAN debug modes, including CAN_TX and CAN_RX pin enable and disable.

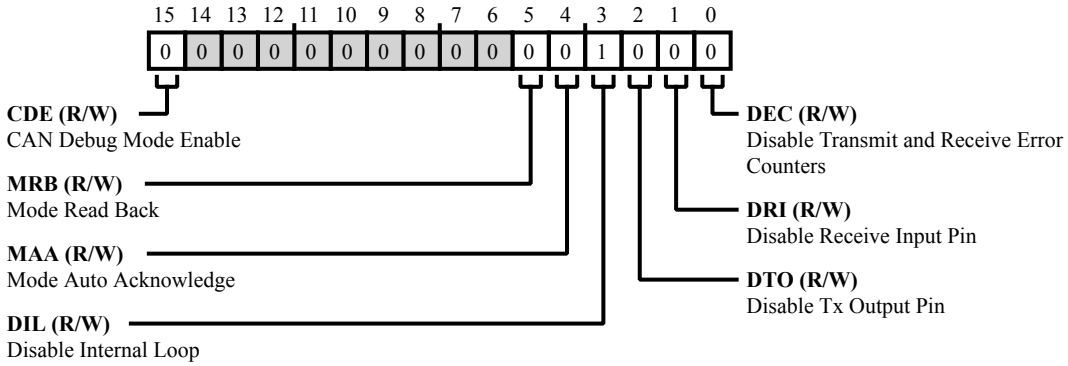

Figure 21-20: CAN_DBG Register Diagram

Table 21-15: CAN_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	CDE	CAN Debug Mode Enable. The CAN_DBG.CDE bit enables debug mode. This bit must be written first before subsequent writes to the CAN_DBG register. When the CAN_DBG.CDE bit is cleared, all CAN debug features are disabled.	
		0	Disable Debug Mode
		1	Enable Debug Mode
5 (R/W)	MRB	Mode Read Back. The CAN_DBG.MRB bit enables read back mode. When enabled, a message transmitted on the CAN bus or through an internal loop back mode is received back directly to the internal receive buffer.	
		0	Disable Read Back Mode
		1	Enable Read Back Mode
4 (R/W)	MAA	Mode Auto Acknowledge. The CAN_DBG.MAA bit enables auto acknowledge mode, allowing the CAN to generate its own acknowledge during the ACK slot of the CAN frame. The CAN_DBG.MAA acknowledge appears on the CAN_TX pin if CAN_DBG.DIL =1 and CAN_DBG.DTO =0. If the acknowledge is only going to be used internally, these test mode bits should be set to CAN_DBG.DIL = 0 and CAN_DBG.DTO =1.	
		0	Disable Auto Acknowledge Mode
		1	Enable Auto Acknowledge Mode

Table 21-15: CAN_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIL	Disable Internal Loop. The CAN_DBG.DIL bit disables internal loop mode, which routes the transmit output to the receive input.	
		0	Enable Internal Loop
		1	Disable Internal Loop
2 (R/W)	DTO	Disable Tx Output Pin. The CAN_DBG.DTO bit disables the CAN_TX pin.	
		0	Enable Tx Output Pin
		1	Disable Tx Output Pin, Drive Recessive
1 (R/W)	DRI	Disable Receive Input Pin. The CAN_DBG.DRI bit disables the CAN_RX pin.	
		0	Enable Rx Input Pin
		1	Disable Rx Input Pin, Drive Recessive Internally
0 (R/W)	DEC	Disable Transmit and Receive Error Counters. The CAN_DBG.DEC bit disables the transmit and receive error counters in the CAN_CEC register. When set, the CAN_CEC holds its current contents and is not allowed to increment or decrement the error counters. Note that this mode does not conform to the CAN specification.	
		0	Enable CEC Tx and Rx Error Counters
		1	Disable CEC Tx and Rx Error Counters

Error Status Register

The CAN_ESR register, CAN_CEC register, and CAN_EWR register control CAN warnings and errors. All bits in the CAN_ESR register are W1C. Note that the CAN updates the CAN_CEC register when error status is detected in the CAN_ESR register. For detailed information about error and warning operations, see the Operating Modes section.

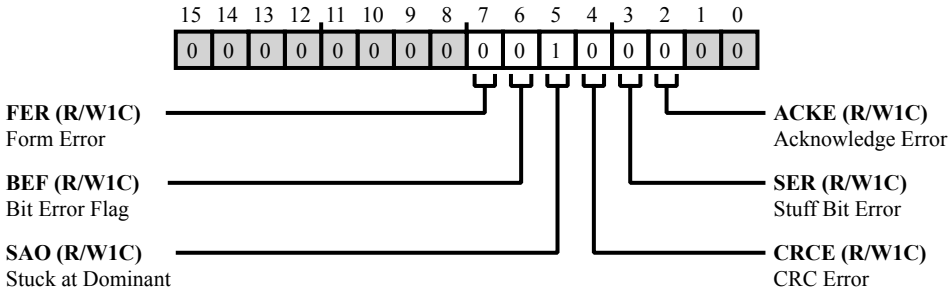

Figure 21-21: CAN_ESR Register Diagram

Table 21-16: CAN_ESR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	FER	Form Error. The CAN_ESR.FER bit indicates when a form error occurs, indicating that a fixed-form bit position in the CAN frame contains one or more illegal bits. This occurs when a dominant bit is detected at a delimiter or end-of-frame bit position.	
		0	No Status
		1	Form Error
6 (R/W1C)	BEF	Bit Error Flag. The CAN_ESR.BEF bit indicates (detected by the transmitting node only) when the value on the CAN_RX pin does not equal what is being transmitted on the CAN_TX pin. When a node is transmitting, it continuously monitors its receive pin (CAN_RX) and compares the received data with the transmitted data. The node postpones the transmission (during the arbitration phase) if the received and transmitted data do not match. After the arbitration phase (CAN_MB[nn]_ID1.RTR bit sent successfully), a bit error is signaled when the value on the CAN_RX pin does not equal what is being transmitted on the CAN_TX pin.	
		0	No Status
		1	Bit Error Flag

Table 21-16: CAN_ESR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	SAO	Stuck at Dominant. The `CAN_ESR.SAO` bit indicates when the `CAN_RX` pin sticks at dominant level, indicating that shorted wires are likely.	
		0	No Status
		1	Stuck At Dominant
4 (R/W1C)	CRCE	CRC Error. The `CAN_ESR.CRCE` bit indicates when a CRC error occurs. This error may occur when a receiver calculates the CRC on the data it received and finds the value different than the CRC that was transmitted on the bus.	
		0	No Status
		1	CRC Error
3 (R/W1C)	SER	Stuff Bit Error. The `CAN_ESR.SER` bit indicates when a stuff bit error (stuffed 6th consecutive bit value is the same as the previous five bits) occurs. The CAN specification requires that the transmitter insert an extra stuff bit of opposite value after 5 bits have been transmitted with the same value. The receiver disregards the value of these stuff bits. The receiver takes advantage of the signal edge to re-synchronize itself. A stuff bit error occurs on receiving nodes when the 6th consecutive bit value is the same as the previous five bits.	
		0	No Status
		1	Stuff Bit Error Receive
2 (R/W1C)	ACKE	Acknowledge Error. The `CAN_ESR.ACKE` bit indicates when an acknowledge error occurs, indicating that a message is sent and no receivers drive an acknowledge bit.	
		0	No Status
		1	Acknowledge Error

Error Counter Warning Level Register

The CAN_EWR register, CAN_CEC register, and CAN_ESR register control CAN warnings and errors. For detailed information about error and warning operations, see the Operating Modes section.

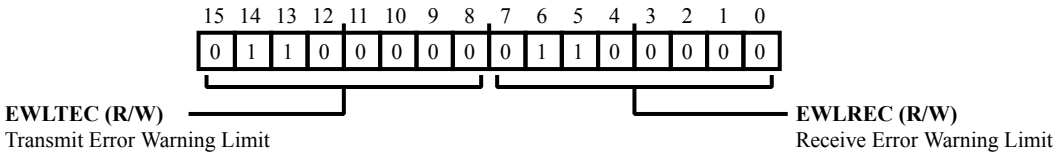

Figure 21-22: CAN_EWR Register Diagram

Table 21-17: CAN_EWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	EWLTEC	Transmit Error Warning Limit. The CAN_EWR.EWLTEC bits select the transmit error warning limit, which is used as a condition for the CAN_GIS.EWTIS interrupt.
7:0 (R/W)	EWLREC	Receive Error Warning Limit. The CAN_EWR.EWLREC bits select the receive error warning limit, which is used as a condition for the CAN_GIS.EWRIS interrupt.

Global CAN Interrupt Flag Register

The CAN_GIF register, CAN_GIF register, and CAN_GIM register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The CAN_GIF register holds the interrupt flag. The CAN_INT.GIRQ bit is only asserted if a bit in the CAN_GIF is set. The CAN_INT.GIRQ bit remains set as long as at least one bit in the CAN_GIF register is set. All bits in this register are W1C.

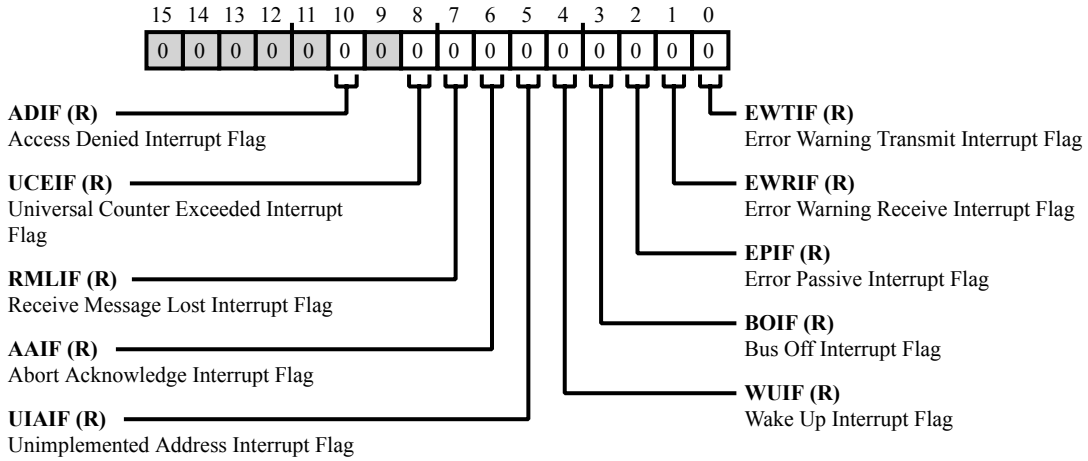

Figure 21-23: CAN_GIF Register Diagram

Table 21-18: CAN_GIF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	ADIF	Access Denied Interrupt Flag. The CAN_GIF.ADIF bit indicates that the access denied interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
8 (R/NW)	UCEIF	Universal Counter Exceeded Interrupt Flag. The CAN_GIF.UCEIF bit indicates that the universal counter exceeded interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)

Table 21-18: CAN_GIF Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	RMLIF	Receive Message Lost Interrupt Flag. The CAN_GIF.RMLIF bit indicates that the receive message lost interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
6 (R/NW)	AAIF	Abort Acknowledge Interrupt Flag. The CAN_GIF.AAIF bit indicates that the abort acknowledge interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
5 (R/NW)	UIAIF	Unimplemented Address Interrupt Flag. The CAN_GIF.UIAIF bit indicates that the unimplemented address interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
4 (R/NW)	WUIF	Wake Up Interrupt Flag. The CAN_GIF.WUIF bit indicates that the wake up interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
3 (R/NW)	BOIF	Bus Off Interrupt Flag. The CAN_GIF.BOIF bit indicates that the bus off interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
2 (R/NW)	EPIF	Error Passive Interrupt Flag. The CAN_GIF.EPIF bit indicates that the error passive mode interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)
1 (R/NW)	EWRIF	Error Warning Receive Interrupt Flag. The CAN_GIF.EWRIF bit indicates that the error warning receive interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)

Table 21-18: CAN_GIF Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	EWTIF	Error Warning Transmit Interrupt Flag. The `CAN_GIF.EWTIF` bit indicates that the error warning transmit interrupt flag is set (latched).	
		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)

Global CAN Interrupt Mask Register

The CAN_GIM register, CAN_GIF register, and CAN_GIF register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The CAN_GIM register holds the interrupt mask. The interrupt mask bits only affect the content of the CAN_GIF register. If the mask bit is not set (enabled/unmasked), the corresponding flag bit is not set when the event occurs.

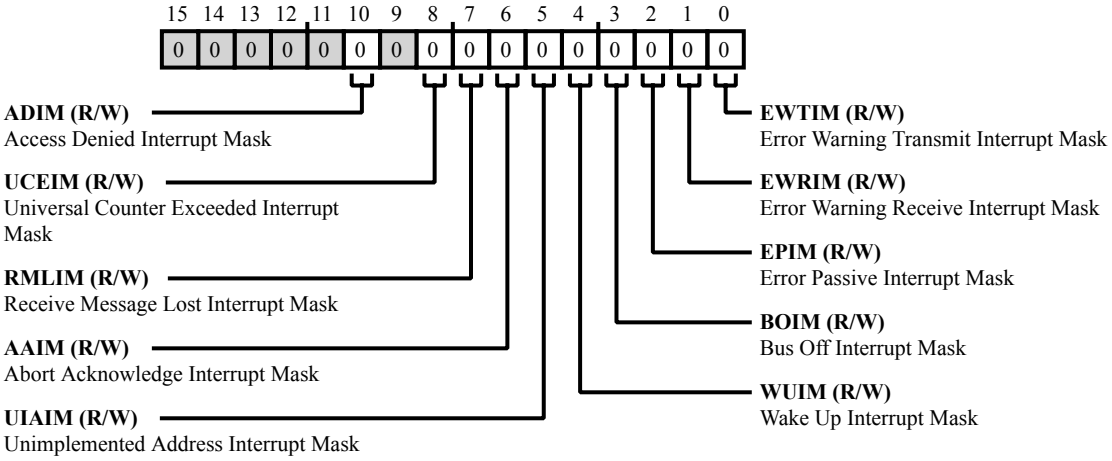

Figure 21-24: CAN_GIM Register Diagram

Table 21-19: CAN_GIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	ADIM	Access Denied Interrupt Mask. The CAN_GIM.ADIM bit enables (unmasks) the access denied interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
8 (R/W)	UCEIM	Universal Counter Exceeded Interrupt Mask. The CAN_GIM.UCEIM bit enables (unmasks) the universal counter exceeded interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
7 (R/W)	RMLIM	Receive Message Lost Interrupt Mask. The CAN_GIM.RMLIM bit enables (unmasks) the receive message lost interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)

Table 21-19: CAN_GIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	AAIM	Abort Acknowledge Interrupt Mask. The CAN_GIM.AAIM bit enables (unmasks) the abort acknowledge interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
5 (R/W)	UIAIM	Unimplemented Address Interrupt Mask. The CAN_GIM.UIAIM bit enables (unmasks) the unimplemented address interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
4 (R/W)	WUIM	Wake Up Interrupt Mask. The CAN_GIM.WUIM bit enables (unmasks) the wake up interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
3 (R/W)	BOIM	Bus Off Interrupt Mask. The CAN_GIM.BOIM bit enables (unmasks) the bus off interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
2 (R/W)	EPIM	Error Passive Interrupt Mask. The CAN_GIM.EPIM bit enables (unmasks) the error passive mode interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
1 (R/W)	EWRIM	Error Warning Receive Interrupt Mask. The CAN_GIM.EWRIM bit enables (unmasks) the error warning receive interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
0 (R/W)	EWTIM	Error Warning Transmit Interrupt Mask. The CAN_GIM.EWTIM bit enables (unmasks) the error warning transmit interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)

Global CAN Interrupt Status Register

The CAN_GIS register, CAN_GIF register, and CAN_GIM register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The CAN_GIS register holds the interrupt status. All bits in this register are W1C.

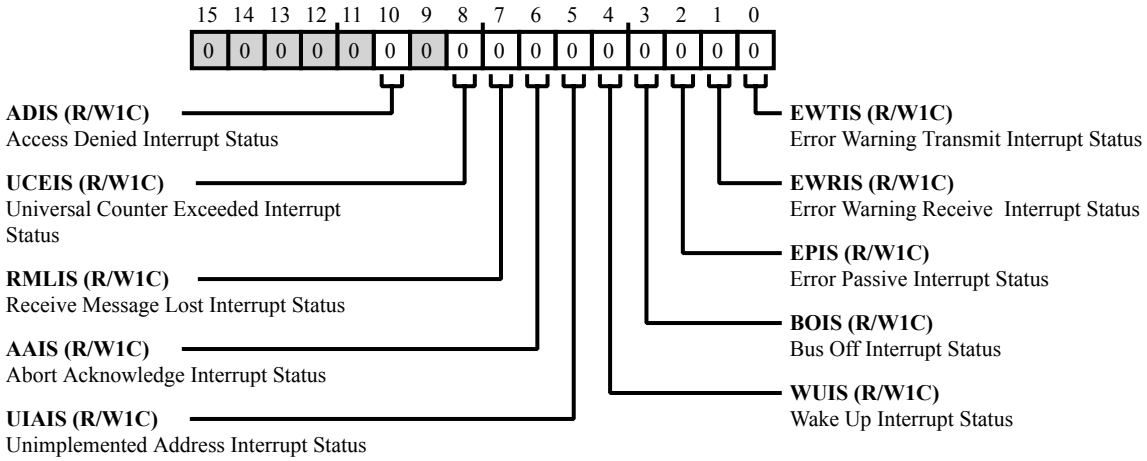

Figure 21-25: CAN_GIS Register Diagram

Table 21-20: CAN_GIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	ADIS	Access Denied Interrupt Status. The CAN_GIS.ADIS bit indicates when at least one access to the mailbox RAM occurred during a data update by internal logic.	
		0	No Interrupt Pending
		1	Interrupt Pending
8 (R/W1C)	UCEIS	Universal Counter Exceeded Interrupt Status. The CAN_GIS.UCEIS bit indicates when there has been an overflow of the universal counter (in time stamp mode or event counter mode) or the counter has reached the value 0x0000 (in watchdog mode).	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 21-20: CAN_GIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RMLIS	Receive Message Lost Interrupt Status. The CAN_GIS.RMLIS bit indicates when a message is received for a mailbox that currently contains unread data. At least one bit in the receive message lost register (CAN_RML1 or CAN_RML2) is set. If the bit in CAN_GIS (and CAN_GIF) is reset and there is at least one bit in CAN_RML1 or CAN_RML2 still set, the bit in CAN_GIF (and CAN_GIF) is not set again. The internal interrupt source signal is only active if a new bit in CAN_RML1 or CAN_RML2 is set.	
		0	No Interrupt Pending
		1	Interrupt Pending
6 (R/W1C)	AAIS	Abort Acknowledge Interrupt Status. The CAN_GIS.AAIS bit indicates when At least one abort acknowledge bit is set in the CAN_AA1 or the CAN_AA2 registers. If the bit in CAN_GIS (and CAN_GIF) is reset and there is at least one bit in CAN_AA1 or CAN_AA2 still set, the bit in CAN_GIS (and CAN_GIF) is not set again. The internal interrupt source signal is only active if a new bit in CAN_AA1 or CAN_AA2 is set. The abort acknowledge bits maintain state even after the corresponding mailbox n is disabled.	
		0	No Interrupt Pending
		1	Interrupt Pending
5 (R/W1C)	UIAIS	Unimplemented Address Interrupt Status. The CAN_GIS.UIAIS bit indicates when there was a processor core access to an address that is not implemented in the CAN.	
		0	No Interrupt Pending
		1	Interrupt Pending
4 (R/W1C)	WUIS	Wake Up Interrupt Status. The CAN_GIS.WUIS bit indicates when the CAN has left the sleep mode because of detected activity on the CAN bus line.	
		0	No Interrupt Pending
		1	Interrupt Pending
3 (R/W1C)	BOIS	Bus Off Interrupt Status. The CAN_GIS.BOIS bit indicates when the CAN has entered the bus-off state. This interrupt source is active if the status of the CAN changes from normal operation mode to the bus-off mode. If the bit in CAN_GIS (and CAN_GIF) is reset and the bus-off mode is still active, this bit is not set again. If the module leaves the bus-off mode, the bit in CAN_GIS (and CAN_GIF) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 21-20: CAN_GIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	EPIS	Error Passive Interrupt Status. The CAN_GIS.EPIS bit indicates when the CAN has entered the error passive state. This interrupt source is active if the status of the CAN changes from the error active mode to the error passive mode. If the bit in CAN_GIS (and CAN_GIF) is reset and the error passive mode is still active, this bit is not set again. If the CAN leaves the error passive mode, the bit in CAN_GIS (and CAN_GIF) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending
1 (R/W1C)	EWRIS	Error Warning Receive Interrupt Status. The CAN_GIS.EWRIS bit indicates when the CAN_CEC.RXECNT has reached the warning limit. If the bit in CAN_GIS (and CAN_GIF) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in CAN_GIS (and CAN_GIF) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending
0 (R/W1C)	EWTIS	Error Warning Transmit Interrupt Status. The CAN_GIS.EWTIS bit indicates when the CAN_CEC.TXECNT has reached the warning limit. If the bit in CAN_GIS (and CAN_GIF) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in CAN_GIS (and CAN_GIF) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending

Interrupt Pending Register

The CAN_INT register indicates the status of pending CAN interrupts and indicates the state of the CAN_RX and CAN_TX pins. Though this register is read-only, a write is allowed to exit the built-in sleep mode of the module on processors supporting this feature.

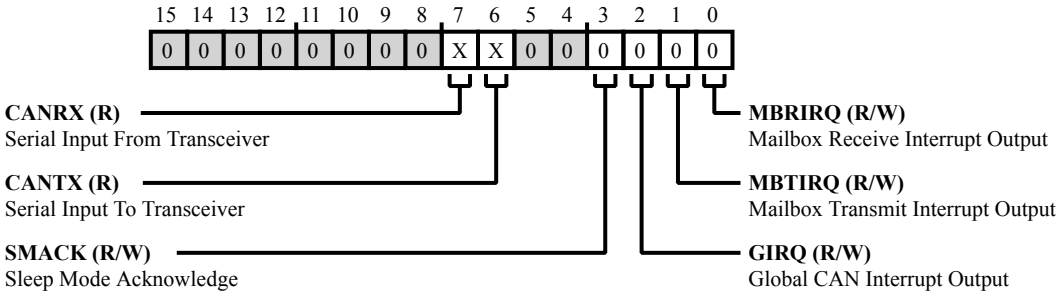

Figure 21-26: CAN_INT Register Diagram

Table 21-21: CAN_INT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	CANRX	Serial Input From Transceiver. The CAN_INT.CANRX bit indicates the logic value that the CAN detects on the CAN_RX pin. Note that the reset/default value for CAN_INT.CANRX is dependent on pin values.	
		0	Dominant Value (Low Active)
		1	Recessive Value (High Active)
6 (R/NW)	CANTX	Serial Input To Transceiver. The CAN_INT.CANTX bit indicates the logic value that the CAN detects on the CAN_TX pin. Note that the reset/default value for CAN_INT.CANTX is dependent on pin values.	
		0	Dominant Value (Low Active)
		1	Recessive Value (High Active)
3 (R/W)	SMACK	Sleep Mode Acknowledge. The CAN_INT.SMACK bit indicates when the CAN has entered sleep mode.	
		0	Not in Sleep Mode
		1	Sleep Mode

Table 21-21: CAN_INT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	GIRQ	Global CAN Interrupt Output. The CAN_INT.GIRQ bit indicates when at least one bit is set in the CAN_GIF register, indicating at least one unmasked CAN is flagged (latched). The CAN_INT.GIRQ bit remains set as long as at least one bit is set in the CAN_GIF register.	
		0	No CAN Global Interrupt Flag Set
		1	CAN Global Interrupt Flag (1 or More) Set
1 (R/W)	MBTIRQ	Mailbox Transmit Interrupt Output. The CAN_INT.MBTIRQ bit indicates when any bits are set in the CAN_MBTIF1 register or CAN_MBTIF2 register, indicating transmit.	
		0	No CAN Transmit Flags Set
		1	CAN Transmit Flags Set (1 or More)
0 (R/W)	MBRIRQ	Mailbox Receive Interrupt Output. The CAN_INT.MBRIRQ bit indicates when any bits are set in the CAN_MBRIF1 register or CAN_MBRIF2 register, indicating receive.	
		0	No CAN Receive Flags Set
		1	CAN Receive Flags Set (1 or More)

Mailbox Interrupt Mask 1 Register

The CAN_MBIM1 register enables transmit and receive interrupt requests for mailboxes 0 through 15. Each bit in this register requests enables the transmit or receive interrupt request for the corresponding mailbox when set (=1).

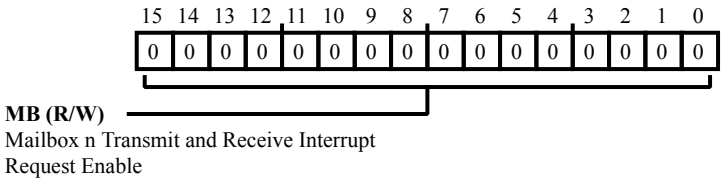

Figure 21-27: CAN_MBIM1 Register Diagram

Table 21-22: CAN_MBIM1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Transmit and Receive Interrupt Request Enable.

Mailbox Interrupt Mask 2 Register

The CAN_MBIM2 register enables transmit and receive interrupt requests for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register requests enables the transmit or receive interrupt request for the corresponding mailbox when set (=1).

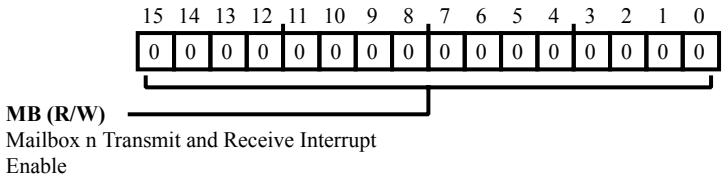

Figure 21-28: CAN_MBIM2 Register Diagram

Table 21-23: CAN_MBIM2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Transmit and Receive Interrupt Enable.

Mailbox Receive Interrupt Flag 1 Register

The CAN_MBRIF1 register indicates when a receive interrupt request is pending---due to successful reception (corresponding CAN_RMP1 bit set) and the interrupt is enabled (corresponding CAN_MBIM1 bit set)---for mailboxes 0 through 15. Each bit in this register indicates the receive interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN_MBRIF1 is set, the CAN receive interrupt request is raised (CAN_INT.MBRIRQ bit set). To clear the interrupt request, all of the set bits in CAN_RMP1 must be cleared by software, then the associated bits set in CAN_MBRIF1 must be cleared (W1C).

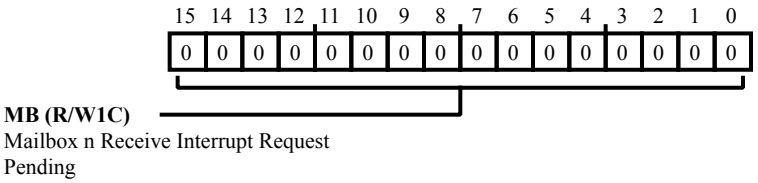

Figure 21-29: CAN_MBRIF1 Register Diagram

Table 21-24: CAN_MBRIF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Receive Interrupt Request Pending.

Mailbox Receive Interrupt Flag 2 Register

The CAN_MBRIF2 register indicates when a receive interrupt request is pending---due to successful reception (corresponding CAN_RMP2 bit set) and the interrupt is enabled (corresponding CAN_MBIM2 bit set)---for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register indicates the receive interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN_MBRIF2 is set, the CAN receive interrupt request is raised (CAN_INT.MBRIRQ bit set). To clear the interrupt request, all of the set bits in CAN_RMP2 must be cleared by software, then the associated bits set in CAN_MBRIF2 must be cleared (W1C). Bits 8 through 15 are reserved and read-only, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

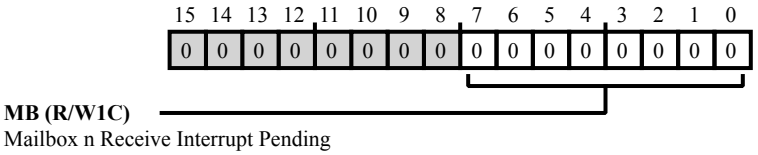

Figure 21-30: CAN_MBRIF2 Register Diagram

Table 21-25: CAN_MBRIF2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	MB	Mailbox n Receive Interrupt Pending.

Temporary Mailbox Disable Register

The CAN_MBTD register supports temporarily and selectively disabling CAN mailboxes. For more information about this feature, see the Operating Modes section.

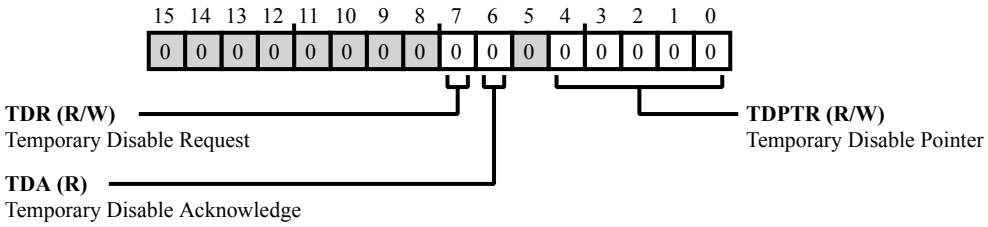

Figure 21-31: CAN_MBTD Register Diagram

Table 21-26: CAN_MBTD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	TDR	Temporary Disable Request. The CAN_MBTD.TDR bit holds the pointer to mailbox, which is disabled when the CAN_MBTD.TDR bit is set.	
		0	No Request
		1	Request Temporary Mailbox Disable
6 (R/NW)	TDA	Temporary Disable Acknowledge. The CAN_MBTD.TDA bit indicates when the mailbox (to which the CAN_MBTD.TDPTR bit points) is disabled. When this bit is set for a mailbox, only the data field of that mailbox may be updated. Accesses that mailboxs control bits and the identifier are denied.	
		0	No Acknowledge
		1	Acknowledge Temporary Mailbox Disable
4:0 (R/W)	TDPTR	Temporary Disable Pointer. The CAN_MBTD.TDPTR bits hold the pointer to mailbox, which is disabled when the CAN_MBTD.TDR bit is set.	

Mailbox Transmit Interrupt Flag 1 Register

The CAN_MBTIF1 register indicates when a transmit interrupt request is pending---due to successful transmission (corresponding CAN_TA1 bit is set) and the interrupt is enabled (corresponding CAN_MBIM1 bit is set)---for mailboxes 8 through 15. Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN_MBTIF1 is set, the CAN transmit interrupt request is raised (CAN_INT.MBTIRQ bit set). To clear the interrupt request, all of the set bits in CAN_MBTIF1 must be cleared by software (W1C). Also, software must clear the associated bits set in CAN_TA1 or set the associated bits in CAN_TRS1 bit to clear the interrupt source asserting the bits in CAN_MBTIF1. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

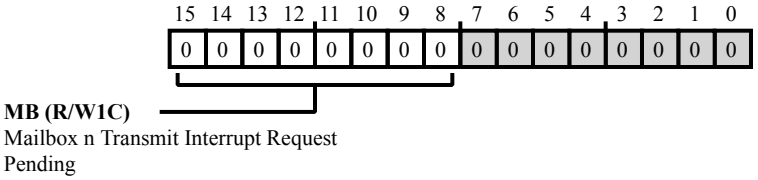

Figure 21-32: CAN_MBTIF1 Register Diagram

Table 21-27: CAN_MBTIF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W1C)	MB	Mailbox n Transmit Interrupt Request Pending.

Mailbox Transmit Interrupt Flag 2 Register

The CAN_MBTIF2 register indicates when a transmit interrupt request is pending---due to successful transmission (corresponding CAN_TA2 bit is set) and the interrupt is enabled (corresponding CAN_MBIM2 bit is set)---for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN_MBTIF2 is set, the CAN transmit interrupt request is raised (CAN_INT.MBTIRQ bit is set). To clear the interrupt request, all of the set bits in CAN_MBTIF2 must be cleared by software (W1C). Also, software must clear the associated bits set in CAN_TA2 or set the associated bits in CAN_TRS2 bit to clear the interrupt source asserting the bits in CAN_MBTIF2.

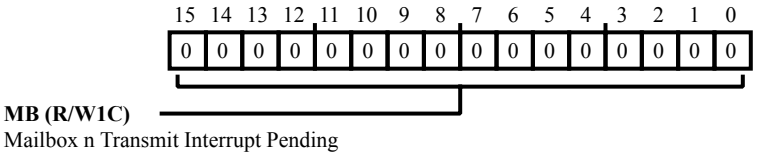

Figure 21-33: CAN_MBTIF2 Register Diagram

Table 21-28: CAN_MBTIF2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Transmit Interrupt Pending.

Mailbox Word 0 Register

The `CAN_MB[nn]_DATA0` register holds mailbox data bytes.

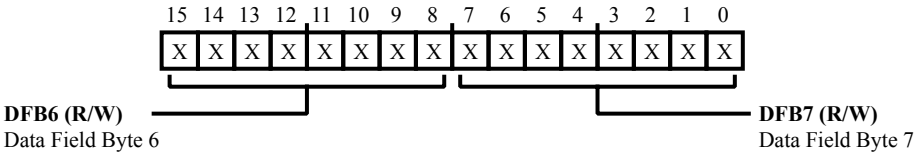

Figure 21-34: CAN_MB[nn]_DATA0 Register Diagram

Table 21-29: CAN_MB[nn]_DATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	DFB6	Data Field Byte 6. The `CAN_MB[nn]_DATA0.DFB6` bits hold mailbox data.
7:0 (R/W)	DFB7	Data Field Byte 7. The `CAN_MB[nn]_DATA0.DFB7` bits hold mailbox data.

Mailbox Word 1 Register

The `CAN_MB[nn]_DATA1` register holds mailbox data bytes.

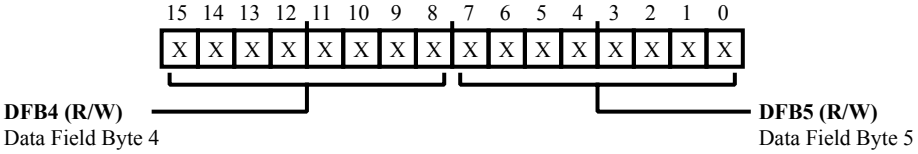

Figure 21-35: CAN_MB[nn]_DATA1 Register Diagram

Table 21-30: CAN_MB[nn]_DATA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	DFB4	Data Field Byte 4. The `CAN_MB[nn]_DATA1.DFB4` bits hold mailbox data.
7:0 (R/W)	DFB5	Data Field Byte 5. The `CAN_MB[nn]_DATA1.DFB5` bits hold mailbox data.

Mailbox Word 2 Register

The CAN_MB[nn]_DATA2 register holds mailbox data bytes.

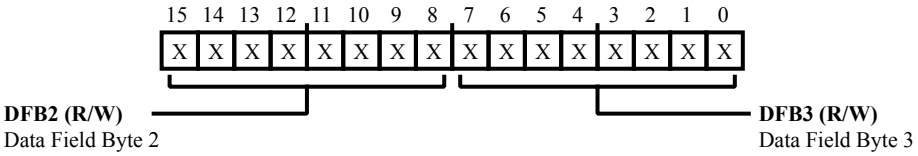

Figure 21-36: CAN_MB[nn]_DATA2 Register Diagram

Table 21-31: CAN_MB[nn]_DATA2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	DFB2	Data Field Byte 2. The CAN_MB[nn]_DATA2.DFB2 bits hold mailbox data.
7:0 (R/W)	DFB3	Data Field Byte 3. The CAN_MB[nn]_DATA2.DFB3 bits hold mailbox data.

Mailbox Word 3 Register

The `CAN_MB[nn]_DATA3` register holds mailbox data bytes.

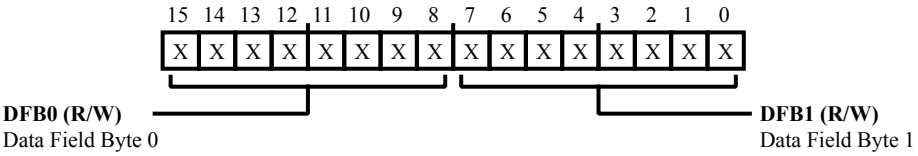

Figure 21-37: CAN_MB[nn]_DATA3 Register Diagram

Table 21-32: CAN_MB[nn]_DATA3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	DFB0	Data Field Byte 0. The `CAN_MB[nn]_DATA3.DFB0` bits hold mailbox data.
7:0 (R/W)	DFB1	Data Field Byte 1. The `CAN_MB[nn]_DATA3.DFB1` bits hold mailbox data.

Mailbox ID 0 Register

The CAN_MB[nn]_ID0 register contains the lower 16 bits of the 18-bit extended identifier.

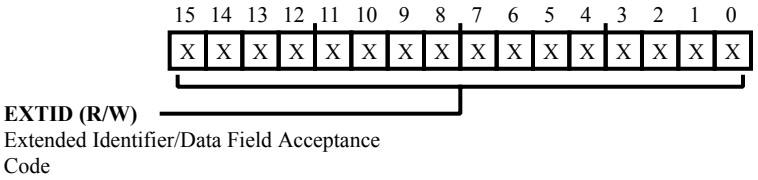

Figure 21-38: CAN_MB[nn]_ID0 Register Diagram

Table 21-33: CAN_MB[nn]_ID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	EXTID	Extended Identifier/Data Field Acceptance Code. The CAN_MB[nn]_ID0.EXTID bits hold the lower 16 bits of the 18-bit extended ID.

Mailbox ID 1 Register

The CAN_MB[nn]_ID1 register contains the identifier bits of mailbox. The 11-bit BASE_ID is mapped to The CAN_MB[nn]_ID1.BASEID field. It also enables the extended identification and contains upper two bits of 18-bit extended identifier.

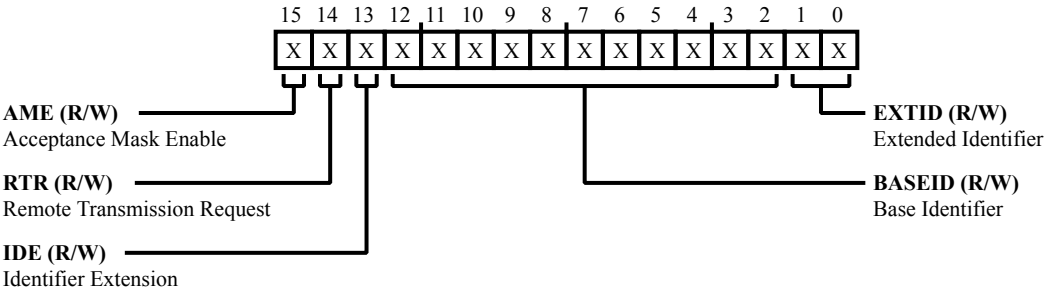

Figure 21-39: CAN_MB[nn]_ID1 Register Diagram

Table 21-34: CAN_MB[nn]_ID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	AME	Acceptance Mask Enable. The CAN_MB[nn]_ID1.AME bit enables acceptance mask operations if the mailbox is configured as receiver. When enabled (=1), only those bits that have the corresponding mask bit cleared are compared to the received message ID. A bit position that is set in the mask register does not need to match. This bit should be set to 0 when the mailbox is configured in transmit mode.
14 (R/W)	RTR	Remote Transmission Request. The CAN_MB[nn]_ID1.RTR bit selects whether the frame contains data (data frame) or contains a request for data associated with the message identifier in the frame being sent (remote frame).
13 (R/W)	IDE	Identifier Extension. The CAN_MB[nn]_ID1.IDE bit enables the comparison of the received message ID to the value in the CAN_MB[nn]_ID1.EXTID and CAN_MB[nn]_ID0.EXTID bits. When configured as transmitter, it sends the extended identifier in addition to the base identifier.
12:2 (R/W)	BASEID	Base Identifier. The CAN_MB[nn]_ID1.BASEID bits hold the base identifier for acceptance mask operations.
1:0 (R/W)	EXTID	Extended Identifier. The CAN_MB[nn]_ID1.EXTID bits hold the upper two bits of 18-bit extended identifier.

Mailbox Length Register

The CAN_MB[nn]_LENGTH register holds the data length code for the received remote frame. For more information about remote frames, see the Remote Frame Handling section.

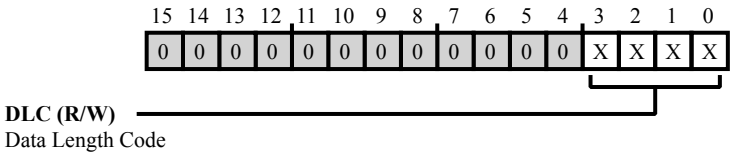

Figure 21-40: CAN_MB[nn]_LENGTH Register Diagram

Table 21-35: CAN_MB[nn]_LENGTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	DLC	Data Length Code. The CAN_MB[nn]_LENGTH.DLC bits hold the DLC value of the received remote frame. The received value overwrites any previous value.

Mailbox Time Stamp Register

The CAN_MB[nn]_TIMESTAMP register holds an indication of the time of reception or transmission for each message, when the universal counter is in time stamp mode (CAN_UCCNF.UCCNF =0x1). In this mode, the CAN writes the value of the counter (CAN_UCCNT) to the CAN_MB[nn]_TIMESTAMP register when a received message is stored or a message is transmitted. For more information about time stamps, see the Time Stamps section.

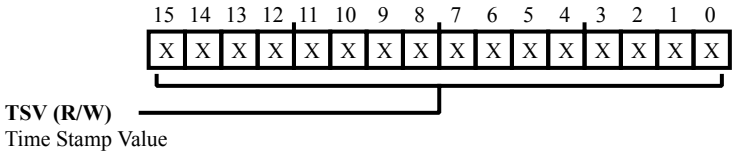

Figure 21-41: CAN_MB[nn]_TIMESTAMP Register Diagram

Table 21-36: CAN_MB[nn]_TIMESTAMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TSV	Time Stamp Value. The CAN_MB[nn]_TIMESTAMP.TSV bits hold the message time stamp value.

Mailbox Configuration 1 Register

The CAN_MC1 register enables mailboxes 0 through 15. Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN_TRS1 bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN_TRS1 bit is reset by the internal logic can cause unpredictable results.

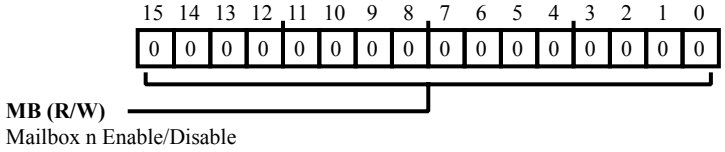

Figure 21-42: CAN_MC1 Register Diagram

Table 21-37: CAN_MC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Enable/Disable.

Mailbox Configuration 2 Register

The CAN_MC2 register enables mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN_TRS2 bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN_TRS2 bit is reset by the internal logic can cause unpredictable results.

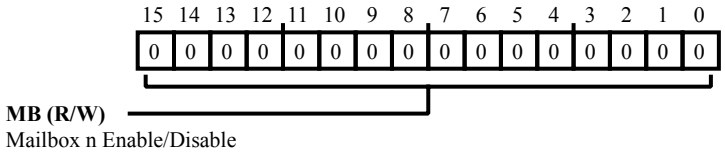

Figure 21-43: CAN_MC2 Register Diagram

Table 21-38: CAN_MC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Enable/Disable.

Mailbox Direction 1 Register

The CAN_MD1 register selects the data transfer direction for mailboxes 0 through 15. Each bit in this register selects receive mode or transmit mode for the corresponding mailbox. For all bits, set the bit (=1) for receive mode from the mailbox, and clear the bit (=0) for transmit mode to the mailbox. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

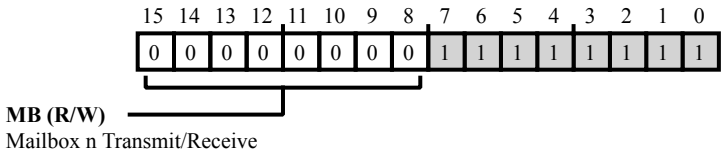

Figure 21-44: CAN_MD1 Register Diagram

Table 21-39: CAN_MD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	MB	Mailbox n Transmit/Receive.

Mailbox Direction 2 Register

The CAN_MD2 register selects the data transfer direction for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register selects receive mode or transmit mode for the corresponding mailbox. For all bits, set the bit (=1) for receive mode from the mailbox, and clear the bit (=0) for transmit mode to the mailbox. Bits 8 through 15 are read-only, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

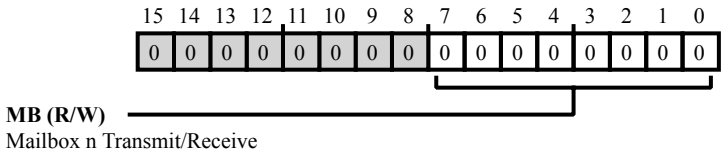

Figure 21-45: CAN_MD2 Register Diagram

Table 21-40: CAN_MD2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MB	Mailbox n Transmit/Receive.

Overwrite Protection/Single Shot Transmission 1 Register

The CAN_OPSS1 register enables overwrite protection for mailboxes 0 through 15. Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

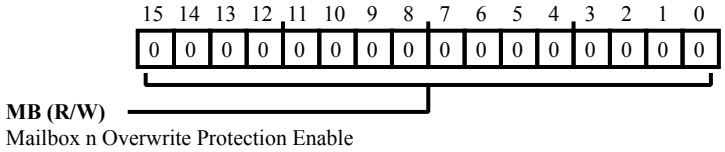

Figure 21-46: CAN_OPSS1 Register Diagram

Table 21-41: CAN_OPSS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Overwrite Protection Enable.

Overwrite Protection/Single Shot Transmission 2 Register

The CAN_OPSS2 register enables overwrite protection for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

Table 21-42: CAN_OPSS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Overwrite Protection Enable.

Remote Frame Handling 1 Register

The CAN_RFH1 register enables remote frame handling for mailboxes 8 through 15. Each bit in this register enables remote frame handling for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote frame handling, see the CAN Operating Modes sections, describing transmit and receive operations. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

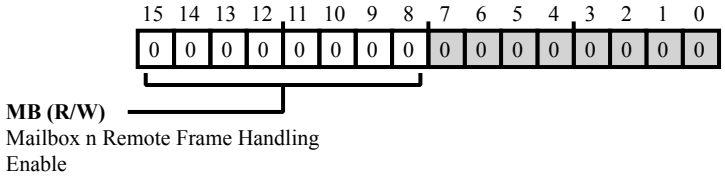

Figure 21-48: CAN_RFH1 Register Diagram

Table 21-43: CAN_RFH1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	MB	Mailbox n Remote Frame Handling Enable.

Remote Frame Handling 2 Register

The CAN_RFH2 register enables remote frame handling for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables remote frame handling for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote frame handling, see the CAN Operating Modes sections, describing transmit and receive operations.

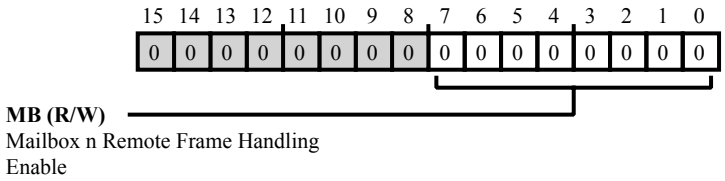

Figure 21-49: CAN_RFH2 Register Diagram

Table 21-44: CAN_RFH2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MB	Mailbox n Remote Frame Handling Enable.

Receive Message Lost 1 Register

The CAN_RML1 register indicates when a message is lost---due to a message coming while there is pending data (corresponding CAN_RMP1 bit set) and overwrite protection is disabled (CAN_OPSS1 bit cleared)---for mailboxes 0 through 15. Each bit in this register indicates the message lost status for the corresponding mailbox when set (=1).

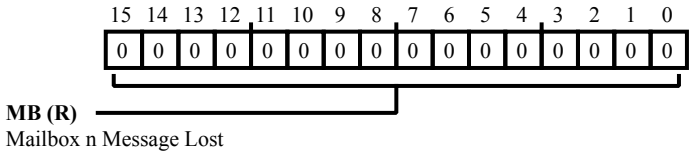

Figure 21-50: CAN_RML1 Register Diagram

Table 21-45: CAN_RML1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	MB	Mailbox n Message Lost.

Receive Message Lost 2 Register

The CAN_RML2 register indicates when a message is lost---due to a message coming while there is pending data (corresponding CAN_RMP2 bit set) and overwrite protection is disabled (CAN_OPSS2 bit cleared)---for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register indicates the message lost status for the corresponding mailbox when set (=1). Bits 8 through 15 are reserved, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

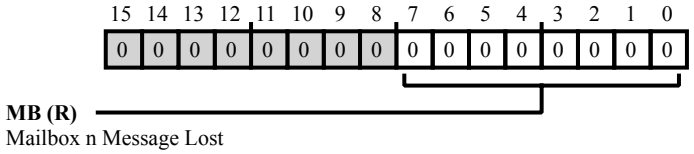

Figure 21-51: CAN_RML2 Register Diagram

Table 21-46: CAN_RML2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	MB	Mailbox n Message Lost.

Receive Message Pending 1 Register

The CAN_RMP1 register indicates when a message is pending (unread data) for mailboxes 0 through 15. Each bit in this register indicates the message pending status for the corresponding mailbox when set (=1).

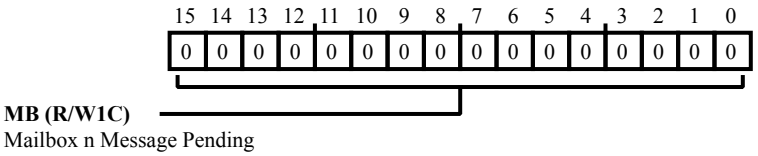

Figure 21-52: CAN_RMP1 Register Diagram

Table 21-47: CAN_RMP1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Message Pending.

Receive Message Pending 2 Register

The CAN_RMP2 register indicates when a message is pending (unread data) for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register indicates the message pending status for the corresponding mailbox when set (=1). Bits 8 through 15 are reserved, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

Table 21-48: CAN_RMP2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	MB	Mailbox n Message Pending.

Status Register

The CAN_STAT register indicates status for CAN modes and error conditions.

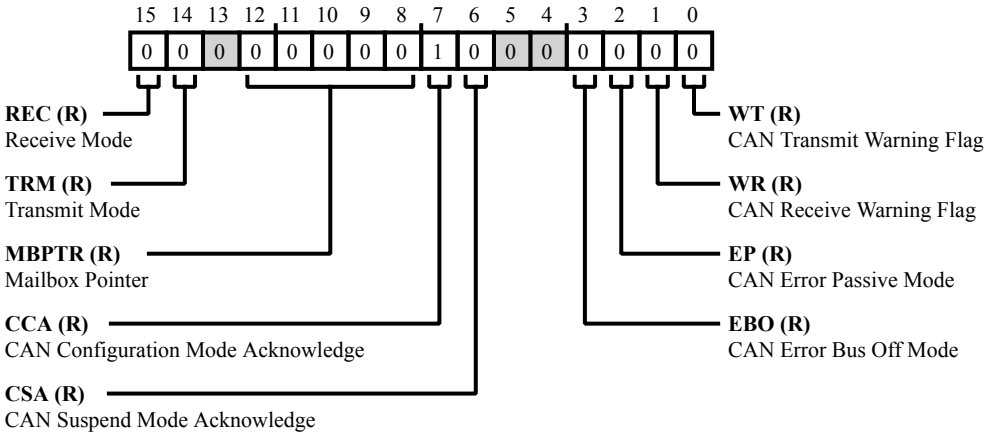

Figure 21-54: CAN_STAT Register Diagram

Table 21-49: CAN_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	REC	Receive Mode. The CAN_STAT.REC bit indicates whether the CAN is in receive mode.	
		0	Not in Receive Mode
		1	Receive Mode
14 (R/NW)	TRM	Transmit Mode. The CAN_STAT.TRM bit indicates whether the CAN is in transmit mode.	
		0	Not in Transmit Mode
		1	Transmit Mode
12:8 (R/NW)	MBPTR	Mailbox Pointer. The CAN_STAT.MBPTR bits represent the mailbox number of the current transmit message. After a successful transmission, these bits remain unchanged.	
		0-31	Processing Mailbox 0 to31 Message
7 (R/NW)	CCA	CAN Configuration Mode Acknowledge. The CAN_STAT.CCA bit indicates whether the CAN is in configuration mode.	
		0	Not in Configuration Mode
		1	Configuration mode

Table 21-49: CAN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/NW)	CSA	CAN Suspend Mode Acknowledge. The CAN_STAT.CSA bit indicates whether the CAN is in suspend mode.	
		0	Not in Suspend Mode
		1	Suspend mode
3 (R/NW)	EBO	CAN Error Bus Off Mode. The CAN_STAT.EBO bit indicates whether the CAN is in error bus off mode.	
		0	TXECNT Below 256
		1	TXECNT Above Bus Off Limit
2 (R/NW)	EP	CAN Error Passive Mode. The CAN_STAT.EP bit indicates whether the CAN is in error passive mode.	
		0	TXECNT and RXECNT Below 128
		1	TXECNT or RXECNT Above EP Level
1 (R/NW)	WR	CAN Receive Warning Flag. The CAN_STAT.WR bit indicates whether the CAN has detected a receive warning flag condition.	
		0	RXECNT Below Limit
		1	RXECNT at Limit
0 (R/NW)	WT	CAN Transmit Warning Flag. The CAN_STAT.WT bit indicates whether the CAN detected a transmit warning flag condition.	
		0	TXECNT Below Limit
		1	TXECNT at Limit

Transmission Acknowledge 1 Register

The CAN_TA1 register indicates transmission success for mailboxes 8 through 15. Each bit in this register indicates transmission success for the corresponding mailbox when set (=1). Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

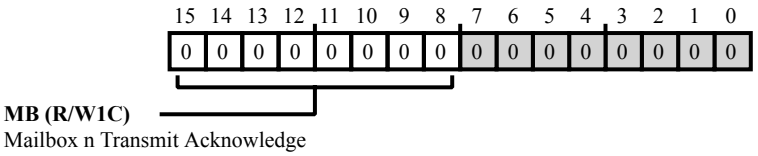

Figure 21-55: CAN_TA1 Register Diagram

Table 21-50: CAN_TA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W1C)	MB	Mailbox n Transmit Acknowledge.

Transmission Acknowledge 2 Register

The CAN_TA2 register indicates transmission success for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register indicates transmission success for the corresponding mailbox when set (=1).

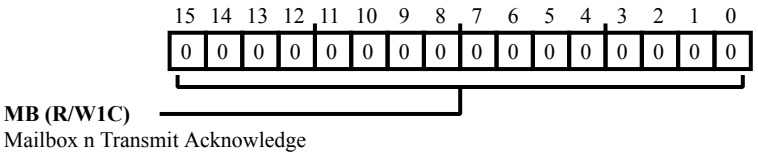

Figure 21-56: CAN_TA2 Register Diagram

Table 21-51: CAN_TA2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Transmit Acknowledge.

Timing Register

The CAN_TIMING register select the time segments, sampling, and synchronization for CAN bit timing. For more information about bit timing and clock operation, see the CAN Operating Modes section.

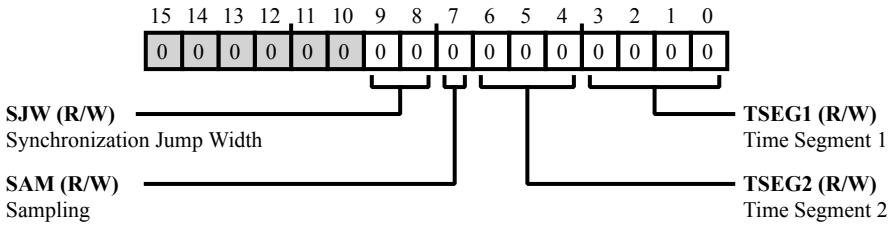

Figure 21-57: CAN_TIMING Register Diagram

Table 21-52: CAN_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:8 (R/W)	SJW	Synchronization Jump Width. The CAN_TIMING.SJW bits select the maximum number of time quanta, ranging from 1 to 4(SJW + 1). This selection allows for a re-synchronization attempt when the CAN detects a recessive-to-dominant edge outside the synchronization segment. The re-synchronization automatically moves the sampling point such that the CAN bit is still handled properly. Note that the CAN_TIMING.SJW value should not exceed CAN_TIMING.TSEG2 or CAN_TIMING.TSEG1.
7 (R/W)	SAM	Sampling. The CAN_TIMING.SAM bit selects whether the CAN performs normal sampling (once at the sampling point described by the CAN_TIMING register) or performs over sampling. If CAN_TIMING.SAM is set, the CAN over samples the input signal at three times at the SCLK rate. The resulting value is generated by a majority decision of the three sample values. Note that the CAN_TIMING.SAM bit should always be cleared if the CAN_CLK.BRP value is less than 4.
6:4 (R/W)	TSEG2	Time Segment 2. The CAN_TIMING.TSEG2 bits and CAN_TIMING.TSEG1 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.
3:0 (R/W)	TSEG1	Time Segment 1. The CAN_TIMING.TSEG1 bits and CAN_TIMING.TSEG2 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.

Transmission Request Reset 1 Register

The CAN_TRR1 register requests transmit abort for mailboxes 8 through 15. Bits in this register request transmit abort for the corresponding mailbox when set (=1). When a transmission completes, the corresponding bits in the transmit request set register (CAN_TRS1) and in the CAN_TRR1 are cleared. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

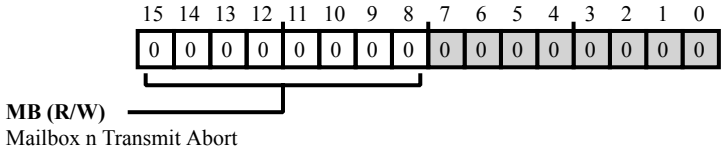

Figure 21-58: CAN_TRR1 Register Diagram

Table 21-53: CAN_TRR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	MB	Mailbox n Transmit Abort.

Transmission Request Reset 2 Register

The CAN_TRR2 register requests transmit abort for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register requests transmit abort for the corresponding mailbox when set (=1). When a transmission completes, the corresponding bits in the transmit request set register (CAN_TRS2) and in the CAN_TRR2 are cleared.

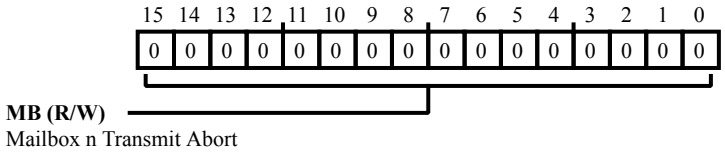

Figure 21-59: CAN_TRR2 Register Diagram

Table 21-54: CAN_TRR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Transmit Abort.

Transmission Request Set 1 Register

The CAN_TRS1 register requests transmit for mailboxes 8 through 15. Bits in this register request transmit for the corresponding mailbox when set (=1). After writing the data and the identifier into the mailbox area, the message is sent after mailbox n is enabled (with the corresponding bit in CAN_MC1 = 1), and (subsequently) the corresponding transmit request bit is set (in CAN_TRS1). When a transmission completes, the corresponding bits in CAN_TRS1 and in the transmit request reset register (CAN_TRR1) are cleared. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

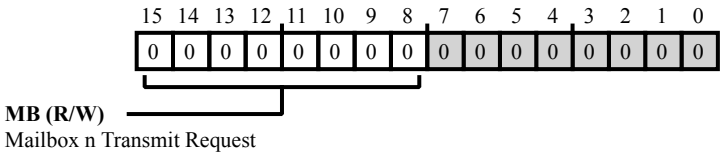

Figure 21-60: CAN_TRS1 Register Diagram

Table 21-55: CAN_TRS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	MB	Mailbox n Transmit Request.

Transmission Request Set 2 Register

The CAN_TRS2 register requests transmit for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register requests transmit for the corresponding mailbox when set (=1). After writing the data and the identifier into the mailbox area, the message is sent after mailbox n is enabled (with the corresponding bit in CAN_MC2 = 1), and (subsequently) the corresponding transmit request bit is set (in CAN_TRS2). When a transmission completes, the corresponding bits in CAN_TRS2 and in the transmit request reset register (CAN_TRR2) are cleared.

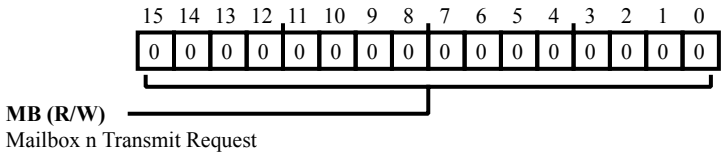

Figure 21-61: CAN_TRS2 Register Diagram

Table 21-56: CAN_TRS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Transmit Request.

Universal Counter Configuration Mode Register

The CAN_UCCNF register controls the operation of the universal counter, including counter enable and counter mode selection.

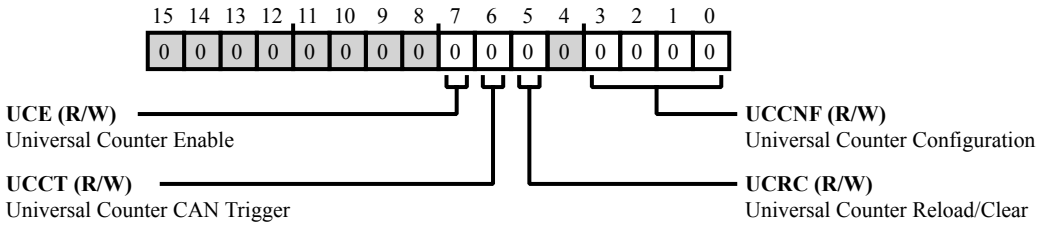

Figure 21-62: CAN_UCCNF Register Diagram

Table 21-57: CAN_UCCNF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	UCE	Universal Counter Enable. The CAN_UCCNF.UCE bit enables universal counter operation in the mode selected by the CAN_UCCNF.UCCNF bits.	
		0	Disable Counter
		1	Enable Counter
6 (R/W)	UCCT	Universal Counter CAN Trigger. The CAN_UCCNF.UCCT bit enables the universal counter trigger, directing the CAN to re-load the counter on mailbox 4 reception in watchdog mode and clear the counter on mailbox 4 reception in time stamp mode. This bit has no effect in all other modes.	
		0	Disable Trigger
		1	Enable Trigger
5 (R/W)	UCRC	Universal Counter Reload/Clear. The CAN_UCCNF.UCRC bit re-loads or clears the universal counter, depending on the counter mode. In watchdog mode, setting this bit directs the CAN to re-load the counter. In all other modes, setting this bit directs the CAN to clear the counter.	
		0	No Action
		1	Re-load or Clear the Counter
3:0 (R/W)	UCCNF	Universal Counter Configuration. The CAN_UCCNF.UCCNF bits select the universal counter operating mode. For more information about these modes, see the Operating Modes section.	
		0	Reserved
		1	Time Stamp Mode
		2	Watchdog Mode

Table 21-57: CAN_UCCNF Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	Auto-transmit Mode
		4	Reserved
		5	Reserved
		6	Count Error Frames
		7	Count Overload Frames
		8	Count Arbitration Lost
		9	Count Aborted Transmissions
		10	Count Successful Transmissions
		11	Count Rejected Receive Messages
		12	Count Receive Message Lost
		13	Count Successful Receptions
		14	Count Stored Receptions
		15	Count Valid Messages

Universal Counter Register

The CAN_UCCNT register holds the current universal count. This register is reloaded from the CAN_UCRC register when counter the decrements to zero in auto-transmit mode.

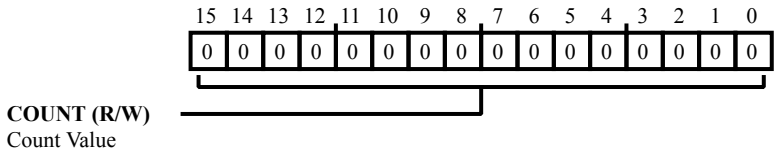

Figure 21-63: CAN_UCCNT Register Diagram

Table 21-58: CAN_UCCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	COUNT	Count Value. The CAN_UCCNT.COUNT bits hold the current universal count value.

Universal Counter Reload/Capture Register

The CAN_UCRC register holds the period value (universal count), which is used in auto-transmit mode as the period for sending the message in mailbox 11 (broadcast heartbeat) to all CAN nodes. Accordingly, messages sent this way usually have high priority.

The period value is written to the CAN_UCRC register. When auto-transmit mode is enabled (CAN_UCCNF.UCCNF = 0x3), the CAN loads the counter with the value in CAN_UCRC. The counter decrements to 0 at the CAN bit clock rate, then is reloaded. Each time the counter decrements to 0, the CAN sets the CAN_TRS1.MB bit for mailbox 11 and sends the corresponding message from mailbox 11.

Note that for auto-transmit mode, mailbox 11 must be configured as a transmit mailbox and must contain valid data (identifier, control bits, and data). This setup must occur before the counter first expires after this mode is enabled.

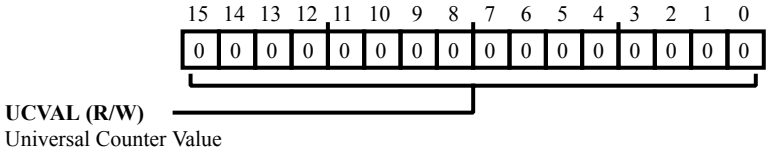

Figure 21-64: CAN_UCRC Register Diagram

Table 21-59: CAN_UCRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	UCVAL	Universal Counter Value. The CAN_UCRC.UCVAL bits hold the value for the universal count period, which is used in auto-transmit mode.

22 Mobile Storage Interface (MSI)

The mobile storage interface (MSI) is a fast, synchronous controller that uses various protocols to communicate with MMC, SD, and SDIO cards. It addresses the growing storage need in embedded systems, handheld, and consumer electronics applications that require low power. The MSI is compatible with the following protocols.

- MMC (Multimedia Card) bus protocol
- SD (Secure Digital) bus protocol
- SDIO (Secure Digital Input Output) bus protocol

All of these storage solutions use similar interface protocols. The main difference between MMC and SD support is the initialization sequence. The main difference between SD and SDIO support is the use of interrupt and read wait signals for SDIO.

NOTE: The MSI does not support the SPI bus protocol.

MSI Features

The MSI includes the following features.

- Supports Secure Digital memory protocol (version 3.0)
- Supports Secure Digital I/O protocol (version 3.0)
- Supports Multimedia Card protocol (MMC version 4.41, eMMC version 4.5)
- Support for a single SD or SDIO card
- Support for a single MMC device (removable or embedded)
- Support for 1-bit and 4-bit SD modes (SPI mode is not supported)
- Support for 1-, 4-, and 8-bit MMC modes (SPI mode is not supported)
- Supports MMC boot operation
- Supports SDIO interrupts
- Supports command completion signal and interrupt to host processor

- Supports CRC generation and error detection
- 1024-byte transmit/receive FIFO
- Integrated DMA controller
- Card detection capabilities
- Programmable clock frequency
- Supports power management and clock control.

MSI Functional Description

This section provides information on the function of the MSI module.

MMC booting

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards and is performed in push-pull mode. Also alternate Boot Operation; removable MMC4.3 card.

CRC generation and error detection

Cyclic redundancy codes (CRC) are used to protect commands, responses, and data transfers from transmission errors.

FIFO controller

Interfaces the internal FIFO to the host or DMA interface and the card controller unit. The FIFO depth is configured for 1024 bytes

Integrated DMA controller

Contains a single transmit or receive engine, which transfers data from host memory to the device port and conversely. The controller uses a descriptor to move data efficiently from source to destination with minimal core intervention

Power management and clock control

A low-power mode is available. A clock control block provides the clock frequencies required for SD/MMC cards

ADSP-SC57x MSI Register List

The Mobile Storage Interface (MSI) supports access to mobile memory and devices. A set of registers governs MSI operations. For more information on MSI functionality, see the MSI register descriptions.

Table 22-1: ADSP-SC57x MSI Register List

Name	Description
MSI_BLKSIZ	Block Size Register
MSI_BUFADDR	Current Buffer Descriptor Address Register
MSI_BUSMODE	Bus Mode Register
MSI_BYTCNT	Byte Count Register
MSI_CDETECT	Card Detect Register
MSI_CDTHRCTL	Card Threshold Control Register
MSI_CLKDIV	Clock Divider Register
MSI_CLKEN	Clock Enable Register
MSI_CMD	Command Register
MSI_CMDARG	Command Argument Register
MSI_CTL	Control Register

MSI Block Diagram

The ***MSI Block Diagram*** shows the functional blocks within the MSI. These blocks are described in more detail in the MSI Architectural Concepts section.

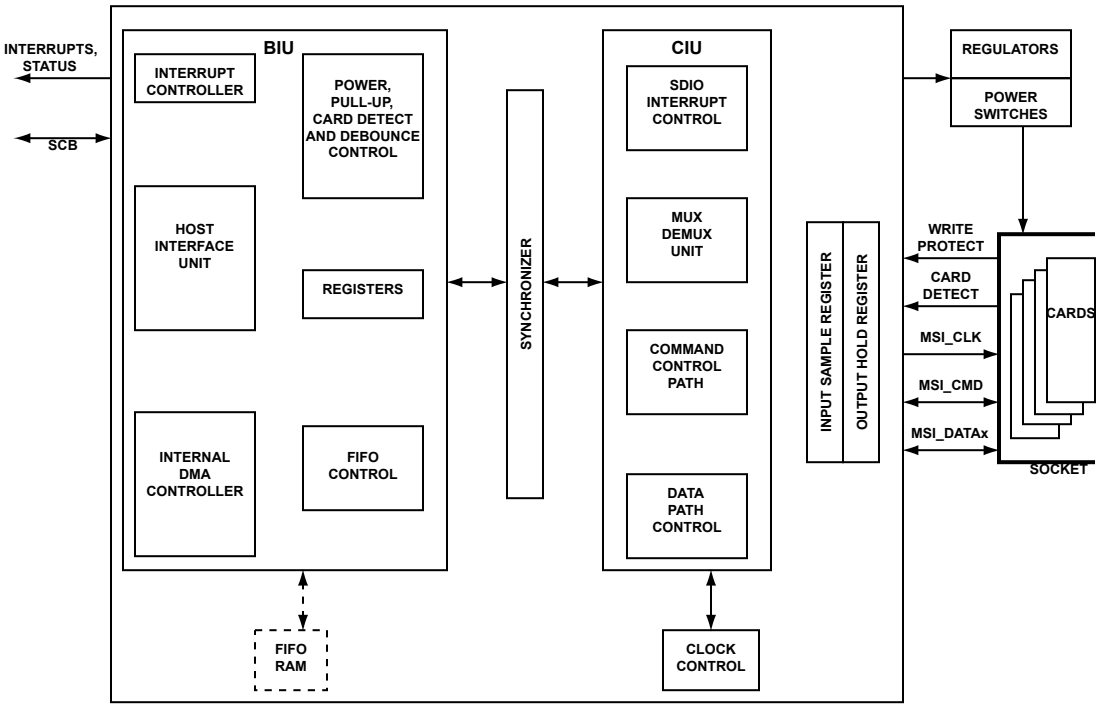

Figure 22-1: MSI Block Diagram

NOTE: The card-detect and write-protect signals are from the SD/MMC card socket and not from the SD/MMC card.

MSI Architectural Concepts

The following sections describe the functions and features of the MSI controller as well as the MMC, SD, and SDIO protocols.

Communication is through a master and slave configuration, where the MSI is the master device and the card is the slave device. The MSI communicates with the device using a message-based bus protocol in which the host sends commands serially using the `MSI_CMD` signal. Some commands require that the card provide a response back to the host. This response is also sent serially on the `MSI_CMD` signal.

Data transfers, both to and from the card, occur using the data signals. The number of data lines used for the data transfer can be configured to 1 (`MSI_D0`), 4 (`MSI_D3–MSI_D0`), or 8 (`MSI_D7–MSI_D0`). All `MSI_CMD` and `MSI_D7–MSI_D0` transfers are synchronous with `MSI_CLK`. Cyclic redundancy codes (CRC) are used to protect commands, responses, and data transfers from transmission errors. A CRC7 code is generated for every command sent by the host and for almost every response returned by the card on the `MSI_CMD` signal.

The MSI architecture can be described in terms of its submodules. The primary parts of the architecture are:

- Bus Interface Unit (BIU). This unit provides the host interface to the registers through the Host Interface Unit (HIU). Additionally, it provides independent data FIFO access through a DMA interface.

- Internal Direct Memory Access Controller (IDMAC). This unit is responsible for exchanging data between the FIFO and the host memory. A set of IDMAC registers is accessible to the host for controlling the IDMAC operation.
- Card Interface Unit (CIU). This unit controls the card-specific protocols. Within the CIU, the command path control unit and datapath control unit interface the controller to the command and data ports of the SD/MMC/SDIO cards. The CIU also provides clock control.

Bus Interface Unit (BIU)

The BIU provides the following functions:

- Host interface
- Interrupt control
- Register access
- FIFO access
- Power and pull-up control and card detection

Host Interface Unit (HIU)

The Host Interface Unit (HIU) is a slave bus interface, which provides the interface between the MSI and the processor system bus. It supports the burst accesses to the data FIFO address region only. The register address region is accessed through the standard accesses.

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the controller interrupt status, the interrupt-mask register, and the global interrupt-enable register bit. Once an interrupt condition is detected, the software sets the corresponding interrupt bit in the interrupt status register. The interrupt status bit remains set until the software clears it by writing a 1 to the interrupt bit (a 0 leaves the bit unchanged).

NOTE: Before enabling the interrupt, programs must write 32'hFFFF_FFFF to the interrupt status register (`MSI_ISTAT`) in order to clear any pending unserviced interrupts. When clearing interrupts during normal operation, only clear the interrupt bits that are serviced.

Register Unit

The register unit is part of the Bus Interface Unit (BIU). It provides read and write access to the registers.

All registers reside in the BIU clock domain. When a command is sent to a card by setting the `MSI_CMD.STARTCMD` bit, all relevant registers needed for the CIU operation are transferred to the CIU block. (The `MSI_CMD.STARTCMD` bit is bit[31] of the `MSI_CMD` register). During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to clear the start bit before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.

Once a command start is issued by setting the `MSI_CMD.STARTCMD` bit, the following registers cannot be reprogrammed until the Card Interface Unit (CIU) accepts the command:

- MSI_CMD – Command
- MSI_CMDARG – Command Argument
- MSI_BYTCNT – Byte Count
- MSI_BLKSIZ – Block Size
- MSI_CLKDIV – Clock Divider
- MSI_CLKEN – Clock Enable
- MSI_TMOUT – Timeout
- MSI_CTYPE – Card Type

The hardware resets the MSI_CMD.STARTCMD bit once the CIU accepts the command. If a host writes to any of these registers during this locked time, then the write is ignored and the hardware lock error bit is set in the MSI_ISTAT (status) register. Additionally, if the interrupt is enabled and not masked for a hardware lock error, then an interrupt is sent to the host.

Once a command is accepted, software can send another command to the CIU which has a one-deep command queue under the following conditions:

- If the previous command was not a data transfer command, the new command is sent to the card once the previous command completes.
- If the previous command is a data transfer command and if the MSI_CMD.WTPRIVDATA bit is set for the new command, the new command is sent to the card only when the data transfer completes.
- If the MSI_CMD.WTPRIVDATA is 0, then the new command is sent to the card as soon as the previous command is sent. Typically, software uses this option only to stop or abort a previous data transfer or query the card status in the middle of a data transfer.

FIFO Controller Unit

The FIFO controller interfaces the internal FIFO to the host or DMA interface and the card controller unit. The FIFO depth is configured for 1024 bytes. A single shared FIFO is used for read and write operations because read and write transfers to the cards do not occur simultaneously.

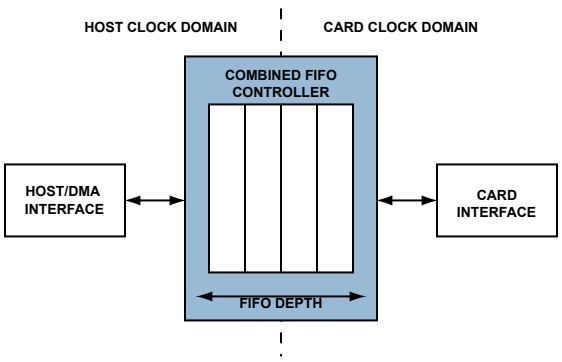

Figure 22-2: Combined Transmit and Receive FIFO

Power and Pull-up Control and Card Detection Unit

The card detection unit looks for any changes in the card-detect signal for card insertion or card removal. The unit filters out the debounce associated with mechanical insertion or removal, and generates one interrupt to the host. The debounce filter value is programmed through the MSI_DEBNCE register.

On power-on, the controller reads in the MSI_CDETECT register and stores the value in the memory. Upon receiving a card-detect interrupt, the controller again reads the MSI_CDETECT register to decide whether card was removed or inserted. The ***Card-Detect Signals*** figure shows the timing for the card-detect signal.

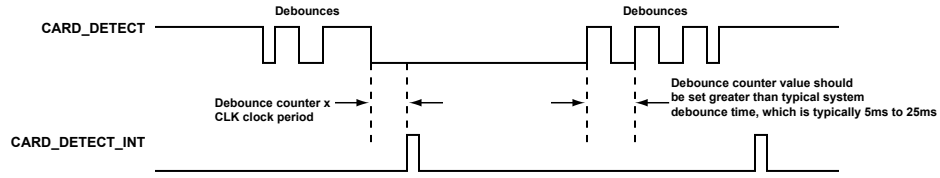

Figure 22-3: Card-Detect Signals

Internal Direct Memory Access Controller (IDMAC)

The Internal Direct Memory Access Controller (IDMAC) contains a single transmit or receive engine, which transfers data from the host memory to the device port and conversely. The controller uses a descriptor to move data efficiently from source to destination with minimal core intervention. Programs can configure the controller to interrupt the core in situations such as data transmit and receive transfer completion from the card, as well as other normal or error conditions.

The IDMAC and the core communicate through a single data structure. The IDMAC transfers the data received from the card to the data buffer in the host memory, and it transfers transmit data from the data buffer in the host memory to the MSI FIFO. Descriptors that reside in the memory act as pointers to these buffers.

A data buffer resides in physical memory space of the processor and consists of complete data or partial data. Buffers contain only data, while buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data.

A single descriptor is used for both reception and transmission. The base address of the list is written into descriptor list base address register (MSI_DBADDR). A descriptor list is forward-linked. The last descriptor can point back to the first entry creating a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.

Programs can enable or disable the IDMAC using the MSI_CTL.INTDMAC bit of the BIU.

DMA Descriptors

The IDMAC uses two types of descriptor structures:

- Dual-Buffer Structure – The skip length value programmed in the MSI_BUSMODE.DSL bit field determines the distance between two descriptors.
- Chain Structure – Each descriptor points to a unique buffer and the next descriptor.

The ***Dual-Buffer Descriptor Structure*** and ***Chain Descriptor Structure*** figures show these descriptor structures.

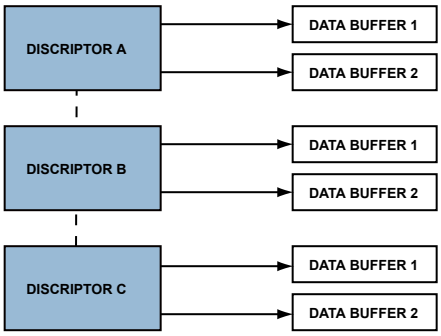

Figure 22-4: Dual-Buffer Descriptor Structure

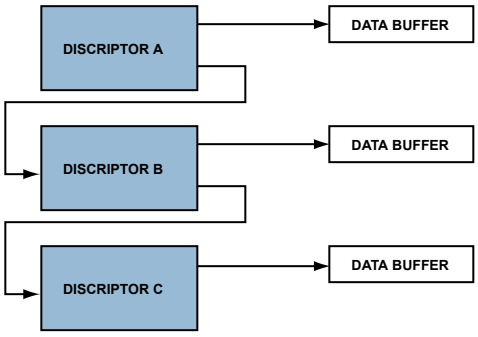

Figure 22-5: Chain Descriptor Structure

The ***Descriptor Format*** figure illustrates the internal format of a descriptor. The descriptor addresses must align with the 32-bit bus width. Each descriptor contains 16 bytes of control and status information. DES0 is a notation used to denote the [31:0] bits, DES1 to denote [63:32] bits, DES2 to denote [95:64] bits, and DES3 to denote [127:96] bits in a descriptor.

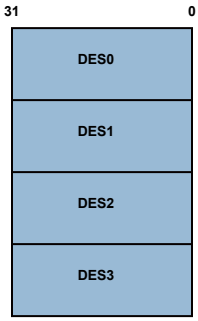

Figure 22-6: Descriptor Format

The following tables provide descriptor bit descriptions. Bits not shown are reserved. The DES0 descriptor in the IDMAC (described in the ***IDMAC DES0 Descriptor*** table) contains control and status information.

Table 22-5: IDMAC DES0 Descriptor

Bits	Name	Description
31	OWN	When set, this bit indicates that the IDMAC owns the descriptor. When this bit is reset, it indicates that the host owns the descriptor. The IDMAC clears this bit when it completes the data transfer.
30	Card Error Summary (CES)	This error bit indicates the status of the transaction to or from the card. This bit is also present in the MSI_ISTAT register and indicates the logical OR of the following bits: EBE: End bit error RTO: Response timeout RCRC: Response CRC SBE: Start bit error DRTO: Data Read timeout DCRC: Data CRC for receive RE: Response error
5	End of Ring (ER)	When set, this bit indicates that the descriptor list reached its final descriptor. The IDMAC returns to the base address of the list, creating a descriptor ring. This feature is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, BS2 (DES1[25:13]) is all zeros.
3	First Descriptor (FS)	When set, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.
2	Last Descriptor (LD)	This bit is associated with the last block of a DMA transfer. When set, the bit indicates that the buffers pointed to by this descriptor are the last buffers of the data. After this descriptor is completed, the remaining byte count is 0. In other words, after the descriptor with the LD bit set is completed, the remaining byte count is 0.
1	Disable Interrupt on Completion (DIC)	When set, this bit prevents the setting of the TI/RI bit of the IDMAC Status Register (IDSTS) for the data that ends in the buffer pointed to by this descriptor.

The DES1 descriptor (described in the ***IDMAC DES1 Descriptor*** table) contains the buffer size.

Table 22-6: IDMAC DES1 Descriptor

Bits	Name	Description
25:13	Buffer 2 Size (BS2)	These bits indicate the second data buffer byte size which must be a multiple of 4. In the case where the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and proceeds to the next buffer if there is a dual-buffer structure. This field is not valid for chain structure; that is, if DES0[4] is set.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size which must be a multiple of 4. In the case where the buffer size is not a multiple of 4, the resulting behavior is undefined. This field must not be zero. Note: If there is only one buffer to be programmed, use only the buffer 1, and not buffer 2.

The DES2 descriptor (described in the ***IDMAC DES2 Descriptor*** table) is the address pointer to the data buffer.

Table 22-7: IDMAC DES2 Descriptor

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The IDMAC ignores DES2 [1:0], internally.

The DES3 descriptor (described in the ***IDMAC DES3 Descriptor*** table) is the address pointer to the next descriptor when the present descriptor is not

- the last descriptor in a chained descriptor structure, or
- the second buffer address for a dual-buffer structure

Table 22-8: IDMAC DES3 Descriptor

Bits	Name	Description
31:0	Buffer Address Pointer 2/ Next Descriptor Address (BAP2)	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set, then this address contains the pointer to the physical memory where the next descriptor is present. If this pointer is not the last descriptor, then the next descriptor address pointer must be bus-width aligned (DES3[1:0] = 0. Internally, the LSBs are ignored.

Initialization

IDMAC initialization occurs as follows.

1. Write to IDMAC bus mode register (`MSI_BUSMODE`) to set host bus access parameters.
2. Write to IDMAC interrupt enable register (`MSI_IDINTEN`) to mask unnecessary interrupt causes.
3. The software driver creates either the transmit or the receive descriptor list. Then it writes to IDMAC descriptor list base address register (`MSI_DBADDR`), which provides the IDMAC the starting address of the list.
4. The IDMAC engine attempts to acquire descriptors from the descriptor lists.

Host Bus Burst Access

The IDMAC executes fixed-length burst transfers on the bus interface when the `MSI_BUSMODE.FB` bit =1. The maximum burst length is indicated and limited by the `MSI_BUSMODE.PBL` bit field. The descriptors are always accessed in the maximum burst-size for the 16-bytes to be read (4-word burst).

The IDMAC initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO or the number of bytes to the end of data, when less than the configured burst-length. The IDMAC indicates the start address and the number of transfers required to the bus interface. When the bus interface is configured for fixed-length bursts, it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. Otherwise, in no fixed-length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.

The transmit and receive data buffers must be aligned to data bus width (32-bit).

NOTE: Due to the bus protocol limitation, the burst mode address should not cross the 1 KB boundary. Address [31:10] should not change during a burst.

Buffer Size Calculations

The software knows the amount of data to transmit or receive. For transmitting to the card, the IDMAC transfers the exact number of bytes to the FIFO, indicated by the buffer size field of DES1.

If a descriptor is not marked as last (LS bit of DES0), then the corresponding buffers of the descriptor are full. Its buffer size field indicates the amount of valid data in a buffer. If a descriptor is marked as last, then the buffer cannot be full, as indicated by the buffer size in DES1. The software is aware of the number of locations that are valid in this case.

Data Transmit/Receive

IDMAC transmission occurs as follows:

1. The software sets up the descriptor (DES0–DES3) for transmission and sets the OWN bit (DES0[31]). The software also prepares the data buffer.
2. The software programs the write data command in the `MSI_CMD` register in the BIU.
3. The software also programs the required transmit threshold level (`MSI_FIFOTH.TXWM` bit field).
4. The IDMAC determines that a write data transfer must occur as a consequence of step 2.
5. The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the software owns the descriptor. In this case, the IDMAC enters the suspend state and asserts the `MSI_IDSTS.DU` bit. The software must release the IDMAC by writing any value to the poll demand register.
6. It then waits for command done (`MSI_ISTAT.CMDDONE`) bit and no errors from BIU which indicates that a transfer can occur.
7. The IDMAC engine waits for a DMA interface request from the BIU. This request is generated based on the programmed transmit threshold value. For the last bytes of data which cannot be accessed using a burst, SINGLE transfers are performed.
8. The IDMAC fetches the transmit data from the data buffer and transfers it to the FIFO for transmission to the card.
9. When data spans across multiple descriptors, the IDMAC fetches the next descriptor and continues with its operation with the next descriptor. The last descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10. When data transmission is complete, status information is updated in IDMAC status register (`MSI_IDSTS`) by setting the transmit interrupt, when enabled. Also, the IDMAC performs a write transaction to DES0 to clear the OWN bit.

IDMAC reception occurs as follows:

1. The software sets up the Descriptor (DES0–DES3) for reception, sets the OWN bit (DES0[31]).

2. The software programs the read data command in the MSI_CMD register in the BIU.
3. The software programs the required receive threshold level (MSI_FIFOTH.RXWM bit field).
4. The IDMAC determines that a read data transfer must occur as a consequence of step 2.
5. The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the host owns the descriptor. In this case, the DMA enters suspend state and asserts the release the IDMAC by writing any value to the poll demand register.
6. It then waits for the command done (MSI_ISTAT.CMDDONE) bit and no errors from BIU which indicates that a transfer can occur.
7. The IDMAC engine waits for a DMA interface request from the BIU. This request is generated based on the programmed receive threshold value. For the last bytes of data which cannot be accessed using a burst, SINGLE transfers are performed.
8. The IDMAC fetches the data from the FIFO and transfers to the memory.
9. When data spans across multiple descriptors, the IDMAC fetches the next descriptor and continues with its operation with the next descriptor. The last descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10. When data reception is complete, status information is updated in the IDMAC status register (MSI_IDSTS) by setting the receive interrupt, when enabled. Also, the IDMAC performs a write transaction to DES0 to clear the OWN bit.

