ADSP-2159x Register List

Preface

Thank you for purchasing and developing systems using an ADSP-2159x SHARC+® processor from Analog Devices, Inc.

Purpose of This Manual

The ***ADSP-2159x/ADSP-SC592/593/594 SHARC+ Processor Hardware Reference*** provides architectural information about the ADSP-2159x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support.

For timing, electrical, and package specifications, refer to the ***SHARC+ Dual-Core DSP with Arm Cortex-A5 ADSP-21591/593/594/ADSP-SC592/594 Data Sheet***.

NOTE: Analog Devices is in the process of updating documentation to provide terminology and language that is culturally appropriate. This is a process with a wide scope and will be phased in as quickly as possible. Thank you for your patience.

Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices processors. The manual assumes the audience has a working knowledge of the appropriate processor architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as programming reference books and data sheets, that describe their target architecture.

What's New in This Manual

This manual is the fourth preliminary revision (0.4) of the

ADSP-2159x/ADSP-SC592/SC593/SC594 SHARC+ Processor Hardware Reference.

Technical or Customer Support

You can reach customer and technical support for processors from Analog Devices in the following ways:

- Post your questions in the processors and DSP support community at ***EngineerZone***®:

  http://ez.analog.com/community/dsp

- Submit your questions to technical support at ***Connect with ADI Specialists***:

  http://www.analog.com/support

- E-mail your questions about software/hardware development tools to:

  processor.tools.support@analog.com
- E-mail your questions about processors and DSPs to:

  processor.support@analog.com (world wide support)

  processor.china@analog.com (China support)
- Contact your Analog Devices sales office or authorized distributor. Locate one at:

  http://www.analog.com/adi-sales
- Send questions by mail to:

  Analog Devices, Inc.

  Three Technology Way

  P.O. Box 9106

  Norwood, MA 02062-9106 USA

Product Information

Product information can be obtained from the Analog Devices Web site.

Analog Devices Web Site

The Analog Devices Web site, http://www.analog.com, provides information about a broad range of products—analog integrated circuits, amplifiers, converters, and digital signal processors.

To access a complete technical library for each processor family, go to: http://www.analog.com/processors/technical_library The manuals selection opens a list of current manuals related to the product as well as a link to the previous revisions of the manuals. When locating your manual title, note a possible errata check mark next to the title that leads to the current correction report against the manual.

Also note, MyAnalog.com is a free feature of the Analog Devices Web site that allows customization of a Web page to display only the latest information about products you are interested in. You can choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. MyAnalog.com provides access to books, application notes, data sheets, code examples, and more.

Visit MyAnalog.com to sign up. If you are a registered user, just log on. Your user name is your e-mail address.

EngineerZone

EngineerZone is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your embedded processing and DSP design questions.

Use EngineerZone to connect with other DSP developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit http://ez.analog.com to sign up.

Supported Processors

The following is the list of Analog Devices, Inc. processors.

Blackfin+® (ADSP-BF7xx) Processors

The name *Blackfin+* refers to the enhanced fixed-point Blackfin core architecture featured by the ADSP-BF70x processor product line, which is a family of 16-bit embedded processors.

Blackfin® (ADSP-BF6xx/BF5xx) Processors

The name *Blackfin* refers to the fixed-point core architecture featured on the following processors: ADSP-BF5xx and ADSP-BF6xx.

SHARC® (ADSP-21xxx) Processors

The name *SHARC* refers to the high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-2116x, ADSP-2126x, ADSP-213xx, and ADSP-214xx. These processors can be used in speech, sound, graphics, and imaging applications.

SHARC+® (ADSP-SC5xx, ADSP-215xx) Processors

The name *SHARC+* refers to the enhanced high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-215xx/ADSP-SC5xx. The connected SHARC+ ADSP-SC5xx processors also contain an Arm® Cortex®-A5 core. These products can be used in speech, sound, graphics, and imaging applications.

The following is the list of Analog Devices, Inc. processors supported by the IAR Embedded WorkBench® development tools. For information about the IAR Embedded WorkBench product and software download, go to http://www.iar.com/en/Products/IAR-Embedded-Workbench .

Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

Example	Description
File > ***Close***	Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the ***Close*** command appears on the ***File*** menu).
`{this | that}`	Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as `this` or `that`. One or the other is required.
`[this | that]`	Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional `this` or `that`.
`[this, …]`	Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of `this`.
`.SECTION`	Commands, directives, keywords, and feature names are in text with `Letter Gothic` font.
`filename`	Non-keyword placeholders appear in text with italic style format.
NOTE:	***NOTE:*** For correct operation, ... A note provides supplementary information on a related topic. In the online version of this book, the word ***NOTE:*** appears instead of this symbol.
CAUTION:	***CAUTION:*** Incorrect device operation may result if ... ***CAUTION:*** Device damage may result if ... A caution identifies conditions or inappropriate usage of the product that could lead to undesirable results or product damage. In the online version of this book, the word ***CAUTION:*** appears instead of this symbol.
ATTENTION:	***ATTENTION:*** Injury to device users may result if ... A warning identifies conditions or inappropriate usage of the product that could lead to conditions that are potentially hazardous for devices users. In the online version of this book, the word ***ATTENTION:*** appears instead of this symbol.
Registers/Bits	All registers and bits in this manual are linked (clickable) to their respective descriptions in the "Register Descriptions" of each chapter.
Miscellaneous Conventions	Interrupt and internal signals are shown in all caps with no other formatting. For example the SPDIFn_RX or SCLK signal or the PKTE0_IRQ interrupt. An overbar denotes an active-low signal as in $\overline{\text{SYS\_FAULT}}$.

Register Documentation Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.

- Bits marked *X* have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved

NOTE: To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

Register description tables use the following conventions:

- Each bit's or bit field's access type appears beneath the bit number in the table in the form (read-access/write-access). The access types include:
  - R = read, RC = read clear, RS = read set, R0 = read zero, R1 = read one, Rx = read undefined
  - W = write, NW = no write, W1C = write one to clear, W1S = write one to set, W0C = write zero to clear, W0S = write zero to set, WS = write to set, WC = write to clear, W1A = write one action
- Many bit and bit field descriptions include enumerations, identifying bit values and related functionality. Unless otherwise indicated (with a prefix), these enumerations are decimal values.

1 Arm Cortex-A5 Subsystem

The ADSP-SC591/2/4 processor includes an Arm® Cortex-A5® core. The Arm Cortex-A5 processor is the smallest, lowest cost and lowest power Armv7 application processor. The A5 sub-system in the ADSP-SC591/2/4 processor includes a Floating-Point Unit, NEON Media Processing Engine, Generic Interrupt Controller and a Level 2 Cache Controller. The A5 also includes support for a L1-Cache sub-system and a full-fledged Memory Management Unit. The A5 implements the Armv7 architecture and runs 32-bit Arm instructions, 16-bit and 32-bit Thumb instructions, and 8-bit Java byte-codes in Jazelle state.

This document describes the Arm Cortex-A5 core and memory architecture used on the ADSP-SC591/2/4 processor, but does not provide detailed programming information for the Arm processor. For more information about programming the Arm processor, visit the Arm Information Center:

- http://infocenter.arm.com.

The applicable documentation for programming the Arm Cortex-A5 processor include:

- Cortex-A5 Technical Reference Manual, Revision: r0p1
- Cortex-A Series Programmer's Guide, Revision: r0p1
- Cortex-A5 NEON Media Processing Engine Technical Reference Manual, Revision: r0p1
- Cortex-A5 Floating-Point Unit Technical Reference Manual, Revision: r0p1
- CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision: r3p3
- PrimeCell Generic Interrupt Controller (PL390) Technical Reference Manual, Revision: r0p0

Cortex A5 Features

The Cortex-A5 subsystem has the following features.

- Thumb / Arm Instruction support
- L1- Instruction Cache and L1-Data Cache
- Floating Point Unit (FPU)
- NEON Media Processing Engine (NEON)

- Generic Interrupt Controller (GIC)
- Level 2 Cache Controller (L2CC)
- Memory Management Unit (MMU)

Functional Description

The following sections provide information on the function of the subsystem.

A5 Block Diagram

The following figure shows the primary blocks of the Cortex A5 subsystem. The performance increases with accesses to lower levels of memory as follows:

1. Level 1 – cache on-chip, separate data/code (highest)
2. Level 2 – cache on-chip, unified
3. Level 3 – memory external, (lowest)

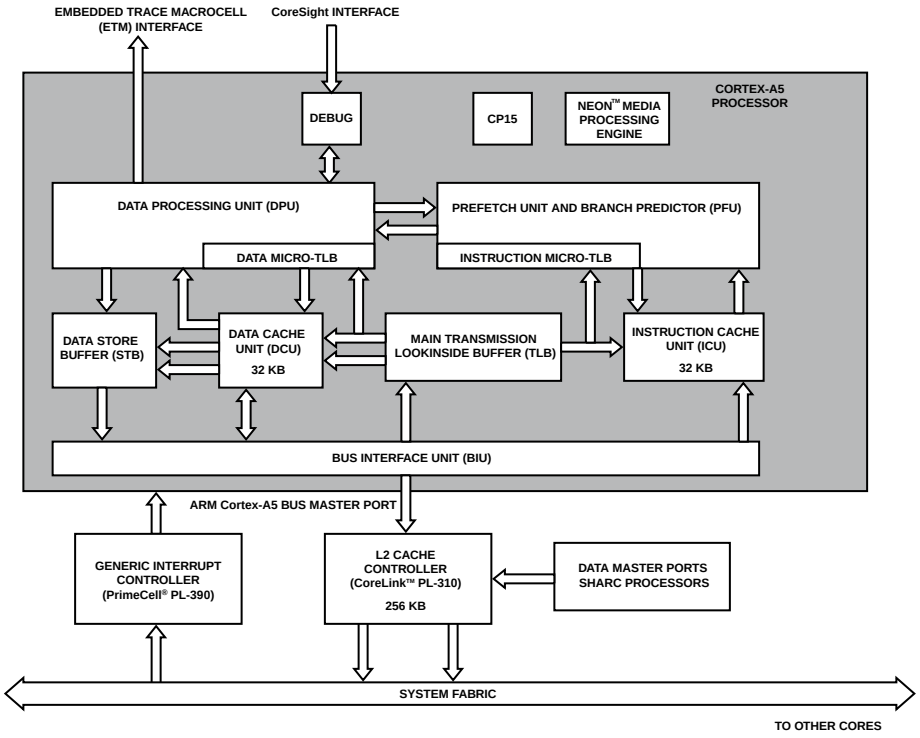

Figure 1-1: A5 Subsystem Block Diagram

Control Coprocessor (CP15)

The system control coprocessor, CP15, controls and provides status information for the functions implemented in the processor. The main functions of the system control coprocessor are:

- Overall system control and configuration
- MMU configuration and management
- Cache configuration and management
- System performance monitoring

All system architecture functions are controlled by reading or writing a general purpose processor register (Rt) from or to a set of registers (CRn) located within co-processor 15. The Op1, Op2, and CRm fields of the instruction can also be used to select registers or operations.

- MRC p15, Op1, Rt, CRn, CRm, Op2; read a CP15 register into an Arm register
- MCR p15, Op1, Rt, CRn, CRm, Op2; write a CP15 register from an Arm register

L1 Cache

The Cortex-A5 processor has separate instruction and data caches that run at Arm core clock speed. The caches have the following features:

- L1 data cache size 32 KB
- L1 instruction cache size 32 KB
- Each cache can be disabled independently, using the system control coprocessor
- Cache replacement policy is pseudo random
- Data cache is 4-way set-associative
- Instruction cache is 2-way set-associative
- The cache line length is eight words.
- On a cache miss, critical word first filling of the cache is performed.

Prefetch Unit (PFU)

The PFU implements a two-level prediction mechanism, comprising the following:

- A 256 entry branch pattern history table
- A four-entry BTAC
- A four-entry return stack

Memory Management Unit (MMU)

The Arm MMU is responsible for translating addresses of code and data from the virtual view of memory to the physical addresses in the real system. The translation is carried out by the MMU hardware and is transparent to the application. In addition, the MMU controls such things as memory access permissions, memory ordering and cache policies for each region of memory.

The MMU enables tasks or applications to be written in a way that requires them to have no knowledge of the physical memory map of the system, or about other programs that might be running simultaneously. This enables programs to use the same virtual memory address space. It also lets programs work with a contiguous virtual memory map, even if the physical memory is fragmented. This virtual address space is separate from the actual physical map of memory in the system. Applications are written, compiled and linked to run in the virtual memory space. Virtual addresses are those used by you, and the compiler and linker, when placing code in memory. Physical addresses are those used by the actual hardware system.

The first level MMU uses a Harvard design with separate micro TLB structures in the PFU for instruction fetches and in the DPU for data read and write requests. A miss in the micro TLB results in a request to the main unified TLB shared between the data and instruction sides of the memory system. The TLB consists of a 128-entry two-way set-associative RAM based structure. The TLB page-walk mechanism supports page descriptors held in the L1 data cache. The caching of page descriptors is configured globally for each translation table base register, TTBRx, in the system coprocessor, CP15.

Page table entries support:

- 16 MB super sections
- 1 MB sections
- 64 KB large pages
- 4 KB small pages

NOTE: Virtual memory translation tables are typically created by operating systems, and are often dynamically managed by the memory management layer. However, even a bare metal system can enable the MMU. For this, a flat mapping technique is used, where all virtual memory addresses shall be programmed exactly same as the physical memory addresses in the system.

NOTE: In order to use L1 data cache, the application has to enable the MMU, via coprocessor 15 in the Arm core. After the MMU and L1 data cache are enabled via CP15: SCTLR, the application can disable/enable cache for individual pages/sections.

L2 Cache

The Level 2 Cache Controller in the processor is a CoreLink Level 2 Cache Controller (L2C-310) from Arm and is clocked at SYSCLK speed. The addition of an on-chip secondary cache, also referred to as a level 2 or L2 cache, is a recognized method of improving the performance of Arm-based systems when significant memory traffic is generated by the processor. By definition a secondary cache assumes the presence of a Level 1 or primary cache, closely coupled or internal to the processor. The cache controller is a unified, physically addressed, physically tagged cache. It includes the following features:

- 256 KB total size
- Lockdown by Line/Way/Requester
- Fixed line length of 32 bytes, eight words or 256 bits

- Direct mapped to 8-way associativity (fixed)
- Prefetching capability
- Event monitoring
- Software option to enable exclusive cache configuration
- Additional Buffers:
  - Line Fill Buffers (LFBs)
  - Line Read Buffers (LRBs)
  - Eviction Buffers (EBs)
  - Store Buffers (STBs)
- TrustZone support, with the following features:
  - Non-Secure (NS) tag bit added in tag RAM and used for lookup in the same way as an address bit. The NS-tag bit is added in all buffers.
  - NS bit in Tag RAM used to determine security level of evictions to L3.
  - Restrictions for NS accesses for control, configuration, and maintenance registers to restrict access to secure data.
- Parity Support

NOTE: The L2CC address filtering registers should not be programmed by the user. Not retaining the reset values can give unpredictable results.

Sharing L2 Cache with SHARC+ Cores

The L2CC (PL310) supports two requester and two completer ports. The SHARC+ core can access the L2 cache without bank conflict versus the Cortex A5 core by programming the L2CC registers. The cache access is restricted to the address range: from `CMMR_L2CC_START` [31:0] to `CMMR_L2CC_END` [31:0]. For more information, see the *SHARC+ Core Programming Reference*.

NOTE: There is no guarantee for the data coherency between the A5 and SHARC+ cores.

NOTE: Programs should perform L2 cache write-back invalidation before changing the value of `CMMR_L2CC_START` and `CMMR_L2CC_END`.

Floating-Point Unit (FPU)

The Cortex-A5 FPU is a VFPv4-D16 implementation of the Armv7 floating-point architecture. It provides low cost high performance floating-point computation. The FPU supports all addressing modes and operations described in the *Arm Architecture Reference Manual*.

The features in the FPU are as follows.

- Support for single-precision and double-precision floating-point formats
- Support for conversion between half-precision and single-precision
- Support for Fused Multiply Accumulate (FMA) operations
- Normalized and denormalized data are all handled in hardware
- Trapless operation enabling fast execution

NeON

The Cortex-A5 NEON MPE extends the Cortex-A5 functionality to provide support for the Arm v7 Advanced SIMD v2 and Vector Floating-Point v4 (VFPv4) instruction sets. The Cortex-A5 NEON MPE supports all addressing modes and data-processing operations described in the *Arm Architecture Reference Manual*.

The Cortex-A5 NEON MPE features are:

- SIMD and scalar single-precision floating-point computation
- scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- SIMD 8, 16, 32, and 64-bit signed and unsigned integer computation
- 8 or 16-bit polynomial computation for single-bit coefficients
- Structured data load capabilities
- Large, shared register file, addressable as:
    - 32 32-bit S (single) registers
    - 32 64-bit D (double) registers
    - 16 128-bit Q (quad) registers
- The operations include:
    - Addition and subtraction
    - Multiplication with optional accumulation
    - Maximum or minimum value driven lane selection operations
    - Inverse square root approximation
    - Comprehensive data structure load instructions, including register-bank-resident table lookup

See the *Arm Architecture Reference Manual* for details of the extension register set.

Generic Interrupt Controller (GIC)

The GIC is an Arm architecture compliant System-on-Chip (SoC) peripheral. It is a high-performance, area-optimized interrupt controller. The GIC implements the Arm generic interrupt controller architecture. The GIC takes interrupts asserted at the system level and signals them to each connected processor as appropriate. The GIC has the following features.

- Registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors
- Support for the Arm architecture security extensions
- Support for enabling, disabling, and generating processor interrupts from hardware (peripheral) interrupt sources
- Support for generating software interrupts
- Support for interrupt masking and prioritization

Refer to GIC Overview for more information on the processor-specific configuration of GIC.

A5 Configurations

The following are the Cortex A5 and processor configurations.

A5 Configurations

Table 1-1: A5 Core Configuration

Core Feature	Comment
JAZELLE Support	Implemented
NEON Engine	Implemented
FPU	Implemented
Instruction cache size	32 KB
Data cache size	32 KB

A5 Configuration Signals

Table 1-2: A5 Configuration Signals

Configuration	A5 TRM Signal Name	Comment
Default Exception Handler Endianness	CFGEND	Little Endian
CPU ID field	CLUSTERID[3:0]	4'b0000
Disable Write access to some CP15 registers	CP15SDISABLE	Not Enabled
Default exception handling state	TEINIT	ARM Mode
Exception vectors' location at reset	VINITHI	start exception vectors at address 0x00000000

Table 1-2: A5 Configuration Signals (Continued)

Configuration	A5 TRM Signal Name	Comment
Disable invalidate entire data cache, instruction cache and TLB at reset	L1RSTDISABLE	Disabled
Enable the RAM interface clamps	CPURAMCLAMP	clamps not active

A5 Power Modes

Table 1-3: ARM Core Power Modes

Mode	Comment
Run mode	Supported
Standby mode	Supported
Dormant mode	Not Supported
Shutdown mode	Not Supported

L2CC Configuration Signals

Table 1-4: L2CC Configuration Signals

Configuration	L2CC TRM Signal Name	Comment
Associativity	ASSOCIATIVITY	8-Way
Cache controller cache ID	CACHEID[5:0]	0
Address filtering Enable out of reset	CFGADDRFILTEN	Enabled
Address filtering End Address out of reset	CFGADDRFILTEND[11:0]	0xFFF
Address filtering Start Address out of reset	CFGADDRFILTSTART[11:0]	0x201
Endian mode for accessing configuration registers out of reset	CFGBIGEND	Little-endian
Base address for accessing configuration registers	REGFILEBASE[19:0]	0x10000
Size of ways	WAYSIZE[2:0]	32 KB

L2CC Power Down Modes

Table 1-5: L2CC Power Down Modes

Mode	Comment
Run mode	Supported
Dynamic Clock Gating	Supported
Standby mode	Not Supported
Dormant mode	Not Supported

Table 1-5: L2CC Power Down Modes (Continued)

Mode	Comment
Shutdown mode	Not Supported

L2CC Configuration

Table 1-6: L2CC Configuration

Feature	Comment
Cache way size	32 KB
Associativity	8 Ways
Default RAM latencies	2 cycles
DATA RAM banking	Disabled
Completer port 1 present	Enabled
Requester port 1 present	Enabled
Parity logic	Enabled
Lock down by requester	Enabled
Lock down by line	Enabled
Address filtering	Enabled
Speculative reading	Disabled

2 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a master clock that runs at a frequency that is a multiple of the CLKIN input clock frequency. The PCU divides down the master clock to generate various system clocks and synchronization signals.

CGU Features

The CGU module supports the following features:

- Provides smooth transitions from the current clock condition to a new condition with PLL logic and executes the changes to clocks due to register programming.
- Provides PLL and clock domain status reporting for event management.
- Supports the capability to bypass the PLL for power savings.
- Software controlled dynamic power management allows control of the core clock frequency (f_{CCLK}).
- Controls clock gating of the core and system clocks.

NOTE: For more information about processor-specific CGU features, see the processor data sheet.

CGU Functional Description

The CGU generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers. The CGU provides the following functionality.

Change the PLL Clock Frequency

The CGU allows programs to change the PLL clock frequency by writing new values to bits in the control register. Any time the PLL relocks, the CGU aligns all core and system clocks.

Change Other Clock Frequencies

The CGU allows programs to change the CCLKn, SYSCLK, SCLKn, DCLK, and OCLK frequencies by writing values to the CGU_DIV register. Any time the clock frequency is changed, the OCLK, CCLKn, SYSCLK, DCLK, and SCLKn clocks exit the frequency change sequence aligned.

Perform Clock Alignment

The CGU can align all clocks by writing to the CGU_DIV register. This function aligns all PLL-based clocks.

For more information on these functions, see the CGU Programming Model section.

ADSP-2159x_SC591_SC592_SC594 CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

Table 2-1: ADSP-2159x_SC591_SC592_SC594 CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

CGU Definitions

DPM

The Dynamic Power Management module (DPM) works with the CGU to provide flexible power dissipation modes for the processor.

PCU

The PLL control unit (PCU) in the CGU controls PLL operations. The MMR registers of the CGU are implemented in the PCU.

PLL

The phase-locked loop (PLL) operates within the CGU.

RCU

The reset control unit (RCU) provides input to the CGU to manage clocks during processor reset.

CDU

The clock distribution unit distributes the clocks from the CGU to different clock domains

CGU

The clock generation unit (CGU) is comprised of the PLL and PCU. The CGU generates the clocks listed in the ***Clock Descriptions*** table.

Table 2-5: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1

CGU PLL Block Diagram

The ***CGU PLL Block Diagram*** provides a top-level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase/frequency detector (PFD), the charge pump, the loop filter and the voltage controlled oscillator (VCO). The VCO multiplies the `SYS_CLKIN0` or `SYS_CLKIN1` input to a higher frequency.

Additional configuration options are configured using the Clock Distribution Unit.

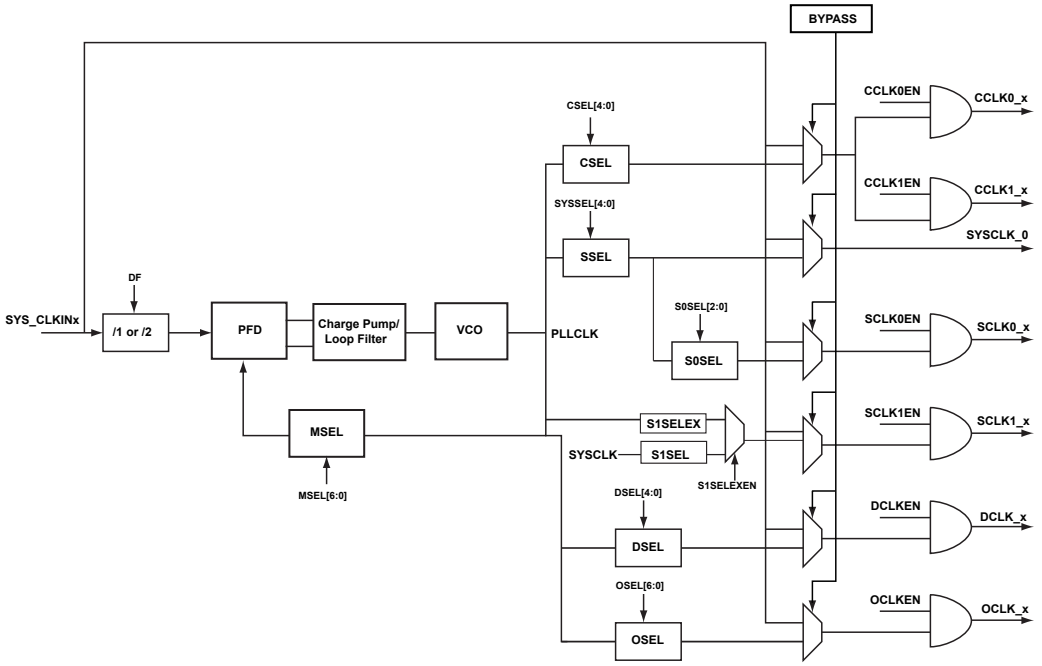

Figure 2-1: CGU PLL Block Diagram

CLKOUT Selections

The ***SYS_CLKOUT Generation*** figure is a conceptual representation of the CLKOUT module. Different clocks that originate from the CGU blocks are available on the SYS_CLKOUT output pin. The selection of the clock output on the SYS_CLKOUT pin is controlled by the `CGU_CLKOUTSEL.CLKOUTSEL` bit field. Most of the clock frequencies are divided with a fixed divider value, for example CGU0_SYSCLK0 has a fixed divider of 8 for the CLKOUT pin.

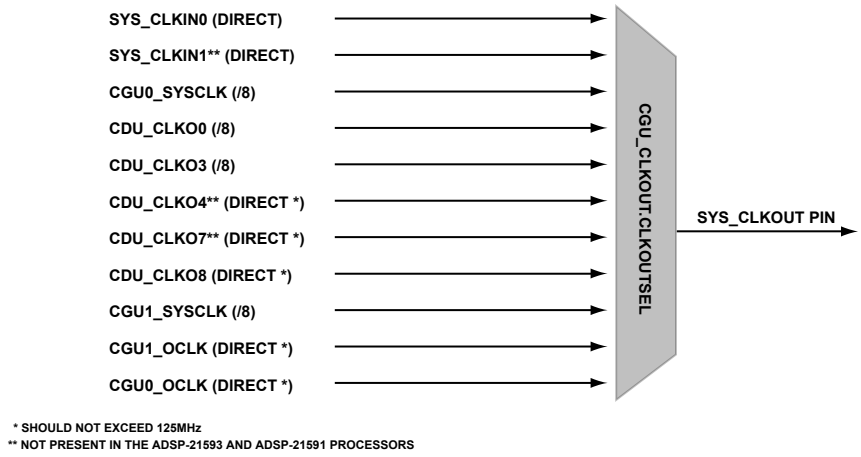

Figure 2-2: SYS_CLKOUT Generation

The BMODE pin affects the CLKOUT pins after a hardware reset is deasserted.

BMODE= 0 — When a hardware reset is deasserted, CGU0_OCLK/PLLCLK0 is selected to come out of the CLKOUT pin. The default value of OSEL and MSEL is the same. This functionality enables the user to verify PLL functionality by checking that the CLKOUT period is identical to CLKIN period.. While programming all values of the `CGU_CLKOUTSEL.CLKOUTSEL` bit field is possible, changing it to 0 (SYS_CLKIN) is not possible until and unless a non-zero value is first programmed to the the `CGU_CLKOUTSEL.CLKOUTSEL` bit field.

BMODE = (non zero) — When a hardware reset is deasserted, SYS_CLKIN is selected by default.

CGU Operating Modes

The CGU does not have configurable operating modes, but CGU operations affect the operating modes of other modules. Some CGU operation issues that affect operation of other modules include the following:

- The PLL of the CGU operates in either normal mode (CGU clock divisors applied) or bypass mode (CGU PLL is bypassed and clock divisors ignored).
- The SCB uses the CGU for clock synchronization across clock domains. For more information, see System Crossbars (SCB).
- The DPM uses the CGU for clock management as power state transitions occur. For more information, see the Dynamic Power Management (DPM) chapter.
- The CGU uses clock gating control to obtain flexible low-power modes.

CGU Power-up Sequence

See the product data sheet for exact power-up requirements. The processor is configured to come up in clock bypass mode. The programs is required to configure full speed clocks and safety monitors. `SYS_CLKIN0` or `SYS_CLKIN1`, and all supplies should be stable before the `SYS_HWRST` signal is deasserted.

CGU Event Control

The CGU generates an event or error for several different reasons. Events and errors are described in the following sections.

Events

After a frequency change, a CGU event indicates that the PLL has locked and clocks are synchronized. If a core was idled while changing frequencies, the CGU can use an event interrupt to break the core idle. While in active mode, a CGU event indicates that the PLL has locked.

CGU Errors

A CGU error occurs under following conditions:

- A write access to the `CGU_DIV`/`CGU_DIVEX` registers trigger an alignment sequence while the PLL is locked and is still aligning the clocks.

The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV/CGU_DIVEX registers.

- A change to the CGU_DIV/CGU_DIVEX registers occur while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV/CGU_DIVEX registers.

- A write access to the CGU_CTL.DF bit field occurs or a write access to the CGU_CTL.MSEL bit field occurs while the PLL is locking.

  The CGU_STAT.WDFMSERR bit state indicates this error. If this error occurs, wait until the PLL has finished locking, clear the error, and rewrite the desired value change.

- A write access to CGU_DIV.S1SEL when CGU_CTL.S1SELEXEN is enabled or a write access to CGU_DIVEX.S1SELEX when CGU_CTL.S1SELEXEN is disabled.

  A write access to CGU_DIV.S0SEL when is enabled or a write access to when is disabled.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV and CGU_DIVEX registers.

The CGU monitors changes to the following fields:

- SYSCLK Divisor – CGU_DIV.SYSSEL

CGU Generated Bus Errors

The CGU generates a bus error when a read or write transaction to an unused address within the CGU address range is attempted. It also generates a bus error when a misaligned access is made to a CGU register. In addition to the bus error, the CGU_STAT.ADDRERR bit is set. If a write to a write-protected CGU register is attempted, the CGU generates a bus error. In addition, the CGU_STAT.LWERR bit is set.

Oscillator Watchdog

The oscillator watchdog detects the absence of input clock transitions and provides a fault warning through the SYS_FAULT pin. To detect harmonic or subharmonic crystal oscillator behavior, the watchdog (under programmable control) also detects and reports input oscillator frequencies above and below the specified limits. Use an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters for this detection. Set the CGU_OSCWDCTL.MONDIS bit and clear the CGU_OSCWDCTL.FAULTEN bit to optionally disable all the input clock monitor and fault detection functions.

Set the CGU_OSCWDCTL.HODEN bit to enable harmonic oscillation detection. The CGU uses the CGU_OSCWDCTL.HODF bit field to indicate the desired lower fail limit (in MHz) for the harmonic oscillation detection. The upper limit is always twice the lower limit.

The ***HODF Settings for Different Input Clock Frequencies*** table shows the recommended values of the CGU_OSCWDCTL.HODF bit settings for different input clock frequencies.

Table 2-6: HODF Settings for Different Input Clock Frequencies

CGU_OSCWDCTL.HODF[5:0]	Subharmonic Frequency (MHz)	Nom. Lower Fail Limit (MHz)	Input Clock Frequency (MHz)	Nom. Upper Fail Limit (MHz)	Second Harmonic Frequency (MHz)
16	10	16	20	32	40
16	12.5	16	25	32	50
20	15	20	30	40	60

NOTE: Use a HODF value of 16 for frequency ranges greater than 20 MHz and less than 25 MHz. For frequency ranges greater than 25 MHz and less than 30 MHz, use a HODF value of 20.

The CGU uses the CGU_OSCWDCTL.BOUF (Bad Oscillator Upper Frequency limit) asynchronous control bit field to indicate the desired upper fail limit for the bad oscillation detection. Set the CGU_OSCWDCTL.BOUEN bit to enable upper-limit bad oscillation detection. A bad oscillation detection condition signals a fault before any processor operations occur. This detection occurs (even in bypass mode) whenever a clock frequency exceeds the specifications.

The CGU_OSCWDCTL.BOUF =0 operation starts with a target of 32 MHz and each additional LSB increases the frequency test limit by 2 MHz. For example:

Target Upper Frequency Limit = CGU_OSCWDCTL.BOUF × 2 MHz + 32 MHz

The CGU_STAT.OSCWDSTATFC status bits indicate the nature of the fault.

The ***Fault Map*** table shows the fault values.

Table 2-7: Fault Map

CGU_STAT.OSCWDSTATFC Bitfield Values	Fault Type
0	No Fault
1	No Input Clock
2	Subharmonic CLKIN
3	Harmonic CLKIN
4	No AUX_CLK
5	CLKIN > Upper Freq Limit (BOUF)
6	Reserved
7	Multiple Limit Faults

There is a priority to the faults given in the case of multiple fault errors. The highest priority is given to No Input clock followed by No AUX_CLK. The other three fault cases share the lowest priority. Multiple limit faults are asserted if more than one type of subharmonic CLKIN, harmonic CLKIN, or BOUF faults are observed.

NOTE: All the CGU_STAT.OSCWDSTATFC faults other than the absence of AUX_CLK (for example, CGU_STAT.OSCWDSTATFC =4) are not reliable and used for debug only.

Program and enable the OSCWDOG to match the actual crystal, before bringing the PLL out of bypass.

CGU Programming Model

The programming model for the CGU involves the various mode configuration techniques.

Configuring CGU Modes

Use the following procedures to configure the clocks and PLL.

NOTE: The program needs to clear the CGU_STAT.CLKSALGN bit before changing clocks. The following sequence is executed once, inside the application, after coming out of reset.

```
*pREG_CGU0_PLLCTL |= BITM_CGU_PLLCTL_PLLBPCL; // come out of bypass and enter
Full ON
while( (pADI_CGU0 ->STAT & 0xF) != 0x5 ) { } // poll
// now clocks are running with hardware default divisors.
// now program can change frequencies If desired the program can put the PLL
again into bypass.
```

Changing the Clock Frequencies

Applications change clock frequencies in two ways. The first way is modifying the PLL multiplication value by writing to the CGU_CTL register and the second is modifying the clock dividers by writing to the CGU_DIV register. Both actions have different implications even if the frequencies of the final clock are the same. Write accesses to change the CGU_CTL.DF or CGU_CTL.MSEL bit fields while the PLL is locking set the CGU_STAT.WDFMSERR error bit. The CGU_STAT.WDIVERR error bit is set when one of following accesses is attempted while the PLL is locked, but still aligning the clocks:

- A write access to the CGU_DIV/CGU_DIVEX to trigger an alignment sequence.
- A write access to the CGU_DIV/CGU_DIVEX to change the CGU_DIV.CSEL/, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL/CGU_DIVEX.S1SELEX bits.

Read-after-write accesses to these registers return the new value, even if the frequency of the clock change is still in-progress.

Modifying the PLL multiplier requires the PLL to relock. Once the PLL locks, the CGU synchronizes the clocks. Changes to the CGU_CTL.DF or CGU_CTL.MSEL bit field result in bypassing the PLL. By setting the CGU_CTL.WFI bit, programs force the PLL to wait for the core to return to the idle or reset state before the frequency changes. If necessary, clear the CGU_DIV.UPDT bit to avoid multiple clock alignment sequences. If the CGU_DIV register is not updated, the CGU uses the current values to determine the frequencies of the clock. It is the programs responsibility to guarantee that the new CGU_CTL.DF or CGU_CTL.MSEL and CGU_DIV/CGU_DIVEX combinations are legal.

Changing the PLL Clock Frequency

To change the phase-locked loop clock (*PLLCLK*) frequency, write new values to the CGU_CTL.MSEL field or CGU_CTL.DF field. Any time the PLL relocks, all core and system clocks are aligned.

1. Read CGU_STAT register and verify that:
    a. The CGU_STAT.PLLEN bit =1 (PLL enabled)
    b. The CGU_STAT.PLOCK bit =1 (PLL is not locking)
    c. The CGU_STAT.CLKSALGN bit =0 (clocks aligned)
2. Write the desired values to the clock divisor select fields of the CGU_DIV/CGU_DIVEX register with the CGU_DIV.UPDT bit =0.
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL fields.
    a. To change the PLL frequency while the core is idle, write to the CGU_CTL register with the CGU_CTL.WFI bit =1.
    b. To change the PLL frequency while the core is active, write to the CGU_CTL register with the CGU_CTL.WFI bit =0.

This sequence performs these actions:

1. Updates the corresponding CGU registers.
2. Bypasses the PLL.
3. Makes the PLL lock to the new values in the CGU_CTL.MSEL or CGU_CTL.DF fields.
4. Changes the clock frequencies.
5. Exits the PLL bypass with all clocks aligned.

When exiting the PLL bypass state, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.PLLEN bit =1, the CGU_STAT.PLOCK bit =1, the CGU_STAT.PLLBP bit =0, and the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.PLOCK bit, CGU_STAT.PLLBP bit, and CGU_STAT.CLKSALGN bit to discover when the PLL is locked and the clocks are aligned.

Changing the frequency of the PLL is allowed while the PLL is bypassed. In this case the new PLLCLK frequency is not used until the PLL is no longer bypassed.

Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies, write new values to CGU_DIV.CSEL or CGU_DIV.SYSSEL bits. The frequency change occurs only when the PLL is not bypassed. Any time the CCLKn or SYSCLK clock frequencies are changed, they exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.CSEL, CGU_DIV.SYSSEL, and CGU_DIV.OSEL bitfield values with the CGU_DIV.UPDT bit = 1 and/or, write to the CGU_DIVEX.S1SELEX field. This write updates the CGU_DIV register, changes the SCLKn and SYSCLK frequencies, and aligns the clocks. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.S0SEL or CGU_DIV.S1SEL bit fields while CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIV register is not modified.

Also, any write attempt to change the CGU_DIVEX.S1SELEX field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIVEX register is not modified.

Programming the SYSCLK frequency to a higher value than CCLKn also triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX register is not modified.

Writing to the CGU_DIV/CGU_DIVEX register is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the SYSCLK frequency is not supported and can have unpredictable results.

Changing the OCLK Frequency

To change the OCLK clock frequency, write a new CGU_DIV.OSEL bit value. Any time the OCLK clock frequency is changed, the OCLK, CCLKn, SYSCLK, and SCLKn clocks exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.OSEL value with the CGU_DIV.UPDT bit =1. This write updates the CGU_DIV register, changes the OCLK frequency, and aligns all clocks except OCLK.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.DSEL field while the CGU_STAT.CLKSALGN bit =1 (clock alignment in progress) triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX is not modified. When the clocks are aligned, a CGU event occurs.

Writing to the CGU_DIV.OSEL bit field is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Selecting SCLK1_0 Source

SCLK1_0 sources the SPDIF receiver clock. This can be sourced from PLL clock or SYSCLK0_0. Programming the CGU_DIVEX enables PLL clock as source (bypassing SYSCLK0_0 that continues to source other peripherals). When CGU_DIVEX is enabled, the PLL clock is divided from CGU_DIVEX register value.

Changing SCLK1_0 Frequencies

Complete the following steps to change the SCLK0 or SCLK1 frequency.

1. Read the CGU_STAT register. Verify that CGU_STAT.CLKSALGN = 0 (Clocks aligned).
2. Read the CGU_CTL register. Verify that the CGU_CTL.S1SELEXEN bit is set as needed. (These bits can only be modified when the PLL is bypassed).
3. Read the CGU_STAT register. Verify that the PLL is not bypassed. (If it is bypassed, see PLL Bypass and PLL Disable topic.)
4. Read the CGU_DIV register. Verify that the CGU_DIV.UPDT bit is set.
5. Write the desired CGU_DIVEX.S1SELEX value to the CGU_DIVEX registers .

Aligning All Clocks

To align the clocks, write 1 to the CGU_DIV.ALGN bit. The frequency can also be changed, if necessary. The clocks aligned include:

- CCLKn
- SYSCLK
- SCLKn
- DCLK
- OCLK

1. Read the CGU_STAT register to verify that CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write 1 to the CGU_DIV.ALGN bit. All other fields can change.

   ADDITIONAL INFORMATION: This write does not alter the CGU_DIV/CGU_DIVEX register unless one of the clock-select fields is modified. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write to the CGU_DIV/CGU_DIVEX register intended to align clocks or to change a clock select field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error. In this case, the CGU_DIV/CGU_DIVEX register is not modified.

Writing 1 to the CGU_DIV.ALGN bit has no effect while the processor is in active (PLL bypassed) mode.

Shutting Off CCLKn from Another Controller

CCLKn can be shut off to save power when it is not in use.

1. Disable interrupts to core n.
2. Set the RCU_SIDIS.SI[n] bit to disable the interfaces of core n in order to:
    a. Stop DMA accesses to its L1
    b. Stop memory accesses to core 0
    c. Stop accesses to MMRs
3. Test the RCU_SISTAT.SI[n] bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
4. Set the CGU_CCBF_DIS.CCBF0 bit to disable the CCLKn buffer.
5. Check the CGU_CCBF_STAT.CCBF0 bit.

If the CGU_CCBF_STAT.CCBF0 bit is set, continue.

Reenable CCLKn From Another Controller

1. Clear the CGU_CCBF_DIS.CCBF0 to enable CCLKn.
2. Check the CGU_CCBF_STAT.CCBF0 bit.
    a. If the CGU_CCBF_DIS.CCBF0 bit is cleared, continue
3. Clear the RCU_SIDIS.SI[n] bit. The core deasserts its acknowledge signal in response to the RCU_SYSRST0signal. This operation clears the RCU_SISTAT.SI[n] bit.

Valid Clock Multiplier Settings

Processor operations depend on valid settings in the CGU_CTL and CGU_DIV registers. These registers control the clock multiplier and divisor values. Set these registers such that the minimum and maximum clocks specified in the data sheet are not violated. All other clock specifications in the data sheet must also be adhered to for correct operation of the processor.

PLL Bypass and PLL Disable

Writing 1 to the CGU_PLLCTL.PLLBPST bit tells the PLL to apply OSC_CLKIN clock to CCLK, SYSCLK, SCLK0, SCLK1, DCLK (PLL Bypass), and OCLK outputs. Writing 1 to the CGU_PLLCTL.PLLBPCL bit tells the PLL to exit its PLL Bypass state and make all output clocks align and transition to their programmed frequencies.

The PLL can be disabled by clearing the CGU_PLLCTL.PLLEN bit while in the bypass state. If necessary, clock buffers can be disabled.

CCLK0 clock can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_CCBF_DIS register.

To determine which core clock buffers were disabled since the last read, software reads the CGU_CCBF_STAT register. The SCLK0, SCLK1, DCLK and OCLK clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_SCBF_DIS register. Software cannot disable SYSCLK.

ADSP-2159x Specific Information

The processor has two system crystal oscillators and two system CGU units to provide the clocks to the system. However, the ADSP-21593 and ADSP-21591 processors have one system crystal oscillator. Both of the CGUs come up in bypass mode out of reset.

CGU0 is the main CGU which provides most of the clocks including CCLK0, SYSCLK (SYSCLK_0), SCLK0 (SCLK0_0), and SCLK1 (SCKL1_0) to the system buses, infrastructure, and most of the peripherals. The rest of the clock outputs from the two CGUs can be routed to a specific peripheral in the system. For details, refer to the Clock Distribution Unit (CDU).

NOTE: The frequency ratio of the core clock to SYSCLK is 2:1.

The frequency ratios of SYSCLK to SCLK0 are 6:1, 4:1 or 2:1.

The processor does not support any other frequency ratio.

ADSP-2159x_SC591_SC592_SC594 CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

Table 2-8: ADSP-2159x_SC591_SC592_SC594 CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register

Table 2-8: ADSP-2159x_SC591_SC592_SC594 CGU Register List (Continued)

Name	Description
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

Core Clock Buffer Disable Register

The CGU_CCBF_DIS register controls each core's clock buffer to determine if the CCLK is enabled.

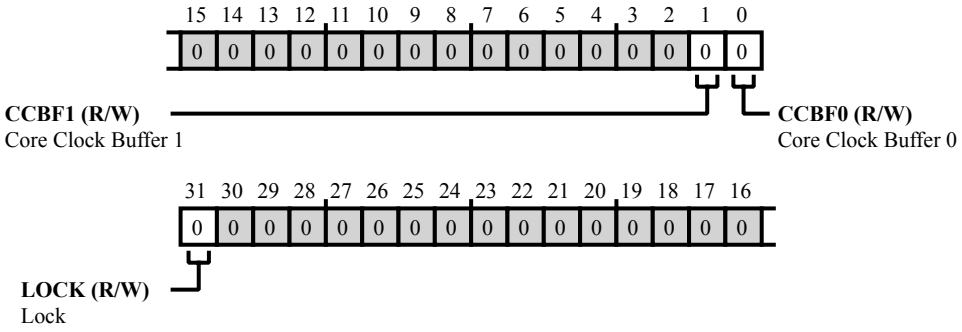

Figure 2-3: CGU_CCBF_DIS Register Diagram

Table 2-9: CGU_CCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If set (=1) the CGU_CCBF_DIS.LOCK bit locks the CGU_CCBF_DIS register.	
		0	Unlock register
		1	Lock register
1 (R/W)	CCBF1	Core Clock Buffer 1. The CGU_CCBF_DIS.CCBF1 bit enables (=0) or disables (=1) CCLK1s buffer.	
0 (R/W)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_DIS.CCBF0 bit enables (=0) or disables (=1) CCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

Core Clock Buffer Status Register

The CGU_CCBF_STAT register shows which core clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_CCBF_STAT.CCBF0 bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

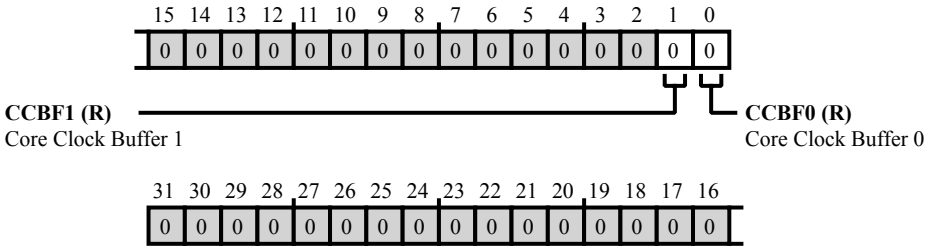

Figure 2-4: CGU_CCBF_STAT Register Diagram

Table 2-10: CGU_CCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	CCBF1	Core Clock Buffer 1. The CGU_CCBF_STAT.CCBF1 bit reports the status of the CGU_CCBF_DIS.CCBF1 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
0 (R/NW)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_STAT.CCBF0 bit reports the status of the CGU_CCBF_DIS.CCBF0 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

CLKOUT Select Register

The CGU_CLKOUTSEL selects the signal that the CGU drives through the CLKOUT multiplexer.

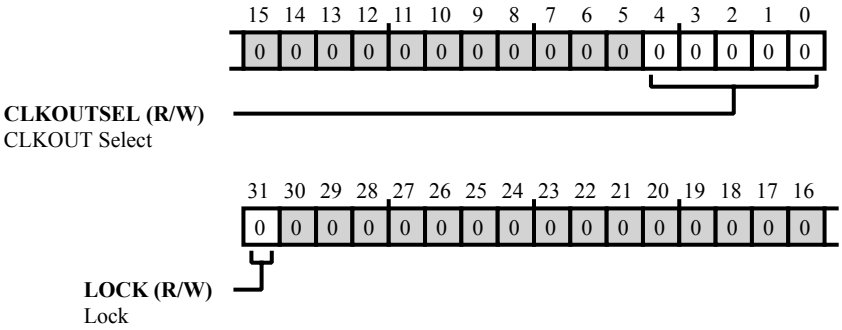

Figure 2-5: CGU_CLKOUTSEL Register Diagram

Table 2-11: CGU_CLKOUTSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CLKOUTSEL.LOCK bit is set, the CGU_CLKOUTSEL register is read only (locked).	
		0	Unlock
		1	Lock
4:0 (R/W)	CLKOUTSEL	CLKOUT Select. The CGU_CLKOUTSEL.CLKOUTSEL selects the signal that the CGU drives through the CLKOUT pin multiplexer.	
		0	CLKIN0
		1	CLKIN1
		2	PLLTOP0.SYSCLKO

		11	Reserved
		12	Reserved
		13	Reserved
		14	PLLTOP0.SCLK1
		15	Reserved
		16	PLLTOP0.SCLK0
		17	Reserved
		18	Reserved
		19	GND

Control Register

The CGU_CTL controls the clock generation divisors for SYS_CLKIN and the PLL. Read after write accesses to the CGU_CTL register returns the new value even if the clock's frequency change is still in progress.

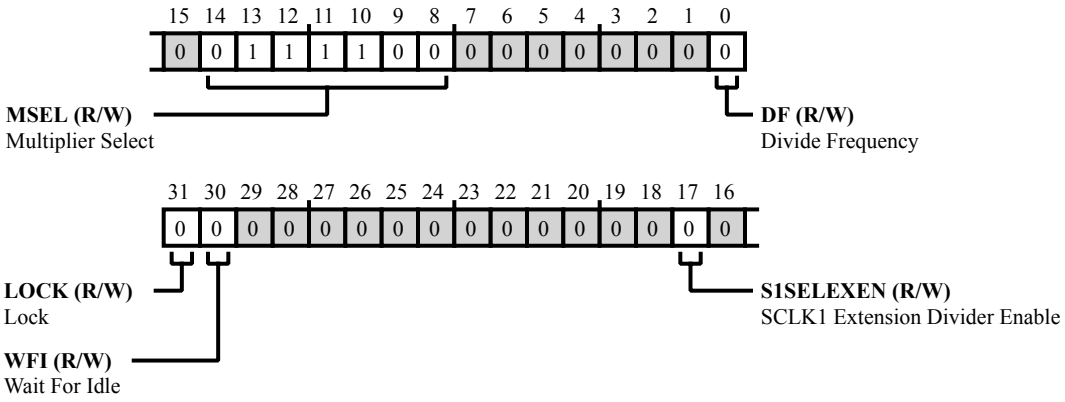

Figure 2-6: CGU_CTL Register Diagram

Table 2-12: CGU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CTL.LOCK bit is set, the CGU_CTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	WFI	Wait For Idle. Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the CGU_CTL.MSEL and the CGU_CTL.DF bit values results in bypassing the PLL. The CGU_CTL.WFI bit forces the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of changes to the CGU_CTL.MSEL or CGU_CTL.DF bits. Write accesses to the CGU_CTL to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking sets the CGU_STAT.WDFMSERR bit.	
		0	Update Immediately
		1	Wait for Idle

Table 2-12: CGU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	S1SELEXEN	SCLK1 Extension Divider Enable. The `CGU_CTL.S1SELEXEN` directs the CGU to select S1SELEX instead of S1SEL. This bit can only be updated when the PLL is bypassed.	
		0	Selects SYSCLK to SCLK1 Divider
		1	Selects PLLCLK to SCLK1 Divider
14:8 (R/W)	MSEL	Multiplier Select. The `CGU_CTL.MSEL` bit field selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL Where the value of MSEL is between 1 and 127.	
		0	MSEL = 128
		1-127	MSEL = 1 to 127
0 (R/W)	DF	Divide Frequency. The `CGU_CTL.DF` bit selects whether or not the CLKIN input is divided by two before being passed to the PLL.	
		0	Pass OSC_CLKIN to PLL
		1	Pass OSC_CLKIN/2 to PLL

Clocks Divisor Register

The CGU_DIV register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the CGU_DIV register returns the new value even if the clock's frequency change is still in progress.

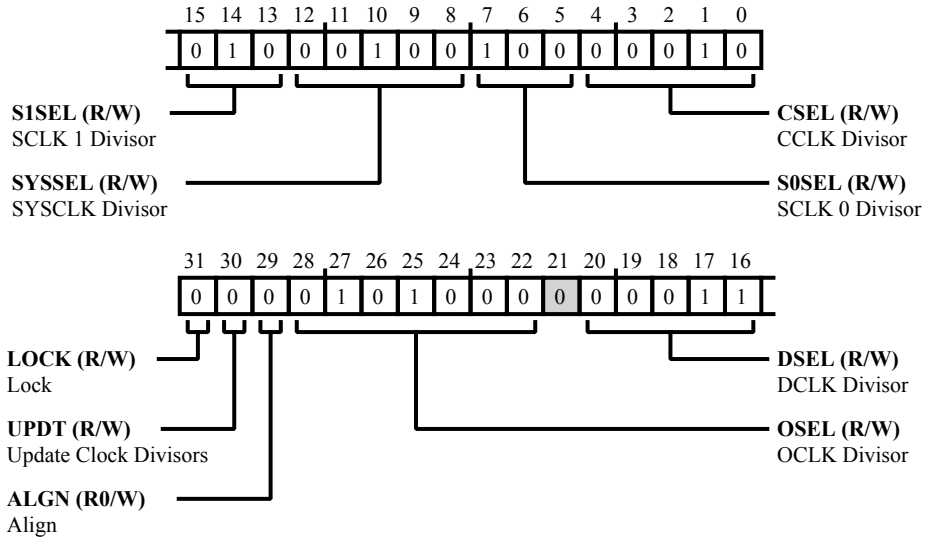

Figure 2-7: CGU_DIV Register Diagram

Table 2-13: CGU_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_DIV.LOCK bit is set, the CGU0_DIV and CGU0_DIVEX registers are read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	UPDT	Update Clock Divisors. The CGU_DIV.UPDT controls whether the CGU drives new CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and CGU_DIV.OSEL values to PLL after CGU_DIV register update.	
		0	No PLL Update
		1	Drive Updated SEL Values to PLL

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R0/W)	ALGN	Align. The CGU_DIV.ALGN directs the CGU to align the PLL-based clocks. The divisor selections (CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and/or CGU_DIV.OSEL) do not have to change.	
		0	No Action
		1	Align PLL Clocks
28:22 (R/W)	OSEL	OCLK Divisor. The CGU_DIV.OSEL selects the divisor in the OCLK equation: OCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.OSEL Where the value of CGU_DIV.OSEL is between 1 and 127.	
		0	OSEL = 128
		1-127	OSEL = 1 to 127
20:16 (R/W)	DSEL	DCLK Divisor. The CGU_DIV.DSEL selects the divisor in the DCLK equation: DCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.DSEL Where the value of CGU_DIV.DSEL is between 1 and 31.	
		0	DSEL = 32
		1-31	DSEL = 1 to 31
15:13 (R/W)	S1SEL	SCLK 1 Divisor. The CGU_DIV.S1SEL selects the divisor in the SCLK1 equation: SCLK1 frequency = (SYSCLK frequency) / CGU_DIV.S1SEL Where the value of CGU_DIV.S1SEL is between 1 and 7.	
		0	S1SEL = 8
		1-7	S1SEL = 1 to 7
12:8 (R/W)	SYSSEL	SYSCLK Divisor. The CGU_DIV.SYSSEL selects the divisor in the SYSCLK equation: SYSCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.SYSSEL Where the value of CGU_DIV.SYSSEL is between 1 and 31.	
		0	SYSSEL = 32
		1-31	SYSSEL = 1 to 31

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:5 (R/W)	S0SEL	SCLK 0 Divisor. The CGU_DIV.S0SEL selects the divisor in the SCLK0 equation: SCLK0 frequency = (SYSCLK frequency) / CGU_DIV.S0SEL Where the value of CGU_DIV.S0SEL is between 1 and 7.	
		0	S0SEL = 8
		1-7	S0SEL = 1 to 7
4:0 (R/W)	CSEL	CCLK Divisor. The CGU_DIV.CSEL bit field selects the divisor in the CCLK equation: CCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.CSEL Where the value of CGU_DIV.CSEL is between 1 and 31.	
		0	CSEL = 32
		1-31	CSEL= 1 to 31

DIV Register Extension

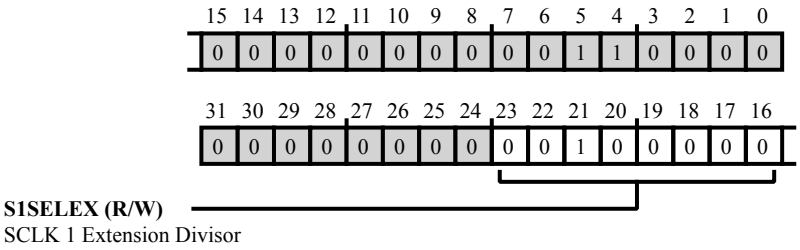

Figure 2-8: CGU_DIVEX Register Diagram

Table 2-14: CGU_DIVEX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/W)	S1SELEX	SCLK 1 Extension Divisor. The `CGU_DIVEX.S1SELEX` selects the divisor in the SCLK1EX equation: SCLK1EX frequency = (PLLCLK frequency) / `CGU_DIVEX.S1SELEX` Where the value of `CGU_DIVEX.S1SELEX` is between 1 and 255.	
		0	S1SELEX = 256
		1-255	S1SELEX = 1 to 255

Oscillator Watchdog Register

The CGU_OSCWDCTL register configures the CGU to allow the detection of the absence of input clock transitions and provides a fault warning via the SYS_FAULT pin. The CGU_OSCWDCTL register also detects and reports input oscillator frequencies above and below specified limits, in order to specifically detect harmonic or sub-harmonic crystal oscillator behavior. This detection is achieved by using an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters.

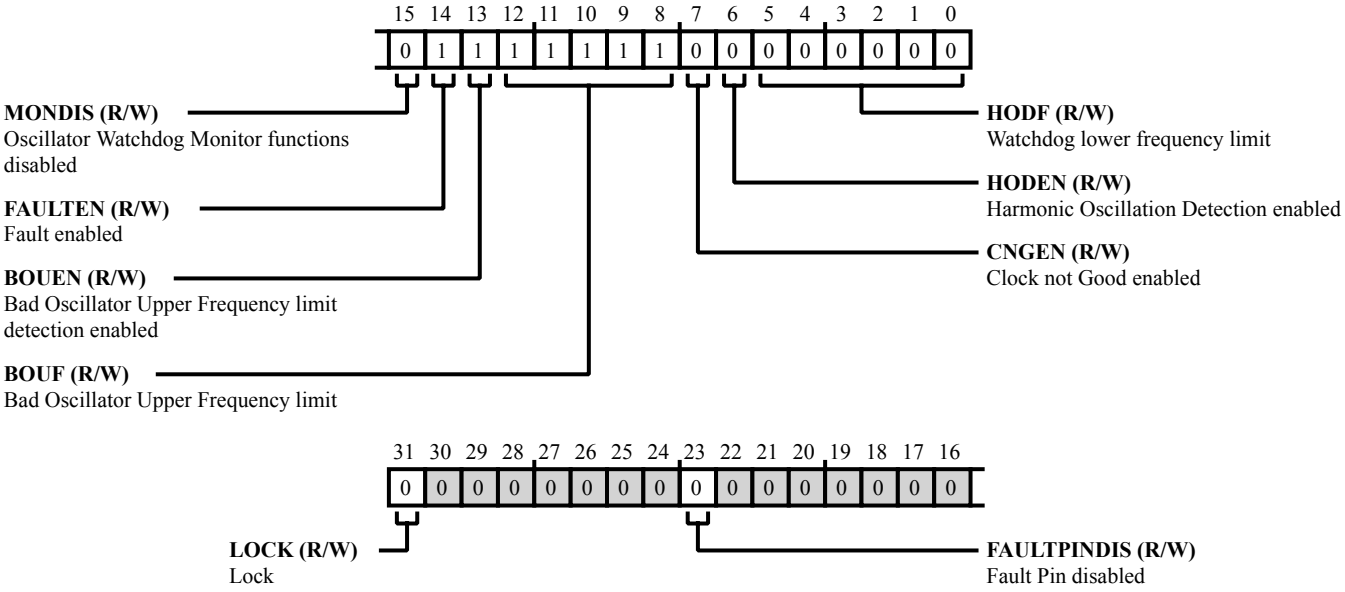

Figure 2-9: CGU_OSCWDCTL Register Diagram

Table 2-15: CGU_OSCWDCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	LOCK	Lock.
23 (R/W)	FAULTPINDIS	Fault Pin disabled. The CGU_OSCWDCTL.FAULTPINDIS bit disables pin fault detection.
15 (R/W)	MONDIS	Oscillator Watchdog Monitor functions disabled. The CGU_OSCWDCTL.MONDIS bit disables all the input clock monitor and fault detection functions.
14 (R/W)	FAULTEN	Fault enabled. The CGU_OSCWDCTL.FAULTEN bit enables fault detection.
13 (R/W)	BOUEN	Bad Oscillator Upper Frequency limit detection enabled. The CGU_OSCWDCTL.BOUEN bit enables upper limit bad oscillation detection.

Table 2-15: CGU_OSCWDCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12:8 (R/W)	BOUF	Bad Oscillator Upper Frequency limit. The `CGU_OSCWDCTL.BOUF` bits indicate the desired upper fail limit for the bad oscillation detection.
7 (R/W)	CNGEN	Clock not Good enabled. The `CGU_OSCWDCTL.CNGEN` bit enables the detection of an oscillator watchdog clock fault.
6 (R/W)	HODEN	Harmonic Oscillation Detection enabled. The `CGU_OSCWDCTL.HODEN` bit enables harmonic oscillation detection.
5:0 (R/W)	HODF	Watchdog lower frequency limit. The `CGU_OSCWDCTL.HODF` bit field is used to indicate the desired lower fail limit for the harmonic oscillation detection in MHz.

PLL Control Register

The CGU_PLLCTL register contains bits that enable and disable the PLL as well as control its function.

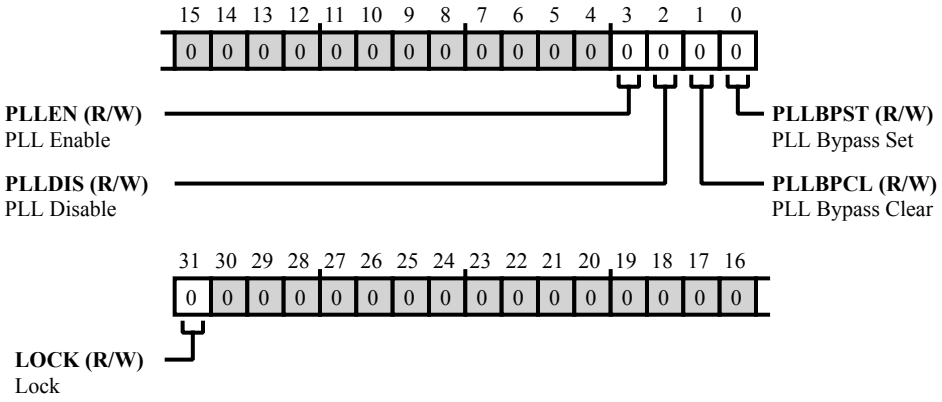

Figure 2-10: CGU_PLLCTL Register Diagram

Table 2-16: CGU_PLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting (=1) the CGU_PLLCTL.LOCK bit locks access to the CGU_PLLCTL register.	
		0	Unlock register
		1	Lock register
3 (R/W)	PLLEN	PLL Enable. Setting (=1) the CGU_PLLCTL.PLLEN bit enables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Enable PLL
2 (R/W)	PLLDIS	PLL Disable. Setting (=1) the CGU_PLLCTL.PLLDIS bit disables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Disable PLL
1 (R/W)	PLLBPCL	PLL Bypass Clear. Setting (=1) the CGU_PLLCTL.PLLBPCL bit takes the PLL out of bypass mode. Check the CGU_STAT.PLLBP bit to verify that the action is complete.	
		0	No action
		1	Exit bypass mode

Table 2-16: CGU_PLLCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PLLBPST	PLL Bypass Set. Setting (=1) the `CGU_PLLCTL.PLLBPST` bit bypasses the PLL and all the clocks run on CLKIN. Check the `CGU_STAT.PLLBP` bit to verify that the action is complete.	
		0	Use PLL
		1	Bypass PLL

Revision ID Register

The CGU_REVID register reports the version of the CGU.

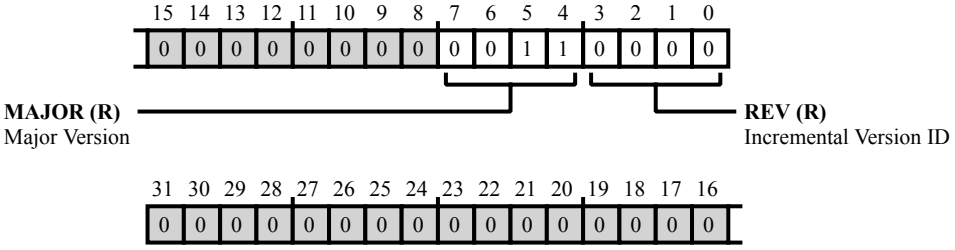

Figure 2-11: CGU_REVID Register Diagram

Table 2-17: CGU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version.
3:0 (R/NW)	REV	Incremental Version ID.

System Clock Buffer Disable Register

The CGU_SCBF_DIS register controls each system's clock buffer to determine if the SCLKn buffer is enabled.

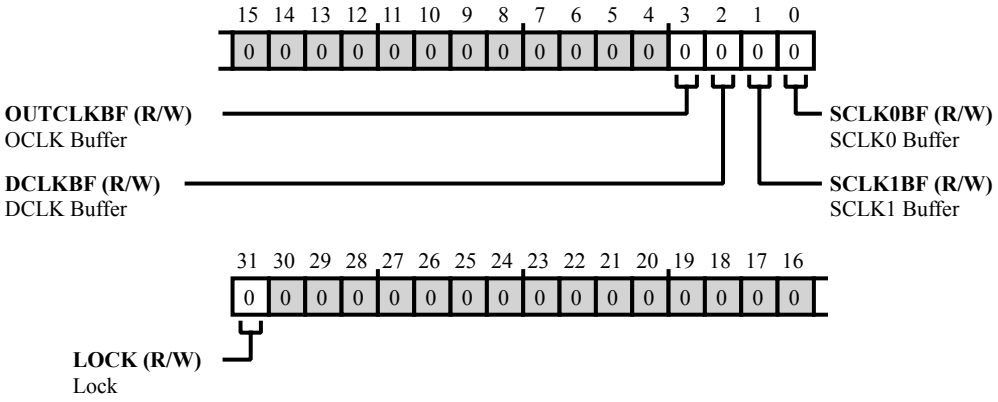

Figure 2-12: CGU_SCBF_DIS Register Diagram

Table 2-18: CGU_SCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. The CGU_SCBF_DIS.LOCK bit allows writes to the CGU_SCBF_DIS register when cleared (=0) or blocks writes if set (=1) and the SPU_CTL.GLCK bit is set.	
		0	Unlock register
		1	Lock register
3 (R/W)	OUTCLKBF	OCLK Buffer. The CGU_SCBF_DIS.OUTCLKBF bit enables (=0, default) or disables (=1) OCLKs buffer.	
		0	Enable buffer
		1	Disable buffer
2 (R/W)	DCLKBF	DCLK Buffer. The CGU_SCBF_DIS.DCLKBF bit enables (=0, default) or disables (=1) DCLKs buffer.	
		0	Enable buffer
		1	Disable buffer

Table 2-18: CGU_SCBF_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SCLK1BF	SCLK1 Buffer. The `CGU_SCBF_DIS.SCLK1BF` bit enables (=0, default) or disables (=1) SCLK1s buffer.	
		0	Enable buffer
		1	Disable buffer
0 (R/W)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_DIS.SCLK0BF` bit enables (=0, default) or disables (=1) SCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

System Clock Buffer Status Register

The CGU_SCBF_STAT register shows which system clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_SCBF_STAT.SCLK0BF bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

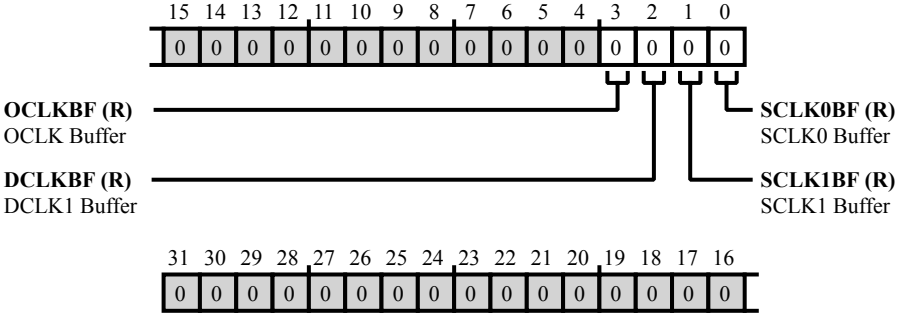

Figure 2-13: CGU_SCBF_STAT Register Diagram

Table 2-19: CGU_SCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	OCLKBF	OCLK Buffer. The CGU_SCBF_STAT.OCLKBF bit reports the status of the CGU_SCBF_DIS.OUTCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
2 (R/NW)	DCLKBF	DCLK1 Buffer. The CGU_SCBF_STAT.DCLKBF bit reports the status of the CGU_SCBF_DIS.DCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
1 (R/NW)	SCLK1BF	SCLK1 Buffer. The CGU_SCBF_STAT.SCLK1BF bit reports the status of the CGU_SCBF_DIS.SCLK1BF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Table 2-19: CGU_SCBF_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_STAT.SCLK0BF` bit reports the status of the `CGU_SCBF_DIS.SCLK0BF` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Status Register

The CGU_STAT register reflects the PLL status and errors detected during the PLL configuration. This register may be cleared asynchronously by a reset signal from the RCU module. All bits---except those defined as W1C (write-1-to-clear)---are read only.

