11:0 (R/NW)	CNTZEROS	Count Zeros. In TRNG_RUN1, this counter is for single bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter is for four bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter is for six and higher bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

TRNG Status Register

The TRNG_STAT register provides status results. This register shares the same address as the Interrupt Acknowledge (TRNG_INTACK) register.

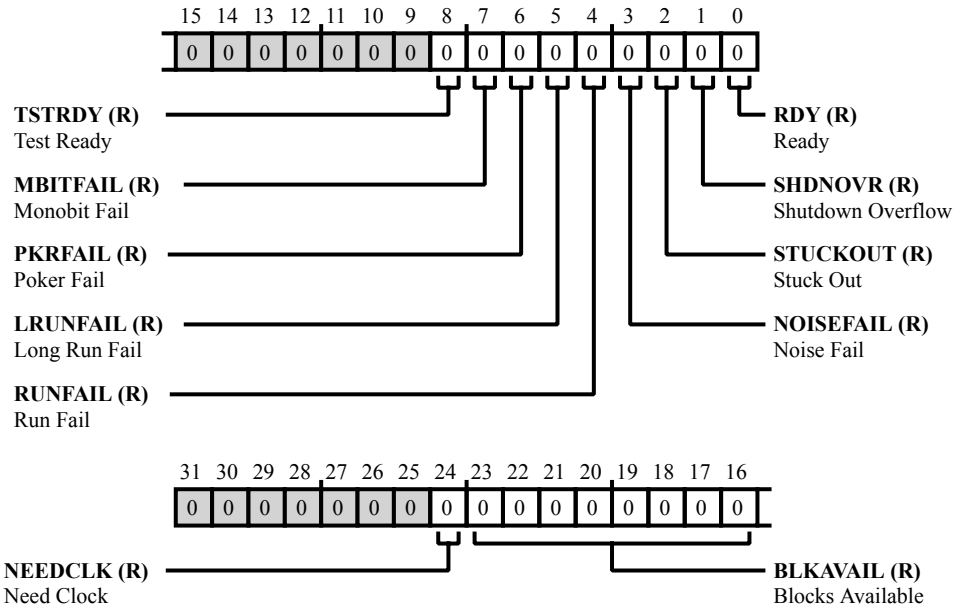

Figure 42-22: TRNG_STAT Register Diagram

Table 42-25: TRNG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/NW)	NEEDCLK	Need Clock. When the TRNG_STAT.NEEDCLK bit is set, it indicates that the TRNG is busy generating entropy or is in one of its test modes the module clock may not be turned off.
23:16 (R/NW)	BLKAVAIL	Blocks Available. This field indicates the number of 128 bits blocks of random data that are available in the random data buffer. If this value is non-zero, the output registers will be re-filled from the random data buffer immediately after acknowledging the TRNG_STAT.RDY by writing a '1' to TRNG_INTACK.RDY.
8 (R/NW)	TSTRDY	Test Ready. When the TRNG_STAT.TSTRDY bit is set, it indicates that data for known-answer tests on the Monobit Test, Run Test, Poker Test and post-processor functions can be written to the TRNG_INPUT[n] registers. When testing the post-processor, result data can be read from those same registers when this bit has become 1 again (after dropping to 0).

Table 42-25: TRNG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	MBITFAIL	Monobit Fail. When the TRNG_STAT.MBITFAIL bit is set, the Monobit Test logic monitoring data, shifted into the main LFSR, detected an out-of-bounds number of 1s after checking 20,000 bits (test T1 as specified in the AIS-31 standard).
6 (R/NW)	PKRFAIL	Poker Fail. When the TRNG_STAT.PKRFAIL bit is set, the Poker Test logic monitoring data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 Poker Counters or an out of bounds sum of squares value after checking 20,000 bits (test T2 as specified in the AIS-31 standard).
5 (R/NW)	LRUNFAIL	Long Run Fail. When the TRNG_STAT.LRUNFAIL bit is set, the Run Test logic monitoring data shifted into the main LFSR detected a sequence of 34 identical bits (test T4 as specified in the AIS-31 standard).
4 (R/NW)	RUNFAIL	Run Fail. When the TRNG_STAT.RUNFAIL bit is set, the Run Test logic monitoring data shifted into the main LFSR detected an out-of-bounds value for at least one of the TRNG_RUN[n].CNTZEROS or TRNG_RUN[n].CNTONES counters after checking 20,000 bits (test T3 as specified in the AIS-31 standard).
3 (R/NW)	NOISEFAIL	Noise Fail. When the TRNG_STAT.NOISEFAIL bit is set, the Run Test logic monitoring data shifted into the main LFSR detected a sequence of 48 identical bits, which is considered a noise source failure as proposed in section E.5 of the AIS-31 standard.
2 (R/NW)	STUCKOUT	Stuck Out. When the TRNG_STAT.STUCKOUT bit is set, the logic around the output data registers detected that the TRNG generates the same value twice in a row.
1 (R/NW)	SHDNOVR	Shutdown Overflow. When the TRNG_STAT.SHDNOVR bit is set, the number of FROs shut down after a second error event (the number of 1 bits in the TRNG_ALMSTP register) has exceeded the threshold set by the TRNG_ALMCNT.SHDNTHRESH bit field.
0 (R/NW)	RDY	Ready. When the TRNG_STAT.RDY bit is set, data is available in the TRNG_OUTPUT0 to TRNG_OUTPUT3 registers. If a new number is already available in the random data buffer, that number is directly moved into the result register. In this case the ready status bit is asserted again, after at most six module clock cycles.

TRNG Test Register

The TRNG_TEST register can be used by the host processor to perform a number of tests on the TRNG logic including:

- Register controlled characterization by connecting the tst_fro_clk_out output to a selected FRO clock output
- FRO logic connectivity and error event detection checking by feeding known patterns through the FRO delay line and error event detection circuits
- Direct XOR-ed FRO outputs capture by disabling the main LFSR feedback logic
- Extend the Monobit Test and Poker Test by not resetting the Monobit count and Poker Test X counters after each 20,000 bits block
- Perform known answer tests on the Run Test, Poker Test and post-processor functions.

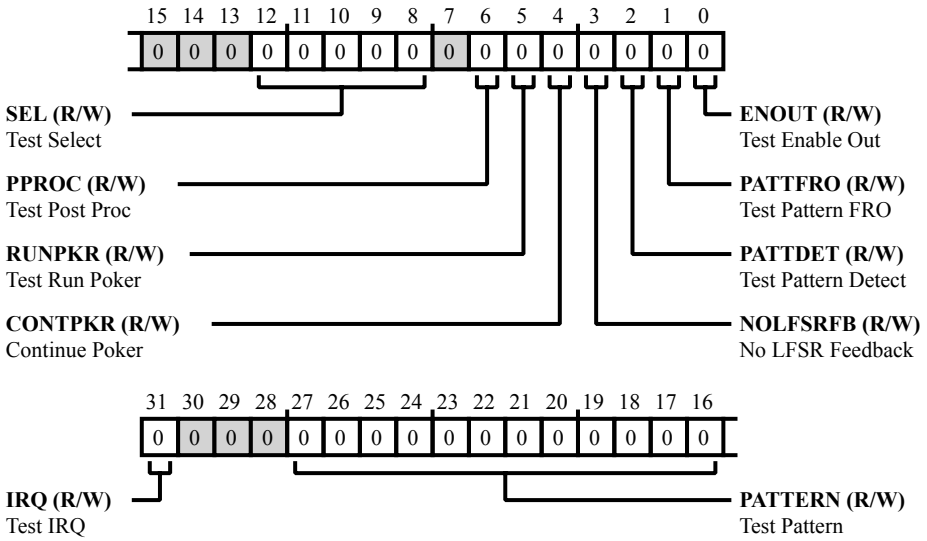

Figure 42-23: TRNG_TEST Register Diagram

Table 42-26: TRNG_TEST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	IRQ	Test IRQ. When the TRNG_TEST.IRQ bit is set force irq output HIGH for interrupt signal connectivity testing.	
		0	Do not force IRQ high
		1	Force IRQ output high

Table 42-26: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/W)	PATTERN	Test Pattern. The TRNG_TEST.PATTERN bit field sets up a repeating sequence of bits to be fed into the selected FRO delay chain TRNG_TEST.PATTFRO =1 and/or the selected FRO error detection circuit TRNG_TEST.PATTDET =1. This field is rotated right over one bit, once every sample period, when either of these control bits is 1. Therefore, bit [16] is the actual pattern bit fed into the test target.
12:8 (R/W)	SEL	Test Select. The TRNG_TEST.SEL bit field configures the number of the FRO to be tested, the value should be in the range of 0 to 7.
6 (R/W)	PPROC	Test Post Proc. When the TRNG_TEST.PPROC bit is set, it provides direct access to the post-processor for known-answer tests (writing input data to the TRNG_INPUT[n] registers). While this bit is set, the TRNG can continue to generate entropy in the main LFSR and any buffered random data is preserved, to be loaded into the output registers as soon as this bit is reset to 0 again. The need clock output is forced active while this bit is set. For X9.31 post-processors, it is advisable to re-seed the post-processor after running known-answer tests as the original key and V values are modified to known values. This bit is only present when post-processing is available and can only be set to 1 when the TRNG_CTL.PPROCEN bit =1 and the test run poker (TRNG_TEST.RUNPKR) bit in this register is 0.
5 (R/W)	RUNPKR	Test Run Poker. When the TRNG_TEST.RUNPKR bit is set, it provides direct access to the inputs of the Monobit, Run and Poker Test circuits (writing input data in chunks of 32 bits to the TRNG_INPUT0 register). While this bit is 1, the TRNG is not allowed to generate entropy but any buffered random data is preserved, to be loaded into the output registers as soon as this bit is reset to 0 again. The TRNG_STAT.NEEDCLK bit is forced active while this bit is 1. The Monobit, Run and Poker Test circuits are reset to their initial states on any change of this bit.
4 (R/W)	CONTPKR	Continue Poker. When the TRNG_TEST.CONTPKR bit is set, Monobit Test and Poker Test keep running continuously by not resetting the Monobit count (TRNG_MONOBITCNT) and poker counters (TRNG_POKER[n] register) at the end of each 20,000 bits test block. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1. 0 – Do not continue poker test 1 – Continue poker test

Table 42-26: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	NOLFSRFB	No LFSR Feedback. When the TRNG_TEST.NOLFSRFB bit is set, it removes XNOR feedback from the main LFSR, converting it into a normal shift register for the XOR-ed outputs of the FROs (shifting data in on the LSB side). A 1 also forces the LFSR to sample continuously. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Keep XNOR feedback
		1	Remove XNOR feedback
2 (R/W)	PATTDET	Test Pattern Detect. When the TRNG_TEST.PATTDET bit is set, it repeatedly feeds test pattern (PATTERN) into the error detection circuit of the FRO selected by the test select (TRNG_TEST.SEL) field. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
1 (R/W)	PATTFRO	Test Pattern FRO. When the TRNG_TEST.PATTFRO bit is set, it repeatedly feeds test pattern (PATTERN) into the delay chain of the FRO selected by the test select (TRNG_TEST.SEL) field by forcing the corresponding FRO enable (FROEN) output LOW. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
0 (R/W)	ENOUT	Test Enable Out. When the TRNG_TEST.ENOUT bit is set, it enables the tst_fro_clk_out output, connecting to the FRO selected by the test select (TRNG_TEST.SEL) field. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Disable tst_fro_clk_out
		1	Enable tst_fro_clk_out

TRNG Post-Process "V" Value Registers

The TRNG_V[n] registers are used to load the V value used for post-processing (if available). These registers are write-only. Reads return the values of the other registers mapped at the same addresses.

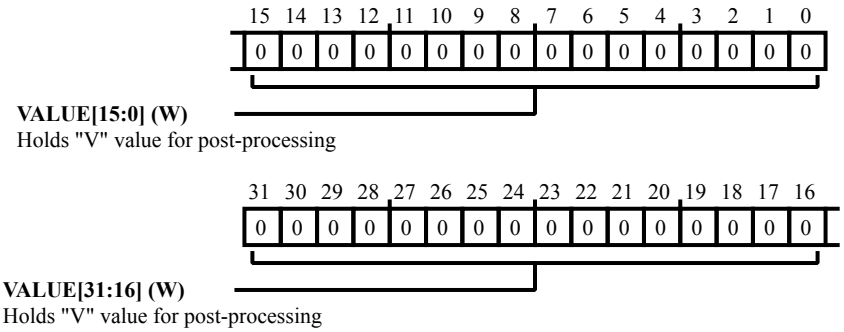

Figure 42-24: TRNG_V[n] Register Diagram

Table 42-27: TRNG_V[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Holds "V" value for post-processing. Bits of the post-processing 'V' value.

43 FIR Accelerator (FIR)

Finite Impulse Response (FIR) filters are frequently used in digital signal processing applications. The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core. FIR filters are used in a wide array of applications including multi-rate processing with an interpolator or decimator.

Features

This hardware module can perform FIR filters without core intervention. This allows programs to use the core to implement complex algorithms, effectively adding more bandwidth to the processor.

The FIR supports the following features:

- Fixed-point and 32-bit IEEE floating-point format
- Four SHARC+ core compatible MAC units that operate in parallel
- Rounding modes compatible with SHARC+ core MACs
- Single rate or multi-rate window processing
- Programmable rates with decimation or interpolation mode
- Up to 32 filter channels available in TDM in legacy mode
- Burst transfers on data or coefficient loads

NOTE: The FIR accelerator module has a local memory that the core cannot access during regular operation. Unlike previous SHARC processors, the FIR accelerator modules each have access to the system memory (on-chip or off-chip).

Also, unlike the previous SHARC processors, where only one of the FIR or IIR accelerators can be used at a time, the SHARC+ processor can use both accelerators simultaneously.

Clocking

The FIR accelerator runs at the speed of the core clock frequency (CCLK).

Functional Description

The ***FIR Block Diagram*** shows the 1024-TAP FIR hardware accelerator. The accelerator consists of a 1024 word coefficient memory, a 1024 deep delay line for data, and four MAC units. The accelerator runs at /CCLK frequency.

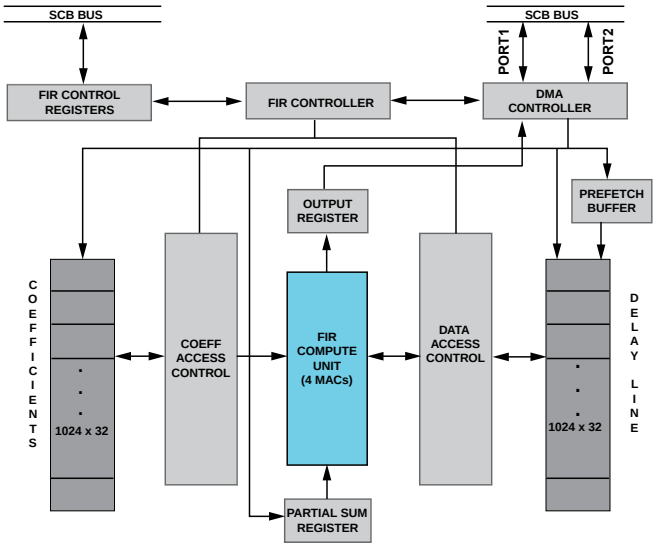

Figure 43-1: FIR Block Diagram

The FIR accelerator has the following logical sub blocks:

- A datapath unit that consists of:
  - A 1024 deep coefficient memory
  - A 1024 deep delay line for the data
  - Four 32-bit floating-point and fixed-point multiplier and adder units
  - One 32-bit prefetch buffer that operates in a pipelined fashion
  - One 32-bit buffer to hold the previous partial sum
  - One 32-bit buffer to hold the output
- Configuration registers for the number of TAPs, number of channels, filter enable, interrupt control, DMA enable, up sample or down sample control, and ratios.
- Core access interface for writing to the DMA and filter configuration registers and reading the status register.
- DMA bus interface for transferring data and coefficients to and from the accelerator.
- DMA configuration registers including chain pointer, input, output, and coefficient registers.

The accelerator block is integrated with the SHARC core. For more information about this, see the SCB Block Diagram.

ADSP-2159x_SC591_SC592_SC594 FIR Register List

The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core.

Compute Block

The MAC unit, shown in the ***FIR MAC Unit*** figure, has four multiply accumulators. The accumulators operate simultaneously on a single filter as described below.

- The MAC unit operates on the data and coefficient fetched from the data and coefficient RAMs
- Each MAC can perform 32-bit floating-point or 32-bit fixed-point MAC operations
- Floating-point format is IEEE-compliant
- Multiply and accumulation operation (addition) are pipelined
- A 32-bit floating-point MAC operation generates 32-bit multiply results
- A 32-bit fixed-point operation generates 80-bit results (64-bit result + 16 guard bits)

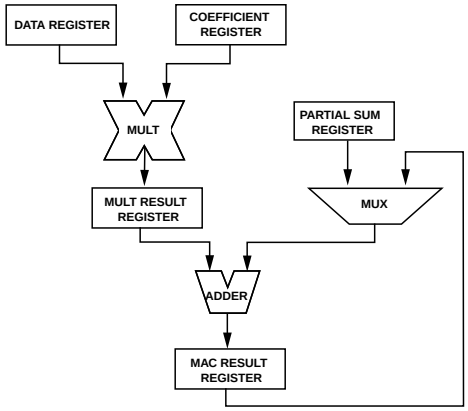

Figure 43-2: FIR MAC Unit

Partial Sum Register

The partial sum register is useful for Floating-point Multi-Iteration mode. For a particular channel, the intermediate MAC result is written to the output buffer of the system memory (on-chip or off-chip). If the same channel is requested again, the partial result register is updated with the intermediate MAC result through DMA from the output buffer of the system memory. The result is added to the current MAC result after each iteration. This process repeats until all iterations complete (the entire soft filter length is processed).

Delay Line Memory

The accelerator has a 1024 TAP delay line to hold the data locally. The DMA controller fetches the data from system memory and loads it into the delay line. Four read accesses can be made to the delay line simultaneously.

Coefficient Memory

The accelerator has a 1024 deep coefficient memory to store the coefficients. The DMA controller loads the coefficients from system memory into coefficient memory. Four coefficients can be fetched from the coefficient memory simultaneously. If the soft filter length is more than 1024, processing happens in multi-iteration mode.

Prefetch Data Buffer

The prefetch data buffer enables pipeline operation. One data sample is prefetched when the compute unit is operating on the delay line corresponding to the current sample. The data prefetched in this buffer is later used to update the delay line for the next sample. This operation happens in parallel again when the compute unit is not accessing the delay line. In other words, it happens when the compute unit is adding the output from the four MACs and the partial sum register.

Table 43-5: Pipeline Operation for Window Size = 1

Cycles	1	2	3	4	5	6
Output DMA			N	N1	N2	N3
Compute		N	N1	N2	N3	

Table 43-5: Pipeline Operation for Window Size = 1 (Continued)

Cycles	1	2	3	4	5	6
Input DMA	N	prefetch N1	prefetch N2	prefetch N3		

Processing Output

The accelerator uses all four MACs simultaneously to calculate one output sample as shown in the ***Multi-Iteration Filtering Flow*** figure and the following procedure.

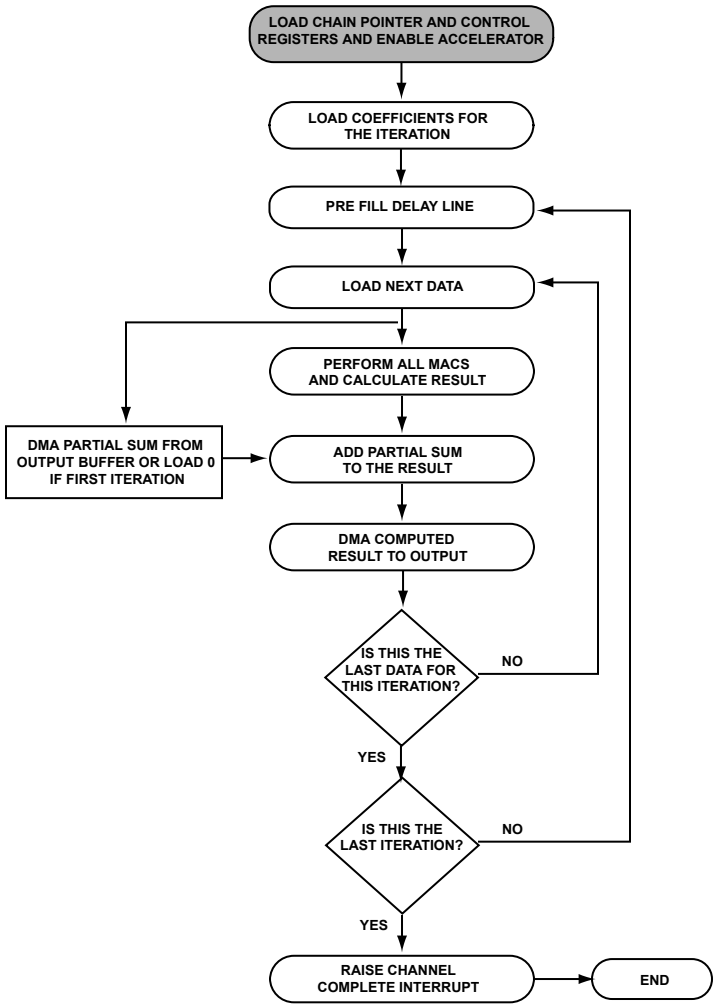

Figure 43-3: Multi-Iteration Filtering Flow

1. The accelerator fetches four input data from the delay line and four corresponding coefficients from the coefficient memory and feeds them to the MAC units for multiply and accumulation operations.
2. The accelerator repeats the procedure with the next four input data and coefficients until all the TAPs complete. For example, this procedure happens N/4 times for an N TAP filter.

3. When all the TAPs are complete, the accelerator adds the four MAC outputs together to the previous partial sum (if any) to calculate the final result.
4. Finally, that output sample is stored back in system memory.

System Memory Storage

The following sections describe the storage format for the accelerator.

CAUTION: Store all data in memory aligned to the word address boundaries. Any other programmed addresses do not flag an error.

Coefficients and Input Buffer Storage

For any N TAP filter with coefficients:

```
C[i] i = 0,1,
...
N - 1
```

store the coefficients in system memory buffer in the order:

```
C[N - 1], C[N - 2]
...
C[1],C[0]
```

and CI should point to `C(N - 1)`.

Single Rate Input Filtering

The total size of the input buffer must at least be equal to `N - 1 + W`. If the input buffer that needs to be processed is:

```
 x[n],x[n+1],x[n+2]
 ...
 x[n+W-1]
```

store it in the memory as

```
x[n-(N-1)], x[n-(N-2)]
...
x[n-1], x[n], x[n+1]
...
x[n+W-1]
```

and the `FIR_INIDX` register value should point to `x[n - (N - 1)]`

Decimation

Assuming M = decimation ratio, the total size of the input buffer should at least be equal to `N - 1 + W x M`. If the input buffer that needs to be processed is:

```
x[n],x[n+1],x[n+2]....x[n+WxM-1],
```

store it in the memory as:

```
x[n-(N-1)], x[n-(N-2)]....x[n-1],
x[n], x[n+1]....x[n+WxM-1]
```

and the FIR_INIDX register value should point to x[n-(N-1)].

Interpolation

Assuming L= interpolation ratio, the total size of the input buffer should be at least equal to:

Ceil ((N-1)/L)+W/L.

If the input buffer that needs to be processed is:

```
x[n], x[n+1], x[n+2]....x[n+W/L-1],
and K = Ceil((N-1)/L)
```

store it in the memory as:

```
x[n-k], x[n-(K-1)], x[n-(K-2)]....x[n-1],
x[n], x[n+1].... x[n+W/L-1]
```

and the FIR_INIDX register value should point to x[n-K].

Operating Modes

The FIR core performs a sum-of-products operation to compute the convolution sum. It supports single-rate, decimation, and interpolation functions.

Single Rate Processing

In a single-rate filter, the output result rate is equal to the input sample rate. The filter output Y(n) is computed according to following equation where N is the number of filter coefficients: c(k) k = 0 to N – 1 are the filter coefficients and x(n) represents the input time-series.

$$Y(n)= \sum_{k=0}^{N-1} c(k) \cdot x(n-k)$$

Figure 43-4: Filter Output Calculation

Single Iteration

Results are computed in a single iteration when the soft filter length is less than or equal to 1024.

Floating-point Multi-Iteration

Results are computed in multiple iterations when the soft filter length is greater than 1024 (for example, 2048 TAPs on a 1024 hard filter length). In this mode, the accelerator implements two iterations of 1024 TAPs.

NOTE: If the soft filter length is not a multiple of the hard filter length, the accelerator iterates until the soft filter length is satisfied.

Example: 550 taps on a 256 tap filter. In this example, the FIR accelerator implements two iterations of 256 taps and one iteration of 38 taps.

NOTE: Multi-iteration mode is not supported in fixed-point format.

Window Processing

In window-based mode, multiple output samples (up to 1024) equal to the window size of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A configurable window size parameter is provided to specify the length of the window.

To select sample-based processing mode, configure the window size to 1. In this mode, one sample from a particular channel is processed through all the taps of that channel and the final output sample is calculated.

Multi-Rate Processing

Multi-rate filters change the sampling rate of a signal—they convert the input samples of a signal to a different set of data that represents the same signal sampled at a different rate.

Decimation

A decimation filter provides a single output result for every M input samples, where M is the decimation ratio. The output rate is 1/M'th of the input rate. The filter implementation exploits the low output sample rate by not starting a computation until a new set of M input samples is available.

In this mode, after low-pass filtering (for anti-aliasing), FIR logic discards the ratio – 1 samples of output data. For performance optimization, FIR logic skips the computation of output samples, which are discarded.

The input buffer size for decimation filters is N – 1 + (W × M) where:

- N is the number of taps
- W is the window size
- M is the decimation ratio

The window size (`FIR_CTL2.WINDOW` bits) must be programmed with the number of output samples.

To start this mode, programs set the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with normal filter setting). Also, the `FIR_CTL2.TAPLEN` bit field value should be greater than or equal to the `FIR_CTL2.RATIO` bit field value for the decimation filter.

Interpolation

An interpolation filter provides L output results for each new input sample, where L is the interpolation ratio. The output rate is L times the input rate.

In this mode, according to the ratio specified in configuration register, FIR logic inserts L – 1 zeros between any two input samples (upsampling). It then performs the interpolation (through the FIR filter).

Both upsampling and downsampling do not support multi-iteration mode. Therefore, the filtering operation only happens on up to 1024 TAPs and the ratio of up and downsampling can only be an integer value.

In an interpolation filter, FIR logic inserts L – 1 zeros between each sample. The program has to make sure that these zeros fully shift out of the delay line before moving on to the next channel. This operation puts a restriction on window size in terms of L – *the sample ratio* as showing in the expression:

WINDOWSIZE = *n* × *SAMPLERATIO*, where *n* is the number of input samples.

The input buffer size is smallest integer greater than or equal to (N – 1 + W) L for interpolation filters where:

- N is the number of taps
- W is the window size
- L is the interpolation ratio

To start the mode, programs configure the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with filter settings).

Floating-Point Data Format

The FIR accelerator treats data and coefficients in 32-bit floating-point format as the default functional mode.

Fixed-Point Data Format

In fixed-point mode, the 32-bit input data or coefficient is treated as fixed-point. A 32-bit fixed-point MAC operation generates an 80-bit result. Fixed-point data or coefficients can be unsigned integer, unsigned fractional and signed integer.

NOTE: In fixed-point mode, the entire 80-bit result register is always written back in bursts of 3 × 32 bits. The first word is the LSW, the second word is the MSW, and the third word is a 16-bit overflow. The remaining 16 bits are padded with zeros. Therefore, for fixed-point mode: WINDOWSIZE = WINDOWSIZE × 3.

If the signed fractional format is used, the output must be scaled by 2. The MAC does not right shift to remove the redundant sign bit. A final routine must decimate the output buffer to the desired samples.

Multi-iteration mode is not supported in this format. Therefore, the maximum TAP length is 1024.

Auto Configuration Mode (ACM)

The accelerator can be operated in legacy mode or Auto Configuration Mode (ACM), controlled by the `FIR_CTL1.ACM` bit. The default functional mode is legacy mode. The accelerator mode can only be changed when the accelerator is disabled.

The ACM provides the following additional features:

- Halt and queuing

The core may pause the current Transfer Control Block (TCB) chain being processed by setting the FIR_CTL1.HALT bit. The accelerator acknowledges the core by setting the FIR_DMASTAT.HALT_STAT bit. The core can appropriately take action to submit/insert new TCB's. After the core takes action, the accelerator processing can be resumed by clearing the FIR_CTL1.HALT bit. Before halting the accelerator, if the initial TCB chain is processed, the accelerator comes to the idle state. In this case, the accelerator has to be disabled and enabled by toggling the FIR_CTL1.EN bit and the FIR_CTL1.HALT bit has to be cleared to resume processing.

- No channel number limitation

  Unlike legacy mode, there is no fixed channel number limitation and, therefore, the accelerator ignores the value programmed in the FIR_CTL1.CH field. The application can queue an unlimited number of channels/TCBs dynamically and the accelerator keeps processing the TCBs until the chain pointer becomes null.

- Selective interrupt

  The core can enable/mask interrupt generation for each channel using the FIR_CTL2.IMASK bit. If the bit is cleared, an interrupt is generated after completion of the channel.

- Selective controller / target trigger

  The core can enable/mask trigger generation by the accelerator after the end of processing of each channel using the FIR_CTL2.TMASK bit. The accelerator can also wait for a trigger after loading the TCB and coefficients and before processing a channel for which the FIR_CTL2.TWAIT bit is set.

In addition to the above features, there are three additional fields as part of the TCB FIR_SCTL1, FIR_SCTL2, and FIR_SGCTL registers. The FIR_SGCTL register can be used to change the FIR_CTL1 parameters such as rounding mode and fixed-point mode for each channel. The FIR_SCTL1 and FIR_SCTL2 registers can be used as general-purpose registers.

Data Transfer

The FIR filter works exclusively through DMA.

Chain Assignment

The structure of a TCB is conceptually the same as a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB can point to itself to continuously re-run the same DMA. The FIR accelerator reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The FIR accelerator DMA supports circular buffer chained DMA. The FIR accelerator does not support circular buffering for the coefficient buffer.

Table 43-6: TCBs for Chained DMA in Legacy Mode

Address	Register
TCB	FIR_CHNPTR
TCB + 0x1	FIR_COEFCNT
TCB + 0x2	FIR_COEFMOD
TCB + 0x3	FIR_COEFIDX
TCB + 0x4	FIR_OUTBASE
TCB + 0x5	FIR_OUTCNT
TCB + 0x6	FIR_OUTMOD
TCB + 0x7	FIR_OUTIDX
TCB + 0x8	FIR_INBASE
TCB + 0x9	FIR_INCNT
TCB + 0xA	FIR_INMOD
TCB + 0xB	FIR_INIDX
TCB + 0xC	FIR_CTL2

Table 43-7: TCBs for Chained DMA in Auto Configuration Mode

Address	Register
TCB	FIR_CHNPTR
TCB + 0x1	FIR_SCTL1
TCB + 0x2	FIR_SCTL2
TCB + 0x3	FIR_SGCTL
TCB + 0x4	FIR_COEFCNT
TCB + 0x5	FIR_COEFMOD
TCB + 0x6	FIR_COEFIDX
TCB + 0x7	FIR_OUTBASE
TCB + 0x8	FIR_OUTCNT
TCB + 0x9	FIR_OUTMOD
TCB + 0xA	FIR_OUTIDX
TCB + 0xB	FIR_INBASE
TCB + 0xC	FIR_INCNT
TCB + 0xD	FIR_INMOD
TCB + 0xE	FIR_INIDX
TCB + 0xF	FIR_CTL2

The FIR_COEFCNT register is loaded with the values in the FIR_COEFCNT TCB field and is decremented from that value onwards. However, coefficient loading continues until the number of coefficients, equal to the tap length, are read. This condition is true even if the FIR_COEFCNT register reaches zero as in the case of a tap length = 10, and the FIR_COEFCNT bit field in the TCB is initialized to 0. The value in the FIR_COEFCNT register is –10 after all coefficients are loaded.

NOTE: Initialize the FIR_CHNPTR register to TCB + 12 in legacy mode and TCB + 15 in ACM mode.

DMA Access

The FIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Burst Access Support

Burst access enhances the throughput of the DMA channel and reduces the overall load on the system fabric. Burst support is provided for TCB, data, and coefficient loads on the DMA channel. The FIR module supports burst transfers of size SINGLE, INCR4 INCR8 and INCR16. For TCB load, a burst access of length 16 is issued which reduces the TCB load time.

An additional bit (FIR_CTL1.BURSTEN) enables the burst feature. Burst transfers are always of size SINGLE when the modifier is other than 1. In cases of burst transfers around the circular buffer boundary, the design ensures that the burst does not cross the buffer boundary.

Data and Coefficient Load in Parallel

To reduce the overall loading time of data and coefficients, the operation occurs over separate channels. After the TCB load, both data and coefficients are loaded in parallel over two DMA channels (CH0 and CH1). If there is no conflict in the system when accessing the data and coefficients, the loading time is significantly improved over when loaded sequentially using a single channel. This mode is enabled by default and can be disabled by setting the FIR_CTL1.DCP_DIS bit. When disabled, coefficient load and data load occur sequentially over a single channel (CH0).

Accelerator TCB

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the internal memory of the processor. In chained DMA operations, the accelerator automatically initializes and starts another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Pointer DMA

The DMA controller supports circular buffer chain pointer DMA. One TCB must be configured for each channel. The DMA conroller contains the following:

- A control register value to configure the filter parameters (such as filter tap length, window size, sample rate conversion settings) for each channel. In ACM mode, additional parameters such as interrupt mask, trigger mask, and trigger wait are also available.
- Software control register values in ACM mode for each channel.
- Secondary control register value to configure rounding mode, fixed-point mode, and two's complement for each channel.
- DMA parameter register values for the input data (delay line).
- DMA parameter register values for coefficient load.
- DMA parameter register values for output data.

Intermediate results in multi-iteration mode are saved in the output buffer.

As shown in the ***Circular Buffer Addressing*** figure, the accelerator loads the TCB into its internal registers and uses these values to fetch coefficients and data and to store results. After processing a window of data for any channel, the accelerator writes back the appropriate values to the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory. Then, data processing can begin from where it left off during the next time slot of that channel.

The write-back value for input buffer is:

- `FIR_INIDX` + W for single rate filtering
- `FIR_INIDX` + W × M for decimation (M = decimation ratio)
- `FIR_INIDX` + W/L for interpolation (L = interpolation ratio)
- The write-back value for output buffer in floating point mode is: `FIR_OUTIDX` + W
- The write-back value for output buffer in fixed-point mode is: `FIR_OUTIDX` + 3 × W

NOTE: The `FIR_CTL2` register is part of the FIR TCB. This configuration allows programming individual FIR channels with different control attributes.

The above index updates are valid only for legacy mode. In ACM mode, the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory are updated to 0x00000000 and 0xFFFFFFFF by the accelerator after processing a window of data.

In ACM mode, when the `FIR_CTL1.SMQ_LIUPS_EN` bit is set, the acclerator updates the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory after processing a window of data and according to the circular buffer scheme. When the `FIR_CTL1.SMQ_LIUPS_EN` bit is cleared, the acclerator updates the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory to 0x00000000 and 0xFFFFFFFF after processing a window of data. The `FIR_CTL1.SMQ_LIUPS_EN` bit is only valid in ACM mode.

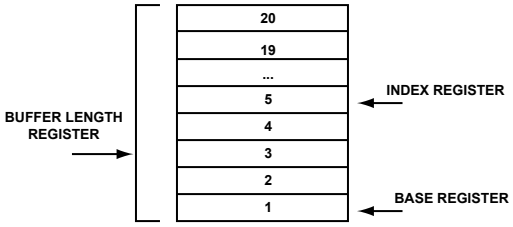

Figure 43-5: Circular Buffer Addressing

Programming Model

The following sections provide general programming information for the FIR accelerator.

Legacy Mode

The ***Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)*** figure shows the diagram for multichannel filtering. Multiple channels are processed in a time division multiplexed (TDM) format. After completing all the channels, the accelerator can either repeat the slots or wait for core intervention.

For multichannel filtering, use the following steps.

1. Program the number of channels using the `FIR_CTL1.CH` bits.
2. Configure the TCBs in system memory with one channel's TCB pointing to the next channel's TCB.
3. Write the first TCB value into the `FIR_CHNPTR` register and enable the accelerator.
    a. The accelerator fetches the first channel's TCB and, using it as pointer, prefills the delay line and coefficient memory and loads the `FIR_CTL2` register to configure the filter parameters corresponding to that channel.
    b. The accelerator then calculates output samples corresponding to one window and stores the data back in internal memory.
    c. At the end of the window the accelerator updates the `FIR_INIDX` and `FIR_OUTIDX` registers in the TCB of system memory and moves to the next channel.
    d. When all the channels are finished and the auto channel iterate bit (`FIR_CTL1.CAI`) =1, the accelerator processes the first channel again and iterates through the channels. If the `FIR_CTL1.CAI` bit =0, the accelerator waits for core intervention.

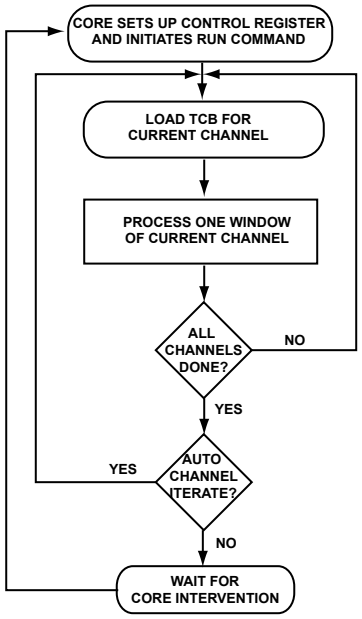

Figure 43-6: Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)

NOTE: All the addresses programmed in the TCB correspond to 32-bit address boundaries and should not contain the lower 2 bits (assumed as zeros).

Auto Configuration Mode (ACM)

The figure shows multi-channel filtering in ACM. Multiple channels are processed in a time multiplexed format (TDM).

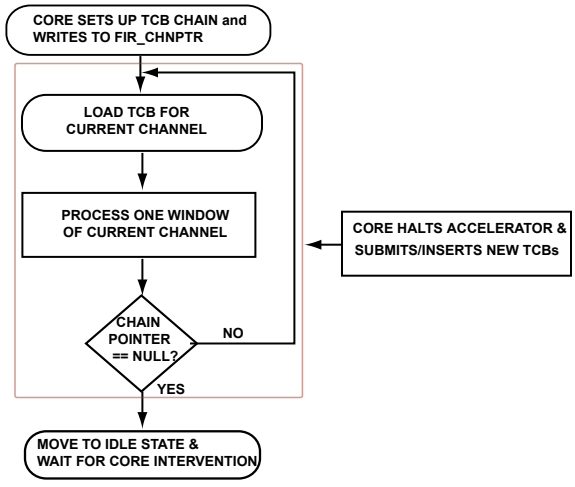

Figure 43-7: Multi-Channel Filtering in Auto Configuration Mode

For multi-channel filtering:

1. Configure the Transfer Control Blocks (TCBs) in system memory with one channel's TCB pointing to the next channel's TCB. There is no limit on the number of channels to be configured.

2. Write the first TCB value to the FIR_CHNPTR register and enable the accelerator.

   The accelerator fetches the first channel's TCB. Using it as pointer, it prefills the delay line and coefficient memory and loads the FIR_CTL2 and FIR_SGCTL registers to configure the filter parameters corresponding to that channel.

   If the FIR_CTL2.TWAIT bit is set, the accelerator waits for a input trigger to start the window processing for the channel.

   The accelerator then calculates output samples corresponding to one window and stores the data back in internal memory. If the FIR_CTL2.TMASK bit is cleared the accelerator sends an output trigger after completion of processing of the channel.

   If the FIR_CTL2.IMASK bit is cleared, the accelerator interrupts the core after completion of processing of a particular channel.

   At the end of the window, the accelerator updates the FIR_INIDX and FIR_OUTIDX registers to 0x00000000 and 0xFFFFFFFF in the TCB of system memory and moves to the next channel.

3. At any instant, as required, the core halts the accelerator. It sets the FIR_CTL1.HALT bit and appropriately takes action to submit or insert new TCBs and clears the FIR_CTL1.HALT bit to resume channel processing.

   If the FIR_CHNPTR register is zero (last channel is being processed or channel processing is complete) after halting the accelerator, the FIR_CHNPTR register is appropriately written before resuming the accelerator channel processing.

   If the accelerator is idle after halt, FIR_CTL1.EN bit is toggled to disable and re-enable the accelerator and the FIR_CTL1.HALT bit is cleared and the accelerator resumes channel processing.

4. The accelerator continues processing until all the channels are complete. Repeat *Step 3* (if required) to submit/insert new channels.

NOTE: Channel auto iterate (FIR_CTL1.CAI) is not supported in ACM.

Debug Mode

The next sections show the steps required for reading and writing local memory in debug mode.

Write to Local Memory

1. Clear the FIR_CTL1.DMAEN bit.
2. Set the FIR_DBG_CTL.EN, FIR_DBG_CTL.MEM, and FIR_DBG_CTL.HLD bits.
3. Set the FIR_DBG_CTL.ADRINC bit for address auto increment.
4. Write the start address to the FIR_DBG_ADDR register.

   NOTE: If bit 11 in the FIR_DBG_ADDR register is set, coefficient memory is selected.

5. Write data to the FIR_DBG_WRDAT register.

Read from Local Memory

1. Clear the FIR_CTL1.DMAEN bit.
2. Set the FIR_DBG_CTL.EN, FIR_DBG_CTL.MEM, and FIR_DBG_CTL.HLD bits.
3. Set the FIR_DBG_CTL.ADRINC bit for address auto increment.
4. Write the start address to the FIR_DBG_ADDR register.

   NOTE: If bit 11 in the FIR_DBG_ADDR register is set, coefficient memory is selected.

5. Read data from the FIR_DBG_RDDAT register.

Single-Step Mode

Single-step mode can be used for debug purposes. An extra debug register is used in this mode.

1. Enable stop DMA during breakpoint hit in the emulator settings.
2. Clear the FIR_DBG_CTL.HLD bit and enable the FIR_DBG_CTL.EN and FIR_DBG_CTL.RUN bits.
3. Program the FIR module according to the application.
4. In single-step mode, each iteration is updated in the emulator session.

Computing FIR Output, Tap Length Greater than 4096

With little core intervention, the FIR accelerator can also be used to calculate output for a tap length greater than 4096 taps. The section demonstrates the calculation with an example of 8192 taps.

1. Divide the transfer function of an 8192 FIR filter into two 4096 FIR filters:

   $H(Z) = b_0 + b_1Z^{-1} + b_2Z^{-2} + ...b_{4095}Z^{-4095} + b_{4096}Z^{-4096}b_{4097}Z^{-4097} + ...b_{8191}Z^{-8191}$

   $= b_0 + b_1Z^{-1} + b_2Z^{-2} + ...b_{4095}Z^{-4095} + Z^{-4096}(b_{4096} + b_{4097} + ...b_{8191}Z^{-4096})$

2. Divide the filter coefficients of an 8192 tap filter among two 4096 tap FIR filters:

   Filter 1

   Coefficients = b0, b1, b2,……, b4095

   Input data = x[n], x [n – 1],…….x[n – 4095]

   Filter 2

   Coefficients = b4096, b4097,……..,b8191

   Input data = x[n – 4096], x[n – 4097],……x[n – 8191]

The accelerator can be used in two-channel mode where:

- channel 1 operates on x[n]…x[n – 4095] input data with the filter coefficients of filter 1 and

- channel 2 operates on x[n – 4096]…x[n – 8191] with the filter coefficients of filter 2.

Once both the channels are processed, add the partial sum output of both the channels to get the final output. Implement this approach (tap length = TAPS = 8192, window size = WINDOW) using the following programming steps.

1. Create a circular input data buffer in system memory (IBUF). The buffer must be large enough to avoid overwriting data before the accelerator processes it. Ideally, the input buffer size for a channel is TAPS + WINDOW – 1.
2. Create a coefficient buffer of size TAPS (8192) (CBUF).
3. Create one output buffer of size WINDOW (OBUF) and another temporary output buffer (OBUF1) to store the partial sum.
4. Create two TCBs in system memory with first TCB chained to the second and second chained to the first in a circular manner.
    a. Point the `FIR_COEFIDX` bit field of the first TCB to the start address of the coefficient buffer (CBUF) and that of the second TCB to 4096 offset from the start of the coefficient buffer (CBUF + 4096).
    b. Point the `FIR_OUTBASE` and `FIR_OUTIDX` bit fields of the first TCB to the start address of OBUF and that of the second TCB to the start address of OBUF1.
    c. Point the `FIR_INIDX` bit field of the first TCB to the start address of IBUF and that of the second TCB to 4096 offset from the start address of IBUF.
    d. Configure the `FIR_CTL2` bit field of both the TCB for tap length = TAP/2 = 4096 and window size = WINDOW.
5. Initialize the `FIR_CHNPTR` register to point to the first TCB.
6. Program the `FIR_CTL1` register to initiate the accelerator processing by setting the `FIR_CTL1.EN` and `FIR_CTL1.DMAEN` bits and the number of channels configured as 2.
7. Wait for the FIR all channel done interrupt (`FIR_DMASTAT.ACDONE`) to occur. Inside the ISR, add the partial sum results using the core from both the output buffers (OBUF and OBUF1) to get the final output. To save memory, replace the contents of the buffer OBUF with the final output result.

Debug Features

The following sections provide information for debugging the FIR accelerator.

Local Memory Access

The contents of FIR delay line and coefficient memories are made observable for debug by setting the `FIR_DBG_CTL.EN`/`FIR_DBG_CTL.MEM` and `FIR_DBG_CTL.HLD` bits. The debug address register (`FIR_DBG_ADDR`) and two data registers are provided for debug operations. Bit 11 of the `FIR_DBG_ADDR` register selects coefficient memory when set (=1) and selects delay line memory when cleared (=0).

In the debug mode, the read data register (FIR_DBG_RDDAT) returns the contents of the memory location pointed to by the address register. Data can be written into any memory location using FIR_DBG_WRDAT register writes. If the address auto-increment bit (FIR_DBG_CTL.ADRINC) is set, the address register auto-increments on FIR_DBG_WRDAT writes and FIR_DBG_RDDAT reads. During auto-increment the FIR_DBG_ADDR register cannot cross the data memory or coefficient memory boundary.

Single-Step Mode

Programs can single step through the MAC operations and observe the memory contents after each step. The FIR_DBG_CTL.EN, FIR_DBG_CTL.HLD, and FIR_DBG_CTL.MEM bits control the FIR MAC units.

Emulation Considerations

In FIR debug mode, the DMA operations are not observable.

Interrupts

The ***FIR Interrupt Overview*** table provides the source of interrupt and service instructions for the FIR interrupts.

Table 43-8: FIR Interrupt Overview

Accelerator Mode	Default Programmable Interrupt	Sources	Masking	Service
Legacy Mode	FIR_DMA	Window Complete	N/A	ROC from FIR_DMASTAT + RTI instruction
		All channels complete		
	FIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from FIR_MACSTAT + RTI instruction
		MAC fixed point overflow		
Auto Configuration Mode	FIR_DMA	Window Complete	FIR_CTL2.IMASK	ROC from FIR_DMASTAT + RTI instruction
	FIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from FIR_MACSTAT + RTI instruction
		MAC fixed point overflow	N/A	

Sources

The FIR module drives two interrupt signals: FIR_DMA for the DMA status and FIR_STAT for the MAC status. The FIR module generates interrupts as described in the following sections.

Window Complete

This interrupt is generated at the end of each channel when all the output samples are calculated corresponding to a window and updated index values are written back.

In legacy mode, if the FIR_CTL1.CCINTR bit is set, an interrupt is generated after completion of window processing of each channel. In ACM, the interrupt generation can be selectively masked using the FIR_CTL2.IMASK bit for each channel.

All Channels Complete

This interrupt is generated when all the channels are complete or when one iteration of time slots completes. Note that the interrupt follows the access completion rule, where the interrupt is generated when all data are written back to system memory.

The all channels complete interrupt source is only applicable in legacy mode. If the FIR_CTL1.CCINTR bit is not set in legacy mode, the all channel complete interrupt is generated. In ACM mode, interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.

NOTE: The FIR_CTL1.CCINTR bit is valid only in legacy mode. In ACM mode, interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.

MAC Status

A MAC status interrupt is generated under the following conditions and is reflected in the FIR_MACSTAT register.

- Multiplier result zero – Set if multiplier result is zero
- Multiplier result infinity – Set if multiplier result is infinity
- Multiply invalid – Set if multiply operation is invalid
- Adder result zero – Set if adder result is zero
- Adder result infinity – Set if adder result is infinity
- Adder invalid – Set if addition is invalid
- Adder overflow – for fixed-point operation

Service

The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state by reading the MAC status register (FIR_MACSTAT). The read of the register clears the (sticky) MAC interrupt status bits.

The status interrupt sources are derived from the FIR_MACSTAT register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result.

ADSP-2159x_SC591_SC592_SC594 FIR Register Descriptions

The FIR accelerator (FIR) contains the following registers.

Table 43-9: ADSP-2159x_SC591_SC592_SC594 FIR Register List

Name	Description
FIR_CHNPTR	FIR Chain Pointer Register
FIR_COEFCNT	FIR Coefficient Count Register
FIR_COEFIDX	FIR Coefficient Index Register
FIR_COEFMOD	FIR Coefficient Modifier Register
FIR_CTL1	FIR Global Control Register
FIR_CTL2	FIR Channel Control Register
FIR_DBG_ADDR	Debug Address Register
FIR_DBG_CTL	FIR Debug Control Register
FIR_DBG_RDDAT	FIR Debug Data Read Register
FIR_DBG_WRDAT	FIR Debug Data Write Register
FIR_DMASTAT	FIR DMA Status Register
FIR_INBASE	FIR Input Data Base Register
FIR_INCNT	FIR Input Data Count Register
FIR_INIDX	FIR Input Data Index Register
FIR_INMOD	FIR Input Data Modifier Register
FIR_MACSTAT	FIR MAC Status Register
FIR_OUTBASE	FIR Output Data Base Register
FIR_OUTCNT	FIR Output Data Count Register
FIR_OUTIDX	FIR Output Data Index Register
FIR_OUTMOD	FIR Output Data Modifier Register
FIR_SCTL1	Software Control Register 1
FIR_SCTL2	Software Control Register 2
FIR_SGCTL	Secondary Global Control Register

FIR Chain Pointer Register

The FIR_CHNPTR register contains the chain pointer address.

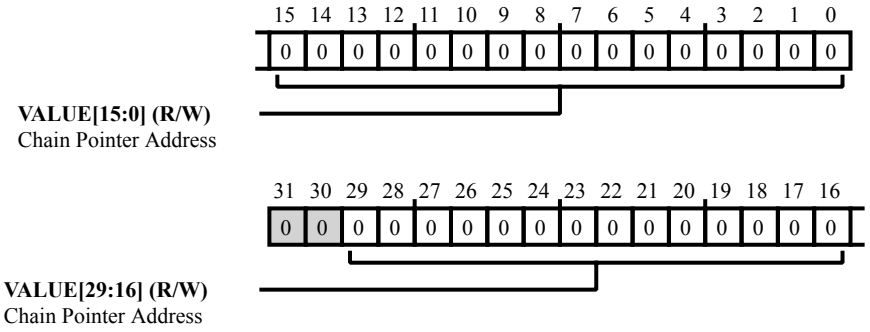

Figure 43-8: FIR_CHNPTR Register Diagram

Table 43-10: FIR_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Chain Pointer Address. The FIR_CHNPTR.VALUE bit field contains the chain pointer address.

FIR Coefficient Count Register

The FIR_COEFCNT register contains the 16-bit coefficient buffer count.

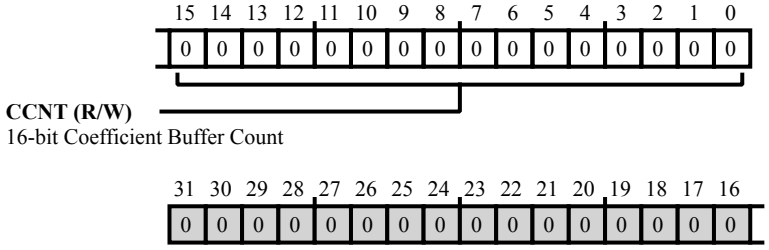

Figure 43-9: FIR_COEFCNT Register Diagram

Table 43-11: FIR_COEFCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	CCNT	16-bit Coefficient Buffer Count. The FIR_COEFCNT.CCNT bit field contains the 16-bit coefficient buffer count.

FIR Coefficient Index Register

The FIR_COEFIDX register contains the coefficient index word address with the lower two bits removed.

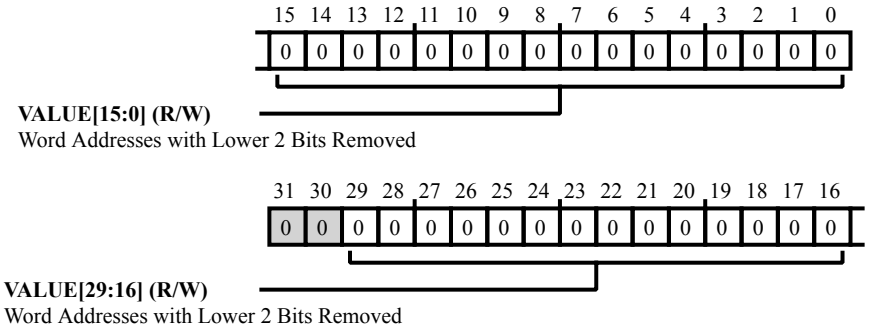

Figure 43-10: FIR_COEFIDX Register Diagram

Table 43-12: FIR_COEFIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Addresses with Lower 2 Bits Removed. The FIR_COEFIDX.VALUE bit field contains the word addresses with the lower 2 bits removed.

FIR Coefficient Modifier Register

The FIR_COEFMOD register contains the 16-bit coefficient index modifier.

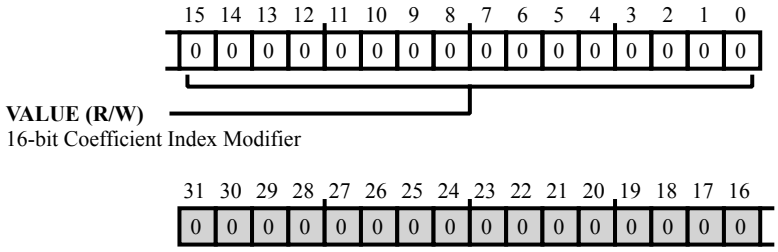

Figure 43-11: FIR_COEFMOD Register Diagram

Table 43-13: FIR_COEFMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Coefficient Index Modifier. The FIR_COEFMOD.VALUE bit field contains the 16-bit coefficient index modifier.

FIR Global Control Register

The FIR_CTL1 register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.

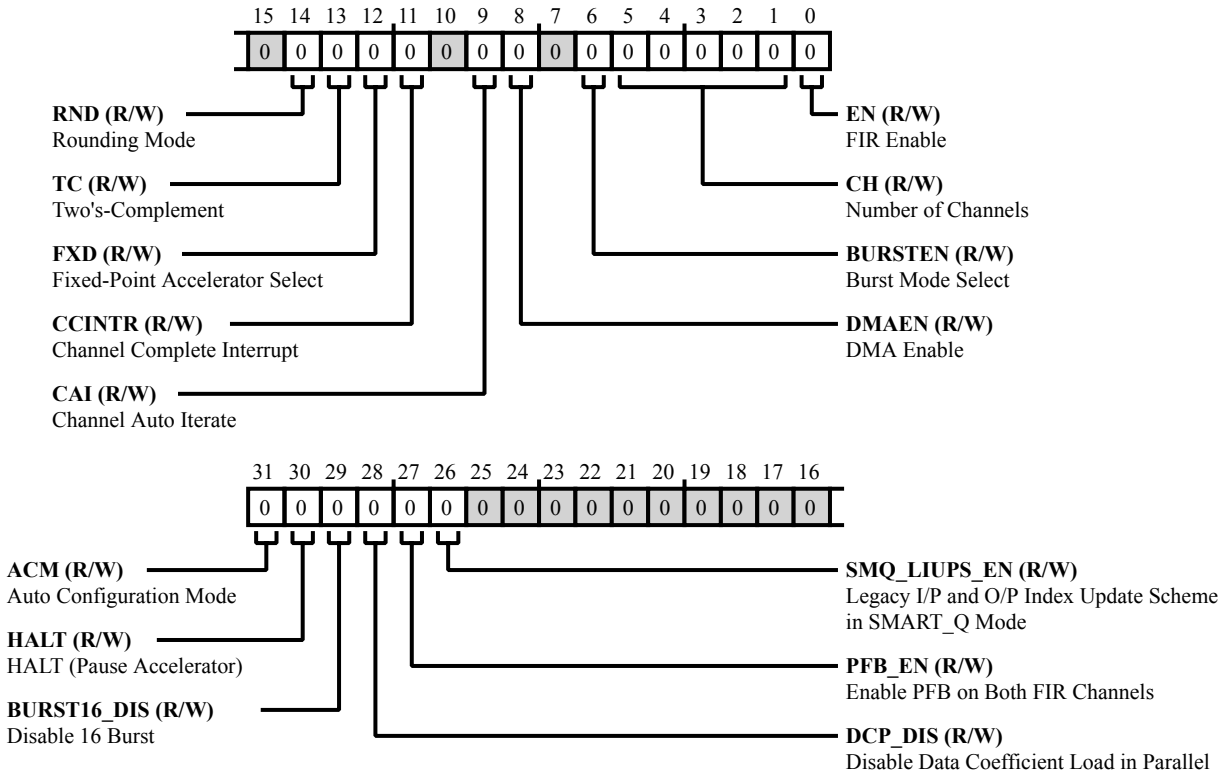

Figure 43-12: FIR_CTL1 Register Diagram

Table 43-14: FIR_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ACM	Auto Configuration Mode. The FIR_CTL1.ACM bit configures the mode for loading the TCB.	
		0	Legacy Mode. Load TCB without the FIR_CTL1 register. Core intervention may be required.
		1	Auto Configuration Mode. Load TCB with the FIR_CTL1 register. Core intervention is not required.

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	HALT	HALT (Pause Accelerator). This bit is only valid in Auto Configuration mode (ACM)	
		0	Release. Release accelerator for further processing of data.
		1	Pause. Pause accelerator for core to check status and modify or submit jobs.
29 (R/W)	BURST16_DIS	Disable 16 Burst. The `FIR_CTL1.BURST16_DIS` bit configures the accelerator to disable 16 burst when in burst mode.	
		0	Maximum burst of INCR16 in burst mode for DMA and TCB
		1	Maximum burst of INCR8 in burst mode for DMA and non-burst for TCB
28 (R/W)	DCP_DIS	Disable Data Coefficient Load in Parallel. The `FIR_CTL1.DCP_DIS` bit enables data and coefficient loading to occur in parallel.	
		0	Enable
		1	Disable
27 (R/W)	PFB_EN	Enable PFB on Both FIR Channels. 0- FIR Pre-Fetch Buffer Disabled 1- FIR Pre-Fetch Buffer Enabled	
26 (R/W)	SMQ_LIUPS_EN	Legacy I/P and O/P Index Update Scheme in SMART_Q Mode. The `FIR_CTL1.SMQ_LIUPS_EN` bit configures the scheme the accelerator uses to update the input index (II) and output index (OI). This bit is only valid in ACM.	
		0	Update the II with all '0' and the OI with all 'F', respectively
		1	Update II and OI after circular buffer scheme
14 (R/W)	RND	Rounding Mode. The `FIR_CTL1.RND` bit configures the accelerator to use a rounding mode.	
		0	Round to Nearest
		1	Truncate (round towards zero)

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TC	Two's-Complement. The `FIR_CTL1.TC` bit configures the accelerator to use either unsigned integer or signed integer	
		0	Unsigned Integer
		1	Signed Integer
12 (R/W)	FXD	Fixed-Point Accelerator Select. The `FIR_CTL1.FXD` bit configures the accelerator to use either 32-bit IEEE floating-point or 32-bit fixed-point.	
		0	32-bit IEEE Floating-Point
		1	32-bit Fixed Point
11 (R/W)	CCINTR	Channel Complete Interrupt. The `FIR_CTL1.CCINTR` bit configures the accelerator to generate an interrupt when each or all channels are done. This bit is only valid in Legacy Mode. In Auto Configuration Mode (ACM), interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.	
		0	Interrupt is Generated Only When All Channels are Done
		1	Interrupt is Generated After Each Channel is Done
9 (R/W)	CAI	Channel Auto Iterate. The `FIR_CTL1.CAI` bit, if cleared, causes the TDM processing to stop (idle) once all channels are done. If set, processing moves to the first channel and continues TDM processing in a loop when all channels are done. Channel Auto Iterate is not available in Auto Configuration Mode (ACM).	
		0	TDM Processing Stops (IDLE) Once All Channels are Over
		1	Moves to First Channel and Continues TDM Processing in a Loop When All Channels are Over
8 (R/W)	DMAEN	DMA Enable. The `FIR_CTL1.DMAEN` bit enables and disables DMA on the FIR accelerator.	
		0	DMA Disabled
		1	DMA Enabled
6 (R/W)	BURSTEN	Burst Mode Select. When the `FIR_CTL1.BURSTEN` bit is set, burst mode is enabled for coefficient loads and data loads. When cleared, burst mode is disabled. By default, burst mode is disabled.	

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:1 (R/W)	CH	Number of Channels. The `FIR_CTL1.CH` bit field configures the number of channels and is programmable from 0 to 31. This bit field is only valid in Legacy Mode. There is no channel number limitation in Auto Configuration Mode (ACM) as the accelerator keeps processing the TCBs until the chain pointer becomes null.	
		0	Channel 1
		1-30	Channel 2-31
		31	Channel 32
0 (R/W)	EN	FIR Enable. The `FIR_CTL1.EN` bit enables and disables the FIR accelerator.	
		0	Disable FIR
		1	Enable FIR

FIR Channel Control Register

The FIR_CTL2 register is used to configure the channel specific parameters such as filter TAP length, window size, sample rate conversion, up/down sampling and ratio. In Auto Configuration Mode(ACM), this register is also used to configure additional channel specific parameters like interrupts and triggers.

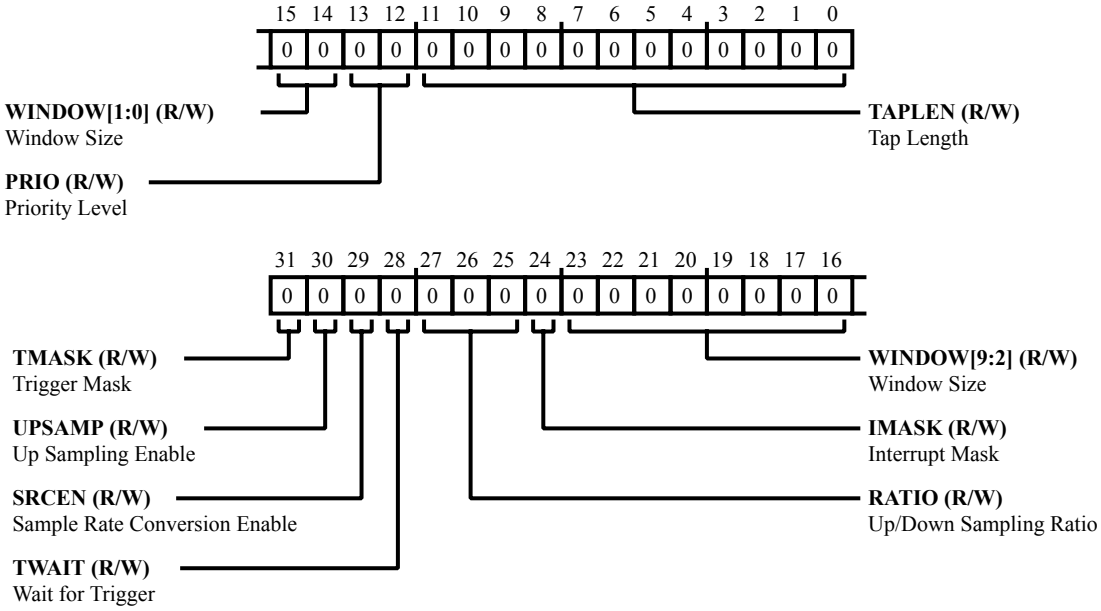

Figure 43-13: FIR_CTL2 Register Diagram

Table 43-15: FIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	TMASK	Trigger Mask. The FIR_CTL2.TMASK bit enables trigger generation for the channel. It is only valid in Auto Configuration Mode (ACM).	
		0	Enable
		1	Mask
30 (R/W)	UPSAMP	Up Sampling Enable. The FIR_CTL2.UPSAMP bit enables up sampling.	
		0	Down Sampling
		1	Up Sampling

Table 43-15: FIR_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SRCEN	Sample Rate Conversion Enable. The `FIR_CTL2.SRCEN` bit field enables sample rate conversion.	
		0	Disabled
		1	Enabled
28 (R/W)	TWAIT	Wait for Trigger. The `FIR_CTL2.TWAIT` bit disables the wait for the trigger. It is only valid in Auto Configuration Mode (ACM).	
		0	Disable wait for trigger for the channel
		1	Enable wait for the external trigger assertion
27:25 (R/W)	RATIO	Up/Down Sampling Ratio. The `FIR_CTL2.RATIO` bit field sets the sampling ratio (`FIR_CTL2.RATIO` + 1).	
24 (R/W)	IMASK	Interrupt Mask. The `FIR_CTL2.IMASK` bit enables interrupt generation for the channel. This bit is only valid in Auto Configuration Mode (ACM).	
		0	Enable
		1	Mask
23:14 (R/W)	WINDOW	Window Size. The `FIR_CTL2.WINDOW` bit field sets the window size which specifies the number of sample/block to process (sample based processing = window size of 0).	
13:12 (R/W)	PRIO	Priority Level. The `FIR_CTL2.PRIO` bit field indicates the priority.	
		0	Level 0 (lowest)
		1	Level 1
		2	Level 2
		3	Level 3 (highest)
11:0 (R/W)	TAPLEN	Tap Length. The `FIR_CTL2.TAPLEN` bit field sets the tap length which is programmable between 0-4095 (Tap Length = `FIR_CTL2.TAPLEN` + 1).	

Debug Address Register

The FIR_DBG_ADDR register holds the debug address.

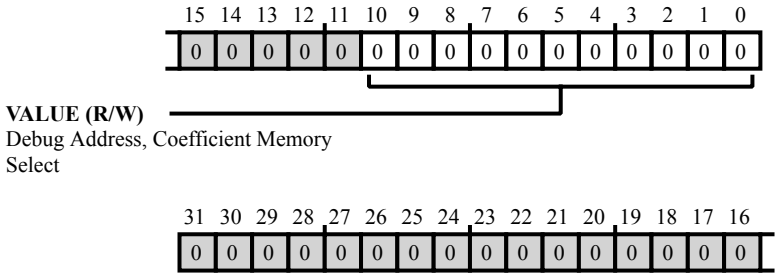

Figure 43-14: FIR_DBG_ADDR Register Diagram

Table 43-16: FIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The FIR_DBG_ADDR.VALUE bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

FIR Debug Control Register

The FIR_DBG_CTL register controls debugging operations such as enabling debug mode running, hold or single stepping.

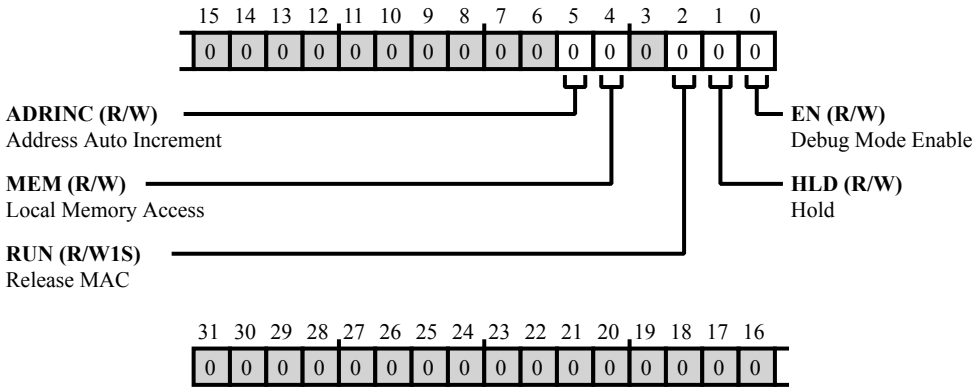

Figure 43-15: FIR_DBG_CTL Register Diagram

Table 43-17: FIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	ADRINC	Address Auto Increment. The FIR_DBG_CTL.ADRINC bit bit allows the address register to auto-increment on FIR_DBG_WRDAT writes and FIR_DBG_RDDAT reads.	
4 (R/W)	MEM	Local Memory Access. When the FIR_DBG_CTL.MEM bit is set, the data and coefficients memory can be indirectly accessed.	
2 (R/W1S)	RUN	Release MAC. The FIR_DBG_CTL.RUN bit releases the MAC. This bit is self-clearing after one FIR clock cycle.	
1 (R/W)	HLD	Hold. The FIR_DBG_CTL.HLD bit holds or single-steps through the FIR.	
		0	Hold
		1	Single-step
0 (R/W)	EN	Debug Mode Enable. The FIR_DBG_CTL.EN bit enables debug mode. For local memory access, the FIR_CTL1 register can be cleared.	
		0	Disable Debug Mode
		1	Enable Debug Mode

FIR Debug Data Read Register

The FIR_DBG_RDDAT register hold the debug read data.

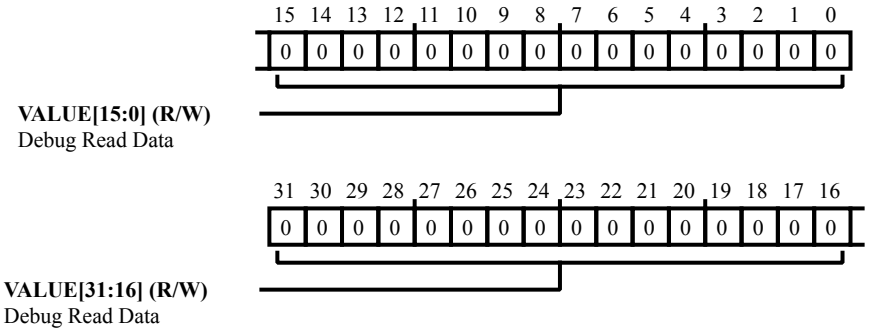

Figure 43-16: FIR_DBG_RDDAT Register Diagram

Table 43-18: FIR_DBG_RDDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Read Data. The FIR_DBG_RDDAT.VALUE bit field holds the debug read data.

FIR Debug Data Write Register

The FIR_DBG_WRDAT register holds the debug write data.

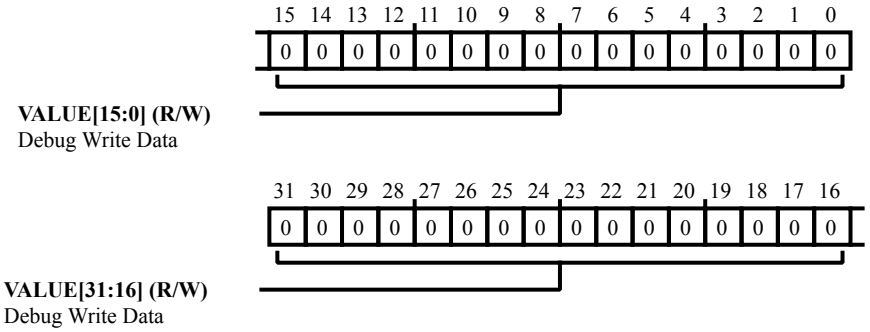

Figure 43-17: FIR_DBG_WRDAT Register Diagram

Table 43-19: FIR_DBG_WRDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Write Data. The FIR_DBG_WRDAT.VALUE bit field holds the debug write data.

FIR DMA Status Register

The FIR_DMASTAT register provides information about chain pointer loading, coefficient DMA, data preload DMA, processing in progress, window complete, all channels complete.

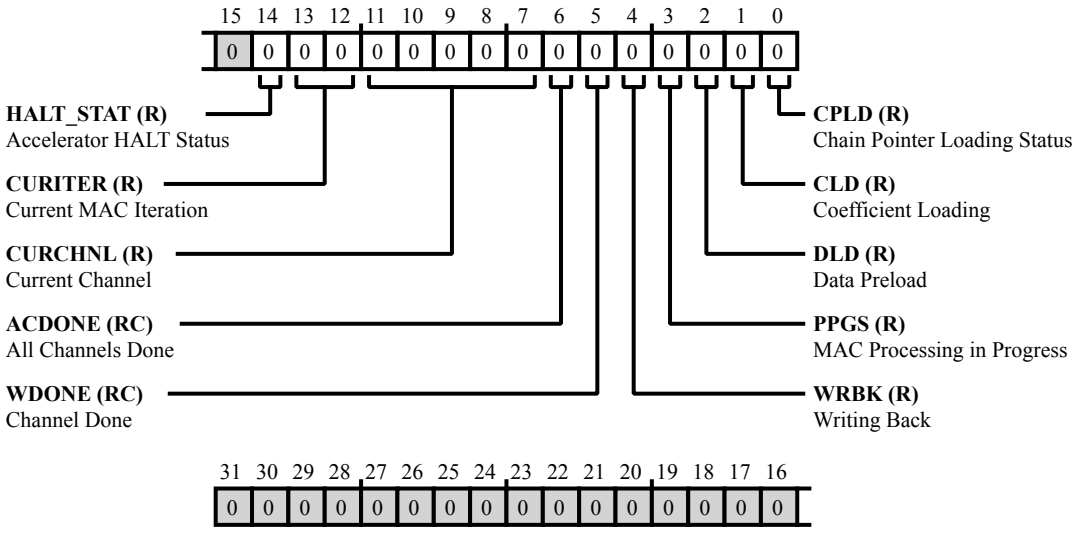

Figure 43-18: FIR_DMASTAT Register Diagram

Table 43-20: FIR_DMASTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	HALT_STAT	Accelerator HALT Status. Accelerator HALT status. 1 - Acknowledge to core that acceleration is in halt state. 0 - Not in halt state
13:12 (R/NW)	CURITER	Current MAC Iteration. The FIR_DMASTAT.CURITER bit indicates the current MAC iteration in multi-iteration mode. Zero indicates the final iteration.
11:7 (R/NW)	CURCHNL	Current Channel. The FIR_DMASTAT.CURCHNL bit indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The FIR_DMASTAT.ACDONE bit indicates the accelerator that processing all channels is complete. This is a sticky bit and is cleared on a register read. The FIR_CTL1.CCINTR bit does not affect the FIR_DMASTAT.ACDONE bit.
5 (RC/NW)	WDONE	Channel Done. The FIR_DMASTAT.WDONE bit indicates the accelerator that processing the current channel is complete. This is a sticky bit and is cleared on a register read. The FIR_CTL1.CCINTR bit does not affect the FIR_DMASTAT.WDONE bit.

Table 43-20: FIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	WRBK	Writing Back. The `FIR_DMASTAT.WRBK` bit indicates the accelerator is writing back the updated index registers.
3 (R/NW)	PPGS	MAC Processing in Progress. The `FIR_DMASTAT.PPGS` bit indicates MAC processing in progress.
2 (R/NW)	DLD	Data Preload. The `FIR_DMASTAT.DLD` bit indicates data preloading.
1 (R/NW)	CLD	Coefficient Loading. The `FIR_DMASTAT.CLD` bit indicates coefficient loading.
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `FIR_DMASTAT.CPLD` bit indicates the state machine is in chain pointer load state.

FIR Input Data Base Register

The FIR_INBASE register contains the input word base address with the lower two bits removed.

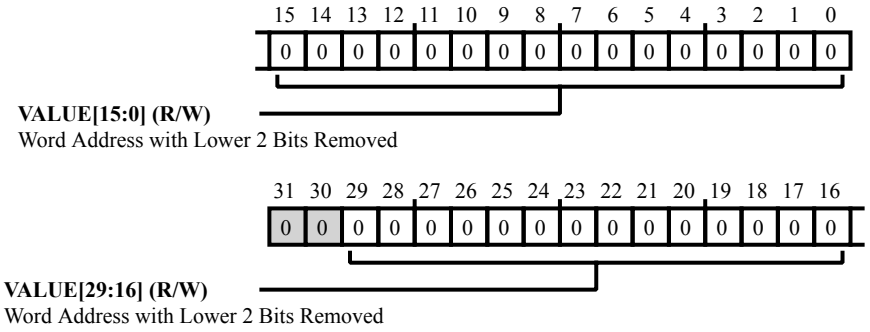

Figure 43-19: FIR_INBASE Register Diagram

Table 43-21: FIR_INBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_INBASE.VALUE bit field contains the the word address with the lower 2 bits removed.

FIR Input Data Count Register

The FIR_INCNT register contains the 16-bit input data count.

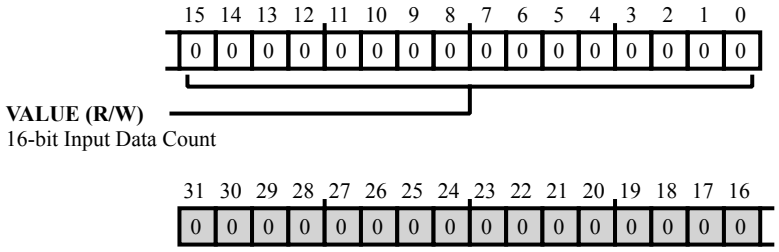

Figure 43-20: FIR_INCNT Register Diagram

Table 43-22: FIR_INCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Count. The FIR_INCNT.VALUE bit field contains the 16-bit input data count.

FIR Input Data Index Register

The FIR_INIDX register contains the input word address with the lower two bits removed.

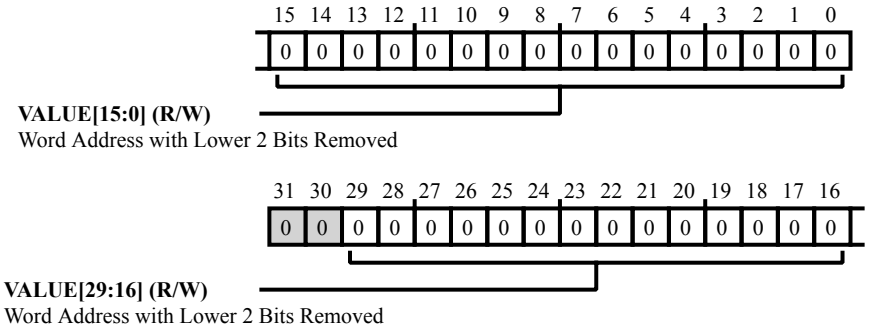

Figure 43-21: FIR_INIDX Register Diagram

Table 43-23: FIR_INIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_INIDX.VALUE bit field contains the input word address with the lower two bits removed.

FIR Input Data Modifier Register

The FIR_INMOD register contains the 16-bit input data buffer modifier.

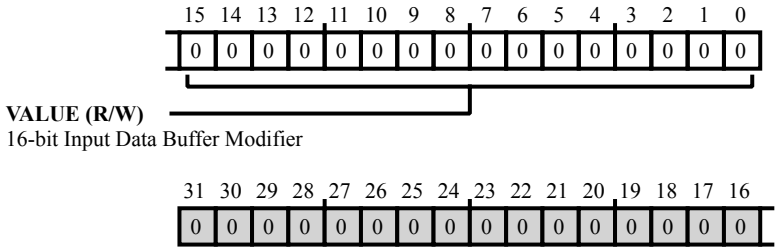

Figure 43-22: FIR_INMOD Register Diagram

Table 43-24: FIR_INMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Modifier. The FIR_INMOD.VALUE bit field contains the 16-bit input data buffer modifier.

FIR MAC Status Register

The FIR_MACSTAT register provides the status of MAC operations. The status of all four multipliers/adders are available separately for programs to poll. In fixed-point mode only, the ARIx bits are used (all other bits are reserved).

