The CNT_CFG register configures counter modes, configures input pins, and enables the CNT.

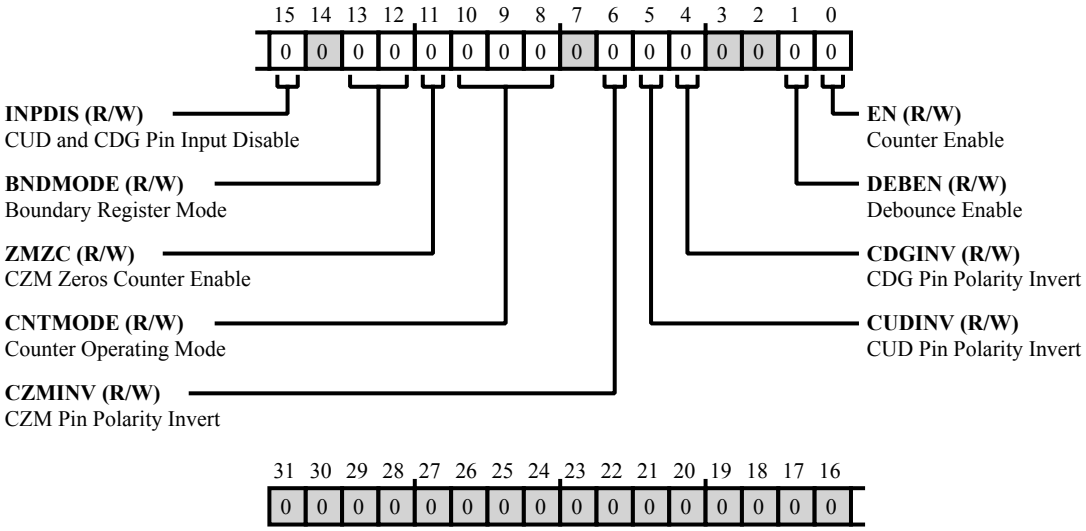

Figure 25-4: CNT_CFG Register Diagram

Table 25-8: CNT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	INPDIS	CUD and CDG Pin Input Disable. The CNT_CFG.INPDIS disables or enables the CNT_UD input pin and the CNT_DG pin.	
		0	Enable
		1	Pin Input Disable
13:12 (R/W)	BNDMODE	Boundary Register Mode. The CNT_CFG.BNDMODE bit field selects the mode for the CNT_MIN and CNT_MAX boundary registers.	
		0	BND_COMP. Boundary Compare Mode
		1	BND_ZERO. Boundary Zero Mode
		2	BND_CAPT. Boundary Capture Mode
		3	BND_AEXT. Boundary Auto-extend Mode

Table 25-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ZMZC	CZM Zeros Counter Enable. The CNT_CFG.ZMZC bit enables or disables level sensitive - active CNT_ZM pin operation to zero the CNT_CNTR register.	
		0	Disable
		1	Enable
10:8 (R/W)	CNTMODE	Counter Operating Mode. The CNT_CFG.CNTMODE bit field selects the operating mode for the CNT_UD input pin and the CNT_DG pin.	
		0	QUAD_ENC. Quadrature Encoder Mode
		1	BIN_ENC. Binary Encoder Mode
		2	UD_CNT. Rotary Counter Mode
		4	DIR_CNT. Direction Counter Mode
		5	DIR_TMR. Direction Timer Mode
6 (R/W)	CZMINV	CZM Pin Polarity Invert. The CNT_CFG.CZMINV bit selects the polarity for the CNT_ZM pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
5 (R/W)	CUDINV	CUD Pin Polarity Invert. The CNT_CFG.CUDINV bit selects the polarity for the CNT_UD pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
4 (R/W)	CDGINV	CDG Pin Polarity Invert. The CNT_CFG.CDGINV bit selects the polarity for the CNT_DG pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge

Table 25-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	DEBEN	Debounce Enable. The `CNT_CFG.DEBEN` bit enables or disables CNT input debounce filtering operation selected with the `CNT_DEBNCE` register.	
		0	Disable
		1	Enable
0 (R/W)	EN	Counter Enable. The `CNT_CFG.EN` bit enables or disables CNT operation.	
		0	Counter Disable
		1	Counter Enable

Command Register

The CNT_CMD register configures the CNT, enabling operations such as zeroing a counter register and copying or swapping boundary registers. These actions are taken by setting the appropriate bit.

Read operations from this register do not return meaningful values, with the exception of the CNT_CMD.W1ZMONCE bit, where a set bit indicates that the bit has been set by software before, but a zero marker event has not yet been detected on the CNT_ZM pin yet. For more information, see the CNT functional description.

The CNT_CNTR, CNT_MIN, and CNT_MAX registers can be initialized to zero by setting the CNT_CMD.W1LCNTZERO, CNT_CMD.W1LMINZERO, and CNT_CMD.W1LMAXZERO bits. In addition to clearing registers, the CNT_CMD register permits modifying the CNT_MIN and CNT_MAX boundary registers in a number of ways. The current counter value in the CNT_CNTR register can be captured and loaded into either of the two boundary registers to create new boundary limits. This operation is performed by setting the CNT_CMD.W1LMAXCNT and CNT_CMD.W1LMINCNT bits. Alternatively, the counter can be loaded from CNT_MAX or CNT_MIN using the CNT_CMD.W1LCNTMAX and CNT_CMD.W1LCNTMIN bits. It is also possible to transfer the current CNT_MAX value into CNT_MIN (or conversely) through the CNT_CMD.W1LMINMAX and CNT_CMD.W1LMAXMIN bits.

Another counter operation is the ability to only have the zero marker clear the CNT_CNTR register once. For more information, see the CNT functional description.

It is possible for multiple actions to be performed simultaneously by setting multiple bits in the CNT_CMD register. However, there are restrictions. The bits associated with each command have been grouped together such that all bits that involve a write to the CNT_CNTR, CNT_MAX, or CNT_MIN registers are located within bits 4-bit groups of the CNT_CMD register.

Note that a maximum of three commands can be issued at any one time, excluding the CNT_CMD.W1ZMONCE command. Also, note that CNT_CMD.W1LCNTMIN, CNT_CMD.W1LCNTMAX, and CNT_CMD.W1LCNTZERO bits have to be used exclusively. Never set more than one of them at the same time.

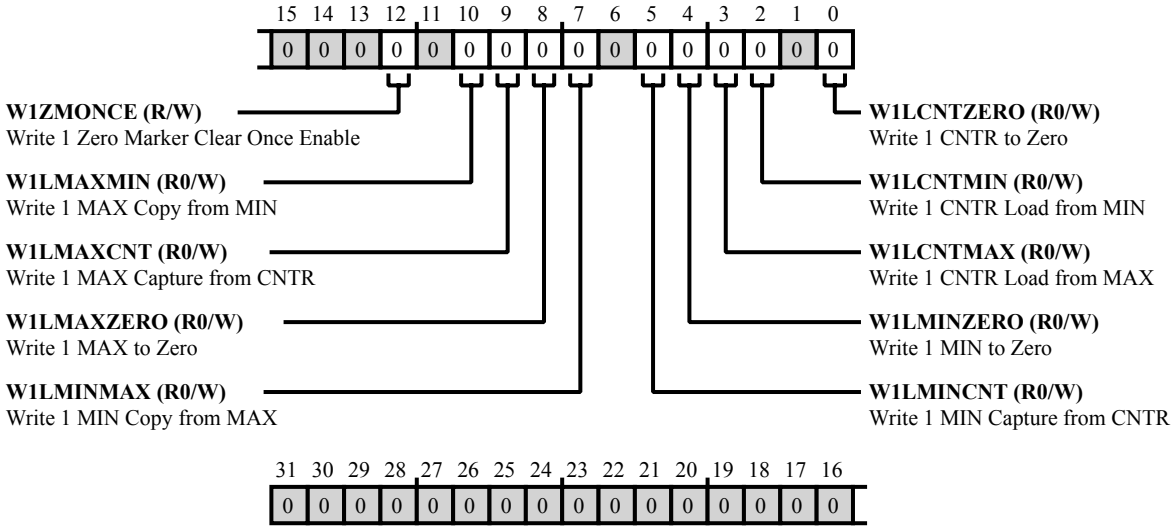

Figure 25-5: CNT_CMD Register Diagram

Table 25-9: CNT_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	W1ZMONCE	Write 1 Zero Marker Clear Once Enable. The CNT_CMD.W1ZMONCE enables a single zero marker clear of the CNT_CNTR register. Reading a 1 in this bit indicates that the bit has been set by software before, but no zero marker event has been detected on the CNT_ZM pin yet.
10 (R0/W)	W1LMAXMIN	Write 1 MAX Copy from MIN. The CNT_CMD.W1LMAXMIN bit transfers the current CNT_MIN register value into CNT_MAX register.
9 (R0/W)	W1LMAXCNT	Write 1 MAX Capture from CNTR. The CNT_CMD.W1LMAXCNT bit loads the current value in the CNT_CNTR register into the CNT_MAX register to create a new boundary limit.
8 (R0/W)	W1LMAXZERO	Write 1 MAX to Zero. Writing a 1 to the CNT_CMD.W1LMAXZERO bit clears the CNT_MAX register.
7 (R0/W)	W1LMINMAX	Write 1 MIN Copy from MAX. The CNT_CMD.W1LMINMAX bit transfers the current CNT_MAX register value into CNT_MIN register.
5 (R0/W)	W1LMINCNT	Write 1 MIN Capture from CNTR. The CNT_CMD.W1LMINCNT bit loads the current value in the CNT_CNTR register into the CNT_MIN register to create a new boundary limit.
4 (R0/W)	W1LMINZERO	Write 1 MIN to Zero. Writing a 1 to the CNT_CMD.W1LMINZERO bit clears the CNT_MIN register.

Table 25-9: CNT_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W)	W1LCNTMAX	Write 1 CNTR Load from MAX. The CNT_CMD.W1LCNTMAX bit loads the current value in the CNT_MAX register into the CNT_CNTR register to create a new boundary limit.
2 (R0/W)	W1LCNTMIN	Write 1 CNTR Load from MIN. The CNT_CMD.W1LCNTMIN bit loads the current value in the CNT_MIN register into the CNT_CNTR register to create a new boundary limit.
0 (R0/W)	W1LCNTZERO	Write 1 CNTR to Zero. Writing a 1 to the CNT_CMD.W1LCNTZERO bit clears the CNT_CNTR register.

Counter Register

The CNT_CNTR register holds the 32-bit, two's-complement count value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows use of the CNT as a 16-bit counter if sufficient for the application.

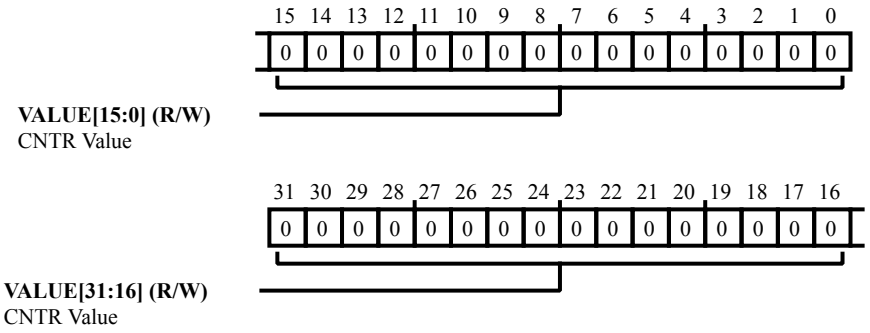

Figure 25-6: CNT_CNTR Register Diagram

Table 25-10: CNT_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CNTR Value. The CNT_CNTR.VALUE bit field holds the 32-bit, two's-complement count value.

Debounce Register

The CNT_DEBNCE register selects the noise filtering characteristic of the three input pins according to the formula:

t_{filter} = 128 x ($2^{DPRESCALE}$/ SCLK0)

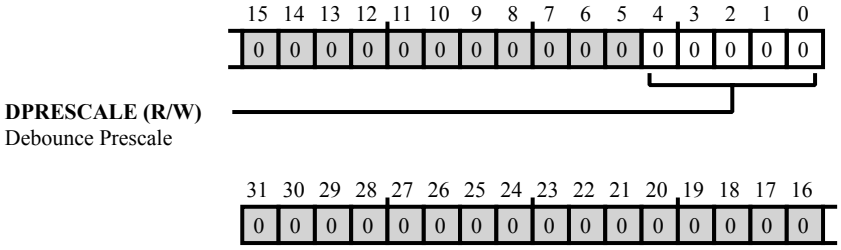

Figure 25-7: CNT_DEBNCE Register Diagram

Table 25-11: CNT_DEBNCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4:0 (R/W)	DPRESCALE	Debounce Prescale. The CNT_DEBNCE.DPRESCALE selects the desired number of input filtering cycles (and resulting input debounce time) in multiples of SCLK0.	
		0	1x cycles = 128 SCLK0 cycles
		1	2x cycles
		2	4x cycles
		3	8x cycles
		4	16x cycles
		5	32x cycles
		6	64x cycles
		7	128x cycles
		8	256x cycles
		9	512x cycles
		10	1024x cycles
		11	2048x cycles
		12	4096x cycles
		13	8192x cycles
		14	16384x cycles
		15	32768x cycles
		16	65536x cycles

Table 25-11: CNT_DEBNCE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		17	131072x cycles
		18	Reserved from this value. The values 10010 - 11111 are reserved.
		31	Reserved until this value

Interrupt Mask Register

The CNT_IMSK register supports enabling (unmasking) interrupt request generation from each of the CNT events.

All bits in CNT_IMSK either disable/mask an interrupt request (if bit cleared) or enable/unmask an interrupt request (if bit set).

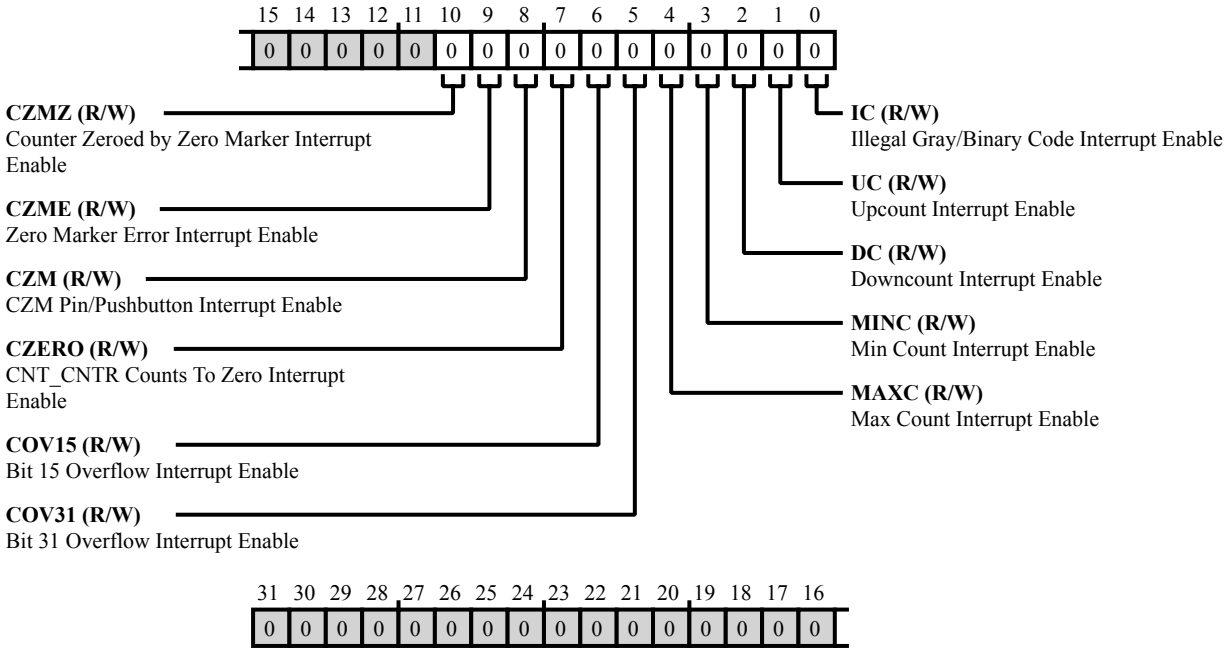

Figure 25-8: CNT_IMSK Register Diagram

Table 25-12: CNT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	CZMZ	Counter Zeroed by Zero Marker Interrupt Enable. The CNT_IMSK.CZMZ bit enables (unmasks) the counter zeroed by zero marker interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
9 (R/W)	CZME	Zero Marker Error Interrupt Enable. The CNT_IMSK.CZME bit enables (unmasks) the zero marker error interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt

Table 25-12: CNT_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	CZM	CZM Pin/Pushbutton Interrupt Enable. The CNT_IMSK.CZM bit enables (unmasks) the CZM pin/pushbutton interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
7 (R/W)	CZERO	CNT_CNTR Counts To Zero Interrupt Enable. The CNT_IMSK.CZERO bit enables (unmasks) the counts to zero interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
6 (R/W)	COV15	Bit 15 Overflow Interrupt Enable. The CNT_IMSK.COV15 bit enables (unmasks) the bit 15 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
5 (R/W)	COV31	Bit 31 Overflow Interrupt Enable. The CNT_IMSK.COV31 bit enables (unmasks) the bit 31 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
4 (R/W)	MAXC	Max Count Interrupt Enable. The CNT_IMSK.MAXC bit enables (unmasks) the max count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
3 (R/W)	MINC	Min Count Interrupt Enable. The CNT_IMSK.MINC bit enables (unmasks) the min count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
2 (R/W)	DC	Downcount Interrupt Enable. The CNT_IMSK.DC bit enables (unmasks) the down count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt

Table 25-12: CNT_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	UC	Upcount Interrupt Enable. The `CNT_IMSK.UC` bit enables (unmasks) the up count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
0 (R/W)	IC	Illegal Gray/Binary Code Interrupt Enable. The `CNT_IMSK.IC` bit enables (unmasks) the illegal Gray/Binary Code interrupt request and should only be used in these modes.	
		0	Mask Interrupt
		1	Unmask Interrupt

Maximum Count Register

The CNT_MAX register holds the 32-bit, two's-complement, higher boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

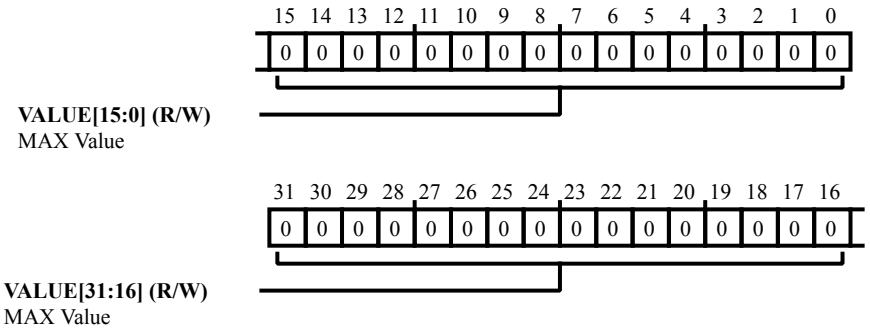

Figure 25-9: CNT_MAX Register Diagram

Table 25-13: CNT_MAX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MAX Value. The CNT_MAX.VALUE bit field holds the 32-bit, two's-complement, higher boundary value.

Minimum Count Register

The CNT_MIN register holds the 32-bit, two's-complement, lower boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

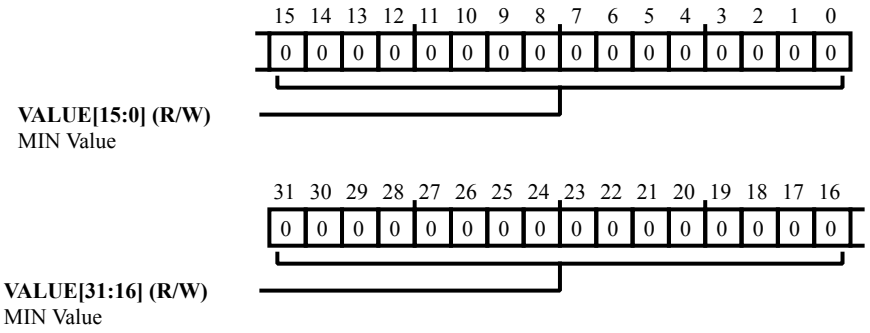

Figure 25-10: CNT_MIN Register Diagram

Table 25-14: CNT_MIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MIN Value. The CNT_MIN.VALUE bit field holds the 32-bit, two's-complement, lower boundary value.

Status Register

The CNT_STAT register provides status information for each of the CNT events as configured in the CNT_IMSK register. When a CNT event is detected, the corresponding bit in this register is set. It remains set until either software writes a 1 to the bit (write-1-to-clear) or the CNT is disabled.

All bits in the CNT_STAT register indicate either no interrupt request pending (if bit cleared) or an interrupt request pending (if bit set).

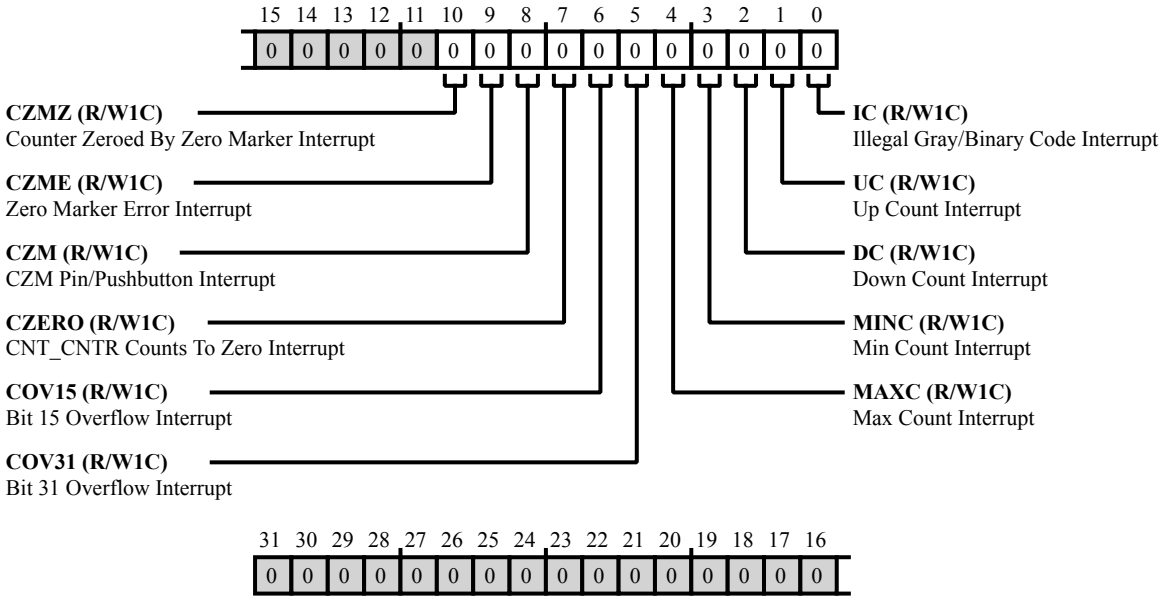

Figure 25-11: CNT_STAT Register Diagram

Table 25-15: CNT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	CZMZ	Counter Zeroed By Zero Marker Interrupt. The CNT_STAT.CZMZ bit indicates a zero marker error. If the CNT_CFG.ZMZC bit =1, this interrupt request is generated when the CZMII latch reports a significant edge on the CZM input. Once cleared by software the CNT_STAT.CZM bit is not set again when the CZM input remains active without pulsing.	
		0	No error
		1	Error occurred

Table 25-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	CZME	Zero Marker Error Interrupt. The CNT_STAT.CZME bit behaves similarly to the CNT_STAT.CZM bit, with the exception that CNT_STAT.CZME is not set on the CZM edge when the lower four bits of the CNT_CNTR are not zero. In many applications this indicates an error condition, as the zero marker might be out of sync with the counter.	
		0	No error
		1	Error occurred
8 (R/W1C)	CZM	CZM Pin/Pushbutton Interrupt. The CNT_STAT.CZM bit indicates a CZM pin/pushbutton error. This interrupt request is generated when a significant edge is seen on the CZM pin, regardless what mode the counter is operating in. This is often used to sense push buttons (especially with the debouncing circuit enabled).	
		0	No error
		1	Error occurred
7 (R/W1C)	CZERO	CNT_CNTR Counts To Zero Interrupt. The CNT_STAT.CZERO bit indicates a counts to zero error. This error is generated when the CNT_CNTR register has incremented or decremented toward 0x0000.0000. The latch is not set when software writes to the CNT_CNTR register directly or when the counter is zeroed by writes to the CNT_CMD register.	
		0	No error
		1	Error occurred
6 (R/W1C)	COV15	Bit 15 Overflow Interrupt. The CNT_STAT.COV15 bit indicates a bit 15 overflow error. This error is generated when the 16-bit twos-complement CNT_CNTR register has incremented from 0xxxxx.7FFF to 0xxxxx.8000 or decremented from 0xxxxx.8000 to 0xxxxx.7FFF.	
		0	No error
		1	Error occurred
5 (R/W1C)	COV31	Bit 31 Overflow Interrupt. The CNT_STAT.COV31 bit indicates a bit 31 overflow error. This error is generated when the 32-bit twos-complement CNT_CNTR register has incremented from 0x7FFF.FFFF to 0x8000.0000 or decremented from 0x8000.0000 to 0x7FFF.FFFF.	
		0	No error
		1	Error occurred

Table 25-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	MAXC	Max Count Interrupt. The CNT_STAT.MAXC bit indicates a max count error. This interrupt is used in boundary compare (BND_COMP) mode. If after incrementing the CNT_CNTR register equals CNT_MAX, the CNT_STAT.MAXC bit is set.	
		0	No error
		1	Error occurred
3 (R/W1C)	MINC	Min Count Interrupt. The CNT_STAT.MINC bit indicates a minimum count error. This interrupt is used in boundary compare (BND_COMP) mode. If, after decrementing, the CNT_CNTR register equals CNT_MIN, the CNT_STAT.MINC bit is set.	
		0	No error
		1	Error occurred
2 (R/W1C)	DC	Down Count Interrupt. The CNT_STAT.DC bit indicates a down count error. This interrupt is generated when the CNT_CNTR register decrements.	
		0	No error
		1	Error occurred
1 (R/W1C)	UC	Up Count Interrupt. The CNT_STAT.UC bit indicates an up count interrupt. This interrupt is generated when the CNT_CNTR register increments.	
0 (R/W1C)	IC	Illegal Gray/Binary Code Interrupt. The CNT_STAT.IC bit indicates a illegal Gray/Binary Code interrupt and should only be used in these modes. In normal operation those codes can increment or decrement the CNT_CNTR register by one at a time. If the sensed inputs instruct the counter to increment or decrement by two, the CNT_STAT.IC bit is set. Hardware sets the CNT_STAT.IC bit in QUAD_ENC and BIN_ENC encoder modes only.	
		0	No error
		1	Error occurred

26 Media Local Bus (MLB)

Media Local Bus (MediaLB®) is an on-PCB or inter-chip communication bus, which allows an application to access the MOST network data. Media Local Bus supports all the MOST network data transport methods including synchronous stream data, asynchronous packet data, control message data and isochronous data. The MLB topology supports communication among the MLB controller and MLB devices, where the MLB controller is the interface between the MLB devices and the MOST network.

The MLB module serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. It supports up to 64 logical channels with up to 468 bytes of data per MediaLB frame. Transmit and receive data can be transferred between MediaLB and on-chip memory with DMA block transfers.

The MLB supports the MOST25, MOST50 and MOST150 standards and this document assumes familiarity with these standards. For more information, refer to the Media Local Bus specification version 4.2.

Features

The objective of MLB is to map all the MOST Network data types (transport methods) into a single low-cost, scalable, and standardized hardware interface between a MediaLB controller and at least one other MediaLB Device. The adoption of MediaLB simplifies the hardware interface, reduces the pin count, and facilitates the design of modular reusable hardware. From a software development perspective, the use of MediaLB relieves the system developer from the complexity of the MOST network, which simplifies software development and enables the design of reusable software for different applications. This simplified, standardized interface shortens time to market and makes software maintenance effortless.

- Compliant to Media Local Bus specification version 4.2
- Support MOST25, MOST50, MOST150 standards
- Support 3-pin and 6-pin mode
    - 6-pin mode supports a data rate of 2048 × FS
    - 3-pin mode support various data rates of 256 × FS, 512 × FS, 1024 × FS

- Support 64 logic channels
- Dedicated PLL for clock recovery and phase alignment
- Dedicated pins for 6-pin mode (LVDS)
- Shared pins for 3-pin mode
- Dedicated internal RAM for data buffering and channel table
- Recovered clock (after division) available out on a shared pin for DAI

NOTE: Only one MLB interface (3-pin mode or 6-pin mode) is active at any given time.

MLB Definitions

The following are standard MLB and MOST terms that are used in this chapter.

AGU

Address Generation Units. To access a particular HBI channel the HC must first configure one of two HBI address generation units. AGUs can be configured by writing the HBI command registers, HCMD0 and HCMD1.

CAT

Channel Allocation Table. The Channel Allocation Table (CAT) is comprised of 16 CTR entries. Each 16-bit CAT entry represents a logical connection to or from a transmit/receive device (for example MediaLB or HBI channel).

CDT

Channel Descriptor Table.

FCE

Flow Control Enable bit. The FCE bit is used by MediaLB isochronous Rx channels only.

HBI

Host Bus Interface. The HBI block provides 16-bit parallel slave access to all MOST channels and data types for the external Host Controller (HC). The HBI supports up to 64 independent channels.

HC

Host Controller (external).

HCMDx

HBI Command registers.

HSTSx

HBI status registers.

MFE

Multi-Frame per sub-buffer enable bit. The MFE bit is used by MediaLB synchronous channels only.

PML

Packet Message Length.

Clocking

The MLB controller provides an external clock pin—the media local bus clock. The MLB controller generates the clock. It is synchronized to the MOST network and provides the timing for the entire MLB interface at FS = 48 kHz.

Functional Description

The ***MediaLB Block Diagram*** figure shows the MLB high-level architecture. The MLB core serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. The MLB core has the following responsibilities.

- Transmit commands and data when functioning as the transmitting device associated with a *Channel Address*
- Receive data and transmit Rx status responses when functioning as the receiving device associated *Channel Address*
- MLB lock detection
- System channel command handling

The MediaLB device can function as either a MediaLB 3-pin interface (single-ended) or MediaLB 6-pin interface (differential) but only one interface can be active at a time. The MediaLB interfaces are capable of exchanging data at speeds up to 1024 × Fs in 3-pin mode or 2048 × Fs in 6-pin mode.

A set of physical channels for exchanging data over the MediaLB bus is supported. These physical channels (4 bytes in length, or a quadlet) can be grouped into logical channels, where each logical channel is referenced using a channel address and represents a uni-directional datapath between a specific MediaLB device transmitting the data and the MediaLB device(s) receiving the data. The MediaLB 6-pin interface provides support for up to 468 bytes of data per frame. The logical channels, configured by system software, can be any combination of channel types (synchronous, asynchronous, isochronous, or control) and direction (transmit or receive).

ADSP-2159x_SC591_SC592_SC594 MLB Register List

The MediaLB Device Interface Macro 2 (MediaLB DIM 2), also referred to as OS62420, implements the required functionality of a Media Local Bus (MediaLB) device. This logic serves as an interface between the inter-chip MediaLB bus and a customer IC, implementing the physical- and link-layer requirements outlined in the MediaLB Specification.

MediaLB Protocol

The MediaLB topology supports communication among all MediaLB devices, including the MediaLB controller. The bus interface consists of a uni-directional line for clock (MLBC), a bidirectional line for signal information (MLBS), and a bidirectional line for data transfer (MLBD). The MediaLB topology supports one controller connected to one or more devices, where the controller is the interface between the MediaLB devices and the MOST network.

The MediaLB controller includes MediaLB device functionality, and also generates the MediaLB clock (MLBC) that is synchronized to the MOST Network. This generated clock provides the timing for the entire MediaLB interface. The MLBS line is a multiplexed signal which carries channel addresses generated by the MediaLB controller, as well as command and RxStatus bytes from MediaLB devices. The MLBD line is driven by the transmitting MediaLB device and is received by all other MediaLB devices, including the MediaLB controller. The MLBD line carries the actual data (synchronous, asynchronous, control, or isochronous).

Once per MOST network frame, the MLB controller generates a unique frame sync pattern on the MLB_SIG line. The end of the frame sync pattern defines the byte boundary and the channel boundary for the MLB_SIG and MLB_DAT lines of all MLB devices.

The MLB controller manages the arbitration for all the channels on the MLB and grants bandwidth for all the MLB devices. An MLB *physical channel* is defined as four bytes wide, or a quadlet. Physical channels can be grouped into multiple quadlets (which do not have to be consecutive) to form an MLB *logical channel*, which is defined by a unique channel address.

As shown in ***MLB Data Structure***, the MLB controller initiates communication by sending out a channel address on the MLB_SIG line for each physical channel. The channel address indicates which MLB device is transmitting and which MLB devices are receiving in the following physical channel. Therefore, four bytes after the controller outputs the channel address on the MLB_SIG line, the transmitting device outputs a command byte command on the MLB_SIG line and outputs the respective data on the MLB_DAT line, concurrently. The MLB command byte contains the type of data currently being transmitted (for example synchronous, asynchronous or control).

The MLB device receiving the channel data outputs a status byte, RxStatus, on the MLB_SIG line immediately after the transmitting device outputs the command byte. The status response can indicate that the receiving device is busy and cannot receive the data at present, or the device is ready to receive the data. Since synchronous stream data is sent in a broadcast fashion, receiving devices cannot return a busy status and should not drive RxStatus onto the MLB_SIG line.

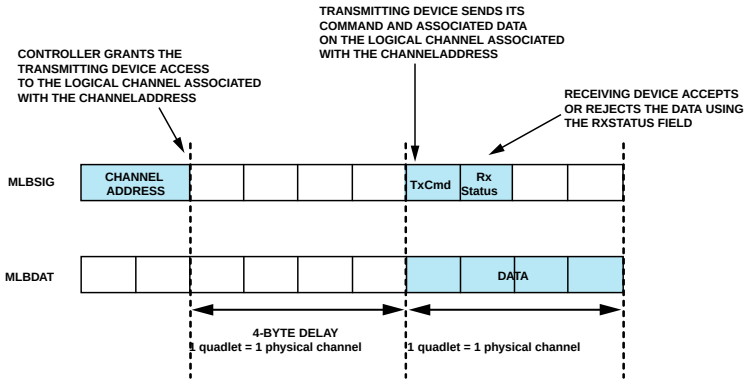

Figure 26-1: MLB Data Structure

MLB Architectural Concepts

The following sections provide information about the MLB architecture.

MediaLB Block Diagram

The ***MediaLB Block Diagram*** shows the various blocks within the interface its connections to the processor.

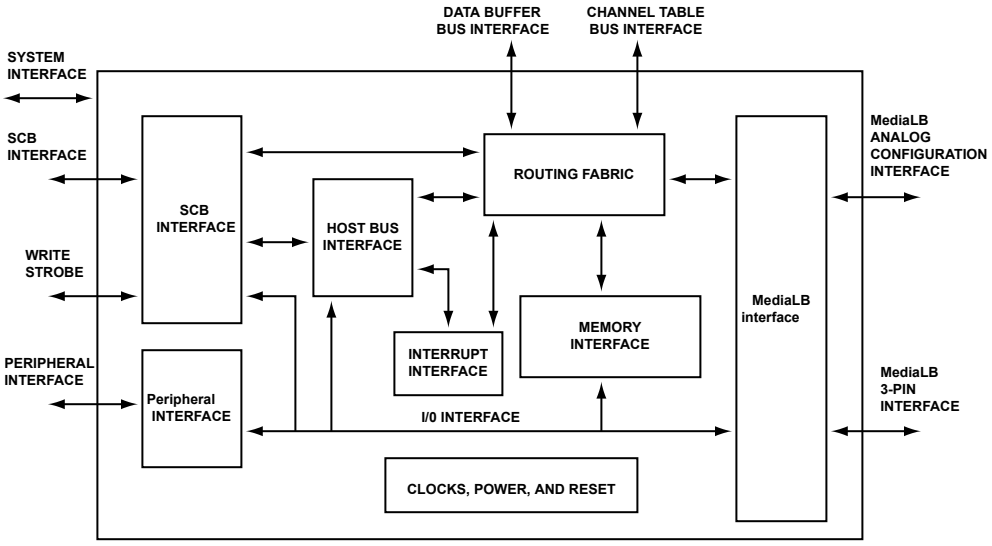

Figure 26-2: MediaLB Block Diagram

MediaLB Interface

The Media Local Bus (MediaLB) block supports both a MediaLB 3-pin interface and MediaLB 6-pin interface; however, only one MediaLB interface can be active at any given time. Both MediaLB interfaces provide real-time access to all network data types - synchronous, asynchronous, control, and isochronous data.

- MediaLB 3-pin interface – Supports the MediaLB protocol for single-ended 3-pin mode, with a maximum data rate of 1024 FS (49.152 MHz at FS = 48 kHz).
- MediaLB 6-pin interface – Supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data

  maximum data rate of 2048 FS (98.304 MHz at FS = 48 kHz).

MediaLB Channel Address to Logical Channel Mapping

The MediaLB channel addresses are mapped to the logical channels as shown in the ***MediaLB Channel Address to Logical Channel Mapping*** table.

Table 26-3: MediaLB Channel Address to Logical Channel Mapping

Channel Address	Logical Address
0x0002	1
0x0004	2
0x0006	3
...	...
0x007C	62
0x007E	63

Table 26-3: MediaLB Channel Address to Logical Channel Mapping (Continued)

Channel Address	Logical Address
0x01FE	0 (Logical channel 0 is the system channel and is reserved)

Routing Fabric

The Routing Fabric (RF) block manages the flow of data between the MediaLB port and the HBI port. It manages accessing the Channel Table RAM (CTR) and Data Buffer RAM (DBR), which are explained in the following sub-sections. The routing fabric uses channel descriptors (stored in the CTR) to manage access to dynamic buffers in the DBR.

Data Buffer RAM

The Data Buffer RAM (DBR) is an 8-bit x 16k entries deep, single-port synchronous SRAM and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the Channel Descriptor Table (CDT), which is located in the Channel Table RAM (CTR), described in following sections.

Channel Table RAM

The Channel Table RAM (CTR) is a 128-bit x 144-entry table that allows system software to dynamically configure channel routing and allocate data buffers in the DBR. The CTR is logically divided into three tables:

- Channel Descriptor Tables
- AHB Descriptor Table (ADT)
- Channel Allocation Table

Address Mapping

The ***CTR Address Mapping*** table shows the address mapping for the CTR.

Table 26-4: CTR Address Mapping

Label	Address	Bits [127:96]	Bits [95:64]	Bits [63:32]	Bits [31:0]
Channel Descriptor Table (CDT)					
CDT	0x00	CDT0[127:0], CL = 0

	0x02	CDT2[127:0], CL = 2			
	...				
	0x3D	CDT61[127:0], CL = 61			
	0x3E	CDT62[127:0], CL = 62			
	0x3F	CDT63[127:0], CL = 63			
AHB Descriptor Table (ADT)					

Table 26-4: CTR Address Mapping (Continued)

Label	Address	Bits [127:96]		Bits [95:64]		Bits [63:32]		Bits [31:0]	
ADT	0x40	ADT0[127:0], CL = 0							
	0x41	ADT1[127:0], CL = 1							
	0x42	ADT2[127:0], CL = 2							
	...								
	0x7D	ADT61[127:0], CL = 61							
	0x7E	ADT62[127:0], CL = 62							
	0x7F	ADT63[127:0], CL = 63							
Channel Allocation Table (CAT)									
CAT for MediaLB	0x80	CAT7	CAT6	CAT5	CAT4	CAT3	CAT2	CAT1	CAT0
	...	...	...	...	...	...	...	...	...
	0x87	CAT63	CAT62	CAT61	CAT60	CAT59	CAT58	CAT57	CAT56
CAT for HBI*1	0x88	CAT71	CAT70	CAT69	CAT68	CAT67	CAT66	CAT65	CAT64
	...	...	...	...	...	...	...	...	...
	0x8F	CAT127	CAT126	CAT125	CAT124	CAT123	CAT122	CAT121	CAT120

*1 A fixed relationship exists between ADT entries and HBI CAT entries. When using HBI channel 0 (CAT64), program ADT0. When using HBI channel 1 (CAT65), program ADT1, and so on.

Channel Allocation Table

The ***Channel Allocation Table (CAT)*** table is comprised of 16 CTR entries (addresses 0x80 0x8F) as shown in the ***CTR Entry Map*** table. Each 16-bit CAT entry represents a logical connection to or from a transmit or receive device. (for example, MediaLB channel). All entries are indexed according to a fixed physical address assigned to every RX/TX channel as shown in the ***CAT Entry Formats*** table. The value stored in a CAT entry includes a 6-bit connection label, which provides a pointer to the CDT. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the RX and TX channels.

Table 26-5: CAT Entry Map

Peripheral	TX Channels	RX Channels	CAT Start Index	CAT End Index	Entries
MediaLB	0 to 64	64 TX Channels	0	63	64
HBI	0 to 64	64 TX Channels	64	127	64

The format of a full CAT entry is shown in the ***CAT Entry Formats*** table, with field descriptions described in the ***CAT Field Definitions*** table. All reserved bits of a CAT entry field should be written as zero.

Table 26-6: CAT Entry Formats

Channel Type	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Isochronous	rsvd	FCE	rsvd	RNW	CE	CT[2:0] = 011			rsvd		CL[5:0]					
Asynchronous	rsvd		MT	RNW	CE	CT[2:0] = 010			rsvd		CL[5:0]					
Control	rsvd		MT	RNW	CE	CT[2:0] = 001			rsvd		CL[5:0]					
Synchronous	rsvd	MFE	MT	RNW	CE	CT[2:0] = 000			rsvd		CL[5:0]					

Table 26-7: CAT Field Definitions

Field	Description
CL[5:0]	Connection Label (offset into CDT)
CT[2:0]	Channel Type (others) 111 = Reserved 110 = Reserved 101 = Reserved 100 = Reserved 011 = Isochronous 010 = Asynchronous 001 = Control 000 = Synchronous
CE	Channel Enable. 0 = Disabled, 1 = Enabled
RNW	Read Not Write. 0 = Write, 1 = Read
MT	Mute Enable. 0 = Disabled When set for synchronous channels, the MT bit forces RX channels to write zeros into the channel data buffer, and TX channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.
FCE	Flow Control Enable. 0 = Disabled, 1 = Enabled The FCE bit is used by MediaLB isochronous RX channels only.
MFE	Multi-Frame per sub-buffer enable. 0 = Disabled, 1 = Enabled The MFE bit is used by MediaLB synchronous channels only.
rsvd	Reserved. Software writes a 0 to all reserved bits when the entry is initialized. These bits are read-only after initialization.

Channel Set Up

Data direction is in reference to the DBR. The data direction of CAT entries corresponding to the same channel is reversed for the HBI CAT and the MediaLB CAT.

- For a Tx channel (from the HC to the MediaLB interface):
    - HBI CAT entry: RNW = 0 (write)

- MediaLB CAT entry: RNW = 1 (read)

- Conversely, for an Rx channel (data from MediaLB to HC):
  - HBI CAT entry: RNW = 1 (read)
  - MediaLB CAT entry: RNW = 0 (write)

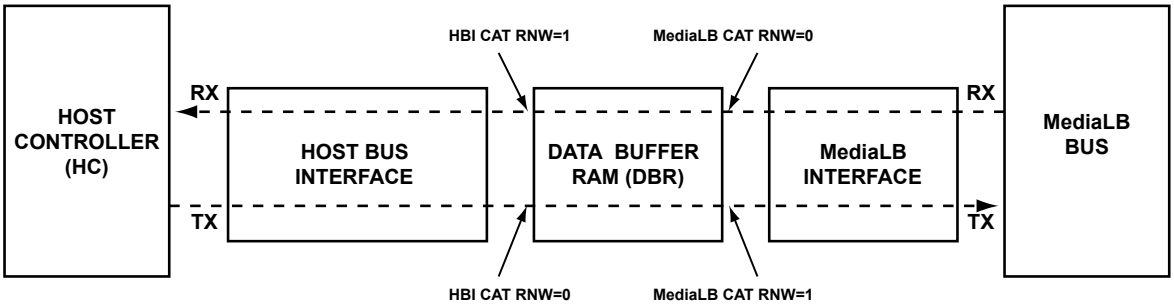

Figure 26-3: DBR Directional Relationship

Channel Descriptor Tables

The Channel Descriptor Table (CDT) is comprised of 64 CTR entries (addresses 0x00 - 0x3F), as shown in the Table 26-4 CTR Address Mapping table. Each 128-bit CDT entry (also referred to as a channel descriptor) is referenced by a connection label and contains information about a data buffer in the DBR (for example buffer size, address pointers). The format of each CDT entry is dependent on the channel type (synchronous, isochronous, asynchronous, or control).

NOTE: All reserved channel descriptor bits must be written to 0 by software when initialized.

Synchronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the ***Synchronous CDT Entry Format*** and ***Synchronous CDT Entry Field Definitions*** tables.

Table 26-8: Synchronous CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

WSTS	Write Status	Software initializes to 0, hardware updates. Status States (only valid for DMA pointers associated with the MLB block, not HBI block pointers): xxx0 = idle xxx1 = command protocol error detected xx0x = *AsyncBreak*/*ControlBreak* command received from TX device	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

AHB Descriptor Table (ADT)

The AHB block manages data exchange between local channel data buffers within MLB module and the system memory buffer. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for AHB Descriptor Table (ADT) entries. The Table 26-4 CTR Address Mapping table provides a complete address map of the CTR, including the location of the ADT.

Each logical channel is assigned a separate 128-bit descriptor, defining the data buffers in the system memory used by the DMA interface for that channel. The descriptors are stored at fixed addresses in the CTR as described in previous section. The ***ADT Field Definitions*** table provides an overview of field definitions for ADT entries.

Table 26-14: ADT Field Definitions

Field	No. of Bits	Description	Access
CE	1	Channel Enable. 0 = Disabled	RW, U
LE	1	Endianness Select. 0 = Big Endian, 1 = Little Endian	RW
PG	1	Page pointer. Software initializes to 0, hardware writes thereafter. 0 = Ping buffer, 1 = Pong buffer	RW, U
RDY1	1	Buffer Ready bit for ping buffer page. 0 = Not ready, 1 = Ready	RW
RDY2	1	Buffer Ready bit for pong buffer page. 0 = Not ready, 1 = Ready	RW
DNE1	1	Buffer Done bit for ping buffer page. 0 = Not done, 1 = Done	R, U, c0
DNE2	1	Buffer Done bit for pong buffer page. 0 = Not done, 1 = Done	R, U, c0
ERR1	1	Error Response detected for ping buffer page. 0 = No error, 1 = Error	R, U, c0
ERR2	1	Error Response detected for pong buffer page. 0 = No error, 1 = Error	R, U, c0
PS1	1	Packet Start bit for ping buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
PS2	1	Packet Start bit for pong buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
MEP1	1	Most Ethernet Packet indicator for ping buffer page. 0 = Not MEP, 1 = MEP. MEP1 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
MEP2	1	Most Ethernet Packet indicator for pong buffer page. 0 = Not MEP, 1 = MEP. MEP2 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
BD1	11 to 13	Buffer Depth for ping buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BD2	11 to 13	Buffer Depth for pong buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BA1	32	Buffer Base Address for ping buffer page	RW
BA2	32	Buffer Base Address for pong buffer page.	RW
Reserved	varies	Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.	RW, U

The ***Ping-Pong System Memory Structure*** figure shows that this system memory structure is similar for all channel types and shows the relationship between the BAn, BDn, and PG descriptor fields.

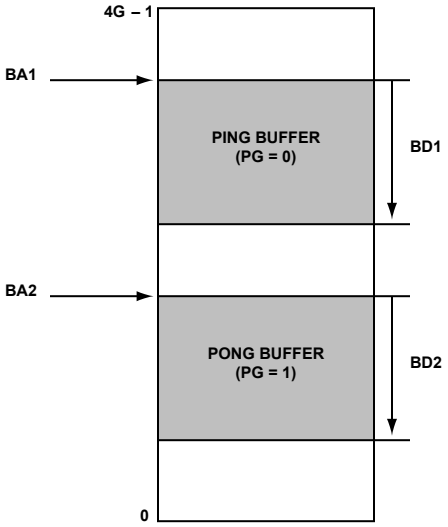

Figure 26-4: Ping-Pong System Memory Structure

Each ADT entry (also referred to as a *Channel Descriptor)* holds a 32-bit BAn field which defines the start of each ping or pong buffer within system memory. The BDn field is used to indicate the size for the respective ping or pong page. The maximum size is 2k entries for asynchronous and control channels and 8k entries for isochronous and synchronous channels.

Synchronous Channel Descriptors

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDn) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (for example BDn = n m bpf 1). The ***Synchronous ADT Entry Format*** table shows the format for a synchronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each synchronous channel buffer can be up to 8k-bytes deep.

Table 26-15: Synchronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDn) must be defined in terms of an integer number (n) and block size (BS) (for example BDn = n (BS + 1) 1).

The ***Isochronous ADT Entry Format*** table shows the format for an isochronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 26-16: Isochronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Asynchronous and Control Channel Descriptors

Every asynchronous and control packet adheres to the Port Message Protocol (PMP), which designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048-bytes (PML 2048).

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt to inform HC. When hardware finishes processing a buffer, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two packet buffering modes are supported by hardware for programming the DMA, single-packet mode (`MLB_ACTL.MPB` =0) and multiple-packet mode (`MLB_ACTL.MPB` =1). The MPB is written prior to enabling the channel DMA.

Single Packet Mode. The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (for example, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (for example, ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers.

The ***Single-Packet Asynchronous and Control Entry Format*** table shows the format for single-packet mode asynchronous and control ADT entries. The field definitions are defined in the ***ADT Field Definitions*** table.

Table 26-17: Single-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Multiple Packet Mode. The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in the ***Asynchronous/Control CDT Entry Format*** table. Multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For TX packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For TX packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for TX packet channels in multiple-packet mode.

NOTE: The PS1 and PS2 bits are only valid for TX channels. Set PS1 and PS2 = 1 at the start of the buffer.

Table 26-18: Multiple-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	BD1[11:0]											
48	RDY2	DNE2	ERR2	PS2	BD2[11:0]											
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Interrupt Interface Block

The interrupt interface raises an interrupt when specific changes to HBI channel descriptors occur, including:

- For asynchronous and control read/write channels:
  - a packet is available to read in the channel buffer, or
  - sufficient empty space is available in the channel buffer to accept a requested packet write
- For isochronous read/write channels:
  - the number of valid bytes in the channel buffer exceeds the block size, or
  - the number of empty bytes in the channel buffer exceeds the block size

Operating Modes

The following sections describe the operating modes of the MLB interface. The channel type selection enables the logical channels to operate in synchronous, asynchronous, isochronous, or control channels.

NOTE: The logical channels can be any combination of channel type (for example synchronous, asynchronous, or control) and direction (transmit or receive).

Isochronous Data Exchange

An isochronous HBI channel is initially opened and synchronized with HCMD0.CMD[2:0]= 010. For isochronous channels, no further synchronization is required from the HBI perspective; however, an optional resynchronization command is available for HC flexibility. Setting HCMD0.CMD[2:0]= 011 reinitializes the address pointer within the data buffer, ensuring that subsequent data exchange with the channel is aligned at an isochronous packet boundary. When the HC must close an isochronous channel before it has read or written an entire data packet, setting HCMD0.CMD[2:0]= 000 reopens the channel without synchronizing the address pointer in the buffer. This action allows reading and writing to continue where the HC previously stopped.

For isochronous data transmission, the ***Exchanging Isochronous Data on an HBI Channel*** figure shows the flow control.

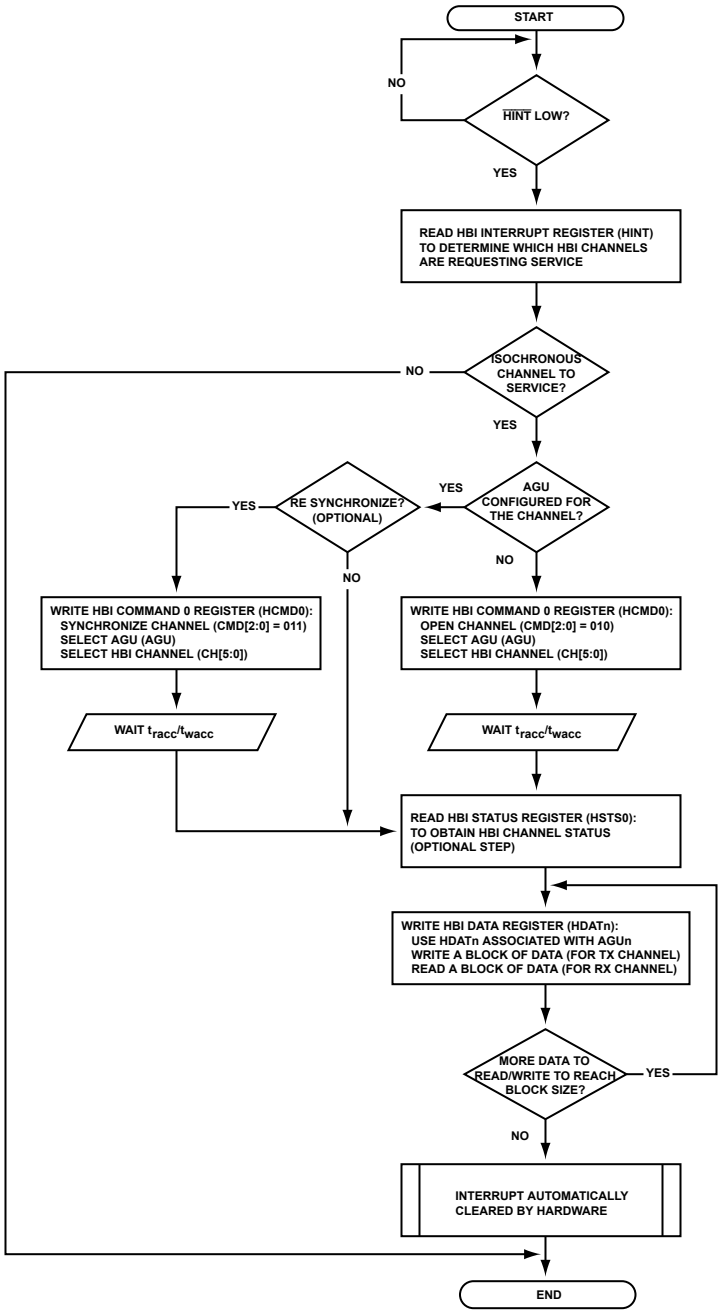

Figure 26-5: Exchanging Isochronous Data on an HBI Channel

Asynchronous and Control Data Exchange

An asynchronous or control HBI channel is initially opened using HCMD0.CMD[2:0]= 010. Occasionally, the HC may need to close a packet channel before it has completed writing or reading the current packet of data (for example, the HC needs to use this AGU to service another HBI channel). In this case, the HC can reopen the previous channel with HCMD0.CMD[2:0]= 000. This situation allows the HC to continue writing or reading a packet from

the point it left off. In this situation, the PML is already known and the packet length is not reread or rewritten by the HC.

During the reading of a packet, if the HC sets HCMD0.CMD[2:0]= 010 for the channel before the last byte of the packet is read, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC reread the PML (from HSTS1) and reread the packet data (from HDATn) from the beginning. In the same manner, if the HC resets HCMD0.CMD[2:0]= 010 for the channel before the last byte of a packet is written, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC rewrite the PML (to HCMD1) and rewrite the packet data (to HDATn) from the beginning. Any previous packet data in the buffer is overwritten.

Frame synchronization is not supported for asynchronous channels.

Synchronous Data Exchange

The MLB core provides two modes of operation; standard and multi-frame per sub-buffer which provide flexibility for implementing synchronous channels. Channels configured for standard mode require less buffer space, but have higher interrupt rates and more stringent latency requirements. Channels setup for multi-frame per sub-buffer mode require more buffer space, but have lower interrupt rates and less stringent latency requirements.

To set up a channel in multi-frame per sub-buffer mode:

1. Program the `MLB_CTL0.FCNT` bit field to select the number of frames per sub-buffer.
2. Program the CAT to enable multi-frame sub-buffering (MFE= 1) for each particular channel.
3. Set the buffer depth in the CDT: BD= 4 × m × bpf 1 where: m = frames per sub-buffer, bpf = bytes per frame.
4. Repeat for additional synchronous channels

A sample synchronous data buffer is shown in the ***Synchronous Data Buffer Structure*** figure. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by the `MLB_CTL0.FCNT` bits.

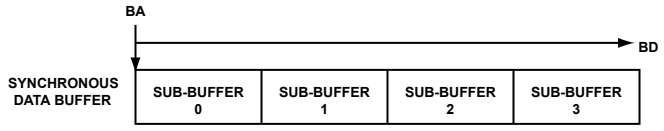

Figure 26-6: Synchronous Data Buffer Structure

Data Transfer

Two modes of operation are supported for transferring channel data between the MLB and internal memory. DMA allows the multi-channel DMA engine to manage data transfers without core intervention. Core driven mode (I/O mode) allows software to manage the transfer of data between MLB and internal memory.

NOTE: All hardware channels must use the same data transfer method. Mixed mode operation where hardware channels operate in both I/O mode and DMA mode is not supported.

DMA

The processor supports DMA mode which uses only INCR8, INCR4 and SINGLE beat bursts. Program the `MLB_ACTL.DMAMODE` = 1 to use DMA mode.

Programming Model

This section provides general guidelines for programming the MediaLB interface.

Channel Initialization

The software flow required to initialize a channel must be performed in order to ensure proper operation.

Configure the Hardware

1. Initialize the CTR and registers.
    a. Set all the CTR (CAT, CDT, and ADT) bits to 0.
    b. Set all bits of all registers to 0.
2. Configure the MediaLB interface.
    a. Select 3-pin or 6-pin MediaLB operation: `MLB_CTL0.PEN` =0 (3-pin), `MLB_CTL0.PEN` =1 (6-pin).
    b. Select MediaLB clock speed via `MLB_CTL0.CLK`.
    c. Set MediaLB enable via `MLB_CTL0.EN`.
3. Configure the HBI interface.
    a. Set `MLB_HCMR0` and `MLB_HCMR1` = 0xFFFFFFFF to activate all channels.
    b. Set the HBI enable bit: `MLB_HCTL.EN` =1.

Program the CAT and the CDT

1. Initialize all bits of the CAT to 0.
2. Select a logical channel: N = 1 – 63.
3. Program the CDT for channel N.
    a. Set the 14-bit base address (BA)
    b. Set the 12-bit or 13-bit buffer depth (BD): BD = buffer depth in bytes 1
    - For synchronous channels: (BD + 1) = 4 frames per sub-buffer (m) bytes-per-frame (bpf)
    - For isochronous channels: (BD + 1) mod (BS + 1) = 0

- For asynchronous channels: (BD + 1) max packet length (1024 for a MOST Data Packet (MDP)
- 1536 for a MOST Ethernet Packet (MEP)
- For control channels: (BD + 1) max packet length (64)

4. Program the CAT for the inbound DMA.
    a. For TX channels (to MediaLB) HBI is the inbound DMA
    b. For RX channels (from MediaLB) MediaLB is the inbound DMA
    c. Set the channel direction: RNW = 0
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the connection label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
5. Program the CAT for the outbound DMA.
    a. For TX channels (to MediaLB) HBI is the outbound DMA
    b. For RX channels (from MediaLB) MediaLB is the outbound DMA
    c. Set the channel direction: RNW = 1
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the channel label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
6. Repeat steps 2 through 5 to initialize all logical channels.

Program the ADT

1. Initialize all bits of the ADT to 0
2. Select a logical channel: N = 1 – 63
3. Program the AMBA AHB block ping page for channel N
    a. Set the 32-bit base address (BA1)

b. Set the 11-bit buffer depth (BD1): BD1 = buffer depth in bytes – 1
   - For synchronous channels: (BD1 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
   - For isochronous channels: (BD1 + 1) mod (BS + 1) = 0
   - For asynchronous channels: 5 (BD1 + 1) 4096 (max packet length)
   - For control channels: 5 (BD1 + 1) 4096 (max packet length)

c. For asynchronous and control Tx channels set the packet start bit (PS1) iff the page contains the start of the packet

d. Clear the page done bit (DNE1)

e. Clear the error bit (ERR1)

f. Set the page ready bit (RDY1)

4. Program the AMBA AHB block pong page for channel N
   a. Set the 32-bit base address (BA2)
   b. Set the 11-bit buffer depth (BD2): BD2 = buffer depth in bytes – 1
      - For synchronous channels: (BD2 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
      - For isochronous channels: (BD2 + 1) mod (BS + 1) = 0
      - For asynchronous channels: 5 (BD2 + 1) 4096 (max packet length)
      - For control channels: 5 (BD2 + 1) 4096 (max packet length)
   c. For asynchronous and control TX channels set the packet start bit (PS2) iff the page contains the start of the packet
   d. Clear the page done bit (DNE2)
   e. Clear the error bit (ERR2)
   f. Set the page ready bit (RDY2)
5. Select Big Endian (LE = 0) or Little Endian (LE = 1)
6. Select the active page: PG = 0 (ping), PG = 1 (pong)
7. Set the channel enable (CE) bit for all active logical channels
8. Repeat steps 2 through 7 for all active logical channels.

Service

After initialization, each channel will require periodic servicing. Use the procedures in the following sections to service DMA and MLB interrupts and to poll for MLB system commands.

Servicing the DMA Channel Interrupts

1. Program the MLB_ACMR0/MLB_ACMR1 registers to enable interrupts from all active DMA channels.
2. Select the status clear method. MLB_ACTL.SCE =0 (hardware clears on read), MLB_ACTL.SCE = 1 (software writes a 1 to clear).
3. Select 1 or 2 interrupt signals. Configure the MLB_ACTL.SMX bit =0 (one interrupt for channels 0 through 31 and another interrupt for channels 32 through 63 on). Configure the MLB_ACTL.SMX bit =1 (single interrupt for all channels).
4. Wait for an interrupt.
5. Read the MLB_ACSR0/MLB_ACSR1 registers to determine which channel or channels are causing the interrupt.
6. If the MLB_ACTL.SCE bit =1, write the results of step 5 back to the MLB_ACSR0 and MLB_ACSR1 registers to clear the interrupt.
7. Select a logical channel (N = 0 – 63) with an interrupt to service.
8. Read the ADT entry for channel N to:
    a. Determine the active page (ping or pong) via the PG bit
    b. Determine which page(s) are done via the DNEn bits
    c. Determine which channels encountered an AHB error via the ERRn bit
    d. Determine which asynchronous and control Rx channel pages contain a packet start via the PSn bit (extract the PML)
9. Repeat steps 6 through 8 for all channels with pending interrupts
10. Repeat steps 4 through 9 while there are active channels.

Servicing the MediaLB Status Interrupts

1. Select the MediaLB channel status register (MLB_MS0/MLB_MS1) to be cleared by software, writing a 0 to the appropriate bits.
2. Program the MLB_MIEN register to enable protocol error interrupts for all active MediaLB channels. (MLB_MIEN.CTXPE =1, MLB_MIEN.CRXPE =1, MLB_MIEN.ATXPE =1, MLB_MIEN.ARXPE =1, MLB_MIEN.SYNCPE =1, and MLB_MIEN.ISOCPE =1).
3. Wait for an interrupt on the MLB_INT0/MLB_INT1 signal.
4. Read the MLB_MS0/MLB_MS1 registers to determine which channel(s) are causing the interrupt.
5. Read the RSTS/WSTS of the appropriate CDT(s) to determine the interrupt type.

6. Clear the RSTS/WSTS errors to ensure that the current status of channel operations is reflected in the register:

Option	Description
For synchronous RX channels	WSTS[3] = 0
For synchronous TX channels	RSTS[3] = 0
For isochronous RX channels	WSTS[2:1] = 00
For isochronous TX channels	RSTS[2:1] = 00
For asynchronous and control RX channels	WSTS[4] = 0 and WSTS[2] = 0
For asynchronous and control TX channels	RSTS[4] = 0 and RSTS[2] = 0

Polling for MediaLB System Commands

The MediaLB System status (`MLB_MSS`) register is used to detect a system command received from the MediaLB controller. The processor's peripheral automatically sends the appropriate system response to the MediaLB controller. The procedure for the application is:

1. The application periodically polls the `MLB_MSS` register.
2. Clear by writing a 0 to the appropriate bit in the `MLB_MSS` register after the application finishes the service.
3. If `MLB_MSS.SWSYSCMD` = 1, read the `MLB_MSD` register to receive the system data sent from MediaLB controller.

ADSP-2159x_SC591_SC592_SC594 MLB Register Descriptions

MediaLB Device Interface Macro 2 (MLB) contains the following registers.

Table 26-19: ADSP-2159x_SC591_SC592_SC594 MLB Register List

Name	Description
`MLB_ACMR0`	Peripheral Channel Mask 0 Register
`MLB_ACMR1`	Peripheral Channel Mask 1 Register
`MLB_ACSR0`	Peripheral Channel Status 0 Register
`MLB_ACSR1`	Peripheral Channel Status 1 Register
`MLB_ACTL`	Bus Control Register
`MLB_CTL0`	MediaLB Control 0 Register
`MLB_CTL1`	Control 1 Register
`MLB_GCTL`	MLB Global Control Register
`MLB_HCBR0`	HBI Channel Busy 0 Register
`MLB_HCBR1`	HBI Channel Busy 1 Register

Table 26-19: ADSP-2159x_SC591_SC592_SC594 MLB Register List (Continued)

Name	Description
MLB_HCER0	HBI Channel Error 0 Register
MLB_HCER1	HBI Channel Error 1 Register
MLB_HCMR0	HBI Channel Mask 0 Register
MLB_HCMR1	HBI Channel Mask 1 Register
MLB_HCTL	HBI Control Register
MLB_MADR	Memory Interface Address Register
MLB_MCTL	Memory Interface Control Register
MLB_MDAT0	Memory Interface Control Data 0 Register
MLB_MDAT1	Memory Interface Control Data 1 Register

MLB_MDWE3	Memory Interface Control Data Write Enable 3 Register
MLB_MIEN	Interrupt Enable Register
MLB_MS0	Channel Status 0 Register
MLB_MS1	Channel Status 1 Register
MLB_MSD	System Data Register
MLB_MSS	System Status Register
MLB_PCTL0	MediaLB 6-pin Control 0 Register

Peripheral Channel Mask 0 Register

The MLB_ACMR0 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR0 register to enable interrupts. Each bit of this register is read/write accessible.

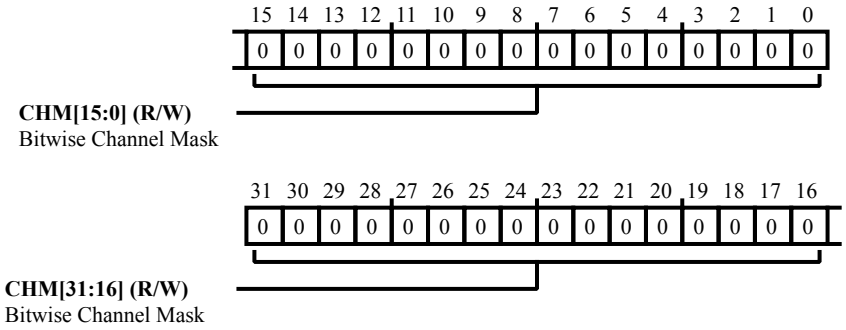

Figure 26-7: MLB_ACMR0 Register Diagram

Table 26-20: MLB_ACMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR0.CHM bit field masks or unmasks channels 31-0.	
		0	Mask interrupt for Channel 31:0 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Mask 1 Register

The MLB_ACMR1 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR1 register to enable interrupts. Each bit of this register is read/write accessible.

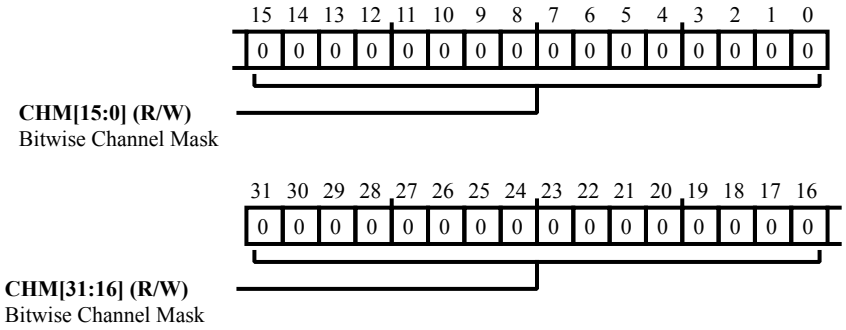

Figure 26-8: MLB_ACMR1 Register Diagram

Table 26-21: MLB_ACMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR1.CHM bit field masks or unmasks channels 63-32.	
		0	Mask interrupt for Channel 63:32 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 63:32 (bitwise; all channels shown)

Peripheral Channel Status 0 Register

The MLB_ACSR0 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR0 and MLB_ACSR1 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of the peripheral channel status registers to clear the interrupt(s).

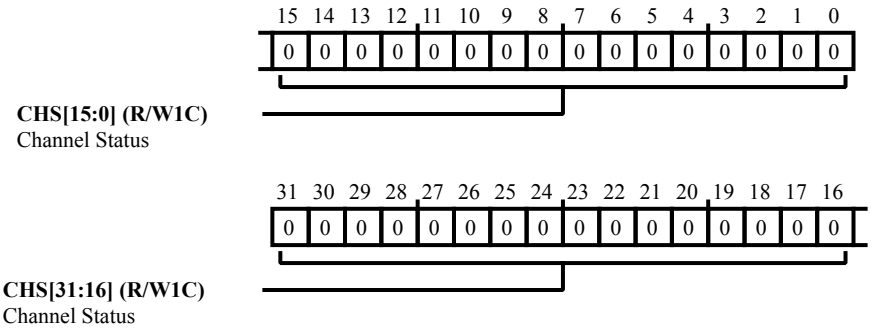

Figure 26-9: MLB_ACSR0 Register Diagram

Table 26-22: MLB_ACSR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR0.CHS bit field indicates channel status for channels 31-0.	
		0	No interrupt on Channel 31:0 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Status 1 Register

The MLB_ACSR1 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR1 and MLB_ACSR0 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of peripheral channel status registers to clear the interrupt(s).

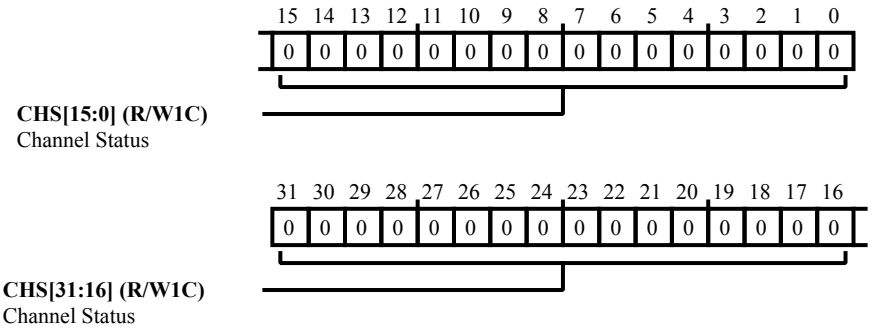

Figure 26-10: MLB_ACSR1 Register Diagram

Table 26-23: MLB_ACSR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR1.CHS bit field indicates channel status for channels 63-32.	
		0	No interrupt on Channel 63:32 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 63:32 (bitwise; all channels shown)

Bus Control Register

The MLB_ACTL register is written by the HC to configure the block for channel interrupts. This register contains bits to select the packet buffering mode and the DMA mode. This register also contains bits that are used to multiplex channel interrupts onto a single interrupt signal and to select the method of clearing channel interrupts.

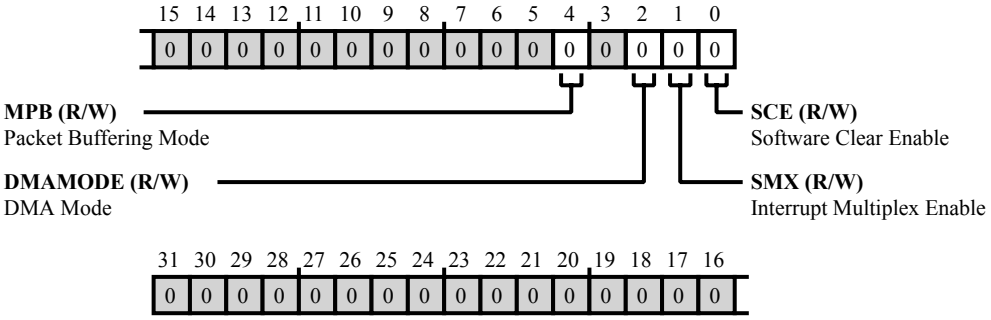

Figure 26-11: MLB_ACTL Register Diagram

Table 26-24: MLB_ACTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	MPB	Packet Buffering Mode. The MLB_ACTL.MPB bit selects whether the buffering mode is single-packet or multiple-packet.	
		0	single-packet mode
		1	multiple-packet mode
2 (R/W)	DMAMODE	DMA Mode. The MLB_ACTL.DMAMODE bit selects between DMA mode 1 and 0. DMA Mode 0 uses incrementing bursts of an unspecified length. This allows the block to perform single beat transfers as well as an incrementing (INCR) burst of unspecified length up to the maximum specified burst length (8 beats). DMA Mode 1 uses only INCR8, INCR4, and SINGLE beat bursts. The hburst[2:0] signal encodes the burst transfer used for a DMA operation.	
		0	DMA Mode 0
		1	DMA Mode 1

Table 26-24: MLB_ACTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SMX	Interrupt Multiplex Enable. The `MLB_ACTL.SMX` bit selects whether ACSR0 generates an interrupt on MLB_INT[0] and ACSR1 generates an interrupt on MLB_INT[1] or ACSR0 and ACSR1 generate an interrupt on MLB_INT[0] only.	
		0	ACSR0 generates an interrupt on MLB_INT[0]; ACSR1 generates an interrupt on MLB_INT[1]
		1	ACSR0 and ACSR1 generate an interrupts on MLB_INT[0] only
0 (R/W)	SCE	Software Clear Enable. The `MLB_ACTL.SCE` bit selects whether hardware clears the interrupt after a ACSRn register read or software clears the interrupt.	
		0	Hardware clears interrupt after a ACSRn register read
		1	Software clears interrupt

MediaLB Control 0 Register

The MLB_CTL0 register contains bit that enable the module and provide module status. Note that the maximum speed for ML6-pin mode is 2048 x FS.

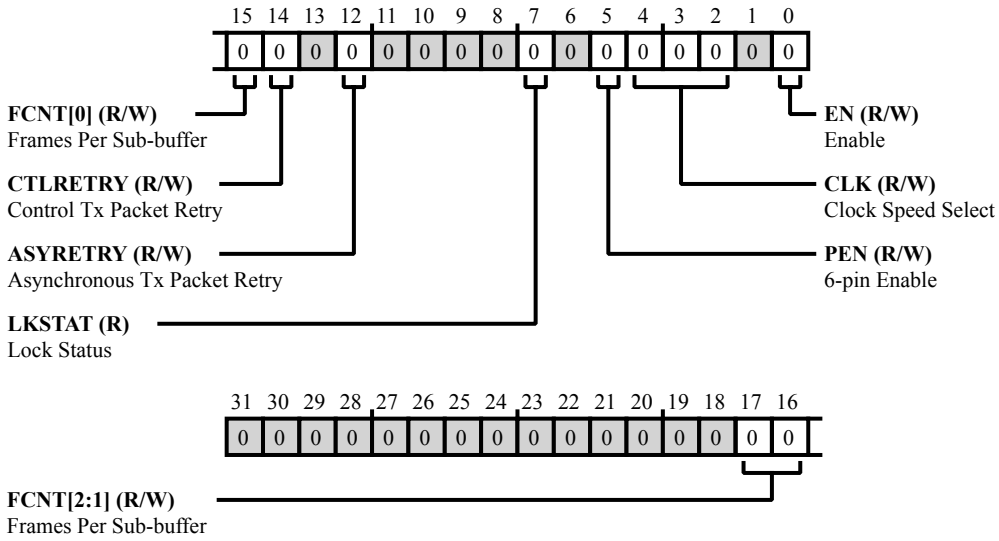

Figure 26-12: MLB_CTL0 Register Diagram

Table 26-25: MLB_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	FCNT	Frames Per Sub-buffer. The MLB_CTL0.FCNT bit field configures the frames per sub-buffer on synchronous channels.	
		0	1 Frame per sub-buffer (Operation is the same as Standard mode)
		1	2 frames per sub-buffer
		2	4 frames per sub-buffer
		3	8 frames per sub-buffer
		4	16 frames per sub-buffer
		5	32 frames per sub-buffer
		6	64 frames per sub-buffer
14 (R/W)	CTLRETRY	Control Tx Packet Retry. When the MLB_CTL0.CTLRETRY bit is set, a control packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, a control packet that is flagged with a Break or Protocol error by the receiver is skipped.	

Table 26-25: MLB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ASYRETRY	Asynchronous Tx Packet Retry. When the MLB_CTL0.ASYRETRY bit is set, an asynchronous packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, an asynchronous packet that is flagged with a Break or ProtocolError by the receiver is skipped.	
7 (R/NW)	LKSTAT	Lock Status. When the MLB_CTL0.LKSTAT bit is set (=0), the MediaLB block is synchronized to the incoming MediaLB frame with the following conditions. • If MLB_CTL1.LOCK =0 (unlocked), MLB_CTL1.LOCK is set after a FRAMESYNC is detected at the same position for three consecutive frames. • If MLB_CTL1.LOCK =1 (locked), MLB_CTL1.LOCK is cleared after not receiving a FRAMESYNC at the expected time for two consecutive frames. In this case FRAMESYNC patterns occurring at locations other than the expected one are ignored.	
5 (R/W)	PEN	6-pin Enable. The MLB_CTL0.PEN bit configures the MLB for 6-pin or 3-pin mode.	
		0	3-pin interface enabled
		1	6-pin interface enabled
4:2 (R/W)	CLK	Clock Speed Select. The MLB_CTL0.CLK bit field sets the clock speed.	
		0	256 x Fs (MLB_CTL.PEN = 0)
		1	512 x Fs (MLB_CTL.PEN = 0)
		2	1024 x Fs (MLB_CTL.PEN = 0)
		3	2048 x Fs (MLB_CTL.PEN = 1)
		4	Reserved
		5	Reserved
		6	Reserved
		7	Reserved
0 (R/W)	EN	Enable. When the MLB_CTL0.EN bit is set (=1), MediaLB clock, signal, and data are received and transmitted on the appropriate MediaLB pins.	

Control 1 Register

The MLB_CTL1 register contains bits that provide lock status and control system commands.

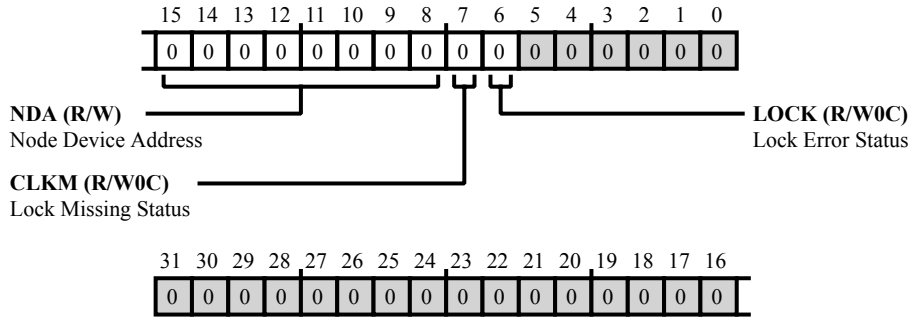

Figure 26-13: MLB_CTL1 Register Diagram

Table 26-26: MLB_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	NDA	Node Device Address. The MLB_CTL1.NDA bit field is used for system commands directed to individual MediaLB nodes.
7 (R/W0C)	CLKM	Lock Missing Status. The MLB_CTL1.CLKM bit is set when the MediaLB clock is not toggling at the pin. This bit is cleared by software.
6 (R/W0C)	LOCK	Lock Error Status. The MLB_CTL1.LOCK bit is set when the MediaLB is unlocked. This bit is cleared by software.

MLB Global Control Register

The MLB_GCTL register contains bits that manage the MLB clock.

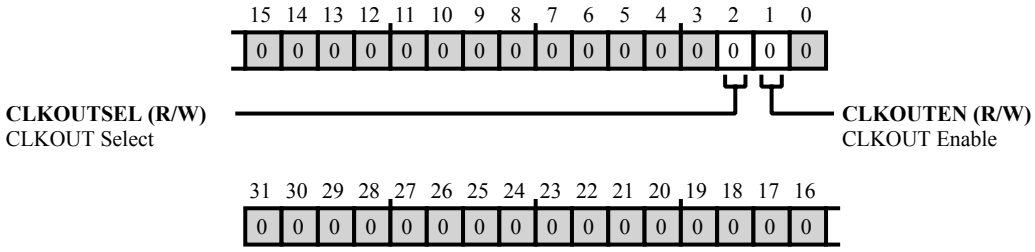

Figure 26-14: MLB_GCTL Register Diagram

Table 26-27: MLB_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CLKOUTSEL	CLKOUT Select. The MLB_GCTL.CLKOUTSEL bit selects either the MLB 3 pin clock or the 6 pin clock as MLBCLKOUT.	
		0	MLB 3 pin clock is selected for MLBCLKOUT
		1	MLB 6 pin clock is selected for MLBCLKOUT
1 (R/W)	CLKOUTEN	CLKOUT Enable.	

HBI Channel Busy 0 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR0 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

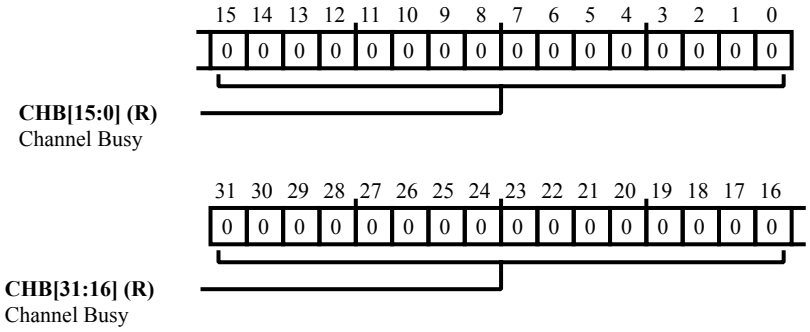

Figure 26-15: MLB_HCBR0 Register Diagram

Table 26-28: MLB_HCBR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR0.CHB bit field contains the bitwise channel busy bit for channels 31:0. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Busy 1 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR1 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

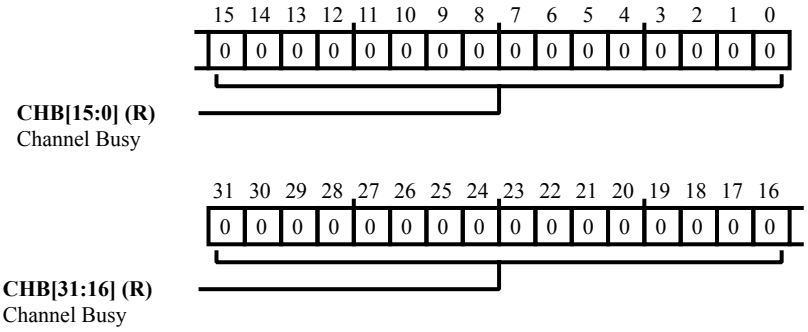

Figure 26-16: MLB_HCBR1 Register Diagram

Table 26-29: MLB_HCBR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR1.CHB bit field contains the bitwise channel busy bit for channels 63:32. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Error 0 Register

The MLB_HCER0 register indicates which channels (channels 31:0) have encountered fatal errors.

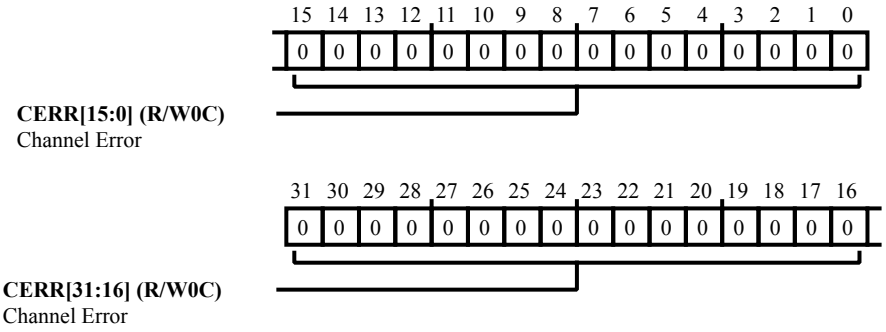

Figure 26-17: MLB_HCER0 Register Diagram

Table 26-30: MLB_HCER0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER0.CERR bit field reports bitwise errors for channels 31:0.

HBI Channel Error 1 Register

The MLB_HCER1 register indicates which channel(s) have encountered fatal errors.

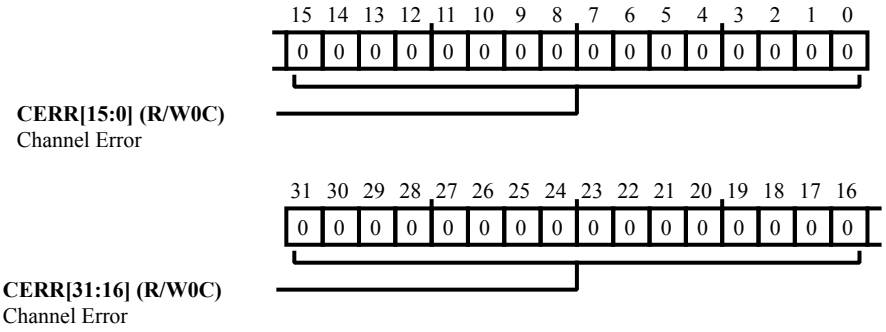

Figure 26-18: MLB_HCER1 Register Diagram

Table 26-31: MLB_HCER1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER1.CERR bite field reports bitwise errors for channels 63:32.

HBI Channel Mask 0 Register

The MLB_HCMR0 register controls which channels (for channels 31:0) are able to generate an HBI interrupt.

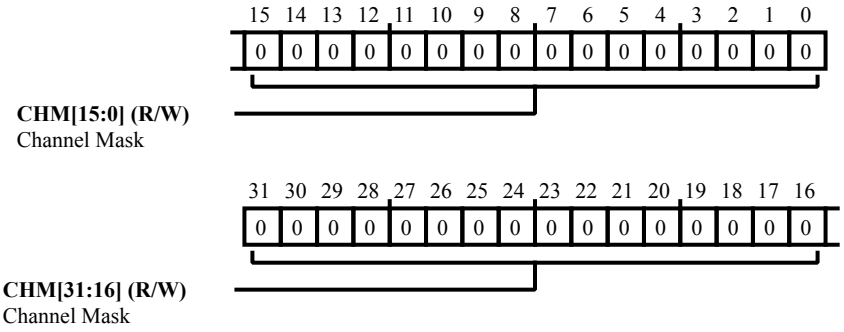

Figure 26-19: MLB_HCMR0 Register Diagram

Table 26-32: MLB_HCMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Channel Mask. The MLB_HCMR0.CHM bit field contains the bitwise channel mask bit for channels 31:0. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Channel Mask 1 Register

The MLB_HCMR1 register controls which channels (for channels 63:32) are able to generate an HBI interrupt.

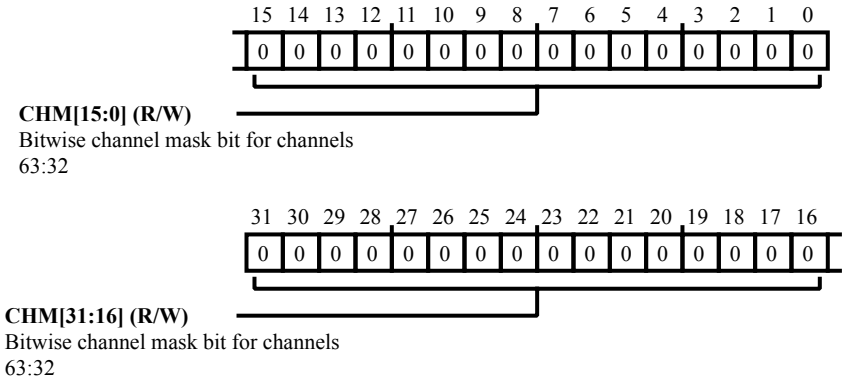

Figure 26-20: MLB_HCMR1 Register Diagram

Table 26-33: MLB_HCMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Bitwise channel mask bit for channels 63:32. The MLB_HCMR1.CHM bit field contains the bitwise channel mask bit for channels 63:32. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Control Register

The MLB_HCTL register controls and monitors general operation of the HBI block through the Address Generation Units) by reading and writing the register through the I/O interface. Each bit of this register is read/write.

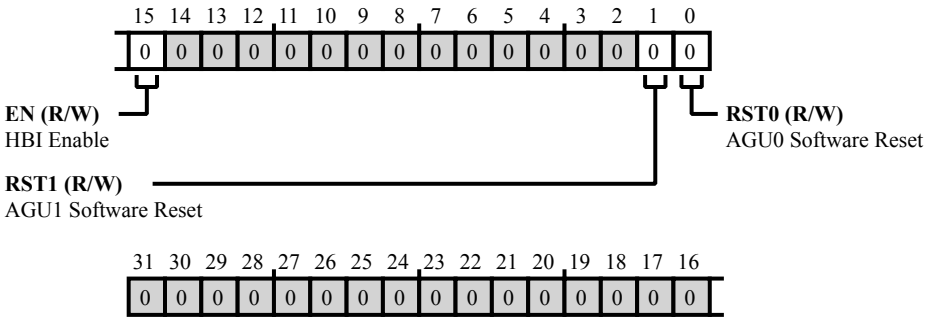

Figure 26-21: MLB_HCTL Register Diagram

Table 26-34: MLB_HCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	EN	HBI Enable. Setting the MLB_HCTL.EN bit enables the HBI.
1 (R/W)	RST1	AGU1 Software Reset. Setting the MLB_HCTL.RST1 bit resets AGU1.
0 (R/W)	RST0	AGU0 Software Reset. Setting the MLB_HCTL.RST0 bit resets AGU0.

Memory Interface Address Register

The MLB_MADR register contains bit fields that contain the Channel Table RAM (CTR) or Data Buffer RAM (DBR) addresses. It also contains bits that set target location and read-not-write parameters.

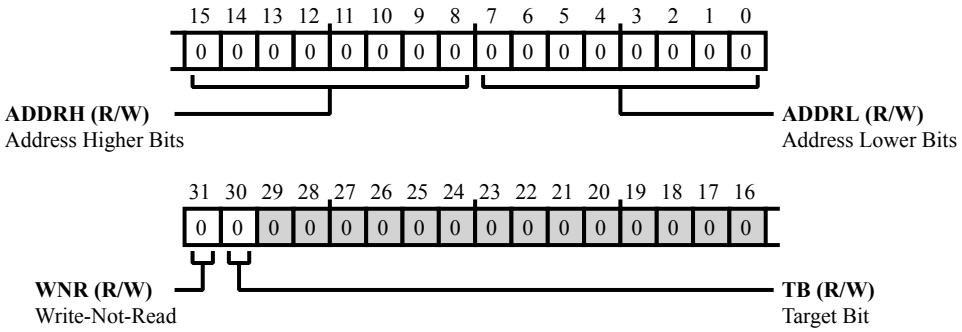

Figure 26-22: MLB_MADR Register Diagram

Table 26-35: MLB_MADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	WNR	Write-Not-Read. The MLB_MADR.WNR bit selects Write-Not-Read.	
		0	Read
		1	Write
30 (R/W)	TB	Target Bit. The MLB_MADR.TB bit sets the target location.	
		0	Channel Table RAM (CTR)
		1	Data Buffer RAM (DBR)
15:8 (R/W)	ADDRH	Address Higher Bits. The MLB_MADR.ADDRH bit field contains the DBR address of the 8-bit entry (bits [13:8]).	
7:0 (R/W)	ADDRL	Address Lower Bits. The MLB_MADR.ADDRL bit field contains the CTR address of the 128-bit entry or the DBR address of the 8-bit entry (bits [7:0]).	

Memory Interface Control Register

The MLB_MCTL register contains a bit that indicates that the data transfer is complete.

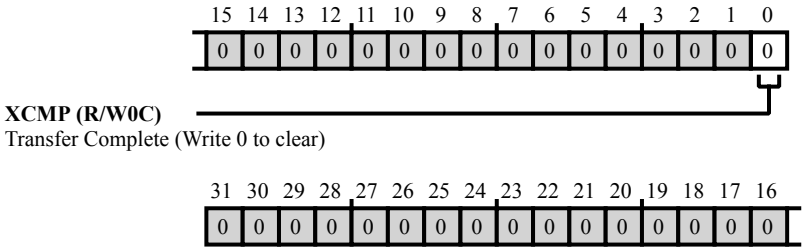

Figure 26-23: MLB_MCTL Register Diagram

Table 26-36: MLB_MCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W0C)	XCMP	Transfer Complete (Write 0 to clear). The MLB_MCTL.XCMP bit indicates that the data transfer is complete.

Memory Interface Control Data 0 Register

The MLB_MDAT0 register contains Channel Table RAM (CTR) data (bits [31:0] of 128-bit entry) or Data Buffer RAM (DBR) data (bits [7:0] of 8-bit entry).

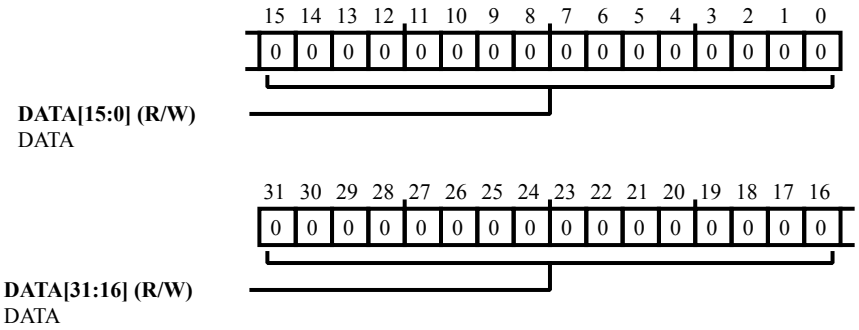

Figure 26-24: MLB_MDAT0 Register Diagram

Table 26-37: MLB_MDAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT0.DATA bit field contains CTR data or DBR data.

Memory Interface Control Data 1 Register

The MLB_MDAT1 register contains Channel Table RAM (CTR) data (bits [63:32] of 128-bit entry).

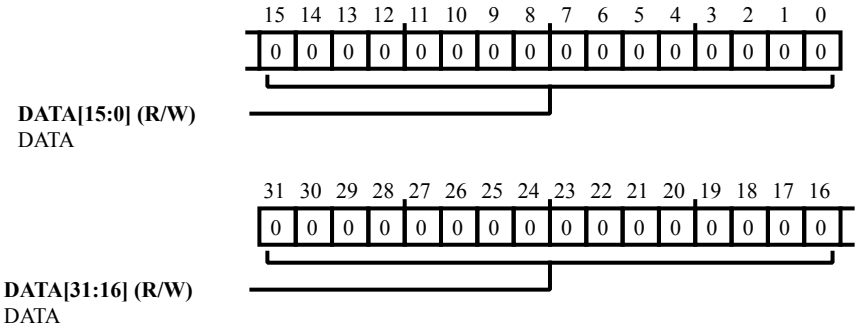

Figure 26-25: MLB_MDAT1 Register Diagram

Table 26-38: MLB_MDAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT1.DATA bit field contains CTR data.

Memory Interface Control Data 2 Register

The MLB_MDAT2 register contains Channel Table RAM (CTR) data (bits [95:64] of 128-bit entry).

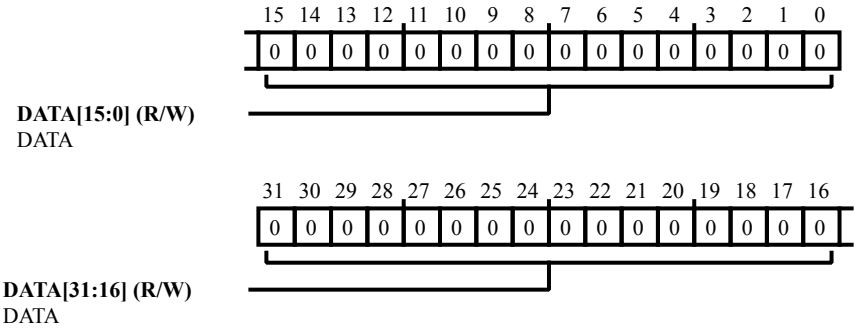

Figure 26-26: MLB_MDAT2 Register Diagram

Interrupt Enable Register

The MLB_MIEN register is used to enable various interrupt conditions.

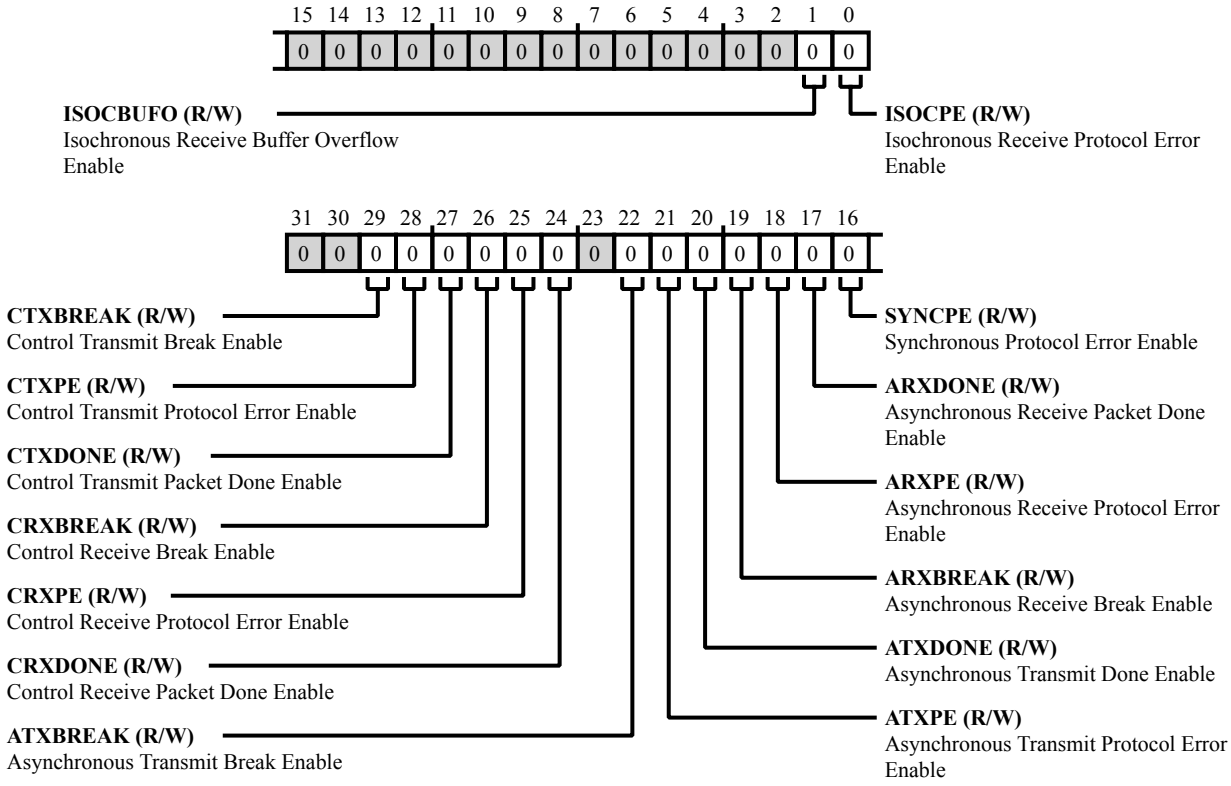

Figure 26-32: MLB_MIEN Register Diagram

Table 26-45: MLB_MIEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	CTXBREAK	Control Transmit Break Enable. When the MLB_MIEN.CTXBREAK bit is set, a ReceiverBreak response received from the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
28 (R/W)	CTXPE	Control Transmit Protocol Error Enable. When the MLB_MIEN.CTXPE bit is set, a ProtocolError generated by the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
27 (R/W)	CTXDONE	Control Transmit Packet Done Enable. When the MLB_MIEN.CTXDONE bit is set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 26-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	CRXBREAK	Control Receive Break Enable. When the MLB_MIEN.CRXBREAK bit is set, a ControlBreak command received from the transmitter on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
25 (R/W)	CRXPE	Control Receive Protocol Error Enable. When the MLB_MIEN.CRXPE bit is set, a ProtocolError detected on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
24 (R/W)	CRXDONE	Control Receive Packet Done Enable. When the MLB_MIEN.CRXDONE bit is set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
22 (R/W)	ATXBREAK	Asynchronous Transmit Break Enable. When the MLB_MIEN.ATXBREAK bit is set, a ReceiverBreak response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
21 (R/W)	ATXPE	Asynchronous Transmit Protocol Error Enable. When the MLB_MIEN.ATXPE bit is set, a ProtocolError generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
20 (R/W)	ATXDONE	Asynchronous Transmit Done Enable. When the MLB_MIEN.ATXDONE bit is set, a packet transmitted with no errors on an asynchronous Tx channel channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
19 (R/W)	ARXBREAK	Asynchronous Receive Break Enable. When the MLB_MIEN.ARXBREAK bit is set, a AsyncBreak command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
18 (R/W)	ARXPE	Asynchronous Receive Protocol Error Enable. When the MLB_MIEN.ARXPE bit is set, a protocol error detected on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
17 (R/W)	ARXDONE	Asynchronous Receive Packet Done Enable. When the MLB_MIEN.ARXDONE bit is set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 26-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	SYNCPE	Synchronous Protocol Error Enable. When the MLB_MIEN.SYNCPE bit is set, a protocol error detected on a synchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
1 (R/W)	ISOCBUFO	Isochronous Receive Buffer Overflow Enable. When the MLB_MIEN.ISOCBUFO bit is set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
0 (R/W)	ISOCPE	Isochronous Receive Protocol Error Enable. When the MLB_MIEN.ISOCPE bit is set, a protocol error detected on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Channel Status 0 Register

The MLB_MS0 register indicates the channel status for MediaLB channels 31 to 0. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MLB_MIEN register are set.

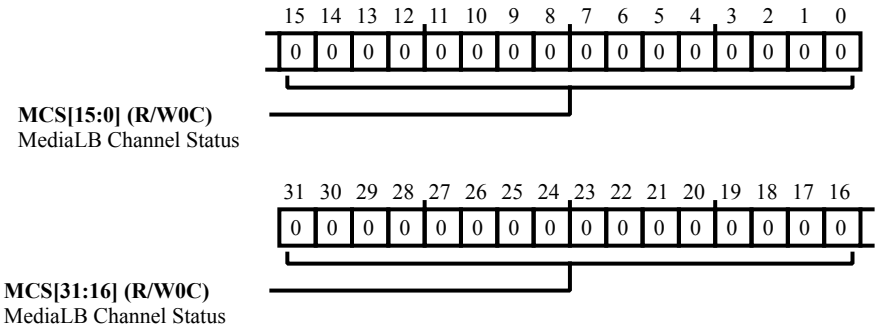

Figure 26-33: MLB_MS0 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	MCS	MediaLB Channel Status. The MLB_MS1.MCS bit field indicates the MediaLB channel status for channels 63 to 32.

System Data Register

The MLB_MSD register allows system software to receive control information from the MLB controller. The MLB_MSD register is updated once per frame by the hardware during the MLB system channel.

The MLB_MSD register is loaded with the data from the MLBDAT_IN signal during the system channel quadlet. System software must read this register before the start of the next MLB frame to prevent the current data from being lost.

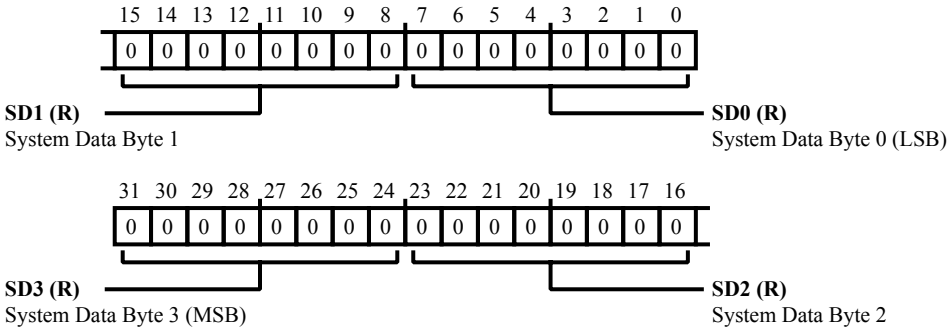

Figure 26-35: MLB_MSD Register Diagram

Table 26-48: MLB_MSD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	SD3	System Data Byte 3 (MSB). The MLB_MSD.SD3 bits are updated with MediaLB Data [31:24] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD3 is not updated.
23:16 (R/NW)	SD2	System Data Byte 2. The MLB_MSD.SD2 bits are updated with MediaLB Data [23:16] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD2 is not updated.
15:8 (R/NW)	SD1	System Data Byte 1. The MLB_MSD.SD1 bits are updated with MediaLB Data [15:8] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD1 is not updated.
7:0 (R/NW)	SD0	System Data Byte 0 (LSB). The MLB_MSD.SD0 bits are updated with MediaLB Data [7:0] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD0 is not updated.

System Status Register

The MLB_MSS register allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB system channel. The bits of this register are not valid until the processor is locked to the MLB interface (except for the bits associated with MLB lock and unlock, SDMU and SDML). System software must service events before the start of the next MLB frame to prevent the current frame status from being lost.

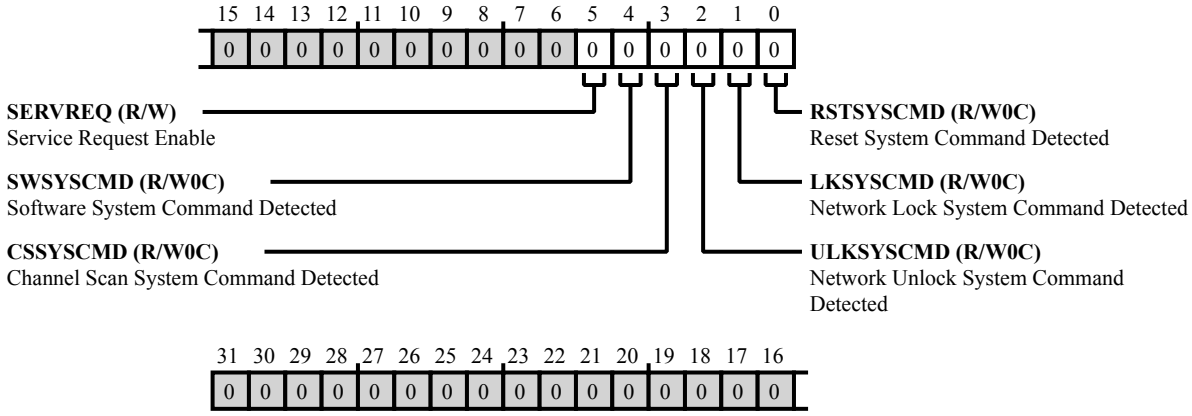

Figure 26-36: MLB_MSS Register Diagram

Table 26-49: MLB_MSS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	SERVREQ	Service Request Enable. When the MLB_MSS.SERVREQ bit set, the MediaLB block responds with a device present, request service system response if a matching channel scan system command is detected. When cleared, the MediaLB block responds with a device present system response.
4 (R/W0C)	SWSYSCMD	Software System Command Detected. The MLB_MSS.SWSYSCMD bit indicates that a software system command was detected (in the system quadlet). The MLB_MSS.SWSYSCMD bit is set by hardware, cleared by software. Data is stored in the MLB_MSD register for this command.
3 (R/W0C)	CSSYSCMD	Channel Scan System Command Detected. The MLB_MSS.CSSYSCMD bit indicates that a channel scan system command was detected (in the system quadlet). The MLB_MSS.CSSYSCMD bit is set by hardware, cleared by software. If the node address specified in the data quadlet matches the value in the MLB_CTL1.NDA bit field, the device responds either device present or device present, request service system response in the next system quadlet.

Table 26-49: MLB_MSS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W0C)	ULKSYSCMD	Network Unlock System Command Detected. The `MLB_MSS.ULKSYSCMD` bit indicates a network unlock system command was detected (in the system quadlet). The `MLB_MSS.ULKSYSCMD` bit is by hardware, cleared by software.
1 (R/W0C)	LKSYSCMD	Network Lock System Command Detected. The `MLB_MSS.LKSYSCMD` bit indicates a network lock system command was detected (in the system quadlet). The `MLB_MSS.LKSYSCMD` bit is set by hardware and cleared by software.
0 (R/W0C)	RSTSYSCMD	Reset System Command Detected. The `MLB_MSS.RSTSYSCMD` bit indicates a reset system command was detected (in the system quadlet). The `MLB_MSS.RSTSYSCMD` bit is set by hardware, cleared by software.

1 (R/W)	CMRES	MediaLB 6-pin common mode resistor enable. This signal is no longer used.

27 Two-Wire Interface (TWI)

The processor has a two-wire interface (TWI), that provides a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I^2C bus standard. Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

The TWI module offers the capabilities of simultaneous requester and completer operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface uses two pins for transferring clock (`TWI_SCL`) and data (`TWI_SDA`) and supports the protocol at speeds up to 400K bits/sec. The TWI interface pins are compatible with 3.3V logic levels.

To preserve processor bandwidth, the TWI module can be set up with transfer-initiated interrupts to only service FIFO buffer data reads and writes. Protocol-related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I^2C bus protocol.

NOTE: All TWI instances (TWI0-5) operate in the SCLK0 domain.

TWI Features

The TWI is fully compatible with the widely used I^2C bus standard.

The TWI controller includes the following features.

- Simultaneous requester and completer operation on multiple device systems
- Support for multi-controller bus arbitration
- 7-bit addressing
- 100K bits/second and 400K bits/second data rates
- General call address support
- Controller clock synchronization and support for clock low extension
- Separate multiple-byte receive and transmit FIFOs
- Low interrupt rate

- Individual override control of data and clock lines in the event of bus lock-up
- Input filter for spike suppression
- Serial camera control bus support as specified in the *OmniVision Serial Camera Control Bus (SCCB) Functional Specification*
- Programmable drive/tolerance of TWI pins. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

TWI Functional Description

The TWI interface is a shift register that serially transmits and receives data bits. It moves data 1 bit at a time at the SCL rate, to and from other TWI devices. The SCL signal synchronizes the shifting and sampling of the data on the serial data pin.

ADSP-2159x_SC591_SC592_SC594 TWI Register List

The Two-Wire Interface controller TWI allows a device to interface to an inter-IC bus as specified by the Philips I^2C Bus Specification version 2.1, dated January 2000. A set of registers governs TWI operations. For more information on TWI functionality, see the TWI register descriptions.

Table 27-1: ADSP-2159x_SC591_SC592_SC594 TWI Register List

Name	Description
TWI_CLKDIV	SCL Clock Divider Register
TWI_CTL	Control Register
TWI_FIFOCTL	FIFO Control Register
TWI_FIFOSTAT	FIFO Status Register
TWI_IMSK	Interrupt Mask Register
TWI_ISTAT	Interrupt Status Register

TWI Block Diagram

The *TWI Block Diagram* figure shows the basic blocks of the TWI interface.

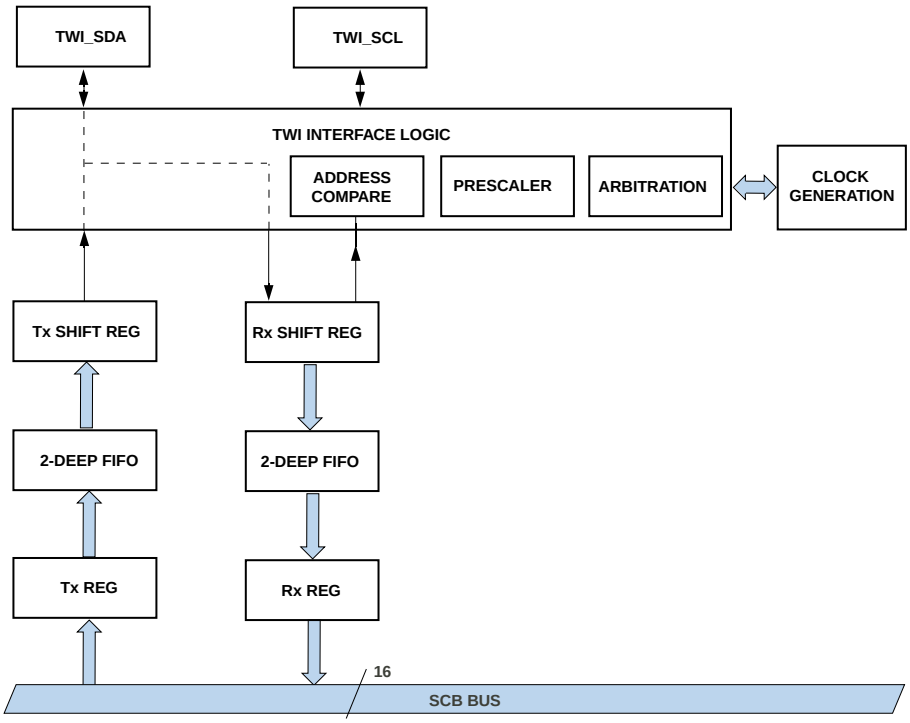

Figure 27-1: TWI Block Diagram

External Interface

The `TWI_SDA` (serial data) and `TWI_SCL` (serial clock) signals are open drain and require pull-up resistors. These bidirectional signals externally interface the TWI controller to the I^2C bus and no other external connections or logic are necessary.

Serial Clock Signal (SCL)

The serial clock signal (TWI_SCL) is an input in completer mode. In requester mode, the TWI controller must set this signal to the desired frequency.

The TWI controller supports the standard mode of operation (up to 100 kHz) or fast mode (up to 400 kHz). The TWI control register (TWI_CTL) sets the TWI_CTL.PRESCALE value which sets the relationship between the system clock (SCLK0) and the internally timed events of the TWI controller. The internal time reference is derived from SCLK0 using a prescaled value. The prescale value is the number of SCLK0 periods used in the generation of one internal time reference. Set the value of prescale to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value as follows.

PRESCALE = f_{SCLK0}/10MHz

NOTE: It is not always possible to achieve 10-MHz accuracy. In such cases, it is safe to round up the PRESCALE value to the next highest integer. For example, if SCLK0 is 100 MHz, the PRESCALE value is calculated as 100 MHz/10 MHz = 10. A prescale value of 14 in this case ensures that all timing requirements are met.

During requester mode operation, the TWI module uses the TWI_CLKDIV register values to create the minimum TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO durations of the TWI_SCL signal. The TWI_CLKDIV.CLKHI field specifies the minimum number of 10-MHz time reference periods the TWI_SCL waits before a new clock low period begins, assuming a single requester. (The 10-MHz time reference periods are represented as an 8-bit binary value). The TWI uses the TWI_CLKDIV.CLKLO field to specify the minimum number of internal time reference periods (represented as an 8-bit binary value); the TWI_SCL signal is held low.

Serial clock frequencies can vary from 400 kHz to less than 20 kHz. The resolution of the clock generated is 1/10 MHz or 100 ns. The following equation describes the frequency.

CLKDIV = TWI_SCL period/10 MHz time reference.

For example, for an TWI_SCL of 400 kHz (period = 1/400 kHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns), the following equation applies:

CLKDIV =2500 ns/100 ns = 25

Therefore, a TWI_SCL signal with a 30% duty cycle has TWI_CLKDIV.CLKLO=17 and TWI_CLKDIV.CLKHI=8. Adding TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI equals CLKDIV.

NOTE: The TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO fields are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for the TWI_SCL signal. Slew rate controls falling edges. The *RC* time constant governs the rising edges. The pull-up resistor and the TWI_SCL capacitance form the time constant. See the “Register Descriptions” section for more details.

Serial Data Signal (SDA)

The TWI transmits and receives serial data, depending on the direction of the transfer, on the bidirectional serial data signal (SDA).

Internal Interface

The peripheral bus interface supports the transfer of 16-bit wide data. The processor uses the interface in the support of register and FIFO buffer reads and writes. The TWI internal interface is comprised of the blocks described as follows.

Register block. Contains all control and status bits and reflects what can be written or read as outlined by the programming model. Each function block updates their corresponding status bits.

FIFO buffer. Configured as a 1-byte-wide, 2-deep transmit FIFO buffer and a 1-byte-wide, 2-deep receive FIFO buffer.

Transmit shift register. Serially shifts its data out externally off chip. The output can be controlled for generation of acknowledgments or it can be manually overwritten.

Receive shift register. Receives its data serially from off chip. The receive shift register is 1 byte wide and data received can either be transferred to the FIFO buffer or used in an address comparison.

Address compare block. Supports address comparison in the event the TWI controller module is accessed as a completer.

Prescaler block. Must be programmed to generate a 10-MHz time reference relative to the system clock. The block uses this time base for filtering of data and timing events specified by the electrical data sheet (See the Philips specification). The block uses the time base to generate the `TWI_SCL` clock as well.

Clock generation module. Generates an external `TWI_SCL` clock when in requester mode. It includes the logic necessary for synchronization in a multi-requester clock configuration and clock stretching when configured in completer mode.

NOTE: The TWI does not support DMA based operation.

TWI Architectural Concepts

The TWI controller follows the transfer protocol of the Philips I^2C Bus specification version 2.1 dated January 2000.

NOTE: The TWI unit does not support DMA-based operation.

TWI Protocol

The ***Data Transfer*** figure shows a simple complete transfer.

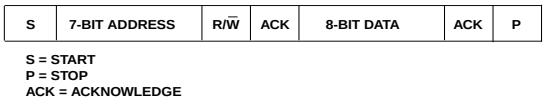

Figure 27-2: Data Transfer

The TWI controller register contents maps to a basic transfer. The ***Data Transfer with Bit Illustration*** figure details the same transfer from the ***Data Transfer*** figure noting the corresponding TWI controller bit names. In this

illustration, the TWI controller successfully transmits 1 byte of data. The completer has acknowledged both address and data.

Figure 27-3: Data Transfer with Bit Illustration

Clock Generation and Synchronization

The TWI controller implementation only issues a clock during requester mode operation and only at the time a transfer initiates. If arbitration for the bus is lost, the serial clock output immediately three-states. If multiple clocks attempt to drive the serial clock line, the TWI controller synchronizes its clock with the other remaining clocks. The ***Clock Synchronization*** figure shows this functionality.

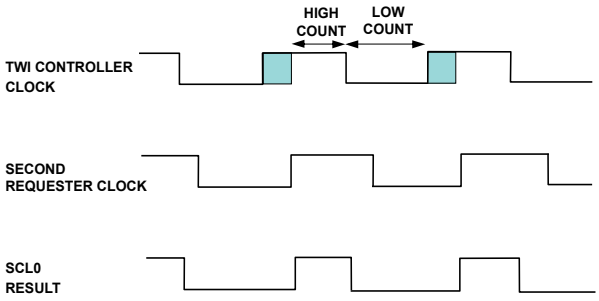

Figure 27-4: Clock Synchronization

The TWI controller serial clock (`TWI_SCL`) output follows these rules:

- Once the clock high (`TWI_CLKDIV.CLKHI`) count is complete, the serial clock output is driven low and the clock low (`TWI_CLKDIV.CLKLO`) count begins.
- Once the clock low count is complete, the serial clock line is three-stated. This state allows the external pull-up resistor to pull the `TWI_SCL` signal high. The clock synchronization logic enters into a delay mode (shaded area) until the `TWI_SCL` signal is detected at logic 1 level. Now, the clock high count begins.

Bus Arbitration

The TWI controller initiates a requester mode transmission only when the bus is idle. If the bus is idle and two requester initiate a transfer, arbitration for the bus begins. The ***Bus Arbitration*** figure shows the arbitration.

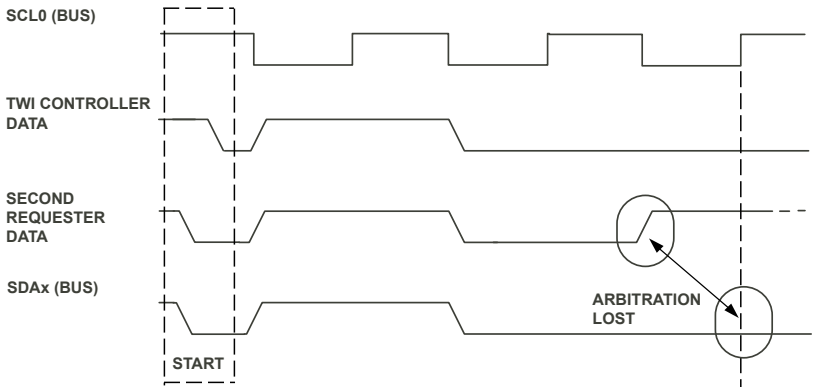

Figure 27-5: Bus Arbitration

The TWI controller monitors the serial data bus (SDA) while the TWI_SCL signal is high. If the TWI_SDA signal is determined to be an active logic 0 level while the data of the TWI controller is a logic 1 level, the TWI controller has lost arbitration. It stops generating the clock and data signals. Arbitration is not only performed at the serial clock edges, but also during the entire time the TWI_SCL signal is high.

Start and Stop Conditions

Start and stop conditions involve serial data transitions while the serial clock is a logic 1 level. The TWI controller generates and recognizes these transitions. Typically, start and stop conditions occur at the beginning and at the conclusion of a transmission, except repeated start combined transfers. The ***Start and Stop Conditions*** figure shows the transitions.

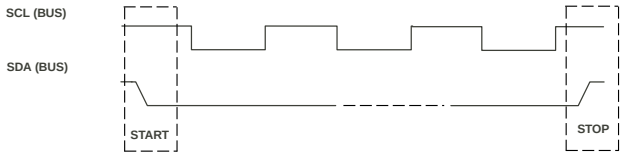

Figure 27-6: Start and Stop Conditions

The TWI special case start and stop conditions of the TWI controller include the following.

- Controller addressed as a completer-receiver. If the requester asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (TWI_ISTAT.SCOMP).
- Controller addressed as a completer-transmitter. If the requester asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (TWI_ISTAT.SCOMP) and indicates a completer transfer error (TWI_ISTAT.SERR).
- Controller as a requester-transmitter or requester-receiver. If the stop bit (TWI_MSTRCTL.STOP) is set during an active requester transfer, the TWI controller issues a stop condition as soon as possible avoiding any error conditions. The TWI controller operates as if data transfer count had been reached.

General Call Support

The TWI controller always decodes and acknowledges a general call address if:

- The TWI controller is enabled as a target
- General call is enabled

The TWI_SLVCTL.GEN bit configures general call addressing (0x00) only when the TWI controller is a target-receiver.

If the data associated with the transfer is (NAK) not acknowledged, the TWI_SLVCTL.NAK bit can be set. If the TWI controller issues a general call as a requester-transmitter, set the appropriate address (TWI_MSTRADDR register) and transfer direction (TWI_MSTRCTL.DIR bit) and load the transmit FIFO data.

NOTE: The byte following the general call address usually defines the completer's response to the call. The interpretation of the command in the second byte is based on the value of its LSB. For a TWI completer device, the bytes received after the general call address are considered data.

Fast Mode

Fast mode essentially uses the same mechanics as the standard mode of operation. Fast mode affects electrical specifications and timing. When fast mode is enabled, (FAST) timing is modified to meet the following electrical requirements.

- Serial data rise times before arbitration evaluation (t_r)
- Stop condition set-up time from serial clock to serial data (t_{SUSTO})
- Bus free time between a stop and start condition (t_{BUF})

TWI Operating Modes

The TWI has two modes of operation: repeated start and clock stretching. The following sections describe the operating modes.

Repeated Start

A repeated start condition is the absence of a stop condition between two transfers. The two transfers can be of any direction type. Examples include a transmit followed by a receive, or a receive followed by a transmit. The following sections guide the programmer in developing a service routine.

Transmit Receive Repeated Start

The ***Repeated Start Followed by Data Receive*** figure shows a repeated start followed by a data receive sequence. The shading in the figure indicates that the completer has control of the bus.

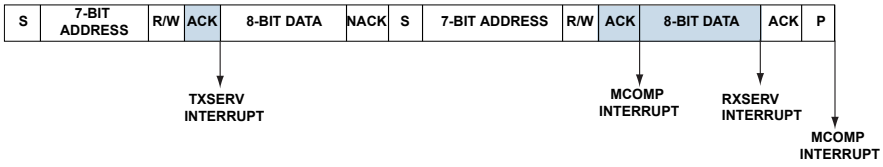

Figure 27-7: Repeated Start Followed by Data Receive

The tasks performed at each interrupt are:

- Transmit FIFO service (`TWI_ISTAT.TXSERV`) interrupt request. This interrupt is generated due to a FIFO access. Since this byte is the last of this transfer, the TWI uses the `TWI_FIFOSTAT` register to indicate that the transmit FIFO is empty. When read, `TWI_MSTRCTL.DCNT` bit field=0. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and set the `TWI_MSTRCTL.DIR` bit if the following transfer is a data receive.
- Requester transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when all data transfers (`TWI_MSTRCTL.DCNT` bit field=0). If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to receive.
- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a byte in the receive FIFO. Simple data handling is the only requirement.
- Requester transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when the transfer completes.

Receive Transmit Repeated Start

The ***Repeated Start Data Receive Followed by Data Transmit*** figure illustrates a repeated start data receive followed by a data transmit sequence. The shading in the figure indicates that the completer has control of the bus.

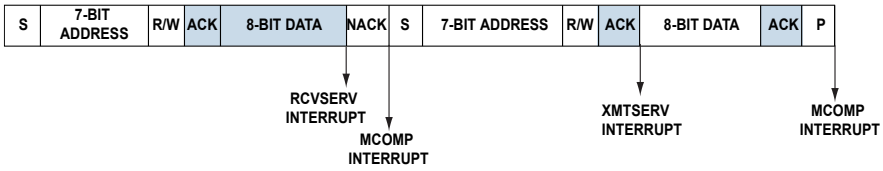

Figure 27-8: Repeated Start Data Receive Followed by Data Transmit

The tasks performed at each interrupt are:

- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a data byte in the receive FIFO. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and clear the `TWI_MSTRCTL.DIR` bit if the following transfer is a data transmit.
- Requester transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request has occurred due to the completion of the data receive transfer. If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to transmit.

- Transmit FIFO service (TWI_ISTAT.TXSERV) interrupt. This interrupt request is generated due to a FIFO access. Simple data handling is the only requirement.
- Requester transfer complete (TWI_ISTAT.MCOMP) interrupt. This interrupt request is generated when the transfer completes.

NOTE: There is no timing constraint to meet the conditions—program the bits as required. Refer to Clock Stretching During Repeated Start section for more on how the controller stretches the clock during repeated start transfers.

Clock Stretching

Clock stretching is an added function of the TWI controller in requester mode operation. This behavior uses self-induced stretching of the I ^{2}C clock while waiting to service interrupts. Hardware initiates stretching automatically. No programming is necessary. The TWI controller as a requester supports three modes of clock stretching:

- Clock Stretching During FIFO Underflow
- Clock Stretching During FIFO Overflow
- Clock Stretching During Repeated Start

Clock Stretching During FIFO Underflow

During a requester mode transmit, an interrupt request occurs the instant the transmit FIFO becomes empty. The most recent byte begins transmission. If the TWI_ISTAT.TXSERV interrupt request is not serviced, the concluding acknowledge phase of the transfer stretches.

Stretching of the clock continues until new data bytes are written to the transmit FIFO (TWI_TXDATA8 or TWI_TXDATA16 registers). No other action is required to release the clock and continue the transmission. This behavior continues until the transmission completes (TWI_MSTRCTL.DCNT=0). The transmission concludes (TWI_ISTAT.MCOMP). The ***Clock Stretching during FIFO Underflow*** figure and table show the stretching.

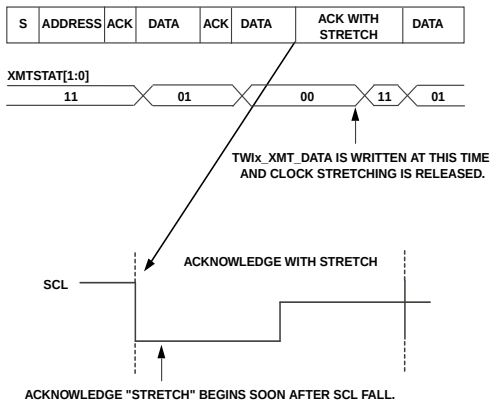

Figure 27-9: Clock Stretching during FIFO Underflow

TWI Controller	Processor
Interrupt: XMTSERV – Transmit FIFO buffer is empty	Acknowledge: Clear the interrupt request source bits. Write to the transmit FIFO buffer
...	...
Interrupt: MCOMP – requester transmit complete (DCNT= 0x00)	Acknowledge: Clear the interrupt request source bits

Clock Stretching During FIFO Overflow

During a requester mode receive operation, an interrupt occurs at the instant the receive FIFO becomes full. It is during the acknowledge phase of this received byte that clock stretching begins. The TWI module makes no attempt to initiate the reception of another byte. Stretching of the clock continues until the data bytes previously received are read from the receive FIFO buffer (`TWI_RXDATA8` or `TWI_RXDATA16` registers). No other action is required to release the clock and continue the reception of data. This behavior continues until the reception is complete (`TWI_MSTRCTL.DCNT`=0). Reception concludes (`TWI_ISTAT.MCOMP`). The ***Clock Stretching During FIFO Overflow*** figure and table show the clock stretching.

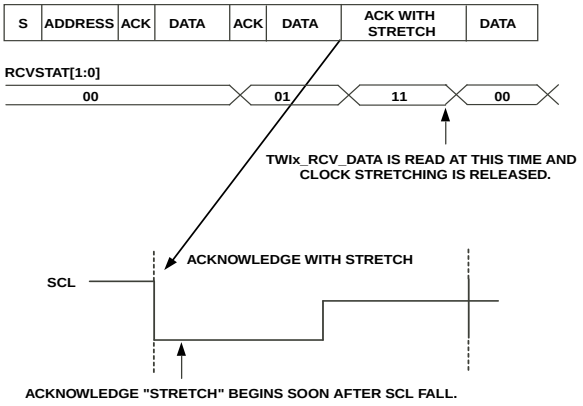

Figure 27-10: Clock Stretching During FIFO Overflow

TWI Controller	Processor
Interrupt: RCVSERV – Receive FIFO buffer is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer
...	...
Acknowledge: Clear the interrupt source bits	Interrupt: MCOMP – requester receive complete

Clock Stretching During Repeated Start

The repeated start feature in I^2C protocol requires a transition between two subsequent transfers. With the use of clock stretching, the task of managing transitions becomes simpler and common to all transfer types.

Once an initial TWI requester transfer completes (transmit or receive), the clock initiates a stretch during the repeated start phase between transfers. Concurrent with this event, the initial transfer generates a `TWI_ISTAT.MCOMP` interrupt to signify the initial transfer has completed (`TWI_MSTRCTL.DCNT`=0). This initial transfer is handled without any special bit setting sequences or timing.

The clock stretching logic described applies here. With no system-related timing constraints, the subsequent transfer (receive or transmit) is set up and activated. This sequence can repeat as many times as required to string a series of repeated start transfers together. The ***Clock Stretching during Repeated Start Condition*** figure and table show the clock stretching.

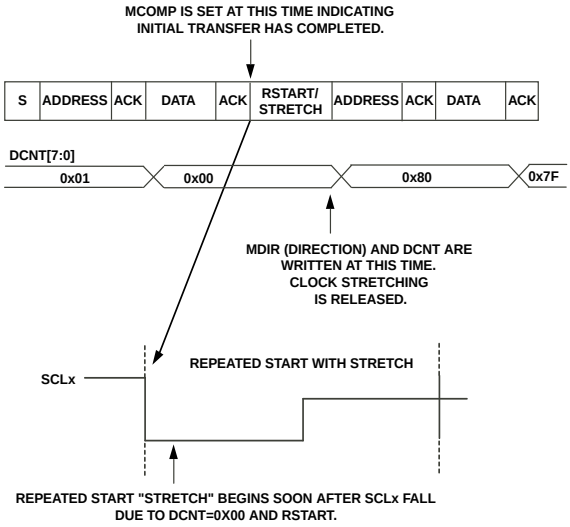

Figure 27-11: Clock Stretching during Repeated Start Condition

TWI Controller	Processor
Interrupt: MCOMP – Initial transmit has completed and DCNT = 0x00. Note: transfer in progress, RSTART previously set.	Acknowledge: Clear the interrupt request source bits. Write to TWIx_MASTER_CTL, setting MDIR (receive), clearing RSTART, and setting new DCNT value (nonzero).
Interrupt: RCVSERV – Receive FIFO is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer
...	...
Interrupt: MCOMP – requester receive complete	Acknowledge: Clear the interrupt request source bits

TWI Programming Model

The topics in this section provide information on the basic programming steps required to set up and run the two wire interface.

General Setup

General setup refers to register writes that are required for both completer mode and requester mode operations.

Perform general setup before setting either the requester or completer enable bits.

1. Program the `TWI_CTL.EN` bit to enable the TWI controller and set the prescale value (`TWI_CTL.PRESCALE` bit).

2. Program the prescale value to the binary representation of f_{SCLK0}/10 MHz. Round up all values to the next whole number.
3. Set the TWI_CTL.EN bit to enable the controller.

Once the TWI controller is enabled, a bus busy condition can be detected. This condition clears after t_{BUF} has expired, assuming no additional bus activity has been detected.

Completer Mode

When enabled, completer mode operation supports both receive and transmit data transfers.

It is not possible to enable only one data transfer direction and not acknowledge (NAK) the other. The following setup reflects this functionality.

1. Program the TWI_SLVADDR register. The TWI uses the appropriate 7 bits in determining a match during the address phase of the transfer.
2. Program the TWI_TXDATA8.VALUE or TWI_TXDATA16 registers. These values are the initial data values for transmission when the completer is addressed and transmission is needed. This step is optional. If no data is written when the completer is addressed and transmission is needed, the serial clock (TWI_SCL) stretches. An interrupt is generated until data is written to the transmit FIFO.
3. Program the TWI_IMSK register. There are enable-bits associated with the desired interrupt sources. For example, programming the value 0x000F results in an interrupt request output to the processor, when the TWI module detects a valid address match. An interrupt request also occurs when a valid completer transfer completes or has an error, or a subsequent transfer has begun and the previous transfer has not been serviced.
4. Program the TWI_SLVCTL register. This step prepares and enables completer mode operation. For example, programming the value 0x0005 enables completer mode operation and requires 7-bit addressing. It indicates that data in the transmit FIFO buffer is for completer mode transmission.

The ***Completer Mode Interaction*** table and ***TWI Completer Mode Program Flow*** diagram represent the interaction between the TWI controller and the processor using this example.

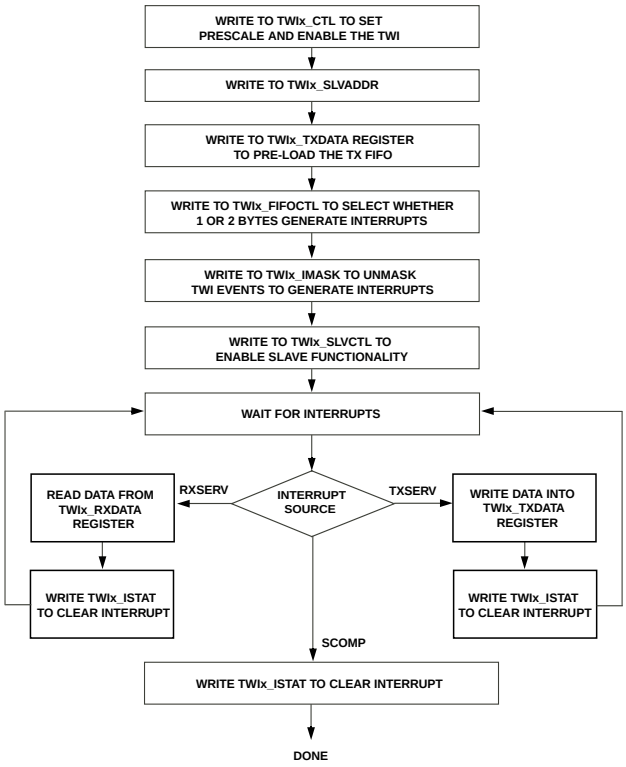

Figure 27-12: TWI Completer Mode Program Flow

Table 27-3: Completer Mode Interaction

TWI Controller	Processor
Interrupt: SINIT – completer transfer in progress.	Acknowledge: Clear the interrupt source bits.
Interrupt: RCVSERV – Receive buffer is full.	Acknowledge: Clear the interrupt source bits. Read TWIx_FIFO_STAT. Read the receive FIFO buffer.
...	...
Interrupt: SCOMP – completer transfer complete.	Acknowledge: Clear the interrupt source bits. Read the receive FIFO buffer.

Requester Mode Program Flow

The ***Requester Mode Program Flow*** figure shows the program for the TWI in requester mode.

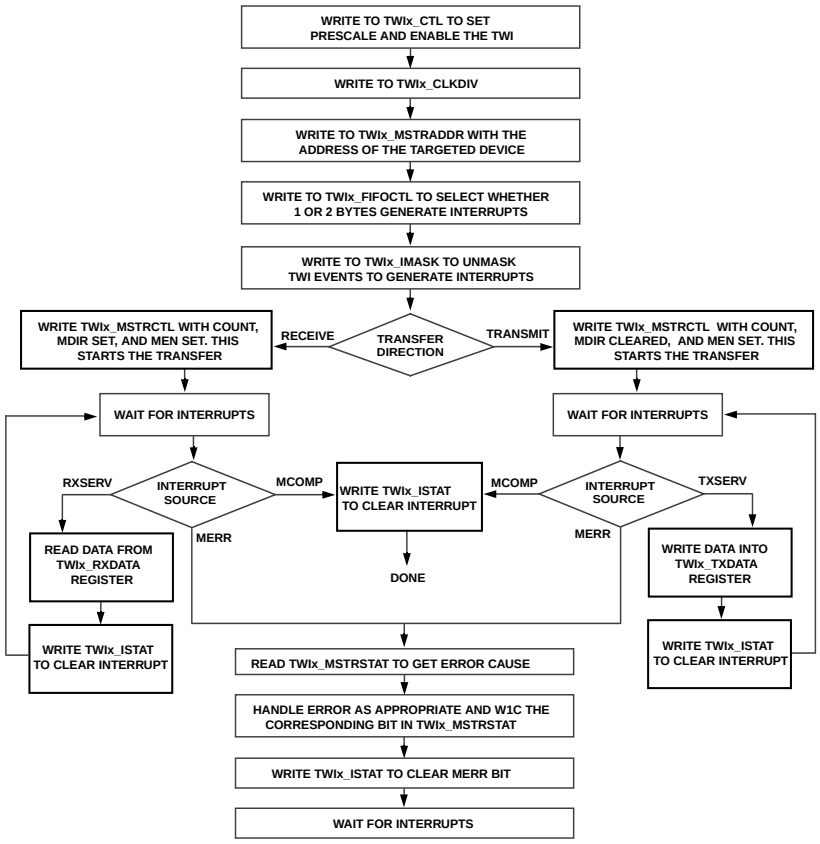

Figure 27-13: Requester Mode Program Flow

Requester Mode Clock Setup

Requester mode operation is set up and executed on a per-transfer basis.

An example of programming steps for a receive and for a transmit is given separately in following sections. The programming step for clock setup listed here is common to both transfer types.

1. Program the `TWI_CLKDIV` register to define the minimum high and minimum low duration for the clock.

The `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` fields do not guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for `TWI_SCL`. The slew rate controls falling edges. The RC time constant formed by the pull-up resistor and the SCL capacitance govern rising edges. See the “Register Descriptions” section for more details.

Requester Mode Transmit

Follow these programming steps for a single requester mode transmission:

1. Program the `TWI_MSTRADDR` register. This step defines the address transmitted during the address phase of the transfer.

2. Program the TWI_TXDATA8 or TWI_TXDATA16 register. This step configures the initial data transmitted. It is an error to complete the address phase of the transfer and not have data available in the transmit FIFO buffer.
3. Program the TWI_FIFOCTL register. The programming indicates if the transmit FIFO buffer interrupt requests occur with each byte transmitted (8-bits) or with every 2 bytes transmitted (16-bits).
4. Program the TWI_IMSK register. This step enables the bits associated with the desired interrupt request sources. For example, programming the value 0x0030 results in an interrupt output to the processor when the requester transfer completes, and the requester transfer has an error.
5. Program the TWI_MSTRCTL register. This step prepares and enables requester mode operation. For example, programming the value 0x0201: enables requester mode operation, generates a 7-bit address, sets the direction to requester-transmit, uses standard mode timing, and transmits 8 data bytes before generating a stop condition.

The ***Requester Mode Transmit Setup Interaction*** table represents the interaction between the TWI controller and the processor using this example.

Table 27-4: Requester Mode Transmit Setup Interaction

TWI Controller	Processor
Interrupt: XMTSERV – Transmit buffer is empty	Acknowledge: Clear the interrupt request source bits and write to the transmit FIFO buffer
...	...
Interrupt: MCOMP – requester transfer complete	Acknowledge: Clear the interrupt request source bits

Requester Mode Receive

Follow these programming steps for a single requester mode receive.

1. Program the TWI_MSTRADDR register. This step defines the address transmitted during the address phase of the transfer.
2. Program the TWI_FIFOCTL register. This step indicates if the receive FIFO buffer interrupt requests occur with each byte received (8-bits) or with every 2 bytes received (16-bits).
3. Program the TWI_IMSK register. This step configures the enable bits associated with the desired interrupt sources. For example, programming the value 0x0030 results in an interrupt request output to the processor when the requester transfer completes, and the requester transfer has an error.
4. Program the TWI_MSTRCTL register. This step prepares and enables requester mode operation. For example, programming the value 0x0205: enables requester mode operation, generates a 7-bit address, sets the direction to requester-receive, uses standard mode timing, and receives 8 data bytes before generating a stop condition.

The ***Requester Mode Receive Setup Interaction*** table shows the interaction between the TWI controller and the processor using this example.

Table 27-5: Requester Mode Receive Setup Interaction

TWI Requester	Processor
Interrupt: RCVSERV – receive buffer is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Interrupt: MCOMP – requester transfer complete	Acknowledge: Clear the interrupt request source bits and read the receive FIFO buffer

NOTE: After the `TWI_MSTRCTL.DCNT` bit decrements to zero, the TWI controller device sends a NAK to indicate to the completer transmitter to release the bus. This operation allows the requester to send the stop signal to terminate the transfer.

ADSP-2159x_SC591_SC592_SC594 TWI Register Descriptions

Two-Wire Interface (TWI) contains the following registers.

Table 27-6: ADSP-2159x_SC591_SC592_SC594 TWI Register List

Name	Description
`TWI_CLKDIV`	SCL Clock Divider Register
`TWI_CTL`	Control Register
`TWI_FIFOCTL`	FIFO Control Register
`TWI_FIFOSTAT`	FIFO Status Register
`TWI_IMSK`	Interrupt Mask Register
`TWI_ISTAT`	Interrupt Status Register
`TWI_MSTRADDR`	Master Mode Address Register
`TWI_MSTRCTL`	Master Mode Control Registers
`TWI_MSTRSTAT`	Master Mode Status Register
`TWI_RXDATA16`	Rx Data Double-Byte Register
`TWI_RXDATA8`	Rx Data Single-Byte Register
`TWI_SLVADDR`	Slave Mode Address Register
`TWI_SLVCTL`	Slave Mode Control Register
`TWI_SLVSTAT`	Slave Mode Status Register
`TWI_TXDATA16`	Tx Data Double-Byte Register
`TWI_TXDATA8`	Tx Data Single-Byte Register

SCL Clock Divider Register

During master mode operation, the TWI_CLKDIV holds values, which the TWI uses to create the high and low durations of the serial clock (SCL). The clock signal SCL is an output in master mode and an input in slave mode. The values in the TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI fields add up to the CLKDIV value the following equation.

CLKDIV = TWI SCL period / 10 MHz time reference

Serial clock frequencies can vary from 400 KHz to less than 20 KHz. The resolution of the clock generated is 1/10 MHz or 100 ns. For example, for an SCL of 400 KHz (period = 1/400 KHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns):

CLKDIV = 2500 ns / 100 ns = 25

For an SCL with a 30% duty cycle, use TWI_CLKDIV.CLKLO = 17 and TWI_CLKDIV.CLKHI = 8.

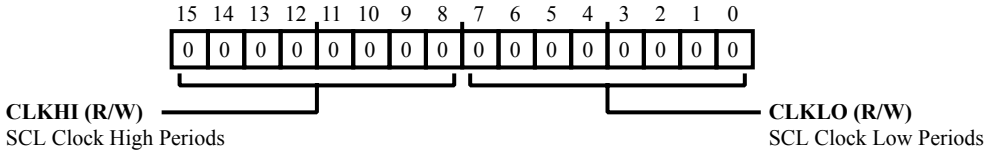

Figure 27-14: TWI_CLKDIV Register Diagram

Table 27-7: TWI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	CLKHI	SCL Clock High Periods. The TWI_CLKDIV.CLKHI specifies the number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single master.
7:0 (R/W)	CLKLO	SCL Clock Low Periods. The TWI_CLKDIV.CLKLO specifies the number of internal time reference periods the serial clock (SCL) is held low.

Control Register

The TWI_CTL enables the TWI, establishes a relationship between the system clock (SCLK0) and the TWI controller's internally timed events, and enables SCCB compatibility.

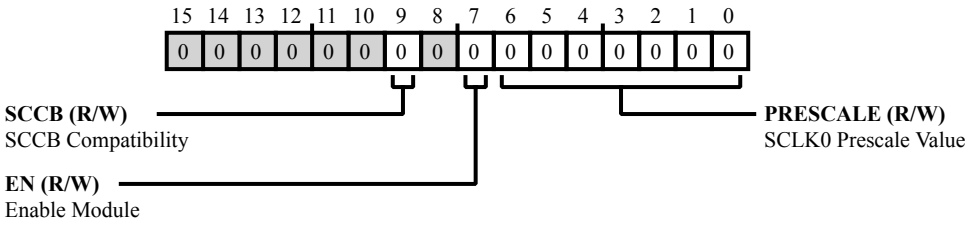

Figure 27-15: TWI_CTL Register Diagram

Table 27-8: TWI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SCCB	SCCB Compatibility. The TWI_CTL.SCCB enables SCCB compatible operation for the TWI. SCCB compatibility is an optional feature and should not be used in an I^2C bus system. When this feature is enabled, all slave asserted acknowledgement bits are ignored by this master. This feature is valid only during transfers where the TWI is mastering an SCCB bus. Slave mode transfers should be avoided when this feature is enabled because the TWI controller always generates an acknowledge in slave mode.	
		0	Disable SCCB compatibility. When disabled, master transfers are not SCCB compatible.
		1	Enable SCCB compatibility. When enabled, master transfers are SCCB compatible. All slave-asserted acknowledgment bits are ignored by this master.
7 (R/W)	EN	Enable Module. The TWI_CTL.EN enables TWI controller operation for either master and/or slave mode of operation. It is recommended that this bit be set at the time TWI_CTL.PRESCALE is initialized and remain set. This method guarantees accurate operation of bus busy detection logic.	
		0	Disable
		1	Enable

Table 27-8: TWI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRESCALE	SCLK0 Prescale Value. The `TWI_CTL.PRESCALE` holds the pre-scaled value for the TWI internal time reference. This reference is derived from SCLK0 according to the formula: `TWI_CTL.PRESCALE` = f_{SCLK0}/10MHz The `TWI_CTL.PRESCALE` specifies the number of system clock (SCLK0) periods used in the generation of one internal time reference. The value of `TWI_CTL.PRESCALE` must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value.

FIFO Control Register

The TWI_FIFOCTL control bits affect only the FIFO and are not tied in any way with master or slave mode operation.

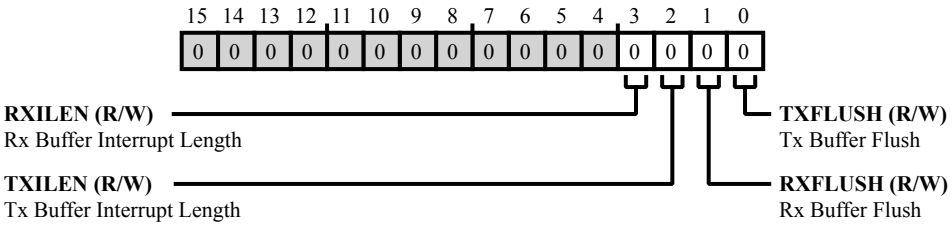

Figure 27-16: TWI_FIFOCTL Register Diagram

Table 27-9: TWI_FIFOCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXILEN	Rx Buffer Interrupt Length. The TWI_FIFOCTL.RXILEN determines the rate at which receive buffer interrupts are to be generated. Interrupts may be generated with each byte received or after two bytes are received. Interrupt status is available in TWI_FIFOSTAT.RXSTAT.	
		0	RXSERVI on 1 or 2 Bytes in FIFO
		1	RXSERVI on 2 Bytes in FIFO
2 (R/W)	TXILEN	Tx Buffer Interrupt Length. The TWI_FIFOCTL.TXILEN determines the rate at which transmit buffer interrupts are to be generated. Interrupts may be generated with each byte transmitted or after two bytes are transmitted. Interrupt status is available in TWI_FIFOSTAT.TXSTAT.	
		0	TXSERVI on 1 Byte of FIFO Empty
		1	TXSERVI on 2 Bytes of FIFO Empty
1 (R/W)	RXFLUSH	Rx Buffer Flush. The TWI_FIFOCTL.RXFLUSH directs the TWI to flush the contents of the receive buffer and update TWI_FIFOSTAT.RXSTAT to indicate the buffer is empty. This state is held until this bit is cleared. During an active receive, the receive buffer in this state responds to the receive logic as if it is full.	
		0	Normal Operation of Rx Buffer
		1	Flush Rx Buffer

Table 27-9: TWI_FIFOCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TXFLUSH	Tx Buffer Flush. The `TWI_FIFOCTL.TXFLUSH` directs the TWI to flush the contents of the transmit buffer and update `TWI_FIFOSTAT.TXSTAT` to indicate the buffer is empty. This state is held until this bit is cleared. During an active transmit, the transmit buffer in this state responds to the transmit logic as if it is empty.	
		0	Normal Operation of Tx Buffer
		1	Flush Tx Buffer

FIFO Status Register

The TWI_FIFOSTAT fields indicate the state of the FIFO buffers' receive and transmit contents. The FIFO buffers do not discriminate between master data and slave data. By using the status and control bits provided, the FIFO can be managed to allow simultaneous master and slave operation.

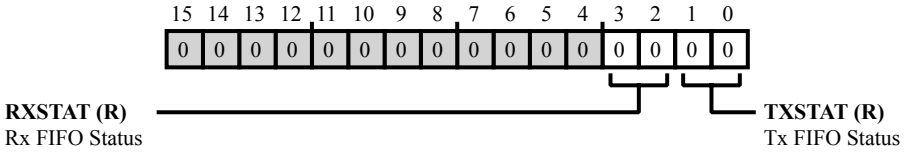

Figure 27-17: TWI_FIFOSTAT Register Diagram

Table 27-10: TWI_FIFOSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	RXSTAT	Rx FIFO Status. The read-only TWI_FIFOSTAT.RXSTAT indicates the number of valid data bytes in the receive FIFO buffer. The status is updated with each FIFO buffer read using the peripheral data bus or write access by the receive shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral read of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data. Either a single or double byte peripheral read of the FIFO is allowed.
1:0 (R/NW)	TXSTAT	Tx FIFO Status. The read-only TWI_FIFOSTAT.TXSTAT field indicates the number of valid data bytes in the FIFO buffer. The status is updated with each FIFO buffer write using the peripheral data bus or read access by the transmit shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty. Either a single or double byte peripheral write of the FIFO is allowed.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral write of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data.

Interrupt Mask Register

The TWI_IMSK enables interrupt sources to assert the interrupt output. Each mask bit corresponds with one interrupt request source bit in TWI_ISTAT. Reading and writing TWI_IMSK does not affect the contents of the TWI_ISTAT.

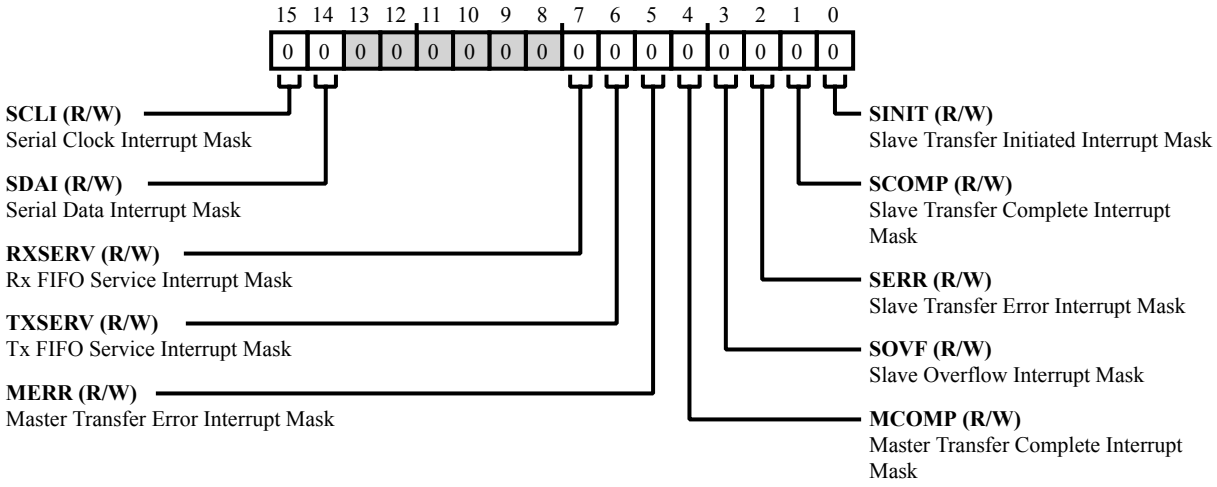

Figure 27-18: TWI_IMSK Register Diagram

Table 27-11: TWI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLI	Serial Clock Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
14 (R/W)	SDAI	Serial Data Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
7 (R/W)	RXSERV	Rx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
6 (R/W)	TXSERV	Tx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Table 27-11: TWI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	MERR	Master Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
4 (R/W)	MCOMP	Master Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
3 (R/W)	SOVF	Slave Overflow Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
2 (R/W)	SERR	Slave Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
1 (R/W)	SCOMP	Slave Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
0 (R/W)	SINIT	Slave Transfer Initiated Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Interrupt Status Register

The TWI_ISTAT contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

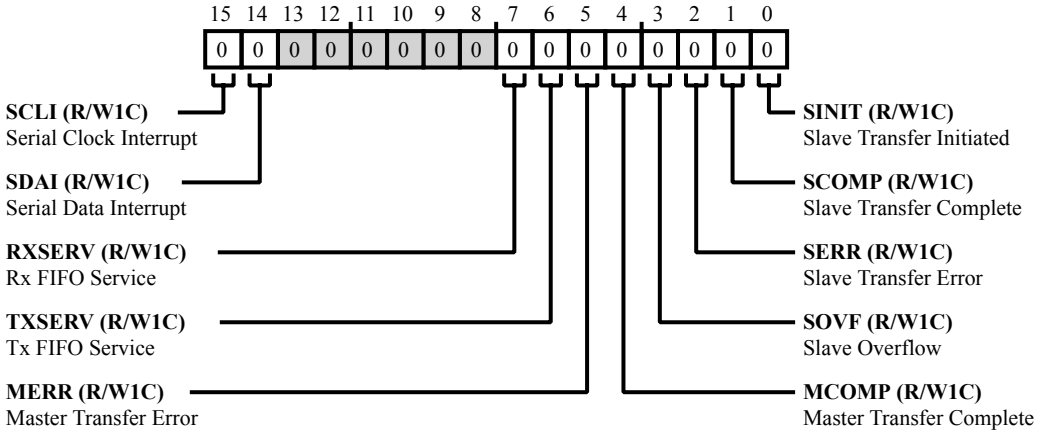

Figure 27-19: TWI_ISTAT Register Diagram

Table 27-12: TWI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SCLI	Serial Clock Interrupt. If the TWI is enabled (TWI_CTL.EN), SCLI is set on a high-to-low transition of the serial clock pin (SCLx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SCLx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SCLx pin. This bit is W1C.
14 (R/W1C)	SDAI	Serial Data Interrupt. If the TWI is enabled (TWI_CTL.EN), SDAI is set on a high-to-low transition of the serial data pin (SDAx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SDAx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SDAx pin. This bit is W1C.

Table 27-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RXSERV	Rx FIFO Service. If TWI_FIFOCTL.RXILEN =0, the TWI_ISTAT.RXSERV is set each time the TWI_FIFOSTAT.RXSTAT field is updated to either 01 or 11. If TWI_FIFOCTL.RXILEN =1, the TWI_ISTAT.RXSERV is set each time TWI_FIFOSTAT.RXSTAT is updated to 11.	
		0	No Interrupt. The FIFO does not require servicing, or the TWI_FIFOSTAT.RXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The receive FIFO buffer has one or two 8-bit words of data available to be read.
6 (R/W1C)	TXSERV	Tx FIFO Service. If TWI_FIFOCTL.TXILEN =0, the TWI_ISTAT.TXSERV is set each time the TWI_FIFOSTAT.TXSTAT field is updated to either 01 or 00. If TWI_FIFOCTL.TXILEN =1, the TWI_ISTAT.TXSERV is set each time TWI_FIFOSTAT.TXSTAT is updated to 00.	
		0	No Interrupt. FIFO does not require servicing, or the TWI_FIFOSTAT.TXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The transmit FIFO buffer has one or two 8-bit locations available to be written.
5 (R/W1C)	MERR	Master Transfer Error. The TWI_ISTAT.MERR indicates that a master error has occurred. The conditions surrounding the error are indicated by the master status register (TWI_MSTRSTAT).	
		0	No Interrupt
		1	Interrupt Detected
4 (R/W1C)	MCOMP	Master Transfer Complete. The TWI_ISTAT.MCOMP indicates that the initiated master transfer has completed. In the absence of a repeat start, the bus has been released.	
		0	No Interrupt
		1	Interrupt Detected
3 (R/W1C)	SOVF	Slave Overflow. The TWI_ISTAT.SOVF indicates that the TWI_ISTAT.SCOMP bit was set at the time a subsequent transfer has acknowledged an address phase. The transfer continues, however, it may be difficult to delineate data of one transfer from another.	
		0	No Interrupt
		1	Interrupt Detected

Table 27-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	SERR	Slave Transfer Error. The `TWI_ISTAT.SERR` indicates that a slave error has occurred. A restart or stop condition has occurred during the data receive phase of a transfer.	
		0	No Interrupt
		1	Interrupt Detected
1 (R/W1C)	SCOMP	Slave Transfer Complete. The `TWI_ISTAT.SCOMP` indicates that the transfer is complete and either a stop, or a restart was detected.	
		0	No Interrupt
		1	Interrupt Detected
0 (R/W1C)	SINIT	Slave Transfer Initiated. The `TWI_ISTAT.SINIT` indicates whether or not a slave transfer is in progress.	
		0	No Interrupt. A transfer is not in progress, or an address match has not occurred since the last time this bit was cleared.
		1	Interrupt Detected. The slave has detected an address match, and a transfer has been initiated.

Master Mode Address Register

During the addressing phase of a transfer, the TWI controller, with its master enabled, transmits the contents of TWI_MSTRADDR. When programming this register, omit the read/write bit. That is, only the upper 7 bits that make up the slave address should be written to this register. For example, if the slave address is b#1010000X, where X is the read/write bit, the TWI_MSTRADDR is programmed with b#1010000, which corresponds to 0x50. When sending out the address on the bus, the TWI controller appends the read/write bit as appropriate based on the state of the TWI_MSTRCTL.DIR bit.

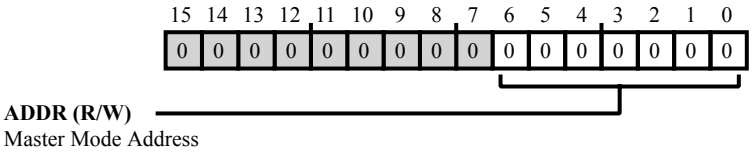

Figure 27-20: TWI_MSTRADDR Register Diagram

Table 27-13: TWI_MSTRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Master Mode Address.

Master Mode Control Registers

The TWI_MSTRCTL controls the logic associated with master mode operation. Bits in this register do not affect slave mode operation and should not be modified to control slave mode functionality.

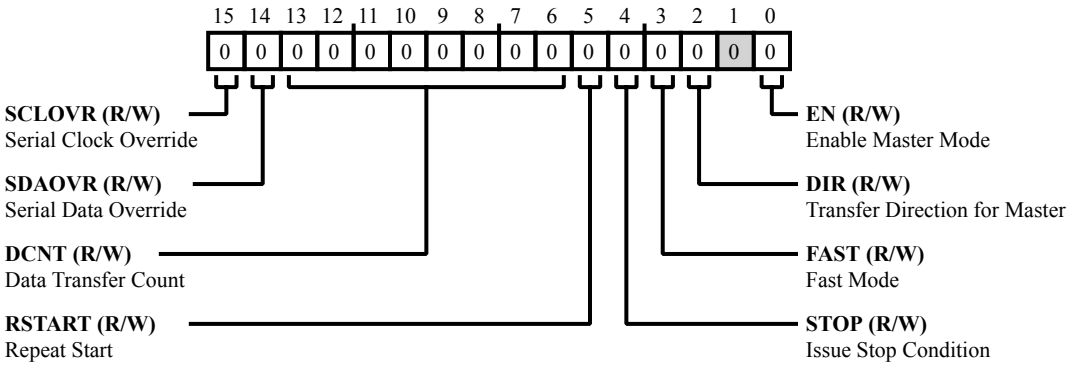

Figure 27-21: TWI_MSTRCTL Register Diagram

Table 27-14: TWI_MSTRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLOVR	Serial Clock Override. The TWI_MSTRCTL.SCLOVR provides direct control of the serial clock line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SCLOVR is set, the TWI overrides normal serial clock output, driving it to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SCLOVR is cleared, the TWI permits normal serial clock operation under the control of master mode clock generation and slave mode clock stretching logic.	
		0	Permit Normal SCL Operation
		1	Override Normal SCL Operation
14 (R/W)	SDAOVR	Serial Data Override. The TWI_MSTRCTL.SDAOVR provides direct control of the serial data line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SDAOVR is set, the TWI overrides normal serial data operation under the control of the transmit shift register and acknowledge logic, driving serial data output to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SDAOVR is cleared, the TWI permits normal serial data operation.	
		0	Permit Normal SDA Operation
		1	Override Normal SDA Operation

Table 27-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:6 (R/W)	DCNT	Data Transfer Count. The TWI_MSTRCTL.DCNT indicates the number of data bytes to transfer. As each data word is transferred, the TWI decrements this counter. When TWI_MSTRCTL.DCNT decrements to 0, a stop condition is generated. Setting TWI_MSTRCTL.DCNT to 0xFF disables the counter. In this transfer mode, data continues to be transferred until it is concluded by setting the TWI_MSTRCTL.STOP bit. In the event a master transmit is aborted due to a slave data NAK, the value of TWI_MSTRCTL.DCNT equals the number of bytes not sent. The byte which was NAK'ed by the slave is counted as a sent byte.	
5 (R/W)	RSTART	Repeat Start. The TWI_MSTRCTL.RSTART enables the TWI to issue a repeat start condition at the conclusion of the current transfer (TWI_MSTRCTL.DCNT =0) and begin the next transfer. The current transfer concludes with updates to the appropriate status and interrupt bits. If errors occurred during the previous transfer, a repeat start does not occur. In the absence of any errors, master enable (TWI_MSTRCTL.EN) does not self clear on a repeat start.	
		0	Disable Repeat Start
		1	Enable Repeat Start
4 (R/W)	STOP	Issue Stop Condition. The TWI_MSTRCTL.STOP directs the TWI to issue a stop condition. The transfer concludes as soon as possible avoiding any error conditions (as if data transfer count had been reached). At that time, the TWI_IMSK is updated along with any associated status bits.	
		0	Permit Normal Operation
		1	Issue Stop
3 (R/W)	FAST	Fast Mode. The TWI_MSTRCTL.FAST selects whether the TWI operates in fast mode or standard mode. In fast mode, the TWI uses timing specifications for transfers at up to 400K bits/s. In standard mode, the TWI uses timing specifications for transfers at up to 100K bits/s.	
		0	Select Standard Mode
		1	Select Fast Mode
2 (R/W)	DIR	Transfer Direction for Master. The TWI_MSTRCTL.DIR selects the transfer direction for the TWI as master initiated receive or transmit.	
		0	Master Transmit
		1	Master Receive

Table 27-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Master Mode. The `TWI_MSTRCTL.EN` enables master mode functionality. A start condition is generated if the bus is idle. This bit self clears at the completion of a transfer (after `TWI_MSTRCTL.DCNT` decrements to zero), including transfers terminated due to errors. If disabled (=0) during operation, the transfer is aborted, and all logic associated with master mode transfers are reset. Serial data and serial clock (SDA, SCL) are no longer driven. Write-1-to-clear status bits are not affected.	
		0	Disable
		1	Enable

Master Mode Status Register

The TWI_MSTRSTAT holds information during master mode transfers and at their conclusion. Generally, master mode status bits are not directly associated with the generation of interrupt requests, but these bits offer information on the current transfer. Slave mode operation does not affect master mode status bits.

Note that while TWI_MSTRSTAT.SCLSEN is set (this condition could be due to having no pull-up resistor on TWI_SCL or another agent is driving TWI_SCL low), the acknowledge bits (TWI_MSTRSTAT.ANAK and TWI_MSTRSTAT.DNAK) do not update. This result occurs because the acknowledge conditions are sampled during the high phase of TWI_SCL.

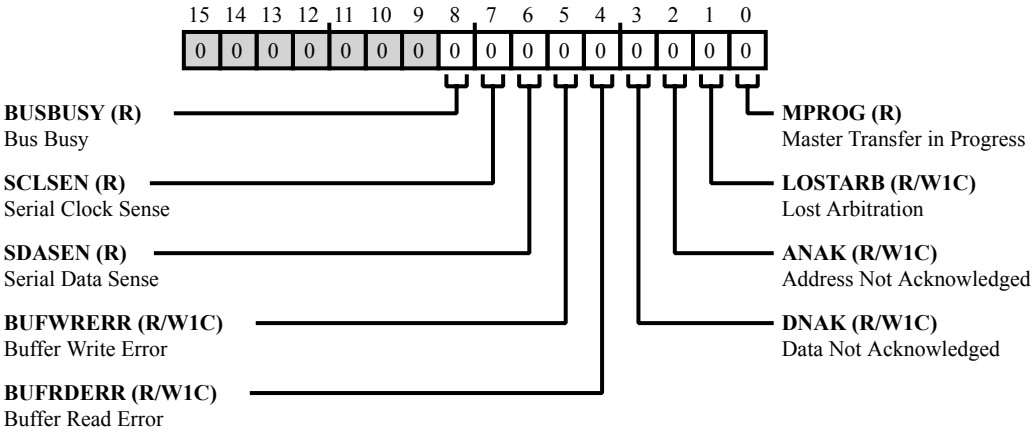

Figure 27-22: TWI_MSTRSTAT Register Diagram

Table 27-15: TWI_MSTRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	BUSBUSY	Bus Busy. The TWI_MSTRSTAT.BUSBUSY indicates whether the bus is currently busy or free. This indication is not limited to only this device but is for all devices. On a start condition, the setting of the register value is delayed due to the input filtering. On a stop condition the clearing of the register value occurs after t_{BUF}.	
		0	Bus Free. The bus is free. The clock and data bus signals have been inactive for the appropriate bus free time.
		1	Bus Busy. The bus is busy. Clock or data activity has been detected.

Table 27-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SCLSEN	Serial Clock Sense. The `TWI_MSTRSTAT.SCLSEN` indicates the active or inactive state of the serial clock. Use this status bit when direct sensing of the serial clock line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SCL Inactive "One". An inactive "one" is being sensed on the serial clock.
		1	SCL Active "Zero". An active "zero" is being sensed on the serial clock. The source of the active driver is not known and can be internal or external.
6 (R/NW)	SDASEN	Serial Data Sense. The `TWI_MSTRSTAT.SDASEN` indicates the active or inactive status of the serial data. Use this status bit when direct sensing of the serial data line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SDA Inactive "One". An inactive "one" is currently being sensed on the serial data line.
		1	SDA Active "Zero". An active "zero" is currently being sensed on the serial data line. The source of the active driver is not known and can be internal or external.
5 (R/W1C)	BUFWRERR	Buffer Write Error. The `TWI_MSTRSTAT.BUFWRERR` indicates whether the current master transfer was aborted due to a receive buffer write error. The receive buffer and receive shift register were both full at the same time. This bit is W1C.	
		0	No Status
		1	Buffer Write Error
4 (R/W1C)	BUFRDERR	Buffer Read Error. The `TWI_MSTRSTAT.BUFRDERR` indicates whether the current master transfer was aborted due to a transmit buffer read error. The error occurs if the buffer is empty when data is required by the transmit shift register. This bit is W1C.	
		0	No Status
		1	Buffer Read Error

Table 27-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W1C)	DNAK	Data Not Acknowledged. The `TWI_MSTRSTAT.DNAK` indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Data NAK
2 (R/W1C)	ANAK	Address Not Acknowledged. The `TWI_MSTRSTAT.ANAK` indicates whether the current master transfer was aborted due to the detection of a NAK during the address phase of the transfer. This bit is W1C.	
		0	No Status
		1	Address NAK
1 (R/W1C)	LOSTARB	Lost Arbitration. The `TWI_MSTRSTAT.LOSTARB` indicates whether the current transfer was aborted due to the loss of arbitration with another master. This bit is W1C.	
		0	No Status
		1	Lost Arbitration
0 (R/NW)	MPROG	Master Transfer in Progress. The `TWI_MSTRSTAT.MPROG` indicates whether or not a master transfer is in progress. If clear (`TWI_MSTRSTAT.MPROG` =0), currently no transfer is taking place. This can occur after a transfer is complete or while an enabled master is waiting for an idle bus.	
		0	No Status
		1	Master Transfer in Progress

Rx Data Double-Byte Register

The TWI_RXDATA16 holds a 16-bit data value read from the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte receive data access can be performed. Two data bytes can be read, effectively emptying the receive FIFO buffer with a single access.

The data is read in little endian byte order, where byte 0 is the first byte received and byte 1 is the second byte received. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated to indicate it is empty. If an access is performed while the FIFO buffer is not full, the read data is unknown and the existing FIFO buffer data and its status remains unchanged.

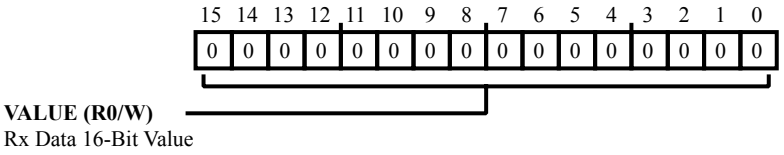

Figure 27-23: TWI_RXDATA16 Register Diagram

Table 27-16: TWI_RXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Rx Data 16-Bit Value.

Rx Data Single-Byte Register

The TWI_RXDATA8 holds an 8-bit data value read from the FIFO buffer. Receive data is read from the corresponding receive buffer in a first-in first-out order. Although peripheral bus reads are 16 bits, a read access to TWI_RXDATA8 accesses only one transmit data byte from the FIFO buffer. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated. If an access is performed while the FIFO buffer is empty, the data is unknown and the FIFO buffer status remains indicating it is empty.

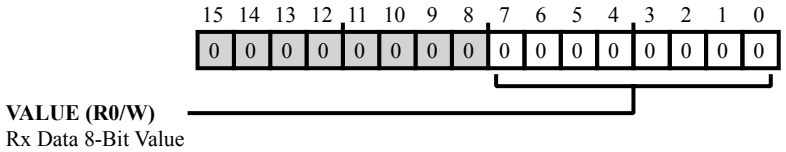

Figure 27-24: TWI_RXDATA8 Register Diagram

Table 27-17: TWI_RXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Rx Data 8-Bit Value.

Slave Mode Address Register

The TWI_SLVADDR holds the slave mode address, which is the valid address to which the slave-enabled TWI controller responds. The TWI controller compares this value with the received address during the addressing phase of a transfer.

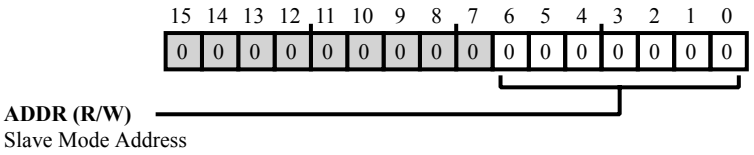

Figure 27-25: TWI_SLVADDR Register Diagram

Table 27-18: TWI_SLVADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Slave Mode Address.

Slave Mode Control Register

The TWI_SLVCTL controls the logic associated with slave mode operation. Settings in this register do not affect master mode operation and should not be modified to control master mode functionality.

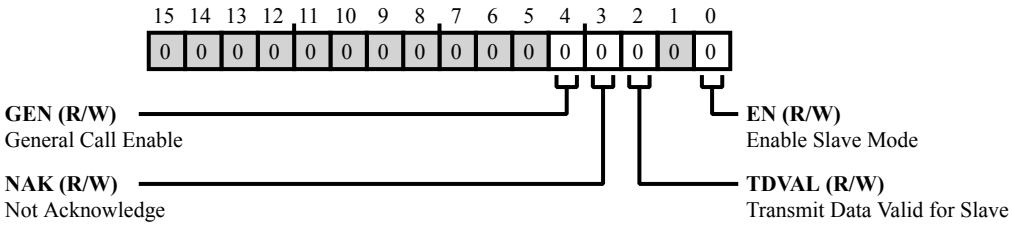

Figure 27-26: TWI_SLVCTL Register Diagram

Table 27-19: TWI_SLVCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	GEN	General Call Enable. The TWI_SLVCTL.GEN enables general call address matching. When enabled, a general call slave receive transfer is accepted. All status and interrupt source bits associated with transfers are updated. Note that general call address detection is available only when slave mode is enabled.	
		0	Disable General Call Matching
		1	Enable General Call Matching
3 (R/W)	NAK	Not Acknowledge. The TWI_SLVCTL.NAK directs the TWI to generate a NAK (if set) or an ACK (if cleared) at the conclusion of data transfer for slave receive. For NAK, the slave is still considered to be addressed at the conclusion of transfer.	
		0	Generate ACK
		1	Generate NAK
2 (R/W)	TDVAL	Transmit Data Valid for Slave. The TWI_SLVCTL.TDVAL selects whether the data in the transmit FIFO is available (valid) for slave transmission (TWI_SLVCTL.TDVAL set). If the FIFO data is not available (invalid) for slave transmission (TWI_SLVCTL.TDVAL cleared), the data in the transmit FIFO is for master mode transmits, and the data is not allowed to be used during a slave transmit; the transmit FIFO is treated as if it is empty.	
		0	Data Invalid for Slave Tx
		1	Data Valid for Slave Tx

Table 27-19: TWI_SLVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Slave Mode. The `TWI_SLVCTL.EN` enables slave operation. Enabling slave and master modes of operation concurrently is allowed. If disabled, no attempt is made to identify a valid address. If `TWI_SLVCTL.EN` is cleared during a valid transfer, clock stretching ceases, the serial data line is released, and the current byte is not acknowledged.	
		0	Disable
		1	Enable

Slave Mode Status Register

During and at the conclusion of register slave mode transfers, the TWI_SLVSTAT holds information on the current transfer. Generally slave mode status bits are not associated with the generation of interrupt requests. Master mode operation does not affect slave mode status bits.

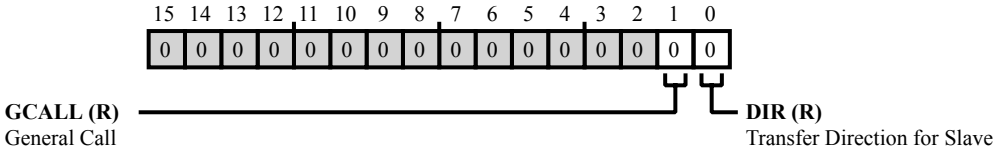

Figure 27-27: TWI_SLVSTAT Register Diagram

Table 27-20: TWI_SLVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	GCALL	General Call. The TWI_SLVSTAT.GCALL indicates whether or not--at the time of addressing--the address was determined to be a general call. This bit self clears if slave mode is disabled (TWI_SLVCTL.EN =0).	
		0	Not a General Call Address
		1	General Call Address
0 (R/NW)	DIR	Transfer Direction for Slave. The TWI_SLVSTAT.DIR indicates whether--at the time of addressing--the transfer direction was determined to be slave transmit or receive. This bit self clears if slave mode is disabled (TWI_SLVCTL.EN =0).	
		0	Slave Receive
		1	Slave Transmit

Tx Data Double-Byte Register

The TWI_TXDATA16 register holds a 16-bit data value written into the FIFO buffer. To reduce interrupt latency output rates and peripheral bus access times, a double byte transfer data access can be done. Two data bytes can be written, effectively filling the transmit FIFO buffer with a single access.

The data is written in little endian byte order, where byte 0 is the first byte to be transferred and byte 1 is the second byte to be transferred. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is not empty, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register when read back returns zero.

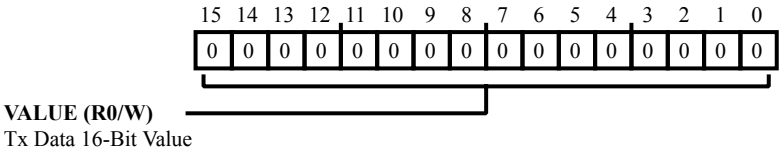

Figure 27-28: TWI_TXDATA16 Register Diagram

Table 27-21: TWI_TXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Tx Data 16-Bit Value.

Tx Data Single-Byte Register

The TWI_TXDATA8 register holds an 8-bit data value written into the FIFO buffer. Transmit data is entered into the corresponding transmit buffer in a first-in first-out order. For 16-bit peripheral bus writes, a write access to this register adds only one transmit data byte to the FIFO buffer. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is full, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register returns zero when read back.

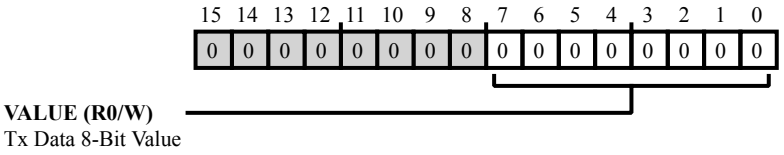

Figure 27-29: TWI_TXDATA8 Register Diagram

Table 27-22: TWI_TXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Tx Data 8-Bit Value.

28 Ethernet Media Access Controller (EMAC)

The EMAC peripheral in the processor enables network connectivity to applications through an Ethernet interface. The module is fully compliant to the following standards:

NOTE: On the processor, EMAC0 is 10/100/1000 BaseT-compliant and supports AVB (Audio Video Bridging) standards.

- Carrier Sense Multiple Access With Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications, Standard 802.3-2005, Institute of Electrical and Electronics Engineers (IEEE).
- Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, Standard 1588–2008, Institute of Electrical and Electronics Engineers (IEEE).
- Reduced Media Independent Interface Specification, Revision 1.2, RMII Consortium.
- Reduced Gigabit Media Independent Interface (RGMII), Revision 2.6, HP/Marvell.
- Timing and Synchronization for Time-Sensitive Applications in Bridged LANs, Standard 802.1AS-2011, Institute of Electrical and Electronics Engineers (IEEE).
- Forwarding and Queuing Enhancements for Time-Sensitive Streams, Standard 802.1Qav-2009, Institute of Electrical and Electronics Engineers (IEEE).
- The EMAC supports IEEE 803.3az-2010 standard for Energy Efficient Ethernet. This feature enables the Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode.

EMAC Features

The Ethernet features include the following:

- Supports 10/100 Mbps data transfer rates with external PHY interfaced through RMII
- Full-duplex and half-duplex support for Ethernet
- Dedicated DMA controller with independent read write channels

- Supports dual-buffer (ring) or linked-list (chained) descriptor chaining
- Direct interface with the system crossbar bus
- Provides support for CSMA/CD protocol for half-duplex operation
- IEEE 802.3x flow control for full-duplex and half-duplex
- Automatic network monitoring statistics with management counters
- Flexible address filtering options for uni-cast, multi-cast, and broadcast addresses
- Support for promiscuous mode in reception
- Supports IEEE 802.1Q VLAN tag detection
- VLAN tag-based frame filtering - Perfect match and hash-based filtering
- Supports programmable Inter-frame Gap (IFG)
- Checksum offload engine for checking IPv4 header checksum and TCP/UDP/ICMP checksum encapsulated in IPv4 or IPv6 datagrams
- Station management interface for PHY device configuration and management
- Automatic CRC and pad generation controllable on a per-frame basis
- CRC replacement, source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted frames with per-frame control
- Layer 3 and layer 4-based frame filtering - TCP or UDP over IPv4 or IPv6
- Supports Gigabit data transfer rates with external PHY interfaced through RGMII
- Ethernet frame timestamping as described in IEEE 1588–2002 and IEEE 1588–2008. The transmit or receive status of each frame include 64-bit timestamps
- Hardware assisted time stamping capable of up to 8-ns resolution
- Automatic detection of PTP messages through Ethernet, IPv4, and IPv6 packets
- Four programmable PPS outputs that physically represent PTP system time
- Auxiliary snapshot to timestamp external events
- Four auxiliary input pins available
- Two separate channels (channel 1 and channel 2) or queues for transmission and reception of time-sensitive traffic. Channel 0 is available by default and carries the legacy best-effort Ethernet traffic on the transmit side.
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for channel 1 and channel 2
- Slot number function to schedule the data fetching by DMA from the system memory for channel 1 and channel 2

- Separate DMA, Tx FIFO, and Rx FIFO (MTL) for each additional channel
- Programmable control to route received VLAN tagged non-AV packets to channels or queues
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet
- EMAC0 supports the following FIFO sizes: 2048 bytes for transmit FIFO and also for receive FIFO
- Supports MII/RMII/RGMII interfaces for external PHY interface

EMAC Functional Description

This section provides information on the function of Ethernet MAC peripheral.

Hardware for the Media Access Control protocol

This function allows applications to support TCP/IP based network communication. At the system end, the module supports direct connection with the system crossbar bus for memory or MMR transactions. It supports RMII (Reduced Media Independent Interface), RGMII (Reduced Gigabit Media Independent Interface), MII (Media Independent Interface), and SMI (Station Management Interface) for interfacing with the external PHY chip.

Dedicated DMA Controller with independent read/write channels

Performs both data and status transfers between the application and the media independent interfaces. Internal transmit and receive FIFOs are used to buffer and regulate the frames. Dedicated interrupt lines connect the EMAC interrupt sources to the System Event Controller (SEC).

MAC Management Counters (MMC) block

An extended set of registers that collect various statistics compliant with IEEE 802.3 definitions regarding the operation of the interface. The registers are updated for each new transmitted or received frame when the condition to update the counter is met. The EMAC provides a set of such counters, along with extended usage control.

PTP (Precision Time Protocol) engine

Provides hardware assistance for the implementation of the IEEE 1588 version 1 and version 2 standards, which allows time synchronization between systems.

Audio Video (AV) functionality

Enables transmission of time-sensitive traffic over bridged local area networks (LANs). The EMAC provides hardware support for IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm. In addition, slot number function allows scheduling of fetching of data by DMA from system memory.

ADSP-2159x_SC591_SC592_SC594 EMAC Register List

The Ethernet MAC (EMAC) module provides an Ethernet interface to the processor. The interface is compliant to IEEE Standard 802.3-2005. A set of registers govern EMAC operations. For more information on EMAC functionality, see the EMAC register descriptions.

Table 28-1: ADSP-2159x_SC591_SC592_SC594 EMAC Register List

Name	Description
EMAC_ADDR0_HI	MAC Address 0 High Register
EMAC_ADDR0_LO	MAC Address 0 Low Register
EMAC_ADDR1_HI	MAC Address 1 High Register

EMAC Definitions

The following definitions are helpful for using the EMAC.

EMAC SCB

System Crossbar Interface of EMAC

EMAC DMA

DMA Controller of EMAC

EMAC MFL

MAC FIFO Layer inside EMAC

EMAC CORE

CORE layer inside EMAC which performs the actual Ethernet operations, including interface with PHY through the reduced media interface(s).

MMC

MAC Management Counter

SMI

Station Management Interface that controls PHY through MDIO and MDC signals.

RMII

Reduced Media Independent Interface

MAC

Media Access Control

PTP

Precision Time Protocol

EMAC Block Diagram and Interfaces

The ***EMAC Simplified Block Diagram*** illustrates the overall functional architecture of the Ethernet MAC peripheral. The EMAC module is comprised of four major layers: EMAC SCB, EMAC DMA, EMAC MFL, and EMAC CORE. Each of these layers (subblocks) is explained in depth in their respective sections in this chapter.

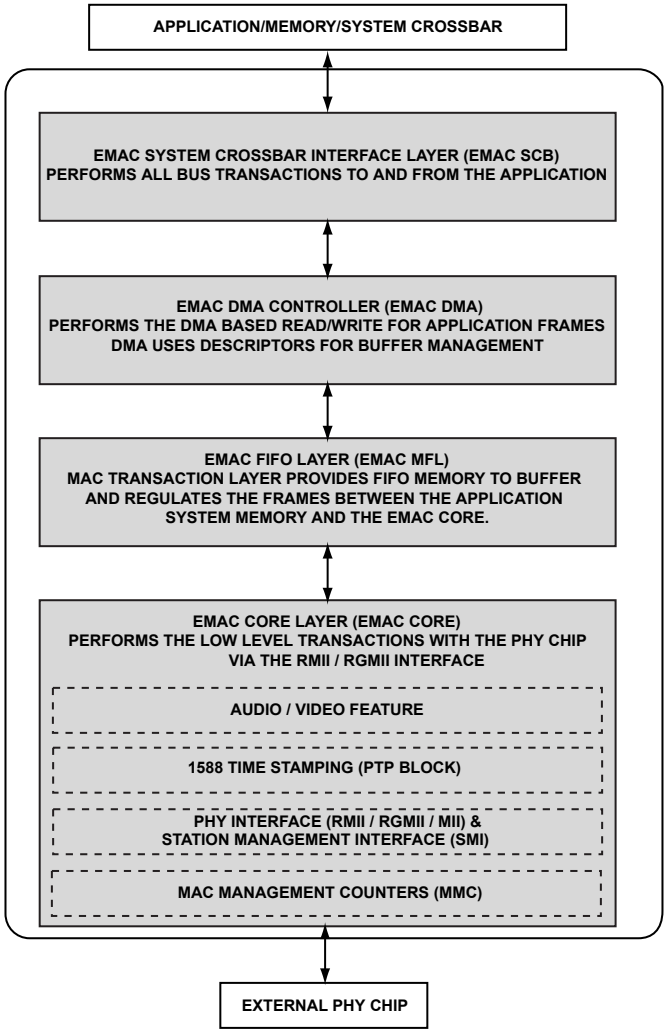

Figure 28-1: EMAC Simplified Block Diagram

A more comprehensive block diagram is shown in the ***EMAC Complete Block Diagram***. It includes most of the important blocks inside the EMAC. The EMAC is connected to processor memory and the system crossbar through the System Crossbar Bus Interface (SCB) and System Peripheral Bus Interface (SPB). These connections are which are part of the SCB layer. The SPB interface is connected to all modules that require MMR programming.

The DMA controller performs application data transfer frame by frame, through well-defined descriptor structures. A FIFO layer acts as a buffer between the DMA controller and EMAC CORE.

The EMAC CORE is the most important block because it contains subblocks to support IEEE802.3 based communication with external network interfaces of 10/100/1000 Mbps speeds. It includes the PTP subblock, which assists applications requiring time synchronization; the AV Feature subblock, which enables transmission of time-sensitive traffic over bridged LANs; and a MMC subblock, which generates packet transfer statistics.

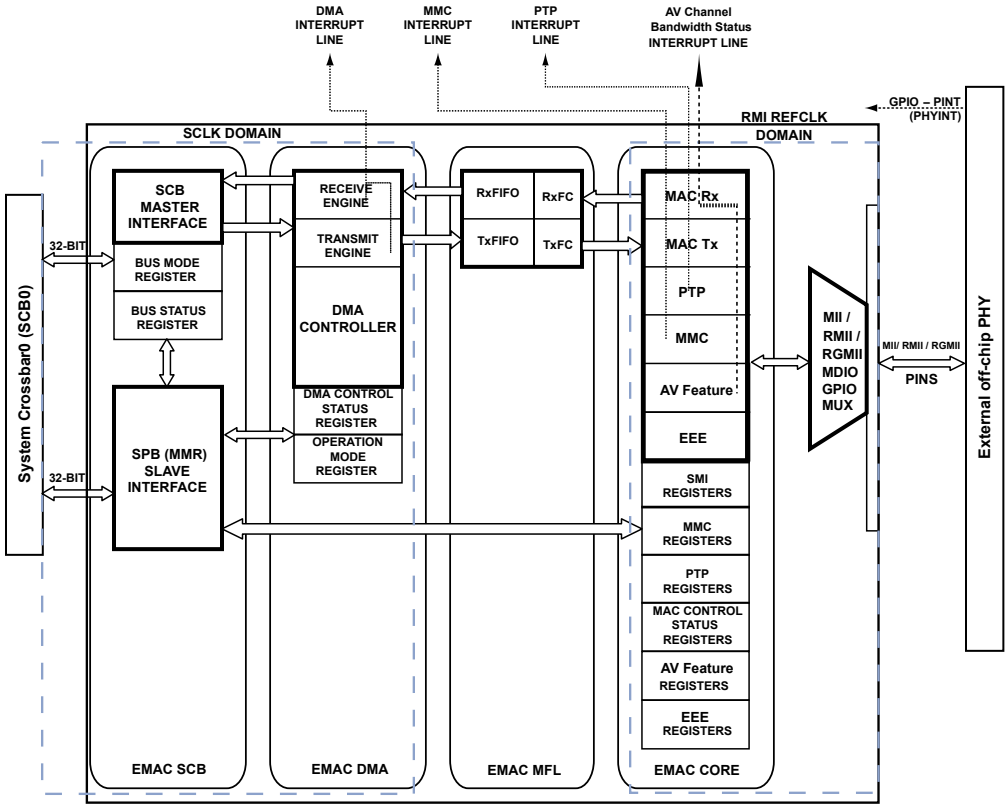

Figure 28-2: EMAC Complete Block Diagram

EMAC CORE Subblocks

The ***Core Transmit Engine Subblocks*** table summarizes the core transmit engine subblocks and their functions. Refer to the EMAC CORE section for further explanation of each of these subblocks.

Table 28-5: CORE Transmit Engine Subblocks

CORE Transmit Engine Sub Block	Function
Transmit Bus Interface	Interface to the FIFO.
Transmit Frame Controller	Appends Zero-PAD data, if required, for short frames. Appends CRC for frame checksum from the CRC generator.
Transmit Protocol Controller	Generates preamble and SFD, as per 802.3 protocol. Generates jam pattern in half-duplex mode, for collisions. Jabber timeout, for excessively large frames. Flow control for half-duplex mode (back pressure). Generates transmit frame status.
Transmit Scheduler	Maintains the inter-frame gap between two transmitted frames. Follows the truncated binary exponential back-off algorithm for half-duplex mode.

Table 28-5: CORE Transmit Engine Subblocks (Continued)

CORE Transmit Engine Sub Block	Function
Transmit CRC Generator	Generate CRC for the frame checksum field of the Ethernet frame.
Transmit Flow Control	Receives the pause frame, appends the calculated CRC, and sends the frame to the protocol engine module.
Transmit Checksum Offload Engine	Supports checksum calculation and insertion in the transmit path, for IPV4/TCP/UDP/ICMP packets.

The ***Core Receive Engine Subblocks*** table summarizes the core receive engine subblocks and their function. Refer to the EMAC CORE section for more information on each of these subblocks.

Table 28-6: Core Receive Engine Subblocks

CORE Receive Engine Subblock	Functionality Overview
Receive Protocol Engine	Strips the incoming preamble and SFD. Checks for correct length or type field. Performs internal loopback, if necessary. Generates receive status. Supports watchdog of received frames. Supports jumbo frames.
Receive CRC Module	Checks for CRC error, by comparing with FCS.
Receive Frame Controller Module	Packs incoming 8-bit input stream to 32-bit data internally. Performs frame filtering, for uni-cast, multi-cast, and broadcast frames. Attaches the calculated IP checksum input from checksum offload engine. Updates the receive status to bus interface.
Receive Flow Control Module	Detects the receiving pause frame and pauses the frame transmission for the delay specified within the received pause frame. Works in full duplex mode.
Receive IP Checksum Offload Engine	Calculates IPv4 header checksums and verify against the received IPv4 header checksums. Identifies a TCP, UDP, or ICMP payload in the received IP datagrams.
Receive Bus Interface Unit Module	Interface to the FIFO.
Address Filtering Module	Filters destination and source address based on uni-cast, multi-cast, and broadcast frames. Provides CRC hash filtering.

EMAC PHY Interface

The EMAC can interface to the PHY through the RMII interface standard. The ***RMII Pins*** table shows the RMII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 28-7: RMII Pins

Signal No.	Generic Signal Name (IEEE Standards)	RMII Pin Functionality
1.	TXD0	RMII transmit data pin D0 (di-bit lower)
2.	TXD1	RMII transmit data pin D1 (di-bit higher)
3.	RXD0	RMII receive data pin D0 (di-bit lower)
4.	RXD1	RMII receive data pin D1 (di-bit higher)
5.	RMII CLK	RMII common clock (for TX and RX), also called reference clock
6.	TXEN	RMII transmit enable pin (TX valid)
7.	CRS	RMII carrier sense / receive data valid
8.	MDC	Serial management clock driven by EMAC
9.	MDIO	Serial management bidirectional data

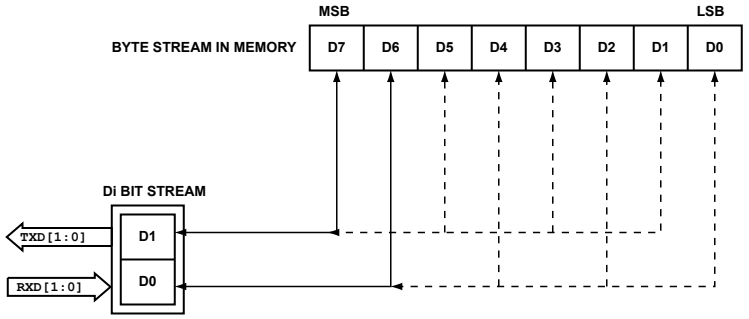

Figure 28-3: RMII Di-bit Data Transfer

Extended EMAC PHY Interface

The EMAC can interface to the PHY through the RGMII interface standard. The ***RGMII Pins*** table shows the RGMII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 28-8: RGMII Pins

Sl. No.	Generic Signal Name (IEEE Standards)	RGMII Pin Functionality
1.	TXD3-0	RGMII transmit data pins D3-0
2.	RXD3-0	RGMII receive data pins D3-0
3.	TXCLK	RGMII transmit reference clock driven by EMAC
4.	RXCLK	RGMII receive reference clock driven by PHY
5.	TXCTL	RGMII transmit enable pin (TX valid)
6.	RXCTL	RGMII receive data valid

Table 28-8: RGMII Pins (Continued)

Sl. No.	Generic Signal Name (IEEE Standards)	RGMII Pin Functionality
7.	MDC	Serial management clock driven by EMAC
8.	MDIO	Serial management bidirectional data

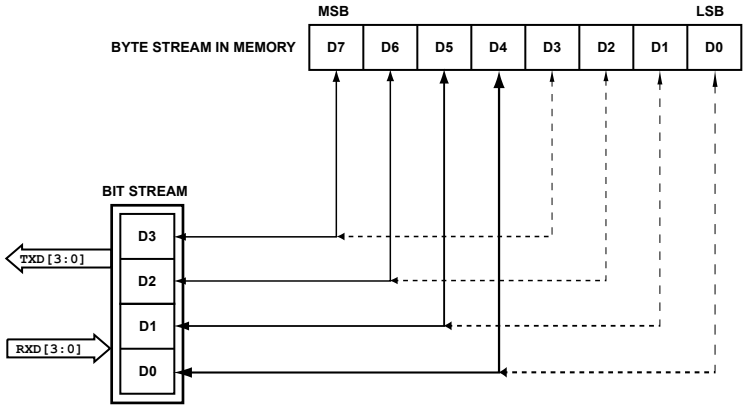

Figure 28-4: RGMII Data Bit Transfer

EMAC PHY Interface

The EMAC can interface to the PHY through the MII interface standard. The ***MII Pins*** table shows the MII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 28-9: MII Pins

Sl. No.	Generic Signal Name (IEEE Standards)	MII Pin Functionality
1.	TXCLK	MII transmit clock
2.	TXD0-3	MII transmit data pins 0-3
3.	TXEN	MII transmit enable
4.	RXCLK	MII receive clock
5.	RXD0-3	MII receive data pins 0-3
6.	RXDV	MII receive data valid
7.	RXER	MII receive error
8.	CRS	MII carrier sense
9.	COL	MII collision detect

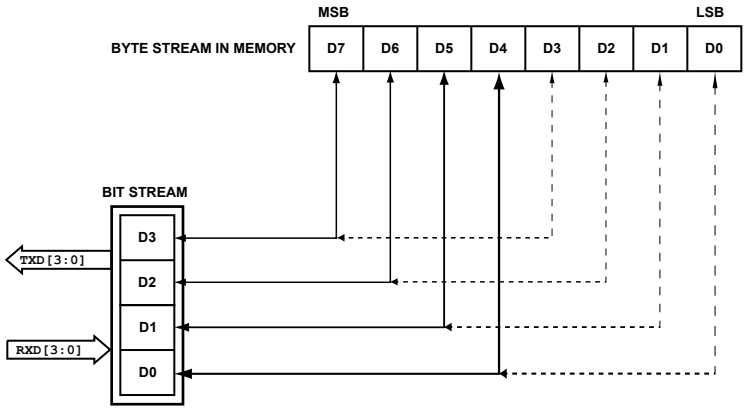

Figure 28-5: MII Data Bit Transfer

PHY Interface Selection

The EMAC0 supports both 10/100 Mbps data-transfer rates with external PHY interfaced through RMII and MII and 10/100/1000 Mbps data-transfer rates with external PHY interfaced through RGMII.

Select the external PHY interface for EMAC0 using the `PADS_PCFG0` register, as shown in the following table.

`PADS_PCFG0.EMACPHYISEL`	0 = MII Interface 1 = RGMII Interface 2 = RMII Interface
`PADS_PCFG0.EMACRESET`	0 = reset is asserted 1 = reset is deasserted To select PHY interface, set `PADS_PCFG0.EMACPHYISEL` bit as required and then set `PADS_PCFG0.EMACRESET`.

RGMII Board Design Recommendations

Use the following guidelines during when performing board design when using the RGMII interface.

MAC to PHY (Transmit)

The Ethernet MAC transmits data to the Ethernet PHY. The Ethernet MAC sends data with tskewT (the timing of TXC at the MAC) that meets the RGMII specification (tskewT = –500 ps to +500 ps skew window for transmitter to drive data). The RGMII specification requires that at the PHY end, tskewR is sampled at 1.0 to 2.6 ns. According to the RGMII standard, clocks must be routed such that an additional trace delay of greater than 1.5 ns and less than 2 ns is added to the associated clock signal.

To meet this standard without adding trace delays, most of the PHYs in the industry already include delay logic that can compensate for this on-board delay. These PHY types can manage a tskewR of ±500 ps (the skew for TXC data sampling seen inside the PHY).

The PHY or the on-board delay must delay the clock signal by 1.5 to 2.0 ns so that tskewR is sampled at 1.0 to 2.6 ns. The ***MAC to PHY Delay Diagram (Transmitting Data)*** figure shows where the delays must occur.

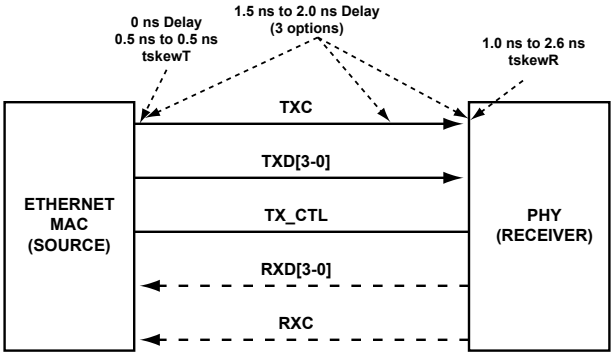

Figure 28-6: MAC to PHY Delay Diagram (Transmitting Data)

PHY to MAC (Receive)

The Ethernet MAC receives data from the Ethernet PHY. Just as in the transmit case, a trace delay of greater than 1.5 ns and less than 2 ns must be added to the associated clock signal, as required by the RGMII specification. Also similar to the transmit case, most of the PHYs in the industry already include delay logic that can compensate for the RXC clock as well.

As shown in the ***MAC to PHY Delay Diagram (Receiving Data)*** figure, a board trace or the PHY can be used to generate the required 1.5–2.0 ns delay to RXC and the 1.0–2.6 ns tskewR.

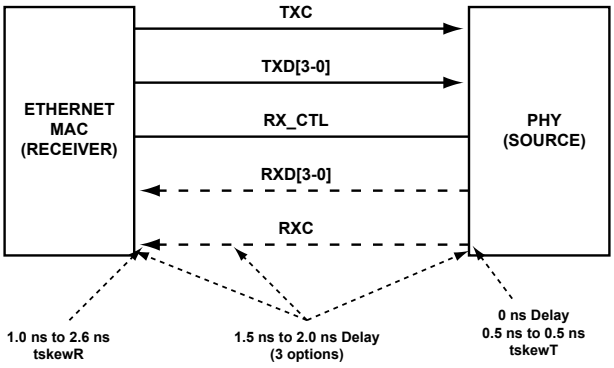

Figure 28-7: MAC to PHY Delay Diagram (Receiving Data)

There following are two options for board design.

- The on-board delay must delay the clock signal by 1.5 to 2.0 ns. In this case, no additional delay must be introduced by the PHY.
- Most of the PHYs in the industry already include a mode that can introduce a delay logic. If this mode of the PHY is used then the trace lengths on the board need to be matched exactly.

The second option is recommended since it is easier to implement the delay by using the mode in the PHY rather than during the board design. This is the approach followed in the ADI EZ-Kits.

NOTE: Refer to the product specific data sheet for exact processor timing.

For the trace length recommendations for the EMAC signals, please refer to the data sheet.

For the exact requirements as recommended by the RGMII protocol, please refer to the RGMII specification.

Clock Sources

The Ethernet MAC is clocked internally from SCLK0. Check the processor data sheet for the valid frequency range of the appropriate SCLK0 signal for Ethernet operation.

Source a 50-MHz clock externally to operate the EMAC in RMII mode. This clock is the same for both transmit and receive. The MDC station management clock is derived from the SCLK0 and driven from the MAC to the PHY, when accessing any PHY registers. .

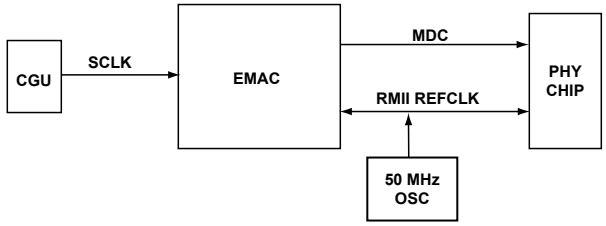

Figure 28-8: EMAC Clock Sources for RMII PHY interface

EMAC0 Clock Sources

EMAC0 supports RGMII, RMII and MII interfaces. The external PHY sources a 2.5 MHz or 25 MHz clock (for 10/100 or gigabit Ethernet respectively) to operate the EMAC RXCLK in RGMII mode. The RGMII TXCLK is driven from CLK07 of the CDU (Clock Distribution Unit) and needs to be configured to 125 MHz regardless of the EMAC0 speeds (10/100/1000 Mbit/s). The `EMAC_MACCFG.PS` and `EMAC_MACCFG.FES` bits are used to divide the clocks down.

The following tables show the clock sources for the RGMII, MII and RMII interfaces.

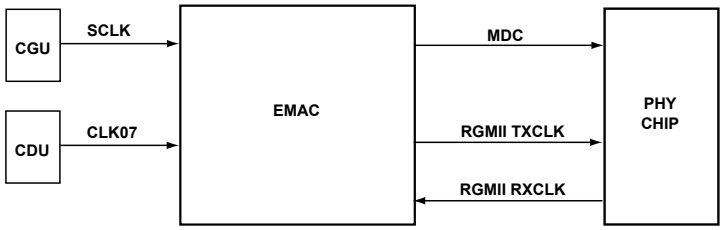

Figure 28-9: EMAC Clock Sources - RGMII PHY Interface

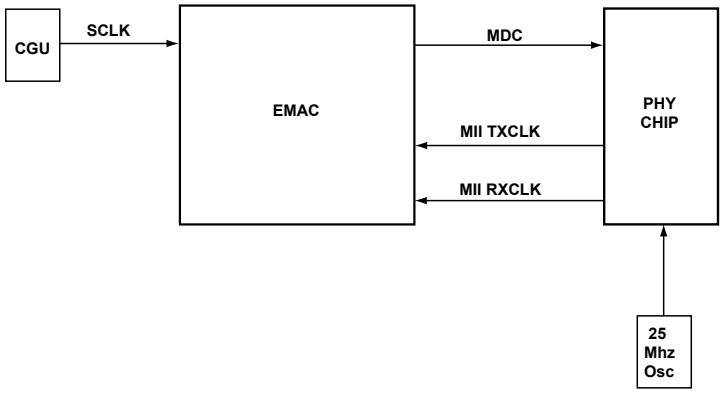

Figure 28-10: EMAC Clock Sources - MII PHY Interface

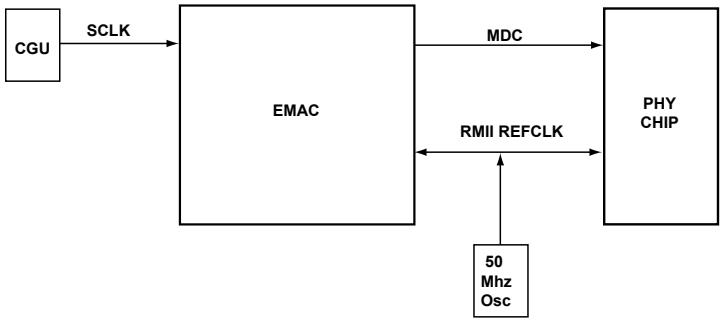

Figure 28-11: EMAC Clock Sources - RMII PHY Interface

EMAC Architectural Concepts

This section explains different architectural concepts relevant to EMAC peripheral, such as EMAC SCB, EMAC DMA, EMAC MFL, EMAC CORE, and others.

EMAC Feature Summary

The ***EMAC Feature Summary*** table provides a summary of the features that are available on EMAC0 .

Table 28-10: EMAC Feature Summary

Feature	Value (EMAC0)
Speed of Operation	10/100/1000 Mbps
EMAC_VER.UVER hardcoded value	0x10
PHY Interface	RGMII or RMII or MII
Receive FIFO Size (in Bytes)	2048
Transmit FIFO Size (in Bytes)	2048
Energy Efficient Ethernet (EEE)	Yes
PTP (IEEE 1588)	Yes

Table 28-10: EMAC Feature Summary (Continued)

Feature	Value (EMAC0)
AV Feature	Yes
No of TX Channels	3
No of RX Channels	3

EMAC System Crossbar Interface (EMAC SCB)

The EMAC SCB bus interface provides the bus connectivity to support highly effective throughput of data traffic. System bus use is maximized by allowing simultaneous read and write transfers initiated from different DMA channels. The EMAC controller connects directly to the SCB0 crossbar. The following interfaces are available with the design.

- A 32-bit SCB controller interface for reading and writing to and from the application memory.
- A 32-bit SPB target interface for register programming.

Refer to the “System Crossbars (SCB)” chapter for more information on how the crossbar operates. This chapter details only the EMAC-specific information.

Table 28-11: EMAC-SCB Interface Data Transfer Specifications with Crossbar

Specification Term	Comments
1 beat in SCB	SINGLE burst
BLEN4 bursts	4 beats in SCB
BLEN8 bursts	8 beats in SCB
BLEN16 bursts	16 beats in SCB
Bus size	32-bit fixed bus size; equals 1 beat
INCR bursts	Incrementing Bursts
INCR ALIGNED bursts	Incrementing aligned bursts
UNDEF bursts	Undefined burst length
PBL	Programmable Burst Length for DMA

The ***EMAC DMA Read/Write channels with System Crossbar*** figure shows DMA write channel and read channel datapaths and their connection to the system crossbar.

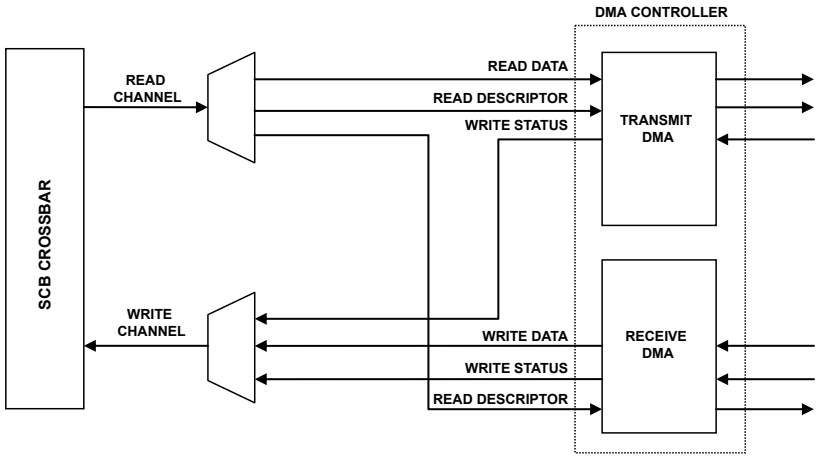

Figure 28-12: EMAC DMA Read/Write channels with System Crossbar

NOTE: Transmit descriptor read and receive descriptor write-back (status update) operations can occur simultaneously. However, transmit descriptor read and write-back operations cannot occur simultaneously. Transmit DMA (or receive DMA) does not initiate the next transfer unless the previous one is complete.

Priority of SCB Requests

The descriptor transfers have higher priority than the data transfers. For example, if there are two bus requests, such as a receive descriptor read and a transmit data read, the receive descriptor read has a higher priority. The next receive data write (subsequent to the receive descriptor read) does not depend on the completion of the transmit data-read transfer.

If there are requests for descriptor reads from both DMA channels, they are serviced based on a first-come first-serve. Receive DMA has higher priority if the descriptor-read requests are generated from both the DMA channels in the same clock cycle. Similarly, in the write channel, descriptor writes from DMA have higher priority than the data-write transfers for the receive DMA.

SCB Interface Programming Options

The SCB bus interface supports the following programmable options for the EMAC module. These options are available using the `EMAC_DMA0_BMMODE` register with the `EMAC_DMA0_BUSMODE` register. These programming options apply to DMA1 and DMA2 as well.

- ***Outstanding transactions.*** The EMAC-SCB supports up to four outstanding read/write requests on the SCB bus. Software can control these requests by programming the `EMAC_DMA0_BMMODE.WROSRLMT` and `EMAC_DMA0_BMMODE.RDOSRLMT` bits. Maximum outstanding requests = `EMAC_DMA0_BMMODE.WROSRLMT` + 1 (or) `EMAC_DMA0_BMMODE.RDOSRLMT` + 1.
- ***Allowed burst sizes.*** The allowed burst sizes are 4 (`EMAC_DMA0_BMMODE.BLEN4`), 8 (`EMAC_DMA0_BMMODE.BLEN8`), 16 (`EMAC_DMA0_BMMODE.BLEN16`) and the SINGLE burst. The EMAC-SCB uses only those burst sizes configured by the program (through the `EMAC_DMA0_BMMODE` register) for data transfer through the SCB bus. However, SINGLE burst is available by default, when the `EMAC_DMA0_BMMODE.UNDEF` bit is cleared. Data transfers are restricted to the maximum burst size from this list of programmed burst sizes.

- ***Burst splitting and burst selection.*** The EMAC-SCB splits the DMA requests into multiple bursts on the SCB system bus. Splitting is based on DMA count and software controllable burst enable bits (shown in the allowed burst sizes) as well as burst types (INCR and INCR_ALIGNED). Burst types are also controllable through the software. SINGLE burst is enabled when the EMAC_DMA0_BMMODE.UNDEF bit is not set. Burst length select priority is in the sequence: UNDEF, 16, 8, and 4.
- ***INCR burst type***
  - If the EMAC_DMA0_BMMODE.UNDEF bit is set, the EMAC-SCB always chooses the maximum allowed burst length based on the EMAC_DMA0_BMMODE.BLEN16, EMAC_DMA0_BMMODE.BLEN8, EMAC_DMA0_BMMODE.BLEN4 bits. When the DMA requests are not multiples of the maximum allowed burst length, the SCB can choose a burst-length of any value less than the maximum enabled. (All lesser burst-length enables are redundant). For example, when length bits are enabled and the DMA requests a burst of 42 beats, the SCB splits it into three bursts of 16, 16 and 10 beats respectively.
  - If EMAC_DMA0_BMMODE.UNDEF is not enabled, then the burst length is based on the priority of the enabled bits in the following order EMAC_DMA0_BMMODE.BLEN16, EMAC_DMA0_BMMODE.BLEN8, EMAC_DMA0_BMMODE.BLEN4. When the DMA requests a burst transfer, the SCB interface splits the requested bursts into multiple transfers using only the enabled burst lengths. This splitting can occur when the requested burst is not a multiple of the maximum enabled burst. If it cannot choose any of the enabled burst lengths, then it selects the burst length as 1.

  For example, the DMA requests a burst transfer of 42 beats, the SCB interface splits it into multiple bursts of size 16, 16, 8, 1 and 1 beats respectively. (In this case, the allowed burst sizes are enabled and the sequence is in decreasing burst sizes).
- ***INCR_ALIGNED burst type.*** When the address-aligned burst-type is enabled (EMAC_DMA0_BMMODE.AAL), the SCB interface splits the DMA requested bursts. The "INCR Burst Type" section explains burst splitting conditions further. Each burst-size aligns to the least significant bits of the start address. The SCB interface initially generates smaller bursts so that the remaining transfers move with the maximum (enabled) fixed burst lengths.

  For example, in the same setting as explained earlier for EMAC_DMA0_BMMODE.UNDEF set, the DMA requests a burst size of 42 beats at the start address of 0x000003A4.(EMAC_DMA0_BMMODE.BLEN16, EMAC_DMA0_BMMODE.BLEN8, and EMAC_DMA0_BMMODE.BLEN4 are enabled). The SCB starts the first transfer with size 3 such that the address of the next burst is aligned (0x000003B0) for a burst of 16. Therefore, the sequence of bursts is 3, 16, 16, and 7, respectively.

  When EMAC_DMA0_BMMODE.UNDEF is not set, then (having a start address of 0x000003A4 with 42 beats), the sequence of burst transfers is 1, 1, 1, 16, 16, 4, and 3 respectively. The sequence of smaller bursts at the beginning is used to align the address to the next higher enabled burst-lengths programmed in the register.
- ***Burst operations for DMA transactions.*** The EMAC_DMA0_BUSMODE.PBL (programmable burst length) field indicates the maximum number of beats to transfer in one DMA transaction. This value is also the maximum used in a single block read/write. It is shown in the following table.

- For example, if EMAC_DMA0_BUSMODE.PBL=32 and if EMAC_DMA0_BMMODE.BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If EMAC_DMA0_BUSMODE.PBL=8, and if EMAC_DMA0_BMMODE.BLEN16 and EMAC_DMA0_BMMODE.BLEN8 are enabled, the maximum burst is limited to EMAC_DMA0_BMMODE.BLEN8. If the EMAC_DMA0_BUSMODE.PBL8 bit is set, the programmed EMAC_DMA0_BUSMODE.PBL value is multiplied by 8 times internally. However, the result cannot be more than the maximum limits specified.
- Set the EMAC_DMA0_BUSMODE.USP bit to make the receive DMA burst length configuration independent of the transmit DMA configuration. When this bit is set, the EMAC uses the EMAC_DMA0_BUSMODE.RPBL bits to define the burst length of receive DMA. If the EMAC_DMA0_BUSMODE.USP bit is not set, the EMAC_DMA0_BUSMODE.RPBL bits are used for both transmit and receive. Programs must ensure that the PBL maximum limit is not violated.
- The receive and transmit descriptors are always accessed in the maximum burst-size for the 16-bytes to be read (PBL-max limit is (TX or RX FIFO size/2)/4 words. (PBL maximum for transmit and receive limits burst-size).

Table 28-12: DMA PBL Max Limits

Burst Limit Max Term	Definition
PBL-maximum limit	(FIFO size/2)/4 words
PBL-maximum limit (transmit)	2048 bytes/2 /4 = 256 words
PBL-maximum limit (receive)	2048 bytes/2 /4 = 256 words

DMA Bursts Using the SCB Interface

The transmit DMA initiates a data transfer when sufficient space to accommodate the configured burst is available in the transmit FIFO. Or, the transmit DMA initiates a data transfer when the number of bytes until the end of frame is less than the configured burst-length. The DMA indicates the start address and the number of transfers required to the SCB controller interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and 1 beat transaction.

The receive DMA initiates a data transfer when sufficient data to accommodate the configured burst is available in the MTL receive FIFO. Or, the receive DMA initiates a data transfer when the end of frame is detected in the receive FIFO. For example, when the amount is less than the configured burst-length. The DMA indicates the start address and the number of transfers required to the SCB controller interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR 4, 8, 16 or 1 beat transaction. If the end-of frame is reached before the fixed-burst ends on the SCB interface, then dummy transfers are performed to complete the fixed-burst. Otherwise (if EMAC_DMA0_BUSMODE.FB is reset), it transfers data using INCR (undefined length) transactions.

When the SCB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer is less than or equal to the configured PBL size. (The address-aligned beats configuration uses the EMAC_DMA0_BUSMODE.AAL bit). Therefore, all subsequent beats start at an address that is aligned to the configured PBL.

SCB Bus Transaction Status

The SCB uses the EMAC_DMA0_BMSTAT.BUSRD and EMAC_DMA0_BMSTAT.BUSWR bits to indicate whether the channel is active or not.

Fatal Bus Error

The EMAC SCB asserts the error interrupt (EMAC_DMA0_STAT.FBI) when the corresponding fatal bus error interrupt is enabled in the DMA interrupt enable register. The application must reset the core to restart the DMA.

DMA Controller (EMAC DMA)

The EMAC has a built-in DMA controller that performs reads and writes of application data and descriptors through the SCB controller interface.

The DMA controller has independent transmit and receive engines, and a CSR (control and status register) space. The transmit engine transfers data from system memory to a FIFO, while the receive engine transfers data from the FIFO to the system memory. The controller uses a descriptor chain-based transfer mechanism to move data efficiently from source to destination with minimal processor core intervention. The DMA is specially designed for packet-oriented data transfers such as Ethernet frames. The controller can be programmed to interrupt the application for situations such as frame transmit and receive transfer completion, and other normal or abnormal conditions.

The DMA and the application device driver communicate through two internal data structures:

1. DMA control and status registers (CSR).
2. Data buffers and descriptor lists. Descriptor lists operate in ring mode and chain mode, as shown in the ***EMAC DMA Descriptor Models*** figure.

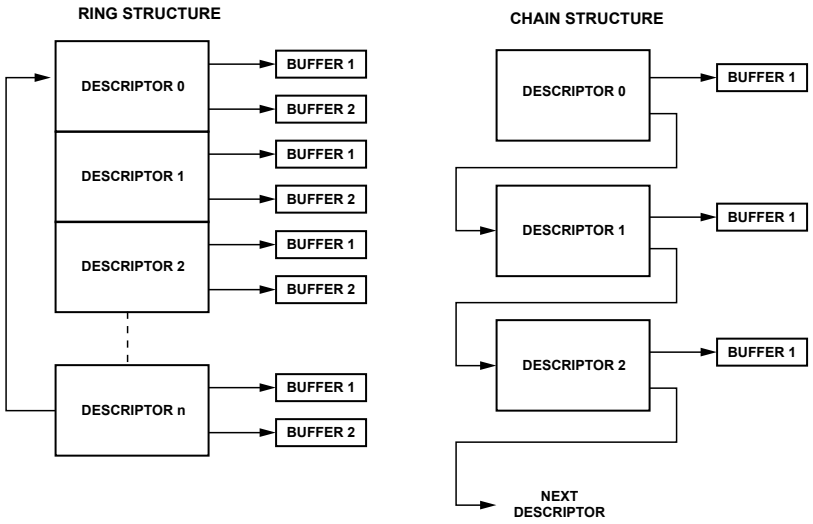

Figure 28-13: EMAC DMA Descriptor Models

Descriptors that reside in the application memory act as pointers to receive and transmit buffers. Descriptors have the following extra attributes.

- There are two descriptor lists, one for receive, and one for transmit. The base address of each list is written into the address registers of the receive and transmit descriptor lists respectively.
- A descriptor list is forward linked (either implicitly or explicitly). The last descriptor can point back to the first entry to create a ring structure.
- Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors.
- The descriptor lists reside in the address space of the application memory.
- Each descriptor can point to a maximum of two buffers. This attribute enables two buffers, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the physical memory space of the application. It consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers can contain only data. The descriptor maintains buffer status. *Data chaining* refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end-of-frame is detected. Data chaining is enabled or disabled.

NOTE: It is possible to define a skip length (in terms of N × 32-bit words) between two subsequent descriptors, when using ring mode. Program the `EMAC_DMA0_BUSMODE.DSL`/`EMAC_DMA1_BUSMODE.DSL`/`EMAC_DMA2_BUSMODE.DSL` field to enable this attribute. With this option available, programs are not always restricted to a contiguous memory location in ring mode.

DMA Related Registers

The ***Summary of DMA Related Registers*** table provides a summary of DMA registers relative to their function. Refer to the “Register Descriptions” sections for complete bit descriptions of each of these registers.

Table 28-13: Summary of DMA Related Registers

Register Name	Description
Bus Mode[*1]	Establishes the bus operating modes for the DMA based on the SCB controller interface.
Transmit Poll Demand	Enables the transmit DMA to check whether the DMA owns the current descriptor. The transmit poll demand command wakes up the TxDMA when it is in suspend mode. The TxDMA can go into suspend mode because of an underflow error in a transmitted frame or because of the unavailability of descriptors owned by transmit DMA. Issue this command anytime and the TxDMA resets this command once it starts refetching the current descriptor from host memory.
Receive Poll Demand	Enables the receive DMA to check for new descriptors. This command wakes up the RxDMA from the SUSPEND state. The RxDMA can go into SUSPEND state only because of the unavailability of descriptors owned by it.
Receive Descriptor List Address	Points to the start of the receive descriptor list. The descriptor lists reside in the application memory space and must be word-aligned (32- bit data bus). The DMA internally converts the descriptor list to a bus width aligned address by making the corresponding LSBs low.

Table 28-13: Summary of DMA Related Registers (Continued)

Register Name	Description
Transmit Descriptor List Address	Points to the start of the transmit descriptor list. The descriptor lists reside in the application memory space and must be word-aligned (for 32-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.
DMA Status	Contains all the status bits that the DMA reports to the application. The software driver reads this register during an interrupt service routine or during polling. Most of the fields in this register interrupt the host.
Operation Mode	Establishes the transmit and receive operating modes and commands. The operation mode register is the last control register written as part of DMA initialization.
Interrupt Enable	Enables the interrupts reported by DMA status register. After a hardware or software reset, all interrupts are disabled.
Missed Frame and Buffer Overflow Counter	The DMA maintains two counters to track the number of missed frames during reception. This register reports the current value of the counter, which is used for diagnostic purposes.
Receive Interrupt Watchdog Timer	When written with non-zero value, enables the watchdog timer for receive interrupt (RI) in the DMA status register.
SCB Bus Mode	Controls the SCB interface controller behavior. It controls the burst splitting and the number of outstanding requests.
SCB Status	Provides the active status of the SCB interface read and write channels.
Current Host Transmit Descriptor	Points to the start address of the current transmit descriptor read by the DMA.
Current Host Receive Descriptor	Points to the start address of the current receive descriptor read by the DMA.
Current Host Transmit Buffer Address	Points to the current transmit buffer address the DMA is reading.
Current Host Receive Buffer Address	Points to the current receive buffer address the DMA is reading.

*1 Do not write to the `EMAC_DMA0_BUSMODE.DSL`/`EMAC_DMA1_BUSMODE.DSL`/`EMAC_DMA2_BUSMODE.DSL` registers until the first write updates. Otherwise, the second write operation does not update properly. For correct operation, the delay between two writes to the same register location must be at least 8 cycles of 50 MHz RMII REFCLK.

Table 28-14: DMA Registers with Consecutive Writes

Registers with Implications for Consecutive Writes
DMA Bus Mode

DMA Descriptors

The DMA module in the Ethernet subsystem transfers data based on a linked list of descriptors. The descriptor addresses must be aligned to the 32-bit bus width. The descriptors can be either 4 x 32-bit words (16 bytes) or 8 x 32-bit words (32 bytes). Configure the controller for the appropriate word length using the DMA bus mode register. The descriptor words are numbered from 0 to 7 for both the transmit and receive engine.

Typical factors for deciding the descriptor word size are as follows:

- When the time stamping or receive checksum engines are not enabled, the extended descriptors are not required. The software can use descriptors with the default size of 16 bytes (4 words).
- When the time stamping feature is enabled, the software must allocate 32 bytes (8 words) of memory for every descriptor. (The time stamping feature is used with the IEEE 1588 PTP engine).
- When only the receive checksum offload is enabled (time stamping disabled), software must allocate 32 bytes (8 words) of memory for every descriptor. However, only word 4 of the extended words (descriptors 4–7) contains the required status information. Treat the rest of the extended words as reserved or dummy.

Transmit Descriptor

The ***Transmit Descriptor Words*** figure shows the transmit descriptor structure in memory. The application software must program the TDES0 control bits during descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits. The following tables give the contents of the transmitter descriptor word 0 (TDES0) through word 7 (TDES7).

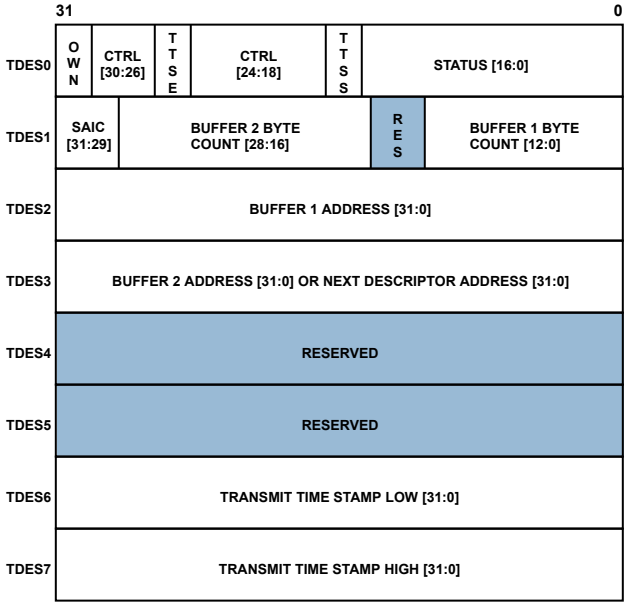

Figure 28-14: Transmit Descriptor Words

Table 28-15: Transmit Descriptor Fields (TDES0)

Bit	Name	Description
31	OWN	Ownership. When set, this bit indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the first descriptor of the frame must be set after all subsequent descriptors belonging to the same frame have been set. This configuration avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30	IC	Interrupt on Completion. When set, this bit sets the transmit interrupt (DMA status register [0]) after the present frame is transmitted.

Table 28-15: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
29	LS	Last Segment. When set, this bit indicates that the buffer contains the last segment of the frame.
28	FS	First Segment. When set, this bit indicates that the buffer contains the first segment of a frame.
27	DC	Disable CRC. When this bit is set, the EMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This functionality is valid only when the first segment (TDES0[28]) is set.
26	DP	Disable Pad. When set, the EMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes. The CRC field is added despite the state of the DC (TDES0[27]) bit. This functionality is valid only when the first segment (TDES0[28]) is set.
25	TTSE	Transmit Time Stamp Enable. When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the first segment control bit (TDES0[28]) is set.
24	CRCR	CRC Replacement Control. When set, the EMAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The host should ensure that the CRC bytes are present in the frame being transferred from the transmit buffer. This bit is valid when the first segment bit (TDES0[28]) and the disable CRC bit (TDES0[27]) are set.
24	Reserved	
23:22	CIC	Checksum Insertion Control. These bits control the checksum calculation and insertion. Bit encodings are as follows: 00 = Checksum Insertion disabled. 01 = Only IP header checksum calculation and insertion are enabled. 10 = IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 = IP header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.
21	TER	Transmit End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
20	TCH	Second Address Chained. When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When TDES0[20] bit is set, TBS2 (TDES1[28:16]) is a ***do-not-care*** value. TDES0[21] takes precedence over TDES0[20].
19:18	Reserved	

Table 28-15: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
19:18	VLIC	VLAN Insertion Control. When set, these bits request the MAC to perform VLAN tagging or untagging before transmitting the frames. If the frame is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. Bit encodings are as follows. 00 = Do not add a VLAN tag. 01 = Remove the VLAN tag from the frames before transmission. This option should be used only with the VLAN frames. 10 = Insert a VLAN tag with the tag value programmed in the VLAN tag inclusion or replacement `EMAC_VLAN_INCL` register. 11 = Replace the VLAN tag in frames with the tag value programmed in the VLAN tag inclusion or replacement `EMAC_VLAN_INCL` register. This option should be used only with the VLAN frames. These bits are valid when the first segment bit (TDES0[28]) is set.
17	TTSS	Transmit Time Stamp Status. This bit is a status bit to indicate that a time stamp is captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the last segment control bit of the descriptor (TDES0[29]) is set.
16	IHE	IP Header Error. When set, this bit indicates that the EMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application. It indicates an error status when there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet length or type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the header length field has a value less than 0x5.
15	ES	Error Summary. Indicates the logical OR of the following bits: TDES0[14] = Jabber Timeout TDES0[13] = Frame Flush TDES0[11] = Loss of Carrier TDES0[10] = No Carrier TDES0[9] = Late Collision TDES0[8] = Excessive Collision TDES0[2] = Excessive Deferral TDES0[1] = Underflow Error TDES0[16] = IP Header Error TDES0[12] = IP Payload Error
14	JT	Jabber Timeout. When set, this bit indicates that the EMAC transmitter has experienced a jabber timeout. This bit is only set when the `EMAC_MACCFG.JB` bit is not set.
13	FF	Frame Flushed. When set, this bit indicates that the DMA or MFL flushed the frame due to a software flush command given by the CPU.

Table 28-15: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
12	IPE	IP Payload Error. When set, this bit indicates that EMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application. It issues an error status when there is a mismatch.
11	LC	Loss of Carrier. When set, this bit indicates a loss of carrier occurred during frame transmission. This functionality is valid only for the frames transmitted without collision when the EMAC operates in half-duplex mode. Loss of Carrier. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble, in RMII mode; 512 byte-times, including preamble and carrier extension, in RGMII mode). This bit is not valid if the underflow error bit is set.
10	NC	No Carrier. When set, this bit indicates that the carrier sense signal from the PHY did not assert during transmission.
9	LC	Late Collision. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble). This bit is not valid if the underflow error bit is set. Late Collision. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble, in RMII mode; 512 byte-times, including preamble and carrier extension, in RGMII mode). This bit is not valid if the underflow error bit is set.
8	EC	Excessive Collision. When set, this bit indicates that the EMAC aborted the transmission after 16 successive collisions, while attempting to transmit the current frame. If the `EMAC_MACCFG.DR` disable retry bit is set, this bit is set after the first collision, and the transmission of the frame aborts.
7	VF	VLAN Frame. When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	CC	Collision Count. When set, these bit indicate that the EMAC aborted the frame transmission due to a collision occurring after the collision window (64 byte-times, including preamble). This bit is not valid if the Underflow Error bit is set. This field is updated only in half-duplex mode.
6:3	SLOTNUM	Slot Number Control Bits. In AV mode, these bits indicate the slot interval in which the data should be fetched from the corresponding buffers, addressed by TDES2 or TDES3. When the transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot function control and status register (RSN). It fetches the data from the buffers only if there is a match in values. These bits are valid only for AV channels (not channel 0).
2	ED	Excessive Deferral. When set, this bit indicates that the transmission has ended because of excessive deferral when the `EMAC_MACCFG.DC` deferral check bit is set high. Excessive deferral is over 24,288-bit times. (155,680-bits times in 1,000-Mbps mode or when jumbo frame is enabled).
1	UF	Underflow Error. When set, this bit indicates that the EMAC aborted the frame because data arrived late from the application memory. Underflow error indicates that the DMA encountered

Table 28-15: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
		an empty transmit buffer while transmitting the frame. The transmission process enters the suspended state and sets both transmit underflow (EMAC_DMA0_STAT.UNF) and transmit interrupt (EMAC_DMA0_STAT.TI) bits.
0	DB	Deferred Bit. When set, this bit indicates that the EMAC defers before transmission because of the presence of carrier. This bit is valid only in half-duplex mode.

Table 28-16: Transmit Descriptor Word 1 (TDES1)

Bit	Name	Description
31-29	Reserved	
31–29	SAIC	Source Address Insertion Control. Request the MAC to add or replace the source address field in the Ethernet frame with the value given in the MAC address register 0 or MAC address register 1. If the source address field is modified in a frame, the MAC automatically recalculates and replaces the CRC bytes. SAIC[2] chooses between MAC address register 0 and MAC address register 1 for source address insertion or replacement. The following list describes SAIC[1:0]. 00 = Do not include the source address. 01 = Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 = Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 = Reserved. This field is valid only when the first segment bit (TDES0[28]) is set.
28–16	TBS2	Transmit Buffer 2 Size. These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set.
15–13	Reserved	
12–0	TBS1	Transmit Buffer 1 Size. These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 28-17: Transmit Descriptor 2 (TDES2)

Bit	Name	Description
31–0	Buffer 1 Address Pointer	These bits indicate the physical address of buffer 1. There is no limitation on the buffer address alignment

Table 28-18: Transmit Descriptor 3 (TDES3)

Bit	Name	Description
31–0	Buffer 2 Address Pointer (Next Descriptor Address)	Indicates the physical address of buffer 2 when DMA uses a descriptor ring structure. If the second address chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. The buffer address pointer must align to the bus width only when TDES1[24] is set. LSBs are ignored internally.

Table 28-19: Transmit Descriptor 6 (TDES6)

Bit	Name	Description
31–0	TTSL	Transmit Frame Time Stamp Low. The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and time stamp status (TTSS) bit is set.

Table 28-20: Transmit Descriptor 7 (TDES7)

Bit	Name	Description
31–0	TTSH	Transmit Frame Time Stamp High. The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and time stamp status (TTSS) bit is set.

DMA Transmit Process

The following sections describe how the transmission process works for direct memory access on the EMAC controller.

- Default (Non-OSF) Mode
- OSF Mode Enabled
- Transmit Frame Processing
- Transmit Polling Suspended

Default (Non-OSF) Mode

The following sequence decribes the default process for DMA transmit works. The sequence applies DMA1 and DMA2 as well.

1. The application sets up the transmit descriptor (using TDES0- TDES3) and sets the OWN bit (TDES0) after setting up the corresponding data buffers with Ethernet frame data.
2. Once the `EMAC_DMA0_OPMODE.ST` bit is set, the DMA enters the run state.
3. While in the run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the application, or if an error condition occurs, transmission suspends. Both the transmit buffer unavailable (`EMAC_DMA0_STAT.TU`) and normal interrupt summary (`EMAC_DMA0_STAT.NIS`) bits are set. The transmit engine proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by DMA (TDES0 [31] = 1#b1), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the application memory and transfers the data to the MFL for transmission.

6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 repeat until the end-of-Ethernet-frame data transfers to the MFL.
7. Frame transmission completes. If IEEE 1588 time stamping was enabled for the frame, the time stamp value obtained from MFL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. (The transmit status indicates if IEEE 1588 time stamping enables). The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the application now owns this descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.
8. Transmit interrupt (`EMAC_DMA0_STAT.TI`) is set after completing transmission of a frame. The frame has interrupt on completion (TDES1 [31]) set in its last descriptor. The DMA engine then returns to Step 3.
9. In the suspend state, the DMA tries to reacquire the descriptor (and returns to Step 3) when it receives a transmit poll demand and the `EMAC_DMA0_STAT.UNF` bit is cleared.

NOTE: If the `EMAC_DMA0_OPMODE.OSF` bit is not set, the actual inter frame gap (IFG) is more than the value programmed in the `EMAC_MACCFG` register.

OSF Mode Enabled

While in the run state, the transmit process can simultaneously acquire two frames without closing the status descriptor of the first (if the `EMAC_DMA0_OPMODE.OSF` bit is set). As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the status information of the first frame.

In OSF mode, the run state transmit DMA operates in the following sequence.

1. The DMA operates as described in steps 1–6 of Default (Non-OSF) Mode.
2. Without closing the previous last descriptor of the frame, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into suspend mode and skips to Step 7.
4. The DMA fetches the transmit frame from the application memory and transfers the frame to the MFL until the end-of-frame data is transferred. It closes the intermediate descriptors when this frame splits across multiple descriptors.
5. The DMA waits for the frame transmission status and time stamp of the previous frame. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if the time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the transmit interrupt is set; the DMA fetches the next descriptor, and then proceeds to Step 3 (when status is normal). If the previous transmission status shows an underflow error, the DMA goes into suspend mode (Step 7).

7. In suspend mode, if a pending status and time stamp are received from the MFL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3. The DMA then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to suspend mode.
8. After receiving a transmit poll demand (EMAC_DMA0_TXPOLL), the DMA can exit suspend mode and enter the run state. (Go to Step 1 or Step 2 depending on pending status)

NOTE: If the EMAC_DMA0_OPMODE.OSF bit is set, the DMA fetches the next descriptor in advance of closing the current descriptor. Therefore, the descriptor chain must have more than two different descriptors for proper operation.

NOTE: If the EMAC_DMA0_OPMODE.OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to update. In the meantime, the MFL receives the second frame into the FIFO while transmitting the first frame. The difference in cycles is not seen for the first descriptor, because the time taken for the complete descriptor processing remains the same whether EMAC_DMA0_OPMODE.OSF is set or not. The difference appears only for the following descriptor because its processing began earlier.

Transmit Frame Processing

The transmit DMA engine expects that the data buffers contain complete Ethernet frames, excluding: preamble, pad bytes, and FCS fields. The destination address, source address, and type or length fields contain valid data. If the transmit descriptor indicates that the EMAC CORE must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the first descriptor (TDES0[28]) and the last descriptor (TDES0[29]), respectively.

As transmission starts, the first descriptor must have (TDES0[28]) set. Frame data transfers from the application buffer to the transmit FIFO. Concurrently, if last descriptor (TDES0[29]) of the current frame clears, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES0[28] clear. If TDES1[29] is clear, it indicates an intermediary buffer. If TDES0[29] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information. The DMA writes to the transmit descriptor 0 (TDES0) word of the descriptor that has the last segment set in transmit descriptor 0 (TDES0[29]). Now, if interrupt-on-completion (TDES0[30]) is set, the transmit interrupt (DMA_STAT [0]) is set, the next descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MFL transmit FIFO has reached either a programmable transmit threshold (EMAC_DMA0_OPMODE.TTC), or a full frame is contained in the FIFO. There is also an option for store-and-forward mode (EMAC_DMA0_OPMODE.TSF). Descriptors are released (OWN bit TDES0 [31] clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Either of the following conditions suspends transmit polling:

1. The DMA detects a descriptor owned by the application (TDES0 [31] = 0).

2. A frame transmission aborts when a transmit error due to underflow is detected. The appropriate transmit descriptor 0 (TDES0) bit is set.

If the second condition occurs, both of the abnormal interrupt summary ([15]) and transmit underflow bits ([5]) are set. The information is written to transmit descriptor 0, causing the suspension. If the DMA goes into a SUSPEND state due to the first condition, then both `EMAC_DMA0_STAT.NIS` and `EMAC_DMA0_STAT.TU` are set.

In both cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA.

The driver must explicitly issue a transmit poll demand command after rectifying the suspension cause. If the first condition occurs, the driver must give descriptor ownership to the DMA and then issue a poll demand command to resume the transfer.

Receive Descriptor

The ***Receive Descriptor Words*** figure shows the structure of the receive descriptor. It can have 32 bytes of descriptor data (8 DWORDs) when advanced time stamping or checksum is enabled.

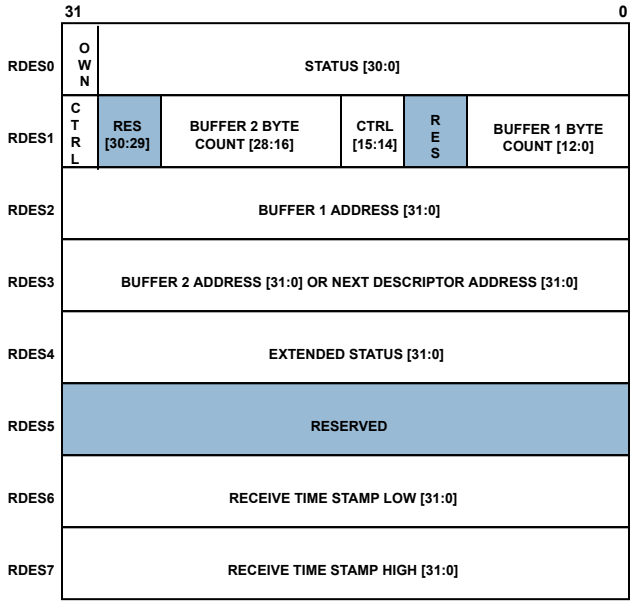

Figure 28-15: Receive Descriptor Words

Table 28-21: Receive Descriptor Fields (RDES0)

Bit	Name	Description
31	OWN	Ownership. When set, this bit indicates that the DMA of the EMAC subsystem owns the descriptor. When this bit is reset, this bit indicates that the application owns the descriptor. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM	Destination Address Filter Fail. When set, this bit indicates a frame that failed in the DA filter in the EMAC CORE.

Table 28-21: Receive Descriptor Fields (RDES0) (Continued)

Bit	Name	Description
29–16	FL	Frame Length. These bits indicate the byte length of the received frame that transferred to application memory (including CRC). This field is valid when last descriptor (RDES0[8]) is set and either the descriptor error (RDES0[14]) or overflow error bits are reset. This field is valid when last descriptor (RDES0[8]) is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that transferred for the current frame.
15	ES	Error Summary. Indicates the logical OR of the following bits. RDES0[1] = CRC Error RDES0[3] = RGMII Receive Error RDES0[4] = Watchdog Timeout RDES0[6] = Late Collision RDES0[7] = Time Stamp Available RDES4[4:3] = IP Header/Payload Error RDES0[11] = Overflow Error RDES0[14] = Descriptor Error. This field is valid only when the last descriptor (RDES0[8]) is set.
14	DE	Descriptor Error. When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers. The DMA does not own the next descriptor. The frame is truncated. This field is valid only when the last descriptor (RDES0[8]) is set.
13	Reserved	
13	SAF	Source Address Filter Fail. When set, this bit indicates that the SA field of frame failed the SA filter in the EMAC Core.
12	LE	Length Error. When set, this bit indicates that the actual length of the frame received and that the length or type field does not match. This bit is valid only when the frame type (RDES0[5]) bit is reset.
11	OE	Overflow Error. When set, this bit indicates that the received frame is damaged due to buffer overflow in MFL.
10	VLAN	VLAN Tag. When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the EMAC CORE.
9	FS	First Descriptor. When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame.
8	LS	Last Descriptor. When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	Time Stamp Available	When set, this bit indicates that a snapshot of the time stamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This functionality is valid only when the last descriptor bit (RDES0[8]) is set
6	LC	Late Collision. When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.

Table 28-21: Receive Descriptor Fields (RDES0) (Continued)

Bit	Name	Description
5	FT	Frame Type. When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for runt frames less than 14 bytes.
4	RWT	Receive Watchdog Timeout. When set, this bit indicates that the receive watchdog timer has expired while receiving the current frame. The current frame is truncated after the watchdog timeout.
3	Reserved	
3	RE	Receive Error. When set, this bit indicates that the RGMII PHY sent RGMII RXERR on RXCTL pin during frame reception. This error also includes the carrier extension error in RGMII and half-duplex mode.
2	DE	Dribble Bit Error. When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles).
1	CE	CRC Error. When set, this bit indicates that a Cyclic Redundancy Check (CRC) error occurred on the received frame. This field is valid only when the last descriptor (RDES0[8]) is set.
0	Extended Status Available	When set, this bit indicates that the extended status is available in descriptor word 4 (RDES4). This functionality is valid only when the last descriptor bit (RDES0[8]) is set.

Table 28-22: Receive Descriptor Fields 1 (RDES1)

Bit	Name	Description
31	DIC	Disable Interrupt on Completion. When set, this bit prevents setting the `EMAC_DMA0_STAT.RI` bit of the status register for the received frame ending in the buffer indicated by this descriptor. This activity, in turn, disables the assertion of the interrupt to the application due to RI for that frame.
30–29	Reserved	
28–16	RBS2	Receive Buffer 2 Size. These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4 (32-bit bus), even if the value of RDES3 (buffer2 address pointer) does not align to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set.
15	RER	Receive End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
14	RCH	Second Address Chained. When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a *do-not-care* value. RDES1[15] takes precedence over RDES1[14].
13	Reserved	
12–0	RBS1	Receive Buffer 1 Size. Indicates the size of the first data buffer in bytes. The buffer size must be a multiple of 4 (32-bit bus), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses buffer 2 or next descriptor depending on the value of RCH (Bit 14).

Table 28-23: Receive Descriptor Fields 2 (RDES2)

Bit	Name	Description
31–0	Buffer 1 Address Pointer	These bits indicate the physical address of buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value stores the start of frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame. However, the frame data shifts per the address pointer of the actual buffer. The DMA ignores RDES2[1:0] when the address pointer is to a buffer where the middle or last part of the frame is stored. (RDES2[1:0] corresponds to a bus width of 32).

Table 28-24: Receive Descriptor Fields 3 (RDES3)

Bit	Name	Description
31–0	Buffer 2 Address Pointer (Next Descriptor Address)	These bits indicate the physical address of buffer 2 when DMA uses a descriptor ring structure. If the second address chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. If RDES1[24] is set, the buffer (next descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0, corresponding to a bus width of 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value stores the start of frame. The DMA ignores RDES3[1:0] when the address pointer is to a buffer where the middle or last part of the frame is stored. (RDES3[1:0] corresponds to a bus width of 32.)

Table 28-25: Receive Descriptor Fields 4 (RDES4)

Bit	Name	Description
31-26	Reserved	
25	Layer 4 Filter Match	When set, this bit indicates that the received frame matches layer 4 filter fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match. • All enabled layer 3 and layer 4 filter fields match.
24	Layer 3 Filter Match	When set, this bit indicates that the received frame matches layer 3 IP address fields. This status is given only when one of the following conditions is true: • All enabled layer 3 fields match and all enabled layer 4 fields are bypassed. • All enabled filter fields match.
23-21	Reserved	
20-18	VLAN Tag Priority	These bits give the VLAN tag's user value in the received packet. These bits are valid only when the RDES4[16] and RDES4[17] are set.
17	AV Tagged Packet Received	When set, this bit indicates that an AV tagged packet is received. Otherwise, this bit indicates that an untagged AV packet is received. This bit is valid when RDES4[16] is set.
16	AV Packet Received	When set, this bit indicates that an AV packet is received.
15	Reserved	

Table 28-25: Receive Descriptor Fields 4 (RDES4) (Continued)

Bit	Name	Description
14	Timestamp Dropped	When set, this bit indicates that the time stamp is captured for this frame but dropped in the MFL RxFIFO because of overflow.
13	PTP Version	When set, this bit indicates that the received PTP message has the IEEE 1588 version 2 format. When reset, it has the version 1 format. This description is valid only if the message type (RDES4[11:8]) is non-zero.
12	PTP Frame Type	When set, this bit indicates that the PTP message transfers directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message transfers over UDP-IPv4 or UDP-IPv6. Bits 6 and 7 have the information on IPv4 or IPv6.
11–8	Message Type	These bits are encoded to give the type of the message received. 0000 = No PTP message received 0001 = SYNC (all clock types) 0010 = Follow_Up (all clock types) 0011 = Delay_Req (all clock types) 0100 = Delay_Resp (all clock types) 0101 = Pdelay_Req (in peer-to-peer transparent clock) or Announce (in ordinary or boundary clock) 0110 = Pdelay_Resp (in peer-to-peer transparent clock) or Management (in ordinary or boundary clock) 0111 = Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) or Signaling (for ordinary or boundary clock) 1xxx - Reserved
7	IPv6 Packet Received	When set, this bit indicates that the received packet is an IPv6 packet.
6	IPv4 Packet Received	When set, this bit indicates that the received packet is an IPv4 packet.
5	IP Checksum Bypassed	When set, this bit indicates that the checksum offload engine is bypassed.
4	IP Payload Error	When set, this bit indicates that the 16-bit IP payload checksum that the core calculated does not match the corresponding checksum field in the received segment. (For example: the TCP, UDP, or ICMP checksum). The bit is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field.
3	IP Header Error	When set, this bit indicates that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes. Or, it indicates that the IP datagram version is not consistent with the Ethernet type value.

Table 28-25: Receive Descriptor Fields 4 (RDES4) (Continued)

Bit	Name	Description
2–0	IP Payload Type	These bits indicate the type of payload encapsulated in the IP datagram processed by the receive checksum offload engine (COE). The COE also sets these bits to 2'b00 when it does not process the payload of the IP datagram. It does not process the payload because of an IP header error or fragmented IP. 000 = Unknown or did not process IP payload 001 = UDP 010 = TCP 011 = ICMP 1xx = Reserved

Table 28-26: Extended Receive Descriptor Fields 4 (RDES4)

Bit	Name	Description
31-26	Reserved	
25	Layer 4 Filter Match	When set, this bit indicates that the received frame matches layer 4 filter fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match. • All enabled layer 3 and layer 4 filter fields match.
24	Layer 3 Filter Match	When set, this bit indicates that the received frame matches layer 3 IP address fields. This status is given only when one of the following conditions is true: • All enabled layer 3 fields match and all enabled layer 4 fields are bypassed. • All enabled filter fields match.
23-21	Reserved	
20-18	VLAN Tag Priority	These bits give the VLAN tag's user value in the received packet. These bits are valid only when the RDES4[16] and RDES4[17] are set.
17	AV Tagged Packet Received	When set, this bit indicates that an AV tagged packet is received. Otherwise, this bit indicates that an untagged AV packet is received. This bit is valid when RDES4[16] is set.
16	AV Packet Received	When set, this bit indicates that an AV packet is received.
15	Reserved	
14	Timestamp Dropped	When set, this bit indicates that the timestamp was captured for this frame but got dropped in the MFL RxFIFO because of overflow.

Table 28-27: Receive Descriptor Fields 6 (RDES6)

Bit	Name	Description
31–0	RTSL	Receive Frame Time Stamp Low. The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame. The status bit (RDES0[8]) indicates the last descriptor.

Table 28-28: Receive Descriptor Fields 7 (RDES7)

Bit	Name	Description
31–0	RTSH	Receive Frame Time Stamp High. The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame. The status bit (RDES0[8]) indicates the last descriptor.

EMAC DMA Receive Process

The following sections describe how the receive process for direct memory access works on the EMAC controller.

- Receive Frame Processing
- Receive Descriptor Acquisition
- Receive Process Suspended

The reception process for DMA works as follows:

1. The application sets up receive descriptors (RDES0–RDES3) and sets the OWN bit (RDES0 [31]).
2. Once the `EMAC_DMA0_OPMODE.SR` bit is set, the DMA enters the run state. While in the run state, the DMA attempts to acquire free descriptors by polling the receive descriptor list. If the fetched descriptor is not free (the application owns the descriptor), the DMA enters the suspend state and jumps to Step 9.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the data buffers of the acquired descriptor.
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor. If the DMA does not own the next fetched descriptor and the frame transfer is not complete, the DMA sets the descriptor error bit in the RDES0. (The bit is set unless flushing is disabled.) The DMA closes the current descriptor (clears the OWN bit). The DMA marks it as intermediate by clearing the last segment (LS) bit in the RDES0 value (marks it as last descriptor if flushing is not disabled). The DMA then proceeds to Step 8. If the DMA owns the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to RDES2 and RDES3 of the current descriptor. The DMA then takes the status of the receive frame from the MFL and writes the status word to RDES0 of the current descriptor. The OWN bit is cleared and the last segment bit is set.

8. The receive engine checks the OWN bit of the latest descriptor. If the host owns the descriptor (OWN bit is 0), the EMAC_DMA0_STAT.RU bit is set. The DMA receive engine enters the suspended state (Step 9). If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the receive engine enters the suspend state, partial frames are flushed from the receive FIFO (programs control flushing using the EMAC_DMA0_OPMODE.DFF bit).
10. The receive DMA exits the suspend state when a receive poll demand is given or the start of next frame is available from the receive FIFO of the MFL. The engine proceeds to Step 2 and refetches the next descriptor.

Receive Frame Processing

The EMAC transfers the received frames to the application memory only when:

- the frame passes the address filter subblock, and
- the frame size is greater than or equal to configurable threshold bytes set for the receive FIFO of MFL, or
- the complete frame is written to the FIFO in store-and-forward mode.

If the frame fails the address filtering, the EMAC block drops the frame (unless the EMAC_MACFRMFILT.RA bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the receive FIFO.

After receiving 64 bytes (configurable threshold), the MFL block requests that the DMA block begin transferring the frame data to the receive buffer pointed to by the current descriptor. The DMA sets first descriptor (RDES0 [9]) after the SCB becomes ready to receive the data (if DMA is not fetching transmit data from the application). The descriptors release when the OWN (RDES [31]) bit is reset to 0. The bit is reset either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both the last descriptor (RDES [8]) and the first descriptor (RDES [9]) are set.

The DMA fetches the next descriptor, sets the last descriptor (RDES [8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then, the DMA sets the EMAC_DMA0_STAT.RI bit. The same process repeats unless the DMA encounters a descriptor the application owns. If this encounter occurs, the receive process sets the EMAC_DMA0_STAT.RU bit and then enters the suspend state. The position in the receive list is retained.

Receive Descriptor Acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted when any of the following conditions is satisfied:

- The EMAC_DMA0_OPMODE.SR bit is set immediately after being placed in the run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller completes frame reception, but the current receive descriptor is not yet closed.
- The receive process suspends because of an application-owned buffer (RDES0 [31] = 0) and a new frame is received.
- A receive poll demand issues.

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the application memory. If the DMA now owns the descriptor, the receive process reenters the run state and starts frame reception. If the application still owns the descriptor, by default, the DMA discards the current frame at the top of the receive FIFO and increments the missed frame counter. If more than one frame is stored in the receive FIFO, the process repeats.

Avoid the discarding or flushing of the frame at the top of the receive FIFO by setting the `EMAC_DMA0_OPMODE.DFF` bit. In such conditions, the receive process sets the receive buffer unavailable status and returns to the suspend state.

OWN Bit (Ownership) Semaphore

Usage or ownership of the transmit or receive descriptor between the application and EMAC is mutually exclusive. While the EMAC accesses the descriptor, the application cannot modify it. Conversely, while the host updates the descriptor, the EMAC cannot use the content of the descriptor. This functionality is implemented through the OWN bit in the transmit or receive descriptor, acting as a semaphore to prevent multiple, simultaneous access to the descriptors.

The following example is based on a usage case of 4 WORDs enabled for descriptors. A chain structure configuration is assumed. (The `EMAC_DMA0_BUSMODE.ATDS` bit is not set). However, the explanation of the `OWN` bit semaphore remains consistent irrespective of any particular mode of operation.

1. Transmit OWN Bit:
    - TDES0 – TDES3 words implement the transmit descriptors. TDES0 [31] is defined as the OWN bit. When TDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer addresses, by updating TDES0 through TDES3.
    - To release ownership of the descriptor to the EMAC, the application sets the transmit `OWN` bit, TDES0 [31], to 1. TDES0 [31] = 1 indicates that the descriptor is ready for the EMAC to use. DMA reads the descriptors, then fetches the data for transmission from the buffer locations pointed to by the transmit descriptors (TDES2 and TDES3). When either the last data buffer is empty or the end-of-frame is reached, DMA clears the TDES0 [31] bit to 0. Now, the transmit descriptor releases to the application for updates.
2. Receive `OWN` Bit:
    - RDES0 – RDES3 words implement the receive descriptors. RDES0 [31] is defined as the `OWN` bit. When RDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer locations for writing the received data, by updating RDES0 through RDES3. To give ownership of the descriptor to the EMAC, the host sets the receive `OWN` bit, RDES0 [31], to 1.
    - RDES0 [31] = 1 indicates that the descriptor is ready for use by the EMAC. DMA reads the descriptors, then writes the received data to the buffers with locations pointed to by the receive descriptors (RDES2

and RDES3). When either the last data buffer is full or the end-of-frame is reached, DMA clears the RDES0 [31] bit to 0. Now, the receive descriptor releases to the application for updates

Application Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on the start address alignment. The start address for the buffers aligns to any of the 4 bytes. However, the DMA always initiates transfers with the address aligned to the bus width with dummy data for the byte lanes not required. This alignment typically happens during the transfer of the beginning or end of an Ethernet frame.

Example for Buffer Read

If the transmit buffer address is 0x0002 and 15 bytes must transfer, the DMA reads 5 full words (5 x 32-bit data) from address 0x0000. However, when transferring data to the EMAC transmit FIFO, the extra bytes (the first 2 bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always transfers a full 32-bit data to the transmit FIFO, unless it is the end-of-frame.

Example for Buffer Write

If the receive buffer address is 0x0002 and 15 bytes of a received frame must transfer, the DMA writes 5 full words (5 x 32-bit data) to address 0x0000. However, the first 2 bytes of first transfer and the last 3 bytes of the third transfer have dummy data.

Buffer Size Calculations

The DMA engines do not update the size fields in the transmit and receive descriptors alone. The DMA updates only the status fields (RDES0 and TDES0) of the descriptors. The driver must perform the size calculations. The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the EMAC CORE. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), the DMA marks the last transfer from that data buffer as the end-of frame to the EMAC.

The receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MFL. If a descriptor is not marked as last (LS bit of RDES0), then the buffers of the descriptor are full. The amount of valid data in a buffer is its buffer size field minus the data buffer pointer offset, when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer aligns to the data bus width. If a descriptor is marked as last, then the buffer cannot be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must:

- Read the frame length (FL bits of RDES0 [29:16]), and
- Subtract the sum of the buffer sizes of the preceding buffers in the frame

The receive DMA always transfers the start of next frame with a new descriptor.

EMAC FIFO Layer (EMAC MFL)

The MAC FIFO layer provides FIFO memory to buffer and regulates the frames between the application system memory and the EMAC CORE. It also allows the transfer of data between the application clock domain and the

EMAC clock domains. The MFL layer has transfer controllers for each direction, called the transmit controller (TxFIFO) and the receive controller (RxFIFO). The datapath for both directions is 32-bit wide and each controller has a dedicated FIFO.

The EMAC0 transmit FIFO size is fixed to 2048 bytes. The EMAC0 receive FIFO size is fixed to 2048 bytes.

FIFO Layer Transmit Path

The DMA engine controls all transactions for the transmit path with the application. Ethernet frames read from the system memory are pushed into the FIFO by the DMA. The frame is then popped out and transferred to the EMAC CORE when triggered. When the end-of-frame transfers, the status of the transmission is taken from the EMAC CORE and transferred back to the DMA. The FIFO fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory through the SCB interface.

When the DMA enables the `EMAC_DMA0_OPMODE.OSF` bit, the MFL receives the second frame into the FIFO while transmitting the first frame. When the first frame has transferred, the status is sent to DMA. If the DMA has already completed sending the second packet to the MFL, it waits for the status of the first packet before proceeding to the next frame.

The following are the modes of operation for FIFO transactions.

1. Threshold mode. When the number of bytes in the FIFO crosses the configured threshold level, the data is ready to be popped out and forwarded to the EMAC CORE. The data is also ready when the end-of-frame is written before the threshold is crossed. The DMA uses the `TTC` bits of the DMA bus mode register to configure the threshold level.
2. Store-and-Forward mode. In this mode, the MFL pops the frame towards the EMAC CORE after a complete frame is stored in the FIFO. If the TX FIFO size is smaller than the Ethernet frame for transmission (such as a jumbo frame), then the frame forwards in two cases. The TX FIFO is almost full or the requested FIFO does not have space to accommodate the requested burst-length. Therefore, the FIFO read controller never stalls in store-and-forward mode even if the Ethernet frame length is bigger than the TX FIFO depth.

   The FIFO threshold in the store-and-forward mode is given by the following formula.

   DataWidth = 32 bits and PBL = Burst Length programmed through the DMA_BUSMODE register.

   NOTE: To avoid occurrences of a TX underflow event when using the store-and-forward mode, or in other words, to ensure that the entire frame is stored in the FIFO before the MFL pops the frame towards the EMAC CORE for transmission, ensure that the FIFO threshold (calculated with the above formula) is greater than the packet size. The PBL needs to be programmed accordingly.

Transmit FIFO and Half-Duplex Retransmissions

While a frame transfers from the FIFO, a collision event can occur on the EMAC line interface in half-duplex mode. The EMAC then indicates a retry attempt to the MFL. The EMAC gives the status before the end-of-frame transfers from MFL. Then, the MFL enables the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes pop out of FIFO, the FIFO controller frees up that space. The controller makes it available to the DMA to push in more data. Retransmission is not possible after this threshold is crossed or when the EMAC CORE indicates a late-collision event.

Transmit FIFO Flush Operation

The EMAC provides control to the software to flush the transmit FIFO in the MFL layer using the `EMAC_DMA0_OPMODE.FTF` bit. The flush operation is immediate. The MFL clears the transmit FIFO and the corresponding pointers to the initial state. It clears the FIFO and pointers even if it is in the middle of transferring a frame to the EMAC CORE. The data that the MAC transmitter has already accepted is not flushed. The data is scheduled for transmission and results in underflow. The transmit FIFO does not complete the transfer of the rest of the frame. As in all underflow conditions, a runt frame is transmitted and observed on the line. The status of the frame is marked with both underflow and frame flush events (TDES0 bits 13 and 1).

The MFL also stops accepting any data from the application (DMA) during the flush operation. The MFL generates and transfers transmit status words to the application for the number of frames flushed inside the MFL (including partial frames). Frames that completely flush in the MFL have the status bit for frame flush (TDES0 bit 13) set. The MFL completes the flush operation when the application (DMA) accepts all of the status words for the frames that flushed. The MFL then clears the transmit FIFO flush control register bit. The MFL starts accepting new frames from the application (DMA).

FIFO Layer Receive Path

The receive controller operates in the following sequence:

1. When the EMAC CORE receives a frame, it pushes in data with the frame start and end indicators. The MFL accepts the data and pushes it into the FIFO.
2. The receive controller takes the data out of the FIFO and sends it to the DMA.
    - Threshold mode (default). This mode is configured using `EMAC_DMA0_OPMODE.RTC`. When the FIFO receives 64 bytes or a full packet of data, the receive controller pops out the data and indicates its availability to the DMA. Some error frames cannot be dropped, because the error status is received at the end-of-frame. By this time, the start of that frame has already been read out of the FIFO.
    - Rx FIFO Store-and-Forward mode. This mode is configured using `EMAC_DMA0_OPMODE.RSF`. A frame is read out only after being written completely into the receive FIFO. In this mode, all error frames are dropped such that only valid frames are read out and forwarded to the application. Error frames are dropped when the EMAC CORE is configured for this feature.
3. After the end-of-frame transfers, the status word from the EMAC CORE is also the pushed FIFO. When the status of a partial frame due to overflow is given out, the frame length field in the status word is not valid.

Receive FIFO Multi-Frame Handling

Since the status is available immediately following the data, the MFL stores any number of frames into the FIFO, as long as it is not full.

Receive FIFO Error Handling

If the MFL Rx FIFO is full before it receives the end of frame data from the EMAC, the DMA declares an overflow condition. The whole frame (including the status word) drops. The overflow counter in the DMA (overflow counter-register) increments. This activity occurs even if the EMAC_DMA0_OPMODE.FEF bit is set. If the start address of such a frame has already transferred, the rest of the frame drops. A dummy end of frame is written to the FIFO along with the status word. The status indicates a partial frame due to overflow. In such frames, the frame length field is invalid.

The MFL receive control logic can filter error and undersized frames using the EMAC_DMA0_OPMODE.FEF and EMAC_DMA0_OPMODE.FUF bits. If the start address of the frame has already transferred to the Rx FIFO read controller, that frame is not filtered. The start address of the frame transfers to the read controller after the frame crosses the receive threshold (set by the EMAC_DMA0_OPMODE.RTC bits).

If the MFL receive FIFO is configured for store-and-forward mode, it can filter and drop all error frames.

EMAC CORE

The EMAC CORE is the lowest block in the EMAC peripheral and it performs all operations with the external world (PHY chip). It has independent transmit and receive modules. The modules interact with the EMAC FIFO layer at one end and interacts with the PHY chip through the RMII interface at the other end. Both modules have several subblocks which are discussed in subsequent sections.

Transmission is initiated when the MFL (FIFO layer) pushes in data with the start of frame. The CORE then transmits to the reduced media-independent interface. After the end of frame transfers out, the CORE gives the status of the transmission back to the MFL. The MFL forwards the transmission to the application through DMA.

A receive operation initiates when the EMAC detects an SFD on the RMII/RGMII. The CORE strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame drops in the core when it fails the address filter.

NOTE: The term *CORE* (written in capitals) refers to the internal block of Ethernet peripheral. Do not confuse the term with the *processor core*.

Table 28-29: EMAC CORE Related Registers

Register Name	Description
MAC Configuration[*1]	Establishes receive and transmit operating modes including: • Watchdog, Jabber, and Jumbo frame sizes • Inter Frame Gap • Speed Control – 10/100/1000 Mbps • Full or Half Duplex • Loopback Mode • Checksum Offload • Enabling Tx or Rx Engines

Table 28-29: EMAC CORE Related Registers (Continued)

Register Name	Description
MAC Frame Filter	Contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as pass bad frames and pass control frames.
Hash Table High/Low[1]	A 64-bit hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame passes through the CRC logic. The upper 6 bits of the CRC register index the contents of the hash table.
SMI Address[1]	Controls the management cycles to the external PHY through the Station Management interface. The register also includes a field to program the frequency of MDC.
SMI Data[1]	Stores write data for the PHY register at the address specified in SMI Address register. This register also stores read data from the PHY register at the address specified by SMI address register.
Flow Control[1]	Controls the generation and reception of the control (pause command) frames by the flow control module of the EMAC. The fields of the control frame are selected as specified in the 802.3x specification. The EMAC uses the pause time value from this register in the pause time field of the control frame. The host must make sure that the activate bit is cleared before writing to the register.
VLAN Tag[1]	Contains the IEEE 802.1Q VLAN tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (length or type) with 16.h8100. The following 2 bytes are compared with the VLAN tag. If a match occurs, it sets the received VLAN bit in the receive frame status. The legal length of the frame increases from 1518 bytes to 1522 bytes.
Debug	Provides the status of all main modules of the transmit and receive datapaths and the FIFOs. An all-zero status indicates that the MAC core is in idle state (and FIFOs are empty) and no activity exists in the datapaths.
Interrupt Status	The contents of this register identify the events in the EMAC-CORE that can generate MMC and PTP-related interrupts.
Interrupt Mask	Enables the program to mask the interrupt signal because of the corresponding PTP event in the interrupt status register.
MAC Address0 High/Low[1]	Holds the upper or lower 16 bits of the MAC address of the station. The first DA byte that is received on the RMII interface corresponds to the LS byte (bits [7:0]) of the MAC address low register. For example, if 0x112233445566 is received (0x11 is the first byte) on the RMII as the destination address, then the macaddress0 register [47:0] is compared with 0x665544332211.
Operation Mode[1]	

*1 There must not be any further writes to these registers until the first write updates. Otherwise, the second write operation is not updated properly. For correct operation, the delay between two writes to the same register location must be at least 8 cycles of 50MHz RMII REFCLK.

NOTE: Refer to the “Register Description” section for the detailed bit-level explanation of the registers.

EMAC CORE Transmission Engine

The following modules constitute the transmission function (transmission engine components) of the EMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Checksum Offload Engine (TCOE)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module (TBU)

This module interfaces the transmit path of the EMAC CORE with the MAC Layer FIFO interface. This module outputs the transmit status to the application at the end of normal transmission or collision.

Transmit Frame Controller Module (TFC)

The transmit frame controller regulates frames as well as converts the 32-bit input data into an 8-bit stream.

When the number of bytes received from the application falls below 60 (DA+SA+LT+DATA), the state machine automatically appends zeros to the transmitting frame. The state machine makes the data length exactly 46 bytes to meet the requirement for minimum data field of IEEE 802.3. The EMAC module can also be programmed to not append any padding.

The frame controller receives the computed CRC and appends it as the FCS field to the data transmitting out. When the EMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC. However, when the EMAC is programmed to append pads for frames (DA+SA+LT +DATA) less than 60 bytes, then the CRC is always appended at the end of padded frame.

Transmit Checksum Offload Engine (TCOE)

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the EMAC has a checksum offload engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

NOTE: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement, this function is enabled only when the transmit FIFO configuration is for store-and-forward mode. (The `EMAC_DMA0_OPMODE.TSF` bit is set.) If the MAC configuration is for threshold (cut-through) mode, the transmit COE is bypassed.

NOTE: Programs must make sure that the transmit FIFO is deep enough to store a complete frame before that frame transfers to the EMAC CORE transmitter. The program must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):

FIFO depth – PBL – 3 FIFO locations, where PBL is the programmed burst-length in the DMA bus mode register.

IP Header Checksum

In IPv4 datagrams, the 16-bit header checksum field indicates the integrity of the header fields (bytes 11 and 12 of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet type field of the frame has the value 0x0800 and the version field of the IP datagram has the value 0x4. The checksum field of the input frame is ignored during calculation and replaced with the calculated value.

The IP header error status bit in transmit descriptor word TDES0 indicates the result of this IP header checksum calculation. The status bit is set whenever the values of the Ethernet type field and the IP header version field are not consistent. Or, the status bit is set when the Ethernet frame does not have enough data, as indicated by the IP header length field. In other words, this bit is set when an IP header error is asserted under the following circumstances.

For IPv4 datagrams:

- The received Ethernet type is 0x0800, but the version field of the IP header is not equal to 0x4.
- The IPv4 header length field indicates a value less than 0x5 (20 bytes).
- The total frame length is less than the value given in the IPv4 header length field.

For IPv6 datagrams:

- The Ethernet type is 0x86dd but the IP header version field is not equal to 0x6.
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding header length field in an extension header) is received.

If the COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload.

NOTE: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

TCP/UDP/ICMP Checksum

The TCP/UDP/ICMP checksum engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

NOTE: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

NOTE: For non-TCP/UDP/ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

NOTE: For ICMP-over-IPv4 packets, the checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum can be inserted into the packet.

NOTE: This engine does not process fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an encapsulated security payload), and IPv6 frames with routing headers. The checksum engine bypasses the checksum insertion for such frames even if the checksum insertion is enabled.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two ways.

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the checksum field of the input frame. This engine includes the checksum field in the checksum calculation, and then replaces the checksum field with the final calculated checksum.
- The engine ignores the checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

The status bit for the payload checksum error in the transmit descriptor word TDES0 indicates the result of this operation. The checksum engine sets the status bit for the payload checksum error when:

- The checksum engine detects that the frame has been forwarded to the MAC transmitter engine in the store-and-forward mode, *and*
- The end of frame (EOF) has not been written to the FIFO, *or*
- The packet ends before the number of bytes indicated by the payload length field in the IP header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When the engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Transmit checksum offloading is enabled by setting the CIC bits [23:22] of TDES0 word in the transmit descriptor.

Transmit Protocol Engine Module (TPE)

The transmit protocol engine consists of a state-machine that controls the protocol-level operation of Ethernet frame transmission. The module performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates carrier extension in half-duplex mode (only in RGMII mode)
- Supports frame bursting in half-duplex mode (only in RGMII mode)
- Generates jam pattern in half-duplex mode
- Contains time stamp snapshot logic for IEEE 1588 support
- Jabber timeout
- Flow control for half-duplex mode (back pressure)
- Generates transmit frame status

When a new frame transmission is requested, the protocol engine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 10101010 pattern. The SFD is defined as 1 byte of 10101011 pattern.

The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps and 4096 bit times for 1000 Mbps). The jam pattern generation is applicable only to half-duplex mode, not to full-duplex mode. A collision can occur any time from the beginning of the frame to the end of the CRC field. When a collision happens, the state machine sends a 32-bit jam pattern of 0x55555555 on the RMII/RGMII. The pattern informs all other stations that a collision has occurred. If the collision happens during the preamble transmission phase, it completes the transmission of preamble and SFD and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, it sends a 32-bit jam pattern. It also sets the late collision bit in the transmit frame status.

In RGMII half-duplex mode (1,000 Mbps), the transmit state machine ensures that all valid carrier events exceed a slot time of 4,096 bit times. To accomplish this, any transmit frame shorter than 512 bytes from the TFC module is extended using a carrier extension. This is signaled to the PHY using RGMII_TXCTL pin and sending 0x00 through RGMII_TXD.

The module maintains a jabber timer to cut off the transmission of Ethernet frames when the TFC module transfers more than 2,048 (default) bytes. The timeout changes to 10,240 bytes when the jumbo frame is enabled.

The transmit state machine uses the deferral mechanism for the flow control (back pressure) in half-duplex mode. When the application asks to stop receiving frames, the module sends a jam pattern of 32 bytes. It sends the pattern whenever it senses a reception of a frame. Transmit flow control must be enabled. This activity results in a collision and the remote station backs off.

The application can request a flow control signal by setting the `EMAC_FLOWCTL.FCBBPA` bit. If the application requests a frame transmission, then it is scheduled and transmitted even when the back pressure is activated. If the back pressure is activated for a long time, then the remote stations abort their transmissions due to excessive collisions. (For example, a long time is when more than 16 consecutive collision events occur.)

If PTP time stamping is enabled for the transmit frame, this block takes a snapshot of the PTP system time when the SFD is put onto the transmit bus.

Transmit Scheduler Module (STX)

The transmit scheduler is responsible for scheduling the frame transmission on the RMII RGMII/MII. The two major functions of this module are:

- Maintain the inter-frame gap between two transmitted frames.
- Follow the truncated binary exponential back-off algorithm for half-duplex mode.

The scheduler maintains an idle period of the configured inter-frame gap (`EMAC_MACCFG.IFG` bits) between any two transmitted frames. The scheduler starts its IFG counter when the carrier signal of the reduced media-independent interface goes inactive. In half-duplex mode and when IFG is configured for 96-bit times, the scheduler follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The module resets its IFG counter when a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the

carrier is detected during the final one third of the IFG interval, the scheduler continues the IFG count and enables the transmitter after the IFG interval.

Transmit CRC Generator Module (CTX)

The transmit CRC generator module generates the CRC for the FCS field of the Ethernet frame (DA + SA + LT + DATA + PAD).

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The following polynomial defines the encoding:

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1.

Transmit Flow Control Module (FTX)

The transmit flow control module generates pause frames and transmits them to the frame controller as necessary, in full-duplex mode. The application can request the flow control module to send a pause frame by setting the `EMAC_FLOWCTL.FCBBPA` bit.

If the application has requested flow control, the flow control module generates and transmits a single pause frame. The value of the pause time in the generated frame contains the programmed pause time value configured using the `EMAC_FLOWCTL.PT` bit. The module can extend the pause or end the pause prior to the time specified in the previously transmitted pause frame. To change the pause, the application must request another pause frame transmission after programming the `EMAC_FLOWCTL.PT` bit with an appropriate value.

If the flow control signal goes inactive prior to the sampling time, the flow control module transmits a pause frame with zero pause time. This event indicates to the remote end that the receive buffer is ready to receive new data frames.

Source Address, VLAN, and CRC Insertion, Replacement, or Deletion

The MAC supports the following functions for transmit frames:

- Source address insertion or replacement
- VLAN insertion, replacement, or deletion
- CRC replacement

Source Address Insertion or Replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for transmit frames:

- Insert the content of the MAC address registers in the SA field.
- Replace the content of the SA field with the content of the MAC address registers.

The software can enable the SA insertion or replacement feature for all transmit frames or selective frames.

- To enable SA insertion or replacement feature for all frames, program bits[30:28] of the MAC Configuration register.

- To enable the SA insertion or replacement feature for selective frames, program the SA insertion control field (TDES1 Bits [31:29]) in the first transmit descriptor of the frame. When bit 31 of TDES1 is set, the SA insertion control field indicates insertion or replacement by MAC address1 registers. When bit 31 of TDES1 is reset, it indicates insertion or replacement by MAC address 0 registers. If MAC address1 registers are not enabled, then EMAC uses MAC address0 registers for insertion or replacement. The choice is not based on the value of the most significant bit of the SA insertion control field.

When SA insertion is enabled, the application ensures that the frames sent to the MAC do not have the SA field. This functionality is because the MAC does not check the presence of SA field in the transmit frame. MAC inserts the content of the MAC address registers in the SA field. Similarly, when SA replacement is enabled, the application ensures that frames sent to the MAC have the SA field. The MAC replaces the 6 bytes, following the destination address field in the transmit frame, with the content of the MAC address registers.

VLAN Insertion, Replacement, or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for transmit frames:

- Insert or replace the VLAN type field (C-VLAN or S-VLAN indicated by bit 19 (CSVL) of VLAN tag inclusion or replacement register and VLAN tag field in the transmit frame with bit [15:0], VLT, of VLAN tag inclusion or replacement register.
- Delete the VLAN type and VLAN tag fields in transmit frame.

The software can enable the VLAN insertion, replacement, or deletion feature for all transmit frames or selective frames. To enable this function for all transmit frames, program Bits[17:16] of the VLAN Tag Inclusion or Replacement register. To enable this function for selective, program the VLAN insertion control field (TDES0 Bits [19:18]) in the first transmit descriptor of the frame. When VLAN replacement or deletion is enabled, the MAC checks the presence of the VLAN type field (0x8100 or 0x88a8), after the Destination Address (DA) and SA fields, in the transmit frame. The replace or delete operation does not occur when the VLAN type field is not detected in the 2 bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN type field in the transmit frame. MAC inserts the VLAN type and VLAN tag fields.

CRC Replacement

The software can use the CRC replacement feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on per-frame basis. To enable the CRC replacement feature, program the CRC replacement control field (bit 24 of transmit descriptor word 0 (TDES0)) in the first transmit descriptor of the frame.

NOTE: This feature is valid only when disable CRC control (bit 27 in TDES0) is enabled. The software provides the FCS field in the transmit frame. If SA or VLAN insertion control is enabled, the MAC appends or replaces the FCS field with the computed CRC when Disable CRC Control is enabled or disabled, respectively.

The ***CRC Replacement*** table shows how CRC replacement is performed based on the values of bit 27 (DC) and bit 24 (CRCR) of transmit descriptor word 0 (TDES0).

Table 28-30: CRC Replacement

DC	CRCR	Description
0	x	Append CRC. When DC = 0, the MAC appends the computed CRC irrespective of the CRCR setting.
1		Replace CRC
1	0	No operation (User has appended the CRC)

Source Address Filtering

The ***Source Address Filtering*** table provides filtering possibilities for the source address using the EMAC AFM module. The MAC receive frame filter register (`EMAC_MACFRMFILT`) contains these bits.

Table 28-31: Source Address Filtering

Frame Type	SA Filter Operation			Result
	PR	SAIF	SAF	
Unicast	1	X	X	Pass all frames
	0	0	0	Pass on perfect or group filter match but do not drop failing frames
	0	1	0	Fail on perfect or group filter match but do not drop frame
	0	0	1	Pass on perfect or group filter match and drop failing frames
	0	1	1	Fail on perfect or group filter match and drop failing frames

EMAC CORE Reception Engine

The following are the functional blocks (reception engine components) in the receive path of the EMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Packet Controller Module (RPC)
- Receive Flow Control Module (FRX)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module (RPE)

The receive protocol engine is a state-machine that strips the preamble, SFD, and carrier extension (in 1000 Mbps half-duplex mode) of the received frame. Once the receive data valid signal (`ETH0_CRS`) signal of RMII or RXCTL signal of RGMII becomes active, the protocol engine begins hunting for the SFD field from the receive modifier

logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, it begins sending the data of the Ethernet frame to the frame controller, beginning with the first byte following the SFD (destination address).

NOTE: According to the IEEE 802.3 Ethernet specifications, the EMAC receiver does not need to look or check for the preamble pattern. It has to wait only for the SFD pattern to identify the start of a frame. Then the EMAC receiver accepts a frame even when no preamble is received before the SFD pattern.

If PTP time stamping is enabled, the RPE takes a snapshot of the PTP system time when detecting any SFD of the frame on the reduced media-independent interface. Unless the MAC filters out and drops the frame, this time stamp passes on to the application

The protocol engine also decodes the length or type field of the receiving Ethernet frame. The state machine sends the data of the frame up to the count specified in the length or type field if these conditions are met:

- The length or type field is less than 0x600
- The MAC is programmed for the auto CRC or PAD stripping option

It then starts dropping bytes (including the FCS field).

If the length or type field is greater than or equal to 0x600, the protocol engine sends all received Ethernet frame data to the frame controller. The transfer does not depend on the value of the programmed auto-CRC strip option.

The EMAC is programmed with the watchdog timer enabled (default setting). In this configuration, frames above 2,048 (10,240 if jumbo frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the protocol engine. Set the `EMAC_MACCFG.WD` bit to disable this feature. However, even when the watchdog timer is disabled, frames greater than 16 KB are cut off and a watchdog timeout status is issued.

The EMAC supports loopback of transmitted frames onto its receiver. By default, the EMAC loopback function is disabled. Set the `EMAC_MACCFG.LM` bit to enable the function.

At the end of every received frame, the protocol engine generates received frame status and sends it to the frame controller. Control, missed frame, and filter fail status are added to the receive status in the frame controller.

Receive CRC Module (CRX)

The receive CRC module checks for any CRC errors in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the destination address field through the FCS field (DA+SA+LT+DATA+PAD+FCS). The following generating polynomial defines the encoding.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

Irrespective of the auto pad or CRC strip, the CRC module receives the entire frame to compute the CRC check for received frame.

Receive Frame Controller Module (RFC)

The main functions of the frame controller are:

- Converting the 8-bit stream data to 32-bit data

- Frame filtering
- Attaching the calculated IP checksum
- Updating the receive status

If the EMAC_MACFRMFILT.RA bit is set, the RFC module initiates the data transfer as soon as possible. At the end of the data transfer, the frame controller sends out the received frame status that includes the address filtering pass or fail status.

If the EMAC_MACFRMFILT.RA bit is reset, the frame controller performs frame filtering based on the destination or source address. (The application still must perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, for example.) After receiving the destination or source address bytes, the frame controller checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFM, the frame is dropped and not transferred to the application.

Receive Flow Control Module (FRX)

The receive flow controller detects the receiving pause frame and pauses the frame transmission for the delay specified within the received pause frame. The flow controller is enabled only in full-duplex mode. The EMAC uses the EMAC_FLOWCTL.RFE bit to enable or disable the function for pause frame detection.

Once the receive flow control is enabled, the flow controller begins monitoring the received frame destination address for any match with the multicast address of the control frame (0x0180C2000001). If a match is detected, it indicates to the frame controller, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether to transfer the received control frame to the application, based on the EMAC_MACFRMFILT.PCF bit setting.

The receive flow controller also decodes the type, opcode, and pause timer field of the receiving control frame. The flow controller requests the MAC transmitter pause the transmission of any data frame.

- If the byte count of the frame status indicates 64 bytes, ***and***
- If there is no CRC error

The transmission is paused for the decoded pause time value, multiplied by the slot time (64-byte times). Meanwhile, if another pause frame is detected with a zero pause time value, the module resets the pause time and gives another pause request to the transmitter. The module does not generate a pause request to the transmitter:

- If the received control frame does not match the type field (0x8808), opcode (0x00001), or byte length (64 bytes), ***or***
- If there is a CRC error

For a pause frame with a multicast destination address, the frame controller filters the frame based on the address match from the flow controller. For a pause frame with a unicast destination address, the filtering in the FRX module depends on:

- If the destination address matched the contents of the MAC address register 0 (EMAC_ADDR0_HI or EMAC_ADDR0_LO), ***and***

- If the EMAC_FLOWCTL.UP bit is set

The module detects a pause frame even with a unicast destination address. The EMAC uses the EMAC_MACFRMFILT.PCF bits to control the filtering for control frames in addition to the address filter module.

Receive Checksum Offload Engine (RCOE)

When checksum offloading is enabled, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. Programs can enable this module by setting the EMAC_MACCFG.IPC bit. The EMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet type field of frames. This identification applies to VLAN-tagged frames as well. *Extended descriptor mode (8 x32-bit words) must be enabled to get the IPC checksum engine status in RDES4.* To check status, poll bit 0 of RDES0 word of receive descriptor. Then, if this bit is set, parse bits [7:0] of RDES4 word.

The receive checksum offload engine calculates IPv4 header checksums and checks if they match the received IPv4 header checksums. The IP header error bit is set for any mismatch between the indicated payload type (Ethernet type field) and the IP header version. The IP header error bit is also set when the received frame does not have enough bytes, as indicated by the length field of the IPv4 header. (The bit is set when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6). The engine calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation appears as a payload checksum error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

NOTE: The COE engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP, or ICMP. This information is given in the receive status(whether the checksum engine is bypassed or not).

The ***Checksum Error Status*** table shows bit combination in receive descriptors (frame status with full checksum offload engine enabled and advanced timestamps not enabled).

Table 28-32: Checksum Error Status

IEEE802.3 Frame: bit 5 of RDES0	Header Checksum Error (HCE): bit 3 of RDES4	Payload Checksum Error (PCE): bit 4 of RDES4	Frame Status
0	0	0	The frame is an IEEE 802.3 frame (length field value is less than 0x0600).
1	0	0	IPv4/IPv6 type frame in which no checksum error is detected.
1	0	1	IPv4/IPv6 type frame in which a payload checksum error (as described for PCE) is detected

Table 28-32: Checksum Error Status (Continued)

IEEE802.3 Frame: bit 5 of RDES0	Header Checksum Error (HCE): bit 3 of RDES4	Payload Checksum Error (PCE): bit 4 of RDES4	Frame Status
1	1	0	IPv4/IPv6 type frame in which IP header checksum error (as described for IPC HCE) is detected.
1	1	1	IPv4/IPv6 type frame in which both PCE and IPC HCE is detected.
0	0	1	IPv4/IPv6 type frame in which there is no IP HCE and the payload check is bypassed due to unsupported payload.
0	1	1	Type frame which is neither IPv4 or IPv6 (COE bypasses the checksum check completely)
0	1	0	Reserved

Receive Bus Interface Unit Module (RBU)

The receive bus interface unit (RBU) constructs the 32-bit data received from the frame controller into a 32-bit FIFO-based protocol.

Address Filtering Module (AFM)

The address filtering (AFM) module performs the destination checking function on all received frames and reports the address filtering status to the frame controller. The address checking is based on different parameters (frame filter register, `EMAC_MACFRMFILT`) chosen by the application. These parameters are inputs to the AFM module as control signals. The AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status. The AFM module uses the physical (MAC) address of the station and the multicast hash table for address checking.

- *Hash or Perfect Address Filter.* The destination address filter can be configured to pass a frame when its destination address matches either the hash filter or the perfect filter. Set the `EMAC_MACFRMFILT.HPF` bit, the corresponding `EMAC_MACFRMFILT.HUC`, or `EMAC_MACFRMFILT.HMC` bits. This configuration applies to both unicast and multicast frames. If the `EMAC_MACFRMFILT.HPF` bit is reset, only one of the filters (hash or perfect) is applied to the received frame.

  NOTE: Hash filtering is not perfect filtering because a 48-bit MAC address is reduced to a 6-bit hash value. So, there can be instances where more than one address has the same hash value.

- *Unicast Destination Address Filter.*
  - The AFM supports one MAC address two MAC addresses for unicast perfect filtering. If perfect filtering is selected, the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. (The `EMAC_MACFRMFILT.HUC` bit is reset for perfect filtering).

- In hash filtering mode, the AFM performs imperfect filtering for unicast addresses using a 64-bit hash table. (The EMAC_MACFRMFILT.HUC bit is set in hash filtering mode.) For hash filtering, the AFM uses the upper 6-bit CRC of the received destination address to index the content of the hash table. A value of 000000 selects bit 0 of the selected register, and a value of 111111 selects bit 63 of the hash table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame has passed the hash filter. Otherwise, the frame has failed the hash filter.

- ***Multicast Destination Address Filter.***
  - Program the EMAC to pass all multicast frames by setting the EMAC_MACFRMFILT.PM bit. If the EMAC_MACFRMFILT.PM bit is reset, the AFM filters multicast addresses based on the EMAC_MACFRMFILT.HMC bit. In perfect filtering mode, the multicast address is compared with the programmed MAC destination address register. The EMAC also supports group address filtering.
  - In hash filtering mode, the AFM performs imperfect filtering using a 64-bit hash table. For hash filtering, the AFM uses the upper 6-bit CRC of the received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of the selected register and a value of 111111 selects bit 63 of the hash table register. If the corresponding bit is set to 1, then the multicast frame has passed the hash filter. Otherwise, the frame has failed the hash filter.

- ***Broadcast Address Filter.*** The AFM does not filter any broadcast frames in the default mode. However, if the EMAC is programmed to reject all broadcast frames by setting the EMAC_MACFRMFILT.DBF bit, the AFM asserts the filter fail signal, whenever a broadcast frame is received.

- ***Unicast Source Addrress Filter.*** EMAC can also perform a perfect filtering, based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC address register 1 can be configured to contain SA instead of DA for comparison, by setting bit 30 of the corresponding register. Group filtering with SA is also supported. User can filter a group of addresses by masking one or more bytes of the address. The frames that fail the SA filter are dropped by the MAC if the EMAC_MACFRMFILT.SAF bit is set. When the bit is set, the result of SA filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result drops the frame and both filters have to pass in order to forward the frame to the application.

- ***Inverse Filtering Operation.*** There is an option to invert the filter-match result at the final output. The EMAC uses the EMAC_MACFRMFILT.DAIF bit to control this operation. The function of this bit applies to both unicast and multicast DA frames. The result of the unicast or multicast destination address filter is inverted in this mode.

- ***Inverse Filtering Operation.*** For both destination and source address filtering, there is an option to invert the filter-match result at the final output. This is controlled by the EMAC_MACFRMFILT.DAIF or EMAC_MACFRMFILT.SAIF bits. The EMAC_MACFRMFILT.DAIF bit is applicable for both unicast and multicast DA frames. The result of the unicast /multicast destination address filter is inverted in this mode. Similarly, when the EMAC_MACFRMFILT.SAIF bit is set, the result of unicast source address filter is reversed.

- ***Inverse Filtering Operation.*** There is an option to invert the filter-match result at the final output. The EMAC uses the `EMAC_MACFRMFILT.DAIF` bit to control this operation. The function of this bit applies to both unicast and multicast DA frames. The result of the unicast or multicast destination address filter is inverted in this mode.

Destination Address Filtering

The ***Destination Address Filtering*** table provides filtering possibilities for the destination address using the EMAC AFM module. The MAC receive frame filter register (`EMAC_MACFRMFILT`) contains these bits.

Table 28-33: Destination Address Filtering

Frame Type	Bit Setting (0 = Cleared, 1 = Set, X = Do-not-care)							DA Filter Operation
	PR	HPF	HUC	HMC	DAIF	PM	DBF	
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	X	0	X	X	Pass on perfect or group filter match
	0	X	0	X	1	X	X	Fail on perfect or group filter match
	0	0	1	X	0	X	X	Pass on hash filter match
	0	0	1	X	1	X	X	Fail on hash filter match
	0	1	1	X	0	X	X	Pass on hash or perfect or group filter match
	0	1	1	X	1	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop PAUSE control frames if PCF = 0x
	0	0	X	1	0	0	X	Pass on hash filter match and drop PAUSE control frames if PCF = 0x
	0	1	X	1	0	0	X	Pass on hash or perfect or group filter match and drop PAUSE control frames if PCF = 0x

Table 28-33: Destination Address Filtering (Continued)

Frame Type	Bit Setting (0 = Cleared, 1 = Set, X = Do-not-care)							DA Filter Operation
	PR	HPF	HUC	HMC	DAIF	PM	DBF	
	0	X	X	0	1	0	X	Fail on perfect or group filter match and drop PAUSE control frames if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop PAUSE control frames if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect or group filter match and drop PAUSE control frames if PCF = 0x

Source Address Filtering

The ***Source Address Filtering*** table provides filtering possibilities for the source address using the EMAC AFM module. The MAC receive frame filter register (EMAC_MACFRMFILT) contains these bits.

Table 28-34: Source Address Filtering

Frame Type	SA Filter Operation			Result
	PR	SAIF	SAF	
Unicast	1	X	X	Pass all frames
	0	0	0	Pass on perfect or group filter match but do not drop failing frames
	0	1	0	Fail on perfect or group filter match but do not drop frame
	0	0	1	Pass on perfect or group filter match and drop failing frames
	0	1	1	Fail on perfect or group filter match and drop failing frames

VLAN Tag Based Filtering

EMAC0 supports VLAN tag perfect filtering and VLAN tag hash filtering.

VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status. It drops the VLAN frames that do not match. Inverse matching for VLAN frames can be enabled using the EMAC_VLANTAG.VTIM bit. In addition, matching of S-VLAN tagged frames along with the default C-VLAN tagged frames can be enabled using EMAC_VLANTAG.ESVL bit. The VLAN frame status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched frames.

NOTE: The source or destination address (if enabled) has precedence over the VLAN tag filters. A frame which fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based perfect filter is available in all configurations.

VLAN Tag Hash Filtering

The MAC provides VLAN tag hash filtering with a 16-bit hash table. The MAC performs the VLAN hash matching based on the EMAC_VLANTAG.VTHM bit setting. If the EMAC_VLANTAG.VTHM bit is set, the most significant 4 bits of VLAN tag's CRC-32 are used to index the content of the VLAN hash table register (EMAC_VLAN_HSHTBL). A value of 1 in the EMAC_VLAN_HSHTBL register, corresponding to the index, indicates that the VLAN tag of the frame matched and the packet is forwarded. A value of 0 indicates that VLAN-tagged frame is dropped.

The MAC also supports the inverse matching of the VLAN frames. In the inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet is dropped. If the VLAN perfect and VLAN hash match are enabled, a frame matches if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch. The ***VLAN Matching and Final VLAN Match Status*** table shows the possibilities for VLAN matching and the final VLAN match status. When the EMAC_MACFRMFILT.RA bit is set, all frames are received and the VLAN match status is indicated in bit 10 of receive descriptor word 0 (RDES0). When the EMAC_MACFRMFILT.RA bit is not set and the EMAC_MACFRMFILT.VTFE bit register is set, the frame is dropped when the final VLAN match status is fail.

When VLAN VID is programmed to 0 in the EMAC_VLANTAG.VL bit field, all VLAN-tagged frames are perfect matches. But the status of the VLAN hash match depends on the VLAN hash enable bit and VLAN inverse filter bit. The ***VLAN Matching and Final VLAN Match Status*** table shows the possibilities for VLAN matching and the final VLAN match status.

Table 28-35: VLAN Matching and Final VLAN Match Status

VID	VLAN Perfect Filter Match Status (VPF)	VLAN Hash Enable Bit	VLAN Hash filter Match Status (VTHMS)	VLAN Inverse Filter Bit (VTIM)	Final VLAN Match Status
VID=0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!=0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail

Table 28-35: VLAN Matching and Final VLAN Match Status (Continued)

VID	VLAN Perfect Filter Match Status (VPF)	VLAN Hash Enable Bit	VLAN Hash filter Match Status (VTHMS)	VLAN Inverse Filter Bit (VTIM)	Final VLAN Match Status
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

Layer 3 and Layer 4 Frame Filtering

The MAC supports layer 3 and layer 4 based frame filtering. The layer 3 filtering refers to the IP source or destination address filtering in the IPv4 or IPv6 frames whereas layer 4 filtering refers to the source or destination port number filtering in TCP or UDP.

When layer 3 and layer 4 filtering is enabled, the frames are filtered in the following way:

Matched Packets. The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the bit is set and one of the following conditions is true:

- All enabled layer 3 and layer 4 fields match
- At least one of the enabled field matches and other fields are bypassed or disabled

When multiple layer 3 and layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.

NOTE: The source or destination address and VLAN tag filters (if enabled) have precedence over layer 3 and layer 4 filter. This means that a packet which fails the source or destination address, or VLAN tag filter is dropped irrespective of the layer 3 and layer 4 filter results.

Unmatched Packets. The MAC drops the packets that do not match any of the enabled fields. Programs can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. When a packet is dropped, the aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed layer 3 and layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.

Non-TCP or UDP IP Packets. By default, all non-TCP or UDP IP packets are bypassed from the layer 3 and layer 4 filters. The program can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 Filtering

The EMAC supports perfect matching or inverse matching for IP source address and destination address. The matching compares all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, the program can enable the last four data registers of a register set to contain the 128-bit IP source address or IP destination address. The IP source address or destination address should be programmed in

the order defined in the IPv6 specification, that is, the first byte of the IP source address or destination address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, the program can enable the second and third data registers of a register set to contain the 32-bit IP source address and IP destination address. The remaining two data registers are reserved. The IP source address or destination address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP source address and destination address in the received packet in the higher byte of the respective register.

Layer 4 Filtering

The EMAC supports perfect matching or inverse matching for TCP or UDP source and destination port numbers. However, only one type (TCP or UDP) can be programmed at a time. The first data register contains the 16-bit source and destination port numbers of TCP or UDP, that is, the lower 16 bits for source port number and higher 16 bits for destination port number.

The TCP or UDP source and destination port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP source and destination port number in the received packet is in the higher byte of the register.

Layer 3 and Layer 4 Filters Registers

The MAC implements a set of registers for layer 3 and layer 4 based frame filtering. In a register set, there is a control register, such as the register (layer 3 and layer 4 control register), to control the frame filtering. In addition, there are five address registers to program the layer 3 and layer 4 fields to be matched, which are:

- (layer 4 Address Register)
- (layer 3 address 0 register)
- (layer 3 address 1 register)
- (layer 3 address 2 register)
- (layer 3 address 3 register)

EMAC Station Management Interface (SMI)

The IEEE 802.3 MII station management interface, also known as the MDIO management interface, allows the processor to monitor and control one or more external Ethernet physical-layer transceivers. (Physical-layer transceivers are commonly called PHYs). The management interface physically consists of a 2-wire serial connection composed of the MDC (management data clock) output signal and the MDIO (management data input/output) bidirectional data signal. The IEEE 802.3 MII station management interface also applies to RMII.

The application can address only one register in the PHY in any given time and send control data or receive status information. All the transfers are initiated by the EMAC CORE, and the PHY chip only acts as a target device.

Standard PHY control and status registers typically provide

- Device capability status bits (for example: auto-negotiation, duplex modes, 10/100 speeds, and protocols)

- Device status bits (for example: auto-negotiation complete, link status, remote fault)
- Device control bits (for example: reset, speed selection, loop back, and auto-negotiation start)

Upon power-up, an MDIO read access (at default rates) of device capabilities in PHY status registers can determine the supported PHY features.

The MII management logical interface specifies:

- A set of 16-bit device control or status registers within the PHYs, including both required registers with standardized bit definitions as well as optional vendor-specified registers.
- A 5-bit device addressing scheme which allows the MAC to select one of up to 32 externally connected PHY devices.
- A 5-bit register addressing scheme for selecting the target register within the addressed device.
- A transfer frame protocol for 16-bit read and write accesses to PHY registers through the MDC and MDIO signals under control of the MAC.

Table 28-36: Station Management Interface pins

Station Management Interface Pins	Pin Description
MDIO – Management Data I/O	A periodic clock that runs at a maximum period of 400 ns. Always driven by the EMAC to PHY.
MDC – Management Data Clock	Data signal driven by EMAC or PHY, depending on write or read access based on EMAC; synchronous to MDC.

MDC Clock Frequency

The EMAC uses the `EMAC_SMI_ADDR.CR` bit field to determine the frequency of MDC as shown in the ***MDC Clock Frequency Selection*** table. The clock range selection determines the frequency of the clock relative to the SCLK0 frequency. The table shows the suggested range of SCLK0 frequency applicable for each value of the `EMAC_SMI_ADDR.CR` field. The programmability based on SCLK0 frequency range ensures that the MDC clock frequency range is within the IEEE specifications of 1.0 MHz to 2.4 MHz. However, the EMAC MDC can also support higher frequencies for PHY devices that support the frequencies.

Table 28-37: MDC Clock Frequency Selection

`EMAC_SMI_ADDR.CR` Selection	Programmed SCLK0 Frequency Range	Frequency of MDC	Min and Max MDC Freq (Per Specifications)
0000	60–100 MHz	SCLK0/42	MIN = 1.43 MHz and MAX = 2.39 MHz
0010	20–35 MHz	SCLK0/16	MIN = 1.25 MHz and MAX = 2.19 MHz
0011	35–60 MHz	SCLK0/26	MIN = 1.35 MHz and MAX = 2.31 MHz

The ***MDIO Frame Parameters*** table provides MDIO data transfer parameters. The write and read sequences provided in the tables, ***MDIO Write Data Sequence*** and ***MDIO Read Data Sequence***, are based on these parameters.

Table 28-38: MDIO Frame Parameters

Parameter	Description
IDLE	The MDIO line is three-state (noted as Z in sequence); there is no clock on MDC.
PREAMBLE	32 continuous bits, each of value 1
START	Start of frame is 01
OPCODE	10 for read and 01 for write
PHY ADDR	5-bit address select for one of 32 PHYs (noted as AAAAA in sequence)
REG ADDR	Register address in the selected PHY (noted as RRRRR in sequence)
TA	Turnaround is Z0 for read and 10 for write (Z = high impedance)
DATA	Any 16-bit value. Driven by MAC or PHY based on direction (noted as DDD...DDD).

Table 28-39: MDIO Write Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	01	AAAAA	RRRRR	10	DDD... DDD	Z

Table 28-40: MDIO Read Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	10	AAAAA	RRRRR	Z0	DDD... DDD	Z

SMI Write Operation

When programs set the `EMAC_SMI_ADDR.SMIW` (write) and `EMAC_SMI_ADDR.SMIB` (busy) bits, the station management interface (SMI) initiates a write operation into the PHY registers. The write operation uses the management frame format (the PHY address, the register address in PHY, and the write data) specified in the IEEE specifications. (Section 22.2.4.5 of IEEE standard). The application must not change the `EMAC_SMI_ADDR` register contents or the `EMAC_SMI_DATA` register while the transaction is ongoing.

Write operations to the `EMAC_SMI_ADDR` register or the `EMAC_SMI_DATA` register during the transfer period are ignored (while the `EMAC_SMI_ADDR.SMIB` bit is high). The transaction completes without error. After the write operation has completed, the SMI indicates the same by resetting the `EMAC_SMI_ADDR.SMIB` bit. The EMAC drives the MDIO line for the complete duration of the frame. The ***SMI Write Operation through MDIO/MDC Pins*** figure shows this operation.

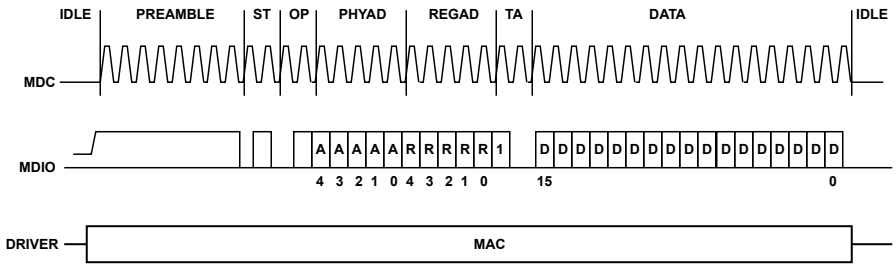

Figure 28-16: SMI Write Operation through MDIO/MDC Pins

SMI Read Operation

When programs set the `EMAC_SMI_ADDR.SMIB` bit with the `EMAC_SMI_ADDR.SMIW` bit cleared (=0), the station management interface (SMI) initiates a read operation in the PHY registers. It transfers the PHY address and the register address in the PHY to the SMI. The application must not change the `EMAC_SMI_ADDR` register contents or the `EMAC_SMI_DATA` register while the transaction is ongoing.

Write operations to the `EMAC_SMI_ADDR` register or the `EMAC_SMI_DATA` register during the transfer period are ignored (while the `EMAC_SMI_ADDR.SMIB` bit is high). The transaction completes without error. After the read operation has completed, the SMI resets the `EMAC_SMI_ADDR.SMIB` bit and updates the `EMAC_SMI_DATA` register with the data read from the PHY. The EMAC drives the MDIO line for the complete duration of the frame except during the data fields when the PHY drives the MDIO line. The ***SMI Read Operation through MDIO/MDC Pins*** figure shows this operation.

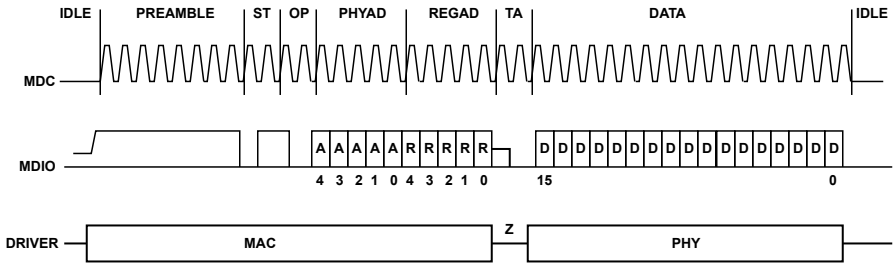

Figure 28-17: SMI Read Operation through MDIO/MDC Pins

EMAC Management Counters (MMC)

The EMAC provides a comprehensive set of 32-bit MAC management counters. It uses these counters for gathering statistics on the received and transmitted frames. The MMC subblock also includes

- A control register (`EMAC_MMC_CTL`) for managing the behavior of the counters
- Two 32-bit registers containing interrupts generated (`EMAC_MMC_RXINT` and `EMAC_MMC_TXINT`)
- Two 32-bit registers containing masks for the interrupt register (`EMAC_MMC_RXIMSK` and `EMAC_MMC_TXIMSK`)

The MMC receive counters are updated for frames passed by the address filtering subblock in the EMAC CORE. Statistics of frames dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes. (Destination address bytes are not received fully.) The module is also capable of gathering statistics on encapsulated IPv4, IPv6, and TCP, UDP, or ICMP payloads in received Ethernet frames.

The MMC register naming conventions are as follows:

- Tx as a prefix or suffix indicates counters associated with transmission.
- Rx as a prefix or suffix indicates counters associated with reception.
- _G as a suffix indicates registers that count good frames only.
- _GB as a suffix indicates registers that count frames regardless of whether they are good or bad.

Transmitted frames are considered *good* when transmitted successfully. In other words, a transmitted frame is good if the frame transmission does not abort due to any of the following errors:

- Jabber timeout
- No carrier or loss of carrier
- Late collision
- Frame underflow
- Excessive deferral
- Excessive collision

Received frames are good when none of the following errors exists:

- CRC error
- Runt frame (shorter than 64 bytes)
- Alignment error
- Length error (non-type frames only)
- Out-of-range (non-type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN frame maxsize = 1522
- Jumbo frame maxsize = 9018
- Jumbo VLAN frame maxsize = 9022

The `EMAC_MMC_CTL` register also contains bits that control preset, freeze and roll-over of counters. The EMAC uses the `EMAC_MMC_CTL.RDRST` bit to enable an auto-reset feature whenever the counters are read. The EMAC uses the `EMAC_MMC_CTL.RST` bit to reset all the counters.

The MMC can trigger an interrupt when the corresponding bits are enabled in the transmit, receive, and IPC mask registers, and when the particular counter reaches half or full. The status is also updated in the corresponding interrupt register.

MMC Receive Interrupt Register

The EMAC_MMC_RXINT register maintains the interrupts that are generated when the receive statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When EMAC_MMC_CTL.NOROLL is set, then interrupts are set, but the counter remains at all ones. The EMAC_MMC_RXINT register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Transmit Interrupt Register

The EMAC_MMC_TXINT register maintains the interrupts generated when the transmit statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When EMAC_MMC_CTL.NOROLL is set, then interrupts are set, but the counter remains at all ones. The EMAC_MMC_TXINT register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Receive Checksum Offload Interrupt Register

The EMAC_MMC_RXINT.CRCERR register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When EMAC_MMC_CTL.NOROLL is set, then interrupts are set, but the counter remains at all ones. The EMAC_MMC_RXINT.CRCERR register is 32 bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The least-significant byte lane (bits 7:0) of the counter must be read to clear the interrupt bit.

EMAC Precision Time Protocol (PTP) Engine

The following sections describe the precision time protocol (PTP) engine.

IEEE1588 and the PTP Engine

The Ethernet MAC peripheral includes a PTP engine to assist applications requiring time synchronization. The PTP module is tightly integrated with the EMAC CORE to aid hardware time stamping defined in the IEEE1588 2002/2008 standards. Applications can use accurate hardware time stamps through TCP/IP stacks (if using network layer communication) to exchange time information across devices connected over network. Applications can also use accurate hardware time stamps through Ethernet device drivers (if using MAC layer communication) to exchange time information.

PTP Engine

For calculation of drift in time between two Ethernet devices, the device records its system time whenever a timing message is sent or received (IEEE 1588 protocol). Due to the indeterministic delay of a software system for a node, the software is unable to capture an accurate time when the message is sent or received. However, the hardware can monitor the signal on the communication media and get an accurate message of arrival and departure time.

The PTP (precision time protocol) module is closely integrated with the EMAC module. It provides hardware assistance to implement both the IEEE 1588–2002 and IEEE 1588–2008 standards on Ethernet (IEEE 802.3). It takes

one input clock signal as its PTP clock and maintains the timing information (called *system time*) at the nanosecond level.

The PTP module includes hardware for clock and system time adjustment. The pulse-per-second (PPS) signals physically represent the system time. PPS can be programmed to a fixed frequency or provide flexibility to the signal in terms of pulse width, interval, start, and stop time of the signals. The PTP module can be programmed to trigger an alarm interrupt when system time reaches specified time.

The PTP module can be programmed to detect different types of received frames, capture the system time, and time stamp those frames with the captured system time. Programs can configure any frame so that the PTP module capture the system time when it is transmitted. The PTP module can also capture the system time when an event is detected on the auxiliary snapshot trigger input pins (EMAC_PTPAUXIN[n]).

IEEE 1588 Standard

Many systems require two independent devices to operate in a time synchronized fashion. If each system relied solely on its oscillator, differences between the characteristics and operating conditions of each oscillator would limit the ability of the clocks to operate synchronously. To serve applications requiring synchronized clocks, the system uses a periodic correction mechanism.

A simple way to synchronize multiple systems is to choose one system (with the best clock) as a requester. The system requester broadcasts the clock and timing information to other systems (completers); subsequently, the completers adjust their clocks and timing according to that of requester. However, this method has limitations. The requester cannot broadcast the time at infinitesimal intervals. Path delay (propagation delay) exists between a requester and a completer and the delay varies between each completer and requester.

IEEE 1588 is also known as precision time protocol or PTP. The standard specifies a protocol used to synchronize the time and clock of multiple devices, dispersed but interconnected by any communication, (for example, Ethernet IEEE 802.3). According to the protocol, timing messages are exchanged between two devices. Then, one of the devices calculates its drift from other device and corrects its system time. (Both devices must have the same representation of their system time). The protocol resolves path delay between devices. It also helps synchronize the clocks of multiple devices and all of the limitations mentioned are resolved.

IEEE 1588 was published in 2002 where four types of timing messages were defined: Sync, Follow_Up, Delay_Req, and Delay_Resp. Here the protocol synchronizes two or more devices where one is a requester and others are completers. The requester device sends Sync, Follow_Up, and Delay_Resp messages to the completer device in the system. The target sends the Delay_Req messages to the requester device. A following section provides more information on IEEE 1588–2002.

In 2008, a newer version of IEEE 1588 was introduced which provides further mechanisms to measure the peer-to-peer delay. Three more timing messages (PdelayReq, PdelayResp, and PdelayRespFollowup) were added to implement peer-to-peer synchronization. The following section provides more information on IEEE 1588–2008.

IEEE 1588–2002

The IEEE 1588–2002 standard defines the precision time protocol (PTP). The protocol allows precise synchronization of clocks in measurement and control systems that use network communication, local computing, and distributed objects. The protocol applies to systems that communicate by local area networks that support multicast

messaging, including (but not limited to) Ethernet. This protocol also allows heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into requester and completer nodes for distributing the timing or clock information. The ***IEEE 1588–2002 PTP Process*** figure shows the process that PTP uses for synchronizing a target node to a controller node by exchanging PTP messages.

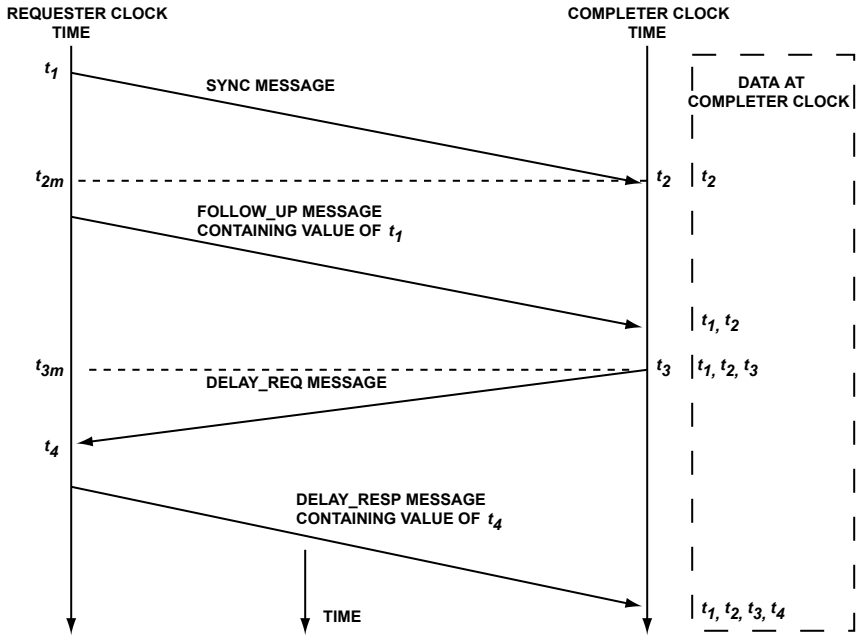

Figure 28-18: IEEE 1588–2002 PTP Process

As shown in the figure, the PTP uses the following process:

1. The requester broadcasts the PTP sync messages to all its nodes. The sync message contains the reference time information of the requester. The time at which this message leaves the system of the requester is t_1. The requester must capture this time for Ethernet ports, at RMII.
2. The completer receives the Sync message and also captures the exact time, t_2, using its timing reference.
3. The requester sends a Follow_up message to the completer, which contains t1 information for later use.
4. The completer sends a Delay_Req message to the requester, noting the exact time, t_3, at which this frame leaves the RMII.
5. The requester receives the message, capturing the exact time, t_4, at which it enters its system.
6. The requester sends the t_4 information to the completer in the Delay_Resp message.
7. The completer uses the four values of t_1, t_2, t_3, and t_4 to synchronize its local timing reference to the timing reference of the requester.

Most of the PTP implementation occurs in the software above the UDP layer. However, the hardware support must capture the exact time when specific PTP packets enter or leave the Ethernet port at the RMII/RGMII. Hardware must capture this timing information and return it to the software for the proper implementation of PTP with high accuracy.

IEEE 1588–2008 Advanced Time Stamps

In addition to the basic time stamp features mentioned in IEEE 1588–2002 time stamps, the EMAC supports the following advanced time stamp features defined in the IEEE 1588–2008 standard.

- Support for the IEEE 1588–2008 (Version 2) time stamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to select the node to be a requester or completer.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to run nanoseconds time in digital or binary format.

Peer-to-Peer (P2P) PTP Message Support

The IEEE 1588–2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Refer to the ***Propagation Delay Calculation between Nodes Supporting P2P Path Correction*** figure. The figure shows the method to calculate the propagation delay between nodes supporting peer-to-peer path correction.

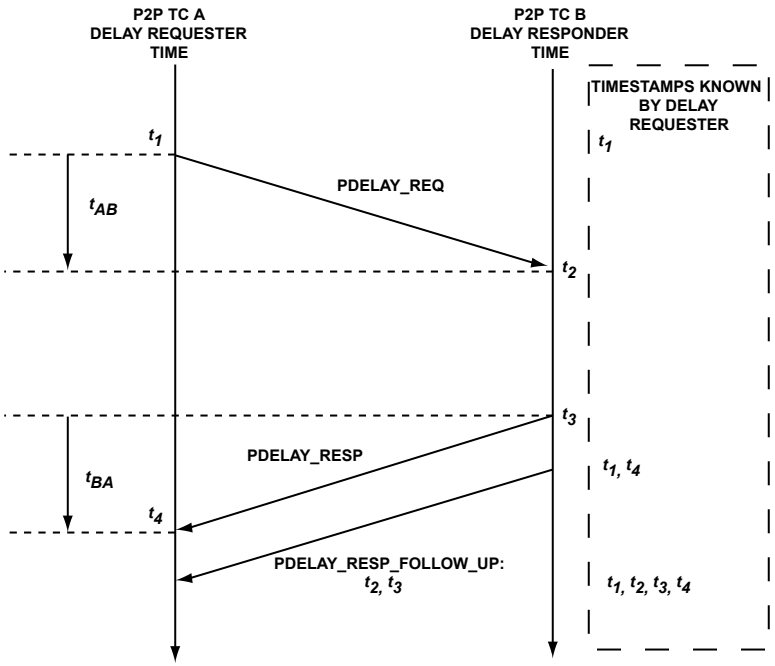

Figure 28-19: Propagation Delay Calculation between Nodes Supporting P2P Path Correction

As shown in the figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a time stamp, t1, for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a time stamp, t2, for this message.
3. Port 2 returns a Pdelay_Resp message and generates a time stamp, t3, for this message. To minimize errors due to frequency offset between the two ports, port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. The port 2 returns any one of the following:
   - The difference between the time stamps t2 and t3 in the Pdelay_Resp message.
   - The difference between the time stamps t2 and t3 in the Pdelay_Resp_Follow_Up message.
   - The time stamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.
4. Port 1 generates a time stamp, t4, on receiving the Pdelay_Resp message.

Port 1 uses all four time stamps to compute the mean link delay.

Block Diagram

The ***PTP Block Diagram*** figure shows the functional block diagram of PTP module.

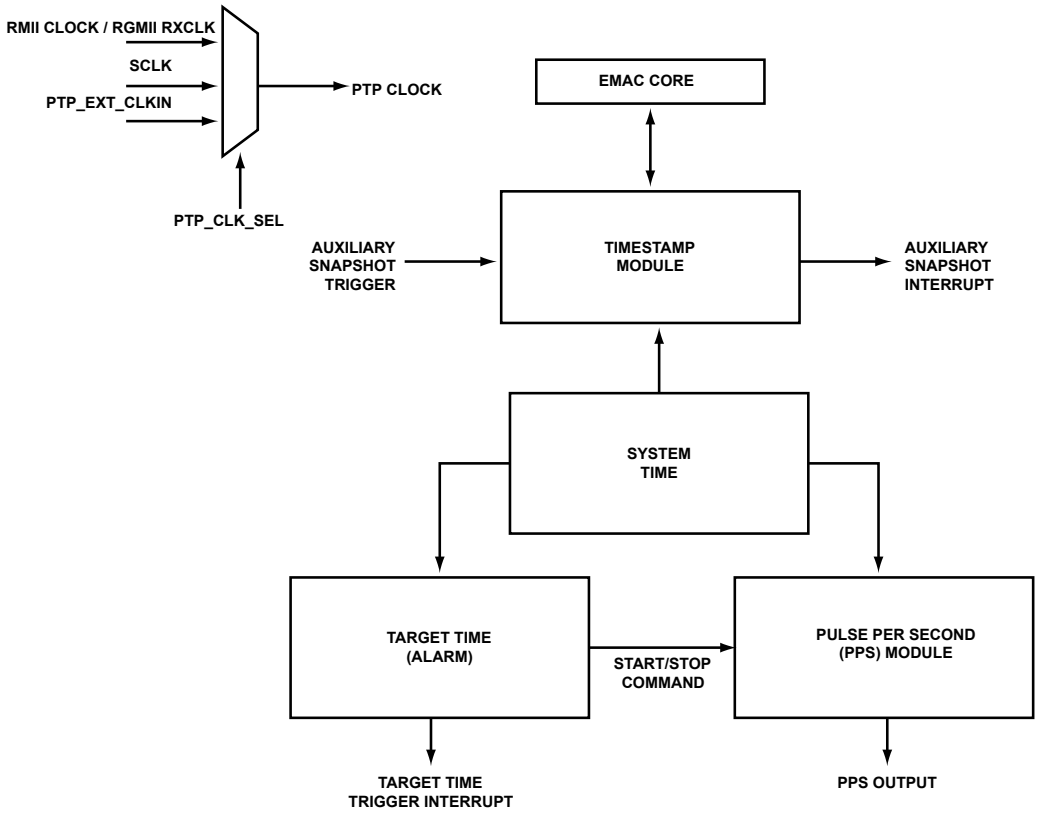

Figure 28-20: PTP Block Diagram

A system time module is present which keeps the time of PTP module. It consists of hardware which can be programmed for time initialization, time correction, and clock correction.

The time stamp module captures the time (provided by the system time module) at various conditions. For example, when the EMAC sends or receives a frame or during the rising edge of the auxiliary snapshot trigger pins. When system time is captured after detection of a frame, the time stamp module automatically includes the time information in the frame descriptor. Time stamping on the detection of a frame can be programmed on a per frame basis.

The PTP clock drives the PTP module. This clock can be selected from three different clock sources.

The Pulse per Second (PPS) module generates a pulse or train of pulse on the PPS output pins, (). It is the physical representation of system time. PPS can be fixed (where only frequency varies) or flexible (where width, interval, start time, and stop time can be programmed).

The target time module acts as an alarm for the PTP module. Whenever system time reaches a value equal to programmed target time, the target time trigger interrupt is generated. By appropriate programming, The target time trigger can also start or stop flexible PPS output at specific time.

PTP Module Clock

The PTP module clock features include Clock Source Selection and Clock Frequency Range.

Clock Source Selection

The PTP module can take one of these clock sources as its input clock — SCLK0, RMII reference RGMII Rx clock, or PTP external clock.

As shown in the ***PTP Clock Source Selection*** table, the `PADS_PCFG0` register selects the PTP clock source.

Table 28-41: PTP Clock Source Selections

PADS_PCFG0 [1:0]	**PTP Clock Source**	**Clock Description**
00 - RMII or MII	ETH0_RXCLK_REFCLK/ETH1REFCLK	MII/RII reference clock
00 - RGMII	CLK07	Processor Ethernet clock
10	PTP external clock	Clock available on EMAC_PTPCLKIN[n] pin
01 or 11	SCLK0	Processor system clock

Clock Frequency Range

The resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. The timing constraints achievable for logic operating on the selected PTP clock source limit the maximum PTP clock frequency.

The minimum PTP clock frequency depends on the time required between two consecutive frames. The IEEE specification determines the RMII clock frequency. The minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. See the ***Minimum PTP Clock Frequency*** table.

A minimum delay required between two consecutive time stamp captures is 8 clock cycles of RMII or 4 clock cycles of RGMIIand 3 clock cycles of PTP clocks. If the delay between two time stamp captures is less than this delay, the EMAC does not take a time stamp snapshot for the second frame.

The following table assumes:

- Minimum Ethernet packet size = 64 bytes
- Miminum IFG = 96 bit times = 12 bytes
- Preamble = 8 bytes
- 3 PTP Clock + 4GMII/MII Clock Min gap between two SFDs (start of frame delimiters)
- 3 PTP Clock + 8 RMII Clock Min gap between two SFDs
- 3 PTP Clock + 4 RGMII Clock Min gap between two SFDs

Mode (Full Duplex in all cases)	Minimum Gap between two SFDs	PTP clock	Comments
10 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 3360 RMII clock cycles	In RMII @ 10 Mbps, 1 byte transmitted in 40 clock cycles
	(2560 + 320 + 480) RMII clock cycles	3 PTP clock cycle 3352 RMII clock cycles	RMII clock = 50 MHz
	3360 RMII clocks	PTP clock cycle 1117.33 20 ns = 22346 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.045 MHz	
10 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4RGMII clock cycle 168 RGMII clock cycles	In RGMII, 1 byte transmitted in 4 clock cycles
	(128 + 16 + 24) MII clock cycles	3 PTP clock cycle<= 164 RGMII clock cycles	RGMII clock at 100 Mbps = 2.5 MHz
	168 MII clock cycles	PTP clock cycle 54.67 400ns = 21860 ns	1 RGMII clock cycle = (1/2.5 MHz) = 400 ns
		PTP frequency min = 0.045 MHz	
100 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 336 RMII clock cycles	In RMII, 1 byte transmitted in 4 clock cycles
	(256 + 32 + 48) RMII clock cycles	3 PTP clock cycle 328 RMII clock cycles	RMII clock = 50 MHz
	336 RMII clocks	PTP clock cycle 109.33 20 ns = 2186 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.45 MHz	

Mode (Full Duplex in all cases)	Minimum Gap between two SFDs	PTP clock	Comments
100 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4RGMII clock cycle 168 RGMII clock cycles	In RGMII, 1 byte transmitted in 4 clock cycles
	(128 + 16 + 24) MII clock cycles	3 PTP clock cycle 164 RGMII clock cycles	RGMII clock at 100 Mbps = 25 MHz
	168 MII clock cycles	PTP clock cycle 54.67 40 ns = 2186 ns	1 RGMII clock cycle = (1/25 MHz) = 40 ns
		PTP frequency min = 0.45 MHz	
1000 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4 RGMII clock cycle 84 RGMII clock cycles	In RGMII @ 1000 Mbps, 1 byte transmitted in 1 clock cycles
	(64 + 8 + 12) RGMII clock cycles	3 PTP clock cycle 80 RGMII clock cycles	RGMII clock at 100 Mbps = 125 MHz
	84 RGMII clocks	PTP clock cycle 26.67 8 ns = 213 ns	1 RGMII clock cycle = (1/125 MHz) = 8 ns
		PTP frequency min = 4.6 MHz	

The minimum PTP clock frequency also depends on the maximum value of the EMAC_TM_SUBSEC register, so that even at the highest EMAC_TM_SUBSEC.SSINC value, the EMAC_TM_SEC register value can be incremented every second. Since the EMAC_TM_SUBSEC.SSINC is an 8-bit field, the minimum PTP clock frequency allowed is approximately 4 MHz.

Time Stamp Module

The time stamp module captures time in seconds and nanoseconds maintained as system time. The time stamp module also captures time when specific events occur. Events include detection of a frame transmitted or received over the EMAC and a rising edge on the pins. The time stamp module does not need to time stamp all of the transmitted or received frames over the EMAC. The PTP module can be programmed to detect specific kinds of frames for time stamping.

Frame Detection and Time Stamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If the module detects an event message, it takes a snapshot of the system time. The PTP module stores the value to the 64-bit fields in transmit or receive descriptor.

The time stamping occurs at the EMAC RMII/RGMII interface when the module sees the start of frame of an event message packet.

Transmit Path Time Stamping

The EMAC captures a time stamp when a frame transmits on the RMII/RGMII. Time stamp capture is controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether a time stamp is captured for that frame or not.

Applications can extend the descriptor word length from 4 words to 8 words by setting the EMAC_DMA0_BUSMODE.ATDS bit. To enable the time stamp function, set the TTSE (transmit time stamp enable) bit in transmit descriptor word TDES0. When the PTP module captures a time stamp of a transmitted frame, it notifies the application by setting the TTSS (transmit time stamp status) in TDES0.

The EMAC returns the time stamp to the software inside the corresponding transmit descriptor, automatically connecting the time stamp to the specific frame. The 64-bit time stamp information is written to the TDES6 and TDES7 fields. The TDES6 field holds the 32-bit LSBs of the time stamp (system time nanoseconds), except as described in transmit time stamp field, and the TDES7 field holds the 32-bit MSBs (system time seconds). After the PTP module time stamps the frame, the application can get the time stamp along with the transmit status from the EMAC.

NOTE: The PTP module time stamps all the transmitting frames having TTSE set in its TDES0. It does not distinguish according to the type of transmitting frame.

Receive Path Time Stamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If an event message is detected, the module takes a snapshot of the system time. The module stores its value to the 64-bit fields in transmit or receive descriptor. The time stamping is done at the EMAC RMII/RGMII interface when the module sees the start of frame of an event message packet.

PTP module captures the time stamp of received frames on the RMII/RGMII. Time stamp capture is controllable on a per-frame and per-type basis. In other words, each received frame is time stamped according to the frame type.

Applications can extend the descriptor word length from 4 words to 8 words by setting the EMAC_DMA0_BUSMODE.ATDS bit to store time stamp and received message status. The PTP notifies the application of receive time stamp availability when it sets bit 7 (time stamp available) in receive descriptor word RDES0.

When bit 0 (extended status available) is set in RDES0, it indicates that the extended status of the PTP frame is provided in the RDES4 word. Extended status includes PTP version, PTP frame type, and message type. The EMAC returns the time stamp to the software inside the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES6 and RDES7 fields in memory. The RDES6 holds the 32-bit LSBs of the time stamp (system time nanoseconds), except as mentioned in receive time stamp field, and the RDES7 field holds 32-bit MSBs (system time seconds).

The time stamp is written only to that receive descriptor for which the last descriptor status field has been set to 1. When the time stamp is not available (for example, because of an RxFIFO overflow), an all-ones pattern is written to the descriptors (RDES6 and RDES7). The write operation indicates that the time stamp is not correct. RDES0 [7] indicates whether the time stamp is updated in RDES6/7.

The PTP module processes received frames to identify valid PTP frames. Use the EMAC_TM_CTL register to control the snapshot of the time sent to the application.

The PTP module can be programmed to detect all received frames or only some types of PTP frames, according to bit settings in the EMAC_TM_CTL register. Refer to the ***PTP Frame Type Selections*** table.

Table 28-42: PTP Frame Type Selections

TSENALL (bit 8)	SNAPTYPSEL (bits [17:16])	TSMSTRENA (bit 15)	TSEVNTENA (bit 14)	Frames
1	X	X	X	All
0	00	X	0	Sync, Follow_Up, Delay_Req, Delay_Resp
0	00	0	1	Sync
0	00	1	1	Delay_Req
0	01	X	0	Sync, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
0	01	0	1	Sync, Pdelay_Req, Pdelay_Resp
0	01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
0	10	X	X	Sync, Delay_Req
0	11	X	X	Pdelay_Req, Pdelay_Resp

PTP Processing and Control

When the EMAC module receives a frame, frame detection and time stamping are based on some of the PTP fields in the frame. The ***PTP Message Format (IEEE 1588–2008)*** table shows the common message header for the PTP messages. This format is derived from the IEEE standard 1588–2008. When the EMAC module sends a PTP frame, the frame follows this format.

When a frame is received, the PTP module compares these fields with standard values and finds out the type of PTP frame and other information (for example, PTP version, IP version, and others). The module then updates the related fields in RDES4. When a frame is transmitted, programs must ensure that all the fields are appropriate. The PTP module on the other end of a communication must correctly detect and decode the frame.

Table 28-43: PTP Message Format (IEEE 1588–2008)

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5

Table 28-43: PTP Message Format (IEEE 1588–2008) (Continued)

Bits	Octets	Offset
flagField	2	6
correctionField	8	8
Reserved	4	16
sourcePortIdentity	10	20
sequenceId	2	30
controlField (used in version 1. For version 2, messageType field is used for detecting different message types.)	1	32
logMessageInterva	1	33

There are some fields in the Ethernet payload that can be used to detect the PTP packet type and control the snapshot taken. These fields are different for the following PTP frames:

- PTP Frames Over IPv4
- PTP Frames Over IPv6
- PTP Frames Over Ethernet

For these PTP frames, EMAC does not consider the PTP version 1 messages as valid when the frame consists of peer delay multicast address as destination address (DA).

PTP Frame Over IPv4

The ***IPv4-UDP PTP Frame Fields Required for Control and Status*** table provides information about the fields that are matched to control snapshot for the PTP packets. The packets are sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format. The format is defined in the ***PTP Message Format (IEEE 1588–2008)*** table in the PTP Processing and Control section.

Table 28-44: IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 Version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132

Table 28-44: IPv4-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
IP Multicast Address (IEEE 1588 Version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-Primary multicast address: 224.0.1.129 PTP-Peer delay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F 0x0140	0x013F - PTP Event Messages. These are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only). 0x0140 - PTP general messages
PTP Control Field (IEEE version 1)	74	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

PTP Frame Over IPv6

The ***IPv6-UDP PTP Frame Fields Required for Control And Status*** table provides information about the fields that are matched to control the snapshots for the PTP packets. The packets are sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format defined in PTP Message Format (IEEE 1588–2008).

Table 28-45: IPv6-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x86DD	IP datagram

Table 28-45: IPv6-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
IP Version	14 (bits [7:4])	0x06	IP version is IPv6
Layer 4 Protocol	20 (IPv6 extension header not defined for PTP packets)	0x11	UDP
PTP Multicast Address	38–53	FF0x:0:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:0:6B (Hex)	PTP - primary multicast address: FF0x: 0:0:0:0:0:0:0:181 (Hex) PTP - Peer delay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57 (IPv6 extension header not defined for PTP packets)	0x013F, 0x0140	0x013F - PTP event messages 0x0140 - PTP general messages
PTP Control Field (IEEE 1588 version 1)	93 (IPv6 extension header not defined for PTP packets)	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management (version1)
PTP Message Type Field (IEEE version 2)	74 (nibble) (IPv6 extension header not defined for PTP packets)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	75 (nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

PTP Frame Over Ethernet

Refer to the ***Ethernet PTP Frame Fields Required for Control and Status*** table. The table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format defined in the table.

Table 28-46: Ethernet PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched value	Description
MAC Destination Multicast Address (The address match of destination address (DA) programmed in MAC address 0 is used when the bit is set)	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses: 01-1B-19-00-00-00 01-80-C2-00-00-0E
MAC Frame Type	12, 13	0x88F7	PTP Ethernet frame
PTP control field (IEEE Version 1)	45	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management
PTP Message Type Field (IEEE version 2)	14 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	15(nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

Auxiliary Time Stamp Snapshot

The auxiliary snapshot feature stores snapshots of the system time whenever a rising edge is detected on the `EMAC_PTPAUXIN[n]` pins.

The PTP stores 64 bits of captured time stamp in a 4-deep FIFO. When a snapshot is stored, the PTP indicates this event to the EMAC with the auxiliary snapshot interrupt. The `EMAC_TM_STMPSTAT.ATSTS` bit is set. The value of the snapshot is read through the `EMAC_TM_AUXSTMP_SEC` and `EMAC_TM_AUXSTMP_NSEC` registers. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then the snapshot trigger-missed status is set in the `EMAC_TM_STMPSTAT.ATSSTM` bit. The latest snapshot is not written to the FIFO when it is full.

When a host reads the 64-bit time stamp from the FIFO through the `EMAC_TM_AUXSTMP_SEC` and `EMAC_TM_AUXSTMP_NSEC` registers, the space becomes available to store the next snapshot.

NOTE: A space in the FIFO is created whenever the EMAC_TM_AUXSTMP_SEC register is read. Therefore, read the EMAC_TM_AUXSTMP_NSEC register before reading the EMAC_TM_AUXSTMP_SEC register.

The program can clear the FIFO by setting the EMAC_TM_CTL.ATSFC bit. When multiple snapshots are present in the FIFO, the EMAC_TM_STMPSTAT.ATSNS bits indicate the count.

NOTE: The minimum gap between two events on the EMAC_PTPAUXIN[n] pin must be 4 cycles of PTP_CLK + 3 cycles of SCLK0). Otherwise, the logic misses the rising-edge of the trigger.

System Time

To get a snapshot of the time, the EMAC requires a reference time in 64-bit format as defined in the IEEE 1588 specification. The PTP module maintains 80-bit time, known as system time. The PTP clock updates system time.

The 80-bit timing reference is split into the following three registers:

- EMAC_TM_NSEC – 32-bit nanoseconds register which provides time in nanoseconds
- EMAC_TM_SEC – 32-bit seconds register which provides time in seconds
- EMAC_TM_HISEC – 16-bit high seconds register which provides time beyond the seconds register. The IEEE 1588 standard does not include this register. Its use is application-specific.

The 64-bit system time (seconds and nanoseconds) is the source for taking time stamps for Ethernet frames being transmitted or received at the RMII.

Since the PTP clock frequency does not correspond to a 1ns period, the EMAC_TM_NSEC register is incremented with a value equal to the PTP clock period for every PTP clock cycle. The function uses the EMAC_TM_SUBSEC register. The EMAC_TM_NSEC value is incremented with the value programmed in EMAC_TM_SUBSEC register every PTP clock cycle.

Whenever the EMAC_TM_SEC register overflows from 0xFFFFFFFF to 0x00000000, the seconds overflow interrupt is triggered. The EMAC uses the EMAC_TM_STMPSTAT.TSSOVF bit to indicate the event. After a seconds overflow, the EMAC_TM_HISEC register increments by one.

The system time module supports the following two types of rollover modes for the EMAC_TM_NSEC register.

- Digital rollover mode. The maximum value in the nanoseconds field is 0x3B9AC9FF, that is, 10^9 nanoseconds. After it reaches this value, the EMAC_TM_SEC register increments and the EMAC_TM_NSEC register restarts counting from zero. Accuracy in digital rollover mode it is 1 ns per bit.
- Binary rollover mode. The nanoseconds field rolls over and increments the seconds field after the value reaches 0x7FFFFFFF. Accuracy in binary rollover mode is ~0.466 ns per bit.

System Time Adjustment

The following sections describe the process for system time adjustment.

System Time Initialization

System time can be initialized with 64-bit time when the PTP module is enabled. The initial value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT system time update registers. The system time counter is written with the value in the registers when the EMAC_TM_CTL.TSINIT bit is set.

Coarse Correction Method

If the completer system time has an offset based on the system time of the requester, then the coarse correction method can correct it. The time offset value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. The offset value is then added to or subtracted from the system time when the EMAC_TM_CTL.TSUPDT bit is set. Use the EMAC_TM_NSECUPDT.ADDSUB bit to choose addition or subtraction. System time correction occurs in one clock cycle using the coarse correction method.

NOTE: During subtraction, the EMAC_TM_SECUPDT register value must be less than the value of the EMAC_TM_SEC register. Check the value prior to subtracting using coarse correction.

Fine Correction Method

If a target PTP clock frequency has a drift based on the controller PTP clock (as defined in IEEE 1588), it can be corrected using the fine correction method. Using this method, system time is corrected over a period (unlike coarse correction where it happens in one clock cycle). This correction helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.

Using this method, an accumulator sums the contents of the EMAC_TM_ADDEND register. The ***System Time Update, Fine Correction Method*** figure shows the method. The arithmetic-carry that the accumulator generates acts as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency divider.

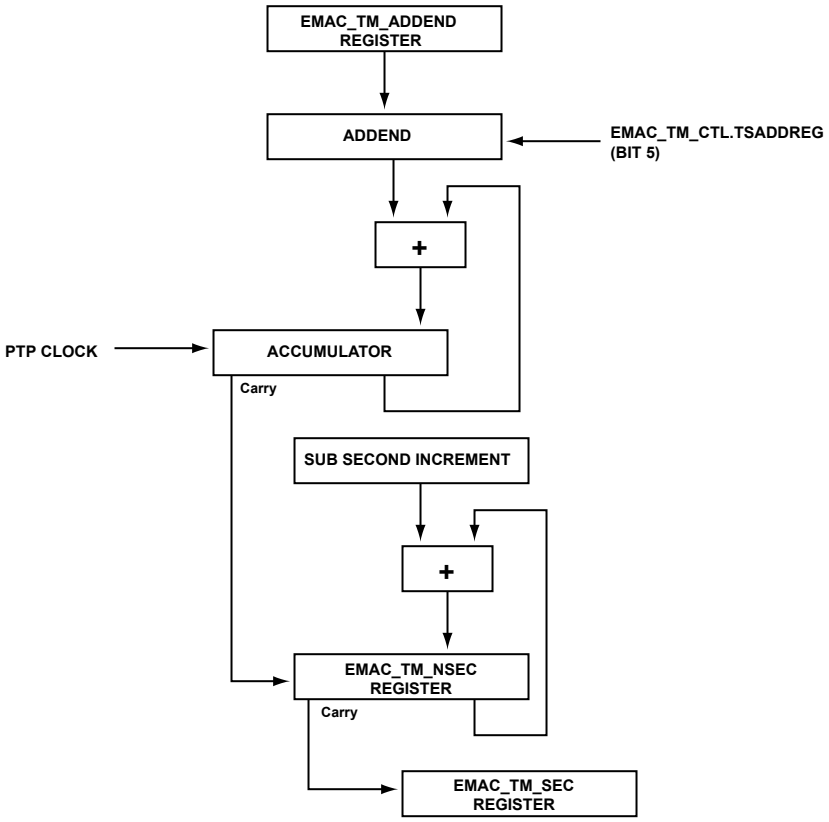

Figure 28-21: System Time Update, Fine Correction Method

Calculating Addend Value

This section describes the fine correction process for system time.

In this example, the requester clock runs at 50 MHz and the completer clock has drifted to 66 MHz. The goal is to adjust the completer system time to 50 MHz, so that the completer PTP module synchronizes with the requester. Using the figure in Fine Correction Method, the nanoseconds increment signal runs at 50 MHz. The nanoseconds increment is the carry from accumulator register. The addend value increments the carry from accumulator at the rate of the completer clock (66 MHz).

The accumulator overflows and generates a carry every N addend value, so N × Addend = 2^{32}.

The accumulator increments at 66 MHz. This addition brings the carry to 50 MHz N = 66/50 = 1.32.

The addend = 2^{32}/1.32 = 0xC1F07C1F.

Therefore, if addend is programmed with 0xC1F07C1F, the completer system time runs at 50 MHz which synchronizes with the requester.

In the Fine Correction Method figure, the subsecond increment is the value programmed in the `EMAC_TM_SUBSEC` register which increments the `EMAC_TM_NSEC` register according to the frequency of the nanoseconds increment signal.

In the example, the sub second increment is 20 (for digital rollover) or 43 (for binary rollover). This addition increments the EMAC_TM_NSEC register by 20 ns (1/50 MHz).

The software must calculate the drift in frequency and update the EMAC_TM_ADDEND register accordingly.

NOTE: The PTP reference clock is the clock at which the system time is updated. When the EMAC_TM_CTL.TSCFUPDT bit is set to 0, this clock equals the PTP clock. Using fine correction, the PTP reference clock is generated on the nanoseconds increment signal at which the system time updates.

Target Time Trigger (Alarm)

The PTP module provides an alarm function by triggering an alarm at a preset time. It sets the EMAC_TM_STMPSTAT.TSTARGT0 bit when the system time matches the value of the EMAC_TM_PPS0TGTM and EMAC_TM_PPS0NTGTM registers. This trigger can generate an interrupt and command the flexible PPS module to start or stop PPS output, depending on value programmed in EMAC_TM_PPSCTL.TRGTMODSEL0 bits.

The trigger is enabled by setting EMAC_TM_CTL.TSTRIG bit. Once an alarm has occurred, if the PTP needs another alarm, the software must:

- Clear the status bit
- Reprogram the EMAC_TM_PPS0TGTM and EMAC_TM_PPS0NTGTM registers to a future value, and
- Set the EMAC_TM_CTL.TSTRIG bit

If the time programmed in the target time registers has elapsed, then a target time programming error is indicated by setting the EMAC_TM_STMPSTAT.TSTRGTERR0 bit.

The alarm time is represented in absolute units, not relative units. For example, if the software must generate an alarm after 10 seconds, it must read the current system time value. Then, the software must add the number corresponding to 10 seconds, and write the result back to the target time registers.

NOTE: The EMAC_TM_CTL.TSTRIG bit is common for all the four PPS outputs and the reset values of the EMAC_TM_PPSCTL.TRGTMODSEL0, EMAC_TM_PPSCTL.TRGTMODSEL1, EMAC_TM_PPSCTL.TRGTMODSEL2, and EMAC_TM_PPSCTL.TRGTMODSEL3 bit fields is zero, so the target time alarm interrupt is active for all PPS outputs by default. To avoid spurious interrupts, for unused PPS outputs set the value of the TRGTMDOSELx bit field in the EMAC_TM_PPSCTL register from 0x0 to 0x3.

Pulse-Per-Second (PPS)

Pulse-per-second (PPS) is a physical representation of system time. It consists of a single pulse or train of pulses. The PTP uses PPS for extra synchronization or to monitor the synchronization performance between clocks. With proper configuration, the PTP module can generate PPS signals that are output on the EMAC_PTPPPS[n] pins. The PTP supports two kinds of PPS output, fixed and flexible.

Fixed Pulse-Per-Second Output

The EMAC supports fixed pulse-per-second (PPS) output that indicates 1-second intervals (default). Change the frequency of the PPS output by configuring the EMAC_TM_PPSCTL.PPSCTL0 bits. The default value for these bits is 0000, which configures a 1Hz signal with a pulse width equal to the period of the PTP clock.

The ***PPS Output Frequencies*** table shows various PPS output frequencies.

Table 28-47: PPS Output Frequencies

PPSCTL Bit Setting	Binary Rollover	Digital Rollover
0001	2 Hz	1 Hz
0010	4 Hz	2 Hz
0011	8 Hz	4 Hz
...	...	...
1111	32.768 kHz	16.384 kHz

In binary rollover mode, the PPS output has a duty cycle of 50% with these frequencies.

In digital rollover mode, the PPS output frequency is an average number. The actual clock is a different frequency that is synchronized every second. PPS output pulses have different periods and duty cycles and this behavior is because of the non-linear toggling of the bits in digital rollover mode. For example:

- When EMAC_TM_PPSCTL.PPSCTL0 = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.
- When EMAC_TM_PPSCTL.PPSCTL0 = 0010, the PPS (2 Hz) is a sequence of:
  - One clock of 50-percent duty cycle and 537-ms period
  - Second clock of 463-ms period (268 ms low and 195 ms high)
- When EMAC_TM_PPSCTL.PPSCTL0 = 0011, the PPS (4 Hz) is a sequence of:
  - Three clocks of 50-percent duty cycle and 268-ms period
  - Fourth clock of 195-ms period (134 ms low and 61 ms high)

Flexible Pulse-Per-Second Output

The EMAC also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the PPS output. Enable this feature, called flexible PPS, by setting the EMAC_TM_PPSCTL.PPSEN bit.

The flexible PPS output options are:

- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of system time. The target time registers program the start and stop time.
- Supports programming the stop time in advance. Programs can configure the stop time before the actual start time has elapsed.

- Supports programming the width, between the rising edge and corresponding falling edge of the PPS signal output, in terms of number of units of subsecond increment. This value is configured in the EMAC_TM_SUBSEC register.
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment. This value is configured in the EMAC_TM_SUBSEC register.
- Provides the option to cancel the programmed PPS start or stop request.
- Indicates error if the start or stop time programmed has already elapsed.

PPS Start or Stop Time

Start time can initially be programmed in the target time registers. If necessary, the start or stop time can be programmed again but only after the earlier programmed value is synchronized to the PTP clock domain. The EMAC_TM_PPS0NTGTM.TSTRBUSY bit indicates the status of synchronization. Programs can configure the start or stop time in advance, even before the earlier stop or start time has elapsed.

Program the start or stop time with advanced system time to ensure proper PPS signal output. If the application programs a start or stop time that has already elapsed, then the EMAC sets the EMAC_TM_STMPSTAT.TSTRGTERR0 bit, indicating the error. If enabled, the EMAC also sets the target time trigger (alarm) interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, the number of the units of subsecond increment value. For example, with the PTP reference clock of 50 MHz, a PPS pulse width of 40 ns, and an interval of 100 ns, program the width and interval to 2 and 5, respectively.

Use a faster PTP reference clock to achieve smaller granularity. Before commanding to trigger a pulse or pulse train on the PPS output, programs must configure or update the interval and width of the PPS signal output.

PPS Command

When the PPS module has a flexible PPS output configuration, the PTP can use the EMAC_TM_PPSCTL.PPSCTL0 bits to command the PPS module to use any of the flexible PPS features.

Programming these bits with a non-zero value instructs the PPS module to initiate an event. Once the command transfers or synchronizes to the PTP clock domain, these bits clear automatically. Software must ensure that these bits are programmed only when they are all-zero.

The ***Flexible PPS Output Commands*** table explains the different commands and their function.

Table 28-48: Flexible PPS Output Commands

PPSCTL (Bits 3–0)	Command	Description
0000	No Command	
0001	Start Single Pulse	Generates single pulse rising at start point defined in target time registers and of duration defined in EMAC_TM_PPS0WIDTH register.

Table 28-48: Flexible PPS Output Commands (Continued)

PPSCTL (Bits 3–0)	Command	Description
0010	Start Pulse Train	Generates train of pulses rising at the start time configured in the target time registers, of duration configured in the EMAC_TM_PPS0WIDTH register. The train of pulses repeats at the interval configured in the EMAC_TM_PPS0INTVL register. By default, the PPS pulse train is free-running unless stopped by stop pulse train at time or stop pulse train immediately commands.
0011	Cancel Start	Cancels the start single pulse and start pulse train commands when the system time has not crossed the programmed start time.
0100	Stop Pulse Train at Time	Stops the train of pulses initiated by the command for start pulse train after the time programmed in the target time registers elapses.
0101	Stop Pulse Train Immediately	Immediately stops the train of pulses initiated by the command for start pulse train.
0110	Cancel Stop Pulse Train	Cancels the stop pulse train at time command when the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
0111-1111	Reserved	

PTP Interrupts

Set the EMAC_IMSK.TS bit to enable interrupts from the PTP module. The EMAC uses the EMAC_ISTAT.TS bit to indicate the status of the interrupt. The PTP supports the following three types of interrupts.

Auxiliary Snapshot Trigger

When an external event occurs on the EMAC_PTPAUXIN[n] pins and a time stamp snapshot occurs, an auxiliary snapshot interrupt is triggered. The EMAC uses the EMAC_TM_STMPSTAT.ATSTS bit to indicate the interrupt.

Target Time Reached

This interrupt is triggered when the system time becomes equal to the value written in the EMAC_TM_PPS0NTGTM and EMAC_TM_PPS0NTGTM registers. Enable or disable the interrupt using the EMAC_TM_CTL.TSTRIG and EMAC_TM_PPSCTL.TRGTMODSEL0 bits. This interrupt can be used as an alarm and is indicated on the EMAC_TM_STMPSTAT.TSTARGT0 bit.

System Time Seconds Register Overflow

This interrupt is triggered when the EMAC_TM_SEC register overflows from 0xFFFF FFFF to 0x0000 0000. This interrupt is indicated on the EMAC_TM_STMPSTAT.TSSOVF bit. As soon as EMAC_TM_SEC register overflows, the EMAC_TM_HISEC register increments by one.

Audio Video Data Transmission

The audio video (AV) feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define the various aspects of the AV feature implementation.

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows reservation of the network resources for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications. For example, audio and video and across bridged and virtual-bridged LANs. Virtual-bridged LANs consist of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

As shown in the ***Transmit and Receive Path Block Diagram*** figure, one SCB controller interface connects to three DMA channels (channel 0, channel 1, and channel 2). The DMA arbiter helps in arbitration of all the paths (transmit and receive) in channel 0, channel 1 and channel 2. Each channel has a separate control and status register (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

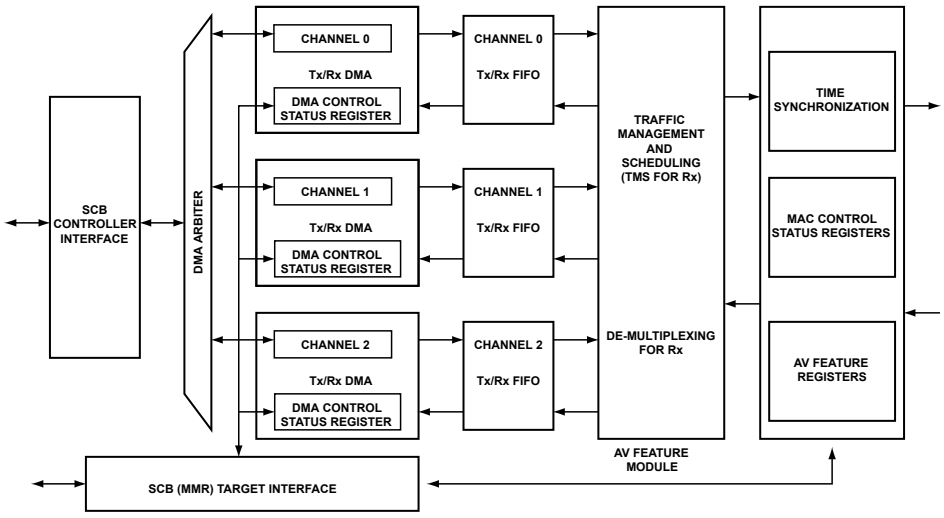

Figure 28-22: Transmit and Receive Path Block Diagram

Transmit Path Functions

The transmit path of channel 0 supports strict-priority algorithm and is used for best-effort traffic. For a channel, the strict-priority algorithm determines that a frame is available for transmission if the channel contains one or more frames. When the threshold mode for EMAC MFL Tx FIFO is enabled, the strict-priority algorithm determines that a frame is available for transmission. The algorithm determines when the channel contains a partial frame of size equal to the programmed threshold limit.

The transmit paths of channel 1 and channel 2 support traffic management by using the credit-based shaper algorithm. For a channel, the credit-based shaper algorithm determines that a frame is available for transmission if the following conditions are true:

- The channel contains one or more frames.

- The credit for the channel is positive as per the algorithm.

Programs can disable the credit-based shaper algorithm for all channels or for lower-priority channels. The credit-based shaper algorithm can be disabled for channel 1 and channel 2 or for channel 1 only. When the credit-based shaper algorithm for a channel is disabled, the channel uses the default strict-priority algorithm.

Each transmit DMA has a separate descriptor chain for fetching the transmit data. The transmit channel that receives access to the system bus depends on the DMA arbiter. For information about the DMA arbiter, see DMA Arbiter.

The transmit path has separate FIFOs for each channel, as shown in the ***Transmit and Receive Path Block Diagram*** figure. The data fetched by the DMA is placed in the respective FIFO. The traffic management and scheduler unit (TMS) controls which FIFO data the MAC transmits. If the credit-based shaper algorithm is enabled for a channel (1 or 2), then the corresponding channel is selected for transmission when the following conditions are true:

- The frame is available in the channel and has a positive or zero credit.
- The higher priority channel has no frame waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all channels, then the frame awaiting transmission from a channel is selected. The selection is made based on the priority scheme described in the ***Fixed Priority Scheme for DMA Channels*** table.

Receive Path Functions

To differentiate between the AV and non-AV traffic, the MAC provides a status. The status indicates if data is an AV packet and identifies its corresponding VLAN Priority tag value. This status is updated in the extended status field of the receive descriptor as explained in "Receive Descriptor". The `EMAC_MAC_AVCTL.AVT`bit field specifies a value that is compared with the EtherType field of the incoming Ethernet frame to detect an AV packet. The AV packets can be of the following two types:

- ***AV data packets.*** The AV data packets are always tagged. The tagged AV control packets are received based on the programmed priority value. The `EMAC_MAC_AVCTL.AVP` bit field specifies the channel to which an AV packet with a given priority must be sent.
- ***AV control packets.*** The AV control packets are either tagged or untagged. The untagged AV control packets are received on channel 0 by default. To receive these packets on channel 1 or channel 2, program the `EMAC_MAC_AVCTL.AVCH` bit field. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

The following describes how tagged AV control packets and AV data packets are sent to a channel.

Table 28-49: AV Packets

Receive paths of channel 1 and channel 2 are enabled.	***Channel 2*** The following packets, with priority value greater than or equal to the value programmed in `EMAC_MAC_AVCTL.AVP` bit field, are received on channel 2: AV packets Non-AV tagged packets (if `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 1 The following packets, with priority value less than the value programmed in AV MAC control register, are received on channel 1: AV packets Non-AV tagged packets (if `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 0 All other packets are received on channel 0.
For example, priority value of 3 is programmed in the `EMAC_MAC_AVCTL.AVP` bit field.	***Channel 2*** The following packets with priority value from 3 to 7 are received on channel 2: AV packets Non-AV tagged packets (if the `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 1 The following packets with priority value 2 are received on channel 1: AV packets Non-AV tagged packets (if the `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 0 All other packets are received on channel 0.

DMA Arbiter

The DMA arbitrates between the transmit and receive paths of DMA channel 0, channel 1, and channel 2 for accessing descriptors and data buffers.

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the highest priority channel (channel 2) always wins the arbitration whenever it requests the bus. The ***Fixed Priority Scheme for DMA Channels*** table provides information about the priority levels of the DMA channels.

Table 28-50: Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1	Channel 1
2 (high)	Channel 2

Slot Number Function

The slot number function schedules the data fetching by DMA from the system memory. This feature is useful when the source AV data must transmit at specific intervals. The transmit descriptor word 0 (TDES0) [6:3] bits program the slot number at which the DMA fetches the data from system memory. This 4-bit field allows the host to schedule data up to 16 slots of 125 micro-second each. This field is applicable only for the AV channels (channel 1 and channel 2).

When DMA fetches a transmit descriptor, it compares the slot number of the transmit descriptor with the internally generated reference slot interval. The slot interval is a counter that updates every 125 usec of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the value in the EMAC_TM_SEC register increments, that is, EMAC_TM_NSEC rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state until there is a match.

Programs can also set the EMAC_DMA1_CHSFCS.ASC bit to enable the DMA to fetch the data only if it matches the current slot or the next two slots.

NOTE: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

Programs can enable the check for slot number by setting the EMAC_DMA1_CHSFCS.ESC bit. When this check is not enabled, the packets are fetched immediately after the descriptor is read. Programs can read the EMAC_DMA1_CHSFCS.RSN bit field to discover the value of the reference slot number in DMA.

Interrupts

Each DMA channel has it own dedicated interrupt channel, the software can take advantage of it for processing various DMA channels.

Credit-Based Shaper Algorithm Functions

The Traffic Manager and Scheduler (TMS) block (shown in the ***Transmit and Receive Path Block Diagram*** figure) uses the credit-based shaper algorithm to arbitrate the AV traffic in all channels and the legacy Ethernet traffic in channel 0. Channel 1 and channel 2 can be programmed to use the credit-based shaper algorithm.The following sections provide information about implementing the Credit-Based Shaper Algorithm:

Credit Value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps or 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional, based on the required idleSlope and sendSlope values as described in the following table.

Table 28-51: idleSlope and sendSlope Values

Mode	Values	Description
100 Mbps	portTransmitRate = 100 Mbps idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) sendSlope = 30 Mbps	Credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when besteffort frame is being transmitted. Credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class frame is being transmitted.

The DMA stores the channel traffic in the respective Tx FIFO based on the slot number in the transmit descriptor (if enabled) or depending on the bandwidth availability on the SCB.

The credit for a channel builds up only when the frame is available but it cannot be transmitted because the MAC is sending a frame from another channel. The EMAC supports another mode in which the credit can build up in advance for a channel in which no frame is available in its FIFO. This enables sending a burst of high priority traffic in a channel as soon as data is available. This can be enabled with the `EMAC_DMA1_CHCBSCTL.CC`/`EMAC_DMA2_CHCBSCTL.CC` bit of the channel 1 and channel 2 CBS control registers.

When the `EMAC_DMA1_CHCBSCTL.CC`/`EMAC_DMA2_CHCBSCTL.CC` bit is reset, the accumulated credit parameter in the Credit-Based Shaper Algorithm is set to zero if there is positive credit and there is no frame to transmit in a channel. The credit does not accumulate when there is no frame waiting in a channel and other channels are transmitting. When the `EMAC_DMA1_CHCBSCTL.CC`/`EMAC_DMA2_CHCBSCTL.CC` bit is set, the accumulated credit parameter in the Credit-Based Shaper Algorithm is not reset to zero if there is positive credit and no frame to transmit in a channel. The credit accumulates even when there is no frame waiting in a channel and other channels are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8x1024=2867 and 1.2x1024=1229 respectively. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values.

This means that if computed hiCredit and loCredit values are 12000 bits and 3036 bits respectively, then the values to be programmed in the `EMAC_DMA1_CHHIC`/`EMAC_DMA2_CHHIC` and `EMAC_DMA1_CHLOC`/`EMAC_DMA2_CHLOC` registers are 12000x1024 bits and two's complement of 3036x1024 respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority channel (channel 1 and channel 2) in the CBS status registers (`EMAC_DMA1_CHCBSSTAT`/`EMAC_DMA2_CHCBSSTAT`). This allows the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 us) in a channel. The status register is updated even if the Credit-Based Shaper Algorithm is not enabled for a channel. The number of slots over which the average bits transmitted per slot are computed is programmed in the EMAC_DMA1_CHCBSCTL.SLC/EMAC_DMA2_CHCBSCTL.SLC bits. For example, if these bit fields are programmed for two slots, then the average bits are computed over slot numbers 0-1, 2-3, 4-5, and so on.

The value programmed in the EMAC_DMA1_CHISC/EMAC_DMA2_CHISC register of a channel is proportional to the bandwidth reserved for the channel. The software can allocate any bandwidth that is not used by the higher priority channel to the reserved bandwidth of the lower priority channel.

A lower priority channel, using the Credit-Based Shaper Algorithm, cannot use the unused reserved bandwidth of any higher priority channel that is using the Credit-Based Shaper Algorithm. However, a lower priority channel that is using the strict-priority algorithm can use the unused reserved bandwidth of any higher priority channel that uses the Credit-Based Shaper Algorithm. For example, channel 1 and channel 2 use the Credit-Based Shaper Algorithm (with reserved bandwidth of 50% and 25% respectively) and channel 0 uses the strict-priority algorithm. If channel 1 uses only 40% of the reserved bandwidth, then the remaining 10% is used by channel 0. The channel 2 cannot exceed the reserved bandwidth of 25%.

Energy-Efficient Ethernet

Energy-Efficient Ethernet (EEE) is an optional operational mode that enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps. The MAC supports the IEEE Standard 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off parts of the communication device functionality when there is no data awaiting transmission and receipt. The systems on both sides of the link can disable some functionality and save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported and then select the set of parameters that common to both devices.

NOTE: The EEE feature is not supported when the MAC is configured to use the RMII interface. You should activate the EEE mode only when the MAC is operating with RGMII interface.

NOTE: According to the Energy-Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

Transmit Path Functions

In the transmit path, the software must set the EMAC_LPI_CTLSTAT.LPIEN bit to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and then starts transmitting the LPI pattern instead of the IDLE pattern during Interframe gap (IFG).

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts the ETH0_TXCTL_TXEN signal.
2. Asserts the TX_ER signal.
3. Sets EMAC_TXD[n][3:0] to 0x1 (for 100 Mbps) or EMAC_TXD[n][7:0] to 0x01 (for 1000 Mbps).

   NOTE: The MAC maintains the same state of the TX_EN, TX_ER, and EMAC_TXD[n] signals for the entire duration during which the PHY remains in the LPI state.

4. Updates the status using the EMAC_LPI_CTLSTAT.TLPIEN bit and generates an interrupt.

To bring the PHY out of the LPI state, that is, when the software resets the EMAC_LPI_CTLSTAT.LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER: The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed using the EMAC_LPI_TMRSCTL.TWT bit field.
3. Updates the LPI exit status using the EMAC_LPI_CTLSTAT.TLPIEX bit and generates an interrupt.

The ***LPI Transitions (Transmit)*** figure shows the behavior of TX_EN, TX_ER, and EMAC_TXD[n] [3:0] signals during the LPI mode transitions.

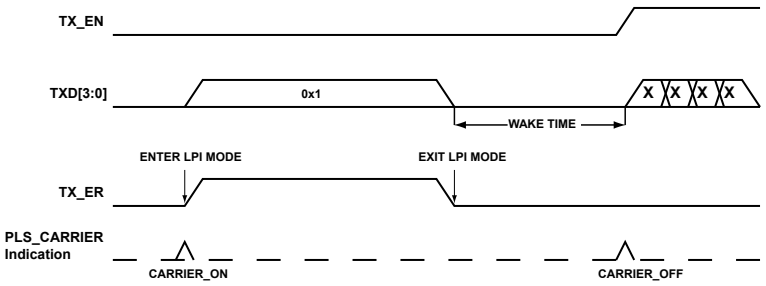

Figure 28-23: LPI Transitions (Transmit)

NOTE: The MAC does not stop the TX_CLK clock.

NOTE: If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

NOTE: If the MAC is in the LPI mode and the host issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

LPI Timers

LPI LS TIMER

The LPI LS timer counts, in milliseconds, the time expired since the link status is up. Programs can enable the monitoring of Bit 3 EMAC_ISTAT.RGMIIIS (link status) of Register 54 (SGMII/RGMII/SMII Control and Status Register) by setting the EMAC_LPI_CTLSTAT.PLSEN bit.

The link status is indicated to the MAC by Bit 3 (link status) of Register 54 (RGMII Control and Status Register) or the value programmed by the software in the EMAC_LPI_CTLSTAT.PLS bit. If the link status is not available in Register 54 (RGMII Control and Status Register), the software should get the PHY link status by reading the PHY register and accordingly update the EMAC_LPI_CTLSTAT.PLS bit.

This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. When the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the EMAC_LPI_TMRSCTL.LST bit field. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10-bit wide. Therefore, the software can program up to 1023 milliseconds

LPI TW TIMER

The LPI TW timer counts, in microseconds, the time expired since the de-assertion of LPI. The terminal should be programmed using the EMAC_LPI_TMRSCTL.TWT bit. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.

The MAC supports the LPI TW timer in units of microsecond. The LPI TW timer is 16-bit wide. Therefore, the software can program up to 65535 us.

NOTE: Program the EMAC_LPI_CTLSTAT.PLS bit to 1'b0 before switching between the GMII and MII modes. This resets the internal timers. If the mode is changed after the LPI LS timer or LPI TW timer starts, the change in the TX clock frequency can result in incorrect timeout.

LPI Interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the EMAC_LPI_CTLSTAT register.

EMAC Event Control

The EMAC has dedicated interrupt signals registered with the system event controller (SEC) module. Various interrupt sources within the EMAC peripheral are shared through this interrupt line. Refer to the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for details on how interrupts work in this product and how to configure them.

EMAC Interrupt Signals

Interrupts from the EMAC are triggered from the EMAC DMA layer or the EMAC CORE layer. Interrupts are triggered from EMAC DMA when a particular status bit is set in the EMAC_DMA0_STAT register. An interrupt line is asserted only when the corresponding bits are enabled in the DMA interrupt enable register. Similarly, interrupts are triggered from the EMAC CORE when a particular MMC status bit, RGMII link status bit, LPI, or PTP status bit is set in the interrupt status register.

An interrupt line is asserted only when the corresponding bits are enabled in the MMC mask registers for MMC counters or the interrupt mask register for PTP. DMA status register also reflects the MMC interrupt status. The following lists show the two groups of interrupts in the DMA status register.

NIS – Normal Interrupt source summary:

- Transmit Interrupt
- Transmit Buffer Unavailable
- Receive Interrupt
- Early Receive Interrupt

AIS – Abnormal Interrupt source summary:

- Transmit Process Stopped
- Transmit Jabber Timeout
- Receive FIFO Overflow
- Transmit Underflow
- Receive Buffer Unavailable
- Receive Process Stopped
- Receive Watchdog Timeout
- Early Transmit Interrupt
- Fatal Bus Error

As an enhancement on ADSP-SC59x processors, to minimize overall interrupt latency, there are two new types of interrupts in addition to the legacy EMAC_STAT interrupt. These new interrupts are called EMAC_MAC and EMAC_DMA interrupts. Each DMA channel contains its own individual EMAC_DMA interrupt.

The interrupts routed to EMAC_MAC are as follows: GLPII – GMAC LPI Interrupt

- TTI – Timestamp Trigger Interrupt
- MCI – MAC MMC Interrupt
- MCI – MAC MMC Interrupt

The interrupts routed to EMAC_DMA (3 EMAC_DMA interrupts for EMAC0 and 1 for EMAC1) are as follows:

Normal Interrupt Sources (NIS):

- TI – Transmit Interrupt
- TU – Transmit Buffer Unavailable
- RI – Receive Interrupt
- ERI – Early receive Interrupt

Abnormal Interrupt Sources (AIS):

- TPS – Transmit Process Stopped
- TJT – Transmit Jabber Timeout
- UNF – Transmit Buffer Underflow
- ETI - Early Transmit Interrupt
- OVF – Receive Buffer Overflow
- RU – Receive Buffer Unavailable
- RPS – Receive Process Stopped
- RWT – Receive Watchdog Timeout
- FBI – Fatal Bus Error

The EMAC generates an interrupt only once for simultaneous, multiple events. The driver must read the EMAC_DMA0_STAT register for the cause of the interrupt. It can generate a new interrupt once the driver has cleared the appropriate bit in DMA status register.

For example, the controller generates a receive interrupt (EMAC_DMA0_STAT.RI bit) and the driver begins reading the EMAC_DMA0_STAT register. Next, a receive buffer unavailable interrupt (EMAC_DMA0_STAT.RU bit) occurs. The driver clears the EMAC_DMA0_STAT.RI bit but the internal interrupt signal is not deasserted, because of the active or pending EMAC_DMA0_STAT.RU interrupt. The driver must scan all of the descriptors, from the last recorded position to the first one owned by the DMA, to know which descriptor has asserted the interrupt.

Interrupts are cleared by writing a 1 to the corresponding bit position in the EMAC_DMA0_STAT register. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

An interrupt delay timer provides (receive interrupt watchdog timer register) flexible control of the receive interrupt.

When the interrupt timer is programmed with a non-zero value, it is activated as soon as the RxDMA transfers a received frame to system memory. The transfer occurs without asserting the receive interrupt. This interrupt is not enabled in the corresponding receive descriptor (RDES1[31] in the receive DMA descriptors).

When this timer runs out (per the programmed value), the EMAC_DMA0_STAT.RI bit is set. The interrupt is asserted when the corresponding EMAC_DMA0_STAT.RI bit is enabled in the interrupt enable register. The timer

is disabled before it runs out, when a frame is transferred to memory and when the EMAC_DMA0_STAT.RI bit is set because it is enabled for that descriptor.

PHYINT Interrupt Signal

A PHY device can notify the EMAC when it detects changes to the link status, such as auto-negotiation or a duplex-mode change. The external PHY chip typically includes an interrupt generation pin to aid this status change notification to the MAC. This signal is typically called PHYINT. A failing or rising edge on this signal can detect a PHY interrupt at the EMAC.

In the processor, any of the GPIO pins can be a used as a PHYINT signal. Use the following procedure to configure a GPIO as a PHYINT signal.

1. Program the GPIO to detect a falling or rising edge sensitive interrupt.
2. Program the PHY to generate the interrupt on a signal status change.
3. If PHYINT is asserted, read the PHY status register through the station management interface.

NOTE: The PHYINT is not part of EMAC module. However, any GPIO pin can be configured to interrupt the processor when a rising edge generated by PHY is detected.

Refer to the PORT chapter for more info on configuring GPIO pins for input.

EMAC Programming Model

This section provides the programming model of Ethernet MAC peripheral for developers.

EMAC Programming Steps

The following sections provide some general programming information. The steps are written for EMAC DMA0, but apply to DMA1 and DMA2 as well.

DMA Initialization

Use the following procedure to initialize DMA. This procedure applies to all DMA channels.

1. Perform a software reset by setting the EMAC_DMA0_BUSMODE.SWR bit. This action resets all of the EMAC internal registers and logic.
2. Wait for the completion of the reset process by polling the EMAC_DMA0_BUSMODE.SWR bit which is only cleared (automatically) after the reset operation completes.
3. Poll the EMAC_DMA0_BMSTAT.BUSRD and EMAC_DMA0_BMSTAT.BUSWR bits to confirm that all previously initiated (before software-reset) or ongoing SCB transactions are complete.
4. Program the required fields in the EMAC_DMA0_BMMODE register:
    a. Address aligned bursts

b. Fixed burst or undefined burst

c. Burst length values and burst mode values

d. Descriptor length (only valid when using ring mode)

5. Program the SCB interface options in the EMAC_DMA0_BMMODE register. If fixed burst-length is enabled, then select the maximum burst-length possible on the SCB bus (bits EMAC_DMA0_BMMODE.BLEN4, EMAC_DMA0_BMMODE.BLEN8, EMAC_DMA0_BMMODE.BLEN16).
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the DMA owns the receive descriptors (the OWN bit of the descriptor is set). For OSF mode, create at least two descriptors.
7. Ensure that the software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.
8. Initialize the EMAC_DMA0_RXDSC_CUR and EMAC_DMA0_TXDSC_CUR registers with the base address of the receive and transmit descriptors respectively.
9. Program the required fields in the EMAC_DMA0_OPMODE register to initialize the mode of operation as follows:

   a. Receive and transmit store and forward

   b. Receive and transmit threshold control

   c. Error Frame and undersized good frame forwarding enable

   d. OSF mode

10. Clear the interrupt requests by writing to those bits of the EMAC_DMA0_STAT register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit.
11. Enable the interrupts by programming the EMAC_DMA0_IEN register.
12. Start the receive and transmit DMA by setting the EMAC_DMA0_OPMODE.SR and EMAC_DMA0_OPMODE.ST bits.

EMAC CORE Initialization

Use the following procedure to initialize the EMAC CORE.

1. Program the EMAC management address register (EMAC_SMI_ADDR) for controlling the management cycles for external PHY. For example, physical layer address (EMAC_SMI_ADDR.PA). In addition, set the EMAC_SMI_ADDR.SMIB bit for writing into PHY and reading from PHY.
2. Read the 16-bit data of management address register (EMAC_SMI_DATA) from the PHY for link up, speed of operation, and mode of operation. Specify the appropriate address value in the EMAC_SMI_ADDR.PA bit field.
3. Program the MAC address in the EMAC_ADDR0_HI and EMAC_ADDR0_LO registers.

4. If using hash filtering, program the hash table high and low registers register (EMAC_HASHTBL_HI, EMAC_HASHTBL_LO).
5. Program the fields to set the appropriate filters for the incoming frames in the MAC frame filter register (EMAC_MACFRMFILT):
    a. Receive all.
    b. Promiscuous mode.
    c. Hash or perfect filter.
    d. Unicast, multicast, broadcast, and control frames filter settings.
6. Program the fields for proper flow control in flow control register (EMAC_FLOWCTL):
    a. Pause time and other pause frame control bits.
    b. Receive and transmit flow control bits.
    c. Flow control busy or backpressure activate.
7. Program the EMAC interrupt mask register bits (EMAC_IMSK), as needed.
8. Program the appropriate fields in MAC configuration register (EMAC_MACCFG). For example, inter-frame gap while transmission and jabber disable. Based on the auto-negotiation desired, set the duplex mode (EMAC_MACCFG.DM bit) or speed select (EMAC_MACCFG.FES bit).
9. Set the transmit enable (EMAC_MACCFG.TE) and receive enable (EMAC_MACCFG.RE) bits.

Performing Normal Transmit and Receive Operations

For normal transmit and receive interrupts, the program must first read the interrupt status.

1. Poll the descriptors, reading the status of the descriptor owned by the application (either transmit or receive).
2. Set the appropriate values for the descriptors, ensuring that transmit and receive descriptors are DMA descriptors to resume the transmission and reception of data.

    ADDITIONAL INFORMATION: If the descriptors are not DMA (or no descriptor is available), the DMA goes into SUSPEND state.
3. Write a 0 into the Tx/Rx poll demand registers (EMAC_DMA0_TXPOLL and EMAC_DMA0_RXPOLL).

    Transmit or receive operations are resumed by freeing the descriptors and issuing a poll demand.
4. Read (for the debug process), the values of the current host transmitter or receiver descriptor address pointer (EMAC_DMA0_TXDSC_CUR, EMAC_DMA0_RXDSC_CUR) registers.
5. Read (for the debug process), the values of the current host transmit buffer address pointer and receive buffer address pointer (EMAC_DMA0_TXBUF_CUR, EMAC_DMA0_TXBUF_CUR) registers.

Stopping and Starting Transfers

Use the following procedure to stop and start EMAC transfers.

1. Disable the transmit DMA (if applicable), by clearing the EMAC_DMA0_OPMODE.ST bit.
2. Wait for any previous frame transmissions to complete. Check for completion by reading the appropriate bits of the debug register (EMAC_DBG).
3. Disable the MAC transmitter and MAC receiver by clearing the EMAC_MACCFG.TE and EMAC_MACCFG.RE bits.
4. Disable the receive DMA (if applicable), after ensuring that the data in the receive FIFO transfers to the system memory by reading the EMAC_DBG register.
5. Make sure that both the transmit and receive FIFOs are empty.
6. To restart the operation, first start the DMA, and then enable the MAC transmitter and receiver.

Interrupts and Interrupt Service Routines

The following procedure describes specific steps for enabling interrupts and using their ISRs.

This procedure is typically performed with EMAC and DMA initialization and operations.

1. Receive interrupts are enabled for descriptors by default. Enable transmit interrupts for individual descriptors by setting the IC bit (bit 30) in the TDES0 word of the transmit descriptor.
2. Enable the required bits in the DMA interrupt enable register (EMAC_DMA0_IEN.NIE) .

   ADDITIONAL INFORMATION: Setting the EMAC_DMA0_IEN.NIE or EMAC_DMA0_IEN.AIE bits can turn on the occurrence of all normal or abnormal interrupt conditions. Individual conditions can also be enabled on using individual bits in the EMAC_DMA0_IEN register.
3. Enable MMC overflow interrupts by setting appropriate bits in the EMAC_MMC_RXIMSK and EMAC_MMC_TXIMSK registers.
4. Enable PTP interrupts by setting the EMAC_IMSK.TS bit.
5. Once an EMAC interrupt is asserted and the SEC branches execution to the EMAC ISR, perform the following software program sequence.
   a. Read DMA status from the EMAC_DMA0_STAT register.
   b. Clear the interrupt source by writing 1 (W1C) to the bits that are set in the EMAC_DMA0_STAT register.
   c. Check for normal/abnormal/mmc/ptp interrupts by parsing the status bits read earlier, and call the appropriate service function.

      ADDITIONAL INFORMATION: Normal interrupt assertions include the transmit and receive interrupt. Abnormal interrupt assertions include the receive underflow.

6. The MMC handler functions use the following sequence.
    a. Read the EMAC_ISTAT register and parse for the EMAC_ISTAT.MMCTX and EMAC_ISTAT.MMCRX bits to determine if the interrupt is a transmit counter or receive counter-interrupt.
    b. Read the EMAC_MMC_RXINT or EMAC_MMC_TXINT registers to determine which of the counters have triggered the interrupt.
    c. Read the respective MMC counter that caused the interrupt to clear it.
7. PTP handler functions use the following sequence:
    a. Read the EMAC_ISTAT.TS bit to determine if a PTP interrupt occurred.
    b. Read EMAC_TM_STMPSTAT register to determine the interrupt source by parsing the EMAC_TM_STMPSTAT.ATSTS, EMAC_TM_STMPSTAT.TSTARGT0 - EMAC_TM_STMPSTAT.TSTARGT3, and EMAC_TM_STMPSTAT.TSSOVF bits.
    c. Clear the interrupt source by reading the EMAC_TM_STMPSTAT register.

Enabling Checksum for Transmit and Receive

Use the following steps to enable transmit and receive checksums.

Enabling receive and transmit checksums is typically performed with EMAC and DMA initialization and operations. Transmit and receive checksum features are independent of each other.

1. To enable transmit checksum insertion:
    a. Enable store-and-forward mode in the FIFO by setting the EMAC_DMA0_OPMODE.TSF bit.
    b. Ensure that the transmit frame can be contained within the 256 byte Tx FIFO conforming to the size rule: FIFO Depth – PBL – 3 FIFO locations, where PBL is burst length.
    c. Program the following necessary parameters for transmit checksum, by programming (CIC) checksum insertion control in TDES0: IP header checksum, IP header checksum and payload checksum, IP header checksum, payload checksum, and pseudo header checksum.

    A higher layer such as the IP stack sends out the packet to the EMAC which inserts the checksum as configured.
2. To enable receive checksum verification:
    a. Enable receive checksum offload engine by setting the EMAC_MACCFG.IPC bit.
    b. Enable 8 word descriptor (32 bytes), by setting the EMAC_DMA0_BUSMODE.ATDS bit.
    c. Provide a total of 8 x 32-bit word space for the receive descriptor.
    d. Wait for the receive interrupt and check for extended status availability by parsing bit 0 in the RDES0 word.
    e. If extended status available, read RDES4 and pass to a higher layer such as the IP stack.

The higher software layer can check for IPv4/IPv6/payload type and checksum payload or header errors.

Programming the System Time Module

Use the following procedure to configure the PTP module

1. Enable the PTP module by setting the EMAC_TM_CTL.TSENA bit 0.
2. System Time Initialization
   a. The time (seconds and nanoseconds) at which system time is initialized. Write the time into the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers.
   b. Set EMAC_TM_CTL.TSINIT bit. System time is initialized and this bit is cleared automatically.
   c. Configure binary or digital rollover of the EMAC_TM_NSEC register using the EMAC_TM_CTL.TSCTRLSSR bit.
3. System Time Coarse Correction
   a. Write the offset time (seconds and nanoseconds) to add to or subtract from the system time using the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers.
   b. Choose between add or subtract offset time using the EMAC_TM_NSECUPDT.ADDSUB bit.
   c. Set the EMAC_TM_CTL.TSUPDT bit to correct system time with offset time. This bit is cleared automatically.
4. System Time Fine Correction
   a. Calculate the addend value based on the input PTP clock frequency and the frequency requirement. See Fine Correction Method.
   b. Write the calculated addend value in EMAC_TM_ADDEND register and set the EMAC_TM_CTL.TSADDREG bit to update the addend value. This bit is cleared automatically.
   c. Configure the EMAC_TM_SUBSEC register based on new PTP frequency.
5. Target Time Trigger (Alarm)
   a. Set the EMAC_IMSK.TS bit to enable PTP interrupts.
   b. Program the EMAC_TM_PPSCTL.TRGTMODSEL0 bit with 00 or 10 (for PPS start or stop time programming).
   c. Program the time when the interrupt must trigger using the EMAC_TM_PPS0TGTM and EMAC_TM_PPS0NTGTM registers. The programmed time must be greater than the current system time.

      ADDITIONAL INFORMATION: If the programmed time is not greater than the target time, a programming error occurs. The EMAC uses the EMAC_TM_STMPSTAT.TSTRGTERR0 bit to indicate the error.

d. Set the EMAC_TM_CTL.TSTRIG bit to enable the target time trigger interrupt.

After the system time reaches the programmed target time (in step 2), the target time trigger interrupt occurs. The EMAC_TM_STMPSTAT.TSTRGTERR0 and EMAC_ISTAT.TS bits indicate the error. The EMAC_TM_CTL.TSTRIG bit is cleared automatically.

Programming the PTP for Frame Detection and Time Stamping

Use the following procedure to configure the PTP module.

1. For time stamping a transmitting frame, set the TTSE bit in the TDES0 register of the corresponding frame.
2. Extend the descriptor word length from 4 words to 8 words by setting the EMAC_DMA0_BUSMODE.ATDS bit.
3. Configure bits 18–10 in the EMAC_TM_CTL register so that the PTP module detects and time stamps only specific types of received frames. Refer to the EMAC_TM_CTL register description for more information.
4. Enable the PTP module by setting the EMAC_TM_CTL.TSENA bit.
5. Initialize the system time.
6. Verify the RDES4 register for the status of the received frame and the RDES6 and RDES7 registers for time stamp nanoseconds and seconds value.

Programming for Auxiliary Time Stamps

1. Set the EMAC_IMSK.TS bit to enable PTP interrupts.
2. Set the EMAC_TM_CTL.TSENA bit to enable the PTP module.
3. Initialize system time.

   ADDITIONAL INFORMATION: Whenever a rising edge on the auxiliary time stamp trigger pin is detected, system time seconds and nanoseconds are captured and stored into 4-deep auxiliary time stamp FIFO. An auxiliary time stamp trigger interrupt occurs. The EMAC uses the EMAC_TM_STMPSTAT.ATSTS and the EMAC_IMSK.TS bits to indicate the interrupt.
4. Read the contents of the FIFO one-by-one through EMAC_TM_AUXSTMP_SEC and EMAC_TM_AUXSTMP_NSEC registers. One level of the FIFO is cleared when the EMAC_TM_AUXSTMP_SEC register is read. Therefore, read the EMAC_TM_AUXSTMP_NSEC register before the EMAC_TM_AUXSTMP_SEC register.
5. Set the EMAC_TM_CTL.ATSFC bit to clear the FIFO.

Programming Fixed Pulse-Per-Second Output

Use the following procedure to program the fixed PPS output.

1. Enable the PTP module by setting the EMAC_TM_CTL.TSENA bit.

2. Output the PPS waveform by configuring the EMAC_TM_PPSCTL.PPSCTL0 bits and binary or digital rollover using the EMAC_TM_CTL.TSCTRLSSR bit. See Fixed Pulse-Per-Second Output.

Programming Flexible Pulse-Per-Second Output

Use the following procedure to program flexible PPS output.

1. Enable the PTP module by setting the EMAC_TM_CTL.TSENA bit.
2. Set the EMAC_TM_PPSCTL.PPSEN bit to enable flexible PPS output.
3. Program the EMAC_TM_PPSCTL.TRGTMODSEL0 bits with 11 or 10 (for target time trigger interrupt).
4. Program the start time value when the PPS output starts using the EMAC_TM_PPS0TGTM and EMAC_TM_PPS0NTGTM registers. Ensure that the EMAC_TM_PPS0NTGTM.TSTRBUSY bit is reset before programming the target time registers again.
5. Program the period of the PPS signal output using the EMAC_TM_PPS0INTVL register for pulse train output. Program the width of the PPS signal output in the EMAC_TM_PPS0WIDTH register for single pulse or pulse train output.
6. Ensure that the EMAC_TM_PPSCTL.PPSCTL0 bits are cleared. Then, program the bits to 0001 to start single pulse, or to 0010 to start pulse train at programmed start time (Step 4).

   ADDITIONAL INFORMATION: The PPS pulse train is free-running unless stopped by a STOP pulse train at time command (EMAC_TM_PPSCTL.PPSCTL0 = 0100) or STOP pulse train immediately command EMAC_TM_PPSCTL.PPSCTL0 = 0101).
7. The start of pulse generation can be canceled by giving the cancel start command (EMAC_TM_PPSCTL.PPSCTL0 = 0011) before the programmed start time (Step 4) elapses.
8. Program the stop time value when the PPS output must stop using theEMAC_TM_PPS0TGTM and EMAC_TM_PPS0NTGTM registers. Ensure that the EMAC_TM_PPS0NTGTM.TSTRBUSY bit is reset before programming the target time registers again.
9. Ensure that the EMAC_TM_PPSCTL.PPSCTL0 bits are cleared. Then, program the bits to 0100. This programming stops the train of pulses on PPS signal output after the programmed stop time (Step 8) elapses.

   ADDITIONAL INFORMATION: The pulse train can be stopped immediately by giving the STOP pulse train immediately command (EMAC_TM_PPSCTL.PPSCTL0 = 0101). Program the EMAC_TM_PPSCTL.PPSCTL0 bits to 0110 before the programmed stop time (Step 8) elapses to cancel the stop pulse train command (given in Step 9).

EMAC Programming Concepts

The following sections provide basic information and guidelines to help with programming the EMAC module.

IEEE 802.3 Ethernet Packet Structure

The ***IEEE 802.3 Frame Structure*** table provides typical frame format of an Ethernet packet. Refer to the IEEE standards for detailed information on Ethernet packets and their format.

Table 28-52: IEEE 802.3 Frame Structure

Parameter	Description	Position in Ethernet Packet	Total Bytes
PREAMBLE	This parameter is a 56-bit (7-byte) pattern of alternating 1 and 0 bits (#10101010), which allows devices on the network to detect a new incoming frame for synchronization.	1	7
SFD	The SFD (#10101011) is a 1-byte pattern designed to break the preamble pattern, and signal the start of the actual frame.	2	1
DA	48-bit destination address. This parameter can be a unicast, multicast, or broadcast address.	3	6
SA	48-bit long source address, typically a unicast, multicast, or broadcast address.	4	6
LT	Typically this field is the length, in terms of the number of bytes, and can be anywhere between 0–1500. When the value is greater than or equal to 0x0600, this field also indicates the type of special payload carried by the frame. Examples include 0x8808 for flow control and 0x0800 for IPv4.	5	2
DATA	Actual application data payload, usually between 0–1500.	6	0–1500
PAD	This field compensates for data frames that are shorter than 64 bytes long, not including the preamble.	7	0–46
FCS	The frame check sequence is a 32-bit cyclic redundancy check that detects corrupted data within the entire frame. This parameter is generated from a CRC-32 polynomial code (CRC-32-IEEE): G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1.	8	4

Frame Size Statistics for Application Software

Table 28-53: Ethernet Frame Size Statistics

Frame size statistics	VLAN-specific change Comments	
Information bytes/Header	4 byte 802.1Q header inserted after source address and before Type/LAN in 802.3 packets = 22 bytes.	6 x 2 + 2 + 4 = 18 bytes (DA+SA+LT+FCS)
Minimum Frame Size (typical)	If DATA is NULL, 42-byte padding makes 64 bytes (42 +22)	64 bytes. If DATA is NULL, 46-byte padding makes 64 bytes (46 +18)
Maximum Frame Size (typical)	1522 bytes	1518 bytes (1500 bytes DATA and 18-bytes header)
Jumbo Frame Size	9022 bytes	Typical industry standard. Ethernet jumbo frame size treated as 9018 bytes.

Software Visualization of Programmable Packet Size

The ***Visualization of Programmable Packet Size*** table provides the byte sizes of packets with various configurations.

Table 28-54: Visualization of Programmable Packet Size

Size in Bytes	Comments
16384	Receive watchdog and transmit jabber disabled, jumbo frames enabled.
10240	Receive watchdog and transmit jabber disabled, jumbo frames disabled.
2048	Receive watchdog and transmit jabber enabled.
1518	Typical max size of Ethernet frame. Receive watchdog and transmit jabber enabled.
64	Typical minimum size of Ethernet frame.
< 64	Runt frames requiring Zero-PAD.

Ethernet Packet Structure in C

The following is an example for Ethernet packet structure in the C language.

```
typedef struct ETHER_PACKET
{
    char  dst_addr[6];             //destination address
    char  src_addr[6];             //source address
    char  length[2];               //length of actual data
    char  data[DATA_SIZE];         //application data
    char  fdlimit[DELIMIT_SIZE];   //32-bit delimit (if manual appending)
    char  fcs[4];                  //crc frame checksum, used by RX buffer.
} ETHER_PACKET;
```

DMA Descriptor Implementation in C

The following code is a simple implementation of descriptors in ring and chain model in C language. Typically 4 WORDs (32-bit) are used for descriptors. Using checksum offload or the PTP engine requires 8 WORDs. Only high-level common functions across transmit and receive descriptors are considered here.

```
/* DMA Ring Descriptor */
typedef struct EMAC_DMADESC_RING
{
    unsigned int        Status;     //TDES0 OR RDES0
    unsigned int        ControlDesc;  //TDES1 OR RDES1
    unsigned int        StartAddr1;   //TDES2 OR RDES2
    unsigned int        StartAddr2;   //TDES3 OR RDES3
    #ifdef CHECKSUM_OFFLOAD
    struct EMAC_EXT_STAT      ExtendedStat;
    #endif
} EMAC_DMADESC_RING;
/* DMA Chain Descriptor */
typedef struct EMAC_DMADESC_CHAIN
```

```
{
    unsigned int        Status;        //TDES0 OR RDES0
    unsigned int        ControlDesc;      //TDES1 OR RDES1
    unsigned int        StartAddr;     //TDES2 OR RDES2
    struct EMAC_DMADESC_CHAIN     *pNextDesc;  //TDES3 OR RDES3
    #ifdef CHECKSUM_OFFLOAD
    struct EMAC_EXT_STAT     ExtendedStat;
    #endif
} EMAC_DMADESC_CHAIN;
/* Extended Status Descriptor with PTP not enabled*/
typedef struct EMAC_EXT_STAT
{
    #ifdef RX_DESC
    unsigned int        CheckSumStat;    //RDES4
    #ifdef TX_DESC
    unsigned int        Reserved;     //TDES4
    #endif
    unsigned int        Reserved;        //RDES5 OR TDES5
    unsigned int        Reserved;     //RDES6 OR TDES6
    unsigned int        Reserved;     //RDES7 OR TDES7
} EMAC_EXT_STAT;
```

PTP Header Structure in C

The following code is an example of the PTP message format.

```
/* PTP Message Format (Refer to PTP Frame Over IPv4)*/
    typedef struct EMAC_PTP_HEADER
    {
    unsigned char    messageType:4,    //PTP Version 2 message type
    transportSpecific:4;
    unsigned char    versionPTP;       //PTP Version (1 or 2)
    unsigned short    messageLength;
    unsigned char    domainNumber;
    unsigned char    RESERVED1;
    unsigned short    flagField;
    unsigned char    correctionField[8];
    unsigned char    RESERVED2[4];
    unsigned char    sourcePortIdentity[10];
    unsigned short    sequenceid;
    unsigned char    controlField;     //PTP Version 1 message type
    unsigned char    logMessageInterval;
    }EMAC_PTP_HEADER;
```

ADSP-2159x_SC591_SC592_SC594 EMAC Register Descriptions

Ethernet MAC (EMAC) contains the following registers.

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List

Name	Description
EMAC_ADDR0_HI	MAC Address 0 High Register
EMAC_ADDR0_LO	MAC Address 0 Low Register
EMAC_ADDR1_HI	MAC Address 1 High Register
EMAC_ADDR1_LO	MAC Address 1 Low Register
EMAC_DBG	Debug Register
EMAC_DMA0_BMMODE	DMA SCB Bus Mode Register
EMAC_DMA0_BMSTAT	DMA SCB Status Register
EMAC_DMA0_BUSMODE	DMA Bus Mode Register
EMAC_DMA0_IEN	DMA Interrupt Enable Register
EMAC_DMA0_MISS_FRM	DMA Missed Frame Register
EMAC_DMA0_OPMODE	DMA Operation Mode Register
EMAC_DMA0_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA0_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA0_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA0_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA0_RXPOLL	DMA Rx Poll Demand register
EMAC_DMA0_STAT	DMA Status Register
EMAC_DMA0_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA0_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA0_TXDSC_CUR	DMA Tx Descriptor Current Register
EMAC_DMA0_TXPOLL	DMA Tx Poll Demand Register
EMAC_DMA1_BUSMODE	DMA Bus Mode Register
EMAC_DMA1_CHCBSCTL	Channel 1 Credit Shaping Control Register
EMAC_DMA1_CHCBSSTAT	Channel 1 Average Traffic Transmitted Register
EMAC_DMA1_CHHIC	Channel 1 High Credit Value Register
EMAC_DMA1_CHISC	Channel 1 Idle Slope Credit Value Register
EMAC_DMA1_CHLOC	Channel 1 Low Credit Value Register
EMAC_DMA1_CHSFCS	Channel 1 Control Bits for Slot Function Register
EMAC_DMA1_CHSSC	Channel 1 Send Slope Credit Value Register
EMAC_DMA1_IEN	DMA Interrupt Enable Register
EMAC_DMA1_MISS_FRM	DMA Missed Frame Register

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List (Continued)

Name	Description
EMAC_DMA1_OPMODE	DMA Operation Mode Register
EMAC_DMA1_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA1_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA1_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA1_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA1_RXPOLL	DMA Rx Poll Demand Register
EMAC_DMA1_STAT	DMA Status Register
EMAC_DMA1_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA1_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA1_TXDSC_CUR	DMA Tx Descriptor Current Register
EMAC_DMA1_TXPOLL	DMA Tx Poll Demand Register
EMAC_DMA2_BUSMODE	DMA Bus Mode Register
EMAC_DMA2_CHCBSCTL	Channel 2 Credit Shaping Control Register
EMAC_DMA2_CHCBSSTAT	Channel 2 Avg Traffic Transmitted Status Register
EMAC_DMA2_CHHIC	Channel 2 High Credit Value Register
EMAC_DMA2_CHISC	Channel 2 Idle Slope Credit Value Register
EMAC_DMA2_CHLOC	Channel 2 Low Credit Value Register
EMAC_DMA2_CHSFCS	Channel 2 Control Bits for Slot Function Register
EMAC_DMA2_CHSSC	Channel 2 Send Slope Credit Value Register
EMAC_DMA2_IEN	DMA Interrupt Enable Register
EMAC_DMA2_MISS_FRM	DMA Missed Frame Register
EMAC_DMA2_OPMODE	DMA Operation Mode Register
EMAC_DMA2_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA2_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA2_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA2_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA2_RXPOLL	DMA Rx Poll Demand register
EMAC_DMA2_STAT	DMA Status Register
EMAC_DMA2_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA2_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA2_TXDSC_CUR	DMA Tx Descriptor Current Register

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List (Continued)

Name	Description
EMAC_DMA2_TXPOLL	DMA Tx Poll Demand Register
EMAC_FLOWCTL	FLow Control Register
EMAC_GIGE_CTLSTAT	RGMII Control and Status Register
EMAC_HASHTBL_HI	Hash Table High Register
EMAC_HASHTBL_LO	Hash Table Low Register
EMAC_IMSK	Interrupt Mask Register
EMAC_IPC_RXIMSK	MMC IPC Rx Interrupt Mask Register
EMAC_IPC_RXINT	MMC IPC Rx Interrupt Register
EMAC_ISTAT	Interrupt Status Register
EMAC_L3L4_CTL	Layer3 and Layer4 Control Register
EMAC_L3_ADDR0	Layer 3 Address0 Register
EMAC_L3_ADDR1	Layer 3 Address1 Register
EMAC_L3_ADDR2	Layer 3 Address2 Register
EMAC_L3_ADDR3	Layer 3 Address3 Register
EMAC_L4_ADDR	Layer 4 Address Register
EMAC_LPI_CTLSTAT	Low Power Idle Control and Status Register
EMAC_LPI_TMRSCTL	Low Power Idle Timeout Register
EMAC_MACCFG	MAC Configuration Register
EMAC_MACFRMFILT	MAC Rx Frame Filter Register
EMAC_MAC_AVCTL	AV MAC Control Register
EMAC_MMC_CTL	MMC Control Register
EMAC_MMC_RXIMSK	MMC Rx Interrupt Mask Register
EMAC_MMC_RXINT	MMC Rx Interrupt Register
EMAC_MMC_TXIMSK	MMC TX Interrupt Mask Register
EMAC_MMC_TXINT	MMC Tx Interrupt Register
EMAC_RX1024TOMAX_GB	Rx 1024- to Max-Byte Frames (Good/Bad) Register
EMAC_RX128TO255_GB	Rx 128- to 255-Byte Frames (Good/Bad) Register
EMAC_RX256TO511_GB	Rx 256- to 511-Byte Frames (Good/Bad) Register
EMAC_RX512TO1023_GB	Rx 512- to 1023-Byte Frames (Good/Bad) Register
EMAC_RX64_GB	Rx 64-Byte Frames (Good/Bad) Register
EMAC_RX65TO127_GB	Rx 65- to 127-Byte Frames (Good/Bad) Register

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List (Continued)

Name	Description
EMAC_RXALIGN_ERR	Rx alignment Error Register
EMAC_RXBCASTFRM_G	Rx Broadcast Frames (Good) Register
EMAC_RXCRC_ERR	Rx CRC Error Register
EMAC_RXCTLFRM_G	Rx Good Control Frames Register
EMAC_RXFIFO_OVF	Rx FIFO Overflow Register
EMAC_RXFRMCNT_GB	Rx Frame Count (Good/Bad) Register
EMAC_RXICMP_ERR_FRM	Rx ICMP Error Frames Register
EMAC_RXICMP_ERR_OCT	Rx ICMP Error Octets Register
EMAC_RXICMP_GD_FRM	Rx ICMP Good Frames Register
EMAC_RXICMP_GD_OCT	Rx ICMP Good Octets Register
EMAC_RXIPV4_FRAG_FRM	Rx IPv4 Datagrams Fragmented Frames Register
EMAC_RXIPV4_FRAG_OCT	Rx IPv4 Datagrams Fragmented Octets Register
EMAC_RXIPV4_GD_FRM	Rx IPv4 Datagrams (Good) Register
EMAC_RXIPV4_GD_OCT	Rx IPv4 Datagrams Good Octets Register
EMAC_RXIPV4_HDR_ERR_FRM	Rx IPv4 Datagrams Header Errors Register
EMAC_RXIPV4_HDR_ERR_OCT	Rx IPv4 Datagrams Header Errors Register
EMAC_RXIPV4_NOPAY_FRM	Rx IPv4 Datagrams No Payload Frame Register
EMAC_RXIPV4_NOPAY_OCT	Rx IPv4 Datagrams No Payload Octets Register
EMAC_RXIPV4_UDSBL_FRM	Rx IPv4 UDP Disabled Frames Register
EMAC_RXIPV4_UDSBL_OCT	Rx IPv4 UDP Disabled Octets Register
EMAC_RXIPV6_GD_FRM	Rx IPv6 Datagrams Good Frames Register
EMAC_RXIPV6_GD_OCT	Rx IPv6 Good Octets Register
EMAC_RXIPV6_HDR_ERR_FRM	Rx IPv6 Datagrams Header Error Frames Register
EMAC_RXIPV6_HDR_ERR_OCT	Rx IPv6 Header Errors Register
EMAC_RXIPV6_NOPAY_FRM	Rx IPv6 Datagrams No Payload Frames Register
EMAC_RXIPV6_NOPAY_OCT	Rx IPv6 No Payload Octets Register
EMAC_RXJAB_ERR	Rx Jab Error Register
EMAC_RXLEN_ERR	Rx Length Error Register
EMAC_RXMCASTFRM_G	Rx Multicast Frames (Good) Register
EMAC_RXOCTCNT_G	Rx Octet Count (Good) Register
EMAC_RXOCTCNT_GB	Rx Octet Count (Good/Bad) Register

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List (Continued)

Name	Description
EMAC_RXOORTYPE	Rx Out Of Range Type Register
EMAC_RXOSIZE_G	Rx Oversize (Good) Register
EMAC_RXPAUSEFRM	Rx Pause Frames Register

EMAC_TXDEFERRED	Tx Deferred Register
EMAC_TXEXCESSCOL	Tx Excess Collision Register
EMAC_TXEXCESSDEF	Tx Excess Deferral Register
EMAC_TXFRMCNT_G	Tx Frame Count (Good) Register
EMAC_TXFRMCNT_GB	Tx Frame Count (Good/Bad) Register
EMAC_TXLATECOL	Tx Late Collision Register

Table 28-55: ADSP-2159x_SC591_SC592_SC594 EMAC Register List (Continued)

Name	Description
EMAC_TXMCASTFRM_G	Tx Multicast Frames (Good) Register
EMAC_TXMCASTFRM_GB	Tx Multicast Frames (Good/Bad) Register
EMAC_TXMULTCOL_G	Tx Multiple Collision (Good) Register
EMAC_TXOCTCNT_G	Tx Octet Count (Good) Register
EMAC_TXOCTCNT_GB	Tx OCT Count (Good/Bad) Register
EMAC_TXOVRSIZE_G	Number of Tx Frames (Good) greater than maxsize
EMAC_TXPAUSEFRM	Tx Pause Frame Register
EMAC_TXSNGCOL_G	Tx Single Collision (Good) Register
EMAC_TXUCASTFRM_GB	Tx Unicast Frames (Good/Bad) Register
EMAC_TXUNDR_ERR	Tx Underflow Error Register
EMAC_TXVLANFRM_G	Tx VLAN Frames (Good) Register
EMAC_VLANTAG	VLAN Tag Register
EMAC_VLAN_HSHTBL	VLAN Hash Table Register
EMAC_VLAN_INCL	VLAN Tag Inclusion or Replacement Register
EMAC_WDOG_TIMOUT	Watchdog Timeout Register

MAC Address 0 High Register

The EMAC_ADDR0_HI register holds the address 0 high bits.

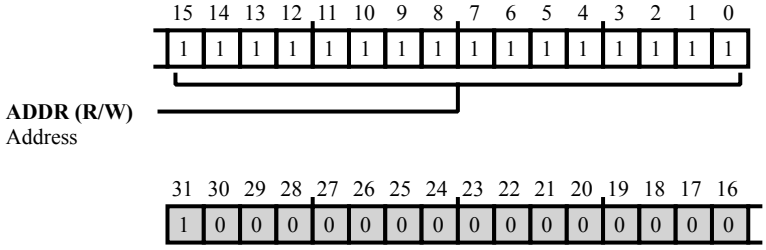

Figure 28-24: EMAC_ADDR0_HI Register Diagram

Table 28-56: EMAC_ADDR0_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	ADDR	Address. The EMAC_ADDR0_HI.ADDR bits contain the upper 16 bits (47:32) of the 6-byte first MAC address. This address is used by the MAC for filtering for received frames and for inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.

MAC Address 0 Low Register

The EMAC_ADDR0_LO register holds the address 0 low bits.

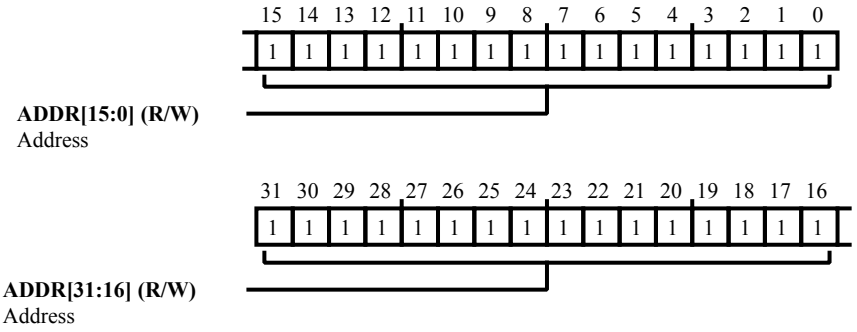

Figure 28-25: EMAC_ADDR0_LO Register Diagram

Table 28-57: EMAC_ADDR0_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Address. The EMAC_ADDR0_LO.ADDR bits contain the lower 32 bits of the 6-byte first MAC address. This address is used by the MAC for filtering for received frames and for inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.

MAC Address 1 High Register

The EMAC_ADDR1_HI register Contains the higher 16 bits of the second MAC address.

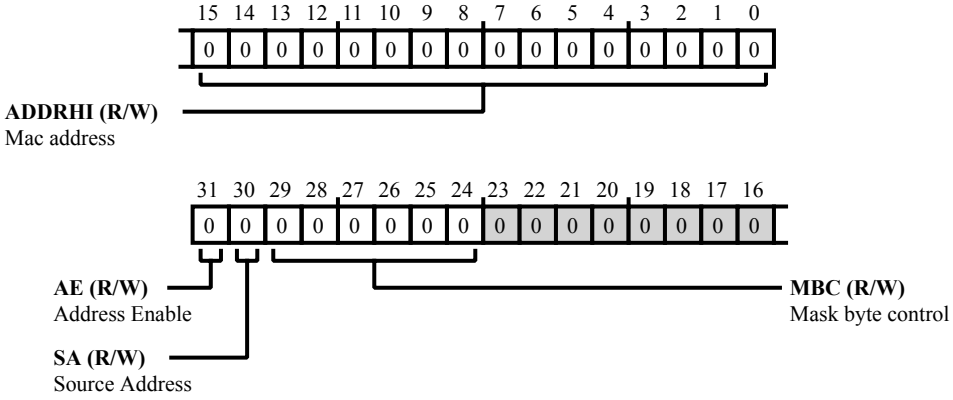

Figure 28-26: EMAC_ADDR1_HI Register Diagram

Table 28-58: EMAC_ADDR1_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	AE	Address Enable. The EMAC_ADDR1_HI.AE bit, When this bit is set, the address filter module uses the second MAC address for perfect filtering.
30 (R/W)	SA	Source Address. The EMAC_ADDR1_HI.SA bit, When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received frame.
29:24 (R/W)	MBC	Mask byte control. The EMAC_ADDR1_HI.MBC bit, are mask control bits for comparison of each of the MAC Address bytes.
15:0 (R/W)	ADDRHI	Mac address. The EMAC_ADDR1_HI.ADDRHI bit, contains the upper 16 bits (47:32) of the second 6-byte MAC address.

MAC Address 1 Low Register

The EMAC_ADDR1_LO register Contains the lower 32 bits of the second MAC address.

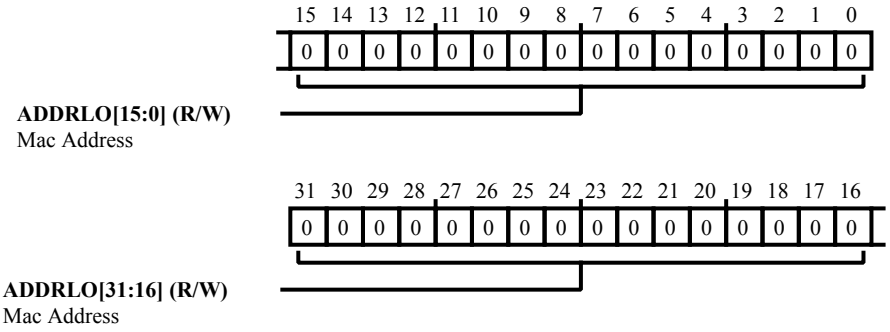

Figure 28-27: EMAC_ADDR1_LO Register Diagram

Table 28-59: EMAC_ADDR1_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDRLO	Mac Address. The EMAC_ADDR1_LO.ADDRLO bit, contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (Pause) Frames.

Debug Register

The EMAC_DBG register contains EMAC debug status information.

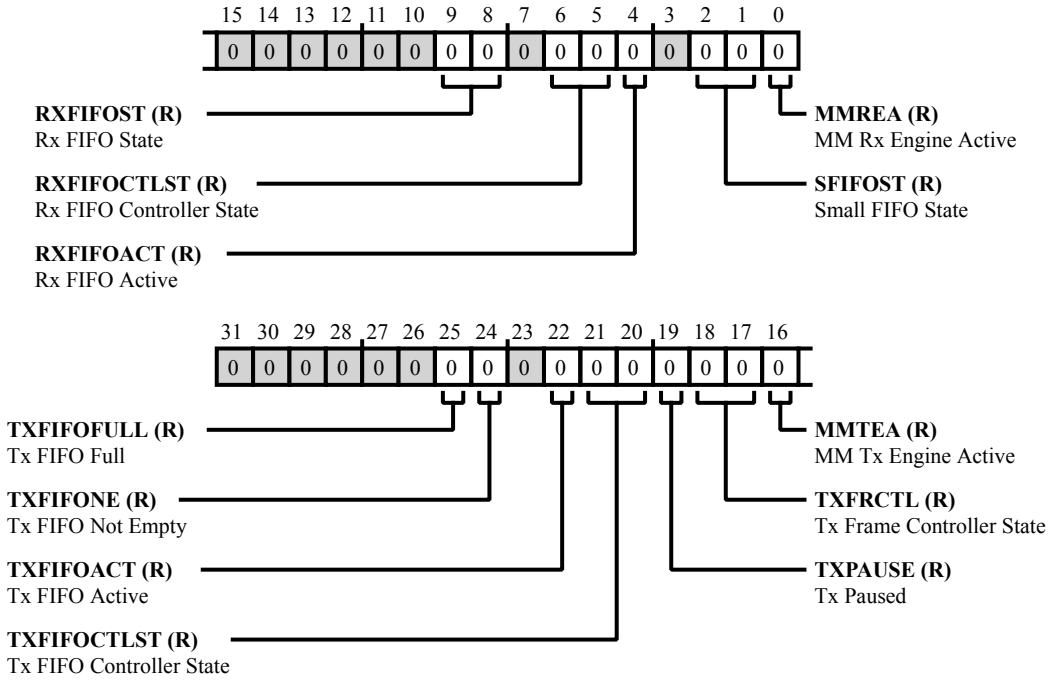

Figure 28-28: EMAC_DBG Register Diagram

Table 28-60: EMAC_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/NW)	TXFIFOFULL	Tx FIFO Full. The EMAC_DBG.TXFIFOFULL bit, when high, indicates that the MFL TxStatus FIFO is full, and the MFL cannot accept any more frames for transmission.
24 (R/NW)	TXFIFONE	Tx FIFO Not Empty. The EMAC_DBG.TXFIFONE bit, when high, indicates that the MFL TxFIFO is not empty and has some data left for transmission.
22 (R/NW)	TXFIFOACT	Tx FIFO Active. The EMAC_DBG.TXFIFOACT bit, when high, indicates that the MFL TxFIFO write controller is active and transferring data to the TxFIFO.
21:20 (R/NW)	TXFIFOCTLST	Tx FIFO Controller State. The EMAC_DBG.TXFIFOCTLST bits indicate the state of the TxFIFO read controller as: 00=IDLE state, 01=READ state (transferring data to MAC transmitter), 10=Waiting for TxStatus from MAC transmitter, and 11=Writing the received TxStatus or flushing the TxFIFO

Table 28-60: EMAC_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	TXPAUSE	Tx Paused. The EMAC_DBG.TXPAUSE bit, when high, indicates that the MAC transmitter is in PAUSE condition (in full-duplex only) and does not schedule any frame for transmission.	
18:17 (R/NW)	TXFRCTL	Tx Frame Controller State. The EMAC_DBG.TXFRCTL bits indicate the state of the MAC transmit frame controller module.	
		0	Idle Frame controller is in idle state.
		1	Wait Frame controller is waiting for status of previous frame or IFG/backoff period end.
		2	Pause Frame controller is generating and transmitting a PAUSE control frame (in full duplex mode).
		3	Transmit Frame controller is transferring input frame for transmission.
16 (R/NW)	MMTEA	MM Tx Engine Active. The EMAC_DBG.MMTEA bit, when high, indicates that the MAC core transmit protocol engine is actively transmitting data and is not in IDLE state.	
9:8 (R/NW)	RXFIFOST	Rx FIFO State. The EMAC_DBG.RXFIFOST bits give the status of the RxFIFO fill level and indicate the relationship to the flow-control activation threshold.	
		0	Rx FIFO Empty
		1	Rx FIFO Below De-activate FCT
		2	Rx FIFO Above De-activate FCT
		3	Rx FIFO Full
6:5 (R/NW)	RXFIFOCTLST	Rx FIFO Controller State. The EMAC_DBG.RXFIFOCTLST bits give the state of the RxFIFO read controller.	
		0	Idle Read controller is in idle state.
		1	Read Data Read controller is reading frame data.
		2	Read Status Read controller is reading frame status or time-stamp.
		3	Flush Read controller is flushing the frame data and status.
4 (R/NW)	RXFIFOACT	Rx FIFO Active. The EMAC_DBG.RXFIFOACT bit, when high, indicates that the MFL RxFIFO write controller is active and is transferring a received frame to the FIFO.	

Table 28-60: EMAC_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:1 (R/NW)	SFIFOST	Small FIFO State. The `EMAC_DBG.SFIFOST` bit, when high, indicates the active state of the small FIFO read and write controllers respectively of the MAC receive frame controller module.
0 (R/NW)	MMREA	MM Rx Engine Active. The `EMAC_DBG.MMREA` bit, when high, indicates that the MAC core receive protocol engine is actively receiving data and is not in IDLE state.

DMA SCB Bus Mode Register

The EMAC_DMA0_BMMODE register selects EMAC DMA system cross bar bus mode features.

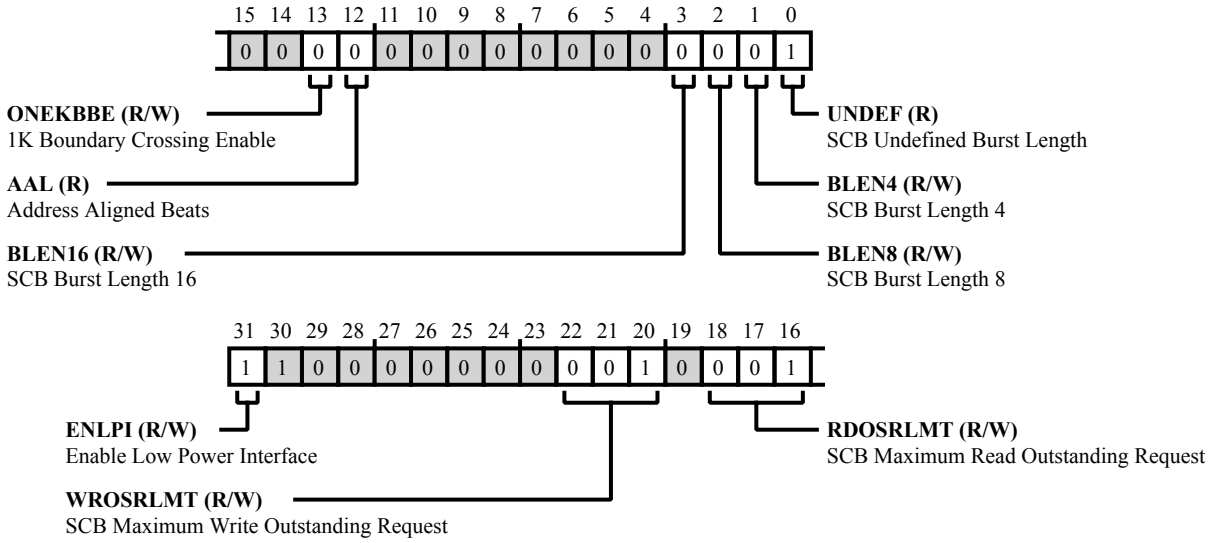

Figure 28-29: EMAC_DMA0_BMMODE Register Diagram

Table 28-61: EMAC_DMA0_BMMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ENLPI	Enable Low Power Interface. The EMAC_DMA0_BMMODE.ENLPI bit field's when set to 1, it enable LPI mode supported by the GMAC configuration and accepts the LPI request from the system Clock controller.
22:20 (R/W)	WROSRLMT	SCB Maximum Write Outstanding Request. The EMAC_DMA0_BMMODE.WROSRLMT bit field's value limits the maximum outstanding request on the SCB write interface. Maximum outstanding requests = WR_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding write requests.
18:16 (R/W)	RDOSRLMT	SCB Maximum Read Outstanding Request. The EMAC_DMA0_BMMODE.RDOSRLMT bit field's value limits the maximum outstanding request on the SCB read interface. Maximum outstanding requests = RD_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding read requests.
13 (R/W)	ONEKBBE	1K Boundary Crossing Enable. When the EMAC_DMA0_BMMODE.ONEKBBE bit is set, the GMAC extensible bus master performs burst transfers that do not cross 1 KB boundary. When reset, the GMAC extensible bus master performs burst transfers that do not cross 4 KB boundary.

Table 28-61: EMAC_DMA0_BMMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/NW)	AAL	Address Aligned Beats. The EMAC_DMA0_BMMODE.AAL bit (read-only) reflects the state of the EMAC_DMA0_BUSMODE.AAL bit. When this bit is set to 1, EMAC-SCB performs address-aligned burst transfers on both read and write channels.
3 (R/W)	BLEN16	SCB Burst Length 16. The EMAC_DMA0_BMMODE.BLEN16 bit, when set (or when EMAC_DMA0_BMMODE.UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 16 on the SCB master interface.
2 (R/W)	BLEN8	SCB Burst Length 8. The EMAC_DMA0_BMMODE.BLEN8 bit, when set (or when EMAC_DMA0_BMMODE.UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 8 on the SCB master interface.
1 (R/W)	BLEN4	SCB Burst Length 4. The EMAC_DMA0_BMMODE.BLEN4 bit, when set (or when EMAC_DMA0_BMMODE.UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 4 on the SCB master interface.
0 (R/NW)	UNDEF	SCB Undefined Burst Length. The EMAC_DMA0_BMMODE.UNDEF bit (read-only) indicates the complement (invert) value of EMAC_DMA0_BUSMODE.FB bit . When this bit is set to 1, the EMAC-SCB is allowed to perform any burst length equal to or below the maximum allowed burst length as programmed in bits[3:1]. When this bit is set to 0, the EMAC-SCB is allowed to perform only fixed burst lengths as indicated by 16/8/4, or a burst length of 1.

DMA SCB Status Register

The EMAC_DMA0_BMSTAT register indicates EMAC DMA system cross bar status.

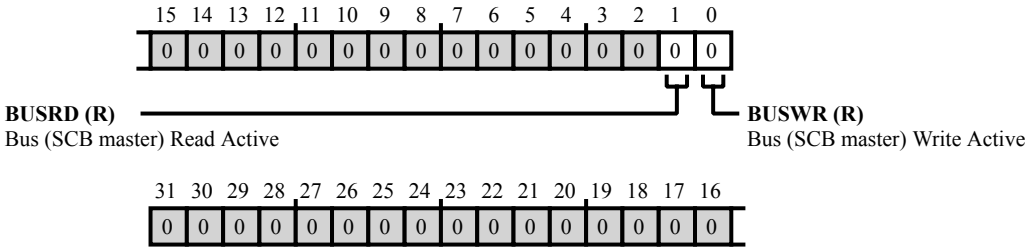

Figure 28-30: EMAC_DMA0_BMSTAT Register Diagram

Table 28-62: EMAC_DMA0_BMSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BUSRD	Bus (SCB master) Read Active. The EMAC_DMA0_BMSTAT.BUSRD bit, when high, indicates that SCB Master's read channel is active and transferring data.
0 (R/NW)	BUSWR	Bus (SCB master) Write Active. The EMAC_DMA0_BMSTAT.BUSWR bit, when high, indicates that SCB Master's write channel is active and transferring data.

DMA Bus Mode Register

The EMAC_DMA0_BUSMODE register selects the DMA bus operating modes for EMAC DMA.

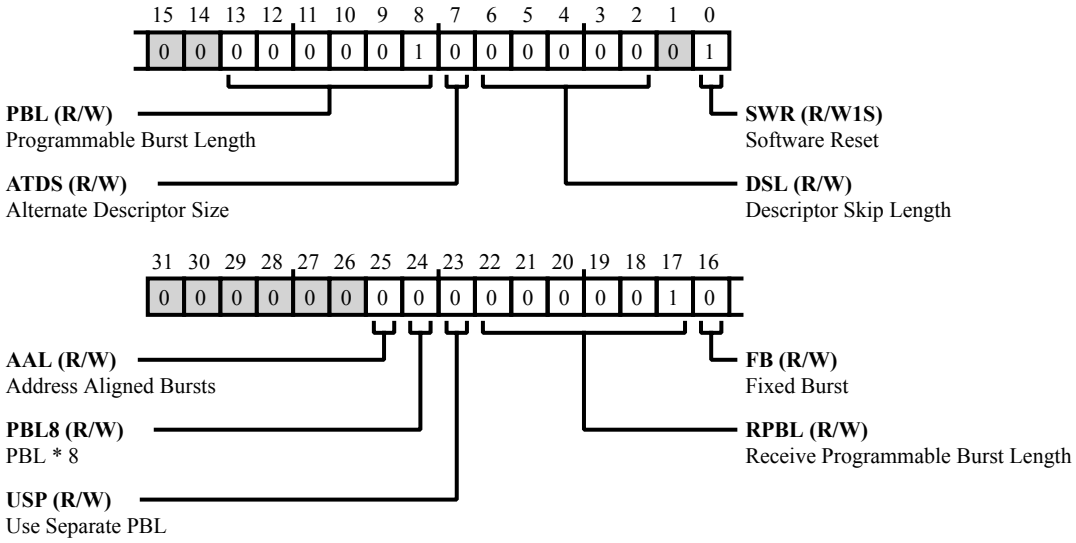

Figure 28-31: EMAC_DMA0_BUSMODE Register Diagram

Table 28-63: EMAC_DMA0_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The EMAC_DMA0_BUSMODE.AAL bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The EMAC_DMA0_BUSMODE.PBL8 bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The EMAC_DMA0_BUSMODE.USP bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 28-63: EMAC_DMA0_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The EMAC_DMA0_BUSMODE.RPBL bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The EMAC_DMA0_BUSMODE.FB bit controls whether the SCB Master interface performs fixed burst transfers or not. See the EMAC_DMA0_BMMODE.UNDEF bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The EMAC_DMA0_BUSMODE.PBL bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If EMAC_DMA0_BUSMODE.PBL =8, and if EMAC_DMA0_BMMODE.BLEN16 is enabled, the max burst is limited to EMAC_DMA0_BMMODE.BLEN8. If EMAC_DMA0_BUSMODE.PBL8 bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The EMAC_DMA0_BUSMODE.ATDS bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 28-63: EMAC_DMA0_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA0_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.
0 (R/W1S)	SWR	Software Reset. The `EMAC_DMA0_BUSMODE.SWR` bit, when set, directs the MAC DMA Controller to reset all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core. Note: The reset operation is completed only when all the resets in all the active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.

DMA Interrupt Enable Register

The EMAC_DMA0_IEN register enables (unmasks) EMAC DMA interrupts.

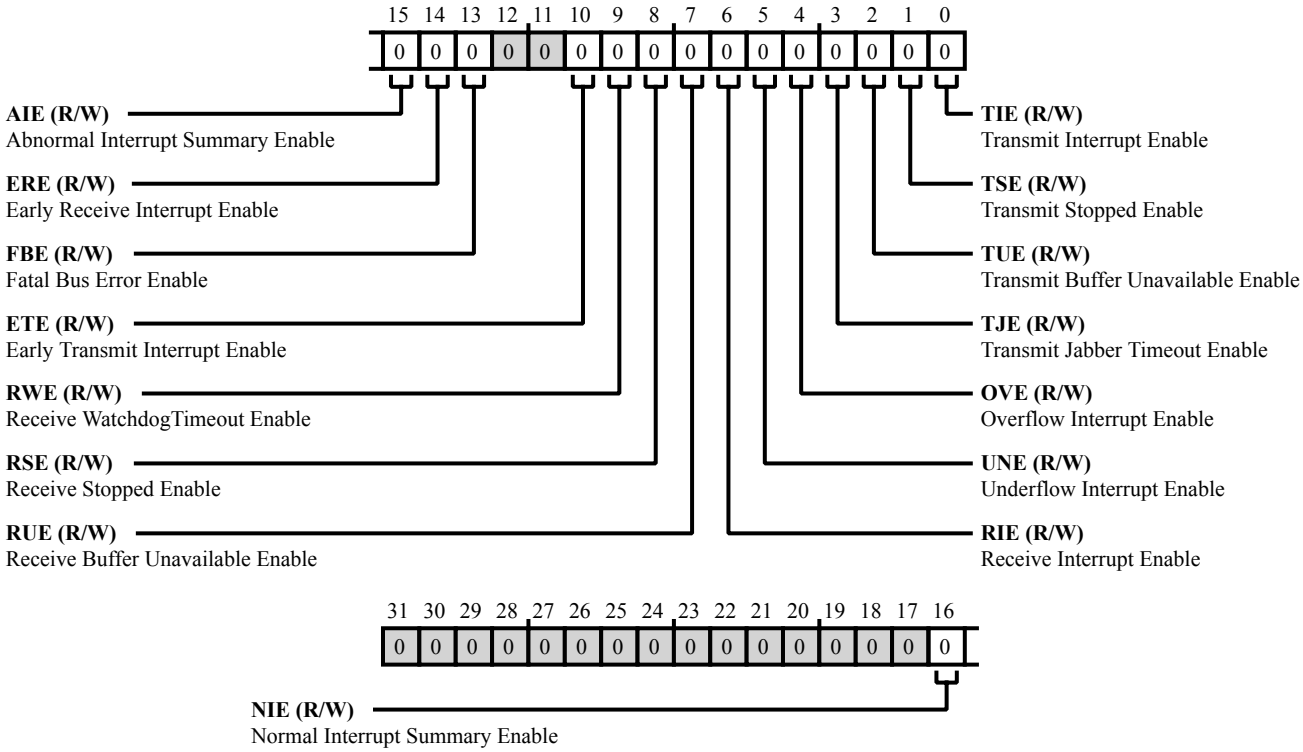

Figure 28-32: EMAC_DMA0_IEN Register Diagram

Table 28-64: EMAC_DMA0_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The EMAC_DMA0_IEN.NIE bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: EMAC_DMA0_STAT.TI, EMAC_DMA0_STAT.TU, EMAC_DMA0_STAT.RI, and EMAC_DMA0_STAT.ERI.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The EMAC_DMA0_IEN.AIE bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: EMAC_DMA0_STAT.TPS, EMAC_DMA0_STAT.TJT, EMAC_DMA0_STAT.OVF, EMAC_DMA0_STAT.RU, EMAC_DMA0_STAT.RPS, EMAC_DMA0_STAT.RWT, EMAC_DMA0_STAT.ETI, and EMAC_DMA0_STAT.FBI.

Table 28-64: EMAC_DMA0_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The EMAC_DMA0_IEN.ERE bit, when set (and with EMAC_DMA0_IEN.NIE =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The EMAC_DMA0_IEN.FBE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The EMAC_DMA0_IEN.ETE bit, when this bit is set (and with EMAC_DMA0_IEN.AIE =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive WatchdogTimeout Enable. The EMAC_DMA0_IEN.RWE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The EMAC_DMA0_IEN.RSE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The EMAC_DMA0_IEN.RUE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The EMAC_DMA0_IEN.RIE bit, when set (and with EMAC_DMA0_IEN.NIE =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The EMAC_DMA0_IEN.UNE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The EMAC_DMA0_IEN.OVE bit, when set (and with EMAC_DMA0_IEN.AIE =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 28-64: EMAC_DMA0_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA0_IEN.TJE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA0_IEN.TUE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA0_IEN.TSE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA0_IEN.TIE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The EMAC_DMA0_MISS_FRM register contains counters for EMAC DMA missed frames and buffer overflows.

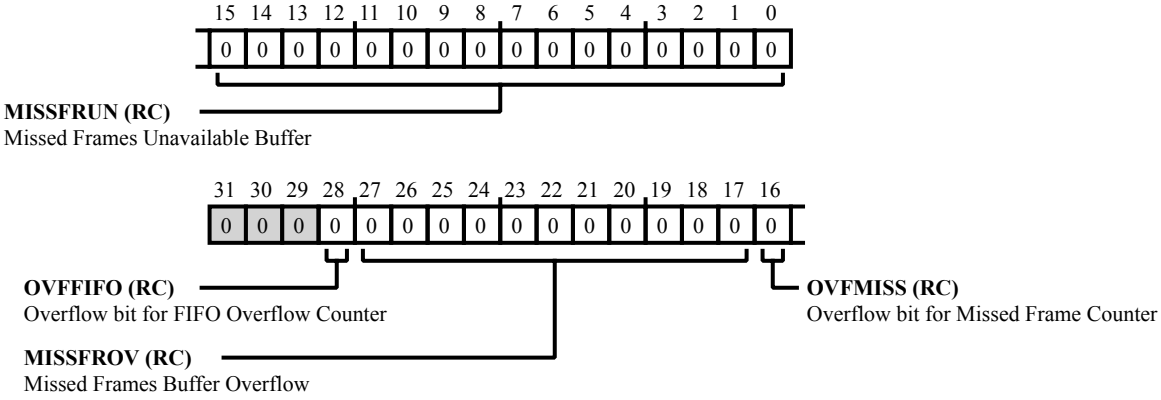

Figure 28-33: EMAC_DMA0_MISS_FRM Register Diagram

Table 28-65: EMAC_DMA0_MISS_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RC/NW)	OVFFIFO	Overflow bit for FIFO Overflow Counter. The EMAC_DMA0_MISS_FRM.OVFFIFO bit holds the overflow bit for FIFO Overflow Counter.
27:17 (RC/NW)	MISSFROV	Missed Frames Buffer Overflow. The EMAC_DMA0_MISS_FRM.MISSFROV bits indicate the number of frames missed by the application due to buffer overflow.
16 (RC/NW)	OVFMISS	Overflow bit for Missed Frame Counter. The EMAC_DMA0_MISS_FRM.OVFMISS bit holds the overflow bit for the Missed Frame Counter.
15:0 (RC/NW)	MISSFRUN	Missed Frames Unavailable Buffer. The EMAC_DMA0_MISS_FRM.MISSFRUN bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable.

DMA Operation Mode Register

The EMAC_DMA0_OPMODE register selects receive and transmit DMA operating modes.

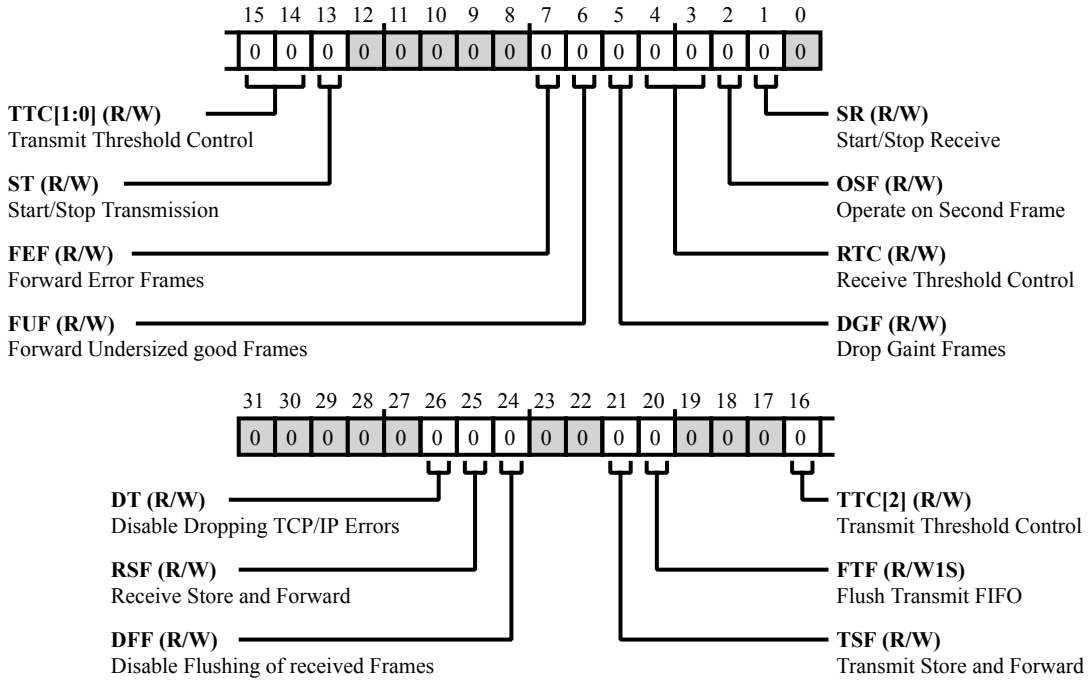

Figure 28-34: EMAC_DMA0_OPMODE Register Diagram

Table 28-66: EMAC_DMA0_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The EMAC_DMA0_OPMODE.DT bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the EMAC_DMA0_OPMODE.FEF bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The EMAC_DMA0_OPMODE.RSF bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the EMAC_DMA0_OPMODE.RTC bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the EMAC_DMA0_OPMODE.RTC bits.
24 (R/W)	DFF	Disable Flushing of received Frames. The EMAC_DMA0_OPMODE.DFF bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 28-66: EMAC_DMA0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	TSF	Transmit Store and Forward. The `EMAC_DMA0_OPMODE.TSF` bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.	
20 (R/W1S)	FTF	Flush Transmit FIFO. The `EMAC_DMA0_OPMODE.FTF` bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.	
16:14 (R/W)	TTC	Transmit Threshold Control. The `EMAC_DMA0_OPMODE.TTC` bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the `EMAC_DMA0_OPMODE.TSF` bit is reset. The value =011 is not used.	
		0	64
		1	128
		2	192
		3	256
		4	40
		5	32
		6	24
		7	16

Table 28-66: EMAC_DMA0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The EMAC_DMA0_OPMODE.ST bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the EMAC_DMA0_STAT.TU bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the EMAC_DMA0_TXDSC_CUR address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The EMAC_DMA0_OPMODE.FEF bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When EMAC_DMA0_OPMODE.FEF bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when EMAC_DMA0_OPMODE.FEF is set.
6 (R/W)	FUF	Forward Undersized good Frames. The EMAC_DMA0_OPMODE.FUF bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, EMAC_DMA0_OPMODE.RTC =01).
5 (R/W)	DGF	Drop Gaint Frames. The EMAC_DMA0_OPMODE.DGF bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 28-66: EMAC_DMA0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	RTC	Receive Threshold Control. The EMAC_DMA0_OPMODE.RTC bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the EMAC_DMA0_OPMODE.RSF bit is zero, and are ignored when the EMAC_DMA0_OPMODE.RSF bit is set to 1. The value =11 is not used.	
		0	64
		1	32
		2	96
		3	128
2 (R/W)	OSF	Operate on Second Frame. The EMAC_DMA0_OPMODE.OSF bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.	
1 (R/W)	SR	Start/Stop Receive. The EMAC_DMA0_OPMODE.SR bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the EMAC_DMA0_STAT.RU bit is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting EMAC_DMA0_RXDSC_CUR address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.	

DMA Rx Buffer Current Register

The EMAC_DMA0_RXBUF_CUR register holds the pointer to the current receive DMA buffer.

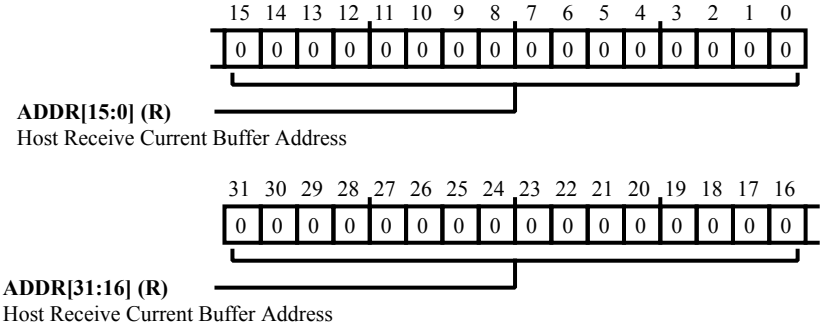

Figure 28-35: EMAC_DMA0_RXBUF_CUR Register Diagram

Table 28-67: EMAC_DMA0_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The EMAC_DMA0_RXBUF_CUR.ADDR bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The EMAC_DMA0_RXDSC_ADDR register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to EMAC_DMA0_RXDSC_ADDR only when Rx DMA has stopped (EMAC_DMA0_OPMODE.SR bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the EMAC_DMA0_OPMODE.SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA0_OPMODE.SR bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

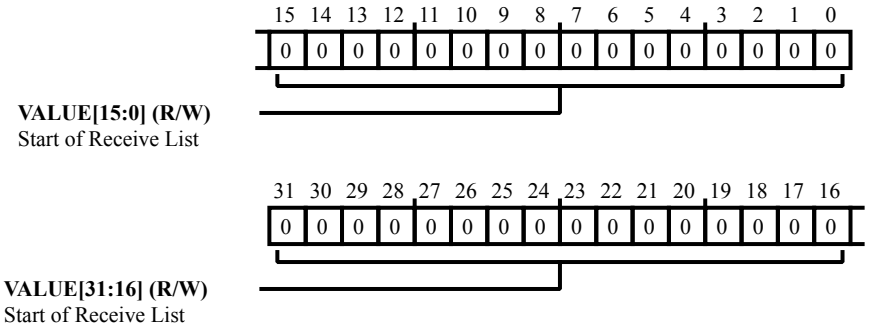

Figure 28-36: EMAC_DMA0_RXDSC_ADDR Register Diagram

Table 28-68: EMAC_DMA0_RXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Receive List. The EMAC_DMA0_RXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Receive Descriptor list. The LSB bits [1:0] for the 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Rx Descriptor Current Register

The EMAC_DMA0_RXDSC_CUR register contains the current DMA receive descriptor.

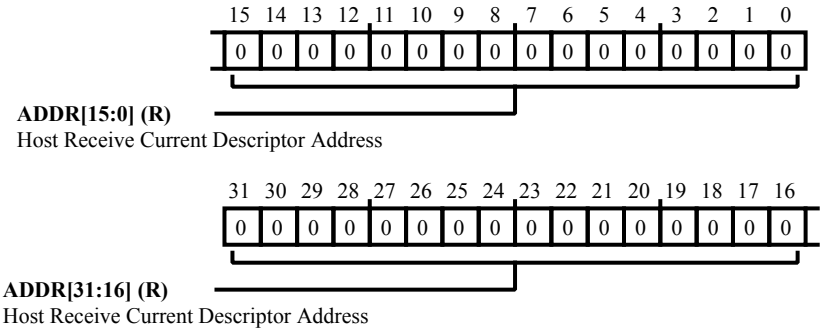

Figure 28-37: EMAC_DMA0_RXDSC_CUR Register Diagram

Table 28-69: EMAC_DMA0_RXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Descriptor Address. The EMAC_DMA0_RXDSC_CUR.ADDR bit field points to the start address of the current Receive Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Interrupt Watch Dog Register

The EMAC_DMA0_RXIWDOG register contains the timeout value for the EMAC DMA receive interrupt watch dog timer.

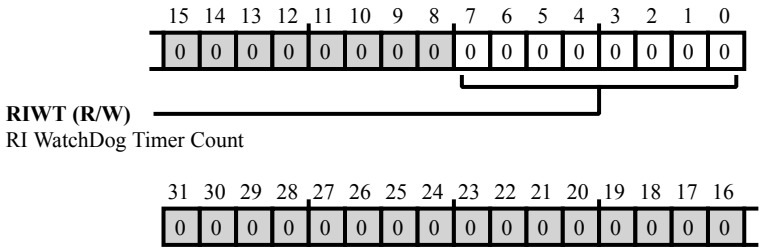

Figure 28-38: EMAC_DMA0_RXIWDOG Register Diagram

Table 28-70: EMAC_DMA0_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI WatchDog Timer Count. The EMAC_DMA0_RXIWDOG.RIWT bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watch-dog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when EMAC_DMA0_STAT.RI bit is set high because of automatic setting of EMAC_DMA0_STAT.RI as per RDES1[31] of any received frame.

DMA Rx Poll Demand register

The EMAC_DMA0_RXPOLL register directs the EMAC to poll the receive descriptor list.

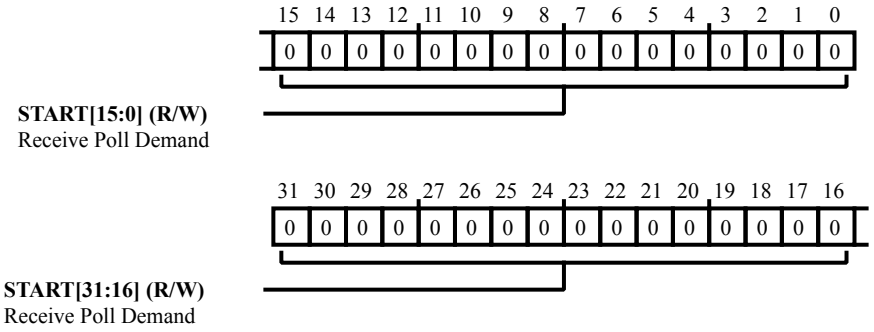

Figure 28-39: EMAC_DMA0_RXPOLL Register Diagram

Table 28-71: EMAC_DMA0_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The EMAC_DMA0_RXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by the EMAC_DMA0_RXDSC_CUR register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the EMAC_DMA0_STAT.RU bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The EMAC_DMA0_STAT register indicates EMAC DMA status.

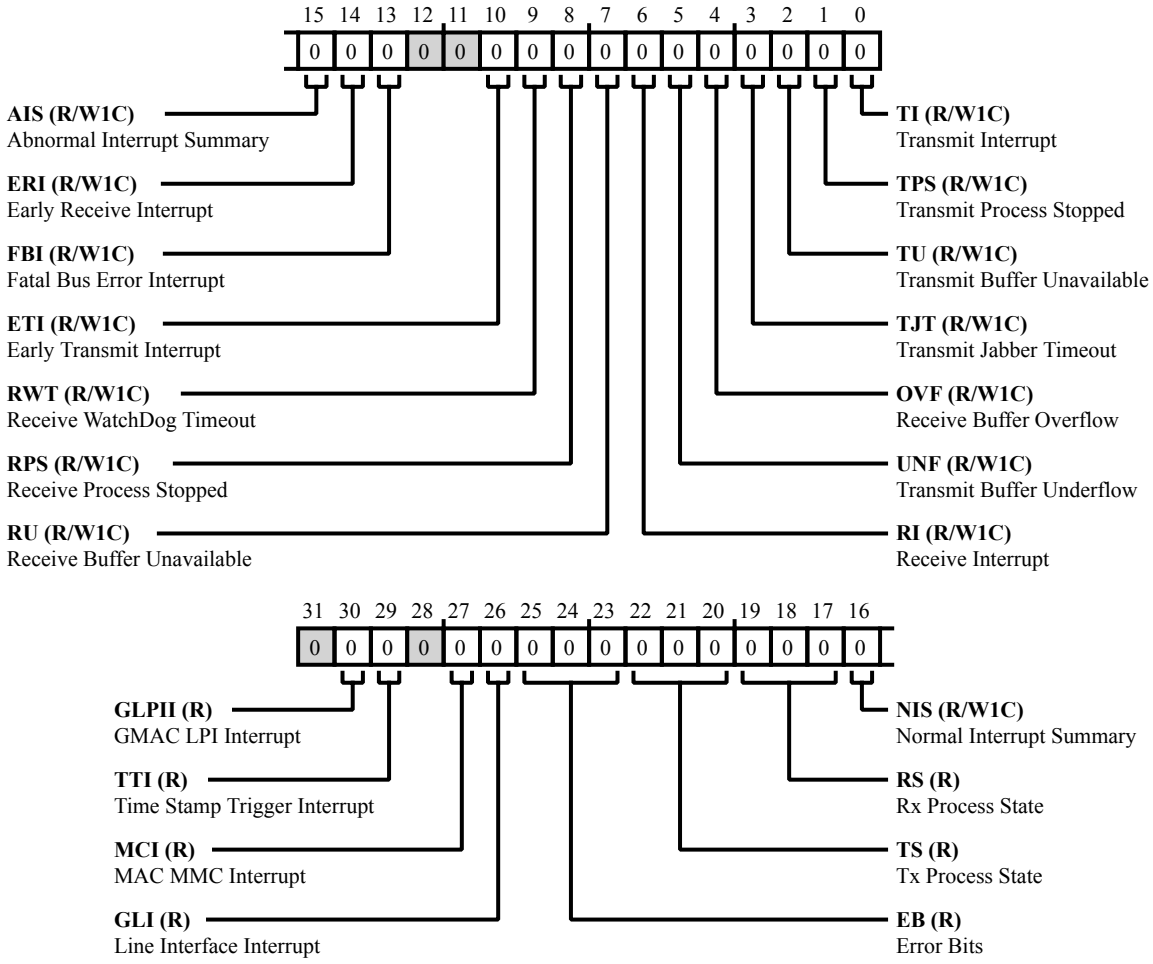

Figure 28-40: EMAC_DMA0_STAT Register Diagram

Table 28-72: EMAC_DMA0_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GLPII	GMAC LPI Interrupt. The EMAC_DMA0_STAT.GLPII bit indicates an interrupt event in the LPI logic of the MAC. To reset this bit to 1'b0, the software must read the corresponding registers in the DWC_gmac to get the exact cause of the interrupt and clear its source.

Table 28-72: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The EMAC_DMA0_STAT.TTI bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interrupt. The EMAC_DMA0_STAT.MCI bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The EMAC_DMA0_STAT.GLI bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The EMAC_DMA0_STAT.EB bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the EMAC_DMA0_STAT.FBI bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The EMAC_DMA0_STAT.TS bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 28-72: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The EMAC_DMA0_STAT.RS bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the EMAC_DMA0_STAT.NIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA0_STAT.TI, EMAC_DMA0_STAT.TU, EMAC_DMA0_STAT.RI, and EMAC_DMA0_STAT.ERI. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes EMAC_DMA0_STAT.NIS to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the EMAC_DMA0_STAT.AIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA0_IEN.TSE, EMAC_DMA0_IEN.TJE, EMAC_DMA0_IEN.OVE, EMAC_DMA0_IEN.UNE, EMAC_DMA0_IEN.RUE, EMAC_DMA0_IEN.RSE, EMAC_DMA0_IEN.RWE, EMAC_DMA0_IEN.ETE, and EMAC_DMA0_IEN.FBE. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes EMAC_DMA0_STAT.AIS to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The EMAC_DMA0_STAT.ERI bit indicates that the DMA had filled the first data buffer of the packet. The EMAC_DMA0_STAT.RI bit automatically clears this bit.	

Table 28-72: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The EMAC_DMA0_STAT.FBI bit indicates that a bus error occurred, as detailed in the EMAC_DMA0_STAT.EB field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The EMAC_DMA0_STAT.ETI bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The EMAC_DMA0_STAT.RWT bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The EMAC_DMA0_STAT.RPS bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The EMAC_DMA0_STAT.RU bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The EMAC_DMA0_STAT.RI bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The EMAC_DMA0_STAT.UNF bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The EMAC_DMA0_STAT.OVF bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The EMAC_DMA0_STAT.TJT bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 28-72: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The `EMAC_DMA0_STAT.TU` bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the `EMAC_DMA0_STAT.TS` bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The `EMAC_DMA0_STAT.TPS` bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The `EMAC_DMA0_STAT.TI` bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The EMAC_DMA0_TXBUF_CUR register holds the pointer to the current transmit DMA buffer.

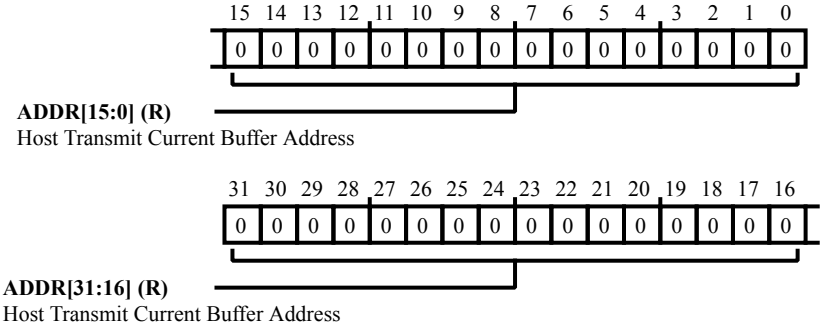

Figure 28-41: EMAC_DMA0_TXBUF_CUR Register Diagram

Table 28-73: EMAC_DMA0_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The EMAC_DMA0_TXBUF_CUR.ADDR bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The EMAC_DMA0_TXDSC_ADDR register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (EMAC_DMA0_OPMODE.ST bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the EMAC_DMA0_OPMODE.ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA0_OPMODE.ST bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

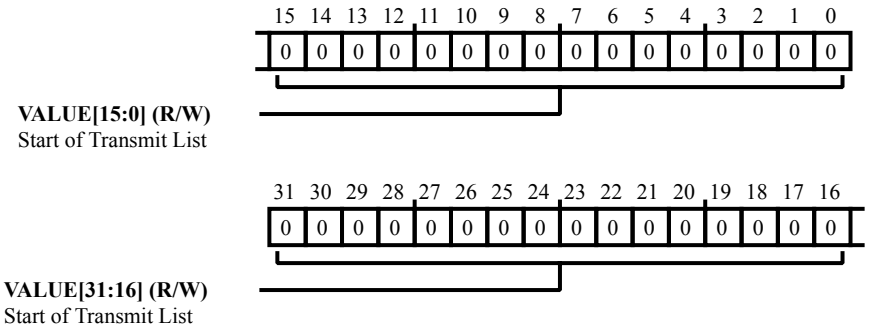

Figure 28-42: EMAC_DMA0_TXDSC_ADDR Register Diagram

Table 28-74: EMAC_DMA0_TXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Transmit List. The EMAC_DMA0_TXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Transmit Descriptor list. The LSB bits [1:0] for 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Tx Descriptor Current Register

The EMAC_DMA0_TXDSC_CUR register contains the current DMA transmit descriptor.

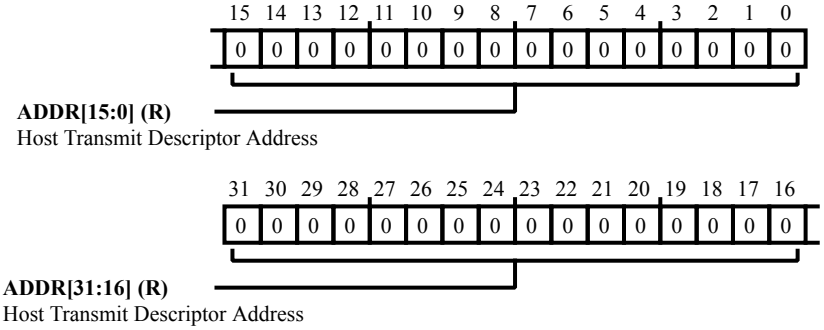

Figure 28-43: EMAC_DMA0_TXDSC_CUR Register Diagram

Table 28-75: EMAC_DMA0_TXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Descriptor Address. The EMAC_DMA0_TXDSC_CUR.ADDR bit field points to the start address of the current Transmit Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Poll Demand Register

The EMAC_DMA0_TXPOLL register directs the EMAC to poll the transmit descriptor list.

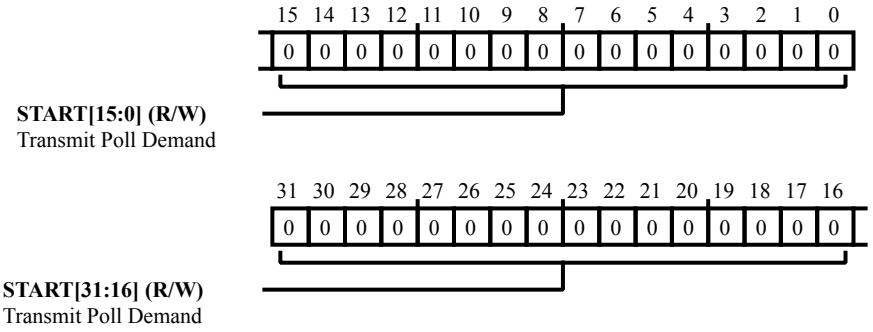

Figure 28-44: EMAC_DMA0_TXPOLL Register Diagram

Table 28-76: EMAC_DMA0_TXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The EMAC_DMA0_TXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by EMAC_DMA0_TXDSC_CUR register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the EMAC_DMA0_STAT.TU bit is asserted. If the descriptor is available, transmission resumes.

DMA Bus Mode Register

The EMAC_DMA1_BUSMODE register selects the DMA bus operating modes for EMAC DMA.

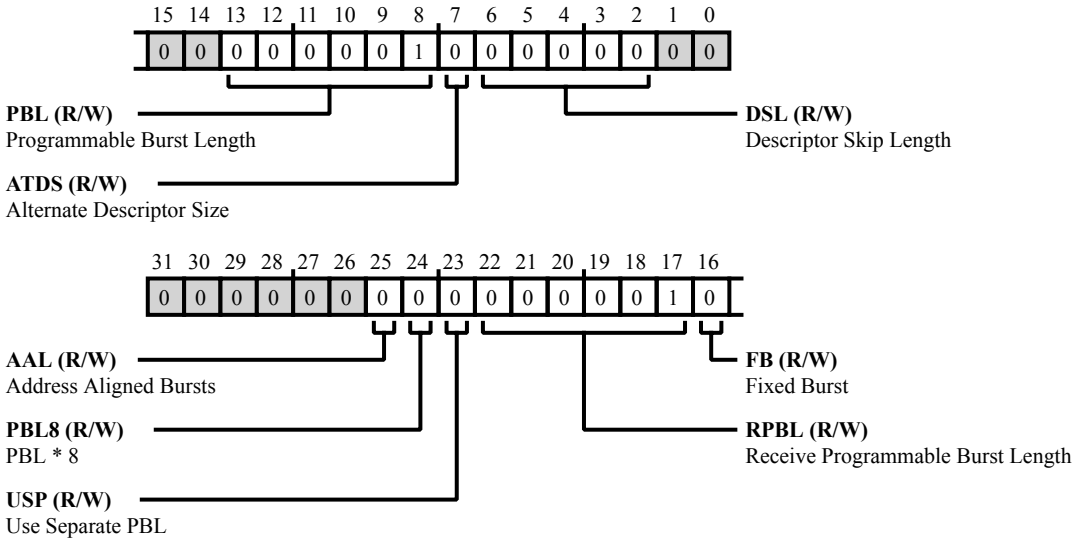

Figure 28-45: EMAC_DMA1_BUSMODE Register Diagram

Table 28-77: EMAC_DMA1_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The EMAC_DMA1_BUSMODE.AAL bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The EMAC_DMA1_BUSMODE.PBL8 bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The EMAC_DMA1_BUSMODE.USP bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 28-77: EMAC_DMA1_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The EMAC_DMA1_BUSMODE.RPBL bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The EMAC_DMA1_BUSMODE.FB bit controls whether the SCB Master interface performs fixed burst transfers or not. See the EMAC_DMA0_BMMODE.UNDEF bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The EMAC_DMA1_BUSMODE.PBL bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If EMAC_DMA1_BUSMODE.PBL =8, and if EMAC_DMA0_BMMODE.BLEN16 is enabled, the max burst is limited to EMAC_DMA0_BMMODE.BLEN8. If EMAC_DMA1_BUSMODE.PBL8 bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The EMAC_DMA1_BUSMODE.ATDS bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 28-77: EMAC_DMA1_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA1_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.

Channel 1 Credit Shaping Control Register

The EMAC_DMA1_CHCBSCTL register controls the credit-based shaper algorithm in the Traffic Manager for scheduling the frames for transmission. This register is present only when you select the Transmit Channel 1 in the AV mode.

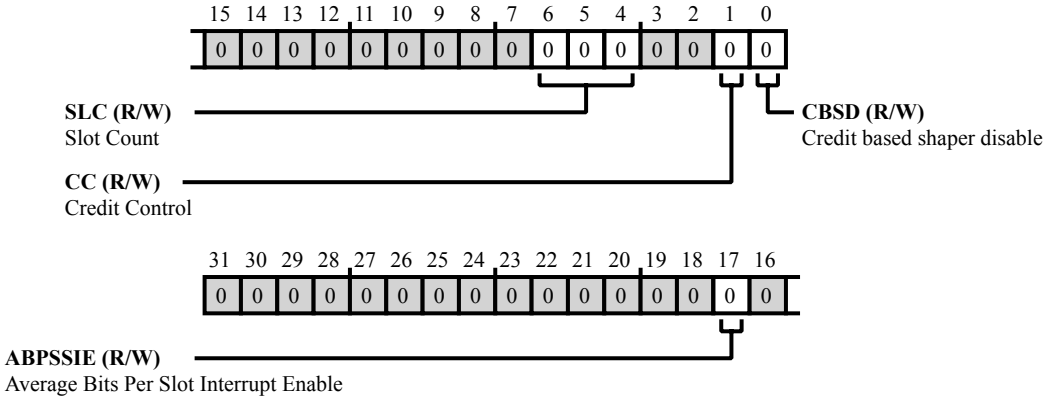

Figure 28-46: EMAC_DMA1_CHCBSCTL Register Diagram

Table 28-78: EMAC_DMA1_CHCBSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ABPSSIE	Average Bits Per Slot Interrupt Enable. When the EMAC_DMA1_CHCBSCTL.ABPSSIE bit is set, the MAC asserts an interrupt (sbd_intr_o or mci_intr_o) when the average bits per slot status is updated for Channel 1. When this bit is cleared, an interrupt is not asserted for such an event.	
6:4 (R/W)	SLC	Slot Count. The EMAC_DMA1_CHCBSCTL.SLC bit field programs the number of slots (of duration 125 micro-sec) over which the average transmitted bits per slot (provided in the CBS Status register) are computed for Channel 1 when the credit-based shaper algorithm is enabled. The encoding is as follows:	
		0	1 Slot
		1	2 Slots
		2	4 Slots
		3	8 Slots
		4	16 Slots
		5	Reserved
		6	Reserved
		7	Reserved

Table 28-78: EMAC_DMA1_CHCBSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	CC	Credit Control. The `EMAC_DMA1_CHCBSCTL.CC` bit, when reset, sets the accumulated credit parameter in the credit-based shaper algorithm logic to zero when there is positive credit and no frame to transmit in Channel 1.
0 (R/W)	CBSD	Credit based shaper disable. The `EMAC_DMA1_CHCBSCTL.CBSD` bit disables the credit-based shaper algorithm for Channel 1 traffic and makes the traffic management algorithm to strict priority for Channel 1 over Channel 0. When reset, the credit-based shaper algorithm schedules the traffic in Channel 1 for transmission.

Channel 1 Average Traffic Transmitted Register

The EMAC_DMA1_CHCBSSTAT register provides the average traffic transmitted in Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

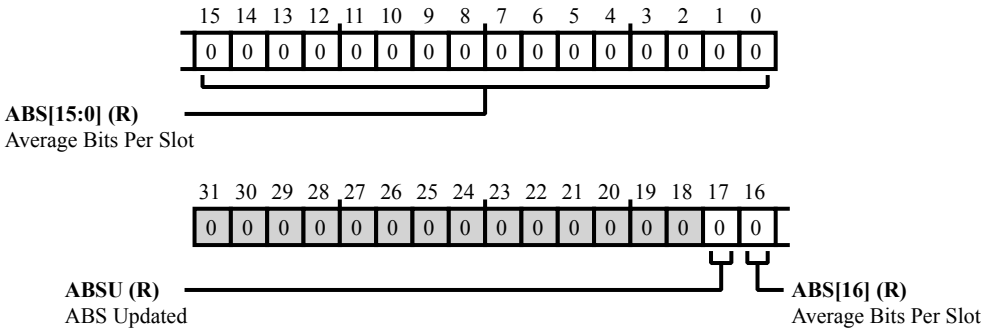

Figure 28-47: EMAC_DMA1_CHCBSSTAT Register Diagram

Table 28-79: EMAC_DMA1_CHCBSSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	ABSU	ABS Updated. The EMAC_DMA1_CHCBSSTAT.ABSU bit indicates that the MAC has updated the ABS value. This bit is cleared when the application reads the ABS value.
16:0 (R/NW)	ABS	Average Bits Per Slot. The EMAC_DMA1_CHCBSSTAT.ABS bit field contains the average transmitted bits per slot. This field is computed over programmed number of slots (EMAC_DMA1_CHCBSCTL.SLC bit field) for Channel 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps.

Channel 1 High Credit Value Register

The EMAC_DMA1_CHHIC register provides the maximum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select the Transmit Channel 1 in the AV mode.

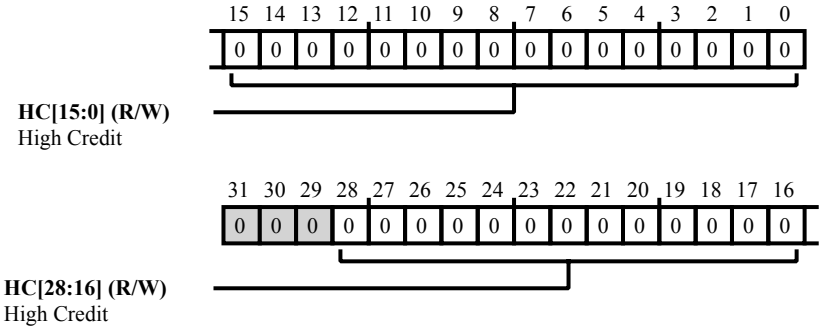

Figure 28-48: EMAC_DMA1_CHHIC Register Diagram

Table 28-80: EMAC_DMA1_CHHIC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	HC	High Credit. The EMAC_DMA1_CHHIC.HC bit field contains the hiCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 1 Idle Slope Credit Value Register

The EMAC_DMA1_CHISC register provides the bandwidth allocated for the AV traffic on Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

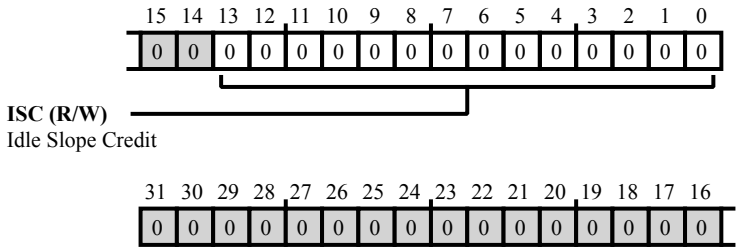

Figure 28-49: EMAC_DMA1_CHISC Register Diagram

Table 28-81: EMAC_DMA1_CHISC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	ISC	Idle Slope Credit. The EMAC_DMA1_CHISC.ISC bit field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 1 Low Credit Value Register

The EMAC_DMA1_CHLOC register provides the minimum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select Transmit Channel 1 in the AV mode.

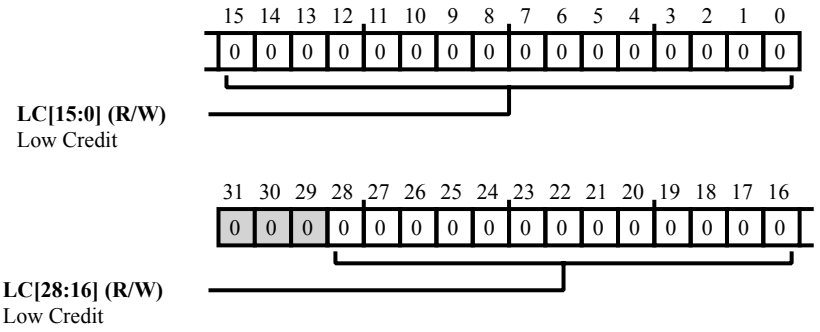

Figure 28-50: EMAC_DMA1_CHLOC Register Diagram

Table 28-82: EMAC_DMA1_CHLOC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	LC	Low Credit. The EMAC_DMA1_CHLOC.LC bit field contains the loCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 1 Control Bits for Slot Function Register

The EMAC_DMA1_CHSFCS register controls the slot comparison feature that the Channel 1 transmit DMA uses to fetch the buffer data from system memory.

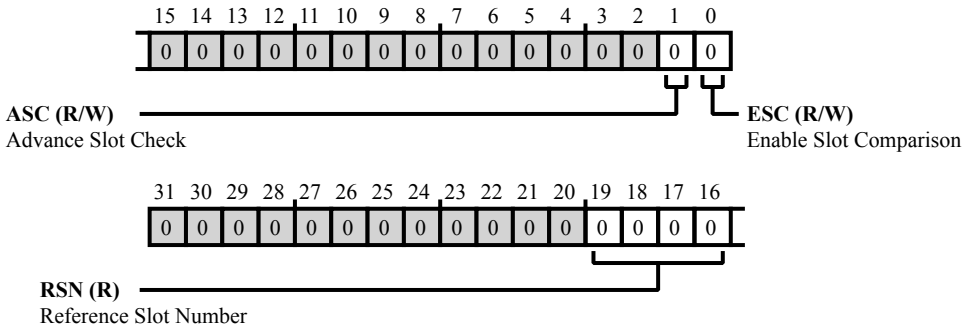

Figure 28-51: EMAC_DMA1_CHSFCS Register Diagram

Table 28-83: EMAC_DMA1_CHSFCS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/NW)	RSN	Reference Slot Number. The EMAC_DMA1_CHSFCS.RSN bits, gives the current value of the reference slot number in DMA used for comparison checking.
1 (R/W)	ASC	Advance Slot Check. When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor is ---equal to the reference slot number given in Bits [19:16] -or- ahead of the reference slot number by up to two slots. This bit is applicable only when Bit 0 (ESC) is set.
0 (R/W)	ESC	Enable Slot Comparison. The EMAC_DMA1_CHSFCS.ESC bits,When set, this bit enables the checking of the slot numbers, programmed in the transmit descriptor, with the current reference given in Bits [19:16]. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or is ahead of the reference slot number by one slot. When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

Channel 1 Send Slope Credit Value Register

The EMAC_DMA1_CHSSC register provides the bandwidth that is available for the AV traffic on other channels. This register is present only when you select the Transmit Channel 1 in the AV mode.

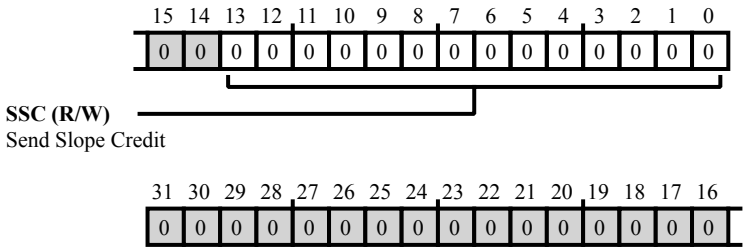

Figure 28-52: EMAC_DMA1_CHSSC Register Diagram

Table 28-84: EMAC_DMA1_CHSSC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	SSC	Send Slope Credit. The EMAC_DMA1_CHSSC.SSC bit field contains the sendSlopeCredit value required for credit-based shaper algorithm for Channel 1.

DMA Interrupt Enable Register

The EMAC_DMA1_IEN register enables (unmasks) EMAC DMA interrupts.

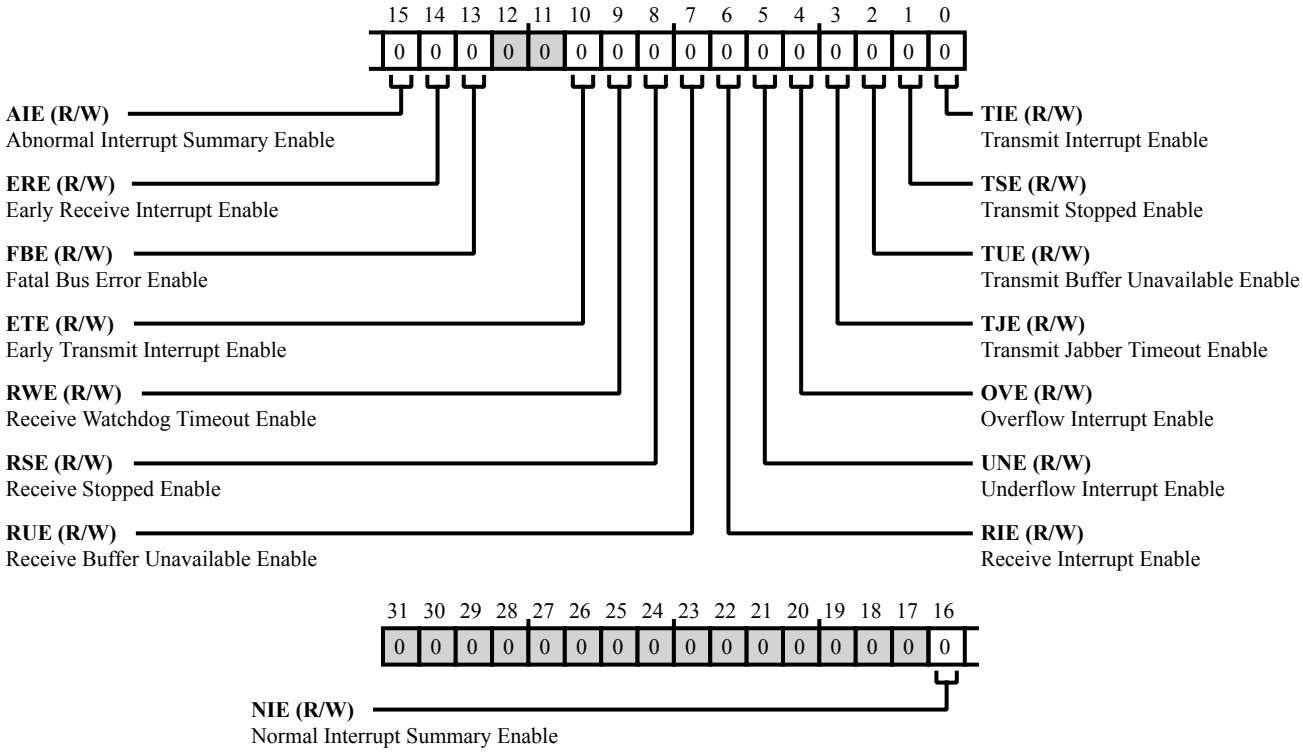

Figure 28-53: EMAC_DMA1_IEN Register Diagram

Table 28-85: EMAC_DMA1_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The EMAC_DMA1_IEN.NIE bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: EMAC_DMA1_STAT.TI, EMAC_DMA1_STAT.TU, EMAC_DMA1_STAT.RI, and EMAC_DMA1_STAT.ERI.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The EMAC_DMA1_IEN.AIE bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: EMAC_DMA1_STAT.TPS, EMAC_DMA1_STAT.TJT, EMAC_DMA1_STAT.OVF, EMAC_DMA1_STAT.RU, EMAC_DMA1_STAT.RPS, EMAC_DMA1_STAT.RWT, EMAC_DMA1_STAT.ETI, and EMAC_DMA1_STAT.FBI.

Table 28-85: EMAC_DMA1_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The EMAC_DMA1_IEN.ERE bit, when set (and with EMAC_DMA1_IEN.NIE =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The EMAC_DMA1_IEN.FBE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The EMAC_DMA1_IEN.ETE bit, when this bit is set (and with EMAC_DMA1_IEN.AIE =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive Watchdog Timeout Enable. The EMAC_DMA1_IEN.RWE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The EMAC_DMA1_IEN.RSE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The EMAC_DMA1_IEN.RUE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The EMAC_DMA1_IEN.RIE bit, when set (and with EMAC_DMA1_IEN.NIE =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The EMAC_DMA1_IEN.UNE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The EMAC_DMA1_IEN.OVE bit, when set (and with EMAC_DMA1_IEN.AIE =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 28-85: EMAC_DMA1_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA1_IEN.TJE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA1_IEN.TUE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA1_IEN.TSE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA1_IEN.TIE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The EMAC_DMA1_MISS_FRM register contains counters for EMAC DMA missed frames and buffer overflows.

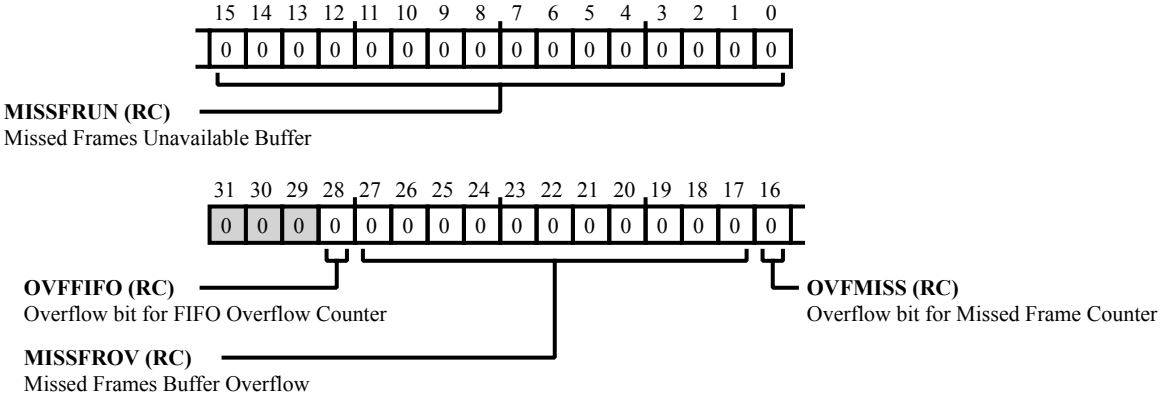

Figure 28-54: EMAC_DMA1_MISS_FRM Register Diagram

Table 28-86: EMAC_DMA1_MISS_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RC/NW)	OVFFIFO	Overflow bit for FIFO Overflow Counter. The EMAC_DMA1_MISS_FRM.OVFFIFO bit holds the overflow bit for FIFO Overflow Counter.
27:17 (RC/NW)	MISSFROV	Missed Frames Buffer Overflow. The EMAC_DMA1_MISS_FRM.MISSFROV bits indicate the number of frames missed by the application due to buffer overflow.
16 (RC/NW)	OVFMISS	Overflow bit for Missed Frame Counter. The EMAC_DMA1_MISS_FRM.OVFMISS bit holds the overflow bit for the Missed Frame Counter.
15:0 (RC/NW)	MISSFRUN	Missed Frames Unavailable Buffer. The EMAC_DMA1_MISS_FRM.MISSFRUN bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable.

DMA Operation Mode Register

The EMAC_DMA1_OPMODE register selects receive and transmit DMA operating modes.

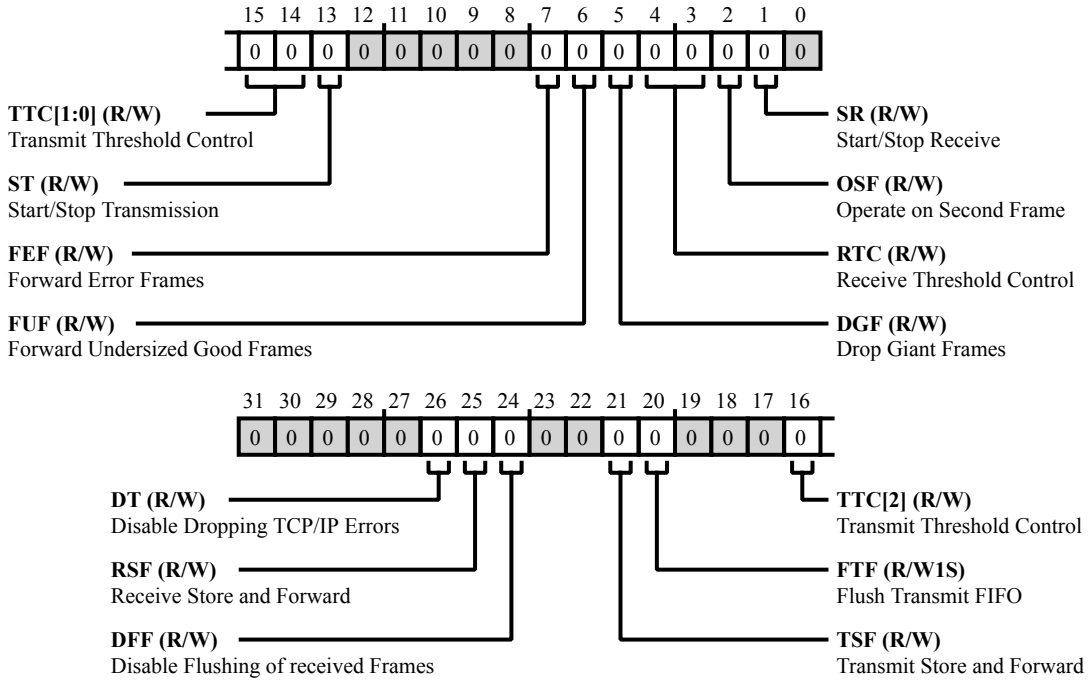

Figure 28-55: EMAC_DMA1_OPMODE Register Diagram

Table 28-87: EMAC_DMA1_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The EMAC_DMA1_OPMODE.DT bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the EMAC_DMA1_OPMODE.FEF bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The EMAC_DMA1_OPMODE.RSF bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the EMAC_DMA1_OPMODE.RTC bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the EMAC_DMA1_OPMODE.RTC bits.
24 (R/W)	DFF	Disable Flushing of received Frames. The EMAC_DMA1_OPMODE.DFF bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 28-87: EMAC_DMA1_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	TSF	Transmit Store and Forward. The `EMAC_DMA1_OPMODE.TSF` bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.	
20 (R/W1S)	FTF	Flush Transmit FIFO. The `EMAC_DMA1_OPMODE.FTF` bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.	
16:14 (R/W)	TTC	Transmit Threshold Control. The `EMAC_DMA1_OPMODE.TTC` bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the `EMAC_DMA1_OPMODE.TSF` bit is reset. The value =011 is not used.	
		0	64
		1	128
		2	192
		3	256
		4	40
		5	32
		6	24
		7	16

Table 28-87: EMAC_DMA1_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The EMAC_DMA1_OPMODE.ST bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the EMAC_DMA1_STAT.TU bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the EMAC_DMA1_TXDSC_CUR address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The EMAC_DMA1_OPMODE.FEF bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When EMAC_DMA1_OPMODE.FEF bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when EMAC_DMA1_OPMODE.FEF is set.
6 (R/W)	FUF	Forward Undersized Good Frames. The EMAC_DMA1_OPMODE.FUF bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, EMAC_DMA1_OPMODE.RTC =01).
5 (R/W)	DGF	Drop Giant Frames. The EMAC_DMA1_OPMODE.DGF bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 28-87: EMAC_DMA1_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	RTC	Receive Threshold Control. The EMAC_DMA1_OPMODE.RTC bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the EMAC_DMA1_OPMODE.RSF bit is zero, and are ignored when the EMAC_DMA1_OPMODE.RSF bit is set to 1. The value =11 is not used.	
		0	64
		1	32
		2	96
		3	128
2 (R/W)	OSF	Operate on Second Frame. The EMAC_DMA1_OPMODE.OSF bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.	
1 (R/W)	SR	Start/Stop Receive. The EMAC_DMA1_OPMODE.SR bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the EMAC_DMA1_STAT.RU bit is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting EMAC_DMA1_RXDSC_CUR address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.	

DMA Rx Buffer Current Register

The EMAC_DMA1_RXBUF_CUR register holds the pointer to the current receive DMA buffer.

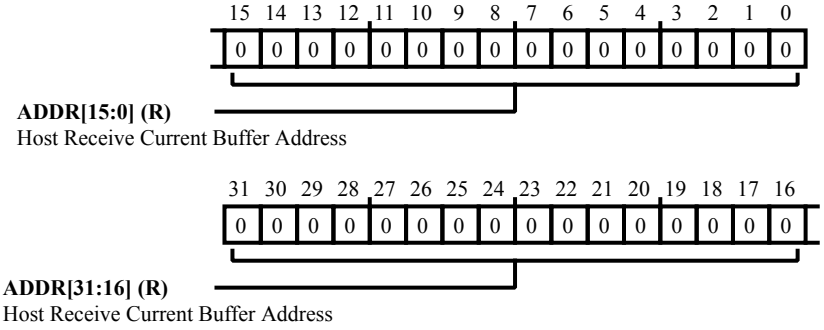

Figure 28-56: EMAC_DMA1_RXBUF_CUR Register Diagram

Table 28-88: EMAC_DMA1_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The EMAC_DMA1_RXBUF_CUR.ADDR bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The EMAC_DMA1_RXDSC_ADDR register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to EMAC_DMA1_RXDSC_ADDR only when Rx DMA has stopped (EMAC_DMA1_OPMODE.SR bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the EMAC_DMA1_OPMODE.SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA1_OPMODE.SR bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

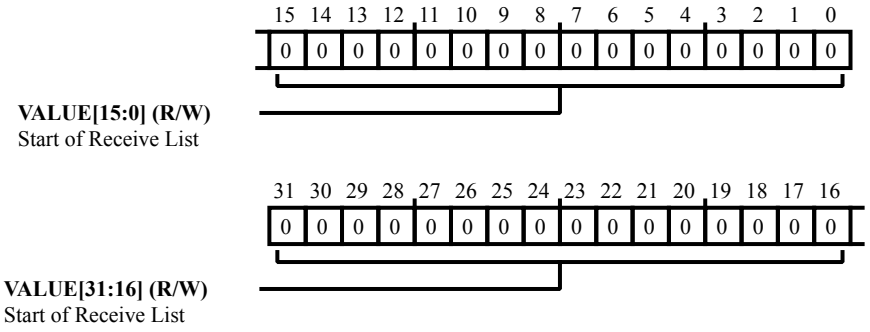

Figure 28-57: EMAC_DMA1_RXDSC_ADDR Register Diagram

Table 28-89: EMAC_DMA1_RXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Receive List. The EMAC_DMA1_RXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Receive Descriptor list. The LSB bits [1:0] for the 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Rx Descriptor Current Register

The EMAC_DMA1_RXDSC_CUR register contains the current DMA receive descriptor.

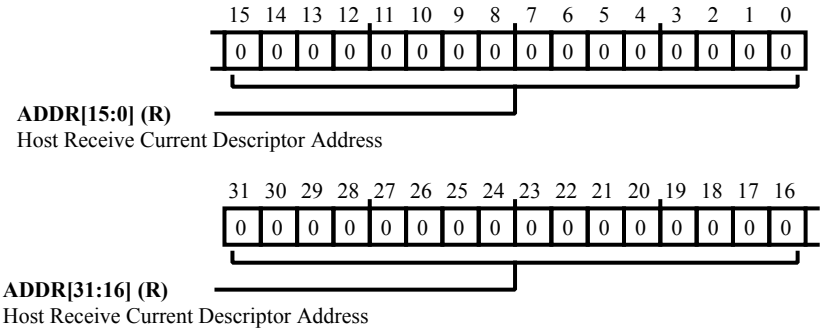

Figure 28-58: EMAC_DMA1_RXDSC_CUR Register Diagram

Table 28-90: EMAC_DMA1_RXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Descriptor Address. The EMAC_DMA1_RXDSC_CUR.ADDR bit field points to the start address of the current Receive Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Interrupt Watch Dog Register

The EMAC_DMA1_RXIWDOG register contains the timeout value for the EMAC DMA receive interrupt watch dog timer.

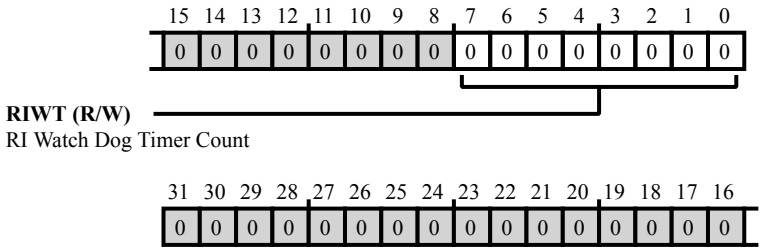

Figure 28-59: EMAC_DMA1_RXIWDOG Register Diagram

Table 28-91: EMAC_DMA1_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI Watch Dog Timer Count. The EMAC_DMA1_RXIWDOG.RIWT bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when EMAC_DMA1_STAT.RI bit is set high because of automatic setting of EMAC_DMA1_STAT.RI as per RDES1[31] of any received frame.

DMA Rx Poll Demand Register

The EMAC_DMA1_RXPOLL register directs the EMAC to poll the receive descriptor list.

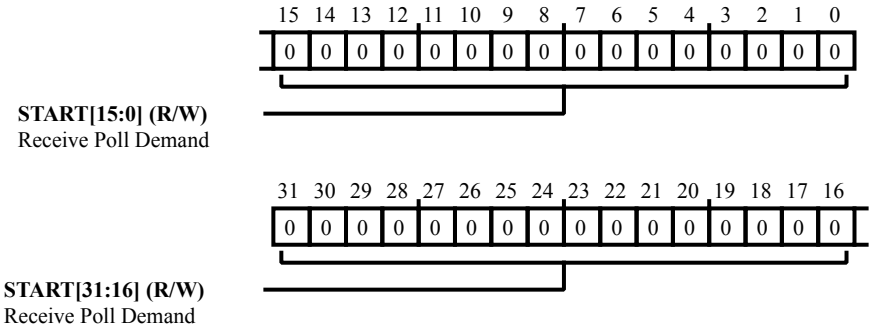

Figure 28-60: EMAC_DMA1_RXPOLL Register Diagram

Table 28-92: EMAC_DMA1_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The EMAC_DMA1_RXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by the EMAC_DMA1_RXDSC_CUR register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the EMAC_DMA1_STAT.RU bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The EMAC_DMA1_STAT register indicates EMAC DMA status.

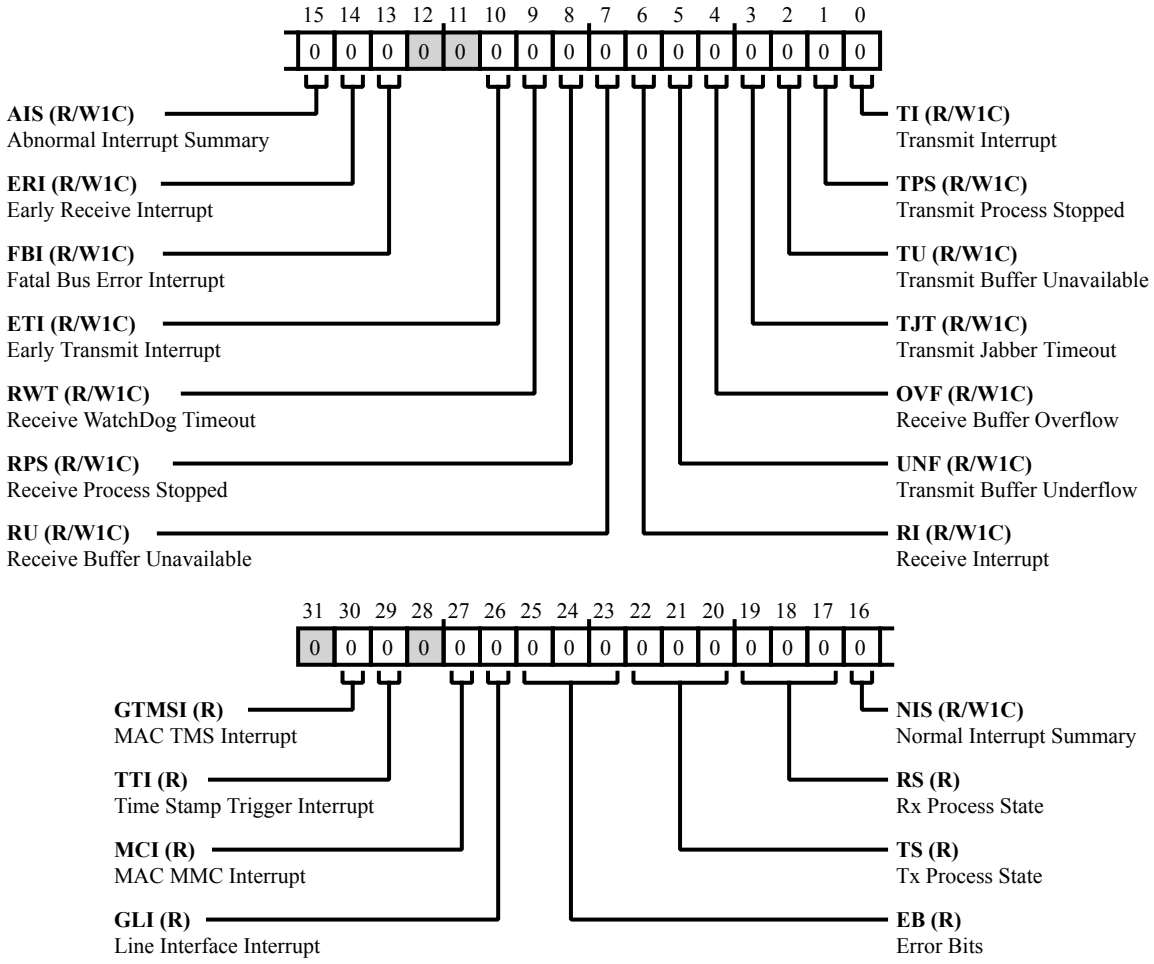

Figure 28-61: EMAC_DMA1_STAT Register Diagram

Table 28-93: EMAC_DMA1_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GTMSI	MAC TMS Interrupt. MAC TMS Interrupt: The EMAC_DMA1_STAT.GTMSI bit indicates an interrupt event in the traffic manager and scheduler logic. To reset this bit, the software must read the corresponding registers (Channel Status Register) to get the exact cause of the interrupt and clear its source.

Table 28-93: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The `EMAC_DMA1_STAT.TTI` bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interrupt. The `EMAC_DMA1_STAT.MCI` bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The `EMAC_DMA1_STAT.GLI` bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The `EMAC_DMA1_STAT.EB` bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the `EMAC_DMA1_STAT.FBI` bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The `EMAC_DMA1_STAT.TS` bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 28-93: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The EMAC_DMA1_STAT.RS bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the EMAC_DMA1_STAT.NIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA1_STAT.TI, EMAC_DMA1_STAT.TU, EMAC_DMA1_STAT.RI, and EMAC_DMA1_STAT.ERI. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes EMAC_DMA1_STAT.NIS to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the EMAC_DMA1_STAT.AIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA1_IEN.TSE, EMAC_DMA1_IEN.TJE, EMAC_DMA1_IEN.OVE, EMAC_DMA1_IEN.UNE, EMAC_DMA1_IEN.RUE, EMAC_DMA1_IEN.RSE, EMAC_DMA1_IEN.RWE, EMAC_DMA1_IEN.ETE, and EMAC_DMA1_IEN.FBE. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes EMAC_DMA1_STAT.AIS to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The EMAC_DMA1_STAT.ERI bit indicates that the DMA had filled the first data buffer of the packet. The EMAC_DMA1_STAT.RI bit automatically clears this bit.	

Table 28-93: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The EMAC_DMA1_STAT.FBI bit indicates that a bus error occurred, as detailed in the EMAC_DMA1_STAT.EB field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The EMAC_DMA1_STAT.ETI bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The EMAC_DMA1_STAT.RWT bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The EMAC_DMA1_STAT.RPS bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The EMAC_DMA1_STAT.RU bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The EMAC_DMA1_STAT.RI bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The EMAC_DMA1_STAT.UNF bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The EMAC_DMA1_STAT.OVF bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The EMAC_DMA1_STAT.TJT bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 28-93: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The EMAC_DMA1_STAT.TU bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the EMAC_DMA1_STAT.TS bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The EMAC_DMA1_STAT.TPS bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The EMAC_DMA1_STAT.TI bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The EMAC_DMA1_TXBUF_CUR register holds the pointer to the current transmit DMA buffer.

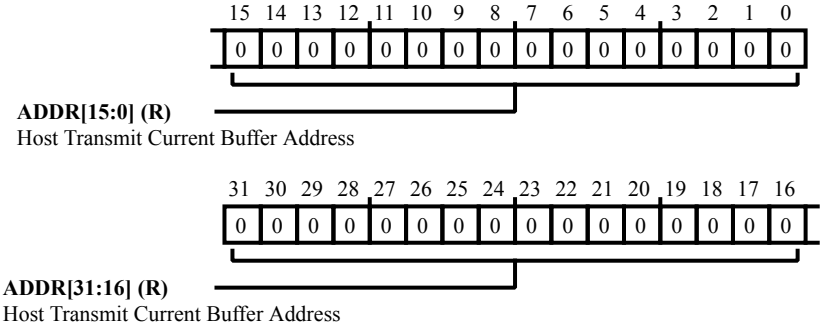

Figure 28-62: EMAC_DMA1_TXBUF_CUR Register Diagram

Table 28-94: EMAC_DMA1_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The EMAC_DMA1_TXBUF_CUR.ADDR bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The EMAC_DMA1_TXDSC_ADDR register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (EMAC_DMA1_OPMODE.ST bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the EMAC_DMA1_OPMODE.ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA1_OPMODE.ST bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

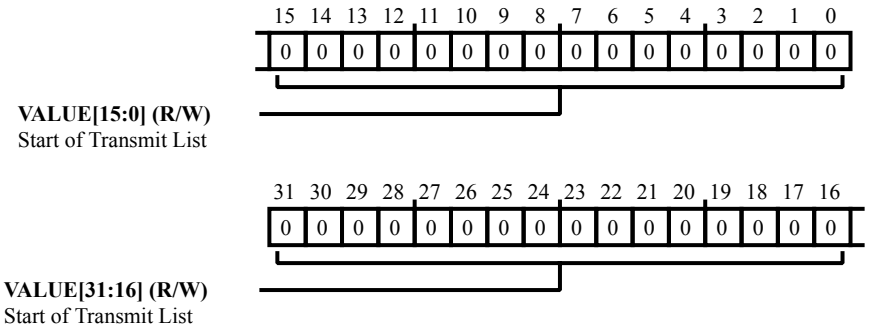

Figure 28-63: EMAC_DMA1_TXDSC_ADDR Register Diagram

Table 28-95: EMAC_DMA1_TXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Transmit List. The EMAC_DMA1_TXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Transmit Descriptor list. The LSB bits [1:0] for 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Tx Descriptor Current Register

The EMAC_DMA1_TXDSC_CUR register contains the current DMA transmit descriptor.

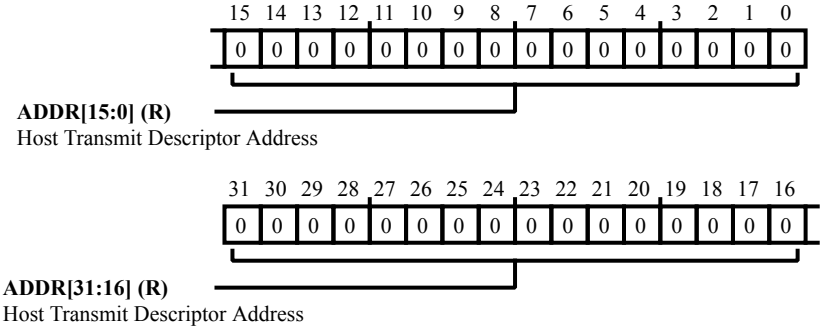

Figure 28-64: EMAC_DMA1_TXDSC_CUR Register Diagram

Table 28-96: EMAC_DMA1_TXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Descriptor Address. The EMAC_DMA1_TXDSC_CUR.ADDR bit field points to the start address of the current Transmit Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Poll Demand Register

The EMAC_DMA1_TXPOLL register directs the EMAC to poll the transmit descriptor list.

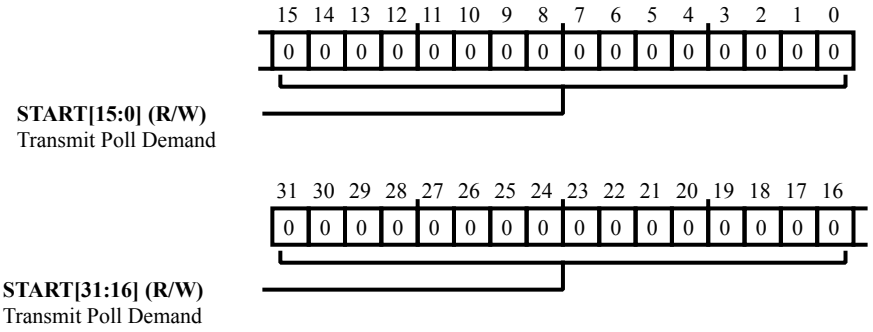

Figure 28-65: EMAC_DMA1_TXPOLL Register Diagram

Table 28-97: EMAC_DMA1_TXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The EMAC_DMA1_TXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by EMAC_DMA1_TXDSC_CUR register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the EMAC_DMA1_STAT.TU bit is asserted. If the descriptor is available, transmission resumes.

DMA Bus Mode Register

The EMAC_DMA2_BUSMODE register selects the DMA bus operating modes for EMAC DMA.

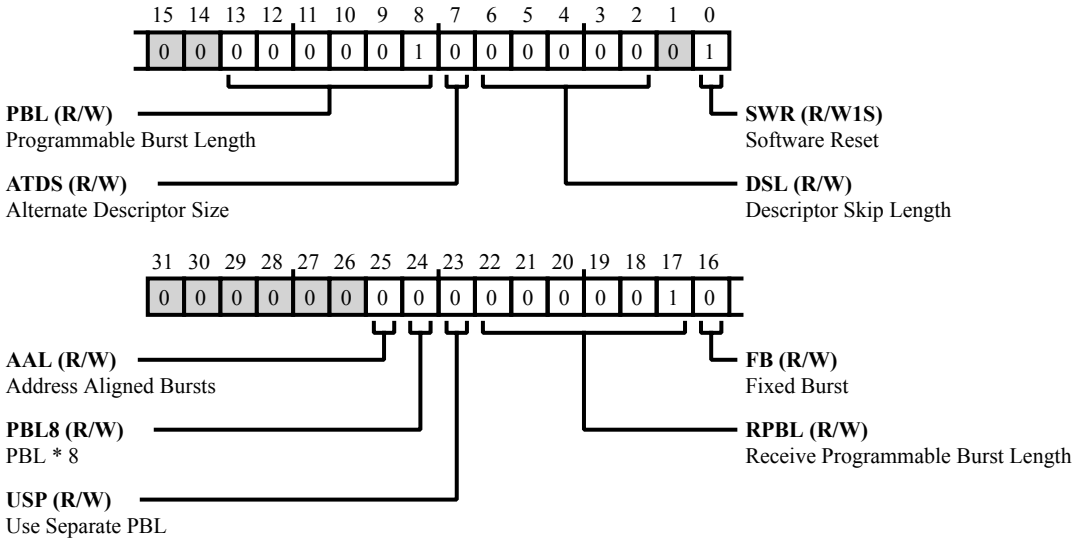

Figure 28-66: EMAC_DMA2_BUSMODE Register Diagram

Table 28-98: EMAC_DMA2_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The EMAC_DMA2_BUSMODE.AAL bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The EMAC_DMA2_BUSMODE.PBL8 bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The EMAC_DMA2_BUSMODE.USP bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 28-98: EMAC_DMA2_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The EMAC_DMA2_BUSMODE.RPBL bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The EMAC_DMA2_BUSMODE.FB bit controls whether the SCB Master interface performs fixed burst transfers or not. See the EMAC_DMA0_BMMODE.UNDEF bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The EMAC_DMA2_BUSMODE.PBL bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If EMAC_DMA2_BUSMODE.PBL =8, and if EMAC_DMA0_BMMODE.BLEN16 is enabled, the max burst is limited to EMAC_DMA0_BMMODE.BLEN8. If EMAC_DMA2_BUSMODE.PBL8 bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The EMAC_DMA2_BUSMODE.ATDS bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 28-98: EMAC_DMA2_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA2_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.
0 (R/W1S)	SWR	Software Reset. The `EMAC_DMA2_BUSMODE.SWR` bit, when set, directs the MAC DMA Controller to reset all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core. Note: The reset operation is completed only when all the resets in all the active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.

Channel 2 Credit Shaping Control Register

The EMAC_DMA2_CHCBSCTL register controls the credit-based shaper algorithm in the Traffic Manager for scheduling the frames for transmission. This register is present only when you select the Transmit Channel 1 in the AV mode.

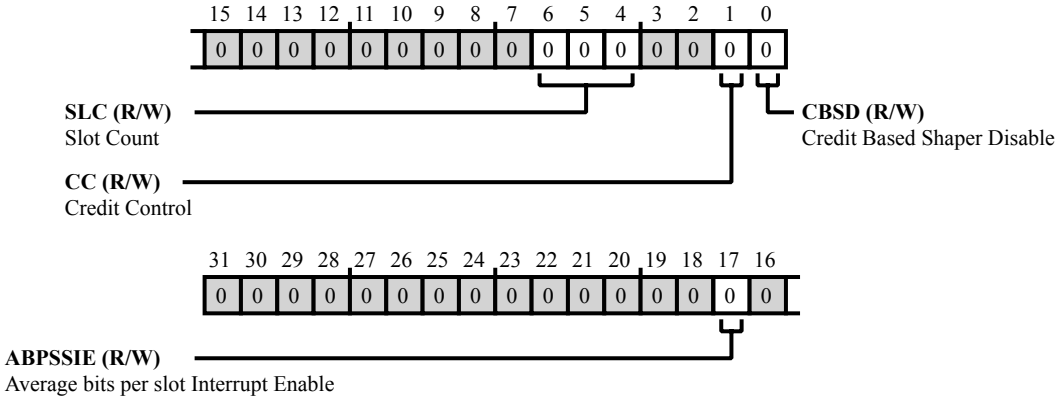

Figure 28-67: EMAC_DMA2_CHCBSCTL Register Diagram

Table 28-99: EMAC_DMA2_CHCBSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	ABPSSIE	Average bits per slot Interrupt Enable. The EMAC_DMA2_CHCBSCTL.ABPSSIE bit asserts an interrupt (sbd_intr_o or mci_intr_o) when the average bits per slot status is updated for Channel 1. When this bit is cleared, interrupt is not asserted for such an event.
6:4 (R/W)	SLC	Slot Count. The EMAC_DMA2_CHCBSCTL.SLC bit field programs the number of slots (of duration 125 micro-sec) over which the average transmitted bits per slot (provided in the CBS Status register) need to be computed for Channel 1 when the credit-based shaper algorithm is enabled. The
1 (R/W)	CC	Credit Control. The EMAC_DMA2_CHCBSCTL.CC bit, when reset, sets the accumulated credit parameter in the credit-based shaper algorithm logic to zero when there is positive credit and no frame to transmit in Channel 1.
0 (R/W)	CBSD	Credit Based Shaper Disable. The EMAC_DMA2_CHCBSCTL.CBSD bit disables the credit-based shaper algorithm for Channel 1 traffic and makes the traffic management algorithm to strict priority for Channel 1 over Channel 0. When reset, the credit-based shaper algorithm schedules the traffic in Channel 1 for transmission.

Channel 2 Avg Traffic Transmitted Status Register

The EMAC_DMA2_CHCBSSTAT register provides the average traffic transmitted in Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

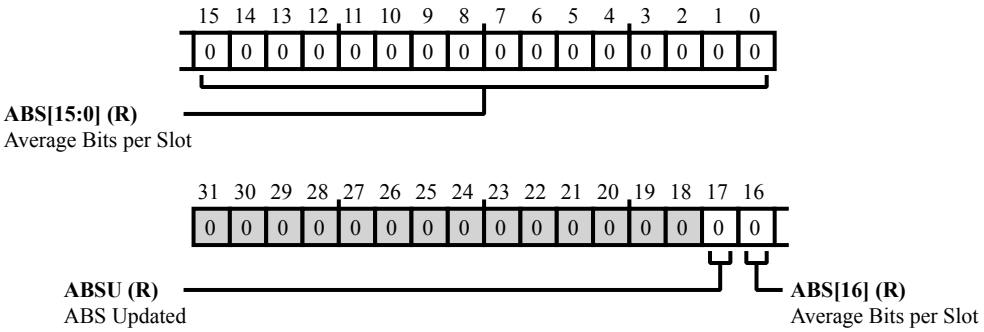

Figure 28-68: EMAC_DMA2_CHCBSSTAT Register Diagram

Table 28-100: EMAC_DMA2_CHCBSSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	ABSU	ABS Updated. The EMAC_DMA2_CHCBSSTAT.ABSU bits When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application reads the ABS value.
16:0 (R/NW)	ABS	Average Bits per Slot. The EMAC_DMA2_CHCBSSTAT.ABS bit field contains the average transmitted bits per slot. This field is computed over programmed number of slots (EMAC_DMA2_CHCBSCTL.SLC bit field) for Channel 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps.

Channel 2 High Credit Value Register

The EMAC_DMA2_CHHIC register provides the maximum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select the Transmit Channel 1 in the AV mode.

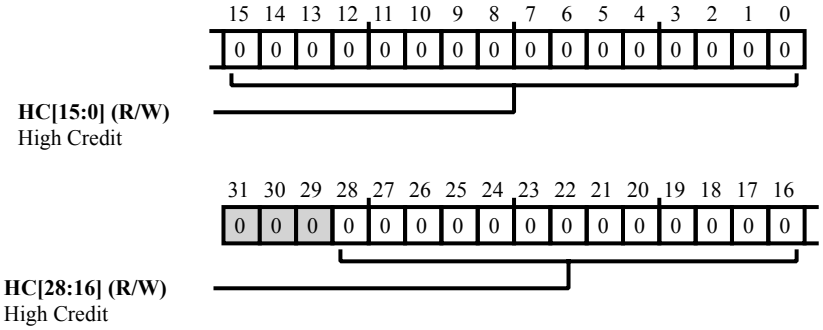

Figure 28-69: EMAC_DMA2_CHHIC Register Diagram

Table 28-101: EMAC_DMA2_CHHIC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	HC	High Credit. The EMAC_DMA2_CHHIC.HC bit field contains the hiCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 2 Idle Slope Credit Value Register

The EMAC_DMA2_CHISC register provides the bandwidth allocated for the AV traffic on Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

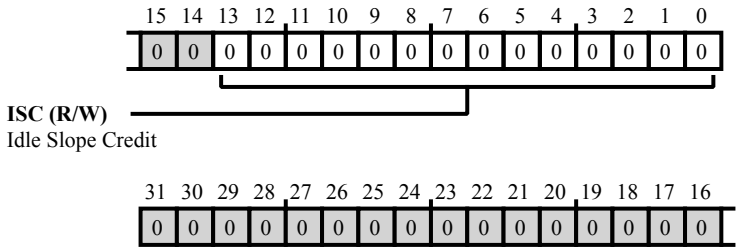

Figure 28-70: EMAC_DMA2_CHISC Register Diagram

Table 28-102: EMAC_DMA2_CHISC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	ISC	Idle Slope Credit. The EMAC_DMA2_CHISC.ISC bit field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 2 Low Credit Value Register

The EMAC_DMA2_CHLOC register provides the minimum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select Transmit Channel 1 in the AV mode.

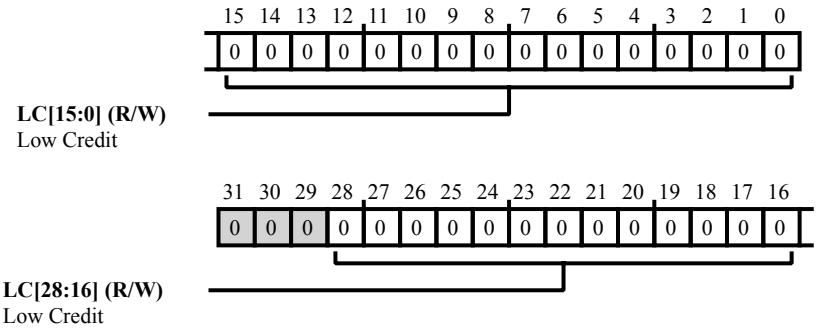

Figure 28-71: EMAC_DMA2_CHLOC Register Diagram

Table 28-103: EMAC_DMA2_CHLOC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	LC	Low Credit. The EMAC_DMA2_CHLOC.LC bit field contains the loCredit value required for the credit-based shaper algorithm for Channel 1.

Channel 2 Control Bits for Slot Function Register

The EMAC_DMA2_CHSFCS register controls the slot comparison feature that the Channel 1 transmit DMA uses to fetch the buffer data from system memory.

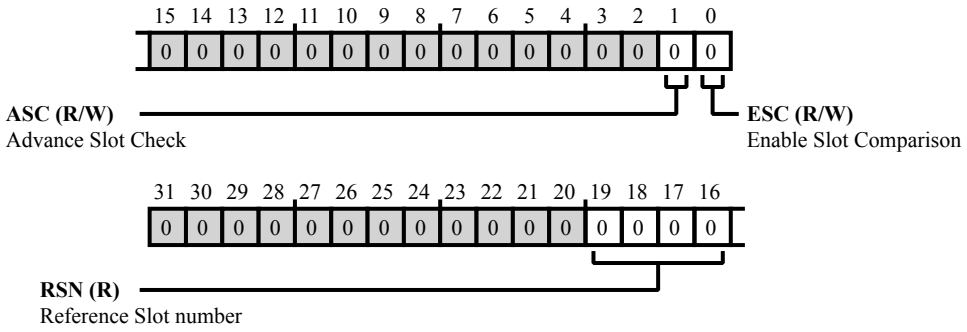

Figure 28-72: EMAC_DMA2_CHSFCS Register Diagram

Table 28-104: EMAC_DMA2_CHSFCS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/NW)	RSN	Reference Slot number. The EMAC_DMA2_CHSFCS.RSN bits, gives the current value of the reference slot number in DMA used for comparison checking.
1 (R/W)	ASC	Advance Slot Check. The EMAC_DMA2_CHSFCS.ASC bits, When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor
0 (R/W)	ESC	Enable Slot Comparison. The EMAC_DMA2_CHSFCS.ESC bit enables the checking of the slot numbers, programmed in the transmit descriptor, with the current reference given in Bits [19:16]. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or is ahead of the reference slot number by one slot. When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

Channel 2 Send Slope Credit Value Register

The EMAC_DMA2_CHSSC register provides the bandwidth that is available for the AV traffic on other channels. This register is present only when you select the Transmit Channel 1 in the AV mode.

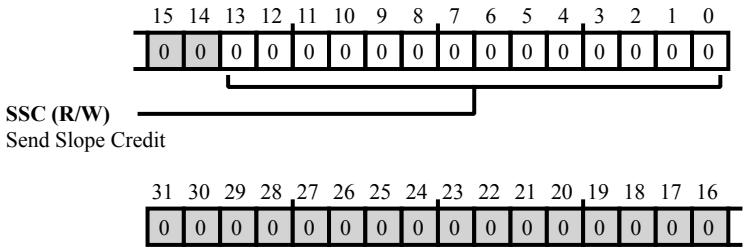

Figure 28-73: EMAC_DMA2_CHSSC Register Diagram

Table 28-105: EMAC_DMA2_CHSSC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	SSC	Send Slope Credit. The EMAC_DMA2_CHSSC.SSC bit field contains the sendSlopeCredit value required for credit-based shaper algorithm for Channel 1.

DMA Interrupt Enable Register

The EMAC_DMA2_IEN register enables (unmasks) EMAC DMA interrupts.

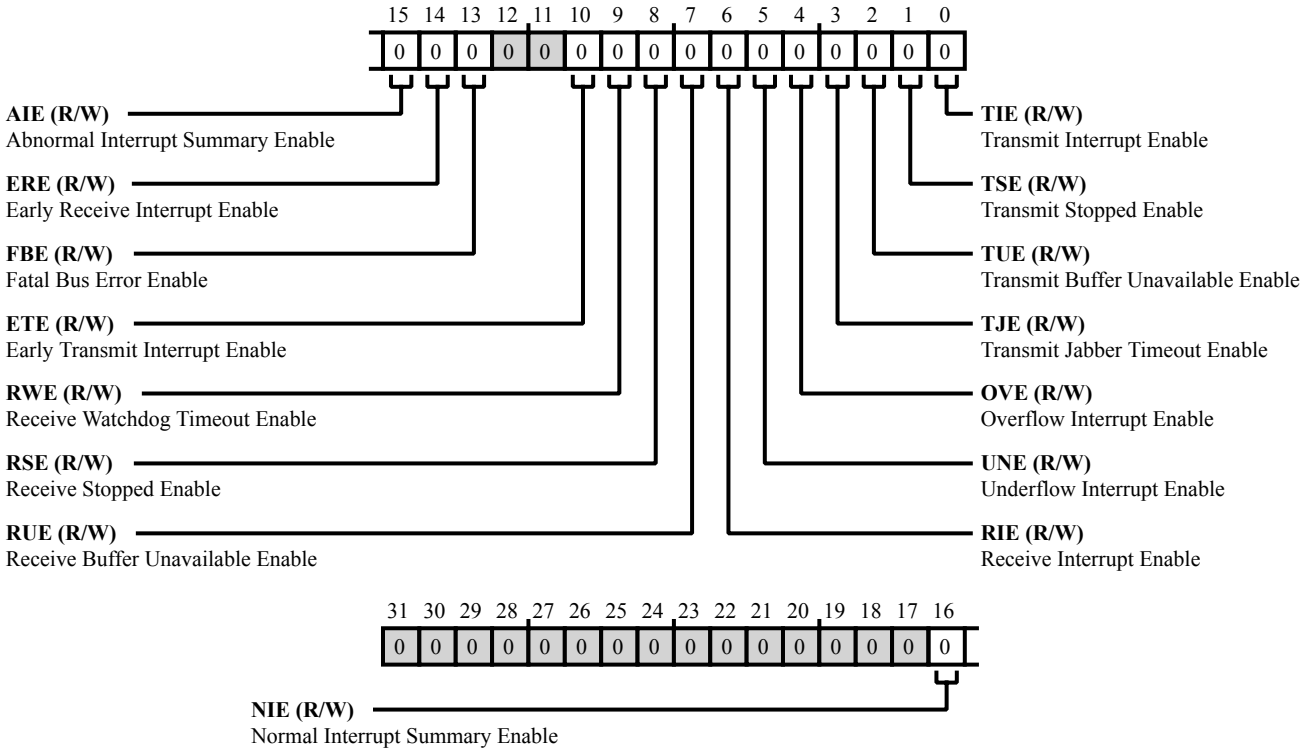

Figure 28-74: EMAC_DMA2_IEN Register Diagram

Table 28-106: EMAC_DMA2_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The EMAC_DMA2_IEN.NIE bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: EMAC_DMA2_STAT.TI, EMAC_DMA2_STAT.TU, EMAC_DMA2_STAT.RI, and EMAC_DMA2_STAT.ERI.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The EMAC_DMA2_IEN.AIE bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: EMAC_DMA2_STAT.TPS, EMAC_DMA2_STAT.TJT, EMAC_DMA2_STAT.OVF, EMAC_DMA2_STAT.RU, EMAC_DMA2_STAT.RPS, EMAC_DMA2_STAT.RWT, EMAC_DMA2_STAT.ETI, and EMAC_DMA2_STAT.FBI.