Interrupts

Interrupts can be generated as a result of various DMAC events. The IDMAC status register (MSI_IDSTS) contains all the bits that can cause an interrupt. The IDMAC interrupt enable register (MSI_IDINTEN) contains an enable bit for each of the events that can cause an interrupt.

There are two groups of summary interrupts—normal and abnormal—as outlined in the MSI_IDSTS register. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

Interrupts are not queued and if the interrupt event occurs before the software has responded to it, no additional interrupts are generated. For example, the receive interrupt (MSI_IDSTS.RI) indicates that one or more data was transferred to the buffer. An interrupt is generated only once for simultaneous, multiple events. The software must scan the MSI_IDSTS register for the interrupt cause.

NOTE: The final interrupt signal from MSI is a logical OR of the interrupt from the BIU and the IDMAC.

Finite State Machine (FSM)

The IDMAC finite state machine can be in any one of the states reflected in the MSI_IDSTS.FSM bit field.

The FSM uses the following sequence.

1. IDMAC performs four accesses for fetching the descriptor.

2. Stores descriptors in internal register and also issues a FIFO reset when it is first descriptor.
3. Each bit is checked for correctness. In case of bit mismatches, appropriate error bit is set. If it is first descriptor, then issues a FIFO reset and wait until FIFO reset is complete. The error status indicates one of the following:
    - Response timeout
    - Response CRC error
    - Data receive timeout
    - Response error
4. The FSM waits in current state until DMA request is asserted, which implies that, FIFO:
    - For DMA write request wait – Holds the number of data, indicated by FIFO RX watermark. In case of error due to response timeout or error, FSM goes to DESC_CLOSE state to close descriptor.
    - For DMA read request wait – Holds number of data, indicated by FIFO TX watermark. In case of error, FSM goes to DESC_CLOSE state to close descriptor.
5. FSM performs the following:
    - For DMA write – Requests a write to SCB. If number of beats in one transfer is greater than PBL, then one of the following occurs:

      Burst count to SCB is PBL value

      Single transfers are initiated
    - For DMA read – Requests a read from SCB. If number of beats in one transfer is greater than PBL, then one of the following occurs:

      Burst count to SCB is PBL value

      Single transfers are initiated
6. After the programmed transfer count is accessed from the memory, the OWN bit in descriptor is closed. If a transfer spans more than one descriptor, the FSM fetches the next descriptor. If the transfer ends with the current descriptor, the FSM goes to the idle state after setting the receive or transmit interrupt. Depending on the descriptor structure—dual buffer or chained—the appropriate starting address of descriptor is loaded. If it is the second data buffer of the dual buffer, the descriptor is not fetched again.

Abort Operation

The host issues CMD12 when a data transfer on the card data lines is in progress. The FSM closes the present descriptor after completing the transfer of data until a DTO interrupt is asserted. Once an abort command is issued, the DMAC performs single burst transfers.

1. For a card write, the FSM keeps pushing data to the FIFO after fetching it from the memory until a DTO interrupt is asserted. The controller asserts a busy clear interrupt after the DTO interrupt. It ensures that the card has completed driving the busy signal. This sequence occurs to keep the card clock running so that CMD12 is reliably sent to the card.

2. For a card read, the FSM keeps popping data from the FIFO and writes to the memory until a DTO interrupt is generated. This sequence is required since the DTO interrupt is not generated until and unless all the FIFO data is emptied.

NOTE: If an FBE occurs, the IDMAC FSM does not close the current descriptor and the remaining unread descriptors.

If a write abort occurs, the IDMAC FSM closes only the current descriptor during which the abort occurred. The IDMAC FSM does not close the current descriptor and the remaining unread descriptors.

If a read abort occurs, the IDMAC FSM pops the data out of the FIFO and writes it to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.

FIFO Overflow and Underflow

During normal data transfer conditions, FIFO overflow and underflow do not occur. If there is a programming error, then a FIFO overflow or underflow can result as shown in the following examples.

Transmit settings: `MSI_BUSMODE.PBL` =4, `MSI_FIFOTH.TXWM` =1

In this example, if the FIFO has only one location empty, it issues a DMA request to the IDMAC FSM. Because `MSI_BUSMODE.PBL` =4, the IDMAC FSM performs 4 pushes into the FIFO which results in a FIFO overflow interrupt.

Receive settings: `MSI_BUSMODE.PBL` =4, `MSI_FIFOTH.RXWM` =1

In this example, if the FIFO has only one location filled, it issues a DMA request to the IDMAC FSM. Because `MSI_BUSMODE.PBL` =4, the IDMAC FSM performs 4 pops to the FIFO which results in a FIFO underflow interrupt.

The software must ensure that the number of bytes to be transferred as indicated in the descriptor are a multiple of 4. For example, if the `MSI_BYTCNT` register =13, the number of bytes indicated in the descriptor must be 16.

Card Interface Unit

The Card Interface Unit (CIU) interfaces with the Bus Interface Unit (BIU) on one side and with the SD/MMC/SDIO cards or devices on other side. The software writes command parameters to the MSI BIU control registers, and these parameters are then passed to the CIU. Depending on control register values, the CIU generates card command and data traffic on a selected card bus according to card protocol.

As shown in the MSI Block Diagram, the CIU consists of the following primary functional blocks:

- Command path
- Datapath
- SDIO interrupt control
- Clock control
- Multiplex or demultiplex unit

The following software restrictions must be met for proper CIU operation:

- Only one data transfer command can be issued at a time.
- During an open-ended card write operation, if the card clock is stopped because the FIFO is empty, the software must first fill the data into the FIFO and start the card clock. It can then issue only a stop or abort command to the card.
- During an SDIO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO and start the resume command as if it were a new data transfer command.
- When issuing card reset commands (CMD0, CMD15 or CMD52) while a card data transfer is in progress, the software must set the `MSI_CMD.STPABORTCMD` bit so that the MSI can stop the data transfer after issuing the card reset command.
- When the data end error bit (`MSI_ISTAT.EBE`) is set, the MSI does not guarantee SDIO interrupts. The software must ignore the SDIO interrupts and issue the stop or abort command to the card, so that the card stops sending the read data.
- If the card clock is stopped because the FIFO is full during a card read, the software or DMA must read at least two FIFO locations to start the card clock.

Command Path

The command path performs the following functions.

- Loads clock parameters
- Loads card command parameters
- Sends commands to card bus
- Receives responses from card bus
- Sends responses to BIU
- Drives the P-bit on command line

A new command is issued to the MSI by programming the BIU registers and setting the `MSI_CMD.STARTCMD` bit. The command path loads this new command (command, command argument, timeout) and sends acknowledge to the BIU.

Once the new command is loaded, the command path state machine sends a command to the SD/MMC bus (this includes the internally generated CRC7). The command path state machine receives a response if there is any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command.

Load Command Parameters

One of the following commands or responses is loaded in the command path:

- New command from BIU when the `MSI_CMD.STARTCMD` bit is set.

- Internally generated auto-stop command when the data path ends, the stop command request is loaded.
- IRQ response with RCA =0x000 when the command path is waiting for an IRQ response from the MMC card, then the MSI_CTL.IRQRESP bit is set.

Loading a new command from the BIU in the command path depends on the following MSI_CMD register bit settings:

- Update clock registers only using the MSI_CMD.UCLKREGS bit. If the MSI_CMD.UCLKREGS bit =1, the command path updates only the clock enable and clock divider registers. If MSI_CMD.UCLKREGS =0, the command path loads the command, command argument, and timeout registers, then starts processing the new command.
- Wait for previous data to complete using the MSI_CMD.WTPRIVDATA bit. If the MSI_CMD.WTPRIVDATA bit =1, the command path loads the new command under one of the following conditions:
  - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (MSI_BYTCNT =0).
  - After completion of the current data transfer, if a predefined data transfer is in progress.

Send Command and Receive Response

Once a new command is loaded in the command path with MSI_CMD.UCLKREGS bit =0, the command path state machine sends out a command on the SD/MMC bus. The ***SD_MMC Command Path State Machine*** figure illustrates the command path state machine.

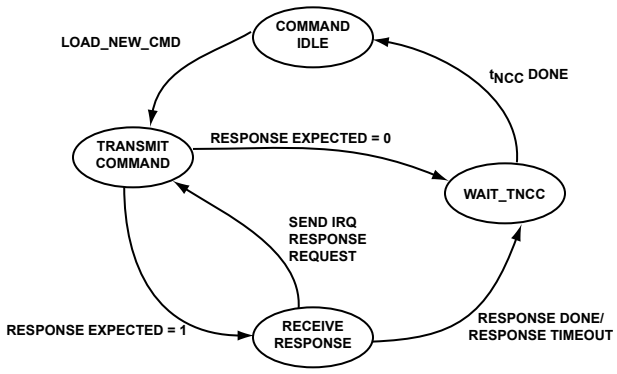

Figure 22-7: SD_MMC Command Path State Machine

The command path state machine performs the following functions, according to following command register bit values:

1. MSI_CMD.SENDINIT (send initialization). Initialization sequence of 80 clocks is sent before sending the command.
2. MSI_CMD.RXPECT (response expected). A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start

bit of the card response is not received within the number of clocks programmed in the timeout register, then the MSI_ISTAT.RTO(response timeout) and MSI_ISTAT.CD (command done) bits are set as a signal to the BIU. If the MSI_CMD.RXPECT bit is not set, the command path sends out a command and signals a response done to the BIU, that is, the MSI_ISTAT.CD bit is set.

3. MSI_CMD.RLEN (response length). If =1, a 136-bit response is received; if =0, a 48-bit response is received.
4. MSI_CMD.CHKRESPCRC (check response CRC). If =1, the command path compares CRC7 received in the response with the internally-generated CRC7. If the two do not match, the response CRC error is signaled to the BIU, that is, the response CRC error bit (MSI_ISTAT.RCRC) is set.

Send Response to BIU

If the MSI_CMD.RXPECT bit =1, the received response is sent to the BIU. The MSI_RESP0 register is updated for a short response, and the MSI_RESP3, MSI_RESP2, MSI_RESP1, and MSI_RESP0 registers are updated on a long response, after which the MSI_ISTAT.CMDDONE bit is set. If the CIU sends an auto-stop command as a response, the response is saved in the MSI_RESP1 register, after which the MSI_ISTAT.ACD (auto command done) bit is set.

Additionally, the command path checks for the following.

- Transmission bit =0
- Command index in response matches command index of the sent command
- End bit =1 in received card response

The command index is not checked for a 136-bit response or if the MSI_CMD.CHKRESPCRC bit is cleared. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved (=111111).

Driving a P-bit on CMD Line

The command path drives a P-bit =1 on the CMD line between two commands when a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command.

Datapath

The datapath block pops the data FIFO and transmits data on MSI data lines during a write data transfer. Or, it receives data from data lines and pushes it into the FIFO during a read data transfer. Whenever a data transfer command is not in-progress, the datapath loads new data parameters;

- data expected
- read/write data transfer
- stream or block transfer
- block size
- byte count

- card type
- timeout registers

If the MSI_CMD.DXPECT bit =1, the new command is a data transfer command and the datapath starts one of the following:

- Data transmit if the MSI_CMD.RDWR (read/write) bit =1
- Data receive if MSI_CMD.RDWR (read/write) bit 0

Auto-Stop

The MSI internally generates a stop command and is loaded in the command path when the MSI_CMD.SENDASTOP bit is set. The auto-stop command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for the SD memory transfer for SD cards.

The software must set the MSI_CMD.SENDASTOP bit according to details listed in the ***Auto-Stop Generation*** table.

Table 22-9: Auto-Stop Generation

Card Type	Transfer Type	Byte Count	**MSI_CMD.SENDASTOP bit =1**	Comments
MMC	Stream read	0	No	Open-ended stream
	Stream read	>0	Yes	Auto-stop after all bytes transfer
	Stream write	0	No	Open-ended stream
	Stream write	>0	Yes	Auto-stop after all bytes transfer
	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	Yes[*1]	Pre-defined multiple block
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	Yes	Pre-defined multiple block
SDMEM	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	Yes	Auto-stop after all bytes transfer
SDIO	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal

Table 22-9: Auto-Stop Generation (Continued)

Card Type	Transfer Type	Byte Count	**MSI_CMD. SENDASTOP bit =1**	Comments
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	No	Pre-defined multiple block
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	No	Pre-defined multiple block

*1 The condition under which the transfer mode blocks transfer and `byte_count` equals block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n × block_size (n = 2, 3, …), the condition is treated as a predefined multiple-block data transfer command. For an MMC card, the host software can perform a predefined data transfer in two ways:

1. Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the `MSI_CMD.SENDASTOP` bit.
2. Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the `MSI_CMD.SENDASTOP` bit set. In this case, an internally generated auto-stop command after the programmed byte count terminates the multiple-block data transfer.

The following list explains different conditions for the auto-stop command.

- Stream read for MMC card with byte count greater than 0. The MSI generates an internal stop command and loads it into the command path. The end bit of the stop command is sent out when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than 6 (48 bits), a few extra data bytes are received from the card before the end bit of the stop command is sent.
- Stream write for MMC card with byte count greater than 0. The MSI generates an internal stop command and loads it into the command path. The end bit of the stop command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than 6 (48 bits), the datapath transmits the data last in order to meet the above condition.
- Multiple-block read memory for SD card with byte count greater than 0. If the block size is less than 4 (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus) bytes, the auto-stop command is loaded in the command path after all the bytes are read. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the last data block is received.
- Multiple-block write memory for SD card with byte count greater than 0. If the block size is less than 3 (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the auto-stop command is loaded in the command path after all data blocks are transmitted. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the end bit of the CRC status is received.
- Precaution for host software during auto-stop. Whenever an auto-stop command is issued, the host software must not issue a new command to the MSI until the MSI sends the auto-stop command and the data transfer completes. If the host issues a new command during a data transfer with the auto-stop in progress, an auto-stop command can be sent after the new command is sent and its response is received. This process can delay sending the stop command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data

that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue a stop or abort command. In this case, the MSI does not generate an auto-stop command.

Non-Data Transfer Commands that Use Datapath

Some non-data transfer commands (non-read/write commands) also use the datapath. The ***Non-Data Transfer Commands and Requirements*** table lists the commands and register programming requirements.

Table 22-10: Non-Data Transfer Commands and Requirements

	CMD27	CMD30	CMD42	ACMD13	ACMD22	ACMD51
Command Register Programming						
Cmd_index	6'h1B	6'h1E	6'h2A	6'h0D	6'h16	6'h33
Response_expect	1	1	1	1	1	1
Response_length	0	0	0	0	0	0
Check_response_crc	1	1	1	1	1	1
Data_expected	1	1	1	1	1	1
Read/write	1	0	1	0	0	0
Transfer_mode	0	0	0	0	0	0
Send_auto_stop	0	0	0	0	0	0
Wait_prevdata_complete	0	0	0	0	0	0
Stop_abort_cmd	0	0	0	0	0	0
Command Argument register programming						
	Stuff bits	32-bit write protect data address	Stuff bits	Stuff bits	Stuff bits	Stuff bits
Block Size register programming						
	16	4	Num_bytes*1	64	4	8
Byte Count register programming						
	16	4	Num_bytes*1	64	4	8

*1 Number of bytes specified as per the lock card data structure (Refer to the SD specification and the MMC specification).

SDIO Interrupt Control

Interrupts for SD cards are reported to the BIU by asserting an interrupt signal for two clock cycles. SDIO cards signal an interrupt by asserting `MSI0_D1` low during the interrupt period; The interrupt control state machine determines an interrupt period for the selected card. An interrupt period is always valid for cards in 1-bit data mode. An interrupt period for a wide-bus active or selected card is valid for the following conditions:

- Card is idle
- Non-data transfer command in progress

- Third clock after end bit of data block between two data blocks
- From two clocks after end bit of last data until end bit of next data transfer command

Bear in mind that, in the following situations, the MSI does not sample the SDIO interrupt of the selected card when the card data width is 4 bits. Since the SDIO interrupt is level-triggered, it is sampled in a further interrupt period and the host does not lose any SDIO interrupt from the card.

1. Read/write resume. The CIU treats the resume command as a normal data transfer command. SDIO interrupts during the resume command are handled similarly to other data commands. According to the SDIO specification, for the normal data command the interrupt period ends after the command end bit of the data command. For the resume command, it ends after the response end bit. For the resume command, the MSI stops the interrupt sampling period after the resume command end bit, instead of stopping after the response end bit of the resume command.
2. Suspend during read transfer. If the host suspends the read data transfer, the host sets the `MSI_CTL.RDABORT` bit to reset the data state machine. In the CIU, the SDIO interrupts are handled such that the interrupt sampling starts after the host sets the `MSI_CTL.RDABORT` bit. In this case, the MSI does not sample SDIO interrupts between the period from response of the suspend command.

Clock Control

The clock control block provides the clock frequencies required for SD/MMC cards.

The source clock for the MSI block and the input clock for clock dividers of the clock control block is clocked by CLK09 clock from CDU module. Refer to CDU chapter for more details on CLK09 clock.

The source clock is used to generate the card clock frequencies. The card clock can have different clock frequencies, since the SD card can be a low-speed SD card or a full-speed SD card. The MSI allows the card to operate at different clock frequencies.

The clock frequency of a card depends on the following clock control registers:

- Clock divider register (`MSI_CLKDIV`). An internal clock divider is used to generate different clock frequencies required for the card. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510. A value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.
- Clock control register (`MSI_CLKEN`). The MSI module can enable or disable the card clock under the following conditions:
  - The clock for a card is enabled when the `MSI_CLKEN.EN0` bit for a card is programmed (= 1) or disabled (= 0).
  - Setting the `MSI_CLKEN.LP0` =1. enables the low-power mode of a card. If low-power mode is enabled to save card power, the clock signal is disabled when the card is idle for at least 8 card clock cycles. It is enabled when a new command is loaded and the command path goes to a non-idle state.

Additionally, the clock of the card is disabled when:

- An internal FIFO is full on a card read (no more data can be received from card)
- The FIFO is empty on a card write (no data is available for transmission).

Disabling the clock in these situations helps to avoid FIFO overrun and underrun conditions.

Under the following conditions, the card clock is stopped or disabled for the card:

- The clock can be disabled by writing to the clock enable `MSI_CLKEN` register.
- If low-power mode is selected and a card is idle, or not selected for 8 clocks.
- The FIFO is full and data path cannot accept more data from the card and data transfer is incomplete to avoid FIFO overrun.
- The FIFO is empty and data path cannot transmit more data to the card and data transfer is incomplete to avoid FIFO underrun.

NOTE: The host software must take care while changing the `MSI_CLKDIV` register values. The card clock must be disabled through the `MSI_CLKEN` register before changing the values of the `MSI_CLKDIV` register.

MSI Data Transfer Modes

The following sections provide information on data transfer using the MSI interface.

Data Transmit

The data transmit state machine starts data transmission two clocks after a response for the data write command is received. The transmission occurs even if the command path detects a response error or response CRC error. See the ***Data Transmit State Machine*** figure. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the `MSI_CMD.XFRMODE` bit, the data transmit state machine puts data on the card data bus in a stream or in blocks.

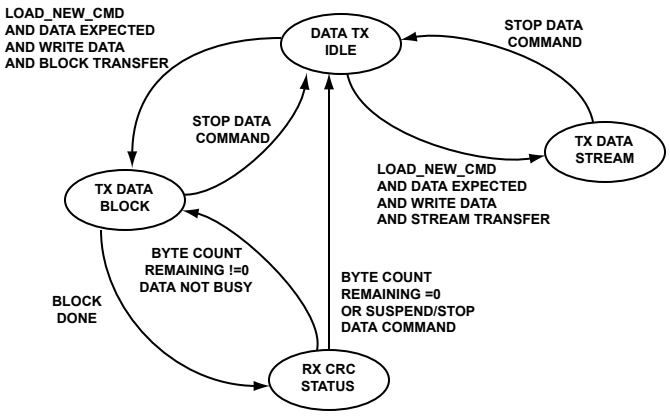

Figure 22-8: Data Transmit State Machine

Stream Data Transmit

If the MSI_CMD.XFRMODE bit =1, it is a stream-write data transfer. The data path pops the FIFO from the BIU and transmits in a stream to the card data bus. If the FIFO becomes empty, the card clock is stopped and restarted once data is available in the FIFO.

If the MSI_BYTCNT register is programmed to 0, it is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues a stop command. A stream data transfer is terminated when the end bit of the stop command and end bit of the data match over two clocks.

If the MSI_BYTCNT register is programmed with a non-zero value and the MSI_CMD.SENDASTOP bit is set, the stop command is internally generated. The command is loaded in the command path when the end bit of the stop command occurs after a match with the last byte of the stream-write transfer. This data transfer can also terminate if the software issues a stop command before all the data bytes transfer to the card bus.

Single Block Data

If the MSI_CMD.XFRMODE bit =0 and the MSI_BYTCNT register value is equal to the value of the MSI_BLKSIZ register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated CRC16.

If the MSI_CTYPE register bit is set for a 1-bit, 4-bit, or 8-bit data transfer, the data transmits on 1, 4, or 8 data lines, respectively. CRC16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This operation happens when the MSI_ISTAT.DTO bit =1. If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the MSI_ISTAT.DCRC bit.

Additionally, if the start bit of the CRC status is not received before two clocks after the end of the data block, a CRC status start bit error is signaled to the BIU. The MSI_ISTAT.EBE bit is set.

Multiple Block Data

A multiple-block write-data transfer occurs if the MSI_CMD.XFRMODE bit =0 and the value in the MSI_BYTCNT register is not equal to the value of the MSI_BLKSIZ register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC16.

If the MSI_CTYPE register bit is set to 1-bit, 4-bit, or 8-bit data transfer, the data transmits on 1, 4, or 8 data lines, respectively. CRC16 is separately generated and transmitted on 1, 4, or 8 data lines, respectively.

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining MSI_BYTCNT becomes 0, the data path signals to the BIU that the data transfer is complete. This operation happens when the MSI_ISTAT.DTO bit =1. If the remaining data bytes are greater than 0, the data path state machine starts to transmit another data block.

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the MSI_ISTAT.DCRC bit. The block continues further data transmission until all the bytes are sent. Additionally, if the CRC status start bit is not received within two clocks after the end of a data block, a CRC status start bit error is signaled to the BIU. The MSI_ISTAT.EBE bit is set. Further data transfer is terminated.

If the MSI_CMD.SENDASTOP is set, the stop command is internally generated during the transfer of the last data block. No extra bytes are transferred to the card. The end bit of the stop command does not always exactly match the end bit of the CRC status in the last data block.

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data has transferred. The internally generated stop command is loaded in the command path.

If the MSI_BYTCNT register =0 (the block size must be greater than 0), it is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues a stop or abort command.

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. See the ***Data Receive State Machine*** figure. If a response is not received from the card because a timeout error occurs, the BIU does not receive the signal that the data transfer is complete. This error happens when the command sent by the MSI is an illegal operation for the card. The error prevents the card from starting a read data transfer.

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the MSI_CMD.XFRMODE bit, the data-receive state machine gets data from the card data bus in a stream or blocks.

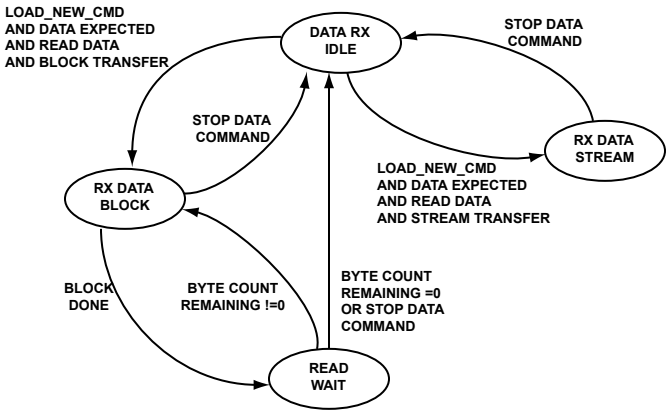

Figure 22-9: Data Receive State Machine

Stream Data Read

A stream-read data transfer occurs if the MSI_CMD.XFRMODE bit =1, at which time the data path receives data from the card and pushes it to the FIFO. If the FIFO becomes full, the card clock stops and restarts once the FIFO is no longer full.

An open-ended stream-read data transfer occurs when the MSI_BYTCNT register equals 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues a stop command. A stream data transfer terminates two clock cycles after the end bit of the stop command.

If the MSI_BYTCNT register contains a non-zero value and the MSI_CMD.SENDASTOP bit =1, a stop command is internally generated and loaded into the command path. In the command path, the end bit of the stop command occurs after the last byte of the stream data transfer is received. This data transfer can terminate if the host issues a stop or abort command before all the data bytes are received from the card.

Single Block Data Read

A single-block read-data transfer occurs if the MSI_CMD.XFRMODE bit =0 and the value of the MSI_BYTCNT register is equal to the value of the MSI_BLKSIZ register. When a start bit is received before the data times out, data bytes equal to the block size and CRC16 are received and checked with the internally-generated CRC16.

If the MSI_CTYPE register bit for the card is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively. CRC16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there is a CRC16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an end-bit error.

Multiple Block Data Read

If the MSI_CMD.XFRMODE =0 and the value of the MSI_BYTCNT register is not equal to the value of the MSI_BLKSIZ register, it is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC16.

If the MSI_CTYPE register bit for the card is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively. CRC16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining MSI_BYTCNT becomes 0, the data path signals a data transfer to the BIU.

If the remaining data bytes are greater than 0, the data path state machine causes another data block to be received. If CRC16 of a received data block does not match the internally-generated CRC16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU. The data-receive state machine terminates data reception, waits for a data timeout, and signals to the BIU that the data transfer is complete.

If the MSI_CMD.SENDASTOP bit =1, the stop command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the stop command does not always exactly match the end bit of the last data block.

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data transfers. The internally-generated stop command is loaded in the command path. The data path ignores any subsequent data received from the card.

If the MSI_BYTCNT =0 (the block size must be greater than 0), it is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues a stop or abort command.

Data Transfer Commands

Data transfer commands transfer data between the memory card and the MSI. To send a data command, the MSI needs a command argument, total data size, and block size.

Prior to a data transfer command, software must confirm that the card is not busy and is in a transfer state. This confirmation uses the CMD13 and CMD7 commands, respectively. For the data transfer commands, it is important that the same bus width that is programmed in the card is set in the MSI_CTYPE register.

The MSI generates an interrupt for different conditions during data transfer, which are reflected in the MSI_ISTAT register.

NOTE: The DCRC, SBEBCI, EBE, and SBEBCI conditions indicate that the received data could have errors. If there was a response timeout, then no data transfer occurred. For more information, see the Register Descriptions section.

Transmission and Reception with Internal DMAC (IDMAC)

The general sequence of events for transmit and receive is as follows.

1. Program the required programming in the bus mode register (MSI_BUSMODE). If the MSI_CTL.INTDMAC bit is disabled during the middle of an IDMAC transfer, it has no effect. It only takes effect for a new data transfer command. Issuing a software reset immediately terminates the transfer. It is recommended that the software issue a reset to the DMA interface by setting the MSI_CTL.DMARST bit and then issuing an IDMAC software reset using the MSI_CTL.CTLRST bit. Program the fixed burst bit (MSI_BUSMODE.FB) appropriately for system performance.
2. When a descriptor unavailable interrupt is asserted, the software must form the descriptor, appropriately set its own bit and then write to poll the demand register for the IDMAC to refetch the descriptor.
3. It is always appropriate for the application to enable abnormal interrupts since any errors related to the transfer are reported to the application.

MSI Event Control

The following sections describe MSI events.

Dedicated Interrupt Pins

Interrupt lines are defined for only eSDIO devices, which are connected to the controller interrupt line in MSI. These interrupt lines can operate even when the card clock is switched off and can be used only during an asynchronous interrupt period.

MSI Status and Error Signals

The following provides information on MSI errors.

Error Detection

The MSI has an error detection mechanism which operates for any of the following situations.

Response

- Response timeout – Response expected with the response start bit is not received within programmed number of clocks in timeout register.
- Response CRC error – Response is expected and check response CRC requested; response CRC7 does not match with the internally-generated CRC7.
- Response error – Response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.

Data Transmit

- No CRC status – During a write data transfer, if the CRC status start bit is not received two clocks after the end bit of the data block is sent out, the datapath does the following:
  - Signals no CRC status error to the BIU
  - Terminates further data transfer
  - Signals data transfer done to the BIU
- Negative CRC – If the CRC status received after the write data block is negative (that is, not 010), a data CRC error is signaled to the BIU and further data transfer is continued.
- Data starvation due to empty FIFO – If the FIFO becomes empty during a write data transmission, or if the card clock is stopped and the FIFO remains empty for data timeout clocks, then a data-starvation error is signaled to the BIU. The datapath continues to wait for data in the FIFO.

Data Receive

- Data timeout – During a read-data transfer, if the data start bit is not received before the number of clocks that are programmed in the timeout register, the datapath does the following.
  - Signals data-timeout error to the BIU
  - Terminates further data transfer
  - Signals data transfer done to BIU

- Data start bit error – During a 4-bit or 8-bit read-data transfer, when an SBE occurs, the application or driver must issue CMD12 for SD/MMC cards and CMD52 for a SDIO card to exit the error condition. After a CMD done is received, the application or driver must reset IDMAC and CIU (if required) to clear the condition. The FIFO must be reset before issuing any data transfer commands in general.
- Data CRC error – During a read-data-block transfer, if the received CRC16 does not match with the internally-generated CRC16, the datapath signals a data CRC error to the BIU and continues further data transfer.
- Data end-bit error – During a read-data transfer, if the end bit of the received data is not 1, the datapath signals an end-bit error to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.
- Data starvation due to FIFO full – During a read data transmission and when the FIFO becomes full, the card clock is stopped. If the FIFO remains full for data timeout clocks, a data starvation error is signaled to the BIU. The datapath continues to wait for the FIFO to start to empty. (The data starvation by host timeout bit is set in the `MSI_ISTAT` register.)

NOTE: In an error situation, DTO generation depends on when the error has occurred, since the descriptors are closed after the error scenarios as follows.

- If the data remains in the FIFO when the DMA detects the error scenario, then a DTO is not generated.
- If the data is completely read out before the error occurs, then a DTO is generated. CMD12 ensures DTO generation in error situations; therefore, issuing CMD12 is recommended.

Error Handling

The MSI implements error checking. Errors are reflected in the `MSI_ISTAT` register and can be communicated to the software through an interrupt, or the software can poll these bits. On power-on, interrupts are disabled, and all the interrupts are masked (bits 31:0 of the `MSI_IMSK` register are all 0). The MSI module captures the following errors:

- Response and data timeout errors. For response timeout, software can retry the command. For a data timeout error, the MSI has not received the data start bit - either for the first block or the intermediate block - within the timeout period. Software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `MSI_TCBCNT` register later, the software can decide how many bytes remain to be copied.
- Response errors. Set when an error is received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.
- Data errors. Set when error in data reception is observed. For example, this error can occur in the data CRC, when the start bit is not found, when the end bit is not found, and so on. These errors could be set for any block-first block, intermediate block, or last block. On receipt of an error, the software can issue a STOP or ABORT command and retry the command for either whole data or partial data.

- Hardware locked error. Set when the MSI cannot load a command issued by software. When software sets the MSI_CMD.STARTCMD bit, the MSI tries to load the command. If the command buffer is already filled with a command, this error is generated. The software then has to reload the command.
- FIFO underrun or overrun error. If the FIFO is full and DMA tries to write data into the FIFO, then an overrun error is set. Conversely, if the FIFO is empty and the DMA tries to read data from the FIFO, an underrun error is set.
- Data starvation by host timeout. Raised when the MSI is waiting for software intervention to transfer the data to or from the FIFO, but the software does not transfer within the stipulated timeout period. Under this condition and when a read transfer is in progress, the software must read data from the FIFO and create space for further data reception. When a transmit operation is in process, the software must fill data in the FIFO to start transferring data to the card.
- CRC Error on command. If a CRC error is detected for a command.

NOTE: During a multiple-block data transfer, if a negative CRC status is received from the device, the datapath signals a data CRC error to the BIU by setting the data MSI_ISTAT.DCRC register. It then continues further data transmission until all the bytes are transmitted.

Fatal Bus Errors (FBE)

An FBE occurs due to an error response from SCB. This response is a system error, so the software driver must not perform any further programming of the MSI. The only recovery mechanism from such scenarios is to do one of the following.

- Issue a hard reset.
- Do a controller reset by writing to the MSI_CTL.CTLRST bit.

MSI Programming Model

This section provides procedures that allow programmers to use the MSI properly. These procedures include MSI initialization, single and multiple block reads and writes and many others.

MSI Programming Concepts

Using the features, operating modes, and event control for the MSI to their greatest potential requires an understanding of the following MSI-related concepts.

Software and Hardware Restrictions

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.

To avoid glitches in the card clock outputs, use the following steps when changing the card clock frequency.

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this status, check for 0 in the MSI_STAT.DBUSY bit.
2. Update the MSI_CLKEN register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting the MSI_CMD.STARTCMD bit, the MSI_CMD.WTPRIVDATA bits, and the MSI_CMD.UCLKREGS bit.
3. Set the MSI_CMD.STARTCMD bit to update the clock divider register, and send a command to the CIU in order to update the clock registers. Wait for the CIU to take the command.
4. Set the MSI_CMD.STARTCMD to update the MSI_CLKEN register to enable the required clocks and send a command to the CIU to update the clock registers. Wait for the CIU to take the command.

If the software issues a controller reset command by setting the MSI_CTL.CTLRST bit, all the CIU state machines are reset and the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued (MSI_CTL.FIFORST), then:

- Any pending DMA transfer on the bus completes correctly
- DMA data reads are ignored
- Write data is unknown (x)

Additionally, if a DMA reset is also issued (MSI_CTL.DMARST), any pending DMA transfer is abruptly terminated.

If any of the previous data commands do not properly terminate, then the software must issue the FIFO reset. The reset removes any residual data, if any, in the FIFO. After asserting the FIFO reset, the program waits until this bit is cleared. One data transfer requirement between the FIFO and host is that the number of transfers must be a multiple of the FIFO data width. For example, if the FIFO data width = 32-bit and the program must write only 15 bytes to the card, the host must program the DMA to do 16-byte transfers to the card. (The program writes to the card using the MSI_BYTCNT register.)

Initializing the MSI

After the power-up, the MSI is reset. The reset initializes the registers, ports, FIFO-pointers, DMA interface controls, and state-machine. After power-on reset, the software performs the following steps which are reflected in the ***Data Transmit State Machine*** figure.

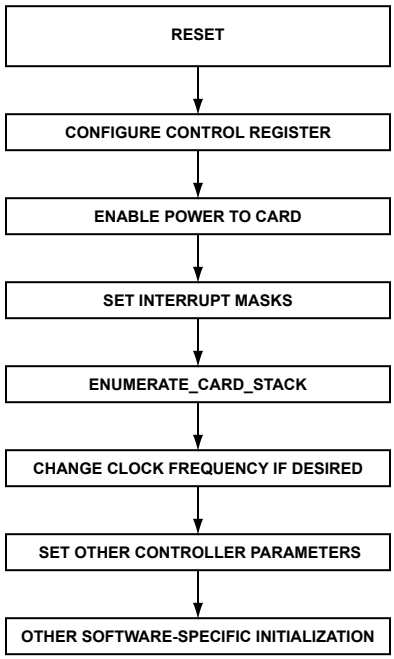

Figure 22-10: Data Transmit State Machine

1. Configure the control register (`MSI_CTL`).
2. Set masks for interrupts by clearing appropriate bits in the interrupt mask register. Set the global `MSI_CTL.INTEN` bit. It is recommended that programs write 0xFFFF_FFFF to the `MSI_ISTAT` register to clear any pending interrupts before setting the `MSI_CTL.INTEN` bit.
3. Enumerate the card stack. Each card is enumerated according to card type. For details, refer to Enumerating the Card Stack. For enumeration, restrict the clock frequency to 400 kHz in accordance with SD/MMC standards.
4. Set the card frequency using the `MSI_CLKDIV` register.
5. Set other parameters, which normally do not need changing with every command, with a typical value such as response and data timeout values. Set the values according to the SD/MMC specifications and the FIFO threshold value.

Enumerating the Card Stack

The card stack does the following:

- Enumerates the connected card
- Sets the RCA for the connected card
- Reads card-specific information
- Stores card-specific information locally

Each card is enumerated separately. The identification procedure depends on whether the card connected is SD, SDIO, or MMC.

Identifying Card Types

The MSI can have an MMC, SD, or SDIO type of card connected to it. All types of SDIO cards are supported; that is, SDIO_IO_ONLY, SDIO_MEM_ONLY, and SDIO_COMBO cards. Each card is enumerated separately. The enumeration sequence includes the following steps:

1. Check if the card is connected.
2. Clear the bits in the MSI_CTYPE register to configure the controller in 1-bit mode
3. Identify the card type; that is, SD, MMC, SDIO, or COMBO card.
    a. Send CMD5 with argument 0.
    b. Read the response register (MSI_RESP0), which gives the voltage window that the card supports-the response to CMD5 gives the voltages that the card supports.
    c. Send CMD5 again with the desired voltage window set in the argument. This CMD5 is used to set the voltage window and move the card state m/c out of the initialization state.
    d. Check the response [27] bit. If this bit = 1, this response indicates that the memory is present and the SDIO card is a COMBO card.
    e. If the card is SDIO go to Step 4. If the card is combinational logic (COMBO) or if the response is not received, continue with the following steps.
    f. Send CMD8 with the following argument:

```
Bit[31:12] = 20'h0; // Reserved bits
Bit[11:8] = 4'b0001 // VHS value
Bit[7:0] = 8'b10101010 // Preferred Check Pattern by SD2.0
```

    g. If the response is received, the card supports high capacity SD2.0; send ACMD41 with the following argument:

```
Bit[31] = 1'b0; // Reserved bits
Bit[30] = 1'b1; // High Capacity Status
Bit[29:25] = 6'h0; // Reserved bits
Bit[24] = 1'b0;
Bit[23:0] = Supported Voltage Range
```

    h. If the response is received for ACMD41, then the card is SD; otherwise the card is MMC.
    i. If the response is not received for initial CMD8, then the card does not support high capacity SD2.0. Issue CMD0 followed byMD41 with the following argument:

```
Bit[31] = 1'b0; // Reserved bits
Bit[30] = 1'b0; // High Capacity Status
```

```
Bit[29:24] = 6'h0; // Reserved bits
Bit[23:0] = Supported Voltage Range
```

j. If the response is received for ACMD41, then the card is SD. Otherwise, the card is MMC.

4. Enumerate the card according to the card type.
5. Use a card clock frequency = f_{OD} (that is, 400 kHz) and use the following enumeration command sequence:
   - SD card – Send CMD0, CMD8, ACMD41, CMD2, CMD3.
   - SDIO – Send CMD5; if the function count is valid, CMD3. For the SDIO memory section, follow the same commands as for the SD card.
   - MMC – Send CMD0, CMD1, CMD2, CMD3.

The card clock frequency can be configured after enumeration.

Programming Card Clocks

The MSI supports programming the desired operational frequency for the card. The clock for the card can also be enabled or disabled. Registers that support this feature are:

- MSI_CLKDIV: Programs clock source frequency.
- MSI_CLKEN: Enables or disables clock for the card and enables low-power mode, which automatically stops the clock to a card when the card is idle for more than 8 clocks.

The MSI loads each of these registers only when the MSI_CMD.STARTCMD bit and the MSI_CMD.UCLKREGS bit in the CMD register are set. When a command is successfully loaded, the MSI clears the MSI_CMD.STARTCMD bit. This operation happens unless the MSI already has another command in the queue, at which point it generates a Hardware Locked Error (HLE).

Software must look for the MSI_CMD.STARTCMD and the MSI_CMD.UCLKREGS bits, and set the MSI_CMD.WTPRIVDATA bit to ensure that clock parameters do not change during data transfer.

NOTE: Even though MSI_CMD.STARTCMD is set for updating clock registers, the MSI does not raise the MSI_DONE signal upon command completion.

Use the following procedure to program the clock-related registers.

1. Confirm that the card is not engaged in any transaction; if there is a transaction, wait until it finishes.
2. Stop all clocks by writing 0 to the MSI_CLKEN register.
3. Set the MSI_CMD.STARTCMD, MSI_CMD.UCLKREGS, and the MSI_CMD.WTPRIVDATA bits.
4. Wait until the MSI_CMD.STARTCMD bit is cleared or an HLE is set; in case of an HLE, repeat the command.
5. Program the MSI_CLKDIV register.

6. Set the MSI_CMD.STARTCMD, MSI_CMD.UCLKREGS, and MSI_CMD.WTPRIVDATA bits.
7. Wait until the MSI_CMD.STARTCMD is cleared or an HLE is set; in case of an HLE, repeat the command.
8. Re enable all clocks by programming the MSI_CLKEN register.
9. Set the MSI_CMD.STARTCMD, MSI_CMD.UCLKREGS, and the MSI_CMD.WTPRIVDATA bits.
10. Wait until the MSI_CMD.STARTCMD bit is cleared or a HLE is set; in case of a HLE, repeat the command.

Sending Non-Data Commands With or Without a Response Sequence

To send any non-data command, the software must program the MSI_CMD register and the MSI_CMDARG register with appropriate parameters. Using these two registers, the MSI forms the command and sends it to the command bus. The MSI reflects the errors in the command response through the error bits of the MSI_ISTAT register. The ***Command Register Settings for No-Data Command*** table shows the MSI_CMD bit settings.

When the MSI receives a response, either erroneous or valid, it sets the MSI_ISTAT.CMDDONE bit. A short response is copied in the MSI_RESP0 register, while a long response is copied to all four response registers. The MSI_RESP3 register bit 31 represents the MSB, and the MSI_RESP0 register bit 0 represents the LSB of a long response.

Table 22-11: Command Register Settings for No-Data Command

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1/0	Choose value based on speed mode in use; refer to “MSI Register Descriptions”
update_clk_regs_only	0	No clock parameters update command
data_expected	0	No data command
card_number	*n*CardNo	Actual card number
cmd_index	command index	
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
user-selectable		
wait_prvdata_complete	0	Before sending a command on a command line, the host must wait for the completion of any data command in process, if any. (It is recommended to set this bit always, unless the current command is to query status or stop data transfer when transfer is in progress)
check_response_crc	1	If host crosschecks, CRC of response received

Use the following procedure to issue basic commands or non-data commands.

1. Program the MSI_CMD register with the appropriate command argument parameter.
2. Program the MSI_CMD register with the settings in the ***Command Register Settings for No-Data Command*** table.
3. Wait for command acceptance by host. When software loads the command into the MSI:
   - The MSI accepts the command for execution and clears the MSI_CMD.STARTCMD bit. This process occurs unless one command is in process. Then, the MSI can load and keep the second command in the buffer.
   - If the MSI is unable to load the command, then it generates an HLE (hardware locked error). (For example, a command is already in progress, a second command is in the buffer, and a third command is attempted).
4. Check if there is an HLE.
5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the MSI sets the MSI_ISTAT.CMDDONE bit. Software can either poll for this bit or respond to a generated interrupt.
6. Check if the response timeout error, response CRC error, or response error is set. This confirmation can be done either by responding to an interrupt raised by these errors or by polling bits RE, RCRC, and RTO from the MSI_ISTAT register. If no response error is received, then the response is valid. If necessary, the software can copy the response from the response registers. Software must not modify clock parameters while a command is executing.

Single-Block or Multiple-Block Read

Use the following procedure to perform a single-block or multiple-block read.

1. Write the data size in bytes in the MSI_BYTCNT register.
2. Write the block size in bytes in the MSI_BLKSIZ register.

   ADDITIONAL INFORMATION: The MSI expects data from the card in blocks of size BLKSIZ each.
3. If card has a round-trip delay of more than 0.5 card clock period, program the MSI_CDTHRCTL.RDTHR bit field. The programming ensures that the card clock does not stop in the middle of a block of data transferring from the card to the host.

   ADDITIONAL INFORMATION: For programming guidelines, refer to the Card Read Threshold section. If the card read threshold feature is not enabled for such cards, then the program must ensure that the Rx FIFO does not become full during a read data transfer. The Rx FIFO must drain out at a rate faster than the rate that data is pushed into the FIFO.

4. Program the MSI_CMDARG register with the data address of the beginning of a data read. Program the MSI_CMD register with the parameters listed in the ***Command Register Settings for Single-Block or Multiple-Block Read*** table.

   ADDITIONAL INFORMATION: For SD and MMC cards, use CMD17 for a single-block read and CMD18 for a multiple-block read. For SDIO cards, use CMD53 for both single-block and multiple-block transfers.

   After writing to the MSI_CMD register, the MSI starts executing the command. When the command is sent to the bus, the CMDONE interrupt is generated.

5. Software looks for data error interrupts on bits 7, 9, 13, and 15 of the MSI_ISTAT register. If required, software can terminate the data transfer by sending a STOP command.

6. Software or the DMA looks for a receive FIFO data request or data starvation by host timeout conditions. In both cases, the DMA reads data from the FIFO and makes space in the FIFO for receiving more data.

When all the data is received, a DTO (Data Transfer Over) interrupt is generated.

Table 22-12: Command Register Settings for Single-Block or Multiple-Block Read

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1/0	Choose value based on speed mode in use; refer to “MSI Register Descriptions”
update_clk_regs_only	0	No clock parameters update command
card_number	*n*CardNo	Actual card number
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0 or 1	See Auto-Stop
transfer_mode	0	Block transfer
read_write	0	Read from card
data_expected	1	Data command
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
user-selectable		
cmd_index	command index	Can be 1 for commands to stop data transfer, such as CMD12
wait_prvdata_complete	1	0 = sends command immediately. 1 = sends command after previous data transfer ends

Table 22-12: Command Register Settings for Single-Block or Multiple-Block Read (Continued)

Parameter	Value	Comment
check_response_crc	1	0 = MSI does not check response CRC 1 = MSI checks response CRC

Single-Block or Multiple-Block Write

Use the following procedure to perform a single-block or multiple-block write.

1. Write the data size in bytes in the MSI_BYTCNT register.
2. Write the block size in bytes in the MSI_BLKSIZ register.

   ADDITIONAL INFORMATION: The MSI sends data in blocks of size BLKSIZ each.
3. Program MSI_CMDARG register with the data address to which data is written.
4. Write data in the FIFO; it is best to start filling data the full depth of the FIFO.
5. Program the MSI_CMD register with the parameters listed the ***Command Register Settings for Single-Block or Multiple-Block Read*** table.

   ADDITIONAL INFORMATION: For SD and MMC cards, use CMD24 for a single-block write and CMD25 for a multiple-block write. For SDIO cards, use CMD53 for both single-block and multiple-block transfers. After writing to the MSI_CMD register, the MSI starts executing a command; when the command is sent to the bus, a CMDONE interrupt is generated.
6. Software looks for data error interrupts in the MSI_ISTAT.DCRC, MSI_ISTAT.DRTO, and MSI_ISTAT.EBE bits. If necessary, software can terminate the data transfer by sending the STOP command.
7. Software looks for a transmit FIFO data request or timeout conditions from data starvation by the host. In both cases, the software or the DMA writes data into the FIFO.
8. When a DTO interrupt is received, the data command is over. For an open-ended block transfer, if the byte count is 0, the software must send the STOP command. If the byte count is not 0, then on completion of a transfer of a given number of bytes, the MSI sends the STOP command, if necessary. The MSI_ISTAT.ACD bit reflects the completion of the AUTO-STOP command. A response to AUTO_STOP is stored in the MSI_RESP1 register.
9. Wait for the busy clear interrupt.

The card can drive the busy clear interrupt on the DAT line; the host controller generates the interrupt after the busy is completed.

Table 22-13: Command Register Settings for Single-Block or Multiple-Block Write

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1 or 0	Choose value based on speed mode in use; refer to “MSI Register Descriptions”
update_clk_regs_only	0	No clock parameters update command
card_number	*n*CardNo	Actual card number
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0 or 1	See Auto-Stop
transfer_mode	0	Block transfer
read_write	1	Write to card
data_expected	1	Data command
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
cmd_index	command index	Can be 1 for commands to stop data transfer, such as CMD12
wait_prvdata_complete	1	0 – sends command immediately 1 – sends command after previous data transfer ends
check_response_crc	1	0 – MSI does not check response CRC 1 – MSI checks response CRC

Stream Reads and Writes

Stream reads and writes are like the block reads and writes described in the previous sections except for the following bits in the `MSI_CMD.XFRMODE` register:

- For reads, the transfer mode (`MSI_CMD.XFRMODE` bit) =1 and the command index =CMD20.
- For writes, the transfer mode (`MSI_CMD.XFRMODE` bit) =1 and the command index =CMD11.

In a stream transfer, if the byte count is 0, then the software must send the STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the MSI sends the STOP command

Packed Commands

In order to reduce overhead, read and write commands can be packed in groups of commands. The groups are either all read or all write. The software transfers the data for all commands in the group in one transfer on the bus.

Packed commands can be of two types:

- Packed write – CMD23 > CMD25
- Packed read – CMD23 > CMD25 >CMD23 > CMD18

The application software puts packed commands in packets. The packets are transparent to the core. For more information on packed commands, refer to the eMMC specification.

Sending Stop or Abort in Middle of Transfer

The STOP command can terminate a data transfer between a memory card and the MSI. The ABORT command can terminate an I/O data transfer for only the SDIO_IOONLY and SDIO_COMBO cards.

- Send STOP command. Can be sent on the command line while a data transfer is in-progress. This command can be sent at any time during a data transfer. For information on sending this command, refer to Sending Non-Data Commands With or Without a Response Sequence. Programs can use an extra setting for this command to set the `MSI_CMD` register bits (5–0) to CMD12 and set the `MSI_CMD.STPABORTCMD` bit to 1. If the `MSI_CMD.STPABORTCMD` bit is not set to 1, the MSI does not know that the program stopped a data transfer. Reset the `MSI_CMD.WTPRIVDATA` bit to 0 in order to make the MSI send the command at once, even though there is a data transfer in progress.
- Send ABORT command. Can be used with only an SDIO_IOONLY or SDIO_COMBO card. To abort the function that is transferring data, program the function number in ASx bits (CCCR register of card, address 0x06, bits (0–2)) using CMD52. This command is a non-data command. For information on sending this command, refer to Sending Non-Data Commands With or Without a Response Sequence.

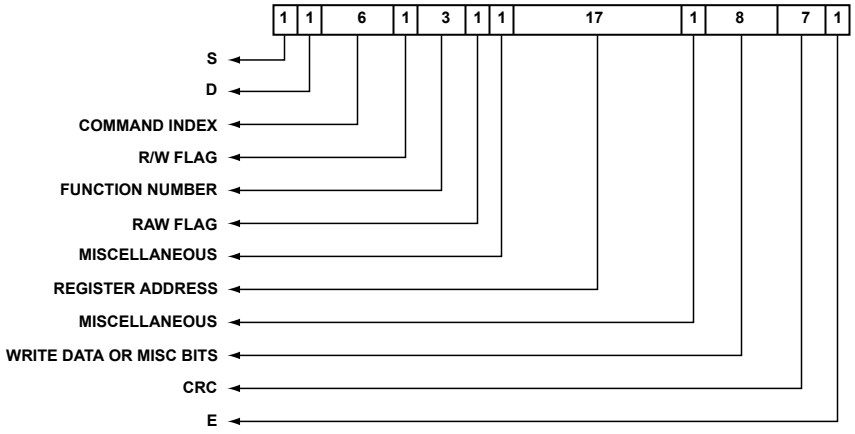

Figure 22-11: Command Format for CMD52

1. Program the `MSI_CMDARG` register with the appropriate command argument parameters listed in the ***Parameters for CMDARG Register*** table.
2. Program the `MSI_CMD` register using the command index as CMD52. Similar to the STOP command, set the `MSI_CMD.STPABORTCMD` bit =1, to inform the MSI that the program aborted the data transfer. Reset the

MSI_CMD.WTPRIVDATA bit =0 in order to make the MSI send the command at once, even though a data transfer is in progress.

3. Wait for command transfer over.
4. Check response (R5) for errors.

Table 22-14: Parameters for CMDARG Register

MSI_CMDARG Bits	Contents	Value
31	R/W flag	1
30–28	Function number	0 = for CCCR access
27	RAW flag	1 = if needed to read after write
26	Do-not-care	N/A
25-9	Register address	0x06
8	Do-not-care	N/A
7–0	Write data	Function number to be aborted

Suspend or Resume Sequence

In an SDIO card, the data transfer between an I/O function and the MSI can be temporarily halted using the SUSPEND command. This command can be necessary to perform a high-priority data transfer with another function. When desired, the data transfer can be resume using the RESUME command.

The following functions can be implemented by programming the appropriate bits in the CCCR register of the SDIO card. To read from or write to the CCCR register, use the CMD52 command.

1. SUSPEND data transfer – Non-data command.
    a. Check if the SDIO card supports the SUSPEND or RESUME protocol; this verification can be done through the SBS bit in the CCCR @0x08 register of the card.
    b. Check if the data transfer for the required function number is in process; the function number that is currently active is reflected in bits 0–3 of the CCCR register @0x0D. If the BS (bus status) bit is 1, then only the function number given by the FSx bits is valid.
    c. To suspend the transfer, set BR (bit 2) of the CCCR register @0x0C.
    d. Poll for clear status of bits BR (bit 1) and BS (bit 0) of the CCCR @0x0C. The BS bit is 1 when the currently selected function uses the data bus; the BR (bus release) bit remains 1 until the bus release is complete. When the BR and BS bits =0, the data transfer from the selected function has been suspended.
    e. During a read-data transfer, the MSI can be waiting for the data from the card. If the data transfer is a read from a card, then the MSI must be informed after the successful completion of the SUSPEND command. The MSI then resets the data state machine and comes out of the wait state. To achieve this state, set the MSI_CTL.RDABORT bit.

f. Wait for data completion. Get pending bytes to transfer by reading the MSI_TCBCNT register.

g. For a write data transfer, wait for the busy clear interrupt after the Data Transfer Over (DTO) interrupt.

2. RESUME data transfer – This command is a data command.

a. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.

b. If the card is in a disconnect state, select it using CMD7. The card status can be retrieved in response to CMD52/CMD53 commands.

c. Check that a function to be resumed is ready for data transfer. Confirm the readiness by reading the RFx flag in CCCR @0x0F. If RF =1, then the function is ready for data transfer.

d. To resume the transfer, use CMD52 to write the function number at the FSx bits (0–3) in the CCCR register @0x0D. Form the command argument for CMD52 and write it in the MSI_CMDARG register. The ***Parameters for CMDARG Register*** table lists the bit values.

e. Write the block size in the MSI_BLKSIZ register. Data transfers in units of this block size.

f. Write the byte count in the MSI_BYTCNT register. This amount is the total size of the data; that is, the remaining bytes for transfer. It is the responsibility of the software to handle the data.

g. Program the MSI_CMD register similarly to a block transfer. For details, refer to the block read and write sections.

h. When the MSI_CMD register is programmed, the command is sent and the function resumes data transfer. Read the DF flag (Resume Data Flag). If it is 1, then the function has data for the transfer and begins a data transfer as soon as the function or memory is resumed. If it is 0, then the function has no data for the transfer.

i. If the DF flag is 0, the MSI waits for data for a read. After the data timeout period, it gives a data timeout error.

Table 22-15: Parameters for CMDARG Register

CMDARG Bits	Contents	Value
31	R/W flag	1
30–28	Function number	0 = for CCCR access
27	RAW flag	1 = read after write
26	Do-not-care	N/A
25-9	Register address	0x0D
8	Do-not-care	N/A
7–0	Write data	Function number that is to be resumed

Read Wait Sequence

Read_wait is used only with SDIO cards. It can temporarily stall the data transfer either from function or memory and allow the host to send commands to any function within the SDIO device. The host can stall this transfer for as long as required. The MSI provides the facility to signal this stall transfer to the card.

1. Check if the card supports the read_wait facility; read SRW (bit 2) of the CCCR register in SDIO card. If this bit is 1, then all functions in the card support the read_wait facility. Use CMD52 to read this bit.
2. If the card supports the read_wait signal, then assert it by setting the `MSI_CTL.RDWAIT` bit.
3. Clear the `MSI_CTL.RDWAIT` bit.

Card Read Threshold

When an application must perform a single or multiple block read command, the application must program the `MSI_CDTHRCTL` register with the appropriate card read threshold size. It also must set the card `MSI_CDTHRCTL.RDTHREN` (read threshold enable) bit. This additional programming ensures that the controller sends a read command only if there is space equal to the `MSI_CDTHRCTL.RDTHR` (card read threshold) available in the Rx FIFO. This programming in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. The card read threshold can be set to the block size of the transfer. This size guarantees that there is a minimum of one block size of space in the Rx FIFO before the controller enables the card clock.

Recommended Usage Guidelines for Card Read Threshold

1. Program the `MSI_CDTHRCTL` register before the programming the CMD register for a data read command.
2. Do not program the `MSI_CDTHRCTL` register when a data transfer command is in progress.
3. Program the `MSI_CDTHRCTL.RDTHR` value greater than or equal to the block size of the read transfer. This programming ensures that the card clock does not stop in between a block of data.
4. If round-trip delay > 0.5 card clock, then enable the card read threshold and program the card threshold as per guideline #3. This programming guarantees that the card clock does not stop in between a block of data. The controller samples data incorrectly if the card clock stops in between a block of data if round-trip delay > 0.5 card clock.
5. `MSI_CDTHRCTL.RDTHR` is greater than or equal to `MSI_BLKSIZ` (recommended). Program the card read threshold size (`MSI_CDTHRCTL.RDTHR`) to at least 1 × BlockSize of the multi-block transfer. This programming guarantees that the card clock does not stop in between a block of data due to the Rx FIFO becoming full during the read transfer.
6. `MSI_CDTHRCTL.RDTHR` is less than `MSI_BLKSIZ`. If the `MSI_CDTHRCTL.RDTHR` bit is programmed to less than the `MSI_BLKSIZ` of the transfer, then the system must ensure that the receive FIFO never becomes full and overflows during the read transfer. This programming can cause the card clock from the MSI to stop. The MSI is not able to guarantee that the card clock does not stop during a read transfer.

NOTE: If the MSI_CDTHRCTL.RDTHR, MSI_FIFOTH.RXWM, and MSI_FIFOTH.DMAMSZ values are programmed incorrectly, then the card clock can stop indefinitely and no interrupts are generated from the controller.

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, typically support block sizes that are specified in the card or are fixed to 512 bytes. For SDIO cards, standard capacity SD cards that support READ_BL_PARTIAL =1 and MMC cards, the block size is variable. The application can choose block size.

Use the following steps for the card read threshold feature. The steps guarantee that the card clock does not stop because of a FIFO full condition in the middle of a block of data being read from the card.

1. Choose the block size (configured using the MSI_BLKSIZ register). The block size requested by the application from the card for the read transfer card must be 32-bit aligned.
2. Enable the card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than the total depth of the FIFO (*BlkSiz* ≤ *FifoDepth*)

   Where: *BlkSiz* = (block size in bytes) × 8 ÷ 32; that is, the number of the block size in terms of FIFO locations

   FifoDepth = total number of FIFO locations.
3. Choose the card read threshold.
   - If *BlkSiz* ≥ ½ *FifoDepth*, configure MSI_CDTHRCTL.RDTHR such that the value ≤ *BlkSize* in bytes
   - If *BlkSiz* < ½ *FifoDepth*, configure MSI_CDTHRCTL.RDTHR such that the value = *BlkSize* in bytes
4. Choose the DMA multiple transaction size using the MSI_FIFOTH.DMAMSZ bit field. The possible values for the bit fields are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Choose the value of MSI_FIFOTH.DMAMSZ from the transfer values so that BlkSiz is a multiple of DMAMSZ. BlkSize% (DMAMSZ) = 0. Note the following special cases:
   - When an MSIZE transfer =1 (configured using the DMA_CFG.MSIZE bit field). The MSI_FIFOTH.DMAMSZ is equal to 1 when the block size chosen in Step 1 is not a multiple of the FIFO width (in bytes). If DMAMSZ =1 is not acceptable and a higher burst size is desired-that is, a higher DMAMSZ. Return to Step 1 and recalculate the block size.
   - Internal DMA (IDMAC). The size of the data buffer (in bytes) for each descriptor must be a multiple of DMAMSZ × 4.
5. Choose the RX watermark using the MSI_FIFOTH.RXWM bit field.

   If DMAMSZ = 1, then the RXWM = 1 or RXWM = BlkSize – 1

   Additionally, for all DMA modes the RXWM must be a multiple of the chosen DMAMSZ.

MSI Programming Model, Boot Operation

This section discusses details on programming the MSI for boot operation.

Normal Boot Operation

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards. It is performed in push-pull mode. The ***Normal Boot Timing*** figure shows the timing for the transmit state machine in a normal boot mode.

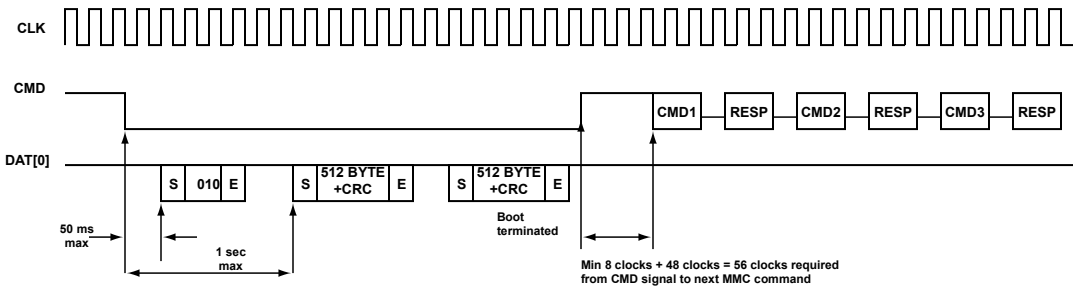

Figure 22-12: Normal Boot Timing

Normal Boot Operation; eMMC

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards. It must be performed in push-pull mode. See the ***Normal Boot Timing*** figure.

Software must adhere to the following steps when working with eMMC or removable MMC 4.3 cards for boot operation. Note that the software knows that the card supports boot operation (the BOOT_PARTITION_ENABLE bit set) in the card.

The software also knows the BOOT_SIZE_MULT value in the card and the data bus width to use during boot operation: cExtend CSD register byte [177] bit[0:1].

1. Set the masks for interrupts by clearing appropriate bits in the `MSI_IMSK` register.
2. Set the `MSI_CTL.INTEN` bit. Before this bit is set, programs should write 0xFFFF_FFFF to the `MSI_ISTAT` and `MSI_IDSTS` registers to clear any pending interrupts. For internal DMAC, unmask all the relevant fields in the `MSI_IDINTEN` register.
3. Set the and `MSI_CTL.INTEN` bits =1. In order to use the internal DMAC to transfer the boot data received, it must also set up the descriptors and program the `MSI_CTL.INTDMAC` bit =1.
4. Set the card frequency to 400 kHz using the clock-divider register.
5. Set Data Time Out = (10 × ((TAAC × f_{OP}) + (100 × NSAC)); this is NAC.
6. Program the `MSI_BLKSIZ` register with 0x200 (512 bytes).
7. Program the `MSI_BYTCNT` register with multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card.

8. Program the Rx FIFO threshold value in bytes in the MSI_FIFOTH register. Typically, the threshold value can be set to half the FIFO depth.
9. Program the following fields: MSI_CMD.STARTCMD =1'b1, MSI_CMD.BOOTEN =1'b1, MSI_CMD.XPECTBOOTACK (for start-acknowledge pattern ACK from the card) and MSI_CMD.DXPECT =1'b1.
10. If MSI_CMD.XPECTBOOTACK =1'b1, the software driver must start a timer after step 9; the terminal value is 50 ms.
    - Before this timer elapses, the BAR interrupt should be received from the MSI. If this action does not occur, program the CMD register as follows:

      MSI_CMD.STARTCMD =1'b1

      MSI_CMD.BOOTDIS =1'b1

      All other fields = 0
    - The MSI generates a Command Done (CD) interrupt after de-asserting the CMD line of the card. In IDMAC:

      Descriptor is closed

      MSI_IDSTS.CES =1, indicating BAR timeout

      MSI_IDSTS.RI =0
    - If the BAR interrupt is received, the software should clear this interrupt by writing a 1 to it. The software should then start another timer with a terminal value of 1 – 0.05 = 0.95 seconds. Before this timer elapses, the BDS interrupt should be received from the MSI. If this action does not occur, the software driver must program the CMD register as follows:

      MSI_CMD.STARTCMD =1'b1

      MSI_CMD.BOOTDIS =1'b1

      All other fields =0
    - The MSI generates a CD interrupt after de-asserting the CMD line of the card. In IDMAC:

      Descriptor is closed

      MSI_IDSTS.CES =1, indicating BDS timeout

      MSI_IDSTS.RI =0
    - If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed RX_WMark level is attained. At the end of a successful boot data transfer from the card, the following interrupts are generated:

      Command Done (CD) with the MSI_ISTAT.CMDDONE bit

Data Transfer Over (DTO) with the MSI_ISTAT.DTO bit

Receive Interrupt (RI) with the MSI_IDSTS.RI bit

- If an error occurs in Boot Ack pattern (010) or an end bit error occurs

  Controller automatically aborts boot by pulling CMD line high

  Controller generates CD interrupt

  Controller does not generate BAR interrupt

  Application aborts boot transfer

- In IDMAC:

  If the software creates more descriptors than the boot data received, the MSI does not close the extra descriptors.

  If the software creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

- If between data block transfers NAC is violated, DRTO (Data Read Timeout) is asserted. If there are errors associated with start or end bits, SBE/EBE interrupts are also generated.

11. If MSI_CMD.XPECTBOOTACK =1'b0, the software should start a timer after the step 9 where the terminal value is 1 second.

    - Before this timer elapses, a BDS interrupt should be received from the MSI. If the interrupt is not received, the software must program their CMD register with the following fields:

      MSI_CMD.STARTCMD =1'b1

      MSI_CMD.BOOTDIS =1'b1

      All other fields =0

    ADDITIONAL INFORMATION: MSI generates a CD interrupt after de-asserting the CMD line of the card. In IDMAC mode, the descriptor is closed and the MSI_IDSTS.CES bit =1, indicating a BDS timeout.

    - If a BDS interrupt is received, it indicates that the boot data is being received from the card. At the end of a successful boot data transfer from card, the following interrupts are generated.

      Command Done (CD) with the MSI_ISTAT.CMDDONE bit

      Data Transfer Over (DTO) with the MSI_ISTAT.DTO bit

      Receive Interrupt (RI) with the MSI_IDSTS.RI bit

Normal Boot Operation; Removable MMC4.3, MMC4.4, and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 cards are different than eMMC in that the software is not aware whether these cards support the boot mode of operation when plugged in. Thus, the software must:

- Enumerate these cards as it would enumerate MMC4.0/4.1/4.2 cards for the first time
- Know the card characteristics
- Decide whether to perform a boot operation or not

Use the following procedure when booting with these card types,

1. Enumerate the card.
2. Read the EXT_CSD register of the card and examine the following fields:
    - BOOT_PARTITION_ENABLE
    - BOOT_SIZE_MULT
    - BOOT_INFO
3. If necessary, the controller can manipulate the boot information in the card.
4. If the controller must perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH (CMD6) command.
5. From this point, use the same steps as in Normal Boot Operation; eMMC.

Alternate Boot Operation; eMMC

The alternate boot operation differs from the normal boot operation in that CMD0 is used to boot the card rather than holding down the CMD-line of the card. The alternate boot operation can occur only if bit 0 in the extended CSD byte[228] (BOOT_INFO) is set to 1.

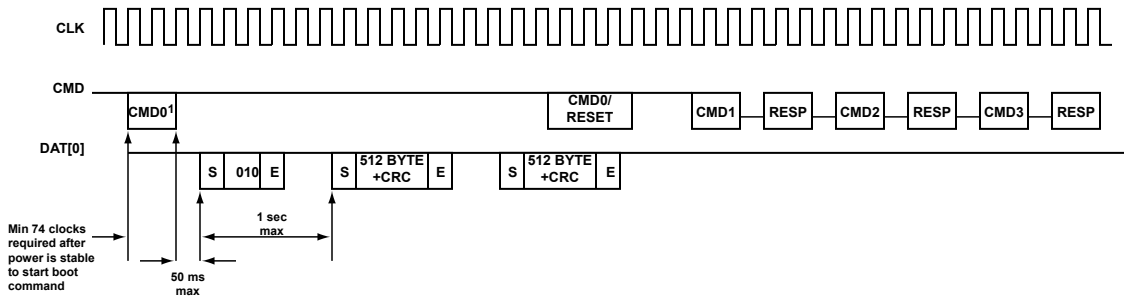

Figure 22-13: Alternate Boot Timing

Use the following procedure when working with eMMC or removable MMC 4.3 cards for the alternative boot operation. The software is aware that the card supports the Alternate Boot operation—the BOOT_INFO bit is set in the card. Also, the software is aware of the BOOT_SIZE_MULT value in the card and the data bus width to use during the boot operation-extend CSD register byte[177] bit[0:1].

1. Set the masks for interrupts by clearing appropriate bits in the Interrupt Mask register.
2. Set the `MSI_CTL.INTEN` bit =1.

ADDITIONAL INFORMATION: Set the MSI_CTL.INTEN bit. Before this bit is set, programs should write 0xFFFF_FFFF to the MSI_ISTAT and MSI_IDSTS registers to clear any pending interrupts. Software also must unmask all the relevant fields in MSI_IDINTEN register.

3. Configure the following bits in the control register.
   a. MSI_CTL.INTEN = 1'b1
   b. Other fields are 1'b0
   c. For IDMAC, set up the descriptors.
   d. Program the MSI_CTL.INTDMAC bit to 1
4. Set the card frequency to 400 kHz using the clock-divider register

   ADDITIONAL INFORMATION: Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.
5. Set Data Time Out = (10 × ((TAAC × f_{OP}) + (100 × NSAC)); this is NAC
6. Program the MSI_BLKSIZ register with 0x200 (512 bytes).
7. Program the MSI_BYTCNT register with multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card
8. Program the Rx FIFO threshold value in bytes in the MSI_FIFOTH register. Typically, the threshold value is set to half the FIFO depth; that is, MSI_FIFOTH.RXWM = (FIFO_DEPTH/2) – 1.
9. Program CMDARG = 0xFFFFFFFA.
10. Program the following fields.
    a. MSI_CMD.STARTCMD = 1'b1
    b. MSI_CMD.BOOTMODE= 1'b1
    c. MSI_CMD.XPECTBOOTACK depending on whether a start-acknowledge pattern is expected from the card.
    d. MSI_CMD.DXPECT = 1'b1
    e. MSI_CMD.INDX = 0
    f. Remainder of MSI_CMD register fields = 1'b0

    ADDITIONAL INFORMATION: Wait for the Command Done (CD) interrupt.
11. If MSI_CMD.XPECTBOOTACK = 1'b1 in step 10, the software driver must start a timer with a terminal value of 50 ms.
    a. Before this timer elapses, the BAR interrupt should be received from the MSI. If this action does not occur, the software must infer that the start-pattern has not been received and must discontinue the boot process and start with normal enumeration. In IDMAC:

- Descriptor is closed
- MSI_IDSTS.CES =1, indicating BAR timeout
- MSI_IDSTS.RI =0

b. If the BAR interrupt is received, the software driver should clear this interrupt by writing a 1 to it. The software driver then starts another timer with a terminal value of 1 - 0.05 = 0.95 seconds. Before this timer elapses, the BDS interrupt should be received from the MSI. If this action does not occur, the software driver discontinues the boot process and start with normal enumeration.

- Descriptor is closed
- MSI_IDSTS.CES =1, indicating BDS timeout
- MSI_IDSTS.RI =0

c. If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed MSI_FIFOTH.RXWM level is hit.

d. It is the responsibility of the software driver to terminate the boot operation by programming the MSI to send a CMD0 by programming the registers MSI_CMDARG =0 and the command register bits MSI_CMD.STARTCMD =1, MSI_CMD.INDX =0, all_other_fields = 0.

e. At the end of a successful boot data transfer from the card, the following status bits are set:

- Command Done (CD) with the MSI_ISTAT.CMDDONE bit
- Data Transfer Over (DTO) with the MSI_ISTAT.DTO bit
- Receive Interrupt (RI) with the MSI_IDSTS.RI bit

f. If an error occurs in Boot Ack pattern (010) or an end bit error occurs:

- Controller does not generate BAR interrupt
- Controller detects boot data start and generates BDS interrupt
- Controller continues to receive boot data
- Application must abort boot after receiving BDS interrupt

g. In IDMAC:

- If the software driver creates more descriptors than the boot data received, the extra descriptors are not closed by the MSI.
- If the software driver creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

h. If between data block transfers NAC is violated, DRTO (Data Read Timeout) is asserted. Apart from this, if there are errors associated with Start/End bits, SBE/EBE interrupts are also generated.

12. If MSI_CMD.XPECTBOOTACK =1'b0 in Step 10, the software should start a timer after Step 10with a terminal value of 1 second.
    a. Before this timer elapses, the BDS interrupt should be received from the MSI. If this does not occur, the software driver should discontinue the boot process and start with normal enumeration. In IDMAC:
        - Descriptor is closed
        - MSI_IDSTS.CES =1, indicating BDS timeout
        - MSI_IDSTS.RI =0
    b. If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed MSI_FIFOTH.RXWM level is hit.
    c. It is the responsibility of the software to terminate the boot operation. Software programs the MSI to send a CMD0 through the MSI_CMDARG register =0 and command register bits MSI_CMD.STARTCMD =1, MSI_CMD.INDX =0, and all_other_fields =0.
    d. At the end of a successful boot data transfer from card, the following interrupts are generated.
        - Command Done (CD) with the MSI_ISTAT.CMDDONE bit
        - Data Transfer Over (DTO) with the MSI_ISTAT.DTO bit
        - Receive Interrupt (RI) with the MSI_IDSTS.RI bit
    e. In IDMAC
        - If the software driver creates more descriptors than the boot data received, the MSI does not close the extra descriptors.
        - If the software driver creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

Alternate Boot Operation; Removable MMC4.3 Card

Removable MMC4.3 cards are different than eMMC in that software is not aware whether these cards support the boot mode of operation. The software must:

- Enumerate these cards as it would enumerate MMC4.0/4.1/4.2 cards for the first time
- Know the card characteristics
- Decide whether to perform a boot operation

Use the following procedure when working with removable MMC 4.3 cards for the Alternative Boot operation.

1. Enumerate the card.
2. Read the EXT_CSD register of the card and examine the following fields:

a. BOOT_PARTITION_ENABLE

b. BOOT_SIZE_MULT

c. BOOT_INFO

3. If necessary, the controller can also manipulate the boot information in the card.
4. If the host controller must perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH (CMD6) command.
5. From this point, use the same steps as in Alternate Boot Operation; eMMC.

ADSP-SC57x MSI Register Descriptions

Mobile Storage Interface (MSI) contains the following registers.

Table 22-16: ADSP-SC57x MSI Register List

Name	Description
MSI_BLKSIZ	Block Size Register
MSI_BUFADDR	Current Buffer Descriptor Address Register
MSI_BUSMODE	Bus Mode Register
MSI_BYTCNT	Byte Count Register
MSI_CDETECT	Card Detect Register
MSI_CDTHRCTL	Card Threshold Control Register
MSI_CLKDIV	Clock Divider Register
MSI_CLKEN	Clock Enable Register
MSI_CMD	Command Register
MSI_CMDARG	Command Argument Register
MSI_CTL	Control Register
MSI_CTYPE	Card Type Register
MSI_DBADDR	Descriptor List Base Address Register
MSI_DEBNCE	Debounce Count Register
MSI_DSCADDR	Current Host Descriptor Address Register
MSI_ENSHIFT	Enable Phase Shift Register
MSI_FIFOTH	FIFO Threshold Watermark Register
MSI_IDINTEN	Internal DMA Interrupt Enable Register
MSI_IDSTS	Internal DMA Status Register
MSI_IMSK	Interrupt Mask Register

Table 22-16: ADSP-SC57x MSI Register List (Continued)

Name	Description
MSI_ISTAT	Raw Interrupt Status Register
MSI_MSKISTAT	Masked Interrupt Status Register
MSI_PLDMND	Poll Demand Register
MSI_RESP0	Response Register 0
MSI_RESP1	Response Register 1
MSI_RESP2	Response Register 2
MSI_RESP3	Response Register 3
MSI_STAT	Status Register
MSI_TBBCNT	Transferred Host to BIU-FIFO Byte Count Register
MSI_TCBCNT	Transferred CIU Card Byte Count Register
MSI_TMOUT	Timeout Register

Block Size Register

The MSI_BLKSIZ register provides bits that configure data block sizes. Sizes supported are 1 to 65,535 bytes.

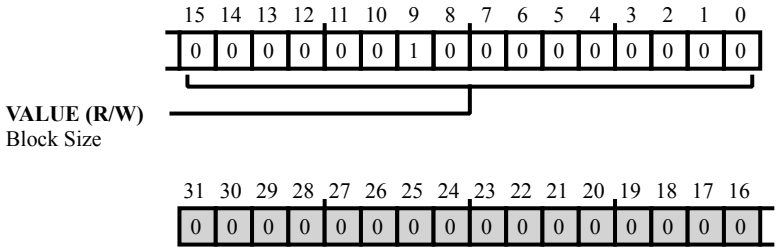

Figure 22-14: MSI_BLKSIZ Register Diagram

Table 22-17: MSI_BLKSIZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Block Size. The MSI_BLKSIZ.VALUE bit field configures data block size in bytes. Sizes supported are 1 to 65,535 bytes.

Current Buffer Descriptor Address Register

The MSI_BUFADDR register points to the data buffer address of the current descriptor read by the IDMAC.

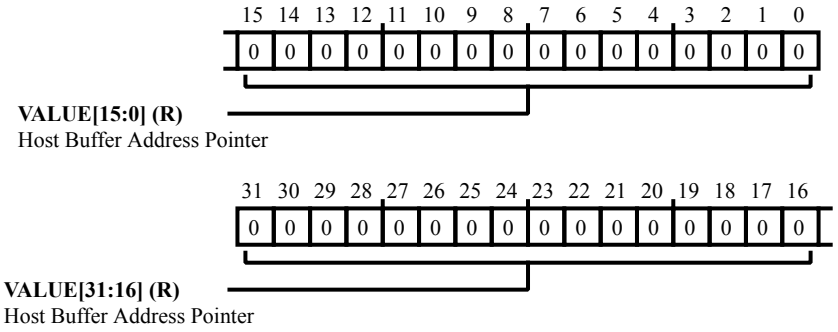

Figure 22-15: MSI_BUFADDR Register Diagram

Table 22-18: MSI_BUFADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Host Buffer Address Pointer. The MSI_BUFADDR.VALUE bit field points to the data buffer address of the current descriptor read by the IDMAC.

Bus Mode Register

The MSI_BUSMODE register provides bits that control the burst mode, descriptor skip length, and IDMAC. This register also provides a software reset bit.

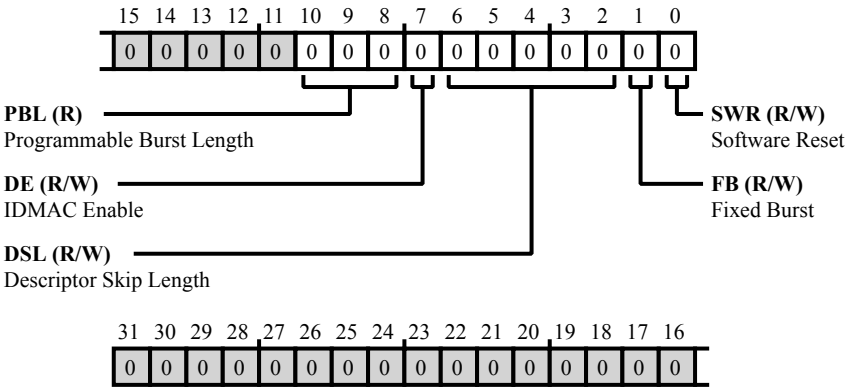

Figure 22-16: MSI_BUSMODE Register Diagram

Table 22-19: MSI_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/NW)	PBL	Programmable Burst Length. The MSI_BUSMODE.PBL bit field indicate the maximum number of beats to be performed in one IDMAC transaction. The IDMAC always attempts to burst as specified in PBL each time it starts a burst transfer on the host bus. This value is the mirror of the MSI_FIFOTH.DMAMSZ bits. In order to change this value, write the required value to MSI_FIFOTH.DMAMSZ bit field. The units for transfer are 32-bit.	
		0	1 transfer
		1	4 transfers
		2	8 transfers
		3	16 transfers
		4	32 transfers
		5	64 transfers
		6	128 transfers
		7	256 transfers
7 (R/W)	DE	IDMAC Enable. Setting the MSI_BUSMODE.DE bit enables the internal DMA interface.	
		0	Disable internal DMA
		1	Enable internal DMA

Table 22-19: MSI_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:2 (R/W)	DSL	Descriptor Skip Length. The `MSI_BUSMODE.DSL` bit field specifies the number of words to skip between two unchained descriptors. This is applicable only for dual buffer structures.	
1 (R/W)	FB	Fixed Burst. The `MSI_BUSMODE.FB` bit controls whether the peripheral bus master interface performs fixed burst transfers or not. When set, the peripheral bus uses only SINGLE, INCR4, INCR8 or INCR16 during the start of normal burst transfers. When reset, the peripheral bus uses SINGLE and INCR burst transfer operations.	
		0	Use SINGLE and INCR
		1	Use SINGLE, INCR4, INCR8 or INCR16
0 (R/W)	SWR	Software Reset. When the `MSI_BUSMODE.SWR` bit is set, the DMA controller resets all its internal registers. The `MSI_BUSMODE.SWR` bit is automatically cleared after 1 clock cycle.	
		0	No reset
		1	Reset internal registers

Byte Count Register

The MSI_BYTCNT register provides bits that configure the byte count to be transferred.

In SDIO mode, if a single transfer is greater than 4 bytes and non-DWORD-aligned, the transfer should be broken where only the last transfer is non-DWORD-aligned and less than 4 bytes. For example, if a transfer of 129 bytes must occur, then the driver should start at least two transfers; one with 128 bytes and the other with 1 byte.

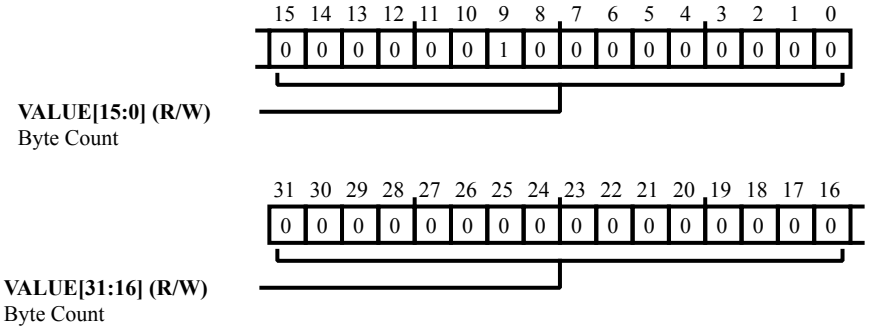

Figure 22-17: MSI_BYTCNT Register Diagram

Table 22-20: MSI_BYTCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Byte Count. The MSI_BYTCNT.VALUE bit field provides bits that configure the byte count to be transferred.

Card Detect Register

The MSI_CDETECT register configures the value on card_detect_n input ports (1 bit per card).

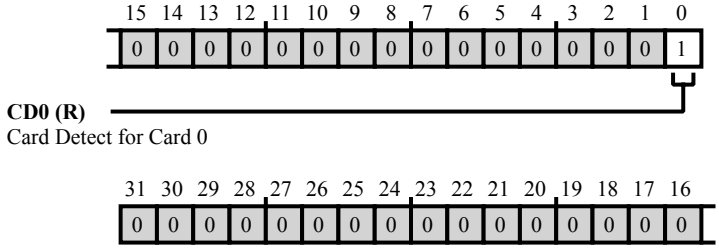

Figure 22-18: MSI_CDETECT Register Diagram

Table 22-21: MSI_CDETECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	CD0	Card Detect for Card 0. The MSI_CDETECT.CD0 bit sets the value on card_detect_n input ports.

Card Threshold Control Register

The MSI_CDTHRCTL register sets the card read threshold size and enables card read threshold. This register also has a Busy Clear interrupt generation bit.

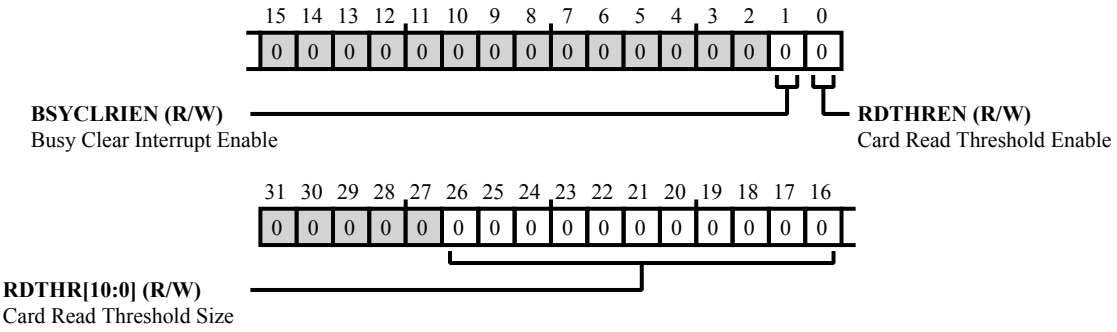

Figure 22-19: MSI_CDTHRCTL Register Diagram

Table 22-22: MSI_CDTHRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
26:16 (R/W)	RDTHR	Card Read Threshold Size. The MSI_CDTHRCTL.RDTHR bit configures the card read threshold size. For information on using this feature, see the "Card Read Threshold" section in the MSI chapter.	
1 (R/W)	BSYCLRIEN	Busy Clear Interrupt Enable. The MSI_CDTHRCTL.BSYCLRIEN bit indicates the completion of a busy driven by the card after a write data transfer.	
		0	Busy clear interrupt disabled
		1	Busy clear interrupt enabled
0 (R/W)	RDTHREN	Card Read Threshold Enable. The MSI_CDTHRCTL.RDTHREN bit enables the card read threshold size feature.	
		0	Card read threshold disabled
		1	Card read threshold enabled

Clock Divider Register

The MSI_CLKDIV register provides clock divider bit fields. The bit field value is: clock division = 2 x n.

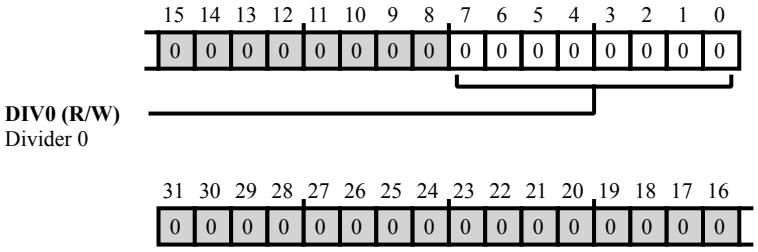

Figure 22-20: MSI_CLKDIV Register Diagram

Table 22-23: MSI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	DIV0	Divider 0. The MSI_CLKDIV.DIV0 bit field provides clock division. The value is 2 x n. For example, a value of 0 means divide by 2 x 0 = 0 (no division, bypass), a value of 1 means divide by 2 x 1 = 2, and a value of 0xFF means divide by 2 x 255 = 510, and so on.

Clock Enable Register

The MSI_CLKEN register enables clock control. This register also provides low-power control for the card clock.