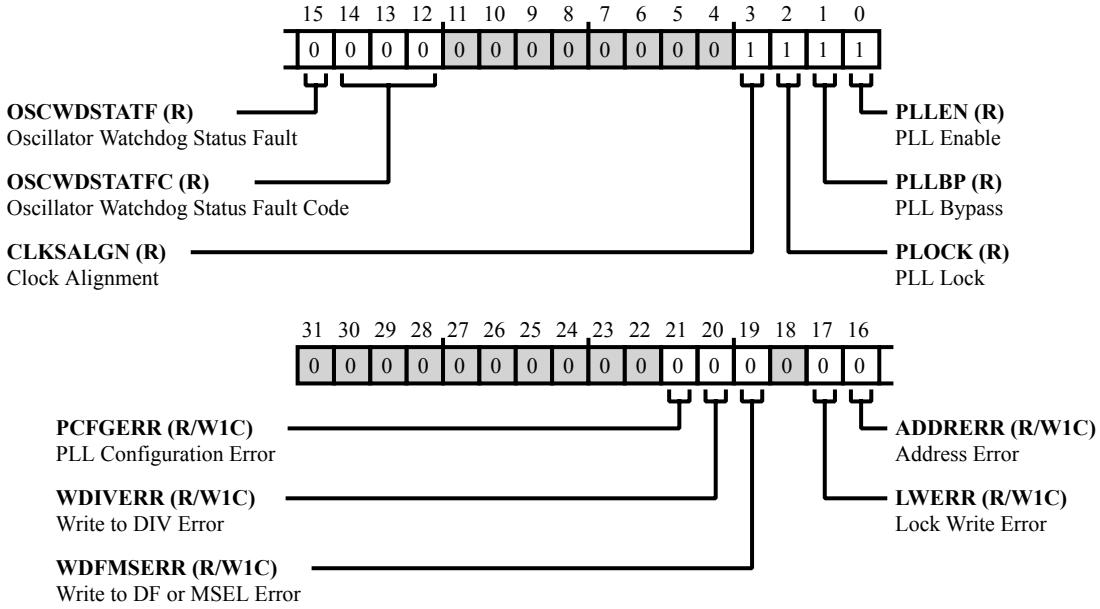

Figure 2-14: CGU_STAT Register Diagram

Table 2-20: CGU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PCFGERR	PLL Configuration Error. If the CGU_PLLCTL.PLLBPST and the CGU_PLLCTL.PLLBPCL bits are set (=1) simultaneously or the CGU_PLLCTL.PLLDIS bit was set (=1) in full-on mode or while trying to enter full-on mode (CGU_PLLCTL.PLLBPCL =1), the CGU_STAT.PCFGERR bit triggers the bus error.	
		0	No Error
		1	Configuration Error

Table 2-20: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W1C)	WDIVERR	Write to DIV Error. The CGU_STAT.WDIVERR bit indicates a write access to the CGU_DIV register (to trigger an alignment sequence or to change the CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL bit values) while the PLL is locked, but still aligning the clocks. Read after write accesses to the CGU_STAT and CGU_DIV registers return the new value even if the clock frequency change is still in progress.	
		0	No Error
		1	Write DIV Error
19 (R/W1C)	WDFMSERR	Write to DF or MSEL Error. The CGU_STAT.WDFMSERR bit indicates a write access to the CGU_CTL register to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking.	
		0	No Error
		1	Write DF/MSEL Error
17 (R/W1C)	LWERR	Lock Write Error. The CGU_STAT.LWERR bit indicates an attempt to write to write-protected (locked) CGU registers. The CGU issues a bus error for this condition.	
		0	No Error
		1	Lock Write Error
16 (R/W1C)	ADDRERR	Address Error. The CGU_STAT.ADDRERR bit indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The CGU issues a bus error for this condition.	
		0	No Error
		1	Address Error
15 (R/NW)	OSCWDSTATF	Oscillator Watchdog Status Fault. The CGU_STAT.OSCWDSTATF bit indicates a fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	Fault
14:12 (R/NW)	OSCWDSTATFC	Oscillator Watchdog Status Fault Code. The CGU_STAT.OSCWDSTATFC bit field indicates the nature of the fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	No Input Clock

Table 2-20: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Subharmonic CLKIN
		3	Harmonic CLKIN
		4	No AUX_CLK
		5	CLKIN > Upper Frequency Limit (BOUF)
		6	Reserved
		7	Multiple Limit Faults
3 (R/NW)	CLKSALGN	Clock Alignment. The CGU_STAT.CLKSALGN bit indicates whether a clock alignment sequence is in progress. This bit is set when clocks alignment is required by changes to CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, or CGU_DIV.OSEL. The CGU_STAT.CLKSALGN bit is cleared when clocks are aligned. Note that (after a PLL frequency change in active state) the CGU_STAT.CLKSALGN bit may indicate that clocks are not aligned even though the clocks are aligned (all clocks are aligned and running at CLKIN frequency).	
		0	Clocks are Aligned
		1	Clocks not Aligned (alignment in progress)
2 (R/NW)	PLOCK	PLL Lock. The CGU_STAT.PLOCK bit indicates whether the PLL is locked. This bit is set when the PLL locks (PLL lock counter end-of-count). The CGU_STAT.PLOCK bit is cleared when requested PLL frequency change (for PLL reset, PLL disable-to-enable transition, or a change to the CGU_CTL.MSEL or CGU_CTL.DF values) is in progress.	
		0	PLL not Locked (PLL frequency change in progress)
		1	PLL Locked
1 (R/NW)	PLLBP	PLL Bypass. The CGU_STAT.PLLBP bit indicates whether the PLL is bypassed. The default value for the CGU_STAT.PLLBP bit is determined by the bypass strap pin.	
		0	PLL not Bypassed
		1	PLL Bypassed
0 (R/NW)	PLLEN	PLL Enable. The CGU_STAT.PLLEN bit indicates whether the PLL is enabled.	
		0	Disabled
		1	Enabled

Time Stamp Counter 32 LSB Register

The CGU_TSCOUNT0 register address is used to read the CoreSight time stamp counter LSB 32-bit (bits [31:0]) value.

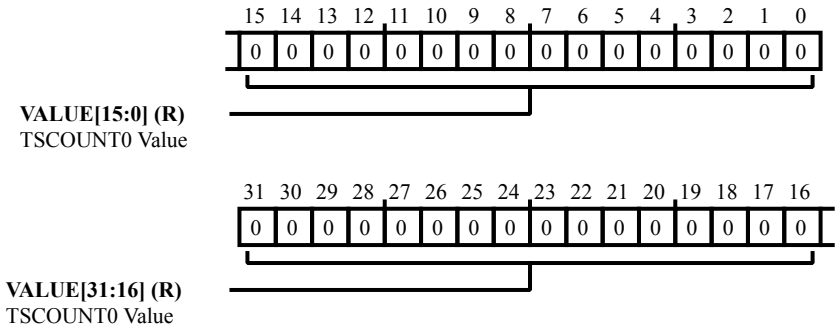

Figure 2-15: CGU_TSCOUNT0 Register Diagram

Table 2-21: CGU_TSCOUNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	TSCOUNT0 Value. The CGU_TSCOUNT0.VALUE bit field holds the time stamp counter 32 LSBs.

Time Stamp Counter 32 MSB Register

The CGU_TSCOUNT1 register address is used to read the CoreSight time stamp counter MSB 32-bit (bits [63:32]) value.

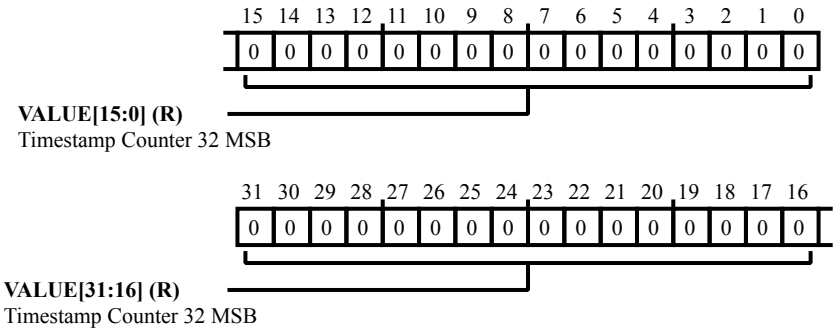

Figure 2-16: CGU_TSCOUNT1 Register Diagram

Table 2-22: CGU_TSCOUNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Timestamp Counter 32 MSB. The CGU_TSCOUNT1.VALUE bit field holds the time stamp counter 32 MSBs.

Time Stamp Control Register

The CGU_TSCTL register controls the operation of the CoreSight time stamp counter.

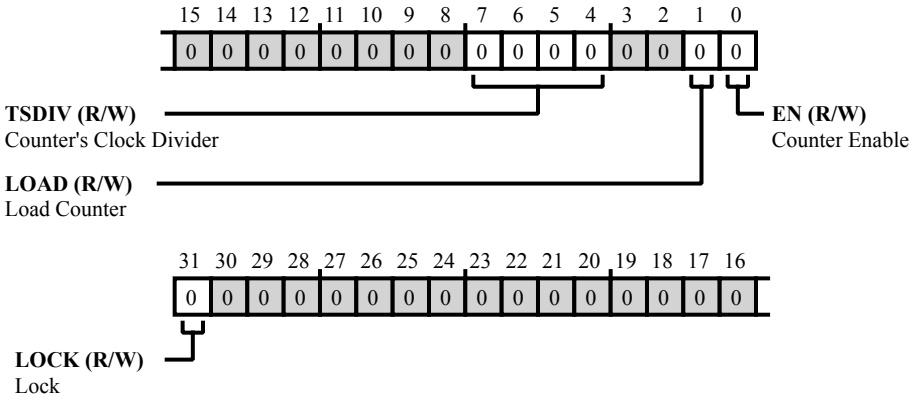

Figure 2-17: CGU_TSCTL Register Diagram

Table 2-23: CGU_TSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting the CGU_TSCTL.LOCK bit locks this register.	
		0	Unlock
		1	Lock
7:4 (R/W)	TSDIV	Counter's Clock Divider. The CGU_TSCTL.TSDIV bit field divides SYSCLK by 2^{TSDIV}.	
		0-15	Divides SYSCLK by 2^{TSDIV}
1 (R/W)	LOAD	Load Counter. Writing one to the CGU_TSCTL.LOAD bit causes CoreSight time stamp counter to be loaded from the CGU_TSVALUE0 and CGU_TSVALUE1 registers.	
		0	Always read as "0"
0 (R/W)	EN	Counter Enable. The CGU_TSCTL.EN bit enables or disables the CoreSight time stamp counter.	
		0	Counter Disabled
		1	Counter Enabled

Time Stamp Counter Initial 32 LSB Value Register

The CGU_TSVALUE0 register holds the least significant bits (bits [31:0]) value that is initially loaded to the Core-Sight time stamp counter.

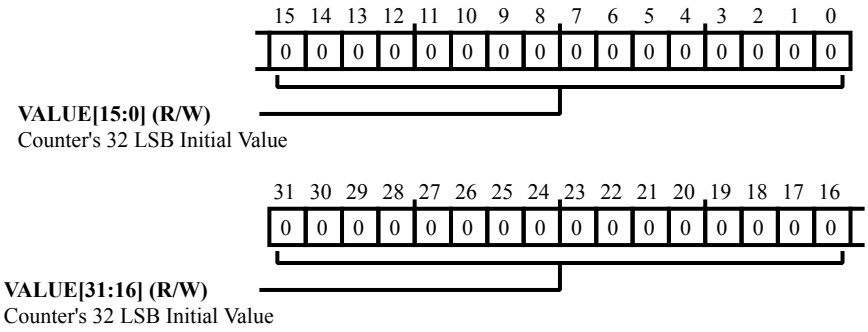

Figure 2-18: CGU_TSVALUE0 Register Diagram

Table 2-24: CGU_TSVALUE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's 32 LSB Initial Value. The CGU_TSVALUE0.VALUE bit field holds the LSBs value that is initially loaded to the CoreSight time stamp counter.

Time Stamp Counter Initial MSB Value Register

The CGU_TSVALUE1 register holds the most significant bits (bits [63:32]) value that is initially loaded to the CoreSight time stamp counter.

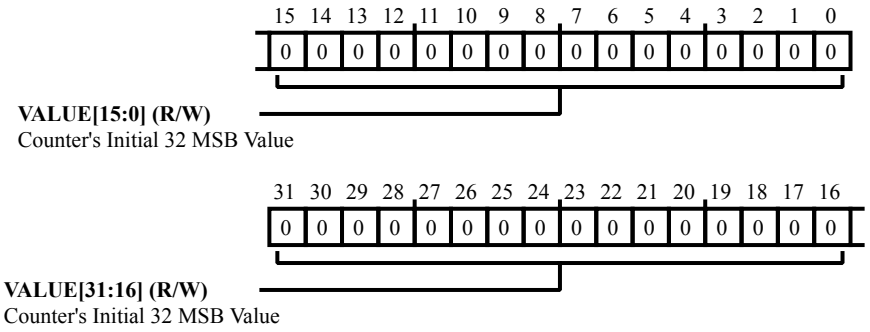

Figure 2-19: CGU_TSVALUE1 Register Diagram

Table 2-25: CGU_TSVALUE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's Initial 32 MSB Value. The CGU_TSVALUE1.VALUE bit field holds the MSBs value that is initially loaded to the CoreSight time stamp counter.

3 Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of multiplexors that select clocks originated from up to four different clock sources. These sources are different clocks that are generated from the CGUs. The multiplexors are configured by software. All clocks multiplexors have up to four different sources. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor.

CDU Features

The CDU modules supports the following features:

- Generation of up to 13 output clocks
- Output clock buffers that can be disabled by software
- Each multiplexor has four input clocks
- Multiplexors that are configured by writing to configuration registers (`CDU_CFG[n]`)
- Clocks originated in CGU0 that are selected by default
- A CDU status register (`CDU_STAT`) that indicates a configuration change is in-progress

CDU Functional Description

The CDU functions as a set of software-configurable multiplexors that select clocks from different sources.

CDU Block Diagram

The ***CDU Block Diagram*** figure shows the functional blocks within the CDU. As shown in the figure, the CDU takes different clocks generated by the CGU blocks and provides flexibility to route any clock from possible options to the output CDU clocks. The output clocks from the CDU are connected to specific targets such as the DDR module. All of the targets are clocked through the CDU output clocks rather than being directly clocked by CGU clocks.

This configuration provides the flexibility to meet the specific clock requirements of the different modules in the system (such as the core, DDR, or SPI module) without compromising the clocking of other modules. Such a flexibility is not possible with a single CGU in the system. With two CGUs:

- Each CGU has its own set of clock multipliers and dividers, providing a greater number of orthogonal clocks than possible with a single CGU.
- The `CDU_CLKINSEL.CGU1` bit determines the input for CGU1.

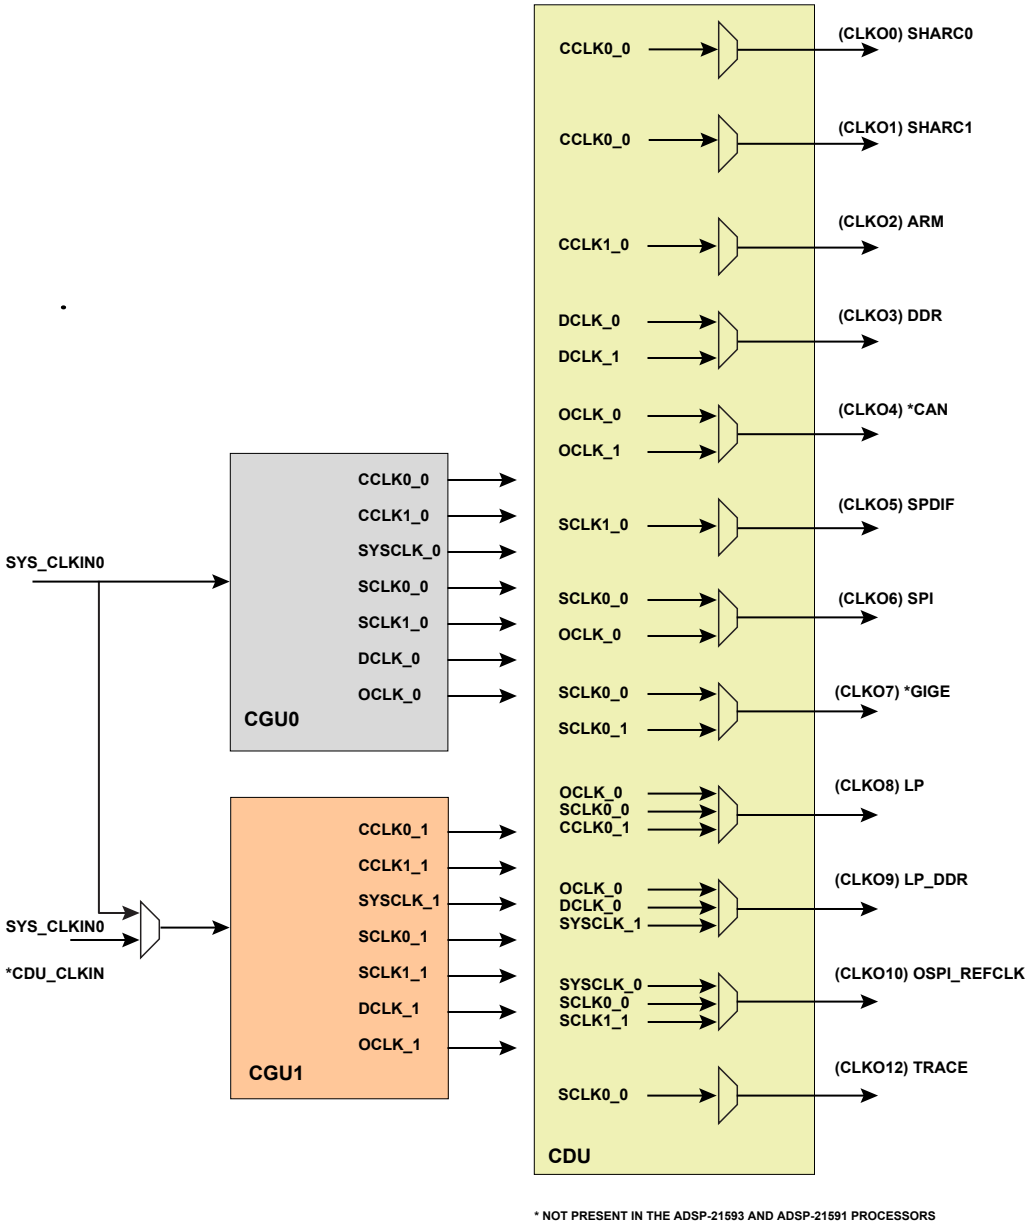

Figure 3-1: CGU/CDU Block Diagram

The DDR is clocked from the DCLK (DCLK_0 and DCLK_1) from CGU0 or CGU1. This configuration provides the flexibility to program the DDR with frequencies orthogonal to the core clock frequencies.

CDU Definitions

The ***Clock Descriptions*** table provides a brief description of the clocks supported by the processor.

Table 3-1: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CDU_CLKOn	Clocks that come out of the CDU module and go to different blocks

CDU Clock Configuration Options

The ***CDU Targets*** table provides information about clock source and destination options.

Table 3-2: CDU Targets

CDU0 Input				CDU0 Output	Target
IN0_CLKOn	IN1_CLKOn	IN2_CLKOn	IN3_CLKOn		
CCLK0_0	N/A	N/A	N/A	CLKO0	SHARC0 and corresponding accerators
CCLK0_0	N/A	N/A	N/A	CLKO1	SHARC1 and corresponding accerators
CCLK1_0	N/A	N/A	N/A	CLKO2	ARM
DCLK_0	DCLK_1	N/A	N/A	CLKO3	DDR

Table 3-2: CDU Targets (Continued)

CDU0 Input				CDU0 Output	Target
IN0_CLKOn	IN1_CLKOn	IN2_CLKOn	IN3_CLKOn		
OCLK_0	OCLK_1	N/A	N/A	CLKO4*	CAN
SCLK1_0	N/A	N/A	N/A	CLKO5	SPDIF
SCLK0_0	OCLK_0	N/A	N/A	CLKO6	SPI
SCLK0_0	SCLK0_1	N/A	N/A	CLKO7*	GIGE
OCLK_0	SCLK0_0	CCLK0_1	N/A	CLKO8	LP
OCLK_0	DCLK_0	SYSCLK_1	N/A	CLKO9	LP_DDR
SYSCLK_0	SCLK0_0	SCLK1_1	N/A	CLKO10	OSPI_REFCLK
SCLK0_0	N/A	N/A	N/A	CLKO12	TRACE

* Clock is not present in the ADSP-21591 and ADSP-21593 processors

NOTE: CLKO11 is used internally by the processor and is not user configurable.

CDU Programming Model

The CDU_CFG[n] registers are a system configuration resource. These registers are accessed by a system configuration routine that also handles the configuration of other system modules. Writes to a CDU_CFG[n] register must occur when there is not a CDU_CLKOn configuration change in progress. If a CGUn inputs are selected, that CGUn configuration must be completed first.

Changing the PLL and Clock Frequency

1. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN =1 (enabled)
   - CGU_STAT.PLOCK =1 (PLL is not locking)
   - CGU_STAT.CLKSALGN =0 (clocks aligned)
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit cleared (= 0).
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL bits.
   - To change the PLL frequency while all cores are idle, set the CGU_CTL.WFI bit (=1).
   - To change the PLL frequency while the cores are active, clear the CGU_CTL.WFI bit (=0).
4. Read the CGU_STAT register. Verify that:

- CGU_STAT.PLLEN = 1 (enabled)
- CGU_STAT.PLOCK = 1 (not locking)
- CGU_STAT.CLKSALGN = 0 (clocks aligned)

5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register. Verify that the CDU_STAT.CLKO0 (no CLKOn configuration change in progress).
7. Write to the CDU_CLKINSEL register to select the CGU's CLKIN input clock.
8. Write to the CDU_CFG[n].SEL bit to select the clock source (the CDU_CFG[n].EN bit should =1.)
9. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.

CLKOn is reconfigured.

Changing the Clock Frequency

Use the following procedure to change a clock frequency.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit = 1.
3. Read the CGU_DIV registers to verify that the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bit values are correct.
4. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN = 0 (clocks aligned).
5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register.
7. Write to the CDU_CFG[n].SEL bit to select the clock source (CDU_CFG[n].EN = 1).
8. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.
9. Verify that the CDU_STAT.CLKO0 = 0.

ADSP-2159x_SC591_SC592_SC594 CDU Register Descriptions

Clock Distribution Unit (CDU) contains the following registers.

Table 3-3: ADSP-2159x_SC591_SC592_SC594 CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_CLKINSEL	CLKIN Select
CDU_REVID	CDU Revision ID
CDU_STAT	CDU Status

CDU Configuration

The CDU_CFG[n] registers control the configuration of the clock multiplexors. CDU0_CFG[n] corresponds to output clock CDU_CLKO[n].

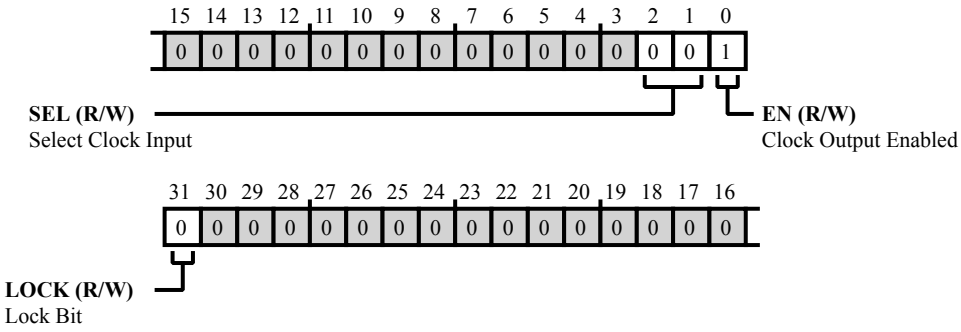

Figure 3-2: CDU_CFG[n] Register Diagram

Table 3-4: CDU_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
2:1 (R/W)	SEL	Select Clock Input.	
		0	IN0_CLKOn Selected
		1	IN1_CLKOn Selected
		2	IN2_CLKOn Selected
		3	IN3_CLKOn Selected
0 (R/W)	EN	Clock Output Enabled. The CDU_CFG[n].EN bit enables clock output.	

CLKIN Select

The CDU_CLKINSEL register controls the configuration of the CLKIN multiplexors. One bit is assigned to each CGU in the system. This bit selects either CLKIN0 or CLKINn CGUn inputs.

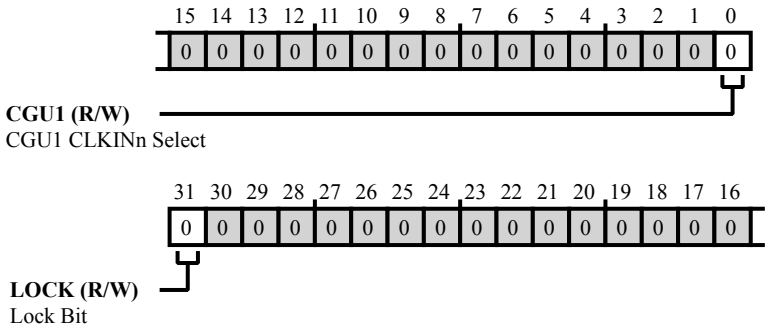

Figure 3-3: CDU_CLKINSEL Register Diagram

Table 3-5: CDU_CLKINSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
0 (R/W)	CGU1	CGU1 CLKINn Select. The CDU_CLKINSEL.CGU1 bit drives CDU_CLKIN_SEL[0] to CGU1.	
		0	Selects CLKIN0
		1	Selects CLKIN1

CDU Revision ID

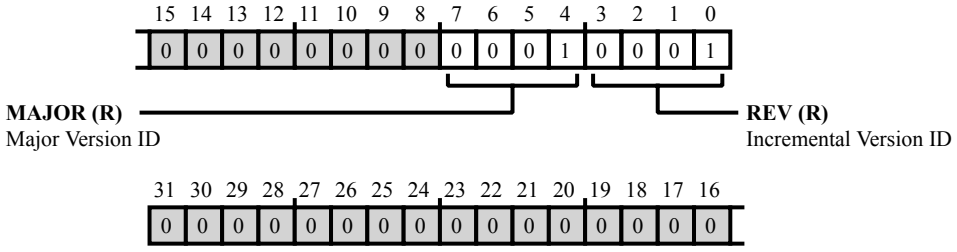

Figure 3-4: CDU_REVID Register Diagram

Table 3-6: CDU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

CDU Status

The CDU_STAT register reflects the status a change in the configuration of the clock muxes.

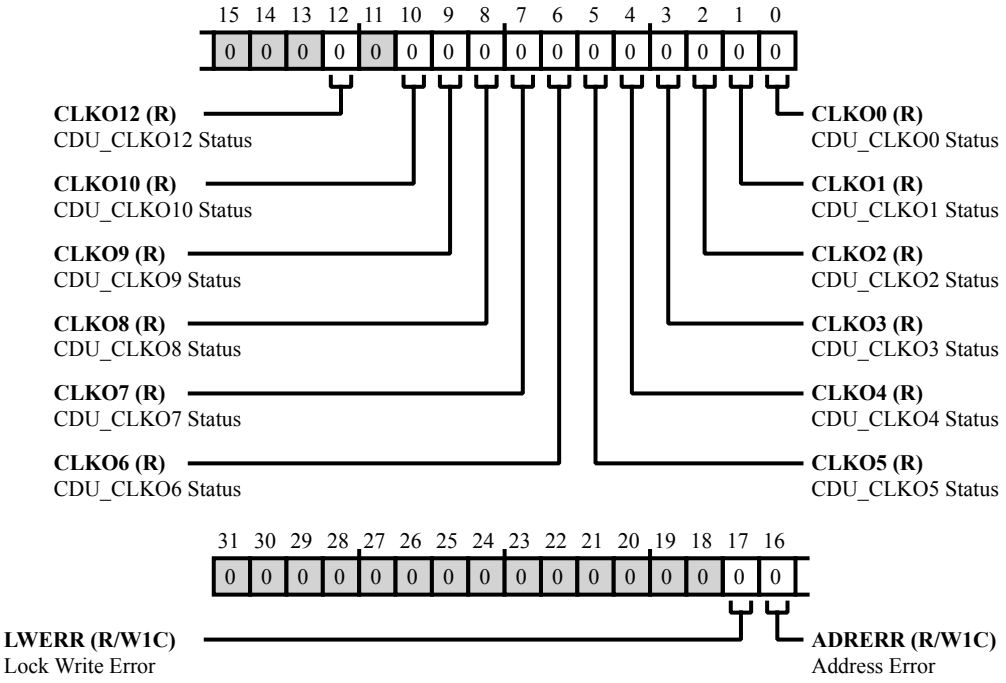

Figure 3-5: CDU_STAT Register Diagram

Table 3-7: CDU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The CDU_STAT.LWERR bit indicates a lock error where write transactions try to access write protected registers.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The CDU_STAT.ADRERR bit indicates an address error where read or write transactions try to access unimplemented addresses or accesses are non-aligned.	
		0	No Address Error
		1	Address Error
12 (R/NW)	CLKO12	CDU_CLKO12 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress

4 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power-saving modes.

DPM provides facility for shutting down clocks for various peripherals. Shutting down peripheral's clocks is considered a power saving feature. To support peripheral clock gating functionality, DPM_PER_DIS0 and DPM_PER_DIS1 are available in the DPM module. The bits in these registers need to be programmed to shut off the clocks to peripherals that are not used in an application to save clock switching power.

DPM Features

The DPM allows programs to control the power mode of the processor as follows.

- Permits operation of multiple, external wake-up sources

DPM Functional Description

The DPM can be programmed to transition between power modes.

ADSP-2159x_SC591_SC592_SC594 DPM Register List

A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

Table 4-1: ADSP-2159x_SC591_SC592_SC594 DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

CGU

Acronym for the clock generation unit (CGU), which is comprised of the PLL and PCU

DPM

Acronym for the dynamic power management (DPM) controller.

Full-on mode

The normal operating mode in which all clock domains are derived from the PLL.

PCU

Acronym for the PLL control unit (PCU).

PLL

Acronym for the phase-locked loop (PLL).

RCU

Acronym for the reset control unit (RCU).

DPM Operating Modes

The DPM includes several operating modes. The modes are:

- Reset
- Full-on

Reset State

Reset is the initial state of the processor and is the result of a hardware or software triggered event. The DPM itself does not trigger entering reset. The external SYS_HWRST pin or the RCU triggers entering reset. The DPM responds to reset by transitioning to its default state.

From Reset, the DPM always transitions to PLL Bypassed state.

Full-on Mode

Full-on mode is the default state of the DPM after Reset.

In full-on mode, the processor can reach its maximum clock rate and power dissipation can be at its highest.

DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. The DPM generates bus errors when a misaligned access to a register occurs. It also generates errors when an attempt is made to access unused DPM address space or a write-protected register.

DPM Events

The DPM event interrupt is triggered when any bit in the DPM_STAT register is set, indicating that an enabled wake-up was asserted. The DPM event interrupt stays active until the user clears any bits that are set in the DPM_STAT register.

DPM Errors

The DPM generates a bus error when a read or write transaction is attempted to an unused address within the DPM address range. It also generates a bus error when a misaligned access is made to a DPM register. In addition to the bus error, the DPM sets the DPM_STAT.ADDRERR bit.

If a write to a write-protected DPM register is attempted, the DPM generates a bus error. In addition, the DPM sets the DPM_STAT.LWERR bit.

DPM Programming Model

The ***DPM_PER_DIS0 Register Mapping*** and ***DPM_PER_DIS01Register Mapping*** tables show the module clocks and the corresponding peripheral. The DPM_PER_DIS0 and DPM_PER_DIS0 registers are used to shut off the clock to each peripheral if it is not required by the application.

Table 4-2: DPM0_PER_DIS0 Register Mapping

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
FIR0	cclk	Not Required	1	0
IIR0	cclk	Not Required	1	1
DAI0	sclk0 sclk1 sysclk	Single Flop Single Flop Not Required	2 2 1	5
DAI1	sclk0 sclk1 sysclk	Single Flop Single Flop Not Required	2 2 1	6

		0	Reserved
		1	Full-On
		2	Reserved
		3	Reserved
		4-15	Reserved

5 Reset Control Unit (RCU)

Reset is the initial state of the processor at power-on or the run-time state of any core, as controlled by another core in the device via the RCU or as a a result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system hardware reset results with only the host core being released from reset and ready to boot (Core 0 on the devices ADSP-SC5x, Core 1 on the ADSP-215xx devices).

The following table shows the cores that are released from reset. Exiting a Core n only reset starts with this Core n being ready to execute the code from the software vector registers (`RCU_SVECT0` , `RCU_SVECT2`).

Additional information on reset and booting can be found in the *Boot ROM and Booting the Processor* chapter.

Product	Core Released from Reset by RCU
ADSP-SC59x	Core 0
ADSP-2159x	Core 1

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset). While core resets and software system resets are controlled directly in the RCU, hardware resets can come from the TRU, SEC, or CGU Oscillator Watchdog.

RCU Features

The RCU module supports the following features:

- Hardware reset through the $\overline{\texttt{SYS\_HWRST}}$ pin
- Software system reset through the RCU control (`RCU_CTL`) register
- Hardware system reset through:
  - TRU module
  - SEC module (System Fault Unit)

- A clock not good reset state (safe state of chip under reset) from the Oscillator Watchdog.
- Core reset through RCU Core Reset Output (RCU_CRCTL) register

RCU Functional Description

This section provides information on the function of RCU module.

Hardware reset using SYS_HWRST pin

Asserting the $\overline{\text{SYS\_HWRST}}$ pin resets all functional units, except the real time clock (RTC) (if present).

Hardware reset through RCU

The RCU can perform a full system reset which can be initiated through hardware blocks like the SEC, the TRU, and the oscillator watchdog.

Software reset using RCU registers

Setting the RCU_STAT.SWRST bit issues a software reset for all system units except the RTC module and RCU_BCODE, RCU_CRCTL and RCU_STAT registers.

Core reset RCU registers

A core can be individually reset by software, or by setting the RCU_CRCTL.CR[n] bit.

ADSP-2159x_SC591_SC592_SC594 RCU Register List

The Reset Control Unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints exist (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way), and these differences define how reset signals are generated. Reset signals propagate through all functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

Table 5-1: ADSP-2159x_SC591_SC592_SC594 RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register

RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

ADSP-2159x_SC591_SC592_SC594 RCU Trigger List

Table 5-2: ADSP-2159x_SC591_SC592_SC594 RCU Trigger List Masters

Trigger ID	Name	Description	Sensitivity
None			

Table 5-3: ADSP-2159x_SC591_SC592_SC594 RCU Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
50	RCU0_SYSRST0	RCU0 System Reset Slave 0	Pulse
51	RCU0_SYSRST1	RCU0 System Reset Slave 1	Pulse

RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The target or source defines the following are types of resets.

Hardware Reset (by target)

All functional units except a small subsection of debug interfaces are set to their default states. State is lost in all non-volatile storage.

System Reset (by target)

All functional units except the RCU, flash interface, and debug are set to their default states.

Core n Only Reset (by target)

Affects Core n only. The system software must guarantee that a bus master cannot access the core in reset state.

Hardware Reset (by source)

The $\overline{\texttt{SYS\_HWRST}}$ input signal is asserted active (pulled low).

System Reset (by source)

Software can trigger the reset by writing to the RCU_CTL register or by another functional unit such as the TRU or any of the generic reset inputs.

RCU Architectural Concepts

To understand the architecture of the RCU, it is important to consider the reset sources and how differing resets affect the functional units of the processor.

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. For example, units in different clock domains must enter reset asynchronously but exit reset in a deterministic way.

The program must guarantee that none of the reset functions put the system in an undefined state or cause resources to stall. This functionality is important when only one of the cores is reset. The program must guarantee that there is no pending system activity involving Core n before it is reset. For example, there must be no pending transactions to core 0 when the core 0 is reset and vice-versa.

The ***RCU Reset Sources*** table defines how reset sources affect the different functional units.

Table 5-4: RCU Reset Sources

Reset Source	Reset Type	Affected Functional Units
$\overline{\texttt{SYS\_HWRST}}$ pin assertion	Hardware Reset	All functional units, except RTC (if present)
SYSCLK clock domain system reset by the Fault Unit (FMU) or TRU completer	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
RCU_CTL.SYSRST bit set (software triggered reset)	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain

Table 5-4: RCU Reset Sources (Continued)

Reset Source	Reset Type	Affected Functional Units
RCU_CRCTL.CR[n] bit set (software triggered reset)	Core Only Reset	Core n only , for (2 ≥ n ≥ 0)

RCU Status and Error Signals

The RCU_STAT register reflects status and error information. There are three kinds of errors that can occur in the RCU. The reset out error is triggered when RSTOUT is both asserted and deasserted at the same time. The lock write error occurs if an attempt is made to write a lock RCU register. The address error occurs if a read-only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

Resetting the Arm Core through Another Core/System Master

The RCU allows reset of a given core n using another core or system master. Core 0 can be individually reset by software, either setting any of CR0 bit in the RCU_CRCTL register. Cores that reset themselves cannot guarantee that all the system transactions to or from it have completed. Although a core n reset can be triggered by core n itself, it is recommended that another core or system master trigger it. Core n can be reset to restore its functionality when it cannot execute software.

The following steps show the suggested programming sequence to reset core n only.

1. Clear the RCU_CRSTAT.CR[n] bit.
2. Disable interrupts to core n.
3. Set the RCU_CRCTL.CR[n] bit to reset core n.
4. Poll the RCU_CRSTAT.CR[n] bit until core n is in reset.
5. Clear the RCU_CRCTL.CR[n] bit to take core n out of reset.
6. Poll the RCU_CRSTAT.CR[n] bit until core n is out of reset.

Resetting a SHARC+ Core Through Another Core

Resetting a SHARC+ core involves a software handshake between the Master core which issues a reset to the SHARC+ core. The handshake is done using a core interrupt along with message passing through a variable in shared L2 memory RAM. Each SHARC+ core needs two bits for handshaking.

- Core Reset Request bit (CRR). This bit is set by the master core to indicate to the SHARC+ core that a core reset needs to be done. If the CRR bit is set the SHARC+ core should disable all interrupts, stop all system and memory accesses and enter the IDLE state.

- IDLE acknowledgement (IDLE). Once the SHARC+ core is ready for reset, it sets this bit before entering the IDLE state to inform the master core that it is ready for reset.

Two bits are needed for SHARC0 core and two bits are needed for SHARC1 core. These bits are:

- CCR0 – SHARC0 core reset request bit in shared variable
- IDLE0 – SHARC0 IDLE acknowledgement bit in shared variable
- CCR1 – SHARC1 core reset request bit in shared variable
- IDLE1 – SHARC1 IDLE acknowledgement bit in shared variable

Use the following programming to reset the SHARC+ core.

1. The master core checks the IDLE status bits in shared variable for the corresponding SHARC+ core (`RCU_MSG.C1IDLE` and `RCU_MSG.C0IDLE`).
2. If one of the core idle bits is set then the program jumps to step 10. Otherwise the process continues to step 3.
3. The master core sets the CCRx bit in message register and raises the SOFT0 software interrupt through the SEC to the SHARC+ core (see Programming Examples for more information).
4. The SHARC+ core goes to into the ISR, and checks the “CCRx” status bit in RCU_MSG register to ensure that software interrupt is for core reset.

   ADDITIONAL INFORMATION: The SOFT0 software interrupt handler can be used for other non-reset/ general purposes as well.

   ADDITIONAL INFORMATION: The ISR should be in L1 memory.
5. The core should disable all interrupts before entering IDLE for reset.
6. The core sets the appropriate idle status bit (`RCU_MSG.C1IDLE` and `RCU_MSG.C0IDLE`).
7. Core enters IDLE.
8. Master core polls for the IDLEx status bit
9. The master core keeps a timeout option where if within N number of cycles the SHARC core doesn’t respond then a system reset is initiated.

   ADDITIONAL INFORMATION: N can be decided by the user depending on timing criticality of the application.
10. Once the IDLEx status bit is found set, the master core initiates a core reset though the RCU.
11. Clear the `RCU_CRSTAT.CR[n]` bit.
12. Set the `RCU_SIDIS.SI[n]` bit to disable the interfaces for core n, to stop DMA accesses to its L1, to stop accesses to memory for core n, and stop accesses to MMRs.

13. Test the RCU_SISTAT.SI[n] bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
14. Set the RCU_CRCTL.CR[n] bit to reset core n.
15. Poll the RCU_CRSTAT.CR[n] bit until core n is in reset.
16. Once the core is in reset, clear the RCU_SIDIS.SI[n] bit to re-enable the core interfaces.
17. Clear the RCU_CRCTL.CR[n] bit to take core n out of reset.
18. Poll the RCU_CRSTAT.CR[n] bit until core n is out of reset.

If a core is servicing a higher priority interrupt and gets stuck then it may not respond to the SEC.

ADSP-2159x_SC591_SC592_SC594 RCU Register Descriptions

Reset Control Unit (RCU) contains the following registers.

Table 5-5: ADSP-2159x_SC591_SC592_SC594 RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

Boot Code Register

The RCU_BCODE register can be used to determine if and how core boots. This register is set to its default values by RESET.

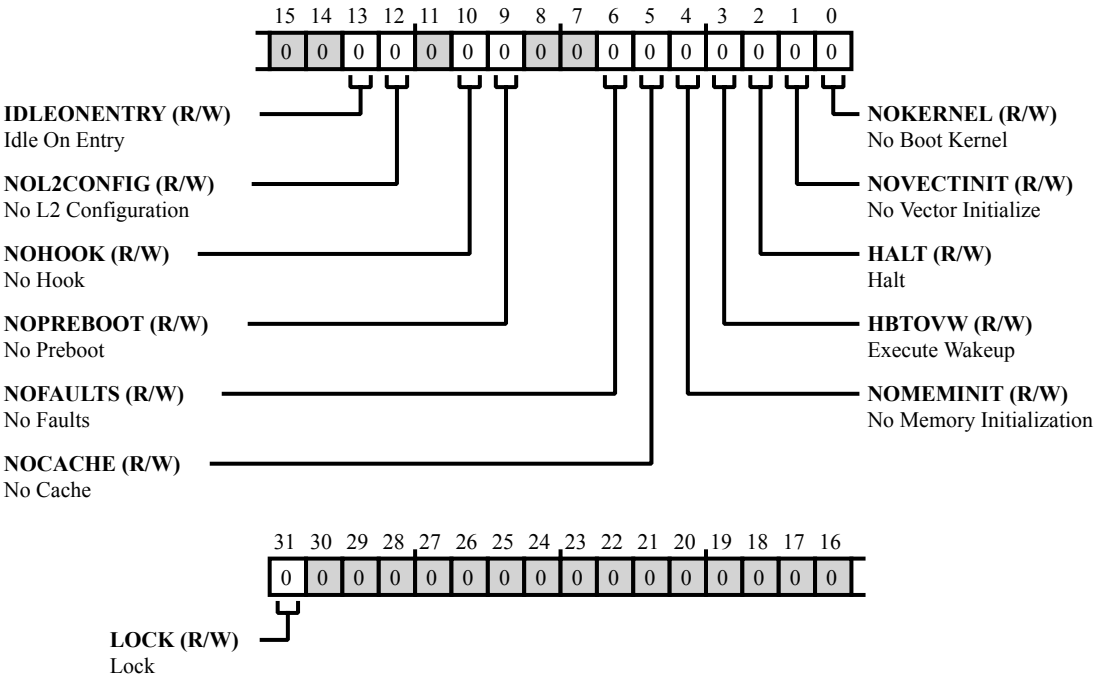

Figure 5-1: RCU_BCODE Register Diagram

Table 5-6: RCU_BCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_BCODE.LOCK bit is set, the RCU_BCODE register is read only (locked).	
		0	Unlock
		1	Lock
13 (R/W)	IDLEONENTRY	Idle On Entry. The RCU_BCODE.IDLEONENTRY bit configures the RCU to enter the idle state at startup.	
		0	Do not enter idle state
		1	Enter idle state

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	NOL2CONFIG	No L2 Configuration. The `RCU_BCODE.NOL2CONFIG` bit configures the RCU to not perform the L2 memory configuration.	
		0	Configure L2 memory
		1	Do not configure L2 memory
10 (R/W)	NOHOOK	No Hook. The `RCU_BCODE.NOHOOK` bit configures the RCU to not perform the hook routine.	
		0	Perform hook routine
		1	Do not perform hook routine
9 (R/W)	NOPREBOOT	No Preboot. The `RCU_BCODE.NOPREBOOT` bit configures the RCU to not perform the customer preboot routine.	
		0	Perform preboot
		1	Do not perform preboot
6 (R/W)	NOFAULTS	No Faults. The `RCU_BCODE.NOFAULTS` bit configures the RCU to not perform fault initialization.	
		0	Perform fault initialization
		1	Do not perform fault initialization
5 (R/W)	NOCACHE	No Cache. The `RCU_BCODE.NOCACHE` bit configures the RCU to not perform a cache initialization and to not enable the cache.	
		0	Enable and initialize cache
		1	Do not initialize or enable cache
4 (R/W)	NOMEMINIT	No Memory Initialization. The `RCU_BCODE.NOMEMINIT` bit configures the RCU to not perform a memory initialization.	
		0	Perform memory initialization
		1	Do not perform memory initialization

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	HBTOVW	Execute Wakeup. The `RCU_BCODE.HBTOVW` bit configures the RCU to execute a wakeup.	
		0	Do not wakeup
		1	Execute wakeup
2 (R/W)	HALT	Halt. The `RCU_BCODE.HALT` bit configures the RCU to execute the no boot routine.	
		0	Do not execute routine
		1	Execute routine
1 (R/W)	NOVECTINIT	No Vector Initialize. The `RCU_BCODE.NOVECTINIT` bit configures the RCU to not vector to the application.	
		0	Vector
		1	Do not vector
0 (R/W)	NOKERNEL	No Boot Kernel. The `RCU_BCODE.NOKERNEL` bit configures the RCU to not execute the boot kernel.	
		0	Execute boot kernel
		1	Do not execute boot kernel

Core Reset Outputs Control Register

The RCU core reset control n registers (RCU_CRCTL) include a lock bit (RCU_CRCTL.LOCK) and a core reset bit (RCU_CRCTL.CR[n]) for each core reset signal on the product.

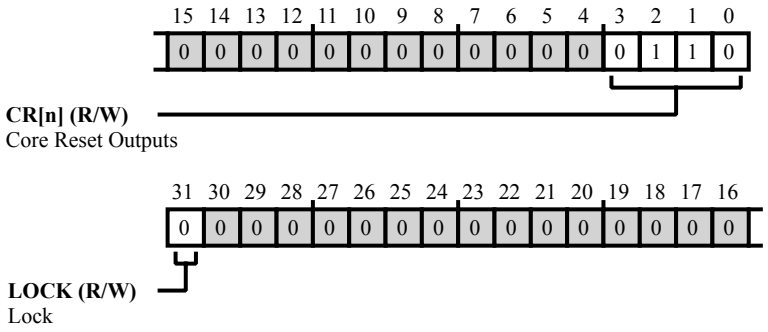

Figure 5-2: RCU_CRCTL Register Diagram

Table 5-7: RCU_CRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CRCTL.LOCK bit is set, the RCU_CRCTL register is read only (locked).	
		0	Unlock
		1	Lock
3:0 (R/W)	CR[n]	Core Reset Outputs. The RCU_CRCTL.CR[n] bits control CRES[1:0] core reset signals. The RCU_CRES[n] signals can be individually controlled. They are reset to their default value by a hard reset or a system reset. For each RCU_CRES[n], the selected RCU0_CRMSKi[n] bit is cleared.	
		0	RCU_CRES[3:0] Deasserted
		1	RCU_CRES[0] ARM A5 reset control bit asserted
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] SHARC1 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] Asserted

Core Reset Outputs Status Register

The RCU core reset status register (RCU_CRSTAT) contains status bits, indicating which core reset signals have been asserted.

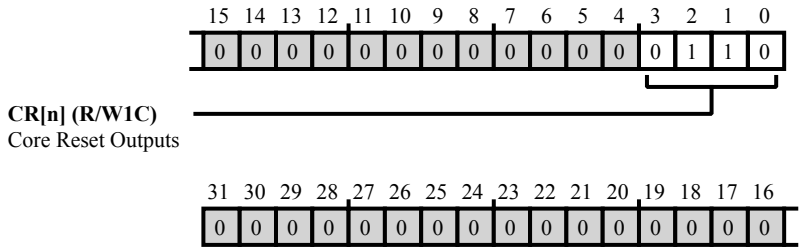

Figure 5-3: RCU_CRSTAT Register Diagram

Table 5-8: RCU_CRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W1C)	CR[n]	Core Reset Outputs. The RCU_CRSTAT.CR[n] bits indicate which cores have been reset since the last time the bit was cleared. Bits masked by CORE_DISABLE_MASK[15:0] are permanently disabled and the corresponding CR bits set. CR bits are sticky, they need to be cleared by software.	
		0	RCU_CRES[1:0] deasserted. CR[n] corresponds to RCU_CRES[n].
		1	RCU_CRES[0] ARM A5 reset control bit asserted
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] SHARC1 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] were asserted since the last time bits were cleared. CR[n] corresponds to RCU_CRES[n].

Control Register

The RCU control register (RCU_CTL) provides a register lock, enables for the core and system reset requests inputs and control for the Reset Output pin.

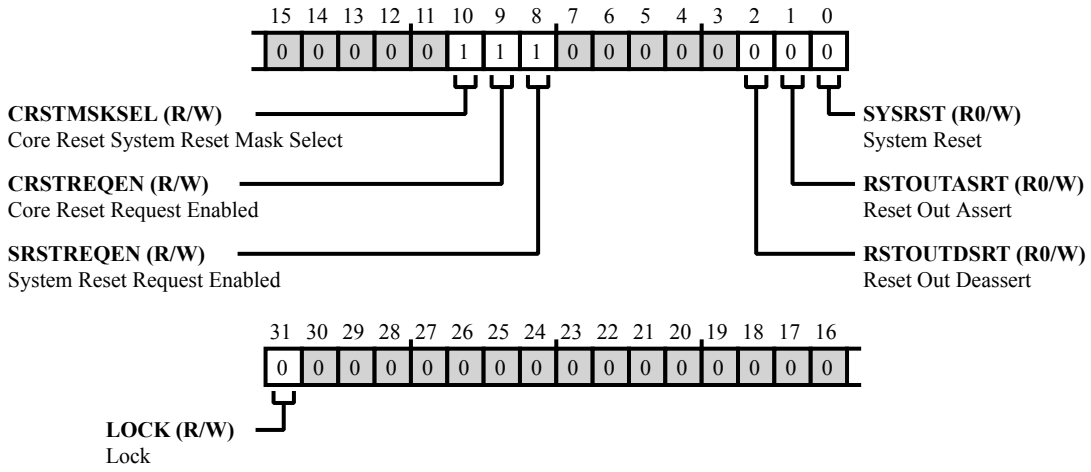

Figure 5-4: RCU_CTL Register Diagram

Table 5-9: RCU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CTL.LOCK bit is set, the RCU_CTL register is read only (locked). This bit is cleared by a hard reset or any system reset event.	
		0	Unlock
		1	Lock
10 (R/W)	CRSTMSKSEL	Core Reset System Reset Mask Select. The RCU_CTL.CRSTMSKSEL bit selects the core reset system reset mask. This bit is cleared by a hard reset.	
9 (R/W)	CRSTREQEN	Core Reset Request Enabled. The RCU_CTL.CRSTREQEN bit controls whether the SYSCLK domain source(s) of reset is/are enabled to reset the core(s) when asserted. This bit is cleared by hard reset or any system reset event.	
		0	Disabled
		1	Enabled

Table 5-9: RCU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SRSTREQEN	System Reset Request Enabled. The `RCU_CTL.SRSTREQEN` bit controls whether the SYSCLK domain sources of reset are enabled to do a system reset when asserted. This bit is cleared by a hard reset.	
		0	Disabled
		1	Enabled
2 (R0/W)	RSTOUTDSRT	Reset Out Deassert. The `RCU_CTL.RSTOUTDSRT` bit controls the deassertion of the system reset pin.	
		0	No Action
		1	Deassert RSTOUT
1 (R0/W)	RSTOUTASRT	Reset Out Assert. The `RCU_CTL.RSTOUTASRT` bit controls assertion of the system reset pin.	
		0	No Action
		1	Assert RSTOUT
0 (R0/W)	SYSRST	System Reset. The `RCU_CTL.SYSRST` bit provides reset for all system units.	
		0	No Action
		1	System Reset

Message Register

The RCU_MSG is a general-purpose register. It is intended to provide flexibility for Boot ROM code and to pass predefined variables to the debugger. Please see the Booting chapter for product-specific details.

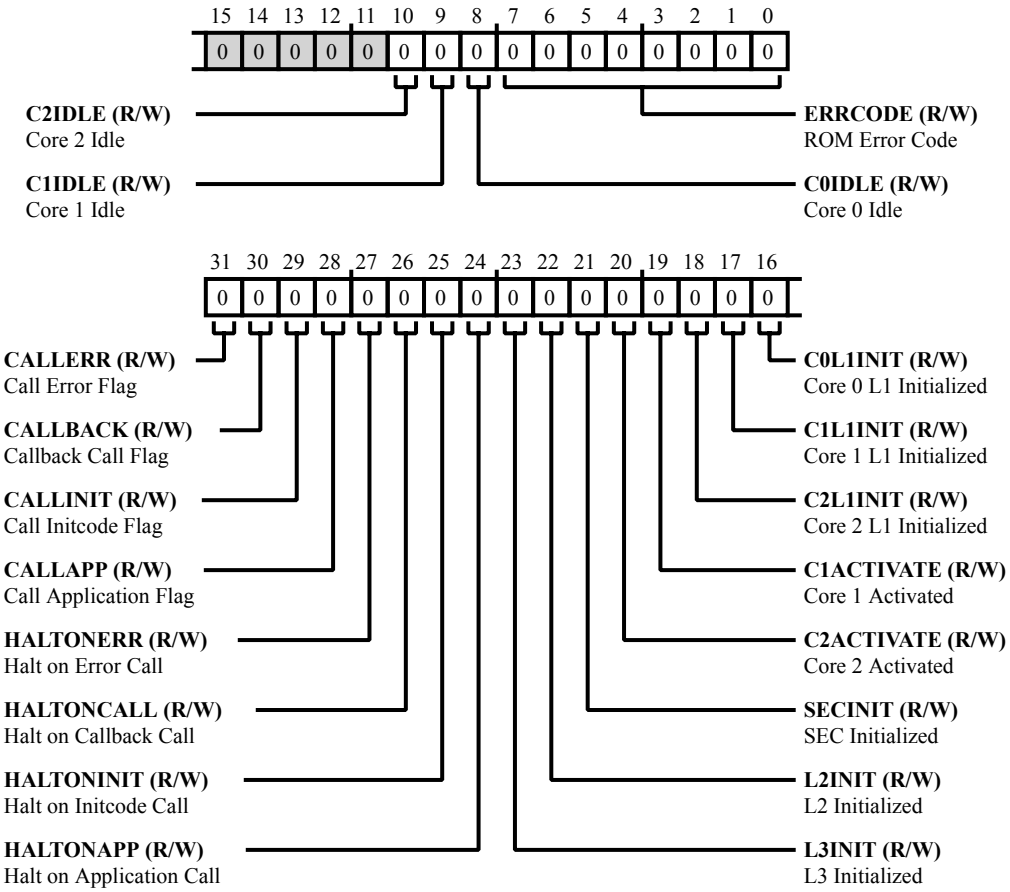

Figure 5-5: RCU_MSG Register Diagram

Table 5-10: RCU_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CALLERR	Call Error Flag. The RCU_MSG.CALLERR bit indicates that a flag has been set by the boot code prior to an error call.	
		0	Flag not set
		1	Flag set

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	CALLBACK	Callback Call Flag. The RCU_MSG.CALLBACK bit indicates that a flag has been set by the boot code prior to a callback call.	
		0	Flag not set
		1	Flag set
29 (R/W)	CALLINIT	Call Initcode Flag. The RCU_MSG.CALLINIT bit indicates that a flag has been set by the boot code prior to an initcode call.	
		0	Flag not set
		1	Flag set
28 (R/W)	CALLAPP	Call Application Flag. The RCU_MSG.CALLAPP bit indicates that a flag has been set by the boot code prior to an application call.	
		0	Flag not set
		1	Flag set
27 (R/W)	HALTONERR	Halt on Error Call. The RCU_MSG.HALTONERR bit generates an emulation exception prior to an error call.	
		0	Do not generate exception
		1	Generate exception
26 (R/W)	HALTONCALL	Halt on Callback Call. The RCU_MSG.HALTONCALL bit generates an emulation exception prior to a callback call.	
		0	Do not generate exception
		1	Generate exception
25 (R/W)	HALTONINIT	Halt on Initcode Call. The RCU_MSG.HALTONINIT bit generates an emulation exception prior to an initcode call.	
		0	Do not generate exception
		1	Generate exception

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	HALTONAPP	Halt on Application Call. The `RCU_MSG.HALTONAPP` bit generates an emulation exception prior to an application call.	
		0	Do not generate exception
		1	Generate exception
23 (R/W)	L3INIT	L3 Initialized. The `RCU_MSG.L3INIT` bit indicates that the L3 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
22 (R/W)	L2INIT	L2 Initialized. The `RCU_MSG.L2INIT` bit indicates that the L2 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
21 (R/W)	SECINIT	SEC Initialized. The `RCU_MSG.SECINIT` bit is used by tools for initialization of the SEC.	
20 (R/W)	C2ACTIVATE	Core 2 Activated. The `RCU_MSG.C2ACTIVATE` bit is used by tools for activation of Core 2.	
19 (R/W)	C1ACTIVATE	Core 1 Activated. The `RCU_MSG.C1ACTIVATE` bit is used by tools for activation of Core 1.	
18 (R/W)	C2L1INIT	Core 2 L1 Initialized. The `RCU_MSG.C2L1INIT` bit indicates that the core 2 L1 resource is initialized.	
17 (R/W)	C1L1INIT	Core 1 L1 Initialized. The `RCU_MSG.C1L1INIT` bit indicates that the core 1 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
16 (R/W)	C0L1INIT	Core 0 L1 Initialized. The `RCU_MSG.C0L1INIT` bit indicates that the core 0 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
10 (R/W)	C2IDLE	Core 2 Idle. The `RCU_MSG.C2IDLE` bit indicates that core 2 is in a safe idle state in ROM.	

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	C1IDLE	Core 1 Idle. The `RCU_MSG.C1IDLE` bit indicates that core 1 is in a safe idle state in ROM.
8 (R/W)	C0IDLE	Core 0 Idle. The `RCU_MSG.C0IDLE` bit indicates that core 0 is in a safe idle state in ROM.
7:0 (R/W)	ERRCODE	ROM Error Code. The `RCU_MSG.ERRCODE` bit indicates the error code of the ROM. It is valid only when in the error handler.

Message Clear Bits Register

The RCU_MSG_CLR register is used to clear bits in RCU_MSG register. Reading this register returns 0x00000000.

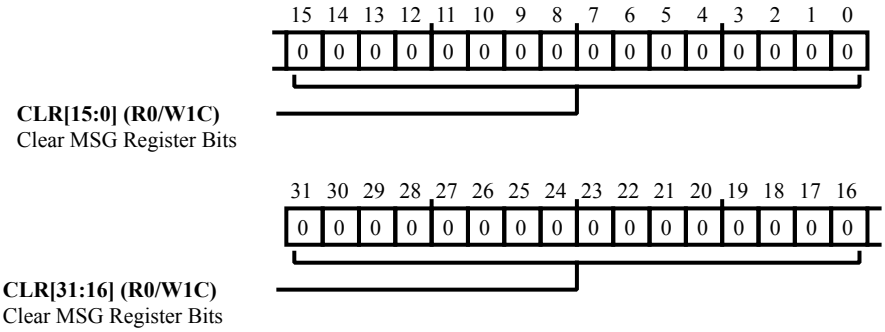

Figure 5-6: RCU_MSG_CLR Register Diagram

Table 5-11: RCU_MSG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1C)	CLR	Clear MSG Register Bits. The RCU_MSG_CLR.CLR bit resets MSG bit n.

Message Set Bits Register

The RCU_MSG_SET register is used to set bits in RCU_MSG register. Reading this register returns 0x00000000.

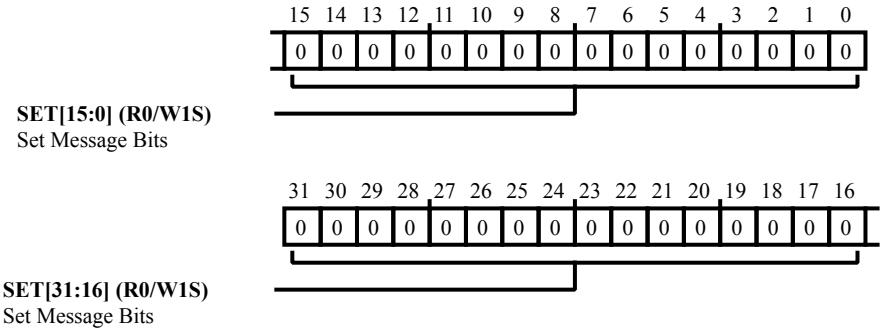

Figure 5-7: RCU_MSG_SET Register Diagram

Table 5-12: RCU_MSG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1S)	SET	Set Message Bits. The RCU_MSG_SET.SET bit sets MSG bit n.

System Interface Disable Register

The RCU system interface disable register (RCU_SIDIS) lets the RCU assert a system interface disable request to functional units in the processor. This register is set to its default values by a hard reset or any system reset event. For information on mapping between RCU_SIDIS bits and functional units, see the RCU functional description.

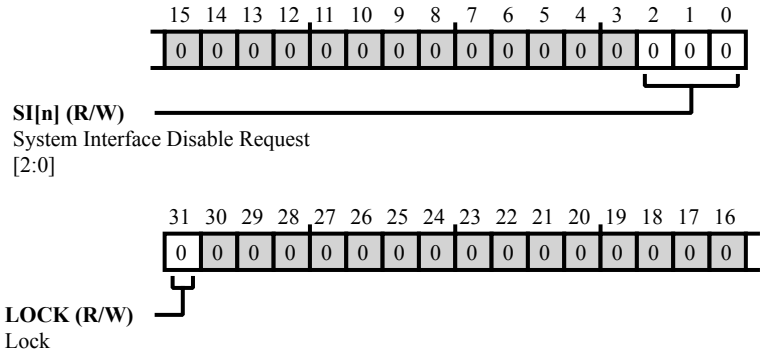

Figure 5-8: RCU_SIDIS Register Diagram

Table 5-13: RCU_SIDIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SIDIS.LOCK bit is set, the RCU_SIDIS register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SI[n]	System Interface Disable Request [2:0]. Each RCU_SIDIS.SI[n] bit corresponds to a functional unit in the processor that supports the system interface disable request-acknowledge protocol.	
		0	RCU_SI_DISABLE_REQ[2:0] deasserted
		1	RCU_SI_DISABLE_REQ[0] system interface disable request to SHARC0 asserted
		2	RCU_SI_DISABLE_REQ[1] system interface disable request to SHARC1 asserted
		4	Reserved
		7	RCU_SI_DISABLE_REQ[2:0] asserted

System Interface Status Register

The RCU system interface status register (RCU_SISTAT) indicates whether a functional unit has or has not acknowledged an RCU unit disable request.

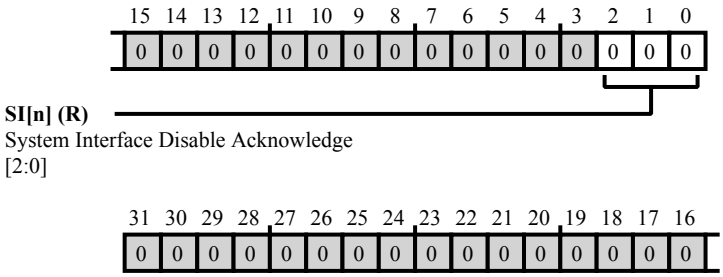

Figure 5-9: RCU_SISTAT Register Diagram

Table 5-14: RCU_SISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/NW)	SI[n]	System Interface Disable Acknowledge [2:0]. The RCU_SISTAT.SI[n] bit indicates whether a functional unit has or has not acknowledged an RCU unit disable request.	
		0	No Acknowledge
		1	RCU_SI_DISABLE_ACK[0] system interface disable acknowledge from SHARC0 asserted
		2	RCU_SI_DISABLE_ACK[1] system interface disable acknowledge from SHARC1 asserted
		4	Reserved
		7	SI_DISABLE_ACK[2:0] asserted

System Reset Request Status Register

The RCU system reset request status register (RCU_SRRQSTAT) contains status bits, indicating which system reset request input triggered a system reset. This register is set to its default values by a hard reset.

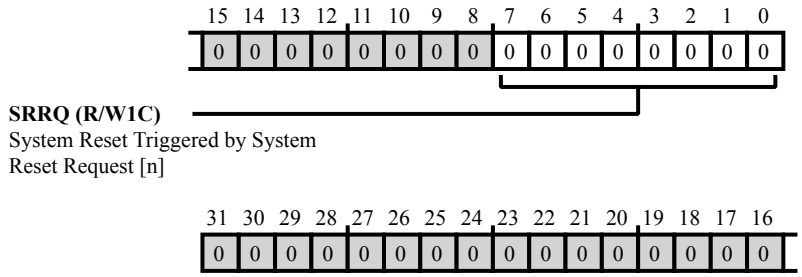

Figure 5-10: RCU_SRRQSTAT Register Diagram

Table 5-15: RCU_SRRQSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:0 (R/W1C)	SRRQ	System Reset Triggered by System Reset Request [n]. The RCU_SRRQSTAT.SRRQ bits are set by the assertion of the corresponding system reset request input and deasserted by writing "1" to the bit. The RCU_SRRQSTAT register is cleared by a hard reset.	
		1	RCU_SRRQ[0], System Reset Request from SEC asserted
		2	RCU_SRRQ[1], System Reset Request from TRGS_RCU0_SYSRST0 asserted
		4	RCU_SRRQ[2], System Reset Request from TRGS_RCU0_SYSRST1 asserted
		8	RCU_SRRQ[3], System Reset Request from CTI3 asserted

Status Register

The RCU status register (RCU_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can cleared by software. Error status bits are cleared by any reset event.

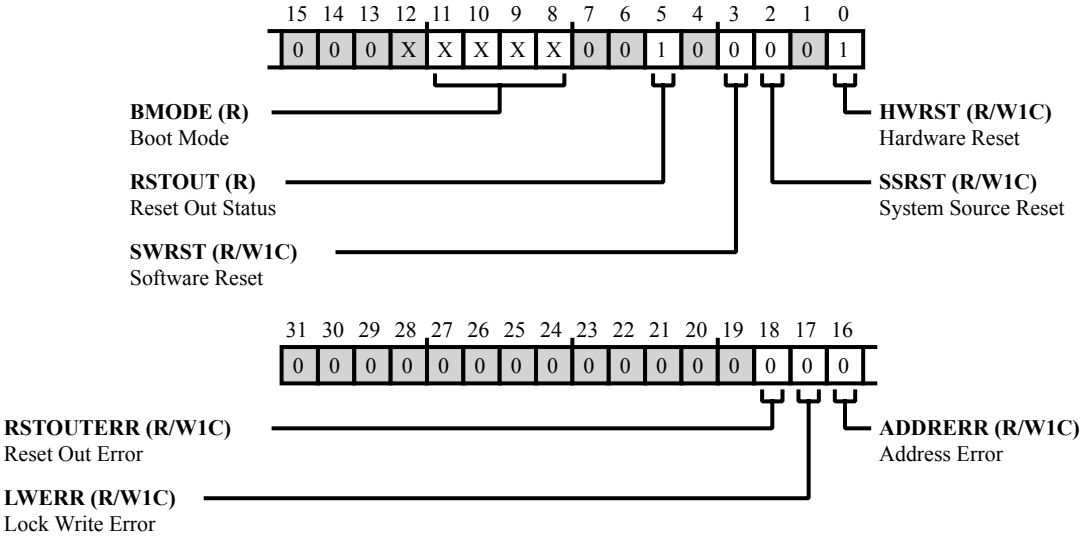

Figure 5-11: RCU_STAT Register Diagram

Table 5-16: RCU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	RSTOUTERR	Reset Out Error. The RCU_STAT.RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL.RSTOUTASRT and RCU_CTL.RSTOUTDSRT simultaneously. This condition triggers a bus error.	
		0	No Error
		1	Error Occurred
17 (R/W1C)	LWERR	Lock Write Error. The RCU_STAT.LWERR bit indicates (when set) there was an attempted write to an RCU register while the RCU_CTL.LOCK bit was set and the global lock bit is enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear	
		0	No Error
		1	Error Occurred

Table 5-16: RCU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ADDRERR	Address Error. The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
11:8 (R/NW)	BMODE	Boot Mode. The RCU_STAT.BMODE bits indicate the input on the boot mode pins.	
5 (R/NW)	RSTOUT	Reset Out Status. The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.	
		0	RSTOUT Deasserted
		1	RSTOUT Asserted
3 (R/W1C)	SWRST	Software Reset. The RCU_STAT.SWRST bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the RCU_STAT.SWRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
2 (R/W1C)	SSRST	System Source Reset. The RCU_STAT.SSRST bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the RCU_STAT.SSRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
0 (R/W1C)	HWRST	Hardware Reset. The RCU_STAT.HWRST bit indicates that a hardware reset has occurred.	
		0	Inactive
		1	Reset Occurred

Software Vector Register 0

The RCU_SVECT0 register contains the default location of the first instruction to execute after a reset.

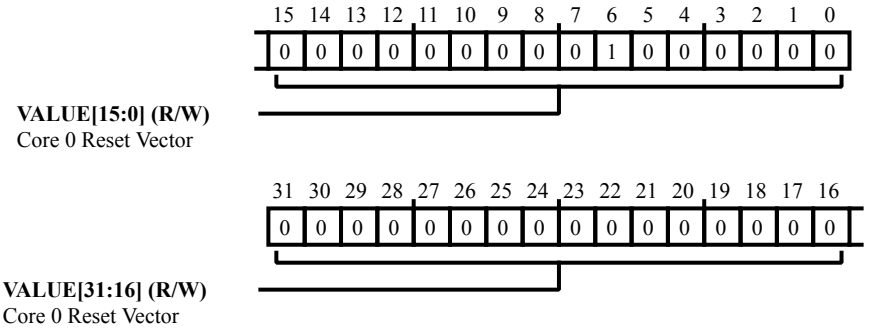

Figure 5-12: RCU_SVECT0 Register Diagram

Table 5-17: RCU_SVECT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Core 0 Reset Vector. The RCU_SVECT0.VALUE bit field contains the default location of the first instruction to execute after a reset.

Software Vector Register 1

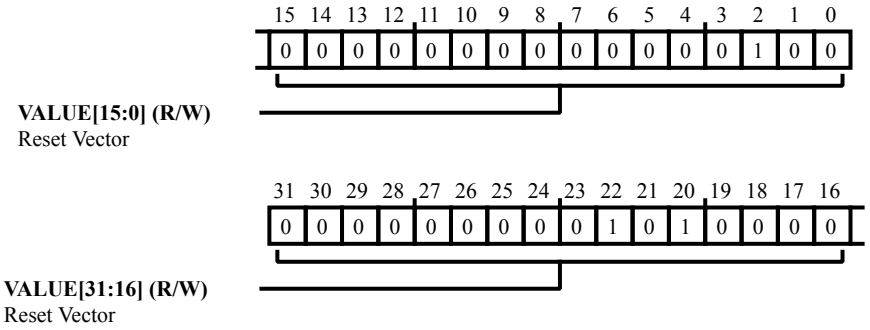

Figure 5-13: RCU_SVECT1 Register Diagram

Table 5-18: RCU_SVECT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector.