Table 28-106: EMAC_DMA2_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The EMAC_DMA2_IEN.ERE bit, when set (and with EMAC_DMA2_IEN.NIE =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The EMAC_DMA2_IEN.FBE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The EMAC_DMA2_IEN.ETE bit, when this bit is set (and with EMAC_DMA2_IEN.AIE =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive Watchdog Timeout Enable. The EMAC_DMA2_IEN.RWE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The EMAC_DMA2_IEN.RSE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The EMAC_DMA2_IEN.RUE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The EMAC_DMA2_IEN.RIE bit, when set (and with EMAC_DMA2_IEN.NIE =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The EMAC_DMA2_IEN.UNE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The EMAC_DMA2_IEN.OVE bit, when set (and with EMAC_DMA2_IEN.AIE =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 28-106: EMAC_DMA2_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA2_IEN.TJE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA2_IEN.TUE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA2_IEN.TSE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA2_IEN.TIE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The EMAC_DMA2_MISS_FRM register contains counters for EMAC DMA missed frames and buffer overflows.

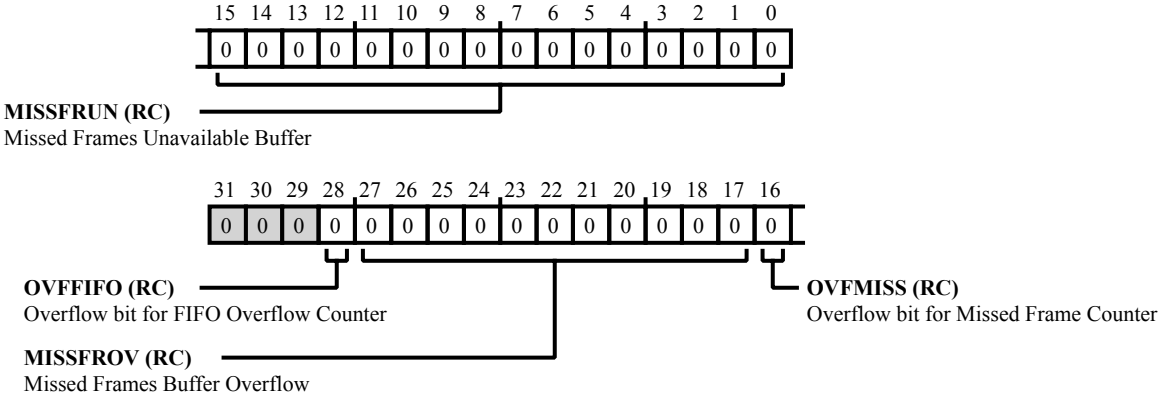

Figure 28-75: EMAC_DMA2_MISS_FRM Register Diagram

Table 28-107: EMAC_DMA2_MISS_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RC/NW)	OVFFIFO	Overflow bit for FIFO Overflow Counter. The EMAC_DMA2_MISS_FRM.OVFFIFO bit holds the overflow bit for FIFO Overflow Counter.
27:17 (RC/NW)	MISSFROV	Missed Frames Buffer Overflow. The EMAC_DMA2_MISS_FRM.MISSFROV bits indicate the number of frames missed by the application due to buffer overflow.
16 (RC/NW)	OVFMISS	Overflow bit for Missed Frame Counter. The EMAC_DMA2_MISS_FRM.OVFMISS bit holds the overflow bit for the Missed Frame Counter.
15:0 (RC/NW)	MISSFRUN	Missed Frames Unavailable Buffer. The EMAC_DMA2_MISS_FRM.MISSFRUN bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable.

DMA Operation Mode Register

The EMAC_DMA2_OPMODE register selects receive and transmit DMA operating modes.

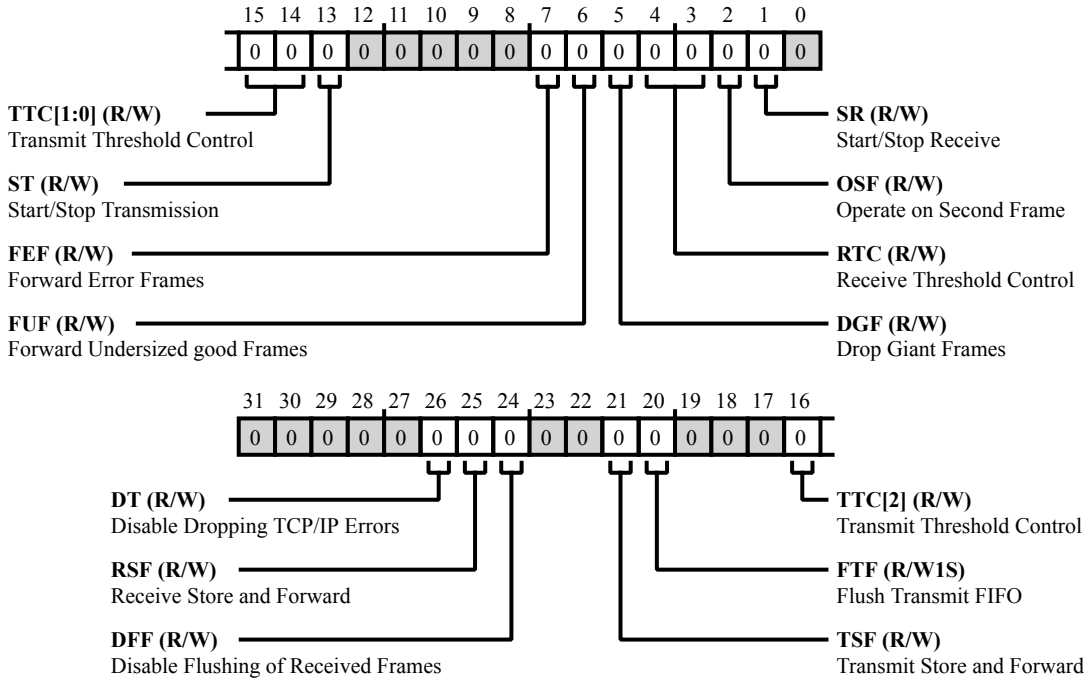

Figure 28-76: EMAC_DMA2_OPMODE Register Diagram

Table 28-108: EMAC_DMA2_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The EMAC_DMA2_OPMODE.DT bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the EMAC_DMA2_OPMODE.FEF bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The EMAC_DMA2_OPMODE.RSF bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the EMAC_DMA2_OPMODE.RTC bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the EMAC_DMA2_OPMODE.RTC bits.
24 (R/W)	DFF	Disable Flushing of Received Frames. The EMAC_DMA2_OPMODE.DFF bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 28-108: EMAC_DMA2_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	TSF	Transmit Store and Forward. The `EMAC_DMA2_OPMODE.TSF` bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.	
20 (R/W1S)	FTF	Flush Transmit FIFO. The `EMAC_DMA2_OPMODE.FTF` bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.	
16:14 (R/W)	TTC	Transmit Threshold Control. The `EMAC_DMA2_OPMODE.TTC` bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the `EMAC_DMA2_OPMODE.TSF` bit is reset. The value =011 is not used.	
		0	64
		1	128
		2	192
		3	256
		4	40
		5	32
		6	24
		7	16

Table 28-108: EMAC_DMA2_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The EMAC_DMA2_OPMODE.ST bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the EMAC_DMA2_STAT.TU bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the EMAC_DMA2_TXDSC_CUR address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The EMAC_DMA2_OPMODE.FEF bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When EMAC_DMA2_OPMODE.FEF bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when EMAC_DMA2_OPMODE.FEF is set.
6 (R/W)	FUF	Forward Undersized good Frames. The EMAC_DMA2_OPMODE.FUF bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, EMAC_DMA2_OPMODE.RTC =01).
5 (R/W)	DGF	Drop Giant Frames. The EMAC_DMA2_OPMODE.DGF bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 28-108: EMAC_DMA2_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	RTC	Receive Threshold Control. The EMAC_DMA2_OPMODE.RTC bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the EMAC_DMA2_OPMODE.RSF bit is zero, and are ignored when the EMAC_DMA2_OPMODE.RSF bit is set to 1. The value =11 is not used.	
		0	64
		1	32
		2	96
		3	128
2 (R/W)	OSF	Operate on Second Frame. The EMAC_DMA2_OPMODE.OSF bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.	
1 (R/W)	SR	Start/Stop Receive. The EMAC_DMA2_OPMODE.SR bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the EMAC_DMA2_STAT.RU bit is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting EMAC_DMA2_RXDSC_CUR address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.	

DMA Rx Buffer Current Register

The EMAC_DMA2_RXBUF_CUR register holds the pointer to the current receive DMA buffer.

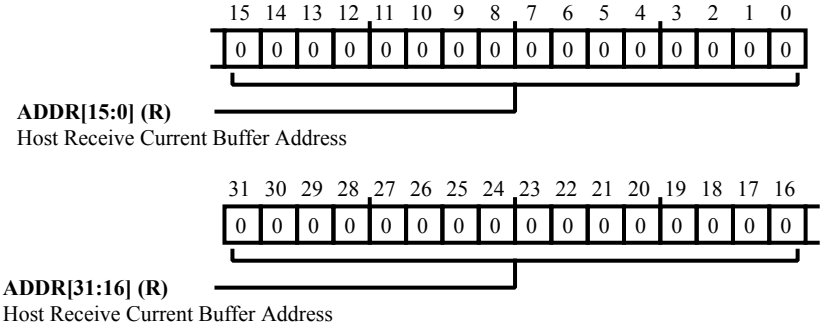

Figure 28-77: EMAC_DMA2_RXBUF_CUR Register Diagram

Table 28-109: EMAC_DMA2_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The EMAC_DMA2_RXBUF_CUR.ADDR bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The EMAC_DMA2_RXDSC_ADDR register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to EMAC_DMA2_RXDSC_ADDR only when Rx DMA has stopped (EMAC_DMA2_OPMODE.SR bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the EMAC_DMA2_OPMODE.SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA2_OPMODE.SR bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

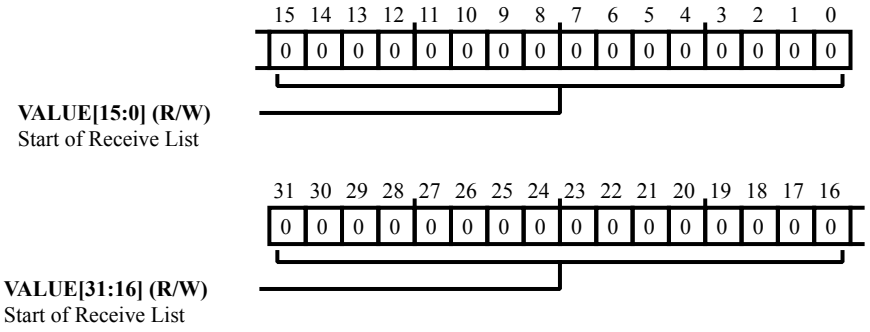

Figure 28-78: EMAC_DMA2_RXDSC_ADDR Register Diagram

Table 28-110: EMAC_DMA2_RXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Receive List. The EMAC_DMA2_RXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Receive Descriptor list. The LSB bits [1:0] for the 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Rx Descriptor Current Register

The EMAC_DMA2_RXDSC_CUR register contains the current DMA receive descriptor.

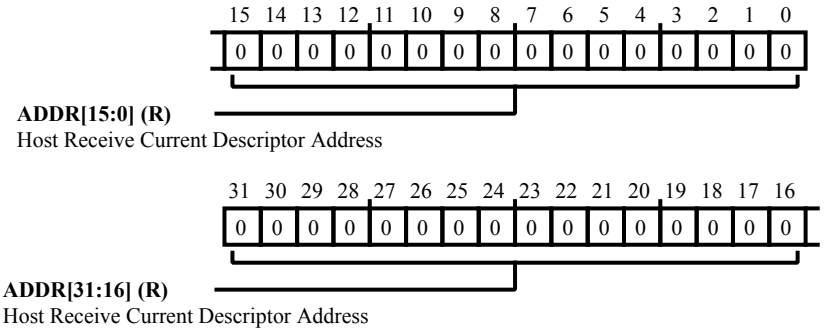

Figure 28-79: EMAC_DMA2_RXDSC_CUR Register Diagram

Table 28-111: EMAC_DMA2_RXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Descriptor Address. The EMAC_DMA2_RXDSC_CUR.ADDR bit field points to the start address of the current Receive Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Interrupt Watch Dog Register

The EMAC_DMA2_RXIWDOG register contains the timeout value for the EMAC DMA receive interrupt watch dog timer.

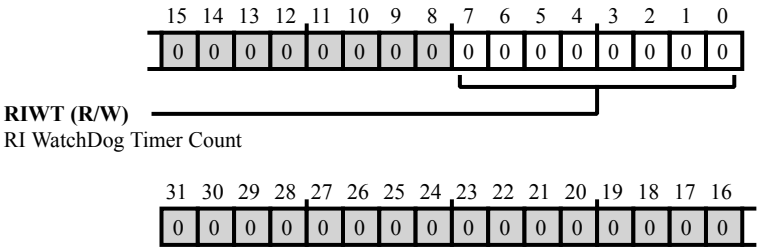

Figure 28-80: EMAC_DMA2_RXIWDOG Register Diagram

Table 28-112: EMAC_DMA2_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI WatchDog Timer Count. The EMAC_DMA2_RXIWDOG.RIWT bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watch-dog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when EMAC_DMA2_STAT.RI bit is set high because of automatic setting of EMAC_DMA2_STAT.RI as per RDES1[31] of any received frame.

DMA Rx Poll Demand register

The EMAC_DMA2_RXPOLL register directs the EMAC to poll the receive descriptor list.

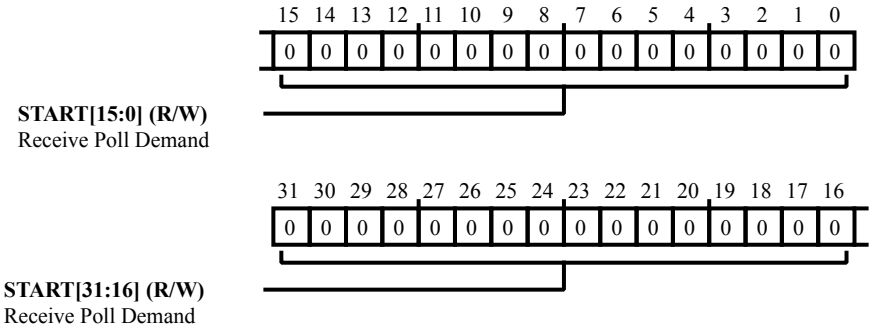

Figure 28-81: EMAC_DMA2_RXPOLL Register Diagram

Table 28-113: EMAC_DMA2_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The EMAC_DMA2_RXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by the EMAC_DMA2_RXDSC_CUR register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the EMAC_DMA2_STAT.RU bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The EMAC_DMA2_STAT register indicates EMAC DMA status.

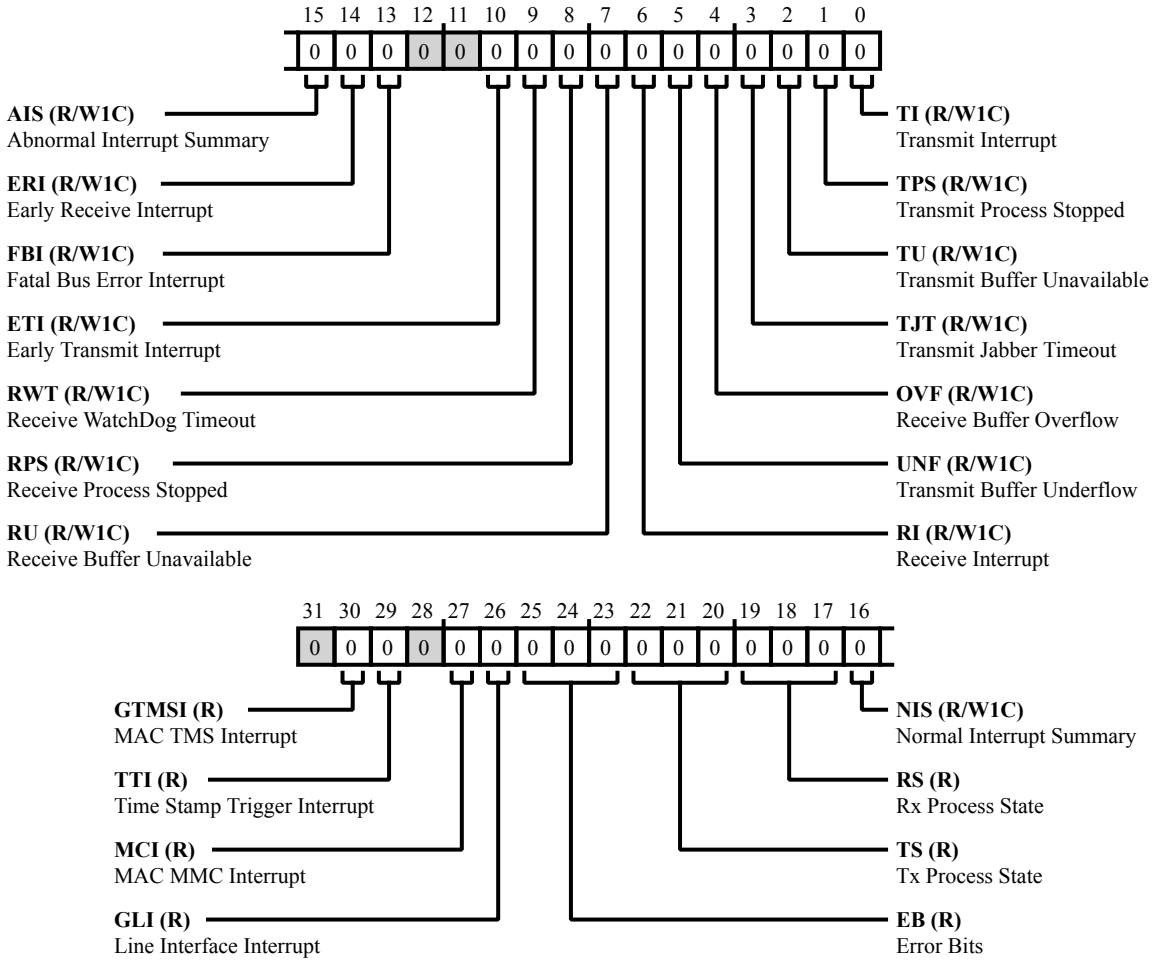

Figure 28-82: EMAC_DMA2_STAT Register Diagram

Table 28-114: EMAC_DMA2_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GTMSI	MAC TMS Interrupt. The EMAC_DMA2_STAT.GTMSI bit indicates an interrupt event in the traffic manager and scheduler logic. To reset this bit, the software must read the corresponding registers (Channel Status Register) to get the exact cause of the interrupt and clear its source.

Table 28-114: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The `EMAC_DMA2_STAT.TTI` bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interrupt. The `EMAC_DMA2_STAT.MCI` bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The `EMAC_DMA2_STAT.GLI` bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The `EMAC_DMA2_STAT.EB` bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the `EMAC_DMA2_STAT.FBI` bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The `EMAC_DMA2_STAT.TS` bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 28-114: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The EMAC_DMA2_STAT.RS bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the EMAC_DMA2_STAT.NIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA2_STAT.TI, EMAC_DMA2_STAT.TU, EMAC_DMA2_STAT.RI, and EMAC_DMA2_STAT.ERI. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes EMAC_DMA2_STAT.NIS to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the EMAC_DMA2_STAT.AIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA2_IEN.TSE, EMAC_DMA2_IEN.TJE, EMAC_DMA2_IEN.OVE, EMAC_DMA2_IEN.UNE, EMAC_DMA2_IEN.RUE, EMAC_DMA2_IEN.RSE, EMAC_DMA2_IEN.RWE, EMAC_DMA2_IEN.ETE, and EMAC_DMA2_IEN.FBE. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes EMAC_DMA2_STAT.AIS to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The EMAC_DMA2_STAT.ERI bit indicates that the DMA had filled the first data buffer of the packet. The EMAC_DMA2_STAT.RI bit automatically clears this bit.	

Table 28-114: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The EMAC_DMA2_STAT.FBI bit indicates that a bus error occurred, as detailed in the EMAC_DMA2_STAT.EB field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The EMAC_DMA2_STAT.ETI bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The EMAC_DMA2_STAT.RWT bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The EMAC_DMA2_STAT.RPS bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The EMAC_DMA2_STAT.RU bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The EMAC_DMA2_STAT.RI bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The EMAC_DMA2_STAT.UNF bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The EMAC_DMA2_STAT.OVF bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The EMAC_DMA2_STAT.TJT bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 28-114: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The EMAC_DMA2_STAT.TU bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the EMAC_DMA2_STAT.TS bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The EMAC_DMA2_STAT.TPS bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The EMAC_DMA2_STAT.TI bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The EMAC_DMA2_TXBUF_CUR register holds the pointer to the current transmit DMA buffer.

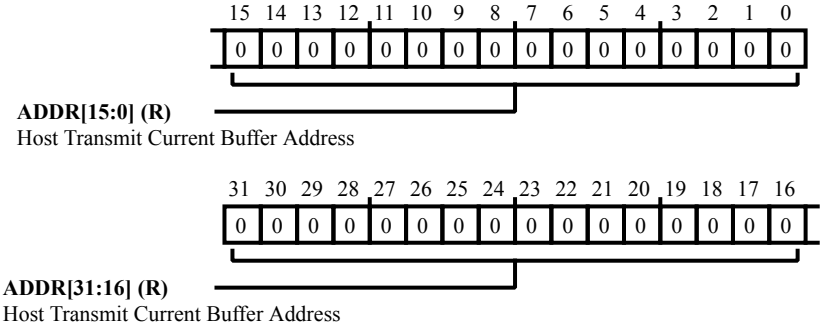

Figure 28-83: EMAC_DMA2_TXBUF_CUR Register Diagram

Table 28-115: EMAC_DMA2_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The EMAC_DMA2_TXBUF_CUR.ADDR bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The EMAC_DMA2_TXDSC_ADDR register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (EMAC_DMA2_OPMODE.ST bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the EMAC_DMA2_OPMODE.ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the EMAC_DMA2_OPMODE.ST bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

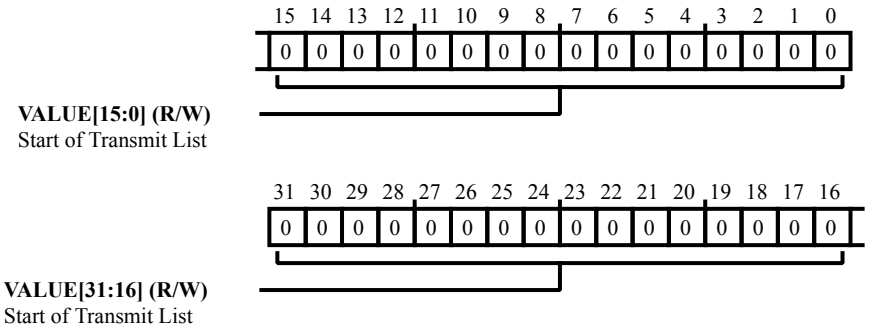

Figure 28-84: EMAC_DMA2_TXDSC_ADDR Register Diagram

Table 28-116: EMAC_DMA2_TXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Transmit List. The EMAC_DMA2_TXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Transmit Descriptor list. The LSB bits [1:0] for 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Tx Descriptor Current Register

The EMAC_DMA2_TXDSC_CUR register contains the current DMA transmit descriptor.

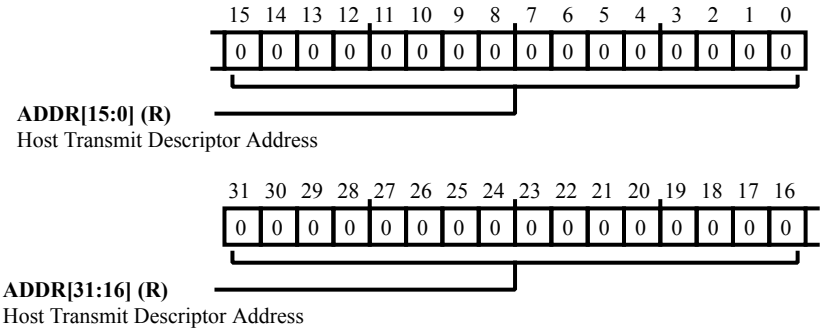

Figure 28-85: EMAC_DMA2_TXDSC_CUR Register Diagram

Table 28-117: EMAC_DMA2_TXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Descriptor Address. The EMAC_DMA2_TXDSC_CUR.ADDR bit field points to the start address of the current Transmit Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Poll Demand Register

The EMAC_DMA2_TXPOLL register directs the EMAC to poll the transmit descriptor list.

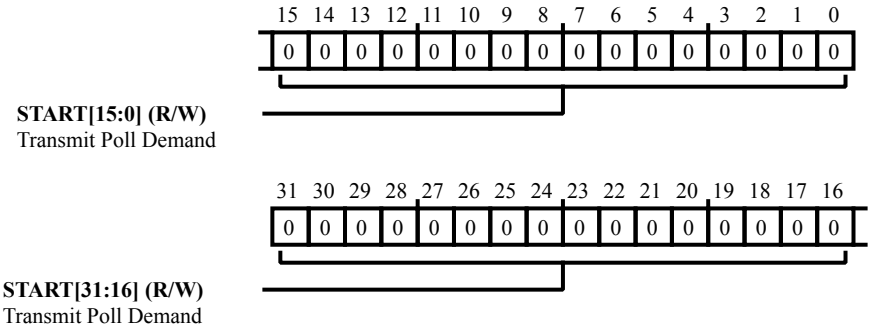

Figure 28-86: EMAC_DMA2_TXPOLL Register Diagram

Table 28-118: EMAC_DMA2_TXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The EMAC_DMA2_TXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by EMAC_DMA2_TXDSC_CUR register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the EMAC_DMA2_STAT.TU bit is asserted. If the descriptor is available, transmission resumes.

FLow Control Register

The EMAC_FLOWCTL register controls EMAC flow control features.

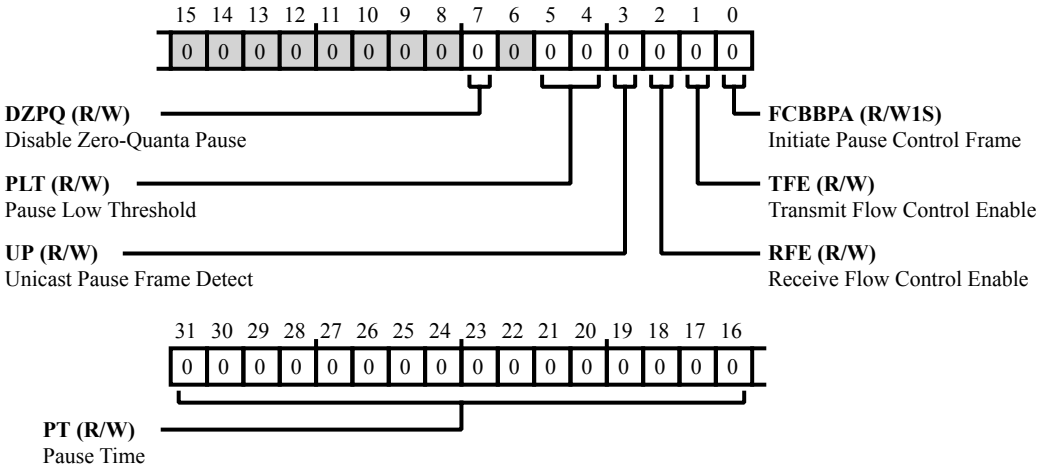

Figure 28-87: EMAC_FLOWCTL Register Diagram

Table 28-119: EMAC_FLOWCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	PT	Pause Time. The EMAC_FLOWCTL.PT bits hold the value to be used in the Pause Time field in the transmit control frame.
7 (R/W)	DZPQ	Disable Zero-Quanta Pause. The EMAC_FLOWCTL.DZPQ bit disables the automatic generation of the Zero-Quanta Pause frames on the de-assertion of the flow-control signal from the FIFO layer
5:4 (R/W)	PLT	Pause Low Threshold. The EMAC_FLOWCTL.PLT bit configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause frame.
3 (R/W)	UP	Unicast Pause Frame Detect. The EMAC_FLOWCTL.UP bit, when set, directs the MAC to detect the Pause frames with the station's unicast address specified in EMAC_ADDR0_HI and EMAC_ADDR0_LO address registers. This bit also directs the MAC to the detect Pause frames with the unique multicast address. When this bit is reset, the MAC will detect only a Pause frame with the unique multicast address specified in the 802.3x standard.

Table 28-119: EMAC_FLOWCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	RFE	Receive Flow Control Enable. The EMAC_FLOWCTL.RFE bit, when set, directs the MAC to decode the received Pause frame and disable its transmitter for a specified (Pause Time) time. When this bit is reset, the decode function of the Pause frame is disabled.
1 (R/W)	TFE	Transmit Flow Control Enable. In Full-Duplex mode, when the EMAC_FLOWCTL.TFE bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In Half-Duplex mode, when this bit is set, the MAC enables the back pressure operation. When this bit is reset, the back pressure feature is disabled.
0 (R/W1S)	FCBBPA	Initiate Pause Control Frame. The EMAC_FLOWCTL.FCBBPA bit initiates a Pause Control frame in Full-Duplex mode and activates the back pressure function in Half-Duplex mode if TFE bit is set. In Full-Duplex mode, this bit should be read as =0 before writing to the EMAC_FLOWCTL register. To initiate a Pause control frame, the Application must set this bit to =1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to =0. The EMAC_FLOWCTL register should not be written to until this bit is cleared. In Half-Duplex mode, when this bit is set (and EMAC_FLOWCTL.TFE is set), the back pressure is asserted by the MAC Core. During back pressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. The EMAC_FLOWCTL.FCBBPA bit is logically OR'ed with the flow control input signal for the back pressure function. When the MAC is configured to Full-Duplex mode, the back pressure function is automatically disabled.

RGMII Control and Status Register

The EMAC_GIGE_CTLSTAT register indicates the status signals received from the PHY through the SGMII, RGMII, or SMII interface.

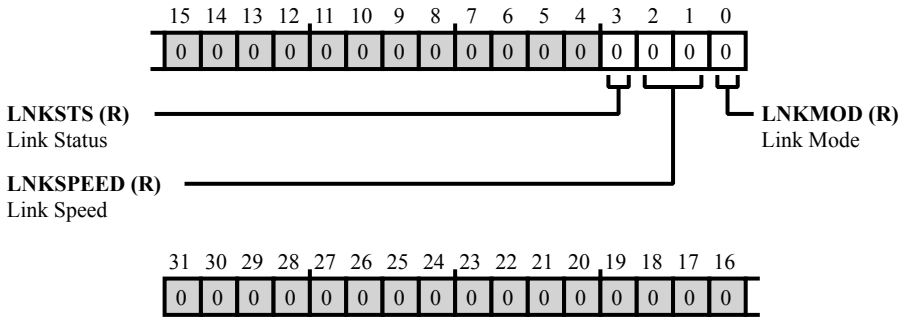

Figure 28-88: EMAC_GIGE_CTLSTAT Register Diagram

Table 28-120: EMAC_GIGE_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/NW)	LNKSTS	Link Status. The EMAC_GIGE_CTLSTAT.LNKSTS bit indicates that the link is up between the local PHY and the remote PHY. When cleared, this bit indicates that the link is down between the local PHY and the remote PHY.
2:1 (R/NW)	LNKSPEED	Link Speed. The EMAC_GIGE_CTLSTAT.LNKSPEED bit indicates the current speed of the link.
0 (R/NW)	LNKMOD	Link Mode. The EMAC_GIGE_CTLSTAT.LNKMOD bit indicates whether the current mode of link operation is half duplex or full duplex.

Hash Table High Register

The EMAC_HASHTBL_HI register contains the upper 32 bits of the hash table.

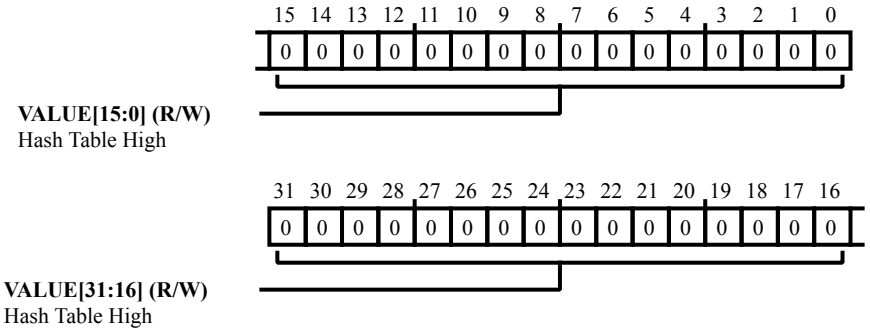

Figure 28-89: EMAC_HASHTBL_HI Register Diagram

Table 28-121: EMAC_HASHTBL_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Hash Table High. The EMAC_HASHTBL_HI.VALUE bits contain the upper 32 bits of Hash table.

Hash Table Low Register

The EMAC_HASHTBL_LO register contains the lower 32 bits of the hash table.

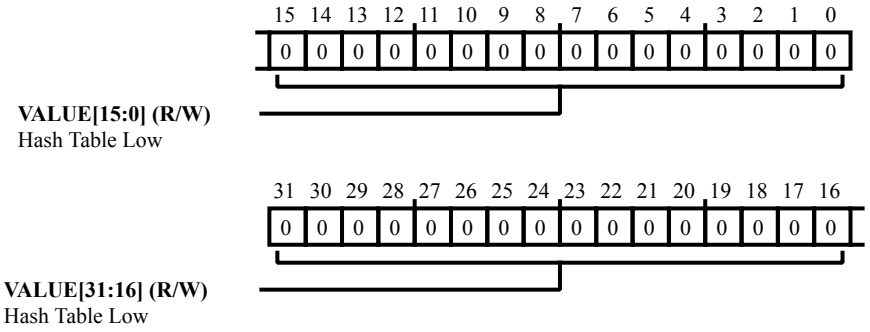

Figure 28-90: EMAC_HASHTBL_LO Register Diagram

Table 28-122: EMAC_HASHTBL_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Hash Table Low. The EMAC_HASHTBL_LO.VALUE bits contain the lower 32 bits of Hash table.

Interrupt Mask Register

The EMAC_IMSK register enables (unmasks) EMAC interrupts.

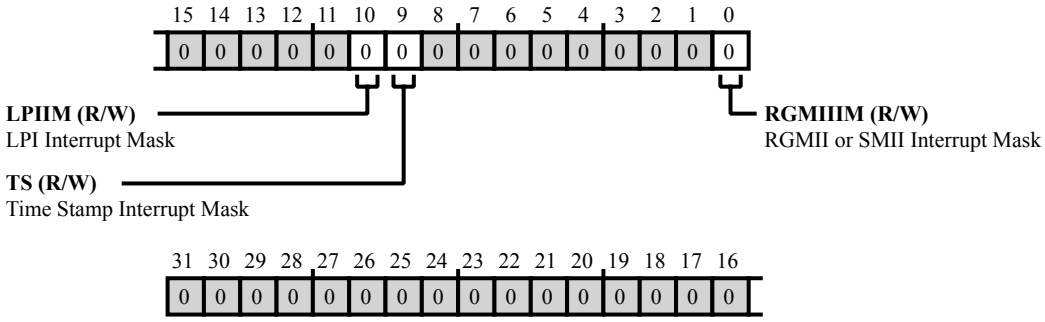

Figure 28-91: EMAC_IMSK Register Diagram

Table 28-123: EMAC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	LPIIM	LPI Interrupt Mask. The EMAC_IMSK.LPIIM bit, When set, disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Interrupt Status Register.
9 (R/W)	TS	Time Stamp Interrupt Mask. The EMAC_IMSK.TS bit, when set, disables the assertion of the interrupt signal, which is generated when the EMAC_ISTAT.TS bit is set.
0 (R/W)	RGMIIIM	RGMII or SMII Interrupt Mask. The EMAC_IMSK.RGMIIIM bit, When set, disables the assertion of the interrupt signal because of the setting of the RGMII Interrupt Status bit in Interrupt Status Register.

MMC IPC Rx Interrupt Mask Register

The EMAC_IPC_RXIMSK register enables (unmasks) MMC IPC receive interrupts.

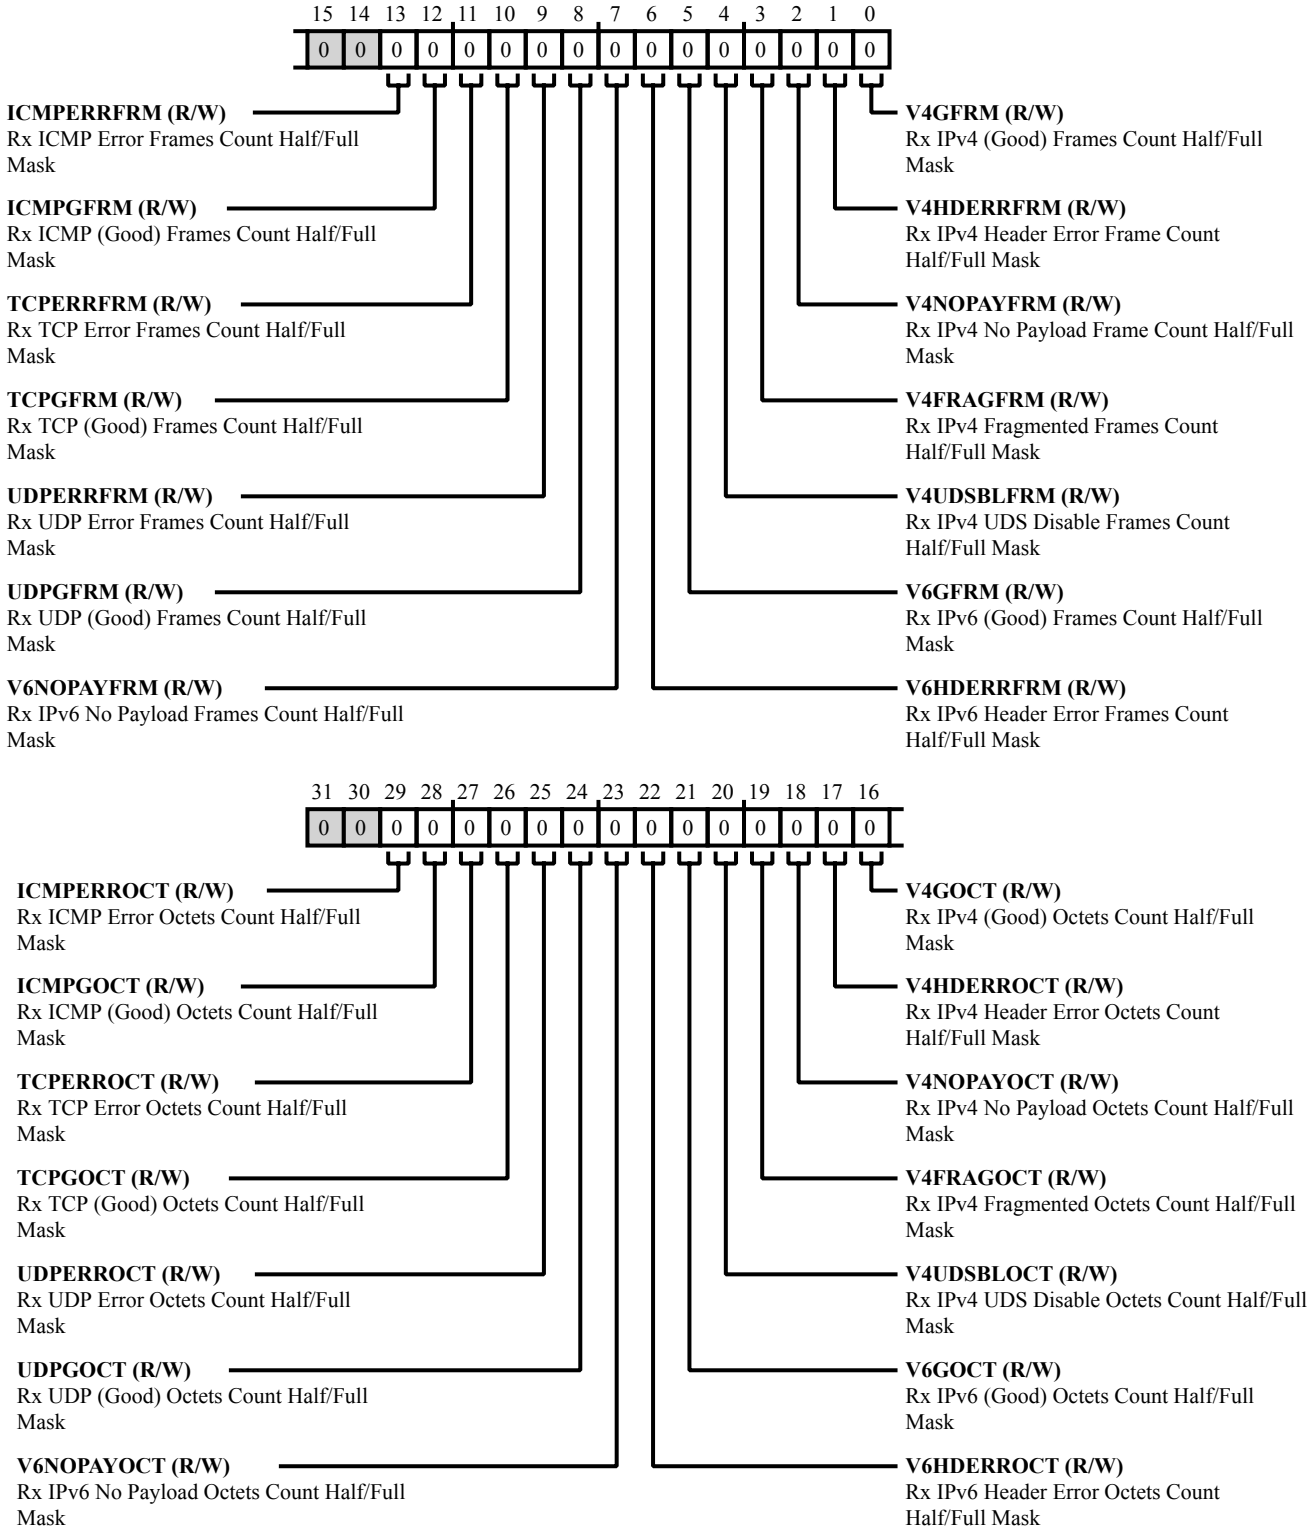

Figure 28-92: EMAC_IPC_RXIMSK Register Diagram

Table 28-124: EMAC_IPC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	ICMPERROCT	Rx ICMP Error Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.ICMPERROCT bit, when set, masks the interrupt when the EMAC_RXICMP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
28 (R/W)	ICMPGOCT	Rx ICMP (Good) Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.ICMPGOCT bit, when set, masks the interrupt when the EMAC_RXICMP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
27 (R/W)	TCPERROCT	Rx TCP Error Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.TCPERROCT bit, when set, masks the interrupt when the EMAC_RXTCP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
26 (R/W)	TCPGOCT	Rx TCP (Good) Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.TCPGOCT bit, when set, masks the interrupt when the EMAC_RXTCP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
25 (R/W)	UDPERROCT	Rx UDP Error Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.UDPERROCT bit, when set, masks the interrupt when the EMAC_RXUDP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
24 (R/W)	UDPGOCT	Rx UDP (Good) Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.UDPGOCT bit, when set, masks the interrupt when the EMAC_RXUDP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
23 (R/W)	V6NOPAYOCT	Rx IPv6 No Payload Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6NOPAYOCT bit, when set, masks the interrupt when the EMAC_RXIPV6_NOPAY_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
22 (R/W)	V6HDERROCT	Rx IPv6 Header Error Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6HDERROCT bit, when set, masks the interrupt when the EMAC_RXIPV6_HDR_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
21 (R/W)	V6GOCT	Rx IPv6 (Good) Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6GOCT bit, when set, masks the interrupt when the EMAC_RXIPV6_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.

Table 28-124: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	V4UDSBLOCT	Rx IPv4 UDS Disable Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4UDSBLOCT bit, when set, masks the interrupt when the EMAC_RXIPV4_UDSBL_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
19 (R/W)	V4FRAGOCT	Rx IPv4 Fragmented Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4FRAGOCT bit, when set, masks the interrupt when the EMAC_RXIPV4_FRAG_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
18 (R/W)	V4NOPAYOCT	Rx IPv4 No Payload Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4NOPAYOCT bit, when set, masks the interrupt when the EMAC_RXIPV4_NOPAY_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
17 (R/W)	V4HDERROCT	Rx IPv4 Header Error Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4HDERROCT bit, when set, masks the interrupt when the EMAC_RXIPV4_HDR_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
16 (R/W)	V4GOCT	Rx IPv4 (Good) Octets Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4GOCT bit, when set, masks the interrupt when the EMAC_RXIPV4_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
13 (R/W)	ICMPERRFRM	Rx ICMP Error Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.ICMPERRFRM bit, when set, masks the interrupt when the EMAC_RXICMP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
12 (R/W)	ICMPGFRM	Rx ICMP (Good) Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.ICMPGFRM bit, when set, masks the interrupt when the EMAC_RXICMP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
11 (R/W)	TCPERRFRM	Rx TCP Error Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.TCPERRFRM bit, when set, masks the interrupt when the EMAC_RXTCP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
10 (R/W)	TCPGFRM	Rx TCP (Good) Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.TCPGFRM bit, when set, masks the interrupt when the EMAC_RXTCP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.

Table 28-124: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	UDPERRFRM	Rx UDP Error Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.UDPERRFRM bit, when set, masks the interrupt when the EMAC_RXUDP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
8 (R/W)	UDPGFRM	Rx UDP (Good) Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.UDPGFRM bit, when set, masks the interrupt when the EMAC_RXUDP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
7 (R/W)	V6NOPAYFRM	Rx IPv6 No Payload Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6NOPAYFRM bit, when set, masks the interrupt when the EMAC_RXIPV6_NOPAY_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
6 (R/W)	V6HDERRFRM	Rx IPv6 Header Error Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6HDERRFRM bit, when set, masks the interrupt when the EMAC_RXIPV6_HDR_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
5 (R/W)	V6GFRM	Rx IPv6 (Good) Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.V6GFRM bit, when set, masks the interrupt when the EMAC_RXIPV6_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
4 (R/W)	V4UDSBLFRM	Rx IPv4 UDS Disable Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4UDSBLFRM bit, when set, masks the interrupt when the EMAC_RXIPV4_UDSBL_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
3 (R/W)	V4FRAGFRM	Rx IPv4 Fragmented Frames Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4FRAGFRM bit, when set, masks the interrupt when the EMAC_RXIPV4_FRAG_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
2 (R/W)	V4NOPAYFRM	Rx IPv4 No Payload Frame Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4NOPAYFRM bit, when set, masks the interrupt when the EMAC_RXIPV4_NOPAY_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
1 (R/W)	V4HDERRFRM	Rx IPv4 Header Error Frame Count Half/Full Mask. The EMAC_IPC_RXIMSK.V4HDERRFRM bit, when set, masks the interrupt when the EMAC_RXIPV4_HDR_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.

Table 28-124: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	V4GFRM	Rx IPv4 (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4GFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

MMC IPC Rx Interrupt Register

The EMAC_IPC_RXINT register indicates status of MMC IPC receive interrupts.

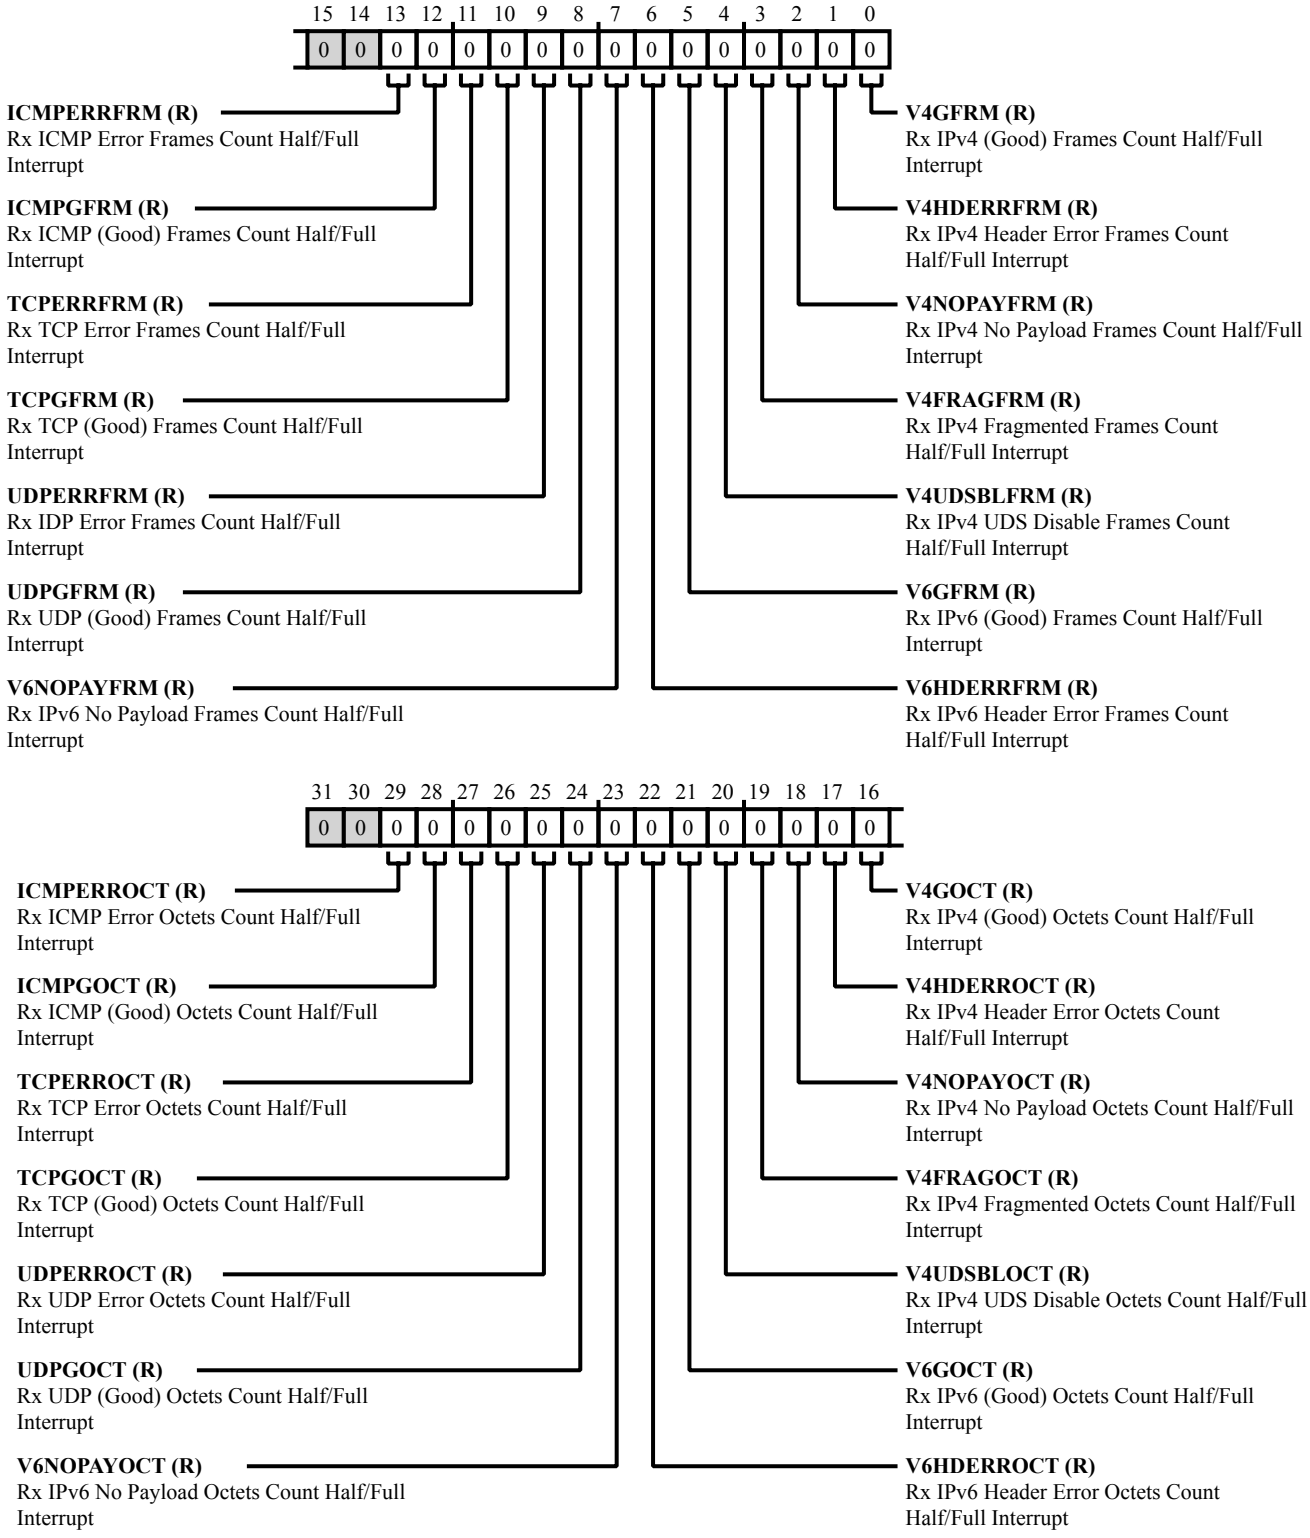

Figure 28-93: EMAC_IPC_RXINT Register Diagram

Table 28-125: EMAC_IPC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/NW)	ICMPERROCT	Rx ICMP Error Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.ICMPERROCT bit is set when the EMAC_RXICMP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
28 (R/NW)	ICMPGOCT	Rx ICMP (Good) Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.ICMPGOCT bit is set when the EMAC_RXICMP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
27 (R/NW)	TCPERROCT	Rx TCP Error Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.TCPERROCT bit is set when the EMAC_RXTCP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
26 (R/NW)	TCPGOCT	Rx TCP (Good) Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.TCPGOCT bit is set when the EMAC_RXTCP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
25 (R/NW)	UDPERROCT	Rx UDP Error Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.UDPERROCT bit is set when the EMAC_RXUDP_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
24 (R/NW)	UDPGOCT	Rx UDP (Good) Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.UDPGOCT bit is set when the EMAC_RXUDP_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
23 (R/NW)	V6NOPAYOCT	Rx IPv6 No Payload Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6NOPAYOCT bit is set when the EMAC_RXIPV6_NOPAY_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
22 (R/NW)	V6HDERROCT	Rx IPv6 Header Error Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6HDERROCT bit is set when the EMAC_RXIPV6_HDR_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
21 (R/NW)	V6GOCT	Rx IPv6 (Good) Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6GOCT bit is set when the EMAC_RXIPV6_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
20 (R/NW)	V4UDSBLOCT	Rx IPv4 UDS Disable Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4UDSBLOCT bit is set when the EMAC_RXIPV4_UDSBL_OCT counter reaches half the maximum value, and also when it reaches the maximum value.

Table 28-125: EMAC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/NW)	V4FRAGOCT	Rx IPv4 Fragmented Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4FRAGOCT bit is set when the EMAC_RXIPV4_FRAG_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
18 (R/NW)	V4NOPAYOCT	Rx IPv4 No Payload Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4NOPAYOCT bit set when the EMAC_RXIPV4_NOPAY_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
17 (R/NW)	V4HDERROCT	Rx IPv4 Header Error Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4HDERROCT bit is set when the EMAC_RXIPV4_HDR_ERR_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
16 (R/NW)	V4GOCT	Rx IPv4 (Good) Octets Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4GOCT bit is set when the EMAC_RXIPV4_GD_OCT counter reaches half the maximum value, and also when it reaches the maximum value.
13 (R/NW)	ICMPERRFRM	Rx ICMP Error Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.ICMPERRFRM bit is set when the EMAC_RXICMP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
12 (R/NW)	ICMPGFRM	Rx ICMP (Good) Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.ICMPGFRM bit is set when the EMAC_RXICMP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
11 (R/NW)	TCPERRFRM	Rx TCP Error Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.TCPERRFRM bit is set when the EMAC_RXTCP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
10 (R/NW)	TCPGFRM	Rx TCP (Good) Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.TCPGFRM bit is set when the EMAC_RXTCP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
9 (R/NW)	UDPERRFRM	Rx IDP Error Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.UDPERRFRM bit is set when the EMAC_RXUDP_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
8 (R/NW)	UDPGFRM	Rx UDP (Good) Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.UDPGFRM bit is set when the EMAC_RXUDP_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.

Table 28-125: EMAC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	V6NOPAYFRM	Rx IPv6 No Payload Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6NOPAYFRM bit is set when the EMAC_RXIPV6_NOPAY_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
6 (R/NW)	V6HDERRFRM	Rx IPv6 Header Error Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6HDERRFRM bit is set when the EMAC_RXIPV6_HDR_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
5 (R/NW)	V6GFRM	Rx IPv6 (Good) Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V6GFRM bit is set when the EMAC_RXIPV6_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
4 (R/NW)	V4UDSBLFRM	Rx IPv4 UDS Disable Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4UDSBLFRM bit is set when the EMAC_RXIPV4_UDSBL_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
3 (R/NW)	V4FRAGFRM	Rx IPv4 Fragmented Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4FRAGFRM bit is set when the EMAC_RXIPV4_FRAG_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
2 (R/NW)	V4NOPAYFRM	Rx IPv4 No Payload Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4NOPAYFRM bit is set when the EMAC_RXIPV4_NOPAY_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
1 (R/NW)	V4HDERRFRM	Rx IPv4 Header Error Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4HDERRFRM bit is set when the EMAC_RXIPV4_HDR_ERR_FRM counter reaches half the maximum value, and also when it reaches the maximum value.
0 (R/NW)	V4GFRM	Rx IPv4 (Good) Frames Count Half/Full Interrupt. The EMAC_IPC_RXINT.V4GFRM bit is set when the EMAC_RXIPV4_GD_FRM counter reaches half the maximum value, and also when it reaches the maximum value.

Interrupt Status Register

The EMAC_ISTAT register indicates EMAC interrupt status.

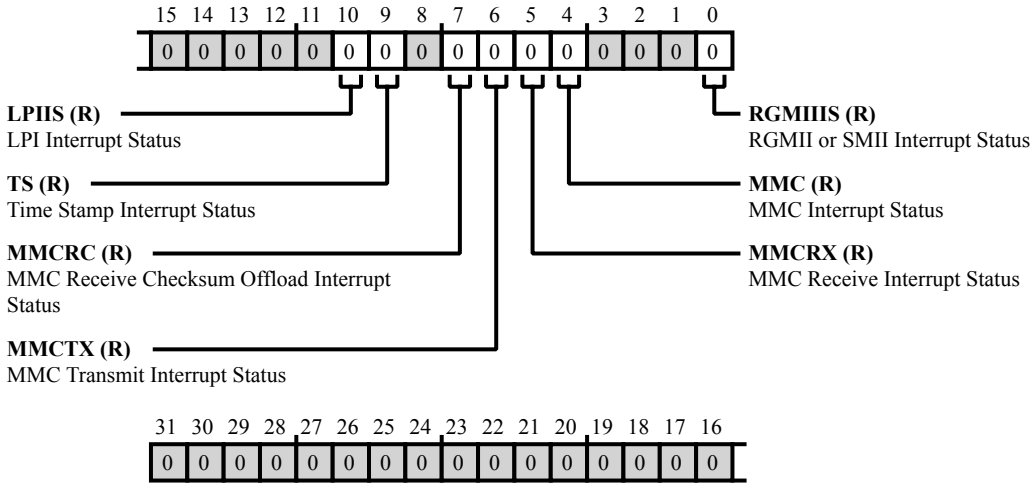

Figure 28-94: EMAC_ISTAT Register Diagram

Table 28-126: EMAC_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/NW)	LPIIS	LPI Interrupt Status. The EMAC_ISTAT.LPIIS bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver.
9 (R/NW)	TS	Time Stamp Interrupt Status. The EMAC_ISTAT.TS bit is set when:
7 (R/NW)	MMCRC	MMC Receive Checksum Offload Interrupt Status. The EMAC_ISTAT.MMCRC bit is set high whenever an interrupt is generated in the EMAC_IPC_RXINT. This bit is cleared when all the bits in this interrupt register are cleared.
6 (R/NW)	MMCTX	MMC Transmit Interrupt Status. The EMAC_ISTAT.MMCTX bit is set high whenever an interrupt is generated in the EMAC_MMC_TXINT register. This bit is cleared when all the bits in this interrupt register are cleared.
5 (R/NW)	MMCRX	MMC Receive Interrupt Status. The EMAC_ISTAT.MMCRX bit is set high whenever an interrupt is generated in the EMAC_MMC_RXINT register. This bit is cleared when all the bits in this interrupt register are cleared.

Table 28-126: EMAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	MMC	MMC Interrupt Status. The `EMAC_ISTAT.MMC` bit is set high whenever any of `EMAC_ISTAT` bits [7:5] is set (=1) and is cleared only when all of these bits are cleared (=0).
0 (R/NW)	RGMIIIS	RGMII or SMII Interrupt Status. The `EMAC_ISTAT.RGMIIIS` bit is set because of any change in value of the Link Status of RGMII interface.

Layer3 and Layer4 Control Register

The EMAC_L3L4_CTL register controls the operations of the filter 0 of Layer 3 and Layer 4. This register is reserved if the Layer 3 and Layer 4 Filtering feature is not selected during core configuration.

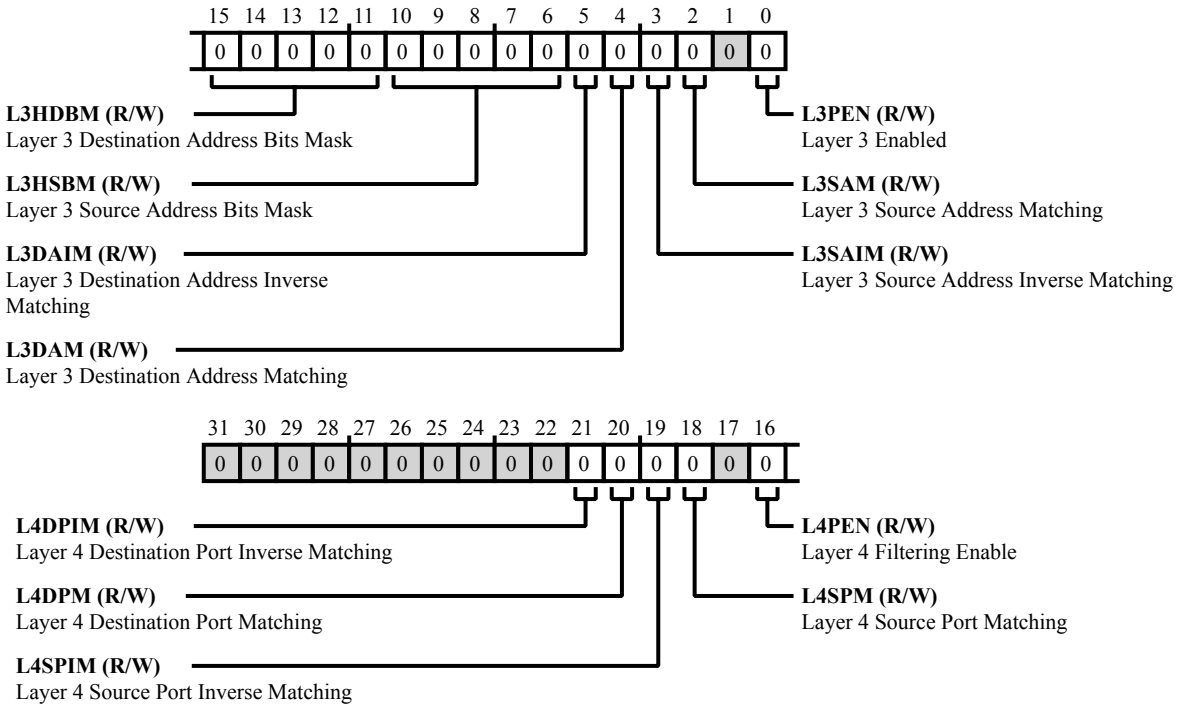

Figure 28-95: EMAC_L3L4_CTL Register Diagram

Table 28-127: EMAC_L3L4_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	L4DPIM	Layer 4 Destination Port Inverse Matching. The EMAC_L3L4_CTL.L4DPIM bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching.
20 (R/W)	L4DPM	Layer 4 Destination Port Matching. The EMAC_L3L4_CTL.L4DPM bit indicates that the Layer 4 Destination Port number field is enabled for matching.
19 (R/W)	L4SPIM	Layer 4 Source Port Inverse Matching. The EMAC_L3L4_CTL.L4SPIM bit indicates that the Layer 4 Source Port number field is enabled for inverse matching.
18 (R/W)	L4SPM	Layer 4 Source Port Matching. The EMAC_L3L4_CTL.L4SPM bit indicates that the Layer 4 Source Port number field is enabled for matching.

Table 28-127: EMAC_L3L4_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	L4PEN	Layer 4 Filtering Enable. The `EMAC_L3L4_CTL.L4PEN` bit indicates that source and destination port number fields for UDP (TCP) frames are used for matching.
15:11 (R/W)	L3HDBM	Layer 3 Destination Address Bits Mask. The `EMAC_L3L4_CTL.L3HDBM` bits are the number of lower bits of IP destination Address that are masked for matching in the IPv4 frames.
10:6 (R/W)	L3HSBM	Layer 3 Source Address Bits Mask. The `EMAC_L3L4_CTL.L3HSBM` bit are the number of lower bits of IP source address that are masked for matching in the IPv4 frames.
5 (R/W)	L3DAIM	Layer 3 Destination Address Inverse Matching. The `EMAC_L3L4_CTL.L3DAIM` bit indicates that the Layer 3 IP destination address field is enabled for inverse matching.
4 (R/W)	L3DAM	Layer 3 Destination Address Matching. The `EMAC_L3L4_CTL.L3DAM` bit indicates that Layer 3 IP destination address field is enabled for matching.
3 (R/W)	L3SAIM	Layer 3 Source Address Inverse Matching. The `EMAC_L3L4_CTL.L3SAIM` bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching.
2 (R/W)	L3SAM	Layer 3 Source Address Matching. The `EMAC_L3L4_CTL.L3SAM` bit indicates that the Layer 3 IP Source Address field is enabled for matching.
0 (R/W)	L3PEN	Layer 3 Enabled. The `EMAC_L3L4_CTL.L3PEN` bit indicates that layer 3 source or destination address matching is enabled for IPV6 (IPV4) frames.

Layer 3 Address0 Register

The EMAC_L3_ADDR0 register tells For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field.

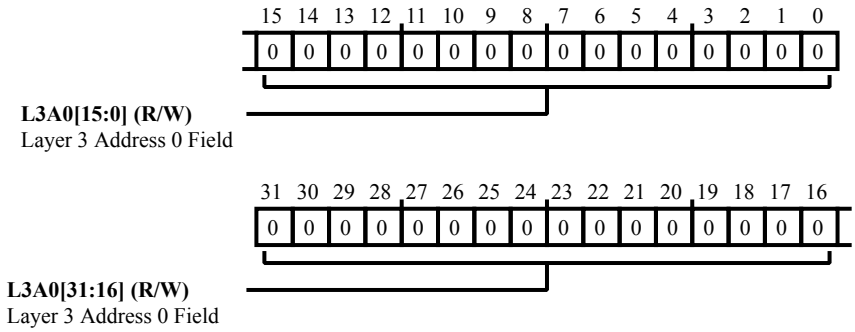

Figure 28-96: EMAC_L3_ADDR0 Register Diagram

Table 28-128: EMAC_L3_ADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A0	Layer 3 Address 0 Field. When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 3 Address1 Register

The EMAC_L3_ADDR1 register tells For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Source Address field.

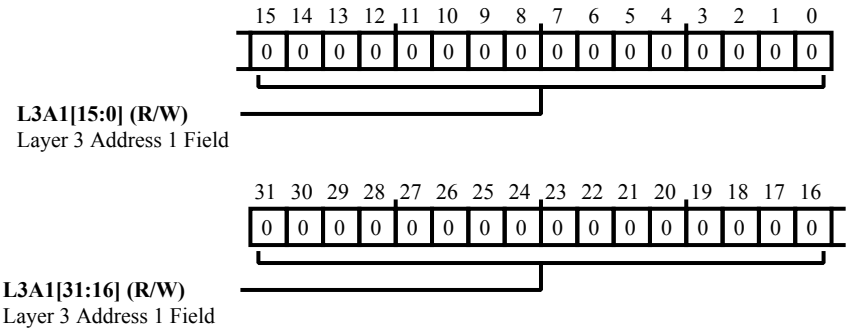

Figure 28-97: EMAC_L3_ADDR1 Register Diagram

Table 28-129: EMAC_L3_ADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A1	Layer 3 Address 1 Field. When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 3 Address2 Register

The EMAC_L3_ADDR2 register tells For IPv4 frames, the Layer 3 Address 2 Register 0 contains the 32-bit IP Source Address field.

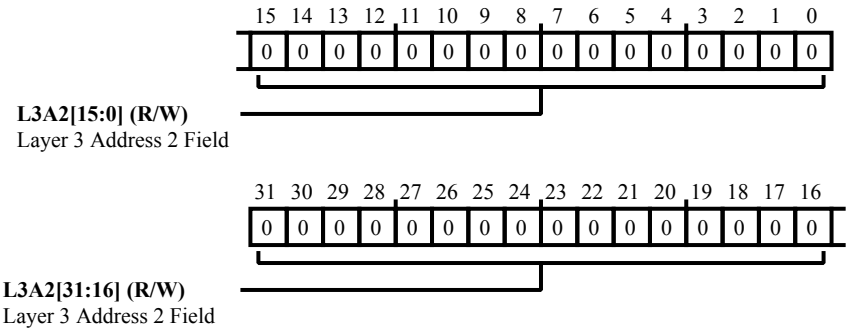

Figure 28-98: EMAC_L3_ADDR2 Register Diagram

Table 28-130: EMAC_L3_ADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A2	Layer 3 Address 2 Field. When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 3 Address3 Register

The EMAC_L3_ADDR3 register tells For IPv4 frames, the Layer 3 Address 3 Register 0 contains the 32-bit IP Source Address field.

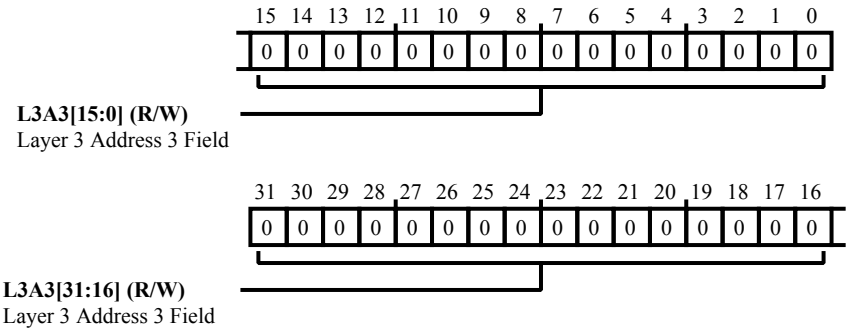

Figure 28-99: EMAC_L3_ADDR3 Register Diagram

Table 28-131: EMAC_L3_ADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A3	Layer 3 Address 3 Field. When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 4 Address Register

The EMAC_L4_ADDR register contains Layer 4 Port number field. It contains the 16-bit Source and Destination Port numbers of the TCP or UDP frame.

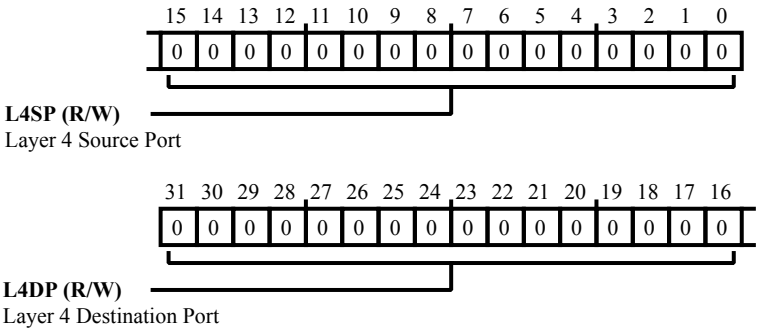

Figure 28-100: EMAC_L4_ADDR Register Diagram

Table 28-132: EMAC_L4_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	L4DP	Layer 4 Destination Port. When EMAC_L3L4_CTL.L4PEN is reset and EMAC_L3L4_CTL.L4DPM is set, the EMAC_L4_ADDR.L4DP bit field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 frames. When EMAC_L3L4_CTL.L4PEN and EMAC_L3L4_CTL.L4DPM are set, the EMAC_L4_ADDR.L4DP bit field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 frames.
15:0 (R/W)	L4SP	Layer 4 Source Port. When EMAC_L3L4_CTL.L4PEN is reset and EMAC_L3L4_CTL.L4DPM is set, the EMAC_L4_ADDR.L4SP bit field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 frames. When EMAC_L3L4_CTL.L4PEN and EMAC_L3L4_CTL.L4DPM are set, the EMAC_L4_ADDR.L4SP bit field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 frames.

Low Power Idle Control and Status Register

The EMAC_LPI_CTLSTAT register controls the behavior of EMAC0 for LPI mode and reports status.

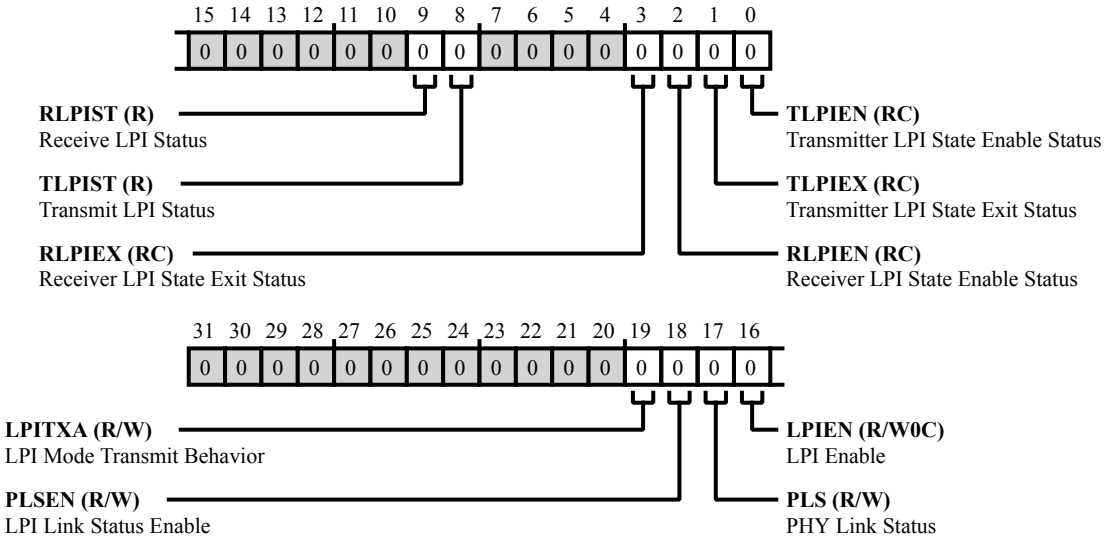

Figure 28-101: EMAC_LPI_CTLSTAT Register Diagram

Table 28-133: EMAC_LPI_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	LPITXA	LPI Mode Transmit Behavior. The EMAC_LPI_CTLSTAT.LPITXA bit controls the behavior of the MAC when it is entering or exiting of the LPI mode on the transmit side.
18 (R/W)	PLSEN	LPI Link Status Enable. The EMAC_LPI_CTLSTAT.PLSEN bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS timer.
17 (R/W)	PLS	PHY Link Status. The EMAC_LPI_CTLSTAT.PLS bit indicates the link status of the PHY
16 (R/W0C)	LPIEN	LPI Enable. The EMAC_LPI_CTLSTAT.LPIEN bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission.
9 (R/NW)	RLPIST	Receive LPI Status. The EMAC_LPI_CTLSTAT.RLPIST bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface.

Table 28-133: EMAC_LPI_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (R/NW)	TLPIST	Transmit LPI Status. The `EMAC_LPI_CTLSTAT.TLPIST` bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface.
3 (RC/NW)	RLPIEX	Receiver LPI State Exit Status. The `EMAC_LPI_CTLSTAT.RLPIEX` bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register.
2 (RC/NW)	RLPIEN	Receiver LPI State Enable Status. The `EMAC_LPI_CTLSTAT.RLPIEN` bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register.
1 (RC/NW)	TLPIEX	Transmitter LPI State Exit Status. The `EMAC_LPI_CTLSTAT.TLPIEX` bit indicates that the MAC transmitter has exited the LPI state after the program has cleared the `EMAC_LPI_CTLSTAT.LPIEN` bit and the LPI TW Timer has expired. This bit is cleared by a read into this register.
0 (RC/NW)	TLPIEN	Transmitter LPI State Enable Status. The `EMAC_LPI_CTLSTAT.TLPIEN` bit indicates that the MAC Transmitter has entered the LPI state due to the setting of the `EMAC_LPI_CTLSTAT.LPIEN` bit. This bit is cleared by a read into this register.

Low Power Idle Timeout Register

The EMAC_LPI_TMRSCTL controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

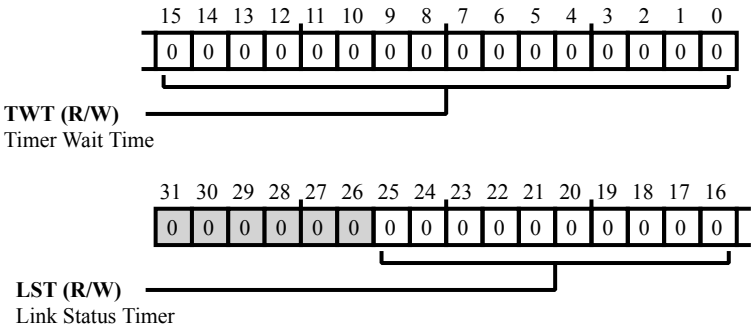

Figure 28-102: EMAC_LPI_TMRSCTL Register Diagram

Table 28-134: EMAC_LPI_TMRSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	LST	Link Status Timer. The EMAC_LPI_TMRSCTL.LST bit, specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY.
15:0 (R/W)	TWT	Timer Wait Time. The EMAC_LPI_TMRSCTL.TWT bit, specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission.

MAC Configuration Register

The EMAC_MACCFG register configures MAC features.

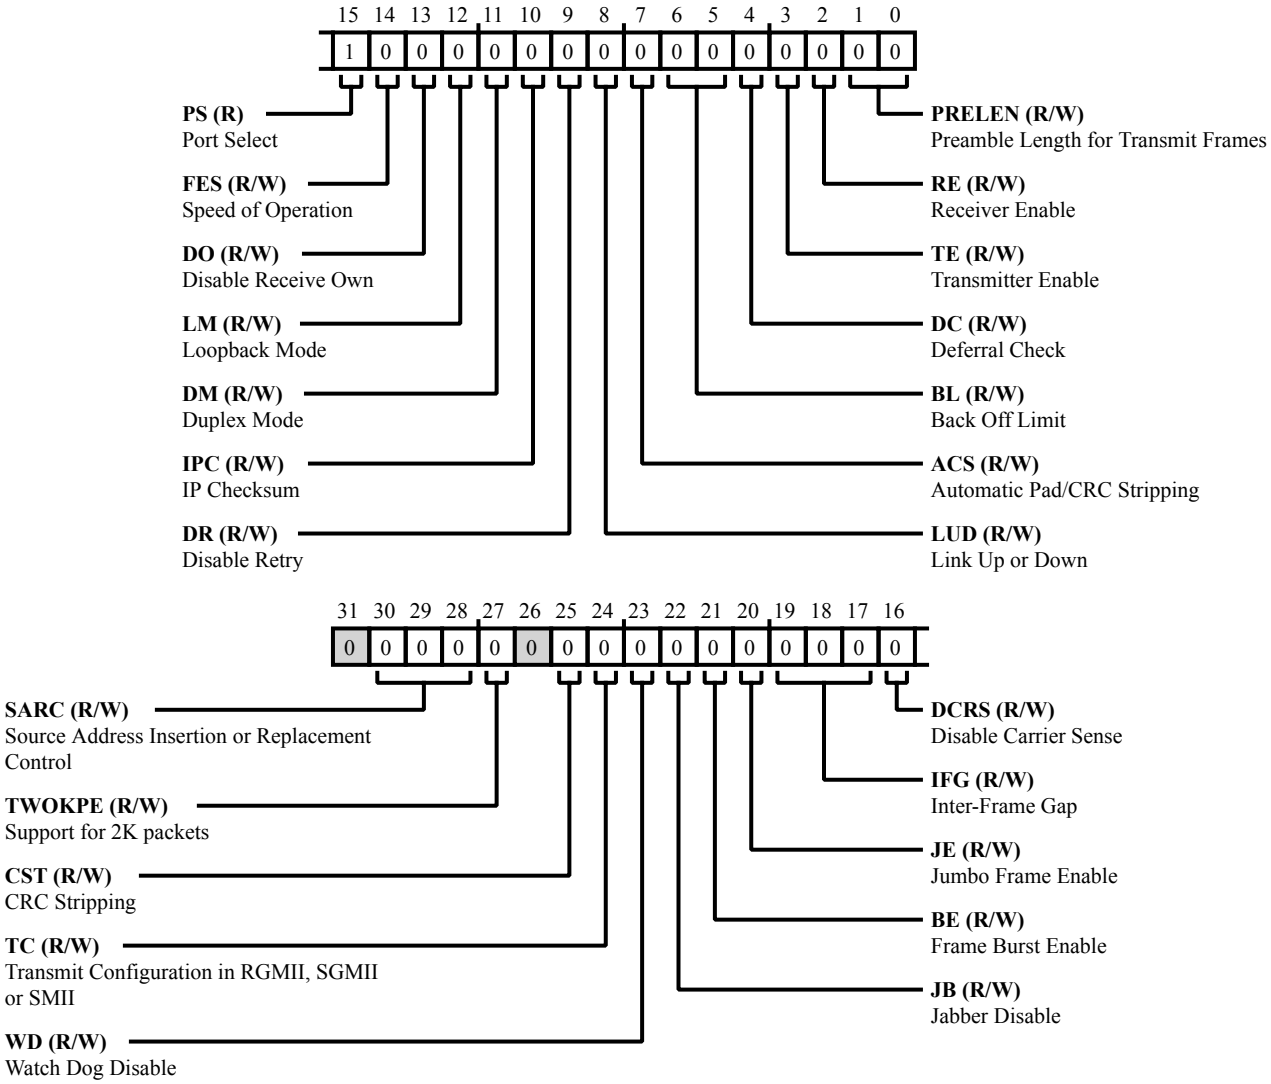

Figure 28-103: EMAC_MACCFG Register Diagram

Table 28-135: EMAC_MACCFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	SARC	Source Address Insertion or Replacement Control. The EMAC_MACCFG.SARC bit, controls the source address insertion or replacement for all transmitted frames.

Table 28-135: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	TWOKPE	Support for 2K packets. The EMAC_MACCFG.TWOKPE bit, IEEE 802.3as Support for 2K Packets When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets.	
25 (R/W)	CST	CRC Stripping. The EMAC_MACCFG.CST bit, when set, directs the MAC to strip the last 4 bytes (FCS) of all frames of Ether type (Type field of frame greater than 0x0600) and drop these bytes before forwarding the frame to the application.	
24 (R/W)	TC	Transmit Configuration in RGMII, SGMII or SMII. The EMAC_MACCFG.TC bit, enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII port.	
23 (R/W)	WD	Watch Dog Disable. The EMAC_MACCFG.WD bit, when set, disables the watchdog timer on the receiver, and can receive frames of up to 16,384 bytes. When this bit is reset, the MAC allows no more than 2,048 bytes (10,240 if EMAC_MACCFG.JE is set high) of the frame being received and cuts off any bytes received after that.	
22 (R/W)	JB	Jabber Disable. The EMAC_MACCFG.JB bit, when set, disables the jabber timer on the transmitter, and can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if EMAC_MACCFG.JE is set high) during transmission.	
21 (R/W)	BE	Frame Burst Enable. The EMAC_MACCFG.BE bit, allows frame bursting during transmission in the GMII half-duplex mode.	
20 (R/W)	JE	Jumbo Frame Enable. The EMAC_MACCFG.JE bit, when set, directs the MAC to allow Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames).	
19:17 (R/W)	IFG	Inter-Frame Gap. The EMAC_MACCFG.IFG bits control the minimum inter-frame gap between frames during transmission. Note that in Half-Duplex mode, the minimum gap can be configured for 64 bit times (EMAC_MACCFG.IFG =100) only. Lower values are not considered.	
		0	96 bit times
		1	88 bit times
		2	80 bit times
		3	72 bit times
		4	64 bit times

Table 28-135: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	56 bit times
		6	48 bit times
		7	40 bit times
16 (R/W)	DCRS	Disable Carrier Sense. The EMAC_MACCFG.DCRS bit, when set, makes the MAC transmitter ignore the CRS signal during frame transmission in Half-Duplex mode. This request results in no errors generated due to Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors due to Carrier Sense and will even abort the transmissions.	
15 (R/NW)	PS	Port Select. The EMAC_MACCFG.PS bit selects between GMII and MII as: 0=GMII (1000 Mbps) and 1=MII (10/100 Mbps). This bit is read-only with the appropriate value in the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, and R_W in the default 10/100/1000 Mbps configuration.	
14 (R/W)	FES	Speed of Operation. The EMAC_MACCFG.FES bit indicates the Ethernet speed as 10 Mbps (bit =0) or 100 Mbps (bit =1).	
13 (R/W)	DO	Disable Receive Own. The EMAC_MACCFG.DO bit, when set, disables MAC reception of frames when MAC is transmitting in Half-Duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in Full-Duplex mode.	
12 (R/W)	LM	Loopback Mode. The EMAC_MACCFG.LM bit, when set, directs the MAC to operate in internal loop back mode. (The media independent interface pins are not driven or sampled.)	
11 (R/W)	DM	Duplex Mode. The EMAC_MACCFG.DM bit, when set, directs the MAC to operate in a Full-Duplex mode where it can transmit and receive simultaneously.	
10 (R/W)	IPC	IP Checksum. The EMAC_MACCFG.IPC bit, when set, directs the MAC to calculate the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 25-26 or 29-30 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The EMAC_MACCFG.IPC bit, when set, enables IPv4 checksum checking for received frame payloads' TCP/UDP/ICMP headers. When this bit is reset, the Checksum Offload Engine function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared.	

Table 28-135: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DR	Disable Retry. The EMAC_MACCFG.DR bit, when set, directs the MAC to attempt only 1 transmission. When a collision occurs on the media independent interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When the EMAC_MACCFG.DR bit is reset, the MAC attempts retries based on the settings of BL. This bit is applicable only to Half-Duplex mode.	
		0	Retry enabled
		1	Retry disabled
8 (R/W)	LUD	Link Up or Down. The EMAC_MACCFG.LUD bit, indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface: 0 means Link down and 1 means Link Up	
7 (R/W)	ACS	Automatic Pad/CRC Stripping. The EMAC_MACCFG.ACS bit, when set, directs the MAC to strip the Pad/FCS field on incoming frames only if the length fields value is less than or equal to 1,500 bytes. All received frames with length field greater than or equal to 1,501 bytes are passed to the application without stripping the Pad/FCS field. When the EMAC_MACCFG.ACS bit is reset, the MAC passes all incoming frames to the Host unmodified.	
6:5 (R/W)	BL	Back Off Limit. The EMAC_MACCFG.BL bit selects the back-off limit, determining the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only to Half-Duplex mode.The random integer r takes the value in the range: 0 less-than-equal-to r less-than 2^k Where k is the minimum of n (number of transmission attempts) or a limit value.	
		0	k = min (n, 10)
		1	k = min (n, 8)
		2	k = min (n, 4)
		3	k = min (n, 1)

Table 28-135: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	DC	Deferral Check. The EMAC_MACCFG.DC bit, when set, enables the deferral check function in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status when the transmit state machine is deferred for more than 24,288 bit times in 10/100-Mbps mode. If the Jumbo frame mode is enabled in 10/100-Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active CRS (carrier sense) signal. Defer time is not cumulative. If the transmitter defers for 10,000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts. When the EMAC_MACCFG.DC bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in Half-Duplex mode.
3 (R/W)	TE	Transmitter Enable. The EMAC_MACCFG.TE bit, when set, enables the transmit state machine of the MAC for transmission. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and will not transmit any further frames.
2 (R/W)	RE	Receiver Enable. The EMAC_MACCFG.RE bit, when set, enables the receiver state machine of the MAC for receiving frames. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames.
1:0 (R/W)	PRELEN	Preamble Length for Transmit Frames. The EMAC_MACCFG.PRELEN bit, control the number of preamble bytes that are added to the beginning of every Transmit frame.

MAC Rx Frame Filter Register

The EMAC_MACFRMFILT register controls receive frame filter features.

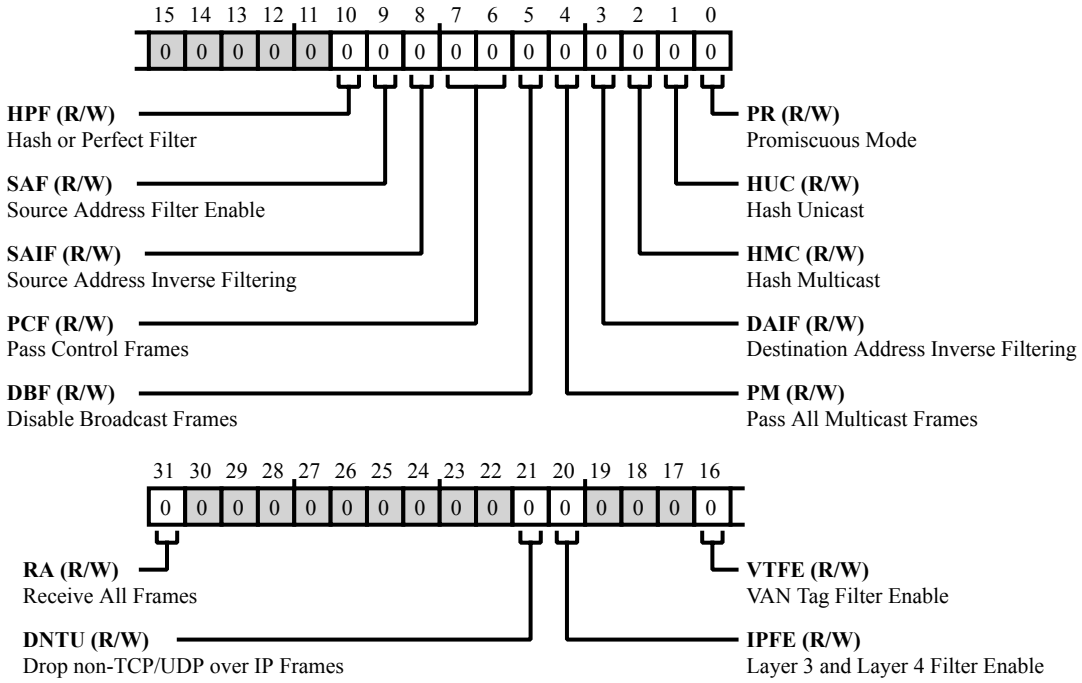

Figure 28-104: EMAC_MACFRMFILT Register Diagram

Table 28-136: EMAC_MACFRMFILT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	RA	Receive All Frames. The EMAC_MACFRMFILT.RA bit, when set, directs the MAC Receiver module to pass to the Application all frames received irrespective of whether they pass the address filter. The result of the DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes to the Application only those frames that pass the DA address filter.
21 (R/W)	DNTU	Drop non-TCP/UDP over IP Frames. The EMAC_MACFRMFILT.DNTU bit, enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames.
20 (R/W)	IPFE	Layer 3 and Layer 4 Filter Enable. The EMAC_MACFRMFILT.IPFE bit, enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.

Table 28-136: EMAC_MACFRMFILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	VTFE	VAN Tag Filter Enable. The EMAC_MACFRMFILT.VTFE bit, enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison.	
10 (R/W)	HPF	Hash or Perfect Filter. The EMAC_MACFRMFILT.HPF bit. when set, configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by EMAC_MACFRMFILT.HMC or EMAC_MACFRMFILT.HUC bits. When EMAC_MACFRMFILT.HPF is low and either the EMAC_MACFRMFILT.HUC bit or EMAC_MACFRMFILT.HMC bit is set, the frame is passed only if it matches the Hash filter.	
9 (R/W)	SAF	Source Address Filter Enable. When the EMAC_MACFRMFILT.SAF bit, is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the frame.	
8 (R/W)	SAIF	Source Address Inverse Filtering. WHen the EMAC_MACFRMFILT.SAIF bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter.	
7:6 (R/W)	PCF	Pass Control Frames. The EMAC_MACFRMFILT.PCF bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on the value of the EMAC_FLOWCTL.RFE bit.	
		0	Pass no control frames All control frames are filtered from reaching the application.
		1	Pass no PAUSE frames All control frames are passed to the application (even if the fail the address filter), except for PAUSE frames.
		2	Pass all control frames All control frames are passed to the application (even if the fail the address filter).
		3	Pass address filtered control frames All control frames that pass the address filter are passed to the application.
5 (R/W)	DBF	Disable Broadcast Frames. The EMAC_MACFRMFILT.DBF bit, when set, directs the AFM module to filter all incoming broadcast frames. When this bit is reset, the AFM module passes all received broadcast frames.	
		0	AFM module passes all received broadcast frames
		1	AFM module filters all incoming broadcast frames

Table 28-136: EMAC_MACFRMFILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	PM	Pass All Multicast Frames. The EMAC_MACFRMFILT.PM bit, when set, indicates that all received frames with a multicast destination address (first bit in the destination address field is =1) are passed. When this bit is reset, filtering of multicast frame depends on EMAC_MACFRMFILT.HMC bit.
3 (R/W)	DAIF	Destination Address Inverse Filtering. The EMAC_MACFRMFILT.DAIF bit, when set, directs the Address Check block to operate in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When this bit is reset, normal filtering of frames is performed.
2 (R/W)	HMC	Hash Multicast. The EMAC_MACFRMFILT.HMC bit, when set, directs the EMAC to perform destination address filtering of received multicast frames according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for multicast frames, that is, the MAC compares the DA field with the values programmed in the EMAC_ADDR0_HI and EMAC_ADDR0_LO address registers.
1 (R/W)	HUC	Hash Unicast. The EMAC_MACFRMFILT.HUC bit, when set, directs the EMAC to perform destination address filtering of unicast frames according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in the EMAC_ADDR0_HI and EMAC_ADDR0_LO address registers.
0 (R/W)	PR	Promiscuous Mode. The EMAC_MACFRMFILT.PR bit, when set, directs the Address Filter module to pass all incoming frames regardless of its destination or source address. The DA Filter Fails status bits of the Receive Status Word is always cleared when EMAC_MACFRMFILT.PR is set.

AV MAC Control Register

The EMAC_MAC_AVCTL register controls the AV traffic by identifying the AV traffic and queuing it to appropriate channel. This register is present only when you select the AV feature during core configuration.

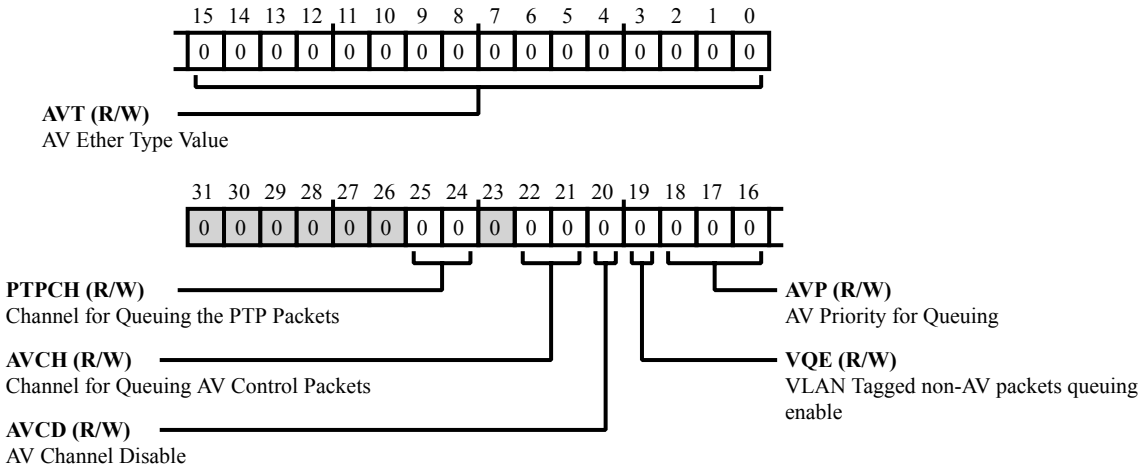

Figure 28-105: EMAC_MAC_AVCTL Register Diagram

Table 28-137: EMAC_MAC_AVCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	PTPCH	Channel for Queuing the PTP Packets. The EMAC_MAC_AVCTL.PTPCH bit field specifies the channel that untagged PTP packets, sent over the Ethernet payload and not over IPv4 or IPv6, are queued on. These bits are reserved if the receive paths of Channel 1 or Channel 2 are not enabled.	
		0	Channel 0
		1	Channel 1
		2	Channel 2
		3	Reserved
22:21 (R/W)	AVCH	Channel for Queuing AV Control Packets. The EMAC_MAC_AVCTL.AVCH bit field specifies the channel the received untagged AV control packets are queued on. These bits are reserved if the receive paths of Channel 1 or Channel 2 are not enabled.	
		0	Channel 0
		1	Channel 1
		2	Channel 2
		3	Reserved

Table 28-137: EMAC_MAC_AVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	AVCD	AV Channel Disable. When the `EMAC_MAC_AVCTL.AVCD` bit is set, the MAC forwards all packets to the default Channel 0 and the values programmed in the AVP, AVCH, and PTPCH fields are ignored. This bit is reserved and read-only if Channel 1 or Channel 2 receive paths are not selected during core configuration.
19 (R/W)	VQE	VLAN Tagged non-AV packets queuing enable. When the `EMAC_MAC_AVCTL.VQE` bit is set, the MAC also queues non-AV VLAN tagged packets into the available channels according to the value of the AVP bits. This bit is reserved and read-only if the Channel 1 and Channel 2 receive paths are not selected during core configuration.
18:16 (R/W)	AVP	AV Priority for Queuing. The value programmed in the `EMAC_MAC_AVCTL.AVP` bits control the receive channel (0, 1, or 2) to which an AV packet with a given priority must be queued. If only Channel 2 receive path is enabled, the AV packets with priority value greater than or equal to the programmed value are queued on Channel 1 and all other packets are queued on Channel 0. If Channel 2 receive path is also enabled, the AV packets with priority value greater than or equal to the programmed value are queued on Channel 2 and all other packets are queued on Channel 0. These bits are applicable only if at least one additional receive channel is selected in the AV mode.
15:0 (R/W)	AVT	AV Ether Type Value. The `EMAC_MAC_AVCTL.AVT` bit field contains the value that is compared with the EtherType field of the incoming (tagged or untagged) Ethernet frame to detect an AV packet.

MMC Control Register

The EMAC_MMC_CTL register selects the MMC operating mode.

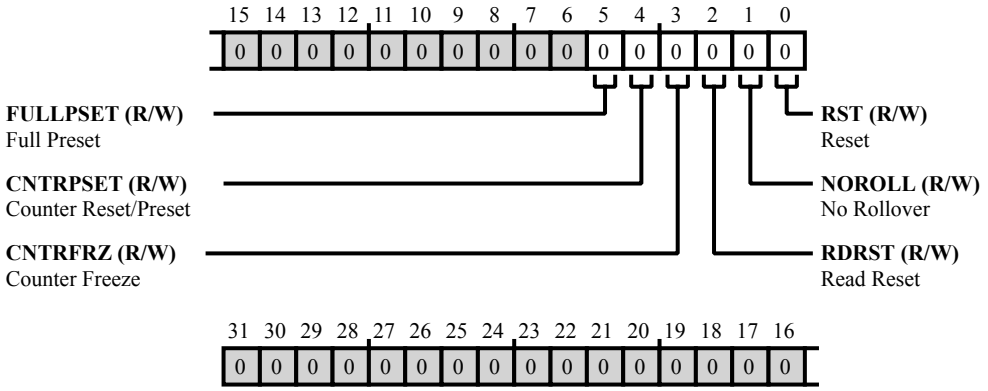

Figure 28-106: EMAC_MMC_CTL Register Diagram

Table 28-138: EMAC_MMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	FULLPSET	Full Preset. The EMAC_MMC_CTL.FULLPSET bit, when =0 (and EMAC_MMC_CTL.CNTRPSET =1), presets all MMC counters to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When EMAC_MMC_CTL.FULLPSET =1 (and EMAC_MMC_CTL.CNTRPSET =1), all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.
4 (R/W)	CNTRPSET	Counter Reset/Preset. The EMAC_MMC_CTL.CNTRPSET bit, when set, initializes all counters or presets counters to almost full or almost half as per EMAC_MMC_CTL.FULLPSET. The EMAC_MMC_CTL.CNTRPSET bit is cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.
3 (R/W)	CNTRFRZ	Counter Freeze. The EMAC_MMC_CTL.CNTRFRZ bit, when set, freezes all the MMC counters to their current value. None of the MMC counters are updated due to any transmitted or received frame, until this bit is reset to 0. If any MMC counter is read with the EMAC_MMC_CTL.RDRST bit set, then that counter is also cleared in this mode.

Table 28-138: EMAC_MMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	RDRST	Read Reset. The `EMAC_MMC_CTL.RDRST` bit, when set, resets the MMC counters to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
1 (R/W)	NOROLL	No Rollover. The `EMAC_MMC_CTL.NOROLL` bit, when set, prevents counter rolls over to 0 after reaching max.
0 (R/W)	RST	Reset. The `EMAC_MMC_CTL.RST` bit, when set, resets all counters. This bit is cleared automatically after 1 clock cycle.

MMC Rx Interrupt Mask Register

The EMAC_MMC_RXIMSK register enables (unmasks) MMC receive interrupts.

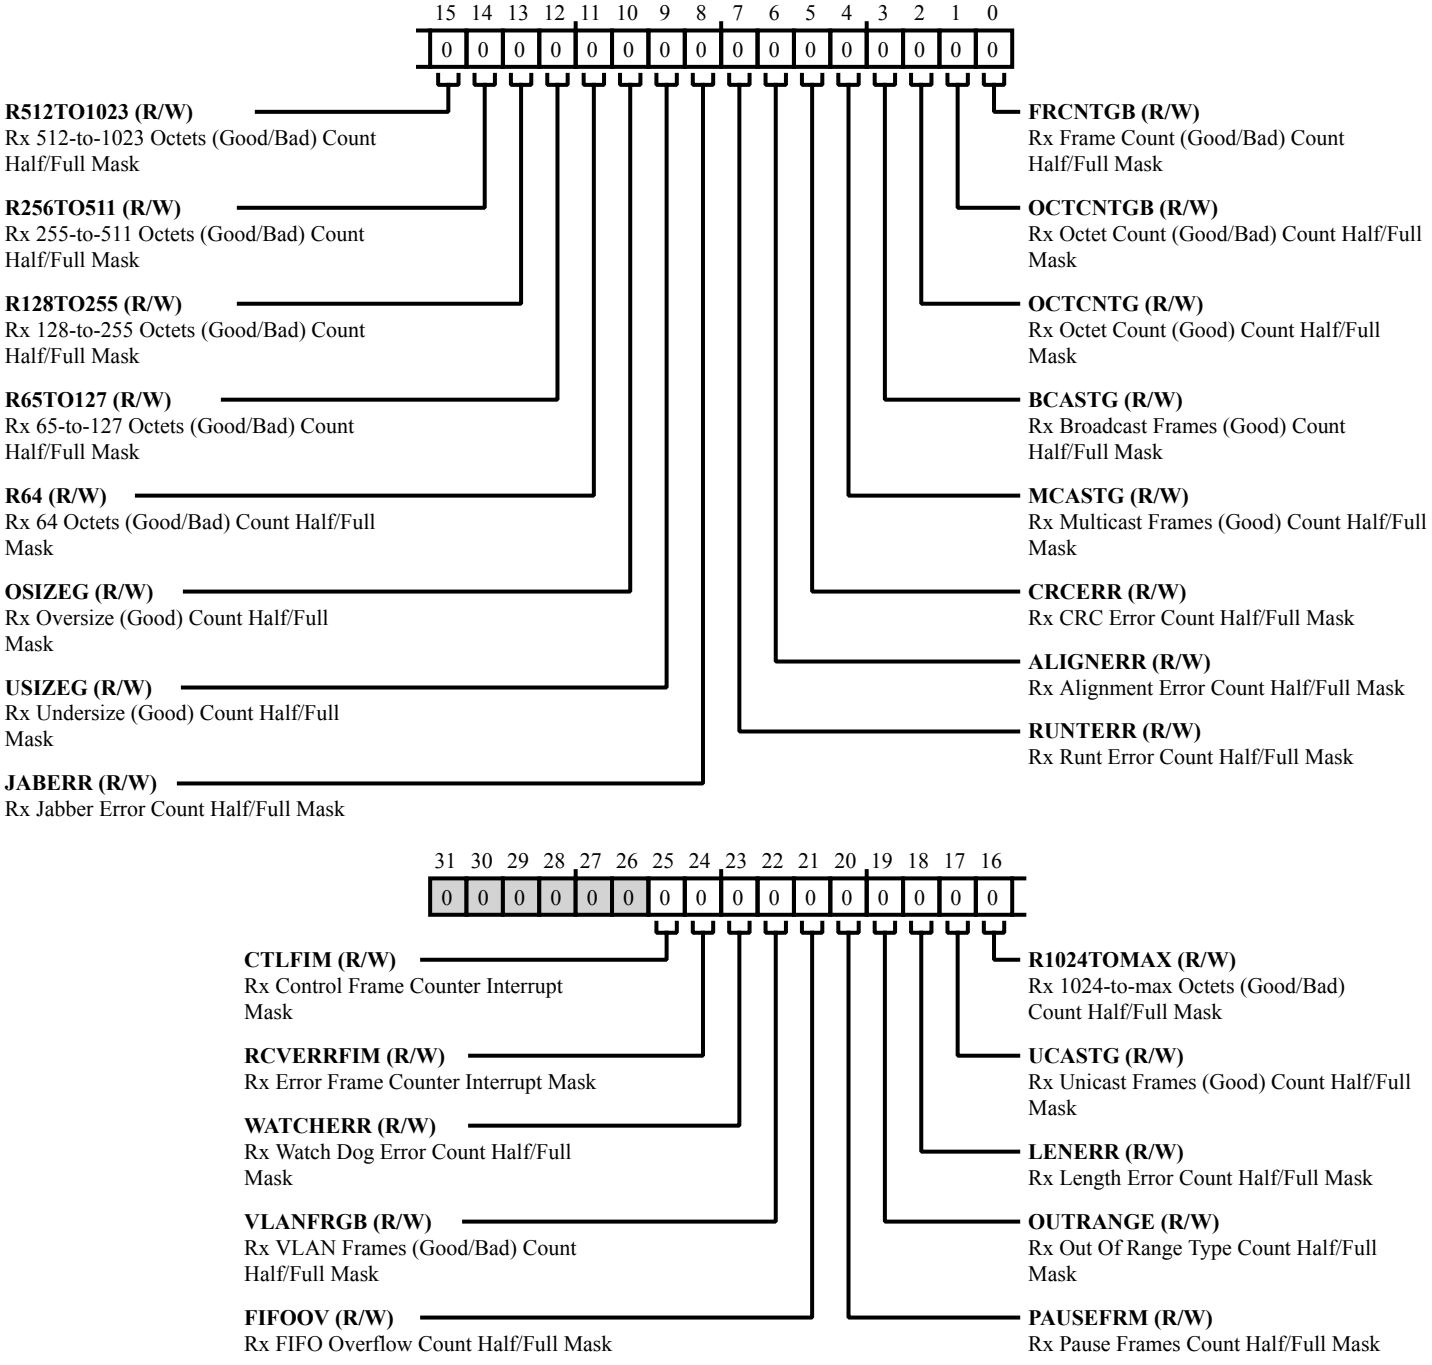

Figure 28-107: EMAC_MMC_RXIMSK Register Diagram

Table 28-139: EMAC_MMC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	CTLFIM	Rx Control Frame Counter Interrupt Mask. The EMAC_MMC_RXIMSK.CTLFIM bit, masks the interrupt when the rxctrlframes_g counter reaches half of the maximum value or the maximum value.
24 (R/W)	RCVERRFIM	Rx Error Frame Counter Interrupt Mask. The EMAC_MMC_RXIMSK.RCVERRFIM bit,masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.
23 (R/W)	WATCHERR	Rx Watch Dog Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.WATCHERR bit, when set, masks the interrupt when EMAC_RXWDOG_ERR counter reaches full or half.
22 (R/W)	VLANFRGB	Rx VLAN Frames (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.VLANFRGB bit, when set, masks the interrupt when EMAC_RXVLANFRM_GB counter reaches full or half.
21 (R/W)	FIFOOV	Rx FIFO Overflow Count Half/Full Mask. The EMAC_MMC_RXIMSK.FIFOOV bit, when set, masks the interrupt when EMAC_RXFIFO_OVF counter reaches full or half.
20 (R/W)	PAUSEFRM	Rx Pause Frames Count Half/Full Mask. The EMAC_MMC_RXIMSK.PAUSEFRM bit, when set, masks the interrupt when EMAC_RXPAUSEFRM counter reaches full or half.
19 (R/W)	OUTRANGE	Rx Out Of Range Type Count Half/Full Mask. The EMAC_MMC_RXIMSK.OUTRANGE bit, when set, masks the interrupt when EMAC_RXOORTYPE counter reaches full or half.
18 (R/W)	LENERR	Rx Length Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.LENERR bit, when set, masks the interrupt when EMAC_RXLEN_ERR counter reaches full or half.
17 (R/W)	UCASTG	Rx Unicast Frames (Good) Count Half/Full Mask. The EMAC_MMC_RXIMSK.UCASTG bit, when set, masks the interrupt when EMAC_RXUCASTFRM_G counter reaches full or half.
16 (R/W)	R1024TOMAX	Rx 1024-to-max Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R1024TOMAX bit, when set, masks the interrupt when EMAC_RX1024TOMAX_GB counter reaches full or half.
15 (R/W)	R512TO1023	Rx 512-to-1023 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R512TO1023 bit, when set, masks the interrupt when EMAC_RX512TO1023_GB counter reaches full or half.
14 (R/W)	R256TO511	Rx 255-to-511 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R256TO511 bit, when set, masks the interrupt when EMAC_RX256TO511_GB counter reaches full or half.

Table 28-139: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	R128TO255	Rx 128-to-255 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R128TO255 bit, when set, masks the interrupt when EMAC_RX128TO255_GB counter reaches full or half.
12 (R/W)	R65TO127	Rx 65-to-127 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R65TO127 bit, when set, masks the interrupt when EMAC_RX65TO127_GB counter reaches full or half.
11 (R/W)	R64	Rx 64 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_RXIMSK.R64 bit, when set, masks the interrupt when EMAC_RX64_GB counter reaches full or half.
10 (R/W)	OSIZEG	Rx Oversize (Good) Count Half/Full Mask. The EMAC_MMC_RXIMSK.OSIZEG bit, when set, masks the interrupt when EMAC_RXOSIZE_G counter reaches full or half.
9 (R/W)	USIZEG	Rx Undersize (Good) Count Half/Full Mask. The EMAC_MMC_RXIMSK.USIZEG bit, when set, masks the interrupt when EMAC_RXUSIZE_G counter reaches full or half.
8 (R/W)	JABERR	Rx Jabber Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.JABERR bit, when set, masks the interrupt when EMAC_RXJAB_ERR counter reaches full or half.
7 (R/W)	RUNTERR	Rx Runt Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.RUNTERR bit, when set, masks the interrupt when EMAC_RXRUNT_ERR counter reaches full or half.
6 (R/W)	ALIGNERR	Rx Alignment Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.ALIGNERR bit, when set, masks the interrupt when EMAC_RXALIGN_ERR counter reaches full or half.
5 (R/W)	CRCERR	Rx CRC Error Count Half/Full Mask. The EMAC_MMC_RXIMSK.CRCERR bit, when set, masks the interrupt when EMAC_RXCRC_ERR counter reaches full or half.
4 (R/W)	MCASTG	Rx Multicast Frames (Good) Count Half/Full Mask. The EMAC_MMC_RXIMSK.MCASTG bit, when set, masks the interrupt when EMAC_RXMCASTFRM_G counter reaches full or half.
3 (R/W)	BCASTG	Rx Broadcast Frames (Good) Count Half/Full Mask. The EMAC_MMC_RXIMSK.BCASTG bit, when set, masks the interrupt when EMAC_RXBCASTFRM_G counter reaches full or half.

Table 28-139: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	OCTCNTG	Rx Octet Count (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OCTCNTG` bit, when set, masks the interrupt when `EMAC_RXOCTCNT_G` counter reaches full or half.
1 (R/W)	OCTCNTGB	Rx Octet Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OCTCNTGB` bit, when set, masks the interrupt when `EMAC_RXOCTCNT_GB` counter reaches half or full.
0 (R/W)	FRCNTGB	Rx Frame Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.FRCNTGB` bit, when set, masks the interrupt when `EMAC_RXFRMCNT_GB` counter reaches half or full.

MMC Rx Interrupt Register

The EMAC_MMC_RXINT register indicates status of MMC receive interrupts.

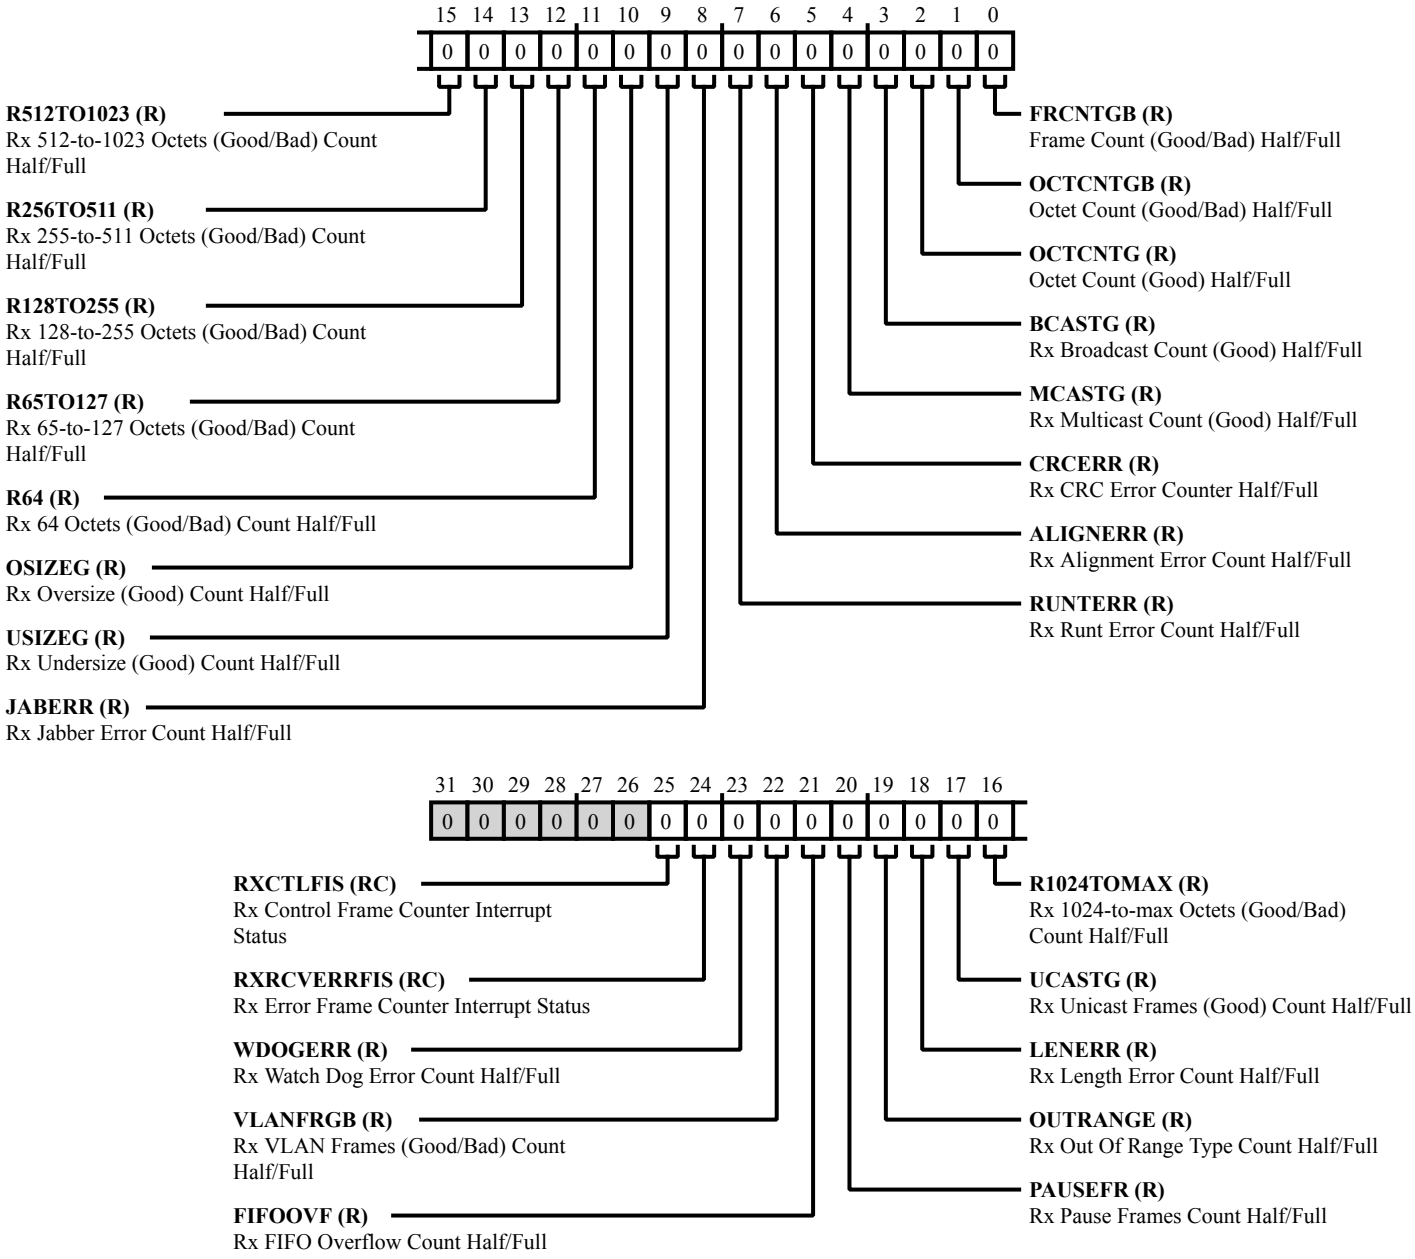

Figure 28-108: EMAC_MMC_RXINT Register Diagram

Table 28-140: EMAC_MMC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (RC/NW)	RXCTLFIS	Rx Control Frame Counter Interrupt Status. The EMAC_MMC_RXINT.RXCTLFIS bit is set when the rxctrlframes_g counter reaches half of the maximum value or the maximum value.
24 (RC/NW)	RXRCVERRFIS	Rx Error Frame Counter Interrupt Status. The EMAC_MMC_RXINT.RXRCVERRFIS bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value.
23 (R/NW)	WDOGERR	Rx Watch Dog Error Count Half/Full. The EMAC_MMC_RXINT.WDOGERR bit is set when the EMAC_RXWDOG_ERR counter reaches full or half.
22 (R/NW)	VLANFRGB	Rx VLAN Frames (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.VLANFRGB bit is set when EMAC_RXVLANFRM_GB counter reaches full or half.
21 (R/NW)	FIFOOVF	Rx FIFO Overflow Count Half/Full. The EMAC_MMC_RXINT.FIFOOVF bit is set when EMAC_RXFIFO_OVF counter reaches full or half.
20 (R/NW)	PAUSEFR	Rx Pause Frames Count Half/Full. The EMAC_MMC_RXINT.PAUSEFR bit is set when EMAC_RXPAUSEFRM counter reaches full or half.
19 (R/NW)	OUTRANGE	Rx Out Of Range Type Count Half/Full. The EMAC_MMC_RXINT.OUTRANGE bit is set when EMAC_RXOORTYPE counter reaches full or half.
18 (R/NW)	LENERR	Rx Length Error Count Half/Full. The EMAC_MMC_RXINT.LENERR bit is set when EMAC_RXLEN_ERR counter reaches full or half.
17 (R/NW)	UCASTG	Rx Unicast Frames (Good) Count Half/Full. The EMAC_MMC_RXINT.UCASTG bit is set when EMAC_RXUCASTFRM_G counter reaches full or half.
16 (R/NW)	R1024TOMAX	Rx 1024-to-max Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R1024TOMAX bit is set when EMAC_RX1024TOMAX_GB counter reaches full or half.
15 (R/NW)	R512TO1023	Rx 512-to-1023 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R512TO1023 bit is set when EMAC_RX512TO1023_GB counter reaches full or half.
14 (R/NW)	R256TO511	Rx 255-to-511 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R256TO511 bit is set when EMAC_RX256TO511_GB counter reaches full or half.

Table 28-140: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/NW)	R128TO255	Rx 128-to-255 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R128TO255 bit is set when EMAC_RX128TO255_GB counter reaches full or half.
12 (R/NW)	R65TO127	Rx 65-to-127 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R65TO127 bit is set when EMAC_RX65TO127_GB counter reaches full or half.
11 (R/NW)	R64	Rx 64 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_RXINT.R64 bit is set when EMAC_RX64_GB counter reaches full or half.
10 (R/NW)	OSIZEG	Rx Oversize (Good) Count Half/Full. The EMAC_MMC_RXINT.OSIZEG bit is set when EMAC_RXOSIZE_G counter reaches full or half.
9 (R/NW)	USIZEG	Rx Undersize (Good) Count Half/Full. The EMAC_MMC_RXINT.USIZEG bit is set when EMAC_RXUSIZE_G counter reaches full or half.
8 (R/NW)	JABERR	Rx Jabber Error Count Half/Full. The EMAC_MMC_RXINT.JABERR bit is set when EMAC_RXJAB_ERR counter reaches full or half.
7 (R/NW)	RUNTERR	Rx Runt Error Count Half/Full. The EMAC_MMC_RXINT.RUNTERR bit is set when EMAC_RXRUNT_ERR counter reaches full or half.
6 (R/NW)	ALIGNERR	Rx Alignment Error Count Half/Full. The EMAC_MMC_RXINT.ALIGNERR bit is set when EMAC_RXALIGN_ERR counter reaches full or half
5 (R/NW)	CRCERR	Rx CRC Error Counter Half/Full. The EMAC_MMC_RXINT.CRCERR bit is set when EMAC_RXCRC_ERR counter reaches full or half.
4 (R/NW)	MCASTG	Rx Multicast Count (Good) Half/Full. The EMAC_MMC_RXINT.MCASTG bit is set when EMAC_RXMCASTFRM_G counter reaches full or half.
3 (R/NW)	BCASTG	Rx Broadcast Count (Good) Half/Full. The EMAC_MMC_RXINT.BCASTG bit is set when EMAC_RXBCASTFRM_G counter reaches full or half.

Table 28-140: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	OCTCNTG	Octet Count (Good) Half/Full. The `EMAC_MMC_RXINT.OCTCNTG` bit is set when `EMAC_RXOCTCNT_G` counter reaches full or half.
1 (R/NW)	OCTCNTGB	Octet Count (Good/Bad) Half/Full. The `EMAC_MMC_RXINT.OCTCNTGB` bit is set when `EMAC_RXOCTCNT_GB` counter reaches half or full.
0 (R/NW)	FRCNTGB	Frame Count (Good/Bad) Half/Full. The `EMAC_MMC_RXINT.FRCNTGB` bit is set when `EMAC_RXFRMCNT_GB` counter reaches half or full.

MMC TX Interrupt Mask Register

The EMAC_MMC_TXIMSK register enables (unmasks) MMC transmit interrupts.

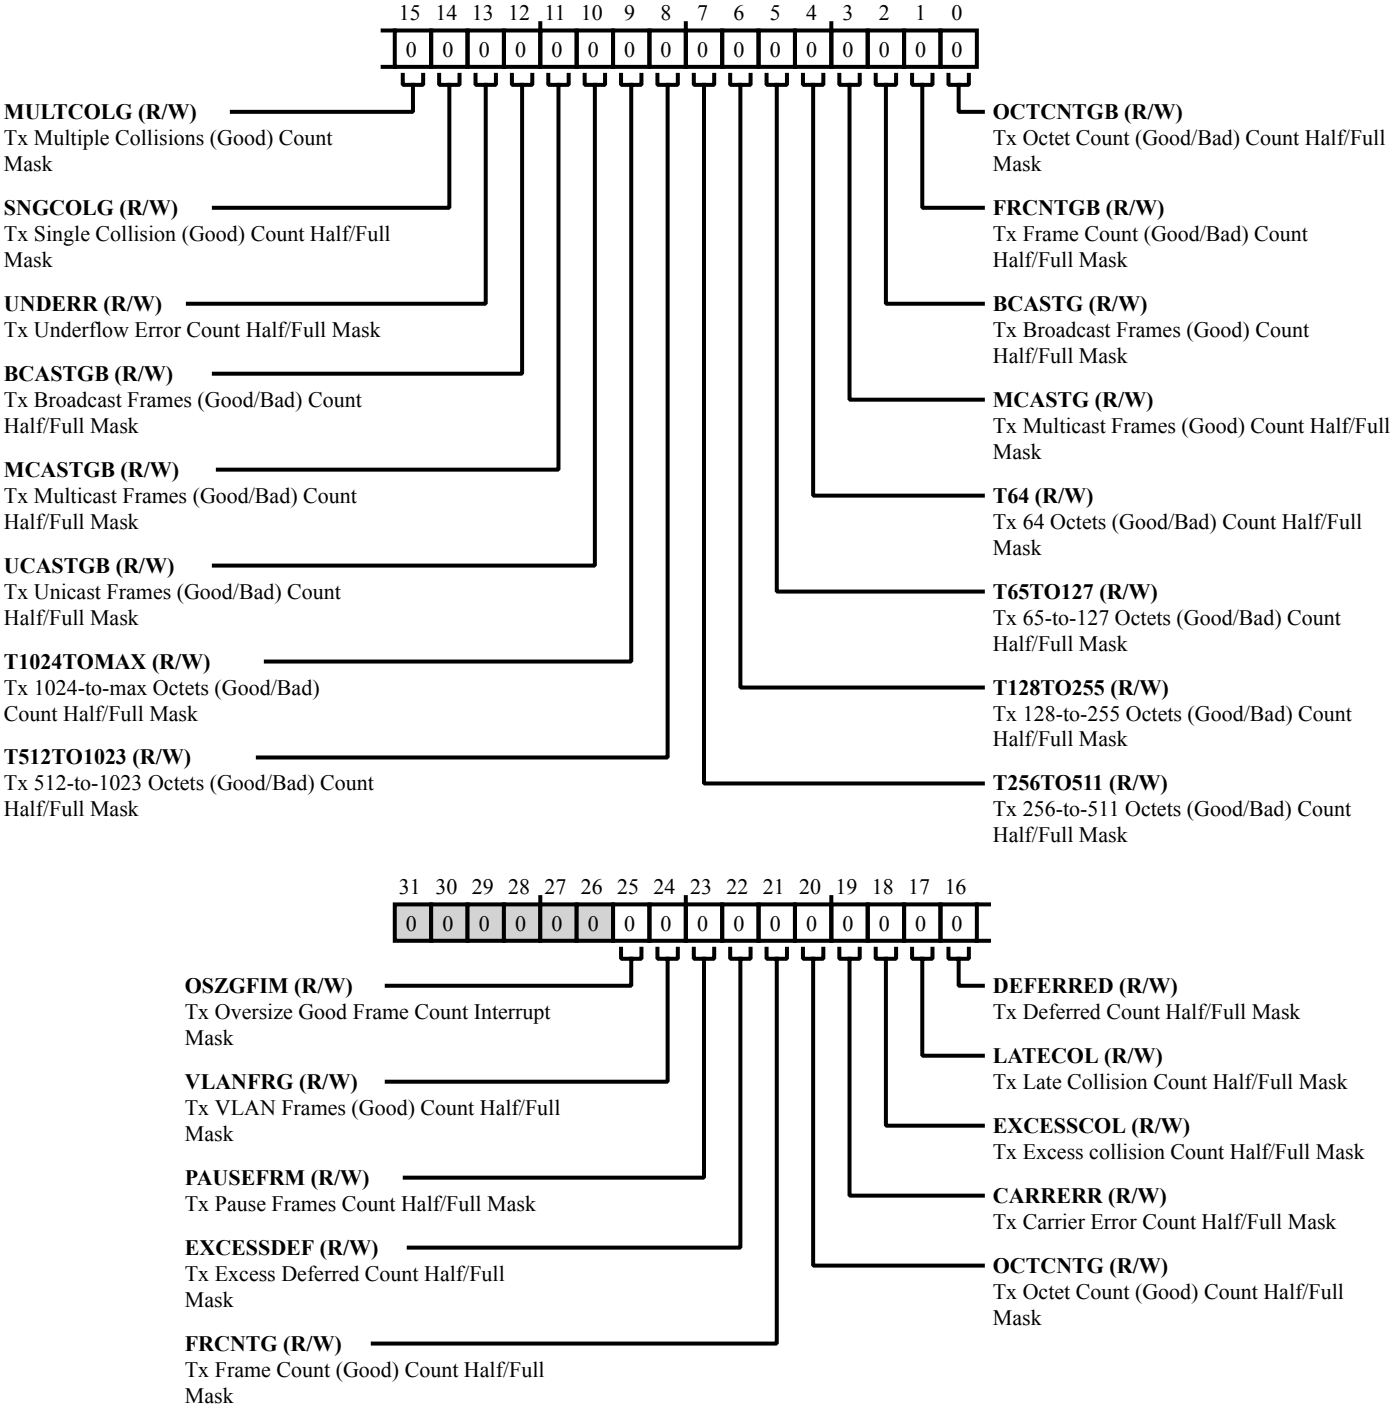

Figure 28-109: EMAC_MMC_TXIMSK Register Diagram

Table 28-141: EMAC_MMC_TXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	OSZGFIM	Tx Oversize Good Frame Count Interrupt Mask. The EMAC_MMC_TXIMSK.OSZGFIM bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
24 (R/W)	VLANFRG	Tx VLAN Frames (Good) Count Half/Full Mask. The EMAC_MMC_TXIMSK.VLANFRG bit, when set, masks the interrupt when EMAC_TXVLANFRM_G counter reaches full or half.
23 (R/W)	PAUSEFRM	Tx Pause Frames Count Half/Full Mask. The EMAC_MMC_TXIMSK.PAUSEFRM bit, when set, masks the interrupt when EMAC_TXPAUSEFRM counter reaches full or half.
22 (R/W)	EXCESSDEF	Tx Excess Deferred Count Half/Full Mask. The EMAC_MMC_TXIMSK.EXCESSDEF bit, when set, masks the interrupt when EMAC_TXEXCESSDEF counter reaches full or half.
21 (R/W)	FRCNTG	Tx Frame Count (Good) Count Half/Full Mask. The EMAC_MMC_TXIMSK.FRCNTG bit, when set, masks the interrupt when EMAC_TXFRMCNT_G counter reaches full or half.
20 (R/W)	OCTCNTG	Tx Octet Count (Good) Count Half/Full Mask. The EMAC_MMC_TXIMSK.OCTCNTG bit, when set, masks the interrupt when EMAC_TXOCTCNT_G counter reaches full or half.
19 (R/W)	CARRERR	Tx Carrier Error Count Half/Full Mask. The EMAC_MMC_TXIMSK.CARRERR bit, when set, masks the interrupt when EMAC_TXCARR_ERR counter reaches full or half.
18 (R/W)	EXCESSCOL	Tx Excess collision Count Half/Full Mask. The EMAC_MMC_TXIMSK.EXCESSCOL bit, when set, masks the interrupt when EMAC_TXEXCESSCOL counter reaches full or half.
17 (R/W)	LATECOL	Tx Late Collision Count Half/Full Mask. The EMAC_MMC_TXIMSK.LATECOL bit, when set, masks the interrupt when EMAC_TXLATECOL counter reaches full or half.
16 (R/W)	DEFERRED	Tx Deferred Count Half/Full Mask. The EMAC_MMC_TXIMSK.DEFERRED bit, when set, masks the interrupt when EMAC_TXDEFERRED counter reaches full or half.
15 (R/W)	MULTCOLG	Tx Multiple Collisions (Good) Count Mask. The EMAC_MMC_TXIMSK.MULTCOLG bit, when set, masks the interrupt when EMAC_TXMULTCOL_G counter reaches full or half.
14 (R/W)	SNGCOLG	Tx Single Collision (Good) Count Half/Full Mask. The EMAC_MMC_TXIMSK.SNGCOLG bit, when set, masks the interrupt when EMAC_TXSNGCOL_G counter reaches full or half.

Table 28-141: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	UNDERR	Tx Underflow Error Count Half/Full Mask. The EMAC_MMC_TXIMSK.UNDERR bit, when set, masks the interrupt when EMAC_TXUNDR_ERR counter reaches full or half.
12 (R/W)	BCASTGB	Tx Broadcast Frames (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.BCASTGB bit, when set, masks the interrupt when EMAC_TXBCASTFRM_GB counter reaches full or half.
11 (R/W)	MCASTGB	Tx Multicast Frames (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.MCASTGB bit, when set, masks the interrupt when EMAC_TXMCASTFRM_GB counter reaches full or half.
10 (R/W)	UCASTGB	Tx Unicast Frames (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.UCASTGB bit, when set, masks the interrupt when EMAC_TXUCASTFRM_GB counter reaches full or half.
9 (R/W)	T1024TOMAX	Tx 1024-to-max Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T1024TOMAX bit, when set, masks the interrupt when EMAC_TX1024TOMAX_GB counter reaches full or half.
8 (R/W)	T512TO1023	Tx 512-to-1023 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T512TO1023 bit, when set, masks the interrupt when EMAC_TX512TO1023_GB counter reaches full or half.
7 (R/W)	T256TO511	Tx 256-to-511 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T256TO511 bit, when set, masks the interrupt when EMAC_TX256TO511_GB counter reaches full or half.
6 (R/W)	T128TO255	Tx 128-to-255 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T128TO255 bit, when set, masks the interrupt when EMAC_TX128TO255_GB counter reaches full or half.
5 (R/W)	T65TO127	Tx 65-to-127 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T65TO127 bit, when set, masks the interrupt when EMAC_TX65TO127_GB counter reaches full or half.
4 (R/W)	T64	Tx 64 Octets (Good/Bad) Count Half/Full Mask. The EMAC_MMC_TXIMSK.T64 bit, when set, masks the interrupt when EMAC_TX64_GB counter reaches full or half.
3 (R/W)	MCASTG	Tx Multicast Frames (Good) Count Half/Full Mask. The EMAC_MMC_TXIMSK.MCASTG bit, when set, masks the interrupt when EMAC_TXMCASTFRM_G counter reaches full or half.

Table 28-141: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	BCASTG	Tx Broadcast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.BCASTG` bit, when set, masks the interrupt when `EMAC_TXBCASTFRM_G` counter reaches full or half.
1 (R/W)	FRCNTGB	Tx Frame Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.FRCNTGB` bit, when set, masks the interrupt when `EMAC_TXFRMCNT_GB` counter reaches full or half.
0 (R/W)	OCTCNTGB	Tx Octet Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.OCTCNTGB` bit, when set, masks the interrupt when `EMAC_TXOCTCNT_GB` counter reaches full or half.

MMC Tx Interrupt Register

The EMAC_MMC_TXINT register indicates status of MMC transmit interrupts.

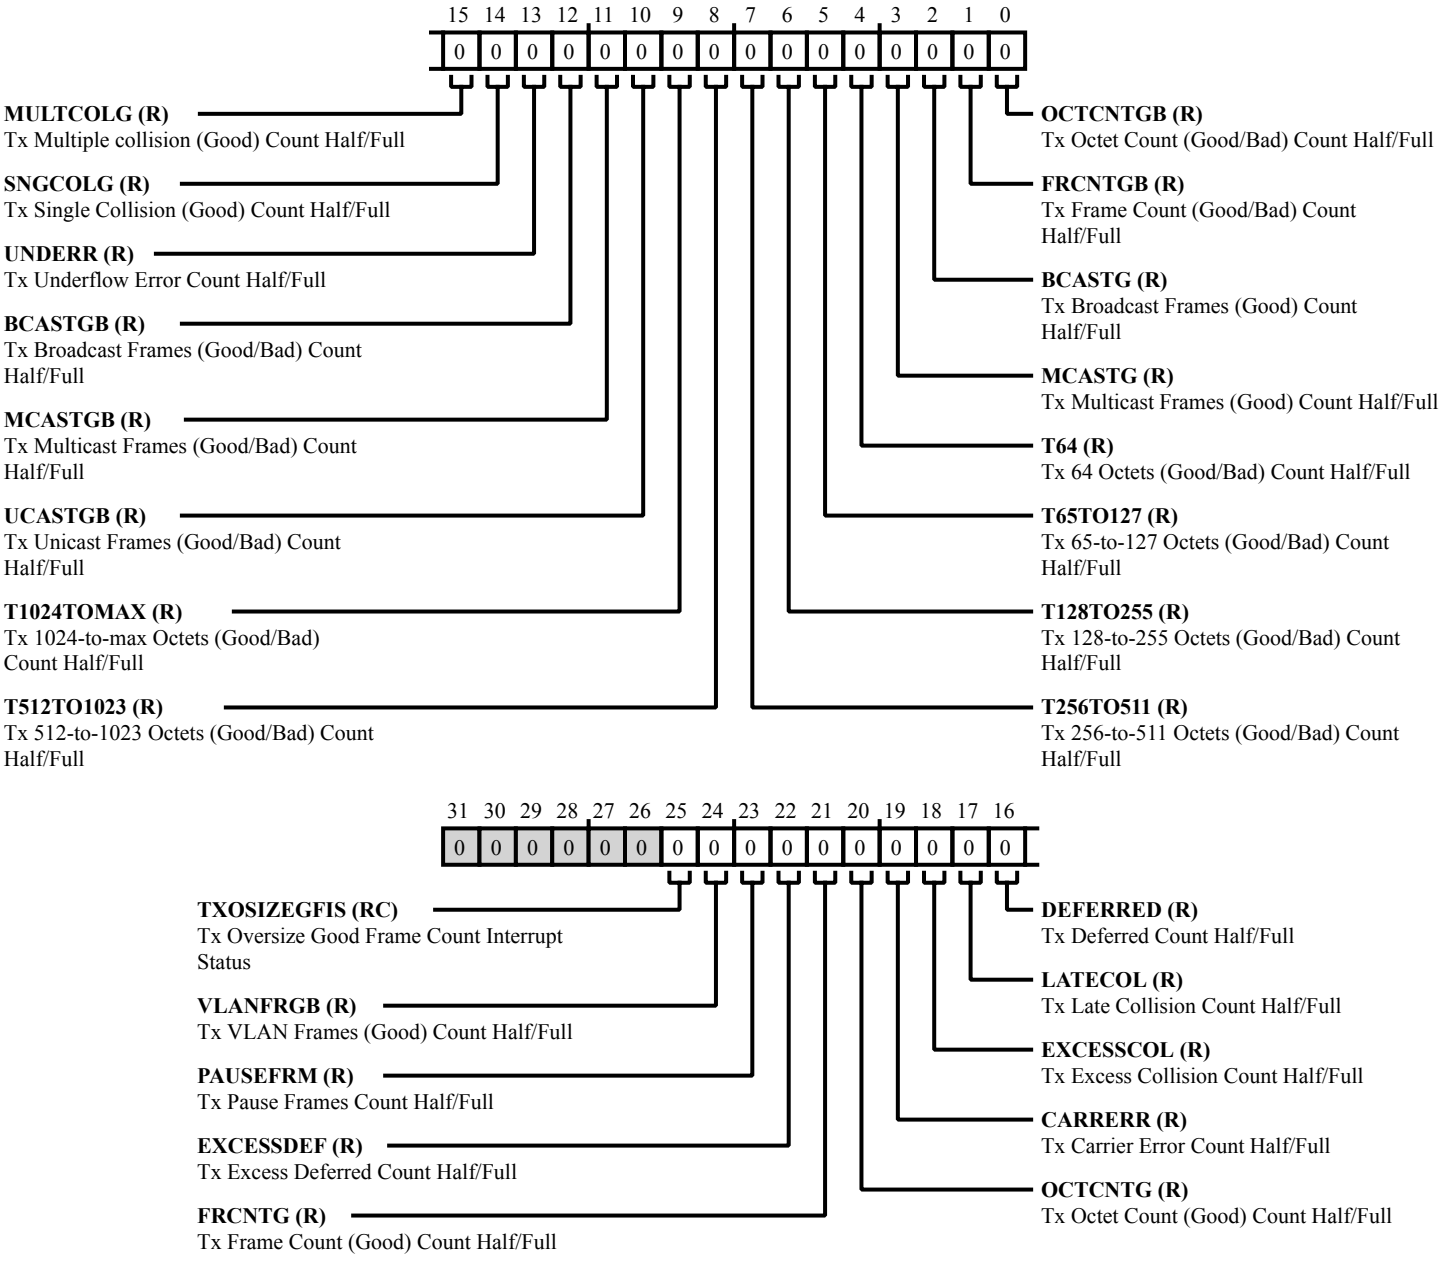

Figure 28-110: EMAC_MMC_TXINT Register Diagram

Table 28-142: EMAC_MMC_TXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (RC/NW)	TXOSIZEGFIS	Tx Oversize Good Frame Count Interrupt Status. The EMAC_MMC_TXINT.TXOSIZEGFIS bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value.
24 (R/NW)	VLANFRGB	Tx VLAN Frames (Good) Count Half/Full. The EMAC_MMC_TXINT.VLANFRGB bit is set when EMAC_TXVLANFRM_G counter reaches full or half.
23 (R/NW)	PAUSEFRM	Tx Pause Frames Count Half/Full. The EMAC_MMC_TXINT.PAUSEFRM bit is set when EMAC_TXPAUSEFRM counter reaches full or half.
22 (R/NW)	EXCESSDEF	Tx Excess Deferred Count Half/Full. The EMAC_MMC_TXINT.EXCESSDEF bit is set when EMAC_TXEXCESSDEF counter reaches full or half.
21 (R/NW)	FRCNTG	Tx Frame Count (Good) Count Half/Full. The EMAC_MMC_TXINT.FRCNTG bit is set when EMAC_TXFRMCNT_G counter reaches full or half.
20 (R/NW)	OCTCNTG	Tx Octet Count (Good) Count Half/Full. The EMAC_MMC_TXINT.OCTCNTG bit is set when EMAC_TXOCTCNT_G counter reaches full or half.
19 (R/NW)	CARRERR	Tx Carrier Error Count Half/Full. The EMAC_MMC_TXINT.CARRERR bit is set when EMAC_TXCARR_ERR counter reaches full or half.
18 (R/NW)	EXCESSCOL	Tx Excess Collision Count Half/Full. The EMAC_MMC_TXINT.EXCESSCOL bit is set when EMAC_TXEXCESSCOL counter reaches full or half.
17 (R/NW)	LATECOL	Tx Late Collision Count Half/Full. The EMAC_MMC_TXINT.LATECOL bit is set when EMAC_TXLATECOL counter reaches full or half.
16 (R/NW)	DEFERRED	Tx Deferred Count Half/Full. The EMAC_MMC_TXINT.DEFERRED bit is set when EMAC_TXDEFERRED counter reaches full or half.
15 (R/NW)	MULTCOLG	Tx Multiple collision (Good) Count Half/Full. The EMAC_MMC_TXINT.MULTCOLG bit is set when EMAC_TXMULTCOL_G counter reaches full or half.
14 (R/NW)	SNGCOLG	Tx Single Collision (Good) Count Half/Full. The EMAC_MMC_TXINT.SNGCOLG bit is set when EMAC_TXSNGCOL_G counter reaches full or half.

Table 28-142: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/NW)	UNDERR	Tx Underflow Error Count Half/Full. The EMAC_MMC_TXINT.UNDERR bit is set when EMAC_TXUNDR_ERR counter reaches full or half.
12 (R/NW)	BCASTGB	Tx Broadcast Frames (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.BCASTGB bit is set when EMAC_TXBCASTFRM_GB counter reaches full or half.
11 (R/NW)	MCASTGB	Tx Multicast Frames (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.MCASTGB bit is set when EMAC_TXMCASTFRM_GB counter reaches full or half.
10 (R/NW)	UCASTGB	Tx Unicast Frames (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.UCASTGB bit is set when EMAC_TXUCASTFRM_GB counter reaches full or half.
9 (R/NW)	T1024TOMAX	Tx 1024-to-max Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T1024TOMAX bit is set when EMAC_TX1024TOMAX_GB counter reaches full or half.
8 (R/NW)	T512TO1023	Tx 512-to-1023 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T512TO1023 bit is set when EMAC_TX512TO1023_GB counter reaches full or half.
7 (R/NW)	T256TO511	Tx 256-to-511 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T256TO511 bit is set when EMAC_TX256TO511_GB counter reaches full or half.
6 (R/NW)	T128TO255	Tx 128-to-255 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T128TO255 bit is set when EMAC_TX128TO255_GB counter reaches full or half.
5 (R/NW)	T65TO127	Tx 65-to-127 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T65TO127 bit is set when EMAC_TX65TO127_GB counter reaches full or half.
4 (R/NW)	T64	Tx 64 Octets (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.T64 bit is set when EMAC_TX64_GB counter reaches full or half.
3 (R/NW)	MCASTG	Tx Multicast Frames (Good) Count Half/Full. The EMAC_MMC_TXINT.MCASTG bit is set when EMAC_TXMCASTFRM_G counter reaches full or half.

Table 28-142: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	BCASTG	Tx Broadcast Frames (Good) Count Half/Full. The EMAC_MMC_TXINT.BCASTG bit is set when EMAC_TXBCASTFRM_G counter reaches full or half.
1 (R/NW)	FRCNTGB	Tx Frame Count (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.FRCNTGB bit is set when EMAC_TXFRMCNT_GB counter reaches full or half.
0 (R/NW)	OCTCNTGB	Tx Octet Count (Good/Bad) Count Half/Full. The EMAC_MMC_TXINT.OCTCNTGB bit is set when EMAC_TXOCTCNT_GB counter reaches full or half.

Rx 1024- to Max-Byte Frames (Good/Bad) Register

The EMAC_RX1024TOMAX_GB register contains a count of the number of good and bad frames received with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble.

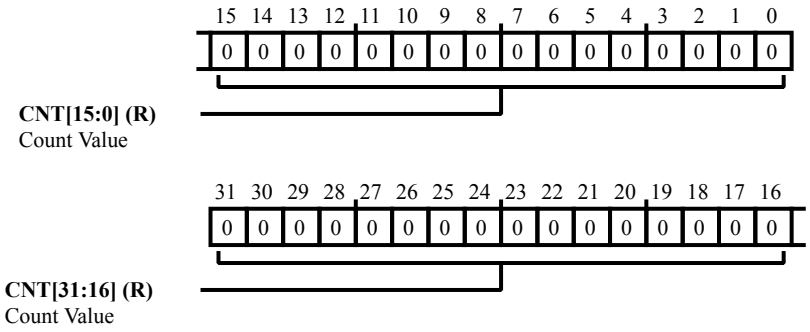

Figure 28-111: EMAC_RX1024TOMAX_GB Register Diagram

Table 28-143: EMAC_RX1024TOMAX_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx 128- to 255-Byte Frames (Good/Bad) Register

The EMAC_RX128TO255_GB register contains a count of the number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

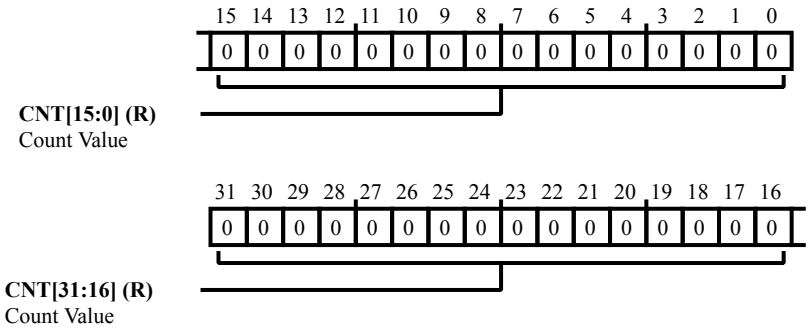

Figure 28-112: EMAC_RX128TO255_GB Register Diagram

Table 28-144: EMAC_RX128TO255_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx 256- to 511-Byte Frames (Good/Bad) Register

The EMAC_RX256TO511_GB register contains a count of the number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

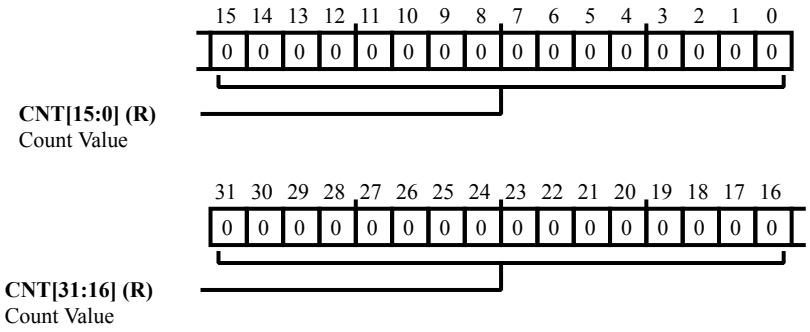

Figure 28-113: EMAC_RX256TO511_GB Register Diagram

Table 28-145: EMAC_RX256TO511_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx 512- to 1023-Byte Frames (Good/Bad) Register

The EMAC_RX512TO1023_GB register contains a count of the number of good and bad frames received with length between 512 and 1023 (inclusive) bytes, exclusive of preamble.

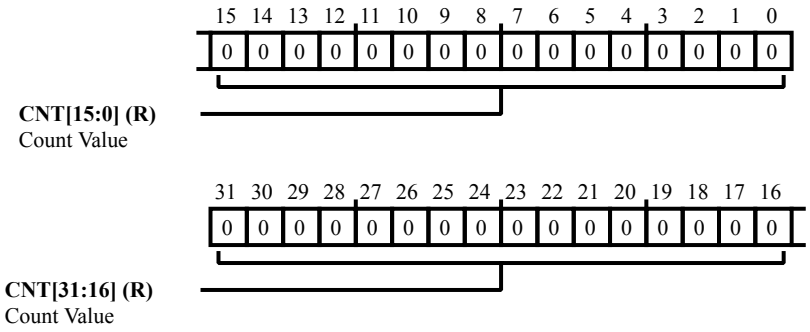

Figure 28-114: EMAC_RX512TO1023_GB Register Diagram

Table 28-146: EMAC_RX512TO1023_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx 64-Byte Frames (Good/Bad) Register

The EMAC_RX64_GB register contains a count of the number of good and bad frames received with length 64 bytes, exclusive of preamble.

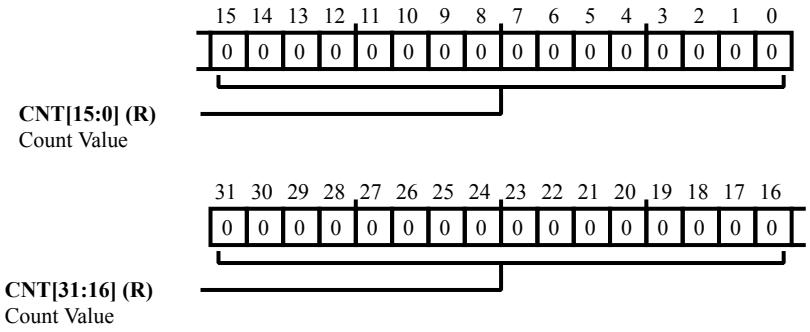

Figure 28-115: EMAC_RX64_GB Register Diagram

Table 28-147: EMAC_RX64_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx 65- to 127-Byte Frames (Good/Bad) Register

The EMAC_RX65TO127_GB register contains a count of the number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

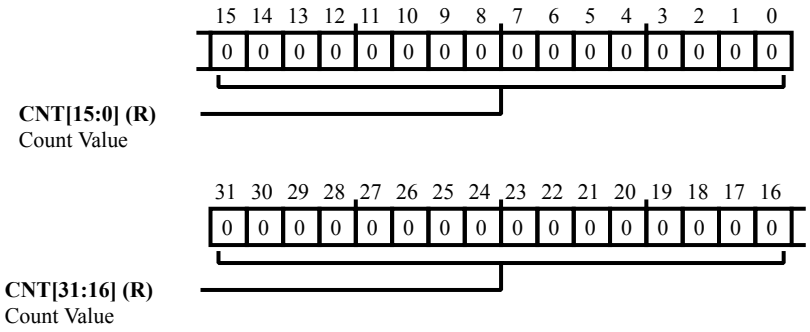

Figure 28-116: EMAC_RX65TO127_GB Register Diagram

Table 28-148: EMAC_RX65TO127_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx alignment Error Register

The EMAC_RXALIGN_ERR register contains a count of the number of frames received with alignment (dribble) error. Valid only in 10/100 mode.

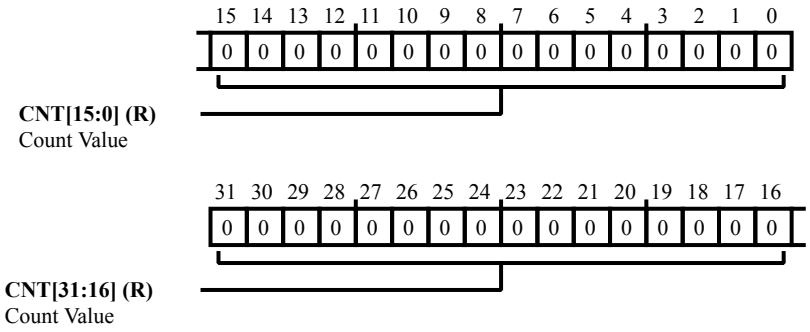

Figure 28-117: EMAC_RXALIGN_ERR Register Diagram

Table 28-149: EMAC_RXALIGN_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Broadcast Frames (Good) Register

The EMAC_RXBCASTFRM_G register contains a count of the number of good broadcast frames received.

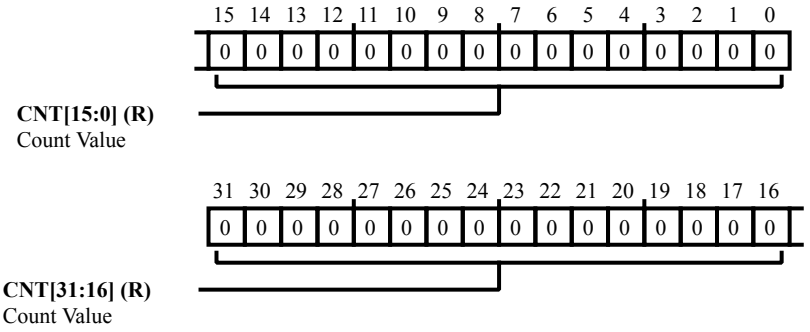

Figure 28-118: EMAC_RXBCASTFRM_G Register Diagram

Table 28-150: EMAC_RXBCASTFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx CRC Error Register

The EMAC_RXCRC_ERR register contains a count of the number of frames received with CRC error.

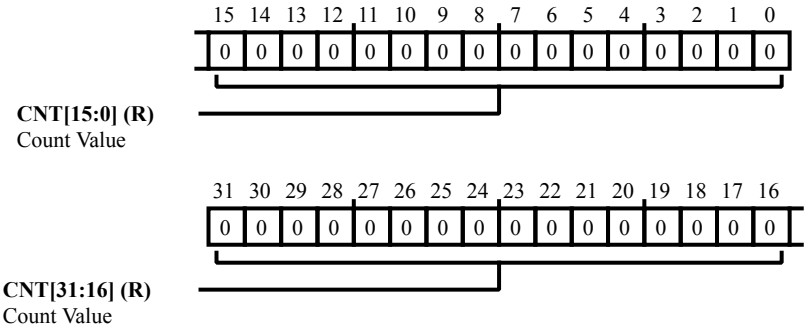

Figure 28-119: EMAC_RXCRC_ERR Register Diagram

Table 28-151: EMAC_RXCRC_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Good Control Frames Register

The EMAC_RXCTLFRM_G register contains a count of the number of good control frames received

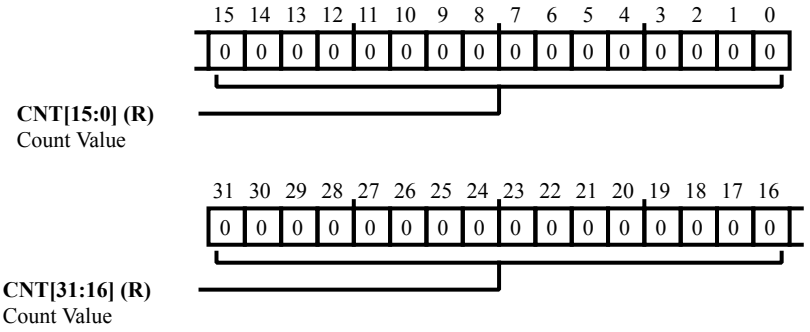

Figure 28-120: EMAC_RXCTLFRM_G Register Diagram

Table 28-152: EMAC_RXCTLFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx FIFO Overflow Register

The EMAC_RXFIFO_OVF register contains a count of the number of missed received frames due to FIFO overflow.

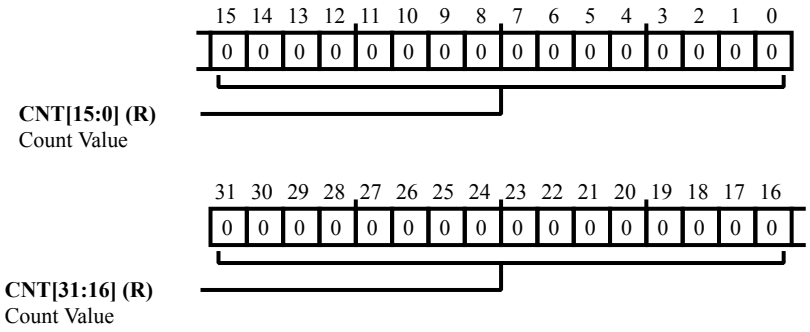

Figure 28-121: EMAC_RXFIFO_OVF Register Diagram

Table 28-153: EMAC_RXFIFO_OVF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Frame Count (Good/Bad) Register

The EMAC_RXFRMCNT_GB register contains a count of the number of good and bad frames received.

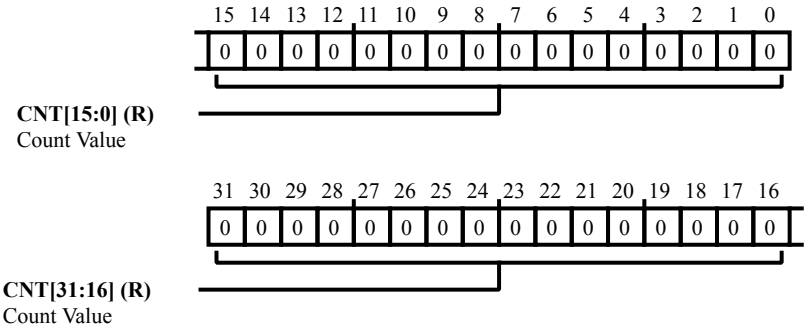

Figure 28-122: EMAC_RXFRMCNT_GB Register Diagram

Table 28-154: EMAC_RXFRMCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx ICMP Error Frames Register

The EMAC_RXICMP_ERR_FRM register contains a count of the number of good IP datagrams whose ICMP payload has a checksum error.

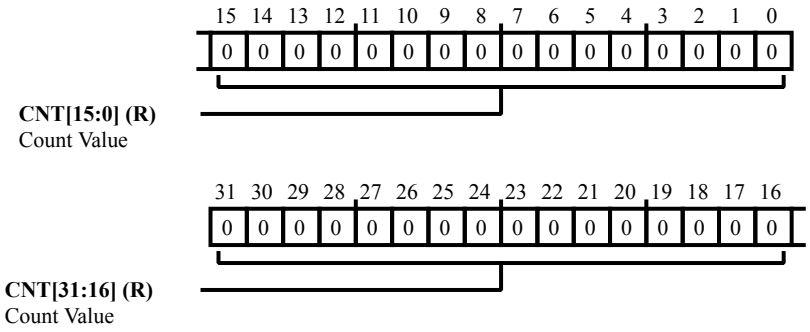

Figure 28-123: EMAC_RXICMP_ERR_FRM Register Diagram

Table 28-155: EMAC_RXICMP_ERR_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx ICMP Error Octets Register

The EMAC_RXICMP_ERR_OCT register contains a count of the number of bytes received in an ICMP segment with checksum errors.

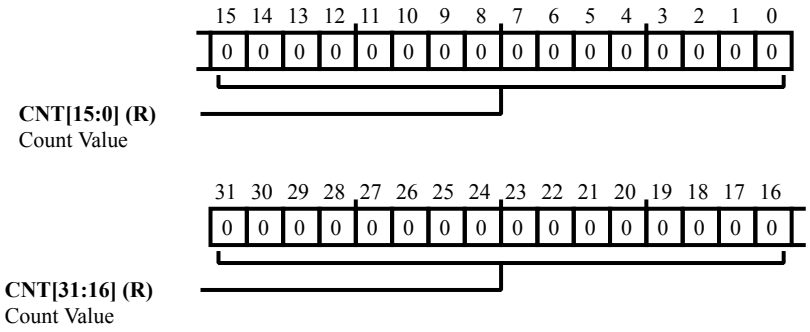

Figure 28-124: EMAC_RXICMP_ERR_OCT Register Diagram

Table 28-156: EMAC_RXICMP_ERR_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx ICMP Good Frames Register

The EMAC_RXICMP_GD_FRM register contains a count of the number of good IP datagrams with a good ICMP payload.

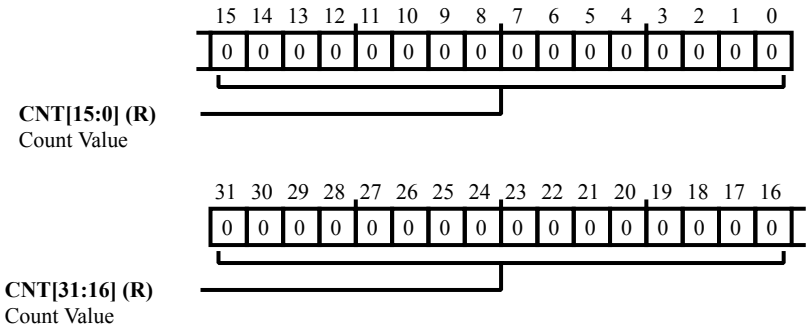

Figure 28-125: EMAC_RXICMP_GD_FRM Register Diagram

Table 28-157: EMAC_RXICMP_GD_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx ICMP Good Octets Register

The EMAC_RXICMP_GD_OCT register contains a count of the Number of bytes received in a good ICMP segment.

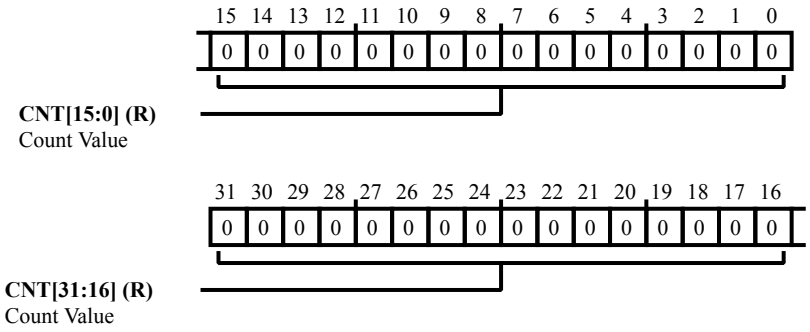

Figure 28-126: EMAC_RXICMP_GD_OCT Register Diagram

Table 28-158: EMAC_RXICMP_GD_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams Fragmented Frames Register

The EMAC_RXIPV4_FRAG_FRM register contains a count of the number of good IPv4 datagrams with fragmentation.

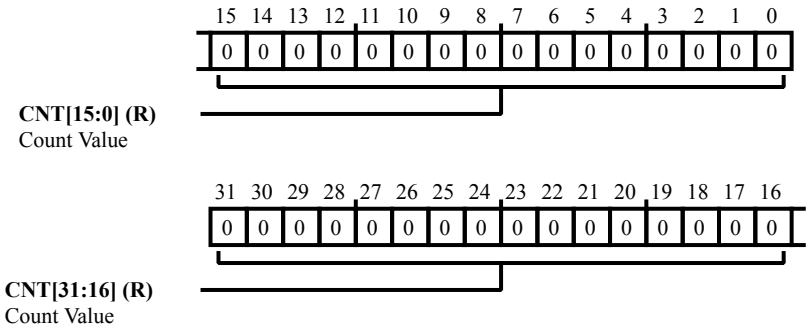

Figure 28-127: EMAC_RXIPV4_FRAG_FRM Register Diagram

Table 28-159: EMAC_RXIPV4_FRAG_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams Fragmented Octets Register

The EMAC_RXIPV4_FRAG_OCT register contains a count of the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.

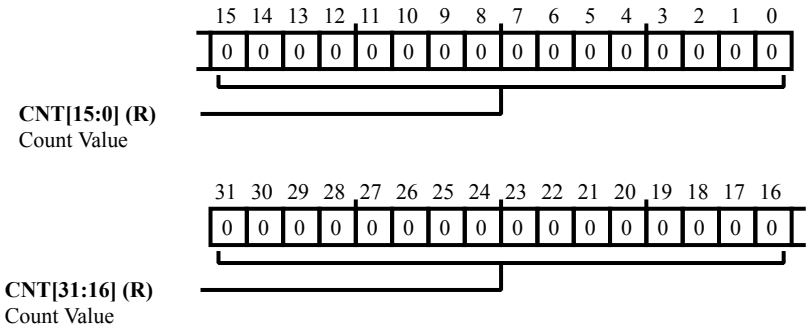

Figure 28-128: EMAC_RXIPV4_FRAG_OCT Register Diagram

Table 28-160: EMAC_RXIPV4_FRAG_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams (Good) Register

The EMAC_RXIPV4_GD_FRM register contains a count of the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

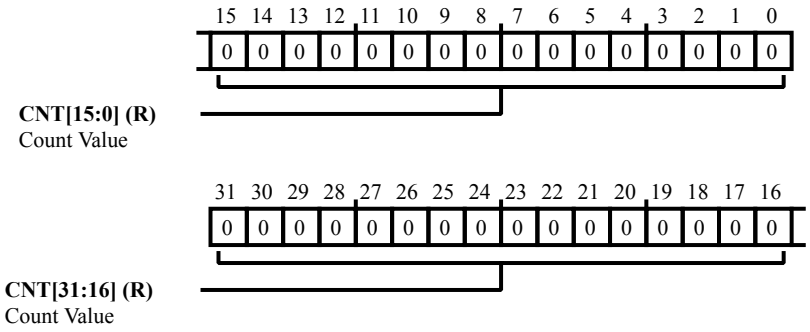

Figure 28-129: EMAC_RXIPV4_GD_FRM Register Diagram

Table 28-161: EMAC_RXIPV4_GD_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams Good Octets Register

The EMAC_RXIPV4_GD_OCT register contains a count of the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

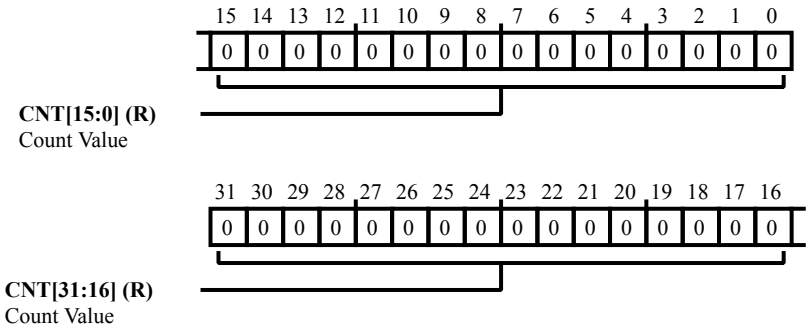

Figure 28-130: EMAC_RXIPV4_GD_OCT Register Diagram

Table 28-162: EMAC_RXIPV4_GD_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams Header Errors Register

The EMAC_RXIPV4_HDR_ERR_FRM register contains a count of the number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors.

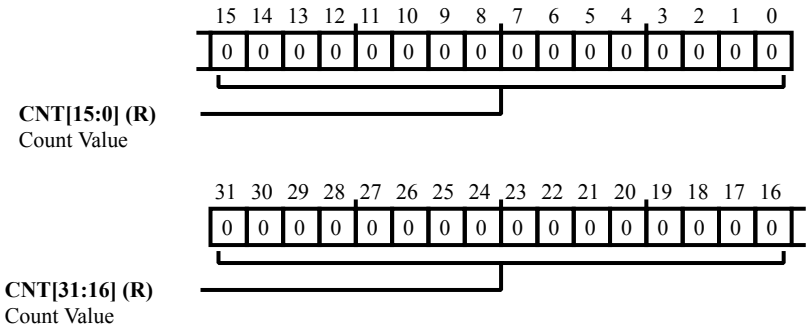

Figure 28-131: EMAC_RXIPV4_HDR_ERR_FRM Register Diagram

Table 28-163: EMAC_RXIPV4_HDR_ERR_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams Header Errors Register

The EMAC_RXIPV4_HDR_ERR_OCT register contains a count of the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter.

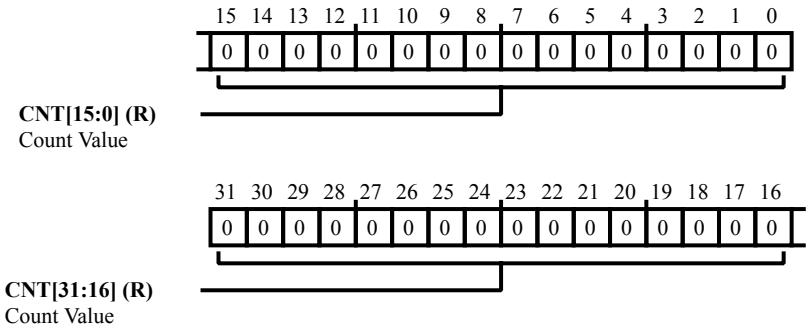

Figure 28-132: EMAC_RXIPV4_HDR_ERR_OCT Register Diagram

Table 28-164: EMAC_RXIPV4_HDR_ERR_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams No Payload Frame Register

The EMAC_RXIPV4_NOPAY_FRM register contains a count of the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine.

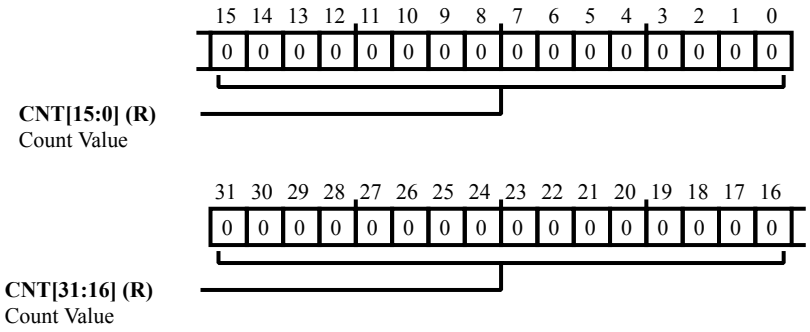

Figure 28-133: EMAC_RXIPV4_NOPAY_FRM Register Diagram

Table 28-165: EMAC_RXIPV4_NOPAY_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 Datagrams No Payload Octets Register

The EMAC_RXIPV4_NOPAY_OCT register contains a count of the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

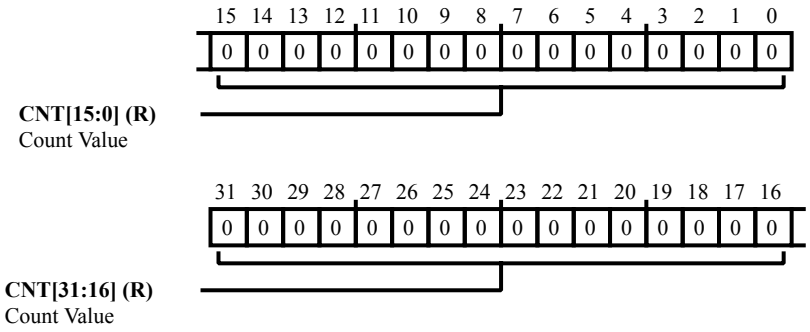

Figure 28-134: EMAC_RXIPV4_NOPAY_OCT Register Diagram

Table 28-166: EMAC_RXIPV4_NOPAY_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 UDP Disabled Frames Register

The EMAC_RXIPV4_UDSBL_FRM register contains a count of the number of good IPv4 datagrams received that had a UDP payload with checksum disabled.

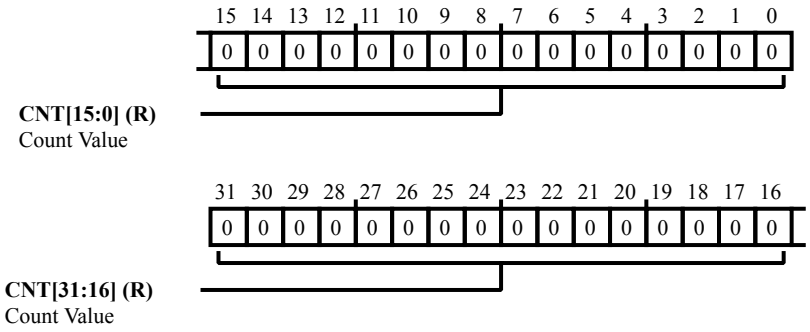

Figure 28-135: EMAC_RXIPV4_UDSBL_FRM Register Diagram

Table 28-167: EMAC_RXIPV4_UDSBL_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv4 UDP Disabled Octets Register

The EMAC_RXIPV4_UDSBL_OCT register contains a count of the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes.

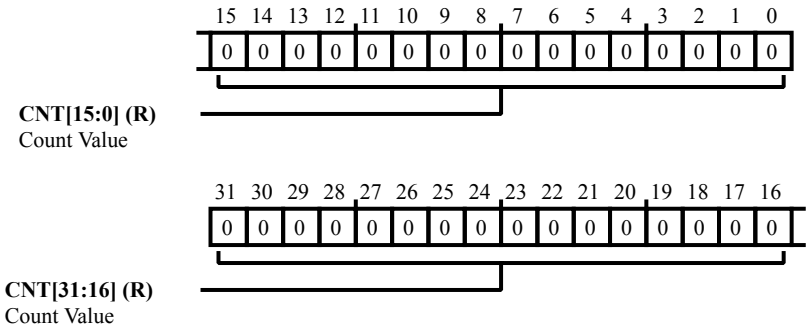

Figure 28-136: EMAC_RXIPV4_UDSBL_OCT Register Diagram

Table 28-168: EMAC_RXIPV4_UDSBL_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 Datagrams Good Frames Register

The EMAC_RXIPV6_GD_FRM register contains a count of the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

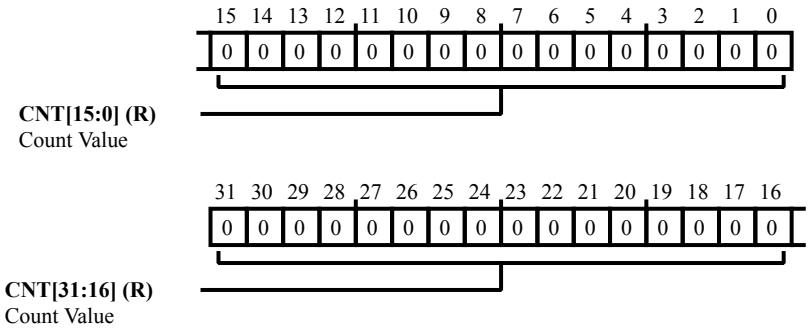

Figure 28-137: EMAC_RXIPV6_GD_FRM Register Diagram

Table 28-169: EMAC_RXIPV6_GD_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 Good Octets Register

The EMAC_RXIPV6_GD_OCT register contains a count of the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data

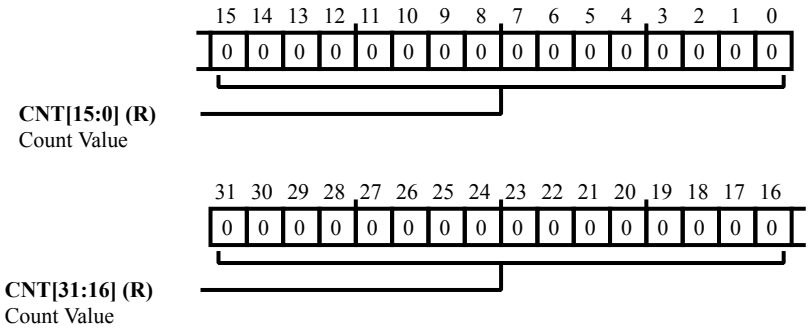

Figure 28-138: EMAC_RXIPV6_GD_OCT Register Diagram

Table 28-170: EMAC_RXIPV6_GD_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 Datagrams Header Error Frames Register

The EMAC_RXIPV6_HDR_ERR_FRM register contains a count of the number of IPv6 datagrams received with header errors (length or version mismatch).

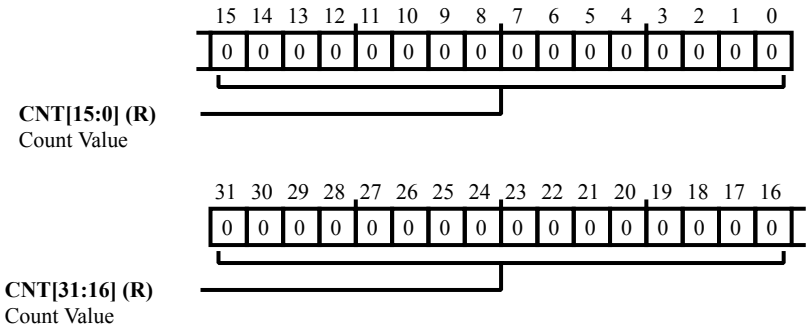

Figure 28-139: EMAC_RXIPV6_HDR_ERR_FRM Register Diagram

Table 28-171: EMAC_RXIPV6_HDR_ERR_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 Header Errors Register

The EMAC_RXIPV6_HDR_ERR_OCT register contains a count of the number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 headers Length field is used to update this counter.

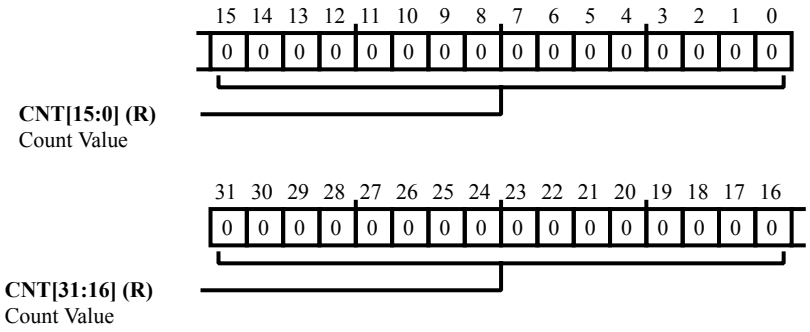

Figure 28-140: EMAC_RXIPV6_HDR_ERR_OCT Register Diagram

Table 28-172: EMAC_RXIPV6_HDR_ERR_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 Datagrams No Payload Frames Register

The EMAC_RXIPV6_NOPAY_FRM register contains a count of the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

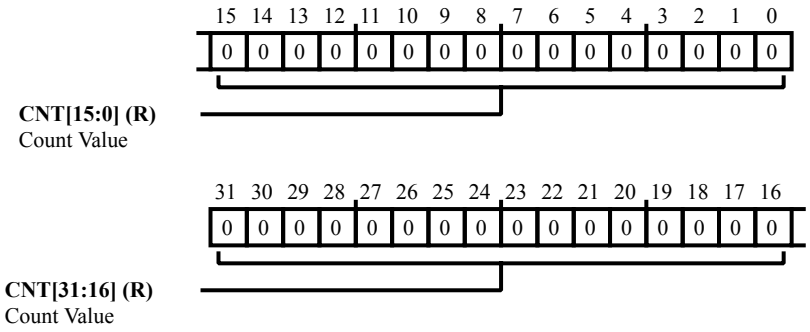

Figure 28-141: EMAC_RXIPV6_NOPAY_FRM Register Diagram

Table 28-173: EMAC_RXIPV6_NOPAY_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx IPv6 No Payload Octets Register

The EMAC_RXIPV6_NOPAY_OCT register contains a count of the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter.

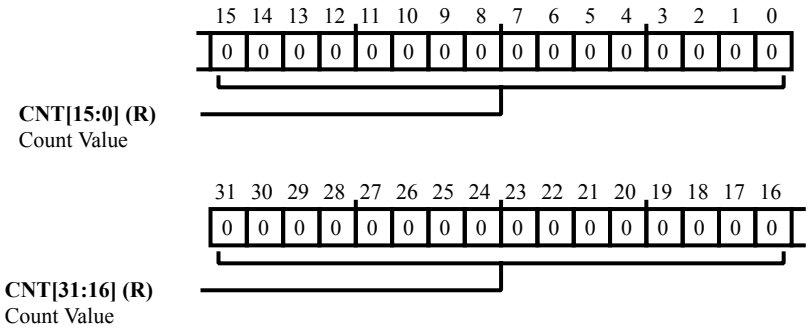

Figure 28-142: EMAC_RXIPV6_NOPAY_OCT Register Diagram

Table 28-174: EMAC_RXIPV6_NOPAY_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Jab Error Register

The EMAC_RXJAB_ERR register contains a count of the number of giant frames received with length greater than 1,518 bytes and with CRC error.

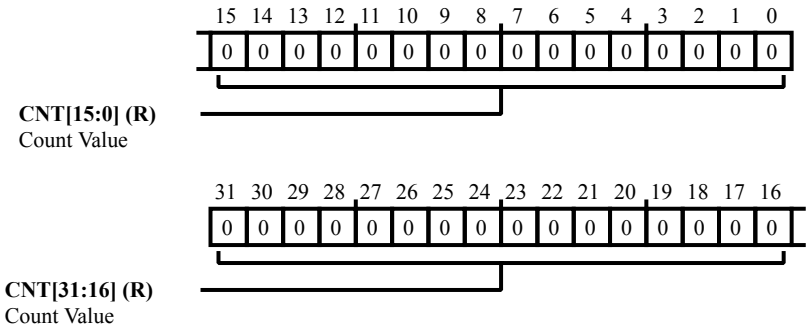

Figure 28-143: EMAC_RXJAB_ERR Register Diagram

Table 28-175: EMAC_RXJAB_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Length Error Register

The EMAC_RXLEN_ERR register contains a count of the number of frames received with length error (Length type field frame size), for all frames with valid length field.

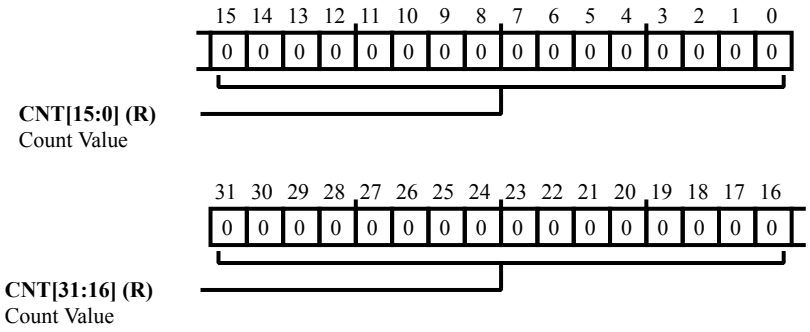

Figure 28-144: EMAC_RXLEN_ERR Register Diagram

Table 28-176: EMAC_RXLEN_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Multicast Frames (Good) Register

The EMAC_RXMCASTFRM_G register contains a count of the number of good multicast frames received.

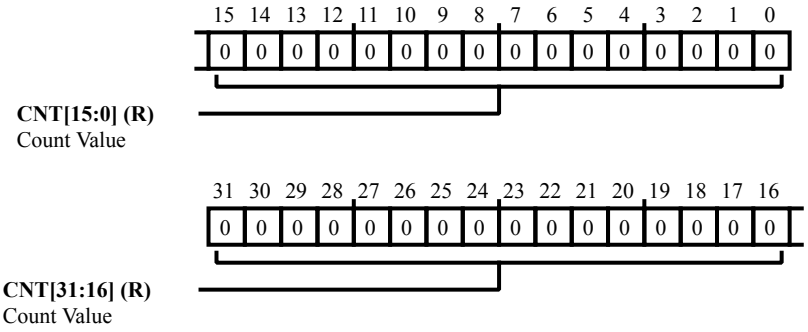

Figure 28-145: EMAC_RXMCASTFRM_G Register Diagram

Table 28-177: EMAC_RXMCASTFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Octet Count (Good) Register

The EMAC_RXOCTCNT_G register contains a count of the number of bytes received, exclusive of preamble, only in good frames.

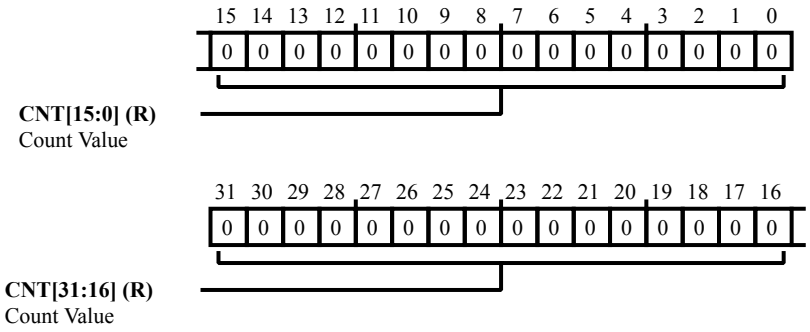

Figure 28-146: EMAC_RXOCTCNT_G Register Diagram

Table 28-178: EMAC_RXOCTCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Octet Count (Good/Bad) Register

The EMAC_RXOCTCNT_GB register contains a count of the number of bytes received, exclusive of preamble, in good and bad frames.

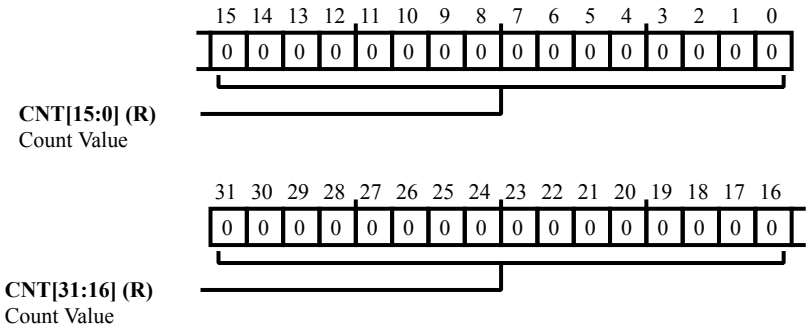

Figure 28-147: EMAC_RXOCTCNT_GB Register Diagram

Table 28-179: EMAC_RXOCTCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Out Of Range Type Register

The EMAC_RXOORTYPE register contains a count of the number of frames received with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

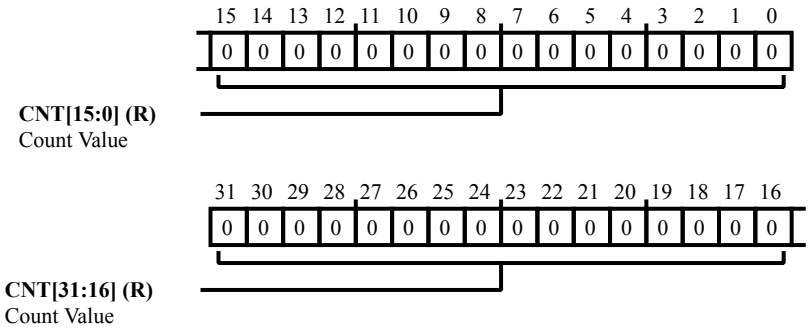

Figure 28-148: EMAC_RXOORTYPE Register Diagram

Table 28-180: EMAC_RXOORTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Oversize (Good) Register

The EMAC_RXOSIZE_G register contains a count of the number of frames received with length greater than the maxsize, without errors.

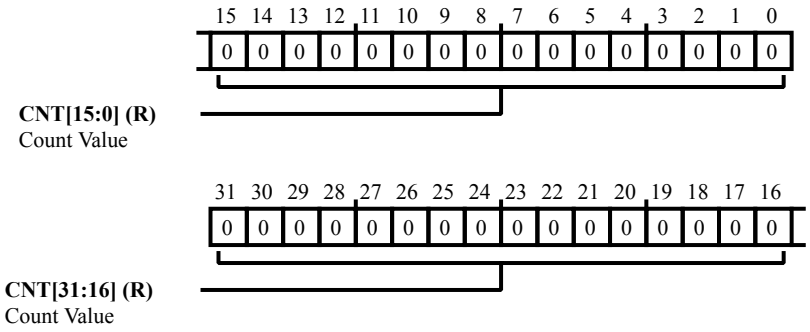

Figure 28-149: EMAC_RXOSIZE_G Register Diagram

Table 28-181: EMAC_RXOSIZE_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Pause Frames Register

The EMAC_RXPAUSEFRM register contains a count of the number of good and valid PAUSE frames received.

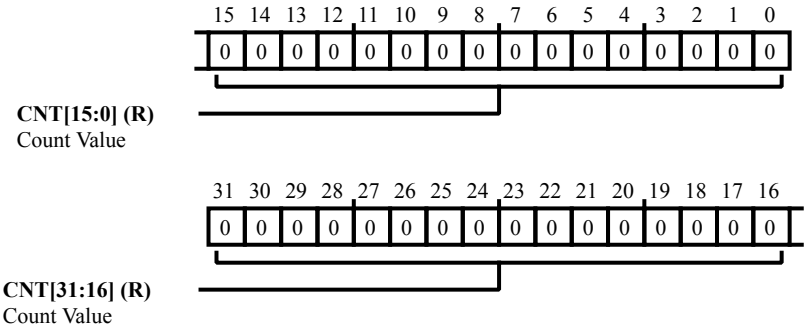

Figure 28-150: EMAC_RXPAUSEFRM Register Diagram

Table 28-182: EMAC_RXPAUSEFRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Error Frames Received Register

The EMAC_RXRCV_ERR register contains a count of the number of frames received with Receive error or Frame Extension error on GMII or MII interface

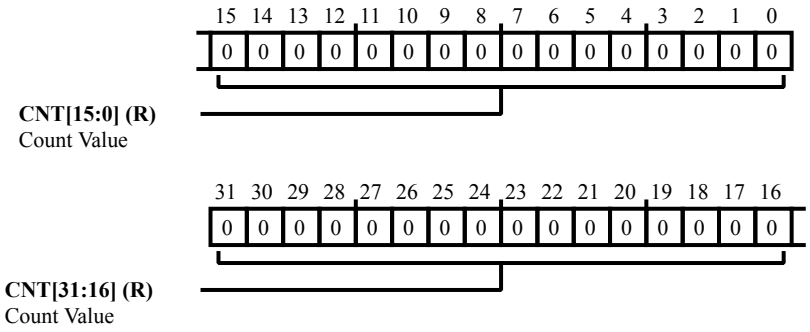

Figure 28-151: EMAC_RXRCV_ERR Register Diagram

Table 28-183: EMAC_RXRCV_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Runt Error Register

The EMAC_RXRUNT_ERR register contains a count of the number of frames received with runt error.

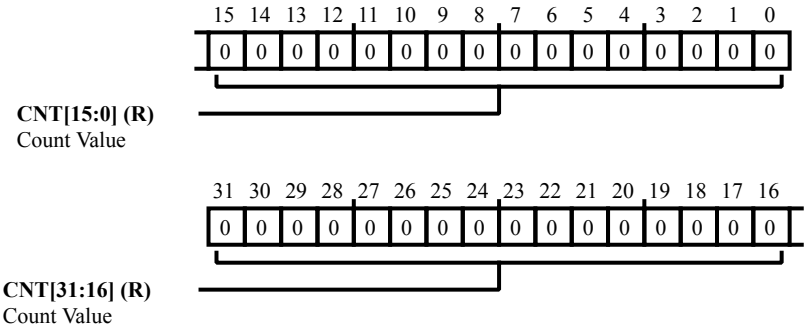

Figure 28-152: EMAC_RXRUNT_ERR Register Diagram

Table 28-184: EMAC_RXRUNT_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx TCP Error Frames Register

The EMAC_RXTCP_ERR_FRM register contains a count of the number of good IP datagrams whose TCP payload has a checksum error.

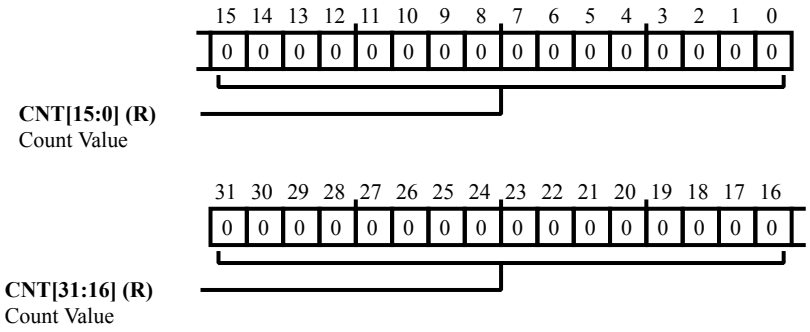

Figure 28-153: EMAC_RXTCP_ERR_FRM Register Diagram

Table 28-185: EMAC_RXTCP_ERR_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx TCP Error Octets Register

The EMAC_RXTCP_ERR_OCT register contains a count of the number of bytes received in a TCP segment with checksum errors.

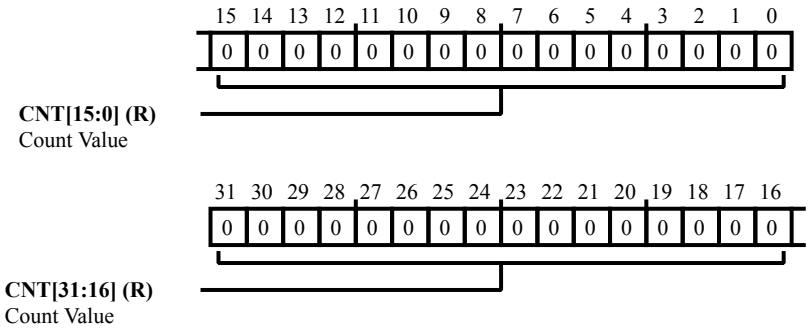

Figure 28-154: EMAC_RXTCP_ERR_OCT Register Diagram

Table 28-186: EMAC_RXTCP_ERR_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx TCP Good Frames Register

The EMAC_RXTCP_GD_FRM register contains a count of the number of good IP datagrams with a good TCP payload.

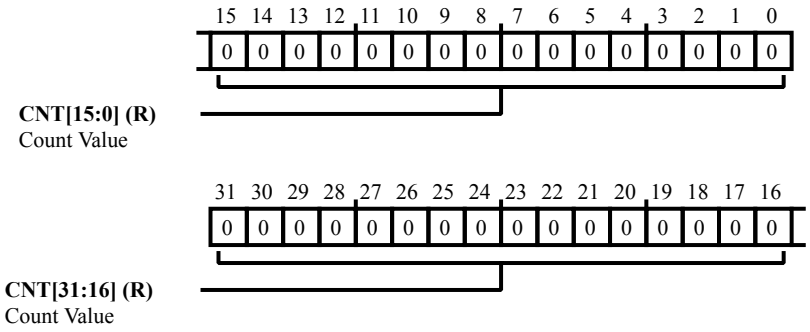

Figure 28-155: EMAC_RXTCP_GD_FRM Register Diagram

Table 28-187: EMAC_RXTCP_GD_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx TCP Good Octets Register

The EMAC_RXTCP_GD_OCT register contains a count of the number of bytes received in a good TCP segment.

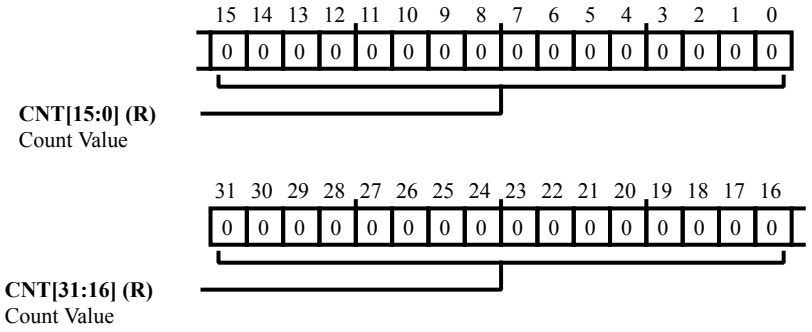

Figure 28-156: EMAC_RXTCP_GD_OCT Register Diagram

Table 28-188: EMAC_RXTCP_GD_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Unicast Frames (Good) Register

The EMAC_RXUCASTFRM_G register contains a count of the number of good unicast frames received.

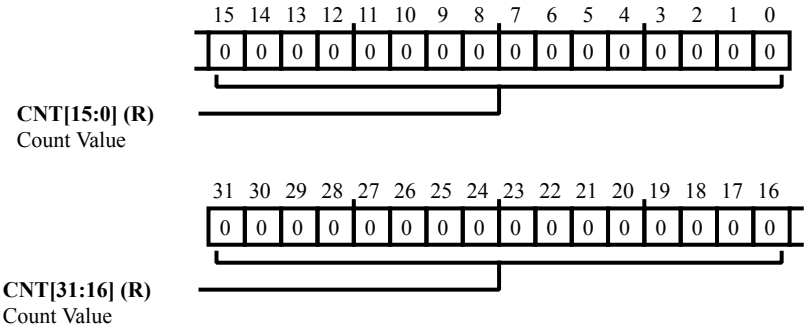

Figure 28-157: EMAC_RXUCASTFRM_G Register Diagram

Table 28-189: EMAC_RXUCASTFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx UDP Error Frames Register

The EMAC_RXUDP_ERR_FRM register contains a count of the number of good IP datagrams whose UDP payload has a checksum error.

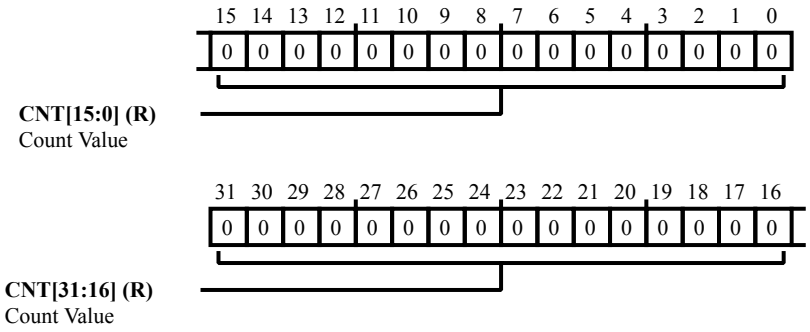

Figure 28-158: EMAC_RXUDP_ERR_FRM Register Diagram

Table 28-190: EMAC_RXUDP_ERR_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx UDP Error Octets Register

The EMAC_RXUDP_ERR_OCT register contains a count of the number of bytes received in a UDP segment that had checksum errors.

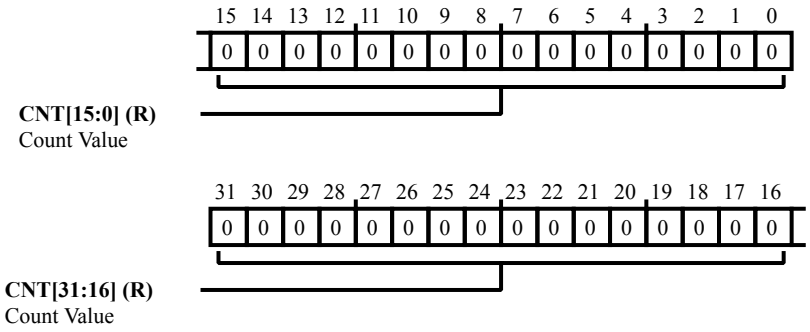

Figure 28-159: EMAC_RXUDP_ERR_OCT Register Diagram

Table 28-191: EMAC_RXUDP_ERR_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx UDP Good Frames Register

The EMAC_RXUDP_GD_FRM register contains a count of the number of good IP datagrams with a good UDP payload. This counter is not updated when the rxipv4_udsbl_frms counter is incremented.

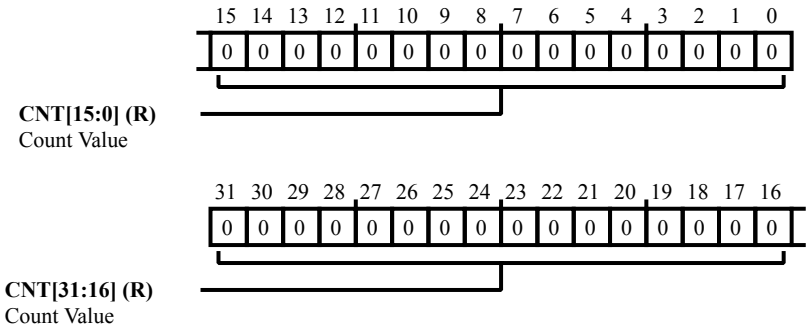

Figure 28-160: EMAC_RXUDP_GD_FRM Register Diagram

Table 28-192: EMAC_RXUDP_GD_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx UDP Good Octets Register

The EMAC_RXUDP_GD_OCT register contains a count of the number of bytes received in a good UDP segment. This counter (and the counters below) does not count IP header bytes.

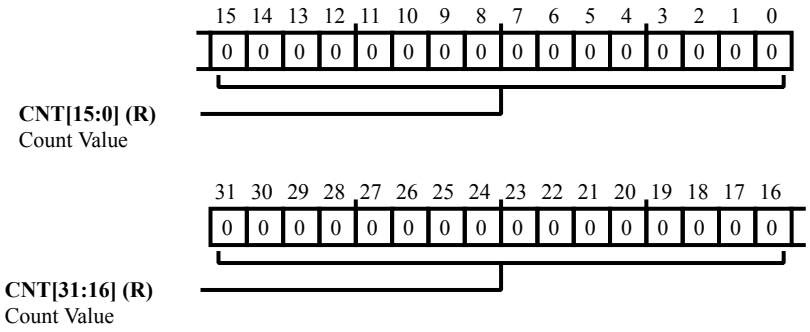

Figure 28-161: EMAC_RXUDP_GD_OCT Register Diagram

Table 28-193: EMAC_RXUDP_GD_OCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Undersize (Good) Register

The EMAC_RXUSIZE_G register contains a count of the number of frames received with length less than 64 bytes, without any errors.

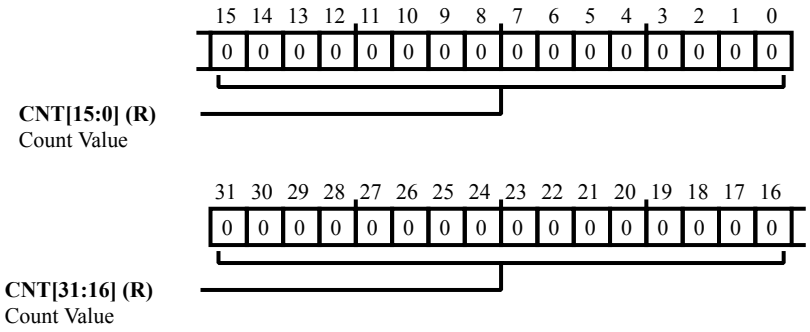

Figure 28-162: EMAC_RXUSIZE_G Register Diagram

Table 28-194: EMAC_RXUSIZE_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx VLAN Frames (Good/Bad) Register

The EMAC_RXVLANFRM_GB register contains a count of the number of good and bad VLAN frames received.

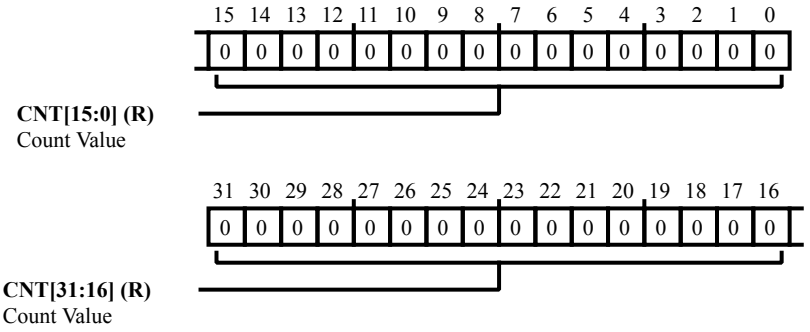

Figure 28-163: EMAC_RXVLANFRM_GB Register Diagram

Table 28-195: EMAC_RXVLANFRM_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Rx Watch Dog Error Register

The EMAC_RXWDOG_ERR register contains a count of the number of frames received with error due to watchdog timeout error (frames with a data load larger than 2,048 bytes).

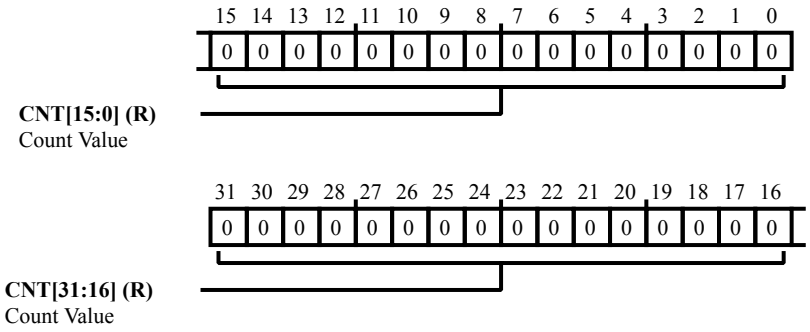

Figure 28-164: EMAC_RXWDOG_ERR Register Diagram

Table 28-196: EMAC_RXWDOG_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

SMI Address Register

The EMAC_SMI_ADDR register contains the station management interface address and feature settings.

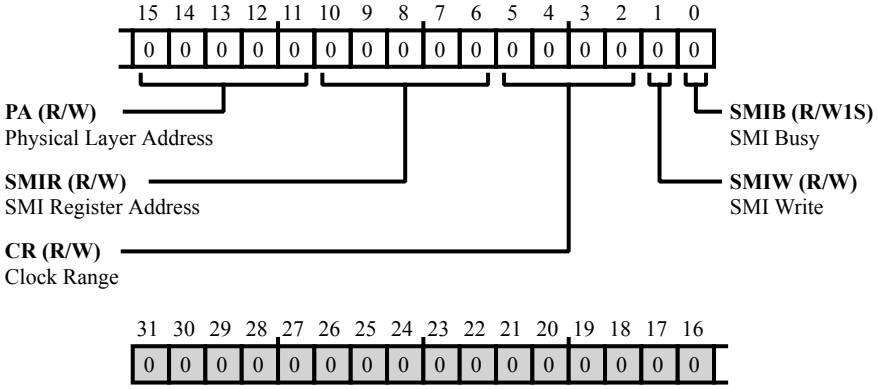

Figure 28-165: EMAC_SMI_ADDR Register Diagram

Table 28-197: EMAC_SMI_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:11 (R/W)	PA	Physical Layer Address. The EMAC_SMI_ADDR.PA bits select the PHY. This field tells which of the 32 possible PHY devices are being accessed.	
10:6 (R/W)	SMIR	SMI Register Address. The EMAC_SMI_ADDR.SMIR bits select the desired Station Management Interface register in the selected PHY device.	
5:2 (R/W)	CR	Clock Range. The EMAC_SMI_ADDR.CR bits select the Clock Range, determining the frequency of the MDC clock as per the SCLK0 frequency. The suggested range of SCLK0 frequency applicable for each value below (when Bit[5] =0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When the MSB of this field is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when SCLK0=100 MHz and you program these bits to b#1010, the resulting MDC clock is 12.5 MHz, which is outside the limit of IEEE 802.3 specified range. Use the values shown only if the interface chips support faster MDC clocks.	
		0	MDC Clock= SCLK0/42 (for SCLK0=60-100MHz)
		1	MDC Clock= SCLK0/62 (for SCLK0=100-125 MHz)
		2	MDC Clock= SCLK0/16 (for SCLK0=20-35 MHz)
		3	MDC Clock= SCLK0/26 (for SCLK0=35-60 MHz)
		8	MDC Clock= SCLK0/4

Table 28-197: EMAC_SMI_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		9	MDC Clock= SCLK0/6
		10	MDC Clock= SCLK0/8
		11	MDC Clock= SCLK0/10
		12	MDC Clock= SCLK0/12
		13	MDC Clock= SCLK0/14
		14	MDC Clock= SCLK0/16
		15	MDC Clock= SCLK0/18
1 (R/W)	SMIW	SMI Write. The `EMAC_SMI_ADDR.SMIW` bit, when set, tells the PHY this is a Write operation using the Station Management Interface Data register. If this bit is not set, this is a Read operation.	
0 (R/W1S)	SMIB	SMI Busy. The `EMAC_SMI_ADDR.SMIB` bit should read low (=0) before writing to the `EMAC_SMI_ADDR` and `EMAC_SMI_DATA` registers. This bit must also =0 during a Write to `EMAC_SMI_ADDR`. During a PHY register access, this bit is set (=1) by the Application to indicate that a Read or Write access is in progress. The `EMAC_SMI_DATA` register should be kept valid until this bit is cleared by the MAC during a PHY Write operation. `EMAC_SMI_DATA` is invalid until this bit is cleared by the MAC during a PHY Read operation. The `EMAC_SMI_ADDR` should not be written to until this bit is cleared.	

SMI Data Register

The EMAC_SMI_DATA register contains the station management interface data.

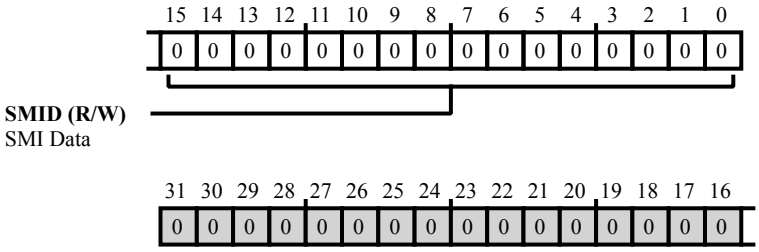

Figure 28-166: EMAC_SMI_DATA Register Diagram

Table 28-198: EMAC_SMI_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SMID	SMI Data. The EMAC_SMI_DATA.SMID bits contain the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.

Time Stamp Addend Register

The EMAC_TM_ADDEND register lets software adjust the clock frequency linearly to match the master clock frequency.

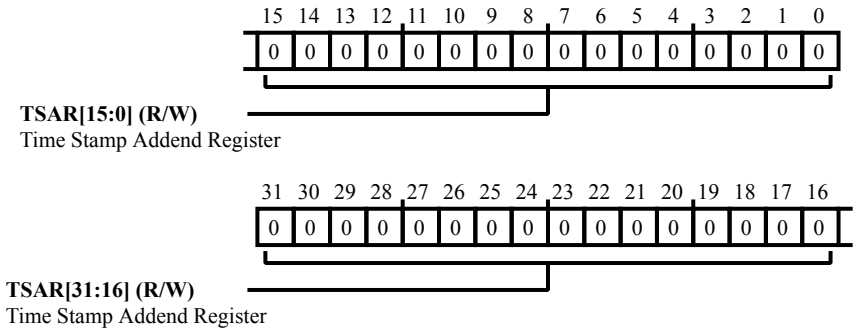

Figure 28-167: EMAC_TM_ADDEND Register Diagram

Table 28-199: EMAC_TM_ADDEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSAR	Time Stamp Addend Register. The EMAC_TM_ADDEND.TSAR bits indicate the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

Time Stamp Auxiliary TS Nano Seconds Register

The EMAC_TM_AUXSTMP_NSEC register contains the low 32 bits (nanoseconds field) of the auxiliary time stamp.

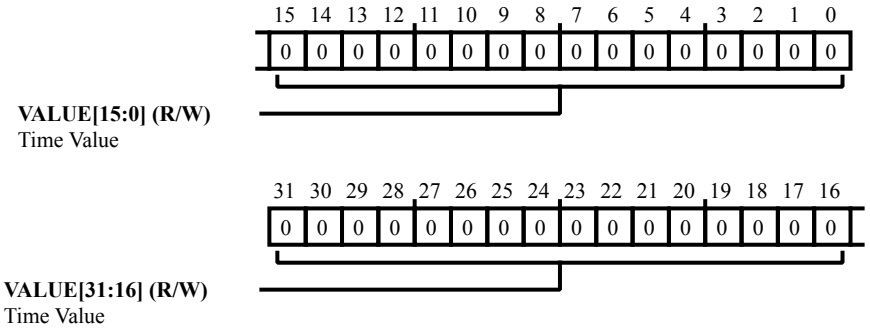

Figure 28-168: EMAC_TM_AUXSTMP_NSEC Register Diagram

Table 28-200: EMAC_TM_AUXSTMP_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Time Value.

Time Stamp Auxiliary TM Seconds Register

The EMAC_TM_AUXSTMP_SEC register contains the low 32 bits of the seconds field of the auxiliary time stamp.

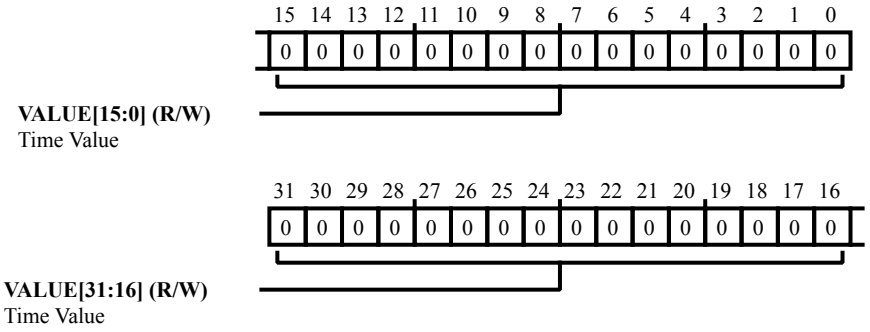

Figure 28-169: EMAC_TM_AUXSTMP_SEC Register Diagram

Table 28-201: EMAC_TM_AUXSTMP_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Time Value.

Time Stamp Control Register

The EMAC_TM_CTL register controls time stamp generation and update. The EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA, and EMAC_TM_CTL.TSEVNTENA bits work together to decide the set of PTP packet types for which snapshot needs to be taken. (Encoding shown in table.)

SNAPTYPSEL()	TSMSTRENA	TSEVNTENA	Messages for which snapshot is taken
00	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	X	X	SYNC, Delay_Req
11	X	X	Pdelay_Req, Pdelay_Resp

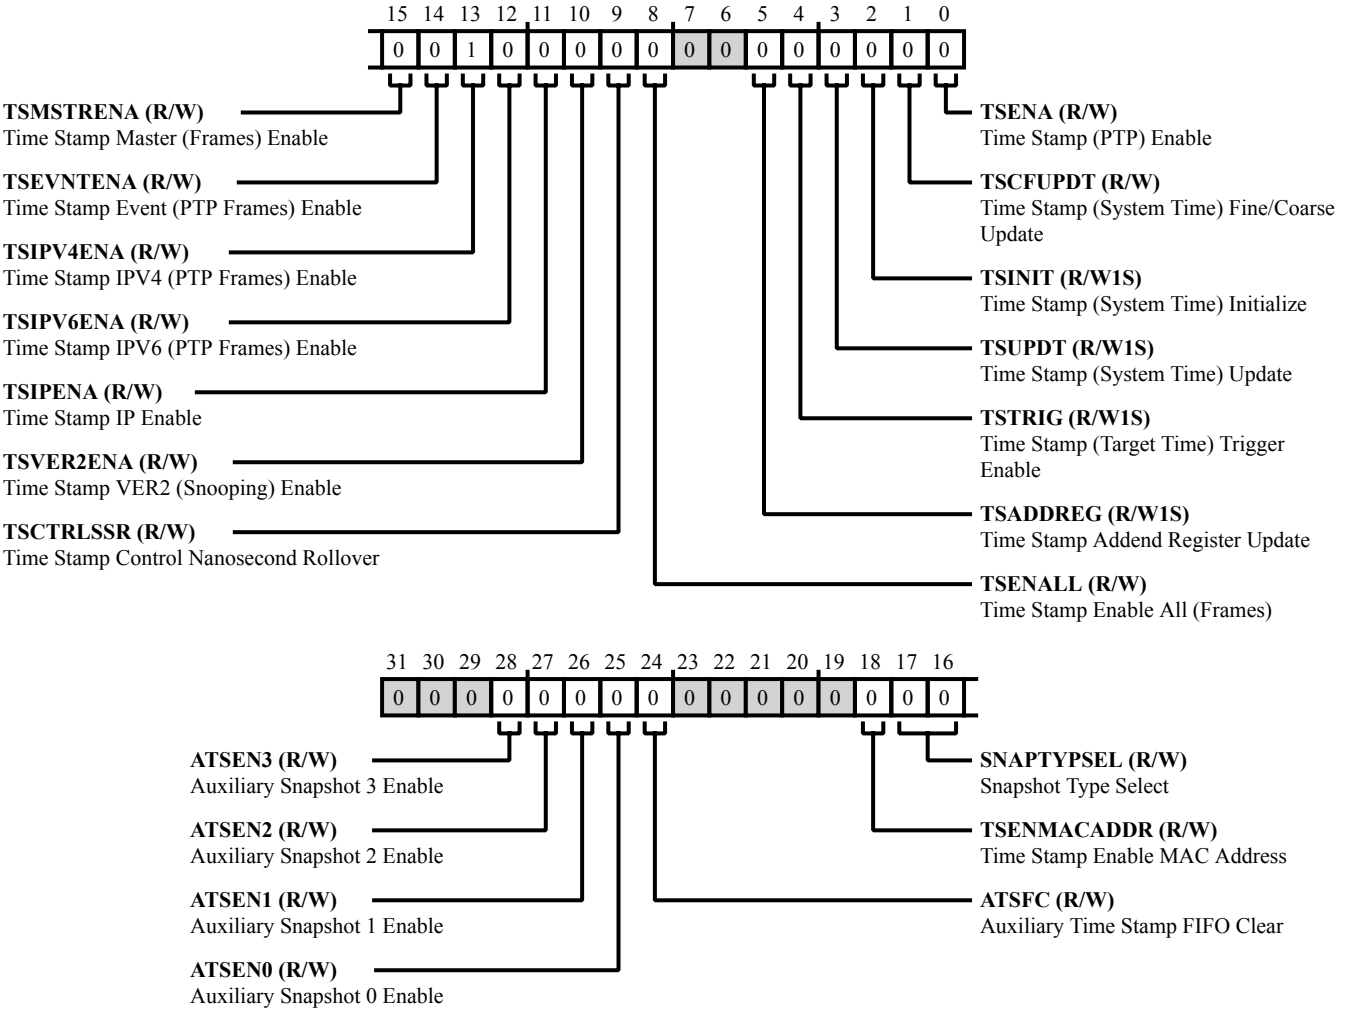

Figure 28-170: EMAC_TM_CTL Register Diagram

Table 28-202: EMAC_TM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (R/W)	ATSEN3	Auxiliary Snapshot 3 Enable. The `EMAC_TM_CTL.ATSEN3` bit, controls capturing the Auxiliary Snapshot Trigger 3
27 (R/W)	ATSEN2	Auxiliary Snapshot 2 Enable. The `EMAC_TM_CTL.ATSEN2` bit, controls capturing the Auxiliary Snapshot Trigger 2
26 (R/W)	ATSEN1	Auxiliary Snapshot 1 Enable. The `EMAC_TM_CTL.ATSEN1` bit, controls capturing the Auxiliary Snapshot Trigger 1

Table 28-202: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	ATSEN0	Auxiliary Snapshot 0 Enable. The EMAC_TM_CTL.ATSEN0 bit, controls capturing the Auxiliary Snapshot Trigger 0	
24 (R/W)	ATSFC	Auxiliary Time Stamp FIFO Clear. The EMAC_TM_CTL.ATSFC bit, when set, resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is cleared, auxiliary snapshots gets stored in the FIFO.	
18 (R/W)	TSENMACADDR	Time Stamp Enable MAC Address. The EMAC_TM_CTL.TSENMACADDR bit, when set, uses the DA MAC address (that matches the EMAC_ADDR0_LO and EMAC_ADDR0_HI registers) to filter the PTP frames when PTP is sent directly over Ethernet.	
		0	Disable PTP MAC address filter
		1	Enable PTP MAC address filter
17:16 (R/W)	SNAPTYPSEL	Snapshot Type Select. The EMAC_TM_CTL.SNAPTYPSEL bits along with bit 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken. (See the table in the EMAC_TM_CTL register description.)	
15 (R/W)	TSMSTRENA	Time Stamp Master (Frames) Enable. The EMAC_TM_CTL.TSMSTRENA bit, when set, takes the snapshot for messages relevant to master node only else snapshot is taken for PTP messages relevant to slave node.	
		0	Enable Snapshot for Slave Messages
		1	Enable Snapshot for Master Messages
14 (R/W)	TSEVNTENA	Time Stamp Event (PTP Frames) Enable. The EMAC_TM_CTL.TSEVNTENA bit, when set, takes the time stamp snapshot for PTP event messages only (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all PTP messages except Announce, Management, and Signaling.	
		0	Enable Time Stamp for All Messages
		1	Enable Time Stamp for Event Messages Only

Table 28-202: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TSIPV4ENA	Time Stamp IPV4 (PTP Frames) Enable. The EMAC_TM_CTL.TSIPV4ENA bit, when set, directs the EMAC receiver to process the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default.	
		0	Disable Time Stamp for PTP Over IPv4 Frames
		1	Enable Time Stamp for PTP Over IPv4 Frames
12 (R/W)	TSIPV6ENA	Time Stamp IPV6 (PTP Frames) Enable. The EMAC_TM_CTL.TSIPV6ENA bit, when set, directs the EMAC receiver to process PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.	
		0	Disable Time Stamp for PTP Over IPv6 frames
		1	Enable Time Stamp for PTP Over IPv6 Frames
11 (R/W)	TSIPENA	Time Stamp IP Enable. The EMAC_TM_CTL.TSIPENA bit, when set, directs the EMAC receiver to process the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores PTP over Ethernet packets.	
		0	Disable PTP Over Ethernet Frames
		1	Enable PTP Over Ethernet Frames
10 (R/W)	TSVER2ENA	Time Stamp VER2 (Snooping) Enable. The EMAC_TM_CTL.TSVER2ENA bit, when set, processes the PTP packets using the 1588 version 2 format (enables PTP packet snooping for VER2) else processed using the version 1 format.	
		0	Disable packet snooping for V2 frames
		1	Enable packet snooping for V2 frames
9 (R/W)	TSCTRLSSR	Time Stamp Control Nanosecond Rollover. The EMAC_TM_CTL.TSCTRLSSR bit, when set, rolls over the EMAC_TM_NSEC register after 0x3B9A_C9FF value (10^9-1) and increments the EMAC_TM_SEC register. When reset, the roll over value of EMAC_TM_NSEC register is 0x7FFF_FFFF. The nanosecond increment has to be programmed correctly depending on the PTP reference clock frequency and this bit value.	
		0	Roll Over Nanosecond After 0x7FFFFFFF
		1	Roll Over Nanosecond After 0x3B9AC9FF

Table 28-202: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	TSENALL	Time Stamp Enable All (Frames). The EMAC_TM_CTL.TSENALL bit, when set, enables the time stamp snapshot for all frames received by the core.	
		0	Disable timestamp for all frames
		1	Enable timestamp for all frames
5 (R/W1S)	TSADDREG	Time Stamp Addend Register Update. The EMAC_TM_CTL.TSADDREG bit, when set, updates the contents of the EMAC_TM_ADDEND register for fine correction. This bit is cleared when the update is completed. This bit should be zero before setting it.	
4 (R/W1S)	TSTRIG	Time Stamp (Target Time) Trigger Enable. The EMAC_TM_CTL.TSTRIG bit, when set, generates the time stamp interrupt when the System Time becomes greater than the value written in Time Stamp Target Time Seconds register. This bit is reset after the generation of the Time Stamp Trigger Interrupt.	
		1	Interrupt (TS) if system time is greater than target time register
3 (R/W1S)	TSUPDT	Time Stamp (System Time) Update. The EMAC_TM_CTL.TSUPDT bit, when set, updates (adds/subtracts) the system time with the value specified in the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. This bit should read =0 before updating it. This bit is reset when the update is completed in hardware. The EMAC_TM_NSEC register is not updated.	
		1	System time updated with Time stamp register values
2 (R/W1S)	TSINIT	Time Stamp (System Time) Initialize. The EMAC_TM_CTL.TSINIT bit, when set, initializes (over-writes) the system time with the value specified in the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. This bit should read =0 before updating it. This bit is reset when the initialization is complete. Only the EMAC_TM_NSEC register can be initialized.	
		1	System time initialized with Time stamp register values
1 (R/W)	TSCFUPDT	Time Stamp (System Time) Fine/Coarse Update. The EMAC_TM_CTL.TSCFUPDT bit, when set, indicates that the system time update is done using the fine correction method. When reset, it indicates the system time correction to be done using Coarse method.	
		0	Use Coarse Correction Method for System Time Update
		1	Use Fine Correction Method for System Time Update

Table 28-202: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TSENA	Time Stamp (PTP) Enable. The `EMAC_TM_CTL.TSENA` bit, when set, enables PTP module for time stamping transmitted and received frames. It also enables System Time which is used for time stamping the frames. Programs should initialize the System Time after setting this bit.	
		0	Disable PTP Module
		1	Enable PTP Module

Time Stamp High Second Register

The EMAC_TM_HISEC register contains the upper 32 bits of the seconds field of the system time.

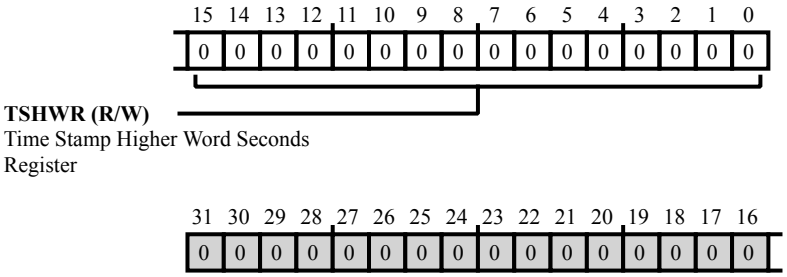

Figure 28-171: EMAC_TM_HISEC Register Diagram

Table 28-203: EMAC_TM_HISEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TSHWR	Time Stamp Higher Word Seconds Register. The EMAC_TM_HISEC.TSHWR bit field contains the most significant 16-bits of the time stamp seconds value. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the EMAC_TM_SEC register.

Time Stamp Nanoseconds Register

The EMAC_TM_NSEC register contains the nanoseconds field of the system time.

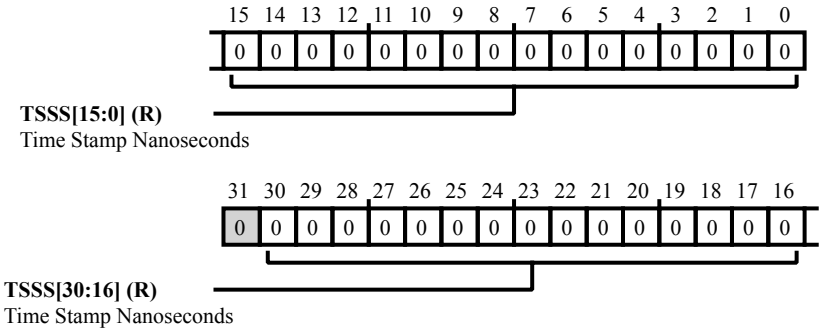

Figure 28-172: EMAC_TM_NSEC Register Diagram

Table 28-204: EMAC_TM_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:0 (R/NW)	TSSS	Time Stamp Nanoseconds. The value in the EMAC_TM_NSEC.TSSS bit field has the nanosecond representation of time, with an accuracy of 0.46 nanosecond. (When EMAC_TM_CTL.TSCTRLSSR is set, each bit represents 1 ns and the maximum value will be 0x3B9A_C9FF, after which it rolls-over to zero).

Time Stamp Nanoseconds Update Register

The EMAC_TM_NSECUPDT register contains the low 32 bits to be added to, subtracted from, or written to the nanoseconds field of the system time.

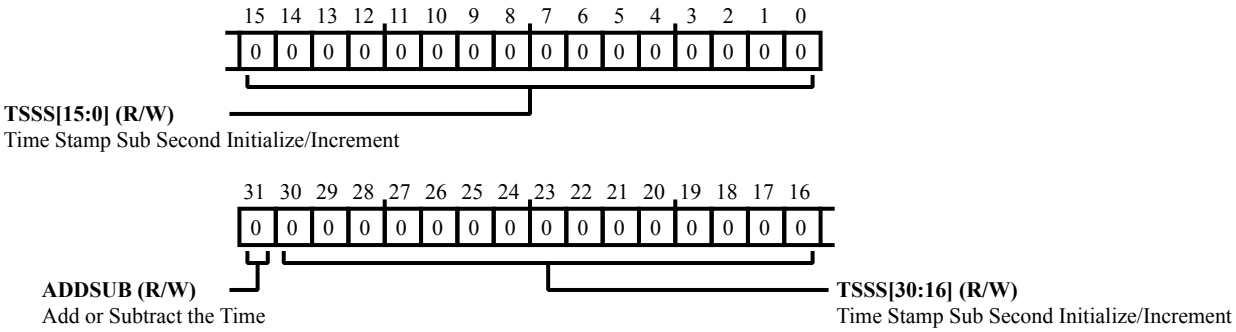

Figure 28-173: EMAC_TM_NSECUPDT Register Diagram

Table 28-205: EMAC_TM_NSECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ADDSUB	Add or Subtract the Time. The EMAC_TM_NSECUPDT.ADDSUB bit, when set, subtracts the time value with the contents of the update registers. When this bit is reset, the time value is added with the contents of the update registers.
30:0 (R/W)	TSSS	Time Stamp Sub Second Initialize/Increment. The value in the EMAC_TM_NSECUPDT.TSSS bit field indicates the time, in nanoseconds, to be initialized or added to or subtracted from the system time nanoseconds.

Time Stamp PPS Interval Register

The EMAC_TM_PPS0INTVL register contains the interval value for the time between rising edges (period) of PPS output.

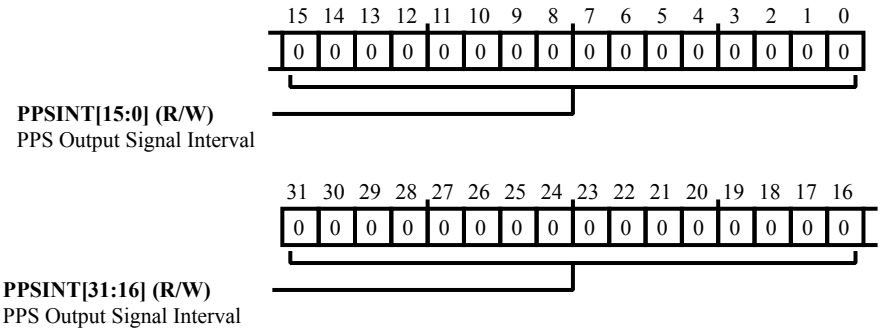

Figure 28-174: EMAC_TM_PPS0INTVL Register Diagram

Table 28-206: EMAC_TM_PPS0INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_TM_PPS0INTVL.PPSINT bits store the interval between the rising edges of PPS signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS signal output is 100ns (that is, 5 units of sub-second increment value), then you should program value 4 (5-1) in this register.

Time Stamp Target Time Nanoseconds Register

The EMAC_TM_PPS0NTGTM register contains the high 32 bits of the target nanoseconds field for comparison to the corresponding system time field.

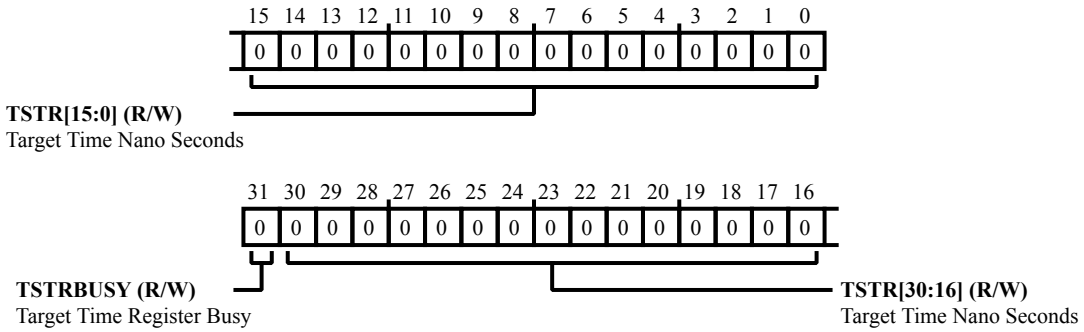

Figure 28-175: EMAC_TM_PPS0NTGTM Register Diagram

Table 28-207: EMAC_TM_PPS0NTGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TSTRBUSY	Target Time Register Busy. The EMAC_TM_PPS0NTGTM.TSTRBUSY bit is set when Flexible PPS is enabled and the PPS Frequency Control bit field in the PPS Control register is programmed to 0001, 0010 or 0100. Programming the PPS Frequency Control bit field to 0001, 0010 or 0100, instructs the core to synchronize the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers to the PTP clock domain. The EMAC clears this bit after synchronizing the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers to the PTP clock domain The application must not update the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.
30:0 (R/W)	TSTR	Target Time Nano Seconds. The EMAC_TM_PPS0NTGTM.TSTR bit field stores the time in (signed) nanoseconds. When the value of the time stamp matches the both EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers, based on the Target Time Register Mode bit field in the PPS control register, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when the Target Time Register Mode bit field is set. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.

Time Stamp Target Time Seconds Register

The EMAC_TM_PPS0TGTM register contains the high 32 bits of the target seconds field for comparison to the corresponding system time field.

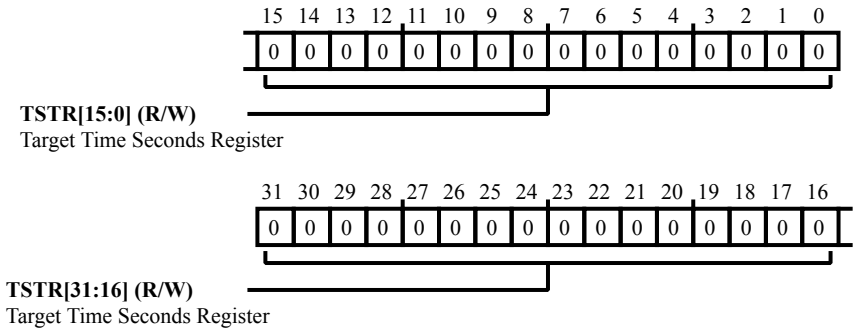

Figure 28-176: EMAC_TM_PPS0TGTM Register Diagram

Table 28-208: EMAC_TM_PPS0TGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSTR	Target Time Seconds Register. The EMAC_TM_PPS0TGTM.TSTR bit field stores the time in seconds. When the time stamp value matches or exceeds both the value in this field and the value in the EMAC_TM_NSEC register, based on the selection in the Target Time Register Mode bit field, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled).

PPS Width Register

The EMAC_TM_PPS0WIDTH register contains the interval value for the time between a rising and the next falling edge (width) of PPS output.

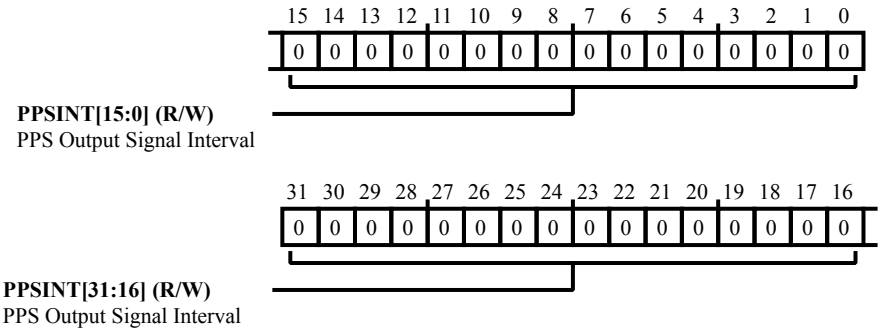

Figure 28-177: EMAC_TM_PPS0WIDTH Register Diagram

Table 28-209: EMAC_TM_PPS0WIDTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_TM_PPS0WIDTH.PPSINT bits store the interval between a rising edge and the next falling edge (width) of PPS output in terms of units of sub second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns) and the desired width of the PPS signal output is 60 ns (3 units of sub-second increment value), program the value 2 (3-1) in this register.

PPS 1 Interval Register

The EMAC_TM_PPS1INTVL register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output.

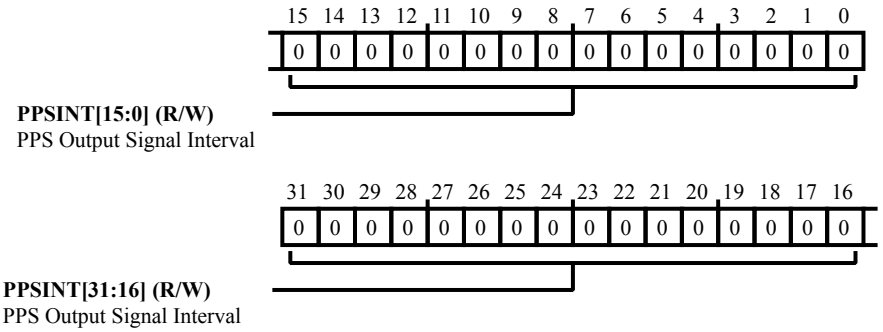

Figure 28-178: EMAC_TM_PPS1INTVL Register Diagram

Table 28-210: EMAC_TM_PPS1INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_TM_PPS1INTVL.PPSINT bit field contains the number of units of sub-second increment value between the rising edges of PPS0 signal output.

PPS 1 Target Time Nanoseconds Register

The EMAC_TM_PPS1NTGTM register is present only when the IEEE 1588 time-stamp feature is selected without external time-stamp input.

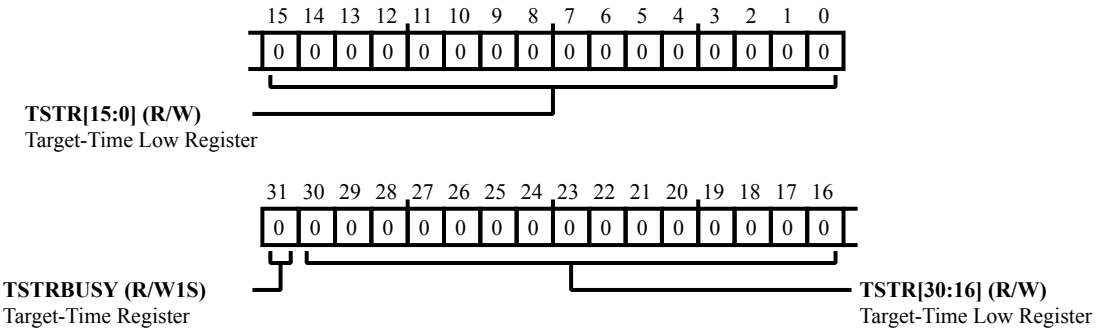

Figure 28-179: EMAC_TM_PPS1NTGTM Register Diagram

Table 28-211: EMAC_TM_PPS1NTGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	TSTRBUSY	Target-Time Register. The EMAC_TM_PPS1NTGTM.TSTRBUSY bit field is cleared to 1b0 by the core (self clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.
30:0 (R/W)	TSTR	Target-Time Low Register.

PPS 1 Target Time Seconds Register

The EMAC_TM_PPS1TGTM register schedule an interrupt event when the system time exceeds the value programmed in these registers.

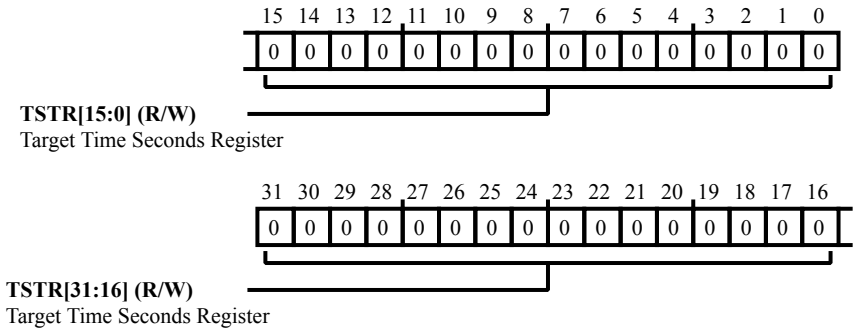

Figure 28-180: EMAC_TM_PPS1TGTM Register Diagram

Table 28-212: EMAC_TM_PPS1TGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSTR	Target Time Seconds Register. The EMAC_TM_PPS1TGTM.TSTR bit field stores the time in seconds. When the time-stamp value matches or exceeds both target time-stamp registers, the MAC starts or stops the PPS signal output and generates an interrupt.

PPS 1 Width Register

The EMAC_TM_PPS1WIDTH register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output

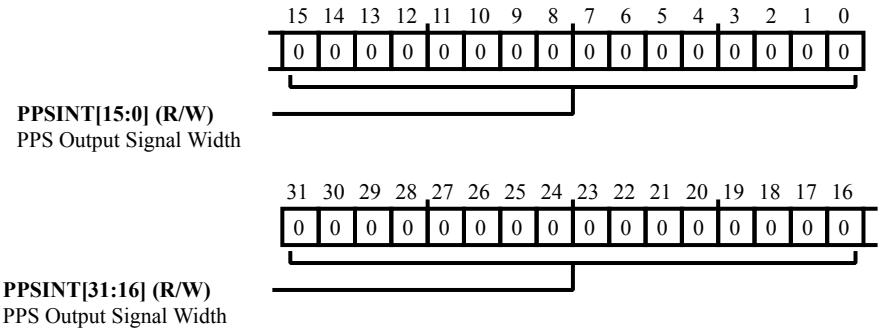

Figure 28-181: EMAC_TM_PPS1WIDTH Register Diagram

Table 28-213: EMAC_TM_PPS1WIDTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Width. The EMAC_TM_PPS1WIDTH.PPSINT bits store the interval between a rising edge and the next falling edge (width) of PPS output in terms of units of sub second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns) and the desired width of the PPS signal output is 60 ns (3 units of sub-second increment value), program the value 2 (3-1) in this register.

PPS 2 Interval Register

The EMAC_TM_PPS2INTVL register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output

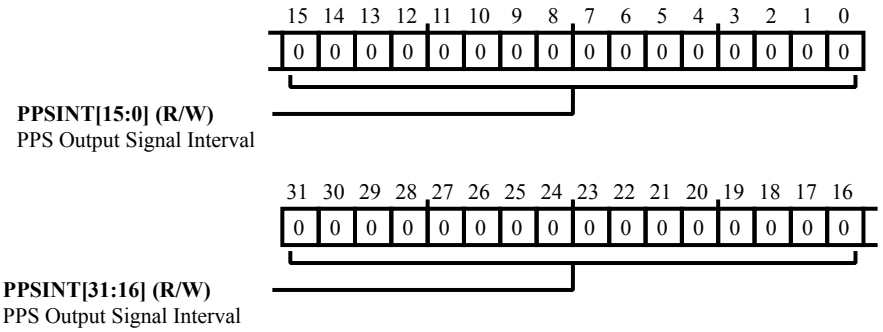

Figure 28-182: EMAC_TM_PPS2INTVL Register Diagram

Table 28-214: EMAC_TM_PPS2INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_TM_PPS2INTVL.PPSINT bit field contains the number of units of sub-second increment value between the rising edges of PPS2 signal output.

PPS 2 Target Time Nanoseconds Register

The EMAC_TM_PPS2NTGTM register is present only when the IEEE 1588 Time stamp feature is selected without external time stamp input.

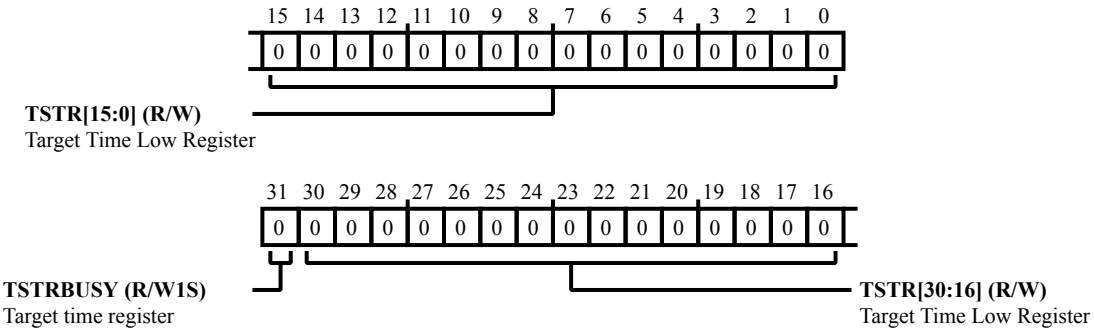

Figure 28-183: EMAC_TM_PPS2NTGTM Register Diagram

Table 28-215: EMAC_TM_PPS2NTGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	TSTRBUSY	Target time register. The EMAC_TM_PPS2NTGTM.TSTRBUSY bit field is cleared to 1b0 by the core (self clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.
30:0 (R/W)	TSTR	Target Time Low Register.

PPS 2 Target Time Seconds Register

The EMAC_TM_PPS2TGTM register schedule an interrupt event when the system time exceeds the value programmed in these registers.

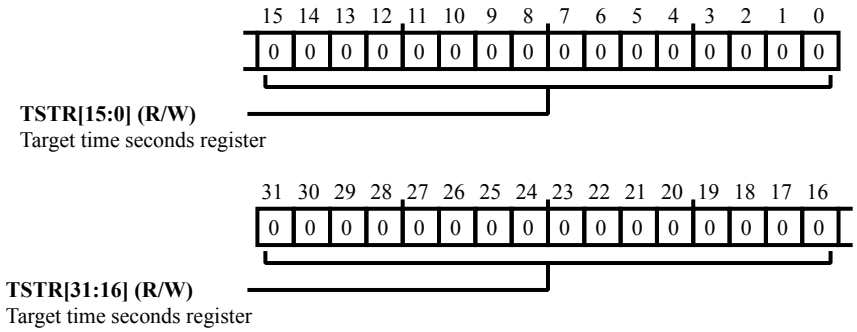

Figure 28-184: EMAC_TM_PPS2TGTM Register Diagram

Table 28-216: EMAC_TM_PPS2TGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSTR	Target time seconds register. The EMAC_TM_PPS2TGTM.TSTR bit field stores the time in seconds. When the time-stamp value matches or exceeds both target time-stamp registers, the MAC starts or stops the PPS signal output and generates an interrupt.

PPS 2 Width Register

The EMAC_TM_PPS2WIDTH register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output

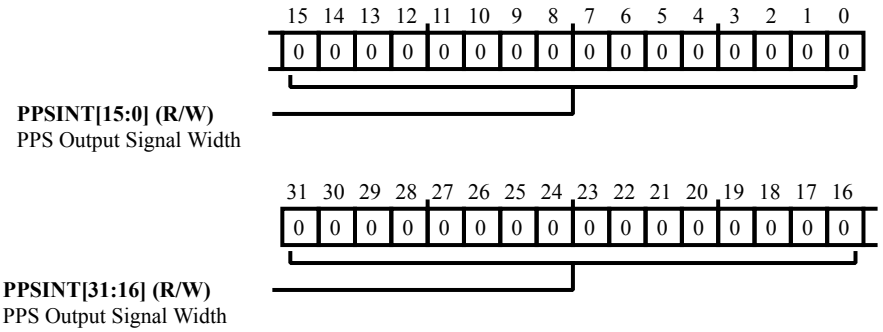

Figure 28-185: EMAC_TM_PPS2WIDTH Register Diagram

Table 28-217: EMAC_TM_PPS2WIDTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Width. The EMAC_TM_PPS2WIDTH.PPSINT bits store the interval between a rising edge and the next falling edge (width) of PPS output in terms of units of sub second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns) and the desired width of the PPS signal output is 60 ns (3 units of sub-second increment value), program the value 2 (3-1) in this register.

PPS 3 Interval Register

The EMAC_TM_PPS3INTVL register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output

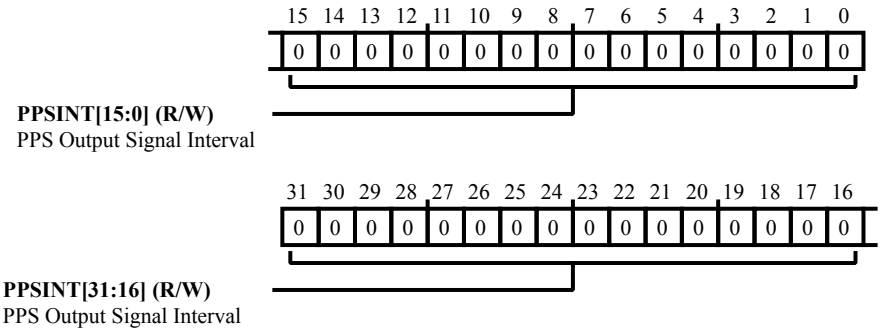

Figure 28-186: EMAC_TM_PPS3INTVL Register Diagram

Table 28-218: EMAC_TM_PPS3INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_TM_PPS3INTVL.PPSINT bit field contains the number of units of sub-second increment value between the rising edges of PPS3 signal output.

PPS 3 Target Time Nanoseconds Register

The EMAC_TM_PPS3NTGTM register is present only when the IEEE 1588 Time stamp feature is selected without external time stamp input.

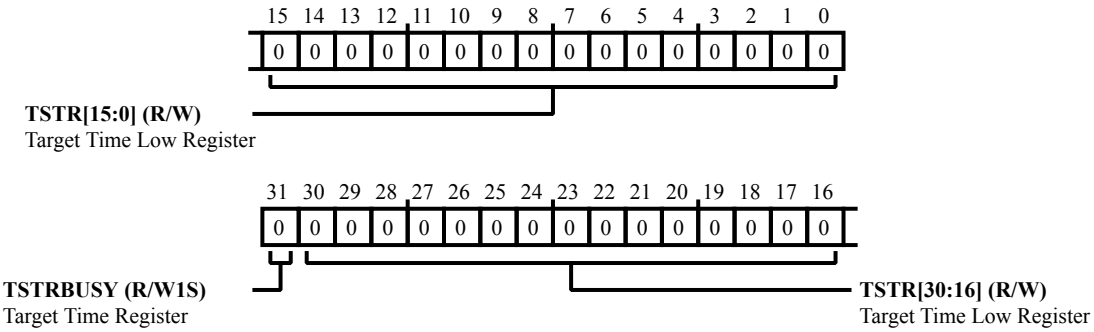

Figure 28-187: EMAC_TM_PPS3NTGTM Register Diagram

Table 28-219: EMAC_TM_PPS3NTGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	TSTRBUSY	Target Time Register. The EMAC_TM_PPS3NTGTM.TSTRBUSY bit field is cleared to 1b0 by the core (self clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.
30:0 (R/W)	TSTR	Target Time Low Register.

PPS 3 Target Time Seconds Register

The EMAC_TM_PPS3TGTM register schedule an interrupt event when the system time exceeds the value programmed in these registers.

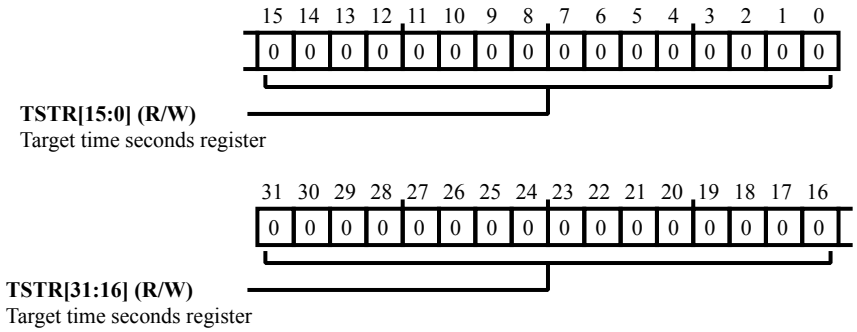

Figure 28-188: EMAC_TM_PPS3TGTM Register Diagram

Table 28-220: EMAC_TM_PPS3TGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSTR	Target time seconds register. The EMAC_TM_PPS3TGTM.TSTR bit field stores the time in seconds. When the time-stamp value matches or exceeds both target time-stamp registers, the MAC starts or stops the PPS signal output and generates an interrupt.

PPS 3 Width Register

The EMAC_TM_PPS3WIDTH register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output

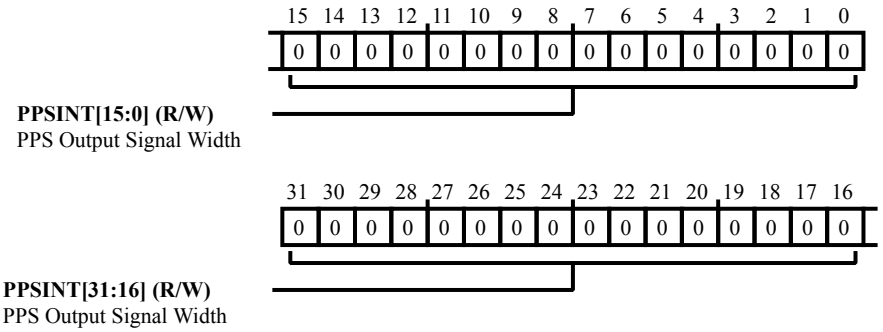

Figure 28-189: EMAC_TM_PPS3WIDTH Register Diagram

Table 28-221: EMAC_TM_PPS3WIDTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Width. The EMAC_TM_PPS3WIDTH.PPSINT bits store the interval between a rising edge and the next falling edge (width) of PPS output in terms of units of sub second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns) and the desired width of the PPS signal output is 60 ns (3 units of sub-second increment value), program the value 2 (3-1) in this register.

PPS Control Register

The EMAC_TM_PPSCTL register controls the interval of PPS output.

When the EMAC_TM_PPSCTL.PPSEN bit is disabled (=0, fixed PPS output), the PPS Frequency Control (PPSCTL0) bits control the behavior of the PPS output signal. The default value of PPSCTRL is 0000 and the PPS output is 1 pulse every second. For other values of PPSCTRL, the PPS output becomes a generated clock. (See bit enumerations for frequencies.) In the binary rollover mode, the PPS output has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. This behavior is because of the non-linear toggling of the bits in the digital rollover mode in System Time - Nanoseconds Register.

When the EMAC_TM_PPSCTL.PPSEN bit is enabled (=1, flexible PPS output), the PPS Frequency Control bits function as PPSCMD. (See bit enumerations for commands.) Programming these bits with a non-zero value instructs the core to initiate an event. After the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are all-zero.

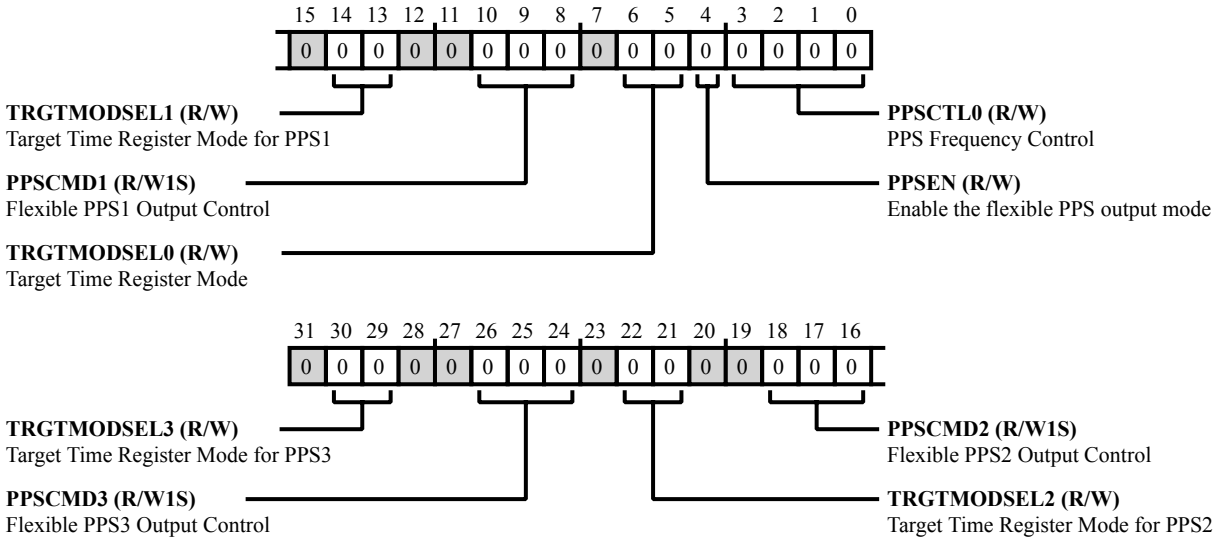

Figure 28-190: EMAC_TM_PPSCTL Register Diagram

Table 28-222: EMAC_TM_PPSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:29 (R/W)	TRGTMODSEL3	Target Time Register Mode for PPS3. The EMAC_TM_PPSCTL.TRGTMODSEL3 bits indicates the Target Time registers mode for PPS3 output signal.

Table 28-222: EMAC_TM_PPSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W1S)	PPSCMD3	Flexible PPS3 Output Control. The EMAC_TM_PPSCTL.PPSCMD3 bits controls the flexible PPS3 output signal.	
22:21 (R/W)	TRGTMODSEL2	Target Time Register Mode for PPS2. The EMAC_TM_PPSCTL.TRGTMODSEL2 bits indicates the Target Time registers mode for PPS2 output signal.	
18:16 (R/W1S)	PPSCMD2	Flexible PPS2 Output Control. The EMAC_TM_PPSCTL.PPSCMD2 bits controls the flexible PPS3 output signal.	
14:13 (R/W)	TRGTMODSEL1	Target Time Register Mode for PPS1. The EMAC_TM_PPSCTL.TRGTMODSEL1 bits indicates the Target Time registers mode for PPS1 output signal.	
10:8 (R/W1S)	PPSCMD1	Flexible PPS1 Output Control. The EMAC_TM_PPSCTL.PPSCMD1 bits controls the flexible PPS1 output signal.	
6:5 (R/W)	TRGTMODSEL0	Target Time Register Mode. The EMAC_TM_PPSCTL.TRGTMODSEL0 bits select the target time register mode.	
		0	Interrupt Only The Target Time registers are programmed only for interrupt event generation.
		1	Reserved
		2	Interrupt and PPS Start/Stop The Target Time registers are programmed for interrupt event and for starting or stopping the PPS output signal generation.
		3	PPS Start/Stop Only The Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.
4 (R/W)	PPSEN	Enable the flexible PPS output mode. The EMAC_TM_PPSCTL.PPSEN bit enables PPS operation. When set low, the PPS Frequency Control field controls frequency of Fixed PPS output. When set high, PPS Frequency Control field is used to command Flexible PPS output.	