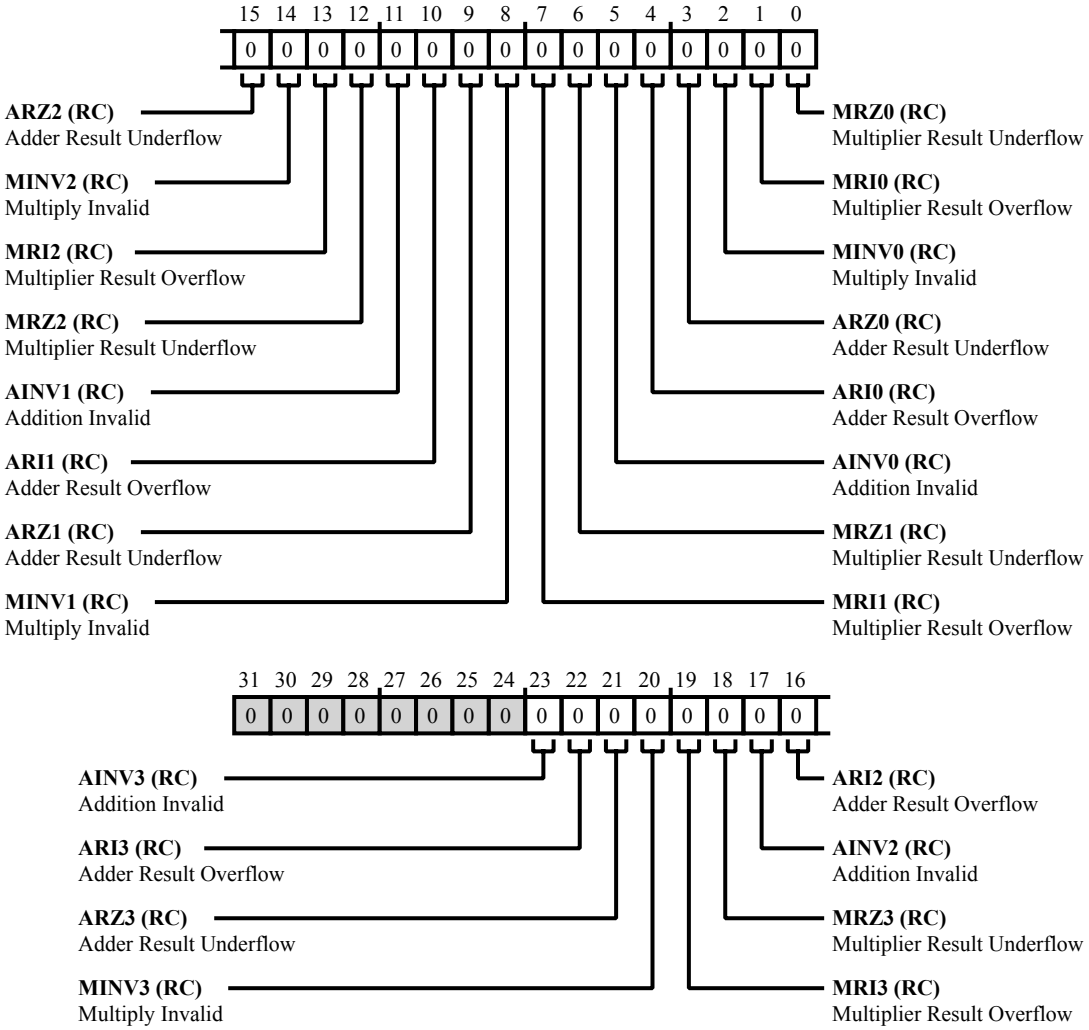

Figure 43-23: FIR_MACSTAT Register Diagram

Table 43-25: FIR_MACSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (RC/NW)	AINV3	Addition Invalid. The FIR_MACSTAT.AINV3 bit is set if the adder 3 addition is invalid.

Table 43-25: FIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (RC/NW)	ARI3	Adder Result Overflow. The `FIR_MACSTAT.ARI3` bit is set if the adder 3 result is infinity. Indicates overflow in fixed-point mode.
21 (RC/NW)	ARZ3	Adder Result Underflow. The `FIR_MACSTAT.ARZ3` bit is set if the adder 3 result is zero.
20 (RC/NW)	MINV3	Multiply Invalid. The `FIR_MACSTAT.MINV3` bit is set if the multiplier 3 multiply operation is invalid.
19 (RC/NW)	MRI3	Multiplier Result Overflow. The `FIR_MACSTAT.MRI3` bit is set if the multiplier 3 result is infinity.
18 (RC/NW)	MRZ3	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ3` bit is set if the multiplier 3 result is zero.
17 (RC/NW)	AINV2	Addition Invalid. The `FIR_MACSTAT.AINV2` bit is set if the adder 2 addition is invalid.
16 (RC/NW)	ARI2	Adder Result Overflow. The `FIR_MACSTAT.ARI2` bit is set if the adder 2 result is infinity. Indicates overflow in fixed-point mode.
15 (RC/NW)	ARZ2	Adder Result Underflow. The `FIR_MACSTAT.ARZ2` bit is set if the adder 2 result is zero.
14 (RC/NW)	MINV2	Multiply Invalid. The `FIR_MACSTAT.MINV2` bit is set if the multiplier 2 multiply operation is invalid.
13 (RC/NW)	MRI2	Multiplier Result Overflow. The `FIR_MACSTAT.MRI2` bit is set if the multiplier 2 result is infinity.
12 (RC/NW)	MRZ2	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ2` bit is set if the multiplier 2 result is zero.
11 (RC/NW)	AINV1	Addition Invalid. The `FIR_MACSTAT.AINV1` bit is set if the adder 1 addition is invalid.
10 (RC/NW)	ARI1	Adder Result Overflow. The `FIR_MACSTAT.ARI1` bit is set if the adder 1 result is infinity. Indicates overflow in fixed-point mode.
9 (RC/NW)	ARZ1	Adder Result Underflow. The `FIR_MACSTAT.ARZ1` bit is set if the adder 1 result is zero.

Table 43-25: FIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (RC/NW)	MINV1	Multiply Invalid. The `FIR_MACSTAT.MINV1` bit is set if the multiplier 1 multiply operation is invalid.
7 (RC/NW)	MRI1	Multiplier Result Overflow. The `FIR_MACSTAT.MRI1` bit is set if the multiplier 1 result is infinity.
6 (RC/NW)	MRZ1	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ1` bit is set if the multiplier 1 result is zero.
5 (RC/NW)	AINV0	Addition Invalid. The `FIR_MACSTAT.AINV0` bit is set if the adder 0 addition is invalid.
4 (RC/NW)	ARI0	Adder Result Overflow. The `FIR_MACSTAT.ARI0` bit is set if the adder 0 result is infinity. Indicates overflow in fixed-point mode.
3 (RC/NW)	ARZ0	Adder Result Underflow. The `FIR_MACSTAT.ARZ0` bit is set if the adder 0 result is zero.
2 (RC/NW)	MINV0	Multiply Invalid. The `FIR_MACSTAT.MINV0` bit is set if the multiplier 0 multiply operation is invalid.
1 (RC/NW)	MRI0	Multiplier Result Overflow. The `FIR_MACSTAT.MRI0` bit is set if the multiplier 0 result is infinity.
0 (RC/NW)	MRZ0	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ0` bit is set if multiplier 0 result is zero.

FIR Output Data Base Register

The FIR_OUTBASE register contains the output word base address with the lower two bits removed

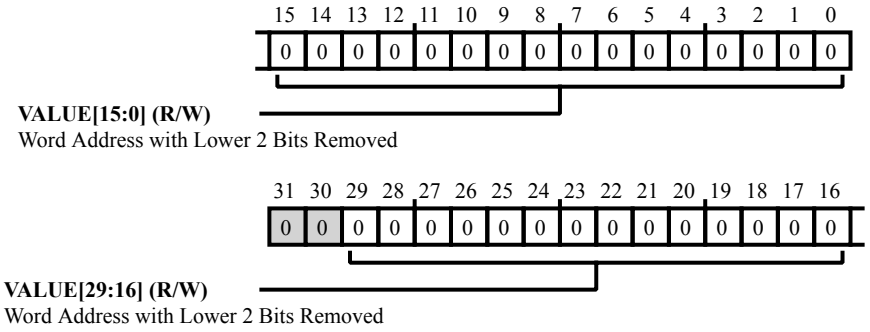

Figure 43-24: FIR_OUTBASE Register Diagram

Table 43-26: FIR_OUTBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_OUTBASE.VALUE bit field contains the word address with the lower 2 bits removed.

FIR Output Data Count Register

The FIR_OUTCNT register contains the 16-bit output buffer count.

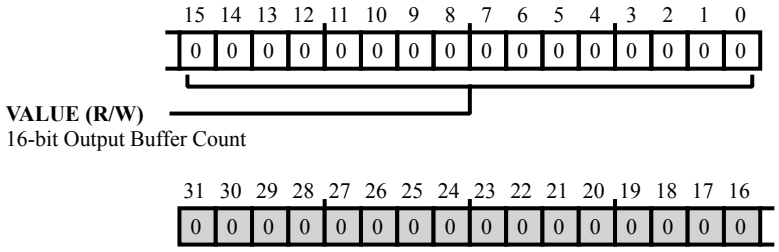

Figure 43-25: FIR_OUTCNT Register Diagram

Table 43-27: FIR_OUTCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Output Buffer Count. The FIR_OUTCNT.VALUE bit field contains the 16-bit output buffer count.

FIR Output Data Index Register

The FIR_OUTIDX register contains the output word address with the lower two bits removed.

Secondary Global Control Register

The FIRSGCTL register is used to configure the global parameters for the accelerator in ACM mode for loading CTL1 register bits as part of TCB.

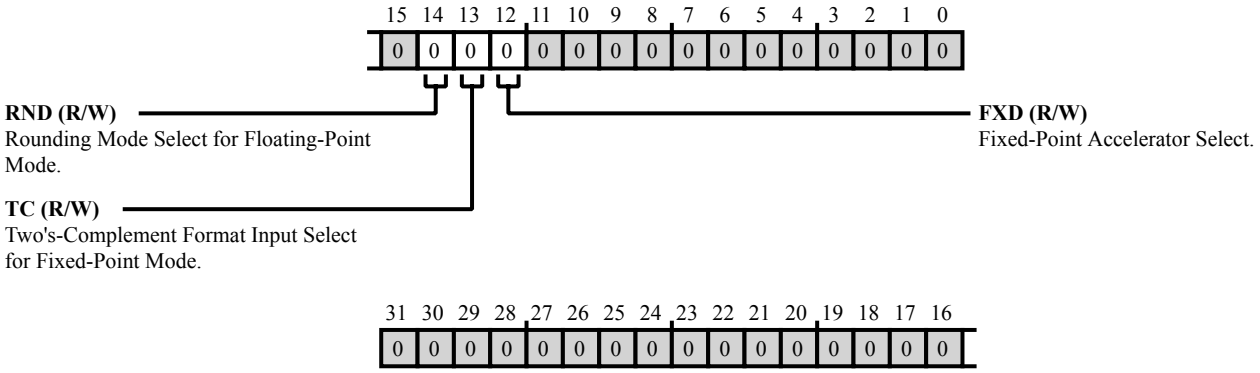

Figure 43-30: FIR_SGCTL Register Diagram

Table 43-32: FIR_SGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	RND	Rounding Mode Select for Floating-Point Mode.. 0- Round to nearest 1 -Truncate (Round towards zero)
13 (R/W)	TC	Two's-Complement Format Input Select for Fixed-Point Mode.. 0 - Unsigned integer 1 - Signed integer
12 (R/W)	FXD	Fixed-Point Accelerator Select.. 0 - 32-bit floating-point compatible to SHARCXI 1 - 32-bit fixed point

44 IIR Accelerator (IIR)

The processor includes an Infinite Impulse Response (IIR) filter accelerator implemented in hardware that reduces the processing load on the core, freeing it up for other tasks.

Features

The accelerator supports a maximum of 32 channels in legacy mode. In Auto Configuration Mode (ACM), there is no limit on number of channels. The accelerator locally stores all the biquad coefficients of 32 channels in legacy mode. Window size can be configured from 1 (sample based) to 1024.

The IIR has the following features:

- Supports IEEE floating point format 32/40-bit
- Rounding modes compatible with SHARC+ core MACs
- Sample-based or window-based processing
- Up to 64 cascaded biquads per channel
- Up to 32 filter channels available in TDM
- Allows biquad save state storage

NOTE: The IIR accelerator module has local memory which is not accessible by the core during regular operation mode. Unlike in the previous SHARC processors, the IIR accelerator modules each have access to the system memory (on-chip/off-chip).

Unlike in the previous SHARC processors, where only one of the IIR or FIR accelerators can be enabled at a time, the processor can use both the IIR and the FIR accelerators at the same time.

Clocking

The IIR accelerator runs at the speed of core clock.

Functional Description

The ***IIR Accelerator Block Diagram*** shows the various blocks of the IIR hardware accelerator.

The accelerator has:

- a coefficient memory size of 1440 × 40 bits (288 biquads x 5 coefficients).
- a data memory size of 576 × 40 bits (288 biquads x 2 states).
- one SHARC+ core compatible MAC unit with an input data buffer to supply data to the MAC.

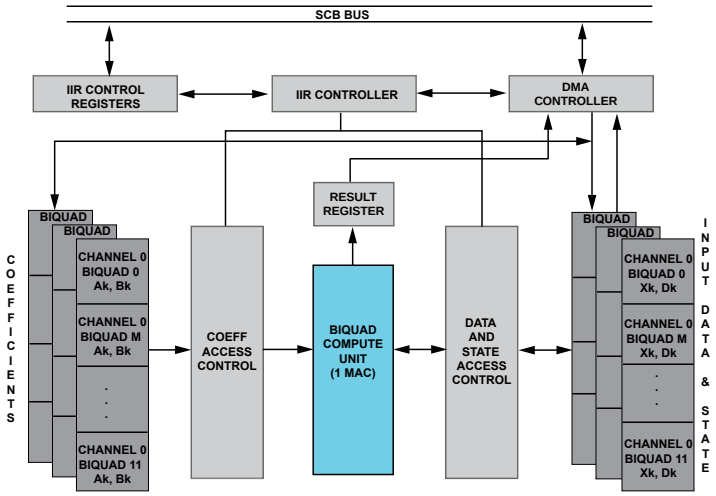

Figure 44-1: IIR Accelerator Block Diagram

The IIR accelerator is implemented using a transposed direct form II biquad which has less coefficient sensitivity. The ***Transposed Direct Form II Biquad*** figure shows the signal flow graph for the biquad structure.

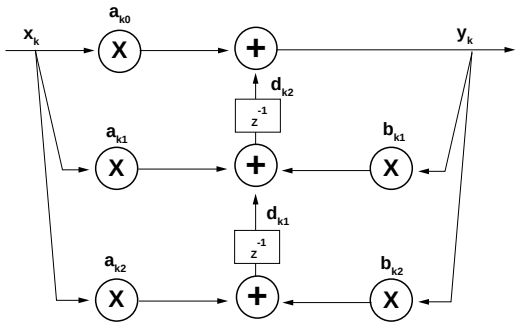

Figure 44-2: Transposed Direct Form II Biquad

The accelerator has the following logical subblocks.

- A datapath unit with the following elements:
  - 32/40-bit coefficient memory (Ak, Bk) for storing biquad coefficients
  - 32/40-bit input data (Xk) and state (Dk)

  - One 40/32-bit floating-point multiplier and adder (MAC) unit
  - An input data buffer to efficiently supply data to MAC
  - One 40-bit result register to hold result of biquad
- Configuration registers for controlling various parameters such as the number of biquads, the number of channels, interrupt control, and DMA control
- A core access interface for writing the DMA/filter configuration registers and for reading the status registers
- A DMA bus interface for transferring data to and from the accelerator. This interface is also used to preload the coefficients (Ak, Bk) and state (Dk) at startup.
- DMA configuration registers for the transfer of input data, output data, and coefficients

The accelerator block is integrated with the SHARC core. For more information about this, see Figure 46-4 SHARC Fabric Connectivity.

ADSP-2159x_SC591_SC592_SC594 IIR Register List

The IIR module reduces the processing load on the core. For more information on IIR functionality, see the IIR register descriptions.

Table 44-1: ADSP-2159x_SC591_SC592_SC594 IIR Register List

Multiply and Accumulate (MAC) Unit

The *IIR MAC Unit* figure shows a pipelined multiplier and accumulator unit that operates on the data and coefficient fetched from the data and coefficient memory. The MAC can perform either 32-bit floating-point or 40-bit floating-point MAC operations. 32-bit floating-point operations generate 32-bit results and 40-bit floating-point operations generate 40-bit results.

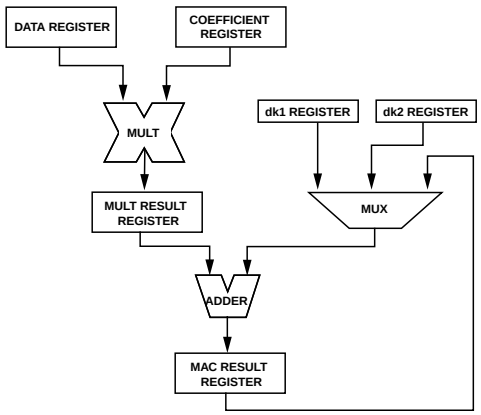

Figure 44-3: IIR MAC Unit

Input Data and Biquad State

The size of data memory is 576 × 40 bits and is used to hold the dk1 and dk2 state of all the biquads locally. The DMA controller fetches the sample data from internal memory and calculates the output as well as the dk1 and dk2 values for each biquad and stores them in local data memory.

Coefficient Memory

The size of coefficient memory is 1440 × 40 bits and is used to store all the coefficients of all the biquads. At start-up, DMA loads the coefficients from system memory into local coefficient memory.

Internal Memory Storage

This section describes the required storage model for the IIR accelerator.

Coefficient Memory Storage

Coefficients and Dk values for a particular biquad BQD[k] should be stored in internal memory in the order: Ak0, Ak1, Bk1, Ak2, Bk2, Dk2, Dk1.

NOTE: The naming convention for the filter coefficients used here is different from the one used in MATLAB. The following conversion should be used when using MATLAB generated coefficients:

(Akx = bx and Bkx = -ax).

Store the coefficients for each biquad in the order:

```
b0, b1, -a1, b2, -a2, dk2, dk1
```

For N biquad stages, store the coefficients in the order:

```
b01, b11, -a11, b21, -a21, dk21, dk11,
b02, b12, -a12, b22, -a22, dk22, dk12,
,......
b0N, b1N, -a1N, b2N, -a2N, dk2N, dk1N.
```

where bxN and axN are the coefficients ([b, a]) for the Nth biquad stage.

Operating Modes

The accelerator operates in Window Processing Mode, 40-Bit Floating-Point Mode and Save Biquad State Mode.

Window Processing Mode

Sample-based processing mode is selected by configuring window size to 1. In this mode, one sample from a particular channel is processed through all the biquads of that channel and the final output sample is calculated.

In window-based mode, multiple output samples (up to 1024) equal to the window size of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A configurable window size parameter is provided to specify the length of the window.

40-Bit Floating-Point Mode

In 40-bit floating-point mode, the input data/coefficient is treated as a 40-bit floating-point number. 40-bit floating-point MAC operations generate 40-bit results. This mode can be selected by setting the `IIR_CTL1.FORTYBIT` bit.

In ACM mode, 40-bit floating-point mode can be selected by setting the `IIR_SGCTL.FORTYBIT` bit field for each channel.

As the DMA bus width is 32 bits, in 40-bit mode the IIR accelerator performs two packed 32-bit accesses to the memory to:

- fetch one 40-bit input or coefficient data, or
- to store one 40-bit output word

The first 32-bit word provides the lower 32 bits and the 8 LSBs of the second 32-bit word provides rest of the upper 8 bits of the complete 40-bit word. The ***32-Bit to 40-Bit Packing*** figure shows the 32–40 bit packing used by accelerator.

NOTE: Overheads could be required to pack the input 40-bit data into the format acceptable by the IIR accelerator and for unpacking the output of accelerator to the format acceptable by the rest of the application.

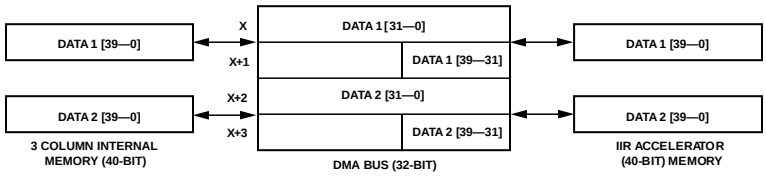

Figure 44-4: 32-Bit to 40-Bit Packing

Save Biquad State Mode

The `IIR_CTL1.SS` bit completely stores the current biquad states in local memory (writes all the Dk1 and Dk2 states back into the system memory states). This is useful in applications that require fast switching to another high-priority accelerator task—a required IIR to FIR processing transition for example. After resuming, these states can be reloaded and IIR processing can be continued. DMA status is automatically stored after each iteration.

NOTE: In legacy mode, the accelerator loads the biquad coefficients for all the channels before processing the first channel. After processing the last channel, if the `IIR_CTL1.SS` bit is set, the accelerator stores the biquad states of all the channels in local memory (writes all the Dk1 and Dk2 states back into the system memory states). In ACM mode, the accelerator loads the biquad coefficients for only the current channel before starting to process the current channel. If the `IIR_SGCTL.SS` bit is set, the accelerator stores the biquad states of the current channel in local memory before moving on to the next channel.

NOTE: Write access to any of the IIR accelerator registers loaded by chaining is not allowed while the save state operation is in progress. Attempted writes to these registers could result in the blocking of IOP core reads until the save state operation completes.

Auto Configuration Mode (ACM)

The accelerator can be operated in legacy mode or Auto Configuration Mode (ACM). ACM is configured by setting the `IIR_CTL1.ACM` bit. The default functional mode is legacy mode. The accelerator mode can only be changed when the accelerator is disabled.

The ACM provides the following additional features:

- Halt and Queuing

  The core may pause processing the current Transfer Control Block (TCB) chain by setting the `IIR_CTL1.HALT` bit. The accelerator acknowledges the core by setting the `IIR_DMASTAT.HALT_STAT` bit. The core can then submit/insert new TCB's. After the core takes action, the accelerator resumes processing by clearing the `IIR_CTL1.HALT` bit. Before halting the accelerator, if the initial TCB chain is processed, the accelerator goes to the idle state. In this case, the accelerator has to be disabled and enabled by toggling the `IIR_CTL1.EN` bit and the `IIR_CTL1.HALT` bit has to be cleared to resume processing.

- No Channel Number Limitation

Unlike in legacy mode, there is no fixed channel number limitation and, therefore, the accelerator ignores the value programmed in the IIR_CTL1.CH field. The application can queue an unlimited number of channels/TCBs dynamically and the accelerator keeps processesing the TCBs until the chain pointer becomes null.

- Selective Interrupt

  The core can enable/mask interrupt generation for each channel using the IIR_CTL2.IMASK bit. If the bit is cleared, an interrupt is generated after completion of the channel.

- Selective Controller/Target Trigger

  The core can enable/mask trigger generation by the accelerator after the end of processing of each channel using the IIR_CTL2.TMASK bit. The accelerator can also wait for a trigger after loading the TCB and coefficients and before processing a channel for which the IIR_CTL2.TWAIT bit is set.

  This feature can also be enabled in legacy mode by setting the IIR_CTL1.L_TIMASK_EN and IIR_CTL1.L_TWAIT_EN bits. In legacy mode, when the IIR_CTL1.L_TIMASK_EN and IIR_CTL1.L_TWAIT_EN bits are set, then the IIR_CTL2.TMASK and IIR_CTL2.TWAIT bits can be used to enable/mask trigger generation and wait for a trigger for each channel respectively.

Additionally, the IIR_CTL1 register is used to change parameters such as rounding mode, forty bit mode and save state for each channel. The IIR_SCTL1 and IIR_SCTL2 registers can be used as general-purpose registers.

Data Transfers

The IIR filter works exclusively through DMA.

IIR Accelerator Transfer Control Block (TCB)

The location of the DMA parameters for the next sequence comes from the chain pointer register. This register points to the next set of DMA parameters stored in the system memory of the processor known as TCB. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as the structure of a traditional linked list. Each TCB has several data values and a pointer to the next TCB. The chain pointer of a TCB can point to itself to re-run the same DMA continuously. The IIR accelerator reads each word of the TCB and loads it into the corresponding register. A TCB with a chain pointer register value of zero indicates the end of the chain (no further TCBs are loaded). The IIR accelerator supports circular buffer chained DMA. The following tables show the required TCBs for chained DMA in legacy mode and ACM. TCB refers to the start address of the TCB array.

NOTE: In the IIR accelerator DMA, two different TCB loading sequences are available: one TCB loads five parameters for the coefficients (IIR_CTL2, IIR_COEFIDX, IIR_COEFMOD, IIR_COEFLEN, and IIR_CHNPTR). The second loads 10 parameters for the data (IIR_CTL2, IIR_INIDX,

IIR_INMOD, IIR_INLEN, IIR_INBASE, IIR_OUTIDX, IIR_OUTMOD, IIR_OUTLEN, IIR_OUTBASE, and IIR_CHNPTR).

Initialize IIR_CHNPTR to TCB+12 in legacy mode and TCB + 15 in ACM.

Table 44-5: IIR TCBs for Chained DMA in Legacy Mode

Address	Register
TCB	IIR_CHNPTR
TCB + 0x1	IIR_COEFLEN
TCB + 0x2	IIR_COEFMOD
TCB + 0x3	IIR_COEFIDX
TCB + 0x4	IIR_OUTBASE
TCB + 0x5	IIR_OUTLEN
TCB + 0x6	IIR_OUTMOD
TCB + 0x7	IIR_OUTIDX
TCB + 0x8	IIR_INBASE
TCB + 0x9	IIR_INLEN
TCB + 0xA	IIR_INMOD
TCB + 0xB	IIR_INIDX
TCB + 0xC	IIR_CTL2

Table 44-6: IIR TCBs for Chained DMA in ACM

Address	Register
TCB	IIR_CHNPTR
TCB + 0x1	IIR_SCTL1
TCB + 0x2	IIR_SCTL2
TCB + 0x3	IIR_SGCTL
TCB + 0x4	IIR_COEFLEN
TCB + 0x5	IIR_COEFMOD
TCB + 0x6	IIR_COEFIDX
TCB + 0x7	IIR_OUTBASE
TCB + 0x8	IIR_OUTLEN
TCB + 0x9	IIR_OUTMOD
TCB + 0xA	IIR_OUTIDX
TCB + 0xB	IIR_INBASE

Address	Register
TCB + 0xC	IIR_INLEN
TCB + 0xD	IIR_INMOD
TCB + 0xE	IIR_INIDX
TCB + 0xF	IIR_CTL2

DMA Access

The IIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Burst Mode Access

Burst mode enhances the throughput of the DMA channel and reduce the overall load on the system fabric. If IIR_CTL1.BURSTEN is set, all the biquads of all the channels are loaded with burst enabled. The IIR module supports only INCR8 burst.

Chain Pointer DMA

The DMA controller supports circular buffer chain pointer DMA. One transfer control block (TCB) must be configured for each channel. The TCB contains:

- A control register value to configure the filter parameters (such as number of biquads, window size) for each channel. In ACM, additional parameter such as interrupt mask, trigger mask, and trigger wait are also available.
- Software control register values in ACM for each channel.
- Secondary control register value in ACM to configure rounding mode, forty bit mode, and save state for each channel.
- DMA parameter register values for the input data
- DMA parameter register values for coefficient load
- DMA parameter register values for output data

In legacy mode, The chain pointer (IIR_CHNPTR) field of the last channel's TCB should point to the first channel's TCB. This configuration exists so that when the IIR accelerator is enabled, the module:

1. Loads the coefficients (Ak, Bk) and state variables (Dk) for all the channels into the local coefficient memory of the IIR, and
2. Loops back to the first channel again to start fetching the input data for processing.

In ACM, the chain pointer field of the last channel's TCB need not be pointing to the first channel's TCB.

When the accelerator is enabled, the module:

1. Loads the coefficients (Ak,Bk) and state variables (Dk) only for the current channel being processed.

2. Starts fetching input data for processing.
3. After processing the current channel, if the IIR_SGCTL.SS bit is set, it saves the biquad states of the current channel in local memory and moves to the next channel.

In ACM, the accelerator keeps processing the TCB's until the chain pointer becomes null.

The accelerator loads the TCB into its internal registers and uses these values to fetch coefficients and data and to store results. After processing a window of data for any channel, the accelerator writes back the IIR_INIDX (input index register) and IIR_OUTIDX (output index register) values to the TCB in memory. Then, data processing can begin from where it left off during the next time slot of that channel.

For 32-bit mode, the write-back values for the index registers are equal to IIRII + W and IIROI + W.

For 40-bit mode, the write-back values are: IIR_INIDX + 2 × W and IIR_OUTIDX + 2 × W.

Accelerator input and output channels connect to system memory.

NOTE: The IIR_CTL2 register is part of the IIR TCB. This configuration allows software to program individual IIR channels having different control attributes.

In ACM, when the IIR_CTL1.SMQ_LIUPS_EN bit is set, the acclerator updates the IIR_INIDX and IIR_OUTIDX bit fields of the TCB in memory after processing a window of data and according to the circular buffer scheme. When the IIR_CTL1.SMQ_LIUPS_EN bit is cleared, the acclerator updates the IIR_INIDX and IIR_OUTIDX bit fields of the TCB in memory to 0x00000000 and 0xFFFFFFFF after processing a window of data. The IIR_CTL1.SMQ_LIUPS_ENbit is only valid in ACM.

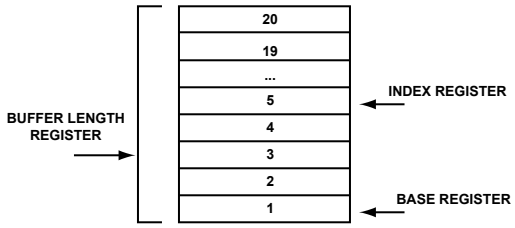

Figure 44-5: Circular Buffer Addressing

Interrupts

The ***IIR Interrupt Overview*** table provides the source of interrupt and service instructions for the IIR interrupts.

Accelerator Mode	Default Programmable Interrupt	Sources	Masking	Service
Legacy Mode	IIR_DMA	Window Complete	N/A	ROC from IIR_DMASTAT + RTI instruction
		All channels complete		
	IIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from IIR_MACSTAT + RTI instruction
		MAC fixed point overflow		
Auto Configuration Mode	IIR_DMA	Window Complete	IIR_CTL2.IMASK	ROC from IIR_DMASTAT + RTI instruction
	IIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from IIR_MACSTAT + RTI instruction
		MAC fixed point overflow	N/A	

Sources

The IIR module drives two interrupt signals, IIR_DMA for the DMA status and IIR_STAT for the MAC status. The IIR module generates interrupts as described in the following sections.

Window Complete

This interrupt is generated at the end of each channel when all the output samples are calculated corresponding to a window and updated index values are written back.

In legacy mode, if the IIR_CTL1.CCINTR bit is set, an interrupt is generated after completion of window processing of each channel. In ACM, the interrupt generation can be selectively masked using the IIR_CTL2.IMASK bit for each channel.

Interrupt masking for each channel can be enabled in legacy mode by setting the IIR_CTL1.L_TIMASK_EN bit. In legacy mode,when the IIR_CTL1.L_TIMASK_EN bit is set, interrupt generation for each channel is controlled using the IIR_CTL2.IMASK bit.

All Channels Complete

This interrupt is generated when all the channels are complete or when one iteration of time slots completes. The interrupt follows the access completion rule, where the interrupt is generated when all data are written back to system memory.

The All Channels Complete interrupt source is only applicable in legacy mode. If the IIR_CTL1.CCINTR and IIR_CTL1.L_TIMASK_EN bits are not set in legacy mode, then the all channel complete interrupt is generated. In ACM, interrupt generation for each channel is controlled using the IIR_CTL2.IMASK bit.

NOTE: In ACM, the Output DMA complete interrupt can be generated after Save State completes for the channel by clearing the `IIR_SGCTL.SSESEL` bit . If this bit is set, the Output DMA interrupt is generated before the Save State completes for the channel.

In Legacy Mode, if the `IIR_CTL1.CCINTR` and `IIR_CTL1.SSESEL` bits are cleared, the All Channel Done Interrupt is generated after the Save State operation is completed for all the channels.

MAC Status

A MAC status interrupt is generated under these conditions:

- Multiplier result zero - Set if multiplier result is zero
- Multiplier result infinity - Set if multiplier result is infinity
- Multiply invalid - Set if multiply operation is invalid
- Adder result zero - Set if adder result is zero
- Adder result infinity - Set if adder result is infinity
- Adder invalid - Set if addition is invalid

Service

The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state (and clear) by reading the MAC status register (`IIR_MACSTAT`). The MAC interrupt status bits are sticky.

The status interrupt sources are derived from the `IIR_MACSTAT` register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result.

Programming Model

The following sections provide programming examples in legacy mode and ACM.

Legacy Mode

The IIR accelerator supports up to 32 channels which are time division multiplexed (TDM). Each channel can have a maximum of 64 biquads. The window size for each channel is configurable using the control registers. The maximum configurable window size is 1024.

For multi-channel filtering:

1. Program the number of channels using the `IIR_CTL1.CH` bits.
2. Configure the TCBs in system memory with one channel's TCB pointing to the next channels TCB. The TCB of the last channel should point to the TCB of the first channel.
3. Write the first TCB value into the `IIR_CHNPTR` register and enable the accelerator.

4. If the IIR_CTL1.BURSTEN bit is set, ensure that the coefficient buffer end address plus 7 words do not fall outside the valid address range and that the buffer is initialized. When the burst feature is enabled, the IIR module issues an INCR8 burst. When the data count % 8 == 7, the extra 7 words are always read, but ignored by the IIR module.

   NOTE: Data count = ∑(Bn*7) or ∑(Bn*14); where Bn is number of biquads for channel N. Each biquads contains 7 words for 32-bit mode or 14 words in 40-bit mode.

The ***Biquad Processing Program Flow*** figure shows the biquad processing program flow.

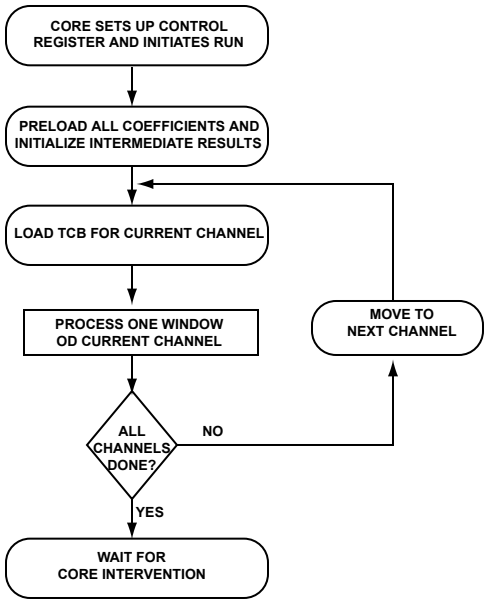

Figure 44-6: Biquad Processing Program Flow

The accelerator uses the following procedure to process biquads:

1. The controller loads all coefficients of all the channels into local storage.
2. Once all the coefficients are loaded, the controller goes to the first biquad of the first channel and calculates the output of the first biquad and updates the intermediate results for that biquad. If the IIR_CTL1.L_TWAIT_EN bit is set and the IIR_CTL2.TWAIT bit is set for the channel, the accelerator waits for the input trigger to start the computation.
3. The accelerator then moves to the next biquad of that channel and repeats the process until all the biquads for that channel are completed and the results are stored to memory.
4. The process is repeated for next sample until one window of the corresponding channel is processed.
5. After one window of the channel is processed, the accelerator moves to the next channel and computes the results.

NOTE: All the addresses programmed in the 32-bit address boundaries and must not contain the lower 2 bits (which are assumed as zeros).

Auto Configuration Mode

In ACM, there is no limit on the number of channels the accelerator can process. The accelerator keeps processing the TCBs until the chain pointer becomes null. Each channel can have a maximum of 64 biquads. Maximum window size configurable is 1024.

The figure shows multi-channel filtering in ACM. Multiple channels are processed in a time multiplexed format (TDM).

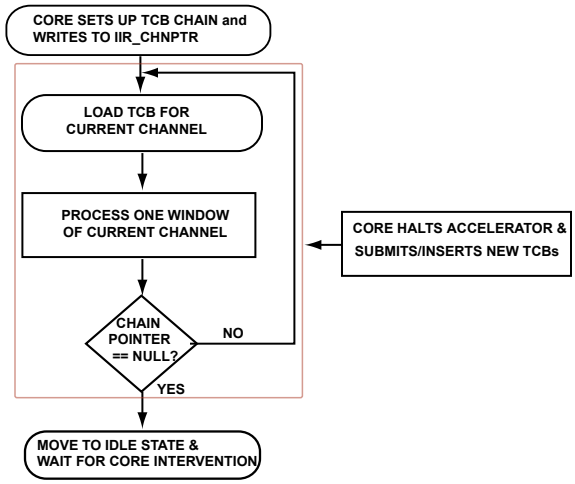

Figure 44-7: Multi-Channel Filtering in Auto Configuration Mode

For multi-channel filtering:

1. Configure the TCBs in system memory with one channel's TCB pointing to the next channel's TCB. There is no limit on the number of channels to be configured. The TCB of the last channel need not be pointing to the TCB of the first channel.
2. Write the first TCB value to the `IIR_CHNPTR` register and enable the accelerator.

   The accelerator fetches the first channel's TCB. Using it as pointer, loads the biquad coefficients and biquad states for that channel into its local memory and loads the `IIR_CTL2` and `IIR_SGCTL` registers to configure the filter parameters corresponding to that channel.

   If the `IIR_CTL2.TWAIT` bit is set, the accelerator waits for a input trigger to start the window processing for the channel.

   The accelerator computes the output of the first biquad and updates the intermediate results for that biquad. Then, the accelerator moves to the next biquad of that channel and repeats the process untill all the biquads for that channel are completed and the results are stored to memory. The process is repeated with the next sample untill one window of the corresponding channel is processed. If the `IIR_CTL1.SS` bit is set, the accelerator saves the states of the biquads of the channel into system memory. If the `IIR_CTL2.TMASK` bit is cleared the accelerator sends an output trigger after completion of processing the channel.

   If the `IIR_CTL2.IMASK` bit is cleared, the accelerator interrupts the core after completion of processing a particular channel.

At the end of the window, the accelerator updates the IIR_INIDX and IIR_OUTIDX registers to 0x00000000 and 0xFFFFFFFF in the TCB of system memory and moves to the next channel.

3. At any instant, as required, the core halts the accelerator. It sets the IIR_CTL1.HALT bit and appropriately takes action to submit/insert new TCBs and and clears the IIR_CTL1.HALT bit to resume channel processing.

   If the IIR_CHNPTR register is zero (last channel is being processed or channel processing is complete) after halting the accelerator, the IIR_CHNPTR register is appropriately written before resuming the accelerator channel processing.

   If the accelerator is idle after halt, IIR_CTL1.EN bit is toggled to disable and re-enable the accelerator and the IIR_CTL1.HALT bit is cleared and the accelerator resumes channel processing.

4. The accelerator continues processing until all the channels are complete. Repeat *Step 3* (if required) to submit/insert new channels.

ADSP-2159x_SC591_SC592_SC594 IIR Register Descriptions

The IIR filter accelerator (IIR) contains the following registers.

Table 44-7: ADSP-2159x_SC591_SC592_SC594 IIR Register List

Name	Description
IIR_CHNPTR	Chain Pointer Register
IIR_COEFIDX	Coefficient Buffer Index Register
IIR_COEFLEN	Coefficient Buffer Length Register
IIR_COEFMOD	Coefficient Index Modifier Register
IIR_CTL1	Global Control Register
IIR_CTL2	Channel Control Register
IIR_DBG_ADDR	IIR Debug Address Register
IIR_DBG_CTL	IIR Debug Control Register
IIR_DBG_RDDAT_HI	IIR Debug Read Data High Register
IIR_DBG_RDDAT_LO	IIR Debug Read Data Low Register
IIR_DBG_WRDAT_HI	IIR Debug Write Data High Register
IIR_DBG_WRDAT_LO	IIR Debug Write Data Low Register
IIR_DMASTAT	DMA Status Register
IIR_INBASE	Input Buffer Base Register
IIR_INIDX	Input Data Index Register
IIR_INLEN	Input Data Buffer Length Register

Table 44-7: ADSP-2159x_SC591_SC592_SC594 IIR Register List (Continued)

Name	Description
IIR_INMOD	Input Data Index Modifier Register
IIR_MACSTAT	MAC Status Register
IIR_OUTBASE	Output Buffer Base Register
IIR_OUTIDX	Output Data Buffer Index Register
IIR_OUTLEN	IIR Output Data Buffer Length Register
IIR_OUTMOD	IIR Output Data Index Modifier Register
IIR_SCTL1	Software Control Register1
IIR_SCTL2	Software Control Register2
IIR_SGCTL	Secondary Global Control Register

Chain Pointer Register

The `IIR_CHNPTR` register should be written with word address without the lower 2 bits.

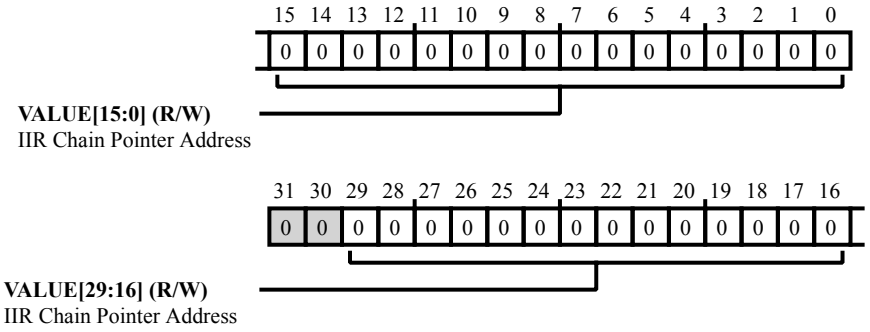

Figure 44-8: IIR_CHNPTR Register Diagram

Table 44-8: IIR_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	IIR Chain Pointer Address. The `IIR_CHNPTR.VALUE` bit field contains the chain pointer address.

Coefficient Buffer Index Register

The IIR_COEFIDX register contains the word address with the lower 2 bits removed.

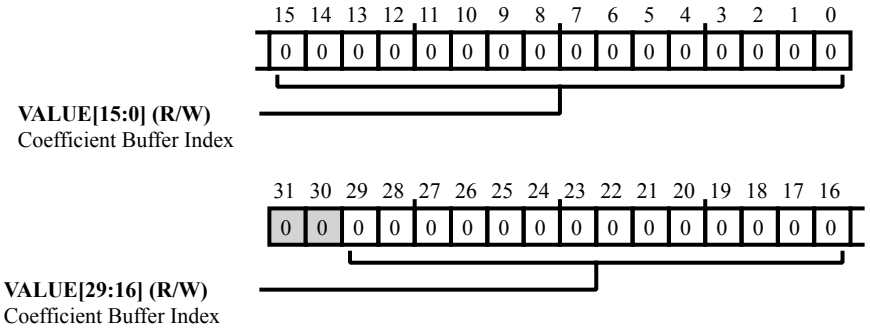

Figure 44-9: IIR_COEFIDX Register Diagram

Table 44-9: IIR_COEFIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Coefficient Buffer Index. The IIR_COEFIDX.VALUE bit field provides the coefficient buffer index.

Coefficient Buffer Length Register

The IIR_COEFLEN register provides the coefficient buffer length.

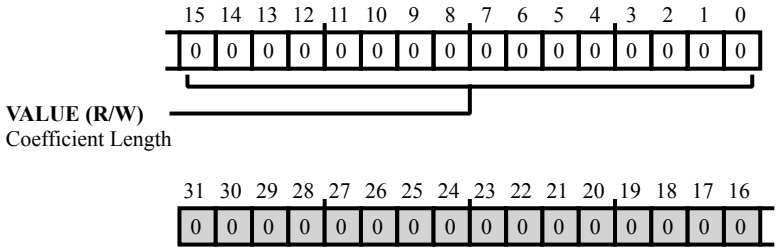

Figure 44-10: IIR_COEFLEN Register Diagram

Table 44-10: IIR_COEFLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Coefficient Length. The IIR_COEFLEN.VALUE bit field provides the coefficient buffer length.

Coefficient Index Modifier Register

The IIR_COEFMOD register provides the coefficient index modifier.

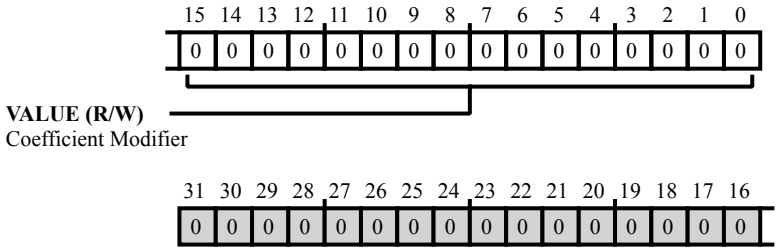

Figure 44-11: IIR_COEFMOD Register Diagram

Table 44-11: IIR_COEFMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Coefficient Modifier. The IIR_COEFMOD.VALUE bit field provides the coefficient modifier.

Global Control Register

The `IIR_CTL1` register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.

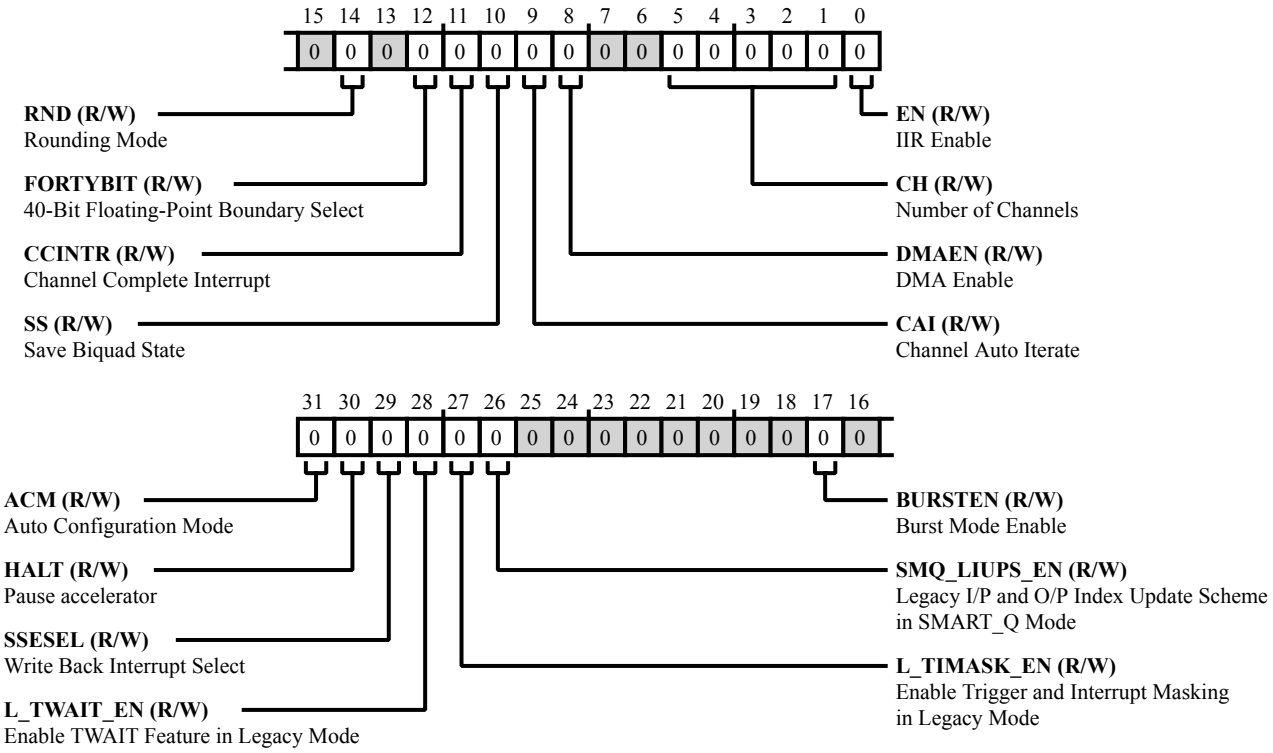

Figure 44-12: IIR_CTL1 Register Diagram

Table 44-12: IIR_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ACM	Auto Configuration Mode. The `IIR_CTL1.ACM` bit configures the mode for loading the TCB.	
		0	Legacy Mode
		1	Auto Configuration Mode
30 (R/W)	HALT	Pause accelerator. The `IIR_CTL1.HALT` bit determines whether the accelerator pauses so that the core can check the status and modify or submit a job or the accelerator is released for further processing of data. This bit is only valid in Auto Configuration Mode (ACM).	
		0	Release accelerator
		1	Pause accelerator

Table 44-12: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SSESEL	Write Back Interrupt Select. The `IIR_CTL1.SSESEL` bit selects whether to generate an interrupt after the write back or after save state completion.	
		0	Generate Interrupt after save state completion
		1	Generate interrupt after write back completion
28 (R/W)	L_TWAIT_EN	Enable TWAIT Feature in Legacy Mode. The `IIR_CTL1.L_TWAIT_EN` bit indicates whether the TWAIT feature is available in legacy mode. This bit is only valid in legacy mode.	
		0	Not Available
		1	Available
27 (R/W)	L_TIMASK_EN	Enable Trigger and Interrupt Masking in Legacy Mode. The `IIR_CTL1.L_TIMASK_EN` bit enables trigger and interrupt masking in legacy mode. This bit is only valid in legacy mode.	
		0	Disable
		1	Enable
26 (R/W)	SMQ_LIUPS_EN	Legacy I/P and O/P Index Update Scheme in SMART_Q Mode. The `IIR_CTL1.SMQ_LIUPS_EN` bit configures the scheme the accelerator uses to update the input index (II) and output index (OI). This bit is only valid in ACM.	
		0	Update the II with all '0' and the OI with all 'F', respectively
		1	Update II and OI after circular buffer scheme
17 (R/W)	BURSTEN	Burst Mode Enable. The `IIR_CTL1.BURSTEN` bit field is set, burst access is enabled.	
		0	Disable burst mode
		1	Enable burst mode
14 (R/W)	RND	Rounding Mode. The `IIR_CTL1.RND` bit field selects the rounding mode for floating-point format.	
		0	Round to nearest (even)
		1	Truncate (Round towards zero)

Table 44-12: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	FORTYBIT	40-Bit Floating-Point Boundary Select. The `IIR_CTL1.FORTYBIT` bit selects between 32-bit IEEE floating-point format or 40-bit IEEE floating-point format.	
		0	32-bit IEEE floating-point
		1	40-bit IEEE floating-point
11 (R/W)	CCINTR	Channel Complete Interrupt. The `IIR_CTL1.CCINTR` bit configures the channel complete interrupt to generate when all channels are done or after each channel is done. This bit is only valid in legacy mode when the IIR_CTL1.L_TIMASK_EN bit is cleared (=0). In Auto Configuration Mode (ACM) or when the IIR_CTL1.L_TIMASK_EN is set (=1), interrupt generation for each channel is controlled using IIR_CTL2.IMASK bit.	
		0	Interrupt is generated only when all channels are done (default)
		1	Interrupt is generated after each channels is done (default)
10 (R/W)	SS	Save Biquad State. The `IIR_CTL1.SS` bit configures the accelerator to store the Dk register settings into the internal memory. This can be used to save the biquad states before switching to another high priority accelerator task. This bit is only valid in legacy mode. In Auto Configuration Mode(ACM), Save State for each channel is controlled using IIR_SGCTL.SS bit	
9 (R/W)	CAI	Channel Auto Iterate. The `IIR_CTL1.CAI` bit sets whether TDM processing stops (idle) once all channels complete processing or moves to first channel and continues TDM processing in a loop when all channels complete processing. Channel Auto Iterate is not available in Auto Configuration Mode(ACM). The accelerator keeps processing the TCBs until the chain pointer becomes null in Auto Configuration Mode(ACM).	
		0	TDM processing stops (idle) once all channels complete processing
		1	Moves to first channel and continues TDM processing in a loop when all channels complete processing
8 (R/W)	DMAEN	DMA Enable. The `IIR_CTL1.DMAEN` bit enables DMA on the accelerator.	
		0	Disable
		1	Enable

Table 44-12: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:1 (R/W)	CH	Number of Channels. The `IIR_CTL1.CH` bit field configures the number of channels and is programmable between 0-31 (channels = NCH + 1). This bit field is only valid in Legacy Mode. In Auto Configuration Mode(ACM), there is no limit on the number of channels. the accelerator keeps processing the TCBs until the chain pointer becomes null.	
0 (R/W)	EN	IIR Enable. The `IIR_CTL1.EN` bit enables or disables the IIR accelerator.	
		0	IIR disabled
		1	IIR enabled

Channel Control Register

The IIR_CTL2 register is used to configure the channel specific parameters. These parameters include the number of biquads and window size. In Auto Configuration Mode(ACM), this register is also used to configure additional channel specific parameters like interrupts and triggers.

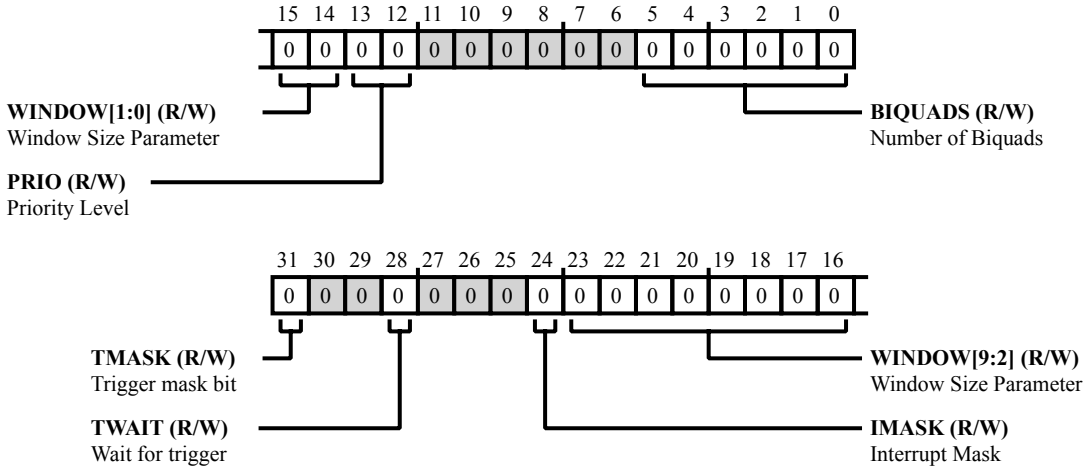

Figure 44-13: IIR_CTL2 Register Diagram

Table 44-13: IIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	TMASK	Trigger mask bit. The IIR_CTL2.TMASK bit enables trigger generation for the channel. It is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Enable
		1	Mask
28 (R/W)	TWAIT	Wait for trigger. The IIR_CTL2.TWAIT bit disables the wait for the trigger. It is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Disable wait for the trigger for the channel
		1	Enable wait for external trigger input assertion for the channel
24 (R/W)	IMASK	Interrupt Mask. The IIR_CTL2.IMASK bit enables interrupt generation for the channel. This bit is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Enable
		1	Mask

Table 44-13: IIR_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:14 (R/W)	WINDOW	Window Size Parameter. The `IIR_CTL2.WINDOW` bit field configures the window size which specifies the number of sample/block to process (sample based processing = window size of 1). This bit field should be programmed to "actual window size required -1". For example, for sample based processing this bit field should be programmed to 0.	
13:12 (R/W)	PRIO	Priority Level. The `IIR_CTL2.PRIO` bit field indicates the priority.	
		0	Level 0 (lowest)
		1	Level 1
		2	Level 2
		3	Level 3 (highest)
5:0 (R/W)	BIQUADS	Number of Biquads. The `IIR_CTL2.BIQUADS` bit field configures the number of biquads and is programmable between 0-63 (number of Biquads = BIQUADS + 1).	

IIR Debug Address Register

The IIR_DBG_ADDR register holds the debug address. If bit 11 is set, coefficient memory is selected.

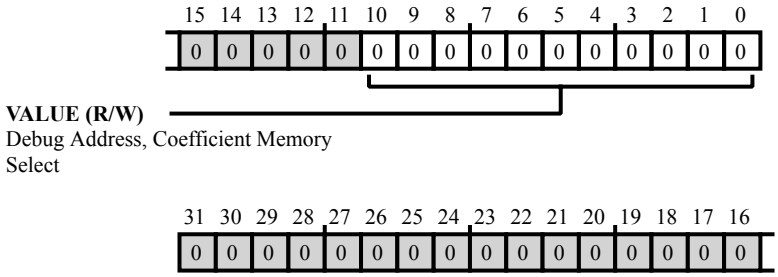

Figure 44-14: IIR_DBG_ADDR Register Diagram

Table 44-14: IIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The IIR_DBG_ADDR.VALUE bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

IIR Debug Control Register

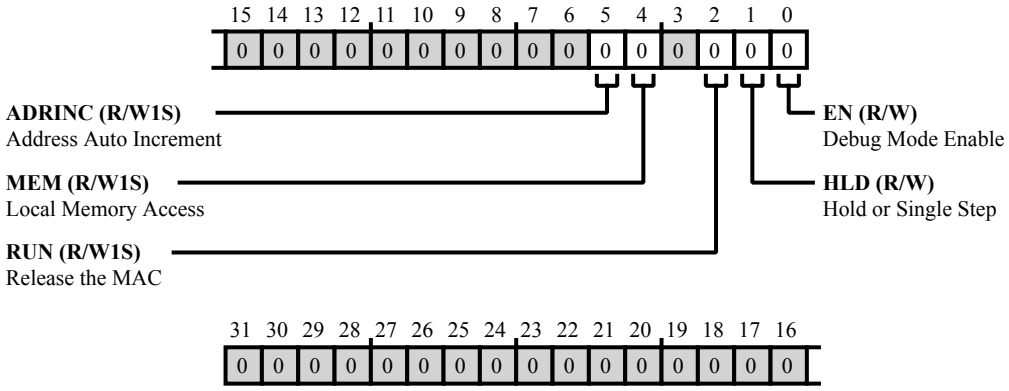

Figure 44-15: IIR_DBG_CTL Register Diagram

Table 44-15: IIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1S)	ADRINC	Address Auto Increment. The `IIR_DBG_CTL.ADRINC` bit allows the address register to auto increment on `IIR_DBG_WRDAT_HI`/`IIR_DBG_WRDAT_LO` writes and `IIR_DBG_RDDAT_HI`/`IIR_DBG_RDDAT_LO` reads.	
4 (R/W1S)	MEM	Local Memory Access. The `IIR_DBG_CTL.MEM` bit allows the data and coefficients memory to be indirectly accessed.	
2 (R/W1S)	RUN	Release the MAC. The `IIR_DBG_CTL.RUN` bit releases the MAC and is is self clearing after one IIR clock cycle.	
1 (R/W)	HLD	Hold or Single Step. The `IIR_DBG_CTL.HLD` bit function is based on the `IIR_DBG_CTL.MEM` bit setting. For `IIR_DBG_CTL.MEM` = 0 this bit sets single step. For `IIR_DBG_CTL.MEM` = 1 this bit sets hold data.	
		0	No effect
		1	Single step (IIR_DBGMEM=0) or Hold data (IIR_DBGMEM=1)
0 (R/W)	EN	Debug Mode Enable. The `IIR_DBG_CTL.EN` bit enables debug mode. For local memory access, the `IIR_CTL1` register can be cleared.	
		0	Disable
		1	Enable

IIR Debug Read Data High Register

The IIR_DBG_RDDAT_HI register is part of the 40-bit wide debug mode read data register and holds the upper 8 bits.

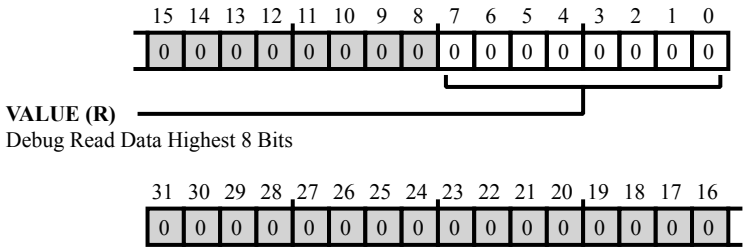

Figure 44-16: IIR_DBG_RDDAT_HI Register Diagram

Table 44-16: IIR_DBG_RDDAT_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	Debug Read Data Highest 8 Bits. The IIR_DBG_RDDAT_HI.VALUE bit field holds the upper 8-bit read data.

IIR Debug Read Data Low Register

The IIR_DBG_RDDAT_LO register is part of the 40-bit wide debug mode read data register and holds the lower 32 bits.

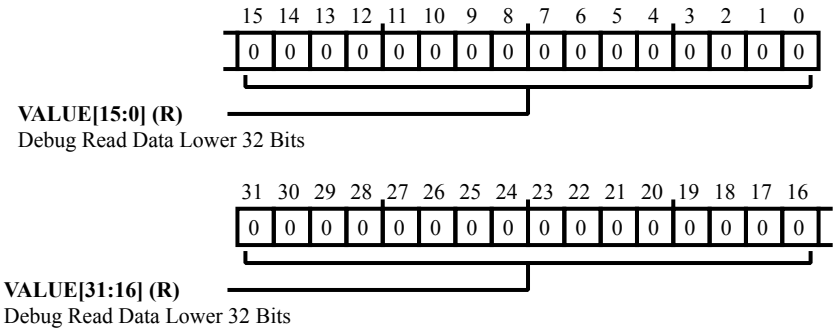

Figure 44-17: IIR_DBG_RDDAT_LO Register Diagram

Table 44-17: IIR_DBG_RDDAT_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Debug Read Data Lower 32 Bits. The IIR_DBG_RDDAT_LO.VALUE bit field holds the lower 32-bit read data.

IIR Debug Write Data High Register

The `IIR_DBG_WRDAT_HI` register is part of the 40-bit wide debug mode write data register and holds the upper 8 bits.

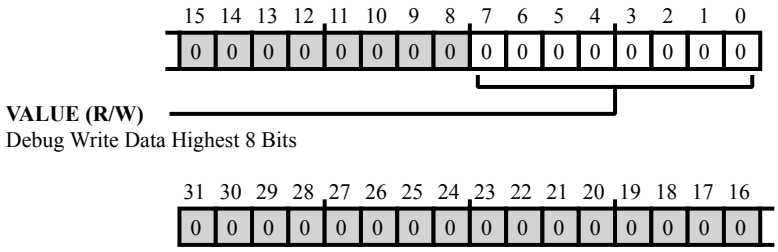

Figure 44-18: IIR_DBG_WRDAT_HI Register Diagram

Table 44-18: IIR_DBG_WRDAT_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Debug Write Data Highest 8 Bits. The `IIR_DBG_WRDAT_HI.VALUE` bit field holds the upper 8-bit write data.

IIR Debug Write Data Low Register

The IIR_DBG_WRDAT_LO register is part of the 40-bit wide debug mode write data register and holds the lower 32 bits.

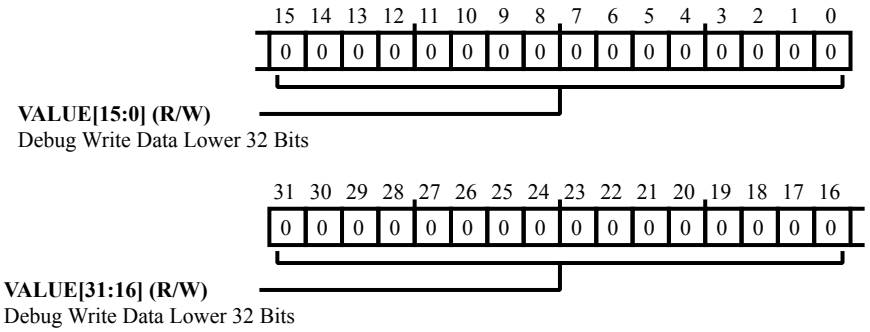

Figure 44-19: IIR_DBG_WRDAT_LO Register Diagram

Table 44-19: IIR_DBG_WRDAT_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Write Data Lower 32 Bits. The IIR_DBG_WRDAT_LO.VALUE bit field holds the lower 32-bit write data.

DMA Status Register

The IIR_DMASTAT registers indicate the status of DMA operations.

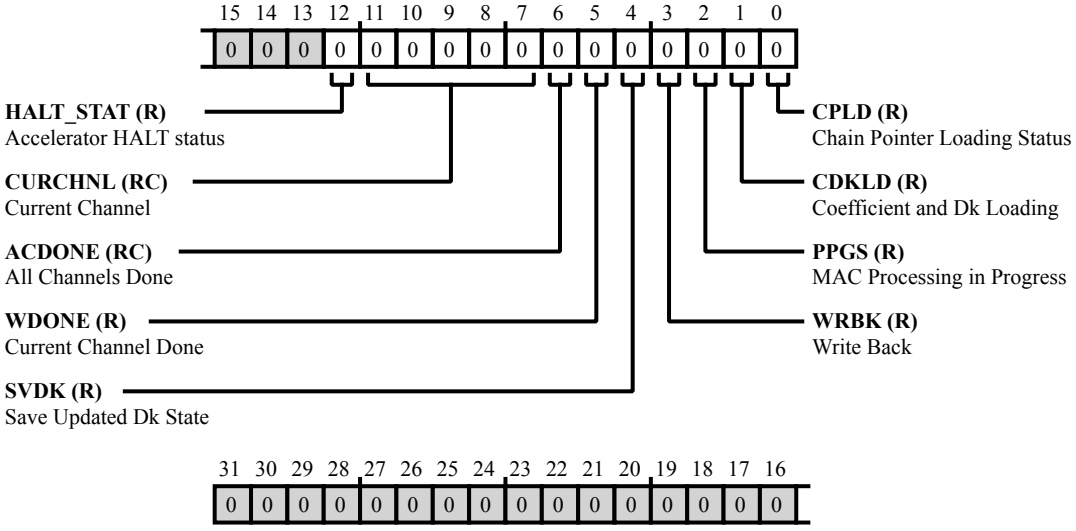

Figure 44-20: IIR_DMASTAT Register Diagram

Table 44-20: IIR_DMASTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/NW)	HALT_STAT	Accelerator HALT status. Acknowledge to core that accelerator is in halt state, if set.
11:7 (RC/NW)	CURCHNL	Current Channel. The IIR_DMASTAT.CURCHNL bit field indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The IIR_DMASTAT.ACDONE bit indicates all channels are done processing. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.
5 (R/NW)	WDONE	Current Channel Done. The IIR_DMASTAT.WDONE bit indicates the processing of the current channel is complete. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.
4 (R/NW)	SVDK	Save Updated Dk State. If there is more than one channel (IIR_CTL1.CH>0), the IIR_DMASTAT.SVDK bit toggles between 0 and 1 as it starts and completes the save state operation on one channel at a time.

Table 44-20: IIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	WRBK	Write Back. The `IIR_DMASTAT.WRBK` bit indicates the accelerator is writing back updated index registers.	
2 (R/NW)	PPGS	MAC Processing in Progress. The `IIR_DMASTAT.PPGS` bit indicates MAC processing is in progress.	
1 (R/NW)	CDKLD	Coefficient and Dk Loading. The `IIR_DMASTAT.CDKLD` bit indicates the coefficient and Dk are loading.	
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `IIR_DMASTAT.CPLD` bit indicates the IIR is in the chain pointer load state.	
		0	State machine not in chain pointer load state
		1	State machine in chain pointer load state

Input Buffer Base Register

The IIR_INBASE register contains the word address with the lower 2 bits removed.

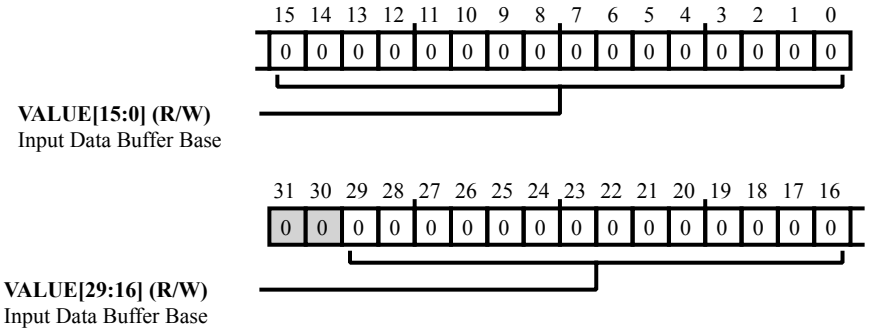

Figure 44-21: IIR_INBASE Register Diagram

Table 44-21: IIR_INBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Input Data Buffer Base. The IIR_INBASE.VALUE bit field value is the input data buffer base address.

Input Data Index Register

The IIR_INIDX register contains a word address with the lower 2 bits removed.

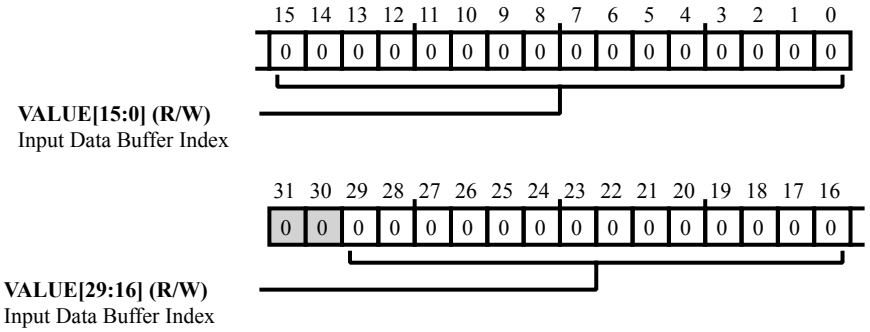

Figure 44-22: IIR_INIDX Register Diagram

Table 44-22: IIR_INIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Input Data Buffer Index. The IIR_INIDX.VALUE bit field value is the input data buffer index.

Input Data Buffer Length Register

The IIR_INLEN register provides the input data buffer length.

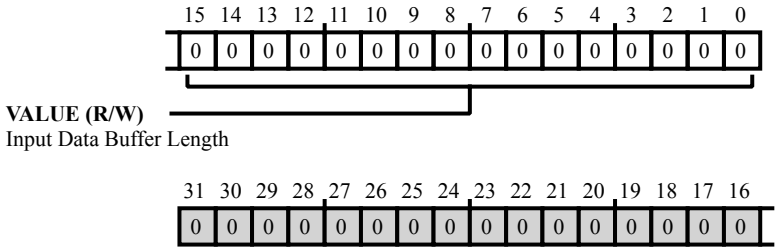

Figure 44-23: IIR_INLEN Register Diagram

Table 44-23: IIR_INLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Input Data Buffer Length. The IIR_INLEN.VALUE bit field value is the input data buffer length.

Input Data Index Modifier Register

The IIR_INMOD register provides the 16-bit input data buffer index modifier.

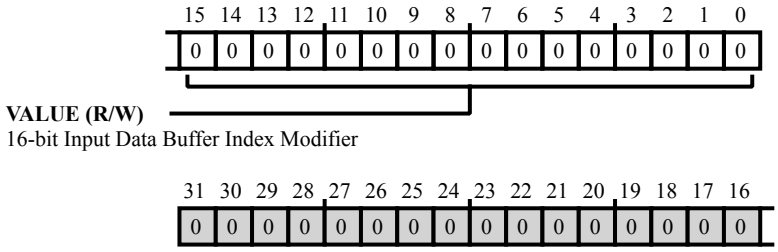

Figure 44-24: IIR_INMOD Register Diagram

Table 44-24: IIR_INMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Index Modifier. The IIR_INMOD.VALUE bit field value is the 16-bit input data buffer modifier.

MAC Status Register

The IIR_MACSTAT register indicates the status of MAC operations.

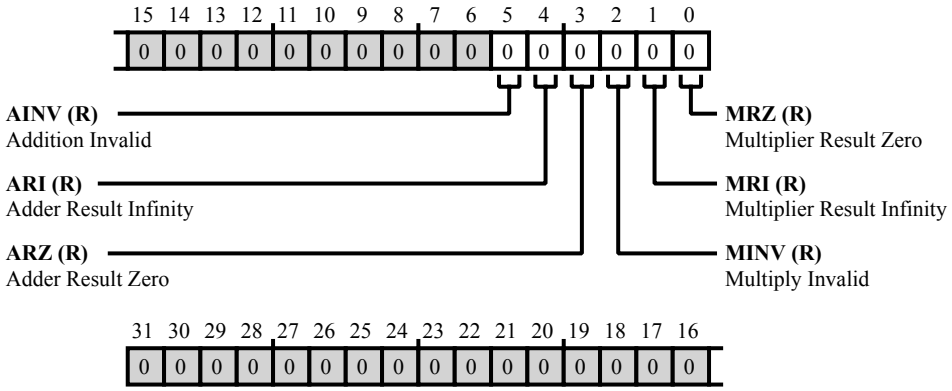

Figure 44-25: IIR_MACSTAT Register Diagram

Table 44-25: IIR_MACSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	AINV	Addition Invalid. The IIR_MACSTAT.AINV bit indicates the addition is invalid.
4 (R/NW)	ARI	Adder Result Infinity. The IIR_MACSTAT.ARI bit indicates the adder result is infinity.
3 (R/NW)	ARZ	Adder Result Zero. The IIR_MACSTAT.ARZ bit indicates the adder result is zero.
2 (R/NW)	MINV	Multiply Invalid. The IIR_MACSTAT.MINV bit indicates the multiply operation is invalid.
1 (R/NW)	MRI	Multiplier Result Infinity. The IIR_MACSTAT.MRI bit indicates the multiplier result is infinity.
0 (R/NW)	MRZ	Multiplier Result Zero. The IIR_MACSTAT.MRZ bit indicates the multiplier result is zero.

Output Buffer Base Register

The IIR_OUTBASE register contains the word address with the lower 2 bits removed.

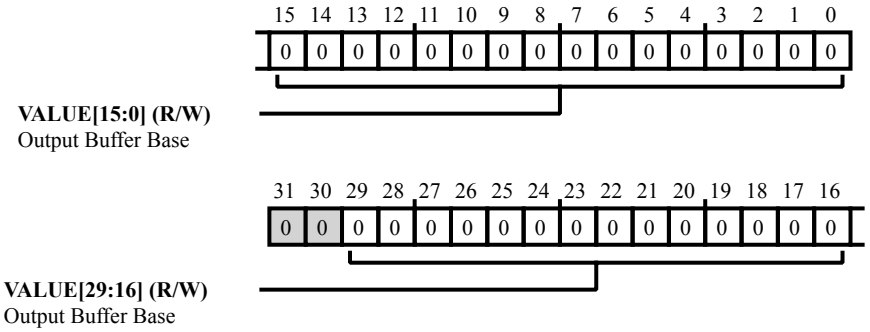

Figure 44-26: IIR_OUTBASE Register Diagram

Table 44-26: IIR_OUTBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Output Buffer Base. The IIR_OUTBASE.VALUE bit field provides the output buffer base address.

Output Data Buffer Index Register

The IIR_OUTIDX register should be written with word address without the lower 2 bits

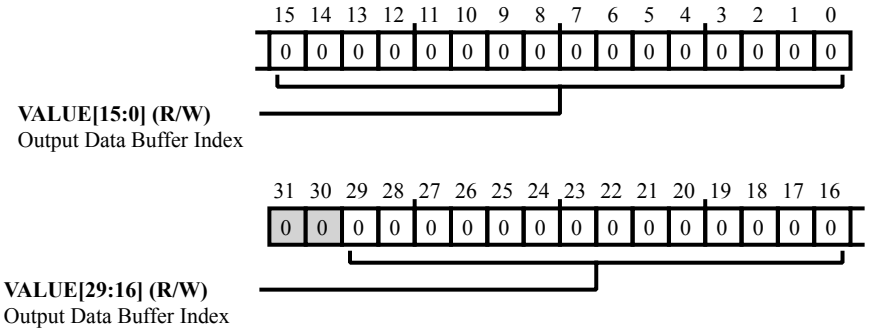

Figure 44-27: IIR_OUTIDX Register Diagram

Table 44-27: IIR_OUTIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Output Data Buffer Index. The IIR_OUTIDX.VALUE bit field provides the output data buffer index.

IIR Output Data Buffer Length Register

The IIR_OUTLEN register provides the output data buffer length.

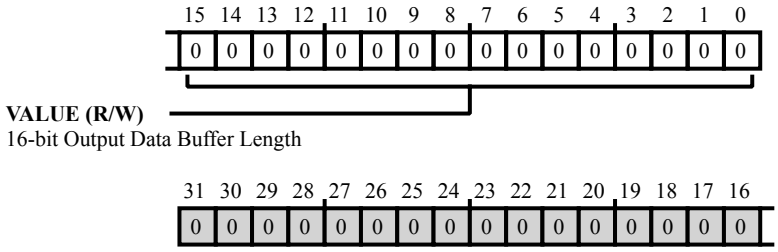

Figure 44-28: IIR_OUTLEN Register Diagram

Table 44-28: IIR_OUTLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Output Data Buffer Length. The IIR_OUTLEN.VALUE bit field provides the output data buffer length.

IIR Output Data Index Modifier Register

The IIR_OUTMOD register provides the output data index modifier.

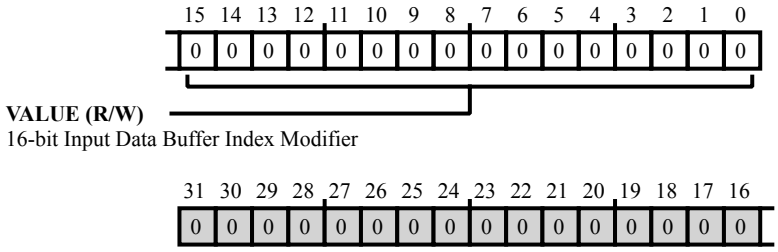

Figure 44-29: IIR_OUTMOD Register Diagram

Table 44-29: IIR_OUTMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Index Modifier. The IIR_OUTMOD.VALUE bit field provides the output data buffer index modifier.

Software Control Register1

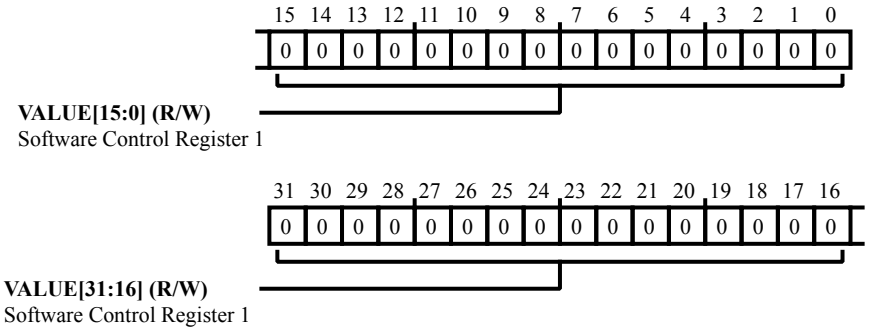

Figure 44-30: IIR_SCTL1 Register Diagram

Table 44-30: IIR_SCTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software Control Register 1.

Software Control Register2

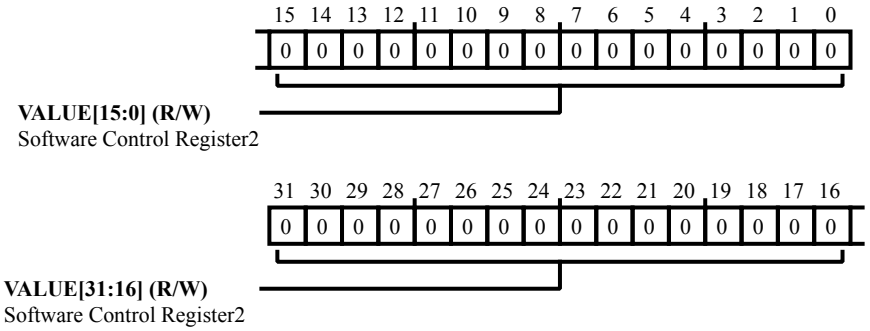

Figure 44-31: IIR_SCTL2 Register Diagram

Table 44-31: IIR_SCTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software Control Register2.

Secondary Global Control Register

The IIR_SGCTL register configures the global parameters for the accelerator in ACM mode for loading CTL1 register as part of TCB.

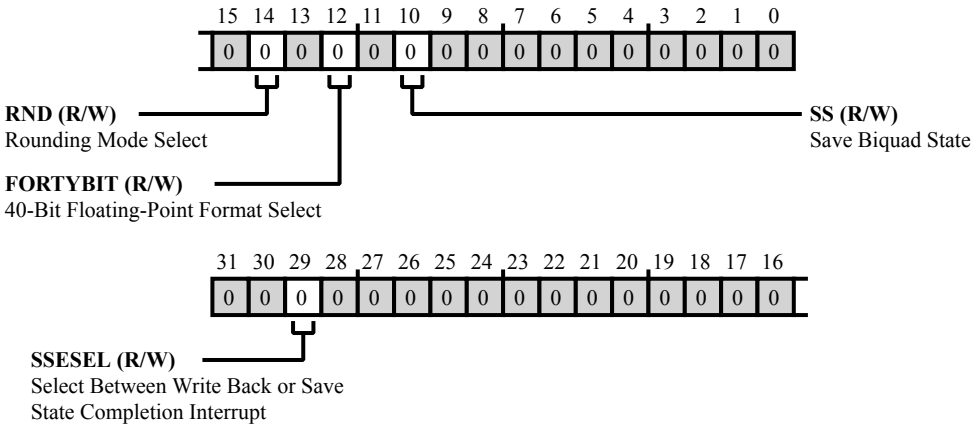

Figure 44-32: IIR_SGCTL Register Diagram

Table 44-32: IIR_SGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SSESEL	Select Between Write Back or Save State Completion Interrupt.	
14 (R/W)	RND	Rounding Mode Select. The IIR_SGCTL.RND bit selects the rounding mode for a floating-point mode compatible with SHARC+.	
		0	Round to nearest (even)
		1	Truncate (Round towards zero)
12 (R/W)	FORTYBIT	40-Bit Floating-Point Format Select. The IIR_SGCTL.FORTYBIT bit selects the floating point format.	
		0	32-bit floating point
		1	40-bit floating point
10 (R/W)	SS	Save Biquad State. The IIR_SGCTL.SS bit configures the accelerator to store the Dk register settings into the internal memory. This can be used to save the biquad states before switching to another high priority accelerator task.	