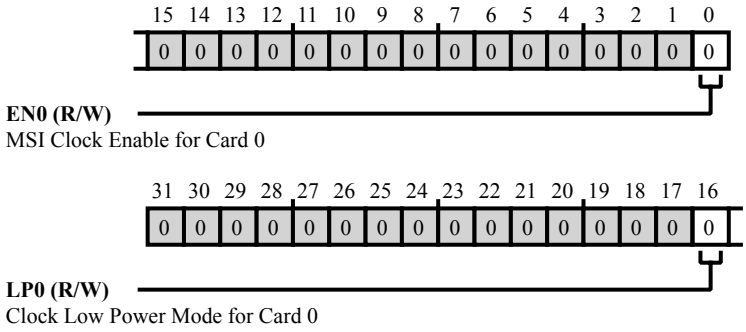

Figure 22-21: MSI_CLKEN Register Diagram

Table 22-24: MSI_CLKEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	LP0	Clock Low Power Mode for Card 0. Setting the MSI_CLKEN.LP0 bit puts the card clock into low-power mode; it stops the clock when the card is in IDLE (it should be normally set to only MMC and SD memory cards. For SDIO cards, if interrupts must be detected, the clock should not be stopped). Clearing the MSI_CLKEN.LP0 bit puts the cards into non-low power mode.
0 (R/W)	EN0	MSI Clock Enable for Card 0. The MSI_CLKEN.EN0 bit is the clock-enable control for the card clock.

Command Register

The MSI_CMD register provides bits that configure various command parameters such as boot modes, data transfer modes, and command response settings.

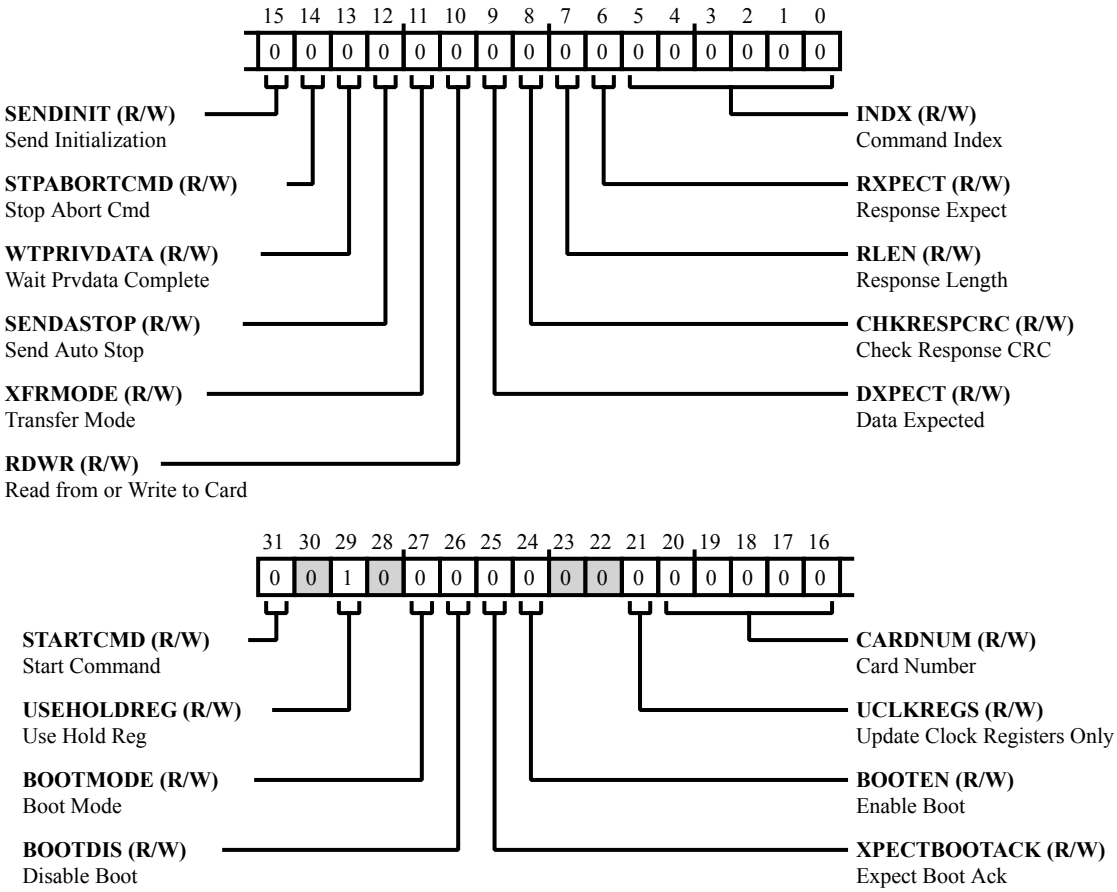

Figure 22-22: MSI_CMD Register Diagram

Table 22-25: MSI_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	STARTCMD	Start Command. Once the command is taken by CIU, the MSI_CMD.STARTCMD bit is cleared. When this bit is set, the host should not attempt to write to any command registers. If a write is attempted, a hardware lock error is set in the raw interrupt register. Once the command is sent and a response is received from the SD_MMC cards, the Command Done bit is set in the raw interrupt register.

Table 22-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	USEHOLDREG	Use Hold Reg. When the MSI_CMD.USEHOLDREG bit is set, CMD and DATA are sent to the card through the HOLD register. When the MSI_CMD.USEHOLDREG bit is cleared, CMD and DATA are sent to the card bypassing the HOLD register.	
		0	CMD and DATA sent to card bypassing the HOLD register
		1	CMD and DATA sent to card through the HOLD register
27 (R/W)	BOOTMODE	Boot Mode. When the MSI_CMD.BOOTMODE bit is set, the MSI has an alternate boot operation. When the MSI_CMD.BOOTMODE bit is cleared, the MSI has a mandatory boot operation.	
		0	Mandatory Boot
		1	Alternate Boot
26 (R/W)	BOOTDIS	Disable Boot. When the MSI_CMD.BOOTDIS bit is set with the MSI_CMD.STARTCMD bit, the CIU terminates the boot operation. Do NOT set MSI_CMD.BOOTDIS and MSI_CMD.BOOTEN together.	
		0	No action
		1	Terminate boot
25 (R/W)	XPECTBOOTACK	Expect Boot Ack. When the MSI_CMD.XPECTBOOTACK bit is set with with the MSI_CMD.BOOTEN bit, the CIU expects a boot acknowledge start pattern of 0-1-0 from the selected card.	
		0	No ACK expected
		1	ACK expected
24 (R/W)	BOOTEN	Enable Boot. The MSI_CMD.BOOTEN bit should be set only for mandatory boot mode. When software sets this bit along with the MSI_CMD.STARTCMD bit, CIU starts the boot sequence for the corresponding card by asserting the CMD line low. Do NOT set the MSI_CMD.BOOTEN bit and the MSI_CMD.BOOTDIS bit together.	

Table 22-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	UCLKREGS	Update Clock Registers Only. When the `MSI_CMD.UCLKREGS` bit is set, do not send commands. Update the clock register value into card clock domain. When cleared, the normal command sequence is used. The following register values are transferred into card clock domain: CLKDIV, and CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During the normal command sequence, when update_clock_registers_only = 0, the following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOUT, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s). When the `MSI_CMD.UCLKREGS` bit is set, there are no Command Done interrupts because no command is sent to SD_MMC cards.	
		0	Normal command sequence
		1	Do not send commands, just update clock register value
20:16 (R/W)	CARDNUM	Card Number. The `MSI_CMD.CARDNUM` bit represents the physical slot number of the card being accessed.	
15 (R/W)	SENDINIT	Send Initialization. When the `MSI_CMD.SENDINIT` bit is set, send an initialization sequence before sending this command. When the `MSI_CMD.SENDINIT` bit is cleared, do not send an initialization sequence (80 clocks of 1) before sending this command. After power-on, 80 clocks must be sent to the card for initialization before sending any commands to the card. The bit should be set while sending the first command to the card, so that the controller will initialize clocks before sending a command to the card. This bit should not be set for either of the boot modes (alternate or mandatory).	
		0	Do not send initialization sequence
		1	Send initialization sequence

Table 22-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	STPABORTCMD	Stop Abort Cmd. When the MSI_CMD.STPABORTCMD bit is set, the stop or abort command is intended to stop the current data transfer in progress. When an open-ended or predefined data transfer is in progress, and the host issues a stop or abort command to stop the data transfer, the MSI_CMD.STPABORTCMD bit should be set, so that the command/data state-machines of CIU can return correctly to an idle state. This is also applicable for boot mode transfers. To abort boot mode, this bit should be set along with CMD[26] = disable_boot. When cleared, neither stop nor abort command to stop current data transfer in progress. If abort is sent to function-number currently selected or not in data-transfer mode, then the bit should be set to 0.	
		0	Neither stop nor abort command
		1	Stop or abort command
13 (R/W)	WTPRIVDATA	Wait Prvdata Complete. When the MSI_CMD.WTPRIVDATA bit is set, wait for the previous data transfer to complete before sending a command. When the MSI_CMD.WTPRIVDATA bit is cleared, send the command at once, even if the previous data transfer has not completed. The MSI_CMD.WTPRIVDATA = 0 option is typically used to query the status of the card during data transfer or to stop the current data transfer; the card number should be the same as in the previous command.	
		0	Send command at once
		1	Wait for previous data transfer completion
12 (R/W)	SENDASTOP	Send Auto Stop. When the MSI_CMD.SENDASTOP bit is set, MSI sends the stop command to SD_MMC cards at the end of the data transfer. Refer to the Auto Stop section in the chapter to determine: • When the MSI_CMD.SENDASTOP bit should be set, since some data transfers do not need explicit stop commands • When software should explicitly send a stop command during open-ended transfers Additionally, when resuming suspended memory access of SD-Combo card, the MSI_CMD.SENDASTOP bit should be set correctly to send a stop command. The bit does not need to be set if no data is expected from the card.	
		0	No stop command sent at end of data transfer
		1	Send stop command at end of data transfer

Table 22-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	XFRMODE	Transfer Mode. When the MSI_CMD.XFRMODE bit is set, stream data transfer command. If no data expected, do-not-care.	
		0	Block data transfer command
		1	Stream data transfer command
10 (R/W)	RDWR	Read from or Write to Card. When the MSI_CMD.RDWR bit is set, write to the card. When the MSI_CMD.RDWR bit is cleared, read from the card.	
		0	Read from card
		1	Write to card
9 (R/W)	DXPECT	Data Expected. When the MSI_CMD.DXPECT bit is set, data transfer is expected. When the MSI_CMD.DXPECT bit is cleared, no data transfer is expected.	
		0	No data transfer expected
		1	Data transfer expected
8 (R/W)	CHKRESPCRC	Check Response CRC. When the MSI_CMD.CHKRESPCRC bit is set, check the response CRC. When cleared, do not check the response. Some of the command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.	
		0	Do not check response
		1	Check response
7 (R/W)	RLEN	Response Length. When the MSI_CMD.RLEN bit is set, a long response is expected from the card. When cleared, a short response is expected.	
		0	Short response expected
		1	Long response expected
6 (R/W)	RXPECT	Response Expect. When the MSI_CMD.RXPECT bit is set, a response is expected from the card. When cleared, no response is expected.	
		0	No response expected
		1	Response expected

Table 22-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	INDX	Command Index.

Command Argument Register

The MSI_CMDARG register provides bits that specify the command argument to be passed to the card.

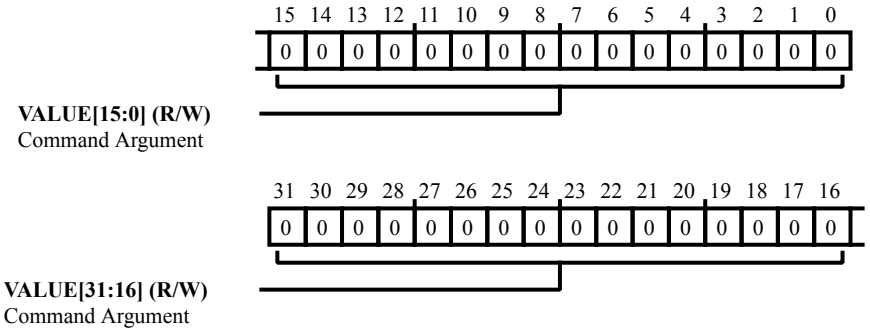

Figure 22-23: MSI_CMDARG Register Diagram

Table 22-26: MSI_CMDARG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Argument. The MSI_CMDARG.VALUE bit field specifies the command argument to be passed to the card.

Control Register

The MSI_CTL register controls the various settings used by the MSI module.

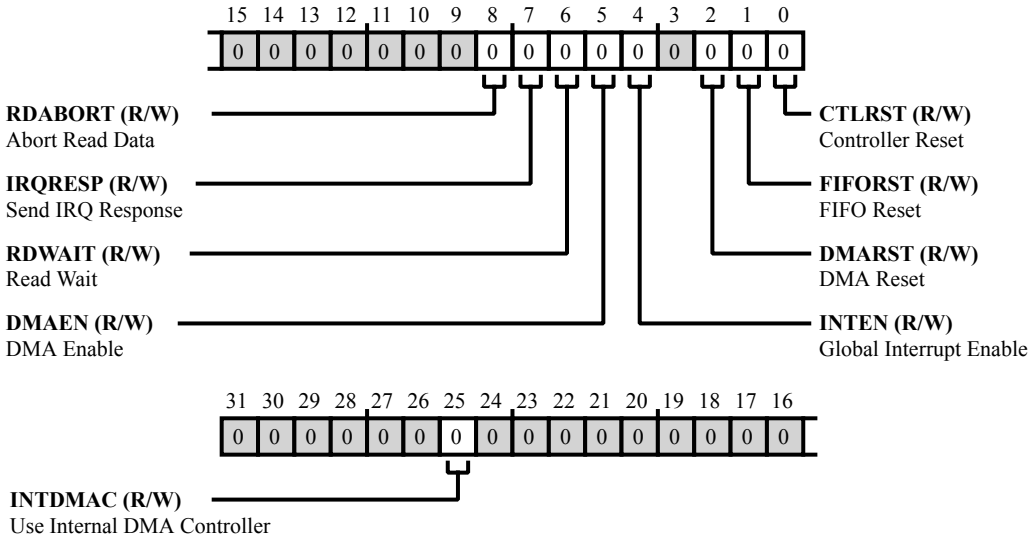

Figure 22-24: MSI_CTL Register Diagram

Table 22-27: MSI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	INTDMAC	Use Internal DMA Controller. The MSI_CTL.INTDMAC bit is present only for the internal DMAC configuration and determines whether the host or DMA is used for data transfers.	
		0	Host performs transfers
		1	DMA performs transfers
8 (R/W)	RDABORT	Abort Read Data. Setting the MSI_CTL.RDABORT bit after the suspend command is issued during a read-transfer operation, software polls the card to find out when the suspend happened. Once the suspend occurs, software sets the bit to reset data state-machine, which is waiting for next block of data. The bit automatically clears once the data state machine resets to idle. It is used in the SDIO card suspend sequence.	
		0	No change
		1	Reset data state machine

Table 22-27: MSI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	IRQRESP	Send IRQ Response. Setting the `MSI_CTL.IRQRESP` bit sends an auto IRQ response. It is cleared once the response is sent. To wait for MMC card interrupts, the host issues CMD40, and the MSI waits for an interrupt response from the MMC card(s). In the meantime, if the host wants the MSI to exit waiting for interrupt state, it can set the `MSI_CTL.IRQRESP` bit, at which time the MSI command state-machine sends the CMD40 response on the bus and returns to the idle state.	
		0	No change
		1	Send auto IRQ response
6 (R/W)	RDWAIT	Read Wait. Setting the `MSI_CTL.RDWAIT` bit allows sending read-wait to SDIO cards.	
		0	Clear read wait
		1	Assert read wait
5 (R/W)	DMAEN	DMA Enable. Setting the `MSI_CTL.DMAEN` bit enables DMA transfer mode.	
		0	Disable
		1	Enable
4 (R/W)	INTEN	Global Interrupt Enable. Setting the `MSI_CTL.INTEN` bit enables global interrupts. The int port is 1 only when this bit is 1 and one or more unmasked interrupts are set.	
		0	Disable
		1	Enable
2 (R/W)	DMARST	DMA Reset. Setting the `MSI_CTL.DMARST` bit resets internal DMA interface control logic. To reset the DMA interface, firmware should set this bit to 1. This bit is auto-cleared after two peripheral clocks.	
		0	No change
		1	Reset

Table 22-27: MSI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FIFORST	FIFO Reset. Setting the `MSI_CTL.FIFORST` bit provides a reset to data FIFO to reset FIFO pointers. To reset FIFO, firmware should set bit to 1. This bit is auto-cleared after completion of reset operation.	
		0	No change
		1	Reset
0 (R/W)	CTLRST	Controller Reset. Setting the `MSI_CTL.CTLRST` bit resets the MSI. To reset the controller, firmware should set the bit to 1. This bit is auto-cleared after two peripheral bus and two cclk_in clock cycles. This resets the: • BIU/CIU interface • CIU and state machines • `MSI_CTL.RDABORT`, `MSI_CTL.IRQRESP`, and `MSI_CTL.RDWAIT` bits • `MSI_CMD.STARTCMD` bit It does not affect any registers or DMA interface, or FIFO or host interrupts.	
		0	No change
		1	Reset

Card Type Register

The MSI_CTYPE register provides bits that configure card widths.

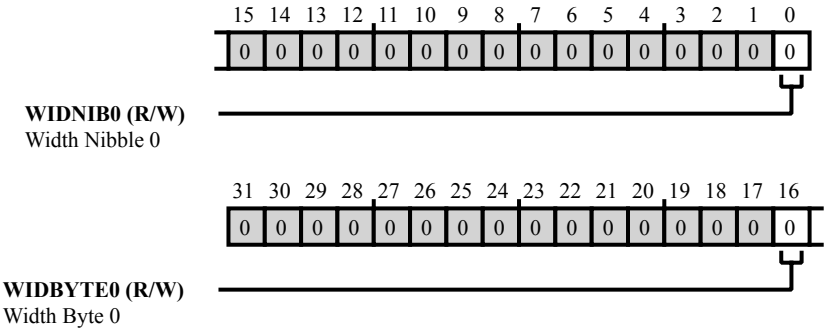

Figure 22-25: MSI_CTYPE Register Diagram

Table 22-28: MSI_CTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	WIDBYTE0	Width Byte 0. The MSI_CTYPE.WIDBYTE0 bit enables 8-bit mode for card 0.
0 (R/W)	WIDNIB0	Width Nibble 0. The MSI_CTYPE.WIDNIB0 bit enables 4-bit mode for card 0.

Descriptor List Base Address Register

The MSI_DBADDR register contains the base address of the first descriptor. The LSB bits [1:0] bits are ignored and taken as all-zero by the IDMAC internally and these LSB bits are read-only.

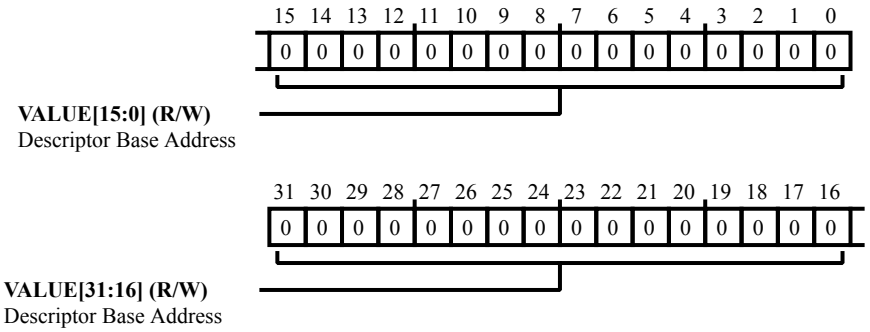

Figure 22-26: MSI_DBADDR Register Diagram

Table 22-29: MSI_DBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Descriptor Base Address. The MSI_DBADDR.VALUE bit field contains the base address of the first descriptor.

Debounce Count Register

The MSI_DEBNCE register provides the number of host clocks (clk) used by debounce filter logic; typical debounce time is 5-25 ms.

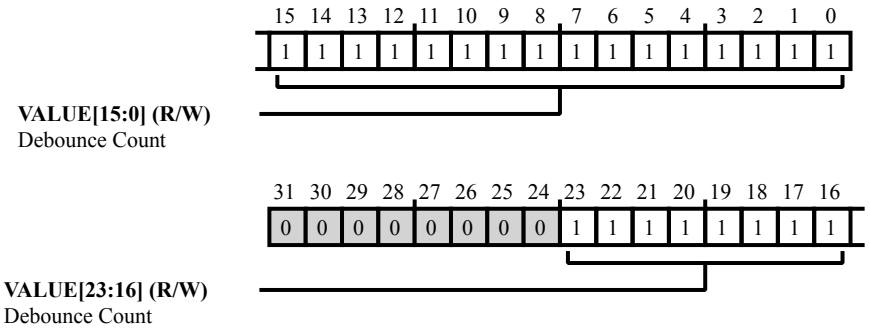

Figure 22-27: MSI_DEBNCE Register Diagram

Table 22-30: MSI_DEBNCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	VALUE	Debounce Count. The MSI_DEBNCE.VALUE bit field provides the number of host clocks (clk) used by debounce filter logic.

Current Host Descriptor Address Register

The MSI_DSCADDR register points to the start address of the current descriptor read by the IDMAC.

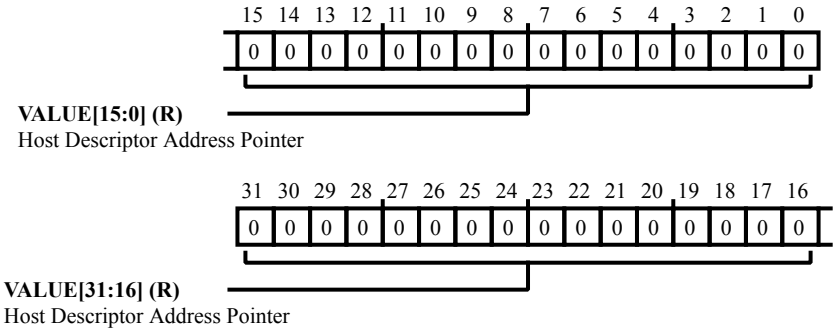

Figure 22-28: MSI_DSCADDR Register Diagram

Table 22-31: MSI_DSCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Host Descriptor Address Pointer. The MSI_DSCADDR.VALUE bit field points to the start address of the current descriptor read by the IDMAC.

Enable Phase Shift Register

The MSI_ENSHIFT register provides control for the amount of phase shift provided on the default enables in the design. Two bits are assigned for each card/slot.

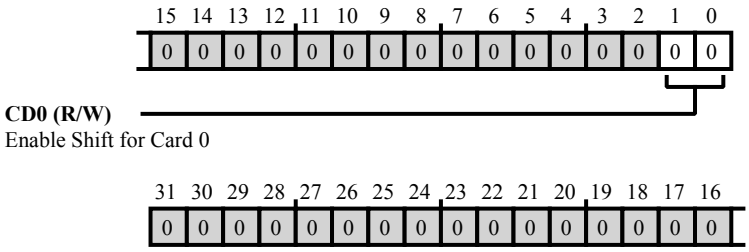

Figure 22-29: MSI_ENSHIFT Register Diagram

Table 22-32: MSI_ENSHIFT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	CD0	Enable Shift for Card 0. The MSI_ENSHIFT.CD0 bit field provides control for the amount of phase shift provided on the default enables in the design.

FIFO Threshold Watermark Register

The MSI_FIFOTH register provides bits that manage the FIFO transactions.

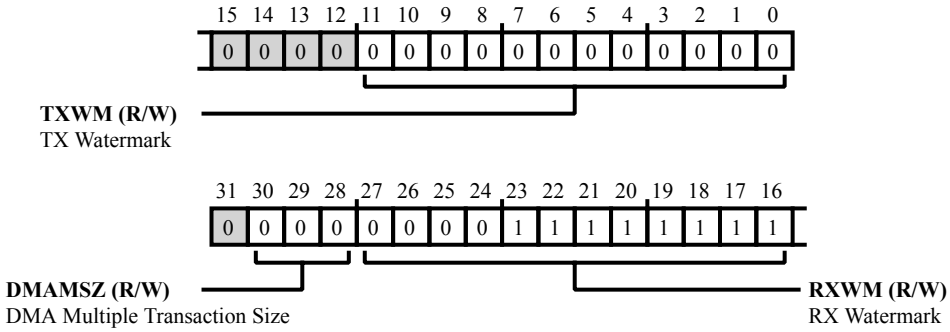

Figure 22-30: MSI_FIFOTH Register Diagram

Table 22-33: MSI_FIFOTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:28 (R/W)	DMAMSZ	DMA Multiple Transaction Size. The MSI_FIFOTH.DMAMSZ bit field configures the burst size of a multiple transaction. The units for transfer are 32-bit.	
		0	1 transfer
		1	4 transfers
		2	8 transfers
		3	16 transfers
		4	32 transfers
		5	64 transfers
		6	128 transfers
		7	256 transfers
27:16 (R/W)	RXWM	RX Watermark. The MSI_FIFOTH.RXWM bit field sets the FIFO threshold watermark level when receiving data to card. When the FIFO data count is greater than this number, a DMA/FIFO request is raised.	
11:0 (R/W)	TXWM	TX Watermark. The MSI_FIFOTH.TXWM bit field sets the FIFO threshold watermark level when transmitting data to card. When the FIFO data count is less than or equal to this number, a DMA/FIFO request is raised.	

Internal DMA Interrupt Enable Register

The MSI_IDINTEN register provides bits for setting various interrupts in DMA mode.

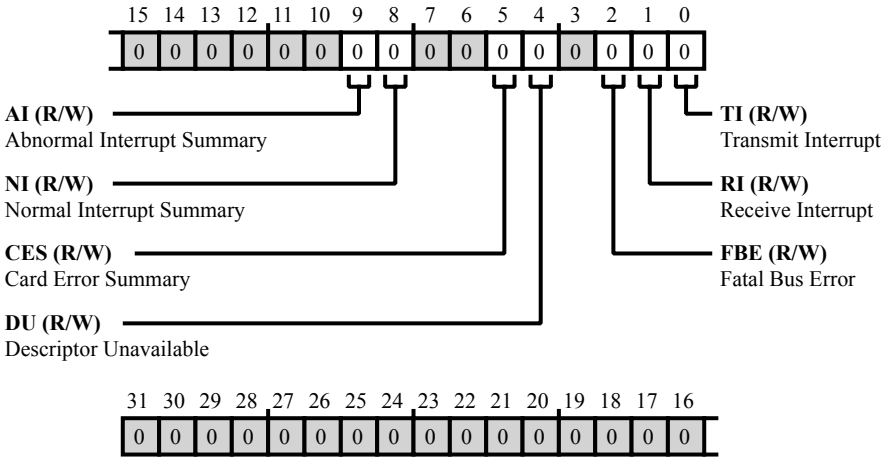

Figure 22-31: MSI_IDINTEN Register Diagram

Table 22-34: MSI_IDINTEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	AI	Abnormal Interrupt Summary. Setting the MSI_IDINTEN.AI bit enables the abnormal interrupt summary. See the bit descriptions in the MSI_IDSTS register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
8 (R/W)	NI	Normal Interrupt Summary. Setting the MSI_IDINTEN.NI bit enables the normal interrupt summary. See the bit descriptions in the MSI_IDSTS register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
5 (R/W)	CES	Card Error Summary. Setting the MSI_IDINTEN.CES bit enables the card error summary interrupt. See the bit descriptions in the MSI_IDSTS register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled

Table 22-34: MSI_IDINTEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DU	Descriptor Unavailable. Setting the `MSI_IDINTEN.DU` bit enables the descriptor unavailable interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
2 (R/W)	FBE	Fatal Bus Error. Setting the `MSI_IDINTEN.FBE` bit enables the FBE interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
1 (R/W)	RI	Receive Interrupt. Setting the `MSI_IDINTEN.RI` bit enables the receive interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
0 (R/W)	TI	Transmit Interrupt. Setting the `MSI_IDINTEN.TI` bit enables the transmit interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled

Internal DMA Status Register

The MSI_IDSTS register provides DMA status information. This register is updated only when the DMA is active.

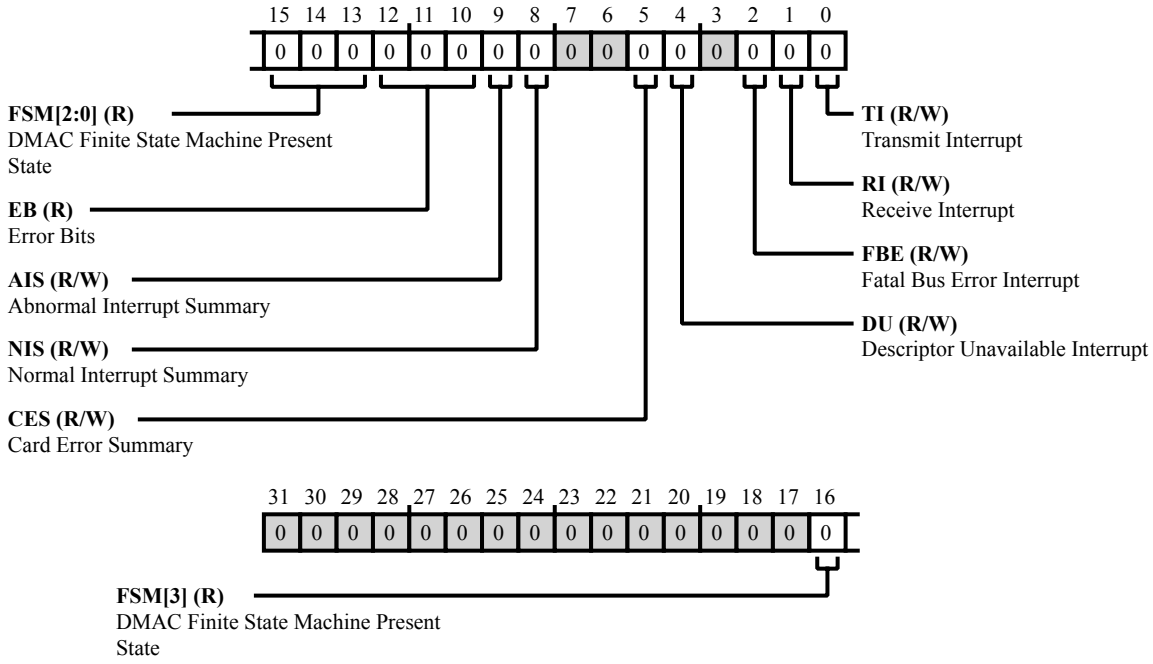

Figure 22-32: MSI_IDSTS Register Diagram

Table 22-35: MSI_IDSTS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:13 (R/NW)	FSM	DMAC Finite State Machine Present State. The MSI_IDSTS.FSM bit field indicates the present state of the finite state machine IDMAC (DMA controller).	
		0	DMA Idle
		1	DMA suspend
		2	DESC_RD
		3	DESC_CHK
		4	DMA_RD_REQ_WAIT
		5	DMA_WR_REQ_WAIT
		6	DMA_RD
		7	DMA_WR
		8	DESC_CLOSE

Table 22-35: MSI_IDSTS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12:10 (R/NW)	EB	Error Bits. The MSI_IDSTS.EB bit field indicates the type of error that caused a bus error. It is valid only with MSI_IDSTS.FBE set. This field does not generate an interrupt. The MSI_IDSTS.EB bit field is read-only.	
		0	3'b001 - Host abort received during transmission
		1	3'b010 - Host abort received during reception
9 (R/W)	AIS	Abnormal Interrupt Summary. The MSI_IDSTS.AIS bit field is a logical OR of the following: IDSTS[2] - Fatal Bus Interrupt IDSTS[4] - DU bit Interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes MSI_IDSTS.AIS to be set is cleared. Writing a 1 clears this bit.	
8 (R/W)	NIS	Normal Interrupt Summary. The MSI_IDSTS.NIS bit field is a logical OR of the following: IDSTS[0] - Transmit Interrupt IDSTS[1] - Receive Interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes MSI_IDSTS.NIS to be set is cleared. Writing a 1 clears this bit.	
5 (R/W)	CES	Card Error Summary. The MSI_IDSTS.CES bit indicates the logical OR of the following bits: • EBE - End Bit Error • RTO - Response Timeout/Boot Ack Timeout • RCRC - Response CRC • SBE - Start Bit Error • DRTO - Data Read Timeout/BDS timeout • DCRC - Data CRC for Receive • RE - Response Error Writing a 1 clears this bit.	
		0	No error occurred
		1	Error occurred

Table 22-35: MSI_IDSTS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DU	Descriptor Unavailable Interrupt. The `MSI_IDSTS.DU` bit indicates a descriptor unavailable error. If software creates less descriptors than the boot data received, the MSI generates this interrupt and does not transfer any further data to system memory.	
		0	No error occurred
		1	Error occurred
2 (R/W)	FBE	Fatal Bus Error Interrupt. The `MSI_IDSTS.FBE` bit indicates a fatal bus error error. An FBE occurs due to an error response from the SCB. Because this is a system error, the software driver should not perform any further programming of the MSI. The only recovery mechanism from such an error is to issue a hard reset or to perform a controller reset by writing to the `MSI_CTL.CTLRST` bit.	
		0	No error occurred
		1	Error occurred
1 (R/W)	RI	Receive Interrupt. The `MSI_IDSTS.RI` bit indicates that data reception is finished for a descriptor.	
		0	No event occurred
		1	Event occurred
0 (R/W)	TI	Transmit Interrupt. The `MSI_IDSTS.TI` bit indicates that data transmission is finished for a descriptor.	
		0	No event occurred
		1	Event occurred

Interrupt Mask Register

The MSI_IMSK register provides bits that allow the masking of unwanted interrupts.

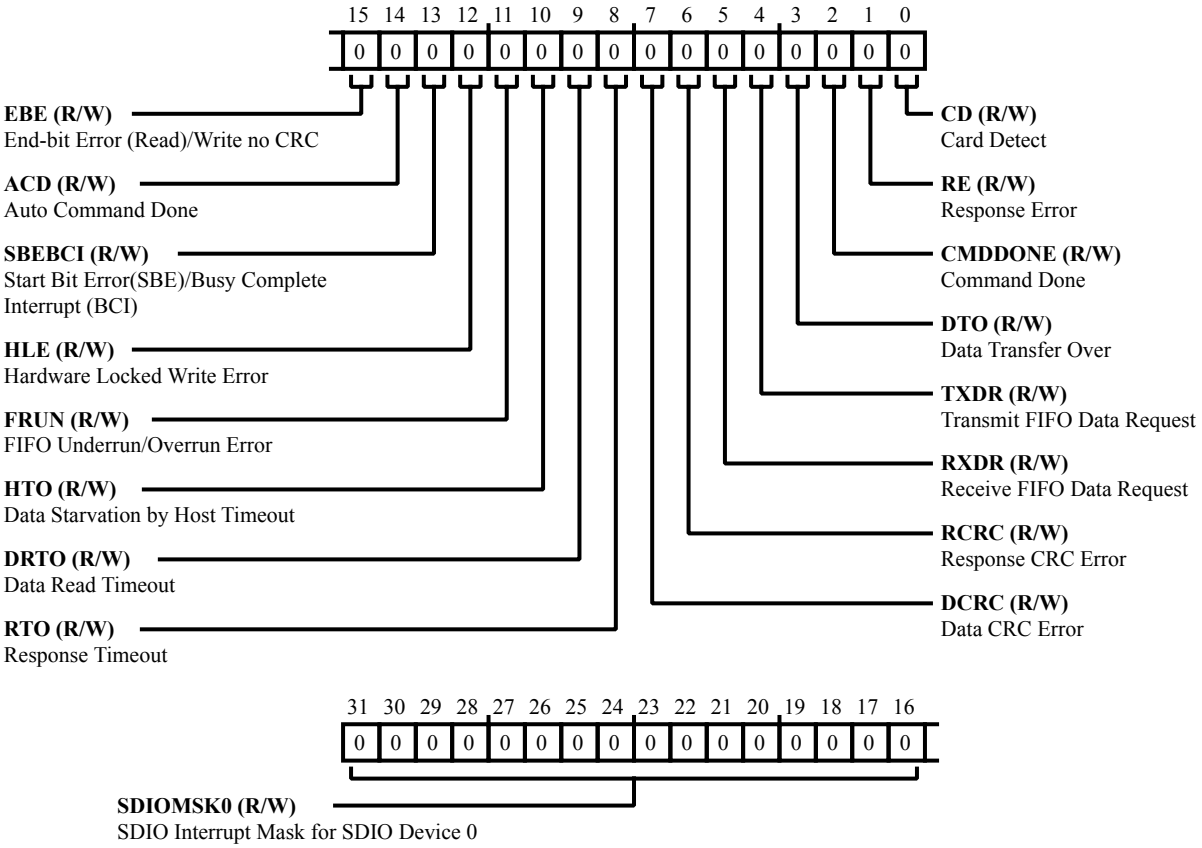

Figure 22-33: MSI_IMSK Register Diagram

Table 22-36: MSI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/W)	SDIOMSK0	SDIO Interrupt Mask for SDIO Device 0. The MSI_IMSK.SDIOMSK0 bits mask SDIO interrupts, one bit for one card. When masked, SDIO interrupt detection for that card is disabled. A 0 masks an interrupt, and 1 enables an interrupt.	
15 (R/W)	EBE	End-bit Error (Read)/Write no CRC. The MSI_IMSK.EBE bit masks the end bit read/write no CRC error.	
		0	Masked
		1	Enabled

Table 22-36: MSI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ACD	Auto Command Done. The `MSI_IMSK.ACD` bit masks the auto command done error.	
		0	Masked
		1	Enabled
13 (R/W)	SBEBCI	Start Bit Error(SBE)/Busy Complete Interrupt (BCI). The `MSI_IMSK.SBEBCI` bit masks the start bit/busy complete error.	
		0	Masked
		1	Enabled
12 (R/W)	HLE	Hardware Locked Write Error. The `MSI_IMSK.HLE` bit masks the hardware locked write error.	
		0	Masked
		1	Enabled
11 (R/W)	FRUN	FIFO Underrun/Overrun Error. The `MSI_IMSK.FRUN` bit masks the FIFO overrun or underrun error.	
		0	Masked
		1	Enabled
10 (R/W)	HTO	Data Starvation by Host Timeout. The `MSI_IMSK.HTO` bit masks the host timeout error.	
		0	Masked
		1	Enabled
9 (R/W)	DRTO	Data Read Timeout. The `MSI_IMSK.DRTO` bit masks the data read timeout error.	
		0	Masked
		1	Enabled
8 (R/W)	RTO	Response Timeout. The `MSI_IMSK.RTO` bit masks the response timeout error.	
		0	Masked
		1	Enabled

Table 22-36: MSI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	DCRC	Data CRC Error. The MSI_IMSK.DCRC bit masks the data CRC error where the received data CRC does not match with locally-generated CRC in CIU. The error can also occur if the write CRC status is incorrectly sampled by the host.	
		0	Masked
		1	Enabled
6 (R/W)	RCRC	Response CRC Error. The MSI_IMSK.RCRC bit masks the response CRC error which is set when the response CRC does not match with the locally-generated CRC in the CIU.	
		0	Masked
		1	Enabled
5 (R/W)	RXDR	Receive FIFO Data Request. The MSI_IMSK.RXDR bit masks the receive FIFO data request interrupt which is set during write operation to card when FIFO level reaches less than or equal to transmit-threshold level.	
		0	Masked
		1	Enabled
4 (R/W)	TXDR	Transmit FIFO Data Request. The MSI_IMSK.TXDR bit masks the transmit FIFO data request interrupt which is set during write operation to card when FIFO level reaches less than or equal to transmit-threshold level.	
		0	Masked
		1	Enabled
3 (R/W)	DTO	Data Transfer Over. The MSI_IMSK.DTO bit masks the data transfer over interrupt which indicates the data transfer completed. Though on detection of errors such as the start bit error, the data CRC error, and so on, DTO may or may not be set; the application must issue CMD12, which ensures that DTO is set.	
		0	Masked
		1	Enabled

Table 22-36: MSI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CMDDONE	Command Done. The `MSI_IMSK.CMDDONE` bit masks the command done interrupt where a command is sent to a card and received a response from the card, even if a response error or a CRC error occurs.	
		0	Masked
		1	Enabled
1 (R/W)	RE	Response Error. The `MSI_IMSK.RE` masks a response error. This is an error in received response set if one of following occurs: transmission bit != 0, command index mismatch, End-bit != 1.	
		0	Masked
		1	Enabled
0 (R/W)	CD	Card Detect. The `MSI_IMSK.CD` bit masks the card detect interrupt. On power-on, the controller should read in the card_detect port and store the value in the memory. Upon receiving a card-detect interrupt, it should again read the card_detect port and XOR with the previous card-detect status to find out which card has interrupted.	
		0	Masked
		1	Enabled

Raw Interrupt Status Register

The MSI_ISTAT register provides bits that clear interrupts. Conditions 6 through 9 indicate that the received data may have errors. If there was a response timeout, then no data transfer occurred.

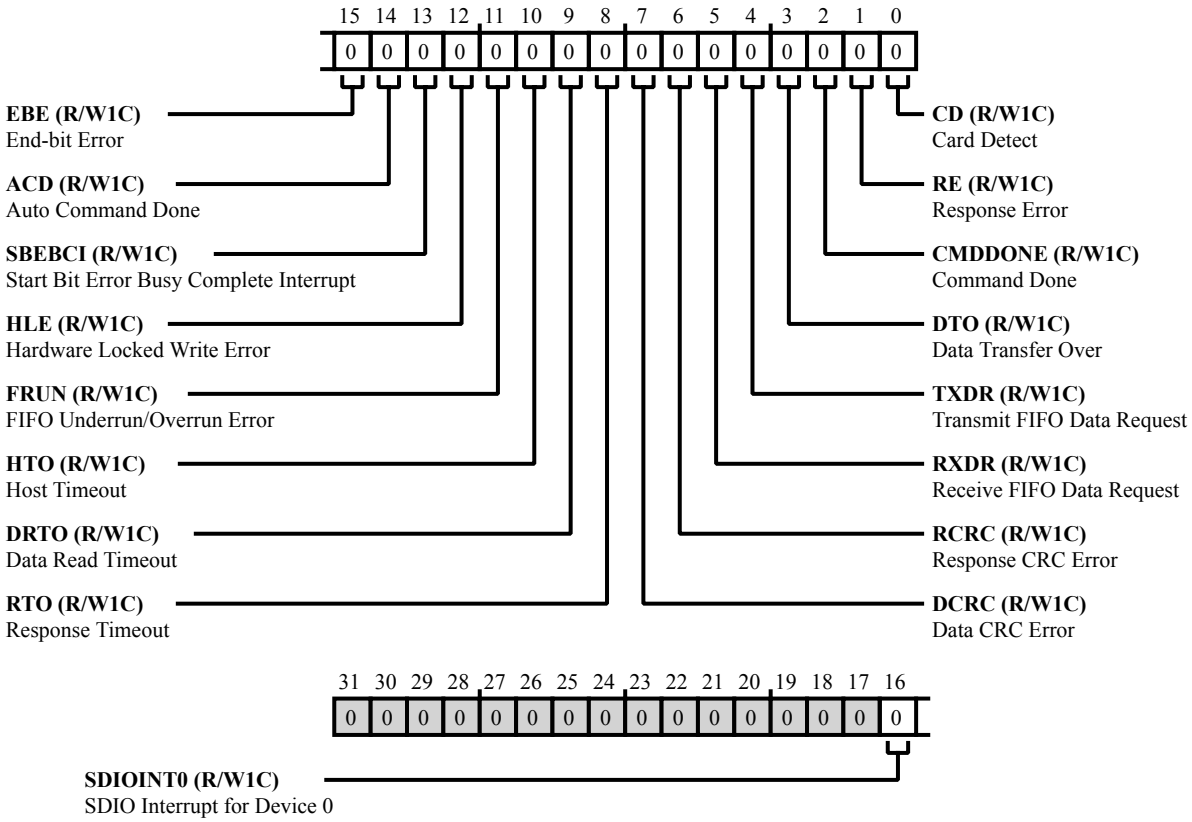

Figure 22-34: MSI_ISTAT Register Diagram

Table 22-37: MSI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	SDIOINT0	SDIO Interrupt for Device 0. The MSI_ISTAT.SDIOINT0 bit indicates that an interrupt occurred on an SDIO card.	
15 (R/W1C)	EBE	End-bit Error. The MSI_ISTAT.EBE bit indicates that the start bit of the CRC status was not received by two clocks after the end of the data block. A CRC error is indicated by the card.	
		0	No error
		1	Error occurred

Table 22-37: MSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ACD	Auto Command Done.	
		0	No error
		1	Error occurred
13 (R/W1C)	SBEBCI	Start Bit Error Busy Complete Interrupt. The `MSI_ISTAT.SBEBCI` bit indicates the completion of a busy signal driven by the card after a write data transfer.	
		0	No error
		1	Error occurred
12 (R/W1C)	HLE	Hardware Locked Write Error.	
		0	No error
		1	Error occurred
11 (R/W1C)	FRUN	FIFO Underrun/Overrun Error.	
		0	No error
		1	Error occurred
10 (R/W1C)	HTO	Host Timeout. The `MSI_ISTAT.HTO` bit indicates that the FIFO is empty during transmission or is full during reception. Unless software/DMA writes data for an empty condition or reads data for a full condition, the MSI cannot continue with data transfer. The clock to the card is stopped.	
		0	No error
		1	Error occurred
9 (R/W1C)	DRTO	Data Read Timeout. The `MSI_ISTAT.DRTO` bit indicates that the card has not sent data within the time-out period.	
		0	No error
		1	Error occurred
8 (R/W1C)	RTO	Response Timeout.	
		0	No error
		1	Error occurred

Table 22-37: MSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	DCRC	Data CRC Error. The `MSI_ISTAT.DCRC` bit indicates that a data CRC error where the received data CRC does not match with the locally-generated CRC in the CIU. This error can also occur if the write CRC status is incorrectly sampled by the host.	
		0	No error
		1	Error occurred
6 (R/W1C)	RCRC	Response CRC Error. The `MSI_ISTAT.RCRC` bit indicates that the response CRC error which is caused when the response CRC does not match with the locally-generated CRC in the CIU.	
		0	No error
		1	Error occurred
5 (R/W1C)	RXDR	Receive FIFO Data Request. The `MSI_ISTAT.RXDR` bit indicates that the FIFO threshold for receiving data was reached and software/DMA is expected to read data from the FIFO.	
		0	No error
		1	Error occurred
4 (R/W1C)	TXDR	Transmit FIFO Data Request. The `MSI_ISTAT.TXDR` bit indicates that the FIFO threshold for transmitting data was reached and is less than or equal to transmit-threshold level. Software/DMA is expected to write data, if available, in the FIFO. This interrupt is set during a write operation to the card.	
		0	No error
		1	Error occurred
3 (R/W1C)	DTO	Data Transfer Over. The `MSI_ISTAT.DTO` bit indicates the data transfer completed. If there is a response timeout error, then the MSI does not attempt any data transfer and this bit is never set.	
		0	No error
		1	Error occurred
2 (R/W1C)	CMDDONE	Command Done. The `MSI_ISTAT.CMDDONE` bit indicates that a command that was sent to a card received a response from the card, even a response error or CRC error occurred.	
		0	No error
		1	Error occurred

Table 22-37: MSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RE	Response Error. The `MSI_ISTAT.RE` bit indicates that an error was received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.	
		0	No error
		1	Error occurred
0 (R/W1C)	CD	Card Detect. The `MSI_ISTAT.CD` bit indicates a card detect interrupt.	
		0	No error
		1	Error occurred

Masked Interrupt Status Register

The MSI_MSKISTAT register indicates the status for the bits which are unmasked in the MSI_IMSK register. In other words, MSI_MSKISTAT = MSI_ISTAT and MSI_IMSK.

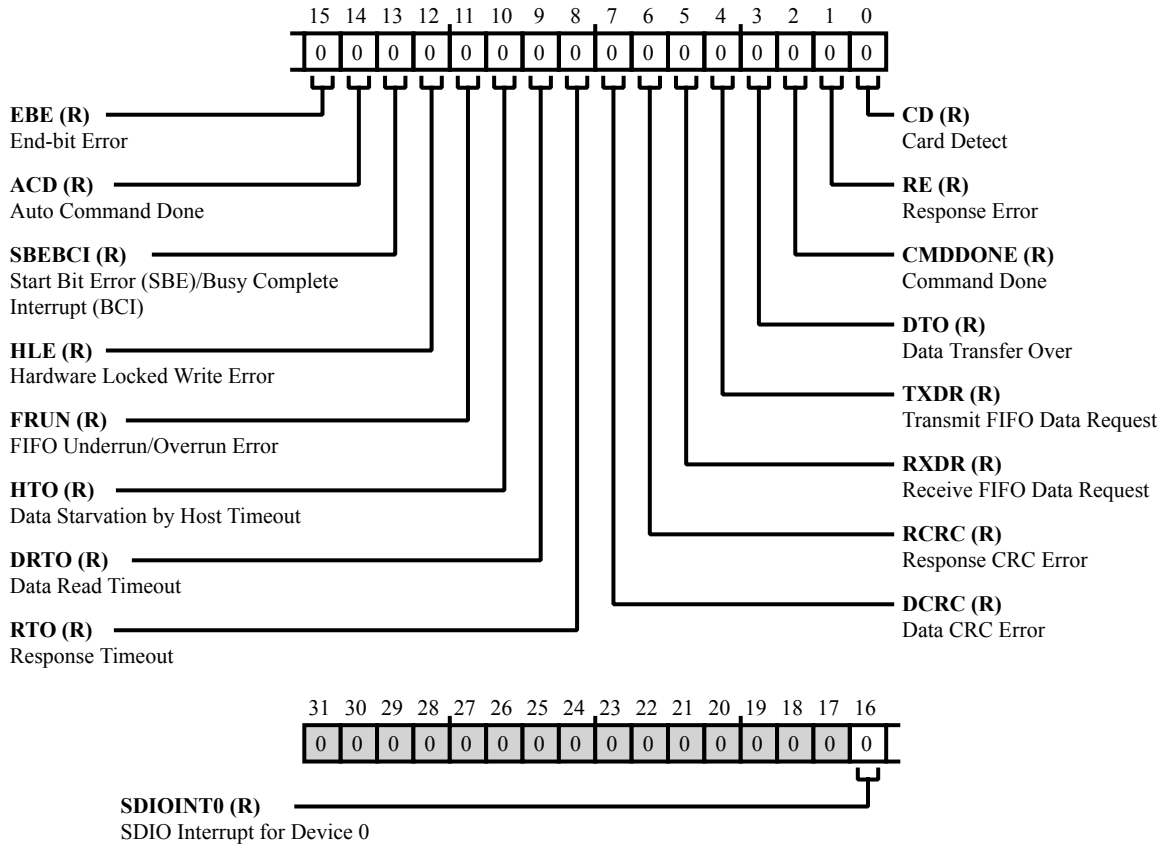

Figure 22-35: MSI_MSKISTAT Register Diagram

Table 22-38: MSI_MSKISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	SDIOINT0	SDIO Interrupt for Device 0. The MSI_MSKISTAT.SDIOINT0 bit indicates an interrupt occurred on the SDIO interrupt for device 0 masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 22-38: MSI_MSKISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	EBE	End-bit Error. The MSI_MSKISTAT.EBE bit indicates an interrupt occurred on the end-bit error (read)/write no CRC masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
14 (R/NW)	ACD	Auto Command Done. The MSI_MSKISTAT.ACD bit indicates an interrupt occurred on the auto command done masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
13 (R/NW)	SBEBCI	Start Bit Error (SBE)/Busy Complete Interrupt (BCI). The MSI_MSKISTAT.SBEBCI bit indicates an interrupt occurred on the start bit error/busy complete masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
12 (R/NW)	HLE	Hardware Locked Write Error. The MSI_MSKISTAT.HLE bit indicates an interrupt occurred on the hardware locked write error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
11 (R/NW)	FRUN	FIFO Underrun/Overrun Error. The MSI_MSKISTAT.FRUN bit indicates an interrupt occurred on the FIFO underrun/overrun error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
10 (R/NW)	HTO	Data Starvation by Host Timeout. The MSI_MSKISTAT.HTO bit indicates an interrupt occurred on the data starvation by host timeout masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 22-38: MSI_MSKISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	DRTO	Data Read Timeout. The `MSI_MSKISTAT.DRTO` bit indicates an interrupt occurred on the data read timeout masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
8 (R/NW)	RTO	Response Timeout. The `MSI_MSKISTAT.RTO` bit indicates an interrupt occurred on the response time-out masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
7 (R/NW)	DCRC	Data CRC Error. The `MSI_MSKISTAT.DCRC` bit indicates an interrupt occurred on the data CRC error request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
6 (R/NW)	RCRC	Response CRC Error. The `MSI_MSKISTAT.RCRC` bit indicates an interrupt occurred on the response CRC error data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
5 (R/NW)	RXDR	Receive FIFO Data Request. The `MSI_MSKISTAT.RXDR` bit indicates an interrupt occurred on the receive FIFO data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
4 (R/NW)	TXDR	Transmit FIFO Data Request. The `MSI_MSKISTAT.TXDR` bit indicates an interrupt occurred on the transmit FIFO data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 22-38: MSI_MSKISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	DTO	Data Transfer Over. The `MSI_MSKISTAT.DTO` bit indicates an interrupt occurred on the data transfer over masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
2 (R/NW)	CMDDONE	Command Done. The `MSI_MSKISTAT.CMDDONE` bit indicates an interrupt occurred on the command done masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
1 (R/NW)	RE	Response Error. The `MSI_MSKISTAT.RE` bit indicates an interrupt occurred on the response error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
0 (R/NW)	CD	Card Detect. The `MSI_MSKISTAT.CD` bit indicates an interrupt occurred on the card detect masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Poll Demand Register

If the OWN bit of a descriptor is not set, the FSM goes into the suspend state. The host needs to write any value into the MSI_PLDMND register for the IDMAC FSM to resume normal descriptor fetch operation. This is a write-only register.

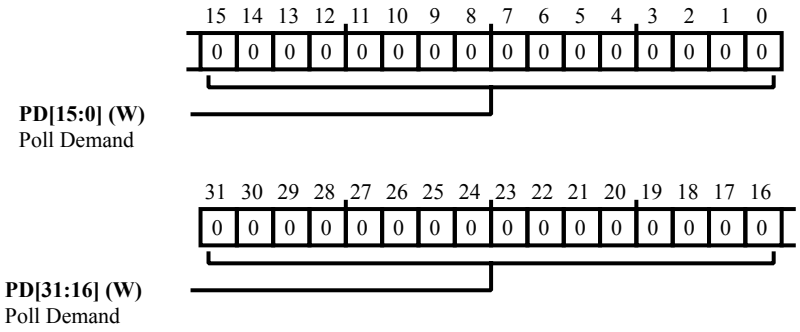

Figure 22-36: MSI_PLDMND Register Diagram

Table 22-39: MSI_PLDMND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	PD	Poll Demand. The MSI_PLDMND.PD bit field needs to be written so that the IDMAC FSM can resume normal descriptor fetch operation.

Response Register 0

The MSI_RESP0 register represents bits[31:0] of a long response.

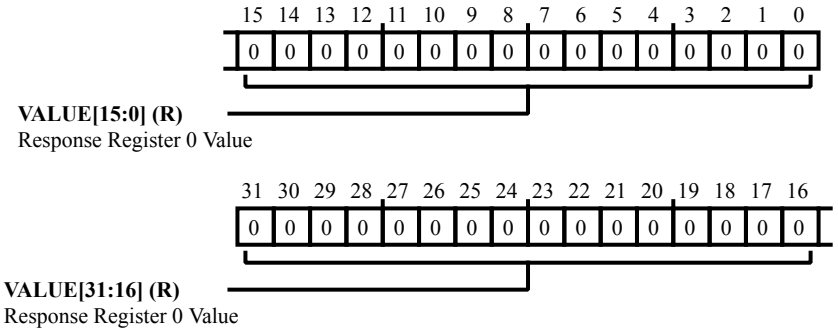

Figure 22-37: MSI_RESP0 Register Diagram

Table 22-40: MSI_RESP0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Response Register 0 Value. The MSI_RESP0.VALUE bit field represents bits[31:0] of a long response.

Response Register 1

The MSI_RESP1 register represents bits[63:32] of a long response.

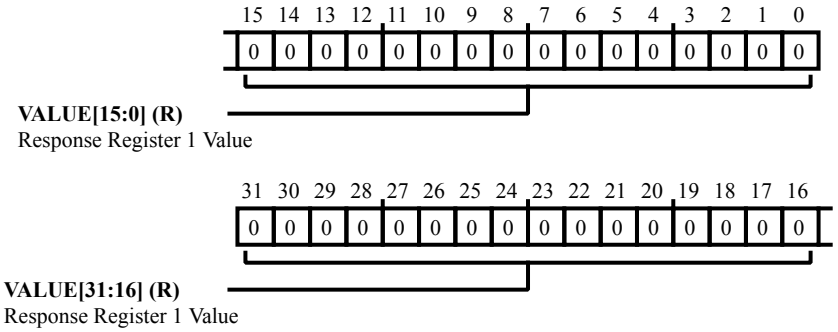

Figure 22-38: MSI_RESP1 Register Diagram

Table 22-41: MSI_RESP1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Response Register 1 Value. The MSI_RESP1.VALUE bit field represents bits[63:32] of a long response.

Response Register 2

The MSI_RESP2 register represents bits[95:64] of a long response.

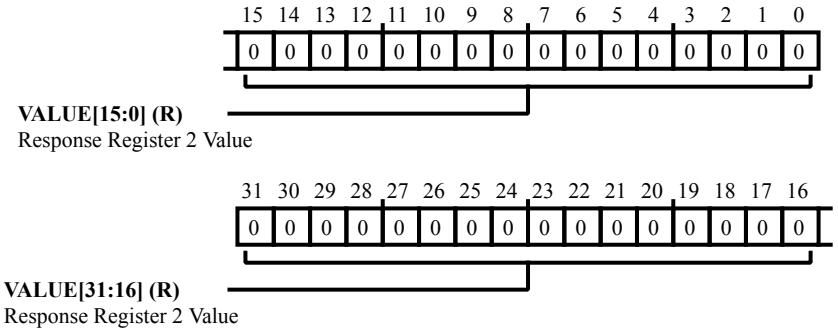

Figure 22-39: MSI_RESP2 Register Diagram

Table 22-42: MSI_RESP2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Response Register 2 Value. The MSI_RESP2.VALUE bit field represents bits[95:64] of a long response.

Response Register 3

The MSI_RESP3 register represents bits[127:96] of a long response.

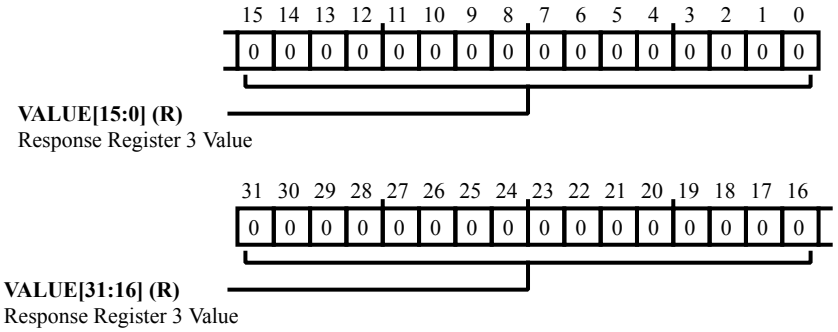

Figure 22-40: MSI_RESP3 Register Diagram

Table 22-43: MSI_RESP3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Response Register 3 Value. The MSI_RESP3.VALUE bit field represents bits[127:96] of a long response.

Status Register

The MSI_STAT register provides MSI DMA and data transfer status and information.

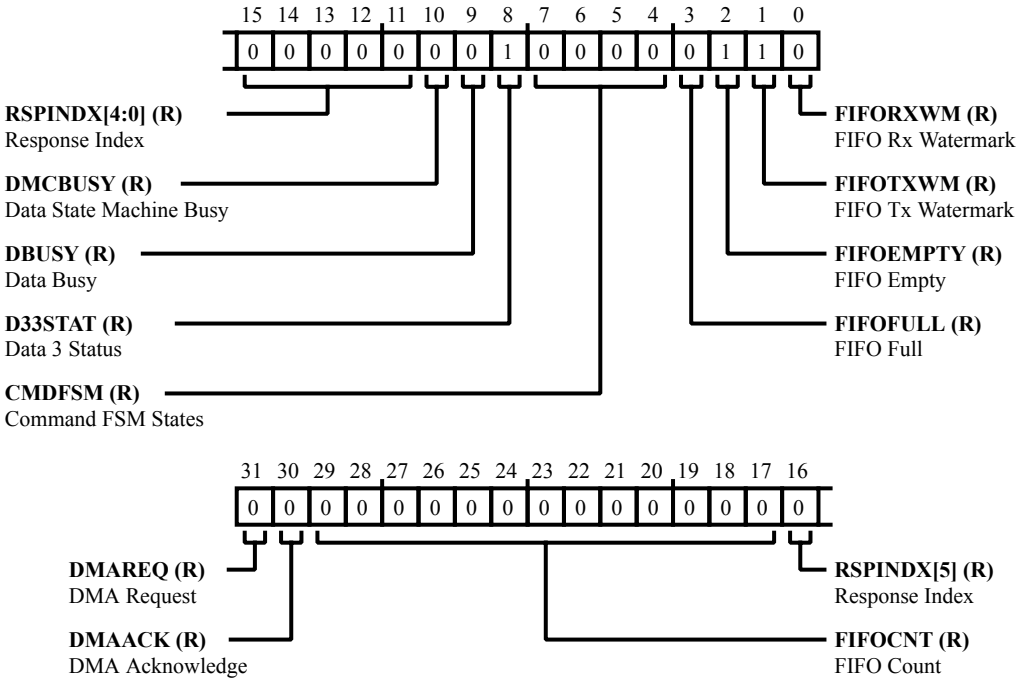

Figure 22-41: MSI_STAT Register Diagram

Table 22-44: MSI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	DMAREQ	DMA Request. The MSI_STAT.DMAREQ bit indicates the DMA request signal state.
30 (R/NW)	DMAACK	DMA Acknowledge. The MSI_STAT.DMAACK bit indicates the DMA acknowledge signal state.
29:17 (R/NW)	FIFOCNT	FIFO Count. The MSI_STAT.FIFOCNT bit field indicates the number of filled locations in the FIFO.
16:11 (R/NW)	RSPINDX	Response Index. The MSI_STAT.RSPINDX bit field indicates the index of the previous response, including any auto-stop sent by core.

Table 22-44: MSI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	DMCBUSY	Data State Machine Busy. The `MSI_STAT.DMCBUSY` bit indicates that the data transmit or receive state-machine is busy.	
		0	DMC idle
		1	DMC busy
9 (R/NW)	DBUSY	Data Busy. The `MSI_STAT.DBUSY` bit indicates the inverted version of the raw selected card_data[0].	
		0	Card data not busy
		1	Card data busy
8 (R/NW)	D33STAT	Data 3 Status.	
		0	Card not present
		1	Card present
7:4 (R/NW)	CMDFSM	Command FSM States. The `MSI_STAT.CMDFSM` bit field indicates the state machine status of CIU (card interface unit) or in general command FSM (not IDMA).	
		0	Idle
		1	Send init sequence
		2	Tx cmd start bit
		3	Tx cmd tx bit
		4	Tx cmd index + arg
		5	Tx cmd CRC7
		6	Tx cmd end bit
		7	Rx resp start bit
		8	Rx resp IRQ response
		9	Rx resp tx bit
		10	Rx resp cmd idx
		11	Rx resp data
		12	Rx resp CRC7
		13	Rx resp end bit
		14	Cmd path wait NCC
		15	Wait; CMD-to-response turnaround

Table 22-44: MSI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	FIFOFULL	FIFO Full. The `MSI_STAT.FIFOFULL` bit indicates that the FIFO is full.	
2 (R/NW)	FIFOEMPTY	FIFO Empty. The `MSI_STAT.FIFOEMPTY` bit indicates that the FIFO is empty.	
1 (R/NW)	FIFOTXWM	FIFO Tx Watermark. The `MSI_STAT.FIFOTXWM` bit indicates that the FIFO reached the transmit watermark level and is not qualified with data transfer.	
		0	Did not reach watermark level
		1	Reached watermark level
0 (R/NW)	FIFORXWM	FIFO Rx Watermark. The `MSI_STAT.FIFORXWM` bit indicates that the FIFO reached the receive watermark level and is not qualified with data transfer.	
		0	Did not reach watermark level
		1	Reached watermark level

Transferred Host to BIU-FIFO Byte Count Register

The MSI_TBBCNT register provides the number of bytes transferred between host/DMA memory and BIU FIFO. The register should be accessed in full to avoid read-coherency problems.

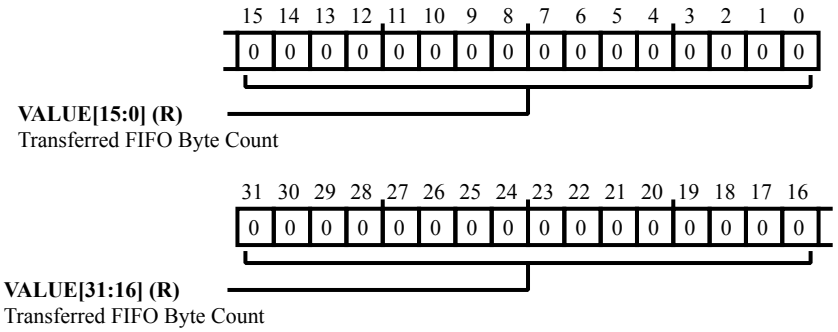

Figure 22-42: MSI_TBBCNT Register Diagram

Table 22-45: MSI_TBBCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Transferred FIFO Byte Count. The MSI_TBBCNT.VALUE bit field provides the number of bytes transferred between the host/DMA memory and the BIU FIFO.

Transferred CIU Card Byte Count Register

The MSI_TCBCNT register provides the number of bytes transferred by the CIU unit to a card. This register should be accessed in full to avoid read-coherency problems. Both the MSI_TCBCNT and MSI_TBBCNT registers share the same coherency register.

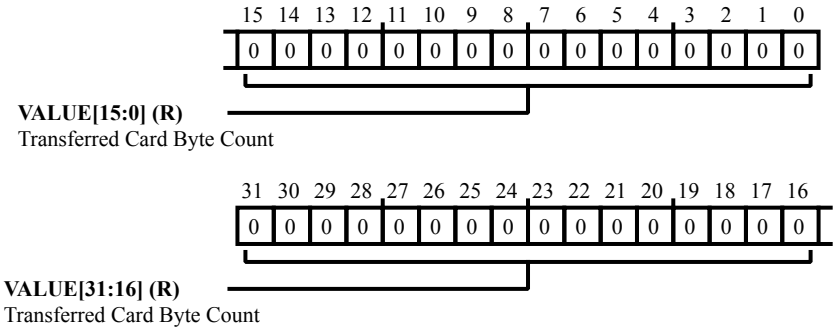

Figure 22-43: MSI_TCBCNT Register Diagram

Table 22-46: MSI_TCBCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Transferred Card Byte Count. The MSI_TCBCNT.VALUE bit field provides the number of bytes transferred by the CIU unit to a card.

Timeout Register

The MSI_TMOUT register provides bits that configure card data read and response timeout values.

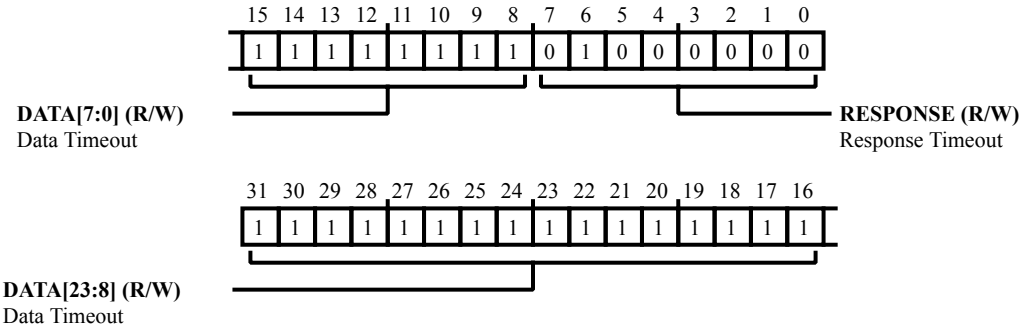

Figure 22-44: MSI_TMOUT Register Diagram

Table 22-47: MSI_TMOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/W)	DATA	Data Timeout. The MSI_TMOUT.DATA bit field configures the value for the card data read timeout; the same value is also used for the data starvation by host timeout. The timeout counter is started only after the card clock is stopped. The value is in number of card output clocks cclk_out of a selected card.
7:0 (R/W)	RESPONSE	Response Timeout. The MSI_TMOUT.RESPONSE bit field configures the response timeout in number of card output clocks.

23 Universal Serial Bus (USB)

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players. It allows these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 Specification.

NOTE: See the On-The-Go Supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF and the Universal Serial Bus Specification 2.0.

The USB module supports:

- Host mode transfers at high-speed (480 Mbp/sec) rate
- Host mode transfers at full-speed (12 Mbp/sec) rate
- Host mode transfers at low-speed (1.5 Mbp/sec) rates. The connection to low-speed devices is only possible through a full-speed hub.
- Peripheral mode transfers at high-speed (480 Mbp/sec) rate
- Peripheral mode transfers at full-speed (12 Mbp/sec) rate

The USB controller uses a peripheral bus slave interface to access its control and status registers as well as read and write to the endpoint packet buffers. Data transfers to and from the USB controller through the 11 transmit and 11 receive endpoint FIFOs (EP1 – EP11), providing a total of 22 data endpoints.

USB Features

The USB controller provides the following features:

- Low-speed, full-speed, and high-speed rates supported
- One bidirectional control endpoint
- 11 transmit and 11 receive unidirectional endpoints
- 16 KB dynamically configured FIFO RAM

- Eight DMA master channels
- Two top-level maskable general-purpose interrupts
- Low-power wake-up on activity
- VBUS control interrupts for external analog VBUS control
- Session request protocol (SRP) and host negotiation protocol (HNP) capability
- Host transaction scheduling in hardware
- Soft connect or disconnect feature
- Full- and high-speed physical layer UTMI+ level 3 interface for on-chip PHY
- Backwards compatible with existing USB 1.1 hosts
- Support for Battery Charging Specification Revision 1.1

Only device requirements or system bandwidth limit the number of active endpoints at one time because each endpoint operates independently from the next. Software determines the type of transfer for each endpoint individually and also the manner in which it is transferred between the USB controller and memory (DMA or interrupt-based). The USB uses endpoint zero solely for receive and transmit control transfer. These transfers are used for device configuration and information gathering.

USB Functional Description

The following sections describe the function of the USB OTG interface.

USB Architectural Concepts

The USB controller operates in either of two USB operation modes (peripheral or host mode) at a given time.

In peripheral mode, the USB controller encodes, decodes, checks, and directs all USB packets sent and received, responding appropriately to host requests. Data is transferred from the processor core memory into the Tx FIFOs of the device onto USB as IN packets. In the other direction, USB OUT packets are received into the Rx FIFOs (having been sent from the host) and transferred to system memory for processing or storage. In peripheral mode, the USB controller acts as a slave device to another USB host; either a personal computer or another OTG host controller.

When operating in host mode, the USB controller uses simple hosting capabilities to master point-to-point connections with another USB peripheral, initiating transfers on the bus for the peripheral to respond. USB IN packets are received into the Rx FIFOs for transfer into the processor core memory. Data written into Tx FIFOs is transmitted onto the bus as USB OUT packets. In this mode, the USB controller encodes, decodes, and checks USB packets sent and received. The controller automatically schedules isochronous and interrupt transfers from the endpoint buffers. It performs one transaction every *n* frames, where n represents the polling interval programmed for the endpoint.

Any of the endpoints can be programmed to be written to or read from using the DMA master channels. This configuration provides the most efficient means of transferring data between the controller and on-chip memory.

USB endpoints 0 through 11 have DMA interrupt lines (USB_DMA_IRQ) providing a total of eight DMA request lines.

The USB provides two top-level maskable interrupts, each of which can be sourced from any or all of transmit endpoint status, receive endpoint status or global USB status. See Interrupt Signals for details.

The RAM interface of the USB controller supports a single block of synchronous single-port RAM used to buffer the USB packets.

16K bytes of SRAM are available.

The UTMI+ level 3 PHY interface provides a means of connecting a selection of high- or full-speed PHYs to the controller, from device-only PHYs through full OTG-compliant PHYs.

For details of the PHY interface, See UTMI Interface.

ATTENTION: Check the processor data sheet for requirements regarding minimum system clock frequency needed for proper USB operation.

The USB controller is configured as either a USB OTG A device or B device depending on the type of plug inserted into its USB receptacle. The state of the USB_ID (connector ID) pin determines this configuration.

The USB controller uses an asynchronous wake-up circuit to detect when another B device is asserting its D+ pull-up. This activity initiates the SRP (session request protocol) when all other clocks are off.

This slow clock is derived from SCLK and enabled using the USB_PHY_CTL.EN bit.

Use of the controller for OTG functionality requires the capability to:

- Drive VBUS (as a default A device powering the bus)
- Discharge VBUS (speeding up the time for VBUS to fall below the *SessionEnd* threshold as a B device checking initial conditions)
- Charge VBUS to 2.1 V (when initiating SRP as a B device).

The UTMI interface drives these controls, but the controller also provides a separate interrupt register, USB_VBUS_CTL, which represents the drive VBUS, discharge VBUS, and charge VBUS signaling. See the register section for more information on these controls.

Multi-Point Support

The USB controller has the facility, when operating in host mode, to act as the host to a range of USB peripheral devices.

High-speed, full-speed, or low-speed devices connect to the USB controller through a USB hub.

The USB controller, as part of its support for multiple devices, permits individual allocation of the functions of the target to the different Rx and Tx endpoints implemented. Furthermore, the USB controller can make this allocation

dynamically, allowing the devices from the targeted peripheral list to be used in different combinations. The numbers of Tx and Rx endpoints implemented in the controller limit the combinations of peripheral devices that can be used together. Devices can only be added where the required endpoints remain available.

On-Chip Bus Interfaces

The USB controller uses two 32-bit wide independent bus interfaces, a master and a slave, to communicate with a processor-based subsystem. The slave interface allows the processor core to access the control and status registers (including DMA master registers) and the endpoint FIFOs. The integrated DMA uses the master interface to drive data into or out of the endpoint FIFOs with minimal processor core interaction. For more information, see USB Block Diagram.

FIFO Configuration

Each bidirectional endpoint (provided as two unidirectional endpoints) has its own endpoint number (0 for control, 1 on up for data transfer). Although two endpoints could use the same number, the endpoints can support different transfer types. Each of these bidirectional endpoints has a fixed region of the SRAM in the USB controller to which it has access. This feature dictates to some extent the types of transfers that can be used for that particular endpoint. This restriction follows from the maximum size of USB packets, which varies with each transfer type. The ***FIFO Sizes and Transfer Types*** table lists the endpoint FIFO configuration, with an indication of the transfer types possible for that particular buffer size.

Table 23-1: FIFO Sizes and Transfer Types

Bidirectional Endpoint (Rx and Tx)	FIFO Size (each direction)	USB Transfer Types
0	64 bytes	Size fixed for control transfers
1–4	Dynamically configured in powers of 2 from 8 to 8192 bytes	Bulk, Interrupt, Isochronous
1–11	Dynamically configured in powers of 2 from 8 to 8192 bytes	Bulk, Interrupt, Isochronous

Each endpoint FIFO can buffer one or two packets (in double-buffered mode). Double-buffering is recommended for most applications to improve efficiency by reducing the frequency of servicing for each endpoint.

Double-buffering bulk transactions means that data transfers over the USB are not slowed when packets are loaded or unloaded from the FIFO in the time it takes to transfer a packet. Double-buffering isochronous transactions allows more time to load or unload the FIFO. It also allows the usage of the SOF interrupt to service the endpoint rather than the endpoint interrupt. This functionality has the following advantages:

- Easy detection of lost packets
- Regular interrupt timing (making it easier to source or sink the data)
- If the USB controller uses more than one isochronous endpoint, one interrupt can service all the endpoints.

The USB controller uses the transmit or receive FIFO address registers to specify the address of each endpoint FIFO.

Clocking

The USB controller uses the system clock SCLK to generate an internal clock (CLK) used to clock the USB registers.

For proper operation, refer to device datasheet for minimum system clock SCLK value.

NOTE: For best performance (best signal integrity), follow the guidelines in the data sheet for selecting an input clock frequency.

When the controller is in the SUSPEND state and when no session is active, the clock and much of the USB controller is stopped to reduce power consumption. The clock becomes operational again when RESUME signaling is detected on the USB lines.

UTMI Interface

The interface to the on-chip PHY uses the industry-standard UTMI+ (universal transceiver macro interface) level 3.

This interface provides full- and high-speed device and OTG functionality and supports communication to a hub.

The PHY is a mixed-signal block and includes the following:

- Full-speed and high-speed drivers and receivers (single-ended and differential)
- Full-speed and high-speed CDR
- Full-speed or high-speed shift registers, NRZI encode or decode and bit-stuff encode or decode
- Data line pull-up and pull-down resistors
- VBUS and `USB_ID` level detection
- Host disconnect detection

Although the UTMI specification indicates that VBUS charging, driving and discharging happen inside the PHY, for process-restricting and power reasons, implement these functions off-chip in a separate USB charge-pump chip.

ADSP-SC57x USB Register List

The Universal Serial Bus controller (USB) is a multi-point high-speed dual-role USB 2.0-compliant controller. The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF. A set of registers governs USB controller operations. For more information on USB controller functionality, see the USB controller register descriptions.

USB Block Diagram

The ***USB OTG Controller Block Diagram*** shows the functional blocks within the USB. For more information about the blocks, see the USB Functional Description.

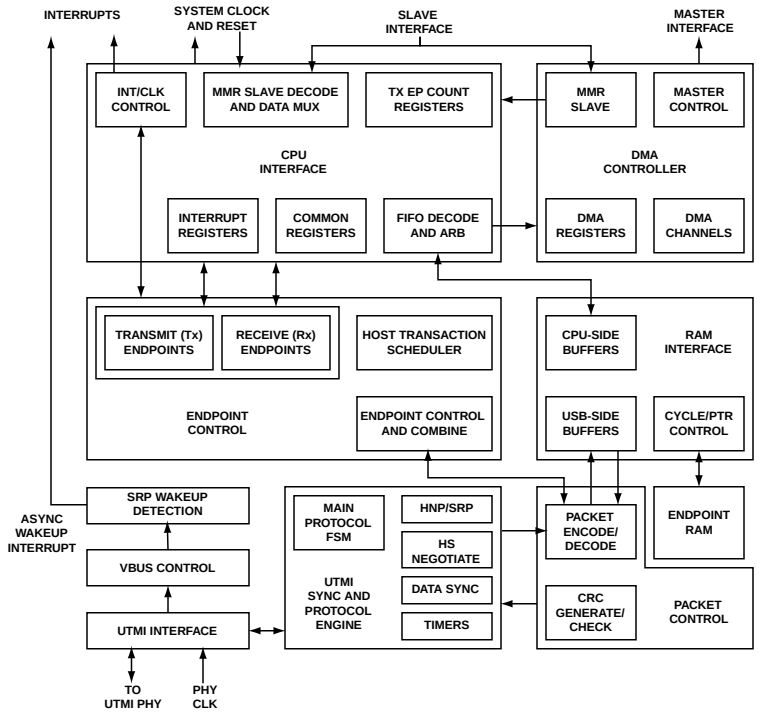

Figure 23-1: USB OTG Controller Block Diagram

USB Definitions

A list of common USB terms and their definitions as used in this specification and based on the USB controller follows:

'A' Device

The USB device with a mini-A plug inserted into its receptacle. The A device always supplies power to VBUS.

'B' Device

The USB device with a standard-B or mini-B plug inserted into its receptacle. The B device starts a session as the peripheral.

Bidirectional endpoint

An endpoint that can concurrently support both receive and transfer packets.

Control endpoint

An endpoint used only for transfer of USB control packets for setup and configuration. In all USB devices, the control endpoint refers to the bidirectional endpoint 0.

Dual role device

A USB device that can operate either as the USB host in an OTG session or as a traditional USB peripheral.

Endpoint

A single physical communication channel for USB, implemented as a FIFO and control logic for that endpoint. Each endpoint has an associated USB transfer type, maximum packet size, bandwidth requirement, endpoint number, and (often) a fixed transfer direction.

Frame

A regular, fixed 1 ms timeslot that can contain several transactions. The transfer type determines the permissible transactions for a given endpoint.

HNP

Host negotiation protocol. Part of the USB OTG supplement that allows the host function to be transferred between two connected dual role devices.

Packet

The lowest level of data exchange on USB. The transfer type and buffer size of the USB peripheral determine the size.

PHY

The PHY is a transceiver circuit that implements the physical layer of USB. For full speed USB OTG, this circuit includes line drivers and receivers, pull-up, or pull-down resistors as well as device ID and VBUS level detection.

Session

A period during which USB transfers take place within an OTG connection. The A device (drives VBUS) or B device (initiates SRP) can initiate this period. VBUS is powered during a session.

SRP

Session request protocol. Part of the USB OTG supplement that allows a B device to turn on VBUS and initiate a USB session.

Transaction

Collection of one or more packets in sequence

Transfer

Collection of one or more transfers in sequence

Unidirectional endpoint

Endpoint with its direction fixed in a single direction (for example, it can only receive packets from the USB) in both host and peripheral modes.

USB References

The following references provide further information regarding the USB.

- *On-The-Go Supplement to the USB 2.0 Specification*, Rev 1.0a, June 24, 2003, USB-IF
- *Universal Serial Bus Specification 2.0*

USB Operating Modes

The USB OTG interface can operate in peripheral mode or host mode.

When the USB controller operates in peripheral mode, the controller can be attached to a conventional host (such as a personal computer) or another OTG device operating in host mode. The second device can be high speed or full speed. When linked to another peripheral device, the USB controller can also act as the host. If the other device is also a dual role controller, the two devices can switch roles, as needed.

The role the USB controller takes depends on the way the devices are cabled together. Each USB cable has an A and a B device end. If the A end of the cable is plugged into the device containing the USB controller, the USB controller takes the role of the host device. It goes into host mode (in this case, the `USB_DEV_CTL.HOSTMODE` bit is set to 1). If the B of the cable is plugged in, the USB controller goes instead into peripheral mode (and the `USB_DEV_CTL.HOSTMODE` bit remains at 0).

When both devices contain dual role controllers, signaling can be used to switch the roles of the two devices, without switching the cable connecting the two devices. See Host Negotiation Protocol for details on the conditions under which the USB controller can switch between peripheral and host mode.

NOTE: The multi-point capability of the USB controller is associated with a range of registers recording the allocation of device functions to individual endpoints and device function characteristics. These characteristics include endpoint number, operating speed, and transaction type on an endpoint-by-endpoint basis. These registers are principally associated with the use of the USB controller as the host to a number of devices. However, set the registers when the core is used as the host for a single target device.

To enable the USB:

1. Configure the USB PLL multiplier settings in the USB PLL control register. Check the processor data sheet for the requirements for input clock frequency.
2. Enable the USB PHY by setting the `USB_PHY_CTL.EN` bit.
3. Poll the bit in the USB PLL control register to ensure that the USB PLL has locked to the new frequency.

Peripheral Mode

USB OTG interface operations for the peripheral mode differ from host mode in a number of ways. The following sections describe peripheral mode operations.

Endpoint Setup

In peripheral mode, the USB uses a few endpoint-specific configuration bits when setting up an endpoint for transfer for all types of peripheral transfer. The configuration determines how the processor core interacts with the endpoint FIFO.

One key parameter required before a transfer can occur through an endpoint is the maximum USB packet size that the endpoint can support. The software sets this value. It depends on various system constraints. These constraints include the size of hardware FIFO available and system latencies as well as the USB transfer type and class used. The `USB_EP[n]_TXMAXP` or `USB_EP[n]_RXMAXP` registers define the maximum amount of data that can be transferred to the selected endpoint in a single frame. The value must match the programmed maximum individual packet size (*MaxPktSize*) of the standard endpoint descriptor for the endpoint.

For transmit endpoints, program the maximum packet size using the `USB_EP[n]_TXMAXP`. For receive endpoints, the USB uses the `USB_EP[n]_RXMAXP` register. The maximum packet size must not exceed the actual hardware endpoint FIFO size.

The settings in the USB_RXFIFOSZ or USB_TXFIFOSZ register determine the corresponding sizes of the transmit or receive FIFOs, as well as, single or double buffered mode for endpoints 1 to 11.

Because the USB controller uses a 32-bit interface, choose an even number for the value of *MaxPktSize*. This selection simplifies transferring data between FIFOs and the processor core.

Configure more setup parameters using the USB_EP[n]_TXCSR_H or USB_EP[n]_RXCSR_H register (depending on whether the endpoint in question is for receive or transmit). The USB uses the USB_EP[n]_RXCSR_H.DMAREQEN bit in this register to enable the assertion of the appropriate DMA request whenever the endpoint is able to receive or transmit another packet. The USB uses the USB_EP[n]_RXCSR_H.AUTOCLR and USB_EP[n]_RXCSR_H.AUTOREQ bits to set the FIFO ready triggers (USB_EP[n]_RXCSR_H.RXPKTRDY and USB_EP[n]_TXCSR_H.TXPKTRDY) automatically whenever a packet is transferred to streamline DMA operation for transfers that span multiple packets. Note, however, that the USB cannot use USB_EP[n]_RXCSR_H.AUTOCLR and USB_EP[n]_RXCSR_H.AUTOREQ bits with high-bandwidth endpoints. Refer to the following register sections for more information: USB_EP[n]_TXCSR_H,USB_EPI[N]_RXCSR_P,USB_EPI[N]_RXCSR_H,USB_EP[n]_TXCSR_P.

IN Transactions as a Peripheral

When the USB controller operates in peripheral mode, the transmit FIFOs handle data for IN transactions. The maximum size of data packet that can be placed in a FIFO for a transmit endpoint is programmable. When applicable, the value written to the USB_EP[n]_TXMAXP register for that endpoint determines the size (maximum payload multiplied by the number of transactions per micro-frame).

The maximum packet size set for any endpoint must not exceed the FIFO size. (See FIFO Configuration.)

ATTENTION: Do not write to the USB_EP[n]_TXMAXP register while there is data in the FIFO, as unexpected results can occur.

The following sections describe the two types of packet buffering used for IN transactions.

Single packet buffering. Set the USB_EP[n]_TXCSR_P.TXPKTRDY bit as each packet for transmission is loaded into the transmit FIFO. If the USB_EP[n]_TXCSR_P.AUTOSET bit is set, the USB_EP[n]_TXCSR_P.TXPKTRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, and where auto-set cannot be used (high-bandwidth isochronous or interrupt transactions), always set the USB_EP[n]_TXCSR_P.TXPKTRDY bit manually (for example by the processor core).

When the USB_EP[n]_TXCSR_P.TXPKTRDY bit is set, either manually or automatically, the USB_EP[n]_TXCSR_P.NEFIFO bit is also set and the packet is ready to be sent. When the packet is successfully sent, both the USB_EP[n]_TXCSR_P.TXPKTRDY and USB_EP[n]_TXCSR_P.NEFIFO bits are cleared. The USB controller generates the appropriate transmit endpoint interrupt (if enabled). The next packet can then be loaded into the FIFO.

Double packet buffering. Set the USB_EP[n]_TXCSR_P.TXPKTRDY bit as each packet for transmission is loaded into the transmit FIFO. If the USB_EP[n]_TXCSR_P.AUTOSET bit is set, the USB_EP[n]_TXCSR_P.TXPKTRDY bit is automatically set when a maximum-sized packet is loaded into the

FIFO. For packet sizes less than the maximum, and where auto-set cannot be used (high-bandwidth isochronous or interrupt transactions), always set the USB_EP[n]_TXCSR_P.TXPKTRDY bit manually (for example by the processor core).

When the USB_EP[n]_TXCSR_P.TXPKTRDY bit is set, either manually or automatically, the USB_EP[n]_TXCSR_P.NEFIFO bit also is set. The USB_EP[n]_TXCSR_P.TXPKTRDY bit is then immediately cleared (and an interrupt generated, if enabled). A second packet can now be loaded into the transmit FIFO and the USB_EP[n]_TXCSR_P.TXPKTRDY bit is set again (either manually or automatically if the packet is the maximum size). Both packets are now ready for transmission.