Table 28-222: EMAC_TM_PPSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	PPSCTL0	PPS Frequency Control. When the EMAC_TM_PPSCTL.PPSEN bit is disabled (=0, fixed PPS output), the EMAC_TM_PPSCTL.PPSCTL0 bits control the behavior of the PPS output signal. When the EMAC_TM_PPSCTL.PPSEN bit is enabled (=1, flexible PPS output), the EMAC_TM_PPSCTL.PPSCTL0 bits function as PPSCMD. (See bit enumerations for PPS output frequency, rollover, and PPS commands.) Programming these bits with a non-zero value instructs the core to initiate an event. After the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are all-zero. All values not shown in the bit enumerations are reserved. For more information about the EMAC_TM_PPSCTL.PPSCTL0 bits, see the pulse-per-second functional description.	
		0	CMD=No Command
		1	CMD=START Single; BR=2kHz; DR=1kHz For more info, see register description.
		2	CMD=START Pulse; BR=4kHz; DR=2kHz For more info, see register description.
		3	CMD=Cancel START; BR=8kHz; DR=4kHz For more info, see register description.
		4	CMD=STOP Pulse Time; BR=16kHz; DR=8kHz For more info, see register description.
		5	CMD=STOP Pulse Now For more info, see register description.
		6	CMD=Cancel STOP Pulse For more info, see register description.

Time Stamp Low Seconds Register

The EMAC_TM_SEC register contains the lower 32 bits of the seconds field of the system time.

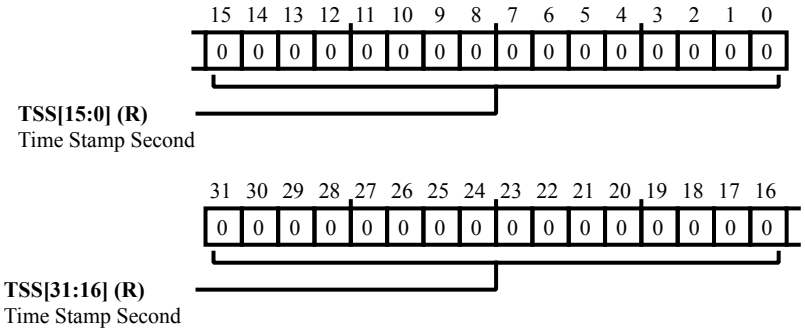

Figure 28-191: EMAC_TM_SEC Register Diagram

Table 28-223: EMAC_TM_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TSS	Time Stamp Second. The value in the EMAC_TM_SEC.TSS bit field indicates the current value in seconds of the System Time maintained by the core.

Time Stamp Seconds Update Register

The EMAC_TM_SECUPDT register contains the low 32 bits to be added to, subtracted from, or written to the seconds field of the system time.

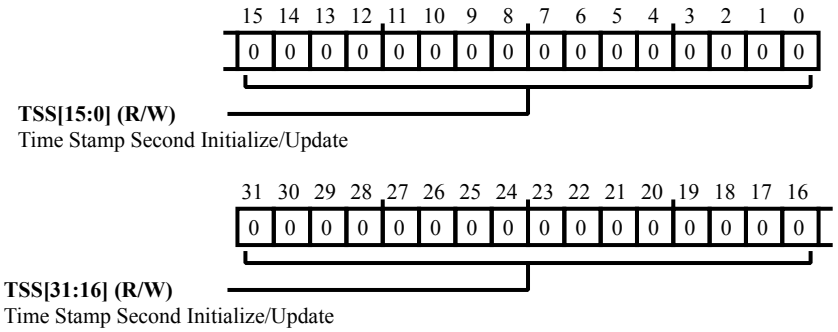

Figure 28-192: EMAC_TM_SECUPDT Register Diagram

Table 28-224: EMAC_TM_SECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSS	Time Stamp Second Initialize/Update. The value in the EMAC_TM_SECUPDT.TSS bit field indicates the time, in seconds, to be initialized or added to or subtracted from the system time seconds.

Time Stamp Status Register

The EMAC_TM_STMPSTAT register contains the PTP status.

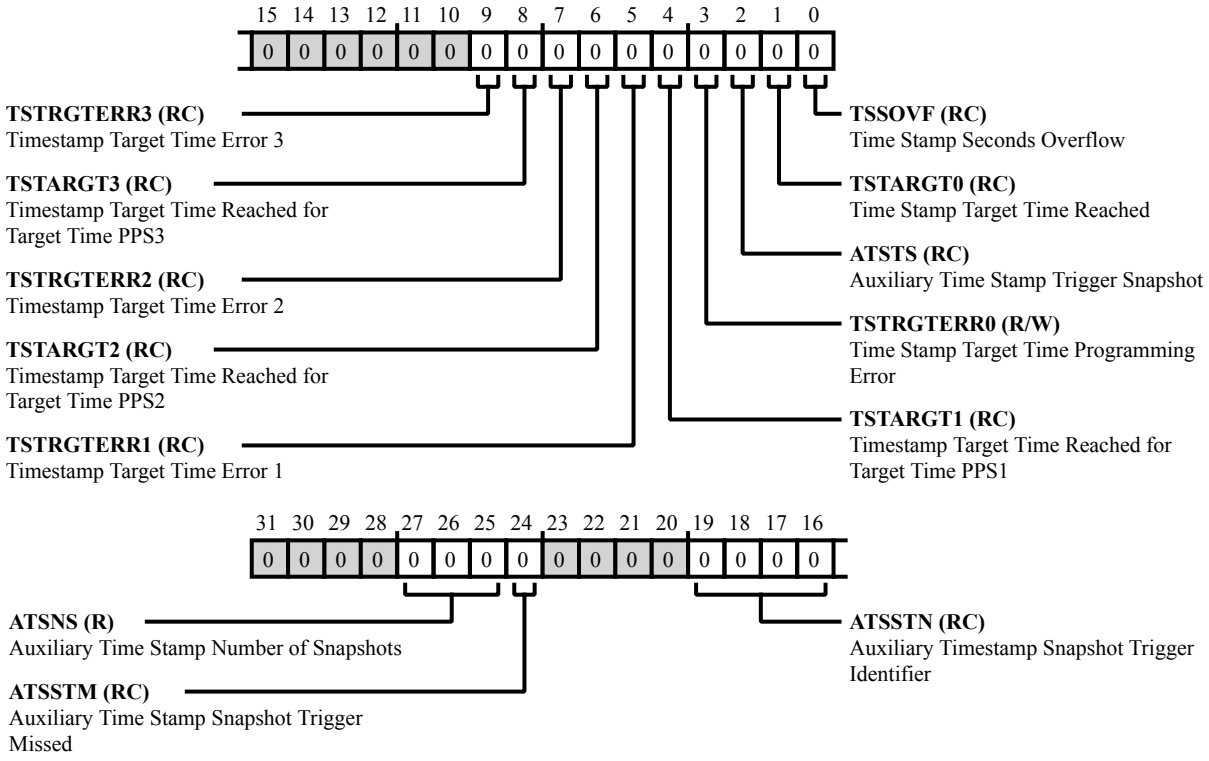

Figure 28-193: EMAC_TM_STMPSTAT Register Diagram

Table 28-225: EMAC_TM_STMPSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:25 (R/NW)	ATSNS	Auxiliary Time Stamp Number of Snapshots. The EMAC_TM_STMPSTAT.ATSNS bits indicate the number of Snapshots available in the FIFO. A value of 4 (100) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 000) when the Auxiliary snapshot FIFO clear bit is set.
24 (RC/NW)	ATSSTM	Auxiliary Time Stamp Snapshot Trigger Missed. The EMAC_TM_STMPSTAT.ATSSTM bit is set when the Auxiliary time stamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot was not stored in the FIFO.
19:16 (RC/NW)	ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier. The EMAC_TM_STMPSTAT.ATSSTN bit identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable.

Table 28-225: EMAC_TM_STMPSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (RC/NW)	TSTRGTERR3	Timestamp Target Time Error 3. The EMAC_TM_STMPSTAT.TSTRGTERR3 bit when set the target time being programmed in PPS3 Target Time High Register and PPS3 Target Time Low Register, is already elapsed.
8 (RC/NW)	TSTARGT3	Timestamp Target Time Reached for Target Time PPS3. The EMAC_TM_STMPSTAT.TSTARGT3 bit indicates that the value of system time is greater than or equal to the value specified in PPS3 Target Time High Register and PPS3 Target Time Low Register.
7 (RC/NW)	TSTRGTERR2	Timestamp Target Time Error 2. The EMAC_TM_STMPSTAT.TSTRGTERR2 bit when set the target time being programmed in PPS2 Target Time High Register and PPS2 Target Time Low Register, is already elapsed.
6 (RC/NW)	TSTARGT2	Timestamp Target Time Reached for Target Time PPS2. The EMAC_TM_STMPSTAT.TSTARGT2 bit indicates that the value of system time is greater than or equal to the value specified in PPS2 Target Time High Register and PPS2 Target Time Low Register.
5 (RC/NW)	TSTRGTERR1	Timestamp Target Time Error 1. The EMAC_TM_STMPSTAT.TSTRGTERR1 bit when set the target time being programmed in PPS1 Target Time High Register and PPS1 Target Time Low Register, is already elapsed.
4 (RC/NW)	TSTARGT1	Timestamp Target Time Reached for Target Time PPS1. The EMAC_TM_STMPSTAT.TSTARGT1 bit indicates that the value of system time is greater than or equal to the value specified in PPS1 Target Time High Register and PPS1 Target Time Low Register.
3 (R/W)	TSTRGTERR0	Time Stamp Target Time Programming Error. The EMAC_TM_STMPSTAT.TSTRGTERR0 bit is set when the target time, which is being programmed in the EMAC_TM_SEC and EMAC_TM_NSEC registers, has already elapsed. This bit is cleared when read by the application.
2 (RC/NW)	ATSTS	Auxiliary Time Stamp Trigger Snapshot. The EMAC_TM_STMPSTAT.ATSTS bit is set high when the auxiliary snapshot is written to the FIFO.
1 (RC/NW)	TSTARGT0	Time Stamp Target Time Reached. The EMAC_TM_STMPSTAT.TSTARGT0 bit, when set, indicates the value of system time has reached or passed the value specified in the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers.

Table 28-225: EMAC_TM_STMPSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (RC/NW)	TSSOVF	Time Stamp Seconds Overflow. The `EMAC_TM_STMPSTAT.TSSOVF` bit, when set, indicates that the seconds value of the time stamp (when supporting PTP version 2 format) has overflowed beyond 0xFFFF_FFFF.

Time Stamp Sub Second Increment Register

The EMAC_TM_SUBSEC register contains the value by which the system time nano second is incremented.

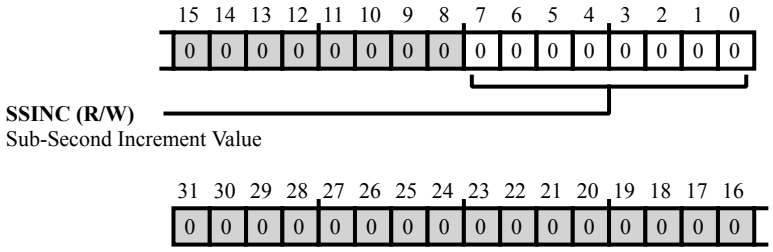

Figure 28-194: EMAC_TM_SUBSEC Register Diagram

Table 28-226: EMAC_TM_SUBSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SSINC	Sub-Second Increment Value. The value in the EMAC_TM_SUBSEC.SSINC bits is accumulated every PTP clock cycle with the contents of the nanosecond register. For example, when PTP clock is 50 MHz (period is 20 ns), the processor should program 20 (0x14) when the EMAC_TM_NSEC register has an accuracy of 1 ns (EMAC_TM_CTL.TSCTRLSSR bit is set). When EMAC_TM_CTL.TSCTRLSSR is clear, the EMAC_TM_NSEC register has a resolution of ~0.465ns. In this case, the processor should program a value of 43 (0x2B) that is derived by 20ns/0.465.

Tx 1024- to Max-Byte Frames (Good/Bad) Register

The EMAC_TX1024TOMAX_GB register contains the count of the number of good and bad frames transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

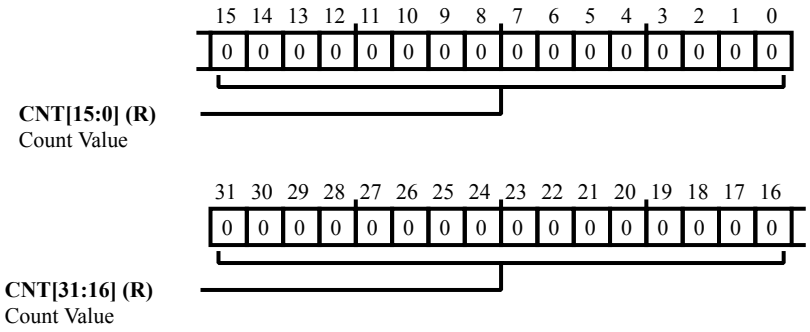

Figure 28-195: EMAC_TX1024TOMAX_GB Register Diagram

Table 28-227: EMAC_TX1024TOMAX_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx 128- to 255-Byte Frames (Good/Bad) Register

The EMAC_TX128TO255_GB register contains the count of the number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

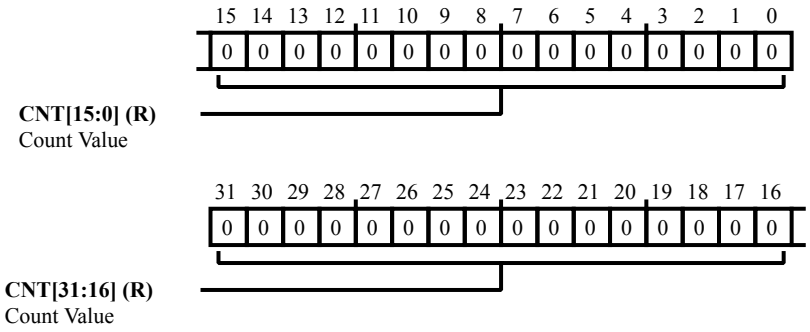

Figure 28-196: EMAC_TX128TO255_GB Register Diagram

Table 28-228: EMAC_TX128TO255_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx 256- to 511-Byte Frames (Good/Bad) Register

The EMAC_TX256TO511_GB register contains the count of the number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

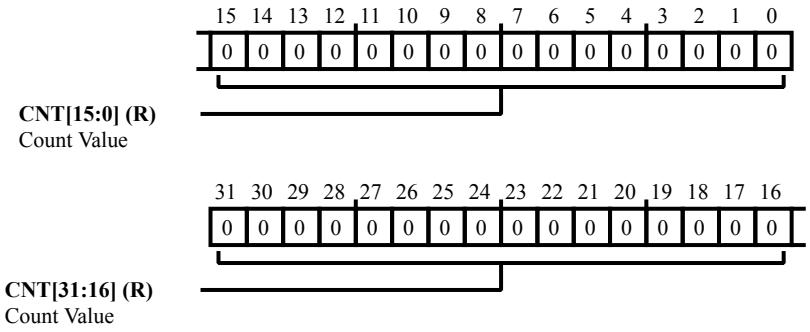

Figure 28-197: EMAC_TX256TO511_GB Register Diagram

Table 28-229: EMAC_TX256TO511_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx 512- to 1023-Byte Frames (Good/Bad) Register

The EMAC_TX512TO1023_GB register contains the count of the number of good and bad frames transmitted with length between 512 and 1023 (inclusive) bytes, exclusive of preamble and retried frames.

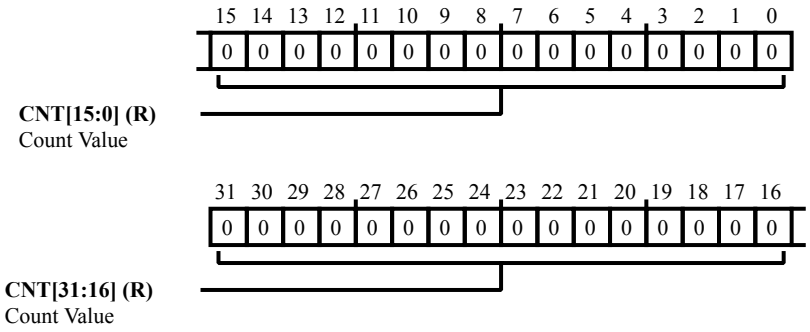

Figure 28-198: EMAC_TX512TO1023_GB Register Diagram

Table 28-230: EMAC_TX512TO1023_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx 64-Byte Frames (Good/Bad) Register

The EMAC_TX64_GB register contains the count of the number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames.

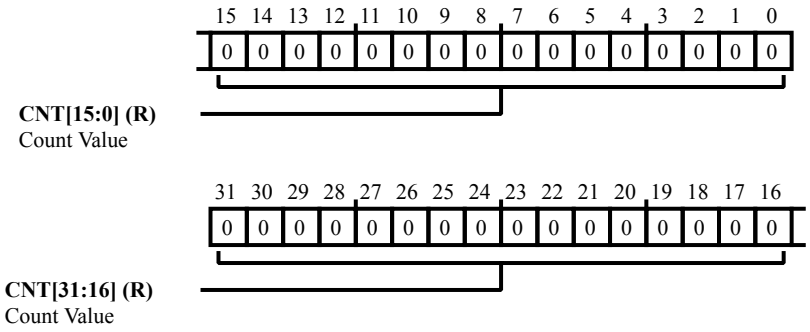

Figure 28-199: EMAC_TX64_GB Register Diagram

Table 28-231: EMAC_TX64_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx 65- to 127-Byte Frames (Good/Bad) Register

The EMAC_TX65TO127_GB register contains the count of the number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

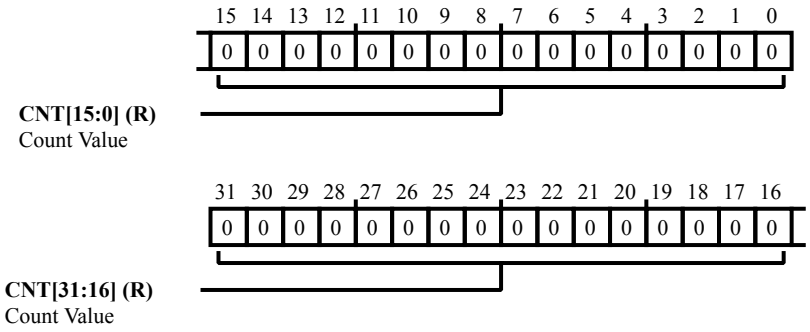

Figure 28-200: EMAC_TX65TO127_GB Register Diagram

Table 28-232: EMAC_TX65TO127_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Broadcast Frames (Good) Register

The EMAC_TXBCASTFRM_G register contains the count of the number of good broadcast frames transmitted.

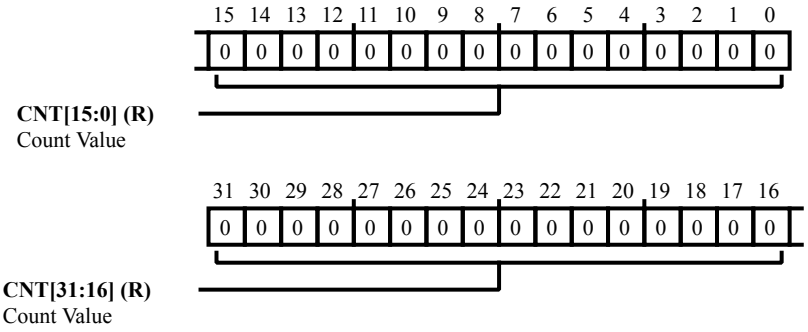

Figure 28-201: EMAC_TXBCASTFRM_G Register Diagram

Table 28-233: EMAC_TXBCASTFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Broadcast Frames (Good/Bad) Register

The EMAC_TXBCASTFRM_GB register contains the count of the number of good and bad broadcast frames transmitted.

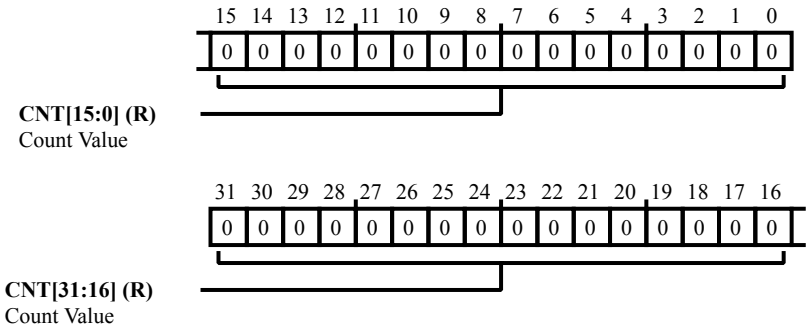

Figure 28-202: EMAC_TXBCASTFRM_GB Register Diagram

Table 28-234: EMAC_TXBCASTFRM_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Carrier Error Register

The EMAC_TXCARR_ERR register contains a count of the number of frames aborted due to carrier sense error (no carrier or loss of carrier).

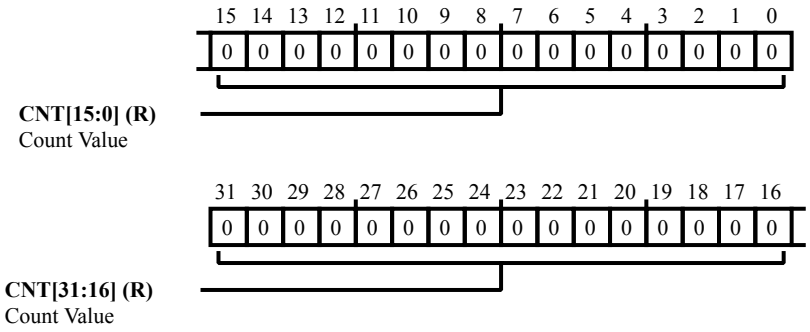

Figure 28-203: EMAC_TXCARR_ERR Register Diagram

Table 28-235: EMAC_TXCARR_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Deferred Register

The EMAC_TXDEFERRED register contains a count of the number of successfully transmitted frames after a deferral in Half-duplex mode.

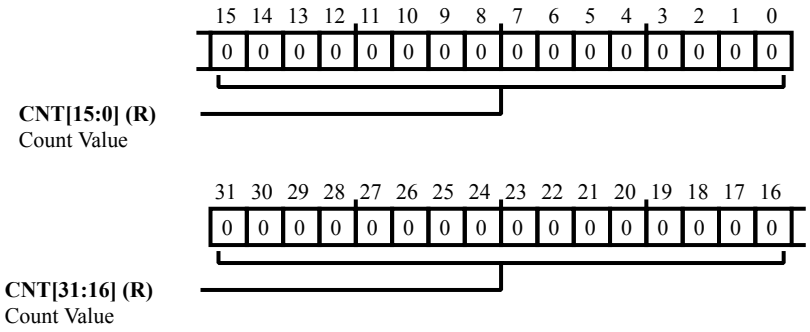

Figure 28-204: EMAC_TXDEFERRED Register Diagram

Table 28-236: EMAC_TXDEFERRED Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Excess Collision Register

The EMAC_TXEXCESSCOL register contains a count of the number of frames aborted due to excessive (16) collision errors.

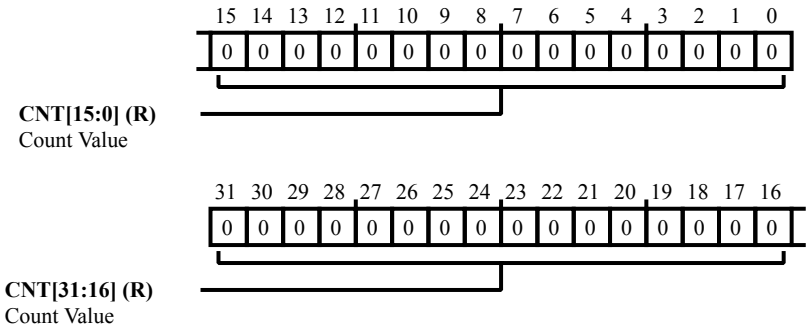

Figure 28-205: EMAC_TXEXCESSCOL Register Diagram

Table 28-237: EMAC_TXEXCESSCOL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Excess Deferral Register

The EMAC_TXEXCESSDEF register contains a count of the number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times).

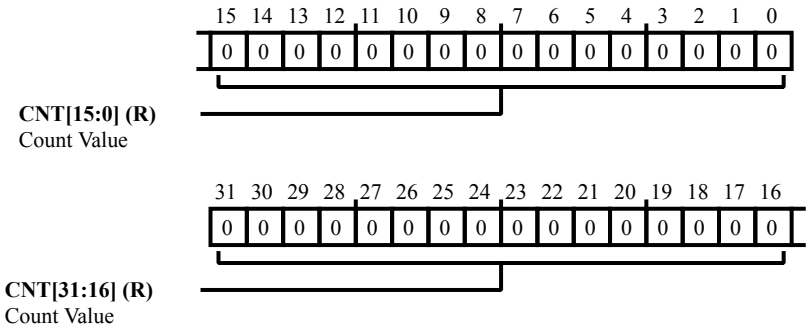

Figure 28-206: EMAC_TXEXCESSDEF Register Diagram

Table 28-238: EMAC_TXEXCESSDEF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Frame Count (Good) Register

The EMAC_TXFRMCNT_G register contains a count of the number of good frames transmitted.

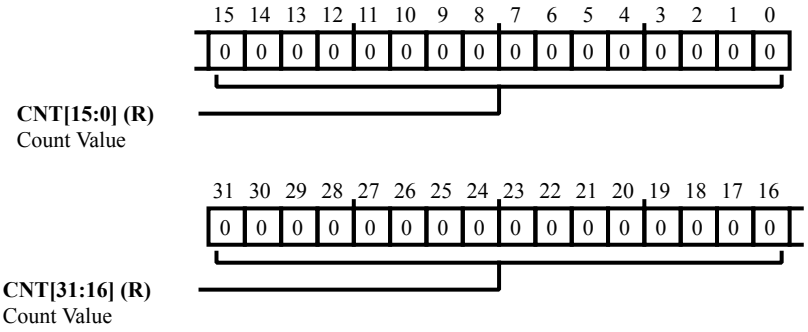

Figure 28-207: EMAC_TXFRMCNT_G Register Diagram

Table 28-239: EMAC_TXFRMCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Frame Count (Good/Bad) Register

The EMAC_TXFRMCNT_GB register contains the count of the number of good and bad frames transmitted, exclusive of retried frames.

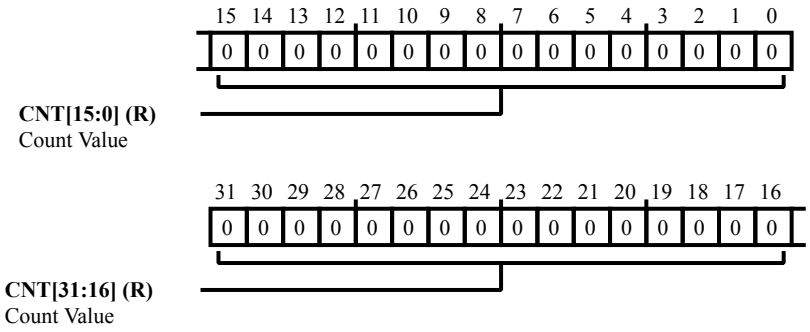

Figure 28-208: EMAC_TXFRMCNT_GB Register Diagram

Table 28-240: EMAC_TXFRMCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Late Collision Register

The EMAC_TXLATECOL register contains a count of the number of frames aborted due to late collision error.

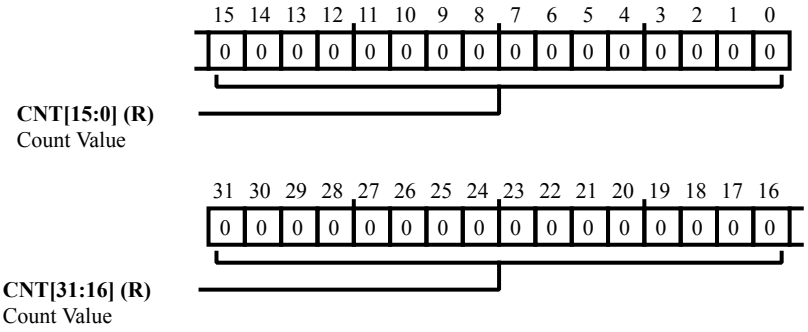

Figure 28-209: EMAC_TXLATECOL Register Diagram

Table 28-241: EMAC_TXLATECOL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Multicast Frames (Good) Register

The EMAC_TXMCASTFRM_G register contains the count of the number of good multicast frames transmitted.

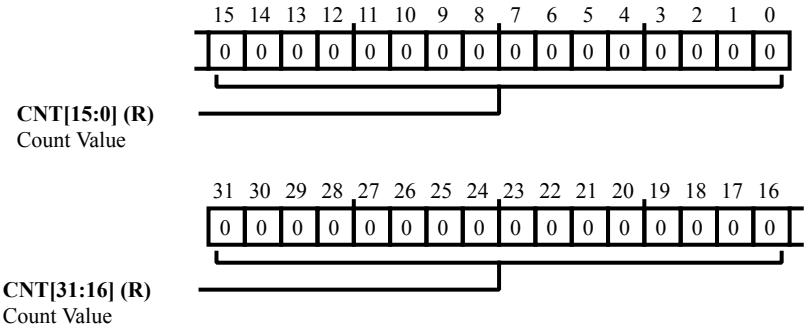

Figure 28-210: EMAC_TXMCASTFRM_G Register Diagram

Table 28-242: EMAC_TXMCASTFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Multicast Frames (Good/Bad) Register

The EMAC_TXMCASTFRM_GB register contains the count of the number of good and bad multicast frames transmitted.

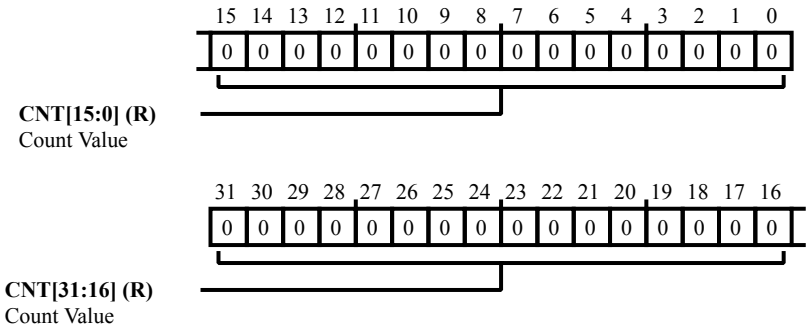

Figure 28-211: EMAC_TXMCASTFRM_GB Register Diagram

Table 28-243: EMAC_TXMCASTFRM_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Multiple Collision (Good) Register

The EMAC_TXMULTCOL_G register contains a count of the number of successfully transmitted frames after more than a single collision in Half-duplex mode.

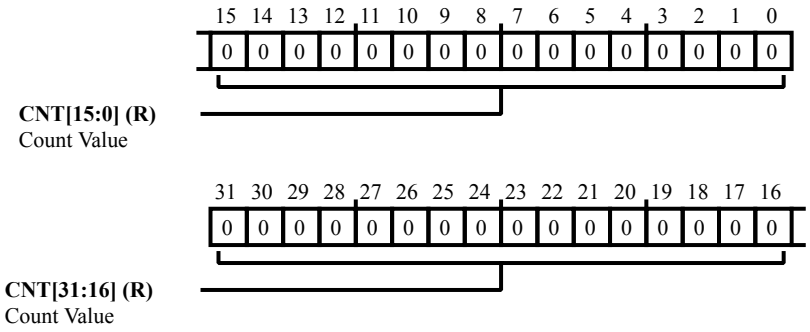

Figure 28-212: EMAC_TXMULTCOL_G Register Diagram

Table 28-244: EMAC_TXMULTCOL_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Octet Count (Good) Register

The EMAC_TXOCTCNT_G register contains a count of the number of bytes transmitted, exclusive of preamble, in good frames only.

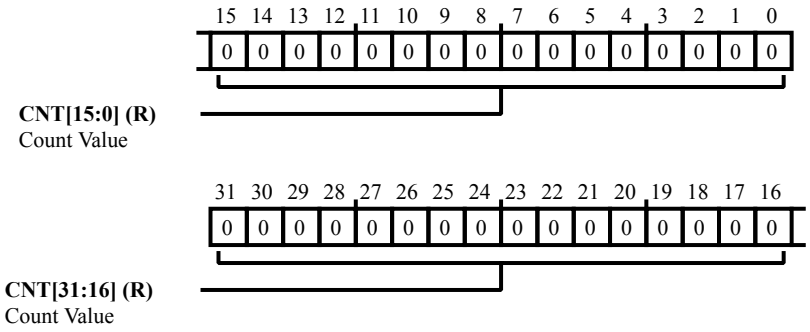

Figure 28-213: EMAC_TXOCTCNT_G Register Diagram

Table 28-245: EMAC_TXOCTCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx OCT Count (Good/Bad) Register

The EMAC_TXOCTCNT_GB register contains the count of the number of bytes transmitted, exclusive of the preamble and retried bytes, in good and bad frames.

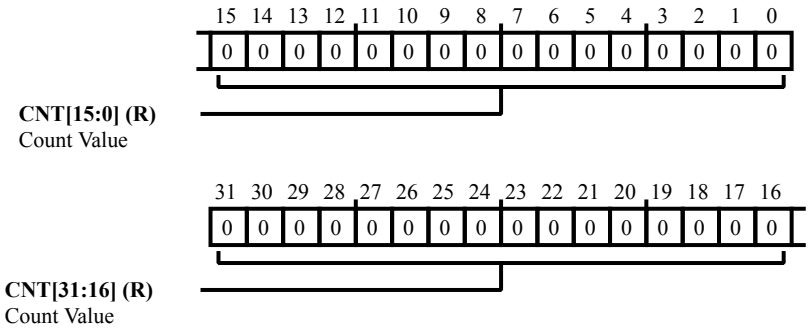

Figure 28-214: EMAC_TXOCTCNT_GB Register Diagram

Table 28-246: EMAC_TXOCTCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Number of Tx Frames (Good) greater than maxsize

The EMAC_TXOVRSIZE_G register contains a count of the number of good frames transmitted with length greater than the maxsize.

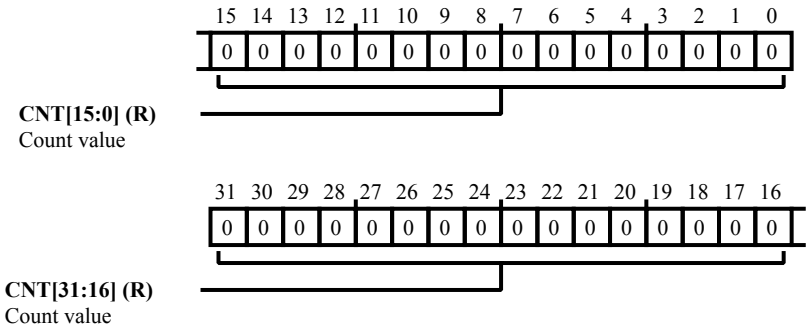

Figure 28-215: EMAC_TXOVRSIZE_G Register Diagram

Table 28-247: EMAC_TXOVRSIZE_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count value.

Tx Pause Frame Register

The EMAC_TXPAUSEFRM register contains a count of the number of good PAUSE frames transmitted.

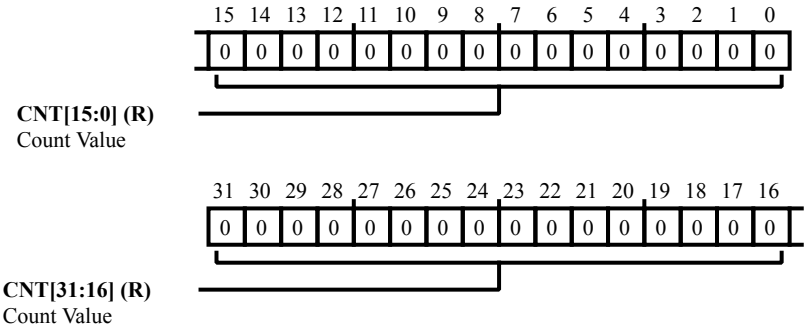

Figure 28-216: EMAC_TXPAUSEFRM Register Diagram

Table 28-248: EMAC_TXPAUSEFRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Single Collision (Good) Register

The EMAC_TXSNGCOL_G register contains a count of the number of successfully transmitted frames after a single collision in Half-duplex mode.

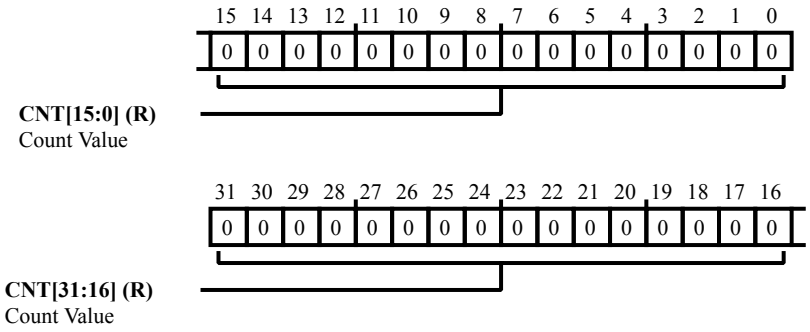

Figure 28-217: EMAC_TXSNGCOL_G Register Diagram

Table 28-249: EMAC_TXSNGCOL_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Unicast Frames (Good/Bad) Register

The EMAC_TXUCASTFRM_GB register contains the count of the number of good and bad unicast frames transmitted.

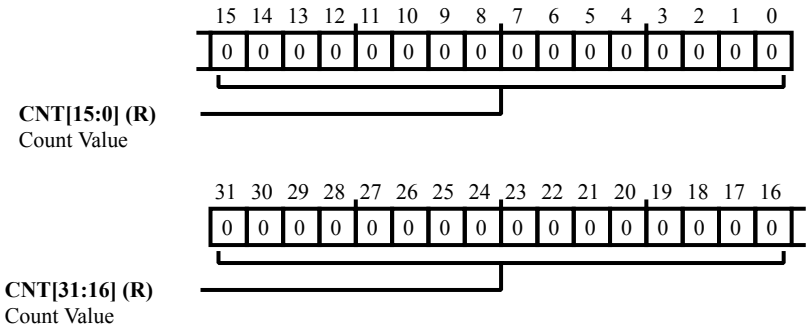

Figure 28-218: EMAC_TXUCASTFRM_GB Register Diagram

Table 28-250: EMAC_TXUCASTFRM_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx Underflow Error Register

The EMAC_TXUNDR_ERR register contains a count of the number of frames aborted due to frame underflow error.

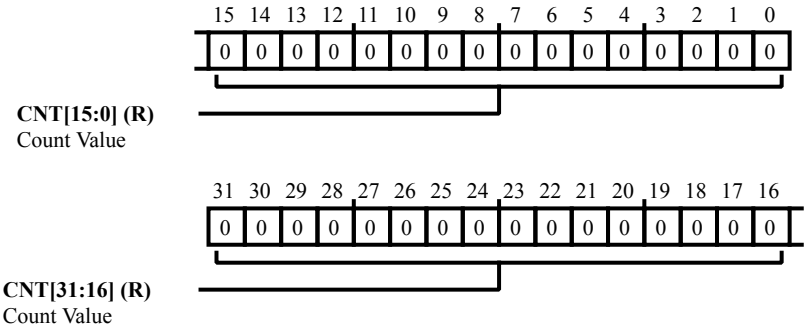

Figure 28-219: EMAC_TXUNDR_ERR Register Diagram

Table 28-251: EMAC_TXUNDR_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

Tx VLAN Frames (Good) Register

The EMAC_TXVLANFRM_G register contains a count of the number of good VLAN frames transmitted, exclusive of retried frames.

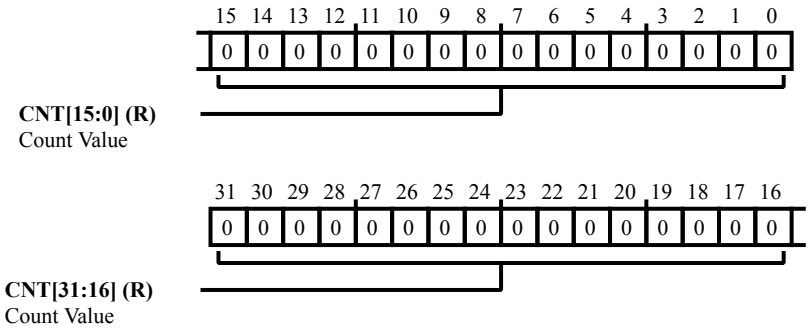

Figure 28-220: EMAC_TXVLANFRM_G Register Diagram

Table 28-252: EMAC_TXVLANFRM_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT	Count Value.

VLAN Tag Register

The EMAC_VLANTAG register contains the VLAN tag.

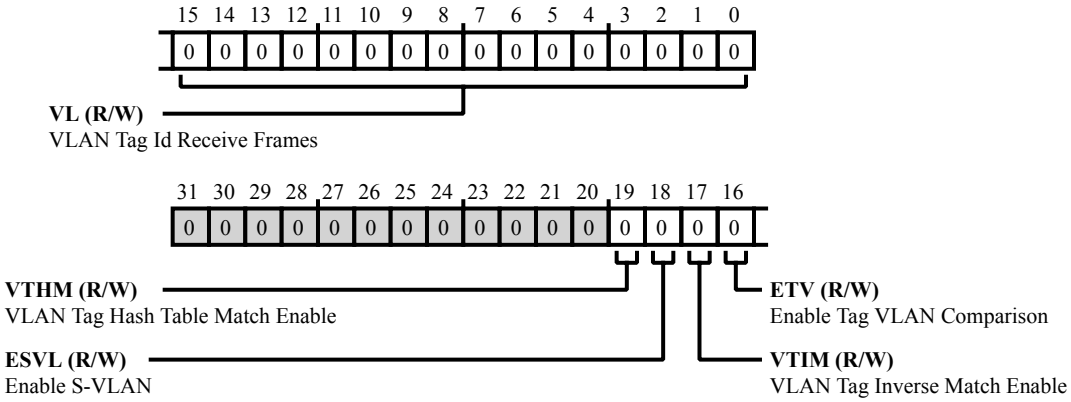

Figure 28-221: EMAC_VLANTAG Register Diagram

Table 28-253: EMAC_VLANTAG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	VTHM	VLAN Tag Hash Table Match Enable. The EMAC_VLANTAG.VTHM bit, When set, the most significant four bits of the VLAN tags CRC are used to index the content of VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table.
18 (R/W)	ESVL	Enable S-VLAN. When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.
17 (R/W)	VTIM	VLAN Tag Inverse Match Enable. The EMAC_VLANTAG.VTIM bit, enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched.
16 (R/W)	ETV	Enable Tag VLAN Comparison. The EMAC_VLANTAG.ETV bit, when set, directs the EMAC to use a 12-bit VLAN identifier, rather than the complete 16-bit VLAN tag, for comparison and filtering. Bits[11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. When this bit is reset, all 16 bits of the received VLAN frame's fifteenth and sixteenth bytes are used for comparison.

Table 28-253: EMAC_VLANTAG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VL	VLAN Tag Id Receive Frames. The `EMAC_VLANTAG.VL` bits contain the 802.1Q VLAN tag to identify VLAN frames, and is compared to the fifteenth and sixteenth bytes of the frames being received for VLAN frames. Bits[15:13] are the User Priority, Bit[12] is the Canonical Format Indicator (CFI) and bits[11:0] are the VLAN tag's VLAN Identifier (VID) field. When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and sixteenth bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 to be VLAN frames.

VLAN Hash Table Register

The EMAC_VLAN_HSHTBL register contains the VLAN hash table

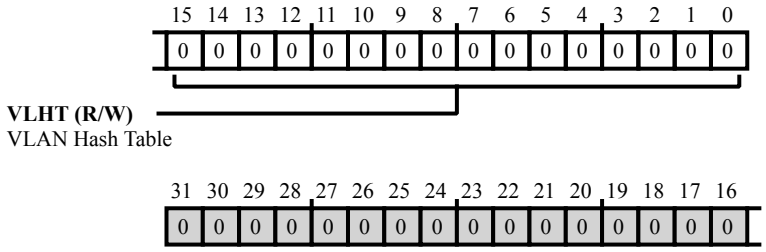

Figure 28-222: EMAC_VLAN_HSHTBL Register Diagram

Table 28-254: EMAC_VLAN_HSHTBL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VLHT	VLAN Hash Table. This field contains the 16-bit VLAN Hash Table.

VLAN Tag Inclusion or Replacement Register

The EMAC_VLAN_INCL register contains the VLAN tag for insertion into or replacement in the transmit frames.

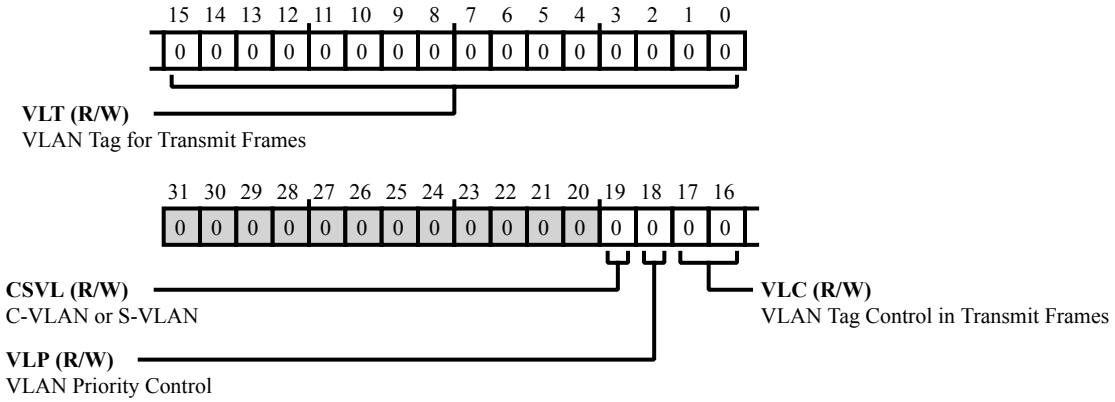

Figure 28-223: EMAC_VLAN_INCL Register Diagram

Table 28-255: EMAC_VLAN_INCL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	CSVL	C-VLAN or S-VLAN. The EMAC_VLAN_INCL.CSVL bit, When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted frames.
18 (R/W)	VLP	VLAN Priority Control. The EMAC_VLAN_INCL.VLP bit, When this bit is set, the control Bits [17:16] are used for VLAN deletion, insertion, or replacement
17:16 (R/W)	VLC	VLAN Tag Control in Transmit Frames. The EMAC_VLAN_INCL.VLC bit, 2'b00:No VLAN tag deletion, insertion, or replacement 2'b01:VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags. 2'b10:VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag. 2'b11:VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8).
15:0 (R/W)	VLT	VLAN Tag for Transmit Frames. The EMAC_VLAN_INCL.VLT bit, contains the value of the VLAN tag to be inserted or replaced.

Watchdog Timeout Register

The EMAC_WDOG_TIMOUT register controls the watchdog timeout for received frames.

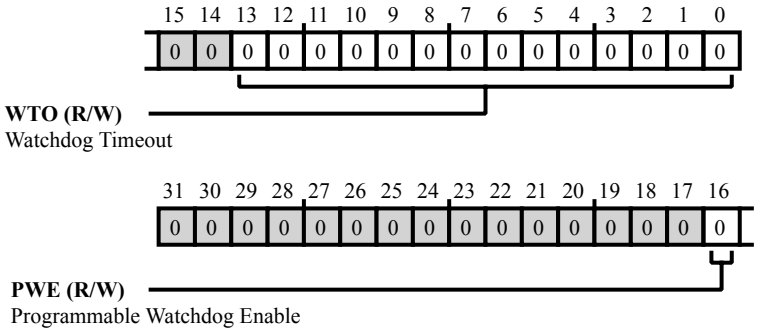

Figure 28-224: EMAC_WDOG_TIMOUT Register Diagram

Table 28-256: EMAC_WDOG_TIMOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	PWE	Programmable Watchdog Enable. The EMAC_WDOG_TIMOUT.PWE bit, When this bit is set and Bit 23 (WD) of Register 0 (MAC Configuration Register) is reset, the WTO field (Bits[13:0]) is used as watchdog timeout for a received frame.
13:0 (R/W)	WTO	Watchdog Timeout. The EMAC_WDOG_TIMOUT.WTO bit, When Bit 16 (PWE) is set and Bit 23 (WD) of Register 0 (MAC Configuration Register) is reset, this field is used as watchdog timeout for a received frame. If the length of a received frame exceeds the value of this field, such frame is terminated and declared as an error frame.

29 Digital Audio Interface (DAI)

The Digital Audio Interfaces (DAIn) are comprised of groups of identical peripherals and their respective Signal Routing Units (SRUn). The SRU connects inputs and outputs of the DAI peripherals with each other and to the external pins. This configuration allows peripherals to be interconnected to accomodate a wide variety of systems without making external pin connections.

In a typical processor, static (multiplexed) pins are assigned to specific peripherals. When certain peripherals are not required for an application, these pins are unnecessary and expensive. The pins may need to be defined as high or low to prevent any illegal conditions. The signal routing units on the SHARC processors addresses this situation by controlling a number of general-purpose pins which can be assigned flexibly (a virtual connectivity between peripherals) depending on system requirements. This virtual connectivity includes pin buffers and routing logic (multiplexer). It also allows the SHARC processors to include an arbitrary number and variety of peripherals while retaining high levels of compatibility without increasing pin count.

SRU Features

The SRU has the following features and capabilities.

- Flexible connections that can be made through software and during run time; no hard-wiring is required.
- At reset, a default routing scheme is already programmed.
- Connectivity can be made internally between peripherals, externally between pin buffers, or a mix of both.
- Status of the pin buffers can be programmed for conditional execution or interrupts.
- Some pin buffers allow control of signal polarity changes.
- No fan-out limitation, a peripheral or pin buffer output that can be routed to multiple peripheral or pin buffer inputs.
- Two independent routing systems are availablethe DAI0 and the DAI1. Signals cannot be interconnected between both routing units with the exception of the following modules under some specific scenarios.
    - The precision clock generator (PCG)
    - A pair of DAI pin buffers from each DAI unit
    - Asynchronous Sample Rate Converter (ASRC) data for daisy chaining across the DAI units

NOTE: The 400–ball CSP BGA package has 2 x 14 DAI pins bonded off-chip (DAIx_PIN01 through DAIx_PIN12, DAIx_PIN19, and DAIx_PIN20). The 400-ball HPC BGA package has 2 x 20 DAI pins bonded off-chip (DAIx_PIN01 through DAIx_PIN20).

Functional Description

The fundamental timing clock of the DAI modules is SCLK0.

The DAI Block Diagram shows how the DAI pin buffers are connected through the SRUn. This configuration allows for flexible signal routing.

The DAI units are comprised of four primary blocks:

- Peripherals (A/B/C) associated with DAIn
- Signal Routing Units (SRUn)
- DAIn I/O pin buffers
- Miscellaneous buffers

The peripherals shown in DAI Block Diagram can have up to three connections (if requester or completer capable); one acts as a signal input, one as a signal output and the third as an output enable. The SRUs are based on a group of multiplexers which are controlled by registers to establish the desired interconnections. The DAI pin buffers have three signals which are used for input and output to or from off-chip and the third for output enable.

The miscellaneous buffers have an input and an output and are used for group interconnection.

The figures are a simplified representation of a DAI system. In a real representation, the SRU and DAI would show several types of data being routed from several sources including the following:

- Serial ports (SPORT)
- Precision clock generators (PCG)
- Asynchronous sample rate converters (SRC)
- S/PDIF transmitter
- S/PDIF receiver
- DAI interrupts (miscellaneous)
- PDM interface

ADSP-2159x_SC591_SC592_SC594 DAI Register List

The Digital Audio Interfaces (DAIn) contain groups of identical peripherals which can be connected internally between peripherals, externally between pin buffers, or a mix of both. This module contains the following registers.

DAI Block Diagram

The ***DAI Functional Block Diagram*** and the ***Digital Audio Interconnect Unit*** figures show the functional blocks within the DAI and the unit connections to the peripherals.

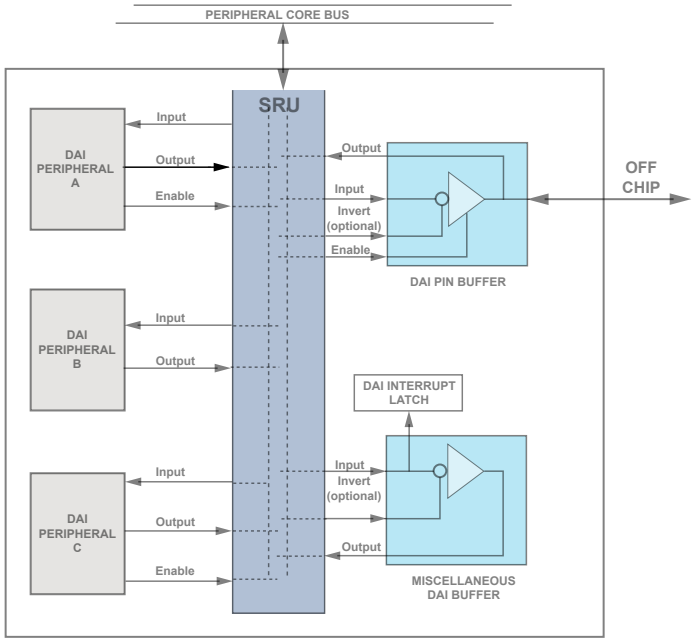

Figure 29-1: DAI Functional Block Diagram

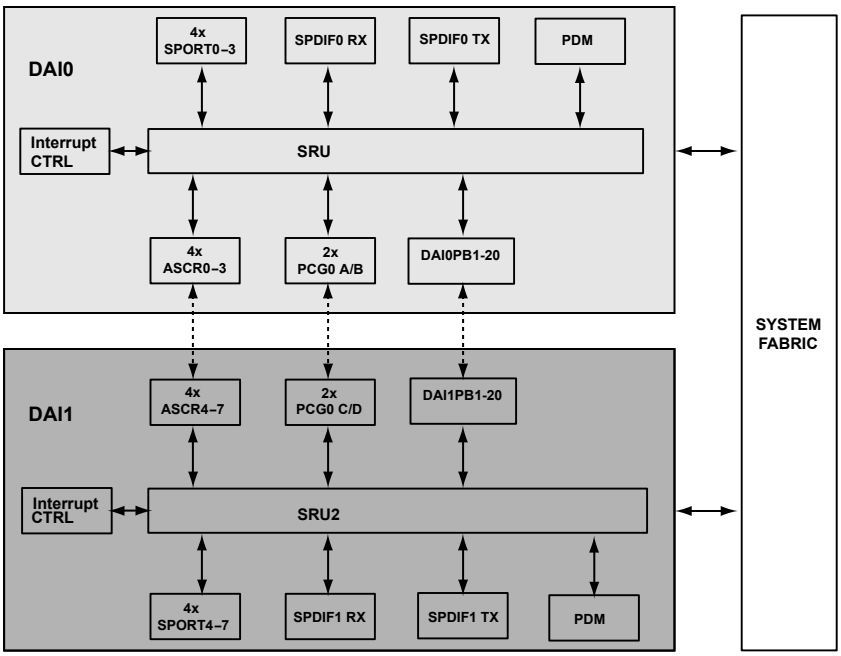

Figure 29-2: Digital Audio Interconnect Unit

DAI Signal Naming Conventions

The peripherals associated with the DAI do not have any dedicated I/O pins for off-chip communication. Instead, the I/O pin is only accessible in the chip internally and is known as an *internal node*. Every internal node of a DAI peripheral (input or output) is given a unique mnemonic. The convention is to begin the name with an identifier for the peripheral that the signal is coming to or from, followed by the function of the signal.

A number is included if the DAI contains more than one peripheral type (for example, serial ports), or if the peripheral has more than one signal that performs this function (for example, serial ports). The mnemonic always ends with *_I* if the signal is an input, or with *_O* if the signal is an output. An example is shown in the ***Example DAI Mnemonics*** figure.

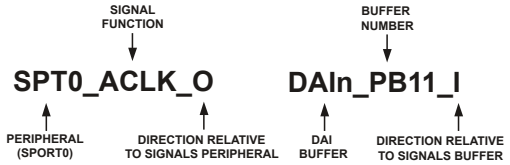

Figure 29-3: Example DAI Mnemonics

I/O Pin Buffers

Within the context of the SRU, physical connections to the DAI pins are replaced by a logical interface known as a *pin buffer*. This three terminal active device is capable of sourcing or sinking output current when its driver is enabled, and passing external input signals when disabled. Each pin has an input, an output, and an enable as shown in the ***Pin Buffer Example*** figure. The inputs and the outputs are defined with respect to the pin, similar to a peripheral device. This naming convention is consistent with the SRU naming convention.

Pin Buffer Signals

The pin buffer is based on three signals shown in the ***Pin Buffer Example*** figure and described in the following sections.

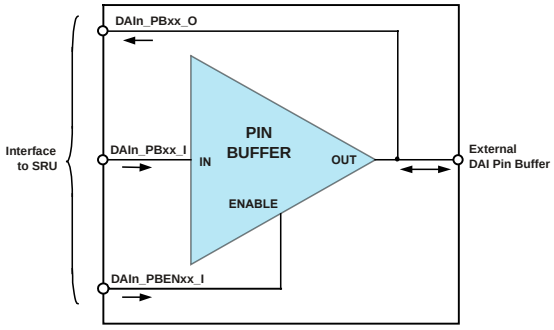

Figure 29-4: Pin Buffer Example

Pin Buffer Input Signal

A pin buffer input (`DAIn_PBxx_I`) is driven as an output from the processor when the pin buffer enable is set (=1). Each physical pin (connected to a bonded pad) can be connected through the SRU to any of the outputs of the DAI peripherals, based on the bit field values. The SRU can also be used to route signals that control the pins in other ways. Many signals can be configured for use as control signals.

Pin Buffer Enable Signal

When a pin buffer enable (`DAIn_PBENxx_I`) is set (=1), the signal present at the corresponding pin buffer input (`DAIn_PBxx_I`) is driven off-chip as an output. When a pin buffer enable is cleared (=0), the signal present at the corresponding pin buffer input is ignored. The pin enable control registers activate the drive buffer for each of the DAI pins. When the pins are not enabled (driven), they can be used as inputs. There are two options to control the pin buffer enable signal; setting the level high for a static solution, or connecting the dedicated peripheral's pin buffer output enable signal to its pin buffer, which automatically enables the pin buffer.

Pin Buffer Functions

Pin buffers can be configured as inputs or outputs as described in the following sections.

Pin Buffers as Signal Input

When the DAI pin is used only as an input, connect the corresponding pin buffer enable to logic low as shown in the ***Pin Buffer as Input*** figure. This configuration disables the buffer amplifier and allows an off-chip source to drive the value present on the DAI pin and at the pin buffer output. When the pin buffer enable (for example, `DAI_PBEN0.PB01`) is cleared (= 0), the pin buffer output (`DAIn_PBxx_O`) is the signal driven onto the DAI pin by an external source, and the pin buffer input signal (`DAIn_PBxx_I`) is not used.

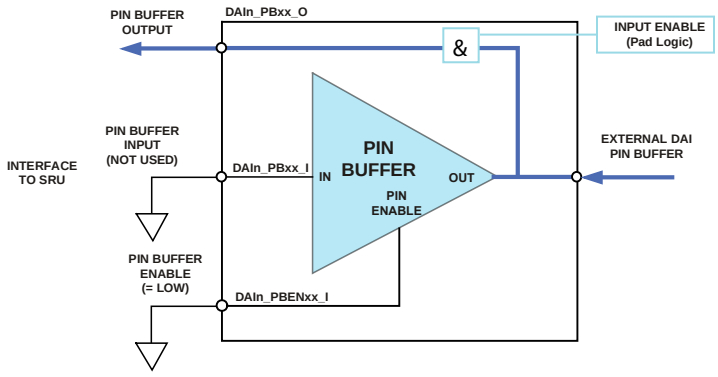

Figure 29-5: Pin Buffer as Input

NOTE: Whether programmed as input or output, a DAI buffer input always routes the same signal to an output internally. DAI pins have programmable internal pull-up resistors. For more information, see the General-Purpose Ports (PORT) chapter for details.

Pin Buffers As Signal Output

In a typical embedded system, most pins are designated as either inputs or outputs when the circuit is designed, even though they can be used in either direction. Each of the DAI pins can be used as either an output or an input. Although the direction of a DAI pin is set simply by writing to a memory-mapped register, most often the direction of the pin is dictated by the designated use of that pin.

When the DAI pin is used only as an output, connect the corresponding pin buffer enable to logic high as shown in the ***Pin Buffer as Output*** figure. This configuration enables the buffer amplifier to operate as a current source and to drive the value present at the pin buffer input onto the DAI pin and off-chip. When the pin buffer enable bits are set (in the `DAIn_PBxx_I` registers) (=1), the pin buffer output (`DAIn_PBxx_O`) is the same signal as the pin buffer input (`DAIn_PBxx_I`), and this signal is driven as an output.

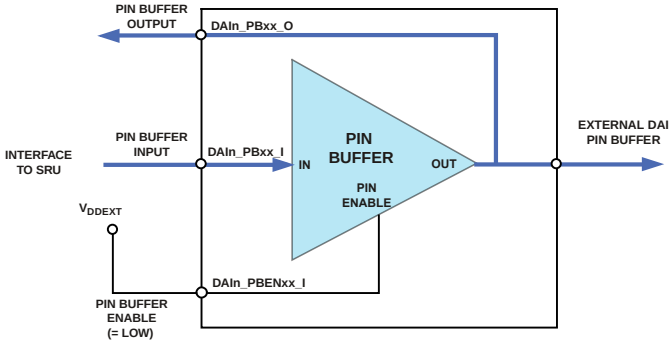

Figure 29-6: Pin Buffer as Output

DAI Pin Buffer Status

The signal levels on the DAI pins can be read with the `DAI_PIN_STAT` registers.

DAIn Peripherals

There are two categories of peripherals associated with the DAI units. These are described in the following sections.

Output Signals With Pin Buffer Enable Control

Many peripherals within the DAIn that have bidirectional pins generate a corresponding pin enable signal. Typically, the settings within the control registers of a peripheral determine if a bidirectional pin is an input or an output. The pin is then driven accordingly.

Though most peripherals are capable of operating bidirectionally, it is not required that all of the `_I` and `_O` signals of a peripheral be connected to the pin buffer. If the system design only uses a signal in one direction, it is simpler to connect the pin buffer accordingly.

NOTE: All available pin buffer output enables must be routed to their pin buffer input enable signals in cases where data streaming connections are used. This arrangement guarantees timing requirements.

NOTE: In some cases, it is necessary to use a peripheral's dedicated pin buffer enable signal instead of static levels. For example, SPORT TDM mode requires the SPORT's dedicated data pin buffer enable signal to be used for the SPORT's data pin to three-state the data pins on inactive channels.

Output Signals Without Pin Buffer Enable Control

Some peripherals have signal outputs without an automated pin buffer control enable signal. The operation of these peripherals is simplified. The routing to a DAIn pin buffer enable input requires a static high from the SRUn. In order to disable the pin buffer output, software must clear the pin buffer enable input accordingly.

Signal Routing Units (SRUs)

The following sections provide details specific to the SRUs.

Signal Routing Matrix by Groups

The SRU is similar to a set of patch bays, which contain a bank of inputs and a bank of outputs. For each input (destination), there is a set of permissible output (source) options. Outputs can feed to any number of inputs in parallel, but every input must be patched to exactly one valid output source. Together, the set of inputs and outputs are called a group. The signal's inputs and outputs that comprise each group all serve similar purposes. They are compatible such that almost any output-to-input patch makes functional sense. With the grouping, the multiplexing scheme becomes highly efficient since it does not make sense (for example) to route a frame sync signal to a data signal.

The SRU for the DAI contains six groups named A through F. Each group routes a unique set of signals with a specific purpose:

- Group A routes clock signals
- Group B routes serial data signals
- Group C routes frame sync signals

- Group D routes pin signals
- Group E routes miscellaneous signals
- Group F routes pin output enable signals

Together, the six groups of the SRU include all of the inputs and outputs of the DAI peripherals, a number of additional signals from the core, and all of the connections to the DAI pins.

NOTE: It is not possible to connect a signal in one group directly to a signal in a different group (analogous to wiring from one patch bay to another). However, group D (DAI) is largely devoted to routing in this vein.

DAI Group Routing

Each group has a unique encoding for its associated output signals and a set of configuration registers. For example, DAI group A is used to route clock signals. The memory-mapped group A registers, `DAI_CLK0` through `DAI_CLK5`, contain bit fields corresponding to the clock inputs of various peripherals. The values written to these bit fields specify a signal source that is an output from another peripheral. All of the possible encodings represent sources that are clock signals (or at least could be clock signals in some systems). The ***Example DAI Group A Multiplexing (DAI_CLKx)*** diagrams the input signals that are controlled by the group A registers. All bit fields in the SRU configuration registers correspond to inputs. The value written to the bit field specifies the signal source. This value is also an output from some other component within the SRU.

The SRU is similar to a set of patch bays. Each bay routes a distinct set of outputs to compatible inputs. These connections are implemented as a set of memory-mapped registers with a bit field for each input. The outputs are implemented as a set of bit encodings. Conceptually, a patch cord is used to connect an output to an input. In the SRU, a bit pattern that is associated with a signal output (shown in the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure) is written to a bit field corresponding to a signal input.

The same encoding can be written to any number of bit fields in the same group. It is not possible to run out of patch points for an output signal.

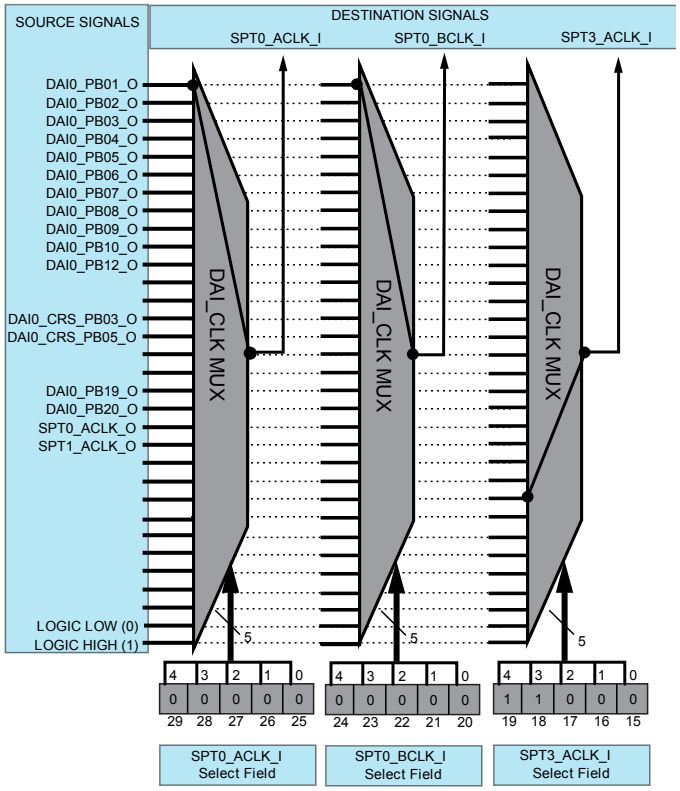

Figure 29-7: Example DAI Group A Multiplexing (DAIn_CLKx)

Just as group A routes clock signals, each of the other groups route a collection of compatible signals. Group B routes serial data streams while group C routes frame sync signals. All of the groups have an encoding that allow a signal to flow from a pin output to the input being specified by the bit field.

Group D routes signals to pins so that they may be driven off-chip (required to route a signal to the pin input). Group F routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input. The input of one pin can be patched to the output of another pin, allowing board-level routing under software control.

Rules for SRU Connections

There are two rules which apply to all routing:

1. One source (output node) can drive different destinations (input nodes).
2. One destination (input node) can only be assigned to one source (output node).

As an example from the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure:

- `DAI0_PB02_O` is routed to `SPT0_ACLK_I`
- `DAI0_PIN02_O` is routed to `SPT0_BCLK_I`
- `SPT2_ACLK_O` is routed to `SPT3_ACLK_I`

NOTE: Inputs may only be connected to outputs.

Miscellaneous Buffers and Functions

The SRU group E provides miscellaneous buffers used for group interconnect.

DAI group E connections are slightly different from the others in that the inputs and outputs being routed vary considerably in function. This group routes control signals and provides a means of connecting signals between groups.

In the ***DAI MISCAx SRU Signal Connections*** table, the `DAIn_MISCAx_I` signals appear as inputs in group E (also connected to the DAI interrupt logic), but do not directly feed any peripheral. Rather, the `MISCAx_O` signals reappear as outputs in group F.

Table 29-5: DAI MISCAx SRU Signal Connections

MISCA Source	DAI Connection	MISCA Destination
	Group E	DAIn_MISCA5-0_I
DAIn_MISCA5-0_O	Group F	

Additional connections among groups provide a great amount of utility. Since the output groups F (DAI) dictate pin direction, these few signal paths enable a number of possible uses and connections for the DAI pins. Other examples include:

- A pin input can be patched to another pin's enable, allowing an off-chip signal to gate an output from the processor.
- Any of the DAI pins can be used as interrupt sources or general-purpose I/O (GPIO) signals.

In summary, the SRU enables many possible functional changes, both within the processor as well as externally. Used creatively, it allows system designers to radically change functionality at run time, and to potentially reuse circuit boards across many products.

DAI Routing Unit (DRU)

The DAI routing unit provides all possible connections across DAIs by interconnecting two DAI units through a multiplexer.

- For every input signal of an SRU, there is a control bit that selects either the original signal from the native DAI or its corresponding signal from the other DAI. For example, either SP0_ACLK_O from DAI0 or SP0_ACLK_O from DAI1 is selected and routed to the SP0_ACLK_O input of the SRU of DAI0 based on the programmed control bit.
- By default, all native signals are connected to their respective SRU (for example, SP0_ACLK_O from DAI0 is connected to SP0_ACLK_O input of the SRU of DAI0.

As a part of fully cross-connected DAI Routing unit, following source signals are added to the existing SRU's source group.

- All the source signals of Group A/B/C/D/E/F from the other DAI are added as source signals to the native group A/B/C/D/E/F's respectively.

The *DAI Routing Unit System* figure depicts the block level view of the DAI Routing Unit connecting DAI0 and DAI1 through a multiplexer.

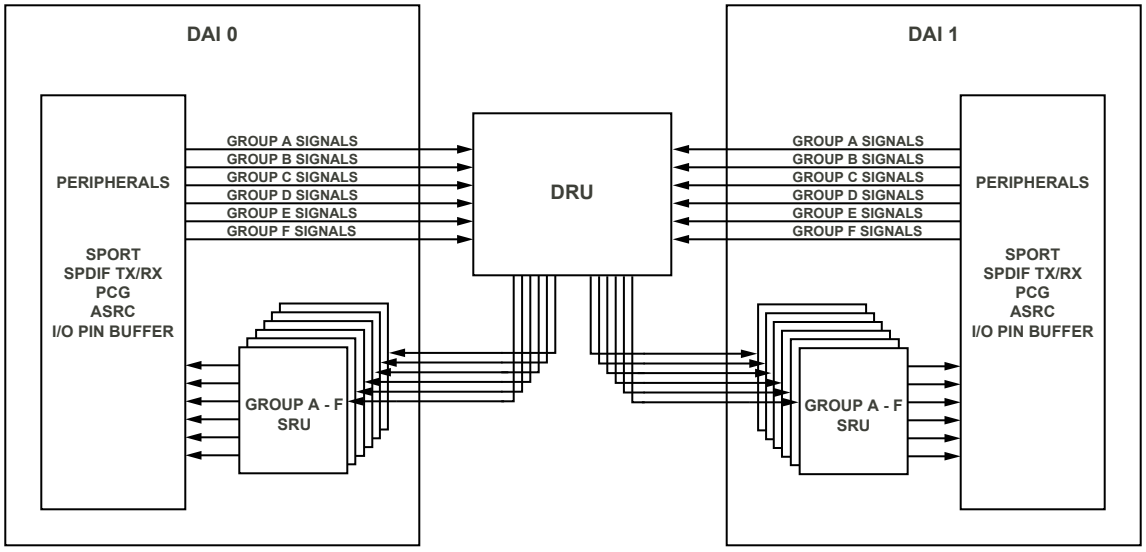

Figure 29-8: DAI Routing Unit System

DAI Routing Capabilities

This section describes the routing options to aid in designing a system using the DAI units. The DAI Default Routing section provides diagrams that show how that DAIs connect at default. The DAI Group tables provide the source signals and selections codes. Finally, the xxx provides information about configuring destinations.

The ***DAI Routing Capabilities*** tables provide an overview of the different routing capabilities for the DAI unit. For information on an individual peripherals routing, see the "SRU Programming" section of the specific peripheral chapter.

DAI Default Routing

When the processor comes out of reset, the SPORT junctions are bidirectional to the DAI pin buffers. This configuration allows systems to use the SPORTs as either requester or completer (without changing the routing scheme). Therefore, programs only need to use the SPORT control register settings to configure requester or completer operations. Note that all DAI inputs which are not routed by default are tied to signal low.

NOTE: All DAI input buffers which are not routed by default are driven low and all DAI pin buffer enable signals are driven low.

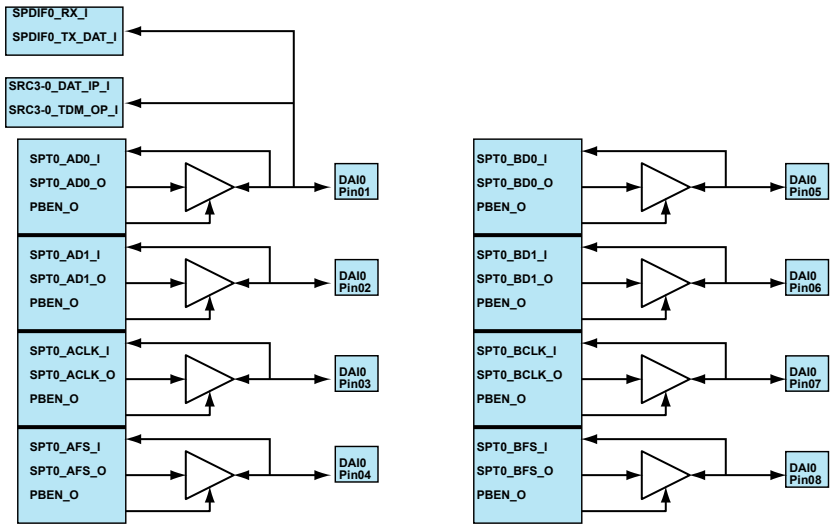

Figure 29-9: DAI0 Default Routing Pins 01-08

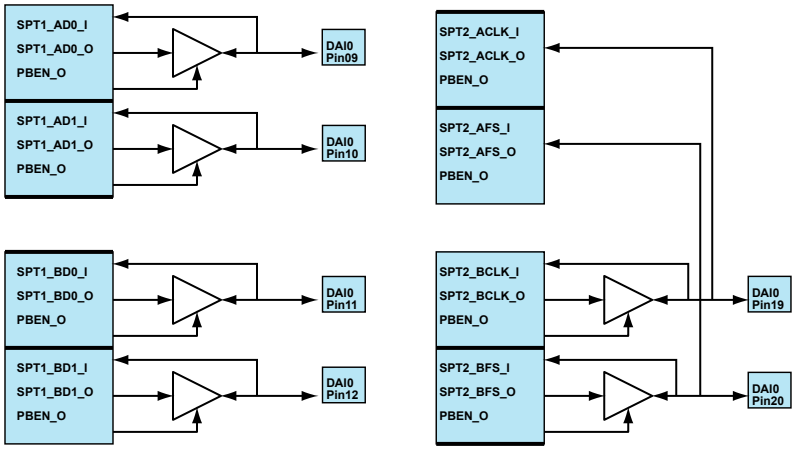

Figure 29-10: DAI0 Default Routing Pins 09-20

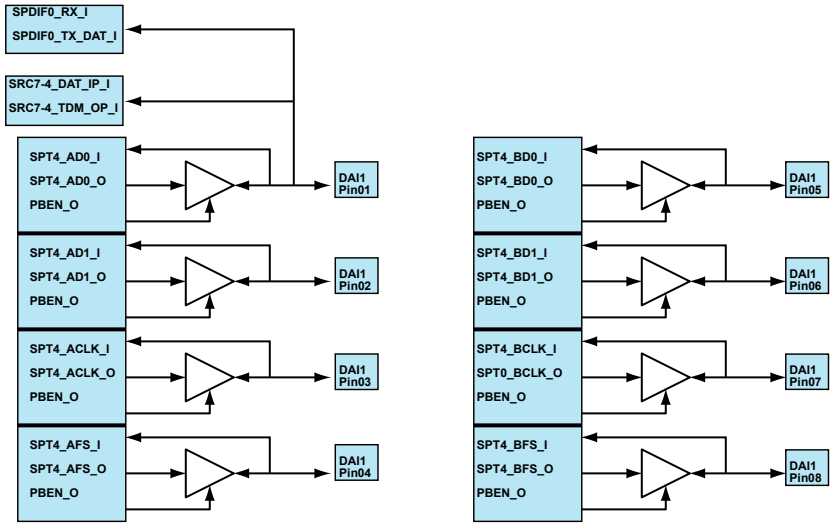

Figure 29-11: DAI1 Default Routing Pins 01-08

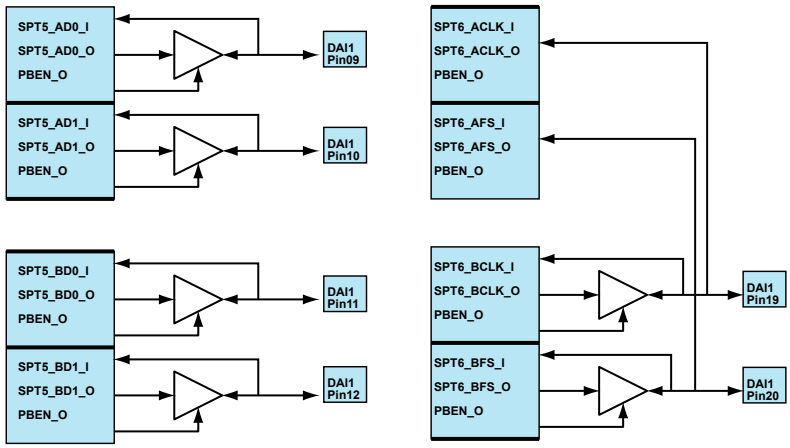

Figure 29-12: DAI1 Default Routing Pins 09-20

Unused DAI Connections

The SRUs have a default general-purpose routing scheme which can be modified to accomodate any number of different system designs. Regardless of the system design, it is good practice to tie all unused inputs to a high or low level to reduce dynamic power consumption.

DAI Operating Modes

Some buffers allow polarity changes, described as follows.

DAI Pin Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the DAI pin buffer 20-19 can change the polarity of the input signal if the corresponding control bits (`DAI_PIN4.INV20`, `DAI_PIN4.INV19`) are set. These bits can be set during run time and the buffer should not loopback to itself.

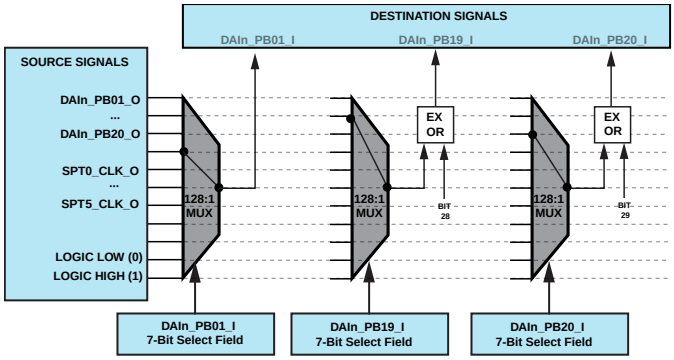

Figure 29-13: Pin Buffer Polarity

DAI Miscellaneous Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the A5-4 miscellaneous buffers can change the polarity of the input signal if the corresponding control bits (`DAI_MISC1.IN5`, `DAI_MISC1.IN4`) are set. Both buffers are not connected to the DAI interrupt latch register. These bits can be set during run time.

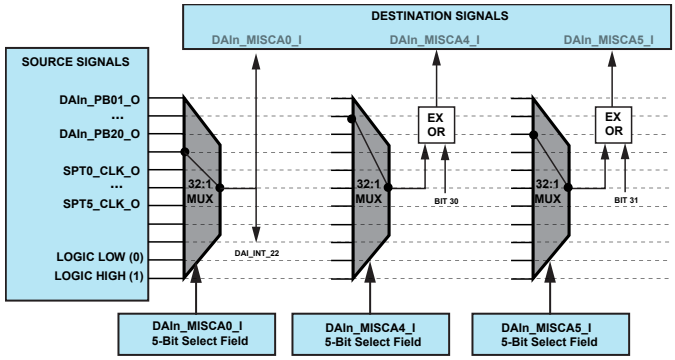

Figure 29-14: Miscellaneous Buffer Polarity

DAI System Interrupt Controller (SIC)

The DAI module incorporates a system interrupt controller (SIC) which is connected to the SEC as seen in the ***DAI System Interrupt Controller*** figure.

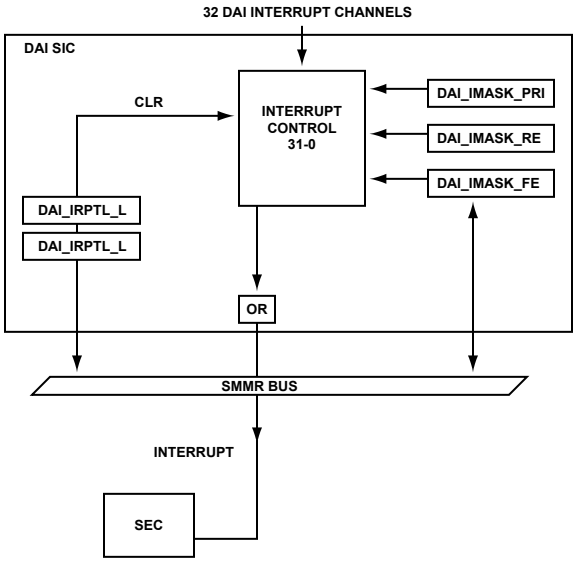

Figure 29-15: DAI System Interrupt Controller

The DAI has its own system interrupt controllers that indicate to the core when DAI audio peripheral-related events have occurred. Since audio events generally occur infrequently relative to the SHARC core, the DAI interrupt controller reduces all of its interrupts onto two interrupt signals within the core's primary interrupt systems. One interrupt is mapped with DAI low priority. The second interrupt is mapped with DAI high priority. This configuration allows programs to broadly indicate priority. In this way, the DAI SIC provides 32 independently configurable sources or channels. The output bus interrupt signals are logically OR'ed into one interrupt line and fed to the interrupt controller logic of the core.

Three registers are used to configure the DAI interrupt controller. Each of the 32 interrupt sources can be independently configured to trigger on a rising edge, falling edge, both edges, or neither edge of an incoming signal. All DAI interrupt control registers are memory-mapped registers and are accessed through the peripheral bus.

Interrupt Sources

The DAI's five peripheral sources are multiplexed into 32 interrupt sources and are labeled DAI_INT31-0 (***DAI Interrupt Sources*** table).

NOTE: There are two naming conventions. The DAI interrupt controller register bits are labeled DAI_31-0_INT. Their corresponding SRU routing signals are labeled DAI_INT_31-0_I.

Table 29-8: DAI Interrupt Sources

Interrupt Source	Description	Signal Response
	S/PDIF RX, 4 channels	Event

Table 29-8: DAI Interrupt Sources (Continued)

Interrupt Source	Description	Signal Response
DAI_INT2–0, DAI_INT4		
DAI_INT2–0, DAI_INT4	S/PDIF RX, 4 channels	Waveform
DAI_INT21–18	ASRC, 4 channels	
DAI_INT31–22	Miscellaneous, S/PDIF TX, 9 channels	

Interrupt Latch Priority Option

The DAI_IMSK_PRI register specifies the priority for the DAI interrupt channels. DAI system interrupt controller has a pair of interrupt latch registers, DAI_IRPTL_H and DAI_IRPTL_L. The configuration of the DAI_IMSK_PRI register also determines the interrupt latch mapping for a particular DAI interrupt. When a DAI interrupt is configured as low priority (DAI_IMSK_PRI bit cleared, default setting), interrupts are mapped to the DAI_INTR_IRQL signal and when an interrupt occurs, the corresponding bit of the DAI_IRPTL_L register is set. When a DAI interrupt is configured as high priority (DAI_IMSK_PRI bit set), interrupts are mapped to the DAI_INTR_IRQH signal and the interrupt is latched to the DAI_IRPTL_H register. The low priority DAI interrupt (INTR_DAI_IRQL) and high priority DAI interrupt (INTR_DAI_IRQH) are connected to the SEC .

Interrupt Mask for Waveforms

The DAI_IMSK_RE and DAI_IMSK_FE registers allow programs to mask or unmask interrupts for specific edges of a signal mapped to the channel. It can be configured for rising edges, falling edges, both rising and falling edges, or neither rising nor falling edges by masking them separately. Signals from the SRU can be used to generate interrupts. For example, when the DAI_IMSK_FE.MISCINT9 bit is set to one, any falling edge signals from the external channel generate an interrupt and the interrupt latch is set.

Interrupt Mask for Events

The system interrupt controller needs information about a peripheral's interrupt sources that correspond to event signals (see the ***DAI Interrupt Sources*** table). As a result, the rising edge is used as an interrupt source only. For DAI peripherals marked as events, programs may unmask an interrupt source on the rising edge only.

Shadow Interrupt Register

The DAI interrupt controller has shadow registers to simplify debug activities since these registers do not manipulate status control. Any read of the shadow registers (DAI_IRPTL_HS, DAI_IRPTL_LS), provides the same data as a read of the DAI_IRPTL_H and DAI_IRPTL_L registers. However, reads of the DAI shadow registers do not change the interrupt acknowledge status to the core interrupt controller.

Interrupt Service

The interrupt acknowledge operates differently when multiple channels are multiplexed into one interrupt output signal. When an interrupt from the DAI must be serviced, any of the two interrupt service routines

(INTR_DAI_IRQL, INTR_DAI_IRQH) must query the SIC to determine the source(s). Sources can be any one or more of the DAI channels (DAI_INT31-0).

- When the `DAI_IRPTL_H` register is read, the high priority latched interrupts are cleared.
- When the `DAI_IRPTL_L` register is read, the low priority latched interrupts are cleared.

If an interrupt occurs in the same cycle as a latch register is cleared, the clear mechanism has lower priority and the new interrupt is registered.

Signal Routing Unit Effect Latency

After the DAIy registers are configured the effect latency is 2 *SCLK0* cycles minimum and 3 *SCLK0* cycles maximum.

DAI Programming Model

As discussed in the previous sections, the signal routing unit is controlled by writing values that provide a plug-in tool in CCES so that configuring the SRU is done graphically. Analog Devices offers macros that are included with the CrossCore or VisualDSP++ tools, greatly easing code development in the SRU.

There is a macro that has been created to connect peripherals used in a DAI configuration. This code can be used in both assembly and C code. See the INCLUDE file SRU.H. In practice the macro is provided and forms the style `SRU(source_O, destination_I)` for DAI0. Example appears as: `SRU(DAI0_PB12_O, SPT0_ACLK_I);`

Debug Features

The following section describes the feature that can be used to help in debugging the DAI.

Loopback Routing

The SPORT serial peripheral supports an internal loopback mode. If the loopback bit for each peripheral is enabled, it connects the transmitter with the receiver block internally (does not signal off-chip). The SRU can be used for this purpose. The ***Loopback Routing*** table describes the different possible routings based on the peripheral.

NOTE: The peripheral's loopback mode for debug is independent from both of the signal routing units.

Table 29-9: Loopback Routing

Peripheral	Loopback Mode	SRU1–0 Internal Routing for Loopback	SRU1–0 External Routing for Loopback
SPORT	Yes	SPTx_xx_O → SPTx_xx_I	SPTx_xx_O → DAIn_PBxx_I DAIn_PBxx_O → SPTx_xx_I
S/PDIF Tx/Rx	No	SPDIFn_TX_O → SPDIFn_RX_I	SPDIFn_TX_O → DAI_PBxx_I DAI_PBxx_O → SPDIFn_RX_I

Table 29-9: Loopback Routing (Continued)

Peripheral	Loopback Mode	SRU1–0 Internal Routing for Loopback	SRU1–0 External Routing for Loopback
SRC	No	SRCx_DAT_OP_O → SRCx_DAT_IP_I	SRCx_DAT_OP_O → DAI_PBxx_I DAI_PBxx_O → SRCx_DAT_IP_I

DAI Sources Overview

The following tables provide information of the various DAI sources sorted by group.

Group A – Clock Routing Signals

The group A clock routing sources are listed in the following table.

Table 29-10: Group A – Clock Routing Sources

Extended Selection Code [1:0]		Selection Code [4:0]	Source Signal	Description (Source Selection)
Bit 1	Bit 0

DAI Destination Registers Overview

The tables in the DAI Routing Capabilities section provide high level descriptions that illustrate source (output) connections to destinations (inputs) depending on the routing groups A through F. This sections lists the various input fields (INx), which are described in detail in the register descriptions section.

Table 29-16: Clock Destination Registers (Group A)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_CLK0	IN0	SPT0_ACLK_I	SPT4_ACLK_I	SPORT0A or SPORT4A Clock
	IN1	SPT0_BCLK_I	SPT4_BCLK_I	SPORT0B or SPORT4B Clock
	IN2	SPT1_ACLK_I	SPT5_ACLK_I	SPORT1A or SPORT5A Clock

Table 29-16: Clock Destination Registers (Group A) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
	IN3	SPT1_BCLK_I	SPT5_BCLK_I	SPORT1B or SPORT5B Clock
	IN4	SPT2_ACLK_I	SPT6_ACLK_I	SPORT2A or SPORT6A Clock
	IN5	SPT2_BCLK_I	SPT6_BCLK_I	SPORT2B or SPORT6B Clock
DAI_CLK1	IN0	SRC0_CLK_IP_I	SRC4_CLK_IP_I	SRC0 or SRC4 Clock Input
	IN1	SRC0_CLK_OP_I	SRC4_CLK_OP_I	SRC0 or SRC4 Clock Output
	IN2	SRC1_CLK_IP_I	SRC5_CLK_IP_I	SRC1 or SRC5 Clock Input
	IN3	SRC1_CLK_OP_I	SRC5_CLK_OP_I	SRC1 or SRC5 Clock Output
	IN4	SRC2_CLK_IP_I	SRC6_CLK_IP_I	SRC2 or SRC6 Clock Input
	IN5	SRC2_CLK_OP_I	SRC6_CLK_OP_I	SRC2 or SRC6 Clock Output
DAI_CLK2	IN0	SRC3_CLK_IP_I	SRC7_CLK_IP_I	SRC3 or SRC7 Clock Input
	IN1	SRC3_CLK_OP_I	SRC7_CLK_OP_I	SRC3 or SRC7 Clock Output
	IN2	SPDIF0_TX_CLK_I	SPDIF1_TX_CLK_I	SPDIF0 or SPDIF1 TX Clock
	IN3	PDM0_CLK0_I	PDM1_CLK0_I	PDM0 or PDM1 Clock0 Input
	IN4	PDM0_BCLK_I	PDM1_BCLK_I	PDM0 or PDM1 Bit Clock Input
DAI_CLK3	IN5	SPDIF0_TX_HFCLK_I	SPDIF1_TX_HFCLK_I	SPDIF0 or SPDIF1 TX HF Clock
DAI_CLK4	IN0	PCG0_EXTCLKA_I	PCG0_EXTCLKC_I	PCG0 External Clock A or C
	IN1	PCG0_EXTCLKB_I	PCG0_EXTCLKD_I	PCG0 External Clock B or D
	IN3	SPDIF0_TX_EXT_SYNC_I	SPDIF1_TX_EXT_SYNC_I	SPDIF0 or SPDIF1 TX External Sync
	IN4	PCG0_SYNC_CLKA_I	PCG0_SYNC_CLKC_I	PCG0 Sync Clock A or C
	IN5	PCG0_SYNC_CLKB_I	PCG0_SYNC_CLKD_I	PCG0 Sync Clock B or D
DAI_CLK5	IN0	SPT3_ACLK_I	SPT7_ACLK_I	SPORT3A or SPORT 7A Clock
	IN1	SPT3_BCLK_I	SPT7_BCLK_I	SPORT3B or SPORT 7B Clock
	IN2	PCG0_SYNC_CLKE_I	PCG0_SYNC_CLKG_I	PCG0 Sync Clock E or G
	IN3	PCG0_SYNC_CLKF_I	PCG0_SYNC_CLKH_I	PCG0 Sync Clock F or H
	IN4	PCG0_EXTCLKE_I	PCG0_EXTCLKG_I	PCG0 External Clock E or G
	IN5	PCG0_EXTCLKF_I	PCG0_EXTCLKH_I	PCG0 External Clock F or H

Table 29-17: Data Destination Registers (Group B)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT0	IN0	SPT0_AD0_I	SPT4_AD0_I	SPORT0A or SPORT4A Primary Data
	IN1	SPT0_AD1_I	SPT4_AD1_I	SPORT0A or SPORT4A Secondary Data
	IN2	SPT0_BD0_I	SPT4_BD0_I	SPORT0B or SPORT4B Primary Data
	IN3	SPT0_BD1_I	SPT4_BD1_I	SPORT0B or SPORT4B Secondary Data
	IN4	SPT1_AD0_I	SPT5_AD0_I	SPORT1A or SPORT5A Primary Data
DAI_DAT1	IN0	SPT1_AD1_I	SPT5_AD1_I	SPORT1A or SPORT5A Secondary Data
	IN1	SPT1_BD0_I	SPT5_BD0_I	SPORT1B or SPORT5B Primary Data
	IN2	SPT1_BD1_I	SPT5_BD1_I	SPORT1B or SPORT5B Secondary Data
	IN3	SPT2_AD0_I	SPT6_AD0_I	SPORT2A or SPORT6A Primary Data
	IN4	SPT2_AD1_I	SPT6_AD1_I	SPORT2A or SPORT6A Secondary Data
DAI_DAT2	IN0	SPT2_BD0_I	SPT6_BD0_I	SPORT2B or SPORT6B Primary Data
	IN1	SPT2_BD1_I	SPT6_BD1_I	SPORT2B or SPORT6B Secondary Data
	IN2	SRC0_DAT_IP_I	SRC4_DAT_IP_I	SRC0 or SRC4 Data
	IN3	SRC1_DAT_IP_I	SRC5_DAT_IP_I	SRC1 or SRC5 Data
	IN4	SRC2_DAT_IP_I	SRC6_DAT_IP_I	SRC2 or SRC6 Data
DAI_DAT3	IN0	SRC3_DAT_IP_I	SRC7_DAT_IP_I	SRC3 or SRC7 Data
	IN1	SRC0_DAT_TDM_OP_I	SRC4_DAT_TDM_OP_I	SRC0 or SRC4 TDM output port
	IN2	SRC1_DAT_TDM_OP_I	SRC5_DAT_TDM_OP_I	SRC1 or SRC5 TDM Output port Data
	IN3	SRC2_DAT_TDM_OP_I	SRC6_DAT_TDM_OP_I	SRC2 or SRC6 TDM Output port Data
	IN4	SRC3_DAT_TDM_OP_I	SRC7_DAT_TDM_OP_I	SRC3 or SRC7 TDM Output port Data
DAI_DAT4	IN0	SPDIF0_TX_DAT_I	SPDIF1_TX_DAT_I	SPDIF0 or SPDIF1 serial transmitter Data
	IN1	PDM0_DAT0_I	PDM1_DAT0_I	PDM0 or PDM1 Data0 Input
	IN2	PDM0_DAT1_I	PDM1_DAT1_I	PDM0 or PDM1 Data1 Input

Table 29-17: Data Destination Registers (Group B) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT5	IN4	SPDIF0_RX_I	SPDIF1_RX_I	SPDIF0 or SPDIF1 receiver bi-phase Data
DAI_DAT6	IN0	SPT3_AD0_I	SPT7_AD0_I	SPORT3A or SPORT7A Primary Data
	IN1	SPT3_AD1_I	SPT7_AD1_I	SPORT3A or SPORT7A Secondary Data
	IN2	SPT3_BD0_I	SPT7_BD0_I	SPORT3B or SPORT7B Primary Data
	IN3	SPT3_BD1_I	SPT7_BD1_I	SPORT3B or SPORT7B Secondary Data
	IN4	Reserved	Reserved	

Table 29-18: Frame Sync Destination Registers (Group C)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_FS0	IN0	SPT0_AFS_I	SPT4_AFS_I	SPORT0A or SPORT4A Frame Sync
	IN1	SPT0_BFS_I	SPT4_BFS_I	SPORT0B or SPORT4B Frame Sync
	IN2	SPT1_AFS_I	SPT5_AFS_I	SPORT1A or SPORT5A Frame Sync
	IN3	SPT1_BFS_I	SPT5_BFS_I	SPORT1B or SPORT5B Frame Sync
	IN4	SPT2_AFS_I	SPT6_AFS_I	SPORT2A or SPORT6A Frame Sync
	IN5	SPT2_BFS_I	SPT6_BFS_I	SPORT2B or SPORT6B Frame Sync
DAI_FS1	IN0	SRC0_FS_IP_I	SRC4_FS_IP_I	SRC0 or SRC4 Frame Sync Input
	IN1	SRC0_FS_OP_I	SRC4_FS_OP_I	SRC0 or SRC4 Frame Sync Output
	IN2	SRC1_FS_IP_I	SRC5_FS_IP_I	SRC1 or SRC5 Frame Sync Input
	IN3	SRC1_FS_OP_I	SRC5_FS_OP_I	SRC1 or SRC5 Frame Sync Output
	IN4	SRC2_FS_IP_I	SRC6_FS_IP_I	SRC2 or SRC6 Frame Sync Input
	IN5	SRC2_FS_OP_I	SRC6_FS_OP_I	SRC2 or SRC6 Frame Sync Output
DAI_FS2	IN0	SRC3_FS_IP_I	SRC7_FS_IP_I	SRC3 or SRC7 Frame Sync Input
	IN1	SRC3_FS_OP_I	SRC7_FS_OP_I	SRC3 or SRC7 Frame Sync Output
	IN2	SPDIF0_TX_FS_I	SPDIF1_TX_FS_I	SPDIF0 or SPDIF1 Transmit Frame Sync

Table 29-18: Frame Sync Destination Registers (Group C) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_FS4	IN0	SPT3_AFS_I	SPT7_AFS_I	SPORT3A or SPORT7A Frame Sync
	IN1	SPT3_BFS_I	SPT7_BFS_I	SPORT3B or SPORT7B Frame Sync
	IN2	TM0_ACI14_I	TM0_ACI15_I	ACI 14 or ACI 15 Timer Input
	IN3	PDM0_LRCLK_I	PDM1_LRCLK_I	PDM0 or PDM1 Left/Right Clock or Frame Sync Input

Table 29-19: Pin Buffer Assignment Destination Registers (Group D)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PIN0	IN0	DAI0_PB01_I	DAI1_PB01_I	Pin Buffer 1
	IN1	DAI0_PB02_I	DAI1_PB02_I	Pin Buffer 2
	IN2	DAI0_PB03_I	DAI1_PB03_I	Pin Buffer 3
	IN3	DAI0_PB04_I	DAI1_PB04_I	Pin Buffer 4
DAI_PIN1	IN0	DAI0_PB05_I	DAI1_PB05_I	Pin Buffer 5
	IN1	DAI0_PB06_I	DAI1_PB06_I	Pin Buffer 6
	IN2	DAI0_PB07_I	DAI1_PB07_I	Pin Buffer 7
	IN3	DAI0_PB08_I	DAI1_PB08_I	Pin Buffer 8
DAI_PIN2	IN0	DAI0_PB09_I	DAI1_PB09_I	Pin Buffer 9
	IN1	DAI0_PB10_I	DAI1_PB10_I	Pin Buffer 10
	IN2	DAI0_PB11_I	DAI1_PB11_I	Pin Buffer 11
	IN3	DAI0_PB12_I	DAI1_PB12_I	Pin Buffer 12
DAI_PIN3*1	IN0	DAI0_PB13_I	DAI1_PB13_I	Pin Buffer 13
	IN1	DAI0_PB14_I	DAI1_PB14_I	Pin Buffer 14
	IN2	DAI0_PB15_I	DAI1_PB15_I	Pin Buffer 15
	IN3	DAI0_PB16_I	DAI1_PB16_I	Pin Buffer 16
DAI_PIN4*2	IN0	DAI0_PB17_I	DAI1_PB17_I	Pin Buffer 17
	IN1	DAI0_PB18_I	DAI1_PB18_I	Pin Buffer 18
	IN2	DAI0_PB19_I	DAI1_PB19_I	Pin Buffer 19
	IN3	DAI0_PB20_I	DAI1_PB20_I	Pin Buffer 20
	IN4	INV_DAI0_PB19_I	INV_DAI1_PB19_I	Inverted Pin Buffer 19
	IN5	INV_DAI0_PB20_I	INV_DAI1_PB20_I	Inverted Pin Buffer 20

*1 This configuration applies to the ADSP-SC591/2/4 only. This configuration is reserved for the ADSP-21591/3

*2 The IN0 and IN1 bit fields apply to the ADSP-SC591/2/4 only. These bits are reserved for the ADSP-21591/3

In Table 29-20 Miscellaneous Control Destination Registers (Group E) , DAI_MISCAx_I is an alias name for DAI_INT_x_I.

Table 29-20: Miscellaneous Control Destination Registers (Group E)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_MISC0	IN6	DAI0_MISCA0_I/ DAI0_INT_6_I	DAI1_MISCA0_I/ DAI1_INT_6_I	DAIx miscellaneous A0 input, or DAIx interrupt 28
	IN7	DAI0_MISCA1_I/ DAI0_INT_7_I	DAI1_MISCA1_I/ DAI1_INT_7_I	DAIx miscellaneous A1 input, or DAIx interrupt 29
	IN8	DAI0_MISCA2_I/ DAI0_INT_8_I	DAI1_MISCA2_I/ DAI1_INT_8_I	DAIx miscellaneous A2 input, or DAIx interrupt 30
	IN9	DAI0_MISCA3_I/ DAI0_INT_9_I	DAI1_MISCA3_I/ DAI1_INT_9_I	DAIx miscellaneous A3 input, or DAIx interrupt 31
	IN10	DAI0_MISCA4_I	DAI1_MISCA4_I	DAIx miscellaneous A4 input
	IN11	DAI0_MISCA5_I	DAI1_MISCA5_I	DAIx miscellaneous A5 input
	IN10	DAI0_INV_MISCA4_I	DAI1_INV_MISCA4_I	DAIx inverted miscellaneous A4 input
	IN11	DAI0_INV_MISCA4_I	DAI1_INV_MISCA5_I	DAIx inverted miscellaneous A5 input
DAI_MISC1	IN0	DAI0_INT_0	DAI1_INT_0	DAIx interrupt 22
	IN1	DAI0_INT_1	DAI1_INT_1	DAIx interrupt 23
	IN2	DAI0_INT_2	DAI1_INT_2	DAIx interrupt 24
	IN3	DAI0_INT_3	DAI1_INT_3	DAIx interrupt 25
	IN4	DAI0_INT_4	DAI1_INT_4	DAIx interrupt 26
	IN5	DAI0_INT_5	DAI1_INT_5	DAIx interrupt 27
DAI_MISC2	IN0	PCG_HWA_TRIG_I	PCG_HWC_TRIG_I	PCG hardware trigger input A or C
	IN1	PCG_HWB_TRIG_I	PCG_HWD_TRIG_I	PCG hardware trigger input B or D
	IN2	PCG_HWE_TRIG_I	PCG_HWG_TRIG_I	PCG hardware trigger input E or G
	IN3	PCG_HWF_TRIG_I	PCG_HWH_TRIG_I	PCG hardware trigger input A or C

Table 29-21: Pin Buffer Enable Destination Registers (Group F)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PBEN0	IN0	DAI0_PBEN01_I	DAI1_PBEN01_I	Pin Buffer 1 Enable
	IN1	DAI0_PBEN02_I	DAI1_PBEN02_I	Pin Buffer 2 Enable
	IN2	DAI0_PBEN03_I	DAI1_PBEN03_I	Pin Buffer 3 Enable
	IN3	DAI0_PBEN04_I	DAI1_PBEN04_I	Pin Buffer 4 Enable
	IN4	DAI0_PBEN05_I	DAI1_PBEN05_I	Pin Buffer 5 Enable
DAI_PBEN1	IN0	DAI0_PBEN06_I	DAI1_PBEN06_I	Pin Buffer 6 Enable
	IN1	DAI0_PBEN07_I	DAI1_PBEN07_I	Pin Buffer 7 Enable
	IN2	DAI0_PBEN08_I	DAI1_PBEN08_I	Pin Buffer 8 Enable
	IN3	DAI0_PBEN09_I	DAI1_PBEN09_I	Pin Buffer 9 Enable
	IN4	DAI0_PBEN10_I	DAI1_PBEN10_I	Pin Buffer 10 Enable
DAI_PBEN2	IN0	DAI0_PBEN11_I	DAI1_PBEN11_I	Pin Buffer 11 Enable
	IN1	DAI0_PBEN12_I	DAI1_PBEN12_I	Pin Buffer 12 Enable
	IN2	DAI0_PBEN13_I	DAI1_PBEN13_I	Pin Buffer 13 Enable
	IN3	DAI0_PBEN14_I	DAI1_PBEN14_I	Pin Buffer 14 Enable
	IN4	DAI0_PBEN15_I	DAI1_PBEN15_I	Pin Buffer 15 Enable
DAI_PBEN3	IN0	DAI0_PBEN16_I	DAI1_PBEN16_I	Pin Buffer 16 Enable
	IN1	DAI0_PBEN17_I	DAI1_PBEN17_I	Pin Buffer 17 Enable
	IN2	DAI0_PBEN18_I	DAI1_PBEN18_I	Pin Buffer 18 Enable
	IN3	DAI0_PBEN19_I	DAI1_PBEN19_I	Pin Buffer 19 Enable
	IN4	DAI0_PBEN20_I	DAI1_PBEN20_I	Pin Buffer 20 Enable

The ***Interrupt Events*** table presents the information for the following registers.

- DAI_IMSK_PRI (Core Interrupt Priority Assignment) register
- DAI_IMSK_FE (Falling-Edge Interrupt Mask) and DAI_IMSK_RE (Rising-Edge Interrupt Mask) registers
- DAI_IRPTL_H (High-Priority Interrupt Latch) and DAI_IRPTL_L (Low-Priority Interrupt Latch) registers
- DAI_IRPTL_HS (Shadow High Interrupt Latch) and DAI_IRPTL_LS (Shadow Low Interrupt Latch) registers

Table 29-22: Interrupt Events

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
RXVALID	SPDIF0_RXVALID_INT	SPDIF1_RXVALID_INT	SPDIF0 or SPDIF1 RX Valid interrupt

Table 29-22: Interrupt Events (Continued)

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
RXLOCK	SPDIF0_RXLOCK_INT	SPDIF1_RXLOCK_INT	SPDIF0 or SPDIF1 RX Lock interrupt
RXLOSSOFLOCK	SPDIF0_RXLOSSOFLOCK_INT	SPDIF1_RXLOSSOFLOCK_INT	SPDIF0 or SPDIF1 RX Loss of Lock interrupt
RXNONAUDIO	SPDIF0_RXNONAUDIO_INT	SPDIF1_RXNONAUDIO_INT	SPDIF0 or SPDIF1 RX Non-audio interrupt
SRC0MUTE	SRC0_MUTE_INT	SRC4_MUTE_INT	DAI0 or DAI1 ASRC0 Mute interrupt
SRC1MUTE	SRC1_MUTE_INT	SRC5_MUTE_INT	DAI0 or DAI1 ASRC1 Mute interrupt
SRC2MUTE	SRC2_MUTE_INT	SRC6_MUTE_INT	DAI0 or DAI1 ASRC2 Mute interrupt
SRC3MUTE	SRC3_MUTE_INT	SRC7_MUTE_INT	DAI0 or DAI1 ASRC3 Mute interrupt
MISCINT0	DAI0_INT_00	DAI1_INT_00	DAI0 or DAI1 Miscellaneous Interrupt 0
MISCINT1	DAI0_INT_01	DAI1_INT_01	DAI0 or DAI1 Miscellaneous Interrupt 1
MISCINT2	DAI0_INT_02	DAI1_INT_02	DAI0 or DAI1 Miscellaneous Interrupt 2
MISCINT3	DAI0_INT_03	DAI1_INT_03	DAI0 or DAI1 Miscellaneous Interrupt 3
MISCINT4	DAI0_INT_04	DAI1_INT_04	DAI0 or DAI1 Miscellaneous Interrupt 4
MISCINT5	DAI0_INT_05	DAI1_INT_05	DAI0 or DAI1 Miscellaneous Interrupt 5
MISCINT6	DAI0_EXTMISCA0_INT/ DAI0_INT_06	DAI1_EXTMISCA0_INT/ DAI1_INT_06	DAI0 or DAI1 Miscellaneous Interrupt 6 / External Miscellaneous A0 Interrupt
MISCINT7	DAI0_EXTMISCA1_INT/ DAI0_INT_07	DAI1_EXTMISCA1_INT/ DAI1_INT_07	DAI0 or DAI1 Miscellaneous Interrupt 7 / External Miscellaneous A1 Interrupt
MISCINT8	DAI0_EXTMISCA2_INT/ DAI0_INT_08	DAI1_EXTMISCA2_INT/ DAI1_INT_08	DAI0 or DAI1 Miscellaneous Interrupt 8 / External Miscellaneous A2 Interrupt
MISCINT9	DAI0_EXTMISCA3_INT/ DAI0_INT_09	DAI1_EXTMISCA3_INT/ DAI1_INT_09	DAI0 or DAI1 Miscellaneous Interrupt 9 / External Miscellaneous A3 Interrupt

SPORT Grouping with DAI

DAI supports two registers DAI_GBL_SP_EN and DAI_GBL_INT_EN to group enabling/disabling and interrupt/trigger generation/reception for multiple SPORTs.

For more information about this, refer to the Grouping of SPORTs section.

Global PCG Enable

The DAI module includes the DAI_GBL_PCG_EN register that enables and disables multiple PCGs globally at the same time. For more information, see Global PCG Enable section in the PCG chapter.

ADSP-2159x_SC591_SC592_SC594 DAI Register Descriptions

The Digital Audio Interface (DAIn) registers are used to configure DAI destinations for the DAI sources shown in the Group A - F Routing tables. (DAI) contains the following registers.

Table 29-23: ADSP-2159x_SC591_SC592_SC594 DAI Register List

Name	Description
DAI_CLK0	Clock Routing Control Register 0
DAI_CLK1	Clock Routing Control Register 1
DAI_CLK2	Clock Routing Control Register 2
DAI_CLK3	Clock Routing Control Register 3
DAI_CLK4	Clock Routing Control Register 4
DAI_CLK5	Clock Routing Control Register 5
DAI_DAT0	Serial Data Routing Control Register 0
DAI_DAT1	Serial Data Routing Control Register 1
DAI_DAT2	Serial Data Routing Control Register 2
DAI_DAT3	Serial Data Routing Control Register 3
DAI_DAT4	Serial Data Routing Control Register 4
DAI_DAT5	Serial Data Routing Control Register 5
DAI_DAT6	Serial Data Routing Control Register 6
DAI_EXTD_CLK0	Extended Clock Routing Control Register 0
DAI_EXTD_CLK1	Extended Clock Routing Control Register 1
DAI_EXTD_CLK2	Extended Clock Routing Control Register 2
DAI_EXTD_CLK3	Extended Clock Routing Control Register 3
DAI_EXTD_CLK4	Extended Clock Routing Control Register 4

Table 29-23: ADSP-2159x_SC591_SC592_SC594 DAI Register List (Continued)

Name	Description
DAI_EXTD_CLK5	Extended Clock Routing Control Register 5
DAI_EXTD_DAT0	Extended Serial Data Routing Control Register 0
DAI_EXTD_DAT1	Extended Serial Data Routing Control Register 1
DAI_EXTD_DAT2	Extended Serial Data Routing Control Register 2
DAI_EXTD_DAT3	Extended Serial Data Routing Control Register 3
DAI_EXTD_DAT4	Extended Serial Data Routing Control Register 4
DAI_EXTD_DAT5	Extended Serial Data Routing Control Register 5
DAI_EXTD_DAT6	Extended Serial Data Routing Control Register 6
DAI_EXTD_FS0	Extended Frame Sync Routing Control Register 0
DAI_EXTD_FS1	Extended Frame Sync Routing Control Register 1
DAI_EXTD_FS2	Extended Frame Sync Routing Control Register 2
DAI_EXTD_FS4	Extended Frame Sync Routing Control Register 4
DAI_EXTD_MISC0	Extended Miscellaneous Control Register 0
DAI_EXTD_MISC1	Extended Miscellaneous Control Register 1
DAI_EXTD_MISC2	Extended Miscellaneous Control Register 2
DAI_EXTD_PBEN0	Extended Pin Buffer Enable Register 0
DAI_EXTD_PBEN1	Extended Pin Buffer Enable Register 1
DAI_EXTD_PBEN2	Extended Pin Buffer Enable Register 2
DAI_EXTD_PBEN3	Extended Pin Buffer Enable Register 3
DAI_EXTD_PIN0	Extended Pin Buffer Assignment Register 0
DAI_EXTD_PIN1	Extended Pin Buffer Assignment Register 1
DAI_EXTD_PIN2	Extended Pin Buffer Assignment Register 2
DAI_EXTD_PIN3	Extended Pin Buffer Assignment Register 3
DAI_EXTD_PIN4	Extended Pin Buffer Assignment Register 4
DAI_FS0	Frame Sync Routing Control Register 0
DAI_FS1	Frame Sync Routing Control Register 1
DAI_FS2	Frame Sync Routing Control Register 2
DAI_FS4	Frame Sync Routing Control Register 4
DAI_GBL_INT_EN	Global SPORT Interrupt Grouping Register
DAI_GBL_PCG_EN	Global PCG Enable Control Register
DAI_GBL_SP_EN	Global SPORT Enable Register

Table 29-23: ADSP-2159x_SC591_SC592_SC594 DAI Register List (Continued)

Name	Description
DAI_IMSK_FE	Falling-Edge Interrupt Mask Register
DAI_IMSK_PRI	Core Interrupt Priority Assignment Register
DAI_IMSK_RE	Rising-Edge Interrupt Mask Register
DAI_IRPTL_H	High Priority Interrupt Latch Register
DAI_IRPTL_HS	Shadow High Priority Interrupt Latch Register
DAI_IRPTL_L	Low Priority Interrupt Latch Register
DAI_IRPTL_LS	Shadow Low Priority Interrupt Latch Register
DAI_MISC0	Miscellaneous Control Register 0
DAI_MISC1	Miscellaneous Control Register 1
DAI_MISC2	Miscellaneous Control Register 1
DAI_PBEN0	Pin Buffer Enable Register 0
DAI_PBEN1	Pin Buffer Enable Register 1
DAI_PBEN2	Pin Buffer Enable Register 2
DAI_PBEN3	Pin Buffer Enable Register 3
DAI_PIN0	Pin Buffer Assignment Register 0
DAI_PIN1	Pin Buffer Assignment Register 1
DAI_PIN2	Pin Buffer Assignment Register 2
DAI_PIN3	Pin Buffer Assignment Register 3
DAI_PIN4	Pin Buffer Assignment Register 4
DAI_PIN_STAT	Pin Status Register

Clock Routing Control Register 0

The DAI_CLK0 register provides clock routing connections for the serial ports (SPORTs).

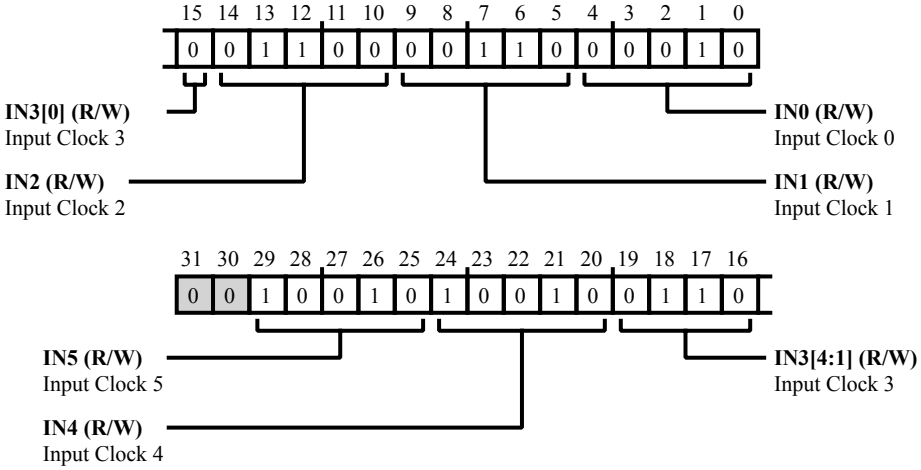

Figure 29-16: DAI_CLK0 Register Diagram

Table 29-24: DAI_CLK0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK0.IN5 holds the Source signal assignment that will be routed to the DAI_CLK0.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK0.IN4 holds the Source signal assignment that will be routed to the DAI_CLK0.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK0.IN3 holds the Source signal assignment that will be routed to the DAI_CLK0.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK0.IN2 holds the Source signal assignment that will be routed to the DAI_CLK0.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK0.IN1 holds the Source signal assignment that will be routed to the DAI_CLK0.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 29-24: DAI_CLK0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK0.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK0.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings

Clock Routing Control Register 1

The DAI_CLK1 register provides clock routing connections for the asynchronous sample rate converters (ASRC).

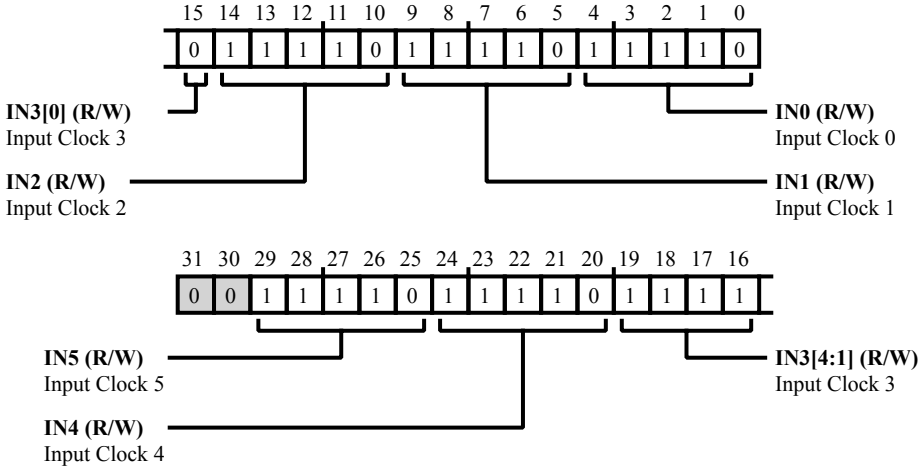

Figure 29-17: DAI_CLK1 Register Diagram

Table 29-25: DAI_CLK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK1.IN5 holds the Source signal assignment that will be routed to the DAI_CLK1.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK1.IN4 holds the Source signal assignment that will be routed to the DAI_CLK1.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK1.IN3 holds the Source signal assignment that will be routed to the DAI_CLK1.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK1.IN2 holds the Source signal assignment that will be routed to the DAI_CLK1.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK1.IN1 holds the Source signal assignment that will be routed to the DAI_CLK1.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Table 29-25: DAI_CLK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK1.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK1.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 2

The DAI_CLK2 register provides clock routing connections for the S/PDIF and ASRC.

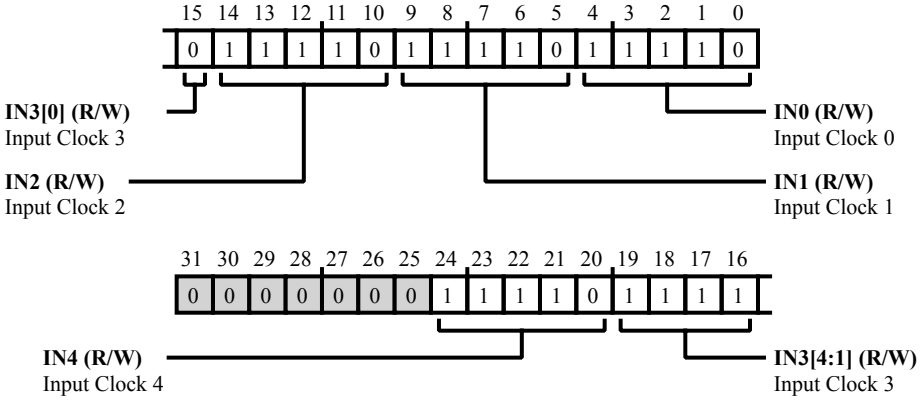

Figure 29-18: DAI_CLK2 Register Diagram

Table 29-26: DAI_CLK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK2.IN4 holds the Source signal assignment that will be routed to the DAI_CLK2.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK2.IN3 holds the Source signal assignment that will be routed to the DAI_CLK2.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK2.IN2 holds the Source signal assignment that will be routed to the DAI_CLK2.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK2.IN1 holds the Source signal assignment that will be routed to the DAI_CLK2.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Clock 0. DAI_CLK2.IN0 holds the Source signal assignment that will be routed to the DAI_CLK2.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 3

The DAI_CLK3 register provides clock routing connections for the S/PDIF.

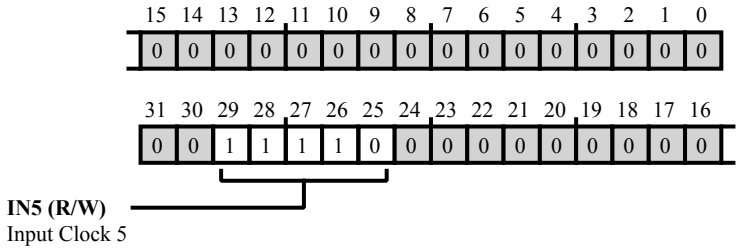

Figure 29-19: DAI_CLK3 Register Diagram

Table 29-27: DAI_CLK3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. The DAI_CLK3.IN5 bit field provides the S/PDIF oversampling clock.

Clock Routing Control Register 4

The DAI_CLK4 register provides clock routing connections for the precision clock generators (PCGs).

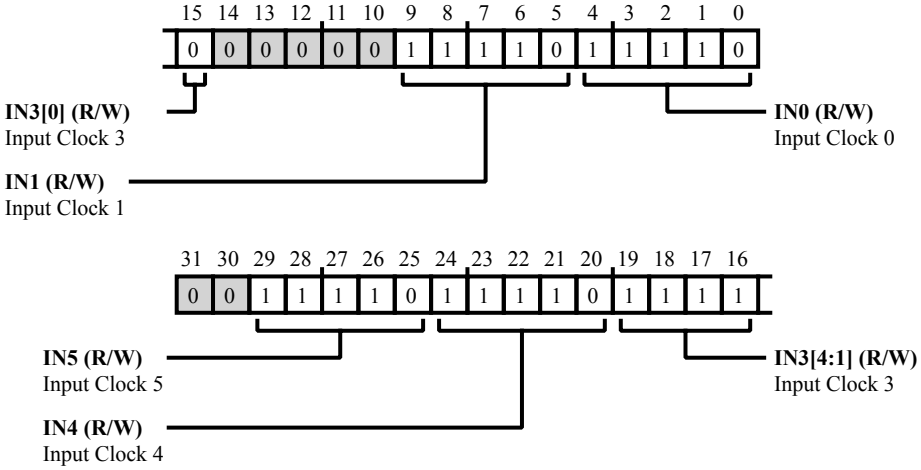

Figure 29-20: DAI_CLK4 Register Diagram

Table 29-28: DAI_CLK4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK4.IN5 holds the Source signal assignment that will be routed to the DAI_CLK4.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK4.IN4 holds the Source signal assignment that will be routed to the DAI_CLK4.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK4.IN3 holds the Source signal assignment that will be routed to the DAI_CLK4.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK4.IN1 holds the Source signal assignment that will be routed to the DAI_CLK4.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Clock 0. DAI_CLK4.IN0 holds the Source signal assignment that will be routed to the DAI_CLK4.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 5

The DAI_CLK5 register provides clock routing connections for the serial ports.

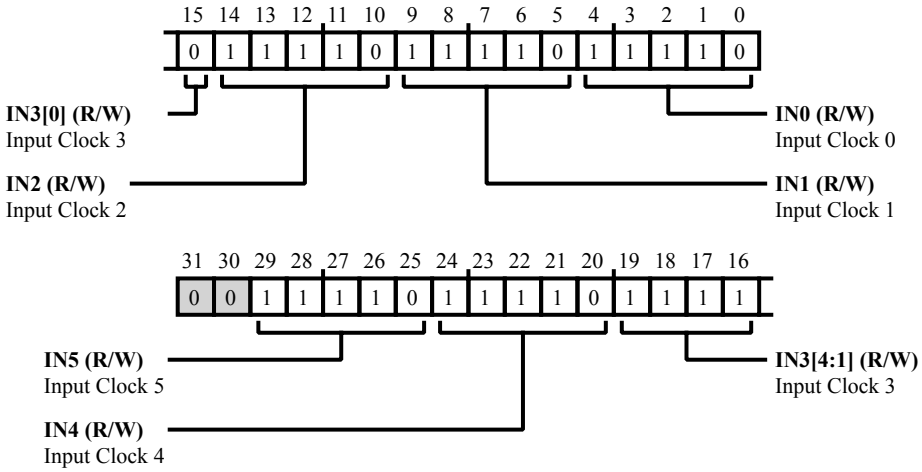

Figure 29-21: DAI_CLK5 Register Diagram

Table 29-29: DAI_CLK5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK5.IN5 holds the Source signal assignment that will be routed to the DAI_CLK5.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK5.IN4 holds the Source signal assignment that will be routed to the DAI_CLK5.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK5.IN3 holds the Source signal assignment that will be routed to the DAI_CLK5.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK5.IN2 holds the Source signal assignment that will be routed to the DAI_CLK5.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK5.IN1 holds the Source signal assignment that will be routed to the DAI_CLK5.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Table 29-29: DAI_CLK5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK5.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK5.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings.

Serial Data Routing Control Register 0

The DAI_DAT0 register routes serial data to the serial ports.

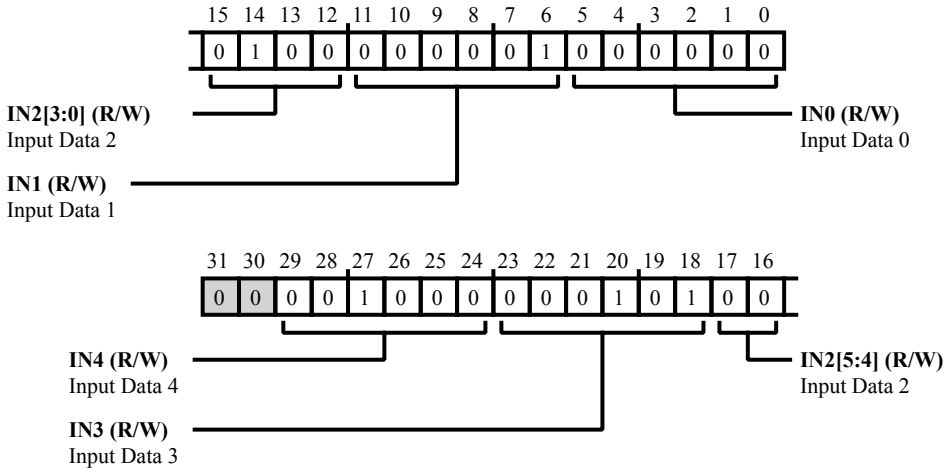

Figure 29-22: DAI_DAT0 Register Diagram

Table 29-30: DAI_DAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT0.IN4 holds the Source signal assignment that will be routed to the DAI_DAT0.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT0.IN3 holds the Source signal assignment that will be routed to the DAI_DAT0.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT0.IN2 holds the Source signal assignment that will be routed to the DAI_DAT0.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT0.IN1 holds the Source signal assignment that will be routed to the DAI_DAT0.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT0.IN0 holds the Source signal assignment that will be routed to the DAI_DAT0.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 1

The DAI_DAT1 register routes serial data to the serial ports.

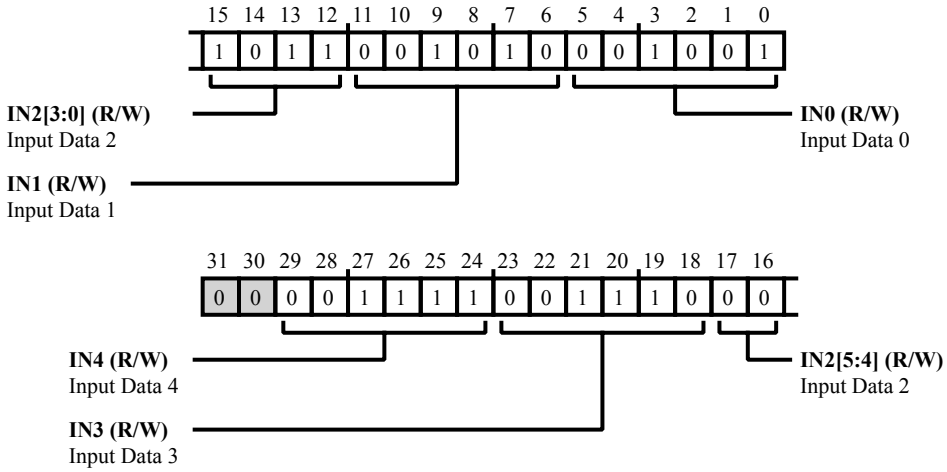

Figure 29-23: DAI_DAT1 Register Diagram

Table 29-31: DAI_DAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT1.IN4 holds the Source signal assignment that will be routed to the DAI_DAT1.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT1.IN3 holds the Source signal assignment that will be routed to the DAI_DAT1.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT1.IN2 holds the Source signal assignment that will be routed to the DAI_DAT1.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT1.IN1 holds the Source signal assignment that will be routed to the DAI_DAT1.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT1.IN0 holds the Source signal assignment that will be routed to the DAI_DAT1.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 2

The DAI_DAT2 register routes serial data to the serial ports and the asynchronous sample rate converter (ASRC).

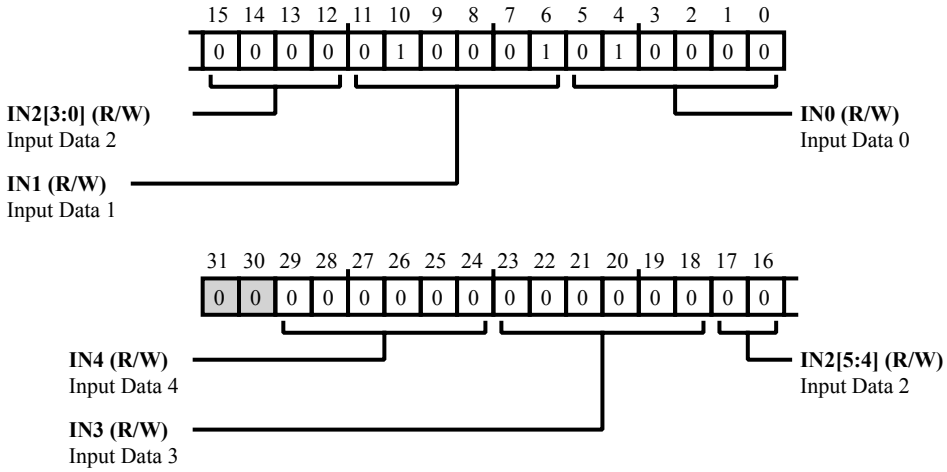

Figure 29-24: DAI_DAT2 Register Diagram

Table 29-32: DAI_DAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT2.IN4 holds the Source signal assignment that will be routed to the DAI_DAT2.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT2.IN3 holds the Source signal assignment that will be routed to the DAI_DAT2.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT2.IN2 holds the Source signal assignment that will be routed to the DAI_DAT2.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT2.IN1 holds the Source signal assignment that will be routed to the DAI_DAT2.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT2.IN0 holds the Source signal assignment that will be routed to the DAI_DAT2.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 3

The DAI_DAT3 register routes serial data to the asynchronous sample rate converter (ASRC).

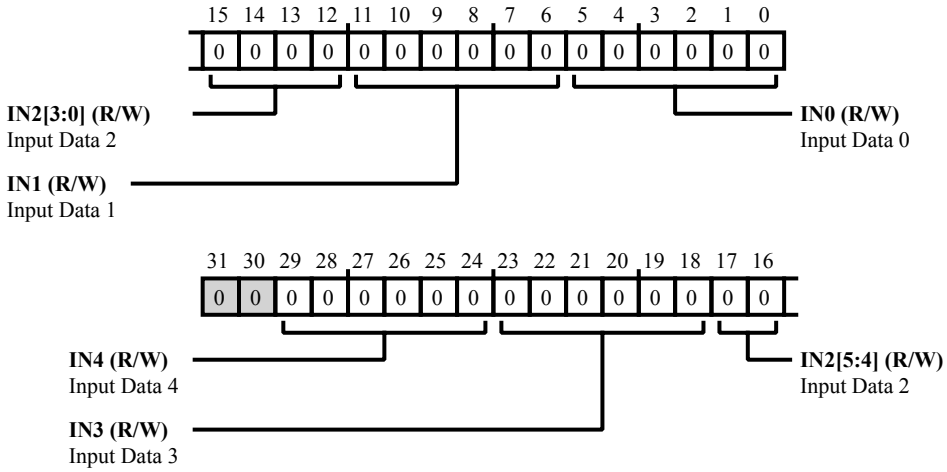

Figure 29-25: DAI_DAT3 Register Diagram

Table 29-33: DAI_DAT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT3.IN4 holds the Source signal assignment that will be routed to the DAI_DAT3.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT3.IN3 holds the Source signal assignment that will be routed to the DAI_DAT3.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT3.IN2 holds the Source signal assignment that will be routed to the DAI_DAT3.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT3.IN1 holds the Source signal assignment that will be routed to the DAI_DAT3.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT3.IN0 holds the Source signal assignment that will be routed to the DAI_DAT3.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 4

The DAI_DAT4 register routes serial data to the S/PDIF.

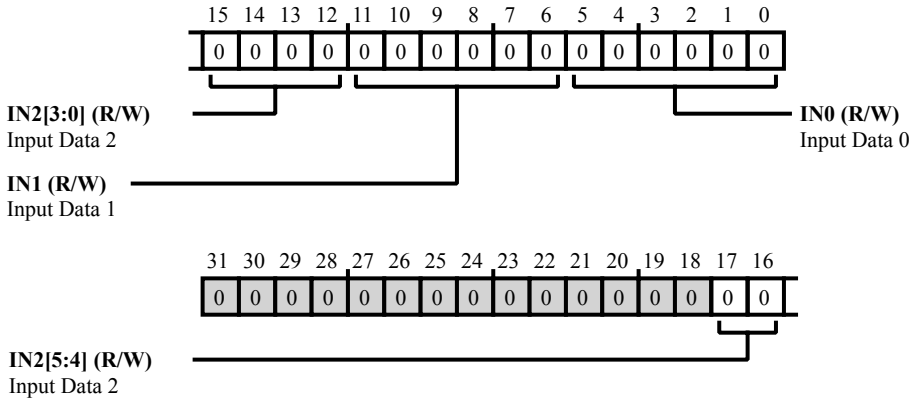

Figure 29-26: DAI_DAT4 Register Diagram

Table 29-34: DAI_DAT4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:12 (R/W)	IN2	Input Data 2. DAI_DAT4.IN2 holds the Source signal assignment that will be routed to the DAI_DAT4.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT4.IN1 holds the Source signal assignment that will be routed to the DAI_DAT4.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT4.IN0 holds the Source signal assignment that will be routed to the DAI_DAT4.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 5

The DAI_DAT5 register routes serial data to the S/PDIF.

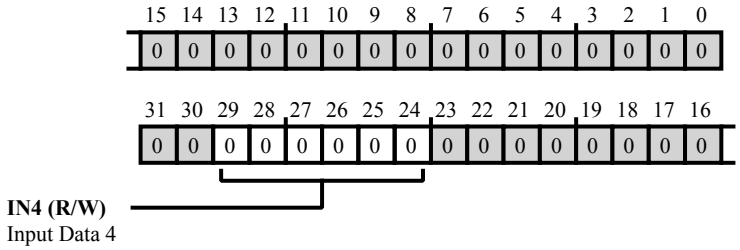

Figure 29-27: DAI_DAT5 Register Diagram

Table 29-35: DAI_DAT5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. The DAI_DAT5.IN4 bit field routes input data to the S/PDIF Biphase receiver stream.

Serial Data Routing Control Register 6

The DAI_DAT6 register routes serial data to the serial ports.

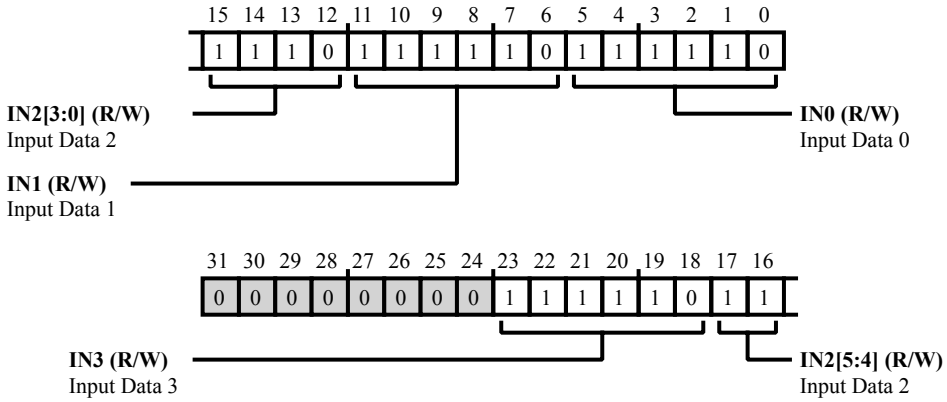

Figure 29-28: DAI_DAT6 Register Diagram

Table 29-36: DAI_DAT6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:18 (R/W)	IN3	Input Data 3. DAI_DAT6.IN3 holds the Source signal assignment that will be routed to the DAI_DAT6.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT6.IN2 holds the Source signal assignment that will be routed to the DAI_DAT6.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT6.IN1 holds the Source signal assignment that will be routed to the DAI_DAT6.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT6.IN0 holds the Source signal assignment that will be routed to the DAI_DAT6.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Clock Routing Control Register 0

The DAI_EXTD_CLK0 and DAI_CLK0 registers together provides the extended clock routing connections for the serial ports (SPORTs).

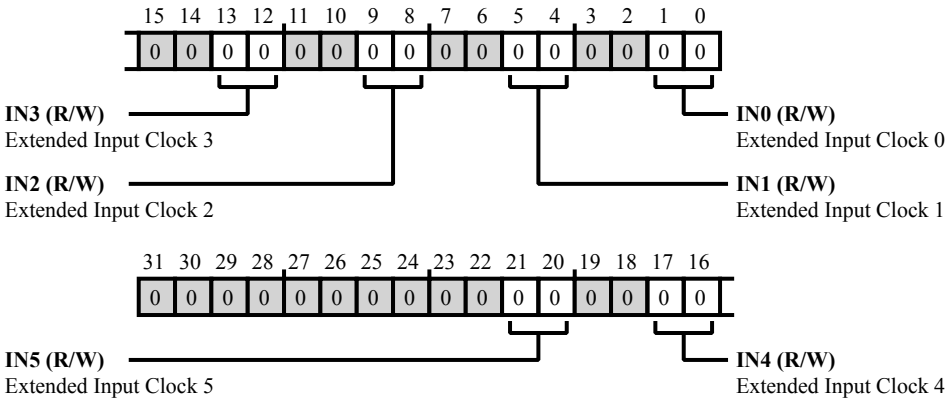

Figure 29-29: DAI_EXTD_CLK0 Register Diagram

Table 29-37: DAI_EXTD_CLK0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK0.IN5 and DAI_CLK0.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK0.IN4 and DAI_CLK0.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK0.IN3 and DAI_CLK0.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK0.IN2 and DAI_CLK0.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK0.IN1 and DAI_CLK0.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 29-37: DAI_EXTD_CLK0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK0.IN0` and DAI_CLK0.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 1

The DAI_EXTD_CLK1 and DAI_CLK1 registers together provides the extended clock routing connections for the serial ports (SPORTs).

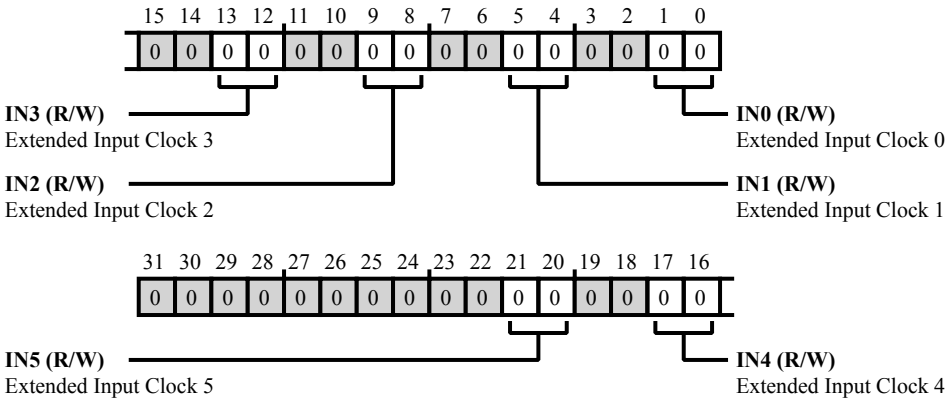

Figure 29-30: DAI_EXTD_CLK1 Register Diagram

Table 29-38: DAI_EXTD_CLK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK1.IN5 and DAI_CLK1.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK1.IN4 and DAI_CLK1.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK1.IN3 and DAI_CLK1.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK1.IN2 and DAI_CLK1.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK1.IN1 and DAI_CLK1.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 29-38: DAI_EXTD_CLK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK1.IN0` and DAI_CLK1.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 2

The DAI_EXTD_CLK2 and DAI_CLK2 registers together provides the extended clock routing connections for the serial ports (SPORTs).

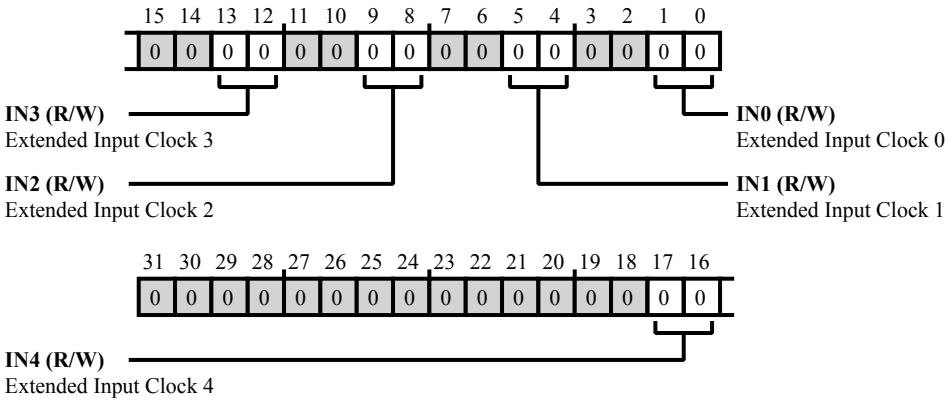

Figure 29-31: DAI_EXTD_CLK2 Register Diagram

Table 29-39: DAI_EXTD_CLK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK2.IN4 and DAI_CLK2.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK2.IN3 and DAI_CLK2.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK2.IN2 and DAI_CLK2.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK2.IN1 and DAI_CLK2.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings
1:0 (R/W)	IN0	Extended Input Clock 0. DAI_EXTD_CLK2.IN0 and DAI_CLK2.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 3

The DAI_EXTD_CLK3 and DAI_CLK3 registers together provides the extended clock routing connections for the serial ports (SPORTs).

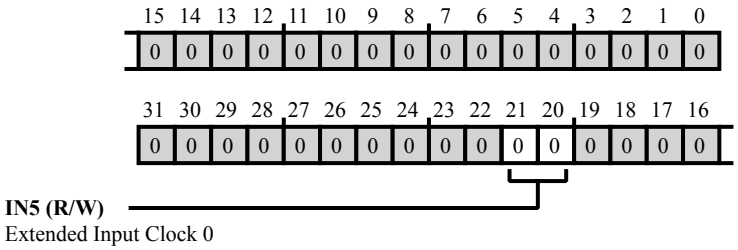

Figure 29-32: DAI_EXTD_CLK3 Register Diagram

Table 29-40: DAI_EXTD_CLK3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 0. DAI_EXTD_CLK3.IN5 and DAI_CLK3.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK3.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 4

The DAI_EXTD_CLK4 and DAI_CLK4 registers together provides the extended clock routing connections for the serial ports (SPORTs).

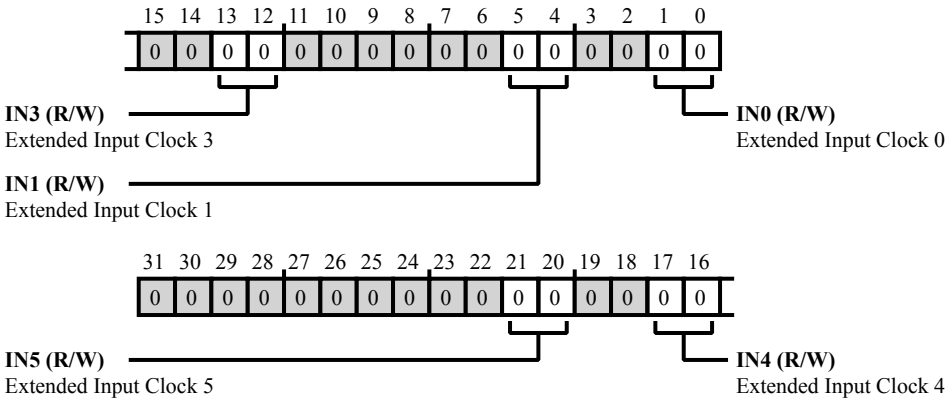

Figure 29-33: DAI_EXTD_CLK4 Register Diagram

Table 29-41: DAI_EXTD_CLK4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK4.IN5 and DAI_CLK4.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK4.IN4 and DAI_CLK4.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK4.IN3 and DAI_CLK4.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK4.IN1 and DAI_CLK4.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings
1:0 (R/W)	IN0	Extended Input Clock 0. DAI_EXTD_CLK4.IN0 and DAI_CLK4.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 5

The DAI_EXTD_CLK5 and DAI_CLK5 registers together provides the extended clock routing connections for the serial ports (SPORTs).

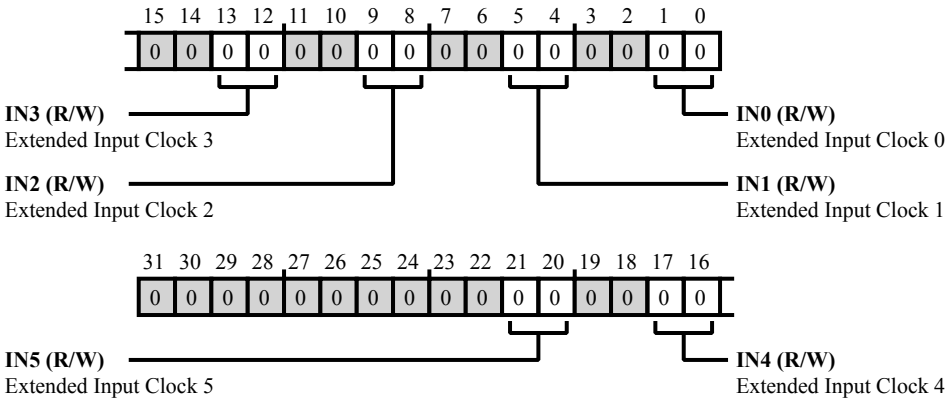

Figure 29-34: DAI_EXTD_CLK5 Register Diagram

Table 29-42: DAI_EXTD_CLK5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK5.IN5 and DAI_CLK5.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK5.IN4 and DAI_CLK5.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK5.IN3 and DAI_CLK5.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK5.IN2 and DAI_CLK5.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK5.IN1 and DAI_CLK5.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 29-42: DAI_EXTD_CLK5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK5.IN0` and DAI_CLK5.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Serial Data Routing Control Register 0

The DAI_EXTD_DAT0 and DAI_DAT0 together provides the extended data routing connections to the serial data of serial ports.

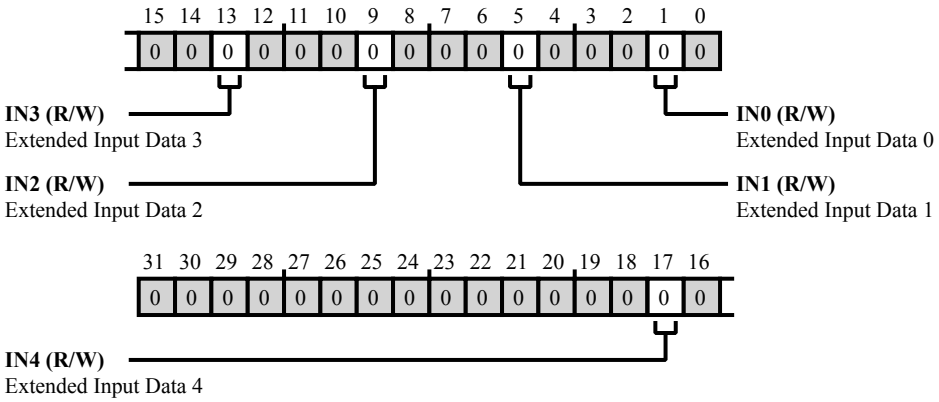

Figure 29-35: DAI_EXTD_DAT0 Register Diagram

Table 29-43: DAI_EXTD_DAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT0.IN4 and DAI_DAT0.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT0.IN3 and DAI_DAT0.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT0.IN2 and DAI_DAT0.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT0.IN1 and DAI_DAT0.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT0.IN0 and DAI_DAT0.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 1

The DAI_EXTD_DAT1 and DAI_DAT1 together provides the extended data routing connections to the serial data of serial ports.

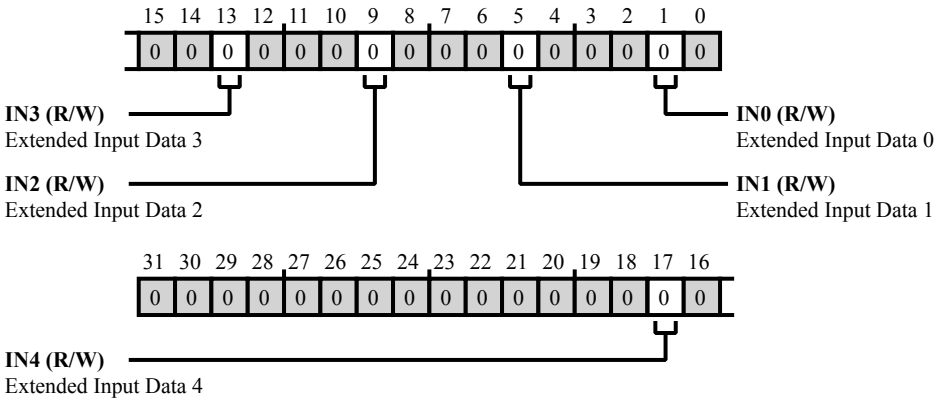

Figure 29-36: DAI_EXTD_DAT1 Register Diagram

Table 29-44: DAI_EXTD_DAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT1.IN4 and DAI_DAT1.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT1.IN3 and DAI_DAT1.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT1.IN2 and DAI_DAT1.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT1.IN1 and DAI_DAT1.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT1.IN0 and DAI_DAT1.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 2

The DAI_EXTD_DAT2 and DAI_DAT2 together provides the extended data routing connections to the serial data of serial ports.

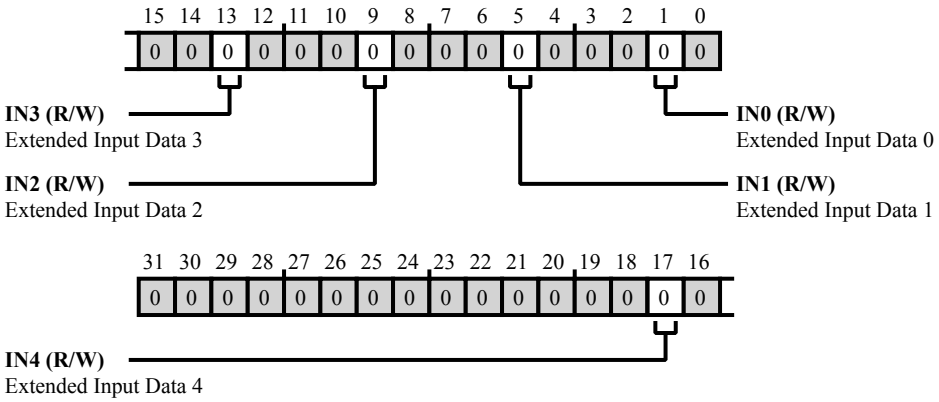

Figure 29-37: DAI_EXTD_DAT2 Register Diagram

Table 29-45: DAI_EXTD_DAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT2.IN4 and DAI_DAT2.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT2.IN3 and DAI_DAT2.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT2.IN2 and DAI_DAT2.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT2.IN1 and DAI_DAT2.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT2.IN0 and DAI_DAT2.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 3

The DAI_EXTD_DAT3 and DAI_DAT3 together provides the extended data routing connections to the serial data of serial ports.

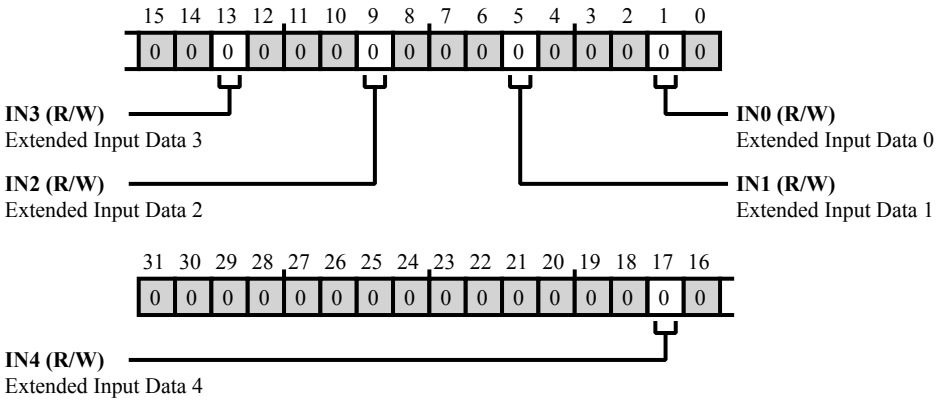

Figure 29-38: DAI_EXTD_DAT3 Register Diagram

Table 29-46: DAI_EXTD_DAT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT3.IN4 and DAI_DAT3.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT3.IN3 and DAI_DAT3.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT3.IN2 and DAI_DAT3.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT3.IN1 and DAI_DAT3.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT3.IN0 and DAI_DAT3.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 4

The DAI_EXTD_DAT4 and DAI_DAT4 together provides the extended data routing connections to the serial data of serial ports.

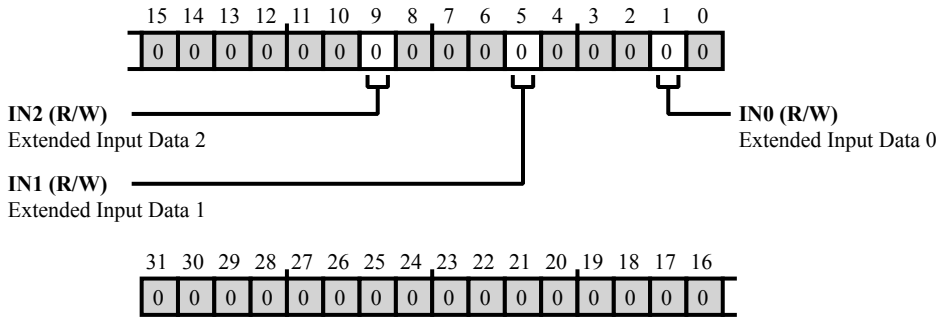

Figure 29-39: DAI_EXTD_DAT4 Register Diagram

Table 29-47: DAI_EXTD_DAT4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT4.IN2 and DAI_DAT4.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT4.IN1 and DAI_DAT4.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT4.IN0 and DAI_DAT4.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 5

The DAI_EXTD_DAT5 and DAI_DAT5 together provides the extended data routing connections to the serial data of serial ports.

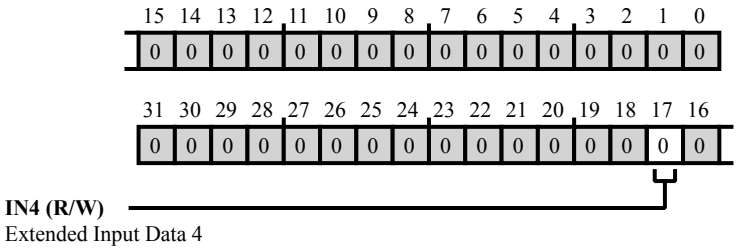

Figure 29-40: DAI_EXTD_DAT5 Register Diagram

Table 29-48: DAI_EXTD_DAT5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT5.IN4 and DAI_DAT5.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT5.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 6

The DAI_EXTD_DAT6 and DAI_DAT6 together provides the extended data routing connections to the serial data of serial ports.

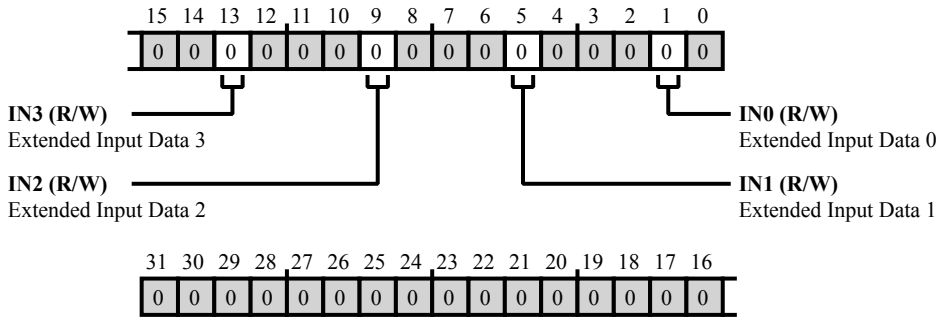

Figure 29-41: DAI_EXTD_DAT6 Register Diagram

Table 29-49: DAI_EXTD_DAT6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT6.IN3 and DAI_DAT6.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT6.IN2 and DAI_DAT6.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT6.IN1 and DAI_DAT6.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT6.IN0 and DAI_DAT6.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 0

The DAI_EXTD_FS0 and DAI_FS0 together provides the extended frame sync routing connections to the frame syncs of serial ports.

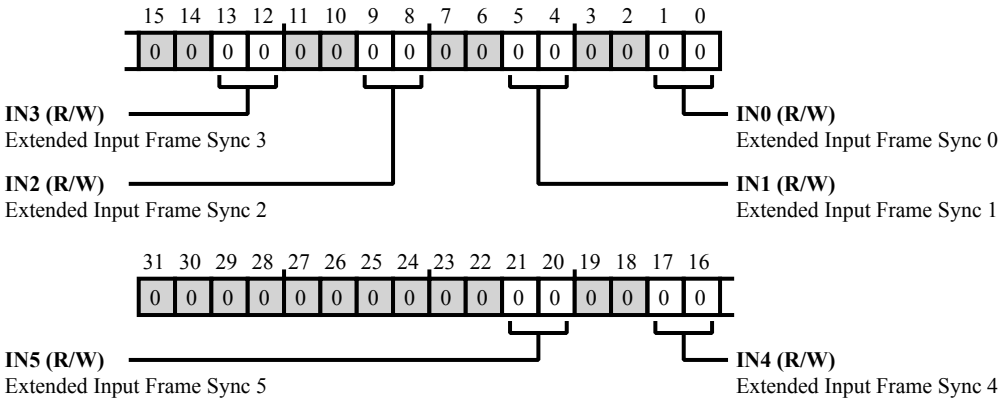

Figure 29-42: DAI_EXTD_FS0 Register Diagram

Table 29-50: DAI_EXTD_FS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Frame Sync 5. DAI_EXTD_FS0.IN5 and DAI_FS0.IN5 together holds the Source signal assignment that will be routed to the DAI_FS0.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
17:16 (R/W)	IN4	Extended Input Frame Sync 4. DAI_EXTD_FS0.IN4 and DAI_FS0.IN4 together holds the Source signal assignment that will be routed to the DAI_FS0.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS0.IN3 and DAI_FS0.IN3 together holds the Source signal assignment that will be routed to the DAI_FS0.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS0.IN2 and DAI_FS0.IN2 together holds the Source signal assignment that will be routed to the DAI_FS0.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS0.IN1 and DAI_FS0.IN1 together holds the Source signal assignment that will be routed to the DAI_FS0.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 29-50: DAI_EXTD_FS0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Frame Sync 0. `DAI_EXTD_FS0.IN0` and DAI_FS0.IN0 together holds the Source signal assignment that will be routed to the DAI_FS0.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 1

The DAI_EXTD_FS1 and DAI_FS1 together provides the extended frame sync routing connections to the frame syncs of serial ports.

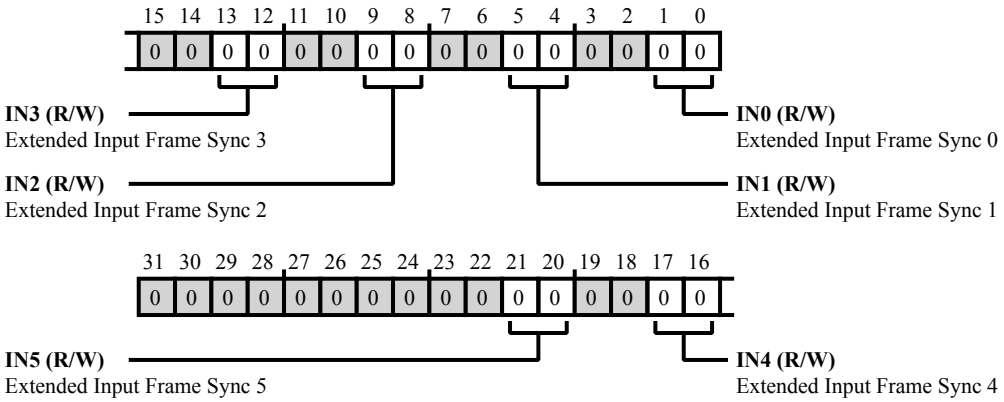

Figure 29-43: DAI_EXTD_FS1 Register Diagram

Table 29-51: DAI_EXTD_FS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Frame Sync 5. DAI_EXTD_FS1.IN5 and DAI_FS1.IN5 together holds the Source signal assignment that will be routed to the DAI_FS1.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
17:16 (R/W)	IN4	Extended Input Frame Sync 4. DAI_EXTD_FS1.IN4 and DAI_FS1.IN4 together holds the Source signal assignment that will be routed to the DAI_FS1.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS1.IN3 and DAI_FS1.IN3 together holds the Source signal assignment that will be routed to the DAI_FS1.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS1.IN2 and DAI_FS1.IN2 together holds the Source signal assignment that will be routed to the DAI_FS1.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS1.IN1 and DAI_FS1.IN1 together holds the Source signal assignment that will be routed to the DAI_FS1.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 29-51: DAI_EXTD_FS1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Frame Sync 0. `DAI_EXTD_FS1.IN0` and DAI_FS1.IN0 together holds the Source signal assignment that will be routed to the DAI_FS1.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 2

The DAI_EXTD_FS2 and DAI_FS2 together provides the extended frame sync routing connections to the frame syncs of serial ports.

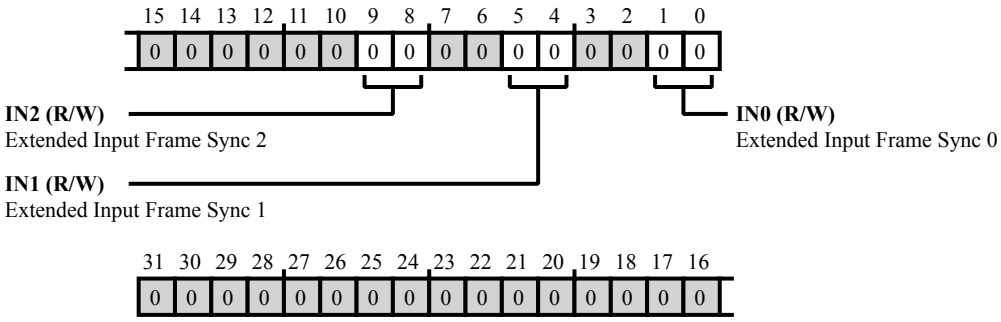

Figure 29-44: DAI_EXTD_FS2 Register Diagram

Table 29-52: DAI_EXTD_FS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS2.IN2 and DAI_FS2.IN2 together holds the Source signal assignment that will be routed to the DAI_FS2.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS2.IN1 and DAI_FS2.IN1 together holds the Source signal assignment that will be routed to the DAI_FS2.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.
1:0 (R/W)	IN0	Extended Input Frame Sync 0. DAI_EXTD_FS2.IN0 and DAI_FS2.IN0 together holds the Source signal assignment that will be routed to the DAI_FS2.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 4

The DAI_EXTD_FS4 and DAI_FS4 together provides the extended frame sync routing connections to the frame syncs of serial ports.

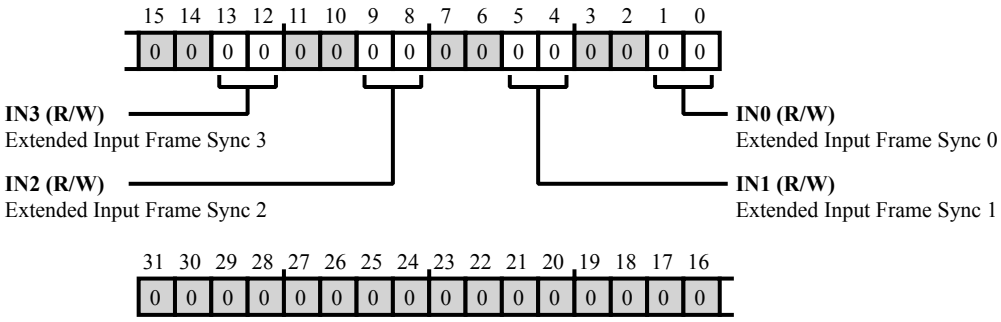

Figure 29-45: DAI_EXTD_FS4 Register Diagram

Table 29-53: DAI_EXTD_FS4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS4.IN3 and DAI_FS4.IN3 together holds the Source signal assignment that will be routed to the DAI_FS4.IN3 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS4.IN2 and DAI_FS4.IN2 together holds the Source signal assignment that will be routed to the DAI_FS4.IN2 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS4.IN1 and DAI_FS4.IN1 together holds the Source signal assignment that will be routed to the DAI_FS4.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.
1:0 (R/W)	IN0	Extended Input Frame Sync 0. DAI_EXTD_FS4.IN0 and DAI_FS4.IN0 together holds the Source signal assignment that will be routed to the DAI_FS4.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Miscellaneous Control Register 0

The DAI_EXTD_MISC0 and DAI_MISC0 register together allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

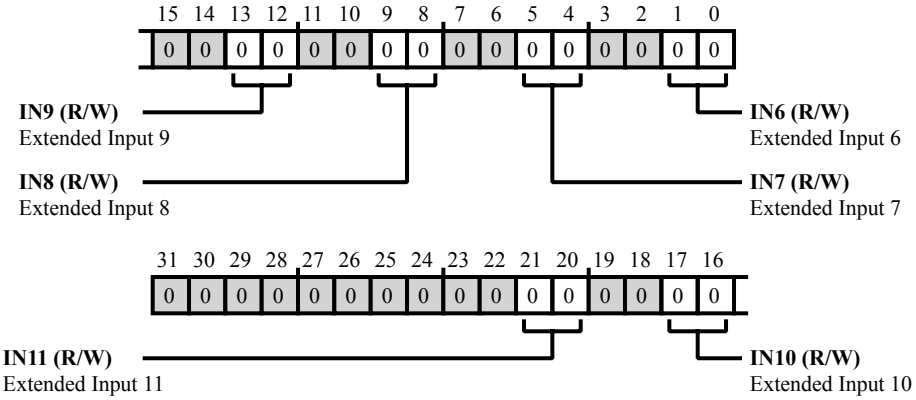

Figure 29-46: DAI_EXTD_MISC0 Register Diagram

Table 29-54: DAI_EXTD_MISC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN11	Extended Input 11. The DAI_EXTD_MISC0.IN11 bit field and DAI_MISC0.IN11 bit field together holds the source signal assignment for miscellaneous A5 input.
17:16 (R/W)	IN10	Extended Input 10. The DAI_EXTD_MISC0.IN10 bit field and DAI_MISC0.IN10 bit field together holds the source signal assignment for miscellaneous A4 input.
13:12 (R/W)	IN9	Extended Input 9. The DAI_EXTD_MISC0.IN9 bit field and DAI_MISC0.IN9 bit field together holds the source signal assignment for miscellaneous A3 input/miscellaneous Interrupt 9(DAI interrupt 31).
9:8 (R/W)	IN8	Extended Input 8. The DAI_EXTD_MISC0.IN8 bit field and DAI_MISC0.IN8 bit field together holds the source signal assignment for miscellaneous A2 input/miscellaneous Interrupt 8(DAI interrupt 30).
5:4 (R/W)	IN7	Extended Input 7. The DAI_EXTD_MISC0.IN7 bit field and DAI_MISC0.IN7 bit field together holds the source signal assignment for miscellaneous A1 input/miscellaneous Interrupt 7(DAI interrupt 29).

Table 29-54: DAI_EXTD_MISC0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN6	Extended Input 6. The `DAI_EXTD_MISC0.IN6` and DAI_MISC0.IN6 bit field together holds the source signal assignment for miscellaneous A0 input/miscellaneous Interrupt 6(DAI interrupt 28).

Extended Miscellaneous Control Register 1

The DAI_EXTD_MISC1 and DAI_MISC1 register together allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

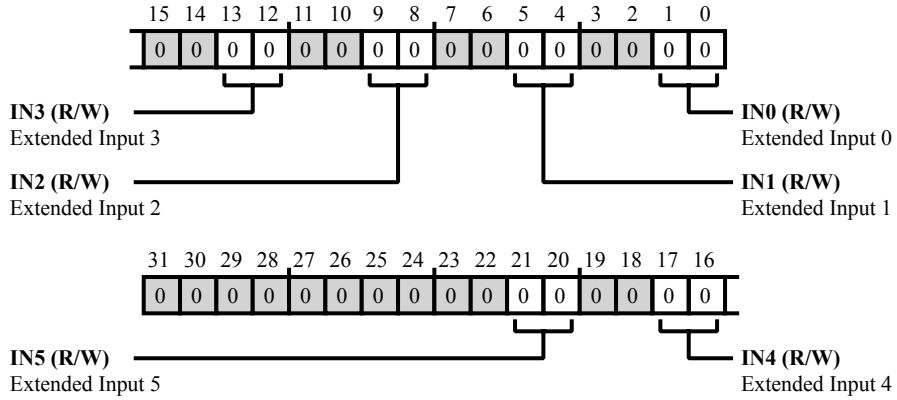

Figure 29-47: DAI_EXTD_MISC1 Register Diagram

Table 29-55: DAI_EXTD_MISC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input 5. The DAI_EXTD_MISC1.IN5 bit field and DAI_MISC1.IN5 bit field together holds the source signal assignment for miscellaneous Interrupt 5(DAI interrupt 27).
17:16 (R/W)	IN4	Extended Input 4. The DAI_EXTD_MISC1.IN4 bit field and DAI_MISC1.IN4 bit field together holds the source signal assignment for miscellaneous Interrupt 4(DAI interrupt 26).
13:12 (R/W)	IN3	Extended Input 3. The DAI_EXTD_MISC1.IN3 bit field and DAI_MISC1.IN3 bit field together holds the source signal assignment for miscellaneous Interrupt 3(DAI interrupt 25).
9:8 (R/W)	IN2	Extended Input 2. The DAI_EXTD_MISC1.IN2 bit field and DAI_MISC1.IN2 bit field together holds the source signal assignment for miscellaneous Interrupt 2(DAI interrupt 24).
5:4 (R/W)	IN1	Extended Input 1. The DAI_EXTD_MISC1.IN1 bit field and DAI_MISC1.IN1 bit field together holds the source signal assignment for miscellaneous Interrupt 1(DAI interrupt 23).
1:0 (R/W)	IN0	Extended Input 0. The DAI_EXTD_MISC1.IN0 bit field and DAI_MISC1.IN0 bit field together holds the source signal assignment for miscellaneous Interrupt 0(DAI interrupt 22).

Extended Miscellaneous Control Register 2

The DAI_EXTD_MISC2 and DAI_MISC2 register together allows programs to route to the DAI interrupt latch, PCGs hardware slave trigger, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

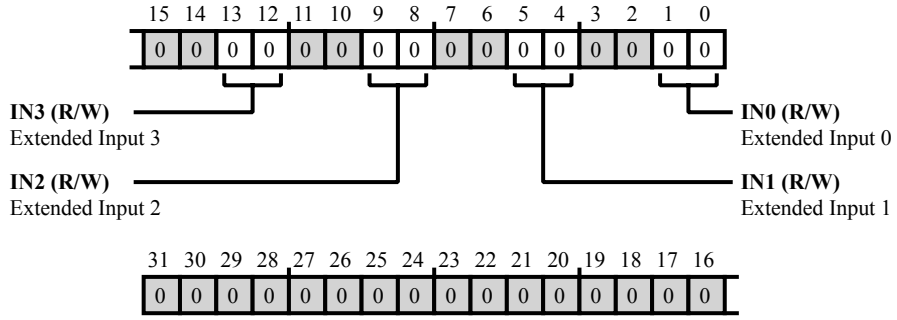

Figure 29-48: DAI_EXTD_MISC2 Register Diagram

Table 29-56: DAI_EXTD_MISC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:12 (R/W)	IN3	Extended Input 3. The DAI_EXTD_MISC2.IN3 bit field and DAI_MISC1.IN3 bit field together holds the source signal assignment for PCG-F's hardware slave trigger input.
9:8 (R/W)	IN2	Extended Input 2. The DAI_EXTD_MISC2.IN2 bit field and DAI_MISC2.IN2 bit field together holds the source signal assignment for PCG-E's hardware slave trigger input.
5:4 (R/W)	IN1	Extended Input 1. The DAI_EXTD_MISC2.IN1 bit field and DAI_MISC2.IN1 bit field together holds the source signal assignment for PCG-B's hardware slave trigger input.
1:0 (R/W)	IN0	Extended Input 0. The DAI_EXTD_MISC2.IN0 bit field and DAI_MISC2.IN0 bit field together holds the source signal assignment for PCG-A's hardware slave trigger input.

Extended Pin Buffer Enable Register 0

The DAI_EXTD_PBEN0 and DAI_PBEN0 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

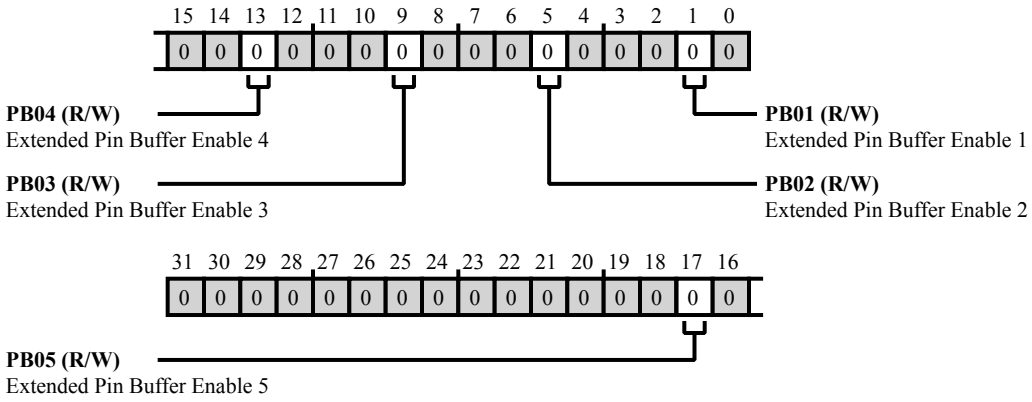

Figure 29-49: DAI_EXTD_PBEN0 Register Diagram

Table 29-57: DAI_EXTD_PBEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB05	Extended Pin Buffer Enable 5. The DAI_EXTD_PBEN0.PB05 bit field and DAI_PBEN0.PB05 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 5.
13 (R/W)	PB04	Extended Pin Buffer Enable 4. The DAI_EXTD_PBEN0.PB04 bit field and DAI_PBEN0.PB04 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 4.
9 (R/W)	PB03	Extended Pin Buffer Enable 3. The DAI_EXTD_PBEN0.PB03 bit field and DAI_PBEN0.PB03 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 3.
5 (R/W)	PB02	Extended Pin Buffer Enable 2. The DAI_EXTD_PBEN0.PB02 bit field and DAI_PBEN0.PB02 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 2.
1 (R/W)	PB01	Extended Pin Buffer Enable 1. The DAI_EXTD_PBEN0.PB01 bit field and DAI_PBEN0.PB01 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 1.

Extended Pin Buffer Enable Register 1

The DAI_EXTD_PBEN1 and DAI_PBEN1 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

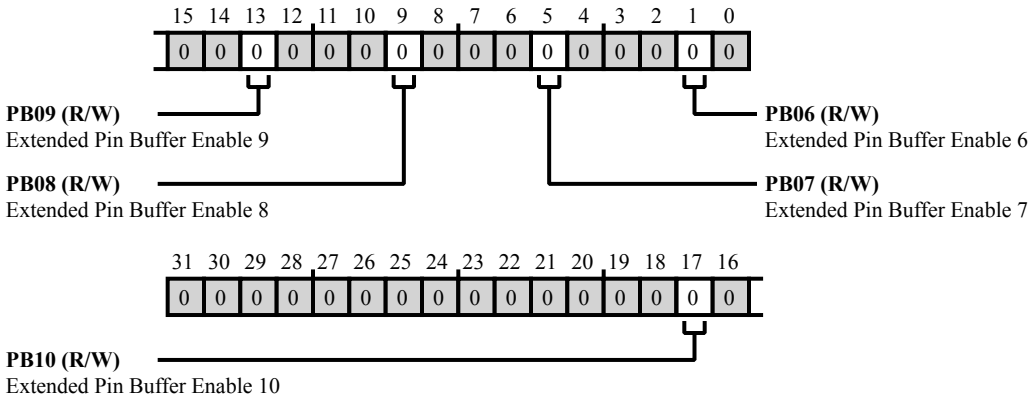

Figure 29-50: DAI_EXTD_PBEN1 Register Diagram

Table 29-58: DAI_EXTD_PBEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB10	Extended Pin Buffer Enable 10. The DAI_EXTD_PBEN1.PB10 bit field and DAI_PBEN0.PB10 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 10.
13 (R/W)	PB09	Extended Pin Buffer Enable 9. The DAI_EXTD_PBEN1.PB09 bit field and DAI_PBEN0.PB09 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 9.
9 (R/W)	PB08	Extended Pin Buffer Enable 8. The DAI_EXTD_PBEN1.PB08 bit field and DAI_PBEN0.PB08 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 8.
5 (R/W)	PB07	Extended Pin Buffer Enable 7. The DAI_EXTD_PBEN1.PB07 bit field and DAI_PBEN0.PB07 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 7.
1 (R/W)	PB06	Extended Pin Buffer Enable 6. The DAI_EXTD_PBEN1.PB06 bit field and DAI_PBEN0.PB06 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 6.

Extended Pin Buffer Enable Register 2

The DAI_EXTD_PBEN2 and DAI_PBEN2 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

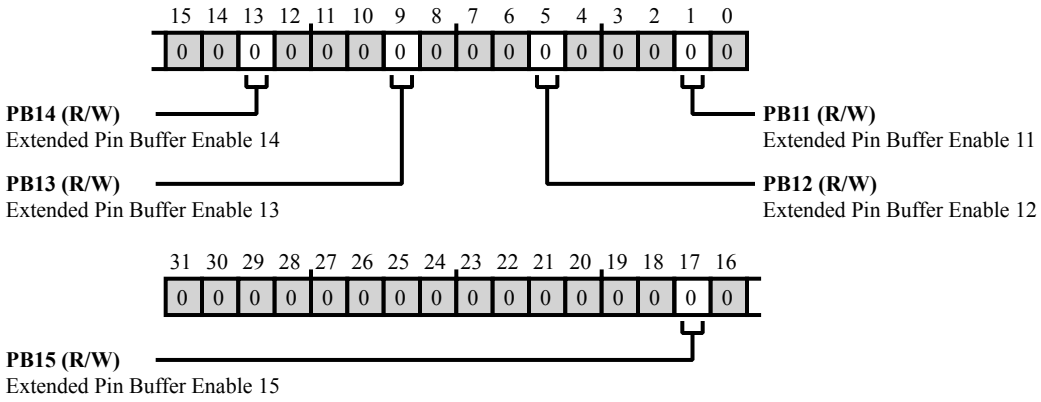

Figure 29-51: DAI_EXTD_PBEN2 Register Diagram

Table 29-59: DAI_EXTD_PBEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB15	Extended Pin Buffer Enable 15. The DAI_EXTD_PBEN2.PB15 bit field and DAI_PBEN0.PB15 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 15.
13 (R/W)	PB14	Extended Pin Buffer Enable 14. The DAI_EXTD_PBEN2.PB14 bit field and DAI_PBEN0.PB14 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 14.
9 (R/W)	PB13	Extended Pin Buffer Enable 13. The DAI_EXTD_PBEN2.PB13 bit field and DAI_PBEN0.PB13 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 13.
5 (R/W)	PB12	Extended Pin Buffer Enable 12. The DAI_EXTD_PBEN2.PB12 bit field and DAI_PBEN0.PB12 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 12.
1 (R/W)	PB11	Extended Pin Buffer Enable 11. The DAI_EXTD_PBEN2.PB11 bit field and DAI_PBEN0.PB11 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 11.

Extended Pin Buffer Enable Register 3

The DAI_EXTD_PBEN3 and DAI_PBEN3 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

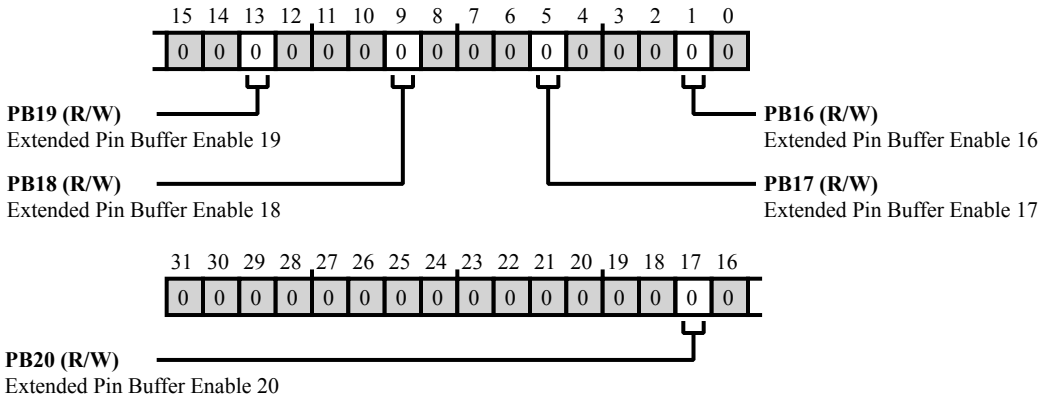

Figure 29-52: DAI_EXTD_PBEN3 Register Diagram

Table 29-60: DAI_EXTD_PBEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB20	Extended Pin Buffer Enable 20. The DAI_EXTD_PBEN3.PB20 bit field and DAI_PBEN0.PB20 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 20.
13 (R/W)	PB19	Extended Pin Buffer Enable 19. The DAI_EXTD_PBEN3.PB19 bit field and DAI_PBEN0.PB19 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 19.
9 (R/W)	PB18	Extended Pin Buffer Enable 18. The DAI_EXTD_PBEN3.PB18 bit field and DAI_PBEN0.PB18 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 18.
5 (R/W)	PB17	Extended Pin Buffer Enable 17. The DAI_EXTD_PBEN3.PB17 bit field and DAI_PBEN0.PB17 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 17.
1 (R/W)	PB16	Extended Pin Buffer Enable 16. The DAI_EXTD_PBEN3.PB16 bit field and DAI_PBEN0.PB16 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 16.

Extended Pin Buffer Assignment Register 0

The DAI_EXTD_PIN0 and DAI_PIN0 register routes extended physical pins that are connected to a bonded pad.

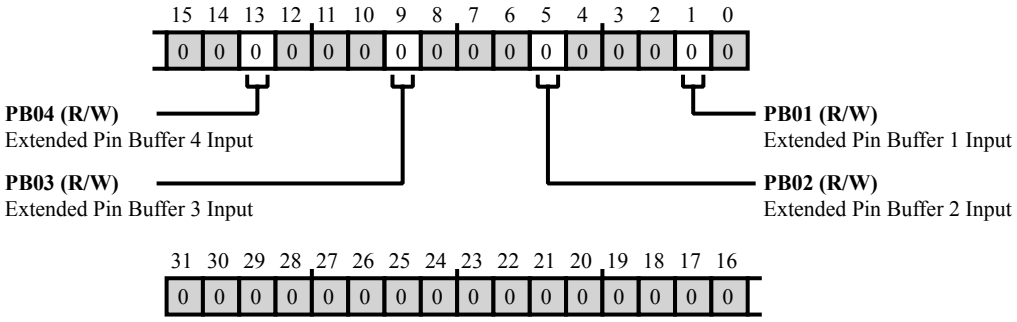

Figure 29-53: DAI_EXTD_PIN0 Register Diagram

Table 29-61: DAI_EXTD_PIN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB04	Extended Pin Buffer 4 Input. DAI_EXTD_PIN0.PB04 and DAI_PIN0.PB04 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB04 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB03	Extended Pin Buffer 3 Input. DAI_EXTD_PIN0.PB03 and DAI_PIN.PB03 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB03 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB02	Extended Pin Buffer 2 Input. DAI_EXTD_PIN0.PB02 and DAI_PIN0.PB02 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB02 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB01	Extended Pin Buffer 1 Input. DAI_EXTD_PIN0.PB01 and DAI_PIN0.PB01 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB01 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 1

The DAI_EXTD_PIN1 and DAI_PIN1 register routes extended physical pins that are connected to a bonded pad.

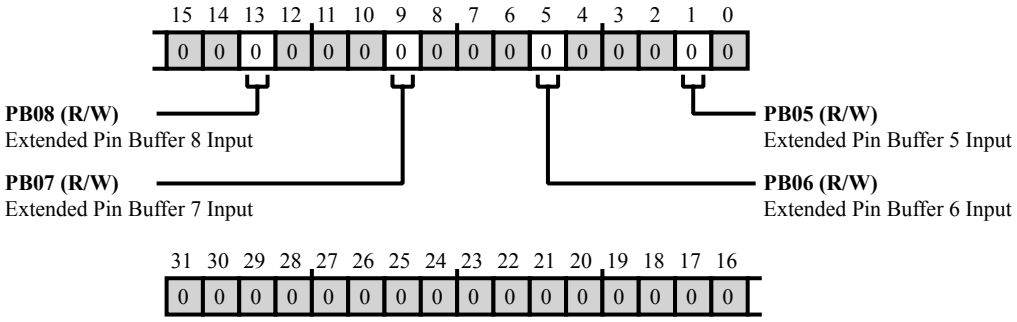

Figure 29-54: DAI_EXTD_PIN1 Register Diagram

Table 29-62: DAI_EXTD_PIN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB08	Extended Pin Buffer 8 Input. DAI_EXTD_PIN1.PB08 and DAI_PIN1.PB08 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB08 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB07	Extended Pin Buffer 7 Input. DAI_EXTD_PIN1.PB07 and DAI_PIN1.PB07 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB07 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB06	Extended Pin Buffer 6 Input. DAI_EXTD_PIN1.PB06 and DAI_PIN1.PB06 together the Source signal assignment that will be routed to the DAI_PIN1.PB06 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB05	Extended Pin Buffer 5 Input. DAI_EXTD_PIN1.PB05 and DAI_PIN1.PB05 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB05 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 2

The DAI_EXTD_PIN2 and DAI_PIN2 register routes extended physical pins that are connected to a bonded pad.

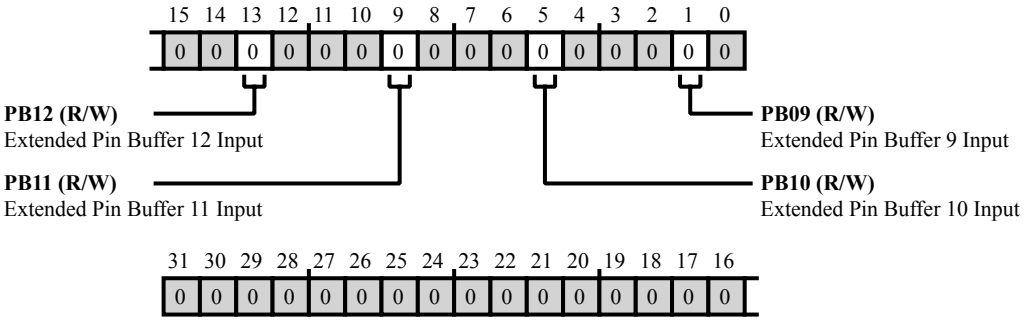

Figure 29-55: DAI_EXTD_PIN2 Register Diagram

Table 29-63: DAI_EXTD_PIN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB12	Extended Pin Buffer 12 Input. DAI_EXTD_PIN2.PB12 and DAI_PIN2.PB12 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB12 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB11	Extended Pin Buffer 11 Input. DAI_EXTD_PIN2.PB11 and DAI_PIN2.PB11 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB11 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB10	Extended Pin Buffer 10 Input. DAI_EXTD_PIN2.PB10 and DAI_PIN2.PB10 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB10 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB09	Extended Pin Buffer 9 Input. DAI_EXTD_PIN2.PB09 and DAI_PIN2.PB09 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB09 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 3

The DAI_EXTD_PIN3 and DAI_PIN3 register routes extended physical pins that are connected to a bonded pad.

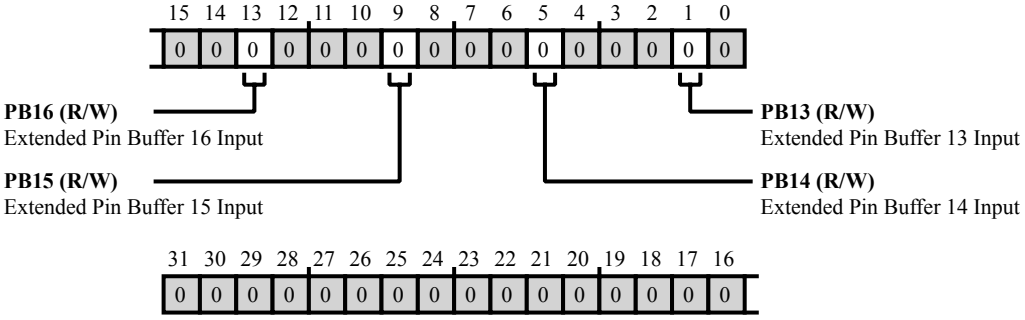

Figure 29-56: DAI_EXTD_PIN3 Register Diagram

Table 29-64: DAI_EXTD_PIN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB16	Extended Pin Buffer 16 Input. DAI_EXTD_PIN3.PB16 and DAI_PIN3.PB16 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB16 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB15	Extended Pin Buffer 15 Input. DAI_EXTD_PIN3.PB15 and DAI_PIN3.PB15 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB15 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB14	Extended Pin Buffer 14 Input. DAI_EXTD_PIN3.PB14 and DAI_PIN3.PB14 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB14 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB13	Extended Pin Buffer 13 Input. DAI_EXTD_PIN3.PB13 and DAI_PIN3.PB13 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB13 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 4

The DAI_EXTD_PIN4 and DAI_PIN4 register routes extended physical pins that are connected to a bonded pad.

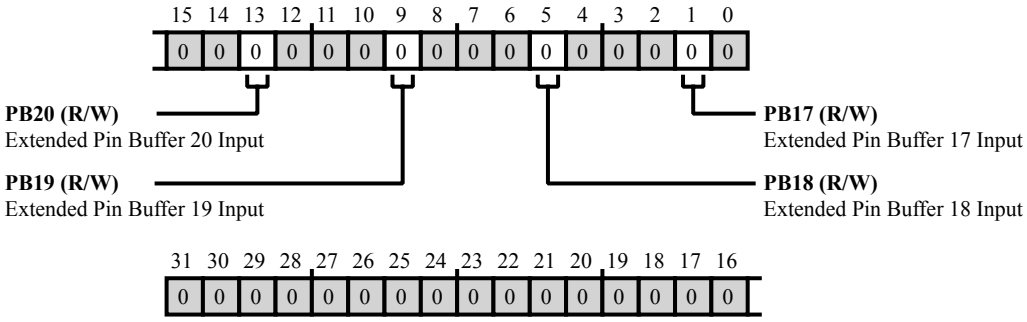

Figure 29-57: DAI_EXTD_PIN4 Register Diagram

Table 29-65: DAI_EXTD_PIN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB20	Extended Pin Buffer 20 Input. DAI_EXTD_PIN4.PB20 and DAI_PIN4.PB20 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB20 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB19	Extended Pin Buffer 19 Input. DAI_EXTD_PIN4.PB19 and DAI_PIN4.PB19 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB19 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB18	Extended Pin Buffer 18 Input. DAI_EXTD_PIN4.PB18 an DAI_PIN4.PB18 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB18 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB17	Extended Pin Buffer 17 Input. DAI_EXTD_PIN4.PB17 and DAI_PIN4.PB17 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB17 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 0

The DAI_FS0 register routes frame syncs to the serial ports.

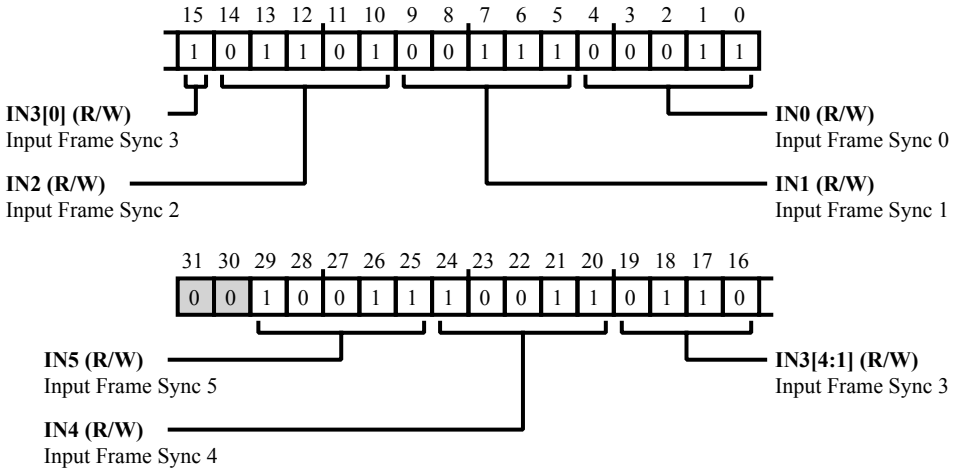

Figure 29-58: DAI_FS0 Register Diagram

Table 29-66: DAI_FS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Frame Sync 5. DAI_FS0.IN5 holds the Source signal assignment that will be routed to the DAI_FS0.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Frame Sync 4. DAI_FS0.IN4 holds the Source signal assignment that will be routed to the DAI_FS0.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Frame Sync 3. DAI_FS0.IN3 holds the Source signal assignment that will be routed to the DAI_FS0.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS0.IN2 holds the Source signal assignment that will be routed to the DAI_FS0.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. DAI_FS0.IN1 holds the Source signal assignment that will be routed to the DAI_FS0.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 29-66: DAI_FS0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS0.IN0` holds the Source signal assignment that will be routed to the `DAI_FS0.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 1

The DAI_FS1 register routes frame syncs to the asynchronous sample rate converter (ASRC).

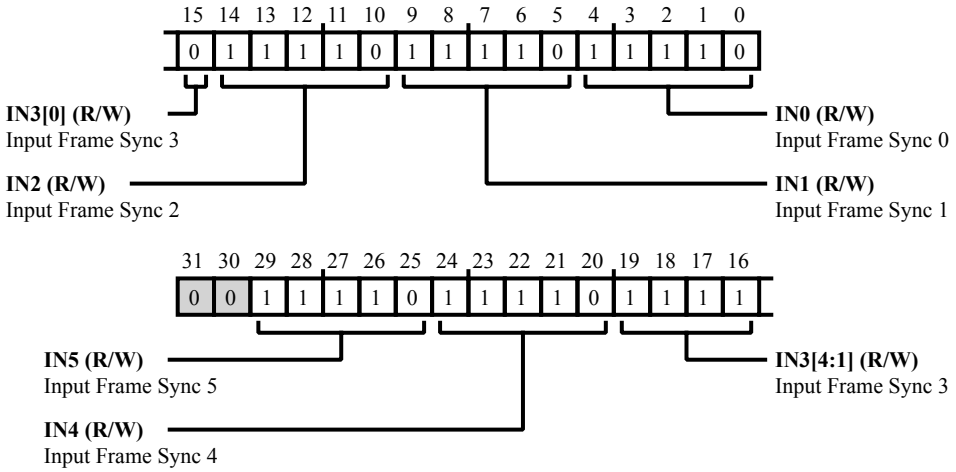

Figure 29-59: DAI_FS1 Register Diagram

Table 29-67: DAI_FS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Frame Sync 5. DAI_FS1.IN5 holds the Source signal assignment that will be routed to the DAI_FS1.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Frame Sync 4. DAI_FS1.IN4 holds the Source signal assignment that will be routed to the DAI_FS1.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Frame Sync 3. DAI_FS1.IN3 holds the Source signal assignment that will be routed to the DAI_FS1.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS1.IN2 holds the Source signal assignment that will be routed to the DAI_FS1.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. DAI_FS1.IN1 holds the Source signal assignment that will be routed to the DAI_FS1.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 29-67: DAI_FS1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS1.IN0` holds the Source signal assignment that will be routed to the `DAI_FS1.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 2

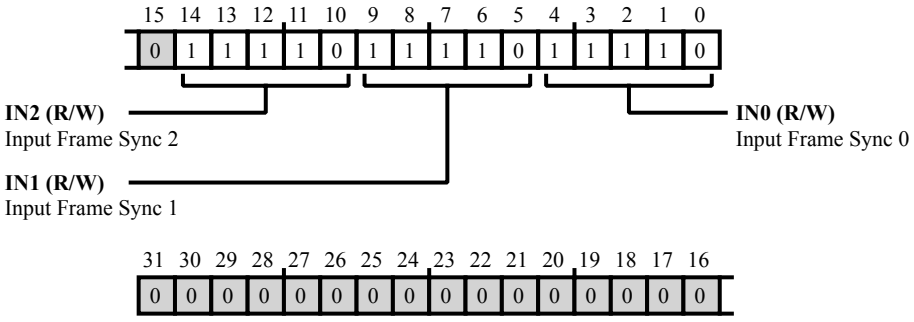

Figure 29-60: DAI_FS2 Register Diagram

Table 29-68: DAI_FS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:10 (R/W)	IN2	Input Frame Sync 2. `DAI_FS2.IN2` holds the Source signal assignment that will be routed to the `DAI_FS2.IN2` Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. The `DAI_FS2.IN1` bit field routes the frame sync output to the ASRC3 frame sync input port.
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS2.IN0` holds the Source signal assignment that will be routed to the `DAI_FS2.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 4

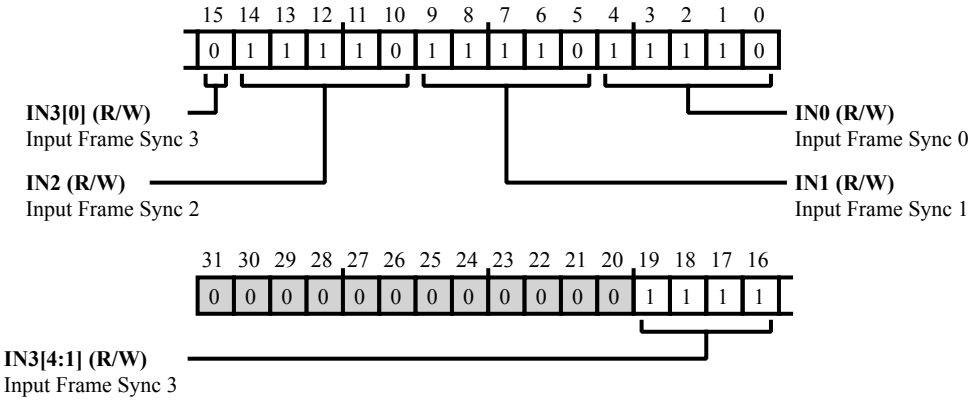

Figure 29-61: DAI_FS4 Register Diagram

Table 29-69: DAI_FS4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:15 (R/W)	IN3	Input Frame Sync 3. `DAI_FS4.IN3` holds the Source signal assignment that will be routed to the `DAI_FS4.IN3` Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. `DAI_FS4.IN2` holds the Source signal assignment that will be routed to the `DAI_FS4.IN2` Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. `DAI_FS4.IN1` holds the Source signal assignment that will be routed to the `DAI_FS4.IN1` Destination. Refer to the Group C Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS4.IN0` holds the Source signal assignment that will be routed to the `DAI_FS4.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Global SPORT Interrupt Grouping Register

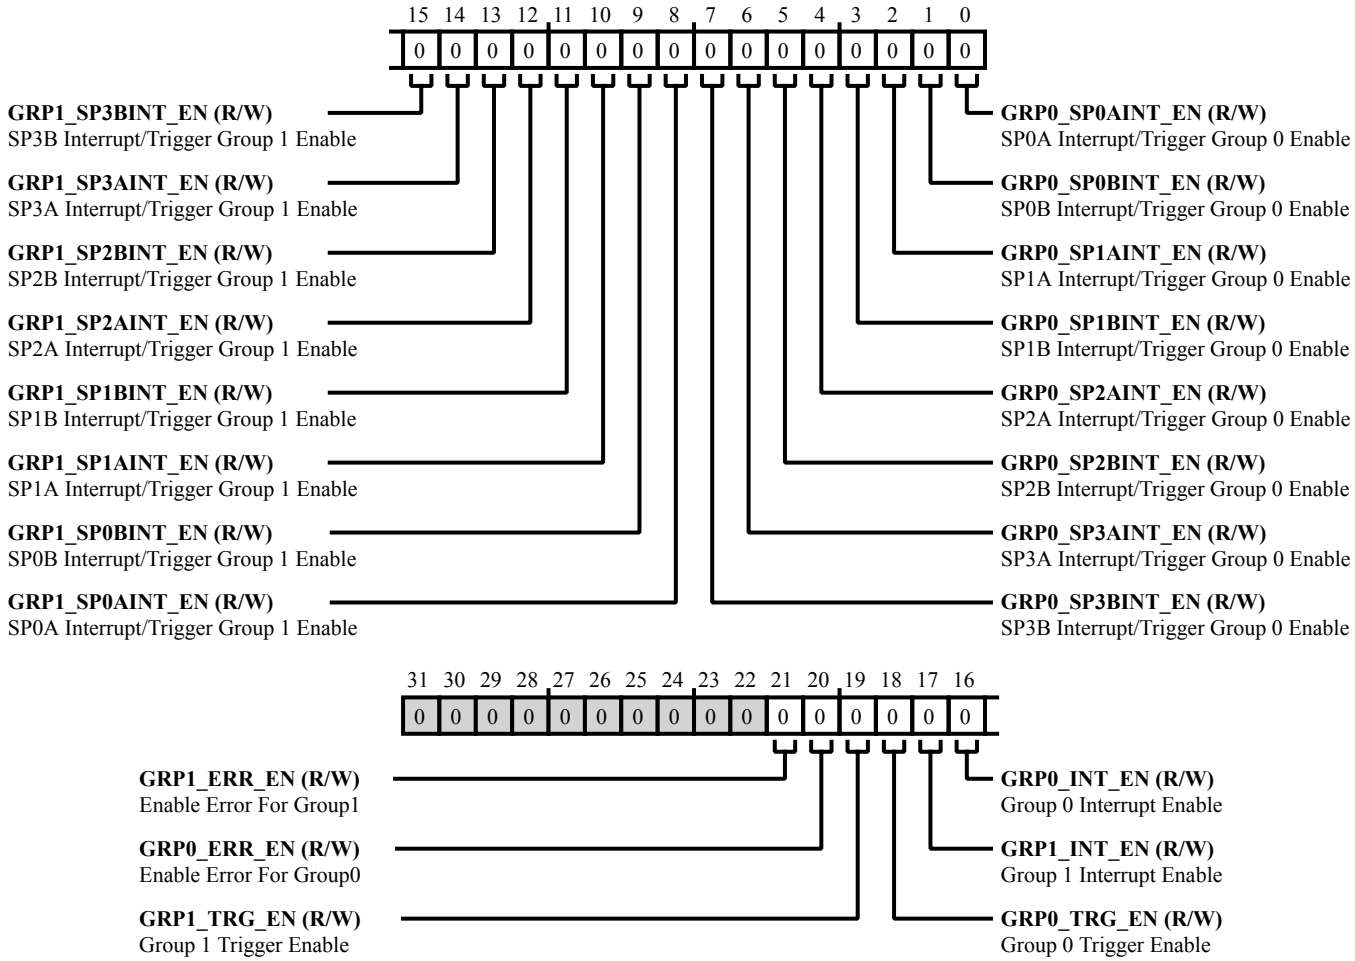

Figure 29-62: DAI_GBL_INT_EN Register Diagram

Table 29-70: DAI_GBL_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	GRP1_ERR_EN	Enable Error For Group1.
20 (R/W)	GRP0_ERR_EN	Enable Error For Group0.
19 (R/W)	GRP1_TRG_EN	Group 1 Trigger Enable. The `DAI_GBL_INT_EN.GRP1_TRG_EN` bit enables the trigger-out for group 1.
18 (R/W)	GRP0_TRG_EN	Group 0 Trigger Enable. The `DAI_GBL_INT_EN.GRP0_TRG_EN` bit enables the trigger-out for group 0.

Table 29-70: DAI_GBL_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	GRP1_INT_EN	Group 1 Interrupt Enable. The DAI_GBL_INT_EN.GRP1_INT_EN bit enables the interrupt for group 1.
16 (R/W)	GRP0_INT_EN	Group 0 Interrupt Enable. The DAI_GBL_INT_EN.GRP0_INT_EN bit enables the interrupt for group 0.
15 (R/W)	GRP1_SP3BINT_EN	SP3B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP3BINT_EN bit enables the interrupt or trigger-out for SPORT3 B when it is part of group 1.
14 (R/W)	GRP1_SP3AINT_EN	SP3A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP3AINT_EN bit enables the interrupt or trigger-out for SPORT3 A when it is part of group 1.
13 (R/W)	GRP1_SP2BINT_EN	SP2B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP2BINT_EN bit enables the interrupt or trigger-out for SPORT2 B when it is part of group 1.
12 (R/W)	GRP1_SP2AINT_EN	SP2A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP2AINT_EN bit enables the interrupt or trigger-out for SPORT2 A when it is part of group 1.
11 (R/W)	GRP1_SP1BINT_EN	SP1B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP1BINT_EN bit enables the interrupt or trigger-out for SPORT1 B when it is part of group 1.
10 (R/W)	GRP1_SP1AINT_EN	SP1A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP1AINT_EN bit enables the interrupt or trigger-out for SPORT1 A when it is part of group 1.
9 (R/W)	GRP1_SP0BINT_EN	SP0B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP0BINT_EN bit enables the interrupt or trigger-out for SPORT0 B when it is part of group 1.
8 (R/W)	GRP1_SP0AINT_EN	SP0A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP0AINT_EN bit enables the interrupt or trigger-out for SPORT0 A when it is part of group 1.
7 (R/W)	GRP0_SP3BINT_EN	SP3B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP3BINT_EN bit enables the interrupt or trigger-out for SPORT3 B when it is part of group 0.
6 (R/W)	GRP0_SP3AINT_EN	SP3A Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP3AINT_EN bit enables the interrupt or trigger-out for SPORT3 A when it is part of group 0.

Table 29-70: DAI_GBL_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	GRP0_SP2BINT_EN	SP2B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP2BINT_EN bit enables the interrupt or trigger-out for SPORT2 B when it is part of group 0.
4 (R/W)	GRP0_SP2AINT_EN	SP2A Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP2AINT_EN bit enables the interrupt or trigger-out for SPORT2 A when it is part of group 0.
3 (R/W)	GRP0_SP1BINT_EN	SP1B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP1BINT_EN bit enables the interrupt or trigger-out for SPORT1 B when it is part of group 0.
2 (R/W)	GRP0_SP1AINT_EN	SP1A Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP1AINT_EN bit enables the interrupt or trigger-out for SPORT1 A when it is part of group 0.
1 (R/W)	GRP0_SP0BINT_EN	SP0B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP0BINT_EN bit enables the interrupt or trigger-out for SPORT0 B when it is part of group 0.
0 (R/W)	GRP0_SP0AINT_EN	SP0A Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP0AINT_EN bit enables the interrupt or trigger-out for SPORT0 A when it is part of group 0.

Global PCG Enable Control Register

The DAI_GBL_PCG_EN register bits indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

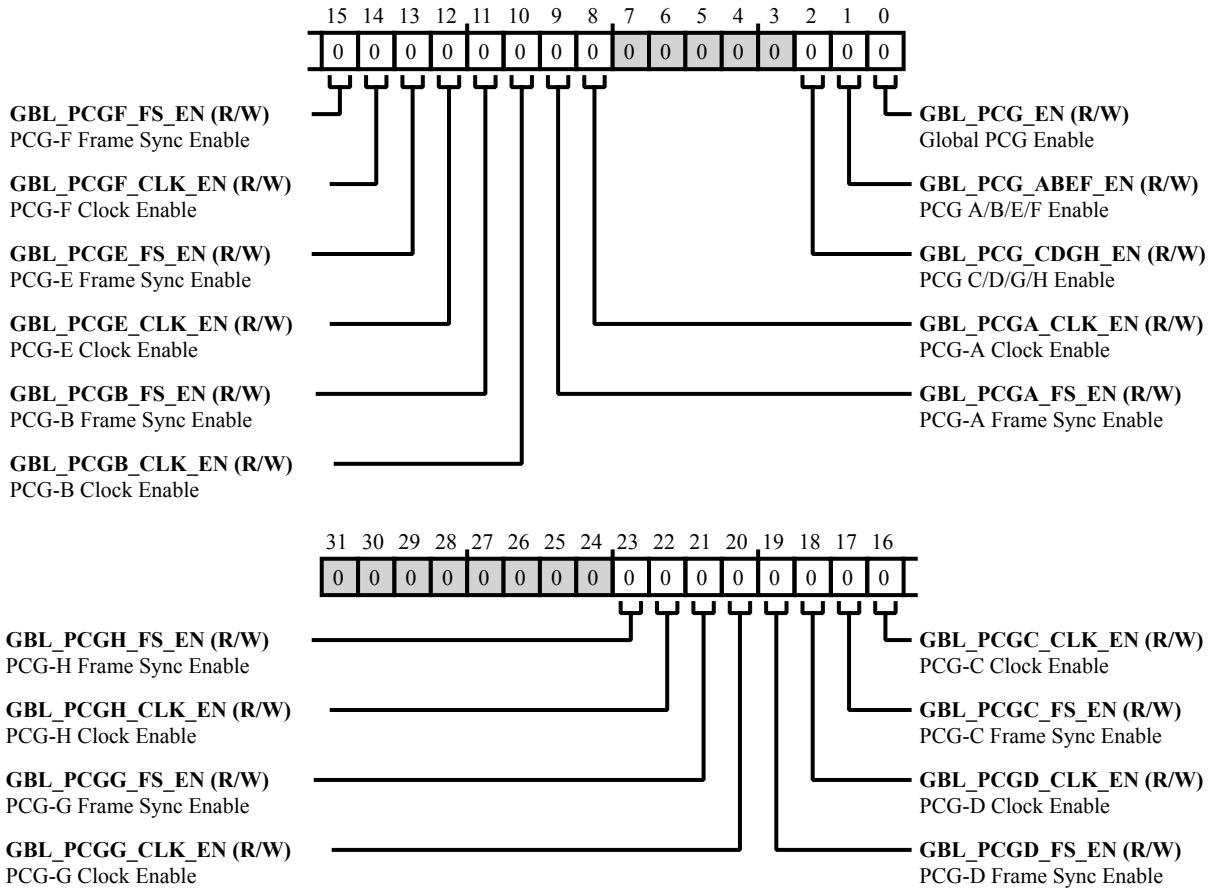

Figure 29-63: DAI_GBL_PCG_EN Register Diagram

Table 29-71: DAI_GBL_PCG_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	GBL_PCGH_FS_EN	PCG-H Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
22 (R/W)	GBL_PCGH_CLK_EN	PCG-H Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.

Table 29-71: DAI_GBL_PCG_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	GBL_PCGG_FS_EN	PCG-G Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
20 (R/W)	GBL_PCGG_CLK_EN	PCG-G Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
19 (R/W)	GBL_PCGD_FS_EN	PCG-D Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
18 (R/W)	GBL_PCGD_CLK_EN	PCG-D Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
17 (R/W)	GBL_PCGC_FS_EN	PCG-C Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
16 (R/W)	GBL_PCGC_CLK_EN	PCG-C Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
15 (R/W)	GBL_PCGF_FS_EN	PCG-F Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
14 (R/W)	GBL_PCGF_CLK_EN	PCG-F Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
13 (R/W)	GBL_PCGE_FS_EN	PCG-E Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
12 (R/W)	GBL_PCGE_CLK_EN	PCG-E Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
11 (R/W)	GBL_PCGB_FS_EN	PCG-B Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
10 (R/W)	GBL_PCGB_CLK_EN	PCG-B Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.

Table 29-71: DAI_GBL_PCG_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	GBL_PCGA_FS_EN	PCG-A Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
8 (R/W)	GBL_PCGA_CLK_EN	PCG-A Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
2 (R/W)	GBL_PCG_CDGH_EN	PCG C/D/G/H Enable. This bit when set to 1 along with bits [23:16] of the same register enables the respective PCGs within a DAI1. This bit when set to 0 disables the PCGs within DAI1.
1 (R/W)	GBL_PCG_ABEF_EN	PCG A/B/E/F Enable. This bit when set to 1 along with bits [15:8] of the same register enables the respective PCGs within a DAI0. This bit when set to 0 disables the PCGs within DAI0.
0 (R/W)	GBL_PCG_EN	Global PCG Enable. This bit Globally enables the PCGs across DAI0 and DAI1. This bit when set to 1 along with bit [2:1] and [23:8] enables all the PCGs across DAI0 and DAI1. This bit when set to 0 disables all the PCGs across DAI0 and DAI1.

Global SPORT Enable Register

The DAI_GBL_SP_EN register indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

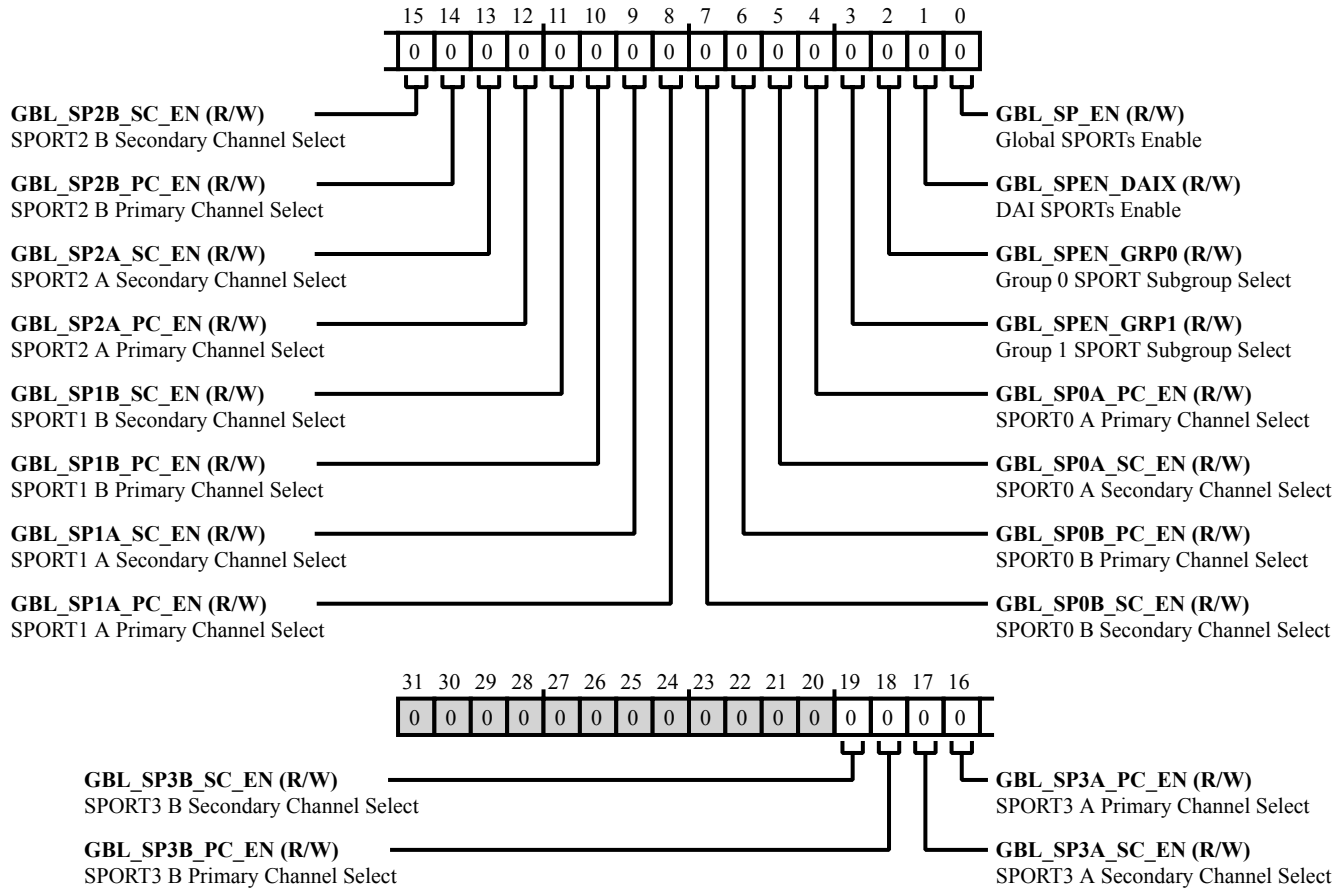

Figure 29-64: DAI_GBL_SP_EN Register Diagram

Table 29-72: DAI_GBL_SP_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	GBL_SP3B_SC_EN	SPORT3 B Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP3B_SC_EN bit selects SPORT3 B as the secondary channel for global enable.
18 (R/W)	GBL_SP3B_PC_EN	SPORT3 B Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP3B_PC_EN bit selects SPORT3 B as the primary channel for global enable.

Table 29-72: DAI_GBL_SP_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	GBL_SP3A_SC_EN	SPORT3 A Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP3A_SC_EN bit selects SPORT3 A as the secondary channel for global enable.
16 (R/W)	GBL_SP3A_PC_EN	SPORT3 A Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP3A_PC_EN bit selects SPORT3 A as the primary channel for global enable.
15 (R/W)	GBL_SP2B_SC_EN	SPORT2 B Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP2B_SC_EN bit selects SPORT2 B as the secondary channel for global enable.
14 (R/W)	GBL_SP2B_PC_EN	SPORT2 B Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP2B_PC_EN bit selects SPORT2 B as the primary channel for global enable.
13 (R/W)	GBL_SP2A_SC_EN	SPORT2 A Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP2A_SC_EN bit selects SPORT2 A as the secondary channel for global enable.
12 (R/W)	GBL_SP2A_PC_EN	SPORT2 A Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP2A_PC_EN bit selects SPORT2 A as the primary channel for global enable.
11 (R/W)	GBL_SP1B_SC_EN	SPORT1 B Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP1B_SC_EN bit selects SPORT1 B as the secondary channel for global enable.
10 (R/W)	GBL_SP1B_PC_EN	SPORT1 B Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP1B_PC_EN bit selects SPORT1 B as the primary channel for global enable.
9 (R/W)	GBL_SP1A_SC_EN	SPORT1 A Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP1A_SC_EN bit selects SPORT1 A as the secondary channel for global enable.
8 (R/W)	GBL_SP1A_PC_EN	SPORT1 A Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP1A_PC_EN bit selects SPORT1 A as the primary channel for global enable.
7 (R/W)	GBL_SP0B_SC_EN	SPORT0 B Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP0B_SC_EN bit selects SPORT0 B as the secondary channel for global enable.
6 (R/W)	GBL_SP0B_PC_EN	SPORT0 B Primary Channel Select. Selects SPORT0 B primary channel for global enable.

Table 29-72: DAI_GBL_SP_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	GBL_SP0A_SC_EN	SPORT0 A Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP0A_SC_EN` bit selects SPORT0 A as the secondary channel for global enable.
4 (R/W)	GBL_SP0A_PC_EN	SPORT0 A Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP0A_PC_EN` bit selects SPORT0 A as the primary channel for global enable.
3 (R/W)	GBL_SPEN_GRP1	Group 1 SPORT Subgroup Select. The `DAI_GBL_SP_EN.GBL_SPEN_GRP1` bit creates a subgroup of selected SPORTs.
2 (R/W)	GBL_SPEN_GRP0	Group 0 SPORT Subgroup Select. The `DAI_GBL_SP_EN.GBL_SPEN_GRP0` bit creates a subgroup of selected SPORTs.
1 (R/W)	GBL_SPEN_DAIX	DAI SPORTs Enable. The `DAI_GBL_SP_EN.GBL_SPEN_DAIX` bit enables the SPORTs selected within a DAI.
0 (R/W)	GBL_SP_EN	Global SPORTs Enable. The `DAI_GBL_SP_EN.GBL_SP_EN` bit enables the selected SPORTs.

Falling-Edge Interrupt Mask Register

The DAI_IMSK_FE register masks and unmasks interrupts generated on the falling edge of a waveform. Note that any of the Group E signals can be mapped to any of the Miscellaneous interrupts (9-0).

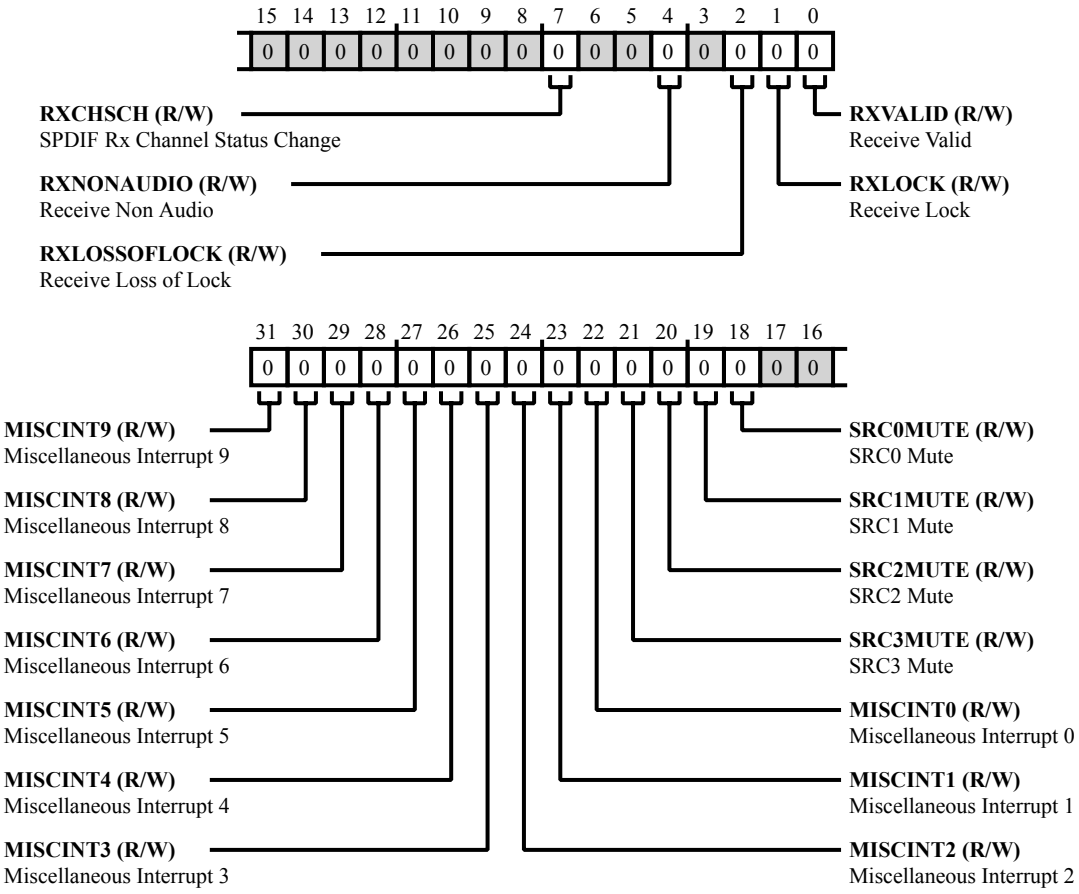

Figure 29-65: DAI_IMSK_FE Register Diagram

Table 29-73: DAI_IMSK_FE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the DAI_IMSK_FE.MISCINT9 bit unmasks the interrupt for the falling edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the DAI_IMSK_FE.MISCINT8 bit unmasks the interrupt for the falling edge of the routed signal.

Table 29-73: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the DAI_IMSK_FE.MISCINT7 bit unmasks the interrupt for the falling edge of the routed signal.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the DAI_IMSK_FE.MISCINT6 bit unmasks the interrupt for the falling edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the DAI_IMSK_FE.MISCINT5 bit unmasks the interrupt for the falling edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the DAI_IMSK_FE.MISCINT4 bit unmasks the interrupt for the falling edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the DAI_IMSK_FE.MISCINT3 bit unmasks the interrupt for the falling edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the DAI_IMSK_FE.MISCINT2 bit unmasks the interrupt for the falling edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the DAI_IMSK_FE.MISCINT1 bit unmasks the interrupt for the falling edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the DAI_IMSK_FE.MISCINT0 bit unmasks the interrupt for the falling edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The DAI_IMSK_FE.SRC3MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The DAI_IMSK_FE.SRC2MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The DAI_IMSK_FE.SRC1MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 29-73: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The DAI_IMSK_FE.SRC0MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IMSK_FE.RXCHSCH bit masks or unmasks RXCHSCH interrupt for the falling edge of this interrupt. This interrupt is set if there is a change in the SPDIF Rx channel status bits (SPDIF_RX_STAT0/1_A/B).
4 (R/W)	RXNONAUDIO	Receive Non Audio. The DAI_IMSK_FE.RXNONAUDIO bit masks or unmasks the non audio frame mode interrupt for the falling edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_FE.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The DAI_IMSK_FE.RXLOCK bit masks or unmasks the S/PDIF receiver lock for the falling edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the DAI_IMSK_FE.RXVALID bit unmasks the interrupt for the falling edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

Core Interrupt Priority Assignment Register

The DAI_IMSK_PRI register masks interrupts for DAI high or DAI low interrupt priority.

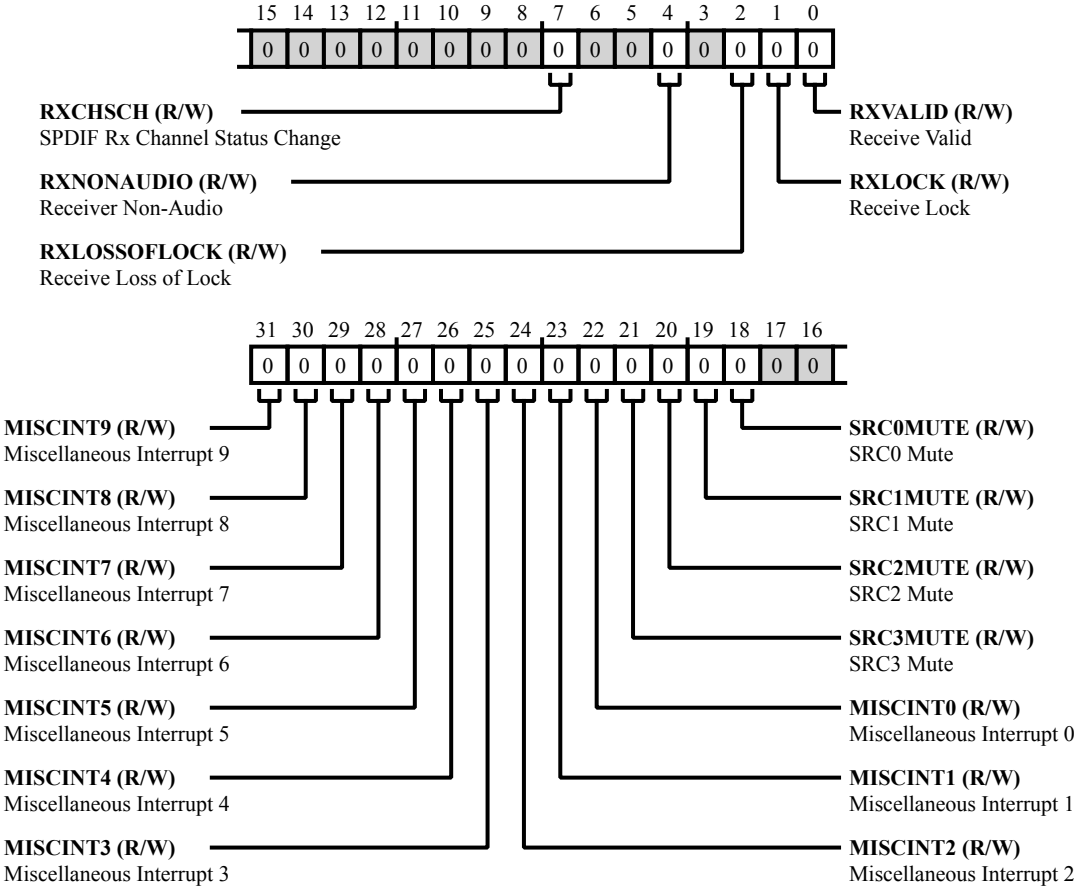

Figure 29-66: DAI_IMSK_PRI Register Diagram

Table 29-74: DAI_IMSK_PRI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. If the DAI_IMSK_PRI.MISCINT9 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT9 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. If the DAI_IMSK_PRI.MISCINT8 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT8 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 29-74: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. If the DAI_IMSK_PRI.MISCINT7 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT7 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. If the DAI_IMSK_PRI.MISCINT6 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT6 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. If the DAI_IMSK_PRI.MISCINT5 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT5 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. If the DAI_IMSK_PRI.MISCINT4 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT4 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. If the DAI_IMSK_PRI.MISCINT3 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT3 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. If the DAI_IMSK_PRI.MISCINT2 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT2 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. If the DAI_IMSK_PRI.MISCINT1 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT1 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. If the DAI_IMSK_PRI.MISCINT0 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT0 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
21 (R/W)	SRC3MUTE	SRC3 Mute. If the DAI_IMSK_PRI.SRC3MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC3MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 29-74: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	SRC2MUTE	SRC2 Mute. If the DAI_IMSK_PRI.SRC2MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC2MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
19 (R/W)	SRC1MUTE	SRC1 Mute. If the DAI_IMSK_PRI.SRC1MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC1MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
18 (R/W)	SRC0MUTE	SRC0 Mute. If the DAI_IMSK_PRI.SRC0MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC0MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. If the DAI_IMSK_PRI.RXCHSCH bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXCHSCH bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
4 (R/W)	RXNONAUDIO	Receiver Non-Audio. If the DAI_IMSK_PRI.RXNONAUDIO bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXNONAUDIO bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_PRI.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. If the DAI_IMSK_PRI.RXLOCK bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXLOCK bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
0 (R/W)	RXVALID	Receive Valid. If the DAI_IMSK_PRI.RXVALID bit is cleared (=0), the interrupt is mapped to the INTR_DAI_IRQL from the SEC. If the DAI_IMSK_PRI.RXVALID bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Rising-Edge Interrupt Mask Register

The DAI_IMSK_RE register masks and unmasks interrupts generated on the rising edge of a waveform. Note that any of the Group E signals can be mapped to any of the miscellaneous interrupts (9-0).

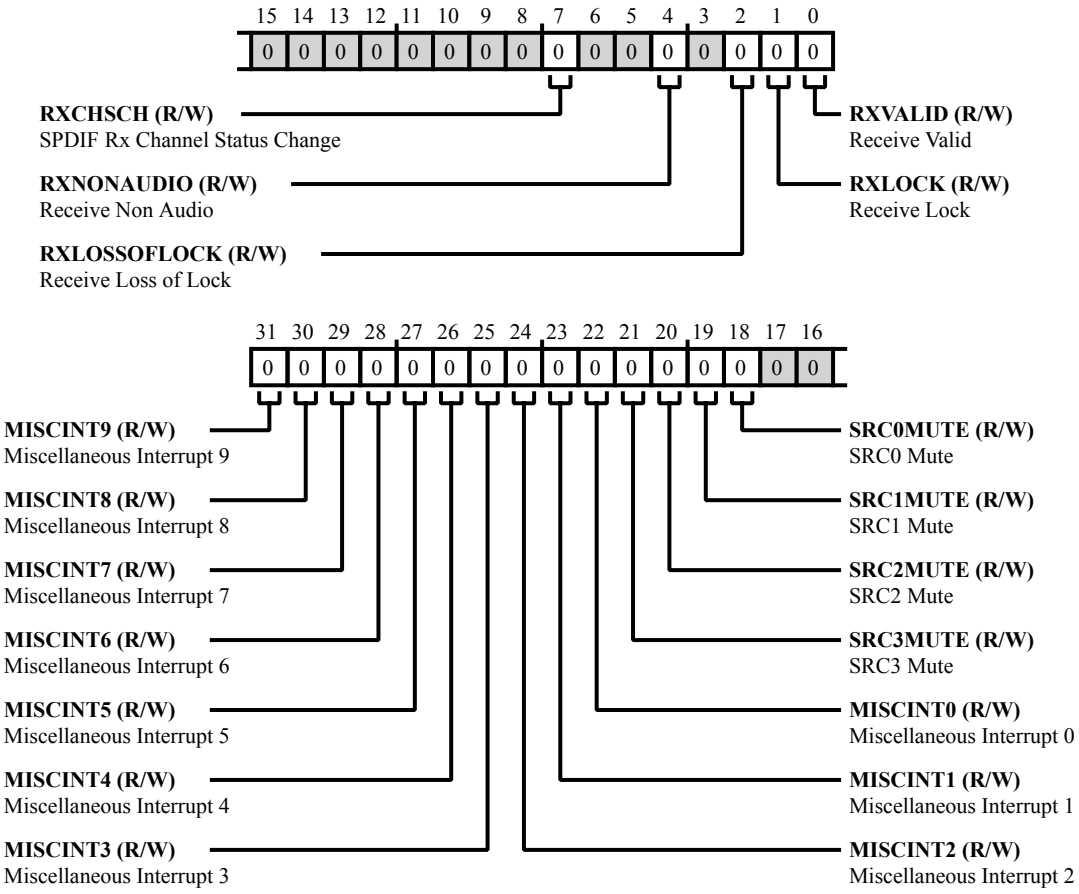

Figure 29-67: DAI_IMSK_RE Register Diagram

Table 29-75: DAI_IMSK_RE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the DAI_IMSK_RE.MISCINT9 bit unmasks the interrupt for the rising edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the DAI_IMSK_RE.MISCINT8 bit unmasks the interrupt for the rising edge of the routed signal.

Table 29-75: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the DAI_IMSK_RE.MISCINT7 bit unmasks the interrupt for the rising edge of the routed signal.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the DAI_IMSK_RE.MISCINT6 bit unmasks the interrupt for the rising edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the DAI_IMSK_RE.MISCINT5 bit unmasks the interrupt for the rising edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the DAI_IMSK_RE.MISCINT4 bit unmasks the interrupt for the rising edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the DAI_IMSK_RE.MISCINT3 bit unmasks the interrupt for the rising edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the DAI_IMSK_RE.MISCINT2 bit unmasks the interrupt for the rising edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the DAI_IMSK_RE.MISCINT1 bit unmasks the interrupt for the rising edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the DAI_IMSK_RE.MISCINT0 bit unmasks the interrupt for the rising edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The DAI_IMSK_RE.SRC3MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The DAI_IMSK_RE.SRC2MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The DAI_IMSK_RE.SRC1MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 29-75: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The DAI_IMSK_RE.SRC0MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IMSK_RE.RXCHSCH bit masks or unmasks RXCHSCH (Status Change) interrupt for the rising edge of this interrupt. This interrupt is set if there is a change in the SPDIF Rx channel status bits (SPDIF_RX_STAT0/1_A/B).
4 (R/W)	RXNONAUDIO	Receive Non Audio. The DAI_IMSK_RE.RXNONAUDIO bit masks or unmasks the non audio frame mode interrupt for the rising edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_RE.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the rising edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The DAI_IMSK_RE.RXLOCK bit masks or unmasks the S/PDIF receiver lock for the rising edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the DAI_IMSK_RE.RXVALID bit unmasks the interrupt for the rising edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

High Priority Interrupt Latch Register

The DAI_IRPTL_H register holds the high priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE registers and mapped to the INTR_DAI_IRQH signal in the SEC by DAI_IMSK_PRI registers. If a bit in this register is already set and the corresponding interrupt is masked in the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until its mask registers (DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI) are reset by software with a W1C operation.

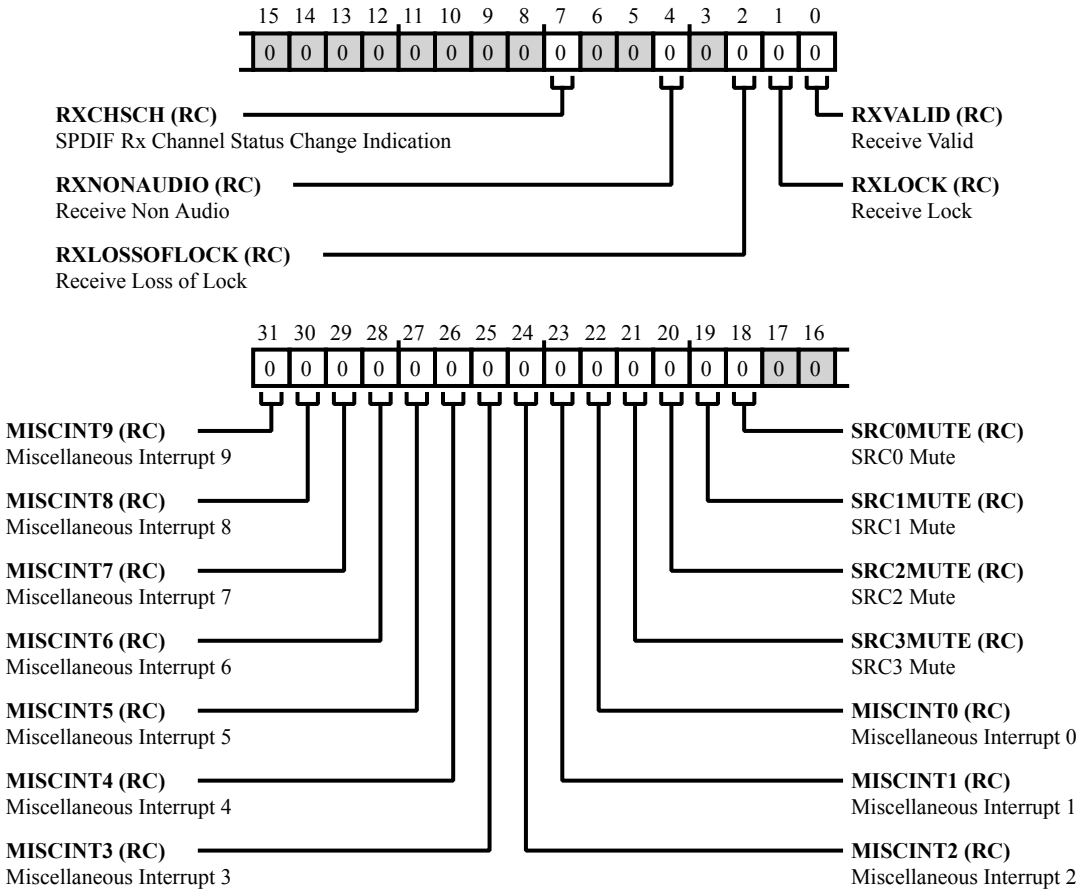

Figure 29-68: DAI_IRPTL_H Register Diagram

Table 29-76: DAI_IRPTL_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RC/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_H.MISCINT9 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Table 29-76: DAI_IRPTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (RC/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_H.MISCINT8 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
29 (RC/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_H.MISCINT7 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
28 (RC/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_H.MISCINT6 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
27 (RC/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_H.MISCINT5 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
26 (RC/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_H.MISCINT4 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
25 (RC/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_H.MISCINT3 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
24 (RC/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_H.MISCINT2 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
23 (RC/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_H.MISCINT1 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
22 (RC/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_H.MISCINT0 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
21 (RC/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_H.SRC3MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
20 (RC/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_H.SRC2MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Table 29-76: DAI_IRPTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (RC/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_H.SRC1MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
18 (RC/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_H.SRC0MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
7 (RC/NW)	RXCHSCH	SPDIF Rx Channel Status Change Indication. The DAI_IRPTL_H.RXCHSCH bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
4 (RC/NW)	RXNONAUDIO	Receive Non Audio. The DAI_IRPTL_H.RXNONAUDIO bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
2 (RC/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IRPTL_H.RXLOSSOFLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
1 (RC/NW)	RXLOCK	Receive Lock. The DAI_IRPTL_H.RXLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
0 (RC/NW)	RXVALID	Receive Valid. The DAI_IRPTL_H.RXVALID bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Shadow High Priority Interrupt Latch Register

The DAI_IRPTL_HS register is the shadow register of the DAI_IRPTL_H register. Its content is the same as the DAI_IRPTL_H register. Reading the DAI_IRPTL_HS register does not affect its contents while reading the contents of the DAI_IRPTL_H registers clears it.

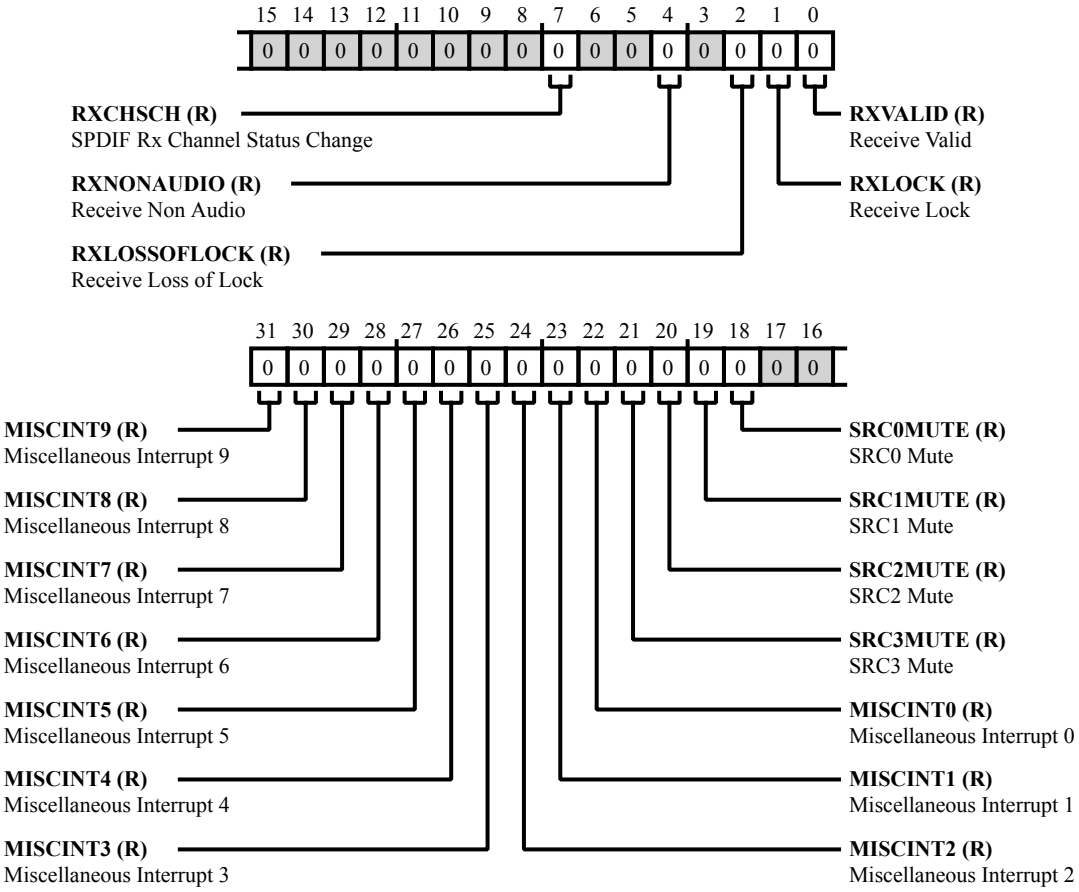

Figure 29-69: DAI_IRPTL_HS Register Diagram

Table 29-77: DAI_IRPTL_HS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_HS.MISCINT9 bit is the shadow of the DAI_IRPTL_H.MISCINT9 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT9 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT9 bit clears it.

Table 29-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_HS.MISCINT8 bit is the shadow of the DAI_IRPTL_H.MISCINT8 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT8 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT8 bit clears it.
29 (R/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_HS.MISCINT7 bit is the shadow of the DAI_IRPTL_H.MISCINT7 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT7 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT7 bit clears it.
28 (R/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_HS.MISCINT6 bit is the shadow of the DAI_IRPTL_H.MISCINT6 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT6 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT6 bit clears it.
27 (R/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_HS.MISCINT5 bit is the shadow of the DAI_IRPTL_H.MISCINT5 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT5 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT5 bit clears it.
26 (R/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_HS.MISCINT4 bit is the shadow of the DAI_IRPTL_H.MISCINT4 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT4 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT4 bit clears it.
25 (R/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_HS.MISCINT3 bit is the shadow of the DAI_IRPTL_H.MISCINT3 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT3 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT3 bit clears it.
24 (R/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_HS.MISCINT2 bit is the shadow of the DAI_IRPTL_H.MISCINT2 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT2 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT2 bit clears it.

Table 29-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_HS.MISCINT1 bit is the shadow of the DAI_IRPTL_H.MISCINT1 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT1 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT1 bit clears it.
22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_HS.MISCINT0 bit is the shadow of the DAI_IRPTL_H.MISCINT0 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT0 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT0 bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_HS.SRC3MUTE bit is the shadow of the DAI_IRPTL_H.SRC3MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC3MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC3MUTE bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_HS.SRC2MUTE bit is the shadow of the DAI_IRPTL_H.SRC2MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC2MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC2MUTE bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_HS.SRC1MUTE bit is the shadow of the DAI_IRPTL_H.SRC1MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC1MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC1MUTE bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_HS.SRC0MUTE bit is the shadow of the DAI_IRPTL_H.SRC0MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC0MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC0MUTE bit clears it.
7 (R/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_HS.RXCHSCH bit is the shadow of the DAI_IRPTL_H.RXCHSCH bit and contains the same content. Reading the DAI_IRPTL_HS.RXCHSCH bit does not affect its contents while reading the DAI_IRPTL_H.RXCHSCH bit clears it.

Table 29-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	RXNONAUDIO	Receive Non Audio. The `DAI_IRPTL_HS.RXNONAUDIO` bit is the shadow of `DAI_IRPTL_H.RXNONAUDIO` bit and contains the same content. Reading this bit does not affect its content.
2 (R/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IRPTL_HS.RXLOSSOFLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOSSOFLOCK` bit and contains the same content. Reading this bit does not affect its content.
1 (R/NW)	RXLOCK	Receive Lock. The `DAI_IRPTL_HS.RXLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOCK` bit and contains the same content. Reading this bit does not affect its content.
0 (R/NW)	RXVALID	Receive Valid. Setting the `DAI_IRPTL_HS.RXVALID` bit is the shadow of `DAI_IRPTL_H.RXVALID` bit and contains the same content. Reading this bit does not affect its content.

Low Priority Interrupt Latch Register

The DAI_IRPTL_L register holds the low priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers. If a bit in DAI_IRPTL_L is already set and the corresponding interrupt is masked in DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until its masked registers (DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI) are reset by software with a W1C operation.

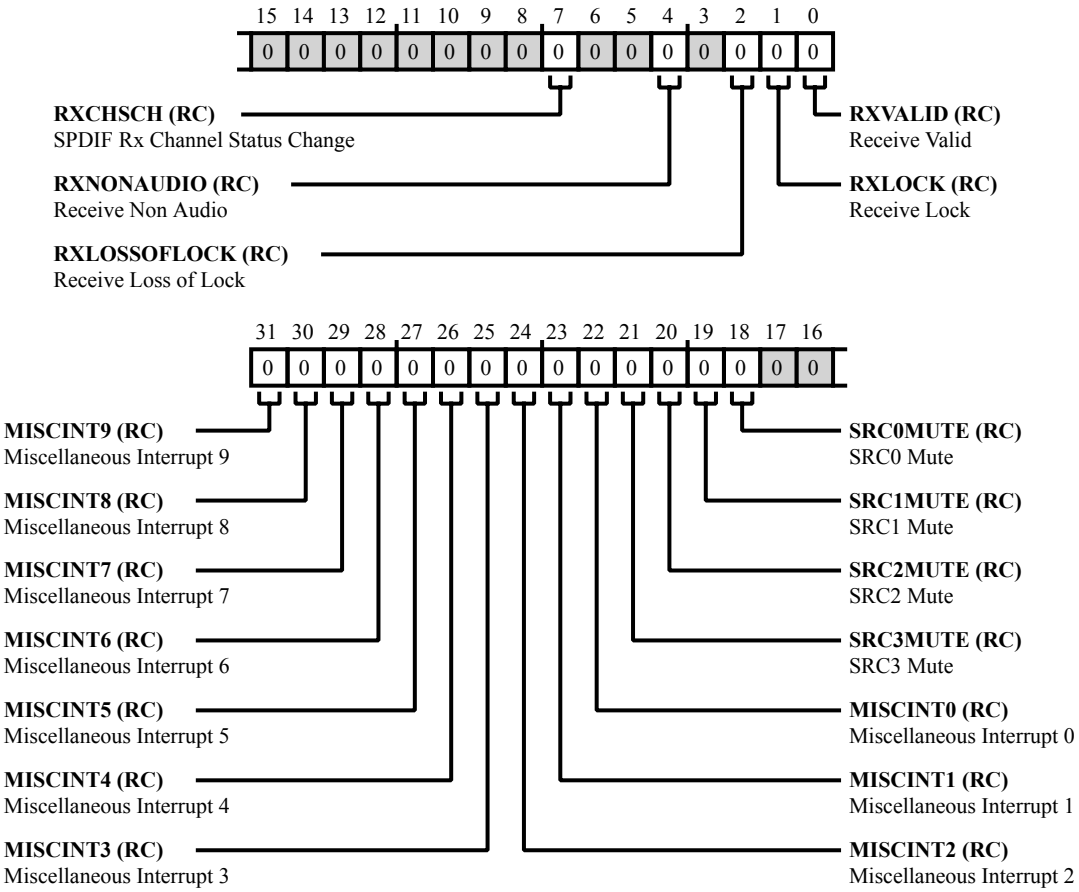

Figure 29-70: DAI_IRPTL_L Register Diagram

Table 29-78: DAI_IRPTL_L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RC/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_L.MISCINT9 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Table 29-78: DAI_IRPTL_L Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (RC/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_L.MISCINT8 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
29 (RC/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_L.MISCINT7 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
28 (RC/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_L.MISCINT6 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
27 (RC/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_L.MISCINT5 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
26 (RC/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_L.MISCINT4 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
25 (RC/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_L.MISCINT3 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
24 (RC/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_L.MISCINT2 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
23 (RC/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_L.MISCINT1 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
22 (RC/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_L.MISCINT0 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
21 (RC/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_L.SRC3MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
20 (RC/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_L.SRC2MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Table 29-78: DAI_IRPTL_L Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (RC/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_L.SRC1MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
18 (RC/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_L.SRC0MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
7 (RC/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_L.RXCHSCH bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
4 (RC/NW)	RXNONAUDIO	Receive Non Audio. The DAI_IRPTL_L.RXNONAUDIO bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
2 (RC/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IRPTL_L.RXLOSSOFLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
1 (RC/NW)	RXLOCK	Receive Lock. The DAI_IRPTL_L.RXLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
0 (RC/NW)	RXVALID	Receive Valid. The DAI_IRPTL_L.RXVALID bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Shadow Low Priority Interrupt Latch Register

The DAI_IRPTL_LS register is the shadow register of the DAI_IRPTL_L register. Its content is the same as the DAI_IRPTL_L register. Reading the DAI_IRPTL_LS register does not affect its contents while reading the contents of the DAI_IRPTL_L registers clears it.

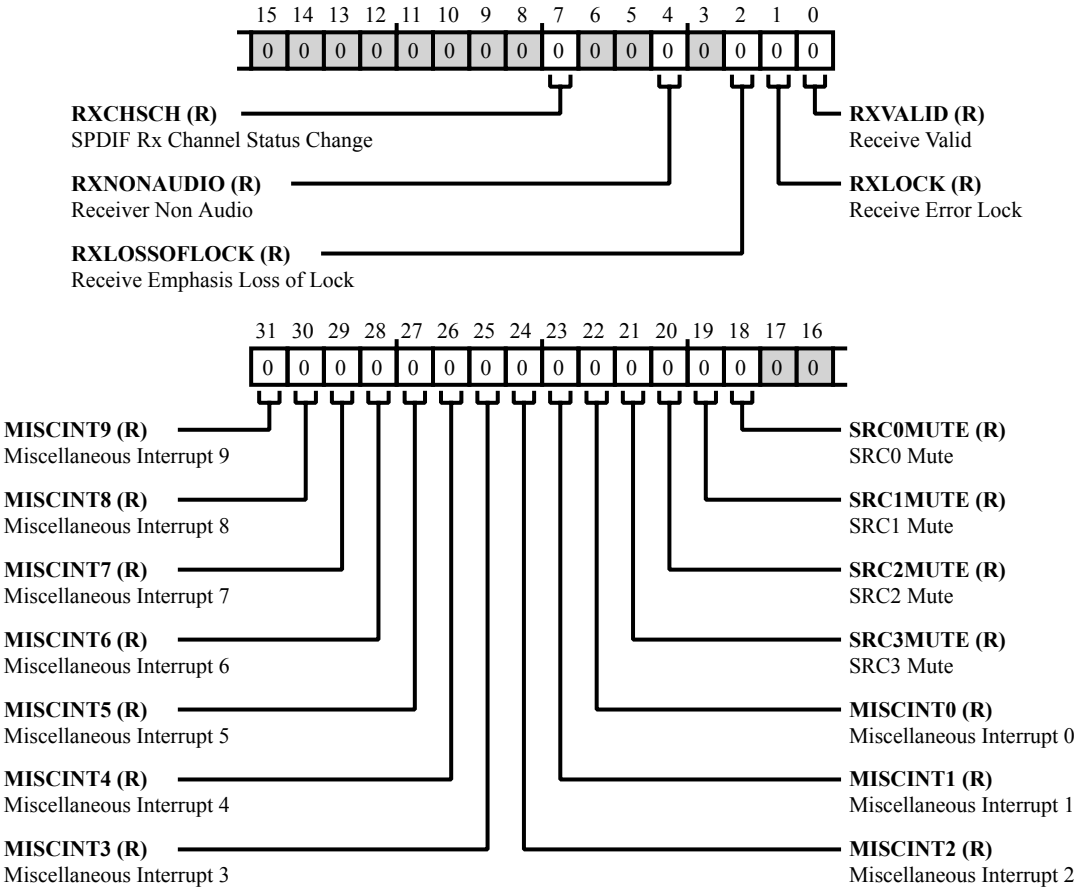

Figure 29-71: DAI_IRPTL_LS Register Diagram

Table 29-79: DAI_IRPTL_LS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_LS.MISCINT9 bit is the shadow of the DAI_IRPTL_L.MISCINT9 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT9 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT9 bit clears it.

Table 29-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_LS.MISCINT8 bit is the shadow of the DAI_IRPTL_L.MISCINT8 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT8 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT8 bit clears it.
29 (R/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_LS.MISCINT7 bit is the shadow of the DAI_IRPTL_L.MISCINT7 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT7 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT7 bit clears it.
28 (R/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_LS.MISCINT6 bit is the shadow of the DAI_IRPTL_L.MISCINT6 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT6 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT6 bit clears it.
27 (R/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_LS.MISCINT5 bit is the shadow of the DAI_IRPTL_L.MISCINT5 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT5 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT5 bit clears it.
26 (R/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_LS.MISCINT4 bit is the shadow of the DAI_IRPTL_L.MISCINT4 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT4 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT4 bit clears it.
25 (R/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_LS.MISCINT3 bit is the shadow of the DAI_IRPTL_L.MISCINT3 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT3 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT3 bit clears it.
24 (R/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_LS.MISCINT2 bit is the shadow of the DAI_IRPTL_L.MISCINT2 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT2 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT2 bit clears it.

Table 29-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_LS.MISCINT1 bit is the shadow of the DAI_IRPTL_L.MISCINT1 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT1 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT1 bit clears it.
22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_LS.MISCINT0 bit is the shadow of the DAI_IRPTL_L.MISCINT0 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT0 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT0 bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_LS.SRC3MUTE bit is the shadow of the DAI_IRPTL_L.SRC3MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC3MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC3MUTE bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_LS.SRC2MUTE bit is the shadow of the DAI_IRPTL_L.SRC2MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC2MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC2MUTE bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_LS.SRC1MUTE bit is the shadow of the DAI_IRPTL_L.SRC1MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC1MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC1MUTE bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_LS.SRC0MUTE bit is the shadow of the DAI_IRPTL_L.SRC0MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC0MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC0MUTE bit clears it.
7 (R/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_LS.RXCHSCH bit is the shadow of the DAI_IRPTL_L.RXCHSCH bit and contains the same content. Reading the DAI_IRPTL_LS.RXCHSCH bit does not affect its contents while reading the DAI_IRPTL_L.RXCHSCH bit clears it.

Table 29-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	RXNONAUDIO	Receiver Non Audio. The DAI_IRPTL_LS.RXNONAUDIO bit is the shadow of the DAI_IRPTL_L.RXNONAUDIO bit and contains the same content. Reading the DAI_IRPTL_LS.RXNONAUDIO bit does not affect its contents while reading the DAI_IRPTL_L.RXNONAUDIO bit clears it.
2 (R/NW)	RXLOSSOFLOCK	Receive Emphasis Loss of Lock. The DAI_IRPTL_LS.RXLOSSOFLOCK bit is the shadow of DAI_IRPTL_L.RXLOSSOFLOCK bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXLOSSOFLOCK bit clears it.
1 (R/NW)	RXLOCK	Receive Error Lock. The DAI_IRPTL_LS.RXLOCK bit is the shadow of DAI_IRPTL_L.RXLOCK bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXLOCK bit clears it.
0 (R/NW)	RXVALID	Receive Valid. The DAI_IRPTL_LS.RXVALID bit is the shadow of DAI_IRPTL_L.RXVALID bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXVALID bit clears it.