45 Boot ROM and Booting the Processor

Bootstrapping or booting is the series of events that occur when the system applies power to the processor or when the processor enters a hardware reset state. This section gives an in-depth description of these events and how to integrate an application effectively.

On reset, the processor begins fetching instruction from an internal ROM. The boot code contained within the ROM is designed to facilitate loading an application. The boot code can automatically initialize certain peripherals for communication based on a chosen boot mode, then load an application. For more information on what boot modes are available, see the Boot Modes section. The boot code can efficiently load an entire application, code, and data, into appropriate locations after the development tools repackage the application into a boot stream.

A boot stream is an application or data that the boot-loader tool splits into blocks. A 16-byte header in each block provides instruction to the boot code for processing the associated data. The processor can perform several boot functions, depending on the flags set in the header. For more details on what options are available and a description of the stream format, refer to the Boot Loader Stream section.

The boot ROM provides a mechanism through available non-volatile programmable memory (OTP on this processor) to customize different aspects of the boot process. These customizations include: overriding default boot-peripheral instance, overriding default peripheral-timing parameters and disabling boot modes.

NOTE: In this chapter the term boot ROM describes the boot code that cannot be altered. The terms *program* and *application* are used to describe code that is used to customize the boot process.

Several utilities of the boot code are also available to the application. These utilities include features such as copying memory, comparing memory, or loading another boot stream at run time. The APIs may be used to help ensure that application code is more compatible with future products. The boot code also provides the ability to define a custom boot mode. This capability helps when support is not available for a desired boot mode. It allows second stage boot loaders for unsupported boot peripherals to leverage a significant amount of the existing boot ROM functionality.

SRAM Requirements

The boot process reserves 8K bytes of L2 ECC Protected SRAM for dedicated use. This topic describes how the reserved memory region is used during boot.

The boot process requires SRAM resources for stack use and to store various data items that require read/write access during the boot process. 8K bytes of L2 ECC protected SRAM is reserved for this purpose. The ***Boot Process SRAM Requirements*** table describes the various items stored in this memory region.

Table 45-1: Boot Process SRAM Requirements

Address	Size (Bytes)	Item	Description
0x201FE000	4	Reserved	
0x201FE004	4	Pointer to the struct ADI_ROM_BOOT_CONFIG object	Pointer to the boot configuration structure that is located on the stack. This location is used to find the location of the boot structure on the stack for debug.
0x201FE008	8	Reserved	
0x201FE010	1024	Internal Intermediate Buffer 0	The first of two internal buffers used for intermediate storage of boot content when using indirect and page mode accesses and for secure boot operations. Two buffers are used to allow SHA-224 and AES-128 operations to be performed on one buffer while simultaneously loading the other buffer.
0x201FE410	1024	Internal Intermediate Buffer 1	The second of two internal buffers used for intermediate storage of boot content when using indirect and page mode accesses and for secure boot operations. Two buffers are used to allow SHA-224 and AES-128 operations to be performed on one buffer while simultaneously loading the other buffer.
0x201FE810	16	struct ADI_ROM_BOOT_HEADER object	Storage location for all the block headers of the boot stream.
0x201FE820	2912	Storage for Secure Boot related descriptors	Contains a number of buffers for the various descriptors used by the Cryptographic Accelerators and provides storage for the secure header of a secure boot stream.
0x201FF400	3072	Stack for the boot process	The primary booting cores stack. The processor core should locate the stack in this region in order to preserve security in secure boot operations.

NOTE: To preserve the security of the product, the 8K byte region described here is not a bootable region of memory. If the boot process determines that a block of data in the boot stream is targeted towards this memory region, the boot process terminates and enters either the default error handler or, if applicable, a user-defined error handler. This reserved memory region is free for use after the boot process completes. In order to preserve security when using the boot API to boot a secure boot stream, the stack used during the execution of the boot API must be located at the default location in this reserved 8K bytes region of memory.

Preboot Operations

Preboot is responsible for configuration of all system resources prior to executing the required boot operation.

The steps performed by the preboot process are described here in the order of execution. Numerous stages of the preboot process are conditional based upon the content of the `RCU_BCODE` register.

NOTE: When a power on reset, hard reset, and software triggered system reset event completes, the processor operates in PLL Bypass mode (default). Partway through the preboot sequence the processor is brought into Full-On mode at the default settings unless the program has provisioned custom CGU settings in the OTP. The Oscillator Watchdog fault, enabled by default when reset completes, is disabled at this stage unless Oscillator Watchdogs settings are also supplied.

Start-up Sequence

This section describes the initial start-up sequence of all cores in the processor.

Upon completion of a power-on reset, hardware reset, or system reset event, only a single core is released from reset. It is responsible for managing the boot process. The following sections describe in detail the sequence of events that occur for each of the cores on the various product derivatives.

Core Reset Sequencing

System and hardware reset events result in the processor state being reset and the boot sequence is executed. Only a single core is initially released from reset and starts execution of the preboot software from the boot ROM. The sequencing between the RCU and the various cores is shown for each of the product derivatives.

For the ADSP-SC59x derivatives, core 0 is responsible for controlling the boot process. Cores 1 and 2 are held in reset until core 0 releases them from reset during the preboot phase of the boot process.

The initial sequence of events after the completion of the reset sequence are shown below.

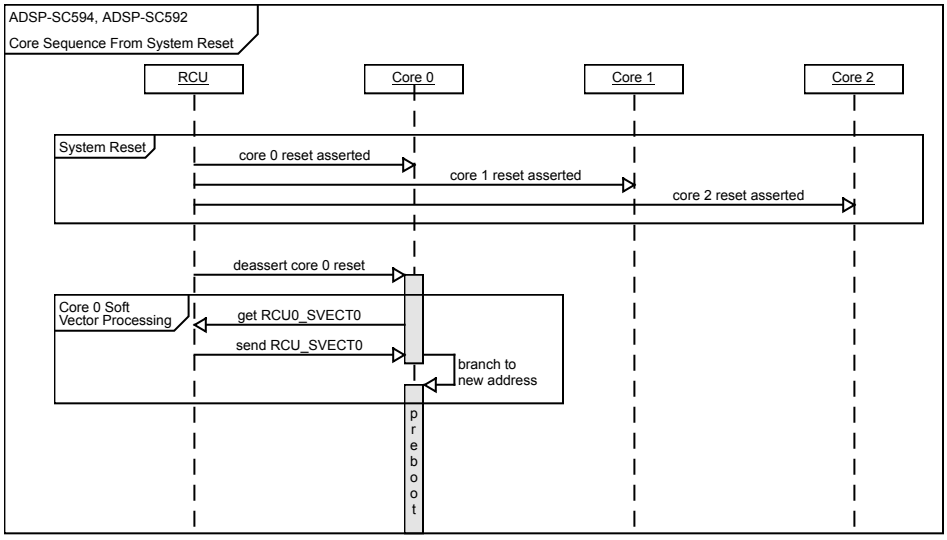

Figure 45-1: Core Reset Sequencing - ADSP-SC59x

The ADSP-2159x derivative contains two cores with IDs of 1 and 2. In this device, core 1 is responsible for controlling the boot process; core 2 is held in reset until released by core 1 during the preboot phase of the boot process. The initial sequence of events after the completion of the reset sequence are shown.

Core 0 Start-up

Describes the initial operations performed by the core 0 immediately after being released from reset and soft vector processing has completed. This topic is only applicable to the ADSP-SC59x processors.

Upon initial release from reset, the soft vectoring process results in core 0 executing the boot process as long as the RCU_SVECT0 register contained the default reset value during the soft vector processing.

The core performs the following initial operations:

- Clear RCU_MSG.C0IDLE
- Check for OTPC boot completion
- Disable MMU
- Disable instruction and data caches
- Invalidate the TLB
- Read RCU_STAT register and store locally in register set
- Install Faults
- Configure L2 controller
- Initiate hardware controlled L2 memory initialization sequence
- Enter IRQ mode and configure the stack pointer
- Enter FIQ mode and configure the stack pointer
- Enter ABT mode and configure the stack pointer
- Enter UND mode and configure the stack pointer
- Enter SVC mode and configure the stack pointer

Core 1 Start-up

Describes the initial operations performed by the core 1 immediately after being released from reset and soft vector processing has completed.

Upon initial release from reset, the soft vectoring process results in core 1 executing from the boot ROM as long as the RCU_SVECT1 register contained the default reset value during the soft vector processing. The operations the core performs varies depending on the product.

ADSP-SC59x Processors - Core 1 is not responsible for the booting of the processor from reset and thus enters a safe IDLE state allowing access to the cores L1 resources by any other core.

The core performs the following initial operations:

- Clear RCU_MSG.C1IDLE
- Check for OTPC boot completion.

- Disable Software Return feature in the BTB.
- Disable the BTB.
- Disable cache via MODE2 register.
- Flush the cache.
- Set IRPTL to 0x00000000.
- Set RCU_MSG.C1IDLE
- Enter an endless IDLE loop

ADSP-2159x Processors - Core 1 is responsible for controlling the boot process and the following actions are performed.

- Clear RCU_MSG.C0IDLE
- Check for OTPC boot completion.
- Disable Software Return feature in the BTB.
- Disable the BTB.
- Disable cache via MODE2 register.
- Flush the cache.
- Set IRPTL to 0x00000000.
- Configure primary and secondary DAG configurations to setup the C run-time environment.
- Clear the CBUFEN, SRD1H, SRD1L, SRD2H, SRD2L, ALUSAT, TRUNCATE bits in the MODE1 register.
- Set the IRPTEN, IPERREN, DPERREN, SPERREN bits in the MODE1 register.
- Read the RCU0_STAT register and store locally in the register set.
- Install the x.
- Configure L2 Controller
- Initiate hardware controlled L2 memory initialization sequence

Table 45-2: Primary/Secondary DAG Configuration for C Run-Time Setup

Primary/Secondary DAG Register	Value	Description
M7, M15	-1	Dedicated registers must always be set to -1
M6, M14	1	Dedicated registers must always be set to 1
M5, M13	0	Dedicated registers must always be set to 0

Table 45-2: Primary/Secondary DAG Configuration for C Run-Time Setup (Continued)

Primary/Secondary DAG Register	Value	Description
L0-L5	0	Preserved registers set initially to 0
L6, L7	0	Stack Length Register set initially to 0
L8-L15	0	Preserved registers set initially to 0
B6, B7	0x201FF400	Stack Base Registers
I7	0x201FFFFC	Stack Pointer
L6, L7	0x000002FF	Stack Length Registers
I6	0x201FFFFC	Frame Pointer

Core 2 Start-up

Describes the initial operations performed by core 2 immediately after being released from reset and soft vector processing has completed.

Upon initial release from reset the soft vectoring process results in core 2 executing from the boot ROM as long as the `RCU_SVECT2` register contained the default reset value during the soft vector processing. The operations the core performs varies depending on the product.

In the *ADSP-SC59x Processors*, core 1 is not responsible for the booting of the processor from reset and thus enters a safe IDLE state allowing access to the cores L1 resources by any other core. Core 2 has no entry point into the main boot rom to execute the preboot process or controller boot process from reset of the device.

From reset, core 2 can perform the following operations:

- Clear `RCU_MSG.C2IDLE`
- Check for OTPC boot completion.
- Disable Software Return feature in the BTB.
- Disable the BTB.
- Disable cache via `MODE2` register.
- Flush the cache.
- Set `IRPTL` to 0x00000000.
- Set `RCU_MSG.C2IDLE`
- Enter an endless IDLE loop

Fault Configuration

Describes the initial fault sources that are enabled allowing the processor to signal a fault to the system.

The following faults are enabled via the SEC. Only the faults are enabled, the boot process does not install any SEC interrupts.

Table 45-3: Initial Faults installed during Preboot

SEC Fault ID	SEC Fault Name	Description
0	INTR_SEC0_ERR	SEC Error
3	INTR_WDOG0_EXP	WDOG Expire
4	INTR_WDOG1_EXP	WDOG Expire
6	INTR_OTPC0_ERR	OTPC Expire
10	INTR_L2CTL0_ECC_ERR	L2 ECC Error
76	INTR_SOFT3_INT	Software Driven Interrupt 3. This is raised in the boot ROM error handler should it be entered.
190	INTR_CRC0_ERR	CRC Error
191	INTR_CRC1_ERR	CRC Error
194	INTR_MDMA1_SRC_ERR	MDMA 1 Source DMA Channel Error
195	INTR_MDMA1_DST_ERR	MDMA 1 Destination DMA Channel Error

The SEC is configured for a fault delay of 0x100 via the SEC_FDLY.COUNT and SEC_FSRDLY.COUNT bit fields. This allows for a delay before the fault assertion is a custom error handler is installed and any SEC interrupts are enabled and handled for more advanced second stage boot scenarios.

The SYSFAULT pin is configured via the SEC to support both incoming and outgoing faults by enabling the SEC_FCTL.FIEN and SEC_FCTL.FOEN bits. The boot process captures an incoming fault if that fault is asserted by the external system on handover to the user application after boot.

NOTE: The installation of the fault sources is enabled by default and may be optionally bypassed using the RCU_BCODE.NOFAULTS bit.

NOTE: In the ADSP-SC594, ADSP-SC592 and ADSP-21594 processors the SYSFAULT pin is dedicated. However, in the ADSP-21593 and ADSP-21591 processors, the SYSFAULT appears on the PC_07 in pin mux. For specific boot modes in the ADSP-21593 and ADSP-21591 processors, the SYSFAULT pin is not available for fault indication due to this pin being used by the booting peripheral.

L2 Controller Configuration

The L2 controller is configured to ensure all L2 memory banks are ECC enabled and that the L2 memory scrub feature is disabled.

NOTE: The L2 Controller configuration is enabled by default and may be optionally bypassed by setting the RCU_BCODE.NOL2CONFIG bit.

L2 Memory Initialization

The L2 memory subsytem is ECC protected by default. The L2 memory must be initialized to ensure that no read from the L2 memory generates an ECC error. All L2 memory banks are initialized using the L2CTL_INIT bit. The boot process waits for each memory bank to signal initialization complete using the L2CTL_ISTAT bit. The RCU_MSG.L2INIT is set when L2 memory initialization is complete.

NOTE: The L2 memory initialization process is enabled by default and may be optionally bypassed by setting the RCU_BCODE.NOMEMINIT bit.

Idle On Entry

The Idle On Entry feature instructs the debugger to halt the boot code before continuing with any further preboot operations.

When this feature is enabled the processor executes a WFI/IDLE instruction and then continues once an event (such as an emulator exception) is serviced.

NOTE: Idle On Entry processing is disabled by default and is enabled by setting the RCU_BCODE.IDLEONENTRY bit prior to performing a system reset operation.

SPU Configuration

The SPU is configured differently depending upon the detected security state of the device. The first operation clears any existing security violations that may be indicated in the SPU_STAT register.

None of the peripherals are configured to ignore security signals and only the following controllers are configured to generate secure transactions.

Table 45-4: SPU Secure Controllers during Boot

SPU Endpoint ID	Controller Name
146	MDMA0 Source DMA Channel
147	MDMA0 Destination DMA Channel
148	MDMA1 Source DMA Channel
149	MDMA1 Destination DMA channel
144	CRC0
145	CRC1
175	PKTE

SMPU Configuration

The SMPU is used to restrict access to various memory regions in the processor. The configuration applied during boot differs depending on the locked state of the processor.

By default the SMPU instances only allow secure read and write transactions. The ***SMPU Configuration*** table describes the configurations for the different security states.

Speculative reads are also disabled by setting the SMPU_CTL.RSDIS bit.

Table 45-5: SMPU Configuration

SMPU Instance	SMPU Instance	Open SMPU_SECURECTL Value	Locked SMPU_SECURECTL Value
Core_L2_RAM_Boot_ROM0	2	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
DMA_L2_RAM_Boot_ROM0	3	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
DMC	9	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
SPI	11	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
Core_L2_ROM1_Boot_ROM1	4	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
Core_L2_ROM2_Boot_ROM2	6	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)
DMA_L2_ROM1_Boot_ROM1	5	SMPU_SECURECTL.WNSEN | SMPU_SECURECTL.RNSEN	0x00000000 (Default Reset Value)

Secure Debug Key Processing

In the event the processor is locked, the debug tools must submit a secure debug key that is matched with a key on the processor. A 128-bit Secure Debug Key must be provided the application program prior to locking the device.

The secure debug key is read from the OTP memory and then written to the corresponding register in the TAPC. After the key has been written the TAPC_SDBGKEY_CTL.VALID bit is set. Once the debug tools then submit their key a key compare operation is performed.

Debug tools must wait for the boot software to load the key before setting the TAPC_SDBGKEY_CTL.VALID bit before submitting the key for comparison.

The 128-bit Secure Debug Key is loaded as follows from the storage area in OTP.

Table 45-6: Secure Debug Key Load Procedure

Secure Debug Key[127:0]	Register
Secure Debug Key[31:0]	TAPC_SDBGKEY0
Secure Debug Key[63:32]	TAPC_SDBGKEY1
Secure Debug Key[95:94]	TAPC_SDBGKEY2
Secure Debug Key[127:96]	TAPC_SDBGKEY3

NOTE: In the ADSP-SC59x processor family, the boot ROM supports two 128-bit secure debug keys, secure_emu_key0 and secure_emu_key1, where only one of them is used by the boot ROM at a time. Each of the secure debug keys is associated with a bypass key(emu_key0_disable or emu_key1_disable) which

decides the validity of the corresponding key. Any non zero value written into the 16-bit bypass key will invalidate that particular secure debug key.

The validity of the secure debug keys can be determined as shown in the ***Secure Debug Key Validation*** table:

Table 45-7: Secure Debug Key Validation

Bypass Key 0 (emu_key0_disable) Value	Bypass Key 1 (emu_key1_disable) Value	Valid Secure Debug Key
Zero	Zero	secure_emu_key0
Zero	Non-zero	secure_emu_key0
Non-zero	Zero	secure_emu_key1
Non-zero	Non-zero	Both keys are valid

CAUTION: The boot code bypasses the key load operation entirely when a 16-bit non-zero value is programmed on both `emu_key0_disable` and `emu_key1_disable` fields in OTP *or* a key of 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF is programmed in both of the secure debug key fields provided in OTP. When debug access is subequently needed, the program must load the key to the TAPC. If the processor fails to boot (due to corrupted firmware) then there is no debug access. The only way to gain access is to load an authenticated boot image that can then load the required keys prior to attempting to connect with a debugger.

CGU Configuration

This step in the preboot process reconfigures the internal clocks on the processor for improved boot performance.

The boot process can optionally configure the CGU in order to improve boot performance. The settings for the CGU are located within the `struct ADI_ROM_OTP_BOOT_CGU_INFO` structure that has storage allocated in the OTP as part of the struct ADI_ROM_OTP_BOOT_INFO structure.

Typically, CGU configuration is performed using an Init Block in the boot stream. This provides greatest flexibility. In situations where boot time must be kept to a minimum, settings in the OTP can be applied at this stage of pre-boot as opposed to during the boot process itself. When a processor is locked, the boot process does not support an Init Block in the boot stream. For a locked processor programs must use the OTP to reconfigure the clocks without adopting a multi-stage boot strategy.

On release from reset, the CGU is configured for PLL Bypass mode. To improve boot performance, the boot software reconfigures the CGU so that Full-On mode is entered with the default CGU settings.

If the program doesn't provide settings in OTP to configure the Oscillator Watchdog, then the Oscillator Watchdog fault, enabled by default after reset, is disabled prior to reconfiguring the CGU.

If settings are provided in the OTP to configure the Oscillator Watchdog, the fault is left enabled and, if applicable, the CGU is configured per the provided settings. The remainder of the boot process completes in Full-On mode.

The CGU configuration object (see struct ADI_ROM_OTP_BOOT_CGU_INFO) allows the boot software to configure the CGU for a more efficient boot process.

Table 45-8: ADI_ROM_OTP_BOOT_CGU_INFO Members

Type	Name	Description
uint32_t	ctl_WEN:1 (bitfield)	Enable write to the CGU_CTL register
uint32_t	div_WEN:1 (bitfield)	Enable write to the CGU_DIV register
uint32_t	reserved0:1 (bitfield)	Reserved
uint32_t	div_DSEL:5 (bitfield)	CGU_DIV.DSEL value
uint32_t	div_CSEL:5 (bitfield)	CGU_DIV.CSEL value
uint32_t	div_S0SEL:3 (bitfield)	CGU_DIV.S0SEL value
uint32_t	div_SYSSEL:5 (bitfield)	CGU_DIV.SYSSEL value

uint32_t	oscwctl1_CNGEN:1 (bitfield)	CGU_OSCWDCTL.CNGEN value

Table 45-8: ADI_ROM_OTP_BOOT_CGU_INFO Members (Continued)

Type	Name	Description
uint32_t	oscwctl1_BOUF:5 (bitfield)	CGU_OSCWDCTL.BOUF value
uint32_t	oscwctl1_BOUEN:1 (bitfield)	CGU_OSCWDCTL.BOUEN value
uint32_t	oscwctl1_FAULTEN:1 (bitfield)	CGU_OSCWDCTL.FAULTEN value
uint32_t	oscwctl1_MONDIS:1 (bitfield)	CGU_OSCWDCTL.MONDIS value
uint32_t	oscwctl1_FAULTPINDIS:1 (bitfield)	CGU_OSCWDCTL.FAULTPINDIS value
uint32_t	Reserved4:14 (bitfield)	Reserved

If a CGU_STAT.WDIVERR, CGU_STAT.WDFMSERR, CGU_STAT.LWERR or CGU_STAT.ADDRERR occurs at the entry to or completion of the configuration routine, the default error handler is called and the boot process terminates.

NOTE: Programs can bypass CGU configuration by setting the RCU_BCODE.NOPREBOOT bit when this part of the boot process is reached.

Releasing All Cores from Reset

The control booting core releases all other cores from reset allowing them to then run by default into a safe endless loop state. By releasing all other cores from reset, any dedicated core L1 memories become accessible to all cores via the system address space. In order for one core to load or read data from dedicated L1 memory of another core, the core must be released from the reset state. By default, the other cores in the processor execute a safe endless loop in the boot ROM.

L1 Memory Initialization

The processor initializes all parity and ECC protected memories to perform subsequent read operations without generating an ECC or parity error.

The ***L1 Memory Initialization*** table describes the methods used to initialize the various parity and ECC supported memories on the processor.

Table 45-9: L1 Memory Initialization

Resource To Fill Memory	Memory Type	Address	Count	Fill Value	Flag Set Upon Completion
Core 1	Core 1 L1 Bank 0	0x00048000	0x6000 (LW)	0x00000000	RCU_MSG.C1L1INIT
Core 1	Core 1 L1 Bank 1	0x00058000	0x6000 (LW)	0x00000000	
Core 1	Core 1 L1 Bank 2	0x00060000	0x4000 (LW)	0x00000000	
Core 1	Core 1 L1 Bank 3	0x00070000	0x4000 (LW)	0x00000000	

Table 45-9: L1 Memory Initialization (Continued)

Resource To Fill Memory	Memory Type	Address	Count	Fill Value	Flag Set Upon Completion
Core 2	Core 2 L1 Bank 0	0x00048000	0x6000 (LW)	0x00000000	RCU_MSG.C2L1INIT
Core 2	Core 2 L1 Bank 1	0x00058000	0x6000 (LW)	0x00000000	
Core 2	Core 2 L1 Bank 2	0x00060000	0x4000 (LW)	0x00000000	
Core 2	Core 2 L1 Bank 3	0x00070000	0x4000 (LW)	0x00000000	

NOTE: The Memory Initialization process is enabled by default and may be optionally bypassed by setting the RCU_BCODE.NOMEMINIT bit.

Default Entry Point

The first instruction executed for the core in the boot ROM is a read of the RCU_SVECT0 register. The boot ROM then vectors to that location.

The ***Default Entry Point*** table defines the default entry point for each core in the processor

Table 45-10: Default Entry Point

Core ID	Register	Entry Point
0	RCU_SVECT0	0x00000000
1	RCU_SVECT1	0x00500004
2	RCU_SVECT2	0x00500004

The boot code does not set any initial default application entry points by writing the entry point to the RCU_SVECT0 register in the processor. It will hold the default values of the power on reset case. The RCU_SVECT0 register is updated at the end of the boot process. For the secure boot, the register is updated only after the successful authentication of the boot stream.

NO-BOOT Processing

No-Boot mode is executed when selected by the SYS_BMODE[n] pins. The boot mode is intended as a recovery boot mode or for debug purposes. The core simply executes in an endless loop in the boot ROM, terminating further execution of the boot process.

This boot mode is primarily intended for debug sessions when no boot source may be configured. It allows for a debugger to safely connect to the device and take control (assuming the debugger has been granted access rights as defined by the processor security implementation).

NOTE: NO-BOOT processing is usually only entered as a result of the boot mode pin sampling resulting in execution of the No-Boot boot mode. This processing can also be optionally enabled by setting RCU_BCODE.HALT field. The RCU_BCODE.HALT setting can be especially useful for debug sessions to force the execution of the NO-BOOT mode regardless of the SYS_BMODE[n] state allowing a user

application to be loaded via the debug tools without fear of the image being corrupted as a result of attempting to boot through another source.

SYS_RESOUT Signal

In order to signal to the external system that the processor is in a configured state and ready to start the boot process, the boot software de-asserts the `SYS_RESOUT` pin via the `RCU_CTL.RSTOUTDSRT` bit.

DMC Configuration

To boot to external DDR memories (to support booting to external memory when the processor is locked) the DMC must be configured.

Typically, DMC configuration is done using the Init Block in the boot stream. When the processor is locked the boot process does not support an Init Block in the boot stream. For a locked processor programs must use the OTP to configure the DMC without adopting a multi-stage boot strategy.

Table 45-62 ADI_ROM_OTP_DMC_CONFIG Members provides details of the OTP region that is used to store the DMC configuration. In the table, the `ADI_ROM_OTP_BOOT_CFG::dmcEn` must be set in order for the settings to apply.

Table 45-11: ADI_ROM_OTP_DMC_CONFIG Members

Type	Name	Description
uint32_t	ulDDR_DLLCTLCFG:16 (bit field)	Content of DMC CFG[15:0]
uint32_t	ulDDR_DLLCTLCFG:16 (bit field)	Content of DMC DLL CTL[15:0]
uint32_t	ulDDR_EMR2EMR3:16 (bit field)	Contents of DMC_EMR3 [15:0]
uint32_t	ulDDR_EMR2EMR3:16 (bit field)	Contents of DMC_EMR2 [15:0]
uint32_t	ulDDR_CTL	Content of DMC CTL[31:0]
uint32_t	ulDDR_MREMR1:16 (bit field)	Content of DMC EMR1[15:0]
uint32_t	ulDDR_MREMR1:16 (bit field)	Content of DMC MR[15:0]
uint32_t	ulDDR_TR0	Content of DMC_TR0[31:0]
uint32_t	ulDDR_TR1	Content of DMC_TR1[31:0]
uint32_t	ulDDR_TR2	Content of DMC_TR2[31:0]
uint32_t	ulDDR_ZQCTL0	Content of DMC PHY ZQCTL0[31:0]
uint32_t	ulDDR_ZQCTL1	Content of DMC PHY ZQCTL1[31:0]
uint32_t	ulDDR_ZQCTL2	Content of DMC PHY ZQCTL2[31:0]
uint32_t	ulDDRPHY_CACTL	Content of DMC PHY CA_CTL [31:0]
uint32_t	uBypassDelay_LANE0CTL1:6 (bit field)	Content of DMC LANE0_CTL1[15:10]
uint32_t	uBypassDelay_LANE1CTL1:6 (bit field)	Content of DMC LANE1_CTL1[15:10]

Table 45-11: ADI_ROM_OTP_DMC_CONFIG Members (Continued)

Type	Name	Description
uint32_t	uBypassDelay_LANE0CTL0:6 (bit field)	Content of DMC LANE0_CTL0[15:10]
uint32_t	uBypassDelay_LANE1CTL0:6 (bit field)	Content of DMC LANE1_CTL0[15:10]
uint32_t	reserved0:8 (bit field)	Reserved

There is an additional single bit located in OTP, `ADI_ROM_OTP_BOOT_CFG::dmcInv` allowing programs to invalidate the DMC settings stored in OTP.

NOTE: Once `ADI_ROM_OTP_BOOT_CFG::dmcInv` has been set in OTP there is no means to configure the DMC during the preboot phase.

The configuration of the DMC is bypassed if the `RCU_BCODE.NOPREBOOT` bit is set when this part of the boot process is reached.

Bypassing the Boot Process

The boot process can be bypassed allowing a program to start execution from the address stored in the core's soft vector register. This is useful when working in emulation sessions as it provides a mechanism to be able to execute programs directly from an accessible memory that already contains executable code.

To bypass the boot process, set the `RCU_BCODE.NOKERNEL` bit. The processor core vectors to the address stored in the core's corresponding `RCU_SVECT0` / `RCU_SVECT1`/ `RCU_SVECT2` register instead of calling the required boot mode.

This feature is used along with other features such as disabling memory initialization.

Boot Mode Disable

Specific boot modes can be permanently disabled via OTP. If the disabled boot mode is enabled using the `SYS_BMODE[n]` pins, a boot error is generated.

A byte of storage is provided in the OTP to disable up to eight boot modes. The boot mode disable field can be programmed using the `adi_rom_otp_pgm()` routine. The `otp_data::bootModeDisable` member is used in the program operation to disable the various boot modes.

Table 45-12: Boot Mode Disable

`otp_data::bootModeDisable` Bit Position	Corresponding Boot Mode
0	SPI Controller Boot Mode
1	SPI Target Boot Mode
2	UART Target Boot Mode
3	Linkport Target Boot Mode

Table 45-12: Boot Mode Disable (Continued)

`otp_data::bootModeDisable` Bit Position	Corresponding Boot Mode
4	OSPI Controller Boot Mode
7–5	Reserved

Boot Command Customization

Boot command customization allows permanent customization of a particular boot mode. For example, it is possible to change the peripheral instance used for boot operation.

Storage is provided in OTP for a command item for each supported boot mode.

Storage is provided in the `struct ADI_ROM_OTP_BOOT_CMD_INFO` member of `struct ADI_ROM_OTP_BOOT_INFO`. Refer to the corresponding boot modes boot command description for details on supported command options.

NOTE: Before programming boot command to the OTP, evaluate the boot command using the adi_rom_Boot() API and ensure that the boot command provides the desired functionality. Once the command is programmed to OTP, it cannot be reverted to original default settings.

Boot Mode Specific SPU Configuration

Prior to performing actual boot process, the processors SPU resources specific to the boot mode selected are configured. This is performed in the preboot phase as opposed to within the boot mode itself when calling the boot API, as it isolates the security functionality of the processor allowing it to be handled specifically by a separate process.

The following additional SPU resources are configured as secure controllers according to the boot mode selected.

Table 45-13: Boot Mode Specific SPU Configuration

Boot Mode	SPU Endpoint ID	Controller Name
SPI Controller Boot (Memory-Mapped Mode) and OSPI Controller Boot	146, 147	MDMA0 Source DMA Channel, MDMA0 Destination DMA Channel
SPI Controller Boot (Peripheral Mode)	100, 98, 96, 94	SPI3 Receive DMA, SPI2 Receive DMA, SPI1 Receive DMA, SPI0 Receive DMA
SPI Target Boot	100, 98, 96, 94	SPI3 Receive DMA, SPI2 Receive DMA, SPI1 Receive DMA, SPI0 Receive DMA
UART Target Boot	79, 81, 83, 85	UART 0 Receive DMA, UART1 Receive DMA, UART2 Receive DMA, UART3 Receive DMA
LINKPORT Target Boot	5, 6	LINKPORT 0 DMA, LINKPORT 1 DMA

NOTE: In the ***Boot Mode Specific SPU Configuration*** table, for a given boot mode, all the SPU resources are not configured. Only a single peripheral instance is enabled according the peripheral instance selected for boot.

For example if the boot command for the boot mode indicates boot from UART0 only the UART0 Receive DMA is configured, the other UART Receive DMAs are not configured for secure access.

Executing the Boot Mode

The boot mode is called adi_rom_Boot() routine. The routine fetches and processes the boot stream from the configured boot source.

The table provides default parameters passed to each of the supported boot modes. For details on the API usage, refer to adi_rom_Boot().

Table 45-14: Default Boot ROM API Parameters

Boot Mode	pAddress	flags	blockCount	pHook	Command
No Boot	0x00000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000000
SPI Controller Boot	0x60000000	0x00040000	0x00000000	Points to an empty routine in ROM	0x00000207
SPI Target Boot	0x00000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000212
UART Target Boot	0x00000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000013
LINKPORT Target Boot	0x00000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000014
OSPI Controller Boot	0x60000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000008
Reserved	0x00000000	0x00000000	0x00000000	Points to an empty routine in ROM	0x00000000

The hook function installed via pHook on this product does not perform any additional configuration.

NOTE: For SPI controller boot and OSPI controller boot modes, start address (pAddress) is set to 0x60000000, This corresponds to the first memory location in the respective flash device (0x0).

Boot Modes

The boot implementation provides built-in support for booting from various peripherals.

The ***Booting Modes*** table describes the supported boot modes.

In target boot mode, the processor functions as a target to any host device. In these modes, the host device usually controls the processor SYS_HWRST input. Typically, the host applies the reset sequence and waits until the processor is ready to boot, depending on the peripheral in use, and transmits the boot stream data to the processor. Handshake signals are used to signal to the host that the processor is ready to accept more data.

In controller boot mode, the processor controls the peripheral and requests data via the peripheral as and when required.

Individual boot modes can be disabled. For more information about disabling boot modes, see Boot ROM OTP Customizations.

Table 45-15: Booting Modes

SYS_BMODE[2:0]	Boot Source	Description
000	No Boot	The processor does not boot. Rather the boot kernel executes some of the preboot operations then enters an endless `WFI/IDLE` state.
001	SPI Controller Boot	Boot from integrated Flash memory through the SPI2 peripheral configured for memory-mapped mode.
010	SPI Target Boot	Boot through the SPI2 peripheral configured as a target.
011	UART Boot	Boots through UART0 configured as a target receiver.
100	LINKPORT Boot	Boot through LINKPORT0 peripheral configured as a target receiver. This boot mode is only applicable to derivatives supporting the LP0 instance.
101	OSPI Controller Boot	Boot from integrated Flash memory through the OSPI peripheral configured for memory-mapped mode.
110, 111	Reserved	

No-Boot Mode

No-Boot mode is intended for device recovery purposes caused due to incorrect programming of the boot source memory allowing for target connection through an emulator. Emulation tools can also leverage the No-Boot functionality allowing for debug sessions to run the preboot software prior to loading an application while preventing the boot process from continuing and clobbering data loaded by the emulator.

This boot mode results in several preboot operations being performed before placing the core in a safe, endless loop located in the boot ROM.

For a complete list of operations performed when No-Boot is selected, see Preboot Operations. The core terminates at the NO-BOOT Processing stage of the preboot process.

SPI Master Boot Mode

The SPI master boot routine provides support for booting the processor from SPI flash memories. The SPI boot mode uses a device auto-detection feature that is enabled by default. This lets the boot stream itself instruct updates to the SPI configuration and the read command used allowing for more efficient transactions.

NOTE: For default SPI master mode, the peripheral fault, SPI2_ERR with fault ID 132 is enabled.

Boot From External SPI Flash Devices

The SPI boot mode supports booting from 24-bit or 32-bit addressable flash devices. The boot mode uses the MDMA channels by default and configures the SPI flash for memory-mapped functionality. Peripheral DMA mode is also supported when calling the boot mode via `adi_rom_Boot()`.

When auto-device detection is enabled, the SPI memory is initially read using the standard 0x03 SPI read command with a reduced clocking frequency for maximum compatibility. The first nibble of the boot stream is then used to reconfigure the SPI interface and possible the SPI flash. Refer to SPI Device Detection Routine.

NOTE: Support for automatic device detection via the first nibble of the boot stream is not supported when booting secure boot streams. Instead when signing the boot image an attribute can be set in the image header that specifies the configuration to use.

For booting, the SPI memory is connected as shown in the ***SPI Memory Connections*** figure.

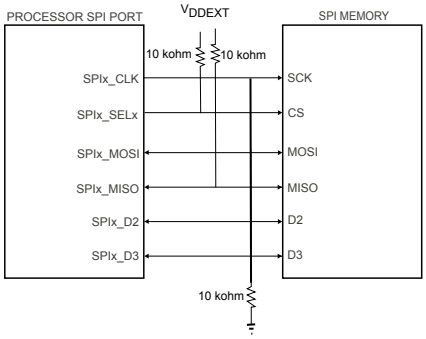

Figure 45-2: SPI Memory Connections

The pull-up resistor on the slave select signal ensures that the memory is deselected when the pin is in a high-impedance mode such as during reset.

Initialization codes are allowed to manipulate the `ADI_ROM_BOOT_CONFIG::dBootCommand` to extend boot mechanism to a second SPI memory connected to another slave select pin. Updating the field that specifies the slave select signal for use, allows the boot process to manage larger boot streams than fit into a single SPI device.

NOTE: If modifying the slave select signal used during the boot process, configure the pin multiplexing to enable the correct functionality for the pin. Once the boot process has proceeded past the configuration function and the boot process has actually started, the boot kernel will not perform any further pin multiplexing operations.

SPI Device Detection Routine

Since the boot mode supports booting from various SPI memories, the boot kernel automatically detects what type of memory is connected. To determine whether the SPI memory device requires a 24-bit or 32-bit addressing scheme, the boot kernel performs a device detection sequence prior to booting. The `SPI_MISO` signal requires a pull-up resistor. The routine relies on the fact that memories do not drive their data outputs unless the right number of address bytes are received.

Initially, the boot kernel transmits the read command on the SPI_MOSI line. Once the command has been sent, the boot kernel proceeds to transmit a single address byte and waits until the receive FIFO indicates that the buffer is no longer empty. The first received byte is discarded. The boot code then proceeds to issue another address byte while simultaneously receiving a byte. The process continues until a non 0xFF or 0x00 byte is received or until the full 4 address bytes is sent without any valid data being returned.

The receiving of a non 0x00 or 0xFF byte tells the boot code whether the memory device requires 24 or 32 address bits. The lower nibble of the received byte is then used to further customize the boot mode. This nibble is referred to as the BCODE. The boot code applies settings to the SPI peripheral according to the ***SPI Master Boot BCODE Descriptions***.

If the received value equals 0x00 or 0xFF, it is assumed that the memory device has not driven its data output thus, another zero byte is transmitted and the received data is tested again.

If the value still equals 0xFF, device detection continues. Device detection aborts immediately when a byte different than 0xFF is received. The boot process continues with normal boot operation and it reissues a command to again read from address 0. Two read sequences load the first block header. Separate read sequences load further block headers and block payload fields.

The ***SPI Device Detection Principle*** figure illustrates how individual devices behave.

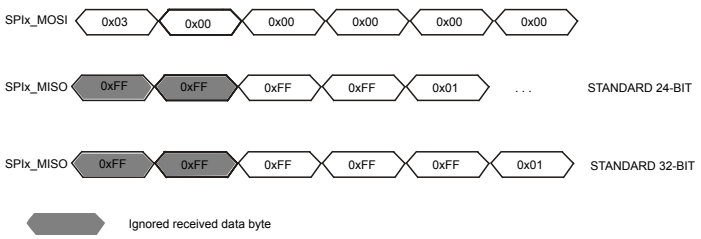

Figure 45-3: SPI Device Detection Principle

nDummy	0x00	0x00	0x00	0x00	0x00	0x00

NOTE: For the above configurations, the addressing scheme can be 3-bytes or 4-bytes depending on the addressing of flash detected in auto-detection. The SPI mode byte issued for all the SPI master peripheral based configurations is 0x00. The mode byte is the first byte transmitted after the address cycles and is used to control the continuous read mode functionality in which the next read operation is not required to issue a command cycle. Continuous read mode is not supported during the boot process.

Supported Quad Mode Enable Methods

The boot ROM does not support enabling quad mode on the SPI flash device. To boot in quad mode, the flash device must be configured outside the boot ROM.

NOTE: It is more beneficial to boot initially in dualmode and use an initcode to enable Quad mode.

Run-Time API

The following table provides descriptions of the adi_rom_Boot() command parameter.

Table 45-18: SPI Master Boot Command Descriptions

Bits	Name	Setting	Description
31:28	ROM_BCMD_SPIM_SPEED	0 to 1111	SPI clock divider. This value written to the SPI peripherals clock divider register
27	Reserved	Reserved	Reserved
26:22	ROM_BCMD_SPIM_DUM-MY	00000	No dummy bytes required after the address
		00001	1 dummy byte required after the address
		....	.....
		11111	31 dummy bytes required after the address
21:20	ROM_BCMD_SPIM_ADDR	00	Flash device requires an 8-bit address
		01	Flash device requires a 16-bit address
		10	Flash device requires a 24-bit address
		11	Flash device requires a 32-bit address
19:16	ROM_BCMD_SPIM_BCODE	0000 to 1111	Boot mode-specific code. Specifies the boot mode-specific code that can further customize and control the boot process.
15	ROM_BCMD_SPIM_CMD	0	Issue the read command over the single bit bus
		1	Issue the read command over the multi-bit bus. Not recommended for use in ADSP-2159x processor.
14:12	ROM_BCMD_SPIM_SSEL	000	Use slave select 1 for SPI chip select
		001	Use slave select 2 for SPI chip select

Table 45-18: SPI Master Boot Command Descriptions (Continued)

Bits	Name	Setting	Description
		010	Use slave select 3 for SPI chip select
		011	Reserved
		100	Reserved

Table 45-18: SPI Master Boot Command Descriptions (Continued)

Bits	Name	Setting	Description
		1000 to 1111	Reserved

NOTE: All bits in the above table that are not defined must be set to zero. Supported features may be limited depending on peripheral instance.

NOTE: SPI master secure boot is only supported in memory mapped mode. SPI2 is the default SPI instance that operates in memory mapped mode. To boot from an SPI instance other than SPI2, ensure that the desired SPI instance supports memory-mapped mode. The ROM_BCMD_SPIM_DEVICE field in the SPI master boot command parameter must be set to 0x7 in OTP or passed as an argument in the ROM API call.

SPI Slave Boot Mode

When using SPI slave mode boot, the processor consumes boot data from an external SPI host device. This mode supports single, dual, and quad-bit modes. The boot kernel always starts in single bit mode and can be changed using the appropriate command. The following figures show the hardware configuration for the modes. As in all slave boot modes, the host device controls the `SYS_HWRST` input of the processor.

NOTE: *Secure Boot Stream Padding*

For slave boot modes, the host must always send data in multiples of 1024 bytes. This requirement is due to the sizing of internal buffers used for DMA.

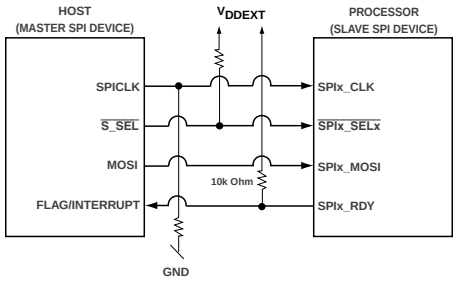

Figure 45-4: Connection between Host (SPI Master) and Processor (SPI Slave)

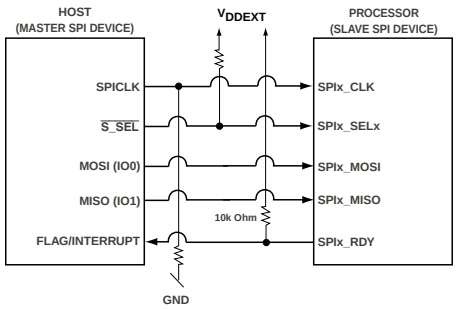

Figure 45-5: Connection between Host (SPI Master) and Processor (SPI Slave) DIOM

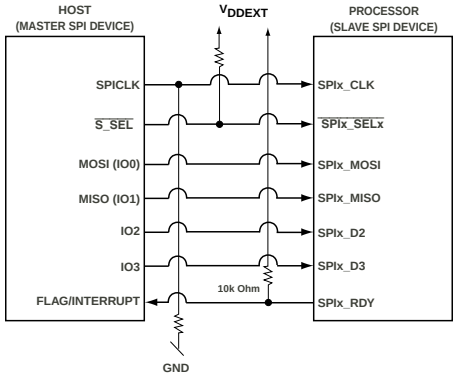

Figure 45-6: Connection between Host (SPI Master) and Processor (SPI Slave) QSPI

The host drives the SPI clock and is responsible for timing. The host must provide an active-low chip select signal that connects to the processor's SPIx_SS input signal with each byte transferred or remain low during the entire procedure. 8-bit data is expected and 16-bit mode is not supported.

In SPI slave boot mode, the boot kernel sets the SPI_CTL.CPHA bit and clears the SPI_CTL.CPOL bit. Therefore the SPI_MISO pin is latched on the falling edge of the SPI_MOSI pin.

The SPI slave processor detects the correct boot mode from the host SPI device by reading the first byte sent, defined as SPICMD. The ***SPICMD Descriptions*** table describes the available codes. These additional bytes must be sent prior to transmitting the data to configure the SPI device.

The ***SPICMD Descriptions*** table describes the following:

- Host starting in single bit mode
- Host starting in a mode other than single bit

Table 45-19: SPICMD Descriptions

SPICMD	Description
If host starts in Single bit Mode	
0x3	Keep single-bit mode
0x7	Switch to dual-bit mode
0xB	Switch to quad-bit mode
If host device starts in DIOM or QSPI	
0xAA,0xBF	Switch to dual-bit mode
0xEE,0xEE,0xFE,0xFF	Switch to quad-bit mode

In SPI slave boot mode, SPIx_RDY functionality is critical. The SPIx_RDY output is used for back pressure and requires a pulling resistor. The boot code requires the SPIx_RDY signal function as active-low. The host is only permitted to transfer data when SPIx_RDY is in the active state. This functionality allows the processor to hold off the host while the processor is in reset or executing the pre-boot and processor initialization sequences. The SPI is configured to deassert SPIx_RDY when the receive FIFO is filled to 75% or more.

NOTE: For default SPI slave mode, the peripheral fault, SPI2_ERR with Fault ID 132 is enabled.

The ***SPI Program Flow on the Host Side*** figure illustrates the required program flow on the host side.

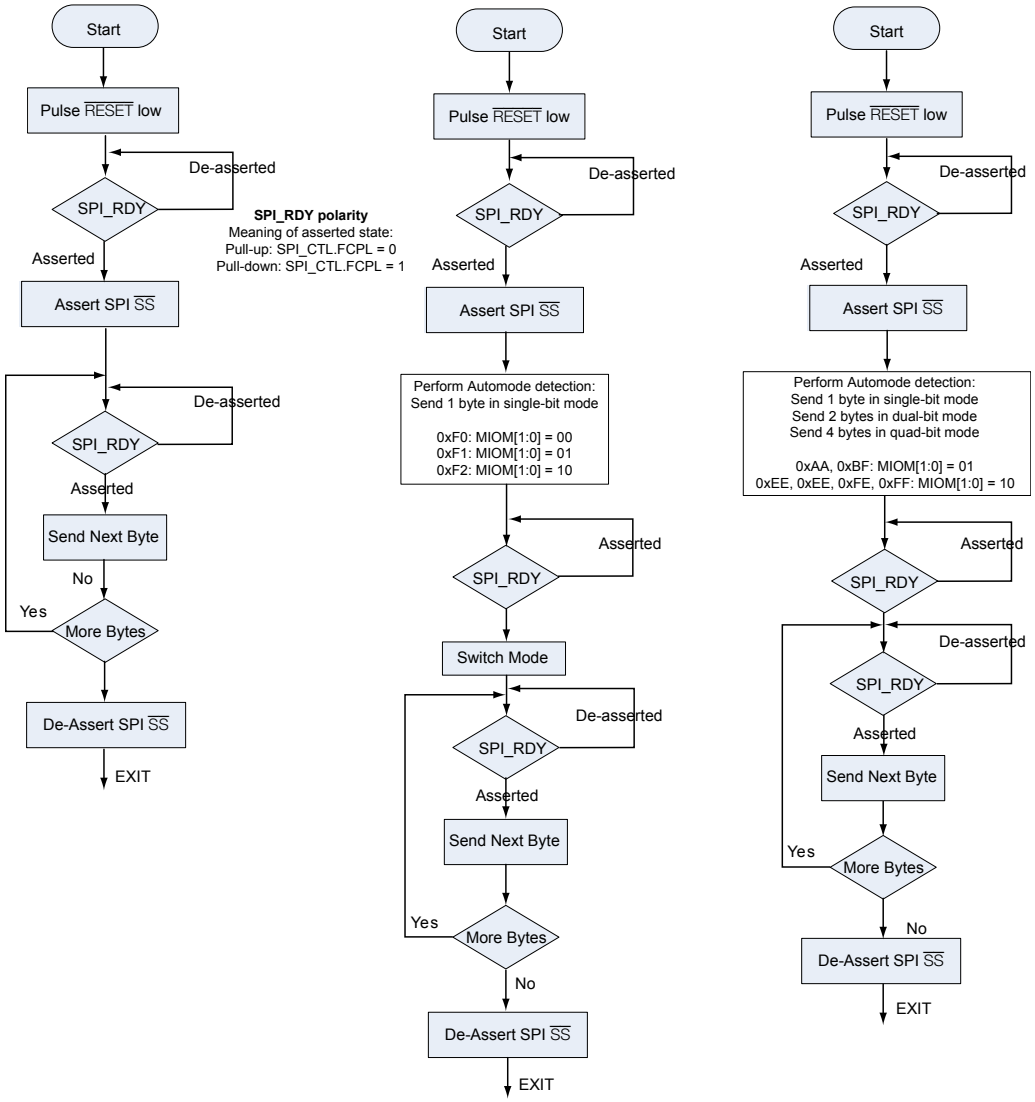

Figure 45-7: SPI Program Flow on the Host Side

Run-time API

The SPI slave boot mode can be called through the Boot Routine API function at run-time. Initiating a boot through the run-time API allows for extra customization such as disabling automatic device configuration or specifying a different SPI device other than the default.

When `ROM_BCMD_NOCFG` flag is specified, it is necessary to program pin multiplexing and other SPI configuration as required, while keeping the `SPI_CTL.EN` bit cleared.

The `ROM_BCMD_NOAUTO` flag can suppress auto mode detection. In that case, the desired configuration must be passed through the `ROM_BCMD_SPIS_BCODE` bit field, even if the `ROM_BCMD_NOCFG` flag is set.

The following table provides descriptions of the `adi_rom_Boot` parameter.

Table 45-20: SPI Slave Boot Command Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16	ROM_BCMD_SPIS_BCODE	Boot Mode Specific BCODE. Specifies the boot mode-specific code that can further customize and control the boot process.	
		00xxb	Single bit SPI bus
		01xxb	Dual SPI bus
		10xxb	Quad SPI bus
		11xxb	Reserved
11:8	ROM_BCMD_DEVENUM	Device enumeration. Specifies the SPI device to use.	
		0x0	SPI0
		0x1	SPI1
		0x2	SPI2
		0x3	SPI3
		0x4 - 0xF	Reserved
6	ROM_BCMD_NOAUTO	Automatic device detection disable. When set, this bit disables automatic device detection and uses the setting provided in the other fields of this register to configure the boot mode.	
5	ROM_BCMD_NOCFG	Device configuration disable. When set, this bit disables device configuration. Device configuration includes reconfiguration of the peripherals MMR registers and device pin muxing.	
4	ROM_BCMD_HOST	Host boot mode enable. When set, enables SPI slave boot mode. Otherwise, use the master boot mode.	
3:0	ROM_BCMD_DEVICE	Boot source device. Specifies the device to boot from.	
		0x2	SPI

NOTE: All bits in the table that are not defined must be set to zero. Supported features may be limited depending on peripheral instance.

Link Port Target Boot Mode

This section describes booting from the link port with the processor as a target.

Link port boot is a target boot mode in which the processor receives boot data from an external link port controller through link port 0. The link port is configured for receive mode and all transfers from the link port to memory are

performed under the control of DMA. The maximum supported operating frequency of the link port is for which the controller boot source is responsible for deriving the clock frequency. The link port receiver operates at an asynchronous frequency up to the maximum supported operating frequency.

The link port protocol supports a way to generate link port transmit and receive service requests. The transmit service request is generated on the processor to transmit data when the transmitter is disabled. The receiver drives the LACKx signal high to initiate this activity. The receive service request is generated on a receiver when it is disabled. The transmitter drives the LCLKx signal high to initiate this activity.

Because the transmitter and receivers can be enabled at different times, external pull-down resistors are required on both the LCLKx and LACKx signals to eliminate any false service request assertions.

The link port target boot mode initialization phase waits for the receive service request before passing control back to the main kernel. Once this initial receive service request has been detected, the receiving link port is enabled and the boot process completes. The receiving link port is not disabled again until after boot is complete. Once the link port is enabled, the receive DMA channel controls all transfers. The load function for the link port receive boot mode can then point to the peripheral DMA routine of the main kernel in a similar way to the SPI slave boot mode.

NOTE: For default Link Port target mode, the peripheral DMA fault, LP0_DMA_ERR with fault ID 252 is enabled.

Run-time API

The linkport target boot mode can be called through the boot routine API function at run time. The run-time API allows for more customization. Both device auto-detection and device configuration can be disabled, and a device other than the default LINKPORT0 can be specified.

If ROM_BCMD_NOCFG flag is specified, it is the programs responsibility to configure pin multiplexing as required.

The following table provides descriptions of the adi_rom_Boot parameter.

Table 45-21: LINKPORT Target Boot command Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8	ROM_BCMD_ DEVENUM	Device enumeration. Specifies the LINKPORT device to use.	
		0x0	LP0
		0x1	LP1
		0x2 - 0xF	Reserved
6	ROM_BCMD_ NOAUTO	Automatic device detection disable. When set disables automatic device detection and uses the setting provided in the other fields of this register to configure the boot mode.	

Table 45-21: LINKPORT Target Boot `command` Bit Descriptions (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5	ROM_BCMD_ NOCFG	Device configuration disable. When set, this bit disables device configuration. Device configuration includes reconfiguration of the peripherals MMR registers and device pin muxing.	
4	ROM_BCMD_ HOST	Host boot mode enable. When set, enables SPI slave boot. Otherwise, use the controller boot mode.	
3:0	ROM_BCMD_ DEVICE	Boot source device. Specifies the device to boot from.	
		0x4	LINKPORT

NOTE: All bits in the above table that are not defined must be set to zero. Supported features may be limited depending on peripheral instance.

UART Controller Boot Mode

When using UART target mode boot, the processor receives boot data from a UART host device connected to the UART interface. The device connected to UART0 is initially detected using an autobaud detection sequence. After finishing the UART target boot process, all control and status registers of the used resources are restored.

Further customization, such as disabling autobaud detection, and changing the device, use the boot routine API.

During boot operation, the host device usually relies on the `RTS` output of the UART device. At boot time, the processor does not evaluate RTS signals driven by the host. Since the RTS is in a high impedance state when the processor is in reset, or while executing a pre-boot, an external pull-up resistor to `VDDEXT` is recommended. The ***Connection Between Host and Processor*** figure shows the interconnection required for booting. The figure does not show physical line drivers and level shifters that are typically required to meet the individual UART-compatible standards.

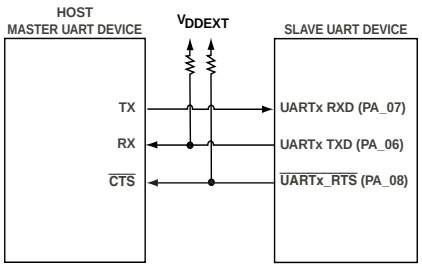

Figure 45-8: Connection Between Host and Processor

When the UART is enabled, the RTS immediately transitions low, encouraging the host to send the first boot stream data as shown in the ***Host Relying on RTS*** figure. For half-duplex UART connections, the host must avoid this action. The host must wait until it has received the 4 bytes from the target processor before sending any data.

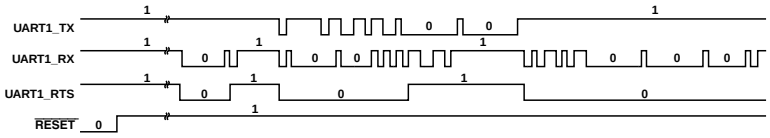

Figure 45-9: Host Relying on RTS

When the boot kernel is processing fill or Initcode blocks, it can require extra processing time and must delay the host from sending more data. This request is signaled using the RTS output.

The ***Host Relying on RTS*** figure shows RTS timing when an extended Initcode routine executes. Since code execution is distracting from the data loading, the host device must be prevented from sending more data. The timing of the RTS depends on the state of the `UART_CTL.RFRT` bit. This bit is cleared during UART target boot mode when RTS is de-asserted, the UART receive FIFO contains 4 or more data words, and another start bit is detected.

NOTE: Secure Boot Stream Padding

For target boot modes, the host must always send data in multiples of 1024 bytes. This requirement is due to the sizing of internal buffers used for DMA.

Autobaud Detection

The kernel supports autobaud detection using the '@' character as data. The host is expected to have its clock set to a rate supported in the UART.

To determine the bit rate when performing autobaud detection, use the following steps:

1. The boot kernel expects an '@' character (0x40, eight bits data, one start bit, one stop bit, no parity bit) on the UART RXD input.
2. The `UART_CLK.EDBO` and the `UART_CLK` register is cleared.
3. The boot kernel acknowledges, and the host then downloads the boot stream. The acknowledgment consists of 4 bytes: 0xBF, `UART_CLK` [15:8], `UART_CLK` [7:0], 0x00.
4. The host is requested to not send further bytes until it has received the complete acknowledge string.
5. Once the 0x00 byte is received, the host can send the entire boot stream.

The host knows the total byte count of the boot stream, but it is not required to know the content of the boot stream.

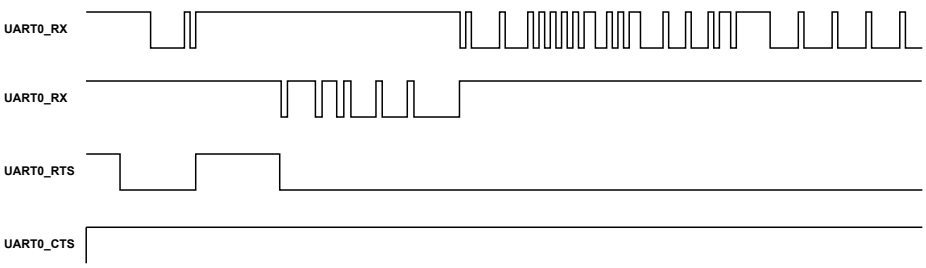

Figure 45-10: UART Autobaud Detection Waveform

The ***UART Autobaud Detection Waveform*** figure provides timing information for UART booting. After the bit rate is known, the UART is enabled and the kernel transmits the 4 acknowledge bytes.

NOTE: For default UART target mode, the peripheral DMA fault, UART2_RXDMA_ERR with fault ID 252 is enabled.

Run-time API

The UART target boot mode can be called through the boot routine API function at run time. The run-time API allows for more customization. Both autobaud detection and device configuration can be disabled, and a device other than the default UART0 can be specified.

If `ROM_BCMD_NOCFG` flag is specified, it is the programs responsibility to configure pin multiplexing as required.

Autobaud detection can be suppressed using the `ROM_BCMD_NOAUTO` flag. In this case, the desired configuration can be passed through the `ROM_BCMD_UART_CLK` bit field. If the `ROM_BCMD_UART_CLK` bit field is zero, `UART_CLK` is evaluated. If a value of 0xFFFF was present, the default error routine of the boot kernel is called and the booting process is aborted. Otherwise, the value in `UART_CLK` remains untouched.

The following table provides descriptions of the `adi_rom_Boot` parameter.

Table 45-22: UART Target Boot `command` Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16	ROM_BCMD_ UART_CLK	UART Clock Divider. When set to zero this field is ignored.	
15	ROM_BCMD_ UART_EDBO	UART Clock Divider Mode When set enables EDBO functionality.	
11:8	ROM_BCMD_ DEVENUM	Device enumeration. Specifies the UART device to use.	
		0x0	UART0
		0x1	UART1
		0x2	UART2
		0x3	UART3
		0x4 - 0xF	Reserved
6	ROM_BCMD_ NOAUTO	Automatic device detection disable. When set disables automatic device detection and uses the setting provided in the other fields of this register to configure the boot mode.	
5	ROM_BCMD_ NOCFG	Device configuration disable. When set, this bit disables device configuration. Device configuration includes reconfiguration of the peripherals MMR registers and device pin muxing.	

Table 45-22: UART Target Boot `command` Bit Descriptions (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4	ROM_BCMD_HOST	Host boot mode enable. When set, enables SPI slave boot. Otherwise, use the controller boot mode.	
3:0	ROM_BCMD_DEVICE	Boot source device. Specifies the device to boot from.	
		0x3	UART

NOTE: All bits in the above table that are not defined must be set to zero. Supported features may be limited depending on peripheral instance.

OSPI Controller Boot Mode

OSPI controller boot supports booting from flash devices via the SPI3 controller. Similar to legacy SPI (SPI0/SPI1/SPI2), it supports boot from many different flash devices provided by different flash vendors further increasing the range of devices due to support for DDR modes of operation. This interface enables to reduce boot times by using faster modes of operation supported by the OSPI controller including DDR modes of operation to achieve higher transfer rates. Most flash vendors support atleast a basic and standard 0x03 read command allowing for a single bit SPI flash interface to be supported.

The OSPI boot mode also uses a device auto-detection feature that is enabled by default. This lets the boot stream itself instruct updates to the SPI configuration and the read command used allowing for more efficient transactions such as for enabling quad bus widths and DDR modes and faster SPI clocks.

Boot from External SPI Flash Devices

The OSPI boot mode supports booting from 24-bit or 32-bit addressable flash devices. The boot mode uses the MDMA channels, which works with OSPI controller to get data from flash memory in memory mapped mode..

When auto-device detection is enabled, the SPI memory is initially read using the standard 0x03 SPI read command with a reduced clocking frequency for maximum compatibility. The first nibble of the boot stream is then used to reconfigure the SPI interface.

NOTE: Support for automatic device detection via the first nibble of the boot stream is not supported when booting secure boot streams. Instead when signing the boot image an attribute can be set in the image header that specifies the configuration to use.

For booting, the SPI memory is connected as shown in the ***SPI Memory Connections*** figure.

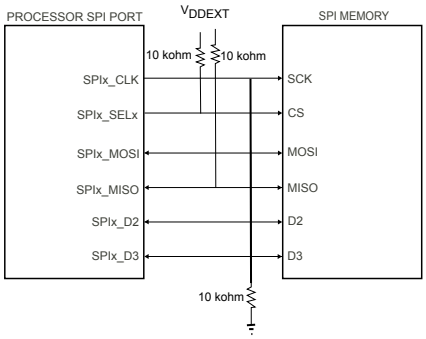

Figure 45-11: SPI Memory Connections

The pull-up resistor on the target select signal ensures that the memory is deselected when the pin is in a high-impedance mode such as during reset.

Initialization codes are allowed to manipulate the `ADI_ROM_BOOT_CONFIG::dBootCommand` to extend boot mechanism to a second SPI memory connected to another target select pin. Updating the field that specifies the target select signal for use, allows the boot process to manage larger boot streams than fit into a single SPI device.

NOTE: If modifying the target select signal used during the boot process, configure the pin multiplexing to enable the correct functionality for the pin. Once the boot process has proceeded past the configuration function and the boot process has actually started, the boot kernel will not perform any further pin multiplexing operations.

OSPI Device Detection Routine

As boot mode supports booting from various SPI memories, the boot kernel automatically detects what type of memory is connected. To determine whether the SPI memory device requires a 24-bit or 32-bit addressing scheme, the boot kernel performs a device detection sequence prior to booting. The `OSPI_MISO` signal requires a pull-up resistor. The routine relies on the fact that memories do not drive their data outputs unless the right number of address bytes are received.

The SPI flash autodetection routine determines the SPI configuration to be used by data in the boot stream. The autodetection first determines the number of address cycles needed to address the flash device.

This operation is performed by configuring the controller in STIG mode initially with the number of expected address bytes programmed to 3 and a basic read command (0x3). A read command from address 0x00000000 with a 3-byte address is issued. If the flash returns a value other than 0x00 or 0xFF, the flash is in 3-byte address mode. Otherwise, the same process is repeated with the STIG controller configured with four address bytes. Only three and four byte address cycles are supported.

The lower nibble of the received byte is then used to further customize the boot mode. This nibble is referred to as the `BCODE`. The boot code applies settings to the OSPI peripheral according to the ***OSPI controller Boot BCODE Descriptions***.

The boot process continues with normal boot operation and it re-issues a command to re-read from address 0. Two read sequences load the first block header. Separate read sequences load further block headers and block payload fields.

The ***SPI Device Detection Principle*** figure illustrates how individual devices behave.

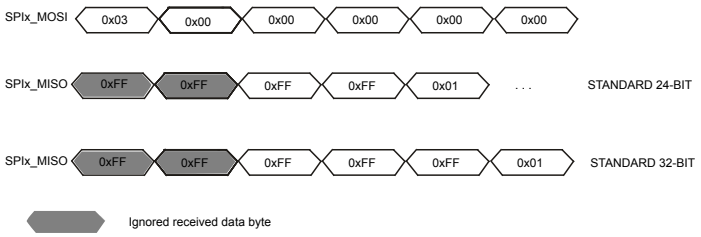

Figure 45-12: SPI Device Detection Principle

NOTE: For the above configurations, the addressing scheme can be 3-bytes or 4-bytes depending on the addressing of flash detected in auto-detection. The SPI mode byte issued for all the SPI controller peripheral based configurations is 0x00. The mode byte is the first byte transmitted after the address cycles and is used to control the continuous read mode functionality in which the next read operation is not required to issue a command cycle. Continuous read mode is not supported during the boot process.

Supported Quad Mode Enable Methods

The boot ROM does not support enabling quad mode on the SPI flash device. To boot in quad mode, the flash device must be configured outside the boot ROM.

To enable quad mode, initially boot in dualmode and use an initcode.

Run-Time API

The following table provides descriptions of the adi_rom_Boot() command parameter.

Table 45-27: OSPI Controller Boot Command Bit Descriptions

Bits	Name	Setting	Description
31:28	ROM_BCMD_SPIM_SPEED	0-1111b	SPI clock divider used. This value is written to the SPI peripherals clock divider register
27	ROM_BCMD_SPIM_CMDSKIP_EN	0	Issue a read command with every read operation
		1	Do not issue a read command with each read operation only issue the read command on the first read.
26:22	ROM_BCMD_SPIM_DUMMY	00000b	No dummy clock cycles required after the address
		00001b	1 dummy clock cycle required after the address
		....	.....
		11111b	31 dummy clock cycle required after the address
21:20	ROM_BCMD_SPIM_ADDR	00b	Flash device requires an 8-bit address
		01b	Flash device requires a 16-bit address
		10b	Flash device requires a 24-bit address
		11b	Flash device requires a 32-bit address
19:16	ROM_BCMD_SPIM_BCODE	0000b-1111b	Applies an initial configuration as described in the SPI Controller Boot BCODE configurations. Not all options may be available.
15	ROM_BCMD_SPIM_CMD	0	Issue the read command over the single bit bus
		1	Issue the read command over the multi-bit bus. Not recommended for use. Intended for use with products with on chip SPI flash only, and even then it can cause complications.
14:12	ROM_BCMD_SPIM_SSEL	000b	Use target select 1 for SPI chip select
		001b	Use target select 2 for SPI chip select
		010b	Use target select 3 for SPI chip select
		011b	Reserved

Table 45-27: OSPI Controller Boot Command Bit Descriptions (Continued)

Bits	Name	Setting	Description
		100b	Reserved
		101b	Reserved
		110b	Reserved
		111b	Reserved
11:8	ROM_BCMD_SPIM_DEVE-NUM	0 to 16	Specifies the boot peripheral enumeration. For OSPI Controller boot, configure this field to 0.
7	Reserved	Reserved	Reserved
6	ROM_BCMD_SPIM_NOAUTO	0	Perform automatic device detection and peripheral configuration based on the BCODE value (first nibble) of the boot streams block header
		1	Do not perform automatic device detection
5	ROM_BCMD_SPIM_NOCFG	0	Instructs the config routine to perform pinmuxing configuration and full peripheral configuration
		1	The config routine will not change the configuration of the peripheral and it will not enable pinmuxing. This can be used if the boot software does not support specific features of a peripheral, users can configure the peripheral prior to calling the boot routine.
4	ROM_BCMD_SPIM_HOST	0	Controller boot mode
		1	Not to be used for OSPI Controller Boot
3:0	ROM_BCMD_SPIM_DEVICE	0000b	Not to be used for OSPI boot
		0001b	Not to be used for OSPI boot
		0010b	Not to be used for OSPI boot
		0011b	Not to be used for OSPI boot
		0100b	Not to be used for OSPI boot
		0101b	Not to be used for OSPI boot
		0110b	Not to be used for OSPI boot
		0111b	Not to be used for OSPI boot
		1000b	OSPI Memory Mapped Boot (Memory mapped mode and MDMA)
		1001b – 1111b	Not to be used for OSPI boot

NOTE: All bits in the above table that are not defined must be set to zero.

To support the above lookup table at varying SPICLK frequency range, boot kernel programs the Read data capture register such that sampling time does not go beyond one full cycle of SPI CLK for STR and half cycle of SPI CLK for DTR mode of operation. If this timing is not sufficient to support all flash vendors, there is a provision to update the Read data capture register crom Customer OTP space with worst case value corresponding to different flash device used by user. This value has to be derived based on the min-max AC timing propagation delay from OSPI controller to pin.

Boot Loader Stream

A loader stream is a set of formatted blocks containing instructions for the boot kernel, as well as the application and data for loading to the chip. This section details the different aspects of the stream, its blocks, some common use cases, and the ROM function.

Each block begins with a block header that contains attributes of the block as well as flags to control its processing by the boot ROM. On power-up or reset, the processor begins executing the on-chip boot ROM. The boot stream is either read from memory or received from a peripheral, depending on the boot mode specified. Each block in the boot stream instructs the boot kernel to perform an action, most commonly to load data to a specified location. For a complete list of actions, refer to the Block Types section.

Some common actions include the following:

- running code that initializes a peripheral
- processing data then loading it to a location

As shown in the ***Project Flow*** figure, a utility is required to process the resulting output from the tool chain to create a valid boot stream. This utility can be in the form of a standalone application or script that parses an application image file, elf output file, or text-based file such as Intel hex. A flash programmer utility can format a boot stream internally.

The elfloader utility parses the application data, and creates a set of blocks representing the segmented application. When processing an actual image that must be loaded to a single contiguous memory block, this representation can contain as little as a single header block. The output of the standalone utility is stored in a loader file (.ldr). The loader file contains the boot stream and becomes available to hardware by:

- programming or burning it into non-volatile external memory, or
- sending it through a peripheral such as the UART during boot time

A loader stream must always begin with a first block and end with a final block. The loader file contains the boot stream and becomes available to hardware by:

- programming or burning it into non-volatile external memory, or
- sending it through a peripheral during boot time

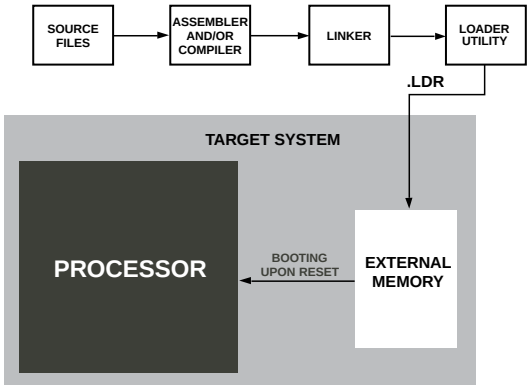

Figure 45-13: Project Flow

The ***Booting Process*** figure shows the parallel or serial boot stream contained in a flash memory device. In host boot scenarios, the non-volatile memory usually connects to the host processor rather than directly to the processor. After reset, the on-chip boot kernel reads and parses the headers and the loader stream is processed block-by-block. Finally, payload data is copied to destination addresses, either in on-chip L1 and L2 memory, or off-chip to SDRAM or SRAM.

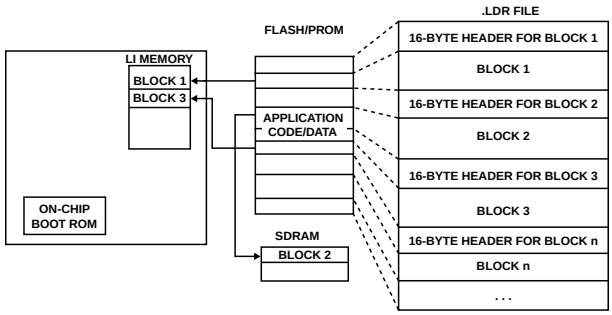

Figure 45-14: Booting Process

In some cases (for example, secure boot or when the `BFLAG_INDIRECT` flag for any block is set), the boot kernel uses another memory block for intermediate data storage. In order to preserve the security of the device processors do not allow these storage regions to be initialized with boot data. The boot stream is loaded to the intermediate storage then processed by the kernel and loaded to the final destination. The final destination cannot be the intermediate storage location otherwise the boot process terminates in an error.

Block Header

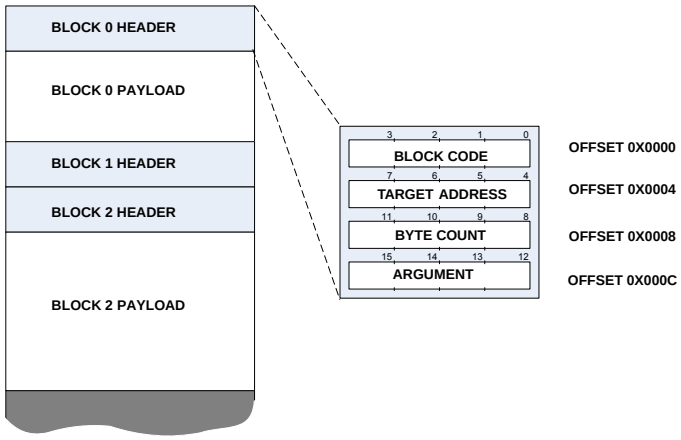

Figure 45-15: Loader Stream Block Structure

A boot stream consists of multiple boot blocks as shown in the figure. A 16-byte block header begins every block. The 16 bytes are functionally grouped into four 32-bit words:

- Block code
- Target address
- Byte count
- Argument field

This section provides a general description describes the fields in general. The use varies depending on the block type and boot mode.

Block Code

Table 45-28: Block Code Flags

Bit	Name	Description
0–3	BCODE	Specific to boot modes (see Boot Modes)
4	BFLAG_SAVE	Intended to allow for a user application to mark blocks for saving the memory of this block to off-chip memory in case of power failure. The on-chip boot kernel does not use this flag.
5	BFLAG_AUX	When set indicates that the byte address space translation for SHARC core boot blocks requires translation to the 48-bit PM address space. When cleared translation to the 32-bit address space is performed.
7–6	Reserved	
8	BFLAG_FILL	Fill the target location with a specified 32-bit value
9	Reserved	
10	BFLAG_CALLBACK	Calls the previously registered callback function

Table 45-28: Block Code Flags (Continued)

Bit	Name	Description
11	BFLAG_INIT	Calls function at target address. If the block contains a payload, the payload is loaded prior to the call.
12	BFLAG_IGNORE	Block payload is ignored
13	BFLAG_INDIRECT	Boots the payload to the intermediate storage location
14	BFLAG_FIRST	Indicates the block that is the beginning of a new application
15	BFLAG_FINAL	Indicates the last block of a loader stream. Booting will complete after processing the block. This flag does not denote the end of an application in a Multi-Application Boot Stream.
16–23	HDRCHK	A simple 8-bit XOR checksum of the other 24 bits in the boot block header.
24–31	HDRSIGN	0xAD, 0xAC or 0xAB. Indicates if the boot block is intended for core 0, core 1 or core 2 respectively.

TARGET_ADDRESS

The TARGET_ADDRESS holds the applicable address for the block, (where the code or data is loaded). However, the interpretation of the field differs depending on what specific flags are set in the block code. Refer to the documentation for each block type for details.

The following attributes must be true:

- The target address must be divisible by 4, as the boot kernel uses 32-bit DMA for certain operations.
- The target address must point to valid on-chip or off-chip memory locations.

BYTE_COUNT

The BYTE_COUNT must be divisible by 4, and can also be zero. This 32-bit field generally holds the size of the block. In some cases, it has a different use (such as when BFLAG_FILL is set). See the Block Types section for information on the variations.

ARGUMENT

The 32-bit field is a user-variable for most block types. The Initcode or callback routine can access this value and use it for optional instructions.

The different block types use the ARGUMENT field in various ways. See the Block Types descriptions for further information.

Block Types

A loader stream is a set of linked blocks and each block is responsible for performing a certain function dependent on the block type. The flags in the block header define a block type. Operations include functions such as loading

data, filling a memory region with data, and instructing the kernel to stop processing. This section describes each block type and its usage within a boot loader stream.

Normal Block

The primary function of a block is to load data into a specified location of memory. A normal block instructs the boot kernel to load the data contained in its payload to the location specified in the TARGET_ADDRESS field. The BYTE_COUNT defines the size of the payload. Once the correct amount of data has been loaded, the kernel moves on to process the next block in the stream.

Table 45-29: Flags

Flag	Required Value	Init
TARGET_ADDRESS	Y	Address where payload is loaded (must be valid)
BYTE_COUNT	Y	Size of block in bytes

First Block

A first block indicates the start of a boot stream and is always needed at the beginning of the boot stream. When a loader stream contains Multi-Application Boot Streams, a first block that occurs within the loader stream indicates the beginning of a new application.

When the kernel processes the first block in a loader stream, the boot kernel uses the TARGET_ADDRESS to determine the application entry location. For more details, refer to Boot Termination and Application Execution .

NOTE: A first block cannot be combined with a fill block.

Table 45-30: Flags

Flag	Required Value	Init
BFLAG_FIRST	Y	1
ARGUMENT	Y	Offset to the next application, or first address following loader stream. Commonly referred to as the NEXTDXE field.
TARGET_ADDRESS	Y	When the block is the first block in a loader stream it defines the start address for the application. If the block is not the first in a loader stream, use the target address as in normal operation.

Final Block

The final block marks the last block in a boot stream. After processing a final block, the boot kernel jumps to the start address of the application. For more information on the definition of the start address, refer to Boot Termination and Application Execution .

There is further customization available to alter the kernel behavior. For example, the kernel can be instructed to return from the boot routine rather than jump to the application using initialization codes or the `adi_rom_Boot()` API.

Before the boot kernel passes program control to the application, it does some housekeeping. Most of the registers in use are set to their default state. However, some register values can differ depending on the boot mode. See Boot Modes for more information.

Table 45-31: Flags

Flag	Required Value	Init
`BFLAG_FINAL`	Y	1

Indirect Block

An indirect block is first loaded to a storage location before being copied to the destination. This block is used in the following situations:

- Some boot modes do not use DMA from the boot peripheral. The core is not always able to access some memory locations directly or efficiently. An intermediate load to a different location improves overall efficiency.
- In some booting situations, the data in the payload must be operated-on or analyzed before it is fully loaded (such as decryption or a checksum calculation). By using an intermediate location, such situations are simplified and are more efficient when loading to off-chip memories.

In some cases, a boot block does not fit into temporary storage memory. Having a larger buffer can improve boot performance. If an entire block cannot fit into the buffer, it is processed in pieces. Initialization code or callback functions can alter the temporary buffer region, including its location and size, by modifying the `ADI_ROM_BOOT_CONFIG::pTempBuffer` and `ADI_ROM_BOOT_CONFIG::dTempByteCount` variables in the struct ADI_ROM_BOOT_CONFIG structure.

Table 45-32: Flags

Flag	Required Value	Init
`BFLAG_INDIRECT`	Y	1
`BFLAG_CALLBACK`	N	Defines a callback function to operate on intermediate data. These 2 flags are often used together.

Ignore Block

It is a block that is ignored by the loader stream (in several cases). These blocks are useful when it is not possible to pass information in another block header. For example, if the first block contains data such as a firmware revision rather than application code, then `BFLAG_IGNORE` can be set with the correct application start address. This step ensures that the loader stream uses the correct start address. Since this block has no other function, identify it as an ignore block. Then, the kernel does not attempt to process any payload.