When the first packet is successfully sent, the USB_EP[n]_TXCSR_P.TXPKTRDY bit is cleared. The USB controller generates the appropriate transmit endpoint interrupt (if enabled) to signal that another packet can now be loaded into the transmit FIFO. The state of the USB_EP[n]_TXCSR_P.NEFIFO bit indicates how many packets can be loaded. If the USB_EP[n]_TXCSR_P.NEFIFO bit is set, then there is another packet in the FIFO and only one more packet can be loaded. If the USB_EP[n]_TXCSR_P.NEFIFO bit is cleared, then there are no packets in the FIFO and two more packets can be loaded.

OUT Transactions as a Peripheral

When the USB controller operates in peripheral mode, the receive FIFOs handle data for OUT transactions.

The value written to the USB_EP[n]_RXMAXP register for an endpoint determines the maximum amount of data received by a receive endpoint in any frame. The value is programmable. The maximum packet size must not exceed the FIFO size.

The value written to the USB_EP[n]_RXMAXP register for an endpoint determines maximum amount of data received by a receive endpoint in any micro-frame (in high-speed mode). The value is programmable. It is the maximum payload multiplied by the number of transactions per micro-frame. The maximum packet size must not exceed the FIFO size.

If the size of the receive endpoint FIFO is less than twice the maximum packet size for this endpoint, only one data packet can be buffered in the FIFO. Single buffering is selected. (The size is set in the USB_EP[n]_RXMAXP register.) When a packet is received and placed in the receive FIFO, the USB_EP[n]_RXCSR_P.RXPKTRDY bit and the USB_EP[n]_RXCSR_P.FIFOFULL bit are set. The USB controller generates the appropriate receive endpoint interrupt (if enabled) to signal that a packet can now be unloaded from the FIFO. After the packet is unloaded, clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit to allow reception of more packets. If the USB_EP[n]_RXCSR_P.AUTOCLR bit is set and a maximum-sized packet is unloaded from the FIFO, the USB_EP[n]_RXCSR_P.RXPKTRDY bit is cleared automatically. The USB_EP[n]_RXCSR_P.FIFOFULL bit is also cleared. For packet sizes less than the maximum, clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit manually (for example by the processor core).

If double packet buffering is enabled, then two data packets can be buffered. When the first packet for reception is loaded into the receive FIFO, the USB_EP[n]_RXCSR_P.RXPKTRDY bit is set. The USB controller generates the appropriate receive endpoint interrupt (if enabled) to signal that a packet can now be unloaded from the FIFO. The USB_EP[n]_RXCSR_P.FIFOFULL bit is not set. This bit is only set if a second packet is received and loaded into the receive FIFO.

After the first packet is unloaded, clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit to allow reception of further packets. If the USB_EP[n]_RXCSR_P.AUTOCLR bit is set and a maximum-sized packet is unloaded from the FIFO, the USB_EP[n]_RXCSR_P.RXPKTRDY bit is cleared automatically. For packet sizes less than the maximum, clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit manually (for example by the processor core).

If the USB_EP[n]_RXCSR_P.FIFOFULL bit is set to 1 when USB_EP[n]_RXCSR_P.RXPKTRDY is cleared, the USB controller first clears the USB_EP[n]_RXCSR_P.FIFOFULL bit. The controller then sets the USB_EP[n]_RXCSR_P.RXPKTRDY bit again, indicating that there is another packet waiting in the FIFO for unloading.

High-Bandwidth Isochronous or Interrupt Transactions

High-bandwidth isochronous or interrupt transactions use much the same protocol as other isochronous or interrupt transactions. There are, however, some special features to conducting high-bandwidth transactions.

- When setting the maximum packet size handled by the endpoint in the USB_EP[n]_TXMAXP/ USB_EP[n]_RXMAXP registers, set the maximum number of transactions per micro-frame using the USB_EP[n]_TXMAXP.MULTM1 and USB_EP[n]_RXMAXP.MULTM1 bits.

  The maximum number of transactions (2 or 3) also represents the maximum number of sections in which any single high-bandwidth packet can be transferred. The configuration sets the maximum size of the packet to 2 or 3 times the maximum payload specified for the endpoint in the same register.

  NOTE: The maximum payload that can be sent in any transaction is 1K byte.

- When sending packets, set the USB_EP[n]_TXCSR_P.TXPKTRDY bit using the application software. Similarly, when unloading packets from the receive endpoint FIFO, clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit using the application software.

  CAUTION: The AutoSet and AutoClear functions cannot be used to set and clear these bits in high-bandwidth transactions.

- The transmission of packets as a number of sections introduces a further type of error – the transmission of incomplete packets.

  For transmit endpoints, transmitting incomplete packets principally applies when the interface is in peripheral mode. It occurs when the transmission fails to receive enough IN tokens from the host to send all the parts of the data packet. It can also apply to high-bandwidth interrupt transactions in host mode where the core does not receive any response from the device to which the packet is transmitted. In both cases, the USB_EP[n]_TXCSR_P.INCOMPTX bit is set.

  For receive endpoints, an incomplete packet issue can occur. The PIDs of the received parts of the data packet show that one or more parts of the data packet have not been received. When this event happens, the USB_EP[n]_RXCSR_P.INCOMPRX bit is set. Usually this bit is set in peripheral mode. However, it can also be set in host mode (using the USB_EP[n]_RXCSR_H.INCOMPRX bit). This event occurs when the USB communicates with a device that fails to respond in accordance with the USB protocol.

High Bandwidth Isochronous or Interrupt IN Endpoints

In high-speed mode, transmit endpoints configured for high-bandwidth isochronous or interrupt transactions can transmit up to three USB packets in any micro-frame. The transmission occurs with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame.

The ***High Bandwidth IN Endpoints*** figure provides an overview of high-bandwidth IN endpoints in USB.

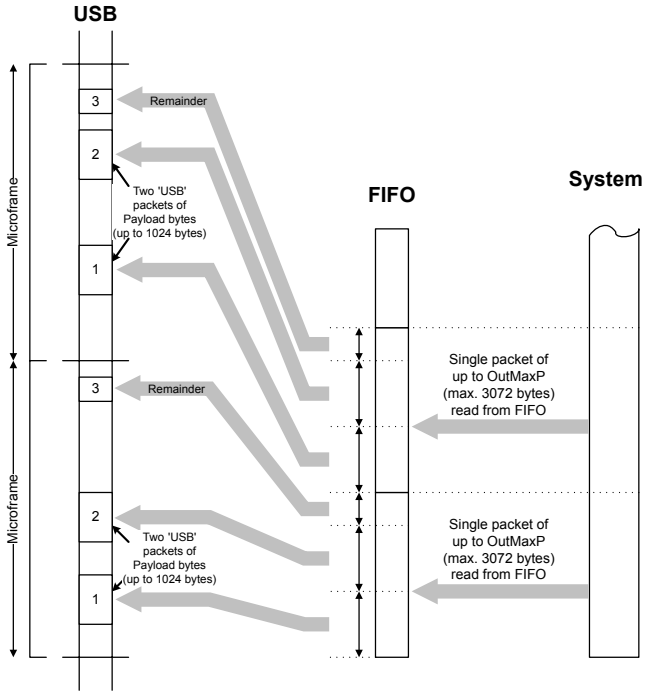

Figure 23-2: High Bandwidth IN Endpoints

The USB controller supports these transfers by permitting the loading of data packets with up to three times the normal packet size into the associated FIFO in a single transaction. From the software viewpoint in the processor core, the ***High Bandwidth IN Endpoints*** figure describes the operation for single or double packet buffering (as appropriate). One exception is that the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit must always be set manually (for example by the processor core) as the auto set feature does not operate with high-bandwidth isochronous transfers.

The USB controller automatically splits any data packet loaded into the FIFO that is larger than the maximum into USB packets of the maximum payload, or smaller, for transmission. The following settings define the number of USB packets transmitted per micro-frame and the maximum payload in each packet:

- Use the `USB_EP[n]_TXMAXP.MAXPAY` bits to set the maximum payload in any USB packet
- Use the `USB_EP[n]_TXMAXP.MULTM1` bits to set the maximum number of such packets for transmission in one micro-frame (2 or 3)

Together, these settings define the maximum size of packet that can be loaded into the FIFO.

At least one USB packet always is sent. The number of further USB packets sent in the same micro-frame depends on the amount of data loaded into the FIFO. The USB_EP[n]_TXCSR_P.TXPKTRDY bit is cleared and an interrupt is generated only when all the packets have been sent. Each USB packet is sent in response to an IN token. If, at the end of a micro-frame, the USB controller has not received enough IN tokens to send all the USB packets, the remaining data is flushed from the FIFO. (For example, one of the IN tokens received is corrupt). The USB_EP[n]_TXCSR_P.TXPKTRDY bit is cleared and the USB_EP[n]_TXCSR_P.INCOMPTX bit is set to indicate that not all of the data loaded into the FIFO transmitted.

High-Bandwidth Isochronous or Interrupt OUT Endpoints

In high-speed mode, isochronous receive endpoints can receive up to three USB packets in any micro-frame. The reception occurs with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame. Similarly, the USB controller can receive high-bandwidth interrupt transactions in host mode, but there is no support for high-bandwidth interrupt transactions in peripheral mode.

The ***High-Bandwidth OUT Endpoints*** figure shows an overview of high-bandwidth OUT endpoints.

The USB controller supports this rate by automatically combining all the USB packets received during a micro-frame into a single packet of up to 3 normal packets within the receive FIFO. From the software viewpoint in the processor core, the ***High Bandwidth IN Endpoints*** figure describes the operation for single or double packet buffering (as appropriate). One exception is that the USB_EP[n]_RXCSR_P.RXPKTRDY bit always must be cleared manually (for example by the processor core) because the auto-clear function does not operate with high-bandwidth isochronous transfers.

The maximum number of USB packets that can be received in any micro-frame and the maximum payload of these packets are configured as follows:

- Use the USB_EP[n]_RXMAXP.MAXPAY bits to set the maximum payload in any USB packet
- Use the USB_EP[n]_RXMAXP.MULTM1 bits to set the maximum number of these packets that can be received in a micro-frame (2 or 3)

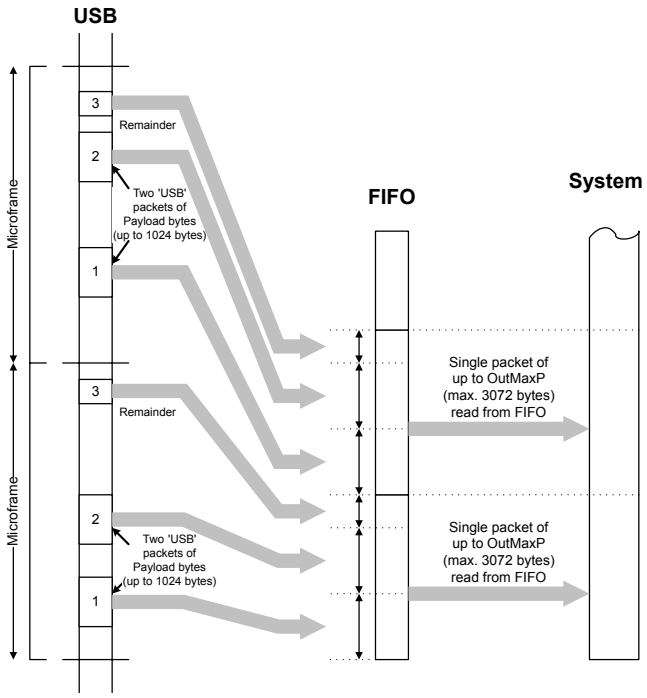

Figure 23-3: High-Bandwidth OUT Endpoints

The number of USB packets sent in any micro-frame depends on the amount of data for transfer, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a micro-frame, the `USB_EP[n]_RXCSR_P.INCOMPRX` bit is set to indicate that the data in the FIFO is incomplete. An interrupt is still generated to allow the data that has been received to be read from the FIFO.

Peripheral Transfer Work Flows

The USB transfer types (control, bulk, isochronous, and interrupt transfers) have different system requirements as well as individual USB transfer-specific features. Software handles each type differently. There is no uniform way of doing transfers across all transfer types using the USB controller.

The following sections provide some guidelines for peripheral mode transfer flows for each of the transfer types, in both IN (transmit) and OUT (receive) directions. For bulk endpoints, the optimal transfer flow depends on whether the final size of the transfer is known or unknown. The USB driver class in use determines whether the transfer size is known or not. Some drivers define the complete transfer size, and others operate on a packet-by-packet basis using a short packet to denote the end of a transfer. (A short packet is less than the value configured in the `USB_EP[n]_TXMAXP` register or less than the value configured in the `USB_EP[n]_RXMAXP` register.)

Each of the work flows uses the following common steps.

1. Configure the endpoint control and status registers and the `USB_EP[n]_TXMAXP` or `USB_EP[n]_RXMAXP` value.
2. Configure the appropriate data transfer mechanism (DMA or interrupt setup).
3. Data transfer occurs.

The work flows do not describe the actions of the USB controller immediately preceding the endpoint setup. (For example, the reception of an IN/OUT token from the host, token validity checking, or NAK generation, among others.) Note also that there is no error-handling contained in the work flows (for example, checking the USB_EP[n]_RXCSR_P.FIFOFULL bit before writing data).

The proceeding sections use terms packets, frames, and transfers with their strict USB definitions (see USB Definitions).

Control Transactions as a Peripheral

Endpoint 0 is the main control endpoint of the USB controller. As such, the routines required to service endpoint 0 are more complicated than the routines required to service other endpoints.

The software is required to handle all the standard device requests that the USB controller sends or receives through endpoint 0. The *Universal Serial Bus Specification*, Revision 2.0, Chapter 9 describes the requirements. The protocol for these device requests involves different numbers and types of transactions per transfer. To accommodate this functionality, the processor must take a state machine approach to command decoding and handling.

The standard device requests a USB peripheral receives fits into three categories:

- Zero data requests (in which the command includes all the information)
- Write requests (in which extra data follows the command)
- Read requests (in which the device sends data back to the host)

The following sections describe the sequence of actions that the software must perform to process these different types of device request.

Write Requests

The host sends an 8-byte command followed by a write request that contains an extra packet (or packets) of data. An example of a write standard device request is SET_DESCRIPTOR.

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The USB_EP[n]_RXCSR_P.RXPKTRDY bit is also set. The host then reads and decodes the 8-byte command from the endpoint 0 FIFO.

As with a zero data request, write to the USB_EP0_CSR[n]_P register to set the USB_EP0_CSR[n]_P.SPKTRDY bit. (The event indicates that the host read the command from the FIFO.) But, in this case, do not set the USB_EP0_CSR[n]_P.DATAEND bit (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the USB_EP0_CSR[n]_P register is read to check the endpoint status. The USB_EP0_CSR[n]_P.RXPKTRDY bit is set to indicate that a data packet is received. Read the USB_EP0_CNT[n] register to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request is greater than the maximum packet size for endpoint 0, the host sends more data packets. (The WLENGTH field in the command indicates the length of the data.) In this case, the USB_EP0_CSR[n]_P.SPKTRDY bit is set, but do not set the USB_EP0_CSR[n]_P.DATAEND bit.

When all the expected data packets have been received, software writes to the USB_EP0_CSR[n]_P register to set the USB_EP0_CSR[n]_P.SPKTRDY bit and to set the USB_EP0_CSR[n]_P.DATAEND bit (indicating that no more data is expected).

When the host moves to the status stage of the request, software generates another endpoint 0 interrupt to indicate that the request has completed. No further action is required from the software; the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or cannot be executed, then when the host decodes it, software must write to the USB_EP0_CSR[n]_P register. This operation sets the USB_EP0_CSR[n]_P.SPKTRDY bit and the USB_EP0_CSR[n]_P.SENDSTALL bit. When the host sends more data, the USB controller sends a stall to tell the host that the request was not executed. Software generates an endpoint 0 interrupt and the USB_EP0_CSR[n]_P.SENTSTALL bit is set.

If the host sends more data after the USB_EP0_CSR[n]_P.DATAEND has been set, then the USB controller sends a stall. Software generates an endpoint 0 interrupt and the USB_EP0_CSR[n]_P.SENTSTALL bit is set.

Read Requests

The function sends the 8-byte command followed by read requests containing a packet (or packets) of data to the host. Examples of standard device requests for read are:

- GET_CONFIGURATION
- GET_INTERFACE
- GET_DESCRIPTOR
- GET_STATUS
- SYNCH_FRAME

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The USB_EP[n]_RXCSR_P.RXPKTRDY bit is also set. The host then reads and decodes the 8-byte command from the endpoint 0 FIFO. Write the USB_EP0_CSR[n]_P.SPKTRDY bit (indicating that the command has been read from the FIFO).

The data to transmit to the host is written to the endpoint 0 FIFO. If the size of the transmit data is greater than the maximum packet size for endpoint 0, only the maximum packet size is written to the FIFO. The USB_EP0_CSR[n]_P.TXPKTRDY bit is then set (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, software generates another endpoint 0 interrupt. The next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, software writes to the USB_EP0_CSR[n]_P register to set the USB_EP0_CSR[n]_P.TXPKTRDY bit and to set the USB_EP0_CSR[n]_P.DATAEND bit. (This activity indicates that there is no more data after this packet.)

When the host moves to the status stage of the request, software generates another endpoint 0 interrupt to indicate that the request has completed. No further action is required from the software; the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when the host decodes it, software must write to the USB_EP0_CSR[n]_P register. This operation sets the USB_EP0_CSR[n]_P.SPKTRDY bit and the USB_EP0_CSR[n]_P.SENDSTALL bit. When the host requests data, the USB controller sends a stall to tell the host that the request was not executed. Software generates an endpoint 0 interrupt and the USB_EP0_CSR[n]_P.SENTSTALL bit is set.

If the host requests more data after USB_EP0_CSR[n]_P.DATAEND is set, then the USB controller sends a stall. Software generates an endpoint 0 interrupt and the USB_EP0_CSR[n]_P.SENTSTALL bit is set.

Zero Data Requests

Zero data requests have all their information included in the 8-byte command and do not require transfer of extra data.

Examples of standard device requests for zero data are:

- SET_FEATURE
- CLEAR_FEATURE
- SET_ADDRESS
- SET_CONFIGURATION
- SET_INTERFACE

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The USB_EP0_CSR[n]_P.RXPKTRDY bit is also set. The host must then read and decode the 8-byte command from the endpoint 0 FIFO, and take appropriate action. For example, if the command is SET_FEATURE, the host writes 7-bit address value contained in the command to the USB_FADDR register.

Software must set the USB_EP0_CSR[n]_P.SPKTRDY bit (indicating that the command has been read from the FIFO) and the USB_EP0_CSR[n]_P.DATAEND bit (indicating that no further data is expected for this request).

When the host moves to the status stage of the request, the USB controller generates a second endpoint 0 interrupt, indicating that the request has completed. No further action is required from the software; the second interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when the host decodes it, the USB_EP0_CSR[n]_P.SPKTRDY bit is set which sets the USB_EP0_CSR[n]_P.SENDSTALL bit. When the host moves to the status stage of the request, the USB controller sends a stall to tell the host that the request was not executed. The USB controller generates a second endpoint 0 interrupt and sets the USB_EP0_CSR[n]_P.SENTSTALL bit.

If the host sends more data after the USB_EP0_CSR[n]_P.DATAEND bit is set, then the USB controller sends a stall. It generates an endpoint 0 interrupt and sets the USB_EP0_CSR[n]_P.SENTSTALL bit.

Endpoint 0 States

When the USB operates as a peripheral, the endpoint 0 control has three modes (IDLE, Tx, and Rx). The modes correspond to the phases of the control transfer and the state that endpoint 0 enters during phases of the transfer. (See Endpoint 0 Service Routine as Peripheral.)

IDLE is the default mode on power-up or reset. The processor sets `RxPktRdy` bit when endpoint 0 is in IDLE state, indicating a new device request. Once the processor unloads the device request from the FIFO, the USB decodes the descriptor. It determines whether there is a data phase and, if so, the direction of the data phase of the control transfer (to set the FIFO direction).

Depending on the direction of the data phase, endpoint 0 goes into either Tx state or Rx state. If there is no data phase, endpoint 0 remains in IDLE state to accept the next device request.

The processor must take different actions at the different phases of the possible transfers (for example, loading the FIFO, setting `TxPktRdy`). The ***Endpoint 0 Control States*** figure shows the actions for the phase. The USB changes the FIFO direction depending on the direction of the data phase, independently of the processor.

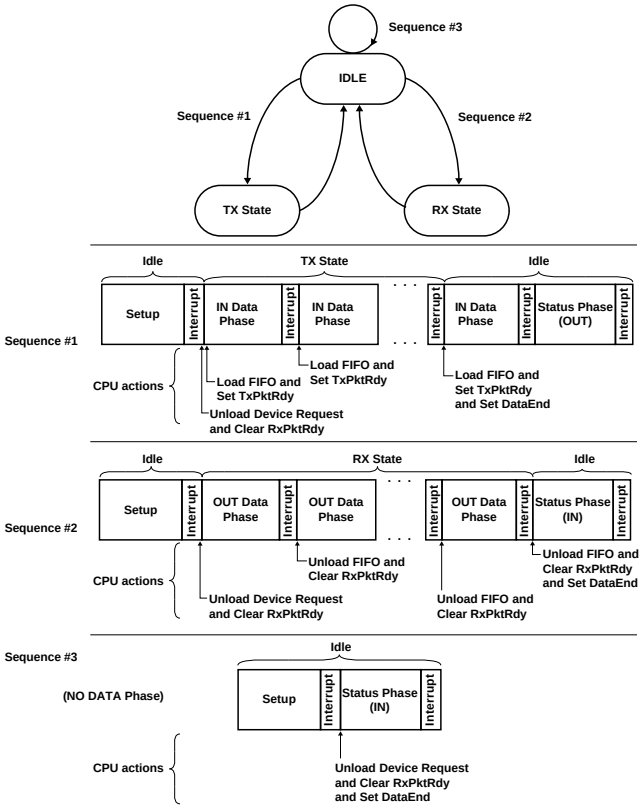

Figure 23-4: Endpoint 0 Control States

Endpoint 0 Service Routine as Peripheral

The USB controller generates an endpoint 0 interrupt when:

- The USB controller sets the `USB_EP0_CSR[n]_P.RXPKTRDY` bit after a valid token has been received and data has been written to the FIFO.

- The USB controller clears the USB_EP0_CSR[n]_P.TXPKTRDY bit after the data packet in the FIFO has been successfully transmitted to the host.
- The USB controller sets the USB_EP0_CSR[n]_P.SENTSTALL bit after a control transaction is ended due to a protocol violation.
- The USB controller sets the USB_EP0_CSR[n]_P.SETUPEND bit because a control transfer has ended before USB_EP0_CSR[n]_P.DATAEND is set.

Whenever the endpoint 0 service routine is entered, the firmware must first check whether the current control transfer has been ended. The transfer can end due to either a stall condition or a premature end-of-control transfer. If the control transfer ends due to a stall condition, the USB controller sets the USB_EP0_CSR[n]_P.SENTSTALL bit. If the control transfer ends due to a premature end-of-control transfer, the USB controller sets USB_EP0_CSR[n]_P.SETUPEND. In either case, the firmware must abort processing the current control transfer and set the state to IDLE.

Once the firmware has determined that an illegal bus state did not generate the interrupt, the next action depends on the endpoint state.

If endpoint 0 is in IDLE state, the only valid reason the USB controller can generate an interrupt is due to the core receiving data from the USB bus. The service routine must check for this state by testing the USB_EP0_CSR[n]_P.RXPKTRDY bit. If the USB controller sets the bit, then the core has received a setup packet. The processor unloads this packet from the FIFO and decodes it to determine the next action. Depending on the command contained within the setup packet, endpoint 0 enters one of the following three states.

- If the command is a single packet transaction (SET_ADDRESS, SET_INTERFACE and the others) without a data phase, the endpoint remains in the IDLE state.
- If the command has an OUT data phase (SET_DESCRIPTOR and others), the endpoint enters the Rx state.
- If the command has an IN data phase (GET_DESCRIPTOR and others), the endpoint enters the Tx state.

NOTE: Command transactions all include a field that indicates the amount of data the host expects to receive or send.

If the endpoint is in Tx state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The firmware must respond to this event by:

- Placing more data in the FIFO when the host still expects more data
- Setting the USB_EP0_CSR[n]_P.DATAEND bit to indicate that the data phase is complete

Once the data phase of the transaction completes, endpoint 0 returns to the IDLE state to await the next control transaction.

If the endpoint is in the Rx state, the interrupt indicates that a data packet has been received. The firmware must respond by unloading the received data from the FIFO. The firmware must then determine whether it has received

all of the expected data. If it has, the firmware must set the USB_EP0_CSR[n]_P.DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware must set the USB_EP0_CSR[n]_P.SPKTRDY bit to indicate that it has read the data in the FIFO and leave the endpoint in the Rx state.

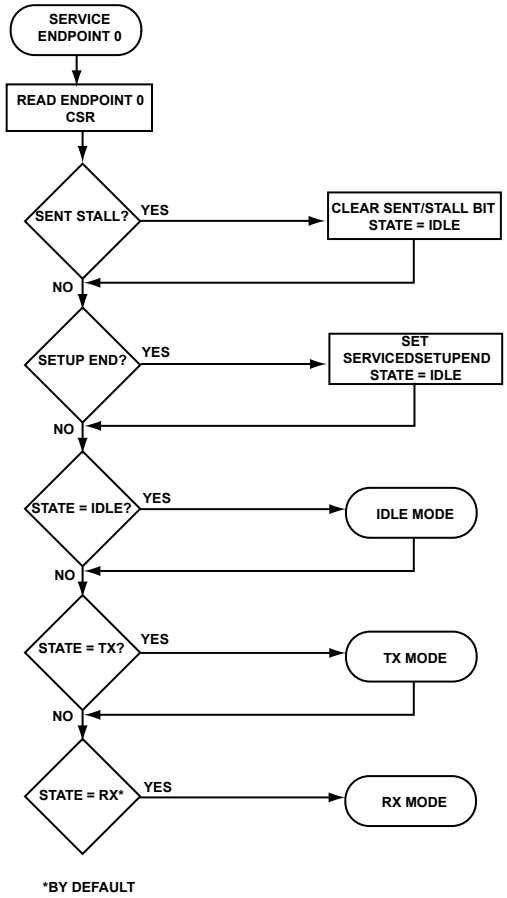

Figure 23-5: Endpoint 0 Service Routine

IDLE Mode

The endpoint 0 control must select IDLE mode at power-on or reset. The endpoint 0 control returns to this mode when the Rx and Tx modes terminate.

As shown in the ***Endpoint 0 Idle Mode (SETUP Phase)*** figure, the SETUP phase of control transfer is handled in IDLE mode.

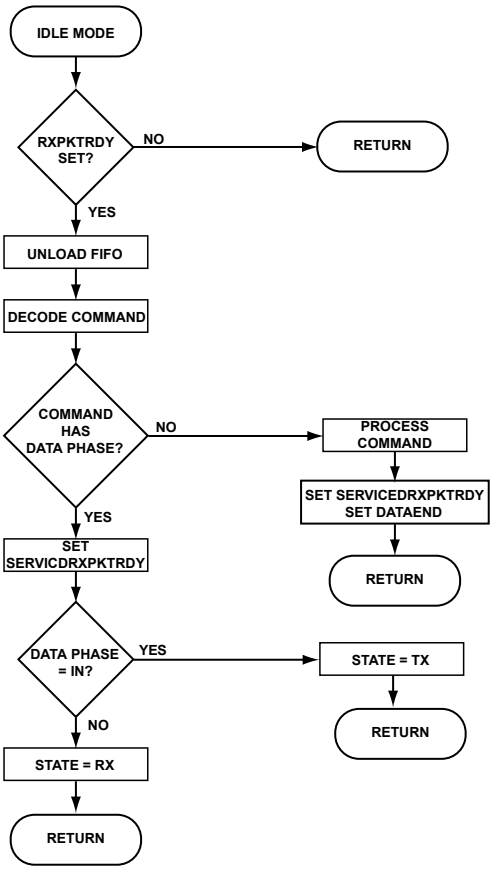

Figure 23-6: Endpoint 0 Idle Mode (SETUP Phase)

Tx Mode

Refer to the ***Endpoint 0 Tx Mode*** figure. When the endpoint is in Tx state, all arriving IN tokens must be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the Tx state, a `USB_EP0_CSR[n]_P.SETUPEND` condition occurs. The core expects only IN tokens.

Three events can cause the Tx mode to terminate before the expected amount of data has been sent:

- The host sends an invalid token which sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.
- The firmware sends a packet containing less than the maximum packet size for endpoint 0.
- The firmware sends an empty data packet.

Until the transaction is terminated, when the firmware receives an interrupt which indicates that a packet has been sent from the FIFO, it simply loads the FIFO. An interrupt is generated when the USB controller clears `USB_EP0_CSR[n]_P.TXPKTRDY`.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it must set the `USB_EP0_CSR[n]_P.DATAEND` bit. This event indicates to the core that the data phase is complete and that the core will receive an acknowledge packet next.

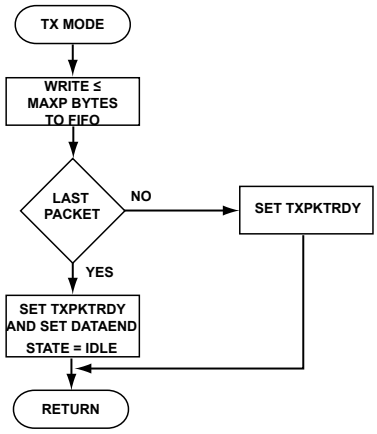

Figure 23-7: Endpoint 0 Tx Mode

Rx Mode

Refer to the ***Endpoint 0 Rx Mode*** figure. In Rx mode, all arriving data must be treated as part of a data phase until the expected amount of data is received. If either a SETUP or an IN token is received while the endpoint is in Rx state, a `USB_EP0_CSR[n]_P.SETUPEND` condition occurs since the core expects only OUT tokens.

Three events can cause the Rx mode to terminate before the expected amount of data is received:

- The host sends an invalid token which sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.
- The host sends a packet which contains less than the maximum packet size for endpoint 0.
- The host sends an empty data packet.

The transaction terminates when the firmware receives an interrupt which indicates that new data has arrived (`USB_EP0_CSR[n]_P.RXPKTRDY` bit is set). Until the transaction terminates, firmware must unload the FIFO and clear `USB_EP0_CSR[n]_P.RXPKTRDY` by setting the `USB_EP0_CSR[n]_P.SPKTRDY` bit.

When the firmware detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it must set the `USB_EP0_CSR[n]_P.DATAEND` bit. This event indicates to the core that the data phase is complete and that the core will receive an acknowledge packet next.

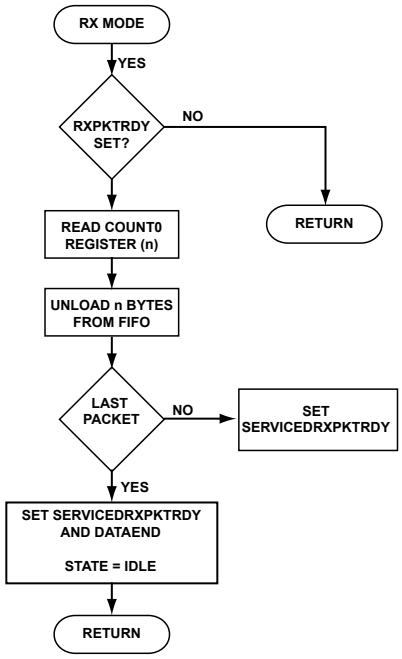

Figure 23-8: Endpoint 0 Rx Mode

Peripheral Mode, Bulk IN, Transfer Size Known

For this process, the maximum size of an individual packet (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes, must be known.

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the following bits: `USB_EP[n]_TXCSR_P.DMAREQEN` = 1, `USB_EP[n]_TXCSR_P.AUTOSET` = 1, `USB_EP[n]_TXCSR_P.ISO` = 0, `USB_EP[n]_TXCSR_P.FRCDATATGL`= 0.
3. Load the *TxferSize* value into the `USB_DMA[n]_CNT` register.
4. Configure the DMA controller to write the data into the corresponding Tx FIFO address.
5. On each `USB_DMA[n]_CNT` transition, the DMA controller writes a new packet into the FIFO. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is automatically set when each new packet is written.

   ADDITIONAL INFORMATION: Repeat Step 5 for each full packet of the transfer. Even if the final packet is a short packet, the USB controller automatically detects the packet because the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set.

Peripheral Mode, Bulk IN, Transfer Size Unknown

For this process, assume the maximum individual packet size (*MaxPktSize*) in bytes is an even number of bytes.

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the following bits: `USB_EP[n]_TXCSR_P.DMAREQEN` = 1, `USB_EP[n]_TXCSR_P.AUTOSET` = 1, `USB_EP[n]_TXCSR_P.ISO` = 0, `USB_EP[n]_TXCSR_P.FRCDATATGL`= 0.

3. Configure the DMA controller to write *MaxPktSize*/2 half words into the corresponding Tx FIFO address on each USB_DMA[n]_CNT.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt, that writes a remaining short packet into the Tx FIFO using processor core DMA. Then, set the USB_EP[n]_TXCSR_P.TXPKTRDY bit or toggle the USB_EP[n]_TXCSR_P.TXPKTRDY bit to send a zero-length packet.
5. On each USB_DMA[n]_CNT transition, the DMA controller writes a new packet into the FIFO. The USB_EP[n]_TXCSR_P.TXPKTRDY bit is set automatically when each new packet is written.

   ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer. The ISR from step 4 manages the final short or zero-length packet.

Peripheral Mode, ISO IN, Small MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes and is an even number of bytes. Assume that double buffering is enabled, and the auto-set feature is not used (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into the USB_EP[n]_TXMAXP register.
2. Set the following bits: USB_EP[n]_TXCSR_P.ISO = 1.
3. Preload the first two packets into the endpoint Tx FIFO and set the USB_EP[n]_TXCSR_P.TXPKTRDY bit.
4. Set up an ISR, sensitive to the USB_IRQ.SOF interrupt, which writes a new packet into the Tx FIFO and sets the USB_EP[n]_TXCSR_P.TXPKTRDY bit.
5. Set the USB_IEN.SOF bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 5 for each ISO packet.

Peripheral Mode, ISO IN, Large MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes and is an even number of bytes. Assume that double buffering is enabled, and the auto-set feature is not used (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into the USB_EP[n]_TXMAXP register.
2. Set the USB_EP[n]_TXCSR_P.ISO bit = 1.
3. Set the USB_POWER.ISOUPDT bit = 1 to prevent the initial packet loaded into the FIFO from transmitting on the USB until the next 1ms frame.
4. Load the total number of bytes for the first two packets into the USB_DMA[n]_CNT register.
5. Configure the DMA controller to pre-load the two packets into the corresponding Tx FIFO address and set the USB_EP[n]_TXCSR_P.TXPKTRDY bit.

6. Set up an ISR, sensitive to the USB_IRQ.SOF interrupt, which writes a new packet into the Tx FIFO by configuring the DMA controller to load the packet.
7. Set the USB_IEN.SOF bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 7 for each ISO packet.

Peripheral Mode, Bulk OUT, Transfer Size Known

For this process, the maximum individual packet size (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes must be known.

1. Load *MaxPktSize* into USB_EP[n]_RXMAXP.
2. Set the following bits: USB_EP[n]_RXCSR_P.DMAREQEN = 1, USB_EP[n]_RXCSR_P.AUTOCLR= 1, USB_EP[n]_RXCSR_P.ISO = 0, USB_EP[n]_RXCSR_P.CLRDATATGL = 0, USB_EP[n]_RXCSR_P.DMAREQMODE = 0.
3. Configure the DMA controller to read the full *TxferSize*/2 half words from the corresponding Rx FIFO address.
4. On each USB_DMA[n]_CNT transition, the DMA controller reads another packet from the FIFO. The USB controller automatically clears the USB_EP[n]_RXCSR_P.RXPKTRDY bit when each new packet is read.

   ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer. If *TxferSize* is not an exact multiple of *MaxPktSize*, the final USB_DMA[n]_CNT transition causes the DMA controller to read out only the short packet that remains.

Peripheral Mode, Bulk OUT, Transfer Size Unknown

For this process, the maximum individual packet size (*MaxPktSize*) in bytes must be known.

1. Load *MaxPktSize* into USB_EP[n]_RXMAXP.
2. Set the following bits: USB_EP[n]_RXCSR_P.DMAREQEN= 1, USB_EP[n]_RXCSR_P.AUTOCLR = 1, USB_EP[n]_RXCSR_P.ISO = 0, USB_EP[n]_RXCSR_P.CLRDATATGL= 0, USB_EP[n]_RXCSR_P.DMAREQMODE = 1.
3. Set the appropriate bit in the USB_INTRRXE register.
4. Configure the DMA controller to read *MaxPktSize*/2 half words from the corresponding Rx FIFO address on each USB_DMA[n]_CNT transition.
5. Set up an ISR, sensitive to the Rx interrupt, which reads the USB_EP[n]_RXCNT register and then transfers USB_EP[n]_RXCNT bytes (in half words) from the Rx FIFO to the processor core.

   ADDITIONAL INFORMATION: Depending on the number of bytes in the FIFO, configure the DMA to read the data, or read it with the processor core.

ADDITIONAL INFORMATION: On each USB_DMA[n]_CNT transition, the DMA controller reads a packet from the FIFO. The USB controller automatically clears the USB_EP[n]_RXCSR_P.RXPKTRDY bit when each new packet is read.

ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer.

6. If a packet is received that is less than *MaxPktSize*, the Rx interrupt goes high, and the ISR from step 5 reads out the remaining short packet.

Peripheral Mode, ISO OUT, Small MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes. Assume that double buffering is enabled.

1. Load the *MaxPktSize* value into the USB_EP[n]_RXMAXP register.
2. Set the USB_EP[n]_RXCSR_P.ISO bit = 1.
3. Set up an ISR, sensitive to the USB_IRQ.SOF interrupt, that reads the USB_EP[n]_RXCSR_P.FIFOFULL bit and then reads the USB_EP0_CNT[n].RXCNT status register. The ISR removes one or two packets (equal to the USB_EP0_CNT[n].RXCNT number of bytes) from the FIFO. It then clears the USB_EP[n]_RXCSR_P.RXPKTRDY bit.
4. Set the USB_IEN.SOF bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 4 for each ISO packet.

Peripheral Mode, ISO OUT, Large MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes. Assume that double buffering is enabled.

1. Load *MaxPktSize* into the USB_EP[n]_RXMAXP register.
2. Set the USB_EP[n]_RXCSR_P.ISO bit = 1.
3. Set up an ISR (sensitive to the USB_IRQ.SOF interrupt), that reads the USB_EP[n]_RXCSR_P.FIFOFULL bit, and then reads the USB_EP[n]_RXCNT status register. The ISR configures the DMA controller to remove one or two packets (equal to the USB_EP[n]_RXCNT number of bytes) from the FIFO.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt to clear the USB_EP[n]_RXCSR_P.RXPKTRDY.
5. Set the USB_IEN.SOF bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 5 for each ISO packet.

Peripheral Mode Suspend

When no activity has occurred on the USB for 3 ms, the USB controller enters suspend mode. If the suspend interrupt (USB_IRQ.SUSPEND) is enabled, an interrupt is generated.

When resume signaling is detected, the USB controller exits suspend mode. If the USB_IRQ.RESUME interrupt is enabled, an interrupt is generated. The processor core can also force the USB controller to exit suspend mode by setting the USB_POWER.RESUME bit. This event initiates a remote wake-up. When this bit is set, the USB controller exits suspend mode and drives resume signaling onto the bus. The processor core must clear this bit after 10 ms (a maximum of 15 ms) to end resume-signaling.

NOTE: The USB_IRQ.RESUME interrupt is not generated when the processor core exits suspend mode. This interrupt is not generated when the software initiates remote wake-up.

Start of Frame (SOF) Packets

When the USB controller operates in peripheral mode, it receives a start of frame packet from the host every millisecond when in full-speed mode, or every 125 microseconds when in high-speed mode.

When the USB controller receives a SOF packet, it writes the 11-bit frame number contained in the packet into the USB_FRAME register. An output pulse, lasting one USB clock bit period, is generated. A start of frame interrupt is also generated (if enabled by the USB_IRQ.SOF bit).

After the USB controller has started to receive SOF packets, the controller expects one every millisecond (faster in high-speed mode). If the USB controller does not receive an SOF packet after 1.00358 ms (faster in high-speed mode), it is assumed that the packet is lost. A start of frame pulse (together with a USB_IRQ.SOF interrupt) is still generated even though the USB_FRAME register is not updated. The USB controller continues to generate an SOF pulse every millisecond (faster in high-speed mode). It resynchronizes these pulses to the received SOF packets when it successfully receives these packets again.

Soft Connect/Soft Disconnect

In peripheral mode, the USB controller sets or clears the USB_POWER.SOFTCONN bit to switch between normal mode and non-driving mode. When USB_POWER.SOFTCONN=1, the USB controller is in normal mode and the D+/D– lines of the USB bus are enabled. When the USB_POWER.SOFTCONN=0, the PHY is put into non-driving mode and D+ and D– are three-stated. The USB controller appears to have been disconnected from the USB bus.

After system reset, USB_POWER.SOFTCONN=0. From that point, the USB controller appears disconnected until the software has set USB_POWER.SOFTCONN =1. The application software can then choose when to set the PHY to its normal mode. Systems with a lengthy initialization procedure can use this functionality to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the USB_POWER.SOFTCONN bit is set to 1, the software can also clear this bit to 0 to simulate a disconnect.

Error Handling As a Peripheral

The host can abort a control transfer due to a protocol error on the USB. The function controller software can also abort the transfer (for example, because it cannot process the command).

The USB controller automatically detects protocol errors and sends a stall packet to the host under the following conditions.

1. The host sends more data during the OUT data phase of a write request than specified in the command. This condition is detected when the host sends an OUT token after the USB_EP0_CSR[n]_P.DATAEND bit is set.
2. The host requests more data during the IN data phase of a read request than specified in the command. This condition is detected when the host sends an IN token after the USB_EP0_CSR[n]_P.DATAEND bit is set.
3. The host sends more than *MaxPktSize* data bytes in an OUT data packet.
4. The host sends a non-zero length DATA1 packet during the status phase of a read request.

When the USB controller has sent the stall packet, it sets the USB_EP0_CSR[n]_P.SENTSTALL bit and generates an interrupt. When the software receives an endpoint 0 interrupt with the USB_EP0_CSR[n]_P.SENTSTALL bit set, it aborts the current transfer, clears the USB_EP0_CSR[n]_P.SENTSTALL bit, and returns to the IDLE state.

If the host enters the status phase before all the data for the request transfers, or sends a new SETUP packet before completing the current transfer, then it prematurely ends the transfer. The USB_EP0_CSR[n]_P.SETUPEND bit is set and an endpoint 0 interrupt is generated. When the software receives an endpoint 0 interrupt with the USB_EP0_CSR[n]_P.SETUPEND bit set, it aborts the current transfer, sets the USB_EP0_CSR[n]_P.SSETUPEND bit, and returns to the IDLE state. If the USB_EP0_CSR[n]_P.RXPKTRDY bit is set, it indicates that the host has sent another SETUP packet and the software must then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it must set the USB_EP0_CSR[n]_P.SENTSTALL bit. The USB controller then sends a stall packet to the host, sets the USB_EP0_CSR[n]_P.SENTSTALL bit, and generates an endpoint 0 interrupt.

Stalls Issued to Control Transfers

In peripheral mode, the USB controller automatically issues a stall handshake to a control transfer under the following conditions:

1. The host sends more data during an OUT data phase of a control transfer than specified in the device request during the SETUP phase. The USB controller detects this condition when the host sends an OUT token (instead of an IN token) after the processor core unloads the last OUT packet and sets the USB_EP0_CSR[n]_P.DATAEND bit.
2. The host requests more data during an IN data phase of a control transfer than specified in the device request during the SETUP phase. The USB controller detects this condition when the host sends an IN token (instead of an OUT token) after the processor core clears USB_EP[n]_TXCSR_P.TXPKTRDY and sets USB_EP0_CSR[n]_P.DATAEND. The processor sets USB_EP0_CSR[n]_P.DATAEND in response to the host-issued ACK for the last packet.
3. The host sends more than *MaxPktSize* data with an OUT data token.

4. The host sends the wrong PID (packet identifier) for the OUT status phase of a control transfer.
5. The host sends more than a zero length data packet for the OUT status phase.

Zero Length OUT Data Packets in Control Transfers

The USB controller uses a zero-length OUT data packet to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request transfers (for example, after the processor core has set the `USB_EP0_CSR[n]_P.DATAEND` bit). If the host sends a zero-length OUT data packet before the entire length of device request transfers, this packet signals the premature end of the transfer. In this case, the USB controller automatically flushes any IN token the processor core has loaded for the data phase from the FIFO and sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.

Host Mode

USB OTG interface operations in host mode differ from peripheral mode in a number of ways. The following sections describe host mode operations.

Transaction Scheduling

When operating as a host, the USB controller maintains a frame counter.

If the target function is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame or micro-frame.

If the target function is a low-speed device, a K state is transmitted on the bus to act as a *keep-alive*. It stops the low-speed device from going into suspend mode.

After the SOF packet is transmitted, the USB controller cycles through all the endpoints looking for active transactions. An active transaction is defined as an Rx endpoint for which the `USB_EP[n]_RXCSR_H.REQPKT` bit is set or a Tx endpoint for which the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set.

An active isochronous or interrupt transaction only starts if:

- It is found on the first transaction scheduler cycle of a frame.
- The interval counter for that endpoint has counted down to zero.

This functionality ensures that only one interrupt or isochronous transaction occurs per endpoint per *n* frames or micro frames (or, up to three, if high-bandwidth support is selected). *n* is the interval set in the `USB_EP[n]_TXINTERVAL` or `USB_EP[n]_RXINTERVAL` register for that endpoint.

An active bulk transaction starts immediately, provided there is sufficient time left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried, then it is not retried until the transaction scheduler has checked all the other endpoints for active transactions first. (For example, the transaction is retried because a NAK was received or the target function did not respond.) This check ensures that an endpoint that is sending many NAKs does not block other transactions on the bus. The USB controller permits specifying a limit (`USB_EP[n]_TXINTERVAL` or `USB_EP[n]_RXINTERVAL` registers) to the length of time in which NAKs can be received from a particular target before the endpoint is timed out.

Endpoint Setup and Data Transfer

When the HOST_MODE bit is set to 1, the USB controller operates as a host for point-to-point communications with another USB device. Or, when attached to a hub, the USB controller operates as a host for communication with a range of devices in a multi-point set-up.

The USB controller supports high-speed, full-speed, and low-speed USB functions, both for point-to-point communication and for operation through a hub.

Where necessary, the core automatically carries out the necessary transaction translation to allow usage of a low-speed or full-speed device with a USB 2.0 hub.

The USB controller supports control, bulk, isochronous, or interrupt transactions.

Transfers between the subsystem and endpoint FIFOs in host mode are similar to peripheral mode. See the descriptions of processor core-to-FIFO data transfer in Peripheral Mode.

Control Transaction as a Host

Host control transactions are conducted through endpoint 0. The software handles all the standard device requests that are sent or received through endpoint 0 (as described in *Universal Serial Bus Specification*, Revision 2.0, Chapter 9).

For a USB peripheral, there are three categories of standard device requests:

- ***Zero data requests.*** Comprised of a SETUP command followed by an IN status phase. The command includes all the information.
- ***Write requests.*** Comprised of a SETUP command, followed by an OUT data phase followed by an IN status phase. Extra data follows the command.
- ***Read requests*** Comprised of a SETUP command, followed by an IN data phase followed by an OUT status phase. The device is required to send data back to the host.

A timeout can be set to limit the length of time during which the USB controller retries a transaction that the target continually NAKs. This limit can be between 2 and 2^{15} frames or micro frames and is set through the USB_EP0_NAKLIMIT[n] register.

The following sections describe the steps taken in different phases of a control transaction and the actions of the core when issuing standard device requests.

Set up Phase as a Host

The processor core driving the host device performs the following actions for the SETUP phase of a control transaction.

1. Load the 8 bytes of the required device request command into the endpoint 0 FIFO.
2. Set the USB_EP0_CSR[n]_H.SETUPPKT bit and USB_EP0_CSR[n]_H.TXPKTRDY bit. These bits must be set together.

The USB controller then sends a SETUP token followed by the 8-byte command to endpoint 0 of the addressed device, retrying as necessary.

3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt (for example, set USB_INTRTXE.EP0). The processor core then reads the USB_EP0_CSR[n]_H register to establish whether the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, or the USB_EP0_CSR[n]_H.NAKTO bits are set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target did not accept the command (for example, because the target device does not support it) and issues a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller tried to send the SETUP packet and the following data packet three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller received a NAK response to each attempt to send the SETUP packet, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the USB_EP0_CSR[n]_H.NAKTO bit.

4. If none of USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR or USB_EP0_CSR[n]_H.NAKTO bits are set, the SETUP phase is correctly acknowledged. The processor core can proceed to the following IN data phase, OUT data phase or IN status phase specified for the particular standard device request.

IN Data Phase as a Host

The processor core driving the host device performs the following actions for the IN data phase of a control transaction.

1. Set the USB_EP0_CSR[n]_H.REQPKT bit.
2. Wait while the USB controller sends the IN token and then receives the required data back.
3. When the USB controller generates the endpoint 0 interrupt (for example, by setting the USB_INTRTXE.EP0 bit), read the USB_EP0_CSR[n]_H register. Determine whether the USB_EP0_CSR[n]_H.RXSTALL bit, the USB_EP0_CSR[n]_H.TOERR bit, the USB_EP0_CSR[n]_H.NAKTO bit, or the USB_EP0_CSR[n]_H.RXPKTRDY bit is set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller has tried to send the required IN token three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or clear USB_EP0_CSR[n]_H.REQPKT before clearing the USB_EP0_CSR[n]_H.NAKTO bit to abort the transaction.

4. If the USB_EP0_CSR[n]_H.RXPKTRDY bit is set, the processor core reads the data from the endpoint 0 FIFO, then clears USB_EP0_CSR[n]_H.RXPKTRDY.
5. If further data is expected, the processor core must repeat the previous steps.

   When all the data is successfully received, the processor core can proceed to the OUT status phase of the control transaction.

OUT Data as a Host (Control)

The processor core driving the host device performs the following actions for the OUT data phase of a control transaction.

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the USB_EP0_CSR[n]_H.TXPKTRDY bit.

   The USB controller sends an OUT token followed by the data from the FIFO to endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt (for example by setting the USB_INTRTX.EP0 bit). The processor core can then read the USB_EP0_CSR[n]_H to establish whether the USB_EP0_CSR[n]_H.RXSTALL bit, the USB_EP0_CSR[n]_H.TOERR bit, or the USB_EP0_CSR[n]_H.NAKTO bit is set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1 the USB controller has tried to send the OUT token and the following data packet three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the USB_EP0_CSR[n]_H.NAKTO bit.

   If none of the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, or USB_EP0_CSR[n]_H.NAKTO bits are set, the OUT data is correctly acknowledged.
4. If further data must be sent, the processor core must repeat the previous steps.

   When all the data is successfully sent, the processor core proceeds to the IN status phase of the control transaction.

IN Status Phase as a Host (Following SETUP Phase or OUT Data Phase)

The processor core driving the host device performs the following actions for the IN status phase of a control transaction.

1. Set the USB_EP0_CSR[n]_H.STATUSPKT and USB_EP0_CSR[n]_H.REQPKT bits. These bits must be set together.

2. Wait while the USB controller both sends an IN token and receives a response from the USB peripheral.
3. When the USB controller generates the endpoint 0 interrupt (for example, it sets the USB_INTRTX.EP0 bit), read the USB_EP0_CSR[n]_H register to establish whether the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, USB_EP0_CSR[n]_H.NAKTO, or the USB_EP0_CSR[n]_H.RXPKTRDY bits are set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target could not complete the command and so has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller has tried to send the required IN token three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or clear USB_EP0_CSR[n]_H.REQPKT before clearing the USB_EP0_CSR[n]_H.NAKTO bit to abort the transaction.
4. If the USB_EP0_CSR[n]_H.RXPKTRDY bit is set, the processor core typically clears it.

OUT Status Phase as a Host (Following IN Data Phase)

The processor core driving the host device performs the following actions for the OUT status phase of a control transaction.

1. Set USB_EP0_CSR[n]_H.STATUSPKT and USB_EP0_CSR[n]_H.TXPKTRDY bits. These bits must be set together.
2. Wait while the USB controller both sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt. The processor core then reads the USB_EP0_CSR[n]_H register to discover when the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, or USB_EP0_CSR[n]_H.NAKTO bits are set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target could not complete the command and so has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller has tried to send the STATUS packet and the following data packet three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the USB_EP0_CSR[n]_H.NAKTO bit.

4. If none of the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, or USB_EP0_CSR[n]_H.NAKTO bits are set, the status phase is correctly acknowledged.

Host IN Transactions

When the USB controller operates as a host, IN transactions are handled in the same way as OUT transactions are handled when the USB controller is operating as a peripheral. First, the USB controller sets USB_EP[n]_RXCSR_H.REQPKT bit to initiate the transaction. This bit indicates to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target function.

When the packet is received and placed in the Rx FIFO, the USB_EP[n]_RXCSR_H.RXPKTRDY bit is set. The appropriate Rx endpoint interrupt is generated (if enabled) to signal that the processor can now unload a packet can now from the FIFO. When the processor unloads the packet, USB_EP[n]_RXCSR_H.RXPKTRDY is cleared. The USB controller uses the USB_EP[n]_RXCSR_H.AUTOCLR bit to clear the USB_EP[n]_RXCSR_H.RXPKTRDY bit automatically when the processor unloads a maximum sized packet from the FIFO. There is also an USB_EP[n]_RXCSR_H.AUTOREQ bit that automatically sets the USB_EP[n]_RXCSR_H.REQPKT bit when the USB_EP[n]_RXCSR_H.RXPKTRDY bit is cleared. The USB controller can use the USB_EP[n]_RXCSR_H.AUTOCLR and USB_EP[n]_RXCSR_H.AUTOREQ bits with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to a bulk or interrupt IN token with a NAK, the USB controller retries the transaction until the NAK limit set in the USB_EP0_NAKLIMIT[n] register is reached. If the target function responds with a stall, the USB controller does not retry the transaction, but sets the USB_EP[n]_RXCSR_H.RXSTALL bit to interrupt the processor core. If the target function does not respond to the IN token within the required time, the USB controller retries the transaction.(USB controller also retries the transaction if there was a CRC or bit-stuff error in the packet). If, after three attempts, the target function still has not responded, the USB controller clears the USB_EP[n]_RXCSR_H.REQPKT bit and interrupts the processor core with the DATAERROR_R bit in USB_RXCSR set.

Host OUT Transactions

When the USB controller operates as a host, OUT transactions are handled like IN transactions are handled when the USB controller operates as a peripheral.

The USB_EP[n]_TXCSR_H.TXPKTRDY bit must be set as the processor loads each packet into the Tx FIFO. The USB controller uses the USB_EP[n]_TXCSR_H.AUTOSET bit to cause the USB_EP[n]_TXCSR_H.TXPKTRDY bit to be automatically set when the processor loads a maximum sized packet into the FIFO. The USB controller can use the USB_EP[n]_TXCSR_H.AUTOSET bit with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to the OUT token with a NAK, the USB controller retries the transaction until the NAK limit set in the USB_EP0_NAKLIMIT[n] register is reached. If the target function responds with a stall, the USB controller does not retry the transaction, but sets the USB_EP[n]_TXCSR_H.RXSTALL bit to interrupt the processor core. If the target function does not respond to the OUT token within the required time, the USB controller retries the transaction.(USB controller also retries the transaction if there was a CRC or bit-stuff

error in the packet). If, after three attempts, the target function still has not responded, the USB controller flushes the FIFO and sets the USB_EP[n]_TXCSR_H.TXTOERR bit to interrupt the processor core.

Multi-Point Support

The following sections describe the multi-point support of the USB controller.

- Allocating Devices to Endpoints
- Multi-Point Operation
- Multi-Point Bandwidth Considerations

Allocating Devices to Endpoints

The separate functions of the connected devices are allocated to the endpoints within the USB controller through a group of three registers. The registers are associated with each implemented Rx or Tx endpoint (including endpoint 0).

The registers are:

- USB_MP[n]_TXFUNCADDR/ USB_MP[n]_RXFUNCADDR
- USB_MP[n]_TXHUBADDR/ USB_MP[n]_RXHUBADDR
- USB_MP[n]_TXHUBPORT/ USB_MP[n]_RXHUBPORT

The location of these registers depends on which of the endpoints is being addressed.

Record the address of the target function that is accessed through the selected endpoint in the transmit and receive function address registers. Record this information separately for each Tx and Rx endpoint used. In particular, set both USB_MP[n]_TXFUNCADDR and USB_MP[n]_RXFUNCADDR for endpoint 0.

The USB controller uses the transmit and receive hub address and hub port registers when a full-speed or low-speed device is connected to it through a high-speed USB 2.0 hub. The hub carries out the required transaction translation between high-speed transmission and low-speed or full-speed transmission. In this situation, the USB_MP[n]_TXHUBADDR/ USB_MP[n]_RXHUBADDR and USB_MP[n]_TXHUBPORT/ USB_MP[n]_RXHUBPORT registers must record the address of the hub that carries out the transaction translation. It must also record the address of the port of that hub through which the associated Tx or Rx endpoint must access the device.

If endpoint 0 is connected to a hub, then set both the Tx and the Rx versions of these registers for this endpoint. The USB controller also uses hub address registers to record whether the hub offers multiple transaction translators or just a single transaction translator. This configuration has a significant effect on the overall bandwidth that can be achieved.

In addition to recording the address of the target function, record the endpoint number and operating speed of the target device and the type of transaction that is executed. For a Tx endpoint, set this information in the USB_EP[n]_TXTYPE register when the index register is set to select the required endpoint. For an Rx endpoint,

set this information in the USB_EP[n]_RXTYPE register when the index register is set to select the required endpoint. In both cases, record the endpoint number in bits [3:0], select the transaction type through bits [5:4], and select the operating speed through bits [7:6].

Set only the speed for endpoint 0 because endpoint 0 only has the facilities to handle control transactions and therefore is always associated with a device endpoint 0. Use bits [7:6] of the Type 0 register to set the speed. The register is located at address 0x1A when the index register is set to 0.

Multi-Point Operation

After allocating functions to endpoints and recording the operating speed of the target device, multi-point operations can be configured. Most operations in a multi-point set-up are the same as for the equivalent actions where the core is attached to a single other device.

However, more steps are required when:

- The option of dynamically switching the allocation of functions to endpoints is taken (for example, to allow the support of a wider range of devices).
- The control packets normally associated with endpoint 0 are handled through a different endpoint.

If dynamic allocation is used, the program must monitor the current data toggle state associated with the endpoint and with each of the devices that are allocated to that endpoint. This knowledge allows the program to select the correct data toggle state when switching occurs between one device and the other. (This action is the programs responsibility. The core cannot determine what data toggle state is expected when a function switches in and out of use.)

The data toggle state can be switched from its current state by writing to the appropriate USB_EP[n]_TXCSR_H or USB_EP[n]_RXCSR_H register. This activity sets the data toggle write enable and data toggle bits that are included in the registers when the core is in host mode.

Data toggle write enable and data toggle bits are also included in the USB_EP0_CSR[n]_H register. However, control operations carried out through endpoint 0 of the core normally leave the data toggle in the expected state.

Where control packets are handled through an endpoint other than endpoint 0, programs must prompt for each setup token to be sent. Programs must set the USB_EP[n]_TXCSR_H.SETUPPKT bit when the core operates in host mode, along with the USB_EP[n]_TXCSR_H.TXPKTRDY bit. If the USB_EP[n]_TXCSR_H.SETUPPKT bit is not set, an OUT token is sent.

Use endpoint 0 of the USB controller to handle control packets for all of the devices attached to the controller, and to switch the allocation of this endpoint, as appropriate. Sending the correct token is ensured, as is ensuring that the data toggle is correctly set for this endpoint.

Using a different endpoint for this function is possible, as described, but note the following:

- The control function must be allocated to an Rx/Tx endpoint pair (with the same endpoint number).
- The chosen endpoints must each be associated with FIFOs that can accommodate the packet size associated with EP0 transactions at the chosen operating speed. The size is a minimum of 8 bytes for low-speed or full-speed transactions but 64 bytes for high-speed transactions.

Multi-Point Bandwidth Considerations

The available bandwidth determines the ability of a multi-point system to cope with isochronous transactions.

Once an endpoint is set up, hardware handles all scheduling. However, as with PC-based EHCI/OHCI/UHCI hosts, before opening a periodic pipe (for use by isochronous or interrupt traffic), software must determine that there is sufficient bandwidth available.

The bandwidth required for different transactions can be determined using algorithms similar to the ones used with PC-based hosts (detailed in Section 5.11.3 of the USB 2.0 Specification).

The available bandwidth is greater where the hub used supports multiple transaction translators.

Babble Interrupt

If the bus is still active at the end of a frame, the USB controller assumes that the function it is connected to has malfunctioned. It suspends all transactions, and generates a babble interrupt (`USB_IRQ.RSTBABBLE`). The USB controller does not start a transaction until the bus is inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame.

To recover from a babble error condition, the processor must take the following actions inside the interrupt service routine.

1. Turn off VBUS. Wait until the VBUS level indicator reads b#01.
2. Turn on VBUS. Wait until the VBUS level indicator reads b#11.
3. Set the `USB_IRQ.SESSREQ` bit.

The VBUS level indicator is the `USB_DEV_CTL.VBUS` bit field.

NOTE: Because VBUS is sourced external to the processor, make sure that the hardware design connects a GPIO or the dedicated `USB_VBUS` signal to the external source. This connection enables software to turn VBUS on and off.

VBUS Events

The USB On-The-Go specification defines a series of thresholds to which the devices involved in point-to-point communications must respond.

- VBUS valid (between 4.4 V and 4.75 V)
- Session valid for A device (between 0.8 V and 2.1 V)
- Session end (between 0.2 V and 0.8 V)

The critical thresholds and the processor response depend on whether the device is an A device or a B device and the circumstances of the event. The following sections describe these actions.

Actions as an A Device

VBUS >VBUS Valid with session initiated by USB controller. VBUS level indicator = b#11 and the session bit is set. When VBUS is greater than VBUS valid, the USB controller selects host mode and waits for a device to connect. It then generates a connect interrupt. The processor resets and enumerates the connected B device.

VBUS > Session valid with session initiated by B device. VBUS level indicator = b#10 and the session bit is clear. When VBUS is greater than session valid, the USB controller generates a session request interrupt. The processor sets the session bit. The USB controller either stays in host mode or changes to peripheral mode, depending upon the state of the pull-up resistor on the B device. For more information, refer to the host negotiation protocol of the OTG specification. The state of the host mode bit indicates the selected mode.

VBUS below VBUS Valid while the Session bit remains set. VBUS level indicator b#11 and the session bit is set. This event indicates a problem with the VBUS power level. For example, the battery power could have dropped too low to sustain VBUS valid. Or, the B device could be drawing more current than the A device can provide. In either case, the USB controller automatically terminates the session and generates a VBUS error interrupt.

To recover from this VBUS error condition, the processor must take the following actions inside the VBUS error interrupt handler.

- Turn off VBUS and wait until the `USB_DEV_CTL.VBUS` reads b#01.
- Turn on VBUS and wait until the `USB_DEV_CTL.VBUS` reads b#11.
- Set the `USB_DEV_CTL.SESSION` bit

The `USB_DEV_CTL.VBUS` bit field indicates the VBUS level.

NOTE: Because VBUS is sourced external to the processor, make sure that the hardware design connects a GPIO or the dedicated `DrvVBUS` signal to the external source. Then, the software can be used to turn VBUS on and off.

Actions as a B Device

VBUS > Session Valid. VBUS level indicator = b#10 and session bit is clear. This event indicates activity from the A device. The USB controller sets the session bit and disconnects the pull down resistor on the D+ line.

VBUS < Session Valid. While the session bit remains set, VBUS level indicator = b#01 and session bit is set. This event indicates that the A device has lost power (or become disconnected). The USB controller clears the session bit and generates a disconnect interrupt. The processor ends the session.

VBUS < Session End. VBUS level indicator = b#00. This event is the condition under which a B device can initiate a session request. If the session bit is set, then after 2 ms of SE0 on the bus, the USB controller starts SRP by first pulsing the data line, then pulsing the `USB_VBUS` signal.

Host Mode Reset

If the `USB_POWER.RESET` is set while the USB controller is in host mode, the USB controller generates reset signaling on the bus. The processor core must keep this bit set for 20 ms to ensure correct resetting of the target device. After the processor core clears the bit, the USB controller starts its frame counter and transaction scheduler.

Host Mode Suspend

The controller has a suspend mode that allows power savings for the processor. The mode operates as follows.

Entry into Suspend mode. When operating as a host, the USB controller can be prompted to go into suspend mode by setting the `USB_POWER.SUSPEND` bit. When this bit is set, the USB controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions start. No SOF packets are generated. If the `USB_POWER.SUSPEND` bit is set, the UTMI+ PHY goes into low-power mode when the USB controller goes into suspend mode and stops the clock.

Sending Resume Signaling. When the application requires the USB controller to leave suspend mode, it must clear and then set the `USB_POWER.RESUME` bit, and leave it set for 20 ms. While the `USB_POWER.RESUME` bit is high, the USB controller generates resume signaling on the bus. After 20 ms, the processor core must clear the `USB_POWER.RESUME` bit, at which point the frame counter and transaction scheduler start.

Responding to Remote Wake-up. If resume signaling is detected from the target while the USB controller is in suspend mode, the UTMI+ PHY is brought out of low-power mode and the clock restarts. The USB controller then exits suspend mode and automatically sets the `USB_POWER.RESUME` bit to take over generating the resume signaling from the target. If the `USB_IRQ.RESUME` bit=1, software generates an interrupt.

Suspending and Resuming the Controller

With the introduction of link power management, there are two basic methods to suspend and resume the USB controller. The ***Basic LPM transaction*** diagram demonstrates these two methods.

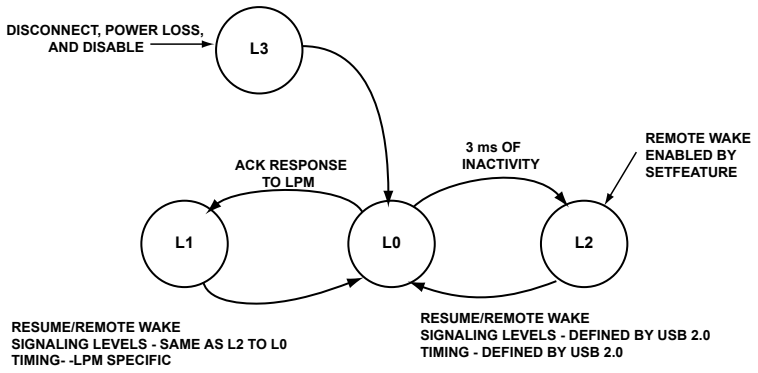

Figure 23-9: Basic LPM Transaction

The procedure that suspends and resumes the USB controller depends on whether the core operates as a device or a host, and the method of suspend desired. The following sections describe these options.

Suspend or Resume by Inactivity on the USB Bus (L0 to L2 State) in Peripheral Mode

The following steps occur in this mode.

1. Entry into suspend mode. When operating as a peripheral, the USB controller monitors activity on the USB and when no activity has occurred for 3 ms, the controller goes into suspend mode. If the `USB_IRQ.SUSPEND` interrupt has been enabled, the USB controller now generates an interrupt. The `USB_IRQ.SUSPEND` output also goes low (if enabled).

The *POWERDWN* signal is also asserted to indicate that the application can stop USB_CLKIN to save power. *POWERDWN* then remains asserted until either power is removed from the bus (indicating that the device has been disconnected) or resume signaling or reset signaling is detected on the bus.

2. When resume signaling occurs on the bus, the USB_CLKIN must be restarted, if necessary. The USB controller then automatically exits suspend mode. If the USB_IRQ.RESUME interrupt is enabled, the USB controller generates an interrupt.
3. Initiating a remote wake-up. To initiate a remote wake-up while the controller is in suspend mode, set the USB_POWER.RESUME bit=1. (If USB_CLKIN has been stopped, it must be restarted before this write can occur.) The software must leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0. By this time the hub is driving resume signaling on the USB.

NOTE: The USB_IRQ.RESUME interrupt is not generated when the software initiates a remote wake-up.

Suspend or Resume by Inactivity on the USB Bus (L0 To L2 State) in Host Mode

The following steps occur in this mode.

1. Entry into suspend mode. When operating as a host, the USB controller can be prompted to go into suspend mode by setting the USB_POWER.SUSPEND bit. When this bit is set, the USB controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions start and no SOF packets are generated. If the USB_POWER.SUSEN bit is set, the UTMI+ PHY goes into low-power mode when the controller goes into suspend mode and stops USB_CLKIN.
2. Sending resume signaling. When the application requires the controller to leave suspend mode, it clears the USB_POWER.SUSPEND bit, sets the USB_POWER.RESUME bit, and leaves it set for 20 ms. While the USB_POWER.RESUME bit is high, the controller generates resume signaling on the bus. After 20 ms, the processor core must clear the USB_POWER.RESUME bit, at which point the frame counter and transaction scheduler start.
3. Responding to remote wake-up. If resume signaling is detected from the target while the USB controller is in suspend mode, the UTMI+ PHY is brought out of low-power mode and restarts USB_CLKIN. The controller then exits suspend mode and automatically sets the USB_POWER.RESUME bit to 1 to take over generating the resume signaling from the target. If the USB_IRQ.RESUME interrupt is enabled, the USB controller generates an interrupt.

Suspend or Resume by an LPM Transaction (L0 To L1 State) in Peripheral Mode

The following steps occur in this mode.

1. Enter into suspend mode. When operating as a peripheral, the controller never initiates an LPM suspend (transition from the L0 state to the L1 state). Rather, the controller only suspends at the request of the host. Configure the USB_LPM_CTL register appropriately to enable the LPM feature. The USB controller uses the register field USB_LPM_CTL.EN bit to enable and support extended and LPM transactions. The USB controller uses the USB_LPM_CTL.TX field to instruct the hardware that it is ready to suspend and to respond to the next LPM transaction with an ACK. In this case, the controller responds to the next LPM transaction with an ACK

if all other conditions are met. The ***Response to LPM Transaction*** table summarizes the response of the USB controller to an LPM transaction.

Table 23-6: Response to LPM Transaction

LPMXMT	LPMCNTRL	Data Pending (Resides in Tx FIFOs)	Response to Next LPM Transaction
1'b0, 1'b0 1'b1 1'b1	2'b00, 2'b10 2'b00 2'b10	Do-not-care	Timeout
1'b0, 1'b1	2'b01	Do-not-care	STALL
1'b0	2'b11	Do-not-care	NYET
1'b1	2'b11	Yes	NYET
1'b1	2'b11	No	ACK

For all cases in the table in which the controller responds (no timeout occurs), an LPM interrupt is generated in the `USB_LPM_IRQ` register. The controller responds with an ACK only if there is no data pending in any of the Tx endpoint FIFOs. If there is data pending, the USB controller responds with a NYET.

Once an LPM transaction is successfully received, three events occur:

a. The `USB_LPM_ATTR` register is updated with values received in the LPM transaction. See the "Register Descriptions" section of this chapter for complete information on this register.

b. The controller suspends 9 µs after transmitting the ACK. The host or the controller can drive resume signaling 50 µs after this event. During the 9 µs interval, the host can continue to transmit the LPM transaction. The controller responds with an ACK in this case regardless of the `USB_LPM_CTL.TX` bit value.

c. An interrupt is generated informing software of the response (an ACK in this case). An ACK response is the indication to software that the controller has suspended.

   Since the primary purpose of LPM is to save power, software reads the `USB_LPM_ATTR` register to determine the attributes of the suspend. Software must make a determination based on these attributes whether there are more potential power savings in the system. In making this determination, note that if the host initiates the resume signaling, the controller must respond to packet transmissions within the time specified by `USB_LPM_ATTR.HIRD` + 10 µs.

2. When resume signaling occurs on the bus. When the host resumes the bus, it drives resume signaling for a minimum time specified by the host initiated resume duration bit field (`USB_LPM_ATTR.HIRD`). The controller must be able to respond to traffic within the time HIRD + 10 µs. The controller transitions to a normal operating state automatically and a resume interrupt is generated in the `USB_LPM_IRQ` register.

   However for this event to occur, the inputs *CLK* and *XCLK* must be available. To facilitate the resume timing requirement, a negative ACK (NAK) is provided using the `USB_LPM_CTL.NAK` bit. If this bit is set to 1'b1,

all endpoints respond to any transaction (other then an LPM) with a NAK. This bit only takes effect after the controller has suspended LPM. Typically, this bit is asserted when the USB_LPM_CTL.TX field is also asserted. Using this feature can simplify the resume timing requirement because the controller only needs *XCLK* to respond (with a NAK) to traffic. Software can continue to restore the system to normal operation while the controller responds to all transactions with a NAK. After software completely restores the system, it can then clear the USB_LPM_CTL.NAK bit.

3. Initiating remote wake-up. To initiate a remote wake-up while in suspend mode, the controller writes a 1'b1 to theUSB_LPM_CTL.RESUME bit. This bit is self clearing. Writing a 1'b1 drives resume signaling on the bus for 50 µs. The host responds by driving resume for 60 µs to 990 µs. 10 µs after the host stops driving resume, the controller transitions to its normal operational state and is ready for packet transmission. A resume interrupt is generated in the USB_LPM_IRQ register.

Suspend or Resume by an LPM Transaction (L0 to L1 State) in Host Mode

The following steps occur in this mode.

1. Enter into suspend mode. When operating as a host, the controller initiates an LPM suspend (transition from the L0 state to the L1 state) by initiating an LPM transaction as follows.
   a. Software sets up the desired attributes of the suspend in the USB_LPM_ATTR register. Enabling remote wake-up and a large HIRD gives the peripheral more opportunity to conserve power.
   b. Enable all LPM interrupts in the USB_LPM_IEN register.
   c. Software writes 0x01 to the USB_LPM_CTL register to initiate the transaction.
   d. An interrupt is generated to inform software of the response to the LPM transaction. If an ACK was received, then the controller suspends automatically within 8 µs. This event indicates that the controller has suspended.

   If the response from the device has a bit stuff error or a PID error, then an USB_LPM_IRQ.LPMERR interrupt is generated. The hardware immediately attempts the LPM transaction two more times. The device does not suspend for 8 µs after the initial LPM so it can respond to either of these subsequent LPM transactions. If an LPM timeout has occurred three times, the USB_LPM_IRQ.LPMNC and the USB_LPM_IRQ.LPMERR interrupts are set. Now, software is unaware of the device state and must deduce it by other means.
2. Send resume signaling. Software generates resume signaling as follows.
   a. Enable all LPM interrupts in the USB_LPM_IEN register.
   b. Software writes to the USB_LPM_CTL.RESUME bit which is self-clearing. This operation causes resume signaling on the bus for the time specified in the USB_LPM_ATTR.HIRD bit field. Hardware assumes that the last LPM transaction that caused the suspend used this value.
   c. After HIRD + 10 µs, the controller transitions to its normal operational state and is ready for packet transmission and a USB_LPM_IRQ.LPMRES interrupt is generated.

   NOTE: Prior to resuming, software must ensure that the system is restored from a low-power state and that the inputs *CLK* and *XCLK* are available.

3. Responding to remote wake-up. If the remote wake-up feature is enabled in the LPM transaction that caused the suspend, then the device can drive resume signaling on the bus. When this event occurs, the device drives resume signaling BUS for 50 µs. The controller immediately begins driving resume signaling on the BUS and continues for 60 µs. 10 µs after completion of the resume signaling, the controller transitions to its normal operating state and is ready for packet transmission. Then, the `USB_LPM_IRQ.LPMRES` interrupt is generated.

USB Event Control

The following sections provide information on the use of interrupts, reset, and the reporting of errors and interface status.

Interrupt Signals

The "Interrupt Table" section at the beginning of this chapter shows the two interrupts generated from the USB controller.

The software generates interrupts from control endpoint zero under the following conditions :

- When a control transaction ends before the end of the data is transferred
- When a data packet is sent or received from the endpoint 0 FIFOs

The USB controller generates interrupts from transmit endpoints (`USB_INTRTX`) under the following conditions:

- A packet is sent from the TX FIFO (host and peripheral mode)
- After three attempts at transmitting a packet, no valid handshake packet is received (host mode)

The software generates interrupts from receive endpoints (`USB_INTRRX`) under the following conditions:

- A packet is received into the RX FIFO (host and peripheral mode)
- A stall handshake is received (host mode)
- After three attempts at receiving a packet, no data packet is received (host mode)

The software generates interrupts from the USB status (`USB_IRQ`) under the following conditions:

- When VBUS drops below the VBUS valid threshold during a session (A device only)
- When SRP signaling is detected (A device only)
- When device disconnect is detected (host mode)
- When a session ends (peripheral mode)
- When a device connection is detected (host mode)
- At start of frame (SOF)
- When reset signaling is detected on USB (peripheral mode)

- When babble is detected (host mode)
- In suspend mode, when resume signaling is detected on USB
- When suspend signaling is detected (peripheral mode)

The software generates interrupts for the following VBUS control requests:

- Drive VBUS greater than 4.4 V (default A device)
- Stop driving VBUS
- Start charging VBUS (peripheral mode)
- Stop charging VBUS
- Start discharging VBUS (peripheral mode)
- Stop discharging VBUS

Interrupt Handling

When interrupted with a USB interrupt, the processor core must read the interrupt status register to determine which endpoints have caused the interrupt and jump to the appropriate routine. If multiple endpoints have caused the interrupt, endpoint 0 must be serviced first, followed by the other endpoints. The ***USB Interrupt Service Routine*** figure shows a flowchart for the USB interrupt service routine.

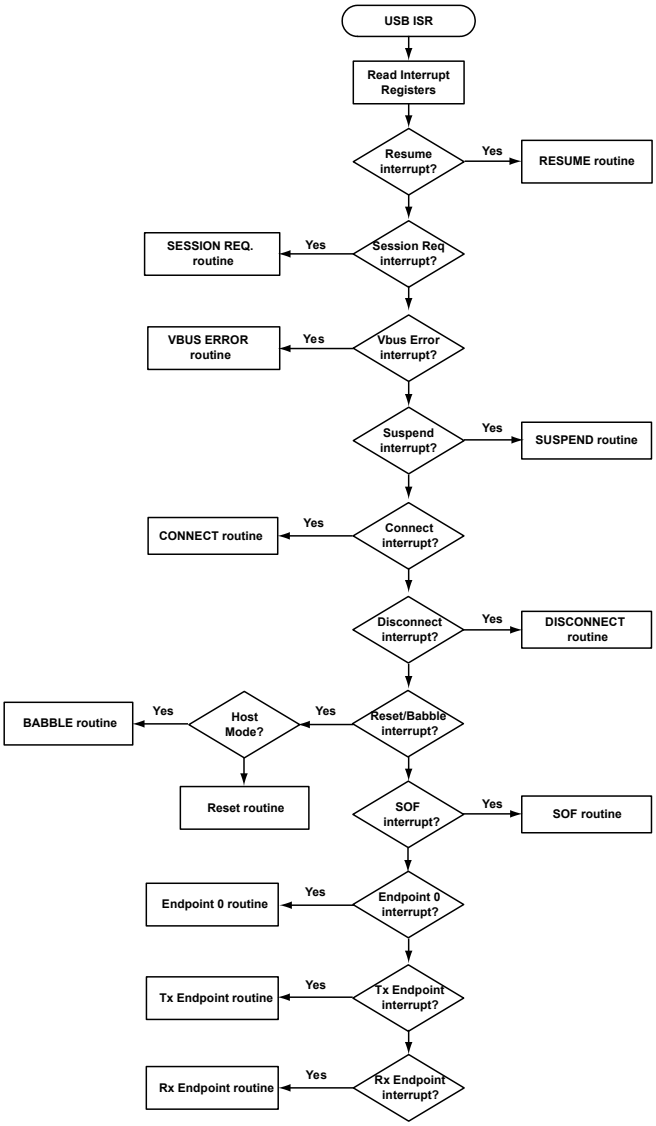

Figure 23-10: USB Interrupt Service Routine

Reset Signals

The USB controller includes an active-high synchronous hardware reset sourced from the processor core. Another source of peripheral reset is through the USB, when USB reset signaling is detected on the I/O lines. Per the USB 2.0 Specification, this state is entered when both the D+ and D- inputs are driven low for 2.5 ms or more. (The USB host typically holds the reset for greater than 10 ms.)

Reset in Peripheral Mode

When the USB controller detects a reset, it performs the following actions:

- Sets the `USB_FADDR` register to zero
- Sets the `USB_INDEX` register to zero

- Flushes all endpoint FIFOs
- Clears all control and status registers
- Enables all interrupts
- Generates a reset interrupt

The USB controller reset does not affect the USB_IRQ and USB_VBUS_CTL registers. These registers are only reset (along with the ones listed) during a system reset.

If the USB_POWER.HSEN bit was set, the USB controller also tries to negotiate for high-speed operation. The USB_POWER.HSMODE bit indicates whether high-speed operation is selected.

When the application software receives a reset interrupt, it closes any open pipes and waits for bus enumeration to begin.

USB Reset in Host Mode

If the USB_POWER.RESET bit =1 while the USB controller is in host mode, the controller generates reset signaling on the bus.

If the USB_POWER.HSEN bit =1, the controller also tries to negotiate for high-speed operation.

The processor core must keep the USB_POWER.RESET bit set for at least 20 ms to ensure correct resetting of the target device. After the processor core clears the bit, the USB controller starts its frame counter and transaction scheduler.

The USB controller uses the USB_POWER.HSMODE bit to select high-speed operation.

USB Programming Model

The following sections describe the USB OTG programming model.

OTG Session Request

To conserve power, the USB on-the-go supplement allows VBUS to only power-up when required and to turn off when the bus is not in use.

The A device on the bus always supplies VBUS. The USB controller samples the `USB_ID` input from the PHY to determine whether it is the A device or the B device. The signal is pulled low when an A-type plug is sensed (signifying that the USB controller is the A device). The input is taken high when a B-type plug is sensed (signifying that the USB controller is the B device).

Starting a Session

When the device containing the USB controller wants to start a session, the processor core must set the `USB_DEV_CTL.SESSION` bit. The USB controller then enables ID pin sensing. This activity results in the `USB_ID` input either being taken low if an A-type connection is detected or high if a B-type connection is detected. The `USB_DEV_CTL.BDEVICE` bit is also set to indicate whether the USB controller has adopted the role of the A device or the B device.

The USB controller is the A device. The USB controller then enters host mode (the A device is always the default host). It waits for VBUS to go above the VBUS valid threshold, as indicated when the `USB_DEV_CTL.VBUS` bits go to 11.

The USB controller then waits for a peripheral to be connected. When the USB controller detects a peripheral, it generates a connect interrupt (USB_IRQ.CON bit) (if enabled). It sets either the USB_DEV_CTL.FSDEV or USB_DEV_CTL.LSDEV bits, depending on whether a full-speed peripheral or a low-speed peripheral was detected. The processor core then resets this peripheral. To end the session, the processor core must clear the USB_DEV_CTL.SESSION bit.

The USB controller is the B device. The USB controller requests a session using the session request protocol defined in the USB on-the-go supplement. This functionality is accomplished by setting the USB_DEV_CTL.SESSION bit.

At the end of the session, typically the USB controller clears the USB_DEV_CTL.SESSION bit. But, the processor core can also clear it when the application software must perform a software disconnect. For more information, see the description of the USB_DEV_CTL register. The USB controller switches on the pull-up resistor on D+. This activity signals to the A device to end the session.

Detecting Activity

When the other device of the OTG set-up wants to start a session, USB controller either:

- Raises VBUS above the session valid threshold (if A device) or
- First pulses the data line, then pulses VBUS (if B device)

Depending on which of these actions happens, the USB controller can determine whether it is the A device or the B device in the current set-up and act accordingly. (The USB_DEV_CTL.VBUS bits=10 indicates if it is the A device.)

If VBUS is raised above the session valid threshold, the USB controller is the B device. The USB controller sets the USB_DEV_CTL.SESSION bit. When reset signaling is detected on the bus, a reset interrupt (USB_IRQ.RSTBABBLE=1) is generated (if enabled) that the processor core interprets as the start of a session. The USB controller is in peripheral mode as the B device is the default peripheral.

At the end of the session, the A device turns off the power to VBUS. When VBUS drops below the session valid threshold, the USB controller detects this state and clears the USB_DEV_CTL.SESSION bit to indicate that the session has ended. (The USB_DEV_CTL.VBUS bits=01 indicates that VBUS has dropped below the session valid threshold). A disconnect interrupt (USB_IRQ.DISCON bit) is also generated (if enabled).

If data line or VBUS pulsing is detected, the USB controller is the A device. The controller generates a USB_IRQ.SESSREQ interrupt to indicate that the B device is requesting a session. The processor core must then start a session by setting the USB_DEV_CTL.SESSION bit.

Host Negotiation Protocol

When the USB controller is the A device (USB_ID low, USB_DEV_CTL.BDEVICE=0), the controller automatically enters host mode when a session starts.

When the USB controller is the B device (USB_ID high, USB_DEV_CTL.BDEVICE=1), the controller automatically enters peripheral mode when a session starts. The processor core can request that the USB controller become

the host by setting the USB_DEV_CTL.HOSTREQ bit. This bit can be set either when requesting a session start by setting the USB_DEV_CTL.SESSION bit or at any time after a session has started.

When the USB controller enters suspend mode (no activity on the bus for 3 ms), and assuming the USB_DEV_CTL.HOSTREQ bit remains set, it then enters host mode. It begins host negotiation (as specified in the USB OTG supplement), causing the PHY to disconnect the pull-up resistor on the D+ line. This event causes the A device to switch to peripheral mode and to connect its own pull-up resistor. When the USB controller detects this activity, it generates a connect interrupt (USB_IRQ.CON bit). The controller also sets the USB_POWER.RESET bit to begin resetting the A device. (The USB controller begins this reset sequence automatically to ensure that reset is started as required within 1 ms of the A device connecting its pull-up resistor.) The processor core must wait at least 20 ms, then clear the USB_POWER.RESET bit and enumerate the A device.

When the USB controller-based B device has finished using the bus, the processor core must put it into suspend mode by setting the USB_POWER.SUSPEND. The A device detects this state and either terminates the session or reverts to host mode. If the A device is USB controller-based, it generates a disconnect interrupt (USB_IRQ.DISCON bit) if enabled.

Data Transfer

Whether the USB controller is operating in host or peripheral mode, data channels through the endpoint FIFOs to construct packets that are sent or received over the USB. The USB controller uses the Rx FIFOs to receive OUT packets when in peripheral mode and IN packets when operating in host mode. Similarly, The USB controller uses the Tx FIFOs to transmit IN packets when in peripheral mode and OUT packets as a host.

Data can be moved between the FIFOs and memory using either DMA or core accesses. Each endpoint FIFO has its own individually programmable options so that each can be set up separately. The system must treat each transfer type differently. Data transfers of significant size almost certainly require DMA to move the data around; but the processor can handle smaller packet sizes completely.

Each data endpoint supports both double and single-buffering modes. In single-buffered operation, the processor loads and unloads FIFOs on a packet-by-packet basis. Double-buffering imposes less burden on the system by allowing two packets to be buffered in a FIFO before it is necessary to use DMA or interrupts to service the FIFO. Double-buffering mode is automatically enabled when a *MaxPktSize* is set for an endpoint that is equal to or less than half the size in bytes of that FIFO.

Loading or Unloading Packets from Endpoints

Transfers to and from the FIFOs can be 32-bit, 16-bit, or 8-bit. When using core accesses, use the same width for transfers associated with one data packet, so that data is consistently byte, half-word, or word aligned. The last transfer can, however, contain fewer bytes than the previous transfers in order to complete an 8-bit or 16-bit transfer.

When using the DMA to access the FIFOs, the starting DMA address must be word aligned, or aligned on a 32-bit boundary. The packet transfer starts with a word transfer, but half-word or byte transfers can be added at the end to handle any leftovers.