Miscellaneous Control Register 0

The DAI_MISC0 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

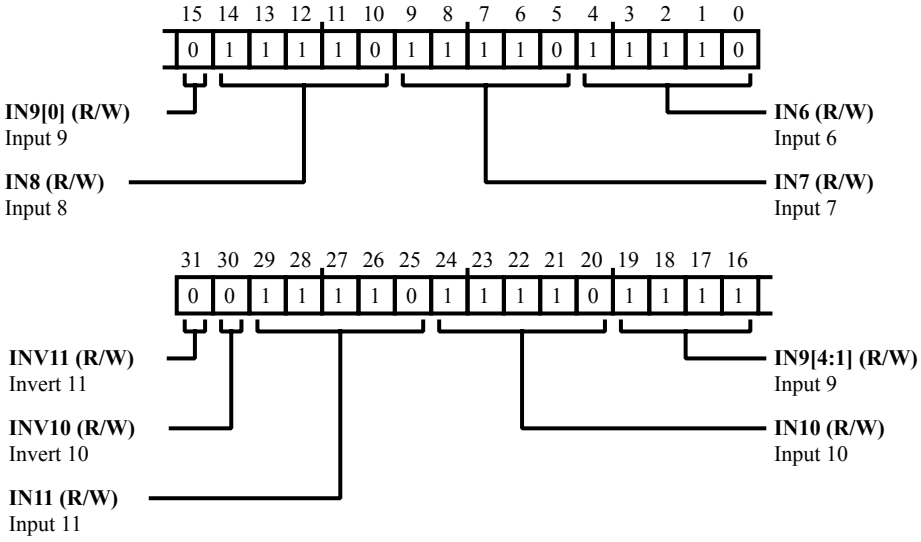

Figure 29-72: DAI_MISC0 Register Diagram

Table 29-80: DAI_MISC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	INV11	Invert 11. The DAI_MISC0.INV11 bit field inverts miscellaneous A5 input.
30 (R/W)	INV10	Invert 10. The DAI_MISC0.INV10 bit field inverts miscellaneous A4 input.
29:25 (R/W)	IN11	Input 11. The DAI_MISC0.IN11 bit field configures miscellaneous A5 input.
24:20 (R/W)	IN10	Input 10. The DAI_MISC0.IN10 bit field configures miscellaneous A4 input.
19:15 (R/W)	IN9	Input 9. The DAI_MISC0.IN9 bit field configures miscellaneous A3 input/miscellaneous Interrupt 9(DAI interrupt 31).
14:10 (R/W)	IN8	Input 8. The DAI_MISC0.IN8 bit field configures miscellaneous A2 input/miscellaneous Interrupt 8(DAI interrupt 30).

Table 29-80: DAI_MISC0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	IN7	Input 7. The `DAI_MISC0.IN7` bit field configures miscellaneous A1 input/miscellaneous Interrupt 7(DAI interrupt 29).
4:0 (R/W)	IN6	Input 6. The `DAI_MISC0.IN6` bit field configures miscellaneous A0 input/miscellaneous Interrupt 6(DAI interrupt 28).

Miscellaneous Control Register 1

The DAI_MISC1 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

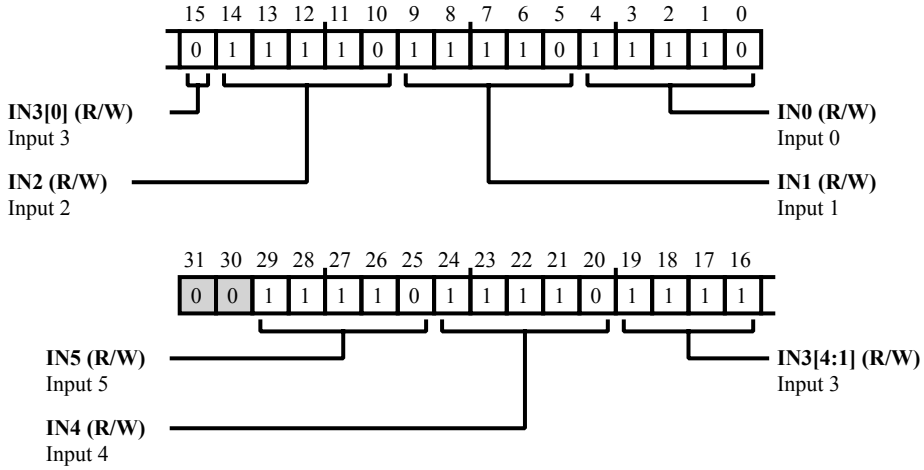

Figure 29-73: DAI_MISC1 Register Diagram

Table 29-81: DAI_MISC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input 5. The DAI_MISC1.IN5 bit field configures miscellaneous Interrupt 5(DAI interrupt 27).
24:20 (R/W)	IN4	Input 4. The DAI_MISC1.IN4 bit field configures miscellaneous Interrupt 4(DAI interrupt 26).
19:15 (R/W)	IN3	Input 3. The DAI_MISC1.IN3 bit field configures miscellaneous Interrupt 3(DAI interrupt 25).
14:10 (R/W)	IN2	Input 2. The DAI_MISC1.IN2 bit field configures miscellaneous Interrupt 2(DAI interrupt 24).
9:5 (R/W)	IN1	Input 1. The DAI_MISC1.IN1 bit field configures miscellaneous Interrupt 1(DAI interrupt 23).

Table 29-81: DAI_MISC1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input 0. The `DAI_MISC1.IN0` bit field configures miscellaneous Interrupt 0(DAI interrupt 22).

Miscellaneous Control Register 1

The DAI_MISC2 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

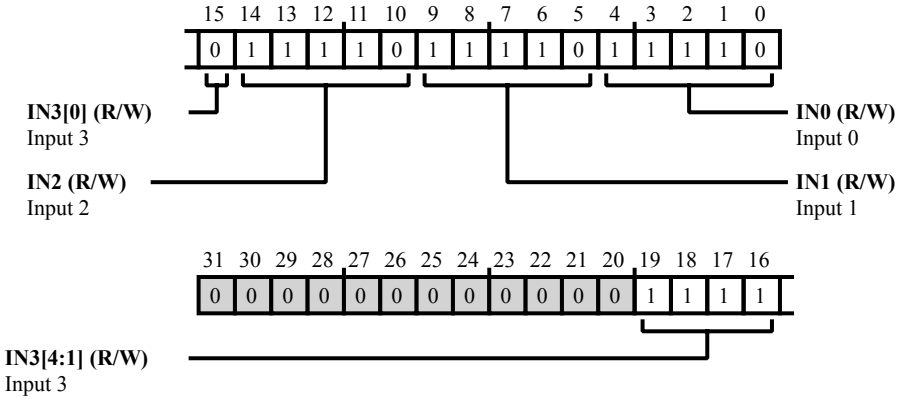

Figure 29-74: DAI_MISC2 Register Diagram

Table 29-82: DAI_MISC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:15 (R/W)	IN3	Input 3. The DAI_MISC2.IN3 bit field configures PCG-F's hardware slave trigger input.
14:10 (R/W)	IN2	Input 2. The DAI_MISC2.IN2 bit field configures PCG-E's hardware slave trigger input.
9:5 (R/W)	IN1	Input 1. The DAI_MISC2.IN1 bit field configures the PCG-B's hardware slave trigger input.
4:0 (R/W)	IN0	Input 0. The DAI_MISC2.IN0 bit field configures the PCG-A's hardware slave trigger input.

Pin Buffer Enable Register 0

The DAI_PBEN0 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

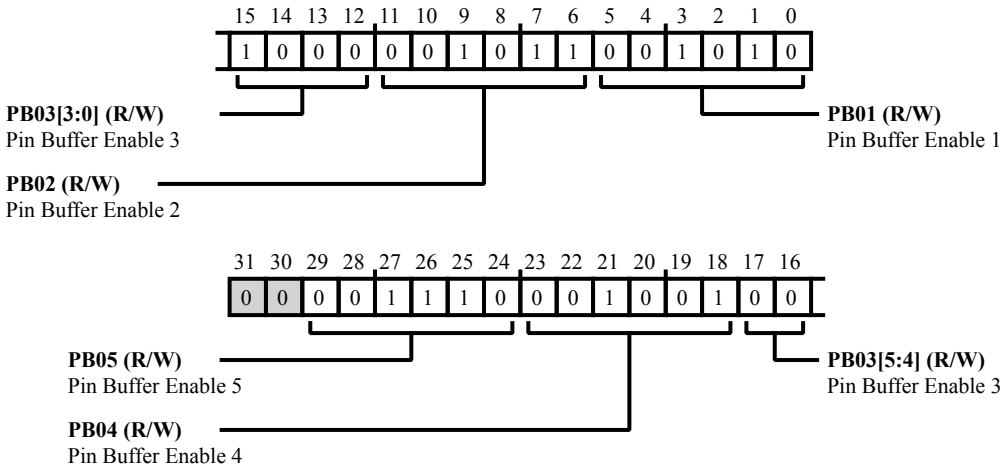

Figure 29-75: DAI_PBEN0 Register Diagram

Table 29-83: DAI_PBEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB05	Pin Buffer Enable 5. The DAI_PBEN0.PB05 bit field is the pin buffer enable for DAI port 5.
23:18 (R/W)	PB04	Pin Buffer Enable 4. The DAI_PBEN0.PB04 bit field is the pin buffer enable for DAI port 4.
17:12 (R/W)	PB03	Pin Buffer Enable 3. The DAI_PBEN0.PB03 bit field is the pin buffer enable for DAI port 3.
11:6 (R/W)	PB02	Pin Buffer Enable 2. The DAI_PBEN0.PB02 bit field is the pin buffer enable for DAI port 2.
5:0 (R/W)	PB01	Pin Buffer Enable 1. The DAI_PBEN0.PB01 bit field is the pin buffer enable for DAI port 1.

Pin Buffer Enable Register 1

The DAI_PBEN1 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

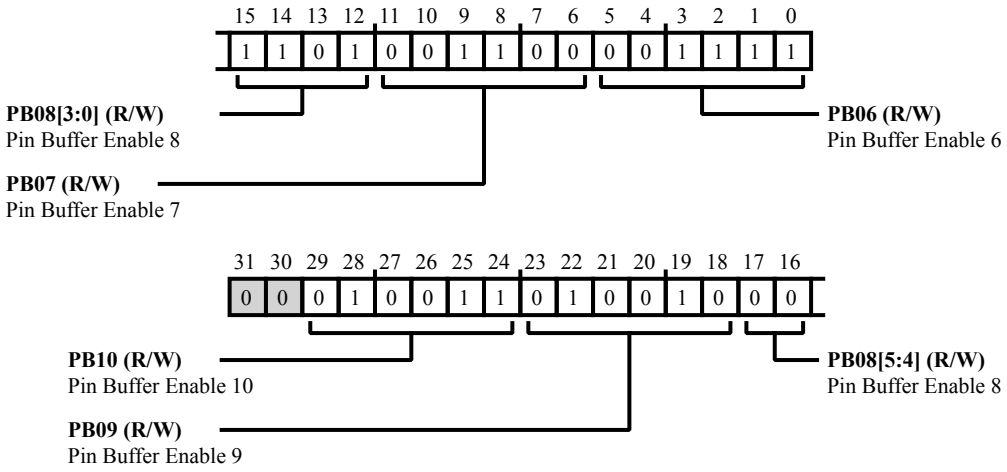

Figure 29-76: DAI_PBEN1 Register Diagram

Table 29-84: DAI_PBEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB10	Pin Buffer Enable 10. The DAI_PBEN1.PB10 bit field is the pin buffer enable for DAI port 10.
23:18 (R/W)	PB09	Pin Buffer Enable 9. The DAI_PBEN1.PB09 bit field is the pin buffer enable for DAI port 9.
17:12 (R/W)	PB08	Pin Buffer Enable 8. The DAI_PBEN1.PB08 bit field is the pin buffer enable for DAI port 8.
11:6 (R/W)	PB07	Pin Buffer Enable 7. The DAI_PBEN1.PB07 bit field is the pin buffer enable for DAI port 7.
5:0 (R/W)	PB06	Pin Buffer Enable 6. The DAI_PBEN1.PB06 bit field is the pin buffer enable for DAI port 6.

Pin Buffer Enable Register 2

The DAI_PBEN2 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

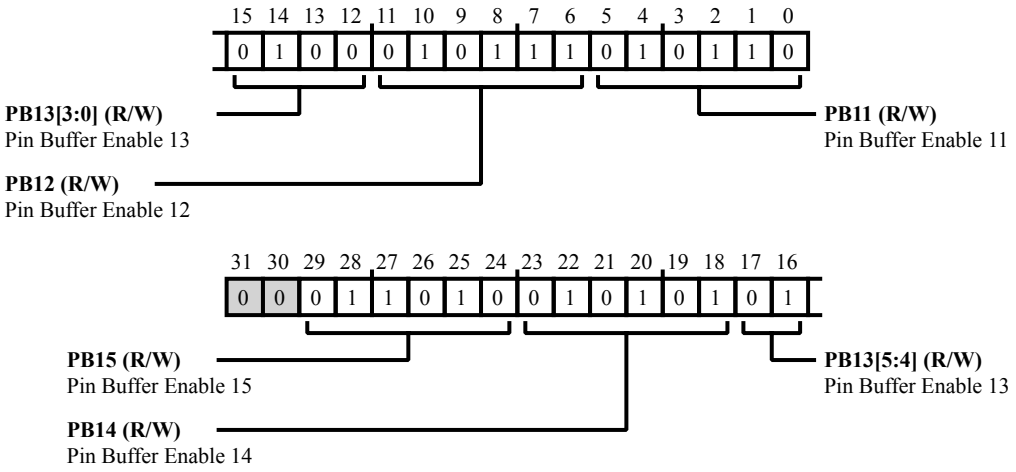

Figure 29-77: DAI_PBEN2 Register Diagram

Table 29-85: DAI_PBEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB15	Pin Buffer Enable 15. The DAI_PBEN2.PB15 bit field is the pin buffer enable for DAI port 15.
23:18 (R/W)	PB14	Pin Buffer Enable 14. The DAI_PBEN2.PB14 bit field is the pin buffer enable for DAI port 14.
17:12 (R/W)	PB13	Pin Buffer Enable 13. The DAI_PBEN2.PB13 bit field is the pin buffer enable for DAI port 13.
11:6 (R/W)	PB12	Pin Buffer Enable 12. The DAI_PBEN2.PB12 bit field is the pin buffer enable for DAI port 12.
5:0 (R/W)	PB11	Pin Buffer Enable 11. The DAI_PBEN2.PB11 bit field is the pin buffer enable for DAI port 11.

Pin Buffer Enable Register 3

The DAI_PBEN3 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

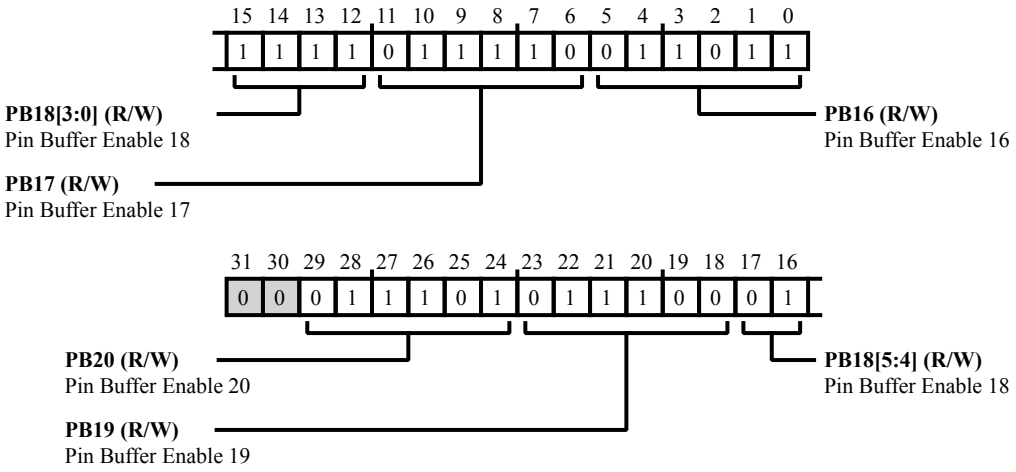

Figure 29-78: DAI_PBEN3 Register Diagram

Table 29-86: DAI_PBEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB20	Pin Buffer Enable 20. The DAI_PBEN3.PB20 bit field is the pin buffer enable for DAI port 20.
23:18 (R/W)	PB19	Pin Buffer Enable 19. The DAI_PBEN3.PB19 bit field is the pin buffer enable for DAI port 19.
17:12 (R/W)	PB18	Pin Buffer Enable 18. The DAI_PBEN3.PB18 bit field is the pin buffer enable for DAI port 18.
11:6 (R/W)	PB17	Pin Buffer Enable 17. The DAI_PBEN3.PB17 bit field is the pin buffer enable for DAI port 17.
5:0 (R/W)	PB16	Pin Buffer Enable 16. The DAI_PBEN3.PB16 bit field is the pin buffer enable for DAI port 16.

Pin Buffer Assignment Register 0

The DAI_PIN0 register routes physical pins that are connected to a bonded pad.

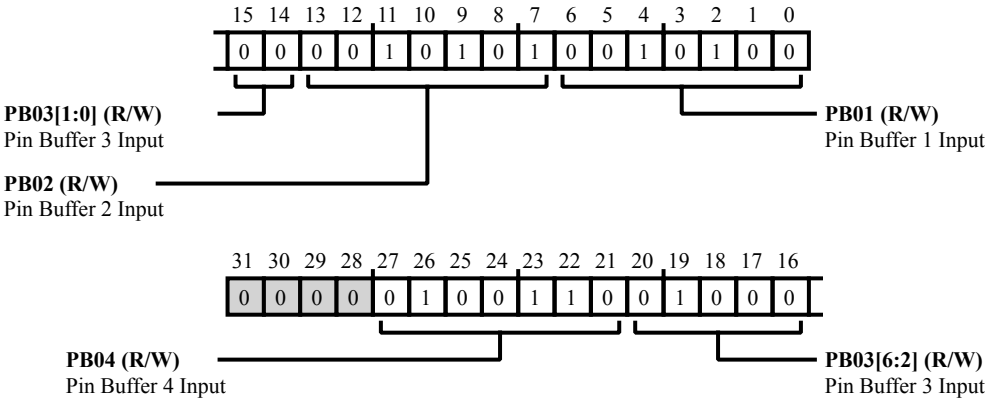

Figure 29-79: DAI_PIN0 Register Diagram

Table 29-87: DAI_PIN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB04	Pin Buffer 4 Input. DAI_PIN0.PB04 holds the Source signal assignment that will be routed to the DAI_PIN0.PB04 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB03	Pin Buffer 3 Input. DAI_PIN0.PB03 holds the Source signal assignment that will be routed to the DAI_PIN0.PB03 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB02	Pin Buffer 2 Input. DAI_PIN0.PB02 holds the Source signal assignment that will be routed to the DAI_PIN0.PB02 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB01	Pin Buffer 1 Input. DAI_PIN0.PB01 holds the Source signal assignment that will be routed to the DAI_PIN0.PB01 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 1

The DAI_PIN1 register routes physical pins that are connected to a bonded pad.

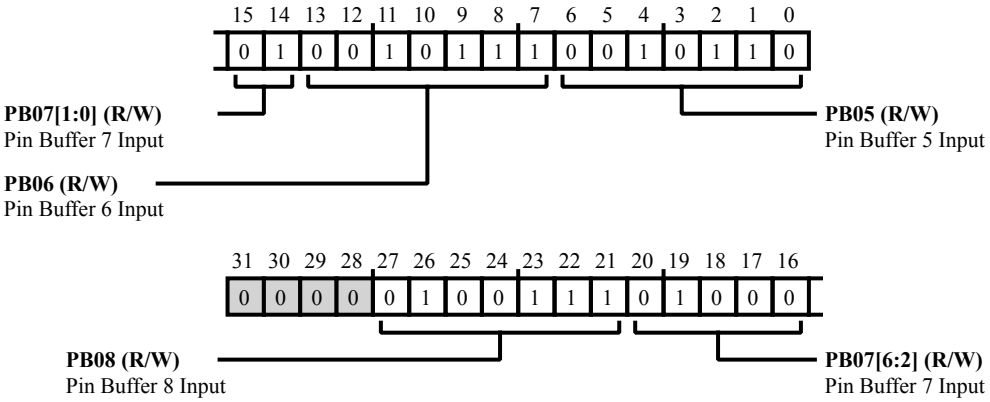

Figure 29-80: DAI_PIN1 Register Diagram

Table 29-88: DAI_PIN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB08	Pin Buffer 8 Input. DAI_PIN1.PB08 holds the Source signal assignment that will be routed to the DAI_PIN1.PB08 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB07	Pin Buffer 7 Input. DAI_PIN1.PB07 holds the Source signal assignment that will be routed to the DAI_PIN1.PB07 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB06	Pin Buffer 6 Input. DAI_PIN1.PB06 holds the Source signal assignment that will be routed to the DAI_PIN1.PB06 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB05	Pin Buffer 5 Input. DAI_PIN1.PB05 holds the Source signal assignment that will be routed to the DAI_PIN1.PB05 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 2

The DAI_PIN2 register routes physical pins that are connected to a bonded pad.

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PB17	Pin Buffer 17 Input. `DAI_PIN4.PB17` holds the Source signal assignment that will be routed to the `DAI_PIN4.PB17` Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Status Register

The DAI_PIN_STAT register bits indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

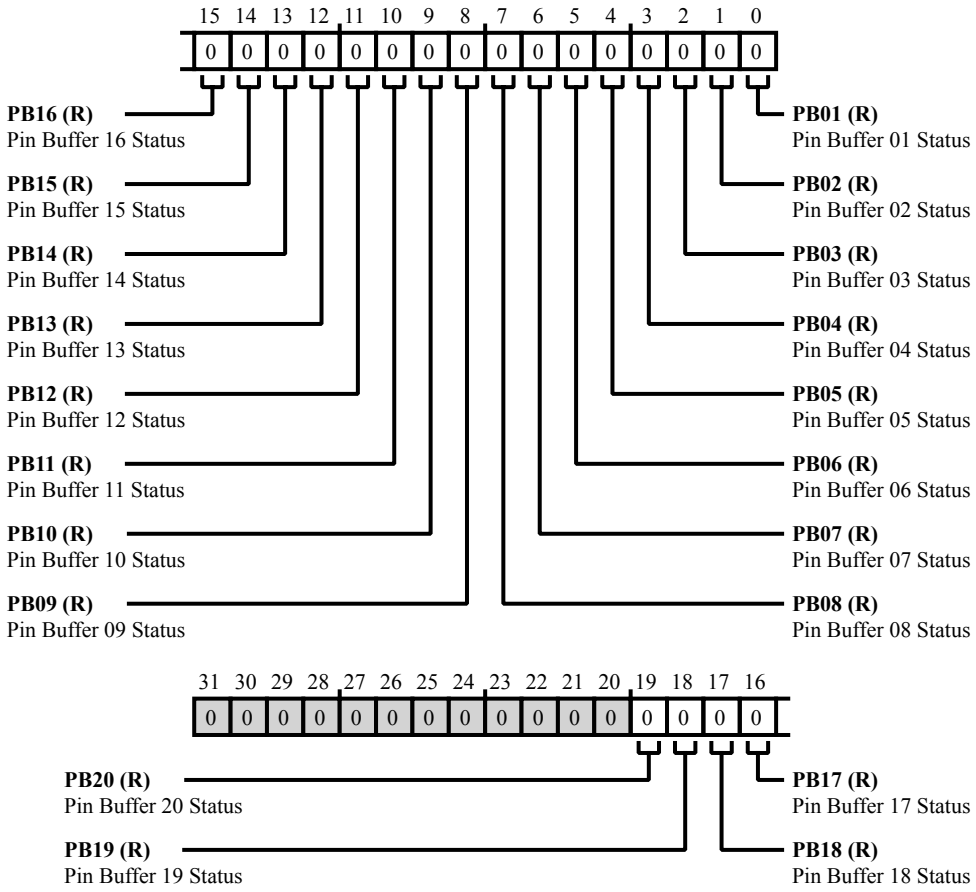

Figure 29-84: DAI_PIN_STAT Register Diagram

Table 29-92: DAI_PIN_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/NW)	PB20	Pin Buffer 20 Status. The DAI_PIN_STAT.PB20 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
18 (R/NW)	PB19	Pin Buffer 19 Status. The DAI_PIN_STAT.PB19 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

Table 29-92: DAI_PIN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	PB18	Pin Buffer 18 Status. The DAI_PIN_STAT.PB18 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
16 (R/NW)	PB17	Pin Buffer 17 Status. The DAI_PIN_STAT.PB17 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
15 (R/NW)	PB16	Pin Buffer 16 Status. The DAI_PIN_STAT.PB16 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
14 (R/NW)	PB15	Pin Buffer 15 Status. The DAI_PIN_STAT.PB15 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
13 (R/NW)	PB14	Pin Buffer 14 Status. The DAI_PIN_STAT.PB14 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
12 (R/NW)	PB13	Pin Buffer 13 Status. The DAI_PIN_STAT.PB13 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
11 (R/NW)	PB12	Pin Buffer 12 Status. The DAI_PIN_STAT.PB12 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
10 (R/NW)	PB11	Pin Buffer 11 Status. The DAI_PIN_STAT.PB11 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
9 (R/NW)	PB10	Pin Buffer 10 Status. The DAI_PIN_STAT.PB10 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
8 (R/NW)	PB09	Pin Buffer 09 Status. The DAI_PIN_STAT.PB09 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
7 (R/NW)	PB08	Pin Buffer 08 Status. The DAI_PIN_STAT.PB08 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

Table 29-92: DAI_PIN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/NW)	PB07	Pin Buffer 07 Status. The DAI_PIN_STAT.PB07 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
5 (R/NW)	PB06	Pin Buffer 06 Status. The DAI_PIN_STAT.PB06 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
4 (R/NW)	PB05	Pin Buffer 05 Status. The DAI_PIN_STAT.PB05 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
3 (R/NW)	PB04	Pin Buffer 04 Status. The DAI_PIN_STAT.PB04 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
2 (R/NW)	PB03	Pin Buffer 03 Status. The DAI_PIN_STAT.PB03 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
1 (R/NW)	PB02	Pin Buffer 02 Status. The DAI_PIN_STAT.PB02 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
0 (R/NW)	PB01	Pin Buffer 01 Status. The DAI_PIN_STAT.PB01 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

30 Serial Port (SPORT)

The programmable serial ports (SPORTs) support various protocols for serial data communication and provide a glueless hardware interface to many industry-standard data converters and codecs. They have high data rates and dual half-duplex datapaths and are ideal for establishing a direct serial connection among two or more processors in a multiprocessor system, as many processors provide compatible serial interfaces.

The SPORT top module consists of two half SPORTs with identical functionality and programming requirements. Each half SPORT can be independently configured as either a transmitter or receiver and can be coupled with the other half SPORT within the same SPORT top module. Further, each half SPORT provides two synchronous half-duplex data lines to double the total supported throughput. As such, a single SPORT top module can be used to provide up to four unidirctional or up to two full-duplex data streams. Further channels are possible as well, but utilization of multiple SPORT top modules is required, thus requiring external connections to provide a common time base.

Features

An individual SPORT top module consists of two independently configurable SPORT halves with identical functionality. These SPORT halves offer the following features:

- Up to two bidirectional data lines - each half SPORT supports up to two transmit or receive channels, thus allowing two unidirectional streams into or out of each half SPORT and providing greater flexibility for serial communications. If full-duplex functionality is desired, two SPORT halves can be combined to enable dual-stream bidirectional communication.
- Six operating modes:
    1. Standard DSP serial mode
    2. I^2S mode
    3. Left-Justified mode
    4. Right-Justified mode
    5. Multichannel (TDM) mode
    6. Packed mode

- Supports internally or externally generated clock.
- Support for both even and odd SCLK0 to SPORT clock (SPORT_CLK) ratios. If both data lines of a half SPORT are active, the maximum throughput is 2 x SPORT_CLK bps.
- Configurable rising or falling edge of the SPORT_CLK for driving and sampling data and frame syncs.
- Gated clock mode support for internallly or externally generated clocks in DSP serial mode and stereo modes (left-justified and I^2S mode).
- Supports frameless operation.
- Supports internally or externally generated frame sync signals.
- Programmable frame sync polarity.
- Programmable frame sync timing (synchronous to data or 1 SPORT clock in advance of it).
- Detection of prematurely received external frame syncs (with optional interrupt request generation).
- Programmable level-/edge-sensitivity for external frame syncs.
- Programmable (4–32-bit) data length, either in most significant bit (MSB) first or in least significant bit (LSB) first format, with optional sign-extension on received data.
- Optional 16-bit to 32-bit word packing (as receiver) and 32-bit to 16-bit word unpacking (as transmitter).
- Support for A-law and μ-law compression/decompression hardware companding, according to the G.711 specification, on transmitted/received words in all operating modes.
- Transmit underrun and receive overflow detection (with optional interrupt request generation).
- TDM mode transfers data on 128 contiguous channels from a stream of up to 1024 total channels (useful for H.100/H.110 and other telephony interfaces as a network communication scheme for multiple processors).
- Performs interrupt-driven, single word core transfers to and from on-chip or off-chip memory.
- Dedicated DMA channel for each SPORT half supporting autobuffer (for a repeated, identical range of transfers) and numerous descriptor-based (individual or repeated ranges of transfers with differing DMA parameters) modes.
- Requester and completer trigger functionality.
- Unique transfer finish interrupt (TFI) signaling when the last transmit word is fully out of the transmit shift register.
- Multiplexer to internally connect critical timing signals between SPORT halves.
- Support for Global Sport Enable functionality, where enabling multiple SPORTs need to be synchronized so that all of them start and/or end at the same time.
- Support for late reception of SPORT data and frame sync.

Signal Descriptions

Each half SPORT module has five dedicated signals, as described in the ***SPORT Signal Descriptions*** table. The actual pin name varies with different SPORT halves. Individual SPORT halves do not share any of its signals across the pair that comprises the SPORT top module; however, it is possible to connect the clock and frame sync signals between the SPORT half pair, as explained in the Multiplexer Logic section.

All of the SPORT signals are multiplexed on the PORT pins, possibly sharing functionality with other peripherals on the device. By default, the PORT pins are in GPIO mode and must be reconfigured for SPORT functionality by setting the appropriate bits in the PORT_FER and PORT_MUX registers. Consult the processor datasheet for details regarding which ports the SPORT signals are available on, and be sure to configure the PORT_MUX register before the PORT_FER register.

Table 30-1: SPORT Signal Descriptions

Internal Node	Direction	Description
SPORTx_CLK	I/O	Transmit or receive serial clock. Data and frame syncs are driven or sampled on this clock's edges. This signal can be either internally or externally generated.
SPORTx_FS	I/O	Transmit or receive frame sync. The frame sync pulse initiates shifting of serial data. This signal is either internally or externally generated.
SPORTx_D0	I/O	Primary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_D1	I/O	Secondary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_TDV	O	Multichannel transmit data valid. This signal is only active in multichannel transmit mode and is asserted during enabled slots, as defined by the channel selection registers (SPORT_CS0_A through SPORT_CS3_B).

The data channel signals are transmit signals when the serial port is configured in transmit mode (SPORT_CTL_A.SPTRAN = 1). They are receive signals when the serial port is configured in receive mode (SPORT_CTL_A.SPTRAN = 0). The following sections further describe the SPORT signals.

NOTE: These sections explicitly refer to the registers associated with half SPORT A, but the same concepts also apply to half SPORT B.

Serial Clock

The serial port clock (SPORT_ACLK) is either a receive serial clock or a transmit serial clock, depending on the transfer direction (SPORT_CTL_A.SPTRAN), governing when the data bits are serially shifted into or out of the SPORT and when the frame sync signal is driven (in internal frame sync mode) or sampled (in external frame sync mode). It can be internally generated from the processor's system clock (SCLK) or externally provided. If the half SPORT is configured in internal clock mode (SPORT_CTL_A.ICLK= 1), then the SPORT_DIV_A.CLKDIV field specifies the divisor applied to SCLK to generate the SPORT clock. As it is a 16-bit divisor, a wide range of serial clock rates is possible. Use the following equation to calculate the serial clock frequency:

SPORT_ACLK = [SCLK ÷ (SPORT_DIV_A.CLKDIV + 1)]

From this, the following equation can be used to determine the value of SPORT_DIV_A.CLKDIV, given the SCLK frequency and the desired frequency of the SPORT clock:

SPORT_DIV_A.CLKDIV= [(SCLK ÷ SPORT_ACLK) - 1]

The half SPORT also supports a 1:1 SPORT_ACLK to ratio (per the equations above, program the clock divisor field to zero). In this case, the resulting SPORT clock frequency is equal to SCLK.

NOTE: Be careful not to exceed the maximum SPORT_ACLK frequency specified in the processor datasheet.

In certain operating modes, the SPORT can be configured to generate a gated clock, which is active only during valid data. In some applications, a SPORT uses it to generate a general-purpose clock in the system. In this case, enable the SPORT with the appropriate SPORT_DIV_A.CLKDIV divisor field in internal clock mode.

If a SPORT is configured in external clock mode (SPORT_CTL_A.ICLK= 0), the serial clock is an input signal, thus making the SPORT operate in completer mode. In this mode, the SPORT_DIV_A.CLKDIV is irrelevant and is ignored. The optional loopback capability provided by the internal SPORT multiplexer (SPMUX) block allows the completer SPORT to use the serial clock from the neighboring SPORT half in the same SPORT top module.

An externally-supplied serial clock does not need to be synchronous with the processor clocks. Further, the external clock can be a gated clock, but it must comply with the requirements described in the Gated Clock Mode section.

Refer to the product datasheet for exact AC timing specifications.

Frame Sync

The SPORT frame sync (SPORT_AFS) signal is either a receive frame sync or a transmit frame sync, depending on the transfer direction (SPORT_CTL_A.SPTRAN), which is used to determine the start of a new word or frame. When this signal goes active, the serial port starts serially shifting data into or out of the SPORT. The frame sync signal can be internally generated based on its serial clock (SPORT_ACLK) or externally provided, as configured by the SPORT_CTL_A.IFS bit.

If the half SPORT is configured to generate frame syncs (SPORT_CTL_A.IFS= 1), then the SPORT_DIV_A.FSDIV field specifies the divisor used to generate the periodic SPORT_AFS signal from the SPORT clock. As this is a 16-bit divisor, a wide range of frame sync rates to initiate periodic transfers is possible. Whether the serial clock is internally or externally generated, this divisor is a count of SPORT clock cycles between frame sync pulses, the formula for which is:

Number of serial clocks between frame syncs = (SPORT_DIV_A.FSDIV + 1)

From this, the following equation can be used to determine the value of SPORT_DIV_A.FSDIV, given the serial clock frequency and the desired frame sync frequency:

SPORT_DIV_A.FSDIV = [(SPORT_ACLK ÷ SPORT_AFS) – 1]

The frame sync is continuously active when SPORT_DIV_A.FSDIV= 0. The value of SPORT_DIV_A.FSDIV cannot be less than the serial word length minus one (the value of the SPORT_CTL_A.SLEN bit field). Failure to

adhere to this guideline can cause an external device to abort the current operation or cause other unpredictable results.

NOTE: After enabling the SPORT, the first internal frame sync appears after a delay of SPORT_DIV_A.FSDIV + 3 SPORT clock cycles.

If a SPORT is configured for external frame syncs (SPORT_CTL_A.IFS = 0), then SPORT_AFS is an input signal and the SPORT_DIV_A.FSDIV field of the SPORT_DIV_A register is irrelevant and ignored. By default, this external signal is level-sensitive, but it can be configured as an edge-sensitive signal by setting the SPORT_CTL_A.FSED bit. The frame sync is expected to be synchronous with the serial clock. If not, it must meet the timing requirements that appear in the datasheet.

The SPORT can be used as a counter for dividing an external clock to generate periodic pulses or periodic interrupts. To do so, enable the SPORT with the appropriate SPORT_DIV_A.FSDIV divisor field with the SPORT configured for an external clock and internal data-independent frame syncs.

In some of the operating modes, the SPORT can be programmed to treat the frame sync signal as an optional signal by clearing the SPORT_CTL_A.FSR bit. Even with this bit cleared, the SPORT requires a single frame sync assertion to start the continuous transfers, after which it is ignored (for externally supplied frame syncs) or not generated (for internally-generated frame syncs). Characteristics of the frame sync depend on the settings in the SPORT control registers and the operating mode of the SPORT. For more information, refer to the SPORT_CTL_A register.

Data Signals

Each half SPORT has two bidirectional data lines known as the primary (SPORT_AD0) and secondary (SPORT_AD1) data channels. Both of the data lines can be configured as either transmitters or receivers using the SPORT_CTL_A.SPTRAN bit, thus permitting dual unidirectional data streams to increase the data throughput of the SPORT.

NOTE: Configuring one transmit data channel and one receive data channel on a single half SPORT is not supported.

The primary and secondary data lines can be individually enabled or disabled using the SPORT_CTL_A.SPENPRI and the SPORT_CTL_A.SPENSEC bits, respectively. However, if using both, enable or disable them concurrently. These data lines operate in a synchronous manner (sharing a clock and frame sync) but have separate datapaths with unique data buffers, shift registers and optional companding logic. All of the SPORT control settings are common for both channels, but the single DMA channel per half SPORT serves both the primary and secondary data channels.

When a SPORT is configured in multichannel transmit mode, the data pins three-state during inactive channel slots, thus allowing multiple transmitters to operate on the same bus with different active channels.

See the Architectural Concepts section for more details about data transfer operation.

Transmit Data Valid Signal

The transmit data valid (SPORT_ATDV) signal is available only in transmit multichannel modes (including packed mode). It is driven active during enabled multichannel slots, and it is driven inactive during the disabled channels. In other words, the SPORT_ATDV signal is active when data is being driven to the data pins and inactive when the data pins are being three-stated. As such, the SPORT_ATDV signal can serve as an output-enable signal for the data transmit pin.

SRU Programming

The SPORT uses the SRU (signal routing unit) to connect the SPORT data, serial clock, frame sync, and external sync (if external synchronization is required). Inputs also must be routed through the SRU. Program the corresponding SRU registers to connect the outputs to the required destinations. For details of the routing, see DAI Routing Capabilities in the *Digital Audio Interface (DAI)* chapter.

SRU SPORT Receive Controller

If the SPORT is operating as receive controller, it must feed its master output clock back to its input clock. This is required to trigger the SPORT's state machine. Using SPORT 0A as an example receive controller, programs should route SPT0_ACLK_O to SPT0_ACLK_I. This is not required if the SPORT is operating as a transmitter in controller mode.

Functional Description

The following sections provide general information about the functionality of the processor's serial ports:

- Architectural Concepts
- Data Types and Companding
- Transmit Path
- Receive Path

ADSP-2159x_SC591_SC592_SC594 SPORT Register List

The Serial Port (SPORT) controller, with its range of clock and frame synchronization options, supports a variety of serial communication protocols and provides a glueless hardware interface to many industry-standard data converters and CODECs. Each SPORT has two independent halves (A and B), and each half contains two channels (primary and secondary). A set of registers governs SPORT operations. For more information on SPORT functionality, see the SPORT register descriptions.

Block Diagram

Each SPORT top module consists of two separate blocks, known as half SPORTs (HSPORT) A and B, each with identical functionality and programming models. The ***Half Serial Port Block Diagram*** shows a detailed block diagram of a half SPORT.

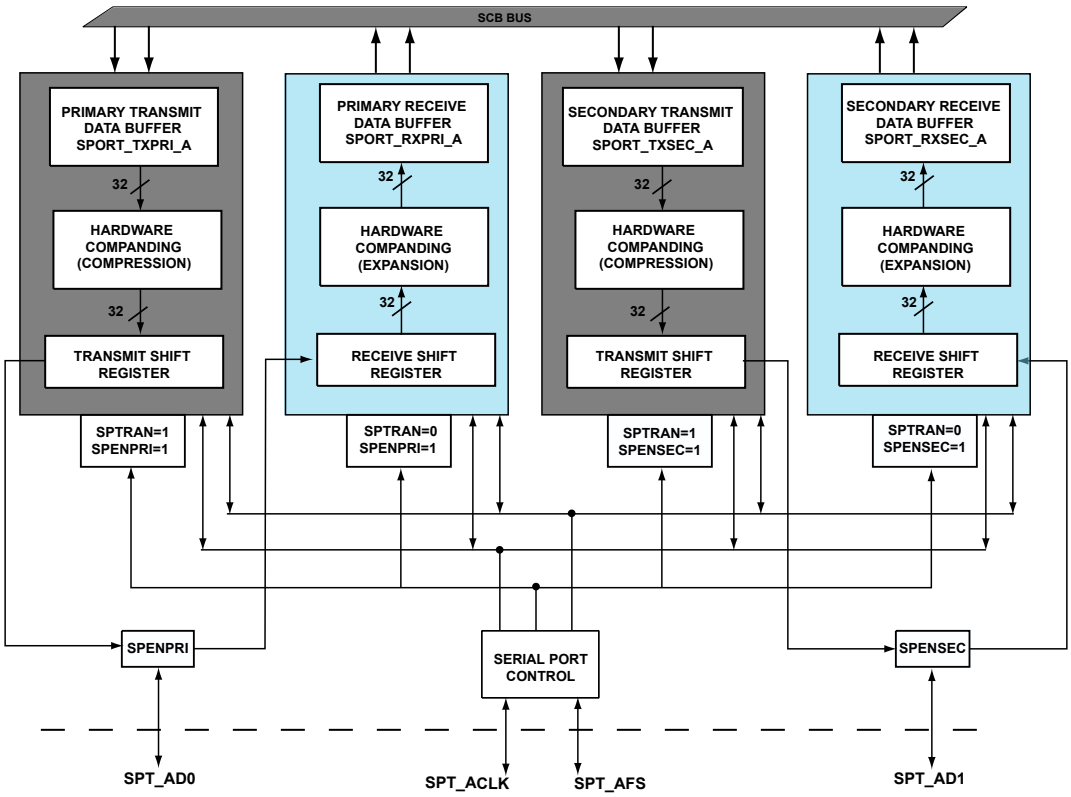

Figure 30-1: Half Serial Port Block Diagram

Architectural Concepts

Each half SPORT (HSPORT) block has its own set of control registers and data buffers, grouped per SPORT module. The HSPORT A and B blocks can be independently configured as either a transmitter or a receiver, with the option to be coupled together internally within the single SPORT top module. Each HSPORT also supports two synchronous bidirectional datapaths, referred to as the primary (`D0`) and secondary (`D1`) data lines, as shown in the ***Top-Level SPORT Diagram*** figure.

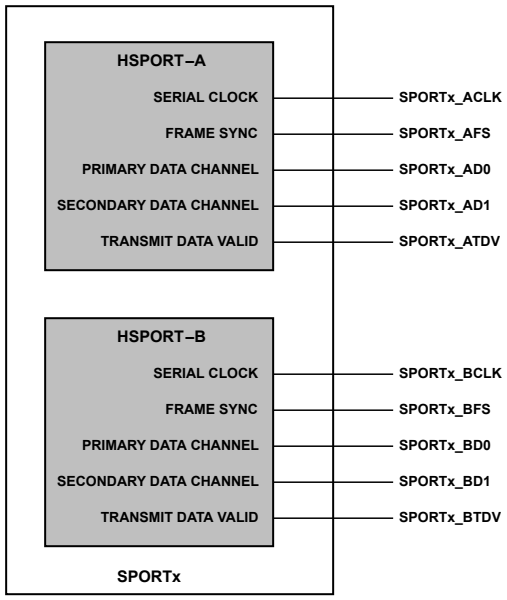

Figure 30-2: Top-Level SPORT Diagram

The SPORT_CTL_A.SPTRAN bit controls the direction for both datapaths of the HSPORT. Depending on whether the HSPORT is a transmitter or a receiver, the pair of data signals respectfully transmit or receive data bits synchronously. The dual data signals of each HSPORT cannot transmit and receive the data simultaneously in support of full-duplex operation, however, two HSPORTs can be combined to achieve this.

Serial communications are synchronized to the serial clock signal, where a valid clock pulse must accompany each data bit. Each HSPORT can take its clock from an external source or internally generate it from the processor's system clock using the SPORT_DIV_A.CLKDIV clock divisor bit field. Both primary and secondary data channels shift data based on the SPORT_CLK rate and the clock polarity defined by the SPORT_CTL_A.CKRE bit.

In addition to the serial clock signal, a frame synchronization signal is used to signify the beginning of an individual data word or a multichannel data stream (block of words). Each SPORT can take the frame sync signal from an external source or generate it (SPORT_FS), depending on the SPORT_CTL_A.IFS bit. An internally generated frame sync is derived from the SPORT clock using the SPORT_DIV_A.FSDIV divisor field. Both primary and secondary datapaths start shifting data either synchronous to or one serial clock in advance of detecting/generating a valid frame sync signal, as determined by the SPORT_CTL_A.LAFS bit. Various communication protocols for serial data can be emulated according to the frame sync format, and all frame sync options are available whether the signal is generated internally or externally.

NOTE: These SPORTs are not UARTs and cannot communicate with an RS-232 device or any other asynchronous communications protocol.

Multiplexer Logic

The SPORT multiplexing block (SPMUX) is situated between the SPORT hardware block and the processor's pin multiplexing logic. It allows the flexibility to route and share the clock and frame sync signals between the HSPORT A and B halves within each SPORT top module, which can double the data throughput (if both SPORT halves are transmitters or both are receivers) or provide full-duplex capabilities (if one HSPORT is a receiver and the other a

transmitter) without the need to allocate pins for the peripheral or make physical connections outside the processor. The SPORT_CTL2_A register is used to configure this loopback feature.

NOTE: Throughout this section, HSPORT A is used as a reference, but all concepts also apply to HSPORT B.

The multiplexing depends on the configuration of the SPORT_CTL_A.IFS and SPORT_CTL_A.ICLK bits, and the SPORT_CTL2_A.CKMUXSEL and SPORT_CTL2_A.FSMUXSEL bit settings control the multiplexing. The ***Frame Sync Combinations*** and ***Clock Combinations*** tables show the valid combinations for the bit settings.

NOTE: All other settings are illegal. However, hardware does not check or prevent the illegal settings. Ensure that programs use only legal combinations.

The column headers in the ***Frame Sync Combinations*** table are defined as follows:

- FS Combination = Frame sync combination, referenced in the notes that follow the ***Clock Combinations*** table.
- HSA_IFS = the setting of the SPORT_CTL_A.IFS configuration bit.
- HSB_IFS = the setting of the SPORT_CTL_B.IFS configuration bit.
- FSAMUX = the setting of the SPORT_CTL2_A.FSMUXSEL configuration bit.
- FSBMUX = the setting of the SPORT_CTL2_B.FSMUXSEL configuration bit.

The Routing column in the ***Frame Sync Combinations*** table defines how the signals are used between the SPORT halves and which pin is used for the frame sync (whether it is an input or an output). Within the column, the inequality characters (≤ and ≥) are used to show the direction of the signal, and the following abbreviations are used (where x = A or B):

- HSx_FI = Frame sync input signal, provided by an external device or the complementing HSPORT.
- HSx_FO = Frame sync output signal.
- SPx_FS = HSPORT's frame sync pin, where the signal is either:
  - provided by an external source and distributed to both HSPORT frame sync signals, or
  - internally generated by one HSPORT and routed to both the pin and to the complementary HSPORT frame sync signal.

Table 30-7: Frame Sync Combinations

FS Combination	HSA_IFS	HSB_IFS	FSAMUX	FSBMUX	Routing
1	0	0	0	0	Native FS Operation
2	0	1	0	0	Native FS Operation
3	1	0	0	0	Native FS Operation
4	1	1	0	0	Native FS Operation

Table 30-7: Frame Sync Combinations (Continued)

FS Combination	HSA_IFS	HSB_IFS	FSAMUX	FSBMUX	Routing
5	0	0	1	0	HSA_FI ≤ SPB_FS; HSB_FI ≤ SPB_FS
6	0	1	1	0	HSA_FI ≤ HSB_FO ≥ SPB_FS
7	0	0	0	1	HSB_FI ≤ SPA_FS; HSA_FI ≤ SPA_FS
8	1	0	0	1	HSB_FI ≤ HSA_FO ≥ SPA_FS

The column headers in the ***Clock Combinations*** table are defined as follows:

- CLK Combination = Clock combination, referenced in the notes that follow the table.
- HSA_ICLK = the setting of the `SPORT_CTL_A.ICLK` configuration bit.
- HSB_ICLK = the setting of the `SPORT_CTL_B.ICLK` configuration bit.
- CKAMUX = the setting of the `SPORT_CTL2_A.CKMUXSEL` configuration bit.
- CKBMUX = the setting of the `SPORT_CTL2_B.CKMUXSEL` configuration bit.

The Routing column in the ***Clock Combinations*** table defines how the signals are used between the SPORT halves and which pin is used for the serial clock (whether it is an input or an output). Within the column, the inequality characters (≤ and ≥) are used to show the direction of the signal, and the following abbreviations are used (x = A or B):

- HSx_CI = Serial clock input signal, provided by an external device or the complementing HSPORT.
- HSx_CO = Serial clock output signal.
- SPx_CLK = HSPORT's serial clock pin, where the signal is either:
  - provided by an external source and distributed to both HSPORT serial clock signals, or
  - internally generated by one HSPORT and routed to both the pin and to the complementary HSPORT serial clock signal.

Table 30-8: Clock Combinations

CLK Combination	HSA_ICLK	HSB_ICLK	CKAMUX	CKBMUX	Routing
9	0	0	0	0	Native CLK Operation
10	0	1	0	0	Native CLK Operation
11	1	0	0	0	Native CLK Operation
12	1	1	0	0	Native CLK Operation

Table 30-8: Clock Combinations (Continued)

CLK Combination	HSA_ICLK	HSB_ICLK	CKAMUX	CKBMUX	Routing
13	0	0	1	0	HSA_CI ≤ SPB_CLK; HSB_CI ≤ SPB_CLK
14	0	1	1	0	HSA_CI ≤ HSB_CO ≥ SPB_CLK
15	0	0	0	1	HSB_CI ≤ SPA_CLK; HSA_CI ≤ SPA_CLK
16	1	0	0	1	HSB_CI ≤ HSA_CO ≥ SPA_CLK

The following is a comprehensive list of the legal combinations for the above described frame sync and clock multiplexing configurations:

- FS Combinations 1–4 are compatible with all CLK Combinations (9–16)
- CLK Combinations 9–12 are compatible with all FS Combinations (1–8)
- FS Combination 5 is only compatible with CLK Combination 13 (and vice versa)
- FS Combination 6 is only compatible with CLK Combination 14 (and vice versa)
- FS Combination 7 is only compatible with CLK Combination 15 (and vice versa)
- FS Combination 8 is only compatible with CLK Combination 16 (and vice versa)

NOTE: Program only the `SPORT_CTL2` register of the HSPORT that is accepting the signal from the other HSPORT. However, be sure to set the `SPORT_CTL_A.CKRE` and `SPORT_CTL_A.LFS` polarity bits to have identical settings between the HSPORTs when making internal connections via the SPMUX block.

Data Types and Companding

The SPORT uses the data type select field `SPORT_CTL_A.DTYPE` bit to specify one of the four data formats supported by serial ports. These formats apply to any of the operating modes of serial port.

Table 30-9: Data Type Bit Field Settings

DTYPE field	SPORT Receiver	SPORT Transmitter
00	Right-justify, zero-fill unused most significant bits	Normal operation
01	Right-justify, sign-extend unused most significant bits	Reserved
10	Expand using µ-law	Compress using µ-law
11	Expand using A-law	Compress using A-law

These formats apply to data words loaded into the SPORT transmit or receive data buffers. The first two data formats (`00` and `01` values of `SPORT_CTL_A.DTYPE`) are applicable only when SPORT is configured as receiver.

When SPORT is configured as transmitter, only the significant bits are transmitted (per the field defined in control register). Therefore, the transmit data buffers are not actually zero-filled or sign-extended.

The other two data formats enable the companding logic on the transmit or receive path. Companding (compressing or expanding) is the process of logarithmically encoding and decoding data to minimize the number of bits sent. The SPORTs of the processor support the two most widely used companding algorithms, A-law, and µ-law. The algorithms are performed according to the CCITT G.711 specification.

If selected, companding applies to both the enabled data channels. When enabled as SPORT transmitter, writes to transmit buffer make the content compressed to 8 bits according to algorithm selected. (The content is zero filled to the width of the transmit word.) Similarly, if configured in receive mode, the 8 bits in the receive data buffers expand in right-justified, zero fill format per the algorithm selected. If companding is enabled in multichannel mode, it applies to all the active channels.

The compression for transmit data requires a minimum word length of 8 for proper function. If `SPORT_CTL_A.SLEN` is less than 7, then expansion does not work correctly. Also, if the data value is greater than 13-bit A-law or 14-bit µ-law maximum, it automatically compresses to the maximum value.

NOTE: The processor companding logic supports in-place companding feature. So, companding can be used for debug without enabling SPORT.

Companding as a Function

Since the values in the transmit and receive buffers are companded in place, the SPORT can use the companding hardware without transmitting or receiving data, which can be useful during testing or debugging. For companding to execute properly, program the SPORT registers prior to loading data values into the SPORT buffers.

To compress data in place without transmitting, use the following procedure:

1. Set the SPORT as a transmitter (`SPORT_CTL_A.SPTRAN` = 1) with both primary and secondary data channels disabled (`SPORT_CTL_A.SPENPRI` = `SPORT_CTL_A.SPENSEC`= 0).
2. Enable companding in the `SPORT_CTL_A.DTYPE` field.
3. Write a 32-bit data word to the transmit buffer.
4. Wait two system clock cycles to allow the SPORT companding hardware to reload the transmit buffer with the companded value. Any instructions that do not access the transmit buffer can be used to cause this delay.
5. Read the 8-bit compressed value from the transmit buffer.

To expand data in place, use the same sequence of operations with the receive buffer instead of the transmit buffer.

Transmit Path

When the `SPORT_CTL_A.SPTRAN` control bit is set, the HSPORT is in transmit mode. Primary and secondary transmit data paths are then enabled using the `SPORT_CTL_A.SPENPRI` and `SPORT_CTL_A.SPENSEC` bits, respectively. The primary and secondary datapaths are unique and identical, each including its own transmit data buffer, optional companding logic, and transmit shift register.

The data buffer on the primary transmit data path is SPORT_TXPRI_A, and the data buffer on the secondary transmit data path is SPORT_TXSEC_A. The transmit data buffer and output shift register form a FIFO type of structure. When packing is disabled (SPORT_CTL_A.PACK = 0), the SPORT can hold as many as three data words. If packing is enabled (SPORT_CTL_A.PACK = 1), the serial port can hold two packed data words at any time.

The transmit data for primary and secondary channels is written to the SPORT_TXPRI_A and SPORT_TXSEC_A transmit data buffers, respectively. The transmit data buffers can be accessed in core mode through the peripheral bus or in DMA mode through the DMA bus. When a SPORT is configured in transmit mode, the receive paths are deactivated and do not respond to serial clock or frame sync signals. Because the receive data buffers and receive shift registers are also deactivated, reading from an empty and inactive receive data buffer can cause the core to hang indefinitely.

NOTE: Be sure to avoid accesses to inactive data buffers. Such accesses can cause unpredictable SPORT behavior or a hang condition and are not reported in any status register.

This data can optionally be compressed in hardware according to the selected algorithm (μ-law or A-law) and then automatically transferred to the transmit shift register. The shift register, clocked by the SPORT_ACLK signal, then serially outputs this data on the SPORT_AD0 and/or SPORT_AD1 pins (if both are enabled, these output data bits are transmitted synchronously). If the SPORT uses a framing signal, the SPORT_AFS signal indicates the start of the serial word transmission.

When using DMA mode, a single DMA feeds the data buffers of the enabled channels (primary and/or secondary). When using both channels, interleave the data of these channels starting with the primary channel in the transmit buffer.

When the SPORT is configured in non-multichannel mode as a transmitter, the enabled SPORT data pins (SPORT_AD0 and/or SPORT_AD1) are always driven. When a SPORT channel is enabled, data from the transmit data buffer is loaded into the transmit shift register. The shift register then immediately latches the first bit of data (either the LSB or MSB, depending on the SPORT_CTL_A.LSBF configuration bit) and drives it to the respective data pin such that it is ready when the frame sync signal asserts. Similarly, if the frame sync period exceeds the serial word length, then the data pins are driven with the first bit of the next word for transmission immediately after the active word completes, and the outputs are held during the inactive serial clock cycles (clock cycles between frame sync pulses).

When the SPORT is configured in multichannel mode, the data pins are driven only during active transmit channels and are always three-stated during inactive channel slots.

The SPORT provides status of transmit data buffers and also error detection logic for transmit errors such as an underrun condition. See the Error Detection (Status) Interrupt section for more details.

Receive Path

When the SPORT_CTL_A.SPTRAN bit is cleared, the SPORT is in receive mode. Primary and/or secondary receive data paths can be enabled by setting the SPORT_CTL_A.SPENPRI and SPORT_CTL_A.SPENSEC configuration bits, respectively. These data paths are unique but identical, each with a receive shift register, optional companding logic, and a receive data buffer.

The data buffer on the primary receive path is SPORT_RXPRI_A, and the data buffer on the secondary receive path is SPORT_RXSEC_A. The receive data paths act like a three-deep (32-bit words) FIFO because they have two data registers plus an input shift register.

Upon enabling the SPORT data channels, the input shift register shifts in data bits on the SPORT_AD0 and/or SPORT_AD1 pins, synchronous to the SPORT clock signal. If the SPORT uses a framing signal, the SPORT_AFS signal indicates the beginning of the serial word (or frame) to be received. When an entire word is shifted into the primary and secondary channels, the data can be optionally expanded in hardware according to a selected algorithm (µ-law or A-law) and then automatically transferred to the SPORT_RXPRI_A and/or SPORT_RXSEC_A data buffers.

The receive data buffers can be read in core mode through the peripheral bus or in DMA mode through the DMA bus. When the SPORT uses DMA mode, a single DMA reads the data buffers of the enabled channels (primary and/or secondary) and interleaves them in memory beginning with the primary channel when both channels are enabled. When using both channels, software must de-interleave the data of these channels.

The SPORT provides the status of receive data buffers and also error detection logic for receive errors such as overflow. See the Error Detection (Status) Interrupt section for more details.

When a SPORT is configured in receive mode, the transmit paths are deactivated and do not respond to serial clock or frame sync signals. As the transmit data buffers and transmit shift registers in the data paths are also deactivated, programs must not try to access them.

NOTE: Be sure to avoid accesses to inactive data buffers. Such accesses can cause unpredictable SPORT behavior or a hang condition and are not reported in any status register.

Operating Modes and Options

The SPORT has a number of operating modes:

- Standard DSP Serial mode
- I^2S mode
- Left-Justified mode
- Right-Justified mode
- Multichannel (TDM) mode
- Packed I^2S mode

The SPORT halves within a SPORT top module can be independently configured in any of these operating modes unless they are coupled together using SPMUX logic, in which case they must be configured identically. Each half SPORT has its own set of control and data registers and is programmed similarly.

The ***Control Bits for SPORT Operating Modes*** table lists all the programmable configuration bits in the SPORT_CTL_A control register, which combine to determine the overall function and operating mode of the SPORT. The columns are arranged according to the setting of the SPORT_CTL_A.OPMODE bit that selects between standard DSP/multichannel modes and the various I²S modes, and the cell contents are defined as follows:

- Yes – bit is programmable for this mode of operation and may be written
- Reserved – bit is not programmable for this mode of operation and must not be written
- = value – bit must be set to this value to enable this mode of operation
- FUNCTION – indicates alternate function for this bit in this mode

NOTE: When changing operating modes, first clear the SPORT_CTL_A register before again writing the register with the new configuration settings.

Table 30-10: Control Bits for SPORT Operating Modes

Name (Bit #)	Standard DSP Serial Mode	I²S and Left-Justified Mode	Right-Justified Mode	Multichannel (TDM) Mode	Packed I²S Mode
SPENPRI (0)	Valid				
DTYPE (2:1)	Valid	Reserved		Valid

RJUST (18)	Reserved		= 1	Reserved	
FSED (19)	Valid	Reserved		Valid	Reserved
TFIEN (20)	Valid				
GCLKEN (21)	Valid		Reserved		

Table 30-10: Control Bits for SPORT Operating Modes (Continued)

Name (Bit #)	Standard DSP Serial Mode	I^2S and Left-Justified Mode	Right-Justified Mode	Multichannel (TDM) Mode	Packed I^2S Mode
SPENSEC (24)	Valid				
SPTRAN (25)	Valid				

Serial Word Length

The SPORT uses the `SPORT_CTL_A.SLEN` field to determine the word length of the serial data to transmit or receive. Each half SPORT can independently handle word lengths up to 32 bits, and the value that must be programmed to the `SPORT_CTL_A.SLEN` field is obtained from:

SLEN = Desired SPORT word length - 1

The minimal word length depends on the selected operating mode. Words smaller than 32 bits are right-justified in the transmit or receive buffers; however, data can be shifted in or out in MSB or LSB first format, as configured by the `SPORT_CTL_A.LSBF` bit. The received word can also be sign-extended or zero-filled when storing the data to processor memory, as governed by the `SPORT_CTL_A.DTYPE` bit.

The ***Data Lengths for SPORT Operating Modes*** table shows the range of valid word lengths for each of the supported SPORT operating modes.

Table 30-11: Data Lengths for SPORT Operating Modes

Mode	SPORT Word Length (SLEN+1)
Standard DSP Serial	4–32
I^2S	5–32
Left-Justified	5–32
Right-Justified	5–32
Multichannel (TDM)	5–32
Packed I^2S	5–32

NOTE: If the companding feature is enabled on the datapath, it limits the word length settings. See Data Types and Companding for more details about word lengths required for companding. If more than 32 bits per frame sync are required to transmit or receive, use the multichannel mode to spread the data across numerous continuous channels.

Clock Sample and Drive Edges

The SPORT uses two control signals to sample or drive the serial data:

1. Serial clock (`SPORT_ACLK`) - bit clock for the serial data.
2. Frame sync (`SPORT_AFS`) - divides the incoming data stream into frames.

These control signals can be internally generated or externally provided, as determined by the SPORT_CTL_A.ICLK and SPORT_CTL_A.IFS bit settings, respectively.

Data and frame syncs can be sampled on the rising or falling edges of the SPORT clock signal, as determined by the SPORT_CTL_A.CKRE bit. By default, the SPORT_CTL_A.CKRE = 0 setting configures the falling edge of the SPORT_ACLK signal as the sampling edge for receive data and externally supplied frame syncs. The receive data and frame syncs can be sampled on the rising edges of SPORT_ACLK when SPORT_CTL_A.CKRE = 1.

NOTE: The SPORT drives transmit data and internal frame sync signals on the opposite serial clock edge of the sampling edge. Be sure to select the same value for SPORT_CTL_A.CKRE for transmit and receive functions for any two HSPORTs that are connected together, and always verify the correct polarity for any external device connected to the SPORT.

The ***Frame Sync and Data Driven on Rising Edge*** figure provides an example of the drive and sample edges when two HSPORTs are connected together, each with SPORT_CTL_A.CKRE = 0. In this example, the HSPORT that is configured as the transmitter drives the serial clock and frame sync signals, and both HSPORTs are configured for early, active high frame syncs and a word length of eight bits.

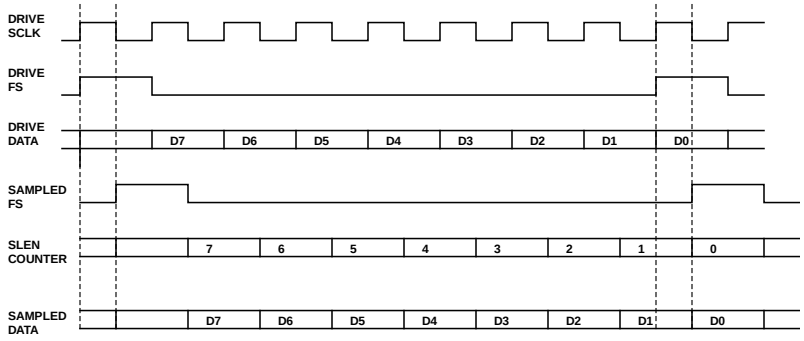

Figure 30-3: Frame Sync and Data Driven on Rising Edge

NOTE: The SCLK in the ***Frame Sync and Data Driven on Rising Edge*** figure is SCLK0.

As shown, the transmitting HSPORT provides the clock and generates the frame sync. Because the HSPORTs are configured for early frame mode, the first bit of data is driven one serial clock later, with subsequent bits being driven on the following rising clock edges in the signal train. When the receiving HSPORT samples the frame sync signal (as indicated in the SAMPLED FS waveform), the SPORT_CTL_A.SLEN bit counter is loaded with the SPORT_CTL_A.SLEN setting, after which each SPORT_ACLK decrements the SPORT_CTL_A.SLEN counter until the full word is received. In this figure, the DRIVE FS and SAMPLED FS waveforms show the frame sync required for the next word in a continuous data stream. Note that it is legal for this frame sync to be sampled synchronous to the last bit of the previous data being sampled, as the early frame mode means that the data lags the frame sync by one serial clock cycle. If the frame sync were sampled as asserted before the D0 bit is sampled, the frame sync error is logged in the receiver's status register.

Since the transmitter drives the internally-generated frame sync and data on the rising edge of the serial clock, the receiver must use the falling edge to sample the externally-supplied frame sync and data.

Frame Sync Options

The following sections provide details regarding the programmable aspects of the SPORT frame sync signal. See the specific operating mode sections for additional information regarding frame sync requirements and behavior for each specific operating modes.

Data-Dependent versus Data-Independent Frame Syncs

By default, the generation of a frame sync signal is data-dependent:

- When the SPORT is configured as a transmitter (`SPORT_CTL_A.SPTRAN` = 1), an internally generated transmit frame sync is output when a new data word has been loaded into the channel transmit buffer of the SPORT (by either the core or the DMA engine).
- When the SPORT is configured as a receiver (`SPORT_CTL_A.SPTRAN` = 0), an internally-generated receive frame sync is output only when the receive data buffer is not full.

The data-independent frame sync option, enabled by setting the `SPORT_CTL_A.DIFS` bit, allows for the generation of a periodic framing signal, regardless of the status of the data buffers. When this bit is set, the frame sync output will be continuous and periodic, according to the setting of the `SPORT_DIV_A.FSDIV` field.

Support for Edge-Detected and Level-Sensitive Frame Syncs

The level-sensitive nature of frame sync signals operates well in a noise-free environment. However, if noise corrupts the signals coming into the SPORT, the internal logic can lose synchronization. For example, excessive noise on the frame sync signal may cause the frame sync to be sampled as inactive on the clock edge that it is intended to be synchronous to, but then be sampled at the correct active level one cycle later. Similarly, a noisy clock signal can cause an unintended clock edge, resulting in potential premature sampling of the frame sync signal being applied to the pin.

The ***Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync*** figure describes a scenario where an external frame sync signal is corrupted due to noise, causing the receiving SPORT module to incorrectly sample the signal. If the frame sync is driven on the rising edge of the serial clock at t_A, the SPORT would normally sample the signal on the falling edge of the serial clock at t_B. Due to the noise, however, the SPORT misses the first edge of the frame sync and instead samples it at t_C.

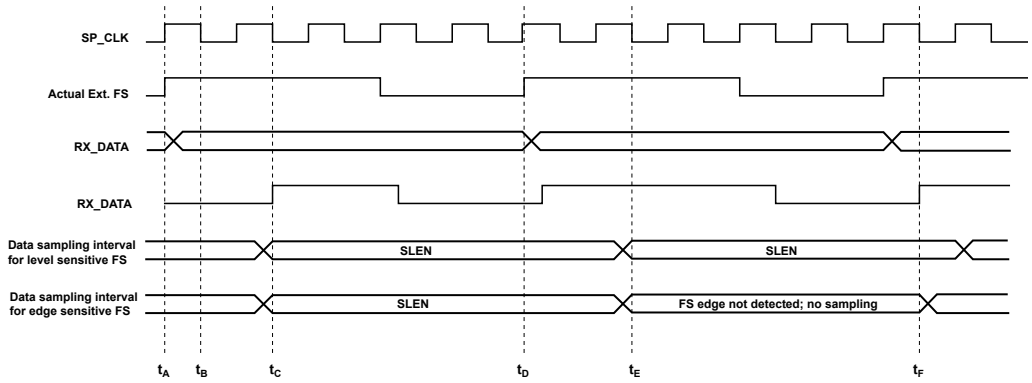

Figure 30-4: Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync

NOTE: SCLK in the ***Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync*** figure is SCLK0.

When the above occurs, the internal word length counter runs for a period equal to the SPORT_CTL_A.SLEN field of the control register, but it erroneously expires at t_E rather than at the appropriate point at t_D, thus receiving incorrect data. Further, if a new level-sensitive frame sync edge arrives at time t_D, the SPORT samples this framing signal again at t_E. As such, the frame sync sampling continues to be misaligned with the external data.

To help address this, the SPORT module provides an option to configure the frame sync signal to instead be edge-sensitive via the SPORT_CTL_A.FSED configuration bit. When this bit is set with active high frame syncs enabled (SPORT_CTL_A.LFS = 0), the rising edge of the frame sync is valid. Conversely, when the frame sync is active low (SPORT_CTL_A.LFS= 1), the falling edge is defined to be valid.

NOTE: SPORT_CTL_A.FSED is valid only in external frame sync mode. In internal frame sync mode, the setting of this bit is irrelevant and ignored.

In the above example, an edge-sensitive frame sync signal is not detected at t_E because the edge of the framing signal already occurred in the previous cycle (t_D) and there is no new edge to detect at t_E. As a result, the internal word length counter remains idle for this frame, thus ignoring the incorrect data, and the counter correctly resumes operation at t_F when a new frame sync edge is detected.

This activity sets the SPORT_ERR_A.FSERRSTAT bit and optionally generates a premature frame sync error interrupt.

Frame sync edge detection is used by default for stereo modes. MCM mode and DSP serial mode choose between edge detection and normal mode of FS detection.

NOTE: When the SPORT is first enabled, an already active externally applied frame sync will not commence operation. The SPORT will wait for a valid change in the frame sync's state from inactive to active before operation begins.

Early versus Late Frame Syncs

Frame sync signals can occur in the same serial clock cycle as the first bit of the data word (late) or one serial clock cycle before the first bit (early), as controlled by the SPORT_CTL_A.LAFS bit.

By default, the frame sync signal is configured to be early (SPORT_CTL_A.LAFS = 0). The first bit of the transmit data word will be driven one serial clock cycle after the frame sync is asserted (whether sensed externally or internally provided), and the first bit of the receive data word is expected to lag the frame sync by one serial clock cycle. The frame sync is not checked again until the entire word has been transferred.

If data transmission is continuous in early framing mode, then an internally-generated frame sync signal will be asserted (pulsed active for one serial clock cycle) synchronous to the last data bit of the current transfer, as the first bit of the next transfer will be immediately driven in the next serial clock cycle (no clocks are wasted). This event is not a premature frame sync error, so the SPORT_ERR_A.FSERRSTAT bit is not set.

The frame sync can alternatively be configured as late (SPORT_CTL_A.LAFS = 1), in which case the first bit of the transmit data word is available in the same serial clock cycle that the frame sync is asserted (whether sensed

externally or internally provided), and the first bit of the receive data word is also latched in the same cycle. Serial clock edges latch the receive data bits, but the frame sync signal is checked only during the first bit of each word. Internally generated frame syncs remain asserted for the entire length of the data word in late framing mode.

The ***Normal Framing (Early Frame Sync) Versus Alternate Framing (Late Frame Sync)*** figure illustrates these concepts.

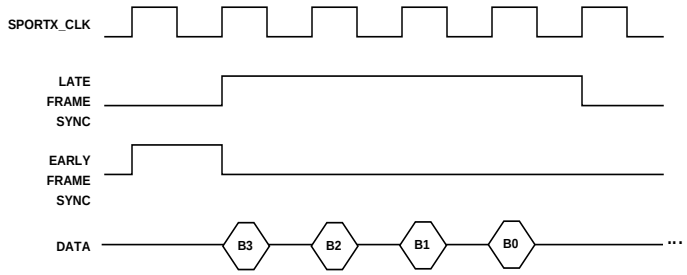

Figure 30-5: Normal Framing (Early Frame Sync) Versus Alternate Framing (Late Frame Sync)

Framed versus Unframed Frame Syncs

The use of a frame sync signal is optional for SPORT operation, as controlled by the `SPORT_CTL_A.FSR` bit. When the frame sync is configured to be required (`SPORT_CTL_A.FSR` = 1), the data is defined to be framed (a frame sync signal must accompany every data word). To allow continuous transmission from the processor, ensure that a new data word is loaded into the transmit buffer before the ongoing transfer is completed (this is automatically cared for when DMA is used to transmit blocks of data).

Data words can be transferred continuously in what is referred to as unframed data mode, which is appropriate for continuous reception, by setting `SPORT_CTL_A.FSR` = 0. In this configuration, a single frame sync is still required to initiate communication, but it is subsequently unrequired once the communication begins. From that point onward, externally provided frame syncs are ignored and internally generated frame syncs are not driven. The ***Framed versus Unframed Data Stream*** figure shows the differences in SPORT operation between framed and unframed data modes with the frame sync configured to be early (`SPORT_CTL_A.LAFS` = 0).

NOTE: When DMA is enabled in a mode where frame syncs are not required, chaining can delay DMA requests. DMA requests are not always serviced frequently enough to guarantee continuous unframed data flow. Monitor status bits or check for a SPORT error interrupt to detect underflow or overflow of data.

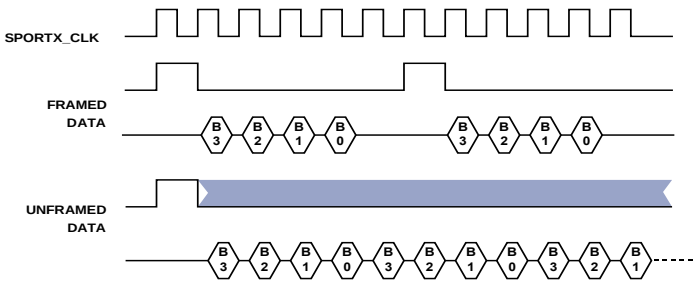

Figure 30-6: Framed versus Unframed Data Stream

Frame Sync Polarity

The framing signals can be active high or active low, as governed by the SPORT_CTL_A.LFS bit:

- When SPORT_CTL_A.LFS = 0, the corresponding frame sync signal is active high.
- When SPORT_CTL_A.LFS = 1, the corresponding frame sync signal is active low.

Active high is the default polarity of the frame sync signal.

Premature Frame Sync Error Detection

A SPORT framing signal is used to synchronize transmit or receive data. In external frame sync mode, any frame sync received during an active frame is premature and invalid. When this occurs, the SPORT_ERR_A.FSERRSTAT bit is set to indicate the framing error, and an optional error interrupt request can be generated for this event by setting the SPORT_ERR_A.FSERRMSK bit.

NOTE: The SPORT_ERR_A.FSERRSTAT bit is not set in the presence of uncleared underflow or overflow errors.

Refer to the ***Frame Sync Error Detection*** figure. The frame sync error bit gets set when an unexpected frame sync occurs during the ongoing data transfer (transmission or reception).

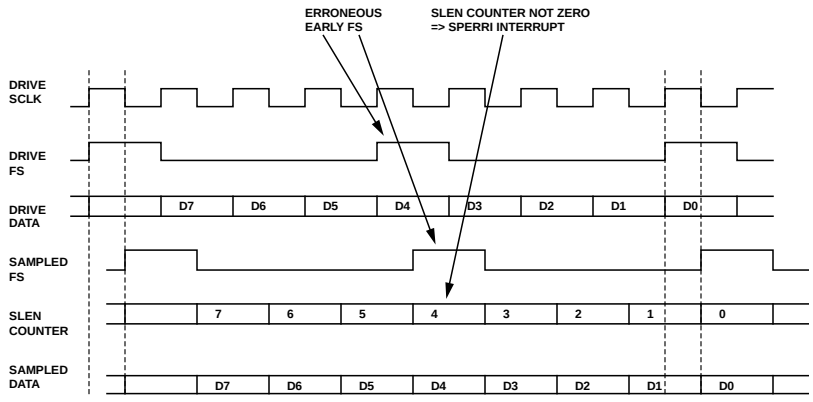

Figure 30-7: Frame Sync Error Detection

NOTE: SCLK in the ***Frame Sync Error Detection*** figure is SCLK0.

Whether a SPORT is receiving or transmitting, its bit count is set to the programmed serial word length when the frame sync is sampled, which is then decremented every subsequent serial clock cycle until the transfer has completed. At this point, the bit count reaches zero and will be reset to the programmed serial length when the next frame sync is sampled. As such, the bit count value is non-zero during an active transfer, and the frame sync error is asserted if a frame sync is sampled when this count is non-zero.

Mode Selection

The SPORT's operating mode is configured in the SPORT_CTL_A and SPORT_MCTL_A registers. The ***SPORT Operating Modes*** table provides specific guidance to properly program these SPORT control registers for the desired mode of operation.

Table 30-12: SPORT Operating Modes

Operating Modes	SPORT_CTL_A.OPMODE	SPORT_CTL_A.LAFS	SPORT_CTL_A.RJUST	SPORT_MCTL_A.MCE
Standard DSP Serial	0	Programmable	Reserved	0
I^2S	1	0	Reserved	0
Left-Justified	1	1	Reserved	0
Right-Justified	1	1	1	0
Multichannel	0	Reserved	Reserved	1
Packed I^2S mode	1	Reserved	Reserved	1

The following sections provide detailed information for each of the supported SPORT modes of operation.

Standard DSP Serial Mode

The SPORT can be configured in standard DSP serial mode by clearing the SPORT_CTL_A.OPMODE and SPORT_MCTL_A.MCE bits. This mode provides great flexibility in terms of programmable options to configure the SPORTs to communicate with various serial devices such as serial data converters and audio codecs. In order to properly connect to such devices, various clocking, framing, and data formatting options are available.

Timing Control Bits

Several bits in the SPORT_CTL_A control register define the configuration of the SPORT in standard DSP serial mode:

- SLEN: serial word length (4–32 bits)
- LSBF: shift LSB or MSB first
- ICLK: internally generated or externally provided serial clock
- CKRE: sample on rising or falling edge of the serial clock
- IFS: internally generated or externally provided frame sync
- FSR: framed or continuous operation
- DIFS: data-dependent or data-independent frame sync
- LFS: active high or active low frame sync
- LAFS: frame sync synchronous to data or one clock cycle before it
- PACK: 16-bit to 32-bit packing option

- GCLKEN: free-running or gated clock

Clocking Options

In standard DSP serial mode, the SPORTs can either accept an external serial clock or generate one internally, as controlled by the SPORT_CTL_A.ICLK bit. For internally generated serial clocks (SPORT_CTL_A.ICLK = 1), the SPORT_DIV_A.CLKDIV field configures the serial clock rate from the system clock.

The SPORT clock can also be gated, where it is only valid during an active transfer, as controlled by the SPORT_CTL_A.GCLKEN bit.

The SPORT clock edge used for driving and sampling of serial data and frame syncs is configured using the SPORT_CTL_A.CKRE bit:

- If SPORT_CTL_A.CKRE = 0, input data and frame sync signals are sampled on the falling edge of the serial clock, and output data and frame sync signals are driven on the rising edge.
- If SPORT_CTL_A.CKRE = 1, input data and frame sync signals are sampled on the rising edge of the serial clock, and output data and frame sync signals are driven on the falling edge.

Stereo Modes

The SPORTs support three widely used stereo modes of operation:

- I^2S mode
- Left-Justified mode
- Right-Justified mode

In these modes, the serial data stream consists of left and right channels. The following sections describe these modes in more detail.

Channel Order

The active low frame sync (SPORT_CTL_A.LFS) bit is used to determine the polarity of the frame sync signal in the non-stereo modes of operation. For the stereo modes of operation, it instead controls whether the right or left channel is first in the data transfer. The ***Channel Order Bit Settings*** table shows which word is transmitted or received first, based on the setting of the SPORT_CTL_A.LFS bit.

Table 30-13: Channel Order Bit Settings

Mode	**SPORT_CTL_A.LFS=0**	**SPORT_CTL_A.LFS=1**
Left-Justified or Right-Justified	Left channel first	Right channel first
I^2S or Packed I^2S	Right channel first	Left channel first

I²S Mode

I²S mode is a commonly used stereo mode, where left and right channel data words are interleaved in the serial data stream and each transition of the frame sync signal is associated with one of the channels. The left channel data is transferred during the low segment of the frame sync signal, and the right channel data is transferred during the high segment of the frame sync signal. As such, the frame sync signal is considered to be a left-right (L/R) clock in this mode.

To set the SPORT up in I²S mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.LFS` = 0
- `SPORT_MCTL_A.MCE` = 0

Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register must be configured to be compliant with the I²S standard, but they can be otherwise configured to support non-standard operation as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 1 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The ***Word Select Timing in I²S Mode*** figure shows the SPORT timing in I²S mode. The data lags the L/R clock transition by one SCLK0 cycle, and the transfer begins with the left channel data word first.

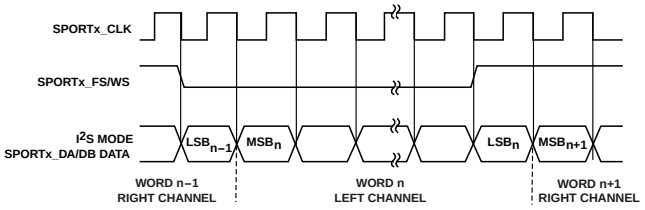

Figure 30-8: Word Select Timing in I²S Mode

Left-Justified Mode

Left-justified mode is a stereo mode subset of the I²S standard. As in I²S mode, the frame sync signal acts as a left-right clock (L/R clock), where left and right data samples are transferred each L/R clock period. The left channel is associated with the high segment of the frame sync, and the right channel aligns with the low segment of the frame sync. The difference between left-justified mode and standard I²S mode is that the channel data is driven in the same bit clock cycle as the L/R clock transition (rather than one bit clock cycle later), such that the MSB is synchronous with the leading edge of the frame sync transition.

To set the SPORT up in left-justified mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.LAFS` = 1
- `SPORT_MCTL_A.MCE` = 0

Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register must be configured to operate the SPORT in left-justified mode, but they can be otherwise configured as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 0 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The ***Word Select Timing in Left-Justified Mode*** figure shows the SPORT timing in left-justified mode. The start of a data sample is synchronous to the L/R clock transition, and the transfer begins with the left channel data word first.

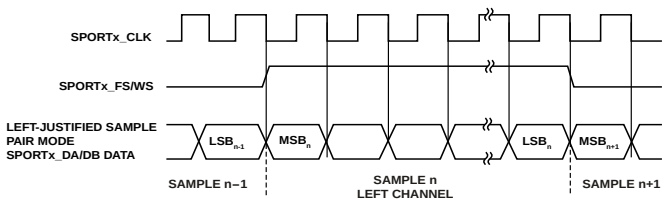

Figure 30-9: Word Select Timing in Left-Justified Mode

Right-Justified Mode

Right-justified mode is a stereo mode subset of the I²S standard. As in I²S mode and left-justified mode, the frame sync signal acts as a left-right clock (L/R clock), where left and right data samples are transferred each L/R clock period. The left channel is associated with the high segment of the frame sync, and the right channel aligns with the low segment of the frame sync. The difference between right-justified mode and standard I²S mode is that the LSB of the channel data ends at the point that the L/R clock transitions to frame the next sample (rather than one bit clock cycle after the L/R clock transition).

To set the SPORT up in right-justified mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.RJUST` = 1
- `SPORT_MCTL_A.MCE` = 0

Timing Control Bits

Several bits in the `SPORT_CTL_A` control register must be configured to operate the SPORT in right-justified mode, but they can be otherwise configured as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 0 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The ***Word Select Timing in Right-Justified Mode*** figure shows the SPORT timing in right-justified mode. The transmitter aligns the transmit data such that the last bit of the serial word is sent in the last clock cycle of the L/R clock (frame sync) signal marking the channels.

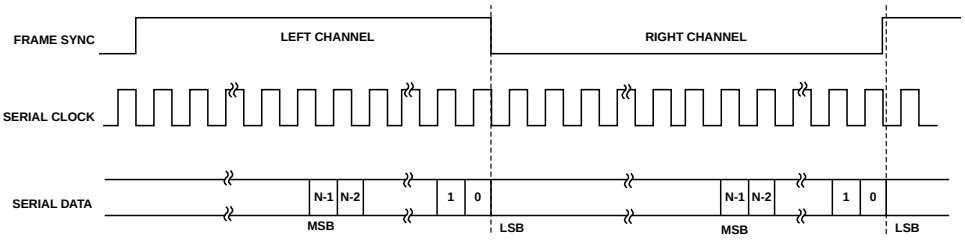

Figure 30-10: Word Select Timing in Right-Justified Mode

NOTE: For some SPORT-compatible ADCs or DACs such as the AD1871, right-justified mode is limited to commonly used ratios such as 64 FS and 128 FS. FS is the sampling frequency of ADCs and DACs, referrd to as the SPORT's L/R clock (frame sync) signal.

Consider the SPORT timing for right-justified mode, as shown in the ***Timing Comparison Between Different Stereo Modes*** figure. The frame sync width is limited to 32 SPORT clock periods (or 32 bits per channel) if:

- the SPORT's frame sync (L/R clock) runs at the FS rate, and
- the SPORT's serial bit clock runs at the 64 FS rate

The limitation applies to the frame sync width of either channel. If the data is confined to 24 bits, the SPORT introduces a 32–24=8-bit clock delay before it starts to transmit or capture data.

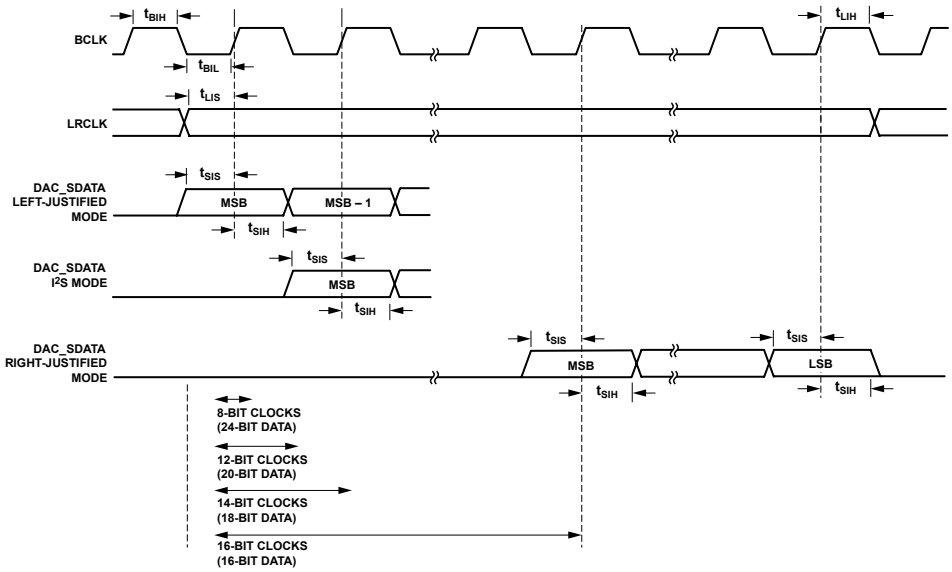

Figure 30-11: Timing Comparison Between Different Stereo Modes

Similarly, to support the 128 FS bit clock frequency, the frame sync width becomes 64 serial bit clock periods per channel. In this case, the delay can be a maximum of 59 bit clocks (64 – 5, which is the minimum serial data length in right-justified mode).

The starting point of the first bit is delayed so that the LSB of the serial data aligns properly with the end of the channel. A 6-bit counter is added for this purpose in the stereo mode counter, which is programmed by writing the least significant six bits of the `SPORT_MCTL_A.WOFFSET` field. Though this is a multichannel mode configuration register, the SPORT uses these bits in right-justified mode to configure the offset from the transition of the L/R

clock to where the first data bit must be driven in order to have the end of the last bit align properly with the next L/R clock transition. Software must program this register with the appropriate delay.

Multichannel (TDM) Mode

The multichannel mode of SPORT operation allows the SPORT to communicate as part of a time division multiplexed (TDM) serial system. In TDM communications, a large frame of streamed serial data words is defined to be a particular length. It consists of a specific number of channels, and each channel contains one serial data word of the defined data length. For example, a 24-word block of 24-bit data can be defined to be a window within a frame, having a duration of 576 bit clocks and comprised of 24 continuous channels. The SPORT is configured to transfer on specific channels within a defined window in this frame.

To set the SPORT up in multichannel mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 0
- `SPORT_MCTL_A.MCE` = 1

In multichannel mode, the SPORT can selectively transfer data on up to a maximum window size of 128 continuous channels out of a maximum 1024-channel frame while ignoring all the disabled channels within the window and all the channels outside the window. The SPORT can do any of the following on each channel:

- Transmit data (`SPORT_CTL_A.SPTRAN` = 1)
- Receive data (`SPORT_CTL_A.SPTRAN` = 0)
- Do nothing (during inactive channels)

Channel selection is configured in the half SPORT multichannel select registers (`SPORT_CS0_A` - `SPORT_CS3_A`) before enabling SPORT operation for multichannel mode. Programming of these registers is especially important in DMA data unpacked mode, since the SPORT data buffers begin operation immediately after the SPORT data lines are enabled. Be sure to enable multichannel operation (set the `SPORT_MCTL_A.MCE` bit) prior to enabling the SPORT itself.

Clocking Options

In multichannel mode, the SPORTs can either accept an external serial clock or generate one internally, as governed by the `SPORT_CTL_A.ICLK` bit. For an internally-generated serial clock (`SPORT_CTL_A.ICLK` = 1), the `SPORT_DIV_A.CLKDIV` bit field is used to configure the serial clock rate, as derived from the system clock.

The serial clock edges used to drive and sample data and frame syncs are also configurable using the `SPORT_CTL_A.CKRE` bit:

- If `SPORT_CTL_A.CKRE`= 0, input data and frame sync signals are sampled on the falling edge of the serial clock, and output data and frame sync signals are driven on the rising edge.
- If `SPORT_CTL_A.CKRE` = 1, input data and frame sync signals are sampled on the rising edge of the serial clock, and output data and frame sync signals are driven on the falling edge.

Frame Sync Options

The frame sync signal synchronizes the channels and restarts each multichannel sequence, starting with the channel 0 data word. For internally-generated frame syncs (SPORT_CTL_A.IFS = 1), the frame sync period in multichannel mode is defined as:

FS period = [(SPORT_CTL_A.SLEN + 1) × number of channels] - 1

The active level for the frame sync signal is also configurable by programming the SPORT_CTL_A.LFS bit. Set this bit to make the frame sync an active low signal, and clear it to make it active high.

In multichannel mode, frame sync timing resembles late framing mode (although the SPORT_CTL_A.LAFS bit is reserved in this mode). The first bit of the transmit data word is driven and the first bit of the receive data word is sampled in the same serial clock cycle as the frame sync, provided there is no programmed frame delay (SPORT_MCTL_A.MFD = 0).

Once the frame sync signal is asserted, word transfers are performed continuously for the duration of the active window, and no further frame syncs are required for different channels within the window. As such, internally-generated frame syncs are always data-independent, and the SPORT_CTL_A.DIFS bit is reserved.

Transmit Data Valid (TDV)

Each SPORT features a transmit data valid signal (SPORT_ATDV), which is driven high during enabled transmit channels. Because the SPORT output data signals are three-stated during inactive channels, the SPORT_ATDV signal signifies when the processor is actively driving the SPORT data outputs, thus serving as an output-enable signal for the data transmit pin(s).

Active Channel Selection Registers

In multichannel mode, the SPORT supports a window size of up to 128 channels for transmitting or receiving data, where it can selectively receive or transmit data in any of these 128 channels. Each channel can be individually enabled or disabled using the multichannel selection registers (SPORT_CS0_A to SPORT_CS3_A) to select the channels in which to transfer data during a multichannel communication stream. Data words associated with enabled channels are transmitted or received in the respective channels, while disabled channels cause a transmit SPORT to three-state the data output pins and a receive SPORT to ignore the data.

The four 32-bit multichannel selection registers combine to form up to a 128-bit meta-register to accommodate the maximum window size of 128 channels. Setting any bit within these registers enables the associated channel. The 128 channels are sequentially numbered from bit 0 in the SPORT_CS0_A register (corresponding to channel 0 of the window) to bit 31 of the SPORT_CS3_A register (corresponding to channel 127 of the window). For example, setting bit 13 of the SPORT_CS1_A register enables channel number 45 (add 32 for the channels in the SPORT_CS0_A). Likewise, setting bit 5 of the SPORT_CS3_A register enables channel number 101 (add 96 for the 32 channels in each of the SPORT_CS0_A, SPORT_CS1_A, and SPORT_CS2_A registers).

Multichannel Frame Delay (MFD)

The multichannel frame delay (SPORT_MCTL_A.MFD) field specifies the delay in serial bit clocks between the frame sync pulse and the first data bit in the frame. This configurability allows the processor to work with different types of telephony interface devices.

As SPORT_MCTL_A.MFD is a 4-bit field, the maximum value allowed for the frame delay is 15 serial clock cycles. When set to 0, the frame sync is concurrent with the first data bit. If SPORT_MCTL_A.MFD>0, a new frame sync can occur during the last channel(s) of a previous frame and still be valid (does not cause a frame sync error).

NOTE: If the required frame delay exceeds 15 serial clocks, use the window offset field (SPORT_MCTL_A.WOFFSET) to delay the start of channel 0 in increments of the serial word length, and then adjust SPORT_MCTL_A.MFDaccordingly. For example, if the serial word length is 12 bits and the desired frame delay is 16 serial clock cycles, set the SPORT_MCTL_A.WOFFSET to 1 to insert a 12-bit delay after the frame sync to where the channel 0 data begins, and then program SPORT_MCTL_A.MFD to 4 (i.e., 16 - 12).

Window Size (WSIZE)

Select the number of channels used in multichannel operation by programming the 7-bit SPORT_MCTL_A.WSIZE field. This field must be set to the actual number of channels minus one (SPORT_MCTL_A.WSIZE = Number of channels -1).

The 10-bit SPORT_MSTAT_A.CURCHAN field holds the channel number currently being serviced during multi-channel operation.

Window Offset (WOFFSET)

The window offset (SPORT_MCTL_A.WOFFSET) field specifies where in the 1024-channel frame to place the start of the active window (up to 128 channels long). A value of 0 specifies no channel offset from the frame sync (channel 0 immediately follows it). Any non-zero value indicates the number of channels that come between the frame sync and the start of channel 0 of the active frame, with 896 (for example, 1024–128) being the largest value that permits using all 128 channels.

As an example, a program could define an active window comprised of eight channels (SPORT_MCTL_A.WSIZE = 7) with a window offset of 93 (SPORT_MCTL_A.WOFFSET = 93). If configured in this fashion, the 8-channel window that the SPORT will transfer within resides in the channel range from 93 to 100 in the up-to-1024-channel frame.

Do not change the window offset or the number of multichannel slots (SPORT_MCTL_A.WSIZE) while the SPORT is enabled. If the combination of the window size and offset place any portion of the window out-of-range relative to the channel counter, none of the channels are enabled.

Companding Selection

Like the other operating modes, companding logic can optionally be applied to serial data (compression logic for transmit mode or expansion logic for receive mode). The two widely used companding algorithms, A-law and μ-law, are selectable using the SPORT_CTL_A.DTYPE field.

If companding is enabled, the companding algorithm is applied to both the primary and secondary datapaths. In multichannel mode, companding can be applied to either all or none of the enabled channels (companding cannot be selected on a per-channel basis).

Multichannel DMA Data Packing (MCPDE)

Multichannel DMA data packing and unpacking are enabled using the SPORT_MCTL_A.MCPDE bit.

When set, data is packed, and the SPORT expects the data in the DMA buffer to correspond only with enabled SPORT channels. For example, if only channels 1 and 9 are enabled in a 10-channel window (SPORT_MCTL_A.WSIZE = 9), the SPORT expects the buffer to be exactly two words in length, where channel 1 is associated with the first element in the buffer and channel 9 is associated with the second.

When cleared, data is unpacked, and the SPORT expects the DMA buffer to have a word for each of the channels in the active window, whether the channel is enabled or not. As such, the DMA buffer size must be exactly the size of the window. Using the same example as the packed case above, if only channels 1 and 9 are enabled in a 10-channel window (SPORT_MCTL_A.WSIZE = 9), then the DMA buffer size is ten words. The data at offsets 1 and 9 within the buffer are associated with the data transfers of channels 1 and 9, respectively. The rest of the words in the buffer are unused.

Packed I²S Mode

The SPORT supports a packed I²S mode, which can be used for audio codec communications using multiple channels. This mode allows applications to send more than the standard 32 bits per channel available through standard I²S mode. Packed mode is implemented using standard multichannel mode (and is therefore programmed similarly to multichannel mode).

To set the SPORT up in packed I²S mode, the following configuration is required:

- SPORT_CTL_A.OPMODE = 1
- SPORT_MCTL_A.MCE = 1

Like multichannel mode, packed I²S mode also supports a maximum of 128 channels, where up to 128 channels of data can be transferred for every transition of the frame sync signal acting as an L/R clock (for example, up to 128 left-channel words transfer during the high portion of the L/R clock, and up to 128 right-channel words transfer during the low portion).

As shown in the ***Packed I²S Mode 128 Operation*** figure, the packed waveforms are the same as those waveforms used in multichannel mode, except the frame sync is toggled for every frame and emulates I²S mode.

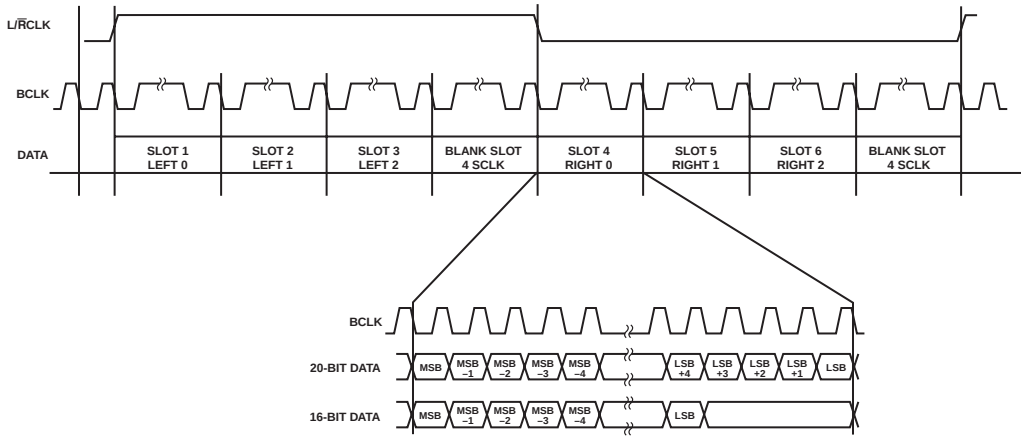

Figure 30-12: Packed I²S Mode 128 Operation

Serial Bit Clock Options

In packed I²S mode, the SPORTs can either accept an external serial bit clock or generate one internally, as governed by the `SPORT_CTL_A.ICLK` configuration bit. For an internally-generated serial bit clock (`SPORT_CTL_A.ICLK` = 1), use the `SPORT_DIV_A.CLKDIV` bit field to configure the serial bit clock rate from the system clock.

The serial bit clock edge that is used for sampling or driving data and frame syncs is programmable using the `SPORT_CTL_A.CKRE` bit.

L/R Clock (Frame Sync) Options

The frame sync period in packed I²S mode is defined as:

FS period = [(`SPORT_CTL_A.SLEN` + 1) × number of channels] - 1.

The L/R clock can be supplied externally or internally generated depending on the `SPORT_CTL_A.IFS` bit setting. The logic level of the L/R clock associated with the left and right channel data can be changed using the `SPORT_CTL_A.LFS` configuration bit.

Gated Clock Mode

Some system components such as ADCs and DACs utilize a SPI-compatible protocol for the interface. To communicate with such devices, the SPORT must support a gated clock, where the data valid information is embedded in the clock (for example, the clock only toggles when data is valid). This gated clock feature is enabled using the `SPORT_CTL_A.GCLKEN` bit.

To enable the gated clock mode of operation, program the SPORT to comply with the following requirements.

- Do not enable gated clock functionality in right-justified or multichannel mode
- Gated clock mode has the following requirements for other control bits:

- The serial clock and frame sync signals must have the same source (SPORT_CTL_A.ICLK = SPORT_CTL_A.IFS)
- Unframed mode is not supported (SPORT_CTL_A.FSR must be set)
- Clear the SPORT_CTL_A.DIFS bit in transmit mode; set it in receive mode

- Satisfy the following necessary conditions when gated clock mode is enabled:
  - Seven serial clock cycles are required between enabling the SPORT and the first frame sync. If this requirement is not met, the SPORT can drop the first data (for subsequent data, this requirement is not applicable)
  - For externally-provided clock and frame sync, the frame sync must be inactive during clock synchronization after the SPORT has been enabled
  - For an edge-detected frame sync (SPORT_CTL_A.FSED = 1), the frame sync must transition back to the inactive state before the current word transfer is complete (or when the clock is still running). If this requirement is not met, the SPORT does not recognize the next valid frame sync and skips the channel. The SPORT continues to skip the frame syncs until the frame sync transitions back to an inactive state while the clock is active.

Data Transfers and Interrupts

SPORT data can be transferred to or from internal or external memory by two methods:

- Core-driven, single-word transfers
- DMA-driven, multiple-word transfers (optionally with multiple work units)

Core-driven transfers use SPORT interrupts to signal the processor core to perform MMR-based single-word transfers to or from the SPORT data buffers. DMA can be set up to automatically transfer a configurable number of serial words between the SPORT transmit/receive data buffers and memory, and then generate a data completion interrupt request when a work unit or a series of work units completes, thus signaling by the SEC to the processor core that a block of data has been transferred.

The following sections provide information on core-driven and DMA-driven data transfers.

Data Buffers

When programming the serial port data channels (primary or secondary) as a transmitter by setting SPORT_CTL_A.SPTRAN =1, only the corresponding transmit data buffers (SPORT_TXPRI_A and SPORT_TXSEC_A) become active. The receive data buffers (SPORT_RXPRI_A and SPORT_RXSEC_A) remain inactive. Similarly, when the SPORT data channels are programmed for receive operation (SPORT_CTL_A.SPTRAN =0), then only corresponding receive data buffers (SPORT_RXPRI_A and SPORT_RXSEC_A) are active. Do not attempt to read or write inactive data buffers. If the processor operates on the inactive transmit or receive buffers while the SPORT is enabled, unpredictable results can occur.

Each of these buffers is 32-bit wide (corresponds to maximum serial data word length). When using word lengths less than 32 bits for SPORT operation, the data in these buffers is automatically right-justified. (The LSB bit of data is at the bit 0 location of the buffer). The upper unused bits can be zero-filled or sign-extended depending on SPORT_CTL_A.DTYPE field.

Transmit Data Buffers (SPORT_TXPRI_A and SPORT_TXSEC_A)

When enabled as a transmitter (SPORT_CTL_A.SPTRAN =1), each SPORT half has its own set of transmit data buffers. The primary (0) and secondary (1) datapaths of each SPORT half have separate data buffers, referred to as SPORT_TXPRI_A and SPORT_TXSEC_A respectively.

These transmit data buffers are 32 bits wide. Load these buffers with the data for transmission on the primary and secondary data channels. The DMA controller loads the data automatically. Or, the program running on the processor core loads the data manually.

Together with the output shift register, transmit data buffers act like a two-location FIFO. If data packing is disabled (SPORT_CTL_A.PACK =0), the transmit path can hold as many as three data words. If data packing is enabled (SPORT_CTL_A.PACK =1), it can hold two packed data words at any given time.

When the transmit shift register becomes empty (transfer out all the bits of previous word), data in the transmit data buffer is automatically loaded into it. An interrupt occurs when the output transmit shift register has been loaded, signifying that the transmit data buffer is empty and ready to accept the next word. This interrupt does not occur when serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary datapath of a SPORT half is enabled, programs must not write to the inactive secondary transmit data buffer and conversely. If the core keeps writing to the inactive buffer, the status of that transmit buffer becomes full. This state can cause the core to hang indefinitely, since data is never transmitted to the output shift register.

Receive Data Buffers (SPORT_RXPRI_A and SPORT_RXSEC_A)

When enabled as receiver (SPORT_CTL_A.SPTRAN =0), each SPORT half has its own set of receive data buffers. The primary (0) and secondary (1) datapaths of each SPORT half have separate data buffers, referred as SPORT_RXPRI_A and SPORT_RXSEC_A respectively. Together with input shift register, the receive data buffers act like a three-location FIFO, as the receive path has two data registers.

These receive data buffers are the 32 bits wide. These buffers are automatically loaded from the receive shift register when a complete word has been received into it. An interrupt occurs when the receive data buffer is loaded, signifying that new data is available in the receive data buffer and is ready to read. This interrupt does not occur when the serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary datapath of a SPORT half is enabled, programs must not read from the inactive secondary receive data buffer and conversely. If the core keeps reading from the inactive buffer, the status of that receive buffer becomes empty. This state can cause the core to hang indefinitely since new data is never received through the input shift register.

Data Buffer Status

The SPORT provides status information about its primary and secondary data buffers through the SPORT_CTL_A.DXSPRI and SPORT_CTL_A.DXSSEC bits, respectively. It also provides error status information through the corresponding SPORT_CTL_A.DERRPRI and SPORT_CTL_A.DERRSEC bits, respectively. Depending on the SPORT_CTL_A.SPTRAN bit setting, these bits reflect the status of either the pair of transmit (SPORT_TXPRI_A and SPORT_TXSEC_A) or receive (SPORT_RXPRI_A and SPORT_RXSEC_A) buffers, indicating whether the buffer is full, partially full, or empty.

When attempting to read from an empty receive buffer or write to a full transmit buffer, the SPORT delays access until the buffer is ready, potentially resulting in excessive MMR bus response times. To avoid this when doing core-driven transfers, always check the buffer status to determine if the access can be made. The SPORT updates the status bits in the SPORT_CTL_A register during reads and writes by the core processor.

NOTE: These status bits are updated during reads and writes from the core processor even when the SPORT is disabled.

Two complete 32-bit words can be stored in the receive buffer while a third word shifts in. Therefore, almost three complete words can be received without the receive buffer being read before an overflow occurs. After receiving the third word completely, the shift register contents overwrite the second word, which will occur if the first word has not yet been read by the processor core or the DMA controller. This receive overflow condition is flagged through the error status bits of the SPORT_CTL_A register on the last bit of the third word.

Data Buffer Packing

When the SPORT is configured as a receiver with a serial data word length of 16 or less, the received data words can be packed into a 32-bit word. Similarly, if the SPORT is configured as a transmitter with a serial data word length of 16 or less, then 32-bit words being transmitted can be unpacked into 16-bit words. The SPORT_CTL_A.PACK bit is used to select this packing or unpacking feature.

When SPORT_CTL_A.PACK = 1, two consecutive received words are packed into a single 32-bit word, or each 32-bit word is unpacked and transmitted as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15–0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31–16. This packing method applies to both receive (packing) and transmit (unpacking) operations. In this case, the transmit and receive interrupt requests are generated for the 32-bit packed words, not for each 16-bit word.

NOTE: When 16-bit received data is packed into 32-bit words and stored in normal word space in the processor's internal memory, the 16-bit words can be read or written using short word space addressing.

Single-Word (Core) Transfers

The SPORTs can transmit or receive individual data words with interrupt requests occurring as each data word is transferred. When a SPORT is enabled with the corresponding DMA channel disabled, interrupt requests are generated when:

- a complete word has been received in the receive data buffer or

- the transmit data buffer is not full

When performing core transfers, be sure to access only those buffers that are associated with enabled datapaths, as governed by the transfer direction (SPORT_CTL_A.SPTRAN) bit and the primary/secondary (SPORT_CTL_A.SPENPRI/SPORT_CTL_A.SPENSEC) data enable bits. If inactive SPORT data buffers are read from or written to by the core while the SPORT is enabled, the core can hang. For example, if a half SPORT is programmed to be a transmitter and the core reads from one of the receive buffers associated with that half SPORT, the core can hang as if it were reading an empty buffer that is active and awaiting new data to arrive. Because this is a transmitting HSPORT, that data will never arrive, thus locking the core up until the SPORT is reset. To avoid such a situation, be sure to check the status of the appropriate data buffer before attempting a core access to it by interrogating the SPORT_CTL_A.DXSPRI or SPORT_CTL_A.DXSSEC status bits.

DMA Transfers

Direct memory access (DMA) provides a mechanism for transferring an entire block of serial data before an interrupt is generated. The processor's on-chip DMA controller automatically handles the DMA transfer, thus allowing the processor core to run in parallel until the entire block of data is transferred. When the interrupt request occurs, a service routine can then process the entire block of data (rather than react to single words), thus significantly reducing overhead.

Each half SPORT has a dedicated DMA channel that serves both the primary and secondary datapaths. When configured as a transmitter (SPORT_CTL_A.SPTRAN = 1) with both the primary and secondary datapaths enabled (SPORT_CTL_A.SPENPRI = SPORT_CTL_A.SPENSEC = 1), the DMA channel requires that the source DMA buffer interleave the data beginning with the primary channel, as it will alternately load to the primary and secondary transmit data buffers once it is enabled. The complementary operation is true in receive mode (SPORT_CTL_A.SPTRAN = 0) when both datapaths are enabled, as the DMA channel alternately reads from the primary and secondary receive data buffers and interleaves them in the destination DMA buffer. As such, software must de-interleave the data corresponding to the primary and secondary channels from the receive DMA buffer.

If the SPORT is configured in stereo mode, the same DMA channel handles both the left and right channels of both datapaths (primary and/or secondary). Therefore, for a transmit DMA with only one datapath enabled, the source buffer must be populated such that the left- and right-channel data is interleaved. If both datapaths are enabled, the DMA channel alternately loads to the primary and secondary transmit data buffers once it is enabled. As such, the interleaving requirement is for the primary left-channel data to be followed by the secondary left-channel data, then the primary right-channel data, and finally the secondary right-channel data. The complementary operation is true in receive mode, where the DMA channel alternately reads from the primary and secondary receive data buffers and interleave them in the destination DMA buffer. For the stereo modes of operation, the destination DMA buffer is interleaved as left-right data for a single data input. If both datapaths are enabled, the destination DMA buffer is written with the primary and secondary left-channel data followed by the primary and secondary right-channel data. As such, software must de-interleave the primary and secondary left- and right-channel data from the receive DMA buffer, as defined by this scheme.

Since both the primary and secondary datapaths share the single DMA channel, each half SPORT has a single interrupt request for data completion, as well as an error interrupt request. The DMA controller can generate an interrupt request at the end of a chain of DMA work units (when using multiple descriptors) or at the end of individual DMA work unit.

The SPORT DMA channels are assigned a higher priority than all the other DMA channels (for example, the SPI port). Having higher priority causes the SPORT DMA transfers to execute first when multiple DMA requests occur in the same cycle. The SPORT DMA channels are numbered and prioritized in the DMA channel list table in the DMA chapter.

Although the most efficient DMA transfers execute with 32-bit words, the SPORTs can handle word sizes from 4 to 32 bits (as defined by `SPORT_CTL_A.SLEN` field). If the serial data length is 16 bits or smaller, two pieces of data can be packed into 32-bit words for each DMA transfer, as selected by setting the `SPORT_CTL_A.PACK` bit. When this bit is set, the SPORT generates the transmit and receive interrupts for the 32-bit packed words, not for each 16-bit word. For more information, see the Data Buffer Status section.

NOTE: The SPORT DMA channel can access both internal memory and external memory of the processor without any core overhead.

Data Transfer Interrupt

Each half SPORT features a data transfer interrupt request that is shared by both the primary and secondary data channels in both transmit and receive modes. To determine the source of the data transfer interrupt request, applications can check the primary and secondary data buffer status bits (`SPORT_CTL_A.DXSPRI` and , `SPORT_CTL_A.DXSSEC` , respectively).

When using core-driven transfers, this interrupt's meaning depends on the direction of the SPORT:

- As transmitter (`SPORT_CTL_A.SPTRAN` = 1) - the transmit data buffer is empty
- As receiver (`SPORT_CTL_A.SPTRAN` = 0) - new data is available in the receive data buffer

NOTE: When data packing is enabled (`SPORT_CTL_A.PACK` = 1), the core-driven transmit and receive interrupt requests are generated for 32-bit packed words, not for each 16-bit word.

In both cases, the interrupt request can be used to signal the core that an individual transfer has completed. For transmit operations, it indicates that the transmit data buffer can be safely loaded (either the buffer is already empty or the last data has moved from the data buffer to the shift register). For receive operations, it indicates that new data has arrived and can be read (or must be read before a subsequent word overwrites it).

When the SPORT is configured to use DMA to move data between memory and the peripheral (the most generic way to use dedicated DMA for sport data transfers), the same data transfer interrupt request instead indicates the completion of the transfer of a block of serial data (rather than a single word). When DMA is used, the DMA count register must be initialized to specify the number of words to transfer. This count decrements after each DMA transfer on the channel, and the data transfer interrupt request signal is asserted when the word count reaches zero (for example, a DMA work unit has finished).

For transmit DMA, the interrupt request is raised when the last word in the DMA work unit is loaded from the source memory to the HSPORT FIFO. This interrupt request can signal to the core that a new DMA work unit can be configured or that other software threads can now run. The transmit interrupt request can optionally be deferred until the last word of the work unit has fully shifted out of the shift register (see the Transfer Finish Interrupt (TFI) section for details).

For receive DMA, the interrupt request is raised when the last word is loaded to the destination memory. In addition to that described for transmit DMA, this interrupt request also serves as an indication to the core that there is a buffer of newly acquired data that is ready to be processed.

See the DMA chapter for further details regarding enabling of the DMA interrupt requests associated with the various modes of DMA operation.

NOTE: As a single DMA channel services both the primary and secondary datapaths associated with the SPORT, there is a single DMA completion interrupt request.

Transfer Finish Interrupt (TFI)

When configured for transmit DMA (`SPORT_CTL_A.SPTRAN` =1), the data transfer interrupt request gets generated by the DMA engine itself when it decrements its count register upon loading the last element from memory to the HSPORT hardware. Alternately, the SPORT can use a Transmit Finish Interrupt (TFI) to signal the actual end of the transmission (for example, when the last bit of the last data word of the buffer has shifted out of the SPORT to the system) by setting the `SPORT_CTL_A.TFIEN` bit. When this bit is set, then DMA signal that would normally assert the data transfer interrupt request instead signals the SPORT that the DMA work unit is complete. The SPORT then waits until all the data in the FIFO is shifted out (including the transmit shift register) and asserts the TFI interrupt request upon completion.

NOTE: To enable this functionality in the DMA engine, be sure to configure the interrupt type field in the DMA configuration register for Peripheral interrupt. See the DMA chapter for further details.

Error Detection (Status) Interrupt

In addition to the dedicated data transfer interrupt request, each half SPORT also features an optional error status interrupt request that can be triggered when error conditions occur relative to data or frame syncs associated with the half SPORT.

Data-related errors depend on the direction of the SPORT and reflect overflow or underflow conditions, which are depicted in the `SPORT_CTL_A` control register as read-only sticky bits `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DERRSEC` (for the primary and secondary channels, respectively).

- When the SPORT is configured as a transmitter, these bits provide transmit data buffer underflow status. When the frame sync signal occurs when the transmit data buffer is empty, the underflow bit corresponding with the offending transmit data buffer is set, as the SPORT will transmit data whenever it detects a valid frame sync signal, whether new data is present or not.
- When the SPORT is configured as a receiver, these bits provide receive overflow status. When a channel receives new data while the receive buffer is already full, the new data overwrites the existing data, thus causing

an overflow. When this occurs, the overflow bit corresponding with the offending receive data buffer is set, as the SPORT receives data whenever it detects a valid frame sync signal, whether there is room in the receive buffer or not.

Each half SPORT also features an error register (SPORT_ERR_A), which is the source for the assertion of the described data-related error status bits. When a data-related error occurs on the primary or secondary datapaths, the error is logged in the SPORT_ERR_A.DERRPSTAT or SPORT_ERR_A.DERRSSTAT bits, respectively. To enable these status bits to generate the HSPORT status interrupt request in the SEC, the corresponding SPORT_ERR_A.DERRPMSK and SPORT_ERR_A.DERRSMSK bits must be set (for the primary and secondary datapaths, respectively).

The SPORT_CTL_A.DERRPRI and SPORT_CTL_A.DERRSEC channel error status bits are sticky read-only bits that can be cleared in two ways:

- Reset the error detection logic by disabling the channel associated with the error condition (clear the SPORT_CTL_A.SPENPRI or SPORT_CTL_A.SPENSEC control bit).
- Clear the source of the interrupt by writing-1-to-clear the SPORT_ERR_A.FSERRSTAT, SPORT_ERR_A.DERRPSTAT, or SPORT_ERR_A.DERRSSTAT status bits.

In addition to data-related errors, SPORT_ERR_A also tracks frame sync errors in the SPORT_ERR_A.FSERRSTAT status bit. Similar to the data-related errors, the frame sync error can be enabled as a source for raising the error status interrupt request via the SEC by setting the SPORT_ERR_A.FSERRMSK bit. A frame sync error occurs when the frame sync is detected prematurely, as explained in the Premature Frame Sync Error Detection section.

A frame sync error is not detected in the following cases:

- When there is no active transmit or receive data, and the frame sync pulse occurs due to noise on the input signal – if there is no active transfer, a noise-induced frame sync pulse is valid.
- If there is an active underflow or overflow error – frame sync errors cannot be detected because the SPORT error logic does not run after one of the data errors has occurred and remains unserviced.
- When the frame sync pulse does not the meet minimum timing requirements – if the frame sync pulse is shorter than a SPORT clock period, there is no guarantee that it gets sampled at all and may go unnoticed.

Grouping of SPORTs

For some applications, enabling multiple SPORTs need to be synchronized so that all of them start and/or end at the same time. It may also be required to generate/receive a single interrupt/trigger for the DMA transfer of all the SPORTs in the same group.

The DAI_GBL_SP_EN register is used to control enabling/disabling. The DAI_GBL_INT_EN register can be used to control interrupt/trigger generation/reception by multiple SPORTs in a group.

NOTE: All references to SPORT 0-3 in the context of DAI1 must be read as SPORT4-7.

SPORT Enable Grouping

The figure shows the block diagram of possible group enabling options for the SPORTs in DAI0 and DA1.

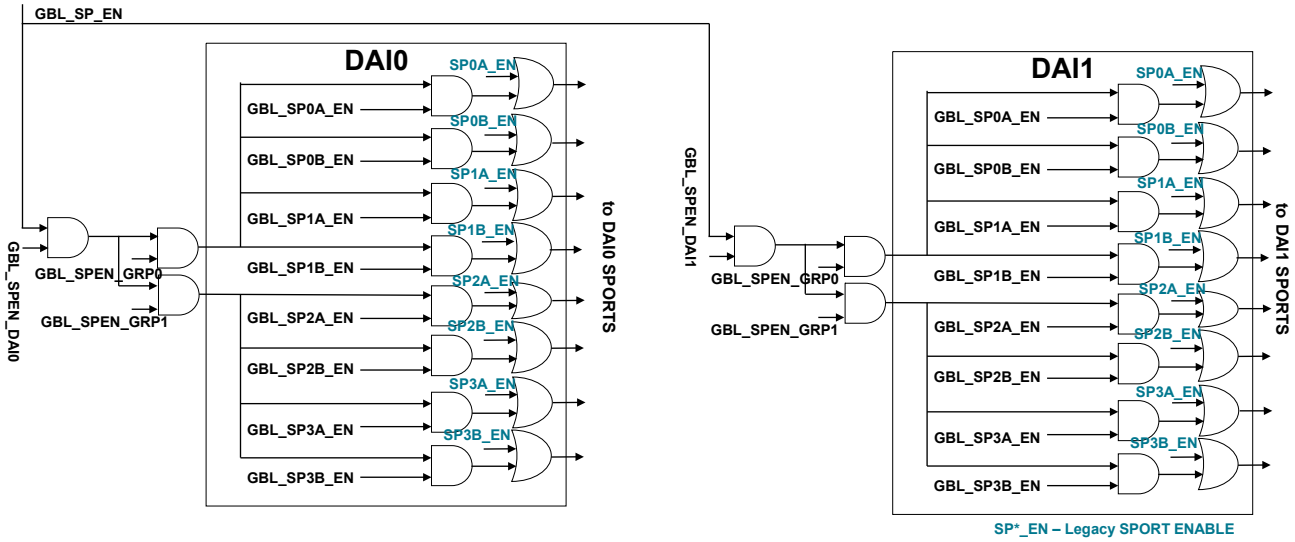

Figure 30-13: Group Enabling Options in DAI0 and DA1

It shows one of the channels in each half sport, same is applicable for other channel as well. For example, `GBL_SP0A_EN` means `GBL_SP0A_PC_EN` or `GBL_SP0A_SC_EN`.

Each DAI has a `DAI_GBL_SP_EN` register. To enable the SPORTs grouped within the same DAI at the same time, write to the corresponding `DAI_GBL_SP_EN` register is required. If a group of SPORTs in different DAIs has to be enabled at the same time, write to the `DAI_GBL_SP_EN.GBL_SP_EN` field is required. This bit is reserved for the DAI1.

The following group enable options are possible:

- Up to 16 channels in 8 half SPORTs in DAI0
- Up to 16 channels in 8 half SPORTs in DAI1
- Up to 8 channels in 4 half SPORTs in each DAI
- Up to 32 channels in 16 half SPORTs (8 half SPORTs in DAI0 and 8 half SPORTs in DAI1)

NOTE: While grouping SPORTs across DAIs, two interrupts (one per DAI) are generated and managed by software. Grouping can be done only once as the `DAI_GBL_SP_EN.GBL_SP_EN` field is used.

NOTE: The grouping of SPORTs and its interrupts/triggers are two separate entities. If the interrupts and triggers must be grouped similar to the SPORT grouping, use the group interrupt/trigger enable register.

SPORT Interrupt/Trigger Grouping

Each DAI has a `DAI_GBL_INT_EN` register. Each of these registers has two group interrupt enable bits `DAI_GBL_INT_EN.GRP0_INT_EN` and `DAI_GBL_INT_EN.GRP1_INT_EN`, two group trigger

(controller) enable bits DAI_GBL_INT_EN.GRP0_TRG_EN and DAI_GBL_INT_EN.GRP1_TRG_EN. There are individual GRPx_SPyINT_EN bits for each group to enable both interrupt/trigger for up to 8 channels (4 half SPORTs). Enable these bits as per the grouping in the DAI_GBL_SP_EN register.

NOTE: To enable or to disable the SPORT interrup/trigger grouping feature, the individual sport interrupt/trigger enable bits must be programmed along with the respective group interrupt/trigger enable bits in the DAI_GBL_INT_EN register.

Regarding grouping of SPORT interrupts/triggers:

- All the interrupts/triggers in a single group are ANDed and a single interrupt/trigger goes to SEC/TRU.
- To generate group interrupt/trigger, all the SPORTs in the corresponding group should be configured to generate interrupt (DMA_CFG.INT)/trigger (DMA_CFG.TRIG).
- The interrupts/triggers generated by the SPORTs in a group can either be used as a single group interrupt/trigger (enabled by the DAI_GBL_INT_EN register) or the individual SPORT DMA done interrupts/triggers.
- As there are no separate status registers for global interrupts, to clear the global interrupts, clear (W1C) the individual SPORT DMA_STAT.IRQDONE bits. Theoretically, the global interrupt gets cleared by clearing the DMA_STAT.IRQDONE bit of at least one SPORT in the group. However, it is recommended to clear the DMA_STAT.IRQDONE bits of all the SPORTs in the group to achieve a clean state for the next global interrupt generation.
- The DAI_GBL_INT_EN.GRP1_TRG_EN/DAI_GBL_INT_EN.GRP0_TRG_EN bits enables group controller trigger functionality for SPORTs in a group.

SPORT Programming Model

The following sections provide programming guidance for setting up the SPORTs for use in an application:

- Initializing Core-Driven (Non-MCM) Transfers
- Initializing Multichannel Transfers
- Using DMA for SPORT Transfers
- Using Companding as a Function

Initializing Core-Driven (Non-MCM) Transfers

The following programming model applies to all of Standard DSP Serial Mode, I^2S Mode, Left-Justified Mode, and Right-Justified Mode for core-driven transfers. More steps are required to properly initialize the SEC to service the SPORT interrupts (see the SEC chapter for details).

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, this example also applies to half SPORT B.

1. Clear the SPORT_CTL_A and SPORT_MCTL_A configuration registers.

   ADDITIONAL INFORMATION: Clearing these registers ensures that the SPORT logic (including the multi-channel logic) is fully reset before attempting to reprogram it.

2. Optionally program the SPORT_DIV_A clock divisor register.

   ADDITIONAL INFORMATION: This step is only required for internally-generated timing signals. Configure the serial bit clock and/or frame sync (or L/R clock, for stereo modes) rates according to the guidance in the Serial Clock and Frame Sync sections.

3. Program the SPORT_CTL_A primary configuration register.

   ADDITIONAL INFORMATION: Set the SPORT operating mode along with the configurable clock, frame sync, word length, direction, and data format options (see the Operating Modes and Options section for details). Do not set the SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC buffer enable bits in this step.

4. Optionally program the SPORT_CTL2_A secondary configuration register.

   ADDITIONAL INFORMATION: This step is required only if internal multiplexing logic must be enabled to share clock and frame sync signals between a top SPORT module's A and B halves (see the Multiplexer Logic section for details).

5. Optionally program the SPORT_ERR_A error register.

   ADDITIONAL INFORMATION: This step is required only if a separate SPORT error interrupt is desired (see the Error Detection (Status) Interrupt section for details).

6. For Right-Justified mode only, program the SPORT_MCTL_A.WOFFSET field.

   ADDITIONAL INFORMATION: In Right-Justified mode, this field serves as the delay count (DCNT) required to align the LSB of each stereo channel with the L/R clock transition and must be programmed manually (see the Right-Justified Mode section for details).

7. Enable the primary/secondary datapath(s) in the SPORT_CTL_A register.

   ADDITIONAL INFORMATION: This should be performed in a read-modify-write operation setting the SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC bits, as appropriate.

8. Write data to be transmitted to the transmit buffer (SPORT_TXPRI_A and/or SPORT_TXSEC_A) *or* read data that has been received from the receive buffer (SPORT_RXPRI_A and/or SPORT_RXSEC_A).

   ADDITIONAL INFORMATION: These accesses are typically performed in the context of an interrupt service routine. See the SEC chapter for further information. Do not attempt to read or write inactive data buffers. If the core attempts to access inactive transmit or receive buffers while the SPORT is enabled, unpredictable results may occur.

Initializing Multichannel Transfers

When in Multichannel (TDM) Mode or Packed I²S Mode, the SPORT is in a multichannel operational mode. Follow the steps below to properly initialize the SPORT for multichannel modes of operation. More steps are required to properly (see the SEC chapter for details).

NOTE: This example uses half SPORT A registers. With appropriate register changes, this example also applies to half SPORT B.

1. Clear the SPORT_CTL_A and SPORT_MCTL_A registers.

   ADDITIONAL INFORMATION: Clearing these registers ensures that the SPORT logic (including the multichannel logic) is fully reset before attempting to reprogram it.

2. Optionally program the SPORT_DIV_A clock divisor register.

   ADDITIONAL INFORMATION: This step is only required for internally-generated timing signals. Configure the serial bit clock and/or frame sync (or L/R clock, for stereo modes) rates according to the guidance in the Serial Clock and SPORT_CTL2_A sections.

3. Program the SPORT_CS0_A - SPORT_CS3_A channel select registers.

4. Program the SPORT_MCTL_A multichannel configuration register.

   ADDITIONAL INFORMATION: The SPORT supports many multichannel options. For more information, see the Multichannel (TDM) Mode section. Do not set the SPORT_MCTL_A.MCE enable bit in this step.

5. Program the SPORT_CTL_A primary configuration register.

   ADDITIONAL INFORMATION: Set the SPORT operating mode along with the configurable clock, frame sync, word length, direction, and data format options (see the Operating Modes and Options section for details). Do not set the SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC buffer enable bits in this step.

6. Optionally program the SPORT_CTL2_A secondary configuration register.

   ADDITIONAL INFORMATION: This step is required only if internal multiplexing logic must be enabled to share clock and frame sync signals between a top SPORT module's A and B halves (see the Multiplexer Logic section for details).

7. Optionally program the SPORT_ERR_A error register.

   ADDITIONAL INFORMATION: This step is required only if a separate SPORT error interrupt request is desired (see the Error Detection (Status) Interrupt section for details).

8. Set the SPORT_MCTL_A.MCE bit to enable multichannel mode.

9. Enable the primary/secondary datapath(s) in the SPORT_CTL_A register.

ADDITIONAL INFORMATION: This should be performed in a read-modify-write operation setting the SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC bits, as appropriate. DMA mode is recommended for multichannel modes of operation. For more information, see the Using DMA for SPORT Transfers programming model.

Using DMA for SPORT Transfers

DMA is supported in all SPORT operating modes (Standard DSP Serial Mode, I²S Mode, Left-Justified Mode, Right-Justified Mode, Multichannel (TDM) Mode or Packed I²S Mode). To enable DMA operation with the SPORT, execute the steps described in this section after initializing and enabling the SPORT. Instead of using the single word read or write operations described in the referenced programming models, the DMA engine automates accesses to the enabled SPORT data buffers.

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, it also applies to half SPORT B.

1. Follow the guidance in the multichannel (Initializing Multichannel Transfers) or non-multichannel (Initializing Core-Driven (Non-MCM) Transfers) programming models to properly initialize and enable the SPORT hardware.
2. Prepare the data buffers in memory.

   ADDITIONAL INFORMATION: Ensure that the DMA buffer is defined according to the DMA Transfers section. For the multichannel modes of operation, be sure to also consider the setting of the SPORT_MCTL_A.MCPDE bit, as described in the Multichannel DMA Data Packing (MCPDE) section.
3. Initialize and enable the DMA channel allocated for the SPORT, as described in the Direct Memory Access (DMA) chapter.

Using Companding as a Function

The data in the transmit and receive buffers are actually companded in place. As such, the following programming model can be used to exercise the companding hardware without transferring data, which is useful for test/debug purposes.

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, this example also applies to half SPORT B.

1. Configure the SPORT as a transmitter (SPORT_CTL_A.SPTRAN=1) with both the primary and secondary data channels disabled (SPORT_CTL_A.SPENPRI=0 and SPORT_CTL_A.SPENSEC=0).
2. Enable the desired companding scheme in the SPORT_CTL_A.DTYPE field.
3. Write a 32-bit word to one of the transmit buffers.
4. Wait two system clock cycles.

ADDITIONAL INFORMATION: This delay is required to allow the SPORT companding hardware to reload the transmit buffer with the companded result. Any instructions that do not access the transmit buffer can be used to cause this delay.

5. Read the 8-bit compressed value from the transmit buffer written above.

To expand data in place, use the same sequence of operations with the receive buffer instead of the transmit buffer. When expanding data in this way, set the appropriate serial word length (SPORT_CTL_A.SLEN).

Programming Global SPORT Groups

Complete the following steps to program global SPORT groups.

NOTE: To complete all of the SPORT group transfers simultaneously, all of the SPORTs in the group must have a similar data/clock/frame sync configuration.

1. For each SPORT, program the following registers for the desired SPORT mode of operation.
   - SPORT_DIV_A/SPORT_DIV_B
   - SPORT_CTL2_A/SPORT_CTL2_B
   - SPORT_CTL_A/SPORT_CTL_B
   - SPORT_MCTL_A/SPORT_MCTL_B
   - SPORT_CS0_A/SPORT_CS0_B
   - SPORT_CS1_ASPORT_CS1_B
   - SPORT_CS2_ASPORT_CS2_B
   - SPORT_CS3_ASPORT_CS3_B

   ADDITIONAL INFORMATION: The sport enable control bits (in SPORT_CTL2_A/SPORT_CTL2_B registers) must be cleared (disabled).
2. For a global group trigger as the controller, program each SPORT DMA in the group as the controller trigger.
3. Program the sport enable and group enable bits in the DAI_GBL_SP_EN register for the desired global sport grouping.

   ADDITIONAL INFORMATION: The grouping of SPORTs (enable and disable) and the associated interrupts/triggers are separate activities. If the interrupts and triggers must be grouped similar to the SPORTs (enable and disable) grouping, use the DAI_GBL_INT_EN register.
4. Program the DAI_GBL_INT_EN register to enable the grouped interrupt or trigger generation for the SPORT group.

ADDITIONAL INFORMATION: To enable the SPORT grouped interrupt and trigger feature, each sport interrupt or trigger enable bit must be programmed with the respective group interrupt and trigger enable bits in the DAI_GBL_INT_EN register.

5. Program the DAI_GBL_SP_EN.GBL_SP_EN bit to enable the global sport groups at the same instance.

Disabling Global SPORT Groups

Complete the following steps to disable global SPORT groups.

1. Use the individual SPORT DMA status register to clear the group interrupt. There is no specific status register for global interrupts.
2. Disable the global SPORT group interrupt and trigger bits for the group in the DAI_GBL_INT_EN register.

   ADDITIONAL INFORMATION: To disable the SPORT grouped interrupt and trigger feature, each sport interrupt and trigger enable bit must be programmed with the respective group interrupt and trigger enable bits in the DAI_GBL_INT_EN register.
3. Disable the global individual SPORT enable and the global SPORT group enable bits in the DAI_GBL_SP_EN register.
4. Disable the DMAs for the SPORTs when the transfer is complete.

ADSP-2159x_SC591_SC592_SC594 SPORT Register Descriptions

Serial Port (SPORT) contains the following registers.

Table 30-14: ADSP-2159x_SC591_SC592_SC594 SPORT Register List

Name	Description
SPORT_CS0_A	Half SPORT 'A' Multichannel 0-31 Select Register
SPORT_CS0_B	Half SPORT 'B' Multichannel 0-31 Select Register
SPORT_CS1_A	Half SPORT 'A' Multichannel 32-63 Select Register
SPORT_CS1_B	Half SPORT 'B' Multichannel 32-63 Select Register
SPORT_CS2_A	Half SPORT 'A' Multichannel 64-95 Select Register
SPORT_CS2_B	Half SPORT 'B' Multichannel 64-95 Select Register
SPORT_CS3_A	Half SPORT 'A' Multichannel 96-127 Select Register
SPORT_CS3_B	Half SPORT 'B' Multichannel 96-127 Select Register
SPORT_CTL2_A	Half SPORT 'A' Control 2 Register
SPORT_CTL2_B	Half SPORT 'B' Control 2 Register
SPORT_CTL_A	Half SPORT 'A' Control Register
SPORT_CTL_B	Half SPORT 'B' Control Register

Table 30-14: ADSP-2159x_SC591_SC592_SC594 SPORT Register List (Continued)

Name	Description
SPORT_DIV_A	Half SPORT 'A' Divisor Register
SPORT_DIV_B	Half SPORT 'B' Divisor Register
SPORT_ERR_A	Half SPORT 'A' Error Register
SPORT_ERR_B	Half SPORT 'B' Error Register
SPORT_MCTL_A	Half SPORT 'A' Multichannel Control Register
SPORT_MCTL_B	Half SPORT 'B' Multichannel Control Register
SPORT_MSTAT_A	Half SPORT 'A' Multichannel Status Register
SPORT_MSTAT_B	Half SPORT 'B' Multichannel Status Register
SPORT_RXPRI_A	Half SPORT 'A' Rx Buffer (Primary) Register
SPORT_RXPRI_B	Half SPORT 'B' Rx Buffer (Primary) Register
SPORT_RXSEC_A	Half SPORT 'A' Rx Buffer (Secondary) Register
SPORT_RXSEC_B	Half SPORT 'B' Rx Buffer (Secondary) Register
SPORT_TXPRI_A	Half SPORT 'A' Tx Buffer (Primary) Register
SPORT_TXPRI_B	Half SPORT 'B' Tx Buffer (Primary) Register
SPORT_TXSEC_A	Half SPORT 'A' Tx Buffer (Secondary) Register
SPORT_TXSEC_B	Half SPORT 'B' Tx Buffer (Secondary) Register

Half SPORT 'A' Multichannel 0-31 Select Register

Each of the bits (when set, =1) of the SPORT_CS0_A register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

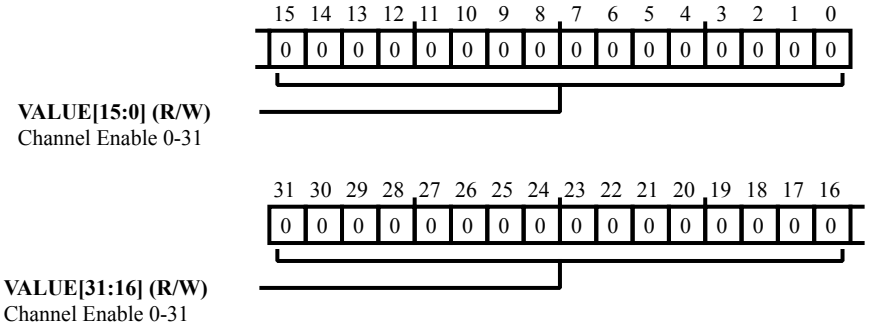

Figure 30-14: SPORT_CS0_A Register Diagram

Table 30-15: SPORT_CS0_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 0-31.

Half SPORT 'B' Multichannel 0-31 Select Register

Each of the bits (when set, =1) of the SPORT_CS0_B register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

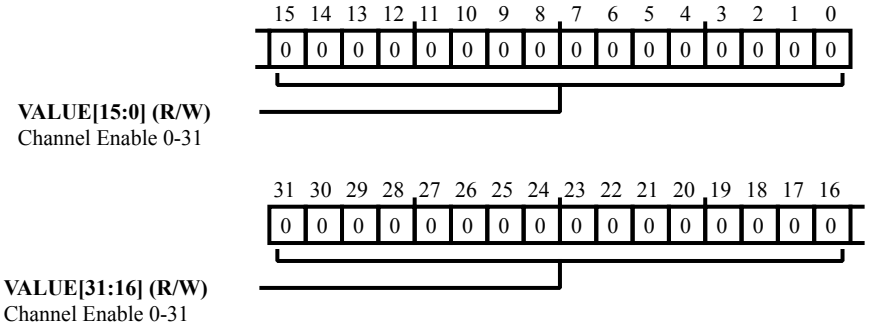

Figure 30-15: SPORT_CS0_B Register Diagram

Table 30-16: SPORT_CS0_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 0-31.

Half SPORT 'A' Multichannel 32-63 Select Register

Each of the bits (when set, =1) of the SPORT_CS1_A register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 32-63.

Half SPORT 'A' Multichannel 64-95 Select Register

Each of the bits (when set, =1) of the SPORT_CS2_A register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 64-95.

Half SPORT 'A' Multichannel 96-127 Select Register

Each of the bits (when set, =1) of the SPORT_CS3_A register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

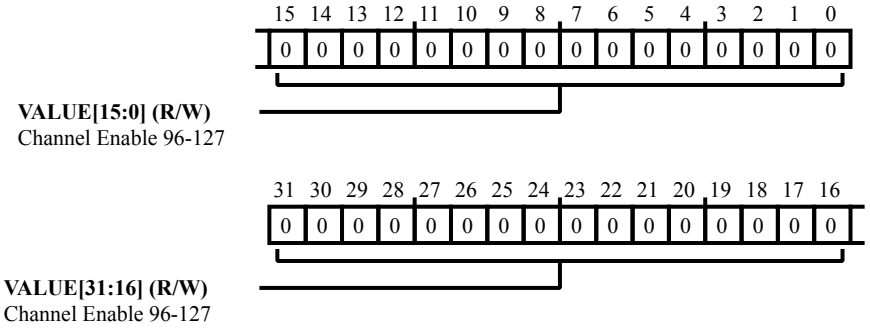

Figure 30-20: SPORT_CS3_A Register Diagram

Table 30-22: SPORT_CS3_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 96-127.

Half SPORT 'A' Control 2 Register

The SPORT_CTL2_A register controls multiplexing options for sharing serial clock and frame sync signals across the related half SPORTs.

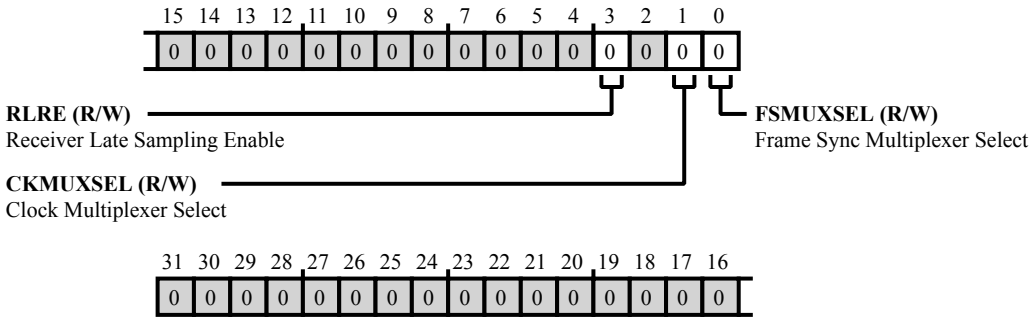

Figure 30-22: SPORT_CTL2_A Register Diagram

Table 30-23: SPORT_CTL2_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RLRE	Receiver Late Sampling Enable. The SPORT_CTL2_A.RLRE bit enables the half SPORT's late sampling of received data and frame sync by half of the operating clock cycle.	
1 (R/W)	CKMUXSEL	Clock Multiplexer Select. The SPORT_CTL2_A.CKMUXSEL bit enables multiplexing of the half SPORT's serial clock. In this mode, the serial clock of the related half SPORT is used instead of the half SPORT's own serial clock. For example, if the SPORT_CTL2_A.CKMUXSEL bit is enabled, half SPORT 'A' uses SPORT_BCLK instead of SPORT_ACLK.	
		0	Disable serial clock multiplexing
		1	Enable serial clock multiplexing
0 (R/W)	FSMUXSEL	Frame Sync Multiplexer Select. The SPORT_CTL2_A.FSMUXSEL bit enables multiplexing of the half SPORT's frame sync. In this mode, the frame sync of the related half SPORT is used instead of the half SPORT's own frame sync. For example, if the SPORT_CTL2_A.FSMUXSEL bit is enabled, half SPORT 'A' uses SPORT_BFS instead of SPORT_AFS.	
		0	Disable frame sync multiplexing
		1	Enable frame sync multiplexing

Half SPORT 'B' Control 2 Register

The SPORT_CTL2_B register controls multiplexing options for sharing serial clock and frame sync signals across the related half SPORTs.

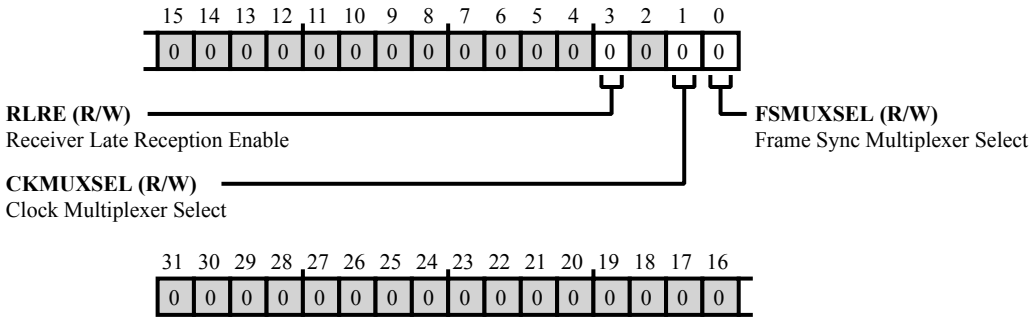

Figure 30-23: SPORT_CTL2_B Register Diagram

Table 30-24: SPORT_CTL2_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RLRE	Receiver Late Reception Enable. The SPORT_CTL2_B.RLRE bit enables the half SPORT's late sampling of received data and frame sync by half of the operating clock cycle.	
1 (R/W)	CKMUXSEL	Clock Multiplexer Select. The SPORT_CTL2_B.CKMUXSEL bit enables multiplexing of the half SPORT's serial clock. In this mode, the serial clock of the related half SPORT is used instead of the half SPORT's own serial clock. For example, if the SPORT_CTL2_B.CKMUXSEL bit is enabled, half SPORT 'B' uses SPORT_ACLK instead of SPORT_BCLK.	
		0	Disable serial clock multiplexing
		1	Enable serial clock multiplexing
0 (R/W)	FSMUXSEL	Frame Sync Multiplexer Select. The SPORT_CTL2_B.FSMUXSEL bit enables multiplexing of the half SPORT's frame sync. In this mode, the frame sync of the related half SPORT is used instead of the half SPORT's own frame sync. For example, if the SPORT_CTL2_B.FSMUXSEL bit is enabled, half SPORT 'B' uses SPORT_AFS instead of SPORT_BFS.	
		0	Disable frame sync multiplexing
		1	Enable frame sync multiplexing

Half SPORT 'A' Control Register

The SPORT_CTL_A register contains transmit and receive control bits for SPORT half 'A', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in the SPORT_CTL_A register vary depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

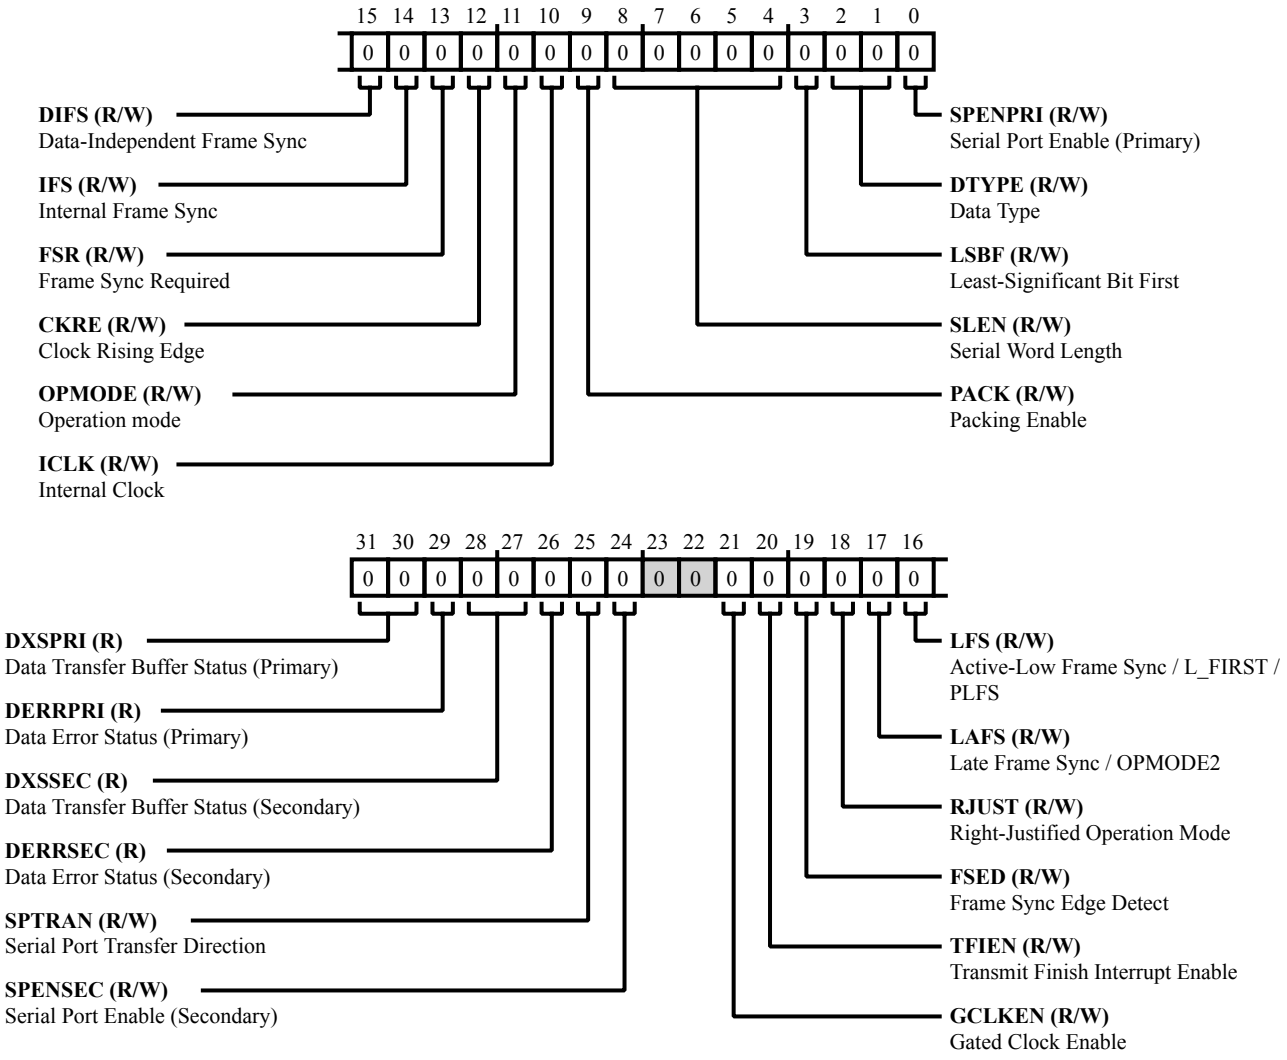

Figure 30-24: SPORT_CTL_A Register Diagram

Table 30-25: SPORT_CTL_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	DXSPRI	Data Transfer Buffer Status (Primary). The SPORT_CTL_A.DXSPRI bit field indicates the status of the half SPORT's primary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full
29 (R/NW)	DERRPRI	Data Error Status (Primary). The SPORT_CTL_A.DERRPRI bit reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the SPORT_CTL_A.FSR bit =1, the SPORT_CTL_A.DERRPRI bit indicates whether the SPORT_AFS signal (from an internal or external source) occurred while the SPORT_TXPRI_A data buffer was empty (during transmit) or the SPORT_RXPRI_A data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_AFS signal. It is important to note that, as a receiver, the SPORT_CTL_A.DERRPRI bit indicates when the channel has received new data while the SPORT_RXPRI_A receive buffer is full. This new data overwrites existing data. If the SPORT_CTL_A.FSR bit =0, the SPORT_CTL_A.DERRPRI bit is set whenever the SPORT is required to transmit while the SPORT_TXPRI_A transmit buffer is empty. It is also set whenever the SPORT is required to receive while the SPORT_RXPRI_A receive buffer is full. The SPORT clears the SPORT_CTL_A.DERRPRI bit if the SPORT_ERR_A.DERRPSTAT bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
28:27 (R/NW)	DXSSEC	Data Transfer Buffer Status (Secondary). The SPORT_CTL_A.DXSSEC bit field indicates the status of the half SPORT's secondary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	DERRSEC	Data Error Status (Secondary). The SPORT_CTL_A.DERRSEC bit reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the SPORT_CTL_A.FSR bit =1, the SPORT_CTL_A.DERRSEC bit indicates whether the SPORT_AFS signal (from an internal or external source) occurred while the SPORT_TXSEC_A data buffer was empty (during transmit) or the SPORT_RXSEC_A data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_AFS signal. It is important to note that, as a receiver, the SPORT_CTL_A.DERRSEC bit indicates when the channel has received new data while the SPORT_RXSEC_A receive buffer is full. This new data overwrites existing data. If the SPORT_CTL_A.FSR bit =0, the SPORT_CTL_A.DERRSEC bit is set whenever the SPORT is required to transmit while the SPORT_TXSEC_A transmit buffer is empty. It is also set whenever the SPORT is required to receive while the SPORT_RXSEC_A receive buffer is full. The SPORT clears the SPORT_CTL_A.DERRSEC bit if the SPORT_ERR_A.DERRSSTAT bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
25 (R/W)	SPTRAN	Serial Port Transfer Direction. The SPORT_CTL_A.SPTRAN bit selects the transfer direction (receive or transmit) for the half SPORT's primary and secondary channels. When the direction is receive, the half SPORT activates the receive buffers, and the SPORT_ACLK and SPORT_AFS pins control the receive buffers. The transmit buffers are inactive when the half SPORT's transfer direction is receive. When the direction is transmit, the half SPORT activates the transmit buffers, and the SPORT_ACLK and SPORT_AFS pins control the transmit shift registers. The receive buffers are inactive when the half SPORT's transfer direction is transmit.	
		0	Receive
		1	Transmit
24 (R/W)	SPENSEC	Serial Port Enable (Secondary). The SPORT_CTL_A.SPENSEC bit enables the half SPORT's secondary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers.	
		0	Disable
		1	Enable

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	GCLKEN	Gated Clock Enable. The SPORT_CTL_A.GCLKEN bit enables gated clock operation for the half SPORT when in DSP serial mode or left-justified stereo modes (SPORT_CTL_A.OPMODE = 0 or 1). This bit is ignored when the half SPORT is in right-justified mode (SPORT_CTL_A.RJUST =1) or multichannel mode (SPORT_MCTL_A.MCE =1). When the SPORT_CTL_A.GCLKEN bit is enabled, the SPORT clock is active when the SPORT is transferring data or when the frame sync changes (transitions to active state).	
		0	Disable
		1	Enable
20 (R/W)	TFIEN	Transmit Finish Interrupt Enable. The SPORT_CTL_A.TFIEN bit selects when the half SPORT issues its transmission complete interrupt request, if a DMA complete interrupt request is enabled by the DMA_CFG.INT configuration. When enabled (SPORT_CTL_A.TFIEN =1), the DMA complete peripheral interrupt request is generated when the last bit of last word in the DMA is shifted out. When disabled (SPORT_CTL_A.TFIEN =0), the DMA interrupt request is generated when the DMA counter expires (the last word goes to the transmit buffer).	
		0	Last word sent (DMA count done) interrupt
		1	Last bit sent (Tx buffer done) interrupt
19 (R/W)	FSED	Frame Sync Edge Detect. The SPORT_CTL_A.FSED bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The SPORT_CTL_A.FSED bit may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (SPORT_CTL_A.FSED =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.	
		0	Level detect frame sync
		1	Edge detect frame sync

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	RJUST	Right-Justified Operation Mode. The SPORT_CTL_A.RJUST bit enables the half SPORT (if SPORT_CTL_A.OPMODE =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the SPORT_MCTL_A.WOFFSET field). For information about appropriate delay selections, see the SPORT operating modes section.	
		0	Disable
		1	Enable
17 (R/W)	LAFS	Late Frame Sync / OPMODE2. When the half SPORT is in DSP standard mode (SPORT_CTL_A.OPMODE =0) or in right-justified mode (SPORT_CTL_A.RJUST =1), the SPORT_CTL_A.LAFS bit selects whether the half SPORT generates a late frame sync (SPORT_AFS during first data bit) or generates an early frame sync signal (SPORT_AFS during serial clock cycle before first data bit). When the half SPORT is in I^2S / left-justified mode (SPORT_CTL_A.OPMODE =1), the SPORT_CTL_A.LAFS bit acts as OPMODE2, selecting whether the half SPORT is in left-justified mode or I^2S mode. When the half SPORT is in multichannel mode (SPORT_MCTL_A.MCE =1), the SPORT_CTL_A.LAFS bit is reserved.	
		0	Early frame sync (or I^2S mode)
		1	Late frame sync (or left-justified mode)
16 (R/W)	LFS	Active-Low Frame Sync / L_FIRST / PLFS. When the half SPORT is in DSP standard mode and multichannel mode (SPORT_CTL_A.OPMODE =0), the SPORT_CTL_A.LFS bit selects whether the half SPORT uses active low or active high frame sync. When the half SPORT is in I^2S / packed / left-justified mode (SPORT_CTL_A.OPMODE =1), the SPORT_CTL_A.LFS bit acts as L_FIRST, selecting whether the half SPORT transfers data first for the left or right channel.	
		0	Active high frame sync (DSP standard mode) or rising edge frame sync (multichannel mode) or right channel first (I^2S/packed mode) or left channel first (left-justified mode)
		1	Active low frame sync (DSP standard mode) or falling edge frame sync (multichannel mode) or left channel first (I^2S/packed mode) or right channel first (left-justified mode)

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	DIFS	Data-Independent Frame Sync. The SPORT_CTL_A.DIFS bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by the SPORT_DIV_A.FSDIV bit. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the SPORT_CTL_A.DIFS bit is automatically set when the half SPORT is in packed or multichannel modes.	
		0	Data-dependent frame sync
		1	Data-independent frame sync
14 (R/W)	IFS	Internal Frame Sync. The SPORT_CTL_A.IFS bit selects whether the half SPORT uses an internal frame sync or uses an external frame sync. Note that the externally-generated frame sync does not need to be synchronous with the processor's system clock.	
		0	External frame sync
		1	Internal frame sync
13 (R/W)	FSR	Frame Sync Required. The SPORT_CTL_A.FSR bit selects whether or not the half SPORT requires frame sync for data transfer. This bit is automatically set when the half SPORT is in I^2S / packed / left-justified mode (SPORT_CTL_A.OPMODE =1) or is in multichannel mode (SPORT_MCTL_A.MCE =1).	
		0	No frame sync required
		1	Frame sync required
12 (R/W)	CKRE	Clock Rising Edge. The SPORT_CTL_A.CKRE bit selects the rising or falling edge of the SPORT_ACLK clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the SPORT_ACLK. Also, note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for the SPORT_CTL_A.CKRE bit. This programming drives the internally-generated signals on one edge of SPORT_ACLK and samples the received signals on the opposite edge.	
		0	Clock falling edge
		1	Clock rising edge

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	OPMODE	Operation mode. The SPORT_CTL_A.OPMODE bit selects whether the half SPORT operates in DSP standard/multichannel mode or operates in I^2S/packed/left-justified mode. The mode selection affects the operation of the SPORT_CTL_A.LAFS and SPORT_CTL_A.LFS bits. Also, the SPORT_CTL_A.OPMODE bit enables or disables operation of the SPORT_CTL_A.GCLKEN, SPORT_CTL_A.FSED, SPORT_CTL_A.RJUST, SPORT_CTL_A.DIFS, SPORT_CTL_A.FSR, and SPORT_CTL_A.CKRE bits.	
		0	DSP standard/multichannel mode
		1	I^2S/packed/left-justified mode
10 (R/W)	ICLK	Internal Clock. When the half SPORT is in DSP standard mode (SPORT_CTL_A.OPMODE =0), the SPORT_CTL_A.ICLK bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the SPORT_ACLK clock signal, and SPORT_ACLK is an output. The SPORT_DIV_A.CLKDIV serial clock divisor value determines the clock frequency. For internal clock disabled, the SPORT_ACLK clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.	
		0	External clock
		1	Internal clock
9 (R/W)	PACK	Packing Enable. The SPORT_CTL_A.PACK bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15:0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31:16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word.	
		0	Disable
		1	Enable

Table 30-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8:4 (R/W)	SLEN	Serial Word Length. The SPORT_CTL_A.SLEN bits selects word length in bits for the half SPORT's data transfers. Word may be from 4- to 32-bits in length. The formula for selecting the word length in bits is: SPORT_CTL_A.SLEN = (serial word length in bits) - 1 For DSP standard mode (SPORT_CTL_A.OPMODE =0), use SPORT_CTL_A.SLEN of 3 to 31 bits. For I^2S / packed / left-justified mode (SPORT_CTL_A.OPMODE =1), use SPORT_CTL_A.SLEN of 4 to 31 bits.	
3 (R/W)	LSBF	Least-Significant Bit First. The SPORT_CTL_A.LSBF bit selects whether the half SPORT transmits or receives data LSB first or MSB first.	
		0	MSB first sent/received (big endian)
		1	LSB first sent/received (little endian)
2:1 (R/W)	DTYPE	Data Type. The SPORT_CTL_A.DTYPE bits selects the data type formatting for the half SPORT's data transfers in DSP standard mode (SPORT_CTL_A.OPMODE =0).	
		0	Right-justify data, zero-fill unused MSBs
		1	Right-justify data, sign-extend unused MSBs
		2	u-law compand data
		3	A-law compand data
0 (R/W)	SPENPRI	Serial Port Enable (Primary). The SPORT_CTL_A.SPENPRI bit enables the half SPORT's primary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers.	
		0	Disable
		1	Enable

Half SPORT 'B' Control Register

The SPORT_CTL_B register contains transmit and receive control bits for SPORT half 'B', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in the SPORT_CTL_B register vary, depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

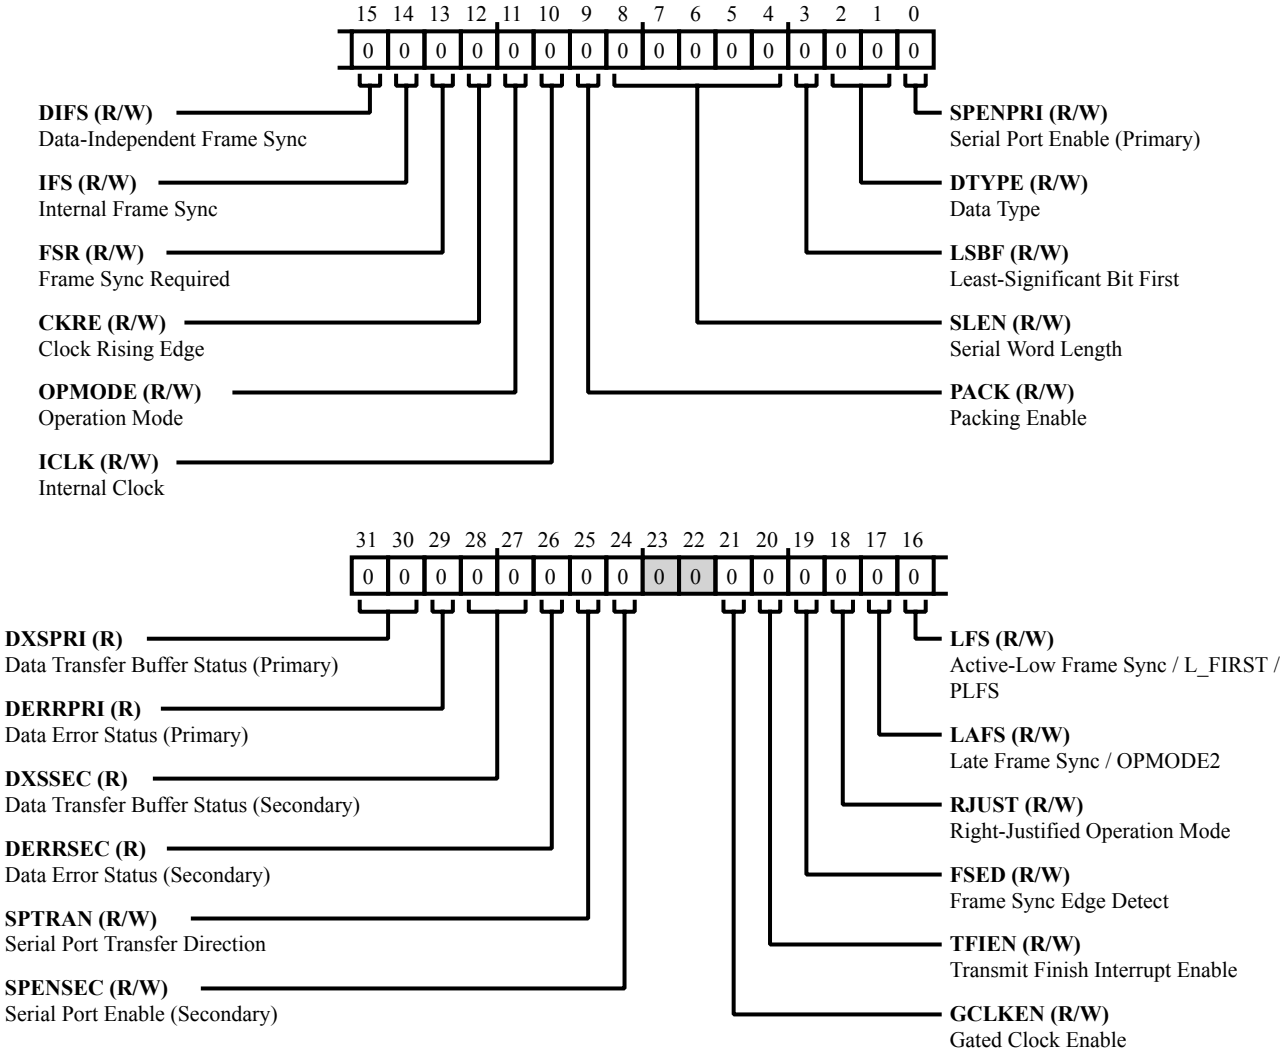

Figure 30-25: SPORT_CTL_B Register Diagram

Table 30-26: SPORT_CTL_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	DXSPRI	Data Transfer Buffer Status (Primary). The SPORT_CTL_B.DXSPRI bit field indicates the status of the half SPORT's primary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full
29 (R/NW)	DERRPRI	Data Error Status (Primary). The SPORT_CTL_B.DERRPRI bit reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the SPORT_CTL_B.FSR bit =1, the SPORT_CTL_B.DERRPRI bit indicates whether the SPORT_BFS signal (from an internal or external source) occurred while the SPORT_TXPRI_B data buffer was empty (during transmit) or the SPORT_RXPRI_B data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_BFS signal. It is important to note that, as a receiver, the SPORT_CTL_B.DERRPRI bit indicates when the channel has received new data while the SPORT_RXPRI_B receive buffer is full. This new data overwrites existing data. If the SPORT_CTL_B.FSR bit =0, the SPORT_CTL_B.DERRPRI bit is set whenever the SPORT is required to transmit while the SPORT_TXPRI_B transmit buffer is empty and is set whenever the SPORT is required to receive while the SPORT_RXPRI_B receive buffer is full. The SPORT clears the SPORT_CTL_B.DERRPRI bit if the SPORT_ERR_B.DERRPSTAT bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
28:27 (R/NW)	DXSSEC	Data Transfer Buffer Status (Secondary). The SPORT_CTL_B.DXSSEC bit field indicates the status of the half SPORT's secondary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	DERRSEC	Data Error Status (Secondary). The SPORT_CTL_B.DERRSEC bit reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the SPORT_CTL_B.FSR bit =1, the SPORT_CTL_B.DERRSEC bit indicates whether the SPORT_BFS signal (from an internal or external source) occurred while the SPORT_TXSEC_B data buffer was empty (during transmit) or the SPORT_RXSEC_B data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_BFS signal. It is important to note that, as a receiver, the SPORT_CTL_B.DERRSEC bit indicates when the channel has received new data while the SPORT_RXSEC_B receive buffer is full. This new data overwrites existing data. If the SPORT_CTL_B.FSR bit =0, the SPORT_CTL_B.DERRSEC bit is set whenever the SPORT is required to transmit while the SPORT_TXSEC_B transmit buffer is empty. It is also set whenever the SPORT is required to receive while the SPORT_RXSEC_B receive buffer is full. The SPORT clears the SPORT_CTL_B.DERRSEC bit if the SPORT_ERR_B.DERRSSTAT bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
25 (R/W)	SPTRAN	Serial Port Transfer Direction. The SPORT_CTL_B.SPTRAN bit selects the transfer direction (receive or transmit) for the half SPORT's primary and secondary channels. When the direction is receive, the half SPORT activates the receive buffers, and the SPORT_BCLK and SPORT_BFS pins control the receive buffers. The transmit buffers are inactive when the half SPORT's transfer direction is receive. When the direction is transmit, the half SPORT activates the transmit buffers, and the SPORT_BCLK and SPORT_BFS pins control the transmit shift registers. The receive buffers are inactive when the half SPORT's transfer direction is transmit.	
		0	Receive
		1	Transmit
24 (R/W)	SPENSEC	Serial Port Enable (Secondary). The SPORT_CTL_B.SPENSEC bit enables the half SPORT's secondary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers.	
		0	Disable
		1	Enable

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	GCLKEN	Gated Clock Enable. The SPORT_CTL_B.GCLKEN bit enables gated clock operation for the half SPORT when in DSP serial mode or left-justified stereo modes (SPORT_CTL_B.OPMODE = 0 or 1). This bit is ignored when the half SPORT is in right-justified mode (SPORT_CTL_B.RJUST =1) or multichannel mode (SPORT_MCTL_B.MCE =1). When SPORT_CTL_B.GCLKEN is enabled, the SPORT clock is active when the SPORT is transferring data or when the frame sync changes (transitions to active state).	
		0	Disable
		1	Enable
20 (R/W)	TFIEN	Transmit Finish Interrupt Enable. The SPORT_CTL_B.TFIEN bit selects when the half SPORT issues its transmission complete interrupt request, if a DMA complete interrupt request is enabled by the DMA_CFG.INT configuration. When enabled (SPORT_CTL_B.TFIEN =1), the DMA complete peripheral interrupt request is generated when the last bit of last word in the DMA is shifted out. When disabled (SPORT_CTL_B.TFIEN =0), the DMA interrupt request is generated when the DMA counter expires (the last word goes to the transmit buffer).	
		0	Last word sent (DMA count done) interrupt
		1	Last bit sent (Tx buffer done) interrupt
19 (R/W)	FSED	Frame Sync Edge Detect. The SPORT_CTL_B.FSED bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The SPORT_CTL_B.FSED may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (SPORT_CTL_B.FSED =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.	
		0	Level detect frame sync
		1	Edge detect frame sync

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	RJUST	Right-Justified Operation Mode. The SPORT_CTL_B.RJUST bit enables the half SPORT (if SPORT_CTL_B.OPMODE =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the SPORT_MCTL_B.WOFFSET field). For information about appropriate delay selections, see the SPORT operating modes section.	
		0	Disable
		1	Enable
17 (R/W)	LAFS	Late Frame Sync / OPMODE2. When the half SPORT is in DSP standard mode (SPORT_CTL_B.OPMODE =0) or in right-justified mode (SPORT_CTL_B.RJUST =1), the SPORT_CTL_B.LAFS bit selects whether the half SPORT generates a late frame sync (SPORT_BFS during first data bit) or generates an early frame sync signal (SPORT_BFS during serial clock cycle before first data bit). When the half SPORT is in I^2S / left-justified mode (SPORT_CTL_B.OPMODE =1), the SPORT_CTL_B.LAFS bit acts as OPMODE2, selecting whether the half SPORT is in left-justified mode or I^2S mode. When the half SPORT is in multichannel mode (SPORT_MCTL_B.MCE =1), the SPORT_CTL_B.LAFS bit is reserved.	
		0	Early frame sync (or I^2S mode)
		1	Late frame sync (or left-justified mode)

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	LFS	Active-Low Frame Sync / L_FIRST / PLFS. When the half SPORT is in DSP standard mode and multichannel mode (SPORT_CTL_B.OPMODE =0), the SPORT_CTL_B.LFS bit selects whether the half SPORT uses active low or active high frame sync. When the half SPORT is in I^2S / packed / left-justified mode (SPORT_CTL_B.OPMODE =1), the SPORT_CTL_B.LFS bit acts as L_FIRST, selecting whether the half SPORT transfers data first for the left or right channel.	
		0	Active high frame sync (DSP standard mode) or rising edge frame sync (multichannel mode) or right channel first (I^2S/packed mode) or left channel first (left-justified mode)
		1	Active low frame sync (DSP standard mode) or falling edge frame sync (multichannel mode) or left channel first (I^2S/packed mode) or right channel first (left-justified mode)
15 (R/W)	DIFS	Data-Independent Frame Sync. The SPORT_CTL_B.DIFS bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by SPORT_DIV_B.FSDIV. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the SPORT_CTL_B.DIFS bit is automatically set when the half SPORT is in packed or multichannel modes.	
		0	Data-dependent frame sync
		1	Data-independent frame sync
14 (R/W)	IFS	Internal Frame Sync. The SPORT_CTL_B.IFS bit selects whether the half SPORT uses an internal frame sync or uses an external frame sync. Note that the externally-generated frame sync does not need to be synchronous with the processor's system clock.	
		0	External frame sync
		1	Internal frame sync

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	FSR	Frame Sync Required. The SPORT_CTL_B.FSR selects whether or not the half SPORT requires frame sync for data transfer. This bit is automatically set when the half SPORT is in I²S / packed / left-justified mode (SPORT_CTL_B.OPMODE =1) or is in multichannel mode (SPORT_MCTL_B.MCE =1).	
		0	No frame sync required
		1	Frame sync required
12 (R/W)	CKRE	Clock Rising Edge. The SPORT_CTL_B.CKRE selects the rising or falling edge of the SPORT_BCLK clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the SPORT_BCLK. Also note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for SPORT_CTL_B.CKRE. This programming drives the internally-generated signals on one edge of SPORT_BCLK and samples the received signals on the opposite edge.	
		0	Clock falling edge
		1	Clock rising edge
11 (R/W)	OPMODE	Operation Mode. The SPORT_CTL_B.OPMODE bit selects whether the half SPORT operates in DSP standard / multichannel mode or operates in I²S / packed / left-justified mode. The mode selection affects the operation of the SPORT_CTL_B.LAFS and SPORT_CTL_B.LFS bits. Also, the SPORT_CTL_B.OPMODE bit enables or disables operation of the SPORT_CTL_B.GCLKEN, SPORT_CTL_B.FSED, SPORT_CTL_B.RJUST, SPORT_CTL_B.DIFS, SPORT_CTL_B.FSR, and SPORT_CTL_B.CKRE bits.	
		0	DSP standard/multichannel mode
		1	I²S/packed/left-justified mode
10 (R/W)	ICLK	Internal Clock. When the half SPORT is in DSP standard mode (SPORT_CTL_B.OPMODE =0), the SPORT_CTL_B.ICLK bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the SPORT_BCLK clock signal, and the SPORT_BCLK is an output. The SPORT_DIV_B.CLKDIV serial clock divisor value determines the clock frequency. For internal clock disabled, the SPORT_BCLK clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.	
		0	External clock
		1	Internal clock

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	PACK	Packing Enable. The SPORT_CTL_B.PACK bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15:0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31:16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word.	
		0	Disable
		1	Enable
8:4 (R/W)	SLEN	Serial Word Length. The SPORT_CTL_B.SLEN bits selects word length in bits for the half SPORT's data transfers. Word may be from 4- to 32-bits in length. The formula for selecting the word length in bits is: SPORT_CTL_B.SLEN = (serial word length in bits) - 1 For DSP standard mode (SPORT_CTL_B.OPMODE =0), use SPORT_CTL_B.SLEN of 3 to 31 bits. For I^2S / packed / left-justified mode (SPORT_CTL_B.OPMODE =1), use SPORT_CTL_B.SLEN of 4 to 31 bits.	
3 (R/W)	LSBF	Least-Significant Bit First. The SPORT_CTL_B.LSBF bit selects whether the half SPORT transmits or receives data LSB first or MSB first.	
		0	MSB first sent/received (big endian)
		1	LSB first sent/received (little endian)
2:1 (R/W)	DTYPE	Data Type. The SPORT_CTL_B.DTYPE bits selects the data type formatting for the half SPORT's data transfers in DSP standard mode (SPORT_CTL_B.OPMODE =0).	
		0	Right-justify data, zero-fill unused MSBs
		1	Right-justify data, sign-extend unused MSBs
		2	u-law compand data
		3	A-law compand data

Table 30-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	SPENPRI	Serial Port Enable (Primary). The `SPORT_CTL_B.SPENPRI` bit enables the half SPORT's primary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers.	
		0	Disable
		1	Enable

Half SPORT 'A' Divisor Register

The SPORT_DIV_A register contains divisor values that determine frequencies of internally-generated clocks and frame syncs for half SPORT 'A'.

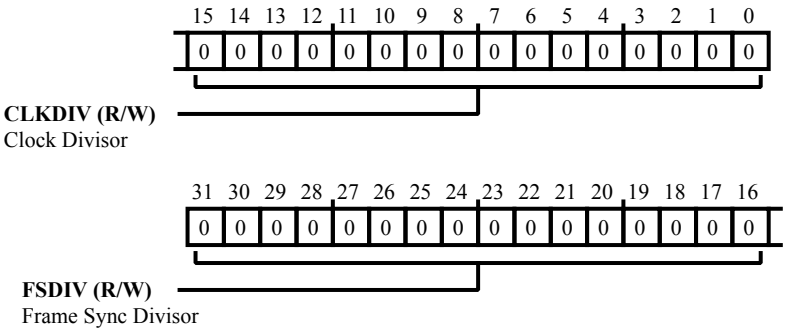

Figure 30-26: SPORT_DIV_A Register Diagram

Table 30-27: SPORT_DIV_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	FSDIV	Frame Sync Divisor. The SPORT_DIV_A.FSDIV bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating SPORT_DIV_A.FSDIV to the number of cycles between frame sync pulses is: SPORT_DIV_A.FSDIV = (number of serial clocks between frame syncs) - 1 Use the following equation to determine the value of SPORT_DIV_A.FSDIV, given the serial clock frequency and desired frame sync frequency: FSDIV = (SPORT_ACLK / SPORT_AFS) - 1 Note that the frame sync is continuously active when SPORT_DIV_A.FSDIV = 0. The value of SPORT_DIV_A.FSDIV should not be less than the serial word length (SPORT_CTL_A.SLEN), as this may cause an external device to abort the current operation or cause other unpredictable results.
15:0 (R/W)	CLKDIV	Clock Divisor. The SPORT_DIV_A.CLKDIV bits select the divisor that the half SPORT uses to calculate the serial clock (SPORT_ACLK) from the processor system clock (SCLK0). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (SPORT_CTL_A.ICLK =1), legal SPORT_DIV_A.CLKDIV values are 0 to 65535. Given the processor system clock frequency and desired serial clock frequency, use the following formula to calculate the value of SPORT_DIV_A.CLKDIV: CLKDIV = (SCLK0 / SPORT_ACLK) - 1 For the maximum serial clock frequency, see the processor data sheet.

Half SPORT 'B' Divisor Register

The SPORT_DIV_B contains divisor values that determine frequencies of internally-generated clocks and frame syncs for SPORT half 'B'.

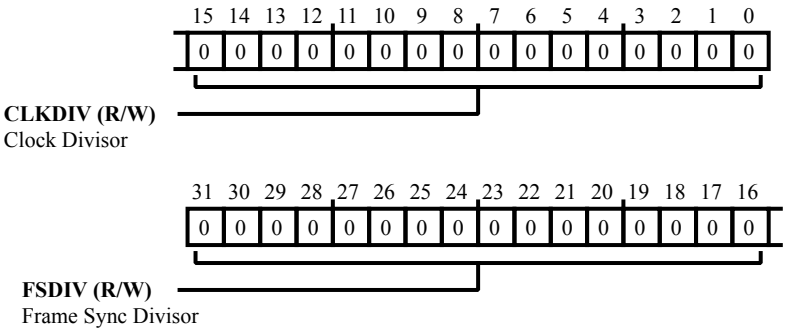

Figure 30-27: SPORT_DIV_B Register Diagram

Table 30-28: SPORT_DIV_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	FSDIV	Frame Sync Divisor. The SPORT_DIV_B.FSDIV bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating SPORT_DIV_B.FSDIV to the number of cycles between frame sync pulses is: SPORT_DIV_B.FSDIV = (number of serial clocks between frame syncs) - 1 Use the following equation to determine the value of SPORT_DIV_B.FSDIV, given the serial clock frequency and desired frame sync frequency: FSDIV = (SPORT_BCLK / SPORT_BFS) - 1 Note that the frame sync is continuously active when SPORT_DIV_B.FSDIV = 0. The value of SPORT_DIV_B.FSDIV should not be less than the serial word length (SPORT_CTL_B.SLEN), as this may cause an external device to abort the current operation or cause other unpredictable results.
15:0 (R/W)	CLKDIV	Clock Divisor. The SPORT_DIV_B.CLKDIV bits select the divisor that the half SPORT uses to calculate the serial clock (SPORT_BCLK) from the processor system clock (SCLK0). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (SPORT_CTL_B.ICLK =1), legal SPORT_DIV_B.CLKDIV values are 0 to 65535. Given the processor system clock frequency and desired serial clock frequency, use the following formula to calculate the value of SPORT_DIV_B.CLKDIV: CLKDIV = (SCLK0 SPORT_BCLK) - 1 For the maximum serial clock frequency, see the processor data sheet.

Half SPORT 'A' Error Register

The SPORT_ERR_A register contains error status and error interrupt mask bits for SPORT half 'A', including error handling bits for the half SPORT's primary and secondary channels and frame sync. Detected errors are frame sync violations or buffer over/underflow conditions.

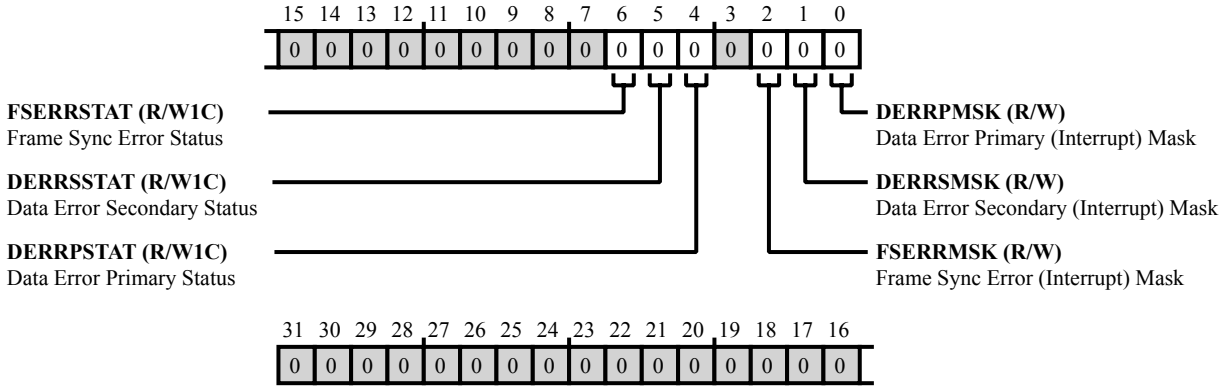

Figure 30-28: SPORT_ERR_A Register Diagram

Table 30-29: SPORT_ERR_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	FSERRSTAT	Frame Sync Error Status. The SPORT_ERR_A.FSERRSTAT bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, SPORT_CTL_A.SLEN = 31). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur after the bit count becomes zero.	
		0	No error
		1	Error (non-zero bit count at frame sync)

Table 30-29: SPORT_ERR_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	DERRSSTAT	Data Error Secondary Status. The SPORT_ERR_A.DERRSSTAT bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (SPORT_CTL_A.SPTRAN =1), the SPORT_ERR_A.DERRSSTAT bit indicates the transmit underflow status. During receive (SPORT_CTL_A.SPTRAN =0), the SPORT_ERR_A.DERRSSTAT bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a secondary data error. This bit can also be used to clear the read-only SPORT_CTL_A.DERRSEC status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
4 (R/W1C)	DERRPSTAT	Data Error Primary Status. The SPORT_ERR_A.DERRPSTAT bit indicates the error status for the half SPORT's primary channel data buffers. During transmit (SPORT_CTL_A.SPTRAN =1), the SPORT_ERR_A.DERRPSTAT bit indicates the transmit underflow status. During receive (SPORT_CTL_A.SPTRAN =0), the SPORT_ERR_A.DERRPSTAT bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a primary data error. This bit can also be used to clear the read-only SPORT_CTL_A.DERRPRI status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
2 (R/W)	FSERRMSK	Frame Sync Error (Interrupt) Mask. The SPORT_ERR_A.FSERRMSK unmasks (enables) the half SPORT to generate the frame sync error interrupt request.	
		0	Mask (disable)
		1	Unmask (enable)
1 (R/W)	DERRSMSK	Data Error Secondary (Interrupt) Mask. The SPORT_ERR_A.DERRSMSK unmasks (enables) the half SPORT to generate the data error interrupt request for the secondary channel.	
		0	Mask (disable)
		1	Unmask (enable)
0 (R/W)	DERRPMSK	Data Error Primary (Interrupt) Mask. The SPORT_ERR_A.DERRPMSK unmasks (enables) the half SPORT to generate the data error interrupt request for the primary channel.	
		0	Mask (disable)
		1	Unmask (enable)

Half SPORT 'B' Error Register

The SPORT_ERR_B register contains error status and error interrupt mask bits for SPORT half 'B', including error handling bits for the half SPORT's primary and secondary channels and frame sync. Detected errors are frame sync violations or buffer over/underflow conditions.

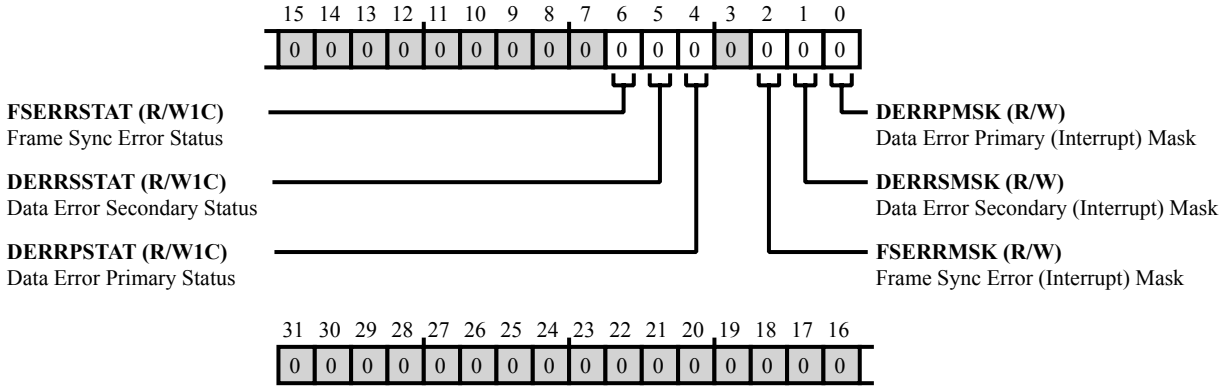

Figure 30-29: SPORT_ERR_B Register Diagram

Table 30-30: SPORT_ERR_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	FSERRSTAT	Frame Sync Error Status. The SPORT_ERR_B.FSERRSTAT bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, SPORT_CTL_B.SLEN = 31). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur after the bit count becomes zero.	
		0	No error
		1	Error (non-zero bit count at frame sync)

Table 30-30: SPORT_ERR_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	DERRSSTAT	Data Error Secondary Status. The SPORT_ERR_B.DERRSSTAT bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (SPORT_CTL_B.SPTRAN =1), SPORT_ERR_B.DERRSSTAT indicates the transmit underflow status. During receive (SPORT_CTL_B.SPTRAN =0), SPORT_ERR_B.DERRSSTAT indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a secondary data error. This bit can also be used to clear the read-only SPORT_CTL_B.DERRSEC status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
4 (R/W1C)	DERRPSTAT	Data Error Primary Status. The SPORT_ERR_B.DERRPSTAT bit indicates the error status for the half SPORT's primary channel data buffers. During transmit (SPORT_CTL_B.SPTRAN =1), the SPORT_ERR_B.DERRPSTAT bit indicates the transmit underflow status. During receive (SPORT_CTL_B.SPTRAN =0), the SPORT_ERR_B.DERRPSTAT bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a primary data error. This bit can also be used to clear the read-only SPORT_CTL_B.DERRPRI status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
2 (R/W)	FSERRMSK	Frame Sync Error (Interrupt) Mask. The SPORT_ERR_B.FSERRMSK unmasks (enables) the half SPORT to generate the frame sync error interrupt request.	
		0	Mask (disable)
		1	Unmask (enable)
1 (R/W)	DERRSMSK	Data Error Secondary (Interrupt) Mask. The SPORT_ERR_B.DERRSMSK unmasks (enables) the half SPORT to generate the data error interrupt request for the secondary channel.	
		0	Mask (disable)
		1	Unmask (enable)
0 (R/W)	DERRPMSK	Data Error Primary (Interrupt) Mask. The SPORT_ERR_B.DERRPMSK unmasks (enables) the half SPORT to generate the data error interrupt request for the primary channel.	
		0	Mask (disable)
		1	Unmask (enable)

Half SPORT 'A' Multichannel Control Register

The SPORT_MCTL_A register controls the half SPORT's multichannel operations. This register enables multichannel operation, enables multichannel data packing, selects the multichannel frame delay, selects the number of multichannel slots, and selects the multichannel window offset size.

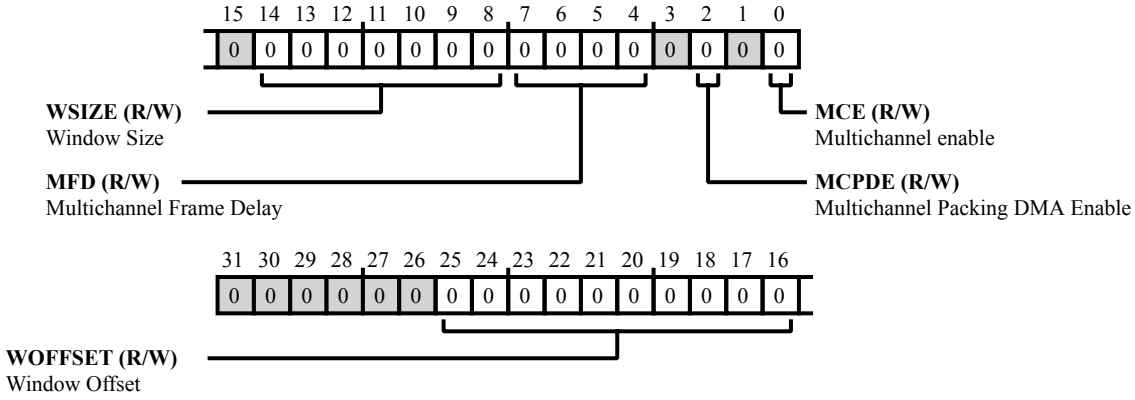

Figure 30-30: SPORT_MCTL_A Register Diagram

Table 30-31: SPORT_MCTL_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	WOFFSET	Window Offset. The SPORT_MCTL_A.WOFFSET bits select the start location for the half SPORT's active window of channels within the 1024-channel range. A value of 0 specifies no offset and 896 is the largest value that permits using all 128 channels. When multichannel mode is disabled (SPORT_MCTL_A.MCE =0) and the right-justified mode is enabled (SPORT_CTL_A.RJUST =1), the least significant 6 bits of SPORT_MCTL_A.WOFFSET serve as the delay count (DCNT) field. These bits introduce a clock delay before the half SPORT state machine starts to capture data. For information about appropriate delay selections, see the SPORT operating modes section.
14:8 (R/W)	WSIZE	Window Size. The SPORT_MCTL_A.WSIZE bits select the window size for the half SPORT's active window of channels. Use the following formula to calculate the window size value: SPORT_MCTL_A.WSIZE = (number of channel slots) -1
7:4 (R/W)	MFD	Multichannel Frame Delay. The SPORT_MCTL_A.MFD bits select the delay (in serial clock cycles) between the half SPORT's multichannel frame sync pulse and channel 0. The 4-bit field allows selecting multichannel frame delay of 0-15 serial clocks.

Table 30-31: SPORT_MCTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	MCPDE	Multichannel Packing DMA Enable. The SPORT_MCTL_A.MCPDE bit enables DMA data packing for transmit and enables DMA data unpacking for the half SPORT's multichannel data transfers.	
		0	Disable
		1	Enable
0 (R/W)	MCE	Multichannel enable. The SPORT_MCTL_A.MCE bit enables multichannel operations for the half SPORT. The half SPORT is configured in normal multichannel mode if SPORT_CTL_A.OPMODE=0; while it is configured in packed mode if SPORT_CTL_A.OPMODE=1. When configuring in these modes, the multichannel enable bit (SPORT_MCTL_A.MCE) should be set before enabling the SPORT data channel enable bits (SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared, and the SPORT_CTL_A.DERRPRI and SPORT_CTL_A.DERRSEC bits are cleared.	
		0	Disable
		1	Enable

Half SPORT 'B' Multichannel Control Register

The SPORT_MCTL_B register controls the half SPORT's multichannel operations. This register enables multichannel operation, enables multichannel data packing, selects the multichannel frame delay, selects the number of multichannel slots, and selects the multichannel window offset size.

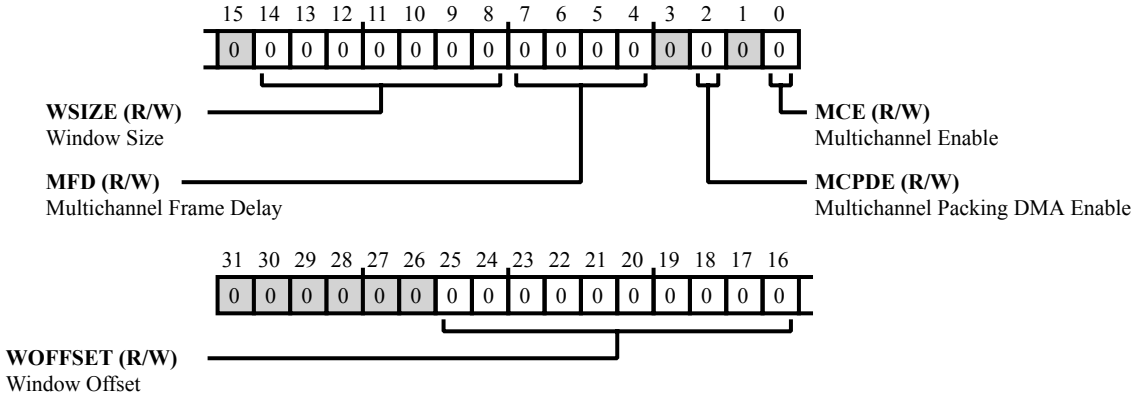

Figure 30-31: SPORT_MCTL_B Register Diagram

Table 30-32: SPORT_MCTL_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	WOFFSET	Window Offset. The SPORT_MCTL_B.WOFFSET bits select the start location for the half SPORT's active window of channels within the 1024-channel range. A value of 0 specifies no offset and 896 is the largest value that permits using all 128 channels. When multichannel mode is disabled (SPORT_MCTL_B.MCE =0) and right-justified mode is enabled (SPORT_CTL_B.RJUST =1), the least significant 6 bits of SPORT_MCTL_B.WOFFSET serve as the delay count (DCNT) field. These bits introduce a clock delay before the half SPORT state machine starts to capture data. For information about appropriate delay selections, see the SPORT operating modes section.
14:8 (R/W)	WSIZE	Window Size. The SPORT_MCTL_B.WSIZE bits select the window size for the half SPORT's active window of channels. Use the following formula to calculate the window size value: SPORT_MCTL_B.WSIZE = (number of channel slots) -1
7:4 (R/W)	MFD	Multichannel Frame Delay. The SPORT_MCTL_B.MFD bits select the delay (in serial clock cycles) between the half SPORT's multichannel frame sync pulse and channel 0. The 4-bit field allows selecting a multichannel frame delay of 0-15 serial clocks.

Table 30-32: SPORT_MCTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	MCPDE	Multichannel Packing DMA Enable. The SPORT_MCTL_B.MCPDE bit enables DMA data packing for transmit and enables DMA data unpacking for the half SPORT's multichannel data transfers.	
		0	Disable
		1	Enable
0 (R/W)	MCE	Multichannel Enable. The SPORT_MCTL_B.MCE bit enables multichannel operations for the half SPORT. The half SPORT is configured in normal multichannel mode if SPORT_CTL_B.OPMODE=0; while it is configured in packed mode if SPORT_CTL_B.OPMODE=1. When configuring in these modes, the multichannel enable bit (SPORT_MCTL_B.MCE) should be set before enabling SPORT data channel enable bits (SPORT_CTL_B.SPENPRI and/or SPORT_CTL_B.SPENSEC). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared, and the SPORT_CTL_B.DERRPRI and SPORT_CTL_B.DERRSEC bits are cleared.	
		0	Disable
		1	Enable

Half SPORT 'A' Multichannel Status Register

The SPORT_MSTAT_A register indicates the current multichannel being serviced among the half SPORT's active channels in multichannel mode. The half SPORT increments the value by one in this register as each channel is serviced. The value in the SPORT_MSTAT_A register restarts at 0 at each frame sync.

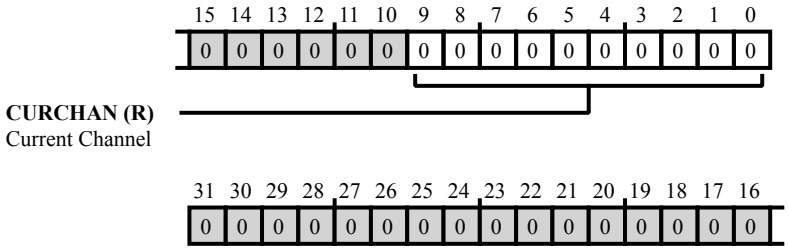

Figure 30-32: SPORT_MSTAT_A Register Diagram

Table 30-33: SPORT_MSTAT_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	CURCHAN	Current Channel. The SPORT_MSTAT_A.CURCHAN bits indicate the half SPORT's current channel being serviced in multichannel mode.

Half SPORT 'B' Multichannel Status Register

The SPORT_MSTAT_B register indicates the current multichannel being serviced among the half SPORT's active channels in multichannel mode. The half SPORT increments the value by one in this register as each channel is serviced. The value in the SPORT_MSTAT_B register restarts at 0 at each frame sync.

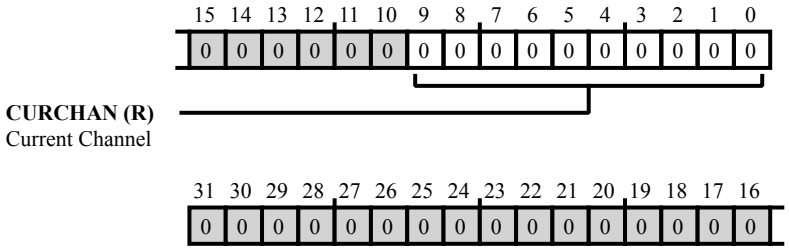

Figure 30-33: SPORT_MSTAT_B Register Diagram

Table 30-34: SPORT_MSTAT_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	CURCHAN	Current Channel. The SPORT_MSTAT_B.CURCHAN bits indicate the half SPORT's current channel being serviced in multichannel mode.

Half SPORT 'A' Rx Buffer (Primary) Register

The SPORT_RXPRI_A register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXPRI_A register. This data can be read in core mode (interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXPRI_A register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

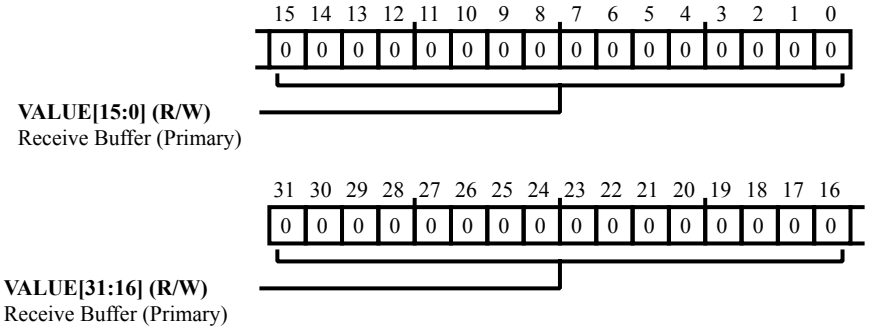

Figure 30-34: SPORT_RXPRI_A Register Diagram

Table 30-35: SPORT_RXPRI_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Receive Buffer (Primary). The SPORT_RXPRI_A.VALUE bits hold the half SPORT's primary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions.

Half SPORT 'B' Rx Buffer (Primary) Register

The SPORT_RXPRI_B register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXPRI_B register. This data can be read in core mode (interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXPRI_B register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

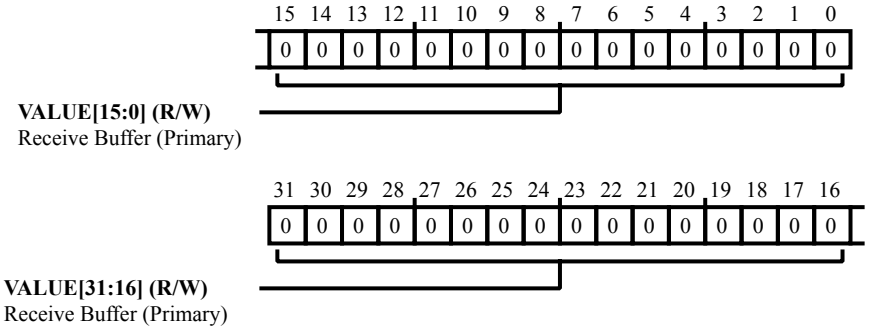

Figure 30-35: SPORT_RXPRI_B Register Diagram

Table 30-36: SPORT_RXPRI_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Receive Buffer (Primary). The SPORT_RXPRI_B.VALUE bits hold the half SPORT's primary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_B.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

Half SPORT 'A' Rx Buffer (Secondary) Register

The SPORT_RXSEC_A register buffers the half SPORT's secondary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the secondary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXSEC_A register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXSEC_A register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

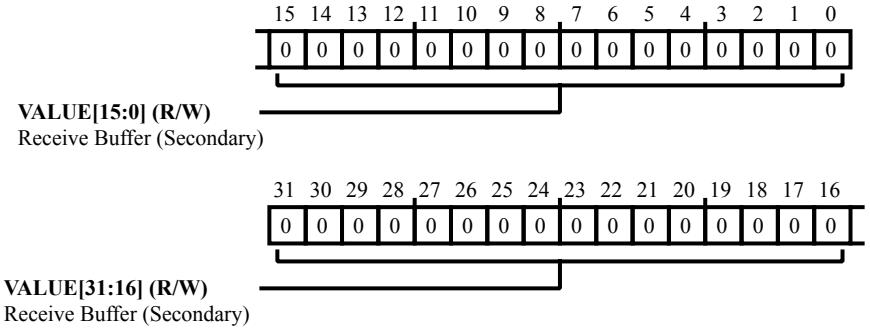

Figure 30-36: SPORT_RXSEC_A Register Diagram

Table 30-37: SPORT_RXSEC_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Receive Buffer (Secondary). The SPORT_RXSEC_A.VALUE bits hold the half SPORT's secondary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions.

Half SPORT 'B' Rx Buffer (Secondary) Register

The SPORT_RXSEC_B register buffers the half SPORT's secondary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the secondary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXSEC_B register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXSEC_B register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

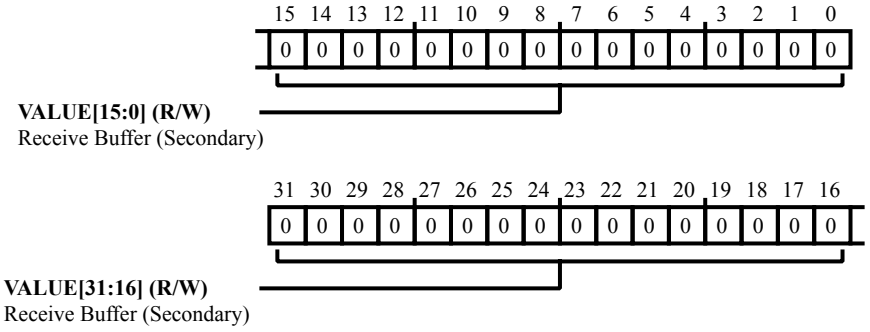

Figure 30-37: SPORT_RXSEC_B Register Diagram

Table 30-38: SPORT_RXSEC_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Receive Buffer (Secondary). The SPORT_RXSEC_B.VALUE bits hold the half SPORT's secondary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_B.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

Half SPORT 'A' Tx Buffer (Primary) Register

The SPORT_TXPRI_A register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The SPORT_TXPRI_A register acts as a three-location buffer if SPORT data packing is disabled (SPORT_CTL_A.PACK =0); while it acts as a two-location buffer when packing is enabled (SPORT_CTL_A.PACK =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT_TXPRI_A register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

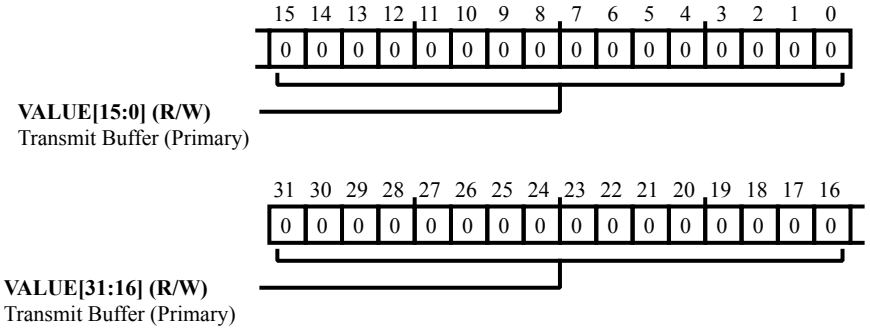

Figure 30-38: SPORT_TXPRI_A Register Diagram

Table 30-39: SPORT_TXPRI_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Transmit Buffer (Primary). The SPORT_TXPRI_A.VALUE bits hold the half SPORT's primary channel transmit data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions.

Half SPORT 'B' Tx Buffer (Primary) Register

The SPORT_TXPRI_B register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The SPORT_TXPRI_B register acts as a three-location buffer if SPORT data packing is disabled (SPORT_CTL_B.PACK =0); while it acts as a two-location buffer when packing is enabled (SPORT_CTL_B.PACK =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT_TXPRI_B register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

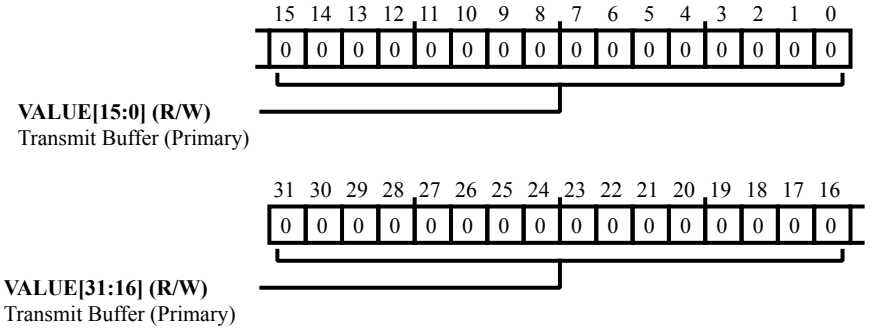

Figure 30-39: SPORT_TXPRI_B Register Diagram

Table 30-40: SPORT_TXPRI_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Transmit Buffer (Primary). The SPORT_TXPRI_B.VALUE bits hold the half SPORT's primary channel transmit data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_B.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

Half SPORT 'A' Tx Buffer (Secondary) Register

The SPORT_TXSEC_A register buffers the half SPORT's secondary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the secondary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The SPORT_TXSEC_A register acts as a three-location buffer if SPORT data packing is disabled (SPORT_CTL_A.PACK =0); while it acts as a two-location buffer when packing is enabled (SPORT_CTL_A.PACK =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT_TXSEC_A register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions.

Half SPORT 'B' Tx Buffer (Secondary) Register

The SPORT_TXSEC_B register buffers the half SPORT's secondary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the secondary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The SPORT_TXSEC_B register acts as a three-location buffer if SPORT data packing is disabled (SPORT_CTL_B.PACK =0); while it acts as two-location buffer when packing is enabled (SPORT_CTL_B.PACK =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT_TXSEC_B register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_B.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

31 Precision Clock Generators (PCG)

The precision clock generators are used to produce a pair of signals from a clock input signal. The two signals generated are normally used as a serial bit clock and frame sync pair. The PCG is part of the DAI.There are four PCG units per DAI. *PCGA*, *PCGB*, *PCGE*, and *PCGF* belong to DAI0; *PCGC*, *PCGD*, *PCGG*, and *PCGH* belong to DAI1.

Each of these four units (A, B, E, and F) generates one clock (CLKA_O, CLKB_O, CLKE_O, and CLKF_O) and one frame sync (FSA_O, FSB_O, FSE_O, and FSF_O) output. In addition to clock and frame sync outputs, each of these four units generates one inverted version of clock output (INV_CLKA_O, INV_CLKB_O, INV_CLKE_O, and INV_CLKF_O) and one inverted version of frame sync output (INV_FSA_O, INV_FSB_O, INV_FSE_O, and INV_FSF_O).

Features

The following list describes the features of the precision clock generators.

- SRU allows the routing of all of the PCG signals in one DAI (two PCG units in DAI)
- Input clock selection: SYS_CLKIN0 and SYS_CLKIN1 can be used as the input clock for PCG, when configured to use CLKIN as clock source
- Provides four different clock dividers for serial clock, frame sync, phase (20-bit), and pulse width (16-bit)
- Phase shift allows adjustment of the frame sync relative to the serial clock and can be shifted the full period and wrapped around
- Provides pulse width control for arbitrary frame sync signal generation
- Bypass mode for external frame sync manipulation
- External trigger mode starts PCG operation
- No additional jitter is introduced when using off-chip clocks
- Global enable. (See the DAI chapter for details)

Functional Description

The *PCG Block Diagram* shows the blocks within the module and its connection to the DAI. The following sections provide information on the function of these blocks.

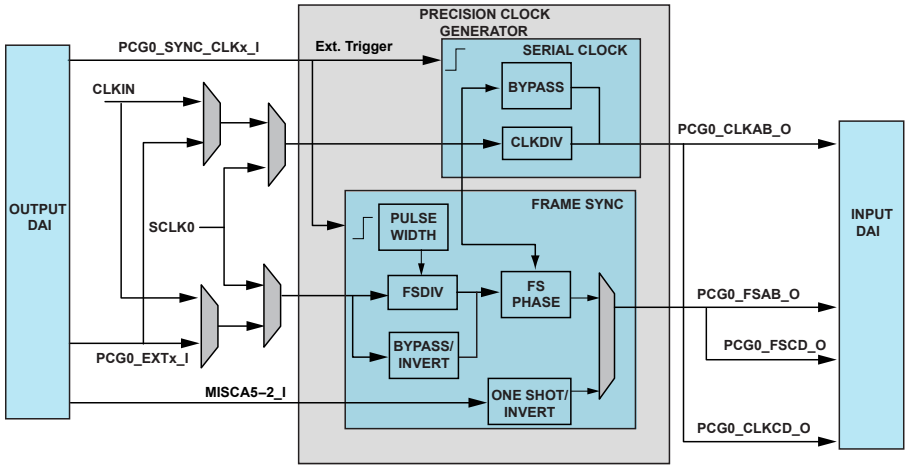

Figure 31-1: PCG Block Diagram

NOTE: In the *PCG Block Diagram*, the CLKINSEL bit field determines whether SYS_CLKIN0 or SYS_CLKIN1 is input to DAI.

PCG_SYNC3	Precision Clock Frame Sync Synchronization 3 Register
PCG_SYNC4	Precision Clock Frame Sync Synchronization 4 Register

Internal Interface

The fundamental clock of the PCG is *SCLK0*. The clock to this module can be shut off for power savings.

Serial Clock

Each of the four units (A, B, C, and D) produces a clock output. Serial clock generation from a unit is independently enabled and controlled. Sources for the serial clock generation can be either from the CLKIN, SCLK0, or a DAI pin source.

When CLKIN is chosen as input clock in PCG, the clock source bits (`PCG_SYNC1.CLKA_CLKINSEL`, `PCG_SYNC1.CLKB_CLKINSEL`) determine whether the clock source is `SYS_CLKIN0` or `SYS_CLKIN1`.

Note that the divider is working in normal mode for `PCG0_CTLx1.CLKDIV` > 1. For `PCG_CTLA1.CLKDIV`/ `PCG_CTLB1.CLKDIV` = 0 or 1, the divider operates in bypass mode (input clock is fed directly to its output). In bypass mode, the clock at the output can theoretically run at up to the SCLK0 frequency. Check the data sheet for the specified maximum operation speed of the DAI pin buffers.

Note that the clock output is always set (as closely as possible) to a 50% duty cycle. If the clock divisor is even, the duty cycle of the clock output is exactly 50%. If the clock divisor is odd, then the duty cycle is slightly less than 50%. The low period of the output clock is one input clock period more than the high period of the output clock. For higher values of an odd divisor, the duty cycle is close to 50%.

NOTE: A PCG clock output cannot be fed to its own input.

Frame Sync

The following sections describe the use of frame syncs in the PCGs.

Frame Sync Output

Each of the four units (A through D) produces a synchronization signal for framing serial data. The frame sync outputs are much more flexible since they must accommodate the wide variety of serial protocols used by peripherals.

Frame sync generation from a unit is independently enabled and controlled. Sources for the frame sync generation can be either from the crystal buffer output, SCLK0, or an external pin source. There is only one external source pin for both frame sync and clock output for a unit.

If an external source is selected for both frame sync and clock output for a unit, then they operate on the same input signal. Apart from enable and source select control bits, a 20-bit divisor controls frame sync generation.

Divider Mode Selection

If a frame sync divisor is greater than 1, the PCG frame sync output frequency is equal to the input clock frequency, divided by a 20-bit integer. This integer is specified in the `PCG_CTLA0.FSDIV`/`PCG_CTLB0.FSDIV` bit field (bits 19:0).

However, if the frame sync divisor is 0 or 1, the PCG's frame sync clock generation unit is bypassed, and the frame sync input is connected directly to the frame sync output. For `PCG_CTLB0.FSDIV` =0, 1 the differently than in normal mode.

Phase Shift

Phase shift is a frame sync parameter that defines the phase shift of the frame sync relative to the input clock of the same unit. This feature allows the shifting of the frame sync signal in time relative to the clock input signal. Frame sync phase shifting is often required by peripherals that need a frame sync signal to lead or lag a clock signal.

For example, the I^2S protocol specifies that the frame sync transition from high-to-low occurs one clock cycle before the beginning of a frame. Since an I^2S frame is 64 clock cycles long, delaying the frame sync by 63 cycles produces the required framing.

Phase shifting is represented as a full 20-bit value. Even when the frame sync is divided by the maximum amount, the phase can be shifted to the full range, from zero to one input clock short of the period.

NOTE: Phase shifting is specified as a 2 x 10-bit divider value in the `PCG_CTLA0.FSPHASEHI` bit field (bits 29:20) and in the `PCG_CTLA1.FSPHASELO` bit field (bits 29:20).

A single 20-bit value spans these two-bit fields. The upper half of the word (bits 19:10) is in the `PCG_CTLA0` register, and the lower half (bits 9:0) is in the `PCG_CTLA1` register.

The phase shift between clock and frame sync outputs can be programmed using the and all of the control registers under these conditions:

- The input clock source for the clock generator output and the frame sync generator output is the same.

- The clock and frame sync are enabled at the same time using a single atomic instruction.
- The frame sync divisor is an integral multiple of the clock divisor.

NOTE: When using a clock and frame sync as a synchronous pair, the units must be enabled in a single atomic instruction before their parameters are modified. Both units must also be disabled in a single atomic instruction.

NOTE: If the phase shift is 0 (see the ***Phase and Pulse Width Settings*** figure), the clock and frame sync outputs rise at the same time.

If the phase shift is 1, the frame sync output transitions one input clock period ahead of the clock transition.

If the phase shift is *divisor* – 1, the frame sync transitions *divisor* – 1 input clock periods ahead of the clock transitions.

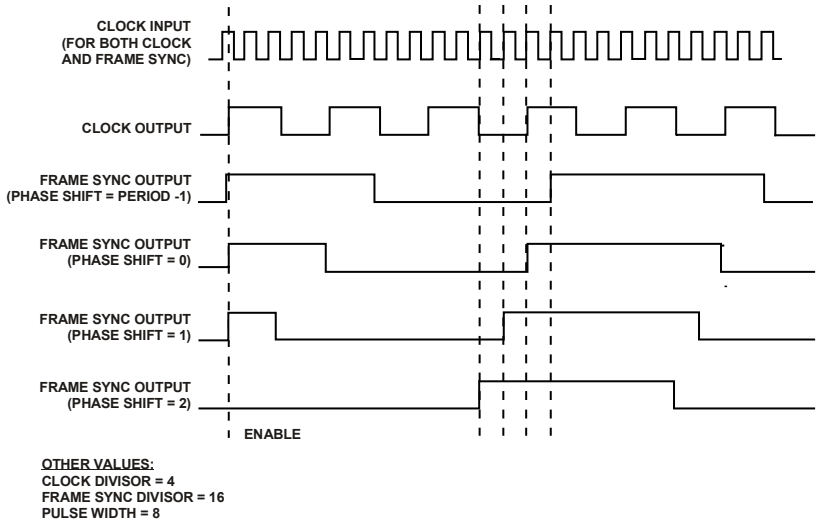

Figure 31-2: Phase and Pulse Width Settings

NOTE: When generating single frame sync pulses (the length of one SPORT clock cycle), take care with respect to the drive and sampling edges. If the rules are violated, for example if the SPORT is not driving data, the module cannot detect a valid sample edge.

Pulse Width

Pulse width is the number of input clock periods for which the frame sync output is high.

A 16-bit value determines the width of the framing pulse. Settings for pulse width can range from zero to `DIV` - 1. The pulse width should be less than the divisor of the frame sync.

Default Pulse Width

If the pulse width count is equal to 0 and if the `PCG_CTLA0.FSDIV`/`PCG_CTLB0.FSDIV` bit field is even, then the actual pulse width of the frame sync output is equal to:

For even divisors: frame sync divisor/2

If the pulse width count is equal to 0 and if the PCG_CTLA0.FSDIV/PCG_CTLB0.FSDIV bit field is odd, then the actual pulse width of the frame sync output is equal to:

For odd divisors: frame sync divisor – 1/2

Input Clock Source Considerations

The core Phase-Locked Loop (PLL) has been designed to provide clocking for the processor core. The performance specifications of this PLL are appropriate for the core. But, they have not been optimized or specified for precision data converters where jitter directly translates into time quantization errors and distortion.

Therefore, the PCG allows the routing of external clock sources which are independent of the core PLL.

Timing Example for I²S Mode

For I²S mode, the frame sync should be driven at the falling edge of SPORT clock. In other words, the frame sync edge must coincide with the falling edge of the SPORT clock. To satisfy this requirement, program the phase of the frame sync accordingly in the PCG control registers.

For example, assume that the input clock source for both clock and frame sync are the same and both the clock and frame sync are enabled at the same time. Also, assume that the clock divisor value for generating the required SPORT clock is PCG_CTLA1.CLKDIV = 4. Then, for a 32-bit word length, the frame sync divisor value is:

PCG_CTLA0.FSDIV = 64, PCG_CTLA1.CLKDIV = 4.

By default, for phase = 0, the rising edge of both SPORT clock and frame sync coincide. To make sure that the frame sync edges coincide with the falling edge of the SPORT clock, program the phase value as:

PCG_CTLA1.CLKDIV/2 = 2.

Cross Mode Connections

The symmetric dual DAI architecture allows cross connections between both PCGs (A,B) and (C,D) to the other DAI. Each PCG (A through D) supports an alternative input clock (PCG0_EXTx_I)(see Figure 31-1 PCG Block Diagram) which can be sourced via a DAI pin buffer from the other DAI. Note however if routing a source (clock or FS) only DAI pin buffer 2 to 20 can be used (DAI pin buffer 1 is no longer available and is replaced by the DAI CRS buffer for the other DAI). See for more information. See DAI Routing Capabilities for more information.

Operating Modes

The following sections provide information on the operating modes of the precision clock generator.

Normal Mode

When the frame sync divisor is set to any value other than zero or one, the PCGs operate in normal mode. In normal mode, the divisor determines the frequency of the frame sync output where:

Frequency of Frame Sync Output = Input Frequency/Divisor

The value of the pulse width control determines the high period of the frame sync output. The value of the pulse width control must be less than the value of the divisor.

The value of the phase control determines the phase of the frame sync output. If the phase is zero, then the positive edges of the clock and frame sync coincide when:

- the clock and frame sync dividers are enabled at the same time using an atomic instruction
- the divisors of the clock and frame sync are the same
- the source for the clock and frame sync is the same

The number of input clock cycles that have already elapsed before the frame sync is enabled is equal to the difference between the divisor and the phase values. If the phase is a small fraction of the divisor, then the frame sync appears to lead the clock. If the phase is only slightly less than the frame sync divisor, then the frame sync appears to lag the clock. The frame sync phase must not be greater than the divisor.

Bypass Mode

When the frame sync divisor for the frame sync has a value of zero or one, the frame sync is in bypass mode, and the different functionality than in normal mode.

NOTE: In normal mode, bits 15:0 and 31:16 of the used to program the pulse width count. In bypass mode, bits 15:2 and 31:18 are ignored. Bits 1:0 and 17:16 are renamed to `PCG_PW1.STROBEA` and `PCG_PW1.INVFSA`, respectively. This functionality is described in more detail as follows.

If the `PCG_PW1.STROBEA` register is cleared, then the input is directly passed (see the ***Bypass and Inverted Bypass*** figure) to the frame sync output either inverted or not inverted, depending on the `PCG_PW1.INVFSA` bits.

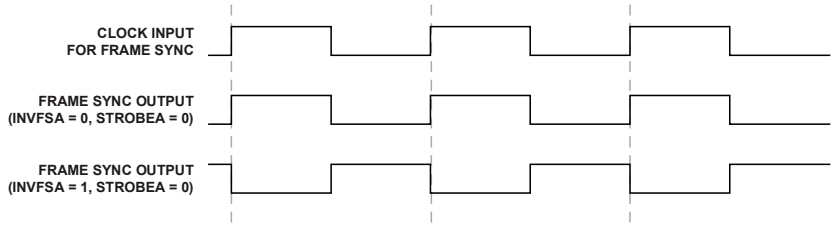

Figure 31-3: Bypass and Inverted Bypass

One-Shot Mode

In the one-shot mode operation shown in the ***One Shot Mode PCG A (MISCA2_I Input)*** figure, the PCG produces a series of periods but does not run continuously.

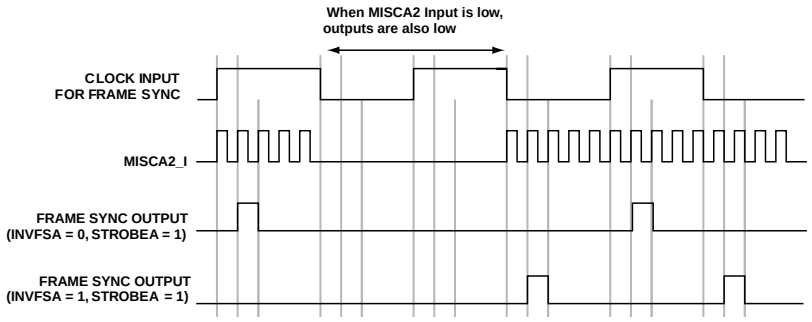

Figure 31-4: One Shot Mode PCG A (MISCA2_I Input)

Bypass mode also enables the generation of a strobe pulse (one-shot frame sync). Strobe usage ignores the divider counters and looks to the SRU to provide the input signal.

In the bypass mode, if the `PCG_PW1.STROBEA` bit =1, then a one-shot pulse is generated. This one-shot pulse has the duration equal to the period of `DAI_MISCAx_I` for the PCGx unit. This pulse is generated either at the falling or rising edge of the input clock, depending on the value of the `PCG_PW1.INVFSA` bit. The output pulse width is equal to the period of the SRU source signal `DAI_MISCAx_I`. The pulse begins at the second rising edge of `MISCAx_I` following a rising edge of the clock input. When the `PCG_PW1.INVFSA` bit is set, the pulse begins at the second rising edge of `DAI_MISCAx_I` coinciding with or following a falling edge of the clock input.

NOTE: A strobe period is defined to be the period of the FS input clock signal as specified by the `PCG_CTLA1.FSSRC` bit.

Audio System Example

The ***PCG Setup for I2S or Left-Justified DAI*** figure shows an example of the interconnections between the S/PDIF receiver, ASRC, and the PCGs. The interconnections are made by programming the signal routing unit. It shows how to set up two precision clock generators using the S/PDIF receiver and an asynchronous sample rate converter (ASRC) to interface to an external audio DAC. The PCG is configured to provide a fixed ASRC/DAC output sample rate of 65.098 kHz. The input to the S/PDIF receiver is typically 44.1 kHz if supplied by a CD player, but can also be from other source at any nominal sample rates.

Similarly, the phase shift for frame syncs B, C, and D is specified in the corresponding control registers (`PCG_CTLA0` through `PCG_CTLB1`).

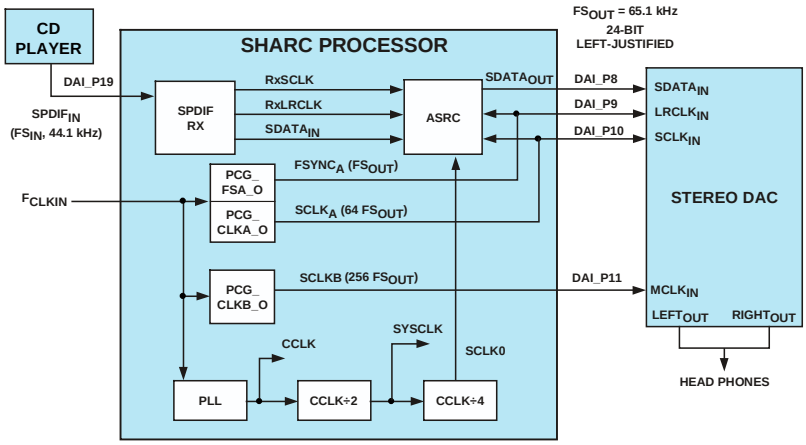

Figure 31-5: PCG Setup for I²S or Left-Justified DAI

Three synchronous clocks are required in audio systems:

1. Frame sync (FS)
2. Serial bit clock (64 FS)
3. Controller DAC clock (256 FS)

Since each PCG has only two outputs, this example requires two PCGs. Furthermore, because the digital audio interface requires a fixed-phase relation between serial clock and FS, these two outputs should come from one PCG (PCG A). The controller clock comes from the second (PCG B).

The combined PCGs can provide a selection of synchronous clock frequencies to support alternate sample rates for the ASRCs and external DACs. However, the range of choices is limited by CLKIN and the ratio of `PCG_CLKx_O`:serial clock:*FS*. The ratio is normally fixed at 256:64:1 to support digital audio left-justified, I²S and right-justified interface modes.

Many DACs also support 384, 512, and 786x FS for `PCG_CLKx_O`, which allows some additional flexibility in choosing serial clock.

Note that the falling edge of serial clock must always be synchronous with both edges of FS. This condition requires that the phase of the serial clock and FS signals for a common PCG (PCG A) be adjustable.

While the frequency of the controller DAC clock (`PCG_CLKx_O`) must be synchronous with the sample rate supplied to the external DAC, there is no fixed-phase requirement.

Set the clock divisor and source and low-phase word first, followed by the control register enable bits, which are set together. When the set to zero (default), the FS pulse width is (divisor /2) for even divisors and (divisor-1)/2 for odd divisors. Alternatively, the can be set high for exactly one-half the period of CLKIN cycles for a 50% duty cycle, provided the FS divisor is an even number.

Hardware Trigger Control

In addition to the existing enable control to generate the clock and frame sync, this feature provides a flexibility to start the clock and frame sync generation upon receiving a hardware trigger (internal slave trigger). This feature applies to all modes of operation.

For example, when the PCG_SYNC1.HWB_TRIGEN bit is set, it enables the synchronization of clock A and frame sync A to the external LRCLK sync (in external LRCLK synchronization mode) upon receiving a hardware trigger. Refer to the PCG_SYNC1.HWA_TRIGEN/ PCG_SYNC1.HWB_TRIGEN and PCG_SYNC2.HWC_TRIGEN/ PCG_SYNC2.HWD_TRIGEN bit descriptions.

NOTE: To exercise the hardware trigger based synchronization, program the destination registers (DAI_MISC2.IN0, DAI_MISC2.IN1 DAI_MISC2.IN2, and DAI_MISC2.IN3) to route the trigger signals to the PCGs . For example, if PCGA must be enabled for the hardware trigger based synchronization, program the DAI_MISC2.IN0 and DAI_EXTD_MISC2.IN0 bit fields to 5'b00000 and 2'b01, respectively. Each PCG has a dedicated trigger control from the TRU unit, there are four trigger controls for DAI0 and four trigger controls for DAI1.

Refer to TRU Slave Trigger list table for the slave trigger information.

Clock Configuration Examples

For a CLKIN = 33.330 MHz, the two PCGs provide the three synchronous clocks PCGx_CLK, serial clock and *FS* for the SRCs and external DAC. These divisors are stored in the PCG_CTLA1.CLKDIV/PCG_CTLB1.CLKDIV bit fields.

The integer divisors for several possible sample rates based on 33.330 MHz *CLKIN* are shown in the ***Precision Clock Generator Division Ratios*** table.

Table 31-2: Precision Clock Generator Division Ratios (33.330 CLKIN)

Sample Rate kHz)	PCG Divisors		FSDIV A*[1]
	CLKDIV B	CLKDIV A	
130.195	1	4	256
65.098	***2***	***8***	***512***
43.398	3	12	768
32.549	4	16	1024
26.039	5	20	1280
21.699	6	24	1536
18.599	7	28	1792

*1 The frame sync divisor must be an even integer to produce a 50% duty cycle waveform. See Frame Sync.

Global PCG Enable

For some applications, enabling multiple PCGs (CLK and FS) must be synchronized. This feature provides the flexibility to enable multiple PCGs (CLK and FS) globally. The global PCG enable feature works independently, while the legacy PCG enable (CLK and FS) remains the same. The legacy PCG enable can be used when the PCGs need to be enabled individually.

The DAI_GBL_PCG_EN register controls the enabling and disabling of PCGs globally. The global enable feature can be used in the following scenarios:

- to enable all the eight PCGs (includes both DAI0 and DAI1) at the same time
- to enable all four PCGs within each DAIx at the same time
- to enable multiple PCGs (across DAIs) at the same time

NOTE: See the DAI_GBL_PCG_EN register description for details.

Programming Guidelines

Complete the following steps to globally enable all of the PCGs :

1. Clear the individual (local) PCG enable bits from PCG_CTLx registers. (for example, PCG_CTLA0.CLKEN and PCG_CTLA0.FSEN bits) without modifying any other settings.
2. Wait for n CCLK cycles; n = PCG source clock period/processor clock period.
3. Program the PCG registers (PCG_CTLx/PCG_SYNC1) with the desired configuration without setting the PCG enable bits.
4. Enable all the required PCGs in the DAI_GBL_PCG_EN register that need to be enabled globally.

Complete the following steps to globally disable the PCGs using the DAI_GBL_PCG_EN register:

1. Disable individual PCG bits to disable a particular PCG.
2. Disable DAI0/1 enable bits to disable PCGs within the DAI.
3. Disable the global PCG enable bit in cases where all PCGs must be disabled.

PCG Event Control

The following sections describe the generation and control of PCG events.

External Event Trigger

The trigger with the external clock is enabled by setting bits 0 and 16 of the PCG_SYNC1/PCG_SYNC2/PCG_SYNC3/PCG_SYNC4 registers .

Refer to the ***FS Output Synchronization With External Trigger Input*** figure. Since the rising edge of the external clock is used to synchronize with the frame sync, the frame sync output is not generated until a rising edge of the external clock is sensed.

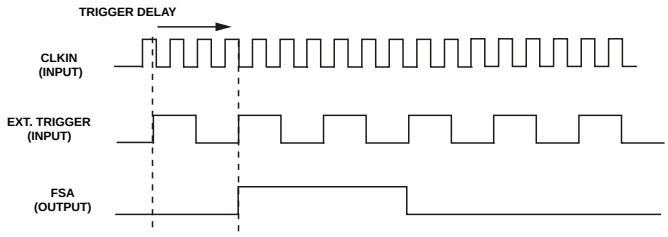

Figure 31-6: FS Output Synchronization With External Trigger Input

External Event Trigger Delay

The time delay between the rising trigger edge and the start of serial clock and frame sync varies between 2.5 to 3.5 input clock periods. If the input clock and the trigger signal are synchronous, the delay is 3 input clock periods. Consider the following cases:

- SCLK0 is the input source. In this case, if the given trigger event is synchronous to SCLK0, the delay is 3 SCLK0 periods. If the trigger signal is asynchronous with SCLK0, the delay varies from 2.5 SCLK0 periods to 3.5 SCLK0 periods. (It depends on whether the trigger edge occurs in the positive half cycle or negative half cycle of SCLK0.)
- The CLKIN source bits of the `PCG_SYNC1` register select the input source for PCG. In this case, if the given trigger signal is synchronous to CLKIN, the delay is 3 CLKIN periods. But if they are asynchronous to CLKIN, the delay can vary between 2.5 CLKIN periods to 3.5 CLKIN periods.
- SRU DAI0 is the input source for PCG A, B. If the input clock and trigger signal are synchronous, the delay is exactly 3 input clock periods. If asynchronous, it varies between 2.5 to 3.5 input clock periods depending on the phase difference between the input clock and trigger signal.

Programming Model

This section describes the sequence of software steps required for successful PCG operation.

If the PCG is disabled to reprogram a parameter, use a delay after writing to the disable bit. This delay in core clock (*CCLK*) cycles = (PCG source clock period/*CCLK* period). In summary, use the following general procedure:

1. Clear the PCG enable bits without modifying any other settings.
2. Wait for N *CCLK* cycles (N = PCG source clock period/processor clock period).
3. Program all new parameters without setting the PCG enable bit.
4. Enable the PCG.

Frame Sync Phase Setting

The phase unit requires that the clock and FS are enabled simultaneously in an atomic instruction.

1. Write the clock divider/low 10-bit phase divider to the PCG_CTLA1/PCG_CTLB1 registers.
2. Program the FS divider/high 10-bit phase divider, enabling both the PCG_CTLA0.CLKEN/PCG_CTLA0.FSEN and the PCG_CTLB0.CLKEN/PCG_CTLB0.FSEN bits.

Note that both units must be disabled in the same way.

External Event Trigger

The trigger with the external clock is is enabled by setting bits 0 and 16 of the PCG_SYNC register. Program the phase to 3, so that the rising edge of the external clock is in-sync with the frame sync (***FS Output Synchronization With External Trigger Input***).

Use the following steps.

1. Program the and the PCG_CTLA0 through PCG_CTLB1 registers appropriately.
2. Enable the clock or frame sync, or both.

Since the rising edge of the external clock is used to synchronize with the frame sync, the frame sync output is not generated until a rising edge of the external clock is sensed.

Debug Features

Take care in cases where any input to the phase unit is modified. Any individual change of the PCG_CTLA1.CLKDIV or PCG_CTLA0.FSDIV dividers can cause a failure in the PCG sync operation between the serial clock and the frame sync. Only the programming model ensures a correct setup for phase settings.

ADSP-2159x_SC591_SC592_SC594 PCG Register Descriptions

Precision Clock Generator (PCG) contains the following registers.

Table 31-3: ADSP-2159x_SC591_SC592_SC594 PCG Register List

Name	Description
PCG_CTLA0	Precision Clock A Control 0 Register
PCG_CTLA1	Precision Clock A Control 1 Register
PCG_CTLB0	Precision Clock B Control 0 Register
PCG_CTLB1	Precision Clock B Control 1 Register
PCG_CTLC0	Precision Clock C Control 0 Register
PCG_CTLC1	Precision Clock C Control 1 Register

Table 31-3: ADSP-2159x_SC591_SC592_SC594 PCG Register List (Continued)

Name	Description
PCG_CTLD0	Precision Clock D Control 0 Register
PCG_CTLD1	Precision Clock D Control 1 Register
PCG_CTLE0	Precision Clock E Control 0 Register
PCG_CTLE1	Precision Clock E Control 1 Register
PCG_CTLF0	Precision Clock F Control 0 Register
PCG_CTLF1	Precision Clock F Control 1 Register
PCG_CTLG0	Precision Clock G Control 0 Register
PCG_CTLG1	Precision Clock G Control 1 Register
PCG_CTLH0	Precision Clock H Control 0 Register
PCG_CTLH1	Precision Clock H Control 1 Register
PCG_PW1	Precision Clock Pulse Width Control 1 Register
PCG_PW2	Precision Clock Pulse Width Control 2 Register
PCG_PW3	Precision Clock Pulse Width Control 3 Register
PCG_PW4	Precision Clock Pulse Width Control 4 Register
PCG_SYNC1	Precision Clock Frame Sync Synchronization 1 Register
PCG_SYNC2	Precision Clock Frame Sync Synchronization 2 Register
PCG_SYNC3	Precision Clock Frame Sync Synchronization 3 Register
PCG_SYNC4	Precision Clock Frame Sync Synchronization 4 Register

Precision Clock A Control 0 Register

The PCG_CTLA0 register enables the clock, frame sync, and select divisor for the PCG0 clock A signal.

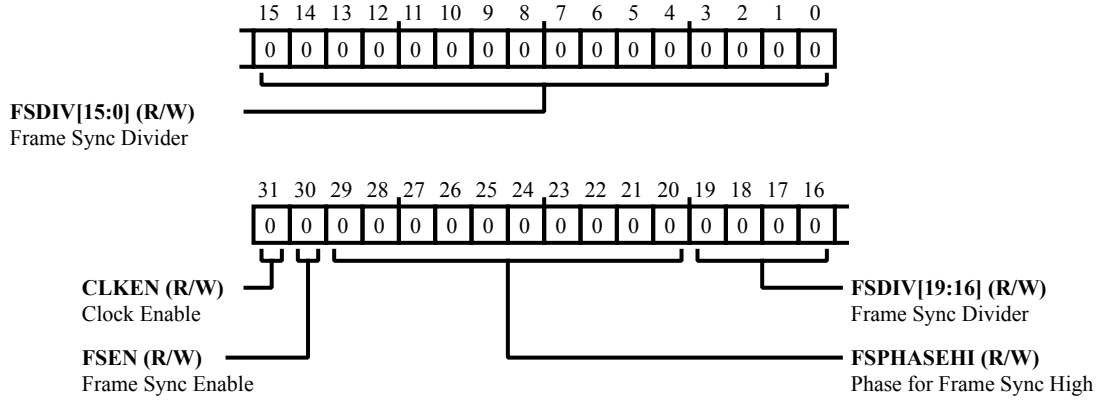

Figure 31-7: PCG_CTLA0 Register Diagram

Table 31-4: PCG_CTLA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLA0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLA0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLA0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLA0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLA0.FSDIV >1 PCGx is in normal mode, PCG_CTLA0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	PCG is in normal mode

Precision Clock A Control 1 Register

The PCG_CTLA1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock A signal.

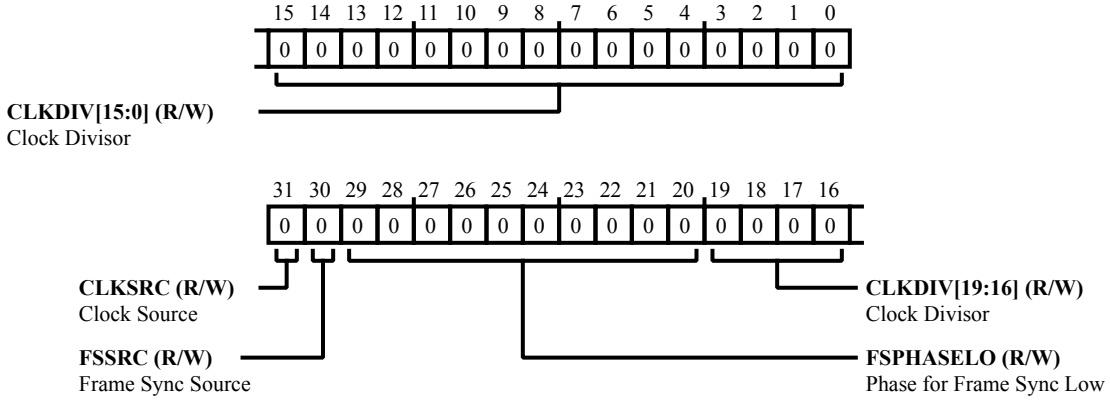

Figure 31-8: PCG_CTLA1 Register Diagram

Table 31-5: PCG_CTLA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLA1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI0 selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLA1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXTX_DAI0 selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLA1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLA1.CLKDIV bit field contains the clock divisor value.	

Precision Clock B Control 0 Register

The PCG_CTLB0 register enables the clock, frame sync, and select divisor for the PCG0 clock B signal.

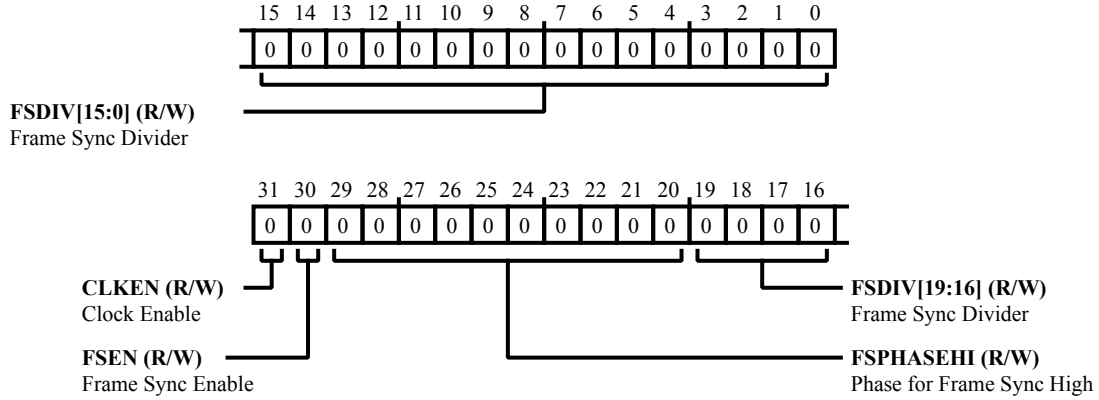

Figure 31-9: PCG_CTLB0 Register Diagram

Table 31-6: PCG_CTLB0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLB0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLB0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLB0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLB0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLB0.FSDIV >1 PCGx is in normal mode, PCG_CTLB0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock B Control 1 Register

The PCG_CTLB1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock B signal.

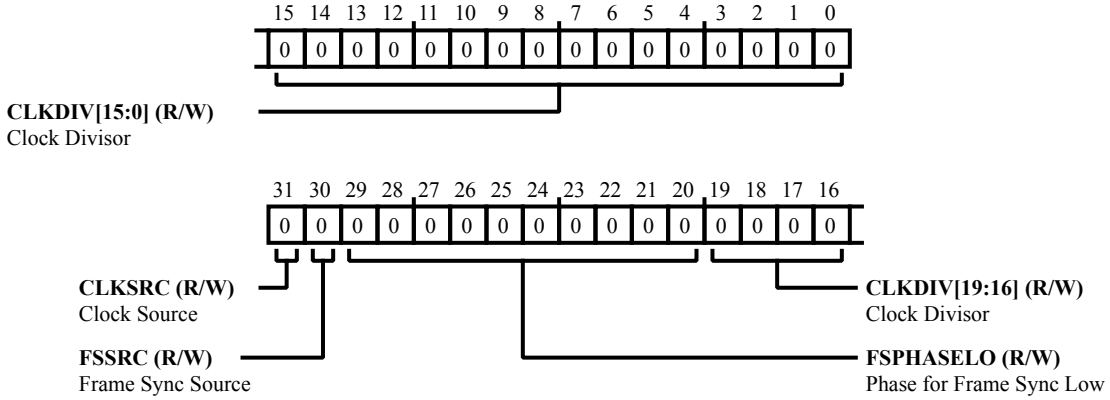

Figure 31-10: PCG_CTLB1 Register Diagram

Table 31-7: PCG_CTLB1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLB1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI0 selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLB1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXT_DAI0 selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLB1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLB1.CLKDIV bit field contains the clock divisor value.	

Precision Clock C Control 0 Register

The PCG_CTLC0 register enables the clock, frame sync, and select divisor for the PCG0 clock C signal.

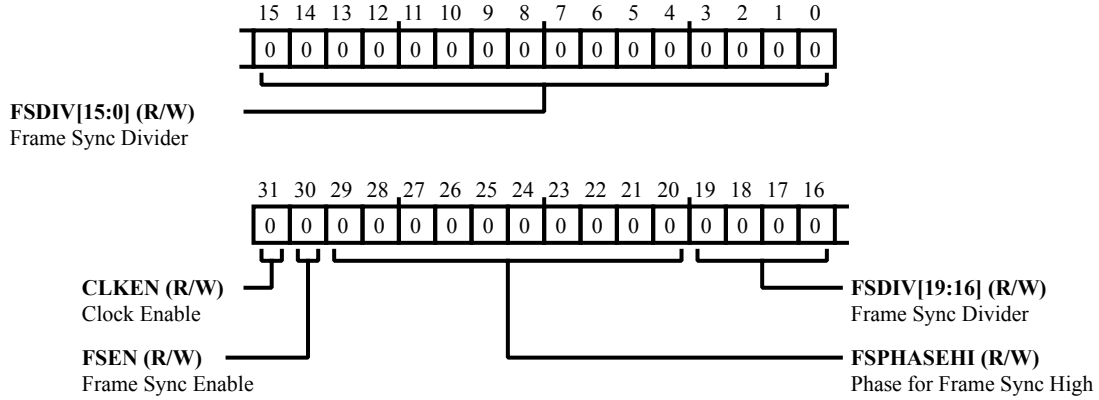

Figure 31-11: PCG_CTLC0 Register Diagram

Table 31-8: PCG_CTLC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLC0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLC0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLC0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLC0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLC0.FSDIV >1 PCGx is in normal mode, PCG_CTLC0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock C Control 1 Register

The PCG_CTLC1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock C signal.

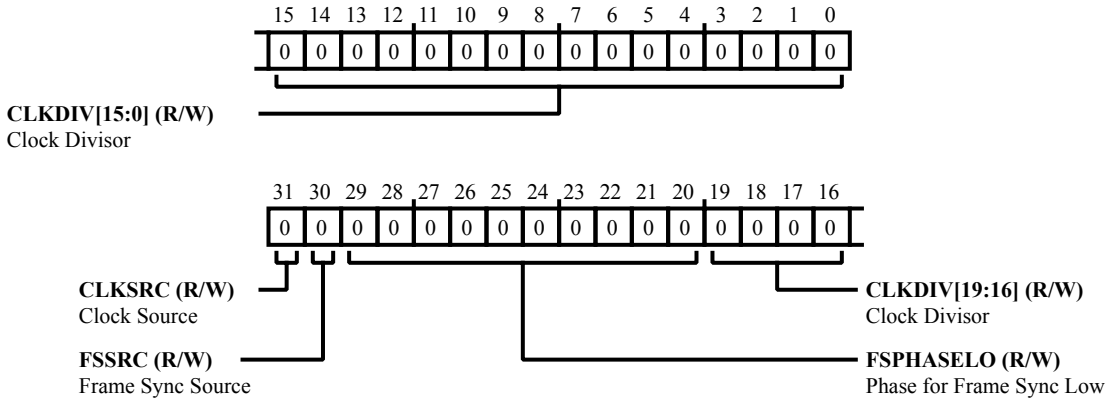

Figure 31-12: PCG_CTLC1 Register Diagram

Table 31-9: PCG_CTLC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLC1.CLKSRC bit specifies the clock source.	
		0	CLKIN1 pin selected for clock
		1	PCG_EXT_DAI1 selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLC1.FSSRC bit specifies the frame sync source.	
		0	CLKIN1 pin selected for frame sync
		1	PCG_EXT_DAI1 selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLC1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLC1.CLKDIV bit field contains the clock divisor value.	

Precision Clock D Control 0 Register

The PCG_CTLD0 register enables the clock, frame sync, and select divisor for the PCG0 clock D signal.

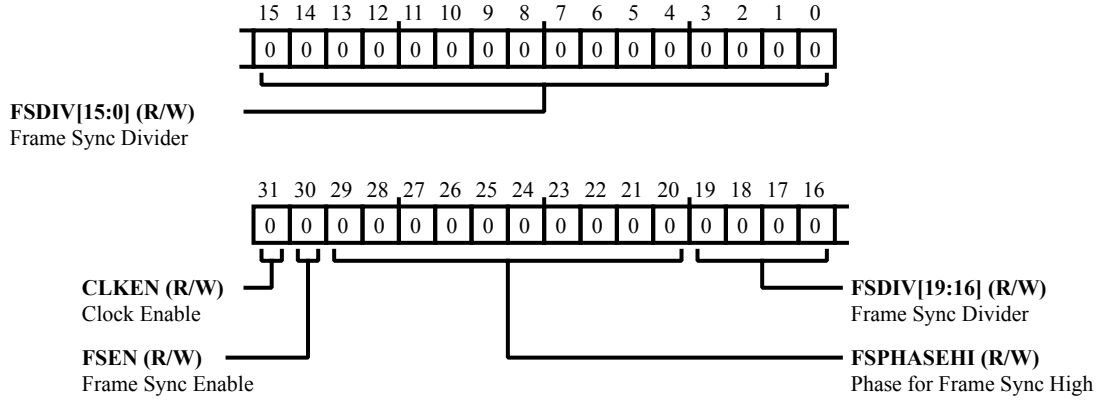

Figure 31-13: PCG_CTLD0 Register Diagram

Table 31-10: PCG_CTLD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLD0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLD0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLD0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLD0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLD0.FSDIV >1 PCGx is in normal mode, PCG_CTLD0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock D Control 1 Register

The PCG_CTLD1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock D signal.

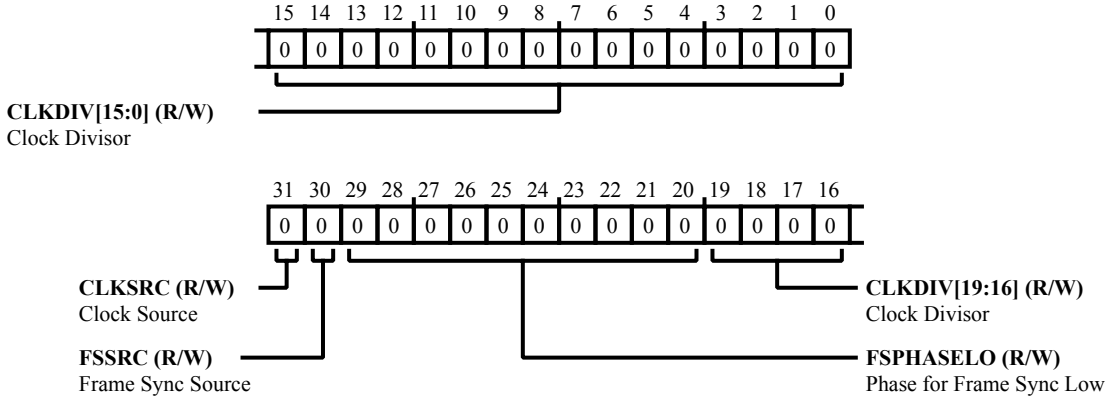

Figure 31-14: PCG_CTLD1 Register Diagram

Table 31-11: PCG_CTLD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLD1.CLKSRC bit specifies the clock source.	
		0	CLKIN1 pin selected for clock
		1	PCG_EXT_DAI1 selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLD1.FSSRC bit specifies the frame sync source.	
		0	CLKIN1 pin selected for frame sync
		1	PCG_EXT_DAI1 selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLD1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLD1.CLKDIV bit field contains the clock divisor value.	

Precision Clock E Control 0 Register

The PCG_CTLE0 register enables the clock, frame sync, and select divisor for the PCG0 clock E signal.

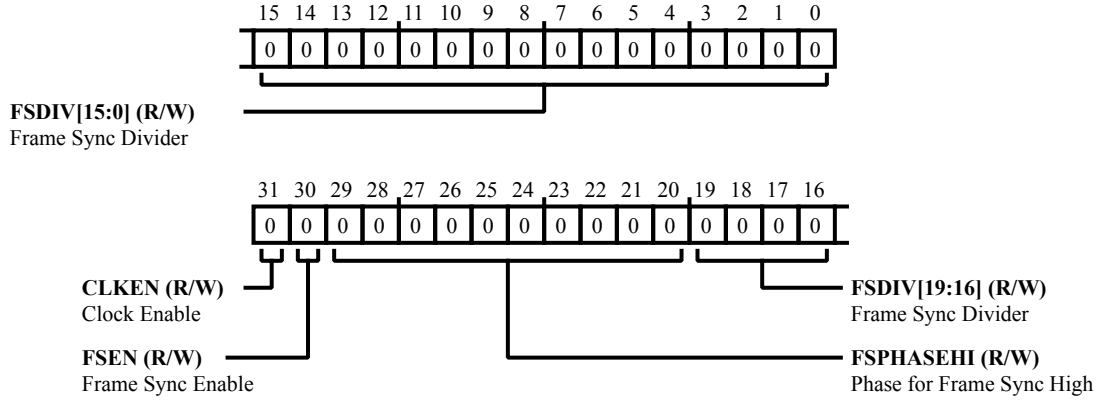

Figure 31-15: PCG_CTLE0 Register Diagram

Table 31-12: PCG_CTLE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLE0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLE0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLE0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLE0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLE0.FSDIV >1 PCGx is in normal mode, PCG_CTLE0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock E Control 1 Register

The PCG_CTLE1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock E signal.

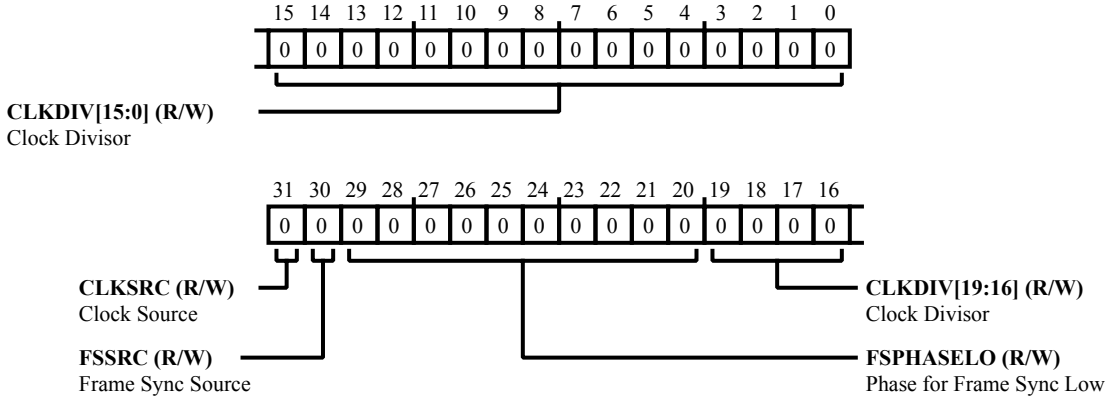

Figure 31-16: PCG_CTLE1 Register Diagram

Table 31-13: PCG_CTLE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLE1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLE1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXT_DAI selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLE1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLE1.CLKDIV bit field contains the clock divisor value.	

Precision Clock F Control 0 Register

The PCG_CTLF0 register enables the clock, frame sync, and select divisor for the PCG0 clock F signal.

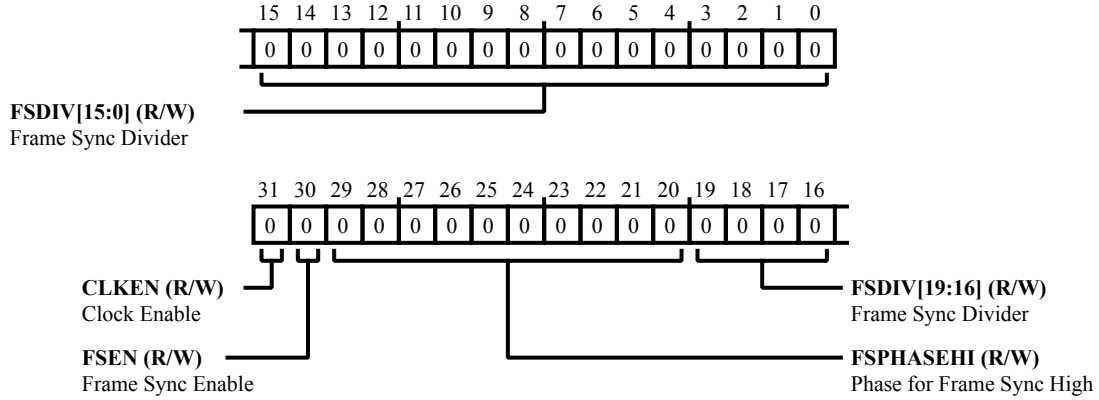

Figure 31-17: PCG_CTLF0 Register Diagram

Table 31-14: PCG_CTLF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLF0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLF0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLF0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLF0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLF0.FSDIV >1 PCGx is in normal mode, PCG_CTLF0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock F Control 1 Register

The PCG_CTLF1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock F signal.

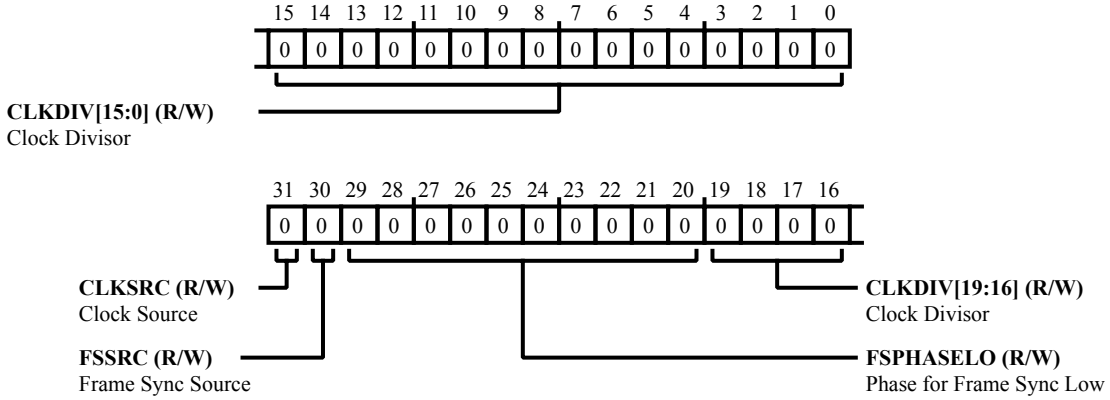

Figure 31-18: PCG_CTLF1 Register Diagram

Table 31-15: PCG_CTLF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLF1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI0 selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLF1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXT_DAI0 selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLF1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLF1.CLKDIV bit field contains the clock divisor value.	

Precision Clock G Control 0 Register

The PCG_CTLG0 register enables the clock, frame sync, and select divisor for the PCG0 clock G signal.