Ignore blocks clear the following flags, disabling the corresponding blocks from being processed if set along with BFLAG_IGNORE:

- BFLAG_INIT
- BFLAG_CALLBACK
- BFLAG_FINAL
- BFLAG_AUX

NOTE: When BFLAG_IGNORE is set along with BFLAG_FIRST, only the payload associated with the first block is ignored. The application entry point retrieved from the first block is always processed.

Table 45-33: Flags

Flag	Required Value	Init
BFLAG_IGNORE	Y	1
BYTE_COUNT	Y	Size of block to ignore; can be zero

Fill Block

A fill block instructs the boot kernel to perform a 32-bit memory fill of the memory region. Fill blocks help minimize the size of a boot stream when an application contains large arrays of data that need are initialized at startup. Zero fill is the most common fill block type. However, any 32-bit fill value is supported.

Table 45-34: Flags

Flag	Required Value	Init
BFLAG_FILL	Y	1
TARGET_ADDRESS	Y	Address where payload is loaded (must be valid)
BYTE_COUNT	Y	Size of block in bytes (must be multiple of 4)
ARGUMENT	Y	32-bit fill value

Init Block

An initialization block instructs the boot kernel to perform a function call to the target address after the entire block has loaded. The function called is referred to as the *initialization code (Initcode) routine*. Refer to the API reference initcode() for full details.

If the Initcode routine has been previously loaded, the block can declare a zero-size and have no payload.

Initcode routines can be used to speed up and customize booting mechanisms exposed by the boot kernel. Traditionally, an Initcode routine is used to set up the system PLL, bit rates, wait states, and the external memory controllers. Boot time can be significantly reduced when an init block is executed early in the boot process.

Initcode routines are required to follow the C language calling conventions. The expected C prototype is:

```
void initcode(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

NOTE: When programming in assembly, use a return from subroutine instruction for returns.

The structure provided to the Initcode routine by the boot kernel contains information about the block being processed. It includes header information, locations of temporary block data (for indirect blocks), target address, and byte count. See struct ADI_ROM_BOOT_CONFIG for a full list and details on the provided data.

In the simplest case, an Initcode routine consists of only a single block in which the BFLAG_INIT flag is set. For larger routines, a sequence of blocks can incrementally load the routine, and only the last block sets the BFLAG_INIT flag. In the latter case, the last block has no payload attached, and simply instructs the boot kernel to issue a call to subroutine instruction.

An Initcode routine can be overwritten by a successive block when it is no longer needed. Otherwise, the routine can be called at multiple points during the boot process, and even remain in memory after the application completes booting.

NOTE: The following list provides requirements for Initcode that is written in C or C++.

- Ensure that the Initcode routine does not contain calls to the run-time libraries
- Do not assume that parts of the run-time environment, such as the heap, are fully functional
- Ensure that all run-time components are loaded and initialized before the routine executes

The loader utility and tool set provide mechanisms to aid in implementing initialization codes and organizing them properly within the boot loader stream. A special project type is provided to allow the creation of Initcode routines as separate projects. Options are available to assign particular pieces of the application to be Initcode routines. For details and more information on the utility, see the *Loader and Utilities Manual*.

Table 45-35: Flags

Flag	Required Value	Init
BFLAG_INIT	Y	1
TARGET_ADDRESS	Y	Location to load payload data. Call to subroutine issued to the same location.
ARGUMENT	N	Can be used to supply block specific arguments
BYTE_COUNT	Y	Size of payload; can be zero

NOTE: Init blocks cause software not located in the boot ROM during the boot process to execute. In the case of a secure boot scenario, initcode routines are not supported. The secure boot authentication process is performed at the end of the boot process. Execution of any user software prior to the authentication process violates the secure boot requirements.

Callback Block

It instructs the boot kernel to call a pre-registered function when the payload of the block is loaded. The purpose of a callback routine is to apply standard processing to the block payload. The callback routine is registered through an Initcode routine prior to loading a block using the routine. Typically, callback routines contain checksum, decryption, decompression or hash algorithms.

To register a callback, create an Init Block whose Initcode modifies the `ADI_ROM_BOOT_CONFIG::pCallBackFunction` with the address of the callback function to execute. A callback function must be registered prior to processing a callback block.

As callback routines require access to the payload data of the boot blocks, load the block data before processing. Often an Indirect Block is used in combination with a callback block. Indirect blocks in combination with callback blocks allow for post processing of the loaded data before it is then transferred to the final destination.

Callback routines are expected to meet the C language calling conventions. The prototype is as follows:

```
ROM_BOOT_RESULT callback(
      ADI_ROM_BOOT_CONFIG * pBootConfig,
      ADI_ROM_BOOT_BUFFER * pBuffer,
      uint32_t nFlags
      )
```

The `pBootConfig` argument contains a pointer to the struct ADI_ROM_BOOT_CONFIG information and `pBuffer` provides access to the address and size of the block (can vary when using indirect). The `nFlags` parameter is specifically used when the`BFLAG_INDIRECT` flag is also used. The `CBFLAG_DIRECT` flag indicates that the `BFLAG_INDIRECT` bit is not active so that the program only calls the callback routine once per block. When the `CBFLAG_DIRECT` flag is set, the `CBFLAG_FIRST` and `CBFLAG_FINAL` flags are also set.

NOTE: Callback blocks result in execution of software that is not located in the boot ROM during the boot process. In the case of a secure boot scenario callback routines are not supported because the secure boot authentication process is performed at the end of the boot process and execution of any program prior to the authentication process violates the secure boot requirements.

Callback Block in Conjunction with Indirect Block

A block using a callback routine is also loaded indirectly and there are slight behavioural differences. The procedure for loading is:

1. Load data into the temporary buffer defined by `ADI_ROM_BOOT_CONFIG::pTempBuffer`.
2. Issue a call to `ADI_ROM_BOOT_CONFIG::pCallBackFunction`.
3. After the callback routine returns and if the return value is zero, the memory DMA copies data to the destination.

When a block does not fit entirely into the temporary buffer, loading is performed similar to indirect blocks. The software calls the callback function after each chunk is loaded into the temporary storage. The `nFlags` parameter provides information on the specific iteration.

When a block does not fit entirely into the temporary storage area, nFlags tells the callback routine whether it is invoked for the first time (CBFLAG_FIRST) or called the last time (CBFLAG_FINAL) for a specific block.

When the software invokes DMA to copy the data, it relies on the supplied pBuffer data, not the ADI_ROM_BOOT_CONFIG::pTempBuffer and ADI_ROM_BOOT_CONFIG::dTempByteCount members of the boot structure.

The callback routine can control the source of the memory DMA by altering the content of the pBuffer structure. This alteration is necessary when the callback routine performs data manipulation such as decompression.

When the software uses an indirect block, the return value of the callback routine determines whether the DMA transfer occurs. If the value is non-zero, then the transfer does not occur.

Table 45-36: Flags

Flag	Required Value	Init
BFLAG_CALLBACK	Y	1

NOTE: Callback blocks cause software not located in the boot ROM during the boot process to execute. In the case of a secure boot scenario callback routines are not supported because the secure boot authentication process is performed at the end of the boot process and execution of any user software prior to the authentication process violates the secure boot requirements.

Save Block

A save block is intended to mark blocks in a boot stream for saving to off-chip memory. The on-chip boot kernel does not use this flag. A program can process the boot steam to find address of regions of memory for saving to external memory. On a reboot the program may then restore the previously saved contents. This block provides a means of doing a context restore after a reboot.

Table 45-37: Flags

Flag	Required Value	Init
BFLAG_SAVE	Y	1

Single-Block Boot Streams

The simplest boot stream consists of a single block header and one contiguous block of instructions and optionally data. When the appropriate flags are set in the block header, the kernel loads the block to the target address, terminates the boot process, and begins executing from the entry address of the application.

The ***Initial Header for Single-Block Stream*** table shows an example of a single-block boot stream header with settings that can be loaded using any boot mode. The BFLAG_FIRST and BFLAG_FINAL flags are both set at the same time. The desired location and size of the application determines the target address and byte count.

When using single block boot streams on products with multiple cores, the boot stream must be targeted towards the primary booting core that manages the boot process. If core 0 is the primary booting core, the boot stream must contain code that is intended for execution by that core. It is possible to boot a single block boot stream when using the API to load an application to the non-booting core. In this case, the BFLAG_RETURN flag must be set so the boot process returns to user application on the core controlling the boot process.

Table 45-38: Initial Header for Single-Block Stream

Field	Description of Value
BLOCK_CODE	0xAD000000|XORSUM|BFLAG_FINAL|BFLAG_FIRST
TARGET_ADDRESS	Start address of block
BYTE_COUNT	Number of bytes in the block
ARGUMENT	Functions as next-application pointer in multi-application boot streams.

Direct Code Execution

Applications can avoid long boot times and execute code from flash or SDRAM memory with minimal processing by the boot kernel. This feature is called direct code execution.

An initial boot block header is required for the processor to fetch and execute program code from the boot device as early as possible. The block uses safety mechanisms to avoid unpredictable processor behavior when boot memory is not yet programmed with valid data. Safety mechanisms include the header signature and the byte-wise XOR checksum. Rather than blindly executing code, the boot kernel first executes the pre-boot routine for system customization. It then loads the first block header and checks it for consistency. If the block header is corrupt, the boot kernel calls the error handler and does not start code execution.

If the initial block header check is good, the boot kernel interrogates the block flags. If the BFLAG_FINAL flag is set, the boot kernel terminates and executes the sequence as described in the Boot Termination and Application Execution section. If the application requires that the boot kernel customize the starting address in advance, the first block must also have the BFLAG_FIRST flag set. The target address field is then saved as the application start address.

When processing direct code execution blocks, the block instructs the processor executing the boot code to execute from the address specified. It is not possible to have core 0 boot the block and have it instruct core 1 to immediately start execution from the address provided.

For example, when the block header described in the ***Direct Code Execution Header*** table is placed at address 0x20000000, the boot kernel is instructed to issue a JUMP command to address 0x20000020.

Table 45-39: Example Direct Code Execution Header

Field	Value	Comments
BLOCK_CODE	0xAD7BD006	0xAD000000|XORSUM|BFLAG_FINAL|BFLAG_FIRST| BFLAG_IGNORE|BCODE

Table 45-39: Example Direct Code Execution Header (Continued)

Field	Value	Comments
TARGET_ADDRESS	0x20000020	Start address of application code. Provided as an example this would be dependent upon the start address required for a given product.
BYTE_COUNT	0x00000010	Ignores 16 bytes to provide space for control data such as version code and build data. This field is optional and can be zero. The payload is ignored due to the `BFLAG_IGNORE` flag being set.
ARGUMENT	0x00000010	Functions as next-application pointer in multi-application boot streams.

Multi-Application Boot Streams

This section describes loader streams that contain multiple applications.

A boot stream is typically generated from an application file. Loader streams with more than one application are commonly refered to as multi-application booting. A loader utility often accepts multiple application files as input parameters and generates a contiguous boot image. The subsequent applications are appended to the first.

The loader utility must also update the argument field of all `BFLAG_FIRST` blocks. The argument field of a `BFLAG_FINAL` block is called the *next-application* pointer.

The next-application pointer of the first application boot stream is a relative pointer to the start address of the second application boot stream. A multi-application boot image can be seen as a linked list of boot streams. The next-application pointer of the last application boot stream is a relative pointer to the next free address. The ***Multi-Application Boot Stream Example*** figure shows an example.

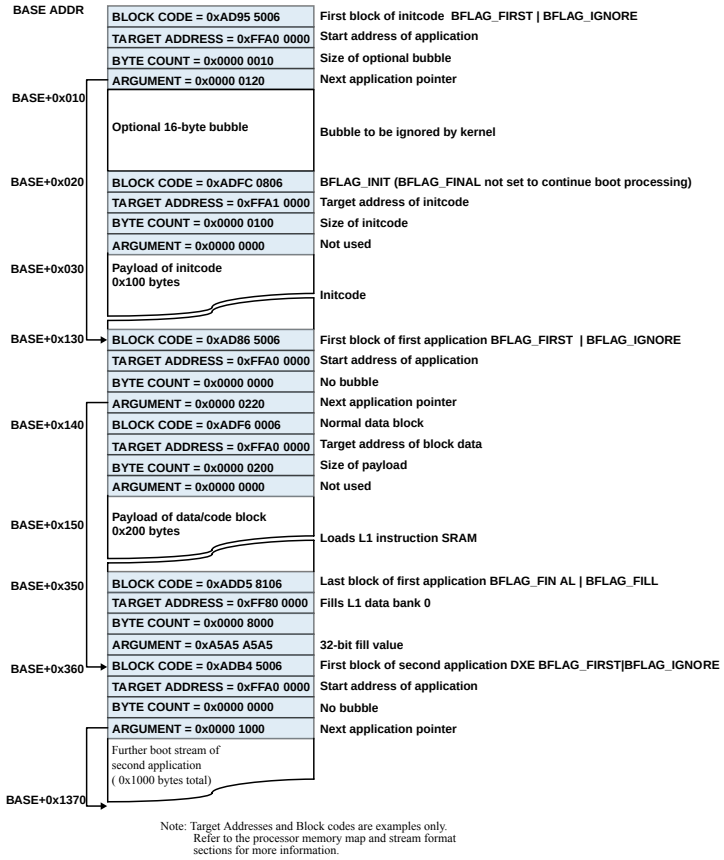

Figure 45-16: Multi-Application Boot Stream Example

The ***Multi-Application Direct Code Execution Example*** figure shows a linked list of initial block headers. The blocks instruct the boot kernel to terminate immediately and to start code execution at the address provided by the target address field of the individual blocks. There is nothing in the boot code that prevents multi-application streams from mixing regular boot streams and direct code execution blocks.

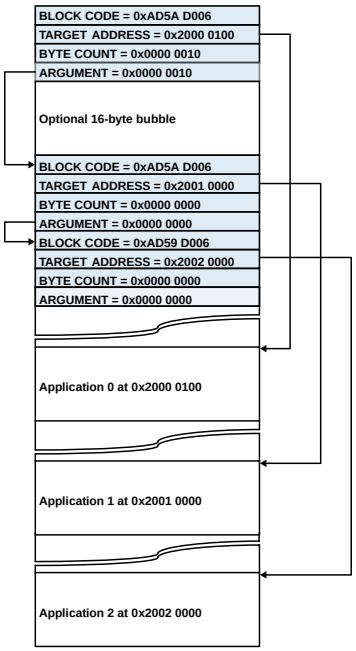

Figure 45-17: Multi-Application Direct Code Execution Example

CRC32 Protection

The boot kernel has mechanisms that allow verification of each block's payload using a 32-bit CRC. The boot ROM contains a function that can be called as an initcode to register the CRC callback and initialize the CRC peripheral with a specified polynomial. CRC32 protected loader streams are supported by the programming tools utlities.

To enable this feature an Block Types must be located in the boot stream with a `TARGET_ADDRESS` that points to the adi_rom_Crc32Init() function in the ROM. The `ARGUMENT` field contains the CRC32 checksum polynomial that is used to initialize the CRC lookup table. Once the CRC initcode function in the ROM has been executed, CRC verification is enabled for all subsequent blocks except:

- Ignore
- First

NOTE: CRC functionality is dependent upon the use of an Initblock and is not supported in secure booting.

Secure Boot

The secure boot process provides a way to integrate security in the processor boot sequence. A chain of trust is established within the system by ensuring the integrity and authenticity of the boot image. Confidentially is also supported.

Secure boot increases protection against malicious, unsecured accesses to critical and confidential resources of the processor. The boot stream application code and data must be digitally signed in order to build up a chain of trust in

the system. This requirement allows the processor to distinguish between authentic and trusted code from non-authentic and untrusted code.

Secure boot also provides confidentiality support. The digitally signed boot image can be optionally encrypted. When loading an encrypted image, the ROM decrypts while loading, then authenticates, before any application code is executed.

Secure boot is an optional feature of the processor that is disabled by default. The feature is enabled using the OTP lock API; secure boot cannot be disabled after it has been enabled. When security is enabled, developers are not dependent on Analog Devices to provision the devices, sign code or provide security certificates. The required tools for signing and encrypting the boot images are provided with the processor development tools.

Integrity and Authenticity Protection

Integrity protection is based on the secure hash SHA-2 224/256-bit algorithm. Authenticity protection is based on the ECDSA algorithm.

ECDSA uses public key cryptography consisting of two keys: a private key and a public key. The public key is stored in OTP memory on the processor so that the secure boot process can verify the authenticity of the signed boot image. Only parties in possession of the private key are able to sign the images.

Confidentiality Protection

Confidentiality protection uses the AES algorithm. Two variants are supported: wrapped and unwrapped.

The wrapped variant uses a 128-bit Key Encryption Key (KEK) stored on the processor to decrypt the 128-bit AES decryption key embedded in the secure header. The unwrapped variant stores the AES description key on the processor and utilizes it to decrypt the entire image.

The privacy of the key stored on the device (whether AES or KEK) is paramount to the security of the system. Disclosure of this key compromises security of the entire system.

Anti-Cloning Protection

Anti-cloning protection is based on the confidentiality protection. If each processor in a system uses a unique private key for confidentiality protection, then cloning between these devices can be prevented. The boot image is incompatible with devices using a different private key for decryption.

Anti-Rollback Protection

The secure boot process supports anti-rollback protection using a 32-bit counter in OTP memory. A value of `0x00000000` in the OTP makes anti-rollback disabled by default. If anti-rollback protection is required, then the program can set the rollback ID when signing the boot image. When the boot image is authenticated, the secure boot software updates the counter in OTP (if the rollback ID in the boot image is greater than the value currently stored in the OTP counter).

The rollback ID stored in the secure boot image header is integrity-protected and cannot be altered.

NOTE: To enable anti-rollback protection for secure boot operations, write a non-zero value to the 32-bit counter in OTP memory. As long as the counter register remains at the default value of zero, anti-rollback protections are not enabled regardless of the rollback ID located in a secure boot stream.

CAUTION: There are a number of restrictions for the rollback ID in the OTP module. Programs should only use the OTP boot program ROM API to set the counter. Refer to the OTP counters section for information on the implementation strategy.

Advanced Encryption Standard

Signing for Secure Boot Images

All boot images must be digitally signed to create secure boot images. The boot image is processed by the security utilities included with the development tools to sign and optionally encrypt the boot image. The security utilities operate with key-pairs consisting of a private and a public key. The private key is used for signing the images, and the public key is used to validate an image being loaded into the processor.

CAUTION: The private key generated from the signing utility, used for signing images, is never required by the processor for successful secure boot. The private key is only ever required by the signing utility and should be made available only within the system responsible for the image signing process.

The image signing utility provides the following functionality:

- Signing and encrypting of images
- Generation of ECDSA key pairs
- Generation of random encryption keys
- Extraction of the public key from an ECDSA key pair
- Setting Secure Boot Image Attributes

For more information on the use of the signing utility, refer to the Loader and Utilities manual.

Secure Boot Image Types

This section provides an overview of the different image types and how to use them.

Plaintext (BLp) Format

The BLp format provides integrity plus authentication protection of the boot image. The boot image is produced using 224-bit or 256-bit Elliptical Curve Digital Signature Algorithm (ECDSA) private key. To authenticate the image, program the corresponding public key into the OTP `public_key` field using the OTP boot program API.

SBH	Boot Loader Stream

Wrapped (BLw) Format

The BLw format provides the highest level of protection: integrity plus authentication, confidentiality, and anti-cloning protection. The image contains an AES wrapped image encryption key (denoted by [K]) within the secure header. The image data is encrypted with the wrapped key, preventing cloning. An extra key is required to unwrap the header; program this key into the OTP `pvt_128key` field using the OTP boot program API.

SBH [K]	Encrypted Boot Loader Stream

Keyless (BLx) Format

The BLx format is similar to the BLw format except that the image does not contain the key at all. This format provides anti-cloning protection only if the secure key is unique per device. Program the decryption key for the data into OTP `pvt_128key` field using the OTP boot program API.

SBH	Encrypted Boot Loader Stream

Secure Boot Image Format

Secure Boot images provide authenticity and integrity protection during the boot process. A secure boot image is comprised of a secure boot header and an optionally encrypted loader stream.

Signed images consist of the following sections to comprise a complete secure boot image:

- Secure Boot Header
- Image Attributes
- Image Section

The Figure 45-18 Secure Boot Image shows that the image attributes are encapsulated within the secure boot header. The image attributes are actually integrity protected along with the image section. The image section contains a standard boot loader stream. Some block types are not allowed as described in Unsupported Boot Stream Blocks.

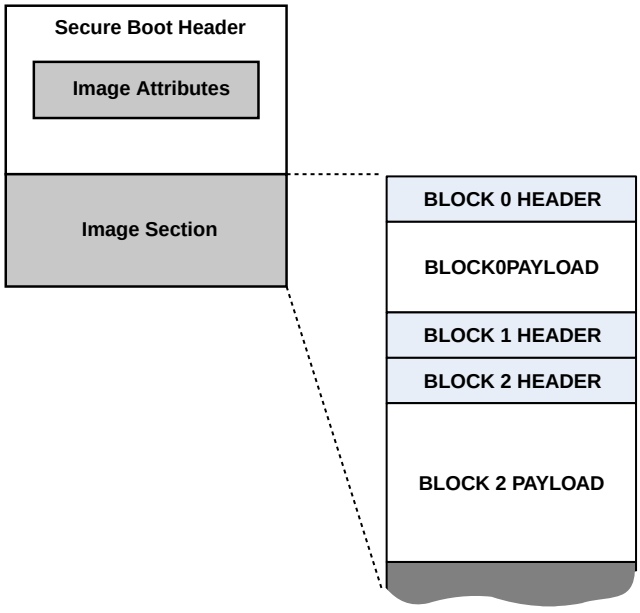

Figure 45-18: Secure Boot Image

Secure Boot Header

Table 45-40: Secure Boot Header

Bytes	Name	Description	Values		
			Keyless Format BLx	Wrapped Format BLw	Plain Text Format BLp
3:0	Type	Format and version of the image. Upper 24 bits are the image format and lower 8 bits are the image version	0x424c7802	0x424c7702	0x424c7002
67:4	Signature	The ECDSA signature of the image	Two 256-bit numbers		
99:68	Hash	Hash of the image	Hash size depends upon whether ECDSA 224 or ECDSA 256 is used. 1. For ECDSA 224 Hash Value: 95:68 bytes 2. For ECDSA 256 Hash Value: 99:68 bytes		
123:100	Key	Confidentiality (only applicable for certain formats)	Reserved	192-bit AES-WRAP data holding a 128-bit AES key	Reserved
139:124	IV	Initialization Vector (only applicable for certain formats)	16-bit IV generated during signing process		Reserved
143:140	Length	The length of the image section in bytes	Maximum supported byte count 0x10000000 bytes		
207:144	Attributes	Image attributes	Support for up to 8 image attributes		
211 :208	Reserved				

Secure Boot Processing Overview

The ***Secure Boot Processing*** figure illustrates how the block is processed using secure features (not all block header type details are shown). For details on the various block types and their function, see Block Types. Some image types are decrypted. Decrypt indicates that the data is decrypted when applicable to the Secure Boot Image Types at that particular stage.

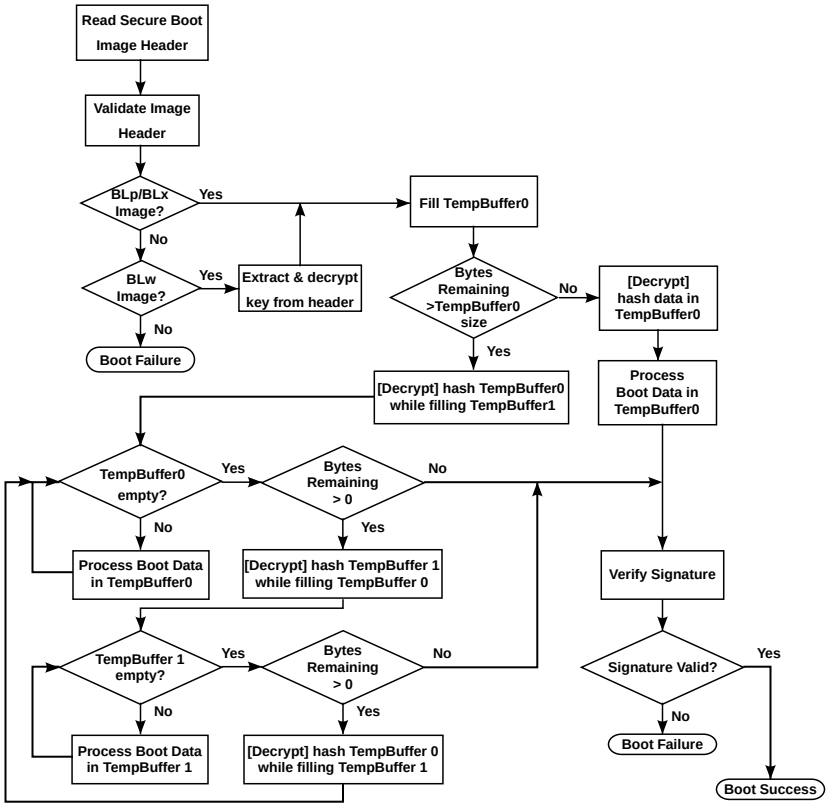

Figure 45-19: Secure Boot Processing

Unsupported Boot Stream Blocks

To ensure the security of the processor, the following block types are not supported in a secure boot image. If the boot kernel finds one of these block types, the boot process terminates.

- Init Block: It require a call to the application code prior to the authentication of the boot image. If customizations or optimizations are necessary to improve the load performance, use a second stage loader style implementation. The first application contains only the custom code. Issue a call using the `api_boot ()` routine to boot using the desired device.
- Call Block: It require a call to a user-defined address prior to the authentication of the boot image, and therefore cannot be supported.

NOTE: Secure boot streams use double buffer Page Mode to optimize the boot process. This functionality allows for the performance of decrypt and hash operations on received data while new data is fetched from the boot source. This host in slave boot mode must ensure that more data is sent after the boot stream to ensure that the temp buffer is filled completely. The size of the secure boot stream minus the size of the secure boot header must be a multiple of the size of the temp buffer. The temp buffer default size is 1024 bytes.

Secure Boot Image Attributes

Secure boot image attributes form part of the secure boot header. The attributes provide more information about the content of the secure boot image.

All image attributes are integrity protected using the same algorithm as the image section. When the image authentication process completes and the image is successfully authenticated, the image attributes are known to be trustworthy.

Attributes are specified as type value pairs with both the type and value being a 32-bit value. The boot code supports the following image attributes.

Table 45-41: Secure Boot Image Attributes

ID	Name	Description	Values	
0x00000000	Unused	Unused attribute	0x00000000	
0x00000001	Version	Version of the attribute format	0x00000000	
0x00000002	Rollback ID	Current value of the rollback counter	0x00000000	Rollback disabled
			0x00000001 - 0x0000001F	Current firmware revision. It must be greater than or equal to the value retrieved from OTP.
0x80000001	NoRestore	Controls whether the boot process restored registers back to default values and clears sensitive security related information from the stack and dedicated structures.	0x1	Do not restore registers and clear security information from stack and dedicated structures.
			Other	Restore registers and clear security sensitive information from the stack and dedicated structures.
0x80000002	BCODE	Used by the boot mode drivers that support autodetection to configure the device from a range of preconfigured settings	Values between 0x00000000 and 0x0000000F supported.	
0x80000003	ECDSA Type	Used by boot ROM to perform Authentication using ECDSA-224 or ECDSA-256 algorithm.	224 : Authentication using ECDSA-224 algorithm 256 : Authentication using ECDSA-256 algorithm	

Secure Boot Streams

The secure boot image sections contain the code and data for loading to the various memory regions of the processor. The content is in the form of a boot stream format consisting of block headers that provide a descriptor for the associated block payloads.

The image section within the secure boot stream consists of a standard Boot Loader Stream consisting of block headers and payloads as generated by the supporting tools and utilities.

The secure boot image section can contain application images for just a single core or for multiple cores allowing for a flexible booting strategy.

A single boot image containing program and data for multiple cores permits a full system boot initializing all internal memories without needing a second stage loader approach. If boot images are required to initialize external memories, then a multi-stage loader approach can be required to configure the memory interfaces. The advantage of a single boot image for multiple cores is that authentication and decryption of the boot image requires only one execution. However, it is over a larger boot image.

Multiple single-core boot images permit one core to boot then execute that core's boot image without booting the other cores. This booting strategy can be needed when a single processor must be brought up quickly to deal with some initial tasks before booting the rest of the system. Or, it can be used to initialize extra peripherals to use for external memory interfaces. The core that has previously booted can then control the boot process for the remaining cores.

Single Core Images

Single core boot images are the result of processing a single core's output from the linker and converting it to a compliant boot stream. The resulting boot stream has a single first block at the beginning of the boot stream and a final block at the end of the boot stream.

The Block Header `HDRSIGN` field of the resulting boot stream is used to identify which core the image is intended for. This identification is required so that the boot code can set the correct (`RCU_SVECT0` - `RCU_SVECT2`) register from the target address in the first block once the authentication is successful. When the boot image is loaded and authentication is successful, the boot code jumps to the location stored in the cores corresponding (`RCU_SVECT0` - `RCU_SVECT2`) register.

This boot stream must then be signed using the secure boot utilities resulting in the final secure boot image for a single core.

A second stage loader option is also available giving maximum flexibility both in terms of using ROM functionality, or creating a custom booting strategy. The simplest option is to have the application use `adi_rom_Boot()` to boot the main application image or indeed a third stage loader when one is required.

The boot stream is generated such that all image contents are in the system address space. Core specific L1 memory sections are converted during the boot stream generation process such that they are loaded through the multiprocessor memory space. The core executing the second stage loader can boot an application image intended for another core.

NOTE: The `ROM_BFLAG_RETURN` flag is set when calling the boot routine for the other cores than the core executing the second stage loader then cleared when loading the cores own image. Failure to do so would result in unintentional behavior.

When the core is used to boot a separately generated boot stream for another core, the `ROM_BFLAG_RETURN` flag should be used when calling `adi_rom_Boot()` to instruct the boot kernel to return to the calling application,

which in this case is back to the core that was running the second stage loader. Failure to set this flag results in the core vectoring to the location in its own (RCU_SVECT0 - RCU_SVECT2) register which is not be the intention.

By default when implementing a scheme such as previously described where one processor is responsible for booting images for another core, the other cores in the system will remain in their existing idle state that they should be placed in prior to the boot commencing. To allow the cores to execute new application, the core that is responsible for booting the other cores must reset the cores via the RCU_CRCTL then release them again from reset. If there is a requirement to release the core from the reset state, then this must be done within the application code of the running core.

Releasing other cores from reset to run application software while other processors are running a boot process requires careful system design. The drivers used by the boot kernel for the boot process assume the various peripheral and infrastructure resources such as MDMA channels and peripherals are available for use, and are not being used by another core. If the boot routine is being executed while other cores are running applications, then those applications must ensure that all the required boot resources are freed up and remain free in order for the boot process to complete on the remaining cores.

Multi-Core Boot Images

Multi-core boot images are generated as a result or processing the multiple linker output files for multiple cores together to create a single compliant boot stream. The resulting boot stream has a first header block at the beginning of each core boot stream and a single final block at the end of the boot stream. The boot stream must only have a single final block to allow the boot kernel to continue processing the entire boot stream. A final block results in the boot kernel terminating triggering the final public key authentication sequence.

The block headers block code HDRSIGN field of the resulting boot stream is used to identify the intended core for the image. This identification is required such that the boot code can set the correct (RCU_SVECT0 - RCU_SVECT2) register when the first block is read to set the application start address for that core. When the boot image is loaded and authentication is successful, the core executing the boot sequence jumps to the location stored in the cores corresponding (RCU_SVECT0 - RCU_SVECT2) register. However, since the boot stream has multiple first blocks present for each of the cores, the (RCU_SVECT0 - RCU_SVECT2) register of the other cores is set for their applications. Upon the booting core running its application, it must release the other cores from reset in order for them to then start running their loaded applications.

If a product supports three or more cores, it is acceptable to create a dual core boot image and then load the other cores later using single core boot images stored elsewhere in the boot source. There are no restrictions on a multi-core boot stream that must contain an application for all the cores in a product.

The resulting multi-core boot stream must then be signed and optionally encrypted resulting in a complaint secure boot stream that can be used to boot a secure device.

Multiple core boot images are advantageous in the fact that applications can be loaded to all cores in the system in a single boot sequence resulting in the requirement to decrypt and authenticate only a single boot image.

NOTE:

If there is a requirement for a multi-core boot stream to load code to memory spaces that require a memory controller to be initialized that is not supported by the boot process a multi-stage booting approach is required that can initialize the peripheral. This boot stream is then authenticated, and executed prior to the loading of the boot stream.

Secure Debug Access

The TAPC controller provides a way to restrict access to secure resources of the processor. Secure access through the debug port is protected through a 128-bit security key that must match a key that has been loaded into OTP for access.

To access a locked processor, the TAPC must allow access to the part. The TAPC only allows access to the part if it is provided with a matching key to the data loaded into its `TAPC_USERKEYn` registers.

With the processor in a locked state, on initial boot the boot ROM reads either the 128-bit `secure_emu_key0` or the 128-bit `secure_emu_key1` from the OTP memory and programs the key into the `TAPC_SDBGKEY0` through the `TAPC_SDBGKEY3` registers before then setting the `TAPC_USERKEY_CTL.USERKEY_VALID` bit. The TAPC is then able to access a matching outside key to allow access. See Secure Debug Key Processing for more information about secure debug key validation.

CAUTION: A 16 bit non-zero value programmed on both `emu_key0_disable` and `emu_key1_disable` fields in OTP or a key of 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF programmed in both the secure debug key fields provided in OTP results in the boot code bypassing the key load operation entirely. If debug access is then ever required the key must be loaded to the TAPC by the program. If the processor fails to boot (due to corrupted firmware) then there is no debug access. The only way to gain access is to load an authenticated boot image that can then load the required keys prior to attempting to connect with a debugger.

The key is set in OTP using the OTP boot program API to program `secure_emu_key0`/ `secure_emu_key1` . The key is read and loaded by the ROM in the following sequence:

1. Bits 31:0 of the key in OTP are stored to `TAPC_SDBGKEY0` bits 31:0
2. Bits 63:32 of the key in OTP are stored to `TAPC_SDBGKEY1` bits 31:0
3. Bits 95:64 of the key in OTP are stored to `TAPC_SDBGKEY2` bits 31:0
4. Bits 127:96 of the key in OTP are stored to `TAPC_SDBGKEY3` bits 31:0

Once the ROM has loaded the user key, a test key can be provided to the TAPC through JTAG. Refer to the Emulator manual for details for providing the key.

A key failure indication can be detected through the `TAPC_SDBGKEY_STAT` register. The boot code does not check the key status, nor does it enable any associated interrupts to signal key failure. The boot code continues to boot upon a key failure in a secure manner. The key failure status remains intact so that the application loaded can check for a failed challenge on the debug port.

The boot code can be configured to bypass the loading of the key during the boot sequence by setting the value of `secure_emu_key0` or `secure_emu_key1` in the OTP to all ones (see struct OTP_DATA). In this case, the only way to gain access to the secure resources through the debug port is to load an alternate key using the application. The alternative key must always reside in a secure region of memory. Or, if sent remotely, it should be transmitted over a secure connection.

NOTE: In the ADSP-SC59x processor family, the boot ROM supports two 128-bit secure debug keys, secure_emu_key0 and secure_emu_key1, where only one of them is used by the Boot ROM at a time. Each of the secure debug keys is associated with a bypass key (`emu_key0_disable` or `emu_key1_disable`) which decides the validity of the corresponding key. Any non zero value written into the 16-bit bypass key invalidates that secure debug key.

Failure Analysis

The boot ROM supports failure analysis on locked parts. Calling adi_rom_otp_fa_enable() activates this feature. The user must activate this feature on a locked part before sending it for failure analysis. Without activation, failure analysis on a locked part is impossible due to security reasons. Do not enable this feature on open parts because it results in boot failure.

Boot ROM Errors and Failures

Any errors encountered while processing a secure boot image results in the ROM jumping to the Error Handler with a specific error code. The error can be of any boot specific error or product specific error. The below table shows different types of errors which are supported by the Boot ROM.

Warning: In secured booting, an incorrect key supplied during boot does not cause a boot failure and the processor continues to boot as normal. A program that supplies an incorrect key is unable to gain access to any secure resources of the processor.

Table 45-42: Secure Boot Header

Error Name	Error ID	Description
ROM_BOOT_ERR_GENERAL	0x0	General Boot Error
ROM_BOOT_ERR_UNSUPPORTED	0x1	Unsupported configuration (device/mode selection)
ROM_BOOT_ERR_BMODE_INIT	0x2	Initialization failure for the selected boot mode
ROM_BOOT_ERR_BMODE_CONFIG	0x3	Configuration failure for the selected boot mode
ROM_BOOT_ERR_BMODE_HOOK	0x4	Hook function failure
ROM_BOOT_ERR_BMODE_REG_FAILURE	0x5	Bmode registration failure
ROM_BOOT_ERR_SEC_AUTH_FAIL	0x6	Authentication failure
ROM_BOOT_ERR_SEC_DECRYPT	0x7	Decryption Failure
ROM_BOOT_ERR_ID	0x8	The image being loaded has a lower ID than was previously recorded, indicating image ID is out dated

Table 45-42: Secure Boot Header (Continued)

Error Name	Error ID	Description
ROM_BOOT_ERR_CLEANUP	0x9	Cleanup failure
ROM_BOOT_ERR_HDRSGN	0xA	Block header signature failure
ROM_BOOT_ERR_HOOK	0xB	Hook function failure
ROM_BOOT_ERR_HDRCHK	0xC	Header checksum failure
ROM_BOOT_SECURE_ERR_HDRCHK	0xD	Secure header failure
ROM_BOOT_ERR_NOFINAL	0xE	No final block
ROM_BOOT_ERR_BLKFILL	0xF	Failure to process fill block

ROM_BOOT_ERR_SH_FIXI_IRQ	0x4B	Fixed-point overflow exception
ROM_BOOT_ERR_SH_FLTOI_IRQ	0x4C	Floating-point overflow exception
ROM_BOOT_ERR_SH_FLTUI_IRQ	0x4D	Floating-point underflow exception
ROM_BOOT_ERR_SH_FLTII_IRQ	0x4E	Floating-point invalid exception
ROM_BOOT_ERR_SH_EMULI_IRQ	0x4F	Emulator low priority interrupt
ROM_BOOT_ERR_SH_SFT0I_IRQ	0x50	User software interrupt 0
ROM_BOOT_ERR_SH_SFT1I_IRQ	0x51	User software interrupt 1
ROM_BOOT_ERR_SH_SFT2I_IRQ	0x52	User software interrupt 2
ROM_BOOT_ERR_SH_SFT3I_IRQ	0x53	User software interrupt 3
ROM_BOOT_ERR_OTPBOOT_IRQ	0x54	OTP Boot Exception
ROM_BOOT_ERR_OTP_INVALIDSTATE_IRQ	0x55	OTP Invalidate State Exception

Boot ROM Programming Model

This section describes the programming model for booting the processor. The programming model includes booting functions, API calls, and data structures.

Boot Mode Driver API

The kernel provides a mechanism to provide a customization of supported boot modes or for implementation of completely new boot modes as second stage boot loaders. This allows programs to customize booting while still taking advantage of the rest of the booting framework. A custom boot mode may provide support for a peripheral that is not supported for boot by the ROM, or it could support one of the same peripherals but with a different configuration.

All the same security features can be supported when using a custom boot mode.

A full boot mode, as perceived by the boot implementation, is a collection of following functions:

1. Register – installs the driver functions listed below so they can be accessed by the boot process
2. Initialization – initialize the boot source
3. Configuration – configure the boot source
4. Load – read from the boot source
5. Cleanup – called after booting

The boot kernel is only aware of functions 2 through 5 and has a requirement to support the Load function. It is this function that is responsible for fetching the boot stream from the boot peripheral. The other functions are used prior to executing the kernel or for cleaning up after the kernel has completed processing the boot stream.

To install a custom boot mode:

1. Create a first stage boot application to define a Load function
2. Use the adi_rom_BootKernel() API to call the boot kernel once the boot peripheral and pinmuxing has configured. Ensure all the fields of struct ADI_ROM_BOOT_CONFIG are configured accordingly prior to performing the call.

The boot mode can use the `pModeData` member of `ADI_ROM_BOOT_CONFIG` to preserve and access shared data across the different function calls if required.

All functions have the following prototype:

```
void apiFunction(ADI_ROM_BOOT_CONFIG* pBootStruct);
```

Another way to support custom boot mode is:

1. Create a first stage boot application to define all Init, Config, Load and Cleanup routines.

2. Use `adi_rom_Boot()` API with hook function installed to update the Init, Config, Load and Clean up functions after the preregister initialization is complete. This is checked by boot ROM to override the above functions inside the `ROM_HOOK_CALL_CAUSE: ROM_HOOK_REG_COMPLETE`

   NOTE: The boot command for the custom boot method is 0xF.

Load Function

The load function is required to read data from the source into the specified destination, according to the parame-Bootters given through the configuration `struct` parameter. The structure provides all of the required information read from the block header, or specified by the kernel to read the block header. The load function often makes use of the DMA APIs in order to simplify the load function implementation.

As the kernel processes the stream, it calls the load function to request data. Initially, the request is for the header, then the kernel makes requests according to the block flags it parses. The load function must only read from the device, and write where requested.

Relevant fields within the `ADI_ROM_BOOT_CONFIG` object for the load function are (but not limited to): `uwDataWidth`, `pSource`, `dByteCount`, `pDestination`, `loadType`.

Custom load functions must meet the following requirements.

- Protect against `dByteCount` values of zero
- Use multiple DMA units if `dByteCount` is greater than 65536 and the peripheral does not support byte count transfers greater than 65536
- The `pSource` and `pDestination` pointers must be properly updated after loading.

In slave boot modes, the boot kernel uses the address of the `dArgument` field in the `pHeader` block as the destination for the required dummy DMAs when payload data is consumed from `ROM_BFLAG_IGNORE` blocks. The load function must read the `ARGUMENT` word of the block early in the function (if required).

Initialization/Configuration Function

The Initialization and Configuration functions are called in sequence when calling a boot operation using an already supported boot peripheral via the adi_rom_Boot() API. These functions are used to configure the boot peripheral prior to calling the boot kernel. Both functions are called in sequence separated only by a call to a user-defined hook function. This hook function is useful when using built-in boot modes to further customize their function. The initialization and configuration functions are responsible for applying any required settings to any devices in use. For example, pin multiplexing may be required and data or pointers that are used by the load function must be initialized. The specific actions depend on the device and functionality used.

Cleanup Function

The cleanup function is called after the entire boot stream is read, and the kernel has completed its boot mode-specific function. This is only performed when using the adi_rom_Boot() API. Resetting any status registers, or device parameters is done to prepare the environment for the execution of the newly loaded application.

Error Handler

This section describes the default error handler for the ROM including information on how to customize the error handling.

The default error handler eventually puts the core into an idle state. This functionality can be overridden by using an Init Block (see Block Types) to modify the error function point in the struct ADI_ROM_BOOT_CONFIG structure. The error handler has access to the entire boot info structure and receives the instruction address that triggered the error.

When a part is locked, and the boot type has not disabled secure boot, only the default error handler is called.

The expected prototype is:

```
void ErrorFunction(ADI_ROM_BOOT_CONFIG* pBootStruct, void *pFailingAddress);
```

The error handler saves the failing address to the `ADI_ROM_BOOT_CONFIG` structure then raises the `INTR_SOFT3` fault signaling a fault condition to the system before then entering an endless loop in the boot rom.

NOTE: When using the adi_rom_Boot() function to perform a boot action, programs may need to manually configure the `INTR_SOFT3` fault signaling depending on the previous application software executed. Calling the boot process using `adi_rom_Boot()` does not result in a reset of the SEC and Fault installation and configuration as described in Preboot Operations.

Page Mode

Page operations are beneficial for page oriented boot source devices, and to improve boot performance for secure boot operations. Page mode optimizes memory reads for block organized devices by always reading a page, rather than reading data on demand. Two 1024 byte buffers are used in page mode where the contents of one buffer are processed by the boot kernel while DMA is used to load the next data into the second buffer.

Blocking DMA is used to load the active buffer, forcing the process to pause until the DMA is complete. Non-blocking DMA is used to load the not active buffer, allowing the active buffer to process while loading the new data in parallel.

Page mode can be enabled when calling a boot mode using `adi_rom_Boot()`. Refer to the API documentation for the various modes supported by this API. Additionally programs can set the flag using the `dFlags` function (see struct ADI_ROM_BOOT_CONFIG) when using hook functions

NOTE: Do not customize page mode settings from the default installed by the boot process.

Boot Hook Function

The boot software allows installation of callback hooks through the use of the adi_rom_Boot() APIs hook function parameter. By using this feature, it is possible to alter the state of the processor, at different stages of the boot process and customize the boot structures to alter the behavior of the boot process.

The hook function must adhere to the following prototype:

```
nt32_t
hookFunction(ADI_ROM_BOOT_CONFIG* pBootconfig,
ROM_HOOK_CALL_CAUSE cause);
```

By modifying settings in the ADI_ROM_BOOT_CONFIG structure, many alterations of the boot process can be achieved. Much of the same functionality that is available in an Init Block can be provided through the hook function, with even more flexibility for customization. The hook function is called once after executing the boot modes Init routine then once again after executing the boot modes Config routine. A flag passed to the hook function allows software to determine at which point the call took place to allow for conditional processing to occur at different stages of the setup phase.

The hook function must return a zero value for normal booting to continue. A non-zero return value causes the ROM to omit loading any data and immediately transfer control according to Boot Termination and Application Execution .

When the hook function is called, a parameter is passed that indicates why the hook function was called. See enum ROM_HOOK_CALL_CAUSE for more details.

enum ROM_HOOK_CALL_CAUSE

Enumeration Type Declaration: ROM_HOOK_CALL_CAUSE

Passed to a user hook routine to indicate the reason of the call.

An optional hook routine is provided as a callback when calling a boot mode via adi_rom_Boot. This hook routine is called by the boot software first after the execution of the boot modes initialization routine then again after execution of the boot modes configuration routine. This parameter allows the users routine to identify at which point the call was made allowing the user to perform different actions for each call.

Table 45-44: ROM_HOOK_CALL_CAUSE Members

Enumerator	Description
ROM_HOOK_CALL_INIT_COMPLETE	Call was as a result of completion of the boot modes initialization function
ROM_HOOK_CALL_CONFIG_ COMPLETE	Call was as a result of the completion of the boot modes configuration function
ROM_HOOK_REG_COMPLETE	Call was as a result of the completion of the boot modes pre-register initialization

Boot Return Feature

The adi_rom_Boot() API provides a feature to bypass calling the loaded application when boot completes, and to return to the routine that made the call instead. The boot software returns the next address after the last loaded application block in the boot source when this feature is enabled.

To enable this feature, set the ROM_BFLAG_RETURN flag in the adi_rom_Boot() flags argument when calling the API.

Boot Termination and Application Execution

When the boot kernel completes the processing of the boot stream, a sequence of events is required to then pass control to the loaded application.

When the boot process is complete, the core is required to vector to the application start address and start executing the newly loaded application. Typically, the first block of a boot stream, which is marked with the BFLAG_FIRST flag, contains the address of the application. In a multi-core system there may be multiple first blocks in the boot-stream indicating the start address of the application for each core. The application entry point for each core is loaded into the cores corresponding RCU_SVECTn register.

Upon boot completion only the core that performed the boot process will vector and start executing the loaded application. This core must then manage the process of resetting then releasing from the reset the other cores in the system in order to make them execute their newly loaded applications.

Execution of the loaded application can be bypassed when calling the boot mode using adi_rom_Boot() and setting the ROM_BFLAG_RETURN flag.

Table 45-45: Application Entry Point Registers

Core ID	Corresponding RCU_SVECTn Register
0	RCU_SVECT0
1	RCU_SVECT1
2	RCU_SVECT2

Boot ROM OTP Customizations

The boot ROM provides a mechanism through available non-volatile programmable memory (OTP on this processor) to customize different aspects of the boot process. These customizations include: overriding default boot-peripheral instance, overriding default peripheral-timing parameters and disabling boot modes.

Data in OTP memory controls all ROM customization. The struct ADI_ROM_OTP_BOOT_INFO data structure accounts for most of the options.

CGU Initializations

Refer to CGU Configuration

Boot Command Customization

Refer to Boot Command Customization

DMC Configuration

Refer to DMC Configuration

Secure Boot Customization

All the public and private keys can be invalidated using the various key invalidation fields provided in the `ADI_ROM_OTP_BOOT_INFO` structure. This configuration is useful when a new key is required. The boot ROM always uses the lowest valid key enumeration. If key0 is valid, then it is used, if key0 is invalid and key1 is valid, then key1 is used. Refer to Secure Boot for details on the secure boot functionality.

Disabling Boot Modes

Refer to Boot Mode Disable

API Reference

The APIs defined in this section are exposed for general use.

adi_rom_Boot()

Provides access to boot an application at run-time through a supported peripheral.

API Details

```
void * adi_rom_Boot(
                     void * pAddress,
                     uint32_t flags,
                     int32_t blockCount,
                     ROM_BOOT_HOOK_FUNC * pHook,
                     uint32_t command
                    )
```

pAddress

Pointer to source address of the boot stream.

flags

Global flags applied to the entire boot process

blockCount

Number of blocks to boot. Zero results in processing until a final block is reached.

pHook

Pointer to user implemented hook function for enabling callbacks during the registering of the boot mode with the boot kernel

command

The boot command defining the boot mode to use, the peripheral instance to boot from as well as some boot mode specific configuration

Returns

The 32-bit address of the next address in the boot source to process

Function Description

This function is used for any kind of second-stage boot for an already supported boot mode. It provides options to boot from any peripheral enumeration. In SPI Master boot the function supports using any SPI slave select signal.

Boot modes may support an auto-detection mechanism to identify the type of connected device. This function provides options to bypass such auto-detection and use custom configuration options. Options are also provided to bypass peripheral configurations such as pinmux settings or a peripheral configuration if an existing peripheral is more appropriately configured to allow communication with the boot source.

These features are all provided via the command parameter which is specific for each particular boot mode.

The source address of the boot stream is required for master boot modes that require that an address is issued in order to request data from the boot source. Slave boot modes are under full control of the host and use a handshake mechanism to indicate that the processor is ready to receive data. For boot modes such as UART Slave and SPI Slave this parameter is of little value in regards to the boot process itself. However it can prove useful in debug to see how far through the boot stream the boot process progressed in the event of a boot failure.

NOTE: The processor supports both SPI Memory-Mapped boot as well as Peripheral based SPI Boot. When the boot mode is called to boot from the memory-mapped boot mode via the command argument, the address must coincide with the processors memory-mapped SPI address space as defined by the processors internal memory map. When using the peripheral based boot mode use the absolute address of the boot stream in flash.

Flags passed using the flags argument are *global* flags and the operation is applied throughout the entire boot process. These must not be confused with the boot *block specific* flags which are part of the boot stream and indicate how a particular block in the boot stream is processed. Internally, the boot kernel takes the global flags supplied using this function call and combines them with a boot block's local flags to determine all the operations to perform on a given block. After processing the boot block the local flags are cleared and are ready to populate from the next boot block while the global flags remain.

Table 45-46: Global Flags

Bit Position	Flag Name	Description
18	ROM_BFLAG_HOOK	Calls the application supplied hook function after execution of bootmode init and config routines
19	ROM_BLAG_PAGEMODE	Enables page mode processing where blocks of data are fetched and processed from internal memory

Table 45-46: Global Flags (Continued)

Bit Position	Flag Name	Description
20	ROM_BFLAG_NOFIRS-THEADER	Set if calling the boot mode and the first block header has already been fetched and is present in the block header storage location
21	ROM_BFLAG_HEADER	Not set by the application, set by the boot code each time it is fetched by a block header
22–25	Reserved	
26	ROM_BFLAG_SLAVE	Slave boot mode. Causes different handling of ignore blocks by the kernel
27	ROM_BFLAG_WAKEUP	Enables conditional processing of boot blocks intended for wakeup events but not exclusively
28	ROM_BFLAG_NEXTDXE	Parses the stream using the next DXE pointer
29	ROM_BFLAG_RETURN	Returns the application after calling the API instead of running the new application
30	ROM_BFLAG_NORESET	No Reset
31	ROM_BFLAG_NORESTORE	Do not execute the boot peripherals cleanup routine to restore register contents

The `blockCount` argument specifies the number of blocks to process before terminating the boot process (default = 0x00000000). This value instructs the boot software to continue processing a boot stream until the `ROM_BFLAG_FINAL` flag is set. To load only a specified number of blocks, programs can use `blockCount` argument.

When `blockCount` is used in combination with the `ROM_BFLAG_NEXTDXE` flag then the block count is re purposed as a next application count. The boot kernel navigates the first blocks of multiple boot streams similar to a linked list. When the requested application count is reached, the program returns the pointer to this application in the boot source. This allows programs to use the boot kernel to find a specific application when multiple application boot streams are stored contiguously in the boot source.

The `pHook` argument is a function pointer to a hook routine. When used with the `ROM_BFLAG_HOOK` global flag the boot mode calls the hook routine after calling the boot modes `init` and functions in the boot mode's driver so that the boot software can be customized and the configuration changed.

The `pHook` argument when used with the `ROM_BFLAG_HOOK` global flag can enable new features not supported by the boot software and to install a custom load function or error handler for example.

The command argument describes the boot peripheral to boot from, the peripheral instance and contains additional boot mode specific configuration information and flags specific to the boot mode.

NOTE: When calling a boot mode via this API the program must first ensure that the boot peripheral is configured in the SPU as a secure master. The boot software does not configure the peripheral security via this API so that device security is fully controlled by a dedicated task.

adi_rom_BootKernel()

Calls the boot kernel allowing for implementation of custom boot modes.

API Details

```
void * adi_rom_BootKernel(ADI_ROM_BOOT_CONFIG * pBoot)
```

pBoot

Pointer to the `struct ADI_ROM_BOOT_CONFIG` boot structure containing the complete context of the boot configuration.

Returns

Pointer containing the address of the byte immediately following the end of the boot stream.

Function Description

The boot kernel performs the core processing of the boot stream. The boot kernel calls a load function to load data from the peripheral to the required destination. The boot kernel itself has no concept of what the boot peripheral is or how that peripheral is configured. The kernel calls the registered load function and the load function must then analyze the boot structure and provide the requested amount of data to the required destination.

The load function called by the kernel is provided via the `struct ADI_ROM_BOOT_REGISTRY` member of `struct ADI_ROM_BOOT_CONFIG`.

The boot kernel fetches a boot stream block header then a payload if one exists. The boot kernel takes care of the size of the data being requested and the destination address.

The load function that is registered with the kernel is required to update the `pSource`. Keeping this control under the load function as opposed to the boot kernel itself allows load functions to better control where the next block of data is fetched in the event the boot stream is fragmented or split into different areas of the boot source.

This function is used to implement a second stage boot loader for a peripheral in which there is no driver support in the boot ROM. The application is responsible for initializing the peripheral and the complete `struct ADI_ROM_BOOT_CONFIG` object before calling this function. The application is responsible for performing a vector to the newly loaded application on return from the function.

NOTE: Programs must ensure that when a new application is loaded it does not clobber the load function and the part of the software responsible for making the core jump to the start of the newly loaded application.

adi_rom_Crc32Init()

The CRC32 Initcode function in the boot rom that is called to enable CRC32 support of boot stream payloads.

API Details

```
ROM_BOOT_RESULT adi_rom_Crc32Init(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

pBootConfig

Pointer to the `struct ADI_ROM_BOOT_CONFIG` object containing the complete boot configuration

Returns

Returns the following results

- `enum ROM_BOOT_RESULT` when `pBootConfig` or `pBootConfig->pHeader` are zero
- `enum ROM_BOOT_RESULT` when the callback is registered and lookup table initialized

Function Description

The boot process supports CRC32 protection of all boot block payloads. In order to enable this feature a global callback must be registered with the boot process using `struct ADI_ROM_BOOT_CONFIG` and the CRC peripherals look up table initialized from the application's polynomial.

An init block header where the `ROM_BFLAG_INIT` flag is set must be included in the boot stream to enable CRC functions. The `ADI_ROM_BOOT_HEADER::pTargetAddress` field must be set to the address of this function and the application polynomial is provided using the block's `struct ADI_ROM_BOOT_HEADER` member.

When the boot kernel processes the init block it calls this function in the boot ROM and registers the callback with the kernel and performs the look up table initialization.

CRC functionality is enabled on MDMA channel 1 interfaced to the CRC0 peripheral instance.

adi_rom_Crc32Poly()

Initializes the CRC peripheral for use with the user supplied polynomial.

API Details

```
ROM_BOOT_RESULT adi_rom_Crc32Poly(
                                    uint32_t CrcPoly,
                                    ROM_BOOT_MDMA_REGS const *const pDma
                                   )
```

CrcPoly

None

pDma

None

Function Description

The CRC lookup table must be initialized for the CRC polynomial of choice to prepare the CRC peripheral for use.

adi_rom_GetAddress()

Used to find the location of various look-up tables and data objects used during the boot process.

API Details

```
int32_t adi_rom_GetAddress(ROM_GETADDR_VALUE value)
```

value

The `enum ROM_GETADDR_VALUE` enumeration specifying the object to retrieve the address of in the ROM memory

Returns

The byte address of the object in memory

Function Description

The function returns the address of the object specified by the enumerator provided as an argument to the function. Using this function can make software more code compatible with future products and silicon revisions.

adi_rom_MemCompare()

Verifies that a block of data is filled with a application supplied 32-bit value.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCompare(
                                    ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                    ROM_BOOT_MDMA_REGS const *const pDma
                                   )
```

pDmaCfg

None

pDma

None

Function Description

The CRC peripheral is used in compare mode and a source MDMA channel is used to read data from a buffer and supply each 32-bit value to the CRC. The CRC peripheral checks that the incoming 32-bit value matches the 32-bit value to compare against.

adi_rom_MemCopy()

Performs a Memory-to-Memory DMA (MDMA) operation using a source and destination pair of DMA channels.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCopy(
                                  ROM_DMA_MDMA_CONFIG * pDmaCfg,
```

```
                                    ROM_BOOT_MDMA_REGS const *const pDma
                                   )
```

pDmaCfg

Pointer to the `struct ROM_DMA_PDMA_CONFIG` object containing the peripheral DMA configuration

pDma

Pointer to the struct ROM_BOOT_MDMA_REGS objects that provides access to the DMA channel MMRs and associated CRC peripheral

Returns

Returns the following results

- enum ROM_BOOT_RESULT for a successful operation or when byte count is 0 as no operation is performed
- `enum ROM_BOOT_RESULT` if a configuration error was detected in the DMA channel prior to configuring the channels for the new operation
- if a configuration error occurred in the source MDMA channel
- if a configuration error occurred in the destination MDMA channel

Function Description

The memory copy routine performs transfers of blocks of data from one memory location to another. The routine takes a basic descriptor providing configuration details of the operation to perform using the `struct ROM_DMA_MDMA_CONFIG` object passed as the first argument. The second argument is a descriptor that provides access to the DMA channel's MMR registers and the associated CRC peripheral. When called from the higher level `adi_rom_MemDma()` routine this object is retrieved from the ROM.

NOTE: Applications are expected to make use the `adi_rom_MemDma()` routine for all MDMA operations as there is little additional optional configuration that is supported by using this routine.

adi_rom_MemCrc()

Performs CRC32 verification of a block of data by reading the contents and comparing them with an expected result.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCrc(
                                    ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                    ROM_BOOT_MDMA_REGS const *const pDma
                                   )
```

pDmaCfg

Pointer to the `struct ROM_DMA_PDMA_CONFIG` object containing the peripheral DMA configuration

pDma

Pointer to the `struct ROM_BOOT_MDMA_REGS` objects that provides access to the DMA channel's MMRs and associated CRC peripheral

Function Description

The routine uses an MDMA channel pair source DMA channel and the CRC peripheral to calculate a CRC32 result of a data block using a previously supplied polynomial.

The polynomial is supplied through the `adi_rom_Crc32Poly()` routine to ensure consistent CRC peripheral configuration for the look up table initialization that uses the polynomial and the

NOTE: Applications are expected to make use the `adi_rom_MemDma()` routine for all MDMA operations, there is little additional optional configuration that is supported by using this routine.

adi_rom_MemDma()

Provides access to all MDMA operations supported by the boot ROM implementation.

API Details

```
ROM_BOOT_RESULT adi_rom_MemDma(ROM_DMA_MDMA_CONFIG * pDmaCfg)
```

pDmaCfg

Pointer to the `struct ROM_DMA_PDMA_CONFIG` object containing the MDMA configuration

Returns

Returns the following results using the `enum ROM_BOOT_RESULT` enumeration.

- ROM_BOOT_SUCCESS Success. General success can be used to indicate any general functional success for an operation during the boot process. This must be the return result for a boot mode drivers initialization, configuration, load and cleanup routines when overriding their functionality in second stage boot loaders to use custom functions. . Successful operation or when byte count is 0 as no operation is performed
- ROM_BOOT_MDMA_ID_ERR Illegal MDMA Channel ID. Returned by adi_rom_MemDma() if the MDMA channel ID is not supported. For supported channel IDs, see ROM_DMA_MDMA_ID . A MDMA channel ID is provided that is not supported
- ROM_BOOT_CRC_SUPPORTED_ERR CRC Not Supported Error. Returned by adi_rom_MemDma(), adi_rom_MemFill(), adi_rom_MemCompare() and adi_rom_Crc32Poly() if the supplied DMA configuration specified a MDMA channel that does not support CRC operations. . A CRC operation was attempted on a MDMA channel that does not support CRC

- ROM_BOOT_MDMA_OPERATION_ERR Illegal MDMA operation Specified. Returned by adi_rom_MemDma() if the MDMA operation is not supported. For supported operations, see ROM_DMA_MDMA_OPERATION . The operation is not supported
- ROM_BOOT_DMA_FAILURE DMA Failure. Returned by the DMA routines if an error was detected in the DMA_STAT.IRQERR prior to setting up a new DMA operation with the newly supplied configuration. . A configuration error is detected in the DMA channel prior to configuring the channel for the new operation
- ROM_BOOT_DMA_FAILURE DMA Failure. Returned by the DMA routines if an error was detected in the DMA_STAT.IRQERR prior to setting up a new DMA operation with the newly supplied configuration. . A configuration error was detected in the DMA channel and the operation requested involves only a single DMA channel
- A configuration error occurred in the source MDMA channel
- A configuration error occurred in the destination MDMA channel
- ROM_BOOT_CRC_COUNT_ERR CRC Byte Count was not a multiple 4. The CRC peripheral operates on 32-bit data only and as such all CRC operations must have a byte count that is a multiple of 4. This result is returned by the higher level adi_rom_MemDma() routine and the underlying adi_rom_MemCompare() and adi_rom_MemFill() routines if the byte count is not a multiple of 4 bytes. . A CRC operation is being requested and the byte count is not a multiple of 4
- ROM_BOOT_CRC_FAILURE MDMA CRC32 Failure. Returned by the higher level adi_rom_MemDma() routine and the underlying adi_rom_MemCompare() routine if the CRC32 result of the block of data did not match the expected result. . A CRC32 verification fails
- ROM_BOOT_CRC_FAILURE MDMA CRC32 Failure. Returned by the higher level adi_rom_MemDma() routine and the underlying adi_rom_MemCompare() routine if the CRC32 result of the block of data did not match the expected result. . A 32-bit memory compare fails

Function Description

The supported MDMA operations are listed in `enum ROM_DMA_MDMA_OPERATION`.

NOTE: The MDMA and CRC peripherals support on-the-fly CRC32 calculations during the transfer of data from one location to another—MDMA in the boot ROM software does not. For CRC calculations data is instead read back from its final destination and verified.

This function is the main entry point for all the MDMA functions supported by the boot ROM software. The individual functions that are called for each operation type are also exposed using the public API.

NOTE: Use this function for all operations. The lower level functions allow for some basic reconfiguration of default parameters but such modifications are not be required where these basic MDMA operations are required.

The boot ROM has an MDMA configuration data structure that is used to specify the overall MDMA configuration of the processor. It provides details on the DMA channel ID associated with each MDMA channel's source and destination DMA channel. It provides information about CRC support and the CRC peripheral instance that is used for a given MDMA channel. See `struct ROM_BOOT_MDMA` and `struct ROM_BOOT_MDMA_REGS` for full details of the content stored.

The configuration provided as the only argument to the function is provided in Table 45-66 ROM_DMA_MDMA_CONFIG Members.

For a basic MDMA transfer from source to destination the program needs to configure:

- The struct ROM_DMA_MDMA_CONFIG type as enum ROM_DMA_MDMA_OPERATION
- The MDMA channel to use via eId MDMA Channel ID for example
- Set the address of the source data via pSource Source Pointer
- Set the destination address of the source data via pDestination Destination Pointer
- Set the byte count via ByteCount Byte Count
- Set `eDoneDetect DMA Done Detection Method` to

  enum ROM_DMA_DONE_DETECT_METHOD in order to poll for DMA completion

NOTE: The implementation of the MDMA operations does not support interrupt driven data transfers. The routines are implemented for polling DMA status during the boot process. The boot stream is restricted where byte counts and source and destination address alignment must all be a multiple of 4 bytes. MDMA routines must comply with these restrictions.

To use the CRC32 function of the MDMA routines, the application must first initialize the CRC lookup table from the application supplied polynomial. This operation can be performed by setting `ROM_DMA_MDMA_CONFIG::eOperation` type as `ROM_DMA_MDMA_OPERATION::ROM_DMA_CRC_LUT_INIT`. If an MDMA channel is specified that does not support CRC function, an error result is returned.

For further details of the individual operations supported see the following API references:

- `adi_rom_MemCopy()`
- `adi_rom_MemCrc()`
- `adi_rom_MemFill()`
- `adi_rom_MemCompare()`
- `adi_rom_Crc32Poly()`

adi_rom_MemFill()

Fills a block of memory with a 32-bit user supplied value.

API Details

```
ROM_BOOT_RESULT adi_rom_MemFill(
                                  ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                  ROM_BOOT_MDMA_REGS const *const pDma
                                )
```

pDmaCfg

None

pDma

None

Returns

Returns the following results

- `enum ROM_BOOT_RESULT` for a successful operation or when byte count is 0 as no operation to be performed
- `enum ROM_BOOT_RESULT` if a configuration error was detected in the DMA channel prior to configuring the channel for the new operation
- A configuration error occurred in the source MDMA channel
- A configuration error occurred in the destination MDMA channel

Function Description

The CRC peripheral is configured for fill mode and the destination MDMA channel is configured to fill a block of memory with a fixed 32-bit value.

adi_rom_PeriphDma()

Provides access to any peripherals dedicated DMA channel for receive operations only.

API Details

```
ROM_BOOT_RESULT adi_rom_PeriphDma(ROM_DMA_PDMA_CONFIG * pDmaCfg)
```

pDmaCfg

Pointer to the `struct ROM_DMA_PDMA_CONFIG` object containing the peripheral DMA configuration

Returns

Returns the following results

- ROM_BOOT_SUCCESS Success. General success can be used to indicate any general functional success for an operation during the boot process. This must be the return result for a boot mode drivers initialization, configuration, load and cleanup routines when overriding their functionality in second stage boot loaders to use custom functions. for a successful operation or when byte count is 0 as no operation is performed
- ROM_BOOT_DMA_ACTIVE DMA Channel is Active Returned only by the peripheral DMA routine when an attempt to run another peripheral DMA operation is attempted and the DMA channel is already running. This is not currently implemented for MDMA operations. if the DMA channel is currently running
- ROM_BOOT_DMA_FAILURE DMA Failure. Returned by the DMA routines if an error was detected in the DMA_STAT.IRQERR prior to setting up a new DMA operation with the newly supplied configuration. if a configuration error was detected in the DMA channel after starting the DMA operation

Function Description

The peripheral DMA routine is used by the load routines of boot peripherals that have dedicated DMA channels and do not support MDMA channel pairs. Examples are the SPI when not configured for memory-mapped mode and UART peripherals.

In the boot implementation this routine is called from the peripheral load function to request data from the boot source. The routine supports both polling on DMA completion and non-blocking operation to allow for immediate return after starting the DMA operation and continuing with further processing.

NOTE: The function only supports read operations from the peripheral to memory. Transmit operations from memory to peripheral are not supported

adi_rom_otp_cfg()

Configures the OTPC to enable read and program operations.

API Details

```
bool adi_rom_otp_cfg(void)
```

Function Description

Programs may call this routine to ensure the OTPC is configured correctly for read and write access.

NOTE: The preboot process configures the OTPC for use and there is no direct requirement to call this function when using the OTP.

adi_rom_otp_get()

Reads the field from OTP as defined by the supplied enum OTPCMD.

API Details

```
bool adi_rom_otp_get(
                      OTPCMD cmd,
                      uint32_t data[]
                     )
```

cmd

The enum OTPCMD enumeration describes the OTP content to read

data[]

Pointer to storage area to store the read OTP contents

Function Description

Programs can read the various fields (Table 45-71 OTPCMD Members) of the OTP via this routine. The supplied enum OTPCMD object is used to specify the object to read.

adi_rom_otp_lock()

Locks the processor, enabling all security features.

API Details

```
bool adi_rom_otp_lock(void)
```

Function Description

This function is used to lock the processor from unauthorized access. Once this function is called the application must supply a secure debug key in order to gain access to the device with debug tools and the processor may only be booted using a secure boot stream.

WARNING: Programs must ensure that the OTP secure boot fields are all programmed. Secure boot can be verified prior to locking the processor. Programs must also provision a secure debug key.

adi_rom_otp_fa_enable()

Enables failure analysis feature for a locked part

API Details

```
bool adi_rom_otp_fa_enable(void)
```

Function Description

This function sets the bit in OTP and enables failure analysis on the locked part.

WARNING: This API should not be called or executed on an open part; it will result in boot failure.

adi_rom_otp_pgm()

Programs the `OTP` Memory with the contents of the `struct OTP_DATA` object.

API Details

```
bool adi_rom_otp_pgm(otp_data * data)
```

data

Pointer to the `::otp_data` object containing the complete OTP contents to program

Function Description

The OTP memory is only programmed with values that are not 0. Any items that are 0 are ignored. Programs are expected to use this function for all OTP program operations.

callback()

Implements custom callbacks to previously loaded code during boot.

API Details

```
ROM_BOOT_RESULT callback(
                          ADI_ROM_BOOT_CONFIG * pBootConfig,
                          ADI_ROM_BOOT_BUFFER * pBuffer,
                          uint32_t nFlags
                         )
```

pBootConfig

Pointer to the `struct ADI_ROM_BOOT_CONFIG` object containing the complete context of the boot procedure

pBuffer

Pointer to the `struct ADI_ROM_BOOT_BUFFER` object containing details of the payload associated with the callback

nFlags

The callback flags as set by the boot kernel

Function Description

A single callback function may be registered with the boot kernel using `pCallBackFunction Pointer to the callback function that is called when processing boot blocks with the callback flag set` . This function is then called whenever a block is processed with the `ROM_BFLAG_CALLBACK` flag set. Only a single callback function can be registered for the complete boot process.

Callbacks may be used alongside indirect blocks when post processing of the received boot data is required before sending the data to the final destination. An example of this is compression applied to block payloads. The compressed payload is loaded indirectly to the intermediate buffer where it is decompressed by the callback. The callback can modify the source address and byte count for the final MDMA transfer of the decompressed payload using the `pBuffer` parameter. The callback returns the boot kernel then handles the final transfer of the uncompressed data to its destination.

There are restrictions on the amount of data that can be loaded using indirect blocks depending on the size of the intermediate buffer. For this reason the nFlags parameter is used to indicate the status of the callback when handling larger blocks of indirect data. The table below defines the supported flags:

Bit Position	Flag Name	Description
0	`ROM_CBFLAG_DIRECT`	When set indicates the call was from the processing of a block header with the `ROM_BFLAG_CALLBACK` flag set
1	`ROM_CBLAG_PAGESTART`	Indicates the callback was a result of a fetch of a page of data to the intermediate buffers
2	`ROM_CBFLAG_FIRST`	Set if the first fetch of payload data
3	`ROM_CBFLAG_FINAL`	Set if the final fetch of payload data
31:4	Reserved	Reserved

When a callback block header is received by the boot kernel, a call to the callback is performed with the `ROM_CBFLAG_DIRECT` flag set. If the `ROM_BFLAG_INDIRECT` flag or the `ROM_BFLAG_PAGEMODE` flags are set they indicate the use of indirect or page mode the `ROM_CBFLAG_FIRST` and `ROM_CBFLAG_FINAL` flags are cleared. If the transfer is a direct transfer straight to the final destination and not via the intermediate buffers, then the `ROM_CBFLAG_FIRST` and `ROM_CBFLAG_FINAL` flags are also set.

This allows software to identify a callback call based on the processing of a block header with the `ROM_BFLAG_CALLBACK` flag set.

Callbacks are also called when processing payloads indirectly or when page mode is enabled.

- The `ROM_CBFLAG_DIRECT` flag is cleared when the callback is a result of processing the payload data using the intermediate buffers.
- The `ROM_CBFLAG_FIRST` flag is set if the callback is a result of fetching the first block of data in the payload. This flag is also set if the complete block of data fits in the intermediate buffer.

- If the payload does not fit completely in the intermediate buffers multiple fetches must take place and thus multiple callbacks are generated.
- If no flags are set it indicates a callback on a payload transfer is neither the first nor the last block of data in the payload, so there is still further data in the payload to fetch.
- If only the `ROM_CBFLAG_FINAL` flag is set then it is the final block in a payload transfer.

The following table provides an overview of the flag states and their meaning for the processing of callbacks.

ROM_CBFLAG_DIRECT	ROM_CBFLAG_PAGESTART	ROM_CBFLAG_FIRST	ROM_CBFLAG_FINAL	Description
1	0	0	0	Callback as a result of processing a block header with indirect or pagemode enabled
1	0	1	1	Callback as a result of processing a block header with indirect and pagemode disabled
0	1	0	0	Callback as a result of fetching a page of data in pagemode
0	1	0	1	Callback as a result of fetching a page of data in pagemode and the final page in the block
0	0	1	0	Callback as a result of fetching the first part of payload in an indirect payload
0	0	0	0	Callback as a result of fetching an indirect payload, not first or last transfer in payload
0	0	0	1	Callback as a result of fetching the final part of payload in an indirect payload
0	0	1	1	Callback as a result of fetching the complete payload in an indirect payload

initcode()

Implements custom callbacks to previously loaded code during boot.

API Details

```
void initcode(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

pBootConfig

Pointer to the `struct ADI_ROM_BOOT_CONFIG` object containing the complete context of the boot procedure

Function Description

Initcode functions are embedded into the boot stream to execute application code during the boot phase. Initcode functions help to optimally configure the CGU or any external memory interface that requires initialization to boot data to those memories.

A boot stream may have any number of initcodes present. The only requirement is that the code must be loaded prior to processing the `BFLAG_INIT` block.

The initcode routine is passed by the pointer to the complete boot context so that extensive boot customization tasks can be supported.

adi_rom_idle_loop()

Jumps to the IDLE loop inside the boot ROM space.

API Details

```
void adi_rom_idle_loop(void)
```

Function Description

This function is used to jump to the forever idle loop inside the boot ROM space.

adi_rom_CguInit()

Can be used for CGU initialization.

API Details

```
bool adi_rom_CguInit(const ADI_ROM_OTP_BOOT_CGU_INFO * const pSettings)
```

pSettings

Pointer to the struct `struct ADI_ROM_OTP_BOOT_CGU_INFO`object containing complete context of CGU initialization

Function Description

This function is used for CGU initialization.

adi_rom_DmcPhyCalibration()

Used for DMC PHY calibration.

API Details

```
void  adi_rom_DmcPhyCalibration(ADI_ROM_OTP_DMC_CONFIG *pConfig,int csel_dsel_r)
```

pConfig

Pointer to the struct `struct ADI_ROM_OTP_DMC_CONFIG`object containing the complete context of the DMC PHY calibration

csel_dsel_r

Holds the CSEL to DSEL ratio

Function Description

This function is used for DMC PHY calibration.

adi_rom_DmcInit()

Used for DMC initialization.

API Details

```
void adi_rom_DmcInit(ADI_ROM_OTP_DMC_CONFIG *pConfig, uint32_t csel_dsel_r)
```

pConfig

Pointer to the struct `struct ADI_ROM_OTP_DMC_CONFIG` object containing the complete context of the DMC PHY calibration.

csel_dsel_r

Holds the CSEL to DSEL ratio.

Function Description

This function is used for DMC PHY calibration.

adi_rom_ShaInit()

Initializes the PKTE module for the SHA-224/256 operation.

API Details

```
void adi_rom_DmcInit(ADI_ROM_OTP_DMC_CONFIG *pConfig, uint32_t csel_dsel_r)
```

pCrypto

Pointer to Crypto descriptors

IV

Initialization Vector

Ecdsa_Word

ECDSA word count for 224/256 bit operation

Function Description

This API is used for the PKTE initialization for the SHA-224/256 bit operation

adi_rom_Sha()

Computes SHA-224/256 bit digest from the PKTE module.