Software Vector Register 2

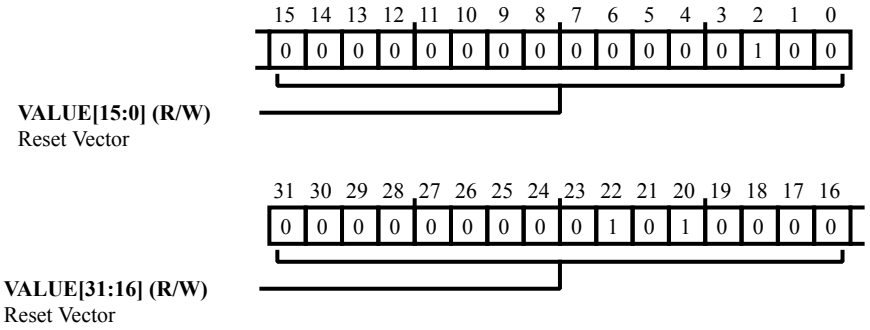

Figure 5-14: RCU_SVECT2 Register Diagram

Table 5-19: RCU_SVECT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector.

SVECT Lock Register

The RCU software vector lock register (RCU_SVECT_LCK) provides a register lock and software vector n enable bits for each processor core on the product. This register is set to its default values by a hard reset or any system reset event.

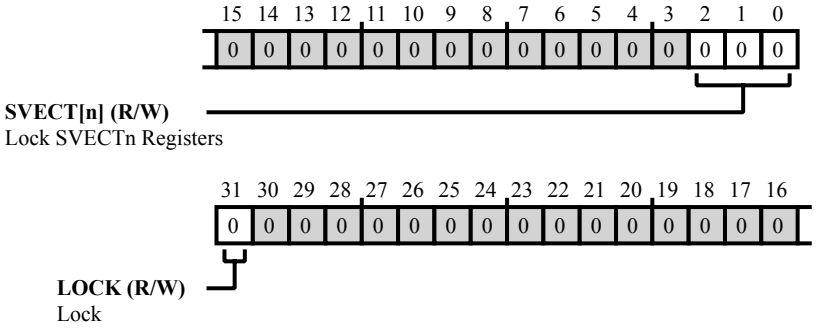

Figure 5-15: RCU_SVECT_LCK Register Diagram

Table 5-20: RCU_SVECT_LCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.LOCK bit is set, the RCU_SVECT_LCK register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SVECT[n]	Lock SVECTn Registers. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.SVECT[n] bit is set, the SVECT registers are read only (locked).	

6 System Event Controller (SEC) and Generic Interrupt Controller (GIC)

There are two interrupt controllers—a generic interrupt controller (GIC) for the Arm core and the system event controller (SEC) for the SHARC cores.

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources. The SEC also manages the propagation of system events to all connected cores and the system fault interface.

All of the peripheral interrupts are routed using a single SEC interrupt to the desired core. The SEC allows programmability of the peripheral interrupt's priority, supporting up to 256 priority levels that are arbitrated within the SEC itself. The SEC also allows these interrupts to be grouped and masked by priority level and provides the flexibility to choose which core(s) the interrupt is routed to.

The SEC also supports self-nesting of interrupts, which is required when sharing a single interrupt request to an individual core, as this allows for a higher-priority peripheral interrupt to be passed to the core while it is currently servicing a lower-priority peripheral interrupt. For more information, refer to "Self-Nesting Mode for System Event Controller Interrupt (SECI)" in the *SHARC+ Core Programming Reference*.

For more information about the Arm GIC, visit the Arm Information Center.

SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, priority, core mapping, and source grouping.
- Fault management including fault action configuration, timeout, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are independent of all others.

- Completer control port which provides access to all SEC registers for configuration, status, and interrupt or fault service model.
- Global locking supports a register level protection model to prevent writes to “locked” registers.

SEC Functional Description

The following sections provide a functional description of the SEC.

The *SEC/GIC Interrupt Signal Flow* figure shows an overview of the interrupt systems.

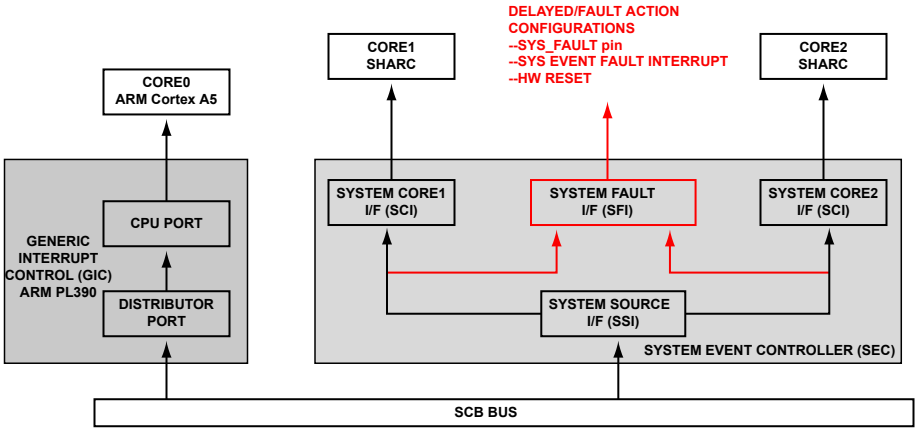

Figure 6-1: SEC/GIC Interrupt Signal Flow

ADSP-2159x_SC591_SC592_SC594 SEC Register List

The System Event Controller (SEC) manages the system fault sources, including control features such as enable/disable, priority, and active/pending source status. For more information on SEC functionality, see the SEC register descriptions.

Table 6-1: ADSP-2159x_SC591_SC592_SC594 SEC Register List

SEC Definitions

The event controller uses the following definitions.

SCI

SEC core interface, core interface subblock of the SEC

SEA

SEC system event aggregator generates an aggregate request to the SEC based on the active events at a given time.

SID (Identification, unique)

Source numeric identifier for each system source connected to the SEC.

SFI

SEC Fault Interface, fault management subblock of the SEC.

SPR

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt. The SPR provides these interrupts in the appropriate registers of the SCI for the priority and nesting model of the SCI.

SSI

SEC source interface, system event source control, and status subblock of the SEC.

System Events

System source indications including interrupts and faults.

System Source

Point of origin of system event.

SEC System Event Aggregator (SEA)

System event sources request event service from the SEC. In order to reduce the number of required SSI channels in the SEC, the System Event Aggregator (SEA) acts as an intermediate aggregator between the source and the SEC. All unique system events have dedicated inputs to the SEA. The SEA generates an aggregate request to the SEC based on which events are active at a given time.

To determine the active event for a given SEC ID, read the `SEC_SSTAT[n].CHID` bit field. The *Combined SEC and GIC Interrupt List* table shows five SEAs connected to SEC ID 251-255. All the sources grouped over the SEA are error events for a set of peripherals like the FIR-IIR, SPI-UART-LP-EPPI, MDMA, SPORT, and SWU. An error event from a peripheral is only expected when that peripheral is enabled. To mask SEA events from sources, disable the source peripheral conditions. There are no registers to mask events from the SEA, but there is a provision to mask the complete group output at the SEC.

Events are handled with a fixed priority order, on a first-come, first-served basis. If multiple events corresponding to the same SEC ID are active at the same time, the priority level is order dependent with the lower SEA IDs having the higher priority. The SEA events are level-based, so they remain high until the events are cleared at the source ensuring no event is missed. There is no support for nesting in a group since they all have same the SEC ID. An SEA event must be handled completely before addressing the next event.

SEC Block Diagram

The ***SEC Block Diagram*** shows the event management architecture.

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

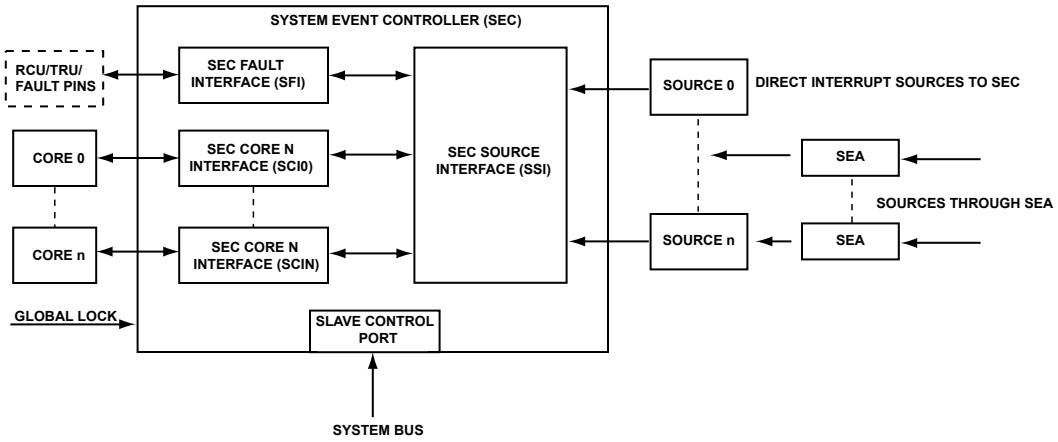

Figure 6-2: SEC Block Diagram

As shown in the figure, the SEC has three blocks for event management. The SFI monitors and manages any fault event triggered from various fault input sources. System interrupt sources are routed to the SFI through SEC source interface (SSI).

SEC Fault Interface (SFI)

The SFI manages fault events and associated actions. The fault management support provided in the SEC helps satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown, and once the countdown expires, takes the prescribed action.

Fault actions which can be configured, as shown in ***SFI Block Diagram***, include

- Trigger Output
- System Reset
- Fault Output
    - Computer Operating Properly (COP) mode
    - Fault Mode

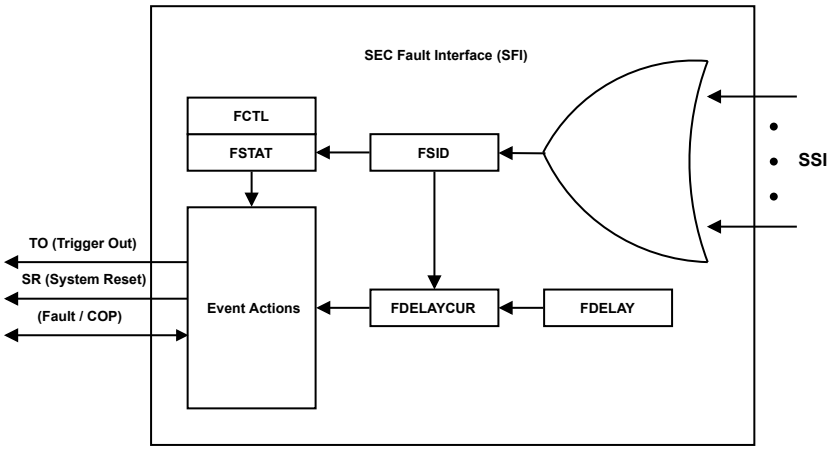

Figure 6-3: SFI Block Diagram

Fault Management

System sources can be enabled as fault sources in the SEC_SCTL[n] register. When a source enabled as a fault moves to pending, it is forwarded to the SFI as a fault indication. The pending bit (SEC_FSTAT.PND) indicates a source has signaled a fault assertion but it has not yet triggered the event actions (if delay is enabled). The SEC fault interface sets the SEC_FSTAT.PND bit when the fault source ID register (SEC_FSID) is updated on assertion of a fault source input. The system source pending triggers a fault pending and after a programmable delay the fault moves to active. Event actions then execute if appropriate action is not taken by the core. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the delay has expired, and the fault actions are enabled.

The SEC_FSTAT.NPND bit indicates if one or more sources have signaled a fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.

A fault indication from an external device can also be detected on sampling the fault signals. When a fault is detected the SEC_FSTAT.ACT and SEC_FSID.FEXT bits are set. The assertion of either signal results in a fault input detection.

The SEC_FEND register receives a fault end indication from the core. The core writes the SID of the fault to the SEC_FEND register. If the SID matches the value in the SEC_FSID register, the SEC_FSTAT.PND and SEC_FSTAT.ACT bits are cleared.

SEC Core Interface (SCI)

The SCI manages communication between the corresponding core and the SEC. The SEC prioritizer (SPR) of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest-priority pending system event and the SCI determines whether it propagates to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

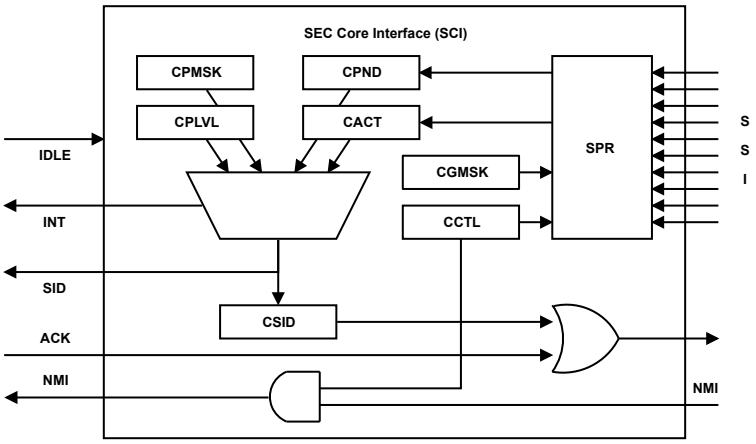

Figure 6-4: SCI Overview Block Diagram

SEC Source Interface (SSI)

The SSI manages all of the system event sources. It maintains the status of each source in the corresponding `SEC_SSTAT[n]` register. The corresponding `SEC_SCTL[n]` register manages the control of each source. A pending and enabled event passes its indication and priority to the SCI to which it is assigned for further processing.

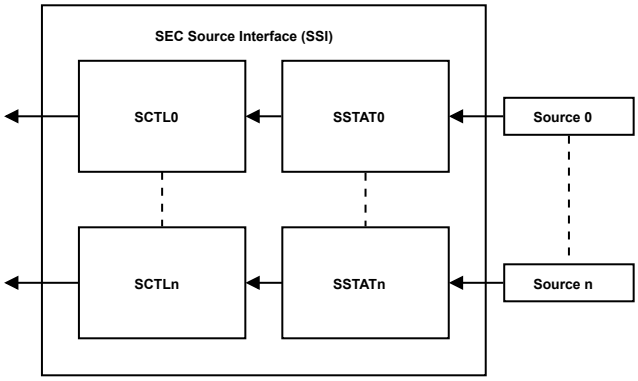

Figure 6-5: SSI Overview Block Diagram

SEC Architectural Concepts

The following sections describe SEC architectural features.

System Interrupt Acknowledge

A system interrupt acknowledge occurs when the core provides an indication that it has acquired the SID of the interrupt last issued by the SEC. The SEC core interface option allows generation by:

- A slave port write to the `SEC_CSID[n]` register.
- The assertion of an input acknowledge signal (the connected core generates the signal).

System Interrupt Groups

System sources can be assigned to groups using the SEC_SCTL[n].GRP bit field. Source groups allow fast context switching for system interrupts at each SCI. The SEC_CGMSK[n] register allows quick masking of interrupt groups of unlimited size with a single write operation.

System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the core target select (SEC_SCTL[n].CTG) bit field setting. The SEC priority ordering determines the highest priority pending system interrupt and the SCI updates the SEC_CPND[n].SID and SEC_CACT[n].PRIO bit field values. The SCI compares the SEC_CPND[n] register value against the highest priority active source in the SEC_CACT[n] register).

The priority level register (SEC_CPLVL[n]) determines how many of the MSBs the SEC uses in the comparison. The priority mask register (SEC_CPMSK[n]) and the group mask register (SEC_CGMSK[n]) determines which pending interrupt sources participate. If the SEC_CPND[n] register value is a higher priority (lower value) than the priority of the SEC_CACT[n] register from the comparison based on the SEC_CPLVL[n] register, the system interrupt output is asserted. The source ID register (SEC_CSID[n]) is updated with the SEC_CPND[n].SID bit field value and forwarded to the connected core.

After the core provides an interrupt acknowledgment, the interrupt source is active, until the SEC completes interrupt service with a write to the SEC_END.SID bit field with the same value. Note the following:

- Interrupt acknowledgement occurs with an MMR write of the SEC_CSID[n] register or the core version of the SEC_CSID[n] register.
- Interrupt active status indication is SEC_SSTAT[n].ACT==1.

The following sequence shows the example flow for a single interrupt.

1. The SEC compares the SEC_CPND[n] register value to the SEC_CACT[n] register value. If the interrupt in the SEC_CPND[n] register is higher priority, continue.
2. The SEC copies the SEC_CPND[n] register value to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the interrupt signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source going active.
6. The core writes the SEC_CSID[n] of the active interrupt to the SEC_END register.
7. The SEC clears theSEC_SSTAT[n].ACT bit of the source being ended.

The following sequence shows the example flow for interrupt nesting where interrupt A is a lower priority and occurs earlier than interrupt B.

1. The SEC compares the SEC_CPND[n] (A) register value to the SEC_CACT[n] register and if the interrupt in the SEC_CPND[n] register is a higher priority, continue.
2. The SEC copies SEC_CPND[n] (A) register to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] (A) register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (A) going active.
6. The SEC compares the SEC_CPND[n] (B) register value to the SEC_CACT[n] (A) register value. If the SEC_CACT[n] (B) register value is a higher priority, continue.
7. The SEC copies the SEC_CPND[n] (B) register value to SEC_CSID[n] register and asserts the interrupt signal.
8. The core reads the SEC_CSID[n] (B) register (or core version).
9. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
10. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (B) going active.
11. The core writes the SEC_CSID[n] of the active interrupt (B) to the SEC_END register.
12. The SEC clears the SEC_SSTAT[n].ACT bit of the source (B) being ended.
13. The core writes the SEC_CSID[n] of the active interrupt (A) to the SEC_END register.
14. The SEC clears the SEC_SSTAT[n].ACT bit of the source (A) being ended.

System Interrupt Priorities

Each system interrupt source has its own programmable priority level which is configured using the SEC_SCTL[n].PRIO bit field. The SCI evaluates the priority of all pending sources to determine the source of the highest-priority pending system interrupt for forwarding to the attached core. If more than one source of the pending system interrupt has the same priority setting, the SCI chooses the one with the lowest SID. For example, if SID 0, SID 1, and SID 2 are all pending and have the same priority setting, the SCI chooses SID 0 as the highest-priority source.

SEC Error

The processor includes an SEC error (SEC_GSTAT.ERR) as a source input to the SEC to allow for handling the error as an interrupt or fault.

SEC Programming Model

Implementing a system interrupt service model using the SEC requires, at a minimum:

- Proper configuration of a system interrupt source (for example a peripheral or DMA)
- A core interrupt or event service model

The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, the processor can use software triggering for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the SEC_RAISE register.

Programming Concepts

The following list provides the basic programming concepts necessary for configuring the SEC.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core (See Configuring a System Source to Interrupt a Core).
- Configuring an SSI as a system fault (See Configuring a System Source as a Fault).
- Configuring the SFI to manage system faults.

Programming Examples

This section provides example programming tasks that are typical for SEC usage.

Fault Management Interface Programming Model

The SFI interface can be programmed to manage fault events from system sources and associated actions such as issuing a system reset when watchdog expiration event occurs.

1. Set the SEC_GCTL.EN bit to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
    - Trigger Output. Set the SEC_FCTL.TOEN bit for the SEC to produce trigger outputs when a fault becomes active. The SEC_FCTL.TES bit can be programmed to select the event that directs the SEC to assert trigger output when a fault is pending or active. Configure slaves for SEC fault trigger master output.

      NOTE: If the SEC_FCTL.TOEN and or the SEC_FCTL.TES bits =1 (Trigger Output Enabled and Trigger on Fault Pending), an external fault (if enabled by the SEC_FCTL.FIEN bit) will not issue a trigger since Fault Pending is bypassed for external faults.
    - System Reset. The Reset Control Unit (RCU) controls how the functional units enter and exit reset. Configure the RCU_CTL.SRSTREQEN bit. This bit controls whether the sources of reset are enabled to perform a system reset. To issue a system reset request when a fault becomes active, set the SEC_FCTL.SREN bit. The SEC fault system reset delay register (SEC_FSRDLY) can be programmed for the delay, if required, from a fault becoming active to system reset request assertion.

- Fault Output. This configuration alows the SEC to indicate the fault status based on the SEC_FCTL.CMS bit configuration.
  - Computer Operating Normally (COP) mode. To configure fault output for COP mode, set the SEC_FCTL.FOEN bit to enable fault output. Set the SEC_FCTL.CMS bit to select COP mode to toggle the fault pin when no fault is active. Program the SEC_FCOPP period register with a desired width value for the COP toggled output pin.
  - Fault mode. Set the SEC_FCTL.FOEN bit to enable fault output. The SEC_FCTL.CMS bit should be set to Fault mode to toggle the fault pin when a fault is active.

3. If required, program the Fault Input to sample fault inputs from external devices on fault pins. Configure the SEC_FCTL.FIEN bit to enable the SEC to sample a fault input from an external device.

   ADDITIONAL INFORMATION: The SEC_FCTL.FIEN bit should be set only while the SEC_FCTL.EN bit is low. If the SEC_FCTL.EN bit is already high and the SEC_FCTL.FIEN bit needs to be set, the SEC_FCTL.EN bit should be cleared first. Fault input can only be enabled when Fault mode is selected by the SEC_FCTL.CMS bit.

4. Program the required fault delay to the SEC_FDLY.COUNT bit field if a delay between fault source assertion and the fault response is required.

5. Configure the SEC_FCTL register to enable the SEC.

   ADDITIONAL INFORMATION: The SEC_FCTL.EN bit should be set only while the SEC_FSTAT.ACT bit is low.

6. Write to the control register of a specific source register using the SEC_SCTL[n] register to enable the source as a fault.

Configuring a System Source to Interrupt a Core

To configure a system source to interrupt a core, the SEC itself must be enabled with the source interface (SSI) and core interface (SCI) properly initialized. Specifically, the SCI must be set up to accept interrupt signaling from the SEC and pass them to the specified core, and the SSI must properly enable each of the peripheral interrupt sources to generate interrupt signals and optionally define a priority scheme that overrides the default priority settings. In summary:

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the appropriate SCI SEC_CCTL[n] register to enable SEC interrupts to be sent to that core.
3. Write to the appropriate SSI SEC_SCTL[n] register to enable that peripheral as an interrupt source and to set the core target field to map the source to the desired SCI.
4. (Optional) By default, all the SEC interrupts are grouped as a single priority level, so passing of peripheral interrupt requests from the SEC is based solely on the default enumerated source ID. By programming the SEC_CPLVL[n].PLVL register, interrupt sources can be grouped into priority levels within the SEC such that arbitration is first performed by source ID within a grouped priority level before proceeding to the next

priority level, thus providing the flexibility to have lower-priority interrupt sources considered before higher-priority sources.

ADDITIONAL INFORMATION: The SEC_CPMSK[n] and SEC_CGMSK[n] registers must also can be programmed to mask the interrupts based on the customized levels and grouping.

Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling

A specific handshake with the SEC is required to handle interrupts associated with an individual core. The handshake ensures that nested interrupts are properly tracked and that new peripheral interrupts being raised within the SEC are either passed immediately to the core or held off and queued within the SEC for later servicing.

Use the following procedure to write a custom dispatcher inside the Interrupt Service Routine. Note that the core needs to read and acknowledge the SEC_CSID[n] register by writing the same value. The core must also write to the SEC_END register after the ISR execution completes.

1. Read the SEC_CSID[n] register to obtain the source ID of the peripheral interrupt request.
2. Write the read value back to the SEC_CSID[n] register to send the acknowledge signal to the SEC that the core has accepted and begun processing the interrupt request.
3. Execute the actual ISR (typically a call to a specific handler function from a look-up table based on the peripheral source ID). Write to the SEC_GCTL register to enable the SEC.
4. Write the value of the SEC_CSID[n] register of the active interrupt (read in step 1 above) to the SEC_END register to signal to the SEC that the interrupt has now been serviced.
5. Return from interrupt.

This procedure allows a higher-priority interrupt raised by the SEC to be serviced by the core after step 2. The SEC knows what it passed to the core because of the write to the SEC_CSID[n] register. After the core acknowledges that write, the SEC knows whether or not newly raised peripheral interrupts are a higher priority than the highest-priority interrupt currently being processed by the core.

- If higher priority, the SEC pushes the current SEC_CSID[n] value to an internal stack, writes the new SEC_CSID[n] value, and asserts a new SEC interrupt request.
- If lower priority, the SEC queues the interrupt until the core writes to the SEC_END register with the source ID of the higher-priority interrupt, confirming that it was fully processed.

At this point the SEC_CSID[n] value is popped from the internal stack and any pending peripheral interrupt requests are arbitrated before the SEC writes the new SEC_CSID[n] value and asserts a new interrupt request. At the same time the core self-nests the latched SEC interrupt requests as needed. When a higher-priority interrupt is presented to the core the write to the SEC_END register in the SEC handler epilog code guarantees that each nested level has the required handshake to signal to the SEC block that each individual source ID interrupt request is fully serviced. See the *SHARC+ Core Programming Reference* for more details about SEC handler code.

Configuring a System Source as a Fault

Use the following procedure configure a system source as a fault.

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
3. Write to the SEC_FDLY bit field to specify fault delay.
4. Write to the control register of a specific source to enable the source as a fault.

Configuring the WDOG Expiry Event to Issue a System Reset

Use the following procedure to configure the WDOG timer to issue a system reset.

1. Configure the SEC_GCTL register to enable the SEC.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_GCTL = BITM_SEC_GCTL_EN;
   ```

2. Configure the SEC_FCTL register to choose the Fault response mode. In the following code example, the system reset is issued.

   ADDITIONAL INFORMATION:

   ```
   *pREG_RCU0_CTL |= BITM_RCU_CTL_SRSTREQEN;
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_SREN;
   ```

3. Configure the SEC_SCTL[n].SEN and SEC_SCTL[n].FEN bits in the registers to determine how the fault source is handled. To configure the WDOG as the fault source, program the register. The program can configure any interrupt as the fault source by programming the corresponding register.

   ADDITIONAL INFORMATION:

   ```
    *pREG_SEC0_SCTL3 = BITM_SEC_SCTL_FEN|BITM_SEC_SCTL_SEN;
   ```

   ADDITIONAL INFORMATION: The SEC ID corresponding to WDOG0 is 3, as indicated in the Combined SEC and GIC Interrupt List .

4. Write to the enable bit.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_EN;
   ```

SEC Programming Restrictions

Setting the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is high can result in unpredictable behavior. To avoid this issue, set the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is low. The SEC_FSTAT.ACT bit is only set when the SEC_FCTL.EN bit is high. Therefore, the problem can only occur if the SEC_FCTL.EN bit transitions from 1 to 0 and then to 1 again.

Writing to SEC_FEND to end a fault with both the SEC_FCTL.FOEN bit and the SEC_FCTL.FIEN bit set can result in erroneous external fault detection. If this operation (ending a fault) and configuration (fault input and fault output enabled) are required by the application, clear the SEC_FCTL.FOEN bit prior to writing to SEC_FEND. The recommended sequence for ending a fault with the SEC_FCTL.FIEN or SEC_FCTL.FOEN==1 is as follows:

1. Clear the SEC_FCTL.FOEN bit.
2. Write to the SEC_FEND register.
3. Set the SEC_FCTL.FOEN bit.

ADSP-2159x_SC591_SC592_SC594 SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

Table 6-6: ADSP-2159x_SC591_SC592_SC594 SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register
SEC_FCOPP	Fault COP Period Register
SEC_FCOPP_CUR	Fault COP Period Current Register
SEC_FCTL	Fault Control Register
SEC_FDLY	Fault Delay Register
SEC_FDLY_CUR	Fault Delay Current Register
SEC_FEND	Fault End Register
SEC_FSID	Fault Source ID Register
SEC_FSRDLY	Fault System Reset Delay Register
SEC_FSRDLY_CUR	Fault System Reset Delay Current Register
SEC_FSTAT	Fault Status Register
SEC_GCTL	Global Control Register

Table 6-6: ADSP-2159x_SC591_SC592_SC594 SEC Register List (Continued)

Name	Description
SEC_GSTAT	Global Status Register
SEC_RAISE	Global Raise Register
SEC_SCTL[n]	Source Control Register n
SEC_SSTAT[n]	Source Status Register n

SCI Active Register n

The SEC SCI active interrupt register (SEC_CACT[n]) contains the source ID and priority of the highest priority active interrupt detected by the SEC prioritizer.

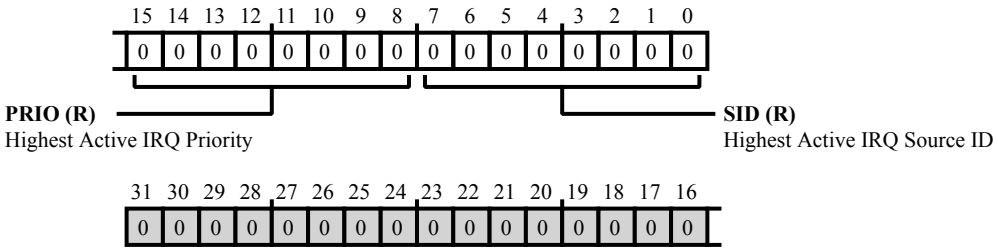

Figure 6-6: SEC_CACT[n] Register Diagram

Table 6-7: SEC_CACT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Active IRQ Priority. The SEC_CACT[n].PRIO indicates the priority value of the highest priority active interrupt for core n.
7:0 (R/NW)	SID	Highest Active IRQ Source ID. The SEC_CACT[n].SID identifies the source ID value of the highest priority active interrupt for core n.

SCI Control Register n

The SEC control register (SEC_CCTL[n]) contains SCI control bits for all system sources.

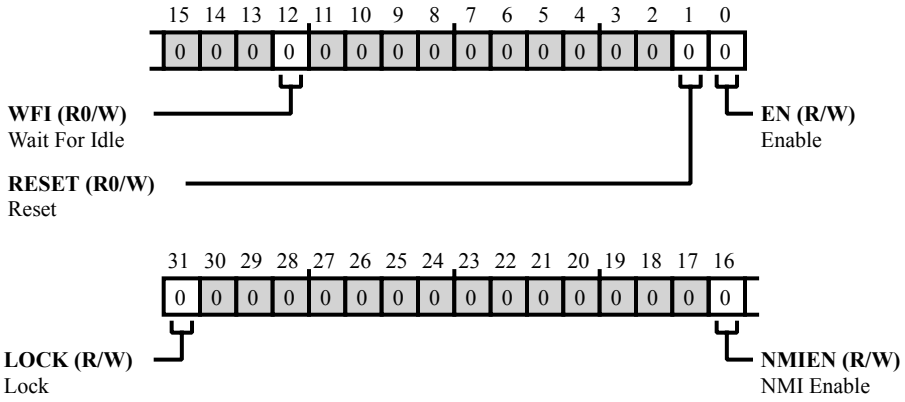

Figure 6-7: SEC_CCTL[n] Register Diagram

Table 6-8: SEC_CCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CCTL[n].LOCK bit is enabled, the SEC_CCTL[n] register is read only.	
		0	Unlock
		1	Lock
16 (R/W)	NMIEN	NMI Enable. The SEC_CCTL[n].NMIEN bit controls NMI propagation to the core. When the SEC_CCTL[n].NMIEN bit is enabled, the SCI allows NMIs to propagate to the core for servicing.	
		0	Disable
		1	Enable
12 (R0/W)	WFI	Wait For Idle. When set, the SEC_CCTL[n].WFI bit forces the SCI to wait for indication of core idle before the SCI resumes activity.	
		0	No Action
		1	Wait for Idle

Table 6-8: SEC_CCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RESET	Reset. When set, the SEC_CCTL[n].RESET bit resets all SCI registers to their default values.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The SEC_CCTL[n].EN bit controls operation of the SCI. Clearing the SEC_CCTL[n].EN bit halts the execution of the SCI without resetting status registers. (The INT signal to a core is not affected.) Setting the SEC_CCTL[n].EN bit enables the SCI to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

SCI Group Mask Register n

The SEC SCI group mask register (SEC_CGMSK[n]) contains selections for a group mask, an ungroup mask, and a register lock. This register contains the system interrupt group masks for the connected core. The core uses the SEC_CGMSK[n].UGRP and SEC_CGMSK[n].GRP fields to mask (disable) interrupts from the specified groups.

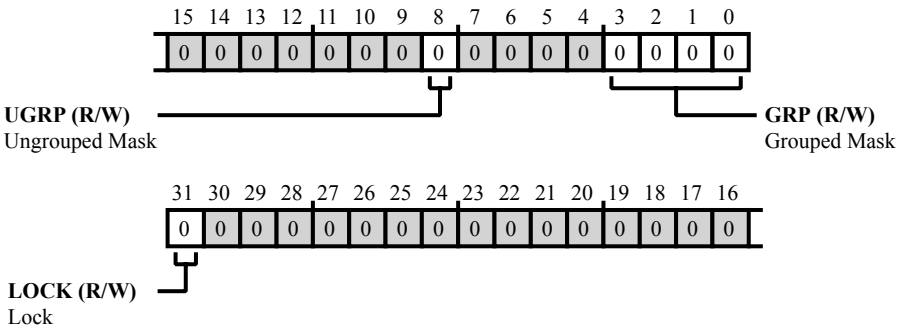

Figure 6-8: SEC_CGMSK[n] Register Diagram

Table 6-9: SEC_CGMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CGMSK[n].LOCK bit is enabled, the SEC_CGMSK[n] register is read only.	
		0	Unlock
		1	Lock
8 (R/W)	UGRP	Ungrouped Mask. The SEC_CGMSK[n].UGRP bit masks interrupts (if set) for the ungrouped interrupt sources for core n.	
		0	Unmask Ungrouped Sources
		1	Mask Ungrouped Sources
3:0 (R/W)	GRP	Grouped Mask. The SEC_CGMSK[n].GRP field selects a group of interrupt sources to mask for core n. (For more information about interrupt source groups, see the SEC_SCTL[n] register description.)	
		0	No groups masked
		1	Mask group 0
		2	Mask group 1
		3	Mask groups 0, 1

Table 6-9: SEC_CGMSK[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Mask group 2
		5	Mask groups 0, 2
		6	Mask groups 1, 2
		7	Mask groups 0, 1, 2
		8	Mask group 3
		9	Mask groups 0, 3
		10	Mask groups 1, 3
		11	Mask groups 0, 1, 3
		12	Mask groups 2, 3
		13	Mask groups 0, 2, 3
		14	Mask groups 1, 2, 3
		15	Mask groups 0, 1, 2, 3

SCI Priority Level Register n

The SEC SCI priority level register (SEC_CPLVL[n]) contains selections for priority levels and a register lock. This register is used to divide the total number of priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same level.

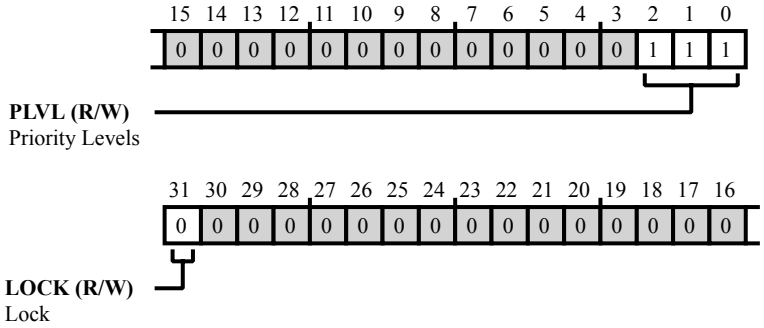

Figure 6-9: SEC_CPLVL[n] Register Diagram

Table 6-10: SEC_CPLVL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPLVL[n].LOCK bit is enabled, the SEC_CPLVL[n] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	PLVL	Priority Levels. The SEC_CPLVL[n].PLVL field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the SEC_CPLVL[n].PLVL field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.	
		0	1 MSBs (2 priority levels)
		1	2 MSBs (4 priority levels)
		2	3 MSBs (8 priority levels)
		3	4 MSBs (16 priority levels)
		4	5 MSBs (32 priority levels)
		5	6 MSBs (64 priority levels)

Table 6-10: SEC_CPLVL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 MSBs (128 priority levels)
		7	8 MSBs (256 priority levels)

SCI Priority Mask Register n

The SEC SCI priority mask register (SEC_CPMSK[n]) contains the SCI priority mask for core n and includes a register lock.

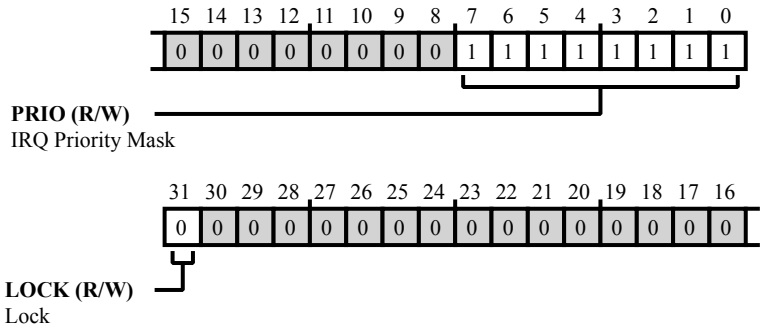

Figure 6-10: SEC_CPMSK[n] Register Diagram

Table 6-11: SEC_CPMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPMSK[n].LOCK bit is enabled, the SEC_CPMSK[n] register is read only.	
		0	Unlock
		1	Lock
7:0 (R/W)	PRIO	IRQ Priority Mask. The SEC_CPMSK[n].PRIO contains the system interrupt priority mask for core n. The core uses the SEC_CPMSK[n].PRIO field to mask (block) interrupts below the specified level.	
		0	Priority level 0 (highest)
		1-254	
		255	Priority level 255 (lowest)

Core Pending Register n

The SCI pending interrupt register (SEC_CPND[n]) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.

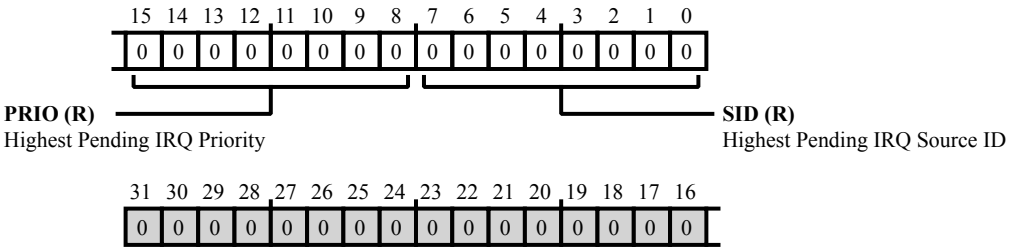

Figure 6-11: SEC_CPND[n] Register Diagram

Table 6-12: SEC_CPND[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Pending IRQ Priority. The SEC_CPND[n].PRIO indicates the priority value of the highest priority pending interrupt for core n.
7:0 (R/NW)	SID	Highest Pending IRQ Source ID. The SEC_CPND[n].SID identifies the source ID value of the highest priority pending interrupt for core n.

SCI Source ID Register n

The SCI source ID register (SEC_CSID[n]) contains the source ID of the interrupt last issued to core n. The SEC_CSID[n] register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the SEC_CSID[n] until after the interface receives an interrupt acknowledge from core n. Writing to the SEC_CSID[n] register generates an interrupt acknowledge, but does not update the value in the register.

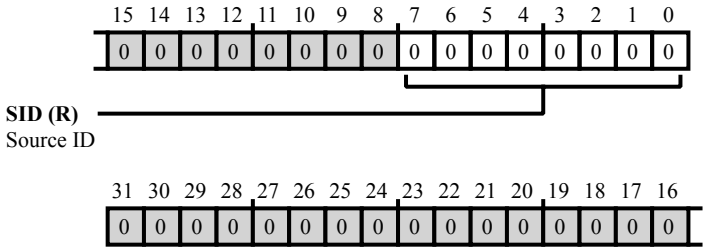

Figure 6-12: SEC_CSID[n] Register Diagram

Table 6-13: SEC_CSID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	SID	Source ID. The SEC_CSID[n].SID bit is the source ID of the interrupt last issued to core n.

SCI Status Register n

The SCI status register (SEC_CSTAT[n]) contains status bits, indicating the operational status of the SCI.

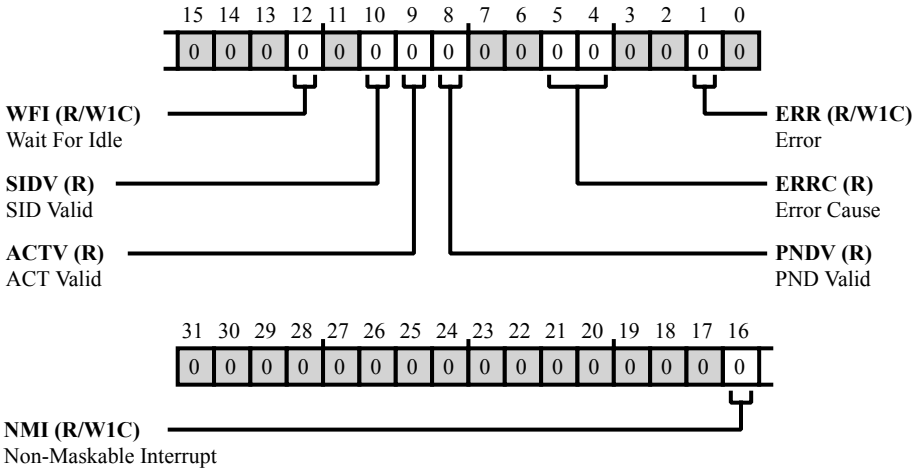

Figure 6-13: SEC_CSTAT[n] Register Diagram

Table 6-14: SEC_CSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	NMI	Non-Maskable Interrupt. The SEC_CSTAT[n].NMI bit indicates whether an NMI has occurred since the bit was last cleared.	
		0	No NMI Occurred
		1	NMI Occurred
12 (R/W1C)	WFI	Wait For Idle. The SEC_CSTAT[n].WFI bit indicates (if set) that the SCI is temporarily disabled, pending a core idle indication. This bit is set when SEC_CCTL[n].WFI is set.	
		0	Not Waiting
		1	Waiting
10 (R/NW)	SIDV	SID Valid. The SEC_CSTAT[n].SIDV bit indicates (if set) that the current value in the SEC_CSID[n] register is valid. The SCI sets the SEC_CSTAT[n].SIDV bit when the updating the SEC_CSID[n] register with a new value. The SEC_CSTAT[n].SIDV bit is cleared when the SEC_CSID[n] register is written. This status indication may be used to extract all pending interrupts in a single interrupt service routine.	
		0	Invalid
		1	Valid

Table 6-14: SEC_CSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	ACTV	ACT Valid. The SEC_CSTAT[n].ACTV bit indicates (if set) that the current value in the SEC_CACT[n] register is valid. The SCI sets the SEC_CSTAT[n].ACTV bit when updating the SEC_CACT[n] registers with a new value. The SEC_CSTAT[n].ACTV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
8 (R/NW)	PNDV	PND Valid. The SEC_CSTAT[n].PNDV bit indicates (if set) that the current value in the SEC_CPND[n] register is valid. The SCI sets the SEC_CSTAT[n].PNDV bit when updating the SEC_CPND[n] register with a new value. The SEC_CSTAT[n].PNDV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
5:4 (R/NW)	ERRC	Error Cause. The SEC_CSTAT[n].ERRC bits are updated on assertion of the SEC_CSTAT[n].ERR bit to indicate the SCI error type. SEC_CSTAT[n].ERRC is only updated on the assertion of SEC_CSTAT[n].ERR. Subsequent errors while SEC_CSTAT[n].ERR is asserted do not update SEC_CSTAT[n].ERRC.	
		0	Reserved
		1	Acknowledge Error. SCI has received an acknowledge without a pending, unacknowledged interrupt present.
		2	Reserved
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_CSTAT[n].ERR bit indicates that an error has occurred in the SCI. When SEC_CSTAT[n].ERR is set, the SCI updates the SEC_CSTAT[n].ERRC field to the value of the corresponding error cause.	
		0	No Error
		1	Error Occurred

Global End Register

The SEC global end register (SEC_END) contains a source ID interrupt service end field (SEC_END.SID). When a core has finished servicing an interrupt, the core writes the SEC_END.SID field in the SEC_END register. This write causes the SEC to clear the SEC_SSTAT[n].ACT bit in the SEC_SSTAT[n] register of the corresponding interrupt.

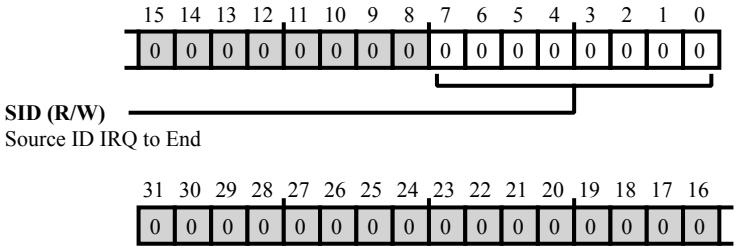

Figure 6-14: SEC_END Register Diagram

Table 6-15: SEC_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID IRQ to End. The SEC_END.SID bit field contains the source ID interrupt service end value.

Fault COP Period Register

The SEC fault COP period register (SEC_FCOPP) contains the width value (count in (SEC) clock cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase value is the SEC_FCOPP.COUNT programmed value plus 1.

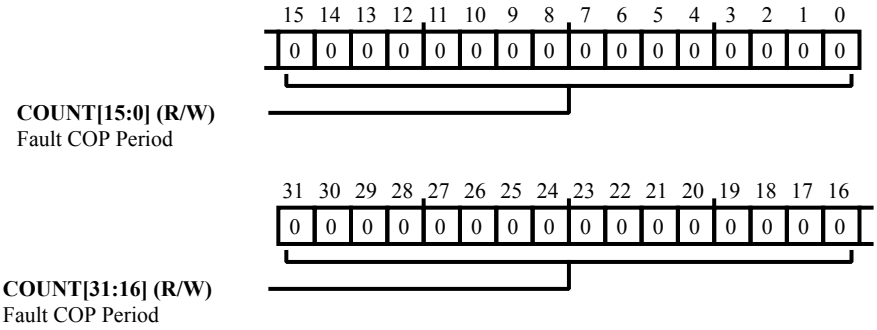

Figure 6-15: SEC_FCOPP Register Diagram

Table 6-16: SEC_FCOPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault COP Period. The SEC_FCOPP.COUNT bit field is the width value for the high and low phase of the computer operating properly (COP) toggled output on the COP pin.

Fault COP Period Current Register

The SEC fault COP period current register (SEC_FCOPP_CUR) contains the active count (in (SEC) clock periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC_FCOPP_CUR register from the SEC_FCOPP register when the SEC_FCOPP_CUR.COUNT field is cleared and the SEC is in COP mode (SEC_FCTL.CMS bit =1). The SEC decrements the SEC_FCOPP_CUR count each (SEC) clock cycle while SEC_FCTL.CMS is set and the SEC_FSTAT.ACT bit is not set.

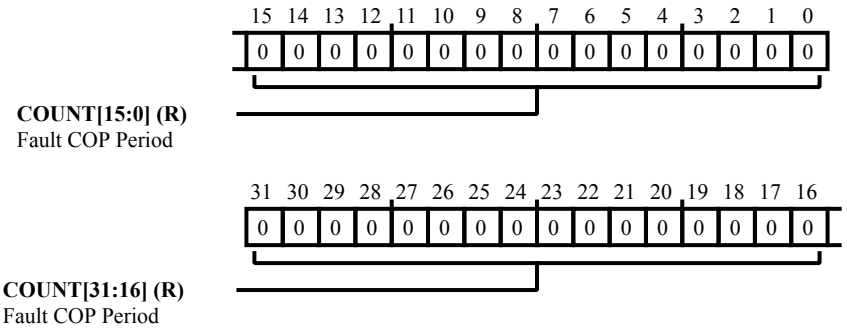

Figure 6-16: SEC_FCOPP_CUR Register Diagram

Table 6-17: SEC_FCOPP_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault COP Period. The SEC_FCOPP_CUR.COUNT bit field is the active count for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin.

Fault Control Register

The SEC fault control register (SEC_FCTL) contains fault control bits for all SEC channels. This register controls the operation of the System Fault Management Interface (SFI).

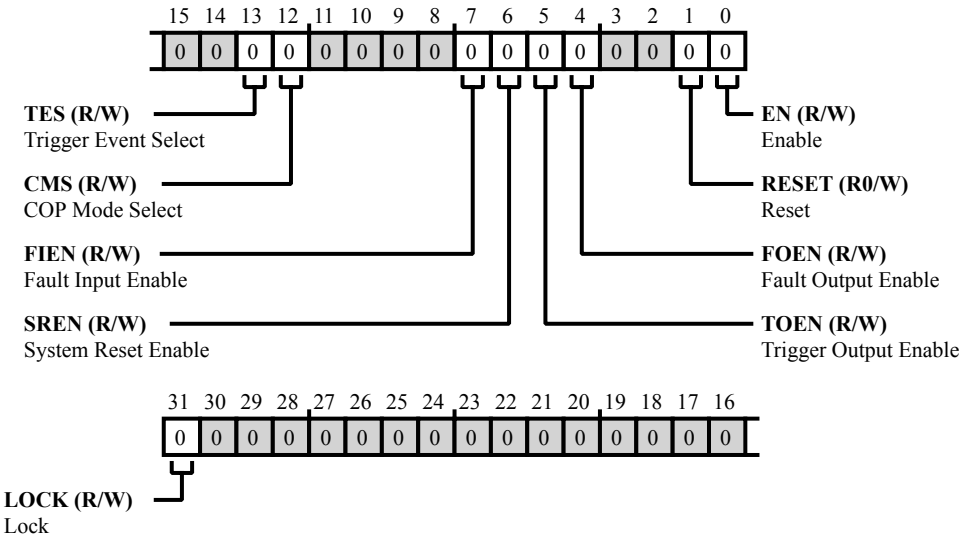

Figure 6-17: SEC_FCTL Register Diagram

Table 6-18: SEC_FCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_FCTL.LOCK bit is enabled, the SEC_FCTL register is read only.	
		0	UnLock
		1	Lock
13 (R/W)	TES	Trigger Event Select. The SEC_FCTL.TES bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.	
		0	Fault Active Mode
		1	Fault Pending Mode

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	CMS	COP Mode Select. The SEC_FCTL.CMS selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. Not all processors feature both the fault and fault_b pins. Refer to the product data sheet for details.	
		0	Fault Mode
		1	COP Mode
7 (R/W)	FIEN	Fault Input Enable. The SEC_FCTL.FIEN bit enables the SEC to sample fault input. If SEC_FCTL.FIEN is set (=1), a fault indication from an external device sets the SEC_FSTAT.ACT bit and SEC_FSID.FEXT bit.	
		0	Disable
		1	Enable
6 (R/W)	SREN	System Reset Enable. The SEC_FCTL.SREN bit enables the SEC to issue a system reset request when a fault becomes active.	
		0	Disable
		1	Enable
5 (R/W)	TOEN	Trigger Output Enable. The SEC_FCTL.TOEN bit enables the SEC to produce trigger output when a fault becomes active.	
		0	Disable
		1	Enable
4 (R/W)	FOEN	Fault Output Enable. The SEC_FCTL.FOEN bit enables the SEC to indicate fault status, according to the SEC_FCTL.CMS bit configuration.	
		0	Disable
		1	Enable
1 (R0/W)	RESET	Reset. Setting the SEC_FCTL.RESET bit resets ALL SEC registers to their default values.	
		0	No Action
		1	Reset

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The SEC_FCTL.EN bit controls the operational state of the SEC. Clearing the SEC_FCTL.EN bit halts the execution of the SEC without resetting status registers. Setting the SEC_FCTL.EN bit enables the SEC to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Fault Delay Register

The SEC fault delay register (SEC_FDLY) contains the number (SEC_FDLY.COUNT field) of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

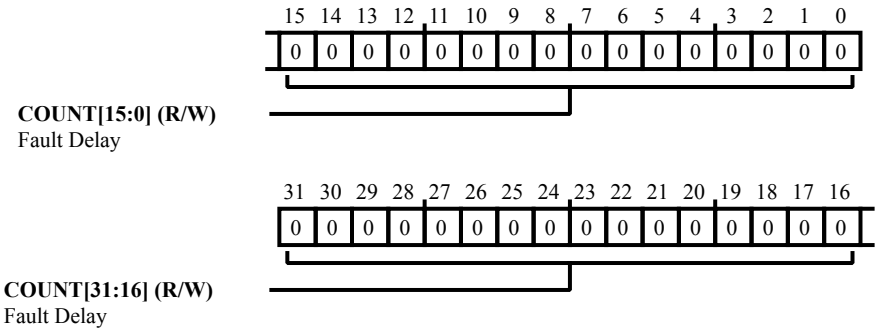

Figure 6-18: SEC_FDLY Register Diagram

Table 6-19: SEC_FDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault Delay. The SEC_FDLY.COUNT bit field is the number of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

Fault Delay Current Register

The SEC fault delay current register (SEC_FDLY_CUR) contains the active count (SEC_FDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the SEC_FDLY register when a fault becomes pending (SEC_FSTAT.PND bit is set). The SEC decrements the value in SEC_FDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.PND bit is set.

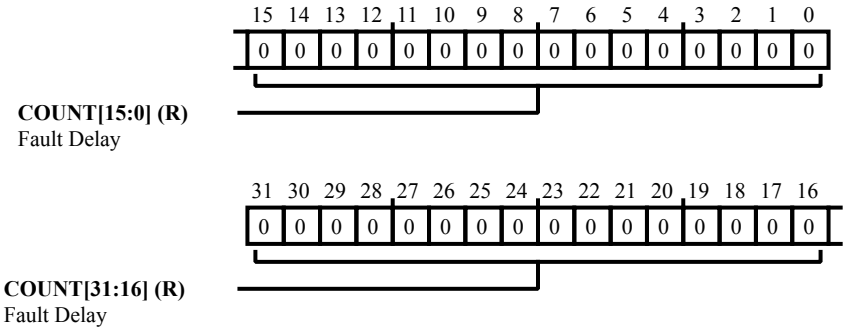

Figure 6-19: SEC_FDLY_CUR Register Diagram

Table 6-20: SEC_FDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault Delay. The SEC_FDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled.

Fault End Register

The SEC fault end register (SEC_FEND) contains fault source ID and internal/external fields. This register receives fault end indication from a core.

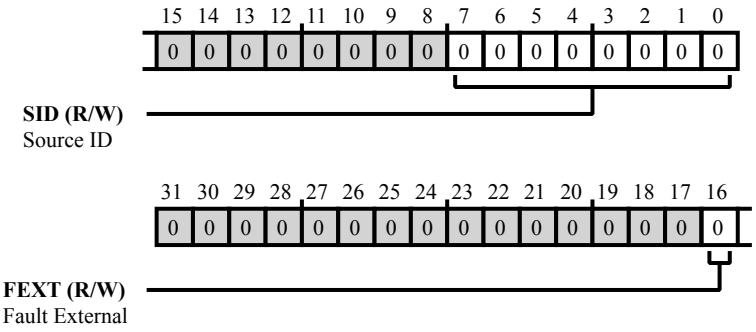

Figure 6-20: SEC_FEND Register Diagram

Table 6-21: SEC_FEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	FEXT	Fault External. Setting the SEC_FEND.FEXT bit, when the SEC_FEND.SID field is cleared, clears an active fault from an external source.	
		0	Fault Internal
		1	Fault External
7:0 (R/W)	SID	Source ID. The SEC_FEND.SID identifies a fault to be ended as indicated to the SEC by the core. The core loads the SEC_FEND.SID field value. If the SEC_FEND.SID value matches the SEC_FSID.SID value, the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit are cleared.	

Fault Source ID Register

The SEC fault source ID register (SEC_FSID) contains a fault source ID and internal/external fields.

NOTE:These bits are not reset by system reset so that a fault that automatically triggers a system reset to avoid a fault may be analyzed after the reset occurs.

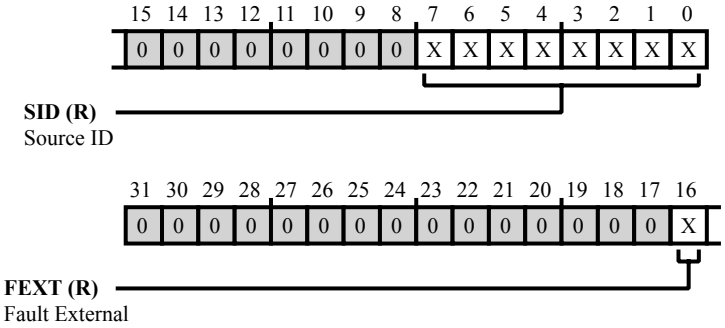

Figure 6-21: SEC_FSID Register Diagram

Table 6-22: SEC_FSID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	FEXT	Fault External. The SEC_FSID.FEXT bit indicates that the last active fault was asserted by an external device. The SEC sets the SEC_FSID.FEXT bit when the SEC_FSTAT.ACT bit is set by the fault input pins. The SEC_FSID.FEXT bit is cleared when the SEC_FSTAT.ACT bit is set by an internal fault or when the external fault is ended. When the SEC_FSID.FEXT bit is set, the SEC_FSID.SID is cleared.	
		0	Fault Internal
		1	Fault External
7:0 (R/NW)	SID	Source ID. The SEC_FSID.SID identifies the fault assertion detected by the SEC fault interface. The SEC loads the SEC_FSID.SID field value when a system fault indication is asserted. The SEC fault interface does not change the SEC_FSID.SID value until the fault is no longer pending or active, as indicated by the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit being cleared in the SEC_FSTAT register.	

Fault System Reset Delay Register

The SEC fault system reset delay register (SEC_FSRDLY) contains the number (SEC_FSRDLY.COUNT field) of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion, if enabled.

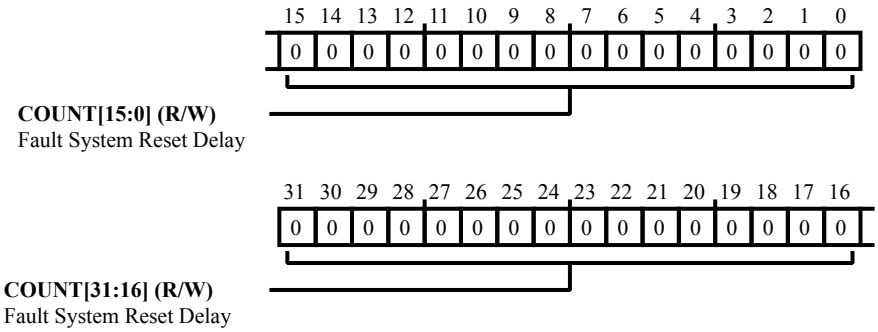

Figure 6-22: SEC_FSRDLY Register Diagram

Table 6-23: SEC_FSRDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault System Reset Delay. The SEC_FSRDLY.COUNT bit field is the number of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion.

Fault System Reset Delay Current Register

The SEC fault system reset delay current register (SEC_FSRDLY_CUR) contains the active count (SEC_FSRDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the SEC_FSRDLY register when a fault becomes active (SEC_FSTAT.ACT bit is set). The SEC decrements the value in SEC_FSRDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.ACT bit is set.

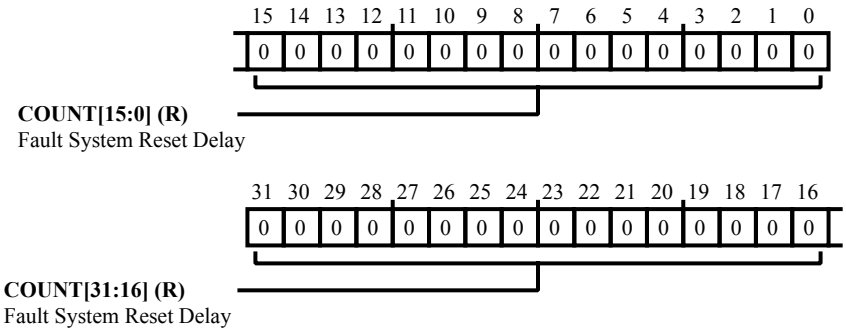

Figure 6-23: SEC_FSRDLY_CUR Register Diagram

Table 6-24: SEC_FSRDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault System Reset Delay. The SEC_FSRDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault active to system reset assertion.

Fault Status Register

The SEC fault status register (SEC_FSTAT) indicates the operational status of the SFI.

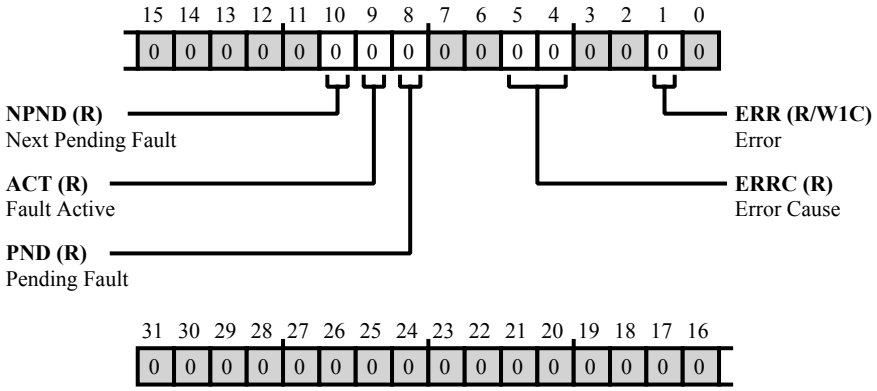

Figure 6-24: SEC_FSTAT Register Diagram

Table 6-25: SEC_FSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	NPND	Next Pending Fault. The SEC_FSTAT.NPND bit indicates that one or more sources have signaled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.	
		0	Not Pending
		1	Pending
9 (R/NW)	ACT	Fault Active. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the ID value of the asserted fault from SEC_FSID register to the SEC_FEND register.	
		0	No Fault
		1	Active Fault

Table 6-25: SEC_FSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	PND	Pending Fault. The SEC_FSTAT.PND bit indicates a fault source has signaled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to the delay selected with the SEC_FDLY register. The SEC fault interface sets the SEC_FSTAT.PND bit when the SEC_FSID is updated on assertion of a fault source input. The SEC_FSTAT.PND bit is only set when the SEC_FSTAT.ACT bit is cleared. The SEC updates the SEC_FSID register with the SID value when the SEC_FSTAT.PND bit is set. The SEC_FSTAT.PND bit is cleared *either* by the SEC fault interface when the current delay count in the SEC_FDLY_CUR register expires *or* by writing the SEC_FSID.SID field value (which indicates the ID of the asserted fault) to the SEC_FEND register.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_FSTAT.ERR bit is asserted, the SEC updates SEC_FSTAT.ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_FSTAT.ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_FSTAT.ERR bit indicates an SEC fault interface error. When SEC_FSTAT.ERR is set, the SEC updates the SEC_FSTAT.ERRC field to indicate the corresponding error cause. When multiple errors occur, the SEC_FSTAT register captures the status for the first error and does not capture subsequent errors until the status is cleared.	
		0	No Error
		1	Error Occurred

Global Control Register

The SEC global control register (SEC_GCTL) provides register locking, reset, and enable for the SEC module.

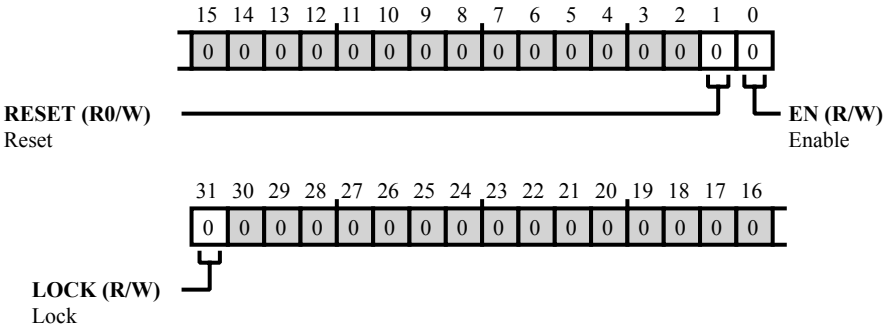

Figure 6-25: SEC_GCTL Register Diagram

Table 6-26: SEC_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_GCTL.LOCK bit is enabled, the SEC_GCTL register is read only.	
		0	Unlock
		1	Lock
1 (R0/W)	RESET	Reset. The SEC_GCTL.RESET bit is write-1-action and triggers a soft reset to all SEC registers.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The SEC_GCTL.EN bit is read/write and must be set for the SEC to begin/resume SEC operation with the current configuration and status. Clearing the SEC_GCTL.EN bit halts the execution of the SFI and all SCIs. All SSIs remain active, along with all error detection, without resetting status registers.	
		0	Disable
		1	Enable

Global Status Register

The SEC global status register (SEC_GSTAT) contains global status bits for the SEC.

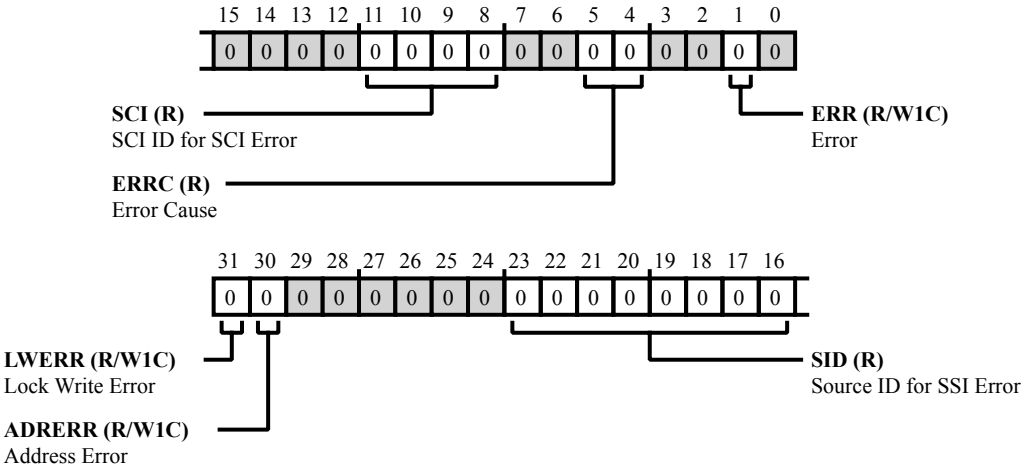

Figure 6-26: SEC_GSTAT Register Diagram

Table 6-27: SEC_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SEC_GSTAT.LWERR bit indicates (when set) there was an attempted write to an SEC register while the SEC_GCTL.LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30 (R/W1C)	ADRERR	Address Error. The SEC_GSTAT.ADRERR bit indicates that the SEC generated and address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
23:16 (R/NW)	SID	Source ID for SSI Error. The SEC_GSTAT.SID bits indicate the source ID that generated the last SSI error conveyed in the SEC_GSTAT.ERRC field.	
11:8 (R/NW)	SCI	SCI ID for SCI Error. The SEC_GSTAT.SCI bits indicate the number for the specific SCI that generated the last SCI error conveyed in the SEC_GSTAT.ERRC field.	

Table 6-27: SEC_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	ERRC	Error Cause. When the SEC updates the `SEC_GSTAT.ERR` bit, the SEC updates the `SEC_GSTAT.ERRC` bits to indicate the error type. Note that for SCI errors, the error status represents an OR of all the errors from each SCI. Note that for SSI errors, the error status indicates an error is active for any SSI input. This error is an OR of all the interrupt source errors.	
		0	SFI Error
		1	SCI Error
		2	SSI Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_GSTAT.ERR` bit indicates an error has occurred in the SEC. When the SEC asserts this bit (=1), the SEC updates the `SEC_GSTAT.ERRC` field to indicate the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of this bit. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred

Global Raise Register

The SEC global raise register (SEC_RAISE) contains a source ID event set-to-pending field (SEC_RAISE.SID). When a source ID value is written to this field, the SEC raises the source's event status to pending.

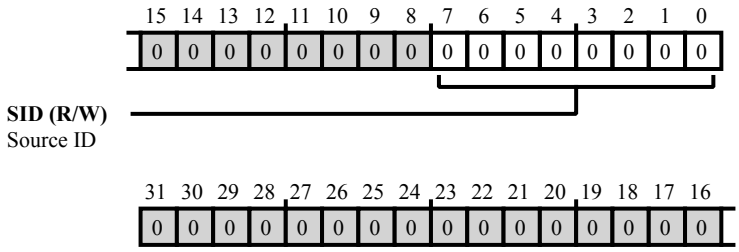

Figure 6-27: SEC_RAISE Register Diagram

Table 6-28: SEC_RAISE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID. The SEC_RAISE.SID bit field is the source ID of event that is set to pending status.

Source Control Register n

The SEC source control register (SEC_SCTL[n]) contains control bits to configure the SEC event sources. This register controls the configuration of the corresponding SEC event source.