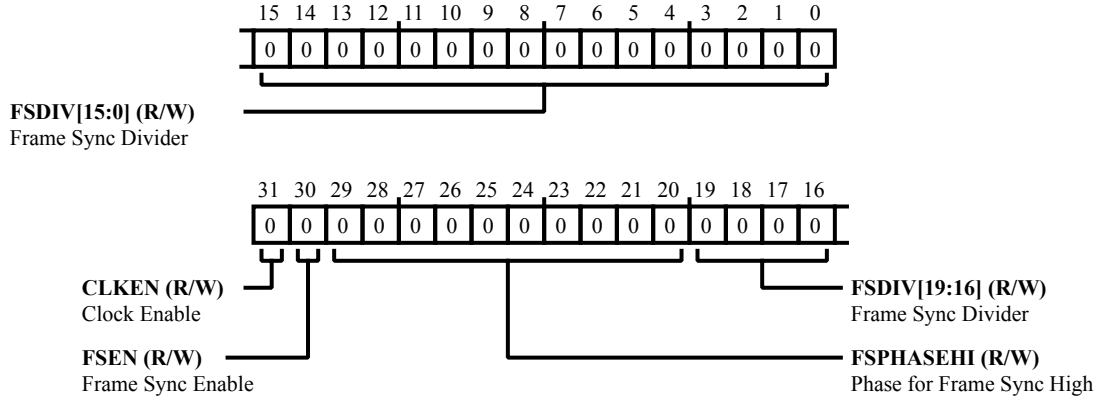

Figure 31-19: PCG_CTLG0 Register Diagram

Table 31-16: PCG_CTLG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLG0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLG0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLG0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLG0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLG0.FSDIV >1 PCGx is in normal mode, PCG_CTLG0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock G Control 1 Register

The PCG_CTLG1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock G signal.

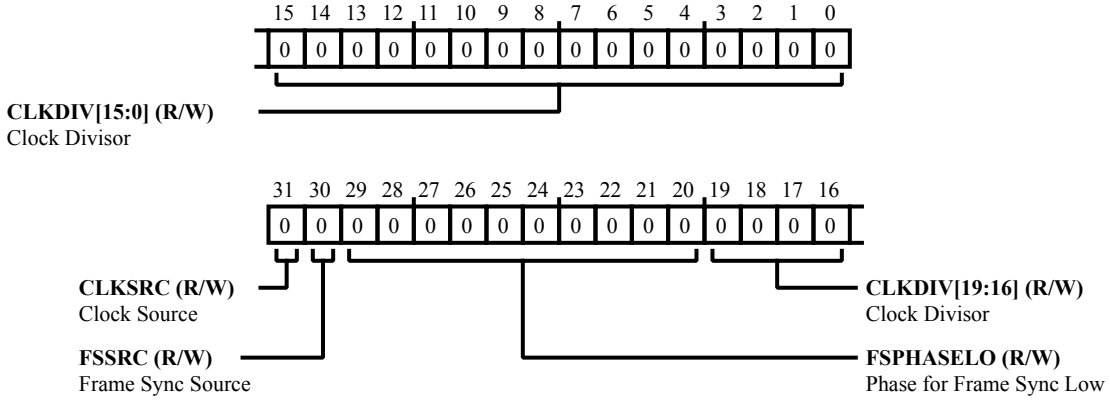

Figure 31-20: PCG_CTLG1 Register Diagram

Table 31-17: PCG_CTLG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLG1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLG1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXT_DAI selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLG1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLG1.CLKDIV bit field contains the clock divisor value.	

Precision Clock H Control 0 Register

The PCG_CTLH0 register enables the clock, frame sync, and select divisor for the PCG0 clock H signal.

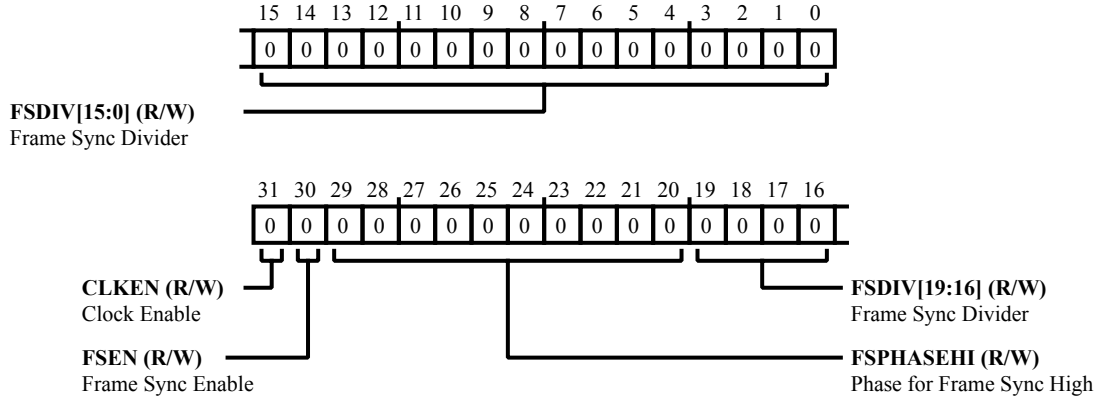

Figure 31-21: PCG_CTLH0 Register Diagram

Table 31-18: PCG_CTLH0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKEN	Clock Enable. The PCG_CTLH0.CLKEN bit enables the clock.	
		0	Clock generation disabled
		1	Clock generation enabled
30 (R/W)	FSEN	Frame Sync Enable. The PCG_CTLH0.FSEN bit enables the frame sync.	
		0	Frame sync generation disabled
		1	Frame sync generation enabled
29:20 (R/W)	FSPHASEHI	Phase for Frame Sync High. The PCG_CTLH0.FSPHASEHI bit field represents the upper half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	FSDIV	Frame Sync Divider. The PCG_CTLH0.FSDIV bit field provides the frame sync divider value. This 20-bit field frame sync divider is multiplexed where: PCG_CTLH0.FSDIV >1 PCGx is in normal mode, PCG_CTLH0.FSDIV = 0, 1 PCGx is in bypass mode.	
		0	PCG is in bypass mode
		1	PCG is in bypass mode
		2-1048575	FSDIV >1 PCG is in normal mode

Precision Clock H Control 1 Register

The PCG_CTLH1 register sets the clock divisor, frame sync source, and clock source for the PCG1 clock H signal.

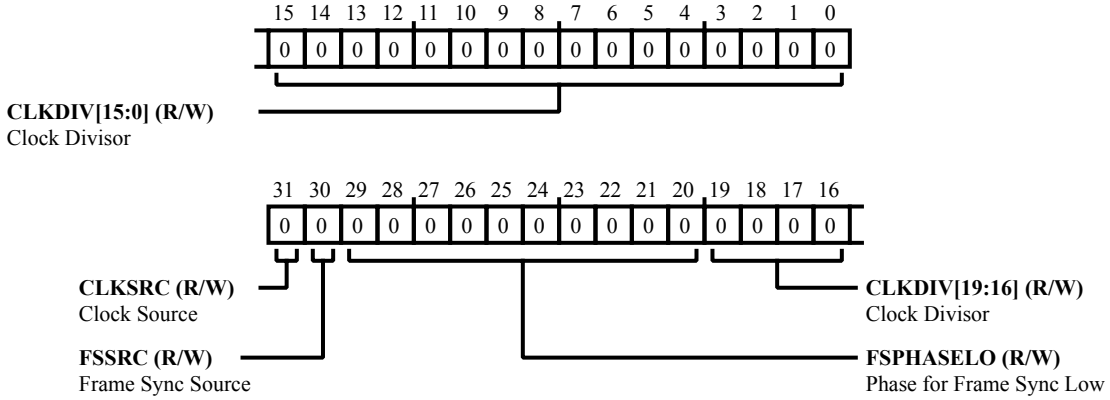

Figure 31-22: PCG_CTLH1 Register Diagram

Table 31-19: PCG_CTLH1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKSRC	Clock Source. The PCG_CTLH1.CLKSRC bit specifies the clock source.	
		0	CLKIN0 pin selected for clock
		1	PCG_EXT_DAI selected for clock
30 (R/W)	FSSRC	Frame Sync Source. The PCG_CTLH1.FSSRC bit specifies the frame sync source.	
		0	CLKIN0 pin selected for frame sync
		1	PCG_EXT_DAI selected for frame sync
29:20 (R/W)	FSPHASELO	Phase for Frame Sync Low. The PCG_CTLH1.FSPHASELO bit field represents the lower half of the 20-bit value for the channel A/B/C/D frame sync phase.	
19:0 (R/W)	CLKDIV	Clock Divisor. The PCG_CTLH1.CLKDIV bit field contains the clock divisor value.	

Precision Clock Pulse Width Control 1 Register

The PCG_PW1 register sets the one shot frame sync and the active low frame sync select for PCG A and PCG B.

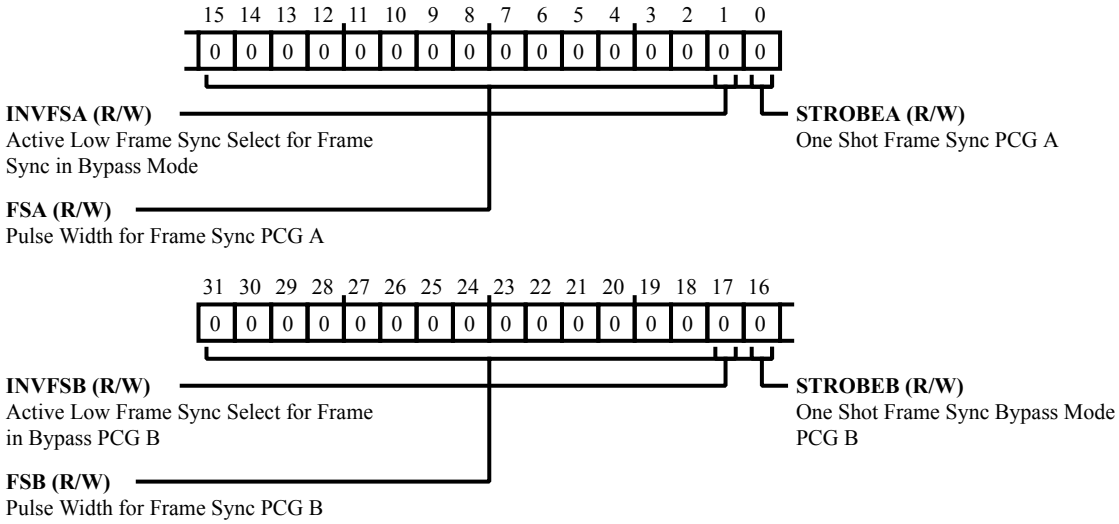

Figure 31-23: PCG_PW1 Register Diagram

Table 31-20: PCG_PW1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	INVFSB	Active Low Frame Sync Select for Frame in Bypass PCG B. The PCG_PW1.INVFSB bit selects active low or active high frame sync in bypass mode for PCG B.
16 (R/W)	STROBEB	One Shot Frame Sync Bypass Mode PCG B. The PCG_PW1.STROBEB bit sets the frame sync pulse in bypass mode for PCG B. This is the duration equal to one period of the DAI_MISCA2_I signal (PCG B) repeating at the beginning of every frame.
31:16 (R/W)	FSB	Pulse Width for Frame Sync PCG B. The PCG_PW1.FSB bit field sets the number of input clock periods for which the frame sync output is high. Pulse width should be less than the divisor of the frame sync.
1 (R/W)	INVFSA	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW1.INVFSA bit selects active low or active high frame sync for PCG A in bypass mode.
15:0 (R/W)	FSA	Pulse Width for Frame Sync PCG A. The PCG_PW1.FSA bit field sets the number of input clock periods for which the frame sync output is high. Pulse width should be less than the divisor of the frame sync.

Table 31-20: PCG_PW1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	STROBEA	One Shot Frame Sync PCG A. The `PCG_PW1.STROBEA` bit sets the frame sync pulse for PCG A in bypass mode. This is the duration equal to one period of the DAI_MISCA2_I signal (PCG A) repeating at the beginning of every frame.

Precision Clock Pulse Width Control 2 Register

The PCG_PW2 register sets the one shot frame sync and the active low frame sync select for PCG C and PCG D.

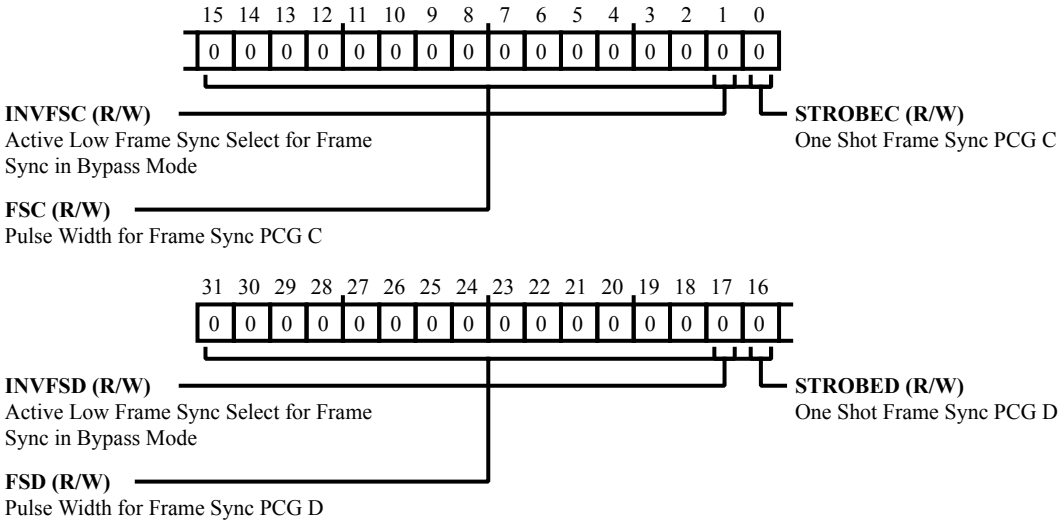

Figure 31-24: PCG_PW2 Register Diagram

Table 31-21: PCG_PW2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	INVFSD	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW2.INVFSD bit selects active low or active high frame sync for PCG D in bypass mode.
16 (R/W)	STROBED	One Shot Frame Sync PCG D. The PCG_PW2.STROBED bit sets the frame sync pulse for PCG D in bypass mode. This is the duration equal to one period of the DAI_MISCA4_I signal (PCG D) repeating at the beginning of every frame.
31:16 (R/W)	FSD	Pulse Width for Frame Sync PCG D. The PCG_PW2.FSD bit field sets the number of input clock periods for which the frame sync output is high for PCG D. Pulse width should be less than the divisor of the frame sync.
1 (R/W)	INVFSC	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW2.INVFSC bit selects active low or active high frame sync for PCG C in bypass mode.
15:0 (R/W)	FSC	Pulse Width for Frame Sync PCG C. The PCG_PW2.FSC bit field sets the number of input clock periods for which the frame sync output is high for PCG C. Pulse width should be less than the divisor of the frame sync.

Table 31-21: PCG_PW2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	STROBEC	One Shot Frame Sync PCG C. The `PCG_PW2.STROBEC` bit sets the frame sync pulse for PCG C in bypass mode. This is the duration equal to one period of the DAI_MISCA3_I signal (PCG C) repeating at the beginning of every frame.

Precision Clock Pulse Width Control 3 Register

The PCG_PW3 register sets the one shot frame sync and the active low frame sync select for PCG E and PCG F.

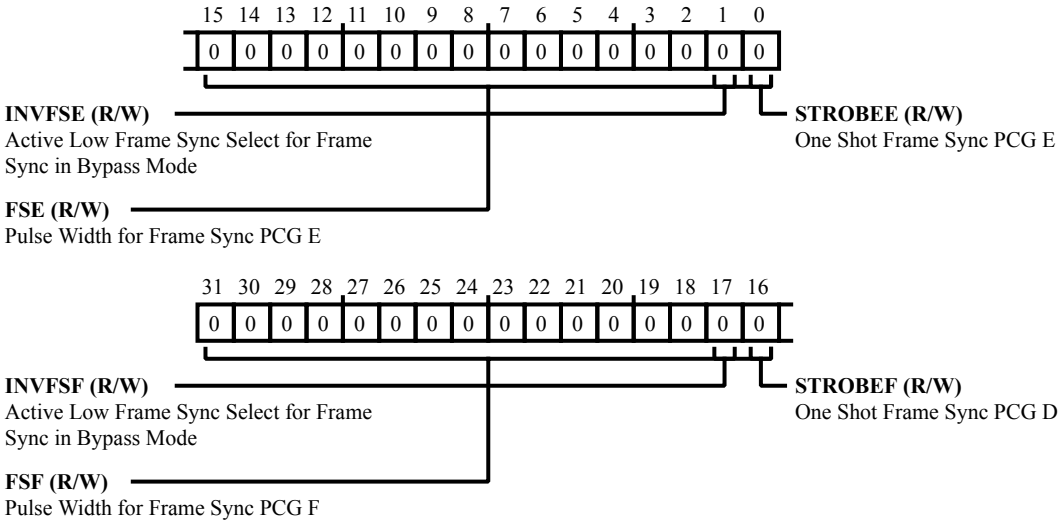

Figure 31-25: PCG_PW3 Register Diagram

Table 31-22: PCG_PW3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	INVFSF	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW3.INVFSF bit selects active low or active high frame sync for PCG F in bypass mode.
16 (R/W)	STROBEF	One Shot Frame Sync PCG D. The PCG_PW3.STROBEF bit sets the frame sync pulse for PCG F in bypass mode. This is the duration equal to one period of the DAI_MISCA4_I signal (PCG F) repeating at the beginning of every frame.
31:16 (R/W)	FSF	Pulse Width for Frame Sync PCG F. The PCG_PW3.FSF bit field sets the number of input clock periods for which the frame sync output is high for PCG F. Pulse width should be less than the divisor of the frame sync.
1 (R/W)	INVFSE	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW3.INVFSE bit selects active low or active high frame sync for PCG E in bypass mode.
0 (R/W)	STROBEE	One Shot Frame Sync PCG E. The PCG_PW3.STROBEE bit sets the frame sync pulse for PCG E in bypass mode. This is the duration equal to one period of the DAI_MISCA3_I signal (PCG E) repeating at the beginning of every frame.

Table 31-22: PCG_PW3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	FSE	Pulse Width for Frame Sync PCG E. The `PCG_PW3.FSE` bit field sets the number of input clock periods for which the frame sync output is high for PCG E. Pulse width should be less than the divisor of the frame sync.

Precision Clock Pulse Width Control 4 Register

The PCG_PW4 register sets the one shot frame sync and the active low frame sync select for PCG G and PCG H.

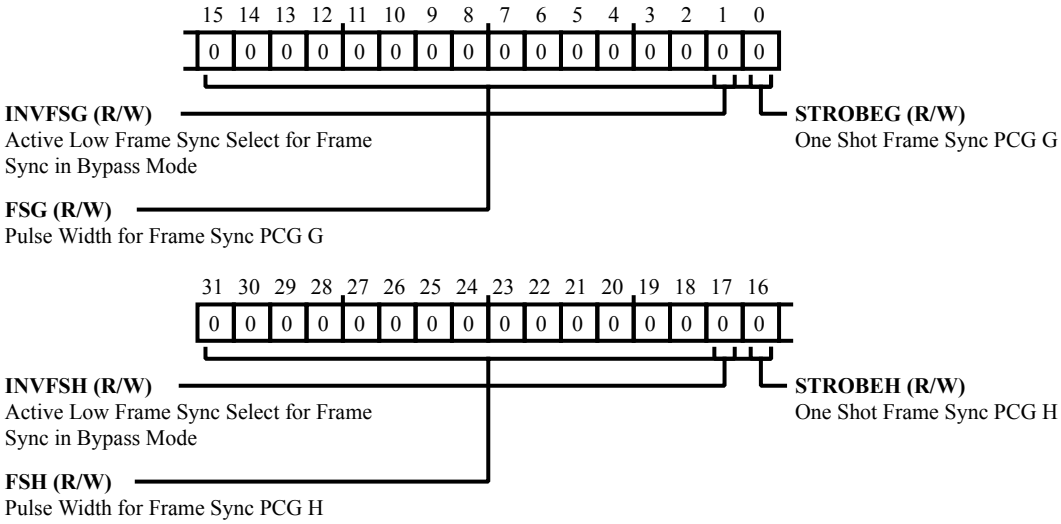

Figure 31-26: PCG_PW4 Register Diagram

Table 31-23: PCG_PW4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	INVFSH	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW4.INVFSH bit selects active low or active high frame sync for PCG H in bypass mode.
16 (R/W)	STROBEH	One Shot Frame Sync PCG H. The PCG_PW4.STROBEH bit sets the frame sync pulse for PCG H in bypass mode. This is the duration equal to one period of the DAI_MISCA4_I signal (PCG H) repeating at the beginning of every frame.
31:16 (R/W)	FSH	Pulse Width for Frame Sync PCG H. The PCG_PW4.FSH bit field sets the number of input clock periods for which the frame sync output is high for PCG H. Pulse width should be less than the divisor of the frame sync.
1 (R/W)	INVFSG	Active Low Frame Sync Select for Frame Sync in Bypass Mode. The PCG_PW4.INVFSG bit selects active low or active high frame sync for PCG G in bypass mode.
15:0 (R/W)	FSG	Pulse Width for Frame Sync PCG G. The PCG_PW4.FSG bit field sets the number of input clock periods for which the frame sync output is high for PCG G. Pulse width should be less than the divisor of the frame sync.

Table 31-23: PCG_PW4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	STROBEG	One Shot Frame Sync PCG G. The `PCG_PW4.STROBEG` bit sets the frame sync pulse for PCG G in bypass mode. This is the duration equal to one period of the DAI_MISCA3_I signal (PCG G) repeating at the beginning of every frame.

Precision Clock Frame Sync Synchronization 1 Register

The PCG_SYNC1 register allows programs to synchronize the clock frame sync units with external frame syncs. Note that the PCG_CTLA1.CLKSRC bit is overridden if PCG_SYNC1.CLKASRC bit in the PCG_SYNC1 register is set.

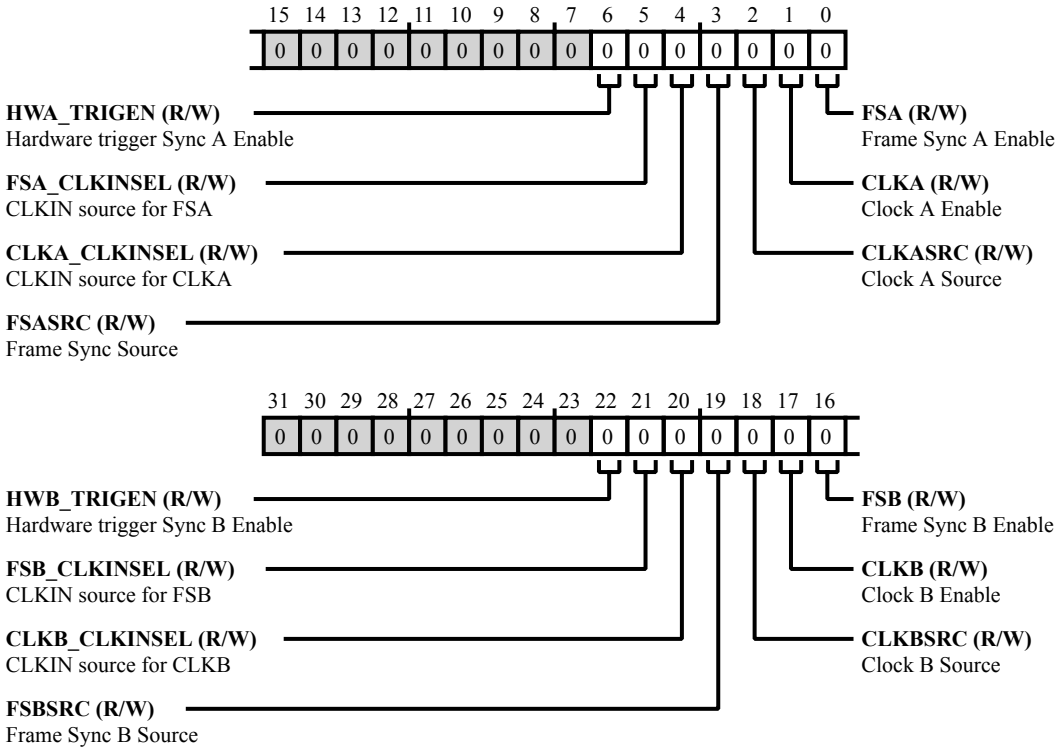

Figure 31-27: PCG_SYNC1 Register Diagram

Table 31-24: PCG_SYNC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	HWB_TRIGEN	Hardware trigger Sync B Enable. The PCG_SYNC1.HWB_TRIGEN bit enables synchronization of clock B and frame sync B with the external frame sync only after an internal slave trigger for PCG B is received.	
21 (R/W)	FSB_CLKINSEL	CLKIN source for FSB. The PCG_SYNC1.FSB_CLKINSEL bit enables the CLKIN input source for FSB	
		0	Selects CLKIN0 source for FSB CLKIN
		1	Selects CLKIN1 source for FSB CLKIN

Table 31-24: PCG_SYNC1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	CLKB_CLKINSEL	CLKIN source for CLKB. The `PCG_SYNC1.CLKB_CLKINSEL` bit enables the CLKIN input source for CLKB	
		0	Select CLKIN0 source for CLKB CLKIN
		1	Select CLKIN1 source for CLKB CLKIN
19 (R/W)	FSBSRC	Frame Sync B Source. The `PCG_SYNC1.FSBSRC` bit enables the frame sync B input source.	
		0	Output selected by FSBSOURCE bit
		1	Clock derived from core PLL selected for frame sync B
18 (R/W)	CLKBSRC	Clock B Source. The `PCG_SYNC1.CLKBSRC` bit enables the clock B input source.	
		0	Output selected by CLKBSOURCE bit
		1	Clock derived from core PLL selected for clock B
17 (R/W)	CLKB	Clock B Enable. The `PCG_SYNC1.CLKB` bit enables synchronization of clock B with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
16 (R/W)	FSB	Frame Sync B Enable. The `PCG_SYNC1.FSB` bit enables synchronization of frame sync B with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled
6 (R/W)	HWA_TRIGEN	Hardware trigger Sync A Enable. The `PCG_SYNC1.HWA_TRIGEN` bit enables synchronization of clock A and frame sync A with the external frame sync only after an internal slave trigger for PCG A is received.	
5 (R/W)	FSA_CLKINSEL	CLKIN source for FSA. The `PCG_SYNC1.FSA_CLKINSEL` bit enables the CLKIN input source for FSA	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-24: PCG_SYNC1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	CLKA_CLKINSEL	CLKIN source for CLKA. The `PCG_SYNC1.CLKA_CLKINSEL` bit enables the CLKIN input source for CLKA	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
3 (R/W)	FSASRC	Frame Sync Source. The `PCG_SYNC1.FSASRC` bit enables the frame sync A input source.	
		0	Output selected by FSASOURCE bit
		1	Clock derived from core PLL selected for frame sync A
2 (R/W)	CLKASRC	Clock A Source. The `PCG_SYNC1.CLKASRC` bit enables the clock A input source.	
		0	Output selected by CLKASOURCE bit
		1	Clock derived from core PLL selected for clock A
1 (R/W)	CLKA	Clock A Enable. The `PCG_SYNC1.CLKA` bit enables synchronization of clock A with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
0 (R/W)	FSA	Frame Sync A Enable. The `PCG_SYNC1.FSA` bit enables synchronization of frame sync A with the external frame sync.	
		0	Frame Sync Disabled
		1	Frame Sync Enabled

Precision Clock Frame Sync Synchronization 2 Register

The PCG_SYNC2 register allows programs to synchronize the clock frame sync units with external frame syncs. Note that the PCG_CTLD1.CLKSRC bit is overridden if PCG_SYNC2.CLKDSRC bit in the PCG_SYNC2 register is set.

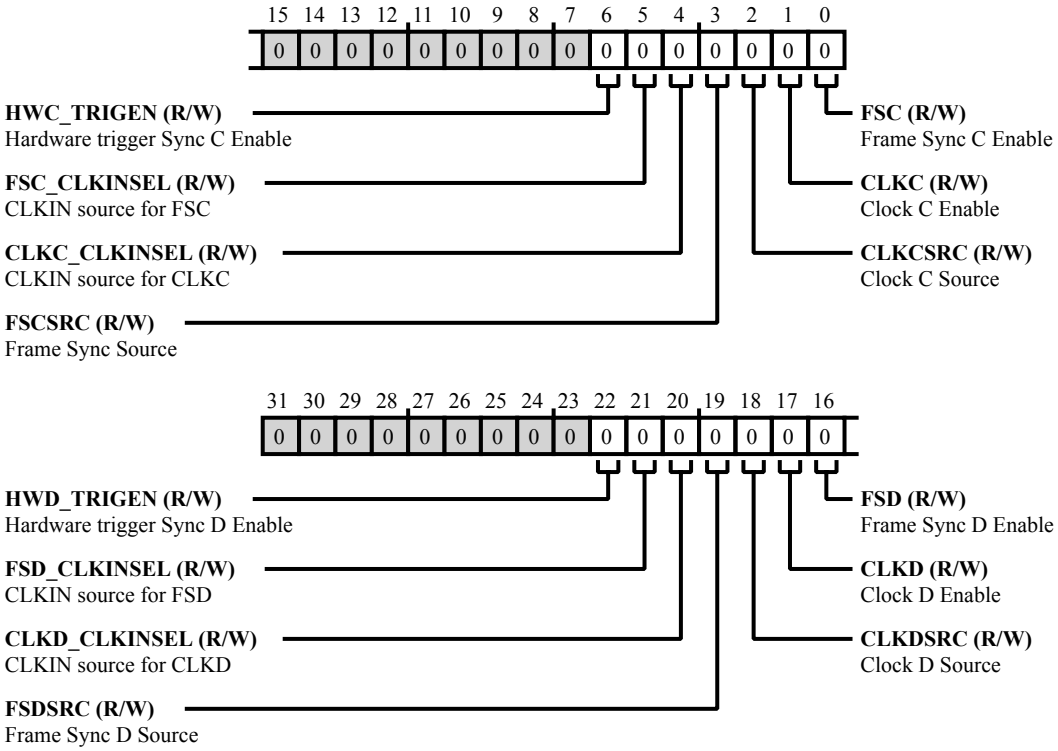

Figure 31-28: PCG_SYNC2 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	HWD_TRIGEN	Hardware trigger Sync D Enable. The PCG_SYNC2.HWD_TRIGEN bit enables synchronization of clock D and frame sync D with the external frame sync only after an internal slave trigger for PCG D is received.	
21 (R/W)	FSD_CLKINSEL	CLKIN source for FSD. The PCG_SYNC2.FSD_CLKINSEL bit enables the CLKIN input source for FSD	
		0	Selects CLKIN0 source for FSB CLKIN
		1	Selects CLKIN1 source for FSB CLKIN

Table 31-25: PCG_SYNC2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	CLKD_CLKINSEL	CLKIN source for CLKD. The `PCG_SYNC2.CLKD_CLKINSEL` bit enables the CLKIN input source for CLKD	
		0	Select CLKIN0 source for CLKB CLKIN
		1	Select CLKIN1 source for CLKB CLKIN
19 (R/W)	FSDSRC	Frame Sync D Source. The `PCG_SYNC2.FSDSRC` bit enables the frame sync D input source.	
		0	Output selected by FSDSOURCE bit
		1	Clock derived from core PLL selected for frame sync D
18 (R/W)	CLKDSRC	Clock D Source. The `PCG_SYNC2.CLKDSRC` bit enables the clock D input source.	
		0	Output selected by CLKDSOURCE bit
		1	Clock derived from core PLL selected for clock D
17 (R/W)	CLKD	Clock D Enable. The `PCG_SYNC2.CLKD` bit enables synchronization of clock D with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
16 (R/W)	FSD	Frame Sync D Enable. The `PCG_SYNC2.FSD` bit enables synchronization of frame sync D with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled
6 (R/W)	HWC_TRIGEN	Hardware trigger Sync C Enable. The `PCG_SYNC2.HWC_TRIGEN` bit enables synchronization of clock C and frame sync C with the external frame sync only after an internal slave trigger for PCG C is received.	
5 (R/W)	FSC_CLKINSEL	CLKIN source for FSC. The `PCG_SYNC2.FSC_CLKINSEL` bit enables the CLKIN input source for FSC	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-25: PCG_SYNC2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	CLKC_CLKINSEL	CLKIN source for CLKC. The `PCG_SYNC2.CLKC_CLKINSEL` bit enables the CLKIN input source for CLKC	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
3 (R/W)	FSCSRC	Frame Sync Source. The `PCG_SYNC2.FSCSRC` bit enables the frame sync C input source.	
		0	Output selected by FSCSOURCE bit
		1	Clock derived from core PLL selected for frame sync C
2 (R/W)	CLKCSRC	Clock C Source. The `PCG_SYNC2.CLKCSRC` bit enables the clock C input source.	
		0	Output selected by CLKCSOURCE bit
		1	Clock derived from core PLL selected for clock C
1 (R/W)	CLKC	Clock C Enable. The `PCG_SYNC2.CLKC` bit enables synchronization of clock C with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
0 (R/W)	FSC	Frame Sync C Enable. The `PCG_SYNC2.FSC` bit enables synchronization of frame sync C with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled

Precision Clock Frame Sync Synchronization 3 Register

The PCG_SYNC3 register allows programs to synchronize the clock frame sync units with external frame syncs. Note that the PCG_CTLD1.CLKSRC bit is overridden if CLKDSRC bit in the PCG_SYNC3 register is set.

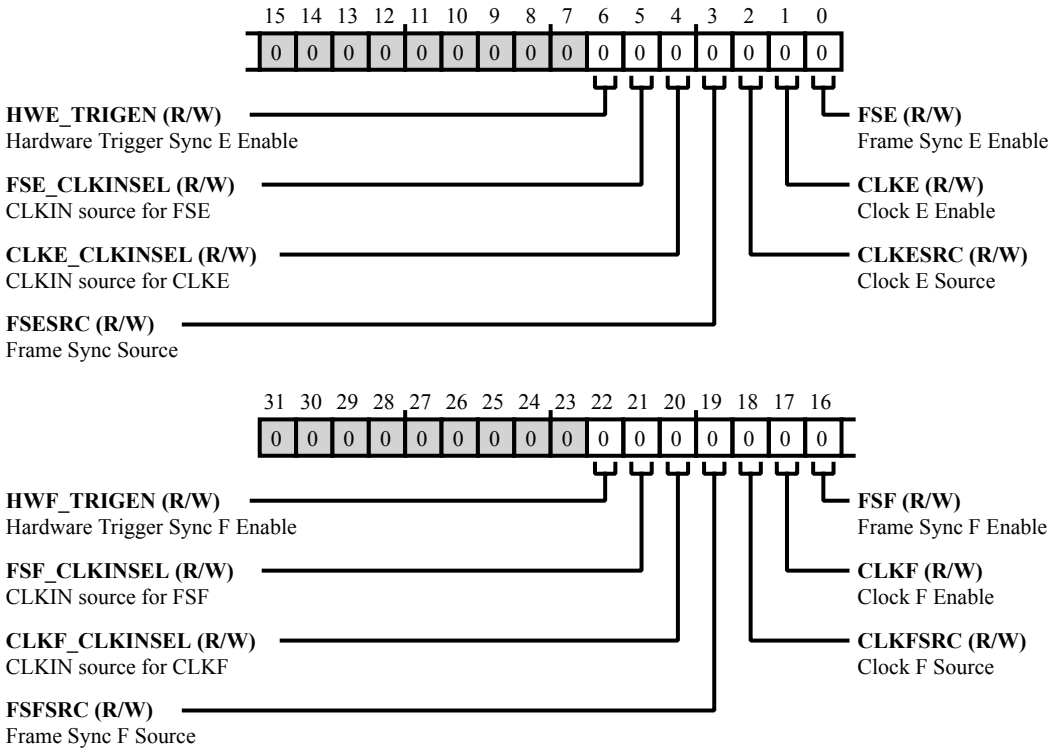

Figure 31-29: PCG_SYNC3 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	HWF_TRIGEN	Hardware Trigger Sync F Enable. The PCG_SYNC3.HWF_TRIGEN bit enables synchronization of clock F and frame sync F with the external frame sync only after an internal slave trigger for PCG-F is received.	
21 (R/W)	FSF_CLKINSEL	CLKIN source for FSF. The PCG_SYNC3.FSF_CLKINSEL bit enables the CLKIN input source for FSF	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-26: PCG_SYNC3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	CLKF_CLKINSEL	CLKIN source for CLKF. The `PCG_SYNC3.CLKF_CLKINSEL` bit enables the CLKIN input source for CLKF	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
19 (R/W)	FSFSRC	Frame Sync F Source. The `PCG_SYNC3.FSFSRC` bit enables the frame sync F input source.	
		0	Output selected by FSDSOURCE bit
		1	Clock derived from core PLL selected for frame sync D
18 (R/W)	CLKFSRC	Clock F Source. The `PCG_SYNC3.CLKFSRC` bit enables the clock F input source.	
		0	Output selected by CLKDSOURCE bit
		1	Clock derived from core PLL selected for clock D
17 (R/W)	CLKF	Clock F Enable. The `PCG_SYNC3.CLKF` bit enables synchronization of clock F with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
16 (R/W)	FSF	Frame Sync F Enable. The `PCG_SYNC3.FSF` bit enables synchronization of frame sync F with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled
6 (R/W)	HWE_TRIGEN	Hardware Trigger Sync E Enable. The `PCG_SYNC3.HWE_TRIGEN` bit enables synchronization of clock E and frame sync E with the external frame sync only after an internal slave trigger for PCG-E is received.	
5 (R/W)	FSE_CLKINSEL	CLKIN source for FSE. The `PCG_SYNC3.FSE_CLKINSEL` bit enables the CLKIN input source for FSE	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-26: PCG_SYNC3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	CLKE_CLKINSEL	CLKIN source for CLKE. The `PCG_SYNC3.CLKE_CLKINSEL` bit enables the CLKIN input source for CLKE	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
3 (R/W)	FSESRC	Frame Sync Source. The `PCG_SYNC3.FSESRC` bit enables the frame sync E input source.	
		0	Output selected by FSCSOURCE bit
		1	Clock derived from core PLL selected for frame sync C
2 (R/W)	CLKESRC	Clock E Source. The `PCG_SYNC3.CLKESRC` bit enables the clock E input source.	
		0	Output selected by CLKCSOURCE bit
		1	Clock derived from core PLL selected for clock C
1 (R/W)	CLKE	Clock E Enable. The `PCG_SYNC3.CLKE` bit enables synchronization of clock E with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
0 (R/W)	FSE	Frame Sync E Enable. The `PCG_SYNC3.FSE` bit enables synchronization of frame sync E with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled

Precision Clock Frame Sync Synchronization 4 Register

The PCG_SYNC4 register allows programs to synchronize the clock frame sync units with external frame syncs. Note that the PCG_CTLD1.CLKSRC bit is overridden if CLKDSRC bit in the PCG_SYNC4 register is set.

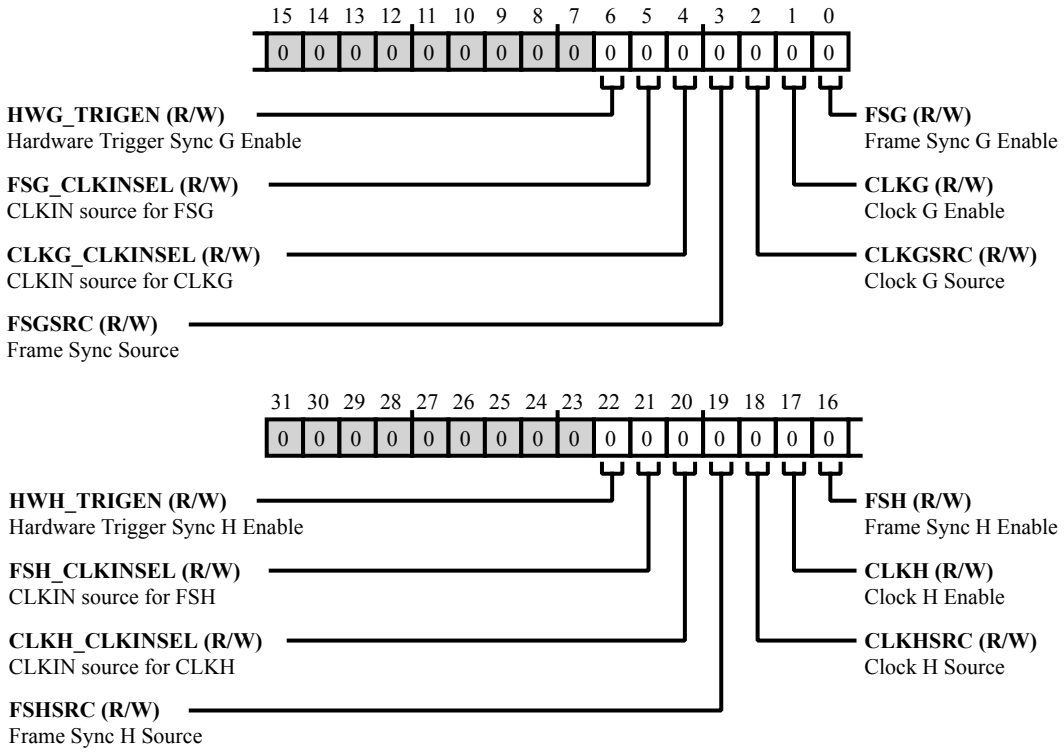

Figure 31-30: PCG_SYNC4 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	HWH_TRIGEN	Hardware Trigger Sync H Enable. The PCG_SYNC4.HWH_TRIGEN bit enables synchronization of clock H and frame sync H with the external frame sync only after an internal slave trigger for PCG-H is received.	
21 (R/W)	FSH_CLKINSEL	CLKIN source for FSH. The PCG_SYNC4.FSH_CLKINSEL bit enables the CLKIN input source for FSH	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-27: PCG_SYNC4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	CLKH_CLKINSEL	CLKIN source for CLKH. The `PCG_SYNC4.CLKH_CLKINSEL` bit enables the CLKIN input source for CLKH	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
19 (R/W)	FSHSRC	Frame Sync H Source. The `PCG_SYNC4.FSHSRC` bit enables the frame sync H input source.	
		0	Output selected by FSDSOURCE bit
		1	Clock derived from core PLL selected for frame sync D
18 (R/W)	CLKHSRC	Clock H Source. The `PCG_SYNC4.CLKHSRC` bit enables the clock H input source.	
		0	Output selected by CLKDSOURCE bit
		1	Clock derived from core PLL selected for clock D
17 (R/W)	CLKH	Clock H Enable. The `PCG_SYNC4.CLKH` bit enables synchronization of clock H with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
16 (R/W)	FSH	Frame Sync H Enable. The `PCG_SYNC4.FSH` bit enables synchronization of frame sync H with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled
6 (R/W)	HWG_TRIGEN	Hardware Trigger Sync G Enable. The `PCG_SYNC4.HWG_TRIGEN` bit enables synchronization of clock G and frame sync G with the external frame sync only after an internal slave trigger for PCG-G is received.	
5 (R/W)	FSG_CLKINSEL	CLKIN source for FSG. The `PCG_SYNC4.FSG_CLKINSEL` bit enables the CLKIN input source for FSG	
		0	Selects CLKIN0 as source for FSA CLKIN
		1	Selects CLKIN1 as source for FSA CLKIN

Table 31-27: PCG_SYNC4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	CLKG_CLKINSEL	CLKIN source for CLKG. The `PCG_SYNC4.CLKG_CLKINSEL` bit enables the CLKIN input source for CLKG	
		0	Select CLKIN0 source for CLKA CLKIN
		1	Select CLKIN1 source for CLKA CLKIN
3 (R/W)	FSGSRC	Frame Sync Source. The `PCG_SYNC4.FSGSRC` bit enables the frame sync G input source.	
		0	Output selected by FSCSOURCE bit
		1	Clock derived from core PLL selected for frame sync C
2 (R/W)	CLKGSRC	Clock G Source. The `PCG_SYNC4.CLKGSRC` bit enables the clock G input source.	
		0	Output selected by CLKCSOURCE bit
		1	Clock derived from core PLL selected for clock C
1 (R/W)	CLKG	Clock G Enable. The `PCG_SYNC4.CLKG` bit enables synchronization of clock G with the external frame sync.	
		0	Clock disabled
		1	Clock enabled
0 (R/W)	FSG	Frame Sync G Enable. The `PCG_SYNC4.FSG` bit enables synchronization of frame sync G with the external frame sync.	
		0	Frame sync disabled
		1	Frame sync enabled

32 Asynchronous Sample Rate Converter (ASRC)

Sample rate converters (SRC) are frequently used in digital signal processing audio applications. The most frequently used sample rate conversions are off-loaded into hardware modules that are dedicated for filter processing and reduce the instruction processing load on the core, freeing it up for other tasks.

Features

The ASRC has these features and capabilities.

- 4 asynchronous stereo SRCs operating in slave mode are available in each DAI
- Simple programming model
- Controllable muting options (hardware, software and automatic)
- Automatically senses input and output sample frequencies
- Supports left-justified, I^2S, right-justified (16-,18-, 20-, 24-bits), and TDM serial port modes
- Daisy-chain configuration in TDM modes (including between DAI0 and DAI1) for input and output ports to create a serial frame
- Different protocols on input/output port allow format conversions
- De-emphasis filter for 32, 44.1 and 48 kHz sampling frequencies
- Up to 192 kHz sample rate input/output continuous sample ratios from 7.5:1 to 1:8
- Group delay (latency of interpolation filter) is 16 samples
- SNR from 128 to 140 dB (depending on processor model)
- Matched phase mode available to compensate for group delays
- Can be used to de-jitter clocks in systems

Functional Description

Conceptually, the sample rate converter interpolates the serial input data at a rate of 220 and samples the interpolated data stream by the output sample rate. In practice, a 64-tap FIR filter with 220 polyphases, a FIFO, a digital servo loop that measures the time difference between the input and output samples within 5 ps, and a digital circuit to track the sample rate ratio are used to perform the interpolation and output sampling.

ADSP-2159x_SC591_SC592_SC594 ASRC Register List

Sample Rate Converter Module

Table 32-1: ADSP-2159x_SC591_SC592_SC594 ASRC Register List

Name	Description
ASRC_CTL01	Control Register for ASRC 0 and 1
ASRC_CTL23	Control Register for ASRC 2 and 3
ASRC_MUTE	Mute Register
ASRC_RAT01	Ratio Register for ASRC 0 and 1
ASRC_RAT23	Ratio Register for ASRC 2 and 3

ASRC Interrupt List

The ASRC interrupts are controlled through the DAI.

Table 32-2: ASRC Interrupt List

Interrupt ID	Interrupt Name	Interrupt Condition
20	DAI0_IRQH	ASRC initialization ASRC sample rate change
21	DAI1_IRQH	
116	DAI0_IRQL	
117	DAI1_IRQL	

ASRC Block Diagram

The ***ASRC Block Diagram*** figure shows a top level block diagram of the ASRC module and the ***Core Architecture*** figure shows architecture details.

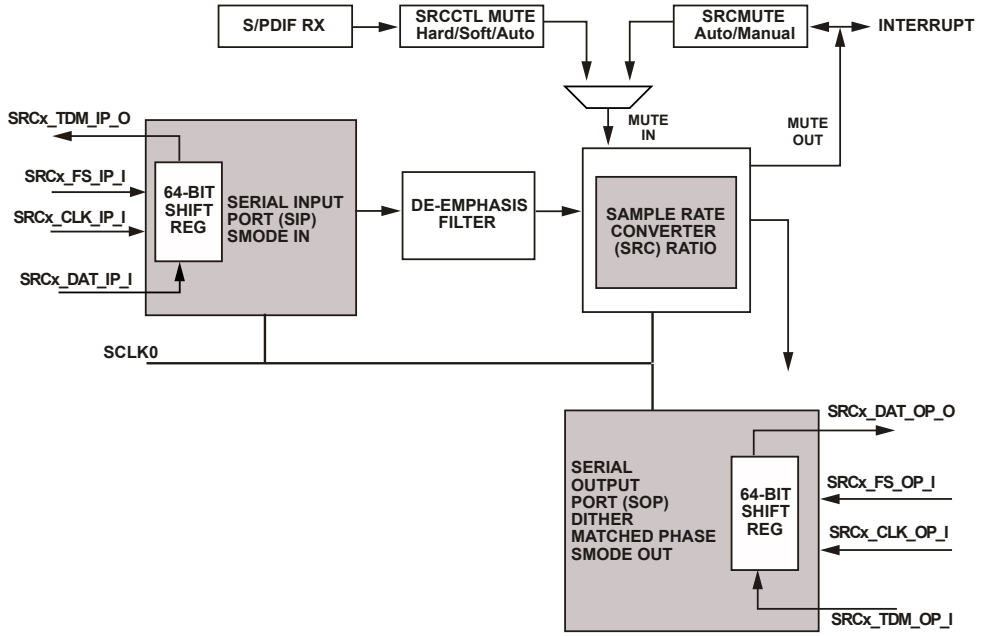

Figure 32-1: ASRC Block Diagram

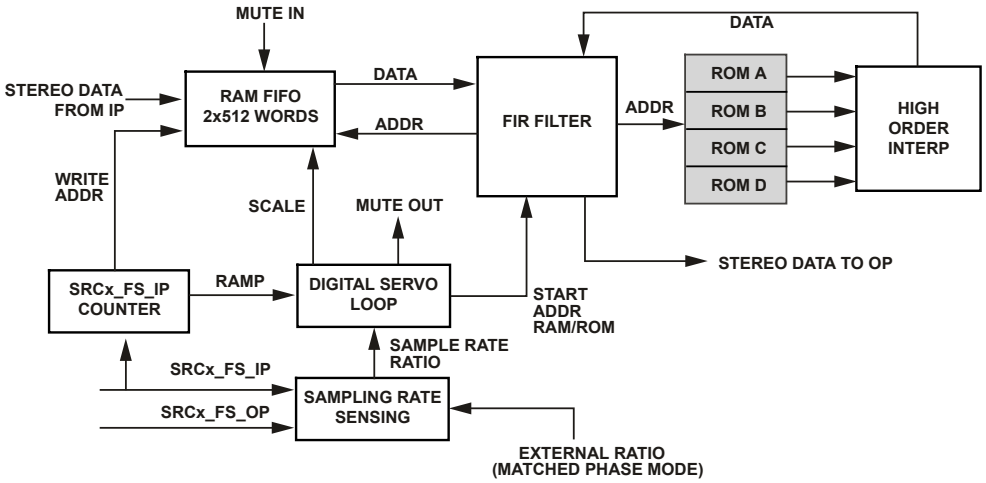

Figure 32-2: ASRC Core Architecture

SRU Programming

The SRU (signal routing unit) needs to be programmed in order to connect the ASRCs to the output pins or any other peripherals. For more information, see the Digital Audio Interface (DAI) chapter.

Clocking

The ASRC module is in the SCLK0 clock domain. An internal divided version of the SCLK0 clock is generated and used as the fundamental clock for the ASRC module.

I/O Ports

The I/O ports provide the interface through which data is transferred asynchronously into and out of the SRC modules. The SRC has a 3-wire interface for the serial input and output ports that supports left-justified, I^2S, and right-justified (16-, 18-, 20-, 24-bit) modes. Additionally, the serial interfaces support TDM mode for daisy-chaining multiple SRCs to form a frame. The serial output data is dithered down to 20, 18, or 16 bits when 20-, 18-, or 16-bit output data is selected.

NOTE: The SRC converts the data from the serial input port to the sample rate of the serial output port. The sample rate at the serial input port can be asynchronous with respect to the output sample rate of the output serial port.

De-Emphasis Filter

The de-emphasis filter is used to de-emphasize audio data that has been emphasized.

Mute Control

When either the SRC starts up (or there is a change in sample ratio), the mute out signal (`SRCx_MUTEOUT`) is asserted (=1). The mute out signal stays high until the SRC settles on the new sample rates. While mute out is asserted high, the mute in signal should be asserted high as well. The mute in signal performs a soft mute of the audio input data when asserted and un-mutes the input audio data softly when deasserted.

Note that it takes 4096 input port FS samples until the audio input data is completely muted and 4096 FS samples until the audio input data is completely unmuted.

SRC Core

As shown in the ***ASRC Core Architecture*** figure, the sample rate converter's RAM FIFO block adjusts the left and right input samples and stores them for the FIR filter's convolution cycle. The `ASRCx_FS_IP` counter provides the write address (for scaling) to the FIFO block and the ramp input to the digital-servo loop. The ROM stores the coefficients for the FIR filter convolution and performs a high-order interpolation between the stored coefficients. The sample rate ratio block measures the sample rate by dynamically altering the ROM coefficients and scaling the FIR filter length and input data. The digital-servo loop automatically tracks the `SRCx_FS_IP` and `SRCx_FS_OP` sample rates and provides the RAM and ROM start addresses for the start of the FIR filter convolution.

NOTE: Unlike other peripherals, the sample rate converters own local memories (RAM and ROM) which are dedicated for the purpose of sample rate conversion only.

The sample rate converter only operates asynchronously and is always a slave to the input and output ports.

RAM FIFO

The RAM FIFO receives the left and right input data and adjusts the amplitude of the data for both the soft muting of the SRC and the scaling of the input data by the sample rate ratio before storing the samples in RAM. The input data is scaled by the sample rate ratio because as the FIR filter length of the convolution increases, so does the

amplitude of the convolution output. To keep the output of the FIR filter from saturating, the input data is scaled down by multiplying it by (SRCx_FS_OP)/(SRCx_FS_IP) when SRCx_FS_OP<SRCx_FS_IP. The FIFO also scales the input data to mute and stop muting the SRC.

Digital Servo Loop

The digital-servo loop is essentially a ramp filter that provides the initial pointer to the address in RAM and ROM for the start of the FIR convolution. The RAM pointer is the integer output of the ramp filter while the ROM pointer is the fractional part. The digital-servo loop must be able to provide excellent rejection of jitter on the SRCx_FS_IP and SRCx_FS_OP clocks as well as measure the arrival of the SRCx_FS_OP clock within 5 ps. The digital-servo loop also divides the fractional part of the ramp output by the ratio of (SRCx_FS_IP)/(SRCx_FS_OP) for the case when SRCx_FS_IP> SRCx_FS_OP, to dynamically alter the ROM coefficients.

The digital-servo loop is implemented with a multi-rate filter. To settle the digital-servo loop filter quickly at startup or at a change in the sample rate, a fast mode has been added to the filter. When the digital-servo loop starts up or the sample rate is changed, the digital-servo loop kicks into fast mode to adjust and settle on the new sample rate. Upon sensing the digital-servo loop settling down to some reasonable value, the digital-servo loop kicks into normal or slow mode. During fast mode, the SRCx_MUTE_OUT bit of the ASRC is asserted to mute the ASRC input which avoids clicks and pops.

FIR Filter

The FIR filter is a 64-tap filter in the case of SRCx_FS_OP<SRCx_FS_IP and is (SRCx_FS_IP)/(SRCx_FS_OP) × 64 taps for the case when SRCx_FS_IP>SRCx_FS_OP. The FIR filter performs its convolution by loading in the starting address of the RAM address pointer and the ROM address pointer from the digital-servo loop at the start of the SRCx_FS_OP period. The FIR filter then steps through the RAM by decrementing its address by 1 for each tap, and the ROM pointer increments its address by the (SRCx_FS_OP/SRCx_FS_IP) × 2^{20} ratio for SRCx_FS_IP>SRCx_FS_OP or 2^{20} for SRCx_FS_OP <SRCx_FS_IP. Once the ROM address rolls over, the convolution is complete. The convolution is performed for both the left and right channels, and the multiply/accumulate circuit used for the convolution is shared between the channels.

Sample Rate Sensing

The (SRCx_FS_IP)/(SRCx_FS_OP) sample rate ratio circuit is used to dynamically alter the coefficients in the ROM for the case when SRCx_FS_IP>SRCx_FS_OP. The ratio is calculated by comparing the output of an SRCx_FS_OP counter to the output of an SRCx_FS_IP counter. If ASRCx_FS_OP>SRCx_FS_IP, the ratio is held at one. If SRCx_FS_IP>SRCx_FS_OP, the sample rate ratio is updated if it is different by more than two SRCx_FS_OP periods from the previous SRCx_FS_OP to SRCx_FS_IP comparison. This is done to provide some hysteresis to prevent the filter length from oscillating and causing distortion.

Digital Filter Group Delay

The RAM in the FIFO is 512 words deep for both left and right channels. An offset of 16 samples to the write address, provided by the SRCx_FS_IP counter, is added to prevent the RAM read pointer from overlapping the write address. The maximum decimation rate can be calculated from the RAM word: depth = (512 – 16) ÷ 64 taps = 7.75:1.

The 64 samples effect latency in the interpolation filter. This latency (group delay) depends on interpolation or decimation ratio and is determined as follows:

Interpolation or Decimation Ratio (1): GDL = $16/f_{S\_IN} + 32/f_{S\_IN}$ seconds for SRC_FS_OP > SRC_FS_IP

Interpolation or Decimation Ratio (2): GDL = $16/f_{S\_IN} + 32/f_{S\_IN} \times f_{S\_IN}/f_{S\_OUT}$ seconds for SRC_FS_OP < SRC_FS_IP

Data Format

The ***ASRC Data Frame Format by Protocol*** figure shows the data input format for a frame (stereo data). The frame format is valid for all protocols. For models which do not support matched phase mode the 8-bit data field is ignored.

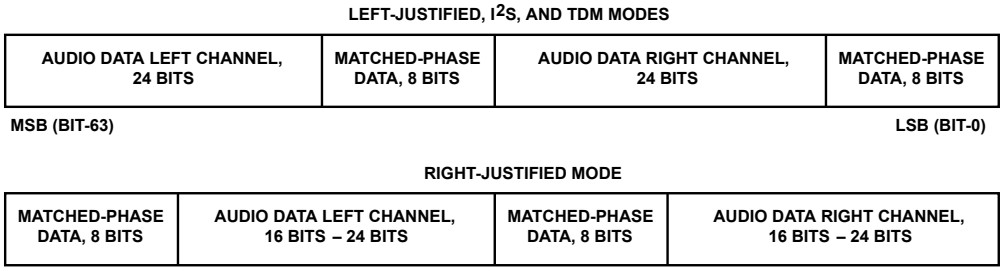

Figure 32-3: ASRC Data Frame Format by Protocol

Operating Modes

The ASRC can operate in TDM, I²S, left-justified, right-justified, and bypass modes. The serial ports of the processor can be used for moving the ASRC data to/from the internal memory.

In I²S, left-justified and right-justified modes, the ASRCs operate individually. The serial data provided in the input port is converted to the sample rate of the output port.

TDM Input Mode

In TDM input port, several ASRCs can be daisy-chained together and connected to the serial input port of a SHARC processor or other processor (see the ***TDM Input/Output Modes*** figure). The ASRC IP contains a 64-bit parallel load shift register. When the SRCx_FS_IP_I pulse arrives, each ASRC parallel loads its left and right data into the 64-bit shift register. The input to the shift register is connected to SRCx_DATA_IP_I, while the output is connected to SRCx_TDM_IP_O. By connecting the SRCx_TDM_IP_O to the SRCx_DATA_IP_I of the next ASRC, a large shift register is created, which is clocked by SRCx_CLK_IP_I.

NOTE: In TDM mode, the ASRC drives at the rising edge and samples at the falling edge of the serial clock. In all other modes, the serial clock rising edge is the sampling edge, and the falling edge is the driving edge.

NOTE: The number of ASRCs that can be daisy-chained together is limited by the maximum frequency of SRCx_CLK_xx_I, refer to the data sheet for exact values. For example, if the maximum frequency of

SRCx_CLK_xx_I is *x* MHz, and the output sample rate is *fS*, then number of ASRCs (n) that can be connected in daisy chained fashion is: n 64 FS ≤ *x* MHz.

TDM Output Mode

As shown in the ***TDM Input/Output Modes*** figure, using the TDM output port several ASRCs can be daisy-chained together and connected to the SPORT of this or another processor. The ASRC OP contains a 64-bit parallel load shift register. When the SRCx_FS_OP_I pulse arrives, each ASRC loads its left and right data into the 64-bit shift register. The input to the shift register is connected to SRCx_TDM_OP_I, and the output is connected to SRCx_DAT_OP_O. By connecting the SRCx_DAT_OP_O to the SRCx_TDM_OP_I of the next ASRC, a large shift register is created, which is clocked by SRCx_CLK_OP_I.

As shown in ***TDM Input/Output Modes***, with three ASRCs in a daisy-chain connection, the serial clock for input/or output port is defined as: SYSCLK = 3 × 64 FS = 192 FS.

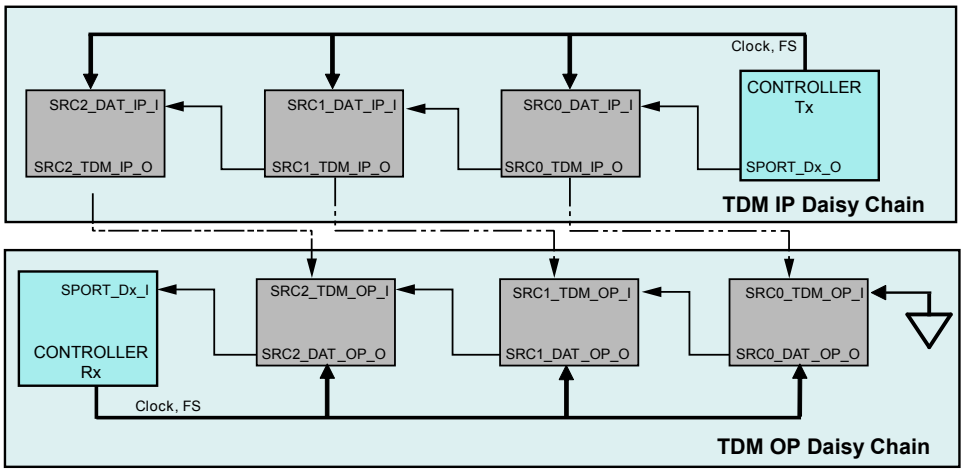

Figure 32-4: TDM Input/Output Modes

Matched-Phase Mode

The matched-phase mode of the sample rate converter, shown in ***Typical Configuration for Matched-Phase Mode Operation***, is enabled by the ASRC_CTL01.MPHASE0, ASRC_CTL01.MPHASE1, ASRC_CTL23.MPHASE2 and ASRC_CTL23.MPHASE3 bits. This mode is used to match the phase (group delay) between two or more adjacent sample rate converters that are operating with the same input and output clocks.

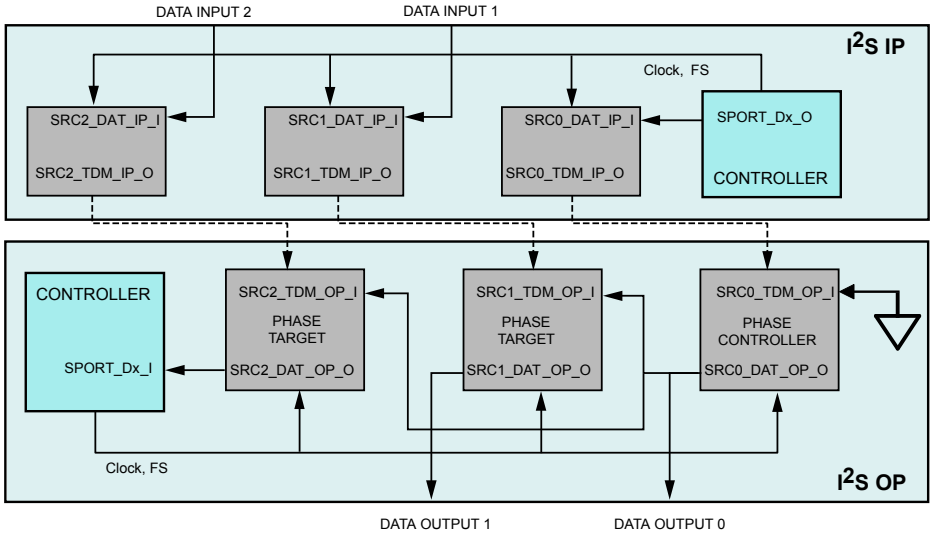

Figure 32-5: Typical Configuration for Matched-Phase Mode Operation

Hysteresis of the (SRCx_FS_OP)/(SRCx_FS_IP) ratio circuit can cause phase mismatching between two ASRCs operating with the same input and output clocks. Since the hysteresis requires a difference of more than two SRCx_FS_OP periods to update the SRCx_FS_OP and SRCx_FS_IP ratios, two ASRCs may have differences in their ratios from 0 to 4 SRCx_FS_OP period counts. The (SRCx_FS_OP)/(SRCx_FS_IP) ratio adjusts the filter length of the ASRC, which corresponds directly with the group delay. Thus, the magnitude in the phase difference depends upon the resolution of the SRCx_FS_OP and SRCx_FS_IP counters. The greater the resolution of the counters, the smaller the phase difference error.

When the completer SRC matched-phase mode bit is set (=1), it accepts the sample rate ratio transmitted by another SRC, (the matched-phase requester) which has its matched-phase mode bit cleared (=0), through its serial output.

The phase requester ASRC device transmits its SRCx_FS_OP/SRCx_FS_IP ratio through the data output pin (SRCx_DAT_OP_O) to the completer's ASRC's data input pins (SRCx_TDM_OP_I). The transmitted data (32-bit subframe) contains 24-bit data and 8-bits matched phase (see the ***ASRC Data Frame Format by Protocol*** figure).

The completer SRCs receive the 8-bit matched phase bits (instead of their own internally-derived ratio) if their SRCx_MPHASE bits are set to 1, respectively. The SRCx_FS_IP and SRCx_FS_OP signals may be asynchronous with respect to each other in this mode. Note that there must be 64 SRCx_CLK_OP cycles per frame in matched-phase mode (two 24-bits data and two 8-bits phase match).

NOTE: By default, matched phased data is sent on the SRCx_DAT_OP_O pin, but only if the SRCx_TDM_OP_I pin is tied low. The completers' simply ignore the matched phased data if their ASRC_CTL01.MPHASE1 through ASRC_CTL23.MPHASE3 bits are cleared (= 0).

Bypass Mode

When the ASRC_CTL01.BYP0, ASRC_CTL01.BYP1, ASRC_CTL23.BYP2 and ASRC_CTL23.BYP3 bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. Dithering is disabled. This mode is ideal when the input and output sample rates are the same and the SRCx_FS_IP_I and

SRCx_FS_OP_I signals are synchronous with respect to each other. In matched phase bypass mode, the SRCx_FS_OP_I signal should come at least one SRCx_CLK_xx_I period before SRCx_FS_IP_I. Cases where this is not met could result in data loss. For example, if internal SPORTS are used then the SRCx_FS_OP_I and SRCx_FS_IP_I signals could be driven by different SPORTs so that the timing of these signals can be controlled by enabling them at different times. This mode can also be used for passing through non-audio data since no processing is performed on the input data.

De-Emphasis Mode

The ASRC_CTL01.DEEMPHASIS0, ASRC_CTL01.DEEMPHASIS1, ASRC_CTL23.DEEMPHASIS2 and ASRC_CTL23.DEEMPHASIS3 bits choose the type of de-emphasis filter based on the input sample rate for 32, 44.1 or 48 kHz sampling rates.

Dithering Mode

The ASRC_CTL01.DITHER0, ASRC_CTL01.DITHER1, ASRC_CTL23.DITHER2, and ASRC_CTL23.DITHER3 control this mode of operation. Serial output data is dithered down to 20, 18, or 16 bits when 20-, 18-, or 16-bit output data is selected. In the case of 20-, 18- and 16-bit word lengths, the least significant bits of the 24-bit word coming from the SRC into the serial output port are truncated. The DITHER_EN signal (not user configurable) automatically adds dithering to the 24-bit word before truncating to the appropriate output word length. The 21BIT_DITHER signal is used for the consumer version of the SRC to reduce the dynamic range performance to approximately 128 dB.

NOTE: The ASRC can be programmed to add the triangular Probability Distribution Function (PDF) dither to the digital audio samples. It is advisable to add dither when the input word width exceeds the output word width, for example the input word is 20 bits and the output word is 16 bits. Triangular PDF is generally considered to create the most favorable noise shaping of the residual quantization noise.

Muting Modes

The mute feature of the ASRC can be controlled automatically in hardware using the MUTE_IN signal by connecting it to the MUTE_OUT signal. Automatic muting can be disabled by setting (=1) the ASRC_MUTE.MUTE0 through ASRC_MUTE.MUTE3 bits.

NOTE: Note that by default, the ASRC_MUTE register connects the MUTE_IN signal to the MUTE_OUT signal, but not conversely.

Soft Mute

When the ASRC_CTL01.SOFTMUTE0, ASRC_CTL01.SOFTMUTE1, ASRC_CTL23.SOFTMUTE2 and ASRC_CTL23.SOFTMUTE3 bits are set, the MUTE_IN signal is asserted, and the ASRC performs a soft mute by linearly decreasing the input data to the ASRC FIFO to zero, (-144 dB) attenuation as described for automatic hardware muting.

A 12-bit counter, clocked by SRCx_FS_IP_I, is used to control the mute attenuation. Therefore, the time it takes from the assertion of the MUTE_IN signal to -144 dB, full mute attenuation is 4096 FS cycles. Likewise, the time it takes to reach 0 dB mute attenuation from the deassertion of the MUTE_IN signal is 4096 FS cycles.

Hard Mute

When the ASRC_CTL01.HARDMUTE0, ASRC_CTL01.HARDMUTE1, ASRC_CTL23.HARDMUTE2 and ASRC_CTL23.HARDMUTE3 bits are set, the ASRC immediately mutes the input data to the ASRC FIFO to zero, (-144 dB) attenuation.

Auto Mute

When the ASRC_CTL01.AUTOMUTE0, ASRC_CTL01.AUTOMUTE1, ASRC_CTL23.AUTOMUTE2 and ASRC_CTL23.AUTOMUTE3 bits are set, the ASRC communicates with the S/PDIF receiver peripheral to determine when the input should mute.

This mode is useful for automatic detection of non-PCM audio data received from the S/PDIF receiver.

Interrupts

The following sections provide information about interrupt sources, masking and servicing.

Sources

Each ASRC module drives one interrupt signal (mute out asserted). All these signals are connected into the DAI_IRPTL_H or DAI_IRPTL_L latch registers. The ASRC ports generate interrupts as described below.

SRC Mute Out

The SRC mute out signal can be used to generate interrupts on their rising edge, falling edge, or both, depending on how the DAI interrupt mask registers (DAI_IMSK_RE/DAI_IMSK_FE) are programmed. This programming allows the generation of DAI_IRPTL_H/DAI_IRPTL_L interrupts either entering mute, exiting muting or both. The SRCx_MUTE_OUT interrupt is generated only once when the SRC is locked (after 4096 FS input samples) and after changes to the sample ratio. Hard mute, soft mute, and auto mute only control the muting of the input data to the SRC.

Masking

The DAI_IMSK_FE, DAI_IMSK_RE, and DAI_IMSK_PRI registers must be unmasked accordingly. The DAI_IRQH and DAI_IRQL signals are routed to the system event controller (SEC) and general interrupt controller (GIC).

Service

The ISR reads the DAI_IRPTL_H and DAI_IRPTL_L registers to clear the interrupt request.

Programming Model

The following is basic information on programming the ASRC module.

1. Program the ASRC_CTL01 and ASRC_CTL23 registers and keep the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits cleared.
2. Set the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits. After 4096 input port FS cycles the ASRC has un-muted.

Debug Features

The asynchronous sample rate converter allow the bypass mode. When the ASRC_CTL01.BYP0 through ASRC_CTL23.BYP3 bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. This mode can be used for testing both ports when the input and output sample rates are at the same frequency, therefore both input and output ports can be routed to the same serial clock and frame sync.

ADSP-2159x_SC591_SC592_SC594 ASRC Register Descriptions

Sample Rate Converter Module (ASRC) contains the following registers.

Table 32-3: ADSP-2159x_SC591_SC592_SC594 ASRC Register List

Name	Description
ASRC_CTL01	Control Register for ASRC 0 and 1
ASRC_CTL23	Control Register for ASRC 2 and 3
ASRC_MUTE	Mute Register
ASRC_RAT01	Ratio Register for ASRC 0 and 1
ASRC_RAT23	Ratio Register for ASRC 2 and 3

Control Register for ASRC 0 and 1

The ASRC_CTL01 register (read/write) controls the operating modes, filters, and data formats used in the ASRC modules 0 and 1.

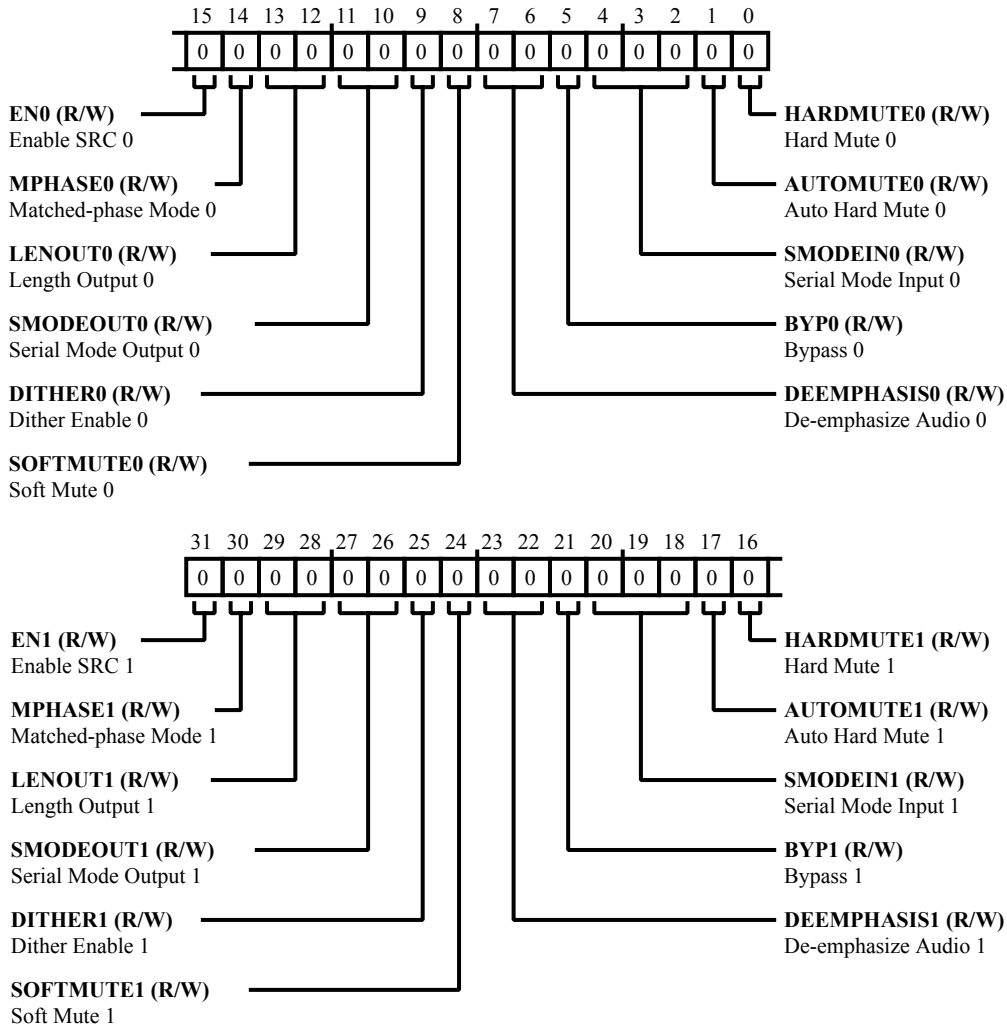

Figure 32-6: ASRC_CTL01 Register Diagram

Table 32-4: ASRC_CTL01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN1	Enable SRC 1. The ASRC_CTL01.EN1 bit enables SRC 1. When (set = 1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT01.MUTEOUT1 bit. Writes to the ASRC_CTL01 register should be at least one cycle before setting the ASRC_CTL01.EN1 bit. When setting and clearing this bit, it should be held low for a minimum of 5 SYSCLK cycles.	
30 (R/W)	MPHASE1	Matched-phase Mode 1. The ASRC_CTL01.MPHASE1 bit configures SRC1 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
29:28 (R/W)	LENOUT1	Length Output 1. The ASRC_CTL01.LENOUT1 bit field selects the serial output word length on SRC1.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT1	Serial Mode Output 1. The ASRC_CTL01.SMODEOUT1 bit field selects the serial output format on SRC1.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER1	Dither Enable 1. The ASRC_CTL01.DITHER1 bit enables dithering before truncation on SRC1 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE1	Soft Mute 1. The ASRC_CTL01.SOFTMUTE1 bit enables soft mute on SRC1.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS1	De-emphasize Audio 1. The ASRC_CTL01.DEEMPHASIS1 bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP1	Bypass 1. The ASRC_CTL01.BYP1 bit makes the output of SRC1 the same as the input.	
20:18 (R/W)	SMODEIN1	Serial Mode Input 1. The ASRC_CTL01.SMODEIN1 bit field selects the serial input format for SRC1.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified
		6	18-bit right-justified
		7	16-bit right-justified
17 (R/W)	AUTOMUTE1	Auto Hard Mute 1. The ASRC_CTL01.AUTOMUTE1 bit auto hard mutes SRC1 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
16 (R/W)	HARDMUTE1	Hard Mute 1. The ASRC_CTL01.HARDMUTE1 bit hard mutes SRC1.	
		0	Unmute
		1	Mute

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EN0	Enable SRC 0. The ASRC_CTL01.EN0 bit enables SRC 0. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT01.MUTEOUT0 bit. Writes to the ASRC_CTL01 register should be at least one cycle before setting the ASRC_CTL01.EN0 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
14 (R/W)	MPHASE0	Matched-phase Mode 0. The ASRC_CTL01.MPHASE0 bit configures SRC0 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
13:12 (R/W)	LENOUT0	Length Output 0. The ASRC_CTL01.LENOUT0 bit field selects the serial output word length on SRC0.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
11:10 (R/W)	SMODEOUT0	Serial Mode Output 0. The ASRC_CTL01.SMODEOUT0 bit field selects the serial output format on SRC0.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
9 (R/W)	DITHER0	Dither Enable 0. The ASRC_CTL01.DITHER0 bit enables dithering before truncation on SRC0 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SOFTMUTE0	Soft Mute 0. The `ASRC_CTL01.SOFTMUTE0` bit enables soft mute on SRC0.	
		0	Unmute
		1	Mute
7:6 (R/W)	DEEMPHASIS0	De-emphasize Audio 0. The `ASRC_CTL01.DEEMPHASIS0` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
5 (R/W)	BYP0	Bypass 0. The `ASRC_CTL01.BYP0` bit makes the output of SRC0 the same as the input.

		0	Unmute
		1	Mute (default)

Control Register for ASRC 2 and 3

The ASRC_CTL23 register (read/write) controls the operating modes, filters, and data formats used in the sample rate converter modules 2 and 3.

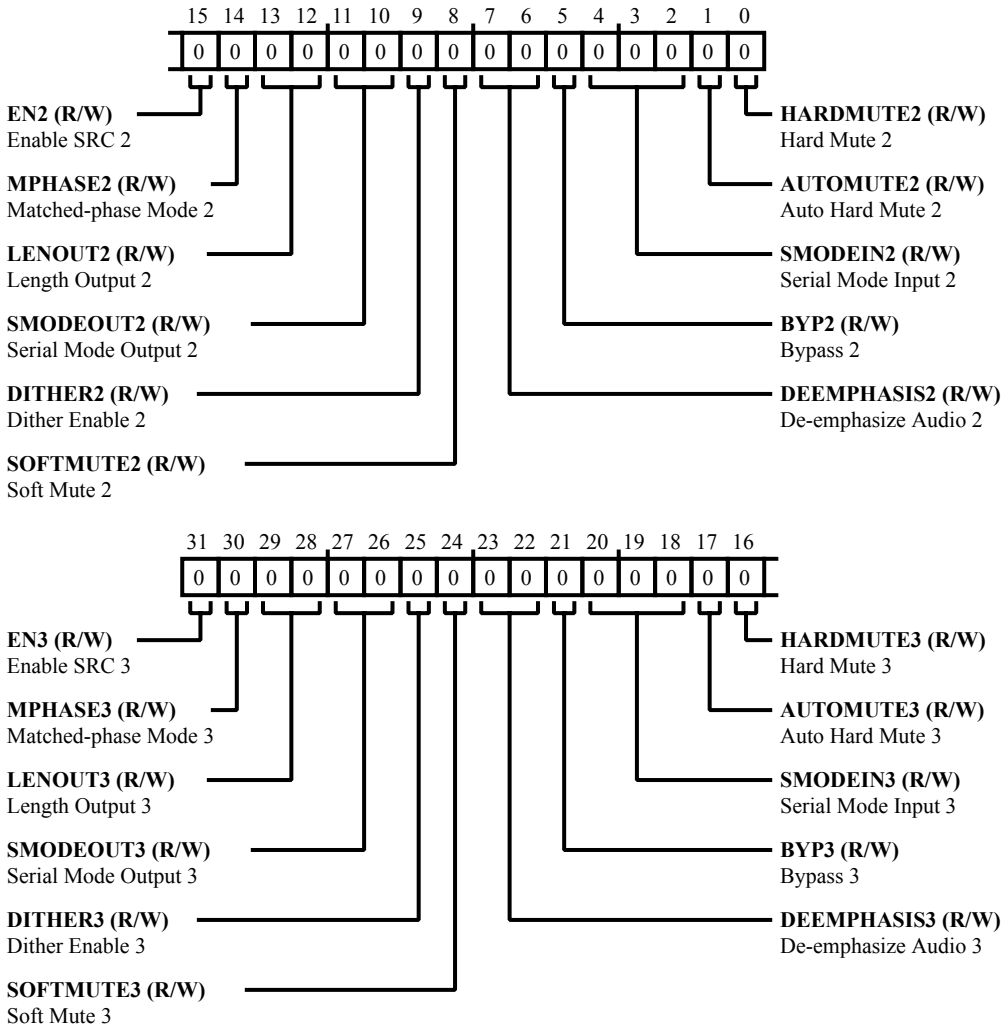

Figure 32-7: ASRC_CTL23 Register Diagram

Table 32-5: ASRC_CTL23 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN3	Enable SRC 3. The ASRC_CTL23.EN3 bit enables SRC 3. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT23.MUTEOUT3 bit. Writes to the ASRC_CTL23 register should be at least one cycle before setting the ASRC_CTL23.EN3 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
30 (R/W)	MPHASE3	Matched-phase Mode 3. The ASRC_CTL23.MPHASE3 bit configures SRC3 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
29:28 (R/W)	LENOUT3	Length Output 3. The ASRC_CTL23.LENOUT3 bit field selects the serial output word length on SRC3.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits

Table 32-5: ASRC_CTL23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EN2	Enable SRC 2. The ASRC_CTL23.EN2 bit enables SRC 2. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT23.MUTEOUT2 bit. Writes to the ASRC_CTL23 register should be at least one cycle before setting the ASRC_CTL23.EN2 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
14 (R/W)	MPHASE2	Matched-phase Mode 2. The ASRC_CTL23.MPHASE2 bit configures SRC2 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
13:12 (R/W)	LENOUT2	Length Output 2. The ASRC_CTL23.LENOUT2 bit field selects the serial output word length on SRC2.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
11:10 (R/W)	SMODEOUT2	Serial Mode Output 2. The ASRC_CTL23.SMODEOUT2 bit field selects the serial output format on SRC2.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
9 (R/W)	DITHER2	Dither Enable 2. The ASRC_CTL23.DITHER2 bit enables dithering before truncation on SRC2 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-5: ASRC_CTL23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SOFTMUTE2	Soft Mute 2. The `ASRC_CTL23.SOFTMUTE2` bit enables soft mute on SRC2.	
		0	Unmute
		1	Mute
7:6 (R/W)	DEEMPHASIS2	De-emphasize Audio 2. The `ASRC_CTL23.DEEMPHASIS2` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
5 (R/W)	BYP2	Bypass 2. The `ASRC_CTL23.BYP2` bit makes the output of SRC2 the same as the input.	
4:2 (R/W)	SMODEIN2	Serial Mode Input 2. The `ASRC_CTL23.SMODEIN2` bit field selects the serial input format for SRC2.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified
		6	18-bit right-justified
		7	16-bit right-justified
1 (R/W)	AUTOMUTE2	Auto Hard Mute 2. The `ASRC_CTL23.AUTOMUTE2` bit auto hard mutes SRC2 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
0 (R/W)	HARDMUTE2	Hard Mute 2. The `ASRC_CTL23.HARDMUTE2` bit hard mutes SRC2.	
		0	Unmute
		1	Mute

Mute Register

This register connects an ASRCx mute input and output when the mute bit is cleared (=0). This allows ASRCx to automatically mute input while the ASRC is initializing (0 = automatic muting and 1 = manual muting). Bit 0 controls ASRC0, bit 1 controls ASRC1, bit 2 controls ASRC2, and bit 3 controls ASRC3.

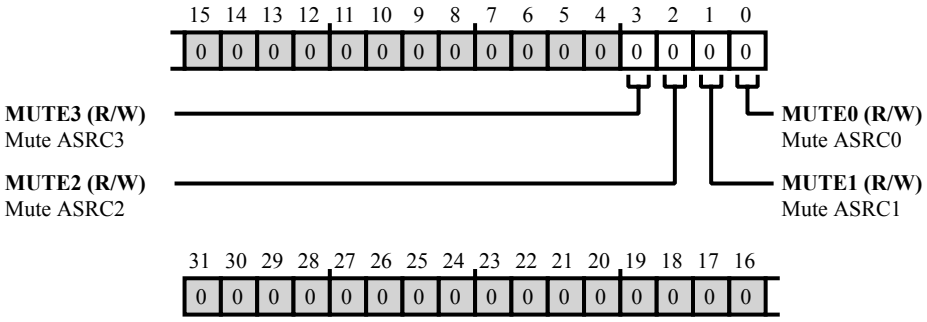

Figure 32-8: ASRC_MUTE Register Diagram

Table 32-6: ASRC_MUTE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	MUTE3	Mute ASRC3. The `ASRC_MUTE.MUTE3` bit automatically mutes ASCR3 output when cleared (=0).
2 (R/W)	MUTE2	Mute ASRC2. The `ASRC_MUTE.MUTE2` bit automatically mutes ASCR2 output when cleared (=0).
1 (R/W)	MUTE1	Mute ASRC1. The `ASRC_MUTE.MUTE1` bit automatically mutes ASCR1 output when cleared (=0).
0 (R/W)	MUTE0	Mute ASRC0. The `ASRC_MUTE.MUTE0` bit automatically mutes ASCR0 output when cleared (=0).

Ratio Register for ASRC 0 and 1

The ASRC_RAT01 register report the mute and I/O sample ratio for ASRC0 and ASRC1.

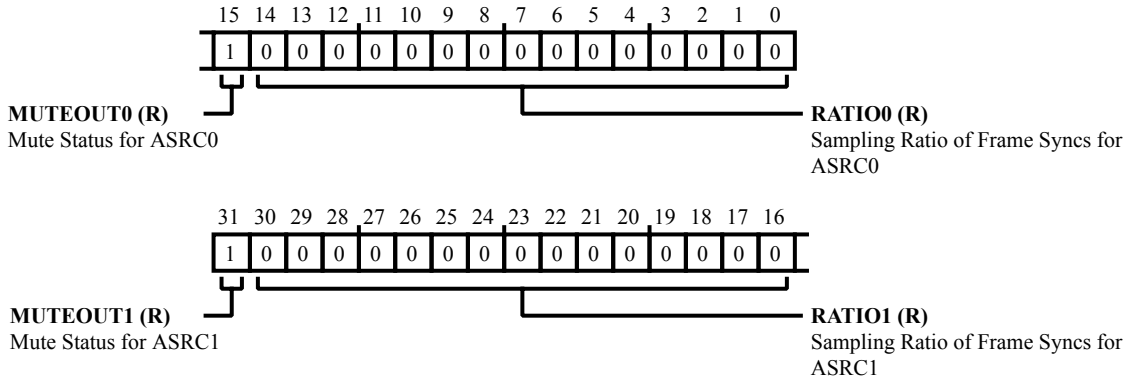

Figure 32-9: ASRC_RAT01 Register Diagram

Table 32-7: ASRC_RAT01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT1	Mute Status for ASRC1. The ASRC_RAT01.MUTEOUT1 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC1 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO1	Sampling Ratio of Frame Syncs for ASRC1. The ASRC_RAT01.RATIO1 bit field is read to find the ratio of output to input sampling frequency for ASRC1 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT0	Mute Status for ASRC0. The ASRC_RAT01.MUTEOUT0 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC0 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-7: ASRC_RAT01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO0	Sampling Ratio of Frame Syncs for ASRC0. The `ASRC_RAT01.RATIO0` bit field is read to find the ratio of output to input sampling frequency for ASRC0 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

Ratio Register for ASRC 2 and 3

The ASRC_RAT23 register report the mute and I/O sample ratio for ASRC0 and ASRC1.

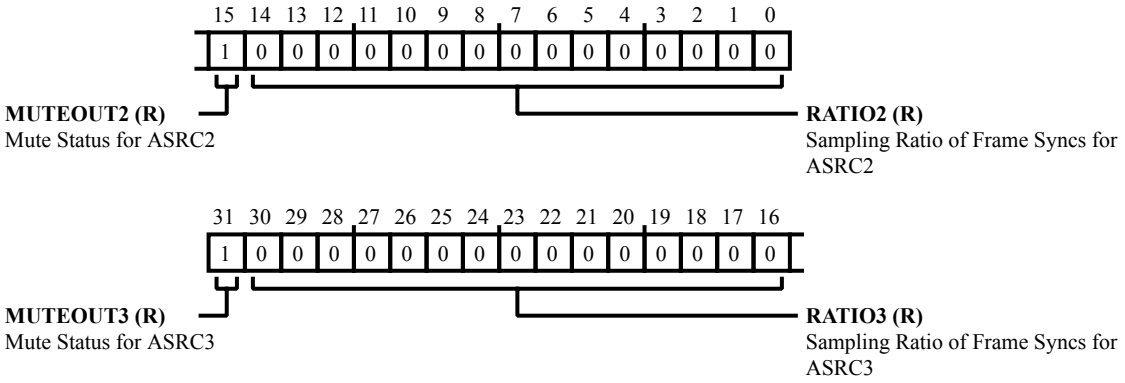

Figure 32-10: ASRC_RAT23 Register Diagram

Table 32-8: ASRC_RAT23 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT3	Mute Status for ASRC3. The ASRC_RAT23.MUTEOUT3 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC3 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO3	Sampling Ratio of Frame Syncs for ASRC3. The ASRC_RAT23.RATIO3 bit field is read to find the ratio of output to input sampling frequency for ASRC3 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT2	Mute Status for ASRC2. The ASRC_RAT23.MUTEOUT2 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC2 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-8: ASRC_RAT23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO2	Sampling Ratio of Frame Syncs for ASRC2. The `ASRC_RAT23.RATIO2` bit field is read to find the ratio of output to input sampling frequency for ASRC2 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

33 Sony/Philips Digital Interface (S/PDIF)

The Sony/Philips Digital Interface (S/PDIF) is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. The digital audio interface carries three types of information; audio data, non audio data (compressed data) and timing information.

Features

The S/PDIF interface has the following features.

- Supports one stereo channel or compressed audio streams.
- AES3-compatible S/PDIF transmitter and receiver.
- Transmitting a biphase mark encoded signal that may contain any number of audio channels (compressed or linear pulse code modulation) or non-audio data.
- S/PDIF receiver managing clock recovery with separate S/PDIF on-chip PLL.
- S/PDIF receiver supports the detection of DTS frames of 256, 512, 1024, 2048, and 4096.
- Manage user status information and provide error-handling capabilities in both the transmitter and receiver.
- DAI allows interactions over DAI by serial ports and the external DAI pins to interface to other S/PDIF devices. This includes using the receiver to decode incoming biphase encoded audio streams and passing them via the SPORTs to internal memory for processing-or using the transmitter to encode audio or digital data and transfer it to another S/PDIF receiver in the audio system.

It is important to be familiar with serial digital audio interface standards IEC-60958, EIAJ CP-340, AES3 and AES11.

ADSP-2159x_SC591_SC592_SC594 SPDIF Register List

The S/PDIF module is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. A set of registers govern S/PDIF operations. For more information on S/PDIF functionality, see the S/PDIF register descriptions.

Table 33-1: ADSP-2159x_SC591_SC592_SC594 SPDIF Register List

Name	Description
SPDIF_RX_CTL	Receive Control
SPDIF_RX_STAT	Receive Status Register

Name	Description
SPDIF_TX_USRUPDT	User Bit Update Register

SRU Programming

The SRU (signal routing unit) is used to connect the S/PDIF transmitter biphase data out to the output pins or to the S/PDIF receiver. The serial clock, frame sync, data, and external sync (if external synchronization is required) inputs also need to be routed through the SRU. For details of the routing, see DAI Routing Capabilities in the *Digital Audio Interface (DAI)* chapter.

The SRU needs to be programmed in order to connect the S/PDIF receiver to the output pins or any other peripherals and also for the connection to the input biphase stream.

Program the corresponding SRU registers to connect the outputs to the required destinations (see DAI Routing Capabilities). The biphase encoded data and the external PLL clock inputs to the receiver are routed through the SRU. The extracted clock, frame sync, and data are also routed through the SRU.

S/PDIF Interrupt List

Table 33-2: S/PDIF Interrupt List

Interrupt Name	Interrupt Condition	Return DAI Register	Return SEC Register	SEC ID
DAI0_IRQH	Block Start	DAIx_IRPTL	SEC_ID	24
DAI0_IRQL	Non Audio			145

Clocking

The fundamental timing clock of the S/PDIF receiver is CLKO5 from the CDU. When CLKO5 is configured, it supports sampling frequencies of 24 kHz to 192 kHz. The fundamental timing clock of the S/PDIF transmitter is *SCLK0*/4.

Sample rates of 24 kHz to 96 kHz are supported using a 170 MHz to 180 MHz setting on CLKO5.

Sample rates of 32 kHz to 192 kHz are supported using a 225.0 MHz setting on CLKO5.

For information on clock programming, see CDU Programming Model.

S/PDIF Transmitter

The following sections provide information on the S/PDIF transmitter.

Functional Description

The S/PDIF transmitter, shown in the ***S/PDIF Transmitter Block Diagram***, resides within the DAI, and its inputs and outputs can be routed via the SRU. It receives audio data in serial format, encloses the specified user status information, and converts it into the biphase encoded signal. The serial data input to the transmitter can be formatted as left-justified, I^{2}S, or right-justified with word widths of 16, 18, 20 or 24 bits. ***AES3 Output Block*** shows the detail of the AES block.

The serial data, clock, and frame sync inputs to the S/PDIF transmitter are routed through the signal routing unit (SRU).

The S/PDIF transmitter output may be routed to an output pin via the SRU and then routed to another S/PDIF receiver or to components for off-board connections to other S/PDIF receivers. The output is also available to the S/PDIF receiver for loop-back testing through SRU.

In addition to encoding the audio data in the bi-phase format, the transmitter also provides a way to easily add the channel status information to the outgoing bi-phase stream. There are status/user registers for a frame (192-bits/24 bytes) in the transmitter that correspond to each channel or subframe.

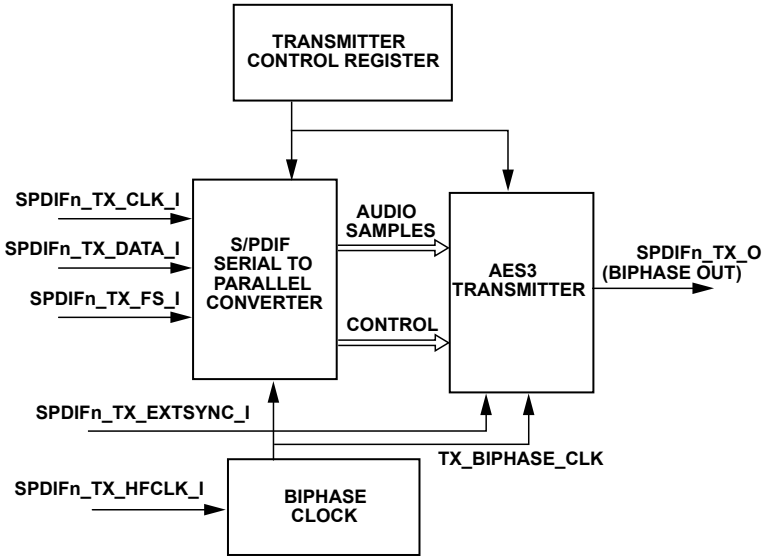

Figure 33-1: S/PDIF Transmitter Block Diagram

Validity bits for both channels may also be controlled by the transmitter control register. Optionally, the user bit, validity bit, and channel status bit are sent to the transmitter with each left/right sample. For each subframe the parity bit is automatically generated and inserted into the bi-phase encoded data.

A mute control and support for double-frequency single-channel mode are also provided. The serial data input format may be selected as left-justified, I^{2}S, or right-justified with 16-, 18-, 20- or 24-bit word widths. The over sampling clock is also selected by the transmitter control register.

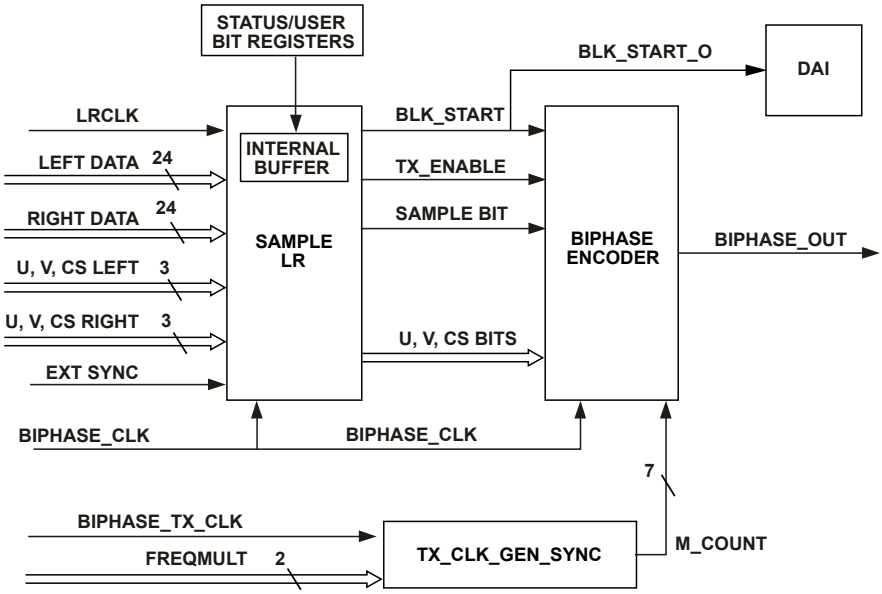

Figure 33-2: AES3 Output Block

Input Data Formats

The *I2S and Left-Justified Formats* and *Right-Justified Formats* figures show the format of data that is sent to the S/PDIF transmitter using a variety of protocol standards.

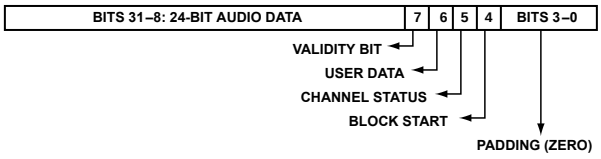

Figure 33-3: I^2S and Left-Justified Formats

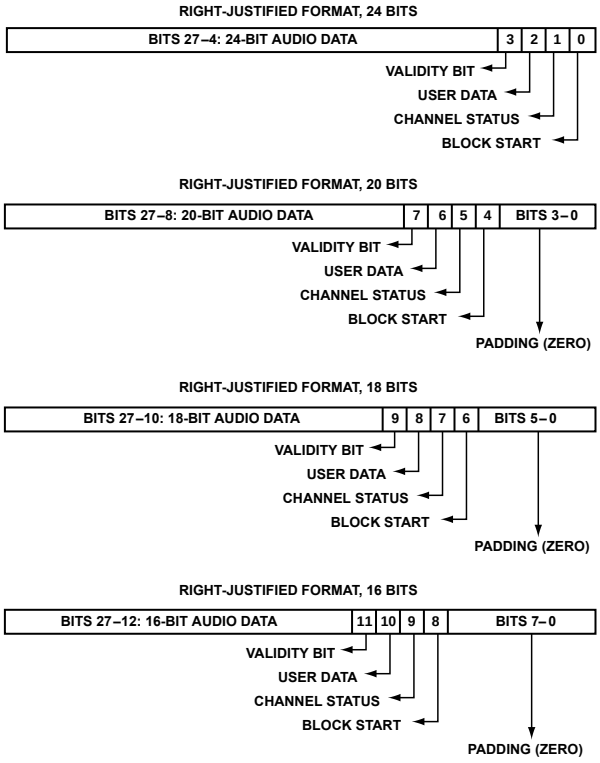

Figure 33-4: Right-Justified Formats

Operating Modes

The S/PDIF transmitter can operate in standalone and full serial modes. The following sections describe these modes in detail.

Full Serial Mode

This mode is selected by clearing the `SPDIF_TX_CTL.AUTO` bit. In this mode all the status bits, audio data and the block start bit (indicating start of a frame), come through the serial data stream (`SPDIF_TX_DATA_I`) pin. The transmitter should be enabled after or at the same time as all of the other control bits.

Standalone Mode

This mode is selected by setting the `SPDIF_TX_CTL.AUTO` bit. In this mode, the block start bit (indicating the start of a frame) is generated internally. The channel status bits come from the channel status buffer registers. The user status bits come from the user bits buffers as shown in the ***AES3 Output Block*** figure.

The validity bits are the `SPDIF_TX_CTL.VALIDR` and `SPDIF_TX_CTL.VALIDL`. In this mode only audio data comes from the `SPDIF_TX_DATA_I` pin. All other data, including the status bit and block start bit is either generated internally or taken from the internal register.

Once the user bits buffer registers (`SPDIF_TX_UBUFF_A0` - `SPDIF_TX_UBUFF_B5`) are programmed, they are used only for the next block of data. This allows programs to change the user bit information in every block of data.

To allow user bit updates, write a 0x1 to the SPDIF_TX_USRUPDT register that is used for further processing. If the SPDIF_TX_CTL.AUTO bit is set:

- and if SPDIF_TX_USRUPDT =1, at every 192nd frame end the user status bits are taken from user bits buffers and transmitted. Simultaneously, the SPDIF_TX_USRUPDT register is cleared automatically by hardware.
- and if SPDIF_TX_USRUPDT =0, at every 192nd frame end the user status bits are updated as zeros and transmitted. The SPDIF_TX_USRUPDT register remains low.

In general, for the next block, programs can update user bits buffers at any time during the transfer of the current block (1 block = 192 frames). There are internal buffers to store the user status bits of the current block of transfer. In other words, at the beginning of every new block, the user status bit (SPDIF_TX_CTL.USRPEND bit) from user bits buffers are copied to internal buffers and transmitted in each frame during the transfer.

Note that since a frame contains 192 bits/8 = 24 bytes, six status/user registers are required to store each four bytes.

Data Output Mode

Two output data formats are supported by the transmitter; *two channel mode* and *single-channel double-frequency* (SCDF) mode. The output format is determined by the transmitter control register (SPDIF_TX_CTL).

In two channel mode, the left channel (channel A) is transmitted when the SPDIF_TX_FS_I is high and the right channel (channel B) is transmitted when the SPDIF_TX_FS_I is low.

In SCDF mode, the transmitter sends successive audio samples of the same signal across both sub frames, instead of channel A and B. The transmitter will transmit at half the sample rate of the input bit stream. The SPDIF_TX_CTL.SCDF bit selects SCDF mode. When in SCDF mode, the SPDIF_TX_CTL.SCDFLR bit determines whether left or right channel data is transmitted.

S/PDIF Receiver

The S/PDIF receiver (***S/PDIF Receiver Block Diagram***) is compliant with all common serial digital audio interface standards including IEC-60958, IEC-61937, AES3, and AES11. For the IEC-60958 standard, all the user-data and channel-status bits (as outlined in this document) are not decoded by the S/PDIF receiver. The interface does make all 192 user-data and channel-status pairs available as an output of the block, for post-decoding.

For the IEC-61937 standard, the S/PDIF only detects compressed AC-3 and DTS formats. No decompression is performed.

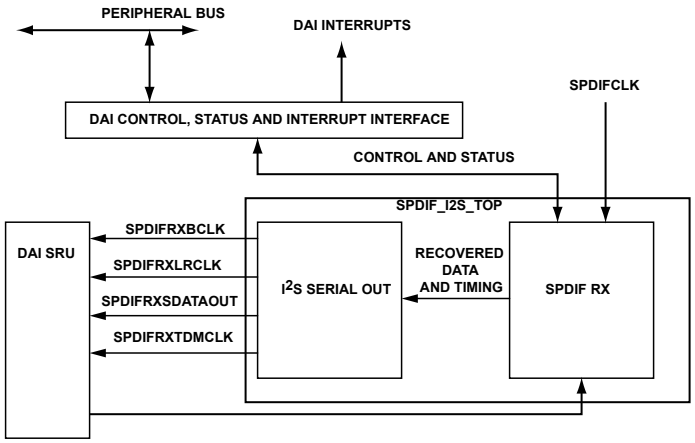

Figure 33-5: S/PDIF Receiver Block Diagram

Functional Description

If the receiver is used, programs need to enable it using the `SPDIF_RX_CTL` register. After the SRU programming is complete, write to the register with control values. At this point, the receiver attempts to lock.

NOTE: The S/PDIF receiver is disabled at default. If the receiver is used in an application, programs should enable the receiver.

The input to the receiver (SPDIFn_RX_I) is a biphase encoded signal that may contain two audio channels (compressed or linear PCM) or non-audio data. The receiver decodes the single biphase encoded stream, producing an I^2S compatible serial data output that consists of a serial clock, a left-right frame sync, and data (channel A/B). It provides the programmer with several methods of managing the incoming status bit information.

The S/PDIF receiver receives any S/PDIF stream with a sampling frequency range of 24 kHz to 192 kHz. Refer to Clocking for more details.

The channel status bits are collected into memory-mapped registers, while other channel status and user bytes must be handled manually. The block start bit, which replaces the parity bit in the serial I^2S stream, indicates the reception of the Z preamble and the start of a new block of channel status and data bits.

Clock Recovery

The S/PDIF receiver recovers the clock that generated the AES3/SPDIF biphase encoded stream from the incoming S/PDIF stream.

This clock is used by the receiver to clock in the biphase encoded data stream and also to provide clocks for either the SPORTs, sample rate converter, or the AES3 and S/PDIF transmitter. The recovered clock may also be used externally to the chip for clocking D/A and A/D converters.

In order to maintain performance, jitter on the clock is sourced to several peripherals.

To comply with the AES11 standard, the recovered left or right clock must be aligned with the preambles within a + or - 5% of the frame period. Since the PLL clock generates a clock 512 times the frame rate clock (512 f_{SCLK}), this clock can be used and divided down to create the phase aligned jitter-free left or right clock.

The SPDIF recovered TDM master clock can be jittery depending on the biphase input source. Do not use this as a clock source in audio applications.

TDM Clock Output

The SPDIF receiver generates the TDMCLK clock signal which is 256 times the sampling rate. For proper generation of TDMCLK, program the SPDIF receiver as shown in the ***TDMCLK Configuration*** table.

IMPORTANT: The SPDIF receiver guarantees 256 clocks in one frame sync. It does not guarantee the duty cycle of the generated clocks. Therefore, do not use this clock in the applications that have duty cycle requirements.

Table 33-3: TDMCLK Configuration

SPDIF_RX_CTL.TDMSEL	Recommended Sampling Rate
0000	≤96K
0001	192K
0011	96K - 192K
0101	96K

Output Data Format

The extracted 24-bit audio data, V, U, C and block start bits are sent on the SPDIF_RX_DAT pin in 32-bit I^2S format as shown in ***I2S and Left-Justified Formats***. The frame sync is transmitted on the SPDIF_RX_FS pin and serial clock is transmitted on the SPDIF_RX_CLK pin. All three pins are routed through the SRU.

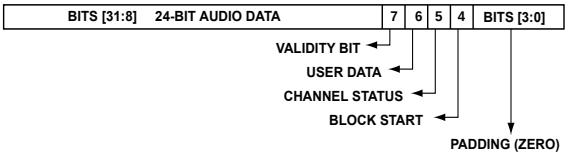

Figure 33-6: I2S Format

Channel Status

The channel status for the first bytes 4-0 (consumer mode) are collected into memory-mapped registers (SPDIF_RX_STAT0_A, SPDIF_RX_STAT0_B, SPDIF_RX_STAT1_A and SPDIF_RX_STAT1_B). All other channel status bytes 23-5 (professional mode) must be manually extracted from the receiver data stream.

NOTE: Only the first 5 channel status bytes (40-bit) for consumer mode of a frame are stored into the S/PDIF receiver status registers.

Operating Modes

This section describes the receiver channel status for the different modes.

Compressed or Non-linear Audio Data

The S/PDIF receiver processes compressed as well as non-linear audio data according to the supported standards. The following sections describe how this peripheral handles different data.

MPEG-2, AC-3, DTS, and AAC compressed data may be transmitted without setting either the `SPDIF_RX_STAT.VALID` bit or bit 1 of byte 0. To detect this data, the IEC61937 and SPMTE 337M standards dictate that there be a 96-bit sync code in the 16-, 20- or 24-bit audio data stream. This sync code consists of four words of zeros followed by a word consisting of 0xF872 and another word consisting of 0x4E1F. When this sync code is detected, the `SPDIF_RX_STAT.COMPMODE` bits hold the information regarding type of compression.

The last two words of the sync code, 0xF872 and 0x4E1F, are called the preamble-A and preamble-B of the burst preamble. Preamble-C of the burst preamble contains burst information and is captured and stored by the receiver. Preamble-D of the burst preamble contains the length code and is captured by the receiver. Even if the validity bit or bit 1 of byte 0 has been set, the receiver still looks for the sync code in order to record the preamble-C and D values. Once the sync code has not been detected in 4096 frames, the preamble-C and D registers are set to zero.

Emphasized Audio Data

Determination as to whether the received audio data is emphasized or not is done in software using the channel status bits as detailed below.

- In professional mode, (bit 0 of byte 0 = 1), channel status bits 2-4 of byte 0 indicate the audio data is emphasized if they are equal to 110 or 111.
- In consumer mode, (bit 0 of byte 0 = 0), channel status bits 3-5 indicate the audio data is emphasized if they are equal to 100, 010 or 110.

Single-Channel Double-Frequency Mode

Unlike previous processors, support for single-channel, double-frequency mode (SCDF) is not supported through specific bits within the `SPDIF_RX_CTL` register, but rather have to be implemented in software using the information provided by the CS (channel status) bits.

- 0111 = single channel double frequency mode
- 1000 = single channel double frequency mode-stereo left
- 1001 = single channel double frequency mode-stereo right

Clock Recovery Modes

The S/PDIF receiver extracts audio data, channel status, and user bits from the biphase encoded AES3 and S/PDIF stream. In addition, a 50% duty cycle reference clock running at the sampling rate of the audio input data is generated for the receiver to recover the oversampling clock.

Number Controlled Oscillator

The receiver can recover the clock from the biphase encoded stream using an on-chip NCO shown in the following figure. Note the dedicated NCO is separate from the PLL that supplies the clock to the processor core and which is the default operation of the receiver.

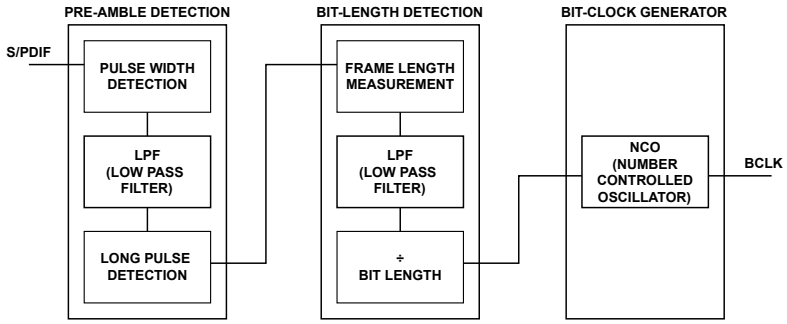

Figure 33-7: S/PDIF Clock Recovery Mechanism

The left/right frame reference clock for the NCO is generated using the preambles. The recovered low jitter left/right frame clock from the NCO attempts to align with the reference clock. However, this recovered left/right clock, like the reference clock, is not phase aligned with the preambles.

Interrupts

The following sections provide information about interrupt sources, masking and servicing.

Sources

The S/PDIF module of each DAI drives five interrupt signals. Four are status signals driven from SPDIFn_RX and one signal is driven from SPDIFn_TX (block start). These signals are connected into the `DAI_IRPTL_L`/`DAI_IRPTL_H` latch register.

Transmit Block Start

The SPDIFn_TX_BLKSTART output signal, if routed to any miscellaneous interrupt bits (DAIn_INT_31-22 in the `DAI_MISC0`/`DAI_MISC1` registers), triggers a block start interrupt during the last frame of current block.

Receiver Status

The following receiver status bits generate an interrupt.

- Validity (`SPDIF_RX_STAT.VALID`)
- Receiver locked (`SPDIF_RX_STAT.LOCK`)
- No audio (`SPDIF_RX_STAT.AUDIOTYPE`)

Receiver Error

The loss of lock (`SPDIF_RX_STAT.LOCKLOSS`) bit generates an interrupt.

Masking

For the S/PDIF receiver the DAI_IMSK_RE register must be unmasked accordingly. For the S/PDIF transmit the DAIn_IMASK_x register must be unmasked accordingly.

The INTR_DAI_IRQH and INTR_DAI_IRQL signals are routed to the SEC and GIC.

Service

The ISR reads the DAI_IRPTL_H and DAI_IRPTL_L registers to clear the interrupt request.

Programming Model

The following sections provide information on programming the transmitter and receiver.

Programming the Transmitter

Since the S/PDIF transmitter data input is not available to the core, programming the transmitter is as simple as: 1) connecting the SRU to the on-chip (serial ports or input data port) or off-chip (DAI pins) serial devices that provide the clock and data to be encoded, and 2) selecting the desired mode in the transmitter control register. This setup can be accomplished in three steps.

1. Connect the transmitter's four required input signals and one biphase encoded output in the SRU. The four input signals are the serial clock (SPDIF_TX_CLK_I), the serial frame sync (SPDIF_TX_FS_I), the serial data (SPDIF_TX_DAT_I), and the high frequency clock (SPDIF_TX_HFCLK_I) used for the encoding. The only output of the transmitter is SPDIF_TX_O.
2. If user bits are required, write 0x1 to the SPDIF_TX_USRUPDT register for the first block of transfer. Also route the SPDIF_TX_BLK_START_O signal to the DAI_INT_31-22 (DAI_IRPTLx register). This generates interrupts during the last frame of the block (192), allowing changes of user bits for the next block.
3. Initialize the SPDIF_TX_CTL register to enable the data encoding.
4. Manually set the block start bit in the data stream once per block (every 384 words). This is necessary if automatic generation of block start information is not enabled using the SPDIF_TX_CTL.AUTO bit = 0.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Programming the Receiver

Since the S/PDIF receiver data output is not available to the core, programming the peripheral is as simple as connecting the SRU to the on-chip (serial ports) or off-chip (DAI pins) serial devices that provide the clock and data to be decoded, and selecting the desired mode in the receiver control register. This setup can be accomplished in two steps.

1. Connect the input signal and three output signals in the SRU. The only input of the receiver is the biphase encoded stream, SPDIFn_RX_I. The three required output signals are the serial clock (SPDIFn_RX_CLK),

the serial frame sync (SPDIFn_RX_FS), and the serial data (SPDIFn_RX_DAT). The high frequency clock (SPDIFn_RX_TDMCLK) derived from the encoded stream is also available if the system requires it.

2. Initialize the SPDIF_RX_CTL register to enable the data decoding. Note that this peripheral is disabled by default.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Interrupted Data Streams on the Receiver

When using the S/PDIF receiver with data streams that are likely to be interrupted, (in other words unplugged and reconnected), it is necessary to take some extra steps to ensure that the S/PDIF receiver's digital PLL will relock to the stream. The steps to accomplish this are described below.

1. Set up interrupts within the DAI so that the S/PDIF receiver can generate an interrupt when the stream is reconnected.
2. Within the interrupt service routine (ISR), stop and restart the NCO. This is accomplished by setting and then clearing the SPDIF_RX_CTL.RST bit.
3. Return from the ISR and continue normal operation.

This method of resetting the NCO has been shown to provide extremely reliable performance when the S/PDIF inputs are interrupted or unplugged momentarily.

Debug Features

The following feature supports S/PDIF debugging.

Loopback Routing

The S/PDIF supports an internal loopback mode by using the SRU. For more information about loopback, see "Loopback Routing" in the the *Digital Audio Interface (DAI)* chapter.

ADSP-2159x_SC591_SC592_SC594 SPDIF Register Descriptions

The S/PDIF module (SPDIF) contains the following registers.

Table 33-4: ADSP-2159x_SC591_SC592_SC594 SPDIF Register List

Name	Description
SPDIF_RX_CTL	Receive Control
SPDIF_RX_STAT	Receive Status Register
SPDIF_RX_STAT0_A	Receive Status A0 Register
SPDIF_RX_STAT0_B	Receive Status B0 Register

Table 33-4: ADSP-2159x_SC591_SC592_SC594 SPDIF Register List (Continued)

Name	Description
SPDIF_RX_STAT1_A	Receive Status A1 Register
SPDIF_RX_STAT1_B	Receive Status B1 Register
SPDIF_TX_CTL	Transmit Control Register
SPDIF_TX_STAT_A0	Transmit Status A0 Register
SPDIF_TX_STAT_A1	Transmit Status A1 Register
SPDIF_TX_STAT_A2	Transmit Status A2 Register
SPDIF_TX_STAT_A3	Transmit Status A3 Register
SPDIF_TX_STAT_A4	Transmit Status A4 Register
SPDIF_TX_STAT_A5	Transmit Status A5 Register
SPDIF_TX_STAT_B0	Transmit Status B0 Register
SPDIF_TX_STAT_B1	Transmit Status B1 Register
SPDIF_TX_STAT_B2	Transmit Status B2 Register
SPDIF_TX_STAT_B3	Transmit Status B3 Register
SPDIF_TX_STAT_B4	Transmit Status B4 Register
SPDIF_TX_STAT_B5	Transmit Status B5 Register
SPDIF_TX_UBUFF_A0	Transmit User Buffer A0 Register
SPDIF_TX_UBUFF_A1	Transmit User Buffer A1 Register
SPDIF_TX_UBUFF_A2	Transmit User Buffer A2 Register
SPDIF_TX_UBUFF_A3	Transmit User Buffer A3 Register
SPDIF_TX_UBUFF_A4	Transmit User Buffer A4 Register
SPDIF_TX_UBUFF_A5	Transmit User Buffer A5 Register
SPDIF_TX_UBUFF_B0	Transmit User Buffer B0 Register
SPDIF_TX_UBUFF_B1	Transmit User Buffer B1 Register
SPDIF_TX_UBUFF_B2	Transmit User Buffer B2 Register
SPDIF_TX_UBUFF_B3	Transmit User Buffer B3 Register
SPDIF_TX_UBUFF_B4	Transmit User Buffer B4 Register
SPDIF_TX_UBUFF_B5	Transmit User Buffer B5 Register
SPDIF_TX_USRUPDT	User Bit Update Register

Receive Control

The SPDIF_RX_CTL register is used to enable and control the S/PDIF receiver.

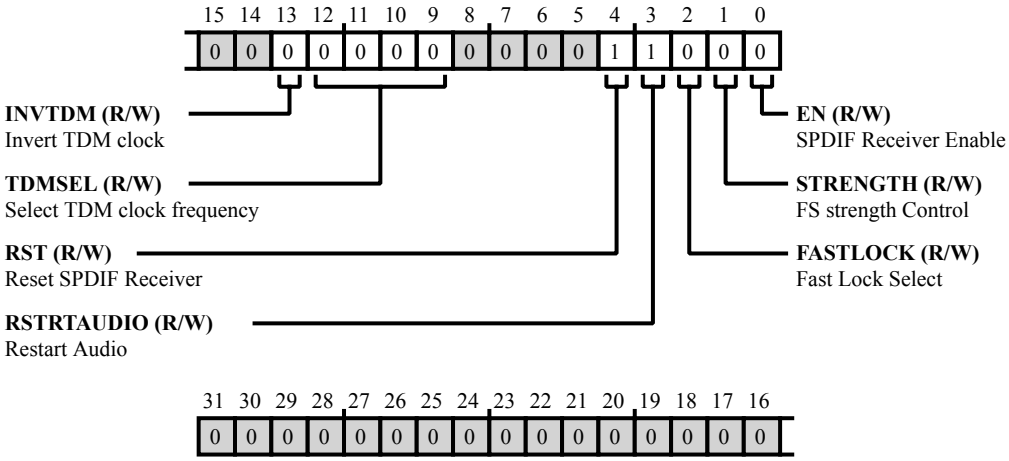

Figure 33-8: SPDIF_RX_CTL Register Diagram

Table 33-5: SPDIF_RX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	INVTDM	Invert TDM clock. When set to 0, inverted TDM clock or non-inverted Bit clock is selected. When set to 1, non-inverted TDM clock or inverted Blit clock is selected.	
12:9 (R/W)	TDMSEL	Select TDM clock frequency. Select TDM clock frequency	
4 (R/W)	RST	Reset SPDIF Receiver. The SPDIF_RX_CTL.RST bit resets the receiver.	
		0	Takes the receiver out of reset
		1	Resets the SPDIF receiver
3 (R/W)	RSTRTAUDIO	Restart Audio. The SPDIF_RX_CTL.RSTRTAUDIO bit restarts the audio once a re-lock has occurred. When the S/PDIF receiver loses lock the audio output is set to 0. This bit determines the behavior of the audio once lock is re-established. Audio can be manually restarted by toggling this bit high and then low.	
		0	Manually restart audio
		1	Automatically restart audio

Table 33-5: SPDIF_RX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	FASTLOCK	Fast Lock Select. The `SPDIF_RX_CTL.FASTLOCK` bit allows the lock mechanism to lock at normal speed or at faster speed. This has the advantage of recovering very quickly whenever the S/PDIF receiver looses lock due to glitches in the signal. In normal mode the S/PDIF receiver locks after 64 consecutive valid samples, in fast mode the S/PDIF receiver locks after 8 consecutive valid samples	
		0	Enable normal mode
		1	Enable fast mode
1 (R/W)	STRENGTH	FS strength Control. The `SPDIF_RX_CTL.STRENGTH` bit controls the strength of the bit clock and Frame sync outputs from the SPDIF receiver. In strong mode these output signals are continued (as best possible) when the receiver notices a loss-of-lock condition. Note that 'as best possible' refers to the fact that this recovered signal may not be accurate, given the loss-of-lock condition. In weak mode these output signals are interrupted as soon as the receiver notices a loss-of-lock condition.	
		0	Enable strong mode
		1	Enable weak mode
0 (R/W)	EN	SPDIF Receiver Enable. When the `SPDIF_RX_CTL.EN` bit =0 the clock to SPDIF is switched off for power savings.	
		0	Disable receiver
		1	Enable receiver

Receive Status Register

The SPDIF_RX_STAT register consists of bits that indicate the status of various functions supported by S/PDIF receiver.

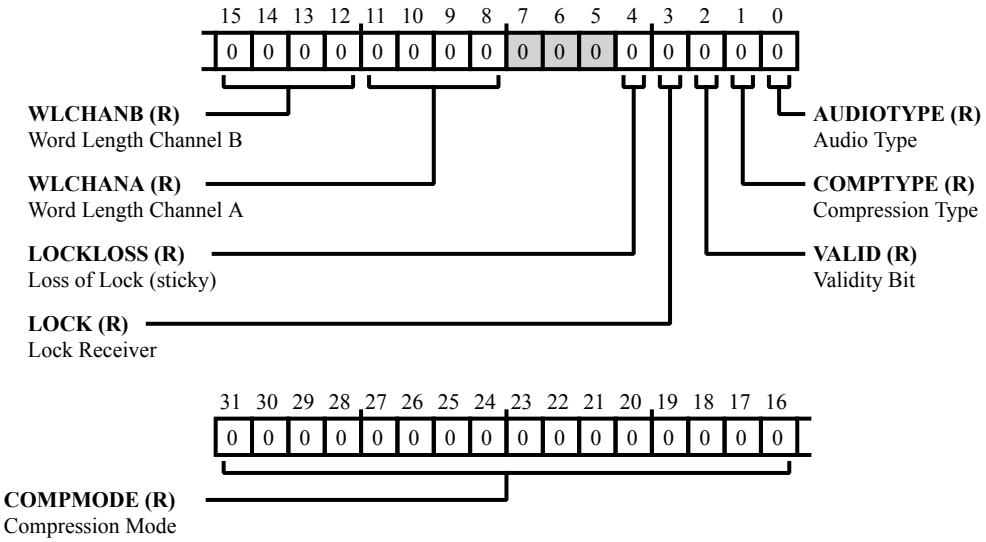

Figure 33-9: SPDIF_RX_STAT Register Diagram

Table 33-6: SPDIF_RX_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	COMPMODE	Compression Mode. The SPDIF_RX_STAT.COMPMODE bit field indicates the type of compression mode used in the Digital audio stream. The value in this field indicates the 16-bit burst information as specified by the IEC 62937-2 standard. Use this document to decode the value in this bit field.	
15:12 (R/NW)	WLCHANB	Word Length Channel B. The SPDIF_RX_STAT.WLCHANB bit field indicates the S/PDIF word length for channel B. May be decoded as follows (from the S/PDIF standard).	
		0	Reserved
		1	Reserved
		2	SPDIF_LENGTH_16
		3	Reserved
		4	SPDIF_LENGTH_18
		5	SPDIF_LENGTH_22
		6	Reserved

Table 33-6: SPDIF_RX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	Reserved
		8	SPDIF_LENGTH_19
		9	SPDIF_LENGTH_23
		10	SPDIF_LENGTH_20
		11	SPDIF_LENGTH_24
		12	SPDIF_LENGTH_17
		13	SPDIF_LENGTH_21
		14	Reserved
		15	Reserved
11:8 (R/NW)	WLCHANA	Word Length Channel A. The `SPDIF_RX_STAT.WLCHANA` bit indicates the S/PDIF word length for channel A. May be decoded as follows (from the S/PDIF standard).	
		0	Reserved
		1	Reserved
		2	SPDIF_LENGTH_16
		3	Reserved
		4	SPDIF_LENGTH_18
		5	SPDIF_LENGTH_22
		6	Reserved
		7	Reserved
		8	SPDIF_LENGTH_19
		9	SPDIF_LENGTH_23
		10	SPDIF_LENGTH_20
		11	SPDIF_LENGTH_24
		12	SPDIF_LENGTH_17
		13	SPDIF_LENGTH_21
		14	Reserved
		15	Reserved

Table 33-6: SPDIF_RX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	LOCKLOSS	Loss of Lock (sticky). The `SPDIF_RX_STAT.LOCKLOSS` bit indicates that the system has lost lock. This is different to the lock register, as it is sticky it goes high when system looses lock, but returns to low once `SPDIF_RX_CTL.RSTRTAUDIO` bit is toggled. This is to allow the programs to poll the lock status.	
		0	SPDIF receiver locked
		1	SPDIF Receiver lost lock
3 (R/NW)	LOCK	Lock Receiver. The `SPDIF_RX_STAT.LOCK` bit indicates the S/PDIF receiver has successfully locked to the S/PDIF stream and is outputting valid data.	
		0	Receiver not locked
		1	Receiver locked
2 (R/NW)	VALID	Validity Bit. The `SPDIF_RX_STAT.VALID` bit indicates the ORed bits of channel A and B.	
		0	Linear PCM data
		1	Non-linear audio data
1 (R/NW)	COMPTYPE	Compression Type. The `SPDIF_RX_STAT.COMPTYPE` bit indicates AC3 or DTS compression. Valid only if `SPDIF_RX_STAT.AUDIOTYPE` indicates compressed data.	
		0	AC3 compressed data
		1	DTS compressed data
0 (R/NW)	AUDIOTYPE	Audio Type. The `SPDIF_RX_STAT.AUDIOTYPE` bit indicates PCM or compressed data.	
		0	PCM data
		1	Compressed Data

Receive Status A0 Register

The SPDIF_RX_STAT0_A register holds the receive channel 0 status for bytes 0-3 for sub frame A.

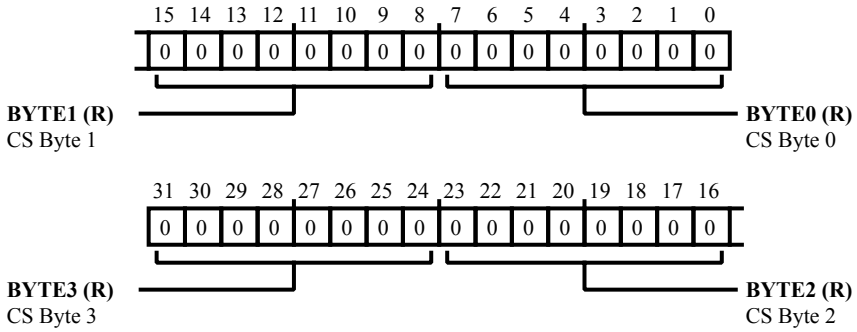

Figure 33-10: SPDIF_RX_STAT0_A Register Diagram

Table 33-7: SPDIF_RX_STAT0_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	BYTE3	CS Byte 3. The SPDIF_RX_STAT0_A.BYTE3 bit field contains byte 3 of received channel A status.
23:16 (R/NW)	BYTE2	CS Byte 2. The SPDIF_RX_STAT0_A.BYTE2 bit field contains byte 2 of received channel A status.
15:8 (R/NW)	BYTE1	CS Byte 1. The SPDIF_RX_STAT0_A.BYTE1 bit field contains byte 1 of received channel A status.
7:0 (R/NW)	BYTE0	CS Byte 0. The SPDIF_RX_STAT0_A.BYTE0 bit field contains the status of byte 0-3 of received channel A.

Receive Status B0 Register

The SPDIF_RX_STAT0_B register holds the receive channel 0 status for bytes 0-3 for sub frame B.

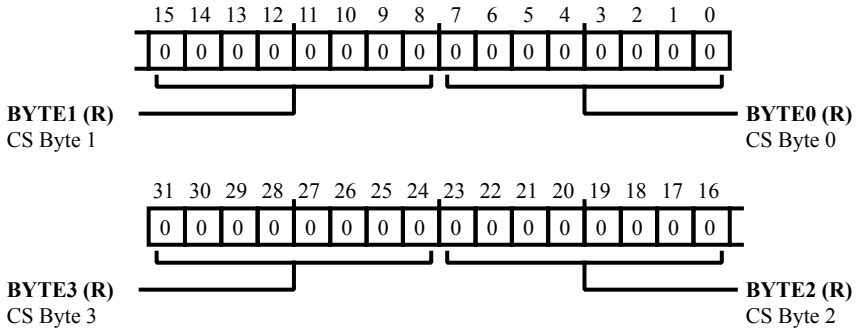

Figure 33-11: SPDIF_RX_STAT0_B Register Diagram

Table 33-8: SPDIF_RX_STAT0_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	BYTE3	CS Byte 3. The SPDIF_RX_STAT0_B.BYTE3 bit field contains byte 3 of received channel B status.
23:16 (R/NW)	BYTE2	CS Byte 2. The SPDIF_RX_STAT0_B.BYTE2 bit field contains byte 2 of received channel B status.
15:8 (R/NW)	BYTE1	CS Byte 1. The SPDIF_RX_STAT0_B.BYTE1 bit field contains byte 1 of received channel B status.
7:0 (R/NW)	BYTE0	CS Byte 0. The SPDIF_RX_STAT0_B.BYTE0 bit field contains byte 0 of received channel B status.

Receive Status A1 Register

The SPDIF_RX_STAT1_A register holds the receive channel 1 status for byte 4 for sub frame A.

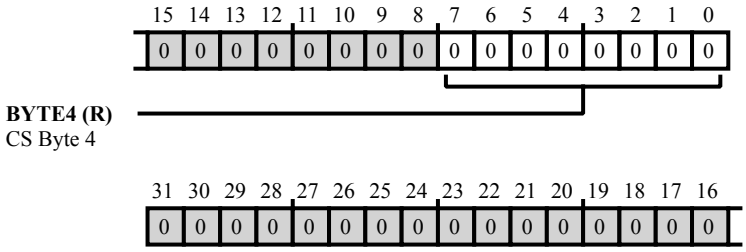

Figure 33-12: SPDIF_RX_STAT1_A Register Diagram

Table 33-9: SPDIF_RX_STAT1_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	BYTE4	CS Byte 4. The SPDIF_RX_STAT1_A.BYTE4 bit field contains byte 4 of received channel A status.

Receive Status B1 Register

The SPDIF_RX_STAT1_B register holds the receive channel 1 status for byte 4 for sub frame B.

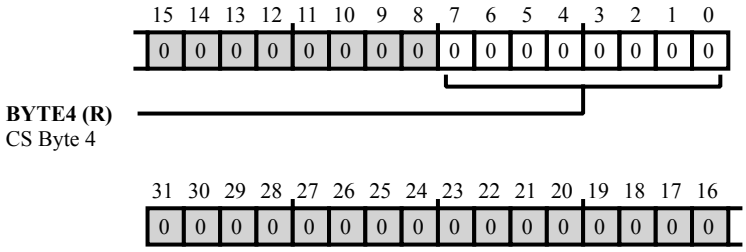

Figure 33-13: SPDIF_RX_STAT1_B Register Diagram

Table 33-10: SPDIF_RX_STAT1_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	BYTE4	CS Byte 4. The SPDIF_RX_STAT1_B.BYTE4 bit field contains byte 4 of received channel B status.

Transmit Control Register

The SPDIF_TX_CTL register provides bits the enable/disable the transmitter and configure several options related to data transmission.

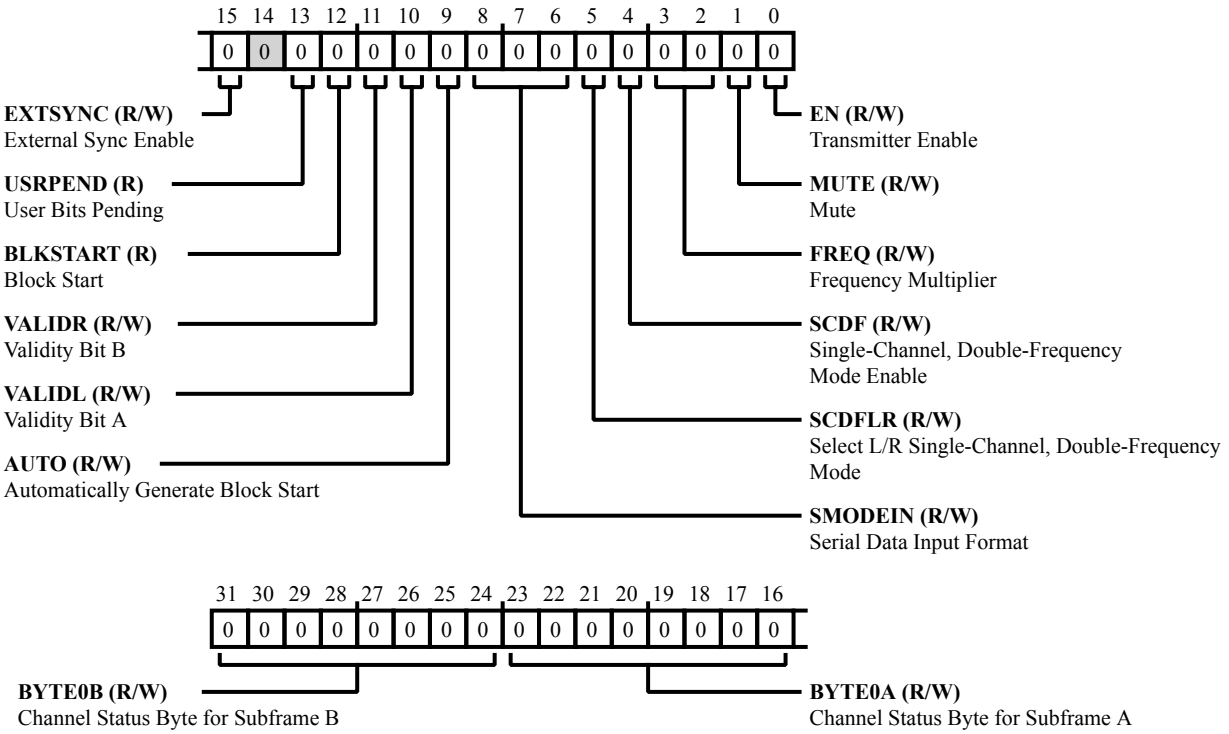

Figure 33-14: SPDIF_TX_CTL Register Diagram

Table 33-11: SPDIF_TX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE0B	Channel Status Byte for Subframe B. The SPDIF_TX_CTL.BYTE0B bit field contains the channel status for the second bytes 95.
23:16 (R/W)	BYTE0A	Channel Status Byte for Subframe A. The SPDIF_TX_CTL.BYTE0A bit field contains the channel status for the first bytes 40.
15 (R/W)	EXTSYNC	External Sync Enable. When the SPDIF_TX_CTL.EXTSYNC bit is set (regardless of the SPDIF_TX_CTL.AUTO bit setting) the internal frame counter is set to zero at an internal LRCLK rising edge followed by an EXTSYNC_I rising edge.

Table 33-11: SPDIF_TX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	USRPEND	User Bits Pending. The SPDIF_TX_CTL.USRPEND bit is set if the update of the internal buffer from the Transmit User Bits Buffer registers has not yet completed.	
12 (R/NW)	BLKSTART	Block Start. The SPDIF_TX_CTL.BLKSTART bit is a status bit that indicates block start (when the SPDIF_TX_CTL.AUTO bit = 1).	
		0	Current word is not block start
		1	Current word is block start
11 (R/W)	VALIDR	Validity Bit B. Use the SPDIF_TX_CTL.VALIDR bit with the channel status buffer.	
10 (R/W)	VALIDL	Validity Bit A. The SPDIF_TX_CTL.VALIDL bit either manually start block transfer according to input stream status bits or automatically start block transfer. Use the SPDIF_TX_CTL.VALIDL bit with the channel status buffer.	
		0	Manually start block transfer
		1	Automatically start block transfer
9 (R/W)	AUTO	Automatically Generate Block Start. When enabled, the transmitter is in standalone mode where it inserts block start, channel status, and validity bits on its own. If the channel status or validity buffer needs to be enabled (after the DAI programming is complete), first write to the buffers with the required data and then enable the buffers by setting the SPDIF_TX_CTL.AUTO bit.	
8:6 (R/W)	SMODEIN	Serial Data Input Format. The SPDIF_TX_CTL.SMODEIN bit selects the data input format.	
		0	Left-justified
		1	I2S
		2	Reserved
		3	Reserved
		4	Right-justified, 24 bits
		5	Right-justified, 20 bits
		6	Right-justified, 18 bits
		7	Right-justified, 16 bits

Table 33-11: SPDIF_TX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SCDFLR	Select L/R Single-Channel, Double-Frequency Mode. The SPDIF_TX_CTL.SCDFLR bit selects the left or right channel in SCDF mode.	
		0	Left channel
		1	Right channel
4 (R/W)	SCDF	Single-Channel, Double-Frequency Mode Enable. The SPDIF_TX_CTL.SCDF bit enables single-channel, double-frequency mode.	
		0	Two-channel mode
		1	SCDF mode
3:2 (R/W)	FREQ	Frequency Multiplier. The SPDIF_TX_CTL.FREQ bit field sets the oversampling ratio.	
		0	256 x frame sync oversampling
		1	384 x frame sync oversampling
		2-3	Reserved
1 (R/W)	MUTE	Mute. The SPDIF_TX_CTL.MUTE bit mutes the serial data output.	
		0	Disable Mute
		1	Enable Mute
0 (R/W)	EN	Transmitter Enable. The SPDIF_TX_CTL.EN bit enables the transmitter and resets the control registers to their defaults.	
		0	Transmitter disabled
		1	Transmitter enabled

Transmit Status A0 Register

The SPDIF_TX_STAT_A0 register holds the transmit channel 0 status for bytes 1-4 for sub frame A.

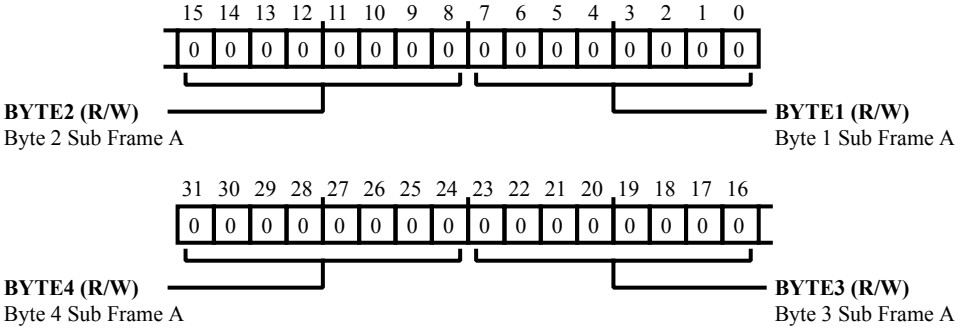

Figure 33-15: SPDIF_TX_STAT_A0 Register Diagram

Table 33-12: SPDIF_TX_STAT_A0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE4	Byte 4 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE4 bit field holds the transmit channel 0 status for byte 4 for sub frame A.
23:16 (R/W)	BYTE3	Byte 3 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE3 bit field holds the transmit channel 0 status for byte 3 for sub frame A.
15:8 (R/W)	BYTE2	Byte 2 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE2 bit field holds the transmit channel 0 status for byte 2 for sub frame A.
7:0 (R/W)	BYTE1	Byte 1 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE1 bit field holds the transmit channel 0 status for byte 1 for sub frame A.

Transmit Status A1 Register

The SPDIF_TX_STAT_A1 register holds the transmit status for bytes 5-8 for sub frame A.

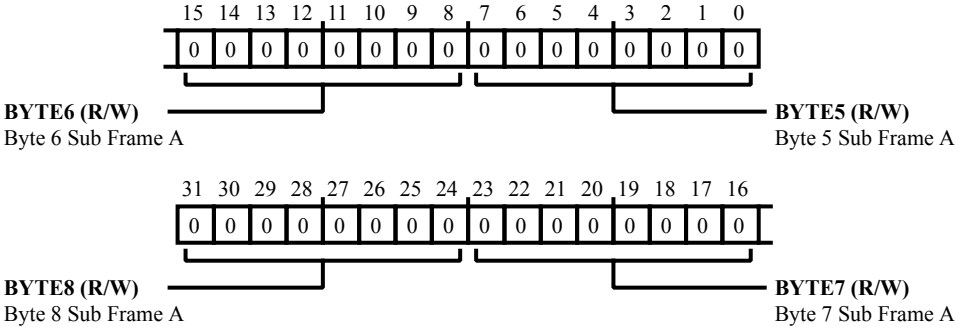

Figure 33-16: SPDIF_TX_STAT_A1 Register Diagram

Table 33-13: SPDIF_TX_STAT_A1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE8	Byte 8 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE8 bit field contains transmit status for byte 8 of sub frame A.
23:16 (R/W)	BYTE7	Byte 7 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE7 bit field contains transmit status for byte 7 of sub frame A.
15:8 (R/W)	BYTE6	Byte 6 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE6 bit field contains transmit status for byte 6 of sub frame A.
7:0 (R/W)	BYTE5	Byte 5 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE5 bit field contains transmit status for byte 5 of sub frame A.

Transmit Status A2 Register

The SPDIF_TX_STAT_A2 register holds the transmit status for bytes 9-12 for sub frame A.

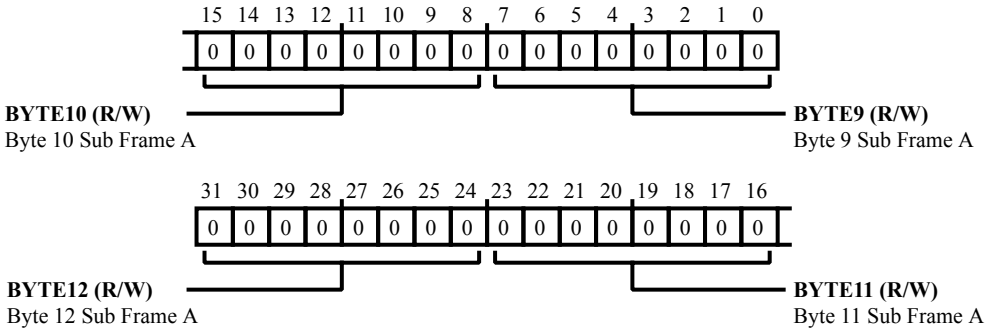

Figure 33-17: SPDIF_TX_STAT_A2 Register Diagram

Table 33-14: SPDIF_TX_STAT_A2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE12	Byte 12 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE12 bit field contains transmit status for byte 12 of sub frame A.
23:16 (R/W)	BYTE11	Byte 11 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE11 bit field contains transmit status for byte 11 of sub frame A.
15:8 (R/W)	BYTE10	Byte 10 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE10 bit field contains transmit status for byte 10 of sub frame A.
7:0 (R/W)	BYTE9	Byte 9 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE9 bit field contains transmit status for byte 9 of sub frame A.

Transmit Status A3 Register

The SPDIF_TX_STAT_A3 register holds the transmit status for bytes 13-16 for sub frame A.

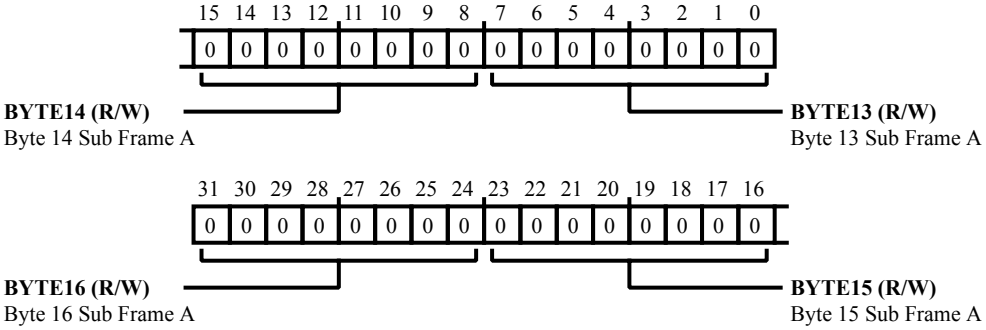

Figure 33-18: SPDIF_TX_STAT_A3 Register Diagram

Table 33-15: SPDIF_TX_STAT_A3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE16	Byte 16 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE16 bit field contains transmit status for byte 16 of sub frame A.
23:16 (R/W)	BYTE15	Byte 15 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE15 bit field contains transmit status for byte 15 of sub frame A.
15:8 (R/W)	BYTE14	Byte 14 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE14 bit field contains transmit status for byte 14 of sub frame A.
7:0 (R/W)	BYTE13	Byte 13 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE13 bit field contains transmit status for byte 13 of sub frame A.

Transmit Status A4 Register

The SPDIF_TX_STAT_A4 register holds the transmit status for bytes 17-20 for sub frame A.

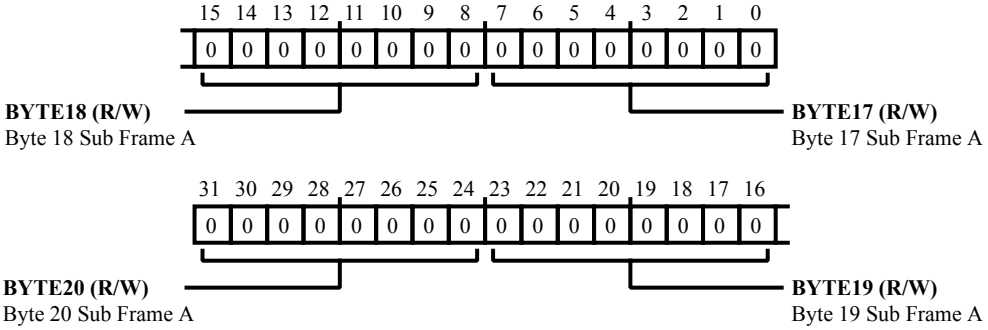

Figure 33-19: SPDIF_TX_STAT_A4 Register Diagram

Table 33-16: SPDIF_TX_STAT_A4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE20	Byte 20 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE20 bit field contains transmit status for byte 20 of sub frame A.
23:16 (R/W)	BYTE19	Byte 19 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE19 bit field contains transmit status for byte 19 of sub frame A.
15:8 (R/W)	BYTE18	Byte 18 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE18 bit field contains transmit status for byte 18 of sub frame A.
7:0 (R/W)	BYTE17	Byte 17 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE17 bit field contains transmit status for byte 17 of sub frame A.

Transmit Status A5 Register

The SPDIF_TX_STAT_A5 register holds the transmit status for bytes 21-23 for sub frame A.

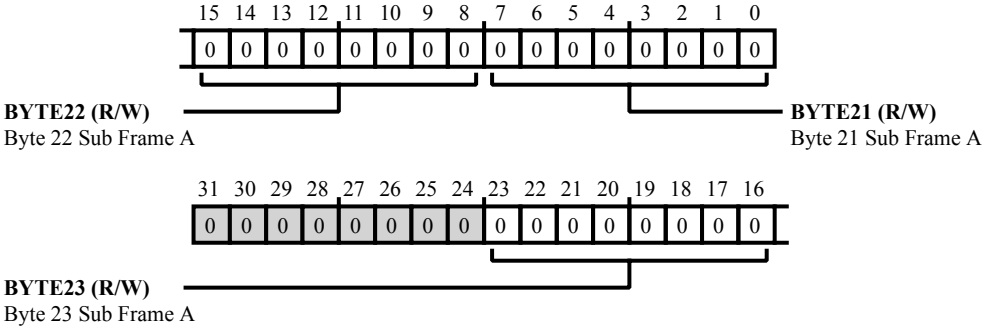

Figure 33-20: SPDIF_TX_STAT_A5 Register Diagram

Table 33-17: SPDIF_TX_STAT_A5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	BYTE23	Byte 23 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE23 bit field contains transmit status for byte 23 of sub frame A.
15:8 (R/W)	BYTE22	Byte 22 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE22 bit field contains transmit status for byte 22 of sub frame A.
7:0 (R/W)	BYTE21	Byte 21 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE21 bit field contains transmit status for byte 21 of sub frame A.

Transmit Status B0 Register

The SPDIF_TX_STAT_B0 register holds the transmit channel 0 status for bytes 1-4 for sub frame B.

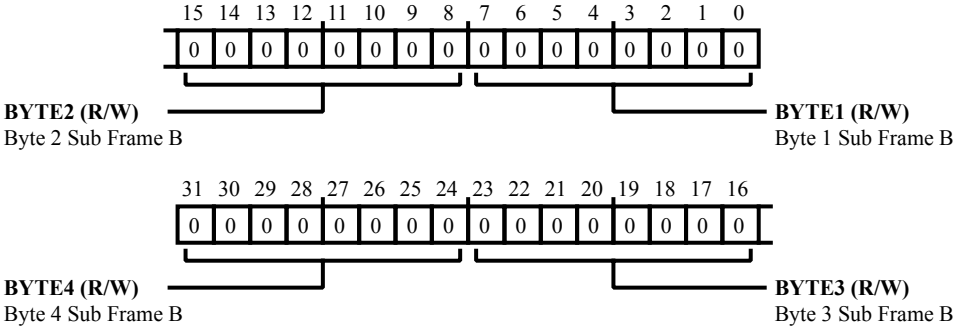

Figure 33-21: SPDIF_TX_STAT_B0 Register Diagram

Table 33-18: SPDIF_TX_STAT_B0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE4	Byte 4 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE4 bit field holds the transmit channel 0 status for byte 4 for sub frame B.
23:16 (R/W)	BYTE3	Byte 3 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE3 bit field holds the transmit channel 0 status for byte 3 for sub frame B.
15:8 (R/W)	BYTE2	Byte 2 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE2 bit field holds the transmit channel 0 status for byte 2 for sub frame B.
7:0 (R/W)	BYTE1	Byte 1 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE1 bit field holds the transmit channel 0 status for byte 1 for sub frame B.

Transmit Status B1 Register

The SPDIF_TX_STAT_B1 register holds the transmit status for bytes 5-8 for sub frame B.

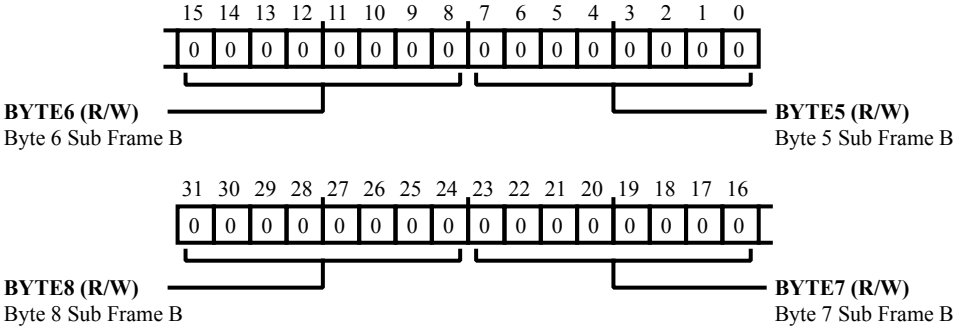

Figure 33-22: SPDIF_TX_STAT_B1 Register Diagram

Table 33-19: SPDIF_TX_STAT_B1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE8	Byte 8 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE8 bit field contains transmit status for byte 8 of sub frame B.
23:16 (R/W)	BYTE7	Byte 7 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE7 bit field contains transmit status for byte 7 of sub frame B.
15:8 (R/W)	BYTE6	Byte 6 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE6 bit field contains transmit status for byte 6 of sub frame B.
7:0 (R/W)	BYTE5	Byte 5 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE5 bit field contains transmit status for byte 5 of sub frame B.

Transmit Status B2 Register

The SPDIF_TX_STAT_B2 register holds the transmit status for bytes 9-12 for sub frame B.

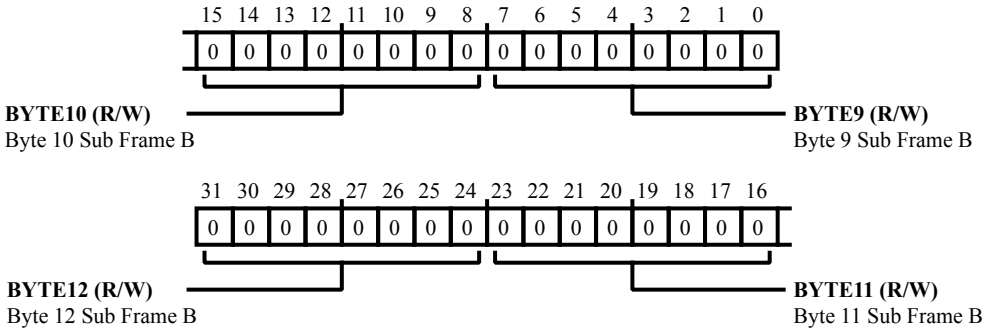

Figure 33-23: SPDIF_TX_STAT_B2 Register Diagram

Table 33-20: SPDIF_TX_STAT_B2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE12	Byte 12 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE12 bit field contains transmit status for byte 12 of sub frame B.
23:16 (R/W)	BYTE11	Byte 11 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE11 bit field contains transmit status for byte 11 of sub frame B.
15:8 (R/W)	BYTE10	Byte 10 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE10 bit field contains transmit status for byte 10 of sub frame B.
7:0 (R/W)	BYTE9	Byte 9 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE9 bit field contains transmit status for byte 9 of sub frame B.

Transmit Status B3 Register

The SPDIF_TX_STAT_B3 register holds the transmit status for bytes 13-16 for sub frame B.

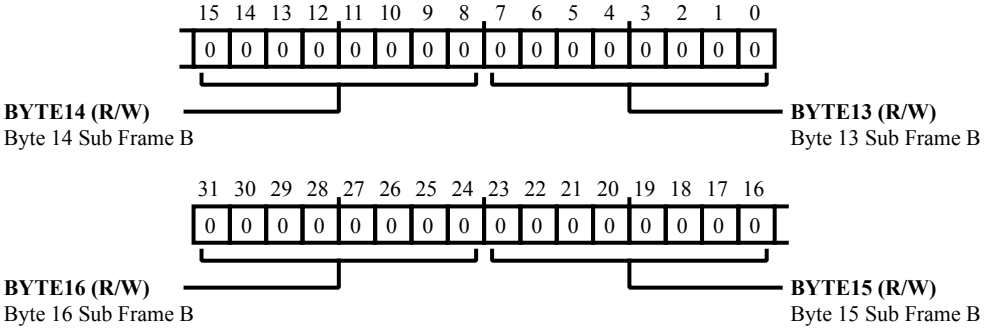

Figure 33-24: SPDIF_TX_STAT_B3 Register Diagram

Table 33-21: SPDIF_TX_STAT_B3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE16	Byte 16 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE16 bit field contains transmit status for byte 16 of sub frame B.
23:16 (R/W)	BYTE15	Byte 15 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE15 bit field contains transmit status for byte 15 of sub frame B.
15:8 (R/W)	BYTE14	Byte 14 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE14 bit field contains transmit status for byte 14 of sub frame B.
7:0 (R/W)	BYTE13	Byte 13 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE13 bit field contains transmit status for byte 13 of sub frame B.

Transmit Status B4 Register

The SPDIF_TX_STAT_B4 register holds the transmit status for bytes 17-20 for sub frame B.

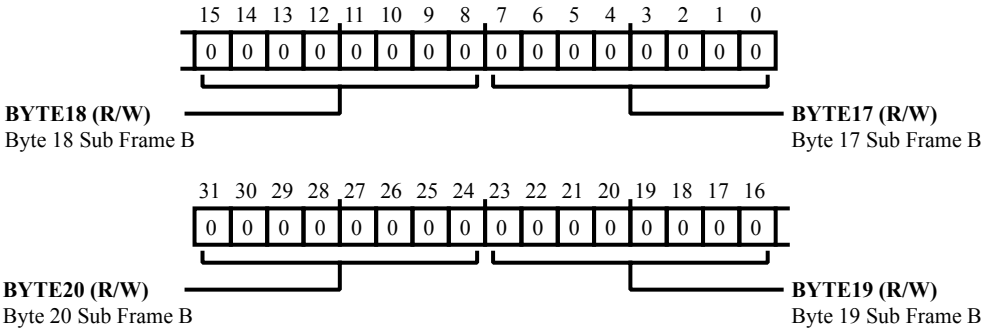

Figure 33-25: SPDIF_TX_STAT_B4 Register Diagram

Table 33-22: SPDIF_TX_STAT_B4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE20	Byte 20 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE20 bit field contains transmit status for byte 20 of sub frame B.
23:16 (R/W)	BYTE19	Byte 19 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE19 bit field contains transmit status for byte 19 of sub frame B.
15:8 (R/W)	BYTE18	Byte 18 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE18 bit field contains transmit status for byte 18 of sub frame B.
7:0 (R/W)	BYTE17	Byte 17 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE17 bit field contains transmit status for byte 17 of sub frame B.

Transmit Status B5 Register

The SPDIF_TX_STAT_B5 register holds the transmit status for bytes 21-23 for sub frame B.

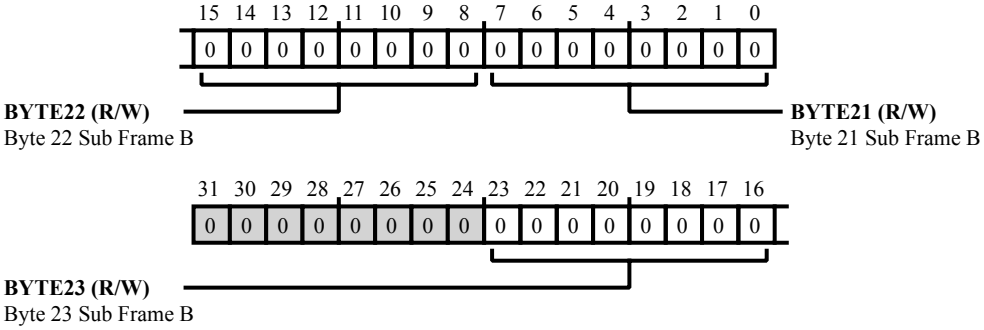

Figure 33-26: SPDIF_TX_STAT_B5 Register Diagram

Table 33-23: SPDIF_TX_STAT_B5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	BYTE23	Byte 23 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE23 bit field contains transmit status for byte 23 of sub frame B.
15:8 (R/W)	BYTE22	Byte 22 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE22 bit field contains transmit status for byte 22 of sub frame B.
7:0 (R/W)	BYTE21	Byte 21 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE21 bit field contains transmit status for byte 21 of sub frame B.

Transmit User Buffer A0 Register

The SPDIF_TX_UBUFF_A0 register holds the transmit user buffer data for bytes 0-3 for sub frame A.

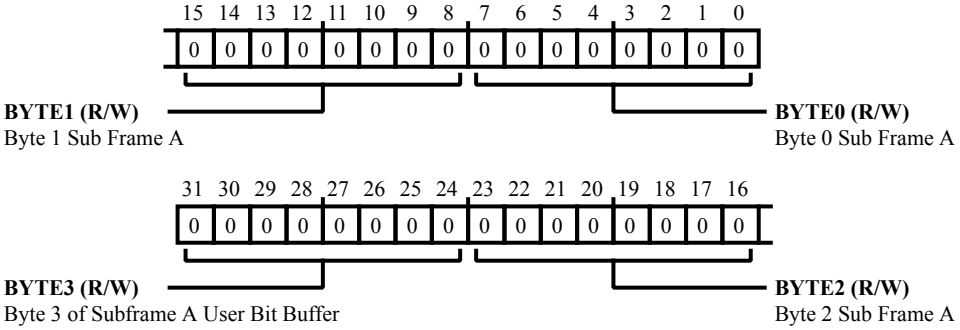

Figure 33-27: SPDIF_TX_UBUFF_A0 Register Diagram

Table 33-24: SPDIF_TX_UBUFF_A0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE3	Byte 3 of Subframe A User Bit Buffer. The SPDIF_TX_UBUFF_A0.BYTE3 bit field contains user bit data for byte 0 of sub frame A.
23:16 (R/W)	BYTE2	Byte 2 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE2 bit field contains user bit data for byte 2 of sub frame A.
15:8 (R/W)	BYTE1	Byte 1 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE1 bit field contains user bit data for byte 1 of sub frame A.
7:0 (R/W)	BYTE0	Byte 0 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE0 bit field contains user bit data for byte 0 of sub frame A.

Transmit User Buffer A1 Register

The SPDIF_TX_UBUFF_A1 register holds the transmit user buffer data for bytes 4-7 for sub frame A.

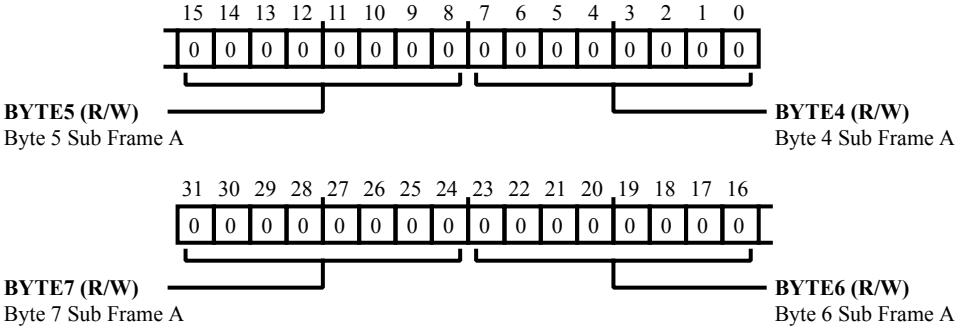

Figure 33-28: SPDIF_TX_UBUFF_A1 Register Diagram

Table 33-25: SPDIF_TX_UBUFF_A1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE7	Byte 7 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE7 bit field contains user bit data for byte 7 of sub frame A.
23:16 (R/W)	BYTE6	Byte 6 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE6 bit field contains user bit data for byte 6 of sub frame A.
15:8 (R/W)	BYTE5	Byte 5 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE5 bit field contains user bit data for byte 5 of sub frame A.
7:0 (R/W)	BYTE4	Byte 4 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE4 bit field contains user bit data for byte 0 of sub frame A.

Transmit User Buffer A2 Register

The SPDIF_TX_UBUFF_A2 register holds the transmit user buffer data for bytes 8-11 for sub frame A.

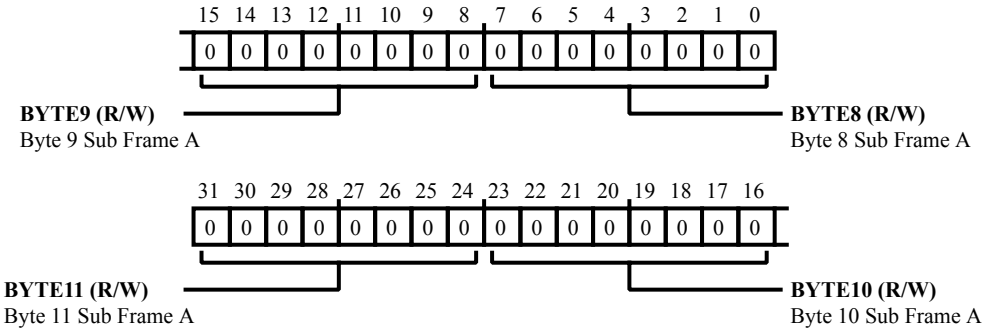

Figure 33-29: SPDIF_TX_UBUFF_A2 Register Diagram

23:16 (R/W)	BYTE22	Byte 22 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE22 bit field contains user bit data for byte 22 of sub frame B.
15:8 (R/W)	BYTE21	Byte 21 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE21 bit field contains user bit data for byte 21 of sub frame B.
7:0 (R/W)	BYTE20	Byte 20 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE20 bit field contains user bit data for byte 20 of sub frame B.

User Bit Update Register

After writing to the transmit user buffer registers, a value of 0x1 must be written into the SPDIF_TX_USRUPDT register to enable the use of these user buffer bits in the next transfer block.

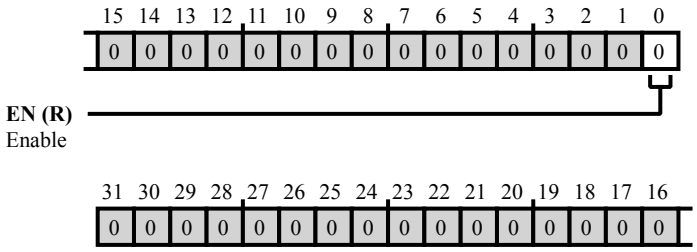

Figure 33-39: SPDIF_TX_USRUPDT Register Diagram

Table 33-36: SPDIF_TX_USRUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	EN	Enable. After writing to the transmit user buffer registers, a value of 0x1 must be written into the SPDIF_TX_USRUPDT register to enable the use of these SPDIF_TX_USRUPDT.EN bits in the next transfer block.

34 Direct Memory Access (DMA)

The processor architecture distributes the DMA channels throughout the infrastructure. Often, the channels cluster together through system crossbars (SCB), sharing a single interface with the main system crossbar.

The DMA channels can perform transfers between memory and a peripheral or between one memory and another memory. Memory-to-memory DMA transfers (MDMA) require two DMA channels. One channel is the source channel, and the second, the destination channel.

All DMA channels can transport data to and from virtually all on-chip and off-chip memories.

DMA transfers on the processor use either a descriptor-based method or register-based method. Register-based DMA allows the processor directly to program DMA controller registers to initiate a DMA transfer. On completion, the controller registers can automatically update with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based transfers allow the chaining together of multiple DMA sequences. In descriptor-based DMA operations, DMA channel programming can automatically set up and start another DMA transfer after the current sequence completes.

The DMA channel does not connect external memories and devices directly. Rather, data passes through an external-memory interface port. DMA operations can access any device the external memory interface supports. These interfaces typically include:

- Flash memory
- SRAM
- FIFOs
- Memory-mapped peripheral devices
- Dynamic Memory (if present)

DMA Channel Features

The processor uses Direct Memory Access (DMA) to transfer data within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure and interface with the system crossbar unit (SCB).

The following is a list of DMA interface features.

- Supports integer byte strides including byte strides of 0 and negative byte strides
- Register-based configuration
  - Core writes DMA configuration
  - Supports automatic reloading for continuous operation
- Flexible descriptor-based configuration
  - DMA descriptors are fetched from memory
  - Support for variable descriptor sizes
- Flexible flow control – Transitions between the various descriptor-based modes and for DMA termination
- Orthogonal transfers
  - Support for three transfer dimensions
  - One and two dimensional (1D and 2D) transfers supported per descriptor set
  - Three dimensional (3D) support provided by chained descriptor sets
- Configurable memory and peripheral-transfer word sizes
  - Memory interface supports 8-bit, 16-bit, 32-bit, 64-bit, 128-bit, and 256-bit transfers
  - Peripheral interface supports for 8-bit, 16-bit, and 32-bit transfers
- Interrupt notification
  - Row or work unit completion
  - Error conditions
- Incoming and outgoing trigger support
  - Trigger generation for row or work unit completion
  - Work unit can wait for incoming trigger
- MMR access bus – Provides access to memory-mapped registers for configuration, monitoring, and debug
- SCB crossbar interface connects the DMA channel to the system crossbar
- Peripheral DMA bus – Interfaces the DMA channel to a peripheral or another DMA channel
- Peripheral data-request interrupt support
- Bandwidth monitoring and limiting for MDMA channels

DMA Channel Functional Description

This section provides a functional description of the DMA channel interface.

NOTE: There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and are described in this chapter. The second type is not controlled by the DDE. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The complete list of DMA supported peripherals are shown in the SCB Block Diagram.

ADSP-2159x_SC591_SC592_SC594 DMA Register List

The DMA channel controller (DMA) supports data transfers within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure, as DMAn's. A set of registers governs DMA operations. For more information on DMA functionality, see the DMA register descriptions.

Table 34-1: ADSP-2159x_SC591_SC592_SC594 DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

DMA ID	DMA Channel Name	Description
DMA55	SPI3_TXDMA	SPI3 TX DMA Channel
DMA56	SPI3_RXDMA	SPI3 RX DMA Channel

DMA Definitions

To make the best use of the DMA controller, it is useful to understand the following terms.

Descriptor

A single element of a descriptor set that maps to a specfic register of a DMA channel.

Descriptor Fetch

The action of retrieving descriptors from memory through memory read operations and loading then into the DMA channel registers upon their read return.

Descriptor Set

A array of descriptors associated with a single work unit. The user can configure the size of the descriptor set. See Descriptor-Based Flow Modes .

Disabled State

The channel is disabled because the enable bit = 0 or as a result of an error.

DMAC

An acronym used for a DMA cluster.

DMA Channel

A single DMA engine that has all the capabilities and registers as defined for a given processor. A DMA channel or engine is connected to a single peripheral.

DMA Cluster

A grouping of multiple DMA channels with a shared SCB crossbar interface, controller, and arbiter. Also known as a DMAC.

Initial Descriptor

The first descriptor in the descriptor set.

MDMA

Memory-to-Memory DMA data transfer. Two DMA channels are paired to perform a memory read from one address location and a memory write of that data to another address location.

Stop State

A time where the channel is enabled but not currently programmed to perform a data transfer. Programming the flow to STOP causes the channel to enter the stop state at the end of the work unit.

User

Any person, debug, emulator, software routine, or action taken by the core that accesses the MMR registers of the DMA channel or peripherals, or sets up data and descriptors in memory.

Wait State

If instructed to wait for a trigger, the channel enters this state once it has completed a work unit. The channel remains in this state until a trigger occurs. If a trigger came in before reaching the wait state, the channel skips over the wait state upon completion of the work unit.

Work Unit

A single data transaction or series of data transactions performed based on the configuration of the DMA channel. For autobuffer mode, a new work unit is defined at the time all current count registers are initialized to start values. Once all the current count registers count down to zero, the work unit has completed.

Work Unit Chain

A single work unit or a series of work units separated by a `STOP` or disabled state. The work units in the chain (except the last one) are programmed to the required descriptor flow. The last work unit in the chain is programmed to a flow of `STOP` or `AUTO`. `STOP` terminates the state at the end of that work unit. `AUTO` must be be terminated by disabling the DMA channel. A work unit chain is also known as a descriptor chain.

Block Diagram

The ***DMA Channel Block Diagram*** shows the functional blocks within the DMA interface.

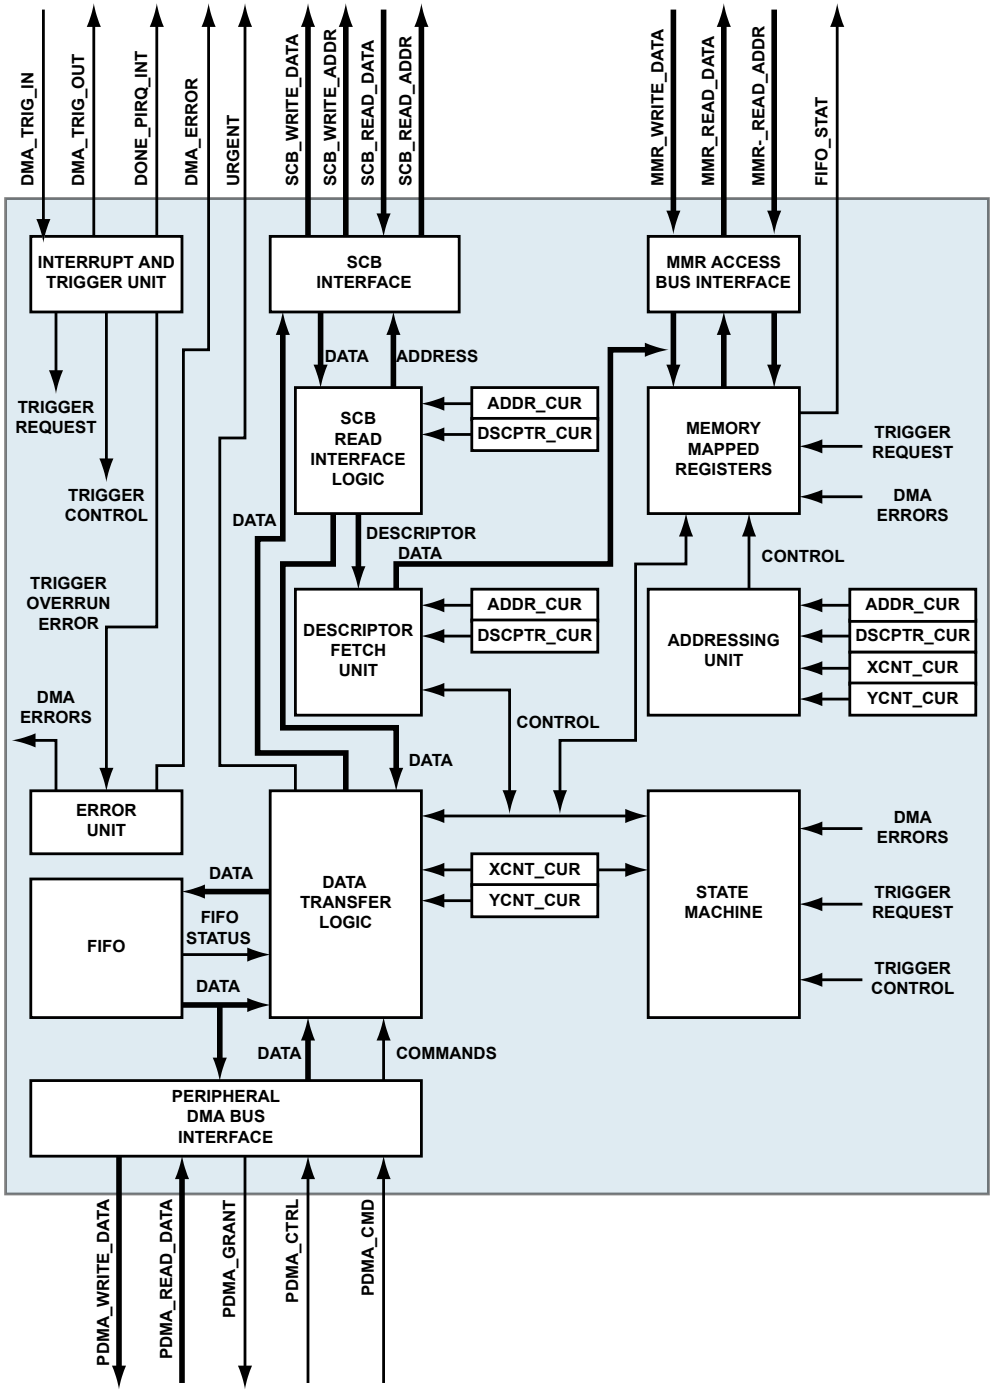

Figure 34-1: DMA Channel Block Diagram

For more information on the interfaces, see:

- DMA Channel Peripheral DMA Bus
- Medium Band Width DMA Channel MMR Access Bus
- DMA Channel Event Control

Architectural Concepts

The DMA channel provides a method to transfer data between memory spaces or between memory and a peripheral using a number of system interfaces. The DMA channel provides an efficient method of distributing data throughout the system, freeing up the processor core for other operations. Each peripheral that supports DMA transfers has its own dedicated DMA channel or channels with its own register set. The register set configures and controls the operating modes of the DMA transfers.

DMA Channel SCB Interface

The SCB interface connects the DMA channel to the SCB crossbar allowing for transfers to and from the processors internal memory and other suitable system resources.

The DMA channel connects to the system interconnect through the SCB interface. This connection lets the DMA channel perform work-unit data transfers with memories such as L1, L2 (internal), and L3 (external). In addition to work unit data transfers, the SCB interface also is used for fetching descriptor sets for all the descriptor-based transfer modes.

The DMA channel can support data bus widths of 16, 32, 64, or 128 bits. The data bus widths for a given DMA channel on a specific processor can vary and are not configurable. Read the `DMA_STAT.MBWID` field to determine the assigned bus widths.

SCB Interface Signals

The DMA channel operates at one of the *SCLKn* frequencies, as does the SCB interface. SYSCLK clocks all eight DMA channels. The SCB crossbar handles the internal arbitration of the transfer requests of all the controllers interfaced to the SCB crossbar instance as shown in the ***SCB Interface Signals*** table.

Table 34-3: SCB Interface Signals

Signal	Width (bits)	Description
SCB_WRITE_DATA	16, 32, 64, or 128	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_WRITE_ADDRESS	32	Write address bus. Provides the address of the first transfer in a burst transaction.
SCB_READ_DATA	16, 32, 64, or 128	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_READ_ADDRESS	32	Read address bus. Provides the address of the first transfer in a burst transaction.

SCB Burst Transfers

The SCB interface supports burst transfers for memory read and write operations. The burst length is a function of the configurable memory size of the DMA channel for the work unit and the fixed bus width of the SCB data bus of the DMA channel.

- If the DMA channel configuration selects a memory transfer size less than or equal to the DMA channels bus width, the burst length is always 1.
- If the configured memory size is greater than the SCB interface bus width, the burst length is sufficient to transfer a transaction as specified by the configured memory size.

Table 34-4: DMA Channel SCB Burst Lengths

Configured Memory Size	Burst Length			
	16-bit Bus	*32-bit Bus*	*64-Bit Bus*	*128-bit Bus*
1 Byte	1	1	1	1
2 Bytes	1	1	1	1
4 Bytes	2	1	1	1
8 Bytes	4	2	1	1
16 Bytes	8	4	2	1
32 Bytes	16	8	4	2

Data Address Alignment

To prevent addressing errors and to maximize bandwidth of the SCB interface to the DMA channel, data addresses align with a multiple of the programmable memory size of the DMA channels configuration. These configuration options appear in the Descriptor Set Address Alignment table.

There are situations in which entire work units may not transfer at the maximum configurable memory size. In this case, the entire work unit can transfer by reducing the configured memory size at the expense of bus bandwidth using descriptor sets as follows:

- The first descriptor set can be configured to transfer data until the larger memory size alignments are met.
- A second descriptor set with a larger memory size configuration then can be used to transfer the bulk of the data in the work unit.
- Finally, a third descriptor set can be used with a smaller memory size to complete any final data transfers that cannot meet the alignment requirements of the previous descriptor set configuration.

Table 34-5: DMA Channel Address Alignment Requirements

Configured Memory Size	Address Restriction
1 Byte	No restriction
2 Bytes	ADDR[0] == 0
4 Bytes	ADDR[1:0] == 0
8 Bytes	ADDR[2:0] == 0
16 Bytes	ADDR[3:0] == 0
32 Bytes	ADDR[4:0] == 0

Descriptor Set Address Alignment

All descriptor set addresses and descriptors within a descriptor set must align to a 32-bit address. For descriptor set fetches, the DMA engine ignores the memory-size configuration of the DMA channel. This feature avoids the need to align descriptor sets based on the memory width configuration of the previous descriptor set.

For descriptor sets containing only a single descriptor, the transfer takes place as a single 32-bit transfer. For descriptor sets containing multiple descriptors, the DMA engine fetches each 32-bit descriptor individually and treats it as multiple 32-bit transfers.

Peripheral Control Commands

The peripheral DMA bus of the DMA channel provides a means for peripherals on the processor to issue commands to the DMA channel. These commands provide greater control over the DMA channel operation. This control improves real-time performance and relieves control and interrupt demands on the core. Peripherals can send commands to the DMA controller over the 3-bit PERI_CMD bus. The DMA control commands extend the set of operations available to the peripheral beyond the simple “request data” command used by peripherals in general. Refer to the appropriate peripheral chapter for a description on how that peripheral uses DMA control commands.

These DMA control commands (see the ***PDMA_CMD Peripheral DMA Control Commands*** table) are not visible to or controlled by the program. But, their use by a peripheral has implications for the structure of the DMA transfers that the peripheral can support. It is important to write application software such that it complies with certain restrictions, regarding work units and descriptor chains. Complying with this guideline makes the peripheral operate properly whenever it issues DMA control commands.

The ***PDMA_CMD Peripheral DMA Control Commands*** table describes the commands the DMA controller issues. The following sections describe these commands in more detail.

Table 34-6: PDMA_CMD Peripheral DMA Control Commands

Command	Name	Description
b#000	NOP	No operation
b#001	Restart	Restarts the current work unit from the beginning
b#010	Finish	Finishes the current work unit and starts the next
b#011	Interrupt	Immediately sets the DMA completion interrupt in the DMA channel
b#100	Request Data	Typical DMA data request
b#101	Request Data Urgent	Urgent DMA data request
b#110	Reserved	Reserved
b#111	Reserved	Reserved

Idle Command

The DMA channel drives this command when the enabled peripheral has no data requests required.

Request-Data Command

The request data command is a request for data transfers between the DMA channel and the peripheral. The request is held by the peripheral until granted or acknowledged by the DMA channel.

Request-Data Urgent Command

The request-data urgent command behaves identically to the request data command, except that---during the commands assertion---the DMA channel performs its memory accesses with urgent priority. This priority includes both data and descriptor fetch memory accesses. For example, a DMA management capable peripheral can use this control command if an internal FIFO approaches a critical condition.

The request is held by the peripheral until granted or acknowledged by the DMA channel.

Peripheral-Control Command Restrictions

The proper operation of the DMA channel FIFO leads to certain restrictions in the sequence of DMA peripheral control commands issued by a peripheral. The following sections describe these restrictions.

DMA Channel Peripheral DMA Bus

The DMA channel connects to peripherals or other DMA channels through the peripheral DMA bus. This bus is a dedicated point-to-point interface supporting data bus widths of 8, 16, 32, or 64 bits. The data bus widths for a given DMA channel on a particular processor can vary and are not configurable. Reading the `DMA_STAT.PBWID` field permits determining the assigned bus width.

The DMA channel operates at one of the SCLK frequencies, as does the peripheral DMA bus. The ***Peripheral DMA Bus Signals*** table provides descriptions of the peripheral DMA bus signals.

Table 34-7: Peripheral DMA Bus Signals

Signal	Width (bits)	Description
PDMA_WRITE_DATA	8, 16, 32, or 64	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_READ_DATA	8, 16, 32, or 64	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_DMA_GRANT		Control signals to indicate that data is valid for DMA channel read operations (peripheral transmit). These signals indicate that the DMA channel is ready to receive data for write operations (peripheral receive).
PDMA_CMD	3	The peripheral uses the signal for issuing DMA channel control commands.
PDMA_CTRL		The peripheral uses the control signals to send various commands to the DMA channel and control the direction of flow.

Memory DMA and Triggering

A memory DMA (MDMA) channel provides a means of doing memory-to-memory DMA transfers among the various memory spaces that have DMA support.

The DMA controller implements memory DMA (MDMA) channels by interfacing two DMA channels through the peripheral DMA bus interface. One DMA channel serves for memory read operations, and the second channel servers for memory writes. Depending on the processor, a memory DMA channel can have an additional peripheral, such as a CRC peripheral. The additional peripheral is inserted into the peripheral DMA bus that optionally can be enabled.

MDMA channel configurations that do not involve an additional peripheral impose no restrictions on which of the DMA channels is used for the read operation or the write operation. But, the configuration of both channels cannot have the same transfer direction. For MDMA channel configurations that enable a peripheral between the read and write channels, be aware of possible restrictions imposed on which channel can be used for a given transfer direction.

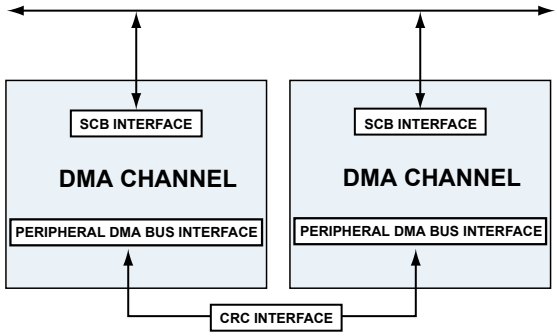

Figure 34-2: MDMA Channel Dedicated Pair

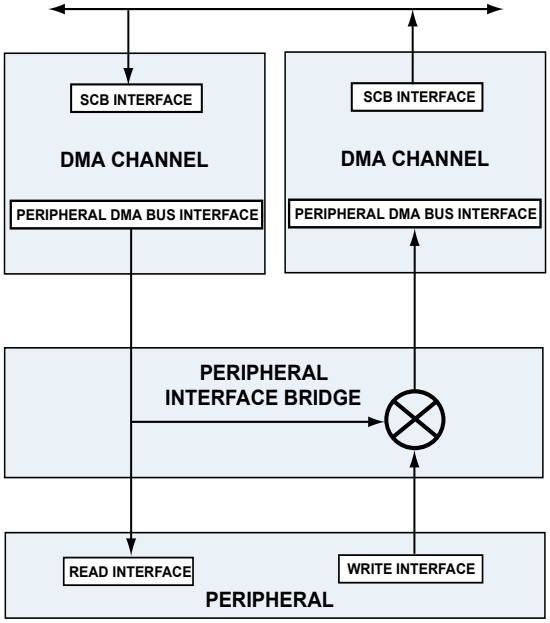

Figure 34-3: MDMA Channel Pair with Peripheral

A memory-to-memory transfer always requires enabled source and destination channels. Because the channels interface through the peripheral DMA bus and can have an additional peripheral inserted into the peripheral DMA bus, programs must make sure to set the same values in the `DMA_CFG.PSIZE` of both the source and destination channels.

The memory DMA channels support the full range of the DMA_CFG.MSIZE options for the DMA transfers to and from the memories.

Because the MDMA channel consists of two DMA channels, the entire MDMA channel has two sets of FIFOs, one in the read channel and one in the write channel. This FIFO usage allows for more efficient bursting of both read and write transactions using the available bandwidth. While the DMA_CFG.PSIZE configuration must be identical for both source and destination DMA channels, this restriction does not apply for the DMA_CFG.MSIZE configuration.

Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From a performance perspective, use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the PSIZE value used.

NOTE: This is applicable for all of the DMA channels, except the enhanced and high-speed MDMA channels. For the enhanced and high-speed MDMAs, the minimum *PSIZE* and *MSIZE* is 4 bytes (32 bits).

The independent source and destination DMA channels also have their own dedicated interrupt and trigger events. While it is normal practice to have only event generation performed at destination DMA completion, programs also can use other means of interrupt generation.

Configuration of an MDMA transfer is done in a similar manner to peripheral DMA transfers, except for writing two DMA channel registers instead of one.

To control the pace of data transfers, use triggers on either the memory read or the memory write channel pair used in an MDMA operation. Setting the DMA_CFG.TWAIT bit in the memory read channel prevents both channels from transferring data before the system is ready. However, only configuring the memory write channel to wait for a trigger allows for data fetch from the memory in anticipation of the memory write operation.

The *MDMA Streams* table shows the details for each supported MDMA stream.

Table 34-8: MDMA Streams

MDMA Stream	Source Channel	Desitnation Channel	CRC Support	Other Names	Operating Clock	Bus Width (bits)	Maximum Theoretical BW (Mbytes/ second)
0	8	9	Yes	CRC0	SYSCLK (500 MHz max)	32	2000
1	18	19	Yes	CRC1			
2	39	40	No	MSMDMA			
3	43	44	No	HSMDMA		64	4000
4	45	46	Yes	CRC2		32	2000
5	47	48	Yes	CRC3			
6	49	50	No	MSMDMA1			

Table 34-8: MDMA Streams (Continued)

MDMA Stream	Source Channel	Desitnation Channel	CRC Support	Other Names	Operating Clock	Bus Width (bits)	Maximum Theoretical BW (Mbytes/second)
7	51	52	No	HSMDMA1		64	4000

Medium Band Width DMA Channel MMR Access Bus

The MMR access bus provides access to all the DMA channels memory-mapped registers for DMA channel configuration, monitoring, and debug. The interface has a fixed 32-bit data bus for read and write accesses.

The ***MMR Access Bus Signals*** table provides descriptions of the MMR access bus signals.

Table 34-9: MMR Access Bus Signals

Signal	Width (bits)	Description
MMR_WRITE_DATA	32	Data bus used for write operations to the MMRs from the core
MMR_READ_DATA	32	Data bus used to return read data from the MMRs
MMR_READ_ADDR	7	Address used to select the MMR to access

DMA Channel Operation Flow

A detailed description of the flow of operation of the DMA channel appears in the following topics:

- Startup Flow
- Refresh Flow
- DMA Operating Modes
- Stop Mode
- DMA Channel Errors

Startup Flow

Enabling a DMA operation on a given channel first requires directly writing some or all of the DMA parameter registers. The minimum set of register required to be initialized depends on the desired mode of operation as described in the following sections.

Startup Minimum-Enable Requirements

To start a DMA operation on a given channel, some or all of the DMA parameter registers must first be initialized and configured to the desired DMA channels operating mode.

- For descriptor-array-based flow modes, at minimum, write the `DMA_DSCPTR_CUR` register prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.

- For descriptor-list-based flow modes, at minimum, write the DMA_DSCPTR_NXT register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.
- For non-descriptor-based flow modes, write the DMA_ADDRSTART, DMA_XCNT, and DMA_XMOD registers prior to writing the DMA_CFG register.

Programs can write other registers that can remain static throughout the course of the DMA activity. The write to the DMA_CFG register begins the DMA operation.

ATTENTION: When software directly writes the DMA_CFG register, the DMA controller recognizes this action as the special startup condition. This condition occurs when starting the DMA controller for the first time on this channel or occurs after the DMA channel stops. It is possible for the channel to flag a DMA error condition regardless of the DMA_CFG.EN bit setting.

Startup Operation

The startup operation is initiated by software directly writing the DMA_CFG register when starting DMA for the first time on a channel or after the channel has entered to the stop state.

When the descriptor fetch is complete and the DMA channel is enabled, the DMA_CFG descriptor element replaces the DMA_CFG register content and assumes control. Before this point, the direct write to the DMA_CFG register had control.

At startup, the selected flow mode and the descriptor size determine the course of the DMA initialization process. The DMA_CFG.FLOW field determines whether to load more current registers from descriptor sets in memory. The DMA_CFG.NDSIZE field details how many descriptor elements to fetch before starting the DMA operation. This process does not affect DMA registers that are not in the descriptor; no modifications are made to their prior values.

For descriptor-list flow modes, the channel copies the DMA_DSCPTR_NXT register value into the DMA_DSCPTR_CUR register. Then, the channel fetches new descriptor elements from memory. The DMA_DSCPTR_CUR register indexes each fetch, and the channel increments the index after each fetch. After completion of the descriptor fetch, the DMA_DSCPTR_CUR register points to the next 32-bit word in memory past the end of the descriptor.

If the descriptor fetch is for a descriptor-array mode transfer, the channel does *not* copy the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register. *Instead*, the descriptor fetch indexing begins with the value in the DMA_DSCPTR_CUR register.

If DMA_CFG is not part of the fetched descriptor set, the previous value (originally as written on startup) controls the work unit operation. If the DMA_CFG register is part of the fetched descriptor set, the value programmed by the MMR access controls only the loading of the first descriptor set fetched from memory. The configuration of the DMA_CFG register controls the subsequent DMA work units of the fetched descriptor set.

After the descriptor fetch is complete or if the flow configuration was originally for one of the register-based flow modes, the DMA operation begins. The DMA channel immediately fills its FIFO. For a memory-write operation, the DMA channel begins accepting data from the peripheral. For a memory-read operation, the DMA channel begins memory reads when the SCB bus grants access to the DMA channel.

When the DMA channel performs its first data-memory access, its address and count computations take their input operands from the start registers. These registers can include DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT, if necessary. The channel writes results back to the current registers. These registers include DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR. Note that the current registers are not valid until the channel performs the first memory access, which can be some time after the write to the DMA_CFG register starts the channel. Once started, the channel automatically loads the current registers from the appropriate descriptor elements, overwriting their previous contents. These automatic-load operations include:

- The channel copies the DMA_ADDRSTART value to DMA_ADDR_CUR.
- The channel copies the DMA_XCNT value to DMA_XCNT_CUR.
- The channel copies the DMA_YCNT to DMA_YCNT_CUR.

Refresh Flow

When the channel completes processing of a work unit, the DMA channel performs the following operations:

- Completes the transfer of all data between memory and the DMA channel.
- Performs a synchronized transition (if the DMA channel configuration is a memory read operation with the DMA_CFG.SYNC bit enabled) *and* transfers all data to the peripheral before continuing.
- Forwards the signals from the DMA channel (if interrupts or triggers are enabled) *and* updates the DMA_STAT register to indicate the interrupt request or trigger events.
- Clears the DMA_STAT.RUN bit field to stop DMA operation (if the flow was set to stop mode) *and* transfers any remaining data in the FIFO of the DMA channel to the peripheral.
- Loads a new descriptor from memory into the DMA registers by way of the contents of the DMA_DSCPTR_CUR register (for descriptor-array mode) *and* increments the DMA_DSCPTR_CUR register

  The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
- Copies the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register (for descriptor-list mode), fetches the descriptor from the new contents of the DMA_DSCPTR_CUR register, *and* places these contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
- Checks for detection of an incoming trigger event (for descriptor-on-demand array mode):
  - If the channel detects a trigger event, the DMA channel loads a new descriptor from memory into the DMA registers from the contents of the DMA_DSCPTR_CUR register, while incrementing the DMA_DSCPTR_CUR register. The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
  - If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers.
- Checks for detection of an incoming trigger event (for descriptor-on-demand list mode):

- If the channel detects a trigger event, the DMA channel copies the DMA_DSCPTR_NXT register value to the DMA_DSCPTR_CUR register, fetches the descriptor memory from the DMA_DSCPTR_CUR register, *and* places the contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
- If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers as described in the next step.

- Begins the next work unit (if flow configuration is anything other than stop mode) by reloading the current registers (DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR) from their descriptor registers (DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT)

Work Unit Transition Flow

The DMA_CFG.SYNC bit controls transitions from one work unit to the next work unit. In general, continuous transitions have lower latency at the cost of restrictions on changes of data format or addressed memory space in the two work units. These latency gains and data restrictions arise from the way the channel handles the DMA FIFO while fetching the next descriptor.

In continuous transitions, with disabled synchronization, the DMA FIFO pipeline continues to transfer data to and from the peripheral or destination memory. These transfers continue during the descriptor fetch and during the DMA channel pause between descriptor chains. By comparison, synchronized transitions provide better real-time synchronization of interrupts and triggers with a given peripheral state. Synchronized transitions also provide greater flexibility in the data formats and memory spaces of the two work units. This flexibility comes at the cost of higher latency in the transition. In synchronized transitions, the DMA FIFO pipeline drains to the destination or flushes (received data discarded) between work units.

NOTE: The DMA_CFG.SYNC bit of the MDMA source channel controls work unit transitions for MDMA streams. Clear this reserved bit of the MDMA destination channel, placing it in the disabled state. In transmit (memory read) channels, the DMA_CFG.SYNC bit of the last descriptor before the transition controls the transition behavior. In contrast, in receive channels, the DMA_CFG.SYNC bit of the first descriptor of the next descriptor chain controls the transition.

Work Unit Transmit and MDMA Source Transitions

In DMA transmit (memory read) and MDMA source channels, the DMA_CFG.SYNC bit controls the interrupt timing at the end of the work unit. This bit also controls the handling of the DMA FIFO between the current and the next work unit.

If the DMA_CFG.SYNC bit configuration disables synchronization, the DMA channel operates in continuous transition. In a continuous transition, just after reading the last data item from memory, the DMA channel starts all of the following operations parallel:

- Signals the interrupt request or trigger
- Updates the DMA_STAT register to indicate DMA completion status
- Begins fetching the next descriptor
- Delivers the final data items from the DMA FIFO to the destination memory or peripheral

This process lets the DMA channel provide data from the FIFO to the peripheral continuously during the descriptor fetch latency period.

If the configuration disables synchronization, the final interrupt request or trigger (if enabled) occurs when the channel reads the last data from memory. This event occurs at the earliest time that the channel safely can modify the output memory buffer without affecting the previous data transmission. There can be a number of data items remaining in the FIFO and not yet at the peripheral. This number depends on the FIFO depth of the DMA channel. In this configuration, do not use the DMA interrupt request as the sole means of synchronizing the shutdown or reconfiguration of the peripheral following a transmission.

NOTE: If the configuration selects continuous transition on a transmit (memory read) descriptor, the next descriptor must have the same:

- Peripheral transfer size (`DMA_CFG.PSIZE`)
- Read or write direction
- Source memory (internal versus external) as the current descriptor

It is possible to disable synchronization by selecting continuous transition on a work unit with configuration for stop-flow mode and with enabled interrupts or triggers. This approach can result in the execution of the event service routine while draining of the final data is ongoing from the FIFO to the peripheral. If data transfers are in-progress, the FIFO is not yet empty. The `DMA_STAT.RUN` bits of the DMA channels indicate this status. Do not start a new work unit with a different peripheral transfer size or direction while data transfers are in-progress.

CAUTION: Disabling the channel with the `DMA_CFG.EN` bit while data transfers are in-progress causes the loss of the data in the FIFO.

A synchronized transition configuration directs the channel to drain the DMA FIFO to the destination memory or peripheral. This FIFO operation occurs before the channel signals any interrupt and before the channel fetches any subsequent descriptor or data. This operation incurs greater latency, but provides direct synchronization between the DMA interrupt and the state of the data at the peripheral.

If the configuration enables synchronization and enables interrupts, on the last descriptor in a work unit, the interrupt occurs when the channel transfers the final data to the peripheral. This event allows the service routine to switch properly to non-DMA transmit operation. When the event vectors to the interrupt service routine, the DMA channel FIFO is empty, and the DMA channel is no longer running (indicated by the `DMA_STAT.RUN` bits).

A synchronized transition also allows greater flexibility in the format of the DMA descriptor chain. When enabled, the next descriptor can have any `DMA_CFG.PSIZE` configuration or read/write direction supported by the peripheral and can come from either memory space (internal or external). This feature can be useful in managing MDMA work unit queues, since it is no longer necessary to interrupt the queue between dissimilar work units.

Work Unit Receive and MDMA Destination Transitions

In DMA receive channels (memory write operations), the `DMA_CFG.SYNC` bit controls the handling of the DMA FIFO between descriptor chains (not individual descriptor sets), during the DMA channel pause. The DMA channel pauses after the descriptor sets configured with stop flow mode are complete. Restart the channel (for example,

after an interrupt) by writing the DMA_CFG register of the channel with a value that enables the DMA channel. If the configuration disables synchronization in the DMA_CFG value of the new work unit, the configuration selects a continuous transition. In this mode, the DMA FIFO retains any data items received during the channel pause, and they are the first items written to memory in the new work unit. This mode of operation provides lower latency at work unit transitions and ensures no dropping of data items during a DMA pause. The channel provides this operation at the cost of certain restrictions on the DMA descriptors.

NOTE: If the DMA_CFG.SYNC bit disables synchronization on the first descriptor of a chain after a DMA pause, do not change the configuration of the DMA_CFG.PSIZE field of the new chain from the previous descriptor chain (active before the pause). This restriction applies unless the DMA channel is reset between chains by disabling and then re-enabling the DMA channel.

If the DMA_CFG.SYNC bit configuration enables synchronization, the channel uses a synchronized transition. In this mode, only the data that the DMA channel receives from the peripheral after the write to the DMA_CFG register gets to memory. The channel discards any prior data items transferred from the peripheral to the DMA FIFO before this register write occurs. This operation provides direct synchronization between the data stream received from the peripheral and the timing of the channel restart, which occurs on the write to the DMA_CFG register.

For receive DMA operations, the synchronization has no effect in transitions between work units in the same descriptor chain. When the flow mode of previous descriptor was not stopped, the DMA channel did not pause.

If a descriptor chain begins with synchronization enabled, there is no restriction on the DMA_CFG.PSIZE of the new chain in comparison with the previous chain.

NOTE: The peripheral transfer size (DMA_CFG.PSIZE) must not change between one descriptor and the next in any DMA receive (memory write) channel within a single descriptor chain, regardless of the DMA_CFG.SYNC bit setting. In other words, all memory write descriptor sets in a descriptor chain must have the same DMA_CFG.PSIZE value. For any DMA receive channel (memory write operation), there is no restriction on changes of peripheral transfer size (internal versus external) between descriptors or descriptor chains.

Transfer Termination and Shutdown Flow

This section describes channel transfer termination and shutdown in stop flow mode and in autobuffer flow mode.

Stop Flow Mode

In stop flow mode, the DMA channel stops automatically after the work unit is complete. If using a list or array of descriptors to control DMA transfers and if every descriptor contains a DMA_CFG descriptor element, configure the flow of the final DMA_CFG descriptor element to stop mode, stopping the channel gracefully. After completion, the DMA channel remains in the stop state. Do not confuse this state with the disabled state, which either occurs due to a DMA error or occurs through disabling the DMA channel by configuring the DMA_CFG.EN bit.

The intention of disabling the DMA channel through a write to the DMA_CFG.EN bit is to shut down the DMA channel and to enter the disabled state. All memory and peripheral data transfers cease, and only peripheral interrupts pass through the DMA channels interrupt signals. However, the DMA channel maintains the

DMA_STAT.RUN bits. For a write to memory, the outstanding memory-transaction counter tracks returning memory write acknowledgments and updates as required.

For memory reads, the outstanding memory-transaction count also tracks returning memory reads. The channel does not write the memory reads into the FIFO. The channel updates the counter to reflect the completion of the transaction, but the channel ignores the data. The DMA_STAT.RUN bits remain in the *waiting for write ACK or FIFO drain to peripheral* state and do not change to *stop or idle state* until the return of all outstanding transactions.

When the DMA_CFG.EN bit again enables the DMA channel, the channel performs a full reset and clears all counters. If an outstanding memory transaction returns an acknowledgment or read data after this event, a memory transaction error occurred, which generates an error event. Programs must ensure that all outstanding memory transactions complete before reconfiguring the DMA channel. For example, programs can poll the DMA_STAT.RUN bits to return to the stop or idle state before proceeding.

Autobuffer Flow Mode

In this mode, the flow does not use any descriptors in stored memory. Instead, the channel performs DMA in a continuous circular buffer fashion, based on user-programmed DMA register settings. On completion of the work unit, the channel reloads the parameter registers into the current registers, and the DMA controller resumes immediately with zero overhead. Consider this mode as a succession of automatically restarted work units.

For autobuffer-flow modes, the only way to cease operations is to disable the DMA channel through the DMA_CFG.EN bit. One method of changing to a new work unit is:

- Disable the DMA channel
- Set up all the registers (and descriptors in memory, if used) except for DMA_CFG
- Poll DMA_STAT.RUN to wait for the status to reflect stop or idle state, and
- Write DMA_CFG to the new configuration to begin the next work unit

In autobuffer-flow mode or for a list or array of descriptor sets without DMA_CFG descriptors, use an MMR write to the DMA_CFG register to terminate the DMA transfer process. Configure the value of the DMA_CFG.EN bit in this register to disable the DMA channel.

CAUTION: When the configuration disables a DMA channel, the DMA controller disables interrupt logic that is based on work unit transitions. Be aware of the system environment and current actions, so that additional interrupts are not required from the DMA channel.

CAUTION: If disabled through DMA_CFG.EN in the middle of a transaction, the DMA channel completes any transactions that have begun and avoids generating bus errors. However, the channel considers the action of re-enabling the DMA as a hard reset for all internal DMA channel components. Therefore, pay attention to that particular action to avoid unexpected results.

DMA Channel Errors

When an error occurs, the DMA channel maintains all the state and register values that allow programs to diagnose error causes more thoroughly. The greatest benefit to the programmer is to know exactly what operational state the DMA channel was in at the exact moment the error occurred.

Take care to address the root cause of the error, whether or not the problem originated in the DMA channel. If not properly resolved, the error can result in an additional error shortly after operations resume. The problem can cause other errors elsewhere in the DMA channel or associated modules and circuitry. So, take care also to address those potential problems. Ensure that all outstanding memory reads and writes are complete or cleared before resuming DMA channel operation.

After addressing all issues and neutralizing all side effects of any errors, clear the DMA_STAT.ERRC status field and restart the DMA channel by disabling then re-enabling the DMA channel through the DMA_CFG.EN bit.

The following sections describe the error types.

Status and Debug Errors

DMA channel error conditions can cause the DMA process to end abnormally. The DMA channel provides error detection as a tool for system development and debug, helping to identify DMA-related programming errors. When the DMA channel detects an error, the channel immediately stops and discards any returned memory-read transactions. The DMA_STAT.RUN field of the DMA channel indicates the idle state after acknowledging all outstanding memory transactions. In addition, the channel asserts an error interrupt request and updates the DMA_STAT.IRQERR field. Also, the channel updates the DMA_STAT.ERRC field, indicating the error cause of the first detected error. Unless the error occurs at the exact moment that modification of register values occurs, the registers contain the error values.

All the DMA error interrupt requests are combined into a single shared interrupt request output. Combined error signals require reading the DMA_STAT register of each DMA channel associated with a combined error interrupt request to determine the DMA channel responsible for the generation of the interrupt.

The DMA channel error interrupt handler performs the following actions:

- Read the DMA_STAT register of each DMA channel, seeking a channel with the DMA_STAT.IRQERR set to indicate an error.
- Read the DMA_STAT.ERRC field of each DMA channel, determining the cause of the error.
- Clear the problem with the DMA channel. For example, fix the register values.
- Clear the error in the DMA channel through a write-1-to-clear operation to the DMA_STAT.IRQERR bit.

If the channel flags any uncleared error other than a bandwidth monitor error, the channel reports no other error. If the channel reports an uncleared bandwidth monitor error, the channel reports any newly detected error through updating the DMA_STAT.ERRC field.

DMA Configuration Register Errors

The channel only flags these configuration errors when the DMA_CFG.EN bit enables the DMA channel. Error flagging occurs when the configuration:

- Uses a reserved setting
- Enables DMA_CFG.TWAIT in descriptor on-demand flow mode
- Uses an illegal DMA_CFG.NDSIZE
- Uses an illegal DMA_CFG.MSIZE
- Configures DMA_XCNT = 0 or, when DMA_YCNT = 0 in 2D DMA mode
- Uses non-zero value in DMA_CFG.NDSIZE when DMA is configured in stop mode or auto mode
- Enables interrupt or outgoing triggers on DMA_YCNT when DMA is configured in 1D mode
- Use a DMA_CFG.MSIZE that exceeds the FIFO size of the DMA channel
- Uses an illegal DMA_CFG.PSIZE
- Uses a DMA_CFG.PSIZE that exceeds the FIFO size
- Uses a DMA_CFG.PSIZE that exceeds the bus width
- Attempts to change from a transmit operation (memory read) to a receive operation without properly synching in the previous work unit or when it is the first work unit in a new chain
- Attempts to change DMA_CFG.PSIZE of a transmit operation (memory read) without properly synching in previous work unit or when it is the first work unit in a new chain
- Attempts to change from receive operation (memory write) to a transmit operation during a descriptor chain.

  The channel only can change from receive to transmit if the new transmit is synchronized and is the first work unit.
- Attempts to change DMA_CFG.PSIZE of a receive operation (memory write) when the operation was not the first work unit (with DMA_CFG.SYNC enabled)

Illegal Register Write During Run

The channel generates an error when a write occurs to writable registers of an enabled, running DMA channel. The channel blocks the write.

Address Alignment Error

The channel generates an address alignment error when any of the following apply:

- Alignment of a descriptor address is not on a 32-bit boundary.
- The current DMA_CFG.MSIZE configuration contains an unaligned transfer address. The DMA_ADDRSTART register is not aligned according to the DMA_CFG.MSIZE field.

Memory Access Error

The channel generates a memory access error when the DMA process:

- attempts to access an unpopulated address,

- attempts to access a location that provokes a security violation

The error returned from the memory triggers the memory access error.

Trigger Overrun Error

A trigger overrun error is generated when a new trigger input occurred while an outstanding trigger is waiting. This error is only generated if `DMA_CFG.TOVEN` is enabled.

Bandwidth-Monitor Error

The channel generates this error when the bandwidth-monitor count expires. This error is not fatal, and the DMA channel continues operation.

Control Interface Error

The channel reports control-interface errors as bus errors to the bus controller. This error can result from:

- An address error
- A register write error (write to a read-only register)

DMA Operating Modes

The DMA channel supports a number of different flow modes that control how the DMA channel progresses from one work unit to the next.

The flow mode of a DMA channel is not a global setting. A DMA descriptor set can include the descriptor responsible for configuring the flow of the work unit. There is no restriction, limiting the flow configuration to be the same for the entire descriptor chain. If the descriptor chain is not endless, the last descriptor set configures the flow to stop mode, which results in termination of the descriptor chain after the work unit completes. Another example for mixing flow modes is to create an endless descriptor-array. The configuration of the last descriptor set in the array selects the descriptor-list mode. The next descriptor pointer in this set of descriptors points to the first descriptor in the array.

Register-Based Flow Modes

Register-based DMA operations require configuration by directly writing to the memory-mapped registers of the DMA channel.

Register-based DMA is the traditional method of DMA operation. Software writes all of the configuration of the DMA channel into the memory-mapped registers. This configuration includes information such as the source or destination address and length of the data in the transfer. The DMA controller then starts channel operation. The DMA channel supports the following register-based flow modes.

- Stop Mode
- Autobuffer Mode

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor. The supported descriptor set sizes can differ between the various descriptor-based flow modes. In addition to the descriptor set size being configurable, descriptor-based DMA also allows altering the flow mode of the next descriptor set. This feature allows for the transition from descriptor-array mode to descriptor-list mode and permits configuring the flow to stop or autobuffer mode.

Stop Mode

In stop mode, the DMA operation executes only once. If started, the DMA channel transfers the desired number of data words and stops itself again when finished. If the DMA channel is no longer used, software configures the enable bit to disable a paused channel. The channel also can generate interrupts and triggers for each row or work unit completion, depending on the desired operation.

Autobuffer Mode

In autobuffer mode, the DMA operates repeatedly in a circular manner. If the transfer of all data words completes, the channel reloads the address pointer (`DMA_ADDR_CUR`) automatically with the `DMA_ADDRSTART` value. The channel also can generate an interrupt.

The `DMA_CFG.FLOW` field enables autobuffer mode. The configuration must load the `DMA_CFG.NDSIZE` field value, such that the next descriptor size is zero.

Descriptor-Based Flow Modes

Descriptor-based DMA operations fetch descriptor sets from memory allowing for autonomous loading of work units on other work units. Software does not need to set up the DMA sequences directly by writing into the DMA controller registers. Rather, software keeps DMA descriptor sets in memory.

Descriptor-based DMA operations have the following additional attributes.

- The DMA controller autonomously loads the descriptor set from memory to the affected DMA controller registers on demand.
- The channel can fetch descriptor sets from any memory space that supports DMA read operations.
- The descriptor set describes the next operation that the DMA controller performs.
- The descriptor set can include information such as the DMA configuration word as well as data source or destination address, transfer count, and address modify values.

A descriptor set describes a single work unit. The next work unit can reuse some values from the previous one descriptor set. But, this reusage is possible only if they are not overwritten in the subsequent descriptor set fetches and only if the work unit requires the use of this descriptor.

The DMA channel supports the following flow modes with descriptor-based operations.

- Descriptor-Array Mode
- Descriptor-List Mode
- Descriptor-On-Demand Modes

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor and the supported descriptor set sizes can differ between the various descriptor-based flow modes. In addition to configurable descriptor set size, descriptor-based DMA also allows for altering of the flow mode of the next descriptor set. Programs can transition from one descriptor-based mode to another descriptor-based mode and can also transition to any of the register-based flow modes.

Descriptor-Array Mode

When configured in this mode, the descriptor sets do not contain further descriptor pointers. Software writes the initial descriptor-pointer value, which points to an array of descriptors. This operation assumes that the individual descriptors reside next to each other and assumes that their addresses are known.

The ***Offsets for Descriptor-Array Mode Parameters and Descriptors*** table illustrates how to structure a descriptor set in memory. The descriptor sets must reside in a contiguous block or memory in the format shown in the table. Locate the first descriptor of the next descriptor set in the memory location immediately following the last descriptor of the current descriptor set. The values have the same order as the corresponding offset addresses of the memory-mapped register.

Table 34-10: Offsets for Descriptor -Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT
0x14	DMA_YMOD

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. The channel reloads all of the current registers between the descriptor set fetch and the start of the DMA operation for the work unit.

NOTE: At a minimum, write the DMA_DSCPTR_CUR register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.

Descriptor-List Mode

In this flow mode, multiple descriptors form a chained list in which each descriptor set contains a pointer to the next descriptor set, allowing greater flexibility in memory layout options. When the channel fetches the descriptor set, the operation loads this pointer value into the next descriptor pointer register of the DMA channel.

Descriptor Sets

The ***Offsets for Descriptor-List Mode Parameters and Descriptors*** table shows how to structure a descriptor set in memory. Disperse the placement of the descriptor sets throughout memory, having sets reside in different memory

blocks. But, each descriptor of the descriptor set must reside in a contiguous section of memory in the format shown in the table. The values have the same order as the corresponding offset addresses of the memory-mapped registers.

Table 34-11: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. The channel reloads all of the current values of the registers between the descriptor set fetch and the start of the DMA operation for the work unit.

Minimum Startup Requirements

At a minimum, write the `DMA_DSCPTR_NXT` register prior to write to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Descriptor-On-Demand Modes

The Descriptor-Array Mode and Descriptor-List Mode each have an on-demand mode of operation.

In on-demand mode, at the end of the work unit, if the DMA channel has not detected an incoming trigger event, the channel repeats the current work unit. If the DMA channel receives an incoming trigger before completion of the work unit, the channel fetches a new descriptor set.

The ***Offsets for Descriptor-Array Mode Parameters and Descriptors*** and ***Offsets for Descriptor-List Mode Parameters and Descriptors*** tables illustrate how to structure each descriptor set in memory.

Table 34-12: Offsets for Descriptor-Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT

Table 34-12: Offsets for Descriptor-Array Mode Parameters and Descriptors (Continued)

Descriptor Offset	Parameter Register
0x14	DMA_YMOD

NOTE: For descriptor-array mode, at a minimum, write the DMA_DSCPTR_CUR register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.

Table 34-13: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

NOTE: For descriptor-list mode, at a minimum, write the DMA_DSCPTR_NXT register prior to write to the DMA_CFG register, which is the special action required to start the DMA channel.

Data Transfer Modes

In addition to supporting basic one-dimensional DMA transfers, the DMA channel also supports two-dimensional functionality.

Two-Dimensional DMA

Register-based flow modes and descriptor-based flow modes support two-dimensional data transfers.

In two-dimensional (2D) mode, the X-direction count (DMA_XCNT), the X-direction modifier (DMA_XMOD), the Y-direction count (DMA_YCNT), and the Y-direction modifier (DMA_YMOD) support arbitrary row and column sizes. Also, the modify values can be negative, allowing implementation of interleaved data streams. The DMA_XCNT value specifies the row size, and the DMA_YCNT value specifies the column size; where the DMA_XCNT value must be 2 or greater.

The DMA start address (DMA_ADDRSTART), the X-direction modifier (DMA_XMOD), and theY-direction modifier (DMA_YMOD) specifications all are in bytes. The alignment must be a multiple of the DMA transfer word size; configured using the DMA_CFG.MSIZE bit. Misalignment results in a DMA channel error.

The DMA_XMOD register value is the byte-address increment that the channel applies after each transfer, decrementing the DMA_XCNT register. The channel does not apply the DMA_XCNT when the inner loop count ends with the DMA_XCNT_CUR register decrementing to 0 from 1. Except, the channel does apply the DMA_XCNT on the final transfer, when the DMA_YCNT register is 1 and the DMA_XCNT register decrements from 1 to 0.

The DMA_YMOD register value is the byte-address increment that the channel applies after each decrement of the value in DMA_YCNT_CUR. However, the channel does not apply the DMA_YMOD value to the last item in the array on which the outer loop count (DMA_YCNT_CUR) also expires by decrementing from 1 to 0.

After the last transfer completes, DMA_YCNT_CUR is 1 and the DMA_XCNT_CUR register is 0. The DMA channels current address points to the last items address plus the DMA_XMOD register value. If the DMA channel programming selects automatic refresh (such as in autobuffer mode), the channel reloads the DMA_XCNT_CUR, DMA_YCNT_CUR, and DMA_ADDR_CUR for the first data transfer of the next work unit.

Interrupt notification is configurable for end-of-row or end-of-work unit completion.

For example, two-dimensional DMA can be used to extract interleaved data (such as RGB values for a video frame) by modifying both of the DMA_XMOD and DMA_YMOD values. The ***Capturing a Video Data Stream 2D DMA Example*** depicts the process of receiving a stream of the R, G, B values from an N*M frame. The inner loop of the 2D DMA configuration has three values (DMA_XCNT = 3) and a stride (DMA_XMOD) of N*M, chosen such that successive elements in each row are 1-2-3, 4-5-6 and so forth. The outer loop of the 2D DMA configuration has N*M values (DMA_YCNT = N*M) and a negative stride (DMA_YMOD) of 1-2*N*M chosen to instruct the DMA controller to jump from element 3 to 4, 6 to 7 and so forth at the end of each inner loop.

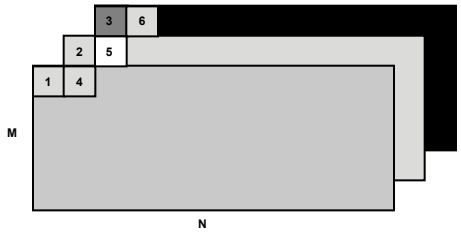

Figure 34-4: Capturing a Video Data Stream 2D DMA Example

DMA Channel Event Control

The DMA channel supports a number of events that provide notification of work unit state, peripheral data request, peripheral interrupt request and completion events, and DMA channel error conditions. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The DMA channel has two interrupt signals for support of a number of events such as work-unit state events, peripheral interrupt request (PIRQ) events, peripheral data request (PDR) events, and DMA channel errors. The channel reports DMA channel errors on a dedicated interrupt signal. All other interrupt sources share an interrupt signal. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The channel can signal the processor on DMA channel events using status information and optional interrupt requests. Programs can use these events to update the progress of data transfers and to request intervention from the processor core. Configure most DMA channel interrupts using bits in the DMA_CFG register. Dedicated bits in the

DMA_STAT register report the occurrence of various events. Use write-one-to-clear (W1C) operations to clear interrupt requests from the status register.

NOTE: Hardware does not clear the interrupt status bits automatically, even when programs disable then reenable the DMA channel. In this situation, the channel deasserts the interrupt signal, after the program disables the DMA channel. But, the status bit remains set until software either re-enables the DMA channel or clears the status bit.

The DMA channel supports the following categories of events on the interrupt signals:

- Work-unit state events generate interrupts on row or on work unit DMA completion.
- A peripheral uses peripheral interrupt request (PIRQ) events to signal when it has completed the transfer of all data.
- A peripheral uses peripheral data request (PDR) events to request data from a disabled or idle DMA channel.
- Error events signal a failure in the work unit.

ATTENTION: While in an error state, the DMA channel does not generate an interrupt to the processor for a work-unit state event or a PIRQ event, nor does the channel forward a PDR event.

Event Signals

The ***Event Signals*** table provides descriptions of DMA channel events.

Table 34-14: Event Signals

Signal	Width (bits)	Description
DMA_ERROR	1	Used to signal an error condition in the DMA channel. The source of the error can be determined by reading the DMA_STAT.ERRC bit.
DONE_PIRQ_INT	1	Signal used to indicate DMA completions events, PIRQ events and also for forwarding PDR events based on configuration. Read the corresponding fields in DMA_STAT to determine the source of the event.
DMA_TRIG_OUT	1	Trigger output that gets routed to the TRU and can be configured to provide notification on row or work unit completion.
DMA_TRIG_IN	1	Trigger input from the TRU that can be used to control the start of a work unit.

Work Unit State Events

Completing a row or a work unit generates a work-unit state event. For either of these events to generate an interrupt request, the configuration of the interrupt of the DMA channel must select one of the available work-unit completion modes.

- Current X count reaching 0 for row completion or 1D DMA work unit completion
- Current Y count reaching 0 for work unit completion of 2D DMA

NOTE: For 1D DMA, a DMA channel configuration error results if the configuration generates the interrupt request when the current Y counter reaches 0.

The DMA channel issues the last memory read or write transaction for the row or work unit, then pauses until the return of the read or write acknowledge. After successful acknowledge of the transfer, the DMA channel issues the interrupt request and continues to process the next row or work unit.

Waiting for acknowledgement of the memory access results in a delay. However, programs can read or modify data in the memory without adversely affecting or being affected by the DMA transfer.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

The channel configuration of the synchronization feature also affects interrupt timing. For memory-read operations with synchronization enabled, the channel delays the interrupt request until the completion of the last transfer from the DMA channel FIFO to the peripheral. The synchronization feature does not affect interrupt timing for memory write operations.

Peripheral Interrupt Request Events

For peripheral-transmit operations, a peripheral connected to the DMA channel can use peripheral interrupt request (PIRQ) events to indicate that data has left the channel FIFO and to indicate transfer completion.

In order to support PIRQ interrupts, correctly configure the interrupt of the DMA channel. This configuration disables the generation of interrupt requests based on the work unit state and, instead, results in generating an interrupt request when the DMA channel receives the command from the peripheral.

The channel only generates the interrupt request under the following conditions:

- The configuration enables the DMA channel
- The DMA channel is in the stop state
- The configuration of the DMA channel interrupt selects PIRQ operation

Peripheral Data Request Events

Peripheral data request (PDR) events occur when an interfaced peripheral requests data from the DMA channel and the DMA channel (either disabled or enabled) is in the stop state.

When a peripheral sends a data request command to a disabled DMA channel, the DMA channel generates an interrupt to the System Event Controller (SEC). There is no status information reported about this event in the status register of the DMA channel. Instead, the channel identifies the PDR event from the fact that the DMA channel generated an interrupt while disabled. It is possible to further confirm event status by verifying the status of the peripheral interfaced to the DMA channel.

This operation forwards data requests as interrupts when the DMA channel is in the disabled state. Also, the DMA channel is able to forward PDR events as an interrupt request when the DMA channel is in the stop state after the

completion of a work unit. The forwarding of this interrupt when the DMA channel is in the stop state is optional and configured by the program during DMA channel configuration.

DMA Channel Triggers

DMA channel triggers are useful for synchronizing the DMA channel with other events in the system. One usage is to combine channel triggers with each other to create ping-pong buffers. Another usage is to combine the triggers with interrupt requests to notify the processor on reaching a particular milestone that requires service. The channel also can use triggers to enforce a handshake DMA operation in which the trigger acts as a signal for a DMA request.

NOTE: Using the trigger to control the pace of data transfers, such as for handshake DMA, requires that all the data for the entire work unit is ready for transfer.

The DMA channel has a single incoming trigger that can control the pace of the data transfers performed by the DMA channel. The configuration can direct the DMA channel to wait for the incoming trigger before starting the work unit transfer or fetching a descriptor set from memory.

The DMA channel also has a single outgoing trigger signal. This configuration can direct this trigger to signal the end of row or an entire work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

Issuing Triggers

The DMA channel configuration can direct the channel to generate an outgoing trigger signal at the end of row or the end of a work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until the return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

Waiting For Triggers

Programs can use triggering to control the pace of data transfers performed by the DMA channel. The DMA channel enters a wait state before beginning the next work unit if the configuration enables `DMA_CFG.TWAIT` and either of the following apply:

- The channel receives a trigger since the last time the DMA channel left the wait state.
- The channel receives a trigger since its transition from disable to enable.

In the wait state, the DMA channel also does not perform a descriptor fetch. After receiving a trigger, the DMA channel leaves the wait state and begins the next work unit or fetches the next descriptor if configured for a descriptor-based mode of operation.

If a memory-mapped register write operation programs the channel with stop flow mode enabled (DMA_CFG.TWAIT bit) and the channel has not already received a trigger, the DMA channel enters a wait state before performing the data transfer. On receiving the trigger, the DMA channel begins the data transfer portion of the work unit. Once the data transfer is complete, the DMA channel enters the stop state.

If a memory-mapped register write operation programs the DMA channel with the flow mode configured to one of the descriptor-based modes, the DMA channel enters the wait state before performing the descriptor fetch. After completing the descriptor fetch, the DMA channel immediately proceeds to the data transfer, regardless of the value of the DMA_CFG.TWAIT bit. If another (next) descriptor fetch follows the descriptor fetch, the DMA channel enters a wait state before fetching the next descriptor.

If the descriptor fetch returns a descriptor with stop flow mode, the DMA_CFG.TWAIT value for that descriptor does not affect the DMA as the channel enters the stop state after completing the data transfer. The DMA channel only enters the wait state based on DMA_CFG.TWAIT before the next work unit or descriptor fetch.

If the descriptor fetch returns a descriptor configured for autobuffer flow mode, the DMA_CFG.TWAIT for that descriptor does not affect the DMA for the first work unit of the autobuffer transfer. After completing the first work unit and not receiving another trigger, the DMA channel enters the wait state before reinitializing its counters and address registers (if not configured for current addressing). The channel performs the next work unit after receiving the trigger.

The incoming trigger can occur when the DMA channel has not entered the wait state. The trigger can occur while the DMA channel is executing a work unit, is performing descriptor fetch, or is in the stop state. The trigger is held internally. After the work unit is complete, the DMA channel skips the wait state and proceeds directly to executing the following work unit. If the DMA_CFG.TWAIT bit is not enabled, the DMA channel also skips the wait state. However, the trigger is held internally and is used the next time the configuration enables DMA_CFG.TWAIT. This trigger retention allows programs to enable the DMA_CFG.TWAIT functionality several work units apart without concern for losing a trigger. The DMA channels trigger-overrun enable functionality can be enabled in all work units to ensure that multiple triggers do not occur between the work units with the DMA_CFG.TWAIT bit enabled.

DMA Channel Programming Model

Several synchronization and control methods are available for use in development of software tasks which manage peripheral DMA and memory DMA. Software must accept requests for new DMA transfers from other software tasks, integrate these transfers into existing transfer queues, and reliably notify other tasks when the transfers are complete.

In the processor, it is possible to manage each peripheral DMA and memory DMA stream with a separate task or to manage them together with any other stream. Each DMA channel has independent, orthogonal control registers, resources, and interrupts. So, the selection of the control scheme for one channel does not affect the choice of control scheme on other channels. For example, one peripheral can use a linked-descriptor-list, interrupt-driven scheme while another peripheral can simultaneously use a demand-driven, buffer-at-a-time scheme synchronized by polling DMA events.

The topics that follow describe the steps required to configure the DMA channel for the various modes in addition to the programming concepts required for software synchronization.

Mode Configuration

Use the step-by-step directions that follow to set up the DMA channel for operating modes.

Register-Based Linear-Buffer Stop Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and to send it to the peripheral for transmission. Upon DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

Assume that the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

1. Write the DMA_ADDRSTART register.

   ADDITIONAL INFORMATION: Software can use the address to calculate the most optimum possible DMA_CFG.MSIZE.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE, and the calculation also must consider the start address alignment.

3. Write the DMA_XCNT register based on the calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: The DMA_XCNT value is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. Always specify this register as a number of bytes.

5. Write the DMA_CFG register with DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW bit for STOP mode. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

- The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
- Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer is transferred. The DMA channel enters the IDLE state upon completion of the work unit.

Register-Based Autobuffer Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and send it to the peripheral for transmission. The transmission of the buffer repeats endlessly. Upon DMA completion, the DMA channel restarts the DMA operation, creating an endless circular buffer transfer.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

1. Write the DMA_ADDRSTART register.

   ADDITIONAL INFORMATION: Use the address to calculate the optimum possible DMA_CFG.MSIZE.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE, and the calculation must consider the start address alignment.

3. Write the DMA_XCNT register based on calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: The DMA_XCNT register value is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. Always specify this register as a number of bytes.

5. Write the DMA_CFG register with the DMA_CFG.EN bit configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW bit for autobuffer mode. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bit to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

- The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
- Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer transfers until the DMA channel is disabled.

Descriptor-Array Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the array, and
- Send the data to the peripheral for transmission.

Descriptor sets are read from an array in memory to configure the individual work units.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel. Assume that the array of descriptors is to be initialized with the last descriptor set configured for STOP flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the array in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the DMA_DSCPTR_CUR register with the address of the array in which the descriptor sets are stored.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the DMA_CFG register with the DMA_CFG.EN bit configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used. Set the DMA_CFG.FLOW bit for descriptor-array mode. Configure the DMA_CFG.NDSIZE bits to describe the number of descriptor elements contained within the first descriptor set. Configure the DMA_CFG.WNR bit for memory read operation.

   - The descriptor set that is fetched controls the DMA_CFG.SYNC configuration and the interrupt or trigger configurations.

   The first descriptor set is fetched from memory location provided by the DMA_DSCPTR_CUR register and loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor array. The DMA channel enters the IDLE state on completion of the final work unit that was configured for STOP flow mode.

Descriptor-List Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the list, and
- Send it to the peripheral for transmission.

The DMA controller reads the descriptor sets from a list of descriptors. With the list, each descriptor set has a descriptor that points to the next descriptor set location in memory.

Assume the peripheral must be in a state where it is ready to transmit data received from the DMA channel. Assume that the list of descriptors must be initialized with the last descriptor set in the list configured for Stop flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the list in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the DMA_DSCPTR_NXT register with the address of the first descriptor in the list to be processed.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the DMA_CFG register with the DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW for descriptor-list mode. Configure the DMA_CFG.NDSIZE bit to describe the number of descriptor elements contained within the first descriptor set. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bit to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

   - The descriptor set that is fetched controls the DMA_CFG.SYNC configuration and controls the interrupt or trigger configurations.

   The first descriptor set is fetched from the memory location provided by DMA_DSCPTR_NXT and is loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor list. The DMA channel enters the idle state when the final work unit that was configured for stop-flow mode is complete.

Register-Based Memory-to-Memory Transfer in Stop Flow Mode

This procedure configures a memory DMA channel pair in stop flow mode. One DMA channel is configured for memory read operations, while the other DMA channel is configured for memory write.

The task involves writing to a number of DMA channels on two DMA channels that create a memory DMA pair. On DMA completion, the DMA channel enters the idle state, until either the DMA channel is disabled or is reconfigured for a new transfer.

1. Write the DMA_ADDRSTART register of the source DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the optimum DMA_CFG.MSIZE possible.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE and the start address alignment must also be considered.

3. Write the DMA_XCNT register of the source DMA channel based on calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: DMA_XCNT is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register of the source DMA channel.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. This register is always specified in the number of bytes.

5. Write the DMA_ADDRSTART register of the destination DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the most optimum DMA_CFG.MSIZE possible.

6. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE and the start address alignment must also be considered.

7. Write the DMA_XCNT register of the destination DMA channel based on the calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: DMA_XCNT is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

8. Write the DMA_XMOD register of the destination DMA channel.

ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. This register is always specified in the number of bytes.

9. Write the DMA_CFG register of the source DMA channel with DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: The DMA_CFG.FLOW bit field must be configured for stop mode. The DMA_CFG.WNR bit must be cleared for memory read operation. The DMA_CFG.PSIZE bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

   - The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
   - Interrupts and triggers also can be configured at this step, depending on requirements. The interrupts and triggers are enabled within the destination DMA channel configuration.

   The memory read DMA transfer begins.

10. Write the DMA_CFG register of the destination DMA channel with DMA_CFG.EN configured to enable the DMA channel.

    ADDITIONAL INFORMATION: The DMA_CFG.FLOW bit field must be configured for stop mode. The DMA_CFG.WNR bit must be set for memory write operation. The DMA_CFG.PSIZE bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus. This value must also match the value written for the source DMA channel configuration.

    - Interrupts and triggers also can be configured at this step depending on requirements.

    The memory write DMA transfer begins.

Both memory DMA channels are now running and the data is transferred from the source address to the destination address. The DMA channel enters the IDLE state upon completion of the work unit.

Programming Concepts

Using the features, operating modes, and event control for the DMA channel to their greatest potential requires an understanding of some DMA channel-related concepts.

Synchronization of Software and DMA

A critical element of software DMA management is the synchronization of DMA work unit completion with software. This synchronization can be achieved using DMA channel interrupt request and trigger events and using a poll of the status bits of these events within the DMA channel registers, or combining these techniques. Processor polling of DMA address/count/status for completion is not a recommended programming practice. The requirements and limitations of processor polling place significant responsibility onto the code developer to be deeply aware of the underlying hardware. The interrupt requests and triggers are designed for efficient code development and reuse.

Interrupt and Trigger Event-Based Synchronization

Interrupt and trigger based synchronization methods must avoid overrun. An overrun occurs when some events fail to invoke the event handler of a DMA channel for every event due to excessive latency in processing of events. The system design must ensure to either:

- Schedule only one event per channel (for example, at the end of a descriptor list), or
- Space the generated events sufficiently far apart in time that system processing budgets can guarantee service of every event.

The DMA channel issues status information through an interrupt request or trigger event or changes event status bits in the DMA_STAT register. This status guarantees that the last memory operation of the work unit is complete. For memory read DMA transactions, this status means that the FIFO of the DMA channel safely receives the final memory read data. For DMA transactions writing to memory, this status indicates that the DMA channel received an acknowledge of completion of the last write transfer of the work unit.

Register Polling Based Synchronization

Do not poll the DMA channel registers (DMA_ADDR_CUR, DMA_DSCPTR_CUR, DMA_XCNT_CUR, or DMA_YCNT_CUR) as a method of precisely synchronizing DMA with data processing. This approach is inaccurate due to the operation of the DMA channel FIFOs and DMA or memory pipelining. The current address, pointer, and count registers change several cycles in advance of the completion of the corresponding memory operation. This timing is measurable from the time at which the results of the operation are first visible to the core by memory read or write instructions.

For example, in a DMA channel memory write operation to external memory, assume DMA channel *A* initiates a DMA channel write operation. For memories with access latency, this operation requires many system-clock cycles. Meanwhile, DMA channel *B* (which does not in itself incur latency) initiates a transfer, which stalls behind the slow operation of channel *A*. Software monitoring channel *B* could not safely conclude whether the memory location pointed to by the DMA_ADDR_CUR of channel *B*. Also, the software cannot conclude whether the register has been written based solely on the contents of this register.

Polling of the current address, pointer, and count registers can permit loose synchronization of DMA with software. But, the software must allow for the lengths of the DMA or memory pipeline. Also, software must consider the length of the DMA FIFO for a particular peripheral. If the FIFOs are filled with incomplete work, the DMA channel does not advance current address, pointer, or count registers. The incomplete work includes reads that have been started but have not yet finished.

Additionally, software must consider the length of the pipelines to the destination memory. If the DMA FIFO length and channel memory-pipeline length are added, software can estimate the maximum number of incomplete memory operations in progress.

NOTE: The estimate would be a maximum, as the DMA or memory pipeline can include traffic from other DMA channels.

Descriptor Queues

A system designer may want to write a DMA manager facility which accepts DMA requests from other software. The DMA manager software does not know in advance when new work requests are received or what these requests contain. The software could manage these transfers using a circular linked list of DMA descriptors. In such a list, each descriptor sets the DMA_DSCPTR_NXT descriptor, which points to the next descriptor set. And, the last descriptor set in the list points to the first descriptor set.

The code that writes into this descriptor list could use the circular addressing modes of the processor. This approach does not need to use comparison and conditional instructions to manage the circular structure. In this case, the DMA_DSCPTR_NXT descriptor of each descriptor set can be written once at startup, and skipped over as new contents are written for each descriptor.

The recommended method for synchronization of a descriptor queue is to use an interrupt or trigger. The descriptor queue is structured, such that (at least) the final valid descriptor set is always programmed to generate an interrupt or trigger event upon completion. More detail is provided in the following sections.

- Queues Using Event Generation for Every Descriptor Set
- Queues Using Minimal Events

Queues Using Event Generation for Every Descriptor Set

In this system, the DMA manager software synchronizes with the DMA channel by enabling an interrupt request or trigger on every descriptor set. Only use this method if the system design can guarantee that each work unit completion event is serviced separately (no interrupt or trigger overrun).

To maintain synchronization of the descriptor set queue, the non-interrupt software maintains a count of descriptor sets added to the queue. The event handler (either interrupt or trigger) maintains a count of completed descriptor sets removed from the queue. The counts are equal only when the DMA channel is paused after having processed all the descriptor sets.

When each new work unit event is received, the DMA manager software initializes a new descriptor set, taking care to set the flow to stop mode. Next, the software compares the descriptor set counts to determine whether the DMA channel is running. If the DMA channel is paused (counts equal), the software increments its count. Then, the software starts the DMA channel by writing the DMA_CFG of the new descriptor set.

If the counts are unequal, the software instead modifies the DMA_CFG of the next-to-last descriptor set, such that it now describes the newly queued descriptor set. This operation does not disrupt the DMA channel provided the rest of the descriptors of the set are initialized in advance. It is necessary to synchronize the software to the DMA to determine whether the DMA channel read the new or the old DMA_CFG value.

The event handler performs the synchronization operation. When an event is detected, the handler reads the DMA_STAT register of the DMA channel. If the DMA_STAT.RUN bit indicates that the DMA channel is running, the channel has moved on to processing another descriptor. The event handler can increment its count and exit. If the DMA_STAT.RUN bit indicates that the channel is not running, the channel is paused because either:

- There are no more descriptor sets to process, or

- The last descriptor set was queued too late

Where *too late* means that the modification of the DMA_CFG of the next-to-last descriptor set occurred *after* that descriptor was read into the DMA channel. In this case, the event handler does the following:

- Writes the DMA_CFG value appropriate for the last descriptor set to DMA_CFG register of the DMA channel,
- Increments the completed descriptor count, and
- Exits

If the event latencies of the system are large enough to cause any of the events to be dropped, this system can fail. An event handler capable of safely synchronizing multiple descriptor set interrupt requests is complex, performing several MMR accesses to ensure robust operation. In such a system environment, a minimal event synchronization method is preferred.

Queues Using Minimal Events

In this system, only one DMA interrupt request or trigger event is generated in the queue at any time. The DMA event handler for this system can also be extremely short. Here, the descriptor queue is organized into an *active* and a *waiting* portion, where events are enabled only on the last descriptor set in each portion.

When each new DMA request is processed, the software fills in the content of a new descriptor set and adds it to the waiting portion of the queue. The DMA_CFG descriptor of the descriptor set must have the flow set to stop mode. If more than one request is received before the DMA queue completion event occurs, the non-interrupt code queues later descriptor sets. It forms a waiting portion of the queue separate from the active portion of the queue that the DMA channel is processing. In other words, all but the last active descriptor sets contain flow values for a descriptor-based mode and have no event enable set.

The last active descriptor set has the stop flow mode and an event generation enabled. Also, all but the last waiting descriptor sets are configured for descriptor-based flow modes with no event generation. Only the last waiting descriptor set is configured for stop flow mode and event generation enabled. This configuration ensures that the DMA channel can automatically process the whole active queue before then issuing one event. Also, this arrangement makes it easy to start the waiting queue within the event handler by a single DMA_CFG register write.

After queuing a new waiting descriptor, the non-interrupt software leaves a message for its interrupt handler in a memory mailbox location. The location contains the desired DMA_CFG value for starting the first waiting descriptor set in the waiting queue (or 0, indicating no waiting descriptors).

The software must not modify the contents of the active descriptor set queue directly once processing by the DMA channel has started, unless careful synchronization measures are taken. In the most straightforward implementation of a descriptor set queue, the DMA manager software never modifies descriptors on the active queue. Instead, the DMA manager waits until the DMA queue completion event indicates that the processing of the entire active queue is complete.

When a DMA queue completion event is received, the event handler reads the mailbox from the non-interrupt software and writes the value to the DMA_CFG register of the DMA channel. This write to a register restarts the queue, effectively transforming the waiting queue to an active queue. The event handler then passes a message back to the non-interrupt software indicating the location of the last descriptor set accepted into the active queue.

However, the event handler can read its mailbox and find a DMA_CFG value of zero, indicating there is no more work to perform. It then passes an appropriate message back to the non-interrupt software indicating that the queue has stopped.

The non-interrupt software which accepts new DMA work unit requests must synchronize the activation of a new work unit with the interrupt handler. If the queue has stopped (the mailbox from the event handler is zero), the non-interrupt software must start the queue. (The queue starts by writing the first descriptor sets DMA_CFG value to the DMA_CFG register of the channel). If the queue is not stopped, the non-interrupt software must not write the DMA_CFG register. (This write causes a DMA error). Instead, it must queue the descriptor onto the waiting queue and update its mailbox directed to the event handler.

ADSP-2159x_SC591_SC592_SC594 DMA Register Descriptions

The Direct Memory Access module (DMA) contains the following registers.

Table 34-15: ADSP-2159x_SC591_SC592_SC594 DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

Start Address of Current Buffer Register

The DMA_ADDRSTART register contains the start address of the work unit currently targeted for DMA. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

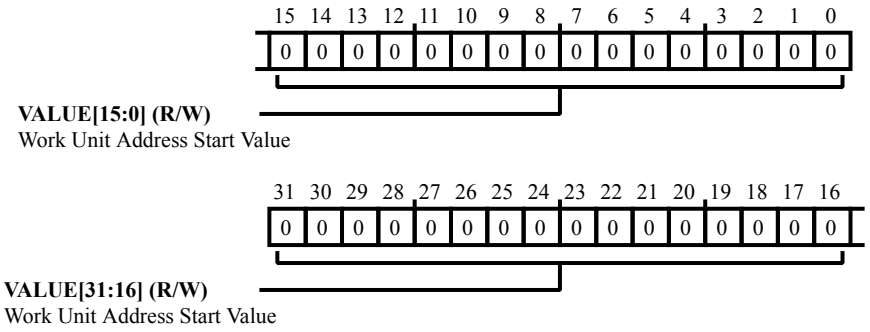

Figure 34-5: DMA_ADDRSTART Register Diagram

Table 34-16: DMA_ADDRSTART Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Address Start Value. The DMA_ADDRSTART.VALUE bit field contains the start address of the work unit currently targeted for DMA.

Current Address Register

The DMA_ADDR_CUR register contains the present memory transfer address for a given work unit. At the start of a work unit, the DMA_ADDR_CUR register is loaded from the DMA_ADDRSTART register, and the DMA_ADDR_CUR register is incremented as each transfer occurs. The DMA_ADDR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel.

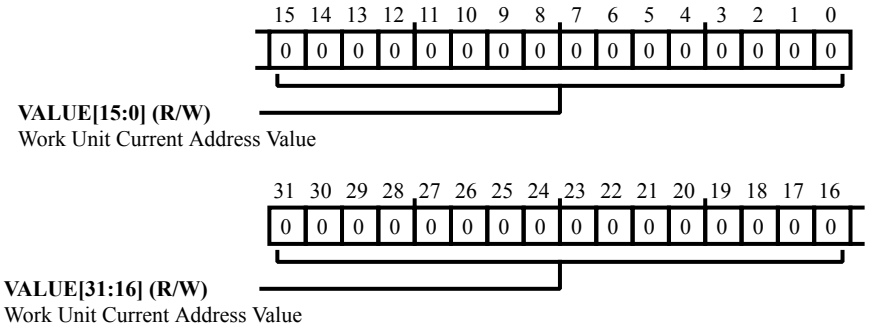

Figure 34-6: DMA_ADDR_CUR Register Diagram

Table 34-17: DMA_ADDR_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Current Address Value. The DMA_ADDR_CUR.VALUE bit field contains the present memory transfer address for a given work unit.

Bandwidth Limit Count Register

The DMA_BWLCNT register contains a count that determines how often the DMA issues memory transactions. The DMA loads the value from the DMA_BWLCNT register into the DMA_BWLCNT_CUR register and decrements the current value each CLKO6 cycle. When DMA_BWLCNT_CUR reaches 0x0000, the next request is issued, and the DMA reloads DMA_BWLCNT_CUR. This bandwidth limit functionality is not applied to descriptor fetch requests. Programming 0x0000 allows the DMA to request as often as possible. 0xFFFF is a special case and causes requests to stop.

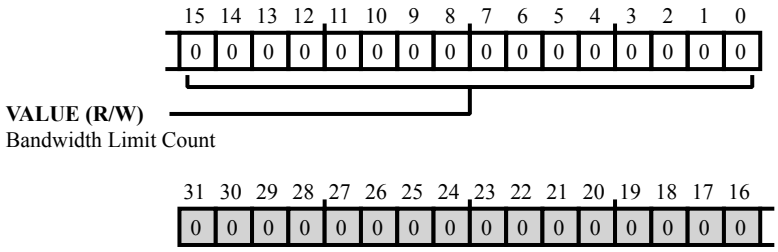

Figure 34-7: DMA_BWLCNT Register Diagram

Table 34-18: DMA_BWLCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Bandwidth Limit Count. The DMA_BWLCNT.VALUE bit field contains a count that determines how often the DMA issues memory transactions.

Bandwidth Limit Count Current Register

The DMA_BWLCNT_CUR register contains the number of CLKO6 count cycles remaining before the next request is issued.

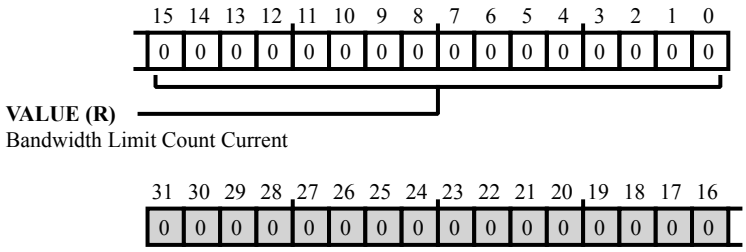

Figure 34-8: DMA_BWLCNT_CUR Register Diagram

Table 34-19: DMA_BWLCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Bandwidth Limit Count Current. The DMA_BWLCNT_CUR.VALUE bit field contains the number of CLKO6 count cycles remaining before the next request is issued.

Bandwidth Monitor Count Register

The DMA_BWMCNT register contains the maximum number of CLKO6 cycles allowed for a work unit to complete. Each time the DMA_CFG register is written (MMR access only), a work unit ends or an autobuffer wraps. The DMA loads the value in this register into the DMA_BWMCNT_CUR register.

The DMA decrements DMA_BWMCNT_CUR every CLKO6 a work unit is active. If the DMA_BWMCNT_CUR register reaches 0x0000_0000, the DMA_STAT.IRQERR bit is set, and the DMA_STAT.ERRC bit field is set to 0x6. The DMA_BWMCNT_CUR remains at 0x0000_0000 until it is reloaded when the work unit completes.

Unlike other errors, a bandwidth monitor error does not stop work unit processing. Programming 0x0000_0000 disables bandwidth monitor functionality.

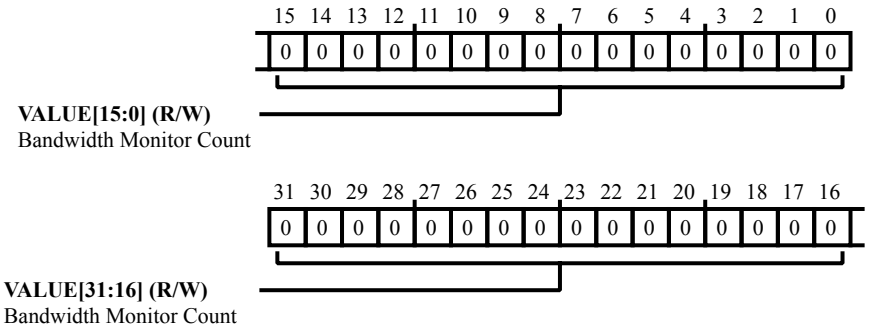

Figure 34-9: DMA_BWMCNT Register Diagram

Table 34-20: DMA_BWMCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Bandwidth Monitor Count. The DMA_BWMCNT.VALUE bit field contains the maximum number of CLKO6 cycles allowed for a work unit to complete.

Bandwidth Monitor Count Current Register

The DMA_BWMCNT_CUR register contains the number of cycles remaining for the current descriptor to complete.

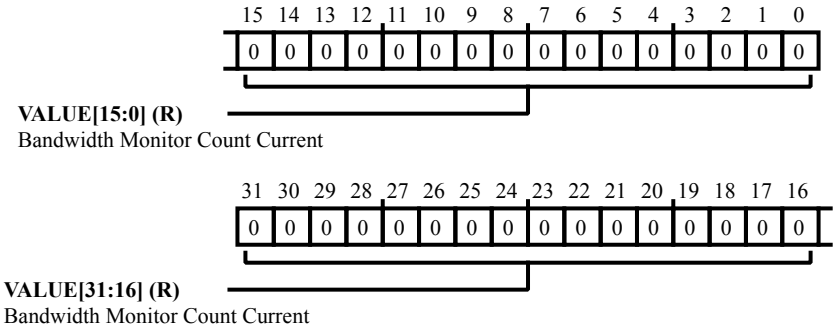

Figure 34-10: DMA_BWMCNT_CUR Register Diagram

Table 34-21: DMA_BWMCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bandwidth Monitor Count Current. The DMA_BWMCNT_CUR.VALUE bit field contains the number of cycles remaining for the current descriptor to complete.

Configuration Register

The DMA_CFG register sets up DMA parameters and operation modes. Writing to the DMA_CFG register while a DMA process is already running causes a DMA error (except when clearing the DMA_CFG.EN bit).

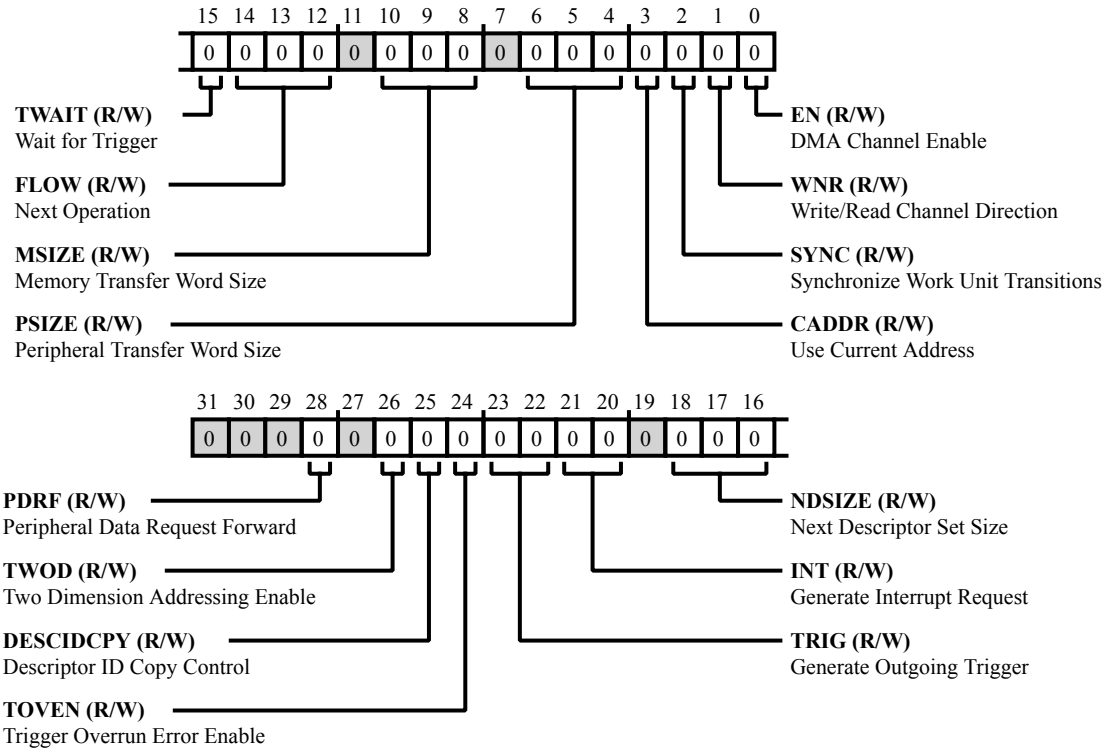

Figure 34-11: DMA_CFG Register Diagram

Table 34-22: DMA_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	PDRF	Peripheral Data Request Forward. The DMA_CFG.PDRF bit defines how the DMA handles data requests from the peripheral while in idle state after a stop mode or memory read work unit. If set, the DMA forwards the peripheral data request as an interrupt. This bit applies only to the DMA_CFG.FLOW bits configured for stop and DMA_CFG.WNR bits configured for memory read.	
		0	Peripheral Data Request Not Forwarded
		1	Peripheral Data Request Forwarded

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	TWOD	Two Dimension Addressing Enable. The DMA_CFG.TWOD bit selects whether the DMA addressing involves only DMA_XCNT and DMA_XMOD (one-dimensional DMA) or also involves DMA_YCNT and DMA_YMOD (two-dimensional DMA).	
		0	One-Dimensional Addressing
		1	Two-Dimensional Addressing
25 (R/W)	DESCIDCPY	Descriptor ID Copy Control. The DMA_CFG.DESCIDCPY bit specifies when to copy the initial descriptor pointer to the DMA_DSCPTR_PRV register. A bus write to the DMA_CFG register to clear the DMA_CFG.EN bit causes the DMA to immediately use the new value of the DMA_CFG.DESCIDCPY bit. To preserve consistency (if required by application), match the new value of this bit to the previous value.	
		0	Never Copy
		1	Copy on Work Unit Complete
24 (R/W)	TOVEN	Trigger Overrun Error Enable. A trigger overrun occurs if more than one trigger was received before the DMA reached the trigger wait state. If DMA_CFG.TOVEN is set, a trigger overrun causes the DMA to flag an error. In cases where a trigger overrun is not a problem, clearing DMA_CFG.TOVEN prevents the overrun from causing an error and halting the DMA. The DMA_CFG.TOVEN operates independently of the DMA_CFG.TWAIT bit selection.	
		0	Ignore Trigger Overrun
		1	Error on Trigger Overrun

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/W)	TRIG	Generate Outgoing Trigger. The DMA_CFG.TRIG selects whether the DMA issues an outgoing trigger, based on the work unit counter values. In one-dimensional mode, the only options are to trigger at the end of the whole work unit (trigger when DMA_XCNT_CUR reaches 0) or not to trigger at all. If in one-dimensional addressing mode, programming the DMA_CFG.TRIG bit field to trigger when DMA_YCNT_CUR reaches 0 (or to reserved) causes the DMA to flag a configuration error. In two-dimensional addressing mode, the trigger options are: at the end of each row of the inner loop (when DMA_XCNT_CUR reaches 0), only after completing the whole work unit (when DMA_YCNT_CUR reaches 0), or no trigger. If in two-dimensional mode and set to trigger when DMA_XCNT_CUR reaches 0, the DMA also issues a trigger at the end of the work unit. If in two-dimensional addressing mode, programming DMA_CFG.TRIG to reserved causes the DMA to flag a configuration error. If DMA_CFG.TRIG is non-zero and the peripheral issues a finish command, the DMA issues a trigger after the finish procedure is complete. For more information about trigger generation timing, see the trigger section of the DMA functional description.	
		0	Never Assert Trigger
		1	Trigger When XCNTCUR Reaches 0
		2	Trigger When YCNTCUR Reaches 0
		3	Reserved

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	INT	Generate Interrupt Request. The DMA_CFG.INT bit field selects whether an interrupt request goes to the core based on work unit status or a peripheral interrupt request. For one-dimensional mode, setting the DMA_CFG.INT bits to generate an interrupt request when the DMA_YCNT_CUR register reaches 0 causes the DMA to flag a configuration error. The peripheral interrupt setting lets the DMA generate the last grant indication and to accept and or forward the peripheral interrupt command. The peripheral interrupt selection applies only to the DMA_CFG.FLOW bits set for stop and the DMA_CFG.WNR bits set for memory read. If the DMA_CFG.INT is set for interrupt request on count completion (DMA_XCNT_CUR or DMA_YCNT_CUR reach 0) and the peripheral issues a finish command, the DMA issues an interrupt request after the finish procedure is complete. For more information, see the sections on interrupt generation and peripheral control in the DMA functional description.	
		0	Never Assert Interrupt
		1	Interrupt When X Count Expires
		2	Interrupt When Y Count Expires
		3	Peripheral Interrupt request
18:16 (R/W)	NDSIZE	Next Descriptor Set Size. The DMA_CFG.NDSIZE bit field specifies the number of descriptor elements in memory to load during the next descriptor fetch. The DMA loads the descriptors in a specific order. The descriptor set contains the next descriptor pointer when it is a descriptor list. The descriptor set does not contain the next descriptor pointer when it is a descriptor array.	
		0	Fetch One Descriptor Element
		1	Fetch Two Descriptor Elements
		2	Fetch Three Descriptor Elements
		3	Fetch Four Descriptor Elements
		4	Fetch Five Descriptor Elements
		5	Fetch Six Descriptor Elements
		6	Fetch Seven Descriptor Elements
		7	Reserved

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	TWAIT	Wait for Trigger. The DMA_CFG.TWAIT bit controls whether the DMA waits for an incoming trigger from another channel or user. If the DMA_CFG.TWAIT bit is set, the DMA enters the wait state before starting the next work unit, including descriptor fetch when in descriptor mode. Do not use the wait for trigger control for descriptor-on-demand mode which causes an error. For more information, see the trigger section of the DMA functional description.	
		0	Begin Work Unit Automatically (No Wait)
		1	Wait for Trigger (Halt before Work Unit)
14:12 (R/W)	FLOW	Next Operation. The DMA_CFG.FLOW bit field selects the descriptor handling options.	
		0	STOP. See the Stop Flow Mode section.
		1	AUTO. See the Autobuffer Flow Mode section.
		2	Reserved
		3	Reserved
		4	DSCL. See the Descriptor List Mode section.
		5	DSCA. See the Descriptor Array Mode section.
		6	Descriptor On-Demand List. See the Descriptor List Mode section.
		7	Descriptor On Demand Array. See the Descriptor On Demand section.
10:8 (R/W)	MSIZE	Memory Transfer Word Size. The DMA_CFG.MSIZE bits select memory transfer sizes of 8-, 16-, 32-, 64-, 128-, or 256-bit words. The transfer start address (DMA_ADDRSTART) and transfer increment values (DMA_XMOD, and, if needed, DMA_YMOD) must be a multiple of the memory transfer unit size.	
		0	1 Byte
		1	2 Bytes
		2	4 Bytes
		3	8 Bytes
		4	16 Bytes
		5	32 Bytes

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:4 (R/W)	PSIZE	Peripheral Transfer Word Size. The DMA_CFG.PSIZE bits select peripheral transfer sizes as 8, 16, 32, or 64 bits wide. Each request and grant results in a single peripheral access. There are no bursts on the peripheral bus, so the DMA_CFG.PSIZE selection must be less than, or equal to, the width of the bus. If the selection is greater than the bus width, a configuration error occurs. The peripheral bus of the processor is dedicated to DMA and peripheral accesses.	
		0	1 Byte
		1	2 Bytes
		2	4 Bytes
		3	8 Bytes
3 (R/W)	CADDR	Use Current Address. When the DMA_CFG.CADDR bit is cleared, the DMA loads the DMA_ADDRSTART register on the first access of the work unit. When the DMA_CFG.CADDR bit is set, the DMA uses the DMA_ADDR_CUR register value for the starting address for the work unit and writes the same value to the DMA_ADDRSTART register. This operation permits continuation of a previous work unit. When DMA uses this mode, the fetched start address value (as part of the descriptor set at the end of a descriptor list or array) is ignored.	
		0	Load Starting Address
		1	Use Current Address

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	SYNC	Synchronize Work Unit Transitions. Setting the DMA_CFG.SYNC bit clears the DMA FIFO and pointers before starting the first work unit of a work unit chain. When the transfer direction is memory read/transmit (DMA_CFG.WNR =0), the DMA waits until all data transmits to a peripheral before moving on to the next work unit, clearing the FIFO and pointers. When the transfer direction is memory write/receive (DMA_CFG.WNR =1), the DMA ignores the DMA_CFG.SYNC bit value after processing the first work unit of a work unit chain. As a channel can receive data when turned on but idle, data from the peripheral can still be in the FIFO even though the channel was not programmed. When the DMA_CFG.SYNC bit field is set at the beginning of a work unit chain (during the first work unit), the DMA clears the FIFO, erasing the data put into the FIFO while the channel was idle. Syncing lets programs change the DMA_CFG.PSIZE between individual work units and (in some cases) work unit chains. The sync resets the pointers in the FIFO, preventing misaligned FIFO access. Programs can change the DMA_CFG.MSIZE field between consecutive work units, independent of the DMA_CFG.SYNC bit setting. Syncing also permits changes to transfer direction. Because the data in the FIFO is eliminated, the data that went into the FIFO from one direction (transmit or receive) is not sent back in the other direction after the direction change.	
		0	No Synchronization
		1	Synchronize Channel
1 (R/W)	WNR	Write/Read Channel Direction. The DMA_CFG.WNR bit selects receive (write to memory) or transmit (read from memory) channel direction.	
		0	Transmit (Read from memory)
		1	Receive (Write to memory)

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Channel Enable. The DMA_CFG.EN bit enables the selected DMA channel. When a peripheral DMA channel is enabled, data requests from the peripheral denote DMA requests. When a channel is disabled, the DMA unit ignores the peripheral data request and passes it directly to the system event controller. To avoid unexpected results, enable the DMA channel before enabling the peripheral, and disable the peripheral before disabling the DMA channel. A transition of the DMA_CFG.EN bit from 0 to 1 creates a hard reset of all internal counters and states, including the DMA_STAT register. (All other register values remain unaffected.) A transition from 1 to 0 maintains all counters and registers for reading and analysis. Note that if a descriptor loads when this bit is cleared (see the DMA_CFG.FLOW field), the DMA transitions to the off or idle state after the descriptor load is complete.	
		0	Disable
		1	Enable

Current Descriptor Pointer Register

The DMA_DSCPTR_CUR register contains the memory address for the next descriptor to be loaded. The DMA_DSCPTR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel. For DMA_CFG.FLOW mode settings that involve descriptor fetches, this register is used to read descriptors into appropriate MMRs before a work unit begins. For descriptor list mode, the DMA_DSCPTR_CUR register is initialized from the DMA_DSCPTR_NXT register before fetching each descriptor set. Then, the address in the DMA_DSCPTR_CUR register increments as each descriptor is read.