API Details

```
adi_rom_Sha(CRYPTO_DESCRIPTORS * pCrypto,uint32_t Ecdsa_Word, void *output_p,
void *input_p, int size, bool finalFlag)
```

pCrypto

Pointer to Crypto descriptors

Ecdsa_Word

ECDSA word count for 224/256 bit operation

output_p

Pointer to the output buffer

input_p

Pointer to the input buffer

size

Size of the input buffer. It must be a multiple of 512

finalFlag

Final block or not

Function Description

This API is used to compute the message digest using SHA-224/256 using the PKTE module.

```

Data Structures

The programming model for booting the processor uses the data structures defined in this section.

struct ADI_ROM_BOOT_BUFFER

Structure Type Declaration: `ADI_ROM_BOOT_BUFFER`

Boot Buffer.

A basic buffer type consisting of a pointer to the buffer and its size

Table 45-47: ADI_ROM_BOOT_BUFFER Members

Type	Name	Description
`void *`	`pBuffer`	Pointer to the buffer
`int32_t`	`dByteCount`	Size of the buffer

pBuffer

Pointer to the buffer

dByteCount

Size of the buffer

struct ADI_ROM_BOOT_CONFIG

Structure Type Declaration: `ADI_ROM_BOOT_CONFIG`

The Boot Configuration Object that contains all context for the boot process.

This structure contains the complete context for the boot process. A pointer to this object is passed through many routines and is presented to customizable routines such as initcodes, custom initialization, configuration, load and cleanup routines. The object is passed to error handlers and callbacks to customize and adapt the boot process for specific applications, especially in regards to multi-stage boot loader development.

Table 45-48: ADI_ROM_BOOT_CONFIG Members

Type	Name	Description
`void *`	`pSource`	Source address from where to fetch the next boot data.
`void *`	`pDestination`	Destination address to store the fetched data.
`int32_t`	`dByteCount`	Number of bytes to fetch from the boot source.
`int32_t`	`dFlags`	Control flags related to the boot kernel processing of blocks.

Table 45-48: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
uint32_t	ulBlockCount	Limit of blocks processed during boot.
uint32_t	ulBlockCurrent	The number of blocks currently processed by the boot kernel
void *	pNextDxe	Pointer to the next application in the boot stream or the first free location after the boot stream.
uint32_t	uByteAddress	The destination address converted to the byte address space.
uint32_t volatile *	pControlRegister	Pointer to the boot peripherals control register.
int32_t	dControlValue	Storage for the boot peripheral main control value to enable that peripheral in a required configuration.
uint32_t volatile *	pPeripheralBase	Pointer to the boot peripherals base MMR address
uint32_t volatile *	pAuxControlRegister	Pointer to any register that may be used for auxiliary operations such as a timer control register for UART auto-baud detection
uint32_t volatile *	pAuxPeripheralBase	Pointer to the base address of any peripheral used for auxiliary operations such as the TIMER block
uint32_t volatile *	pSecControlRegister	Base MMR address of the SEC SSI instance associated with the boot peripheral if required for advanced second stage boot loader development
ADI_DMA_TypeDef *	pDmaBaseRegister	Base MMR address of the DMA channel associated with the boot peripheral.
ROM_DMA_DONE_DETECT_METHOD	loadType	Set by the kernel to specify to the boot peripherals load function if it is requesting a blocking or non-blocking DMA
ROM_DMA_MDMA_CONFIG	MdmaCfg	An MDMA descriptor that is used by the boot kernel for internal MDMA operations.
uint16_t	uwDataWidth	The maximum data width supported by the boot peripherals DMA channel. Set to 0 for 8-bit, 1 for 16-bit and 2 for 32-bit
uint16_t	uwSrcModifyMult	The source modify multiplier used to set DMA_XMOD for source MDMA operations or peripheral DMA transmit operations
uint16_t	uwDstModifyMult	The destination modify multiplier used to set DMA_XMOD for destination MDMA operations or peripheral DMA receive operations
uint16_t	uwUserShort	Free to use
int32_t	dUserLong	Free to use
int32_t	dReserved0	Reserved for future use

Table 45-48: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
`void *`	`pModeData`	Pointer to the boot mode specific data structure.
`int32_t`	`dBootCommand`	The boot command value supplied during the call to the `adi_rom_Boot()` routine.
`ADI_ROM_BOOT_HEADER*`	`pHeader`	Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel.
`void *`	`pTempBuffer`	Pointer to the internal intermediate buffer. Used for processing of indirect blocks.
`void`	`dReserved1`	Reserved
`int32_t`	`dTempByteCount`	Size of the internal intermediate buffer in bytes.
`void *`	`pTempSource`	Current source address that is processed in the internal intermediate buffer.
`int32_t`	`dPageByteCount`	The page size used for page mode processing. On this product page size is fixed to 1024 bytes and this member is not used for the load requests.
`ADI_ROM_BOOT_INTER_BUFFERS`	`bootBuffers`	The internal intermediate buffer descriptors required when using indirect and page mode features.
`ROM_BOOT_REGISTRY`	`bootRegistry`	The registry object that is used to register a boot peripheral routines with the kernel.
`ROM_BOOT_ERROR_FUNC *`	`pErrorFunction`	Pointer to the error handler called in the event of an error.
`ROM_BOOT_CALLBACK_FUNC *`	`pCallBackFunction`	Pointer to the callback function that is called when processing boot blocks with the callback flag set.
`ROM_BOOT_CALLBACK_FUNC *`	`pCrcFunction`	Pointer to the CRC function that is used to perform CRC validation of the boot stream payload data.
`ROM_BOOT_CALLBACK_FUNC *`	`pForwardFunction`	Feature not supported on this product.
`ADI_ROM_BOOT_MODES`	`bootModes`	Access to all boot mode specific resources.
`void *`	`pLogBuffer`	Pointer to the log buffer. Logging is disabled by default on this product and must be configured from within initcodes or hook routines.
`void *`	`pLogCurrent`	The current position within the log buffer. Logging is disabled by default on this product and must be configured from within initcodes or hook routines.
`int32_t`	`dLogByteCount`	The size of the log buffer. Logging is disabled by default on this product and must be configured from within initcodes or hook routines.

Table 45-48: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
ADI_ROM_OTP_BOOT_INFO*	pOtpBootInfo	Pointer to the ADI_ROM_OTP_BOOT_INFO boot information block that is read from OTP and contains boot customization options.
ADI_ROM_BOOT_KEY_TYPE	keyType	When set to a specific value allows keys not stored in OTP to perform secure boot evaluation on an open processor.
ADI_ROM_BOOT_TYPE	bootType	A key to indicate if the boot type is secure or non-secure for open parts.
ROM_SB_IMAGE_TYPE	secureBootImageType	The type of secure boot image.
SBIF_ECDSA_Header_t*	pSecureHeader	Pointer to the secure boot stream header that is loaded by the boot peripheral from the boot source during the configuration phase.
ADI_SBIF_ECDSA_PublicKey_t	publicKey	The public key used for secure boot image authentication.
CRYPTO_DESCRIPTORS	cryptoDescriptors	The descriptor items as required for PKTE operations.
SB_StorageArea_t*	pSB_Storage	Storage area reserved for some crypto operations.
int32_t	secureBytesRemaining	The number of bytes remaining to be processed in the secure boot stream.
uint32_t[4]	aesKey	The 128-bit AES decryption key.
uint32_t[6]	aesWrapKey	The key wrapped key from the BLw secure boot image.
uint32_t[4]	IV	The IV as read from the secure boot header, required to initialize the PKTE.
uint8_t *	pHash	Pointer to the output destination of the SHA-224 result that is required for authentication of the secure boot stream.
uint8_t *	esdsaType	Type of ECDSA algorithm to sign the image.
uint32_t	errorReturn	Storage location for the address of the instruction line following a call to the error handler.

pSource

Source address from where to fetch the next boot data.

The source address must be maintained by the boot peripheral's load function. The kernel does not update the source pointer automatically after requesting data. This lets load routines control and change the source address. It is useful when advanced second stage loaders need to change the source address (due to a fragmented boot stream) or to reset the address (if expanding into a second SPI flash device).

During debug it is useful in identifying the block in the boot stream that is currently being processed.

pDestination

Destination address to store the fetched data.

Used by the boot kernel to indicate the destination address for the fetched data. A boot peripheral's load function must transfer the data to this location before returning back to the kernel. The boot kernel updates this field depending on whether a block header or payload is being fetched. In normal operation mode the kernel loads this field with the storage area location of the block header. After processing the block header loads `pDestination` with the `pTargetAddress Destination address of payload` contents read from the fetched block header. When using page mode the destination points to the internal buffers and is then updated to transfer data to the final destination.

dByteCount

Number of bytes to fetch from the boot source.

The kernel sets this parameter to indicate to the load function the number of bytes requested by the kernel. The kernel is responsible for adjusting the byte count for page mode based accesses. The peripheral load function must return the required number of bytes to the destination address provided.

dFlags

Control flags related to the boot kernel block processing.

When calling a boot mode using the `adi_rom_Boot()` routine the `flags` supplied to that routine are used to initialize `dFlags`. These become global flags that remain set through the entire boot process. When a block header is received the lower 16 bits of the block header are OR'ed with the global flags. The boot software may clear some flags if it detects they are not compatible with other flags and then writes the resulting flags back to this member. The boot kernel then processes the block payload as instructed by the combination of global and boot block specific flags. Upon completion of the block processing original set of global flags are restored and the process repeated.

ulBlockCount

Limit of blocks processed during boot.

When calling the boot process the `adi_rom_Boot()` routine can accept a block limit for the number of blocks to process before terminating the boot process. If the block count is set to zero then the boot process will continue until a final block reached indicating end of the boot stream. This member holds the program's specified limit for the number of blocks to process and is used by the boot kernel after processing each block to compare it against the `ADI_ROM_BOOT_CONFIG::ulBlockCurrent` value. Boot process terminates when `ADI_ROM_BOOT_CONFIG::ulBlockCurrent` equals `ADI_ROM_BOOT_CONFIG::ulBlockCount`

ulBlockCurrent

The number of blocks currently processed by the boot kernel

pNextDxe

Pointer to the next application in the boot stream or the first free location after the boot stream.

This member is initialized when processing a first block in the boot stream. The `dArgument Argument function varies depending on operation` field of a first block contains the number of bytes left in the boot stream before we reach the end of that boot stream. This lets this pointer point to the next boot stream or to the first empty location after the boot stream. This allows for a feature when using the `adi_rom_Boot()` routine to find the address of an application in a linked list of boot streams or to find the first empty location after the boot stream.

uByteAddress

The destination address converted to the byte address space.

This member is used to store the byte address space equivalent of SHARC L1 memory addresses, allowing any core to load content to any SHARC cores L1 memory. The SHARC core in which the load is targeted is determined by the block header.

pControlRegister

Pointer to the boot peripherals control register.

This can be used by a boot mode peripherals driver in order to gain efficient access to a control MMR register in the boot peripheral.

NOTE: This is not used in this products boot implementation but may be leveraged by developers of second stage boot loaders if required

dControlValue

Storage for the boot peripheral main control value to enable that peripheral in a required configuration.

This can be used by a boot modes peripheral driver in order to store a control value that can be used to enable the peripheral for a required configuration.

pPeripheralBase

Pointer to the boot peripherals base MMR address

pAuxControlRegister

Pointer to any register that may be used for auxiliary operations such as a timer control register for UART autobaud detection

pAuxPeripheralBase

Pointer to the base address of any peripheral used for auxiliary operations such as the TIMER block

pSecControlRegister

Base MMR address of the SEC SSI instance associated with the boot peripheral should they be required for advanced second stage boot loader development

pDmaBaseRegister

Base MMR address of the DMA channel associated with the boot peripheral.

This is used by the boot kernel to gain access to the DMA channels status when using non blocking DMA operations when page mode or secure boot is required, so it must be set when implementing custom boot loaders in order for the kernel to get access to that peripherals DMA status.

NOTE: If a custom boot peripheral does not support the standard DMA instance then the custom driver will be required to set up a DMA instance in SRAM that this location points to and the load function would need to update the status accordingly to indicate when the DMA was running and when the DMA completed.

loadType

Set by the kernel to specify to the boot peripherals load function if it is requesting a blocking or non-blocking DMA

MdmaCfg

An MDMA descriptor that is used by the boot kernel for internal MDMA operations.

The boot kernel may be required to perform internal MDMA operations outside the control of the boot peripheral driver. Such operations include processing of fill blocks CRC callbacks for CRC verification and MDMA operations from the internal intermediate buffers for indirect block and page mode processing.

NOTE: Users must not use this item or reconfigure this item when developing custom boot drivers, it is intended purely for the internal use by the boot kernel

uwDataWidth

The maximum data width supported by the boot peripherals DMA channel. Set to 0 for 8-bit, 1 for 16-bit and 2 for 32-bit

uwSrcModifyMult

The source modify multiplier used to set `DMA_XMOD` for source MDMA operations or peripheral DMA transmit operations

uwDstModifyMult

The destination modify multiplier used to set `DMA_XMOD` for destination MDMA operations or peripheral DMA receive operations

uwUserShort

Free to use by the user

dUserLong

Free to use by the user

pModeData

Pointer to the boot mode specific data structure.

Can be set by a boot peripheral driver to allow for a single point of access to the boot mode specific object containing control and configuration information specific to that single boot mode.

dBootCommand

The boot command value supplied during the call to the `adi_rom_Boot()` routine

pHeader

Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel

pTempBuffer

Pointer to the internal intermediate buffer. Used for processing of indirect blocks

dTempByteCount

Size of the internal intermediate buffer in bytes

pTempSource

Current source address that is being processed in the internal intermediate buffer

dPageByteCount

The page size used for page mode processing. On this product page size is fixed to 1024 bytes and this member is not used for the load requests

bootBuffers

The internal intermediate buffer descriptors required when using indirect and page mode features

bootRegistry

The registry object that is used to register a boot peripherals routines with the kernel.

When using the `adi_rom_Boot()` function the boot software calls a peripherals initialization, configuration, load and cleanup routines from the pointers stored in this object. The kernel itself only makes calls to the load function for the peripheral so when using the `adi_rom_BootKernel()` function the load function that is called by the boot kernel to fetch data from the boot source must be registered using `pLoadFunctionPointer to the boot modes Load function .`

pErrorFunction

Pointer to the error handler called in the event of an error

pCallBackFunction

Pointer to the callback function that is called when processing boot blocks with the callback flag set

pCrcFunction

Pointer to the CRC function that is used to perform CRC validation of the boot stream payload data

pForwardFunction

Feature not supported on this product

bootModes

Access to all boot mode specific resources

pLogBuffer

Pointer to the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

pLogCurrent

The current position within the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

dLogByteCount

The size of the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

pOtpBootInfo

Pointer to the `struct ADI_ROM_OTP_BOOT_INFO` boot information block that gets read from `OTP` and contains boot customization options

keyType

When set to a specific value allows keys not stored in OTP to be used for secure boot evaluation on an open processor.

By default when performing boot on an open part the decryption keys and the public key are fetched from `OTP`. By setting this field to enum ADI_ROM_BOOT_KEY_TYPE users can disable the fetching of the keys from `OTP` and instead provision the keys directly in the `ADI_ROM_BOOT_CONFIG::publicKey` and `ADI_ROM_BOOT_CONFIG::aesKey` members via hook routines when using the `adi_rom_Boot()` function.

bootType

A key to indicate if the boot type is secure or non-secure for open parts

secureBootImageType

The type of secure boot image

pSecureHeader

Pointer to the secure boot stream header that is loaded by the boot peripheral from the boot source during the configuration phase

publicKey

The public key used for secure boot image authentication

cryptoDescriptors

The descriptor items as required for the PKTE operations

pSB_Storage

Storage area reserved for some crypto operations

secureBytesRemaining

The number of bytes remaining to be processed in the secure boot stream

aesKey

The 128-bit AES decryption key

aesWrapKey

The key wrapped key from the `BLw` secure boot image

IV

The `IV` as read from the secure boot header as required to initialize the PKTE

pHash

Pointer to the output destination of the SHA-224 result that is required for authentication of the secure boot stream

ecdsaType

This holds the ecdsa type to be used for authentication. It can be 224-bit or 256-bit.

errorReturn

Storage location for the address of the instruction line following a call to the error handler

struct ADI_ROM_BOOT_HEADER

Structure Type Declaration: `ADI_ROM_BOOT_HEADER`

Boot Block Header.

Boot block headers control the loading process of the boot stream, For full details on the contents of the block header and supported flags see Boot Stream.

Table 45-49: ADI_ROM_BOOT_HEADER Members

Type	Name	Description
`int32_t`	`dBlockCode`	Instructs the boot kernel how to process the block.
`void *`	`pTargetAddress`	Destination Address of Payload
`int32_t`	`dByteCount`	Byte Count of the Payload
`int32_t`	`dArgument`	Argument functionality varies depending on operation

dBlockCode

Instructs the boot kernel how to process the block.

Contains a number of fields for verification of the block header and flags to indicate the type of block. This allows the kernel to process the block correctly.

pTargetAddress

Destination address of payload

dByteCount

Byte count of the payload

dArgument

Argument function varies depending on operation

struct ADI_ROM_BOOT_INTER_BUFFER

Structure Type Declaration: `ADI_ROM_BOOT_INTER_BUFFER`

The buffer object for the internal intermediate buffers used for indirect and page mode operations.

Table 45-50: ADI_ROM_BOOT_INTER_BUFFER Members

Type	Name	Description
`uint8_t *`	`pBuffer`	Pointer to the buffer
`uint32_t`	`size`	Size of the buffer
`uint32_t`	`pageSize`	Page size for block based devices.

pBuffer

Pointer to the buffer

size

Size of the buffer

pageSize

Page size for block based devices.

NOTE: This field is not used in this product. A fixed page size of 1024 bytes is used.

struct ADI_ROM_BOOT_INTER_BUFFERS

Structure Type Declaration: `ADI_ROM_BOOT_INTER_BUFFERS`

The boot kernels internal buffer object used to access the intermediate buffers and obtain buffer status.

Table 45-51: ADI_ROM_BOOT_INTER_BUFFERS Members

Type	Name	Description
`ADI_ROM_BOOT_INTER_BUFFER[2]`	`buffer`	The two buffer descriptors
`ADI_ROM_BOOT_BUFFER_STATE`	`state`	Buffer Status Information
`void *`	`pSource`	Original source address pointer of data loaded to active buffer. Not used on this product
`ADI_DMA_TypeDef *`	`pDma`	TBD

buffer

The two buffer descriptors

state

Buffer Status Information

pSource

Original source address pointer of data loaded to active buffer. Not used on this product

struct ADI_ROM_BOOT_LINKPORT

Structure Type Declaration: `ADI_ROM_BOOT_LINKPORT`

The linkport slave boot mode specific structure.

This structure contains all the boot context information that is specific to the linkport slave boot mode.

Table 45-52: ADI_ROM_BOOT_LINKPORT Members

Type	Name	Description
`uint32_t`	`nFlags`	Flags related to linkport boot mode
`ADI_LP_TypeDef *`	`pRegisters`	Pointer to the LP peripherals base MMR address, not used on this product

Table 45-52: ADI_ROM_BOOT_LINKPORT Members (Continued)

Type	Name	Description
`ADI_DMA_TypeDef *`	`pRxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product
`ADI_DMA_TypeDef *`	`pTxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

nFlags

Flags related to linkport boot mode

pRegisters

Pointer to the LP peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

struct ADI_ROM_BOOT_MODES

Structure Type Declaration: `ADI_ROM_BOOT_MODES`

Holds all boot mode specific configuration items.

A boot mode may have requirements for some dedicated storage. This object is used to collect all storage items for all the boot modes supported by the boot ROM.

Table 45-53: ADI_ROM_BOOT_MODES Members

Type	Name	Description
`ADI_ROM_BOOT_SPI`	`spi`	Access to all SPI boot mode resources
`ADI_ROM_BOOT_UART`	`uart`	Access to all UART boot mode resources
`ADI_ROM_BOOT_LINKPORT`	`linkport`	Access to all LINKPORT boot mode resources
`ADI_ROM_BOOT_OSPI`	`ospi`	Access to all OSPI boot mode resources
`ADI_ROM_BOOT_CUSTOM`	`custom`	Access to all custom boot mode resources

spi

Access to all SPI boot mode resources

uart

Access to all UART boot mode resources

linkport

Access to all LINKPORT boot mode resources

custom

Access to all custom boot mode resources

Spi3

Access to all OSPI boot mode resources

struct ADI_ROM_BOOT_REGISTRY

Structure Type Declaration: `ADI_ROM_BOOT_REGISTRY`

Boot Mode Registration.

Used to hold pointers for the boot mode initialization, configuration, load and cleanup functions. Can customize the registered content via hook routines or install load functions or cleanup functions from within init codes.

When using `adi_rom_Boot()` the boot process makes a call to the initialization function and the configuration function before calling the kernel. The kernel then runs and makes calls to the load function. The cleanup function is called when the kernel reaches the end of the boot stream.

When using the adi_rom_BootKernel() function only the load function is called during execution of the software in the boot ROM. All the functions here must return a `enum ROM_BOOT_RESULT` result in order for the boot process to continue. All functions expect a single argument that is the pointer to the boot structure object `struct ADI_ROM_BOOT_CONFIG`.

Table 45-54: ADI_ROM_BOOT_REGISTRY Members

Type	Name	Description
`ROM_BOOT_MODE_INIT_FUNC *`	`pInitFunction`	Pointer to the boot modes Initialization function
`ROM_BOOT_MODE_CONFIG_FUNC *`	`pConfigFunction`	Pointer to the boot modes Configuration function
`ROM_BOOT_MODE_LOAD_FUNC *`	`pLoadFunction`	Pointer to the boot modes Load function
`ROM_BOOT_MODE_CLEANUP_FUNC *`	`pCleanUpFunction`	Pointer to the boot modes Cleanup function
`void *`	`pReserved`	Reserved for future use
`int32_t`	`dReserved`	Reserved for future use

pInitFunction

Pointer to the boot modes Initialization function

pConfigFunction

Pointer to the boot modes Configuration function

pLoadFunction

Pointer to the boot modes Load function

pCleanUpFunction

Pointer to the boot modes Cleanup function

struct ADI_ROM_BOOT_SPI

Structure Type Declaration: `ADI_ROM_BOOT_SPI`

The SPI Master Boot Mode Specific Structure.

This structure contains all the boot context information that is specific for SPI master boot mode. During auto-detection information is copied from the required `::ROM_SPI_LUTENTRY` item into this structure and used to configure the SPI peripheral for the mode of operation.

Table 45-55: ADI_ROM_BOOT_SPI Members

Type	Name	Description
`uint8_t`	`ubReadCommand`	Read command to read data from the SPI device
`uint8_t`	`ubDummyBytes`	Number of dummy bytes to issue after the read command
`uint8_t`	`ubAddressBytes`	Number of address bytes required to access the device
`uint8_t`	`ubDataBits`	Bus width when reading the data. 0 = single bit, 1 = dual bit, 2 = quad bit
`uint16_t`	`uwClkLower`	SPI clock divider value
`uint16_t`	`uReserved0`	Reserved
`uint32_t`	`nTxCtl`	The value written to the `SPI_TXCTL` register used for address transmit operations such as address cycles
`uint32_t`	`nRxCtl`	The value written to the `SPI_RXCTL` register that is used for all receive operations
`uint32_t`	`nCmdCtl`	The value written to the `SPI_TXCTL` register that is used for sending the read command to the SPI Flash
`ROM_BOOT_SPIM_IO_ENABLE_FUNC *`	`pMIOEnFunction`	Pointer to the function used to enable quad mode on the SPI flash
`uint8_t`	`nDummy`	The Dummy Byte value if dummy byte transfers are required and the bus is not three-stated
`uint8_t`	`nFlags`	Flags used for additional SPI configuration processing.
`uint16_t`	`uReserved2`	Reserved
`void *`	`pXIPAddress`	The memory-mapped SPI address to boot from
`ADI_SPI_TypeDef *`	`pRegisters`	Pointer to the SPI peripherals base MMR address, not used on this product

Table 45-55: ADI_ROM_BOOT_SPI Members (Continued)

Type	Name	Description
ADI_DMA_TypeDef *	pRxDmaRegisters	Pointer to the DMA peripherals base MMR address, for receive operations, not used on this product
ADI_DMA_TypeDef *	pTxDmaRegisters	Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

ubReadCommand

Read command to use to read data from the SPI device

ubDummyBytes

Number of dummy bytes to issue after the read command

ubAddressBytes

Number of address bytes required to access the device

ubDataBits

The bus width used when reading the data. 0 for single bit, 1 for dual, 2 for quad

uwClkLower

The SPI clock divider value

nTxCtl

The value written to the SPI_TXCTL register that is used for the address transmit operations such as address cycles

nRxCtl

The value written to the SPI_RXCTL register that is used for all receive operations

nCmdCtl

The value written to the SPI_TXCTL register that is used for sending the read command to the SPI Flash

pMIOEnFunction

Pointer to the function used to enable quad mode on the SPI flash

nDummy

The Dummy Byte value if dummy byte transfers are required and the bus is not tri-stated

nFlags

Flags used for some additional SPI configuration processing. The flags supported are defined as follows:

Bit Position	Name	Description
0	ROM_SPI_FLAGS_CMDSKIP_EN	When set the configuration routine enables command skip mode where the SPI does not issue a read command for read operations
1	ROM_SPI_FLAGS_MULTICMD_EN	Configuration routine enables sending command cycles over dual or quad bit bus

pXIPAddress

The memory-mapped SPI address to boot from

pRegisters

Pointer to the SPI peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address, for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address, for transmit operations, not used on this product

struct ADI_ROM_BOOT_OSPI

Structure Type Declaration: ADI_ROM_BOOT_OSPI

The SPI Master Boot Mode Specific Structure.

This structure contains all the boot context information that is specific for OSPI master boot mode. During auto-detection information is copied from the required ::ROM_OSPI_LUTENTRY item into this structure and used to configure the OSPI peripheral for the mode of operation.

Table 45-56: ADI_ROM_BOOT_OSPI Members

Type	Name	Description
uint8_t	ubReadCommand	Read command to read data from the OSPI device
uint8_t	ubDummyCycles	Number of dummy cycles to issue after the read command
uint8_t	ubAddressBytes	Number of address bytes required to access the device
uint8_t	ubDataBits	Bus width when reading the data
uint16_t	uwClkLower	OSPI clock divider value
uint16_t	uReserved0	Reserved
uint32_t	nCfg	Value written to lower 16 bits of the OSPI_CFG register
uint32_t	nDsr	Value written to OSPI device size register
uint32_t	nDrir	Value written to OSPI device read instruction control register

Table 45-56: ADI_ROM_BOOT_OSPI Members (Continued)

Type	Name	Description
uint32_t	reserved1	Reserved
uint8_t	nDummy	The dummy byte value to be used
uint8_t	nFlags	Flags used for some additional SPI configuration processing
uint16_t	uReserved2	Reserved
void *	pXIPAddress	The memory-mapped OSPI address to boot
ADI_OSPI_TypeDef *	pRegisters	Pointer to the OSPI peripherals base MMR address, not used on this product
ADI_DMA_TypeDef *	pRxDmaRegisters	Pointer to the DMA peripherals base MMR address, for receive operations, not used on this product
ADI_DMA_TypeDef *	pTxDmaRegisters	Pointer to the DMA peripherals base MMR address, for transmit operations, not used on this product

ubReadCommand

Read command to use to read data from the SPI device

ubDummyCycles

Number of dummy cycles to issue after the read command

ubAddressBytes

Number of address bytes required to access the device

ubDataBits

The bus width used when reading the data. 0 for single bit, 1 for dual, 2 for quad

uwClkLower

The SPI clock divider value

nCfg

The value written to the Lower 16 bits of the OSPI Control register

nDsr

The value written to the OSPI Device Size register

nDrir

The value written to the OSPI Device Read Instruction Control register

nDummy

The Dummy Byte value if dummy byte transfers are required and the bus is not tri-stated

nFlags

Flags used for some additional SPI configuration processing. The flags supported are defined as follows:

- `ROM_SPI_FLAGS_CMDSKIP_EN` (Bit position 0): When set the configuration routine enables command skip mode where the SPI does not issue a read command for read operations
- `ROM_SPI_FLAGS_MULTICMD_EN` (Bit position 1): Configuration routine enables sending command cycles over dual or quad bit bus

pXIPAddress

The memory-mapped SPI address to boot

pRegisters

Pointer to the OSPI peripherals base MMR address (not used on this product)

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address for receive operations (not used on this product)

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address, for transmit operations (not used on this product)

struct ADI_ROM_BOOT_UART

Structure Type Declaration: `ADI_ROM_BOOT_UART`

The UART slave boot mode specific structure.

This structure contains all the boot context information that is specific for the UART slave boot mode.

Table 45-57: ADI_ROM_BOOT_UART Members

Type	Name	Description
`uint32_t`	`nFlags`	Flags related to UART Boot mode
`ADI_UART_TypeDef*`	`pRegisters`	Pointer to the UART peripherals base MMR address, not used on this product
`ADI_DMA_TypeDef*`	`pRxDmaRegisters`	Pointer to the DMA peripherals base MMR address for receive operations, not used on this product
`ADI_DMA_TypeDef*`	`pTxDmaRegisters`	Pointer to the DMA peripherals base MMR address for transmit operations, not used on this product

nFlags

Flags related to UART Boot mode

pRegisters

Pointer to the UART peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR addres for transmit operations, not used on this product

struct ADI_ROM_OTP_BOOT_CFG

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CFG`

The boot configuration object for storing further boot customization objects.

This is a 160-bit structure that is allocated to one contiguous region in the `OTP` memory array. The functionality allows for individual flags to enable or disable specific features of the boot process. Each flag is allocated in a separate 16-bit word so that each flag can be set at different times and the ECC information will not impact the setting of another flag.

Table 45-58: ADI_ROM_OTP_BOOT_CFG Members

Type	Name	Description
`uint32_t`	`ctl_WEN:1` (bitfield)	Enable a write to the CGU_CTL register
`uint32_t`	`div_WEN:1` (bitfield) (bitfield)	Enable a write to the CGU_DIV register
`uint32_t`	`reserved0:1` (bitfield)	Reserved
`uint32_t`	`div_DSEL:5` (bitfield)	CGU_DIV.DSEL value
`uint32_t`	`div_CSEL:5` (bitfield) (bitfield)	CGU_DIV.CSEL value
`uint32_t`	`div_S0SEL:3` (bitfield)	CGU_DIV.S0SEL value
`uint32_t`	`div_SYSSEL:5` (bitfield)	CGU_DIV.SYSSEL value
`uint32_t`	`div_S1SEL:3` (bitfield)	CGU_DIV.S1SEL value
`uint32_t`	`div_OSEL:7` (bitfield)	CGU_DIV.OSEL value
`uint32_t`	`div_DF:1` (bitfield)	CGU_CTL.DF value
`uint32_t`	`div_MSEL:1` (bitfield) (bitfield)	CGU_CTL.MSEL value
`uint32_t`	`auto_disable:1`(bitfield)	Disable polling on auto alignment of clocks (not recommended)

Table 45-58: ADI_ROM_OTP_BOOT_CFG Members (Continued)

Type	Name	Description
uint32_t	reserved1:16 (bitfield)	Reserved
uint32_t	clkoutsel_CLKOUTSEL:5 (bitfield)	CGU_CLKOUTSEL.CLKOUTSEL value
uint32_t	reserved5:15 (bitfield)	Reserved
uint32_t	clkoutsel_WEN:1 (bitfield) (bitfield)	Enable write to the CGU_CLKOUTSEL register
uint32_t	reserved2:12 (bitfield)	Reserved
uint32_t	oscwctl0_WEN:1 (bitfield)	Enables write to the instance 0 register
uint32_t	oscwctl0_HODF:6 (bitfield)	Value
uint32_t	oscwctl0_HODEN:1 (bitfield)	Value
uint32_t	oscwctl0_CNGEN:1 (bitfield)	Value
uint32_t	oscwctl0_BOUF:1 (bitfield)	Value
uint32_t	oscwctl0_BOUEN:5 (bitfield)	Value
uint32_t	oscwctl0_FAULTEN:1 (bitfield)	Value
uint32_t	oscwctl0_MONDIS:1 (bitfield)	Value
uint32_t	oscwctl0_FAULTPINDIS:1 (bitfield)	Value
uint32_t	reserved3:15 (bitfield)	Reserved
uint32_t	oscwctl1_WEN:1 (bitfield)	Enables write to the instance 1 register
uint32_t	oscwctl1_HODF:6 (bitfield)	Value
uint32_t	oscwctl1_HODEN:1 (bitfield)	Value
uint32_t	oscwctl1_CNGEN:1 (bitfield)	Value

Table 45-58: ADI_ROM_OTP_BOOT_CFG Members (Continued)

Type	Name	Description
uint32_t	oscwctl1_BOUF:1 (bitfield)	Value
uint32_t	oscwctl1_BOUEN:5 (bitfield)	Value
uint32_t	oscwctl1_FAULTEN:1 (bitfield)	Value
uint32_t	oscwctl1_MONDIS:1 (bitfield)	Value
uint32_t	oscwctl1_FAULTPINDIS:1 (bitfield)	Value
uint32_t	reserved4:14 (bitfield)	Reserved

lockMonitor

Flag to enable the status checking of ADI private OTP area.

pubkey0Inv

Invalidate Public Key 0, use next public key for secure boot

pubkey1Inv

Invalidate Public Key 1, Secure boot will no longer be operational as no further public keys

privkey0Inv

Invalidate Decryption Key 0, use next Decryption key for secure boot

privkey1Inv

Invalidate Decryption Key 1, use next Decryption key for secure boot

privkey2Inv

Invalidate Decryption Key 2, use next Decryption key for secure boot

privkey3Inv

Invalidate Decryption Key 3, once invalidated part will no longer be bootable

dmcEn

Enables configuration of the DMC from values in OTP stored in the format of the ADI_ROM_OTP_DMC_CONFIG object

dmcInv

Invalidates the DMC values in the OTP resulting is bypassing of DMC configuration

struct ADI_ROM_OTP_BOOT_CGU_INFO

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CGU_INFO`

The CGU configuration object located in `OTP` for configuration of the CGU by the boot software.

This is a 128-bit structure that is allocated to one contiguous region in the `OTP` memory array. Allows the boot software to configure the CGU for a more efficient boot process.

Table 45-59: ADI_ROM_OTP_BOOT_CGU_INFO Members

Type	Name	Description
`uint32_t`	`ctl_WEN:1` (bitfield)	Enable write to the `CGU_CTL` register
`uint32_t`	`div_WEN:1` (bitfield)	Enable write to the `CGU_DIV` register
`uint32_t`	`reserved0:1` (bitfield)	Reserved
`uint32_t`	`div_DSEL:5` (bitfield)	`CGU_DIV.DSEL` value
`uint32_t`	`div_CSEL:5` (bitfield)	`CGU_DIV.CSEL` value
`uint32_t`	`div_S0SEL:3` (bitfield)	`CGU_DIV.S0SEL` value
`uint32_t`	`div_SYSSEL:5` (bitfield)	`CGU_DIV.SYSSEL` value
`uint32_t`	`div_S1SEL:3` (bitfield)	`CGU_DIV.S1SEL` value
`uint32_t`	`div_OSEL:7` (bitfield)	`CGU_DIV.OSEL` value
`uint32_t`	`ctl_DF:1` (bitfield)	`CGU_CTL.DF` value
`uint32_t`	`ctl_MSEL:7` (bitfield)	`CGU_CTL.MSEL` value
`uint32_t`	`auto_disable:1` (bitfield)	disable polling on auto-alignment of clocks (not recommended)
`uint32_t`	`Reserved1:6` (bitfield)	Reserved
`uint32_t`	`clkoutsel_CLKOUTSEL:5` (bitfield)	`CGU_CLKOUTSEL.CLKOUTSEL` value
`uint32_t`	`clkoutsel_WEN:1` (bitfield)	Enable write to the `CGU_CLKOUTSEL` register
`uint32_t`	`reserved2:12` (bitfield)	Reserved
`uint32_t`	`oscwctl0_WEN:1` (bitfield)	Enable write to the `CGU_OSCWDCTL` instance 0 register
`uint32_t`	`oscwctl0_HODF:6` (bitfield)	`CGU_OSCWDCTL.HODF` value
`uint32_t`	`oscwctl0_HODEN:1` (bitfield)	`CGU_OSCWDCTL.HODEN` value
`uint32_t`	`oscwctl0_CNGEN:1` (bitfield)	`CGU_OSCWDCTL.CNGEN` value
`uint32_t`	`oscwctl0_BOUF:5` (bitfield)	`CGU_OSCWDCTL.BOUF` value
`uint32_t`	`oscwctl0_BOUEN:1` (bitfield)	`CGU_OSCWDCTL.BOUEN` value
`uint32_t`	`oscwctl0_FAULTEN:1` (bitfield)	`CGU_OSCWDCTL.FAULTEN` value
`uint32_t`	`oscwctl0_MONDIS:1` (bitfield)	`CGU_OSCWDCTL.MONDIS` value
`uint32_t`	`oscwctl0_FAULTPINDIS:1` (bitfield)	`CGU_OSCWDCTL.FAULTPINDIS` value

Table 45-59: ADI_ROM_OTP_BOOT_CGU_INFO Members (Continued)

Type	Name	Description
uint32_t	reserved3:14 (bitfield)	Reserved
uint32_t	oscwctl1_WEN:1 (bitfield)	Enable write to the CGU_OSCWDCTL instance 1 register
uint32_t	oscwctl1_HODF:6 (bitfield)	CGU_OSCWDCTL.HODF value
uint32_t	oscwctl1_HODEN:1 (bitfield)	CGU_OSCWDCTL.HODEN value
uint32_t	oscwctl1_CNGEN:1 (bitfield)	CGU_OSCWDCTL.CNGEN value
uint32_t	oscwctl1_BOUF:5 (bitfield)	CGU_OSCWDCTL.BOUF value
uint32_t	oscwctl1_BOUEN:1 (bitfield)	CGU_OSCWDCTL.BOUEN value
uint32_t	oscwctl1_FAULTEN:1 (bitfield)	CGU_OSCWDCTL.FAULTEN value
uint32_t	oscwctl1_MONDIS:1 (bitfield)	CGU_OSCWDCTL.MONDIS value
uint32_t	oscwctl1_FAULTPINDIS:1 (bitfield)	CGU_OSCWDCTL.FAULTPINDIS value
uint32_t	reserved4:14 (bitfield)	Reserved

ctl_WEN

Enable write to the CGU_CTL register

div_WEN

Enable write to the CGU_DIV register

div_DSEL

CGU_DIV.DSEL value

div_CSEL

CGU_DIV.CSEL value

div_S0SEL

CGU_DIV.S0SEL value

div_SYSSEL

CGU_DIV.SYSSEL value

div_S1SEL

CGU_DIV.S1SEL value

div_OSEL

CGU_DIV.OSEL value

ctl_DF

CGU_CTL.DF value

ctl_MSEL

CGU_CTL.MSEL value

auto_disable

disable polling on auto-alignment of clocks, NOT RECOMMENDED!

clkoutsel_CLKOUTSEL

CGU_CLKOUTSEL.CLKOUTSEL value

clkoutsel_WEN

Enable write to the CGU_CLKOUTSEL register

oscwctl0_WEN

Enable write to the CGU_OSCWDCTL instance 0 register

oscwctl0_HODF

CGU_OSCWDCTL.HODF value

oscwctl0_HODEN

CGU_OSCWDCTL.HODEN value

oscwctl0_CNGEN

CGU_OSCWDCTL.CNGEN value

oscwctl0_BOUF

CGU_OSCWDCTL.BOUF value

oscwctl0_BOUEN

CGU_OSCWDCTL.BOUEN value

oscwctl0_FAULTEN

CGU_OSCWDCTL.FAULTEN value

oscwctl0_MONDIS

CGU_OSCWDCTL.MONDIS value

oscwctl0_FAULTPINDIS

CGU_OSCWDCTL.FAULTPINDIS value

oscwctl1_WEN

Enable write to the CGU_OSCWDCTL instance 1 register

oscwctl1_HODF

`CGU_OSCWDCTL.HODF` value

oscwctl1_HODEN

`CGU_OSCWDCTL.HODEN` value

oscwctl1_CNGEN

`CGU_OSCWDCTL.CNGEN` value

oscwctl1_BOUF

`CGU_OSCWDCTL.BOUF` value

oscwctl1_BOUEN

`CGU_OSCWDCTL.BOUEN` value

oscwctl1_FAULTEN

`CGU_OSCWDCTL.FAULTEN` value

oscwctl1_MONDIS

`CGU_OSCWDCTL.MONDIS` value

oscwctl1_FAULTPINDIS

`CGU_OSCWDCTL.FAULTPINDIS` value

struct ADI_ROM_OTP_BOOT_CMD_INFO

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CMD_INFO`

The boot command object for storing a customized boot command for each boot mode within the `OTP` memory array.

This is a 160-bit structure that is allocated to one contiguous region in the `OTP` memory array. Allows the boot ROM software to pass a custom boot command to a specific boot mode which changes the default boot behavior on startup. Can be used to change the default UART instance used for a UART boot operation (for example).

Table 45-60: ADI_ROM_OTP_BOOT_CMD_INFO Members

Type	Name	Description
`uint32_t`	`spiMasterBootCmd`	SPI Master Boot Mode
`uint32_t`	`spiSlaveBootCmd`	SPI Slave Boot Mode
`uint32_t`	`lpBootCmd`	Link Port Target Boot Mode
`uint32_t`	`uartBootCmd`	UART Controller Boot Mode

Table 45-60: ADI_ROM_OTP_BOOT_CMD_INFO Members (Continued)

Type	Name	Description
uint32_t	ospiMasterBootCmd	OSPI Controller Boot Mode

spiMasterBootCmd

SPI Master Boot Mode

spiSlaveBootCmd

SPI Slave Boot Mode

lpBootCmd

Link Port Target Boot Mode

uartBootCmd

UART Controller Boot Mode

ospiMasterBootCmd

OSPI Controller Boot Mode

struct ADI_ROM_OTP_BOOT_INFO

Structure Type Declaration: ADI_ROM_OTP_BOOT_INFO

The 576-bit boot info object located in OTP for boot customization.

This is a 576-bit structure that is allocated to one contiguous region in the OTP memory array. The content in OTP is stored in the format of this structure so boot can read the contents directly into this object.

Programs can read this object using the adi_rom_otp_get() routine supplying the enum OTPCMD enumeration

Table 45-61: ADI_ROM_OTP_BOOT_INFO Members

Type	Name	Description
struct ADI_ROM_OTP_BOOT_CGU_INFO	cgu	CGU Configuration information
uint32_t	flashStartAddress	Flash Start address for the SPI/OSPI master boot mode
struct ADI_ROM_OTP_BOOT_CMD_INFO	bcmd	Boot Command customization for each boot mode to change default boot peripheral instance and configuration
struct ADI_ROM_OTP_BOOT_CMD_INFO	rdcr	Additional OSPI configuration used for OSPI boot mode

Table 45-61: ADI_ROM_OTP_BOOT_INFO Members (Continued)

Type	Name	Description
uint16_t	ospi_rdcr_ reserved0	Reserved
struct ADI_ROM_OTP_BOOT_CFG	bcfg	Additional boot configuration flags for key invalidation and to enable DMC configuration
uint32_t	val14	Reserved
uint16_t	otpReadTiming	Reserved, Must always be zero
uint16_t	reserved1	Reserved

cgu

CGU Configuration information

flashStartAddress

Flash start address for the SPI/OSPI master boot mode

bcmd

Boot Command customization for each boot mode to change the default boot peripheral instance and configuration

rdcr

Additional OSPI configuration info that is used for OSPI boot mode

bcfg

Additional boot configuration flags for key invalidation and for enabling DMC configuration

otpReadTiming

Reserved, Must always be zero

struct ADI_ROM_OTP_DMC_CONFIG

Structure Type Declaration: `ADI_ROM_OTP_DMC_CONFIG`

The 384-bit configuration object located in OTP for configuration of the DMC during preboot.

Makes use of the memories connected to the DMC peripheral during boot without the use of init codes in the boot stream. The settings can be applied to this object in the OTP memory. During preboot the boot software reads the object from OTP and configures the peripheral accordingly.

NOTE: When the device is open programs should avoid using OTP and instead use initcodes to initialize DMC because the initcode method is highly customizable. To lock the device to enable secure boot (to boot to

memories interfaced to the DMC) the configuration must be provisioned to OTP because initcodes are not supported in secure boot.

Table 45-62: ADI_ROM_OTP_DMC_CONFIG Members

Type	Name	Description
uint32_t	ulDDR_DLLCTLCFG	Content of DDR DLLCTL and DMC_CFG register
uint32_t	ulDDR_MR2MR3	Content of the DDR MR2 and MR3 register
uint32_t	ulDDR_CTL	Content of the DDR Control register
uint32_t	ulDDR_MRMR1	Content of the DDR MR and MR1 register
uint32_t	ulDDR_TR0	Content of the DDR Timing register
uint32_t	ulDDR_TR1	Content of the DDR Timing register
uint32_t	ulDDR_TR2	Content of the DDR Timing register
uint32_t	ulDDR_ZQCTL0	Content of ZQCTL0 register
uint32_t	ulDDR_ZQCTL1	Content of ZQCTL1 register
uint32_t	ulDDR_ZQCTL2	Content of ZQCTL2 register
uint32_t	ulDDRPHY_CACTL	Content of DDRPHY_DDR_CA_CTL register
uint32_t	uBypassDelay_LANE0CTL1:6	Content of DDR_LANE0_CTL1[15:10] register
uint32_t	uBypassDelay_LANE1CTL1:6	Content of DDR_LANE1_CTL1[15:10] register
uint32_t	uBypassDelay_LANE0CTL0:6	Content of DDR_LANE0_CTL0[15:10] register
uint32_t	uBypassDelay_LANE1CTL0:6	Content of DDR_LANE1_CTL0[15:10] register
uint32_t	reserved0:8	Reserved

struct ROM_BOOT_DMA_INSTANCE

Structure Type Declaration: ROM_BOOT_DMA_INSTANCE

DMA Channel Instance.

Specifies the base MMR address of the DMA channel as well as trigger and interrupt IDs

Table 45-63: ROM_BOOT_DMA_INSTANCE Members

Type	Name	Description
ADI_DMA_TypeDef *	pReg	Pointer to the base address of the DMA channel MMR registers
DMA_CHANn_TypeDef	eDmaChannelId	The actual DMA channel ID in the system
uint8_t	TriggerId	The trigger ID associated with the DMA channel
uint8_t	InterruptId	The interrupt ID associated with the DMA channel

pReg

Pointer to the base address of the DMA channel MMR registers

eDmaChannelId

The actual DMA channel ID in the system

TriggerId

The trigger ID associated with the DMA channel

InterruptId

The interrupt ID associated with the DMA channel

struct ROM_BOOT_MDMA

Structure Type Declaration: `ROM_BOOT_MDMA`

MDMA Channels.

Provides access to all the MDMA channels and CRC peripherals supported by the processor

Table 45-64: ROM_BOOT_MDMA Members

Type	Name	Description
`ROM_BOOT_MDMA_REGS[PARAM_SYS0_NUM_MDMA_STREAMS]`	`Stream`	Array of MDMA channel configurations supported by the processor

Stream

Array of MDMA channel configurations supported by the processor

struct ROM_BOOT_MDMA_REGS

Structure Type Declaration: `ROM_BOOT_MDMA_REGS`

MDMA Channel Registers.

Contains the Source and Destination MDMA channel instances for access to the MMRs and interrupt and trigger information. Information is also provided on the CRC support of the MDMA channel and access is provided to the corresponding CRC peripheral.

Table 45-65: ROM_BOOT_MDMA_REGS Members

Type	Name	Description
`struct ROM_BOOT_DMA_INSTANCE`	`Src`	The source DMA Channel in the MDMA pair
`ROM_BOOT_DMA_INSTANCE`	`Dst`	The destination DMA Channel in the MDMA pair
`ADI_CRC_TypeDef *`	`pCrc`	The base MMR address of the associated CRC peripheral if one exists

Table 45-65: ROM_BOOT_MDMA_REGS Members (Continued)

Type	Name	Description
enum ROM_BOOT_MDMA_CRC_SUPPORT	eCrcSupport	Indicates if the MDMA channel supports CRC or not

Src

The source DMA Channel in the MDMA pair

Dst

The destination DMA Channel in the MDMA pair

pCrc

The base MMR address of the associated CRC peripheral if one exists

eCrcSupport

Indicates if the MDMA channel supports CRC or not

struct ROM_DMA_MDMA_CONFIG

Structure Type Declaration: ROM_DMA_MDMA_CONFIG

MDMA Configuration Object.

The configurable structure for controlling the MDMA operation supplied to the adi_rom_MemDma() routine.

Table 45-66: ROM_DMA_MDMA_CONFIG Members

Type	Name	Description
enum ROM_DMA_MDMA_OPERATION	eOperation	Type of operation to perform
enum ROM_DMA_MDMA_ID	eId	MDMA Channel ID
void *	pSource	Source Pointer
void *	pDestination	Destination Pointer
uint32_t	ByteCount	Byte Count
enum ROM_DMA_DONE_DETECT_METHOD	eDoneDetect	DMA Done Detection Method
uint32_t	CrcCtl	CRC_CTL value when CRC operations are required
uint32_t	FillVal	Fill value for memory fill operations
uint32_t	CrcPoly	CRC Polynomial for CRC operations

Table 45-66: ROM_DMA_MDMA_CONFIG Members (Continued)

Type	Name	Description
uint32_t	CrcCompare	Value used for CRC compare operations or for a CRC32 result compare

eOperation

Type of operation to perform

eId

MDMA Channel ID

pSource

Source Pointer

pDestination

Destination Pointer

ByteCount

Byte Count

eDoneDetect

DMA Done Detection Method

CrcCtl

CRC_CTL value when CRC operations are required

FillVal

Fill value for memory fill operations

CrcPoly

CRC Polynomial for CRC operations

CrcCompare

Value used for CRC compare operations or for a CRC32 result compare

struct ROM_DMA_PDMA_CONFIG

Structure Type Declaration: ROM_DMA_PDMA_CONFIG

PDMA Configuration Object.

The user configurable structure for controlling the PDMA operation via the adi_rom_PeriphDma() function.

Table 45-67: ROM_DMA_PDMA_CONFIG Members

Type	Name	Description
enum ROM_DMA_PDMA_OPERATION	eOperation	Type of operation to perform
ADI_DMA_TypeDef volatile *	pRegs	Pointer to the base address of the DMA channel MMR registers
uint16_t	dataWidth	The maximum supported data width of the DMA channel. Used to configure the DMA_CFG.PSIZE PSIZE field in DMA_CFG
uint16_t	dstModifyMult	The modify multiplier, usually set to 1
void *	pSource	Source Pointer used for transmit operations
void *	pDestination	Destination Pointer used for receive operations
uint32_t	byteCount	Number of bytes to transfer
enum ROM_DMA_DONE_DETECT_METHOD	eDoneDetect	DMA Done Detection method used for the transfer
enum ROM_DMA_DONE_DETECT_METHOD	loadType	Defines whether the load function DMA waits for the load to complete or returns to the kernel

eOperation

Type of operation to perform

pRegs

Pointer to the base address of the DMA channel MMR registers

dataWidth

The maximum supported data width of the DMA channel. Used to configure the DMA_CFG.PSIZE PSIZE field in DMA_CFG

dstModifyMult

The modify multiplier, usually set to 1

pSource

Source Pointer used for transmit operations

pDestination

Destination Pointer used for receive operations

byteCount

Number of bytes to transfer

eDoneDetect

DMA Done Detection method used for the transfer

loadType

Defines whether the load function DMA waits for the load to complete or returns to the kernel

struct OTP_DATA

Structure Type Declaration: `otp_data`

Container for accessing data to be written to `OTP` via the `adi_rom_otp_pgm()` routine.

Any pointers that are `NULL` will result in the object not being written. Any data values of 0 will not be written.

Table 45-68: otp_data Members

Type	Name	Description
`void (*)`	`reserved`	
`uint32_t(*) [ROM_OTP_SZ_huk]`	`huk`	Pointer to 256-bit Hardware Unique Key
`uint32_t(*) [ROM_OTP_SZ_rkek]`	`rkek`	Pointer to 128-bit Root Key Encryption Key
`uint 32_t(*) [ROM_OTP_SZ_dek]`	`dek`	Pointer to 128-bit Local Encryption Key
`uint32_t(*) [ROM_OTP_SZ_oem_public _key]`	`oem_public_key`	Pointer to 512-bit OEM Public Key
`uint32_t(*) [ROM_OTP_SZ_pvt_ 128key0]`	`pvt_128key0`	Pointer to 128-bit AES Key
`uint32_t(*) [ROM_OTP_SZ_pvt_ 128key1]`	`pvt_128key1`	Pointer to 128-bit AES Key
`uint32_t(*) [ROM_OTP_SZ_pvt_ 128key2]`	`pvt_128key2`	Pointer to 128-bit AES Key
`uint32_t(*) [ROM_OTP_SZ_pvt_ 128key3]`	`pvt_128key3`	Pointer to 128-bit AES Key
`uint32_t(*) [ROM_OTP_SZ_ek]`	`ek`	Pointer to 256-bit endorsement key
`uint32_t(*) [ROM_OTP_SZ_secure_emu _key0]`	`secure_emu_key0`	Pointer to 128-bit Secure Debug Key

Table 45-68: otp_data Members (Continued)

Type	Name	Description
`uint32_t(*) [ROM_OTP_SZ_secure_emu_key1]`	`secure_emu_key1`	Pointer to 128-bit Secure Debug Key
`uint32_t`	`emu_key0_disable :16` (bitfield)	Secure Debug key disable
`uint32_t`	`emu_key1_disable :16` (bitfield)	Secure Debug key disable
`uint32_t(*) [ROM_OTP_SZ_public_key0]`	`public_key0`	Pointer to 512-bit public key used for boot stream authentication
`uint32_t(*) [ROM_OTP_SZ_public_key1]`	`public_key1`	Pointer to 512-bit public key used for boot stream authentication
`uint32_t(*) [ROM_OTP_SZ_boot_info]`	`boot_info`	Pointer to 608-bit boot customization structure, see also `struct ADI_ROM_OTP_BOOT_INFO`
`uint8_t`	`antiroll_nv_cntr`	Anti-rollback counter to prevent loading of older firmware during secure boot.
`uint32_t(*) [ROM_OTP_SZ_gp1]`	`gp1`	Pointer to 512-bit General purpose user space
`uint32_t`	`bootModeDisable: 8` (bitfield)	Boot mode disable for permanently disabling specific boot modes
`uint32_t(*) [ROM_OTP_SZ_preboot_ddr_cfg]`	`preboot_ddr_cfg`	Pointer to 384-bit DMC configuration. See also `struct ADI_ROM_OTP_BOOT_INFO`
`uint32_t(*) [ROM_OTP_SZ_stageID]`	`stageID`	Pointer to 64-bit staging ID

huk

Pointer to 256-bit Hardware Unique Key

rkek

Pointer to 128-bit Root key Encryption Key

dek

Pointer to 128-bit Local Encryption Key

oem_public_key

Pointer to 512-bit OEM Public Key

pvt_128key0

Pointer to 128-bit AES Key

pvt_128key1

Pointer to 128-bit AES Key

pvt_128key2

Pointer to 128-bit AES Key

pvt_128key3

Pointer to 128-bit AES Key

ek

Pointer to 256-bit endorsement key

secure_emu_key0

Pointer to 128-bit Secure Debug Key

secure_emu_key1

Pointer to 128-bit Secure Debug Key

emu_key0_disable

Secure debug key disable

emu_key1_disable

Secure debug key disable

public_key0

Pointer to 512-bit public key used for boot stream authentication

public_key1

Pointer to 512-bit public key used for boot stream authentication

boot_info

Pointer to 608-bit boot customization structure, see also `struct ADI_ROM_OTP_BOOT_INFO`

antiroll_nv_cntr

Anti-rollback counter to prevent loading of older firmware during secure boot.

The counter supports values of 0 through 31. The counter feature is disabled as long as the counter is set initially to 0.

gp1

Pointer to 512-bit General purpose user space

bootModeDisable

Boot mode disable for permanently disabling specific boot modes

preboot_ddr_cfg

Pointer to 384-bit DMC Configuration. See also `struct ADI_ROM_OTP_DMC_CONFIG`

stageID

Pointer to 64-bit staging ID

Enumerations

The programming model for booting the processor uses the enumerations defined in this section.

enum ADI_ROM_BOOT_KEY_TYPE

Enumeration Type Declaration: `ADI_ROM_BOOT_KEY_TYPE`

Indicates if custom security keys are used for evaluation of secure boot.

By default the boot process fetches all security keys from OTP for use during secure boot. Custom security lets the program set their custom keys in the `struct ADI_ROM_BOOT_CONFIG` item (not from OTP). Secure boot is evaluated using the `adi_rom_Boot()` function without provisioning keys in OTP.

Table 45-69: ADI_ROM_BOOT_KEY_TYPE Members

Enumerator	Description
`ADI_ROM_CUSTOM_SECURITY`	Enable use of custom security keys for authentication and decryption

ADI_ROM_CUSTOM_SECURITY

Enable use of custom security keys for authentication and decryption

enum ADI_ROM_BOOT_TYPE

Enumeration Type Declaration: `ADI_ROM_BOOT_TYPE`

Indicate to the boot kernel (in an open processor) if secure or non secure boot is required.

The boot kernel defaults to a secure boot unless the boot structure has been configured to indicate Non-Secure Boot

Table 45-70: ADI_ROM_BOOT_TYPE Members

Enumerator	Description
`ADI_ROM_SECURE_BOOT_DIS`	Non-Secure Boot
`ADI_ROM_SECURE_BOOT`	Secure Boot

Table 45-70: ADI_ROM_BOOT_TYPE Members (Continued)

Enumerator	Description
`ADI_ROM_SECURE_BOOT_HASH_ONLY`	Boot kernel supports for hash compare only if this boot type selected using the ROM API. ECDSA verification is skipped.

ADI_ROM_SECURE_BOOT_DIS

Non-Secure Boot

ADI_ROM_SECURE_BOOT

Secure Boot

ADI_ROM_SECURE_BOOT_HASH_ONLY

Boot kernel supports for hash compare only if this boot type selected using ROM API. ECDSA verification is skipped.

enum OTPCMD

Enumeration Type Declaration: `OTPCMD`

Commands required by the `adi_rom_otp_get()` routine to retrieve specific fields from the OTP memory.

Table 45-71: OTPCMD Members

Enumerator	Description
`otpcmd_huk`	Hardware Unique Key
`otpcmd_rkek`	Root key Encryption Key
`otpcmd_dek`	Local Encryption Key
`otpcmd_oem_public_key`	OEM Public Key