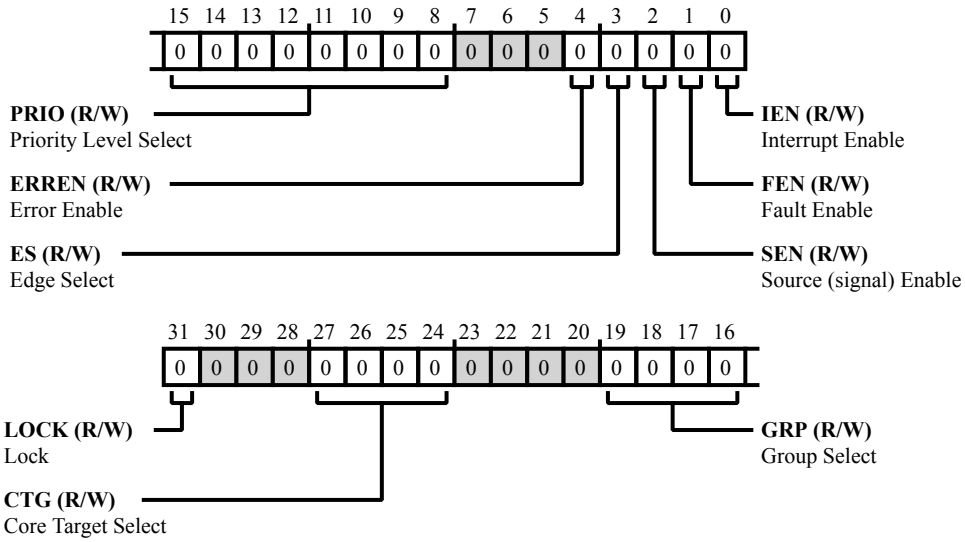

Figure 6-28: SEC_SCTL[n] Register Diagram

Table 6-29: SEC_SCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_SCTL[n].LOCK bit is enabled, the SEC_SCTL[n] register is read only.	
		0	Unlock
		1	Lock
27:24 (R/W)	CTG	Core Target Select. The SEC_SCTL[n].CTG bits selects the specific SEC core interface to which the interrupt is mapped. Each system interrupt is mapped uniquely to one specific SEC core interface and (as a result) to a specific core.	
		1	CORE1 SHARC0
		2	CORE2 SHARC1

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	GRP	Group Select. The SEC_SCTL[n].GRP bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the SEC_SCTL[n].GRP field. For example, consider the situation where SEC_SCTL[n].GRP0 represents interrupt group 0, SEC_SCTL[n].GRP1 represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset. Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all SEC_SCTL[n].GRP bits = 0) places the interrupt source in the category of "ungrouped".	
15:8 (R/W)	PRIO	Priority Level Select. The SEC_SCTL[n].PRIO bits sets the relative priority for an interrupt request. A pending interrupt request forwards its SEC_SCTL[n].PRIO value to the SEC core interface.	
4 (R/W)	ERREN	Error Enable. The SEC_SCTL[n].ERREN bit permits the SEC_SSTAT[n].ERR status bit to be set on error detection. If SEC_SCTL[n].ERREN is cleared, no errors are detected.	
		0	Disable
		1	Enable
3 (R/W)	ES	Edge Select. The SEC_SCTL[n].ES bit selects the operational and sensitivity mode of the SEC source interface input.	
		0	Level Sensitive
		1	Edge Sensitive
2 (R/W)	SEN	Source (signal) Enable. The SEC_SCTL[n].SEN bit controls whether the system event source input signal may affect the pending status of the source. Clearing the SEC_SCTL[n].SEN bit disables the source input signal from affecting the pending status. Setting SEC_SCTL[n].SEN enables the source input signal to affect the pending status.	
		0	Disable
		1	Enable

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FEN	Fault Enable. The `SEC_SCTL[n].FEN` bit controls whether the SEC may forward an interrupt request to the SEC fault interface as a fault source. This bit does not affect the ability of an interrupt source to set an interrupt as pending. The `SEC_SCTL[n].FEN` bit only affects whether the pending request may be forwarded to the SEC fault interface.	
		0	Disable
		1	Enable
0 (R/W)	IEN	Interrupt Enable. The `SEC_SCTL[n].IEN` bit controls whether the SEC may forward an interrupt request to a core for servicing. This bit does not affect the ability of an interrupt source to set an interrupt as pending.	
		0	Disable
		1	Enable

Source Status Register n

The SEC event source status register (SEC_SSTAT[n]) contains bits indicating the status of the corresponding event source n. An event source may be: pending, active, active and pending, or neither pending nor active.

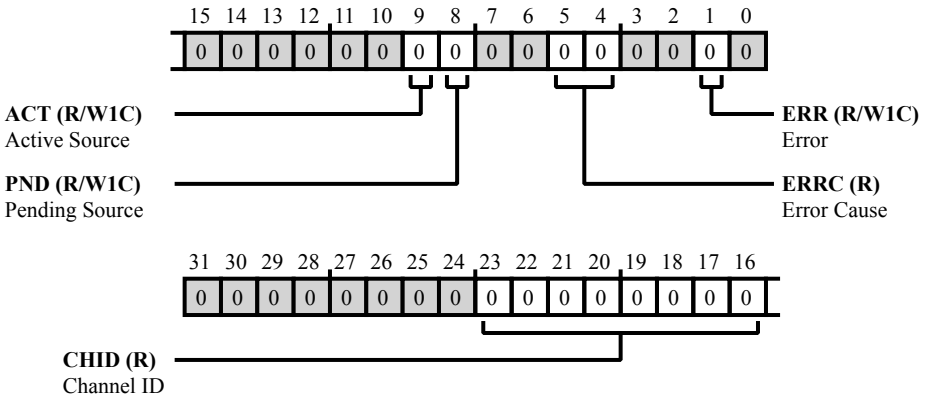

Figure 6-29: SEC_SSTAT[n] Register Diagram

Table 6-30: SEC_SSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/NW)	CHID	Channel ID. The SEC_SSTAT[n].CHID bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The SEC_SSTAT[n].CHID field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The SEC_SSTAT[n].CHID is captured when the SEC source interface input is acknowledged.	
9 (R/W1C)	ACT	Active Source. The SEC_SSTAT[n].ACT bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An SEC_SSTAT[n].ACT bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An SEC_SSTAT[n].ACT bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.	
		0	Not Active
		1	Active

Table 6-30: SEC_SSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	PND	Pending Source. The SEC_SSTAT[n].PND bit indicates the source has signaled an event request, but the event request has not been (or is not currently being) serviced. A SEC_SSTAT[n].PND bit is set by the SEC on detection of an assertion of the corresponding system source input. A SEC_SSTAT[n].PND bit is cleared by the SEC when the specific system event is acknowledged by the core through the SEC core interface or by a W1C operation.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_SSTAT[n].ERR bit is asserted, the SEC updates SEC_SSTAT[n].ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_SSTAT[n].ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_SSTAT[n].ERR bit indicates an error for a specific system interrupt source. When the SEC_SSTAT[n].ERR bit is set, the SEC updates the SEC_SSTAT[n].ERRC field to the value of the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of the SEC_SSTAT[n].ERR bit.	
		0	No Error
		1	Error Occurred

GIC Overview

The generic interrupt controller (GIC) provides an interface to the uniprocessor Cortex A5 core in the processor and collects up to 270 interrupt requests from all processor system sources. In addition, the GIC also supports eight software generated interrupts that are internal to the Cortex A5 core and not connected to the SECs. All GIC interrupts are also connected to the SEC in the same order.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The "Register Descriptions" section in this chapter provide brief descriptions of these ARM-based registers. For complete information refer to the *ARM® Generic Interrupt Controller Architecture version 1.0 Architecture Specification*.

GIC Functional Description

The GIC splits logically into a GICPORT0 (distributor block) and one GICPORT1 (CPU interface blocks).

General Interrupt Controller Port0 (GIC Distributer)

The distributor block provides a programming interface to perform the following tasks.

- Globally enable the forwarding of interrupts to the CPU interfaces
- Enable or disable each interrupt
- Set the priority level of each interrupt
- Set the target processor list of each interrupt
- Set each peripheral interrupt to be level-sensitive or edge-triggered
- Set each interrupt as either Group 0 or Group 1
- Forward an SGI to one or more target processors

In addition, the Distributor provides:

- Visibility of the state of each interrupt
- A mechanism for software to set or clear the pending state of a peripheral interrupt.

General Interrupt Controller Port1 (GIC CPU)

GICPORT1 (CPU interface) block performs priority masking and preemption handling for a connected processor in the system. GICPORT1 supports 8 SGIs (software generated interrupts) and 262 SPIs (shared peripheral interrupts).

Each CPU interface provides a programming interface to perform the following tasks.

- Enable signaling of interrupt requests to the processor
- Acknowledge interrupts
- Indicate that interrupt processing is complete
- Set interrupt priority masks for the processor
- Define the preemption policy for the processor
- Determine the highest priority pending interrupt for the processor

GIC Block Diagram

The *GIC Block Diagram* shows the event management architecture.

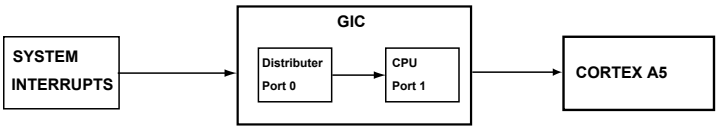

Figure 6-30: GIC Block Diagram

ADSP-2159x_SC591_SC592_SC594 GICDST Register Descriptions

GIC Distributor Port (GICDST) contains the following registers.

Table 6-31: ADSP-2159x_SC591_SC592_SC594 GICDST Register List

Name	Description
GICDST_EN	GIC Port 0 Enable
GICDST_SGI_PRIO[n]	Software Generated Interrupt Priority Register
GICDST_SPI_PRIO[n]	Shared Peripheral Interrupt Priority Register
GICDST_SGI_ACTIVE	Software Generated Interrupt Active Register
GICDST_SGI_CTL	Software Generated Interrupt Control Register
GICDST_SGI_PND_CLR	Software Generated Interrupt Clear-Pending Register
GICDST_SGI_PND_SET	Software Generated Interrupt Pending Set Register
GICDST_SGI_SECURITY	Software Generated Interrupt Security Register
GICDST_SPI[n]	Shared Peripheral Interrupt Register
GICDST_SPI_ACTIVE[n]	Shared Peripheral Interrupt Active Register
GICDST_SPI_CFG[n]	Shared Peripheral Interrupt Configuration Register
GICDST_SPI_EN_CLR[n]	Shared Peripheral Interrupt Enable Clear Register
GICDST_SPI_EN_SET[n]	Shared Peripheral Interrupt Enable Set Register
GICDST_SPI_PND_CLR[n]	Shared Peripheral Interrupt Pending Clear Register
GICDST_SPI_PND_SET[n]	Shared Peripheral Interrupt Pending Set Register
GICDST_SPI_SECURITY[n]	Shared Peripheral Interrupt Security Register
GICDST_SPI_TRGT[n]	Shared Peripheral Interrupt Processor Targets Register

GIC Port 0 Enable

The GICDST_EN register enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

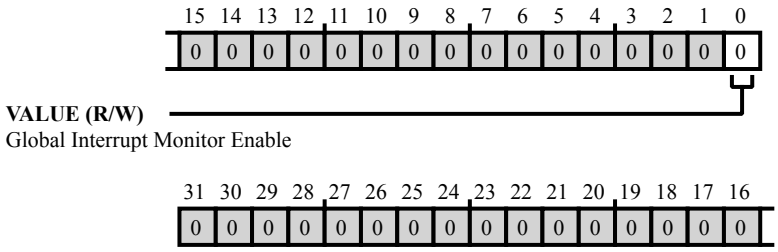

Figure 6-31: GICDST_EN Register Diagram

Table 6-32: GICDST_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Global Interrupt Monitor Enable. The GICDST_EN.VALUE bit field enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

Software Generated Interrupt Priority Register

The GICDST_SGI_PRIO[n] register provides the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

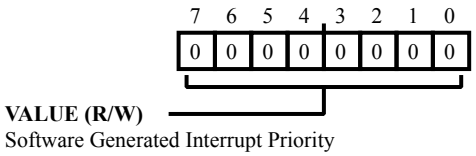

Figure 6-32: GICDST_SGI_PRIO[n] Register Diagram

Table 6-33: GICDST_SGI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Software Generated Interrupt Priority. The GICDST_SGI_PRIO[n].VALUE bit field contains the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

Shared Peripheral Interrupt Priority Register

The GICDST_SPI_PRIO[n] registers provide an 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

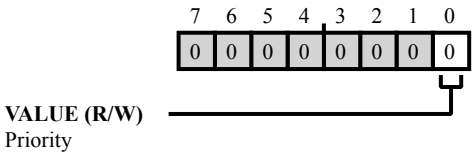

Figure 6-33: GICDST_SPI_PRIO[n] Register Diagram

Table 6-34: GICDST_SPI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Priority. The GICDST_SPI_PRIO[n].VALUE bit field stores the priority of the corresponding interrupt (byte offset 3 to Byte offset 0).

Software Generated Interrupt Active Register

The GICDST_SGI_ACTIVE registers provide a Set-active bit for each interrupt that the GIC supports. Writing to a Set-active bit Activates the corresponding interrupt. These registers are used when preserving and restoring GIC state.

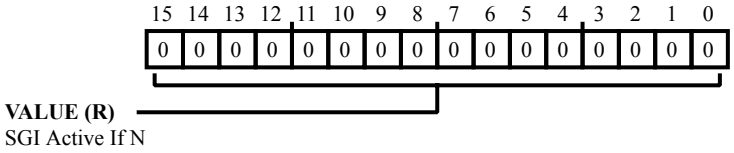

Figure 6-34: GICDST_SGI_ACTIVE Register Diagram

Table 6-35: GICDST_SGI_ACTIVE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	SGI Active If N. The GICDST_SGI_ACTIVE.VALUE bit field provides a Set-active bit for each interrupt that the GIC supports.

Software Generated Interrupt Control Register

The GICDST_SGI_CTL register controls the generation of SGIs.It is implementation defined whether this register has any effect when the forwarding of interrupts by Distributor is disabled by the GICD_CTLR settings.

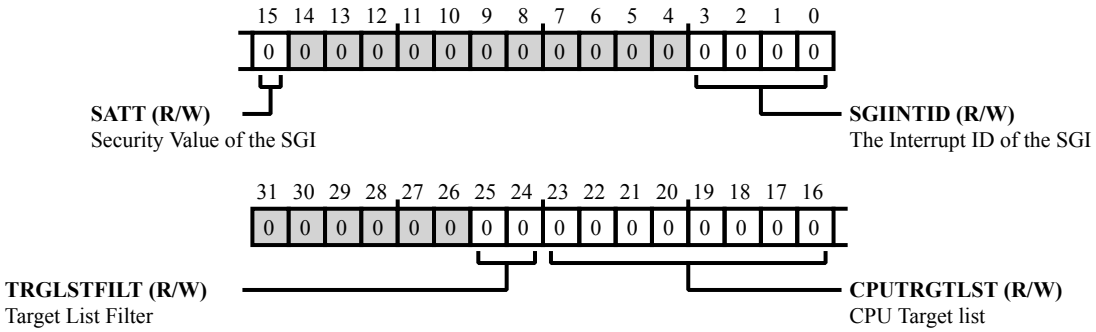

Figure 6-35: GICDST_SGI_CTL Register Diagram

Table 6-36: GICDST_SGI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRGLSTFILT	Target List Filter. The GICDST_SGI_CTL.TRGLSTFILT bit field determines how the distributor must process the requested SGI.	
		0	Forward the interrupt to the CPU interfaces specified in the CPUTargetList field
		1	Forward the interrupt to all CPU interfaces except that of the processor that requested the interrupt
		2	Forward the interrupt only to the CPU interface of the processor that requested the interrupt
		3	Reserved
23:16 (R/W)	CPUTRGTLST	CPU Target list. When the GICDST_SGI_CTL.CPUTRGTLST bit field TargetList Filter = 0b00, defines the CPU interfaces to which the Distributor must forward the interrupt. Each bit of the GICDST_SGI_CTL.CPUTRGTLST bit field refers to the corresponding CPU interface, for example CPUTargetList[0] corresponds to CPU interface 0. Setting a bit to 1 indicates that the interrupt must be forwarded to the corresponding interface. If this field is 0x00 when TargetListFilter is 0b00, the Distributor does not forward the interrupt to any CPU interface.	

Table 6-36: GICDST_SGI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SATT	Security Value of the SGI. The `GICDST_SGI_CTL.SATT` bit is implemented only if the GIC includes the Security Extensions. This field is writable only by a Secure access. Any Non-secure write to the GICD_SGIR generates an SGI only if the specified SGI is programmed as Group 1, regardless of the value of bit[15] of the write.	
		0	Forward the SGI specified in the SGIINTID field to a specified CPU interface only if the SGI is configured as Group 0 on that interface.
		1	Forward the SGI specified in the SGIINTID field to a specified CPU interfaces only if the SGI is configured as Group 1 on that interface.
3:0 (R/W)	SGIINTID	The Interrupt ID of the SGI.	

Software Generated Interrupt Clear-Pending Register

The GICDST_SGI_PND_CLR register provides a clear pending bit for each interrupt supported by the GIC. Writing 1 to a clear-pending bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

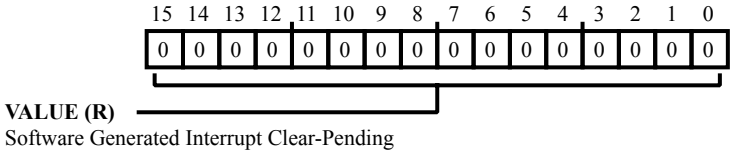

Figure 6-36: GICDST_SGI_PND_CLR Register Diagram

Table 6-37: GICDST_SGI_PND_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Software Generated Interrupt Clear-Pending. Writing 1 to a clear-pending bit in the GICDST_SGI_PND_CLR.VALUE bit field clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Pending Set Register

The GICDST_SGI_PND_SET register provides a set-pending bit for each interrupt supported by the GIC.

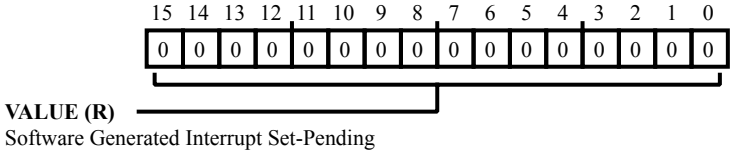

Figure 6-37: GICDST_SGI_PND_SET Register Diagram

Table 6-38: GICDST_SGI_PND_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Software Generated Interrupt Set-Pending. Writing 1 to a Set-pending bit in the GICDST_SGI_PND_SET.VALUE bit field sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Security Register

The GICDST_SGI_SECURITY registers provide a status bit for each interrupt supported by the GIC. Each bit controls whether the corresponding interrupt is in Group 0 or Group 1. Typically, when used with a processor that implements the ARM Security Extensions, Group 0 interrupts are Secure interrupts, and Group 1 interrupts are Non-secure interrupts,

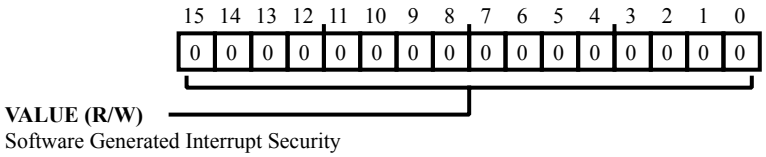

Figure 6-38: GICDST_SGI_SECURITY Register Diagram

Table 6-39: GICDST_SGI_SECURITY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Software Generated Interrupt Security. Each bit in the GICDST_SGI_SECURITY.VALUE bit field controls whether the corresponding interrupt is in Group 0 or Group 1.

Shared Peripheral Interrupt Register

The `GICDST_SPI[n]` register contains bits that provide the status of the SPI[987:0] inputs.

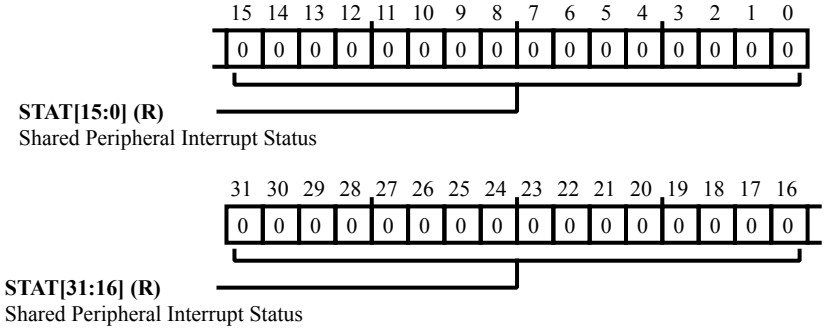

Figure 6-39: GICDST_SPI[n] Register Diagram

Table 6-40: GICDST_SPI[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	STAT	Shared Peripheral Interrupt Status. The `GICDST_SPI[n].STAT` bit field returns the status of the SPI[987:0] inputs on the distributor where bit [x] = 0 SPI[x] is low and bit [x] = 1 SPI[x] is high.

Shared Peripheral Interrupt Active Register

The GICDST_SPI_ACTIVE[n] register provides an active bit for each interrupt supported by the GIC.

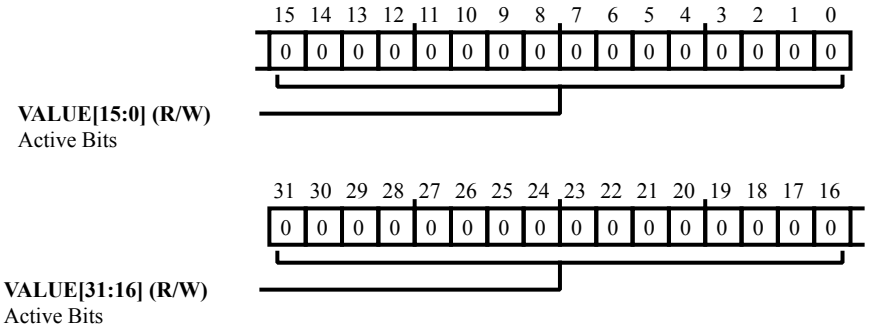

Figure 6-40: GICDST_SPI_ACTIVE[n] Register Diagram

Table 6-41: GICDST_SPI_ACTIVE[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Active Bits. The GICDST_SPI_ACTIVE[n].VALUE bit field contains an Active bit for each interrupt supported by the GIC. Reading an active bit identifies whether the corresponding interrupt is active (=1) or not active (=0).

Shared Peripheral Interrupt Configuration Register

The GICDST_SPI_CFG[n] register provides a 2-bit Int_config field for each interrupt supported by the GIC.

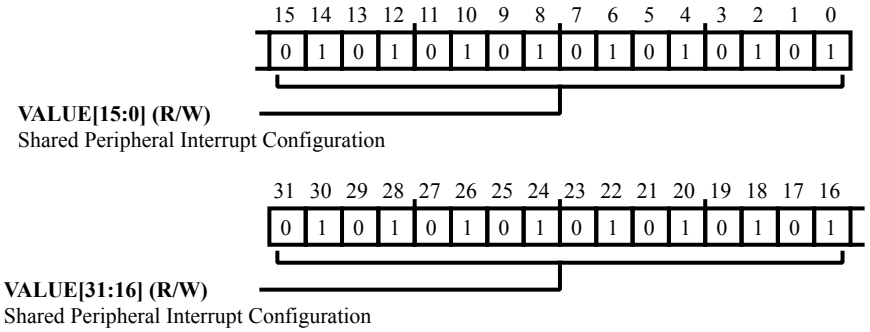

Figure 6-41: GICDST_SPI_CFG[n] Register Diagram

Table 6-42: GICDST_SPI_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Configuration. The GICDST_SPI_CFG[n].VALUE bit field identifies whether the corresponding interrupt is: edge-triggered or level-sensitive handled using the 1-N model or using the N-N model

Shared Peripheral Interrupt Enable Clear Register

The GICDST_SPI_EN_CLR[n] register provides a clear-enable bit for each interrupt supported by the GIC.

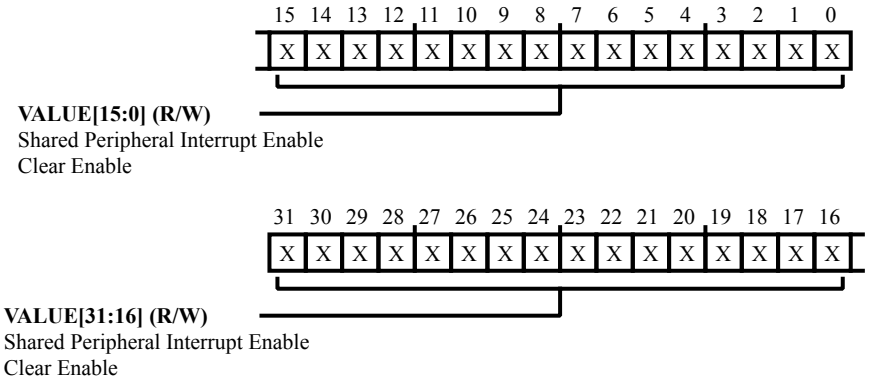

Figure 6-42: GICDST_SPI_EN_CLR[n] Register Diagram

Table 6-43: GICDST_SPI_EN_CLR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Enable Clear Enable. Writing 1 to a GICDST_SPI_EN_CLR[n].VALUE bit disables forwarding of the corresponding interrupt to the CPU interfaces. Reading a bit identifies whether the interrupt is enabled.

Shared Peripheral Interrupt Enable Set Register

The GICDST_SPI_EN_SET[n] register provides a set-enable bit for each interrupt supported by the GIC.

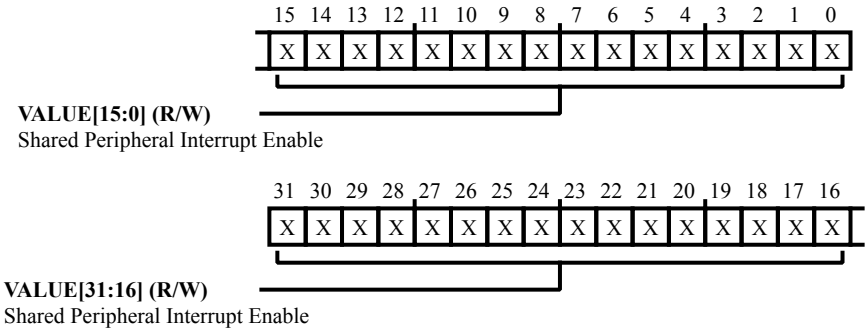

Figure 6-43: GICDST_SPI_EN_SET[n] Register Diagram

Table 6-44: GICDST_SPI_EN_SET[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Enable. Writing 1 to a GICDST_SPI_EN_SET[n].VALUE bit enables forwarding of the corresponding interrupt to the CPU interfaces. Reading a bit identifies whether the interrupt is enabled.

Shared Peripheral Interrupt Pending Clear Register

The GICDST_SPI_PND_CLR[n] register provides a clear-pending bit for each interrupt supported by the GIC.

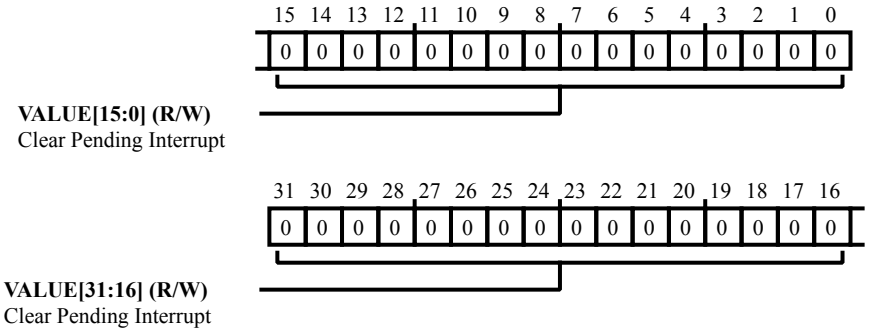

Figure 6-44: GICDST_SPI_PND_CLR[n] Register Diagram

Table 6-45: GICDST_SPI_PND_CLR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Clear Pending Interrupt. Writing 1 to a GICDST_SPI_PND_CLR[n].VALUE bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.

Shared Peripheral Interrupt Pending Set Register

The GICDST_SPI_PND_SET[n] register provides a set-pending bit for each interrupt supported by the GIC.

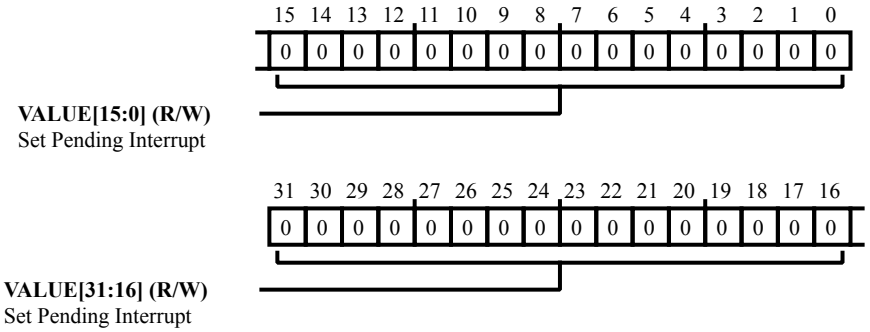

Figure 6-45: GICDST_SPI_PND_SET[n] Register Diagram

Table 6-46: GICDST_SPI_PND_SET[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Set Pending Interrupt. Writing 1 to a GICDST_SPI_PND_SET[n].VALUE bit sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Shared Peripheral Interrupt Security Register

The GICDST_SPI_SECURITY[n] register provides a security status bit for each interrupt supported by the GIC.

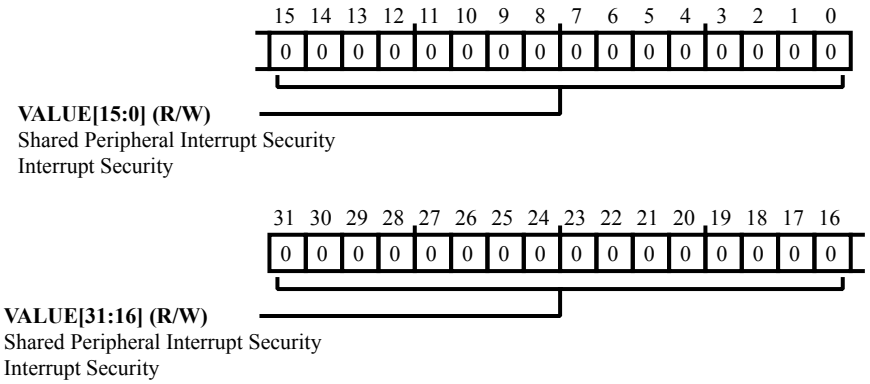

Figure 6-46: GICDST_SPI_SECURITY[n] Register Diagram

Table 6-47: GICDST_SPI_SECURITY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Security Interrupt Security. The GICDST_SPI_SECURITY[n].VALUE bits control the security status of the corresponding interrupt.

Shared Peripheral Interrupt Processor Targets Register

The `GICDST_SPI_TRGT[n]` register provides an 8-bit CPU targets field for each interrupt supported by the GIC.

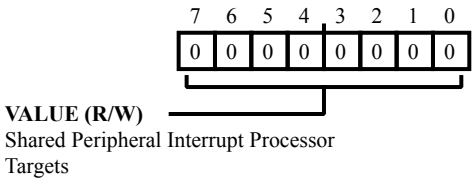

Figure 6-47: GICDST_SPI_TRGT[n] Register Diagram

Table 6-48: GICDST_SPI_TRGT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Shared Peripheral Interrupt Processor Targets. The `GICDST_SPI_TRGT[n].VALUE` bit field stores the list of processors that the interrupt is sent to if it is asserted.

7 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger requesters (generators of triggers) to trigger completers (receivers of triggers). Completer endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

TRU Features

The TRU supports the following features:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes. Once a DMA channel completes data transfer, it can act as a trigger requester and signal an internal trigger pulse to the programmed trigger completer which can also be another DMA channel. The completer trigger connected to the DMA channel kicks off the DMA transfer automatically. None of this requires core intervention once the initialization is done.
- Software triggers. The best use of triggers is to minimize core intervention. It is also possible to initiate a trigger pulse to a trigger completer, in the software.
- Synchronization of concurrent activities. A single trigger requester can initiate a trigger pulse to multiple trigger completers so that several system level activities can be synchronized on an internally or externally generated event.
- Configuration protection through register-level lock bits and global lock indication

TRU Functional Description

The following sections provide a description of the TRU.

ADSP-2159x_SC591_SC592_SC594 TRU Register List

The Trigger Routing Unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU receives trigger inputs from all master trigger inputs (MTI) and the TRU master trigger register (TRU_MTR). Based on these inputs, the TRU logic generates trigger outputs that initiate slave operations in the processor core and peripherals. A set of registers governs TRU operations. For more information on TRU functionality, see the TRU register descriptions.

Table 7-1: ADSP-2159x_SC591_SC592_SC594 TRU Register List

Name	Description
TRU_ERRADDR	Error Address Register

TRU Definitions

The following definitions are helpful when using the TRU module.

Trigger Requester

A trigger requester is any system module that provides trigger event indication to the TRU. Trigger requester modules define trigger events and conditions for assertion.

Trigger Requester ID

Trigger requesters are assigned a unique numeric ID according to their physical connection to the TRU. Trigger requester ID 0 is reserved and defined as null.

Trigger Completer

A trigger completer is any system module that receives a trigger event indication from the TRU. Trigger completer modules define a trigger event response.

NOTE: For peripherals configured as a completer receiver: if the corresponding peripheral DMA is kept waiting for trigger from a requester, it can receive stale or garbage data. The peripheral receiver begins shifting in data as soon as it is enabled and it does not wait for the trigger requester. Upon receiving the trigger, this data is moved into the DMA FIFO. Therefore, this sequence can result in the completer receiver getting unusable data.

TRU Block Diagram

The trigger requester and the Controller Trigger register (MTR) generate trigger assertions. Each trigger completer has a dedicated Target Select register (SSR) that specifies the unique trigger requester from which it receives the trigger indication.

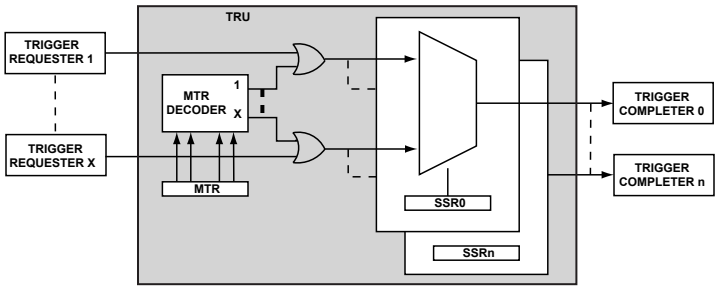

Figure 7-1: TRU Block Diagram

TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger requesters are mapped to trigger inputs of trigger completers through a set of programmable registers (`TRU_SSR[n]`).

System modules are trigger requester only, trigger completer only, or trigger requester and trigger completer.

All of the trigger input and output signals are connected to a trigger routing unit (TRU) which manages the connections of triggers between modules.

In multi-processor systems, multiple TRU units are provided. These TRUs are networked together. Generic Trigger Ports (GTPs) are provided to forward trigger events from one TRU unit to another, forming a pathway from trigger requesters to trigger completers wherever they might lie in the system.

TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger completer, a trigger requester, and the TRU module itself. The only requirement for the configuration procedure is that the trigger requester is configured and enabled as the last step.

Complete the following other steps:

- Configure the trigger completer for response to triggers
- Configure the TRU to map the trigger requester to the trigger completer through the `TRU_SSR[n]` registers
- Configure the trigger requester to generate trigger assertions
- Alternatively, use software triggering for trigger assertion. Writing the trigger requester ID to the MTR register generates software triggers.

Programming Concepts

The following concepts aid in programming the TRU.

- ***Trigger Sequence Configuration.*** A simple sequence consists of one trigger requester and one trigger completer. More complex trigger sequences consist of several trigger completers functioning as trigger completer and

trigger requester. Additionally, trigger sequences can loopback to the original requester forming a perpetual sequence.

- ***Software Triggering.*** Writing a trigger requester ID to the MTR generates a trigger within the TRU from the trigger requester ID specified.
- ***Synchronization.*** The TRU can be used to coarsely synchronize events by mapping multiple trigger completers to the same trigger requester or by generating multiple trigger requester assertions simultaneously through the MTR.
- ***Configuration Protection.*** The `TRU_SSR[n].LOCK` bit and the `TRU_GCTL.LOCK` bit enable register level write-protection when the global lock is asserted in the SPU.

Programming Examples

The following examples shows the steps to create a single trigger.

Configuring a Simple Trigger Sequence

The following example shows the steps to create a simple trigger.

1. Write to the `TRU_GCTL` register to enable the TRU.
2. Write to the `TRU_SSR[n]` register of a specific completer target to assign it to a specific trigger requester.
3. Enable the trigger completer to wait for and accept a trigger.
4. Enable the trigger requester to generate a trigger.

TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and can extend to support the interrupt and fault management models as well.

TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Completer errors are reported to the requester over the standard peripheral bus protocol.

ADSP-2159x_SC591_SC592_SC594 TRU Register Descriptions

Trigger Routing Unit (TRU) contains the following registers.

Table 7-5: ADSP-2159x_SC591_SC592_SC594 TRU Register List

Name	Description
`TRU_ERRADDR`	Error Address Register

Table 7-5: ADSP-2159x_SC591_SC592_SC594 TRU Register List (Continued)

Name	Description
TRU_GCTL	Global Control Register
TRU_MTR	Master Trigger Register
TRU_SSR[n]	Slave Select Register
TRU_STAT	Status Information Register

Error Address Register

The TRU error address register (TRU_ERRADDR) holds the address from the memory-mapped register access generating an access error of TRU registers.

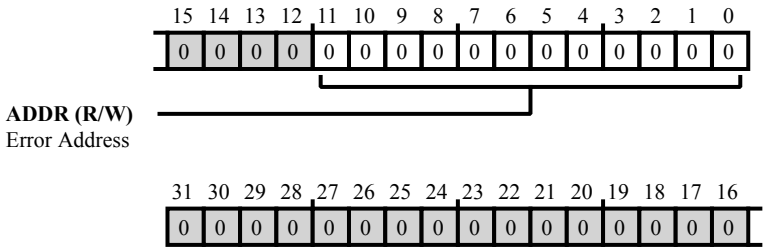

Figure 7-2: TRU_ERRADDR Register Diagram

Table 7-6: TRU_ERRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ADDR	Error Address. The TRU_ERRADDR.ADDR holds the address from the memory-mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_SSR[n] or TRU_MTR registers when these registers are locked or on access to an invalid address. See the TRU_SSR[n] and TRU_MTR register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of multiple errors occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared.

Global Control Register

The TRU global control register (TRU_GCTL) provides register locking, TRU reset, and TRU enable.

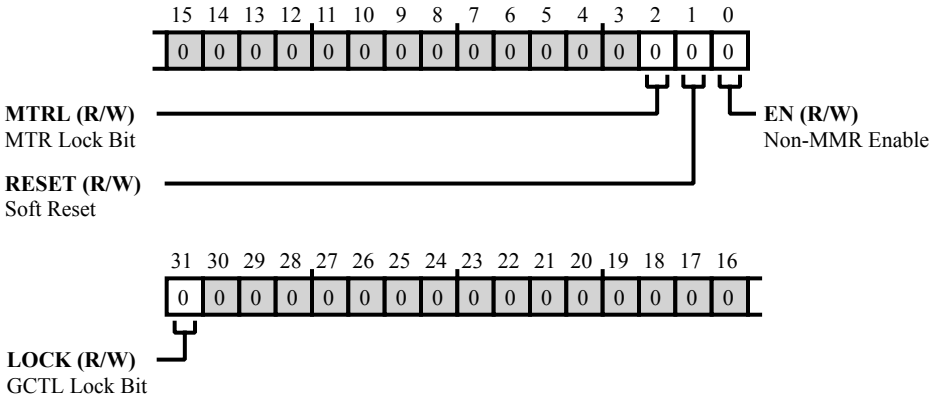

Figure 7-3: TRU_GCTL Register Diagram

Table 7-7: TRU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	GCTL Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is enabled, the TRU_GCTL register is read only.	
		0	Read write
		1	Read only
2 (R/W)	MTRL	MTR Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.MTRL bit is enabled, the TRU_MTR register is read only.	
		0	Read write
		1	Read only
1 (R/W)	RESET	Soft Reset. The TRU_GCTL.RESET bit is write-1-action and triggers a soft reset to all TRU registers.	
		0	No action
		1	Soft reset

Table 7-7: TRU_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Non-MMR Enable. The `TRU_GCTL.EN` bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the `TRU_GCTL.EN` bit.	
		0	No trigger events
		1	Propagate trigger events

Master Trigger Register

The TRU master trigger register (TRU_MTR) permits trigger generation through software by writing a trigger master ID value to one of the four fields in the TRU_MTR register. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is set, the TRU_MTR register is read only. Note this register is primarily used for debug to trigger a TRU output

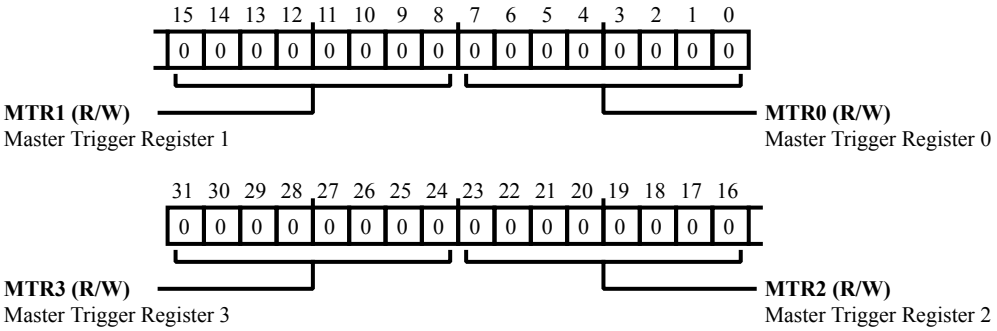

Figure 7-4: TRU_MTR Register Diagram

Table 7-8: TRU_MTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	MTR3	Master Trigger Register 3. The TRU_MTR.MTR3 bit field is the trigger master ID value for master 3.	
		0	No master specified
		1-182	Range of valid masters
23:16 (R/W)	MTR2	Master Trigger Register 2. The TRU_MTR.MTR2 bit field is the trigger master ID value for master 2.	
		0	No master specified
		1-182	Range of valid masters
15:8 (R/W)	MTR1	Master Trigger Register 1. The TRU_MTR.MTR1 bit field is the trigger master ID value for master 1.	
		0	No master specified
		1-182	Range of valid masters
7:0 (R/W)	MTR0	Master Trigger Register 0. The TRU_MTR.MTR0 bit field is the trigger master ID value for master 0.	
		0	No master specified
		1-182	Range of valid masters

Slave Select Register

The TRU slave select registers (TRU_SSR[n]) each provide slave selection and register locking.

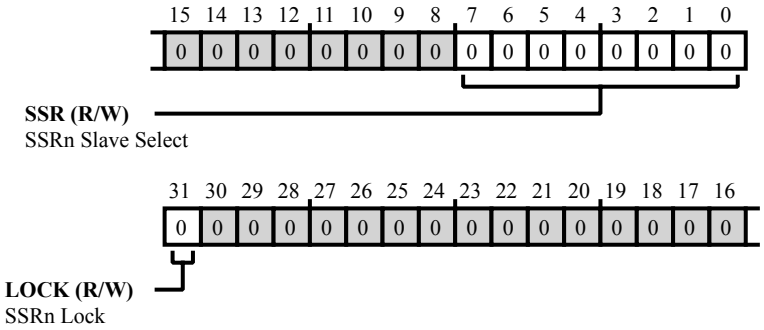

Figure 7-5: TRU_SSR[n] Register Diagram

Table 7-9: TRU_SSR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	SSRn Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_SSR[n].LOCK bit is enabled, the TRU_SSR[n] register is read only.	
		0	Unlock register
		1	Lock register
7:0 (R/W)	SSR	SSRn Slave Select. The TRU_SSR[n] register selects the trigger master ID to which the trigger slave responds. For example, when a TRU_SSR[n] register is set to respond to trigger master ID n, a trigger that is generated by trigger master ID n results in a trigger out to the slave.	
		0	No master specified
		1-182	Range of valid masters

Status Information Register

The TRU status register (TRU_STAT) contains the status of TRU_MTR and TRU_SSR[n] register writes and status of bus read/write errors.

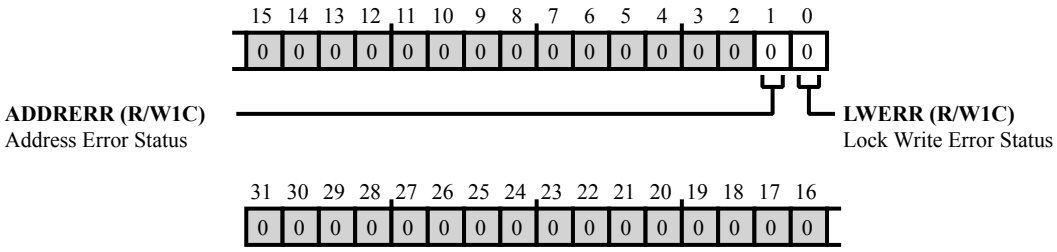

Figure 7-6: TRU_STAT Register Diagram

Table 7-10: TRU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ADDRERR	Address Error Status. The TRU_STAT.ADDRERR bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected.	
		0	No error
		1	Error occurred
0 (R/W1C)	LWERR	Lock Write Error Status. If TRU_STAT.LWERR is set, a lock write error has occurred. Writing a one to this bit clears the error indication.	
		0	No error
		1	Error occurred

8 L2 System Memory

L2 system memories have significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

L2 System Memory Features

The L2 system memory features include:

- Operation at `SYSCLK` frequency
- ECC protection of SRAM area
- ECC memory refresh

There is one instance of L2 system memory: L2CTL0.

- L2CTL0 contains 2M byte of RAM grouped into eight banks, 256K bytes each and 192K bytes of boot ROM.
- SHARC core data ports can access L2 memory through direct path as well as through Arm L2 cache.

L2 System Memory Functional Description

The L2 system memory manages all of the L2 SRAM and ROM memory banks. The system memory interface arbitrates competing accesses, write protection, and ensures SRAM data integrity. The L2 system memory domain is a unified instruction and data memory. It can hold any mixture of code and data required by the system design.

The following sections provide a functional description of the L2 system memory.

ADSP-2159x_SC591_SC592_SC594 L2CTL Register List

The L2 memory controller (L2CTL) includes the controls to manage each L2 memory bank independently. A set of registers governs L2CTL operations. For more information on L2CTL functionality, see the L2CTL register descriptions.

Table 8-2: ADSP-2159x_SC591_SC592_SC594 L2CTL Register List

L2 System Memory Block Diagram

The ***ADSP-2159x Complete L2 System Memory Block Diagram*** shows the complete L2 system memory, including the memory block instance L2CTL0. The L2CTL0 block contains boot ROM code for Arm and eight banks of L2 RAM containing 256 Kbytes each. The Arm reset ISR (location 0x00000000) is mapped to this block.

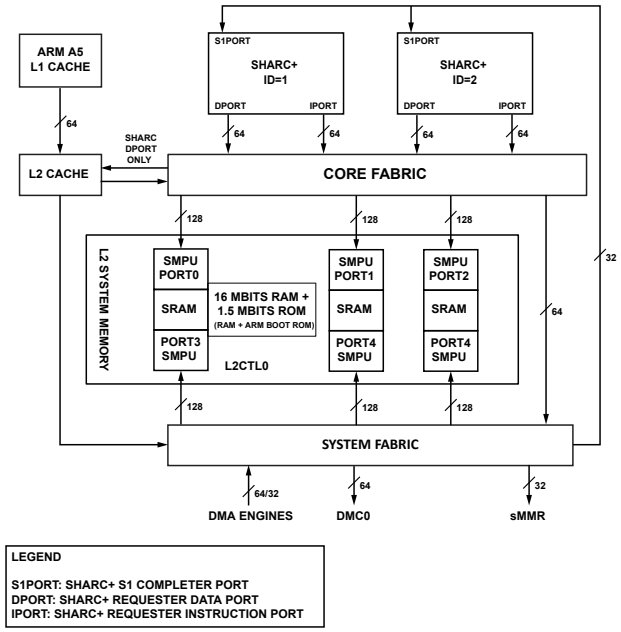

Figure 8-1: ADSP-2159x Complete L2 System Block Diagram

L2 System Memory Architectural Concepts

The following sections describe architecture features of the L2 system memory.

- Read/Write Latency and Throughput
- Arbitration and Priority

Access Characteristics

The L2 system memory interface converts all 8-bit, 16-bit, 32-bit, and 64-bit accesses to 128-bit accesses. Additionally, it converts 8-bit, 16-bit, 32-bit, and 64-bit bursts to an equivalent internal 128-bit access. For example, the L2 system memory interface converts a 128-bit address-aligned burst of 8-bit accesses of burst length 16 to a single 128-bit access.

Read/Write Latency and Throughput

The L2 memory design is optimized for burst accesses at the crossbar interface. The L2 system memory buffers and converts write data of 8/16/32/64-bit to an equivalent 128-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8-bit or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an extra latency of two SYSCLK cycles. No extra latency is seen if the ECC is disabled.

NOTE: Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

L2 Memory Controller Block Diagram (Instance)

As shown in the ***L2 System Memory Block Diagram***, the L2 controller has five ports that interface to system crossbars. Port 0, port 1, and port 2 are 128-bit interfaces dedicated to core and MDMA3 traffic. Port 3 and port 4 are 128-bit interfaces that connect through DMA. For L2 SRAM, all ports (0/1/2/3/4) have a read channel and a write channel; for L2 ROM, all ports (0/1/2/3/4) have read channels only. The SRAM is organized in multiple banks; each bank has 256K Bytes. The 192KB ROM is divided into three banks of 64KB.

Within each bank, data is organized into 16384 words, with each word comprising 128 bits of data and 28 bits of ECC checksum. ROM memory is not protected by the ECC scheme. When the L2 controller accesses RAM and ROM cells, it always reads and writes whole 128-bit words. Despite this, the L2 controller supports 8-, 16-, 32-, and 64-bit reads and writes from cores and system by applying respective data masks.

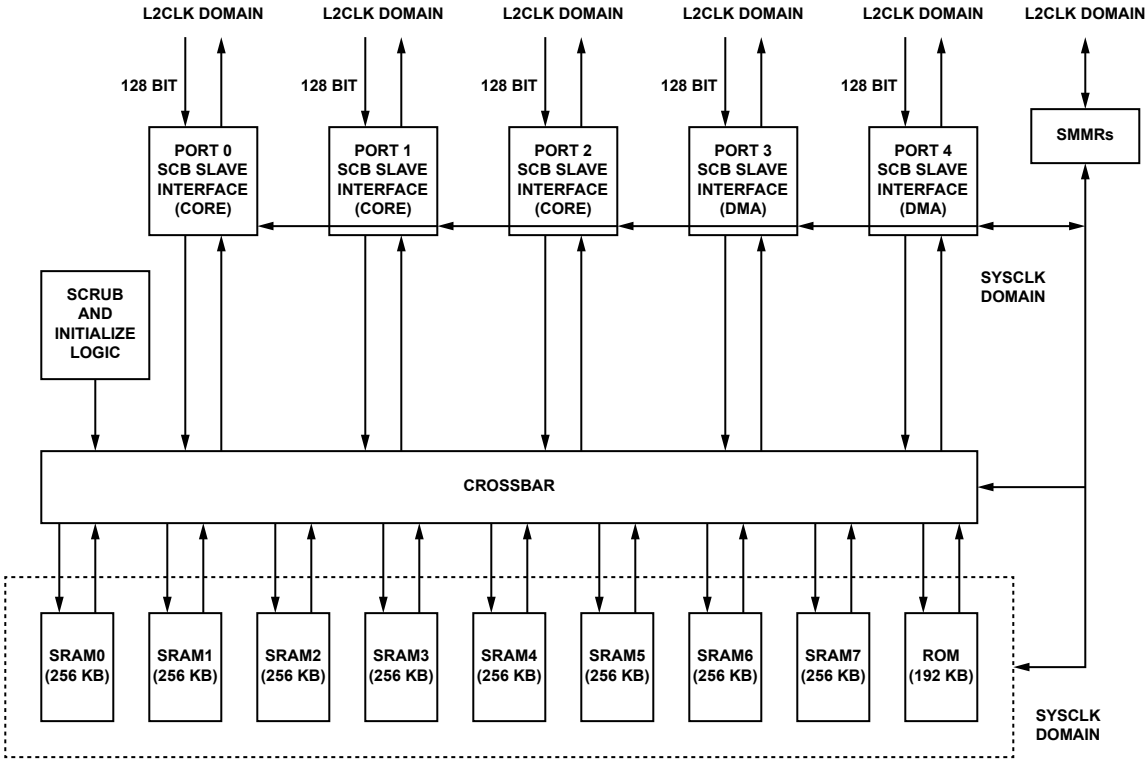

Figure 8-2: L2 System Memory Block Diagram

Arbitration and Priority

Each bank of L2 RAM or ROM has an arbiter which receives requests from the five crossbar ports.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through urgent priority requests.

NOTE: Attempting a write access to both L2 ROM spaces returns an error.

The ***Fixed Priority*** table shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

If two cores (or the 64-bit Max BW DMA) simultaneously try to access L2 for the same instance (both read or both write), even to different banks, software allows only one controller access at a time. One access port can support one read and write at the same time. However, if one core issues a write and the other issues a read, then access can proceed simultaneously. There is no extra latency inside L2, as long as the accesses are to different banks (assuming pending DMA traffic is also to a non-conflicting bank).

When a core and DMA both access the same bank via the same port (both read or both writes), the best access rate that DMA can achieve is one 128-bit access in every three SYSCLK cycles during the conflict period. This access rate is achieved by programming the read priority count register (`L2CTL_RPCR0.RPC0`) bit and the write priority count register (`L2CTL_WPCR0.WPC0`) to 0, while programming the `L2CTL_RPCR0.RPC1` and the `L2CTL_WPCR0.WPC1` bits to 1.

The arbiters also support priority elevation for a particular channel that has been starved of grants for many SYSCLK cycles. If a channel does not get a grant for *N* cycles after its request, then that channel can elevate the priority of its request by issuing an urgent priority request. This request causes that particular channel to become the highest priority controller for the next grant cycle (pipelined arbitration for urgent priority). The number of cycles *N*, after which the priority is elevated, can be programmed for each channel separately using the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers.

Programming the bits in the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers appropriately achieves the best grant rate for DMA. This grant rate of one in three SYSCLK cycles during the conflict period is achievable under the following conflict conditions:

- An access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme with core activity always prioritized over DMA activity
- An access conflict within the pipelined implementation of urgent priority

To disable urgent priority requests, set the `L2CTL_CTL.DISURP` bit. This bit disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

The ***Fixed Priority With Priority Elevation*** table provides the various priority levels for the L2 system memory.

Table 8-6: Fixed Priority With Priority Elevation

Channel	Priority Level
L2 Scrub/Initialization Request	21 (highest)
Port 0 Read Channel Urgent Request	20
Port 0 Write Channel Urgent Request	19
Port 1 Read Channel Urgent Request	18
Port 1 Write Channel Urgent Request	17
Port 2 Read Channel Urgent Request	16

Table 8-6: Fixed Priority With Priority Elevation (Continued)

Channel	Priority Level
Port 2 Write Channel Urgent Request	15
Port 3 Read Channel Urgent Request	14
Port 3 Write Channel Urgent Request	13
Port 4 Read Channel Urgent Request	12
Port 4 Write Channel Urgent Request	11
Port 0 Read Channel Normal Request	10
Port 0 Write Channel Normal Request	9
Port 1 Read Channel Normal Request	8
Port 1 Write Channel Normal Request	7
Port 2 Read Channel Normal Request	6
Port 2 Write Channel Normal Request	5
Port 3 Read Channel Normal Request	4
Port 3 Write Channel Normal Request	3
Port 4 Read Channel Normal Request	2
Port 4 Write Channel Normal Request	1 (lowest)

Data Integrity

The following sections provide information on how the L2 system memory ensures data integrity.

ECC Algorithm

Hsaio encoding calculates the ECC syndrome. A 7-bit syndrome is generated during write operation and stored as a 7-bit parity field along with the 32 data bits. Each data bit contributes to three parity bits according. Each parity bit represents the XOR value of 13 or 14 data bits according to the following mapping:

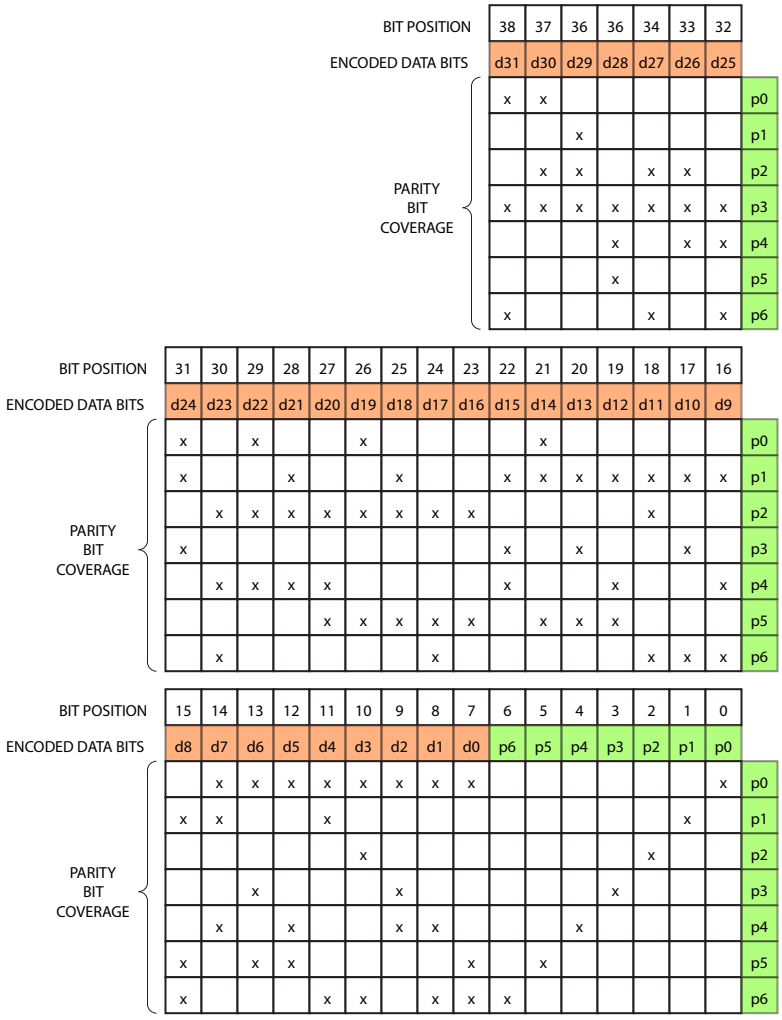

Figure 8-3: Hsaio Parity Bit Mapping

During read operation, the parity bits become part of the syndrome equation. The new syndrome bits are now the XOR values of the 13 or 14 data bits plus the respective stored parity bit. If any of the seven syndrome bits is set, an error situation is detected. An OR gate cross of the 7 bits reports the error, without specifying the type of the error.

If a single parity bit failed, the new 7-bit syndrome has 1 bit that is set. If a single data bit failed, the new syndrome has 3 bits that are set, because all three related parity bits fail. So, an XOR gate cross of all seven syndrome bits detects a single-bit error, indicating that an odd number of syndrome bits is set.

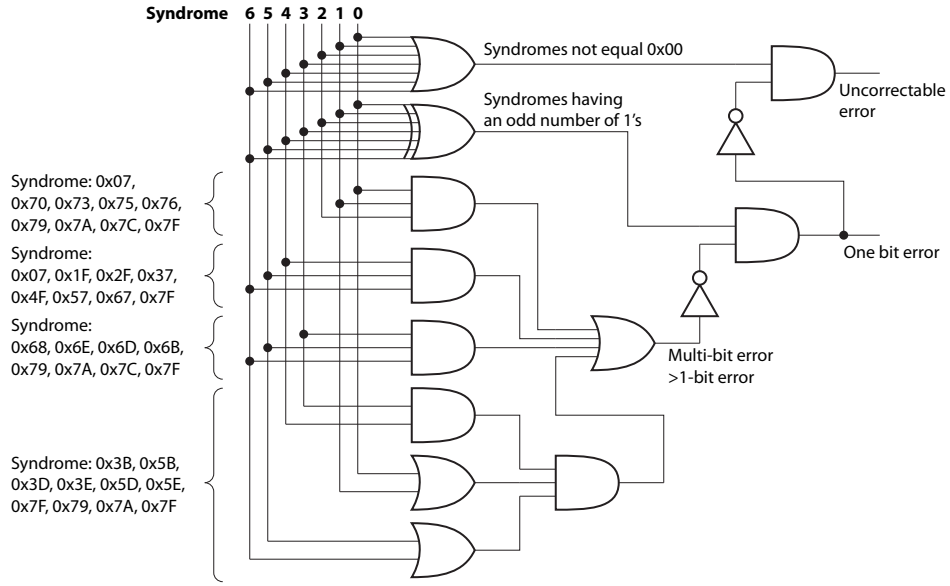

Figure 8-4: Hsiao Error Reports

The XOR gate detects single-bit errors and does not flag any dual-bit error. But, the gate does flag 50% of the other multi-bit errors undesirably. Extra logic is implemented to increase the detection rate of multi-bit errors to 68.7% as shown in the figure.

If a single-bit error is detected, the failing bit can be localized and corrected. If all three syndrome bits corresponding to a specific data bit are 1, a data error is assumed. The respective data bit is toggled on its way to the system bus.

ECC Hardware Control

After reset, ECC protection is enabled. The boot code initializes all L2 SRAM data and checksum cells. ECC protection adds some cycle penalty when 8-bit and 16-bit values write L2 memory. Disable ECC protection for individual SRAM banks by setting the through `L2CTL_CTL.BK7EDIS` disable bits. Due to caching mechanisms of the processor cores and data bursting of the DMA channels, 8-bit and 16-bit write accesses are rather uncommon. Typically, only two-dimensional DMA operations or uncached 8-bit and 16-bit store instruction can trigger these writes.

ECC Error Management

The L2 system memory flags 2-bit and multi-bit errors to the system by:

- Raising the ECC_ERR interrupt
- Reporting a read error to the system bus
- Setting the sticky `L2CTL_STAT.ECCERR7-L2CTL_STAT.ECCERR0` status flag
- Latching the address of the failing operation into the respective `L2CTL_ERRADDR7-L2CTL_ERRADDR0` register.

There is one error status bit and one error address register per L2 SRAM bank.

Typically, ECC_ERR events are declared as system faults in the system event controller (SEC). Whether these faults are reported, the interrupt service routine can consult the L2CTL_STAT register and the L2CTL_ERRADDR0 through L2CTL_ERRADDR7 registers to determine whether:

- The data at the failing L2 address was critical enough to require an immediate reboot of the system
- The data at the failing L2 address was less critical or can be restored

The L2CTL_STAT.ECCERR0 through L2CTL_STAT.ECCERR7 flags are cleared with a W1C operation.

Memory Refresh

If data in L2 SRAM contains single-bit errors, the data is corrected on its way to the system buses. The corrected value is not written back to the SRAM location. To prevent any risk of accumulation of single-bit errors over time and to minimize likelihood of multi-bit errors, the L2 system memory provides a special memory refresh mechanism.

If there are dual-bit or multi-bit errors, the ECC_ERR interrupt is raised, and data is not written back to memory.

- TheL2CTL_SADR register with the start address of the scrub
- The L2CTL_SCNT register with the total number of 128-bit addresses to be scrubbed starting from the L2CTL_SADR address

Program the number of cycles between each scrub using the L2CTL_SCTL register. During the scrub, the L2 system memory issues a read, followed by a write-back operation if there is a single-bit ECC error. Once the L2 system memory completes scrubbing the programmed memory region, it generates an interrupt and starts again from the L2CTL_SADR address unless the L2CTL_SCTL.SEN bit is disabled. If the L2CTL_SCTL.SEN bit is cleared before completing the programmed address range, the scrub stops after completing any already issued scrub access. The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read, and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-bit, 16-bit, or 32-bit addresses in the L2CTL_SADR register. The lower 4 bits of this register are treated as *do-not-care* values because the internal memory array is always accessed when using 128 bits.

Memory refresh operation is meaningless when the L2CTL_CTL.BK0EDIS through L2CTL_CTL.BK7EDIS disable bits are set.

Power Modes

Each L2 memory bank supports low-power modes.

If the bank is not in use, put each L2 system memory bank into the following low-power modes to save power.

Deep Sleep Mode

Set the L2CTL_PCTL.BK7DS through L2CTL_PCTL.BK0DS control bits to enter this mode. This mode preserves the memory contents.

Shut Down Mode

Set the L2CTL_PCTL.BK7SD through L2CTL_PCTL.BK0SD control bits to enter this mode. The memory banks do not retain the data (existing data is lost).

NOTE: It may take up to 11 SYSCLK cycles to deactivate the power mode after writing to the L2CTL_PCTL register. Therefore, L2 access must be issued after this delay.

Access to a memory bank in shut down or deep sleep mode may result in an unpredictable behavior. Ensure that initialization/refresh and memory access to such banks are not issued.

There is no deep sleep or shut down mode for ROM memories.

L2 System Memory Event Control

The following sections describe event control features of the L2 system memory, such as error response.

ECC Error Interrupt

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space
- An ECC multi-bit error in an ECC-enabled bank. A non-modulo, 32-bit write to an ECC-enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This response is because the L2 system memory implements a 32-bit ECC, and therefore a non-modulo, 32-bit write results in a read. This read can create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the L2CTL_STAT register, and the addresses that generated the error on a given port are stored in the L2CTL_EADDR0/L2CTL_EADDR1 register of that port. The details of the error are stored in the L2CTL_ET0/L2CTL_ET1 register of the port.

ADSP-2159x_SC591_SC592_SC594 L2CTL Register Descriptions

L2 Memory Controller (L2CTL) contains the following registers.

Table 8-7: ADSP-2159x_SC591_SC592_SC594 L2CTL Register List

Name	Description
L2CTL_CTL	Control Register
L2CTL_EADDR0	Error Type 0 Address Register

L2CTL_WPCR1	Write Priority Count Register

Control Register

The L2CTL_CTL register includes a write protection bit, enables L2 banks, and selects mapping of banks (as ECC RAM or data RAM).

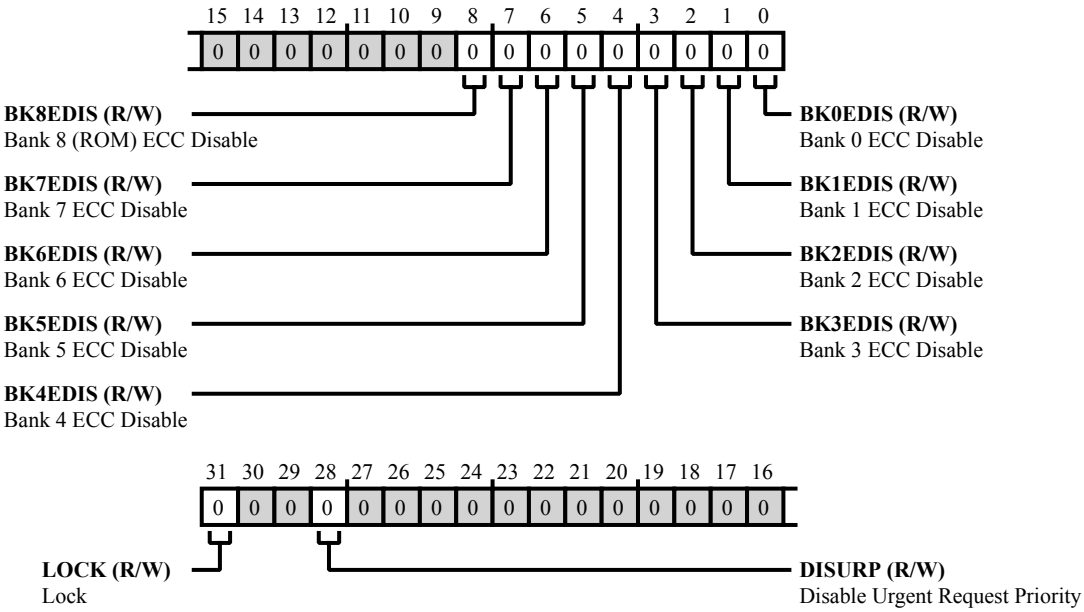

Figure 8-5: L2CTL_CTL Register Diagram

Table 8-8: L2CTL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_CTL.LOCK bit is set, the L2CTL_CTL register is read only (locked).	
		0	Unlock
		1	Lock
28 (R/W)	DISURP	Disable Urgent Request Priority. The L2CTL_CTL.DISURP disables urgent request priority mode for all L2 banks.	
		0	Enable URP
		1	Disable URP
8 (R/W)	BK8EDIS	Bank 8 (ROM) ECC Disable. The L2CTL_CTL.BK8EDIS bit disables L2 bank 8 (ROM) ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Table 8-8: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	BK7EDIS	Bank 7 ECC Disable. The `L2CTL_CTL.BK7EDIS` bit disables L2 bank 7 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
6 (R/W)	BK6EDIS	Bank 6 ECC Disable. The `L2CTL_CTL.BK6EDIS` bit disables L2 bank 6 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
5 (R/W)	BK5EDIS	Bank 5 ECC Disable. The `L2CTL_CTL.BK5EDIS` bit disables L2 bank 5 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
4 (R/W)	BK4EDIS	Bank 4 ECC Disable. The `L2CTL_CTL.BK4EDIS` bit disables L2 bank 4 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
3 (R/W)	BK3EDIS	Bank 3 ECC Disable. The `L2CTL_CTL.BK3EDIS` bit disables L2 bank 3 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
2 (R/W)	BK2EDIS	Bank 2 ECC Disable. The `L2CTL_CTL.BK2EDIS` bit disables L2 bank 2 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Table 8-8: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	BK1EDIS	Bank 1 ECC Disable. The `L2CTL_CTL.BK1EDIS` bit disables L2 bank 1 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
0 (R/W)	BK0EDIS	Bank 0 ECC Disable. The `L2CTL_CTL.BK0EDIS` bit disables L2 bank 0 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Error Type 0 Address Register

The L2CTL_EADDR0 register holds the address that created an access error on the L2 port 0 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR0) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

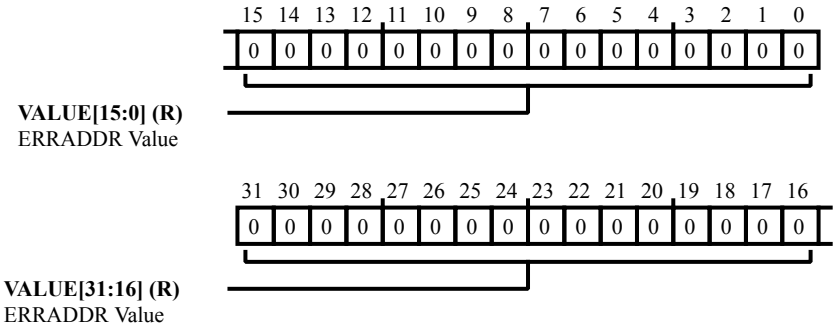

Figure 8-6: L2CTL_EADDR0 Register Diagram

Table 8-9: L2CTL_EADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR0.VALUE bits hold the address causing the bus error.

Error Type 1 Address Register

The L2CTL_EADDR1 register holds the address that created an access error on the L2 port 1 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR1) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

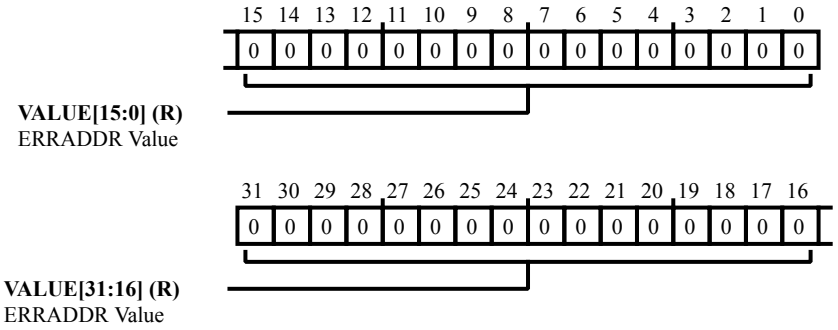

Figure 8-7: L2CTL_EADDR1 Register Diagram

Table 8-10: L2CTL_EADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR1.VALUE bits hold the address causing the bus error.