DMA Master Channels

The USB controller provides eight DMA master channels.

These channels provide a more efficient transfer of larger amounts of data between the FIFOs and the processor core, and the channels free up the processor core for other tasks. The processor uses the DMA control registers to configure and control each of these channels.

Each DMA controller can operate in one of two DMA modes: 0 or 1. When operating in mode 0, the DMA controller can only be programmed to load or unload one packet, so processor intervention is required for each packet transferred over the USB. The DMA controller can use this mode with any endpoint, whether it uses control, bulk, isochronous, or interrupt transactions.

When operating in DMA mode 1, the DMA controller can only be programmed to load or unload a complete bulk transfer, which can be many packets. After set up, the DMA controller loads or unloads the packets, interrupting the processor only when the transfer has completed. DMA mode 1 can only be used with endpoints that use bulk transactions. It is most valuable where large blocks of data are transferred to a bulk endpoint. The USB protocol requires splitting such packets into a series of packets of *MaxPktSize* for the endpoint.

The DMA controller can use mode 1 to avoid the overhead of having to interrupt the processor after each individual packet. It interrupts the processor only after the transfer completes. In some cases, the block of data transferred consists of a predefined number of these packets that the controlling software counts through the transfer process. In other cases, the last packet in the series can be less than the maximum packet size. The receiver can use this short packet to signal the end of the transfer. If the total size of the transfer is an exact multiple of the maximum packet size, the transmitting software must send a null packet for the receiver to detect.

NOTE: Each channel can be independently programmed for the selected operating mode.

For bulk OUT transfers using DMA mode 1, the DMA request line is asserted only when:

- There is an edge transition of the state of the `USB_EP[n]_RXCSR_H.RXPKTRDY`, and
- A payload of *MaxPktSize* has been received

If a data packet is in the FIFO prior to setting the DMA request mode bits, the DMA request line is not asserted when the DMA is enabled. DMA is enabled using the `USB_DMA[n]_CTL.EN` bit. (DMA request mode bits are `USB_EP[n]_RXCSR_H.DMAREQMODE` or `USB_EP[n]_RXCSR_P.DMAREQMODE`). The data is not read from the Rx FIFO in this situation, resulting in a DMA hang. However, since the packet arrived before DMA request mode and DMA request enable bits (`USB_EP[n]_RXCSR_H.DMAREQEN` or `USB_EP[n]_RXCSR_P.DMAREQEN`) were enabled, an Rx interrupt is generated for the corresponding endpoint. Therefore, the software must set the DMA request mode to request mode 0 to unload the pre-received packet. The Rx interrupt service routine can be similar to the following:

If `USB_EP[n]_RXCNT` = MaxPktSize

Switch to DMA mode 0 and unload the packet (in mode 0, the DMA request enable is always asserted, whenever there is data in the FIFO)

Set the `USB_EP[n]_RXCNT` to MaxPktSize so as to unload only one packet

If USB_EP[n]_RXCSR_H.AUTOCLR is set, it is not necessary to clear USB_EP[n]_RXCSR_H.RXPKTRDY manually

Switch back to DMA Mode 1 and set the count to

(Total_Count – MaxPktSize)

Else

Handle as normal for case of short packet

DMA transfers can be 8-bit, 16-bit, or 32-bit. All transfers associated with one packet (except for the last) must be of the same width, so that the data is consistently byte-aligned or word-aligned. The last transfer can contain fewer bytes than the previous transfers to complete an odd-byte or odd-word transfer.

DMA Bus Cycles

The DMA controller uses incrementing bursts of an unspecified length on the peripheral DMA bus. The controller starts a new burst when it is first granted bus mastership and when the peripheral address starts a new 1 KB block. (The controller is granted bus mastership at the start of a USB packet or when regaining the bus after losing it following a partial packet).

When unloading packets from the FIFOs, the DMA controller requests ahead to the USB controller. The DMA controller starts the transfer with two BUSY cycles while it is gets the first word from the FIFO. All subsequent words of the packet are immediately available and no further BUSY cycles are required. The DMA controller is associated with a two-word buffer, so it does not lose data when it loses bus mastership in the middle of unloading a packet. When the controller regains bus mastership, it can continue unloading the packet without adding any BUSY cycles.

The DMA start address (written to the USB_DMA[n]_ADDR register) must be word aligned. The DMA controller supports split transactions and retries.

The DMA request lines are individually enabled using the appropriate DMA request enable bit (there are four options: Tx peripheral and host and Rx peripheral and host) and operate in two modes, referred to as DMA request mode 0 and DMA request mode 1. The operating mode is configured using the appropriate DMA request mode bit (there are four options: Tx peripheral and host and Rx peripheral and host).

NOTE: When operating in host mode, if the USB_EP[n]_TXCSR_H.RXSTALL bit or the USB_EP[n]_TXCSR_H.TXTOERR is set following three failed transmit attempts, the DMA request line is disabled until the bits are cleared.

The mode selected also affects the generation of endpoint interrupts (if enabled). In DMA request mode 0, no interrupt is generated when packets are received but the appropriate endpoint interrupt is generated to prompt the loading of all packets. In DMA request mode 1, the endpoint interrupt is suppressed except following the receipt of a short packet (one less than USB_EP[n]_RXMAXP bytes).

Table 23-7: Endpoint Interrupt Associated with the Receive Packet Ready Bit=1

DMAReqEnab	DMAReqMode	EP Interrupt Generated?
0	X	YES

0	X	YES
1	0	YES
1	1	NO

NOTE: Set the `USB_EP[n]_TXMAXP`/`USB_EP[n]_RXMAXP` registers to an even number of bytes for proper interrupt generation in DMA mode 1.

DMA transfers can be 8-bit, 16-bit, or 32-bit as required. However, all transfers associated with one packet (except for the last) must be of the same width so that the data is consistently byte-aligned, word-aligned, or double-word-aligned. The last transfer can contain fewer bytes than the previous transfers to complete an odd-byte or odd-word transfer.

NOTE: Disable DMA requests before changing the DMA request mode bit. In particular, do not set the `USB_EP[n]_TXCSR_H.DMAREQMODE` bit to zero either before or in the same cycle as the corresponding `USB_EP[n]_TXCSR_H.DMAREQEN` bit is cleared to zero.

Transferring Packets Using DMA

Both the channel and the endpoint must be programmed appropriately to use the the DMA master channels to access the USB controller FIFOs. Many variations are possible. The following sections detail the standard set ups used for the basic actions of transferring individual and multiple packets.

Individual Rx Endpoint Packet

The transfer of individual packets normally uses DMA mode 0. Program the USB controller Rx endpoint as follows.

1. Set to 1 the relevant bit in the `USB_INTRRXE` register.
2. Set to 0 the DMA enable bit of the appropriate `USB_EP[n]_RXCSR_H.DMAREQEN`/ `USB_EP[n]_RXCSR_P.DMAREQEN` register. (There is no need to set the USB controller to support DMA for this operation.)
3. When the USB controller receives a packet, it generates the appropriate endpoint interrupt (using the `USB_INTRRXE` register). The processor must then program the appropriate DMA master channel as follows.
    - Configure the `USB_DMA[n]_ADDR` register with the memory address to store the packet

- Configure the USB_DMA[n]_CNT register with the size of packet (determined by reading the USB controller USB_RQPKTCNT[n] register)
- Configure the USB_DMA[n]_CTL register using the following bit settings:USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.DIR=0, USB_DMA[n]_CTL.MODE=0

The DMA controller then requests bus mastership and transfers the packet to memory. It interrupts the processor when it has completed the transfer. The processor then clears the USB_EP[n]_RXCSR_H.RXPKTRDY bit.

Individual Tx Endpoint Packet

Using DMA mode 0, program a USB controller Tx endpoint as follows.

1. Set to 1 the relevant bit in the USB_INTRTXE register.
2. Set to 0 the DMA enable bit of the appropriate USB_EP[n]_TXCSR_H.DMAREQEN/ USB_EP[n]_TXCSR_P.DMAREQEN register. (There is no need to set the USB controller to support DMA for this operation.)
3. When the FIFO can accommodate data, the USB controller interrupts the processor with the appropriate Tx endpoint interrupt. The processor must then program the DMA channel as follows:
   - Configure the USB_DMA[n]_ADDR register with the memory address to store the packet.
   - Configure the USB_DMA[n]_CNT register with the size of packet.
   - Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.DIR=1, USB_DMA[n]_CTL.MODE=0.

The DMA controller then requests bus mastership and transfers the packet to the USB controller FIFO. When it has completed the transfer, it generates a DMA interrupt. The processor then sets the USB_EP[n]_TXCSR_H.TXPKTRDY bit.

Multiple Rx Endpoint Packets

The transfer of multiple packets normally uses DMA mode 1. Program the DMA controller using the DMA registers:

- Configure the USB_DMA[n]_ADDR register with the memory address of data block to send.
- Configure the USB_DMA[n]_CNT register with the maximum size of data buffer.
- Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.IE=1, USB_DMA[n]_CTL.DIR=0, USB_DMA[n]_CTL.MODE=1.

Program the USB controller Rx endpoint as follows:

1. Set to 1 the relevant bit in the USB_INTRRX register.
2. Set to 1 the USB_EP[n]_RXCSR_H.AUTOCLR, USB_EP[n]_RXCSR_H.DMAREQEN, and USB_EP[n]_RXCSR_H.DMAREQMODE bits of the appropriate receive control and status register (host or

peripheral). In host mode, set to 1 the USB_EP[n]_RXCSR_H.AUTOREQ and USB_EP[n]_RXCSR_H.DMAREQMODE bits.

As the USB controller receives each packet, the DMA master channel requests bus mastership and transfers the packet to memory. With USB_EP[n]_RXCSR_H.AUTOCLR set, the USB controller automatically clears its USB_EP[n]_RXCSR_H.RXPKTRDY bit. This process continues automatically until the USB controller receives a short packet (one of less than the maximum packet size for the endpoint) signifying the end of the transfer. The DMA controller does not transfer this short packet: instead the USB controller interrupts the processor by generating the appropriate endpoint interrupt. The processor can then read the USB_EP[n]_RXCNT register to see the size of the short packet. It either unloads the packet manually or reprograms the DMA controller in mode 0 to unload the packet.

The USB_DMA[n]_ADDR register is incremented as the DMA controller unloads the packets. The processor determines the size of the transfer by comparing the current value of USB_DMA[n]_ADDR with the start address of the memory buffer.

If the size of the transfer exceeds the data buffer size, the DMA controller stops unloading the FIFO and interrupts the processor.

Multiple Tx Endpoint Packets

Using DMA mode 1 for a Tx endpoint, program the DMA controller as follows:

- Configure the USB_DMA[n]_ADDR register with the memory address of data block to send.
- Configure the USB_DMA[n]_CNT register with the size of the data block.
- Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.DIR=1, USB_DMA[n]_CTL.MODE=1.

Program the USB controller Tx endpoint as follows:

1. Set to 1 the relevant bit in the USB_INTRTXE register.
2. Set to 1 the USB_EP[n]_TXCSR_H.AUTOSET and USB_EP[n]_TXCSR_H.DMAREQEN bits of the appropriate transmit control and status register (host or peripheral).

When the FIFO in the USB controller becomes available, the DMA controller requests bus mastership and transfers a packet to the FIFO. With USB_EP[n]_TXCSR_H.AUTOSET set, the USB controller automatically sets the USB_EP[n]_TXCSR_H.TXPKTRDY bit. This process continues until the entire data block is transferred to the USB controller.

The DMA controller then interrupts the processor by taking the appropriate USB_DMA_IRQ register bit low.

- If the last packet loaded was less than the maximum packet size for the endpoint, the USB_EP[n]_TXCSR_H.TXPKTRDY bit is not set for this packet. The processor must respond to the DMA interrupt by setting the USB_EP[n]_TXCSR_H.TXPKTRDY bit to allow the last short packet to be sent.

- If the last packet loaded is the maximum packet size, then the appropriate action depends on whether the transfer is under the control of an application. One example is the mass storage software on Windows system that keeps count of the individual packets sent.
- If the transfer is not under such control, the processor must respond to the DMA interrupt by setting the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit. This operation sends a null packet for the receiving software to interpret as indicating the end of the transfer.

ADSP-SC57x USB Register Descriptions

Universal Serial Bus Controller (USB) contains the following registers.

Table 23-9: ADSP-SC57x USB Register List

Name	Description
USB_BAT_CHG	Battery Charging Control Register
USB_CT_HHSRTN	Host High-Speed Return to Normal Register
USB_CT_HSBT	High-Speed Timeout Register
USB_CT_UCH	Chirp Timeout Register
USB_DEV_CTL	Device Control Register
USB_DMA[n]_ADDR	DMA Channel n Address Register
USB_DMA[n]_CNT	DMA Channel n Count Register
USB_DMA[n]_CTL	DMA Channel n Control Register
USB_DMA_IRQ	DMA Interrupt Register
USB_EP0I_CFGDATA[N]	EP0 Configuration Information Register
USB_EP0I_CNT[N]	EP0 Number of Received Bytes Register
USB_EP0I_CSR[N]_H	EP0 Configuration and Status (Host) Register
USB_EP0I_CSR[N]_P	EP0 Configuration and Status (Peripheral) Register
USB_EP0I_NAKLIMIT[N]	EP0 NAK Limit Register
USB_EP0I_TYPE[N]	EP0 Connection Type Register
USB_EP0_CFGDATA[n]	EP0 Configuration Information Register
USB_EP0_CNT[n]	EP0 Number of Received Bytes Register
USB_EP0_CSR[n]_H	EP0 Configuration and Status (Host) Register
USB_EP0_CSR[n]_P	EP0 Configuration and Status (Peripheral) Register
USB_EP0_NAKLIMIT[n]	EP0 NAK Limit Register
USB_EP0_TYPE[n]	EP0 Connection Type Register
USB_EPINFO	Endpoint Information Register

Table 23-9: ADSP-SC57x USB Register List (Continued)

Name	Description
USB_EPI[N]_RXCNT	EPn Number of Bytes Received Register
USB_EPI[N]_RXCSR_H	EPn Receive Configuration and Status (Host) Register
USB_EPI[N]_RXCSR_P	EPn Receive Configuration and Status (Peripheral) Register
USB_EPI[N]_RXINTERVAL	EPn Receive Polling Interval Register
USB_EPI[N]_RXMAXP	EPn Receive Maximum Packet Length Register
USB_EPI[N]_RXTYPE	EPn Receive Type Register
USB_EPI[N]_TXCSR_H	EPn Transmit Configuration and Status (Host) Register
USB_EPI[N]_TXCSR_P	EPn Transmit Configuration and Status (Peripheral) Register
USB_EPI[N]_TXINTERVAL	EPn Transmit Polling Interval Register
USB_EPI[N]_TXMAXP	EPn Transmit Maximum Packet Length Register
USB_EPI[N]_TXTYPE	EPn Transmit Type Register
USB_EP[n]_RXCNT	EPn Number of Bytes Received Register
USB_EP[n]_RXCSR_H	EPn Receive Configuration and Status (Host) Register
USB_EP[n]_RXCSR_P	EPn Receive Configuration and Status (Peripheral) Register
USB_EP[n]_RXINTERVAL	EPn Receive Polling Interval Register
USB_EP[n]_RXMAXP	EPn Receive Maximum Packet Length Register

USB_EP[n]_TXCSR_H	EPn Transmit Configuration and Status (Host) Register
USB_EP[n]_TXCSR_P	EPn Transmit Configuration and Status (Peripheral) Register
USB_EP[n]_TXINTERVAL	EPn Transmit Polling Interval Register
USB_EP[n]_TXMAXP	EPn Transmit Maximum Packet Length Register
USB_EP[n]_TXTYPE	EPn Transmit Type Register
USB_FADDR	Function Address Register
USB_FIFOB[n]	FIFO Byte (8-Bit) Register
USB_FIFOH[n]	FIFO Half-Word (16-Bit) Register
USB_FIFO[n]	FIFO Word (32-Bit) Register
USB_FRAME	Frame Number Register
USB_FS_EOF1	Full-Speed EOF 1 Register
USB_HS_EOF1	High-Speed EOF 1 Register
USB_IEN	Common Interrupts Enable Register
USB_INDEX	Index Register

Table 23-9: ADSP-SC57x USB Register List (Continued)

Name	Description
USB_INTRRX	Receive Interrupt Register
USB_INTRRXE	Receive Interrupt Enable Register
USB_INTRTX	Transmit Interrupt Register
USB_INTRTXE	Transmit Interrupt Enable Register
USB_IRQ	Common Interrupts Register
USB_LINKINFO	Link Information Register
USB_LPM_ATTR	LPM Attribute Register
USB_LPM_CTL	LPM Control Register
USB_LPM_FADDR	LPM Function Address Register
USB_LPM_IEN	LPM Interrupt Enable Register
USB_LPM_IRQ	LPM Interrupt Status Register
USB_LS_EOF1	Low-Speed EOF 1 Register
USB_MP[n]_RXFUNCADDR	MPn Receive Function Address Register
USB_MP[n]_RXHUBADDR	MPn Receive Hub Address Register
USB_MP[n]_RXHUBPORT	MPn Receive Hub Port Register
USB_MP[n]_TXFUNCADDR	MPn Transmit Function Address Register
USB_MP[n]_TXHUBADDR	MPn Transmit Hub Address Register
USB_MP[n]_TXHUBPORT	MPn Transmit Hub Port Register
USB_PHY_CTL	PHY Control Register
USB_PLL_OSC	PLL and Oscillator Control Register
USB_POWER	Power and Device Control Register
USB_RAMINFO	RAM Information Register
USB_RQPKTCNT[n]	EPn Request Packet Count Register
USB_RXFIFOADDR	Receive FIFO Address Register
USB_RXFIFOSZ	Receive FIFO Size Register
USB_SOFT_RST	Software Reset Register
USB_TESTMODE	Testmode Register
USB_TXFIFOADDR	Transmit FIFO Address Register
USB_TXFIFOSZ	Transmit FIFO Size Register
USB_VBUS_CTL	VBUS Control Register
USB_VPLEN	VBUS Pulse Length Register

Battery Charging Control Register

The USB_BAT_CHG register controls USB controller battery change-related features.

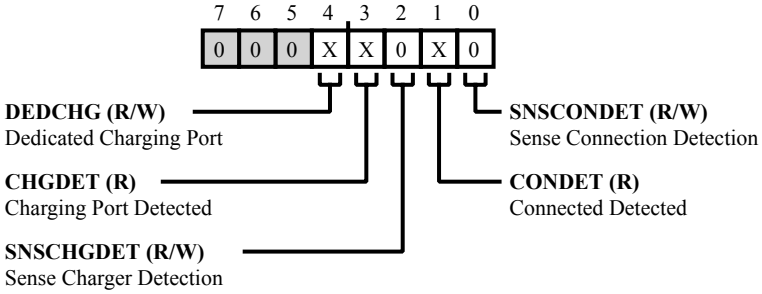

Figure 23-34: USB_BAT_CHG Register Diagram

Table 23-10: USB_BAT_CHG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	DEDCHG	Dedicated Charging Port. The USB_BAT_CHG.DEDCHG bit is asserted if both D+ and D- are high. This can be used to determine if the attached device is a dedicated charging port. This bit is the decode of LineState[1] and LineState[0]. This bit is only valid when a session is initiated, which enables a pullup on D+ when acting as a B-device.
3 (R/NW)	CHGDET	Charging Port Detected. The USB_BAT_CHG.CHGDET bit indicates when a charging port is detected. This bit indicates that D+/- is above V_{DAT_REF} and below V_{LGC}.
2 (R/W)	SNSCHGDET	Sense Charger Detection. The USB_BAT_CHG.SNSCHGDET bit enables charger detection. Setting this bit enables VD_SRC and ID_SINK.
1 (R/NW)	CONDET	Connected Detected. The USB_BAT_CHG.CONDET bit is valid when USB_BAT_CHG.SNSCONDET is enabled. This bit reflects the inverse of D+ (!LineState[0]). If nothing is connected, D+ is pulled high. If a charger or USB port is connected, D+ is pulled low.
0 (R/W)	SNSCONDET	Sense Connection Detection. The USB_BAT_CHG.SNSCONDET bit enables connection detection. Enabling this bit enables I_{DP_SRC} and R_{DM_DWN}.

Host High-Speed Return to Normal Register

The USB_CT_HHSRTN register selects the delay from the end of the high-speed resume signaling (acting as a host) to the return to normal mode operation. This value is multiplied by 4 times the XCLK period (or 16.7 ns). The default setting corresponds to a delay of 100us.

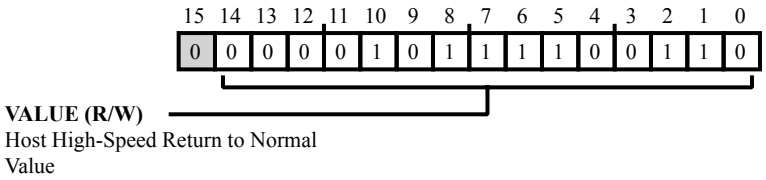

Figure 23-35: USB_CT_HHSRTN Register Diagram

Table 23-11: USB_CT_HHSRTN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Host High-Speed Return to Normal Value.

High-Speed Timeout Register

The USB_CT_HSBT register selects an amount of time to add to the minimum high-speed timeout in units of 64 bit times. The USB 2.0 specification section 7.1.19.2 states that the controller must not timeout less than 736 bit times and must timeout after 816 bit times. The value in USB_CT_HSBT is multiplied by 64-bit times and added to the minimum 736 bit times. Settings less than 1 violate the USB 2.0 specification, making the controller non-compliant.

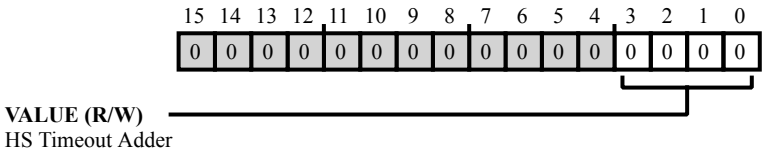

Figure 23-36: USB_CT_HSBT Register Diagram

Table 23-12: USB_CT_HSBT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	VALUE	HS Timeout Adder. The USB_CT_HSBT.VALUE bits selects an amount of time to add to the minimum high-speed timeout in units of 64 bit times.	
		0	HS Timeout = 736 (bit time)
		1	HS Timeout = 800 (bit time)
		2	HS Timeout = 864 (bit time)

Chirp Timeout Register

The USB_CT_UCH register selects chirp timeout value. The value is multiplied by 4 times the XCLK period (or 67ns). The default setting is 1.1ms.

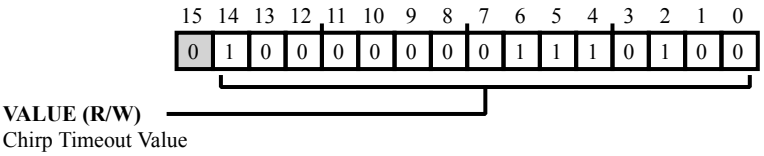

Figure 23-37: USB_CT_UCH Register Diagram

Table 23-13: USB_CT_UCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Chirp Timeout Value. The USB_CT_UCH.VALUE bits select the chirp timeout value.

Device Control Register

The USB_DEV_CTL register selects whether the USB controller is operating in peripheral mode or in host mode. It is used for controlling and monitoring the VBUS line.

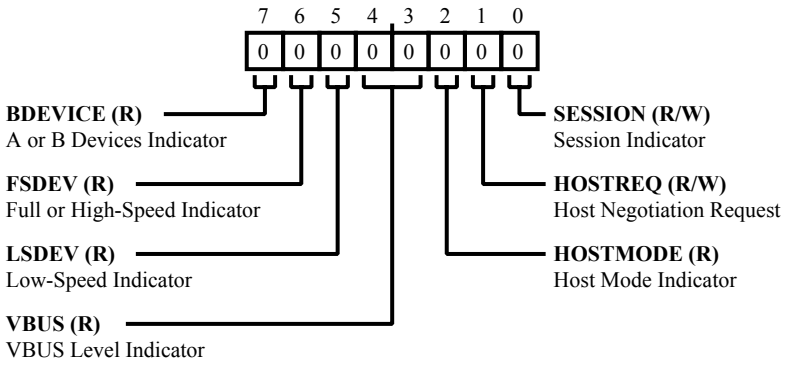

Figure 23-38: USB_DEV_CTL Register Diagram

Table 23-14: USB_DEV_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	BDEVICE	A or B Devices Indicator. The USB_DEV_CTL.BDEVICE bit indicates whether the USB controller is operating as the A device or the B device. This bit is only valid while a session is in progress.	
		0	A Device Detected
		1	B Device Detected
6 (R/NW)	FSDEV	Full or High-Speed Indicator. The USB_DEV_CTL.FSDEV bit is set when a full-speed or high-speed device is detected being connected to the port. High-speed devices are distinguished from full-speed by checking for high-speed chirps when the device detects a USB controller reset. This bit is only valid in host mode.	
		0	Not Detected
		1	Full or High-Speed Detected
5 (R/NW)	LSDEV	Low-Speed Indicator. The USB_DEV_CTL.LSDEV bit is set when a low-speed device is detected being connected to the port. This bit is only valid in host mode.	
		0	Not Detected
		1	Low-Speed Detected

Table 23-14: USB_DEV_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/NW)	VBUS	VBUS Level Indicator. The USB_DEV_CTL.VBUS bits indicated the current VBUS level.	
		0	Below SessionEnd
		1	Above SessionEnd, below AValid
		2	Above AValid, below VBUSValid
		3	Above VBUSValid
2 (R/NW)	HOSTMODE	Host Mode Indicator. The USB_DEV_CTL.HOSTMODE bit is set when the USB controller is acting as a host.	
		0	Peripheral Mode
		1	Host Mode
1 (R/W)	HOSTREQ	Host Negotiation Request. When the USB_DEV_CTL.HOSTREQ bit is set, the USB controller initiates the host negotiation when suspend mode is entered. This bit is cleared when host negotiation is completed. The USB_DEV_CTL.HOSTREQ bit applies when the USB controller is operating as a B device only.	
		0	No Request
		1	Place Request
0 (R/W)	SESSION	Session Indicator. When operating as an A device, the USB_DEV_CTL.SESSION bit is set or cleared by the processor core to start or end a session. When operating as a B device, the USB_DEV_CTL.SESSION bit is set or cleared by the USB controller when a session starts or ends. This bit is also set by the processor core to initiate the session request protocol. When the USB controller is in suspend mode, the bit may be cleared by the processor core to perform a software disconnect.	
		0	Not Detected
		1	Detected Session

DMA Channel n Address Register

The USB_DMA[n]_ADDR register indicates the location in on-chip memory where DMA data is written or read. The address must be aligned to 32-bit words (The lower two address bits are always zero.) This register increments as the DMA transfer progresses.

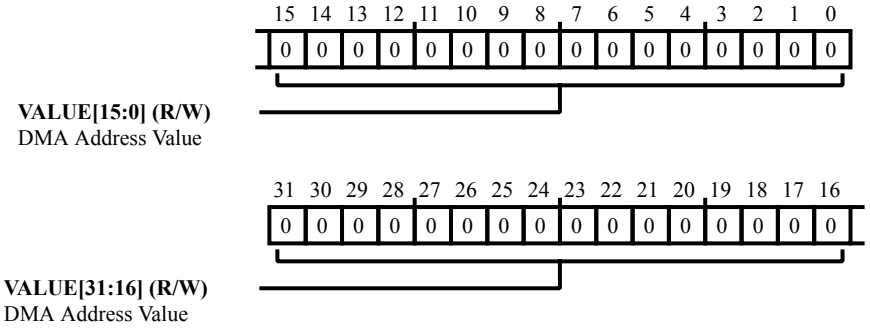

Figure 23-39: USB_DMA[n]_ADDR Register Diagram

Table 23-15: USB_DMA[n]_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Address Value. The USB_DMA[n]_ADDR.VALUE bits hold the address value for the location in on-chip memory where DMA data is written or read.

DMA Channel n Count Register

The USB_DMA[n]_CNT register holds the DMA count, indicating the number of bytes to be transferred for a given DMA work block. If this field is set to zero, no data is transferred, and an interrupt is generated.

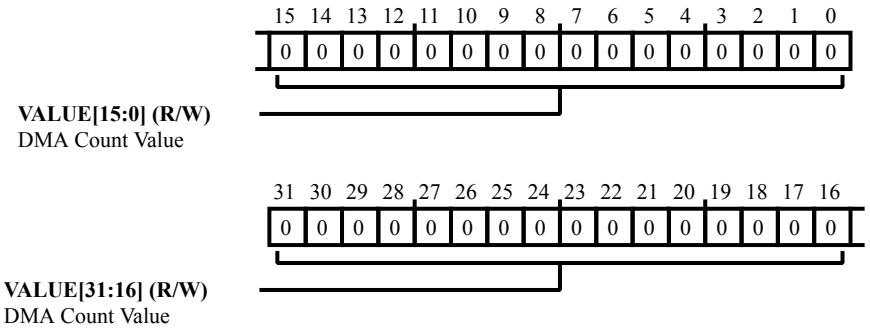

Figure 23-40: USB_DMA[n]_CNT Register Diagram

Table 23-16: USB_DMA[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Count Value. The USB_DMA[n]_CNT.VALUE bits indicate the number of bytes to be transferred for a given DMA work block.

DMA Channel n Control Register

There is a USB_DMA[n]_CTL register for each DMA master channel. This register assigns, configures, and controls each endpoint with a corresponding DMA master channel.

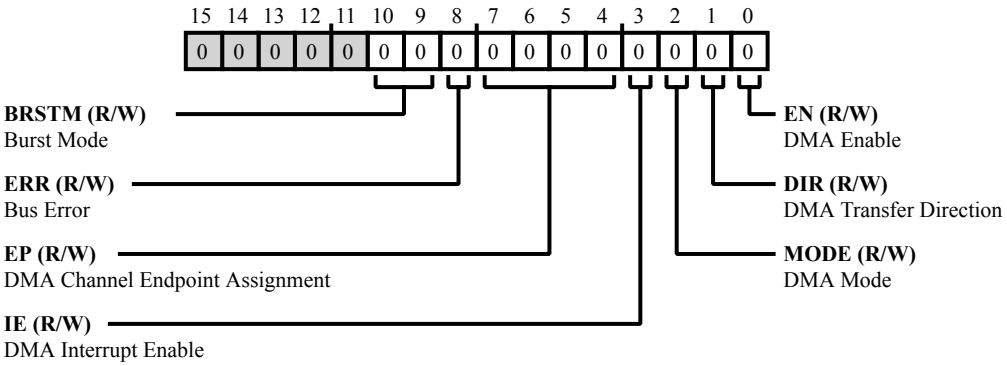

Figure 23-41: USB_DMA[n]_CTL Register Diagram

Table 23-17: USB_DMA[n]_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10:9 (R/W)	BRSTM	Burst Mode. The USB_DMA[n]_CTL.BRSTM bits select the type or length of burst transfer used by the corresponding DMA channel to transfer data.	
		0	Unspecified Length
		1	INCR4 or Unspecified Length
		2	INCR8, INCR4, or Unspecified Length
		3	INCR16, INCR8, INCR4, or Unspecified Length
8 (R/W)	ERR	Bus Error. The USB_DMA[n]_CTL.ERR bit indicates when a peripheral bus error has been encountered by the master channel. This bit is cleared by software.	
		0	No Status
		1	Bus Error
7:4 (R/W)	EP	DMA Channel Endpoint Assignment. The USB_DMA[n]_CTL.EP bits select the endpoint assignments for the DMA channel. (Enumeration values not shown are reserved.)	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3

Table 23-17: USB_DMA[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15
3 (R/W)	IE	DMA Interrupt Enable. The `USB_DMA[n]_CTL.IE` bit enables DMA interrupts for the DMA channel, enabling operation of the channels corresponding bit in the `USB_DMA_IRQ` register.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	MODE	DMA Mode. The `USB_DMA[n]_CTL.MODE` bit selects whether the DMA channel operates in DMA mode 0 or operates in DMA mode 1. Note that DMA mode 1 may only be used with bulk endpoints.	
		0	DMA Mode 0
		1	DMA Mode 1
1 (R/W)	DIR	DMA Transfer Direction. The `USB_DMA[n]_CTL.DIR` bit selects the DMA channel transfer direction, which must be selected for use with receive endpoints (DMA write=0) or transmit endpoints (DMA read=1).	
		0	DMA Write (for Rx Endpoint)
		1	DMA Read (for Tx Endpoint)

Table 23-17: USB_DMA[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Enable. The `USB_DMA[n]_CTL.EN` bit enables the DMA channel to start the DMA transfer.	
		0	Disable DMA
		1	Enable DMA (Start Transfer)

DMA Interrupt Register

The USB_DMA_IRQ register indicates which of the DMA master channels have a pending interrupt. The USB controller generates the interrupt when the corresponding DMA count register (USB_DMA[n]_CNT) reaches zero. The USB controller clears this register when it is read.

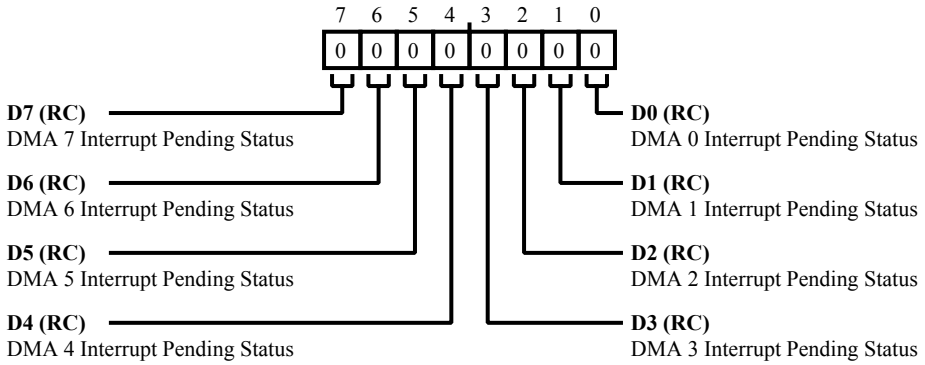

Figure 23-42: USB_DMA_IRQ Register Diagram

Table 23-18: USB_DMA_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (RC/NW)	D7	DMA 7 Interrupt Pending Status. The USB_DMA_IRQ.D7 indicates whether there is a DMA 7 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
6 (RC/NW)	D6	DMA 6 Interrupt Pending Status. The USB_DMA_IRQ.D6 indicates whether there is a DMA 6 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
5 (RC/NW)	D5	DMA 5 Interrupt Pending Status. The USB_DMA_IRQ.D5 indicates whether there is a DMA 5 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
4 (RC/NW)	D4	DMA 4 Interrupt Pending Status. The USB_DMA_IRQ.D4 indicates whether there is a DMA 4 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt

Table 23-18: USB_DMA_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RC/NW)	D3	DMA 3 Interrupt Pending Status. The `USB_DMA_IRQ.D3` indicates whether there is a DMA 3 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
2 (RC/NW)	D2	DMA 2 Interrupt Pending Status. The `USB_DMA_IRQ.D2` indicates whether there is a DMA 2 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
1 (RC/NW)	D1	DMA 1 Interrupt Pending Status. The `USB_DMA_IRQ.D1` indicates whether there is a DMA 1 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
0 (RC/NW)	D0	DMA 0 Interrupt Pending Status. The `USB_DMA_IRQ.D0` indicates whether there is a DMA 0 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt

EP0 Configuration Information Register

The USB_EP0I_CFGDATA[N] register describes the USB controller hardware configuration. This register only exists for endpoint 0.

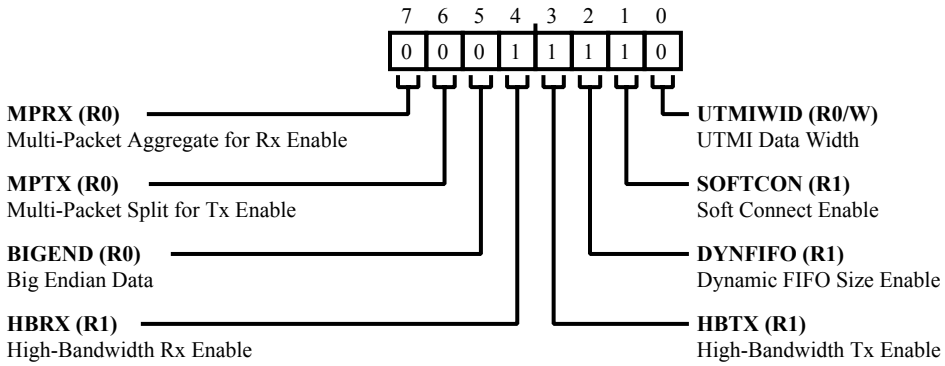

Figure 23-43: USB_EP0I_CFGDATA[N] Register Diagram

Table 23-19: USB_EP0I_CFGDATA[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R0/NW)	MPRX	Multi-Packet Aggregate for Rx Enable. The USB_EP0I_CFGDATA[N].MPRX bit indicates whether the USB controller aggregates receive packets into bulk packets before the processor core reads the data.	
		0	No Aggregate Rx Bulk Packets
		1	Aggregate Rx Bulk Packets
6 (R0/NW)	MPTX	Multi-Packet Split for Tx Enable. The USB_EP0I_CFGDATA[N].MPTX bit indicates whether the USB controller permits transmit of large packets through writing to bulk endpoints. The USB controller splits the transmit data into packets, which are appropriately sized for transmit.	
		0	No Split Tx Bulk Packets
		1	Split Tx Bulk Packets
5 (R0/NW)	BIGEND	Big Endian Data. The USB_EP0I_CFGDATA[N].BIGEND bit indicates whether the USB controller uses big endian configuration or little endian configuration.	
		0	Little Endian Configuration
		1	Big Endian Configuration

Table 23-19: USB_EP0I_CFGDATA[N] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R1/NW)	HBRX	High-Bandwidth Rx Enable. The `USB_EP0I_CFGDATA[N].HBRX` bit indicates whether the USB controller supports high-bandwidth receive ISO endpoint.	
		0	No High-Bandwidth Rx
		1	High-Bandwidth Rx
3 (R1/NW)	HBTX	High-Bandwidth Tx Enable. The `USB_EP0I_CFGDATA[N].HBTX` bit indicates whether the USB controller supports high-bandwidth transmit ISO endpoint.	
		0	No High-Bandwidth Tx
		1	High-Bandwidth Tx
2 (R1/NW)	DYNFIFO	Dynamic FIFO Size Enable. The `USB_EP0I_CFGDATA[N].DYNFIFO` bit indicates whether the USB controller uses dynamic FIFO size support (on products supporting this feature), enabling the dynamic FIFO registers. These registers are accessed using the configuration set in the endpoints indexed FIFO size and FIFO address registers, except for endpoint 0.	
		0	No Dynamic FIFO Size
		1	Dynamic FIFO Size
1 (R1/NW)	SOFTCON	Soft Connect Enable. The `USB_EP0I_CFGDATA[N].SOFTCON` bit indicates whether the USB controller uses soft connect.	
		0	No Soft Connect
		1	Soft Connect
0 (R0/W)	UTMIWID	UTMI Data Width. The `USB_EP0I_CFGDATA[N].UTMIWID` bit indicates whether the USB controller uses an 8-bit or 16-bit UTMI data width.	
		0	8-bit UTMI Data Width
		1	16-bit UTMI Data Width

EP0 Number of Received Bytes Register

The USB_EP0I_CNT[N] register indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change. It is only valid while the USB_EP0_CSR[n]_H.RXPKTRDY bit or USB_EP0_CSR[n]_P.RXPKTRDY bit is set.

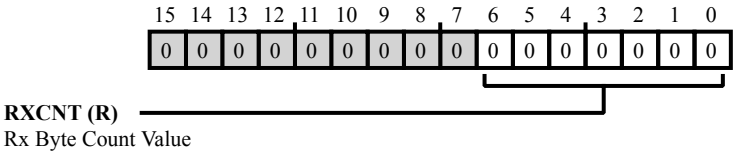

Figure 23-44: USB_EP0I_CNT[N] Register Diagram

Table 23-20: USB_EP0I_CNT[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/NW)	RXCNT	Rx Byte Count Value. The USB_EP0I_CNT[N].RXCNT bits holds the number of data bytes currently in line ready to be read from the Rx FIFO. The value returned changes as the FIFO is unloaded. It is only valid while the USB_EP0_CSR[n]_H.RXPKTRDY bit or USB_EP0_CSR[n]_P.RXPKTRDY bit is set.

EP0 Configuration and Status (Host) Register

The USB_EP0I_CSR[N]_H register provides control and status bits for endpoint 0 in host mode. Note that some bits may be set to clear automatically.

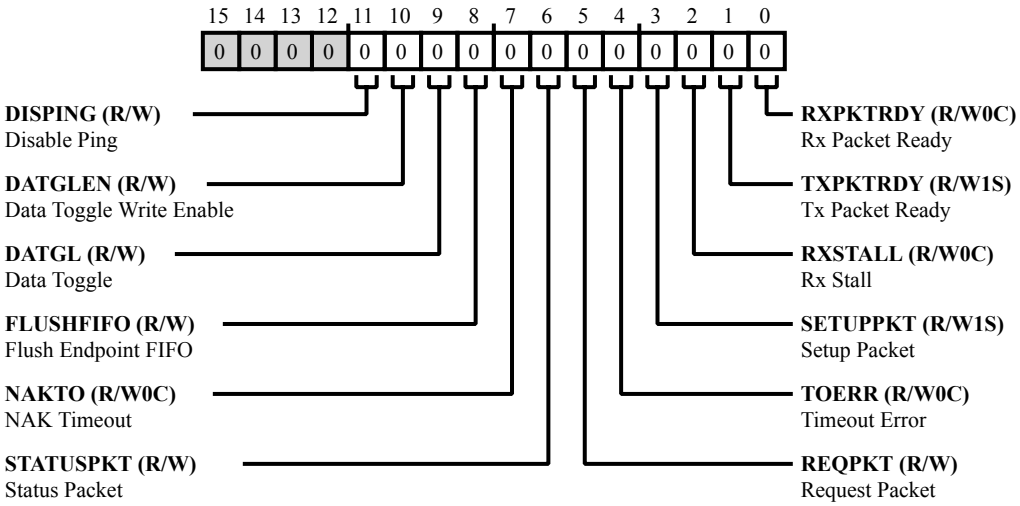

Figure 23-45: USB_EP0I_CSR[N]_H Register Diagram

Table 23-21: USB_EP0I_CSR[N]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	DISPING	Disable Ping. The USB_EP0I_CSR[N]_H.DISPING bit disables (in host mode) high-speed PING tokens for the data and status phases of a control transfer.	
		0	Issue PING tokens
		1	Do not issue PING
10 (R/W)	DATGLEN	Data Toggle Write Enable. The USB_EP0I_CSR[N]_H.DATGLEN bit enables (in host mode) the USB controller to write the current state of the endpoint 0 USB_EP0I_CSR[N]_H.DATGL bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL

Table 23-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DATGL	Data Toggle. The `USB_EP0I_CSR[N]_H.DATGL` bit indicates (in host mode) the current state of the endpoint 0 data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0I_CSR[N]_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits. The `USB_EP0I_CSR[N]_H.FLUSHFIFO` bit should only be set if the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W0C)	NAKTO	NAK Timeout. The `USB_EP0I_CSR[N]_H.NAKTO` bit indicates (in host mode) when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the `USB_EP0_NAKLIMIT[n]` register. The processor core should clear this bit to allow the endpoint to continue.	
		0	No Status
		1	Endpoint Halted (NAK Timeout)
6 (R/W)	STATUSPKT	Status Packet. The `USB_EP0I_CSR[N]_H.STATUSPKT` bit directs (in host mode) the USB controller to perform a status stage transaction. This bit is set at the same time as the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits. Setting this bit ensures that the data toggle is set to 1 so that a DATA1 packet is used for the status stage transaction.	
		0	No Request
		1	Request Status Transaction

Table 23-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	REQPKT	Request Packet. The `USB_EP0I_CSR[N]_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when the `USB_EP0I_CSR[N]_H.RXPKTRDY` bit is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W0C)	TOERR	Timeout Error. The `USB_EP0I_CSR[N]_H.TOERR` bit indicates (in host mode) when three attempts have been made to perform a transaction with no response from the peripheral. The processor core should clear this bit. An interrupt is generated when this bit is set.	
		0	No Status
		1	Timeout Error
3 (R/W1S)	SETUPPKT	Setup Packet. The `USB_EP0I_CSR[N]_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP0I_CSR[N]_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP token
2 (R/W0C)	RXSTALL	Rx Stall. The `USB_EP0I_CSR[N]_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0I_CSR[N]_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

Table 23-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0I_CSR[N]_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 Configuration and Status (Peripheral) Register

The USB_EP0I_CSR[N]_P register provides control and status bits for endpoint 0 in peripheral mode. Note that some bits may be set to clear automatically.

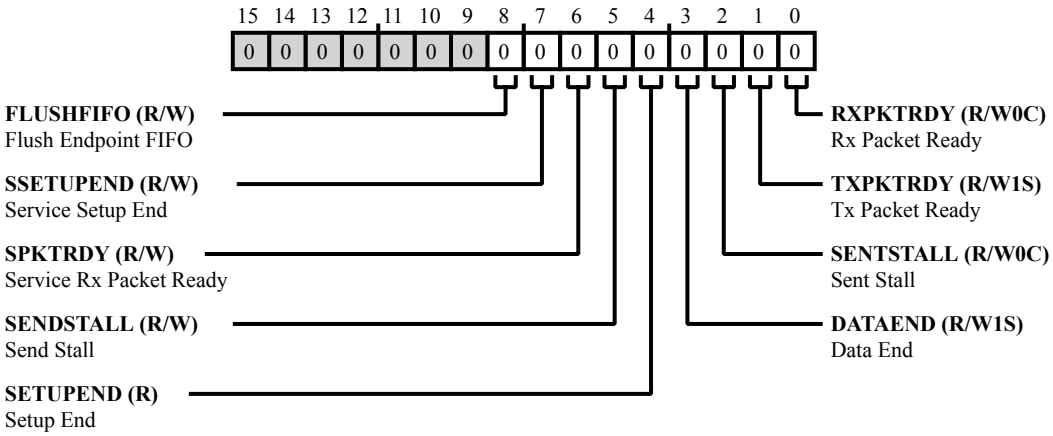

Figure 23-46: USB_EP0I_CSR[N]_P Register Diagram

Table 23-22: USB_EP0I_CSR[N]_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The USB_EP0I_CSR[N]_P.FLUSHFIFO bit directs (in peripheral mode) the USB controller to flush data from the endpoint 0 FIFO and clear the USB_EP0I_CSR[N]_P.TXPKTRDY and USB_EP0I_CSR[N]_P.RXPKTRDY bits. The USB_EP0I_CSR[N]_P.FLUSHFIFO bit should only be set if the USB_EP0I_CSR[N]_P.TXPKTRDY and USB_EP0I_CSR[N]_P.RXPKTRDY bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W)	SSETUPEND	Service Setup End. The USB_EP0I_CSR[N]_P.SSETUPEND bit is set (in peripheral mode) by the processor core to clear the USB_EP0I_CSR[N]_P.SETUPEND. This bit is cleared automatically.	
		0	No Action
		1	Clear SETUPEND Bit

Table 23-22: USB_EP0I_CSR[N]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SPKTRDY	Service Rx Packet Ready. The `USB_EP0I_CSR[N]_P.SPKTRDY` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0I_CSR[N]_P.RXPKTRDY` bit. This bit is cleared automatically.	
		0	No Action
		1	Clear RXPKTRDY Bit
5 (R/W)	SENDSTALL	Send Stall. The `USB_EP0I_CSR[N]_P.SENDSTALL` bit is set (in peripheral mode) by the processor core to terminate the current transaction. The STALL handshake is transmitted, then this bit automatically is cleared.	
		0	No Action
		1	Terminate Current Transaction
4 (R/NW)	SETUPEND	Setup End. The `USB_EP0I_CSR[N]_P.SETUPEND` bit indicates (in peripheral mode) when a control transaction ends before the `USB_EP0I_CSR[N]_P.DATAEND` bit is set. An interrupt is generated and the FIFO is flushed at this time. This bit is cleared when the processor core sets the `USB_EP0I_CSR[N]_P.SSETUPEND` bit.	
		0	No Status
		1	Setup Ended before DATAEND
3 (R/W1S)	DATAEND	Data End. The `USB_EP0I_CSR[N]_P.DATAEND` bit is set (in peripheral mode) by the processor core sets when the core: • Sets the `USB_EP0I_CSR[N]_P.TXPKTRDY` bit for the last data packet. • Clears the `USB_EP0I_CSR[N]_P.RXPKTRDY` bit after unloading the last data packet. • Sets the `USB_EP0I_CSR[N]_P.TXPKTRDY` bit for a zero-length data packet. The `USB_EP0I_CSR[N]_P.DATAEND` bit is cleared automatically.	
		0	No Status
		1	Data End Condition
2 (R/W0C)	SENTSTALL	Sent Stall. The `USB_EP0I_CSR[N]_P.SENTSTALL` bit is set (in peripheral mode) when a STALL handshake is transmitted. The processor core should clear this bit.	
		0	No Status
		1	Transmitted STALL Handshake

Table 23-22: USB_EP0I_CSR[N]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0I_CSR[N]_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	
		1	Set this bit after loading a data packet into the FIFO
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0I_CSR[N]_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core clears this bit by setting the `USB_EP0I_CSR[N]_P.SPKTRDY` bit.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 NAK Limit Register

The USB_EP0I_NAKLIMIT[N] register determines the number of frames/micro-frames after which endpoint 0 should timeout on receiving a stream of NAK responses for bulk endpoints.

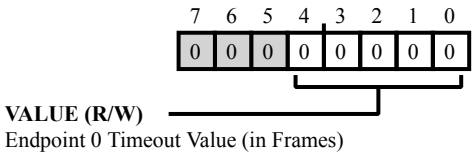

Figure 23-47: USB_EP0I_NAKLIMIT[N] Register Diagram

Table 23-23: USB_EP0I_NAKLIMIT[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Endpoint 0 Timeout Value (in Frames). The USB_EP0I_NAKLIMIT[N].VALUE bits hold the endpoint 0 timeout value (number of frames).

EP0 Connection Type Register

The USB_EP0I_TYPE[N] register selects the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub.

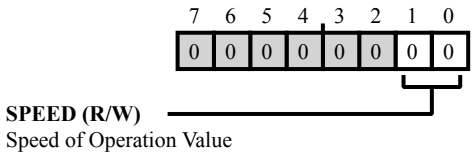

Figure 23-48: USB_EP0I_TYPE[N] Register Diagram

Table 23-24: USB_EP0I_TYPE[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPEED	Speed of Operation Value. The USB_EP0I_TYPE[N].SPEED bits select the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub. In these instances. the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as Processor Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed

EP0 Configuration Information Register

The USB_EP0_CFGDATA[n] register describes the USB controller hardware configuration. This register only exists for endpoint 0.

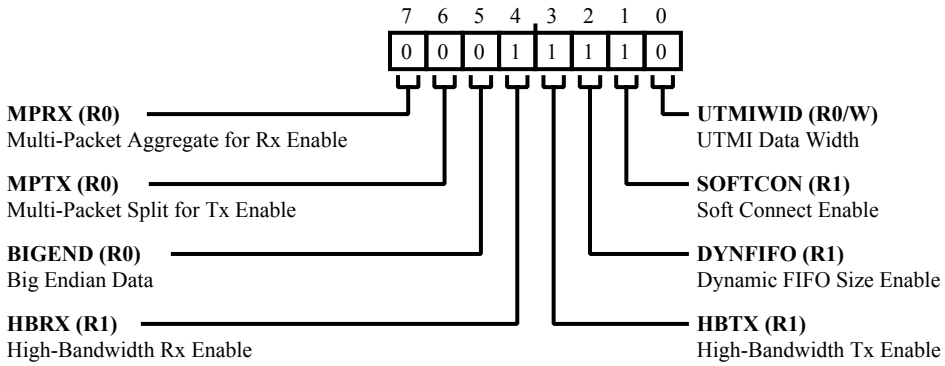

Figure 23-49: USB_EP0_CFGDATA[n] Register Diagram

Table 23-25: USB_EP0_CFGDATA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R0/NW)	MPRX	Multi-Packet Aggregate for Rx Enable. The USB_EP0_CFGDATA[n].MPRX bit indicates whether the USB controller aggregates receive packets into bulk packets before the processor core reads the data.	
		0	No Aggregate Rx Bulk Packets
		1	Aggregate Rx Bulk Packets
6 (R0/NW)	MPTX	Multi-Packet Split for Tx Enable. The USB_EP0_CFGDATA[n].MPTX bit indicates whether the USB controller permits transmit of large packets through writing to bulk endpoints. The USB controller splits the transmit data into packets, which are appropriately sized for transmit.	
		0	No Split Tx Bulk Packets
		1	Split Tx Bulk Packets
5 (R0/NW)	BIGEND	Big Endian Data. The USB_EP0_CFGDATA[n].BIGEND bit indicates whether the USB controller uses big endian configuration or little endian configuration.	
		0	Little Endian Configuration
		1	Big Endian Configuration

Table 23-25: USB_EP0_CFGDATA[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R1/NW)	HBRX	High-Bandwidth Rx Enable. The `USB_EP0_CFGDATA[n].HBRX` bit indicates whether the USB controller supports high-bandwidth receive ISO endpoint.	
		0	No High-Bandwidth Rx
		1	High-Bandwidth Rx
3 (R1/NW)	HBTX	High-Bandwidth Tx Enable. The `USB_EP0_CFGDATA[n].HBTX` bit indicates whether the USB controller supports high-bandwidth transmit ISO endpoint.	
		0	No High-Bandwidth Tx
		1	High-Bandwidth Tx
2 (R1/NW)	DYNFIFO	Dynamic FIFO Size Enable. The `USB_EP0_CFGDATA[n].DYNFIFO` bit indicates whether the USB controller uses dynamic FIFO size support (on products supporting this feature), enabling the dynamic FIFO registers. These registers are accessed using the configuration set in the endpoints indexed FIFO size and FIFO address registers, except for endpoint 0.	
		0	No Dynamic FIFO Size
		1	Dynamic FIFO Size
1 (R1/NW)	SOFTCON	Soft Connect Enable. The `USB_EP0_CFGDATA[n].SOFTCON` bit indicates whether the USB controller uses soft connect.	
		0	No Soft Connect
		1	Soft Connect
0 (R0/W)	UTMIWID	UTMI Data Width. The `USB_EP0_CFGDATA[n].UTMIWID` bit indicates whether the USB controller uses an 8-bit or 16-bit UTMI data width.	
		0	8-bit UTMI Data Width
		1	16-bit UTMI Data Width

EP0 Number of Received Bytes Register

The USB_EP0_CNT[n] register indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change. It is only valid while the USB_EP0_CSR[n]_H.RXPKTRDY bit or USB_EP0_CSR[n]_P.RXPKTRDY bit is set.

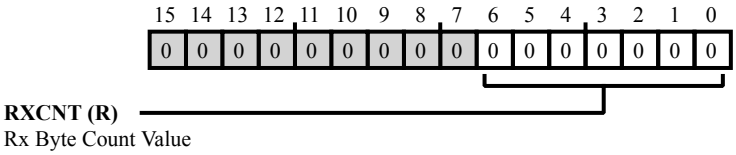

Figure 23-50: USB_EP0_CNT[n] Register Diagram

Table 23-26: USB_EP0_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/NW)	RXCNT	Rx Byte Count Value. The USB_EP0_CNT[n].RXCNT bits holds the number of data bytes currently in line ready to be read from the Rx FIFO. The value returned changes as the FIFO is unloaded. It is only valid while the USB_EP0_CSR[n]_H.RXPKTRDY bit or USB_EP0_CSR[n]_P.RXPKTRDY bit is set.

EP0 Configuration and Status (Host) Register

The USB_EP0_CSR[n]_H register provides control and status bits for endpoint 0 in host mode. Note that some bits may be set to clear automatically.

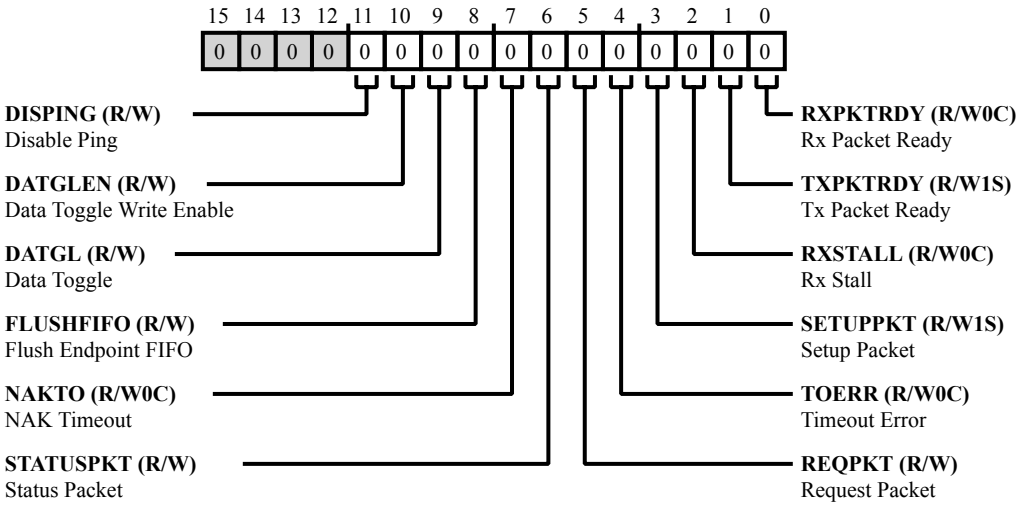

Figure 23-51: USB_EP0_CSR[n]_H Register Diagram

Table 23-27: USB_EP0_CSR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	DISPING	Disable Ping. The USB_EP0_CSR[n]_H.DISPING bit disables (in host mode) high-speed PING tokens for the data and status phases of a control transfer.	
		0	Issue PING tokens
		1	Do not issue PING
10 (R/W)	DATGLEN	Data Toggle Write Enable. The USB_EP0_CSR[n]_H.DATGLEN bit enables (in host mode) the USB controller to write the current state of the endpoint 0 USB_EP0_CSR[n]_H.DATGL bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL

Table 23-27: USB_EP0_CSR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DATGL	Data Toggle. The `USB_EP0_CSR[n]_H.DATGL` bit indicates (in host mode) the current state of the endpoint 0 data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0_CSR[n]_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits. The `USB_EP0_CSR[n]_H.FLUSHFIFO` bit should only be set if the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W0C)	NAKTO	NAK Timeout. The `USB_EP0_CSR[n]_H.NAKTO` bit indicates (in host mode) when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the `USB_EP0_NAKLIMIT[n]` register. The processor core should clear this bit to allow the endpoint to continue.	
		0	No Status
		1	Endpoint Halted (NAK Timeout)
6 (R/W)	STATUSPKT	Status Packet. The `USB_EP0_CSR[n]_H.STATUSPKT` bit directs (in host mode) the USB controller to perform a status stage transaction. This bit is set at the same time as the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits. Setting this bit ensures that the data toggle is set to 1 so that a DATA1 packet is used for the status stage transaction.	
		0	No Request
		1	Request Status Transaction

Table 23-27: USB_EP0_CSR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	REQPKT	Request Packet. The `USB_EP0_CSR[n]_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when the `USB_EP0_CSR[n]_H.RXPKTRDY` bit is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W0C)	TOERR	Timeout Error. The `USB_EP0_CSR[n]_H.TOERR` bit indicates (in host mode) when three attempts have been made to perform a transaction with no response from the peripheral. The processor core should clear this bit. An interrupt is generated when this bit is set.	
		0	No Status
		1	Timeout Error
3 (R/W1S)	SETUPPKT	Setup Packet. The `USB_EP0_CSR[n]_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP0_CSR[n]_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP token
2 (R/W0C)	RXSTALL	Rx Stall. The `USB_EP0_CSR[n]_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0_CSR[n]_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

Table 23-27: USB_EP0_CSR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0_CSR[n]_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 Configuration and Status (Peripheral) Register

The USB_EP0_CSR[n]_P register provides control and status bits for endpoint 0 in peripheral mode. Note that some bits may be set to clear automatically.

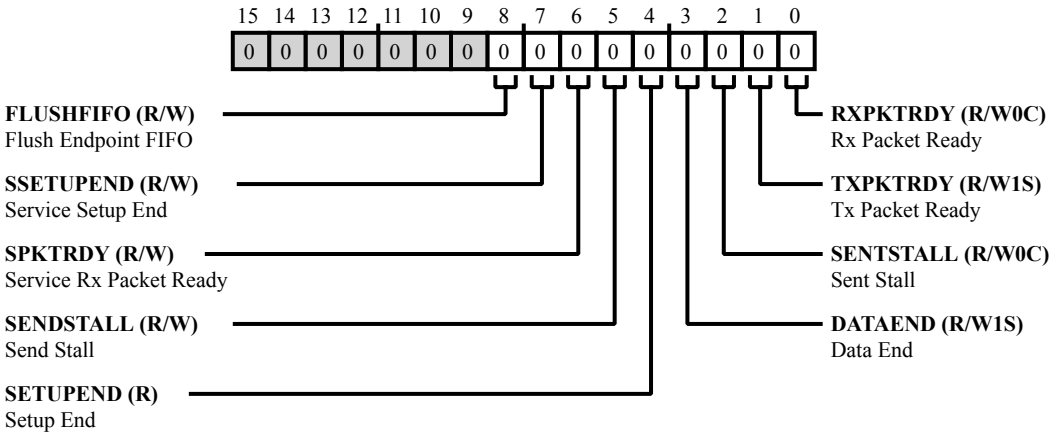

Figure 23-52: USB_EP0_CSR[n]_P Register Diagram

Table 23-28: USB_EP0_CSR[n]_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The USB_EP0_CSR[n]_P.FLUSHFIFO bit directs (in peripheral mode) the USB controller to flush data from the endpoint 0 FIFO and clear the USB_EP0_CSR[n]_P.TXPKTRDY and USB_EP0_CSR[n]_P.RXPKTRDY bits. The USB_EP0_CSR[n]_P.FLUSHFIFO bit should only be set if the USB_EP0_CSR[n]_P.TXPKTRDY and USB_EP0_CSR[n]_P.RXPKTRDY bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W)	SSETUPEND	Service Setup End. The USB_EP0_CSR[n]_P.SSETUPEND bit is set (in peripheral mode) by the processor core to clear the USB_EP0_CSR[n]_P.SETUPEND. This bit is cleared automatically.	
		0	No Action
		1	Clear SETUPEND Bit

Table 23-28: USB_EP0_CSR[n]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SPKTRDY	Service Rx Packet Ready. The `USB_EP0_CSR[n]_P.SPKTRDY` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0_CSR[n]_P.RXPKTRDY` bit. This bit is cleared automatically.	
		0	No Action
		1	Clear RXPKTRDY Bit
5 (R/W)	SENDSTALL	Send Stall. The `USB_EP0_CSR[n]_P.SENDSTALL` bit is set (in peripheral mode) by the processor core to terminate the current transaction. The STALL handshake is transmitted, then this bit automatically is cleared.	
		0	No Action
		1	Terminate Current Transaction
4 (R/NW)	SETUPEND	Setup End. The `USB_EP0_CSR[n]_P.SETUPEND` bit indicates (in peripheral mode) when a control transaction ends before the `USB_EP0_CSR[n]_P.DATAEND` bit is set. An interrupt is generated and the FIFO is flushed at this time. This bit is cleared when the processor core sets the `USB_EP0_CSR[n]_P.SSETUPEND` bit.	
		0	No Status
		1	Setup Ended before DATAEND
3 (R/W1S)	DATAEND	Data End. The `USB_EP0_CSR[n]_P.DATAEND` bit is set (in peripheral mode) by the processor core sets when the core: • Sets the `USB_EP0_CSR[n]_P.TXPKTRDY` bit for the last data packet. • Clears the `USB_EP0_CSR[n]_P.RXPKTRDY` bit after unloading the last data packet. • Sets the `USB_EP0_CSR[n]_P.TXPKTRDY` bit for a zero-length data packet. The `USB_EP0_CSR[n]_P.DATAEND` bit is cleared automatically.	
		0	No Status
		1	Data End Condition
2 (R/W0C)	SENTSTALL	Sent Stall. The `USB_EP0_CSR[n]_P.SENTSTALL` bit is set (in peripheral mode) when a STALL handshake is transmitted. The processor core should clear this bit.	
		0	No Status
		1	Transmitted STALL Handshake

Table 23-28: USB_EP0_CSR[n]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0_CSR[n]_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	
		1	Set this bit after loading a data packet into the FIFO
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0_CSR[n]_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core clears this bit by setting the `USB_EP0_CSR[n]_P.SPKTRDY` bit.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 NAK Limit Register

The `USB_EP0_NAKLIMIT[n]` register determines the number of frames/micro-frames after which endpoint 0 should timeout on receiving a stream of NAK responses for bulk endpoints.

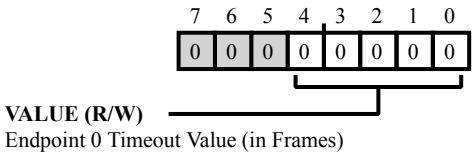

Figure 23-53: USB_EP0_NAKLIMIT[n] Register Diagram

Table 23-29: USB_EP0_NAKLIMIT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Endpoint 0 Timeout Value (in Frames). The `USB_EP0_NAKLIMIT[n].VALUE` bits hold the endpoint 0 timeout value (number of frames).

EP0 Connection Type Register

The `USB_EP0_TYPE[n]` register selects the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub.

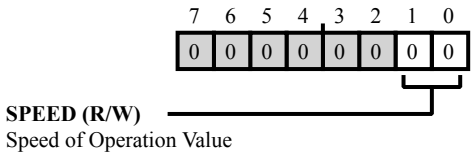

Figure 23-54: USB_EP0_TYPE[n] Register Diagram

Table 23-30: USB_EP0_TYPE[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPEED	Speed of Operation Value. The `USB_EP0_TYPE[n].SPEED` bits select the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub. In these instances. the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as Processor Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed

Endpoint Information Register

The USB_EPINFO register allows read-back of the number of Tx and Rx endpoints available

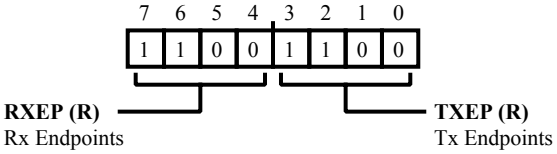

Figure 23-55: USB_EPINFO Register Diagram

Table 23-31: USB_EPINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	RXEP	Rx Endpoints. The USB_EPINFO.RXEP bits indicate the number of receive endpoints. excluding EP0.
3:0 (R/NW)	TXEP	Tx Endpoints. The USB_EPINFO.TXEP bits indicate the number of transmit endpoints, excluding EP0.

EPn Number of Bytes Received Register

The USB_EPI[N]_RXCNT register indicates the number of received data bytes in the endpoint receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while the USB_EP[n]_RXCSR_H.RXPKTRDY bit or USB_EP[n]_RXCSR_P.RXPKTRDY bit is set.

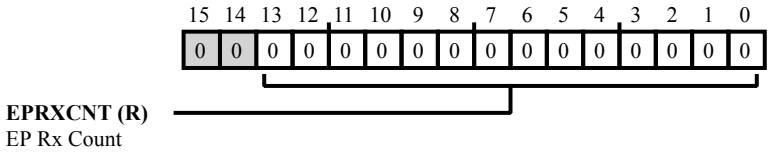

Figure 23-56: USB_EPI[N]_RXCNT Register Diagram

Table 23-32: USB_EPI[N]_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	EPRXCNT	EP Rx Count. The USB_EPI[N]_RXCNT.EPRXCNT bits hold the number of data bytes ready to be read from the receive FIFO.

EPn Receive Configuration and Status (Host) Register

The USB_EPI[N]_RXCSR_H register provides (in host mode) control and status bits for transfers through the currently selected receive endpoint.

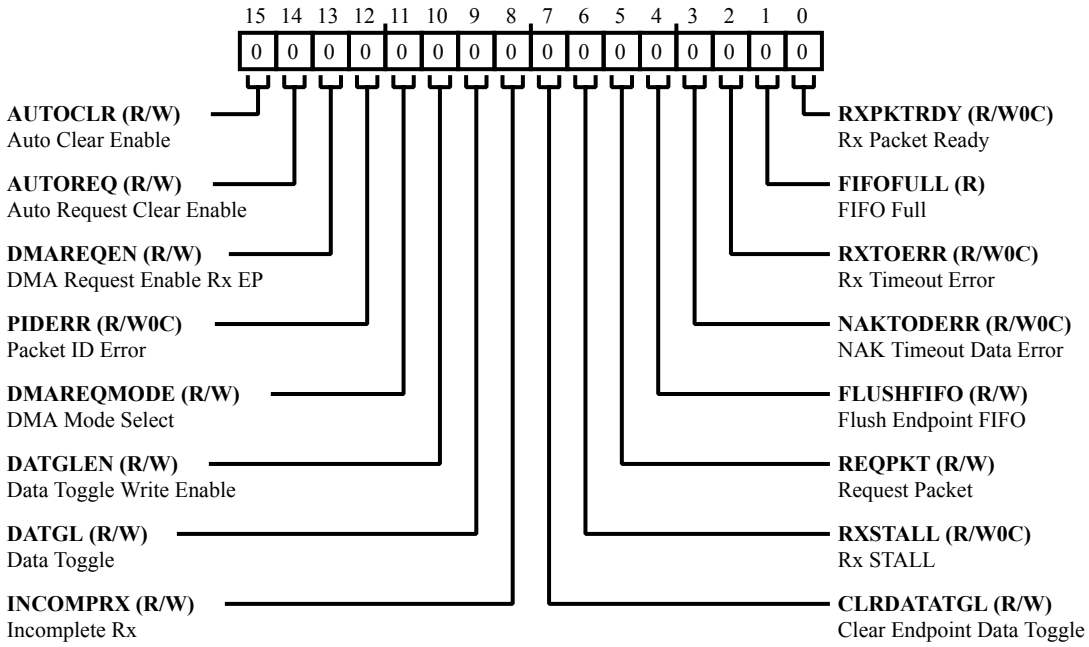

Figure 23-57: USB_EPI[N]_RXCSR_H Register Diagram

Table 23-33: USB_EPI[N]_RXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The USB_EPI[N]_RXCSR_H.AUTOCLR bit directs (in host mode) the USB controller to automatically clear the USB_EPI[N]_RXCSR_H.RXPKTRDY bit when a packet of size USB_EP[n]_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EPI[N]_RXCSR_H.RXPKTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EP[n]_RXMAXP value. The USB controller auto clears the USB_EPI[N]_RXCSR_H.RXPKTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the USB_EPI[N]_RXCSR_H.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	AUTOREQ	Auto Request Clear Enable. The USB_EPI[N]_RXCSR_H.AUTOREQ bit directs (in host mode) the USB controller to automatically clear the USB_EPI[N]_RXCSR_H.REQPKT bit when USB_EPI[N]_RXCSR_H.RXPKTRDY bit is cleared. This bit is automatically cleared when a short packet is received.	
		0	Disable Auto Request Clear
		1	Enable Auto Request Clear
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The USB_EPI[N]_RXCSR_H.DMAREQEN bit enables (in host mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W0C)	PIDERR	Packet ID Error. The `USB_EPI[N]_RXCSR_H.PIDERR` bit indicates (in host mode) when a PID error occurs for isochronous transactions. This bit is ignored in host mode for bulk or interrupt transactions.	
		0	No Status
		1	PID Error
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_RXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EPI[N]_RXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EPI[N]_RXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EPI[N]_RXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
9 (R/W)	DATGL	Data Toggle. The `USB_EPI[N]_RXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EPI[N]_RXCSR_H.INCOMPRX` bit indicates (in host mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EPI[N]_RXCSR_H.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx

Table 23-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_RXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	RXSTALL	Rx STALL. The `USB_EPI[N]_RXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
5 (R/W)	REQPKT	Request Packet. The `USB_EPI[N]_RXCSR_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when `USB_EPI[N]_RXCSR_H.RXPKTRDY` is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_RXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit. The `USB_EPI[N]_RXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 23-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W0C)	NAKTODERR	NAK Timeout Data Error. The `USB_EPI[N]_RXCSR_H.NAKTODERR` bit indicates (in host mode for isochronous transfers) a NAK timeout data error when the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is cleared. The `USB_EPI[N]_RXCSR_H.NAKTODERR` bit indicates (in host mod for bulk transfers) when a receive endpoint is halted following the receipt of NAK responses greater than the limit set in the `USB_EP[n]_RXINTERVAL` register. The processor should clear this bit to allow the endpoint to continue. If double packet buffering is enabled, the `USB_EPI[N]_RXCSR_H.REQPKT` bit should also be set in the same cycle as this bit is cleared.	
		0	No Status
		1	NAK Timeout Data Error
2 (R/W0C)	RXTOERR	Rx Timeout Error. The `USB_EPI[N]_RXCSR_H.RXTOERR` bit indicates (in host mode) when three attempts have been made to receive a packet and no data packet has been received. The USB controller generates an interrupt for this condition. The processor should clear this bit. Note that `USB_EPI[N]_RXCSR_H.RXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Rx Timeout Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EPI[N]_RXCSR_H.FIFOFULL` bit indicates (in host mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EPI[N]_RXCSR_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Configuration and Status (Peripheral) Register

The USB_EPI[N]_RXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected receive endpoint.

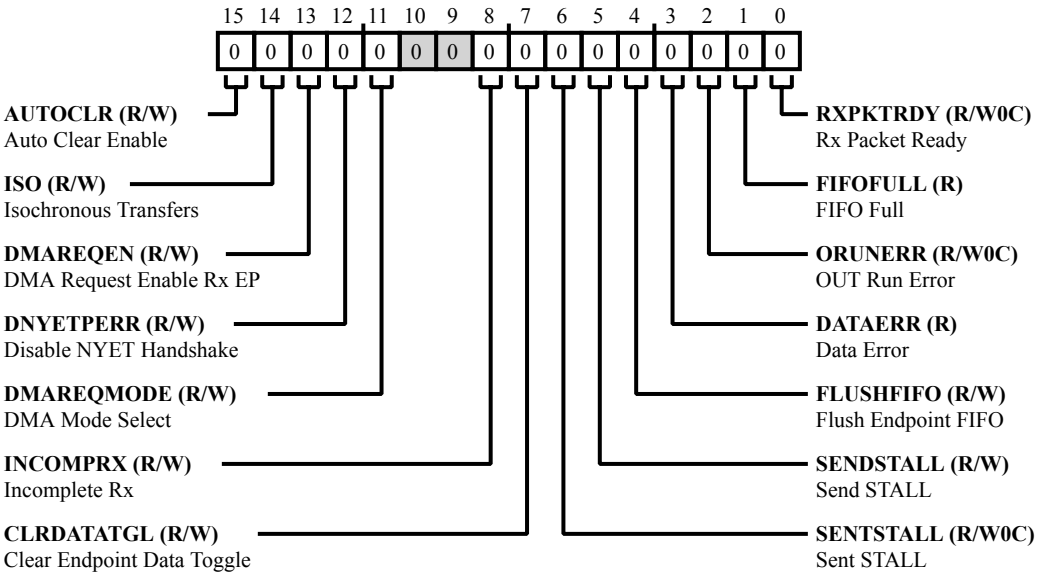

Figure 23-58: USB_EPI[N]_RXCSR_P Register Diagram

Table 23-34: USB_EPI[N]_RXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The USB_EPI[N]_RXCSR_P.AUTOCLR bit directs (in peripheral mode) the USB controller to automatically clear the USB_EPI[N]_RXCSR_P.RXPKTRDY bit when a packet of size USB_EP[n]_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EPI[N]_RXCSR_P.RXPKTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EP[n]_RXMAXP value. The USB controller auto clears the USB_EPI[N]_RXCSR_P.RXPKTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the USB_EPI[N]_RXCSR_P.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	ISO	Isochronous Transfers. The USB_EPI[N]_RXCSR_P.ISO bit selects (in peripheral mode) between isochronous transfers and bulk/interrupt transfers.	
		0	This bit should be cleared for bulk or interrupt transfers.
		1	This bit should be set for isochronous transfers.
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The USB_EPI[N]_RXCSR_P.DMAREQEN bit enables (in peripheral mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DNYETPERR	Disable NYET Handshake. The `USB_EPI[N]_RXCSR_P.DNYETPERR` bit disables (in peripheral mode for high speed bulk/interrupt transactions) NYET handshakes. When this bit is set, all successful receive packets are ACK'd, including the point at which the FIFO becomes full. The `USB_EPI[N]_RXCSR_P.DNYETPERR` bit must be set for all interrupt endpoints in high speed mode.	
		0	Enable NYET Handshake
		1	Disable NYET Handshake
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_RXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EPI[N]_RXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EPI[N]_RXCSR_P.INCOMPRX` bit indicates (in peripheral mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EPI[N]_RXCSR_P.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_RXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EPI[N]_RXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when a STALL handshake is transmitted. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted

Table 23-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SENDSTALL	Send STALL. The `USB_EPI[N]_RXCSR_P.SENDSTALL` bit is set (in peripheral mode) by the processor to send a STALL handshake. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Action
		1	Request STALL Handshake
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_RXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit. The `USB_EPI[N]_RXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
3 (R/NW)	DATAERR	Data Error. The `USB_EPI[N]_RXCSR_P.DATAERR` bit indicates (in peripheral mode for isochronous transfers) when the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when `USB_EPI[N]_RXCSR_P.RXPKTRDY` is cleared. The `USB_EPI[N]_RXCSR_P.DATAERR` bit is always zero for bulk endpoints in peripheral mode.	
		0	No Status
		1	Data Error
2 (R/W0C)	ORUNERR	OUT Run Error. The `USB_EPI[N]_RXCSR_P.ORUNERR` bit indicates (in peripheral mode for isochronous transfers) when an OUT packet cannot be loaded into the receive FIFO. The processor should clear this bit. The `USB_EPI[N]_RXCSR_P.ORUNERR` bit always returns zero in bulk mode.	
		0	No Status
		1	OUT Run Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EPI[N]_RXCSR_P.FIFOFULL` bit indicates (in peripheral mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full

Table 23-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EPI[N]_RXCSR_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Polling Interval Register

The USB_EPI[N]_RXINTERVAL register defines the polling interval for the currently-selected receive endpoint for interrupt, isochronous, and bulk transfers. There is a USB_EPI[N]_RXINTERVAL register for each configured receive endpoint, except endpoint 0. The transfer types related to speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full -speed, USB_EPI[N]_RXINTERVAL = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, USB_EPI[N]_RXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, USB_EPI[N]_RXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, USB_EPI[N]_RXINTERVAL = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a USB_EPI[N]_RXINTERVAL value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

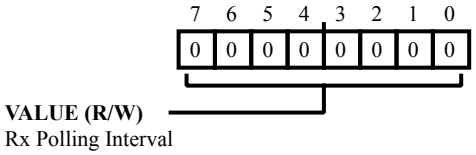

Figure 23-59: USB_EPI[N]_RXINTERVAL Register Diagram

Table 23-35: USB_EPI[N]_RXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Rx Polling Interval. The USB_EPI[N]_RXINTERVAL.VALUE bits define the polling interval value for interrupt and isochronous transfers and select the number of frames (or microframes, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Receive Maximum Packet Length Register

The USB_EPI[N]_RXMAXP register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame.

Note that a value greater than the maximum allowed of 1023 for full-speed USB operation produces unpredictable results. Also, note that the total amount of data represented by the value written to this register must not exceed the receive FIFO size, and should not exceed half the FIFO size if double-buffering is required.

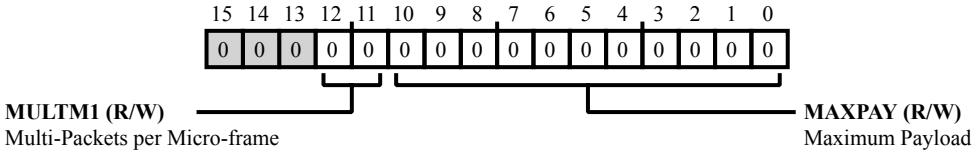

Figure 23-60: USB_EPI[N]_RXMAXP Register Diagram

Table 23-36: USB_EPI[N]_RXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-frame. The USB_EPI[N]_RXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller combines multiple packets received within a micro-frame into a single packet in the FIFO.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EPI[N]_RXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024, but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EPI[N]_RXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Receive Type Register

The USB_EPI[N]_RXTYPE register selects the endpoint number and transaction protocol to use for the currently selected receive endpoint. There is a USB_EPI[N]_RXTYPE register for each receive endpoint. Note that this register is only used in host mode.

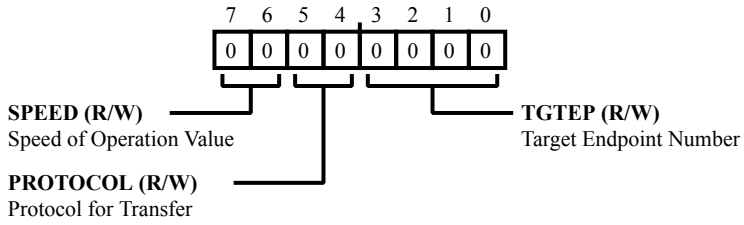

Figure 23-61: USB_EPI[N]_RXTYPE Register Diagram

Table 23-37: USB_EPI[N]_RXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The USB_EPI[N]_RXTYPE.SPEED bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When it is not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The USB_EPI[N]_RXTYPE.PROTOCOL bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The USB_EPI[N]_RXTYPE.TGTEP bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the receive endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 23-37: USB_EPI[N]_RXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

EPn Transmit Configuration and Status (Host) Register

The USB_EPI[N]_TXCSR_H register provides (in host mode) control and status bits for transfers through the currently-selected transmit endpoint.

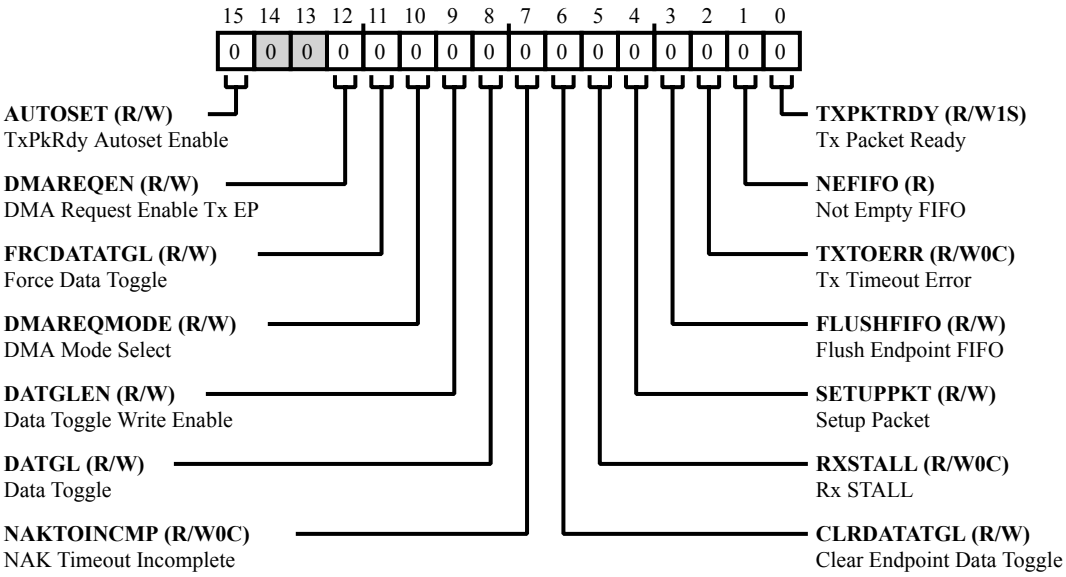

Figure 23-62: USB_EPI[N]_TXCSR_H Register Diagram

Table 23-38: USB_EPI[N]_TXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EPI[N]_TXCSR_H.AUTOSET bit enables (in host mode) the automatic setting of the USB_EPI[N]_TXCSR_H.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPI[N]_TXCSR_H.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EPI[N]_TXCSR_H.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The USB_EPI[N]_TXCSR_H.DMAREQEN bit enables (in host mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-38: USB_EPI[N]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EPI[N]_TXCSR_H.FRCDATATGL` bit forces (in host mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_TXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or the same cycle that the `USB_EPI[N]_TXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
9 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EPI[N]_TXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EPI[N]_TXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
8 (R/W)	DATGL	Data Toggle. The `USB_EPI[N]_TXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is set
		1	DATA1 is set

Table 23-38: USB_EPI[N]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W0C)	NAKTOINCMP	NAK Timeout Incomplete. The `USB_EPI[N]_TXCSR_H.NAKTOINCMP` bit indicates (for bulk endpoints in host mode) when the transmit endpoint is halted following the receipt of NAK responses for longer than the time set in the `USB_EP[n]_TXINTERVAL` register. The processor should clear this bit, allowing the endpoint to continue. For products supporting high-speed operation, for high-bandwidth isochronous endpoints in host mode, this bit indicates when no response is received from the device to which the packet is being sent.	
		0	No Status
		1	NAK Timeout Over Maximum
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_TXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	RXSTALL	Rx STALL. The `USB_EPI[N]_TXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
4 (R/W)	SETUPPKT	Setup Packet. The `USB_EPI[N]_TXCSR_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP Token
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_TXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit. The `USB_EPI[N]_TXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 23-38: USB_EPI[N]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W0C)	TXTOERR	Tx Timeout Error. The `USB_EPI[N]_TXCSR_H.TXTOERR` bit indicates (in host mode) when three attempts have been made to send a packet and no handshake packet has been received. The USB controller generates an interrupt for this condition, clears the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit, and flushes the FIFO. The processor should clear this bit. Note that `USB_EPI[N]_TXCSR_H.TXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Tx Timeout Error
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EPI[N]_TXCSR_H.NEFIFO` bit indicates (in host mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Configuration and Status (Peripheral) Register

The USB_EPI[N]_TXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected transmit endpoint.