When the entire descriptor set has been read, the DMA_DSCPTR_CUR register contains this value:

DMA_DSCPTR_CUR = Descriptor Start Address + Descriptor Size (# of elements)

For descriptor array mode, the DMA_DSCPTR_CUR register, and not the DMA_DSCPTR_NXT register, must be programmed by a MMR access before starting DMA operation.

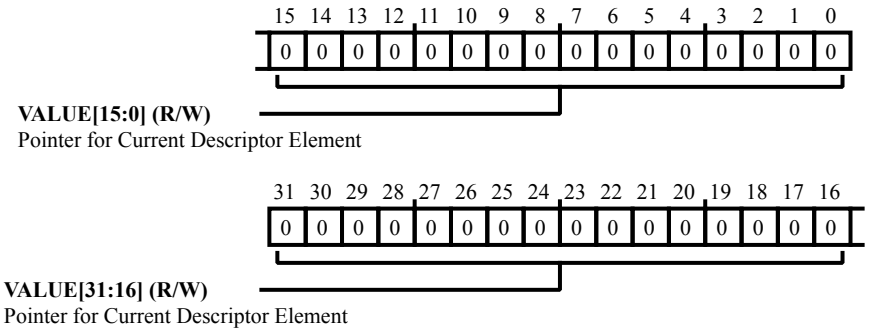

Figure 34-12: DMA_DSCPTR_CUR Register Diagram

Table 34-23: DMA_DSCPTR_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Pointer for Current Descriptor Element. The DMA_DSCPTR_CUR.VALUE bit field contains the memory address for the next descriptor to be loaded.

Pointer to Next Initial Descriptor Register

The DMA_DSCPTR_NXT register specifies the start location of the next descriptor set, which begins when the DMA activity specified by the current descriptor set completes. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

The DMA_DSCPTR_NXT register is only used in descriptor list mode. At the start of a descriptor fetch in this mode, the DMA_DSCPTR_NXT register is copied into the DMA_DSCPTR_CUR register. During descriptor fetch, the DMA increments the DMA_DSCPTR_CUR register value after reading each element of the descriptor set.

In descriptor list mode, the DMA_DSCPTR_NXT register (not the DMA_DSCPTR_CUR register) must be programmed directly through MMR access, before the DMA operation is started. In descriptor array mode, the DMA disregards the DMA_DSCPTR_NXT register and uses the DMA_DSCPTR_CUR register to control descriptor fetch.

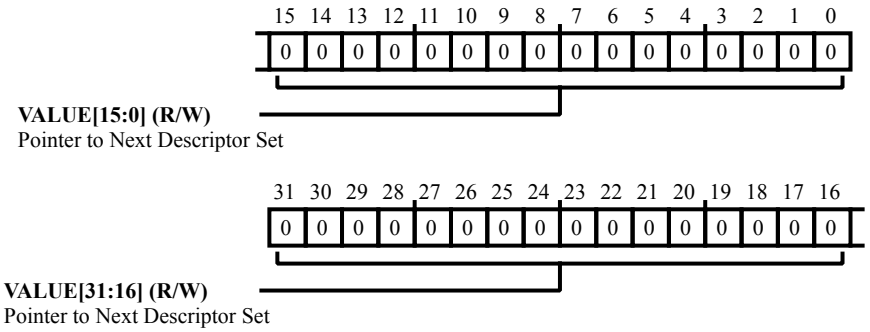

Figure 34-13: DMA_DSCPTR_NXT Register Diagram

Table 34-24: DMA_DSCPTR_NXT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Pointer to Next Descriptor Set. The DMA_DSCPTR_NXT.VALUE bit field specifies the start location of the next descriptor set.

Previous Initial Descriptor Pointer Register

The DMA_DSCPTR_PRV register contains the initial descriptor pointer for the previous work unit. If DMA_CFG.DESCIDCPYis set, the DMA copies the initial descriptor pointer to DMA_DSCPTR_PRV after the work unit completes. Otherwise, the value is not updated.

To indicate an overrun, bit 0 of the DMA_DSCPTR_PRV register is used as a previous descriptor pointer overrun (PDPO) status bit. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error occurs when used for descriptor fetches. As a result, bit 1 and 0 of the DMA_DSCPTR_PRV register can be used for status. For more information, see the section on descriptor pointer capture in the DMA functional description.

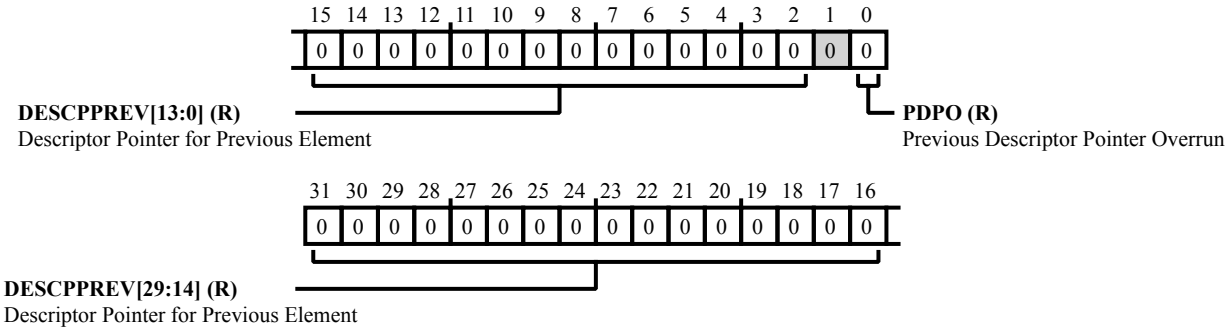

Figure 34-14: DMA_DSCPTR_PRV Register Diagram

Table 34-25: DMA_DSCPTR_PRV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	DESCPPREV	Descriptor Pointer for Previous Element. The DMA_DSCPTR_PRV.DESCPPREV bit field contains the initial descriptor pointer for the previous work unit.	
0 (R/NW)	PDPO	Previous Descriptor Pointer Overrun. The DMA_DSCPTR_PRV.PDPO bit signifies an alignment error. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error would occur when used for descriptor fetches.	
		0	No Error Occurred
		1	Error Occurred

Status Register

The DMA_STAT register indicates the status of DMA work units, the FIFO, errors, interrupts, and triggers.

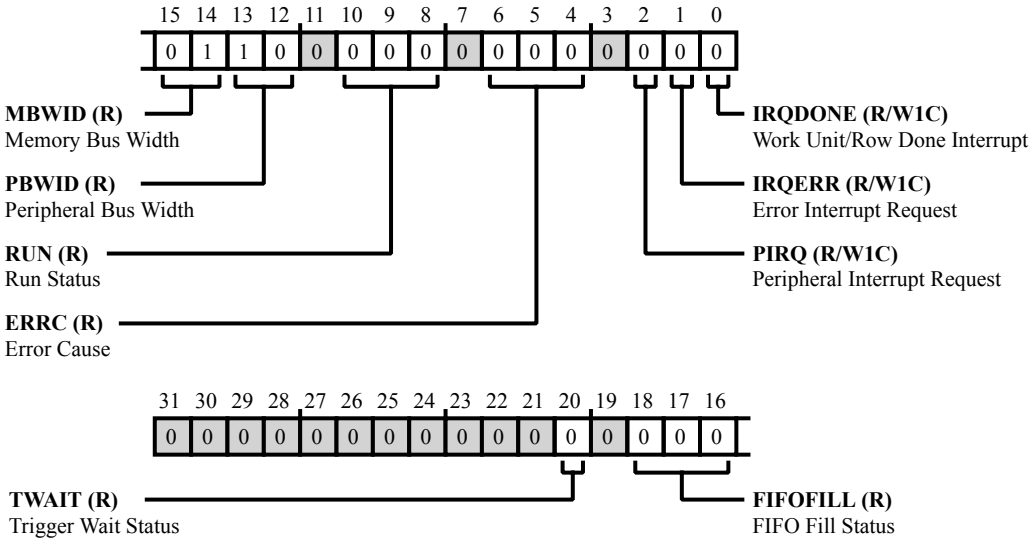

Figure 34-15: DMA_STAT Register Diagram

Table 34-26: DMA_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	TWAIT	Trigger Wait Status. The DMA_STAT.TWAIT bit indicates whether the DMA has or has not received a trigger. This bit is set until it reaches the next wait state. At that point, the bit is cleared, the DMA stops processing that work unit, and the following work unit processes. The DMA does not distinguish between one or more triggers received.	
		0	No Trigger Received
		1	Trigger Received
18:16 (R/NW)	FIFOFILL	FIFO Fill Status. The DMA_STAT.FIFOFILL bit field reports the quantity of data in the FIFO relative to available space.	
		0	Empty
		1	Empty < FIFO = 1/4 Full
		2	1/4 Full < FIFO = 1/2 Full
		3	1/2 Full < FIFO = 3/4 Full
		4	3/4 Full < FIFO = Full
		5	Reserved

Table 34-26: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Reserved
		7	Full
15:14 (R/NW)	MBWID	Memory Bus Width. The DMA_STAT.MBWID bit field indicates the width of the memory bus connected to this DMA.	
		0	2 Bytes
		1	4 Bytes
		2	8 Bytes
		3	16 Bytes
13:12 (R/NW)	PBWID	Peripheral Bus Width. The DMA_STAT.PBWID bit field indicates the width of the peripheral bus connected to this DMA.	
		0	1 Byte
		1	2 Bytes
		2	4 Bytes
		3	8 Bytes
10:8 (R/NW)	RUN	Run Status. The DMA_STAT.RUN bit field reports the DMA's current operational state. If the DMA is in idle or stop state, the DMA_CFG.EN bit is either 0 or 1. This bit field does not clear when a transition of the DMA_CFG.EN bit from 0 to 1 occurs. The DMA_STAT.RUN clears automatically when the DMA completes.	
		0	Idle/Stop State
		1	Descriptor Fetch
		2	Data Transfer
		3	Waiting for Trigger
		4	Waiting for Write ACK/FIFO Drain to Peripheral
		5	Reserved
		6	Reserved
		7	Reserved
6:4 (R/NW)	ERRC	Error Cause. When an interrupt request error occurs (DMA_STAT.IRQERR), the DMA updates the DMA_STAT.ERRC bit field to identify the type of error. For more information, see the errors section of the DMA functional description.	

Table 34-26: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Configuration Error
		1	Illegal Write Occurred While Channel Running
		2	Address Alignment Error
		3	Memory Access or Fabric Error
		4	Reserved
		5	Trigger Overrun
		6	Bandwidth Monitor Error
		7	Reserved
2 (R/W1C)	PIRQ	Peripheral Interrupt Request. The DMA_STAT.PIRQ bit indicates a peripheral interrupt request. Programs can use the DMA_STAT.PIRQ bit status to help determine which DMA asserted the interrupt request. This bit also helps to distinguish between an interrupt request caused by the state of the work unit and an interrupt request caused by the peripheral.	
		0	No Interrupt request
		1	Interrupt Request signaled by peripheral
1 (R/W1C)	IRQERR	Error Interrupt Request. The DMA_STAT.IRQERR bit indicates that the DMA has detected a documented rule violation during DMA programming or operation. The DMA cannot, however, flag all possible programming or operation issues to indicate errors. Programmers can use the DMA_STAT.IRQERR bit to help determine which DMA issued the error interrupt request. The DMA_STAT.IRQERR does not clear a transition of the DMA_CFG.EN bit from 0 to 1. Clear the DMA_STAT.IRQERR bit with a write-1-to-clear operation prior to the DMA_CFG.EN transition for the fields to be reset.	
		0	No Error
		1	Error Occurred
0 (R/W1C)	IRQDONE	Work Unit/Row Done Interrupt. The DMA_STAT.IRQDONE bit indicates that the DMA has detected the completion of a work unit or row (inner loop count) and has issued an interrupt request. Programs can use the DMA_STAT.IRQDONE status to help determine which DMA asserted the interrupt request. Programs can also use these bits to help distinguish between an interrupt request based on the state of the work unit and an interrupt request made by the peripheral. For more information, see the interrupts section of the DMA functional description.	
		0	Inactive
		1	Active

Inner Loop Count Start Value Register

For 2D DMA, the DMA_XCNT register contains the inner loop count. This value selects the number of DMA_CFG.MSIZE size data transfers that make up the length of a row. For 1D DMA, the DMA_XCNT register specifies the number of DMA_CFG.MSIZE size data transfers for the entire work unit. The DMA_XCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

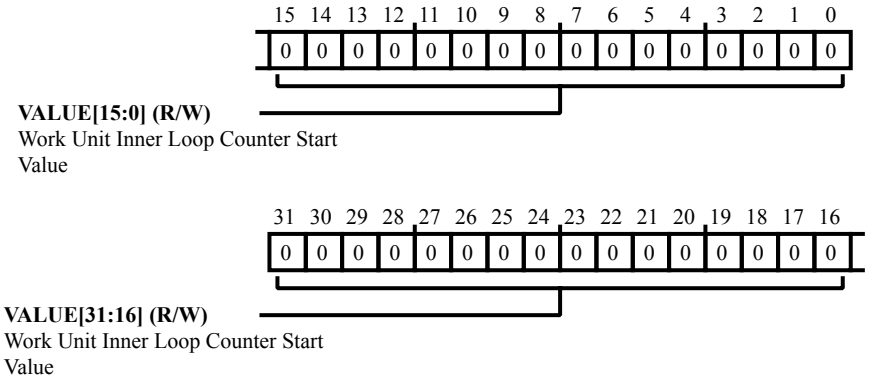

Figure 34-16: DMA_XCNT Register Diagram

Table 34-27: DMA_XCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Inner Loop Counter Start Value. For 2D DMA, the DMA_XCNT.VALUE bit field contains the inner loop count. For 1D DMA, DMA_XCNT.VALUE specifies the number of DMA_CFG.MSIZE size data transfers for the entire work unit.

Current Count (1D) or Intra-row XCNT (2D) Register

For 1D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register at the beginning of each work unit. For 2D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register after the end of each row. The DMA decrements the value in DMA_XCNT_CUR register each time a DMA_CFG.MSIZE size data transfer occurs. When the count in DMA_XCNT_CUR register expires, the work unit is complete. In 2D DMA, the DMA_XCNT_CUR value is 0 only when the entire transfer is complete.

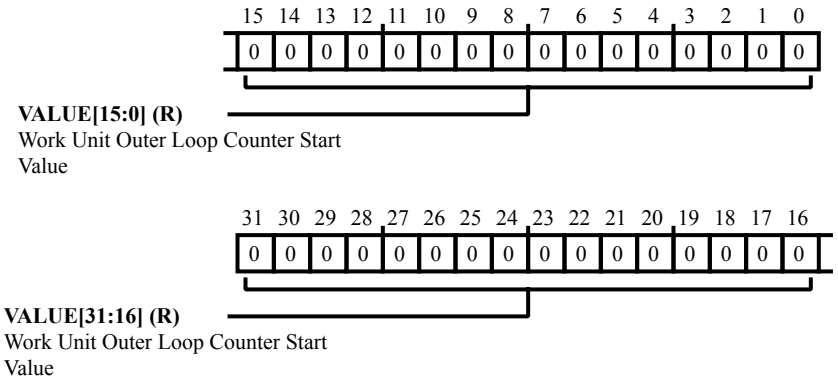

Figure 34-17: DMA_XCNT_CUR Register Diagram

Table 34-28: DMA_XCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Work Unit Outer Loop Counter Start Value. For 1D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value at the beginning of each work unit. For 2D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value after the end of each row.

Inner Loop Address Increment Register

The DMA_XMOD register contains a signed, two's-complement byte address increment. In 1D DMA, this increment is the stride that is applied after each DMA_CFG.MSIZE size data transfer. The DMA_XMOD register is read/write prior to enabling the channel, but is read-only after enabling the channel.

The DMA_XMOD register value is specified in bytes, regardless of the work unit size. In 2D DMA, this increment is applied after each DMA_CFG.MSIZE size data transfer in the inner loop, up to but not including the last DMA_CFG.MSIZE size data transfer in each inner loop. After the last DMA_CFG.MSIZE size data transfer in each inner loop, the DMA_YMOD register is applied instead, including the last DMA_CFG.MSIZE size data transfer of a work unit.

The DMA_XMOD field can be set to 0. In this case, DMA is performed repeatedly to or from the same address. This approach can be useful for transferring data between a data register and an external memory-mapped peripheral.

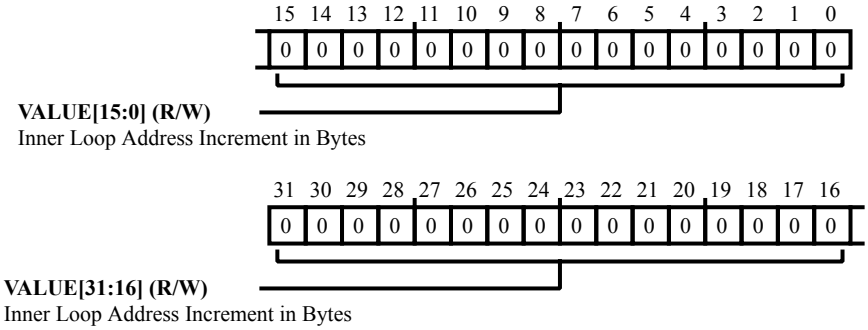

Figure 34-18: DMA_XMOD Register Diagram

Table 34-29: DMA_XMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Inner Loop Address Increment in Bytes. The DMA_XMOD.VALUE bit field contains a signed, two's-complement byte address increment.

Outer Loop Count Start Value (2D only) Register

For 2D DMA, the DMA_YCNT register contains the outer loop count. This register is not used in 1D DMA mode. The DMA_YCNT register specifies the number of rows in the outer loop of a 2D DMA sequence. The DMA_YCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

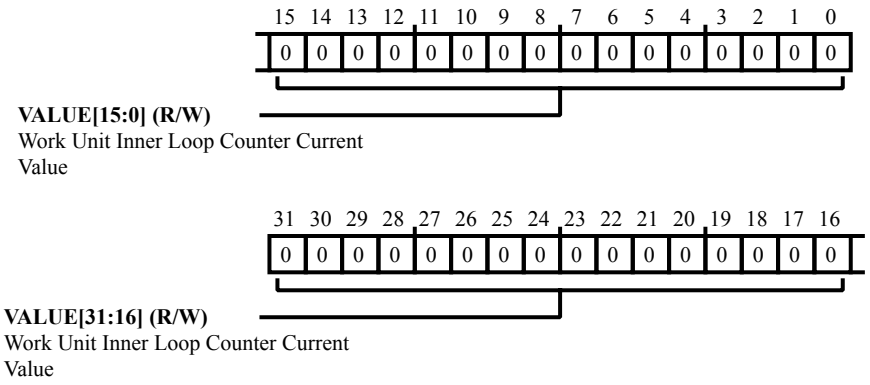

Figure 34-19: DMA_YCNT Register Diagram

Table 34-30: DMA_YCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Inner Loop Counter Current Value. For 2D DMA, the DMA_YCNT.VALUE bit field contains the outer loop count.

Current Row Count (2D only) Register

For 2D DMA, the DMA loads the DMA_YCNT_CUR register from the DMA_YCNT register at the beginning of each 2D DMA session. The DMA_YCNT_CUR register is not used for 1D DMA. The DMA decrements the DMA_YCNT_CUR register each time the DMA_XCNT_CUR register expires during 2D DMA operation, signifying the completion of an entire row transfer.

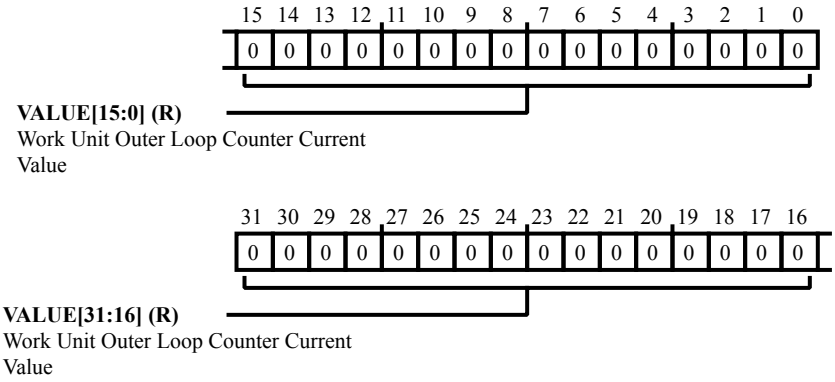

Figure 34-20: DMA_YCNT_CUR Register Diagram

Table 34-31: DMA_YCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Work Unit Outer Loop Counter Current Value. For 2D DMA, the DMA_YCNT_CUR.VALUE bit field holds the value from the DMA_YCNT register at the beginning of each 2D DMA session.

Outer Loop Address Increment (2D only) Register

The DMA_YMOD register contains a signed, two's-complement value. This byte address increment is applied after each decrement of the DMA_YCNT_CUR register. The value is the offset between the last word of one row and the first word of the next row. Note that DMA_YMOD is specified in bytes, regardless of the work unit size. The DMA_YMOD register is read/write prior to enabling the channel, but is read-only after enabling the channel.

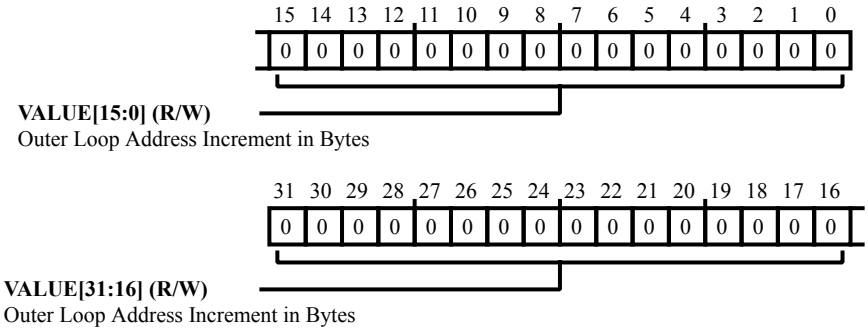

Figure 34-21: DMA_YMOD Register Diagram

Table 34-32: DMA_YMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Outer Loop Address Increment in Bytes. The DMA_YMOD.VALUE bit field contains a signed, two's-complement value.

35 Extended Memory DMA (EMDMA)

The Extended Memory DMA engine can be used in applications that copy data in a non-sequential manner. This includes delay lines, scatter and gather, and circular access types.

NOTE: Previous SHARC processors featured external port DMA. Current SHARC products use EMDMA that can access all memory locations (L1/L2/L3) for source and destination DMA operations.

EMDMA Features

EMDMA frees the processor core, allowing it to perform other operations while the data transfers between memories occurs as a background task.

EMDMA has the following features and capabilities.

- Standard mode DMA Transfer
- Chained mode with direction on-the-fly
- Tap list mode (scatter/gather)
- Delay line mode (write to read)
- All the DMA modes can operate in circular fashion
- In circular operation, some modes allow a write back of the index pointer for correct addressing of the next Transfer Control Block (TCB)

EMDMA Functional Description

The following sections provide information on the functional operations and operating modes of EMDMA.

Internal-to-internal DMA

This is accomplished by indexing all external parameter registers with internal addresses.

DMA bursting

DMA supports burst transfers only when the modifier is 1, for any other modifier values, single accesses are performed. The burst size is not user configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

Transfer control blocks

The structure of a TCB is conceptually the same as that of a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously re-run the same DMA.

Chain pointer DMA

In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete.

ADSP-2159x_SC591_SC592_SC594 EMDMA Register List

The EMDMA controllers support a variety of direct memory access operations which can access any system memory and transfer the entire block of data. A set of registers govern EMDMA operations. For more information on EMDMA functionality, see the EMDMA register descriptions.

Table 35-1: ADSP-2159x_SC591_SC592_SC594 EMDMA Register List

Name	Description
EMDMA_BASE	External Base Address Register
EMDMA_BUFLEN	Circular Buffer Length Register
EMDMA_CHNPTR	Chain Pointer Register
EMDMA_CNT0	Internal Count Register
EMDMA_CNT1	External Count Register
EMDMA_CTL	External Memory DMA Control Register
EMDMA_INDX0	Internal Index Register
EMDMA_INDX1	External Index Register
EMDMA_MOD0	Internal Modifier Register
EMDMA_MOD1	External Modifier Register
EMDMA_TCNT	Delay Line Tap Count Register
EMDMA_TPTR	Tap List Pointer Register

ADSP-2159x_SC591_SC592_SC594 EMDMA Interrupt List

Table 35-2: ADSP-2159x_SC591_SC592_SC594 EMDMA Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
210	EMDMA0_DONE	EMDMA0 Transfer Done	Edge	
211	EMDMA1_DONE	EMDMA1 Transfer Done	Edge	

ADSP-2159x_SC591_SC592_SC594 EMDMA Trigger List

Table 35-3: ADSP-2159x_SC591_SC592_SC594 EMDMA Trigger List Masters

Trigger ID	Name	Description	Sensitivity

Table 35-4: ADSP-2159x_SC591_SC592_SC594 EMDMA Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
None			

DMA Addressing

Besides the traditional internal-to-external addressing type, the DMA module also supports internal-to-internal transfers. This is accomplished by indexing all external parameter registers with internal addresses. The DMA controller recognizes the transfer by addresses and not by an additional control bit setting.

All the DMA addresses given by EMDMA are word-aligned byte addresses. The programming for the index registers is provided in the *Register Descriptions* section.

DMA Burst Transfers

DMA supports burst transfers only when the modifier is 1. For any other modifier values, single accesses are performed.

The burst size is not user-configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

The EMDMA uses appropriate burst transfer sizes for optimal throughput. For example, if the word count is 15, then 5 bursts are performed with burst sizes of 8+4+1+1+1 transfers.

Transfer Control Block (TCB) Memory Storage

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the processor's internal memory. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as that of a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously rerun the same DMA. The EMDMA reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The address field of the chain pointer registers is only 30 bits wide. If a program writes a symbolic address to bit 30 of the chain pointer there may be a conflict with the EMDMA_CHNPTR.PCI bit. Programs should clear the upper bits of the address then AND the EMDMA_CHNPTR.PCI bit separately, if needed.

Starting Chain Loading

A DMA sequence is defined as the sum of the DMA transfer from when the parameter registers initialize to when the count register decrements to zero. The EMDMA module has a chaining enable bit (EMDMA_CTL.CHEN).

To start the chain, write the internal (channel 0) index address of the first TCB to the chain pointer register (EMDMA_CHNPTR). When chaining is enabled, DMA transfers are initiated by writing a memory address to the chain pointer register. This is also an easy way to start a single DMA sequence, with no subsequent chained DMAs.

During TCB chain loading, the EMDMA loads the DMA channel parameter registers with values retrieved from system memory.

The address in the chain pointer register points to the highest address of the TCB. This contains the internal (channel 0) index parameter. This means that if a program declares an array to hold the TCB, the chain pointer register should point to the last location of the array and not to the first TCB location.

Buffered Chain Loading Register

The chain pointer register (EMDMA_CHNPTR) is buffered. Before the chain loading starts, the buffer is copied into the chain pointer register and is decremented after each register is loaded.

The chain pointer register can be loaded with a new address at any time during the DMA sequence (EMDMA_CTL.CHEN =1). This allows a DMA channel to have chaining status deactivated (chain pointer register = 0x0) until some event occurs that loads the chain pointer register with a non-zero value. Writing all zeros to the address field of the chain pointer register also deactivates chaining for the next TCB.

TCB Storage

The EMDMA supports several types of DMA, resulting in different lengths of TCBs. The TCB size varies from six locations (chained DMA) to 13 locations (delay line DMA). The ***EMDMA TCBs*** table shows the required TCBs for chained DMA.

In the following tables, TCB refers to the start address of the TCB array.

Table 35-5: EMDMA TCBs for Standard DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_MOD1
TCB + 0x2	EMDMA_INDX1
TCB + 0x3	EMDMA_CNT0
TCB + 0x4	EMDMA_MOD0
TCB + 0x5	EMDMA_INDX0

The order the descriptors are fetched with circular buffering enabled is shown in the ***EMDMA TCBs for Standard Circular DMA*** table.

Table 35-6: EMDMA TCBs for Standard Circular DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_BUFLEN
TCB + 0x2	EMDMA_BASE
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_INDX1
TCB + 0x5	EMDMA_CNT0
TCB + 0x6	EMDMA_MOD0
TCB + 0x7	EMDMA_INDX0

For delay line DMA, TCB loading is split into two sequences to improve overall priority. The first TCB loads the write parameters (EMDMA_INDX0 – EMDMA_BUFLEN) and the second loads the read parameters (EMDMA_INDX0 – EMDMA_CHNPTR). This two stage loading is transparent to the application. The order the descriptors are fetched for delay line DMA, as shown in the ***EMDMA TCBs for Delay Line DMA*** table.

Table 35-7: EMDMA TCBs for Delay Line DMA

Address	Register
Delay Line Read	
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_TPTR
TCB + 0x2	EMDMA_TCNT
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_CNT0

Table 35-7: EMDMA TCBs for Delay Line DMA (Continued)

Address	Register
TCB + 0x5	EMDMA_INDX0
Delay Line Write	
TCB + 0x6	EMDMA_BUFLEN
TCB + 0x7	EMDMA_BASE
TCB + 0x8	EMDMA_MOD1
TCB + 0x9	EMDMA_INDX1
TCB + 0xA	EMDMA_CNT0
TCB + 0xB	EMDMA_MOD0
TCB + 0xC	EMDMA_INDX0

The order the descriptors are fetched for scatter/gather DMA with circular buffering disabled is shown in the ***EMDMA TCBs for Scatter/Gather DMA*** table.

Table 35-8: EMDMA TCBs for Scatter/Gather DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_TPTR
TCB + 0x2	EMDMA_TCNT
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_INDX1
TCB + 0x5	EMDMA_CNT0
TCB + 0x6	EMDMA_MOD0
TCB + 0x7	EMDMA_INDX0

The order the descriptors are fetched for scatter/gather DMA with circular buffering enabled is shown in the ***EMDMA TCBs for Circular Scatter/Gather DMA*** table.

Table 35-9: EMDMA TCBs for Circular Scatter/Gather DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_BUFLEN
TCB + 0x2	EMDMA_BASE
TCB + 0x3	EMDMA_TPTR
TCB + 0x4	EMDMA_TCNT

Table 35-9: EMDMA TCBs for Circular Scatter/Gather DMA (Continued)

Address	Register
TCB + 0x5	EMDMA_MOD1
TCB + 0x6	EMDMA_INDX1
TCB + 0x7	EMDMA_CNT0
TCB + 0x8	EMDMA_MOD0
TCB + 0x9	EMDMA_INDX0

EMDMA Operating Modes

This section and the ***EMDMA_CTL Register Bit to Operating Modes*** table show the different DMA modes which can be used. The complete register bit descriptions are in the ***External Memory DMA Control Registers (EMDMA_CTL)***.

Table 35-10: EMDMA_CTL Register Bit to Operating Modes

Bit (Name)	Standard	Chained	Scatter/Gather	Delay Line
Control Bits				
0 (EN)	Valid			
1 (TRAN)	Valid			N/A
2 (CHEN)	Valid			
3 (DLEN)	N/A			Valid
4 (CBEN)	Valid			
5 (DFLSH)	Valid			
6	N/A			
7 (WRBEN)	N/A	Valid	(=0)	(=1)
8 (OFCEN)	Valid			N/A
9 (TLEN)	N/A		Valid	N/A
11–10	N/A			
12 (INTDONE0)	Valid			
15–13	N/A			
Status Bits				
17–16 (DFS)	Valid			
19–18	N/A			
20 (DMAS0)	Valid			
21 (CHS)	N/A	Valid	N/A	Valid

Table 35-10: EMDMA_CTL Register Bit to Operating Modes (Continued)

Bit (Name)	Standard	Chained	Scatter/Gather	Delay Line
22 (TLS)	N/A		Valid	N/A
23 (WBS)	N/A			Valid
24 (DMAS1)	Valid			
25 (DIRS)	Valid			
31–26	N/A			

NOTE: Reading additional bit-field information from N/A (Not applicable) bits does not generate a meaningful result.

A program sets up a DMA channel by writing the transfer's parameters to the DMA parameter registers.

NOTE: The `EMDMA_CNT1` parameter register (read only) is a copy of the `EMDMA_CNT0` register. If `EMDMA_CNT0` is written, the `EMDMA_CNT1` register is updated automatically.

Standard DMA

A standard DMA (once it is configured) transfers data from location A to location B. An interrupt can be used to indicate the end of the transfer. To start a new DMA sequence after the current one is finished, a program must first clear the DMA enable bit (`EMDMA_CTL.EN`), write new parameters to the index, modify, and count registers (parameter registers), then set the DMA enable bit to re-enable DMA.

This DMA type resembles the traditional DMA type to initialize the different internal and external parameters (channel0 and channel1) (index, modify and count) registers and configuration of the DMA control registers.

Circular Buffered DMA

Circular buffered DMA resembles the traditional core DAG circular buffered mode by using registers for circular buffering. In this mode, the DMA needs two additional registers (base and length) to support reads and writes to a circular buffer. The ***Circular Buffering Write DMA*** and ***Circular Buffering Read DMA*** figures illustrate circular buffered DMA, in contrast with the ***Standard Write DMA*** figure.

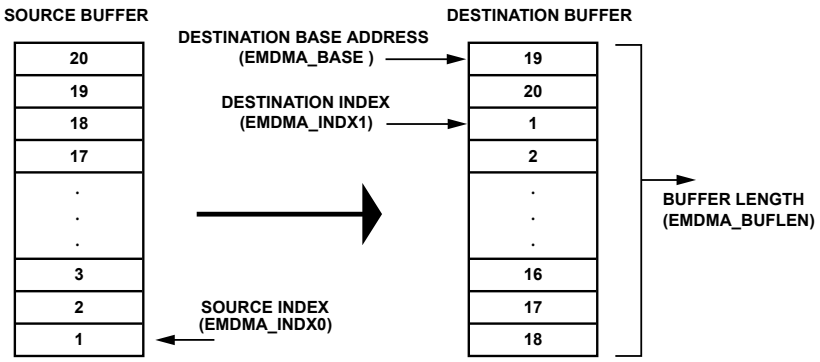

Figure 35-1: Circular Buffering Write DMA

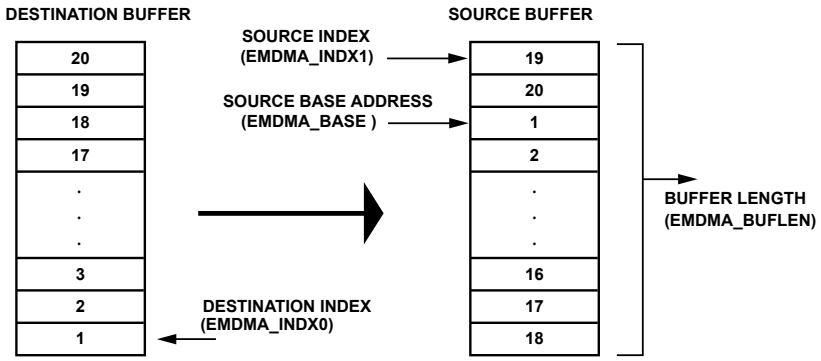

Figure 35-2: Circular Buffering Read DMA

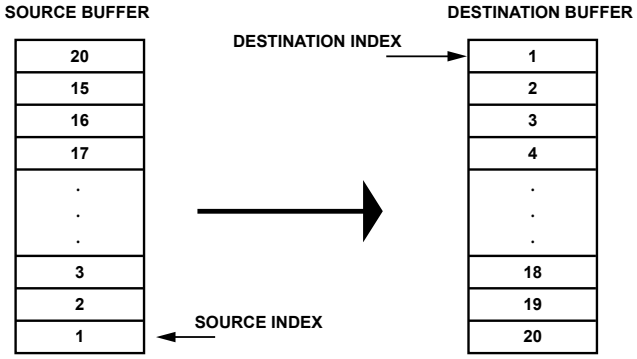

Figure 35-3: Standard Write DMA

NOTE: Circular buffering is available for all operating modes (standard, chained, tap list and delay line DMA).

Chained DMA Mode

Chained DMA sequences are a set of multiple DMA operations, each auto-initializing the next in line. It is used to support automated access by a linked list (repetitive reads and writes to a defined location defined by the individual TCBs). To start a new DMA sequence after the current one is finished, the EMDMA automatically loads new index, modify, and count values pointed to by that channel's `EMDMA_CHNPTR` register. Using chaining, programs can set up consecutive DMA operations and each operation can have different attributes.

DMA data transfers can be set up as continuous or periodic. With chained DMA, the attributes of a specific DMA are stored in internal memory and are referred to as a Transfer Control Block or TCB. Extended Memory DMA loads these attributes in chains for execution. This allows for multiple chains that are finite or infinite.

NOTE: When chaining is enabled, polling should not be used to determine DMA status only because the DMA appears inactive if it is sampled while the next TCB is loading. In such cases where chaining is enabled, along with the polling of DMA status bit, polling of the chaining status bit should also occur to so that the correct status of the DMA is known. For example, the `EMDMA_CTL.CHS` bit should be polled as well as the `EMDMA_CTL.DMAS0` and `EMDMA_CTL.DMAS1` bits when EMDMA is configured in DMA chaining mode.

Data Direction On-the-Fly

A change of external memory data direction for each individual TCB in a chain sequence is allowed.

The EMDMA_CHNPTR.CPDR bit changes the data flow direction. If the EMDMA_CHNPTR.CPDR =0, writes through channel 0 are performed; if EMDMA_CHNPTR.CPDR =1, channel 0 reads are performed. This works similarly to the EMDMA_CHNPTR.PCI bit. The EMDMA_CTL.OFCEN and EMDMA_CTL.CHEN bits must be set (=1) to enable this functionality.

NOTE: If chaining is enabled with the EMDMA_CTL.OFCEN =1, then the EMDMA_CTL.TRAN bit has no effect, and the data direction is determined by the EMDMA_CHNPTR.CPDR bit.

Write Back Circular Index Pointer

Operating the DMA in circular mode requires some special considerations. The index pointer of start address within the buffer may wrap around for the case when IC × IM > EL or it does not finish if IC × IM < EL where:

IC is the value of the EMDMA_INDX0 register

IM is the value of the EMDMA_MOD0 register

EL is the value of the EMDMA_BUFLEN register

In both cases, the TCB start address is no longer valid.

Setting the EMDMA_CTL.WRBEN bit writes (at the end of current TCB block) the current index address + 1 into the TCB memory which is the start address for the next TCB. This bit is only selectable for chained DMA mode. For tap list and delay line modes, this bit is hardwired to 0 or 1.

Scatter/Gather DMA

The purpose of scatter/gather DMA is the transfer of data from/to non-contiguous memory blocks.

The scatter/gather DMA type is a fixed block size scatter/gather DMA that relies on tap list entries in system memory to calculate the (Channel 1 DMA Address) to scatter/gather the DMA. If the DMA direction is Channel 1 write (EMDMA_CTL.TRAN =1) then it is a scatter DMA. If EMDMA_CTL.TRAN =0 then it is a gather DMA. This mode also supports chained and circular buffer chained DMAs.

See the ***Scatter DMA (Writes)***, ***Gather DMA (Reads)***, ***Circular Buffering Scatter DMA (Writes)***, and ***Circular Gather DMA (Reads)*** figures.

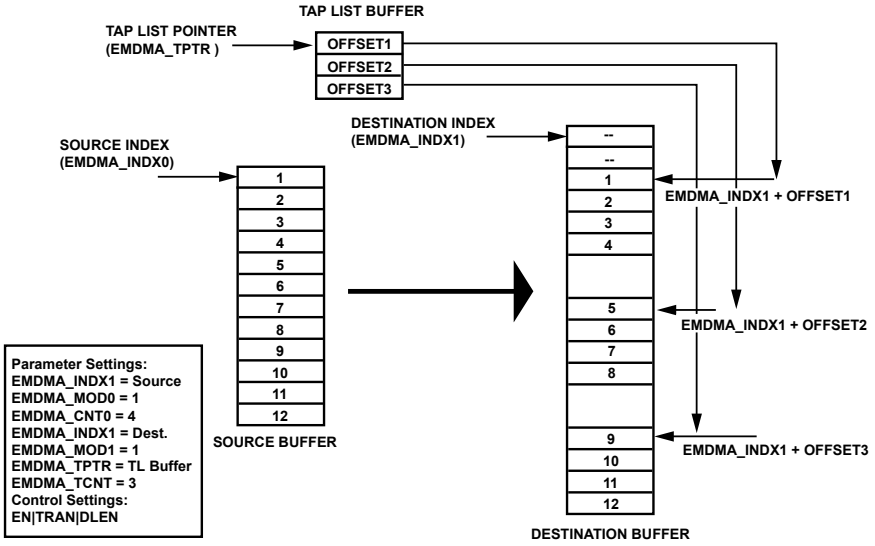

Figure 35-4: Scatter DMA (Writes)

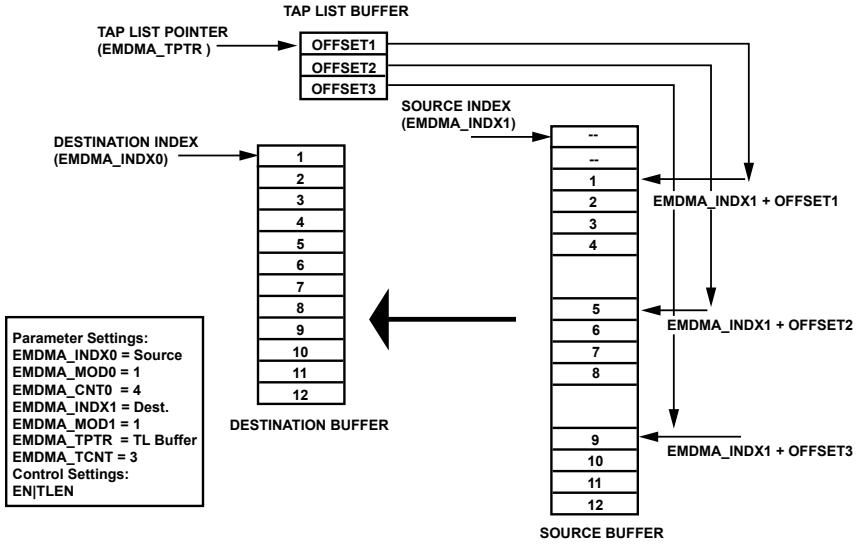

Figure 35-5: Gather DMA (Reads)

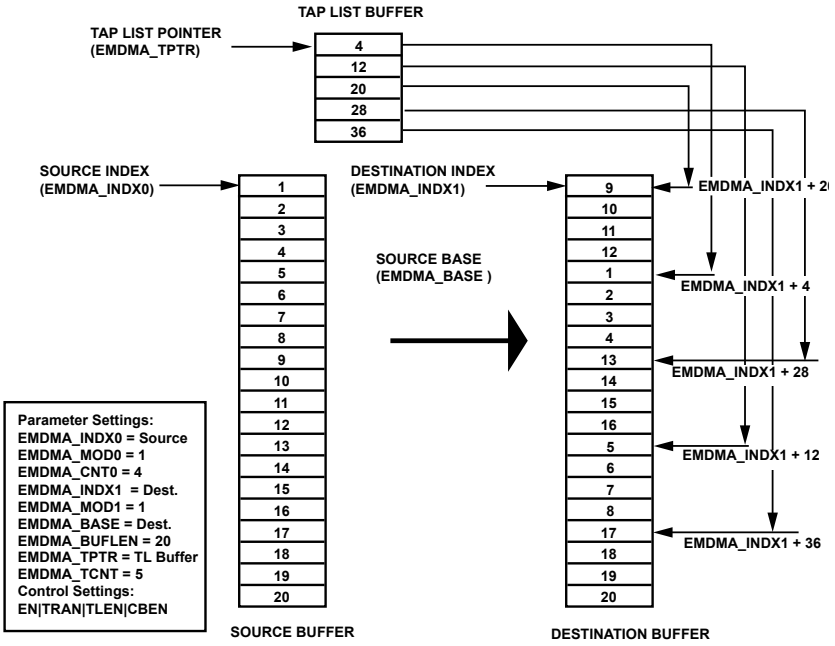

Figure 35-6: Circular Buffering Scatter DMA (Writes)

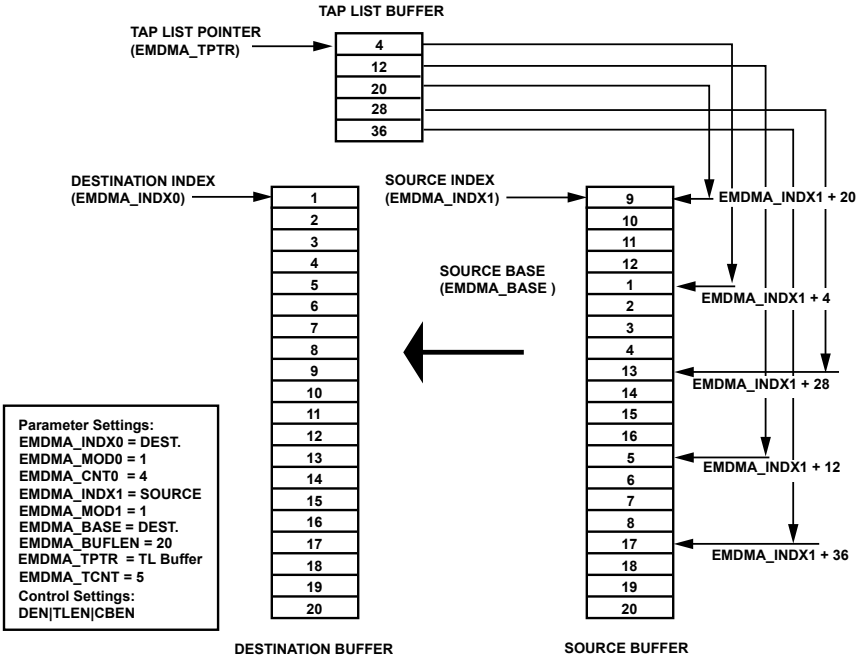

Figure 35-7: Circular Gather DMA (Reads)

For each 32-bit tap read, the Channel 1 read index is shown in the ***Read/Write Index Pre-Modify (Scatter/Gather DMA)*** table. Note that one tap list entry starts multiple reads.

Table 35-11: Read/Write Index Pre-Modify (Scatter/Gather DMA)

Pre-Modify Address Equation **EMDMA_INDX1** + **EMDMA_TPTR** [**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT0**)	Result	
	Block Size	Tap
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 1	N	0
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 3		
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × N		
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 1	N	1
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 3		
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × N		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 1	N	M
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 3		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × N		

Pre Modified Read/Write Index

For scatter/gather DMA, the tap list modifiers are employed and the number of taps is determined by the tap list count register (EMDMA_TCNT). The number of sequential reads (block size) from every tap is determined by the internal count register (EMDMA_CNT0), and is the same for every tap. The read/write pointer in external index register (EMDMA_INDX1) serves as the index address for these read/writes.

TL[N] is the first tap list entry in the memory as pointed to by the tap list pointer register (EMDMA_TPTR). The tap list entries are 27-bit signed integers. For each read/write block, the DMA state machine fetches the offset from the tap list. The offset is added to the EMDMA_INDX1 register value to get the start address of the next block. The Channel 1 addresses are circular buffered if circular buffering is enabled (see the ***Circular Buffering Scatter DMA (Writes)*** and ***Circular Buffering Gather DMA (Reads)*** figures in Scatter/Gather DMA).

Once the EMDMA_CNT0 register for the final tap decrements to zero (both EMDMA_TCNT and EMDMA_CNT0 are zero), then the tap list DMA access is complete and the DMA completion interrupt is generated (if chaining is enabled the interrupt depends on the EMDMA_CHNPTR.PCI bit setting).

The write back mode (EMDMA_CTL.WRBEN bit) is hardwired to zero for tap list based DMA (as the addressing is pre-modify, and therefore the EMDMA_INDX1 value coincides with the TCB value even at the end of the DMA).

Delay Line DMA

Delay line DMA is used to support reads and writes to delay line buffers with limited core interaction. In this sense, delay line DMA is a quantity of integrated writes followed by reads from channel 1 (a delay line DMA access). Delay line DMA is described in the following sections.

NOTE: Delay line DMA can only operate by using chained DMA mode (EMDMA_CTL.CHEN bit set). In order to use delay line DMA for a single DMA sequence, initialize the EMDMA_CHNPTR register to zero in the TCB.

NOTE: Delay line DMA can be used in any system memory.

The delay line DMA operation follows these steps:

1. Load the first half of TCB for writing (seven parameters).
2. DMA writes to the delay line buffer until IC = 0.
3. Update the EI index pointer if circular mode is enabled.
4. Load the second half of TCB for reading (six parameters).
5. DMA tap based reads from the delay line buffer until RC = 0.

   Jump to step 1.

Writes to delay line. The number of writes is determined by the EMDMA_CNT0 register. The data is fetched from the EMDMA_INDX0 register and the EMDMA_MOD0 register is used as the internal modifier. The EMDMA_INDX1 register serves as the external index and is incremented by the EMDMA_MOD1 register after each write. These writes are circular buffered if circular buffering is enabled. See the ***Write to Delay Line Buffer*** figure.

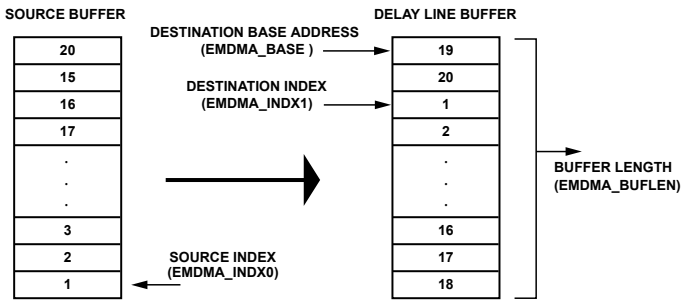

Figure 35-8: Write to Delay Line Buffer

When the writes are complete, (EMDMA_CNT0 =0) the EMDMA_INDX1 register, which serves as the write pointer of the delay line, is written back (EMDMA_CTL.WRBEN is hardwired to 1) to the TCB location from where it was fetched.

Reads from the delay line. For reads, the tap list (TL) modifiers are used and the number of reads is determined by the EMDMA_CNT0 register. The write pointer in the EMDMA_INDX0 register serves as the index address for these reads (reads start from where writes end). The EMDMA_INDX0 register, along with tap list modifiers, are used in a pre-modify addressing mode to create the external address for the reads. Therefore, for each read, the DMA controller fetches the external modifier (EMDMA_TCNT register) from the tap list and the reads are circular buffered (if enabled). See the ***Read From Delay Line Buffer*** figure.

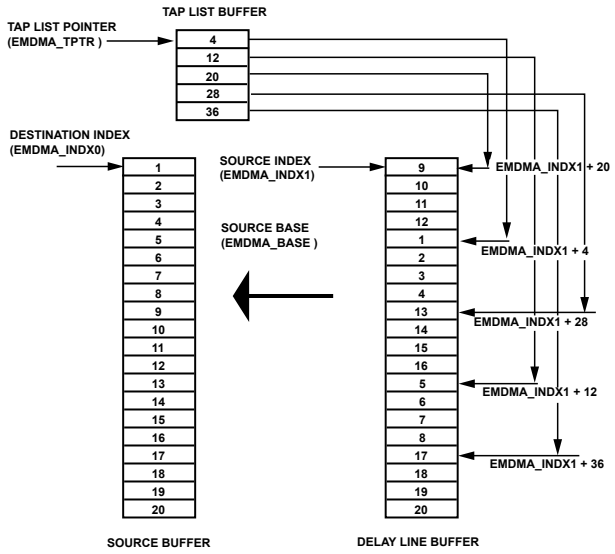

Figure 35-9: Read From Delay Line Buffer

Pre-Modified Read Index

Note that TL[N] is the first tap list entry in memory pointed to by the tap list pointer register (EMDMA_TPTR). Tap list entries are 27-bit signed integers. Therefore, for each read-block, the DMA state machine fetches the offset external modifier from the tap list. The reads are circular buffered if circular buffering is enabled.

NOTE: The channel 1 DMA address generation follows pre-modify addressing for reads in delay line DMA and therefore the EMDMA_INDX1 register values are not updated. Also the EMDMA_MOD1 register does not have any effect during these delay line reads. Once the read count completes, the EMDMA_CNT0 register decrements to zero (both EMDMA_CNT0 and EMDMA_TCNT are zero) for the final tap. Finally, the delay line DMA access completes and the DMA completion interrupt is generated. If chaining is enabled, the interrupt is dependent on the EMDMA_CHNPTR.PCI bit setting. The delay line DMA can only be initialized using the TCB. In order to use the delay line DMA for a single DMA sequence, initialize the EMDMA_CHNPTR register to zero in the TCB.

For each 32-bit tap read, the channel 1 read index is shown in the ***Read/Write Index Pre-Modify (Scatter/Gather DMA)*** table. Note that one tap list entry starts multiple reads.

Table 35-12: Read/Write Index Pre-Modify (Scatter/Gather DMA)

Pre-Modify Address Equation	Result	
EMDMA_INDX0 + **EMDMA_TPTR**[**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT0**)	Block Size	Tap
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 1	N	0
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 2		
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 3		
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × N		

Table 35-12: Read/Write Index Pre-Modify (Scatter/Gather DMA) (Continued)

Pre-Modify Address Equation **EMDMA_INDX0** + **EMDMA_TPTR**[**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT0**)	Result	
	Block Size	Tap
EMDMA_INDX0 + EMDMA_TPTR[1] + EMDMA_MOD1 × 1	N	1

EMDMA_INDX0 + EMDMA_TPTR[M] + EMDMA_MOD1 × N		

ADSP-2159x_SC591_SC592_SC594 EMDMA Register Descriptions

Extended Memory DMA (EMDMA) contains the following registers.

Table 35-13: ADSP-2159x_SC591_SC592_SC594 EMDMA Register List

Name	Description
EMDMA_BASE	External Base Address Register
EMDMA_BUFLEN	Circular Buffer Length Register
EMDMA_CHNPTR	Chain Pointer Register
EMDMA_CNT0	Internal Count Register
EMDMA_CNT1	External Count Register
EMDMA_CTL	External Memory DMA Control Register
EMDMA_INDX0	Internal Index Register
EMDMA_INDX1	External Index Register
EMDMA_MOD0	Internal Modifier Register
EMDMA_MOD1	External Modifier Register
EMDMA_TCNT	Delay Line Tap Count Register
EMDMA_TPTR	Tap List Pointer Register

External Base Address Register

The EMDMA_BASE register contains the external base address of the Delay Line buffer. This is used for maintaining circular buffered read/writes to the delay line.

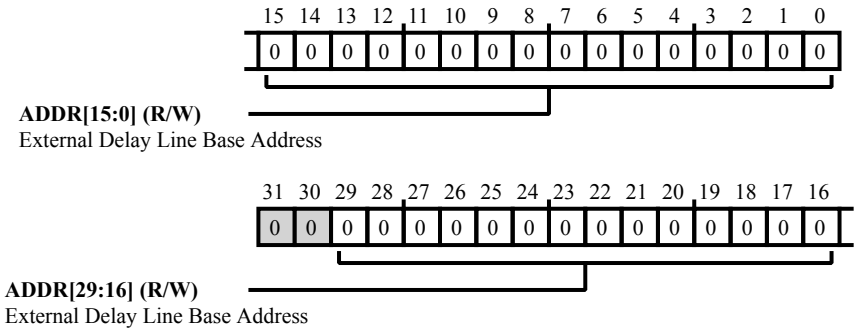

Figure 35-10: EMDMA_BASE Register Diagram

Table 35-14: EMDMA_BASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	ADDR	External Delay Line Base Address. The EMDMA_BASE.ADDR bit field contains the external base address of the Delay Line buffer.

Circular Buffer Length Register

The EMDMA_BUFLEN register holds the circular buffer length for the Delay-line DMA.

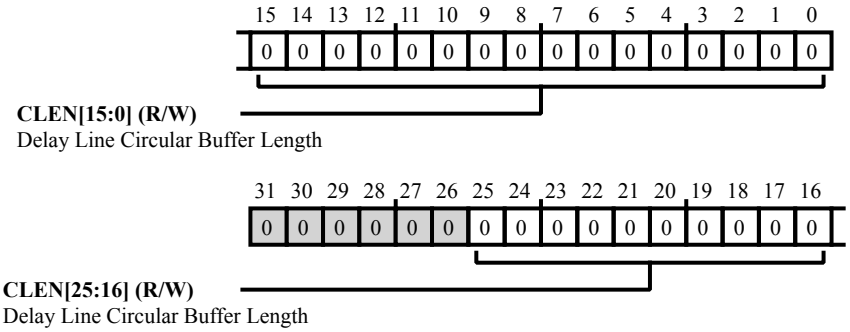

Figure 35-11: EMDMA_BUFLEN Register Diagram

Table 35-15: EMDMA_BUFLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:0 (R/W)	CLEN	Delay Line Circular Buffer Length. The EMDMA_BUFLEN.CLEN bit field holds the circular buffer length for the Delay-line DMA.

Chain Pointer Register

The EMDMA_CHNPTR register contains the address of the next descriptor in memory when the EMDMA_CTL.CHEN bit =1. This register also has bits to change DMA directions for each descriptor and the PCI bit. Note that the lower 30-bits of this register are to be written with 30 MSB's of the Word Aligned Byte addresses of the corresponding next descriptor address.

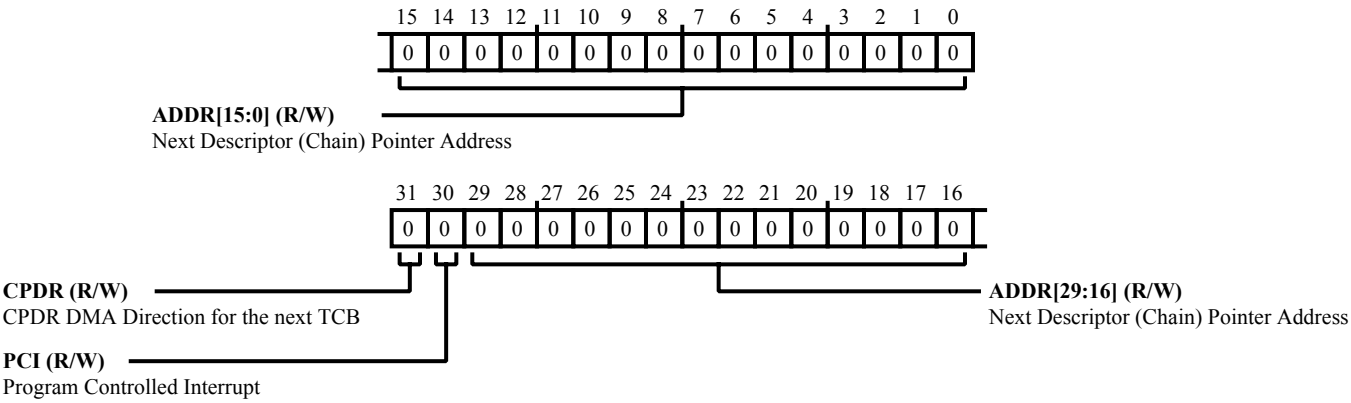

Figure 35-12: EMDMA_CHNPTR Register Diagram

Table 35-16: EMDMA_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CPDR	CPDR DMA Direction for the next TCB. The EMDMA_CHNPTR.CPDR bit configures whether the DMA is a write to internal memory or a read from internal memory. Note that this setting is applicable only if EMDMA_CTL.OFCEN =1 and is not applicable for Delay Line DMA.	
		0	Write to Channel 0 (Channel 1 reads)
		1	Read from Channel 0 (Channel 1 Writes)
30 (R/W)	PCI	Program Controlled Interrupt. The EMDMA_CHNPTR.PCI bit PCI sets whether an interrupt is generated after the current TCB or if no interrupt is generated. (Only affects DMA if chaining is enabled)	
		0	Enable DMA Channel interrupt to occur at the completion of the entire DMA chained transfer
		1	Enable DMA Channel interrupt to occur at the completion of current DMA sequence
29:0 (R/W)	ADDR	Next Descriptor (Chain) Pointer Address. The EMDMA_CHNPTR.ADDR bit field provides the address of the next descriptor in memory.	

Internal Count Register

The EMDMA_CNT0 register contains the number of words to be transferred for channel 0 DMA. Note: If Delay Line DMA is enabled then the EMDMA_CNT0 register serves as the count register for the Delay Line writes.

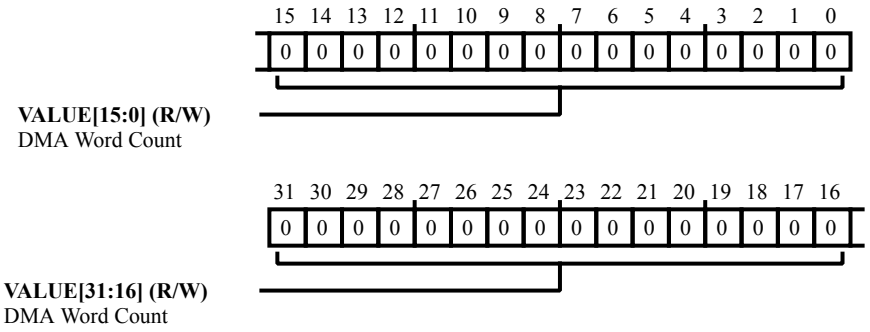

Figure 35-13: EMDMA_CNT0 Register Diagram

Table 35-17: EMDMA_CNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Word Count. The EMDMA_CNT0.VALUE bit field is the DMA word count.

External Count Register

The EMDMA_CNT1 register contains the number of words to be transferred for channel 1 DMA. Note: If Delay Line DMA is enabled then the EMDMA_CNT1 register serves as the count register for the Delay Line writes.

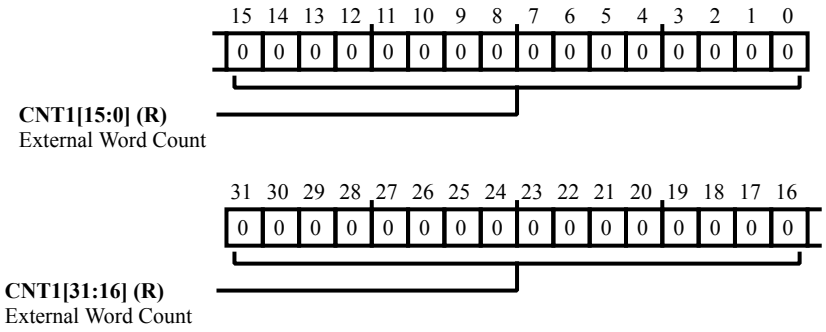

Figure 35-14: EMDMA_CNT1 Register Diagram

Table 35-18: EMDMA_CNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT1	External Word Count. The EMDMA_CNT1.CNT1 bit field is the external word count.

External Memory DMA Control Register

The EMDMA_CTL register contains bits that enable and configure EMDMA and indicate DMA transfer status.

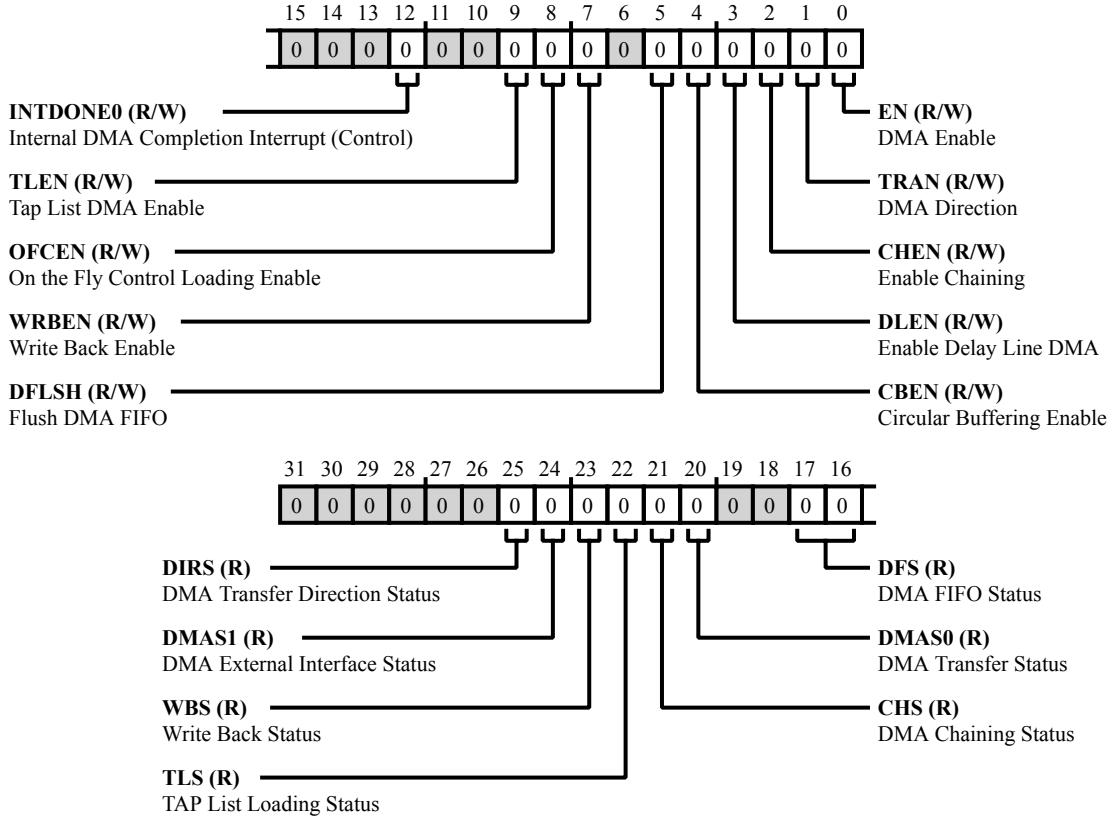

Figure 35-15: EMDMA_CTL Register Diagram

Table 35-19: EMDMA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	DIRS	DMA Transfer Direction Status. The EMDMA_CTL.DIRS bit provides the DMA transfer status direction. This is useful for delay line DMA where the transfer direction changes with the state of the DMA state machine. For standard DMA, the EMDMA_CTL.DIRS bit reflects the state of the EMDMA_CTL.TRAN bit.	
		0	DMA direction is Channel 1 Reads
		1	DMA direction is Channel 1 Writes

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	DMAS1	DMA External Interface Status. The EMDMA_CTL.DMAS1 bit provides the DMA channel 1 transfer status.	
		0	Channel 1 DMA does not have any access pending
		1	Channel 1 DMA access are pending
23 (R/NW)	WBS	Write Back Status. The EMDMA_CTL.WBS bit provides the delay line write pointer write back status.	
		0	Write pointer write back is not active
		1	Write pointer write back is active
22 (R/NW)	TLS	TAP List Loading Status. The EMDMA_CTL.TLS bit provides the DMA tap list loading status.	
		0	TAP list loading is not active
		1	TAP list loading is active
21 (R/NW)	CHS	DMA Chaining Status. The EMDMA_CTL.CHS bit provides the DMA chaining status.	
		0	DMA chain loading is not active
		1	DMA chain loading is active
20 (R/NW)	DMAS0	DMA Transfer Status. The EMDMA_CTL.DMAS0 bit provides the DMA channel 0 transfer status.	
		0	DMA idle
		1	DMA in progress
17:16 (R/NW)	DFS	DMA FIFO Status. The EMDMA_CTL.DFS bit field provides the DMA FIFO status.	
		0	FIFO EMPTY
		1	FIFO Partially Full
		2	Reserved
		3	FIFO Full

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	INTDONE0	Internal DMA Completion Interrupt (Control). The EMDMA_CTL.INTDONE0 bit configures when the DMA complete interrupt is generated. The EMDMA_CTL.INTDONE0 =1 setting is provided for backward compatibility with older SHARC processors.	
		0	Interrupt on access completion (Channel 0 or Channel 1 DMA completion)
		1	Interrupt on Channel 0 DMA completion.
9 (R/W)	TLEN	Tap List DMA Enable. The EMDMA_CTL.TLEN bit enables scatter/gather tap list DMA.	
		0	Disables the tap list based scatter/gather DMA
		1	Enables the tap list based scatter/gather DMA
8 (R/W)	OFCEN	On the Fly Control Loading Enable. The control bits in EMDMA_CHNPTR register are used to describe the next TCB behavior if the EMDMA_CTL.OFCEN bit is set and therefore the DMA controls can be changed from TCB to TCB. 0 = disables the control bits in the EMDMA_CHNPTR register 1 = Enables the control bits in the EMDMA_CHNPTR register. If chaining is enabled with EMDMA_CTL.OFCEN bit set then the EMDMA_CTL.TRAN bit has no effect, and direction is determined by EMDMA_CHNPTR.CPDR bit.	
7 (R/W)	WRBEN	Write Back Enable. The EMDMA_CTL.WRBEN bit enables write back of the EIEP register after reads and or writes.Write back is automatically enabled for delay line DMA. WRBEN is applicable only if chaining is enabled (EMDMA_CTL.CHEN =1).	
5 (R/W)	DFLSH	Flush DMA FIFO. The EMDMA_CTL.DFLSH bit flushes the DMA FIFO. The buffer is only flushed if this bit is set. It can be set with the enable bit. Setting this bit also clears the EMDMA_CTL.DFS bit.	
4 (R/W)	CBEN	Circular Buffering Enable. The EMDMA_CTL.CBEN bit enables circular buffering. Circular buffering can be used with normal DMA as well, if circular buffering is enabled with chaining for normal DMA then ELEP and EBEP should be part of the TCB.	
		0	Disables circular buffering with delay line DMA
		1	Enables circular buffering with delay line DMA

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DLEN	Enable Delay Line DMA. The EMDMA_CTL.DLEN bit enables delay line DMA. This bit is applicable only if the EMDMA_CTL.CHEN bit =1.	
		0	Delay-line DMA disabled
		1	Delay-line DMA enabled
2 (R/W)	CHEN	Enable Chaining. The EMDMA_CTL.CHEN bit enables DMA chaining.	
		0	Chaining disabled
		1	Chaining enabled
1 (R/W)	TRAN	DMA Direction. The EMDMA_CTL.TRAN bit determines the DMA data direction. Note: If delay line DMA is enabled then this bit does not have any effect. For delay line DMA, transfer direction depends on the state of delay line transfers. For Internal-Internal or External-External DMA this bit has to be set.	
		0	Write through Channel 0 (Channel 1 reads)
		1	Read from Channel 0(Channel 1 writes)
0 (R/W)	EN	DMA Enable. The EMDMA_CTL.EN bit enables DMA.	
		0	Disable DMA
		1	Enable DMA

Internal Index Register

The EMDMA_INDX0 register contains the start address of the buffer for Channel 0 DMA. Note: For delay line DMA the EMDMA_INDX0 register serves as the delay line write index which is the start address of the channel 0 DMA buffer for the channel 1 write data.

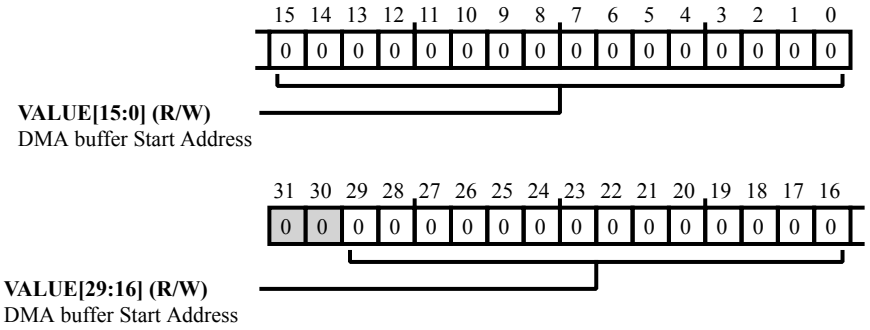

Figure 35-16: EMDMA_INDX0 Register Diagram

Table 35-20: EMDMA_INDX0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	DMA buffer Start Address. The EMDMA_INDX0.VALUE bit field is written with the 30 MSBs of the Word Aligned Byte addresses.

External Index Register

The EMDMA_INDX1 register contains the start address of the buffer for channel 1 DMA.

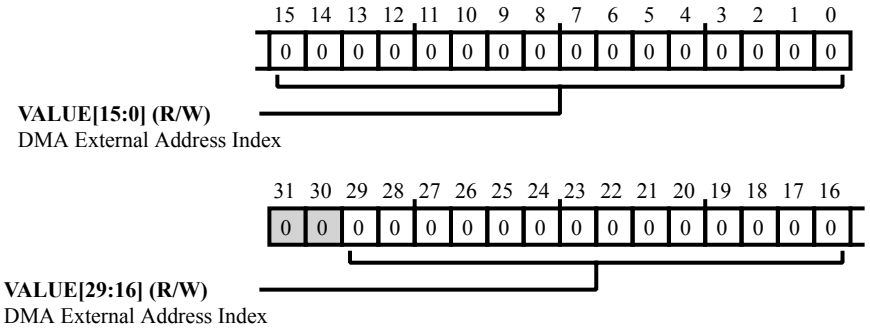

Figure 35-17: EMDMA_INDX1 Register Diagram

Table 35-21: EMDMA_INDX1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	DMA External Address Index. The EMDMA_INDX1.VALUE bit field is the DMA external address index.

Internal Modifier Register

The EMDMA_MOD0 register contains the channel 0 DMA address modifier.

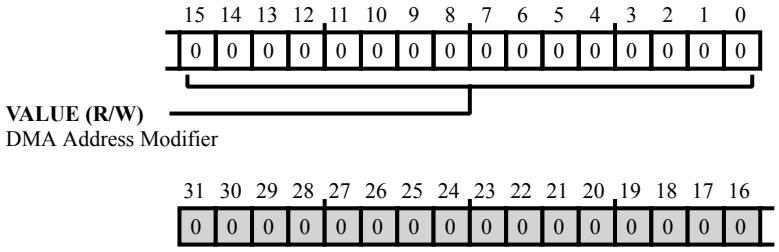

Figure 35-18: EMDMA_MOD0 Register Diagram

Table 35-22: EMDMA_MOD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	DMA Address Modifier. The EMDMA_MOD0.VALUE bit field is the DMA address modifier.

External Modifier Register

The EMDMA_MOD1 register contains the external (channel 1 DMA) address modifier.

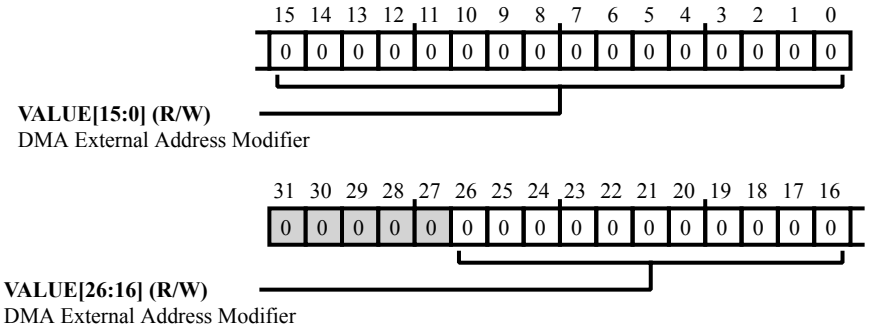

Figure 35-19: EMDMA_MOD1 Register Diagram

Table 35-23: EMDMA_MOD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26:0 (R/W)	VALUE	DMA External Address Modifier. The EMDMA_MOD1.VALUE bit field is the DMA external address modifier.

Delay Line Tap Count Register

The EMDMA_TCNT register is the tap count register for Delay Line DMA. This register holds the length of the tap list (the number of taps). The total number of words read from the delay line is equal to the EMDMA_TCNT (tap count) multiplied by the EMDMA_CNT1 (read block size).

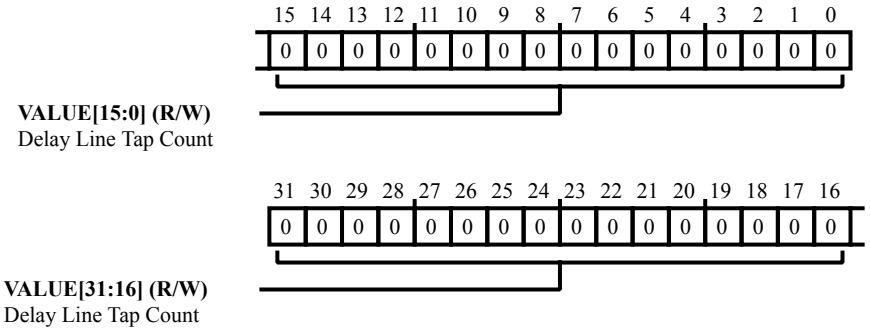

Figure 35-20: EMDMA_TCNT Register Diagram

Table 35-24: EMDMA_TCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Line Tap Count. The EMDMA_TCNT.VALUE bit field is the tap count register for Delay Line DMA.

Tap List Pointer Register

The EMDMA_TPTR register holds the address of an array in memory which holds offsets to be used when accessing a Delay-line in system memory. The offset represents the first address of each read block. Note that the lower 30-bits of this register are to be written with 30 MSBs of the Word Aligned Byte address of the Array.

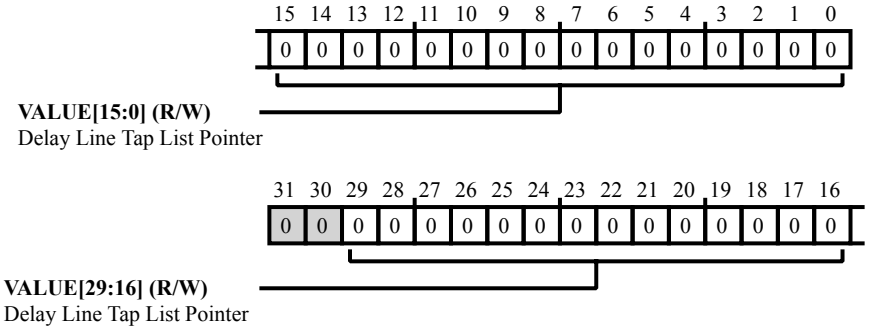

Figure 35-21: EMDMA_TPTR Register Diagram

Table 35-25: EMDMA_TPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Delay Line Tap List Pointer. The EMDMA_TPTR.VALUE bit field contains the offsets to be used when accessing a Delay-line in system memory.

36 Cyclic Redundancy Check (CRC)

The CRC peripheral performs the cyclic redundancy check (CRC) of the block of data that is presented to the peripheral. The peripheral provides a means to verify periodically the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects. It is based on a CRC32 engine that computes the signature of 32-bit data presented to the peripheral.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature. If the two signatures fail to match, the peripheral generates an error.

The source channel of the memory-to-memory DMA channels can provide data. The CRC optionally forwards data to memory through the destination DMA channel. Alternatively, the peripheral supports data presented by any qualified controller of the CRC peripheral bus.

The CRC peripheral implements a reduced table-look-up algorithm to compute the signature of the data. The CRC uses a programmable 32-bit CRC polynomial to generate the look-up table (LUT) contents automatically.

More CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

NOTE: CRC is supported by MDMA0, MDMA1, MDMA4, and MDMA5 channels only.

CRC Features

The CRC peripheral supports a number of key features.

- Memory scan modes for memory verification
- Memory transfer modes for on-the-fly CRC calculations while transferring data from one memory to another
- A programmable 32-bit CRC polynomial with automatic LUT generation
- Data mirroring options

The CRC module also includes the following features.

- CRC checksum computation and comparison modes
- 32-bit programmable CRC polynomial with bit reverse option
- Automatic look-up table (LUT) generation

- Data mirroring options for endian and reflected polynomial cases
- Automatic clear and preset of results
- Fault and error interrupt reporting
- DMA and MMR based operation

Because the CRC module is closely tied to memory-to-memory DMA (MDMA) channel pairs, the use cases include the following features.

- Memory scan mode with CRC compute or compare
- Memory transfer mode with CRC compute or compare
- Memory fill operation with 32-bit data patterns
- Memory verify operation
- MMR write access to FIFO of destination DMA
- MMR read access to FIFO of source DMA
- Profiting from advanced DMA features, like descriptor mode and bandwidth control or monitor

CRC Functional Description

The CRC peripheral supports a number of modes of operation that allow for the initialization and verification of regions of memory. The peripheral supports efficient memory-fill and verification operations on regions of memory with or against a constant value. These modes of operation do not require the CRC engine to calculate a signature. Other modes of operation allow for the calculation of CRC signature and verification for a memory region. The modes allow for on-the-fly CRC calculation when performing memory-to-memory DMA transfers from one memory region to another.

To minimize the need for core accesses, the peripheral interfaces with one or more (depending on processor features) memory-to memory DMA (MDMA) channels. This connectivity permits flexible configuration, in which data can be written-to or read-from the peripheral using DMA transactions, core transactions, or a combination of both.

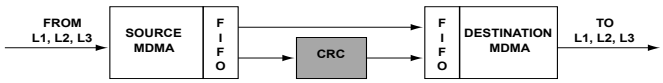

Figure 36-1: Memory Flow

ADSP-2159x_SC591_SC592_SC594 CRC Register List

The Cyclic Redundancy Check (CRC) unit includes the data comparison, polynomial operation, and look up table generation features needed for CRC operation. The CRC provides CRC protection as specified by many functional safety requirements. This unit facilitates the system software's ability to periodically check the correctness of the code/data available in memory. A set of registers govern CRC operations. For more information on CRC functionality, see the CRC register descriptions.

Table 36-1: ADSP-2159x_SC591_SC592_SC594 CRC Register List

Name	Description
CRC_COMP	Data Compare Register
CRC_CTL	Control Register
CRC_DCNT	Data Word Count Register
CRC_DCNTCAP	Data Count Capture Register
CRC_DCNTRLD	Data Word Count Reload Register
CRC_DFIFO	Data FIFO Register
CRC_FILLVAL	Fill Value Register
CRC_INEN	Interrupt Enable Register
CRC_INEN_CLR	Interrupt Enable Clear Register
CRC_INEN_SET	Interrupt Enable Set Register

205	CRC3_DCNTEXP	CRC3 Data Count Expiration	Level	

CRC Definitions

To make the best use of the CRC, it is useful to understand the following terms.

CRC

Acronym for Cyclic Redundancy Check. An error detection code that can detect changes within a block of data.

CRC Polynomial

The 32-bit polynomial used by the CRC engine to generate the look-up table required for the CRC implementation

LUT

Acronym for the Look-up Table. The look-up table is automatically generated from the supplied 32-bit CRC polynomial.

DMA

Acronym for Direct Memory Access. Used to describe a data transfer that takes place through a DMA channel allowing data distribution around a system without intervention from the core.

MDMA

Acronym for Memory-To-Memory DMA transfer that often requires the use of two DMA channels to transfer data from one memory region to another memory region. One DMA channel is configured as a source channel and the second as a destination channel.

CRC Block Diagram

The ***CRC Block Diagram*** shows the functional block diagram of the CRC. The following sections describe the blocks.

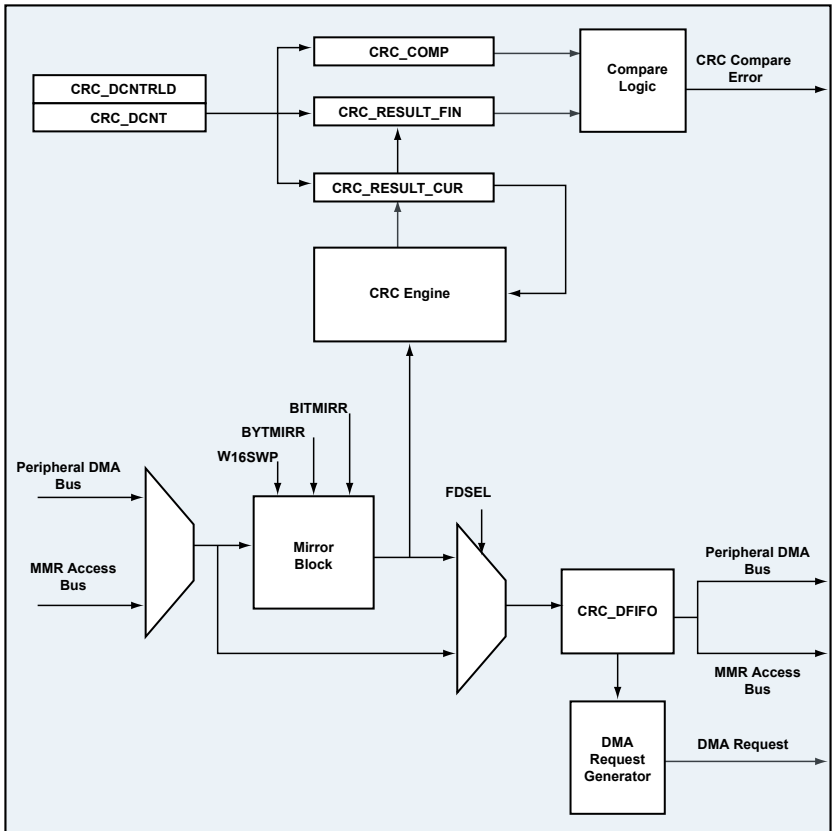

Figure 36-2: CRC Block Diagram

Peripheral DMA Bus

The CRC peripheral provides both an incoming and outgoing datapath to the peripheral DMA bus. The MDMA source channel is interfaced to the incoming datapath providing data to the CRC peripheral. For memory transfer and data fill modes, the CRC uses the MDMA destination channel to either output the data from the CRC FIFO or use the data for the fill operation.

MMR Access Bus

The core uses the MMR access bus to access all the memory-mapped registers of the peripheral for configuration, status, and debug purposes. The core can also use the MMR access bus to feed data to the CRC peripheral or read data from the FIFO of the CRC peripheral. The CRC operation is an alternative to the DMA channel operation to read data from the FIFO.

Data received by MMR writes can transfer to destination DMA. Similarly, data received by source DMA can be output through the MMR interface. Optionally, intermediate results can be made available to the MMR interface.

Mirror Block

The mirror block individually controls bit-reversing of the polynomial, the computation results, and the expected result. Bit mirroring, byte mirroring, word swapping, and any combination of these operations can control endian and the reflection of processed data.

Data FIFO

The CRC data FIFO is a 32-bit-wide 4-entry FIFO. The FIFO is accessible to both the peripheral DMA bus and the MMR access bus. The FIFO status is accessible from the CRC_STAT register.

DMA Request Generator

The DMA request generator is responsible for granting incoming DMA requests from the source DMA channel and issuing outgoing DMA requests to the destination DMA channel.

CRC Engine

The CRC engine is a 32-bit CRC engine that implements the reduced table look-up scheme. The CRC engine provides support for a user-programmable 32-bit polynomial that the CRC uses to load the look-up table parameters required for the CRC calculation. The CRC engine is a single cycle implementation operating on 32 bits of data per cycle.

Compare Logic

The compare logic takes the final CRC signature and compares it to the expected CRC signature, generating a CRC compare error when the signatures do not match. A compare error can flag a system fault.

CRC Architectural Concepts

A 32-bit polynomial is required before calculation of the CRC signature can occur. The CRC uses the polynomial to generate the contents of an internal look-up table that the reduced table look-up implementation requires. The look-up table is automatically generated when the polynomial is written. It must be initialized prior to any operation that requires the use of the CRC engine.

The mirror block logic can manipulate the data presented to the CRC engine before the CRC uses the data in the calculation of the CRC signature. The data mirror operation is configurable to allow for bit reversing, byte reversing, and 16-bit word swapping operations on the incoming data. For memory transfer compute-and-compare operations, programs can configure the peripheral to output the data in the same form in which it was received. Or, the operation can output the mirrored data in the same manner that it is presented to the CRC engine.

While the CRC peripheral is in operation, the status of the FIFO is continually updated and reflected in the CRC_STAT register. The FIFO status is required for core-based accesses to the CRC peripheral. The status indicates when:

- The CRC peripheral can receive data

- Data is available for reading from the FIFO
- The result of the CRC_RESULT_CUR register has been updated

The status of the CRC_RESULT_CUR register indicates that the current CRC calculation has completed and the result is available.

Look-up Table

The look-up table consists of a set of sixteen 32-bit registers that hardware populates automatically when a write access takes place to the CRC_POLY register. 16 clock cycles are required to generate all 16 look-up table entries. The status of the process for generating the look-up table is reflected in CRC_STAT.LUTDONE allowing for software to poll on the completion of the event or for generation of an interrupt.

NOTE: Hardware must populate the look-up table before any operation using the CRC peripheral can take place, even if the operation does not use the CRC engine. The peripheral does not issue any data requests until the table generation process is complete. In addition, the CRC_STAT.IBR field, that indicates the input buffer status as required for core-based transfers, is only valid upon completion of the process for generating the look-up table.

Data Mirroring

The data mirror block can be configured to manipulate the incoming data before the data passes to the CRC engine and, optionally, to the FIFO. This configuration allows the peripheral to handle various forms of endianness and to function with reflected polynomials.

There are three configuration bits that control the data mirroring process: CRC_CTL.BITMIRR, CRC_CTL.BYTMIRR, and CRC_CTL.W16SWP. The ***Data Mirroring Options*** table details how these options affect the incoming data and the output generated by the mirror block.

Table 36-3: Data Mirroring Options

W16SWP	BYTMIRR	BITMIRR	Output Data
0	0	0	Dout[31:0] = Din[31:0]
0	0	1	Dout[31:0] = Din[24:31],Din[16:23],Din[8:15],Din[0:7]
0	1	0	Dout[31:0] = Din[7:0],Din[15:8],Din[23:16],Din[31:24]
0	1	1	Dout[31:0] = Din[0:7],Din[8:15],Din[16:23],Din[24:31]
1	0	0	Dout[31:0] = Din[15:0], D[31:16]
1	0	1	Dout[31:0] = Din[8:15],Din[0:7], Din[24:31],Din[16:23]
1	1	0	Dout[31:0] = Din[23:16],Din[31:24], Din[7:0],Din[15:8]
1	1	1	Dout[31:0] = Din[16:23],Din[24:31], Din[0:7],Din[8:15]

When the CRC is configured to operate in the memory transfer compute-and-compare mode, the bit-reversed output data can be written to the FIFO. This feature is controlled through the CRC_CTL.FDSEL field.

In addition to providing bit swapping and mirror options to the incoming data, the CRC peripheral also supports bit mirroring on the following registers.

- CRC_RESULT_CUR and CRC_RESULT_FIN, controlled through the CRC_CTL.RSLTMIRR field. When mirroring is enabled, the values to be written to these registers are fully bit-reversed before the write operation occurs.
- CRC_POLY, controlled through the CRC_CTL.POLYMIRR field. When mirroring is enabled, the 32-bit polynomial is fully bit-reversed before the write operation to the register occurs.
- CRC_COMP, controlled through the CRC_CTL.CMPMIRR field. When mirroring is enabled, the contents to be loaded to this register are fully bit-reversed before the write operation occurs.

FIFO Status and Data Requests

The CRC peripheral provides indication of the input and output buffer status through CRC_STAT.IBR and CRC_STAT.OBR respectively. For core-based operations, software must monitor these status fields prior to writing to or reading from the CRC FIFO. No write to the CRC FIFO can occur while CRC_STAT.IBR indicates that the buffer is not ready to accept data. Similarly, the CRC FIFO cannot be read until CRC_STAT.OBR indicates that data is available.

The memory scan modes of operation only require the monitoring of the input buffer status. The memory transfer, compute-and-compare mode uses both input and output buffer status. If the current result of the CRC computation is required, then software must verify that the current operation has completed and that the intermediate result is ready. The CRC_STAT.IRR indicates the status.

NOTE: The memory transfer fill mode of operation requires the use of a DMA channel. The CRC does not support core reads from the CRC FIFO for this mode of operation.

Memory transfer, compute-and-compare mode uses burst transactions to make the most efficient use of the available resources. In this mode, when the FIFO is initially empty and the peripheral is enabled, the CRC_STAT.IBR bit indicates that the CRC is ready to accept data. The peripheral generates data requests to the source DMA channel (if the CRC uses DMA). While the number of words remaining in the CRC_DCNT register is greater than the FIFO depth, the peripheral issues data requests or accepts incoming data in bursts. The peripheral continues until the CRC FIFO becomes full.

Once full, the CRC_STAT.IBR and CRC_STAT.OBR bits are updated, and then the CRC issues outgoing data requests. Only when the FIFO is empty can the peripheral accept further incoming data, and the CRC_STAT.IBR and CRC_STAT.OBR bits are updated once again.

Once CRC_DCNT is decremented such that the number of words waiting for processing is less than the number required to fill the FIFO, the burst mode of operation is disabled. Incoming data is accepted as long as the FIFO is not full. Outgoing data is available as long the FIFO is not empty. Therefore, there are no restrictions requiring the word count to be a multiple of the FIFO depth.

All other CRC modes of operation indicate that incoming data can be accepted as long as the FIFO is not full. Outgoing data is available as long as the FIFO is not empty.

The CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit configurations also influence how the CRC generates data requests and status bits. The following list describes the bits.

- The CRC_CTL.OBRSTALL bit can be configured such that the CRC peripheral stalls as soon as there is output data available in the FIFO. Use this mode of operation only in memory transfer, compute-and-compare mode. This mode results in the processing of one 32-bit word at a time. The peripheral does not request or accept incoming data until the current value being processed is read from the peripheral.
- The CRC_CTL.IRRSTALL bit can be configured so that the CRC peripheral stalls all further incoming data requests until the CRC_RESULT_CUR register is read after being updated. Use this mode of operation for CRC signature generation. It is not applicable to memory transfer data-fill mode or memory scan data-verify mode of operation.

CRC Operating Modes

The following sections describe the various operating modes of the CRC interface.

Data Transfer Modes

The CRC peripheral supports two main categories of operation involving data transfers:

- Memory scan mode
- Memory transfer mode

Memory scan modes are read-only operations that allow the contents of memory to be read into the peripheral and verified for correctness. There are two forms of memory scan mode:

- CRC compute-and-compare performs a CRC calculation on data presented to the peripheral and compares the CRC result with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data verify compares each 32-bit data word presented to the CRC peripheral to a pre-loaded 32-bit value and generates an error when the data differs.

Both of these modes of operation require, at the most, a single DMA channel to read the data from memory into the peripheral. No data is forwarded to the data output or destination DMA. The CRC can also use core-driven transfers for either of these modes of operation.

The memory transfer modes involve memory write or memory read-and-write operations allowing for memory to be initialized or transferred from one region of memory to another. There are two forms of memory transfer mode:

- CRC compute-and-compare performs a full data transfer from one memory region to another memory region. The CRC generates a signature on the data presented and compares it with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data fill initializes a region of memory with a pre-loaded 32-bit constant value.

The CRC compute-and-compare mode of operation requires both incoming and outgoing data channels. The operation occurs either using DMA channels, using core-driven write or read operations to and from the FIFO or using

a combination of both. The data fill mode of operation requires only a memory write DMA destination channel—this mode does not support core driven operations.

Memory Scan Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the CRC_CTL.OPMODE field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the CRC_DCNT register. The accumulated result of the CRC operation is contained in the CRC_RESULT_CUR register. As the CRC engine processes each 32-bit word, the CRC_DCNT register is decremented and CRC_RESULT_CUR is updated.

Once CRC_DCNT decrements to zero, the contents of the CRC_RESULT_CUR register are copied to CRC_RESULT_FIN and CRC_STAT.DCNTEXP is updated accordingly. The CRC uses the CRC_COMP register to store the expected result of the operation. After the CRC calculation, CRC_COMP is compared with CRC_RESULT_FIN and CRC_STAT.CMPERR is updated to reflect the status of the compare operation. CRC_STAT.CMPERR must be cleared before the next CRC operation is performed.

The CRC peripheral also contains the CRC_DCNTRLD register. The CRC uses this register to reload CRC_DCNT upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF. This configuration provides a way to reset CRC_RESULT_CUR to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Scan Data Verify

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the CRC_CTL.OPMODE field. Each 32-bit word of the data stream is compared with a constant value that is stored in the CRC_COMP register. The CRC_DCNT register contains the number of words for comparison. The CRC_DCNT register is decremented upon receiving a new 32-bit word from the data stream. If the compare operation fails, the CRC_STAT.CMPERR bit is updated and the contents of CRC_DCNT are captured in the CRC_DCNTCAP register. This information can be used to identify the location in the data stream where the error occurred. Clear the CRC_STAT.CMPERR field to reenable capturing of further errors.

Once CRC_DCNT decrements to zero, CRC_STAT.DCNTEXP is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the CRC_CTL.OPMODE field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the CRC_DCNT register. The accumulated result of the CRC operation is contained in the CRC_RESULT_CUR register. As the CRC engine processes each 32-bit word, the CRC_DCNT register is decremented and CRC_RESULT_CUR is updated.

Once CRC_DCNT decrements to zero, the contents of the CRC_RESULT_CUR register are copied to CRC_RESULT_FIN and CRC_STAT.DCNTEXP is updated accordingly. The CRC uses the CRC_COMP register to store the expected result of the operation. Upon completion of the CRC calculation, CRC_COMP is compared with CRC_RESULT_FIN and CRC_STAT.CMPERR is updated to reflect the status of the compare operation. Clear CRC_STAT.CMPERR before the next CRC operation is performed.

The CRC peripheral also contains CRC_DCNTRLD register. The CRC uses this register to reload CRC_DCNT upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF. This configuration provides a means to reset CRC_RESULT_CUR to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Data Fill Mode

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the CRC_CTL.OPMODE field. The CRC_FILLVAL register is written with a 32-bit value. The CRC uses this value to initialize a block memory through the memory-to-memory DMA destination channel. When the CRC peripheral and the DMA destination channel are enabled, the contents of the CRC_FILLVAL register is written to the DMA channel to initialize the memory region. The CRC_DCNT register contains the number of words for the write operation.

Once CRC_DCNT decrements to zero, CRC_STAT.DCNTEXP is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the data expiration event to generate an interrupt.

CRC Event Control

The CRC peripheral can enable certain CRC status operations to generate an interrupt event to the system event controller. There, a CRC error can be qualified as a system fault.

Interrupt Signals

The CRC peripheral can generate two interrupt requests that are optionally enabled as interrupts with the Arm core, or as events to SEC1 for fault operations. One is a CRC status interrupt and the other is a CRC error interrupt.

The CRC_STAT.CMPERR status bit can be configured as an interrupt and is signaled through the CRC error interrupt signal. The CRC_STAT.CMPERR status field is set whenever the CRC peripheral performs a compare operation that fails. This status can be the result of a failed memory scan data-verify operation that compares the contents of a memory range with a constant 32-bit value. Or, it can be the result of a CRC signature calculated for a memory region that does not match the expected pre-programmed result for a memory-compare operation.

The CRC_STAT.DCNTEXP status bit is set when the CRC_DCNT register has decremented to zero. The status indicates that the CRC peripheral has now processed all the data requested for the current CRC operation. The CRC can also use this signal to generate an interrupt. The interrupt is signaled on the CRC status interrupt signal.

Both these status bits can be configured to generate and interrupt through the CRC_INEN register. The CRC_INEN register also has bit set, CRC_INEN_SET, and bit clear CRC_INEN_CLR equivalent registers that the CRC uses for the enabling and disabling of these interrupt sources.

The CRC_STAT register has two write one to clear (W1C) fields for clearing the two interrupt sources.

NOTE: Disabling the CRC peripheral through the CRC_CTL.BLKEN bit does not result in the clearing of interrupt sources. Clear the interrupt sources using a W1C operation to the CRC_STAT register.

CRC Programming Model

It is important to note the following restrictions when using the CRC peripheral with the DMA channels:

1. When enabling the CRC peripheral and the DMA channels, enable the CRC peripheral prior to enabling the DMA channels.
2. When disabling the CRC peripheral and the DMA channels, disable the DMA channels prior to disabling the CRC peripheral.

CRC Mode Configuration

Describes a number of tasks showing the various operation modes of the CRC peripheral.

- Look-up Table Generation
- Core Driven Memory Scan Compute-and-Compare Mode
- DMA Driven Memory Scan Compute-and-Compare Mode
- Core Driven Memory Scan Data Verify Mode
- DMA Driven Memory Scan Data Verify Mode
- Core Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Data Fill Mode

Look-up Table Generation

Describes the steps required to initialize the CRC peripheral LUT.

1. Write the 32-bit CRC polynomial of choice to the CRC_POLY register.

   ADDITIONAL INFORMATION: This operation results in the CRC peripheral starting the LUT initialization process. The CRC_STAT.LUTDONE bit is updated to reflect the operation is in progress.

2. Poll the CRC_STAT.LUTDONE bit until the status bit indicates that the operation is completed.

The CRC peripheral has completed initialization of all the LUT registers and is now ready for data operations. The CRC_STAT.LUTDONE bit remains in the current state until the CRC_POLY register is written again, or the peripheral or processor are reset.

Core Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using core transactions. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling the CRC_CTL register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per CRC_CTL.BLKEN

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute-and-compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.
   - Disable the CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit options for this task example.
   - Configure all mirroring and bit reversal options.

- Configure CRC auto-clear options.

The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral.
   a. While CRC_STAT.IBR bit indicates that the input buffer is ready, write the CRC_DFIFO register with 32-bit data.

      ADDITIONAL INFORMATION: Repeat this step until all data has been written.
8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.
9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.
10. Write to the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear of these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed. The final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing more CRC operations.

DMA Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using DMA transactions. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling CRC_CTL.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   - Disable the CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit options for this task example.
   - Configure all mirroring and bit reversal options.
   - Configure all CRC auto clear options.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed and the final result indicated is through CRC_STAT.CMPERR and the corresponding interrupt, when enabled.

Clear any W1C CRC status bits before performing a further CRC operation. Clear any W1C status bits of the memory-to-memory source DMA channel before the next CRC operation.

Core Driven Memory Scan Data Verify Mode

Reads a region of memory using core transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per CRC_CTL.BLKEN

The interrupt service routine for the compare error interrupt reads and stores the contents of CRC_DCNTCAP register to a buffer before clearing the compare error interrupt.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan data verify mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

6. Write memory region data to the CRC peripheral.

a. Poll the CRC_STAT.IBR bit until input buffer is ready.

b. Write the CRC_DFIFO register with 32-bit data.

ADDITIONAL INFORMATION: Repeat these two steps until the entire memory region has been written to the CRC peripheral.

7. Poll the CRC_INEN_SET.DCNTEXP bit if the interrupt was disabled.

ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the CRC_DCNTCAP register upon a compare error has any new entries.

ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write to the CRC_STAT to clear both the CRC_INEN_SET.DCNTEXP and CRC_INEN.CMPERR bits.

ADDITIONAL INFORMATION: If interrupts were enabled, the clear these status bits within the interrupt handlers for the respective interrupts.

The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the CRC_INEN.CMPERR bit and the corresponding interrupt, when enabled. Each comparison error is traceable due to the logging of CRC_DCNTCAP from within the compare error interrupt handler.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Scan Data Verify Mode

The memory scan data verify mode reads a region of memory using DMA transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

The interrupt service routine for the compare error interrupt reads and stores the contents of the CRC_DCNTCAP register to a buffer before clearing the compare error interrupt.

1. Initialize the CRC_DCNT register.

ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: The CRC module uses this register to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan data verify mode and CRC_CTL.BLKEN configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write the data.

6. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

7. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the CRC_DCNTCAP register upon a compare error has any new entries.

   ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

   The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled. Each comparison error is traceable due to the logging of the CRC_DCNTCAP register from within the compare error interrupt handler.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

Core Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using core transactions while copying the contents to another memory region. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling the CRC_CTL register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of the current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute-and-compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   a. Disable the CRC_CTL.OBRSTALL bit and the CRC_CTL.IRRSTALL bit options for this task example.

   b. Configure all mirroring and bit reversal options.

c. Configure CRC auto clear options

The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral and read it back to the new destination.

   a. While the CRC_STAT.IBR bit indicates that the input buffer is ready, write the CRC_DFIFO register with 32-bit data.

   b. While the CRC_STAT.OBR bit indicates that the output buffer is ready, read the CRC_DFIFO register and store data to new destination.

   ADDITIONAL INFORMATION: Repeat these two steps until all required data has been processed through the CRC peripheral and copied to the new destination.

8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the CRC_STAT register to clear both CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The memory region has been copied to a new location and an integrity check of the memory through the expected CRC signature has also completed. The final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using DMA transactions. The memory region is also copied to another memory region using memory-to-memory DMA transfers. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling CRC_CTL.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)

- The CRC block is disabled per the CRC_CTL.BLKEN register.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute compare mode and CRC_CTL.BLKEN configured to enable the CRC peripheral.

   a. Disable the CRC_CTL.OBRSTALL and the CRC_CTL.IRRSTALL bit options for this task example.

   b. Configure all mirroring and bit reversal options

   c. Configure CRC auto clear options

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode and destination DMA channel for memory write STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from one memory region to another through the memory-to-memory DMA channels and the CRC peripheral.

8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and the CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The integrity check of the memory through the expected CRC signature has completed and the final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled. The memory region has also been copied to its final destination.

Clear any W1C CRC status bits before performing a further CRC operation. Also, clear any W1C status bits of the memory-to-memory source and destination DMA channels before the next CRC operation.

DMA Driven Memory Transfer Data Fill Mode

This mode initializes a region of memory to a constant 32-bit value using DMA transactions.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_FILLVAL register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the CRC module uses to fill the memory region.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of block completion. Configure these interrupts as required. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory transfer fill mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and is ready for the DMA channel to write data.

6. Configure and enable the memory-to-memory destination DMA channel for memory write STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer taking the constant 32-bit value from the CRC peripheral and writing the data to the DMA channel.

7. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.

8. Write the CRC_STAT register to clear the CRC_STAT.DCNTEXP bit.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear this status bit within the interrupt handlers for the respective interrupts.

   The CRC memory transfer fill operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

The memory region is now filled with the constant data and the CRC peripheral is ready to be configured for a new operation.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

ADSP-2159x_SC591_SC592_SC594 CRC Register Descriptions

Cyclic Redundancy Check Unit (CRC) contains the following registers.

Table 36-4: ADSP-2159x_SC591_SC592_SC594 CRC Register List

Name	Description
CRC_COMP	Data Compare Register
CRC_CTL	Control Register
CRC_DCNT	Data Word Count Register
CRC_DCNTCAP	Data Count Capture Register
CRC_DCNTRLD	Data Word Count Reload Register
CRC_DFIFO	Data FIFO Register
CRC_FILLVAL	Fill Value Register
CRC_INEN	Interrupt Enable Register
CRC_INEN_CLR	Interrupt Enable Clear Register
CRC_INEN_SET	Interrupt Enable Set Register

Table 36-4: ADSP-2159x_SC591_SC592_SC594 CRC Register List (Continued)

Name	Description
CRC_POLY	Polynomial Register
CRC_RESULT_CUR	CRC Current Result Register
CRC_RESULT_FIN	CRC Final Result Register
CRC_STAT	Status Register

Data Compare Register

The CRC_COMP register contains the value corresponding to the expected CRC result or signature for the current data stream. At the end of the operation, the content of this register is used to compare against the result produced by the CRC operation. In data verify mode, each incoming data value is compared with the content of this register.

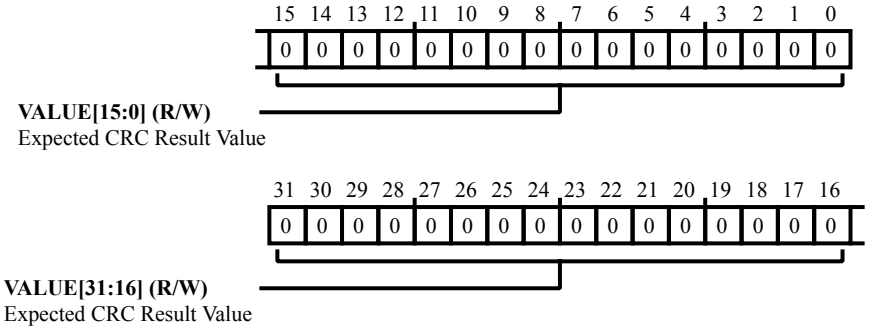

Figure 36-3: CRC_COMP Register Diagram

Table 36-5: CRC_COMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Expected CRC Result Value. The CRC_COMP.VALUE bit field contains the value corresponding to the expected CRC result or signature for the current data stream.

Control Register

The CRC_CTL register configures the operation modes and settings for the CRC.

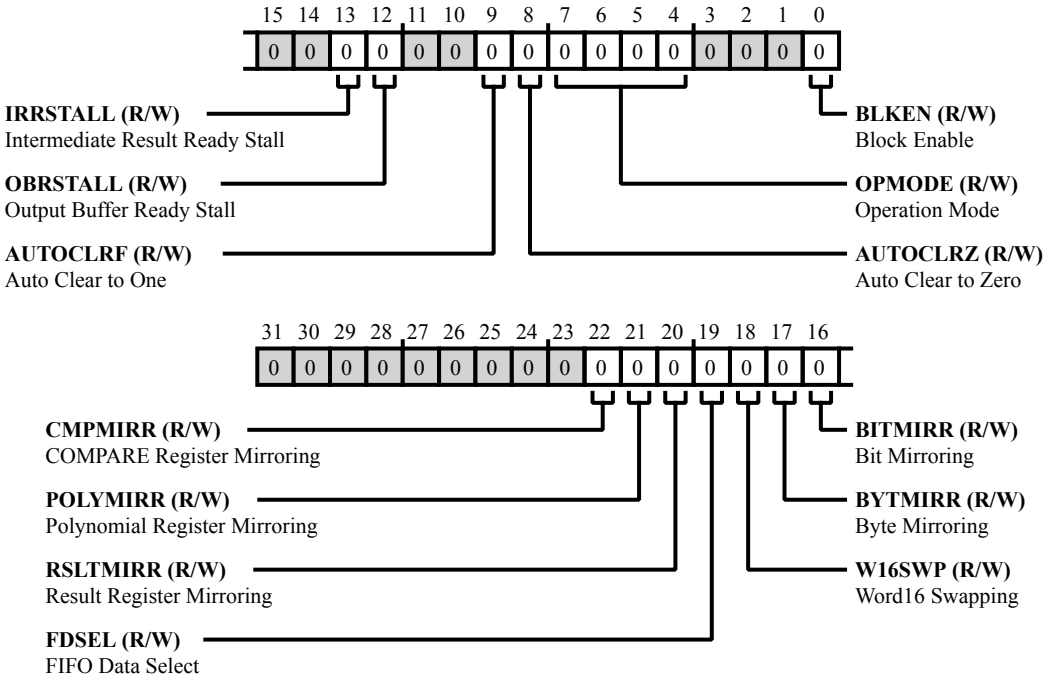

Figure 36-4: CRC_CTL Register Diagram

Table 36-6: CRC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	CMPMIRR	COMPARE Register Mirroring. The CRC_CTL.CMPMIRR bit enables data mirroring for the CRC_COMP compare register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for comparison with the CRC_RESULT_FIN register.	
		0	Disable compare mirroring
		1	Enable compare mirroring
21 (R/W)	POLYMIRR	Polynomial Register Mirroring. The CRC_CTL.POLYMIRR bit enables data mirroring for the CRC_POLY polynomial register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for CRC computations.	
		0	Disable polynomial mirroring
		1	Enable polynomial mirroring

Table 36-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	RSLTMIRR	Result Register Mirroring. The CRC_CTL.RSLTMIRR bit enables data mirroring for the CRC_RESULT_CUR and CRC_RESULT_FIN result registers. When enabled, the 32-bit values in these registers are fully bit mirrored (reversed).	
		0	Disable result mirroring
		1	Enable result mirroring
19 (R/W)	FDSEL	FIFO Data Select. The CRC_CTL.FDSEL bit selects whether the CRC writes modified or unmodified data to the FIFO in memory transfer mode. If enabled, the data written is affected by the state of the data mirroring selections (CRC_CTL.BITMIRR, CRC_CTL.BYTMIRR, and CRC_CTL.W16SWP) before being written to the FIFO.	
		0	Write unmodified data to FIFO
		1	Write modified data to FIFO
18 (R/W)	W16SWP	Word16 Swapping. The CRC_CTL.W16SWP bit enables the CRC's data mirror block to swap the upper and lower 16-bit words within the 32-bit input data, before further processing.	
		0	Disable word16 swapping
		1	Enable word16 swapping
17 (R/W)	BYTMIRR	Byte Mirroring. The CRC_CTL.BYTMIRR bit enables the CRC's data mirror block to mirror the bytes within the 32-bit input data, before further processing.	
		0	Disable byte mirroring
		1	Enable byte mirroring
16 (R/W)	BITMIRR	Bit Mirroring. The CRC_CTL.BITMIRR bit enables the CRC's data mirror block to mirror the bits within each byte of the 32-bit input data, before further processing.	
		0	Disable bit mirroring
		1	Enable bit mirroring
13 (R/W)	IRRSTALL	Intermediate Result Ready Stall. The CRC_CTL.IRRSTALL bit enables stalling the state machine for input data when there is a valid intermediate result to be read in the CRC_RESULT_CUR register. This feature should be used only in CRC computation modes (for example, CRC_CTL.OPMODE =1 or =3).	
		0	Do not stall
		1	Stall on IRR

Table 36-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	OBRSTALL	Output Buffer Ready Stall. The CRC_CTL.OBRSTALL bit enables stalling the state machine for input data when there is valid data in the output buffer. This feature should be used only in memory-to-memory transfer modes (for example, CRC_CTL.OPMODE =1).	
		0	Do not stall
		1	Stall on OBR
9 (R/W)	AUTOCLRF	Auto Clear to One. The CRC_CTL.AUTOCLRF bit enables auto clear to one when the CRC is in intermediate results ready stall mode (CRC_CTL.IRRSTALL=1) and the CRC data count expires (CRC_DCNT=0). Note that the CRC_CTL.AUTOCLRZ bit must be disabled, or the CRC_CTL.AUTOCLRF bit has no effect.	
		0	No auto clear
		1	Auto clear
8 (R/W)	AUTOCLRZ	Auto Clear to Zero. The CRC_CTL.AUTOCLRZ bit enables auto clear to zero when the CRC is in intermediate results ready stall mode (CRC_CTL.IRRSTALL=1) and the CRC data count expires (CRC_DCNT=0). Note that CRC_CTL.AUTOCLRF must be disabled, or the CRC_CTL.AUTOCLRZ has no effect.	
		0	No auto clear
		1	Auto clear
7:4 (R/W)	OPMODE	Operation Mode. The CRC_CTL.OPMODE bit field selects the memory transfer or scan mode.	
		0	Reserved
		1	CRC compute/compare memory transfer
		2	Data fill memory transfer
		3	CRC compute/compare memory scan
		4	Data verify memory scan
0 (R/W)	BLKEN	Block Enable. The CRC_CTL.BLKEN bit enables and disables the CRC operation.	
		0	Disable
		1	Enable

Data Word Count Register

The CRC_DCNT register holds the word count that is used for the CRC operation. On transfer of every 32-bit word, the CRC decrements by 1 the content of this register. When the count decrements to zero, this event triggers a CRC compare action, and the CRC_DCNT register is automatically loaded from the CRC_DCNTRLD register for the next CRC operation.

Note that the initial value programmed into the CRC_DCNT register may be different from what is programmed in the CRC_DCNTRLD register.

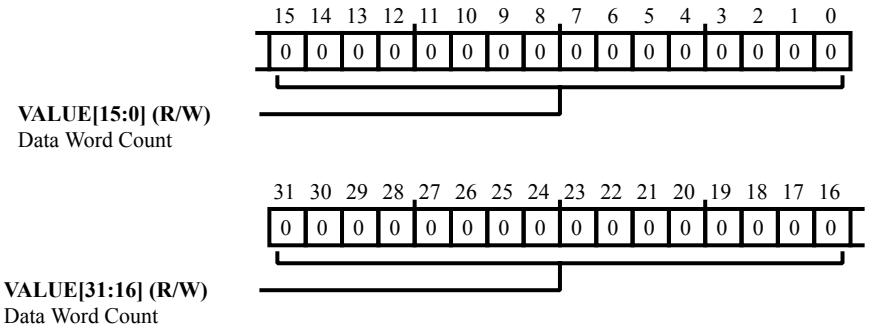

Figure 36-5: CRC_DCNT Register Diagram

Table 36-7: CRC_DCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data Word Count. The CRC_DCNT.VALUE bit field holds the word count that is used for the CRC operation.

Data Count Capture Register

The CRC_DCNTCAP register captures the CRC_DCNT value when a compare operation fails in data verify mode. This capture can be used to track the position of an error in the data stream. The capture operation is enabled only if the CRC_STAT.CMPERR bit indicates no compare error. After an error occurs and the data count is captured, no further errors are logged until the CRC_STAT.CMPERR bit is cleared. To obtain the position of an error in the data stream, subtract the CRC_DCNTCAP register value from the initial CRC_DCNT.

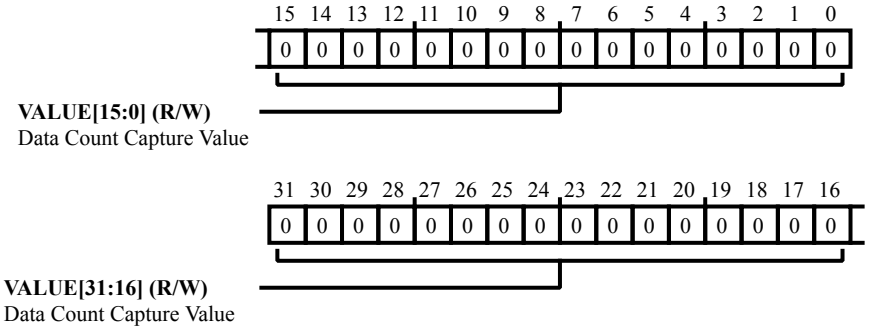

Figure 36-6: CRC_DCNTCAP Register Diagram

Table 36-8: CRC_DCNTCAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data Count Capture Value. The CRC_DCNTCAP.VALUE bit field contains the CRC_DCNT value when a compare operation fails in data verify mode.

Data Word Count Reload Register

The CRC_DCNTRLD register holds the value that the CRC automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0. At startup, the value programmed in CRC_DCNT and the CRC_DCNTRLD register could be different. So, for the first iteration, the CRC operation happens for the count initially programmed in the CRC_DCNT register. While for subsequent CRC operations, the count is taken from the CRC_DCNTRLD register.

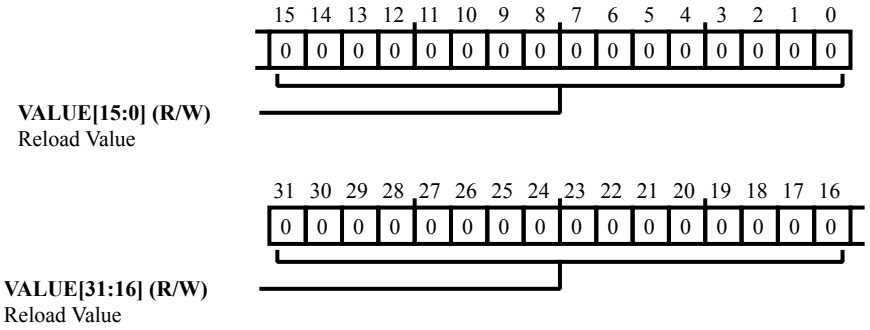

Figure 36-7: CRC_DCNTRLD Register Diagram

Table 36-9: CRC_DCNTRLD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reload Value. The CRC_DCNTRLD.VALUE bit field holds the value that automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0.

Data FIFO Register

In memory transfer mode (non-data fill mode), the data from the DMA or processor core buses is written into the CRC_DFIFO on each input data grant (DMA grant or core write). Data is read from this FIFO on each output data grant (DMA grant or core read). FIFO status information is available in the CRC_STAT register. Whenever, the FIFO has valid data, output data requests are generated.

Note that in non-memory transfer mode and in data fill mode, the input data does not get written into this FIFO. So, this register should not be read in these modes.

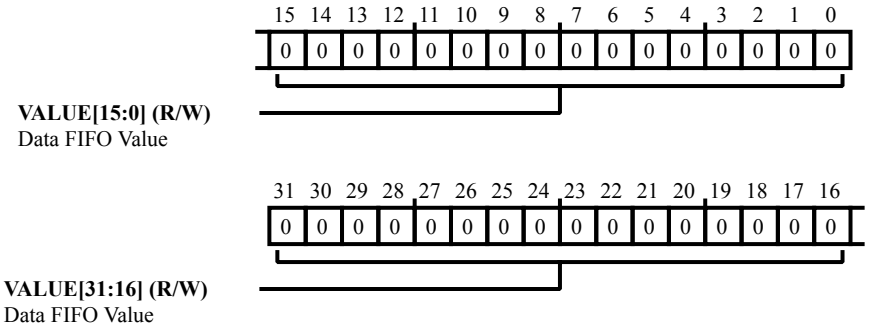

Figure 36-8: CRC_DFIFO Register Diagram

Table 36-10: CRC_DFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data FIFO Value. The CRC_DFIFO.VALUE bit field is the data from the DMA or processor core buses.

Fill Value Register

The CRC_FILLVAL register holds the value that the CRC uses for the memory fill operation. In data fill mode, the value programmed in this register is used for the memory fill operation.

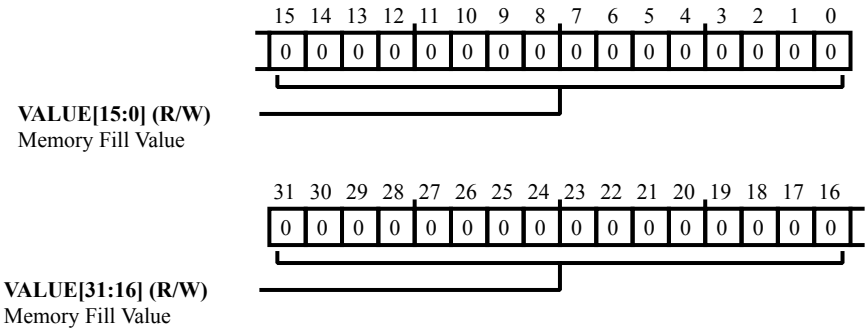

Figure 36-9: CRC_FILLVAL Register Diagram

Table 36-11: CRC_FILLVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Memory Fill Value. The CRC_FILLVAL.VALUE bit field holds the value that the CRC uses for the memory fill operation.

Interrupt Enable Register

The CRC_INEN register unmasks (enables) or masks (disables) interrupt requests generated in the CRC from going to the processor core.

Note that CRC interrupts are not disabled when the CRC is disabled (CRC_CTL.BLKEN =0).

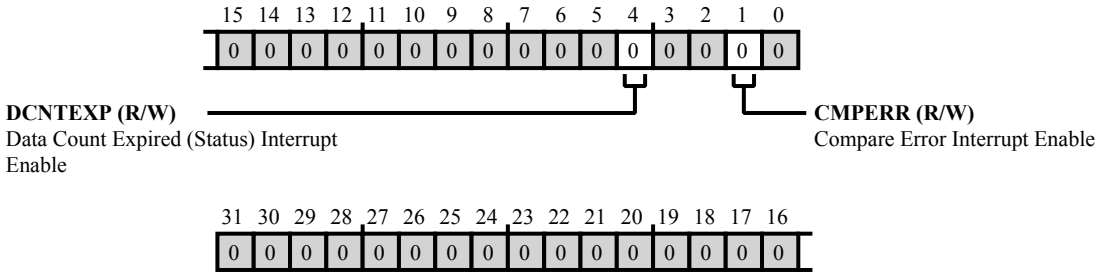

Figure 36-10: CRC_INEN Register Diagram

Table 36-12: CRC_INEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DCNTEXP	Data Count Expired (Status) Interrupt Enable. The CRC_INEN.DCNTEXP enables (unmasks) the data count expired (CRC status) interrupt.	
		0	Disable (mask) interrupt
		1	Enable (unmask) interrupt
1 (R/W)	CMPERR	Compare Error Interrupt Enable. The CRC_INEN.CMPERR enables (unmasks) the data compare interrupt, which is generated when CRC data comparison fails.	
		0	Disable (mask) interrupt
		1	Enable (unmask) interrupt

Interrupt Enable Clear Register

The CRC_INEN_CLR register permits clearing individual bits in the CRC_INEN register without affecting other bits in the register.

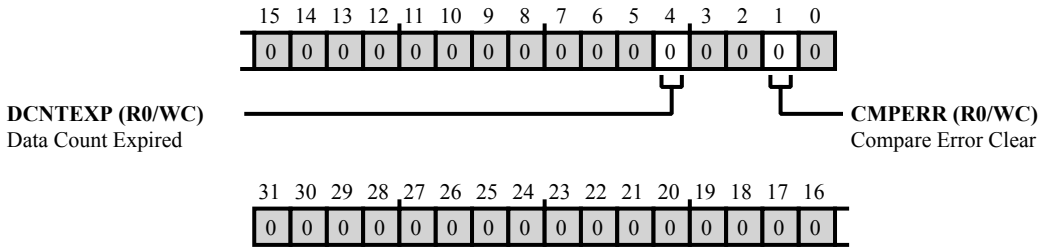

Figure 36-11: CRC_INEN_CLR Register Diagram

Table 36-13: CRC_INEN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/WC)	DCNTEXP	Data Count Expired. The CRC_INEN_CLR.DCNTEXP bit clears the data count expired (status) interrupt.	
		0	No effect
		1	Clear bit
1 (R0/WC)	CMPERR	Compare Error Clear. The CRC_INEN_CLR.CMPERR bit clears the compare error interrupt.	
		0	No effect
		1	Clear bit

Interrupt Enable Set Register

The CRC_INEN_SET register permits setting individual bits in the CRC_INEN register without affecting other bits in the register.

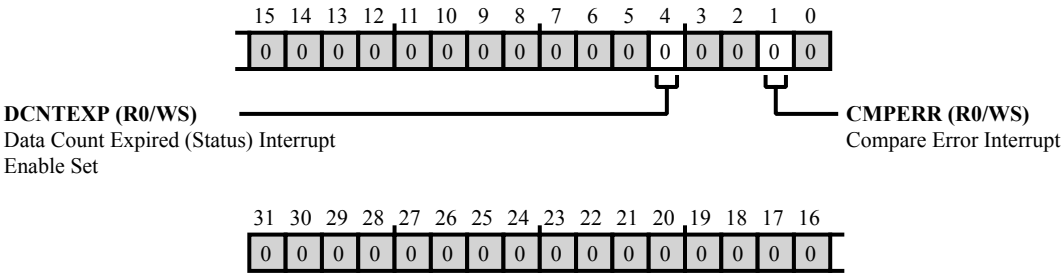

Figure 36-12: CRC_INEN_SET Register Diagram

Table 36-14: CRC_INEN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/WS)	DCNTEXP	Data Count Expired (Status) Interrupt Enable Set. The CRC_INEN_SET.DCNTEXP bit sets the data count expired (status) interrupt.	
		0	No effect
		1	Set bit
1 (R0/WS)	CMPERR	Compare Error Interrupt. The CRC_INEN_SET.CMPERR bit sets the compare error interrupt.	
		0	No effect
		1	Set bit

Polynomial Register

The CRC_POLY register holds a 32-bit polynomial for CRC operations. Bit 31 corresponds to the coefficient of x31 of the CRC polynomial, bit 30 corresponds to the coefficient of x30, and so on through bit 0. A coefficient of x32 is assumed to be "1" for any polynomial that is selected. Based on the polynomial in the CRC_POLY register, the CRC generates a look-up table (LUT), which is used to compute the CRC of the incoming data stream.

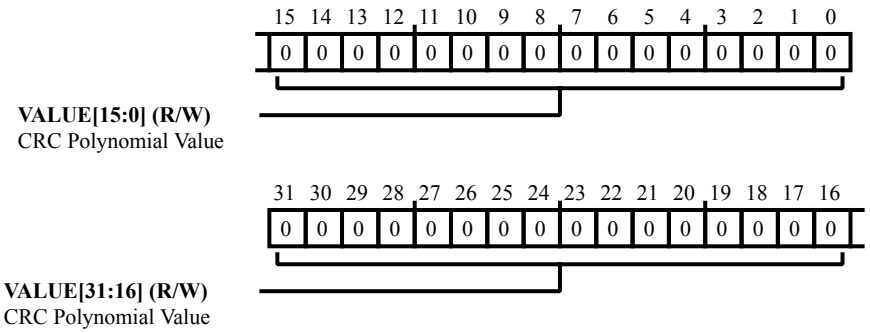

Figure 36-13: CRC_POLY Register Diagram

Table 36-15: CRC_POLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CRC Polynomial Value. The CRC_POLY.VALUE bit field holds the 32-bit polynomial for CRC operations.

CRC Current Result Register

The CRC_RESULT_CUR register holds the current or intermediate CRC result. It is updated when new data is written into the CRC. Each time the CRC_DCNT expires, the CRC loads the value from this register into the CRC_RESULT_FIN register. The CRC_RESULT_CUR register may be set to auto clear to zero or auto clear to ones when CRC_DCNT expires by configuring the CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF bits. Before starting a CRC operation, the CRC_RESULT_CUR register should be programmed to the desired value.

Note that this register can be read by the processor core at any time.

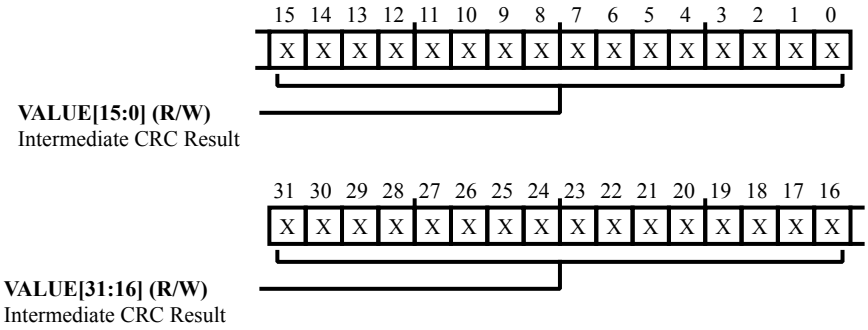

Figure 36-14: CRC_RESULT_CUR Register Diagram

Table 36-16: CRC_RESULT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Intermediate CRC Result. The CRC_RESULT_CUR.VALUE bit field holds the current or intermediate CRC result.

CRC Final Result Register

The CRC_RESULT_FIN register holds the final CRC computed for a data stream. A data stream is a DMA of CRC_DCNT number of words into the CRC. When CRC_DCNT decrements to zero for each data stream, the CRC loads the CRC_RESULT_FIN register with the value from the CRC_RESULT_CUR register.

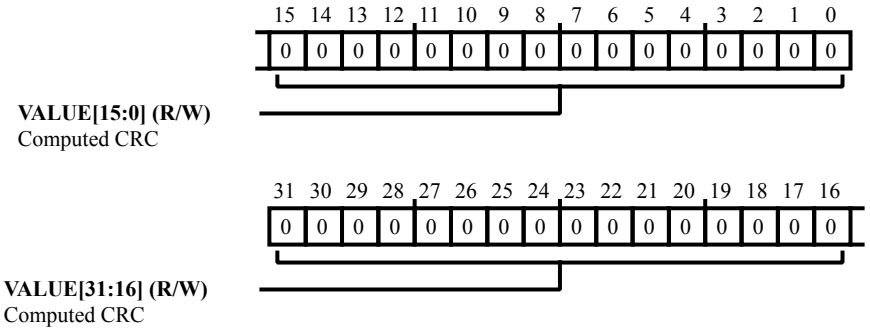

Figure 36-15: CRC_RESULT_FIN Register Diagram

Table 36-17: CRC_RESULT_FIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Computed CRC. The CRC_RESULT_FIN.VALUE bit field holds the final CRC computed for a data stream.

Status Register

The CRC_STAT register indicates the status for CRC operations and interrupt generation.

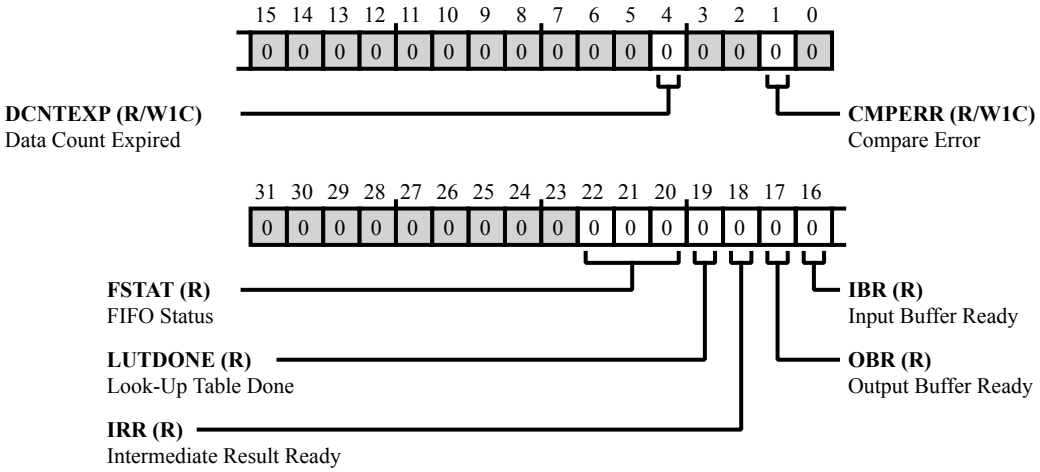

Figure 36-16: CRC_STAT Register Diagram

Table 36-18: CRC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22:20 (R/NW)	FSTAT	FIFO Status. The CRC_STAT.FSTAT indicates the current FIFO status. This field is read-only.	
		0	FIFO empty
		1	FIFO has 1 data
		2	FIFO has 2 data
		3	FIFO has 3 data
		4	FIFO has 4 data (full)
19 (R/NW)	LUTDONE	Look-Up Table Done. The CRC_STAT.LUTDONE bit indicates that the CRC has generated the look-up table for the current polynomial. This read-only bit is cleared at reset and cleared when the CRC_POLY is written.	
		0	No status
		1	LUT generation done

Table 36-18: CRC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	IRR	Intermediate Result Ready. The CRC_STAT.IRR bit indicates that the CRC has updated the CRC_RESULT_CUR register with intermediate CRC results for the new data written to the CRC. The processor core should read from the CRC_RESULT_CUR register only after detecting CRC_STAT.IRR =1. This read-only bit is cleared by CRC hardware and is valid when the CRC_CTL.IRRSTALL bit is enabled.	
		0	No status
		1	Intermediate results ready
17 (R/NW)	OBR	Output Buffer Ready. The CRC_STAT.OBR bit indicates that the CRC has data ready for the processor core to read. The processor core should read from the CRC only after detecting CRC_STAT.OBR =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Output buffer ready
16 (R/NW)	IBR	Input Buffer Ready. The CRC_STAT.IBR bit indicates that the CRC is ready to accept a processor core write. The processor core should write to the input register only after detecting that CRC_STAT.IBR =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Input buffer ready
4 (R/W1C)	DCNTEXP	Data Count Expired. The CRC_STAT.DCNTEXP bit indicates that the CRC_DCNT has expired. This W1C bit is not automatically cleared when the CRC is disabled (CRC_CTL.BLKEN =0). When the CRC sets this bit on CRC_DCNT expiry, the CRC generates the CRC_INEN.DCNTEXP interrupt.	
		0	No status
		1	Data counter expired
1 (R/W1C)	CMPERR	Compare Error. The CRC_STAT.CMPERR bit indicates that a CRC mismatch or data mismatch has been detected. This W1C bit is not automatically cleared when the CRC is disabled (CRC_CTL.BLKEN =0). When the CRC sets this bit on detecting a mismatch, the CRC generates the CRC_INEN.CMPERR interrupt. While this bit is set, the CRC_DCNTCAP register is disabled from capturing the data count values.	
		0	No status
		1	Compare error

37 System Security

The requirement to protect content, keys, IP and other sensitive information have become increasingly prevalent. The processor contains several modules and system elements that contribute to creating a secure operating environment for trusted code to execute.

The modules and system elements that can be used are:

- Boot Kernel
- Secure Core
- System Protection Unit (SPU)
- System Memory Protection Unit (SMPU)
- DEBUG through the Test Access Port Controller (TAPC)
- One-Time Programmable (OTP) memory
- Cryptographic Accelerators (optionally)

NOTE: This product includes security features that can be used to protect embedded non-volatile memory contents and prevent execution of non-authorized code. When security is enabled on this device (either by the ordering party or the subsequent receiving parties), Analog Devices' ability to conduct Failure Analysis on returned devices will be limited. Contact Analog Devices, Inc. for details on the Failure Analysis limitations for this device.

Security Features

The security infrastructure in the system provides the following features:

- Secure operating environment for secure code execution
- Protect sensitive IP from theft by malicious users or competitors
- Protect sensitive data (for example cipher keys)
- Allow debugging while still maintaining security

Security Functional Description

In order to provide secure operating environment in a system, it requires the involvement of multiple elements.

Boot Kernel

The Boot Kernel is the root of trust for a secure system. Since the boot kernel is developed by Analog Devices, Inc and is stored in ROM and can't be changed, it can be trusted. The boot kernel validates the authenticity of the application binary image that needs to be booted in. It also handles decrypting the binary image if it's encrypted.

Verifying the authenticity of the application binary asserts that

1. The image is not tampered with or altered
2. The image came from a trusted developer

If the image is encrypted, it ensures confidentiality since the boot image is stored on an external storage device and can be more easily read or stolen than in the part.

Once the boot kernel can verify and optionally decrypt the boot image, it can be loaded into the processor for execution. At this point, the *chain of trust* is continued with the verified application.

Secure Booting

Secure booting is when the boot kernel uses cryptographic algorithms to perform checks on the application binary and to decrypt it. When security is enabled, signature verification and optional decryption on the application binary are both performed by secure boot. See Security Mode Configuration.

Secure Core

In a system with multiple requester and completer resources, not everything is considered secure. There are secure and non-secure peripherals and secure and non-secure segments of memory.

For a system to be considered secure, a secure core that can access and execute instructions (verified application) from secure memory must be configured. Typically, in a single core processor, either the core is hardwired to be secure or the core can switch between secure and non-secure modes.

System Protection Unit (SPU)

The SPU in the system serves two functions. First, it acts as a gatekeeper, guarding against non-secure accesses to secure resources (peripherals). Second, it is used to define which resources in the system are secure or non-secure requesters and which resources in the system are secure or non-secure completers.

NOTE: Though the SPU can be configured by secure or non-secure requester, the first steps that the verified secure application must perform are:

1. Configure the SPU as a secure completer itself so only other secure requesters can configure it
2. Define and configure the secure requesters and completers using the SPU

This way, once the SPU is secure and other secure requesters and completers are configured, non-secure requesters cannot tamper with the security privileges of secure requesters and completers nor can non-secure resources be changed to a secure resource.

System Memory Protection Unit (SMPU)

Similar to the SPU protecting the MMR address range for peripherals, the SMPU can guard memory ranges or pages. Memory pages can be configured as secure or non-secure. Again, like in the case of the SPU, the SMPU can guard against non-secure transaction attempts to secure memory.

NOTE: A verified application should reside in memory configured as secure. By default the SMPU has all memory configured as secure. If the program needs to update the memory protections via the SMPU, the application and it's data should remain in secure memory.

Debug

The typical way of accessing a system is through the debug port via a JTAG or serial wire interface. If these access points are not secure sensitive IP such as cipher keys can be exposed and code can be changed to disable other security settings. To guard against this type of attack or security hole and still provide debugging capabilities for a developer, a debug unit with security features is used.

When the developer first receives the part, they can define a JTAG/DEBUG key that is programmed into OTP memory. Once security is enabled, the debug unit compares the key sent from the host debugger with the key inside the system. If a match occurs, debug access to secure resources are allowed. There is also a provision to bypass the loading of the JTAG/DEBUG key from the OTP memory. See Boot ROM and Booting the Processor

One-Time-Programmable (OTP) Memory

Customer programmable OTP memory is used to safely and securely store sensitive information such as cipher keys.

In a public key algorithm (for example, ECDSA which is used in secure boot), the public key is used to verify the digital signature that accompanies the application binary. The private key is used by the developer on the host development machine to create the digital signature. The public and private key pair is unique and the public key needs to be stored in non-volatile, one-time-programmable memory. If the public key is allowed to be changed than users can generate their own public/private key pairs and successfully boot in malicious code. This can either re-purpose the part or change security configurations to allow easier access to sensitive information stored elsewhere in OTP memory.

When security is not enabled, OTP can be accessed freely. When a user decides to set the LOCK bit in OTP memory to enable security, portions of the OTP, specifically the first 6K bits and another 1K bits for the customer boot information are will also be locked. From then on, only secure requesters are allowed to access those memory regions.

Cryptographic Accelerators

Cryptographic algorithms are mathematical tools to help provide security. Hardware engines provide some advantages but are not necessarily required. For computationally expensive operations like those used in Elliptic Curve Cryptography, like ECDSA used in secure boot, the operations can be accelerated while the core performs other tasks. Also, it's less likely that the hardware engine can be hacked to change the results.

Security Mode Configuration

Security as a feature does not necessarily be employed by the user. There are no steps to disable security, if security protection is not required. The part does not have security enabled.

To use the security features, perform the following steps:

- Generate the public/private key pair on the host development machine.[1]
- Program OTP memory with the public key.[2]
- Program OTP memory with the decryption key if the application binary needs to be encrypted.[2]
- Program OTP memory with the debug/JTAG key.[2]
- Develop the application and sign it, creating the digital signature with the private key.[1]
- If confidentiality is required, encrypt the application binary before signing it.
- Set the LOCK bit in OTP memory to enable security. After this, subsequent boots are secure boots.[2, 3]

[1] Software tools are provided with developments tools to generate keys, sign boot streams and also perform encryption. Refer to the development tools manuals for information on usage.

[2]Refer to the OTP Chapter for programming the OTP and other related information.

[3]Refer to the Booting Chapter for more information on Secure Booting and other related information.

Status and Error Signals

In a fully functional secure system, non-secure resources should not even attempt to access a secure resource. If this does occur, then either the code has been altered or replaced with malicious code or the system contains a bug.

Errors or error events are dependant on the configuration of the SPU and SMPU, the protection units which guard against security violations. In the case of the SMPU, the error can simply be captured, captured and interrupt generated, or the access prevented without capturing any error. It is the developer's responsibility to:

1. Determine if there was an error due to a blocked access.
2. Determine how to handle a blocked access. For example fix the bug (offline), or try to use a different resource (run time).

38 System Protection Unit (SPU)

In a system with multiple system MMR requesters, peripheral configurations can be changed unintentionally, leading to bad data or even system malfunctions. The peripherals are shared resources in the system. The SPU restricts access to certain MMRs, similar to the functionality of a semaphore.

The SPU also protects peripherals based on security settings. It is part of the overall security infrastructure of the processor.

SPU Features

The SPU has the following features:

- Write-protect system MMR from certain system requesters and core requesters.
- Simultaneously lock multiple peripheral configuration registers through a global lock mechanism.
- Write-protect and block access to its own write-protection registers from other system requesters.
- Defined security privileges to peripherals and system resources.
- Security protection to guard secure peripheral MMRs against non-secure accesses.

SPU Functional Description

The following sections provide information on the function of the SPU.

ADSP-2159x_SC591_SC592_SC594 SPU Register List

The System Protection Unit (SPU) provides a set of registers that can protect system resources from errant writes. The protection categories are global lock (protects configuration registers) and write protect register lock (protects the write protect register). For more information on SPU functionality, see the SPU register descriptions.

Table 38-1: ADSP-2159x_SC591_SC592_SC594 SPU Register List

Name	Description
SPU_CTL	Control Register
SPU_SECURECHK	Secure Check Register

Table 38-1: ADSP-2159x_SC591_SC592_SC594 SPU Register List (Continued)

Interrupt ID	Name	Description	Sensitivity	DMA Channel
216	SPU0_INT	SPU0 Interrupt	Level	

Peripheral Register Write Protection

The SPU has a write-protection register (SPU_WP[n]) associated with each peripheral. Each of these write-protection registers has the exact same bits that correspond to a particular SMMR requester (for example, Core 0, MDMA). When the bits are set, the SPU locks the corresponding SMMR requesters from accessing the register address space of the associated peripheral. The bits in the register can be cleared to allow access to the registers of the peripheral again. When the SPU intiates the write-protection register, any writes that are in-progress complete before the SPU blocks subsequent writes.

In the ***SPU Write Protect Registers*** figure, each write-protect register in the SPU is associated with a particular peripheral.

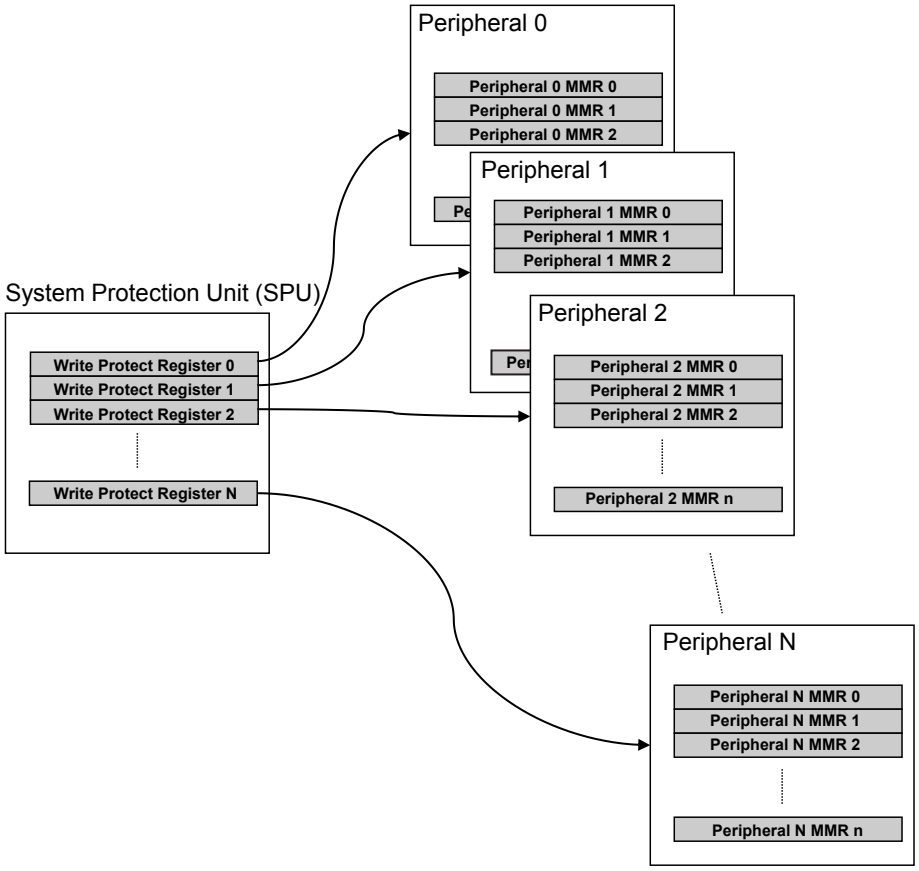

Figure 38-1: SPU Write Protect Registers

In the figure, a write-protect register in the SPU module blocks write-attempts to the MMR space of the associated peripheral. The bits in the write-protect register specify from which requesters to block write-access.

NOTE: A SPU write protection register (`SPU_WP[n]`) exists for the SPU alone. If all defined bits are set in this register for the SPU, any configurations in the SPU are locked and cannot be changed. Only a system reset can restore access to the SPU.

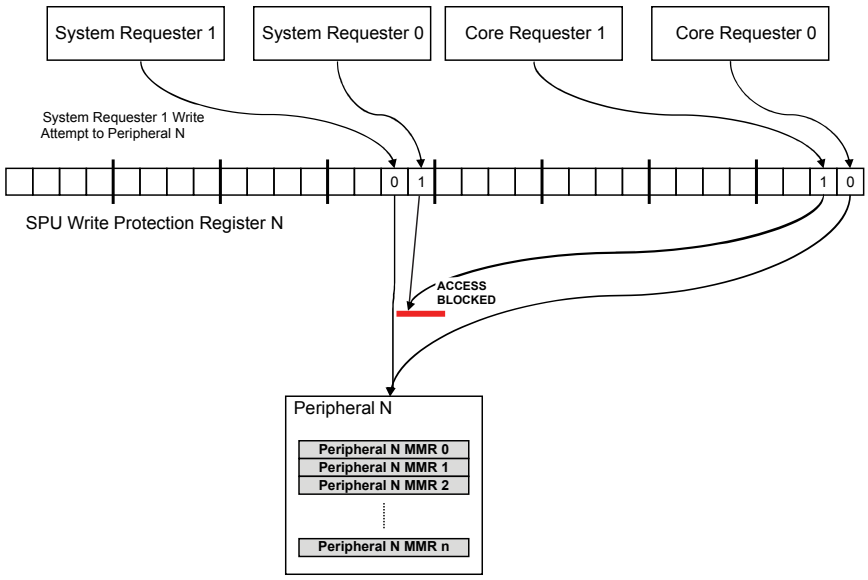

Figure 38-2: SPU Write-Protect Register Blocking Access from System Requester 0 and Core Requester 1

Global Locking

The SPU also has global locking capability. When enabled by setting `SPU_CTL.GLCK` bit field to a value other than 0xAD, a system-wide global lock signal is active. Some peripherals have a lock enable bit in their control register. When this bit is set, the peripheral recognizes the global lock signal and blocks further write-accesses to its own control register. Access to the configuration register of the peripheral is enabled when the global lock is turned off in the SPU.

The ***Global Locking*** figure is a conceptual diagram. The diagram shows how the SPU module (or any peripheral) blocks any write attempts to its control register when:

- The global lock signal from the SPU is active, and
- The global lock enable bit is set in the control register of the peripheral

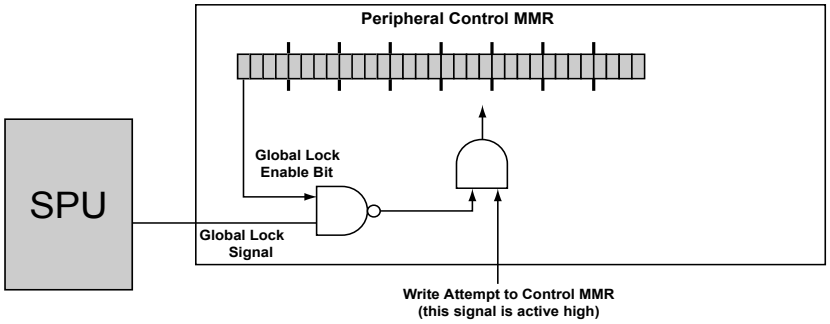

Figure 38-3: Global Locking

The SPU can write-protect its own registers. When the `SPU_CTL.WPLCK` bit is set and global locking is enabled, the SPU blocks accesses to the SPU write-protection registers. To enable write access to the write-protection registers in the SPU, disable the global locking.

SPU Block Diagram

The ***SPU System-Level Block Diagram*** shows a system-level block diagram of where the SPU is located in the system. It resides between the SMMR interface and the system crossbar. Depending on the configuration of the SPU write-protect registers, it can block access to some peripherals from certain SMMR requesters.

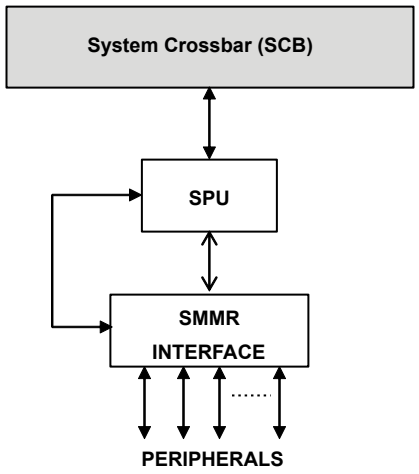

Figure 38-4: SPU System-Level Block Diagram

SPU Architectural Concepts

As shown in the block diagram, the SPU sits between the system crossbar (SCB) and the SMMR interface to the peripherals. The SPU gates any MMR access to any peripheral from any requester that comes through the SCB. Depending on the configuration of the write-protection registers in the SPU, the SPU does or does not allow the MMR write to go through.

The SPU also checks whether the transaction is a secure or non-secure transaction and blocks it according to the configured security setting for the target destination. A secure requester can generate secure read or secure write transactions which can access secure or non-secure completers. A non-secure requester can generate non-secure read or non-secure write transactions and can only access non-secure completers.

SPU Event Control

The system protection unit provides write-protection against MMRs peripherals and its own write-protect registers. If a write attempt is made to any locked MMR peripheral the SPU has write-protected, it blocks the write. The SPU generates a bus error to the requester that attempted the write. That requester does or does not generate an event, based on the returned error.

The SPU can be configured to generate an interrupt for the write-protection violation by setting the `SPU_CTL.PINTEN` bit. The SPU can also be configured to generate an interrupt for a security violation by setting the `SPU_SECURECTL.SINTEN` bit. If either one or both bits is triggered, the `SPU_STAT.VIRQ` bit is set.

The SPU can also lock its own registers from write attempts. If a write-attempt is made to a locked register in the SPU, the SPU blocks it and records it as an error in the SPU_STAT.LWERR bit. Again, the SPU generates a bus error to the requester that attempted the write.

The requester does or does not generate an event, based on the returned error.

The SPU does not generate an event for a blocked write access to an SPU register. If the SPU_CTL.PINTEN bit is set, the SPU triggers an interrupt for this blocked access attempt.

The global lock is enabled by setting the SPU_CTL.GLCK bit to something other than 0xAD. If the lock bit is set in that same configuration register, a peripheral can block write access to its configuration register. When the SPU blocks a write attempt, the peripheral logs and reports the failed attempt. The SPU is unaware and therefore does not provide any indication of a failed write attempt to the configuration register of the peripheral.

SPU Programming Model

The system protection unit (SPU) consists of write-protect and access-protect registers. Each one corresponds to a different peripheral instance. Bits in the write-protect registers correspond to system requesters that can modify the MMR contents of the peripherals. By writing to these write-protect registers, the corresponding memory-mapped registers of the peripheral are write-protected against requesters whose bits in the write-protect register are set.

The SPU globally locks the control register of the peripheral. Peripherals that support this feature have a lock enable bit in their control register. The peripheral blocks any additional write attempts to its control register from any requester when:

- The global lock signal is active from the SPU, and
- The lock enable bit of the peripheral is set

If the lock enable bit of a peripheral is not set and the global lock signal is active, access to that control register of the peripheral is still allowed. To grant access again, disable the global lock signal from the SPU by writing the value 0xAD into the SPU_CTL.GLCK bit field.

Another protection mechanism that the SPU offers is write-protection against the write-protection registers. If the write protect register lock bit (SPU_CTL.WPLCK) is set and the global lock signal is active, writes to the write-protect registers of the SPU are blocked. To reenable access to the write-protect registers in the SPU, deactivate the global lock signal by writing 0xAD into the SPU_CTL.GLCK bit field.

For security, the SPU provides a set of SPU_SECUREC[n] registers (one for each processor core from Analog Devices) to configure their security settings. The SPU also provides a set of SPU_SECUREP[n] registers (one for each peripheral instance) to configure their security settings.

Enabling and Disabling the SPU

The SPU is always operating. There are no bits to enable or disable the SPU. The SPU configuration can be updated at any time. Any ongoing transactions finish before a new configuration is in effect. By default, the SPU does not write-protect any of the MMRs.

Write-Protecting the SPU

The SPU is treated like any other peripheral in the system. As such, the SPU also has an associated write-protection register. If this write-protection register is configured to block all writes from all requesters, any SPU configuration remains the same until the next system reset.

Checking the Security State

In some cases while running a peripheral, an application system requester does not know whether they are a secure requester generating secure transactions or not. The SPU provides a means for checking the security state of the requester through the SPU_SECURECHK register. When read by a secure requester, the register reads 0xFFFFFFFF and when read by a non-secure requester, the value is 0x00000000.

SPU Mode Configuration

The SPU can provide address range-wide protection by write-protecting the peripherals MMR address range from system MMR requesters. It can also provide register wide protection using global locking. Peripherals that support this feature can enable it in their respective configuration register. When the SPU enables the global lock signal, all subsequent writes to the configuration register of the peripheral are blocked until the global lock signal is deasserted. Similarly, the write-protection registers of the SPU can be write-protected using the global lock signal as well. The SPU uses all these modes of operation together.

Locking Write-Protect Registers

Use the following steps to lock (write-protect) a register.

1. Set the SPU_CTL.WPLCK bit and configure the SPU_CTL.GLCK field to something other than 0xAD.

The SPU write-protect registers are blocked from further write accesses.

Protecting a Peripheral

Use the following procedure to protect a peripheral.

1. Determine which peripheral needs protection and locate the corresponding write-protect register (SPU_WP[n]) in the SPU. See the Write-Protect and Secure Peripheral Registers section.
2. Determine the SMMR requesters from which the peripheral needs protection. Then, set the corresponding bit or bits in the write-protect register (SPU_WP[n]) for the peripheral. See the Write-Protect and Secure Peripheral Registers section.

After setting the write-protect register for the particular peripheral, the identified SMMR requesters are blocked from writing to any MMR in the address space of the peripheral. This block remains in place until the bits in the write-protect register are cleared.

Configuring Security Privileges of a Peripheral

Use the following procedure to configure the security privileges of a peripheral.

1. Determine the peripheral and its corresponding secure peripheral register (SPU_SECUREP[n]) in the SPU. See the Write-Protect and Secure Peripheral Registers section.
2. If the peripheral is to be a secure completer that only accepts secure transactions, set bit 0 (SPU_SECUREP[n].SSEC).
3. If the peripheral is to be a secure requester that generates secure transactions (keeping in mind not all peripherals can be requesters), set bit 1 (SPU_SECUREP[n].MSEC).

This procedure sets the security privileges of a peripheral.

NOTE: Only a secure requester can set security privileges, keeping the chain of trust intact. If a non-secure requester configures the security privileges, it can undermine security protection.

ADSP-2159x_SC591_SC592_SC594 SPU Register Descriptions

System Protection Unit (SPU) contains the following registers.

Table 38-3: ADSP-2159x_SC591_SC592_SC594 SPU Register List

Name	Description
SPU_CTL	Control Register
SPU_SECURECHK	Secure Check Register
SPU_SECURECTL	Secure Control Register
SPU_SECUREC[n]	Secure Core Registers
SPU_SECUREP[n]	Secure Peripheral Register
SPU_STAT	Status Register
SPU_WP[n]	Write Protect Register n

Control Register

The SPU control register (SPU_CTL) provides a global lock for configuration registers as well as control for locking the write protect (SPU_WP[n]) registers. It also controls the generation of an interrupt to report blocked accesses.

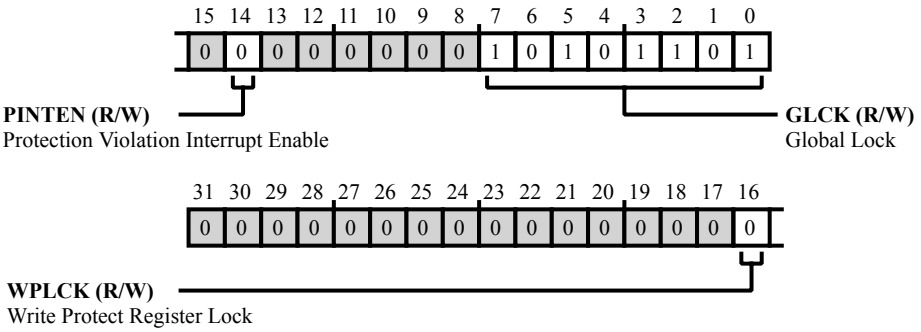

Figure 38-5: SPU_CTL Register Diagram

Table 38-4: SPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	WPLCK	Write Protect Register Lock. When the SPU_CTL.WPLCK bit is set in combination with the SPU_CTL.GLCK bit, writes to the SPU's write protect registers are blocked and return an error.	
		0	Disable
		1	Enable
14 (R/W)	PINTEN	Protection Violation Interrupt Enable. When the SPU_CTL.PINTEN bit is set (=1), a block of any transaction according to the configured settings produces an interrupt.	
		0	Disable
		1	Enable
7:0 (R/W)	GLCK	Global Lock. The SPU_CTL.GLCK controls the global lock signal. The global lock signal provides register-based write protection. Writing 0xAD to this field disables the lock, and writing any other value enables the lock.	

Secure Check Register

The SPU_SECURECHK register reads by secure masters return 0xFFFFFFFF. Reads by non-secure masters return 0x00000000.

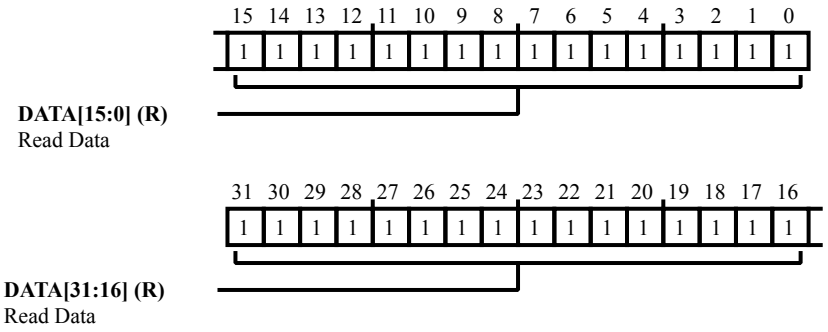

Figure 38-6: SPU_SECURECHK Register Diagram

Table 38-5: SPU_SECURECHK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Read Data. The SPU_SECURECHK.DATA bit field performs reads. Reads by secure masters return 0xFFFFFFFF. Reads by non-secure masters return 0x00000000.

Secure Control Register

The SPU Secure Control Register (SPU_SECURECTL) allows the user to lock write access to all the SPU_SECUREC[n] and SPU_SECUREP[n] registers as well as configure the interrupt generation in an event of a security error. It also allows bulk clear of the SSEC bits and/or MSEC bits in the SPU_SECUREP[n] registers.

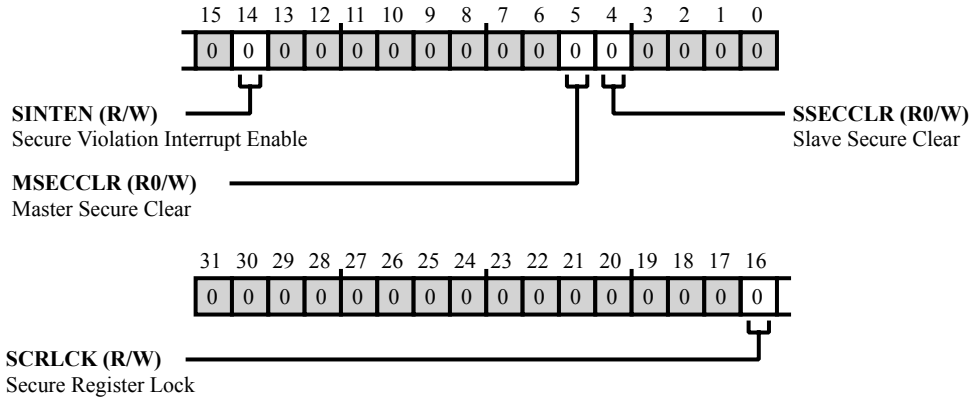

Figure 38-7: SPU_SECURECTL Register Diagram

Table 38-6: SPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	SCRLCK	Secure Register Lock. When the SPU_SECURECTL.SCRLCK bit is set in combination with the SPU_CTL.GLCK bit, writes to the Security Configuration registers (SPU_SECUREC[n] and SPU_SECUREP[n]) are blocked and return an error which is captured in the SPU_STAT.LWERR bit.	
		0	Disable
		1	Enable
14 (R/W)	SINTEN	Secure Violation Interrupt Enable. The SPU_SECURECTL.SINTEN bit generates an interrupt if a security violation was captured. Interrupt status is provided in the SPU_STAT.VIRQ bit.	
		0	Disable
		1	Enable
5 (R0/W)	MSECCLR	Master Secure Clear. When the SPU_SECURECTL.MSECCLR bit is set, the SPU_SECUREP[n].MSEC bits in all SPU_SECUREP[n] registers are cleared. The SPU_SECURECTL.MSECCLR bit always reads back as a 0.	
		0	No Action
		1	Clear All Master Secure Control Bits

Table 38-6: SPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/W)	SSECCLR	Slave Secure Clear. When the `SPU_SECURECTL.SSECCLR` bit is set, the `SPU_SECUREP[n].SSEC` bits in all `SPU_SECUREP[n]` registers are cleared. The `SPU_SECURECTL.SSECCLR` bit always reads back as a 0.	
		0	No Action
		1	Clear All Slave Secure Control Bits

Secure Core Registers

A SPU register exists for every DSP core in the system. The bits enable or disable security for features in the core.

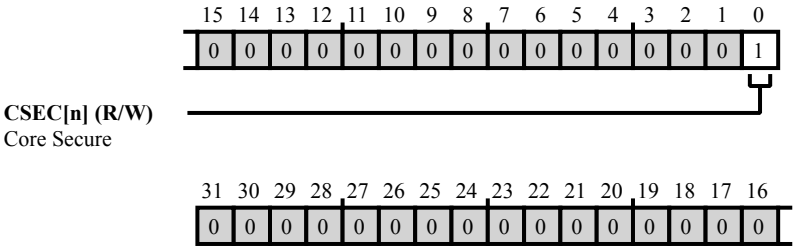

Figure 38-8: SPU_SECUREC[n] Register Diagram

Table 38-7: SPU_SECUREC[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CSEC[n]	Core Secure. The `SPU_SECUREC[n].CSEC[n]` bit controls whether non-secure accesses are allowed to L1 memory of the processor core. When =1, the core (as a slave) is set as secure meaning only secure transactions are allowed to L1.	
		0	Disable
		1	Enable

Secure Peripheral Register

In the system, each SPU_SECUREP[n] register is assigned to a specific MMR address range associated with one peripheral. Each SPU_SECUREP[n] has a Slave Secure (SSEC) bit and a Master Secure (MSEC) bit. When the Slave Secure (SSEC) bit is set, the SPU will only allow Secure Masters generating secure transactions to access the peripheral's MMR address space. When the Master Secure (MSEC) bit is set, the associated peripheral will be secure and will generate secure transactions.

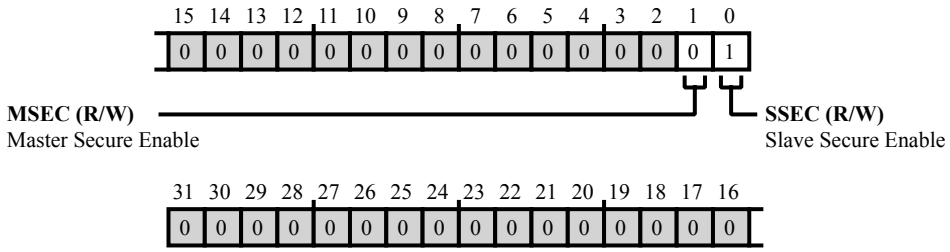

Figure 38-9: SPU_SECUREP[n] Register Diagram

Table 38-8: SPU_SECUREP[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	MSEC	Master Secure Enable. The SPU_SECUREP[n].MSEC bit controls whether the peripheral generates secure transactions as a master. When clear (=0), the peripheral generates non-secure transactions as a master (if applicable). When set (=1), the peripheral generates secure transactions as a master.	
		0	Disable
		1	Enable
0 (R/W)	SSEC	Slave Secure Enable. The SPU_SECUREP[n].SSEC bit controls whether the peripheral is protected from non-secure transactions. When clear (=0), the security status of the transaction is ignored. When set (=1), only secure transactions are allowed to access the address space of the peripheral and non-secure transactions are blocked.	
		0	Disable
		1	Enable

Status Register

The SPU_STAT register indicates if there have been any errors, active interrupts and global lock status.

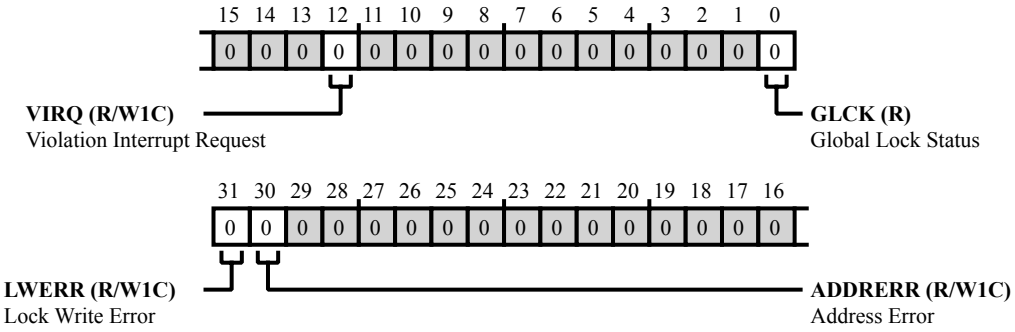

Figure 38-10: SPU_STAT Register Diagram

Table 38-9: SPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SPU_STAT.LWERR indicates whether there has been an attempted write to a register in the SPU with its lock bit (SPU_CTL.WPLCK or SCRLCK) set while SPU_CTL.GLCK was asserted. This bit is W1C.	
		0	Inactive
		1	Active
30 (R/W1C)	ADDRERR	Address Error. The SPU_STAT.ADDRERR indicates whether there has been an attempted write to a read-only register or an access an invalid address in the SPU MMR address range. This bit is W1C.	
		0	Inactive
		1	Active
12 (R/W1C)	VIRQ	Violation Interrupt Request. The SPU_STAT.VIRQ bit indicates that a security and/or protection violation has been detected and interrupt asserted. This is a W1C bit.	
		0	Inactive
		1	Active
0 (R/NW)	GLCK	Global Lock Status. The SPU_STAT.GLCK indicates whether the global lock is enabled or disabled.	
		0	Disabled (global_lock=0)
		1	Enabled (global_lock=1)

Write Protect Register n

In the system, each SPU_WP[n] register is assigned to a specific MMR address range associated with one peripheral. When the appropriate bits are set, writes to the peripheral from a specific master are blocked and an error is returned to the master. For more information, see the processor specific additional information for the SPU_WP[n] register.

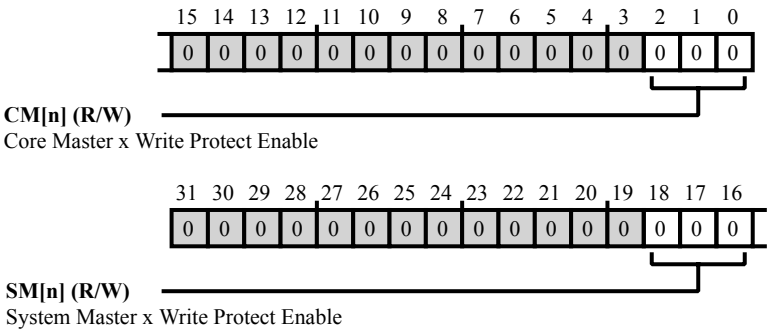

Figure 38-11: SPU_WP[n] Register Diagram

Table 38-10: SPU_WP[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/W)	SM[n]	System Master x Write Protect Enable. The SPU_WP[n].SM[n] bits correspond to different system masters in the system. When a particular bit is set in this field, the corresponding system master cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU.
2:0 (R/W)	CM[n]	Core Master x Write Protect Enable. The SPU_WP[n].CM[n] bits correspond to different cores in the system. When a particular bit is set in this field, the corresponding core cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU.

Write-Protect, Secure Peripheral, and Secure Core Registers

The SPU consists of a collection of write-protect registers each of which are associated with a specific peripheral or target. The SPU also has a collection of secure peripheral registers which are also associated with specific peripherals. The table gives the write-protect register and secure peripheral number for each of the peripherals that are provided with write protection and security through the SPU. The SPU for the processor is configured with 136 write-protect registers and also 136 secure peripheral registers. The number corresponding to a peripheral correlates to both the Write-Protect register and the Secure Peripheral register.

For each processor, there are different numbers of controllers that are able to access the SMMR space.

The SPU_WP[n] register shows which bits enable the protection against which controller.

For each peripheral, there is a corresponding write-protect register, SPU_WP[n], and secure peripheral register, SPU_SECUREP[n]. The table shows the write-protect register and secure peripheral number for each peripheral.

Table 38-11: Write-Protect Register and Secure Peripheral Number(n)

ADSP-2159x Specific Information

Global Locking

The global lock signal from the SPU along with the peripheral lock bit can be used to provide lock functionality for the control MMR of the peripheral. The Global Lock (`SPU_CTL.GLCK`) field determines whether global lock is enabled or not. Global Lock is disabled if the `SPU_CTL.GLCK` field is 0xAD (default value), otherwise it is enabled. The following is a list of peripherals that have the global lock bit in their control MMR.

- General-Purpose IO (GPIO)
- System Event Controller (SEC0)
- Trigger Routing Unit (TRU0
- Clock Generation Unit (CGU0)

- Clock Generation Unit1 (CGU1)
- Clock Distribution Unit (CDU0)
- Dynamic Power Management (DPM)
- Reset Control Unit (RCU0)
- System Protection Unit (SPU0)
- L2 Memory Controller (L2CTL0)

39 Security Packet Engine (PKTE)

The PKTE is a security packet engine designed to off-load the host processor to improve the speed of applications requiring cryptographic processing. The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation.

PKTE Features

The PKTE has the following features.

- Hardware assisted processing for the cryptographic ciphers, hashes, and pseudo-random number generation
- Header and trailer processing for Internet security protocols
- DMA capability to move data in and out of the engine efficiently and to allow the engine to run autonomously while moving data
- Interrupt controller to signal module status and errors
- Clock manager for enabling or disabling different features to save power

NOTE: Not all algorithms, decrypt, and hash functions and extra features are available on all product models. For complete information on included features, see the product-specific data sheet.

NOTE: This packet engine provides support for various network security protocols by processing headers and trailers as well as accelerating cryptographic functions. Not all processors have direct support for Ethernet. As such, the packet engine can still be used if Ethernet is indirectly used.

PKTE Functional Description

The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation. The following sections describe these functional blocks.

ADSP-2159x_SC591_SC592_SC594 PKTE Register List

The Security Packet Engine (PKTE) provides security-related features. A set of registers governs PKTE operations. For more information on PKTE functionality, see the PKTE register descriptions.

Table 39-1: ADSP-2159x_SC591_SC592_SC594 PKTE Register List

Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers

Table 39-1: ADSP-2159x_SC591_SC592_SC594 PKTE Register List (Continued)

Name	Description
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers

Table 39-2: ADSP-2159x_SC591_SC592_SC594 PKTE Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
161	PKTE0_IRQ	PKTE0 Interrupt	Level	

PKTE Definitions

Command Descriptor

An 8-word structure that is either written directly into the packet command MMR set or is placed in a Command Descriptor Ring (CDR) in the processor memory. The packet engine sequentially processes the structure. The command descriptor contains the information that varies for every packet. This information includes pointers to the SA record, the state information, the source packet, and the destination packet.

Command Descriptor Ring (CDR)

A circular contiguous portion of memory which is used to manage one or more command descriptions for the packet engine.

Result Descriptor

When the packet engine completes the processing of a packet, it writes a result descriptor with the state information. The result descriptor can be read directly from the result register set or from the Result Descriptor Ring (RDR) in the processor memory.

Result Descriptor Ring (RDR)

A circular contiguous portion of memory which holds the mirror or copy of the CDR but contains the result descriptors. The RDR and CDR can be overlaid on top of each other.

Security Association (SA) Record

A structure that contains the remainder of the information the packet engine requires to process a packet. Most of the information fields in the SA record such as the key and encryption mode are static for the lifetime of the association. The fields do not require frequent manipulation by the processor core. The SA record non-static fields are the sequence number and sequence number mask. The SA record can have a corresponding state record for saving results from the current operations that are useful for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

Cipher

A method or algorithm to encrypt or decrypt information

Hash

A cryptographic hash is a function that takes an arbitrary block of data and returns a fixed-size bit string. Four main properties define the function:

- It is easy to compute a hash value for any given input

- It is infeasible to generate the original input from a given hash
- It is infeasible to modify the input without changing the resulting hash
- It is infeasible to find two different inputs that result in the same hash

Autonomous Ring Mode (ARM)

Mode of operation in which most of the parameters as well as the data are set up in memory and moved to the engine for configuration and processing through DMA.

Target Command Mode (TCM)

Mode of operation where some parameters are set up in memory and moved into the packet engine through DMA while the other parameters are directly written to the registers. DMA moves the input and output data in and out of the engine.

Direct Host Mode (DHM)

Mode of operation that does not use DMA. All parameters are directly written to and read from the MMRs. The input and output are written to and read from the FIFO buffers.

Cipher Module

The cipher module does the symmetric encrypt or decrypt operations for:

- Data Encryption Standard (DES)
- Triple-DES
- ARC4
- Advanced Encryption Standard (AES) algorithms

The cipher module supports standard modes for DES and AES that include Electronic Code Book (ECB) and Cipher Block Chaining (CBC). The key size for DES is 56 bits, for Triple-DES is 168 bits. The AES module also provides support for AES counter-modes for IPsec and SRTP. All AES modes can use key sizes of 128 bits and 192/256 bits. Key scheduling is automatic and done in parallel with the encrypt or decrypt operation.

Hash Module

The hash module is tightly coupled with the encrypt or decrypt module and provides hardware accelerated one-way hash functions. Operations that combine both hash and encrypt or decrypt functions are provided to reduce processing time for data that needs both applied. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of hashing and the start of encryption to support protocols such as IPsec or SRTP. The HMAC keyed hashing mechanism is supported

for MD5, SHA-1, SHA-2-224 and SHA-2-256. The SSL-MAC is supported for MD5 and SHA-1. A second AES-CBC module for the hash function enables parallel processing for AES-CCM, a combined hash and encrypt algorithm.

Pseudo-Random Number Generator

Cipher algorithms that operate in CBC mode or counter-mode, require an IV. This IV must not be secret; however the IV must be unpredictable and unique for each execution of the encryption process. Pseudo-random number generators are deterministic algorithms that output statistically independent and unbiased numbers. True random number generators are non-deterministic and use the randomness that occurs in a physical process. The packet engine incorporates an ANSI X9.31 compliant Pseudo Random Number Generator (PRNG) that it can use to generate unique IVs using strong encryption. The ANSI X9.31 PRNG is defined as part of the ANSI X9 standards that are used to secure financial transactions. The function can also be used for pseudo-random number generation as part of an implementation of the digital signature standard described in NIST FIPS PUB 186-2.

The PRNG function, as defined by ANSI X9.31, is based on the AES cipher. This section describes the function to promote understanding of the different inputs and outputs of the PRNG function itself.

NOTE: The PRNG in the packet engine is only based on the AES cipher with 128-bit keys. Other ciphers and key lengths are not supported for the PRNG based on ANSI X9.31.

Let $e \times K(Y)$ represent the AES encryption of Y under the key K.

The PRNG function uses three inputs:

- K, a 128-bit key
- V, a 128-bit seed value
- DT, a 128-bit date/ time vector which is updated on each iteration

The intermediate value I is the result of an AES encryption of the data and time vector under key K.

$I = e \times K(DT)$

That value I is then XOR-ed with the seed V and AES encrypted under key K. The result R is the output of the PRNG function.

$R = e \times K(I \text{ XOR } V)$

A new seed value V is generated from the AES encryption of the result R XOR'ed with the intermediate value I under the key K.

$V = e \times K(R \text{ XOR } I)$

The PRNG function is deeply integrated inside the datapath of the packet engine. The function is controlled indirectly through the PRNG mode bits in the `PKTE_CTL_STAT.PRNGMD` bit field of the command descriptor and the IV source selection bits in the `PKTE_SA_CMD0.IVSRC` bit field of the SA record.

The PKTE module supports four different modes.

1. Load IV from PRNG for the current operation: PKTE_CTL_STAT.PRNGMD = 0b00 and PKTE_SA_CMD0.IVSRC = 0b11.
2. PRNG init mode initializes the PRNG with a key, seed, and date/time value: PKTE_CTL_STAT.PRNGMD = 0b01.

   Before the PRNG function can be used, it must be initialized with a key, seed, and date/time value. At initialization, the key, seed, and date/time values are programmed. Other PRNG operations do not change the key, however the seed, and date/time values are updated (not re-programmed). The date/time is updated every 128 system clock cycles.

   The date/time is a 128-bit value with randomly distributed number of ones and zeros. It must not be all zeros.

   The ***SA Record for PRNG Init Operation*** table shows how the key, seed and date/time values are loaded into the PKTE registers for initialization.

Table 39-3: SA Record for PRNG Init Operation

Parameter	SA Field	Description
K	SA_KEY0	PRNG key [127:96]
	SA_KEY1	PRNG key [95:64]
	SA_KEY2	PRNG key [63:32]
	SA_KEY3	PRNG key [31:0]
V	SA_IDIGEST0	PRNG seed [127:96]
	SA_IDIGEST1	PRNG seed [95:64]
	SA_IDIGEST2	PRNG seed [63:32]
	SA_IDIGEST3	PRNG seed [31:0]
DT	SA_ODIGEST0	PRNG date/time [127:96]
	SA_ODIGEST1	PRNG date/time [95:64]
	SA_ODIGEST2	PRNG date/time [63:32]
	SA_ODIGEST3	PRNG date/time [31:0]

3. PRNG generate mode generates pseudo-random data on initialized key, seed, and date/time value: PKTE_CTL_STAT.PRNGMD = 0b10.

   The PRNG function can be used to generated pseudo-random data for other purposes than IVs. For this mode, the PRNG must have been initialized once with the PRNG init mode.

   The PRNG generate mode uses the initialized key and unique changing date/time value as inputs. The pseudo-random data is output to the output buffer of the packet engine.

   The LEN field in the command descriptor indicates the amount of pseudo random data that is generated in multiples of 16 bytes. The maximum is 255 × 16 = 4080 bytes.

In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

Directly after the PRNG generate mode, a new pseudo-random number is generated and available for the next operation that uses the option `PKTE_SA_CMD0.IVSRC = PRNG`.

4. PRNG test mode generates pseudo-random data on initialized key, seed, and input (test) data: `PKTE_CTL_STAT.PRNGMD` = 0b11.

   The PRNG test mode can be used to test the correctness of the PRNG function. This mode is similar to the PRNG generate mode, except that the data is read from the input buffer of the packet engine, instead of the date/time value.

   For this mode, the PRNG must have been initialized once with the PRNG Init mode.

   The `LEN` field in the command descriptor indicates the amount of pseudo-random data to be generated in multiples of 16 bytes. The maximum is limited to the `LEN` field in bytes.

   In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In the direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

   Directly after the PRNG test mode, a new pseudo-random number is generated and available for the next operation that uses the option `PKTE_SA_CMD0.IVSRC = PRNG`.

Packet Engine Processing Details

This section describes data processing through the packet engine. It describes padding and supported algorithms for each protocol.

A valid Security Association (SA) must be created before packet processing can start. A formatted SA record must reside in memory and be accessible to the packet engine. The host processor application is responsible for these tasks.

Crypto Padding

Padding is the process of adding data to fill-out a fixed-size plain text data structure. Three factors determine when to use a pad field:

1. If a block cipher encryption algorithm is used, a pad field is used to expand the plain text to a multiple of the block size.
2. Padding can be used to ensure that the cipher text terminates on an n-byte boundary.
3. Padding can conceal the actual length of the payload.

To facilitate peak encrypt or decrypt performance, the packet engine supports the following most commonly used padding functions in hardware:

1. Pad generation and insertion of pad bytes to the end of plain text prior to encryption, for outbound operations.

2. Pad verification to check for correct padding after decrypting a packet for inbound operations.
3. Pad consumption to strip the pad bytes from the plain text data after decrypting a packet, for inbound operations.

Pad Generation and Insertion

The pad type and quantity of bytes the packet engine inserts depends on the plain text length and the value of the following fields:

- `PKTE_SA_CMD0.PADTYPE` and `PKTE_SA_CMD0.EXTPAD` defines the type of padding
- `PKTE_CTL_STAT.PADVAL` defines a value that is inserted in the pad
- `PKTE_SA_CMD0.CIPHER` enforces a certain pad alignment
- `PKTE_SA_CMD1.CIPHERMD` enforces a certain pad alignment
- `PKTE_SA_CMD0.SCPAD` allows stream ciphers to be padded
- `PKTE_CTL_STAT.PADCTLSTAT` controls the pad alignment

The `PKTE_CTL_STAT.PADCTLSTAT` bit field of the result descriptor returns the total number of inserted pad bytes.

Pad Types

The pad type bit field (`PKTE_SA_CMD0.PADTYPE`) and the extended pad bit (`PKTE_SA_CMD0.EXTPAD`) select the pad type for the extended protocol group. The packet engine can generate different pad types in hardware as described in the ***Pad Examples*** table.

The `PKTE_CTL_STAT.PADVAL` bit field, together with the number of pad bytes, defines the value that is inserted in the pad. The format of the pad and the use of this field is best explained in an example (see the ***Pad Examples*** table).

For the IPsec pad type, this field holds the value that is inserted into the next header field (in the ESP trailer) of the innermost operation's header. For the Constant pad type or the Constant SSL pad type, this field holds the inserted fixed constant pad value. For all other pad types, this field is not used and must be zero.

Table 39-4: Pad Types

Pad Type	Value	Description
IPSec	0b000	Append 0 to 255 pad bytes, followed by a pad length byte and a next header byte. The first pad byte appended to the plain text is numbered 1, with subsequent pad bytes making up a monotonically increasing sequence: 1, 2, 3 and up. Append the pad length field that indicates the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Append the next header byte as specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A minimum of 2 bytes are appended; zero pad bytes plus the pad length byte plus the next header byte, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the result descriptor returns 0x02. A maximum of 257 bytes can be appended, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the descriptor returns 0x01.
PKCS#7	0b001	Appends 1–128 pad bytes with a pad byte value equal to the pad length (1–128).
Constant	0b010	Appends 0–255 pad bytes of a user-specified character to the plain text data. This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor.
Zero	0b011	Appends 0–255 pad bytes of 0x00 to the plain text data.
Constant SSL	0b110	Appends 0–255 pad bytes of a user-specified character to the plain text data, followed by a 'pad length' byte (0–255). This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A total of 256 bytes can be appended, in which case the pad field returns 0x00.

For example, the ***Pad Examples*** table shows the appended pad for any of the pad types for an outbound (encrypt) operation. The table shows a plain text input of 2 bytes using the 8-byte block cipher crypto-algorithm DES-ECB and a `PKTE_CTL_STAT.PADVAL` field value of 0xAA.

Table 39-5: Pad Examples

Pad Type	Pad field (extended to Plain Text)	`PKTE_CTL_STAT`
IPSec	0x01, 0x02, 0x03, 0x04, 0x04, 0xAA	0x06
PKCS#7	0x06, 0x06, 0x06, 0x06, 0x06, 0x06	0x06
Constant	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0xAA	0x06
Zero	0x00, 0x00, 0x00, 0x00, 0x00, 0x00	0x06
Constant SSL	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0x05	0x06

Pad Length

The ***Pad Alignment*** table lists the alignment (boundaries) to which the packet engine will pad, based on:

- The selected crypto-algorithm
- Crypto mode
- The value of the pad stream cipher bit
- The value of pad control

The minimum number of inserted pad bytes depends on the cipher algorithm, selected using the PKTE_SA_CMD0.CIPHER bit field, and the cipher mode, selected using the PKTE_SA_CMD1.CIPHERMD bit field.

For block ciphers, the plain text data is always (as a minimum) padded to the next block boundary. More pad bytes beyond the algorithm or protocol alignment requirements can be inserted using the pad control (PKTE_CTL_STAT.PADCTLSTAT) in the command descriptor. This feature can be used for *traffic flow security* to conceal the number of plain text bytes in an encrypted packet.

Encrypt operations that use block ciphers have minimum pad requirements based on their block size. The packet engine enforces a minimum pad alignment for block ciphers according to the ***Pad Alignment*** table. For ESP outbound operations, the minimum pad alignment is forced to 4 bytes.

For stream ciphers and null crypto the data is never padded when the stream cipher pad bit (PKTE_SA_CMD0.SCPAD) =0. When PKTE_SA_CMD0.SCPAD =1 the plain text data is padded to the length as defined by the PKTE_CTL_STAT.PADCTLSTAT bits in the command descriptor.

NOTE: The SSL protocol does not allow padding to exceed the ciphers block length. This length is 8 bytes for DES/Triple-DES and 16 bytes for AES. For SSL, the packet engine does not enforce this pad alignment value. The host processor must ensure that the PKTE_CTL_STAT.PADCTLSTAT bit field is configured correctly.

Table 39-6: Pad Alignment

Pad Control **PADCTLSTAT = PKTE_CTL_STAT[31:24]**			**0x00**	**0x01**[*1]	**0x02**	**0x04**	**0x08**	**0x10**	**0x20**	**0x40**	**0x80**[*2]
Crypto Algorithm	**Crypto Mode**	**Pad Stream Ciphers**	**%8**	**%1**	**%4**	**%8**	**%16**	**%32**	**%64**	**%128**	**%256**
DES	ECB, CBC	N/A	8	8	8	8	16	32	64	128	256
AES	ECB, CBC	N/A	16	16	16	16	16	32	64	128	256
	CTR, ICM with ESP	N/A	8	4	4	8	16	32	64	128	256
	CTR, ICM no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
NULL	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	8	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
ARC4	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256

*1 If PKTE_CTL_STAT.PADCTLSTAT is configured for no padding (0x01), it does not mean that no padding bytes are inserted. When PKCS#7 padding is selected, a pad length field with a value =1 is inserted. When SSL or TLS padding is selected, a pad length field with a value =0 is inserted. When IPsec padding is selected, a pad length field is forced to (PKTE_CTL_STAT.PADCTLSTAT=0x20). When zero pad and constant pad are selected, no pad bytes are inserted.

*2 Pad type PKCS#7 supports a maximum length of 128 pad bytes, so the packet engine overrules a 256-byte alignment (PKTE_CTL_STAT.PADCTLSTAT=0x80) to a 128-byte boundary (PKTE_CTL_STAT.PADCTLSTAT=0x40).

The packet engine does not constrain the pad type that is used for an operation; any pad type can be used for each operation. The user must be aware that some protocol specifications only allow specific pad types. The SRTP specification does not have padding defined as padding performed by RTP. The host must pad the RTP packet.

The host software can implement padding that is not supported in hardware. In this case, the host must select the *zero pad* type and set the PKTE_CTL_STAT.PADCTLSTAT bit field in the packet descriptor to zero (no padding). The hardware padding engine does not add any bytes. When using a block cipher, the host must insert pad bytes. Then, the data to be encrypted (plain text and pad bytes) are a multiple of the block ciphers boundary. For stream ciphers, any number of pad bytes can be added.

Pad Verification and Consumption

The packet engine can validate a pad type against the expected values. The value of the following bits controls the pad verify function:

- PKTE_SA_CMD0.PADTYPE and PKTE_SA_CMD0.EXTPAD define the type of padding
- PKTE_SA_CMD0.CIPHER enforces a certain pad alignment
- PKTE_SA_CMD1.CIPHERMD enforces a certain pad alignment
- PKTE_SA_CMD0.SCPAD allows stream ciphers to be padded

When packet processing is complete, the status byte in the first word of the result descriptor reports the pad verification status. Refer to the Table 39-28 Extended Error Codes - Status Encoding table.

The PKTE_CTL_STAT.PADCTLSTAT bits in the first word of the result descriptor return the total number of detected pad bytes and returns zero for a pad verify error.

When the IPsec pad type is selected, the PKTE_CTL_STAT.PADVAL bit field of the result descriptor returns the next header field. For IPsec ESP outbound operations, this field returns the decimal value 50. For IPsec inbound operations and basic inbound operations that use the IPsec pad mode, the packet engine returns the next header field it detects on the header of the innermost operation. This value is typical for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other inbound operations, the returned pad value is zero.

Pad verification is performed for inbound (decrypt) operations that use IPsec, TLS/DTLS or PKCS#7 pad type:

- In combination with a block cipher algorithm: DES-ECB, DES-CBC, AES-ECB, AES-CBC,
- In combination with a stream cipher and stream cipher padding PKTE_SA_CMD0.SCPAD enabled: AES-CTR, AES-ICM and ARC4
- In combination with null-crypto (no encryption).

Pad Types

The PKTE_SA_CMD0.PADTYPE bit field and the extended pad PKTE_SA_CMD0.EXTPAD bit selects the pad type for the extended protocol group pad type. The packet engine can verify the different pad types in hardware as described in the ***Pad Types*** table.

The constant and zero pad types are not verified since they do not include a pad length field. The SSL pad type is not verified since it does not have a defined pattern.

Table 39-7: Pad Types

Pad Type	SA_CMD0[18, 7:6]	Description
IPSec	0b000	Verify that the pad field includes 0–255 pad bytes, followed by a correct pad length and a next header byte. Verify that pad bytes appended to the plain text are an incremental count, starting at one. Verify that the pad length field is the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Verify that a next header byte is present as the last byte of the packet, the value is not verified. This is after removal of the ICV. The total number of detected pad bytes is returned in the PKTE_CTL_STAT.PADCTLSTAT field in the result descriptor. **NOTE:** A minimum of 2 bytes must be present, zero pad bytes plus the pad length byte plus the next header byte. In this case the PKTE_CTL_STAT.PADCTLSTAT field in the descriptor returns 0x02. A maximum of 257 bytes can be present, in which case the PKTE_CTL_STAT.PADCTLSTAT field in the result descriptor returns 0x01. The value of the next header byte is returned in the PKTE_CTL_STAT.PADVAL field in the result descriptor.
PKCS#7	0b001	Verify that the pad field includes 1–128 pad bytes, with a pad byte value equal to the pad length (1–128).

When a block cipher is used and the payload is not padded to the nearest block size boundary, as required by the protocol, a *block size error* is generated for all pad types.

Pad Consumption

The packet engine can optionally consume the decrypted pad bytes for an inbound operation that uses the IPsec, SSL, TLS/DTLS, or PKCS#7 pad types. The pad types constant and zero are not consumed since they do not include a pad length field.

Pad consumption (or stripping) is selected on a flow-by-flow basis in the SA-record with the PKTE_SA_CMD1.CPYPAD bit. When this bit is set, the length returned in the LEN field of the result descriptor is the total length of the plain text including the pad. When the PKTE_SA_CMD1.CPYPAD is disabled, the detected pad length, as returned in the PKTE_CTL_STAT.PADCTLSTAT bits, is subtracted from the total length and then returned in the LEN field of the result descriptor.

The pad is always written to the result packet buffer in memory. When the PKTE_SA_CMD1.CPYPAD bit is disabled, only the result length is corrected.

Crypto and Hash Algorithms

The packet engine supports a wide range of crypto and hash algorithms to accelerate basic operations and protocol operations. These algorithms are:

- Basic Encrypt and Basic Decrypt Operations
- Basic Hash Operations
- Basic Encrypt-Hash and Basic Hash-Decrypt Operations
- IPSec ESP Operations
- SRTP Operations

The following tables provide allowed algorithm combinations. Those algorithms not listed in the tables are invalid and can give unexpected results.

NOTE: Not all crypto and hash algorithms are available on all product models. For information on algorithm availability, see the product-specific data sheet.

IV Processing

An initialization vector (IV) is necessary to start a cipher stream or a block cipher in any of the streaming modes of operation. The IV must be unique for each packet. The IV ensures that all cipher texts are unique even if produced by the same encryption key. This functionality prevents every packet from needing a unique encryption key.

Depending on the packet engine operation, the IV can be loaded from different sources. The IV format depends on the algorithm and the source of the IV. The ***Format of the IV*** table provides an overview of all IV formats.

Table 39-15: Format of the IV

Algorithm	IV Source (`PKTE_SA_CMD0.IVSRC`)	Format	IV Offset (`PKTE_SA_CMD1.HSHCOFFST`)
DES/Triple-DES (CBC)	Previous Result of IV	Internal IV register [63:0]	0x00
	Input Buffer	Input buffer [63:0]	0x02
	Saved IV	State Record Saved IV [63:0]	0x00
	Automatic	PRNG output [63:0]	0x00
AES (CBC)	Previous Result of IV	Internal IV register [127:0]	0x00
	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	PRNG output [127:0]	0x00
AES (ICM) for Basic and SRTP	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
AES (CTR) for Basic and IP-sec	Input Buffer	SA_NONCE || Input Buffer[63:0] || 0x00000001	0x02
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	SA_NONCE || PRNG output [95:32] || 0x00000001	0x00

Notes:

1. The `PKTE_SA_CMD1.HSHCOFFST` bit field provides the IV offset. The offset is only applicable for basic hash or encrypt operations. For protocol operations, the offset is automatically enforced.

2. AES-CTR: The Nonce value as described in RFC 3686, is mapped to the PKTE_SA_NONCE register. This Nonce value remains constant for the lifetime of the security association.
3. The host processor controls the IV update using the save-IV bit (PKTE_SA_CMD0.SVIV). When part of a packet is processed using a stream cipher and the encrypt or decrypt data is not an integer multiple of the block size, the saved IV is invalid. It must not be used to resume processing the packet.
4. The packet engine supports automatic IV generation for outbound operations. A new IV is generated for every packet with the internal PRNG. This automatic IV generation can be used for all DES, Triple-DES, and AES modes that use an IV, except for AES-ICM mode.
5. For outbound operations, automatic IV generation is the most efficient. No additional I/O is required, and the host processor does not need to provide the IV. When the saved IV option supplies the IV, the IV must be changed for each packet sent. This activity happens when the packet engine writes back the IV to the state record after processing.
6. Outbound IPsec operations put the IV explicitly at the front of the packet. For an inbound IPsec operation, loading from the input buffer is most efficient and always used.
7. CBC processing must not use a predictable IV. Do not use the saved IV and previous result IV options for CBC processing. Refer to RFC 3602 for more details.

ARC4 Processing

The ARC4 algorithm supports two modes of operation: stateless and stateful. For SSL, TLS and DTLS operations that use the ARC4 algorithm, the mode must be set to stateful.

Stateless Mode. Each packet is processed with a newly initialized ARC4 key taken from the key field of the SA record. In this mode, the state information from the SA is never to be read.

CAUTION: If an ARC4 operation in stateless mode is interrupted by an *Interface Error* and the ARC4 state building process is aborted, the next packet fails. The ARC4 is not reset between two packets. For the next packet the ARC4 proceeds from the internal state that it was aborted. Even a soft-reset does not reset the ARC4 internal state, a hardware reset is required.

Stateful Mode. When the PKTE_CTL_STAT.INITARC4 bit =1, the ARC4 algorithm initializes using the key specified in the SA record. When the PKTE_CTL_STAT.INITARC4 bit =0, the ARC4 context is read from the ARC4 state field of the SA record and the*i* and *j* pointer field of the SA record. The encrypt and decrypt processing continues from this algorithm state.

The packet engine supports ARC4 key sizes of 40 bits to 128 bits. Longer keys can be used, but they cannot be made inside the packet engine.

The host processor applies ARC4 key scheduling function to the s-box and puts the 256-byte result into the ARC4 state record. It writes the *i* and *j* pointers in the SA (initial $i = 1$, $j = 0$). The host programs the packet engine and specifies stateful operation to continue the ARC4 algorithm.

Hash State Loading

The hash state can be loaded from various sources, depending on the selected protocol and hash algorithm. The *Different Sources for Loading the Hash State* table provides a list of all the options.

Table 39-16: Different Sources for Loading the Hash State

Hash Algorithm PKTE_SA_CMD0.HASHSRC =	From SA 0b00	RESERVED 0b01	From State 0b10	No Load 0b11
SHA-1	yes	-	yes	Yes
SHA-224	Yes	-	Yes	Yes
SHA-256	Yes	-	Yes	Yes
Null hash	x	x	x	x

Sequence Number Processing

The packet engine supports sequence number generation and verification for IPsec and extended SSL, TLS, and DTLS protocol operations.

A Sequence Number (SN) is an unsigned number that a sender must implement and a receiver can use to support anti-replay service (replay attacks) for a specific SA. This processing includes detection of the same packet that arrives more than once and detection of packets that arrive in an incorrect sequence and is outside an accepted level of order relative to the last received packet.

The packet engine supports the following options.

- Sequence number loaded from SA for outbound operations and is retrieved from the input packet for inbound operations.

The sequence number and sequence number mask fields are part of the SA record.

Sequence Number Processing in Extended SSL/TLS

SSL and TLS use an implicit sequence number of 64 bits that is not send in the packet but part of the hash.

For inbound operations, no sequence number verification is performed; instead an incorrect sequence number results in an authentication error (PKTE_CTL_STAT.AUTHERR).

For outbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine generates a sequence number error when the 64-bit sequence number counter overflows (counter is 2^{64}-1 and increments to 0). The host processor must not send the packet.

For both outbound and inbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine reads the sequence number from the PKTE_SA_SEQNUM[n] registers in the SA. When the operation is finished, the packet engine stores the incremented sequence number in the same SA fields. The sequence number mask PKTE_SA_SEQNUM_MSK[n] registers in the SA are not used.

For both outbound and inbound operations, with PKTE_SA_CMD0.HDRPROC disabled, the packet engine does not increment the sequence number. It expects the host to provide the sequence number through the input buffer as part of the header.

Sequence Number Processing in DTLS

DTLS uses an explicit sequence number of 64 bits that is sent in the packet. The DTLS sequence number is composed of the epoch (16 bits) and packet sequence number (48 bits) that together form the 64-bit number, like the TLS sequence number. The epoch is incremented after each *Change Cipher Spec* message. The packet sequence number is incremented per packet starting from zero after each change cipher spec message.

For outbound operations, with PKTE_SA_CMD0.HDRPROC enabled, the packet engine reads the sequence number from the PKTE_SA_SEQNUM[n] fields in the SA, then inserts the sequence number in the packet. Then the packet engine stores the incremented sequence number in the PKTE_SA_SEQNUM[n] fields in the SA. The sequence number mask PKTE_SA_SEQNUM_MSK[n] fields in the SA are not used.

For outbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine generates a sequence number error when the 48-bit sequence number counter overflows (counter is $2^{48} - 1$ and increments to 0). The host must not send the packet.

For outbound operations, with PKTE_SA_CMD0.HDRPROC disabled or PKTE_SA_CMD1.ENSQNCHK disabled, the packet engine does not increment and verify a sequence number counter overflow, and therefore never generates a sequence number error. With PKTE_SA_CMD0.HDRPROC disabled the Packet Engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

For inbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine verifies the PKTE_SA_SEQNUM[n] fields against the sequence number in the packet using the PKTE_SA_SEQNUM_MSK[n] from the SA. Three situations can occur:

1. If the received sequence number falls outside and above the 64-bit sequence number mask, the mask is shifted. The packet engine updates the SA with the received sequence number and the shifted sequence number mask.
2. If the received sequence number falls inside the 64-bit sequence number mask and is not a duplicate sequence number (the same as received before), the corresponding bit in the mask is set. The packet engine updates the SA with the received sequence number and the updated sequence number mask.
3. If the received sequence number falls outside the 64-bit sequence number mask or matches and earlier received number a sequence number error is generated. The packet engine does not update the sequence number and sequence number mask fields in the SA. The host must discard the packet.

For inbound operations, with PKTE_SA_CMD0.HDRPROC disabled or PKTE_SA_CMD1.ENSQNCHK disabled, the packet engine does not verify the sequence number against the sequence number in the packet and therefore never generates a sequence number error.

With PKTE_SA_CMD0.HDRPROC disabled the packet engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

The following tables provide details of sequence number processing.

Table 39-17: Sequence Number Generation and Verification Control (Outbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Outbound		
1	1	Sequence number generation (increment)
1	1	Sequence number overflow check (2^{32}–1) to zero for IPsec, (2^{48}–1) to zero for DTLS and (2^{64}–1) to zero for Extended SSL/TLS.
1	0/1	Sequence number update in SA
0/1	0/1	Extended sequence number update in SA

Table 39-18: Sequence Number Generation and Verification Control (Inbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Inbound		
1	1	Sequence number verification (check against sequence number and sequence number mask in SA). Applicable only for IPsec and DTLS.
1	0/1	Sequence number update in SA, except on authentication error
1	1	Sequence number mask update in SA. Applicable only for IPsec and DTLS.
0/1	0/1	Extended sequence number update in SA

Table 39-19: Header Processing Enabled, Anti-replay Service Enabled

PKTE Block Diagram

The ***PKTE Block Diagram*** shows the functional blocks within the PKTE.

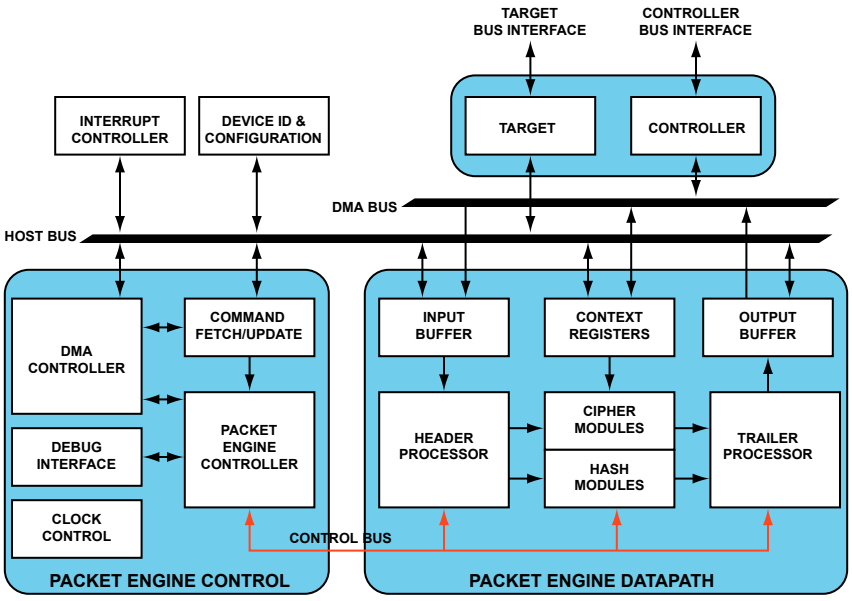

Figure 39-1: PKTE Block Diagram

PKTE Architectural Concepts

The following descriptions provide details on the functional blocks within the security packet engine.

Packet Engine

The packet engine contains symmetric cipher and hash engines. It is optimized to off-load intensive cryptographic operations from the host processor. It can perform parallel and pipelined encryption and hashing operations, reducing the latency, and processing time for packets that need both operations applied. The processor core provides the command information and packet data for the packet engine. The packet engine can run autonomously, using its local DMA controller to perform DMA transfers across the main bus to access the memory of the processor core. The DMA process incorporates flow-control to guarantee proper data flow. Two elements provide the command information that defines the processing for each packet:

- Command descriptor
- SA record

When the packet engine finishes the operation, it updates the SA record, when needed, and provides a result descriptor.

The packet engine has four different modes of operation. The modes give the processor core various levels of control over the command information and packet data transfers to and from the packet engine.

- Autonomous Ring Mode (ARM)
- Target Command Mode (with and without result descriptor ring) (TCM)
- Direct Host Mode (DHM)

Input/Output FIFO Buffers

The data for the packet engine is buffered at both input and output. These buffers decouple the DMA I/O process from the cipher and hash modules inside the packet engine. This functionality enables large DMA burst sizes and allows the crypto-engines to process data during I/O latency periods. Data moves automatically from the input buffer through the encryption and hash engines to the output buffer. If the output buffer is full, the process stops until the data is read and space is available in the output buffer. Each buffer is a 256-byte dual-port RAM.

Parallel Operations

The hash functionality and encrypt or decrypt functionality are tightly coupled. Operations that combine both hash and encrypt or decrypt functions are available to reduce processing time for data that must apply both. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of the hashing and the start of the encryption to support protocols such as IPSec and SRTP.

DMA Controller

The packet engine uses a high-performance DMA controller for autonomous data transfers for:

- Command descriptor reads
- SA record and state record reads
- Packet data read
- Result packet writes
- SA record and state record writes
- Result descriptor writes

Interrupt Controller

The packet engine includes an interrupt controller that, under programmable configuration control, can generate an interrupt on completion of certain operations. Individual interrupts can be masked and cleared. The interrupt registers show both the raw and masked interrupt status of the internal interrupts. The processor core can use interrupts, together with their associated threshold settings, to optimize the overall packet processing in the system. One interrupt can inform the processor core that the input side of the packet engine is almost empty to avoid a stall-on-empty condition. One interrupt can inform the host that the output side is almost full to avoid a stall-on-full condition. The controller uses several interrupts to inform the processor core about errors inside the packet engine. All available interrupts are combined into a single output port as either a level- or edge-active programmable interrupt output.

Clock Controller

The packet engine includes a clock controller that generates clock enable signals. A clock manager external to the packet engine uses the clock enable signals to switch the clocks to modules in the packet engine, reducing power consumption. The power saving can be significant, depending on the crypto-operation and the idle time of the packet engine. The clock controller generates the clock enable signals dynamically depending on the current crypto-operation. A clock control register provides the processor core the possibility to override this dynamic process.

PKTE Operating Modes

The packet engine can be configured in one of three command modes. For all modes the packet engine can generate an interrupt at completion of packet processing:

- Autonomous Ring Mode (ARM). The core prepares descriptors in the CDR and then initiates a descriptor fetch by triggering the packet engine. When a packet operation is complete, the packet engine writes the result descriptor out into a ring in host memory using the system requester bus interface.
- Target Command Mode (TCM). The core directly writes the command descriptors to the packet command register set to initiate a packet operation. This process eliminates an extra DMA transfer to fetch a descriptor, but requires the core to synchronously initiate packet processing. This mode can be configured both without RDR or with RDR. In the latter case, the packet engine writes the result descriptor out into the RDR in host memory using the system requester bus interface.
- Direct Host Mode (DHM). The core has full control over the packet engine and uses the system completer bus interface. The core provides all the command descriptors, SA record and state record, and packet input data.

When the packet engine completes processing, the core must read the packet output data, the SA record, the state record, and the result descriptors.

Autonomous Ring Mode (ARM)

The *Autonomous Ring Mode* allows the packet engine and the host processor to operate asynchronously. A queue of multiple packets in the host processor memory can be processed continuously to provide the highest possible throughput. The packet engine autonomously fetches the command descriptor, the SA record, and optionally the state record and the input data from host processor memory. After the packet engine finishes processing, it autonomously writes the output data, updates the SA record and state record and writes the result descriptor in the host processor memory. It accesses the host processor memory through DMA read transfers across the system bus requester.

This mode uses both command descriptor ring (CDR) and result descriptor ring (RDR).

Physically the CDR, RDR, SA record, source packet, and result packet can all be in different memories depending on the system memory architecture. The host processor writes command descriptors to the CDR in host processor memory. Then, it writes to the `PKTE_CDSC_INCR` register with the number of command descriptors that it prepared in the CDR. This write to the `PKTE_CDSC_INCR` register is the trigger for the packet engine to fetch the command descriptors sequentially from the CDR. When a command descriptor is fetched and written to the internal packet command register set, the descriptor is validated. If the ownership bits are set for the packet engine and the command is valid, processing starts. If not, that command is discarded and a result descriptor is written to the RDR with the error code *invalid command descriptor*. In this mode, the host processor can set a threshold on the CDR and enable an associated interrupt. The packet engine generates an interrupt when the number of command descriptors in the CDR is equal or below the threshold value.

The SA record and state record that contains the crypto context information are stored in a memory area. The packet engine autonomously accesses the memory area through DMA transfers across the system bus requester. Also, the source packet and result packet are stored in a memory area that the packet engine autonomously accesses through the same bus requester interface.

After decoding the command descriptor, the packet engine fetches the SA record and then, optionally, the state record.

Then, the source packet is fetched and stored in the input buffer. Packets less than the size of the input buffers are fetched entirely at once. Larger packets are fetched in parts that completely fill the input buffer. The packet engine initiates a new fetch each time the number of empty spaces in the input buffer reaches its threshold value. When the first packet data is available in the input buffer, the crypto engines start processing the data. After processing, the crypto engines write the result packet to the output buffer.

The packet engine writes the result packet from the output buffer to host processor memory when the number of bytes in the output buffer reaches its threshold value. Packets less than the threshold value are written entirely at once. Larger packets are written in parts that completely empty the output buffer

The source packet data fetching, data processing, and result packet data writing are parallel processes that continue until the last result packet is written to host processor memory. Then, the packet engine optionally writes the SA

record and the state record to update the crypto context information. As a final step, the packet engine writes the result descriptor to the RDR. The host processor must either poll the RDR or wait for an interrupt from the packet engine to determine when packet processing is complete.

Target Command Mode (TCM)

This mode provides a synchronous interface between the processor core and the packet engine. The Command Descriptor Ring (CDR) is disabled and the processor core initiates packet processing by writing the command descriptor directly to the internal command descriptor MMRs of the packet engine. The Result Descriptor Ring (RDR) is optional.

- For `PKTE_CFG.MODE` =01, the RDR is disabled and the processor core reads the result descriptor directly from the internal result descriptor register set for the packet engine.
- For `PKTE_CFG.MODE` =10, the RDR is enabled and stored in a memory area that the packet engine can access through its requester bus interface as in autonomous ring mode.

In target command mode, the packet engine autonomously fetches the SA record, state record, source packet data as in autonomous ring mode. Also, as in ARM, after processing, the packet engine updates state fields of the SA record and state record in the host processor memory.

Direct Host Mode (DHM)

This mode provides a synchronous interface between the processor core and the packet engine. The packet engine is under full control of the processor core. The host processor writes the command descriptors, SA record, and state record directly to the packet engine registers. Then, the processor core writes the source packet data into the input buffer. When processing is complete, the processor core reads back the result packet data from the output buffer. Finally, it reads the result descriptor, the updated SA record, and state record directly from the packet engine registers.

PKTE Event Control

The following section provides information about interrupts in the PKTE module.

PKTE Interrupt Signals

The Packet Engine has an internal Interrupt Controller with 9 interrupt sources. There are 7 registers associated with the interrupt controller:

1. Interrupt Unmasked Status - `PKTE_IUMSK_STAT`
2. Interrupt Mask Status - `PKTE_IMSK_STAT`
3. Interrupt Clear Register - `PKTE_INT_CLR`
4. Interrupt Enable Register - `PKTE_INT_EN`
5. Interrupt Mask Disable - `PKTE_IMSK_DIS`

6. Interrupt Mask Enable - PKTE_IMSK_EN
7. Interrupt Configuration - PKTE_INT_CFG

The ***Packet Engine Interrupt Controller Block Diagram*** shows the blocks of the interrupt controller.

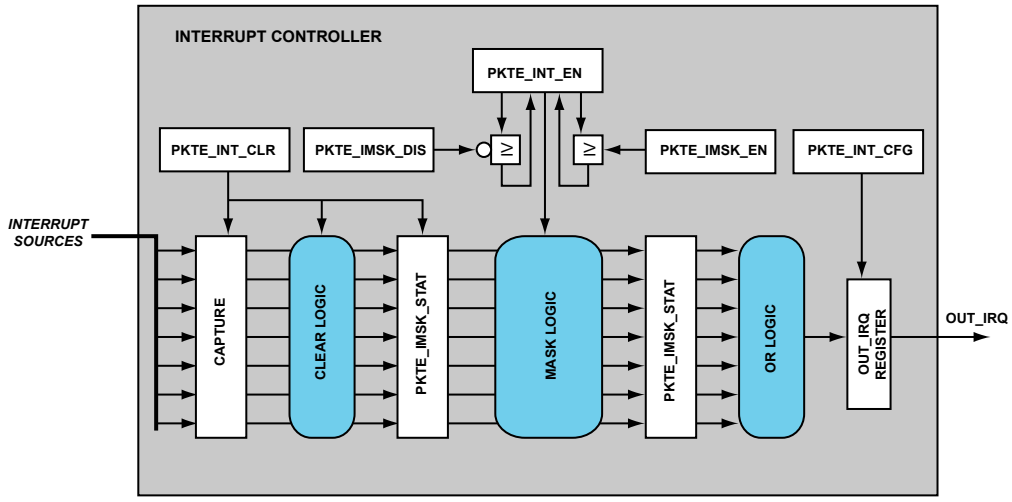

Figure 39-2: Packet Engine Interrupt Controller Block Diagram

All of the interrupt sources are pulse or level events in their native form.

These interrupts are captured and stored at their unmasked and masked status in their respective PKTE_IUMSK_STAT and PKTE_IMSK_STAT registers. This allows the host processor to read the status of any interrupt source either before or after the mask is applied.

The PKTE_INT_EN register provides a mask to select what interrupt source are enabled to the output interrupt request. Writing a one to the PKTE_INT_CLR register resets both the masked and unmasked interrupt.

The PKTE_IMSK_EN and PKTE_IMSK_DIS registers can be set to enable and disable individual interrupts respectively in the PKTE_INT_EN register. This avoids the need for read-modify-write operations from the host processor.

Ring Interrupts

Two interrupts are provided for efficient ring management: The CDR threshold interrupt (*cdrthrs*h) and the RDR threshold interrupt (*rdrthrsh*).

Command Descriptor Ring

The CDR threshold interrupt (cdrthrsh) is a level-based interrupt and connects to the threshold value in the PKTE_RING_THRESH.CDRTHRSH bit field. It enables the host processor to efficiently fill the CDR. The host processor writes command descriptors to the CDR with this interrupt masked until the CDR is full. Then the host processor enables the CDR threshold interrupt. When the interrupt is activated, the host processor clears the interrupt and it is guaranteed that it can put CDR threshold number of descriptors in the CDR.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.CDRTHRSH=224,
PKTE_INT_EN.CDRTHRSH=0 /*(IRQ disabled)*/
```

1. The host writes 8 Command Descriptors at once, then writes the PKTE_CDSC_INCR register to 8.
2. This is repeated until there are less than 8 empty entries in the CDR.
3. The fill level is now equal to he threshold (224)
4. The host enables the CDR threshold IRQ (PKTE_INT_EN.CDRTHRSH=1)
5. The packet engine processes packets and the fill level (PKTE_CDSC_CNT register) decreases.
6. Then the CDR threshold IRQ is activated as the fill level equals 224.
7. The host handles the interrupt, clears it and continues with step 1.

Result Descriptor Ring

The RDR threshold interrupt (rdrthrsh) is a level-based interrupt and connects to the threshold value in the PKTE_RING_THRESH.RDRTHRSH bit field and the timeout value in the RD timeout (PKTE_RING_THRESH.RDTO) bit field. It enables the host processor to efficiently empty the RDR. The timeout reminds the host processor that when the threshold kicks in result descriptors stay long in the RDR and must be processed to reduce latency. The timeout counts when the ring is not empty, regardless of the fill level and restarts when the host processor writes the PKTE_RDSC_CNT register. Initially the host processor enables the RDR threshold interrupt. When the interrupt is activated the host processor reads result descriptors until the RDR is empty or contains less than the PKTE_RING_THRESH.RDRTHRSH number of descriptors.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.RDRTHRSH=32, timeout=1ms
PKTE_INT_EN.RDRTHRSH=1     /*(IRQ enabled)*/
```

1. The Packet Engine writes the Result Descriptor, timeout counter starts.
2. The Packet Engine writes 32 more Result Descriptors, fill level (PKTE_RDSC_CNT register) increases to 33.
3. The fill level exceeds threshold within 1ms, the RDR threshold IRQ is activated.
4. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. The write to the PKTE_RDSC_DECR register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.
5. The Packet Engine writes 8 more Result Descriptors, fill level increases to 33.
6. The fill level exceeds threshold within 1 ms, the RDR threshold IRQ is activated.
7. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. The write to the PKTE_RDSC_DECR register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.

8. After 1 ms, the timeout counter interrupt is activated.
9. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. This is repeated until there are less than 8 full entries in the RDR. The fill level is now under the threshold and the RDR threshold IRQ interrupt is inactive. Each write to the PKTE_RDSC_DECR register restarts the timeout counter.

PKTE Programming Model

The host processor must always follow a pre-defined sequence of five phases required by the packet engine on a per packet basis when using direct host mode. The following sections describe the five phases.

Phase 1. Write the Command Descriptor

1. Write the first command descriptor word with status and control information to the PKTE_CTL_STAT register.
2. Optionally, write the user ID to the PKTE_USERID register.
3. Write the last descriptor word to the PKTE_LEN register.
4. Write the value 0x1 to the PKTE_CDSC_CNT register. This opertion triggers the packet engine to validate the command descriptor. If the command descriptor is invalid, an error is generated. (See the PKTE_CTL_STAT section in the Register Descriptions). If the command descriptor is valid, the packet engine waits for an PKTE_SA_RDY register write.

Phase 2. Write the State Registers, (ARC4 Buffer) and SA Registers

All required fields of the SA record and state record must be written. The fields required depend on the operation. The last field to be written is the PKTE_SA_RDY register. This register triggers the packet engine to start processing.

1. Write the required state record fields.
   - ARC4 state
   - IV
   - Digest count
   - State digest
2. Write the required SA record data.
3. To complete the SA record and state record, write the PKTE_SA_RDY register.

Phase 3. Write the Source Packet Data and Read Result Packet Data

The packet engine has input and output buffers. If a source packet is smaller than the size of the input buffer, then the packet can be written in one part. Otherwise, it must be written in multiple parts. The same applies to the

output data. If the result packet size is smaller than the size of the output buffer, then the packet can be read in one part. Otherwise, it must be read in multiple parts.

NOTE: An outbound packet that is smaller than the size of the input buffer can increase in size due to padding and does not always fit in the output buffer. Conversely, an inbound packet that is larger than the size of the input buffer can decrease in size, and due to de-padding, can fit in the output buffer. If the input buffer becomes empty or the output buffer becomes full, the engine stalls.

Two following steps describe different situations:

- Source packet smaller than the size of the input buffer, start at step 1.
- Source packet larger than the size of the input buffer, start at step 3.

The host processor must follow these steps:

1. Write the source packet data. Write the full source packet to the input buffer. Go to step 4.
2. Write the input buffer count register (PKTE_INBUF_CNT) with the number of valid bytes that are written to the input buffer. This value must correspond to the value in thePKTE_LEN.TOTLEN field of the command descriptor rounded up to the next multiple of 4 bytes. Go to step 5 to check the packet engine status.
3. Write part of the source packet data. The PKTE_STAT.IBUFEMPTYCNT field indicates the amount of free space in the input buffer. Programs write the number of bytes determined by the setting in the PKTE_BUF_THRESH register. Write the (partial) source packet to the input buffer. The host processor must resume where it ended the previous write operation. Do not write more than the buffer size at once. Go to step 4.
4. Write the PKTE_INBUF_CNT register with the number of valid bytes written to the input buffer. Go to step 5 to check the packet engine status.
5. Check packet engine status. Wait for an interrupt or poll the PKTE_STAT register for any of the following conditions:
   - Condition 1 - An error interrupt or any of the bits [7:5] in the PKTE_STAT register becomes active to indicate a packet processing error. Depending on the type of error, the host processor must take appropriate action. Usually, the result packet is not valid after a processing error has occurred. Go to phase 5 to read the result descriptor.
   - Condition 2 - An operation done interrupt or the PKTE_STAT.OPDN bit becomes active (the packet engine completed processing). Go to step 8 to read the remaining output data.
   - Condition 3 - An output buffer threshold interrupt or the PKTE_STAT.OBUFREQ bit becomes active. Go to step 6 to read a block of output data.
   - Condition 4 - An input buffer threshold interrupt or the PKTE_STAT.IBUFREQ bit becomes active. Go to step 3 to write a block of input data.
6. Read part of the output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to full words. Programs read the number of bytes indicated in the

PKTE_BUF_THRESH register. Read the (partial) output packet from the output buffer. The host processor must resume where it ended the previous read operation. Do not read more than the input buffer size at once. Go to step 7.

7. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to step 5 to check the packet engine status.
8. Read the remaining output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to words. Read the (partial) packet output data from the output buffer. The host processor must resume where it ended the previous read operation. Go to step 9.
9. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to phase 4.

Phase 4. Read the Result Descriptor

1. Read the first result descriptor word from the PKTE_CTL_STAT.
2. Optionally read the user ID from the PKTE_USERID register.
3. Read the last result descriptor word from the PKTE_LEN register.
4. Write the value 0x1 to the PKTE_RDSC_DECR register. This operation allows the packet engine to accept new command descriptors. Go to phase 5.

Phase 5. Read the SA Record and State Record

Depending on the operation, the SA record or state record is updated. Check the bit fields [23:16] in the PKTE_CTL_STAT register for the following conditions:

- Condition 1 - At least one error bit in the bit fields [23:16] of the PKTE_CTL_STAT register is set. Do not update the local host processor maintained version of the SA record and state record but take any required action.
- Condition 2 - None of the error bits in the bit fields [23:16] of the PKTE_CTL_STAT register is set, the packet is processed normally (without errors). Update the host processor maintained version of the SA record and state record with the result read from the packet engine registers:
  - ARC4 state
  - Sequence number
  - Sequence number mask
  - Result IV
  - Result digest count
  - Result digest

PKTE Mode Configuration

Before using the packet engine, it must be configured. The mode of the packet engine must be defined and the PRNG (if used) must be initialized.

Configure the packet engine in one of three command modes:

- Autonomous Ring Mode: `PKTE_CFG.MODE` =b'11
- Target Command Mode: `PKTE_CFG.MODE` =b'10
- Direct Host Mode: `PKTE_CFG.MODE` =b'00

PKTE Programming Concepts

The following sections provide conceptual information for programming the PKTE.

Packet Engine Descriptor

IMPORTANT: Depending on the mode, ARM, TCM, or DHM, the descriptor is either:

- in the memory of the host processor in the command descriptor ring, or
- written directly to the descriptor registers in the packet engine

References to descriptor registers are for either the register that is mirrored in the descriptor structure in memory or for the actual register itself.

Command descriptors are host-supplied commands that control the real-time operation of the packet engine. The packet engine returns result descriptors at the end of an operation that provide the status information to the host. The ***Command Descriptor Structure*** and the ***Result Descriptor Structure*** tables show these descriptors.

Table 39-20: Command Descriptor Structure

When the packet engine is configured for autonomous ring mode, command descriptors and result descriptors reside in a ring in host memory. Command descriptors are automatically fetched from the Command Descriptor Ring (CDR) through DMA into the command descriptor registers. When an operation is complete, the result descriptors are automatically read from the packet engine and through DMA to the Result Descriptor Ring (RDR).

When the packet engine is configured for direct host mode, the host processor manually writes the command descriptor directly to the internal command descriptor MMR set. When an operation is complete, the host processor manually reads the result descriptor directly from the result descriptor MMR set.

The target command mode is a combination of the direct host mode and the autonomous ring mode. The host processor writes the command descriptor directly to the internal command descriptor register set. When an operation is complete there are two options.

1. The host processor can read the result descriptor directly from the result descriptor registers.
2. The result descriptors reside in a ring in host memory and the result descriptors are automatically DMA'd from the packet engine to the RDR.

When the host processor writes a command descriptor to the command descriptor registers, the packet engine is triggered when the host processor updates the `PKTE_CDSC_CNT` register. This functionality guarantees that all fields in the command descriptor are valid before the command is executed.

Descriptor Processing

This section describes the functional steps of the packet engine while processing the command descriptors.

Descriptor Ring Configuration

At initialization, the host processor specifies the size of the Command Descriptor Ring (CDR). The Result Descriptor Ring (RDR) has the same size.

NOTE: In some configurations, these two rings overlay each other with the results written on top of the command descriptors. This configuration is called overlaid ring mode.

When the packet engine is configured and enabled, it fetches the descriptors from the CDR using system bus requester reads.

Descriptor Ring Processing

To validate the descriptor exchange between the host processor and the packet engine, the ownership bits PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY are used. One pair of ownership bits is in the first word of the descriptor (PKTE_CTL_STAT), and one pair is in the last word (PKTE_LEN). The 'consumer' of a descriptor must verify that both ownership pairs match to ensure that a race condition did not occur between one party writing and the other party reading the descriptor. A race condition can occur when a memory locking scheme is not used.

Each pair [PKTE_CTL_STAT.PERDY, PKTE_CTL_STAT.HOSTRDY] of ownership bits provide 3 states:

- b'00 = idle or null descriptor
- b'01 = host processor has written a descriptor in the CDR and passed ownership to the packet engine
- b'10 = packet engine processing complete: packet engine has written the descriptor in the RDR and passed ownership back to the host.
- b'11 = Reserved

At initialization, the host sets the entire CDR memory area to zero, when the CDR is used.

1. The host processor writes one or more command descriptors to the CDR. The host processor must set the PKTE_CTL_STAT.HOSTRDY bit to 1 and the PKTE_CTL_STAT.PERDY bit to 0 to indicate that ownership has passed to the packet engine. These bits are mirrored in the PKTE_LEN descriptor word.
2. The host processor must write the PKTE_CDSC_INCR register with the number of new valid command descriptors in the CDR.
3. The packet engine reads and validates one command descriptor.
4. The packet engine reads the SA record and state record, processes the packet and updates the SA record and state record.
5. If the rings are not overlaid and the PKTE_CFG.ENCDRUPDT bit is 1, the packet engine writes the result descriptor to the CDR with the PKTE_CTL_STAT.HOSTRDY bit set to 0 and PKTE_CTL_STAT.PERDY bit set to 1. These bits are mirrored in the PKTE_LEN descriptor word.
6. The packet engine writes the result descriptor to the RDR. The packet engine sets the PKTE_CTL_STAT.PERDY bit to 1 and the PKTE_CTL_STAT.HOSTRDY bit to 0 to indicate that the ownership has passed to the host. These bits are mirrored in the PKTE_LEN descriptor word.
7. The packet engine decrements the value in the PKTE_CDSC_CNT register. If the value is not zero, the packet engine reads with the next command descriptor (step 3).

8. The packet engine increments the value in the PKTE_RDSC_CNT register.
9. The host processor reads one or more result descriptors from the RDR and processes the results.
10. The host processor must write the PKTE_RDSC_DECR register with the number of processed result descriptors in the RDR.

Descriptor Ownership

The ownership of the command descriptor and result descriptor is set by ownership bits in the first and last word of the respective descriptor, in the PKTE_CTL_STAT register and the PKTE_LEN register. For the command descriptor, it is the processor core that sets the ownership to the packet engine. For the result descriptor, it is the packet engine that sets the ownership to the host processor.

The packet engine reads the ownership bits before processing, irrespective of the mode of the packet engine. The ownership bits are used to validate and identify the descriptor. When two separate rings are used, the packet engine can be programmed to clear the ownership bits of the command descriptors in the CDR so the host processor knows which descriptors are processed.

NOTE: This update of the ownership bits can be disabled in the PKTE_CFG register when the host processor actively counts the number of descriptors in the CDR to prevent ring wrapping.

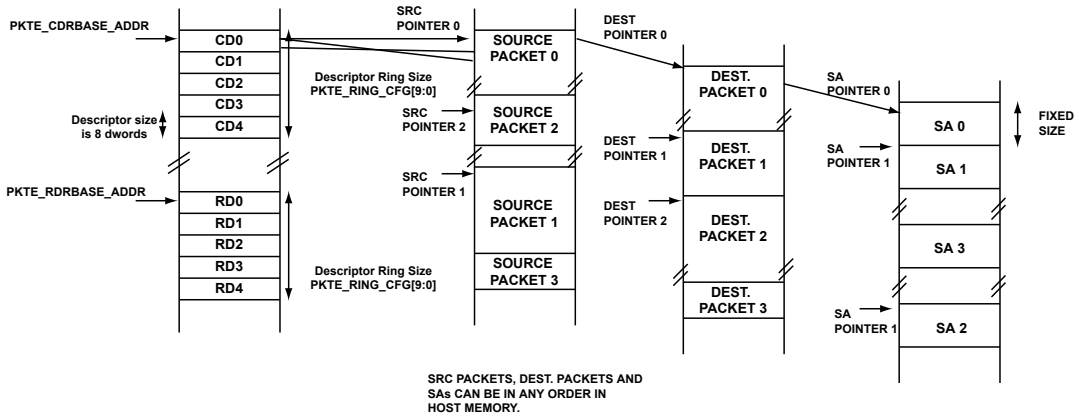

Figure 39-3: Descriptor Rings in Autonomous Ring Mode

SA Record and State Record Structure

The SA record is a packed structure that contains the remainder of the information needed by the packet engine to process a packet. Most of the information fields in the SA record, such as the key and encryption mode, are static for the lifetime of the association. The fields do not require frequent manipulation by the host processor. The SA record non-static fields are the sequence number and sequence number mask.

The SA record can have a corresponding state record that is used to save results from the current operations that can be used for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

If an SA record is used for operations that use ARC4 processing in stateful mode, it has a corresponding ARC4 state record that holds the ARC4 State.

In this manual, the state record and the ARC4 state record are referred to as state record.

There is no practical limit to how many SA records and corresponding state records the packet engine can support.

In the autonomous ring mode and target command mode, once the packet engine has validated a command descriptor, it automatically fetches the SA record and optional state record. After processing, the packet engine updates the stateful fields in the SA record and state record in the host processor memory.

In direct host mode, after the descriptor is validated, the host must write the SA record directly into the internal registers of the packet engine. After processing, the host reads the stateful fields from the SA registers of the packet engine and saves them back to the SA record in the host processor memory.

SA Record Structure

The ***SA Record Structure*** table shows the structure for an SA Record. When using direct host mode, the corresponding elements are accessed directly with the registers. When using autonomous ring mode or target command mode, the SA Record is defined, configured and accessed in host memory.

Table 39-22: SA Record Structure

Word Offset	Description (name)	Use
0	PKTE_SA_CMD0[31:0]	SA Control word 0 (all operations)
1	PKTE_SA_CMD1[31:0]	SA Control word 1 (all operations)
2	PKTE_SA_KEY0[31:0]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)
3	PKTE_SA_KEY1[63:32]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)
4	PKTE_SA_KEY2[95:64]	Key word (Triple-DES, AES-128/192/256, ARC4,)
5	PKTE_SA_KEY3[127:96]	Key word (Triple-DES, AES-128/192/256, ARC4,)
6	PKTE_SA_KEY4[159:128]	Key word (Triple-DES, AES-192/256)
7	PKTE_SA_KEY5[191:160]	Key word (Triple-DES, AES-192/256)
8	PKTE_SA_KEY6[223:192]	Key word (AES-256)
9	PKTE_SA_KEY7[255:224]	Key word (AES-256)
10	PKTE_SA_IDIGEST0[31:0]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
11	PKTE_SA_IDIGEST1[63:32]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
12	PKTE_SA_IDIGEST2[95:64]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
13	PKTE_SA_IDIGEST3[127:96]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)

Table 39-22: SA Record Structure (Continued)

Word Offset	Description (name)	Use
14	PKTE_SA_IDIGEST4[159:128]	Inner Hash digest (Basic Hash and HMAC with SHA-1, SHA-224, SHA-256)
15	PKTE_SA_IDIGEST5[191:160]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)
16	PKTE_SA_IDIGEST6[223:192]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)
17	PKTE_SA_IDIGEST7[255:224]	Inner Hash digest (Basic Hash and HMAC with SHA-256)
18	PKTE_SA_ODIGEST0[31:0]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
19	PKTE_SA_ODIGEST1[63:32]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
20	PKTE_SA_ODIGEST2[95:64]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
21	PKTE_SA_ODIGEST3[127:96]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
22	PKTE_SA_ODIGEST4[159:128]	Outer Hash digest (HMAC with SHA-1, SHA-224, SHA-256)
23	PKTE_SA_ODIGEST5[191:160]	Outer Hash digest (HMAC with SHA-224, SHA-256)
24	PKTE_SA_ODIGEST6[223:192]	Outer Hash digest (HMAC with SHA-224, SHA-256)
25	PKTE_SA_ODIGEST7[255:224]	Outer Hash digest (HMAC with SHA-256)
26	PKTE_SA_SPI[31:0]	SPI (IPsec), Type[23:16] / Version [15:0] (SSL, TLS, DTLS)
27	PKTE_SA_SEQNUM0[31:0]	Sequence Number (IPsec, SSL, TLS, DTLS with Header Processing)
28	PKTE_SA_SEQNUM1[63:32]	
29	PKTE_SA_SEQNUM_MSK0[31:0]	Sequence Number Mask (IPsec, DTLS in-bound with Header Processing)
30	PKTE_SA_SEQNUM_MSK1[63:32]	
31	PKTE_SA_NONCE[31:0] / PKTE_SA_READY	Nonce value (AES-CTR, AES-ICM)/ARC4, i and j pointers (ARC4,)/SA ready indicator (Direct Host Mode)

Some of these fields may be updated by the packet engine. These include:

- PKTE_SA_SEQNUM0
- PKTE_SA_SEQNUM1
- PKTE_SA_SEQNUM_MSK0

- PKTE_SA_SEQNUM_MSK1

All the other fields remain unchanged.

SA State Structure

The security association state structure contains information that may be updated after each packet, such as the IV and the intermediate hash result. The ***SA State Structure*** table shows the SA state structure and usage. In direct host mode, the elements are accessed directly using the PKTE registers. In target command mode and autonomous ring mode, this structure is defined and updated in host memory.

Table 39-23: SA State Structure

Word Offset	Description (name)	Use
0	PKTE_STATE_IV0[31:0]	Initialization Vector (DES, Triple DES, AES)
1	PKTE_STATE_IV1[63:32]	Initialization Vector (DES, Triple DES, AES)
2	PKTE_STATE_IV2[95:64]	Initialization Vector (AES)
3	PKTE_STATE_IV3[127:96]	Initialization Vector (AES)
4	PKTE_STATE_BYTE_CNT0[31:0]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
5	PKTE_STATE_BYTE_CNT1[63:32]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
6	PKTE_STATE_IDIGEST0[31:0]	Inner Hash digest (mirror of PKTE_SA_IDIGEST0)
7	PKTE_STATE_IDIGEST1[63:32]	Inner Hash digest (mirror of PKTE_SA_IDIGEST1)
8	PKTE_STATE_IDIGEST2[95:64]	Inner Hash digest (mirror of PKTE_SA_IDIGEST2)
9	PKTE_STATE_IDIGEST3[127:96]	Inner Hash digest (mirror of PKTE_SA_IDIGEST3)
10	PKTE_STATE_IDIGEST4[159:128]	Inner Hash digest (mirror of PKTE_SA_IDIGEST4)
11	PKTE_STATE_IDIGEST5[191:160]	Inner Hash digest (mirror of PKTE_SA_IDIGEST5)
12	PKTE_STATE_IDIGEST6[223:192]	Inner Hash digest (mirror of PKTE_SA_IDIGEST6)
13	PKTE_STATE_IDIGEST7[255:224]	Inner Hash digest (mirror of PKTE_SA_IDIGEST7)

ARC4 State Structure

The ***ARC4 State Structure*** table describes the state structure used with ARC4. When using the PKTE in direct host mode, these fields are accessed with the registers, starting at the value in the `PKTE_ARC4STATE_BUF` register. When using the PKTE in autonomous ring mode or target command mode, these fields are defined and accessed in a structure in host memory.

Table 39-24: ARC4 State Structure

Word Offset	Description (name)*1	Use
0	PKTE_ARC4_STATE0[3:0]*2	ARC4 (Basic, SSL and TLS)
1	PKTE_ARC4_STATE1[7:4]	
...	...	
62	PKTE_ARC4_STATE2[251:248]	
63	PKTE_ARC4_STATE3[255:252]	

*1 The indices in these fields indicate bytes.

*2 There are no corresponding named registers for these fields. PKTE_ARC4_STATE0 corresponds to `PKTE_ARC4STATE_BUF` and PKTE_ARC4_STATE1 corresponds to the 32-bit register following `PKTE_ARC4STATE_BUF` and so on.

Configuring Operations in the PKTE

The operation (cipher, hash function, and others) that the PKTE performs is configured primarily in the `PKTE_SA_CMD0` register. The following sections include a series of tables to help configure the least significant 16 bits of the `PKTE_SA_CMD0` register. These fields include:

- The operation code field (`PKTE_SA_CMD0.OPCD`)
- The direction field (`PKTE_SA_CMD0.DIR`)
- The operation group field (`PKTE_SA_CMD0.OPGRP`)
- The padding type (`PKTE_SA_CMD0.PADTYPE`)
- The cipher selection (`PKTE_SA_CMD0.CIPHER`)
- The hash selection (`PKTE_SA_CMD0.HASH`)

Basic Operations and Decoding

Table 39-25: Basic Operation Decoding

Outbound				Inbound			
OpGroup	Dir	OpCode	Operation	OpGroup	Dir	OpCode	Operation
0b00	0	0b000	Encrypt	0b00	1	0b000	Decrypt

Error Code Description

The PKTE_CTL_STAT register is used to configure the packet engine for processing in Direct Host Mode (DHM) or Target Command Mode (TCM). The PKTE_CTL_STAT structure element in memory is used when the packet

engine is configured for Autonomous Ring Mode (ARM). In both cases, when an operation is started, errors are reported in the status field (bits [23:16]) of this register or structure element. The ***Extended Error Codes - Status Encoding*** table provides a guide on how to decipher the meaning of the bits that are set when an error occurs.

Extended Error Codes

The following table provides information about the extended errors associated with the PKTE module.

Table 39-28: Extended Error Codes - Status Encoding

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0000_0000	0x00	NA	Successful completion. No errors occurred during processing of the packet.	Packet fully processed
0b----_---1	0x-1	NA	Authentication Error. For an inbound IPsec ESP operation, the Integrity Check Value (ICV) does not match the computed value. For an inbound SRTP operation, the authentication tag does not match the computed value. For a basic SSL/TLS, Extended SSL/TLS or DTLS operation the Message Authentication Code (MAC) does not match the computed value.	Packet fully processed
0b----_--1-	0x-2	NA	Pad Verify Error. For inbound operations that use pad type Constant TLS, IPsec or PKCS#7, the decrypted pad does not match the expected values for the selected pad type.	Packet fully processed
0b----_-1--	0x-4	NA	Sequence Number Error. For an inbound IPsec or DTLS operation, there was a fault in the Anti-Replay Sequence Number. For an outbound IPsec packet, the sequence number overflows; count is 2^{32}– 1 and increments to 0. For an outbound DTLS operation, the sequence number overflows; count is 2^{48}– 1 and increments to 0. For an outbound SSL or TLS operation, the sequence number overflows; count is 2^{64}– 1 and increments to 0.	Packet fully processed
0b0000_1---	0x08	1	System Bus error. The requester bus interface generates an error due to ERROR response from system completer. The completer bus interface generates an error due to request for non-word (32-bit) access.	Packet is aborted. The host must reject the packet and apply a hardware reset to the system.

Table 39-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0001_1---	0x18	2	Invalid Command Descriptor Error. The ownership bits in the command descriptor are not set to the packet engine, after the PKTE_CDSC_CNT register is incremented.	Command descriptor is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0010_1---	0x28	3	Invalid Crypto Operation Error. A reserved operation is selected.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0011_1---	0x38	4	Invalid Crypto Algorithm Error. A reserved cipher is selected, refer to PKTE_SA_CMD0.CIPHER. A reserved hash is selected, refer to PKTE_SA_CMD0.HASH.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0100_1---	0x48	5	SPI Error. On an inbound packet, the 32-bit SPI value in the packet does not match the value in the SA while header processing is enabled. Note: A failure caused by an SPI mismatch, in general should not occur because the host checks the SPI and does not send an incorrect SPI to the packet engine.	Packet is fully processed. The host must reject the packet.
0b0101_1---	0x58	3	Zero Length Error. The packet length defined in the command descriptor PKTE_LEN.TOTLEN is zero, which is illegal.	Packet command is ignored, no packet processed. The host must reject the packet.

Table 39-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0110_1xxx	0x68	6	Invalid Packet Length Error. For Basic Encrypt-Hash and Hash-Decrypt operations: PKTE_LEN.TOTLEN < Hash/Encrypt Offset For IPsec ESP inbound operations: PKTE_LEN.TOTLEN < ICV length or PKTE_LEN.TOTLEN is non-4 byte aligned For SRTP inbound operations: PKTE_LEN.TOTLEN ≤ IV (opt.) + Bypass Offset + ROC For SSL inbound operations: PKTE_LEN.TOTLEN ≤ 1 or packet length > 65535 bytes (SSL packet-bypass length) For TLS and DTLS inbound operations: PKTE_LEN.TOTLEN ≤ 13 or payload length > 65535 bytes (data to be hashed) Note: For IPsec ESP the ICV is stripped before the length is checked.	Packet processing is aborted. Result packet length is zero. The host must reject the packet and apply a software reset of the packet engine.
0b0111_1xxx	0x78	7	Block Size Error. The length of the inbound packet defined in the Command Descriptor PKTE_LEN.TOTLEN is not a multiple of the DES or AES block cipher length. For outbound packets the size is always automatically aligned (padded) to the correct block size. The hashed packet length is not a multiple of the hash block size for intermediate hash operation. For a final hash operation no error is generated. Note: For IPsec ESP operations the ICV is stripped before the block size is checked.	Packet is fully processed. The host must reject the packet.
0b1000_1xxx	0x88	8	Processing Error. The number of bytes in the input buffer is more than defined in the PKTE_LEN.TOTLEN field. The number of bytes written to the output buffer is less than processed in the datapath.	Packet processing aborted. Result packet length is zero. The host must reject the packet and apply a software reset.
0b1010_1xxx 0b1111_1xxx	Reserved			

Number Format

When dealing with cryptographic functions, data and keys are large vectors. For instance, AES supports keys of sizes 128, 192, and 256 bits. When a key needs to be loaded or read, multiple 32-bit key registers are used, namely

PKTE_SA_KEY[n] registers. The first key register PKTE_SA_KEY[n]0 holds bits 31:0, and PKTE_SA_KEY[n]1 holds the next thirty two bits 63:32, and so on.

Generally, for large vectors defined as Byte0, Byte1, Byte2, Byte3 and so on, the values are stored in the PKTE registers as PKTE_REG0 = Byte3Byte2Byte1Byte0, followed by PKTE_REG1 = Byte7Byte6Byte5Byte4 and so on.

PKTE Programming Examples

Use these examples to extend your understanding of PKTE features, operating modes, event control, and programming modes.

Calculating SHA in Direct Host Mode

This section describes how to configure the packet engine to calculate a hash digest using one of supported SHA algorithms in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the PKTE_CFG.MODE bit =0
2. Set the ownership back to the packet engine to process a command descriptor by setting the PKTE_CTL_STAT.PERDY bit =0 and the PKTE_CTL_STAT.HOSTRDY bit =1.
3. Set the PKTE_CTL_STAT.HASHFINAL bit to indicate this command descriptor handles all the input data for the hash calculation. This configuration is needed for the packet engine because the last block requires special handling (see FIPS 180-4 for details).
4. Set size of the input data in bytes in the PKTE_LEN.TOTLEN bit field.
5. Also set the PKTE_LEN.PEDONE bit =0 and the PKTE_LEN.HSTRDY bit =1. These bits must be the same as the PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY bits to guarantee ownership.
6. Set the PKTE_CDSC_CNT register =1 to trigger the packet engine to start validating the command descriptor. In this case, the PKTE_CTL_STAT, PKTE_LEN and PKTE_CDSC_CNT registers are the only command descriptor registers modified.
7. Configure the PKTE_SA_CMD0 and PKTE_SA_CMD1 registers to define the operation. For an SHA, set the PKTE_SA_CMD0.OPCD bit field =0b011 for hash operation and the PKTE_SA_CMD0.OPGRP bit field =0b00 for basic operation.
8. Select the specific SHA function using the PKTE_SA_CMD0.HASH bit field as follows.
    - For SHA-1, PKTE_SA_CMD0.HASH =0b0001
    - SHA-224, PKTE_SA_CMD0.HASH =0b0010
    - for SHA-256, PKTE_SA_CMD0.HASH =0b0011
9. Depending on the SHA selected, the appropriate digest length must be chosen for the PKTE_SA_CMD0.DIGESTLEN bit field as follows.

- For SHA-1, PKTE_SA_CMD0.DIGESTLEN =0b0101 (5 words)
- For SHA-224, PKTE_SA_CMD0.DIGESTLEN =0b0111 (7 words)
- For SHA-256, PKTE_SA_CMD0.DIGESTLEN =0b1000 (8 words)

10. The SHA specifies initial constants. These constants can be pre-loaded or read from memory. In this example, by setting the PKTE_SA_CMD0.HASHSRC bit field =0b11, the packet engine provides the correct initial constants depending on the SHA chosen.
11. Next, set the PKTE_SA_CMD1.CPYDGST bit =1 and PKTE_SA_CMD1.CPYPAD bit =1 to move the result to the output buffer of the packet engine at the PKTE_DATAIO_BUF location.
12. At this point, write to the PKTE_SA_RDY register with any value to trigger the operation.
13. Start writing the input to the data buffer of the packet engine starting at the PKTE_DATAIO_BUF location.
14. Write the PKTE_INBUF_CNT register with the length of the input rounded up to the next multiple of 4. For example, if the input length is 30 bytes, set this register to 32.
15. Poll the PKTE_STAT register to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the digest is available in the packet engine data I/O buffer.

NOTE: The input data or message is input into the packet engine data buffer in big endian format while the result or digest is little endian format.

Performing AES Decryption in Direct Host Mode

This section describes how to configure the packet engine to decrypt using AES-128 in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the PKTE_CFG.MODE bit =0
2. Start configuring the command descriptor registers. Set the ownership back to the packet engine to process a command descriptor by setting the PKTE_CTL_STAT.PERDY bit =0 and the PKTE_CTL_STAT.HOSTRDY bit =1.
3. Next, configure the PKTE_LEN.TOTLEN bit field with the size of the packet or message to decrypt. If the entire input message (cipher text) fits into the 256-byte data I/O buffer of the packet engine, the process can be done in one shot.
4. Set the PKTE_LEN.PEDONE bit =0 and the PKTE_LEN.HSTRDY bit =1. These bits must have the same setting as the PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY bits to guarantee ownership.
5. Set the PKTE_CDSC_CNT register =1 to trigger the packet engine to start validating the command descriptor. In this case, the PKTE_CTL_STAT, PKTE_LEN, and PKTE_CDSC_CNT registers are the only command descriptor registers modified.
6. Next, configure the PKTE_SA_CMD0 and PKTE_SA_CMD1 registers to define the operation.

- For a AES decrypt inbound cipher operation, set the PKTE_SA_CMD0.OPCD bit field =0b000 and the PKTE_SA_CMD0.DIR bit field =0b1.
- Set thePKTE_SA_CMD0.OPGRP bit field =0b00 for basic operation.
- To choose the AES cipher, set the PKTE_SA_CMD0.CIPHER bit field =0b0011. Set the PKTE_SA_CMD0.HASH bit field to 0b1111 to choose the NULL function.

7. Next, set the PKTE_SA_CMD1.AESKEYLEN bit field to select the appropriate key length. In this case, setting it to 0b10 select 128 bits. Also, set PKTE_SA_CMD1.CIPHERMD bit field to select the mode. In this case, setting it to 0b01 select CBC mode.
8. Continue configuring the Security Association (SA) record by loading the key in the PKTE_SA_KEY[n] registers.
9. Next load the initialization vector in the SA state registers (PKTE_STATE_IV[n]).
10. Finally, write anything in to the PKTE_SA_RDY register to trigger the operation.
11. The input data can now be written into the data I/O buffer starting at PKTE_DATAIO_BUF.
12. After the data is written, write the length (or next multiple of 4) into PKTE_INBUF_CNT register.
13. Poll PKTE_STAT to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the result can be found in the same data I/O buffer.

ADSP-2159x_SC591_SC592_SC594 PKTE Register Descriptions

Security Packet Engine (PKTE) contains the following registers.

Table 39-29: ADSP-2159x_SC591_SC592_SC594 PKTE Register List

Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register

Table 39-29: ADSP-2159x_SC591_SC592_SC594 PKTE Register List (Continued)

Name	Description
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers

Table 39-29: ADSP-2159x_SC591_SC592_SC594 PKTE Register List (Continued)

Name	Description
PKTE_SA_NONCE	SA Initialization Vector Register
PKTE_SA_ODIGEST[n]	SA Outer Hash Digest Registers
PKTE_SA_RDY	SA Ready Indicator
PKTE_SA_SEQNUM[n]	SA Sequence Number Register
PKTE_SA_SEQNUM_MSK[n]	SA Sequence Number Mask Registers
PKTE_SA_SPI	SA SPI Register
PKTE_SRC_ADDR	Packet Engine Source Address
PKTE_STAT	Packet Engine Status Register
PKTE_STATE_ADDR	Packet Engine State Record Address
PKTE_STATE_BYTE_CNT[n]	State Hash Byte Count Registers
PKTE_STATE_IDIGEST[n]	State Inner Digest Registers
PKTE_STATE_IV[n]	State Initialization Vector Registers
PKTE_USERID	Packet Engine User ID

Packet Engine ARC4 State Record Address

The PKTE_ARC4STATE_ADDR register holds the start address of the SA ARC4 state record.

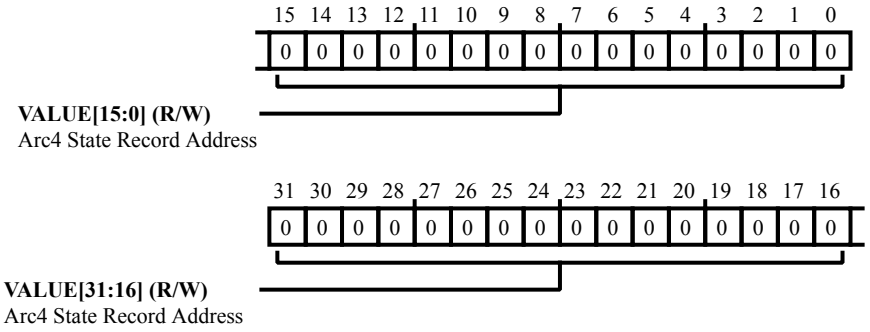

Figure 39-4: PKTE_ARC4STATE_ADDR Register Diagram

Table 39-30: PKTE_ARC4STATE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Arc4 State Record Address.

Starting Entry of 256-byte ARC4 State Buffer

The PKTE_ARC4STATE_BUF register is used to store the pre-processed key that initializes the ARC4 module. In direct host mode, before processing starts, the Host must write the ARC4 state, starting from the base address and increment the address pointer for each write. When processing completes the Host must read the ARC4 state and copy it to the local Host maintained state record. After a reset, a read from any address in the address range of the ARC4 buffer returns an undefined value.

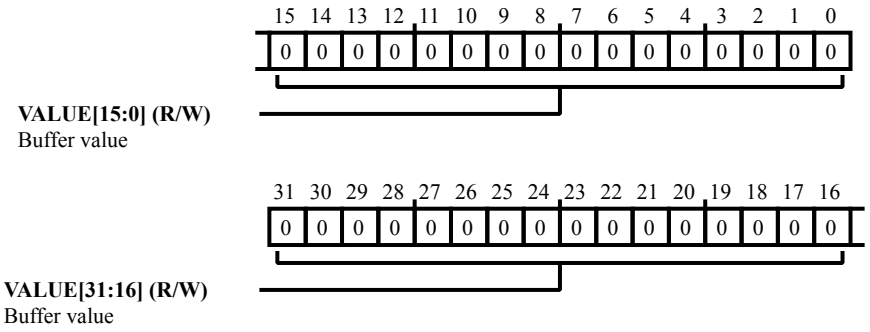

Figure 39-5: PKTE_ARC4STATE_BUF Register Diagram

Table 39-31: PKTE_ARC4STATE_BUF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Buffer value. The PKTE_ARC4STATE_BUF.VALUE bit field stores the pre-processed key that initializes the ARC4 module.

Packet Engine Buffer Pointer Register

The PKTE_BUF_PTR register contains the offset of the next buffer address (entry) to be read or written by the packet engine. This register is used in direct host mode only.