Error Type 2 Address Register

The L2CTL_EADDR2 register holds the address that created an access error on the L2 port 2 bus interface (cores). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR2) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

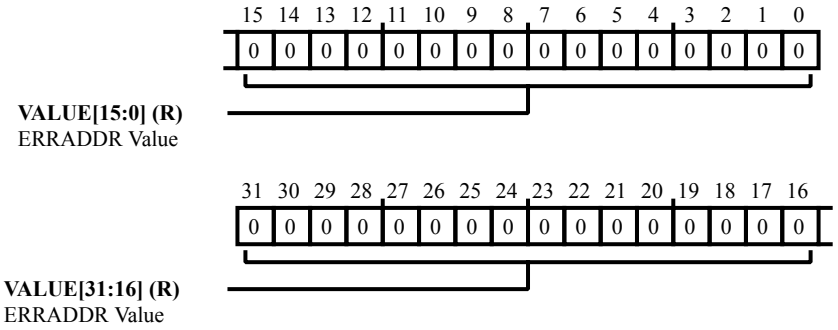

Figure 8-8: L2CTL_EADDR2 Register Diagram

Table 8-11: L2CTL_EADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR2.VALUE bits hold the address causing the bus error.

Error Type 3 Address Register

The L2CTL_EADDR3 register holds the address that created an access error on the L2 port 3 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR3) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

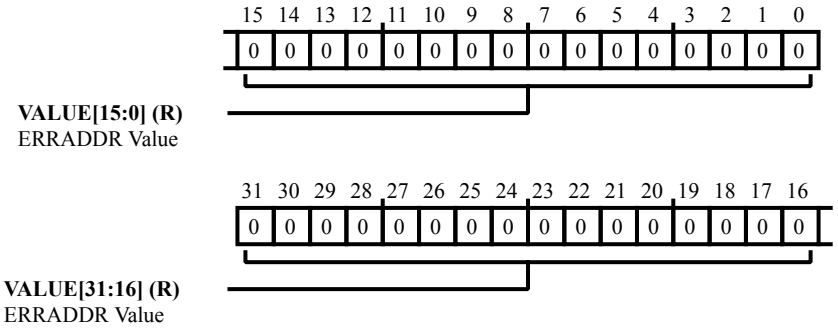

Figure 8-9: L2CTL_EADDR3 Register Diagram

Table 8-12: L2CTL_EADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR3.VALUE bits hold the address causing the bus error.

Error Type 4 Address Register

The L2CTL_EADDR4 register holds the address that created an access error on the L2 port 4 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR4) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

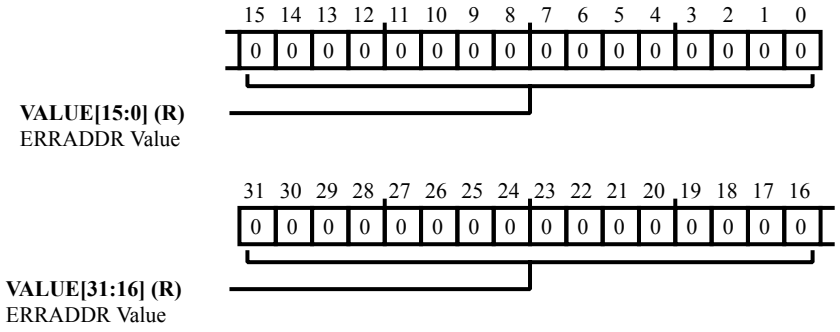

Figure 8-10: L2CTL_EADDR4 Register Diagram

Table 8-13: L2CTL_EADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR4.VALUE bits hold the address causing the bus error.

ECC Error Address 0 Register

The L2CTL_ERRADDR0 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR0) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

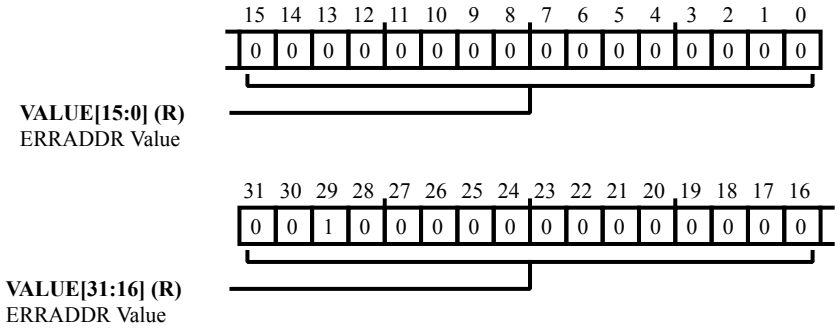

Figure 8-11: L2CTL_ERRADDR0 Register Diagram

Table 8-14: L2CTL_ERRADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR0.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 1 Register

The L2CTL_ERRADDR1 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR1) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

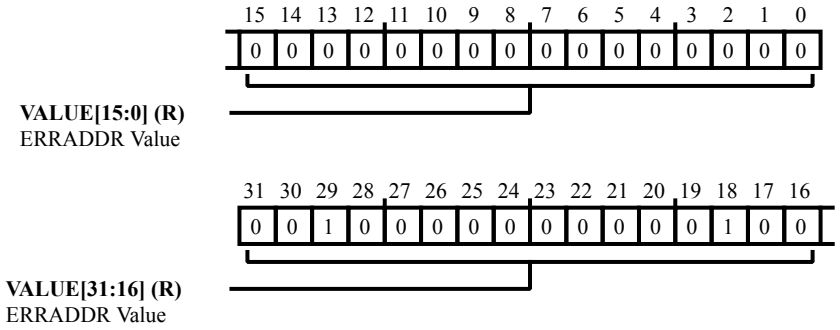

Figure 8-12: L2CTL_ERRADDR1 Register Diagram

Table 8-15: L2CTL_ERRADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR1.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 2 Register

The L2CTL_ERRADDR2 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR2) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

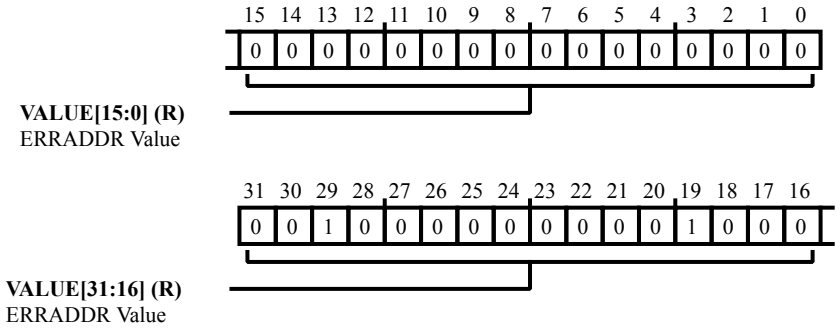

Figure 8-13: L2CTL_ERRADDR2 Register Diagram

Table 8-16: L2CTL_ERRADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR2.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 3 Register

The L2CTL_ERRADDR3 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR3) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

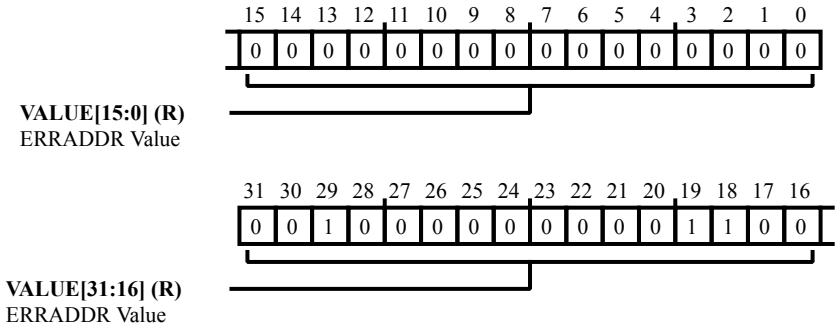

Figure 8-14: L2CTL_ERRADDR3 Register Diagram

Table 8-17: L2CTL_ERRADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR3.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 4 Register

The L2CTL_ERRADDR4 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR4) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

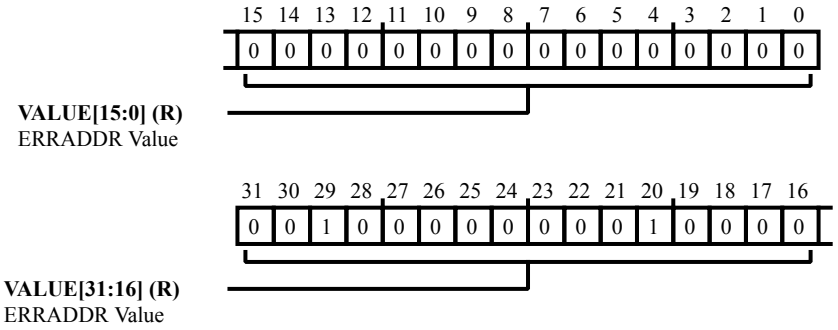

Figure 8-15: L2CTL_ERRADDR4 Register Diagram

Table 8-18: L2CTL_ERRADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR4.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 5 Register

The L2CTL_ERRADDR5 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR5) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

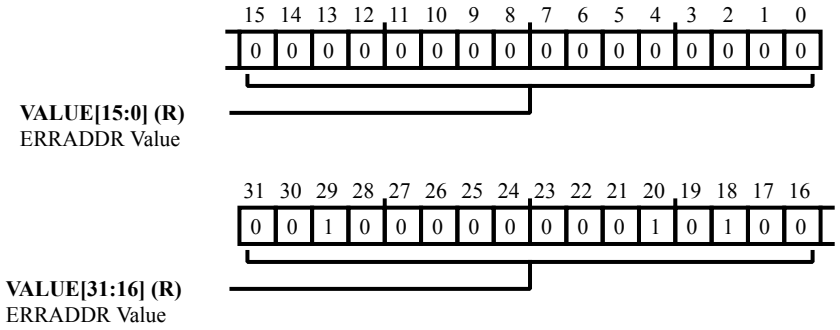

Figure 8-16: L2CTL_ERRADDR5 Register Diagram

Table 8-19: L2CTL_ERRADDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR5.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 6 Register

The L2CTL_ERRADDR6 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR6) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

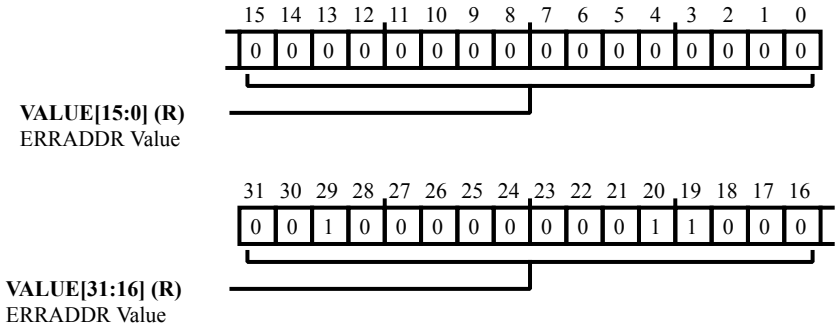

Figure 8-17: L2CTL_ERRADDR6 Register Diagram

Table 8-20: L2CTL_ERRADDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR6.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 7 Register

The L2CTL_ERRADDR7 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR7) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

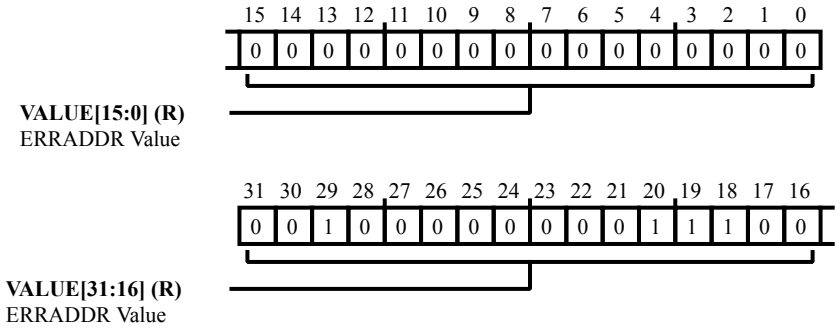

Figure 8-18: L2CTL_ERRADDR7 Register Diagram

Table 8-21: L2CTL_ERRADDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR7.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 8 Register

The L2CTL_ERRADDR8 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR8) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

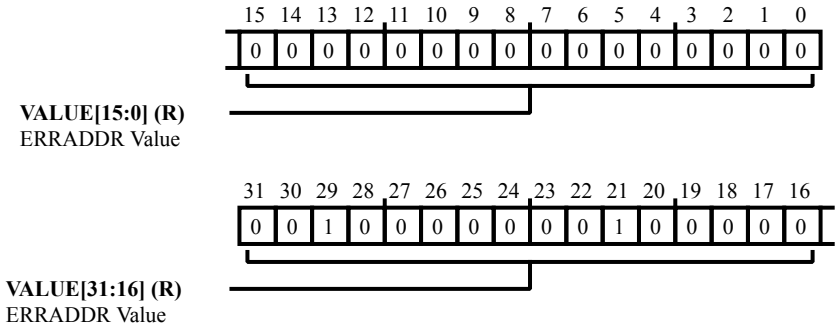

Figure 8-19: L2CTL_ERRADDR8 Register Diagram

Table 8-22: L2CTL_ERRADDR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR8.VALUE bits hold the address containing the ECC double-bit error.

Error Type 0 Register

The L2CTL_ET0 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 0. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR0 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET0 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR0).

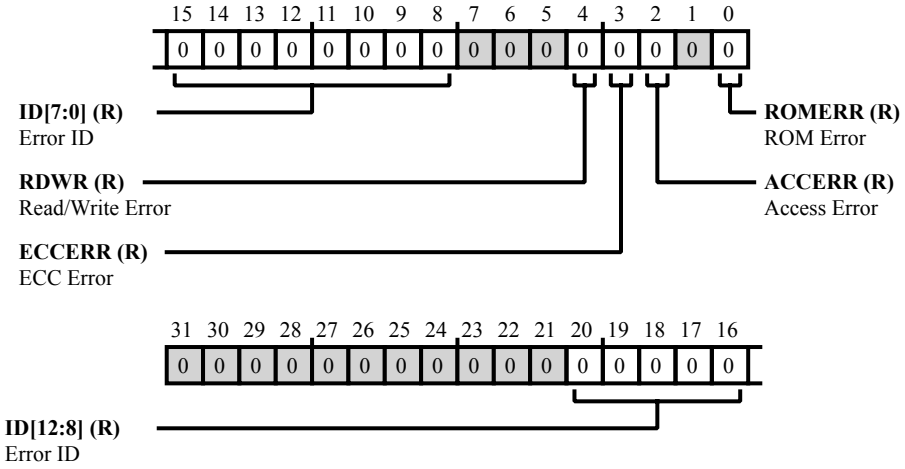

Figure 8-20: L2CTL_ET0 Register Diagram

Table 8-23: L2CTL_ET0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET0.ID bits hold the bus master ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET0.RDWR bit indicates whether a read or write access caused an error.	
		0	Read Access created Error
		1	Write Access created Error
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET0.ECCERR bit indicates whether the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. The L2CTL_ET0.ACCERR bit indicates whether the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. The L2CTL_ET0.ROMERR bit indicates whether a write access went to a ROM area.	

Error Type 1 Register

The L2CTL_ET1 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 1. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR1 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET1 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR1).

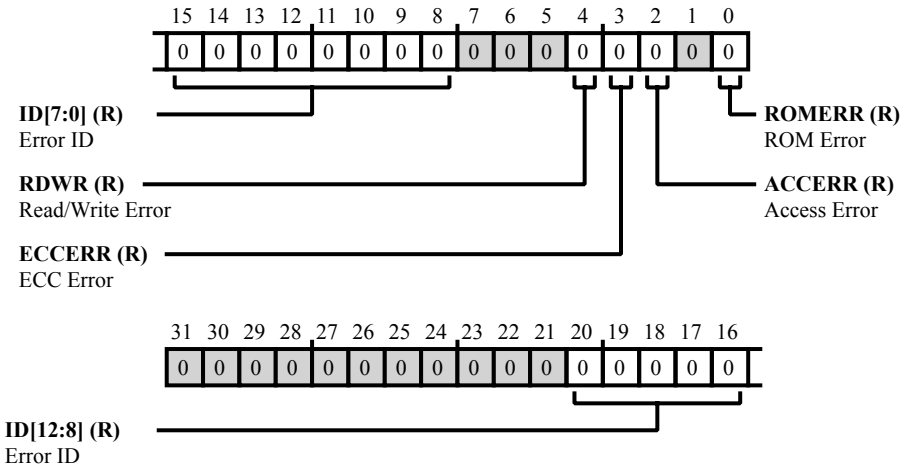

Figure 8-21: L2CTL_ET1 Register Diagram

Table 8-24: L2CTL_ET1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET1.ID bits hold the bus master ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET1.RDWR bit indicates whether a read or write access caused an error.	
		0	Read access created error
		1	Write access created error
3 (R/NW)	ECCERR	ECC Error. If the L2CTL_ET1.ECCERR bit =1, the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET1.ACCERR bit =1, the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET1.ROMERR bit =1, a write access went to a ROM area.	

Error Type 2 Register

The L2CTL_ET2 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 2 (cores). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR2 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET2 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR2).

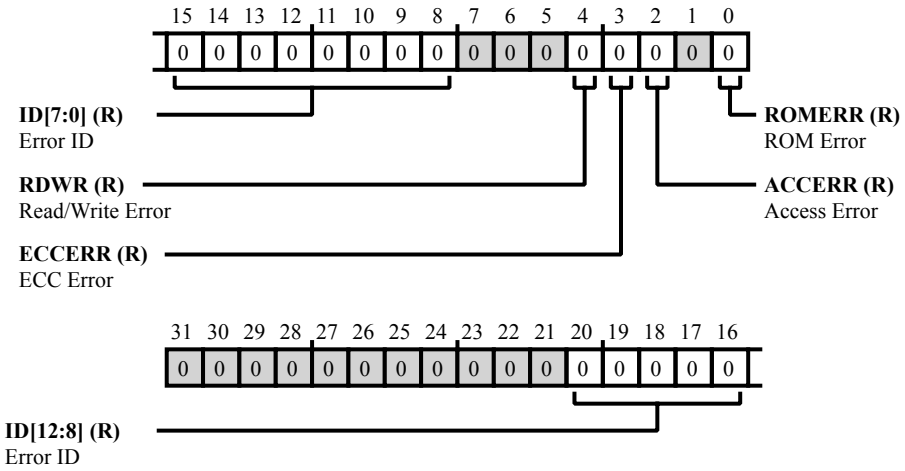

Figure 8-22: L2CTL_ET2 Register Diagram

Table 8-25: L2CTL_ET2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET2.ID bits hold the bus master ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET2.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET2.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET2.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET2.ROMERR bit =1, a write access went to a ROM area.

Error Type 3 Register

The L2CTL_ET3 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 3 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR3 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET3 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR3).

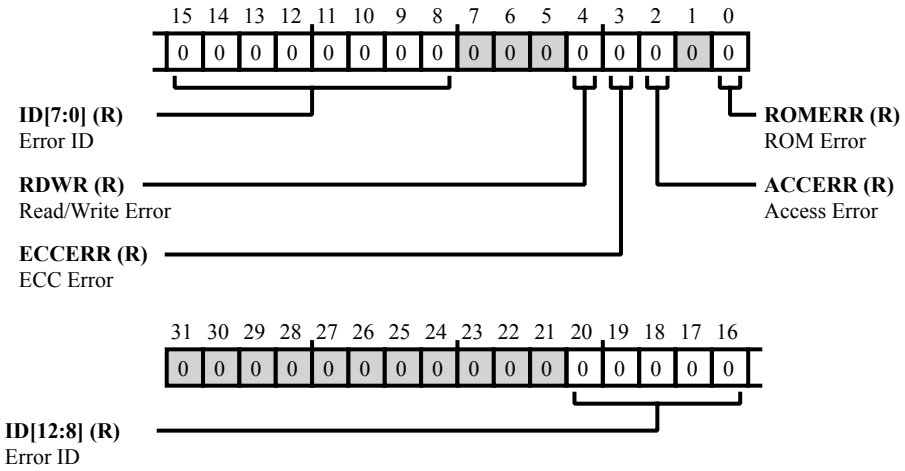

Figure 8-23: L2CTL_ET3 Register Diagram

Table 8-26: L2CTL_ET3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET3.ID bits hold the bus master ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET3.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET3.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET3.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET3.ROMERR bit =1, a write access went to a ROM area.

Error Type 4 Register

The L2CTL_ET4 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 4 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR4 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET4 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR4).

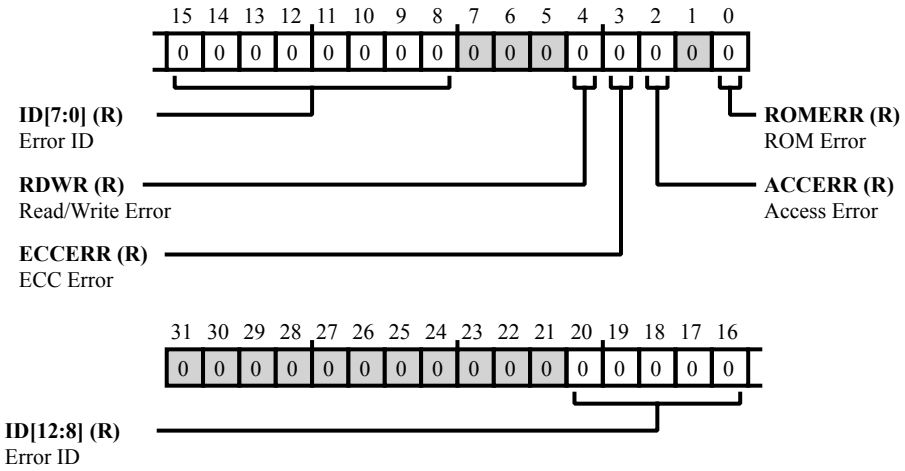

Figure 8-24: L2CTL_ET4 Register Diagram

Table 8-27: L2CTL_ET4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET4.ID bits hold the bus master ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET4.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET4.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET4.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET4.ROMERR bit =1, a write access went to a ROM area.

Initialization Register

The L2CTL_INIT register initializes memory banks with 128'b0 and ECC bits corresponding to 128'b0. Any writes to the bits in this register while initialization is occurring to any of the banks is ignored. All bits are W1A (Write 1 for Action).

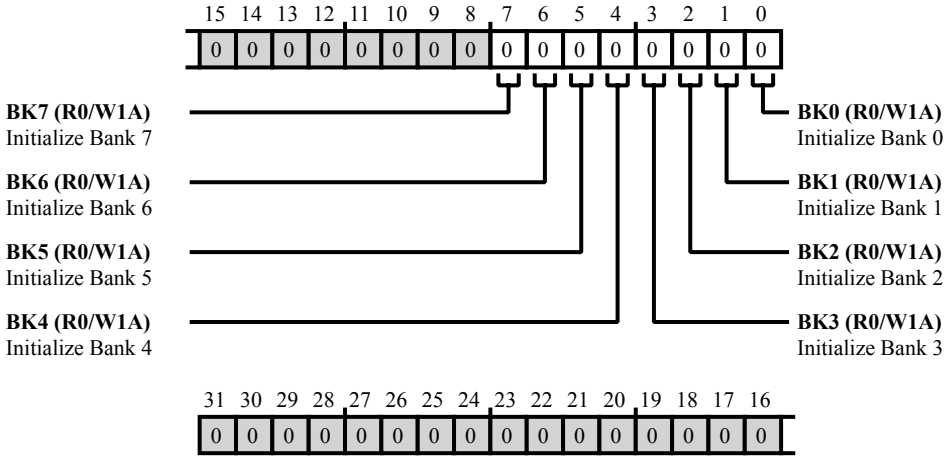

Figure 8-25: L2CTL_INIT Register Diagram

Table 8-28: L2CTL_INIT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R0/W1A)	BK7	Initialize Bank 7. The write-1 to the L2CTL_INIT.BK7 bit initializes bank 7 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
6 (R0/W1A)	BK6	Initialize Bank 6. The write-1 to the L2CTL_INIT.BK6 bit initializes bank 6 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
5 (R0/W1A)	BK5	Initialize Bank 5. The write -1 to the L2CTL_INIT.BK5 bit initializes bank 5 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
4 (R0/W1A)	BK4	Initialize Bank 4. The write-1 to the L2CTL_INIT.BK4 bit initializes bank 4 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Table 8-28: L2CTL_INIT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W1A)	BK3	Initialize Bank 3. The write-1 to the `L2CTL_INIT.BK3` bit initializes bank 3 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
2 (R0/W1A)	BK2	Initialize Bank 2. The write-1 to the `L2CTL_INIT.BK2` bit initializes bank 2 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
1 (R0/W1A)	BK1	Initialize Bank 1. The write-1 to the `L2CTL_INIT.BK1` bit initializes bank 1 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
0 (R0/W1A)	BK0	Initialize Bank 0. The write-1 to the `L2CTL_INIT.BK0` bit initializes bank 0 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Initialization Status Register

The L2CTL_ISTAT register holds the status of the RAM bank initialization. If set, the corresponding bank is initialized.

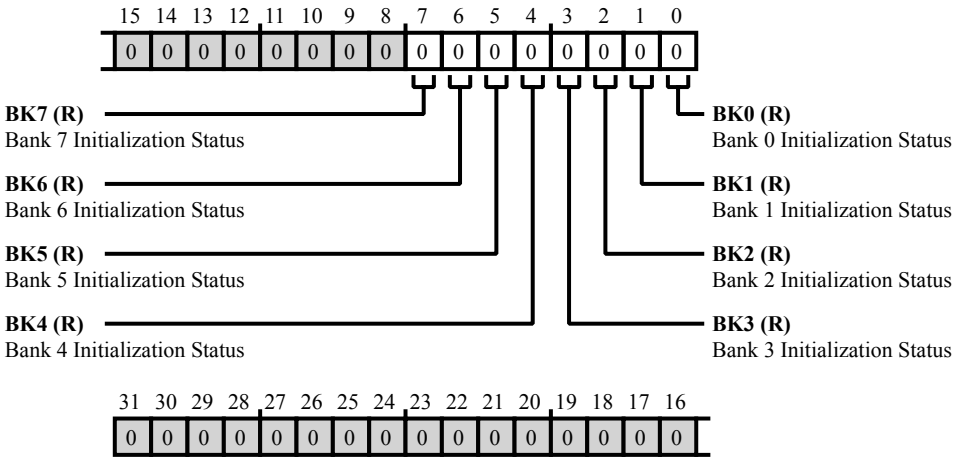

Figure 8-26: L2CTL_ISTAT Register Diagram

Table 8-29: L2CTL_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	BK7	Bank 7 Initialization Status. The L2CTL_ISTAT.BK7 bits hold the bank 7 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
6 (R/NW)	BK6	Bank 6 Initialization Status. The L2CTL_ISTAT.BK6 bits hold the bank 6 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
5 (R/NW)	BK5	Bank 5 Initialization Status. The L2CTL_ISTAT.BK5 bits hold the bank 5 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
4 (R/NW)	BK4	Bank 4 Initialization Status. The L2CTL_ISTAT.BK4 bits hold the bank 4 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
3 (R/NW)	BK3	Bank 3 Initialization Status. The L2CTL_ISTAT.BK3 bits hold the bank 3 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
2 (R/NW)	BK2	Bank 2 Initialization Status. The L2CTL_ISTAT.BK2 bits hold the bank 2 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Table 8-29: L2CTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BK1	Bank 1 Initialization Status. The `L2CTL_ISTAT.BK1` bits hold the bank 1 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
0 (R/NW)	BK0	Bank 0 Initialization Status. The `L2CTL_ISTAT.BK0` bits hold the bank 0 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Power Control Register

The L2CTL_PCTL register has the various control settings for selectively enabling the deep sleep and shut down power saving features.

NOTE: The corresponding L2 bank should not be accessed if the power control feature is enabled for that bank. An access to a bank in deep sleep/shut down may create unpredictable behavior.

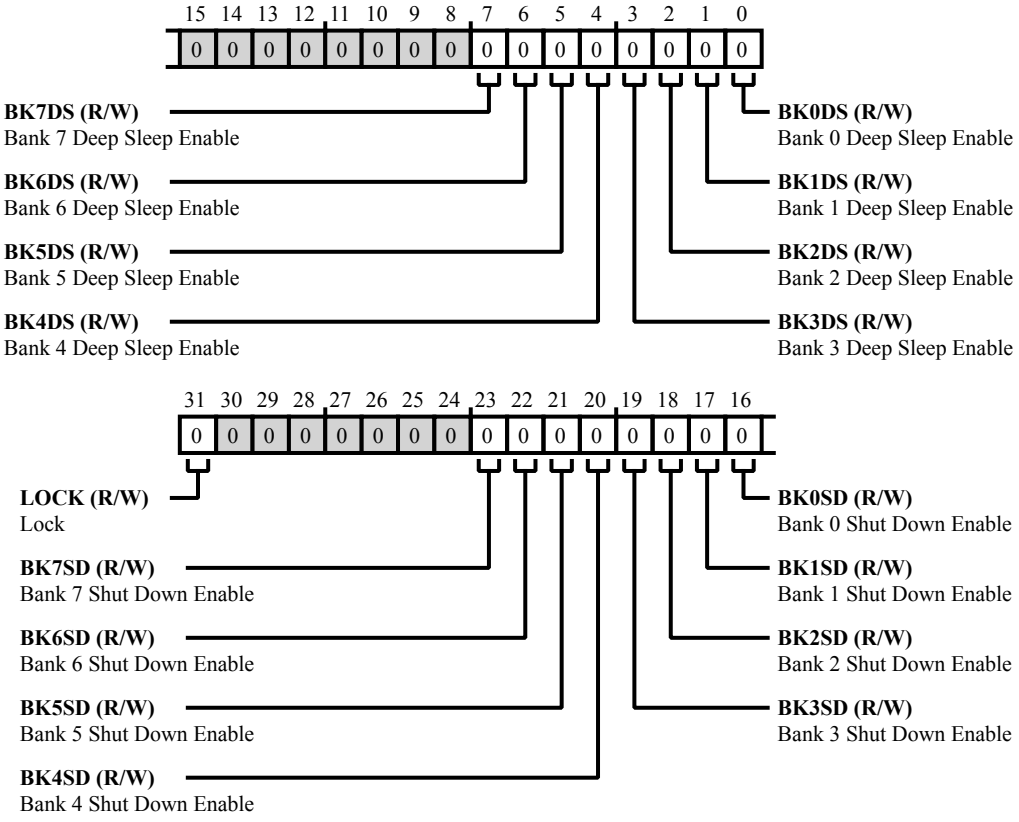

Figure 8-27: L2CTL_PCTL Register Diagram

Table 8-30: L2CTL_PCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_PCTL.LOCK bit is set, the L2CTL_PCTL register is read only (locked).	
		0	Unlock
		1	Lock
23 (R/W)	BK7SD	Bank 7 Shut Down Enable. The L2CTL_PCTL.BK7SD bits enables bank 7 shut down.	

Table 8-30: L2CTL_PCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/W)	BK6SD	Bank 6 Shut Down Enable. The L2CTL_PCTL.BK6SD bits enables bank 6 shut down.
21 (R/W)	BK5SD	Bank 5 Shut Down Enable. The L2CTL_PCTL.BK5SD bits enables bank 5 shut down.
20 (R/W)	BK4SD	Bank 4 Shut Down Enable. The L2CTL_PCTL.BK4SD bits enables bank 4 shut down.
19 (R/W)	BK3SD	Bank 3 Shut Down Enable. The L2CTL_PCTL.BK3SD bits enables bank 3 shut down.
18 (R/W)	BK2SD	Bank 2 Shut Down Enable. The L2CTL_PCTL.BK2SD bits enables bank 2 shut down.
17 (R/W)	BK1SD	Bank 1 Shut Down Enable. The L2CTL_PCTL.BK1SD bits enables bank 1 shut down.
16 (R/W)	BK0SD	Bank 0 Shut Down Enable. The L2CTL_PCTL.BK0SD bits enables bank 0 shut down.
7 (R/W)	BK7DS	Bank 7 Deep Sleep Enable. The L2CTL_PCTL.BK7DS bits enables bank 7 deep sleep.
6 (R/W)	BK6DS	Bank 6 Deep Sleep Enable. The L2CTL_PCTL.BK6DS bits enables bank 6 deep sleep.
5 (R/W)	BK5DS	Bank 5 Deep Sleep Enable. The L2CTL_PCTL.BK5DS bits enables bank 5 deep sleep.
4 (R/W)	BK4DS	Bank 4 Deep Sleep Enable. The L2CTL_PCTL.BK4DS bits enables bank 4 deep sleep.
3 (R/W)	BK3DS	Bank 3 Deep Sleep Enable. The L2CTL_PCTL.BK3DS bits enables bank 3 deep sleep.
2 (R/W)	BK2DS	Bank 2 Deep Sleep Enable. The L2CTL_PCTL.BK2DS bits enables bank 2 deep sleep.
1 (R/W)	BK1DS	Bank 1 Deep Sleep Enable. The L2CTL_PCTL.BK1DS bits enables bank 1 deep sleep.
0 (R/W)	BK0DS	Bank 0 Deep Sleep Enable. The L2CTL_PCTL.BK0DS bits enables bank 0 deep sleep.

Revision ID Register

The L2CTL_REVID register provides the L2 Revision ID.

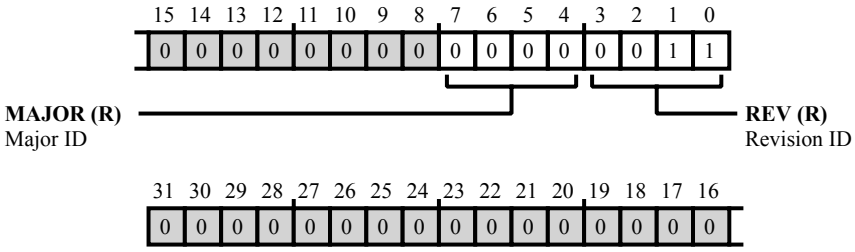

Figure 8-28: L2CTL_REVID Register Diagram

Table 8-31: L2CTL_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major ID. The L2CTL_REVID.MAJOR bit indicates L2 Major ID.
3:0 (R/NW)	REV	Revision ID. The L2CTL_REVID.REV bit indicates the L2 Revision ID.

Read Priority Count Register

The L2CTL_RPCR0 register stores the count value to be used for priority elevation for bus read channels of Port0 to Port3. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPCx) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value wait cycle for each channel is 15..

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

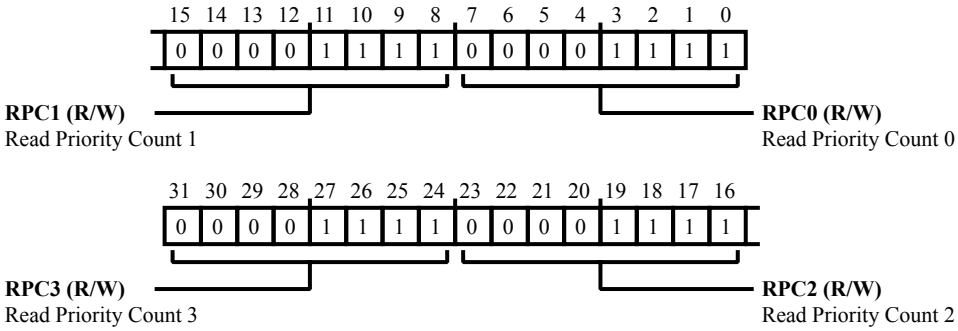

Figure 8-29: L2CTL_RPCR0 Register Diagram

Table 8-32: L2CTL_RPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RPC3	Read Priority Count 3. The L2CTL_RPCR0.RPC3 bits hold the priority count for L2 bus read channel 3.
23:16 (R/W)	RPC2	Read Priority Count 2. The L2CTL_RPCR0.RPC2 bits hold the priority count for L2 bus read channel 2.
15:8 (R/W)	RPC1	Read Priority Count 1. The L2CTL_RPCR0.RPC1 bits hold the priority count for L2 bus read channel 1.
7:0 (R/W)	RPC0	Read Priority Count 0. The L2CTL_RPCR0.RPC0 bits hold the priority count for L2 bus read channel 0.

Read Priority Count Register

The L2CTL_RPCR1 register stores the count value to be used for priority elevation for bus read channel 4. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPC4) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value of RPC4 is 15.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

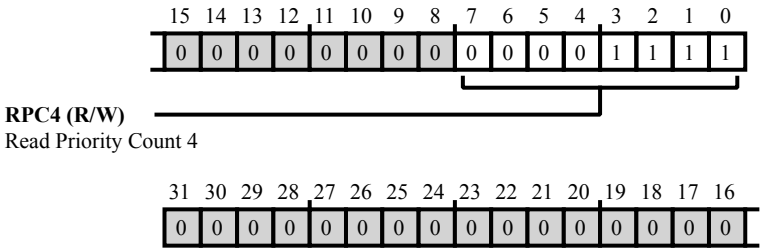

Figure 8-30: L2CTL_RPCR1 Register Diagram

Table 8-33: L2CTL_RPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RPC4	Read Priority Count 4. The L2CTL_RPCR1.RPC4 bits hold the priority count for L2 bus read channel 4.

Scrub Start Address Register

The L2CTL_SADR register stores the scrub start address value. Writes to this register can be prevented by setting the L2CTL_SCTL.LOCK bit and the global lock.

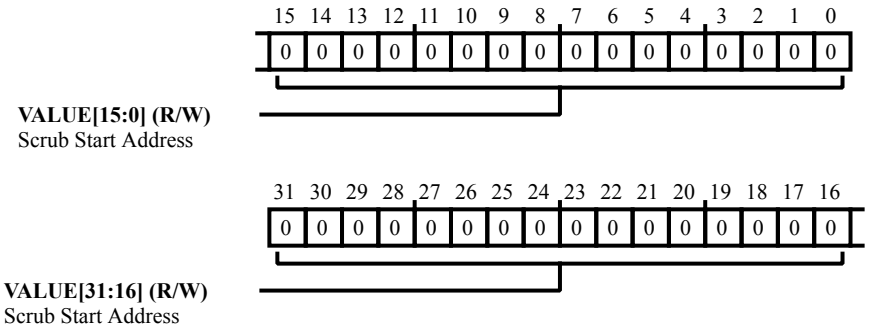

Figure 8-31: L2CTL_SADR Register Diagram

Table 8-34: L2CTL_SADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Scrub Start Address. The L2CTL_SADR.VALUE bits hold the scrub start address. The writes to this register can be prevented by setting the L2_SCTL.LOCK and the global lock.

Scrub Count Register

The L2CTL_SCNT register determines the number of 128-bit locations scrubbed starting from the start address (L2CTL_SADR register). Writes to the L2CTL_SCNT register can be prevented by setting the L2CTL_CTL.LOCK bit and the global lock.

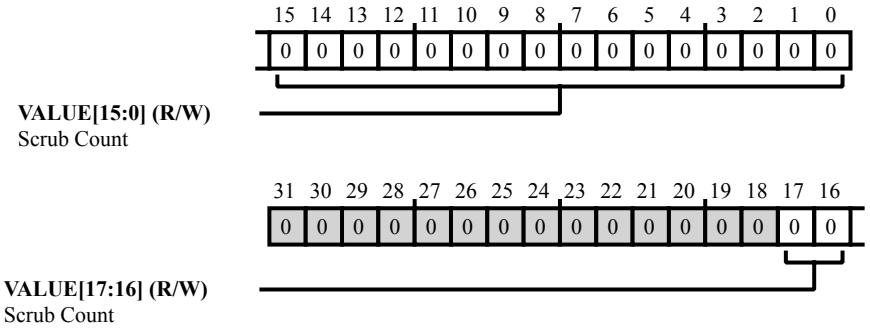

Figure 8-32: L2CTL_SCNT Register Diagram

Table 8-35: L2CTL_SCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:0 (R/W)	VALUE	Scrub Count. The L2CTL_SCNT.VALUE bits determines the number of 128-bit locations scrubbed starting from the start address. Ensure value programmed is less than the total addressable 128-bit L2 RAM locations available.

Scrub Control Register

The L2CTL_SCTL register holds the automatic scrub related controls. This is a read/write register. Memory scrub can be performed by programming the L2CTL_SADR (scrub start address) register with the start address of the scrub and the L2CTL_SCNT register with the total number of 128 -bit addresses to be scrubbed starting from the L2CTL_SADR register. The number of cycles between each scrub can be programmed with the L2CTL_SCTL.SRT bit.

During the scrub the controller issues a read followed by write back if there is a single bit ECC error. Once the L2 controller completes scrubbing the memory region mentioned using the L2CTL_SADR and the L2CTL_SCNT registers, an interrupt is generated and scrubbing re-starts from the start unless the scrub enable bit is disabled in the control register. If scrub enable is cleared before completing the address range used in the L2CTL_SADR and L2CTL_SCNT registers, the scrub stops after completing any already issued scrub access.

The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-, 16-, or 32-bit addresses in the L2CTL_SADR register but the lower 3 bits are treated as don't care because the internal memory array is always accessed in a 128-bit mode.

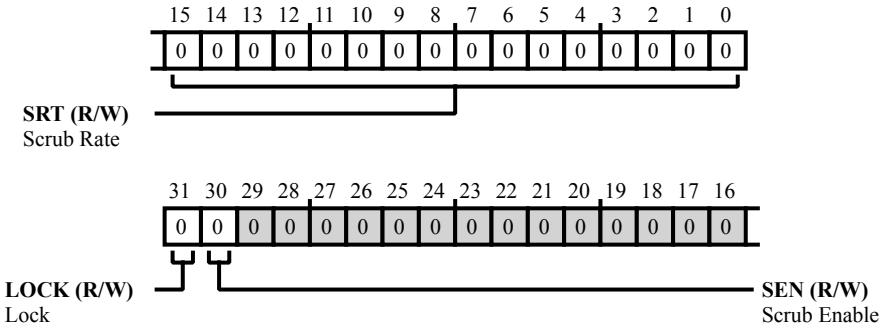

Figure 8-33: L2CTL_SCTL Register Diagram

Table 8-36: L2CTL_SCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_SCTL.LOCK bit is set, the L2CTL_SCTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	SEN	Scrub Enable. The L2CTL_SCTL.SEN bits enable automatic scrub.	

Table 8-36: L2CTL_SCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SRT	Scrub Rate. The `L2CTL_SCTL.SRT` bits determines the number of clock cycles that elapsed between two automatic scrubs.

Status Register

The L2CTL_STAT register indicates ECC error status, refresh register status, and bus error status of Port0 and Port1.

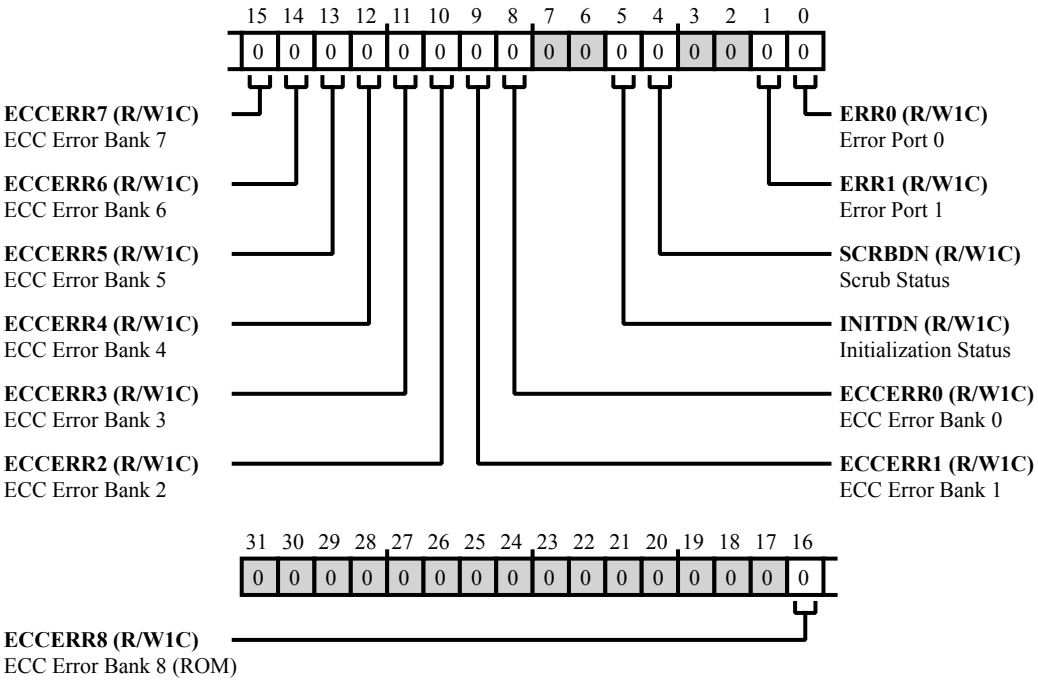

Figure 8-34: L2CTL_STAT Register Diagram

Table 8-37: L2CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ECCERR8	ECC Error Bank 8 (ROM). The L2CTL_STAT.ECCERR8 bit indicates that an ECC double-bit error occurred inside L2 bank 8 (ROM).	
		0	No Status
		1	ECC Double Bit Error
15 (R/W1C)	ECCERR7	ECC Error Bank 7. The L2CTL_STAT.ECCERR7 bit indicates that an ECC double-bit error occurred inside L2 bank 7.	
		0	No Status
		1	ECC Double Bit Error

Table 8-37: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ECCERR6	ECC Error Bank 6. The `L2CTL_STAT.ECCERR6` bit indicates that an ECC double-bit error occurred inside L2 bank 6.	
		0	No Status
		1	ECC Double Bit Error
13 (R/W1C)	ECCERR5	ECC Error Bank 5. The `L2CTL_STAT.ECCERR5` bit indicates that an ECC double-bit error occurred inside L2 bank 5.	
		0	No Status
		1	ECC Double Bit Error
12 (R/W1C)	ECCERR4	ECC Error Bank 4. The `L2CTL_STAT.ECCERR4` bit indicates that an ECC double-bit error occurred inside L2 bank 4.	
		0	No Status
		1	ECC Double Bit Error
11 (R/W1C)	ECCERR3	ECC Error Bank 3. The `L2CTL_STAT.ECCERR3` bit indicates that an ECC double-bit error occurred inside L2 bank 3.	
		0	No Status
		1	ECC Double Bit Error
10 (R/W1C)	ECCERR2	ECC Error Bank 2. The `L2CTL_STAT.ECCERR2` bit indicates that an ECC double-bit error occurred inside L2 bank 2.	
		0	No Status
		1	ECC Double Bit Error
9 (R/W1C)	ECCERR1	ECC Error Bank 1. The `L2CTL_STAT.ECCERR1` bit indicates that an ECC double-bit error occurred inside L2 bank 1.	
		0	No Status
		1	ECC Double Bit Error

Table 8-37: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	ECCERR0	ECC Error Bank 0. The `L2CTL_STAT.ECCERR0` bit indicates that an ECC double-bit error occurred inside L2 bank 0.	
		0	No Status
		1	ECC Double Bit Error
5 (R/W1C)	INITDN	Initialization Status. The `L2CTL_STAT.INITDN` bit indicates whether initialization has been completed.	
		0	Initialization Not Complete
		1	Initialization Completed
4 (R/W1C)	SCRBDN	Scrub Status. The `L2CTL_STAT.SCRBDN` bit indicates whether a round of memory scrub has completed.	
		0	Scrub Not Complete
		1	Scrub Completed
1 (R/W1C)	ERR1	Error Port 1. The `L2CTL_STAT.ERR1` indicates whether the L2CTL has detected a bus access error on L2s bus port 1.	
		0	No Error
		1	Bus Access Error
0 (R/W1C)	ERR0	Error Port 0. The `L2CTL_STAT.ERR0` indicates whether the L2CTL has detected a bus access error on L2s bus port 0.	
		0	No Error
		1	Bus Access Error

L2 Port Error Status Register

The L2CTL_STAT_1 register stores the AXI Error Status from Port2 onwards. The register bits are sticky - once set it has to be explicitly reset by writing a 1 to that particular bit.

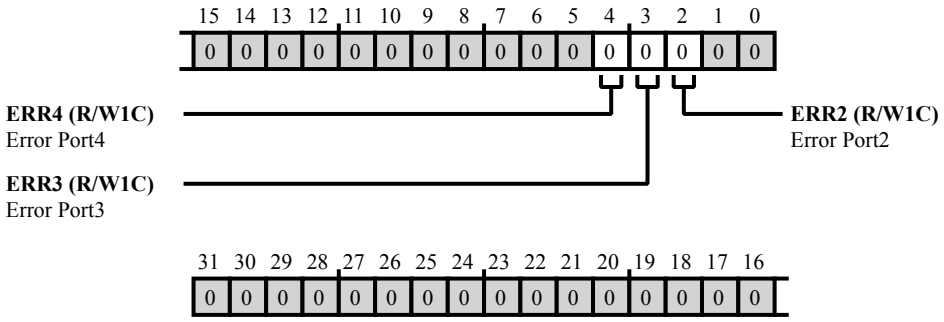

Figure 8-35: L2CTL_STAT_1 Register Diagram

Table 8-38: L2CTL_STAT_1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	ERR4	Error Port4. The L2CTL_STAT_1.ERR4 indicates whether the L2CTL has detected a bus access error on L2s bus port 4.
3 (R/W1C)	ERR3	Error Port3. The L2CTL_STAT_1.ERR3 indicates whether the L2CTL has detected a bus access error on L2s bus port 3.
2 (R/W1C)	ERR2	Error Port2. The L2CTL_STAT_1.ERR2 indicates whether the L2CTL has detected a bus access error on L2s bus port 2.

Write Priority Count Register

The L2CTL_WPCR0 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

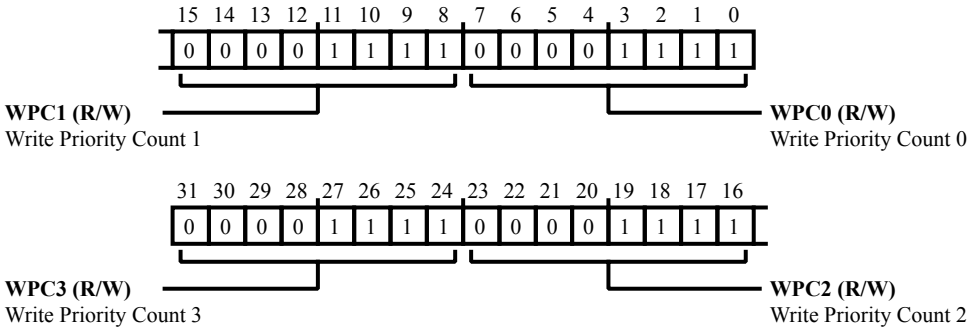

Figure 8-36: L2CTL_WPCR0 Register Diagram

Table 8-39: L2CTL_WPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	WPC3	Write Priority Count 3. The L2CTL_WPCR0.WPC3 bits hold the priority count for L2 bus write channel 3.
23:16 (R/W)	WPC2	Write Priority Count 2. The L2CTL_WPCR0.WPC2 bits hold the priority count for L2 bus write channel 2.
15:8 (R/W)	WPC1	Write Priority Count 1. The L2CTL_WPCR0.WPC1 bits hold the priority count for L2 bus write channel 1.
7:0 (R/W)	WPC0	Write Priority Count 0. The L2CTL_WPCR0.WPC0 bits hold the priority count for L2 bus write channel 0.

Write Priority Count Register

The L2CTL_WPCR1 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

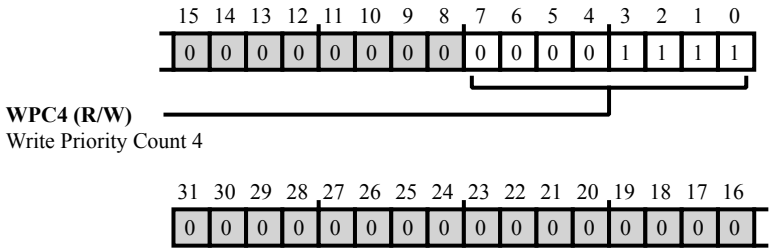

Figure 8-37: L2CTL_WPCR1 Register Diagram

Table 8-40: L2CTL_WPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	WPC4	Write Priority Count 4. The L2CTL_WPCR1.WPC4 bits hold the priority count for L2 bus write channel 4.

9 Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glueless interface between DDR3 SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR3 SDRAM respectively.

NOTE: The term DDR3 is referred to generically as DDR SDRAM in the rest of this chapter unless otherwise noted.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the *protocol controller*. An access and operation reordering mechanism is incorporated as an *efficiency controller*. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient completer implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC can be accessed using the MMR access bus.

The DMC supports access to the external memory by core and DMA accesses.

DMC Features

The DMC includes a protocol controller that supports:

- JESD79-3E compatible double data rate DDR3 SDRAM devices

The features of the dynamic memory controller are:

- Provides 16-bit data only interface to SDRAM devices
- Supports a single external rank (one chip select)
- Provides page hit detection that supports multiple column accesses to the same row
- User-specified active, precharge, and refresh commands.
- Programmable SDRAM access timing parameters
- Enables automatic refresh generation with programmable refresh intervals
- Self-refresh mode to reduce system power consumption

- Efficient transaction processing to improve throughput and bandwidth using:
  - Software programmable SCB IDs to allow SCB ID-based priority
  - The ability to postpone up to eight auto-refresh commands
  - Software selectable closed page scheme on a per bank basis
  - Simple transaction scheduling mechanism to reduce read write turnaround frequency on the memory bus
  - Accesses with the same SCB ID are scheduled back-to-back to take advantage of same page access in SDRAM
  - Caching of SDRAM read data burst for specific controllers to reduce the latency for same burst accesses.

The DDR3 features are:

- 512 Mb to 8 Gb device sizes
- Burst length BL = 8
- Support for additive latency
- Support for programmable (and ZQ calibration) ODT and drive impedance
- Support for read leveling
- Support for write leveling

Feature Exclusions

The DMC exclusions are as follows:

For DDR3:

- 4-bit and 8-bit wide DDR3 DRAM memories are not supported
- Burst interleaved accesses are not supported
- Both burst chop-BC4 and BC4-on-the-fly are not supported
- Auto refresh pull-in is not supported
- DLL off mode is not supported

DMC Functional Description

The dynamic memory controller consists of controller and target interfaces, a protocol controller, and an efficiency controller. The following sections describe the function of these interfaces and controllers.

ADSP-2159x_SC591_SC592_SC594 DMC Register List

The Dynamic Memory Controller module (DMC) provides an interface to external double-data-rate SDRAM. This interface supports various DDR standards (see chapter descriptions). A set of registers governs DMC controller operations. For more information on DMC controller functionality, see the DMC Controller Register Descriptions.

Table 9-1: ADSP-2159x_SC591_SC592_SC594 DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR3	Shadow EMR3 Register
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register
DMC_TR1	Timing 1 Register
DMC_TR2	Timing 2 Register

ADSP-2159x DMC Register List

DMCPHY (DMC) contains the following registers.

Table 9-2: ADSP-2159x DMC Register List

Name	Description
DMC_DDR_CA_CTL	DDR CA Lane Control Register
DMC_DDR_LANE0_CTL0	Data Lane 0 Control Register 0
DMC_DDR_LANE0_CTL1	Data Lane 0 Control Register 1
DMC_DDR_LANE1_CTL0	Data Lane 1 Control Register 0
DMC_DDR_LANE1_CTL1	Data Lane 1 Control Register 1
DMC_DDR_ROOT_CTL	DDR ROOT Module Control Register
DMC_DDR_ZQ_CTL0	DDR Calibration Control Register 0
DMC_DDR_ZQ_CTL1	DDR Calibration Control Register 1
DMC_DDR_ZQ_CTL2	DDR Calibration Control Register 2

Protocol Controller

The DDR SDRAM protocol controller translates memory access requests from the SCB (system crossbar) interface to JEDEC protocol-specific transactions used by DDR SDRAM devices.

The protocol controller ensures that the various timing parameters are met before reading and writing the SDRAM. The controller also performs the SDRAM initialization sequence as mandated by the standard. The protocol controller can:

- Issue reads and writes
- Precharge a row in a bank
- Activate a row in a bank
- Put the SDRAM devices in self-refresh and power-down modes

The protocol controller takes mode register writes from the MMR interface and translates them into mode register writes to SDRAM. Writing into the mode register is restricted through a mask register.

Efficiency Controller

The efficiency controller controls the ordering of transfers buffered in the read and write command buffers. It attempts to order transfers to optimize the available memory bandwidth. The DMC uses a number of schemes, described in the following sections, to increase the throughput.

Page-Based Scheduling

The DMC parses each write and read transaction that it buffered and gets the information of the row (page) and bank address. The protocol controller maintains the information about the pages that are opened in each bank. The efficiency controller uses the information about the opened pages while scheduling the buffered transactions. The transactions to the opened pages are given higher priority than the other outstanding transactions.

Same Controller Transaction Scheduling

The DMC also stores the ID of each transaction that it buffered. In most of the cases, the transactions related to a controller result in page hits from the locality of reference rule. The efficiency controller uses the ID information of the transactions while scheduling. When the page-based scheduling of the buffered transactions is complete, same controller transaction scheduling is triggered. If multiple transactions from a controller are received, the efficiency controller schedules the transactions back-to-back.

DMC Read Data Buffer

The DMC read data buffer contains a data buffer and an address buffer. The depth of the data buffer is equal to the burst length that is programmed in SDRAM. The address buffer holds the corresponding SDRAM burst address. When an SDRAM write address from any controller matches an address in the DMC read data buffer, the DMC invalidates the related data in the read buffer. When the DMC_RDDATABUFMSK1 or DMC_RDDATABUFMSK2 register is programmed with a value other than zero, the DMC read data buffer operation is enabled. The set of controllers whose data is buffered and retrieved are programmed in the DMC_RDDATABUFID1 or DMC_RDDATABUFID2 registers. The DMC can use the DMC_RDDATABUFMSK1 and DMC_RDDATABUFMSK2 ID registers to select a set of controllers similar to the programming of the DMC_PRIOMSK and DMC_PRIOMSK2 registers.

See the SCB ID-Based Priority section for details.

Closed Page Per Bank

The DMC_EFFCTL register provides per-bank granularity for closing pages. The software can determine that most accesses to a given bank in memory always result in a missed page. In this case, set the PREC_BANK bit corresponding to the required bank to close the row after every transfer. This proactive step can result in reduced thrashing and increases memory throughput.

SCB ID-Based Priority

The primary goal of the dynamic memory controller is to improve sustainable memory system bandwidth so that the service time for the average request can be reduced. However, to service critical requests from any controller in the system, the DMC provides a mechanism to elevate priority of a given access. The DMC priority ID registers (DMC_PRIO and DMC_PRIO2) can be programmed with up to two SCB IDs with elevated priority.

After every access in a snapshot, the command buffers are searched to determine whether an ID of a command matches with the ID programmed in the DMC_PRIO and DMC_PRIO2 registers. The priority SCB ID access is sent before the subsequent access in the snapshot if:

- A match occurs, and
- The direction of the access (for example write) is the same as the direction of the snapshot (write)

There is an alternative to providing priority to a specific SCB ID. If a number of IDs from the same controller require priority, program the DMC priority mask ID registers (DMC_PRIOMSK and DMC_PRIOMSK2) so that the corresponding bits are 0. The DMC uses a combination of the DMC_PRIO and DMC_PRIO2 registers and the

DMC_PRIOMSK/DMC_PRIOMSK2 registers to elevate the priority of a select few or all IDs that belong to a controller. By default, none of the IDs are prioritized. The following are a few possibilities:

- The DMC_PRIOMSK field is set to 0x00000000. If a single ID (7234) needs priority, set the DMC_PRIOMSK field to 0xFFFFFFFF and set the DMC_PRIO field to 7234.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFE, the SCB IDs 7234 and 7235 are given priority.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFC, the SCB IDs 7234, 7235, 7236, and 7237 are given priority.
- If two transactions with priority, one read and the other a write, are outstanding, the priority transaction that does not change the direction of the DMC access gets priority. The other priority transaction is handled at the beginning of the next snapshot. For example, if a write snapshot is in-progress, the write priority transaction is sent. The read priority transaction is sent at the beginning of the next read snapshot.

NOTE: Use SCB ID-based priority judiciously because it can significantly reduce the throughput of the DMC.

Delaying up to Eight Auto-Refresh Commands

The DMC uses this method to ensure that auto-refresh does not interfere with any critical data transfers. Up to eight auto-refresh commands can accumulate in the DMC. The exact number of auto-refresh commands can be programmed using the DMC_EFFCTL.NUMREF bit.

After the first refresh command is accumulated, the DMC constantly looks for an opportunity to schedule a refresh command. When the SCB read and write command buffers become empty for the programmed number of clock cycles (DMC_EFFCTL.IDLECYC bit field), the accumulated number of refresh commands are sent back-to-back to the DRAM. (The empty state of the SCB command buffers implies that no access is outstanding.)

After every refresh, the SCB command buffers are checked to ensure that they stay empty. If the SCB command buffers are always full, once the programmed number of refresh commands accumulates, the refresh operation is elevated to urgent priority. One refresh command is sent immediately. After this process, the DMC continues to wait for an opportunity to send out refresh commands. If self-refresh mode is enabled, all pending refresh commands are given out only after that DMC enters into self-refresh mode.

Page and Bank Interleaving

Page and bank interleaving allow consecutive row accesses to fall into the same bank (bank interleaving) or into a different bank (page interleaving). The DMC uses bank interleaving by default (DMC_CTL.ADDRMODE bit =0). If the DMC_CTL.ADDRMODE bit =1, the DMC uses page interleaving. Page misses in one addressing mode result in hits in the other addressing mode.

System Crossbar Completer Interface

The DMC uses the system crossbar completer interface to move all data. The system crossbar interface accepts interleaved write transactions and sends out-of-order responses. The read and write interfaces consist of buffers for address, data, and control information transferred to or from the system crossbar bus.

The system crossbar interface transactions are sent to the SDRAM only after the SDRAM has been initialized. However, if transactions arrive before or during initialization, they accumulate in the system crossbar interface and are sent out to the protocol controller once the initialization completes.

To increase throughput, the system crossbar write-response is sent out as soon as the final DDR burst is scheduled for transfer into the SDRAM. However, if an auto-refresh is needed, the scheduled write data is sent only after the auto-refresh. A delay can occur. The delay is a maximum of 64 clock cycles from the moment the write response is sent on the SCB to the write operation of the data into SDRAM.

The system crossbar interface performs the following operations:

- Buffers read and write command requests from the system crossbar bus
- Processes the requests by converting them to protocol controller user-interface transfers
- Sends and receives data to or from the protocol controller
- Creates a suitable read/write response and sends read data back to the system crossbar bus

The system crossbar completer interface supports the following:

- All burst lengths (1–16)
- Incremental and wrap bursts
- Data transfer sizes of 8-bit, 16-bit, or 32-bit
- Arrival of write data before write address
- Generation of error responses which include:
    - Any access to an unimplemented region of the external memory space
    - Any access when the SDRAM is in self-refresh mode/power-down mode
    - Any access when the direct command interface is in operation

Read/Write Command and Data Buffers

The system crossbar interface consists of a four-deep read command buffer and a four-deep write command buffer. Up to four write commands and four read commands can be waiting for access to the SDRAM. The system crossbar write buffer is 32 deep. It can support write data interleaving of two. The system crossbar read buffer is 32 deep.

Peripheral Bus Completer Interface

The peripheral bus completer interface connects the dynamic memory controller to the peripheral bus and provides a host controller with access to the registers. The peripheral bus completer interface supports the following features:

- Read and write word accesses
- 32-bit data bus

Architectural Concepts

The following sections provide information on the architecture of the interface.

Controller On Die Termination (ODT)

The controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers. Controller ODT involves extra overhead in terms of power consumption during reads.

The DMC implements dynamic on die termination at processor pads. When controller ODT is enabled, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller writes to the DRAM.

Mode Register Set and Extended Mode Register Set Command

The load mode register command initializes the SDRAM operation parameters. The DMC supports the mode register set and extended mode register set commands. The controller automatically issues the mode register set command during power-on initialization and also when the DMC_MR register is written with the DMC_MSK.MR bit. The mode register set command is sent after the ongoing data transfer completes.

DDR3 Reset Functionality

DDR3 contains an additional pin corresponding to reset functionality. Reset is part of the initialization sequence but it can be performed asynchronously when needed. The reset procedure is similar to the steps involved in the initialization except the initial part of power-up.

To perform reset on the DDR3 module:

1. Check to ensure the module is in the idle state by polling the DMC_STAT.IDLE bit (0x0008).
2. Set the DMC_CTL.RESET bit (0x0004).
3. Monitor the DMC_STAT.RESETDONE bit for the completion of the reset function.

Do not perform any transactions during a module reset. Wait for the DMC_STAT.RESETDONE signal.

DDR3 SDRAM Organization

The DMC supports DDR3 SDRAM memory modules ranging from 512 Mb to 8 Gb. The following tables list the address translation mechanism from the user interface to DDR3 memory interface. The controller also supports two types of addressing modes: bank interleaving (DMC_CTL.ADDRMODE =1) and page interleaving (DMC_CTL.ADDRMODE =0).

Bank Interleaving

The ***DDR3 Bank Interleaving*** table shows DDR3 bank interleaving.

Table 9-3: DDR3 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
512 Mb	25:24	23:11	10:1
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1
8 Gb	29:27	26:11	10:1

Page Interleaving

The ***DDR3 Page Interleaving*** table shows DDR3 page interleaving.

Table 9-4: DDR3 Page Interleaving

SDRAM size	Row address bits	Bank address bits	Column address bits
512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10:1
4 Gb	28:14	13:11	10.1
8 Gb	29:14	13:11	10.1

DMC Clocking

The DMC uses a divided-down version of the *PLLCLK* (PLL clock) to generate an internal clock for clocking the DMC block and interface. The specific value of the *DCLK* frequency is programmed in the `CGU_DIV` register.

For information on the maximum clock frequency supported for specific modes, refer to the processor data sheet.

NOTE: For details on DMC clocking, see the Clock Generation Unit (CGU) and Clock Generation Unit (CGU) chapters.

DMC DMA

The DMC supports DMA-based transfers to and from external DDR SDRAM memory and internal memory.

The DMC DMA controller, part of the distributed DMA engines (DDE) that are dispersed through the infrastructure, connects to the system crossbar fabric.

The DMC uses two DDEs for memory-to-memory DMA (MDMA). One channel is the source channel, and the second, the destination channel.

DMA transfers on the processor are descriptor-based or register-based. Register-based DMA allows the processor to program DMA control registers directly to initiate a DMA transfer. On completion, the control registers can be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. This transfer allows the chaining

together of multiple DMA sequences. In descriptor-based DMA operations, a DMA channel can be programmed to set up and start another DMA transfer automatically after the current sequence completes.

Enhanced DMA operations (such as delay line DMA, scatter or gather DMA) are also supported to or from the DMC module.

DMC Operating Modes

DDR3 Mode

The DMC module supports JESD79-3E compatible double data rate DDR3 SDRAM. To configure this mode of operation, first set (=1) the DMC_CTL.DDR3EN bit

Self-Refresh Mode

For low-power consumption, the SDRAM can be put in self-refresh mode. When no data activity occurs, the DMC can put the SDRAM in self refresh to save power. The DMC_STAT.IDLE bit indicates the activity on the DMC. If this bit is set, there is no activity in the DMC.

Enable self-refresh mode by writing the DMC_CTL.SRREQ bit. The DMC stays in a self-refresh state as long as this bit is asserted. The DMC_STAT.SRACK bit indicates when the SDRAM enters self-refresh mode.

When the DMC is in self-refresh mode, the DMC generates an SCB error when any data accesses (read or write requests) is requested.

The DMC can be brought out of self-refresh mode by clearing the DMC_CTL.SRREQ bit again. The controller clears the DMC_STAT.SRACK bit after the self-refresh operation completes.

DMC Event Control

The DMC has no related interrupt or trigger event information.

DMC Programming Model

The dynamic memory controller contains five groups of memory-mapped registers. The DMC uses the MMR access bus to connect to these registers.

- Control and status registers. These registers control the various operation modes of the dynamic memory controller and provide status.
- Timing parameter registers. The value programmed in these registers depends on the speed grade of the SDRAM device used.
- Mode register mirror registers. These shadow registers are copies of the mode registers residing in the SDRAM device.
- PHY control and status registers. The DMC uses these registers to control the operation of the PHY.

- PAD control registers. The DMC uses these registers to control the various aspects of the I/O pads.

The DMC control registers contain sensitive timing parameters and settings for the DDR SDRAM. These registers are programmed with values that are in the operating range of the DDR used.

Writing to reserved fields or writing any reserved values in register bits can cause the dynamic memory controller to function erroneously.

PHY DLL Calibration

The PHY DLL calibration is performed as part of the SDRAM power-up initialization. It calibrates data against the DQS and CLK signal. However, running DLL calibration after self-refresh or at an arbitrary time is required in certain cases.

The DMC allows PHY DLL calibration to start by setting the `DMC_CTL.DLLCAL` bit. The `DMC_STAT.DLLCALDONE` bit can be used to monitor the progress of the calibration. Once calibration is over, this bit is set. Once the calibration procedure is started by writing to the `DMC_CAL_PADCTL0.CALSTRT` bit, the full calibration takes 300 DCLK cycles to complete.

NOTE: DLL calibration can be initiated only when the DMC is idle (`DMC_STAT.IDLE`= 1).

DDR3 ZQ Calibration Short CMD

The ZQ calibration short command is generally used to correct small variations in ZQ (~0.5%). To perform ZQ calibration, the controller is first checked for its idle state. Once the idle bit is obtained, a ZQCS command can be issued by setting the `DMC_STAT.ZQCSDONE` bit (0x0004). The `DMC_STAT.ZQCSDONE` bit (0x0008) can be used to monitor the calibration sequence. When this bit is 0, it indicates that the calibration is ongoing. When it is 1, it indicates that the calibration is done. As an example, a GP timer can be used to periodically trigger a ZQCS command to address tiny variations.

NOTE: The ZQ calibration function is essential for normal operation of DDR3. With the reference of the external resistance (240 Ω ± 1%) connected to the DMC_RZQ pin, DDR3 calibrates the R_{on} and R_{tt} values of the ZQ pin against temperature and voltage variations.