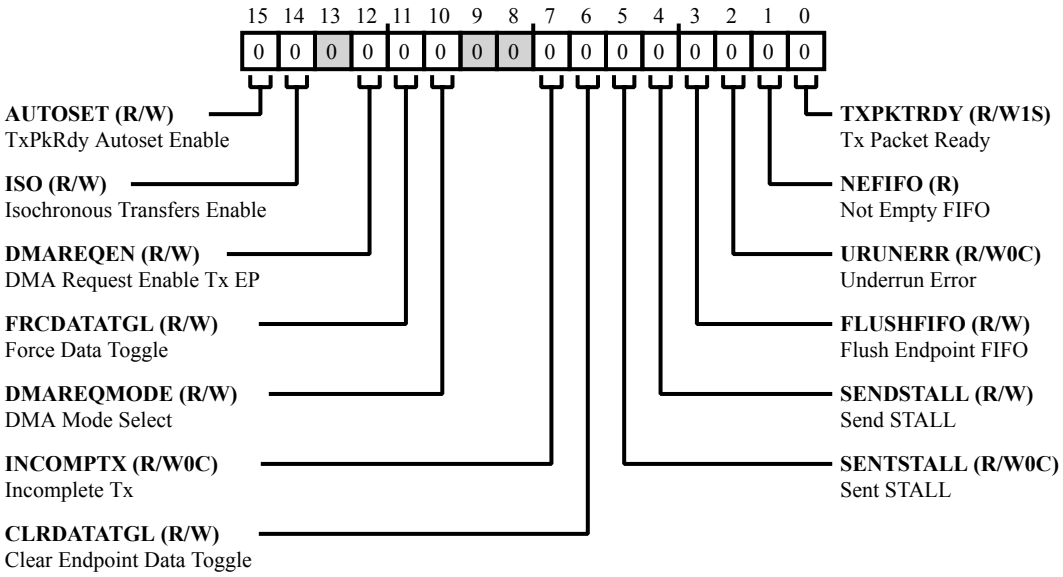

Figure 23-63: USB_EPI[N]_TXCSR_P Register Diagram

Table 23-39: USB_EPI[N]_TXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EPI[N]_TXCSR_P.AUTOSET bit enables (in peripheral mode) automatic setting of the USB_EPI[N]_TXCSR_P.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPI[N]_TXCSR_P.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EPI[N]_TXCSR_P.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset

Table 23-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ISO	Isochronous Transfers Enable. The `USB_EPI[N]_TXCSR_P.ISO` bit enables (in peripheral mode) the transmit endpoint for isochronous transfers. This bit should be disabled for bulk or interrupt endpoints.	
		0	Disable Tx EP Isochronous Transfers
		1	Enable Tx EP Isochronous Transfers
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The `USB_EPI[N]_TXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EPI[N]_TXCSR_P.FRCDATATGL` bit forces (in peripheral mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_TXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or in the same cycle that the `USB_EPI[N]_TXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
7 (R/W0C)	INCOMPTX	Incomplete Tx. The `USB_EPI[N]_TXCSR_P.INCOMPTX` bit indicates (for high-bandwidth isochronous endpoints in peripheral mode) when a large packet has been split into two or three packets for transmission, but insufficient IN tokens have been received to send all parts.	
		0	No Status
		1	Incomplete Tx (Insufficient IN Tokens)

Table 23-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_TXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EPI[N]_TXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when the USB controller transmits a STALL handshake. When this condition occurs, the USB controller flushes the FIFO and clears the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted
4 (R/W)	SENDSTALL	Send STALL. The `USB_EPI[N]_TXCSR_P.SENDSTALL` bit (in peripheral mode) is set by the processor to issue a STALL handshake to an IN token. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Request
		1	Request STALL Handshake Transmission
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_TXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit. The `USB_EPI[N]_TXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush endpoint FIFO
2 (R/W0C)	URUNERR	Underrun Error. The `USB_EPI[N]_TXCSR_P.URUNERR` bit indicates (in peripheral mode) when an IN token is received while the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is not set. The processor should clear this bit.	
		0	No Status
		1	Underrun Error

Table 23-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EPI[N]_TXCSR_P.NEFIFO` bit indicates (in peripheral mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Polling Interval Register

The USB_EPI[N]_TXINTERVAL register defines the polling interval for the currently-selected transmit endpoint for interrupt, isochronous, and bulk transfers. There is a USB_EPI[N]_TXINTERVAL register for each configured transmit endpoint, except endpoint 0. The transfer types related to the speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full-speed, USB_EPI[N]_TXINTERVAL = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, USB_EPI[N]_TXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, USB_EPI[N]_TXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, USB_EPI[N]_TXINTERVAL = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a USB_EPI[N]_TXINTERVAL value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

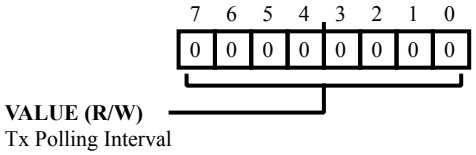

Figure 23-64: USB_EPI[N]_TXINTERVAL Register Diagram

Table 23-40: USB_EPI[N]_TXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Tx Polling Interval. The USB_EPI[N]_TXINTERVAL.VALUE bits define the polling interval value for interrupt and isochronous transfers. The USB_EPI[N]_TXINTERVAL.VALUE bits select the number of frames (or micro-frames, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Transmit Maximum Packet Length Register

The USB_EPI[N]_TXMAXP register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. The USB_EPI[N]_TXMAXP register provides indexed access to the maximum packet length register for each Tx endpoint, except endpoint 0.

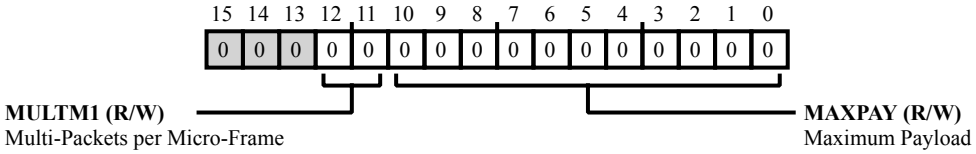

Figure 23-65: USB_EPI[N]_TXMAXP Register Diagram

Table 23-41: USB_EPI[N]_TXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-Frame. The USB_EPI[N]_TXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller splits the FIFO data into multiple packets less than or equal to the maximum payload size.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EPI[N]_TXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EPI[N]_TXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Transmit Type Register

The USB_EPI[N]_TXTYPE register selects the endpoint number and transaction protocol to use for the currently selected transmit endpoint. There is a USB_EPI[N]_TXTYPE register for each transmit endpoint. Note that this register is only used in host mode.

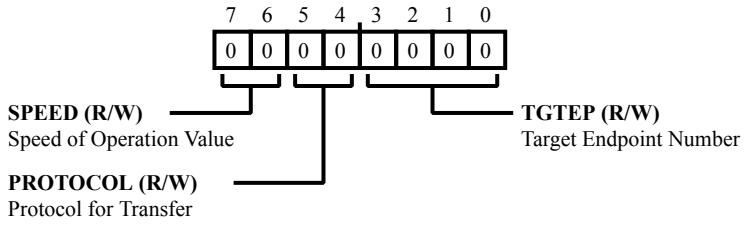

Figure 23-66: USB_EPI[N]_TXTYPE Register Diagram

Table 23-42: USB_EPI[N]_TXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The USB_EPI[N]_TXTYPE.SPEED bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The USB_EPI[N]_TXTYPE.PROTOCOL bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The USB_EPI[N]_TXTYPE.TGTEP bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the transmit endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 23-42: USB_EPI[N]_TXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

EPn Number of Bytes Received Register

The USB_EP[n]_RXCNT register indicates the number of received data bytes in the endpoint receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while the USB_EP[n]_RXCSR_H.RXPKTRDY bit or USB_EP[n]_RXCSR_P.RXPKTRDY bit is set.

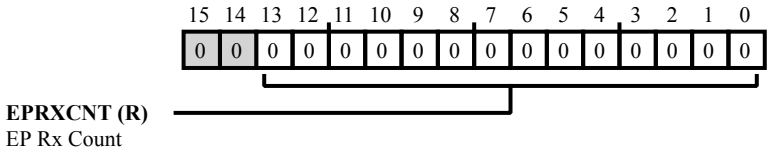

Figure 23-67: USB_EP[n]_RXCNT Register Diagram

Table 23-43: USB_EP[n]_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	EPRXCNT	EP Rx Count. The USB_EP[n]_RXCNT.EPRXCNT bits hold the number of data bytes ready to be read from the receive FIFO.

EPn Receive Configuration and Status (Host) Register

The USB_EP[n]_RXCSR_H register provides (in host mode) control and status bits for transfers through the currently selected receive endpoint.

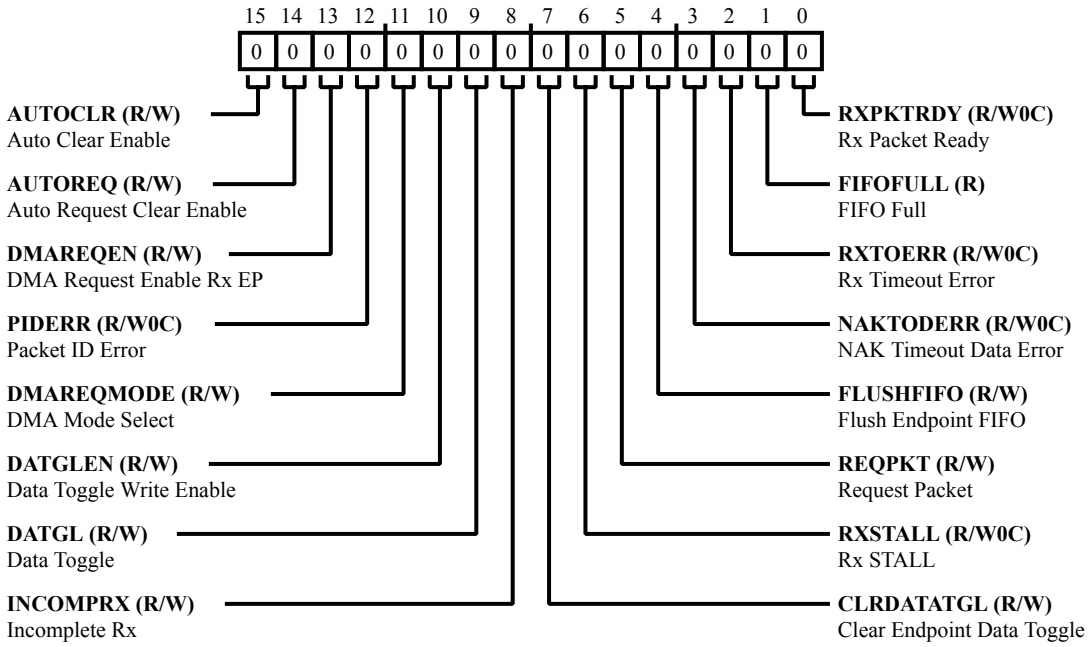

Figure 23-68: USB_EP[n]_RXCSR_H Register Diagram

Table 23-44: USB_EP[n]_RXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The USB_EP[n]_RXCSR_H.AUTOCLR bit directs (in host mode) the USB controller to automatically clear the USB_EP[n]_RXCSR_H.RXPKTRDY bit when a packet of size USB_EP[n]_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EP[n]_RXCSR_H.RXPKTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EP[n]_RXMAXP value. The USB controller auto clears the USB_EP[n]_RXCSR_H.RXPKTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the USB_EP[n]_RXCSR_H.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	AUTOREQ	Auto Request Clear Enable. The USB_EP[n]_RXCSR_H.AUTOREQ bit directs (in host mode) the USB controller to automatically clear the USB_EP[n]_RXCSR_H.REQPKT bit when USB_EP[n]_RXCSR_H.RXPKTRDY bit is cleared. This bit is automatically cleared when a short packet is received.	
		0	Disable Auto Request Clear
		1	Enable Auto Request Clear
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The USB_EP[n]_RXCSR_H.DMAREQEN bit enables (in host mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W0C)	PIDERR	Packet ID Error. The `USB_EP[n]_RXCSR_H.PIDERR` bit indicates (in host mode) when a PID error occurs for isochronous transactions. This bit is ignored in host mode for bulk or interrupt transactions.	
		0	No Status
		1	PID Error
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_RXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EP[n]_RXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP[n]_RXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EP[n]_RXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
9 (R/W)	DATGL	Data Toggle. The `USB_EP[n]_RXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EP[n]_RXCSR_H.INCOMPRX` bit indicates (in host mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EP[n]_RXCSR_H.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx

Table 23-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_RXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	RXSTALL	Rx STALL. The `USB_EP[n]_RXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
5 (R/W)	REQPKT	Request Packet. The `USB_EP[n]_RXCSR_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when `USB_EP[n]_RXCSR_H.RXPKTRDY` is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_RXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit. The `USB_EP[n]_RXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 23-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W0C)	NAKTODERR	NAK Timeout Data Error. The `USB_EP[n]_RXCSR_H.NAKTODERR` bit indicates (in host mode for isochronous transfers) a NAK timeout data error when the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is cleared. The `USB_EP[n]_RXCSR_H.NAKTODERR` bit indicates (in host mod for bulk transfers) when a receive endpoint is halted following the receipt of NAK responses greater than the limit set in the `USB_EP[n]_RXINTERVAL` register. The processor should clear this bit to allow the endpoint to continue. If double packet buffering is enabled, the `USB_EP[n]_RXCSR_H.REQPKT` bit should also be set in the same cycle as this bit is cleared.	
		0	No Status
		1	NAK Timeout Data Error
2 (R/W0C)	RXTOERR	Rx Timeout Error. The `USB_EP[n]_RXCSR_H.RXTOERR` bit indicates (in host mode) when three attempts have been made to receive a packet and no data packet has been received. The USB controller generates an interrupt for this condition. The processor should clear this bit. Note that `USB_EP[n]_RXCSR_H.RXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Rx Timeout Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EP[n]_RXCSR_H.FIFOFULL` bit indicates (in host mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP[n]_RXCSR_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Configuration and Status (Peripheral) Register

The USB_EP[n]_RXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected receive endpoint.

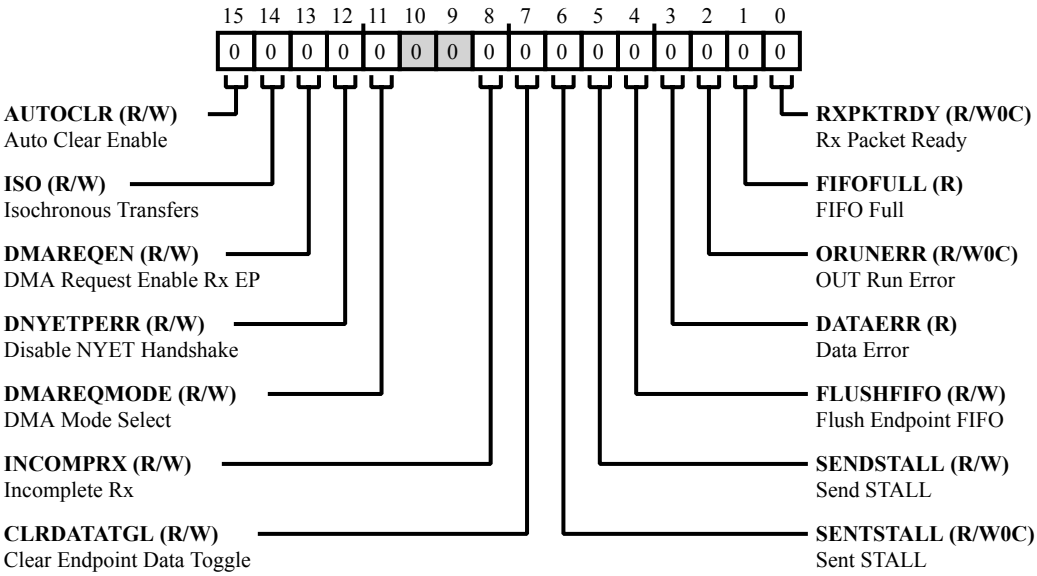

Figure 23-69: USB_EP[n]_RXCSR_P Register Diagram

Table 23-45: USB_EP[n]_RXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The USB_EP[n]_RXCSR_P.AUTOCLR bit directs (in peripheral mode) the USB controller to automatically clear the USB_EP[n]_RXCSR_P.RXPKTRDY bit when a packet of size USB_EP[n]_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EP[n]_RXCSR_P.RXPKTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EP[n]_RXMAXP value. The USB controller auto clears the USB_EP[n]_RXCSR_P.RXPKTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the USB_EP[n]_RXCSR_P.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	ISO	Isochronous Transfers. The USB_EP[n]_RXCSR_P.ISO bit selects (in peripheral mode) between isochronous transfers and bulk/interrupt transfers.	
		0	This bit should be cleared for bulk or interrupt transfers.
		1	This bit should be set for isochronous transfers.
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The USB_EP[n]_RXCSR_P.DMAREQEN bit enables (in peripheral mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DNYETPERR	Disable NYET Handshake. The `USB_EP[n]_RXCSR_P.DNYETPERR` bit disables (in peripheral mode for high speed bulk/interrupt transactions) NYET handshakes. When this bit is set, all successful receive packets are ACK'd, including the point at which the FIFO becomes full. The `USB_EP[n]_RXCSR_P.DNYETPERR` bit must be set for all interrupt endpoints in high speed mode.	
		0	Enable NYET Handshake
		1	Disable NYET Handshake
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_RXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EP[n]_RXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EP[n]_RXCSR_P.INCOMPRX` bit indicates (in peripheral mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EP[n]_RXCSR_P.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_RXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EP[n]_RXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when a STALL handshake is transmitted. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted

Table 23-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SENDSTALL	Send STALL. The `USB_EP[n]_RXCSR_P.SENDSTALL` bit is set (in peripheral mode) by the processor to send a STALL handshake. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Action
		1	Request STALL Handshake
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_RXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit. The `USB_EP[n]_RXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
3 (R/NW)	DATAERR	Data Error. The `USB_EP[n]_RXCSR_P.DATAERR` bit indicates (in peripheral mode for isochronous transfers) when the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when `USB_EP[n]_RXCSR_P.RXPKTRDY` is cleared. The `USB_EP[n]_RXCSR_P.DATAERR` bit is always zero for bulk endpoints in peripheral mode.	
		0	No Status
		1	Data Error
2 (R/W0C)	ORUNERR	OUT Run Error. The `USB_EP[n]_RXCSR_P.ORUNERR` bit indicates (in peripheral mode for isochronous transfers) when an OUT packet cannot be loaded into the receive FIFO. The processor should clear this bit. The `USB_EP[n]_RXCSR_P.ORUNERR` bit always returns zero in bulk mode.	
		0	No Status
		1	OUT Run Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EP[n]_RXCSR_P.FIFOFULL` bit indicates (in peripheral mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full

Table 23-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP[n]_RXCSR_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Polling Interval Register

The USB_EP[n]_RXINTERVAL register defines the polling interval for the currently-selected receive endpoint for interrupt, isochronous, and bulk transfers. There is a USB_EP[n]_RXINTERVAL register for each configured receive endpoint, except endpoint 0. The transfer types related to speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full -speed, USB_EP[n]_RXINTERVAL = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, USB_EP[n]_RXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, USB_EP[n]_RXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, USB_EP[n]_RXINTERVAL = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a USB_EP[n]_RXINTERVAL value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

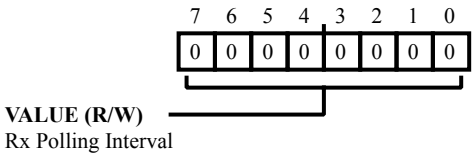

Figure 23-70: USB_EP[n]_RXINTERVAL Register Diagram

Table 23-46: USB_EP[n]_RXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Rx Polling Interval. The USB_EP[n]_RXINTERVAL.VALUE bits define the polling interval value for interrupt and isochronous transfers and select the number of frames (or microframes, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Receive Maximum Packet Length Register

The USB_EP[n]_RXMAXP register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame.

Note that a value greater than the maximum allowed of 1023 for full-speed USB operation produces unpredictable results. Also, note that the total amount of data represented by the value written to this register must not exceed the receive FIFO size, and should not exceed half the FIFO size if double-buffering is required.

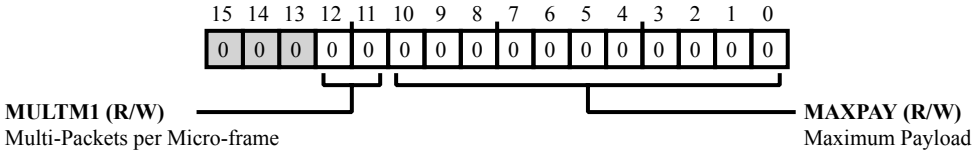

Figure 23-71: USB_EP[n]_RXMAXP Register Diagram

Table 23-47: USB_EP[n]_RXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-frame. The USB_EP[n]_RXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller combines multiple packets received within a micro-frame into a single packet in the FIFO.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EP[n]_RXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024, but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EP[n]_RXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Receive Type Register

The USB_EP[n]_RXTYPE register selects the endpoint number and transaction protocol to use for the currently selected receive endpoint. There is a USB_EP[n]_RXTYPE register for each receive endpoint. Note that this register is only used in host mode.

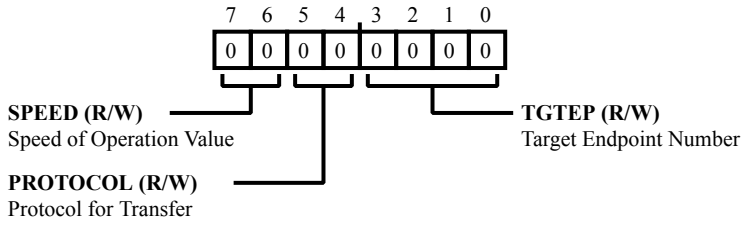

Figure 23-72: USB_EP[n]_RXTYPE Register Diagram

Table 23-48: USB_EP[n]_RXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The USB_EP[n]_RXTYPE.SPEED bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When it is not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The USB_EP[n]_RXTYPE.PROTOCOL bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The USB_EP[n]_RXTYPE.TGTEP bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the receive endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 23-48: USB_EP[n]_RXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

EPn Transmit Configuration and Status (Host) Register

The USB_EP[n]_TXCSR_H register provides (in host mode) control and status bits for transfers through the currently-selected transmit endpoint.

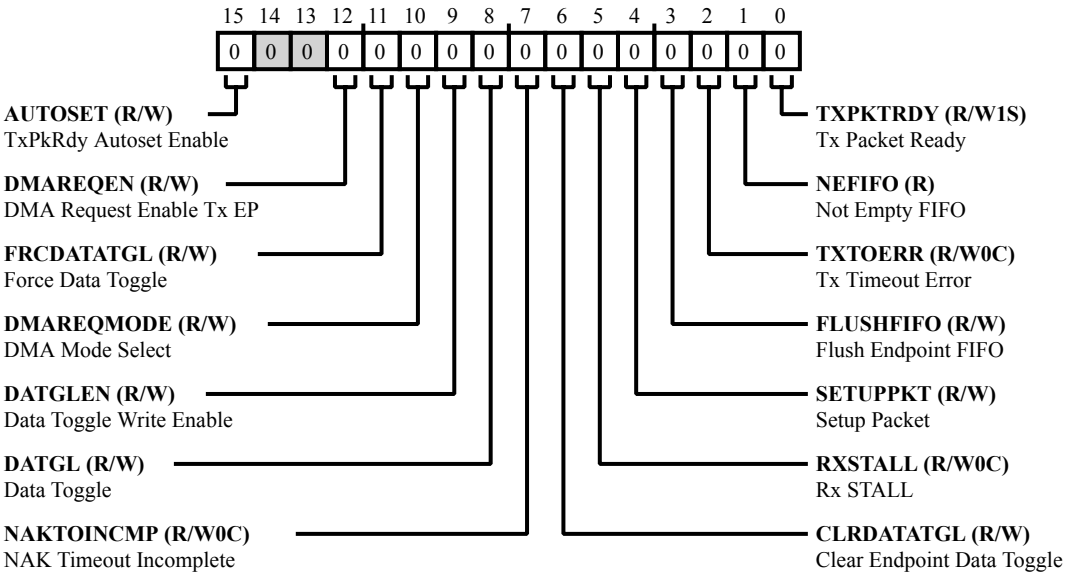

Figure 23-73: USB_EP[n]_TXCSR_H Register Diagram

Table 23-49: USB_EP[n]_TXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EP[n]_TXCSR_H.AUTOSET bit enables (in host mode) the automatic setting of the USB_EP[n]_TXCSR_H.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EP[n]_TXCSR_H.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EP[n]_TXCSR_H.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The USB_EP[n]_TXCSR_H.DMAREQEN bit enables (in host mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 23-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EP[n]_TXCSR_H.FRCDATATGL` bit forces (in host mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_TXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or the same cycle that the `USB_EP[n]_TXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
9 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP[n]_TXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EP[n]_TXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
8 (R/W)	DATGL	Data Toggle. The `USB_EP[n]_TXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is set
		1	DATA1 is set

Table 23-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W0C)	NAKTOINCMP	NAK Timeout Incomplete. The `USB_EP[n]_TXCSR_H.NAKTOINCMP` bit indicates (for bulk endpoints in host mode) when the transmit endpoint is halted following the receipt of NAK responses for longer than the time set in the `USB_EP[n]_TXINTERVAL` register. The processor should clear this bit, allowing the endpoint to continue. For products supporting high-speed operation, for high-bandwidth isochronous endpoints in host mode, this bit indicates when no response is received from the device to which the packet is being sent.	
		0	No Status
		1	NAK Timeout Over Maximum
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_TXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	RXSTALL	Rx STALL. The `USB_EP[n]_TXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
4 (R/W)	SETUPPKT	Setup Packet. The `USB_EP[n]_TXCSR_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP Token
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_TXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit. The `USB_EP[n]_TXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 23-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W0C)	TXTOERR	Tx Timeout Error. The `USB_EP[n]_TXCSR_H.TXTOERR` bit indicates (in host mode) when three attempts have been made to send a packet and no handshake packet has been received. The USB controller generates an interrupt for this condition, clears the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit, and flushes the FIFO. The processor should clear this bit. Note that `USB_EP[n]_TXCSR_H.TXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Tx Timeout Error
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EP[n]_TXCSR_H.NEFIFO` bit indicates (in host mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP[n]_TXCSR_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Configuration and Status (Peripheral) Register

The USB_EP[n]_TXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected transmit endpoint.

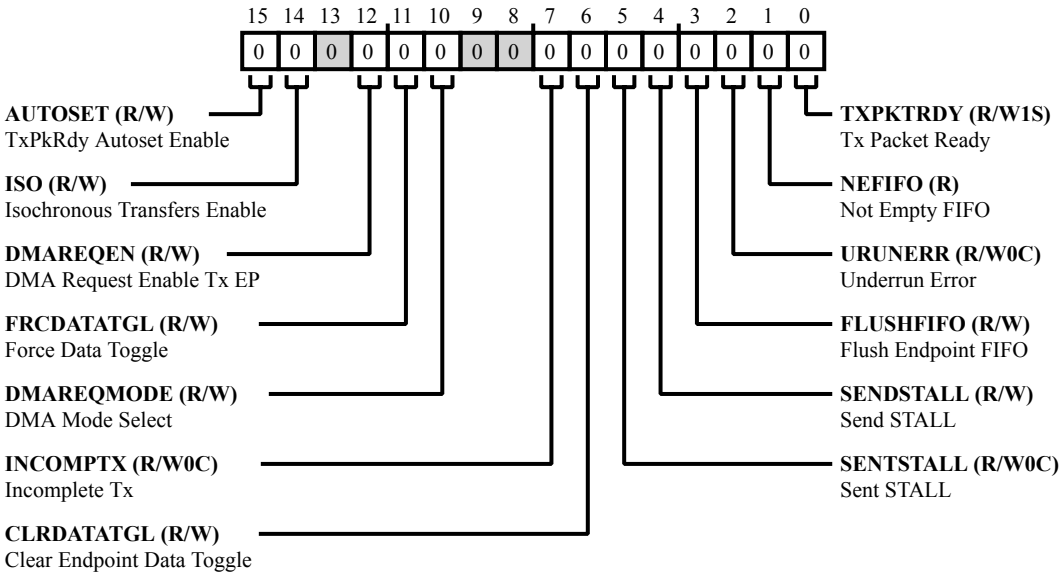

Figure 23-74: USB_EP[n]_TXCSR_P Register Diagram

Table 23-50: USB_EP[n]_TXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EP[n]_TXCSR_P.AUTOSET bit enables (in peripheral mode) automatic setting of the USB_EP[n]_TXCSR_P.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EP[n]_TXCSR_P.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EP[n]_TXCSR_P.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset

Table 23-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ISO	Isochronous Transfers Enable. The `USB_EP[n]_TXCSR_P.ISO` bit enables (in peripheral mode) the transmit endpoint for isochronous transfers. This bit should be disabled for bulk or interrupt endpoints.	
		0	Disable Tx EP Isochronous Transfers
		1	Enable Tx EP Isochronous Transfers
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The `USB_EP[n]_TXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EP[n]_TXCSR_P.FRCDATATGL` bit forces (in peripheral mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_TXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or in the same cycle that the `USB_EP[n]_TXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
7 (R/W0C)	INCOMPTX	Incomplete Tx. The `USB_EP[n]_TXCSR_P.INCOMPTX` bit indicates (for high-bandwidth isochronous endpoints in peripheral mode) when a large packet has been split into two or three packets for transmission, but insufficient IN tokens have been received to send all parts.	
		0	No Status
		1	Incomplete Tx (Insufficient IN Tokens)

Table 23-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_TXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EP[n]_TXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when the USB controller transmits a STALL handshake. When this condition occurs, the USB controller flushes the FIFO and clears the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted
4 (R/W)	SENDSTALL	Send STALL. The `USB_EP[n]_TXCSR_P.SENDSTALL` bit (in peripheral mode) is set by the processor to issue a STALL handshake to an IN token. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Request
		1	Request STALL Handshake Transmission
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_TXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit. The `USB_EP[n]_TXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush endpoint FIFO
2 (R/W0C)	URUNERR	Underrun Error. The `USB_EP[n]_TXCSR_P.URUNERR` bit indicates (in peripheral mode) when an IN token is received while the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is not set. The processor should clear this bit.	
		0	No Status
		1	Underrun Error

Table 23-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EP[n]_TXCSR_P.NEFIFO` bit indicates (in peripheral mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Polling Interval Register

The USB_EP[n]_TXINTERVAL register defines the polling interval for the currently-selected transmit endpoint for interrupt, isochronous, and bulk transfers. There is a USB_EP[n]_TXINTERVAL register for each configured transmit endpoint, except endpoint 0. The transfer types related to the speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full-speed, USB_EP[n]_TXINTERVAL = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, USB_EP[n]_TXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, USB_EP[n]_TXINTERVAL = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, USB_EP[n]_TXINTERVAL = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a USB_EP[n]_TXINTERVAL value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

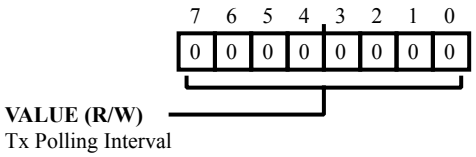

Figure 23-75: USB_EP[n]_TXINTERVAL Register Diagram

Table 23-51: USB_EP[n]_TXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Tx Polling Interval. The USB_EP[n]_TXINTERVAL.VALUE bits define the polling interval value for interrupt and isochronous transfers. The USB_EP[n]_TXINTERVAL.VALUE bits select the number of frames (or micro-frames, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Transmit Maximum Packet Length Register

The USB_EP[n]_TXMAXP register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. The USB_EP[n]_TXMAXP register provides indexed access to the maximum packet length register for each Tx endpoint, except endpoint 0.

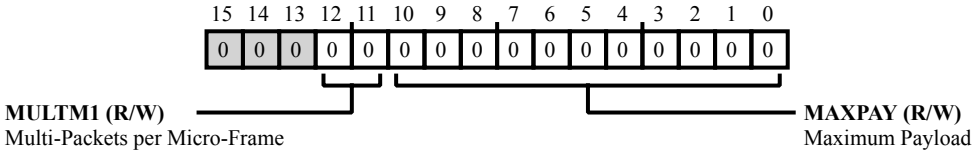

Figure 23-76: USB_EP[n]_TXMAXP Register Diagram

Table 23-52: USB_EP[n]_TXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-Frame. The USB_EP[n]_TXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller splits the FIFO data into multiple packets less than or equal to the maximum payload size.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EP[n]_TXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EP[n]_TXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Transmit Type Register

The USB_EP[n]_TXTYPE register selects the endpoint number and transaction protocol to use for the currently selected transmit endpoint. There is a USB_EP[n]_TXTYPE register for each transmit endpoint. Note that this register is only used in host mode.

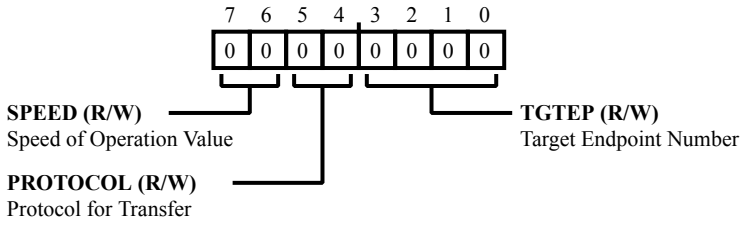

Figure 23-77: USB_EP[n]_TXTYPE Register Diagram

Table 23-53: USB_EP[n]_TXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The USB_EP[n]_TXTYPE.SPEED bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The USB_EP[n]_TXTYPE.PROTOCOL bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The USB_EP[n]_TXTYPE.TGTEP bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the transmit endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 23-53: USB_EP[n]_TXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

Function Address Register

The USB_FADDR register contains the device address used in peripheral mode. The processor writes this register with the address received through a SET_ADDRESS command from the host.

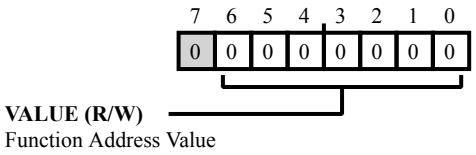

Figure 23-78: USB_FADDR Register Diagram

Table 23-54: USB_FADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Function Address Value. The USB_FADDR.VALUE bits contain the address of the peripheral part of the transaction.

FIFO Byte (8-Bit) Register

Writes to the USB_FIFOB[n] register go to the endpoint Tx FIFO and reads from the USB_FIFOB[n] register come from the endpoint Rx FIFO. The USB_FIFOB[n], USB_FIFOH[n], and USB_FIFO[n] registers are the same register. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB_FIFO[n] register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, the program should use a half-word (USB_FIFOH[n] register) or byte (USB_FIFOB[n] register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

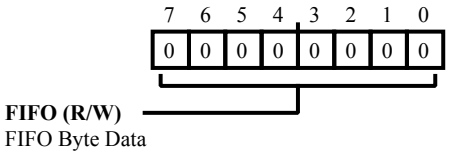

Figure 23-79: USB_FIFOB[n] Register Diagram

Table 23-55: USB_FIFOB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FIFO	FIFO Byte Data. The USB_FIFOB[n].FIFO bits provide byte access to the USB Tx and Rx endpoint FIFOs.

FIFO Half-Word (16-Bit) Register

Writes to the USB_FIFOH[n] register go to the endpoint Tx FIFO and reads from the USB_FIFOH[n] register come from the endpoint Rx FIFO. The USB_FIFOB[n], USB_FIFOH[n], and USB_FIFO[n] registers are the same register. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB_FIFO[n] register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, programs should use a half-word (USB_FIFOH[n] register) or byte (USB_FIFOB[n] register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

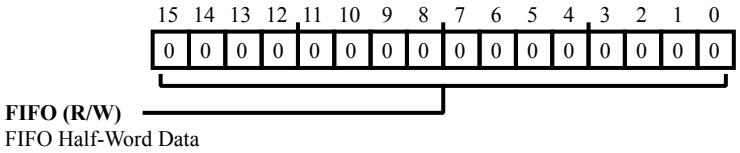

Figure 23-80: USB_FIFOH[n] Register Diagram

Table 23-56: USB_FIFOH[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	FIFO	FIFO Half-Word Data. The USB_FIFOH[n].FIFO bits provide half-word access to the USB Tx and Rx endpoint FIFOs.

FIFO Word (32-Bit) Register

Writes to the USB_FIFO[n] register go to the endpoint Tx FIFO and reads from the USB_FIFO[n] register come from the endpoint Rx FIFO. The USB_FIFOB[n], USB_FIFOH[n], and USB_FIFO[n] registers are the same registers. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB_FIFO[n] register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, programs should use a half-word (USB_FIFOH[n] register) or byte (USB_FIFOB[n] register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

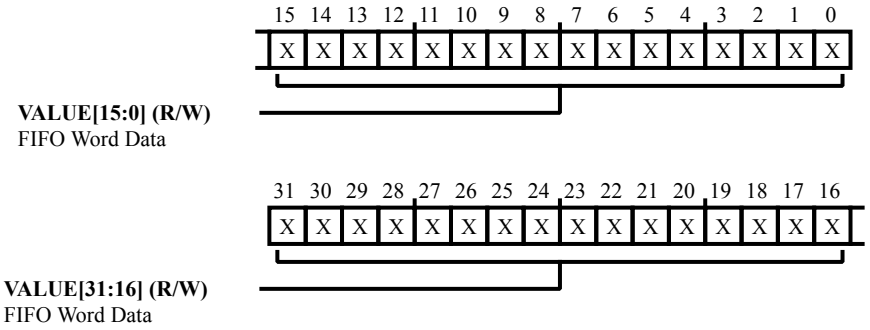

Figure 23-81: USB_FIFO[n] Register Diagram

Table 23-57: USB_FIFO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	FIFO Word Data. The USB_FIFO[n].VALUE bits provide word access to the USB Tx and Rx endpoint FIFOs.

Frame Number Register

The USB_FRAME register contains the frame number of the last received frame. The data in this register has bit 10 as the MSB and bit 0 as the LSB.

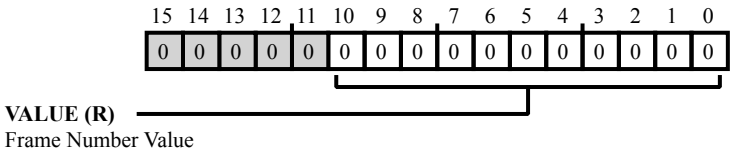

Figure 23-82: USB_FRAME Register Diagram

Table 23-58: USB_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Frame Number Value. The USB_FRAME.VALUE bits contains the frame number of the last received frame. The data in this field has bit 10 as the MSB and bit 0 as the LSB.

Full-Speed EOF 1 Register

The USB_FS_EOF1 register defines the minimum time gap allowed between the start of the last transaction and the end of frame for full-speed transactions.

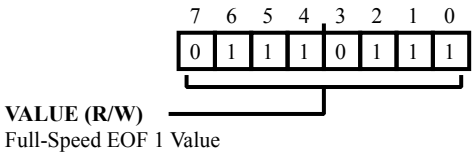

Figure 23-83: USB_FS_EOF1 Register Diagram

Table 23-59: USB_FS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Full-Speed EOF 1 Value. The USB_FS_EOF1.VALUE bits set the time before the end of the frame to stop beginning new transactions (in units of 533.3ns) for full-speed transactions. The default setting corresponds to 63.46us.

High-Speed EOF 1 Register

The USB_HS_EOF1 register defines the minimum time gap allowed between the start of the last transaction and the end of frame for high-speed transactions.

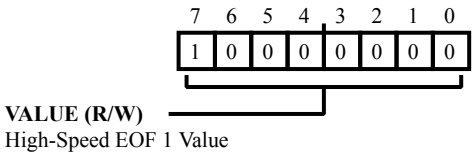

Figure 23-84: USB_HS_EOF1 Register Diagram

Table 23-60: USB_HS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	High-Speed EOF 1 Value. The USB_HS_EOF1.VALUE sets the time before the end of the frame to stop beginning new transactions (in units of 133.3ns) for high-speed transactions. The default setting corresponds to 17.07us.

Common Interrupts Enable Register

The USB_IEN register enables interrupts for USB controller system sources. Enabling an interrupt in this register directs the USB controller to generate an interrupt if the corresponding interrupt pending bit in the USB_IRQ register is set.

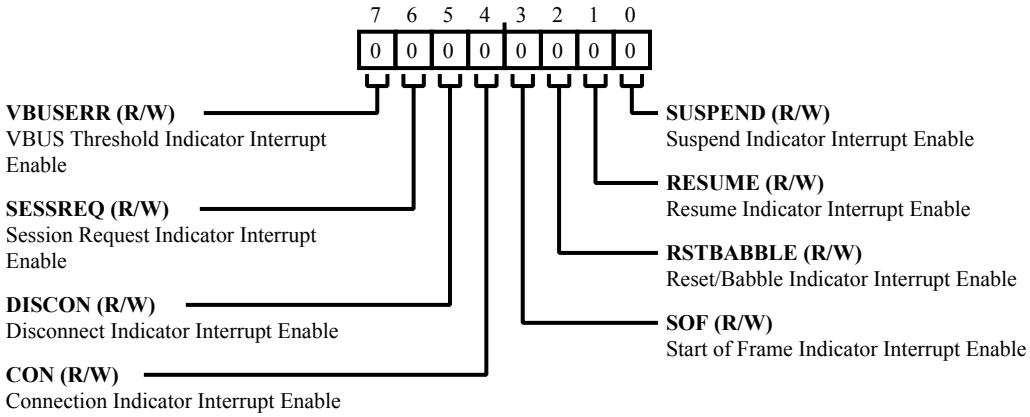

Figure 23-85: USB_IEN Register Diagram

Table 23-61: USB_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	VBUSERR	VBUS Threshold Indicator Interrupt Enable. The USB_IEN.VBUSERR bit enables the USB_IRQ.VBUSERR interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
6 (R/W)	SESSREQ	Session Request Indicator Interrupt Enable. The USB_IEN.SESSREQ bit enables the USB_IRQ.SESSREQ interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
5 (R/W)	DISCON	Disconnect Indicator Interrupt Enable. The USB_IEN.DISCON bit enables the USB_IRQ.DISCON interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
4 (R/W)	CON	Connection Indicator Interrupt Enable. The USB_IEN.CON bit enables the USB_IRQ.CON interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-61: USB_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	SOF	Start of Frame Indicator Interrupt Enable. The `USB_IEN.SOF` bit enables the `USB_IRQ.SOF` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	RSTBABBLE	Reset/Babble Indicator Interrupt Enable. The `USB_IEN.RSTBABBLE` bit enables the `USB_IRQ.RSTBABBLE` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
1 (R/W)	RESUME	Resume Indicator Interrupt Enable. The `USB_IEN.RESUME` bit enables the `USB_IRQ.RESUME` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
0 (R/W)	SUSPEND	Suspend Indicator Interrupt Enable. The `USB_IEN.SUSPEND` bit enables the `USB_IRQ.SUSPEND` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt

Index Register

The USB_INDEX register contains an index value for mirrored addressing of USB controller endpoint control and status registers.

There is one set of registers, but they are mirrored at two address locations if the endpoint is selected by the USB_INDEX register. An endpoint's register set only appears in the indexed location if the USB_INDEX register is written with that endpoint number. You can read/write an endpoint's register in either the directly mapped location which is always visible, or in the indexed location which is only visible if the USB_INDEX register is written with the endpoint number. The USB_INDEX register and indexed address locations only affect address decoding. For example, loading a 0 into the USB_INDEX register selects endpoint 0 access.

The USB_INDEX register can be used for indexed access of the directly mapped control/status registers from USB controller address offset 0x100-0x1FF. For products supporting the dynamic FIFO size feature, the endpoint Tx/Rx size and address registers always use the USB_INDEX register, there is no direct mapping for these endpoint-specific registers. The multi-point USB_MP[n]_TXFUNCADDR, USB_MP[n]_TXHUBADDR, USB_MP[n]_TXHUBPORT, USB_MP[n]_RXFUNCADDR, USB_MP[n]_RXHUBADDR, and USB_MP[n]_RXHUBPORT registers only have direct mapping, no indexed mapping.

Before accessing an endpoint's control/status registers using the indexed range, write the endpoint number to the USB_INDEX register to ensure that the correct control/status registers appear in the indexed range of the memory map.

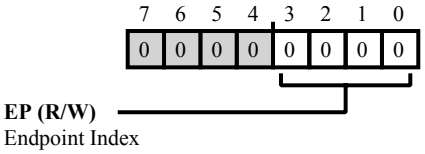

Figure 23-86: USB_INDEX Register Diagram

Table 23-62: USB_INDEX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	EP	Endpoint Index. The USB_INDEX.EP bits select mirrored access for an endpoints indexed control and status registers. Valid values for this bit field are 0-11.

Receive Interrupt Register

The USB_INTRRX register indicates which interrupts are currently active for the receive (Rx) endpoints. Note that the USB controller automatically clears this register when it is read.

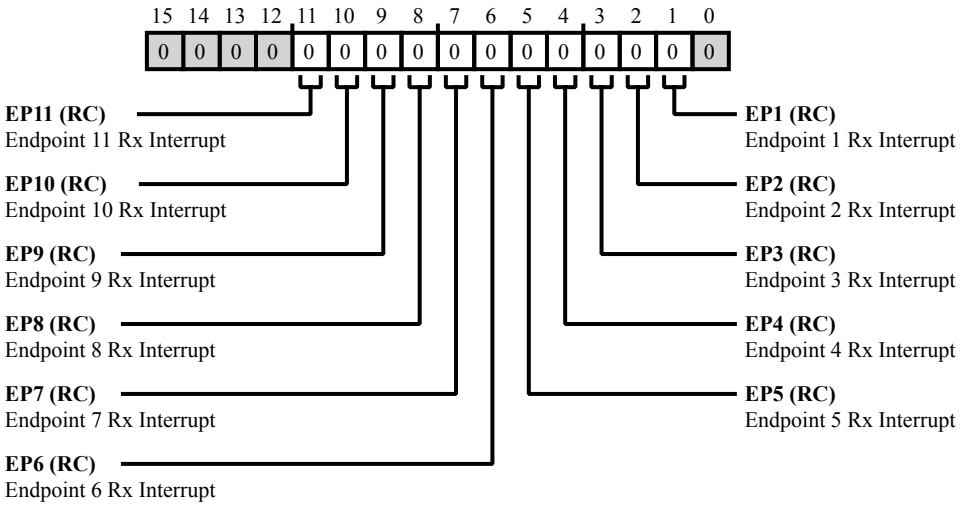

Figure 23-87: USB_INTRRX Register Diagram

Table 23-63: USB_INTRRX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (RC/NW)	EP11	Endpoint 11 Rx Interrupt. The USB_INTRRX.EP11 bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
10 (RC/NW)	EP10	Endpoint 10 Rx Interrupt. The USB_INTRRX.EP10 bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
9 (RC/NW)	EP9	Endpoint 9 Rx Interrupt. The USB_INTRRX.EP9 bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Table 23-63: USB_INTRRX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (RC/NW)	EP8	Endpoint 8 Rx Interrupt. The `USB_INTRRX.EP8` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
7 (RC/NW)	EP7	Endpoint 7 Rx Interrupt. The `USB_INTRRX.EP7` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
6 (RC/NW)	EP6	Endpoint 6 Rx Interrupt. The `USB_INTRRX.EP6` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
5 (RC/NW)	EP5	Endpoint 5 Rx Interrupt. The `USB_INTRRX.EP5` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
4 (RC/NW)	EP4	Endpoint 4 Rx Interrupt. The `USB_INTRRX.EP4` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
3 (RC/NW)	EP3	Endpoint 3 Rx Interrupt. The `USB_INTRRX.EP3` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Table 23-63: USB_INTRRX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (RC/NW)	EP2	Endpoint 2 Rx Interrupt. The `USB_INTRRX.EP2` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
1 (RC/NW)	EP1	Endpoint 1 Rx Interrupt. The `USB_INTRRX.EP1` bit indicates whether or not a receive interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Receive Interrupt Enable Register

The USB_INTRRXE register enables interrupts for the receive (Rx) endpoints. Enabling an interrupt in this register directs the USB controller to generate an interrupt if the corresponding interrupt pending bit in the USB_INTRRX register is set.

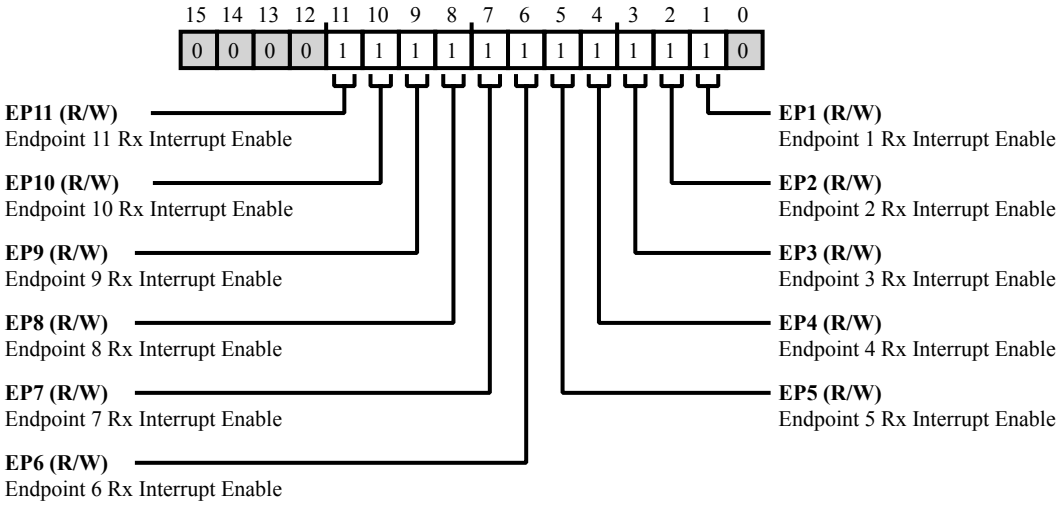

Figure 23-88: USB_INTRRXE Register Diagram

Table 23-64: USB_INTRRXE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EP11	Endpoint 11 Rx Interrupt Enable. The USB_INTRRXE.EP11 bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
10 (R/W)	EP10	Endpoint 10 Rx Interrupt Enable. The USB_INTRRXE.EP10 bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
9 (R/W)	EP9	Endpoint 9 Rx Interrupt Enable. The USB_INTRRXE.EP9 bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-64: USB_INTRRXE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	EP8	Endpoint 8 Rx Interrupt Enable. The `USB_INTRRXE.EP8` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
7 (R/W)	EP7	Endpoint 7 Rx Interrupt Enable. The `USB_INTRRXE.EP7` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
6 (R/W)	EP6	Endpoint 6 Rx Interrupt Enable. The `USB_INTRRXE.EP6` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
5 (R/W)	EP5	Endpoint 5 Rx Interrupt Enable. The `USB_INTRRXE.EP5` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
4 (R/W)	EP4	Endpoint 4 Rx Interrupt Enable. The `USB_INTRRXE.EP4` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
3 (R/W)	EP3	Endpoint 3 Rx Interrupt Enable. The `USB_INTRRXE.EP3` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	EP2	Endpoint 2 Rx Interrupt Enable. The `USB_INTRRXE.EP2` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-64: USB_INTRRXE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	EP1	Endpoint 1 Rx Interrupt Enable. The `USB_INTRRXE.EP1` bit enables the receive interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Transmit Interrupt Register

The USB_INTRTX register indicates which interrupts are currently active for endpoint 0 and the transmit (Tx) endpoints. Note that the USB controller automatically clears this register when it is read.

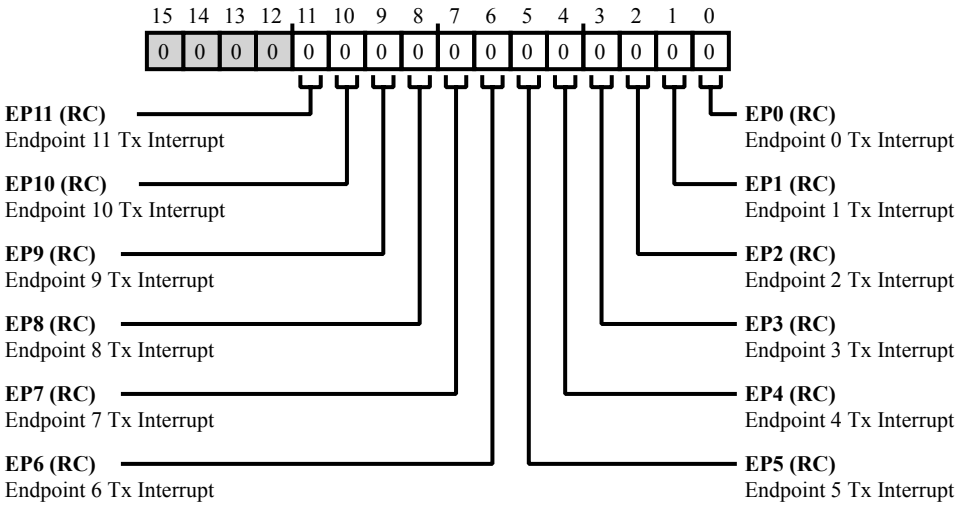

Figure 23-89: USB_INTRTX Register Diagram

Table 23-65: USB_INTRTX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (RC/NW)	EP11	Endpoint 11 Tx Interrupt. The USB_INTRTX.EP11 bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
10 (RC/NW)	EP10	Endpoint 10 Tx Interrupt. The USB_INTRTX.EP10 bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
9 (RC/NW)	EP9	Endpoint 9 Tx Interrupt. The USB_INTRTX.EP9 bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Table 23-65: USB_INTRTX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (RC/NW)	EP8	Endpoint 8 Tx Interrupt. The `USB_INTRTX.EP8` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
7 (RC/NW)	EP7	Endpoint 7 Tx Interrupt. The `USB_INTRTX.EP7` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
6 (RC/NW)	EP6	Endpoint 6 Tx Interrupt. The `USB_INTRTX.EP6` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
5 (RC/NW)	EP5	Endpoint 5 Tx Interrupt. The `USB_INTRTX.EP5` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
4 (RC/NW)	EP4	Endpoint 4 Tx Interrupt. The `USB_INTRTX.EP4` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
3 (RC/NW)	EP3	Endpoint 3 Tx Interrupt. The `USB_INTRTX.EP3` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Table 23-65: USB_INTRTX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (RC/NW)	EP2	Endpoint 2 Tx Interrupt. The `USB_INTRTX.EP2` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
1 (RC/NW)	EP1	Endpoint 1 Tx Interrupt. The `USB_INTRTX.EP1` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending
0 (RC/NW)	EP0	Endpoint 0 Tx Interrupt. The `USB_INTRTX.EP0` bit indicates whether or not a transmit interrupt is pending for this endpoint.	
		0	No Interrupt
		1	Interrupt Pending

Transmit Interrupt Enable Register

The USB_INTRTXE register enables interrupts for endpoint 0 and the transmit (Tx) endpoints. Enabling an interrupt in this register directs the USB controller to generate an interrupt if the corresponding interrupt pending bit in the USB_INTRTX register is set.

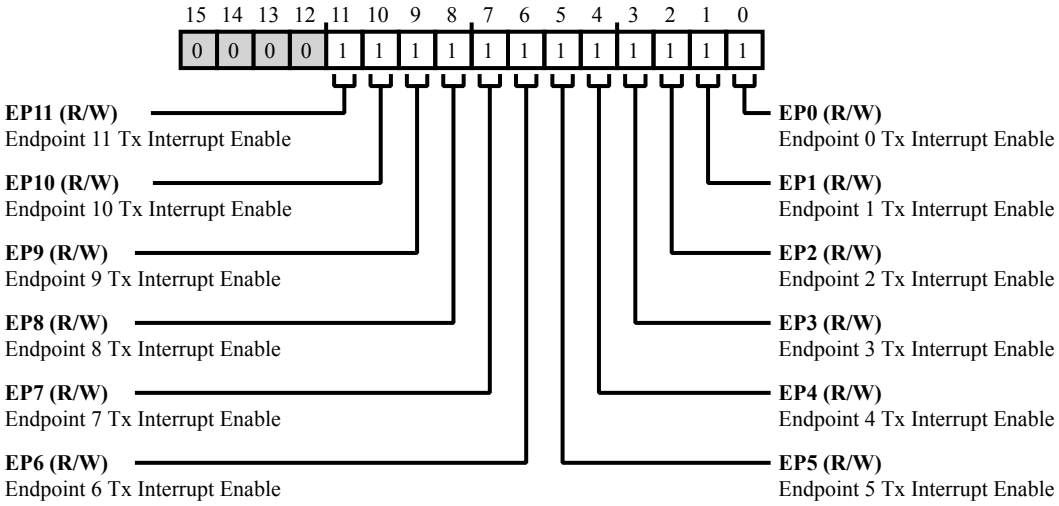

Figure 23-90: USB_INTRTXE Register Diagram

Table 23-66: USB_INTRTXE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EP11	Endpoint 11 Tx Interrupt Enable. The USB_INTRTXE.EP11 bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
10 (R/W)	EP10	Endpoint 10 Tx Interrupt Enable. The USB_INTRTXE.EP10 bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
9 (R/W)	EP9	Endpoint 9 Tx Interrupt Enable. The USB_INTRTXE.EP9 bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-66: USB_INTRTXE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	EP8	Endpoint 8 Tx Interrupt Enable. The `USB_INTRTXE.EP8` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
7 (R/W)	EP7	Endpoint 7 Tx Interrupt Enable. The `USB_INTRTXE.EP7` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
6 (R/W)	EP6	Endpoint 6 Tx Interrupt Enable. The `USB_INTRTXE.EP6` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
5 (R/W)	EP5	Endpoint 5 Tx Interrupt Enable. The `USB_INTRTXE.EP5` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
4 (R/W)	EP4	Endpoint 4 Tx Interrupt Enable. The `USB_INTRTXE.EP4` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
3 (R/W)	EP3	Endpoint 3 Tx Interrupt Enable. The `USB_INTRTXE.EP3` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	EP2	Endpoint 2 Tx Interrupt Enable. The `USB_INTRTXE.EP2` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-66: USB_INTRTXE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	EP1	Endpoint 1 Tx Interrupt Enable. The `USB_INTRTXE.EP1` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt
0 (R/W)	EP0	Endpoint 0 Tx Interrupt Enable. The `USB_INTRTXE.EP0` bit enables the transmit interrupt for this endpoint.	
		0	Disable Interrupt
		1	Enable Interrupt

Common Interrupts Register

The USB_IRQ register indicates which interrupts are currently active for USB controller system sources. Note that the USB controller automatically clears this register when it is read.

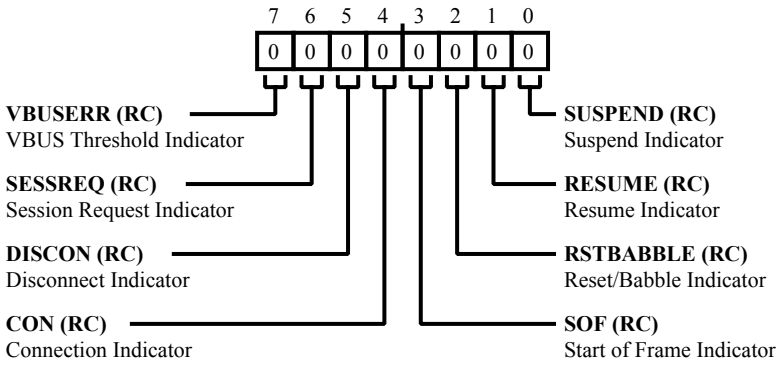

Figure 23-91: USB_IRQ Register Diagram

Table 23-67: USB_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (RC/NW)	VBUSERR	VBUS Threshold Indicator. The USB_IRQ.VBUSERR bit indicates whether the USB controller has detected that the VBUS is below the VBUS valid threshold. This bit is valid only when the USB controller is an A device. Note that the USB_IRQ.VBUSERR bit and the USB_VBUS_CTL.DRVINT bit share an interrupt source line.	
		0	No Interrupt
		1	Interrupt Pending
6 (RC/NW)	SESSREQ	Session Request Indicator. The USB_IRQ.SESSREQ bit indicates whether the USB controller has detected a session request signal. This bit is valid only when the USB controller is an A device.	
		0	No Interrupt
		1	Interrupt Pending
5 (RC/NW)	DISCON	Disconnect Indicator. The USB_IRQ.DISCON bit indicates whether the USB controller has detected a device disconnect (host mode) or has detected a session end (peripheral mode).	
		0	No Interrupt
		1	Interrupt Pending

Table 23-67: USB_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (RC/NW)	CON	Connection Indicator. The USB_IRQ.CON bit indicates whether the USB controller has detected a device connection. This bit is valid only in host mode.	
		0	No Interrupt
		1	Interrupt Pending
3 (RC/NW)	SOF	Start of Frame Indicator. The USB_IRQ.SOF bit indicates whether the USB controller has detected a start of a frame.	
		0	No Interrupt
		1	Interrupt Pending
2 (RC/NW)	RSTBABBLE	Reset/Babble Indicator. The USB_IRQ.RSTBABBLE bit indicates whether the USB controller has detected reset signalling on the bus. In host mode, the USB controller also indicates when the USB controller detects babble. Note that the USB_IRQ.RSTBABBLE bit is only active after the first SOF has been sent.	
		0	No Interrupt
		1	Interrupt Pending
1 (RC/NW)	RESUME	Resume Indicator. The USB_IRQ.RESUME bit indicates whether the USB controller has detected resume signaling on the bus while the USB controller is in suspend mode.	
		0	No Interrupt
		1	Interrupt Pending
0 (RC/NW)	SUSPEND	Suspend Indicator. The USB_IRQ.SUSPEND bit indicates whether the USB controller has detected suspend signalling on the bus. This bit is valid only in peripheral mode.	
		0	No Interrupt
		1	Interrupt Pending

Link Information Register

The USB_LINKINFO register specifies the PHY-related delays.

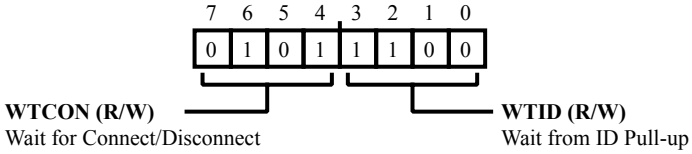

Figure 23-92: USB_LINKINFO Register Diagram

Table 23-68: USB_LINKINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	WTCON	Wait for Connect/Disconnect. The USB_LINKINFO.WTCON bits set the wait time to be applied to allow the users to connect or disconnect filter.
3:0 (R/W)	WTID	Wait from ID Pull-up. The USB_LINKINFO.WTID bits set the delay to be applied from IDPULLUP being asserted to IDDIG being considered valid.

LPM Attribute Register

The USB_LPM_ATTR register defines the link power management (LPM) attributes for LPM transactions and sleep/wake operation. In peripheral mode, the USB_LPM_ATTR register contains values received in the most recent, accepted (ACK'd) LPM transaction. In host mode, the USB_LPM_ATTR register contains values (loaded by software) that set up the next LPM transaction. The USB controller inserts the LPM values within the next LPM transaction.

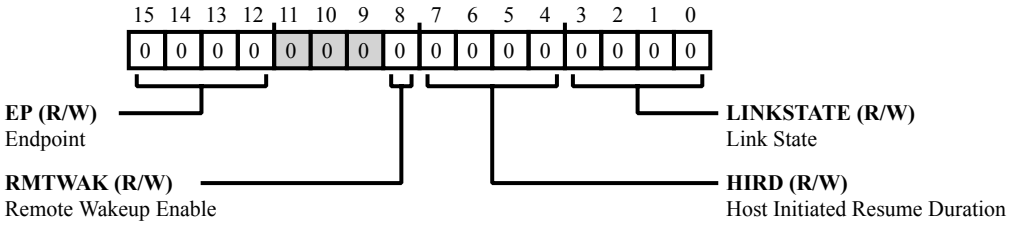

Figure 23-93: USB_LPM_ATTR Register Diagram

Table 23-69: USB_LPM_ATTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	EP	Endpoint. The USB_LPM_ATTR.EP bits select the endpoint in the token packet of the LPM transaction.	
8 (R/W)	RMTWAK	Remote Wakeup Enable. The USB_LPM_ATTR.RMTWAK bit enables remote wakeup. This bit is applied on a temporary basis only and is only applied to the current suspend state. After the current suspend cycle, the remote wakeup capability that was negotiated during enumeration applies.	
		0	Disable Remote Wakeup
		1	Enable Remote Wakeup
7:4 (R/W)	HIRD	Host Initiated Resume Duration. The USB_LPM_ATTR.HIRD bits select the host-initiated resume duration. This value is the minimum time that the host drives resume on the bus. The value in this register corresponds to an actual resume time of: Resume Time = 50us + HIRD*75us. This equation produces results in a range of 50us to 1200us.	
3:0 (R/W)	LINKSTATE	Link State. The USB_LPM_ATTR.LINKSTATE bits is value is provided by the host to the peripheral to indicate what state the peripheral must transition to after the receipt and acceptance of a LPM transaction. (Enumerations not shown are reserved.)	
		1	Sleep State (L1)

LPM Control Register

The USB_LPM_CTL register controls link power management (LPM) operations, including LPM enable, NAK, resume, and mode transition.

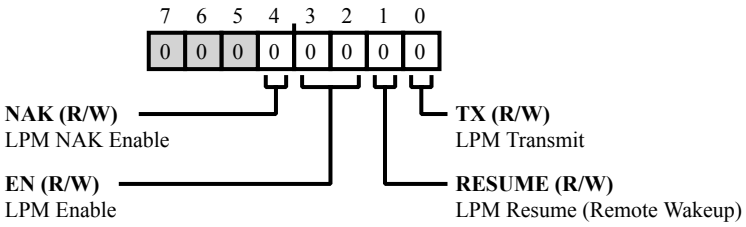

Figure 23-94: USB_LPM_CTL Register Diagram

Table 23-70: USB_LPM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	NAK	LPM NAK Enable. The USB_LPM_CTL.NAK bit enables (in peripheral mode) a NAK-all-non-LPM transactions mode for all end points, forcing a NAK response to all transactions other than an LPM transaction. This bit only takes effect after the controller has been LPM suspended. In this case, the USB controller continues to NAK, until this bit has been cleared by software.	
		0	Disable LPM NAK
		1	Enable LPM NAK
3:2 (R/W)	EN	LPM Enable. The USB_LPM_CTL.EN bits enable (In peripheral mode) LPM operations. The LPM operation may be enabled at different levels, which determine the response of the USB controller to LPM transactions.	
		0	Disable LPM. LPM and extended transactions are not supported. The USB controller does not respond to LPM transactions, and these transaction timeout.
		1	Disable LPM. LPM and extended transactions are not supported. The USB controller does not respond to LPM transactions, and these transaction timeout.
		2	Enable Extended Transactions. LPM is not supported, but extended transactions are supported. The USB controller responds to an LPM transaction with a STALL.
		3	Enable LPM and Extended Transactions. Both LPM and extended transactions are supported. The USB controller responds with a NYET or an ACK as determined by the value of LPMXMT and other conditions.

Table 23-70: USB_LPM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	RESUME	LPM Resume (Remote Wakeup). The USB_LPM_CTL.RESUME bit initiates resume (remote wakeup). The operation of this bit differs from the USB_POWER.RESUME bit in that the LPM resume signal timing is controlled by hardware. When set, the USB controller asserts resume signaling for 50us in host mode or asserts resume signaling for the time specified by the USB_LPM_ATTR.HIRD field in device mode. The USB_LPM_CTL.RESUME bit is self-clearing.	
		0	No Action
		1	LPM Resume
0 (R/W)	TX	LPM Transmit. The USB_LPM_CTL.TX bit puts the USB controller in LPM transmit mode. But, this mode operates differently in host mode versus peripheral mode. In peripheral mode, this bit is set by software to instruct the controller to transition to the L1 state upon receipt of the next LPM transaction. This bit is only effective if LPM enable (USB_LPM_CTL.EN) is set to 0x3. The LPM transmit enable bit can be set in the same cycle as LPM enable. If the USB_LPM_CTL.TX and USB_LPM_CTL.EN bits are enabled, the USB controller can respond in the following ways: • If no data is pending (all transmit FIFOs are empty), the USB controller responds with an ACK, clears the USB_LPM_CTL.TX bit, and generates a software interrupt. • If data is pending (data resides in at least one transmit FIFO), the USB controller responds with a NYET, does not clear the USB_LPM_CTL.TX bit, and generates a software interrupt. In host mode, this bit is set by software to transmit an LPM transaction. This bit is self-clearing. The USB controller clears this bit immediately on receipt of any token or after three timeouts have occurred.	
		0	Disable LPM Tx
		1	Enable LPM Tx

LPM Function Address Register

The USB_LPM_FADDR register selects the link power management (LPM) function address.

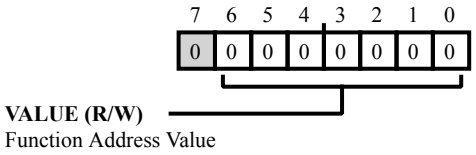

Figure 23-95: USB_LPM_FADDR Register Diagram

Table 23-71: USB_LPM_FADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Function Address Value. The USB_LPM_FADDR.VALUE bits hold the LPM function address value that the USB controller places in the LPM payload.

LPM Interrupt Enable Register

The USB_LPM_IEN register enables the link power management (LPM) related interrupts. When an interrupt is enabled in this register and the corresponding interrupt is pending in USB_LPM_IRQ, the USB controller generates the interrupt. When an interrupt is disabled in this register, the corresponding interrupt may be pending in USB_LPM_IRQ, but the USB controller does not generate an interrupt.

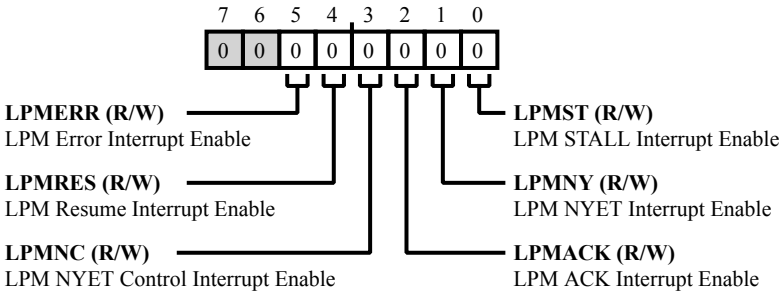

Figure 23-96: USB_LPM_IEN Register Diagram

Table 23-72: USB_LPM_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	LPMERR	LPM Error Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt
4 (R/W)	LPMRES	LPM Resume Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt
3 (R/W)	LPMNC	LPM NYET Control Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	LPMACK	LPM ACK Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt
1 (R/W)	LPMNY	LPM NYET Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 23-72: USB_LPM_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	LPMST	LPM STALL Interrupt Enable.	
		0	Disable Interrupt
		1	Enable Interrupt

LPM Interrupt Status Register

The USB_LPM_IRQ register indicates link power management (LPM) related interrupt status. The USB controller clears this register when it is read.

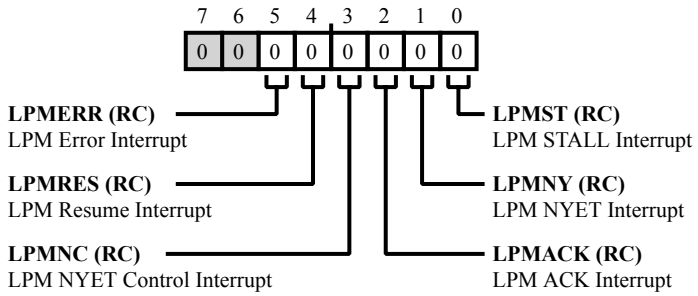

Figure 23-97: USB_LPM_IRQ Register Diagram

Table 23-73: USB_LPM_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RC/NW)	LPMERR	LPM Error Interrupt. The USB_LPM_IRQ.LPMERR bit indicates an LPM error interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set if an LPM transaction is received that has a USB_LPM_ATTR.LINKSTATE field that is not supported. The USB controller responds to the transaction with a STALL. Note that the USB controller updates the USB_LPM_ATTR register, so software can observe the non-compliant LPM packet payload. In host mode, this bit is set if the response to a LPM transaction is received with a bit stuff or PID error. No suspend occurs and the state of the device is now unknown.	
		0	No Interrupt Pending
		1	Interrupt Pending
4 (RC/NW)	LPMRES	LPM Resume Interrupt. The USB_LPM_IRQ.LPMRES bit indicates that the USB controller has been resumed for any reason. This bit is mutually exclusive from the USB_POWER.RESUME bit.	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 23-73: USB_LPM_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RC/NW)	LPMNC	LPM NYET Control Interrupt. The USB_LPM_IRQ.LPMNC bit indicates an LPM NYET control interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with a NYET due to data pending in the transmit FIFOs. This interrupt may only occur when the USB_LPM_CTL.EN field is set to 11, the USB_LPM_CTL.TX field is set to 1, and there is data pending in the transmit FIFOs. In host mode, this bit is set when an LPM transaction has been transmitted, but has failed to complete. The transaction failure is due to a timeout or bit errors in the response for three attempts.	
		0	No Interrupt Pending
		1	Interrupt Pending
2 (RC/NW)	LPMACK	LPM ACK Interrupt. The USB_LPM_IRQ.LPMACK bit indicates an LPM ACK interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with an ACK. This interrupt may only occur when the USB_LPM_CTL.EN field is set to 11, the USB_LPM_CTL.TX field is set to 1, and there is no data pending in the controller transmit FIFOs. In host mode, this bit is set when an LPM transaction is transmitted, and the device responds with an ACK.	
		0	No Interrupt Pending
		1	Interrupt Pending
1 (RC/NW)	LPMNY	LPM NYET Interrupt. The USB_LPM_IRQ.LPMNY bit indicates an LPM NYET interrupt condition, but this interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with a NYET. This interrupt may only occur when the USB_LPM_CTL.EN field is set to 11, and the USB_LPM_CTL.TX field is set to 0. In host mode, this bit is set when an LPM transaction is transmitted and the device responds with a NYET.	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 23-73: USB_LPM_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (RC/NW)	LPMST	LPM STALL Interrupt. The `USB_LPM_IRQ.LPMST` bit indicates an LPM STALL interrupt condition, but this interrupt has differing conditions for host mode versus peripheral mode. This bit is set when an LPM transaction is received, and the USB controller responds with a STALL. This interrupt may only occur when the `USB_LPM_CTL.EN` field is set to 01. In host mode, this bit is set when an LPM transaction is transmitted, and the device responds with a STALL.	
		0	No Interrupt Pending
		1	Interrupt Pending

Low-Speed EOF 1 Register

The USB_LS_EOF1 register defines the minimum time gap allowed between the start of the last transaction and the end of frame for low-speed transactions.

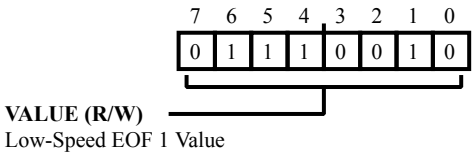

Figure 23-98: USB_LS_EOF1 Register Diagram

Table 23-74: USB_LS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Low-Speed EOF 1 Value. The USB_LS_EOF1.VALUE bits set the time before end of frame to stop beginning new transactions (in units of 1.067us) for low-speed transactions. The default setting corresponds to 121.6us.

MPn Receive Function Address Register

The USB_MP[n]_RXFUNCADDR register specifies the receive endpoint's target address in host mode. This register is not used in device mode. Note that the USB_MP[n]_RXFUNCADDR register does not exist for EP0.

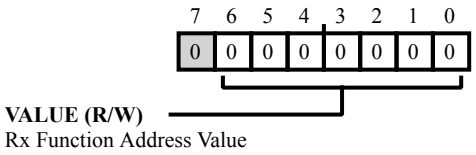

Figure 23-99: USB_MP[n]_RXFUNCADDR Register Diagram

Table 23-75: USB_MP[n]_RXFUNCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Rx Function Address Value. The USB_MP[n]_RXFUNCADDR.VALUE bits hold the address of the target device for this endpoint.

MPn Receive Hub Address Register

The USB_MP[n]_RXHUBADDR register specifies the hub address of the endpoint in host mode. This register is not used in device mode. Note that this register only needs to be programmed when a full-speed or low-speed device is connected to a high-speed hub, which carries out the necessary transaction translation. Note that the USB_MP[n]_RXHUBADDR register does not exist for EP0.

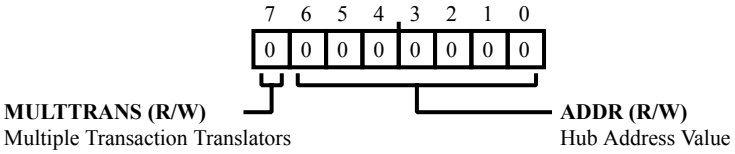

Figure 23-100: USB_MP[n]_RXHUBADDR Register Diagram

Table 23-76: USB_MP[n]_RXHUBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	MULTTRANS	Multiple Transaction Translators. The USB_MP[n]_RXHUBADDR.MULTTRANS bit should be set if the hub has multiple transaction translators.	
		0	Single Transaction Translator
		1	Multiple Transaction Translators
6:0 (R/W)	ADDR	Hub Address Value. The USB_MP[n]_RXHUBADDR.ADDR bits hold the address of the hub to which this device is connected.	

MPn Receive Hub Port Register

The USB_MP[n]_RXHUBPORT register specifies the hub port for full-speed and low-speed endpoints in host mode. This register is not used in device mode. The USB_MP[n]_RXHUBPORT register lets the USB controller support SPLIT transactions. Note that the USB_MP[n]_RXHUBPORT register does not exist for EP0.

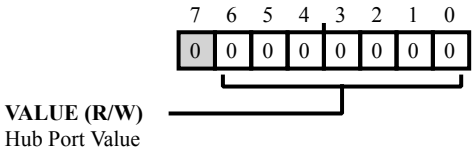

Figure 23-101: USB_MP[n]_RXHUBPORT Register Diagram

Table 23-77: USB_MP[n]_RXHUBPORT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Hub Port Value. The USB_MP[n]_RXHUBPORT.VALUE bits hold the hub port value of the target device for this endpoint.

MPn Transmit Function Address Register

The USB_MP[n]_TXFUNCADDR register specifies the transmit endpoint's target address in host mode. This register is not used in device mode. Note that the USB_MP[n]_TXFUNCADDR register must be setup for EP0. (The USB_MP[n]_RXFUNCADDR register does not exist for EP0.)

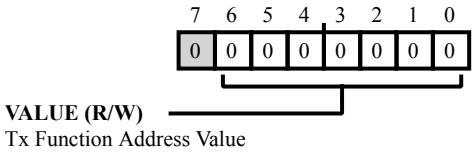

Figure 23-102: USB_MP[n]_TXFUNCADDR Register Diagram

Table 23-78: USB_MP[n]_TXFUNCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Tx Function Address Value. The USB_MP[n]_TXFUNCADDR.VALUE bits hold the address of the target device for this endpoint.

MPn Transmit Hub Address Register

The USB_MP[n]_TXHUBADDR register specifies the hub address of the endpoint in host mode. This register is not used in device mode. Note that this register only needs to be programmed when a full-speed or low-speed device is connected to a high-speed hub, which carries out the necessary transaction translation. Also, note that EP0 only uses the USB_MP[n]_TXHUBADDR register. (The USB_MP[n]_RXHUBADDR register does not exist for EP0.)

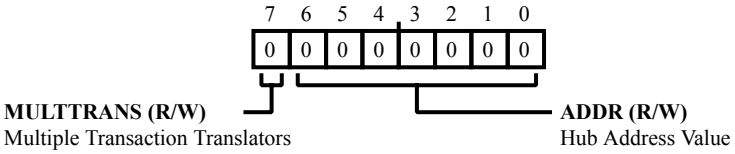

Figure 23-103: USB_MP[n]_TXHUBADDR Register Diagram

Table 23-79: USB_MP[n]_TXHUBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	MULTTRANS	Multiple Transaction Translators. The USB_MP[n]_TXHUBADDR.MULTTRANS bit should be set if the hub has multiple transaction translators.	
		0	Single Transaction Translator
		1	Multiple Transaction Translators
6:0 (R/W)	ADDR	Hub Address Value. The USB_MP[n]_TXHUBADDR.ADDR bits hold the address of the hub to which this device is connected.	

MPn Transmit Hub Port Register

The USB_MP[n]_TXHUBPORT register specifies the hub port for full-speed and low-speed endpoints in host mode. This register is not used in device mode. The USB_MP[n]_TXHUBPORT register lets the USB controller support SPLIT transactions. EP0 only uses the USB_MP[n]_TXHUBPORT register. (The USB_MP[n]_RXHUBPORT register does not exist for EP0.)

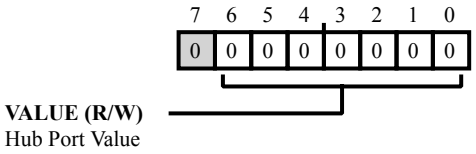

Figure 23-104: USB_MP[n]_TXHUBPORT Register Diagram

Table 23-80: USB_MP[n]_TXHUBPORT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Hub Port Value. The USB_MP[n]_TXHUBPORT.VALUE bits hold the hub port value of the target device for this endpoint.

PHY Control Register

The USB_PHY_CTL register provides access to PHY control features.

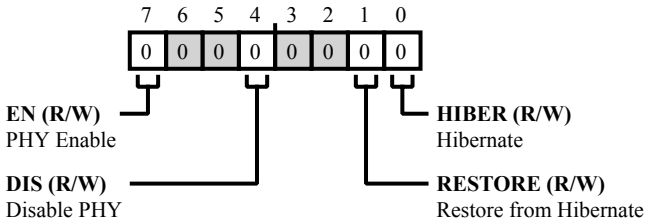

Figure 23-105: USB_PHY_CTL Register Diagram

Table 23-81: USB_PHY_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EN	PHY Enable. The USB_PHY_CTL.EN bit enables the USB controller PHY. This bit enables the schmitt-trigger inputs on D+ and D- to detect session request protocol. The bit also enables the bias circuits and VBUS comparators to detect when a host is connected. This bit should be set for all USB controller operations.	
4 (R/W)	DIS	Disable PHY. The USB_PHY_CTL.DIS bit disables the PHY, so it draws minimal power.	
		0	Enable USB PHY and 5V protection on USB signals.
		1	Disable USB PHY and 5V protection on USB signals. Caution: When 5V protection is disabled, the absolute max voltage on USB signals is reduced. See the data sheet for details.
1 (R/W)	RESTORE	Restore from Hibernate. The USB_PHY_CTL.RESTORE bit causes the PHY to come out of hibernate and release its latches.	
0 (R/W)	HIBER	Hibernate. The USB_PHY_CTL.HIBER bit causes the PHY to prepare for hibernate. Latches hold the pullup/pulldown state when the core power is removed.	

PLL and Oscillator Control Register

The USB_PLL_OSC register provides access to PLL and oscillator-related control features.

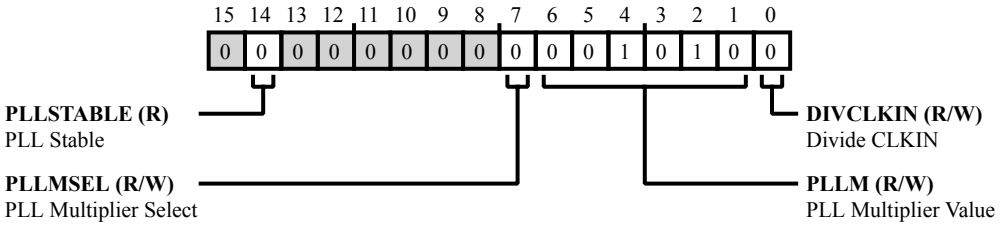

Figure 23-106: USB_PLL_OSC Register Diagram

Table 23-82: USB_PLL_OSC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PLLSTABLE	PLL Stable. The USB_PLL_OSC.PLLSTABLE status bit indicates that the oscillator and PLL clock are stable.
7 (R/W)	PLLMSEL	PLL Multiplier Select. The USB_PLL_OSC.PLLMSEL bit directs the PLL to use the PLL multiplier value stored in the USB_PLL_OSC.PLLM bits.
6:1 (R/W)	PLLM	PLL Multiplier Value. The USB_PLL_OSC.PLLM bit field contains the PLL multiplier. This field should be set such that CLKIN * USB_PLL_OSC.PLLM value = 480MHz.
0 (R/W)	DIVCLKIN	Divide CLKIN. The USB_PLL_OSC.DIVCLKIN bit enables a divide CLKIN by 2 function for the PLL.

Power and Device Control Register

The USB_POWER register controls suspend and resume signaling and some operational aspects of the USB controller.

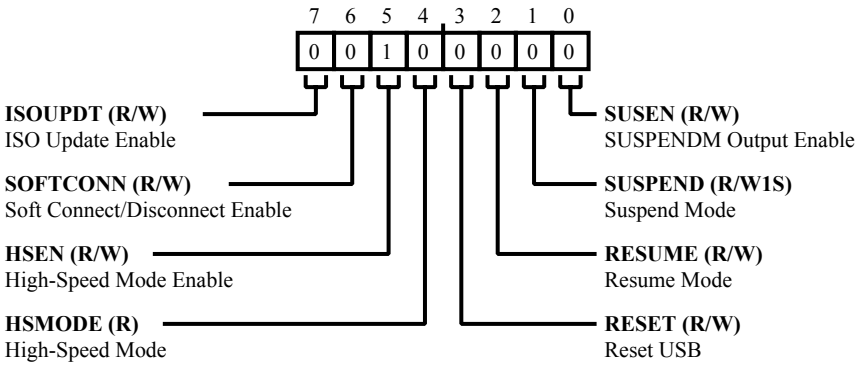

Figure 23-107: USB_POWER Register Diagram

Table 23-83: USB_POWER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	ISOUPDT	ISO Update Enable. The USB_POWER.ISOUPDT bit directs the USB controller to waits for an SOF token from the time the USB_EP[n]_TXCSR_P.TXPKTRDY bit is set before sending the packet. If an IN token is received before an SOF token, the USB controller send a zero length data packet. This USB_POWER.ISOUPDT bit only affects endpoints performing isochronous transfers. This bit only is valid in peripheral mode (USB_DEV_CTL.HOSTMODE = 0).	
		0	Disable ISO Update
		1	Enable ISO Update
6 (R/W)	SOFTCONN	Soft Connect/Disconnect Enable. In peripheral mode, the D+/- lines default to disconnected. Setting this bit enables the D+/- termination resistors. This bit is automatically set when the USB_DEV_CTL.SESSION bit is written with 1. The USB_POWER.SOFTCONN bit enables USB controller soft connect/disconnect, enabling the termination resistors for USB_DP (Data +) and USB_DM (Data -) pins. When disabled, these pins are three-stated. Note that USB_POWER.SOFTCONN only is valid in peripheral mode (USB_DEV_CTL.HOSTMODE = 0).	
		0	Disable Soft Connect/Disconnect
		1	Enable Soft Connect/Disconnect

Table 23-83: USB_POWER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	HSEN	High-Speed Mode Enable. The USB_POWER.HSEN bit enables USB controller negotiation for high speed (on devices supporting high-speed mode) when the device is reset by the hub/host. If disabled, the USB controller only operates in full-speed mode. When operating in full-speed mode, this bit should be cleared.	
		0	Disable Negotiation for HS Mode
		1	Enable Negotiation for HS Mode
4 (R/NW)	HSMODE	High-Speed Mode. The USB_POWER.HSMODE bit indicates whether or not the USB controller successfully negotiated high-speed mode during a USB controller reset. In peripheral mode (USB_DEV_CTL.HOSTMODE = 0), this bit has valid data when the USB controller completes reset. In host mode (USB_DEV_CTL.HOSTMODE = 1), this bit has valid data when the USB_IRQ.RSTBABBLE bit is cleared, remaining valid for the duration of the session.	
		0	Full-Speed Mode (HS fail during reset)
		1	High-Speed Mode (HS success during reset)
3 (R/W)	RESET	Reset USB. The USB_POWER.RESET bit indicates (in both host and peripheral modes) that the USB controller has detected that reset signaling is present on the bus. In peripheral mode (USB_DEV_CTL.HOSTMODE = 0), this bit is read only, but in host mode (USB_DEV_CTL.HOSTMODE = 1), this bit is read/write, permitting the processor core to set the bit and initiate a USB controller reset.	
		0	No Reset
		1	Reset USB
2 (R/W)	RESUME	Resume Mode. The USB_POWER.RESUME bit directs the USB controller to generate resume signaling when the function is in suspend mode (USB_POWER.SUSPEND =1). The processor core should clear this bit after 10 ms (a maximum of 15 ms) to end resume signaling. When the USB controller is in host mode (USB_DEV_CTL.HOSTMODE = 1), the USB controller automatically sets the USB_POWER.RESUME bit when resume signaling from the target is detected while the USB controller is suspended.	
		0	Disable Resume Signaling
		1	Enable Resume Signaling

Table 23-83: USB_POWER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	SUSPEND	Suspend Mode. When the USB controller is in host mode (`USB_DEV_CTL.HOSTMODE` = 1), the `USB_POWER.SUSPEND` bit enables suspend mode. When the USB controller is in peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0), the USB controller sets the `USB_POWER.SUSPEND` bit on entry to suspend mode and clears the bit when the processor reads the `USB_IRQ` register. Note that the USB controller automatically clears this bit if the `USB_POWER.RESUME` bit is set.	
		0	Disable Suspend Mode (Host)
		1	Enable Suspend Mode (Host)
0 (R/W)	SUSEN	SUSPENDM Output Enable. The `USB_POWER.SUSEN` bit enables the SUSPENDM output (internal USB controller signal). When enabled, the SUSPENDM output signal is used by the USB controller PHY to power-down its drivers when the USB controller is not active.	
		0	Disable SUSPENDM Output
		1	Enable SUSPENDM Output

RAM Information Register

The USB_RAMINFO register provides information about the width of the USB controller RAM.