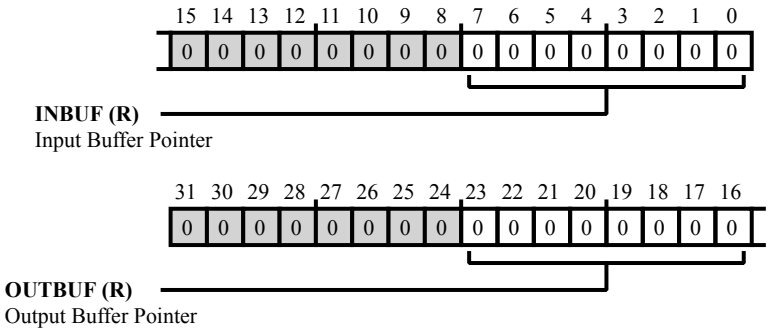

Figure 39-6: PKTE_BUF_PTR Register Diagram

Table 39-32: PKTE_BUF_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	OUTBUF	Output Buffer Pointer. The PKTE_BUF_PTR.OUTBUF bit field indicates the offset of the next address (entry) in the output buffer that will be written next by the packet engine. This bit field is reset to zero after starting up and decremented by 4 at every output buffer write operation. Pointers wrap around; the maximum value this field can have equals the output buffer size minus 4.
7:0 (R/NW)	INBUF	Input Buffer Pointer. The PKTE_BUF_PTR.INBUF bit field indicates the offset of the next address (entry) in the input buffer that will be read next by the packet engine. The bit field is reset to zero after starting up and incremented by 4 at every input buffer read operation. Pointers wrap around; the maximum value this field can have equals the input buffer size minus 4.

Packet Engine Buffer Threshold Register

When in autonomous ring mode or target command mode, the PKTE_BUF_THRESH register defines the high- and low-level value at which the packet engine starts to transfer packet data in or out of the internal packet buffers. These parameters can be used to control the DMA burst size for packet data input and output from the packet engine. In direct host mode, this register contains both threshold values to reduce the amount of packet engine interrupts.

The input buffer threshold (ibufthrsh) interrupt indicates that the input buffer counter is less than or equal to the input buffer threshold value set in this register - this interrupt can be used to wake up a process that stalled on a full input buffer.

The output buffer threshold (obufthrsh) interrupt indicates that the output buffer counter exceeds the output buffer threshold setting. The output buffer interrupt remains active until the output buffer counter is decremented to zero again.

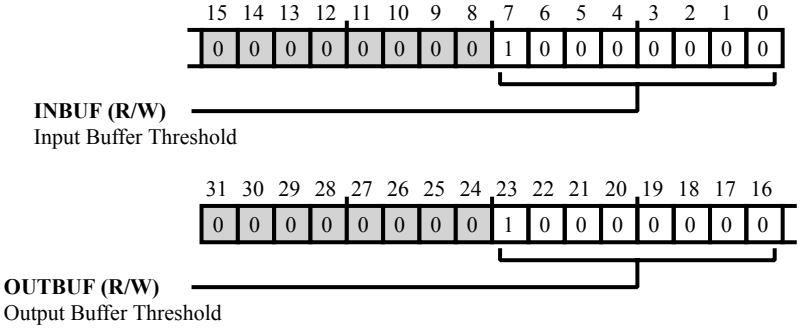

Figure 39-7: PKTE_BUF_THRESH Register Diagram

Table 39-33: PKTE_BUF_THRESH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	OUTBUF	Output Buffer Threshold. The PKTE_BUF_THRESH.OUTBUF bit field specifies how many bytes must be available in the packet engine output buffer before an output transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the output buffer threshold (obufthrsh) interrupt activates when the output buffer counter for the output buffer exceeds the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Table 39-33: PKTE_BUF_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	INBUF	Input Buffer Threshold. The `PKTE_BUF_THRESH.INBUF` bit field specifies how many bytes must be free in the packet engine input buffer before an input transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the input buffer threshold (ibufthrsh) interrupt activates when the input buffer counter for the input buffer is below or equal the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Packet Engine Command Descriptor Ring Base Address

The PKTE_CDRBASE_ADDR register holds the command descriptor ring base address in host memory. It is only applicable in autonomous ring mode. The PKTE_CDRBASE_ADDR register is ignored for all other modes when command descriptors are directly written into the descriptor registers.

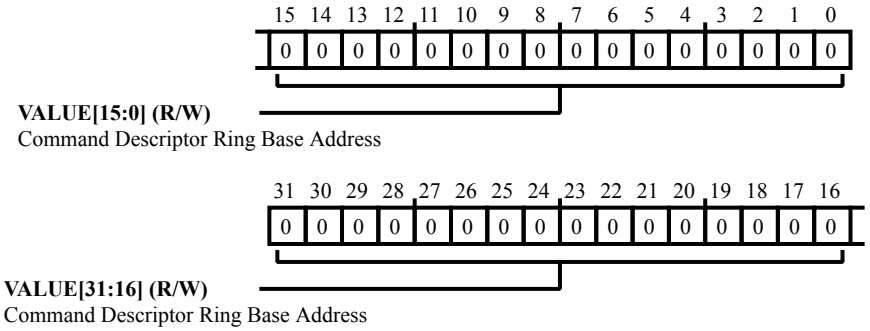

Figure 39-8: PKTE_CDRBASE_ADDR Register Diagram

Table 39-34: PKTE_CDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor Ring Base Address. The PKTE_CDRBASE_ADDR.VALUE bit field specifies the base location of the command descriptor ring in the host memory space.

Packet Engine Command Descriptor Count Register

The PKTE_CDSC_CNT register holds the counter for the number of descriptors in the Command Descriptor Ring (CDR). It is decremented by the packet engine each time a valid descriptor is read from the CDR and processed.

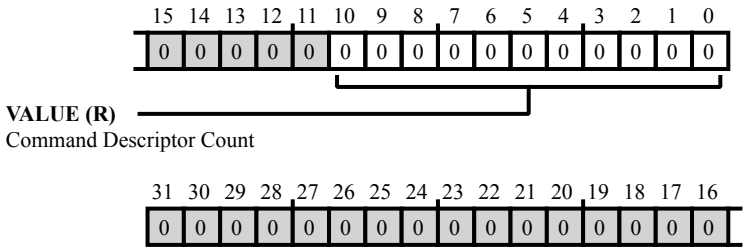

Figure 39-9: PKTE_CDSC_CNT Register Diagram

Table 39-35: PKTE_CDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Command Descriptor Count. The PKTE_CDSC_CNT.VALUE bit field provides the number of command descriptors in the command descriptor ring. The packet engine decrements the counter when a valid command descriptor is read from the CDR and processed.

Packet Engine Command Descriptor Count Increment Register

The PKTE_CDSC_INCR register is accessible by the host connected through the system slave bus. The host can increment the command descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

In autonomous ring mode, the host must prepare 1 to 255 valid command descriptors in the CDR and then write this register with a value between 1 and 255. The write triggers the packet engine to fetch the command descriptors from the CDR. In direct host mode or target command mode, the host must write one valid command descriptor to the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is available.

A CDR threshold interrupt is activated when the command descriptor counter is less than or equal to the threshold value set in the PKTE_RING_THRESH register. This interrupt can be used to wake up a process that stalled on a full CDR.

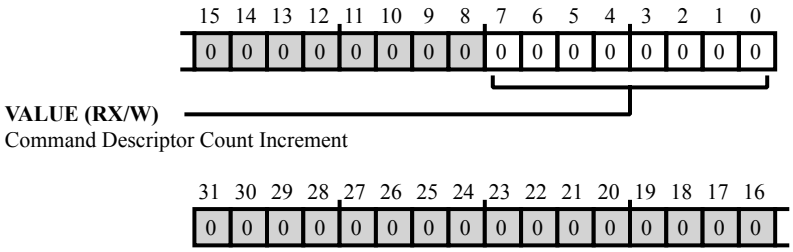

Figure 39-10: PKTE_CDSC_INCR Register Diagram

Table 39-36: PKTE_CDSC_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Command Descriptor Count Increment. The value written to the PKTE_CDSC_INCR.VALUE bit field is added to the command descriptor counter. The counter is protected against overflow (see the PKTE_RING_STAT register description). Note that bits[10:8] should be written with zeros.

Packet Engine Configuration Register

The PKTE_CFG register is used to select static settings that control the packet-processing path. This register is typically the last one to be written during the initialization sequence. These settings are typically set at initialization and not changed again.

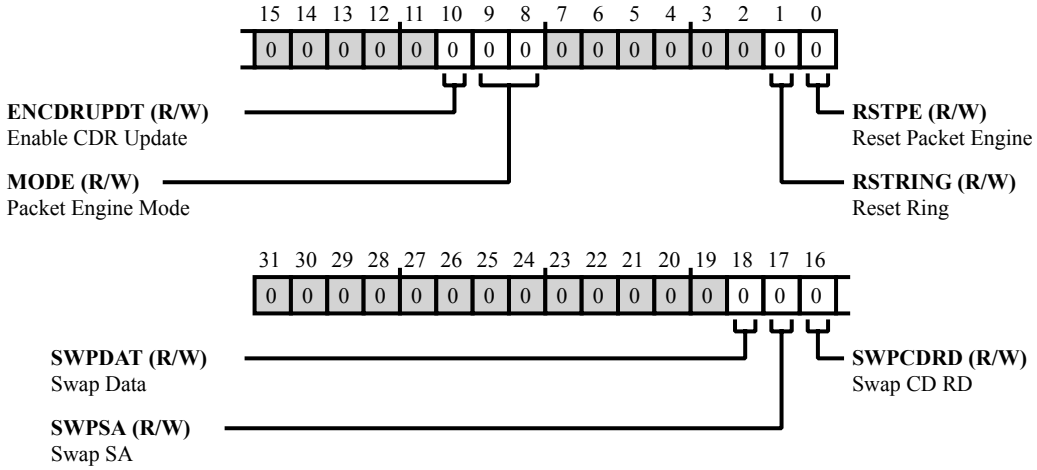

Figure 39-11: PKTE_CFG Register Diagram

Table 39-37: PKTE_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	SWPDAT	Swap Data. The PKTE_CFG.SWPDAT bit enables endian swap for packet data as configured in the PKTE_ENDIAN_CFG.MSTRBSWP bits for the packet data DMA read and write.	
		0	No Endian Swap
		1	Apply Endian Swap
17 (R/W)	SWPSA	Swap SA. The PKTE_CFG.SWPSA bit enables endian swap for a SA record as configured in the PKTE_ENDIAN_CFG.MSTRBSWP bits for the SA record and state record DMA read and write. If the PKTE_ENDIAN_CFG.MSTRBSWP bits specify no endian swap, this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap

Table 39-37: PKTE_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	SWPCDRD	Swap CD RD. The PKTE_CFG.SWPCDRD bit enables endian swap for descriptors as configured in the PKTE_ENDIAN_CFG.MSTRBSWP bits for the command descriptor DMA read and result descriptor DMA write. If the PKTE_ENDIAN_CFG.MSTRBSWP bits specify no endian swap, this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap
10 (R/W)	ENCDRUPDT	Enable CDR Update. The PKTE_CFG.ENCDRUPDT bit enables the packet engine to update, (clear the ownership bits) in the command descriptor in the CDR.	
		0	Do Not Clear Ownership Bits. The packet engine does not clear the ownership bits in the command descriptor when it completes an operation. The host application must clear the ownership bits in "old descriptors" before the packet engine is allowed to wrap around the CDR to re-encounter these "old descriptors". This setting has the advantage of eliminating a separate DMA write to the CDR.
		1	Clear Ownership Bits. The packet engine clears (set to zero) the ownership bits in the current command descriptor in the CDR. This prevents the packet engine from re-processing an "old descriptor" when it wraps around the CDR.
9:8 (R/W)	MODE	Packet Engine Mode. The PKTE_CFG.MODE bit field selects how the packet engine receives commands.	
		0	Direct Host Mode.
		1	Target Command Mode with Result Descriptor Ring Disabled.
		2	Target Command Mode with Result Descriptor Ring Enabled.
		3	Autonomous Ring Mode

Table 39-37: PKTE_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	RSTRING	Reset Ring. The PKTE_CFG.RSTRING bit resets the internal counters for the CDR and RDR, PKTE_CDSC_CNT and PKTE_RDSC_CNT registers) to zero. Resets the PKTE_RING_PTR register to the base address. After the reset the rings are empty. This bit must be written with a '1' to reset the descriptor ring manager and then re-written with a '0' to release the reset. Note that this bit can remain in the reset state if the CDR ring is disabled (PKTE_CFG.MODE is not 0b11). Note that this reset must be coordinated with the 'owner' of the descriptor ring to ensure that the pointers are in sync after the reset.	
		0	Release the Descriptor Ring Manager Reset
		1	Reset the Descriptor Ring Manager
0 (R/W)	RSTPE	Reset Packet Engine. The PKTE_CFG.RSTPE bit resets the packet engine and the state machine logic that drives header processing, DMA, and context management. The PKTE_CFG.RSTPE bit resets the PKTE_CTL_STAT and PKTE_LEN internal registers. This bit must be written with a 1 to reset the packet engine and then re-written with a 0 to release the reset. Note that this bit should not be used by a typical application. It is provided to use during development testing or to recover from critical errors. Note that the PKTE_CTL_STAT.PADVAL and PKTE_CTL_STAT.PADCTLSTAT bit fields are only reset when in autonomous ring mode, but the PKTE_CTL_STAT.PRNGMD bit is not reset. Halt mode is not affected by this reset as well. When exiting out of halt mode, a HW reset is required or a write to the PKTE_CONT register.	
		0	Release the Packet Engine Reset
		1	Reset the Packet Engine

PE Clock Control Register

The PKTE_CLK_CTL register controls the clock enable signals. This register can be used to enable the clock for read and write access to SA registers or to enable the required clock signals for certain crypto functions. The setting of this register overrides the packet engine dynamic clock enable.

In autonomous ring mode and target command modes, this register can be all zeros; the packet engine dynamically requests the external clock manager to activate the module clocks. This register can be used in combination with the debugging interface for internal register access.

In direct host mode, the clock enable bits for the packet engine (PKTE_CLK_CTL.ENPECLK) and for ARC4 (PKTE_CLK_CTL.ENARC4CLK) must be enabled to write and read the SA record and state record registers. All module clocks that are required for the current operation must be enabled during processing.

Note that all the clocks are enabled by default to reset all the registers within the packet engine. After a system reset the host can program this register to disable clocks for power reduction.

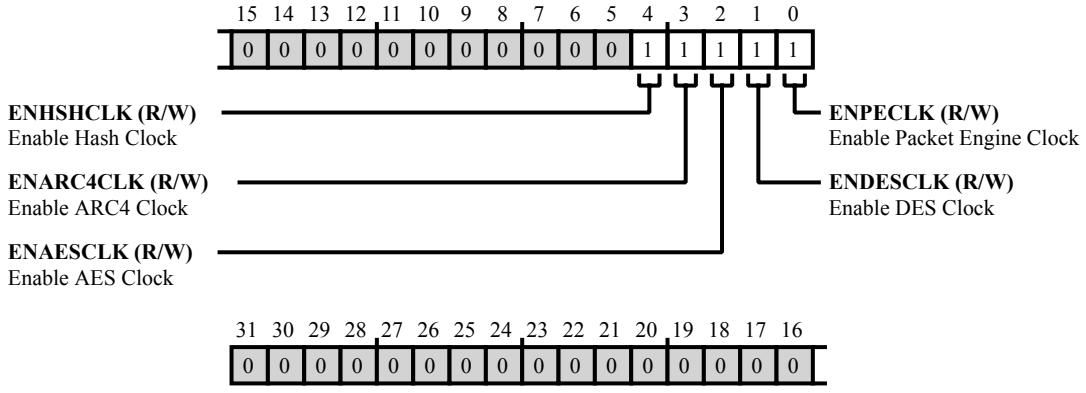

Figure 39-12: PKTE_CLK_CTL Register Diagram

Table 39-38: PKTE_CLK_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	ENHSHCLK	Enable Hash Clock. The PKTE_CLK_CTL.ENHSHCLK bit enables the clock to the hash functions.	
		0	Do not enable the hash clock
		1	Enable the hash clock
3 (R/W)	ENARC4CLK	Enable ARC4 Clock. The PKTE_CLK_CTL.ENARC4CLK bit enables the clock to the ARC4 function.	
		0	Do not enable the ARC4 clock
		1	Enable the ARC4 clock

Table 39-38: PKTE_CLK_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	ENAESCLK	Enable AES Clock. The `PKTE_CLK_CTL.ENAESCLK` bit enables the clock to the AES encrypt/decrypt function.	
		0	Do not enable the AES clock
		1	Enable the AES clock
1 (R/W)	ENDESCLK	Enable DES Clock. The `PKTE_CLK_CTL.ENDESCLK` bit enables the clock to the DES function.	
		0	Do not enable the DES clock
		1	Enable the DES clock
0 (R/W)	ENPECLK	Enable Packet Engine Clock. The `PKTE_CLK_CTL.ENPECLK` bit enables the clock in the PKTE data path.	
		0	Do not enable the PKTE data path clock
		1	Enable the PKTE data path clock

PKTE Continue Register

A write to the PKTE_CONT register (with any value) releases the packet engine from a halt state when in halt mode.

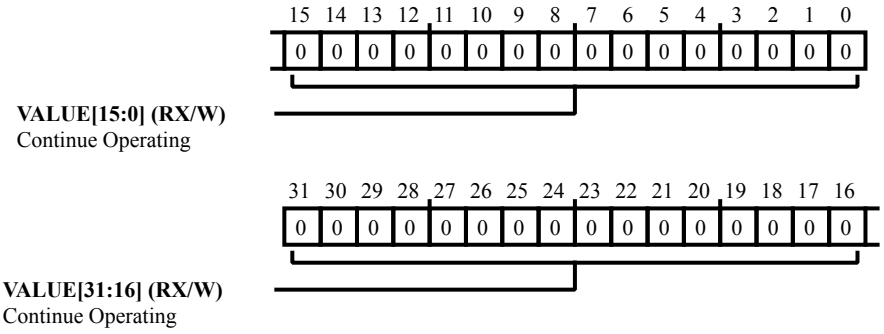

Figure 39-13: PKTE_CONT Register Diagram

Table 39-39: PKTE_CONT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Continue Operating. The PKTE_CONT.VALUE bit field releases the packet engine from a halt state when written with any value in halt mode.

Packet Engine Control Register

The PKTE_CTL_STAT register has a dual function. Together with the data in the SA, this register provides the basic command information for the packet engine to process a packet. When the packet engine successfully or unsuccessfully completes an operation, the packet engine control/status register provides the result status for the host.

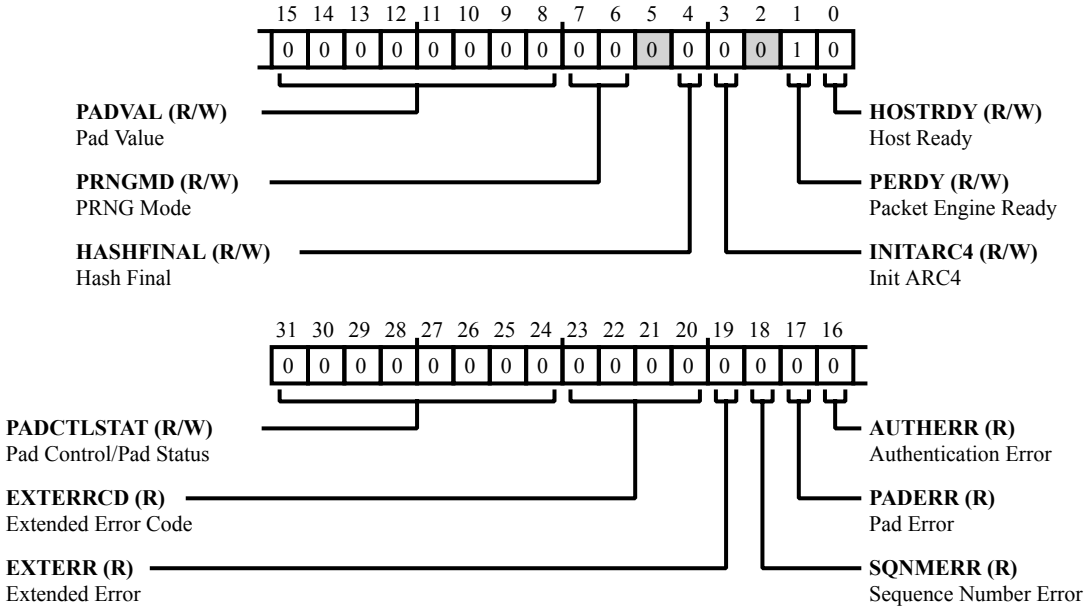

Figure 39-14: PKTE_CTL_STAT Register Diagram

Table 39-40: PKTE_CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PADCTLSTAT	Pad Control/Pad Status. The PKTE_CTL_STAT.PADCTLSTAT bit field is used to control the pad boundary for pad insertion (outbound) and after processing returns the number of inserted (outbound) or detected (inbound) pad bytes. For the command descriptor, the enumerations below provide the codes for the pad boundary for the outbound operations. This can be used for traffic flow security to conceal the number of payload bytes in an encrypted packet. For the result descriptor inbound operations that use pad types SSL, TLS, IPsec or PKCS#7, it returns the number of detected pad bytes. For all other inbound operations, it returns zero since the other pad modes do not allow implicit determination of pad count. If a pad verify failure occurs, it returns zero. For an outbound operation, it returns the number of inserted pad bytes for all pad types. The pad value includes added bytes such as the pad length and the next header field in an IPsec ESP pad type.	
		0	Align packet end to modulo 8-byte boundary
		1	Align packet end to modulo 1-byte boundary

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Align packet end to modulo 4-byte boundary
		4	Align packet end to modulo 8-byte boundary
		8	Align packet end to modulo 16-byte boundary
		16	Align packet end to modulo 32-byte boundary
		32	Align packet end to modulo 64-byte boundary
		64	Align packet end to modulo 128-byte boundary
		128	Align packet end to modulo 256-byte boundary
23:20 (R/NW)	EXTERRCD	Extended Error Code. The PKTE_CTL_STAT.EXTERRCD bit field represents an encoded error condition.	
19 (R/NW)	EXTERR	Extended Error. The PKTE_CTL_STAT.EXTERR bit field provides an extended error code.	
		0	No Extended Error
		1	Extended Error
18 (R/NW)	SQNMERR	Sequence Number Error. The PKTE_CTL_STAT.SQNMERR bit indicates that for an inbound operation, there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition.	
		0	No Sequence Number Error
		1	Sequence Number Error
17 (R/NW)	PADERR	Pad Error. The PKTE_CTL_STAT.PADERR bit indicates that for an inbound operation the decrypted pad does not match the expected values.	
		0	No Pad Error
		1	Pad Error
16 (R/NW)	AUTHERR	Authentication Error. The PKTE_CTL_STAT.AUTHERR bit indicates that for an inbound operation the authentication value in the packet does not match the computed value.	
		0	No Authentication Error
		1	Authentication Error

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	PADVAL	Pad Value. The PKTE_CTL_STAT.PADVAL bit field is used to pass the pad value between the host and the packet engine. Command Descriptor: (write-only) For outbound operations that use pad type IPsec, the host must populate this field with the value that is to be inserted into the next header field. For the IPsec ESP operation, this next header is part of the ESP trailer of the innermost operation's header and the value must be 50 decimal. For outbound encrypt operations that use the pad type constant or constant SSL, the host must specify the fixed constant value in this field. For all other outbound and inbound operations, this field is not used. Result Descriptor: (read only) For inbound operations that use pad type IPsec, the packet engine returns the next header field that it detects. For IPsec ESP inbound operations, this is the next header field in the innermost operation's header, which will typically be the value for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other outbound operations, the packet engine will not update this field. For all other inbound operations, the returned pad value is zero.	
7:6 (R/W)	PRNGMD	PRNG Mode. The PKTE_CTL_STAT.PRNGMD bits select the pseudo-random number generator mode.	
		0	Operation does not use the PRNG function. Operation does not use the PRNG function.
		1	PRNG Init. PRNG is initialized with a SEED, KEY and an LFSR value as defined in the SA.
		2	PRNG Generate. Pseudo-random data is generated with the LFSR as input value. Before this mode can be used, the PRNG must be initialized with a valid SEED, KEY and LFSR using PRNG Init (PKTE_CTL_STAT.PRNGMD=b'01).
		3	PRNG Test. It can be used to test the PRNG function with custom input data. Before this mode can be used, the PRNG must be initialized once with a valid SEED using PRNG Init (PKTE_CTL_STAT.PRNGMD=b'01).

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	HASHFINAL	Hash Final. When the PKTE_CTL_STAT.HASHFINAL bit is zero, the data to be hashed must be a multiple of the hash block size, 64 bytes for SHA-1, MD5, SHA-224, SHA-256. This bit is only applicable for Basic Hash, Basic Encrypt-Hash and Basic Hash-Decrypt operations that use the SHA-1, MD5, SHA-224, SHA-256 hash algorithm. The PKTE_CTL_STAT.HASHFINAL bit is overruled for HMAC operations that always completes the hash and always returns the last written value on a read by the host.	
		0	Perform Intermediate Hash Operation. The packet engine performs an intermediate hash operation by generating an intermediate hash digest on the data presented on the input. No hash pad is applied.
		1	Perform Final Hash Operation. The packet engine appends the required final hash pad and generates the final hash digest on the data presented on the input. This completes the hash operation.
3 (R/W)	INITARC4	Init ARC4. The PKTE_CTL_STAT.INITARC4 bit initializes the ARC4 crypto algorithm with a new key. This bit always returns the last written value on a read by the Host. This bit is only applicable for operations that use the ARC4 algorithm and must be zero for all other operations.	
		0	Load ARC4 State and ARC4 i/j pointer from the SA The ARC4 State and ARC4 i/j pointer are loaded from the SA to continue the encrypt/decrypt processing from the previous algorithm state.
		1	Read ARC4 key from the SA-record and initialize ARC4 S-boxes using this key The ARC4 key is read from the SA-record, the ARC4 S-boxes are initialized using this key, prior to the encryption/decryption of data. This bit overrules Stateful mode as defined in bits [9:8] of PKTE_SA_CMD1.
1 (R/W)	PERDY	Packet Engine Ready. The PKTE_CTL_STAT.PERDY bit indicates that the packet engine has completed processing the command descriptor and returns the result descriptor with ownership set to the host. This bit can be reset to 0 by the host and the packet engine, but only the packet engine can set this bit. When the packet engine is idle (not processing), this bit always returns '1' on a read by the host.	

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	HOSTRDY	Host Ready. The `PKTE_CTL_STAT.HOSTRDY` bit indicates that the host has populated the command descriptor. This bit can be reset to 0 by the host and the packet engine, but only the host can set this bit. When the packet engine is idle (not processing), this bit always returns '0' on a read by the host.

Starting Entry of 256-byte Data Input/Output Buffer

When in direct host mode, the source packet data is written here to be transferred to the packet engine. The host can monitor the available space in the input buffer through the PKTE_STAT register. This is also the location in the packet engine from where output data is read when in direct host mode. The host can monitor the available bytes in the output buffer through the PKTE_STAT register.

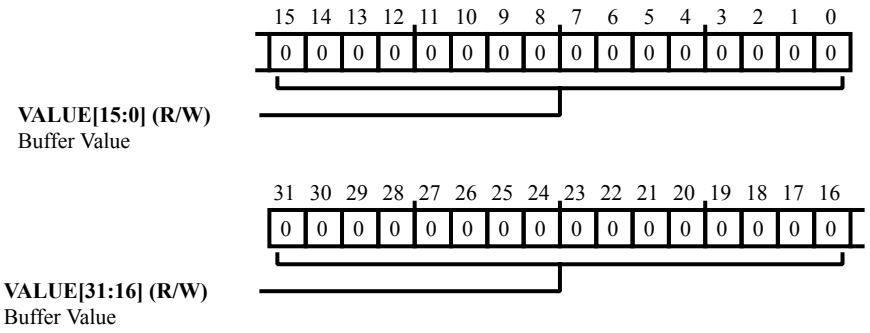

Figure 39-15: PKTE_DATAIO_BUF Register Diagram

Table 39-41: PKTE_DATAIO_BUF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Buffer Value.

Packet Engine Destination Address

The PKTE_DEST_ADDR register holds the starting (byte) address to write the result packet from the requested operation.

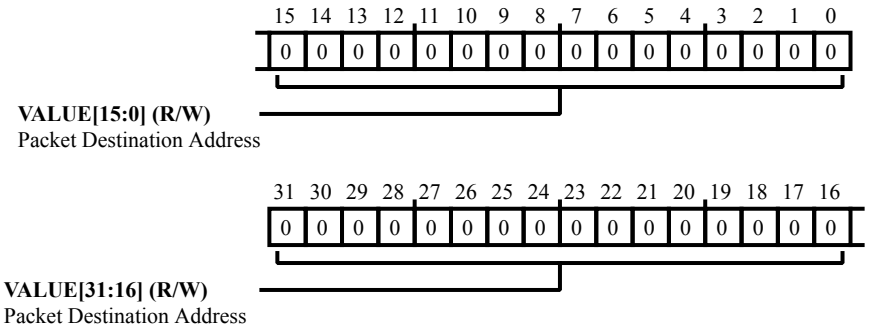

Figure 39-16: PKTE_DEST_ADDR Register Diagram

Table 39-42: PKTE_DEST_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Packet Destination Address.

Packet Engine DMA Configuration Register

The PKTE_DMA_CFG register configures the maximum burst transfer size, enables incremental transfers, and insertions IDLE cycles between two bus transfers.

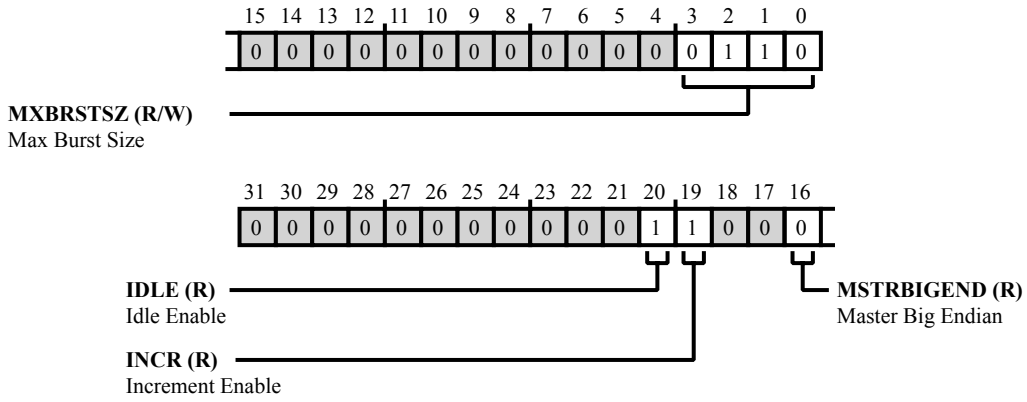

Figure 39-17: PKTE_DMA_CFG Register Diagram

Table 39-43: PKTE_DMA_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	IDLE	Idle Enable. The PKTE_DMA_CFG.IDLE bit allows the peripheral bus master to insert one additional IDLE transfer between two successive peripheral bus master burst operations. This provides the arbiter one additional cycle to hand over the grant to another peripheral bus master.	
		0	The peripheral bus master inserts no IDLE cycle between two successive burst operations
		1	The peripheral bus master inserts one additional IDLE transfer between two successive burst operations

Table 39-43: PKTE_DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	INCR	Increment Enable. The PKTE_DMA_CFG.INCR bit lets the peripheral bus master generate INC4, INC8 and INC16 type of burst transfers. By default, the peripheral bus master generates the largest possible incremental burst of unspecified length (INCR) with a maximum length (in bytes) as configured by the PKTE_DMA_CFG.MXBRSTSZ bit field. In case there are less than 4 bytes of data available or the 1kB boundary will be crossed using a burst operation, then a single transfer of size byte is generated. When the PKTE_DMA_CFG.INCR bit is set, the peripheral bus master generates one or more incremental burst of specified length (INC4, INC8, INC16). In case there is less data available then the smallest possible burst (INC4) or the 1kB boundary will be crossed using a burst operation, then an unspecified length burst or a single transfer of size byte is generated.	
		0	The bus master will generate only INCR burst types
		1	The bus master will generate INC4, INC8 and INC16 burst types
16 (R/NW)	MSTRBIGEND	Master Big Endian. The PKTE_DMA_CFG.MSTRBIGEND bit determines whether the engine is used in a little or big endian system.	
		0	Little endian
		1	Big endian
3:0 (R/W)	MXBRSTSZ	Max Burst Size. The PKTE_DMA_CFG.MXBRSTSZ bit field configures the maximum size of an unspecified length burst (INC) at the bus in bytes. When there is less data available than the PKTE_DMA_CFG.MXBRSTSZ bit field setting or the 1kB boundary will be crossed using a burst operation, then the length of the burst can be less than PKTE_DMA_CFG.MXBRSTSZ. Any requested transfers larger than this size are broken up in to multiple burst transfers of this size or less.	

Packet Engine Endian Configuration Register

The packet engine incorporates a powerful interface specific endian handler. This endian handler allows byte lane swapping in each direction for data passing through the host interface.

The PKTE_ENDIAN_CFG register configures the byte order function for the peripheral bus master and peripheral bus slave interface. The bits for the peripheral bus master are combined in four sets of two bits; each group configures a byte swap function for a particular DMA transfer. The same applies for the peripheral bus slave interface.

The PKTE_ENDIAN_CFG register also defines the endian swapping that occurs for host-initiated target transfers and for packet engine master DMA read and write transfers. Individual endian swap enable bits in the configuration (PKTE_CFG) register can enable the endian swap for various transaction types: command descriptors and result descriptors, SA records and state records, packet data.

In direct host mode, only target operations are supported. Only the target endian configuration of this register is applicable.

Note: This register is typically programmed once during the initialization phase, although software is allowed to dynamically change the setting in this register just before initiating a data transfer. The developer will have to analyze the benefit of the cycles needed to write the endian register dynamically versus handling endian swapping for some data structures in the host system (most modern processors support a byte swap in zero cycles). Certainly the endian swap should be set correctly for the packet data, since this represents the majority of the data transferred.

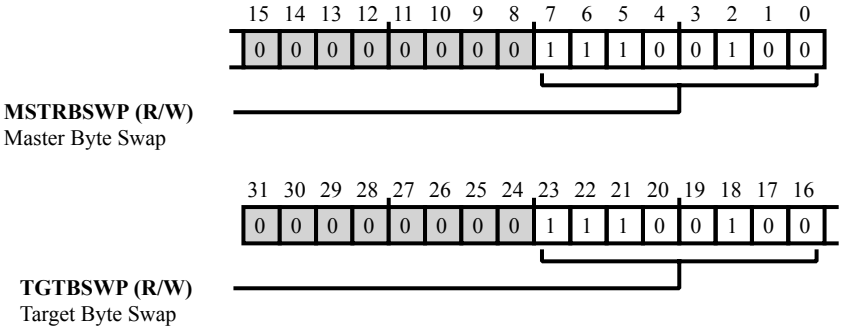

Figure 39-18: PKTE_ENDIAN_CFG Register Diagram

Table 39-44: PKTE_ENDIAN_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	TGTBSWP	Target Byte Swap. The PKTE_ENDIAN_CFG.TGTBSWP bit field configures the byte swap for peripheral bus target transfers. Note that only target word transfers are supported. Each double-bit field in this register specifies the source of the indicated byte lane. The field values are interpreted as follows: 00 = byte 0, 01 = byte 1, 10 = byte 2, 11 = byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).

Table 39-44: PKTE_ENDIAN_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MSTRBSWP	Master Byte Swap. The PKTE_ENDIAN_CFG.MSTRBSWP bit field configures the byte swap for peripheral bus master multi-byte transfers, including command descriptors, result descriptors, SA records, state records and packet data. Separate controls in the PKTE_CFG register can enable this swap individually for each of the 4 types of data. Each double-bit field in this register specifies the source of the indicated peripheral bus byte lane. The field values are interpreted as follows: 00=byte 0, 01=byte 1, 10=byte 2, 11=byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).

Packet Engine Halt Control Register

Th PKTE_HLT_CTL register controls the packet engine halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. During the halt mode, the host can read all internal registers for examination without side-effects. When halted, the host should not write to any registers. To continue packet engine operation, the host must write to the PKTE_CONT (PKTE continue) register.

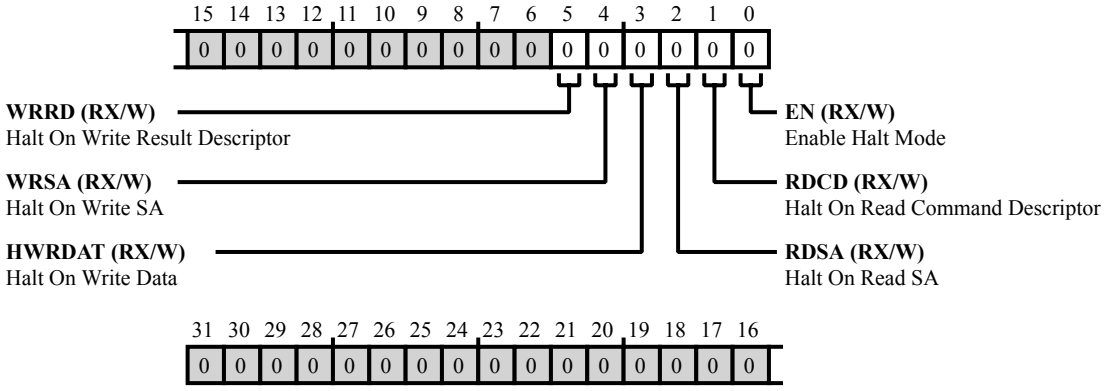

Figure 39-19: PKTE_HLT_CTL Register Diagram

Table 39-45: PKTE_HLT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	WRRD	Halt On Write Result Descriptor. The PKTE_HLT_CTL.WRRD bit halts the packet engine in the HALT_WRITE_STATUS state after it completes a result descriptor write operation to the result descriptor ring. The host can use this bit to examine the result descriptor that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
4 (RX/W)	WRSA	Halt On Write SA. The PKTE_HLT_CTL.WRSA bit halts the packet engine in the HALT_WRITE_SA state after it completes an SA write operation to the host memory. The host can use this bit to examine the security context that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation

Table 39-45: PKTE_HLT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RX/W)	HWRDAT	Halt On Write Data. The PKTE_HLT_CTL.HWRDAT bit halts the packet engine in the HALT_DATA state after it completes writing the result packet data to the host memory. The host can use this bit to examine the result packet that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
2 (RX/W)	RDSA	Halt On Read SA. The PKTE_HLT_CTL.RDSA bit halts the packet engine in the HALT_READ_SA state after it completes an SA read operation from the host memory. The host can use this bit to examine the security context that is currently in the SA registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
1 (RX/W)	RDCD	Halt On Read Command Descriptor. The PKTE_HLT_CTL.RDCD bit halts the packet engine in the HALT_READ_DESCR state after it completes a command descriptor read operation from the command descriptor ring. It will halt whether the descriptor is valid or invalid. The host can use this bit to examine the command descriptor that is currently in the internal command descriptor registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
0 (RX/W)	EN	Enable Halt Mode. The PKTE_HLT_CTL.EN bit enables halt mode where the packet engine can halt processing at any processing state as indicated by bits [5:1]. When halted, the packet engine continues operation on a write to the PKTE_CONT register.	
		0	Do not enable halt mode
		1	Enable halt mode

Packet Engine Halt Status Register

The PKTE_HLT_STAT register reflects the status of the packet engine in halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. When the packet engine is halted, the host can read all internal registers for examination without side effects. The host should not write to any registers.

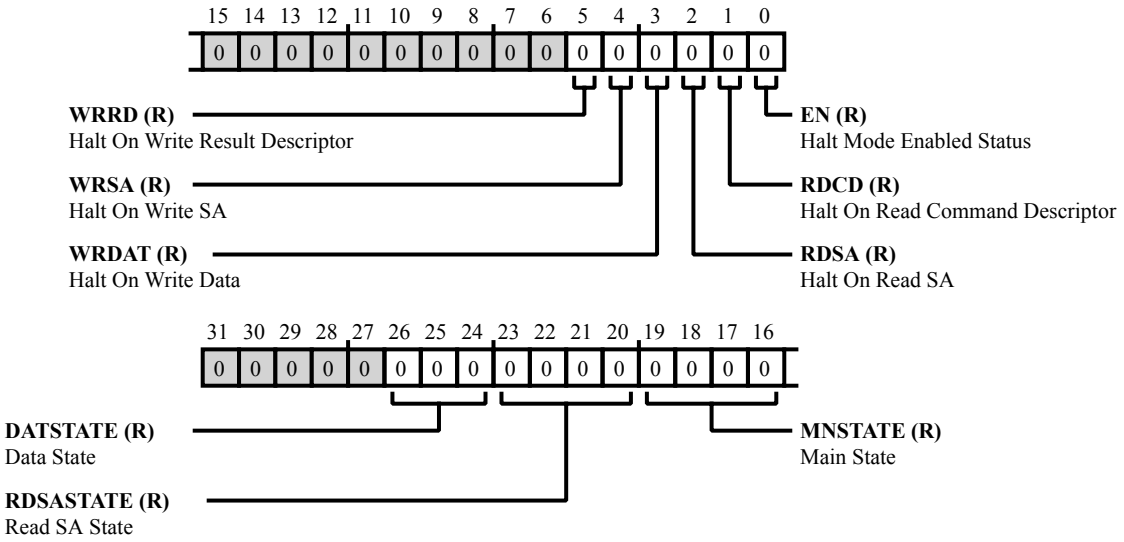

Figure 39-20: PKTE_HLT_STAT Register Diagram

Table 39-46: PKTE_HLT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/NW)	DATSTATE	Data State. The PKTE_HLT_STAT.DATSTATE bit field indicates the state of the packet engine read data FSM.	
		0	DATA_IDLE, no operation
		1	DATA_READ
		2	DATA_WRITE
		3	DATA_WAIT
		5	DATA_PAD_READ
		6	DATA_BYP_READ
		7	RESERVED
23:20 (R/NW)	RDSASTATE	Read SA State. The PKTE_HLT_STAT.RDSASTATE bit field indicates the state of the packet engine read SA FSM.	

Table 39-46: PKTE_HLT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	SA_IDLE, no operation
		1	SA_READ_CMD
		2	SA_READ_STATE_IV
		3-5	RESERVED
		6	SA_READ_ARC4_STATE
		7	SA_READ_WAIT
		8	RESERVED
		9	SA_WRITE_PROT_HDR
		10	RESERVED
		11	SA_WRITE_IV
		12	SA_WRITE_DIGEST
		13	SA_WRITE_ARC4_IJ_PNTR
		14	SA_WRITE_ARC4_STATE
		15	SA_WRITE_WAIT
19:16 (R/NW)	MNSTATE	Main State. The `PKTE_HLT_STAT.MNSTATE` bit field indicates the state of the packet engine main FSM.	
		0	MAIN_IDLE, no operation
		1	MAIN_READ_CD, reading command descriptor
		2	MAIN_READ_SA, reading SA
		3	MAIN_DATA, processing data
		4	MAIN_WRITE_SA, writing SA
		5	MAIN_WRITE_STATUS, writing status
		6	MAIN_WRITE_CD, updating command descriptor
		7	MAIN_WRITE_RD, updating result descriptor
		8	MAIN_INIT_WAIT, wait single clock
		9	MAIN_HALT_READ_CD, halt after read command descriptor
		10	MAIN_HALT_READ_SA, halt after read SA
		11	MAIN_HALT_DATA, halt after processing data
		12	MAIN_HALT_WRITE_SA, halt after write SA

Table 39-46: PKTE_HLT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		13	MAIN_WAIT_FOR_CLOCK, wait for clocks to be active
		15	MAIN_HALT_WRITE_RD, halt after write result descriptor
5 (R/NW)	WRRD	Halt On Write Result Descriptor. The PKTE_HLT_STAT.WRRD bit reflects the value in the PKTE_HLT_CTL.WRRD bit.	
4 (R/NW)	WRSA	Halt On Write SA. The PKTE_HLT_STAT.WRSA bit reflects the value in the PKTE_HLT_CTL.WRSA bit.	
3 (R/NW)	WRDAT	Halt On Write Data. The PKTE_HLT_STAT.WRDAT bit reflects the value in the PKTE_HLT_CTL.HWRDAT bit.	
2 (R/NW)	RDSA	Halt On Read SA. The PKTE_HLT_STAT.RDSA bit reflects the value in the PKTE_HLT_CTL.RDSA bit.	
1 (R/NW)	RDCD	Halt On Read Command Descriptor. The PKTE_HLT_STAT.RDCD bit reflects the value in the PKTE_HLT_CTL.RDCD bit.	
0 (R/NW)	EN	Halt Mode Enabled Status.	
		0	Halt mode not enabled
		1	Halt mode enabled

Interrupt Mask Disable Register

The host can use the PKTE_IMSK_DIS register to clear individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 clears the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Clearing the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

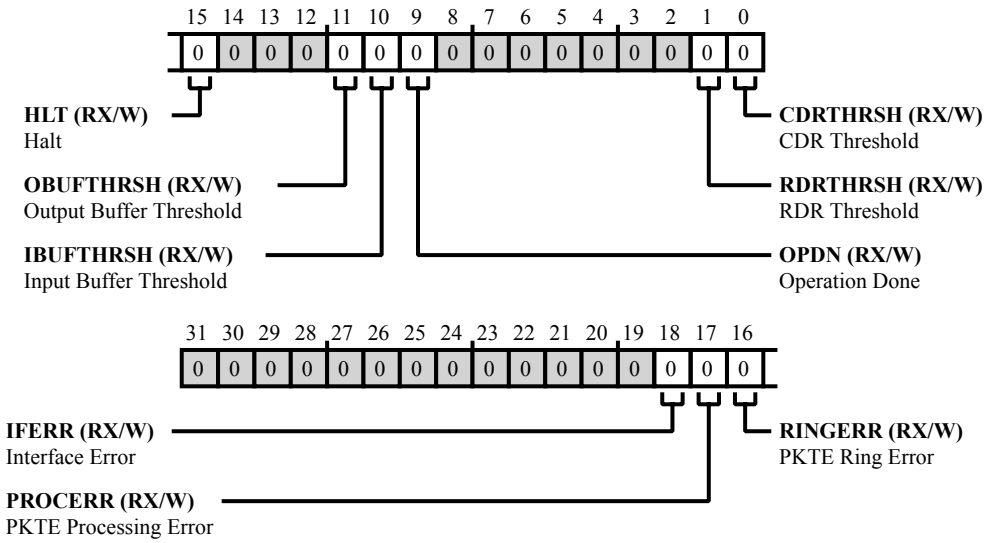

Figure 39-21: PKTE_IMSK_DIS Register Diagram

Table 39-47: PKTE_IMSK_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. Write the PKTE_IMSK_DIS.IFERR bit to clear when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. Write the PKTE_IMSK_DIS.PROCERR bit to clear an extended error that occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error. Write the PKTE_IMSK_DIS.RINGERR bit to clear a CDR overflow or an RDR underflow.
15 (RX/W)	HLT	Halt. Write the PKTE_IMSK_DIS.HLT bit to clear when the packet engine is in the halt state.

Table 39-47: PKTE_IMSK_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. Write the `PKTE_IMSK_DIS.OBUFTHRSH` bit to clear the output buffer counter exceeds the output buffer threshold value defined in `PKTE_BUF_THRESH.OUTBUF` bit.
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Write the `PKTE_IMSK_DIS.IBUFTHRSH` bit to clear when the input buffer counter is less than or equal to the input buffer threshold value defined in `PKTE_BUF_THRESH.INBUF` bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Write the `PKTE_IMSK_DIS.RDRTHRSH` bit to clear when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in the `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Write the `PKTE_IMSK_DIS.CDRTHRSH` bit to clear when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Mask Enable Register

The host can use the PKTE_IMSK_EN register to set individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 sets the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Setting the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

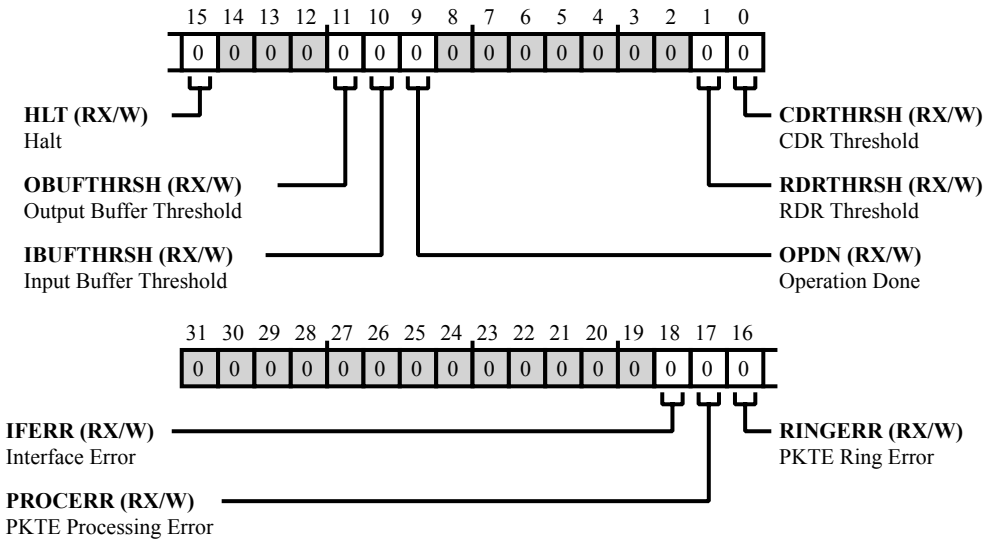

Figure 39-22: PKTE_IMSK_EN Register Diagram

Table 39-48: PKTE_IMSK_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. Set the PKTE_IMSK_EN.IFERR bit to indicate a host request for a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. Set the PKTE_IMSK_EN.PROCERR bit to indicate an extended error occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error.
15 (RX/W)	HLT	Halt. Set the PKTE_IMSK_EN.HLT bit to indicate when the packet engine is in the halt state.

Table 39-48: PKTE_IMSK_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. Set the PKTE_IMSK_EN.OBUFTHRSH bit to indicate that the output buffer counter exceeds the output buffer threshold value defined in the PKTE_BUF_THRESH.OUTBUF bit.
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Set the PKTE_IMSK_EN.IBUFTHRSH bit to indicate the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Set the PKTE_IMSK_EN.RDRTHRSH bit to indicate when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Set the PKTE_IMSK_EN.CDRTHRSH bit to indicate when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Masked Status Register

The PKTE_IMSK_STAT register provides interrupt status visibility to the host, after the interrupt mask is applied. This lets the host view the selected sources of interrupts that are directed to the interrupt output signal, that is connected to the system interrupt controller. As with the unmasked status register, all interrupt bits are latched and must be cleared using the PKTE_INT_CLR register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

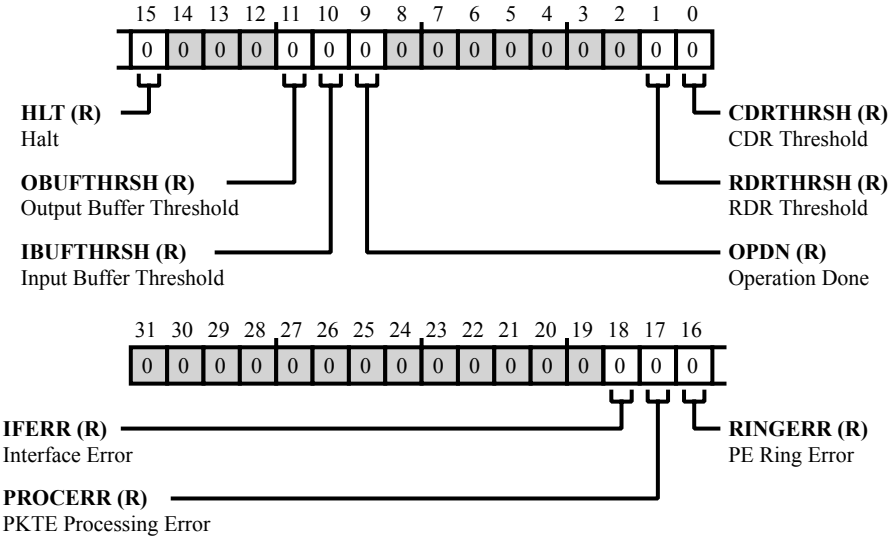

Figure 39-23: PKTE_IMSK_STAT Register Diagram

Table 39-49: PKTE_IMSK_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/NW)	IFERR	Interface Error. The PKTE_IMSK_STAT.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (R/NW)	PROCERR	PKTE Processing Error. The PKTE_IMSK_STAT.PROCERR bit is when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (R/NW)	RINGERR	PE Ring Error. The PKTE_IMSK_STAT.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (R/NW)	HLT	Halt. The PKTE_IMSK_STAT.HLT bit is set when the packet engine is in the HALT state.

Table 39-49: PKTE_IMSK_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	OBUFTHRSH	Output Buffer Threshold. The PKTE_IMSK_STAT.OBUFTHRSH bit is set when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.
10 (R/NW)	IBUFTHRSH	Input Buffer Threshold. The PKTE_IMSK_STAT.IBUFTHRSH bit is set when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (R/NW)	OPDN	Operation Done.
1 (R/NW)	RDRTHRSH	RDR Threshold. The PKTE_IMSK_STAT.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/NW)	CDRTHRSH	CDR Threshold. The PKTE_IMSK_STAT.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Packet Engine Input Buffer Count Register

The PKTE_INBUF_CNT register provides the number of bytes available in the input buffer. The PKTE_INBUF_CNT register is used in direct host mode only.

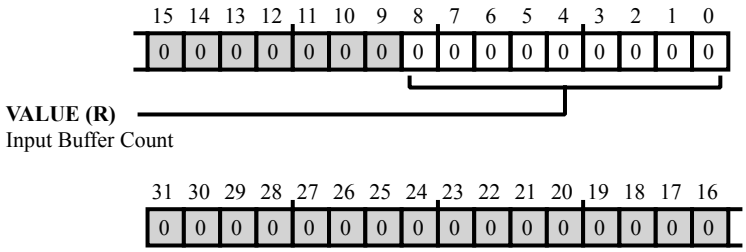

Figure 39-24: PKTE_INBUF_CNT Register Diagram

Table 39-50: PKTE_INBUF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	VALUE	Input Buffer Count. The PKTE_INBUF_CNT.VALUE bit field provides the number of bytes in the input buffer. The packet engine decrements the counter by 4 when a 32-bit word is read from the input buffer.

Packet Engine Input Buffer Count Increment Register

A host connected through the system slave bus can increment the input buffer counter by writing a value between 4 and 256, in multiples of 4, to the lowest bits of this register. The PKTE_INBUF_INCR register is used in direct host mode only.

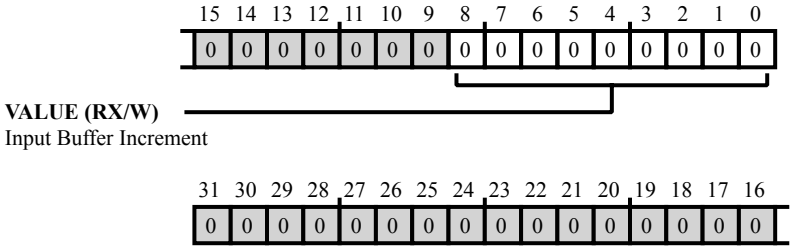

Figure 39-25: PKTE_INBUF_INCR Register Diagram

Table 39-51: PKTE_INBUF_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Input Buffer Increment. The value written is added to the input buffer counter. Valid values range from 4 to 256, in multiples of 4.

Interrupt Configuration Register

The PKTE_INT_CFG register configures the interrupt type that is sent to the interrupt line connected to the system interrupt controller. (Note that this only effects the final output of the interrupt subsystem).

Configuring the interrupt output type for pulse causes the interrupt signal to pulse low for two clock cycles when activated. When set for level, the interrupt signal is set low until cleared by the host (it follows the bit in the masked status register). For the host, this is typically set to level.

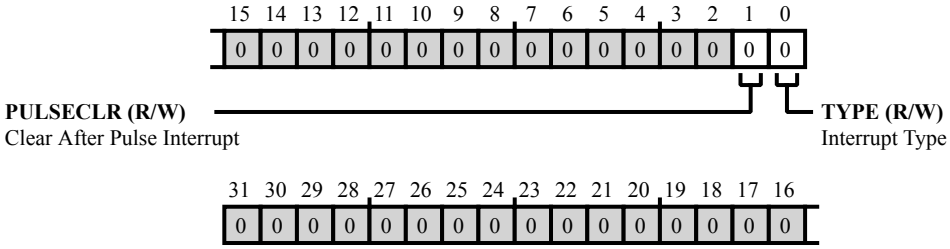

Figure 39-26: PKTE_INT_CFG Register Diagram

Table 39-52: PKTE_INT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PULSECLR	Clear After Pulse Interrupt. The PKTE_INT_CFG.PULSECLR bit clears the latched interrupt source after the pulse interrupt.	
		0	Manually clear pulse interrupt source. Do not automatically clear the interrupt sources after pulsing the interrupt output. Clear the source by writing to the PKTE_INT_CLR register.
		1	Automatically clear pulse interrupt source. After pulsing the interrupt output, automatically clear the sources.
0 (R/W)	TYPE	Interrupt Type. The PKTE_INT_CFG.TYPE bit selects the type, pulse or level, for the interrupt output to the system.	
		0	Level. The interrupt output is a level signal that is set low when an enabled interrupt is active until the interrupt is cleared.
		1	Pulse. The interrupt output is a two clock cycle low-active pulse, activated when an enabled interrupt is active.

Interrupt Clear Register

The PKTE_INT_CLR register allows the host processor to clear pending interrupts. A 1 written to a given bit in this register clears the corresponding interrupt. A 0 leaves the interrupt latch unchanged for that position.

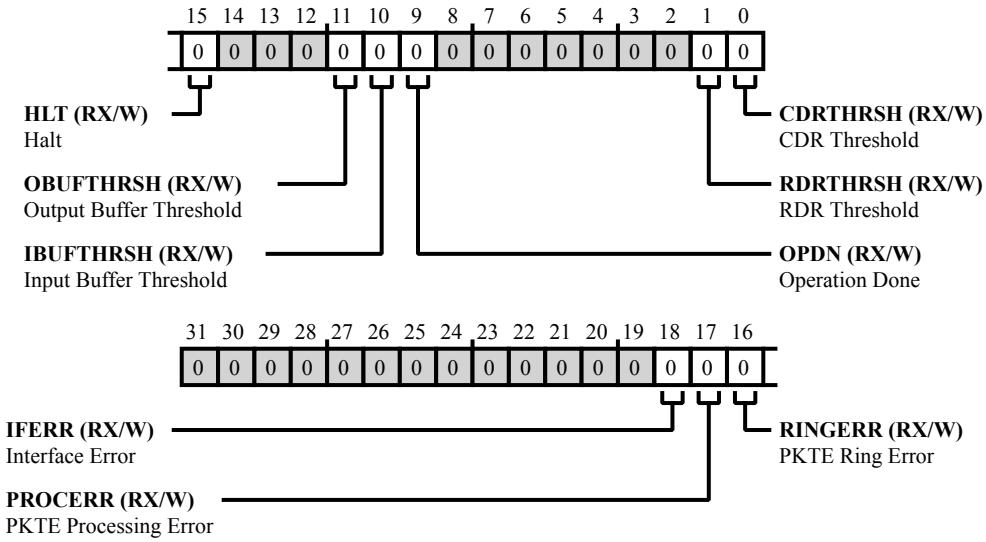

Figure 39-27: PKTE_INT_CLR Register Diagram

Table 39-53: PKTE_INT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. The PKTE_INT_CLR.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. The PKTE_INT_CLR.PROCERR bit is set when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error. The PKTE_INT_CLR.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (RX/W)	HLT	Halt. The PKTE_INT_CLR.HLT bit is set when the packet engine is in the HALT state.
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. The PKTE_INT_CLR.OBUFTHRSH bit is set when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.

Table 39-53: PKTE_INT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. The PKTE_INT_CLR.IBUFTHRSH bit is set when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. The PKTE_INT_CLR.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. The PKTE_INT_CLR.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Enable Register

The PKTE_INT_EN register configures the interrupt mask for the host interrupt. This register is a bitmap for each of the possible interrupt sources. A 1 enables the interrupt source and a 0 disables the source. If an interrupt source is disabled, a cleared bit also clears the matching interrupt in the PKTE_IMSK_STAT register.

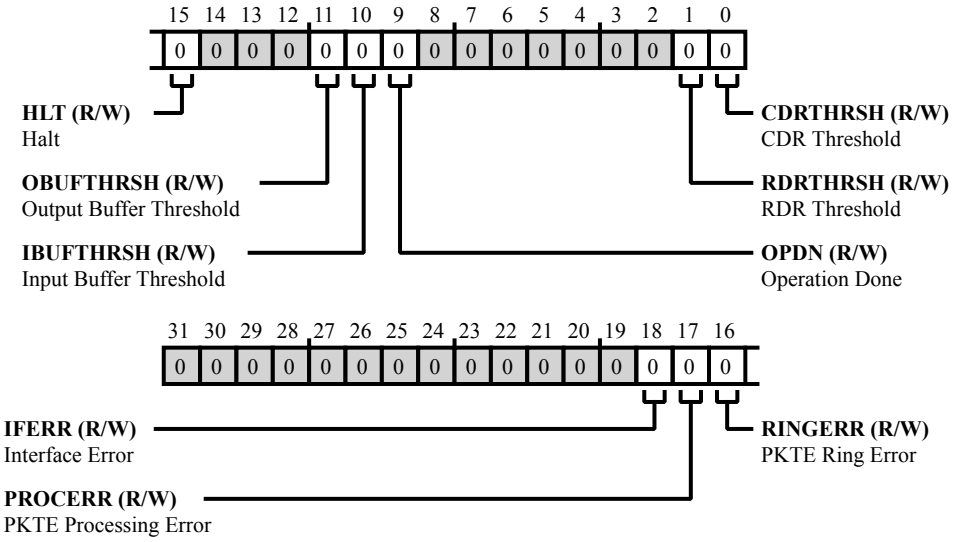

Figure 39-28: PKTE_INT_EN Register Diagram

Table 39-54: PKTE_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	IFERR	Interface Error. Set the PKTE_INT_EN.IFERR bit for host requests for a non 32-bit access to the packet engine interrupt or when the packet engine receives an error writing data back out to the host memory system.
17 (R/W)	PROCERR	PKTE Processing Error. Set the PKTE_INT_EN.PROCERR bit to enable the extended error occurred before, during or after processing the current packet in the packet engine interrupt.
16 (R/W)	RINGERR	PKTE Ring Error. Set the PKTE_INT_EN.RINGERR bit to enable the CDR overflow or RDR underflow interrupt.
15 (R/W)	HLT	Halt. Set the PKTE_INT_EN.HLT bit for when the packet engine is in the HALT state.
11 (R/W)	OBUFTHRSH	Output Buffer Threshold. Set the PKTE_INT_EN.OBUFTHRSH bit for to trigger an interrupt when the output buffer counter exceeds the output buffer threshold value defined in the PKTE_BUF_THRESH.OUTBUF bit.

Table 39-54: PKTE_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	IBUFTHRSH	Input Buffer Threshold. Set the PKTE_INT_EN.IBUFTHRSH bit for to trigger an interrupt when the input buffer counter is less than or equal to the input buffer threshold value defined in the PKTE_BUF_THRESH.INBUF bit.
9 (R/W)	OPDN	Operation Done.
1 (R/W)	RDRTHRSH	RDR Threshold. Set the PKTE_INT_EN.RDRTHRSH bit for to trigger an interrupt when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/W)	CDRTHRSH	CDR Threshold. Set the PKTE_INT_EN.CDRTHRSH bit for to trigger an interrupt when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Unmasked Status Register

The PKTE_IUMSK_STAT register provides interrupt status visibility to the host, prior to the interrupt mask being applied. Using this register, the host can view all potential sources of incoming interrupts. All of these sources, whether masked in or out, are latched in this register and must be cleared using the PKTE_INT_CLR register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

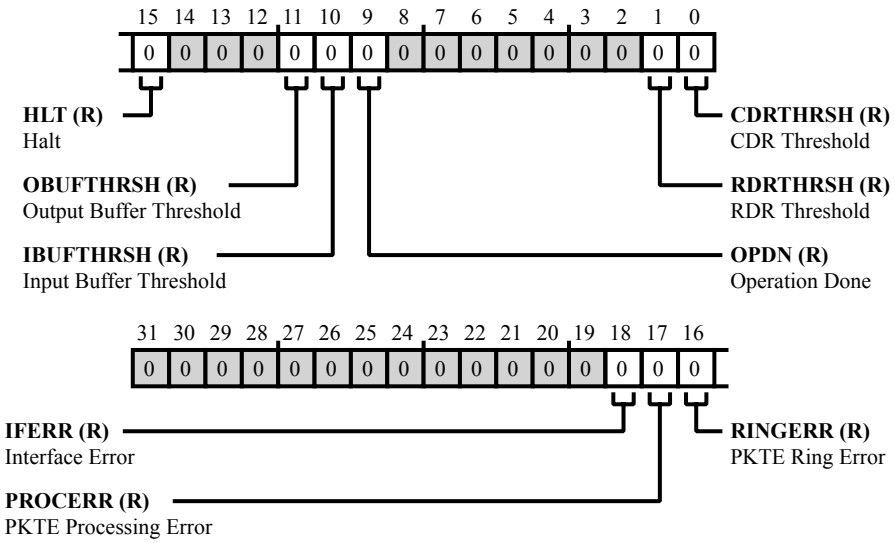

Figure 39-29: PKTE_IUMSK_STAT Register Diagram

Table 39-55: PKTE_IUMSK_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/NW)	IFERR	Interface Error. The PKTE_IUMSK_STAT.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (R/NW)	PROCERR	PKTE Processing Error. The PKTE_IUMSK_STAT.PROCERR bit is set when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (R/NW)	RINGERR	PKTE Ring Error. The PKTE_IUMSK_STAT.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (R/NW)	HLT	Halt. The PKTE_IUMSK_STAT.HLT bit is set when the packet engine is in the HALT state.

Table 39-55: PKTE_IUMSK_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	OBUFTHRSH	Output Buffer Threshold. The PKTE_IUMSK_STAT.OBUFTHRSH interrupt is triggered when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.
10 (R/NW)	IBUFTHRSH	Input Buffer Threshold. The PKTE_IUMSK_STAT.IBUFTHRSH interrupt is triggered when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (R/NW)	OPDN	Operation Done.
1 (R/NW)	RDRTHRSH	RDR Threshold. The PKTE_IUMSK_STAT.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/NW)	CDRTHRSH	CDR Threshold. The PKTE_IUMSK_STAT.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Packet Engine Length Register

The PKTE_LEN register gives the length of the packet, the bypass data and a second set of ownership bits.

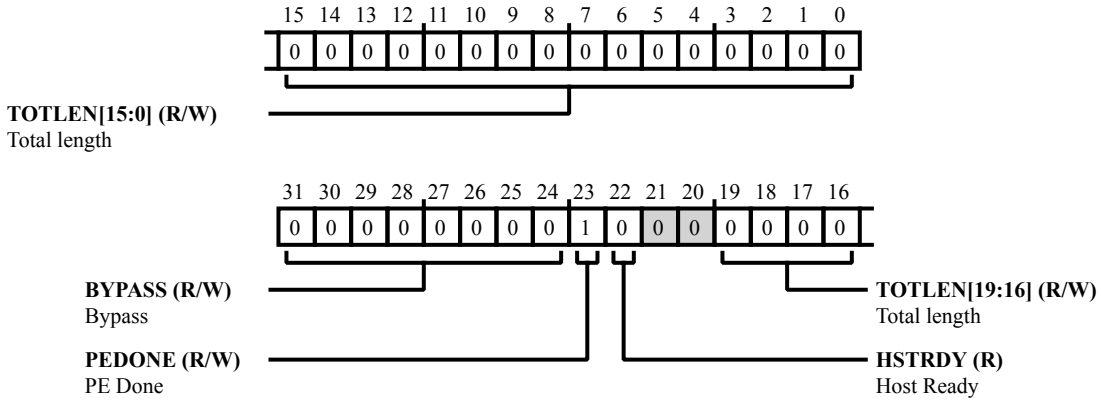

Figure 39-30: PKTE_LEN Register Diagram

Table 39-56: PKTE_LEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYPASS	Bypass. The PKTE_LEN.BYPASS bit field indicates the length of data in words that must bypass the packet engine and are directly copied from the source buffer to the destination buffer. The packet engine does not process this data. Valid bypass offsets range from 0 (0x00) to 255 (0xFF) words. For SRTP operations, this field specifies the offset in words between the hash and encrypt/decrypt data.
23 (R/W)	PEDONE	PE Done. The PKTE_LEN.PEDONE bit is a mirrored bit from the PKTE_CTL_STAT.PERDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.
22 (R/NW)	HSTRDY	Host Ready. The PKTE_LEN.HSTRDY bit is a mirrored bit of the PKTE_CTL_STAT.HOSTRDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. It should also be set along with the PKTE_CTL_STAT.HOSTRDY bit when the command descriptor is finished being populated. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.

Table 39-56: PKTE_LEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	TOTLEN	Total length. Command Descriptor: The PKTE_LEN.TOTLEN bit field indicates the total length (in bytes) of all data to be passed to the packet engines input buffer for an operation. Exceptions are the PRNG init and PRNG generate operations. The PRNG init operation does not require any input data; this field must be zero. For the PRNG generate operation, this field indicates the number of pseudo-random bytes to be generated. Valid lengths range from 16 (0x00010) to 255*16 = 4080 (0x00FF0) bytes in multiples of 16 bytes. Valid lengths for the basic operation range from 1 (0x00001) to 1,048,575 (0xFFFFF) bytes. This is the length of the data to be encrypted or hashed and includes the bypass data and padding bytes. Valid lengths for IPsec ESP range from 1 (0x00001) to 65535 (0x0FFFF) bytes. This is the length of the IP payload. Valid lengths for SSL v3.0, TLS v1.x and DTLS range from 1 (0x00001) to 16383 (0x03FFF). This is the length of the payload. Valid lengths for SRTP range from 1 (0x00001) to 65535 (0x0FFFF). This is the length of the payload. Note: A length of zero bytes is illegal and will result in an error status code in the result descriptor. Result Descriptor: Upon completion of an operation, the PKTE_LEN.TOTLEN field indicates the result length of the result packet. Valid lengths range from 1 (0x001) to 1,048,575 (0xFFFFF) bytes. This includes the bypass data and padding bytes. Note: When an extended error (PKTE_CTL_STAT[18]=1) is reported in the result descriptor and no packet data is processed, this field returns zero.

Packet Engine Output Buffer Count Register

The PKTE_OUTBUF_CNT register provides the number of data bytes there are in the output buffer. The PKTE_OUTBUF_CNT register is used in direct host mode only.

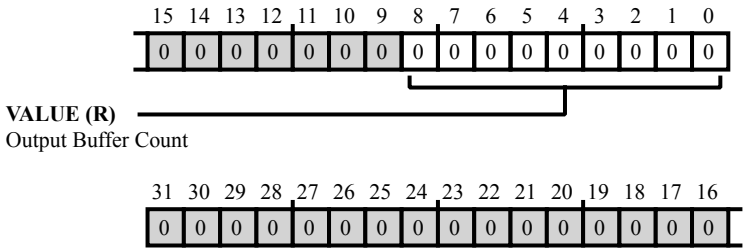

Figure 39-31: PKTE_OUTBUF_CNT Register Diagram

Table 39-57: PKTE_OUTBUF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	VALUE	Output Buffer Count. The PKTE_OUTBUF_CNT.VALUE bit field provides the number of bytes in the output buffer. The packet engine increments the counter by 4 when a 32-bit word is written to the output buffer.

Packet Engine Output Buffer Count Decrement Register

A host connected via the system slave bus can decrement the output buffer counter by writing a value between 4 and 256, in multiples of 4, to the lowest bits of this register. The PKTE_OUTBUF_DECR register is used in direct host mode only.

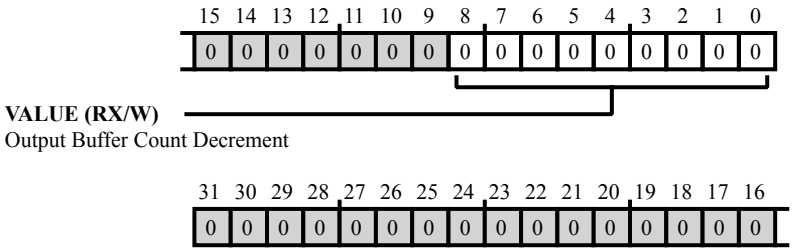

Figure 39-32: PKTE_OUTBUF_DECR Register Diagram

Table 39-58: PKTE_OUTBUF_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Output Buffer Count Decrement. The PKTE_OUTBUF_DECR.VALUE bit field is the value written is subtracted to the output buffer counter. Valid values range from 4 to 256, in multiples of 4.

Packet Engine Result Descriptor Ring Base Address

The PKTE_RDRBASE_ADDR register holds the result descriptor ring base address in host memory. It is only applicable in autonomous ring mode and target command mode with RDR enabled. Note that in target command mode, the CDR is not used, but the RDR must be configured when enabled so that the packet engine knows where to write the result descriptors.

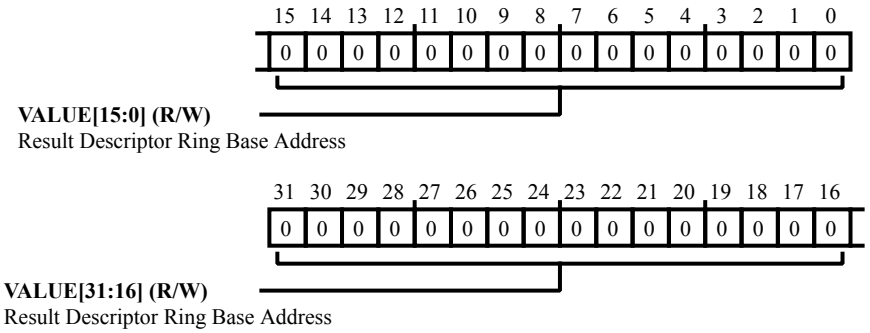

Figure 39-33: PKTE_RDRBASE_ADDR Register Diagram

Table 39-59: PKTE_RDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Result Descriptor Ring Base Address. The PKTE_RDRBASE_ADDR.VALUE bit field specifies the base location of the result descriptor ring in the host memory space.

Packet Engine Result Descriptor Count Registers

The PKTE_RDSC_CNT register holds the counter for the number of descriptors in the Result Descriptor Ring (RDR). It is incremented by the packet engine each time a valid result descriptor is written to the RDR.

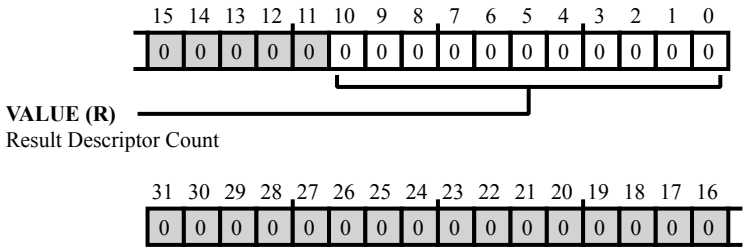

Figure 39-34: PKTE_RDSC_CNT Register Diagram

Table 39-60: PKTE_RDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Result Descriptor Count. The PKTE_RDSC_CNT.VALUE bit field provides the number of result descriptors in the result descriptor ring. The packet engine increments the counter when a valid result descriptor is written to the RDR.

Packet Engine Result Descriptor Count Decrement Registers

The PKTE_RDSC_DECR register is accessible by the host connected through the system slave bus can decrement the result descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

With an RDR enabled, this is the number of result descriptors that have been read by the host. With an RDR disabled, this indicates that the host has read one valid result descriptor.

In autonomous ring mode or target command mode with the RDR enabled, the host must process 1 to 255 result descriptors from the RDR and then write this register with the number of result descriptors that have been processed by the host.

In direct host mode or target command mode with the RDR disabled, the host must read one result descriptor from the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is read. An RDR threshold interrupt is activated when the result descriptor counter exceeds the threshold value set in the PKTE_RING_THRESH register. This interrupt can be used to wake up a process that stalled on an empty RDR.

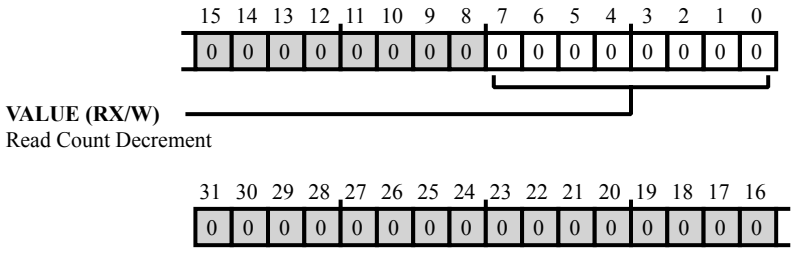

Figure 39-35: PKTE_RDSC_DECR Register Diagram

Table 39-61: PKTE_RDSC_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Read Count Decrement. The value written to the PKTE_RDSC_DECR.VALUE bit field is subtracted from the result descriptor counter. The counter is protected against underflow (See the PKTE_RING_STAT register). Note that bits [10:8] should be written with zeros.

Packet Engine Ring Configuration

The PKTE_RING_CFG register configures the size (in number of descriptor ring entries minus 1) for both the command descriptor ring and result descriptor ring in host memory. This register is only applicable for autonomous ring mode and target command mode with RDR enabled.

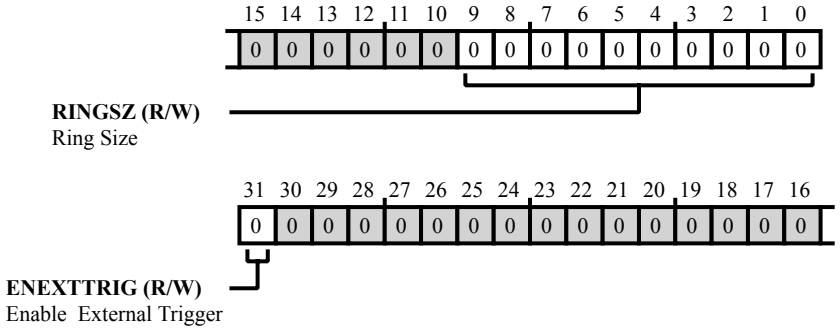

Figure 39-36: PKTE_RING_CFG Register Diagram

Table 39-62: PKTE_RING_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ENEXTTRIG	Enable External Trigger. The PKTE_RING_CFG.ENEXTTRIG signal enables the increment of the PKTE_CDSC_CNT register through the external input pin ext_cd_cnt_incr and enables the decrement of the PKTE_RDSC_CNT fields through the external input pin ext_rd_cnt_decr.
9:0 (R/W)	RINGSZ	Ring Size. The PKTE_RING_CFG.RINGSZ bit field specifies the size of the command ring in number of descriptors, minus 1. Valid sizes range from 1 (for 2 descriptors) to 1023 (for 1024 descriptors). The accompanying result ring will have the same size.

Packet Engine Ring Pointer Status

The PKTE_RING_PTR register holds the pointers to the current entry of the Command Descriptor Ring (CDR) and Result Descriptor Ring (RDR).

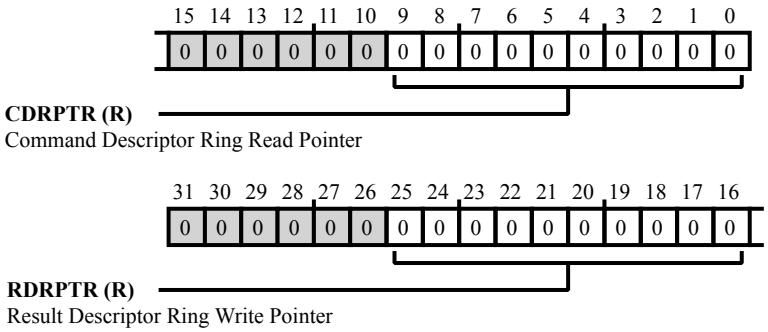

Figure 39-37: PKTE_RING_PTR Register Diagram

Table 39-63: PKTE_RING_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/NW)	RDRPTR	Result Descriptor Ring Write Pointer. The PKTE_RING_PTR.RDRPTR bit field indicates the entry number in the RDR that will be written next by the packet engine. The PKTE_RING_PTR.RDRPTR bit field is reset to zero after starting up and updated after every result descriptor write DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) bit field.
9:0 (R/NW)	CDRPTR	Command Descriptor Ring Read Pointer. The PKTE_RING_PTR.CDRPTR bit field indicates the entry number in the CDR that will be read next by the packet engine. The PKTE_RING_PTR.CDRPTR bit field is reset to zero after starting up and updated after every command descriptor read DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) field.

Packet Engine Ring Status

The PKTE_RING_STAT register gives indication of either a Command Descriptor Ring (CDR) overflow or a Result Descriptor Ring (RDR) underflow. A ring error (ringerr) interrupt in the interrupt controller is activated on a command descriptor ring overflow or a result descriptor ring underflow. This type of error can occur when the host and the packet engine get out-of-sync. The host can read this register to retrieve information on which ring is corrupted. The corrupted ring must be reset and reinitialized. See the PKTE_CFG.RSTRING bit.

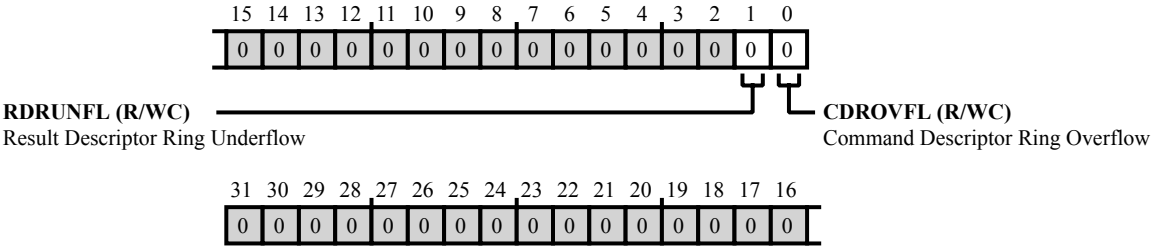

Figure 39-38: PKTE_RING_STAT Register Diagram

Table 39-64: PKTE_RING_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/WC)	RDRUNFL	Result Descriptor Ring Underflow. The PKTE_RING_STAT.RDRUNFL bit is set when the command descriptor count (PKTE_RDSC_CNT) register is decremented below zero. This bit is reset with a write of any value.
0 (R/WC)	CDROVFL	Command Descriptor Ring Overflow. The PKTE_RING_STAT.CDROVFL bit is set when the command descriptor count (PKTE_CDSC_CNT) register is incremented above the ring size (PKTE_RING_CFG.RINGSZ) bits. This bit is reset with a write of any value.

Packet Engine Ring Threshold Registers

To reduce the amount of packet engine result interrupts, the PKTE_RING_THRESH register contains threshold and time-out values.

The CDR threshold (cdrthrsh) interrupt indicates that the command descriptor counter is less than or equal to the CDR threshold (cdrthrsh) value set in this register. This interrupt can be used to wake up a process that stalled on a full CDR.

The RDR threshold (rdrthrsh) interrupt indicates that the result descriptor counter exceeds the result descriptor threshold set here, or that the result descriptor counter is non-zero for a time longer than the result descriptor time-out setting. The RDR result interrupt remains active until the result descriptor counter is decremented below the RDR threshold (rdrthrsh) value. In case the interrupt is the result of a time-out and the result descriptor counter is below the threshold value, the result descriptor counter must be decremented once before the interrupt can be cleared in the interrupt controller.

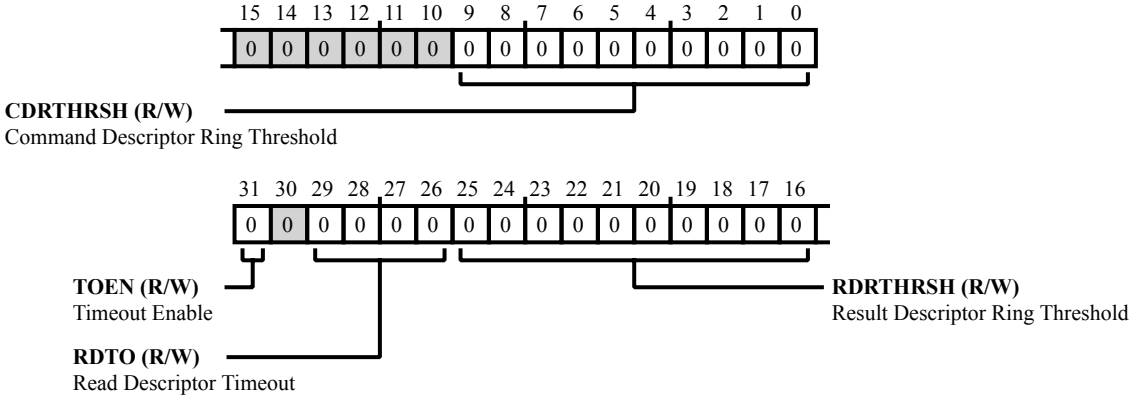

Figure 39-39: PKTE_RING_THRESH Register Diagram

Table 39-65: PKTE_RING_THRESH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TOEN	Timeout Enable. A 1 in the PKTE_RING_THRESH.TOEN bit indicates the result descriptor timeout counter is enabled. This bit can be used to de-activate the timeout counter to save power.

Table 39-65: PKTE_RING_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:26 (R/W)	RDTO	Read Descriptor Timeout. The timeout enable (PKTE_RING_THRESH.TOEN) bit in this register must be set to activate this PKTE_RING_THRESH.RDTO result descriptor timeout counter. The rdrthrsh interrupt activates when the RD counter for the RDR is non-zero for more than $2^{(N+10)}$ internal system clock cycles, where 'N' is the value set in this field. Valid settings range from 0 to 15. The minimum time-out value for N=0 is 1024 clock cycles and the maximum time-out value for N=15 is 33554432 clock cycles. At 100 MHz, this is 5.12 us for N=0 and ~335.55 ms for N=15. Note: The time-out delay may not be exact - expect a variation on the order of 1024 system clock cycles (just more than one microsecond at 100 MHz system clock frequency).
25:16 (R/W)	RDRTHRSH	Result Descriptor Ring Threshold. The rdrthrsh interrupt activates when the RD counter for the RDR exceeds the value set in the PKTE_RING_THRESH.RDRTHRSH field. Valid settings range from 0 to 1023.
9:0 (R/W)	CDRTHRSH	Command Descriptor Ring Threshold. The cdrthrsh interrupt activates when CD counter for the CDR is below or equal the value set in the PKTE_RING_THRESH.CDRTHRSH field. Valid settings range from 0 to 1023.

Packet Engine SA Address

The PKTE_SA_ADDR register holds the start address of the SA record.

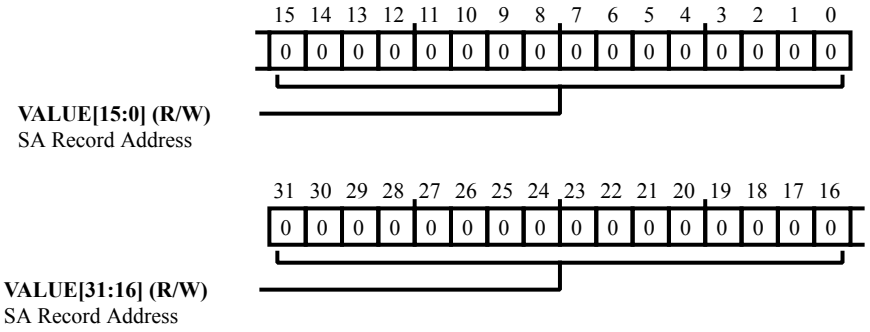

Figure 39-40: PKTE_SA_ADDR Register Diagram

Table 39-66: PKTE_SA_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Record Address. The PKTE_SA_ADDR.VALUE bit field holds the start address of the SA record.

ARC4 i and j Pointer Register

When starting a new ARC4 operation the PKTE_SA_ARC4IJPTR register contains the initialization value, which is zeros. After processing the ARC4 algorithm it contains the latest status of the ARC4_IJ_PNTR.

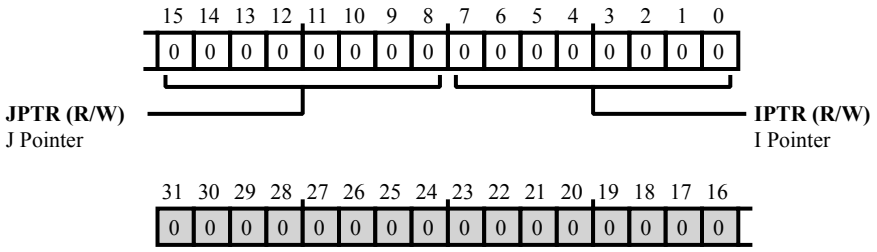

Figure 39-41: PKTE_SA_ARC4IJPTR Register Diagram

Table 39-67: PKTE_SA_ARC4IJPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	JPTR	J Pointer. The PKTE_SA_ARC4IJPTR.JPTR bit field contains the j pointer into s-box array for swapping bytes with i pointer.
7:0 (R/W)	IPTR	I Pointer. The PKTE_SA_ARC4IJPTR.IPTR bit field contains the i pointer into s-box array for swapping bytes with j pointer.

SA Command 0

The two SA command registers, PKTE_SA_CMD0 and PKTE_SA_CMD1, are used to control the cryptographic operation of the packet engine. The PKTE_SA_CMD0 register contains the major control bits to define an operation while the PKTE_SA_CMD1 register contains the minor control bits. In direct host mode, this is a write-only register.

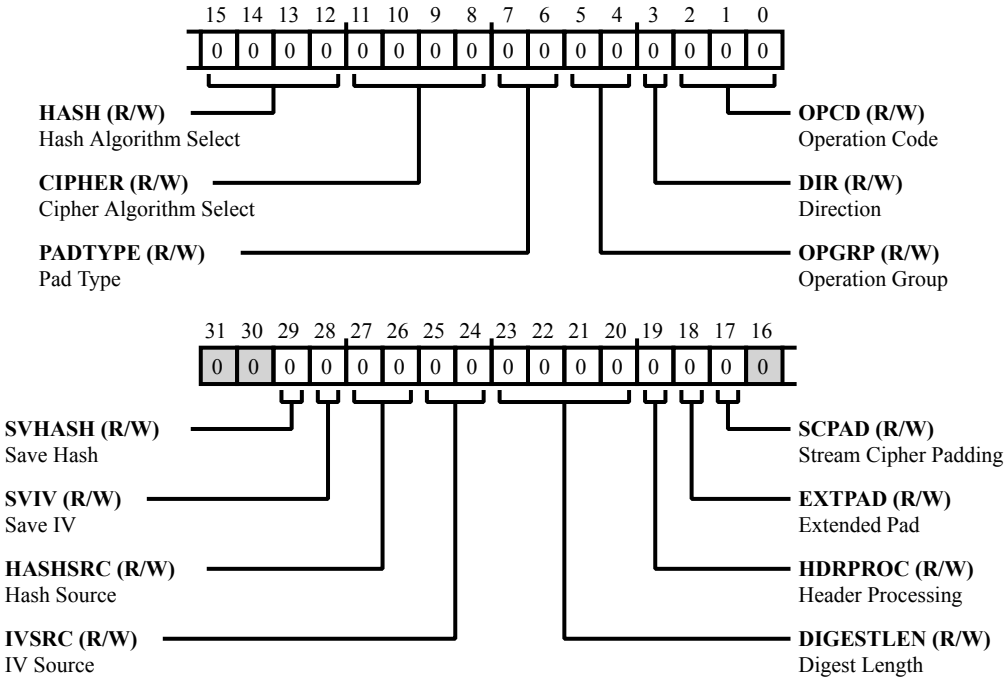

Figure 39-42: PKTE_SA_CMD0 Register Diagram

Table 39-68: PKTE_SA_CMD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SVHASH	Save Hash. The PKTE_SA_CMD0.SVHASH bit indicates that the Hash State is saved to the STATE_BYTE_CNT_X and STATE_IDIGEST_X fields in the SA record in memory after completion of a crypto operation.	
		0	Hash state is not saved
		1	Hash state is saved

Table 39-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	SVIV	Save IV. The PKTE_SA_CMD0.SVIV bit field indicates that for DES or the AES the Initialization Vector (IV) is saved to the STATE_IV_X fields in the state record , or the ARC4 state is saved to the ARC4 state record, after completion of the crypto operation.	
		0	ARC4 State is not saved.
		1	ARC4 State is not saved.
27:26 (R/W)	HASHSRC	Hash Source. The PKTE_SA_CMD0.HASHSRC bit field selects the source of the hash digest used by the algorithm.	
		0	From SA. Digest only hash byte count is forced to 0x40.
		1	Reserved
		2	From State. Read saved inner hash digest and saved hash byte count.
		3	No Load. Use the hash algorithm defined constants for the initial hash. Hash byte count is 0x00.
25:24 (R/W)	IVSRC	IV Source. The PKTE_SA_CMD0.IVSRC bit field selects the source of the initialization vector used by the crypto algorithm.	
		0	No load. Use previous result IV, not applicable for inbound data. This option should never be used for operations with DES-CBC or AES-CBC, (see RFC3602) or any AES counter modes
		1	From input buffer. The IV is provided as part of the input data stream.
		2	From State. Read STATE_IV_X, from the SA structure. Refer to inner hash digest register structure. Useful for resume operations.
		3	From internal PRNG. Not applicable for inbound operations.
23:20 (R/W)	DIGESTLEN	Digest Length. The PKTE_SA_CMD0.DIGESTLEN bit field defines the length of the hash digest in words as put in the output buffer.	
		0	3 Words (96-bit output)
		1	1 Word
		2	2 Words

Table 39-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Words (IPsec)
		4	4 Words (MD5 and AES-based hash)
		5	5 Words (SHA-1)
		6	6 Words
		7	7 Words (SHA-224)
		8	8 Words (SHA-256)
		9	Reserved
		10	10 bytes (SRTP and TLS)
		11-15	Reserved
19 (R/W)	HDRPROC	Header Processing. The `PKTE_SA_CMD0.HDRPROC` bit enables header processing for protocol operations. There is no header-processing support for basic SSL, basic TLS and SRTP protocol operations as defined in the protocol group (see the Crypto and Hash Algorithms section). This bit must be zero for these operations; however, the protocol header must be supplied to the packet engine since it is part of the hash calculation. Refer to the protocol specifications for more information about header-processing support for a protocol.	
		0	No header processing
		1	Header processing; insert the protocol header for outbound operations, verify the protocol header for inbound operations.
18 (R/W)	EXTPAD	Extended Pad. The `PKTE_SA_CMD0.EXTPAD` bit extends the number of padding types. Used in combination with `PKTE_SA_CMD0.PADTYPE`.	
17 (R/W)	SCPAD	Stream Cipher Padding. The `PKTE_SA_CMD0.SCPAD` bit enables padding for stream ciphers algorithms.	
15:12 (R/W)	HASH	Hash Algorithm Select. The `PKTE_SA_CMD0.HASH` bit field selects the hash algorithm.	
		0	MD5
		1	SHA-1
		2	SHA-224
		3	SHA-256
		4-14	Reserved
		15	Null

Table 39-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	CIPHER	Cipher Algorithm Select. The PKTE_SA_CMD0.CIPHER bit field selects the cipher algorithm to be used for encryption and decryption. Note: Each type of protocol operation supports different sets of crypto algorithms. Refer to the Crypto and Hash Algorithms general processing section for details of the supported algorithms.	
		0	DES
		1	Triple-DES
		2	ARC4
		3	AES
		4-14	Reserved
		15	Null
7:6 (R/W)	PADTYPE	Pad Type. The PKTE_SA_CMD0.PADTYPE bit field indicates the type of crypto that must be generated for outbound packets or checked for inbound packets.	
		0	Select IPSec operation (if Bit 18=0); Reserved (if Bit 18=1)
		1	PKCS#7 (if Bit 18=0); Select TLS/DTLS Pad, required for TLS/DTLS operation (if Bit 18=1)
		2	Constant pad (if Bit 18=0); Select Constant SSL Pad, required for SSL operation (if Bit 18=1)
		3	Zero pad (if Bit 18=0), Reserved (if Bit 18=1)
5:4 (R/W)	OPGRP	Operation Group. The PKTE_SA_CMD0.OPGRP bit field defines the operation groups. Refer to the Basic Operations and Decoding section for more information.	
		0	Basic operation group
		1	Protocol operation group
		2	Extended protocol operations group
		3	Reserved
3 (R/W)	DIR	Direction. The PKTE_SA_CMD0.DIR bit field selects the direction of operation.	
		0	Outbound operations
		1	Inbound operations

Table 39-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	OPCD	Operation Code. The `PKTE_SA_CMD0.OPCD` bit field selects the operation within the operation group.

SA Command 1

The PKTE_SA_CMD1 register contains the minor control bits that define an operation. In direct host mode, this is a write-only register.

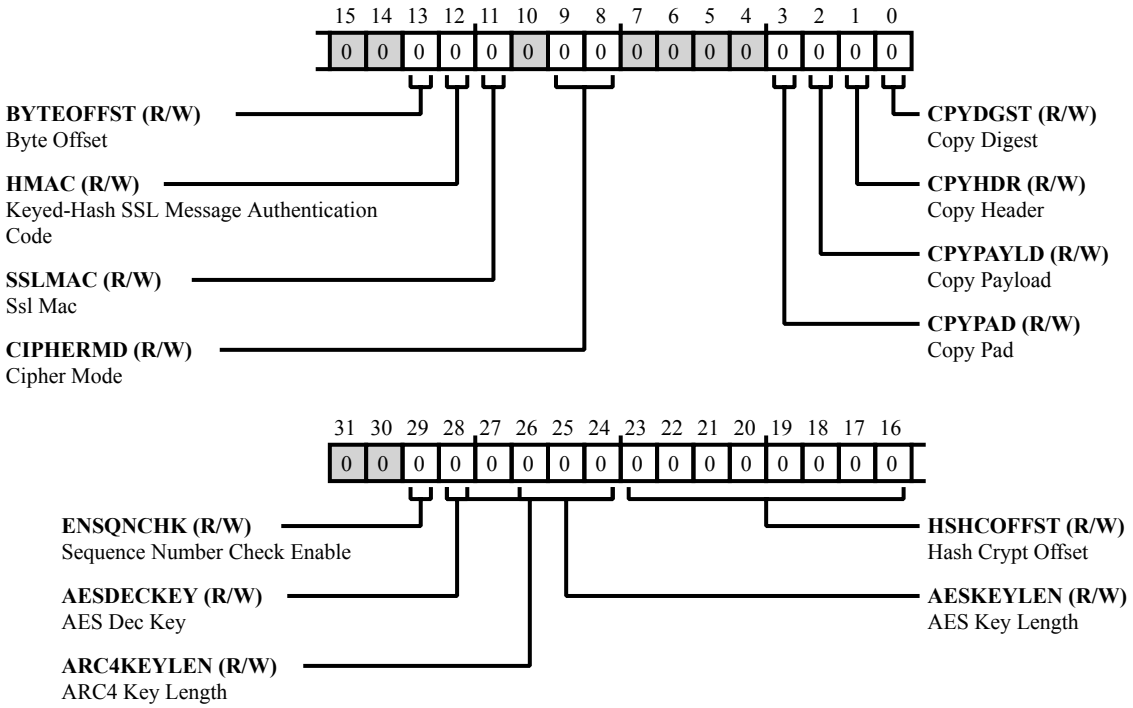

Figure 39-43: PKTE_SA_CMD1 Register Diagram

Table 39-69: PKTE_SA_CMD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	ENSQNCHK	Sequence Number Check Enable. The PKTE_SA_CMD1.ENSQNCHK bit defines that the key in the SA key field is an AES encrypt key or an AES decrypt key.	
		0	Disable sequence number check
		1	Enable sequence number check
28 (R/W)	AESDECKEY	AES Dec Key. If the PKTE_SA_CMD1.AESDECKEY bit is set, the key in loaded in the PKTE_SA_KEY[n] registers are expected to be the key from the last round from key expansion. If not set, the key loaded in the PKTE_SA_KEY[n] registers are expected to be the same key used during the encryption process.	
		0	AES key is an encrypt key.
		1	AES key is a decrypt key.

Table 39-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W)	AESKEYLEN	AES Key Length. The PKTE_SA_CMD1.AESKEYLEN bit field select the size of the key used for the AES algorithm in increments of 64 bits.	
		0-1	Reserved
		2	128 Bits
		3	192 Bits
		4	256 Bits
		5-7	Reserved
28:24 (R/W)	ARC4KEYLEN	ARC4 Key Length.	
23:16 (R/W)	HSHCOFFST	Hash Crypt Offset. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the PKTE_SA_CMD1.HSHCOFFST bit field specifies the offset between the hash data and the encrypt/decrypt data. The data to be hashed is assumed to come first, with an offset to the beginning of encrypt/decrypt data. When PKTE_SA_CMD1.BYTEOFFST, bit 13, is zero, then the offset is defined in 32-bit words. When an initialization vector is loaded through the input buffer, valid values range from IV size to 255. In all other cases, valid values range from 0 to 255. When PKTE_SA_CMD1.BYTEOFFST, bit 13, is one, then the offset is defined in 8-bit bytes. When an initialization vector is loaded through the input buffer, valid values range from IV size to 255. In all other cases, valid values range from 4 to 255. (The IV size is two words for DES, Triple-DES and AES-CTR and four words for AES-CBC and AES-ICM operations). Other operations do not use these bits (a default value is applied by the packet engine).	
13 (R/W)	BYTEOFFST	Byte Offset. The PKTE_SA_CMD1.BYTEOFFST bit defines how the PKTE_SA_CMD1.HSHCOFFST, bits of this register are used.	
		0	HASH_CRYPT_OFFSET is defined in 32-bit words
		1	HASH_CRYPT_OFFSET is defined in 8-bit bytes
12 (R/W)	HMAC	Keyed-Hash SSL Message Authentication Code. For basic operations that include hashing, the PKTE_SA_CMD1.HMAC bit enables the HMAC processing, which calls for an extra outer hash operation.	
		0	Standard Hash
		1	HMAC Processing

Table 39-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SSLMAC	Ssl Mac.	
		0	Standard Hash
		1	SSL-MAC processing
9:8 (R/W)	CIPHERMD	Cipher Mode. The `PKTE_SA_CMD1.CIPHERMD` bit field selects the crypto mode to be used for the cipher algorithm.	
		0	Electronic Code Book (ECB) used for DES and AES
		1	Cipher Block Chaining (CBC) used for DES and AES
		2	AES Counter Mode (CTR) for IPsec using a 32-bit counter
		3	AES Integer Counter Mode (ICM) for SRTP using a 16-bit counter. Note: This is implemented as a 32-bit counter, the Host must check for an overflow from the value 0xFF to zero and then refresh the IV.
3 (R/W)	CPYPAD	Copy Pad. The `PKTE_SA_CMD1.CPYPAD` bit indicates that the padding data for an inbound operation is copied to the output buffer and saved in memory.	
		0	Do not copy the padding to output
		1	Copy padding to output
2 (R/W)	CPYPAYLD	Copy Payload. The `PKTE_SA_CMD1.CPYPAYLD` bit indicates that the payload data is copied to the output buffer and saved in memory.	
		0	Do not copy the payload to output
		1	Copy payload to output
1 (R/W)	CPYHDR	Copy Header. The `PKTE_SA_CMD1.CPYHDR` bit indicates that the protocol header is copied to the output buffer and saved in memory. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the header is defined as the Hash/Crypt Offset data (authenticated only).	
		0	Do not copy the header to output
		1	Copy header to output

Table 39-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CPYDGST	Copy Digest. The PKTE_SA_CMD1.CPYDGST bit copies the hash result is to the output buffer and saves in memory. The length of the hash result is defined by the PKTE_SA_CMD0.DIGESTLEN field.	
		0	Do not copy hash result to output
		1	Copy hash result to output, when the command descriptor PKTE_CTL_STAT.HASHFINAL bit is set.

SA Inner Hash Digest Registers

The PKTE_SA_IDIGEST[n] registers are a set of eight 32-bit read/write registers.

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers are used to enter a start hash state, and to read the interim or final hash digest.

For IPsec, TLS and DTLS operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with basic hash or HMAC authentication with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the pre-computed inner hash digest. This is the hash of the hash-key padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the inner hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the hash-key pad (0x36 hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

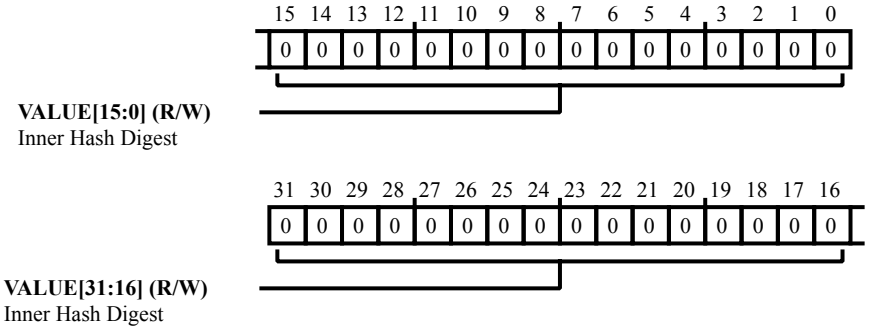

Figure 39-44: PKTE_SA_IDIGEST[n] Register Diagram

Table 39-70: PKTE_SA_IDIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Inner Hash Digest.

SA Key Registers

These are the PKTE_SA_KEY[n] registers for DES, Triple-DES, ARC4 and AES: A set of eight 32-bit write only registers. The reset value of these registers is zero.

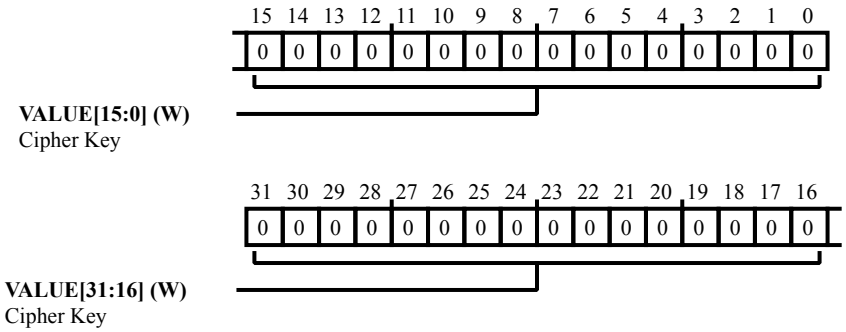

Figure 39-45: PKTE_SA_KEY[n] Register Diagram

Table 39-71: PKTE_SA_KEY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Cipher Key.

SA Initialization Vector Register

The PKTE_SA_NONCE register is used for operations that make use of the IV value loaded from the SA record. This register is used both to enter a starting IV state, as well as for reading the interim or final IV. For IPsec outbound operations, it is recommended that the automatic IV insertion mode be used, this register is not needed. For IPsec inbound operations, the IV is extracted from the header of the packet.

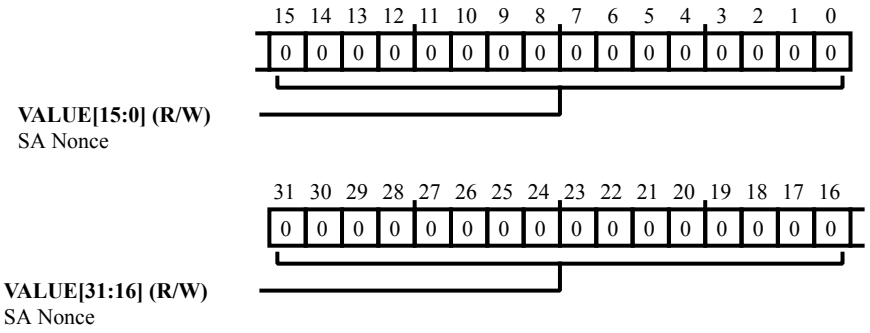

Figure 39-46: PKTE_SA_NONCE Register Diagram

Table 39-72: PKTE_SA_NONCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Nonce.

SA Outer Hash Digest Registers

The PKTE_SA_ODIGEST[n] registers are a set of five eight 32-bit write-only registers.

For write operations, these registers contain the pre-computed outer hash digest for IPsec operations with basic HMAC operations with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA).

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers hold a start hash state, or the interim outer hash digest. They are only used for HMAC processing.

For IPsec, SSL, TLS, DTLS and SRTP operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with HMAC authentication with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the pre-computed outer hash digest. This is the hash of the hash-key padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the outer hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the required hash-key pad (0x5C hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

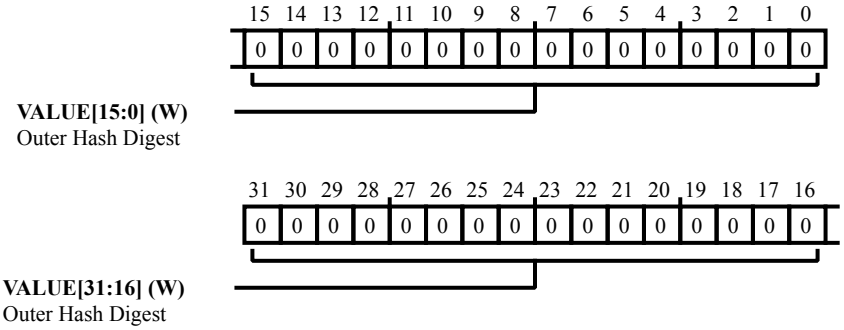

Figure 39-47: PKTE_SA_ODIGEST[n] Register Diagram

Table 39-73: PKTE_SA_ODIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Outer Hash Digest.

SA Ready Indicator

In direct host mode, a write to the PKTE_SA_RDY register triggers the packet engine to start processing using the command descriptor, SA record and state record in the packet engine registers. This register MUST be written for all direct host mode packet operations. It is intended that this register is written in sequence; as the entire SA record is written.

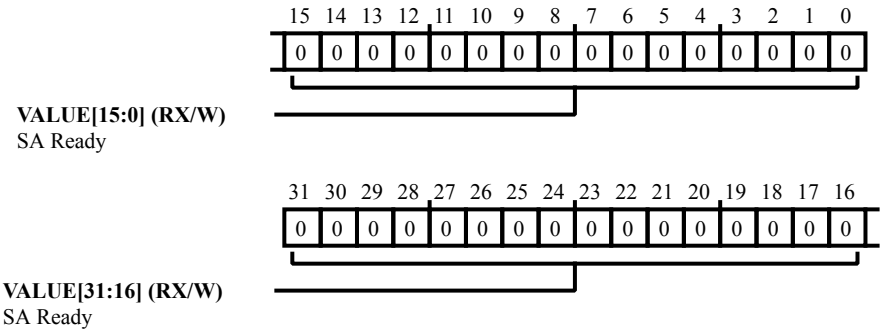

Figure 39-48: PKTE_SA_RDY Register Diagram

Table 39-74: PKTE_SA_RDY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	SA Ready.

SA Sequence Number Register

The PKTE_SA_SEQNUM[n] registers are a set of two read/write registers and are used for IPsec ESP, SSL, TLS, DTLS operations to specify the anti-replay sequence number value that is to be placed in the ESP header (outbound), or to be checked against for inbound packets. The packet engine manages this counter value for both inbound and outbound operations.

Outbound: The host writes the counter value stored in the SA record to this register to start an IPsec, SSL, TLS, DTLS operation. The packet engine automatically increments the count if header processing is selected. Upon successful completion, the host reads back this value and writes it to the SA record.

Inbound: The host writes the counter value stored in the SA record to this register to start an IPsec or DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the expected count value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Note: The description is only for the direct host mode. The sequence number for autonomous ring mode and target command mode are updated by the packet engine.

The reset value of this register is zero.

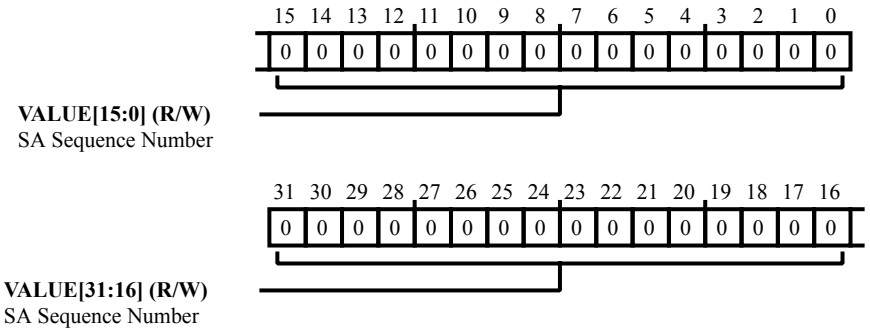

Figure 39-49: PKTE_SA_SEQNUM[n] Register Diagram

Table 39-75: PKTE_SA_SEQNUM[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Sequence Number.

SA Sequence Number Mask Registers

The PKTE_SA_SEQNUM_MSK[n] registers are a set of two read/write registers and are used for IPsec ESP and DTLS operations to specify the anti-replay sequence number mask value for inbound operations. The packet engine manages this counter value automatically.

Inbound: The host writes the counter value stored in the SA record into this register upon starting an IPsec, DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the new mask value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Outbound: not used.

Note that the above description only applies to the direct host mode, for autonomous ring mode and target command mode the packet engine extracts the sequence number mask from the SA record.

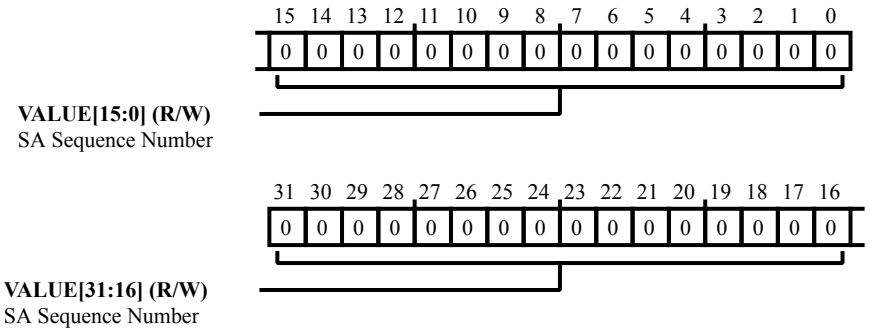

Figure 39-50: PKTE_SA_SEQNUM_MSK[n] Register Diagram

Table 39-76: PKTE_SA_SEQNUM_MSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Sequence Number.

SA SPI Register

For IPsec operations, the PKTE_SA_SPI register is written with the SPI (Security Parameters Index) associated with the inbound or outbound flow.

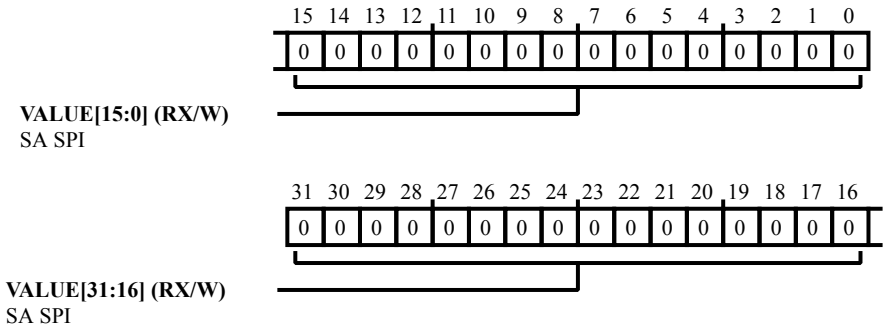

Figure 39-51: PKTE_SA_SPI Register Diagram

Table 39-77: PKTE_SA_SPI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	SA SPI. The PKTE_SA_SPI.VALUE bit field is used for IPsec ESP operations to specify the Security. Parameters Index (SPI) value that is to be placed in the ESP header. There is no need to read back this value at the end of an operation, since the Packet Engine does not change it. For SSL, TLS and DTLS this register stores the 8-bit TYPE field in bits [23:16], and the 16-bit Version field in bits [15:0] that are part of the protocol header.

Packet Engine Source Address

The PKTE_SRC_ADDR register holds the starting (byte) address for the packet to be processed.

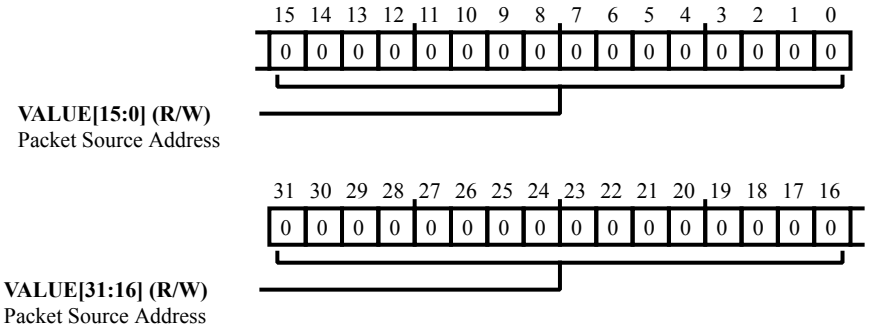

Figure 39-52: PKTE_SRC_ADDR Register Diagram

Table 39-78: PKTE_SRC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Packet Source Address. The PKTE_SRC_ADDR.VALUE bit field holds the starting (byte) address for the packet to be processed.

Packet Engine Status Register

The PKTE_STAT register is used to provide the status of the packet engine. This register is useful in the direct host mode to determine when data must be written to or read from the packet engine, or for debugging the software when errors occur. This register can be ignored in autonomous ring mode and target command mode where the DMA engine controls the packet data I/O. This is a read-only register. A write to any of the bits has no effect.

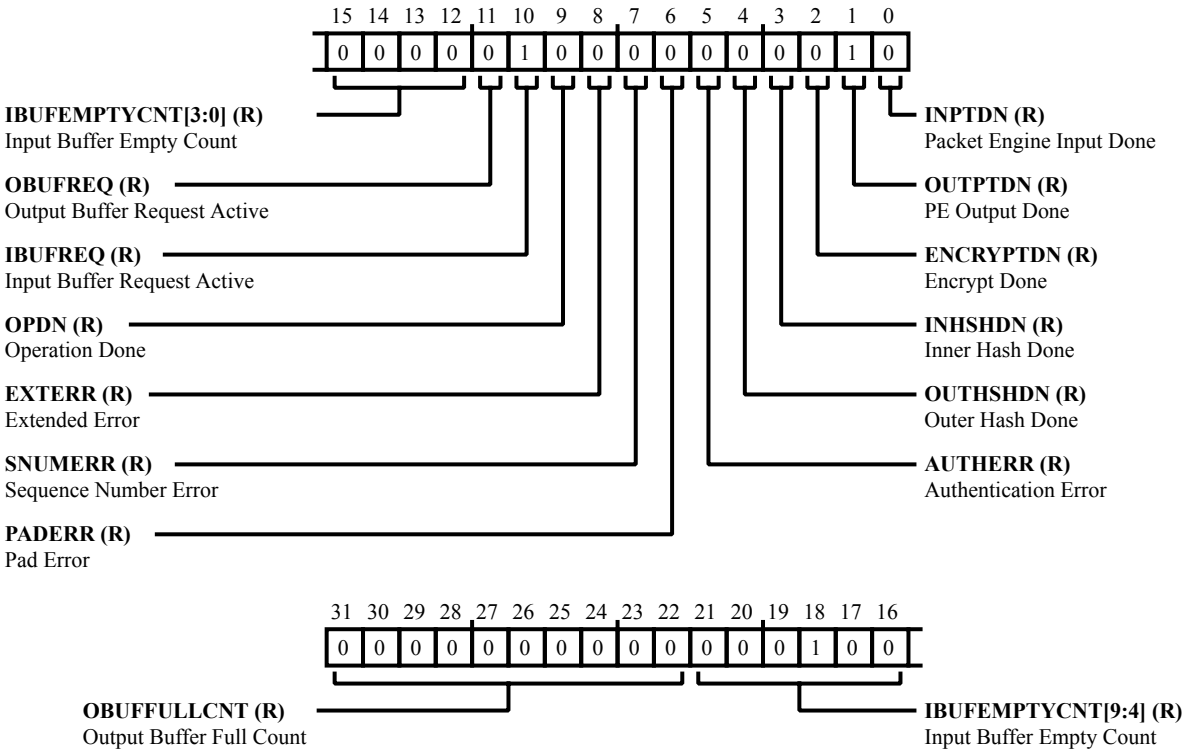

Figure 39-53: PKTE_STAT Register Diagram

Table 39-79: PKTE_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:22 (R/NW)	OBUFFULLCNT	Output Buffer Full Count. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of 32-bit words that are available in the packet engine output buffer. It works in conjunction with bit 11 from this register. When bit 11 is asserted, to indicate a request for output, the word count matches the specified output buffer threshold setting in the PKTE_BUF_THRESH register. For the last output for a given packet, any value from 1 dword to the full output buffer threshold can be seen. Transfers must be a multiple of full dwords. The application must read the PKTE_LEN field in the result descriptor to determine the exact byte-length of the result.

Table 39-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:12 (R/NW)	IBUFEMPTYCNT	Input Buffer Empty Count. The PKTE_STAT.IBUFEMPTYCNT bit field indicates the number of 32-bit empty spaces that are available in the packet engine input buffer. It works in conjunction with the PKTE_STAT.IBUFREQ bit (10) from this register. The value in the register is deducted from the specified packet length, so will never exceed the number of dwords that remain in the packet. For packets smaller than the buffer size, this register typically indicates that buffer space is available for the entire packet (rounded up to the nearest dword). For very large packets, these bits usually have a value around the maximum buffer size, indicating that the full input buffer is available.	
11 (R/NW)	OBUFREQ	Output Buffer Request Active. The PKTE_STAT.OBUFREQ bit indicates that the packet engine requests output data to be read from the output buffer.	
		0	No request for output data
		1	Request for output data
10 (R/NW)	IBUFREQ	Input Buffer Request Active. The PKTE_STAT.IBUFREQ bit indicates that the packet engine requests input data to be written to the input buffer.	
		0	No request for input data
		1	Request for input data
9 (R/NW)	OPDN	Operation Done. The PKTE_STAT.OPDN bit indicates that the packet engine has finished processing a packet when in direct host mode. This bit is zero in autonomous ring mode and target command mode.	
		0	Packet engine is idle
		1	Packet engine has finished processing a packet
8 (R/NW)	EXTERR	Extended Error. The PKTE_STAT.EXTERR bit indicates that an extended error occurred for this packet. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No extended error
		1	Extended error

Table 39-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SNUMERR	Sequence Number Error. For an inbound operation, the PKTE_STAT.SNUMERR bit indicates that there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No sequence number error
		1	Input done, all bytes written to input buffer
6 (R/NW)	PADERR	Pad Error. The PKTE_STAT.PADERR bit indicates that an inbound crypto pad fault is detected. For more information about pad verification, refer to the Pad Verification and Consumption section.	
		0	No pad error
		1	Pad error
5 (R/NW)	AUTHERR	Authentication Error. The PKTE_STAT.AUTHERR bit indicates that an inbound ICV (for IPsec) or TAG (for SRTP) or MAC (for SSL/TLS/DTLS) fault is detected; the value carried within the packet did not match the value just computed.	
		0	No authentication error
		1	Authentication error
4 (R/NW)	OUTHSHDN	Outer Hash Done. The PKTE_STAT.OUTHSHDN bit indicates that the outer hash processing for this packet is finished.	
		0	Outer hash busy
		1	Outer hash done
3 (R/NW)	INHSHDN	Inner Hash Done. The PKTE_STAT.INHSHDN bit indicates that the inner hash processing for this packet is finished.	
		0	Inner hash busy
		1	Inner hash done
2 (R/NW)	ENCRYPTDN	Encrypt Done. The PKTE_STAT.ENCRYPTDN bit indicates that the encryption or decryption for this packet is finished.	
		0	Encryption or decryption busy
		1	Encryption or decryption done

Table 39-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	OUTPTDN	PE Output Done. The `PKTE_STAT.OUTPTDN` bit indicates that the output data for the current packet is read from the packet engine output buffer.	
		0	Output not done, more output bytes available
		1	Output done, all bytes read from the output buffer
0 (R/NW)	INPTDN	Packet Engine Input Done. The `PKTE_STAT.INPTDN` bit indicates that the number of bytes specified in the command descriptor `PKTE_LEN` field is written into the packet engine input buffer.	
		0	Input not done, more input bytes expected
		1	Input done, all bytes written to input buffer

Packet Engine State Record Address

The PKTE_STATE_ADDR register holds the start address of the SA state record.

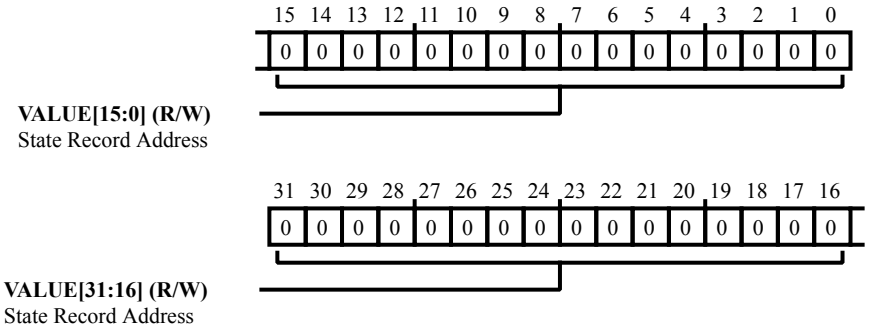

Figure 39-54: PKTE_STATE_ADDR Register Diagram

Table 39-80: PKTE_STATE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	State Record Address. The PKTE_STATE_ADDR.VALUE bit field holds the start address of the SA state record.

State Hash Byte Count Registers

The PKTE_STATE_BYTE_CNT[n] registers are used to enter a starting hash byte count, as well as to read the interim or final byte count.

For some hash operations, these registers are ignored and the byte count is internally set to 64 (0x40 hex) to indicate that the first 64 bytes (512 bits) hash block has been processed using a pre-computed hash state. These operations are:

All IPsec, SSL, TLS, DTLS and SRTP operations that use authentication; the "pre-computed" inner and outer hash digests are loaded from SA words 10 - 19.

Basic operations with PKTE_SA_CMD0.HASHSRC bits = 00 (from SA) specified. For Basic Hash with no HMAC, a pre-computed digest is loaded from SA words 10 - 14. For Basic Hash with HMAC, the inner and outer digests are loaded from SA words 10 - 19.

Note: Protocol operations can not be suspended in mid-packet and resumed later, therefore protocol operations do not use these registers.

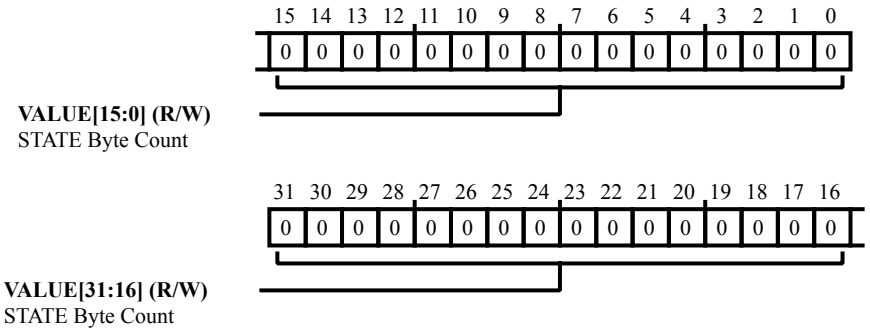

Figure 39-55: PKTE_STATE_BYTE_CNT[n] Register Diagram

Table 39-81: PKTE_STATE_BYTE_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	STATE Byte Count.

State Inner Digest Registers

The PKTE_STATE_IDIGEST[n] registers consist of eight 32-bit registers. These read/write registers are used to read the interim or final hash digest. The PKTE_STATE_IDIGEST[n] registers are only used with basic operations involving basic hash, and are typically used for operations that must be suspended and resumed in the middle of a hash. The interim hash state can be read from these registers along with the hash byte-count from the previous register. Both can be restored when resuming the hash. The appropriate save hash state (PKTE_SA_CMD0.SVHASH=1) and load hash from state (PKTE_SA_CMD0.HASHSRC=0b10) settings must be used. These registers are a mirror of the SA record inner hash digest register.

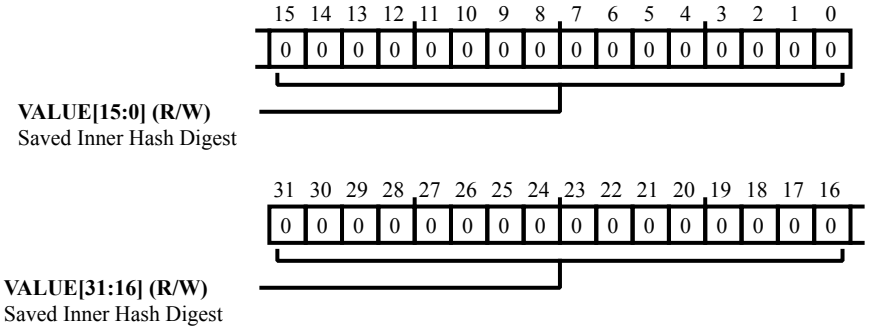

Figure 39-56: PKTE_STATE_IDIGEST[n] Register Diagram

Table 39-82: PKTE_STATE_IDIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Saved Inner Hash Digest.

State Initialization Vector Registers

The PKTE_STATE_IV[n] consists of four 32-bit registers. These registers are used to enter a starting IV state and to read the interim or final IV. PKTE_STATE_IV0 and PKTE_STATE_IV1 are used with DES/3DES cipher while PKTE_STATE_IV0 to PKTE_STATE_IV3 are used with AES cipher. The reset value of these registers is zero.

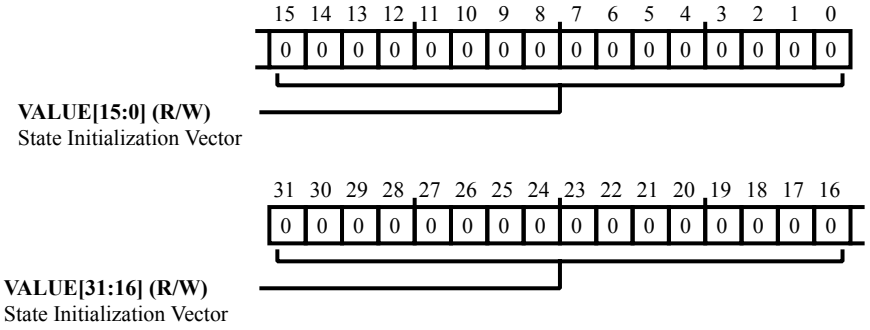

Figure 39-57: PKTE_STATE_IV[n] Register Diagram

Table 39-83: PKTE_STATE_IV[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	State Initialization Vector. The PKTE_STATE_IV[n].VALUE bit field is used to enter a starting IV state and to read the interim or final IV.

Packet Engine User ID

The PKTE_USERID register is a read/write register that gives identification to a command descriptor and the resultant result descriptor. The host is free to use this field for its own purpose. The host can write a unique identifier to the register in direct host mode or includes it as part of the command descriptor in autonomous ring mode. The PKTE_USERID register value passes though the packet engine without alteration to the result descriptor to be read back by the host.

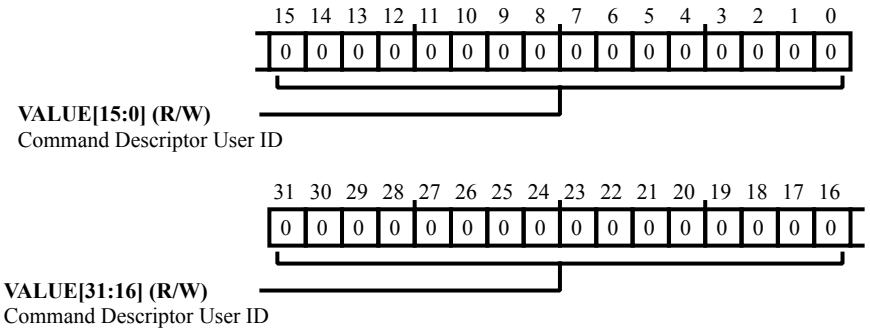

Figure 39-58: PKTE_USERID Register Diagram

Table 39-84: PKTE_USERID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor User ID. The PKTE_USERID.VALUE bit field gives identification to a command descriptor and the resultant result descriptor.

40 Public Key Accelerator (PKA)

The PKA helps offload computationally-intensive operations commonly found in public key cryptography algorithms.

PKA Features

The PKA engine provides the following basic operations:

- Large vector addition, subtraction, and combined addition/subtraction
- Large vector shift right or left
- Large vector multiplication, division (with and without quotient)
- Large vector compare and copy

The PKA engine provides the following complex operations:

- Large vector unsigned value modular exponentiation
- Large vector unsigned value modular exponentiation using the 'Chinese Remainders Theorem' (CRT) method with pre-calculated Q inverse vector
- Modular inversion: Given A and M, calculate B such that ((A × B) MOD M) = 1
- ECC point addition/doubling on elliptic curve $y^2 = x^3 + ax + b \pmod p$ with prime number *p* and input values *a* and *b* to the operation. Adding two identical points automatically performs point doubling.
- ECC point multiplication on elliptic curve $y^2 = x^3 + ax + b \pmod p$ with prime number *p* and input values *a* and *b* to the operation. A version of the 'Montgomery ladder' algorithm is used to provide side channel attack resistance.

The PKA also contains hardware logic to automatically zero out the PKA RAM buffer to clear out any information that is considered sensitive or secure.

PKA Functional Description

The following sections provide details on the function of the PKA module.

ADSP-2159x_SC591_SC592_SC594 PKA Register List

The Public Key Accelerator module (PKA) provides security-related features. A set of registers governs PKA operations. For more information on PKA functionality, see the PKA register descriptions.

Table 40-1: ADSP-2159x_SC591_SC592_SC594 PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Definitions

The following definitions are helpful when using the PKA module.

Elliptic Curve Cryptography (ECC)

A form of public key cryptography based on elliptic curves over finite fields.

RSA

An acronym for Ron Rivest, Adi Shamir, and Leonard Adleman. It is another form of a public key cryptosystem.

Chinese Remainder Theorem (CRT)

A mathematical theorem used for simplifying time-consuming arithmetic used in public key algorithm computations.

Addition Chaining Table (ACT)

A method of speeding up exponentiation by repeatedly squaring the input and storing the result and reusing the result as input. ACT2 uses a table with 2 address bits (4 entries) and ACT4 uses a table with 4 address bits (16 entries).

PKA Architectural Concepts

The following sections describe the PKA architecture.

Public Key Co-Processor (PKCP)

The Public Key Co-Processor (PKCP) handles the basic large vector processing such as addition, subtraction, multiplication, etc.

Sequencer

The sequencer is small processor that is part of the PKA which handles the more complicated vector processing for public key algorithms. Algorithms include modular exponentiation and the ECC addition and ECC multiply used in Elliptic Curve Cipher algorithms. It executes instructions stored from an internal pre-programmed ROM that handles these operations.

RAM

Input and output vectors are stored in a 4 kB RAM buffer that is part of the MMR space. The address of PKA_RAM is the beginning of the RAM space. This memory is also used as a scratchpad or workspace for the sequencer and PKCP. Programs must place the vectors appropriately following the constraints described in the ***Functional Description*** section of this chapter.

PKA Block Diagram

The ***PKA Block Diagram*** shows the top-level block diagram of the PKA engine. The PKA engine is comprised of five parts:

1. Registers for input, output, status, and control
2. Public Key Co-processor (PKCP) module which performs the basic suite of big number (vector) operations typically found in public key cryptography applications
3. Sequencer which controls modular exponentiation, elliptic curve cryptography, and modular inversion operations.
4. Program ROM associated with the PKA engine exclusively for the sequencer
5. PKA RAM holds the large input and output values as well as the workspace/scratchpad required from the sequencer and PKCP for operations.

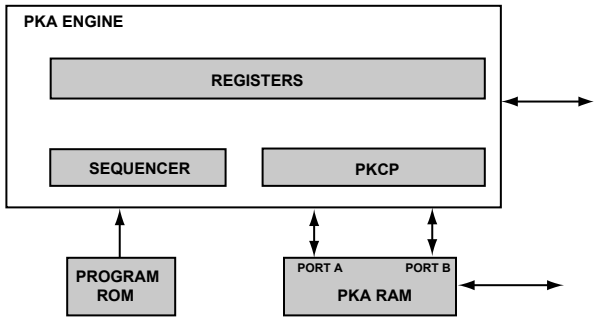

Figure 40-1: PKA Block Diagram

PKCP Vector Operations

The ***Summary of PKCP Vector Operations*** table lists the arguments and results for each PKCP vector operation.

Table 40-2: Summary of PKCP Vector Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
Multiply	A x B → C	Multiplicand	Multiplier	Product	N/A
Add	A + B → C	Addend	Addend	Sum	N/A
Subtract	A - B → C	Minuend	Subtracthend	Difference	N/A
AddSub	A + C - B → D	Addend	Subtracthend	Addend	Result
Right Shift	A >> Shift → C	Input	N/A	Result	N/A
Left Shift	A << Shift → C	Input	N/A	Result	N/A
Divide	A mod B → C, A div B → D	Dividend	Divisor	Remainder	Quotient
Modulo	A mod B → C	Dividend	Divisor	Remainder	N/A
Compare	A = B, A < B, A > B	Input 1	Input 2	N/A	N/A
Copy	A → C	Input	N/A	Result	N/A

To obtain correct result, the input vectors must meet the requirements presented in the ***Operational Restrictions on Input Vectors for PKCP Operations*** table.

Note the following:

- The PKCP does not check input restrictions
- A_Len and B_Len indicate the size of vectors A and B in (32-bit) words
- Max_Len equals 128 (32-bit) words, for example, the standard maximum vector size is 4096 bit

Table 40-3: Operational Restrictions on Input Vectors for PKCP Operations

Function	Requirement
Multiply	0 < A_Len, B_Len <= Max_Len
Add	0 < A_Len, B_Len <= Max_Len
Subtract	0 < A_Len, B_Len <= Max_Len Result must be positive (A>=B)
AddSub	0 < A_Len <= Max_Len (B and C operands have A_Len as length, B_Len ignored) Result must be positive ((A + C) >= B)
Right Shift	0 < A_Len <= Max_Len
Left Shift	0 < A_Len <= Max_Len
Divide, Modulo	1 < B_Len <= A_Len <= Max_Len Most significant 32-bit word of B operand cannot be zero
Compare	0 < A_Len <= Max_Len (B operand has A_Len as length, B_Len ignored)
Copy	0 < A_Len <= Max_Len

The host processor is responsible for allocating a block of contiguous memory in PKA RAM for the result vectors. The ***PKCP Result Vector Memory Allocation*** table indicates how much memory is allocated for the result vectors.

Table 40-4: PKCP Result Vector Memory Allocation

Function	Result Vector	Result Vector Length (in 32-bit words)
Multiply	C	A_Len + B_Len + 6 (the 6 'scratchpad' words should be discarded)
Add	C	Max(A_Len, B_Len) + 1
Subtract	C	Max(A_Len, B_Len)
AddSub	D	A_Len + 1
Right Shift	C	A_Len
Left Shift	C	A_Len + 1 (when Shift Value is non-zero) A_Len (when Shift Value is zero)
Divide	C	Remainder → B_Len + 1 (one 'scratchpad' word should be discarded)
	D	Quotient → A_Len – B_Len + 1
Modulo	C	Remainder → B_Len + 1 (one 'scratchpad' word should be discarded)
Compare	None	Compare updates the PKA_COMPARE register
Copy	C	A_Len

Input vectors for an operation are always allowed to overlap in memory (partially or completely). The ***PKCP Result Vector/Input Overlap Restrictions*** table gives restrictions for the overlap of output and input vectors of the operations.

Table 40-5: PKCP Result Vector/Input Overlap Restrictions

Function	Result Vector	Restrictions
Multiply	C	No overlap with A or B vectors allowed
Add, Subtract	C	May overlap with A and/or B vector, provided the start address of the C vector does not lie above the start address of the vectors with which it overlaps
AddSub	D	May overlap with A, B and/or C vector, provided the start address of the D vector does not lie above the start address of the vectors with which it overlaps
Right Shift, Left Shift	C	May overlap with A vector, provided the start address of the C vector does not lie above the start address of the A vector
Divide	C	No overlap with A, B, or D vectors allowed
	D	No overlap with A, B, or C vectors allowed
Modulo	C	No overlap with A or B vectors allowed
Compare	None	Compare does not write a result vector
Copy	None	Same restrictions as for right or left shift, copy of a vector to a lower address is always allowed even if source and destination overlap†

†The copy operation can be used to fill memory by breaking the overlap restrictions, but it requires setting up TWO initial (32-bit) words. To zero a block of memory, set the A vector pointer to the block start, set the C vector pointer two words higher and the A vector length to the block length minus two (words). Fill the first two words of the block with constant zero and perform a PKCP copy operation to zero the remainder of the block.

Modular Exponentiation Operations

The ***Summary of ExpMod Operations*** table summarizes the modular exponentiation operations that the PKA supports.

Table 40-6: Summary of ExpMod Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	$C^A \bmod B \rightarrow D$	Exponent, length = A_Len	Modulus, length = B_Len	Base, length = B_Len	Result and Workspace
ExpMod-CRT	See below	Exp P followed by Exp Q at next higher even word address†, both A_Len long	Mod P + buffer word followed by Mod Q at next higher even word address‡, both B_Len long	Q inverse, length = B_Len	Input, Result (both 2xB-Len long) and Workspace

† If A_Len is even, Exp Q follows Exp P immediately – if A_Len is odd, there is one empty word between Exp Q and Exp P.

‡ If B_Len is even, there are two empty words between Mod P and Mod Q – if B_Len is odd, there is one empty (buffer) word between Mod Q and Mod P. Note that the engine may zero the words following Mod P and Mod Q.

The ExpMod-CRT operation performs the following computation steps. (These steps implement Garner's recombination algorithm after the basic exponentiations.)

- X <- (Input mod Mod P)Exp P mod Mod P
- Y <- (Input mod Mod Q)Exp Q mod Mod Q
- Z <- ((((X – Y) mod Mod P) · Q inverse) mod Mod P) · Mod Q
- Result <- Y + Z

The ExpMod-ACT2, -ACT4, and -variable functions implement the same mathematical operation but with a differently sized table with pre-calculated *odd powers*. The ExpMod-ACT2 function uses a table with two entries whereas ExpMod-ACT4 uses a table with eight entries. The ACT4 version gives better performance but needs more memory. ExpMod-variable and ExpMod-CRT operations allow the selection of a variable number (from 1 up to and including 16) of odd powers through the register normally used to specify the number of bits to shift for shift operations.

The exponentiation functions are extensions of the set of PKA functions. Input and result vectors are passed the same way as basic PKCP operations. The ***Restrictions on Input Vectors for ExpMod Operations*** table shows the restrictions on the input and result vectors for the exponentiation operations.

Table 40-7: Restrictions on Input Vectors for ExpMod Operations

Function	Requirements
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B > 2^{32} Base C < Modulus B Vectors B and C must be followed by an empty 32-bit *buffer* word
ExpMod-CRT	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Mod P and Mod Q must be odd (for example, the least significant bits must be ONE) Mod P > Mod Q > 2^{32}(note that Mod P must be larger than Mod Q) Mod P and Mod Q must be co-prime (their GCD must be 1) 0 < Exp P < (Mod P – 1) 0 < Exp Q < (Mod Q – 1) (Q inverse · Mod Q) 1 (modulo Mod P) Input < (Mod P · Mod Q) Mod P and Mod Q must be followed by an empty 32-bit *buffer* word

The ***ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR*** table shows the required scratchpad sizes for the exponentiation operations. These sizes depend on the PKA type. The 'M_Len' used in the table is the 'real' Modulus length in 32-bit words, for example, without trailing zero words at the end. (This description also applies to Mod P in an ExpMod-CRT operation and Modulus B in the other operations.) If the last word of the modulus vector as given is non-zero, 'M_Len' equals B_Len.

Table 40-8: ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR

Function	Scratchpad Area Size (in 32-bit words), Result Vector is either M_Len or 2xM_Len 32-bit words long
ExpMod-ACT2	5 x (M_Len + 2)
ExpMod-ACT4	11 x (M_Len + 2)
ExpMod-variable	(# odd powers + 3) x (M_Len + 2)
ExpMod-CRT	(# odd powers + 3) x (M_Len + 2) + (M_Len + 2 – (M_Len MOD 2))

NOTE: During execution of an ExpMod-ACT2, -ACT4 or -variable operation, the last 34 bytes of the PKA RAM are used as the general scratchpad for the sequencer program execution. The ExpMod-CRT operation requires the last 72 bytes of the PKA RAM as the scratchpad. These (fixed location) areas may not overlap with any of the input vectors and/or the D vector scratchpad area. They can be used freely when executing basic PKCP operations.

Table 40-9: ExpMod Scratchpad Area / Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	D	Scratchpad area starting at D may not overlap with any of the other vectors, except that base C may be co-located with result vector D to save space (for example, PKA_CPTR= PKA_DPTR is allowed).
ExpMod-CRT	D	Scratchpad area starting at D may not overlap with any of the other vectors. This area is also the location of the main input vector (with length 2 x B_Len)

The ***Maximum Number of Odd Powers*** table indicates the maximum number of odd powers that can be used for different standard PKA RAM sizes and PKA types (non-CRT operations using PKA_CPTR = PKA_DPTR). As a rule of thumb, for optimal performance, use one odd power for *Verify* operations and 4 (or as many as the implemented PKA RAM size allows) for *Sign* operations. Note the following points about odd powers:

- Using more than eight odd powers is not advisable as the speed advantage for each extra odd power decreases rapidly (and can even become negative for short exponent vector lengths due to the extra pre-processing required).
- The maximum number of odd powers is 16 (limited by the firmware). All '16 odd powers' entries in the table above hit this limit – they are not limited by the PKA RAM size.

Table 40-10: Maximum Number of Odd Powers

Operation	Modulus and Exponent Sizes	Maximum Number of Odd Powers
Non-CRT	1024 bits	16
	2048 bits	10
	4096 bits	2
CRT	2 × 512 bits	16
	2 ×1024 bits	16
	2 × 2048 bits	6

The ***2K-bit Modular Exponentiation PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for modular exponentiation operations with and without using CRT. The *free space* start address is the first free byte following the vector workspace. The sequencer execution scratchpad of 34 bytes (non-CRT) or 72 bytes (using CRT) must fit between this address and the end of the PKA RAM. Note that the non-CRT operations use `PKA_CPTR` = `PKA_DPTR` to save space.

Table 40-11: 2K-bit Modular Exponentiation PKA RAM Allocation Examples

Operation	(sub-)vector	Start address (Byte Offset)	Size (words)	Buffer (words)
non-CRT (`PKA_ALEN` = 0x040, `PKA_BLEN` = 0x040, 4 odd-powers)	Exponent	0x000 (`PKA_APTR` = 0x000)	64	0
	Modulus	0x100 (`PKA_BPTR` = 0x040)	64	2
	Base	0x208 (`PKA_CPTR` = 0x082)	64	2
	Result	0x208 (`PKA_DPTR` = 0x082)	64	2
	Vector Workspace	0x208 (= Result)	7 × (64+2)=462	0
	Free space	0x940 (2368 bytes used)	-	-
using CRT (`PKA_ALEN` = 0x020, `PKA_BLEN` = 0x020, 4 odd-powers)	Exp P	0x000 (`PKA_APTR` = 0x000)	32	0
	Exp Q	0x080	32	0
	Mod P	0x100 (`PKA_BPTR` = 0x040)	32	2
	Mod Q	0x188	32	2
	Q inverse	0x210 (`PKA_CPTR` = 0x084)	32	0
	Input, Result	0x290 (`PKA_DPTR` = 0x0A4)	64	0
	Vector workspace	0x290 (= Result)	7 × (32+2)+32+2-0 = 272	0
	Free space	0x6D0 (1744 bytes used)	-	-

The following example in pseudo-code describes the execution of a non-CRT modular exponentiation operation using a 512 bits modulus and a 160 bits exponent, using actual test vectors:

```
// Perform a 512/160 bits
modular exponentiation without CRT (using 4 'odd-powers')
// Exponent equals value 0x8FD84098_8A0930CC_9CDC1E8A_B246EB46_2D39F064
// write as vector A to PKA
```

Modular Inversion

Besides modular exponentiation, the sequencer also controls modular inversion operations.

Table 40-12: Summary of ModInv Operation

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ModInv	A^{-1} mod B → D	NumToInvert, length = A_Len	Modulus, length = B_Len	Not Used	Result and Workspace

The above function appears to be an extension of the set of basic PKCP functions with the following exceptions:

- Vector D not only addresses the result but also a workspace
- The `PKA_SHIFT` register field is used to return info on the operation's result.

Table 40-13: PKA_SHIFT Result Values for ModInv Operation

Function	PKA_SHIFT Register Field Value At Conclusion
ModInv	0 → success; VectorD holds result 7 → no inverse exists (GCD(A, B) != 1, for example, A and B have common factors); result undefined 31 → error, modulus even; result undefined other values are reserved

The following tables list the restrictions on the input and result vectors for the ModInv operation:

Table 40-14: Operational Restrictions on Input Vectors for the ModInv Operation

Function	Requirements
ModInv	0 < A_Len <= Max_Len 0 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B may not have value 1 (result is undefined, no error indicated) The highest word of the modulus vector, as indicated by B_Len, may not be zero.

Table 40-15: ModInv Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ModInv	D	Scratchpad area starting at D may not overlap with any of the other vectors

The following table shows the required scratchpad sizes for the ModInv Operation:

Table 40-16: ModInv Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is B_Length 32-bit words long
ModInv	5 x (M + ε(M)), with M = Max(A_Length, B_Length) ε(n) = 2 + (n MOD 2), for example, 2 (for n even) or 3 (for n odd)

NOTE: During execution of a ModInv operation, the last 34 bytes of the PKA RAM are used as general scratchpad for the sequencer program execution. This (fixed location) area may not overlap with any of the input vectors and/or the D vector scratchpad area during execution.

Modular Inversion with an Even Modulus

The ModInv operation requires the modulus to be odd. At first, this requirement appears to make the operation useless in the case of RSA key generation where the private key exponent *d* is derived from a chosen public exponent *e* as follows:

d = ModInv(e, φ); where φ = (p-1) × (q-1) and *p* and *q* both prime

Note that φ is even. However, since *e* must be odd (otherwise no inverse exists), *d* can be calculated as:

d = (1 + (φ × (e – ModInv(φ, e))) / e

With four more basic PKCP operations, ModInv can also be used to find inverse values in case the modulus is even.

Modular Inversion with a Prime Modulus

Modular inversion can be performed with a modular exponentiation using the modulus value minus two as exponent, provided that the modulus value is a prime. This is due to the following:

$(A^M) \bmod M = A \Rightarrow$

$(A^{M-1}) \bmod M = 1 \Rightarrow$

$(A^{M-2}) \bmod M = A–1 \pmod M$

Under the constraint that M is a prime value.

Especially with the large PKA engines containing an LNME, it is worthwhile to check whether this method is faster than using the ModInv operation directly. The modulus values for the ECC curves supported by this PKA engine must be prime, so this method can be used in ECDSA operations.

ECC Operations

Besides modular exponentiation and modular inversion, the sequencer also controls ECC operations.

Table 40-17: Summary of ECC Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ECC-ADD	Point addition/ doubling† on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ pntA + pntC → pntD	pntA.x followed‡ by pntA.y both B_Len long (A_Len *not* used)	Curve parameter *p* followed‡ by *a* (*b* is not needed) all B_Len long	pntC.x followed by pntC.y both B_Len long	Result, for example, pntD.x followed‡ by pntD.y and workspace
ECC-MUL	Point multiplication on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ *k* x pntC → pntD	Scalar *k* A_Len long	Curve parameter *p* followed‡ by *a*and *b* all B_Len long.	pntC.x followed‡ by pntC.y both B_Len long	Result, for example pntD.x followed‡ by pntD.y and workspace

† If pntA = pntC, a point doubling operation is performed automatically.

‡ All input components must be located on a 64-bit boundary and must have extra 'buffer' words (of 32 bits each) after their most significant word. ε must be 3 (B_Len odd) or 2 (B_Len even). Each result component (for example, pntD.x, pntD.y) is followed by ε buffer (zero) words.

The above functions appear to be extensions of the set of PKCP basic functions with the following exceptions:

- Input and result vectors can now be composite (for example, consist of two or three equal-sized subvectors)
- Vector D not only addresses the result but also a workspace
- The `PKA_SHIFT` register is used to return info on the result of the operation

Table 40-18: PKA_SHIFT Result Values for ECC Operations

Function	PKA_SHIFT Register Field Value at Conclusion
ECC-ADD ECC-MUL	0 → success; VectorD holds result point 7 → result is point-at-infinity; VectorD result point undefined 31 → error, (p not odd, p too short, etc); VectorD result point undefined Other values are reserved

The following tables below list the restrictions on the input and result vectors for the ECC operations.

Table 40-19: Operational Restrictions on Input Vectors for ECC Operations

Function	Requirements
ECC-ADD	1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. *a*< p and *b*< p pntA and pntC must be on the curve (this condition is not checked) Neither pntA nor pntC can be the point-at-infinity, although ECC-ADD can return this point as a result
ECC-MUL	0 < A_Len <= 24 (maximum vector length is 768 bits) 1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. *a*< p and *b*< p pntC must be on the curve (this condition is not checked) pntC cannot be the point-at-infinity, although ECC-MUL can return this point as a result

† Modulus lengths of 112 and 521 bits are exceptions to this rule.

Table 40-20: ECC Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ECC-ADD ECC-MUL	D	Scratchpad area starting at D may not overlap with any of the other vectors

The ***>ECC Result Vector/Scratchpad Area Memory Allocation*** table shows the required scratchpad sizes for the ECC operations:

Table 40-21: ECC Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is 2x(B_Length+ ε †(B_Length)) 32-bit words long
ECC-ADD	2 × L + 5 x M, where L = B_Length + ε(B_Length) M = B_Length + 1 + ε(B_Length + 1)
ECC-MUL	18 x L + Max(8, L), where L = (B_Length + ε(B_Length))

† ε(*n*) = 2 + (*n* MOD 2), for example, 2 (for *n* even) or 3 (for *n* odd)

NOTE: During execution of an ECC-ADD or ECC-MUL operation, the last 72 bytes of the PKA RAM are used as a general scratchpad for the sequencer program execution. These (fixed location) areas must not overlap with any of the input vectors and the D vector scratchpad area during execution.

The ***ECC Point Multiplication PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for ECC point multiplication operations. The *free space* start address is the first free byte following the vector scratchpad. The sequencer execution scratchpad of 72 bytes must fit between this address and the end of the PKA RAM. Because of this requirement, a 521-bit ECC point multiplication cannot be performed with 2K byte PKA RAM.

Table 40-22: ECC Point Multiplication PKA RAM Allocation Examples

Modulus Length	(sub-)vector	Start Address (byte offset)	Size (words)	Buffer (words)
192 bits (=6 words, PKA_ALEN=0x006, PKA_BLEN=0x006)	Scalar *k*	0x000 (PKA_APTR = 0x000)	6	0

ADSP-2159x_SC591_SC592_SC594 PKA Register Descriptions

Public Key Accelerator (PKA) contains the following registers.

Table 40-23: ADSP-2159x_SC591_SC592_SC594 PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Vector_A Length

During execution of basic PKCP operations, the PKA_ALEN register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_ALEN register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

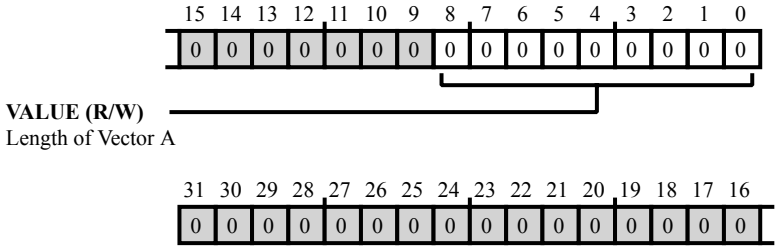

Figure 40-2: PKA_ALEN Register Diagram

Table 40-24: PKA_ALEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Length of Vector A. Length (in 32-bit words) of Vector A.

PKA Vector_A Address

During execution of basic PKCP operations, the PKA_APTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_APTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

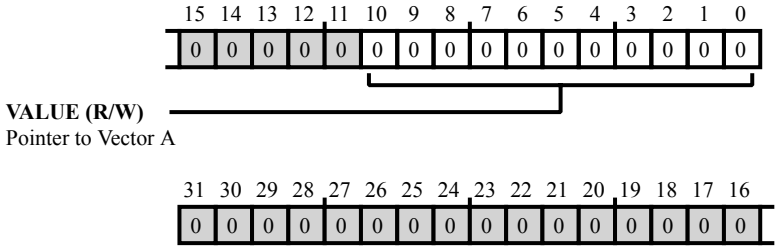

Figure 40-3: PKA_APTR Register Diagram

Table 40-25: PKA_APTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector A. The PKA_APTR.VALUE bit field is the location of Vector A within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Vector_B Length

During execution of basic PKCP operations, the PKA_BLEN register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_BLEN register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

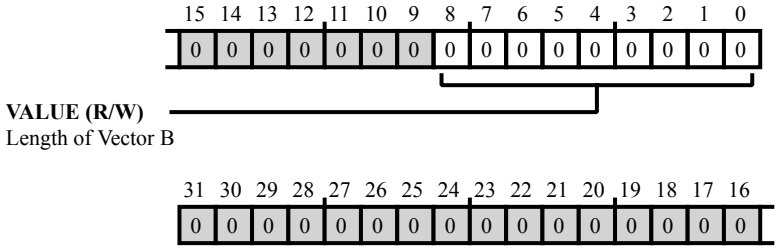

Figure 40-4: PKA_BLEN Register Diagram

Table 40-26: PKA_BLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Length of Vector B. Length (in 32-bit words) of Vector B.

PKA Vector_B Address

During execution of basic PKCP operations, the PKA_BPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_BPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

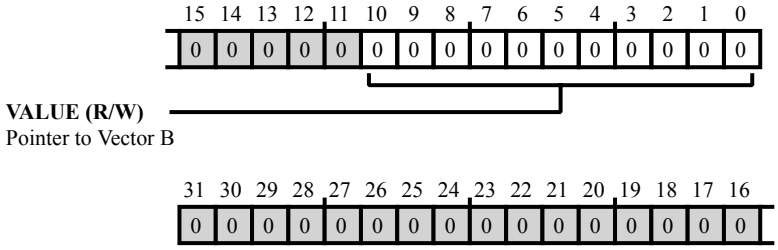

Figure 40-5: PKA_BPTR Register Diagram

Table 40-27: PKA_BPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector B. The PKA_BPTR.VALUE bit field is the location of Vector B within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Compare Result

The PKA_COMPARE register provides the result of a basic PKCP Compare operation. It is updated when the PKA_FUNC.RUN bit is reset at the end of that operation. The status after a complex sequencer operation is unknown.

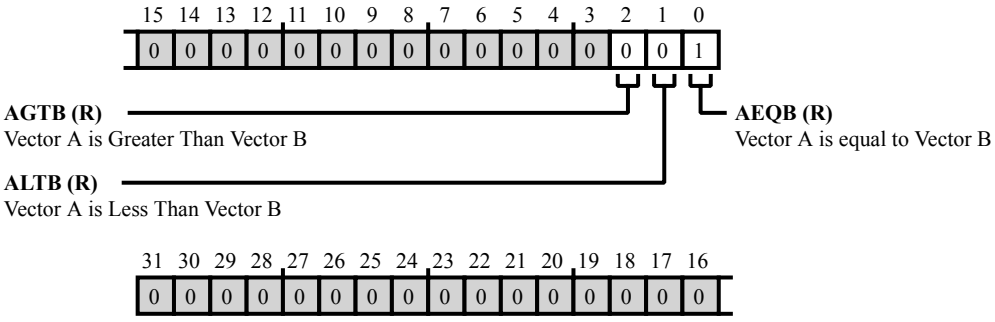

Figure 40-6: PKA_COMPARE Register Diagram

Table 40-28: PKA_COMPARE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	AGTB	Vector A is Greater Than Vector B. The PKA_COMPARE.AGTB bit shows the result of the basic compare operation is PKCP Vector_A is greater than Vector_B.
1 (R/NW)	ALTB	Vector A is Less Than Vector B. The PKA_COMPARE.ALTB bit shows the result of the basic compare operation is Vector_A is less than Vector_B.
0 (R/NW)	AEQB	Vector A is equal to Vector B. The PKA_COMPARE.AEQB bit shows the result of the basic compare operation is Vector_A is equal to Vector_B.

PKA Vector_C Address

During execution of basic PKCP operations, the PKA_CPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_CPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

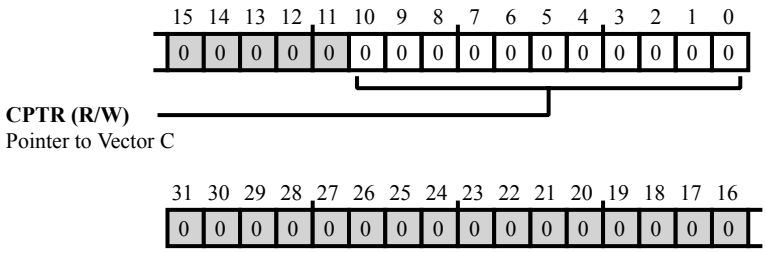

Figure 40-7: PKA_CPTR Register Diagram

Table 40-29: PKA_CPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	CPTR	Pointer to Vector C. The PKA_CPTR.CPTR bit field is the location of Vector C within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Most-Significant-Word of Divide Remainder

The PKA_DIVMSW register indicates the (32-bit word) address in the PKA RAM where the most significant non-zero 32-bit word of the Remainder result for the basic Divide and Modulo operations is stored. Bits [4:0] are loaded with the bit number of the most significant non-zero bit in the most significant non-zero word when MS one control bit is set. For Divide, Modulo and MS one reporting, this register is updated when the PKA_FUNC.RUN bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating bits [4:0] of this register with the actual result's most significant bit location is done near the end of the operation. Note that the result is only meaningful if no errors were detected and that for ECC operations, the PKA_DIVMSW register provides information for the x-coordinate of the result point only.

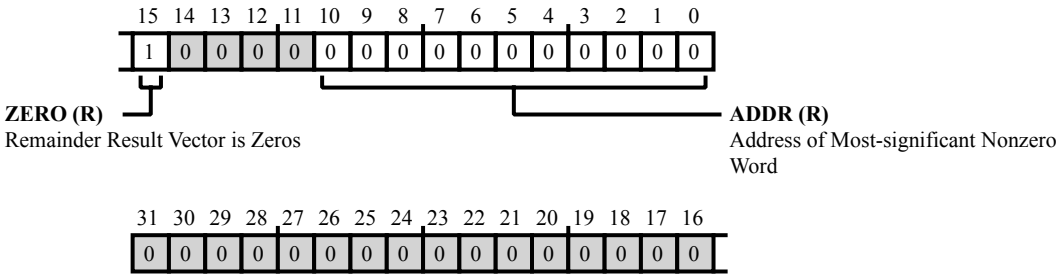

Figure 40-8: PKA_DIVMSW Register Diagram

Table 40-30: PKA_DIVMSW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Remainder Result Vector is Zeros. The PKA_DIVMSW.ZERO bit shows the remainder result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The PKA_DIVMSW.ADDR bit shows the address of the most significant non-zero 32-bit word of the remainder result vector in PKA RAM.

PKA Vector_D Address

During execution of basic PKCP operations, the PKA_DPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_DPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

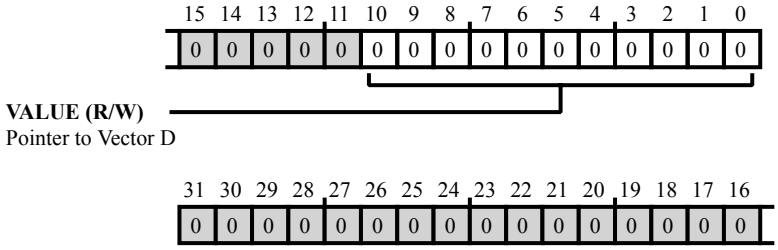

Figure 40-9: PKA_DPTR Register Diagram

Table 40-31: PKA_DPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector D. The PKA_DPTR.VALUE bit field is the location of Vector D within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Function

The PKA_FUNC register contains the control bits to start basic PKCP as well as complex sequencer operations. The PKA_FUNC.RUN bit can be used to poll for the completion of the operation. Modifying bits [11:0] is made impossible during the execution of a basic PKCP operation.

During the execution of Sequencer controlled complex operations, this register is modified - the PKA_FUNC.RUN and PKA_FUNC.STALLRSLT bits are set to zero at the conclusion, but other bits are undefined.

Continuously reading this register to poll the PKA_FUNC.RUN bit is NOT allowed when executing complex sequencer operations (the sequencer cannot access the PKCP when this is done).

Leave at least one SCLK cycle between poll operations.

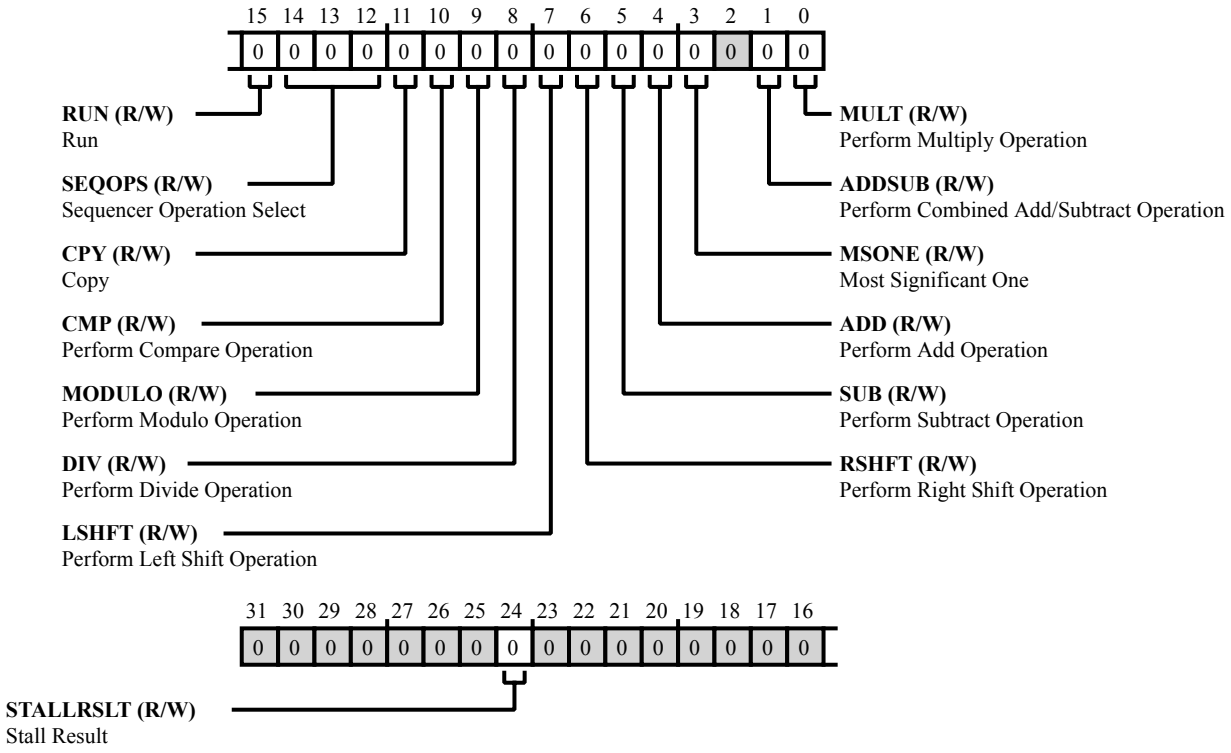

Figure 40-10: PKA_FUNC Register Diagram

Table 40-32: PKA_FUNC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	STALLRSLT	Stall Result. When the PKA_FUNC.STALLRSLT bit is set, updating the PKA_COMPARE, PKA_RESULTMSW and PKA_DIVMSW registers, as well as resetting the Run bit, is stalled beyond the point that a running operation is actually finished. Use this to allow software enough time to read results from a previous operation when the newly started operation is known to take only a short amount of time. If a result is waiting, the result registers is updated and the Run bit is reset in the clock cycle following writing the Stall Result bit back to 0. The Stall result function may only be used for basic PKCP operations.	
15 (R/W)	RUN	Run. Set the PKA_FUNC.RUN bit to instruct the PKA module to begin processing the basic PKCP or complex Sequencer operation. This bit is reset low automatically when the operation is complete. The complement of this bit is output as the pkaint1 interrupt. After a reset, the Run bit is always set to 1b but the first Sequencer firmware instruction sets this bit to 0 immediately after the hardware reset is released. A few clock cycles are needed before the first instruction is executed and the Run bit state has been propagated.	
14:12 (R/W)	SEQOPS	Sequencer Operation Select. The PKA_FUNC.SEQOPS bit field select the complex Sequencer operation to perform.	
		0	None
		1	ExpMod-CRT
		2	ExpMod-ACT4
		3	ECC-ADD
		4	ExpMod-ACT2
		5	ECC-MUL
		6	ExpMod-variable
		7	ModInv
11 (R/W)	CPY	Copy. Setting the PKA_FUNC.CPY bit performs the copy operation. For more information, see the "PKCP Vector Operations" section.	
10 (R/W)	CMP	Perform Compare Operation. Setting the PKA_FUNC.CMP bit performs the compare operation. For more information, see the "PKCP Vector Operations" section.	

Table 40-32: PKA_FUNC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	MODULO	Perform Modulo Operation. Setting the PKA_FUNC.MODULO bit performs the modulo operation. For more information, see the "PKCP Vector Operations" section.
8 (R/W)	DIV	Perform Divide Operation. Setting the PKA_FUNC.DIV bit performs the divide operation. For more information, see the "PKCP Vector Operations" section.
7 (R/W)	LSHFT	Perform Left Shift Operation. Setting the PKA_FUNC.LSHFT bit performs the Left shift operation. For more information, see the "PKCP Vector Operations" section.
6 (R/W)	RSHFT	Perform Right Shift Operation. Setting the PKA_FUNC.RSHFT bit performs the right shift operation. For more information, see the "PKCP Vector Operations" section.
5 (R/W)	SUB	Perform Subtract Operation. Setting the PKA_FUNC.SUB bit performs the subtract operation. For more information, see the "PKCP Vector Operations" section.
4 (R/W)	ADD	Perform Add Operation. Setting the PKA_FUNC.ADD bit performs the add operation. For more information, see the "PKCP Vector Operations" section.
3 (R/W)	MSONE	Most Significant One. Setting the PKA_FUNC.MSONE bit loads the location of the Most Significant one bit within the result word indicated in the PKA_RESULTMSW register into bits [4:0] of the PKA_DIVMSW register can only be used with basic PKCP operations, except for Divide, Modulo and Compare.
1 (R/W)	ADDSUB	Perform Combined Add/Subtract Operation. Setting the PKA_FUNC.ADDSUB bit performs the combined Add/Subtract operation. For more information, see the "PKCP Vector Operations" section.
0 (R/W)	MULT	Perform Multiply Operation. Setting the PKA_FUNC.MULT bit performs the multiply operation. For more information, see the "PKCP Vector Operations" section.

Start of PKA RAM space

The PKA_RAM register provides the the starting location of the RAM space to hold the input, output and other vectors.

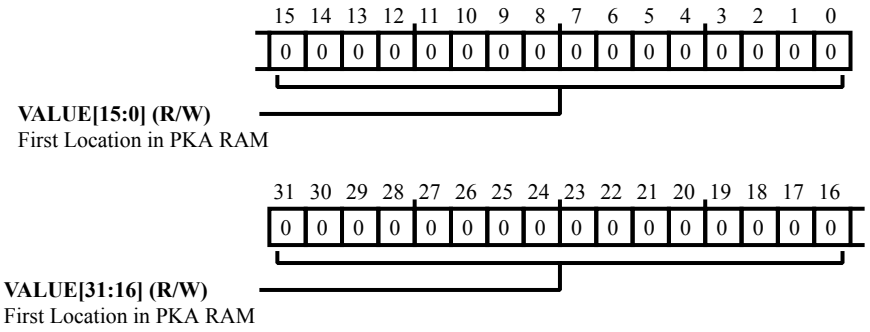

Figure 40-11: PKA_RAM Register Diagram

Table 40-33: PKA_RAM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	First Location in PKA RAM. The PKA_RAM.VALUE bit field provides the the starting location of the RAM space to hold the input, output and other vectors.

PKA Most-Significant-Word of Result Vector

The PKA_RESULTMSW register indicates the (word) address in the PKA RAM where the most significant non-zero 32-bit word of the result is stored and should be ignored for modulo operations. For basic PKCP operations, the PKA_RESULTMSW register is updated when the PKA_FUNC.RUN bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating the final value matching the actual result is done near the end of the operation. Note that the result is only meaningful if no errors are detected and that for ECC operations, the PKA_DIVMSW register provides information for the x-coordinate of the result point only.

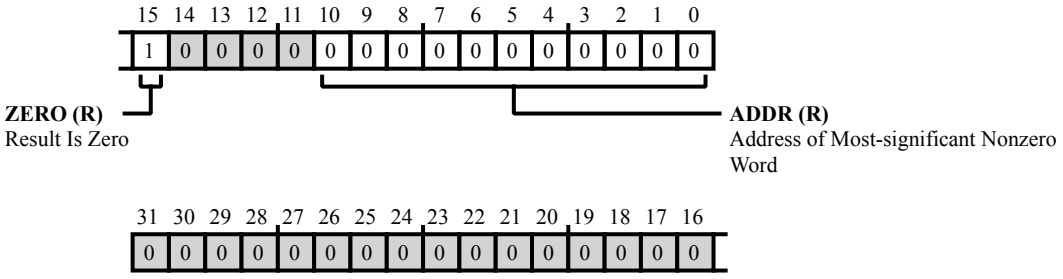

Figure 40-12: PKA_RESULTMSW Register Diagram

Table 40-34: PKA_RESULTMSW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Result Is Zero. The PKA_RESULTMSW.ZERO bit indicates the result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The PKA_RESULTMSW.ADDR bit is the address of the most significant non-zero 32-bit word of the result vector in PKA RAM.

PKA Bit Shift Value

For basic PKCP operations, modifying the contents of the PKA_SHIFT register is made impossible while the operation is being performed. For the ExpMod-variable and ExpMod-CRT operations, the PKA_SHIFT register is used to indicate the number of odd powers to use (directly as a value in the range 1-16). For the ModInv and ECC operations, this register is used to hold a completion code.

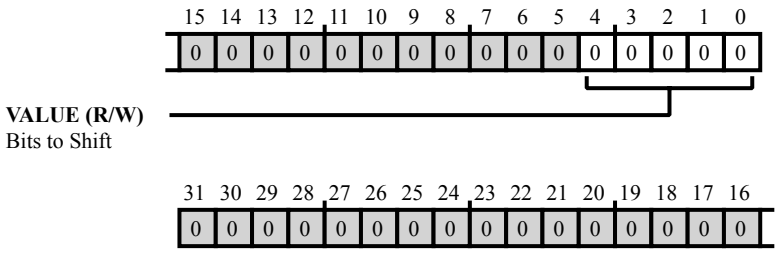

Figure 40-13: PKA_SHIFT Register Diagram

Table 40-35: PKA_SHIFT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Bits to Shift. The PKA_SHIFT.VALUE bit field is the number of bits to shift the input vector (in the range 0-31) during a Rshift or Lshift operation.

41 Public Key Interrupt Controller (PKIC)

The Public Key Accelerator (PKA) and the True Random Number Generator (TRNG) share a common interrupt controller, the Public Key Interrupt Controller (PKIC). The host processor configures the PKIC to generate interrupts when certain operations are complete or interrupts are caused by errors.

PKIC Functional Description

The main purpose and function of the PKIC is to capture the interrupts from different sources, either from the PKA or the TRNG and combine them to one interrupt output. The interrupt controller is managed using the following register groups:

- Control for polarity, edge, and level detection and enabling of individual interrupts
- Acknowledgment (to clear edge detected interrupts)
- Status:
  - A raw source status register after edge detection, if edge selected.
  - A status register after masking with the interrupt enable control bits.

ADSP-2159x_SC591_SC592_SC594 PKIC Register List

The Public Key Processor Interrupt Controller (PKIC) provides security-related features. A set of registers governs PKIC operations. For more information on PKIC functionality, see the PKIC register descriptions.

Table 41-1: ADSP-2159x_SC591_SC592_SC594 PKIC Register List

Name	Description
PKIC_ACK	Acknowledge Register
PKIC_EN_CLR	Enable Clear Register
PKIC_EN_CTL	Enable Control Register
PKIC_EN_SET	Enable Set Register
PKIC_EN_STAT	Enabled Status Register
PKIC_POL_CTL	Polarity Control Register

Table 41-1: ADSP-2159x_SC591_SC592_SC594 PKIC Register List (Continued)

Name	Description
PKIC_RAW_STAT	Raw Status Register
PKIC_TYPE_CTL	Type Control Register

Table 41-2: ADSP-2159x_SC591_SC592_SC594 PKIC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
160	PKIC0_IRQ	PKIC0 Interrupt	Level	

PKIC Programming Model

The following sections provide information on how to program the PKIC.

Enabling/Disabling and Status

The PKIC_EN_STAT register provides the mask to which interrupt source is enabled. There are two status registers, PKIC_RAW_STAT and PKIC_EN_STAT. They allow the host processor to read the status of the interrupt source before and after the mask is applied.

Level or Edge

All of the interrupt sources are level or edge events. The PKIC_TYPE_CTL register configures each interrupt to either level or edge. The PKIC_POL_CTL register controls the polarity of the signal.

These interrupts are latched at both status registers in case edge detection is selected. The edge detectors are reset by clearing the interrupts using the PKIC_ACK registers.

PKIC Programming Concepts

The following concepts help with proper programming for the PKIC module.

Interrupt Handling

When an interrupt is triggered, the handler must first examine this module, the PKIC to determine what triggered the interrupt. By reading the PKIC_EN_STAT, the bits that are set are the pending interrupts of the ones that were not masked. After determining the source of the interrupt, the appropriate action must be taken to service the interrupt from the corresponding module, the PKA, or the TRNG. After handling the interrupt in a particular module, the corresponding interrupt must be acknowledged and cleared in the PKIC to allow further interrupts.

While handling an interrupt, any events that would cause another interrupt would happen without triggering another interrupt.

Overlapping Registers

There are two sets of overlapping registers in the PKIC. The PKIC_EN_STAT and PKIC_ACK registers share one address. If read, the register tells which enabled interrupts are pending. If written to (W1C), the interrupt is acknowledged and cleared. The PKIC_RAW_STAT and PKIC_EN_SET registers are another pair that share the address. When read, the register tells which interrupts are pending and if written to will enabled certain interrupts. This register cannot be used to disable any interrupts.

ADSP-2159x_SC591_SC592_SC594 PKIC Register Descriptions

Public Key Processor Interrupt Controller (PKIC) contains the following registers.

Table 41-3: ADSP-2159x_SC591_SC592_SC594 PKIC Register List

Name	Description
PKIC_ACK	Acknowledge Register
PKIC_EN_CLR	Enable Clear Register
PKIC_EN_CTL	Enable Control Register
PKIC_EN_SET	Enable Set Register
PKIC_EN_STAT	Enabled Status Register
PKIC_POL_CTL	Polarity Control Register
PKIC_RAW_STAT	Raw Status Register
PKIC_TYPE_CTL	Type Control Register

Acknowledge Register

The PKIC_ACK register is used to acknowledge the interrupt and clear the corresponding interrupt bit in the status register.

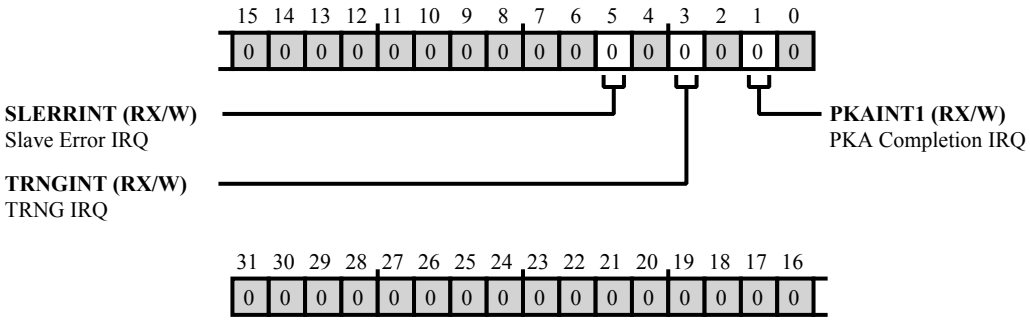

Figure 41-1: PKIC_ACK Register Diagram

Table 41-4: PKIC_ACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Slave Error IRQ. The PKIC_ACK.SLERRINT bit is the acknowledge bit for the Slave Error interrupt. When set =1 the PKIC_ACK.SLERRINT bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	
		0	Do not acknowledge interrupt and clear status bit
		1	Acknowledge interrupt and clear status bit
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_ACK.TRNGINT bit is the acknowledge bit for the TRNG interrupt. When set =1 the PKIC_ACK.TRNGINT bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	
		0	Do not acknowledge interrupt and clear status bit
		1	Acknowledge interrupt and clear status bit
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_ACK.PKAINT1 bit is the acknowledge bit for the PKA completion interrupt. When set =1 the PKIC_ACK.PKAINT1 bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	

Enable Clear Register

The PKIC_EN_CLR register allows the user to disable certain interrupts without enabling others. The disabled interrupts are also reflected in PKIC_EN_CTL register.

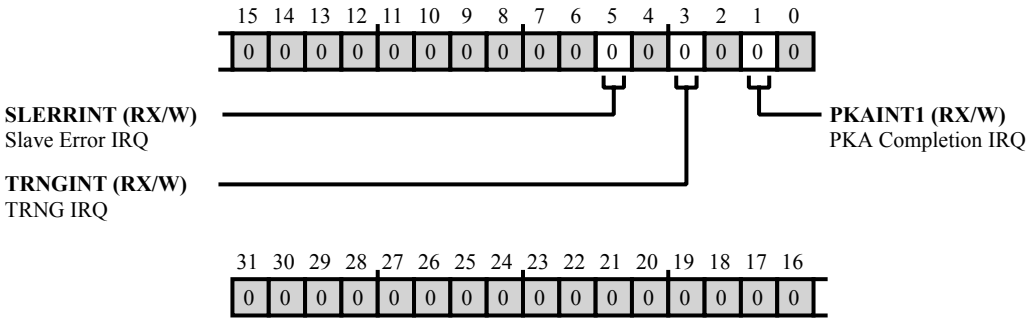

Figure 41-2: PKIC_EN_CLR Register Diagram

Table 41-5: PKIC_EN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Slave Error IRQ. The PKIC_EN_CLR.SLERRINT bit is the individual disable for the Slave Error interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically.	
		0	No action
		1	Clear/reset corresponding CTL bit
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_EN_CLR.TRNGINT bit is the individual disable for the TRNG interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically. 0= no effect.	
		0	No action
		1	Clear/reset corresponding CTL bit
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_CLR.PKAINT1 bit is the individual disable for the PKA Completion interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically. 0= no effect.	
		0	No action
		1	Clear/reset corresponding CTL bit

Enable Control Register

The PKIC_EN_CTL register provides individual enable bits for the interrupt sources.

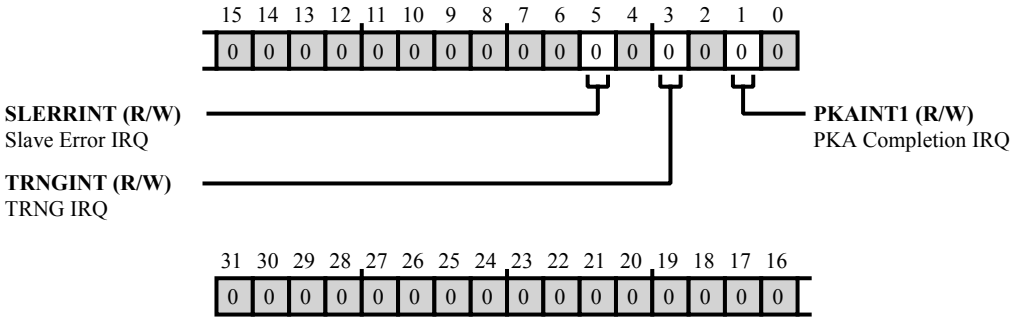

Figure 41-3: PKIC_EN_CTL Register Diagram

Table 41-6: PKIC_EN_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Slave Error IRQ. The PKIC_EN_CTL.SLERRINT bit enables control for the Slave Error interrupt.	
		0	Disable interrupt
		1	Enable interrupt
3 (R/W)	TRNGINT	TRNG IRQ. The PKIC_EN_CTL.TRNGINT bit enables control for the TRNG interrupt.	
		0	Disable interrupt
		1	Enable interrupt
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_CTL.PKAINT1 bit enables control for the PKA completion interrupt.	
		0	Disable interrupt
		1	Enable interrupt

Enable Set Register

The PKIC_EN_SET register allows the user to only set certain interrupt sources without disabling any others. The enabled interrupts are reflected in PKIC_EN_CTL register.

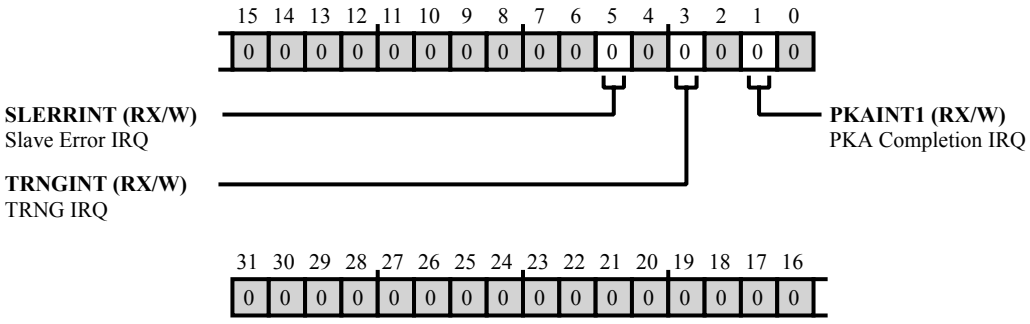

Figure 41-4: PKIC_EN_SET Register Diagram

Table 41-7: PKIC_EN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Slave Error IRQ. The PKIC_EN_SET.SLERRINT bit is the individual enable for the Slave Error interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically. 0=no effect	
		0	No effect
		1	Enable interrupt
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_EN_SET.TRNGINT bit is the individual enable for the TRNG interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically.	
		0	No effect
		1	Enable interrupt
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_SET.PKAINT1 bit is the individual enable for the PKA Completion interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically.	
		0	No effect
		1	Enable interrupt

Enabled Status Register

The PKIC_EN_STAT register is used to tell the status of the interrupts after the gating with the PKIC_EN_CTL register.

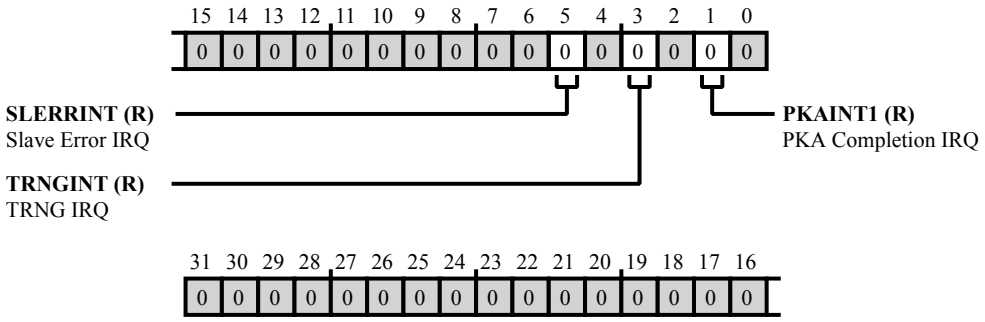

Figure 41-5: PKIC_EN_STAT Register Diagram

Table 41-8: PKIC_EN_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SLERRINT	Slave Error IRQ. The PKIC_EN_STAT.SLERRINT bit provides the status of the Slave Error interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending
3 (R/NW)	TRNGINT	TRNG IRQ. The PKIC_EN_STAT.TRNGINT bit provides the status of the TRNG interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending
1 (R/NW)	PKAINT1	PKA Completion IRQ. The PKIC_EN_STAT.PKAINT1 bit provides the status of the PKA Completion interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending

Polarity Control Register

The PKIC_POL_CTL register is used to configure the signal polarity for each individual interrupt. During the initialization phase of the PKA the host processor must set each interrupt in this register to (high level/rising edge or low level/falling edge).

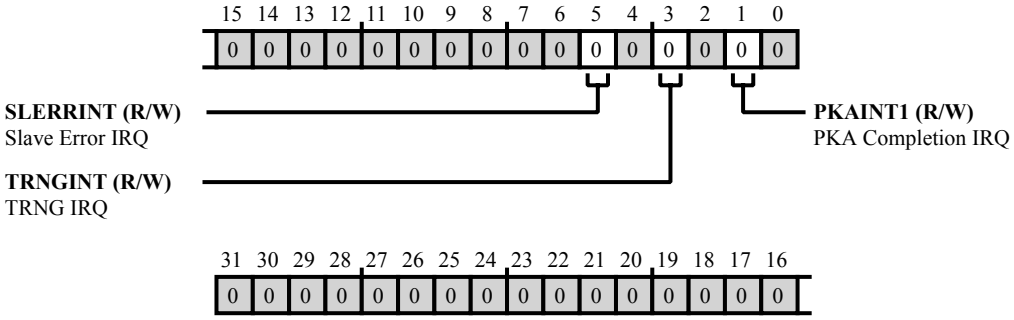

Figure 41-6: PKIC_POL_CTL Register Diagram

Table 41-9: PKIC_POL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Slave Error IRQ. The PKIC_POL_CTL.SLERRINT bit provides polarity control for the Slave Error interrupt.	
		0	Low level/falling edge
		1	High level/rising edge
3 (R/W)	TRNGINT	TRNG IRQ. The PKIC_POL_CTL.TRNGINT bit provides polarity control for the TRNG interrupt.	
		0	Low level/falling edge
		1	High level/rising edge
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_POL_CTL.PKAINT1 bit provides polarity control for PKA completion interrupt.	
		0	Low level/falling edge
		1	High level/rising edge

Raw Status Register

The PKIC_RAW_STAT register reflects the status of the individual interrupts before masking with the PKIC_EN_CTL register.

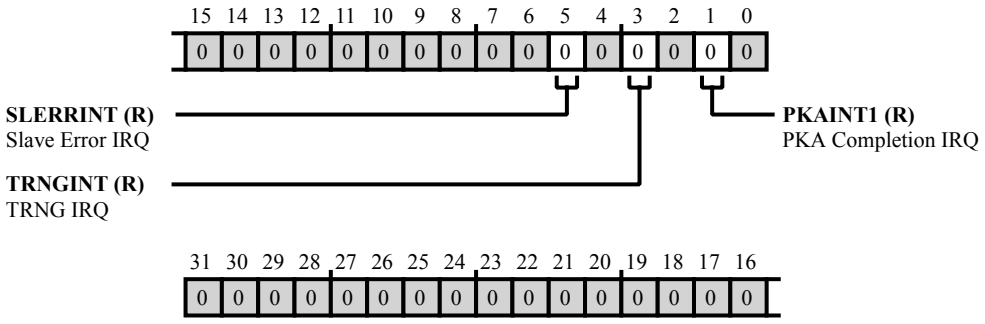

Figure 41-7: PKIC_RAW_STAT Register Diagram

Table 41-10: PKIC_RAW_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SLERRINT	Slave Error IRQ. The PKIC_RAW_STAT.SLERRINT bit provides the raw status of the Slave Error interrupt.	
		0	Inactive interrupt
		1	Pending interrupt
3 (R/NW)	TRNGINT	TRNG IRQ. The PKIC_RAW_STAT.TRNGINT bit provides the raw status of the TRNG interrupt where 1=pending and 0=inactive.	
		0	Inactive interrupt
		1	Pending interrupt
1 (R/NW)	PKAINT1	PKA Completion IRQ. The PKIC_RAW_STAT.PKAINT1 bit provides raw status of the PKA completion interrupt where 1=pending and 0=inactive.	
		0	Inactive interrupt
		1	Pending interrupt

Type Control Register

The PKIC_TYPE_CTL register is used to configure the signal type for each individual interrupt. During the initialization phase of the PKA the host processor must set each interrupt in this register to level or edge.

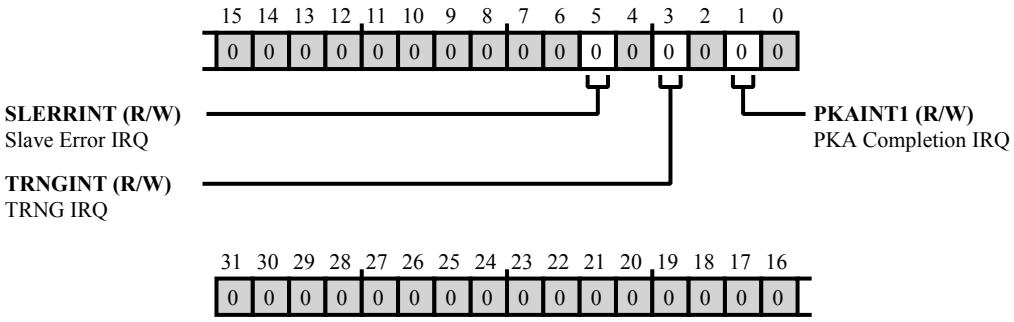

Figure 41-8: PKIC_TYPE_CTL Register Diagram

Table 41-11: PKIC_TYPE_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Slave Error IRQ. The PKIC_TYPE_CTL.SLERRINT bit provides signal type control for the Slave Error interrupt.	
		0	Level
		1	Edge
3 (R/W)	TRNGINT	TRNG IRQ. The PKIC_TYPE_CTL.TRNGINT bit provides signal type control for the TRNG interrupt.	
		0	Level
		1	Edge
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_TYPE_CTL.PKAINT1 bit provides signal type control for the PKA completion interrupt.	
		0	Level
		1	Edge

42 True Random Number Generator (TRNG)

The TRNG engine provides a true, non-deterministic, noise source for generating keys, Initialization Vectors (IVs), and other random number requirements. Other non-cryptographic purposes include statistical sampling, retry timers for communications protocols and noise generation.

TRNG Features

The TRNG features include:

- Hardware-based non-deterministic random number generator
- ANSI X9.31 postprocessing (depending on processor)
- Redundant 'fail-safe' design with self-test circuits
- Reliable shot noise oscillator implementation with auto-tuning
- Debug output to allow monitoring of internal operation
- Alarm count overflow and auto-tuning error interrupts
- Buffer to allow generation of large blocks of random data in the background

TRNG Functional Description

The following sections provide details on the function of the TRNG module.

ADSP-2159x_SC591_SC592_SC594 TRNG Register List

The True Random Number Generator (TRNG) provides random number generation, intended mainly for security-related applications. A set of registers governs TRNG operations. For more information on TRNG functionality, see the TRNG register descriptions.

Table 42-1: ADSP-2159x_SC591_SC592_SC594 TRNG Register List

Name	Description
TRNG_ALMCNT	TRNG Alarm Counter Register

Table 42-1: ADSP-2159x_SC591_SC592_SC594 TRNG Register List (Continued)

Name	Description
TRNG_ALMMSK	TRNG Alarm Mask Register
TRNG_ALMSTP	TRNG Alarm Stop Register
TRNG_BLKCNT	TRNG Block Count Register
TRNG_CFG	TRNG Configuration Register
TRNG_CNT	Counter Register
TRNG_CTL	TRNG Control Register
TRNG_FRODETUNE	TRNG FRO De-tune Register
TRNG_FROEN	TRNG FRO Enable Register
TRNG_INPUT[n]	TRNG Input Registers
TRNG_INTACK	TRNG Interrupt Acknowledge Register
TRNG_KEY[n]	Post-Process Key Registers

TRNG_POKER[n]	TRNG Poker Test Result Registers
TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register
TRNG_V[n]	TRNG Post-Process "V" Value Registers

Random Number Generation

The random numbers that the TRNG generates are produced by sampling Free Running Oscillators (FRO). The (TRNG_CTL.STARTUPCYC) bit field along with TRNG_CFG.MINREFCYC (minimum refill cycles) and TRNG_CFG.MAXREFCYC (maximum refill cycles) bit fields determine the number of samples taken to generate the first random value and subsequent random values.

1. After enabling the TRNG (TRNG_CTL.TRNGEN bit =1), a number of FRO output samples defined by the TRNG_CTL.STARTUPCYC bit field are gathered in the main linear-feedback shift register (LFSR) before taking a snapshot of the LFSR and storing that snapshot in the random data buffer (after optional post-processing).

2. After taking a snapshot of the LFSR, a number of FRO output samples defined by the TRNG_CFG.MINREFCYC bit field, are gathered in the main LFSR. If the random data buffer is full, sample-taking continues until the number of samples (counting from the snapshot) matches the number of samples defined by the TRNG_CFG.MAXREFCYC bit field. At that point, the TRNG switches off the FROs and powers down.
3. If, after the TRNG_CFG.MINREFCYC sampling period, the random data buffer is not completely filled, a new snapshot of the LFSR is taken and stored in the random data buffer (after optional postprocessing). Control branches back to point step 2 above and a new TRNG_CFG.MINREFCYC sample period starts.

Locking Detection and Prevention

Lock detection in functional mode uses the sampled outputs of the individual FROs. A FRO alarm event is declared when a repeating pattern (of up to four sample lengths) is detected continuously for the number of samples defined in the alarm threshold TRNG_ALMCNT.ALMTHRESH bit field. The alarm event is logged by setting the bit that corresponds to the FRO that caused the alarm in the TRNG_ALMMSK register. If that bit was already set, the corresponding bit in the TRNG_ALMSTP register is set. The FRO is switched off to prevent further alarm events from that FRO. If the TRNG_ALMMSK register bit was not yet set, the FRO is restarted automatically in an attempt to break locking.

The shutdown count field in the alarm count TRNG_ALMCNT.SHDNCNT register monitors the number of FROs switched off. (It counts the number of 1 bits in the TRNG_ALMSTP register.) The shutdown threshold field (TRNG_ALMCNT.SHDNTHRESH) can be configured to generate the shutdown overflow interrupt (TRNG_STAT.SHDNOVR). When the shutdown count in the TRNG_ALMCNT.SHDNCNT bit field exceeds the shutdown threshold in the TRNG_ALMCNT.SHDNTHRESH bit field, the shutdown overflow bit (TRNG_STAT.SHDNOVR) is set to 1 (which can be used to generate an interrupt).

Software can use two strategies for the TRNG operation:

- ***Monitored Operation***. Software checks the TRNG_ALMMSK register at regular intervals (on the order of seconds). If a bit is set in that register, then the program must also check the TRNG_ALMSTP register to determine if a FRO was shut down due to multiple alarm events. If no FROs are shut down, the program clears the TRNG_ALMMSK register to remove the incidental alarm events. If one or more FROs are shut down, the host processor can modify the delay selection of those FROs using the TRNG_FRODETUNE register to prevent further locking. For this type of operation, the shutdown threshold is normally set to a low value (two, for example). The shutdown overflow interrupt can then be used to signal abnormal operation conditions or the breakdown of FROs.
- ***Unmonitored Operation.*** Software sets the shutdown threshold to the acceptable number of FROs to be shut down before taking corrective actions. It then uses the shutdown overflow interrupt to initiate corrective actions (clearing the TRNG_ALMMSK and TRNG_ALMSTP registers, toggling bits in the TRNG_FRODETUNE register). The software must monitor the time interval between these interrupts. If they occur too often (for example, within a minute after each other), this frequency indicates abnormal operating conditions or the breakdown of FROs.

Run Testing

Run Test

The TRNG block counts the number of consecutive zeros and ones (runs) in the data stream shifted into the main LFSR. The run length and bit value is then used to increment a specific bucket counter for these values. After 20,000 bits, the bucket counters must be within specified limits for this test to pass. If not, a run fail interrupt (RUNFAIL) is generated.

Table 42-2: Allowable Limits on Runs of 0's and 1's

Run Count	Bit Value	Min (inclusive)	Max (inclusive)
1	0	2267	2733
	1	2267	2733
2	0	1079	1421
	1	1079	1421
3	0	502	748
	1	502	748
4	0	233	402
	1	233	402
5	0	90	223
	1	90	223
6 and up	0	90	233
	1	90	233

Long Run Test

The long run test fails immediately when a run longer than 33 bits is found and a long run fail (`TRNG_STAT.LRUNFAIL`) interrupt is generated.

Noise Source Test

A noise source failure is declared when a run of 48 or more identical bits is found and a noise fail interrupt (`TRNG_STAT.NOISEFAIL`) is generated.

The status and counts are stored in the `TRNG_RUNCNT` and `TRNG_RUN[n]` registers. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the monobit fail acknowledge (`TRNG_INTACK.MBITFAIL`), the run fail acknowledge (`TRNG_INTACK.RUNFAIL`), or the poker fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

Monobit Testing

The TRNG block performs the monobit test on blocks of 20,000 bits (in parallel with the run test and poker test). It monitors the number of zeros and ones in the data stream shifted into the main LFSR. At the start of the block,

the counter is initialized to 10,000. Each 1 value increments the counter, each 0 value decrements the counter. After 20,000 bits, the counter value must be within 9310–10690 (inclusive) for this test to pass. If not, a monobit fail interrupt (TRNG_STAT.MBITFAIL) is generated. The AIS-31 standard (test T1, ref 0) specifies this run time testing of the TRNG and the parameters.

NOTE: The actual limits stated here are different than the limits stated in the AIS-31 standard due to the implementation. The circuitry in the TRNG uses an up-down counter while the standard just evaluates the sum of the 20,000 bits.

When the continue poker (TRNG_TEST.CONTPKR) bit is set to 1, the test is not stopped after 20,000 bits. The counter keeps incrementing and decrementing (protected against overflow and underflow). But, no actual limit checking happens. The offset from starting value 10,000 indicates the balance of 0 and 1 bits that were checked since the start of the continuous test. The offset is twice the number of missing or extra 1 bits. (An extra 1 bit adds an increment operation and removes one decrement operation. So, having 10,001 1 bits in the block gives a counter value of 10,002.)

Poker Testing

The poker test is run in parallel with the monobit test and run test. Counters in the TRNG_POKER[n] registers are used to count the occurrences of one specific 4-bit value in the data stream fed into the main LFSR. All of the counters are decremented by one every 64 data bits and reset to their start value every 20,000 bits. All counters start at a value of –1 and are decremented 312 times during the 20,000-bit test run.

Each 8-bit counter holds a two's complement value and does not overflow past the range of –128 to +127. At the end of the 20,000-bits block, the values of the counters that contain a single 1 bit appended at the least significant bit side are individually squared and then added. The poker test fails with a poker fail (PKRFAIL) interrupt when:

- the resulting sum (accumulated in the TRNG_MONOBITCNT register) is outside the range 1288 – 71750 (inclusive), or
- one of the counters tries to increment or decrement outside its limit range

NOTE: The poker test fails when the 4-bit values of the data stream are distributed too evenly (with eight counters having incremented 312 times and the others incremented 313 times). This failure is intentional. The minimum mean deviation from the expected value of 312.5 is 4.5. Failure at counter overflow is not an official part of the poker test as specified in the AIS-31 standard (ref 0). It can be shown that the maximum deviation for one counter's value from the mean value of 312.5 (without the poker test failing) is 129.5. Since this deviation is more than 40% of the mean value, it indicates that something is wrong. Here, the counter overflow failure is combined with the official poker test failure.

When the continue poker (TRNG_TEST.CONTPKR) bit is set to 1, the test does not stop after 20,000 bits. The counters keep incrementing and decrementing (the latter every 64 bits). A PKRFAIL interrupt is generated when one of the counters tries to increment or decrement outside its limit range.

Data for Tests

For the monobit test, run test and poker test circuits self-test, the test data written to the TRNG_INPUT[n]0 register is used for the monobit test and run test bit-by-bit. It executes from bit 31 down to bit 0. For the poker test, the written test data is used in eight blocks of 4 bits, starting from bits 31:28 down to bits 3:0.

When the TRNG_TEST.CONTPKR bit =0 during run test and poker test circuits self-tests, the state of the poker and runs test status registers is frozen after all calculations are made and after inputting 20,000 test bits. This state allows time to read the test results. These calculations take around 20 clock cycles to complete. The status registers are reset to their starting states when the first word for the next test block of test bits is written to the TRNG_INPUT[n]0 register. Then, the contents of this word are processed.

X9.31 Postprocessing

Postprocessing is available on some parts using the TRNG. If available, the postprocessing block is situated after the main LFSRs and before the output buffer that stores the random numbers for consumption. The online test logic for monobit, run, and poker testing is before the postprocessor block. The bits used for testing are from the main LFSR.

The postprocessor is based on the ANSI X9.31 specification using 3-Key 3DES cipher algorithm. It does not provide any more entropy than is what is already achieved from sampling the Free Running Oscillators (FROs). The use of the postprocessor only helps with applications requiring the use of an X9.31 compliant RNG.

The following section is an example of postprocessing.

The variables include:

- DT is a 64-bit date/time vector. This value is the input coming from random bits from the main LFSR.
- I is an intermediate value, a 64-bit value
- R is the final result, a 64-bit value
- V is a 64-bit seed value that is to be kept secret
- K is the 3-key for 3DES, each being 64-bits

The postprocessing uses the steps:

1. The intermediate value I is calculated: I = $3DES_{EDE}$(K, DT) with 3DES.
2. The result R is calculated: R = $3DES_{EDE}$(K, I XOR V).
3. Finally, V is updated: V = $3DES_{EDE}$(K, R XOR I).

TRNG Block Diagram

The ***System Block Diagram of the TRNG*** diagram shows the system block for the TRNG. The system includes:

- Free Running Oscillators (FROs) that are the source of sampled bits
- A post-processing unit (processor dependent) for standards compliance

- Test circuitry to detect non-randomness due to failures in the system

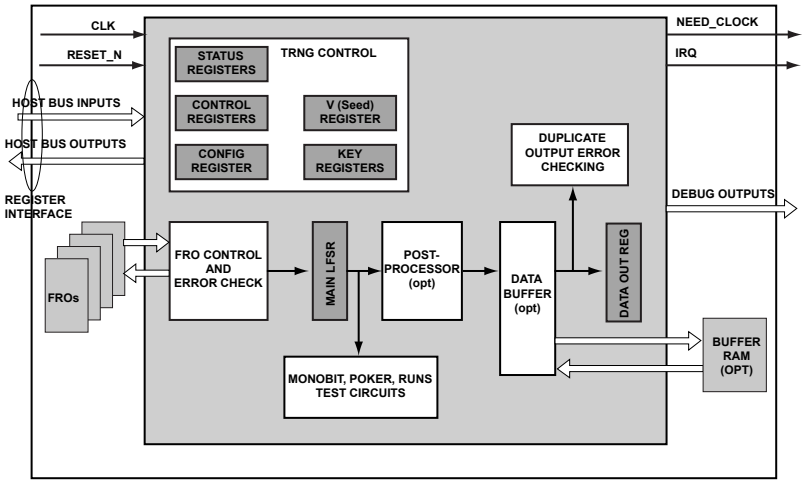

Figure 42-1: System Block Diagram of the TRNG

TRNG Architectural Concepts

The random numbers are accessible to the host processor in four 32-bit registers allowing a single burst read of a 128-bit random number. Acknowledging the data ready (interrupt) state causes the TRNG to move a new value (when available in the data buffer) to the TRNG output register. The TRNG always tries to keep the data buffer completely full. Pulling out data starts the regeneration of a new number by:

- Enabling the FROs
- Capturing their outputs in the LFSR, and
- Cryptographically postprocessing the values from the LFSR

The process produces new random values to replenish the buffer.

The major functional blocks of the TRNG module are:

- The actual TRNG core with control and test circuits, optional post-processor, and optional data buffer control logic
- Free Running Oscillators (FROs) instantiated outside the TRNG core
- A 128-byte buffer RAM instantiated outside the TRNG core

In the TRNG core, the true entropy source uses FROs as the basic building block. The accumulation of timing jitter, caused (for the largest part) by shot noise, creates uncertainty intervals for the output transitions of each FRO. Sampling within an uncertainty interval generates a single bit of entropy, which is ‘accumulated’ in a LFSR. As the uncertainty interval is very narrow compared to the cycle time of a FRO, the mean amount of entropy generated per sample is small (less than 1/100 bit per sample). To increase the entropy generation rate, multiple FROs are used in parallel.

The FROs are asynchronous to one another and asynchronous to the sampling clock to make their behavior truly non-deterministic.

The output signals of the FROs are sampled at regular intervals (in general, at the TRNG core module clock frequency). The samples feed into an error detection circuit that checks for repeating patterns coming out of a FRO. If a repeating pattern persists for a configurable number of samples, the FRO is suspect of having synchronized to (a harmonic of) the sampling interval. This activity drastically reduces the amount of entropy generated by that FRO. The error detection circuit signals this activity as a FRO error event.

Error events can occur during normal operation. The FRO control circuit attempts to restart a FRO that on a first error event. A second error event causes an automatic shutdown of the FRO. Because there are multiple FROs, shutting down a FRO reduces the amount of entropy generated, but it does not immediately jeopardize the TRNG operation. A limit can be configured below which the number of operational FROs does not drop. If this limit is crossed, an interrupt can be generated on the host processor. Software on the host processor can then attempt to prevent frequent locking of a FRO by *de-tuning* it to a slightly different frequency.

An XOR tree combines the sampled outputs and feeds them into an 81-bit LFSR to accumulate entropy and whiten the random bits stream.

NOTE: Here, *whitening* means balancing the number of one and zero bits in the stream.

TRNG Operating Modes

The TRNG has the following operating modes.

Normal Reading Mode

In normal reading mode, random data can only be read out of the output registers of the TRNG module when the ready bit (`TRNG_STAT.RDY`) =1. Acknowledging the data by writing a 1 to the ready acknowledge bit in the `TRNG_INTACK.RDY` register clears the ready bit from the status register and clears the output registers. The registers remain at zero until the next 128-bit data block is available.

Secure Reading Mode

An attacker can try to read the output registers (without acknowledging the data) to obtain a copy of data to be read later by an application. To block this attack, secure reading mode is used. In this mode, enable reading from the output registers (by writing 0x00 to the open read gate bits (`TRNG_INTACK.OPENRDGATE`) before it is possible to access the output registers. Enabling the reading starts a timeout (controlled by the `TRNG_CFG.RDTIMEOUT` bit field). When this timeout expires, reading is disabled and the offered data is acknowledged so that it is not offered again. The host processor must set this timeout such that there is enough time to read the output registers and perform a normal data acknowledge (which aborts the timeout).

Test Mode

In addition to the test circuitry that operates during normal operation, the TRNG has a test mode that allows further diagnosis when errors occur. In test mode, programs have access to the main LFSR through the

TRNG_LFSR_L, TRNG_LFSR_M, and TRNG_LFSR_H registers. Programs can also control the finite state machine sample counter using the TRNG_CNT register.

In test mode, the TRNG can be configured to test individual or a chosen set of FROs. It can also be configured to feed test patterns to the delay chain.

TRNG Data Transfer Modes

The host processor reads four 32-bit registers to access the random numbers. Once the registers are read and the data ready interrupt has been acknowledged, the TRNG moves more data from the internal buffer to the output registers (TRNG_OUTPUT[n]).

TRNG Event Control

There are eight events that the TRNG generates. The events are common error events from the run-time testing of the TRNG. While the TRNG is operating and generating random bits, test circuitry is also running statistical tests. The tests determine if the sources of the random bits have started to fail and are not truly producing random bits. There is also a single event to signal when data is ready in the output registers.

These events are captured in the TRNG_STAT register and can generate a single interrupt in the Public Key Interrupt Controller (PKIC). The individual events can be masked so the interrupt is not triggered. This configuration uses the TRNG_CTL register. The event and associated interrupt can be acknowledged in the TRNG_INTACK register.

The ***TRNG Interrupt Signals*** table lists all events or interrupts that the TRNG can generate.

TRNG Interrupt Signals

The TRNG provides a total of eight interrupts multiplexed into one output.

Table 42-3: TRNG Interrupt Signals

Interrupt	Name	Description
0	RDY	Ready. Random number is ready to be read from registers
1	SHDNOVR	Shutdown Overflow. The number of FRO's automatically shut down due to failures or errors have gone above the threshold specified in TRNG_ALMCNT.SHDNTHRESH.
2	STUCKOUT	Stuck Out. Logic circuitry around the output registers has detected the same output has been provided twice.
3	NOISEFAIL	Noise Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 48 identical bits, which is considered a noise source failure.
4	RUNFAIL	Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value for at least one of the TRNG_RUN[n] counters after checking 20,000 bits.

Table 42-3: TRNG Interrupt Signals (Continued)

Interrupt	Name	Description
5	LRUNFAIL	Long Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 34 identical bits.
6	PKRFAIL	Poker Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 TRNG_POKER[n] counters or an out-of-bounds sum of squares values after checking 20,000 bits.
7	MBITFAIL	Monobit Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds number of 1's after checking 20,000 bits.

ADSP-2159x_SC591_SC592_SC594 TRNG Register Descriptions

True Random Number Generator (TRNG) contains the following registers.

Table 42-4: ADSP-2159x_SC591_SC592_SC594 TRNG Register List

Name	Description
TRNG_ALMCNT	TRNG Alarm Counter Register
TRNG_ALMMSK	TRNG Alarm Mask Register
TRNG_ALMSTP	TRNG Alarm Stop Register
TRNG_BLKCNT	TRNG Block Count Register
TRNG_CFG	TRNG Configuration Register
TRNG_CNT	Counter Register
TRNG_CTL	TRNG Control Register
TRNG_FRODETUNE	TRNG FRO De-tune Register
TRNG_FROEN	TRNG FRO Enable Register
TRNG_INPUT[n]	TRNG Input Registers
TRNG_INTACK	TRNG Interrupt Acknowledge Register
TRNG_KEY[n]	Post-Process Key Registers
TRNG_LFSR_H	TRNG LFSR Access Register
TRNG_LFSR_L	TRNG LFSR Access Register
TRNG_LFSR_M	TRNG LFSR Access Register
TRNG_MONOBITCNT	TRNG Monobit Test Result Register
TRNG_OUTPUT[n]	TRNG Output Registers
TRNG_POKER[n]	TRNG Poker Test Result Registers
TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers

Table 42-4: ADSP-2159x_SC591_SC592_SC594 TRNG Register List (Continued)

Name	Description
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register
TRNG_V[n]	TRNG Post-Process "V" Value Registers

TRNG Alarm Counter Register

The TRNG_ALMCNT register, together with the TRNG_ALMMSK and TRNG_ALMSTP registers, can be used by the host processor to determine if the FRO/sample cycle locking is a problem. Note that incidental alarm events are expected to occur during normal operation. This register also controls the way the monobit test and poker test circuits operate (using the standard 20,000 bit blocks or running continuously).

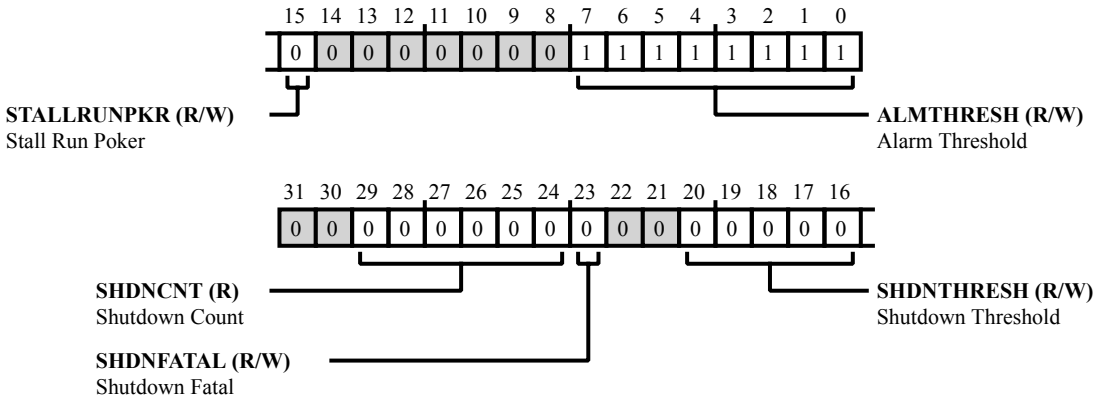

Figure 42-2: TRNG_ALMCNT Register Diagram

Table 42-5: TRNG_ALMCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	SHDNCNT	Shutdown Count. This read-only field indicates the number of 1 bits in the TRNG_ALMSTP register, the number of FRO's that's been turned off.
23 (R/W)	SHDNFATAL	Shutdown Fatal. When the TRNG_ALMCNT.SHDNFATAL bit field is set, the shutdown overflow (SHDNOVR) interrupt is considered a fatal error requiring taking the complete TRNG engine off-line.
20:16 (R/W)	SHDNTHRESH	Shutdown Threshold. The TRNG_ALMCNT.SHDNTHRESH bit field provides the threshold setting for generating the shutdown overflow (SHDNOVR) interrupt, which is activated when the shutdown count (TRNG_ALMCNT.SHDNCNT) value in this register exceeds the threshold value set here.
15 (R/W)	STALLRUNPKR	Stall Run Poker. When the TRNG_ALMCNT.STALLRUNPKR bit is set, stalls the Monobit Test, Run Test and Poker Test circuits when either the TRNG_STAT.MBITFAIL, TRNG_STAT.RUNFAIL or TRNG_STAT.PKRFAIL bits =1. This allows inspection of the state of the result counters (which would otherwise be reset immediately for the next 20,000 bits block to test).

Table 42-5: TRNG_ALMCNT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ALMTHRESH	Alarm Threshold. The `TRNG_ALMCNT.ALMTHRESH` bit field sets the alarm detection threshold for the repeating pattern detectors on each FRO. A FRO alarm event is declared when a repeating pattern (of up to four samples length) is detected continuously for the number of samples defined by this fields value. Reset value 255 (decimal) should keep the number of alarm events to a manageable level.

TRNG Alarm Mask Register

A set bit (=1) in the TRNG_ALMMSK register signifies an alarm event and is used by the host processor to determine which of the individual FROs generated the alarm. If a bit in this register is set, the corresponding bit in the TRNG_ALMSTP register is set and the FRO is turned off by clearing the corresponding bit in the TRNG_FROEN register. If a bit is not set, the FRO restarts automatically to try to break sample cycle locking that could have caused the alarm event.

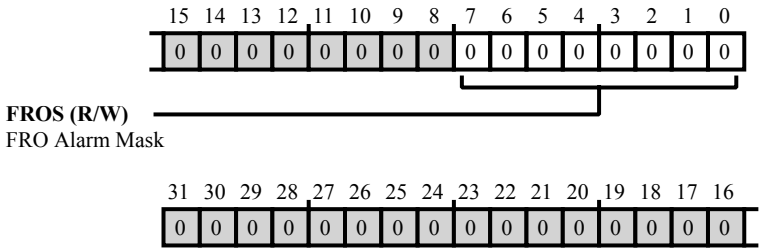

Figure 42-3: TRNG_ALMMSK Register Diagram

Table 42-6: TRNG_ALMMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Mask. The TRNG_ALMMSK.FROS bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced an alarm event.

TRNG Alarm Stop Register

The TRNG_ALMSTP register is used by the host processor to determine which of the individual FROs generated more than one alarm event in quick succession. If a FRO generates an alarm event while a previous event is still logged in the TRNG_ALMMSK register, the corresponding bit in this register is set (=1) and the FRO is turned off by clearing (=0) the corresponding bit in the TRNG_FROEN register. The TRNG_ALMCNT.SHDNCNT bit field keeps track of the number of bits that are set in this register.

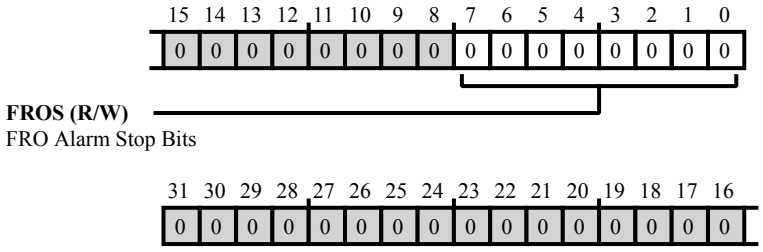

Figure 42-4: TRNG_ALMSTP Register Diagram

Table 42-7: TRNG_ALMSTP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Stop Bits. The TRNG_ALMSTP.FROS bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced more than one alarm event in quick succession and has been turned off. A 1 in this field forces the corresponding bit in the TRNG_FROEN register to 0.

TRNG Block Count Register

The TRNG_BLKCNT register is the counter for the 128-bit blocks generated by the post-processor. These bits are forced to zero when the post-processor is disabled and are cleared to zero when an internal re-seed operation has finished. This register can be used by driver software to determine when to re-seed the post-processor.

The whole 32 bits of this register represent the amount of data (in bytes) generated since a re-seed. The TRNG_BLKCNT register is only present when a post-processor is available.

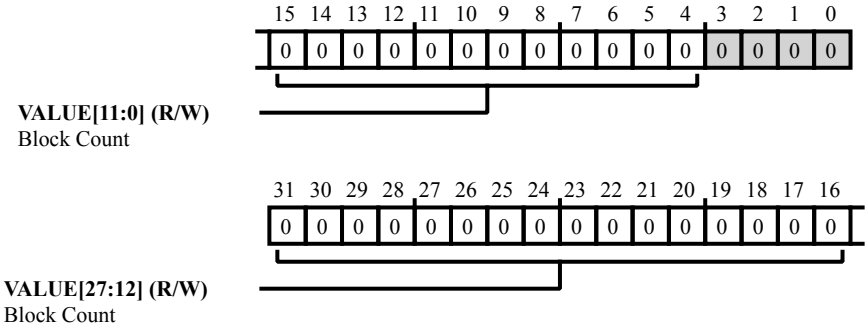

Figure 42-5: TRNG_BLKCNT Register Diagram

Table 42-8: TRNG_BLKCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/W)	VALUE	Block Count. The TRNG_BLKCNT.VALUE bit field is the counter for the 128-bit blocks generated by the post-processor. These bits are forced to zero when the post-processor is disabled and are cleared to zero when an internal re-seed operation has finished.

TRNG Configuration Register

The TRNG_CFG register holds the lower and upper limits of the samples taken from the FROs in order to refill the random data buffer. This register also holds the time out value used for secure reading mode.

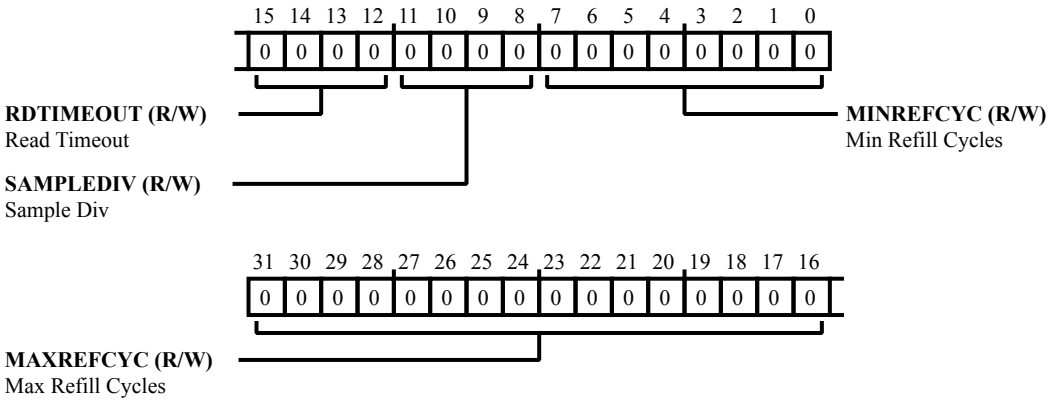

Figure 42-6: TRNG_CFG Register Diagram

Table 42-9: TRNG_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	MAXREFCYC	Max Refill Cycles. The TRNG_CFG.MAXREFCYC bit field determines the maximum number of samples (between 2^8 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64 bit random number. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8. This field can only be modified while the TRNG_CTL.TRNGEN bit =0.
15:12 (R/W)	RDTIMEOUT	Read Timeout. The TRNG_CFG.RDTIMEOUT bit field controls the Secure Reading Mode. When this field is 0, Secure Reading Mode is disabled. Values in the range 115 enable Secure Reading and set a read gate closure timeout of approximately (read_timeout + 1) x 16 clock input cycles. This field can only be modified while the TRNG_CTL.TRNGEN bit =0.
11:8 (R/W)	SAMPLEDIV	Sample Div. The TRNG_CFG.SAMPLEDIV bit field directly controls the number of input cycles between samples taken from the FROs. The default value 0 indicates that samples are taken every cycle, maximum value 15 (decimal) takes one sample every 16 cycles. This field must be set to a value such that the slowest FRO (even under worst-case conditions) has a cycle time less than twice the sample period. The default configuration of the FROs allows this field to remain 0. This field can only be modified while TRNG_CTL.TRNGEN=0.

Table 42-9: TRNG_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MINREFCYC	Min Refill Cycles. The TRNG_CFG.MINREFCYC bit field determines the minimum number of samples (between 2^6 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64 bit random number. If the value of this field is zero, the number of samples is fixed to the value determined by the maximum refill cycles (TRNG_CFG.MAXREFCYC) field, otherwise the minimum number of samples equals the written value times 64 (which can be up to 2^{14}). The number of samples defined here cannot be higher than the number defined by the TRNG_CFG.MAXREFCYC field (i.e. that field takes precedence). This field can only be modified while the TRNG_CTL.TRNGEN bit =0.

Counter Register

The TRNG_CNT register is used to access the main control Finite State Machine's (FSM) sample counter while the TRNG_CTL.TSTMODE bit =1.

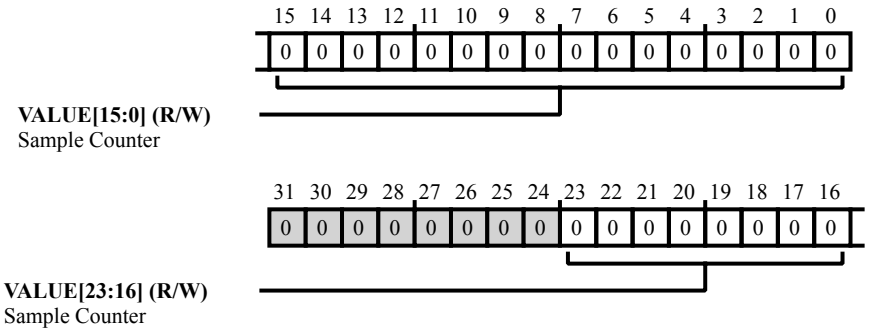

Figure 42-7: TRNG_CNT Register Diagram

Table 42-10: TRNG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	VALUE	Sample Counter. The TRNG_CNT.VALUE bit field is the sample counter used by control finite state machine. This counter can only be accessed when the TRNG_CTL.TSTMODE bit =1.

TRNG Control Register

The TRNG_CTL register must be written to start accumulating entropy before random numbers can be generated. In most cases, the TRNG_CFG register must also be written prior to writing the TRNG_CTL register. To enable the TRNG, set the TRNG_CTL.TRNGEN bit. This register also controls post-processing (if available). Note that when the TRNG_CTL.TRNGEN bit =1, the start up cycles field (TRNG_CTL.STARTUPCYC) and the post-processing enable bit (if available) are locked. Any writes to these fields are ignored.

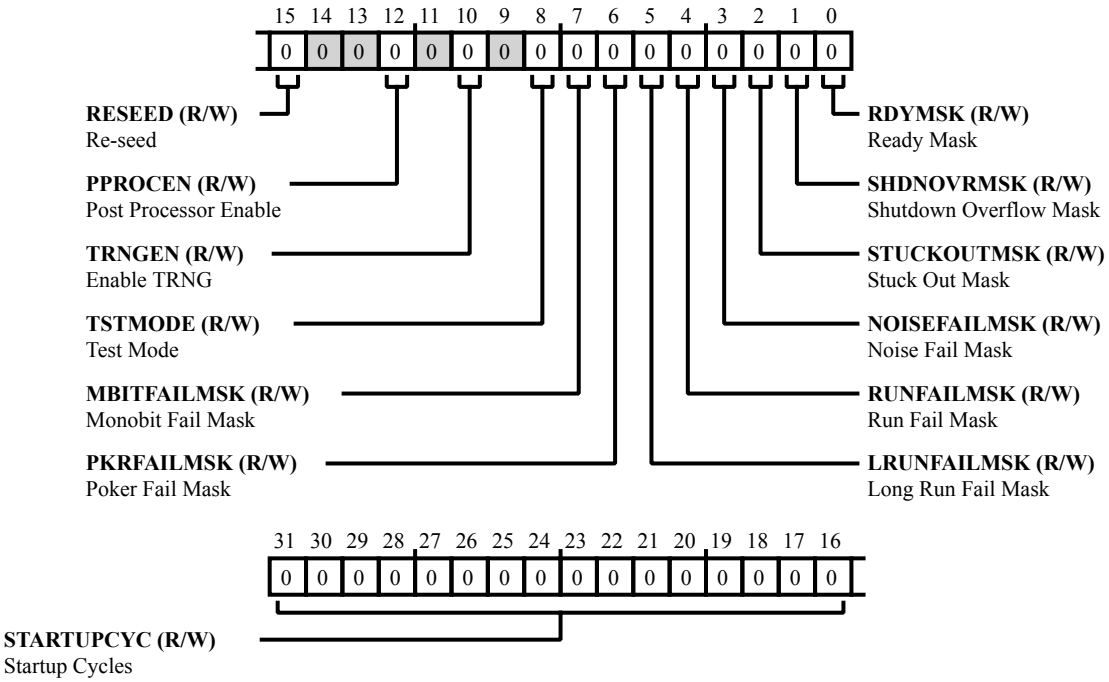

Figure 42-8: TRNG_CTL Register Diagram

Table 42-11: TRNG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	STARTUPCYC	Startup Cycles. The TRNG_CTL.STARTUPCYC bit field determines the number of samples (between 2^8 and 2^{24}) taken to gather entropy from the FROs during startup. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8 . This field can only be written when TRNG_CTL.TRNGEN=0 before the write.

Table 42-11: TRNG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	RESEED	Re-seed. The TRNG_CTL.RESEED bit is set-only, writing a 1 starts a re-seed cycle and writing a 0 has no effect. A re-seed cycle entails loading the TRNG_KEY[n] and TRNG_V[n] registers with random values generated internally these values are not visible outside the TRNG core. This bit falls back to 0 automatically after the re-seed operation is complete at that time the TRNG_BLKCNT register is reset to zero and the random data buffer is zeroized so that any new data read from the TRNG will use the new seed values. This bit is only present when post-processing is available and can only be set to 1 when TRNG_CTL.TRNGEN=1 before the write. Note that re-seeding can be done with the post-processor disabled (normally used to seed the post-processor before enabling it). When writing a 1 to this bit, all other bits in this register remain unchanged.
12 (R/W)	PPROCEN	Post Processor Enable. Setting the TRNG_CTL.PPROCEN bit enables the FIPS post-processor. If this bit is reset to 0, the post-processor is forced back into the idle state immediately. This bit is only present when post-processing is available and can only be changed when the TRNG_CTL.TRNGEN bit (enable TRNG) was 0 before the write. To change the TRNG_CTL.PPROCEN bit during operation, first put the TRNG into reset (TRNG_CTL.TRNGEN =0). If the post-processor is enabled, it can be disabled by a subsequent write of 0 to this bit (writing this bit when the TRNG_CTL.TRNGEN bit is still 1 has no effect). The post-processor then stops immediately. To enable it, this bit bit must be written with 1. Changing the enabled/disabled state does not affect the contents of the the TRNG_KEY[n] and TRNG_V[n] registers. After changing the state, the TRNG must be started again by setting the TRNG_CTL.TRNGEN bit to 1. Note that it is required to re-gather entropy, so the same number of start-up cycles must be used as when starting the TRNG out of a system reset state.
10 (R/W)	TRNGEN	Enable TRNG. Setting the TRNG_CTL.TRNGEN bit to 1 starts the TRNG, gathering entropy from the FROs for the number of samples determined by the value in the TRNG_CTL.STARTUPCYC (Startup Cycles) field. Resetting this bit to 0 forces all TRNG logic back into the idle state immediately. Resetting this bit to 0 also performs the Un-instantiate operation, clearing all internal post-processor registers.
8 (R/W)	TSTMODE	Test Mode. When the TRNG_CTL.TSTMODE bit is set, access is enabled to the TRNG_CNT and TRNG_LFSR_L, TRNG_LFSR_M and TRNG_LFSR_H registers (the latter are cleared before enabling access) and sets the TRNG_STAT.NEEDCLK bit for testing purposes. This bit must be set to 1 before various test modes in the TRNG_TEST register can be enabled.

Table 42-11: TRNG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W)	MBITFAILMSK	Monobit Fail Mask. When the TRNG_CTL.MBITFAILMSK bit is set, this mask allows the TRNG_STAT.MBITFAIL bit to activate the (active HIGH) interrupt output.
6 (R/W)	PKRFAILMSK	Poker Fail Mask. When the TRNG_CTL.PKRFAILMSK bit is set, this mask allows the TRNG_STAT.PKRFAIL bit to activate the (active HIGH) interrupt output.
5 (R/W)	LRUNFAILMSK	Long Run Fail Mask. When the TRNG_CTL.LRUNFAILMSK bit is set, this mask allows the TRNG_STAT.LRUNFAIL bit to activate the (active HIGH) interrupt output.
4 (R/W)	RUNFAILMSK	Run Fail Mask. When the TRNG_CTL.RUNFAILMSK bit is set, this mask allows the TRNG_STAT.RUNFAIL bit to activate the (active HIGH) interrupt output.
3 (R/W)	NOISEFAILMSK	Noise Fail Mask. When the TRNG_CTL.NOISEFAILMSK bit is set, this mask allows the TRNG_STAT.NOISEFAIL bit to activate the (active HIGH) interrupt output.
2 (R/W)	STUCKOUTMSK	Stuck Out Mask. When the TRNG_CTL.STUCKOUTMSK bit is set, this mask allows the TRNG_STAT.STUCKOUT bit to activate the (active HIGH) interrupt output.
1 (R/W)	SHDNOVRMSK	Shutdown Overflow Mask. When the TRNG_CTL.SHDNOVRMSK bit is set, this mask allows the TRNG_STAT.SHDNOVR bit to activate the (active HIGH) interrupt output.
0 (R/W)	RDYMSK	Ready Mask. When the TRNG_CTL.RDYMSK bit is set, this mask allows the TRNG_STAT.RDY bit to activate the (active HIGH) interrupt output.

TRNG FRO De-tune Register

The TRNG_FRODETUNE register is used by the host processor to change the frequencies of individual FROs. This can reduce the number of alarm events generated by a specific FRO.

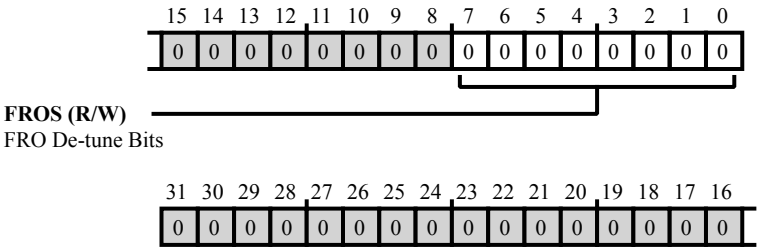

Figure 42-9: TRNG_FRODETUNE Register Diagram

Table 42-12: TRNG_FRODETUNE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO De-tune Bits. The TRNG_FRODETUNE.FROS bits De-tune the FROs. A 1 in bit [n] lets FRO n run approximately 5% faster. The value of one of these bits may only be changed while the corresponding FRO is turned off (by temporarily writing a 0 in the corresponding bit of the TRNG_FROEN register).

TRNG FRO Enable Register

The TRNG_FROEN register can be used by the host processor to enable and disable FROs individually. Only enabled FROs contribute to entropy generation, but require power to do so. Disabled FROs cannot generate alarm events.

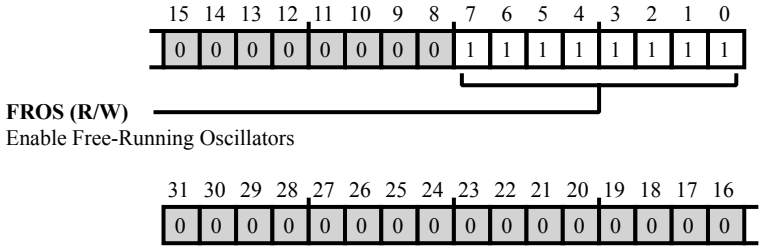

Figure 42-10: TRNG_FROEN Register Diagram

Table 42-13: TRNG_FROEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	Enable Free-Running Oscillators. The TRNG_FROEN.FROS bits are the enables for the individual FROs. A 1 in bit [n] enables FRO n. The default state is all ones to enable all FROs after power-up. Note that the FROs are not actually started up before the TRNG_CTL.TRNGEN bit is set to 1. These bits are automatically forced to 0 (and cannot be written to 1) when the corresponding bit in the TRNG_ALMSTP register has value 1.

TRNG Input Registers

The TRNG_INPUT[n] registers are used as input for post-processor testing (if post processing is available) and as input for Monobit Test, Run Test and Poker Test functionality tests (TRNG_INPUT0 only). They share their addresses with the corresponding TRNG_OUTPUT[n] registers. The least significant word is contained in the TRNG_INPUT0 register.

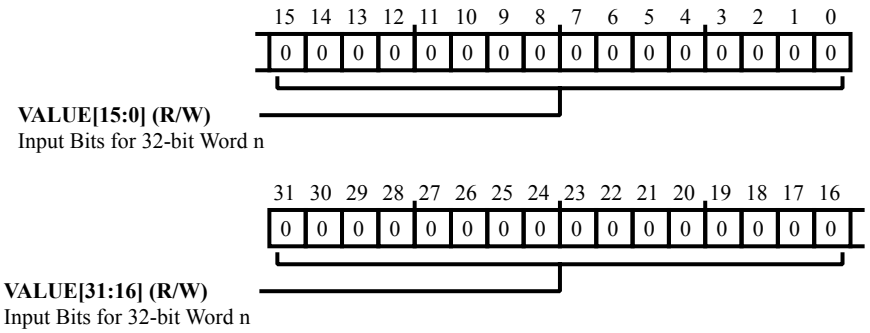

Figure 42-11: TRNG_INPUT[n] Register Diagram

Table 42-14: TRNG_INPUT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Input Bits for 32-bit Word n. The TRNG_INPUT[n].VALUE bit field is used to hold 32-bits of the 64-bit word of test data for 3-DES post-processor (if available). Or, the TRNG_INPUT[n].VALUE bit field is used to hold 32-bit data word for Run Test and Poker Test circuits self test. Can only be written to when the TRNG_STAT.TSTRDY bit =1.

TRNG Interrupt Acknowledge Register

The TRNG_INTACK register is written to acknowledge interrupts indicated in bits [7:0] of the TRNG_STAT register. Writing a 1 to any of the bits [7:2] has side effects in resetting various parts of the TRNG core logic which can also be used even if no interrupts are actually active.

When acknowledging the interrupts, these bits are write '1' to clear the associated bit in TRNG_STAT register. The bit in this register will also automatically be reset to zero.

When secure reading mode is enabled, write bits [7:0] of this register with zeros to enable TRNG data reads from the TRNG_OUTPUT[n] registers. Writing bits [7:0] also starts the (configurable) timeout counter that automatically acknowledges the TRNG data (and disables reads) if the TRNG_INTACK.RDY bit is not written with a 1 within that timeout period.

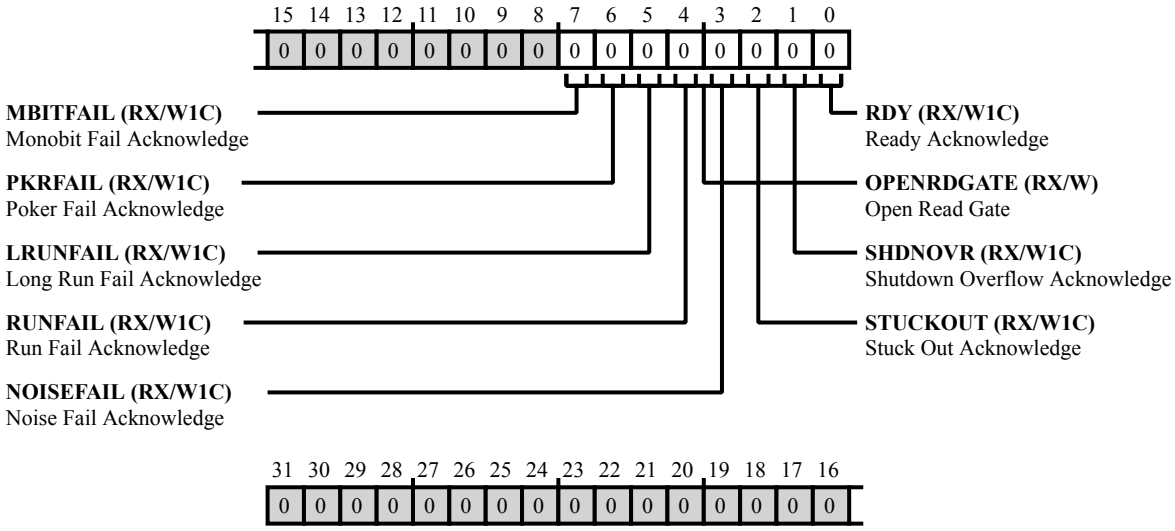

Figure 42-12: TRNG_INTACK Register Diagram

Table 42-15: TRNG_INTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (RX/W1C)	MBITFAIL	Monobit Fail Acknowledge. Set the TRNG_INTACK.MBITFAIL bit to acknowledge the Monobit Fail Interrupt. This also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).
6 (RX/W1C)	PKRFAIL	Poker Fail Acknowledge. Set the TRNG_INTACK.PKRFAIL bit to acknowledge the Poker Fail Interrupt. This also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).

Table 42-15: TRNG_INTACK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (RX/W1C)	LRUNFAIL	Long Run Fail Acknowledge. Set the TRNG_INTACK.LRUNFAIL bit to acknowledge the Long Run Fail Interrupt. Also clears the TRNG_RUNCNT.LENMAX field.
4 (RX/W1C)	RUNFAIL	Run Fail Acknowledge. Set the TRNG_INTACK.RUNFAIL bit to acknowledge the Run Fail Interrupt. Also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).
3 (RX/W1C)	NOISEFAIL	Noise Fail Acknowledge. Set the TRNG_INTACK.NOISEFAIL bit to acknowledge the Noise Fail Interrupt. Setting this bit also clears the TRNG_RUNCNT.LENMAX (Run Length Max) field, the random data buffer, the TRNG_OUTPUT[n] registers and the TRNG_STAT.RDY bit.
2 (RX/W1C)	STUCKOUT	Stuck Out Acknowledge. Set the TRNG_INTACK.STUCKOUT bit to acknowledge the Stuck Out Interrupt. Setting this bit also clears the random data buffer, the TRNG_OUTPUT[n] registers and the TRNG_STAT.RDY bit.
1 (RX/W1C)	SHDNOVR	Shutdown Overflow Acknowledge. Set the TRNG_INTACK.SHDNOVR bit to acknowledge the Shutdown Overflow Interrupt.
0 (RX/W1C)	RDY	Ready Acknowledge. The TRNG_INTACK.RDY bit allows a new number (if it is ready in the random data buffer), to directly move into the result register. Once done, the TRNG_STAT.RDY bit is reset, after at most size clock cycles.
7:0 (RX/W)	OPENRDGATE	Open Read Gate. In Secure Reading Mode, the TRNG_INTACK.OPENRDGATE bit writes an all zeros value to bits [7:0] to enable reading of TRNG data from the TRNG_OUTPUT[n] registers. This starts the timeout counter that automatically acknowledges the TRNG data (and disables reading) if the TRNG_INTACK.RDY bit is not written with a 1 within that timeout period.

Post-Process Key Registers

The TRNG_KEY[n] registers are used to load the key used for post-processing (if available). These registers are write-only. Reads return the values of the other registers mapped at the same addresses.

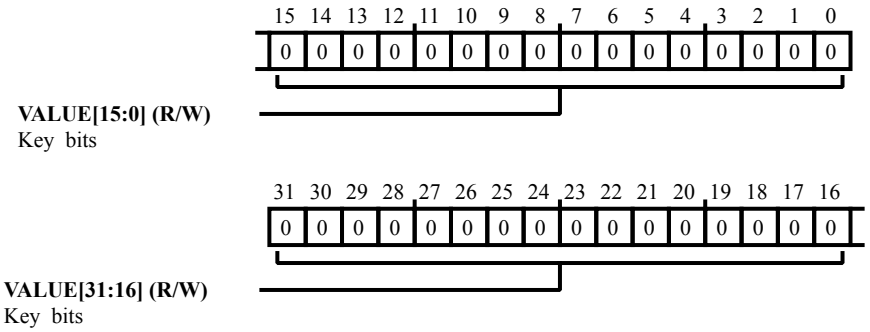

Figure 42-13: TRNG_KEY[n] Register Diagram

Table 42-16: TRNG_KEY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Key bits. Bits for cipher key used in the post-processor.

TRNG LFSR Access Register

The TRNG_LFSR_H register is used to access bits [80:64] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

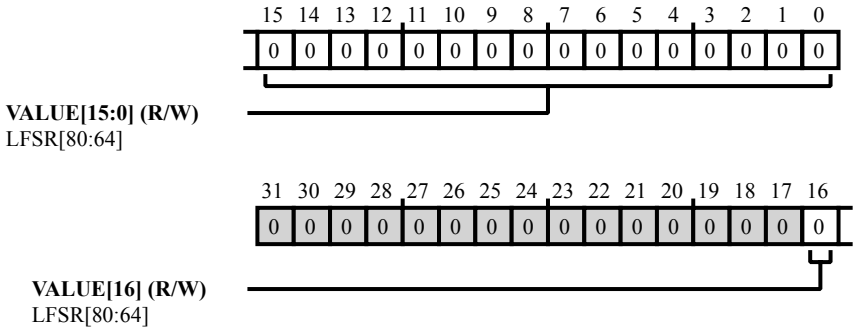

Figure 42-14: TRNG_LFSR_H Register Diagram

Table 42-17: TRNG_LFSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16:0 (R/W)	VALUE	LFSR[80:64]. The TRNG_LFSR_H.VALUE bit field contains bits [80:64] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG LFSR Access Register

The TRNG_LFSR_L register is used to access bits [31:0] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

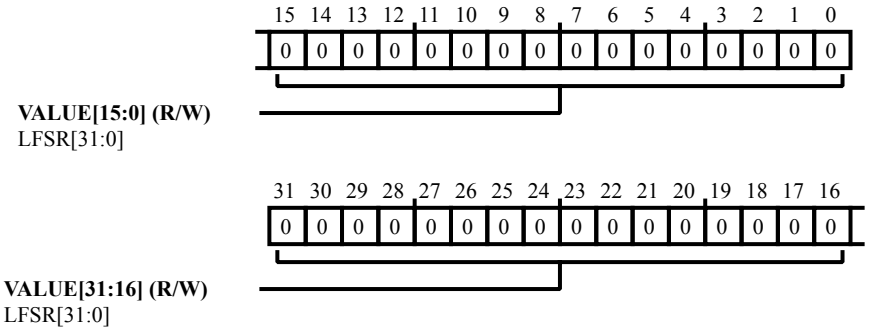

Figure 42-15: TRNG_LFSR_L Register Diagram

Table 42-18: TRNG_LFSR_L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	LFSR[31:0]. The TRNG_LFSR_L.VALUE bit field contains bits [31:0] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG LFSR Access Register

The TRNG_LFSR_M register is used to access bits [63:32] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

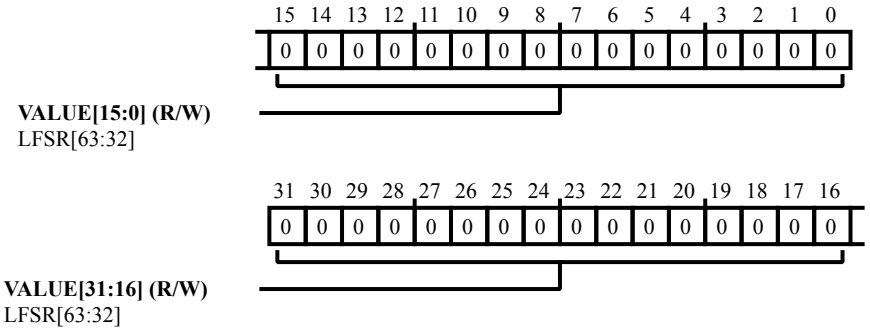

Figure 42-16: TRNG_LFSR_M Register Diagram

Table 42-19: TRNG_LFSR_M Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	LFSR[63:32]. The TRNG_LFSR_M.VALUE bit field contains bits [63:32] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG Monobit Test Result Register

The TRNG_MONOBITCNT register accesses the counter used perform a Monobit Test as specified by the AIS-31 standard (test T1, ref 4). This test is performed on blocks of 20,000 bits (in parallel to the run test and Poker Test).

Note: Immediately after performing the actual Monobit Test at the end of the 20,000 bits block, the counter is used to accumulate the Poker Test results. As a result, the actual Monobit Test count result value can only be read in the TRNG_MONOBITCNT register if the test fails and the stall run Poker (TRNG_ALMCNT.STALLRUNPKR) bit =1.

The monobit test result register is read-only; writing it accesses the registers mapped at the same address. The counter in this register is reset when writing a 1 to either the monobit fail acknowledge (TRNG_INTACK.MBITFAIL), run fail acknowledge (TRNG_INTACK.RUNFAIL) or the poker fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

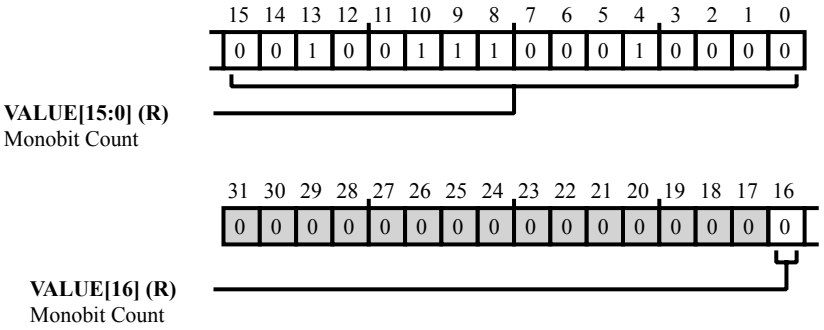

Figure 42-17: TRNG_MONOBITCNT Register Diagram

Table 42-20: TRNG_MONOBITCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16:0 (R/NW)	VALUE	Monobit Count. The TRNG_MONOBITCNT.VALUE bit field is the up/down counter which monitors 1 and 0 bits. After 20,000 bits, this counter should have a value in the range 9310 through 10690 (inclusive) to pass the Monobit Test. This counter is protected against overflow and underflow.

TRNG Output Registers

The TRNG_OUTPUT[n] registers provide read access to the 128-bit random number output. A subset of these registers are also used as output for post-processor testing (if available). They share their addresses with the TRNG_INPUT0 through TRNG_INPUT3 registers. The least significant word is contained in the TRNG_OUTPUT0 register.

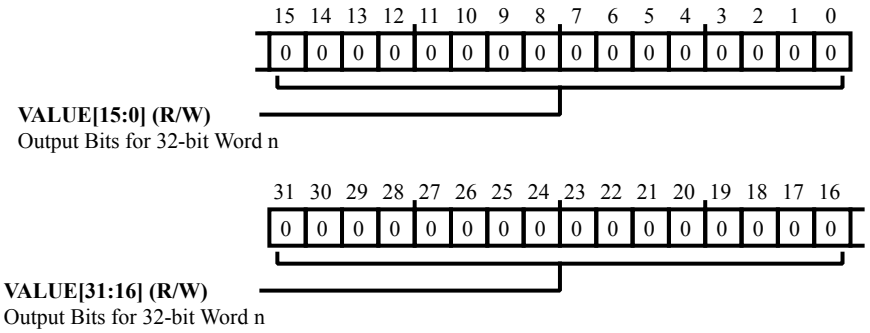

Figure 42-18: TRNG_OUTPUT[n] Register Diagram

Table 42-21: TRNG_OUTPUT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Output Bits for 32-bit Word n. The TRNG_OUTPUT[n].VALUE bit field is used to holds 32 bits of the 128-bit word of random data. Only valid when the TRNG_STAT.RDY bit =1. Alternatively, this register holds the 32-bits of the 42-bit word of result data for 3-DES post-processing testing. Only valid when the TRNG_STAT.TSTRDY bit =1.

TRNG Poker Test Result Registers

The TRNG_POKER[n] registers are used to access the 16 counters used perform a poker test on blocks of 20,000 bits (in parallel to the monobit and run tests).

Poker test result registers are read-only; writing them accesses the registers mapped at these same addresses. All counters in these registers are reset when writing a 1 to either the monobit fail acknowledge (TRNG_INTACK.MBITFAIL), run fail acknowledge (TRNG_INTACK.RUNFAIL) or the poker fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

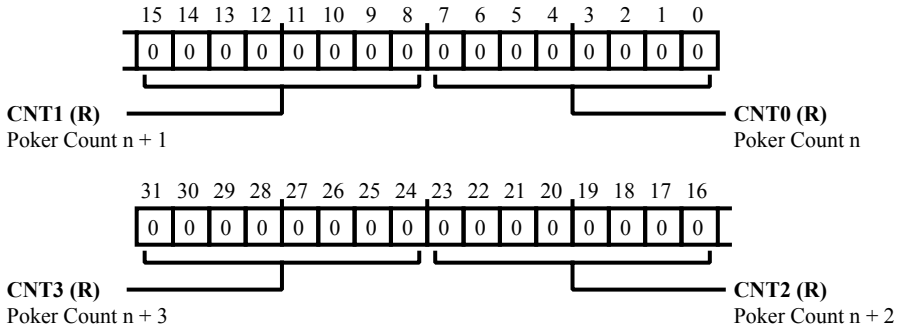

Figure 42-19: TRNG_POKER[n] Register Diagram

Table 42-22: TRNG_POKER[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	CNT3	Poker Count n + 3. The TRNG_POKER[n].CNT3 bit field provides the counter for 4-bit value 0x3, 0x7, 0xB, 0xF in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
23:16 (R/NW)	CNT2	Poker Count n + 2. The TRNG_POKER[n].CNT2 bit field provides the counter for 4-bit value 0x2, 0x6, 0xA, 0xE in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
15:8 (R/NW)	CNT1	Poker Count n + 1. The TRNG_POKER[n].CNT1 bit field provides the counter for 4-bit value 0x1, 0x5, 0x9, 0xD in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
7:0 (R/NW)	CNT0	Poker Count n. The TRNG_POKER[n].CNT0 bit field provides the counter for 4-bit value 0x0, 0x4, 0x8, 0xC in the TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.

TRNG Run Count Registers

The TRNG_RUNCNT registers are used to access the 10 counters that perform a run test and long run test as specified by the AIS-31 standard (tests T3 and T4, ref 4). They are also used to perform the noise source failure test proposed in section E.5 of that same standard.

The TRNG_RUNCNT registers are read-only; writing them accesses the other registers which are mapped at the same addresses. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the Monobit Fail acknowledge (TRNG_INTACK.MBITFAIL), Run Fail acknowledge (TRNG_INTACK.RUNFAIL) or the Poker Fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

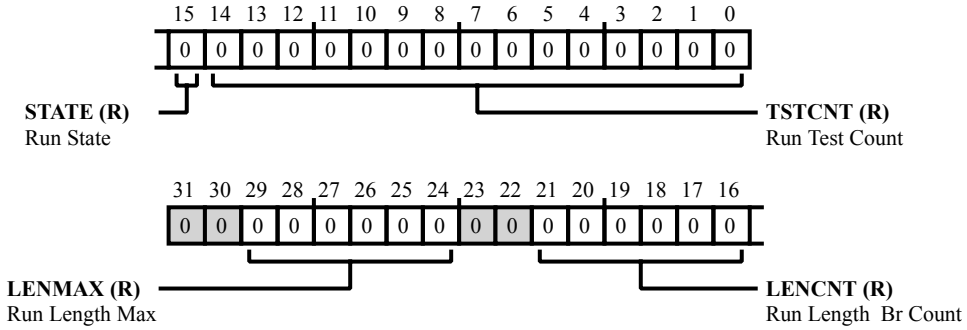

Figure 42-20: TRNG_RUNCNT Register Diagram

Table 42-23: TRNG_RUNCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	LENMAX	Run Length Max. The TRNG_RUNCNT.LENMAX bit field configures the maximum run length count value encountered since start of test. This value is reset back to zero when writing a 1 to either the Noise Fail acknowledge (TRNG_INTACK.NOISEFAIL) or the Long Run Fail acknowledge (TRNG_INTACK.LRUNFAIL) bits.
21:16 (R/NW)	LENCNT	Run Length Br Count. The TRNG_RUNCNT.LENCNT bit field configures the counter for the current run of consecutive 0/1 bits; cannot increment past its maximum value of 63.
15 (R/NW)	STATE	Run State. The TRNG_RUNCNT.STATE bit field provides th state of bits in the current run.
14:0 (R/NW)	TSTCNT	Run Test Count. The TRNG_RUNCNT.TSTCNT bit field configures the block length counter for the run and poker tests - counts up for 20,000 tested bits and then controls testing of the run_X_count_... and poker_count_X counters to contain expected values, after which they - and this counter - are reset for the next block.

TRNG Run Test State and Result Registers

The TRNG_RUN[n] registers holds the counts for the associated run bucket for 1's and 0's.

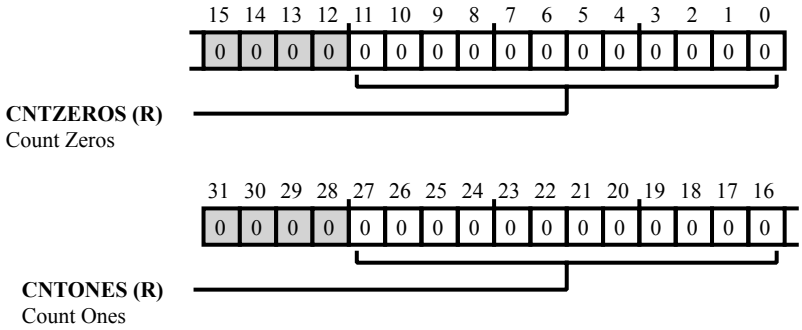

Figure 42-21: TRNG_RUN[n] Register Diagram

Table 42-24: TRNG_RUN[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/NW)	CNTONES	Count Ones. In TRNG_RUN1, this counter is for single bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter for four bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter for six and higher bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

Table 42-24: TRNG_RUN[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