DDR3 ZQ Calibration Long CMD

Several DDR3 impedance calibrations are implemented for optimal signal integrity. The long ZQ calibration is used after power-up and the short ZQ calibration is used periodically during normal operation to compensate for voltage and temperature drift. These calibration sequences improve connectivity between the SDRAM pads and the PCB trace. The DMC_RZQ pin on the SDRAM is connected to an external precision resistor that adjusts the output driver impedance Rtt and ODT values to match the trace impedance. The connection reduces impedance discontinuity and minimizes signal reflections.

The command has two variants named as ZQ calibration long (ZQCL) and ZQ calibration short (ZQCS). The ZQCL command is issued during initialization and after self-refresh exit command. It can be issued later depending on the system environment.

The DMC pads can be autocalibrated to the required driver impedance Rtt using an external resistance RZQ and the On Die Termination (ODT) value using the corresponding bits (DMC_CAL_PADCTL2). The autocalibration logic translates these values into a corresponding drive strength control inside the PHY and then routed to the PADS. Autocalibration starts as soon as the bit is programmed (set the DCLK at the required frequency before setting this DMC_CAL_PADCTL0.CALSTRT bit). Autocalibration expects the program to select two different member sets of pads (address/command pads versus CLK/Data/DQS/DM pads).

On Die Termination ()

The DMC supports dynamic On Die Termination (ODT) at the pads. When the controller ODT is set, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller is writing to the DRAM. Controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers.

DDR3 SDRAM provides extended ODT mode.

- *Asynchronous ODT*: ODT timing in the slow exit power-down mode
- *Dynamic ODT*: Function that can dynamically switch the ODT resistance during a write operation without an MRS command. It improves signal quality during a write operation.

Leveling Techniques

The DMC controller supports read and write leveling.

Write Leveling

It is difficult to meet the specifications with the on-board parasitic, trace length variability along with high frequency. The DMC controller supports leveling to compensate the skews between clock and strobe. This skew compensation is done independently for every byte lane. Write leveling is performed by the DDR3 memory controller as a part of initialization by programming the DMC_MR1.WL bit.

To dynamically perform write leveling:

1. Ensure that the DMC is idle.
2. Program the DMC_MR1.WL bit.
3. Enable the DMC_MSK register for the DMC_MR1 register.
4. Wait for 2000 DMC clock cycles to complete write leveling.

Read Leveling

Read leveling is useful for calibrating read data timing. It is compensated for imbalanced loading on read path. Read leveling can be performed on LSB or byte lane. It is performed as a part of initialization sequence by setting the DMC_EMR3.MPR bit.

To dynamically perform read leveling:

1. Ensure that the DMC is idle.
2. Program the DMC_EMR3.MPR bit.
3. Enable DMC mask register DMC_EMR3 register.
4. Wait for 2000 DMC clock cycles to complete read leveling.

Read Leveling during DQS Strobe Gating

To ensure robust read timing, read leveling must be done individually for all data bits. Some DDR3 memory devices do not drive read leveling patterns on all data pins. The devices send pattern only information on the LSBs of each byte lane. In these cases, the DMC_EMR3 register cannot be used for read leveling. Instead, use the DMC_CTL.RL_DQS bit for read leveling.

Read leveling during DQS strobe gating is dynamically supported except during initialization.

Initializing the DMC

Complete the following procedures to initialize the DMC module.

- Resetting the DMC Lane
- Performing ZQ Calibration
- Programming the DMC Controller

Resetting the DMC Lane

If there is a change in the DMC clock frequency, the DDR lane must be reset using the following procedure. Once the lane is reset, wait 9000 DDR clock cycles for the DDR DLL to lock before restarting the DDR.

1. Set the DMC_DDR_LANE0_CTL0.CB_RSTDLL and DMC_DDR_LANE1_CTL0.CB_RSTDLL bits.
2. Change the DMC clock frequency.
3. Clear the DMC_DDR_LANE0_CTL0.CB_RSTDLL and DMC_DDR_LANE1_CTL0.CB_RSTDLL bits.

Performing ZQ Calibration

Perform the following ZQ calibration procedure for the proper impedance matching.

1. Program the DMC_DDR_ZQ_CTL0.IMPWRADD bit field with the drive strength of the address and command signals. A 100Ω drive strength is recommended for the drive strength of address and command signals. When programming a drive strength of 100Ω, write 0x64 into this bit field.
2. Program the DMC_DDR_ZQ_CTL0.IMPWRDQ bit field with the drive strength of the DQ, DQS, DM and clock signals. A 100Ω drive strength is recommended for the drive strength of address and command signals. When programming a drive strength of 100Ω, write 0x64 into this bit field.

3. Program the DMC_DDR_ZQ_CTL0.IMPRTT bit field with the adjusted On Die Termination (ODT) for the Data and DQS signals for the read operation. Due to a correction factor, program this field to 80% of the equivalent ODT.

   DMC_DDR_ZQ_CTL0.IMPRTT value = ODT*2*0.8

   For example, if a 50Ω terminating resistance is required on the data pads to match the trace impedance to the board impedance, there will be two 50Ω resistance data pads in parallel. The value is programmed to 100 × 0.8 = 80.

4. Write 0 to the DMC_DDR_ZQ_CTL1 register.
5. Program 0x70000000 to the DMC_DDR_ZQ_CTL2 register.
6. Program 0x0000000 to the DMC_DDR_CA_CTL register.
7. Program 0x0000000 to the DMC_DDR_ROOT_CTL register.
8. Program 0x00010000 to the DMC_DDR_ROOT_CTL register.
9. Wait for 8000 DMC clock cycles.
10. Program 0x0C000001 to the DMC_DDR_CA_CTL register.
11. Wait for 8000 DMC clock cycles.
12. Program 0x0000000 to the DMC_DDR_CA_CTL register.
13. Program 0x0000000 to the DMC_DDR_ROOT_CTL register.

Programming Duty Cycles

Perform the following procedure to program the DQS duty cycle and clock duty cycle trim.

1. Program the DMC_DDR_LANE0_CTL0 and DMC_DDR_LANE1_CTL0 registers with DMC_DDR_LANE0_CTL0.BYPCODE/DMC_DDR_LANE0_CTL1.BYPCODE , DMC_DDR_LANE1_CTL0.BYPSELP/DMC_DDR_LANE0_CTL1.BYPCODE and DMC_DDR_LANE0_CTL0.BYPENB/DMC_DDR_LANE1_CTL0.BYPENB to trim the DQS duty cycle adjustment.
2. Program DMC_DDR_CA_CTL registers with DMC_DDR_CA_CTL.BYPCODE0, DMC_DDR_CA_CTL.BYPCODE1, DMC_DDR_CA_CTL.BYPSELP and DMC_DDR_CA_CTL.BYPENB to trim the clock duty cycle adjustment.

Programming the DMC Controller

Perform the following procedure to program the DMC controller.

1. Program the DMC_CFG register with the size of the DDR memory device. Program the DMC_CFG.IFWID and DMC_CFG.SDRWID bit fields to 16-bits wide.

2. Program the DMC_TR0, DMC_TR1, DMC_TR2 registers with the timing parameters as required by the DDR memory device.
3. Program the DMC_MR and DMC_MR1 registers with the appropriate values. A memory ODT of 120Ω is recommended. Write leveling is recommended for a 666 MHz operating frequency.
4. Program the DMC_MR2 register. If read leveling is required, program the DMC_EMR3 register. Read leveling is recommended for a 666 MHz operating frequency.
5. Program the DMC_DLLCTL register. Program the DMC_DLLCTL.DATACYC bit field with 15ns/ddr clock period in ns. Program the DMC_DLLCTL.DLLCALRDCNT bit field with 247.
6. Wait for 2000 DMC clock cycles.
7. Set the DMC_DDR_CA_CTL.SW_REFRESH bit, keeping the other bits unchanged.
8. Wait for five DMC clock cycles.
9. Set the DMC_DDR_ROOT_CTL.SW_REFRESH bit. Program the DMC_DDR_ROOT_CTL.PIPE_OFSTDCYCLE bit field with 2.
10. Program the DMC_CTL register.
    - DMC_CTL.RDTOWR = 5
    - Set the DMC_CTL.DDR3EN bit.
    - Set DMC_CTL.AL_EN if the operating frequency is above 667 MHz.
    - Set DMC_CTL.RL_DQS if operating frequency above 667 MHz and to enable read leveling during data strobing.
    - Set the DMC_CTL.INIT bit.
11. If write leveling is enabled, wait for 600 DMC clock cycles or until the DMC_MR1.WL bit auto clears.
12. If read leveling is enabled wait for 2000 DMC clock cycles or until the DMC_EMR3.MPR bit auto clears.
13. If read leveling during data strobe gating is enabled, wait for 600 DMC clock cycles or until the DMC_CTL.RL_DQS bit auto clears.
14. Wait for 722000 DMC clock cycles to complete DMC initialization or until the DMC_STAT.INITDONE bit is set.
15. Set the DMC_DDR_LANE0_CTL1.COMP_DCYCLE and DMC_DDR_LANE1_CTL1.COMP_DCYCLE bits, without affecting other bits.
16. Wait for 10 DMC clock cycles.
17. Clear the DMC_DDR_LANE0_CTL1.COMP_DCYCLE and DMC_DDR_LANE1_CTL1.COMP_DCYCLE bits, without affecting other bits.
18. Set and then clear the DMC_DDR_LANE0_CTL0.CB_RSTDAT bit, without affecting other bits.

19. Set and then clear DMC_DDR_LANE1_CTL0.CB_RSTDAT bit, without affecting other bits.
20. Wait for 2500 DMC clock cycles.
21. Read the DMC_STAT.PHYRDPHASE bit field. Program this value into the DMC_DLLCTL.DATACYC bit field, without affecting other bits in the DMC_DLLCTL register.
22. Reprogram the DMC_CTL.DDR3EN and DMC_CTL.RDTOWR bits. If the operation frequency is above 667 MHz set the DMC_CTL.AL_EN bit.

Programming DQ Delay Trim

In order to trim or fine tune the delay on the data lane, write leveling code should be read first from the data lanes. The write leveling code can be incremented to increase setup time or decremented to increase hold time before writing it back to the data lanes.

For lane 0, complete the following steps:

1. Write 0x000000D0 to the DMC_DDR_LANE0_CTL1 register without changing other bits.
2. Wait 2500 DMC clock cycles.
3. Write 0x00400000 to the DMC_DDR_ROOT_CTL register.
4. Wait 2500 DMC clock cycles.
5. Write 0x00000000 to the DMC_DDR_ROOT_CTL register.
6. Bits [20:16] of the DMC_DDR_SCRATCH_4 holds the write leveling code for lane 0.
7. Increment or decrement the write leveling code as needed. Write it to the DMC_DDR_LANE0_CTL1.BYPCODE bit. Set the DMC_DDR_LANE0_CTL1.BYPDELCHAINEN
8. Wait 2500 DMC clock cycles.

For lane 1, complete the following steps:

1. Write 0x000000D0 to the DMC_DDR_LANE1_CTL1 register without changing other bits.
2. Wait 2500 DMC clock cycles.
3. Write 0x00800000 to the DMC_DDR_ROOT_CTL register.
4. Wait 2500 DMC clock cycles.
5. Write 0x00000000 to the DMC_DDR_ROOT_CTL register.
6. Bits [20:16] of the DMC_DDR_SCRATCH_5 holds the write leveling code for lane 1.
7. Increment or decrement the write leveling code as needed. Write it to the DMC_DDR_LANE1_CTL1.BYPCODE bit. Set the DMC_DDR_LANE1_CTL1.BYPDELCHAINEN

8. Wait 2500 DMC clock cycles.

ADSP-2159x_SC591_SC592_SC594 DMC Register Descriptions

Dynamic Memory Controller (DMC) contains the following registers.

Table 9-5: ADSP-2159x_SC591_SC592_SC594 DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR3	Shadow EMR3 Register
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register
DMC_TR1	Timing 1 Register
DMC_TR2	Timing 2 Register

Configuration Register

The DMC_CFG register selects SDRAM device specific parameters and selects the SDRAM interface width.

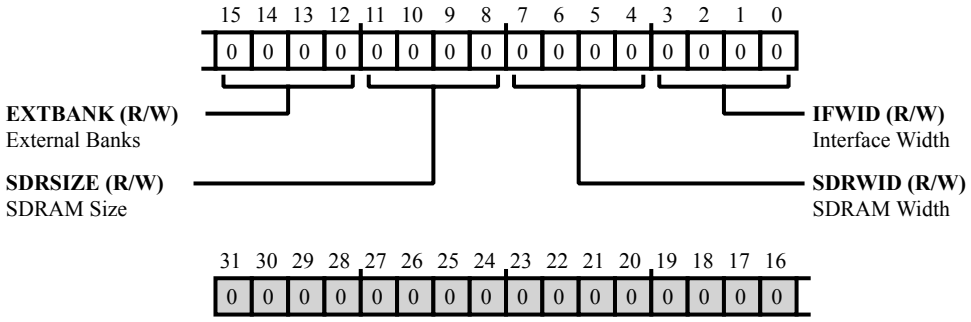

Figure 9-1: DMC_CFG Register Diagram

Table 9-6: DMC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	EXTBANK	External Banks. The DMC_CFG.EXTBANK bits select the number of external banks connected to the DMC. Note that all values other than those shown are reserved.	
		0	1 External Bank
		1-15	Reserved
11:8 (R/W)	SDRSIZE	SDRAM Size. The DMC_CFG.SDRSIZE bits select the size of individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		3	512M Bit SDRAM
		4	1G Bit SDRAM
		5	2G Bit SDRAM
		6	4G Bit SDRAM
		7	8G Bit SDRAM
7:4 (R/W)	SDRWID	SDRAM Width. The DMC_CFG.SDRWID bits select the width of the individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide SDRAM
		3-15	Reserved

Table 9-6: DMC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	IFWID	Interface Width. The `DMC_CFG.IFWID` bits select the width of the interface between the DMC and SDRAM. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide Interface. All other values are reserved. This field specifies the interface width between the controller and the SDRAM.
		3-15	Reserved

Control Register

The DMC_CTL register controls DMC modes, DLL calibration, and DRAM initialization.

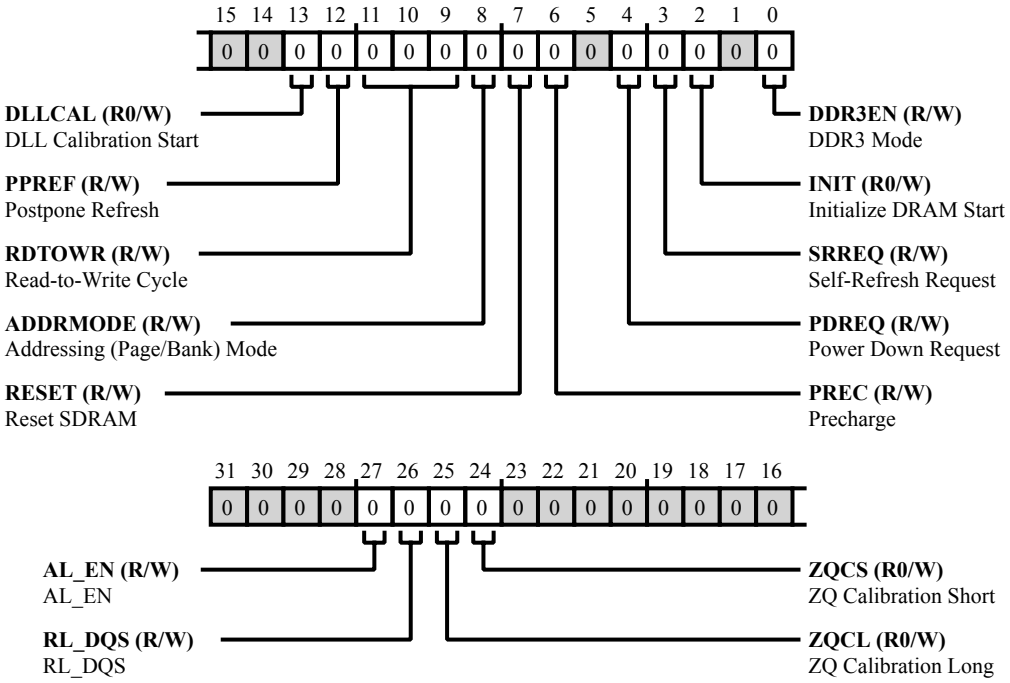

Figure 9-2: DMC_CTL Register Diagram

Table 9-7: DMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	AL_EN	AL_EN. When set, enables 800MHz operation	
		0	Disables greater than 667MHz operation
		1	Enables greater than 667MHz operation
26 (R/W)	RL_DQS	RL_DQS. When set, enables Read leveling during DQS Gating Training. This bit auto-clears on read leveling completion	
		0	Enables Read leveling during DQS Gating Training
		1	Disables Read leveling during DQS Gating training

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R0/W)	ZQCL	ZQ Calibration Long. The DMC_CTL.ZQCL bit starts the ZQ calibration long sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration long sequence
24 (R0/W)	ZQCS	ZQ Calibration Short. The DMC_CTL.ZQCS bit starts the ZQ calibration short sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration short sequence
13 (R0/W)	DLLCAL	DLL Calibration Start. The DMC_CTL.DLLCAL bit starts the PHY DLL calibration sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Start PHY DLL calibration
12 (R/W)	PPREF	Postpone Refresh. The DMC_CTL.PPREF bit enables postponing the DMCs sending of auto-refresh commands. When enabled, the DMC accumulates refresh commands. The DMC_EFFCTL.NUMREF field selects the number of refresh commands that the DMC may accumulate. When disabled, the DMC_TR1.TREF field selects the interval for auto-refresh command distribution. A maximum of eight auto-refresh commands can be accumulated in DDR3 mode.	
		0	Disable Postpone Refresh
		1	Enable Postpone Refresh
11:9 (R/W)	RDTOWR	Read-to-Write Cycle. The DMC_CTL.RDTOWR bits select the number of cycles that the DMC adds when a write operation follows a read operation. For proper operation, it should be programmed with the value of 010.	
		0	1 Cycle Added from JEDEC Spec Value
		1	2 Cycles Added from JEDEC Spec Value
		2	3 Cycles Added from JEDEC Spec Value
		3	4 Cycles Added from JEDEC Spec Value
		4	5 Cycles Added from JEDEC Spec Value
		5	6 Cycles Added from JEDEC Spec Value

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 Cycles Added from JEDEC Spec Value
		7	8 Cycles Added from JEDEC Spec Value
8 (R/W)	ADDRMODE	Addressing (Page/Bank) Mode. The DMC_CTL.ADDRMODE bit selects whether the DMC uses page or bank interleaving for addressing. When using page interleaving, the bank address bits follow the most significant column address bits. When using bank interleaving, the bank address bits follow the most significant row address bits.	
		0	Bank Interleaving
		1	Page Interleaving
7 (R/W)	RESET	Reset SDRAM. The DMC_CTL.RESET bit starts the reset sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Starts reset sequence
6 (R/W)	PREC	Precharge. The DMC_CTL.PREC bit enables precharge, which closes DRAM rows immediately after access. When disabled, all accesses result in the respective DRAM rows remaining open, until the DMC needs to close them.	
		0	No Effect
		1	Enable Precharge
4 (R/W)	PDREQ	Power Down Request. The DMC_CTL.PDREQ bit enables power-down mode. When the DMC is in power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in power-down mode as along as this bit is 1.	
		0	Disable Power-Down
		1	Enable Power-Down
3 (R/W)	SRREQ	Self-Refresh Request. The DMC_CTL.SRREQ bit enables self-refresh mode. When the DMC is in self-refresh mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in self-refresh mode as along as this bit is 1.	
		0	Disable Self-Refresh
		1	Enable Self-Refresh

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R0/W)	INIT	Initialize DRAM Start. The `DMC_CTL.INIT` bit starts the power up DRAM initialization sequence and DLL calibration sequence. Note that this bit always reads as 0.	
		0	No Effect
		1	Start DRAM Initialization
0 (R/W)	DDR3EN	DDR3 Mode. The `DMC_CTL.DDR3EN` bit selects whether the DMC operates in DDR3 mode.	
		0	Reserved
		1	Enable DDR3 mode

DLL Control Register

The DMC_DLLCTL register holds the programmable parameters associated with the DLLs within the DMC PHY.

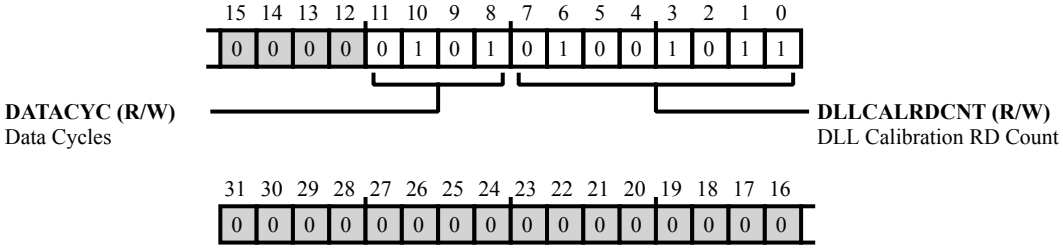

Figure 9-3: DMC_DLLCTL Register Diagram

Table 9-8: DMC_DLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	DATACYC	Data Cycles. The DMC_DLLCTL.DATACYC bits select the latency after which the DMC reads data from the PHY. This field must be written with the value indicated in the DMC_STAT.PHYRDPHASE field, or data corruption occurs on all SDRAM reads.	
		2	2 Clock Cycles Latency
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7 Clock Cycles Latency
		8	8 Clock Cycles Latency
		9	9 Clock Cycles Latency
		10	10 Clock Cycles Latency
		11	11 Clock Cycles Latency
		12	12 Clock Cycles Latency
		13	13 Clock Cycles Latency
		14	14 Clock Cycles Latency
		15	15 Clock Cycles Latency
7:0 (R/W)	DLLCALRDCNT	DLL Calibration RD Count. The DMC_DLLCTL.DLLCALRDCNT field selects the number of read operations that the PHY uses for DLL calibration.	

Data Calibration Address Register

The DMC_DT_CALIB_ADDR register provides the address used for the data calibration for read and write. During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written and a series of reads are performed back to back to calibrate the PHY. The DMC PHY needs prior information about the data that would be read during the PHY DLL calibration. The controller performs one burst write operation to the address programmed in DMC_DT_CALIB_ADDR (0x0090).

Note: While the exact address chosen does not matter much during memory initialization, if calibration of the PHY is performed when the DRAM contains valid data, care needs to be taken to ensure that this address points to an unused address. Else, this operation will modify application data stored at the address selected.

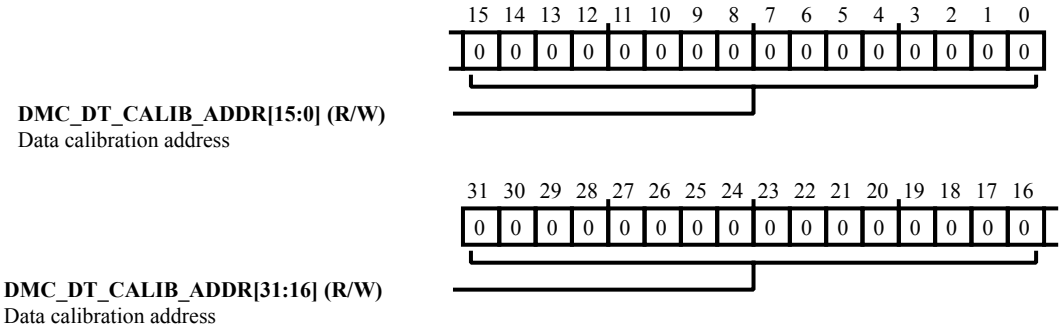

Figure 9-4: DMC_DT_CALIB_ADDR Register Diagram

Table 9-9: DMC_DT_CALIB_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_CALIB_ADDR	Data calibration address. The DMC_DT_CALIB_ADDR.DMC_DT_CALIB_ADDR bit field contains the address to be programmed for the data calibration for read and write.

Data Calibration Data 0 Register

The DMC_DT_DATA_CALIB_DATA0 register contains the first 32-bit data used for the write during the data calibration.

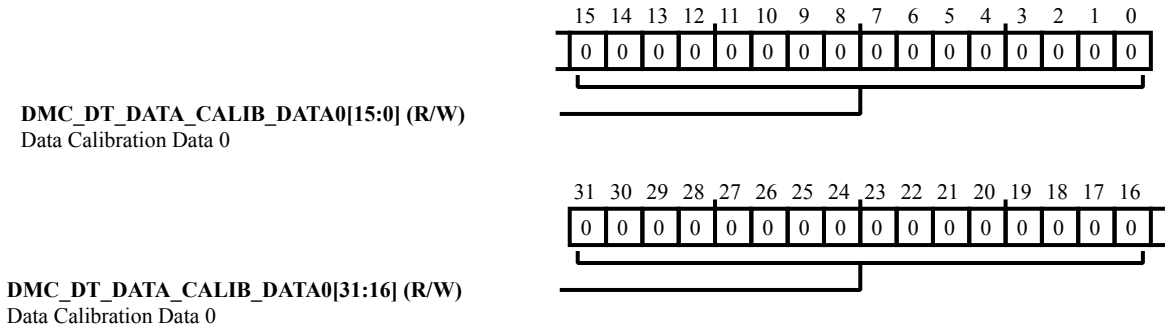

Figure 9-5: DMC_DT_DATA_CALIB_DATA0 Register Diagram

Table 9-10: DMC_DT_DATA_CALIB_DATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0. The DMC_DT_DATA_CALIB_DATA0.DMC_DT_DATA_CALIB_DATA0 bit field contains the first 32 bit data used for the write during the data calibration.

Data Calibration Data 1 Register

The DMC_DT_DATA_CALIB_DATA1 register contains the second 32-bit data used for the write during the data calibration.

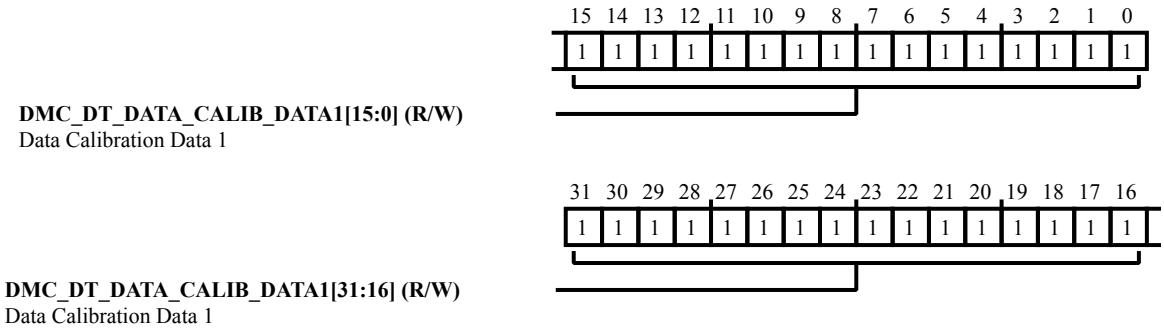

Figure 9-6: DMC_DT_DATA_CALIB_DATA1 Register Diagram

Table 9-11: DMC_DT_DATA_CALIB_DATA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1. The DMC_DT_DATA_CALIB_DATA1.DMC_DT_DATA_CALIB_DATA1 bit field contains the second 32 bit data used for the write during the data calibration.

Efficiency Control Register

The DMC_EFFCTL register control DMC features that improve throughput efficiency. These include features such as auto-refresh management, precharge options, and write data options.

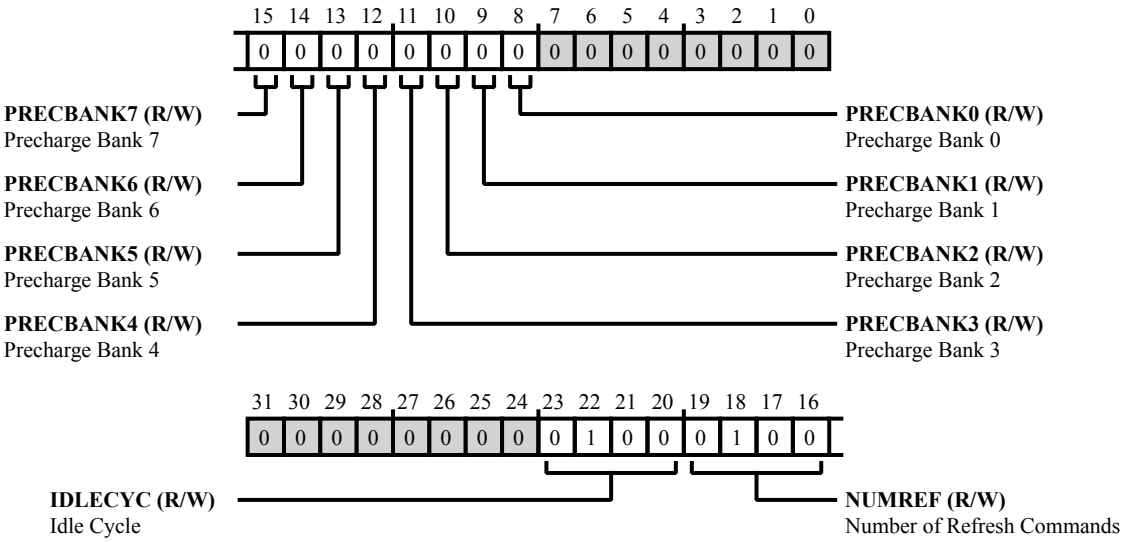

Figure 9-7: DMC_EFFCTL Register Diagram

Table 9-12: DMC_EFFCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	IDLECYC	Idle Cycle. The DMC_EFFCTL.IDLECYC bits select the number of cycles after which the DMC issues any accumulated auto-refresh commands if postpone refresh is enabled (DMC_CTL.PPREF =1). When DMC_EFFCTL.IDLECYC is set to 0, the DMC ignores the DMC_CTL.PPREF selection and does not accumulate/postpone periodic auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set. Note 3: Setting this value to 0000 overrides the "postpone refresh" feature and does not accumulate/postpone periodic auto refreshes.	
		0-15	0 to 15 Idle Cycles to Postpone Refresh Commands

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	NUMREF	Number of Refresh Commands. The DMC_EFFCTL.NUMREF bits select the number of auto-refresh commands that the DMC can accumulate if postpone refresh is enabled (DMC_CTL.PPREF =1). In DDR3 mode, the DMC may accumulate up to eight auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set.	
		0	No Refresh Commands Accumulate
		1	1 Refresh Command May Accumulate
		2	2 Refresh Commands May Accumulate
		3	3 Refresh Commands May Accumulate
		4	4 Refresh Commands May Accumulate
		5	5 Refresh Commands May Accumulate
		6	6 Refresh Commands May Accumulate
		7	7 Refresh Commands May Accumulate
		8	8 Refresh Commands May Accumulate
15 (R/W)	PRECBANK7	Precharge Bank 7. The DMC_EFFCTL.PRECBANK7 bit enables precharge (closes the page) of bank 7 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 7
		1	Enable Precharge Bank 7
14 (R/W)	PRECBANK6	Precharge Bank 6. The DMC_EFFCTL.PRECBANK6 bit enables precharge (closes the page) of bank 6 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 6
		1	Enable Precharge Bank 6

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PRECBANK5	Precharge Bank 5. The DMC_EFFCTL.PRECBANK5 bit enables precharge (closes the page) of bank 5 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 5
		1	Enable Precharge Bank 5
12 (R/W)	PRECBANK4	Precharge Bank 4. The DMC_EFFCTL.PRECBANK4 bit enables precharge (closes the page) of bank 4 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 4
		1	Enable Precharge Bank 4
11 (R/W)	PRECBANK3	Precharge Bank 3. The DMC_EFFCTL.PRECBANK3 bit enables precharge (closes the page) of bank 3 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 3
		1	Enable Precharge Bank 3
10 (R/W)	PRECBANK2	Precharge Bank 2. The DMC_EFFCTL.PRECBANK2 bit enables precharge (closes the page) of bank 2 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 2
		1	Enable Precharge Bank 2
9 (R/W)	PRECBANK1	Precharge Bank 1. The DMC_EFFCTL.PRECBANK1 bit enables precharge (closes the page) of bank 1 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 1
		1	Enable Precharge Bank 1

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PRECBANK0	Precharge Bank 0. The DMC_EFFCTL.PRECBANK0 bit enables precharge (closes the page) of bank 0 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 0
		1	Enable Precharge Bank 0

Shadow EMR3 Register

The DMC_EMR3 register in the DMC shadows the EMR3 register in the SDRAM when the DMC is in DDR3 mode (DMC_CTL.DDR3EN =1). If unmasked by the corresponding bit in the shadow mask register (DMC_MSK.EMR3 =1), a write to DMC_EMR3 triggers an extended “mode register set” command on the memory interface. If masked, a write to DMC_EMR3 only updates the register in the DMC, not the register in the SDRAM.

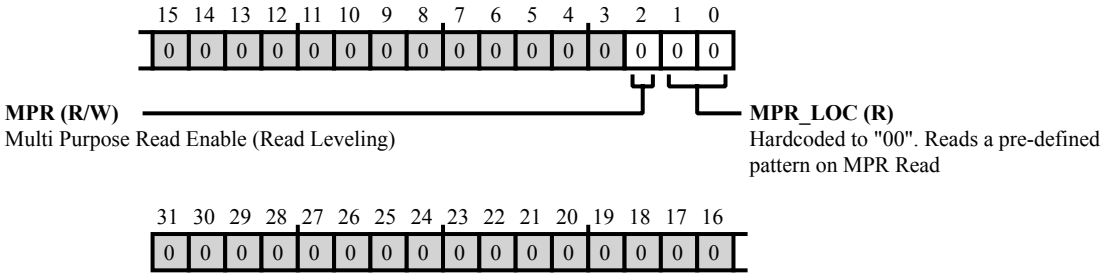

Figure 9-8: DMC_EMR3 Register Diagram

Table 9-13: DMC_EMR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	MPR	Multi Purpose Read Enable (Read Leveling). The DMC_EMR3.MPR bit enables high temperature self-refresh rate.	
		0	Disable
		1	Enable
1:0 (R/NW)	MPR_LOC	Hardcoded to "00". Reads a pre-defined pattern on MPR Read.	

Shadow MR0 Register (DDR3)

The DMC_MR register in the DMC shadows the MR register in the SDRAM when the DMC is DDR3 mode (DMC_CTL.DDR3EN =1). If unmasked by the corresponding bit in the shadow mask register (DMC_MSK.MR =1), a write to DMC_MR triggers a “mode register set” command on the memory interface. If masked, a write to DMC_MR only updates the register in the DMC, not the register in the SDRAM.

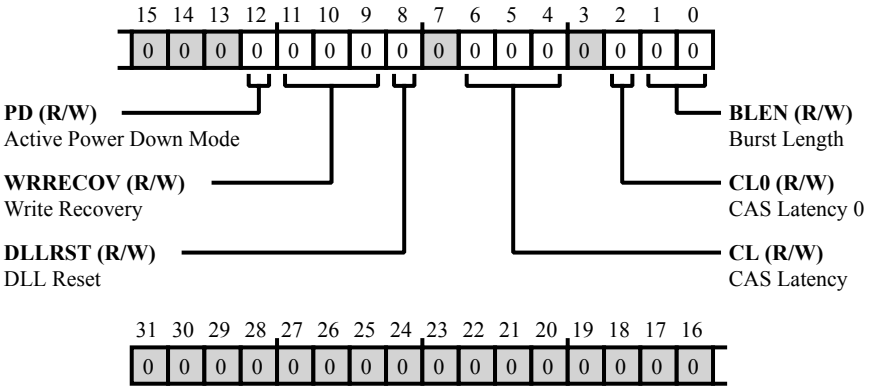

Figure 9-9: DMC_MR Register Diagram

Table 9-14: DMC_MR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PD	Active Power Down Mode. The DMC_MR.PD bit selects the active power-down mode. Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	Fast Exit (normal)
		1	Slow Exit (low power)
11:9 (R/W)	WRRECOV	Write Recovery. The DMC_MR.WRRECOV bit selects the write recovery time in terms of clock cycles (t_{CK}). Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	16 clock cycles for DDR3
		1	5 clock cycles for DDR3
		2	6 clock cycles for DDR3
		3	7 clock cycles for DDR3
		4	8 clock cycles for DDR3
		5	10 clock cycles for DDR3
		6	12 clock cycles for DDR3

Table 9-14: DMC_MR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	14 clock cycles for DDR3
8 (R/W)	DLLRST	DLL Reset. The DMC_MR.DLLRST bit initiates a DLL reset on the SDRAM. Note that this parameter applies only for DDR3 mode. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Normal Operation
		1	Reset DLL
6:4 (R/W)	CL	CAS Latency. The DMC_MR.CL bit field select latency from the assertion of a read/write signal to the SDRAM until the first valid data on the output from the SDRAM in terms of clock cycles. For more information about this operation, see the data sheet for the SDRAM being used in your system. For DDR3 only, Bit[2] of this register must be used along with [6:4]. Following CAS values are seen. "0010": 5 "0100": 6 "0110": 7 "1000": 8 "1010": 9 "1100": 10 "1110": 11 "0001": 12 "0011": 13 "0101": 14 All other combinations are reserved.	
2 (R/W)	CL0	CAS Latency 0. The DMC_MR.CL0 bit is applicable for DDR3 only and is used in conjunction with the DMC_MR.CL bits.	
1:0 (R/W)	BLEN	Burst Length. The DMC_MR.BLEN bits select burst length for transfers. For more information about this operation, see the data sheet for the SDRAM being used in your system. Note that values other than those shown are not supported.	
		0	8-Bit Burst Length - DDR3 only
		2	Reserved
		3	Reserved

Shadow MR1 Register (DDR3)

The DMC_MR1 register is a mirror of the DDR3 SDRAM Mode register 1. This register is used only when the DMC is operating in DDR3 mode. A write to this register triggers an extended "mode register 1 set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

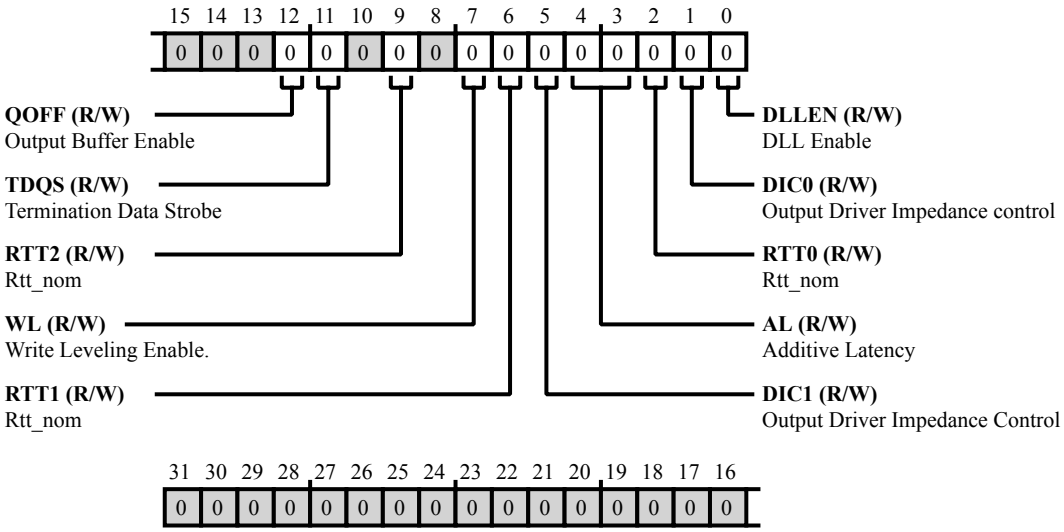

Figure 9-10: DMC_MR1 Register Diagram

Table 9-15: DMC_MR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	QOFF	Output Buffer Enable. The DMC_MR1.QOFF bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Output buffer enabled
		1	Output buffer disabled
11 (R/W)	TDQS	Termination Data Strobe. The DMC_MR1.TDQS bit provides additional termination resistance outputs that may be useful in some system configurations. The DMC_MR1.TDQS bit is not supported in x4 or x16 configurations. When enabled via the mode register, the same termination resistance function is applied to the TDQS/TDQS# pins that is applied to the DQS/DQS# pins.	
		0	Enable
		1	Disable

Table 9-15: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	RTT2	Rtt_nom. The DMC_MR1.RTT2 bit is used in conjunction with the DMC_MR1.RTT0 and DMC_MR1.RTT1 bits. (9 6 2) 0 0 0 Rtt_Nom disabled 0 0 1 RZQ/4 0 1 0 RZQ/2 0 1 1 RZQ/6 1 0 0 RZQ/12 (reserved if Rtt_Nom is used during writes) 1 0 1 RZQ/8 (reserved if Rtt_Nom is used during writes) 1 1 0 Reserved 1 1 1 Reserved
7 (R/W)	WL	Write Leveling Enable.. The DMC_MR1.WL bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system. 0 Disable 1 Enable
6 (R/W)	RTT1	Rtt_nom. The DMC_MR1.RTT1 bit combines with the DMC_MR1.RTT0 bit to set the termination resistance. See the DMC_MR1.RTT2 and DMC_MR1.RTT0 bit description for more information.
5 (R/W)	DIC1	Output Driver Impedance Control. The DMC_MR1.DIC1 bit is used in conjunction with the DMC_MR1.DIC0 bit. (5, 1) 0 0 RZQ/6 0 1 RZQ/7 1 0 Reserved 1 1 Reserved

Table 9-15: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	AL	Additive Latency. The DMC_MR1.AL bits select a number of added latency time for CAS operations in terms of clock cycles (t_{CK}). For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	AL disabled
		1	CL-1
		2	CL-2
		3	Reserved
2 (R/W)	RTT0	Rtt_nom. The DMC_MR1.RTT0 bit combines with the DMC_MR1.RTT1 and DMC_MR1.RTT1 bits to set the termination resistance. See the DMC_MR1.RTT1 and DMC_MR1.RTT2 bit descriptions for more information.	
1 (R/W)	DIC0	Output Driver Impedance control. The DMC_MR1.DIC0 bit is used with the DMC_MR1.DIC1 bit.	
0 (R/W)	DLLEN	DLL Enable. The DMC_MR1.DLLEN bit enables the DLL in the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable
		1	Disable

Shadow MR2 Register (DDR3)

The DMC_MR2 register mirrors DDR3 SDRAM device Mode register 2 when the controller is operating in DDR3 mode. A write to this register triggers an extended "mode register set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

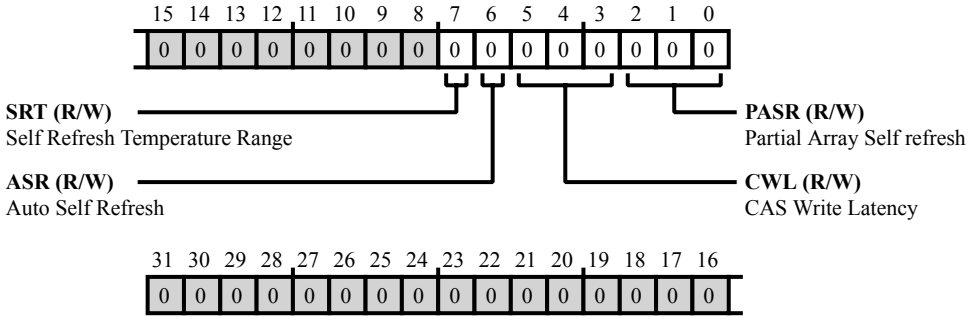

Figure 9-11: DMC_MR2 Register Diagram

Table 9-16: DMC_MR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SRT	Self Refresh Temperature Range. The DMC_MR2.SRT bit enables high temperature self-refresh rate.	
		0	Disable
		1	Enable
6 (R/W)	ASR	Auto Self Refresh.	
		0	Manual SR Reference (SRT)
		1	ASR enable (Optional)
5:3 (R/W)	CWL	CAS Write Latency.	
		0	5 clock cycles
		1	6 clock cycles
		2	7 clock cycles
		3	8 clock cycles
		4	9 clock cycles
		5	10 clock cycles
		6	11 clock cycles
		7	12 clock cycles

Table 9-16: DMC_MR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	PASR	Partial Array Self refresh. The `DMC_MR2.PASR` bits select the amount of memory to be refreshed during self refresh. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	4 banks: full array, 8 banks: full array
		1	4 banks: Half Array (BA[1:0]=00&01), 8 banks: Half Array (BA[2:0] = 000, 001, 010, &011)
		2	4 banks: Quarter Array (BA[1:0]=00), 8 banks: Quarter Array (BA[2:0] = 000&001)
		3	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 000)
		4	4 banks: 3/4 Array (BA[1:0]=01, 10&11), 8 banks: 3/4 Array (BA[2:0] = 010, 011, 100, 101, 110, &111)
		5	4 banks: Half Array (BA[1:0]=10&11), 8 banks: Half Array (BA[2:0] = 100, 101, 110, &111)
		6	4 banks: Quarter Array (BA[1:0]=11), 8 banks: Quarter Array (BA[2:0] =110 & 111)
		7	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 111)

Mask (Mode Register Shadow) Register

The DMC_MSK register permits masking (disabling) writes to the MR and EMRn registers in the SDRAM in DDR3 Mode. When masked, writes to these registers go instead to shadow copies of these registers (DMC_MR, DMC_MR1, DMC_MR2), which are maintained within the DMC. When a shadow register's corresponding bit is unmasked (enabled), the DMC generates the MRS or EMRS command to transfer the contents of the shadow register (in the DMC) to the actual register (in the SDRAM).

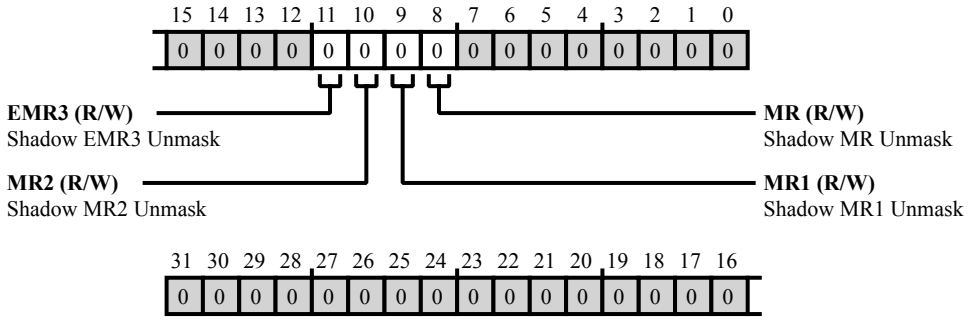

Figure 9-12: DMC_MSK Register Diagram

Table 9-17: DMC_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EMR3	Shadow EMR3 Unmask. The DMC_MSK.EMR3 bit masks or unmasks writes to the EMR3 register in the SDRAM. When masked, writes to this register instead go to the EMR3 register. When unmasked, the DMC writes the EMR3 value to the EMR3 register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR3
		1	Unmask (Enable) Write to EMR3
10 (R/W)	MR2	Shadow MR2 Unmask. The DMC_MSK.MR2 bit masks or unmasks writes to the MR2 register (in DDR3 mode) in the SDRAM. When masked, writes to this register instead go to the DMC_MR2 register. When unmasked, the DMC writes the DMC_MR2 value to the MR2 register (in DDR3 mode) in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR2
		1	Unmask (Enable) Write to EMR2

Table 9-17: DMC_MSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	MR1	Shadow MR1 Unmask. The DMC_MSK.MR1 bit masks or unmasks writes to the MR1 register in the DDR3 SDRAM. When masked, writes to this register instead go to the DMC_MR1 register. When unmasked, the DMC writes the DMC_MR1 value to the MR1 register in the SDRAM. After completing the write, the DMC clears this bit. Note that this bit is valid only for DDR3 Mode of operation.	
		0	Mask (Disable) Write to EMR1
		1	Unmask (Enable) Write to EMR1
8 (R/W)	MR	Shadow MR Unmask. The DMC_MSK.MR bit masks or unmasks writes to the MR register in the SDRAM. When masked, writes to this register instead go to the DMC_MR register. When unmasked, the DMC writes the DMC_MR value to the MR register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to MR
		1	Unmask (Enable) Write to MR

Priority ID Register 1

The DMC_PRIO register allows transactions from selected masters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK register to obtain a single SCB ID or a range of IDs that get elevated priority.

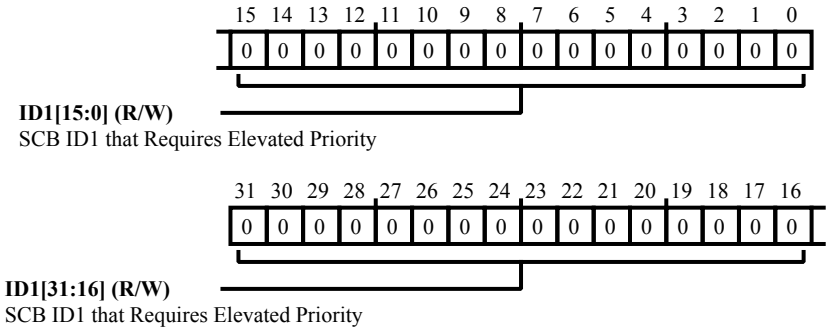

Figure 9-13: DMC_PRIO Register Diagram

Table 9-18: DMC_PRIO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1	SCB ID1 that Requires Elevated Priority.

Priority ID Register 2

The DMC_PRIO2 register is another register which allows transactions from selected masters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

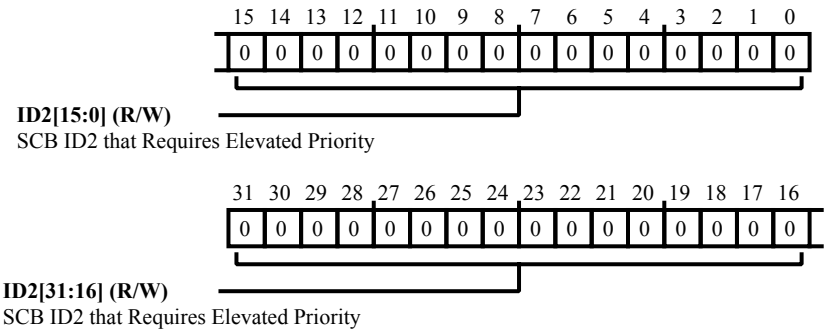

Figure 9-14: DMC_PRIO2 Register Diagram

Table 9-19: DMC_PRIO2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2	SCB ID2 that Requires Elevated Priority.

Priority ID Mask Register 1

The DMC_PRIOMSK register masks the respective ID bits in the DMC_PRIOMSK register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

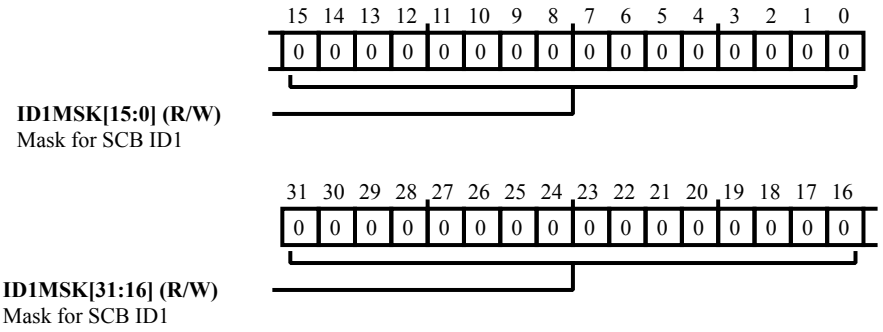

Figure 9-15: DMC_PRIOMSK Register Diagram

Table 9-20: DMC_PRIOMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1MSK	Mask for SCB ID1.

Priority ID Mask Register 2

The DMC_PRIOMSK2 register bits mask the respective ID bits in the DMC_PRIO2 register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

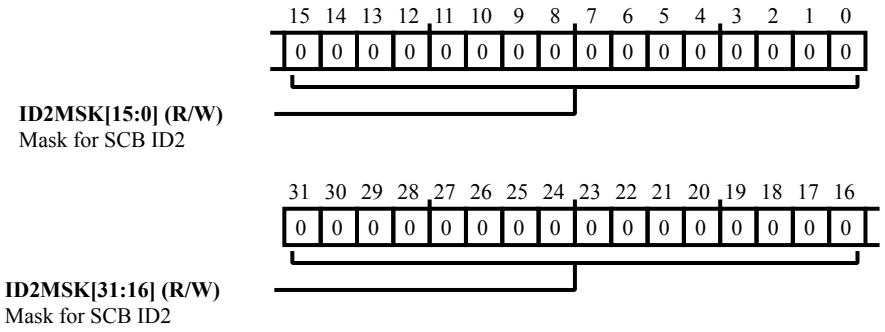

Figure 9-16: DMC_PRIOMSK2 Register Diagram

Table 9-21: DMC_PRIOMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2MSK	Mask for SCB ID2.

DMC Read Data Buffer ID Register 1

The DMC_RDDATABUFID1 register allows read transactions from selected masters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK1 register to obtain a single SCB ID or a range of IDs that get elevated priority.

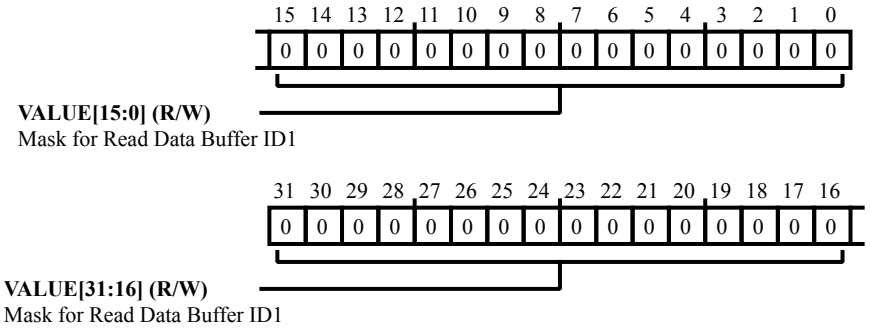

Figure 9-17: DMC_RDDATABUFID1 Register Diagram

Table 9-22: DMC_RDDATABUFID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer ID Register 2

The DMC_RDDATABUFID2 register allows read transactions from selected masters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

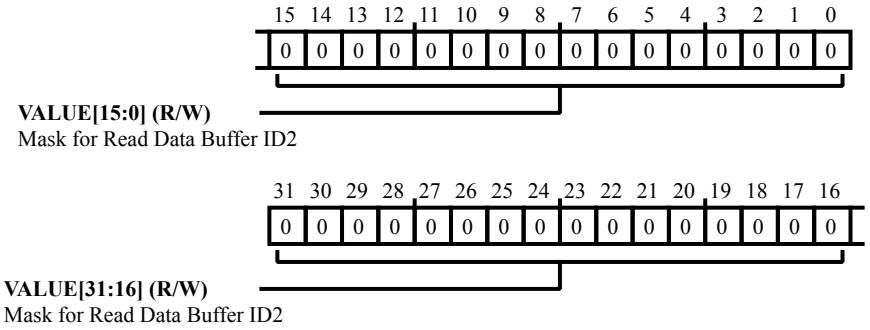

Figure 9-18: DMC_RDDATABUFID2 Register Diagram

Table 9-23: DMC_RDDATABUFID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

DMC Read Data Buffer Mask Register 1

The DMC_RDDATABUFMSK1 register bits mask the respective ID bits in the DMC Priority Mask ID register.

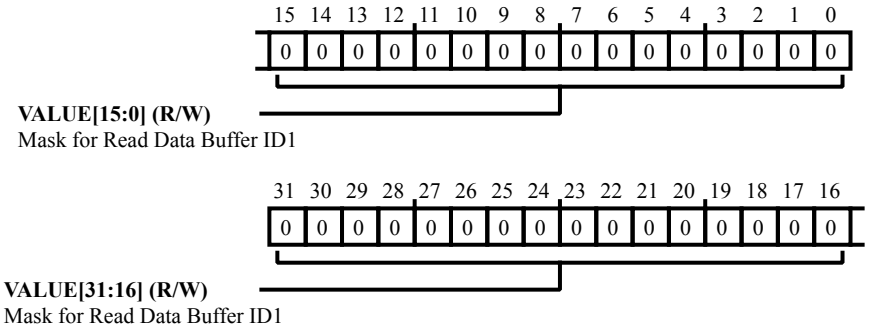

Figure 9-19: DMC_RDDATABUFMSK1 Register Diagram

Table 9-24: DMC_RDDATABUFMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer Mask Register 2

The DMC_RDDATABUFMSK2 register bits mask the respective ID bits in the DMC Priority Mask ID register.

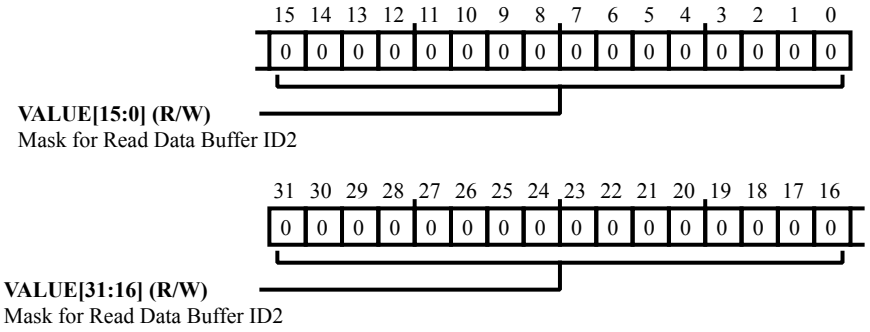

Figure 9-20: DMC_RDDATABUFMSK2 Register Diagram

Table 9-25: DMC_RDDATABUFMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

Status Register

The DMC_STAT register indicates status for modes selected with the DMC_CTL register and indicates status DMC operations.

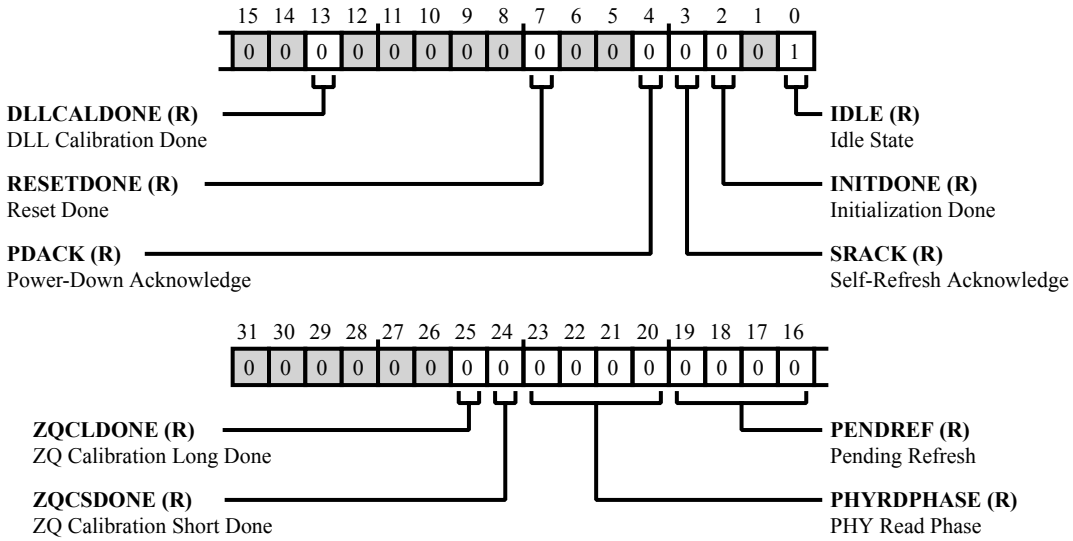

Figure 9-21: DMC_STAT Register Diagram

Table 9-26: DMC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	ZQCLDONE	ZQ Calibration Long Done. The DMC_STAT.ZQCLDONE bit checks if the ZQ calibration long sub routine is done.	
		0	ZQ Calibration long is ongoing
		1	ZQ Calibration long is done
24 (R/NW)	ZQCSDONE	ZQ Calibration Short Done. The DMC_STAT.ZQCSDONE bit checks if the ZQ calibration short sub routine is done.	
		0	ZQ Calibration short is ongoing
		1	ZQ Calibration Short is done
23:20 (R/NW)	PHYRDPHASE	PHY Read Phase. The DMC_STAT.PHYRDPHASE bits indicate the latency after which the DMC may read from the PHY. Taking round trip delay into account, the DLL indicates the exact number of clock cycles after which the controller needs to read data. Values other than those shown are reserved.	
		2	2 Clock Cycles Latency

Table 9-26: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7Clock Cycles Latency
		8	8Clock Cycles Latency
		9	9Clock Cycles Latency
		10	10Clock Cycles Latency
		11	11Clock Cycles Latency
		12	12Clock Cycles Latency
		13	13Clock Cycles Latency
		14	14Clock Cycles Latency
		15	15Clock Cycles Latency
19:16 (R/NW)	PENDREF	Pending Refresh. The DMC_STAT.PENDREF bits indicate the number of pending auto-refresh commands whose value can be from "0000" to "0111".	
13 (R/NW)	DLLCALDONE	DLL Calibration Done. The DMC_STAT.DLLCALDONE indicates that the PHY DLL calibration sequence is complete.	
		0	No Status
		1	Completed PHY DLL Calibration
7 (R/NW)	RESETDONE	Reset Done. The DMC_STAT.RESETDONE bit indicates that the reset sequence is complete.	
		0	SDRAM Reset is ongoing
		1	SDRAM Reset is done
4 (R/NW)	PDACK	Power-Down Acknowledge. The DMC_STAT.PDACK bit indicates that power-down mode is active.	
		0	Not in Power-Down Mode
		1	Power-Down Mode Active

Table 9-26: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	SRACK	Self-Refresh Acknowledge. The `DMC_STAT.SRACK` bit indicates that self-refresh mode is active.	
		0	Not in Self-Refresh Mode
		1	Self-Refresh Mode Active
2 (R/NW)	INITDONE	Initialization Done. The `DMC_STAT.INITDONE` bit indicates that the initialization sequence is complete.	
		0	No Status
		1	Initialize Done
0 (R/NW)	IDLE	Idle State. The `DMC_STAT.IDLE` bit indicates whether the DMC is idle or busy.	
		0	Busy
		1	Idle

Timing 0 Register

The DMC_TR0 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR0 are in increments of clock cycle time (t_{CK}).

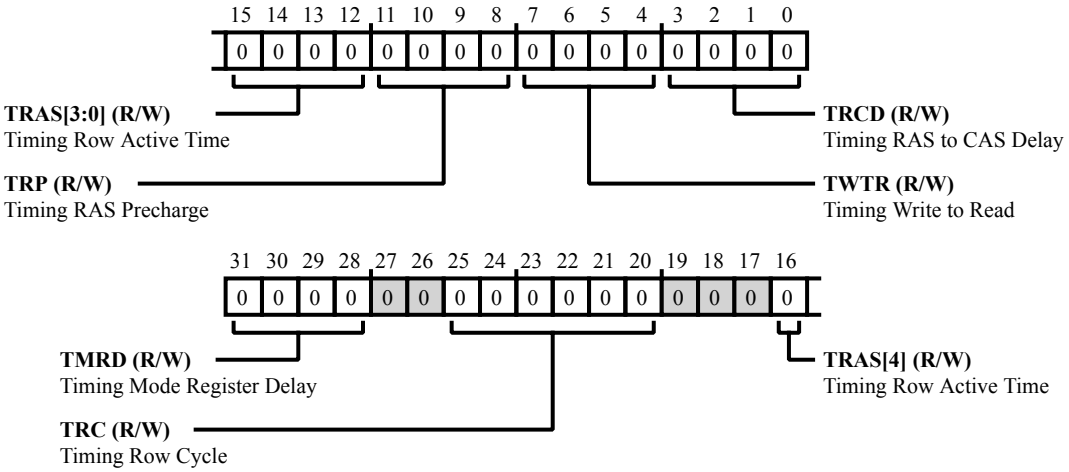

Figure 9-22: DMC_TR0 Register Diagram

Table 9-27: DMC_TR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	TMRD	Timing Mode Register Delay. The DMC_TR0.TMRD field selects the set-to-active timing parameter (t_{MRD}), which is the number of clock cycles that occur after the mode registers in the SDRAM are set and before the next command is issued.
25:20 (R/W)	TRC	Timing Row Cycle. The DMC_TR0.TRC field selects the active-to-active time (t_{RC}), which is the minimum number of clock cycles that occur from an active command to the next active command in the same bank.
16:12 (R/W)	TRAS	Timing Row Active Time. The DMC_TR0.TRAS field selects the active-to-precharge time (t_{RAS}), which is the number of clock cycles that occur from an active command until a precharge command is allowed.
11:8 (R/W)	TRP	Timing RAS Precharge. The DMC_TR0.TRP field selects the precharge-to-active time (t_{RP}), which is the number of clock cycles that occur while the SDRAM recovers from a precharge command and becomes ready to accept the next active command.

Table 9-27: DMC_TR0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	TWTR	Timing Write to Read. The `DMC_TR0.TWTR` field selects the write-to-read delay time (t_{WTR}), which is the number of clock cycles that occur from the last write data to the next read command.
3:0 (R/W)	TRCD	Timing RAS to CAS Delay. The `DMC_TR0.TRCD` field selects the RAS to CAS delay time (t_{RCD}), which is the number of clock cycles that occur from an active command to a read/write assertion.

Timing 1 Register

The DMC_TR1 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR1 are in increments of clock cycle time (t_{CK}).

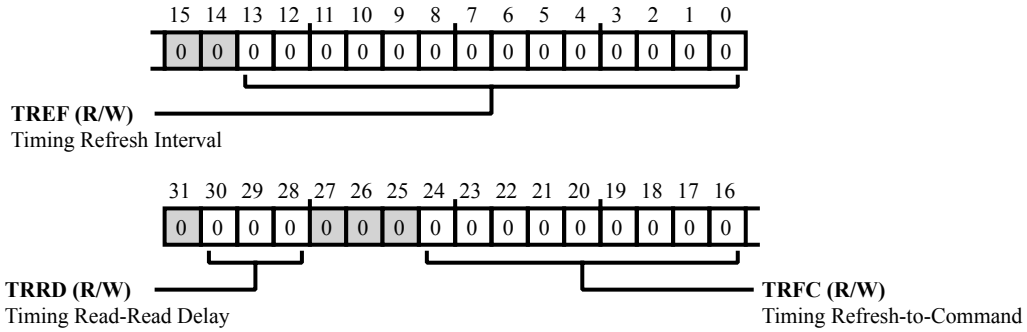

Figure 9-23: DMC_TR1 Register Diagram

Table 9-28: DMC_TR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	TRRD	Timing Read-Read Delay. The DMC_TR1.TRRD field selects the active-to-active time (t_{RRD}), which is the minimum number of clock cycles occurring from a bank x active command to a bank y active command.
24:16 (R/W)	TRFC	Timing Refresh-to-Command. The DMC_TR1.TRFC field selects the refresh-to-active command delay (t_{RFC}), which is the number of clock cycles required for the SDRAM to recover from a refresh signal to be ready to take the next command. It is also the number of clock cycles needed for the SDRAM to recover from executing one active command and ready to accept the next active command.
13:0 (R/W)	TREF	Timing Refresh Interval. The DMC_TR1.TREF field selects the refresh interval time (t_{REF}), which is the number of clock cycles occurring from one refresh command to the next refresh command. The actual timing of issuing a precharge command may be delayed by if the SDRAM is processing a normal access. However, the delay is not accumulative so there is no need to shorten the refresh interval to account for the memory access time. The non-accumulative refresh delay typically increases memory bandwidth by a few percentage points.

Timing 2 Register

The DMC_TR2 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and before initializing the SDRAM.

Note that all values for bit fields in DMC_TR2 are in increments of clock cycle time (t_{CK}).

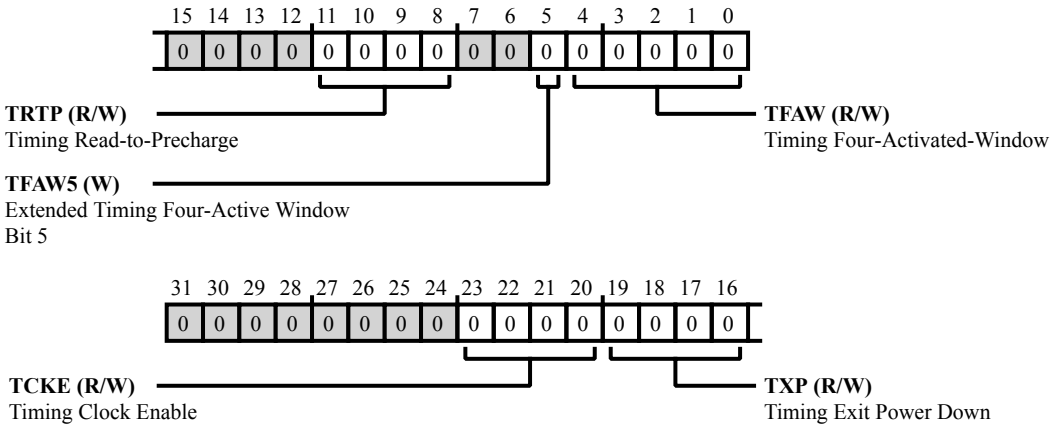

Figure 9-24: DMC_TR2 Register Diagram

Table 9-29: DMC_TR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:20 (R/W)	TCKE	Timing Clock Enable. The DMC_TR2.TCKE field selects the CKE minimum pulsewidth (t_{CKE}).
19:16 (R/W)	TXP	Timing Exit Power Down. The DMC_TR2.TXP field selects the exit power down to next valid command time (t_{XP}).
11:8 (R/W)	TRTP	Timing Read-to-Precharge. The DMC_TR2.TRTP field selects the internal read to precharge time (t_{RTP}). If the resulting value is less than 2, the register needs to be programmed with two. Note: Minimum t_{RTP} that needs to be programmed is 2.
5 (RX/W)	TFAW5	Extended Timing Four-Active Window Bit 5. The DMC_TR2.TFAW5 bit is the extended bit for FAW timing for 800 MHz operation for values greater than 31. It is only applicable when DMC_CTL. AL_EN= 1. When DMC_CTL. AL_EN = 0, the DMC_TR2.TFAW5 bit is reserved. When DMC_CTL. AL_EN = 1, the total FAW[5:0] = {TFAW5,TFAW[4:0]}. NOTE: This bit is write-only. Read as zero.

Table 9-29: DMC_TR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	TFAW	Timing Four-Activated-Window. The DMC_TR2.TFAW field selects the four-banks activated window time (t_{FAW}). No more than four SDRAM banks should be activated within this window.

ADSP-2159x_SC591_SC592_SC594 DMC Register Descriptions

1600MHz DMCPHY (DDR3/DDR3L) (DMC) contains the following registers.