`otpcmd_pvt_128key0`	Customer Private AES Key0
`otpcmd_pvt_128key1`	Customer Private AES Key1
`otpcmd_pvt_128key2`	Customer Private AES Key2
`otpcmd_pvt_128key3`	Customer Private AES Key3
`otpcmd_ek`	Endorsement Key
`otpcmd_secure_emu_key0`	Secure Emulation Key 0
`otpcmd_secure_emu_key1`	Secure Emulation Key 1
`otpcmd_emu_key0_disable`	Secure emulation key 0 disable
`otpcmd_emu_key1_disable`	Secure emulation key 1 disable
`otpcmd_public_key0`	Customer Public Key0
`otpcmd_public_key1`	Customer Public Key1

Table 45-71: OTPCMD Members (Continued)

Enumerator	Description
otpcmd_boot_info	Customer Programmable Boot Information
otpcmd_otpTiming	OTP Read timing override
otpcmd_antiroll_nv_cntr	AntiRollback NV Counter
otpcmd_gp1	General Purpose 1
otpcmd_bootModeDisable	Boot Mode Disable Bits
otpcmd_preboot_ddr_cfg	User DMC configuration
otpcmd_stageID	StageID

otpcmd_huk

Hardware Unique Key

otpcmd_rkek

Root Encryption Key

otpcmd_dek

Local Encryption Key

otpcmd_oem_public_key

OEM Public Key

otpcmd_pvt_128key0

Customer Private AES Key0

otpcmd_pvt_128key1

Customer Private AES Key1

otpcmd_pvt_128key2

Customer Private AES Key2

otpcmd_pvt_128key3

Customer Private AES Key3

otpcmd_ek

Endorsement Key

otpcmd_secure_emu_key0

Secure Emulation Key 0

otpcmd_secure_emu_key1

Secure Emulation Key 1

otpcmd_emu_key0_disable

Secure emulation key 0 disable

otpcmd_emu_key2_disable

Secure emulation key 2 disable

otpcmd_public_key0

Customer Public Key0

otpcmd_public_key1

Customer Public Key1

otpcmd_boot_info

Customer Programmable Boot Information

otpcmd_otpTiming

OTP Read timing override

otpcmd_antiroll_nv_cntr

AntiRollback NV Counter

otpcmd_gp1

General Purpose 1

otpcmd_bootModeDisable

Boot Mode Disable Bits

otpcmd_preboot_ddr_cfg

User DMC configuration

otpcmd_stageID

StageID

enum ROM_BOOT_MDMA_CRC_SUPPORT

Enumeration Type Declaration: `ROM_BOOT_MDMA_CRC_SUPPORT`

MDMA Channel CRC support.

Specifies whether the MDMA channel supports CRC operations or not

Table 45-72: ROM_BOOT_MDMA_CRC_SUPPORT Members

Enumerator	Description
ROM_BOOT_DMA_CRC_SUPPORTED	MDMA Channel supports CRC
ROM_BOOT_DMA_CRC_NOT_SUPPORTED	MDMA Channel does not support CRC

ROM_BOOT_DMA_CRC_SUPPORTED

MDMA Channel supports CRC

ROM_BOOT_DMA_CRC_NOT_SUPPORTED

MDMA Channel does not support CRC

enum ROM_BOOT_RESULT

Enumeration Type Declaration: ROM_BOOT_RESULT

General Boot ROM Return Types.

Used throughout the boot software to indicate various success and failure events that can occur during boot.

Table 45-73: ROM_BOOT_RESULT Members

Enumerator	Description
ROM_BOOT_FAILURE	Failure
ROM_BOOT_SUCCESS	Success
ROM_BOOT_HDR_CHKSUM_ERR	Boot Stream Block Header Checksum Error
ROM_BOOT_HDR_SIGN_ERR	Boot Stream Block Header Sign Failure
ROM_BOOT_HDR_DEST_ERR	Boot Stream Block Payload Destination Error
RESERVED0	Reserved
RESERVED1	Reserved
RESERVED2	Reserved
RESERVED3	Reserved
ROM_BOOT_CGU_WRITE_ERR	CGU Write Error
ROM_BOOT_DMA_SUCCESS	DMA operation was successful
ROM_BOOT_DMA_FAILURE	DMA Failure.
ROM_BOOT_DMA_ACTIVE	DMA Channel is Active
ROM_BOOT_DMA_CONFIG_ERR	DMA configuration error
ROM_BOOT_MDMA_ID_ERR	Illegal MDMA Channel ID
ROM_BOOT_MDMA_OPERATION_ERR	Illegal MDMA operation Specified

Table 45-73: ROM_BOOT_RESULT Members (Continued)

Enumerator	Description
ROM_BOOT_MDMA_CONFIG_ERR	Memory DMA configuration error
ROM_BOOT_MDMA_SRC_ERR	MDMA Source Channel Configuration Error
ROM_BOOT_MDMA_DST_ERR	MDMA Destination Channel Configuration Error
ROM_BOOT_MDMA_DONE_DETECT_ERR	Memory DMA Completed with errors
ROM_BOOT_MDMA_SUCCESS	Memory DMA Completed successfully
ROM_BOOT_PDMA_CONFIG_ERR	Peripheral DMA configuration invalid
ROM_BOOT_PDMA_SUCCESS	Peripheral DMA completed successfully
ROM_BOOT_CRC_FAILURE	MDMA CRC32 Failure
ROM_BOOT_CRC_CONFIG_ERR	MDMA CRC32 CONFIG error
ROM_BOOT_CRC_COUNT_ERR	CRC Byte Count was not a multiple 4
ROM_BOOT_CRC_SUPPORTED_ERR	CRC Not Supported Error.
ROM_BOOT_CRC_INITCODE_ERR	CRC32 Enable Failure During Boot
ROM_BOOT_CRC_CALLBACK_ERR	Error in Execution of the CRC Callback
ROM_BOOT_CRC_SUCCESS	MDMA CRC Success

ROM_BOOT_FAILURE

Failure.

General failure can be used to indicate any general failure throughout the boot process

ROM_BOOT_SUCCESS

Success.

General success can be used to indicate any general functional success for an operation during the boot process.

NOTE: This must be the return result for a boot mode drivers initialization, configuration, load and cleanup routines when overriding their functionality in second stage boot loaders to use custom functions.

ROM_BOOT_HDR_CHKSUM_ERR

Boot Stream Block Header Checksum Error.

Indicates that the 8-bit XOR checksum of the 16-byte block header failed to generated the expected result.

ROM_BOOT_HDR_SIGN_ERR

Boot Stream Block Header Sign Failure.

The 0xAD block required as byte 4 of the boot block header was not found.

ROM_BOOT_HDR_DEST_ERR

Boot Stream Block Payload Destination Error.

The target address field of the block header indicates that the payload for the block is destined towards an address that is not supported. Indicates an attempt to load data to the reserved 8 KB non-bootable region of memory reserved by the boot process.

ROM_BOOT_CGU_WRITE_ERR

CGU Write Error

Returned by the CGU configuration routine if a CGU error is set during its initialization from settings provisioned in the OTP.

ROM_BOOT_DMA_SUCCESS

DMA operation was successful

ROM_BOOT_DMA_FAILURE

DMA Failure.

Returned by the DMA routines if an error was detected in the `DMA_STAT.IRQERR` prior to setting up a new DMA operation with the newly supplied configuration.

ROM_BOOT_DMA_ACTIVE

DMA Channel is Active

Returned only by the peripheral DMA routine when an attempt to run another peripheral DMA operation is attempted and the DMA channel is already running.

NOTE: This is not currently implemented for MDMA operations.

ROM_BOOT_DMA_CONFIG_ERR

DMA configuration error

ROM_BOOT_MDMA_ID_ERR

Illegal MDMA Channel ID.

Returned by `adi_rom_MemDma()` if the MDMA channel ID is not supported. For supported channel IDs, see enum ROM_DMA_MDMA_ID

ROM_BOOT_MDMA_OPERATION_ERR

Illegal MDMA operation Specified.

Returned by `adi_rom_MemDma()` if the MDMA operation is not supported. For supported operations, see `enum ROM_DMA_MDMA_OPERATION`

ROM_BOOT_MDMA_CONFIG_ERR

Memory DMA configuration error

ROM_BOOT_MDMA_SRC_ERR

MDMA Source Channel Configuration Error.

Set by the MDMA routines if after configuring the MDMA source channel to start a DMA operation, an error is generated in the source channels `DMA_STAT.IRQERR`

ROM_BOOT_MDMA_DST_ERR

MDMA Destination Channel Configuration Error.

Set by the MDMA routines when an error is generated in the destination channels `DMA_STAT.IRQERR` bit (after configuring the MDMA source channel to start a DMA operation)

ROM_BOOT_MDMA_DONE_DETECT_ERR

Memory DMA Completed with errors

ROM_BOOT_MDMA_SUCCESS

Memory DMA Completed successfully

ROM_BOOT_PDMA_CONFIG_ERR

Peripheral DMA configuration invalid

ROM_BOOT_PDMA_SUCCESS

Peripheral DMA completed successfully

ROM_BOOT_CRC_FAILURE

MDMA CRC32 Failure.

Returned by the higher level `adi_rom_MemDma()` routine and the underlying `adi_rom_MemCompare()` routine if the CRC32 result of the block of data did not match the expected result.

ROM_BOOT_CRC_CONFIG_ERR

MDMA CRC32 CONFIG error

ROM_BOOT_CRC_COUNT_ERR

CRC Byte Count was not a multiple 4.

The CRC peripheral operates on 32-bit data only and as such all CRC operations must have a byte count that is a multiple of 4. This result is returned by the higher level `adi_rom_MemDma()` routine and the underlying `adi_rom_MemCompare()` and `adi_rom_MemFill()` routines if the byte count is not a multiple of 4 bytes.

ROM_BOOT_CRC_SUPPORTED_ERR

CRC Not Supported Error.

Returned by `adi_rom_MemDma()`, `adi_rom_MemFill()`, `adi_rom_MemCompare()` and `adi_rom_Crc32Poly()` if the supplied DMA configuration specified a MDMA channel that does not support CRC operations.

ROM_BOOT_CRC_INITCODE_ERR

CRC32 Enable Failure During Boot.

Returned by adi_rom_Crc32Init() if the boot process cannot enable the CRC32 functionality due to a `NULL` `struct ADI_ROM_BOOT_CONFIG` pointer or `NULL` `struct ADI_ROM_BOOT_HEADER` pointer located in `pHeader Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel`

ROM_BOOT_CRC_CALLBACK_ERR

Error in Execution of the CRC Callback.

Returned by the default CRC callback function located in the boot ROM if any of the following conditions are met:

- The `struct ADI_ROM_BOOT_CONFIG` pointer passed to the callback is a `NULL` pointer
- The `struct ADI_ROM_BOOT_BUFFER` pointer to the buffer to run CRC validation is a `NULL` pointer
- The `ROM_CBFLAG_DIRECT` flag is not set in the supplied flags parameter indicating it was a direct callback
- The `struct ADI_ROM_BOOT_HEADER` pointer located in `pHeader Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel` is a `NULL` pointer

ROM_BOOT_CRC_SUCCESS

MDMA CRC Success

enum ROM_CORE_ID

Enumeration Type Declaration: `ROM_CORE_ID`

Core ID.

An enumeration for referencing a particular core

Table 45-74: ROM_CORE_ID Members

Enumerator	Description
ROM_CORE_ID0	Core 0
ROM_CORE_ID1	Core 1
ROM_CORE_ID2	Core 2
ROM_CORE_NUM_CORES	Number of Cores

ROM_CORE_ID0

Core 0

ROM_CORE_NUM_CORES

Number of Cores

enum ROM_DMA_DONE_DETECT_METHOD

Enumeration Type Declaration: ROM_DMA_DONE_DETECT_METHOD

DMA Done Detection Method.

Specifies the method used to detect the completion of the requested DMA operation.

When a program requests a non-blocking DMA operation, separate software is required to check the status of the DMA channel. The boot ROM does not provide an API for this operation.

NOTE: Trigger mode is not supported on this product

Table 45-75: ROM_DMA_DONE_DETECT_METHOD Members

Enumerator	Description
ROM_DMA_DONE_NON_BLOCKING	Return without waiting for the DMA to complete
ROM_DMA_DONE_POLL_IRQDONE	Poll on the IRQDONE bit in the DMA Status register
ROM_DMA_DONE_WAKEUP_TRIGGER	Configure a trigger to wakeup the core on completion

ROM_DMA_DONE_NON_BLOCKING

Return without waiting for the DMA to complete

ROM_DMA_DONE_POLL_IRQDONE

Poll on the IRQDONE bit in the DMA Status register

ROM_DMA_DONE_WAKEUP_TRIGGER

Configure a trigger to wakeup the core on completion

enum ROM_DMA_MDMA_ID

Enumeration Type Declaration: `ROM_DMA_MDMA_ID`

MDMA Channel ID.

The ID of the Memory DMA channel. Used in the `struct ROM_DMA_MDMA_CONFIG` configuration to specify the Memory DMA channel to use for operations accessible using the `adi_rom_MemDma()` routine

Table 45-76: ROM_DMA_MDMA_ID Members

Enumerator	Description
`ROM_DMA_MDMA0`	Memory DMA Stream 0
`ROM_DMA_MDMA1`	Memory DMA Stream 1
`ROM_DMA_MDMA2`	Memory DMA Stream 2
`ROM_DMA_MDMA3`	Memory DMA Stream 3
`ROM_DMA_MEMDMA_END_COUNT`	Number of Memory DMA Streams

ROM_DMA_MDMA0

Memory DMA Stream 0

ROM_DMA_MDMA1

Memory DMA Stream 1

ROM_DMA_MDMA2

Memory DMA Stream 2

ROM_DMA_MDMA3

Memory DMA Stream 3

ROM_DMA_MEMDMA_END_COUNT

Number of Memory DMA Streams

enum ROM_DMA_MDMA_OPERATION

Enumeration Type Declaration: `ROM_DMA_MDMA_OPERATION`

MDMA Operation.

The operation determines if only an MDMA is required, or whether a CRC operation must be used in conjunction with the MDMA.

Table 45-77: ROM_DMA_MDMA_OPERATION Members

Enumerator	Description
ROM_DMA_MEM_COPY	Standard MDMA transfer from a source to a destination
ROM_DMA_MEM_CRC	Performs a CRC32 MDMA read operation and compares the result with an expected result
ROM_DMA_MEM_FILL	Uses the CRC peripheral to perform a fill operation with a 32-bit value
ROM_DMA_MEM_COMPARE	Uses the CRC peripheral to compare data with a constant 32-bit value
ROM_DMA_CRC_LUT_INIT	Initializes the CRC LUT from the supplied CRC Polynomial

ROM_DMA_MEM_COPY

Standard MDMA transfer from a source to a destination

ROM_DMA_MEM_CRC

Performs a CRC32 MDMA read operation and compares the result with an expected result

ROM_DMA_MEM_FILL

Uses the CRC peripheral to perform a fill operation with a 32-bit value

ROM_DMA_MEM_COMPARE

Uses the CRC peripheral to compare data with a constant 32-bit value

ROM_DMA_CRC_LUT_INIT

Initializes the CRC LUT from the supplied CRC Polynomial

enum ROM_DMA_PDMA_OPERATION

Enumeration Type Declaration: ROM_DMA_PDMA_OPERATION

Table 45-78: ROM_DMA_PDMA_OPERATION Members

Enumerator	Description
ROM_DMA_PERI_TX	Peripheral Transmit Operation
ROM_DMA_PERI_RX	Peripheral Receive Operation

ROM_DMA_PERI_TX

Peripheral Transmit Operation

ROM_DMA_PERI_RX

Peripheral Receive Operation

enum ROM_GETADDR_VALUE

Enumeration Type Declaration: `ROM_GETADDR_VALUE`

Parameter for `adi_rom_GetAddress()` function to retireve the address of a data object stored in the boot ROM.

Table 45-79: ROM_GETADDR_VALUE Members

Enumerator	Description
`ROM_GETADDR_CONSTANTS`	Retrieve the address of the `ROM_CONSTANTS_TYPE` object
`ROM_GETADDR_BMODE`	Retrieve the address of the lookup table sorting the default `adi_rom_boot()` parameters for each boot mode
`ROM_GETADDR_MDMAREGS`	Retrieve the address of the `struct ROM_BOOT_MDMA_REGS` object
`ROM_GETADDR_SPILUT`	Retrieve the address of the lookup table in the ROM describing the various SPI master boot BCODE configurations
`ROM_GETADDR_ECDSA_DOMAIN`	Retrieve the address of the domain parameteres used for ECDSA

ROM_GETADDR_CONSTANTS

Retrieve the address of the `ROM_CONSTANTS_TYPE` object

ROM_GETADDR_BMODE

Retrieve the address of the lookup table sotring the default adi_rom_boot() parameters for each boot mode

ROM_GETADDR_MDMAREGS

Retrieve the address of the `struct ROM_BOOT_MDMA_REGS` object

ROM_GETADDR_SPILUT

Retrieve the address of the lookup table in the rom describing the various SPI master boot BCODE configurations

ROM_GETADDR_ECDSA_DOMAIN

Retrieve the address of the domain parameteres used for ECDSA

enum ROM_HOOK_CALL_CAUSE

Enumeration Type Declaration: `ROM_HOOK_CALL_CAUSE`

Passed to a user hook routine to indicate the reason of the call.

An optional hook routine is provided as a callback when calling a boot mode via adi_rom_Boot. This hook routine is called by the boot software first after the execution of the boot modes initialization routine then again after execution of the boot modes configuration routine. This parameter allows the users routine to identify at which point the call was made allowing the user to perform different actions for each call.

Table 45-80: ROM_HOOK_CALL_CAUSE Members

Enumerator	Description
ROM_HOOK_CALL_INIT_COMPLETE	Call was as a result of completion of the boot modes initialization function
ROM_HOOK_CALL_CONFIG_ COMPLETE	Call was as a result of the completion of the boot modes configuration function
ROM_HOOK_REG_COMPLETE	Call was as a result of the completion of the boot modes pre-register initialization

enum ROM_SB_IMAGE_TYPE

Enumeration Type Declaration: ROM_SB_IMAGE_TYPE

Secure Boot Image Types.

The secure boot header contains a type field for the secure boot image type, this enumeration provides a complete list of all image types.

NOTE: The secure boot process does not necessarily support all image types defined.

Table 45-81: ROM_SB_IMAGE_TYPE Members

Enumerator	Description
ROM_SB_IMAGE_UNKNOWN	Unknown Secure Boot image type, used by software to initialize the type before detection of boot image type takes place
ROM_SB_IMAGE_BLP	Plain text BLp secure boot image supports authentication only with no decryption
ROM_SB_IMAGE_BLW	Keywrapped BLw secure boot image supports authentication and decryption, boot stream decryption key wrapped in the secure header
ROM_SB_IMAGE_BLE	Not supported by any Secure boot products. Secure boot image with key stored in plain text form in the secure header
ROM_SB_IMAGE_BLX	BLx Secure boot image supports authentication and decryption, boot stream decryption key wrapped located in OTP
ROM_SB_IMAGE_UNSUPPORTED	Used by software to indicate any other unsupported image type

ROM_SB_IMAGE_UNKNOWN

Unknown Secure Boot image type, used by software to initialize the type before detection of boot image type takes place

ROM_SB_IMAGE_BLP

Plain text BLp secure boot image supports authentication only with no decryption

ROM_SB_IMAGE_BLW

Keywrapped BLw secure boot image supports authentication and decryption, boot stream decryption key wrapped in the secure header

ROM_SB_IMAGE_BLE

Not supported by any Secure boot products. Secure boot image with key stored in plain text form in the secure header

ROM_SB_IMAGE_BLX

`BLx` Secure boot image supports authentication and decryption, boot stream decryption key wrapped located in `OTP`

ROM_SB_IMAGE_UNSUPPORTED

Used by software to indicate any other unsupported image type

enum ROM_SPI_PROTOCOL

Enumeration Type Declaration: `ROM_SPI_PROTOCOL`

The SPI Protocol to use.

SPI Flash devices can support multiple protocols to send commands to the SPI flash. Commands are usually sent over the single-bit bus, however a number of newer devices also support sending commands over the dual- or quad-bit bus.

WARNING: In system reset type events where the processor attempts to reboot and the flash may not have been reset, using the DUALIO or QUADIO protocols for the command cycles risks the boot process being unable to communicate with the SPI flash. Do not enable these features on SPI Flash devices if they are also the primary boot source used for booting from hardware reset and system reset events.

Table 45-82: ROM_SPI_PROTOCOL Members

Enumerator	Description
`ROM_SPI_EXT_PROTOCOL`	Extended protocol where the command cycle is sent on the single bit bus
`ROM_SPI_DUALIO_PROTOCOL`	DualIO protocol where the command cycle is sent on the dual bit bus
`ROM_SPI_QUADIO_PROTOCOL`	QuadIO protocol where the command cycle is sent on the quad bit bus

ROM_SPI_EXT_PROTOCOL

Extended protocol where the command cycle is sent on the single bit bus

ROM_SPI_DUALIO_PROTOCOL

DualIO protocol where the command cycle is sent on the dual bit bus

ROM_SPI_QUADIO_PROTOCOL

QuadIO protocol where the command cycle is sent on the quad bit bus

46 System Crossbars (SCB)

A modern system on a chip (SoCs) contains multi-cores, memory controllers, security blocks, and other high speed peripherals. As system integration increases, SoCs need to provide bus connectivity that allows better throughput to reduce performance bottlenecks. While traditional point-to-point connection buses have performed well in smaller systems, there is a need to use advanced switching based bus architectures for efficient handling of data transfer between multiplicity of data sources and sinks in the system. Additionally, mixing various traffic types in the same SoC (for example control, communication over peripherals and computing) while sharing the same bus resources, create different requirements from the Quality of Service (QoS) perspective.

The system crossbars (SCB) are the fundamental building blocks of a switch-fabric style for (on-chip) system bus interconnection. The SCBs connect system bus requesters to system bus completers, providing concurrent data transfer between multiple bus requesters and multiple bus completers. The SCB architecture addresses the challenges described above. The SCB provides sustainable throughput for simultaneous transactions in the system with configurable quality of service for each type of transaction (traffic) as required. A hierarchical model, built from multiple SCBs, provides a power and area efficient system interconnect, which satisfies the performance and flexibility requirements of a specific system.

SCB Features

The SCBs provide the following features:

- Efficient, pipelined bus transfer protocol for sustained throughput
- Full-duplex bus operation for flexibility and reduced latency
- Concurrent bus transfer support to allow multiple bus requesters to access bus completers simultaneously
- Protection model (privileged or secure) support for selective bus interconnect protection
- Simple priority-based QoS based arbitration model
- Programmable quality of service

SCB Functional Description

The following sections provide a functional description of the SCB.

- SCB Architectural Concepts

ADSP-2159x SCB0 Register List

Table 46-1: ADSP-2159x SCB0 Register List

Name	Description
SCB0_CRC0_CH0_READ_QOS	CRC0 Channel 0 Read Quality of Service Register
SCB0_CRC0_CH0_WRITE_QOS	CRC0 Channel 0 Write Quality of Service Register
SCB0_CRC0_CH1_READ_QOS	CRC0 Channel 1 Read Quality of Service Register
SCB0_CRC0_CH1_WRITE_QOS	CRC0 Channel 1 Write Quality of Service Register
SCB0_CRC1_CH0_READ_QOS	CRC1 Channel 0 Read Quality of Service Register
SCB0_CRC1_CH0_WRITE_QOS	CRC1 Channel 0 Write Quality of Service Register

SCB Architectural Concepts

This section describes the components of the SCB and the modules connected to it. The basic elements in the SCB are SCB requesters, completers, requester interfaces, and completer interfaces.

Requesters

The system bus controllers include peripheral Direct Memory Access (DMA) channels. These include the Serial Port (SPORT) DMA, and SPI DMAs, among others. Also included are the Memory-to-Memory DMA channels (MDMA), the L1 code fill block, and the processor cores.

Completers

Completers are SCB connections that are responding to transfer requests. Completers include MMR registers, memory units, and various peripherals depending upon individual configurations. Each system completer has its own latencies and response times.

SCB Block Diagram

The SCB architectural model is shown in the ***SCB Overview*** figure. This figure shows a high level representation of a basic SCB connecting n completers to x requesters. A variable number of requesters connect to a variable number of completers in each SCB. In this example, all SIs connect to all MIs as indicated by the lines connecting them.

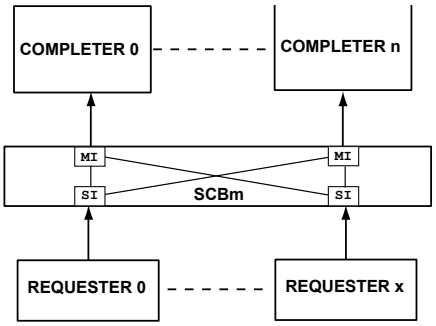

Figure 46-1: SCB Overview

Hierarchy Block Diagram

A system interconnect built from multiple SCBs in a hierarchical model is illustrated in the ***SCB Hierarchy Overview*** figure. The system requester node level SCBs requester connects multiple SIs to a single MI, which in turn connects to an SI of the system completer level node SCB.

As discussed above, all the requesters in the system are distributed across different SCBs. A given SCB at system requester node level connects directly to the system requesters. These SCBs connect to SCB0 through its SIs forming a hierarchal structure. While a requester has to access any completer, its first access goes through the SCB it is connected to, and then through SCB0, to reach its intended completer. This simplifies the connecting hardware in the basic SCB block by limiting the requesters. Care must be taken when sharing requesters to allow adequate throughput for their individual data transfer requirements.

In this example, all SIs are connected to all MIs.

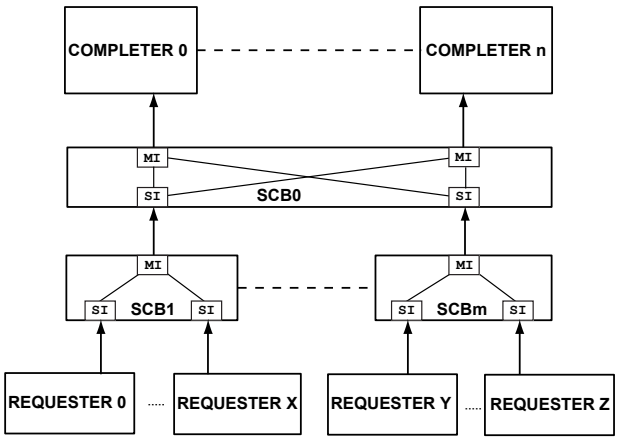

Figure 46-2: SCB Hierarchy Overview

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

SCB Block Diagram

The ***SCB Block Diagram*** shows the functional blocks of the SCB module.

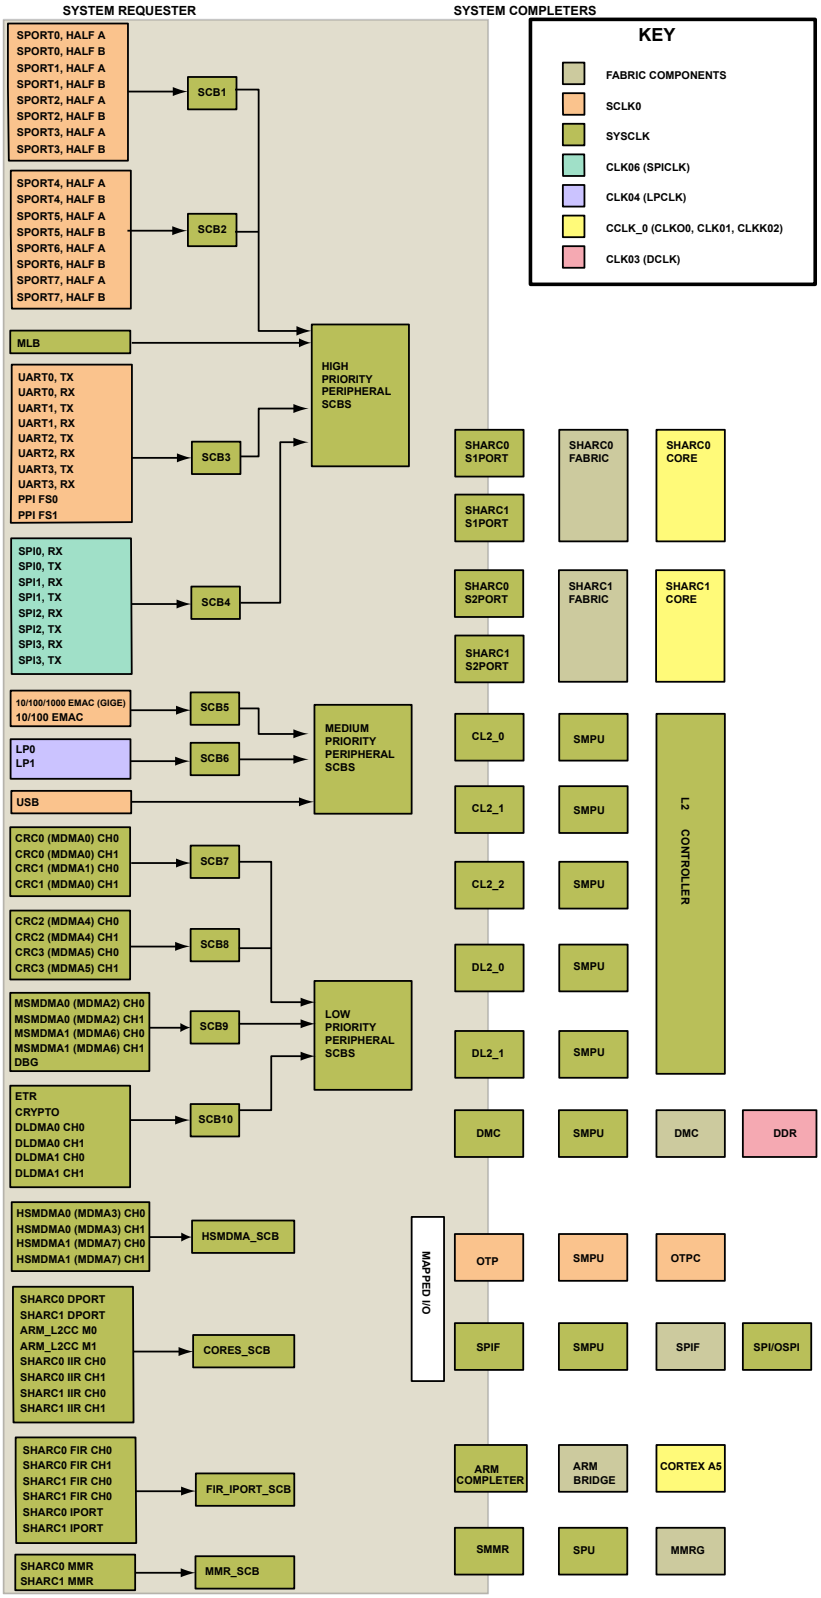

Figure 46-3: SCB Block Diagram

The following are important points related to the system fabric on the ADSP-SC59x processors.

- The hierarchy of SCBs manages the system bus interconnections, multiplexing, and arbitration among the peripherals on the processor.
- The SCBs connections support DMA channels for some peripherals and support dedicated connections for others. The connections also support memory-mapped register access for internal memory (L1 and L2) and for external memory.

  The completer interface of the crossbar where requesters such as DMA connect to performs two functions. The first function is arbitration. SCBx handles arbitration. The second function is clock conversion. The programmable QoS registers can be viewed as being associated with the SCBx.
- Most of the peripherals and their SCBs are in the *SCLK0* domain. MDMA0-7, EMDMA0/1, Crypto, FIR/IIR accelerators, MLB, DBG, ETR, SHARC+ and Arm cores and their SCBs are in the *SYSCLK* domain. The link port is in the CLK04 domain. SPI is in the CLK06 domain.
- Each peripheral has a latency for access across the SCB. The latency varies with the nature of the peripheral. Also, the number of active peripherals (especially for cases where multiple peripherals are active on a shared SCB) affects SCB performance. Refer to the L2 System Memory chapter for details on the L2 memory organization.

  The MDMA2, MDMA3, MDMA6, and MDMA7 channels are unidirectional. For example, MSMDMA0 CH0 is read-only and MSMDMA0 CH1 is write-only. Access to the MMR space of SCB0 is allowed only in secure mode. The MMR space of SCB0 has registers for programming the QoS of various requesters and controlling the clock domain crossing.
- Access to the GPV (Global Programmers View) space is allowed only in secure mode. This space has registers for programming the QoS and CDC relationships and the remapping of various requesters.
- The S2 completer port of SHARCs is intended primarily for MDMA between the L1 of the 2 SHARCs. Hence, only the HSMDMA0 (MDMA3) and HSMDMA1 (MDMA7) is given access to S2 ports while all other requesters are given access to S1 port. This arrangement also means that S1 and S2 port share the same address space.
- SPI2/OSPI0 is low bandwidth completer – SCLK0 with a 32-bit interface. Only MDMA0/1/2/4/5/6 is used to perform MDMA to these completer nodes. HSMDMA0/1 (MDMA4 and 7) are intended for L1, L2 and DDR (these completers have the same bandwidth capability as HSMDMA0/1).
- SPIF is a read-only flash. Peripherals are not able to read out of the SPI flash directly. Only MDMAs, crypto, cores, and debug tools are given access to it.
- LP to SPI2/OSPI0 access is allowed.
- The SPIF completer in the system fabric has remapping options in the SPIF fabric for SPI2 and OSPI0 in the same address space. The address map configuration is programmable using remap registers.

IMPORTANT: The following points are important changes from ADSP-2156x processors:

- All peripherals (including debugger) access L2 memory through the new DL2_1 subordinate port on the ADSP-SC59x processor. On the ADSP-2156x processor, these accesses were on the DL2_0 port of L2.
- To reduce the probability of port conflict in a mulicore system, the cores are connected on the CL2_0 and CL2_1 ports of L2. CL2_0 has access only to the first 1MB of L2. CL2_1 has access to second 1MB of L2.
- Booting of the Arm core occurs through the CL2_0 port; booting of the SHARC cores occurs through CL2_1 (to avoid any conflict during multi-core boot). The respective BOOTROM addresses have been routed accordingly.

The following acronyms are used in the ***SCB Interconnections*** figure.

SCB0-10

Indicate SCB interfaces, connecting the system bus requesters and completers

SCLK0, SYSCLK, CLK03, CLK04, CLK06

Indicate clock domains in which the specific SCBs operate. For more information on clock domains, see the Clock Generation Unit (CGU) chapter and the product data sheet.

CDC

Indicates the clock domain crossing

CL2_0, CL2_1, CL2_2

Indicates a 128-bit L2 completer

DL2_0, DL2_1

Indicates a 128-bit L2 completer

L1C1_S1

Indicates the S1 completer of the SHARC1 processor

L1C1_S2

Indicates the S2 completer of the SHARC1 processor

SHARC1_IPORT

Indicates the SHARC1 processor instruction requester port

SHARC1_MMR

Indicates the SHARC1 MMR interface

A5_L2CC_M0/1

Indicates the Cortex A5 requesters (0 and 1)

Arm Completer

Indicates the Cortex A5 completer

SHARC Fabric with FIR/IIR Accelerator

The accelerator block on each SHARC core of ADSP-SC59x processor has one FIR and four IIR accelerators. All instances of the FIR and IIR accelerators operate at the core clock (CCLK) frequency. Accelerator requester ports can directly access the respective SHARC L1 memory with reduced latency. The access does not go through the system fabric. The SHARC core can also directly access the MMR registers of its respective accelerator. The accesses between one SHARC core and the accelerators that belong to the other SHARC core still go though the main system fabric.

The ***SHARC Fabric Connectivity*** figure shows a block diagram of the SHARC fabric with FIR/IIR accelerators integrated closely with the SHARC core.

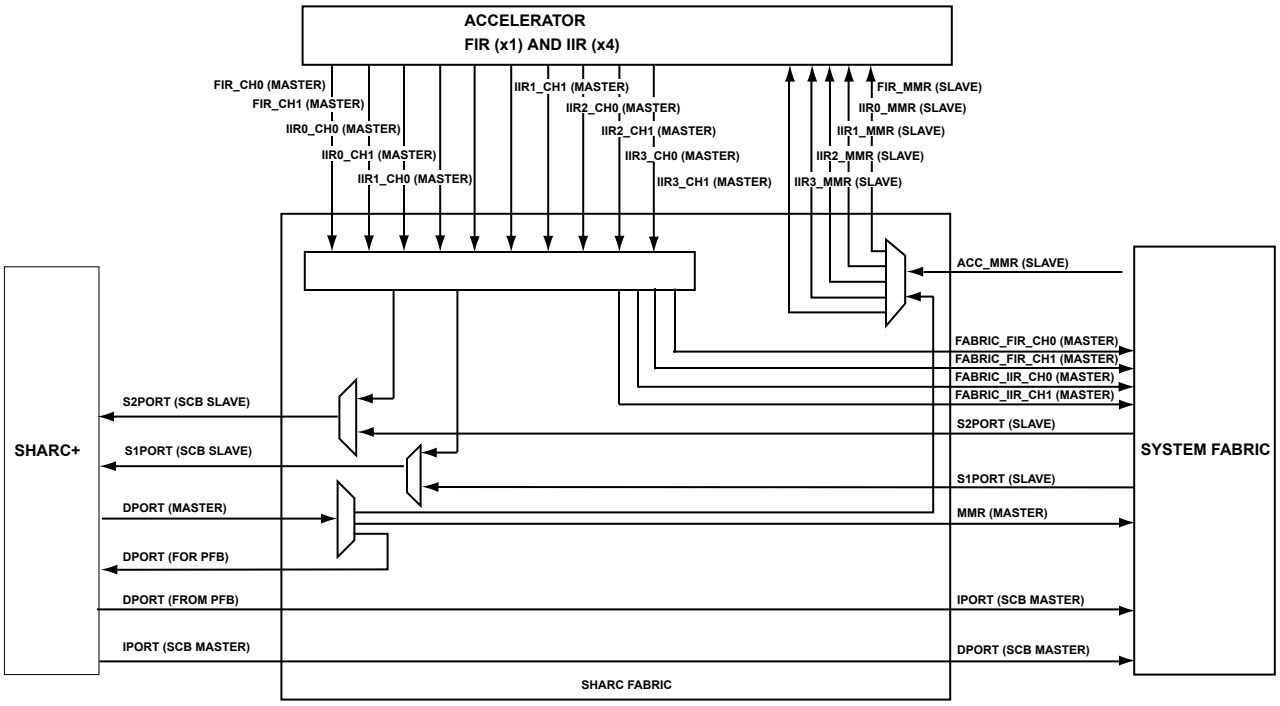

Figure 46-4: SHARC Fabric Connectivity

Note the following:

- The SHARC+ core can directly access the MMR space using its accelerators.
- The MMR port of the SHARC+ core is separate from the data port (DPORT). It is a separate requester port for the main system fabric.
- PFB (prefetch buffer) — after the MMR split, the DPORT comes into the SHARC+ core for the PFB connection and returns to the SHARC+ fabric again for the clock domain crossing.
- Accelerators share the same security level as the respective core. The SHARC+ core associated with the accelerator can always access the MMR space of the accelerator. Accesses from the other requesters such as other SHARC+ core/Arm Core/MSMDMA/DBG are allowed provided that the security requirements of the requester are met.

To ensure complete bandwidth utilization and optimal performance of the L2 ports, the controllers are allocated as shown in ***L2 Port Requester Allocation*** table.

Table 46-6: L2Port Requester Allocation

Requesters	CL2_0	CL2_1	CL2_2	DL2_0	DL2_1
SHARC0 (Core 1)	✓	✓			
SHARC1 (Core 2)	✓	✓			
Cortex A5 (Core 0)	✓	✓			
SHARC0 IPORT			✓		
SHARC1 IPORT			✓		
SHARC0_FIR_CH0			✓		
SHARC0_FIR_CH1			✓		
SHARC0_IIR_CH0	✓	✓			
SHARC0_IIR_CH1	✓	✓

SHARC1_IIR_CH1	✓	✓			
SHARC1_IIR_CH1	✓	✓			
HSMDMA0				✓	
HSMDMA0				✓	
Peripherals					✓

Note the following:

- To reduce the probability of port conflict in a multicore system, the cores are connected on the CL2_0 and CL2_1 ports of L2. CL2_0 has access only to the first 1MB of L2. CL2_1 has access to second 1MB of L2

- To avoid conflict during multi-core boot, the booting of the Arm core happens through the CL2_0 port while the booting of the SHARC cores happens through the CL2_1 port. The respective bootROM addresses are routed accordingly.

The addressable range for each of the ports is shown in the ***L2 Port Address Allocation*** table.

To support exclusive accesses to the 5 port L2 memory on the processor, the configuration of SMPUs as shown in the ***SMPU Access Scheme for L2 Ports*** figure is used.

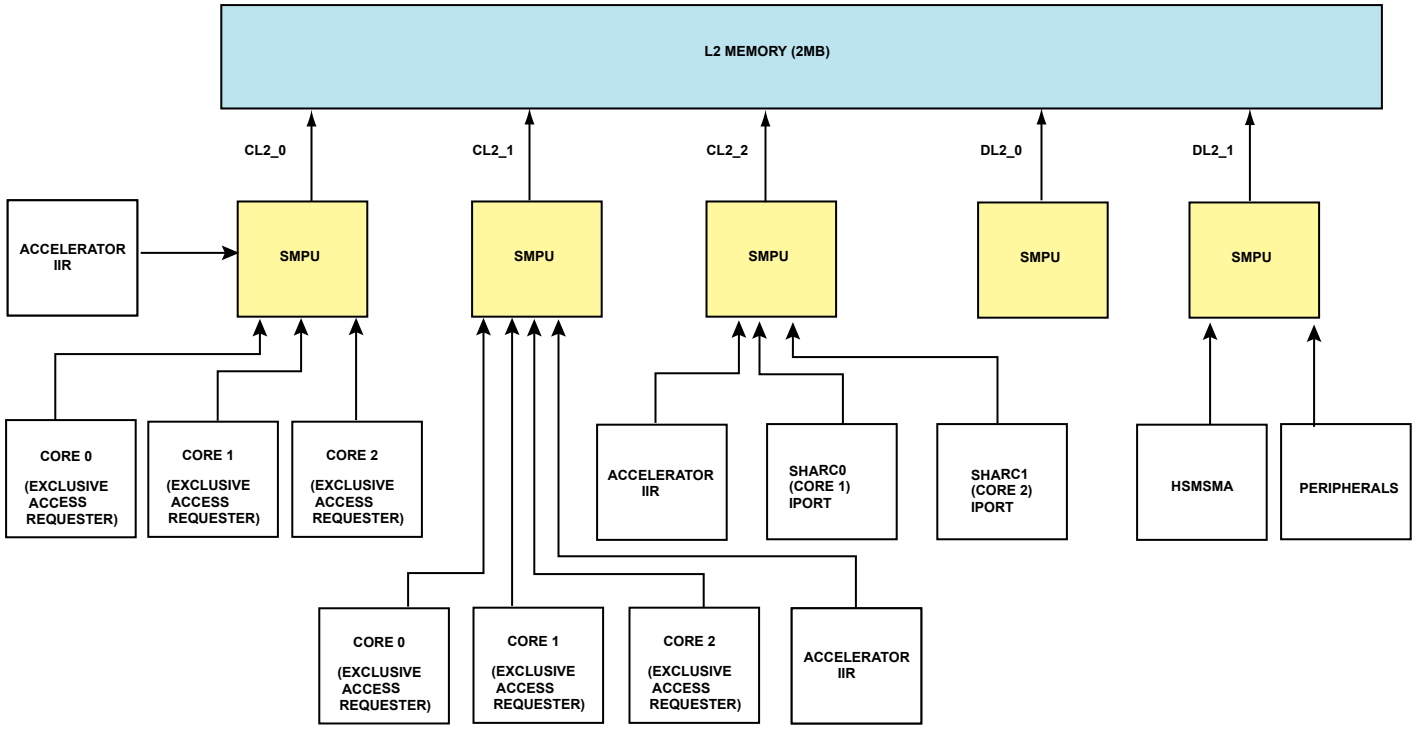

Figure 46-5: SMPU Access Scheme for L2 Ports

There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and have the same operating modes (see DMA Operating Modes) and use the same programming model (DMA Channel Programming Model). The second type is not controlled by the DDE module. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The peripheral types are shown in the ***SCB-Controlled DMA Channel Peripherals*** table.

System Crossbars

The System Crossbars (SCB) are the fundamental building blocks of the system bus interconnect. The SCB (often referred to as the system interconnect fabric), is a collection of inter-connection units connecting system requesters to completer memory spaces. The SCB connects one or more requester devices to one or more memory-mapped completer devices. Each connected requester can be a core that originates an SCB transaction, or a requester

interface of an upstream SCB cascaded interconnect. Each connected completer can be the final completer of an SCB transaction or a completer interface of a downstream cascaded SCB interconnect (forming a hierarchy of SCBs).

Each SCB that has multiple requesters and completers share the total bandwidth of the SCB. (In a M:N configuration where M requesters are connected to N completers through the SCBx.)

The SCB provides separate channels for reads and writes. Read and write accesses through a given SCB do not share bandwidth. All the SCBs are 32 bits wide and run at SYSCLK speed, and can provide a bandwidth of up to 400 Mbytes per second for reads and writes separately (when SYSCLK = 100 MHz). Only SCB0, which is the major SCB in the SCB hierarchy, has the multiple paths between multiple requester and completer interfaces.

See the SCB Block Diagram.

All other SCBs in the chip connect to SCB0 through different completer interfaces. Other primary requesters (DMAs, cores, and so on) in the system are distributed across these small SCBs. For a given SCB, all the requester and completers share the total bandwidth of the SCB. (Only SCB0 is the exception). Since different DMA channels are scattered across different SCBs (SCB1, SCB2 SCB3, and so on), they do not conflict for the bandwidth as long as they are in different SCB and are accessing different completers. SCB0 allows for concurrent data transfer between multiple bus requesters and multiple bus completers, providing flexibility, and full-duplex operation.

If system accesses are carefully architected, SCB has a potential of providing sufficient sustained bandwidth in the end system.

Since the SCBs support burst transfers, it is important to configure the requesting requester appropriately to make best use of available SCB bandwidth. For a DMA requester, choosing the appropriate `DMA_CFG.MSIZE` value, is important from both a functional and a performance perspective. The value in the `DMA_CFG.PSIZE` bit field determines the width of the peripheral bus in use. It can be configured to 1-byte, 2-bytes, or 4-bytes. The `DMA_CFG.MSIZE` value determines the actual size of the SCB bus in use. It also determines the minimum number of bytes which are transferred from or to memory corresponding to a single DMA request or grant. The transfer can be 1-, 2-, 4-, 8-, 16-, or 32-bytes. If the `DMA_CFG.MSIZE` value is greater than the SCB bus width, the SCB performs burst transfers according to the width defined in `DMA_CFG.MSIZE`. When `DMA_CFG.MSIZE` is less than the SCB bus width, bursting is not supported and partial bus use results.

Each of the SCB unit in the fabric consists of N completer interfaces (MSTn). Each of these interfaces has controls for read quality of service, write quality of service, and functional mode. A subset of these matrices includes controls for IB (Interface Block) sync mode, and bus functional mode. For more details on IB, see the clock domain synchronization section.

SCB Bus Requester IDs

The SCB ***Bus Requester IDs*** table indicates which requesters are connected to each of the completer ports of SCB0. The tables also indicate the precise value of the ID as seen by the completer. These values are useful for SWU programming.

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

Table 46-8: Bus Requester IDs

Requester	Hex ID Values	Binary Values
DMA0 (SPORT0, HALF A)	0x0000, 0x0100	13'b0000x00000000

SCB Programming Model

The following sections provide information for programming the SCB properly.

Programming SCB Arbitration

Each completer interface has a QoS value (priority) associated with both read and write channels. These values are 4 bits present in the `SCB0_MSTx_RQOS` and `SCB0_MSTx_WQOS` registers. At the entry point to the infrastructure, all transactions are allocated this programmable local QoS value. The arbitration of the transaction throughout the infrastructure uses this QoS. At any arbitration node, a fixed priority exists for transactions with a different QoS. The highest value has the highest priority.

If there are coincident transactions at an arbitration node with the same QoS that require arbitration, then the network uses a Least Recently Granted (LRG) algorithm. At each switch, the requester with the highest QoS acquires access and that switch output takes the QoS value of the winner for that transaction. At the next switch completer interface, the requester uses the QoS value of the winner. QoS can have values from 0 (lowest priority) to 15 (highest priority).

For example in the following figure, ***SCB Arbitration***:

1. At SCB1, requesters (1, 2, 3) have RQOS values of (6, 4, 2)
2. At SCB2, requesters (4, 5, 6) have RQOS values of (12, 13, 1)

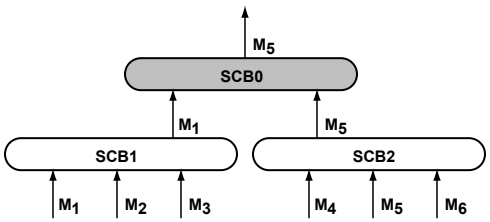

Figure 46-6: SCB Arbitration

In this case, requester 1 wins at SCB1, and requester 5 wins at SCB2. However, in a perfect competition at SCB0, requesters 4 and 5 had the highest overall RQOS values. requesters 4 and 5 would have fought for arbitration directly at SCB0. However, because of the mini*SCBs, requester 1, at a much lower RQOS value, is able to win against requester 4 and make it all the way to SCB0.

Programming Clock Domain Crossing Registers

The ***Clock Domain Crossing Options*** table shows the various clock domain crossings that are available on the ADSP-SC59x processor. The clocking relationships are defined with respect to SYSCLK. The followng clock domains are programmable: CLKO3: SYSCLK, CLKO4: SYSCLK and CLKO8: SYSCLK CDC. The registers to configure the CDC mode are present within the GPV space of the respective fabric. For example: To program the CLKO3: SYSCLK relationship, program the GPV registers within the DMC_CDC fabric and the MMRG fabric.

Table 46-9: Clock Domain Crossing Options

		Clocking Relationships with respect to SYSCLK					
Functional Clocks	**Possible Completers**	**System Fabric**	**MMRG Fabric**	**MC Fabric**	**SHARC Fabric**	**Arm Fabric**	**SPIF Fabric**
SYSCLK	System Fabric and Infrastructure Modules	1:1	1:1	*1	*	*	*
SCLK0	SCLK0 Clock Doamin	Synchronous (m:1)	Synchronous (m:1)	*	*	*	*
CLKO0	SHARC0 and its Accelerators	*	*	*	Synchronous (m:1)	*	*
CLKO1	SHARC1 and its Accelerators	*	*	*	Synchronous (m:1)	*	*
CLKO2	ARM	*	*	*	*	Synchronous (m:1)	*
CLKO3	DMC	*	Programmable	Programmable	*	*	*

Table 46-9: Clock Domain Crossing Options (Continued)

		Clocking Relationships with respect to SYSCLK					
Functional Clocks	**Possible Completers**	**System Fabric**	**MMRG Fabric**	**MC Fabric**	**SHARC Fabric**	**Arm Fabric**	**SPIF Fabric**
CLKO4	CAN	*	Programmable	*	*	*	*
CLKO6	SPI	Synchronous (m:n) (except SPIF completer)	Synchronous (m:n)	*	*	*	Synchronous (m:n)
CLKO8	LP	Programmable	Programmable	*	*	*	*

*1 * Either the interface is not present or CDC is not required

Table 46-10: Sync Mode Bit Field Description

Sync Mode	Description
0	sync 1:1
1	sync n:1
2	sync 1:n
3	sync m:n
4	async

To change the clock domain crossing mode, follow the actions described in the ***Changing Clock Domain Crossing Modes*** table.

Table 46-11: Changing Clock Domain Crossing Modes

Original Mode	Required Mode	Action
ASYNC	Any other mode	Change the clocks, then change the MMR register
Any mode	ASYNC	Change the MMR register, then change clocks to ASYNC.
m:n	1:1	Change the clocks, then change the register.
1:1	m:n	Change the register, then change the clocks.

SCB Programming Concepts

The SCB arbitration model among requester or completer SCBs of the processor is fixed (not programmable). But, each completer does have a quality of service (QoS) programmable feature that affects arbitration.

The arbitration of transactions in SCB is based on the QoS value or the priority of the transaction. All requesters with the same priority form a priority group. Arbitration is granted to the highest priority group from which a member is trying to win access, and within that group, to the highest requester at that time. When a requester wins arbitration, it is relegated to the bottom of its group to ensure that it cannot prevent other requesters in its group from accessing the completer.

If you configure all requester priorities to different levels, the arbiter implements a fixed priority scheme. This scheme occurs because each requester is in a group of its own, and therefore, requesters maintain their ordering.

The LRG and fixed priority modes concurrently exist when the requester priority value registers are programmed with a combination of identical and unique values.

NOTE: The SCB arbitration hierarchy is fixed (for example, SCB1 requester to SCB1 completer). However, multiple requester inputs to the same completer permit QoS programming.

The *LRG Arbitration Example* figure shows three groups with different QoS values. Requesters in the same group share a QoS value. The arbitration occurs using an LRG scheme.

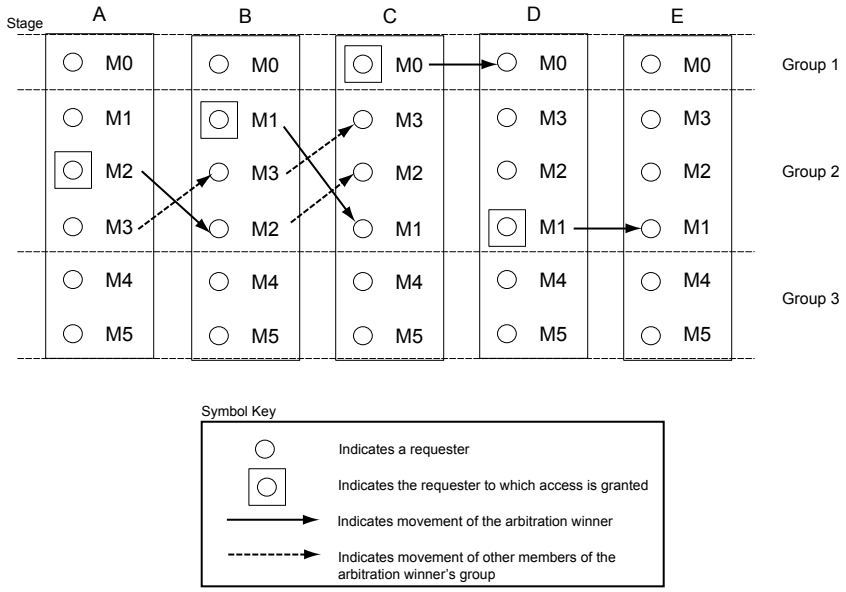

Figure 46-7: LRG Arbitration Example

The QoS value assigned to a transaction at entry point is carried forward by the transaction as it passes through all arbitration stages in the SCB. QoS for all requesters is configured as programmable in the system fabric interconnect.

The priority of the requesters fits into three groups:

- Group A - Peripherals with an external interface, without flow control and with real-time processing requirements
- Group B - Cores, peripherals with flow control, and offload engines
- Group C - MDMAs

Group A: Peripherals with external interface, without flow control and with real-time processing requirements

These requesters are assigned the highest priority. They are latency-critical – a large increase in latency could potentially result in data corruption and catastrophic failure. This high priority SCB group includes requesters connected to SCB1, SCB2, SCB3, and SCB4. Requesters in this group are assigned the QOS reset value of 12.

Group B: Cores, peripherals with flow control, and offload engines

Core is latency-sensitive. Once a core requests data, it typically waits for the data without performing anything else in parallel. An increase in the latency has a direct impact on the performance of the core. This group is assigned medium priority and a QOS reset value of 7. Group B requesters are connected to SCB5, SCB6, CORES_SCB, FIR_IPORT_SCB, and MMR_SCB.

Group C: MDMAs

These requesters are assigned the lowest priority. MDMAs are data intensive and do not have any external interface. Requesters in this group are assigned the QOS reset value of 1. The Group C requesters are connected to SCB7, SCB8, SCB9, and SCB10.

Table 46-12: QoS Register Table

Requester ID	Requester	read_qos Reset Value	write_qos Reset Value
1	SPORT0_A_DMA	12	12

QoS Programming

Adhere to the following guidelines if software is modifying the reset value of QoS:

- The highest QoS of any requester in a low priority SCB group must be less than the lowest QoS of any requester in a medium priority SCB group

- The highest QoS of any requester in medium priority SCB group must be less than the lowest QoS of any requester in high priority SCB group

Reset values of QoS have been spaced out to allow software to lower or higher the priority of a few requesters without having to modify the priority all the requesters. For example, the QoS of the LP can be reduced from 12 to 11 without violating the guidelines.

ADSP-2159x SCB0 Register Descriptions

System Crossbar (SCB0) contains the following registers.

Table 46-13: ADSP-2159x SCB0 Register List

Name	Description
SCB0_CRC0_CH0_READ_QOS	CRC0 Channel 0 Read Quality of Service Register
SCB0_CRC0_CH0_WRITE_QOS	CRC0 Channel 0 Write Quality of Service Register
SCB0_CRC0_CH1_READ_QOS	CRC0 Channel 1 Read Quality of Service Register

SCB0_SP5A_READ_QOS	SP5A Read Quality of Service Register
SCB0_SP5A_WRITE_QOS	SP5A Write Quality of Service Register
SCB0_SP5B_READ_QOS	SP5B Read Quality of Service Register

Table 46-13: ADSP-2159x SCB0 Register List (Continued)

Name	Description
SCB0_SP5B_WRITE_QOS	SP5B Write Quality of Service Register
SCB0_SP6A_READ_QOS	SP6A Read Quality of Service Register
SCB0_SP6A_WRITE_QOS	SP6A Write Quality of Service Registers
SCB0_SP6B_READ_QOS	SP6B Read Quality of Service Register
SCB0_SP6B_WRITE_QOS	SP6B Write Quality of Service Register
SCB0_SP7A_READ_QOS	SP7A Read Quality of Service Register
SCB0_SP7A_WRITE_QOS	SP7A Write Quality of Service Register
SCB0_SP7B_READ_QOS	SP7B Read Quality of Service Register
SCB0_SP7B_WRITE_QOS	SP7B Write Quality of Service Register
SCB0_SPI0RX_READ_QOS	SPI0 RX Read Quality of Service Register
SCB0_SPI0RX_WRITE_QOS	SPI0 RX Write Quality of Service Register
SCB0_SPI0TX_READ_QOS	SPI0 TX Read Quality of Service Register
SCB0_SPI0TX_WRITE_QOS	SPI0 TX Write Quality of Service Register
SCB0_SPI1RX_READ_QOS	SPI1 RX Read Quality of Service Register
SCB0_SPI1RX_WRITE_QOS	SPI1 RX Write Quality of Service Register
SCB0_SPI1TX_READ_QOS	SPI1 TX Read Quality of Service Register
SCB0_SPI1TX_WRITE_QOS	SPI1 TX Write Quality of Service Register
SCB0_SPI2RX_READ_QOS	SPI2 RX Read Quality of Service Register
SCB0_SPI2RX_WRITE_QOS	SPI2 RX Write Quality of Service Register
SCB0_SPI2TX_READ_QOS	SPI2 TX Read Quality of Service Register
SCB0_SPI2TX_WRITE_QOS	SPI2 TX Write Quality of Service Register
SCB0_SPI3RX_READ_QOS	SPI3 RX Read Quality of Service Register
SCB0_SPI3RX_WRITE_QOS	SPI3 RX Write Quality of Service Register
SCB0_SPI3TX_READ_QOS	SPI3 TX Read Quality of Service Register
SCB0_SPI3TX_WRITE_QOS	SPI3 TX Write Quality of Service Register
SCB0_UART0_RX_READ_QOS	UART0 RX Read Quality of Service Register
SCB0_UART0_RX_WRITE_QOS	UART0 RX Write Quality of Service Register
SCB0_UART0_TX_READ_QOS	UART0 TX Read Quality of Service Register
SCB0_UART0_TX_WRITE_QOS	UART0 TX Write Quality of Service Register
SCB0_UART1_RX_READ_QOS	UART1 RX Read Quality of Service Register
SCB0_UART1_RX_WRITE_QOS	UART1 RX Write Quality of Service Register

Table 46-13: ADSP-2159x SCB0 Register List (Continued)

Name	Description
SCB0_UART1_TX_READ_QOS	UART1 TX Read Quality of Service Register
SCB0_UART1_TX_WRITE_QOS	UART1 TX Write Quality of Service Registers
SCB0_UART2_RX_READ_QOS	UART2 RX Read Quality of Service Register
SCB0_UART2_RX_WRITE_QOS	UART2 RX Write Quality of Service Register
SCB0_UART2_TX_READ_QOS	UART2 TX Read Quality of Service Register
SCB0_UART2_TX_WRITE_QOS	UART2 TX Write Quality of Service Register
SCB0_UART3_RX_READ_QOS	UART3 RX Read Quality of Service Register
SCB0_UART3_RX_WRITE_QOS	UART3 RX Write Quality of Service Register
SCB0_UART3_TX_READ_QOS	UART3 TX Read Quality of Service Register
SCB0_UART3_TX_WRITE_QOS	UART3 TX Write Quality of Service Register
SCB0_USB0_READ_QOS	USB0 Read Quality of Service Register
SCB0_USB0_WRITE_QOS	USB0 Write Quality of Service Register

CRC0 Channel 0 Read Quality of Service Register

		1	Selects map for OSPI only 0x6000_0000 - 0x7FFF_FFFF - OSPI
		2	Selects map for SPI2/OSPI split sharing 0x6000_0000 - 602F_FFFF - SPIF 0x6030_0000 - 0x7FFF_FFFF - OSPI

47 System Watchpoint Unit (SWU)

The system watchpoint unit (SWU) is a single module used for transaction monitoring. The SWU is attached to each system slave through the system crossbar interface and provides ports for all address channel signals for the system crossbar. The SWU does not have ports for the read/write data channel signals or the low-power interface signals.

Each SWU contains four match groups of registers with associated hardware. These four SWU match groups operate independently, but share common event (interrupt and trigger) outputs. Each match group can monitor either the write or read address channel and can operate in either watchpoint mode or bandwidth mode.

In this chapter, the naming convention for registers omit the numeric reference to any of the SWUs or it's groups. For example, SWU_GCTL represents registers SWU1_GCTL, SWU2_GCTL, and so on. Similarly, SWU_CUR[n] represents SWU1_CUR0/CUR1/CUR2/CUR3, SWU2_CUR0/CUR1/CUR2/CUR3 and so on.

SWU Features

The system watchpoint unit has the following features.

- Four independent match groups for each SWU
- Each match group can operate in either bandwidth mode or watchpoint mode

SWU Functional Description

This section describes the function of the SWU match block, interface block, and MMR block.

NOTE: In the *SWU Interrupt List* table, there are three SWUs, SWU1 (CL2_0), SWU3 (CL2_1) and SWU5 (CL2_2) for L2 Memory Core access and two SWUs, SWU2 (DL2_0) and SWU4 (DL2_1) for L2 Memory DMA access. CL2_2, DL2_0 and DL2_1 have access to the entire L2 range. CL2_0 has access to first 1MB and CL2_1 has access to second 1MB of L2.

ADSP-2159x_SC591_SC592_SC594 SWU Register List

The System Watchpoint Unit (SWU) provides debug and development support through flexible transaction level and bandwidth monitoring and associated event triggering. The SWU can generate events based on monitoring transactions at the system slaves through watchpoint-match groups. The SWU also provides watchpoint event status

reporting, a global lock, and processor reset capability. A set of registers governs SWU operations. For more information on SWU functionality, see the SWU register descriptions.

Table 47-1: ADSP-2159x_SC591_SC592_SC594 SWU Register List

SWU Definitions

The following definitions are helpful when using the SWU module.

Watchpoint Mode

Mode in which transactions are recognized on an exact match. Actions can be configured to be taken after a specified number of matches have occurred.

Bandwidth Mode

Mode in which transactions are recognized and counted inside sampling window.

SWU Architectural Concepts

The information in this section provides basic module design concepts.

SWU-to-SCB Interface

The SWU system crossbar interface block latches all transactions on the system crossbar read and write address channels when the SWU_GCTL.EN register enable bit is set.

SWU Block Diagram

The ***System Watchpoint Unit Top-Level Block Diagram*** figure shows the SWU block diagram.

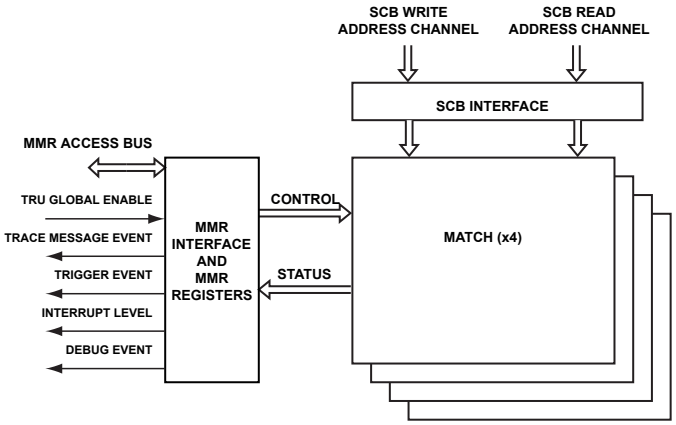

Figure 47-1: System Watchpoint Unit Top-Level Block Diagram

SCB Interface Block

The SWU system crossbar (SCB) latches all transactions on the SCB read and write address channels when the `SWU_GCTL.EN` bit is set.

MMR Interface Block

The SWU MMR block contains the peripheral bus interface and the SWU MMR registers. It also merges all interrupt requests and events from each match block into common outputs.

SWU Operating Modes

There are two operating modes supported by the SWU: bandwidth mode and watchpoint mode.

Bandwidth Mode

In bandwidth mode, the SWU module counts transactions which match the properties specified in the `SWU_CTL[n]` register during a sampling window determined by the respective `SWU_CNT[n]` register. At the end of the sampling window, the SWU stores results in the `SWU_HIST[n]` register. If the sampled bandwidth falls outside a programmed range, then the programmed action occurs.

Watchpoint Mode

In watchpoint mode, if the `SWU_CTL[n].CNTEN` bit is set, the SWU module decrements the `SWU_CUR[n]` register for each match, until it equals zero, at which point any programmed actions occur. The `SWU_CUR[n]` register is then reloaded from the `SWU_CNT[n]` register (if the `SWU_CTL[n].CNTRPTEN` bit is set), and the cycle repeats. If the `SWU_CTL[n].CNTRPTEN` bit is not set, any programmed actions happen on every match.

Match Block

There are four match blocks for each SWU. Each SWU match block can monitor either the read or write address channel, selected by the `SWU_CTL[n].DIR` bit. The SWU match block can operate in either watchpoint or bandwidth mode, as selected by the `SWU_CTL[n].BWEN` bit.

In either mode, the SWU match block can be programmed to match based on address (exact, inclusive or exclusive range), ID (with masking), security, and lock type. All enabled matches are AND'ed together to determine a match.

Scaling

Scaling allows the SWU to count more transactions by scaling the number of transactions and the number of clock cycles in bandwidth window (CNTn register) by 10,100 or 1000. This functionality is applicable only in bandwidth mode (`SWU_CTL[n].BWEN`==1).

Consider a case where the `SWU_TARG[n].BWMAX` bit field is programmed to 2. In the absence of any scaling, bandwidth overflow occurs when the `SWU_CUR[n].CURBW` bit field value > the `SWU_TARG[n].BWMAX` bit field value (2). With scaling set to 1:100 and after 275 transactions, the `SWU_CUR[n].CURBW` value is still 2 and equal to `SWU_TARG[n].BWMAX`. This event triggers a bandwidth overflow as the actual number of transactions is greater than 200 (2 × 100). The code can be rerun with a smaller scaling selected to analyze the cause for the overflow.

The counter increments after every group of N transactions with scaling enabled, where N is either 10,100 or 1000. (For N = 10, 0–9 transactions == 0 scaled transaction, 10–19 transactions == 1 scaled transaction, 20–29 transactions == 2 scaled transactions, and so on).

Fractional counts with scaling enabled are discarded and not rolled over from one bandwidth window to the next. For example, consider a case where scaling by 1000 is configured and the first window has 1200 transactions. The second window has 2800 transactions. The bandwidth for the first window is read as 1 and the second as 2. The 200 transactions from the first window do not get carried forward to the next window.

Do not use scaling by 10 with the `SWU_CTL[n].BLENINC` bit enabled if any of the requesters accessing the completer can launch a transaction of burst length 16.

SWU Event Control

The SWU can generate the following events when a match occurs and when the event is enabled by configuring the proper bits in the control register.

1. Trace Message
2. Trigger
3. Interrupt request
4. Debug

SWU Interrupts

All interrupt requests and events from each match block are merged into common outputs.

SWU Status and Errors

SWU status and errors are reported in the SWU_GSTAT register. The SWU records an address error when a write or read attempt is made to the MMR address space of the SWU and the register does not exist. This error is the only one the SWU records. The register contains bits that perform the following functions.

- Indicate whether a particular match group sampled a transaction that is below a minimum target or above a maximum target in bandwidth mode.
- Indicate whether a watchpoint match occurred for each match group.
- Indicate whether an interrupt request was triggered due to a match event from one of the match groups.

Triggers

The SWU can be either a trigger requester or a trigger completer depending on the trigger routing unit (TRU) configuration. As a trigger requester, programs must set the SWU_CTL[n].TRGEN bit so that when a match condition is met, a trigger event is generated. Each SWU in the system can also be a trigger completer when mapped as one in the TRU.

When the SWU is a completer, a trigger event activates the SWU by automatically setting the SWU_GCTL.EN bit. Since the SWU can be automatically enabled through a trigger event, programs must pre-configure the SWU before enabling the TRU. Furthermore, although a trigger event can enable the SWU as a completer, to disable the SWU, programs must manually clear the SWU_GCTL.EN bit.

SWU Programming Model

Program the appropriate registers to use the SWU. Each control register configures aspects such as:

- The direction of monitoring (reads or writes)
- Whether SWU uses bandwidth mode or watchpoint mode
- The setup of events that are triggered when a condition is met while monitoring using the SWU

Configure supplemental registers such as the lower (SWU_LA[n]) and upper (SWU_UA[n]) address boundaries before enabling the SWU.

Once the SWU has been enabled and the monitoring conditions are met, events are generated when configured.

The global status register (SWU_GSTAT) can be read to observe the status of the units.

The ***SWU Logical Flow*** diagram shows the logical program flow of the SWU.

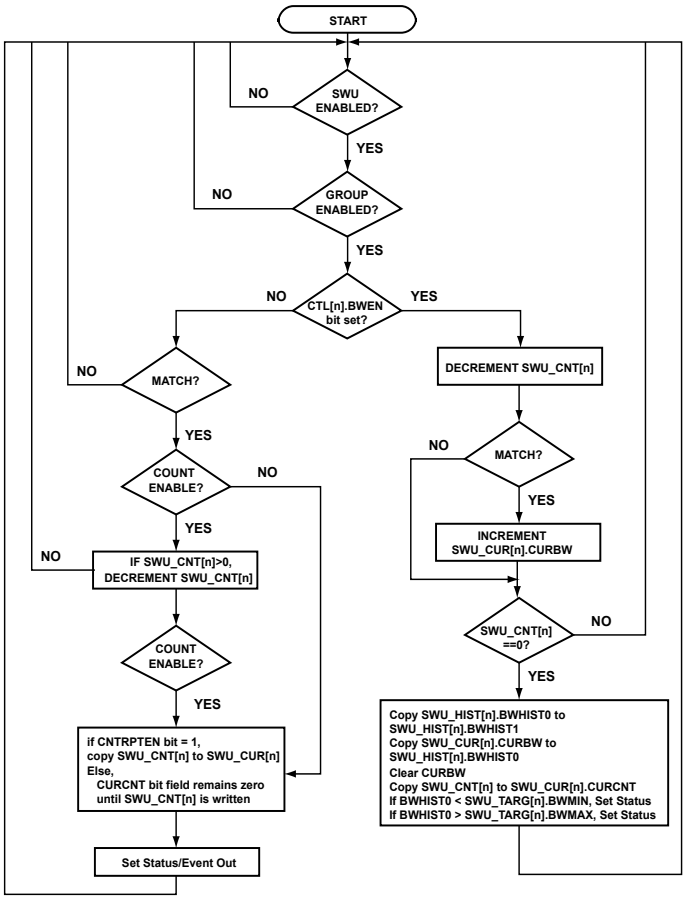

Figure 47-2: SWU Logical Flow

SWU Mode Configuration

The following sections show the steps for configuring SWU bandwidth mode and watchpoint mode.

Configuring the SWU for Bandwidth Mode

In bandwidth mode, the SWU counts transactions which match during a sampling window. At the end of the sampling window, the SWU stores the results. An action can be taken if the sampled bandwidth goes above or falls below a programmed range.

1. Configure the `SWU_CTL[n].DIR` bit to test the match on writes or reads.