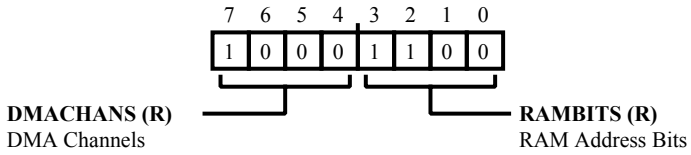

Figure 23-108: USB_RAMINFO Register Diagram

Table 23-84: USB_RAMINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	DMACHANS	DMA Channels. The USB_RAMINFO.DMACHANS bits indicate the number of DMA channels.
3:0 (R/NW)	RAMBITS	RAM Address Bits. The USB_RAMINFO.RAMBITS bits indicate the number of RAM address bits. The USB controller FIFO RAM is 32-bits wide. The number of bytes in the FIFO RAM may be calculated from the formula: RAM_bytes = $2^{(RAM\_Bits+2)}$

EPn Request Packet Count Register

The USB_RQPKTCNT[n] register specifies (in host mode) the number of packets to request in a block transfer of one or more bulk packets of size USB_EP[n]_RXMAXP from a receive endpoint. This register only applies for receive endpoints 1 through 11 in host mode.

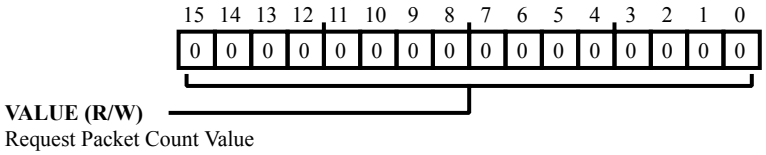

Figure 23-109: USB_RQPKTCNT[n] Register Diagram

Table 23-85: USB_RQPKTCNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Request Packet Count Value. The USB_RQPKTCNT[n].VALUE bits specify the number of bulk packets to request in a block transfer from a receive endpoint. This field is used with the auto request feature (USB_EP[n]_RXCSR_H.AUTOREQ).

Receive FIFO Address Register

The USB_RXFIFOADDR sets the start address for the selected Rx FIFO for endpoints 1-11. There is one receive FIFO address register for each endpoint, except endpoint 0. The USB_RXFIFOADDR register is indexed and selected by the USB_INDEX register. Note that the endpoint 0 FIFO has a fixed 64-byte size and is always located at address 0.

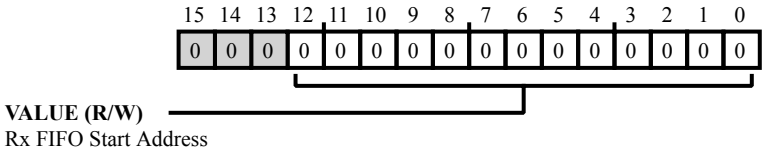

Figure 23-110: USB_RXFIFOADDR Register Diagram

Table 23-86: USB_RXFIFOADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VALUE	Rx FIFO Start Address. The USB_RXFIFOADDR.VALUE bits hold the start address of the selected endpoint FIFO (selected with the USB_INDEX register) in units of 8 bytes, according to the formula: FIFO address = USB_RXFIFOADDR.VALUE * 8

Receive FIFO Size Register

The USB_RXFIFOSZ register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed-access to the FIFO (packet) size selection for each Rx endpoint (except endpoint 0).

Note that a value greater than the maximum allowed of 1023 for full-speed USB controller operation produces unpredictable results.

Also, note that the value written to this register should match the programmed maximum individual packet size (MaxPktSize) of the standard endpoint descriptor for the associated endpoint. (See the Universal Serial Bus Specification Revision 2.0, Chapter 9). A mismatch could cause unexpected results. The total amount of data represented by the value written to this register must not exceed the Rx FIFO size, and should not exceed half the FIFO size if double-buffering is required.

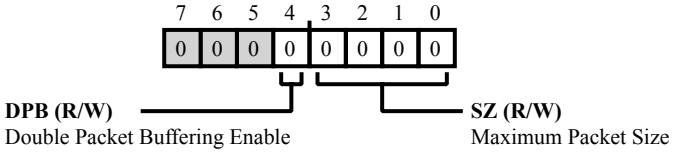

Figure 23-111: USB_RXFIFOSZ Register Diagram

Table 23-87: USB_RXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DPB	Double Packet Buffering Enable. The USB_RXFIFOSZ.DPB bit enables double packet buffering, doubling the FIFO (packet) size selected with the USB_RXFIFOSZ.SZ field.	
		0	Single Packet Buffering
		1	Double Packet Buffering
3:0 (R/W)	SZ	Maximum Packet Size. The USB_RXFIFOSZ.SZ bits select the maximum FIFO (packet) size according to the formula: FIFOSZ= $2^{(SZ+3)}$ If the USB_RXFIFOSZ.DPB is cleared, the FIFO size is FIFOSZ from this formula. If the USB_RXFIFOSZ.DPB is set, the FIFO is twice this size. For each enumeration value, the enumerations descriptions show the packet size (PktSz=), the FIFO size if DPB=0 (DPB0=), and the FIFO size if DPB=1 (DPB1=); these values are in bytes.	
		0	PktSz=8, DPB0=8, DPB1=16
		1	PktSz=16, DPB0=16, DPB1=32

Table 23-87: USB_RXFIFOSZ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	PktSz=32, DPB0=32, DPB1=64
		3	PktSz=64, DPB0=64, DPB1=128
		4	PktSz=128, DPB0=128, DPB1=256
		5	PktSz=256, DPB0=256, DPB1=512
		6	PktSz=512, DPB0=512, DPB1=1024
		7	PktSz=1024, DPB0=1024, DPB1=2048
		8	PktSz=2048, DPB0=2048, DPB1=4096
		9	PktSz=4096, DPB0=4096, DPB1=8192

Software Reset Register

The USB_SOFT_RST register provides reset controls for the USB controller CLK domain and XCLK domain. The USB controller PHY operates in the controller's XCLK domain, and the USB controller interface to the processor core operates in the controller's CLK domain. Note that for correct operation, both of the reset control bits (USB_SOFT_RST.RST and USB_SOFT_RST.RSTX) should always be asserted simultaneously.

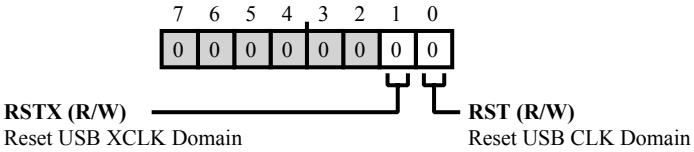

Figure 23-112: USB_SOFT_RST Register Diagram

Table 23-88: USB_SOFT_RST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	RSTX	Reset USB XCLK Domain. The USB_SOFT_RST.RSTX bit resets logic in the USB XCLK domain. This bit is self-clearing. Note that this bit should always be asserted simultaneously with the USB_SOFT_RST.RST bit.	
		0	No Reset
		1	Reset USB XCLK Domain
0 (R/W)	RST	Reset USB CLK Domain. The USB_SOFT_RST.RST bit resets logic in the USB CLK domain. This bit is self-clearing. Note that this bit should always be asserted simultaneously with the USB_SOFT_RST.RSTX bit.	
		0	No Reset
		1	Reset USB CLK Domain

Testmode Register

The USB_TESTMODE register places the USB controller into the test mode state and can also put the USB controller into one of the test modes for high-speed operation. For more information about these modes, see the USB 2.0 specification.

Note that the USB_TESTMODE register is not used in normal operation. Only one of the test mode (bits 0-6) selection bits may be set at a time.

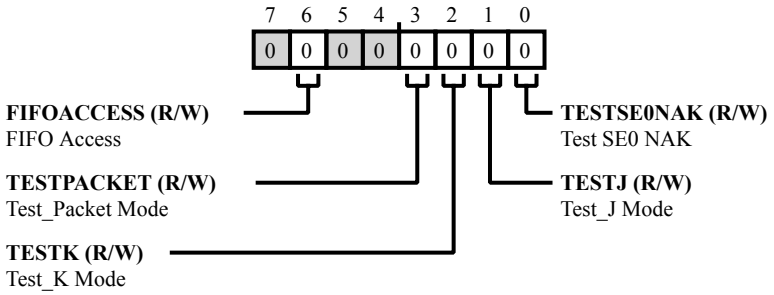

Figure 23-113: USB_TESTMODE Register Diagram

Table 23-89: USB_TESTMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	FIFOACCESS	FIFO Access. The USB_TESTMODE bit directs the USB controller to transfer the packet in the endpoint 0 Tx FIFO to the endpoint 0 Rx FIFO. The bit is cleared automatically.
3 (R/W)	TESTPACKET	Test_Packet Mode. The USB_TESTMODE.TESTPACKET bit selects Test_Packet test mode, which applies only when the USB controller is in high-speed mode. In this mode, the USB controller repetitively transmits on the bus a 53-byte test packet, whose form is defined in the USB 2.0 Specification, Section 7.1.20. Note that the test packet has a fixed format and must be loaded into the endpoint 0 FIFO before this test mode is entered.
2 (R/W)	TESTK	Test_K Mode. The USB_TESTMODE.TESTK bit selects Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.
1 (R/W)	TESTJ	Test_J Mode. The USB_TESTMODE.TESTJ bit selects Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.
0 (R/W)	TESTSE0NAK	Test SE0 NAK. The USB_TESTMODE.TESTSE0NAK bit selects Test_SE0_NAK test mode, which applies only when the USB controller is in high-speed mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.

Transmit FIFO Address Register

The USB_TXFIFOADDR register sets the start address for the selected Tx FIFO for endpoints 1-11. There is one transmit FIFO address register for each endpoint, except endpoint 0. The USB_TXFIFOADDR register is indexed and selected by the USB_INDEX register. Note that the endpoint 0 FIFO has a fixed 64-byte size and is always located at address 0.

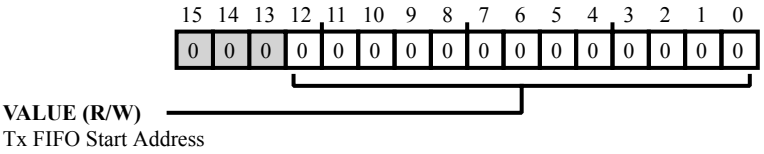

Figure 23-114: USB_TXFIFOADDR Register Diagram

Table 23-90: USB_TXFIFOADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VALUE	Tx FIFO Start Address. The USB_TXFIFOADDR.VALUE bits hold the start address of the selected endpoint FIFO (selected with the USB_INDEX register) in units of 8 bytes, according to the formula: FIFO address = USB_TXFIFOADDR.VALUE * 8

Transmit FIFO Size Register

The USB_TXFIFOSZ register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed access to the FIFO (packet) size selection for each Tx endpoint (except endpoint 0).

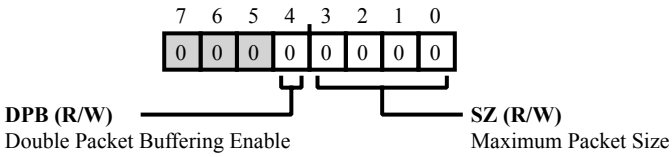

Figure 23-115: USB_TXFIFOSZ Register Diagram

Table 23-91: USB_TXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DPB	Double Packet Buffering Enable. The USB_TXFIFOSZ.DPB bit enables double packet buffering, doubling the FIFO (packet) size selected with the USB_TXFIFOSZ.SZ field.	
		0	Single Packet Buffering
		1	Double Packet Buffering
3:0 (R/W)	SZ	Maximum Packet Size. The USB_TXFIFOSZ.SZ bits select the maximum FIFO (packet) size according to the formula: FIFOSZ= $2^{(SZ+3)}$ If the USB_TXFIFOSZ.DPB is cleared, the FIFO size is FIFOSZ from this formula. If the USB_TXFIFOSZ.DPB is set, the FIFO is twice this size. For each enumeration value, the enumerations descriptions show the packet size (PktSz=), the FIFO size if DPB=0 (DPB0=), and the FIFO size if DPB=1 (DPB1=); these values are in bytes.	
		0	PktSz=8, DPB0=8, DPB1=16
		1	PktSz=16, DPB0=16, DPB1=32
		2	PktSz=32, DPB0=32, DPB1=64
		3	PktSz=64, DPB0=64, DPB1=128
		4	PktSz=128, DPB0=128, DPB1=256
		5	PktSz=256, DPB0=256, DPB1=512
		6	PktSz=512, DPB0=512, DPB1=1024
		7	PktSz=1024, DPB0=1024, DPB1=2048

Table 23-91: USB_TXFIFOSZ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		8	PktSz=2048, DPB0=2048, DPB1=4096
		9	PktSz=4096, DPB0=4096, DPB1=8192

VBUS Control Register

The USB_VBUS_CTL controls USB controller VBUS-related features.

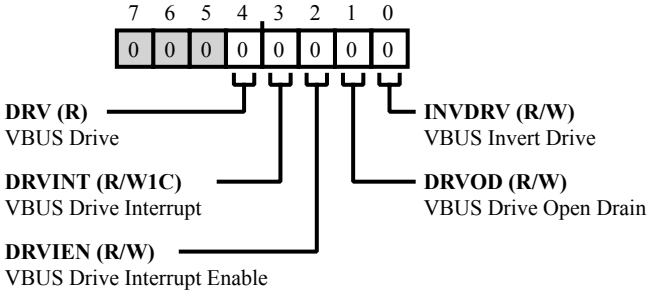

Figure 23-116: USB_VBUS_CTL Register Diagram

Table 23-92: USB_VBUS_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	DRV	VBUS Drive. The USB_VBUS_CTL.DRV bit indicates the state of the UTMI+ DrvVBUS signal from the USB controller.
3 (R/W1C)	DRVINT	VBUS Drive Interrupt. The USB_VBUS_CTL.DRVINT bit indicates the state of the DrvVBUSInt interrupt.
2 (R/W)	DRVIEN	VBUS Drive Interrupt Enable. The USB_VBUS_CTL.DRVIEN bit enables the DrvVBUS interrupt.
1 (R/W)	DRVOD	VBUS Drive Open Drain. The USB_VBUS_CTL.DRVOD selects whether the DrvVBUS output is open drain.
0 (R/W)	INVDRV	VBUS Invert Drive. The USB_VBUS_CTL.INVDRV bit selects whether the DrvVBUS output is inverted.

VBUS Pulse Length Register

The USB_VPLEN register defines the duration of the VBUS pulsing charge for SRP initiation.

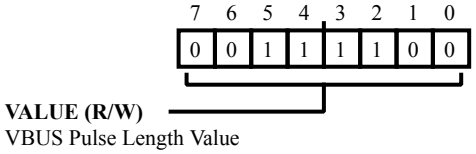

Figure 23-117: USB_VPLEN Register Diagram

Table 23-93: USB_VPLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	VBUS Pulse Length Value. The USB_VPLEN.VALUE bits sets the duration of the VBUS pulsing charge in units of 546.1us. The default setting corresponds to 32.77ms. Note that VBUS pulsing was removed in the OTG specification v2.0, section 5.1.4.

24 Media Local Bus (MLB)

Media Local Bus (MediaLB®) is an on-PCB or inter-chip communication bus, which allows an application to access the MOST network data. Media Local Bus supports all the MOST network data transport methods including synchronous stream data, asynchronous packet data, control message data and isochronous data. The MLB topology supports communication among the MLB controller and MLB devices, where the MLB controller is the interface between the MLB devices and the MOST network.

The MLB module serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. It supports up to 64 logical channels with up to 468 bytes of data per MediaLB frame. Transmit and receive data can be transferred between MediaLB and on-chip memory with DMA block transfers.

The MLB supports the MOST25, MOST50 and MOST150 standards and this document assumes familiarity with these standards. For more information, refer to the Media Local Bus specification version 4.2.

Features

The objective of MLB is to map all the MOST Network data types (transport methods) into a single low-cost, scalable, and standardized hardware interface between a MediaLB controller and at least one other MediaLB Device. The adoption of MediaLB simplifies the hardware interface, reduces the pin count, and facilitates the design of modular reusable hardware. From a software development perspective, the use of MediaLB relieves the system developer from the complexity of the MOST network, which simplifies software development and enables the design of reusable software for different applications. This simplified, standardized interface shortens time to market and makes software maintenance effortless.

- Compliant to Media Local Bus specification version 4.2
- Support MOST25, MOST50, MOST150 standards
- Support 3-pin and 6-pin mode
    - 6-pin mode supports a data rate of 2048 × FS
    - 3-pin mode support various data rates of 256 × FS, 512 × FS, 1024 × FS

- Support 64 logic channels
- Dedicated PLL for clock recovery and phase alignment
- Dedicated pins for 6-pin mode (LVDS)
- Shared pins for 3-pin mode
- Dedicated internal RAM for data buffering and channel table
- Recovered clock (after division) available out on a shared pin for DAI

NOTE: Only one MLB interface (3-pin mode or 6-pin mode) is active at any given time.

MLB Definitions

The following are standard MLB and MOST terms that are used in this chapter.

AGU

Address Generation Units. To access a particular HBI channel the HC must first configure one of two HBI address generation units. AGUs can be configured by writing the HBI command registers, HCMD0 and HCMD1.

CAT

Channel Allocation Table. The Channel Allocation Table (CAT) is comprised of 16 CTR entries. Each 16-bit CAT entry represents a logical connection to or from a transmit/receive device (for example MediaLB or HBI channel).

CDT

Channel Descriptor Table.

FCE

Flow Control Enable bit. The FCE bit is used by MediaLB isochronous Rx channels only.

HBI

Host Bus Interface. The HBI block provides 16-bit parallel slave access to all MOST channels and data types for the external Host Controller (HC). The HBI supports up to 64 independent channels.

HC

Host Controller (external).

HCMDx

HBI Command registers.

HSTSx

HBI status registers.

MFE

Multi-Frame per sub-buffer enable bit. The MFE bit is used by MediaLB synchronous channels only.

PML

Packet Message Length.

Clocking

The MLB controller provides an external clock pin—the media local bus clock. The MLB controller generates the clock. It is synchronized to the MOST network and provides the timing for the entire MLB interface at FS = 48 kHz.

Functional Description

The ***MediaLB Block Diagram*** figure shows the MLB high-level architecture. The MLB core serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. The MLB core has the following responsibilities.

- Transmit commands and data when functioning as the transmitting device associated with a *Channel Address*
- Receive data and transmit Rx status responses when functioning as the receiving device associated *Channel Address*
- MLB lock detection
- System channel command handling

The MediaLB device can function as either a MediaLB 3-pin interface (single-ended) or MediaLB 6-pin interface (differential) but only one interface can be active at a time. The MediaLB interfaces are capable of exchanging data at speeds up to 1024 × Fs in 3-pin mode or 2048 × Fs in 6-pin mode.

A set of physical channels for exchanging data over the MediaLB bus is supported. These physical channels (4 bytes in length, or a quadlet) can be grouped into logical channels, where each logical channel is referenced using a channel address and represents a uni-directional datapath between a specific MediaLB device transmitting the data and the MediaLB device(s) receiving the data. The MediaLB 6-pin interface provides support for up to 468 bytes of data per frame. The logical channels, configured by system software, can be any combination of channel types (synchronous, asynchronous, isochronous, or control) and direction (transmit or receive).

ADSP-SC57x MLB Register List

The MediaLB Device Interface Macro 2 (MediaLB DIM 2), also referred to as OS62420, implements the required functionality of a Media Local Bus (MediaLB) device. This logic serves as an interface between the inter-chip MediaLB bus and a customer IC, implementing the physical- and link-layer requirements outlined in the MediaLB Specification.

143	MLB0_STAT	MLB0 Status		

MediaLB Protocol

The MediaLB topology supports communication among all MediaLB devices, including the MediaLB controller. The bus interface consists of a uni-directional line for clock (MLBC), a bidirectional line for signal information (MLBS), and a bidirectional line for data transfer (MLBD). The MediaLB topology supports one controller connected to one or more devices, where the controller is the interface between the MediaLB devices and the MOST network.

The MediaLB controller includes MediaLB device functionality, and also generates the MediaLB clock (MLBC) that is synchronized to the MOST Network. This generated clock provides the timing for the entire MediaLB interface. The MLBS line is a multiplexed signal which carries channel addresses generated by the MediaLB controller, as well as command and RxStatus bytes from MediaLB devices. The MLBD line is driven by the transmitting MediaLB device and is received by all other MediaLB devices, including the MediaLB controller. The MLBD line carries the actual data (synchronous, asynchronous, control, or isochronous).

Once per MOST network frame, the MLB controller generates a unique frame sync pattern on the MLB_SIG line. The end of the frame sync pattern defines the byte boundary and the channel boundary for the MLB_SIG and MLB_DAT lines of all MLB devices.

The MLB controller manages the arbitration for all the channels on the MLB and grants bandwidth for all the MLB devices. An MLB *physical channel* is defined as four bytes wide, or a quadlet. Physical channels can be grouped into multiple quadlets (which do not have to be consecutive) to form an MLB *logical channel*, which is defined by a unique channel address.

As shown in ***MLB Data Structure***, the MLB controller initiates communication by sending out a channel address on the MLB_SIG line for each physical channel. The channel address indicates which MLB device is transmitting and which MLB devices are receiving in the following physical channel. Therefore, four bytes after the controller outputs the channel address on the MLB_SIG line, the transmitting device outputs a command byte command on the MLB_SIG line and outputs the respective data on the MLB_DAT line, concurrently. The MLB command byte contains the type of data currently being transmitted (for example synchronous, asynchronous or control).

The MLB device receiving the channel data outputs a status byte, RxStatus, on the MLB_SIG line immediately after the transmitting device outputs the command byte. The status response can indicate that the receiving device is busy and cannot receive the data at present, or the device is ready to receive the data. Since synchronous stream data is sent in a broadcast fashion, receiving devices cannot return a busy status and should not drive RxStatus onto the MLB_SIG line.

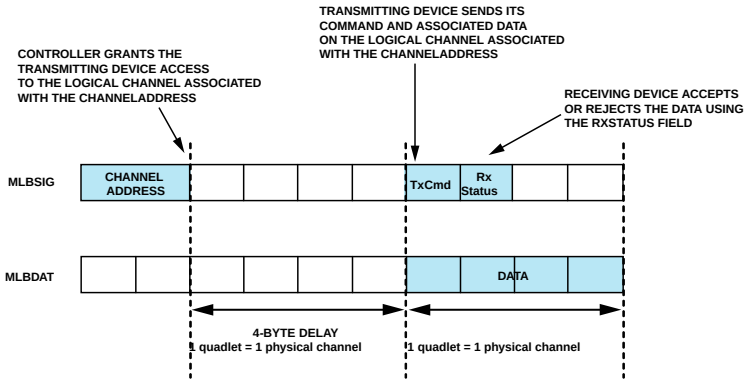

Figure 24-1: MLB Data Structure

MLB Architectural Concepts

The following sections provide information about the MLB architecture.

MediaLB Block Diagram

The ***MediaLB Block Diagram*** shows the various blocks within the interface its connections to the processor.

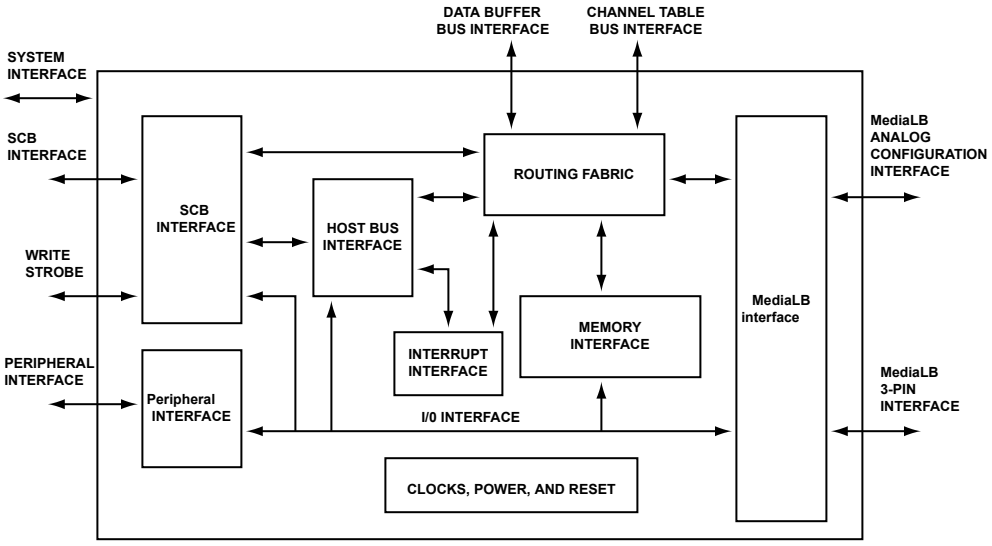

Figure 24-2: MediaLB Block Diagram

MediaLB Interface

The Media Local Bus (MediaLB) block supports both a MediaLB 3-pin interface and MediaLB 6-pin interface; however, only one MediaLB interface can be active at any given time. Both MediaLB interfaces provide real-time access to all network data types - synchronous, asynchronous, control, and isochronous data.

- MediaLB 3-pin interface – Supports the MediaLB protocol for single-ended 3-pin mode, with a maximum data rate of 1024 FS (49.152 MHz at FS = 48 kHz).
- MediaLB 6-pin interface – Supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data

  maximum data rate of 2048 FS (98.304 MHz at FS = 48 kHz).

MediaLB Channel Address to Logical Channel Mapping

The MediaLB channel addresses are mapped to the logical channels as shown in the ***MediaLB Channel Address to Logical Channel Mapping*** table.

Table 24-3: MediaLB Channel Address to Logical Channel Mapping

Channel Address	Logical Address
0x0002	1
0x0004	2
0x0006	3
...	...
0x007C	62
0x007E	63

Table 24-3: MediaLB Channel Address to Logical Channel Mapping (Continued)

Channel Address	Logical Address
0x01FE	0 (Logical channel 0 is the system channel and is reserved)

Routing Fabric

The Routing Fabric (RF) block manages the flow of data between the MediaLB port and the HBI port. It manages accessing the Channel Table RAM (CTR) and Data Buffer RAM (DBR), which are explained in the following sub-sections. The routing fabric uses channel descriptors (stored in the CTR) to manage access to dynamic buffers in the DBR.

Data Buffer RAM

The Data Buffer RAM (DBR) is an 8-bit x 16k entries deep, single-port synchronous SRAM and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the Channel Descriptor Table (CDT), which is located in the Channel Table RAM (CTR), described in following sections.

Channel Table RAM

The Channel Table RAM (CTR) is a 128-bit x 144-entry table that allows system software to dynamically configure channel routing and allocate data buffers in the DBR. The CTR is logically divided into three tables:

- Channel Descriptor Tables
- AHB Descriptor Table (ADT)
- Channel Allocation Table

Address Mapping

The ***CTR Address Mapping*** table shows the address mapping for the CTR.

Table 24-4: CTR Address Mapping

Label	Address	Bits [127:96]	Bits [95:64]	Bits [63:32]	Bits [31:0]
Channel Descriptor Table (CDT)					
CDT	0x00	CDT0[127:0], CL = 0			
	0x01	CDT1[127:0], CL = 1			
	0x02	CDT2[127:0], CL = 2			
	...

	...	...	...	...	...	...	...	...	...
	0x8F	CAT127	CAT126	CAT125	CAT124	CAT123	CAT122	CAT121	CAT120

*1 A fixed relationship exists between ADT entries and HBI CAT entries. When using HBI channel 0 (CAT64), program ADT0. When using HBI channel 1 (CAT65), program ADT1, and so on.

Channel Allocation Table

The ***Channel Allocation Table (CAT)*** table is comprised of 16 CTR entries (addresses 0x80 0x8F) as shown in the ***CTR Entry Map*** table. Each 16-bit CAT entry represents a logical connection to or from a transmit or receive device. (for example, MediaLB channel). All entries are indexed according to a fixed physical address assigned to every RX/TX channel as shown in the ***CAT Entry Formats*** table. The value stored in a CAT entry includes a 6-bit connection label, which provides a pointer to the CDT. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the RX and TX channels.

Table 24-5: CAT Entry Map

Peripheral	TX Channels	RX Channels	CAT Start Index	CAT End Index	Entries
MediaLB	0 to 64	64 TX Channels	0	63	64
HBI	0 to 64	64 TX Channels	64	127	64

The format of a full CAT entry is shown in the ***CAT Entry Formats*** table, with field descriptions described in the ***CAT Field Definitions*** table. All reserved bits of a CAT entry field should be written as zero.

Table 24-6: CAT Entry Formats

Channel Type	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Isochronous	rsvd	FCE	rsvd	RNW	CE	CT[2:0] = 011			rsvd		CL[5:0]					
Asynchronous	rsvd		MT	RNW	CE	CT[2:0] = 010			rsvd		CL[5:0]					
Control	rsvd		MT	RNW	CE	CT[2:0] = 001			rsvd		CL[5:0]					
Synchronous	rsvd	MFE	MT	RNW	CE	CT[2:0] = 000			rsvd		CL[5:0]					

Table 24-7: CAT Field Definitions

Field	Description
CL[5:0]	Connection Label (offset into CDT)
CT[2:0]	Channel Type (others) 111 = Reserved 110 = Reserved 101 = Reserved 100 = Reserved 011 = Isochronous 010 = Asynchronous 001 = Control 000 = Synchronous
CE	Channel Enable. 0 = Disabled, 1 = Enabled
RNW	Read Not Write. 0 = Write, 1 = Read
MT	Mute Enable. 0 = Disabled When set for synchronous channels, the MT bit forces RX channels to write zeros into the channel data buffer, and TX channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.
FCE	Flow Control Enable. 0 = Disabled, 1 = Enabled The FCE bit is used by MediaLB isochronous RX channels only.
MFE	Multi-Frame per sub-buffer enable. 0 = Disabled, 1 = Enabled The MFE bit is used by MediaLB synchronous channels only.
rsvd	Reserved. Software writes a 0 to all reserved bits when the entry is initialized. These bits are read-only after initialization.

Channel Set Up

Data direction is in reference to the DBR. The data direction of CAT entries corresponding to the same channel is reversed for the HBI CAT and the MediaLB CAT.

- For a Tx channel (from the HC to the MediaLB interface):
    - HBI CAT entry: RNW = 0 (write)

- MediaLB CAT entry: RNW = 1 (read)

- Conversely, for an Rx channel (data from MediaLB to HC):
  - HBI CAT entry: RNW = 1 (read)
  - MediaLB CAT entry: RNW = 0 (write)

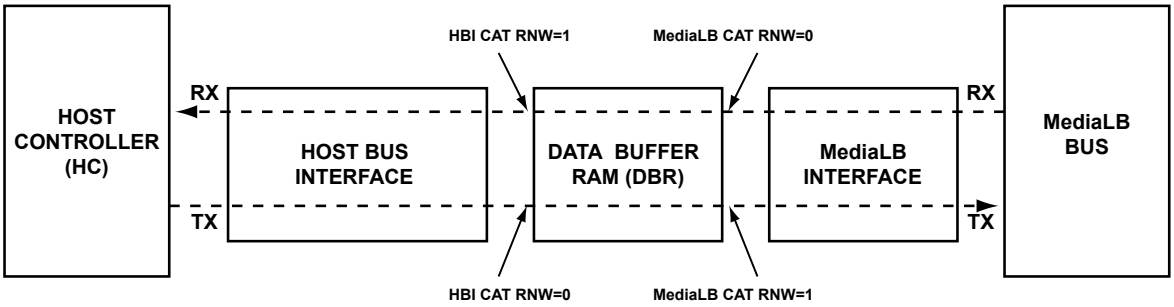

Figure 24-3: DBR Directional Relationship

Channel Descriptor Tables

The Channel Descriptor Table (CDT) is comprised of 64 CTR entries (addresses 0x00 - 0x3F), as shown in the Table 24-4 CTR Address Mapping table. Each 128-bit CDT entry (also referred to as a channel descriptor) is referenced by a connection label and contains information about a data buffer in the DBR (for example buffer size, address pointers). The format of each CDT entry is dependent on the channel type (synchronous, isochronous, asynchronous, or control).

NOTE: All reserved channel descriptor bits must be written to 0 by software when initialized.

Synchronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the ***Synchronous CDT Entry Format*** and ***Synchronous CDT Entry Field Definitions*** tables.

Table 24-8: Synchronous CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

48	Reserved															
64	WSTS[3:0]				WPTR[11:0]											
80	RSTS[3:0]				RPTR[11:0]											
96	Reserved				BD[11:0]											
112	Reserved		BA[13:0]													

Table 24-9: Synchronous CDT Entry Field Definitions

Field	Description	Details	Access
BA	Buffer Base Address	Can start at any byte in the 16k DBR	RW
BD	Buffer Depth	BD = size of buffer in bytes 1. Buffer end address = BA + BD. BD = 4 m bpf 1 where: m = frames per sub-buffer (for MFE = 0, m = 1) bpf = bytes per frame.	RW
RPTR	Read Pointer	Software initializes to 0, hardware updates. Counts the read address offset within a buffer. DMA read address = BA + RPTR.	RWU
WPTR	Write Pointer	Software initializes to 0, hardware updates. Counts the write address offset within a buffer. DMA read address = BA + WPTR.	RWU
RSBC	Read Sub-buffer Counter	Software initializes to 0, hardware updates. Counts the read sub-buffer offset. DMA uses for pointer management.	RWU
WSBC	Write Sub-buffer Counter	Software initializes to 0, hardware updates. Counts the write sub-buffer offset. DMA uses for pointer management.	RWU
RSTS	Read Status	Software initializes to 0, hardware updates. RSTS States: xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle	RWU
WSTS	Write Status	Software initializes to 0, hardware updates. WSTS States: xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle 1xxx = command protocol error	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

Isochronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the ***Isochronous Entry Formats*** and ***Isochronous CDT Entry Field Definitions*** tables.

Table 24-10: Isochronous Entry Formats

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	Reserved

80	RSTS[3:0]				RPTR[12:0]											
96	Reserved				BD[12:0]											
112	BF	Rsvd		BA[13:0]												

Table 24-11: Isochronous CDT Entry Field Definitions

Field	Description	Details	Access
BA	Buffer Base Address	Can start at any byte in the 16k DBR.	RW
BD	Buffer Depth	BD = size of buffer in bytes 1. Buffer end address = BA + BD. Isochronous buffers must be large enough to hold at least 3 blocks (packets) of data. BD Must be an integer multiple of blocks.	RW
BF	Buffer Full	Software initializes to 0, hardware updates. DMA write hardware sets BF when the buffer is full. DMA read hardware clears BF when the buffer is empty. BF is valid only when buffer is full or empty, otherwise ignore.	RWU
BS	Block Size	BS defines when to begin the DMA to the data buffer. BS = buffer block size in bytes 1. For RX channels, the DMA writes start when the number of empty bytes in the data buffer the block size. For TX channels, the DMA reads start when the number of valid bytes in the data buffer the block size.	RWU
RPTR	Read Pointer	Software initializes to 0, hardware updates. Counts the read address offset within a buffer. DMA read address = BA + RPTR.	RWU
WPTR	Write Pointer	Software initializes to 0, hardware updates. Counts the write address offset within a buffer. DMA write address = BA + WPTR.	RWU

Table 24-11: Isochronous CDT Entry Field Definitions (Continued)

Field	Description	Details	Access
RSTS	Read Status	Software initializes to 0, hardware updates. RSTS States: xx1 = active xx0 = idle	RWU
WSTS	Write Status	Software initializes to 0, hardware updates. WSTS States: xxx0 =active xxx1 = idle xx0x = command protocol error 1xxx = buffer overflow (FCE = 0 only)	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

Asynchronous/Control Channel Descriptors

The format and field definitions for an Asynchronous/Control CDT entry are shown in the ***Asynchronous/Control CDT Entry Format*** and ***Asynchronous/Control CDT Entry Field Definitions*** tables.

Table 24-12: Asynchronous/Control CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-13: Asynchronous/Control CDT Entry Field Definitions

Field	Description	Details	Access
BA	Buffer Base Address	Can start at any byte in the 16k DBR.	RW
BD	Buffer Depth	BD = size of buffer in bytes 1. Buffer end address = BA + BD. BD = max packet length 1.	RW

Table 24-13: Asynchronous/Control CDT Entry Field Definitions (Continued)

Field	Description	Details	Access
RPC	Read Packet Count	Software initializes to 0, hardware updates. Used with RPC, RPTR and WPTR to determine if the buffer is empty or full.	RWU
WPC	Write Packet Count	Software initializes to 0, hardware updates. Used with RPC, RPTR and WPTR to determine if the buffer is empty or full.	RWU
RPTR	Read Pointer	Software initializes to 0, hardware updates. Counts the read address offset within a buffer. DMA read address = BA + RPTR.	RWU
WPTR	Write Pointer	Software initializes to 0, hardware updates. Counts the write address offset within a buffer. DMA read address = BA + WPTR.	RWU
RSTS	Read Status	Software initializes to 0, hardware updates. RSTS States: x0x00 = idle xx1xx = *ReceiverProtocolError* response received from RX device 1xxxx = *ReceiverBreak* command received from RX device	RWU
WSTS	Write Status	Software initializes to 0, hardware updates. Status States (only valid for DMA pointers associated with the MLB block, not HBI block pointers): xxx0 = idle xxx1 = command protocol error detected xx0x = *AsyncBreak*/*ControlBreak* command received from TX device	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

AHB Descriptor Table (ADT)

The AHB block manages data exchange between local channel data buffers within MLB module and the system memory buffer. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for AHB Descriptor Table (ADT) entries. The Table 24-4 CTR Address Mapping table provides a complete address map of the CTR, including the location of the ADT.

Each logical channel is assigned a separate 128-bit descriptor, defining the data buffers in the system memory used by the DMA interface for that channel. The descriptors are stored at fixed addresses in the CTR as described in previous section. The ***ADT Field Definitions*** table provides an overview of field definitions for ADT entries.

Table 24-14: ADT Field Definitions

Field	No. of Bits	Description	Access
CE	1	Channel Enable. 0 = Disabled	RW, U
LE	1	Endianness Select. 0 = Big Endian, 1 = Little Endian	RW
PG	1	Page pointer. Software initializes to 0, hardware writes thereafter. 0 = Ping buffer, 1 = Pong buffer	RW, U
RDY1	1	Buffer Ready bit for ping buffer page. 0 = Not ready, 1 = Ready	RW
RDY2	1	Buffer Ready bit for pong buffer page. 0 = Not ready, 1 = Ready	RW
DNE1	1	Buffer Done bit for ping buffer page. 0 = Not done, 1 = Done	R, U, c0
DNE2	1	Buffer Done bit for pong buffer page. 0 = Not done, 1 = Done	R, U, c0
ERR1	1	Error Response detected for ping buffer page. 0 = No error, 1 = Error	R, U, c0
ERR2	1	Error Response detected for pong buffer page. 0 = No error, 1 = Error	R, U, c0
PS1	1	Packet Start bit for ping buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
PS2	1	Packet Start bit for pong buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
MEP1	1	Most Ethernet Packet indicator for ping buffer page. 0 = Not MEP, 1 = MEP. MEP1 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
MEP2	1	Most Ethernet Packet indicator for pong buffer page. 0 = Not MEP, 1 = MEP. MEP2 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
BD1	11 to 13	Buffer Depth for ping buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BD2	11 to 13	Buffer Depth for pong buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BA1	32	Buffer Base Address for ping buffer page	RW
BA2	32	Buffer Base Address for pong buffer page.	RW
Reserved	varies	Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.	RW, U

The ***Ping-Pong System Memory Structure*** figure shows that this system memory structure is similar for all channel types and shows the relationship between the BAn, BDn, and PG descriptor fields.

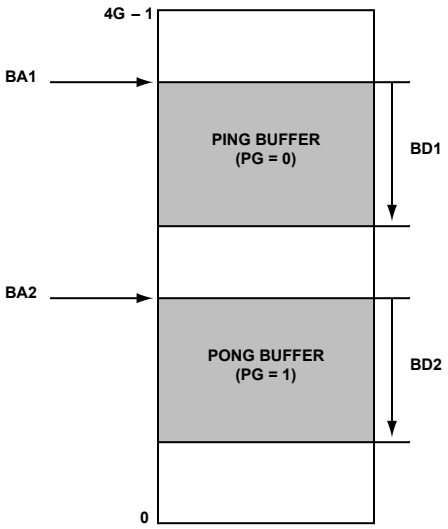

Figure 24-4: Ping-Pong System Memory Structure

Each ADT entry (also referred to as a *Channel Descriptor)* holds a 32-bit BAn field which defines the start of each ping or pong buffer within system memory. The BDn field is used to indicate the size for the respective ping or pong page. The maximum size is 2k entries for asynchronous and control channels and 8k entries for isochronous and synchronous channels.

Synchronous Channel Descriptors

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDn) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (for example BDn = n m bpf 1). The ***Synchronous ADT Entry Format*** table shows the format for a synchronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each synchronous channel buffer can be up to 8k-bytes deep.

Table 24-15: Synchronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDn) must be defined in terms of an integer number (n) and block size (BS) (for example BDn = n (BS + 1) 1).

The ***Isochronous ADT Entry Format*** table shows the format for an isochronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 24-16: Isochronous ADT Entry Format

112	BA2[31:16]															

Asynchronous and Control Channel Descriptors

Every asynchronous and control packet adheres to the Port Message Protocol (PMP), which designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048-bytes (PML 2048).

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt to inform HC. When hardware finishes processing a buffer, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two packet buffering modes are supported by hardware for programming the DMA, single-packet mode (`MLB_ACTL.MPB` =0) and multiple-packet mode (`MLB_ACTL.MPB` =1). The MPB is written prior to enabling the channel DMA.

Single Packet Mode. The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (for example, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (for example, ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers.

The ***Single-Packet Asynchronous and Control Entry Format*** table shows the format for single-packet mode asynchronous and control ADT entries. The field definitions are defined in the ***ADT Field Definitions*** table.

Table 24-17: Single-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Multiple Packet Mode. The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in the ***Asynchronous/Control CDT Entry Format*** table. Multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For TX packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For TX packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for TX packet channels in multiple-packet mode.

NOTE: The PS1 and PS2 bits are only valid for TX channels. Set PS1 and PS2 = 1 at the start of the buffer.

Table 24-18: Multiple-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

112	BA2[31:16]															

Interrupt Interface Block

The interrupt interface raises an interrupt when specific changes to HBI channel descriptors occur, including:

- For asynchronous and control read/write channels:
  - a packet is available to read in the channel buffer, or
  - sufficient empty space is available in the channel buffer to accept a requested packet write
- For isochronous read/write channels:
  - the number of valid bytes in the channel buffer exceeds the block size, or
  - the number of empty bytes in the channel buffer exceeds the block size

Operating Modes

The following sections describe the operating modes of the MLB interface. The channel type selection enables the logical channels to operate in synchronous, asynchronous, isochronous, or control channels.

NOTE: The logical channels can be any combination of channel type (for example synchronous, asynchronous, or control) and direction (transmit or receive).

Isochronous Data Exchange

An isochronous HBI channel is initially opened and synchronized with HCMD0.CMD[2:0]= 010. For isochronous channels, no further synchronization is required from the HBI perspective; however, an optional resynchronization command is available for HC flexibility. Setting HCMD0.CMD[2:0]= 011 reinitializes the address pointer within the data buffer, ensuring that subsequent data exchange with the channel is aligned at an isochronous packet boundary. When the HC must close an isochronous channel before it has read or written an entire data packet, setting HCMD0.CMD[2:0]= 000 reopens the channel without synchronizing the address pointer in the buffer. This action allows reading and writing to continue where the HC previously stopped.

For isochronous data transmission, the ***Exchanging Isochronous Data on an HBI Channel*** figure shows the flow control.

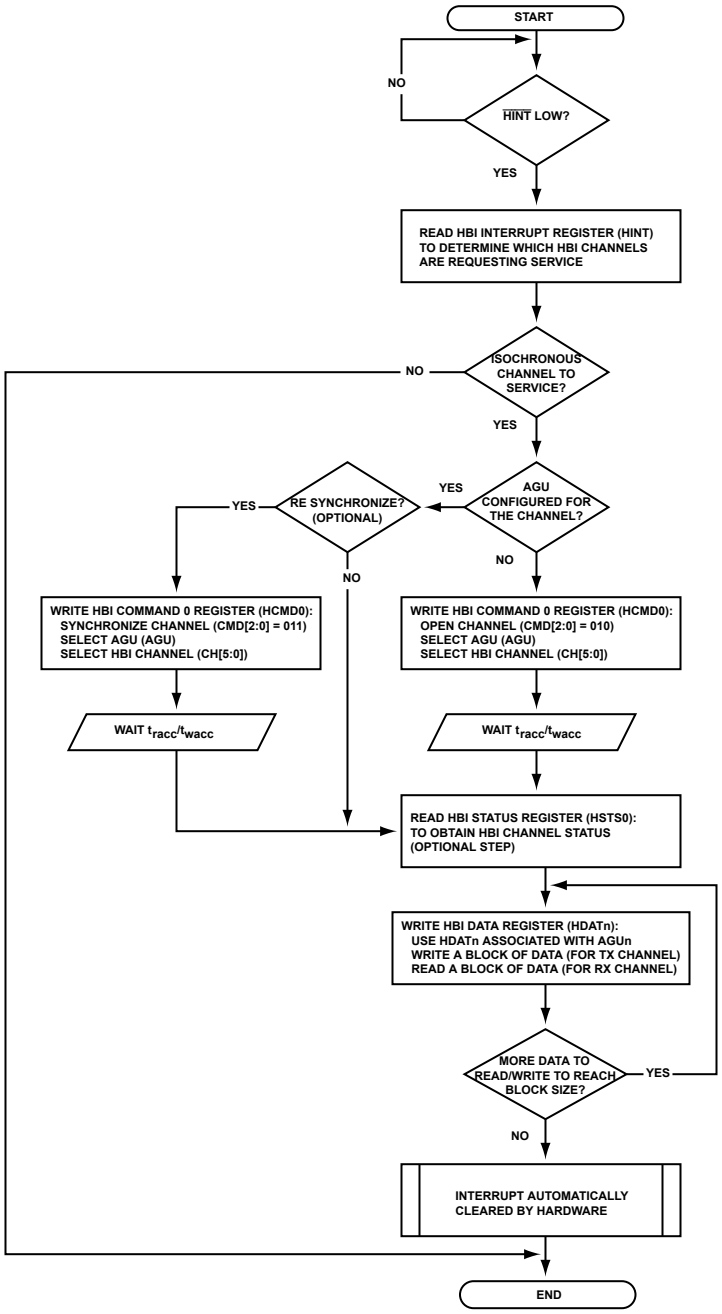

Figure 24-5: Exchanging Isochronous Data on an HBI Channel

Asynchronous and Control Data Exchange

An asynchronous or control HBI channel is initially opened using HCMD0.CMD[2:0]= 010. Occasionally, the HC may need to close a packet channel before it has completed writing or reading the current packet of data (for example, the HC needs to use this AGU to service another HBI channel). In this case, the HC can reopen the previous channel with HCMD0.CMD[2:0]= 000. This situation allows the HC to continue writing or reading a packet from

the point it left off. In this situation, the PML is already known and the packet length is not reread or rewritten by the HC.

During the reading of a packet, if the HC sets HCMD0.CMD[2:0]= 010 for the channel before the last byte of the packet is read, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC reread the PML (from HSTS1) and reread the packet data (from HDATn) from the beginning. In the same manner, if the HC resets HCMD0.CMD[2:0]= 010 for the channel before the last byte of a packet is written, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC rewrite the PML (to HCMD1) and rewrite the packet data (to HDATn) from the beginning. Any previous packet data in the buffer is overwritten.

Frame synchronization is not supported for asynchronous channels.

Synchronous Data Exchange

The MLB core provides two modes of operation; standard and multi-frame per sub-buffer which provide flexibility for implementing synchronous channels. Channels configured for standard mode require less buffer space, but have higher interrupt rates and more stringent latency requirements. Channels setup for multi-frame per sub-buffer mode require more buffer space, but have lower interrupt rates and less stringent latency requirements.

To set up a channel in multi-frame per sub-buffer mode:

1. Program the `MLB_CTL0.FCNT` bit field to select the number of frames per sub-buffer.
2. Program the CAT to enable multi-frame sub-buffering (MFE= 1) for each particular channel.
3. Set the buffer depth in the CDT: BD= 4 × m × bpf 1 where: m = frames per sub-buffer, bpf = bytes per frame.
4. Repeat for additional synchronous channels

A sample synchronous data buffer is shown in the ***Synchronous Data Buffer Structure*** figure. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by the `MLB_CTL0.FCNT` bits.

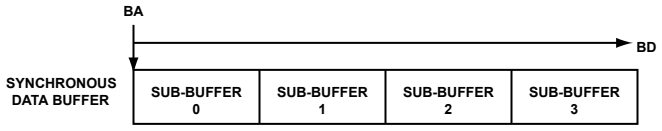

Figure 24-6: Synchronous Data Buffer Structure

Data Transfer

Two modes of operation are supported for transferring channel data between the MLB and internal memory. DMA allows the multi-channel DMA engine to manage data transfers without core intervention. Core driven mode (I/O mode) allows software to manage the transfer of data between MLB and internal memory.

NOTE: All hardware channels must use the same data transfer method. Mixed mode operation where hardware channels operate in both I/O mode and DMA mode is not supported.

DMA

The processor supports DMA mode which uses only INCR8, INCR4 and SINGLE beat bursts. Program the `MLB_ACTL.DMAMODE` = 1 to use DMA mode.

Programming Model

This section provides general guidelines for programming the MediaLB interface.

Channel Initialization

The software flow required to initialize a channel must be performed in order to ensure proper operation.

Configure the Hardware

1. Initialize the CTR and registers.
    a. Set all the CTR (CAT, CDT, and ADT) bits to 0.
    b. Set all bits of all registers to 0.
2. Configure the MediaLB interface.
    a. Select 3-pin or 6-pin MediaLB operation: `MLB_CTL0.PEN` =0 (3-pin), `MLB_CTL0.PEN` =1 (6-pin).
    b. Select MediaLB clock speed via `MLB_CTL0.CLK`.
    c. Set MediaLB enable via `MLB_CTL0.EN`.
3. Configure the HBI interface.
    a. Set `MLB_HCMR0` and `MLB_HCMR1` = 0xFFFFFFFF to activate all channels.
    b. Set the HBI enable bit: `MLB_HCTL.EN` =1.

Program the CAT and the CDT

1. Initialize all bits of the CAT to 0.
2. Select a logical channel: N = 1 – 63.
3. Program the CDT for channel N.
    a. Set the 14-bit base address (BA)
    b. Set the 12-bit or 13-bit buffer depth (BD): BD = buffer depth in bytes 1
    - For synchronous channels: (BD + 1) = 4 frames per sub-buffer (m) bytes-per-frame (bpf)
    - For isochronous channels: (BD + 1) mod (BS + 1) = 0

- For asynchronous channels: (BD + 1) max packet length (1024 for a MOST Data Packet (MDP)
- 1536 for a MOST Ethernet Packet (MEP)
- For control channels: (BD + 1) max packet length (64)

4. Program the CAT for the inbound DMA.
    a. For TX channels (to MediaLB) HBI is the inbound DMA
    b. For RX channels (from MediaLB) MediaLB is the inbound DMA
    c. Set the channel direction: RNW = 0
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the connection label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
5. Program the CAT for the outbound DMA.
    a. For TX channels (to MediaLB) HBI is the outbound DMA
    b. For RX channels (from MediaLB) MediaLB is the outbound DMA
    c. Set the channel direction: RNW = 1
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the channel label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
6. Repeat steps 2 through 5 to initialize all logical channels.

Program the ADT

1. Initialize all bits of the ADT to 0
2. Select a logical channel: N = 1 – 63
3. Program the AMBA AHB block ping page for channel N
    a. Set the 32-bit base address (BA1)

b. Set the 11-bit buffer depth (BD1): BD1 = buffer depth in bytes – 1
   - For synchronous channels: (BD1 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
   - For isochronous channels: (BD1 + 1) mod (BS + 1) = 0
   - For asynchronous channels: 5 (BD1 + 1) 4096 (max packet length)
   - For control channels: 5 (BD1 + 1) 4096 (max packet length)

c. For asynchronous and control Tx channels set the packet start bit (PS1) iff the page contains the start of the packet

d. Clear the page done bit (DNE1)

e. Clear the error bit (ERR1)

f. Set the page ready bit (RDY1)

4. Program the AMBA AHB block pong page for channel N

a. Set the 32-bit base address (BA2)

b. Set the 11-bit buffer depth (BD2): BD2 = buffer depth in bytes – 1
   - For synchronous channels: (BD2 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
   - For isochronous channels: (BD2 + 1) mod (BS + 1) = 0
   - For asynchronous channels: 5 (BD2 + 1) 4096 (max packet length)
   - For control channels: 5 (BD2 + 1) 4096 (max packet length)

c. For asynchronous and control TX channels set the packet start bit (PS2) iff the page contains the start of the packet

d. Clear the page done bit (DNE2)

e. Clear the error bit (ERR2)

f. Set the page ready bit (RDY2)

5. Select Big Endian (LE = 0) or Little Endian (LE = 1)
6. Select the active page: PG = 0 (ping), PG = 1 (pong)
7. Set the channel enable (CE) bit for all active logical channels
8. Repeat steps 2 through 7 for all active logical channels.

Service

After initialization, each channel will require periodic servicing. Use the procedures in the following sections to service DMA and MLB interrupts and to poll for MLB system commands.

Servicing the DMA Channel Interrupts

1. Program the MLB_ACMR0/MLB_ACMR1 registers to enable interrupts from all active DMA channels.
2. Select the status clear method. MLB_ACTL.SCE =0 (hardware clears on read), MLB_ACTL.SCE = 1 (software writes a 1 to clear).
3. Select 1 or 2 interrupt signals. Configure the MLB_ACTL.SMX bit =0 (one interrupt for channels 0 through 31 and another interrupt for channels 32 through 63 on). Configure the MLB_ACTL.SMX bit =1 (single interrupt for all channels).
4. Wait for an interrupt.
5. Read the MLB_ACSR0/MLB_ACSR1 registers to determine which channel or channels are causing the interrupt.
6. If the MLB_ACTL.SCE bit =1, write the results of step 5 back to the MLB_ACSR0 and MLB_ACSR1 registers to clear the interrupt.
7. Select a logical channel (N = 0 – 63) with an interrupt to service.
8. Read the ADT entry for channel N to:
    a. Determine the active page (ping or pong) via the PG bit
    b. Determine which page(s) are done via the DNEn bits
    c. Determine which channels encountered an AHB error via the ERRn bit
    d. Determine which asynchronous and control Rx channel pages contain a packet start via the PSn bit (extract the PML)
9. Repeat steps 6 through 8 for all channels with pending interrupts
10. Repeat steps 4 through 9 while there are active channels.

Servicing the MediaLB Status Interrupts

1. Select the MediaLB channel status register (MLB_MS0/MLB_MS1) to be cleared by software, writing a 0 to the appropriate bits.
2. Program the MLB_MIEN register to enable protocol error interrupts for all active MediaLB channels. (MLB_MIEN.CTXPE =1, MLB_MIEN.CRXPE =1, MLB_MIEN.ATXPE =1, MLB_MIEN.ARXPE =1, MLB_MIEN.SYNCPE =1, and MLB_MIEN.ISOCPE =1).
3. Wait for an interrupt on the MLB_INT0/MLB_INT1 signal.
4. Read the MLB_MS0/MLB_MS1 registers to determine which channel(s) are causing the interrupt.
5. Read the RSTS/WSTS of the appropriate CDT(s) to determine the interrupt type.

6. Clear the RSTS/WSTS errors to ensure that the current status of channel operations is reflected in the register:

Option	Description
For synchronous RX channels	WSTS[3] = 0
For synchronous TX channels	RSTS[3] = 0
For isochronous RX channels	WSTS[2:1] = 00
For isochronous TX channels	RSTS[2:1] = 00
For asynchronous and control RX channels	WSTS[4] = 0 and WSTS[2] = 0
For asynchronous and control TX channels	RSTS[4] = 0 and RSTS[2] = 0

Polling for MediaLB System Commands

The MediaLB System status (`MLB_MSS`) register is used to detect a system command received from the MediaLB controller. The processor's peripheral automatically sends the appropriate system response to the MediaLB controller. The procedure for the application is:

1. The application periodically polls the `MLB_MSS` register.
2. Clear by writing a 0 to the appropriate bit in the `MLB_MSS` register after the application finishes the service.
3. If `MLB_MSS.SWSYSCMD` = 1, read the `MLB_MSD` register to receive the system data sent from MediaLB controller.

ADSP-SC57x MLB Register Descriptions

MediaLB Device Interface Macro 2 (MLB) contains the following registers.

Table 24-19: ADSP-SC57x MLB Register List

Name	Description
`MLB_ACMR0`	Peripheral Channel Mask 0 Register
`MLB_ACMR1`	Peripheral Channel Mask 1 Register
`MLB_ACSR0`	Peripheral Channel Status 0 Register
`MLB_ACSR1`	Peripheral Channel Status 1 Register
`MLB_ACTL`	Bus Control Register
`MLB_CTL0`	MediaLB Control 0 Register
`MLB_CTL1`	Control 1 Register
`MLB_GCTL`	MLB Global Control Register
`MLB_HCBR0`	HBI Channel Busy 0 Register
`MLB_HCBR1`	HBI Channel Busy 1 Register

Table 24-19: ADSP-SC57x MLB Register List (Continued)

Name	Description
MLB_HCER0	HBI Channel Error 0 Register
MLB_HCER1	HBI Channel Error 1 Register
MLB_HCMR0	HBI Channel Mask 0 Register
MLB_HCMR1	HBI Channel Mask 1 Register
MLB_HCTL	HBI Control Register
MLB_MADR	Memory Interface Address Register
MLB_MCTL	Memory Interface Control Register

MLB_MS0	Channel Status 0 Register
MLB_MS1	Channel Status 1 Register
MLB_MSD	System Data Register
MLB_MSS	System Status Register
MLB_PCTL0	MediaLB 6-pin Control 0 Register

Peripheral Channel Mask 0 Register

The MLB_ACMR0 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR0 register to enable interrupts. Each bit of this register is read/write accessible.

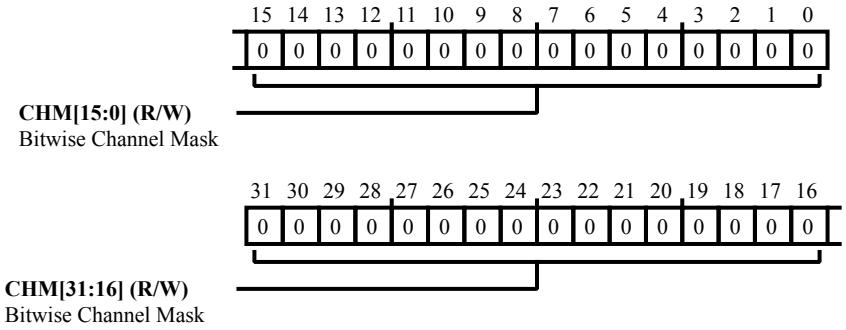

Figure 24-7: MLB_ACMR0 Register Diagram

Table 24-20: MLB_ACMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR0.CHM bit field masks or unmasks channels 31-0.	
		0	Mask interrupt for Channel 31:0 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Mask 1 Register

The MLB_ACMR1 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR1 register to enable interrupts. Each bit of this register is read/write accessible.

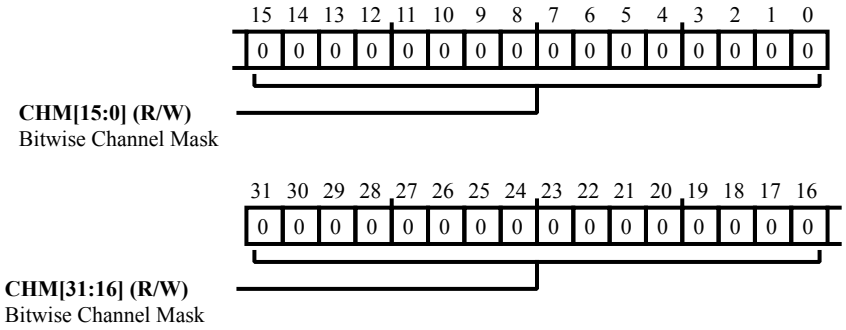

Figure 24-8: MLB_ACMR1 Register Diagram

Table 24-21: MLB_ACMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR1.CHM bit field masks or unmasks channels 63-32.	
		0	Mask interrupt for Channel 63:32 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 63:32 (bitwise; all channels shown)

Peripheral Channel Status 0 Register

The MLB_ACSR0 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR0 and MLB_ACSR1 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of the peripheral channel status registers to clear the interrupt(s).

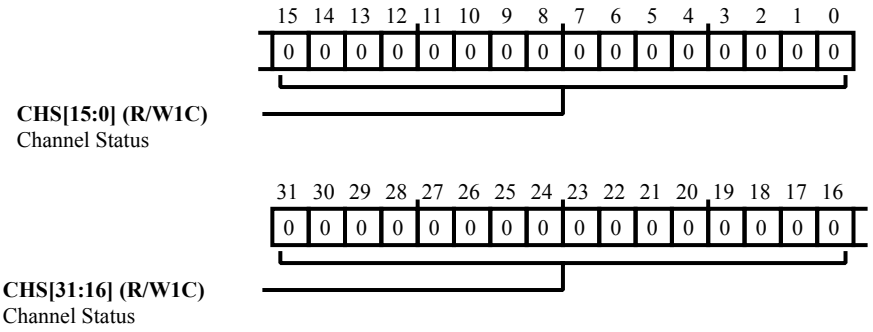

Figure 24-9: MLB_ACSR0 Register Diagram

Table 24-22: MLB_ACSR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR0.CHS bit field indicates channel status for channels 31-0.	
		0	No interrupt on Channel 31:0 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Status 1 Register

The MLB_ACSR1 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR1 and MLB_ACSR0 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of peripheral channel status registers to clear the interrupt(s).

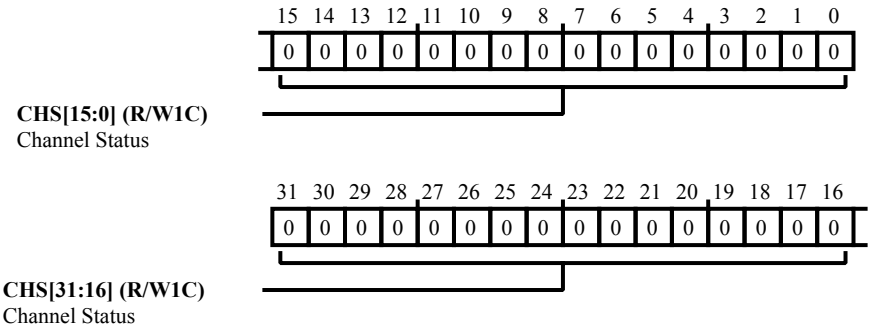

Figure 24-10: MLB_ACSR1 Register Diagram

Table 24-23: MLB_ACSR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR1.CHS bit field indicates channel status for channels 63-32.	
		0	No interrupt on Channel 63:32 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 63:32 (bitwise; all channels shown)

Bus Control Register

The MLB_ACTL register is written by the HC to configure the block for channel interrupts. This register contains bits to select the packet buffering mode and the DMA mode. This register also contains bits that are used to multiplex channel interrupts onto a single interrupt signal and to select the method of clearing channel interrupts.

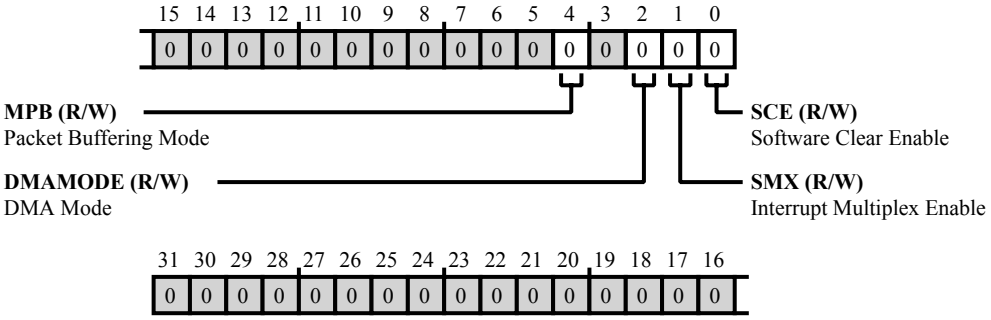

Figure 24-11: MLB_ACTL Register Diagram

Table 24-24: MLB_ACTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	MPB	Packet Buffering Mode. The MLB_ACTL.MPB bit selects whether the buffering mode is single-packet or multiple-packet.	
		0	single-packet mode
		1	multiple-packet mode
2 (R/W)	DMAMODE	DMA Mode. The MLB_ACTL.DMAMODE bit selects between DMA mode 1 and 0. DMA Mode 0 uses incrementing bursts of an unspecified length. This allows the block to perform single beat transfers as well as an incrementing (INCR) burst of unspecified length up to the maximum specified burst length (8 beats). DMA Mode 1 uses only INCR8, INCR4, and SINGLE beat bursts. The hburst[2:0] signal encodes the burst transfer used for a DMA operation.	
		0	DMA Mode 0
		1	DMA Mode 1

Table 24-24: MLB_ACTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SMX	Interrupt Multiplex Enable. The `MLB_ACTL.SMX` bit selects whether ACSR0 generates an interrupt on MLB_INT[0] and ACSR1 generates an interrupt on MLB_INT[1] or ACSR0 and ACSR1 generate an interrupt on MLB_INT[0] only.	
		0	ACSR0 generates an interrupt on MLB_INT[0]; ACSR1 generates an interrupt on MLB_INT[1]
		1	ACSR0 and ACSR1 generate an interrupts on MLB_INT[0] only
0 (R/W)	SCE	Software Clear Enable. The `MLB_ACTL.SCE` bit selects whether hardware clears the interrupt after a ACSRn register read or software clears the interrupt.	
		0	Hardware clears interrupt after a ACSRn register read
		1	Software clears interrupt

MediaLB Control 0 Register

The MLB_CTL0 register contains bit that enable the module and provide module status. Note that the maximum speed for ML6-pin mode is 2048 x FS.

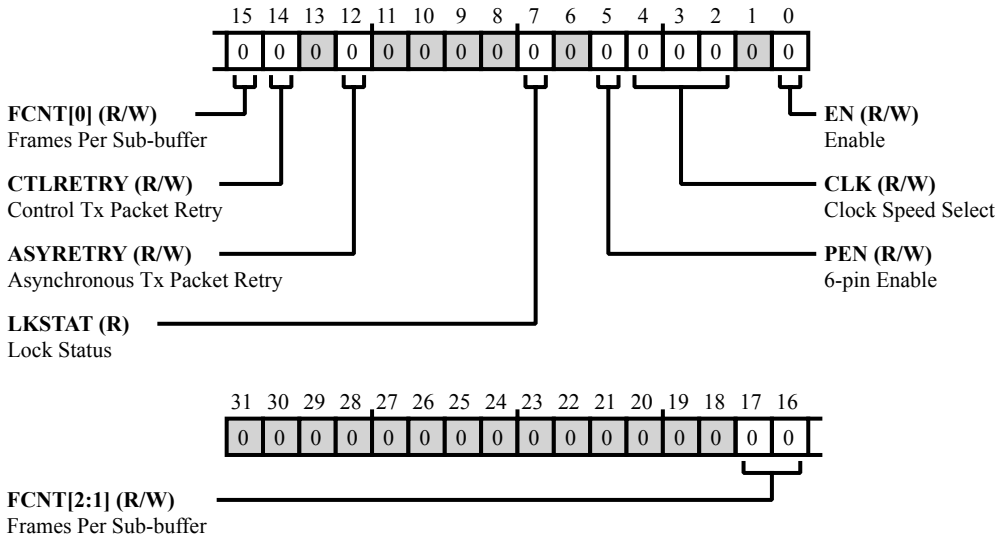

Figure 24-12: MLB_CTL0 Register Diagram

Table 24-25: MLB_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	FCNT	Frames Per Sub-buffer. The MLB_CTL0.FCNT bit field configures the frames per sub-buffer on synchronous channels.	
		0	1 Frame per sub-buffer (Operation is the same as Standard mode)
		1	2 frames per sub-buffer
		2	4 frames per sub-buffer
		3	8 frames per sub-buffer
		4	16 frames per sub-buffer
		5	32 frames per sub-buffer
		6	64 frames per sub-buffer
14 (R/W)	CTLRETRY	Control Tx Packet Retry. When the MLB_CTL0.CTLRETRY bit is set, a control packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, a control packet that is flagged with a Break or Protocol error by the receiver is skipped.	

Table 24-25: MLB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ASYRETRY	Asynchronous Tx Packet Retry. When the MLB_CTL0.ASYRETRY bit is set, an asynchronous packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, an asynchronous packet that is flagged with a Break or ProtocolError by the receiver is skipped.	
7 (R/NW)	LKSTAT	Lock Status. When the MLB_CTL0.LKSTAT bit is set (=0), the MediaLB block is synchronized to the incoming MediaLB frame with the following conditions. • If MLB_CTL1.LOCK =0 (unlocked), MLB_CTL1.LOCK is set after a FRAMESYNC is detected at the same position for three consecutive frames. • If MLB_CTL1.LOCK =1 (locked), MLB_CTL1.LOCK is cleared after not receiving a FRAMESYNC at the expected time for two consecutive frames. In this case FRAMESYNC patterns occurring at locations other than the expected one are ignored.	
5 (R/W)	PEN	6-pin Enable. The MLB_CTL0.PEN bit configures the MLB for 6-pin or 3-pin mode.	
		0	3-pin interface enabled
		1	6-pin interface enabled
4:2 (R/W)	CLK	Clock Speed Select. The MLB_CTL0.CLK bit field sets the clock speed.	
		0	256 x Fs (MLB_CTL.PEN = 0)
		1	512 x Fs (MLB_CTL.PEN = 0)
		2	1024 x Fs (MLB_CTL.PEN = 0)
		3	2048 x Fs (MLB_CTL.PEN = 1)
		4	Reserved
		5	Reserved
		6	Reserved
		7	Reserved
0 (R/W)	EN	Enable. When the MLB_CTL0.EN bit is set (=1), MediaLB clock, signal, and data are received and transmitted on the appropriate MediaLB pins.	

Control 1 Register

The MLB_CTL1 register contains bits that provide lock status and control system commands.

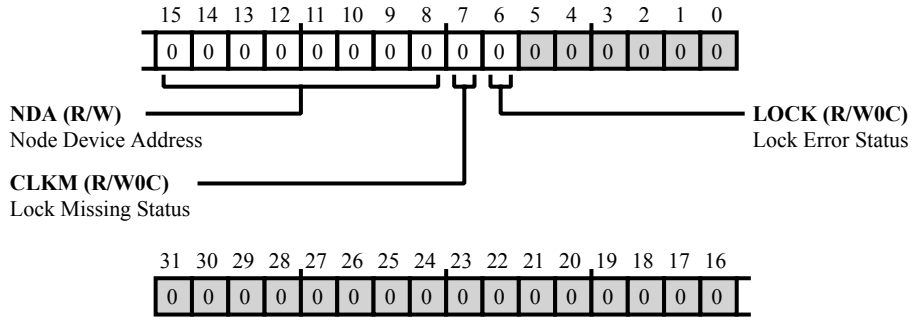

Figure 24-13: MLB_CTL1 Register Diagram

Table 24-26: MLB_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	NDA	Node Device Address. The MLB_CTL1.NDA bit field is used for system commands directed to individual MediaLB nodes.
7 (R/W0C)	CLKM	Lock Missing Status. The MLB_CTL1.CLKM bit is set when the MediaLB clock is not toggling at the pin. This bit is cleared by software.
6 (R/W0C)	LOCK	Lock Error Status. The MLB_CTL1.LOCK bit is set when the MediaLB is unlocked. This bit is cleared by software.

MLB Global Control Register

The MLB_GCTL register contains bits that manage the MLB clock.

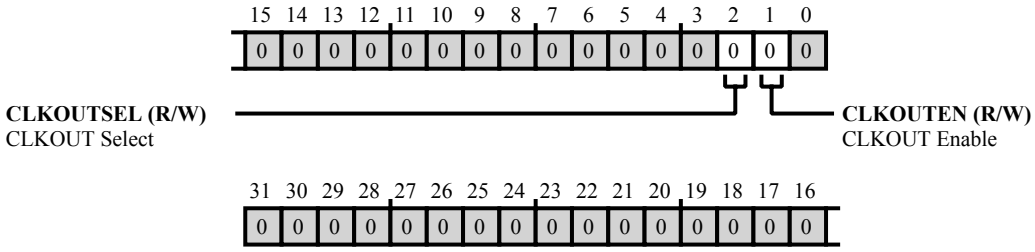

Figure 24-14: MLB_GCTL Register Diagram

Table 24-27: MLB_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CLKOUTSEL	CLKOUT Select. The MLB_GCTL.CLKOUTSEL bit selects either the MLB 3 pin clock or the 6 pin clock as MLBCLKOUT.	
		0	MLB 3 pin clock is selected for MLBCLKOUT
		1	MLB 6 pin clock is selected for MLBCLKOUT
1 (R/W)	CLKOUTEN	CLKOUT Enable.	

HBI Channel Busy 0 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR0 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

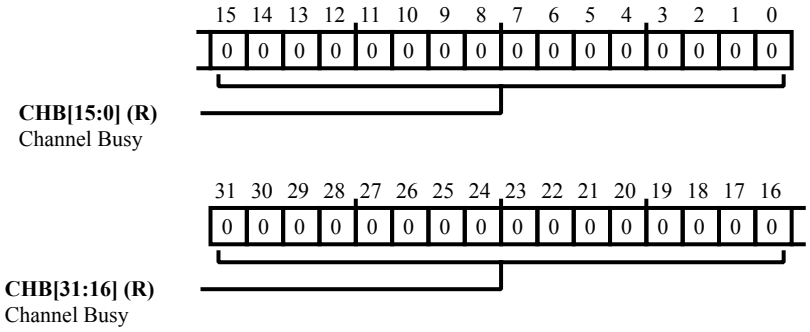

Figure 24-15: MLB_HCBR0 Register Diagram

Table 24-28: MLB_HCBR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR0.CHB bit field contains the bitwise channel busy bit for channels 31:0. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Busy 1 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR1 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

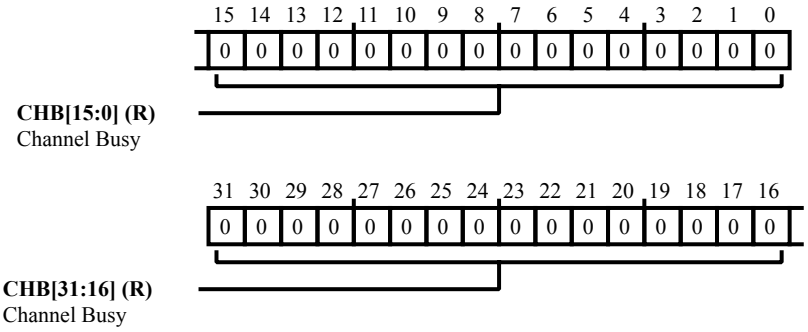

Figure 24-16: MLB_HCBR1 Register Diagram

Table 24-29: MLB_HCBR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR1.CHB bit field contains the bitwise channel busy bit for channels 63:32. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Error 0 Register

The MLB_HCER0 register indicates which channels (channels 31:0) have encountered fatal errors.

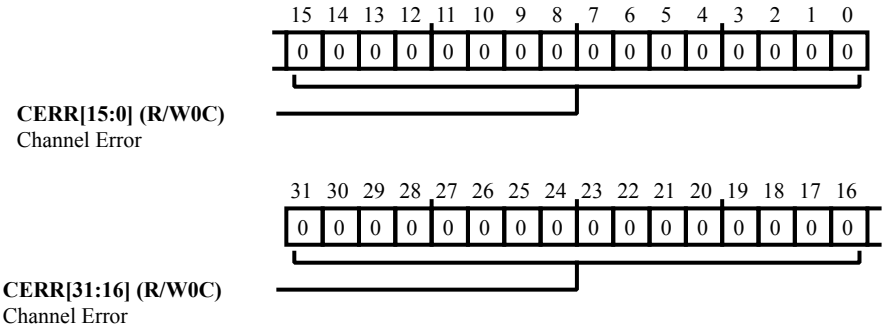

Figure 24-17: MLB_HCER0 Register Diagram

Table 24-30: MLB_HCER0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER0.CERR bit field reports bitwise errors for channels 31:0.

HBI Channel Error 1 Register

The MLB_HCER1 register indicates which channel(s) have encountered fatal errors.

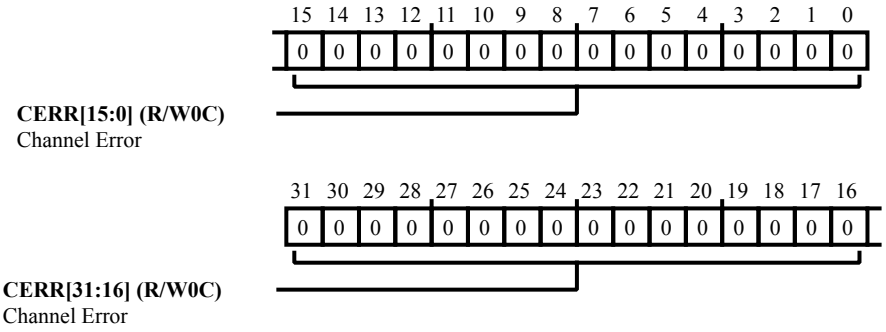

Figure 24-18: MLB_HCER1 Register Diagram

Table 24-31: MLB_HCER1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER1.CERR bite field reports bitwise errors for channels 63:32.

HBI Channel Mask 0 Register

The MLB_HCMR0 register controls which channels (for channels 31:0) are able to generate an HBI interrupt.

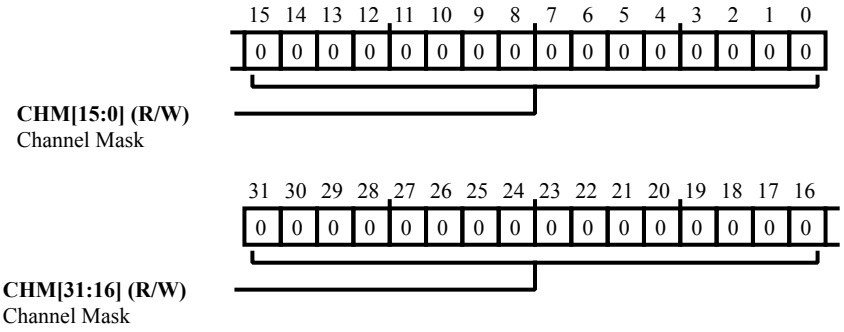

Figure 24-19: MLB_HCMR0 Register Diagram

Table 24-32: MLB_HCMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Channel Mask. The MLB_HCMR0.CHM bit field contains the bitwise channel mask bit for channels 31:0. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Channel Mask 1 Register

The MLB_HCMR1 register controls which channels (for channels 63:32) are able to generate an HBI interrupt.

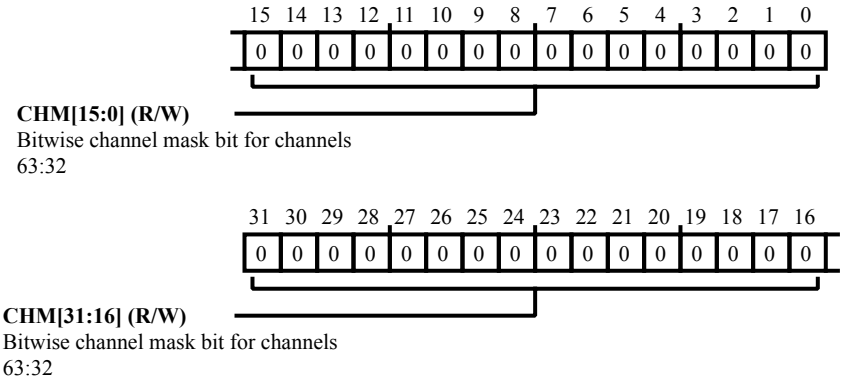

Figure 24-20: MLB_HCMR1 Register Diagram

Table 24-33: MLB_HCMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Bitwise channel mask bit for channels 63:32. The MLB_HCMR1.CHM bit field contains the bitwise channel mask bit for channels 63:32. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Control Register

The MLB_HCTL register controls and monitors general operation of the HBI block through the Address Generation Units) by reading and writing the register through the I/O interface. Each bit of this register is read/write.

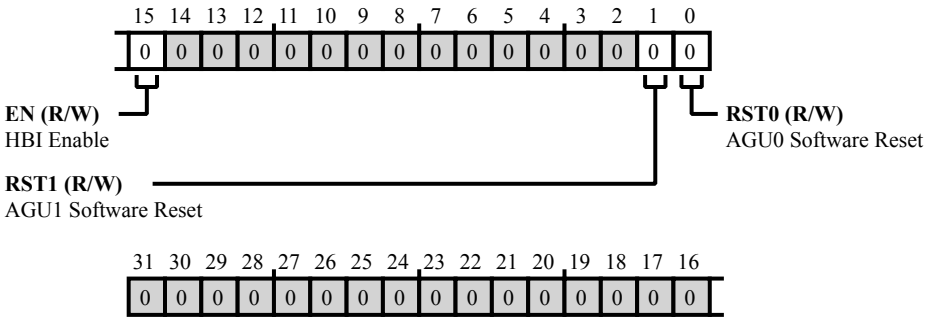

Figure 24-21: MLB_HCTL Register Diagram

Table 24-34: MLB_HCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	EN	HBI Enable. Setting the MLB_HCTL.EN bit enables the HBI.
1 (R/W)	RST1	AGU1 Software Reset. Setting the MLB_HCTL.RST1 bit resets AGU1.
0 (R/W)	RST0	AGU0 Software Reset. Setting the MLB_HCTL.RST0 bit resets AGU0.

Memory Interface Address Register

The MLB_MADR register contains bit fields that contain the Channel Table RAM (CTR) or Data Buffer RAM (DBR) addresses. It also contains bits that set target location and read-not-write parameters.

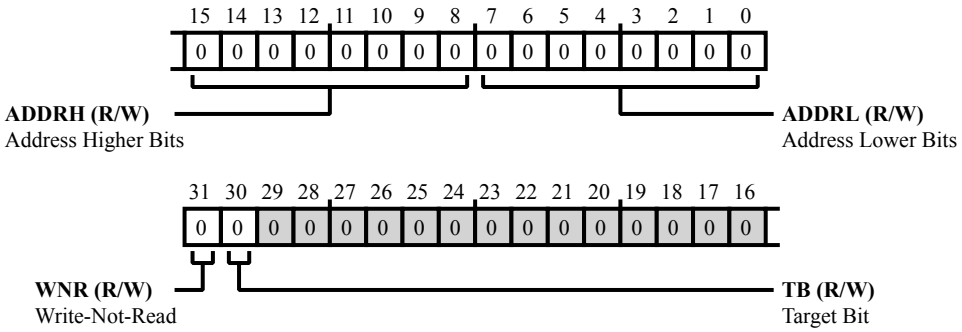

Figure 24-22: MLB_MADR Register Diagram

Table 24-35: MLB_MADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	WNR	Write-Not-Read. The MLB_MADR.WNR bit selects Write-Not-Read.	
		0	Read
		1	Write
30 (R/W)	TB	Target Bit. The MLB_MADR.TB bit sets the target location.	
		0	Channel Table RAM (CTR)
		1	Data Buffer RAM (DBR)
15:8 (R/W)	ADDRH	Address Higher Bits. The MLB_MADR.ADDRH bit field contains the DBR address of the 8-bit entry (bits [13:8]).	
7:0 (R/W)	ADDRL	Address Lower Bits. The MLB_MADR.ADDRL bit field contains the CTR address of the 128-bit entry or the DBR address of the 8-bit entry (bits [7:0]).	

Memory Interface Control Register

The MLB_MCTL register contains a bit that indicates that the data transfer is complete.

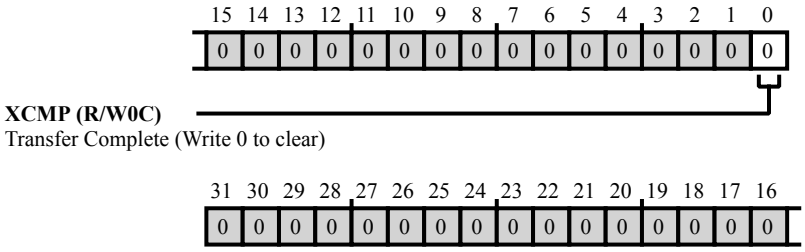

Figure 24-23: MLB_MCTL Register Diagram

Table 24-36: MLB_MCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W0C)	XCMP	Transfer Complete (Write 0 to clear). The MLB_MCTL.XCMP bit indicates that the data transfer is complete.

Memory Interface Control Data 0 Register

The MLB_MDAT0 register contains Channel Table RAM (CTR) data (bits [31:0] of 128-bit entry) or Data Buffer RAM (DBR) data (bits [7:0] of 8-bit entry).

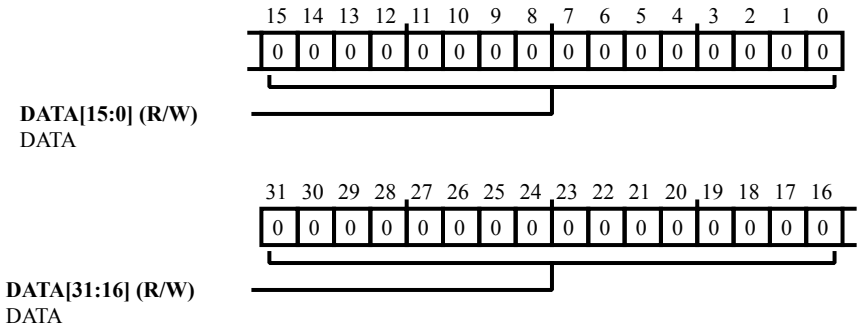

Figure 24-24: MLB_MDAT0 Register Diagram

Interrupt Enable Register

The MLB_MIEN register is used to enable various interrupt conditions.