Table 9-30: ADSP-2159x_SC591_SC592_SC594 DMC Register List

Name	Description
DMC_DDR_CA_CTL	DDR CA Lane Control Register
DMC_DDR_LANE0_CTL0	Data Lane 0 Control Register 0
DMC_DDR_LANE0_CTL1	Data Lane 0 Control Register 1
DMC_DDR_LANE1_CTL0	Data Lane 1 Control Register 0
DMC_DDR_LANE1_CTL1	Data Lane 1 Control Register 1
DMC_DDR_ROOT_CTL	DDR ROOT Module Control Register
DMC_DDR_SCRATCH_2	Scratch Register 2
DMC_DDR_SCRATCH_3	Scratch Register 3
DMC_DDR_SCRATCH_4	Scratch Register 4
DMC_DDR_SCRATCH_5	Scratch Register 5
DMC_DDR_SCRATCH_6	Scratch Register 6
DMC_DDR_SCRATCH_7	Scratch Register 7
DMC_DDR_ZQ_CTL0	DDR Calibration Control Register 0
DMC_DDR_ZQ_CTL1	DDR Calibration Control Register 1
DMC_DDR_ZQ_CTL2	DDR Calibration Control Register 2

DDR CA Lane Control Register

Table 9-45: DMC_DDR_ZQ_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	PDCALEN	Driver Pull-down Strength Calibration Enable.
29 (R/W)	PUCALEN	Driver Pull-up Strength Calibration Enable.
28 (R/W)	CALSTRT	New Impedance Calibration Enable.
27 (R/W)	CALTYPE	Calibration Type. Short or Long Calibration
26:21 (R/W)	BYPPDDQ	Bypass Code for DQ,DQS,CLK,DM Pull-down Driver Code.
20:15 (R/W)	BYPPUDQ	Bypass Code for DQ,DQS,CLK,DM Pull-up Code.

Table 9-45: DMC_DDR_ZQ_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:9 (R/W)	BYPPDADD	Address/Command Bypass Pull-down Code.
8:3 (R/W)	BYPPUADD	Address/Command Bypass Pull-up Codes. Bypass pull-up codes for address and command pads
2 (R/W)	BYPIMRD	Bypass Termination Code Enable.
1 (R/W)	BYPIMDQ	DQ/DQS/CLK/DM Bypass Driver Code Enable.
0 (R/W)	BYPIMAD	Address/Command Bypass Code Enable. Bypass code enable for address and command pads.

10 One-Time Programmable Memory Controller (OTPC)

This chapter describes the operation of the OTP controller. The OTP module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

OTP memory access is through the OTP API Overview provided by the ROM.

CAUTION: OTP memory does not support burst transfers, which are required to support cache line fills. As such, OTP memory should not be made cacheable. If it is, the OTP controller returns an error when a read access is attempted.

OTPC Features

The OTP memory and controller have the following features:

- Built-in redundant read mode
- Built-in integrated power supply
- Built-in Hamming Code Error Correction (ECC)
- Full word serial (single bit at a time) programming with internal VPP

NOTE: The OTP module is protected by the System Memory Protection Unit (SMPU) and is always secure by default. Non secure access to the OTP by any module will fail unless allowed by the SMPU.

OTPC Functional Description

ADSP-2159x_SC591_SC592_SC594 OTPC Register List

The One-Time-Programmable Memory controller (OTPC) supports programming the OTP memory. A set of registers governs OTPC operations. For more information on OTPC functionality, see the OTPC register descriptions.

Table 10-1: ADSP-2159x_SC591_SC592_SC594 OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register
OTPC_STAT	OTP Status Register

ADSP-2159x_SC591_SC592_SC594 OTPC Interrupt List

Table 10-2: ADSP-2159x_SC591_SC592_SC594 OTPC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
6	OTPC0_ERR	OTPC0 Dual-bit Error	Level	

Error Correction

The OTP memory features a Hamming error correction implementation. Signal bit errors are automatically corrected, and dual-bit errors are detected. Refer to OTPC Interrupt Signals.

ECC is always enabled. ECC applies to each 16-bit segment. Because of this functionality, each 16-bit location can only be written to once. Writing to a 16-bit location a second time results in unexpected behavior.

OTP Layout

This section details the memory layout of the OTP memory.

Table 10-3: ADSP –2159x OTP Layout

Name	Size (bits)	32–bit Aligned Byte Address	Description
huk	256	0x5c	Hardware Unique Key
rkek	128	0x7c	Root Key encryption key

OTPC Event Control

The following sections provide information on OTP events and error management.

OTPC Interrupt Signals

When making 32-bit accesses to OTP memory, a double-bit error in any 16-bit segment triggers the OTPC_INT interrupt. The OTPC also has the OTPC dual bit error (OTPC0_ERR) with the interrupt ID of 6. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for more information.

OTPC Status and Error Signals

The OTP controller does not produce error signals.

OTP API Overview

The ROM provides a set of functions to facilitate OTP field access. The OTP memory is broken up into a set of specialized fields that are described in this section. The API removes the requirement of understanding the details of the layout or OTP access procedures.

All OTP accesses are made through the provided API.

OTP Programming

The OTP programming API provides a simple access, abstracting particulars of the OTP controller.

Any fields that contain zero or null pointers are skipped.

All addresses are assumed to be byte addresses unless otherwise noted.

A list of APIs follows:

`bool adi_rom_otp_pgm(otp_data* data);`	OTP Program
`bool adi_rom_lock();`	Lock API

OTP Program

Program OTP memory using a struct containing the following predefined data fields.

Name	OTP Program	-

PP Define	FUNC_ROM_OTPPGM	
Prototype	bool adi_rom_otp_pgm(otp_data* data);	-
Argument	data	struct containing data to program OTP with
Return Value	bool	true for programming success
Stack Requirements	valid stack	-

```
bool res = adi_rom_otp_pgm(data);
```

The following type of struct is available for programming. Refer to the ROM header file for the exact definition

```
typedef struct {
  void     *reserved2;
  uint32_t ospi_read_data_capture:16;
  uint32_t (*huk)[ROM_OTP_SZ_huk];
  uint32_t (*pvt_128key0)[ROM_OTP_SZ_pvt_128key0];
  uint32_t (*pvt_128key1)[ROM_OTP_SZ_pvt_128key1];
  uint32_t (*pvt_128key2)[ROM_OTP_SZ_pvt_128key2];
  uint32_t (*pvt_128key3)[ROM_OTP_SZ_pvt_128key3];
  uint32_t (*ek)[ROM_OTP_SZ_ek];
  uint32_t (*secure_emu_key)[ROM_OTP_SZ_secure_emu_key];
  uint32_t emu_key_disable:16;
  uint32_t (*public_key0)[ROM_OTP_SZ_public_key0];
  uint32_t (*public_key1)[ROM_OTP_SZ_public_key1];
  uint32_t (*boot_info)[ROM_OTP_SZ_boot_info];
  uint8_t antiroll_nv_cntr;
  uint32_t (*gp1)[ROM_OTP_SZ_gp1];
  uint32_t bootModeDisable:8;
  uint32_t (*preboot_ddr_cfg)[ROM_OTP_SZ_preboot_ddr_cfg];
  uint32_t (*stageID)[ROM_OTP_SZ_stageID];
  } otp_data;
```

NOTE: Make OTP memory a non-cacheable region if the core needs access to it.

OTP Reading

This API provides a unified source for retrieving OTP data fields.

All addresses are assumed to be byte addresses, unless otherwise noted.

A list of APIs follow:

bool adi_rom_otp_get(OTPCMD cmd, uint32_t* data);	OTP Get Field

OTP Get Field

Retrieves indicated data from OTP memory.

Name	OTP Get Field	
Prototype	`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	
Argument	cmd	Indicates what data to fetch, based on the`OTPCMD` enum.
Argument	data	memory location to write the data to
Return Value	bool	true for a successful read
Stack Requirements	valid stack	

```
bool res = adi_rom_otp_get(otpcmd_info,data);
```

The data specified by the `OTPCMD` enum parameter is fetched from OTP memory and placed in the location specified by data. The `OTPCMD` enum contains entries for each field defined in OTP memory, for the most current list, refer to the OTP header file.

An example of the enum style follows:

```
typedef enum {
  otpcmd_huk = 2,           /*!< Hardware Unique Key */
  otpcmd_rkek,              /*!< Root Key encryption key */
  otpcmd_dek,               /*!< Local encryption key  */
  otpcmd_oem_public_key,    /*!< OEM Public Key */
  otpcmd_pvt_128key0,       /*!< Customer Privatekey 0 128bits */
  otpcmd_pvt_128key1,       /*!< Customer Privatekey 1 128bits */
  otpcmd_pvt_128key2,       /*!< Customer Privatekey 2 128bits */
  otpcmd_pvt_128key3,       /*!< Customer Privatekey 3 128bits */
  otpcmd_ek,                /*!< Endorsement Key */
  otpcmd_secure_emu_key0,   /*!< Secure Emulation Key0 */

OTP Counters

The OTPC module implements a counter API to allow easy reading or writing of the counter without dealing with the complexities of rewriting OTP memory sections that are ECC protected.

The OTPC module provides two functional APIs for counters. These APIs are not extra; the module uses the same `get` and `pgm` APIs. The APIs are functionally unique in the way that they set and retrieve data as counters in OTP memory.

The API uses a different method to count bits because each bit in OTP memory can only be set =1 once, and the ECC protects each 16-bit unit. This functionality essentially means that each 16-bit unit can only be written to once. Therefore, a counter that can count 0–31 requires 32 × 16 bits of memory.

The API receives and returns the value of the counter as a `uint8_t` binary number. Writing a value less than the current value of the counter or greater than the maximum value results in an error.

To implement this functionality, the driver counts by shifting 1's from the left, treating each block as 1 bit. A three-bit counter is encoded as follows.

bit 2	bit 1	bit 0	Value
0000	0000	0000	0
0001	0000	0000	1
0001	0001	0000	2
0001	0001	0001	3

Lock API

This API locks the device.

Name	Lock API	-
PP Define	`FUNC_ROM_LOCK`	-
Prototype	`bool adi_rom_lock();`	-
Return Value	bool	true for success
Stack Requirements	valid stack	-