2. Configure the `SWU_CTL[n].ACMPM` bits to address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the `SWU_CTL[n].IDCMPEN` bit.
4. Set the `SWU_CTL[n].BLENINC` bit to increment by burst length or clear it to increment by 1.
5. Configure the `SWU_CTL[n].MAXACT` and `SWU_CTL[n].MINACT` bits to enable actions taken when the bandwidth goes above the maximum, or falls below the minimum, respectively.

6. Set the SWU_CTL[n].BWEN=1 to enable bandwidth mode.
7. Program the lower address register, SWU_LA[n], and upper address register, SWU_UA[n], to define the memory range for comparison.
8. If ID comparison is enabled, program the ID register, SWU_ID[n].
9. Program the count register, SWU_CNT[n], with the number of clock cycles for which the SWU counts the number of matches.
10. If the SWU is set to respond when the bandwidth measurement underflows or overflows, program the min and max values into the SWU_TARG[n] register.
11. Enable the SWU

The SWU counts the number of matches in a pre-defined number of clock cycles as programmed. As an option, it can define lower and upper limits. If the matches fall outside the limits, an action can be taken.

Configuring the SWU for Watchpoint Mode

In watchpoint mode, the SWU can trigger a programmed action after every match or after a number of matches. This sequence can be automatically reset.

1. Set the SWU_CTL[n].DIR bit to test the match on writes or reads.
2. Configure the SWU_CTL[n].ACMPM bits for address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the SWU_CTL[n].IDCMPEN.
4. Set the SWU_CTL[n].CNTEN bit to enable the events to be triggered when the count decrements to zero.
5. If needed, set the SWU_CTL[n].CNTRPTEN bit to automatically reload the counter after it has decremented to zero to start another match sequence.
6. Clear the SWU_CTL[n].BWEN = 0 to configure watchpoint mode.
7. Configure the lower address register, SWU_LA[n], and upper address register, SWU_UA[n], to define the memory range for comparison.
8. If ID comparison is enabled, configure the ID register, SWU_ID[n].
9. Configure the count register, SWU_CNT[n], to determine how many matches occur before the watchpoint group responds.
10. Enable the SWU.

The SWU detects and counts down the number of match occurrences. When the counter expires, an action is taken.

ADSP-2159x_SC591_SC592_SC594 SWU Register Descriptions

System Watchpoint Unit (SWU) contains the following registers.

Table 47-5: ADSP-2159x_SC591_SC592_SC594 SWU Register List

Name	Description
SWU_CNT[n]	Count Register n
SWU_CTL[n]	Control Register n
SWU_CUR[n]	Current Register n
SWU_GCTL	Global Control Register
SWU_GSTAT	Global Status Register
SWU_HIST[n]	Bandwidth History Register n
SWU_ID[n]	ID Register n
SWU_LA[n]	Lower Address Register n
SWU_TARG[n]	Target Register n
SWU_UA[n]	Upper Address Register n

Count Register n

The SWU count registers (SWU_CNT[n]) contain a 16-bit count field (SWU_CNT[n].COUNT) whose usage differs depending on the mode of the watchpoint group. In bandwidth mode, the SWU_CNT[n].COUNT field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the SWU_CNT[n].COUNT field value determines how many matches occur before the watchpoint group takes action.

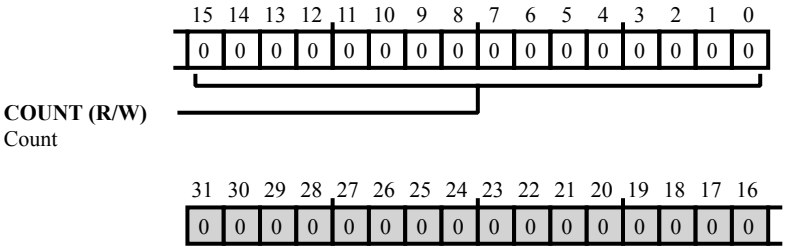

Figure 47-3: SWU_CNT[n] Register Diagram

Table 47-6: SWU_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	COUNT	Count. The SWU_CNT[n].COUNT field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the SWU_CNT[n].COUNT field value determines how many matches occur before the watchpoint group takes action.

Control Register n

The SWU control registers (SWU_CTL[n]) contain watchpoint attribute controls for all four watchpoint groups. These controls include enabling watchpoints, selecting the transaction direction for match, selecting address comparison mode, enabling ID comparison, enabling security comparison, enabling cycle count, enabling count repeat, enabling debug events, enabling interrupts, enabling triggers, enabling trace messages, enabling bandwidth mode, selecting the burst length increment, and enabling bandwidth underflow and overflow detection.

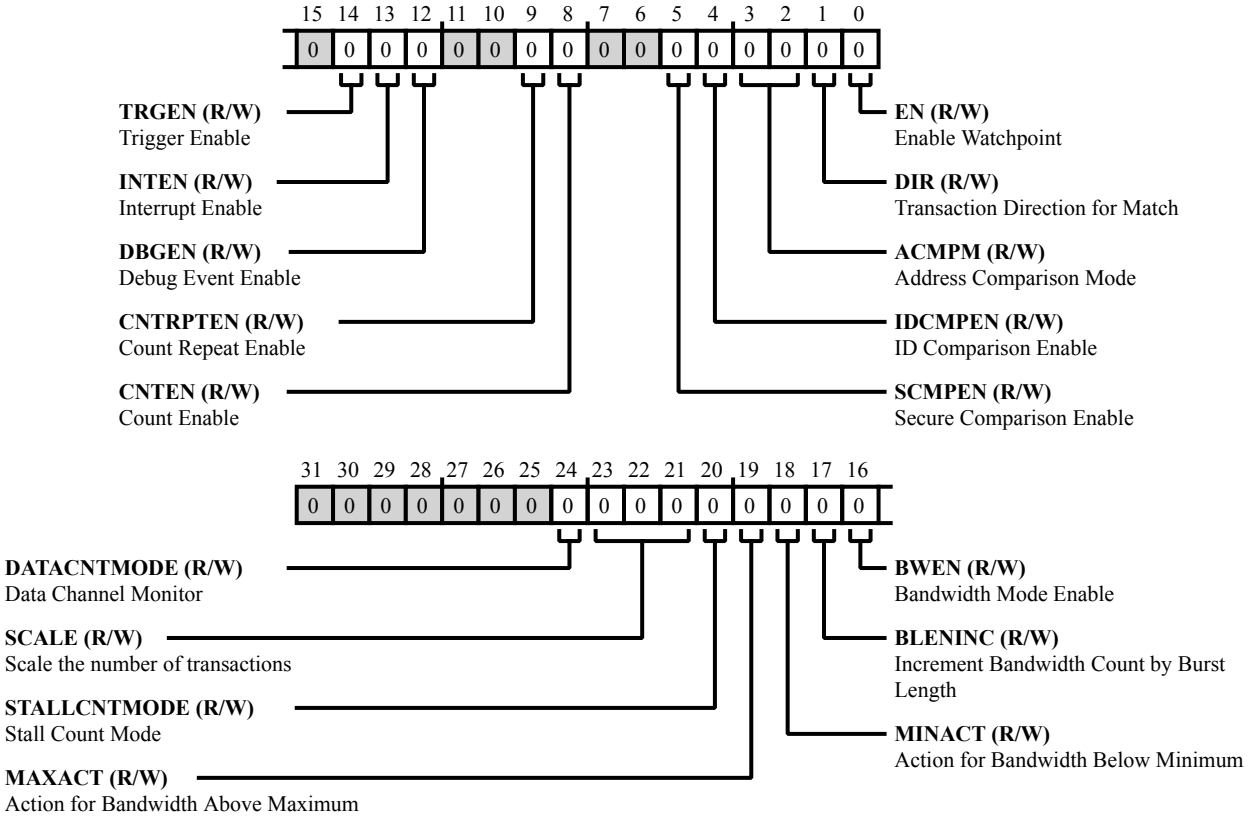

Figure 47-4: SWU_CTL[n] Register Diagram

Table 47-7: SWU_CTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	DATACNTMODE	Data Channel Monitor. The SWU_CTL[n].DATACNTMODE bit determines whether an address channel or a data channel is monitored. Note that in data channel only ID,READY and VALID signals are monitored and hence other comparisons (Address, Lock, Secure) will be ignored even if enabled. SWU_CTL[n].STALLCNTMODE and SWU_CTL[n].DIR can be used in conjunction with this bit	
		0	Monitor address channel
		1	Monitor data channel
23:21 (R/W)	SCALE	Scale the number of transactions. The SWU_CTL[n].SCALE bit field allows a program to count more transactions by scaling the number of transactions and also the number of clock cycles in the bandwidth window (SWU_CNT[n] register) by 10,100 or 1000. This is applicable only in bandwidth mode (SWU_CTL[n].BWEN==1).	
		0	No scaling
		1	1:10
		2	1:100
		3	Reserved
		4	1:1000
		5-7	Reserved
20 (R/W)	STALLCNTMODE	Stall Count Mode. The SWU_CTL[n].STALLCNTMODE bit determines whether the number of stalls are counted or whether the number of transactions are counted. This feature is only valid in bandwidth mode.	
		0	Count number of transactions
		1	Count number of stalls
19 (R/W)	MAXACT	Action for Bandwidth Above Maximum. Each SWU_CTL[n].MAXACT bit determines whether a watchpoint group takes action on bandwidth overflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action
18 (R/W)	MINACT	Action for Bandwidth Below Minimum. Each SWU_CTL[n].MINACT bit determines whether a watchpoint group takes action on bandwidth underflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action

Table 47-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	BLENINC	Increment Bandwidth Count by Burst Length. Each SWU_CTL[n].BLENINC bit controls how a watchpoint group's bandwidth count is incremented in the SWU_CUR[n] register's SWU_CUR[n].CURBW field. If the SWU_CTL[n].BLENINC bit is cleared (= 0), the SWU increments the bandwidth count by 1 for each matching transaction. If the SWU_CTL[n].BLENINC bit is set (=1), the SWU increments the bandwidth count by the burst length of the transaction for each matching transaction. This feature is only valid for bandwidth mode (SWU_CTL[n].BWEN bit == 1). Note that if the address range match is enabled (SWU_CTL[n].ACMPM bits) and if any address of a burst falls within the address range, the SWU_CUR[n].CURBW field is incremented by the burst length even if some of the burst address fall outside of the range. Also, note that the burst size of the transaction is not included in the increment, only the burst length of the transaction. This increment operation provides an approximate (not exact) number of bus cycles consumed during the bandwidth.	
		0	Increment by 1
		1	Burst Length Increment for Bandwidth Count
16 (R/W)	BWEN	Bandwidth Mode Enable. Each SWU_CTL[n].BWEN bit controls whether a watchpoint group operates in watchpoint mode or bandwidth mode. In watchpoint mode, the SWU_CTL[n].CNTEN and (optionally) SWU_CTL[n].CNTRPTEN registers control usage of the cycle count for watchpoint group operations. In bandwidth mode, the SWU_CTL[n].BLENINC, SWU_TARG[n], and SWU_HIST[n] registers control usage of watchpoint matches for watchpoint group operations.	
		0	Watchpoint Mode
		1	Bandwidth Mode
14 (R/W)	TRGEN	Trigger Enable. Each SWU_CTL[n].TRGEN bit controls whether a match for a watchpoint group generates a trigger event. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable
13 (R/W)	INTEN	Interrupt Enable. Each SWU_CTL[n].INTEN bit controls whether a match for a watchpoint group generates an interrupt. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable

Table 47-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DBGEN	Debug Event Enable. Each SWU_CTL[n].DBGEN bit controls debug event comparison for a watchpoint group, permitting matches based on debug status.	
		0	Disable
		1	Enable
9 (R/W)	CNTRPTEN	Count Repeat Enable. Each SWU_CTL[n].CNTRPTEN bit controls whether the watchpoint group's cycle count is reloaded and repeated after cycle countdown. If the SWU_CTL[n] register's SWU_CTL[n].CNTRPTEN bit is set, the SWU_CUR[n] register's SWU_CUR[n].CURCNT field is reloaded from SWU_CNT[n] register's SWU_CNT[n].COUNT field, and the countdown starts again. If SWU_CTL[n].CNTRPTEN bit is cleared, the expired count remains zero, and no further events are signalled. (See the SWU_CTL[n].CNTEN bit description for information regarding the countdown setup.)	
		0	Disable
		1	Enable
8 (R/W)	CNTEN	Count Enable. Each SWU_CTL[n].CNTEN bit controls whether the cycle count in the watchpoint group's SWU_CNT[n] register is decremented each cycle until it reaches zero. This feature is only valid in watchpoint mode (SWU_CTL[n].BWEN bit == 0).When the count reaches zero, any enabled watchpoint events are triggered. (See the SWU_CTL[n].CNTRPTEN bit description for optional actions at that may occur at the end of the countdown.)	
		0	Disable
		1	Enable
5 (R/W)	SCMPEN	Secure Comparison Enable. Each SWU_CTL[n].SCMPEN bit controls secure transaction comparison operation of an SWU watchpoint group, permitting matches based on transaction security.	
		0	Match on all transaction
		1	Match only secure transactions
4 (R/W)	IDCMPEN	ID Comparison Enable. Each SWU_CTL[n].IDCMPEN bit controls the ID comparison operation of an SWU watchpoint group. The ID match is based on comparison with the value in the SWU_ID[n] register.	

Table 47-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	ACMPM	Address Comparison Mode. Each set of `SWU_CTL[n].ACMPM` bits control the address comparison operation of an SWU watchpoint group. The address within range for comparison is defined as (`SWU_LA[n]` register <= address < `SWU_UA[n]` register). The address outside range for comparison is defined as (address < `SWU_LA[n]`) or (`SWU_UA[n]` <= address).	
		0	No address comparison
		1	Exact match on LAn
		2	Match on address within range
		3	Match on address outside range
1 (R/W)	DIR	Transaction Direction for Match. Each `SWU_CTL[n].DIR` bit determines whether the SWU check reads or writes for watchpoint matches.	
		0	Match on reads only
		1	Match on writes only
0 (R/W)	EN	Enable Watchpoint. Each `SWU_CTL[n].EN` bit controls the operation of one SWU watchpoint group. Clearing the `SWU_CTL[n].EN` bit halts the execution of watchpoint or bandwidth tracking operations in the watchpoint group without resetting status or configuration registers. Setting the `SWU_CTL[n].EN` bit enables the SWU watchpoint group to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Current Register n

The SWU current register (SWU_CUR[n]) operation varies depending whether the watchpoint group is in bandwidth mode or watchpoint mode. In both modes, the watchpoint count begins when the SWU loads the register's SWU_CUR[n].CURCNT field from the SWU_CNT[n] register's SWU_CNT[n].COUNT field when the watchpoint count is enabled (SWU_CTL[n] register, SWU_CTL[n].CNTEN bit =1).

In bandwidth mode, the current count field (SWU_CUR[n].CURCNT) contains the cycle count remaining within the current watchpoint period. The SWU decrements this value every cycle until the count reaches zero. At that point, the SWU reloads the SWU_CUR[n].CURCNT field from SWU_CNT[n] register's SWU_CNT[n].COUNT field. In bandwidth mode, the current bandwidth field (SWU_CUR[n].CURBW) contains the count of watchpoint matches (bandwidth) accumulated in the current watchpoint period.

In watchpoint mode, the current count field (SWU_CUR[n].CURCNT) contains the watchpoint match count remaining within the current watchpoint period. The SWU decrements this value with every watchpoint match until the count reaches zero. At that point, the SWU reloads the SWU_CUR[n].CURCNT field from SWU_CNT[n] register's SWU_CNT[n].COUNT field if the SWU_CTL[n] register's SWU_CTL[n].CNTRPTEN bit is set (=1). In watchpoint mode, the current bandwidth field (SWU_CUR[n].CURBW) is undefined.

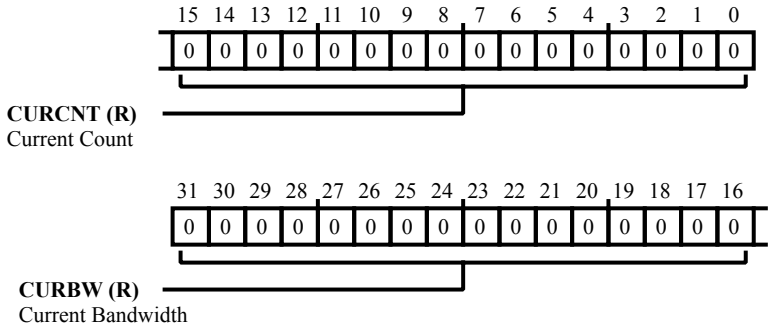

Figure 47-5: SWU_CUR[n] Register Diagram

Table 47-8: SWU_CUR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	CURBW	Current Bandwidth.
15:0 (R/NW)	CURCNT	Current Count.

Global Control Register

The SWU global control register (SWU_GCTL) provides SWU reset and enable.

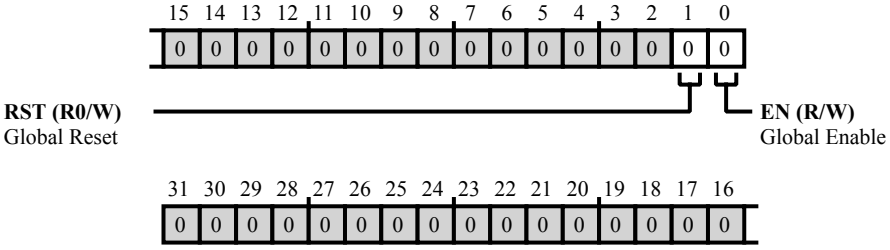

Figure 47-6: SWU_GCTL Register Diagram

Table 47-9: SWU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RST	Global Reset. The SWU_GCTL.RST) is write-1-action/read zero and controls the SWU operational state. Setting SWU_GCTL.RST resets all SWU registers to their default values and halts all SWU operations.	
		0	No Action
		1	Reset
0 (R/W)	EN	Global Enable. The SWU_GCTL.EN controls the SWU operational state. Clearing SWU_GCTL.EN halts the execution of all watchpoint and bandwidth tracking operations without resetting status registers or associated signals. Setting SWU_GCTL.EN enables the SWU to begin/resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Global Status Register

The SWU global status register (SWU_GSTAT) contains status bits for all four watchpoint groups.

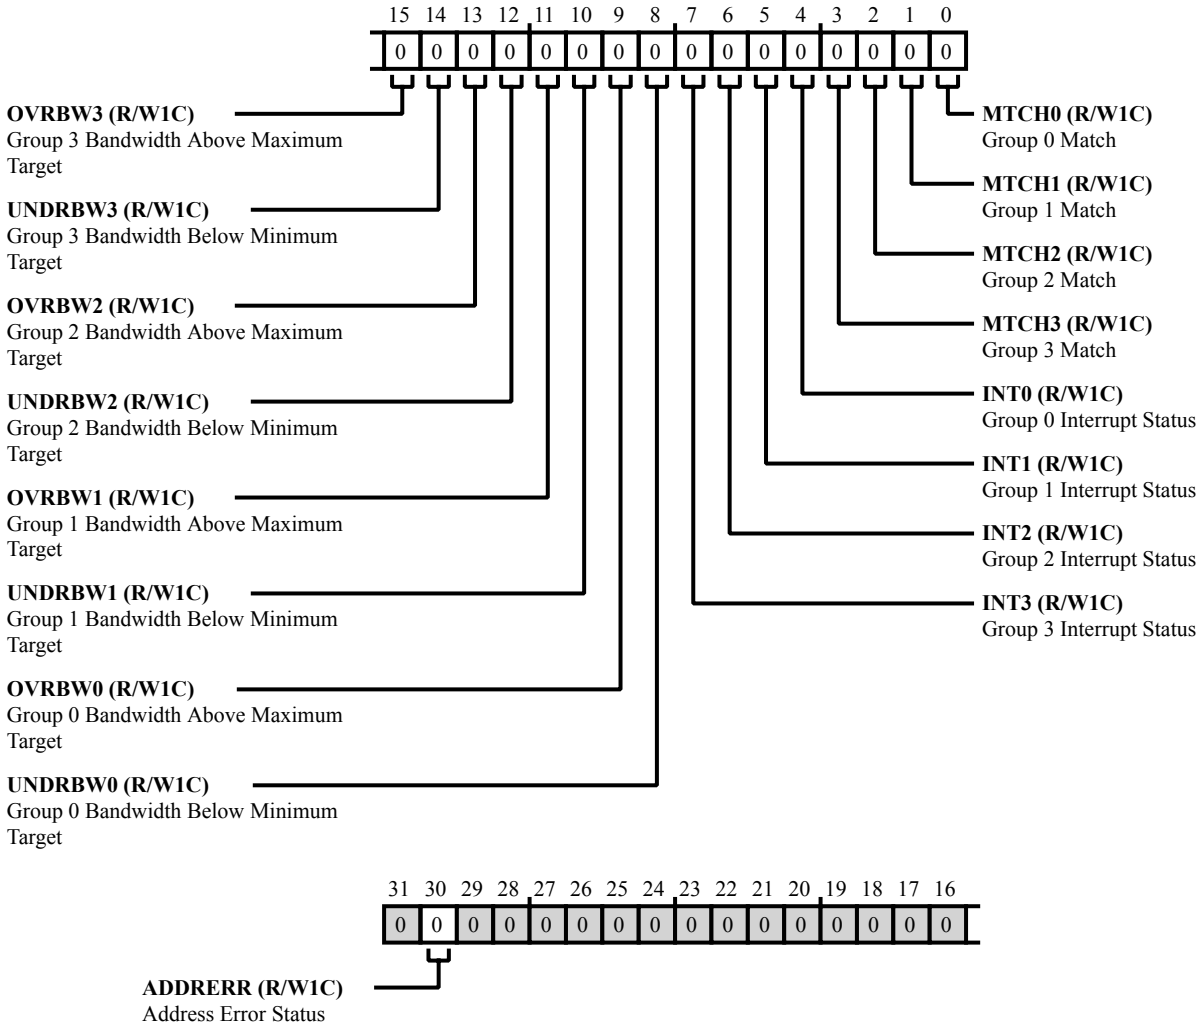

Figure 47-7: SWU_GSTAT Register Diagram

Table 47-10: SWU_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W1C)	ADDRERR	Address Error Status. The SWU_GSTAT.ADDRERR indicates that the SWU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	Inactive
		1	Active

Table 47-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	OVRBW3	Group 3 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 3 was not above maximum bandwidth
		1	Group 3 was above maximum bandwidth
14 (R/W1C)	UNDRBW3	Group 3 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 3 was not below minimum bandwitdth
		1	Group 3 was below minimum bandwitdth
13 (R/W1C)	OVRBW2	Group 2 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 2 was not above maximum bandwidth
		1	Group 2 was above maximum bandwidth
12 (R/W1C)	UNDRBW2	Group 2 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 2 was not below minimum bandwidth
		1	Group 2 was below minimum bandwidth
11 (R/W1C)	OVRBW1	Group 1 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 1 was not above maximum bandwidth
		1	Group 1 was above maximum bandwidth
10 (R/W1C)	UNDRBW1	Group 1 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 1 was not below minimum bandwidth
		1	Group 1 was below minimum bandwidth
9 (R/W1C)	OVRBW0	Group 0 Bandwidth Above Maximum Target. The SWU_GSTAT.OVRBW0 - SWU_GSTAT.OVRBW3 -- Group 0 through 3 watch-point bandwidth over maximum target bits. Each maximum bandwidth bit indicate (for each group)s that the measured bandwidth over the period defined by the SWU_CNT[n] register was over the maximum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not above maximum bandwidth
		1	Group 0 was above maximum bandwidth

Table 47-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	UNDRBW0	Group 0 Bandwidth Below Minimum Target. The SWU_GSTAT.UNDRBW0 - SWU_GSTAT.UNDRBW3 -- Group 0 through 3 watchpoint bandwidth below minimum target bits. Each minimum bandwidth bit indicates (for each group) that the measured bandwidth over the period defined by the SWU_CNT[n] register was below the minimum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not below minimum bandwidth
		1	Group 0 was below minimum bandwidth
7 (R/W1C)	INT3	Group 3 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
6 (R/W1C)	INT2	Group 2 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
5 (R/W1C)	INT1	Group 1 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
4 (R/W1C)	INT0	Group 0 Interrupt Status. The SWU_GSTAT.INT0 - SWU_GSTAT.INT3 -- Group 0 through 3 interrupt bits. Each interrupt bit indicates (for each group) whether a watchpoint group is contributing to the SWU's interrupt output. This status bit is sticky; write-1-to-clear it.	
		0	No interrupt
		1	Interrupt Occurred
3 (R/W1C)	MTCH3	Group 3 Match. See SWU_GSTAT.MTCH0 description.	
		0	No Match
		1	Group 3 Watchpoint Match

Table 47-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	MTCH2	Group 2 Match. See SWU_GSTAT.MTCH0 description.	
		0	No match
		1	Group 2 Watchpoint Match
1 (R/W1C)	MTCH1	Group 1 Match. See SWU_GSTAT.MTCH0 description.	
		0	No match
		1	Group 1 Watchpoint Match
0 (R/W1C)	MTCH0	Group 0 Match. The SWU_GSTAT.MTCH0 - SWU_GSTAT.MTCH3 -- Group 0 through 3 match bits. Each match bit indicates (for each group) whether a watchpoint match has occurred in a SWU watchpoint group, as controlled by the group's related watchpoint control register (SWU_CTL[n]). This status bit is sticky; write-1-to-clear it.	
		0	No match
		1	Group 0 Watchpoint Match

Bandwidth History Register n

The SWU bandwidth history registers (SWU_HIST[n]) contain data copied from a watchpoint group's current bandwidth value (SWU_CUR[n] register, SWU_CUR[n].CURBW bits) at the end of the last two watchpoint periods. At the end of each watchpoint period, the SWU copies the previous bandwidth value from the SWU_HIST[n].BWHIST0 field to the SWU_HIST[n].BWHIST1 field and copies the new bandwidth value from the SWU_CUR[n].CURBW field to the SWU_HIST[n].BWHIST0 field.

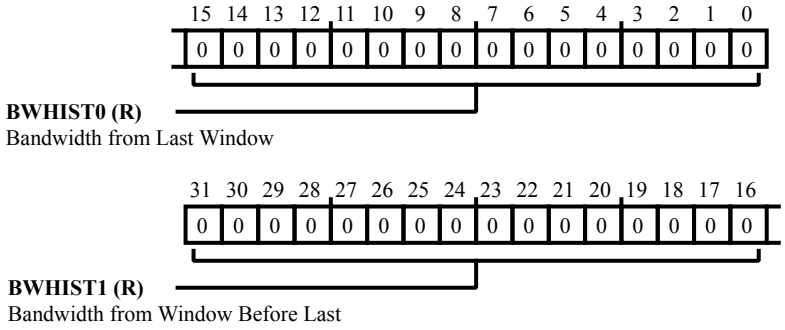

Figure 47-8: SWU_HIST[n] Register Diagram

Table 47-11: SWU_HIST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	BWHIST1	Bandwidth from Window Before Last.
15:0 (R/NW)	BWHIST0	Bandwidth from Last Window.

ID Register n

The SWU ID registers (SWU_ID[n]) contain a 16-bit ID field (SWU_ID[n].ID) and a 16-bit ID mask field (SWU_ID[n].IDMASK) that watchpoint groups use for ID comparison. The ID on the bus is AND'ed with the SWU_ID[n].IDMASK field, then the watchpoint group compares the result against the SWU_ID[n].ID field.

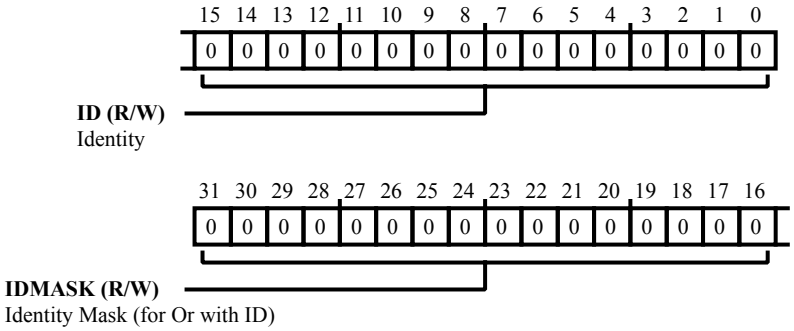

Figure 47-9: SWU_ID[n] Register Diagram

Table 47-12: SWU_ID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	IDMASK	Identity Mask (for Or with ID).
15:0 (R/W)	ID	Identity.

Lower Address Register n

The SWU lower address registers (SWU_LA[n]) contain each watchpoint group's lower address for address match comparison. In exact match on SWU_LA[n] address mode (SWU_CTL[n].ACMPM bits =01), the watchpoint group uses only this address for match comparison.

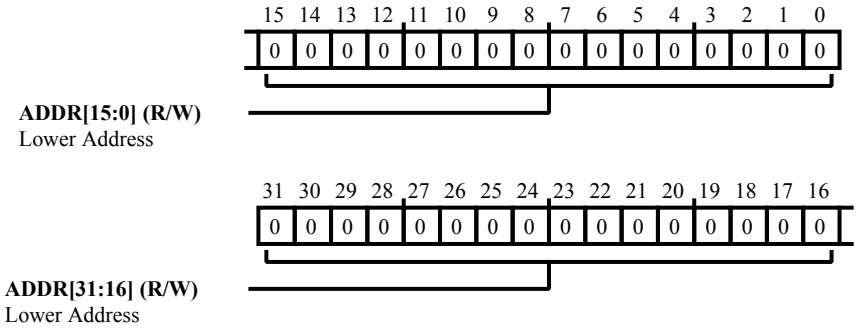

Figure 47-10: SWU_LA[n] Register Diagram

Table 47-13: SWU_LA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Lower Address.

Target Register n

The SWU target registers (SWU_TARG[n]) contain a minimum value field (SWU_TARG[n].BWMIN) and maximum value field (SWU_TARG[n].BWMAX) of bandwidth targets used by watchpoint groups in bandwidth mode. When the bandwidth period expires, if the current bandwidth value (SWU_CUR[n] register, SWU_CUR[n].CURBW bits) is below the minimum target or above the maximum target, the watchpoint group takes action as enabled by the SWU_CTL[n] register's SWU_CTL[n].MINACT or SWU_CTL[n].MAXACT bits.

In bandwidth mode, note that the watchpoint group increments its count of either data bus transactions or address bus transactions (bursts) as selected by the SWU_CTL[n].BLENINC bit. Keep this mode selection in mind when programming the bandwidth target values.

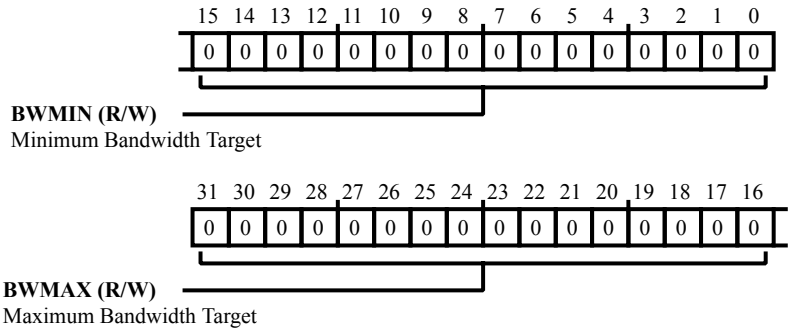

Figure 47-11: SWU_TARG[n] Register Diagram

Table 47-14: SWU_TARG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	BWMAX	Maximum Bandwidth Target.
15:0 (R/W)	BWMIN	Minimum Bandwidth Target.

Upper Address Register n

The SWU upper address registers (SWU_UA[n]) contain each watchpoint group's upper address for address match comparison. In exact match on SWU_LA[n] address mode (SWU_CTL[n].ACMPM bits =01), the SWU_UA[n] is not used for match comparison.

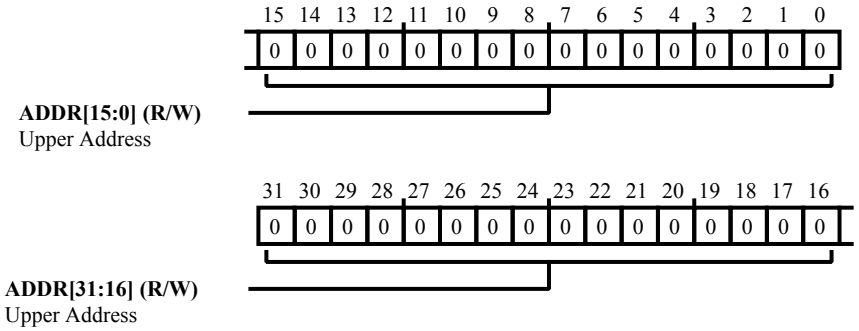

Figure 47-12: SWU_UA[n] Register Diagram

Table 47-15: SWU_UA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Upper Address.

48 Memory Error Protection Unit (MEPU)

Memory Error Protection Unit (MEPU) handles single-bit and double-bit memory error detection and correction across the memories in the chip and controls routing of their interrupts/triggers.

It consists of following blocks:

- Memory Error Controller (MEC)
- Parity Controller (PCTL)

Memory Error Controller (MEC)

The Memory Error Controller (MEC) manages memory parity, ECC errors and warning inputs from various cores and peripherals and sends out interrupt and trigger outputs. It is a generic N x M multiplexer and interrupt controller for error or warning inputs to interrupt and trigger outputs. It has control features such as enable and disable and interrupt masking, and status signaling for input/outputs. For more information on MEC functionality, see the MEC registers description.

MEC Features

The MEC unit has the following features:

- Interrupt controller for memory parity, ECC errors and warnings
- N x M multiplexer for error or warning inputs to interrupt and trigger outputs
- Peripheral bus slave interface for register read and write
- Control and status registers
    - Control for enabling or disabling each input error status and masking its interrupt
    - Control for enabling or disabling each output error interrupt
    - Input error status bits are sticky and write-1-to-clear
    - Output error interrupt status bits are read only
    - Lock feature for control registers write. Status registers capture lock write error.

- Peripheral and component identification registers
- Capability to retain parity, ECC error and warning status even after any reset for fault source debug
- Fully-configurable design

Parity Controller (PCTL)

The Parity Controller (PCTL) handles parity encoding and decoding to and from memory data for single bit memory error detection.

PCTL Features

The PCTL unit has the following features:

- Generic memory parity controller
    - Generation of write parity bits from write data bits
    - Concatenation of parity bits with data bits for memory write data
    - Generation of write enable mask for parity bits to memory
    - Extraction of read data bits from memory read data
    - Detection of read parity error from memory read data
- Even parity logic for parity generation and error detection
- Provision for parity bit interleaving
- Single parity error output per memory instance
- Memory initialization control logic
- Fully-configurable design

MEC Functional Description

The MEC works with the PCTL to detect and correct memory error across the memories in the chip. It also controls the routing of the generated interrupts and triggers.

ADSP-2159x_SC591_SC592_SC594 MEC Register List

The Memory Error Controller (MEC) manages memory parity/ecc errors/warning inputs from various cores and peripherals and sends out interrupt/trigger outputs. It is generic N x M multiplexer and interrupt controller for error/warning inputs to interrupt/trigger outputs. It has control features such as enable/disable and interrupt masking, and status signaling for inputs/outputs. For more information on MEC functionality, see the MEC register descriptions.

MEC Architectural Concepts

The MEC unit communicates with the Cortex-A5 directly through the subsystem's SYS bus crossbar. It services MMR addresses associated with the MEC function unit and translates the addresses into specific transcendental MEC functions. The results are read from common result registers shared by all the functions in single-precision floating-point format. The block stalls all read-accesses until the result is ready.

MEC Configuration

The following tables describe the range of values for configuration and the mapping of parity errors.

Table 48-5: Mapping of Input Parity Errors (PERR)

PERR ID	Name	Description
0	PERR_C0_L1CR	Core0 (ARM) L1 Cache RAM Parity Error
1	PERR_C0_L2CR	Core0 (ARM) L2 Cache RAM Parity Error
2	PERR_C1_L1R	Core1 (SHARC0) L1 RAM Parity Error
3	PERR_C1_L1CR	Core1 (SHARC0) L1 Cache RAM Parity Error
4	PERR_C1_BPR	Core1 (SHARC0) Branch Predictor RAM Parity Error
5	PERR_C2_L1R	Core2 (SHARC1) L1 RAM Parity Error

Table 48-5: Mapping of Input Parity Errors (PERR) (Continued)

PERR ID	Name	Description
6	PERR_C2_L1CR	Core2 (SHARC1) L1 Cache RAM Parity Error
7	PERR_C2_BPR	Core2 (SHARC1) Branch Predictor RAM Parity Error
8	PERR_ASRC0_FR	ASRC0 FIFO RAM Parity Error
9	PERR_ASRC1_FR	ASRC1 FIFO RAM Parity Error
10	PERR_ASRC2_FR	ASRC2 FIFO RAM Parity Error
11	PERR_ASRC3_FR	ASRC3 FIFO RAM Parity Error
12	PERR_IIR0_R	IIR0 RAM Parity Error
13	PERR_FIR0_R	FIR0 RAM Parity Error
14	PERR_USB0_FR	USB0 FIFO RAM Parity Error
15	PERR_CAN0_MBR	CAN0 Mailbox RAM Parity Error
16	PERR_CAN0_AMR	CAN0 Acceptance Mask RAM Parity Error
17	PERR_CAN1_MBR	CAN1 Mailbox RAM Parity Error
18	PERR_CAN1_AMR	CAN1 Acceptance Mask RAM Parity Error
19	PERR_TRNG0_DBR	TRNG0 Data Buffer RAM Parity Error
20	PERR_PKA0_DR	PKA0 Data RAM Parity Error
21	PERR_SPE0_BR	SPE0 Buffer RAM Parity Error
22	PERR_SPE0_AR	SPE0 ARC4 RAM Parity Error
23	PERR_EMAC0_TFR	EMAC0 Transmit FIFO RAM Parity Error
24	PERR_EMAC0_RFR	EMAC0 Receive FIFO RAM Parity Error
25	PERR_MSI0_FR	MSI0 FIFO RAM Parity Error

Table 48-6: Mapping of Output Parity Errors (PERR)

PERR ID	Name	Description
0	PEIRQ_C0	Core0 (ARM) Parity Error Interrupt
1	PEIRQ_C1	Core1 (SHARC0) Parity Error Interrupt
2	PEIRQ_C2	Core2 (SHARC1) Parity Error Interrupt
3	PEIRQ_SYS	System Peripheral Parity Error Interrupt

Table 48-7: Mapping of Input ECC Errors (ECCERR)

PERR ID	Name	Description
0	ECCERR_L2CTL0	L2CTL0 ECC Error

Table 48-8: Mapping of Output ECC Errors (EEIRQ)

PERR ID	Name	Description
0	EWIRQ_L2CTL0	L2CTL0 ECC Error Interrupt

PCTL Integration

There is one PCTL instance per port per memory instance (for example, one PCTL instance for single port memory and two PCTL instances for dual port memories).

Memory initialization control logic supported by PCTL is used only for instances attached to Arm L1 cache memories.

An additional softwer trigger requester and initialization trigger completer is provided in TRU for starting memory initialization. A pulse from this trigger completer starts initialization of Arm L1 cache memories. When all the locations of a particular memory instance get initialized, the PCTL generates a memory initialization done signal for the corresponding memory instance. These signals from all PCTL instances corresponding to Arm L1 cache memories are AND'ed to generate a single memory initialization done output which is connected as an interrupt to SEC/GIC and a trigger requester to TRU.

ADSP-2159x_SC591_SC592_SC594 MEC Register Descriptions

Memory Error Controller (MEC) contains the following registers.

Table 48-9: ADSP-2159x_SC591_SC592_SC594 MEC Register List

Name	Description
MEC_CID0	Component ID0 Register
MEC_CID1	Component ID1 Register
MEC_CID2	Component ID2 Register
MEC_CID3	Component ID3 Register
MEC_CLR	Clear Register
MEC_ECCERR_CTL[y]	ECC Error Control Register
MEC_ECCERR_IMASK[y]	ECC Error Interrupt Mask Register
MEC_ECCERR_STAT[y]	ECC Error Status Register
MEC_EEIRQ_GCTL[q]	ECC Error Interrupt Request Global Control Register
MEC_EEIRQ_GSTAT[q]	ECC Error Interrupt Request Global Status Register

Table 48-9: ADSP-2159x_SC591_SC592_SC594 MEC Register List (Continued)

Name	Description
MEC_PEIRQ_GCTL[p]	Parity Error Interrupt Request Global Control Register
MEC_PEIRQ_GSTAT[p]	Parity Error Interrupt Request Global Status Register
MEC_PERR_CTL0	Parity Error Control Register
MEC_PERR_CTL1	Parity Error Control Register
MEC_PERR_IMASK0	Parity Error Interrupt Mask Register
MEC_PERR_IMASK1	Parity Error Interrupt Mask Register
MEC_PERR_STAT0	Parity Error Status Register
MEC_PERR_STAT1	Parity Error Status Register
MEC_PID0	Peripheral ID0 Register
MEC_PID1	Peripheral ID1 Register
MEC_PID2	Peripheral ID2 Register
MEC_PID3	Peripheral ID3 Register
MEC_PID4	Peripheral ID4 Register
MEC_PID5	Peripheral ID5 Register
MEC_PID6	Peripheral ID6 Register
MEC_PID7	Peripheral ID7 Register

Component ID0 Register

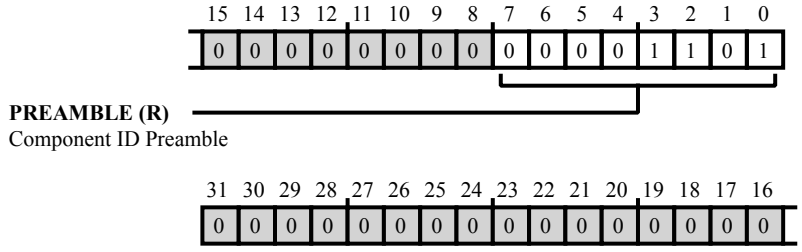

Figure 48-5: MEC_CID0 Register Diagram

Table 48-10: MEC_CID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PREAMBLE	Component ID Preamble. The `MEC_CID0.PREAMBLE` field indicates the component ID preamble.

Component ID1 Register

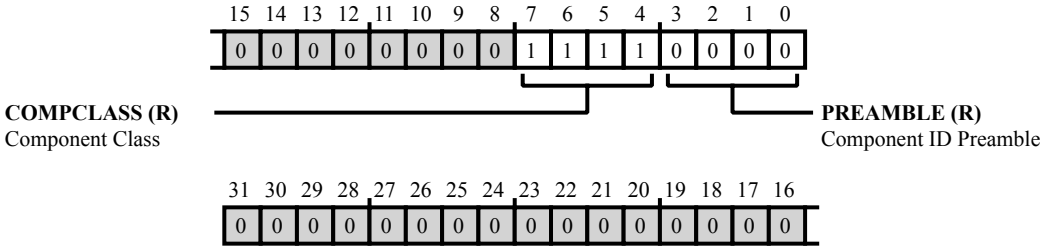

Figure 48-6: MEC_CID1 Register Diagram

Table 48-11: MEC_CID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	COMPCLASS	Component Class. The `MEC_CID1.COMPCLASS` field indicates the component class. Dedicated debug blocks (core debug access port, Program Trace, etc.) should identify as CoreSight (i.e. 0x9) and implement the full compliment of CoreSight registers including DEVTYPE. All other ADI components should identify as System (i.e. 0xF) components. See CoreSight Architecture Specification for details.	
		9	CoreSight
		15	System
3:0 (R/NW)	PREAMBLE	Component ID Preamble. The `MEC_CID1.PREAMBLE` field indicates the component ID preamble.	

Component ID2 Register

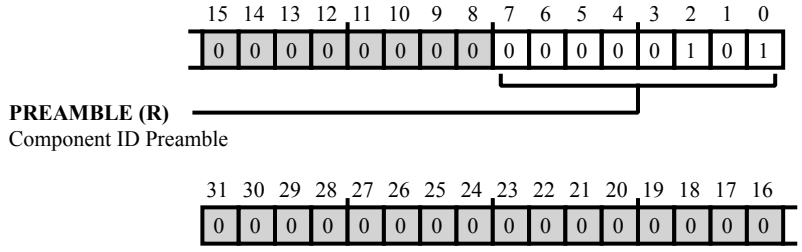

Figure 48-7: MEC_CID2 Register Diagram

Table 48-12: MEC_CID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PREAMBLE	Component ID Preamble. The `MEC_CID2.PREAMBLE` field indicates the component ID preamble.

Component ID3 Register

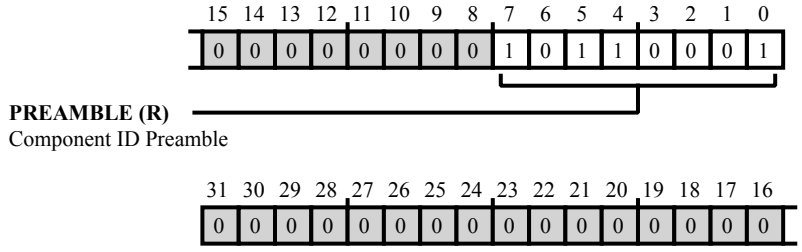

Figure 48-8: MEC_CID3 Register Diagram

Table 48-13: MEC_CID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PREAMBLE	Component ID Preamble. The `MEC_CID3.PREAMBLE` field indicates the component ID preamble.

Clear Register

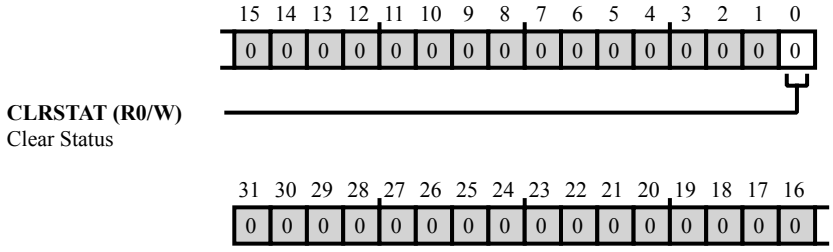

Figure 48-9: MEC_CLR Register Diagram

Table 48-14: MEC_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R0/W)	CLRSTAT	Clear Status. Write of '1' to the `MEC_CLR.CLRSTAT` bit clears all status registers of MEC

ECC Error Control Register

MEC_ECCERR_CTL[y] register bits control enable/disable for ECC error inputs from various cores/peripherals and decide whether their status will be reflected in ECC error status register bits.

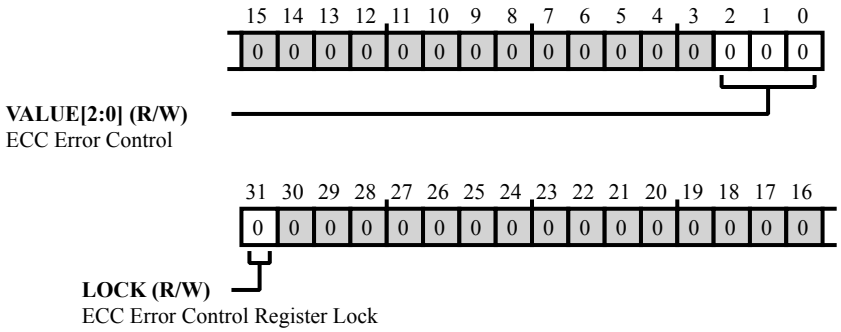

Figure 48-10: MEC_ECCERR_CTL[y] Register Diagram

Table 48-15: MEC_ECCERR_CTL[y] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_ECCERR_CTL[y].LOCK bit is enabled, the MEC_ECCERR_CTL[y] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	VALUE	ECC Error Control. The MEC_ECCERR_CTL[y].VALUE bit indicates whether ECC control is enabled (=1) or disabled (=0).	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error

ECC Error Interrupt Mask Register

MEC_ECCERR_IMASK[y] register bits control interrupt masks for ECC error inputs from various cores/peripherals.

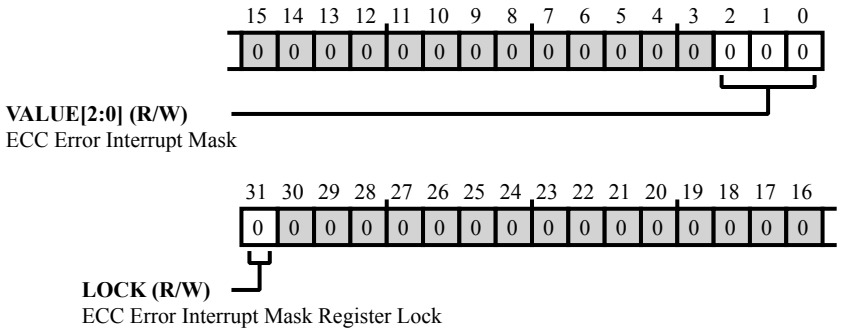

Figure 48-11: MEC_ECCERR_IMASK[y] Register Diagram

Table 48-16: MEC_ECCERR_IMASK[y] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Interrupt Mask Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_ECCERR_IMASK[y].LOCK bit is enabled, the MEC_ECCERR_IMASK[y] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	VALUE	ECC Error Interrupt Mask. The MEC_ECCERR_IMASK[y].VALUE bit indicates when the ECC error interrupt is masked (=1) or unmasked (=0).	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error

ECC Error Status Register

MEC_ECCERR_STAT[y] register bits reflect status for ECC error inputs from various cores/peripherals. Writing '1' to these bits clear corresponding ECC error status.

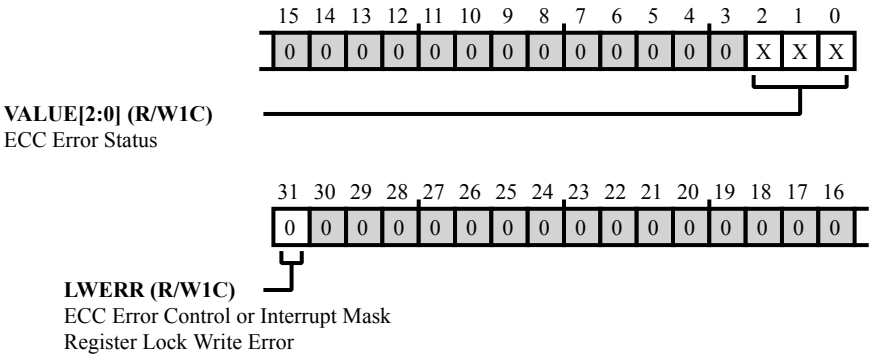

Figure 48-12: MEC_ECCERR_STAT[y] Register Diagram

Table 48-17: MEC_ECCERR_STAT[y] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	ECC Error Control or Interrupt Mask Register Lock Write Error. The MEC_ECCERR_STAT[y].LWERR bit indicates (when set) there was an attempted write to an MEC register while the MEC_ECCERR_CTL[y].LOCK bit was set and while the global lock bit was enabled ({SPU:CTL:GLCK} bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
2:0 (R/W1C)	VALUE	ECC Error Status. . '1' indicates error and '0' indicates no error. Sticky bit, write '1' to clear.	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error

ECC Error Interrupt Request Global Control Register

MEC_EEIRQ_GCTL[q] register bits control enable/disable of ECC error interrupt/trigger outputs.

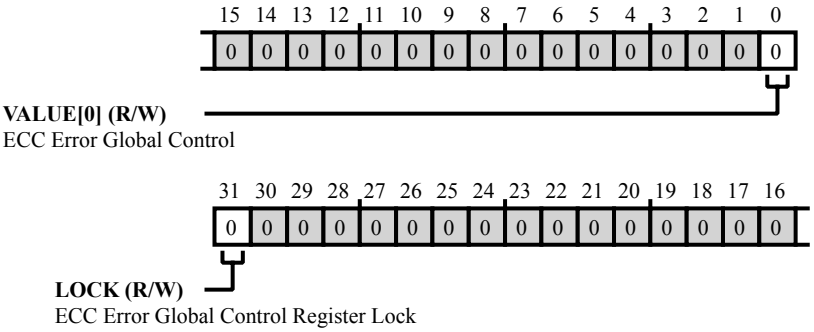

Figure 48-13: MEC_EEIRQ_GCTL[q] Register Diagram

Table 48-18: MEC_EEIRQ_GCTL[q] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Global Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_EEIRQ_GCTL[q].LOCK bit is enabled, the MEC_EEIRQ_GCTL[q] register is read only.	
		0	Unlock
		1	Lock
0 (R/W)	VALUE	ECC Error Global Control. '1' indicates enable and '0' indicates disable.	

ECC Error Interrupt Request Global Status Register

MEC_EEIRQ_GSTAT[q] register bits reflect status of ECC error interrupt/trigger outputs.

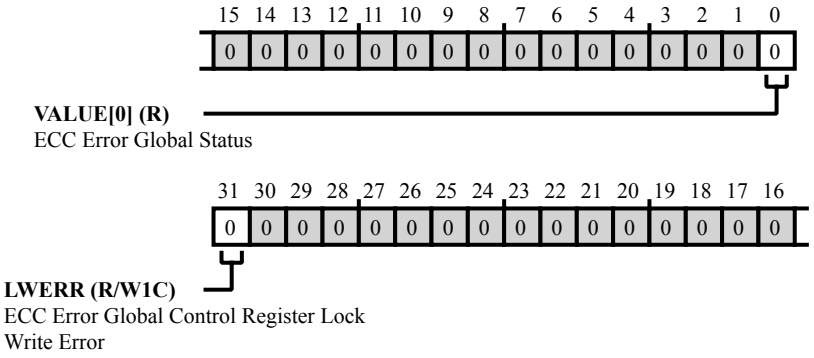

Figure 48-14: MEC_EEIRQ_GSTAT[q] Register Diagram

Table 48-19: MEC_EEIRQ_GSTAT[q] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	ECC Error Global Control Register Lock Write Error. The MEC_EEIRQ_GSTAT[q].LWERR bit indicates (when set) there was an attempted write to an MEC register while the MEC_EEIRQ_GCTL[q].LOCK bit was set and while the global lock bit was enabled ({SPU:CTL:GLCK} bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
0 (R/NW)	VALUE	ECC Error Global Status. '1' indicates assertion of interrupt/trigger and '0' indicates no interrupt/trigger.	

Parity Error Interrupt Request Global Control Register

MEC_PEIRQ_GCTL[p] register bits control enable/disable of parity error interrupt/trigger outputs.

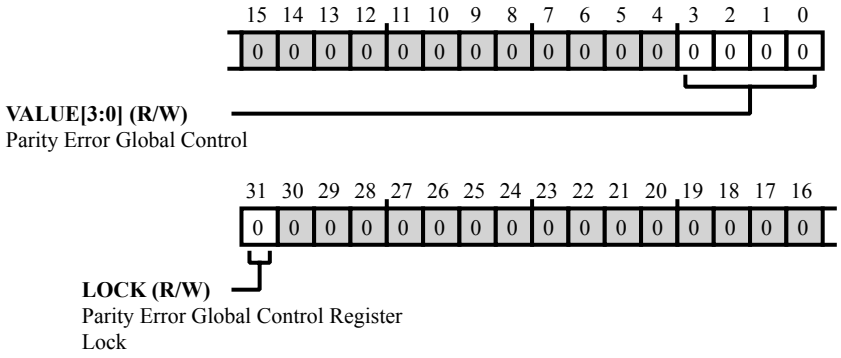

Figure 48-15: MEC_PEIRQ_GCTL[p] Register Diagram

Table 48-20: MEC_PEIRQ_GCTL[p] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Parity Error Global Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_PEIRQ_GCTL[p].LOCK bit is enabled, the MEC_PEIRQ_GCTL[p] register is read only.	
		0	Unlock
		1	Lock
3:0 (R/W)	VALUE	Parity Error Global Control. The MEC_PEIRQ_GCTL[p].VALUE field indicates parity error global control. '1' indicates enable and '0' indicates disable.	

Parity Error Interrupt Request Global Status Register

MEC_PEIRQ_GSTAT[p] register bits reflect status of parity error interrupt/trigger outputs.

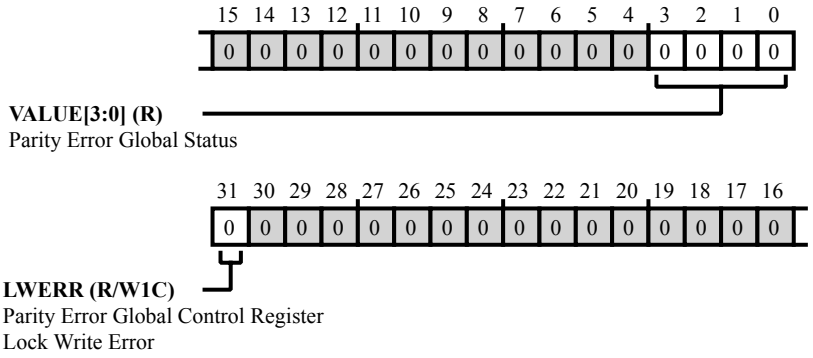

Figure 48-16: MEC_PEIRQ_GSTAT[p] Register Diagram

Table 48-21: MEC_PEIRQ_GSTAT[p] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Parity Error Global Control Register Lock Write Error. The MEC_PEIRQ_GSTAT[p].LWERR bit indicates (when set) there was an attempted write to an MEC register while the MEC_PEIRQ_GCTL[p].LOCK bit was set and while the global lock bit was enabled ({SPU:CTL:GLCK} bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
3:0 (R/NW)	VALUE	Parity Error Global Status. The MEC_PEIRQ_GSTAT[p].VALUE field indicates the parity error global status. '1' indicates assertion of interrupt/trigger, '0' indicates no interrupt/trigger.	

Parity Error Control Register

MEC_PERR_CTL0 register bits control enable/disable for parity error inputs from various cores/peripherals and decide whether their status will be reflected in parity error status register bits.

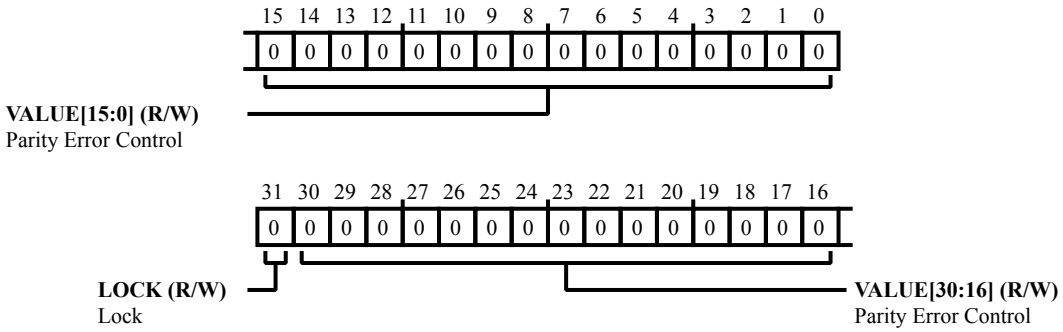

Figure 48-17: MEC_PERR_CTL0 Register Diagram

Table 48-22: MEC_PERR_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_PERR_CTL0.LOCK bit is enabled, the MEC_PERR_CTL0 register is read only.	
		0	Unlock
		1	Lock
30:0 (R/W)	VALUE	Parity Error Control. 1 indicates enable and 0 indicates disable	
		1	Core 0 L1 Cache RAM Parity Error
		2	Core 0 L2 Cache RAM Parity Error
		4	Core 1 L1 RAM Parity Error
		8	Core 1 L1 Cache Parity Error

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled ({SPU:CTL:GLCK} bit =1) and the MEC_PERR_IMASK1.LOCK bit is enabled, the MEC_PERR_IMASK1 register is read only.	
		0	Unlock
		1	Lock
6:0 (R/W)	VALUE	Parity Error Interrupt Mask bit.. '1' indicates interrupt masked and '0' indicates interrupt unmasked.	
		1	EMAC0 Transmit FIFO RAM Parity Error
		2	EMAC0 Receive FIFO RAM Parity Error
		4	MLB0 Data Buffer RAM Parity Error
		8	MLB0 Channel Table RAM Parity Error
		16	TMC0 Trace Data RAM Parity Error
		32	EMAC1 Transmit FIFO RAM Parity Error
		64	EMAC1 Receive FIFO RAM Parity Error

Parity Error Status Register

MEC_PERR_STAT0 register bits reflect status for parity error inputs from various cores/peripherals. Writing '1' to these bits clear corresponding parity error status.

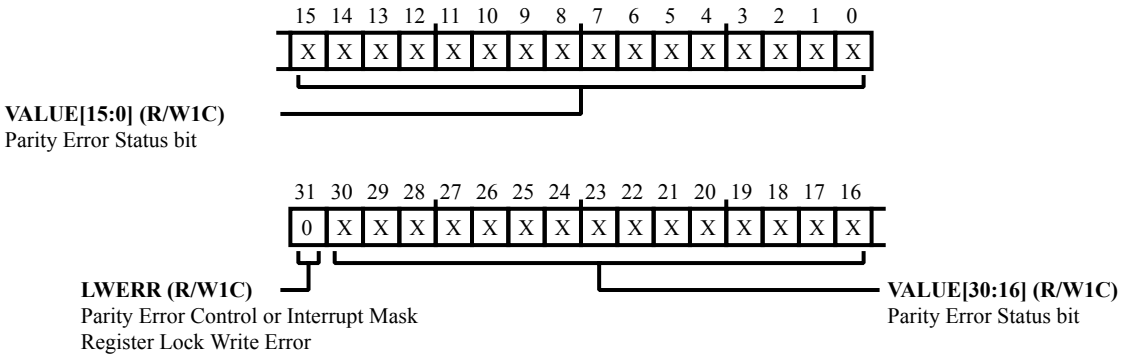

Figure 48-21: MEC_PERR_STAT0 Register Diagram

Table 48-26: MEC_PERR_STAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Parity Error Control or Interrupt Mask Register Lock Write Error. The MEC_PERR_STAT0.LWERR bit indicates (when set) there was an attempted write to an MEC register while the MEC_PERR_CTL0.LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30:0 (R/W1C)	VALUE	Parity Error Status bit. '1' indicates error and '0' indicates no error. Sticky bit, write '1' to clear.	
		1	Core 0 L1 Cache RAM Parity Error
		2	Core 0 L2 Cache RAM Parity Error
		4	Core 1 L1 RAM Parity Error
		8	Core 1 L1 Cache Parity Error
		16	Core 1 Branch Predictor Parity Error
		32	Core 2 L1 RAM Parity Error
		64	Core 2 L1 Cache Parity Error
		128	Core 2 Branch Predictor Parity Error
		256	ASRC0 FIFO Parity Error
		512	ASRC1 FIFO Parity Error

Table 48-26: MEC_PERR_STAT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1024	ASRC2 FIFO Parity Error
		2048	ASRC3 FIFO Parity Error

49 System Debug and Trace Unit (DBG)

The system debug and trace unit is based on Arm Core Sight technology. CoreSight is a set of architecture specifications defining debug and trace architecture. The processor uses CoreSight infrastructure to provide industry standard debug and trace capabilities.

http://infocenter.arm.com/help/

The applicable documentation for more details about the ArmCoreSight feature includes:

- CoreSight PFT Architecture Specification , ARM IHI 0035B (PFT)
- System Trace Macrocell, Programmers' Model Architecture Specification, ARM IHI 0054A (STM)
- CoreSight Trace Memory Controller, ARM DDI0461B (TMC)
- CoreSight Components Technical Reference Manual, ARM DDI 0314H (TPIU)
- Embedded Cross Trigger Technical Reference Manual, ARM DDI 0291A
- ETM for A5 Technical Reference Manual, DDI0435C

DBG Features

The system debug and trace unit contains the following features.

- System JTAG TAP controller for system debug features, boundary scan, and public JTAG features
- A debug interface to core, and other system resources
- Direct and run-time access to the memory system and system MMRs
- Direct control over system reset
- Support for debug immediately after reset (boot debug)
- Group halt (debug event immediately halts all specified endpoints)
- Real-time on-chip visibility is made available to all developers, including software developers

DBG Functional Description

The following sections provide functional descriptions of the DBG unit.

ADSP-2159x_SC591_SC592_SC594 CSPFT Register List

The CoreSight (TM) Program Flow Trace unit (CSPFT) provides debug features. A set of registers governs CSPFT operations. For more information on CSPFT functionality, see the CSPFT register descriptions.

Table 49-1: ADSP-2159x_SC591_SC592_SC594 CSPFT Register List

Name	Description
CSPFT_ACTR[n]	Address Comparator Access Type Register
CSPFT_ACVR[n]	Address Comparator Value Register
CSPFT_AUTHSTATUS	Authentication Status Register
CSPFT_CCER	Configuration Code Extension Register
CSPFT_CID0	Component ID0 Register
CSPFT_CID1	Component ID1 Register
CSPFT_CID2	Component ID2 Register
CSPFT_CID3	Component ID3 Register
CSPFT_CIDCMR	Context ID Comparator Mask Register
CSPFT_CIDCVR[n]	Context ID Comparator Value
CSPFT_CLAIMCLR	Claim Tag Clear Register
CSPFT_CLAIMSET	Claim Tag Set Register
CSPFT_CNTENR[n]	Counter Enable Event Register
CSPFT_CNTRLDEVR[n]	Counter Reload Event Register
CSPFT_CNTRLDVR[n]	Counter Reload Value Register
CSPFT_CNTVR[n]	Counter Value Register
CSPFT_CTL	Main Control Register
CSPFT_DEVTYPE	Device Type Identifier Register
CSPFT_EXTOUTEVR[n]	External Output Event Register
CSPFT_HWFEAT	Hardware Feature Register
CSPFT_LAR	Lock Access Register
CSPFT_LSR	Lock Status Register
CSPFT_PID0	Peripheral ID0 Register
CSPFT_PID1	Peripheral ID1 Register
CSPFT_PID2	Peripheral ID2 Register

Table 49-1: ADSP-2159x_SC591_SC592_SC594 CSPFT Register List (Continued)

Name	Description
CSPFT_PID3	Peripheral ID3 Register
CSPFT_PID4	Peripheral ID4 Register
CSPFT_STAT	Status Register
CSPFT_SYNCFR	Synchronization Frequency Register
CSPFT_TECTL	TraceEnable Control Register
CSPFT_TEEVENT	TraceEnable Event Register
CSPFT_TRACEIDR	CoreSight Trace ID Register
CSPFT_TRIGGER	Trigger Event Register
CSPFT_TSSCTL	TraceEnable Start/Stop Control Register

ADSP-2159x_SC591_SC592_SC594 TAPC Register List

The Test Access Port Controller (TAPC) provides access to debug features. A set of registers governs TAPC operations. For more information on TAPC functionality, see the TAPC register descriptions.

Table 49-2: ADSP-2159x_SC591_SC592_SC594 TAPC Register List

Name	Description
TAPC_DBGCTL	Debug Control Register
TAPC_IDCODE	IDCODE Register
TAPC_SDBGKEY0	Secure Debug Key 0 Register
TAPC_SDBGKEY1	Secure Debug Key 1 Register
TAPC_SDBGKEY2	Secure Debug Key 2 Register
TAPC_SDBGKEY3	Secure Debug Key 3 Register
TAPC_SDBGKEY_CTL	Secure Debug Key Control Register
TAPC_SDBGKEY_STAT	Secure Debug Key Status Register
TAPC_USERCODE	USERCODE Register

DBG Block Diagram

The block diagram is shown below.

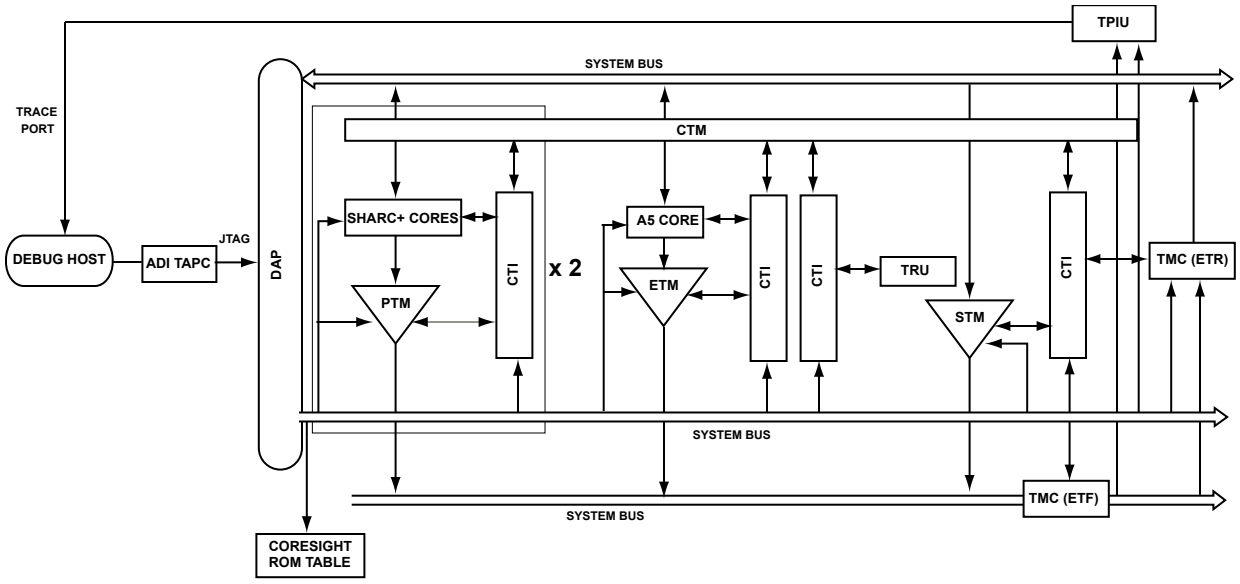

Figure 49-1: ADSP-SC58x Block Diagram

DBG Definitions

The following terms are useful when working with the debug features of the processor and programming tools.

Test Access Port Controller (TAPC)

Provides IDCODE and SDBGKEY features.

Debug Access Port (DAP)

Core Sight Interface providing a single port for two debug options: JTAG-DP (JTAG Debug Port), SW-DP (Serial Wire Debug Port)

Embedded Trace Macrocell (ETM)

Provides Arm Core Trace.

Program Trace Macrocell (PTM)

Provides DSP (SHARC +) Core Trace.

Standard Trace Macrocell (STM)

Provides capability to trace up to 32 hardware events and supports 32 software stimulus for data transfer between the user and emulator.

Embedded Cross Trigger (ECT)

The ECTs are responsible managing events and triggers as follows.

- CTI (Cross Trigger Interface) is a CoreSight component for enabling cross triggering of events across a system. From the view of the ECT, it is responsible for combining and mapping trigger requests.
- CTM (Cross Trigger Matrix) is a CoreSight component for connecting multiple CTIs. From the view of the ECT, it is responsible for connecting CTIs and distribution of events.

NOTE: An embedded cross trigger is not the same as the requester and completer trigger in the trigger routing unit.

Trace Capture Devices

The trace capture devices capture and format the trace data. There are two trace capture devices in the system:

- ETF - Embedded Trace FIFO - Provides a buffer for burst trace data.
- ETR - Embedded Trace Router - Provides interface for trace data to be stored in system memories.

Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the on-chip trace data, with separate IDs, to a data stream. It encapsulates IDs, when required, that the Trace Port Analyzer (TPA) captures.

Serial Wire Output (SWO)

SWO is a trace data drain that acts as a bridge between the on-chip trace data and a data stream that the Trace Port Analyzer (TPA) captures.

Test Access Port Controller (TAPC)

TAPC is an independent component daisy-chained to the DAP in the JTAG scan path. The TAPC component provides the product IDCODE (Chip ID) and a security feature.

The TAPC component provides security features to the chip using a debug key match features. This feature permits only those components which have the SDBGKEY to connect and debug the chip. Initially, a 128-bits user key is programmed in the SDBGKEY registers (`TAPC_SDBGKEY0`, `TAPC_SDBGKEY1`, `TAPC_SDBGKEY2`, `TAPC_SDBGKEY3`) in TAPC by a secure requester. The `TAPC_SDBGKEY_CTL.VALID` bit is set.

Then, a user key is entered through the emulator for a match to the initially programmed-entered user key. On a successful match, the chip connects to the emulator. It can be debugged on a failed user key match. Further attempts at keys matching are disabled. JTAG reset or system reset is required to reenable the user key match logic.

Embedded Trace Macrocell (ETM)

ETM is the standard trace support provided for the Arm processor. For details of programming and functionality, refer to the Arm documentation.

Debug Access Ports

The DAP provides access to all debug and trace capabilities through a single external interface, a JTAG Debug Port (JTAG-DP). The JTAG-DP is based on the IEEE 1149.1 Test Access Port (TAP) and Boundary Scan Architecture. DAP has some additions to support BSCA and IDCODE features that Core Sight DAP does not support.

Trace Unit

The trace module provides instruction, data tracing, and system activity tracing for the processor. The program trace module on the processor is similar to the embedded trace macrocell module provided by the Arm processor. System trace is provided using the system trace macrocell as part of the CoreSight debug and trace interface. The trace module uses an interface based on the AMBA Trace Bus (ATB) standard to output its trace data. The trace data can be either exported to an off-chip trace port analyzer or captured on an on-chip buffer. The PFT and STM modules capture information on the processor both before and after a specific event. The modules add no burden to the processor performance when it runs at full speed.

- Programmable Flow Trace (CSPFT)
- System Trace Module (STM)
- Embedded Trace Macrocell (ETM)

Programmable Flow Trace (CSPFT)

When tracing processor execution, trace information can be generated for every instruction the processor executes. This information would be easy to interpret, but would require a prohibitively high trace bandwidth to get the trace data off the chip. With program flow tracing, only branch points are traced. The debugger uses the source code to infer the rest of the executed code.

Certain instructions in the program and events are identified as waypoints. A waypoint is a point where instruction execution involves a change of program flow. The CSPFT only traces those waypoints. These waypoints are:

- All indirect branches
- All direct branches
- Exceptions or interrupts
- Emulator debug entry and exit

When a waypoint occurs, trace data is generated to describe it. From this data and the source code, a trace decompressor can determine what instructions were executed and recreate the instruction flow. To allow the decompressor to calculate where it is in the source code, conditional instructions are marked as waypoints, regardless of whether they pass or fail their condition test. Events like interrupts or debug entry and exit can be promoted from non-waypoint instructions to waypoints to trace the interrupted program flow.

Tracing a waypoint implies the execution of all instructions from the target address of the previous waypoint up to the current waypoint. Non-waypoint instructions are not explicitly traced but the debugger must infer them using the source code. The concept of an instruction block is used throughout this manual and refers to the contiguous block of instructions between two waypoints.

The programming model and function is a subset of the PTM (Programmable Trace Module) of Arm.

System Trace Module (STM)

The STM is a trace source that is integrated into a CoreSight system, and is designed primarily for high-bandwidth trace of instrumentation embedded into software. The STM enables tracing of system activity from various sources:

- Instrumented software, using memory-mapped stimulus ports
- Hardware events

The STM supports the following features:

- Multiple software requesters writing software instrumentation independently. Each requester can use multiple stimulus ports.
- Time stamping of the system activity. The time stamp is a global time stamp which can be shared with other trace sources in the system to enable correlation of activity from multiple trace sources.
- Indication that specific events have occurred, such as a particular hardware event or a piece of software instrumentation. These events are known as triggers and can be indicated in the trace stream, or through signals to other system components.

Thirty-two hardware event resources are connected as output from the TRU which allows monitoring all of the hardware events that can generate a trigger.

Embedded Cross Trigger (ECT)

ECT provides an interface to the CoreSight debug system enabling the subsystems to interact (cross trigger) with each other. ECT provides a mechanism to forward debug events from one connected subsystem to another connected subsystem. The different subsystems connected to the ECT depend on the processor design. For example, in a multiprocessor system, the interface can be connected to each of the cores and one to the trace subsystem. For a uniprocessor system, the interface can include just the core and trace subsystem connection.

- CTI cross trigger interface. A CoreSight component for enabling cross triggering of events across a system.
- CTM cross trigger matrix. A CoreSight component for connecting multiple cross trigger interfaces.

The main function of the ECT (CTI and CTM) is to pass debug events from one connected subsystem to another connected subsystem.

For example, the ECT can communicate debug state information from the core to trace subsystem for a single processor system or to another core in a multiprocessor-based system. Program execution on both the subsystem can be stopped at the same time.

The ***Trigger Flow*** figure shows a simple debug trigger flow sequence. On each CTI, there are four channel, eight input, and eight output debug triggers. All the eight inputs and outputs can be mapped to a single channel or different channels based on the debug trigger to channel mapping. When a trigger input occurs, it creates a channel event. The channel event causes all the output debug triggers to be triggered. The embedded cross trigger depends on the debug trigger it connects to.

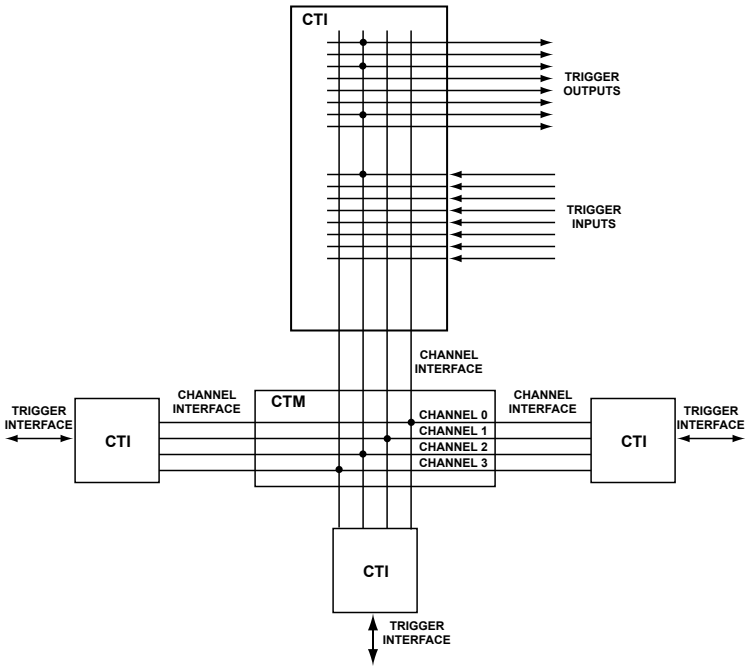

Figure 49-2: Trigger Flow

Refer to the ***ECT Integration*** figure. There are 5 CTIs in the system that connect to the core, trace, and system module, respectively. The CTIs all interconnect through the CTM. This configuration allows the core to trigger debug events on the trace, on the system and on the core itself. CTI0 handles all the ETM and core0 debug triggers. CTI1 handles all the PFT and core1 debug triggers. CTI2 handles all the PFT and core2 debug triggers. CTI3 handles all the system debug triggers. CTI4 handles all the trace components debug triggers.

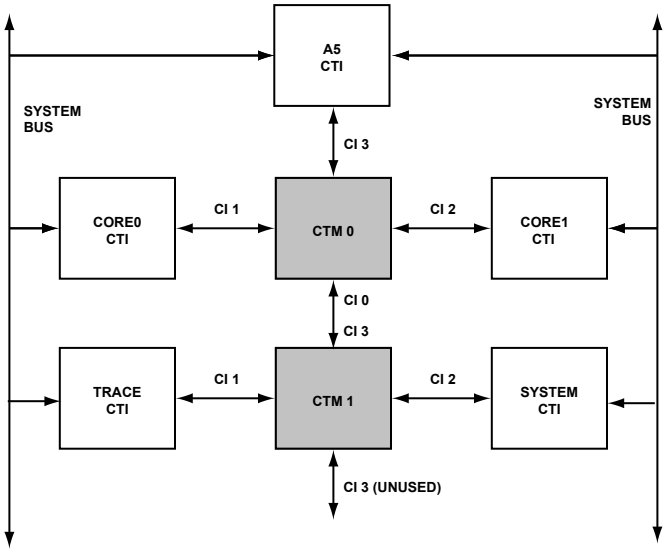

Figure 49-3: ECT Integration

CTI Debug Trigger Tables

The ***System CTI Trigger Connection*** tables show the debug trigger that connects to each CTI.

Table 49-3: System CTI Trigger Connection

Table 49-7: Trigger Descriptions

Signal Name	Description
STM ASYNCOUT	Alignment synchronization output. This signal is asserted for one clock cycle when an ASYNC-VERSION-FREQ sequence is completely output on the ATB, and can be used for cross-triggering.
STM TRIGOUTHETE	Trigger output. This signal is asserted for one clock cycle when a trigger event is detected on match using STMHETER.
STM TRIGOUTSW	Trigger output. This signal is asserted for one clock cycle when a trigger event is generated on writes to a TRIG location in the extended stimulus port registers.
STM TRIGOUTSPTE	Trigger output. This signal is asserted for one clock cycle when a trigger event is detected on match using STMSPTER.

Table 49-7: Trigger Descriptions (Continued)

Signal Name	Description
ETR / ETF FULL	This output indicates the value of the full bit in the ETR/ETF status register. A full bit indicates the amount of data in ETF/ETR. An output signal indicating when the circular buffer or FIFO is full, or within a programmable amount of being full.
ETR / ETF ACQCOMP	This output indicates the value of the FtEmpty bit in the ETR/ETF status register. The bit it is set when trace capture has stopped. An output signal indicating when trace capture has stopped, usually following a trigger condition.
ETR/ETF/ TPIU TRIGIN	This input can cause a trigger event (Start /Stop Trigger). An input signal indicating when a trigger condition has occurred.
ETR/ETF /TPIU FLUSHIN	This input can cause a Trace flush. An input signal indicating a flush request
PTM/ETM TRIGGER	Trigger Input. Trigger event specifies the conditions that must be met to generate a trigger.
PTM/ETM EXTOUT[3:0]	PTM Output.
PTM/ETM EXTIN[3:0]	PTM Input
SEC	CTI Interrupt
DBGRESTART	This is an output from the CTI to a processor core or to system to return from debug mode.
DBGTRIGGER	This is a processor core output signal indicating that the core has moved to debug mode. If the CTIs are setup for synchronous halt, it will generate EDBGRQ to everyone else.
EDBGRQ	This is an output from CTI and an input (as debug halt) to a processor core and to the system in general. It can assert as a result of another core going to emulation space (DBGTRIGGER) or by setting the corresponding bit in the CTI.
SYS_DBGRESTART	This is an output from the CTI to system to return from debug mode.
To TRU	TRU Requester Event
From TRU	TRU Completer Event

ADSP-2159x_SC591_SC592_SC594 CSPFT Register Descriptions

Program Flow Trace (CSPFT) contains the following registers.

Table 49-8: ADSP-2159x_SC591_SC592_SC594 CSPFT Register List

Name	Description
CSPFT_ACTR[n]	Address Comparator Access Type Register
CSPFT_ACVR[n]	Address Comparator Value Register
CSPFT_AUTHSTATUS	Authentication Status Register

Table 49-8: ADSP-2159x_SC591_SC592_SC594 CSPFT Register List (Continued)

Name	Description
CSPFT_CCER	Configuration Code Extension Register
CSPFT_CID0	Component ID0 Register
CSPFT_CID1	Component ID1 Register
CSPFT_CID2	Component ID2 Register
CSPFT_CID3	Component ID3 Register
CSPFT_CIDCMR	Context ID Comparator Mask Register
CSPFT_CIDCVR[n]	Context ID Comparator Value
CSPFT_CLAIMCLR	Claim Tag Clear Register
CSPFT_CLAIMSET	Claim Tag Set Register
CSPFT_CNTENR[n]	Counter Enable Event Register
CSPFT_CNTRLDEVR[n]	Counter Reload Event Register
CSPFT_CNTRLDVR[n]	Counter Reload Value Register
CSPFT_CNTVR[n]	Counter Value Register
CSPFT_CTL	Main Control Register
CSPFT_DEVTYPE	Device Type Identifier Register
CSPFT_EXTOUTEVR[n]	External Output Event Register
CSPFT_HWFEAT	Hardware Feature Register
CSPFT_LAR	Lock Access Register
CSPFT_LSR	Lock Status Register
CSPFT_PID0	Peripheral ID0 Register
CSPFT_PID1	Peripheral ID1 Register
CSPFT_PID2	Peripheral ID2 Register
CSPFT_PID3	Peripheral ID3 Register
CSPFT_PID4	Peripheral ID4 Register
CSPFT_STAT	Status Register
CSPFT_SYNCFR	Synchronization Frequency Register
CSPFT_TECTL	TraceEnable Control Register
CSPFT_TEEVENT	TraceEnable Event Register
CSPFT_TRACEIDR	CoreSight Trace ID Register
CSPFT_TRIGGER	Trigger Event Register
CSPFT_TSSCTL	TraceEnable Start/Stop Control Register

Address Comparator Access Type Register

The `CSPFT_ACTR[n]` register specifies whether the context ID needs to match.

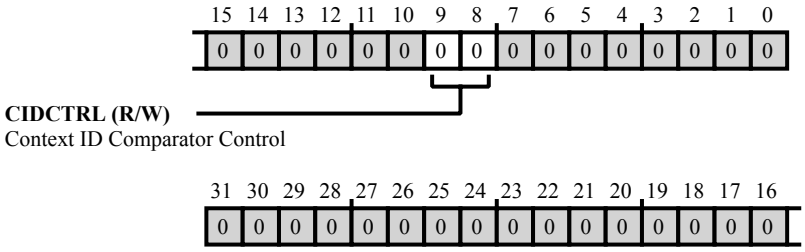

Figure 49-4: CSPFT_ACTR[n] Register Diagram

Table 49-9: CSPFT_ACTR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	CIDCTRL	Context ID Comparator Control. The `CSPFT_ACTR[n].CIDCTRL` contains the ID comparator control value.	
		0	Ignore Context ID
		1	Match if Context ID Comparator 0 Matches
		2	Match if Context ID Comparator 1 Matches
		3	Match if Context ID Comparator 2 Matches

Address Comparator Value Register

The CSPFT_ACVR[n] register holds an address for comparison.

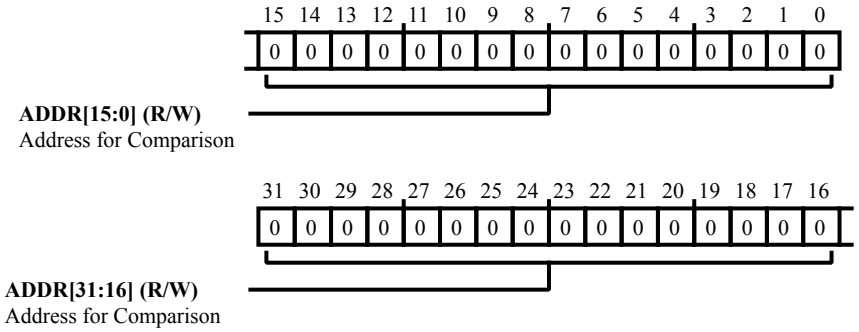