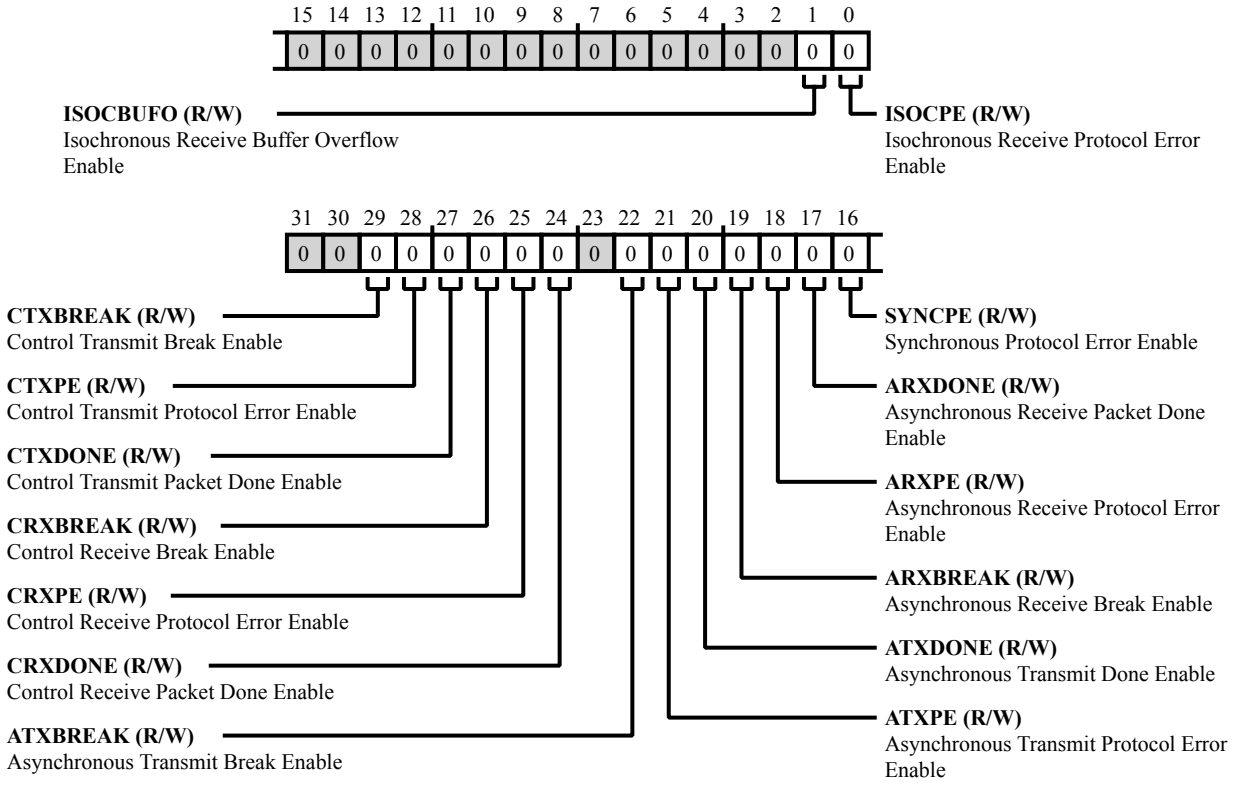

Figure 24-32: MLB_MIEN Register Diagram

Table 24-45: MLB_MIEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	CTXBREAK	Control Transmit Break Enable. When the MLB_MIEN.CTXBREAK bit is set, a ReceiverBreak response received from the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
28 (R/W)	CTXPE	Control Transmit Protocol Error Enable. When the MLB_MIEN.CTXPE bit is set, a ProtocolError generated by the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
27 (R/W)	CTXDONE	Control Transmit Packet Done Enable. When the MLB_MIEN.CTXDONE bit is set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 24-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	CRXBREAK	Control Receive Break Enable. When the MLB_MIEN.CRXBREAK bit is set, a ControlBreak command received from the transmitter on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
25 (R/W)	CRXPE	Control Receive Protocol Error Enable. When the MLB_MIEN.CRXPE bit is set, a ProtocolError detected on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
24 (R/W)	CRXDONE	Control Receive Packet Done Enable. When the MLB_MIEN.CRXDONE bit is set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
22 (R/W)	ATXBREAK	Asynchronous Transmit Break Enable. When the MLB_MIEN.ATXBREAK bit is set, a ReceiverBreak response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
21 (R/W)	ATXPE	Asynchronous Transmit Protocol Error Enable. When the MLB_MIEN.ATXPE bit is set, a ProtocolError generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
20 (R/W)	ATXDONE	Asynchronous Transmit Done Enable. When the MLB_MIEN.ATXDONE bit is set, a packet transmitted with no errors on an asynchronous Tx channel channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
19 (R/W)	ARXBREAK	Asynchronous Receive Break Enable. When the MLB_MIEN.ARXBREAK bit is set, a AsyncBreak command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
18 (R/W)	ARXPE	Asynchronous Receive Protocol Error Enable. When the MLB_MIEN.ARXPE bit is set, a protocol error detected on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
17 (R/W)	ARXDONE	Asynchronous Receive Packet Done Enable. When the MLB_MIEN.ARXDONE bit is set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 24-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	SYNCPE	Synchronous Protocol Error Enable. When the MLB_MIEN.SYNCPE bit is set, a protocol error detected on a synchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
1 (R/W)	ISOCBUFO	Isochronous Receive Buffer Overflow Enable. When the MLB_MIEN.ISOCBUFO bit is set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
0 (R/W)	ISOCPE	Isochronous Receive Protocol Error Enable. When the MLB_MIEN.ISOCPE bit is set, a protocol error detected on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Channel Status 0 Register

The MLB_MS0 register indicates the channel status for MediaLB channels 31 to 0. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MLB_MIEN register are set.

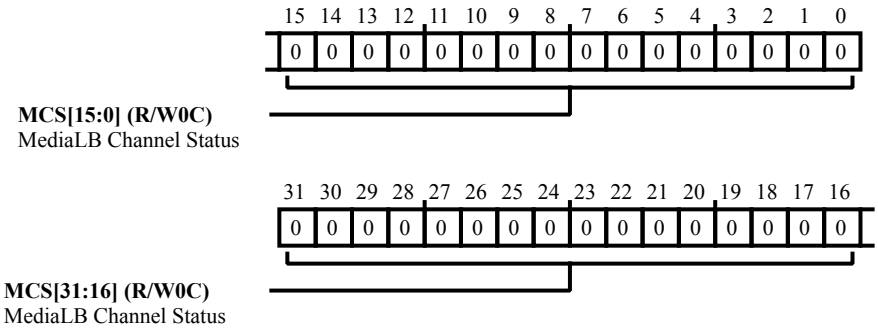

Figure 24-33: MLB_MS0 Register Diagram

Table 24-46: MLB_MS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	MCS	MediaLB Channel Status. The MLB_MS0.MCS bit field indicates the MediaLB channel status for channels 31 to 0.

Channel Status 1 Register

The MLB_MS1 register indicates the channel status for MediaLB channels 32 to 63. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MLB_MIEN register are set.

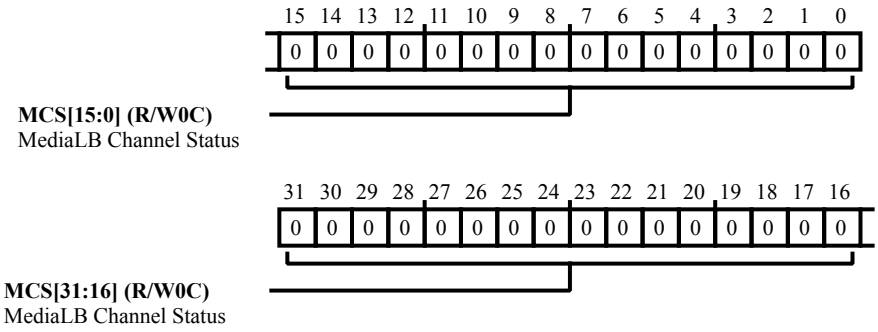

Figure 24-34: MLB_MS1 Register Diagram

Table 24-47: MLB_MS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	MCS	MediaLB Channel Status. The MLB_MS1.MCS bit field indicates the MediaLB channel status for channels 63 to 32.

System Data Register

The MLB_MSD register allows system software to receive control information from the MLB controller. The MLB_MSD register is updated once per frame by the hardware during the MLB system channel.

The MLB_MSD register is loaded with the data from the MLBDAT_IN signal during the system channel quadlet. System software must read this register before the start of the next MLB frame to prevent the current data from being lost.

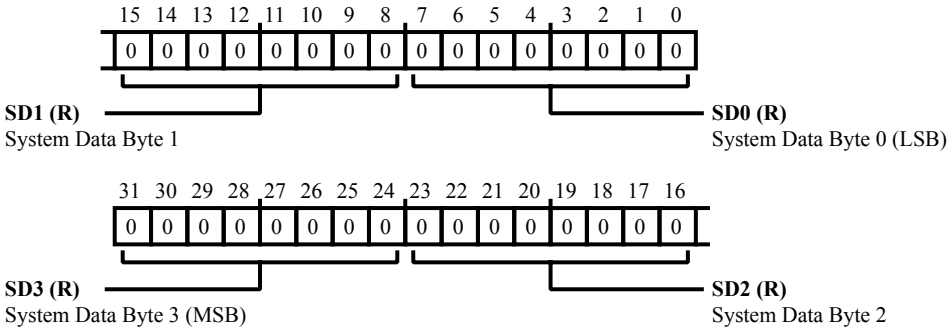

Figure 24-35: MLB_MSD Register Diagram

Table 24-48: MLB_MSD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	SD3	System Data Byte 3 (MSB). The MLB_MSD.SD3 bits are updated with MediaLB Data [31:24] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD3 is not updated.
23:16 (R/NW)	SD2	System Data Byte 2. The MLB_MSD.SD2 bits are updated with MediaLB Data [23:16] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD2 is not updated.
15:8 (R/NW)	SD1	System Data Byte 1. The MLB_MSD.SD1 bits are updated with MediaLB Data [15:8] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD1 is not updated.
7:0 (R/NW)	SD0	System Data Byte 0 (LSB). The MLB_MSD.SD0 bits are updated with MediaLB Data [7:0] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD0 is not updated.

System Status Register

The MLB_MSS register allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB system channel. The bits of this register are not valid until the processor is locked to the MLB interface (except for the bits associated with MLB lock and unlock, SDMU and SDML). System software must service events before the start of the next MLB frame to prevent the current frame status from being lost.

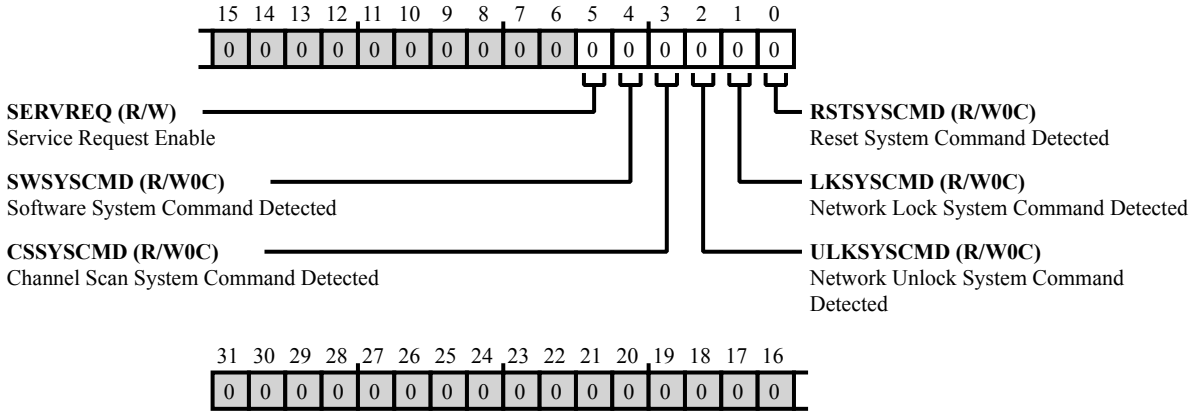

Figure 24-36: MLB_MSS Register Diagram

Table 24-49: MLB_MSS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	SERVREQ	Service Request Enable. When the MLB_MSS.SERVREQ bit set, the MediaLB block responds with a device present, request service system response if a matching channel scan system command is detected. When cleared, the MediaLB block responds with a device present system response.
4 (R/W0C)	SWSYSCMD	Software System Command Detected. The MLB_MSS.SWSYSCMD bit indicates that a software system command was detected (in the system quadlet). The MLB_MSS.SWSYSCMD bit is set by hardware, cleared by software. Data is stored in the MLB_MSD register for this command.
3 (R/W0C)	CSSYSCMD	Channel Scan System Command Detected. The MLB_MSS.CSSYSCMD bit indicates that a channel scan system command was detected (in the system quadlet). The MLB_MSS.CSSYSCMD bit is set by hardware, cleared by software. If the node address specified in the data quadlet matches the value in the MLB_CTL1.NDA bit field, the device responds either device present or device present, request service system response in the next system quadlet.

Table 24-49: MLB_MSS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W0C)	ULKSYSCMD	Network Unlock System Command Detected. The `MLB_MSS.ULKSYSCMD` bit indicates a network unlock system command was detected (in the system quadlet). The `MLB_MSS.ULKSYSCMD` bit is by hardware, cleared by software.
1 (R/W0C)	LKSYSCMD	Network Lock System Command Detected. The `MLB_MSS.LKSYSCMD` bit indicates a network lock system command was detected (in the system quadlet). The `MLB_MSS.LKSYSCMD` bit is set by hardware and cleared by software.
0 (R/W0C)	RSTSYSCMD	Reset System Command Detected. The `MLB_MSS.RSTSYSCMD` bit indicates a reset system command was detected (in the system quadlet). The `MLB_MSS.RSTSYSCMD` bit is set by hardware, cleared by software.

MediaLB 6-pin Control 0 Register

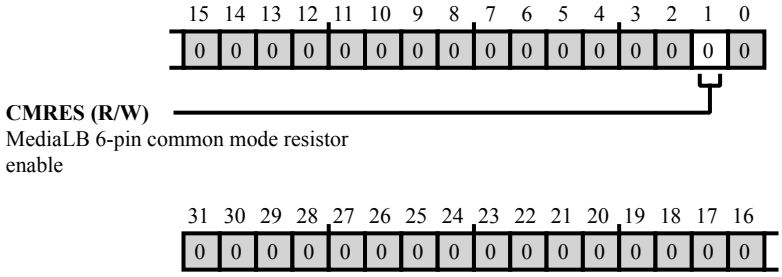

Figure 24-37: MLB_PCTL0 Register Diagram

Table 24-50: MLB_PCTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	CMRES	MediaLB 6-pin common mode resistor enable. This signal is no longer used.

25 Two-Wire Interface (TWI)

The processor has a two-wire interface (TWI), that provides a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I^2C bus standard. Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

The TWI module offers the capabilities of simultaneous master and slave operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface uses two pins for transferring clock (`TWI_SCL`) and data (`TWI_SDA`) and supports the protocol at speeds up to 400K bits/sec. The TWI interface pins are compatible with 5V logic levels.

To preserve processor bandwidth, the TWI module can be set up with transfer-initiated interrupts to only service FIFO buffer data reads and writes. Protocol-related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I^2C bus protocol.

TWI Features

The TWI is fully compatible with the widely used I^2C bus standard.

The TWI controller includes the following features.

- Simultaneous master and slave operation on multiple device systems
- Support for multi-master bus arbitration
- 7-bit addressing
- 100K bits/second and 400K bits/second data rates
- General call address support
- Master clock synchronization and support for clock low extension
- Separate multiple-byte receive and transmit FIFOs
- Low interrupt rate
- Individual override control of data and clock lines in the event of bus lock-up
- Input filter for spike suppression

- Serial camera control bus support as specified in the *OmniVision Serial Camera Control Bus (SCCB) Functional Specification*
- Programmable drive/tolerance of TWI pins. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

TWI Functional Description

The TWI interface is a shift register that serially transmits and receives data bits. It moves data 1 bit at a time at the SCL rate, to and from other TWI devices. The SCL signal synchronizes the shifting and sampling of the data on the serial data pin.

ADSP-SC57x TWI Register List

The Two-Wire Interface controller TWI allows a device to interface to an inter-IC bus as specified by the Philips I^2C Bus Specification version 2.1, dated January 2000. A set of registers governs TWI operations. For more information on TWI functionality, see the TWI register descriptions.

Table 25-1: ADSP-SC57x TWI Register List

Name	Description
TWI_CLKDIV	SCL Clock Divider Register
TWI_CTL	Control Register
TWI_FIFOCTL	FIFO Control Register
TWI_FIFOSTAT	FIFO Status Register
TWI_IMSK	Interrupt Mask Register
TWI_ISTAT	Interrupt Status Register
TWI_MSTRADDR	Master Mode Address Register
TWI_MSTRCTL	Master Mode Control Registers
TWI_MSTRSTAT	Master Mode Status Register
TWI_RXDATA16	Rx Data Double-Byte Register
TWI_RXDATA8	Rx Data Single-Byte Register
TWI_SLVADDR	Slave Mode Address Register
TWI_SLVCTL	Slave Mode Control Register
TWI_SLVSTAT	Slave Mode Status Register
TWI_TXDATA16	Tx Data Double-Byte Register
TWI_TXDATA8	Tx Data Single-Byte Register

ADSP-SC57x TWI Interrupt List

Table 25-2: ADSP-SC57x TWI Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
115	TWI0_DATA	TWI0 Data Interrupt	Level	
116	TWI1_DATA	TWI1 Data Interrupt	Level	
117	TWI2_DATA	TWI2 Data Interrupt	Level	

TWI Block Diagram

The ***TWI Block Diagram*** figure shows the basic blocks of the TWI interface.

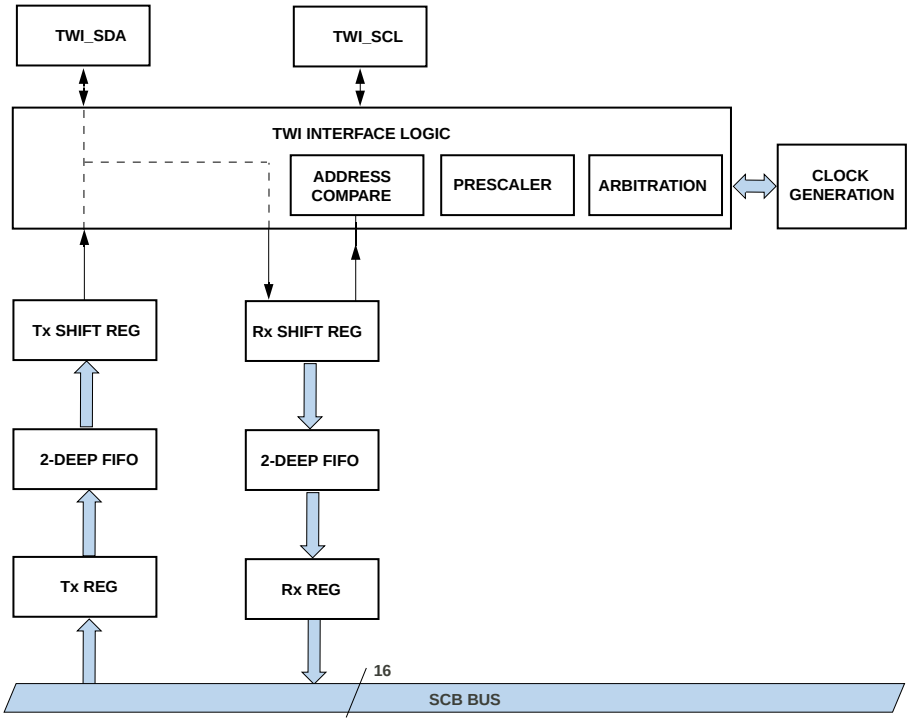

Figure 25-1: TWI Block Diagram

External Interface

The `TWI_SDA` (serial data) and `TWI_SCL` (serial clock) signals are open drain and require pull-up resistors. These bidirectional signals externally interface the TWI controller to the I^2C bus and no other external connections or logic are necessary.

Serial Clock Signal (SCL)

The serial clock signal (`TWI_SCL`) is an input in slave mode. In master mode, the TWI controller must set this signal to the desired frequency.

The TWI controller supports the standard mode of operation (up to 100 kHz) or fast mode (up to 400 kHz). The TWI control register (`TWI_CTL`) sets the `TWI_CTL.PRESCALE` value which sets the relationship between the

system clock (SCLK) and the internally timed events of the TWI controller. The internal time reference is derived from SCLK using a prescaled value. The prescale value is the number of SCLK periods used in the generation of one internal time reference. Set the value of prescale to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value as follows.

PRESCALE = f_{SCLK}/10MHz

NOTE: It is not always possible to achieve 10-MHz accuracy. In such cases, it is safe to round up the PRESCALE value to the next highest integer. For example, if SCLK is 100 MHz, the PRESCALE value is calculated as 100 MHz/10 MHz = 10. A prescale value of 14 in this case ensures that all timing requirements are met.

During master mode operation, the TWI module uses the TWI_CLKDIV register values to create the minimum TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO durations of the TWI_SCL signal. The TWI_CLKDIV.CLKHI field specifies the minimum number of 10-MHz time reference periods the TWI_SCL waits before a new clock low period begins, assuming a single master. (The 10-MHz time reference periods are represented as an 8-bit binary value). The TWI uses the TWI_CLKDIV.CLKLO field to specify the minimum number of internal time reference periods (represented as an 8-bit binary value). The TWI_SCL signal is held low.

Serial clock frequencies can vary from 400 kHz to less than 20 kHz. The resolution of the clock generated is 1/10 MHz or 100 ns. The following equation describes the frequency.

TWI_CLKDIV = TWI_SCL period/10 MHz time reference.

For example, for an TWI_SCL of 400 kHz (period = 1/400 kHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns), the following equation applies:

TWI_CLKDIV = 2500 ns/100 ns = 25

Therefore, a TWI_SCL signal with a 30% duty cycle has TWI_CLKDIV.CLKLO=17 and TWI_CLKDIV.CLKHI=8. Adding TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI equals TWI_CLKDIV.

NOTE: The TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO fields are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for the TWI_SCL signal. Slew rate controls falling edges. The *RC* time constant governs the rising edges. The pull-up resistor and the TWI_SCL capacitance form the time constant. See the “Register Descriptions” section for more details.

Serial Data Signal (SDA)

The TWI transmits and receives serial data, depending on the direction of the transfer, on the bidirectional serial data signal (SDA).

Internal Interface

The peripheral bus interface supports the transfer of 16-bit wide data. The processor uses the interface in the support of register and FIFO buffer reads and writes. The TWI internal interface is comprised of the blocks described as follows.

Register block. Contains all control and status bits and reflects what can be written or read as outlined by the programming model. Each function block updates their corresponding status bits.

FIFO buffer. Configured as a 1-byte-wide, 2-deep transmit FIFO buffer and a 1-byte-wide, 2-deep receive FIFO buffer.

Transmit shift register. Serially shifts its data out externally off chip. The output can be controlled for generation of acknowledgments or it can be manually overwritten.

Receive shift register. Receives its data serially from off chip. The receive shift register is 1 byte wide and data received can either be transferred to the FIFO buffer or used in an address comparison.

Address compare block. Supports address comparison in the event the TWI controller module is accessed as a slave.

Prescaler block. Must be programmed to generate a 10-MHz time reference relative to the system clock. The block uses this time base for filtering of data and timing events specified by the electrical data sheet (See the Philips specification). The block uses the time base to generate the `TWI_SCL` clock as well.

Clock generation module. Generates an external `TWI_SCL` clock when in master mode. It includes the logic necessary for synchronization in a multi-master clock configuration and clock stretching when configured in slave mode.

NOTE: The TWI does not support DMA based operation.

TWI Architectural Concepts

The TWI controller follows the transfer protocol of the Philips I^2C Bus specification version 2.1 dated January 2000.

NOTE: The TWI unit does not support DMA-based operation.

TWI Protocol

The ***Data Transfer*** figure shows a simple complete transfer.

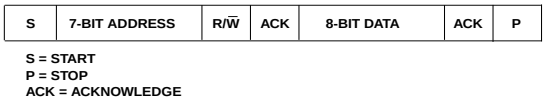

Figure 25-2: Data Transfer

The TWI controller register contents maps to a basic transfer. The ***Data Transfer with Bit Illustration*** figure details the same transfer from the ***Data Transfer*** figure noting the corresponding TWI controller bit names. In this illustration, the TWI controller successfully transmits 1 byte of data. The slave has acknowledged both address and data.

Figure 25-3: Data Transfer with Bit Illustration

Clock Generation and Synchronization

The TWI controller implementation only issues a clock during master mode operation and only at the time a transfer initiates. If arbitration for the bus is lost, the serial clock output immediately three-states. If multiple clocks attempt to drive the serial clock line, the TWI controller synchronizes its clock with the other remaining clocks. The ***Clock Synchronization*** figure shows this functionality.

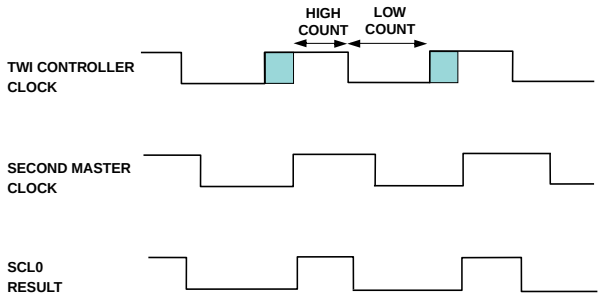

Figure 25-4: Clock Synchronization

The TWI controller serial clock (`TWI_SCL`) output follows these rules:

- Once the clock high (`TWI_CLKDIV.CLKHI`) count is complete, the serial clock output is driven low and the clock low (`TWI_CLKDIV.CLKLO`) count begins.
- Once the clock low count is complete, the serial clock line is three-stated. This state allows the external pull-up resistor to pull the `TWI_SCL` signal high. The clock synchronization logic enters into a delay mode (shaded area) until the `TWI_SCL` signal is detected at logic 1 level. Now, the clock high count begins.

Bus Arbitration

The TWI controller initiates a master mode transmission only when the bus is idle. If the bus is idle and two masters initiate a transfer, arbitration for the bus begins. The ***Bus Arbitration*** figure shows the arbitration.

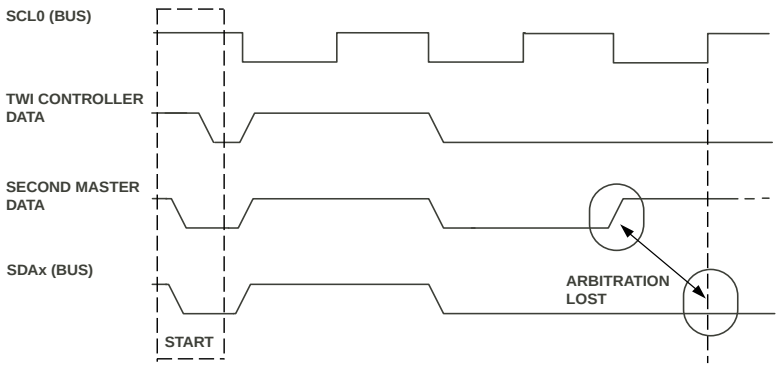

Figure 25-5: Bus Arbitration

The TWI controller monitors the serial data bus (SDA) while the `TWI_SCL` signal is high. If the `TWI_SDA` signal is determined to be an active logic 0 level while the data of the TWI controller is a logic 1 level, the TWI controller has lost arbitration. It stops generating the clock and data signals. Arbitration is not only performed at the serial clock edges, but also during the entire time the `TWI_SCL` signal is high.

Start and Stop Conditions

Start and stop conditions involve serial data transitions while the serial clock is a logic 1 level. The TWI controller generates and recognizes these transitions. Typically, start and stop conditions occur at the beginning and at the conclusion of a transmission, except repeated start combined transfers. The ***Start and Stop Conditions*** figure shows the transitions.

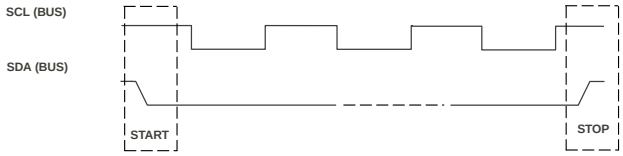

Figure 25-6: Start and Stop Conditions

The TWI special case start and stop conditions of the TWI controller include the following.

- Controller addressed as a slave-receiver. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`).
- Controller addressed as a slave-transmitter. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`) and indicates a slave transfer error (`TWI_ISTAT.SERR`).
- Controller as a master-transmitter or master-receiver. If the stop bit (`TWI_MSTRCTL.STOP`) is set during an active master transfer, the TWI controller issues a stop condition as soon as possible avoiding any error conditions. The TWI controller operates as if data transfer count had been reached.

General Call Support

The TWI controller always decodes and acknowledges a general call address if:

- The TWI controller is enabled as a slave
- General call is enabled

The `TWI_SLVCTL.GEN` bit configures general call addressing (0x00) only when the TWI controller is a slave-receiver.

If the data associated with the transfer is (NAK) not acknowledged, the `TWI_SLVCTL.NAK` bit can be set. If the TWI controller issues a general call as a master-transmitter, set the appropriate address (`TWI_MSTRADDR` register) and transfer direction (`TWI_MSTRCTL.DIR` bit) and load the transmit FIFO data.

NOTE: The byte following the general call address usually defines the slaves response to the call. The interpretation of the command in the second byte is based on the value of its LSB. For a TWI slave device, the bytes received after the general call address are considered data.

Fast Mode

Fast mode essentially uses the same mechanics as the standard mode of operation. Fast mode affects electrical specifications and timing. When fast mode is enabled, (FAST) timing is modified to meet the following electrical requirements.

- Serial data rise times before arbitration evaluation (t_r)
- Stop condition set-up time from serial clock to serial data (t_{SUSTO})
- Bus free time between a stop and start condition (t_{BUF})

TWI Operating Modes

The TWI has two modes of operation: repeated start and clock stretching. The following sections describe the operating modes.

Repeated Start

A repeated start condition is the absence of a stop condition between two transfers. The two transfers can be of any direction type. Examples include a transmit followed by a receive, or a receive followed by a transmit. The following sections guide the programmer in developing a service routine.

Transmit Receive Repeated Start

The ***Repeated Start Followed by Data Receive*** figure shows a repeated start followed by a data receive sequence. The shading in the figure indicates that the slave has control of the bus.

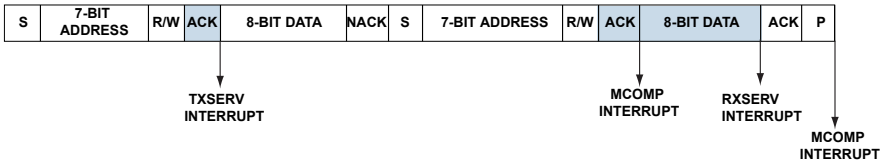

Figure 25-7: Repeated Start Followed by Data Receive

The tasks performed at each interrupt are:

- Transmit FIFO service (`TWI_ISTAT.TXSERV`) interrupt request. This interrupt is generated due to a FIFO access. Since this byte is the last of this transfer, the TWI uses the `TWI_FIFOSTAT` register to indicate that the transmit FIFO is empty. When read, `TWI_MSTRCTL.DCNT` bit field=0. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and set the `TWI_MSTRCTL.DIR` bit if the following transfer is a data receive.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when all data transfers (`TWI_MSTRCTL.DCNT` bit field=0). If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to receive.

- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a byte in the receive FIFO. Simple data handling is the only requirement.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when the transfer completes.

Receive Transmit Repeated Start

The ***Repeated Start Data Receive Followed by Data Transmit*** figure illustrates a repeated start data receive followed by a data transmit sequence. The shading in the figure indicates that the slave has control of the bus.

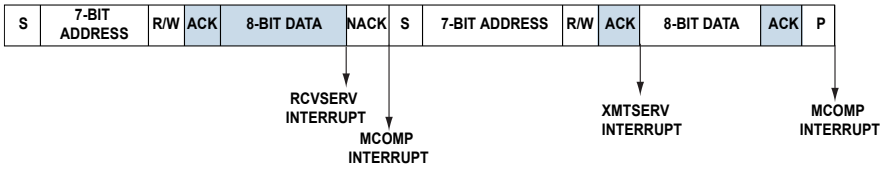

Figure 25-8: Repeated Start Data Receive Followed by Data Transmit

The tasks performed at each interrupt are:

- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a data byte in the receive FIFO. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and clear the `TWI_MSTRCTL.DIR` bit if the following transfer is a data transmit.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request has occurred due to the completion of the data receive transfer. If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to transmit.
- Transmit FIFO service (`TWI_ISTAT.TXSERV`) interrupt. This interrupt request is generated due to a FIFO access. Simple data handling is the only requirement.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when the transfer completes.

NOTE: There is no timing constraint to meet the conditions—program the bits as required. Refer to Clock Stretching During Repeated Start section for more on how the controller stretches the clock during repeated start transfers.

Clock Stretching

Clock stretching is an added function of the TWI controller in master mode operation. This behavior uses self-induced stretching of the I ^{2}C clock while waiting to service interrupts. Hardware initiates stretching automatically. No programming is necessary. The TWI controller as a master supports three modes of clock stretching:

- Clock Stretching During FIFO Underflow
- Clock Stretching During FIFO Overflow

- Clock Stretching During Repeated Start

Clock Stretching During FIFO Underflow

During a master mode transmit, an interrupt request occurs the instant the transmit FIFO becomes empty. The most recent byte begins transmission. If the TWI_ISTAT.TXSERV interrupt request is not serviced, the concluding acknowledge phase of the transfer stretches.

Stretching of the clock continues until new data bytes are written to the transmit FIFO (TWI_TXDATA8 or TWI_TXDATA16 registers). No other action is required to release the clock and continue the transmission. This behavior continues until the transmission completes (TWI_MSTRCTL.DCNT=0). The transmission concludes (TWI_ISTAT.MCOMP). The ***Clock Stretching during FIFO Underflow*** figure and table show the stretching.

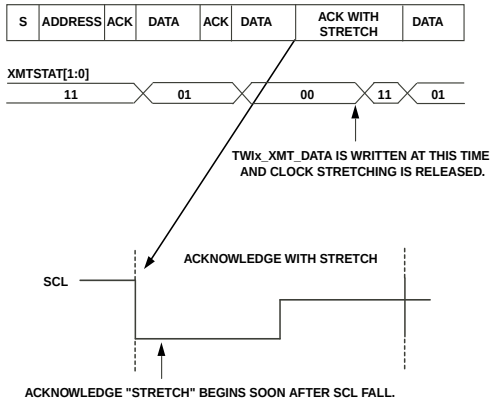

Figure 25-9: Clock Stretching during FIFO Underflow

TWI Controller	Processor
Interrupt: XMTSERV – Transmit FIFO buffer is empty.	Acknowledge: Clear the interrupt request source bits. Write to the transmit FIFO buffer.
...	...
Interrupt: MCOMP – Master transmit complete (DCNT= 0x00).	Acknowledge: Clear the interrupt request source bits.

Clock Stretching During FIFO Overflow

During a master mode receive operation, an interrupt occurs at the instant the receive FIFO becomes full. It is during the acknowledge phase of this received byte that clock stretching begins. The TWI module makes no attempt to initiate the reception of another byte. Stretching of the clock continues until the data bytes previously received are read from the receive FIFO buffer (TWI_RXDATA8 or TWI_RXDATA16 registers). No other action is required to release the clock and continue the reception of data. This behavior continues until the reception is complete (TWI_MSTRCTL.DCNT=0). Reception concludes (TWI_ISTAT.MCOMP). The ***Clock Stretching During FIFO Overflow*** figure and table show the clock stretching.

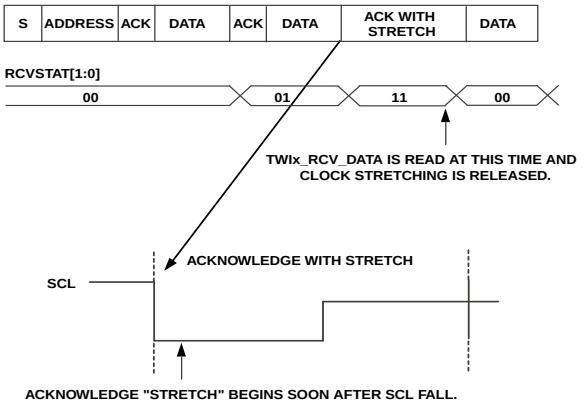

Figure 25-10: Clock Stretching During FIFO Overflow

TWI Controller	Processor
Interrupt: RCVSERV – Receive FIFO buffer is full.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Acknowledge: Clear the interrupt source bits.	Interrupt: MCOMP – Master receive complete.

Clock Stretching During Repeated Start

The repeated start feature in I^2C protocol requires a transition between two subsequent transfers. With the use of clock stretching, the task of managing transitions becomes simpler and common to all transfer types.

Once an initial TWI master transfer completes (transmit or receive), the clock initiates a stretch during the repeated start phase between transfers. Concurrent with this event, the initial transfer generates a `TWI_ISTAT.MCOMP` interrupt to signify the initial transfer has completed (`TWI_MSTRCTL.DCNT=0`). This initial transfer is handled without any special bit setting sequences or timing.

The clock stretching logic described applies here. With no system-related timing constraints, the subsequent transfer (receive or transmit) is set up and activated. This sequence can repeat as many times as required to string a series of repeated start transfers together. The ***Clock Stretching during Repeated Start Condition*** figure and table show the clock stretching.

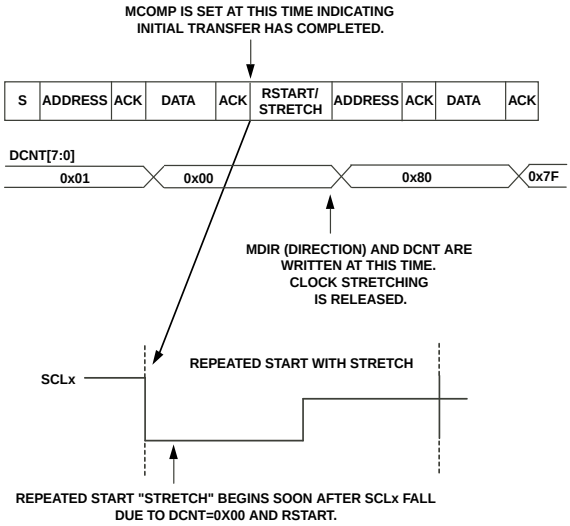

Figure 25-11: Clock Stretching during Repeated Start Condition

TWI Controller	Processor
Interrupt: MCOMP – Initial transmit has completed and DCNT = 0x00. Note: transfer in progress, RSTART previously set.	Acknowledge: Clear the interrupt request source bits. Write to TWIx_MASTER_CTL, setting MDIR (receive), clearing RSTART, and setting new DCNT value (nonzero).
Interrupt: RCVSERV – Receive FIFO is full.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Interrupt: MCOMP – Master receive complete	Acknowledge: Clear the interrupt request source bits.

TWI Programming Model

The topics in this section provide information on the basic programming steps required to set up and run the two wire interface.

General Setup

General setup refers to register writes that are required for both slave mode and master mode operations.

Perform general setup before setting either the master or slave enable bits.

1. Program the `TWI_CTL.EN` bit to enable the TWI controller and set the prescale value (`TWI_CTL.PRESCALE` bit).
2. Program the prescale value to the binary representation of f_{SCLK0}/10 MHz. Round up all values to the next whole number.
3. Set the `TWI_CTL.EN` bit to enable the controller.

Once the TWI controller is enabled, a bus busy condition can be detected. This condition clears after t_{BUF} has expired, assuming no additional bus activity has been detected.

Slave Mode

When enabled, slave mode operation supports both receive and transmit data transfers.

It is not possible to enable only one data transfer direction and not acknowledge (NAK) the other. The following setup reflects this functionality.

1. Program the `TWI_SLVADDR` register. The TWI uses the appropriate 7 bits in determining a match during the address phase of the transfer.
2. Program the `TWI_TXDATA8.VALUE` or `TWI_TXDATA16` registers. These values are the initial data values for transmission when the slave is addressed and transmission is needed. This step is optional. If no data is written when the slave is addressed and transmission is needed, the serial clock (`TWI_SCL`) stretches. An interrupt is generated until data is written to the transmit FIFO.
3. Program the `TWI_IMSK` register. There are enable-bits associated with the desired interrupt sources. For example, programming the value 0x000F results in an interrupt request output to the processor, when the TWI module detects a valid address match. An interrupt request also occurs when a valid slave transfer completes or has an error, or a subsequent transfer has begun and the previous transfer has not been serviced.
4. Program the `TWI_SLVCTL` register. This step prepares and enables slave mode operation. For example, programming the value 0x0005 enables slave mode operation and requires 7-bit addressing. It indicates that data in the transmit FIFO buffer is for slave mode transmission.

The ***Slave Mode Interaction*** table and ***TWI Slave Mode Program Flow*** diagram represent the interaction between the TWI controller and the processor using this example.

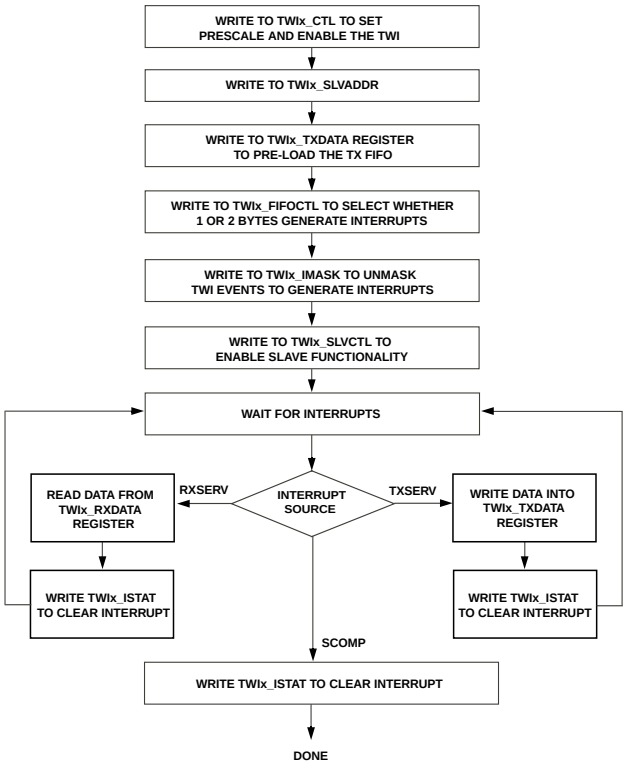

Figure 25-12: TWI Slave Mode Program Flow

Table 25-3: Slave Mode Interaction

TWI Controller	Processor
Interrupt: SINIT – Slave transfer in progress.	Acknowledge: Clear the interrupt source bits.
Interrupt: RCVSERV – Receive buffer is full.	Acknowledge: Clear the interrupt source bits. Read TWIx_FIFO_STAT. Read the receive FIFO buffer.
...	...
Interrupt: SCOMP – Slave transfer complete.	Acknowledge: Clear the interrupt source bits. Read the receive FIFO buffer.

Master Mode Program Flow

The ***Master Mode Program Flow*** figure shows the program for the TWI in master mode.

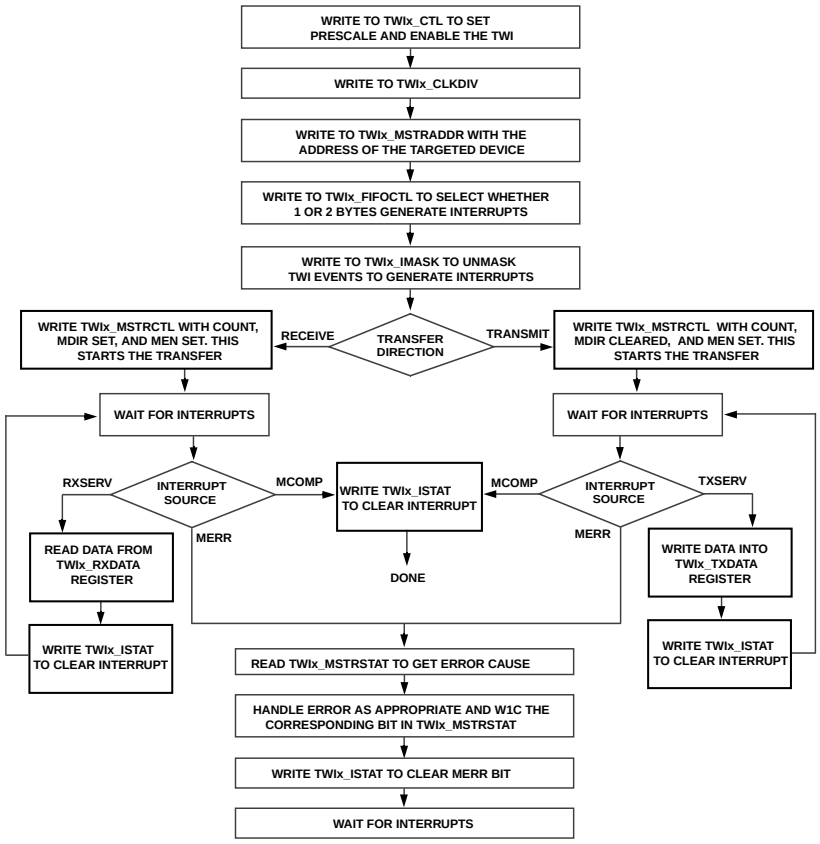

Figure 25-13: Master Mode Program Flow

Master Mode Clock Setup

Master mode operation is set up and executed on a per-transfer basis.

An example of programming steps for a receive and for a transmit is given separately in following sections. The programming step for clock setup listed here is common to both transfer types.

1. Program the `TWI_CLKDIV` register to define the minimum high and minimum low duration for the clock.

The `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` fields do not guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for `TWI_SCL`. The slew rate controls falling edges. The RC time constant formed by the pull-up resistor and the SCL capacitance govern rising edges. See the “Register Descriptions” section for more details.

Master Mode Transmit

Follow these programming steps for a single master mode transmission:

1. Program the `TWI_MSTRADDR` register. This step defines the address transmitted during the address phase of the transfer.

2. Program the TWI_TXDATA8 or TWI_TXDATA16 register. This step configures the initial data transmitted. It is an error to complete the address phase of the transfer and not have data available in the transmit FIFO buffer.
3. Program the TWI_FIFOCTL register. The programming indicates if the transmit FIFO buffer interrupt requests occur with each byte transmitted (8-bits) or with every 2 bytes transmitted (16-bits).
4. Program the TWI_IMSK register. This step enables the bits associated with the desired interrupt request sources. For example, programming the value 0x0030 results in an interrupt output to the processor when the master transfer completes, and the master transfer has an error.
5. Program the TWI_MSTRCTL register. This step prepares and enables master mode operation. For example, programming the value 0x0201: enables master mode operation, generates a 7-bit address, sets the direction to master-transmit, uses standard mode timing, and transmits 8 data bytes before generating a stop condition.

The ***Master Mode Transmit Setup Interaction*** table represents the interaction between the TWI controller and the processor using this example.

Table 25-4: Master Mode Transmit Setup Interaction

TWI Controller	Processor
Interrupt: XMTSERV – Transmit buffer is empty.	Acknowledge: Clear the interrupt request source bits. Write to the transmit FIFO buffer.
...	...
Interrupt: MCOMP – Master transfer complete.	Acknowledge: Clear the interrupt request source bits.

Master Mode Receive

Follow these programming steps for a single master mode receive.

1. Program the TWI_MSTRADDR register. This step defines the address transmitted during the address phase of the transfer.
2. Program the TWI_FIFOCTL register. This step indicates if the receive FIFO buffer interrupt requests occur with each byte received (8-bits) or with every 2 bytes received (16-bits).
3. Program the TWI_IMSK register. This step configures the enable bits associated with the desired interrupt sources. For example, programming the value 0x0030 results in an interrupt request output to the processor when the master transfer completes, and the master transfer has an error.
4. Program the TWI_MSTRCTL register. This step prepares and enables master mode operation. For example, programming the value 0x0205: enables master mode operation, generates a 7-bit address, sets the direction to master-receive, uses standard mode timing, and receives 8 data bytes before generating a stop condition.

The ***Master Mode Receive Setup Interaction*** table shows the interaction between the TWI controller and the processor using this example.

Table 25-5: Master Mode Receive Setup Interaction

TWI Controller	Processor
Interrupt: RCVSERV – Receive buffer is full.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Interrupt: MCOMP – Master transfer complete.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.

NOTE: After the `TWI_MSTRCTL.DCNT` bit decrements to zero, the TWI master device sends a NAK to indicate to the slave transmitter to release the bus. This operation allows the master to send the stop signal to terminate the transfer.

ADSP-SC57x TWI Register Descriptions

Two-Wire Interface (TWI) contains the following registers.

Table 25-6: ADSP-SC57x TWI Register List

Name	Description
TWI_CLKDIV	SCL Clock Divider Register
TWI_CTL	Control Register
TWI_FIFOCTL	FIFO Control Register
TWI_FIFOSTAT	FIFO Status Register
TWI_IMSK	Interrupt Mask Register
TWI_ISTAT	Interrupt Status Register
TWI_MSTRADDR	Master Mode Address Register
TWI_MSTRCTL	Master Mode Control Registers
TWI_MSTRSTAT	Master Mode Status Register
TWI_RXDATA16	Rx Data Double-Byte Register
TWI_RXDATA8	Rx Data Single-Byte Register
TWI_SLVADDR	Slave Mode Address Register
TWI_SLVCTL	Slave Mode Control Register
TWI_SLVSTAT	Slave Mode Status Register
TWI_TXDATA16	Tx Data Double-Byte Register
TWI_TXDATA8	Tx Data Single-Byte Register

SCL Clock Divider Register

During master mode operation, the TWI_CLKDIV holds values, which the TWI uses to create the high and low durations of the serial clock (SCL). The clock signal SCL is an output in master mode and an input in slave mode. The values in the TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI fields add up to the CLKDIV value the following equation.

CLKDIV = TWI SCL period / 10 MHz time reference

Serial clock frequencies can vary from 400 KHz to less than 20 KHz. The resolution of the clock generated is 1/10 MHz or 100 ns. For example, for an SCL of 400 KHz (period = 1/400 KHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns):

CLKDIV = 2500 ns / 100 ns = 25

For an SCL with a 30% duty cycle, use TWI_CLKDIV.CLKLO = 17 and TWI_CLKDIV.CLKHI = 8.

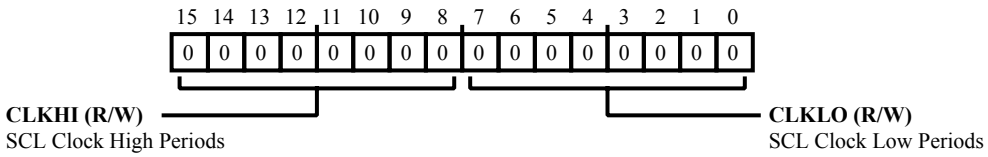

Figure 25-14: TWI_CLKDIV Register Diagram

Table 25-7: TWI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	CLKHI	SCL Clock High Periods. The TWI_CLKDIV.CLKHI specifies the number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single master.
7:0 (R/W)	CLKLO	SCL Clock Low Periods. The TWI_CLKDIV.CLKLO specifies the number of internal time reference periods the serial clock (SCL) is held low.

Control Register

The TWI_CTL enables the TWI, establishes a relationship between the system clock (SCLK) and the TWI controller's internally timed events, and enables SCCB compatibility.

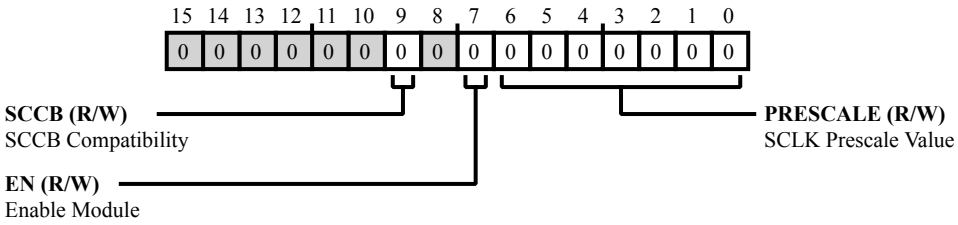

Figure 25-15: TWI_CTL Register Diagram

Table 25-8: TWI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SCCB	SCCB Compatibility. The TWI_CTL.SCCB enables SCCB compatible operation for the TWI. SCCB compatibility is an optional feature and should not be used in an I^2C bus system. When this feature is enabled, all slave asserted acknowledgement bits are ignored by this master. This feature is valid only during transfers where the TWI is mastering an SCCB bus. Slave mode transfers should be avoided when this feature is enabled because the TWI controller always generates an acknowledge in slave mode.	
		0	Disable SCCB compatibility. When disabled, master transfers are not SCCB compatible.
		1	Enable SCCB compatibility. When enabled, master transfers are SCCB compatible. All slave-asserted acknowledgment bits are ignored by this master.
7 (R/W)	EN	Enable Module. The TWI_CTL.EN enables TWI controller operation for either master and/or slave mode of operation. It is recommended that this bit be set at the time TWI_CTL.PRESCALE is initialized and remain set. This method guarantees accurate operation of bus busy detection logic.	
		0	Disable
		1	Enable

Table 25-8: TWI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRESCALE	SCLK Prescale Value. The `TWI_CTL.PRESCALE` holds the pre-scaled value for the TWI internal time reference. This reference is derived from SCLK according to the formula: `TWI_CTL.PRESCALE` = f_{SCLK}/10MHz The `TWI_CTL.PRESCALE` specifies the number of system clock (SCLK) periods used in the generation of one internal time reference. The value of `TWI_CTL.PRESCALE` must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value.

FIFO Control Register

The TWI_FIFOCTL control bits affect only the FIFO and are not tied in any way with master or slave mode operation.

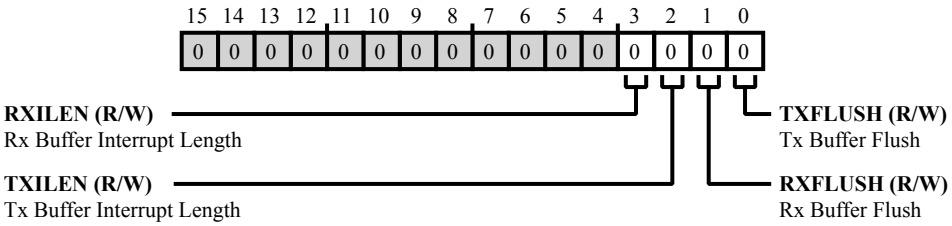

Figure 25-16: TWI_FIFOCTL Register Diagram

Table 25-9: TWI_FIFOCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXILEN	Rx Buffer Interrupt Length. The TWI_FIFOCTL.RXILEN determines the rate at which receive buffer interrupts are to be generated. Interrupts may be generated with each byte received or after two bytes are received. Interrupt status is available in TWI_FIFOSTAT.RXSTAT.	
		0	RXSERVI on 1 or 2 Bytes in FIFO
		1	RXSERVI on 2 Bytes in FIFO
2 (R/W)	TXILEN	Tx Buffer Interrupt Length. The TWI_FIFOCTL.TXILEN determines the rate at which transmit buffer interrupts are to be generated. Interrupts may be generated with each byte transmitted or after two bytes are transmitted. Interrupt status is available in TWI_FIFOSTAT.TXSTAT.	
		0	TXSERVI on 1 Byte of FIFO Empty
		1	TXSERVI on 2 Bytes of FIFO Empty
1 (R/W)	RXFLUSH	Rx Buffer Flush. The TWI_FIFOCTL.RXFLUSH directs the TWI to flush the contents of the receive buffer and update TWI_FIFOSTAT.RXSTAT to indicate the buffer is empty. This state is held until this bit is cleared. During an active receive, the receive buffer in this state responds to the receive logic as if it is full.	
		0	Normal Operation of Rx Buffer
		1	Flush Rx Buffer

Table 25-9: TWI_FIFOCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TXFLUSH	Tx Buffer Flush. The `TWI_FIFOCTL.TXFLUSH` directs the TWI to flush the contents of the transmit buffer and update `TWI_FIFOSTAT.TXSTAT` to indicate the buffer is empty. This state is held until this bit is cleared. During an active transmit, the transmit buffer in this state responds to the transmit logic as if it is empty.	
		0	Normal Operation of Tx Buffer
		1	Flush Tx Buffer

FIFO Status Register

The TWI_FIFOSTAT fields indicate the state of the FIFO buffers' receive and transmit contents. The FIFO buffers do not discriminate between master data and slave data. By using the status and control bits provided, the FIFO can be managed to allow simultaneous master and slave operation.

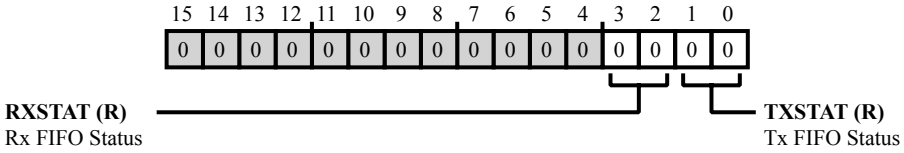

Figure 25-17: TWI_FIFOSTAT Register Diagram

Table 25-10: TWI_FIFOSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	RXSTAT	Rx FIFO Status. The read-only TWI_FIFOSTAT.RXSTAT indicates the number of valid data bytes in the receive FIFO buffer. The status is updated with each FIFO buffer read using the peripheral data bus or write access by the receive shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral read of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data. Either a single or double byte peripheral read of the FIFO is allowed.
1:0 (R/NW)	TXSTAT	Tx FIFO Status. The read-only TWI_FIFOSTAT.TXSTAT field indicates the number of valid data bytes in the FIFO buffer. The status is updated with each FIFO buffer write using the peripheral data bus or read access by the transmit shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty. Either a single or double byte peripheral write of the FIFO is allowed.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral write of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data.

Interrupt Mask Register

The TWI_IMSK enables interrupt sources to assert the interrupt output. Each mask bit corresponds with one interrupt request source bit in TWI_ISTAT. Reading and writing TWI_IMSK does not affect the contents of the TWI_ISTAT.

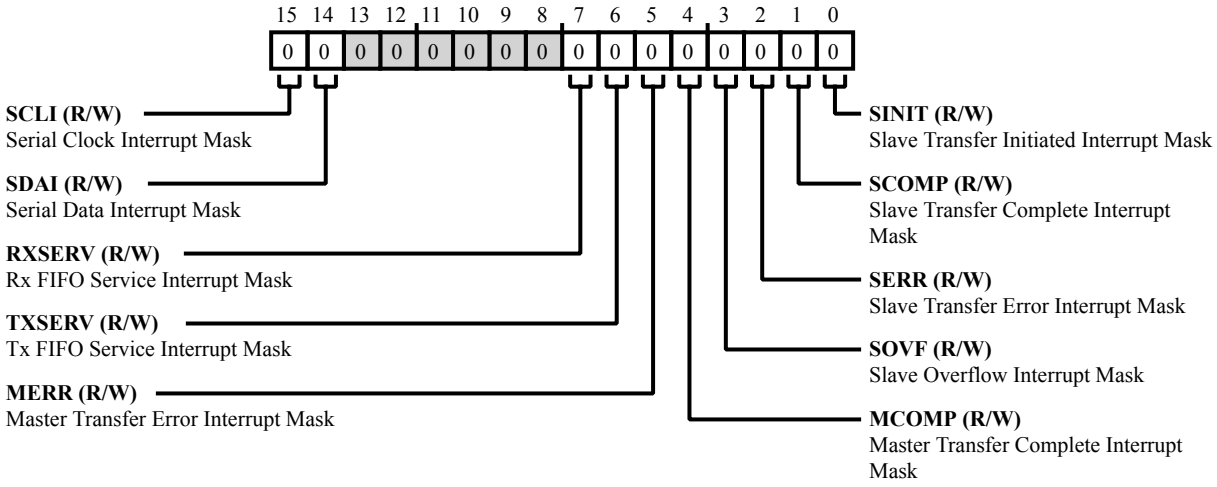

Figure 25-18: TWI_IMSK Register Diagram

Table 25-11: TWI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLI	Serial Clock Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
14 (R/W)	SDAI	Serial Data Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
7 (R/W)	RXSERV	Rx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
6 (R/W)	TXSERV	Tx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Table 25-11: TWI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	MERR	Master Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
4 (R/W)	MCOMP	Master Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
3 (R/W)	SOVF	Slave Overflow Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
2 (R/W)	SERR	Slave Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
1 (R/W)	SCOMP	Slave Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
0 (R/W)	SINIT	Slave Transfer Initiated Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Interrupt Status Register

The TWI_ISTAT contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

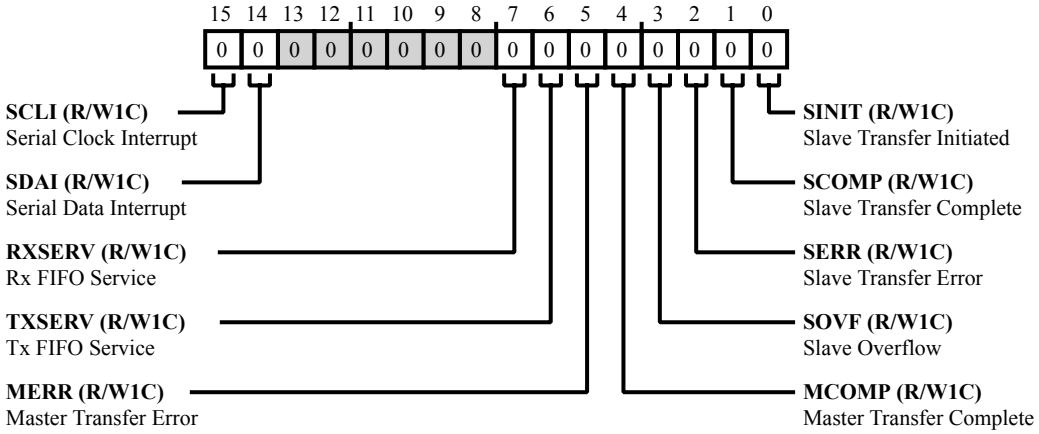

Figure 25-19: TWI_ISTAT Register Diagram

Table 25-12: TWI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SCLI	Serial Clock Interrupt. If the TWI is enabled (TWI_CTL.EN), SCLI is set on a high-to-low transition of the serial clock pin (SCLx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SCLx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SCLx pin. This bit is W1C.
14 (R/W1C)	SDAI	Serial Data Interrupt. If the TWI is enabled (TWI_CTL.EN), SDAI is set on a high-to-low transition of the serial data pin (SDAx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SDAx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SDAx pin. This bit is W1C.

Table 25-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RXSERV	Rx FIFO Service. If TWI_FIFOCTL.RXILEN =0, the TWI_ISTAT.RXSERV is set each time the TWI_FIFOSTAT.RXSTAT field is updated to either 01 or 11. If TWI_FIFOCTL.RXILEN =1, the TWI_ISTAT.RXSERV is set each time TWI_FIFOSTAT.RXSTAT is updated to 11.	
		0	No Interrupt. The FIFO does not require servicing, or the TWI_FIFOSTAT.RXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The receive FIFO buffer has one or two 8-bit words of data available to be read.
6 (R/W1C)	TXSERV	Tx FIFO Service. If TWI_FIFOCTL.TXILEN =0, the TWI_ISTAT.TXSERV is set each time the TWI_FIFOSTAT.TXSTAT field is updated to either 01 or 00. If TWI_FIFOCTL.TXILEN =1, the TWI_ISTAT.TXSERV is set each time TWI_FIFOSTAT.TXSTAT is updated to 00.	
		0	No Interrupt. FIFO does not require servicing, or the TWI_FIFOSTAT.TXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The transmit FIFO buffer has one or two 8-bit locations available to be written.
5 (R/W1C)	MERR	Master Transfer Error. The TWI_ISTAT.MERR indicates that a master error has occurred. The conditions surrounding the error are indicated by the master status register (TWI_MSTRSTAT).	
		0	No Interrupt
		1	Interrupt Detected
4 (R/W1C)	MCOMP	Master Transfer Complete. The TWI_ISTAT.MCOMP indicates that the initiated master transfer has completed. In the absence of a repeat start, the bus has been released.	
		0	No Interrupt
		1	Interrupt Detected
3 (R/W1C)	SOVF	Slave Overflow. The TWI_ISTAT.SOVF indicates that the TWI_ISTAT.SCOMP bit was set at the time a subsequent transfer has acknowledged an address phase. The transfer continues, however, it may be difficult to delineate data of one transfer from another.	
		0	No Interrupt
		1	Interrupt Detected

Table 25-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	SERR	Slave Transfer Error. The `TWI_ISTAT.SERR` indicates that a slave error has occurred. A restart or stop condition has occurred during the data receive phase of a transfer.	
		0	No Interrupt
		1	Interrupt Detected
1 (R/W1C)	SCOMP	Slave Transfer Complete. The `TWI_ISTAT.SCOMP` indicates that the transfer is complete and either a stop, or a restart was detected.	
		0	No Interrupt
		1	Interrupt Detected
0 (R/W1C)	SINIT	Slave Transfer Initiated. The `TWI_ISTAT.SINIT` indicates whether or not a slave transfer is in progress.	
		0	No Interrupt. A transfer is not in progress, or an address match has not occurred since the last time this bit was cleared.
		1	Interrupt Detected. The slave has detected an address match, and a transfer has been initiated.

Master Mode Address Register

During the addressing phase of a transfer, the TWI controller, with its master enabled, transmits the contents of TWI_MSTRADDR. When programming this register, omit the read/write bit. That is, only the upper 7 bits that make up the slave address should be written to this register. For example, if the slave address is b#1010000X, where X is the read/write bit, the TWI_MSTRADDR is programmed with b#1010000, which corresponds to 0x50. When sending out the address on the bus, the TWI controller appends the read/write bit as appropriate based on the state of the TWI_MSTRCTL.DIR bit.

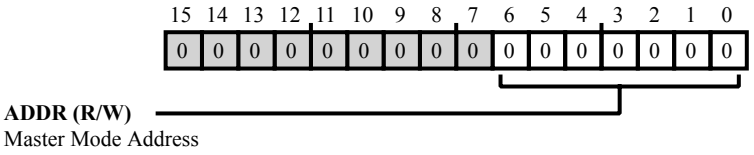

Figure 25-20: TWI_MSTRADDR Register Diagram

Table 25-13: TWI_MSTRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Master Mode Address.

Master Mode Control Registers

The TWI_MSTRCTL controls the logic associated with master mode operation. Bits in this register do not affect slave mode operation and should not be modified to control slave mode functionality.

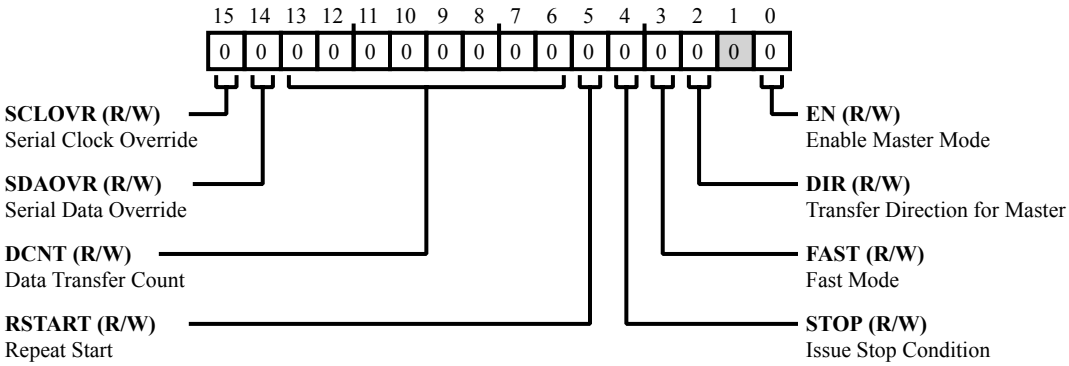

Figure 25-21: TWI_MSTRCTL Register Diagram

Table 25-14: TWI_MSTRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLOVR	Serial Clock Override. The TWI_MSTRCTL.SCLOVR provides direct control of the serial clock line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SCLOVR is set, the TWI overrides normal serial clock output, driving it to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SCLOVR is cleared, the TWI permits normal serial clock operation under the control of master mode clock generation and slave mode clock stretching logic.	
		0	Permit Normal SCL Operation
		1	Override Normal SCL Operation
14 (R/W)	SDAOVR	Serial Data Override. The TWI_MSTRCTL.SDAOVR provides direct control of the serial data line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SDAOVR is set, the TWI overrides normal serial data operation under the control of the transmit shift register and acknowledge logic, driving serial data output to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SDAOVR is cleared, the TWI permits normal serial data operation.	
		0	Permit Normal SDA Operation
		1	Override Normal SDA Operation

Table 25-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:6 (R/W)	DCNT	Data Transfer Count. The TWI_MSTRCTL.DCNT indicates the number of data bytes to transfer. As each data word is transferred, the TWI decrements this counter. When TWI_MSTRCTL.DCNT decrements to 0, a stop condition is generated. Setting TWI_MSTRCTL.DCNT to 0xFF disables the counter. In this transfer mode, data continues to be transferred until it is concluded by setting the TWI_MSTRCTL.STOP bit. In the event a master transmit is aborted due to a slave data NAK, the value of TWI_MSTRCTL.DCNT equals the number of bytes not sent. The byte which was NAK'ed by the slave is counted as a sent byte.	
5 (R/W)	RSTART	Repeat Start. The TWI_MSTRCTL.RSTART enables the TWI to issue a repeat start condition at the conclusion of the current transfer (TWI_MSTRCTL.DCNT =0) and begin the next transfer. The current transfer concludes with updates to the appropriate status and interrupt bits. If errors occurred during the previous transfer, a repeat start does not occur. In the absence of any errors, master enable (TWI_MSTRCTL.EN) does not self clear on a repeat start.	
		0	Disable Repeat Start
		1	Enable Repeat Start
4 (R/W)	STOP	Issue Stop Condition. The TWI_MSTRCTL.STOP directs the TWI to issue a stop condition. The transfer concludes as soon as possible avoiding any error conditions (as if data transfer count had been reached). At that time, the TWI_IMSK is updated along with any associated status bits.	
		0	Permit Normal Operation
		1	Issue Stop
3 (R/W)	FAST	Fast Mode. The TWI_MSTRCTL.FAST selects whether the TWI operates in fast mode or standard mode. In fast mode, the TWI uses timing specifications for transfers at up to 400K bits/s. In standard mode, the TWI uses timing specifications for transfers at up to 100K bits/s.	
		0	Select Standard Mode
		1	Select Fast Mode
2 (R/W)	DIR	Transfer Direction for Master. The TWI_MSTRCTL.DIR selects the transfer direction for the TWI as master initiated receive or transmit.	
		0	Master Transmit
		1	Master Receive

Table 25-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Master Mode. The `TWI_MSTRCTL.EN` enables master mode functionality. A start condition is generated if the bus is idle. This bit self clears at the completion of a transfer (after `TWI_MSTRCTL.DCNT` decrements to zero), including transfers terminated due to errors. If disabled (=0) during operation, the transfer is aborted, and all logic associated with master mode transfers are reset. Serial data and serial clock (SDA, SCL) are no longer driven. Write-1-to-clear status bits are not affected.	
		0	Disable
		1	Enable

Master Mode Status Register

The TWI_MSTRSTAT holds information during master mode transfers and at their conclusion. Generally, master mode status bits are not directly associated with the generation of interrupt requests, but these bits offer information on the current transfer. Slave mode operation does not affect master mode status bits.

Note that while TWI_MSTRSTAT.SCLSEN is set (this condition could be due to having no pull-up resistor on TWI_SCL or another agent is driving TWI_SCL low), the acknowledge bits (TWI_MSTRSTAT.ANAK and TWI_MSTRSTAT.DNAK) do not update. This result occurs because the acknowledge conditions are sampled during the high phase of TWI_SCL.

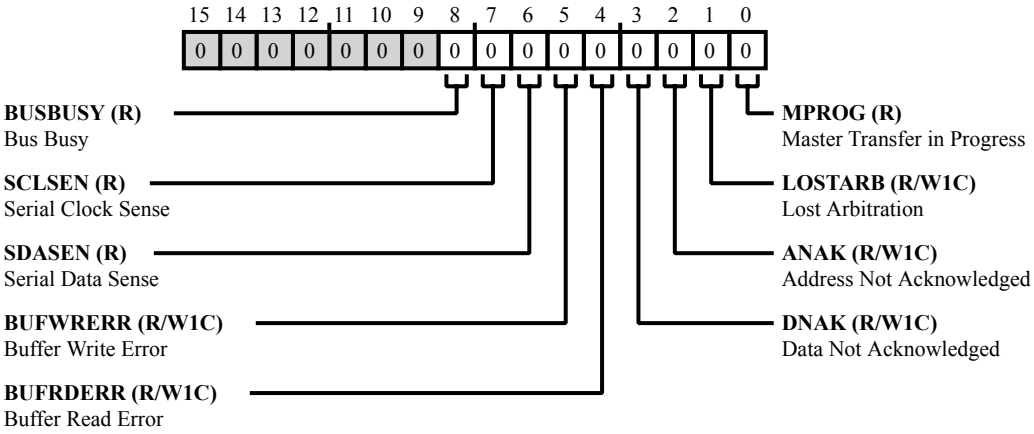

Figure 25-22: TWI_MSTRSTAT Register Diagram

Table 25-15: TWI_MSTRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	BUSBUSY	Bus Busy. The TWI_MSTRSTAT.BUSBUSY indicates whether the bus is currently busy or free. This indication is not limited to only this device but is for all devices. On a start condition, the setting of the register value is delayed due to the input filtering. On a stop condition the clearing of the register value occurs after t_{BUF}.	
		0	Bus Free. The bus is free. The clock and data bus signals have been inactive for the appropriate bus free time.
		1	Bus Busy. The bus is busy. Clock or data activity has been detected.

Table 25-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SCLSEN	Serial Clock Sense. The `TWI_MSTRSTAT.SCLSEN` indicates the active or inactive state of the serial clock. Use this status bit when direct sensing of the serial clock line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SCL Inactive "One". An inactive "one" is being sensed on the serial clock.
		1	SCL Active "Zero". An active "zero" is being sensed on the serial clock. The source of the active driver is not known and can be internal or external.
6 (R/NW)	SDASEN	Serial Data Sense. The `TWI_MSTRSTAT.SDASEN` indicates the active or inactive status of the serial data. Use this status bit when direct sensing of the serial data line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SDA Inactive "One". An inactive "one" is currently being sensed on the serial data line.
		1	SDA Active "Zero". An active "zero" is currently being sensed on the serial data line. The source of the active driver is not known and can be internal or external.
5 (R/W1C)	BUFWRERR	Buffer Write Error. The `TWI_MSTRSTAT.BUFWRERR` indicates whether the current master transfer was aborted due to a receive buffer write error. The receive buffer and receive shift register were both full at the same time. This bit is W1C.	
		0	No Status
		1	Buffer Write Error
4 (R/W1C)	BUFRDERR	Buffer Read Error. The `TWI_MSTRSTAT.BUFRDERR` indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Buffer Read Error
3 (R/W1C)	DNAK	Data Not Acknowledged. The `TWI_MSTRSTAT.DNAK` indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Data NAK

Table 25-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	ANAK	Address Not Acknowledged. The `TWI_MSTRSTAT.ANAK` indicates whether the current master transfer was aborted due to the detection of a NAK during the address phase of the transfer. This bit is W1C.	
		0	No Status
		1	Address NAK
1 (R/W1C)	LOSTARB	Lost Arbitration. The `TWI_MSTRSTAT.LOSTARB` indicates whether the current transfer was aborted due to the loss of arbitration with another master. This bit is W1C.	
		0	No Status
		1	Lost Arbitration
0 (R/NW)	MPROG	Master Transfer in Progress. The `TWI_MSTRSTAT.MPROG` indicates whether or not a master transfer is in progress. If clear (`TWI_MSTRSTAT.MPROG` =0), currently no transfer is taking place. This can occur after a transfer is complete or while an enabled master is waiting for an idle bus.	
		0	No Status
		1	Master Transfer in Progress

Rx Data Double-Byte Register

The TWI_RXDATA16 holds a 16-bit data value read from the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte receive data access can be performed. Two data bytes can be read, effectively emptying the receive FIFO buffer with a single access.

The data is read in little endian byte order, where byte 0 is the first byte received and byte 1 is the second byte received. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated to indicate it is empty. If an access is performed while the FIFO buffer is not full, the read data is unknown and the existing FIFO buffer data and its status remains unchanged.

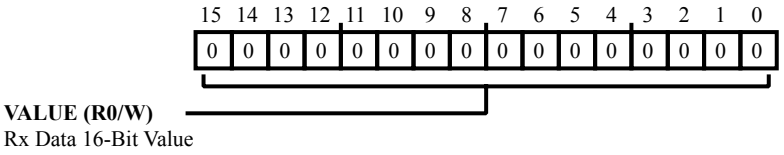

Figure 25-23: TWI_RXDATA16 Register Diagram

Table 25-16: TWI_RXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Rx Data 16-Bit Value.

Rx Data Single-Byte Register

The TWI_RXDATA8 holds an 8-bit data value read from the FIFO buffer. Receive data is read from the corresponding receive buffer in a first-in first-out order. Although peripheral bus reads are 16 bits, a read access to TWI_RXDATA8 accesses only one transmit data byte from the FIFO buffer. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated. If an access is performed while the FIFO buffer is empty, the data is unknown and the FIFO buffer status remains indicating it is empty.

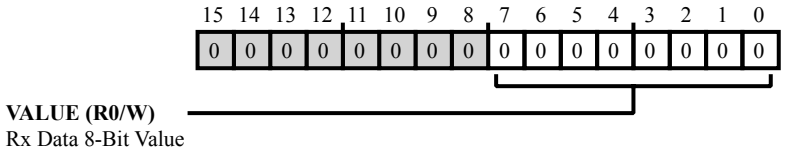

Figure 25-24: TWI_RXDATA8 Register Diagram

Table 25-17: TWI_RXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Rx Data 8-Bit Value.

Slave Mode Address Register

The TWI_SLVADDR holds the slave mode address, which is the valid address to which the slave-enabled TWI controller responds. The TWI controller compares this value with the received address during the addressing phase of a transfer.

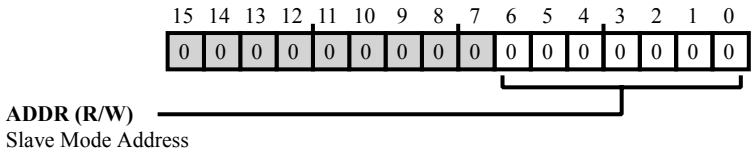

Figure 25-25: TWI_SLVADDR Register Diagram

Table 25-18: TWI_SLVADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Slave Mode Address.

Slave Mode Control Register

The TWI_SLVCTL controls the logic associated with slave mode operation. Settings in this register do not affect master mode operation and should not be modified to control master mode functionality.

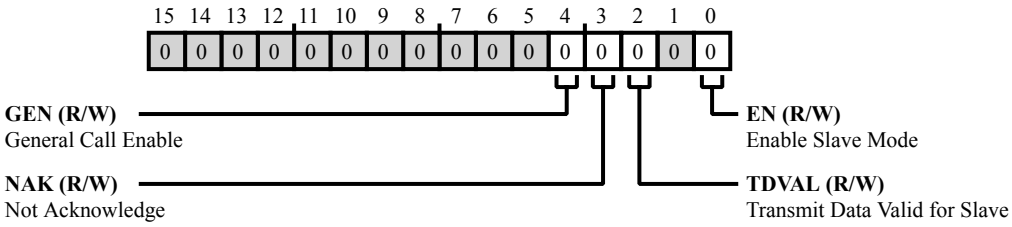

Figure 25-26: TWI_SLVCTL Register Diagram

Table 25-19: TWI_SLVCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	GEN	General Call Enable. The TWI_SLVCTL.GEN enables general call address matching. When enabled, a general call slave receive transfer is accepted. All status and interrupt source bits associated with transfers are updated. Note that general call address detection is available only when slave mode is enabled.	
		0	Disable General Call Matching
		1	Enable General Call Matching
3 (R/W)	NAK	Not Acknowledge. The TWI_SLVCTL.NAK directs the TWI to generate a NAK (if set) or an ACK (if cleared) at the conclusion of data transfer for slave receive. For NAK, the slave is still considered to be addressed at the conclusion of transfer.	
		0	Generate ACK
		1	Generate NAK
2 (R/W)	TDVAL	Transmit Data Valid for Slave. The TWI_SLVCTL.TDVAL selects whether the data in the transmit FIFO is available (valid) for slave transmission (TWI_SLVCTL.TDVAL set). If the FIFO data is not available (invalid) for slave transmission (TWI_SLVCTL.TDVAL cleared), the data in the transmit FIFO is for master mode transmits, and the data is not allowed to be used during a slave transmit; the transmit FIFO is treated as if it is empty.	
		0	Data Invalid for Slave Tx
		1	Data Valid for Slave Tx

Table 25-19: TWI_SLVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Slave Mode. The `TWI_SLVCTL.EN` enables slave operation. Enabling slave and master modes of operation concurrently is allowed. If disabled, no attempt is made to identify a valid address. If `TWI_SLVCTL.EN` is cleared during a valid transfer, clock stretching ceases, the serial data line is released, and the current byte is not acknowledged.	
		0	Disable
		1	Enable

Slave Mode Status Register

During and at the conclusion of register slave mode transfers, the TWI_SLVSTAT holds information on the current transfer. Generally slave mode status bits are not associated with the generation of interrupt requests. Master mode operation does not affect slave mode status bits.

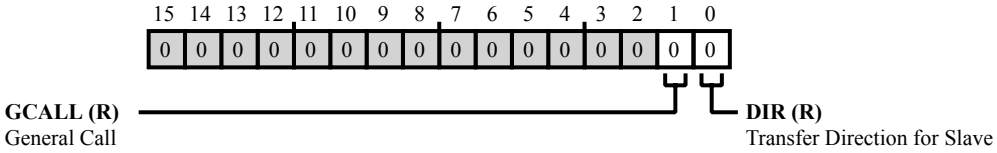

Figure 25-27: TWI_SLVSTAT Register Diagram

Table 25-20: TWI_SLVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	GCALL	General Call. The TWI_SLVSTAT.GCALL indicates whether or not--at the time of addressing--the address was determined to be a general call. This bit self clears if slave mode is disabled (TWI_SLVCTL.EN =0).	
		0	Not a General Call Address
		1	General Call Address
0 (R/NW)	DIR	Transfer Direction for Slave. The TWI_SLVSTAT.DIR indicates whether--at the time of addressing--the transfer direction was determined to be slave transmit or receive. This bit self clears if slave mode is disabled (TWI_SLVCTL.EN =0).	
		0	Slave Receive
		1	Slave Transmit

Tx Data Double-Byte Register

The TWI_TXDATA16 register holds a 16-bit data value written into the FIFO buffer. To reduce interrupt latency output rates and peripheral bus access times, a double byte transfer data access can be done. Two data bytes can be written, effectively filling the transmit FIFO buffer with a single access.

The data is written in little endian byte order, where byte 0 is the first byte to be transferred and byte 1 is the second byte to be transferred. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is not empty, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register when read back returns zero.

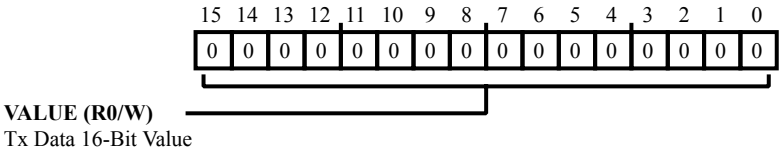

Figure 25-28: TWI_TXDATA16 Register Diagram

Table 25-21: TWI_TXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Tx Data 16-Bit Value.

Tx Data Single-Byte Register

The TWI_TXDATA8 register holds an 8-bit data value written into the FIFO buffer. Transmit data is entered into the corresponding transmit buffer in a first-in first-out order. For 16-bit peripheral bus writes, a write access to this register adds only one transmit data byte to the FIFO buffer. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is full, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register returns zero when read back.

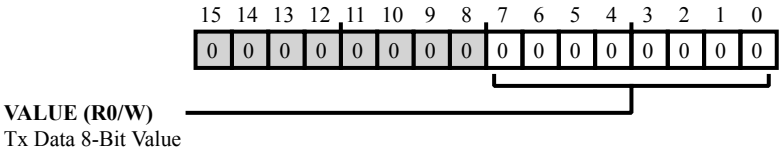

Figure 25-29: TWI_TXDATA8 Register Diagram

Table 25-22: TWI_TXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Tx Data 8-Bit Value.

26 Ethernet Media Access Controller (EMAC)

The EMAC peripheral in the processor enables network connectivity to applications through an Ethernet interface. The module is fully compliant to the following standards:

NOTE: On the processor, EMAC0 is 10/100/1000 BaseT-compliant and supports AVB (Audio Video Bridging) standards.

- Carrier Sense Multiple Access With Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications, Standard 802.3-2005, Institute of Electrical and Electronics Engineers (IEEE).
- Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, Standard 1588–2008, Institute of Electrical and Electronics Engineers (IEEE).
- Reduced Media Independent Interface Specification, Revision 1.2, RMII Consortium.
- Reduced Gigabit Media Independent Interface (RGMII), Revision 2.6, HP/Marvell.
- Timing and Synchronization for Time-Sensitive Applications in Bridged LANs, Standard 802.1AS-2011, Institute of Electrical and Electronics Engineers (IEEE).
- Forwarding and Queuing Enhancements for Time-Sensitive Streams, Standard 802.1Qav-2009, Institute of Electrical and Electronics Engineers (IEEE).
- The EMAC supports IEEE 803.3az-2010 standard for Energy Efficient Ethernet. This feature enables the Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode.

EMAC Features

The Ethernet features include the following:

- Full-duplex and half-duplex support for Ethernet
- Dedicated DMA controller with independent read write channels
- Supports dual-buffer (ring) or linked-list (chained) descriptor chaining

- Direct interface with the system crossbar bus
- Provides support for CSMA/CD protocol for half-duplex operation
- IEEE 802.3x flow control for full-duplex and half-duplex
- Automatic network monitoring statistics with management counters
- Flexible address filtering options for uni-cast, multi-cast, and broadcast addresses
- Support for promiscuous mode in reception
- Supports IEEE 802.1Q VLAN tag detection
- VLAN tag-based frame filtering - Perfect match and hash-based filtering
- Supports programmable Inter-frame Gap (IFG)
- Checksum offload engine for checking IPv4 header checksum and TCP/UDP/ICMP checksum encapsulated in IPv4 or IPv6 datagrams
- Station management interface for PHY device configuration and management
- Automatic CRC and pad generation controllable on a per-frame basis
- CRC replacement, source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted frames with per-frame control
- Layer 3 and layer 4-based frame filtering - TCP or UDP over IPv4 or IPv6
- Supports Gigabit data transfer rates with external PHY interfaced through RGMII
- Ethernet frame timestamping as described in IEEE 1588–2002 and IEEE 1588–2008. The transmit or receive status of each frame include 64-bit timestamps
- Hardware assisted time stamping capable of up to 8-ns resolution
- Automatic detection of PTP messages through Ethernet, IPv4, and IPv6 packets
- Four programmable PPS outputs that physically represent PTP system time
- Auxiliary snapshot to timestamp external events
- Four auxiliary input pins available
- Two separate channels (channel 1 and channel 2) or queues for transmission and reception of time-sensitive traffic. Channel 0 is available by default and carries the legacy best-effort Ethernet traffic on the transmit side.
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for channel 1 and channel 2
- Slot number function to schedule the data fetching by DMA from the system memory for channel 1 and channel 2
- Separate DMA, Tx FIFO, and Rx FIFO (MTL) for each additional channel

- Programmable control to route received VLAN tagged non-AV packets to channels or queues
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet
- EMAC0 supports the following FIFO sizes: 2048 bytes for transmit FIFO and also for receive FIFO
- Supports MII/RMII/RGMII interfaces for external PHY interface

EMAC Functional Description

This section provides information on the function of Ethernet MAC peripheral.

Hardware for the Media Access Control protocol

This function allows applications to support TCP/IP based network communication. At the system end, the module supports direct connection with the system crossbar bus for memory or MMR transactions. It supports RMII (Reduced Media Independent Interface), RGMII (Reduced Gigabit Media Independent Interface), MII (Media Independent Interface), and SMI (Station Management Interface) for interfacing with the external PHY chip.

Dedicated DMA Controller with independent read/write channels

Performs both data and status transfers between the application and the media independent interfaces. Internal transmit and receive FIFOs are used to buffer and regulate the frames. A dedicated interrupt line connects the EMAC interrupt sources to the System Event Controller (SEC).

MAC Management Counters (MMC) block

An extended set of registers that collect various statistics compliant with IEEE 802.3 definitions regarding the operation of the interface. The registers are updated for each new transmitted or received frame when the condition to update the counter is met. The EMAC provides a set of such counters, along with extended usage control.

PTP (Precision Time Protocol) engine

Provides hardware assistance for the implementation of the IEEE 1588 version 1 and version 2 standards, which allows time synchronization between systems.

Audio Video (AV) functionality

Enables transmission of time-sensitive traffic over bridged local area networks (LANs). The EMAC provides hardware support for IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm. In addition, slot number function allows scheduling of fetching of data by DMA from system memory.

ADSP-SC57x EMAC Register List

The Ethernet MAC (EMAC) module provides an Ethernet interface to the processor. The interface is compliant to IEEE Standard 802.3-2005. A set of registers govern EMAC operations. For more information on EMAC functionality, see the EMAC register descriptions.

Table 26-1: ADSP-SC57x EMAC Register List

Name	Description
EMAC_ADDR0_HI	MAC Address 0 High Register
EMAC_ADDR0_LO	MAC Address 0 Low Register
EMAC_ADDR1_HI	MAC Address 1 High Register
EMAC_ADDR1_LO	MAC Address 1 Low Register
EMAC_DBG	Debug Register
EMAC_DMA0_BMMODE	DMA SCB Bus Mode Register
EMAC_DMA0_BMSTAT	DMA SCB Status Register
EMAC_DMA0_BUSMODE	DMA Bus Mode Register
EMAC_DMA0_IEN	DMA Interrupt Enable Register
EMAC_DMA0_MISS_FRM	DMA Missed Frame Register