Figure 49-5: CSPFT_ACVR[n] Register Diagram

Table 49-10: CSPFT_ACVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Address for Comparison. The CSPFT_ACVR[n].ADDR bit field contains the address used for comparison.

Authentication Status Register

The CSPFT_AUTHSTATUS register reports the level of tracing currently permitted based on the DBGEN signal.

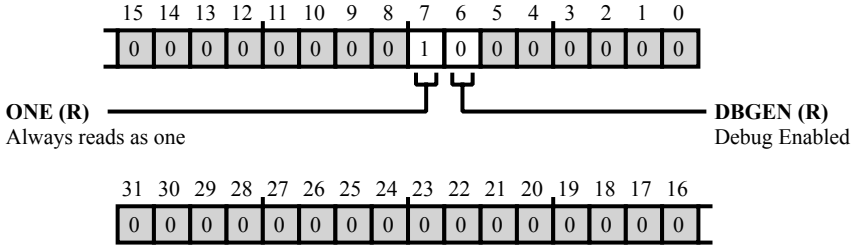

Figure 49-6: CSPFT_AUTHSTATUS Register Diagram

Table 49-11: CSPFT_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ONE	Always reads as one.
6 (R/NW)	DBGEN	Debug Enabled. The CSPFT_AUTHSTATUS.DBGEN bit indicates that invasive debug is enabled. Normally, NIDEN is used in conjunction with a signal that enables invasive debug, DBGEN. Non-invasive debug is disabled only if both NIDEN and DBGEN signals are LOW. In a PTM, typically these signals are ORed together and the result is used to determine whether non-invasive debug is enabled.

Configuration Code Extension Register

The CSPFT_CCER register holds extra feature information. (See CSPFT_HWFEAT.)

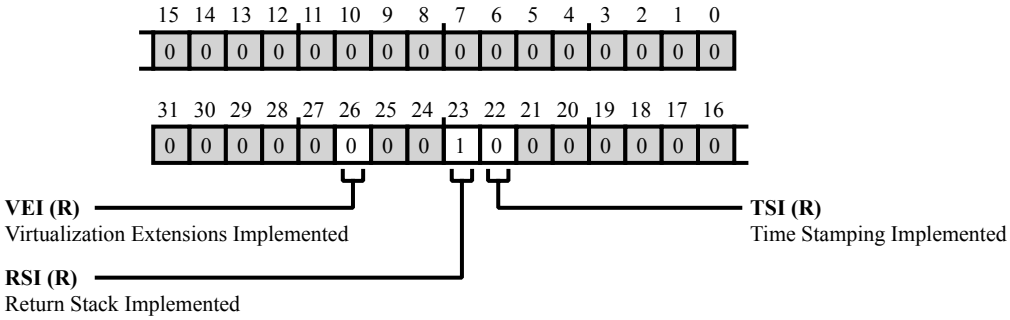

Figure 49-7: CSPFT_CCER Register Diagram

Table 49-12: CSPFT_CCER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	VEI	Virtualization Extensions Implemented. The CSPFT_CCER.VEI bit indicates if the virtualization extensions are implemented	
		0	Not Implemented
		1	Implemented
23 (R/NW)	RSI	Return Stack Implemented. The CSPFT_CCER.RSI bit indicates if a return stack is implemented.	
		0	Not Implemented
		1	Implemented
22 (R/NW)	TSI	Time Stamping Implemented. The CSPFT_CCER.TSI bit indicates if time stamping is implemented.	
		0	Disabled
		1	Enabled

Component ID0 Register

The CSPFT_CID0 register holds sections of the CoreSight Component ID for CSPFT.

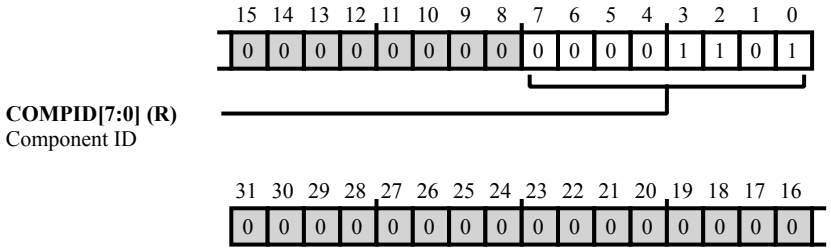

Figure 49-8: CSPFT_CID0 Register Diagram

Table 49-13: CSPFT_CID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	COMPID	Component ID. The CSPFT_CID0.COMPID bit field identifies this component as a CoreSight component.

Component ID1 Register

The `CSPFT_CID1` register holds sections of the CoreSight Component ID for CSPFT.

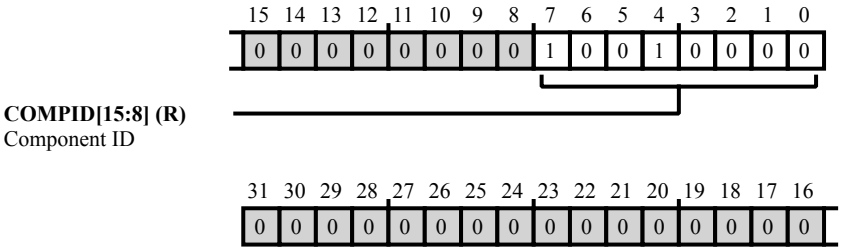

Figure 49-9: CSPFT_CID1 Register Diagram

Table 49-14: CSPFT_CID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	COMPID	Component ID. The `CSPFT_CID1.COMPID` bit field identifies this component as a CoreSight component.

Component ID2 Register

The CSPFT_CID2 register holds sections of the CoreSight Component ID for CSPFT.

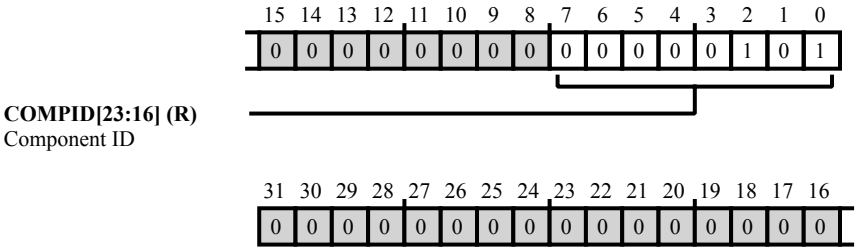

Figure 49-10: CSPFT_CID2 Register Diagram

Table 49-15: CSPFT_CID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	COMPID	Component ID. The CSPFT_CID2.COMPID bit field identifies this component as a CoreSight component.

Component ID3 Register

The CSPFT_CID3 register holds sections of the CoreSight Component ID for CSPFT.

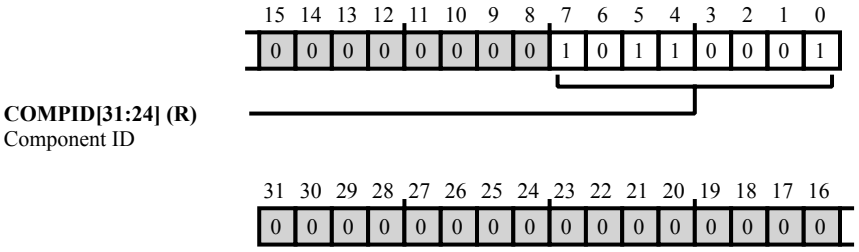

Figure 49-11: CSPFT_CID3 Register Diagram

Table 49-16: CSPFT_CID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	COMPID	Component ID. The CSPFT_CID3.COMPID bit field identifies this component as a CoreSight component.

Context ID Comparator Mask Register

The CSPFT_CIDCMR register holds a 32-bit mask for use for all context ID comparisons.

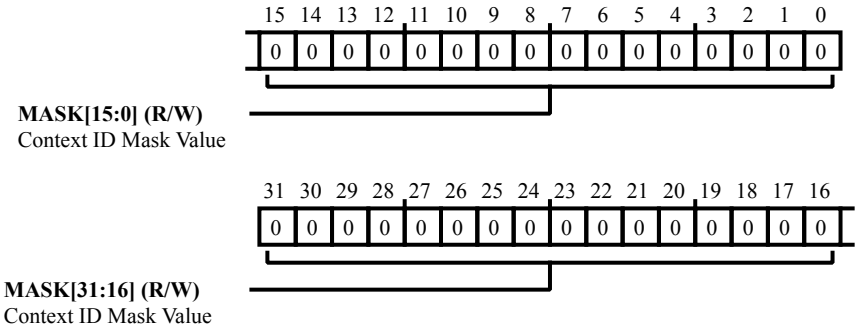

Figure 49-12: CSPFT_CIDCMR Register Diagram

Table 49-17: CSPFT_CIDCMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MASK	Context ID Mask Value. The CSPFT_CIDCMR.MASK bit field holds a 32-bit mask for use in all context ID comparisons.

Context ID Comparator Value

The CSPFT_CIDCVR[n] register holds a context ID value for comparison.

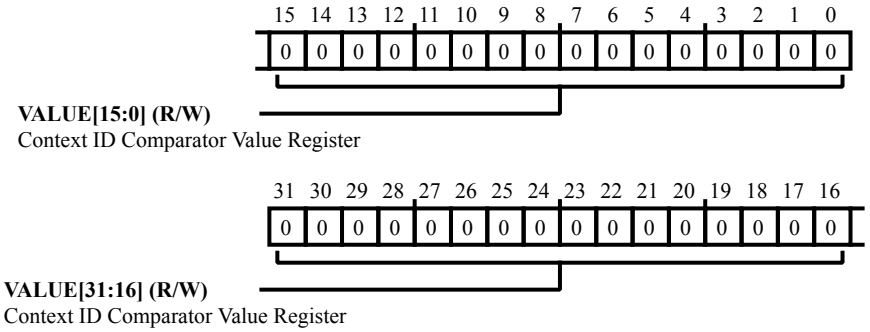

Figure 49-13: CSPFT_CIDCVR[n] Register Diagram

Table 49-18: CSPFT_CIDCVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Context ID Comparator Value Register. The CSPFT_CIDCVR[n].VALUE bit field holds a context ID value for comparison.

Claim Tag Clear Register

The CSPFT_CLAIMCLR register is used to clear bits in the claim tag or get the current value of the claim tag.

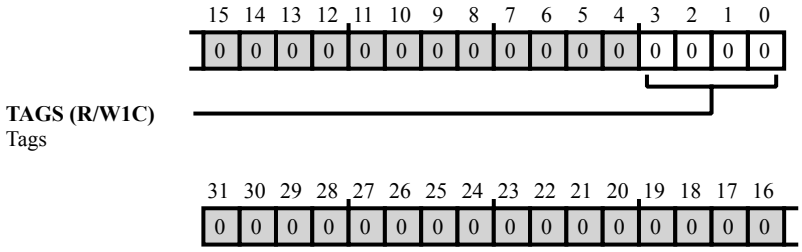

Figure 49-14: CSPFT_CLAIMCLR Register Diagram

Table 49-19: CSPFT_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W1C)	TAGS	Tags. A read of the CSPFT_CLAIMCLR.TAGS bit field returns the current value, a write clears bits.

Claim Tag Set Register

The CSPFT_CLAIMSET register is used to set bits in the claim tag and find the number of bits supported by the claim tag.

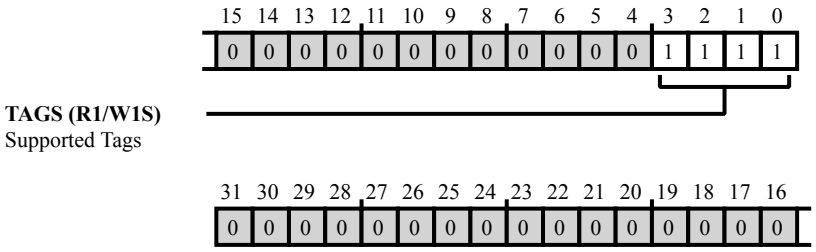

Figure 49-15: CSPFT_CLAIMSET Register Diagram

Table 49-20: CSPFT_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R1/W1S)	TAGS	Supported Tags. The CSPFT_CLAIMSET.TAGS bit field sets bits in the claim tag and finds the number of bits supported by the claim tag.

Counter Enable Event Register

The CSPFT_CNTENR[n] register describes the event that enables the corresponding counter.

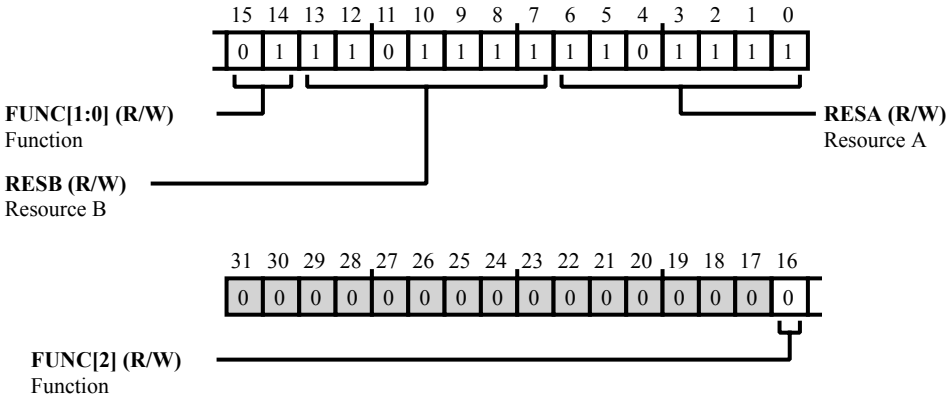

Figure 49-16: CSPFT_CNTENR[n] Register Diagram

Table 49-21: CSPFT_CNTENR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	FUNC	Function. The CSPFT_CNTENR[n].FUNC bit field specifies the logical operation that combines the two resources that define the event.	
		0	A
		1	NOT(A)
		2	A AND B
		3	NOT(A) AND B
		4	NOT(A) AND NOT(B)
		5	A OR B
		6	NOT(A) OR B
		7	NOT(A) OR NOT(B)
13:7 (R/W)	RESB	Resource B. The CSPFT_CNTENR[n].RESB bit field specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_CNTENR[n].FUNC field (See CSPFT_CNTENR[n].RESA for list of possible values).	
6:0 (R/W)	RESA	Resource A. The CSPFT_CNTENR[n].RESA bit field specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_CNTENR[n].FUNC field.	

Table 49-21: CSPFT_CNTENR[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Single Addr Comparator 0
		1	Single Addr Comparator 1
		2	Single Addr Comparator 2

		110	Trace Prohibited
		111	Always TRUE

Counter Reload Event Register

The CSPFT_CNTRLDEVR[n] register defines the event that causes the corresponding counter to be reloaded with the value held in the corresponding CSPFT_CNTRLDVR[n] register.

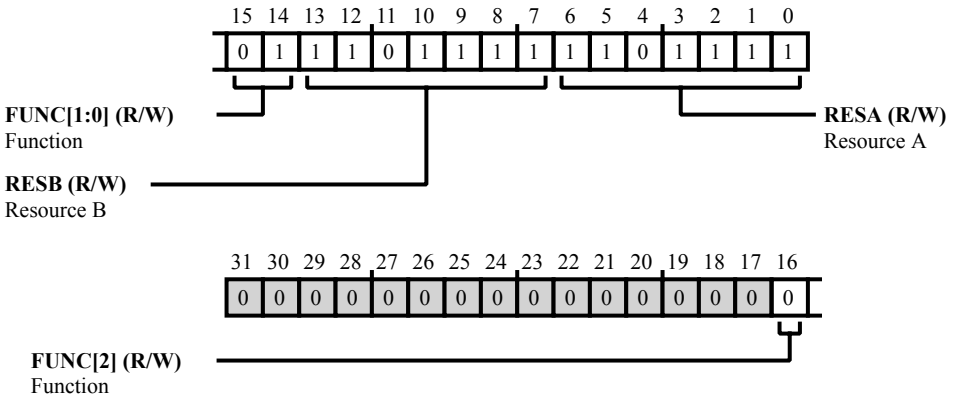

Figure 49-17: CSPFT_CNTRLDEVR[n] Register Diagram

Table 49-22: CSPFT_CNTRLDEVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	FUNC	Function. The CSPFT_CNTRLDEVR[n].FUNC bit field specifies the logical operation that combines the two resources that define the event.

		110	Trace prohibited
		111	Always TRUE

Counter Reload Value Register

The CSPFT_CNTRLDVR[n] register specifies the starting value of the corresponding counter.

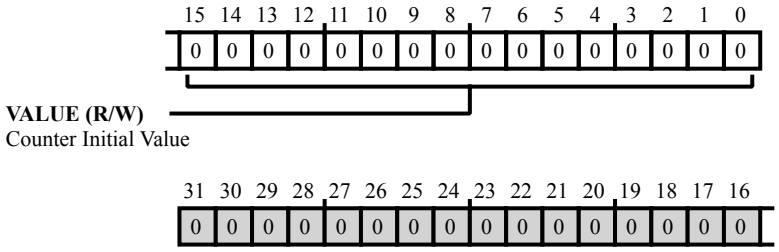

Figure 49-18: CSPFT_CNTRLDVR[n] Register Diagram

Table 49-23: CSPFT_CNTRLDVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Counter Initial Value. The CSPFT_CNTRLDVR[n].VALUE bit field specifies the starting value of the corresponding counter.

Counter Value Register

The CSPFT_CNTVR[n] register holds the current value of the corresponding counter.

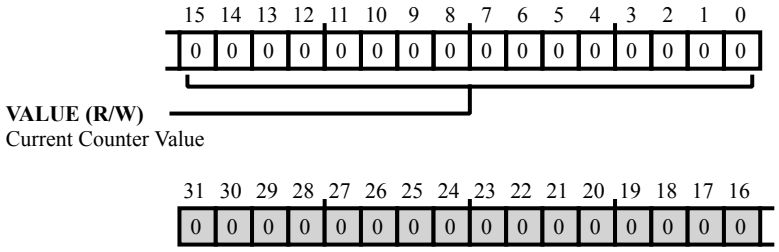

Figure 49-19: CSPFT_CNTVR[n] Register Diagram

Table 49-24: CSPFT_CNTVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Current Counter Value. The CSPFT_CNTVR[n].VALUE bit field specifies the current value of the corresponding counter.

Main Control Register

The CSPFT_CTL register controls general operation of the PTM, such as whether tracing is enabled.

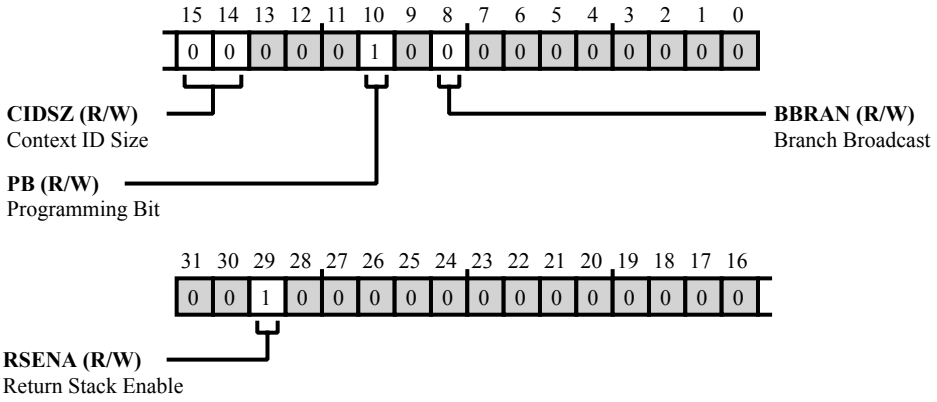

Figure 49-20: CSPFT_CTL Register Diagram

Table 49-25: CSPFT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	RSENA	Return Stack Enable. When the CSPFT_CTL.RSENA bit is set, the first indirect branch back to an address generates a branch without exception packet, and subsequent branches back to the same address generate E Atoms. This compresses inner loops of HW loops and code that indirectly branches back.	
15:14 (R/W)	CIDSZ	Context ID Size. The CSPFT_CTL.CIDSZ bit field specifies the byte size to trace. Only the bytes specified are traced, even if the new Context ID value is larger than this.	
		0	No Context ID Tracing
		1	One byte Traced
		2	Two Bytes Traced
		3	Three Bytes Traced

Table 49-25: CSPFT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	PB	Programming Bit. To program the CSPFT, use the following procedure. 1. Set the `CSPFT_CTL.PB` bit to disable all trace functionality. 2. Poll the `CSPFT_STAT.PB` bit waiting for it to be 1 (FIFO drained, trace halted). 3. Program the trace registers, counter and other registers, as required. 4. Set this bit to 0. 5. Poll the `CSPFT_STAT.PB` bit until it reads 0 (trace status reset, trace restarted). When the `CSPFT_CTL.PB` bit is set, the FIFO is drained and no more trace is produced. All counters are held in their present state and the external outputs are forced low. After the FIFO is drained, the `CSPFT_STAT.PB` is set to reflect that the part is ready to program. When this bit is cleared, the trace status is cleared and trace is restarted.	
		0	Trace Enabled
		1	Trace Disabled
8 (R/W)	BBRAN	Branch Broadcast. Set the `CSPFT_CTL.BBRAN` bit to 1 to enable branch broadcasting. Branch broadcasting traces the address of direct branch instructions rather than producing E atoms.	

Device Type Identifier Register

The CSPFT_DEVTYPE register is read-only. It provides a debugger with information about the component when the part number field is not recognized. The debugger can then report this information.

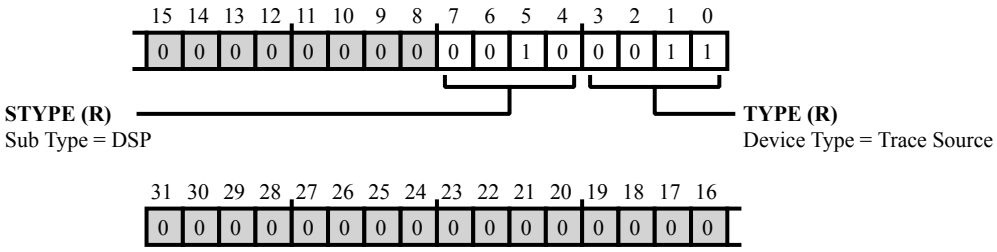

Figure 49-21: CSPFT_DEVTYPE Register Diagram

Table 49-26: CSPFT_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	STYPE	Sub Type = DSP.
3:0 (R/NW)	TYPE	Device Type = Trace Source.

External Output Event Register

The CSPFT_EXTOUTEVR[n] register defines the event that controls the corresponding EXTOUT external output signal.

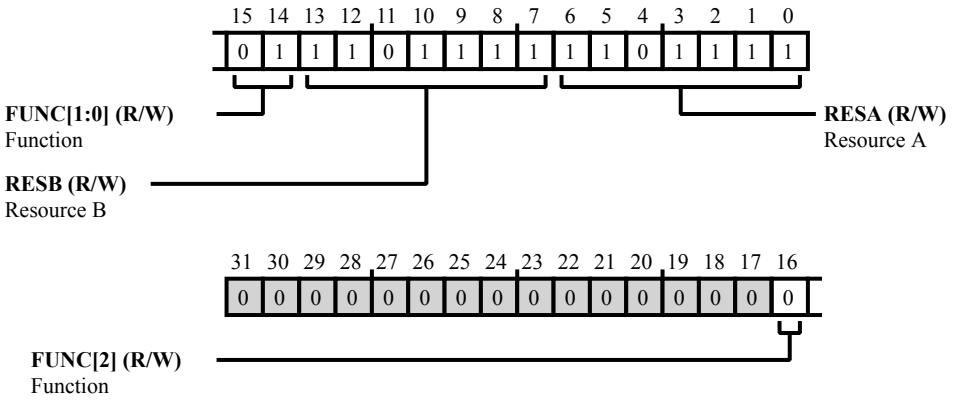

Figure 49-22: CSPFT_EXTOUTEVR[n] Register Diagram

Table 49-27: CSPFT_EXTOUTEVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	FUNC	Function. The CSPFT_EXTOUTEVR[n].FUNC bit field specifies the logical operation that combines the two resources that define the event.	
		0	A
		1	NOT(A)
		2	A AND B
		3	NOT(A) AND B
		4	NOT(A) AND NOT(B)
		5	A OR B
		6	NOT(A) OR B
		7	NOT(A) OR NOT(B)
13:7 (R/W)	RESB	Resource B. The CSPFT_EXTOUTEVR[n].RESB bit field specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_EXTOUTEVR[n].FUNC field (See CSPFT_EXTOUTEVR[n].RESA for list of possible values).	

Table 49-27: CSPFT_EXTOUTEVR[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:0 (R/W)	RESA	Resource A. The `CSPFT_EXTOUTEVR[n].RESA` bit field specifies one of the two resources that can be combined by the logical operation specified in the `CSPFT_EXTOUTEVR[n].FUNC` field.	
		0	Single Addr Comparator 0
		1	Single Addr Comparator 1
		2	Single Addr Comparator 2
		3	Single Addr Comparator 3
		4	Single Addr Comparator 4
		5	Single Addr Comparator 5
		6	Single Addr Comparator 6
		7	Single Addr Comparator 7
		8	Single Addr Comparator 8
		9	Single Addr Comparator 9
		10	Single Addr Comparator 10
		11	Single Addr Comparator 11
		12	Single Addr Comparator 12
		13	Single Addr Comparator 13
		14	Single Addr Comparator 14
		15	Single Addr Comparator 15
		16	Addr Range Comparator 0
		17	Addr Range Comparator 1
		18	Addr Range Comparator 2
		19	Addr Range Comparator 3
		20	Addr Range Comparator 4
		21	Addr Range Comparator 5
		22	Addr Range Comparator 6
		23	Addr Range Comparator 7
		64	Counter 0 at Zero
		65	Counter 1 at Zero
		66	Counter 2 at Zero

Table 49-27: CSPFT_EXTOUTEVR[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		67	Counter 3 at Zero
		88	Context ID Comparator 0
		89	Context ID Comparator 1
		90	Context ID Comparator 2
		95	TraceEnable Start/Stop Resource 0 or 1
		96	External Inputs 0
		97	External Inputs 1
		98	External Inputs 2
		99	External Inputs 3
		110	Trace Prohibited
		111	Always TRUE

Hardware Feature Register

The CSPFT_HWFEAT register enables software to read the implementation defined configuration of the PTM, giving the number of each type of hardware resource. Each field indicates the number of instances of a particular resource, zero indicates that there are no implemented resources of that type.

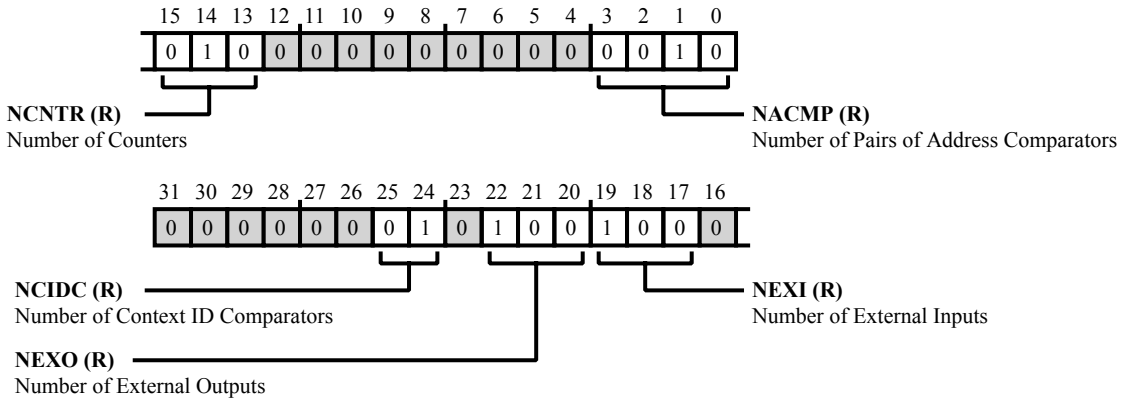

Figure 49-23: CSPFT_HWFEAT Register Diagram

Table 49-28: CSPFT_HWFEAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:24 (R/NW)	NCIDC	Number of Context ID Comparators. The CSPFT_HWFEAT.NCIDC bit field identifies the number of context ID comparators.
22:20 (R/NW)	NEXO	Number of External Outputs. The CSPFT_HWFEAT.NEXO bit field identifies the number of external outputs (up to four).
19:17 (R/NW)	NEXI	Number of External Inputs. The CSPFT_HWFEAT.NEXI bit field identifies the number of external inputs (up to four).
15:13 (R/NW)	NCNTR	Number of Counters. The CSPFT_HWFEAT.NCNTR bit field identifies the number of counters (up to four) that are configured using the counter registers.
3:0 (R/NW)	NACMP	Number of Pairs of Address Comparators. The CSPFT_HWFEAT.NACMP bit field identifies the number of pairs of address comparators as address range comparators (ARCs). In this case, two adjacent address comparators form the ARC, so you can use address comparators 1 and 2 to define the first ARC. An ARC matches when any instruction in the specified range is committed for execution, regardless of whether the instruction passes its condition code test.

Table 49-28: CSPFT_HWFEAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	No Address Comparators
		1	1 Pair of Address Comparators
		2	2 Pairs of Address Comparators
		3	3 Pairs of Address Comparators
		4	4 Pairs of Address Comparators
		5	5 Pairs of Address Comparators
		6	6 Pairs of Address Comparators
		7	7 Pairs of Address Comparators
		8	8 Pairs of Address Comparators

Lock Access Register

The CSPFT_LAR register is used to provide lock and unlock access to all other CSPFT registers.

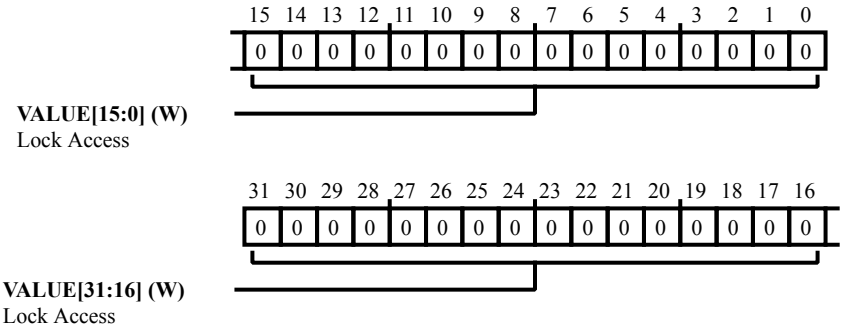

Figure 49-24: CSPFT_LAR Register Diagram

Table 49-29: CSPFT_LAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Lock Access. Write 0xC5ACCE55 to the CSPFT_LAR.VALUE bit field to unlock. Write any other value to lock.

Lock Status Register

The CSPFT_LSR register is used to detect if the lock registers are implemented and if they are currently locked.

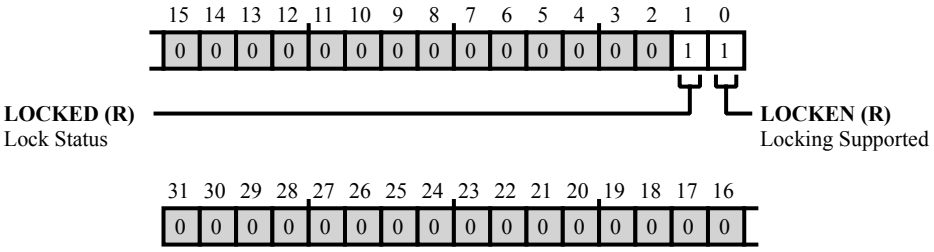

Figure 49-25: CSPFT_LSR Register Diagram

Table 49-30: CSPFT_LSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	LOCKED	Lock Status. The CSPFT_LSR.LOCKED bit indicates whether the PFT is locked.	
		0	Writes are permitted
		1	Locked. Writes are ignored
0 (R/NW)	LOCKEN	Locking Supported. The CSPFT_LSR.LOCKEN bit indicates whether the lock registers are implemented for this interface.	
		0	Locking is Not Required. This access is from an interface that ignores the lock registers.
		1	Locking is Required. This access is from an interface that requires the PFT to be unlocked.

Peripheral ID0 Register

The CSPFT_PID0 register holds peripheral identification information.

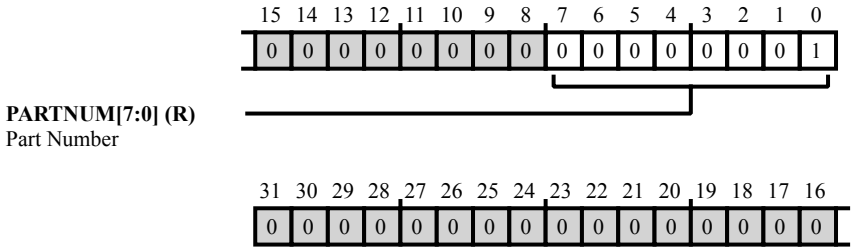

Figure 49-26: CSPFT_PID0 Register Diagram

Table 49-31: CSPFT_PID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PARTNUM	Part Number. The CSPFT_PID0.PARTNUM bit field holds the peripheral identification number.

Peripheral ID1 Register

The CSPFT_PID1 register holds peripheral identification information.

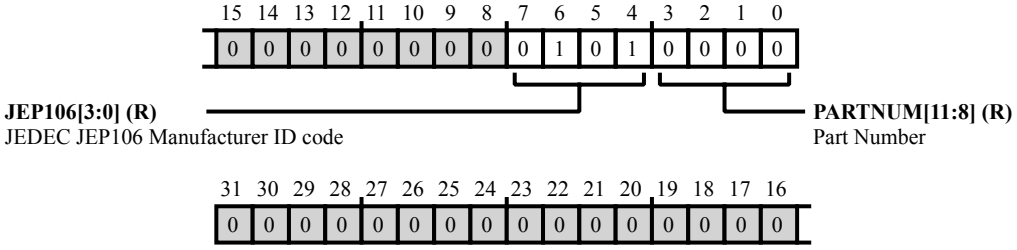

Figure 49-27: CSPFT_PID1 Register Diagram

Table 49-32: CSPFT_PID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	JEP106	JEDEC JEP106 Manufacturer ID code.
3:0 (R/NW)	PARTNUM	Part Number. The CSPFT_PID1.PARTNUM bit field holds the peripheral identification number.

Peripheral ID2 Register

The CSPFT_PID2 register holds peripheral identification information.

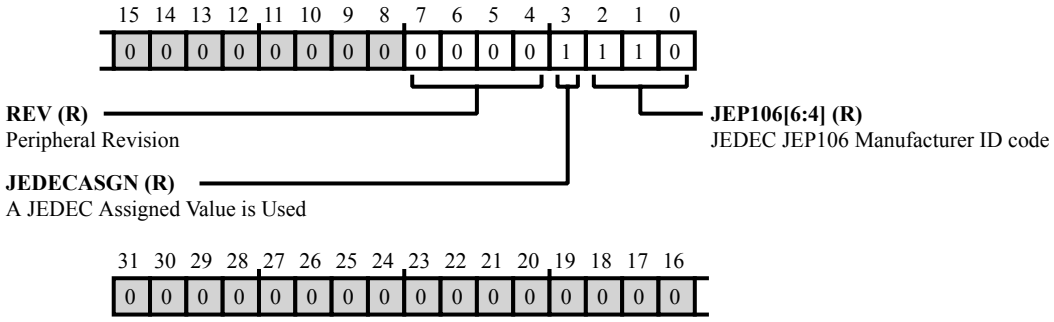

Figure 49-28: CSPFT_PID2 Register Diagram

Table 49-33: CSPFT_PID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	REV	Peripheral Revision.
3 (R/NW)	JEDECASGN	A JEDEC Assigned Value is Used. The CSPFT_PID2.JEDECASGN bit indicates that a JEDEC assigned value is used.
2:0 (R/NW)	JEP106	JEDEC JEP106 Manufacturer ID code.

Peripheral ID3 Register

The CSPFT_PID3 register holds peripheral identification information.

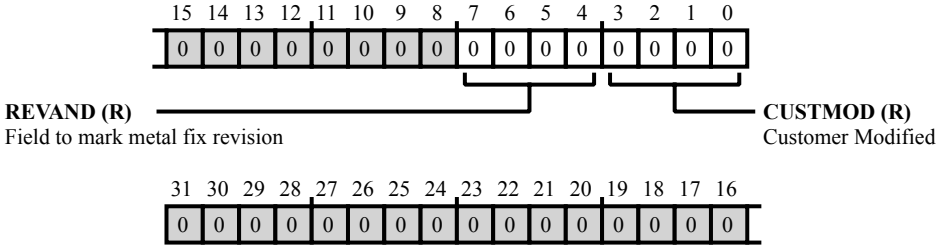

Figure 49-29: CSPFT_PID3 Register Diagram

Table 49-34: CSPFT_PID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	REVAND	Field to mark metal fix revision.
3:0 (R/NW)	CUSTMOD	Customer Modified.

Peripheral ID4 Register

The `CSPFT_PID4` register holds peripheral identification information.

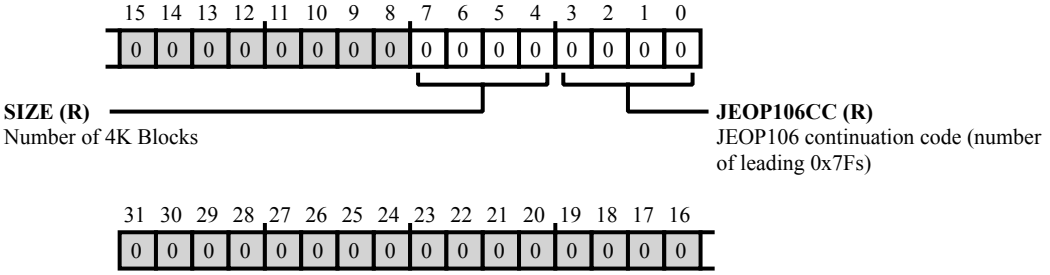

Figure 49-30: CSPFT_PID4 Register Diagram

Table 49-35: CSPFT_PID4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	SIZE	Number of 4K Blocks. The `CSPFT_PID4.SIZE` bit field contains the size of the component in 4K chunks minus 1 (for example 0=4K).
3:0 (R/NW)	JEOP106CC	JEOP106 continuation code (number of leading 0x7Fs).

Status Register

The CSPFT_STAT register provides information about the current status of the trace and trigger logic.

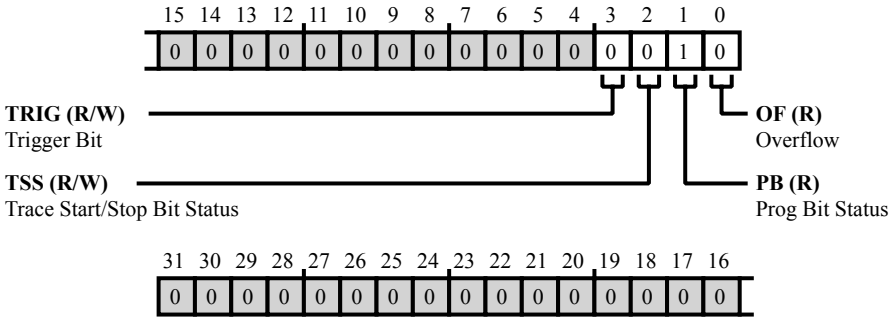

Figure 49-31: CSPFT_STAT Register Diagram

Table 49-36: CSPFT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TRIG	Trigger Bit. The CSPFT_STAT.TRIG bit is set when the trigger occurs, and prevents the trigger from being output until the CSPFT is next programmed. This bit is reset when the CSPFT_CTL.PB bit transitions from 1 to 0.
2 (R/W)	TSS	Trace Start/Stop Bit Status. The CSPFT_STAT.TSS bit holds the current status of the trace start/stop resource. If = 1, it indicates that a trace start address has been matched, without a corresponding trace stop address match. This bit =0 when trace is restarted (the CSPFT_CTL.PB bit transitions from 1 to 0).
1 (R/NW)	PB	Prog Bit Status. The CSPFT_STAT.PB bit indicates the current effective value of the CSPFT_CTL.PB bit. The program must wait for this bit to =1 before programming the CSPFT. (See the CSPFT_CTL.PB bit description).
0 (R/NW)	OF	Overflow. If the CSPFT_STAT.OF bit is =1, there is an overflow. This bit is cleared =0 when the trace is restarted (CSPFT_CTL.PB transitions from 1 to 0)

Synchronization Frequency Register

The CSPFT_SYNCFR register holds the trace synchronization frequency value.

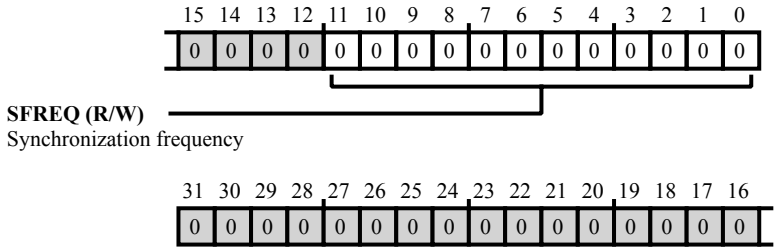

Figure 49-32: CSPFT_SYNCFR Register Diagram

Table 49-37: CSPFT_SYNCFR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	SFREQ	Synchronization frequency. The CSPFT_SYNCFR.SFREQ bit field is the number of 128-byte blocks of trace data after which you want to drop an address synchronization packet. If the circular buffer size is 16k, ensure that there are a few A-syncs in the buffer, so setting this to 16 means that every 2k there is an A-Sync packet.

TraceEnable Control Register

The CSPFT_TECTL register controls the start stop logic, whether resources specified are used for include or exclude, and specifies the address range comparators to use.

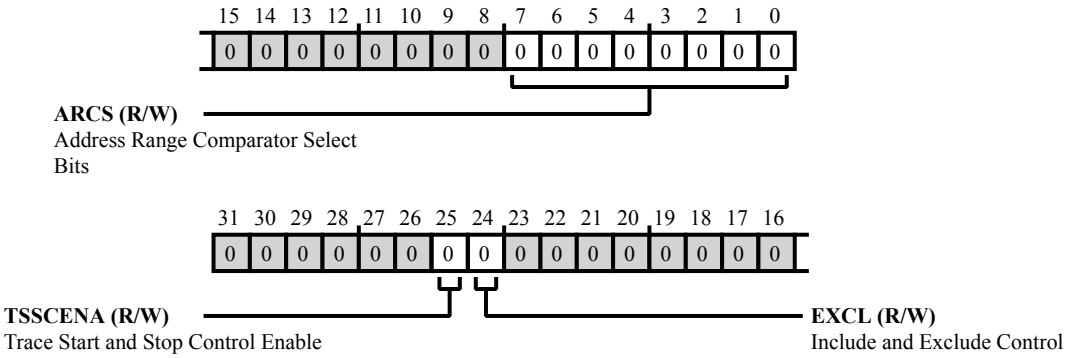

Figure 49-33: CSPFT_TECTL Register Diagram

Table 49-38: CSPFT_TECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	TSSCENA	Trace Start and Stop Control Enable.	
		0	Tracing is not affected by the trace start/stop logic
		1	Tracing is controlled by the trace on and off address comparators
24 (R/W)	EXCL	Include and Exclude Control.	
		0	Include. The specified address range comparators indicate the regions where tracing can occur. When outside the region trace is prevented.
		1	Exclude. The specified address range comparators indicate regions to be excluded from the trace. When outside the range tracing is enabled.
7:0 (R/W)	ARCS	Address Range Comparator Select Bits. When a bit in the CSPFT_TECTL.ARCS bit field is set to 1, it selects an address range comparator, for include/exclude control.	

TraceEnable Event Register

The CSPFT_TEEVENT register defines the TraceEnable enabling event.

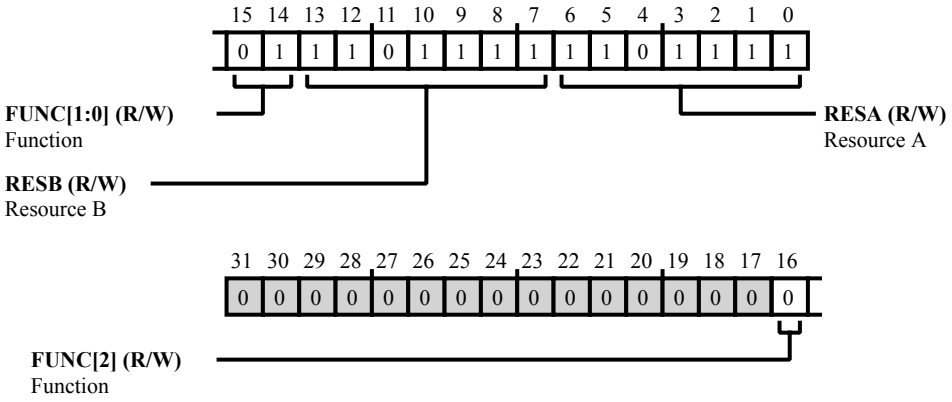

Figure 49-34: CSPFT_TEEVENT Register Diagram

Table 49-39: CSPFT_TEEVENT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	FUNC	Function. The CSPFT_TEEVENT.FUNC bit field specifies the logical operation that combines the two resources that define the event.	
		0	A
		1	NOT(A)
		2	A AND B
		3	NOT(A) AND B
		4	NOT(A) AND NOT(B)
		5	A OR B
		6	NOT(A) OR B
		7	NOT(A) OR NOT(B)
13:7 (R/W)	RESB	Resource B. The CSPFT_TEEVENT.RESB bit field specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_TEEVENT.FUNC field. (See CSPFT_TEEVENT.RESA for list of possible values).	
6:0 (R/W)	RESA	Resource A. The CSPFT_TEEVENT.RESA bit field specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_TEEVENT.FUNC field.	
		0	Single Addr Comparator 0

Table 49-39: CSPFT_TEEVENT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	Single Addr Comparator 1
		2	Single Addr Comparator 2
		3	Single Addr Comparator 3
		4	Single Addr Comparator 4
		5	Single Addr Comparator 5
		6	Single Addr Comparator 6

		22	Addr Range Comparator 6
		23	Addr Range Comparator 7
		64	Counter 0 at Zero
		65	Counter 1 at Zero
		66	Counter 2 at Zero
		67	Counter 3 at Zero
		88	Context ID Comparator 0
		89	Context ID Comparator 1
		90	Context ID Comparator 2

Table 49-39: CSPFT_TEEVENT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		95	TraceEnable Start/Stop Resource 0 or 1
		96	External Inputs 0
		97	External Inputs 1
		98	External Inputs 2
		99	External Inputs 3
		110	Trace Prohibited
		111	Always TRUE

CoreSight Trace ID Register

The CSPFT_TRACEIDR register defines the 7-bit trace ID, for output to the trace bus.

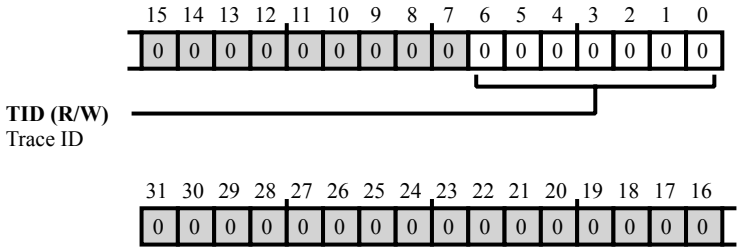

Figure 49-35: CSPFT_TRACEIDR Register Diagram

Table 49-40: CSPFT_TRACEIDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	TID	Trace ID. Defines the 7-bit trace ID, for output to the trace bus. Used in systems where multiple trace sources are present and tracing simultaneously. For example, when outputs trace onto the AMBA 3 Advanced Trace Bus, a unique ID is required for each trace source.

Trigger Event Register

The CSPFT_TRIGGER register defines the event that controls the trigger. This event creates the trigger output signal that is in the ATCLK domain.

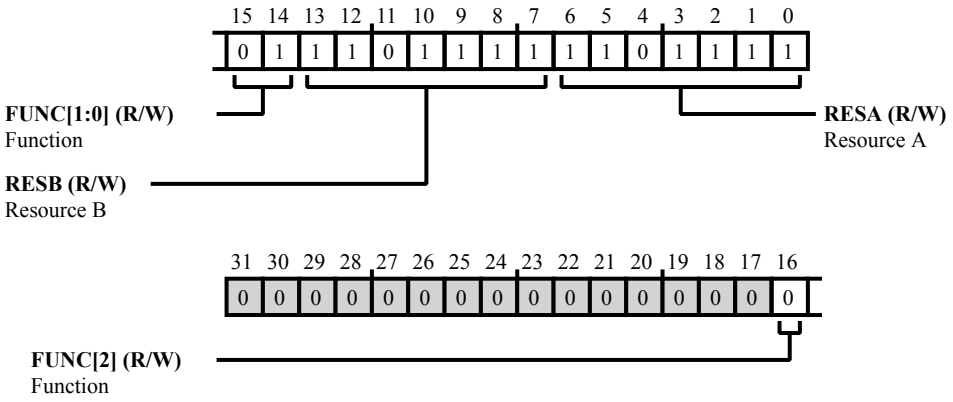

Figure 49-36: CSPFT_TRIGGER Register Diagram

Table 49-41: CSPFT_TRIGGER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	FUNC	Function. Specifies the logical operation that combines the two resources that define the event	
		0	A
		1	NOT(A)
		2	A AND B
		3	NOT(A) AND B
		4	NOT(A) AND NOT(B)
		5	A OR B
		6	NOT(A) OR B
		7	NOT(A) OR NOT(B)
13:7 (R/W)	RESB	Resource B. Specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_TRIGGER.FUNC field. (See CSPFT_TRIGGER.RESA for list of possible values.)	
6:0 (R/W)	RESA	Resource A. Specifies one of the two resources that can be combined by the logical operation specified in the CSPFT_TRIGGER.FUNC field	
		0	Single Addr Comparator 0

Table 49-41: CSPFT_TRIGGER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	Single Addr Comparator 1

		65	Counter 1 at Zero
		66	Counter 2 at Zero
		67	Counter 3 at Zero
		88	Context ID Comparator 0
		89	Context ID Comparator 1
		90	Context ID Comparator 2

Table 49-41: CSPFT_TRIGGER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		95	TraceEnable Start/Stop Resource 0 or 1
		96	External Inputs 0
		97	External Inputs 1
		98	External Inputs 2
		99	External Inputs 3
		110	Trace Prohibited
		111	Always TRUE

TraceEnable Start/Stop Control Register

The CSPFT_TSSCTL register specifies the single address comparators that hold the trace start and stop addresses.

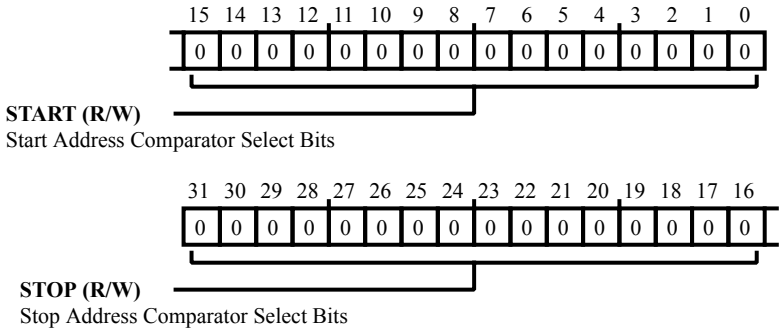

Figure 49-37: CSPFT_TSSCTL Register Diagram

Table 49-42: CSPFT_TSSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/W)	STOP	Stop Address Comparator Select Bits. When a bit is set to 1, it selects a single address comparator as a stop address for the TraceEnable start/stop block.	
		0	disabled
		1	Address Comparator 1
		2	Address Comparator 2
		4	Address Comparator 3
		8	Address Comparator 4

		32768	Address Comparator 16

ADSP-2159x_SC591_SC592_SC594 TAPC Register Descriptions

TAPC (TAPC) contains the following registers.

Table 49-43: ADSP-2159x_SC591_SC592_SC594 TAPC Register List

Name	Description
TAPC_DBGCTL	Debug Control Register
TAPC_IDCODE	IDCODE Register
TAPC_SDBGKEY0	Secure Debug Key 0 Register
TAPC_SDBGKEY1	Secure Debug Key 1 Register

Table 49-43: ADSP-2159x_SC591_SC592_SC594 TAPC Register List (Continued)

Name	Description
TAPC_SDBGKEY2	Secure Debug Key 2 Register
TAPC_SDBGKEY3	Secure Debug Key 3 Register
TAPC_SDBGKEY_CTL	Secure Debug Key Control Register
TAPC_SDBGKEY_STAT	Secure Debug Key Status Register
TAPC_USERCODE	USERCODE Register

Debug Control Register

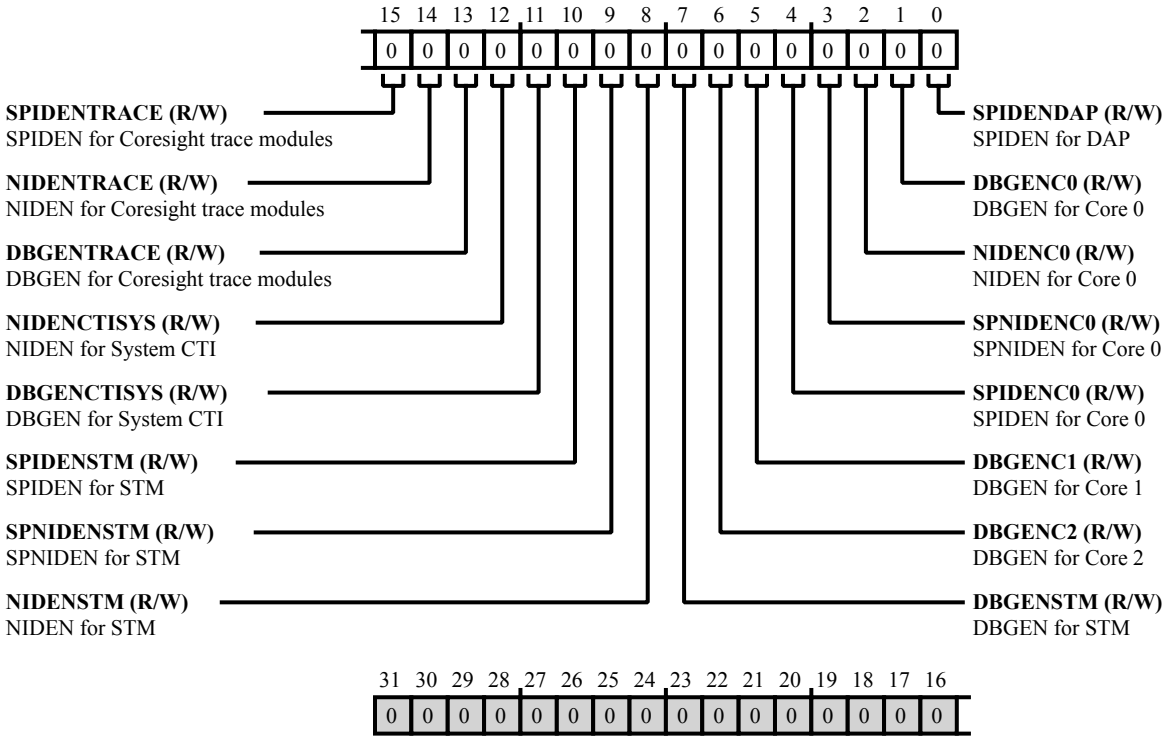

Figure 49-38: TAPC_DBGCTL Register Diagram

Table 49-44: TAPC_DBGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	SPIDENTRACE	SPIDEN for Coresight trace modules.
14 (R/W)	NIDENTRACE	NIDEN for Coresight trace modules.
13 (R/W)	DBGENTRACE	DBGEN for Coresight trace modules.
12 (R/W)	NIDENCTISYS	NIDEN for System CTI.
11 (R/W)	DBGENCTISYS	DBGEN for System CTI.
10 (R/W)	SPIDENSTM	SPIDEN for STM.

Table 49-44: TAPC_DBGCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	SPNIDENSTM	SPNIDEN for STM.
8 (R/W)	NIDENSTM	NIDEN for STM.
7 (R/W)	DBGENSTM	DBGEN for STM.
6 (R/W)	DBGENC2	DBGEN for Core 2.
5 (R/W)	DBGENC1	DBGEN for Core 1.
4 (R/W)	SPIDENC0	SPIDEN for Core 0.
3 (R/W)	SPNIDENC0	SPNIDEN for Core 0.
2 (R/W)	NIDENC0	NIDEN for Core 0.
1 (R/W)	DBGENC0	DBGEN for Core 0.
0 (R/W)	SPIDENDAP	SPIDEN for DAP.

IDCODE Register

The TAPC_IDCODE register holds the IDCODE. The bit field is defined as follows.

IDCODE[31:28] = 0x1* – REVID

IDCODE[27:12] = 0x280B – JTAG ID

IDCODE[11:1] = 0x65 – Manufacturer ID

IDCODE[0] = 0x1

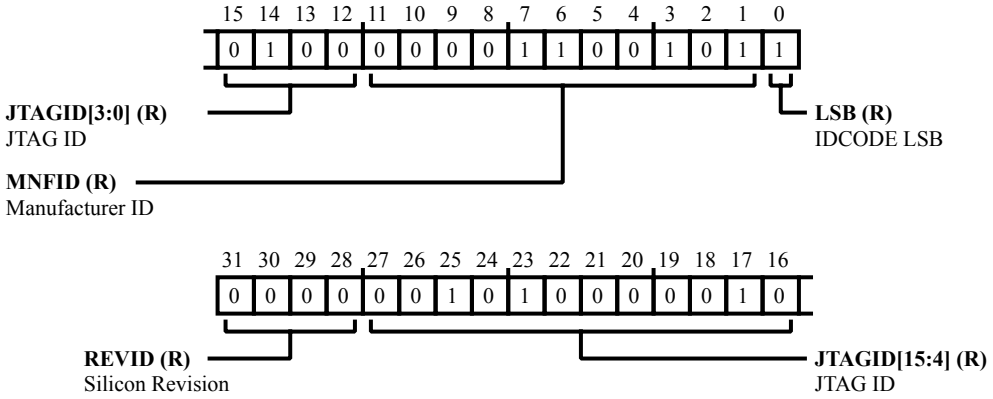

Figure 49-39: TAPC_IDCODE Register Diagram

Table 49-45: TAPC_IDCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	REVID	Silicon Revision. The TAPC_IDCODE.REVID bit field holds the silicon revision. See the processor anomaly list for details.
27:12 (R/NW)	JTAGID	JTAG ID.
11:1 (R/NW)	MNFID	Manufacturer ID.
0 (R/NW)	LSB	IDCODE LSB.

Secure Debug Key 0 Register

The TAPC_SDBGKEY0 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. A debug key of 128 bits needs to be written into the Secure Debug Key registers (TAPC_SDBGKEY0, TAPC_SDBGKEY1, TAPC_SDBGKEY2, TAPC_SDBGKEY3) in the TAPC through the peripheral bus interface.

These registers hold the value of the key against which a matching key provided by the debug user is compared to enable a debug session. The task of writing these registers is performed (initially) by boot ROM code which copies a customer-selected key from the Flash memory info block to these registers.

An SDBGKEY value of all 0's is always an invalid key, a value of all 1's match the default value of the Secure Debug Key Compare registers and requires no entry in these registers. It is recommended programs have a significant number of 0's and 1's in a pseudo-random pattern throughout the 128-bit code for maximum protection.

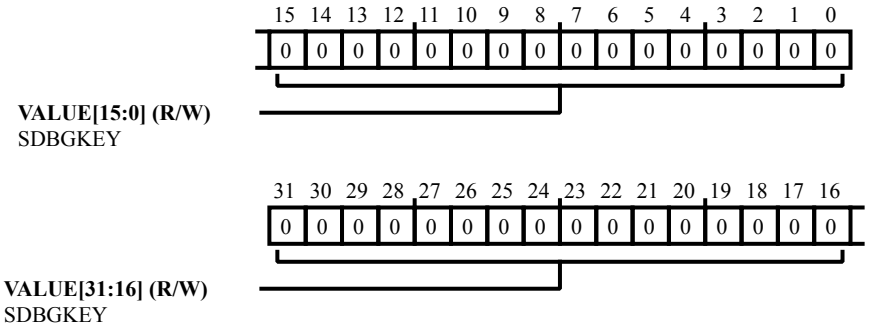

Figure 49-40: TAPC_SDBGKEY0 Register Diagram

Table 49-46: TAPC_SDBGKEY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SDBGKEY. The TAPC_SDBGKEY0.VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 1 Register

The TAPC_SDBGKEY1 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

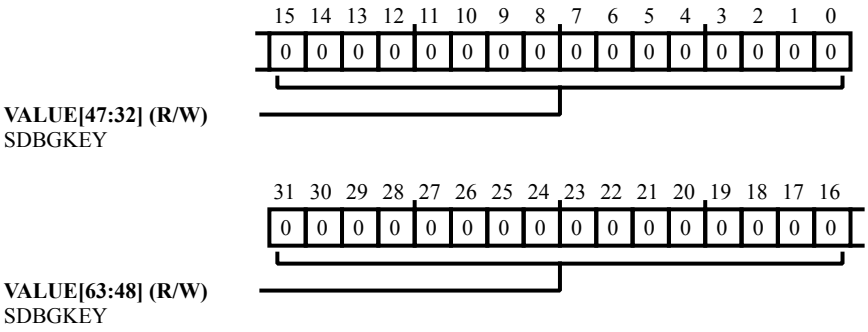

Figure 49-41: TAPC_SDBGKEY1 Register Diagram

Table 49-47: TAPC_SDBGKEY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SDBGKEY. The TAPC_SDBGKEY1.VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 2 Register

The TAPC_SDBGKEY2 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

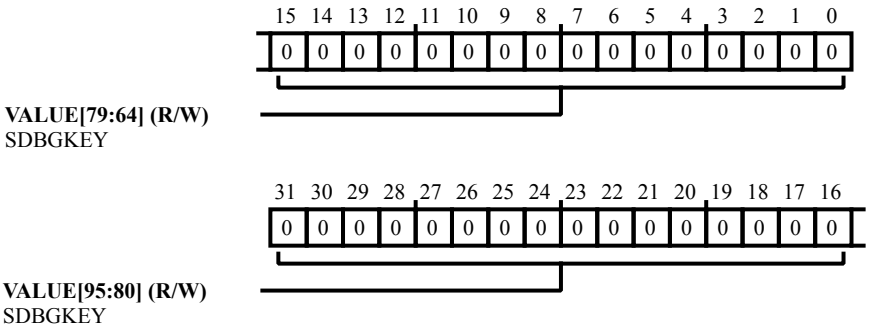

Figure 49-42: TAPC_SDBGKEY2 Register Diagram

Table 49-48: TAPC_SDBGKEY2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SDBGKEY. The TAPC_SDBGKEY2.VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 3 Register

The TAPC_SDBGKEY3 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

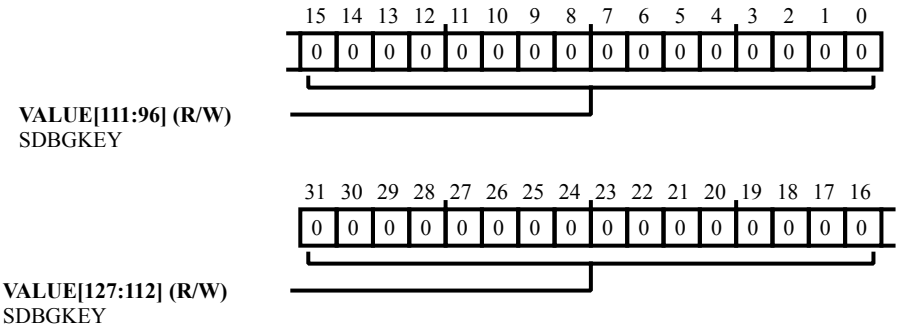

Figure 49-43: TAPC_SDBGKEY3 Register Diagram

Table 49-49: TAPC_SDBGKEY3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SDBGKEY. The TAPC_SDBGKEY3.VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key Control Register

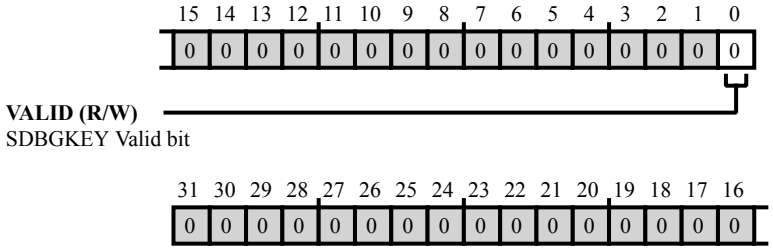

Figure 49-44: TAPC_SDBGKEY_CTL Register Diagram

Table 49-50: TAPC_SDBGKEY_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALID	SDBGKEY Valid bit.

Secure Debug Key Status Register

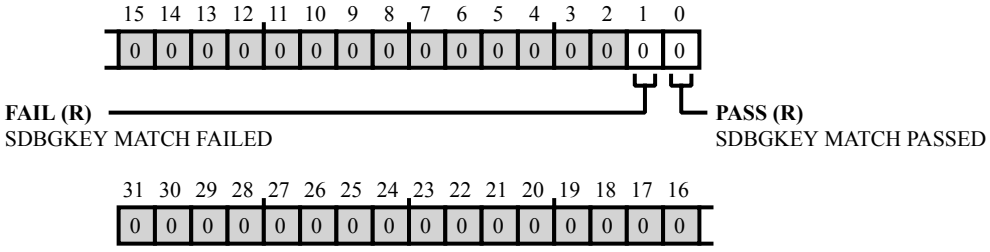

Figure 49-45: TAPC_SDBGKEY_STAT Register Diagram

Table 49-51: TAPC_SDBGKEY_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	FAIL	SDBGKEY MATCH FAILED.
0 (R/NW)	PASS	SDBGKEY MATCH PASSED.

USERCODE Register

The TAPC_USERCODE register

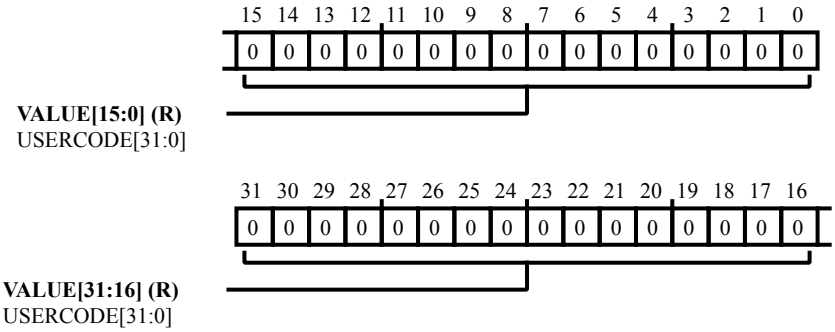

Figure 49-46: TAPC_USERCODE Register Diagram

Table 49-52: TAPC_USERCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	USERCODE[31:0].

ADSP-2159x_SC591_SC592_SC594 CTI Register Descriptions

CSCTI_Register_Definitions (CTI) contains the following registers.

Table 49-53: ADSP-2159x_SC591_SC592_SC594 CTI Register List

Name	Description
CTI_ASICCTL	External Multiplexor Control Register
CTI_AUTHSTATUS	Authentication Status
CTI_CLAIMCLR	Claim Tag Clear Register
CTI_CLAIMSET	Claim Tag Set Register
CTI_COMPID0	Component ID0
CTI_COMPID1	Component ID1
CTI_COMPID2	Component ID2
CTI_COMPID3	Component ID3
CTI_CTIAPPCLEAR	CTI Application Trigger Clear Register
CTI_CTIAPPPULSE	CTI Application Pulse Register
CTI_CTIAPPSET	CTI Application Trigger Set Register

Table 49-53: ADSP-2159x_SC591_SC592_SC594 CTI Register List (Continued)

Name	Description
CTI_CTICHINSTATUS	CTI Channel In Status Register
CTI_CTICHOUTSTATUS	CTI Channel Out Status Register
CTI_CTICONTROL	CTI Control Register
CTI_CTIGATE	Enable CTI Channel Gate Register
CTI_CTIINEN0	CTI Trigger 0 to Channel Enable Register
CTI_CTIINEN1	CTI Trigger 1 to Channel Enable Register
CTI_CTIINEN2	CTI Trigger 2 to Channel Enable Register
CTI_CTIINEN3	CTI Trigger 3 to Channel Enable Register
CTI_CTIINEN4	CTI Trigger 4 to Channel Enable Register
CTI_CTIINEN5	CTI Trigger 5 to Channel Enable Register
CTI_CTIINEN6	CTI Trigger 6 to Channel Enable Register
CTI_CTIINEN7	CTI Trigger 7 to Channel Enable Register
CTI_CTIINTACK	CTI Interrupt Acknowledge Register
CTI_CTIOUTEN0	CTI Channel to Trigger 0 Enable Register
CTI_CTIOUTEN1	CTI Channel to Trigger 1 Enable Register
CTI_CTIOUTEN2	CTI Channel to Trigger 2 Enable Register
CTI_CTIOUTEN3	CTI Channel to Trigger 3 Enable Register
CTI_CTIOUTEN4	CTI Channel to Trigger 4 Enable Register
CTI_CTIOUTEN5	CTI Channel to Trigger 5 Enable Register
CTI_CTIOUTEN6	CTI Channel to Trigger 6 Enable Register
CTI_CTIOUTEN7	CTI Channel to Trigger 7 Enable Register
CTI_CTITRIGINSTATUS	CTI Trigger In Status Register
CTI_CTITRIGOUTSTATUS	CTI Trigger Out Status Register
CTI_DEVID	Device ID
CTI_DEVTYPE	Device Type
CTI_ITCHIN	ITCHIN
CTI_ITCHINACK	ITCHINACK
CTI_ITCHOUT	ITCHOUT
CTI_ITCHOUTACK	ITCHOUTACK
CTI_ITCTRL	Integration Mode Control Register
CTI_ITTRIGIN	ITTRIGIN

Table 49-53: ADSP-2159x_SC591_SC592_SC594 CTI Register List (Continued)

Name	Description
CTI_ITTRIGINACK	ITTRIGINACK
CTI_ITTRIGOUT	ITTRIGOUT
CTI_ITTRIGOUTACK	ITTRIGOUTACK
CTI_LAR	Lock Access Register
CTI_LSR	Lock Status Register
CTI_PERIPHID0	Peripheral ID0
CTI_PERIPHID1	Peripheral ID1
CTI_PERIPHID2	Peripheral ID2
CTI_PERIPHID3	Peripheral ID3
CTI_PERIPHID4	Peripheral ID4
CTI_PERIPHID5	Peripheral ID5
CTI_PERIPHID6	Peripheral ID6
CTI_PERIPHID7	Peripheral ID7

External Multiplexor Control Register

Table 49-95: CTI_ITTRIGIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	CTTRIGIN	Read the values of the CTTRIGIN inputs.

ITTRIGINACK

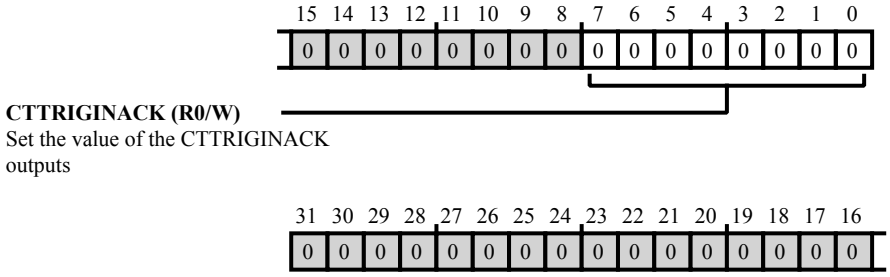

Figure 49-89: CTI_ITTRIGINACK Register Diagram

Table 49-96: CTI_ITTRIGINACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	CTTRIGINACK	Set the value of the CTTRIGINACK outputs.

ITTRIGOUT

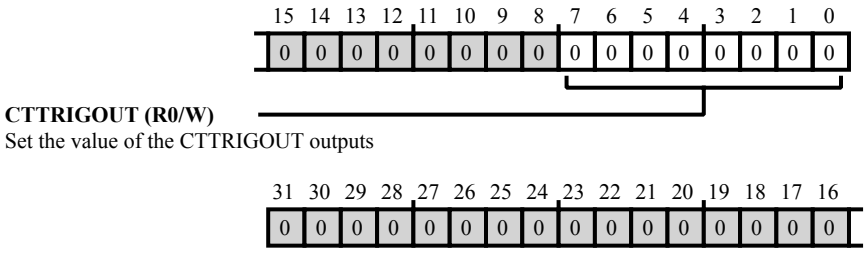

Figure 49-90: CTI_ITTRIGOUT Register Diagram

Table 49-97: CTI_ITTRIGOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	CTTRIGOUT	Set the value of the CTTRIGOUT outputs.

ITTRIGOUTACK

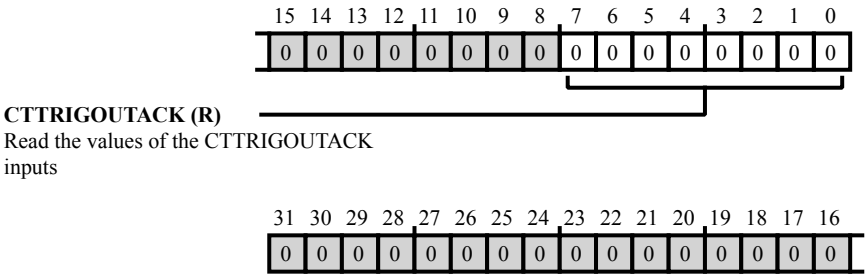

Figure 49-91: CTI_ITTRIGOUTACK Register Diagram

Table 49-98: CTI_ITTRIGOUTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	CTTRIGOUTACK	Read the values of the CTTRIGOUTACK inputs.

Lock Access Register

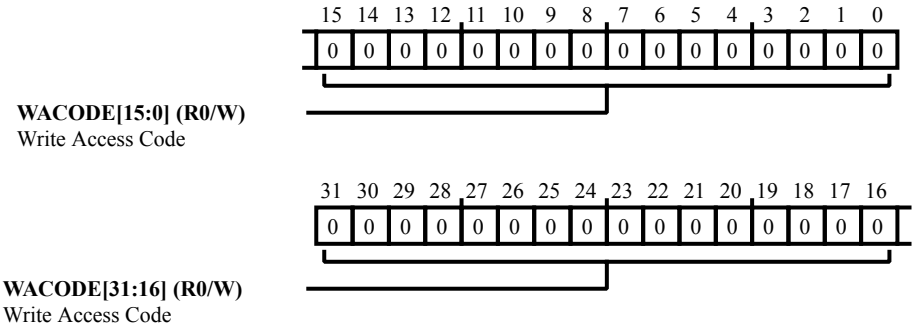

Figure 49-92: CTI_LAR Register Diagram

Table 49-99: CTI_LAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	WACODE	Write Access Code.

Lock Status Register

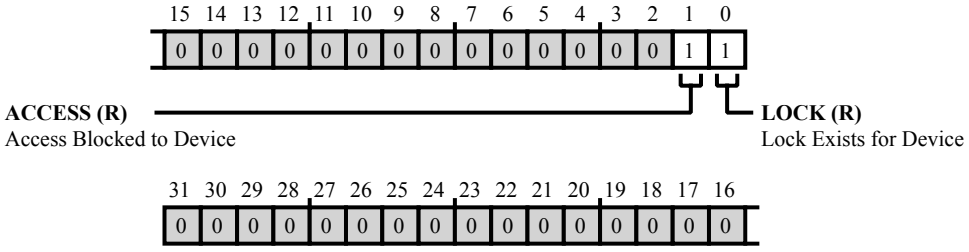

Figure 49-93: CTI_LSR Register Diagram

Table 49-100: CTI_LSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	ACCESS	Access Blocked to Device.
0 (R/NW)	LOCK	Lock Exists for Device.

Peripheral ID0

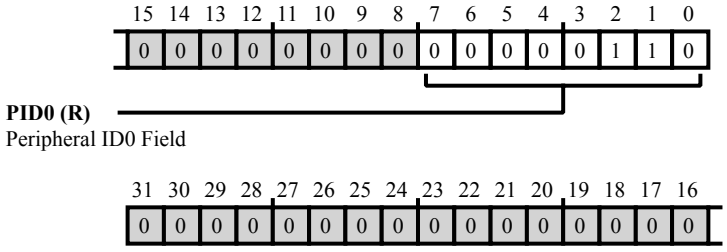

Figure 49-94: CTI_PERIPHID0 Register Diagram

Table 49-101: CTI_PERIPHID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID0	Peripheral ID0 Field.

Peripheral ID1

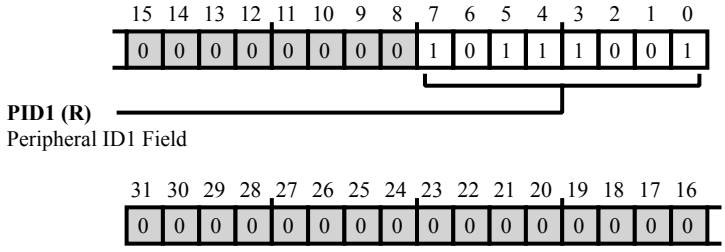

Figure 49-95: CTI_PERIPHID1 Register Diagram

Table 49-102: CTI_PERIPHID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID1	Peripheral ID1 Field.

Peripheral ID2

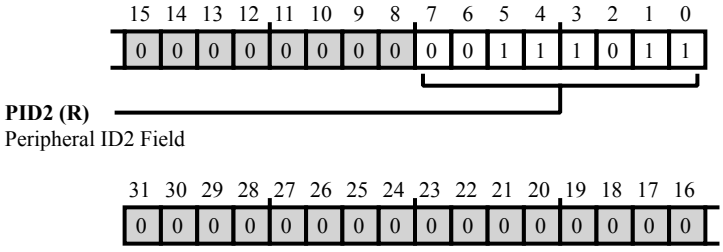

Figure 49-96: CTI_PERIPHID2 Register Diagram

Table 49-103: CTI_PERIPHID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID2	Peripheral ID2 Field.

Peripheral ID3

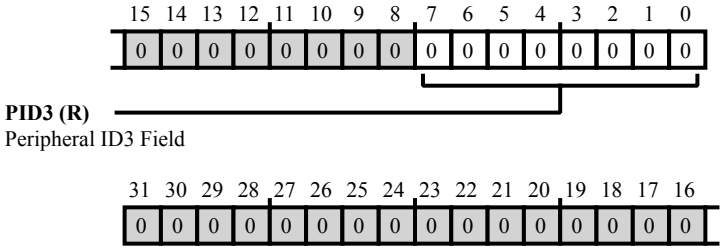

Figure 49-97: CTI_PERIPHID3 Register Diagram

Table 49-104: CTI_PERIPHID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID3	Peripheral ID3 Field.

Peripheral ID4

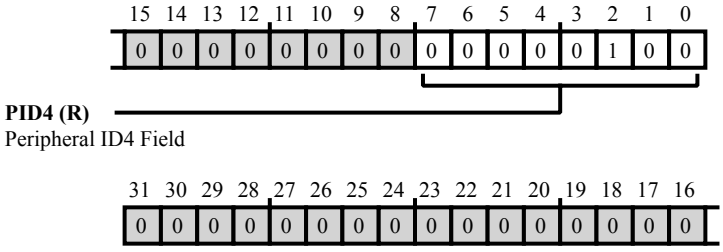

Figure 49-98: CTI_PERIPHID4 Register Diagram

Table 49-105: CTI_PERIPHID4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID4	Peripheral ID4 Field.

Peripheral ID5

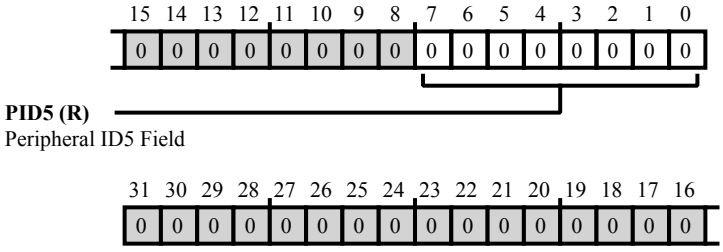

Figure 49-99: CTI_PERIPHID5 Register Diagram

Table 49-106: CTI_PERIPHID5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID5	Peripheral ID5 Field.

Peripheral ID6

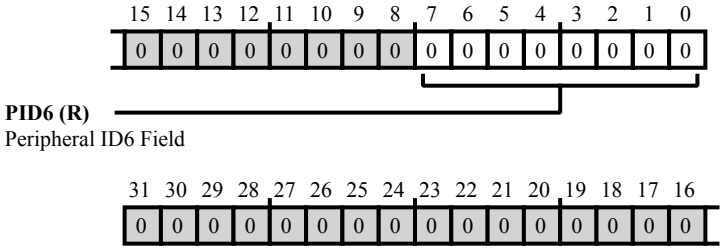

Figure 49-100: CTI_PERIPHID6 Register Diagram

Table 49-107: CTI_PERIPHID6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID6	Peripheral ID6 Field.

Peripheral ID7

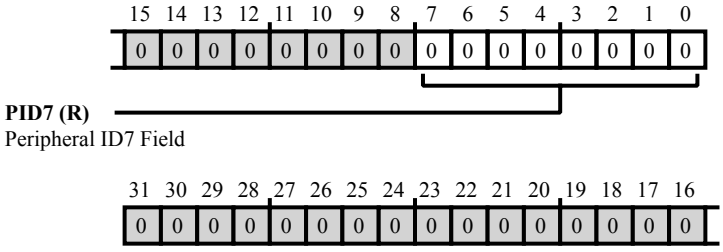

Figure 49-101: CTI_PERIPHID7 Register Diagram

Table 49-108: CTI_PERIPHID7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PID7	Peripheral ID7 Field.

Appendix A ADSP-2159x Register List

This appendix lists Memory-Mapped Register address and register names. The modules are presented in alphabetical order.

Table A-1: ADSP-2159x DMC0 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31071000	DMC0_DDR_LANE0_CTL 0	DMC0 Data Lane 0 Control Register 0	0x00000000
0x31071004	DMC0_DDR_LANE0_CTL 1	DMC0 Data Lane 0 Control Register 1	0x00000000
0x3107100C	DMC0_DDR_LANE1_CTL 0	DMC0 Data Lane 1 Control Register 0	0x00000000
0x31071010	DMC0_DDR_LANE1_CTL 1	DMC0 Data Lane 1 Control Register 1	0x00000000
0x31071018	DMC0_DDR_ROOT_CTL	DMC0 DDR ROOT Module Control Register	0x00000800
0x31071034	DMC0_DDR_ZQ_CTL0	DMC0 DDR Calibration Control Register 0	0xE0000000
0x31071038	DMC0_DDR_ZQ_CTL1	DMC0 DDR Calibration Control Register 1	0x00000000
0x3107103C	DMC0_DDR_ZQ_CTL2	DMC0 DDR Calibration Control Register 2	0x00000000
0x31071068	DMC0_DDR_CA_CTL	DMC0 DDR CA Lane Control Register	0x00000000

Table A-2: ADSP-2159x ARMDBG0 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31120000	ARMDBG0_DIDR	ARMDBG0 Debug ID Register.	0x1203F001
0x31120018	ARMDBG0_WFAR	ARMDBG0 The Watchpoint Fault Address Register.	0x00000000
0x3112001C	ARMDBG0_VCR	ARMDBG0 Vector Catch Register.	0x00000000
0x31120024	ARMDBG0_ECR	ARMDBG0 Event Catch Register.	0x00000000
0x31120028	ARMDBG0_DSCCR	ARMDBG0 Debug State Cache Control Register.	0x00000000
0x3112002C	ARMDBG0_DSMCR	ARMDBG0 Debug State MMU Control Register.	0x00000000
0x31120080	ARMDBG0_DTRRX	ARMDBG0 Read Data Transfer Register.	0x00000000
0x31120084	ARMDBG0_ITR	ARMDBG0 Instruction Transfer Register.	0xFFFFFFFF
0x31120088	ARMDBG0_DSCR	ARMDBG0 Debug Status and Control Register.	0x02030002
0x3112008C	ARMDBG0_DTRTX	ARMDBG0 Write Data Transfer Register.	0x00000000
0x31120090	ARMDBG0_DRCR	ARMDBG0 Debug Run Control Register.	0x00000000
0x311200A0	ARMDBG0_PCSR	ARMDBG0 Program Counter Sampling Register.	0xFFFFFFFF

Table A-2: ADSP-2159x ARMDBG0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x311200A4	ARMDBG0_CIDSR	ARMDBG0 Context ID Sampling Register.	0x00000000
0x31120100	ARMDBG0_BVR0	ARMDBG0 Breakpoint Value Register 0.	0x00000000
0x31120104	ARMDBG0_BVR1	ARMDBG0 Breakpoint Value Register 1.	0x00000000
0x31120108	ARMDBG0_BVR2	ARMDBG0 Breakpoint Value Register 2.	0x00000000
0x31120140	ARMDBG0_BCR0	ARMDBG0 Breakpoint Control Register 0.	0x00000000
0x31120144	ARMDBG0_BCR1	ARMDBG0 Breakpoint Control Register 1.	0x00000000
0x31120148	ARMDBG0_BCR2	ARMDBG0 Breakpoint Control Register 2.	0x00000000
0x31120180	ARMDBG0_WVR0	ARMDBG0 Watchpoint Value Register 0.	0x00000000
0x31120184	ARMDBG0_WVR1	ARMDBG0 Watchpoint Value Register 1.	0x00000000
0x311201C0	ARMDBG0_WCR0	ARMDBG0 Watchpoint Control Register 0.	0x00000000
0x311201C4	ARMDBG0_WCR1	ARMDBG0 Watchpoint Control Register 1.	0x00000000
0x31120300	ARMDBG0_OSLAR	ARMDBG0 Operating System Lock Access Register.	0x00000000
0x31120304	ARMDBG0_OSLSR	ARMDBG0 Operating System Lock Status Register.	0x00000000
0x31120310	ARMDBG0_PRCR	ARMDBG0 Device Powerdown and Reset Control Register.	0x00000000
0x31120314	ARMDBG0_PRSR	ARMDBG0 Device Powerdown and Reset Status Register.	0x00000009
0x31120D00	ARMDBG0_MIDR	ARMDBG0 Main ID Register.	0x410FC051
0x31120D04	ARMDBG0_CTR	ARMDBG0 Cache Type Register.	0x83338003
0x31120D08	ARMDBG0_TCMTR	ARMDBG0 TCM Type Register.	0x00000000
0x31120D0C	ARMDBG0_TLBTR	ARMDBG0 TCM Type Register.	0x00000000
0x31120D10	ARMDBG0_MPUIR	ARMDBG0 MPU Type Register (alias of MIDR in VMSA).	0x410FC051
0x31120D14	ARMDBG0_MPIDR	ARMDBG0 Multiprocessor Affinity Register.	0xC0000000
0x31120D18	ARMDBG0_MIDRALIAS1	ARMDBG0 Main ID Register (alias at 0xd18).	0x410FC051
0x31120D1C	ARMDBG0_MIDRALIAS2	ARMDBG0 Main ID Register (alias at 0xd1c).	0x410FC051
0x31120D20	ARMDBG0_ID_PFR0	ARMDBG0 Processor Feature Register 0.	0x00001231
0x31120D24	ARMDBG0_ID_PFR1	ARMDBG0 Processor Feature Register 1.	0x00000011
0x31120D28	ARMDBG0_ID_DFR0	ARMDBG0 Debug Feature Register 0.	0x02010444
0x31120D2C	ARMDBG0_ID_AFR0	ARMDBG0 Auxiliary Feature Register 0.	0x00000000
0x31120D30	ARMDBG0_ID_MMFR0	ARMDBG0 Memory Model Feature Register 0.	0x00100003
0x31120D34	ARMDBG0_ID_MMFR1	ARMDBG0 Memory Model Feature Register 1.	0x40000000

Table A-2: ADSP-2159x ARMDBG0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31120D38	ARMDBG0_ID_MMFR2	ARMDBG0 Memory Model Feature Register 2.	0x01230000
0x31120D3C	ARMDBG0_ID_MMFR3	ARMDBG0 Memory Model Feature Register 3.	0x00102211
0x31120D40	ARMDBG0_ID_ISAR0	ARMDBG0 ISA Feature Register 0.	0x00101111

Table A-49: ADSP-2159x DMA28 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026400	DMA28_DSCPTR_NXT	DMA28 Pointer to Next Initial Descriptor Register	0x00000000
0x31026404	DMA28_ADDRSTART	DMA28 Start Address of Current Buffer Register	0x00000000
0x31026408	DMA28_CFG	DMA28 Configuration Register	0x00000000
0x3102640C	DMA28_XCNT	DMA28 Inner Loop Count Start Value Register	0x00000000
0x31026410	DMA28_XMOD	DMA28 Inner Loop Address Increment Register	0x00000000
0x31026414	DMA28_YCNT	DMA28 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026418	DMA28_YMOD	DMA28 Outer Loop Address Increment (2D only) Register	0x00000000

Table A-49: ADSP-2159x DMA28 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31026424	DMA28_DSCPTR_CUR	DMA28 Current Descriptor Pointer Register	0x00000000
0x31026428	DMA28_DSCPTR_PRV	DMA28 Previous Initial Descriptor Pointer Register	0x00000000
0x3102642C	DMA28_ADDR_CUR	DMA28 Current Address Register	0x00000000
0x31026430	DMA28_STAT	DMA28 Status Register	0x00006000
0x31026434	DMA28_XCNT_CUR	DMA28 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31026438	DMA28_YCNT_CUR	DMA28 Current Row Count (2D only) Register	0x00000000
0x31026440	DMA28_BWLCNT	DMA28 Bandwidth Limit Count Register	0x00000000
0x31026444	DMA28_BWLCNT_CUR	DMA28 Bandwidth Limit Count Current Register	0x00000000
0x31026448	DMA28_BWMCNT	DMA28 Bandwidth Monitor Count Register	0x00000000
0x3102644C	DMA28_BWMCNT_CUR	DMA28 Bandwidth Monitor Count Current Register	0x00000000

Table A-50: ADSP-2159x DMA29 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026480	DMA29_DSCPTR_NXT	DMA29 Pointer to Next Initial Descriptor Register	0x00000000
0x31026484	DMA29_ADDRSTART	DMA29 Start Address of Current Buffer Register	0x00000000
0x31026488	DMA29_CFG	DMA29 Configuration Register	0x00000000
0x3102648C	DMA29_XCNT	DMA29 Inner Loop Count Start Value Register	0x00000000
0x31026490	DMA29_XMOD	DMA29 Inner Loop Address Increment Register	0x00000000
0x31026494	DMA29_YCNT	DMA29 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026498	DMA29_YMOD	DMA29 Outer Loop Address Increment (2D only) Register	0x00000000
0x310264A4	DMA29_DSCPTR_CUR	DMA29 Current Descriptor Pointer Register	0x00000000
0x310264A8	DMA29_DSCPTR_PRV	DMA29 Previous Initial Descriptor Pointer Register	0x00000000
0x310264AC	DMA29_ADDR_CUR	DMA29 Current Address Register	0x00000000
0x310264B0	DMA29_STAT	DMA29 Status Register	0x00006000
0x310264B4	DMA29_XCNT_CUR	DMA29 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310264B8	DMA29_YCNT_CUR	DMA29 Current Row Count (2D only) Register	0x00000000
0x310264C0	DMA29_BWLCNT	DMA29 Bandwidth Limit Count Register	0x00000000
0x310264C4	DMA29_BWLCNT_CUR	DMA29 Bandwidth Limit Count Current Register	0x00000000

Table A-50: ADSP-2159x DMA29 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310264C8	DMA29_BWMCNT	DMA29 Bandwidth Monitor Count Register	0x00000000
0x310264CC	DMA29_BWMCNT_CUR	DMA29 Bandwidth Monitor Count Current Register	0x00000000

Table A-51: ADSP-2159x DMA3 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31022180	DMA3_DSCPTR_NXT	DMA3 Pointer to Next Initial Descriptor Register	0x00000000
0x31022184	DMA3_ADDRSTART	DMA3 Start Address of Current Buffer Register	0x00000000
0x31022188	DMA3_CFG	DMA3 Configuration Register	0x00000000
0x3102218C	DMA3_XCNT	DMA3 Inner Loop Count Start Value Register	0x00000000
0x31022190	DMA3_XMOD	DMA3 Inner Loop Address Increment Register	0x00000000
0x31022194	DMA3_YCNT	DMA3 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31022198	DMA3_YMOD	DMA3 Outer Loop Address Increment (2D only) Register	0x00000000
0x310221A4	DMA3_DSCPTR_CUR	DMA3 Current Descriptor Pointer Register	0x00000000
0x310221A8	DMA3_DSCPTR_PRV	DMA3 Previous Initial Descriptor Pointer Register	0x00000000
0x310221AC	DMA3_ADDR_CUR	DMA3 Current Address Register	0x00000000
0x310221B0	DMA3_STAT	DMA3 Status Register	0x00006000
0x310221B4	DMA3_XCNT_CUR	DMA3 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310221B8	DMA3_YCNT_CUR	DMA3 Current Row Count (2D only) Register	0x00000000
0x310221C0	DMA3_BWLCNT	DMA3 Bandwidth Limit Count Register	0x00000000
0x310221C4	DMA3_BWLCNT_CUR	DMA3 Bandwidth Limit Count Current Register	0x00000000
0x310221C8	DMA3_BWMCNT	DMA3 Bandwidth Monitor Count Register	0x00000000
0x310221CC	DMA3_BWMCNT_CUR	DMA3 Bandwidth Monitor Count Current Register	0x00000000

Table A-52: ADSP-2159x DMA30 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x30FFF000	DMA30_DSCPTR_NXT	DMA30 Pointer to Next Initial Descriptor Register	0x00000000
0x30FFF004	DMA30_ADDRSTART	DMA30 Start Address of Current Buffer Register	0x00000000
0x30FFF008	DMA30_CFG	DMA30 Configuration Register	0x00000000
0x30FFF00C	DMA30_XCNT	DMA30 Inner Loop Count Start Value Register	0x00000000

Table A-52: ADSP-2159x DMA30 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x30FFF010	DMA30_XMOD	DMA30 Inner Loop Address Increment Register	0x00000000
0x30FFF014	DMA30_YCNT	DMA30 Outer Loop Count Start Value (2D only) Register	0x00000000
0x30FFF018	DMA30_YMOD	DMA30 Outer Loop Address Increment (2D only) Register	0x00000000
0x30FFF024	DMA30_DSCPTR_CUR	DMA30 Current Descriptor Pointer Register	0x00000000
0x30FFF028	DMA30_DSCPTR_PRV	DMA30 Previous Initial Descriptor Pointer Register	0x00000000
0x30FFF02C	DMA30_ADDR_CUR	DMA30 Current Address Register	0x00000000
0x30FFF030	DMA30_STAT	DMA30 Status Register	0x00006000
0x30FFF034	DMA30_XCNT_CUR	DMA30 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x30FFF038	DMA30_YCNT_CUR	DMA30 Current Row Count (2D only) Register	0x00000000
0x30FFF040	DMA30_BWLCNT	DMA30 Bandwidth Limit Count Register	0x00000000
0x30FFF044	DMA30_BWLCNT_CUR	DMA30 Bandwidth Limit Count Current Register	0x00000000
0x30FFF048	DMA30_BWMCNT	DMA30 Bandwidth Monitor Count Register	0x00000000
0x30FFF04C	DMA30_BWMCNT_CUR	DMA30 Bandwidth Monitor Count Current Register	0x00000000

Table A-53: ADSP-2159x DMA34 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026180	DMA34_DSCPTR_NXT	DMA34 Pointer to Next Initial Descriptor Register	0x00000000
0x31026184	DMA34_ADDRSTART	DMA34 Start Address of Current Buffer Register	0x00000000
0x31026188	DMA34_CFG	DMA34 Configuration Register	0x00000000
0x3102618C	DMA34_XCNT	DMA34 Inner Loop Count Start Value Register	0x00000000
0x31026190	DMA34_XMOD	DMA34 Inner Loop Address Increment Register	0x00000000
0x31026194	DMA34_YCNT	DMA34 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026198	DMA34_YMOD	DMA34 Outer Loop Address Increment (2D only) Register	0x00000000
0x310261A4	DMA34_DSCPTR_CUR	DMA34 Current Descriptor Pointer Register	0x00000000
0x310261A8	DMA34_DSCPTR_PRV	DMA34 Previous Initial Descriptor Pointer Register	0x00000000
0x310261AC	DMA34_ADDR_CUR	DMA34 Current Address Register	0x00000000
0x310261B0	DMA34_STAT	DMA34 Status Register	0x00006000

Table A-53: ADSP-2159x DMA34 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310261B4	DMA34_XCNT_CUR	DMA34 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310261B8	DMA34_YCNT_CUR	DMA34 Current Row Count (2D only) Register	0x00000000
0x310261C0	DMA34_BWLCNT	DMA34 Bandwidth Limit Count Register	0x00000000
0x310261C4	DMA34_BWLCNT_CUR	DMA34 Bandwidth Limit Count Current Register	0x00000000
0x310261C8	DMA34_BWMCNT	DMA34 Bandwidth Monitor Count Register	0x00000000
0x310261CC	DMA34_BWMCNT_CUR	DMA34 Bandwidth Monitor Count Current Register	0x00000000

Table A-54: ADSP-2159x DMA35 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026100	DMA35_DSCPTR_NXT	DMA35 Pointer to Next Initial Descriptor Register	0x00000000
0x31026104	DMA35_ADDRSTART	DMA35 Start Address of Current Buffer Register	0x00000000
0x31026108	DMA35_CFG	DMA35 Configuration Register	0x00000000
0x3102610C	DMA35_XCNT	DMA35 Inner Loop Count Start Value Register	0x00000000
0x31026110	DMA35_XMOD	DMA35 Inner Loop Address Increment Register	0x00000000
0x31026114	DMA35_YCNT	DMA35 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026118	DMA35_YMOD	DMA35 Outer Loop Address Increment (2D only) Register	0x00000000
0x31026124	DMA35_DSCPTR_CUR	DMA35 Current Descriptor Pointer Register	0x00000000
0x31026128	DMA35_DSCPTR_PRV	DMA35 Previous Initial Descriptor Pointer Register	0x00000000
0x3102612C	DMA35_ADDR_CUR	DMA35 Current Address Register	0x00000000
0x31026130	DMA35_STAT	DMA35 Status Register	0x00006000
0x31026134	DMA35_XCNT_CUR	DMA35 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31026138	DMA35_YCNT_CUR	DMA35 Current Row Count (2D only) Register	0x00000000
0x31026140	DMA35_BWLCNT	DMA35 Bandwidth Limit Count Register	0x00000000
0x31026144	DMA35_BWLCNT_CUR	DMA35 Bandwidth Limit Count Current Register	0x00000000
0x31026148	DMA35_BWMCNT	DMA35 Bandwidth Monitor Count Register	0x00000000
0x3102614C	DMA35_BWMCNT_CUR	DMA35 Bandwidth Monitor Count Current Register	0x00000000

Table A-55: ADSP-2159x DMA36 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x30FFF080	DMA36_DSCPTR_NXT	DMA36 Pointer to Next Initial Descriptor Register	0x00000000
0x30FFF084	DMA36_ADDRSTART	DMA36 Start Address of Current Buffer Register	0x00000000
0x30FFF088	DMA36_CFG	DMA36 Configuration Register	0x00000000
0x30FFF08C	DMA36_XCNT	DMA36 Inner Loop Count Start Value Register	0x00000000
0x30FFF090	DMA36_XMOD	DMA36 Inner Loop Address Increment Register	0x00000000
0x30FFF094	DMA36_YCNT	DMA36 Outer Loop Count Start Value (2D only) Register	0x00000000
0x30FFF098	DMA36_YMOD	DMA36 Outer Loop Address Increment (2D only) Register	0x00000000
0x30FFF0A4	DMA36_DSCPTR_CUR	DMA36 Current Descriptor Pointer Register	0x00000000
0x30FFF0A8	DMA36_DSCPTR_PRV	DMA36 Previous Initial Descriptor Pointer Register	0x00000000
0x30FFF0AC	DMA36_ADDR_CUR	DMA36 Current Address Register	0x00000000
0x30FFF0B0	DMA36_STAT	DMA36 Status Register	0x00006000
0x30FFF0B4	DMA36_XCNT_CUR	DMA36 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x30FFF0B8	DMA36_YCNT_CUR	DMA36 Current Row Count (2D only) Register	0x00000000
0x30FFF0C0	DMA36_BWLCNT	DMA36 Bandwidth Limit Count Register	0x00000000
0x30FFF0C4	DMA36_BWLCNT_CUR	DMA36 Bandwidth Limit Count Current Register	0x00000000
0x30FFF0C8	DMA36_BWMCNT	DMA36 Bandwidth Monitor Count Register	0x00000000
0x30FFF0CC	DMA36_BWMCNT_CUR	DMA36 Bandwidth Monitor Count Current Register	0x00000000

Table A-56: ADSP-2159x DMA37 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026280	DMA37_DSCPTR_NXT	DMA37 Pointer to Next Initial Descriptor Register	0x00000000
0x31026284	DMA37_ADDRSTART	DMA37 Start Address of Current Buffer Register	0x00000000
0x31026288	DMA37_CFG	DMA37 Configuration Register	0x00000000
0x3102628C	DMA37_XCNT	DMA37 Inner Loop Count Start Value Register	0x00000000
0x31026290	DMA37_XMOD	DMA37 Inner Loop Address Increment Register	0x00000000
0x31026294	DMA37_YCNT	DMA37 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026298	DMA37_YMOD	DMA37 Outer Loop Address Increment (2D only) Register	0x00000000

Table A-56: ADSP-2159x DMA37 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310262A4	DMA37_DSCPTR_CUR	DMA37 Current Descriptor Pointer Register	0x00000000
0x310262A8	DMA37_DSCPTR_PRV	DMA37 Previous Initial Descriptor Pointer Register	0x00000000
0x310262AC	DMA37_ADDR_CUR	DMA37 Current Address Register	0x00000000
0x310262B0	DMA37_STAT	DMA37 Status Register	0x00006000
0x310262B4	DMA37_XCNT_CUR	DMA37 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310262B8	DMA37_YCNT_CUR	DMA37 Current Row Count (2D only) Register	0x00000000
0x310262C0	DMA37_BWLCNT	DMA37 Bandwidth Limit Count Register	0x00000000
0x310262C4	DMA37_BWLCNT_CUR	DMA37 Bandwidth Limit Count Current Register	0x00000000
0x310262C8	DMA37_BWMCNT	DMA37 Bandwidth Monitor Count Register	0x00000000
0x310262CC	DMA37_BWMCNT_CUR	DMA37 Bandwidth Monitor Count Current Register	0x00000000

Table A-57: ADSP-2159x DMA38 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31026200	DMA38_DSCPTR_NXT	DMA38 Pointer to Next Initial Descriptor Register	0x00000000
0x31026204	DMA38_ADDRSTART	DMA38 Start Address of Current Buffer Register	0x00000000
0x31026208	DMA38_CFG	DMA38 Configuration Register	0x00000000
0x3102620C	DMA38_XCNT	DMA38 Inner Loop Count Start Value Register	0x00000000
0x31026210	DMA38_XMOD	DMA38 Inner Loop Address Increment Register	0x00000000
0x31026214	DMA38_YCNT	DMA38 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31026218	DMA38_YMOD	DMA38 Outer Loop Address Increment (2D only) Register	0x00000000
0x31026224	DMA38_DSCPTR_CUR	DMA38 Current Descriptor Pointer Register	0x00000000
0x31026228	DMA38_DSCPTR_PRV	DMA38 Previous Initial Descriptor Pointer Register	0x00000000
0x3102622C	DMA38_ADDR_CUR	DMA38 Current Address Register	0x00000000
0x31026230	DMA38_STAT	DMA38 Status Register	0x00006000
0x31026234	DMA38_XCNT_CUR	DMA38 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000

Table A-127: ADSP-2159x PKA0 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x310D4000	PKA0_APTR	PKA0 PKA Vector_A Address	0x00000000
0x310D4004	PKA0_BPTR	PKA0 PKA Vector_B Address	0x00000000
0x310D4008	PKA0_CPTR	PKA0 PKA Vector_C Address	0x00000000
0x310D400C	PKA0_DPTR	PKA0 PKA Vector_D Address	0x00000000
0x310D4010	PKA0_ALEN	PKA0 PKA Vector_A Length	0x00000000
0x310D4014	PKA0_BLEN	PKA0 PKA Vector_B Length	0x00000000
0x310D4018	PKA0_SHIFT	PKA0 PKA Bit Shift Value	0x00000000
0x310D401C	PKA0_FUNC	PKA0 PKA Function	0x00000000
0x310D4020	PKA0_COMPARE	PKA0 PKA Compare Result	0x00000001
0x310D4024	PKA0_RESULTMSW	PKA0 PKA Most-Significant-Word of Result Vector	0x00008000
0x310D4028	PKA0_DIVMSW	PKA0 PKA Most-Significant-Word of Divide Remainder	0x00008000
0x310D6000	PKA0_RAM	PKA0 Start of PKA RAM space	0x00000000

Table A-128: ADSP-2159x PKIC0 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x310D8000	PKIC0_POL_CTL	PKIC0 Polarity Control Register	0x00000000
0x310D8004	PKIC0_TYPE_CTL	PKIC0 Type Control Register	0x00000000
0x310D8008	PKIC0_EN_CTL	PKIC0 Enable Control Register	0x00000000
0x310D800C	PKIC0_RAW_STAT	PKIC0 Raw Status Register	0x00000000
0x310D800C	PKIC0_EN_SET	PKIC0 Enable Set Register	0x00000000
0x310D8010	PKIC0_ACK	PKIC0 Acknowledge Register	0x00000000
0x310D8010	PKIC0_EN_STAT	PKIC0 Enabled Status Register	0x00000000
0x310D8014	PKIC0_EN_CLR	PKIC0 Enable Clear Register	0x00000000

Table A-129: ADSP-2159x PKTE0 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x310CD000	PKTE0_CTL_STAT	PKTE0 Packet Engine Control Register	0x00000002
0x310CD004	PKTE0_SRC_ADDR	PKTE0 Packet Engine Source Address	0x00000000
0x310CD008	PKTE0_DEST_ADDR	PKTE0 Packet Engine Destination Address	0x00000000
0x310CD00C	PKTE0_SA_ADDR	PKTE0 Packet Engine SA Address	0x00000000

Table A-129: ADSP-2159x PKTE0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310CD010	PKTE0_STATE_ADDR	PKTE0 Packet Engine State Record Address	0x00000000
0x310CD014	PKTE0_ARC4STATE_ADDR	PKTE0 Packet Engine ARC4 State Record Address	0x00000000
0x310CD018	PKTE0_USERID	PKTE0 Packet Engine User ID	0x00000000
0x310CD01C	PKTE0_LEN	PKTE0 Packet Engine Length Register	0x00800000
0x310CD080	PKTE0_CDRBASE_ADDR	PKTE0 Packet Engine Command Descriptor Ring Base Address	0x00000000
0x310CD084	PKTE0_RDRBASE_ADDR	PKTE0 Packet Engine Result Descriptor Ring Base Address	0x00000000
0x310CD088	PKTE0_RING_CFG	PKTE0 Packet Engine Ring Configuration	0x00000000
0x310CD08C	PKTE0_RING_THRESH	PKTE0 Packet Engine Ring Threshold Registers	0x00000000
0x310CD090	PKTE0_CDSC_INCR	PKTE0 Packet Engine Command Descriptor Count Increment Register	0x00000000
0x310CD090	PKTE0_CDSC_CNT	PKTE0 Packet Engine Command Descriptor Count Register	0x00000000
0x310CD094	PKTE0_RDSC_CNT	PKTE0 Packet Engine Result Descriptor Count Registers	0x00000000
0x310CD094	PKTE0_RDSC_DECR	PKTE0 Packet Engine Result Descriptor Count Decrement Registers	0x00000000
0x310CD098	PKTE0_RING_PTR	PKTE0 Packet Engine Ring Pointer Status	0x00000000
0x310CD09C	PKTE0_RING_STAT	PKTE0 Packet Engine Ring Status	0x00000000
0x310CD100	PKTE0_CFG	PKTE0 Packet Engine Configuration Register	0x00000000
0x310CD104	PKTE0_STAT	PKTE0 Packet Engine Status Register	0x00040402
0x310CD10C	PKTE0_BUF_THRESH	PKTE0 Packet Engine Buffer Threshold Register	0x00800080
0x310CD110	PKTE0_INBUF_INCR	PKTE0 Packet Engine Input Buffer Count Increment Register	0x00000000
0x310CD110	PKTE0_INBUF_CNT	PKTE0 Packet Engine Input Buffer Count Register	0x00000000
0x310CD114	PKTE0_OUTBUF_CNT	PKTE0 Packet Engine Output Buffer Count Register	0x00000000
0x310CD114	PKTE0_OUTBUF_DECR	PKTE0 Packet Engine Output Buffer Count Decrement Register	0x00000000
0x310CD118	PKTE0_BUF_PTR	PKTE0 Packet Engine Buffer Pointer Register	0x00000000
0x310CD120	PKTE0_DMA_CFG	PKTE0 Packet Engine DMA Configuration Register	0x00180006
0x310CD1D0	PKTE0_ENDIAN_CFG	PKTE0 Packet Engine Endian Configuration Register	0x00E400E4
0x310CD1E0	PKTE0_HLT_CTL	PKTE0 Packet Engine Halt Control Register	0x00000000

Table A-129: ADSP-2159x PKTE0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310CD1E0	PKTE0_HLT_STAT	PKTE0 Packet Engine Halt Status Register	0x00000000