```
bool res = adi_rom_lock();
```

Calling this function locks the device, making it a secure. Once locked, the `OTPC_SECU_STATE` register indicates that the part is locked, and access is limited. For more information, refer to the security documentation regarding a locked device.

NOTE: Locked Status. The `OTPC_SECU_STATE` register is updated only after the part is rebooted. After calling the lock function, the register still indicates that the part is open.

ADSP-2159x_SC591_SC592_SC594 OTPC Register Descriptions

OTP Memory Controller (OTPC) contains the following registers.

Table 10-4: ADSP-2159x_SC591_SC592_SC594 OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register
OTPC_STAT	OTP Status Register

OTP Security State Register

The OTPC_SECU_STATE register indicates the secure state. The register is updated only after the part is rebooted and locked.

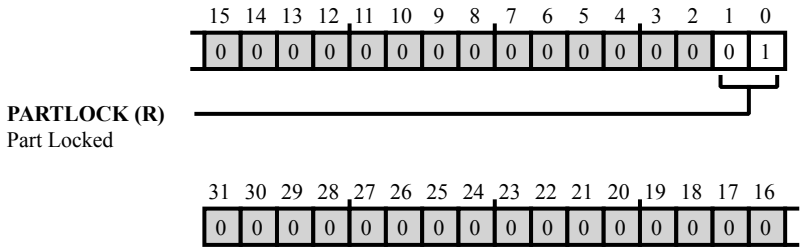

Figure 10-1: OTPC_SECU_STATE Register Diagram

Table 10-5: OTPC_SECU_STATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PARTLOCK	Part Locked. The OTPC_SECU_STATE.PARTLOCK field indicates a locked part.	
		0	OPEN part
		1	Locked part
		2	Reserved

OTP Status Register

The OTPC_STAT register bits indicate errors and flag status and control the protection bits.

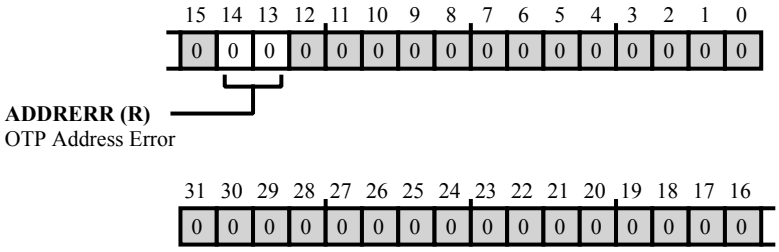

Figure 10-2: OTPC_STAT Register Diagram

Table 10-6: OTPC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/NW)	ADDRERR	OTP Address Error. The OTPC_STAT.ADDRERR bit field indicates errors which occur when the OTP programming address is out of range or tries to access protected space.	
		0	No error - proper OTP address
		1	OTP address out of range
		2	8-bit OTP address
		3	Protected OTP address

11 System Memory Protection Unit (SMPU)

The SMPU provides a flexible way of protecting memory regions against read or write access from any or all masters in the system. In addition, it can guard against memory access depending on security privileges of the system master.

SMPU Features

The system memory protection unit has the following features.

- After reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces by any controller.
- Each SMPU instance can be configured to monitor multiple regions. Each can be individually enabled.
- Each region can be configured with its own protection settings.
- Provides general read or write protection.
- Read and write transactions are restricted or allowed depending on the transaction ID.

On the ADSP-2159x processor, four SMPU instances are available to protect the L2, external memory (DMC) interface.

Table 11-1: SMPU Instances

Module	SMPU Instance
L2-Core Port 0	2
L2 DMA Port 0	3
L2-Core Port 1	4
L2 DMA Port 1	5
L2-Core Port 2	6
DMC0	9
SPI2/OSPI0 Flash Address Space	11
OTP Memory	12

All the SMPU instances can be configured up to eight regions.

- Up to eight outstanding read or write transactions supported on SMPU instances for Core_L2 and DMC0. Up to four outstanding read or write transactions supported on the SMPU instances for DMA_L2 and SPI flash address space.

SMPU Functional Description

The following sections provide details on the function of the SMPU module. If the region security settings allow transactions to go through, the ID in the ID-based region protection settings can still filter the transactions.

For the memory that an SMPU protects, programs can configure region-based settings with the `SMPU_RCTL[n]` registers. (There can be multiple SMPUs in a system.) The `SMPU_RCTL[n]` registers define the ID-based protection for memory regions.

If the target address does not reside in any configured memory region, the transaction permission resorts back to the global configuration setting.

Protection Units

Each SMPU provides two protection units, A and B for ID-based matching in the region-based memory protection. This feature provides a degree of flexibility for the user to match against multiple IDs.

Instruction Fetches

When the core executes instructions from memory, this operation is also considered a memory transaction. If the SMPU is configured to protect a memory region from read accesses that contain instructions, the core cannot fetch and execute these instructions.

Using Cache

When the processor uses both cache and the SMPU, there are a few issues to be aware of. If the SMPU is configured to protect a memory region from write accesses, instruction fetches from a core are still possible since instructions are not updated and replaced during run time.

NOTE: The debugger typically replaces an instruction with a breakpoint instruction for software breakpoints. If a memory region is protected against write accesses, software breakpoints are not possible unless the SMPU is configured with the appropriate system controller ID of the debugger. The configuration allows it to perform a write-access.

In the case where memory is used for data, a read access or cache fill is not possible if the memory is blocked from read accesses. If read accesses are allowed but write accesses are disallowed, then there is an issue with coherency. The cache is filled but when the cache is updated and must be written back to the SMPU protected memory, the write-access is blocked.

In general, exercise caution when using both the SMPU and cache.

Speculative Reads

If speculative reads are enabled (SMPU_CTL.RSDIS =0), the SMPU forwards the read transaction directly to the memory before checking the protection setting corresponding to the addressed memory region. This functionality saves one clock cycle in the clock domain of the SMPU. The SMPU checks the protection setting while the read transaction occurs with the memory. If the protection setting dictates that the target memory address is blocked, the SMPU blocks the read to the controller.

If speculative reads are disabled (SMPU_CTL.RSDIS =1), the SMPU checks the protection settings first and forwards the transaction to memory only if it passes the configured protection settings. This functionality incurs a one-cycle latency per read.

NOTE: Reads affect certain memory operations such as automatic clearing of the memory (that is, FIFOs). When the SMPU protects this type of memory, disable read speculation since the blocking can occur without the read transaction reaching the target memory.

ADSP-2159x_SC591_SC592_SC594 SMPU Register List

The System Memory Protection Unit (SMPU) provides selective protection of the processor's memory resources. The SMPU includes a set of processor events that can be monitored during program execution. A set of registers governs SMPU operations. For more information on SMPU functionality, see the SMPU register descriptions.

Table 11-2: ADSP-2159x_SC591_SC592_SC594 SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register

Name	Description
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

SMPU Interrupts

The SMPU has one interrupt with the SEC ID = 217. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for complete information on interrupt generation and use.

Memory Writes

A write transaction to address n is prevented when the following is true.

Address n is in memory region m and memory region m is write-protected (SMPU_RCTL[n].WPROTEN =1) and ID is not a match. (See ID Comparison). The block occurs because the memory region is configured for write-protection and the ID comparison does not result in a match. If an ID comparison results in a match, the write transaction is allowed through.

Memory Reads

A read transaction from address n is prevented when the following is true:

- Address n is in memory region and memory region m is read-protected (SMPU_RCTL[n].RPROTEN =1) and
- ID is not a match

The block occurs because the memory region is configured for read-protection and the ID comparison does not result in a match. If the ID comparison results in a match, the read transaction is permitted. (See ID Comparison).

ID Comparison

ID comparison automatically occurs during region-based memory protection. ID matches allow the transaction to bypass the configured memory protection for that region. The following sections describe the calculation of a write ID match and read ID match.

Write Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming write transaction:

- The SMPU_RCTL[n].WIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Write IDA match = ((ID of incoming write transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Write IDB match = ((ID of incoming write transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Write ID match = (Write IDA match OR Write IDB match) XOR SMPU_RCTL[n].WIDCINV bit

Read Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming read transaction:

- The SMPU_RCTL[n].RIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Read IDA match = ((ID of incoming read transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Read IDB match = ((ID of incoming read transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Read ID match = (Read IDA match OR Read IDB match) XOR SMPU_RCTL[n].RIDCINV

In the two cases described above, the incoming transaction (either write or read) ID is AND'ed with the configured mask value in protection unit A. It is then compared to the value of the configured ID value which is also AND'ed with the configured mask value in protection unit A. The mask provides a method to allow a group of IDs to match. This process is also performed for protection unit B. The two outcomes (from A and B) are then OR'ed together.

Depending on the setting of the SMPU_RCTL[n].RIDCINV or the SMPU_RCTL[n].WIDCINV bits, the ID match comparison is inverted or not. The final result after applying the inversion, SMPU_RCTL[n].RIDCINV, or SMPU_RCTL[n].WIDCINV, determines whether the transaction bypasses the protection.

Usage

The masks, SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n], are AND'ed with both the incoming transaction ID and the configured ID in SMPU_RIDA[n].ID and SMPU_RIDB[n].ID, respectively. By default the masks are zero. If ID-based region protection is enabled by setting the SMPU_RCTL[n].WPROTEN or SMPU_RCTL[n].RPROTEN bit fields and the masks are not set, the ID comparison essentially compares zeros. The comparison allows all transactions to bypass (if the region-based security setting is also configured in a way to allow transactions to go through for the region). To have the ID-based region protection to function, the mask registers and ID registers must also be set.

System IDs

The ***System controller IDs*** table provides the IDs for the system controllers. An x means that the bit can be a 0 or a 1. There are multiple IDs associated with that particular system controller.

Table 11-3: System Controller IDs

ASIB Name	IID	SIID	ID

Memory Region

Memory regions can start at address 0x00000000 or at any address that is a multiple of its size. The ***Supported Memory Region Size and Alignment*** table shows the memory region sizes that the processor supports and the alignment of the memory region. (X values are do-not-care).

SMPU supports a maximum of eight regions.

Table 11-4: Supported Memory Region Size and Alignment

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
4KB	0b00000	0xXXXXX000	-
8KB	0b00001	0xXXXXN000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
16KB	0b00010	0xXXXXN000	0x0, 0x4, 0x8, 0xC

Table 11-4: Supported Memory Region Size and Alignment (Continued)

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
32KB	0b00011	0xXXXXN000	0x0, 0x8
64KB	0b00100	0xXXXX0000	-
128KB	0b00101	0xXXXN0000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
256KB	0b00110	0xXXXN0000	0x0, 0x4, 0x8, 0xC
512KB	0b00111	0xXXXN0000	0x0, 0x8
1MB	0b01000	0xXXX00000	-
2MB	0b01001	0xXXN00000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
4MB	0b01010	0xXXN00000	0x0, 0x4, 0x8, 0xC
8MB	0b01011	0xXXN00000	0x0, 0x8
16MB	0b01100	0xXX000000	-
32MB	0b01101	0xXN000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
64MB	0b01110	0xXN000000	0x0, 0x4, 0x8, 0xC
128MB	0b01111	0xXN000000	0x0, 0x8
256MB	0b10000	0xX0000000	-
512MB	0b10001	0xN0000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
1GB	0b10010	0xN0000000	0x0, 0x4, 0x8, 0xC
2GB	0b10011	0xN0000000	0x0, 0x8
4GB	0b10100	0x00000000	-

For the case where the region size is selected as 4 GB, the region address must be at address 0x00000000.

NOTE: If a memory region address is not aligned to its size, the memory region start address protected by the SMPU is the configured address with the corresponding least significant bits masked. For example, if the size is configured for 16 KB (`SMPU_RCTL[n].SIZE` =0b00010), and the base address is configured for `SMPU_RADDR[n].BADDR`=0x00005018, the actual base address used by the SMPU is 0x00004000. When `SMPU_RADDR[n].BADDR` is read back, the program reads 0x00005000. This functionality is because only bits [11:0] are reserved as 0's. Programs must use care when setting the base address as it is not always the true base address.

SMPU Definitions

To make the best use of the SMPU, it is useful to understand the terms in this section.

Global Protection

Guarding of the entire memory space for the particular SMPU instantiation.

Region-Based Protection

Guarding individual segments of memory inside the memory space for the particular SMPU instantiation.

ID Match

A successful comparison of the ID associated with the incoming transaction and the ID and MASK configured in the SMPU.

SMPU Block Diagram

The ***SMPU Top-Level Block Diagram*** shows the SMPU block.

As seen in the diagram, the SMPU sits between the memory port (SCB master port) and the SCB fabric (SCB slave port). It acts as a gateway analyzing the transaction requests. It either rejects the transaction request or allows access based on the user-programmed configuration of the SMPU.

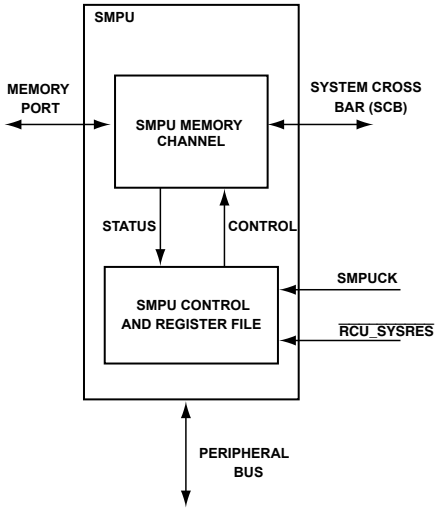

Figure 11-1: SMPU Top-Level Block Diagram

SMPU Architectural Concepts

The following sections provide brief descriptions of the architecture of the SMPU module.

Default Setting

At reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces.

Latency

The SMPU adds latency to all the transactions to the memory except reads when read speculation is enabled (`SMPU_CTL.RSDIS` =0). In this case, read accesses are always forwarded to the memory and read responses are generated according to the SMPU settings. If read speculation is disabled (`SMPU_CTL.RSDIS` =1), reads are

blocked if they cause a security or protection violation. The SMPU generates the SCB read response that corresponds to a blocked transaction.

If read speculation is enabled, the SMPU adds 1 clock cycle latency to the read transaction. If read speculation is disabled, the SMPU adds 2 clock cycles latency to the read transaction.

SMPU Operating Modes

The SMPU does not have any strict modes of operation. However, it can be configured for region-based protection where a controller with a particular ID can be blocked or allowed based on settings in the SMPU_RCTL[n] register.

Region-based protection is programmed with registers:

- SMPU_RCTL[n]
- SMPU_RADDR[n]
- SMPU_RIDA[n]
- SMPU_RIDMSKA[n]
- SMPU_RIDB[n]
- SMPU_RIDMSKB[n]

SMPU Interrupt Signals

There is one interrupt signal associated with the SMPU. If interrupts are enabled, the SMPU_STAT.IRQ bit is set. The SMPU_IRQ signal is asserted when the SMPU detects a memory access violation. The target address triggering the interrupt is found in the SMPU_IADDR register. The SMPU_IDTLS register provides further details about the cause of the interrupt.

Write errors are prioritized over read errors.

Protection violations (an ID-based violation) can trigger the SMPU interrupt, and can be enabled independently. The protection violation interrupt is enabled by setting the SMPU_CTL.PINTEN bit.

The SMPU interrupt is asserted for any of the following conditions:

If a second memory access violation occurs while the SMPU_STAT.IRQ bit is set, the SMPU_STAT.IOVR (interrupt overrun) bit is set. The SMPU_IADDR and the SMPU_IDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. Any information on the subsequent interrupt is lost. Once the SMPU_STAT.IRQ bit and the SMPU_STAT.IOVR bit are cleared, any new memory access violations can trigger an interrupt and its details can be captured.

NOTE: When a blocked access occurs, the SMPU triggers an interrupt when interrupt generation is enabled. The SMPU can also be configured to generate a bus error that propagates back to the system controller. The system controller can also trigger an interrupt due to this bus error.

NOTE: On the processor, each SMPU instance has an interrupt. All of the SMPU interrupts are OR'ed and mapped to a single SMPU interrupt on the SEC. While servicing the SMPU interrupt, check all of the SMPU_STAT registers to determine which triggered the interrupt. The interrupt service routine clears the SMPU_STAT.IRQ bit of the all of the SMPU_STAT registers for which the interrupt is triggered.

SMPU Status and Error Signals

If bus errors are enabled (SMPU_CTL.PBEDIS =0), the SMPU generates and returns a bus error to the controller initiating the blocked access. This bit also sets the SMPU_STAT.BERR bit. The SMPU_BADDR and SMPU_BDTLS registers can be read to get the address and details of the transaction that caused the SMPU to generate the error.

Write errors are prioritized over read errors.

A bus error status is returned to the system controller if:

- an ID-based violation happened and the SMPU_CTL.PBEDIS bit =0

If a second memory access violation occurs while the SMPU_STAT.BERR bit is set, the SMPU_STAT.BEOVR bit (bus error overrun) is set. The SMPU_BADDR and the SMPU_BDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. The information about the transaction that caused the SMPU_STAT.BEOVR bit to be set is lost.

NOTE: If both the protection violation interrupt is not enabled (SMPU_CTL.PINTEN =0) and the protection bus error is disabled (SMPU_CTL.PBEDIS =1), the SMPU blocks invalid transactions. However, it does not provide any status or interrupt information indicating that a transaction is blocked.

ADSP-2159x_SC591_SC592_SC594 SMPU Register Descriptions

The System Memory Protection Unit (SMPU) contains the following registers.

Table 11-5: ADSP-2159x_SC591_SC592_SC594 SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register

Table 11-5: ADSP-2159x_SC591_SC592_SC594 SMPU Register List (Continued)

Name	Description
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

Bus Error Address Register

Programs read the SMPU_BADDR and the SMPU_BDTLS registers to determine the cause of a bus error. Write errors are prioritized over read errors.

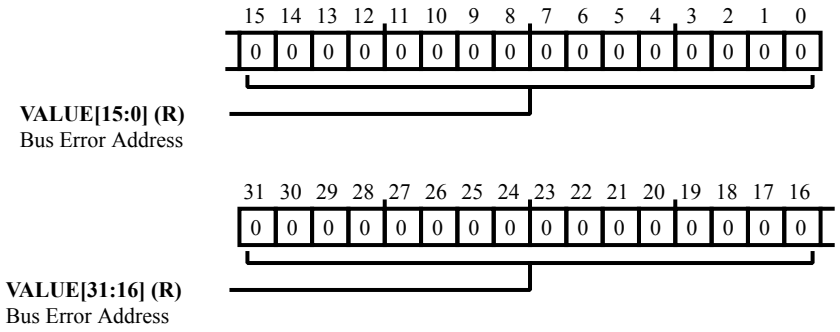

Figure 11-2: SMPU_BADDR Register Diagram

Table 11-6: SMPU_BADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bus Error Address. The SMPU_BADDR.VALUE bit field contains the address of the bus error.

Bus Error Details Register

The SMPU_BDTLS register indicates the ID of the bus error transaction, whether the transaction that caused the last bus error was a read, a write, secure or non-secure.

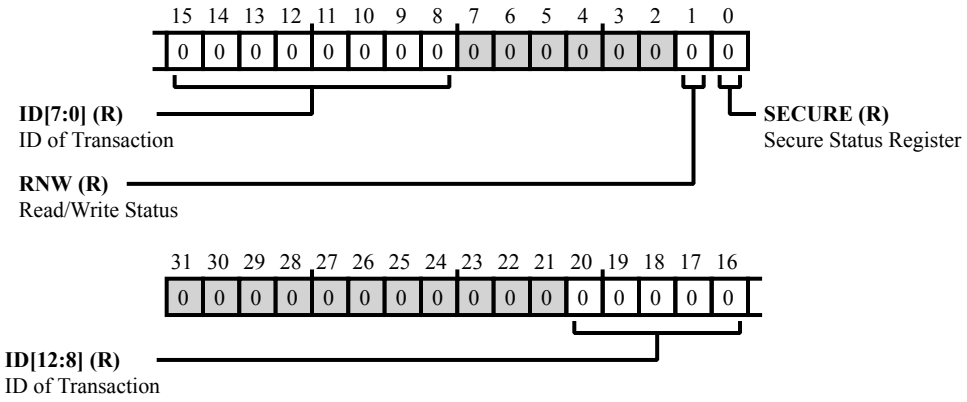

Figure 11-3: SMPU_BDTLS Register Diagram

Table 11-7: SMPU_BDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_BDTLS.ID bit field provides the ID of the transaction that caused the bad address error.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_BDTLS.RNW bit indicates whether the last transaction that caused the bad address error was a read or write.	
		0	Transaction that caused last bus error was a write
		1	Transaction that caused last bus error was a read
0 (R/NW)	SECURE	Secure Status Register. The SMPU_BDTLS.SECURE bit indicates whether the last transaction that caused the bad address error was secure or non-secure.	
		0	Transaction that caused last bus error was non-secure
		1	Transaction that caused last bus error was secure

SMPU Control Register

The SMPU_CTL register provides access to the locking control, error interrupts and SMPU violations.

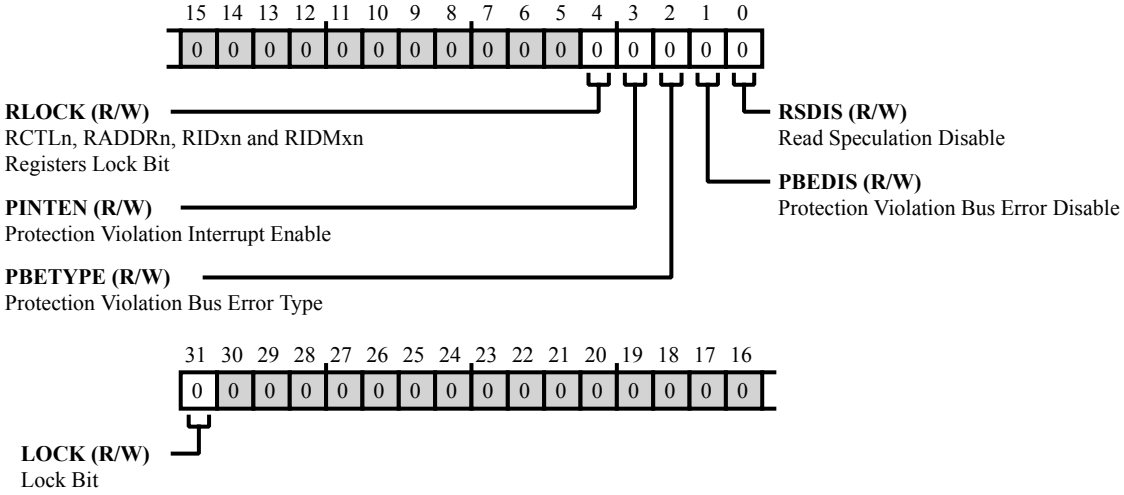

Figure 11-4: SMPU_CTL Register Diagram

Table 11-8: SMPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_CTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_CTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	CTL Global Lock Disable. The SMPU_CTL register is not write-protected.
		1	CTL Global Lock Enable. The SMPU_CTL register is write-protected.
4 (R/W)	RLOCK	RCTLn, RADDRn, RIDxn and RIDMxn Registers Lock Bit. When the SMPU_CTL.RLOCK bit is set, all the registers associated with region-based control (SMPU_RCTL[n], SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n]) are write-protected when the global lock signal is active from the SPU. Write access is allowed again when the global lock signal is deasserted.	
		0	Region Registers Write-Protect Enable. All region registers are not write-protected.
		1	Region Registers Write-Protect Disable. All region registers are write-protected.

Table 11-8: SMPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PINTEN	Protection Violation Interrupt Enable. The SMPU_CTL.PINTEN bit controls whether or not an interrupt is generated when a protection violation occurs.	
		0	Protection Violation IRQ Disable. The protection violation interrupt is disabled.
		1	Protection Violation IRQ Enable. The protection violation interrupt is enabled.
2 (R/W)	PBETYPE	Protection Violation Bus Error Type. The SMPU_CTL.PBETYPE bit controls whether a protection violation produces a decode error or a slave error.	
		0	Decode Error Type. Decode error for transactions that violate the configured protection.
		1	Save Error Type. Slave Error for transactions which violate the configured protection
1 (R/W)	PBEDIS	Protection Violation Bus Error Disable. If set, the SMPU_CTL.PBEDIS bit blocks protection violations, but does not cause a bus error.	
		0	Bus Error Generation Enable. Transactions which violate the configured protection are blocked and cause a bus error.
		1	Bus Error Generation Disable. Transactions which violate the configured protection are blocked but do not cause a bus error.
0 (R/W)	RSDIS	Read Speculation Disable. The SMPU_CTL.RSDIS bit controls whether or not the read addresses are checked before being sent to the slave.	
		0	Read Speculation Enable. Read addresses are sent to the slave without checking.
		1	Read Speculation Disable. Read addresses are checked before being sent to the slave.

Exclusive Access IDn Address

The SMPU_EXACADD[n] register provides the address ID of an exclusive access.

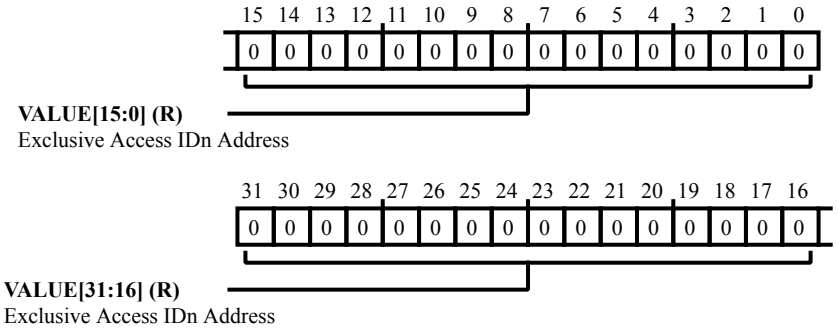

Figure 11-5: SMPU_EXACADD[n] Register Diagram

Table 11-9: SMPU_EXACADD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Exclusive Access IDn Address.

Exclusive Access Status

The SMPU_EXACSTAT[n] register provides the exclusive access ID, read size and read length as well as the indication that the access was valid.

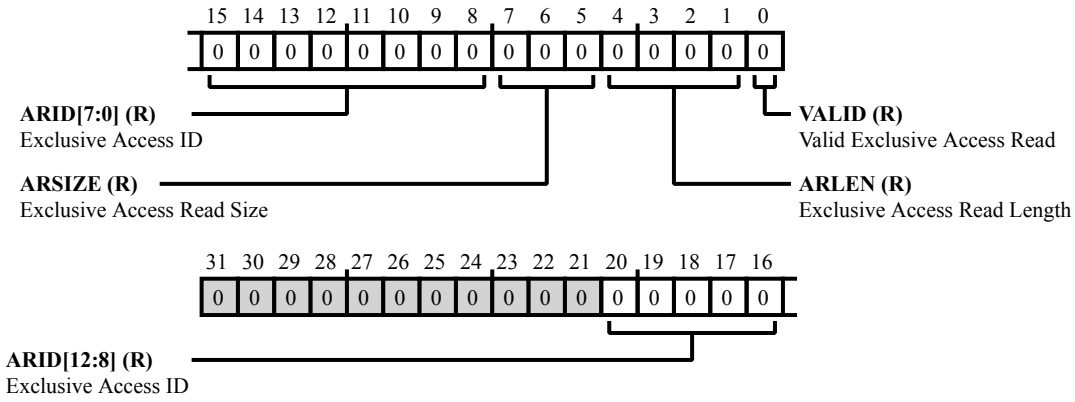

Figure 11-6: SMPU_EXACSTAT[n] Register Diagram

Table 11-10: SMPU_EXACSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ARID	Exclusive Access ID.
7:5 (R/NW)	ARSIZE	Exclusive Access Read Size.
4:1 (R/NW)	ARLEN	Exclusive Access Read Length.
0 (R/NW)	VALID	Valid Exclusive Access Read.

Interrupt Address Register

The SMPU_IADDR register indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The SMPU issues a bus error for this condition.

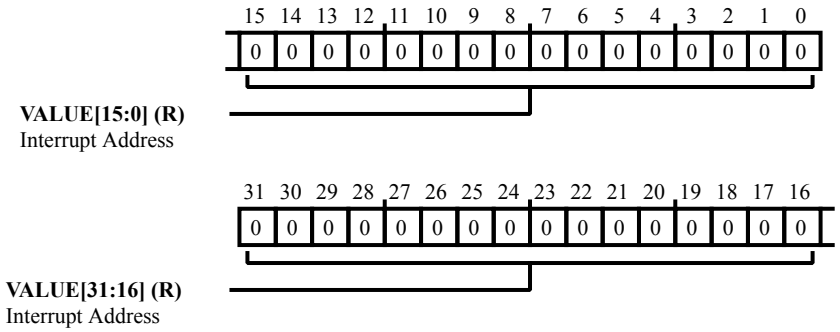

Figure 11-7: SMPU_IADDR Register Diagram

Table 11-11: SMPU_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Interrupt Address. The SMPU_IADDR.VALUE bit field is the address where an attempt to access an unimplemented address or a non-aligned access has occurred.

Interrupt Details Register

The SMPU_IDTLS register provides the ID of the last signaled interrupt, whether the interrupt was caused by a read or write, and whether the transaction that caused the last signaled interrupt was secure.

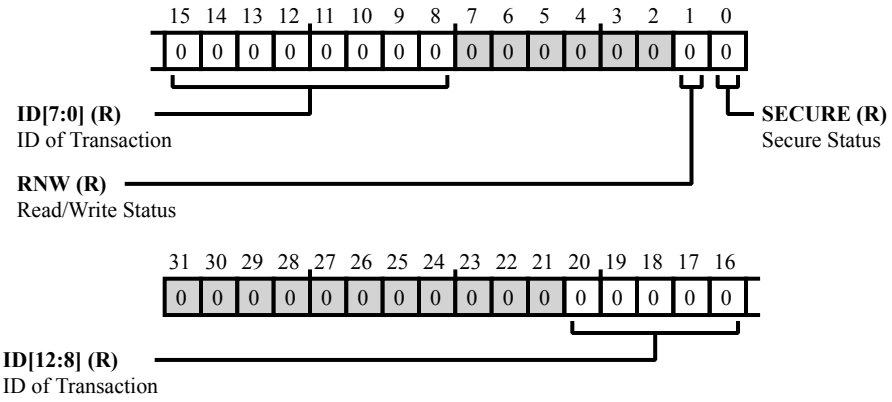

Figure 11-8: SMPU_IDTLS Register Diagram

Table 11-12: SMPU_IDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_IDTLS.ID bit field provides the ID of the transaction that caused the interrupt.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_IDTLS.RNW bit indicates whether the last transaction that caused the interrupt was a read or write.	
		0	Transaction that caused last signaled interrupt was a write
		1	Transaction that caused last signaled interrupt was a read
0 (R/NW)	SECURE	Secure Status. The SMPU_IDTLS.SECURE bit indicates whether the last transaction that caused the interrupt was secure or non-secure.	
		0	Transaction that caused last signaled interrupt was non-secure
		1	Transaction that caused last signaled interrupt was secure

Region n Address Register

The SMPU_RADDR[n] register is used to define the base address for a memory region to be protected.

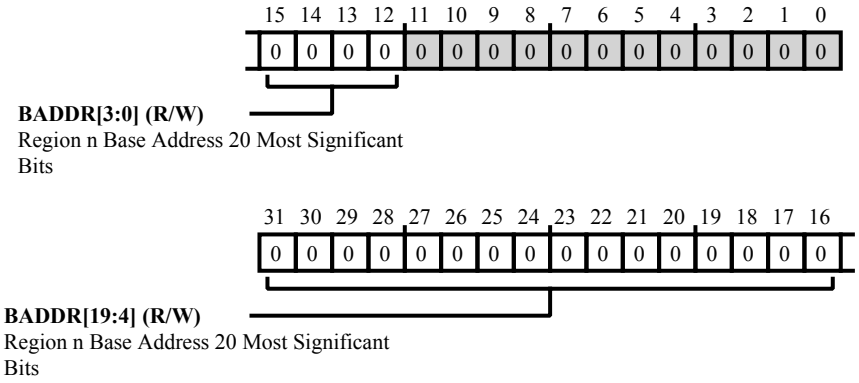

Figure 11-9: SMPU_RADDR[n] Register Diagram

Table 11-13: SMPU_RADDR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/W)	BADDR	Region n Base Address 20 Most Significant Bits. The SMPU_RADDR[n].BADDR bit field defines the base address for a memory region to be protected.

Region n Control Register

The SMPU_RCTL[n] register is used to define the level of protection for a region of memory. The protection of a region is controlled and defined by this register and the SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n], and SMPU_RIDMSKB[n] registers.

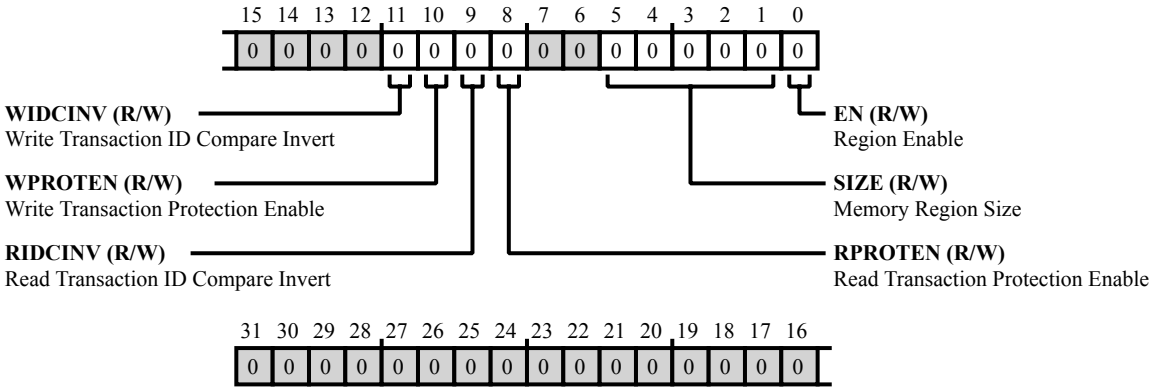

Figure 11-10: SMPU_RCTL[n] Register Diagram

Table 11-14: SMPU_RCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	WIDCINV	Write Transaction ID Compare Invert. The SMPU_RCTL[n].WIDCINV bit inverts the write ID match result.	
		0	Write transaction ID comparison result not inverted
		1	Write transaction ID comparison result inverted
10 (R/W)	WPROTEN	Write Transaction Protection Enable. The SMPU_RCTL[n].WPROTEN bit enables protection against ID-based write transactions for the memory region.	
		0	Write transaction ID-based protection disabled
		1	Write transaction ID-based protection enabled
9 (R/W)	RIDCINV	Read Transaction ID Compare Invert. When the SMPU_RCTL[n].RIDCINV bit is set, the read ID match result is inverted.	
		0	Read transaction ID comparison result not inverted
		1	Read transaction ID comparison result inverted

Table 11-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RPROTEN	Read Transaction Protection Enable. The `SMPU_RCTL[n].RPROTEN` bit enable bit to turn on protection against ID-based read transactions for the memory region.	
		0	Read transaction ID-based protection disabled
		1	Read transaction ID-based protection enabled
5:1 (R/W)	SIZE	Memory Region Size. The `SMPU_RCTL[n].SIZE` bit defines the size of the memory region to be protected.	
		0	4 KB
		1	8 KB
		2	16 KB
		3	32 KB
		4	64 KB
		5	128 KB
		6	256 KB
		7	512 KB

Table 11-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Region Enable. The `SMPU_RCTL[n].EN` bit enables the protection of a region.	
		0	Disabled
		1	Enabled

SMPU Revision ID Register

The SMPU_REVID register provides the major and minor revision numbers of this module.

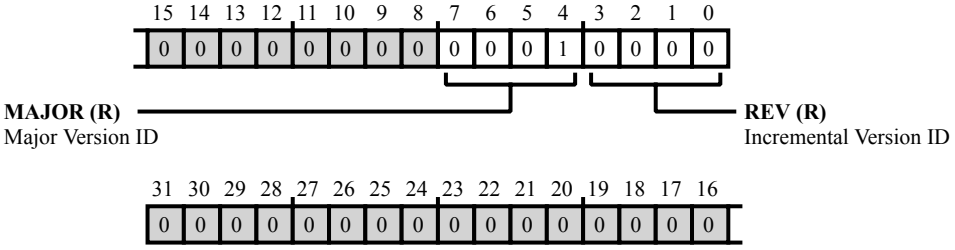

Figure 11-11: SMPU_REVID Register Diagram

Table 11-15: SMPU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Region n ID A Register

The SMPU_RIDA[n] register is used for ID comparison 'A'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more detail, refer to the ID Comparison section.

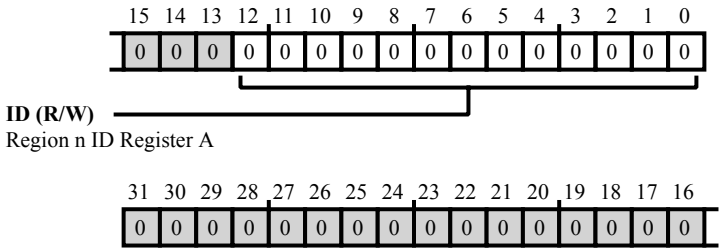

Figure 11-12: SMPU_RIDA[n] Register Diagram

Table 11-16: SMPU_RIDA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register A. The SMPU_RIDA[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID B Register

The SMPU_RIDB[n] register is used for ID comparison 'B'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more details, refer to the ID Comparison section.

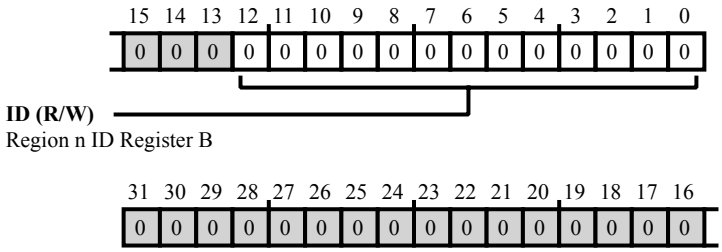

Figure 11-13: SMPU_RIDB[n] Register Diagram

Table 11-17: SMPU_RIDB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register B. The SMPU_RIDB[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID Mask A Register

The SMPU_RIDMSKA[n] register is used for ID comparison 'A'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

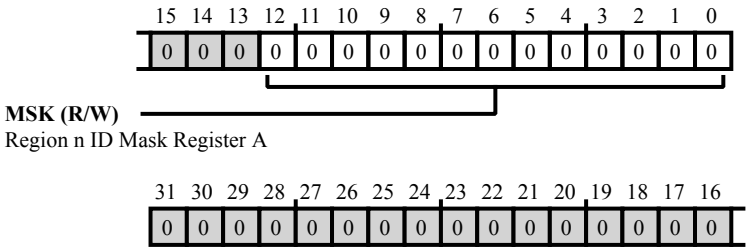

Figure 11-14: SMPU_RIDMSKA[n] Register Diagram

Table 11-18: SMPU_RIDMSKA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register A. The SMPU_RIDMSKA[n].MSK bit field, combined with the incoming transaction, provides the means to bypass the configured memory protection for a region.

Region n ID Mask B Register

The SMPU_RIDMSKB[n] register is used for ID comparison 'B'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

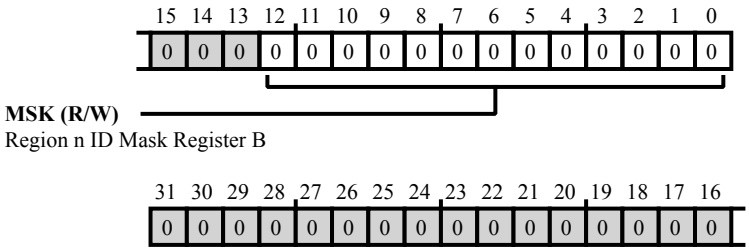

Figure 11-15: SMPU_RIDMSKB[n] Register Diagram

Table 11-19: SMPU_RIDMSKB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register B. The SMPU_RIDMSKB[n].MSK bit field, combined with the incoming transaction provides the means to bypass the configured memory protection for a region.

SMPU Control Secure Accesses Register

The SMPU_SECURECTL register provides the bits required to set up the security settings for the processor. These settings includes error generation and read/write security.

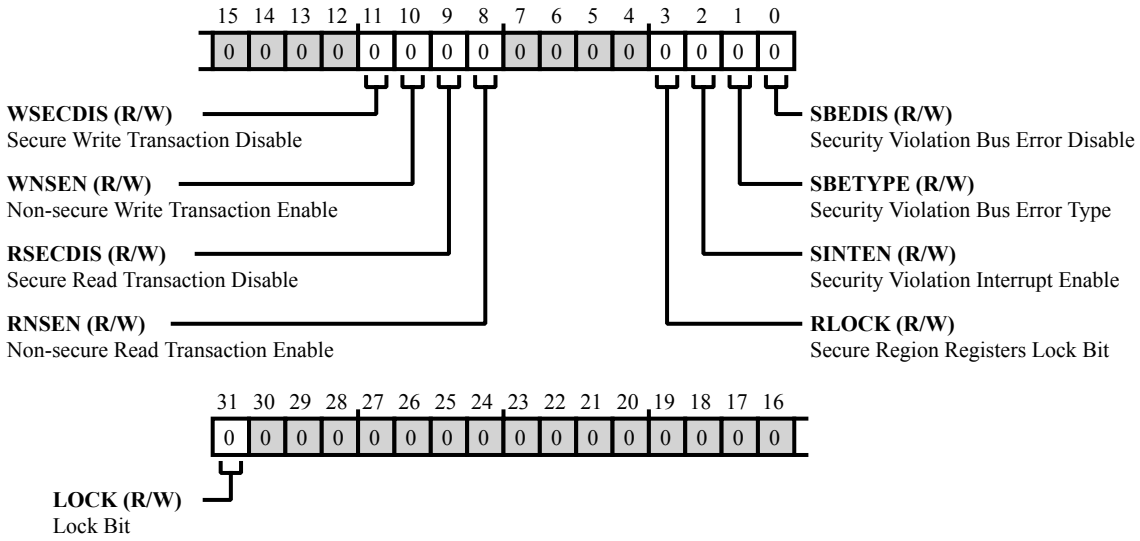

Figure 11-16: SMPU_SECURECTL Register Diagram

Table 11-20: SMPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_SECURECTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_SECURECTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	SMPU_SECURECTL is not write-protected
		1	SMPU_SECURECTL is write-protected
11 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURECTL.WSECDIS bit disables secure write transactions.	
		0	Enable secure write transactions
		1	Disable secure write transactions
10 (R/W)	WNSEN	Non-secure Write Transaction Enable. The SMPU_SECURECTL.WNSEN bit enables non-secure write transactions.	
		0	Disable non-secure writes
		1	Enable non-secure writes

Table 11-20: SMPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURECTL.RSECDIS bit disables secure read transactions.	
		0	Enable secure read transactions
		1	Disable secure read transactions
8 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURECTL.RNSEN bit enables non-secure read transactions.	
		0	Disable non-secure read transactions
		1	Enable non-secure read transactions
3 (R/W)	RLOCK	Secure Region Registers Lock Bit. When the SMPU_SECURECTL.RLOCK bit is set, the secure region control registers, SMPU_SECURERCTL[n], are write-protected when the global lock signal is active from the SPU. When the global lock signal is deasserted, write access is allowed again.	
		0	Disable write-protection on secure region registers
		1	Enable write-protection on secure region registers
2 (R/W)	SINTEN	Security Violation Interrupt Enable. The SMPU_SECURECTL.SINTEN bit enables interrupt generation when a security violation occurs.	
		0	Disable security settings violation interrupt
		1	Enable security settings violation interrupt
1 (R/W)	SBETYPE	Security Violation Bus Error Type. The SMPU_SECURECTL.SBETYPE bit controls whether a decode error or a slave error is returned when a security violation occurs.	
		0	Return a decode error error which violates the security settings
		1	Return a slave error which violates the security settings
0 (R/W)	SBEDIS	Security Violation Bus Error Disable. The SMPU_SECURECTL.SBEDIS bit controls whether or not a bus error is caused when a security violation occurs.	
		0	Enable bus error
		1	Disable bus error

Region n Control Secure Accesses Register

The SMPU_SECURERCTL[n] register contains bits that configure read/write security for a specific region.

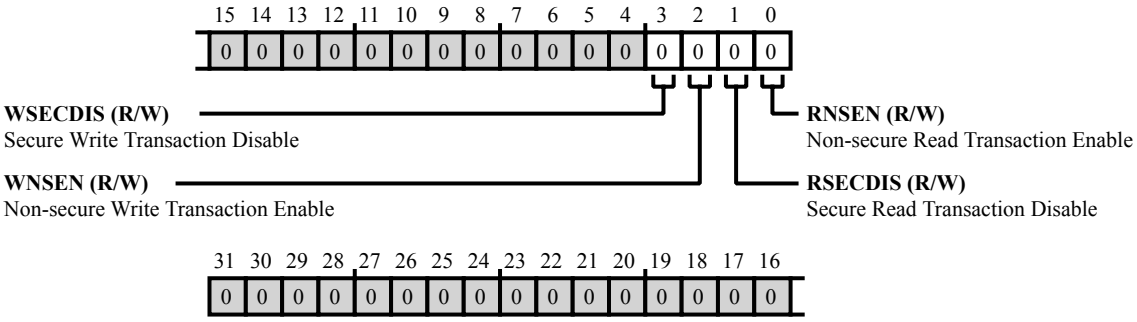

Figure 11-17: SMPU_SECURERCTL[n] Register Diagram

Table 11-21: SMPU_SECURERCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURERCTL[n].WSECDIS bit disables secure write transactions for the memory region.	
		0	Enable secure write transactions to this region
		1	Disable secure write transactions to this region
2 (R/W)	WNSEN	Non-secure Write Transaction Enable. This SMPU_SECURERCTL[n].WNSEN bit enables non-secure write transactions for the memory region.	
		0	Disable non-secure write transactions to this region
		1	Enable non-secure write transactions to this region
1 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURERCTL[n].RSECDIS bit disables secure read transactions for the memory region.	
		0	Enable secure read transactions to this region
		1	Disable secure read transactions to this region
0 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURERCTL[n].RNSEN bit enables non-secure read transactions for the memory region.	
		0	Disable non-secure read transactions to this region
		1	Enable non-secure read transactions to this region

SMPU Status Register

The SMPU_STAT register provides the state of the SMPU and indicates various errors. All bits in this register are write 1 to clear.

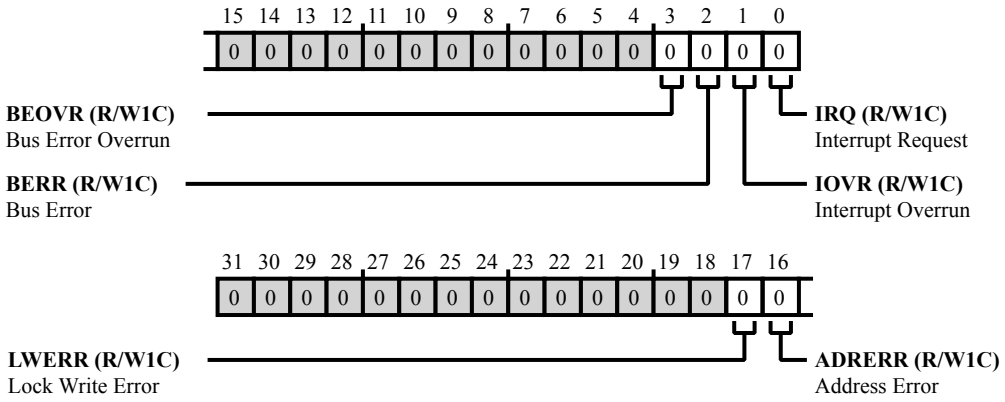

Figure 11-18: SMPU_STAT Register Diagram

Table 11-22: SMPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The SMPU_STAT.LWERR bit is set when SMPU_CTL.LOCK bit =1, the global lock signal is asserted from the SPU and a read or write attempt was made to the SMPU_CTL MMR.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The SMPU_STAT.ADRERR bit is set when the SMPU MMR is accessed as an un-aligned address, or when a read-only MMR is written to.	
		0	No Address Error
		1	Address Error
3 (R/W1C)	BEOVR	Bus Error Overrun. The SMPU_STAT.BEOVR bit indicates that another bus error had occurred. Any new information about the most recent violation which caused the bus error is not captured.	
		0	No Bus Error overrun
		1	Bus Error overrun has occurred

Table 11-22: SMPU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	BERR	Bus Error. This SMPU_STAT.BERR bit indicates if a bus error was generated.	
		0	No Bus Error since this bit has been cleared
		1	Bus Error has been generated
1 (R/W1C)	IOVR	Interrupt Overrun. The SMPU_STAT.IOVR bit indicates if another violation occurred while the previous violation interrupt was not finished being serviced. Information about the most recent violation is then not captured.	
		0	No Interrupt overrun
		1	Interrupt overrun has occurred
0 (R/W1C)	IRQ	Interrupt Request. The SMPU_STAT.IRQ bit provides an indication that an interrupt has been generated.	
		0	No Interrupt since this bit has been cleared
		1	Interrupt has been generated

12 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts. The general-purpose ports provide the following three functions:

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupt requests

NOTE: In this chapter, the naming convention for registers and bits omits the alphabetic group enumeration to refer to any and all of the ports. For example, `PORT_FER` represents registers `PORTA_FER`, `PORTB_FER`, and so on. Likewise `PORT_FER.PX1` represents bits PA1, PB1, and so on.

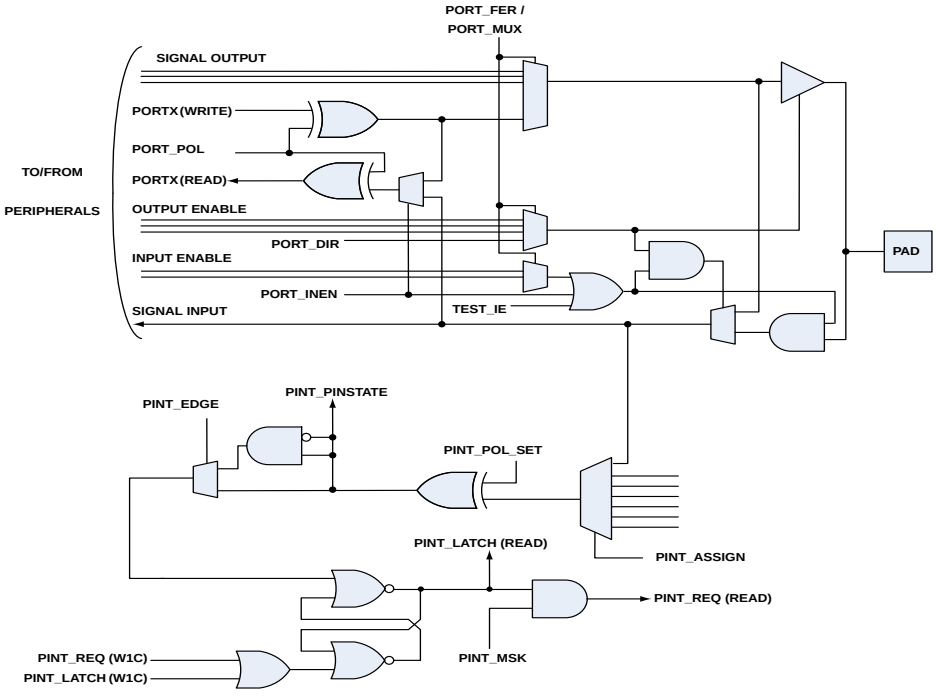

Figure 12-1: Simplified GPIO and Pin Interrupt Signal Flow

PORT Features

The PORTs include the following features:

- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled on a pin-by-pin basis
- No external glue hardware required for unused pins
- All port pins provide interrupt request functionality
- Byte-wide pin-to-interrupt request assignment

PORT Functional Description

The number of ports and each's composition are defined in the processor datasheet. Each port has a dedicated set of MMR registers that control pin functions and operates in general-purpose I/O (GPIO) mode by default, as controlled by the port-specific PORT_FER register. Each bit in this register, as well as the other PORT MMRs, represents a specific GPIO pin on the specified port.

Input Mode, Output Mode, and Open-Drain Mode of GPIO Operation

At reset, every GPIO pin defaults to input mode with the input drivers disabled. To enable any GPIO input driver, set the bits corresponding to the individual pins in the appropriate input enable register (PORT_INEN).

The GPIO output drivers are enabled by setting the corresponding bits in the direction registers (PORT_DIR).

The PORT can use every GPIO in open-drain mode by clearing the respective bit in the PORT_DATA register or setting the respective bit in the PORT_DATA_CLR register. Then, set the corresponding bit in the PORT_INEN register. Read from the PORT_DATA register to obtain the status from the pin.

Port Multiplexing Controlled on Pin-by-Pin Basis

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

All Port Pins Provide Interrupt Functionality

Pin interrupts are completely decoupled from GPIO functionality. Pins are connected to the system event controller (SEC) via the PINTx modules, each of which is configurable in terms of which port pins are sensed for interrupt generation.

ADSP-2159x_SC591_SC592_SC594 PORT Register List

The PORT module (PORT) regulates the use of the multiplexable processor pins. Every port pin can operate in general-purpose I/O (GPIO) mode or as an alternate function. This GPIO operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

Table 12-1: ADSP-2159x_SC591_SC592_SC594 PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register
PORT_DATA_CLR	Port x GPIO Data Clear Register
PORT_DATA_SET	Port x GPIO Data Set Register
PORT_DATA_TGL	Port x GPIO Output Toggle Register

ADSP-2159x_SC591_SC592_SC594 PINT Register List

The Pin Interrupt module (PINT) controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control. For more information, see the PINT register descriptions.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

Table 12-4: ADSP-2159x_SC591_SC592_SC594 PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

ADSP-2159x_SC591_SC592_SC594 PINT Interrupt List

Table 12-5: ADSP-2159x_SC591_SC592_SC594 PINT Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel

PORT Architectural Concepts

These sections describe in more detail how the PORT module connects externally to pins and internally to the MMR bus. Ports are named alphabetically beginning with A.

- Internal Interfaces
- External Interfaces
- GPIO Pin Function
- Port Multiplexing Control

Internal Interfaces

All of the pin multiplexing, GPIO, and pin interrupt control block MMRs can be accessed through the MMR bus. There is no DMA support. Each of the pin interrupt (PINTx) modules has its own dedicated interrupt request output signal that connects directly to the system event controller (SEC).

External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the silicon pads connecting to the physical pins/balls or the package, as controlled by the PORT unit.

GPIO Pin Function

By default, the PORT sets every GPIO pin to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and external termination resistors on unused pins.

Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the bits corresponding to the PORT pins in the appropriate input enable register (`PORT_INEN`). When enabled, a read from the `PORT_DATA` register returns the logical state of the input pins. However, the input signal does not overwrite the state of the internal flip-flop used for providing output to the same pin. Only software can alter the state. If the input driver is enabled, a write to the `PORT_DATA` register can alter the state of the flip-flop, but the change cannot be read back.

Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the bits corresponding to the PORT pins in the appropriate direction register. The PORT implements direction registers as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs called `PORT_DIR_SET` and `PORT_DIR_CLR`, respectively. As such, software can alter the direction of the signal flow on individual GPIO pins without impacting other GPIOs on the same port.

Both the `PORT_DIR_SET` and `PORT_DIR_CLR` registers return the same value when read, and a logical 1 indicates an enabled output. The `PORT_DATA` registers control the state of output pins. A logical 0 drives the output low while a logical 1 drives the output high.

While writes to the `PORT_DATA` register can alter all of the GPIOs on a specific port at once, there are also a pair of W1S and W1C MMRs called `PORT_DATA_SET` and `PORT_DATA_CLR`, respectively. These registers enable

the manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the PORT_DATA registers. Because the state of the GPIO output can be controlled before the output driver is enabled, set or clear the internal flip-flop first by programming this register to avoid volatile levels on the output pin.

Trigger Toggle Mode

Any GPIO pin that has been configured for output mode can be toggled using a trigger input from the Trigger Routing Unit (TRU). To enable this functionality for a particular GPIO, set the appropriate bit in the PORT_TRIG_TGL register. Any subsequent trigger for the designated port causes all GPIO outputs set in the PORT_TRIG_TGL register to toggle.

To avoid unpredictable behavior, do not set, clear, or toggle the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, or PORT_DATA_TGL registers when the GPIO output has the corresponding PORT_TRIG_TGL bit set. To change the state of the GPIO output using one of these registers, first clear the corresponding bit in the PORT_TRIG_TGL register.

Open-Drain Mode

Every GPIO can also be used in open-drain mode. First, either clear the respective bit in the PORT_DATA register or set the respective bit in the PORT_DATA_CLR register. Then, set the appropriate bit in the PORT_INEN register. Read from the PORT_DATA register to return the status from the pin rather than the state of the internal flip-flop.

By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated, as required. The polarity of the driven signal can be inverted when the internal flip-flop is set. When using a GPIO port in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pins.

Port Multiplexing Control

To configure pins properly, consult the processor datasheet to determine which bits in the PORT_FER and PORT_MUX register map to the pin of interest, and then set these registers appropriately for the desired function.

After reset, all port pins default to GPIO input mode with their output and input drivers disabled. As a result, all unused port pins can be left unconnected. Disabled pins appear as high-impedance to external circuits.

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

The function enable register specifies whether the pin is used as a GPIO pin or allocated for use by a specific peripheral, but it does not specify what the peripheral function is. Each bit in the 16-bit PORT_FER register corresponds to an individual port pin. For example, if bit 1 (PA1) of the PORTA_FER register is cleared, the PA_01 pin is configured as a GPIO. When set, one of the available peripheral functions becomes active on the PA_01 pin instead.

Pairs of bits in the PORT_MUX register control the multiplexing between the peripheral functions available to an individual pin, as some PORT pins provide up to four possible peripheral functions.

Refer to the Signal Muxing table in the datasheet for the specific PORT_MUX settings.

PORT Event Control

The following sections describe event generation in the PORT module.

PORT Interrupt Signals

The pin interrupts are decoupled from GPIO functionality, providing the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.
- Interrupt requests work on input and output pins regardless of whether the pin is functioning as a GPIO or a peripheral.

The processor has a number of interrupt channels dedicated to pin interrupts, managed by a set of pin interrupt (PINTx) blocks. Each PINTx block can sense up to 32 GPIO pins, as described in the following list and figure.

- PINT0 can sense pin activity on PORTA and PORTB
- PINT1 can sense pin activity on PORTB and PORTC
- PINT2 can sense pin activity on PORTC and PORTD
- PINT3 can sense pin activity on PORTD and PORTE
- PINT4 can sense pin activity on PORTE and PORTF
- PINT5 can sense pin activity on PORTF and PORTG
- PINT6 can sense pin activity on PORTG and PORTH
- PINT7 can sense pin activity on PORTH and PORTI

The processor supports both 32-bit and 16-bit peripheral bus accesses to PINTx registers.

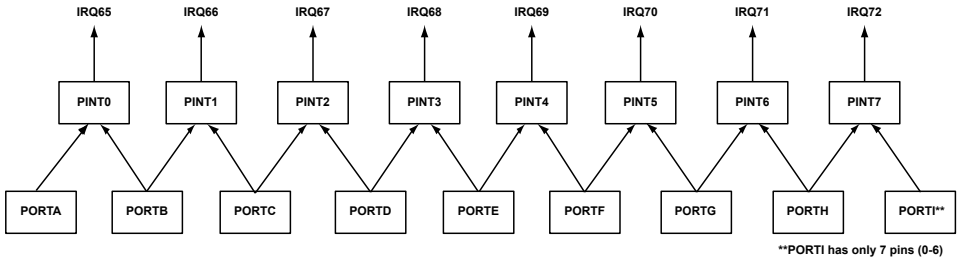

Figure 12-2: GPIO to PINTx Assignment

Pins connect to the PINTx module and then to the system event controller (SEC), as shown in the ***PINTx Block Diagram***.

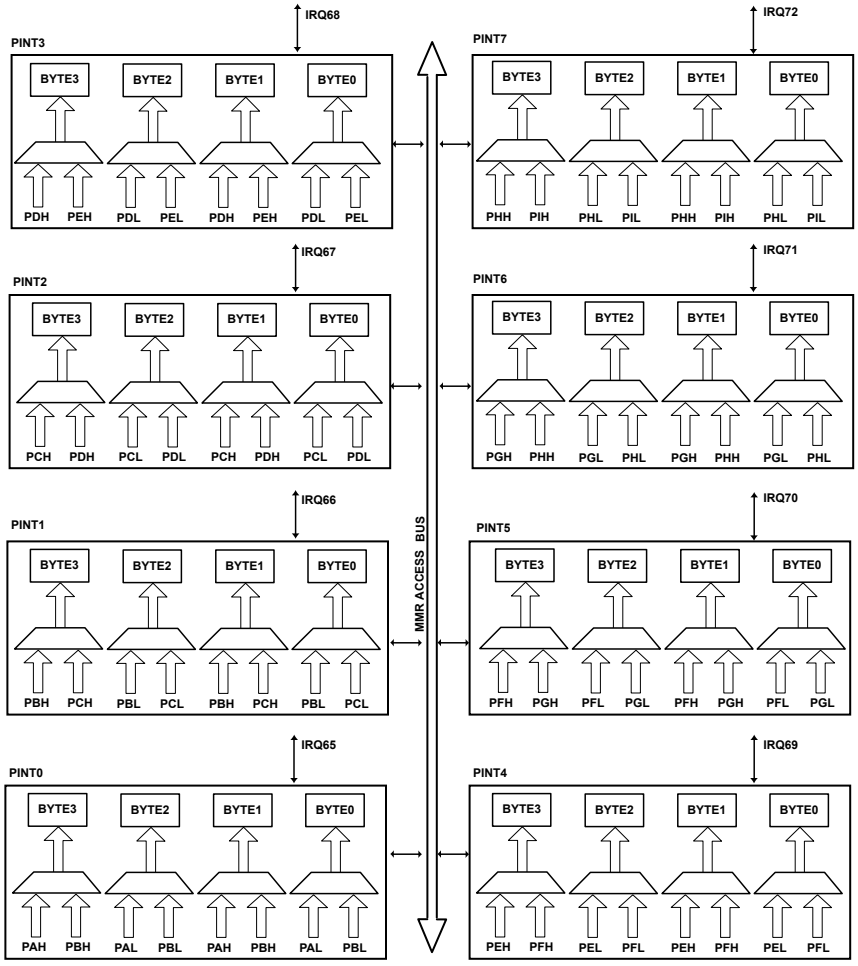

Figure 12-3: PINTx Block Diagram

As shown in the ***PINTx Block Diagram***, each port is subdivided into two 8-pin half ports, upper (`PxH`) and lower (`PxL`). The `PINT_ASSIGN` registers control the 8-bit multiplexers associated with these half ports, where the lower half units (eight pins) can be forwarded to either byte 0 or byte 2 of the PINTx blocks, and the upper half units (eight pins) can be forwarded to either byte 1 or byte 3 of the PINTx blocks.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins appears in the `PINT_PINSTATE` register, regardless of whether the pin is enabled for GPIO or peripheral functions (input or output). When neither the input nor output drivers of the pin are enabled, the pin state is read as zero. The `PINT_PINSTATE` register reports the inverted state of the pin when the `PINT_INV_SET` register activates the signal inverter. The inverter can be enabled on an individual bit-by-bit basis. Each bit in the `PINT_INV_SET`/`PINT_INV_CLR` register pair represents a pin signal.

By default, PORT interrupt request generation is level-sensitive, and an interrupt request occurs when the enabled pin is sensed as active high. Use the `PINT_EDGE_SET` register to change the interrupt request genearion scheme to instead be edge-sensitive (rising edge generates the interrupt request). Use the `PINT_INV_SET` register to invert the polarity such that the PINTx block generates the interrupt request on active-low signals or falling edges.

The PINTx modules also assist when both signal edges must generate unique interrupt requests. If two different interrupt requests are required, the PINT_ASSIGN registers can route a single input signal to two different PINTx blocks, where one block inverts the signal in the PINT_INV_SET register and the other one does not. In this fashion, a unique software routine is associated with the hardware PINTx block that is generating the unique interrupt request for each signal edge. When both signal edges can be serviced by the same interrupt request, each half port can be routed to two separate bytes within a single PINTx block using the PINT_ASSIGN register, and then one of the half ports needs to have the inversion enabled in the PINT_INV_SET register. The servicing software routine can then detect from the PINT_LATCH register whether a falling, rising, or both edges have occurred.

Regardless of whether level-sensitive or edge-sensitive mode is used, the hardware always latches an interrupt request. Latched signals can be read from the PINT_LATCH registers. Only a software or hardware reset clears the latches. To clear the latch, a W1C operation must be performed to the PINT_REQ or PINT_LATCH register. When in level-sensitive mode, the interrupt request remains asserted if the pin state does not change by the time the interrupt service routine exits.

Because every PINTx block groups up to 32 pin signals, the PINT_MSK_SET/ PINT_MSK_CLR register pair can control which of the signals can request an interrupt at the system level. Software can interrogate the PINT_REQ register for signaling pins. The PINT_REQ bits represent a logical AND between the mask and the latch. When any of these bits is set, the block output interrupt request is asserted.

PORT Programming Model

The ***GPIO Programming Model Flow (Part 1)***, ***GPIO Programming Model Flow (Part 2)***, and ***GPIO Programming Model Flow (Part 3)*** figures show the programming model for the general-purpose ports. This programming includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

NOTE: These process flow diagrams connect where call-out letters appear. For example, call-out A in the ***GPIO Programming Model Flow (Part 1)*** diagram connects to call-out A in the ***GPIO Programming Model Flow (Part 2)*** diagram.

The following flowcharts describe the processes for setting up pins for various functions. Begin the process from the start label in the ***GPIO Programming Model Flow (Part 1)*** figure. The first decision (GPIO or peripheral) determines how to program the PORT_FER register. Set the bit(s) corresponding to the pin(s) to 1 to enable peripheral functionality or to 0 to enable GPIO mode. For more information on setting up for peripheral functions, refer to Port Multiplexing Control.

If the pin is to be a GPIO pin, a subsequent series of decisions must be made that will impact how the PORT_DATA, PORT_POL, PORT_DIR, and PORT_INEN configuration registers must be programmed. Depending on the type of GPIO pin desired, some configurations do not apply and can have different meanings. The following paragraphs briefly describe the function of the different settings for each of the pin functions in the input, output, and open-drain GPIO modes. It is a best practice to use the SET or CLR versions of the PORT registers, where applicable, to effect changes on a pin-by-pin basis rather than on the full port.

For output mode, first clear the PORT_DATA register to set all the pins low. Then write the PORT_DIR register to define the direction of each pin (set the bits associated with the desired output pins to 1). In output mode, the other registers are not significant. The ***GPIO Programming Model Flow (Part 1)*** chart shows this flow starting at label 2.

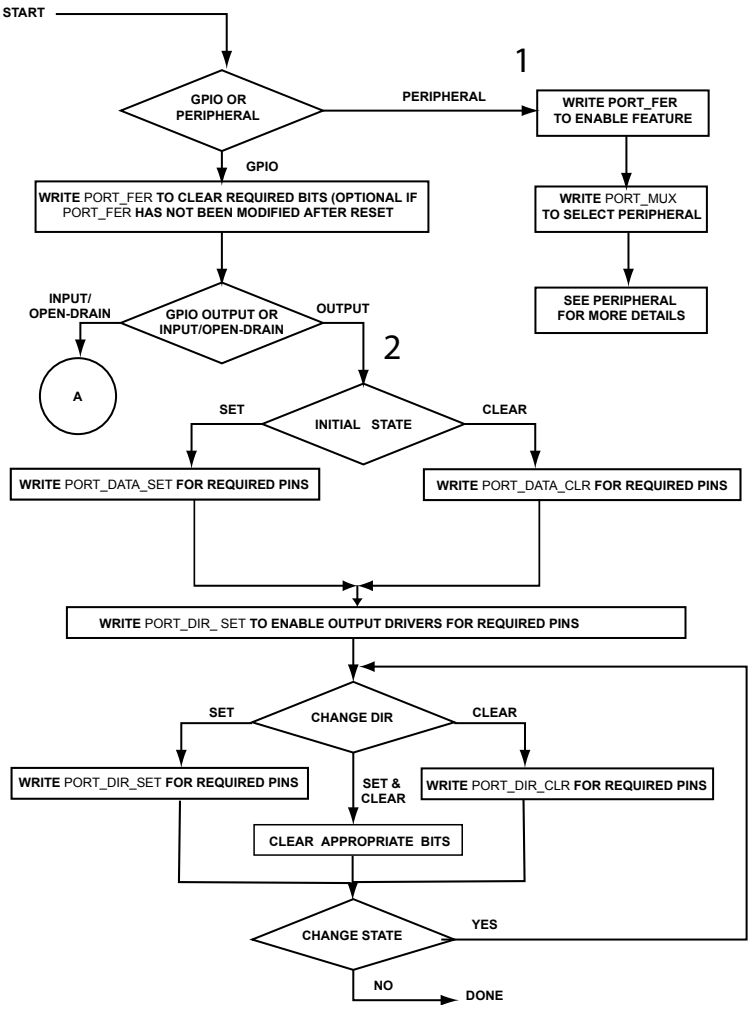

Figure 12-4: GPIO Programming Model Flow (Part 1)

For input mode, first decide the polarity for each pin using the PORT_POL register. Program the PORT_DIR register to define the appropriate pins as inputs (write a 0 to the bit location associated with the pin). If interrupt requests are desired, configure the PINT module as shown in the ***GPIO Programming Model Flow (Part 3)*** figure starting at label B. Finally, write the PORT_INEN register to enable the associated input drivers. The ***GPIO Programming Model Flow (Part 2)*** chart shows this entire flow starting at label 3.

For open-drain mode, set all pins low by clearing the PORT_DATA register. Then, use the PORT_INEN register to enable the appropriate input drivers. Set the PORT_DIR register in this mode to indicate whether the pin is in an active state or not (active being 0). The ***GPIO Programming Model Flow (Part 2)*** chart shows this flow starting at label 4.

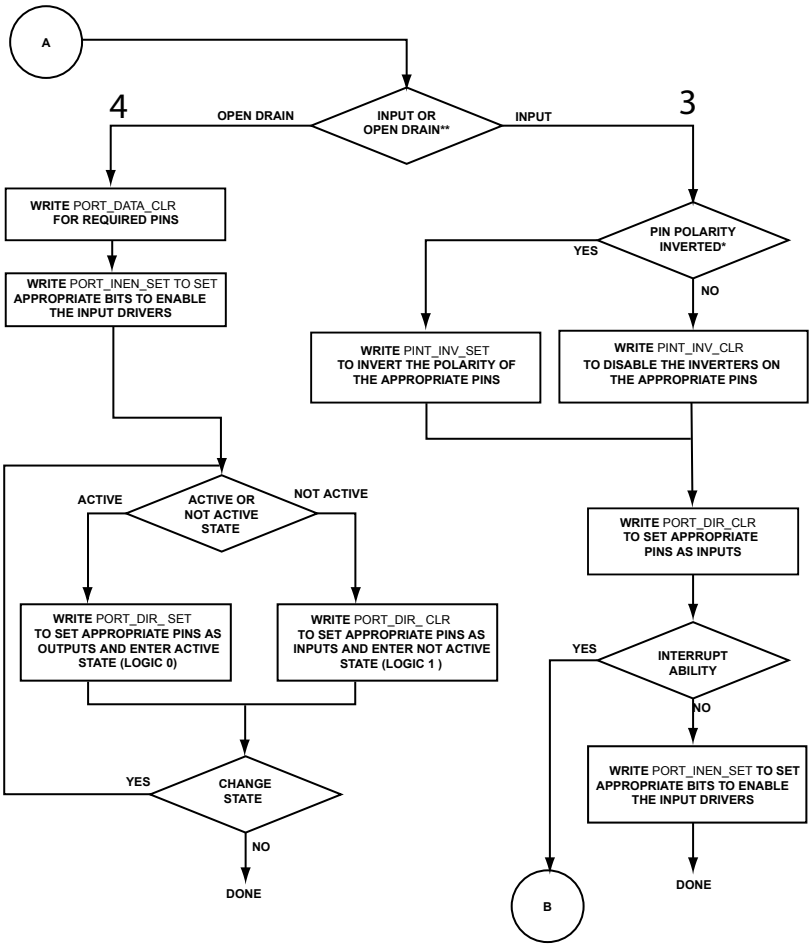

Figure 12-5: GPIO Programming Model Flow (Part 2)

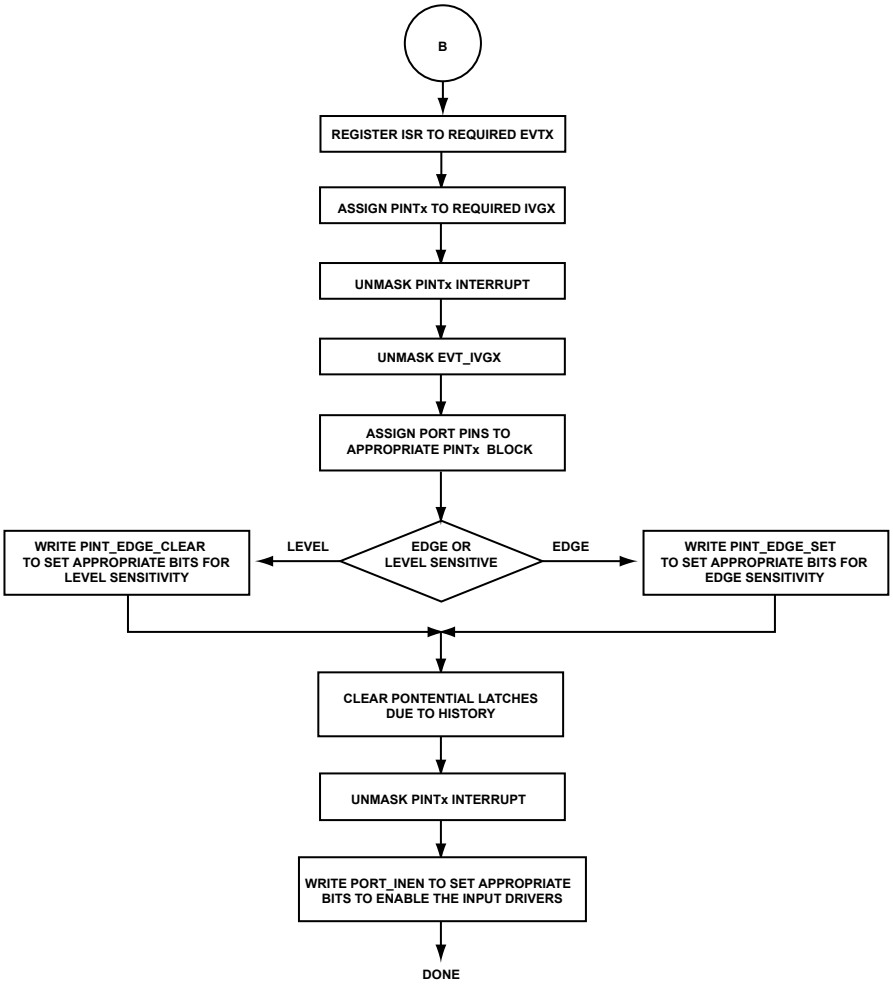

Figure 12-6: GPIO Programming Model Flow (Part 3)

Programmable Pull-up Resistors for PORT and DAI

There are programmable weak pull-up resistors for DAI and PORT pins. These resistors can be enabled or disabled by configuring the `PADS_DAI[n]_PUE`, `PADS_PORT[n]_PUE`, `PADS_DAI[n]_PDE`, and `PADS_PORT[n]_PDE` registers.

For DAI pins, if both the `PADS_DAI[n]_PDE` and `PADS_DAI[n]_PUE` registers are set (=1) for the same pin, then the `PADS_DAI[n]_PDE` register takes priority over `PADS_DAI[n]_PUE` register.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

Refer to the ***DAI Pull-up Resistor States*** table. To enable the pull-up on a DAI pin, the `PADS_DAI[n]_PDE.PUD` bit must be cleared (=0) ***AND*** the `PADS_DAI[n]_PUE.PUE` bit must be set (=1). To disable the pull-up on a DAI pin, the `PADS_DAI[n]_PDE.PUD` bit must be set (=1) and `PADS_DAI[n]_PUE.PUE` bit can be any value.

Table 12-9: DAI Pull-up Resistor States

PADS_DAI[n]_PUE.PUE	PADS_DAI[n]_PDE.PUD	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

Similarly, for PORT pins, if both PADS_PORT[n]_PDE.PUD and PADS_PORT[n]_PUE registers are set (=1) for the same pin, then the PADS_PORT[n]_PDE.PUD register takes priority over PADS_PORT[n]_PUE register.

Refer to the ***PORT Pull-up Resistor States*** table. To enable the pull-up on a PORT pin, the PADS_PORT[n]_PDE.PUD bit must be cleared (=0) ***AND*** the PADS_PORT[n]_PUE.PUE bit must be set (=1). To disable the pull-up on a PORT pin, PADS_DAI[n]_PDE.PUD bit must be set (=1) and PADS_PORT[n]_PUE.PUE bit can be any value.

Table 12-10: PORT Pull-up Resistor States

PADS_PORT[n]_PUE.PUE	PADS_PORT[n]_PDE.PUD	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

NOTE: Refer to the ***Designer Quick Reference*** section of the datasheet for handling unused PORT and DAI pins.

NOTE: The internal pull-up on GPIO pins are very weak. These pins hold a defined logic level when pins are left floating. The internal pull-up resistance varies over a wide range. If an application needs a specified pull-up on the pin, use an external resistor.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

ADSP-2159x_SC591_SC592_SC594 PORT Register Descriptions

The General-Purpose Input/Output Port (PORT) contains the following registers.

Table 12-11: ADSP-2159x_SC591_SC592_SC594 PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register
PORT_DATA_CLR	Port x GPIO Data Clear Register

Table 12-11: ADSP-2159x_SC591_SC592_SC594 PORT Register List (Continued)

Name	Description
PORT_DATA_SET	Port x GPIO Data Set Register
PORT_DATA_TGL	Port x GPIO Output Toggle Register
PORT_DIR	Port x GPIO Direction Register
PORT_DIR_CLR	Port x GPIO Direction Clear Register
PORT_DIR_SET	Port x GPIO Direction Set Register
PORT_FER	Port x Function Enable Register
PORT_FER_CLR	Port x Function Enable Clear Register
PORT_FER_SET	Port x Function Enable Set Register
PORT_INEN	Port x GPIO Input Enable Register
PORT_INEN_CLR	Port x GPIO Input Enable Clear Register
PORT_INEN_SET	Port x GPIO Input Enable Set Register
PORT_LOCK	Port x GPIO Lock Register
PORT_MUX	Port x Multiplexer Control Register
PORT_POL	Port x GPIO Polarity Invert Register
PORT_POL_CLR	Port x GPIO Polarity Invert Clear Register
PORT_POL_SET	Port x GPIO Polarity Invert Set Register
PORT_TRIG_TGL	Port x GPIO Trigger Toggle Register

Port x GPIO Data Register

The operation of the PORT_DATA register depends on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the PORT_DATA register corresponds to a signal high on a GPIO pin. A cleared bit in the PORT_DATA register corresponds to a signal low on a GPIO pin.

The PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the PORT_DIR_SET and PORT_DIR_CLR registers.

Writes to the PORT_DATA register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the PORT_DATA_SET and PORT_DATA_CLR registers.

When the GPIO pins are in input mode (input driver is enabled with the PORT_INEN register), reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the value previously written to the registers.

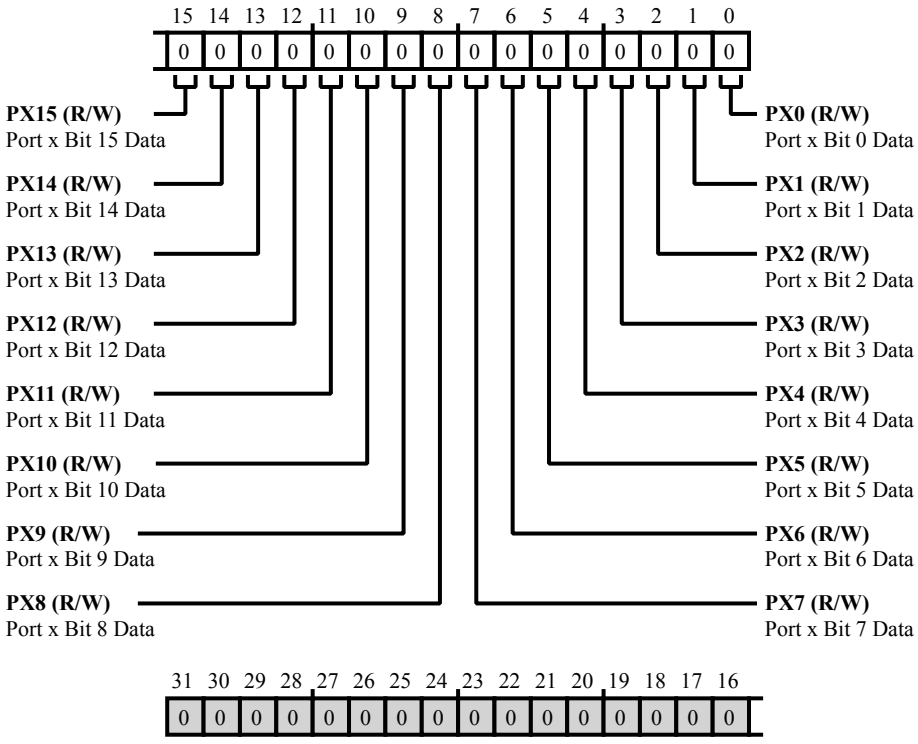

Figure 12-7: PORT_DATA Register Diagram

Table 12-12: PORT_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Data. The PORT_DATA.PX15 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
14 (R/W)	PX14	Port x Bit 14 Data. The PORT_DATA.PX14 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
13 (R/W)	PX13	Port x Bit 13 Data. The PORT_DATA.PX13 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
12 (R/W)	PX12	Port x Bit 12 Data. The PORT_DATA.PX12 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
11 (R/W)	PX11	Port x Bit 11 Data. The PORT_DATA.PX11 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
10 (R/W)	PX10	Port x Bit 10 Data. The PORT_DATA.PX10 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
9 (R/W)	PX9	Port x Bit 9 Data. The PORT_DATA.PX9 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 12-12: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PX8	Port x Bit 8 Data. The PORT_DATA.PX8 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
7 (R/W)	PX7	Port x Bit 7 Data. The PORT_DATA.PX7 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
6 (R/W)	PX6	Port x Bit 6 Data. The PORT_DATA.PX6 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
5 (R/W)	PX5	Port x Bit 5 Data. The PORT_DATA.PX5 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
4 (R/W)	PX4	Port x Bit 4 Data. The PORT_DATA.PX4 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
3 (R/W)	PX3	Port x Bit 3 Data. The PORT_DATA.PX3 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
2 (R/W)	PX2	Port x Bit 2 Data. The PORT_DATA.PX2 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 12-12: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PX1	Port x Bit 1 Data. The `PORT_DATA.PX1` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
0 (R/W)	PX0	Port x Bit 0 Data. The `PORT_DATA.PX0` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Port x GPIO Data Clear Register

The PORT_DATA_CLR register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

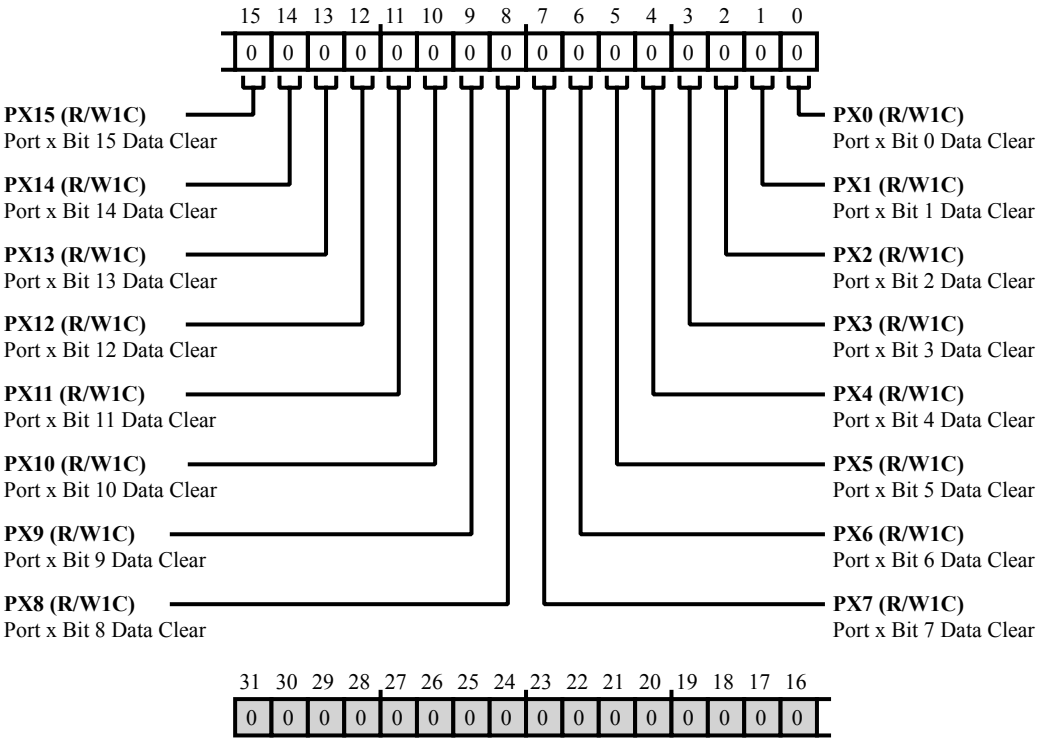

Figure 12-8: PORT_DATA_CLR Register Diagram

Table 12-13: PORT_DATA_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Data Clear. The PORT_DATA_CLR.PX15 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
14 (R/W1C)	PX14	Port x Bit 14 Data Clear. The PORT_DATA_CLR.PX14 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1C)	PX13	Port x Bit 13 Data Clear. The PORT_DATA_CLR.PX13 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
12 (R/W1C)	PX12	Port x Bit 12 Data Clear. The PORT_DATA_CLR.PX12 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
11 (R/W1C)	PX11	Port x Bit 11 Data Clear. The PORT_DATA_CLR.PX11 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
10 (R/W1C)	PX10	Port x Bit 10 Data Clear. The PORT_DATA_CLR.PX10 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
9 (R/W1C)	PX9	Port x Bit 9 Data Clear. The PORT_DATA_CLR.PX9 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
8 (R/W1C)	PX8	Port x Bit 8 Data Clear. The PORT_DATA_CLR.PX8 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	PX7	Port x Bit 7 Data Clear. The PORT_DATA_CLR.PX7 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
6 (R/W1C)	PX6	Port x Bit 6 Data Clear. The PORT_DATA_CLR.PX6 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
5 (R/W1C)	PX5	Port x Bit 5 Data Clear. The PORT_DATA_CLR.PX5 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
4 (R/W1C)	PX4	Port x Bit 4 Data Clear. The PORT_DATA_CLR.PX4 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
3 (R/W1C)	PX3	Port x Bit 3 Data Clear. The PORT_DATA_CLR.PX3 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
2 (R/W1C)	PX2	Port x Bit 2 Data Clear. The PORT_DATA_CLR.PX2 bit clears the pin without impacting other pins of the port.	
		0	No Effect Write 0 has no effect in output mode.
		1	Clear Bit Write 1 for signal low in output mode.

Table 12-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	PX1	Port x Bit 1 Data Clear. The `PORT_DATA_CLR.PX1` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
0 (R/W1C)	PX0	Port x Bit 0 Data Clear. The `PORT_DATA_CLR.PX0` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Port x GPIO Data Set Register

The PORT_DATA_SET register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

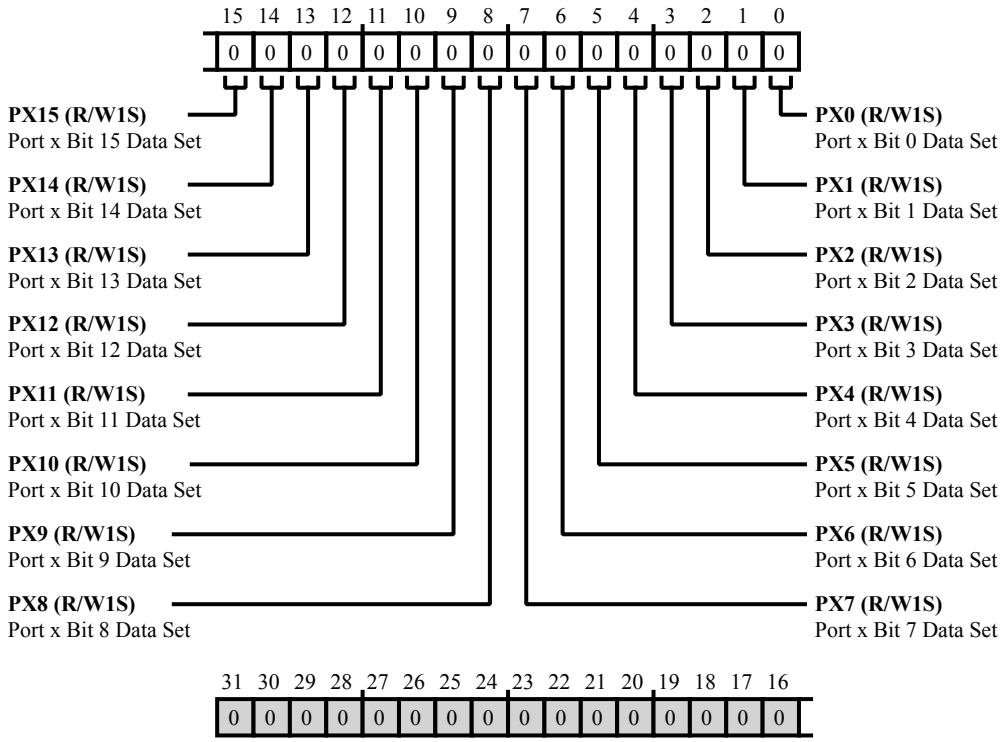

Figure 12-9: PORT_DATA_SET Register Diagram

Table 12-14: PORT_DATA_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
14 (R/W1S)	PX14	Port x Bit 14 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
13 (R/W1S)	PX13	Port x Bit 13 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 12-14: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1S)	PX12	Port x Bit 12 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
11 (R/W1S)	PX11	Port x Bit 11 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit.
10 (R/W1S)	PX10	Port x Bit 10 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
9 (R/W1S)	PX9	Port x Bit 9 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
8 (R/W1S)	PX8	Port x Bit 8 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
7 (R/W1S)	PX7	Port x Bit 7 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
6 (R/W1S)	PX6	Port x Bit 6 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
5 (R/W1S)	PX5	Port x Bit 5 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
4 (R/W1S)	PX4	Port x Bit 4 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
3 (R/W1S)	PX3	Port x Bit 3 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 12-14: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1S)	PX2	Port x Bit 2 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
1 (R/W1S)	PX1	Port x Bit 1 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
0 (R/W1S)	PX0	Port x Bit 0 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Port x GPIO Output Toggle Register

The PORT_DATA_TGL register permits toggling the state of output GPIO pins. Setting bits in the PORT_DATA_TGL register affects the state of specific pins without impacting other pins of the port.

Reading the PORT_DATA_TGL returns the state of the PORT_DATA register output pin state, but does not return the input pin/signal state.

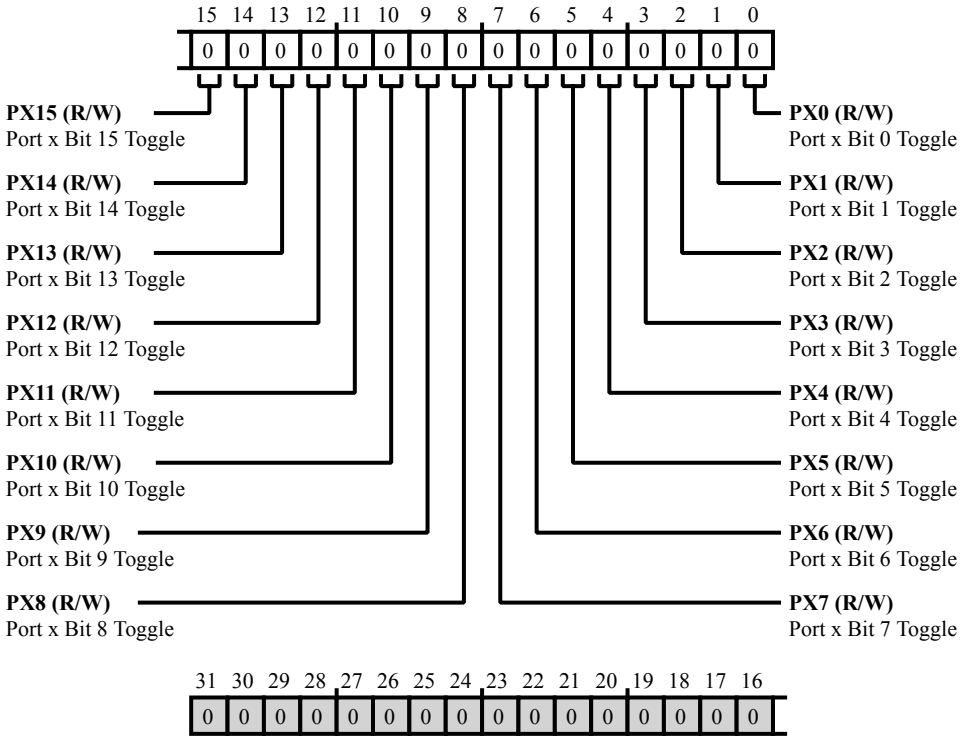

Figure 12-10: PORT_DATA_TGL Register Diagram

Table 12-15: PORT_DATA_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Toggle. The PORT_DATA_TGL.PX15 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit.
14 (R/W)	PX14	Port x Bit 14 Toggle. The PORT_DATA_TGL.PX14 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

		0	No Effect
		1	Toggle Bit
12 (R/W)	PX12	Port x Bit 12 Toggle. The `PORT_DATA_TGL.PX12` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
11 (R/W)	PX11	Port x Bit 11 Toggle. The `PORT_DATA_TGL.PX11` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
10 (R/W)	PX10	Port x Bit 10 Toggle. The `PORT_DATA_TGL.PX10` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
9 (R/W)	PX9	Port x Bit 9 Toggle. The `PORT_DATA_TGL.PX9` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
8 (R/W)	PX8	Port x Bit 8 Toggle. The `PORT_DATA_TGL.PX8` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
7 (R/W)	PX7	Port x Bit 7 Toggle. The `PORT_DATA_TGL.PX7` bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Table 12-15: PORT_DATA_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	PX6	Port x Bit 6 Toggle. The PORT_DATA_TGL.PX6 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
5 (R/W)	PX5	Port x Bit 5 Toggle. The PORT_DATA_TGL.PX5 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
4 (R/W)	PX4	Port x Bit 4 Toggle. The PORT_DATA_TGL.PX4 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
3 (R/W)	PX3	Port x Bit 3 Toggle. The PORT_DATA_TGL.PX3 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
2 (R/W)	PX2	Port x Bit 2 Toggle. The PORT_DATA_TGL.PX2 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
1 (R/W)	PX1	Port x Bit 1 Toggle. The PORT_DATA_TGL.PX1 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
0 (R/W)	PX0	Port x Bit 0 Toggle. The PORT_DATA_TGL.PX0 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Port x GPIO Direction Register

The PORT_DIR, PORT_DIR_SET, and PORT_DIR_CLR registers select output or input mode for GPIO pins and enable output drivers. Use the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers to enable or disable input drivers.

Writes to the PORT_DIR register affect the state of all pins of the port. To select a direction for specific pins without impacting other pins of the port, use the PORT_DIR_SET and PORT_DIR_CLR registers.

Setting a bit in the PORT_DIR register enables output mode on the corresponding a GPIO pin. Clearing a bit in the PORT_DIR register disables output mode on the corresponding GPIO pin.

Input Mode - The default mode of every GPIO pin after reset is the input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the corresponding bits in the PORT_INEN register. When enabled, a read from the PORT_DATA register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the bit, but the change cannot be read back.

Output Mode - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the PORT_DIR, PORT_DIR_SET, or PORT_DIR_CLR registers. By using the PORT_DIR_SET and PORT_DIR_CLR registers, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers) to avoid any volatile levels on the output.

Open-Drain Mode - Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the PORT_DATA or PORT_DATA_CLR register. Then, set the one bit in the PORT_INEN register. Reads from the PORT_DATA register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pin.

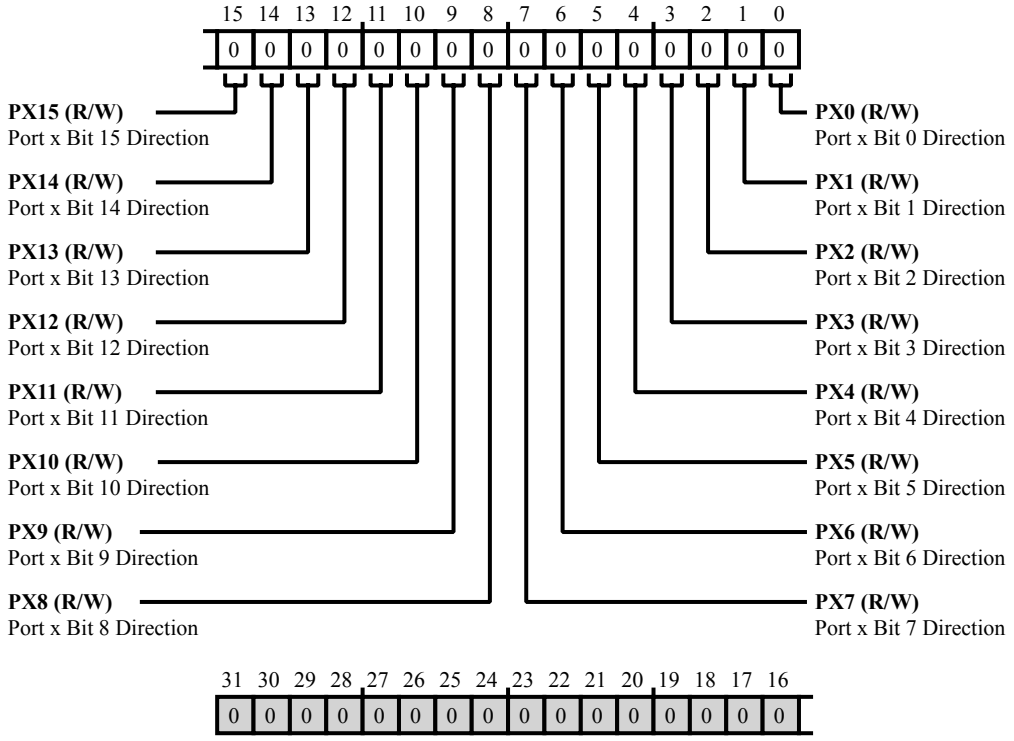

Figure 12-11: PORT_DIR Register Diagram

Table 12-16: PORT_DIR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
14 (R/W)	PX14	Port x Bit 14 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
13 (R/W)	PX13	Port x Bit 13 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
12 (R/W)	PX12	Port x Bit 12 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 12-16: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	PX11	Port x Bit 11 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
10 (R/W)	PX10	Port x Bit 10 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
9 (R/W)	PX9	Port x Bit 9 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
8 (R/W)	PX8	Port x Bit 8 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
7 (R/W)	PX7	Port x Bit 7 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
6 (R/W)	PX6	Port x Bit 6 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
5 (R/W)	PX5	Port x Bit 5 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
4 (R/W)	PX4	Port x Bit 4 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
3 (R/W)	PX3	Port x Bit 3 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
2 (R/W)	PX2	Port x Bit 2 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 12-16: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration

		0	No Effect
		1	Enable output mode/driver
3 (R/W1S)	PX3	Port x Bit 3 Direction Set. The PORT_DIR_SET.PX3 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
2 (R/W1S)	PX2	Port x Bit 2 Direction Set. The PORT_DIR_SET.PX2 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
1 (R/W1S)	PX1	Port x Bit 1 Direction Set. The PORT_DIR_SET.PX1 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
0 (R/W1S)	PX0	Port x Bit 0 Direction Set. The PORT_DIR_SET.PX0 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Port x Function Enable Register

The PORT_FER register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the PORT_FER registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the PORT_MUX registers as to which peripheral takes control.

		0	GPIO Mode
		1	Peripheral Mode

Port x Function Enable Clear Register

The PORT_FER_CLR register permits enabling GPIO mode for each bit and corresponding GPIO pin. Writing 1 to a bit in PORT_FER_CLR enables GPIO mode for the corresponding pin.

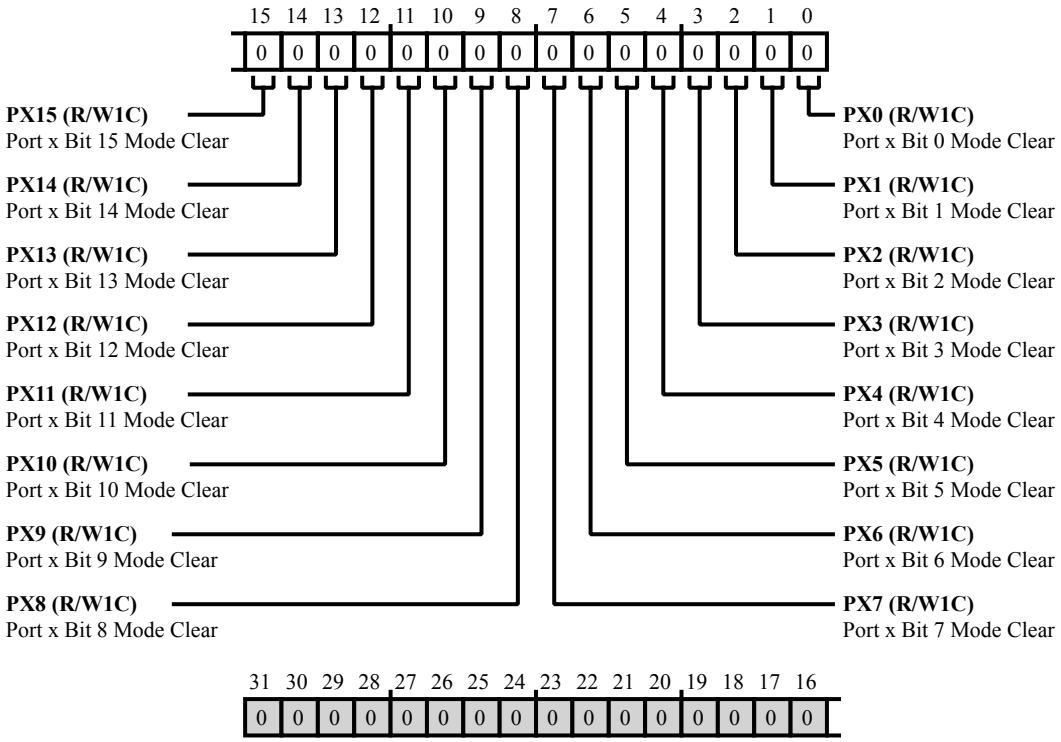

Figure 12-15: PORT_FER_CLR Register Diagram

Table 12-20: PORT_FER_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Mode Clear. The PORT_FER_CLR.PX15 bit enables GPIO mode.	
		0	No Effect
		1	Set Bit for GPIO Mode
14 (R/W1C)	PX14	Port x Bit 14 Mode Clear. The PORT_FER_CLR.PX14 bit enables GPIO mode.

Port x Function Enable Set Register

The PORT_FER_SET register permits enabling peripheral mode for each bit and corresponding GPIO pin. Writing 1 to a bit in PORT_FER_SET enables peripheral mode for the corresponding pin.

Port x GPIO Input Enable Register

The PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the PORT_INEN register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the PORT_INEN_SET and PORT_INEN_CLR registers.

If the input is enabled, reads from the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information, see the PORT_DATA register description and the PORT_DIR register description.

Port x GPIO Lock Register

The PORT_LOCK register enables (unlocks) or disables (locks) write access selectively for the PORT control registers.

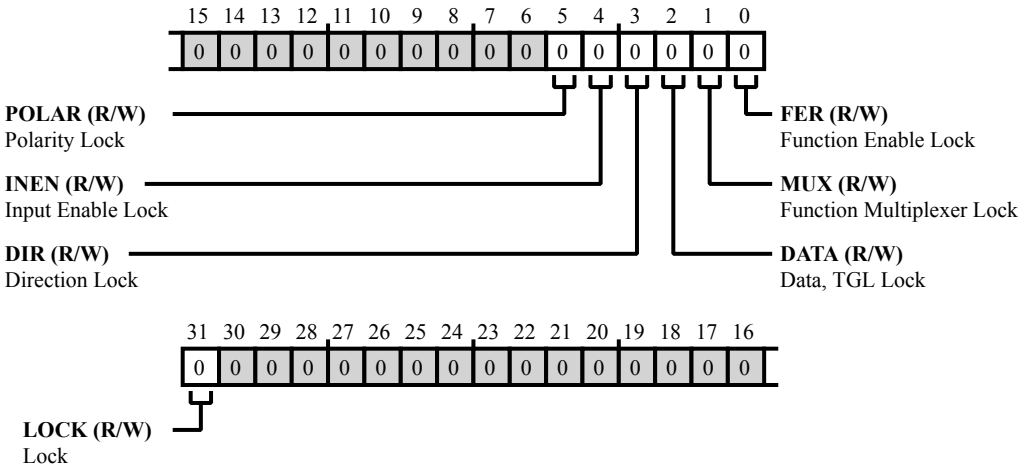

Figure 12-20: PORT_LOCK Register Diagram

Table 12-25: PORT_LOCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the PORT_LOCK.LOCK bit is set, the PORT_LOCK register is read only (locked).	
		0	Unlock
		1	Lock
5 (R/W)	POLAR	Polarity Lock. The PORT_LOCK.POLAR disables write access to the PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers.	
		0	Unlock POL
		1	Lock POL
4 (R/W)	INEN	Input Enable Lock. The PORT_LOCK.INEN disables write access to the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers.	
		0	Unlock INEN
		1	Lock INEN

Table 12-25: PORT_LOCK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIR	Direction Lock. The PORT_LOCK.DIR disables write access to the PORT_DIR, PORT_DIR_SET, PORT_DIR_CLR registers.	
		0	Unlock DIR
		1	Lock DIR
2 (R/W)	DATA	Data, TGL Lock. The PORT_LOCK.DATA disables write access to the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, and PORT_DATA_TGL registers.	
		0	Unlock DATA
		1	Lock DATA
1 (R/W)	MUX	Function Multiplexer Lock. The PORT_LOCK.MUX disables write accesses to the PORT_MUX register.	
		0	Unlock MUX
		1	Lock MUX
0 (R/W)	FER	Function Enable Lock. The PORT_LOCK.FER disables write access to the PORT_FER, PORT_FER_SET, and PORT_FER_CLR registers.	
		0	Unlock FER
		1	Lock FER

Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the PORT_MUX register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, bit 0 and bit 1 of the PORT_MUX register control the multiplexer of pin 0, bit 2 and bit 3 of PORT_MUX control the multiplexer of pin 1, and so on. The value of any PORT_MUX bit has no effect on the port pins when the associated bit in the PORT_FER register is 0 (selects GPIO mode). Even if a port has only one function, the PORT_MUX register is still present. For single function ports (no multiplexing is needed), leave the PORT_MUX bits at 0 (default). For all PORT_MUX bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

See the processor data sheet for details regarding the peripheral options associated with each port.

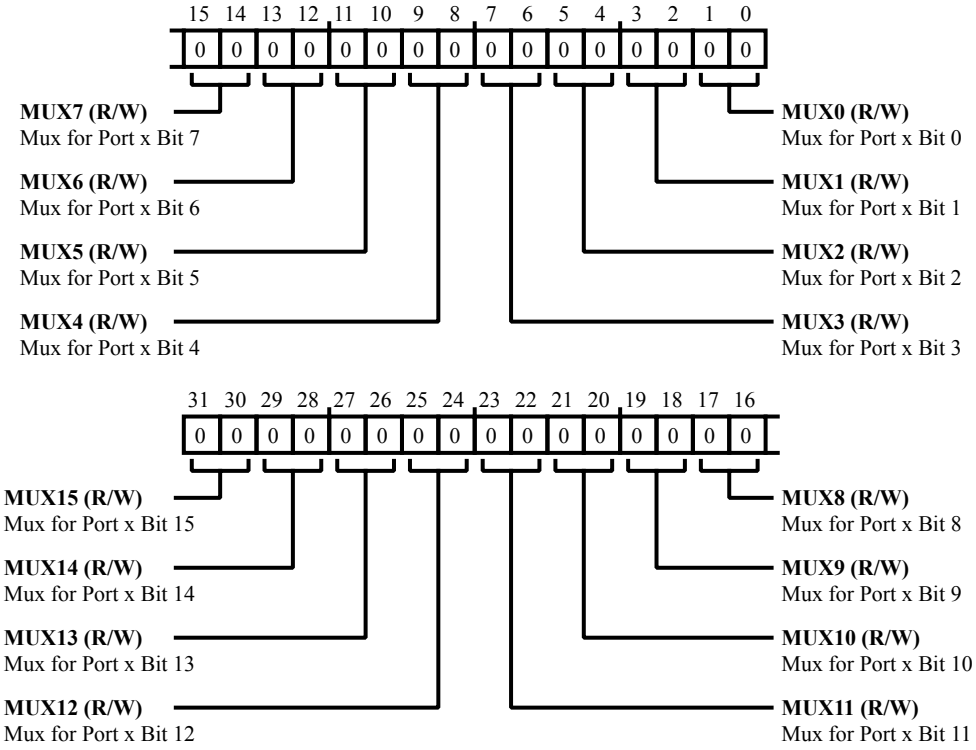

Figure 12-21: PORT_MUX Register Diagram

Table 12-26: PORT_MUX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	MUX15	Mux for Port x Bit 15. The PORT_MUX.MUX15 bit provides multiplexer control for port x bit 15.

Table 12-26: PORT_MUX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:28 (R/W)	MUX14	Mux for Port x Bit 14. The PORT_MUX.MUX14 bit provides multiplexer control for port x bit 14.
27:26 (R/W)	MUX13	Mux for Port x Bit 13. The PORT_MUX.MUX13 bit provides multiplexer control for port x bit 13.
25:24 (R/W)	MUX12	Mux for Port x Bit 12. The PORT_MUX.MUX12 bit provides multiplexer control for port x bit 12.
23:22 (R/W)	MUX11	Mux for Port x Bit 11. The PORT_MUX.MUX11 bit provides multiplexer control for port x bit 11.
21:20 (R/W)	MUX10	Mux for Port x Bit 10. The PORT_MUX.MUX10 bit provides multiplexer control for port x bit 10.
19:18 (R/W)	MUX9	Mux for Port x Bit 9. The PORT_MUX.MUX9 bit provides multiplexer control for port x bit 9.
17:16 (R/W)	MUX8	Mux for Port x Bit 8. The PORT_MUX.MUX8 bit provides multiplexer control for port x bit 8.
15:14 (R/W)	MUX7	Mux for Port x Bit 7. The PORT_MUX.MUX7 bit provides multiplexer control for port x bit 7.
13:12 (R/W)	MUX6	Mux for Port x Bit 6. The PORT_MUX.MUX6 bit provides multiplexer control for port x bit 6.
11:10 (R/W)	MUX5	Mux for Port x Bit 5. The PORT_MUX.MUX5 bit provides multiplexer control for port x bit 5.
9:8 (R/W)	MUX4	Mux for Port x Bit 4. The PORT_MUX.MUX4 bit provides multiplexer control for port x bit 4.
7:6 (R/W)	MUX3	Mux for Port x Bit 3. The PORT_MUX.MUX3 bit provides multiplexer control for port x bit 3.
5:4 (R/W)	MUX2	Mux for Port x Bit 2. The PORT_MUX.MUX2 bit provides multiplexer control for port x bit 2.
3:2 (R/W)	MUX1	Mux for Port x Bit 1. The PORT_MUX.MUX1 bit provides multiplexer control for port x bit 1.
1:0 (R/W)	MUX0	Mux for Port x Bit 0. The PORT_MUX.MUX0 bit provides multiplexer control for port x bit 0.

Port x GPIO Polarity Invert Register

The PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the PORT_POL register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the PORT_POL_SET and PORT_POL_CLR registers.

Setting a bit in the PORT_POL register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the PORT_POL register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

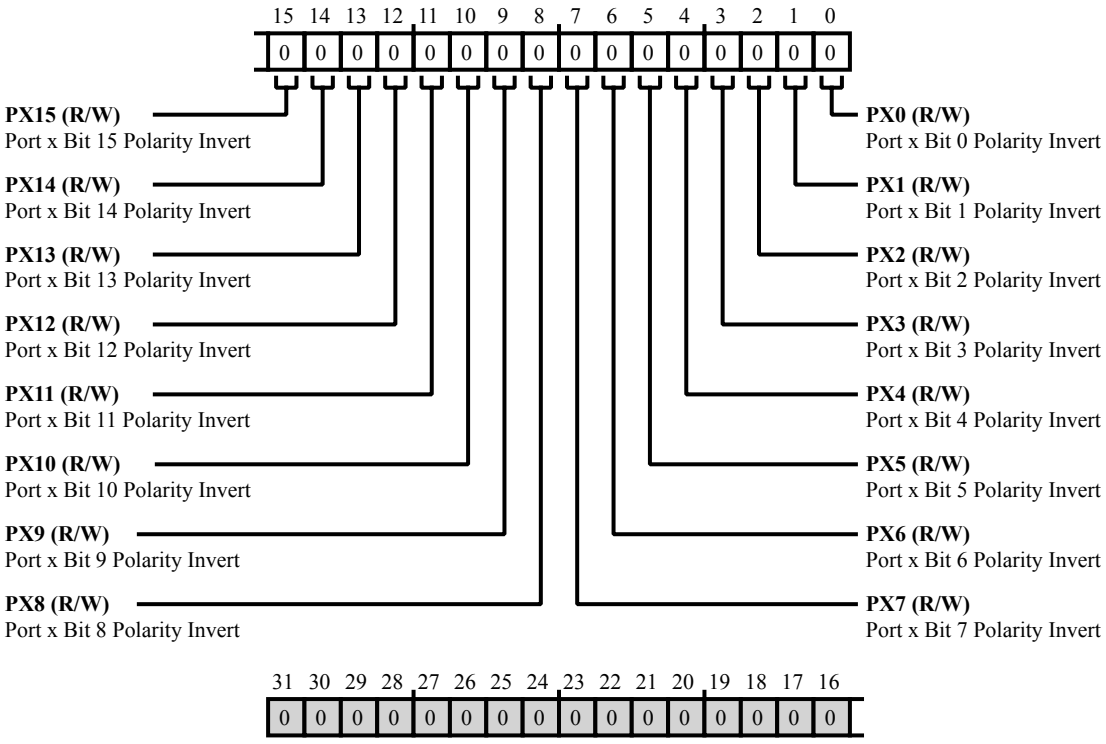

Figure 12-22: PORT_POL Register Diagram

Table 12-27: PORT_POL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Polarity Invert. The PORT_POL.PX15 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	PX14	Port x Bit 14 Polarity Invert. The PORT_POL.PX14 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
13 (R/W)	PX13	Port x Bit 13 Polarity Invert. The PORT_POL.PX13 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
12 (R/W)	PX12	Port x Bit 12 Polarity Invert. The PORT_POL.PX12 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
11 (R/W)	PX11	Port x Bit 11 Polarity Invert. The PORT_POL.PX11 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
10 (R/W)	PX10	Port x Bit 10 Polarity Invert. The PORT_POL.PX10 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
9 (R/W)	PX9	Port x Bit 9 Polarity Invert. The PORT_POL.PX9 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
8 (R/W)	PX8	Port x Bit 8 Polarity Invert. The PORT_POL.PX8 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PX7	Port x Bit 7 Polarity Invert. The PORT_POL.PX7 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
6 (R/W)	PX6	Port x Bit 6 Polarity Invert. The PORT_POL.PX6 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
5 (R/W)	PX5	Port x Bit 5 Polarity Invert. The PORT_POL.PX5 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
4 (R/W)	PX4	Port x Bit 4 Polarity Invert. The PORT_POL.PX4 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
3 (R/W)	PX3	Port x Bit 3 Polarity Invert. The PORT_POL.PX3 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
2 (R/W)	PX2	Port x Bit 2 Polarity Invert. The PORT_POL.PX2 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
1 (R/W)	PX1	Port x Bit 1 Polarity Invert. The PORT_POL.PX1 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 12-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PX0	Port x Bit 0 Polarity Invert. The `PORT_POL.PX0` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Port x GPIO Polarity Invert Clear Register

The PORT_POL_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

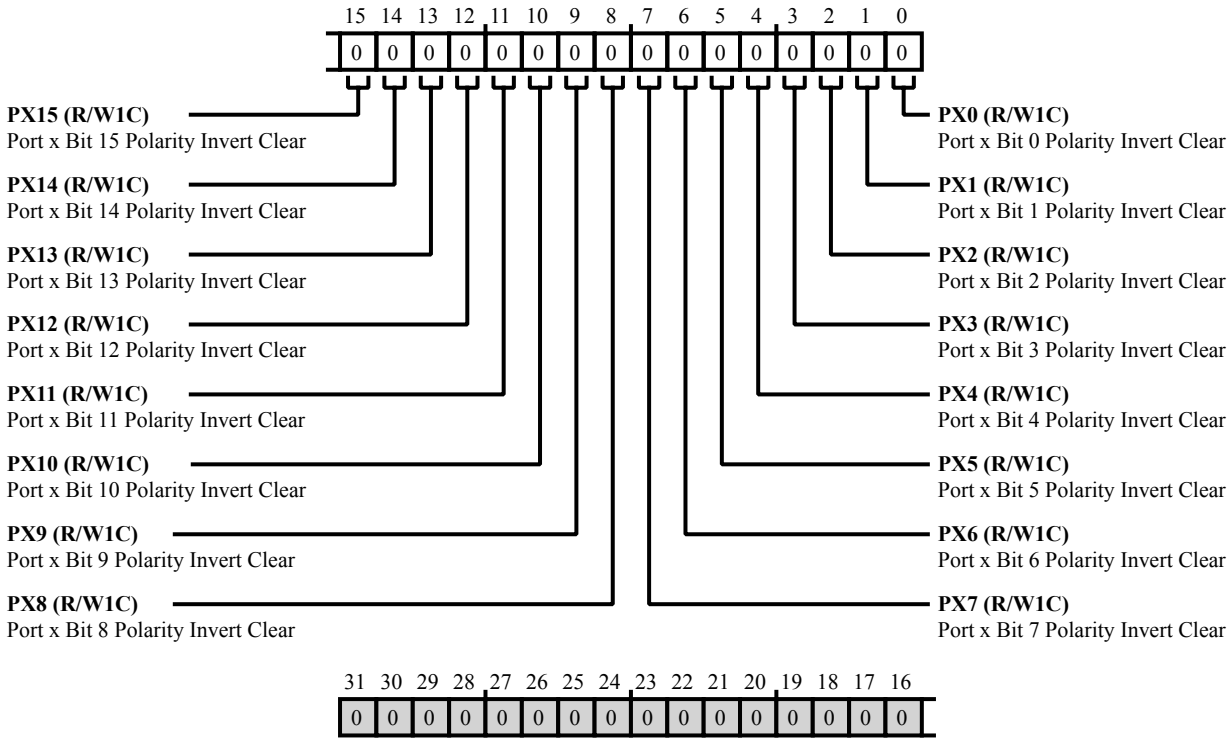

Figure 12-23: PORT_POL_CLR Register Diagram

Table 12-28: PORT_POL_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
14 (R/W1C)	PX14	Port x Bit 14 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
13 (R/W1C)	PX13	Port x Bit 13 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 12-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	PX12	Port x Bit 12 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
11 (R/W1C)	PX11	Port x Bit 11 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
10 (R/W1C)	PX10	Port x Bit 10 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
9 (R/W1C)	PX9	Port x Bit 9 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
8 (R/W1C)	PX8	Port x Bit 8 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
7 (R/W1C)	PX7	Port x Bit 7 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
6 (R/W1C)	PX6	Port x Bit 6 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
5 (R/W1C)	PX5	Port x Bit 5 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
4 (R/W1C)	PX4	Port x Bit 4 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
3 (R/W1C)	PX3	Port x Bit 3 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 12-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	PX2	Port x Bit 2 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
1 (R/W1C)	PX1	Port x Bit 1 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
0 (R/W1C)	PX0	Port x Bit 0 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Port x GPIO Polarity Invert Set Register

The PORT_POL_SET register enables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

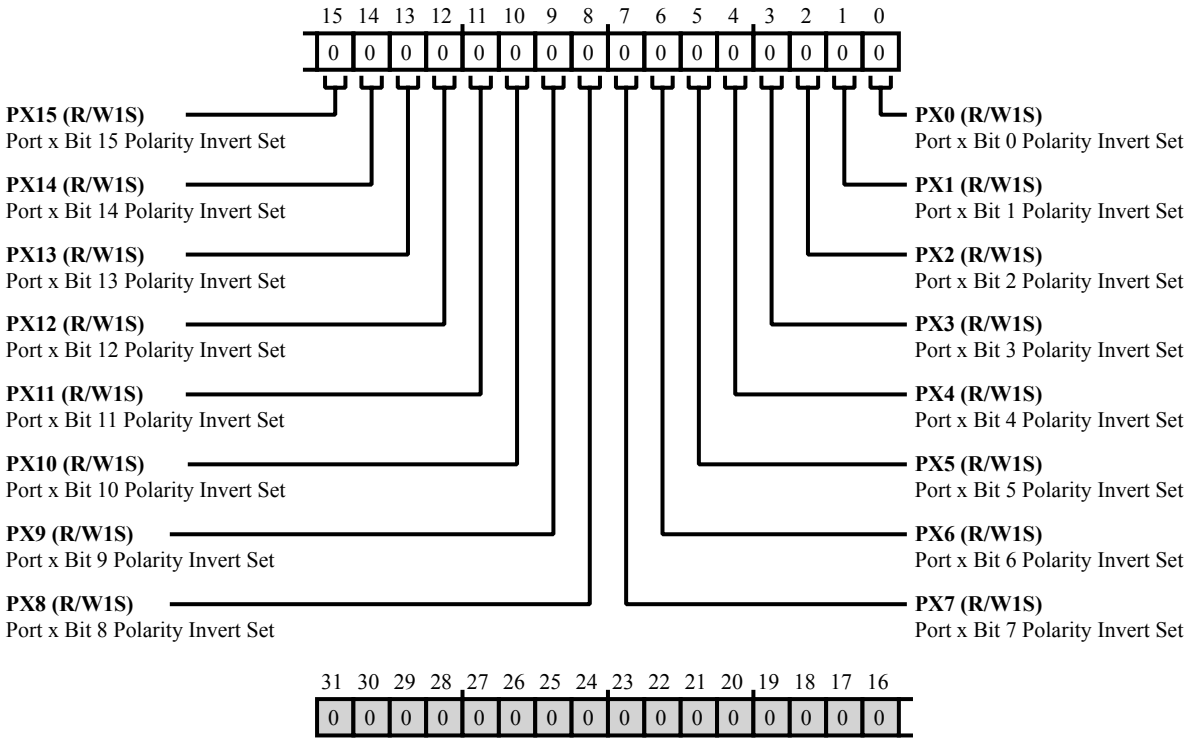

Figure 12-24: PORT_POL_SET Register Diagram

Table 12-29: PORT_POL_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Polarity Invert Set. The PORT_POL_SET.PX15 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
14 (R/W1S)	PX14	Port x Bit 14 Polarity Invert Set. The PORT_POL_SET.PX14 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 12-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Polarity Invert Set. The PORT_POL_SET.PX13 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
12 (R/W1S)	PX12	Port x Bit 12 Polarity Invert Set. The PORT_POL_SET.PX12 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
11 (R/W1S)	PX11	Port x Bit 11 Polarity Invert Set. The PORT_POL_SET.PX11 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
10 (R/W1S)	PX10	Port x Bit 10 Polarity Invert Set. The PORT_POL_SET.PX10 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
9 (R/W1S)	PX9	Port x Bit 9 Polarity Invert Set. The PORT_POL_SET.PX9 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
8 (R/W1S)	PX8	Port x Bit 8 Polarity Invert Set. The PORT_POL_SET.PX8 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
7 (R/W1S)	PX7	Port x Bit 7 Polarity Invert Set. The PORT_POL_SET.PX7 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 12-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Polarity Invert Set. The PORT_POL_SET.PX6 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
5 (R/W1S)	PX5	Port x Bit 5 Polarity Invert Set. The PORT_POL_SET.PX5 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
4 (R/W1S)	PX4	Port x Bit 4 Polarity Invert Set. The PORT_POL_SET.PX4 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
3 (R/W1S)	PX3	Port x Bit 3 Polarity Invert Set. The PORT_POL_SET.PX3 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
2 (R/W1S)	PX2	Port x Bit 2 Polarity Invert Set. The PORT_POL_SET.PX2 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
1 (R/W1S)	PX1	Port x Bit 1 Polarity Invert Set. The PORT_POL_SET.PX1 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
0 (R/W1S)	PX0	Port x Bit 0 Polarity Invert Set. The PORT_POL_SET.PX0 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Port x GPIO Trigger Toggle Register

The PORT_TRIG_TGL register permits toggling the state of output GPIO pins in response to a trigger from the TRU for the corresponding port. Setting bits in the PORT_TRIG_TGL register enables triggers to toggle the state of those specific pins without impacting other pins of the port.

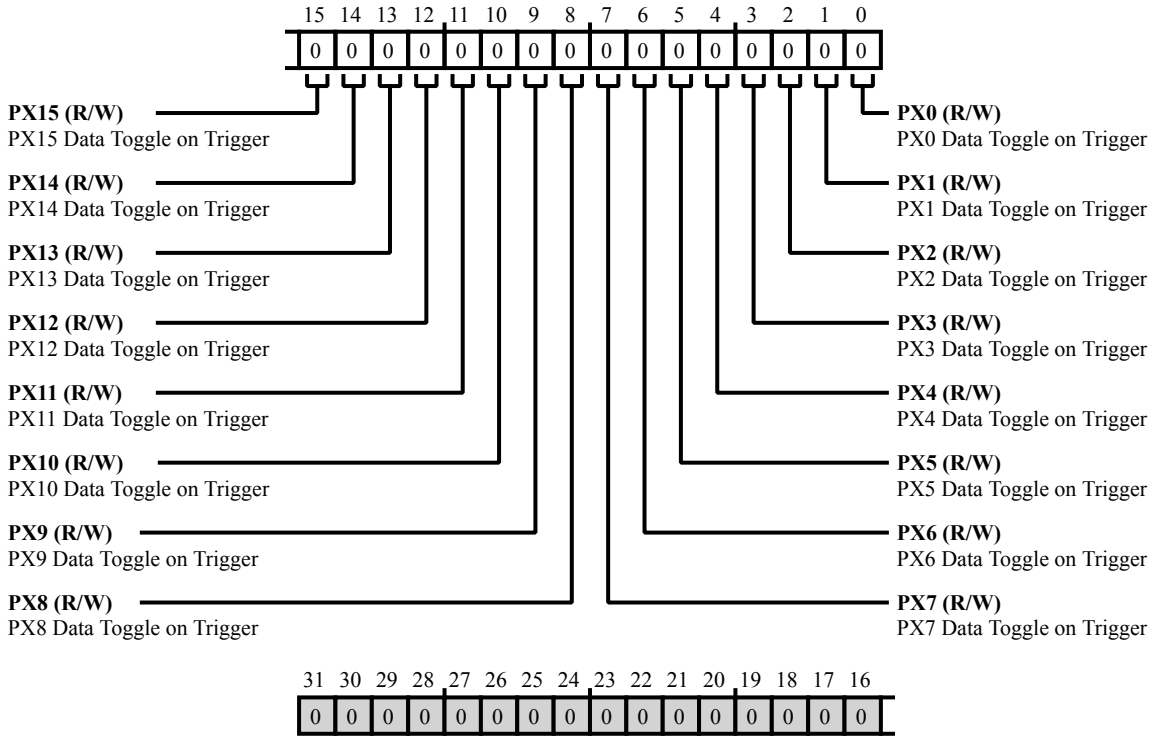

Figure 12-25: PORT_TRIG_TGL Register Diagram

Table 12-30: PORT_TRIG_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PX15	PX15 Data Toggle on Trigger. The PORT_TRIG_TGL.PX15 bit enables triggers to toggle the state of the pin.
14 (R/W)	PX14	PX14 Data Toggle on Trigger. The PORT_TRIG_TGL.PX14 bit enables triggers to toggle the state of the pin.
13 (R/W)	PX13	PX13 Data Toggle on Trigger. The PORT_TRIG_TGL.PX13 bit enables triggers to toggle the state of the pin.
12 (R/W)	PX12	PX12 Data Toggle on Trigger. The PORT_TRIG_TGL.PX12 bit enables triggers to toggle the state of the pin.
11 (R/W)	PX11	PX11 Data Toggle on Trigger. The PORT_TRIG_TGL.PX11 bit enables triggers to toggle the state of the pin.

Table 12-30: PORT_TRIG_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	PX10	PX10 Data Toggle on Trigger. The PORT_TRIG_TGL.PX10 bit enables triggers to toggle the state of the pin.
9 (R/W)	PX9	PX9 Data Toggle on Trigger. The PORT_TRIG_TGL.PX9 bit enables triggers to toggle the state of the pin.
8 (R/W)	PX8	PX8 Data Toggle on Trigger. The PORT_TRIG_TGL.PX8 bit enables triggers to toggle the state of the pin.
7 (R/W)	PX7	PX7 Data Toggle on Trigger. The PORT_TRIG_TGL.PX7 bit enables triggers to toggle the state of the pin.
6 (R/W)	PX6	PX6 Data Toggle on Trigger. The PORT_TRIG_TGL.PX6 bit enables triggers to toggle the state of the pin.
5 (R/W)	PX5	PX5 Data Toggle on Trigger. The PORT_TRIG_TGL.PX5 bit enables triggers to toggle the state of the pin.
4 (R/W)	PX4	PX4 Data Toggle on Trigger. The PORT_TRIG_TGL.PX4 bit enables triggers to toggle the state of the pin.
3 (R/W)	PX3	PX3 Data Toggle on Trigger. The PORT_TRIG_TGL.PX3 bit enables triggers to toggle the state of the pin.
2 (R/W)	PX2	PX2 Data Toggle on Trigger. The PORT_TRIG_TGL.PX2 bit enables triggers to toggle the state of the pin.
1 (R/W)	PX1	PX1 Data Toggle on Trigger. The PORT_TRIG_TGL.PX1 bit enables triggers to toggle the state of the pin.
0 (R/W)	PX0	PX0 Data Toggle on Trigger. The PORT_TRIG_TGL.PX0 bit enables triggers to toggle the state of the pin.

ADSP-2159x_SC591_SC592_SC594 PINT Register Descriptions

The Pin Interrupt module (PINT) contains the following registers.

Table 12-31: ADSP-2159x_SC591_SC592_SC594 PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register

Table 12-31: ADSP-2159x_SC591_SC592_SC594 PINT Register List (Continued)

Name	Description
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

PINT Assign Register

The PINT_ASSIGN register controls the pin-to-interrupt request assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block. The upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

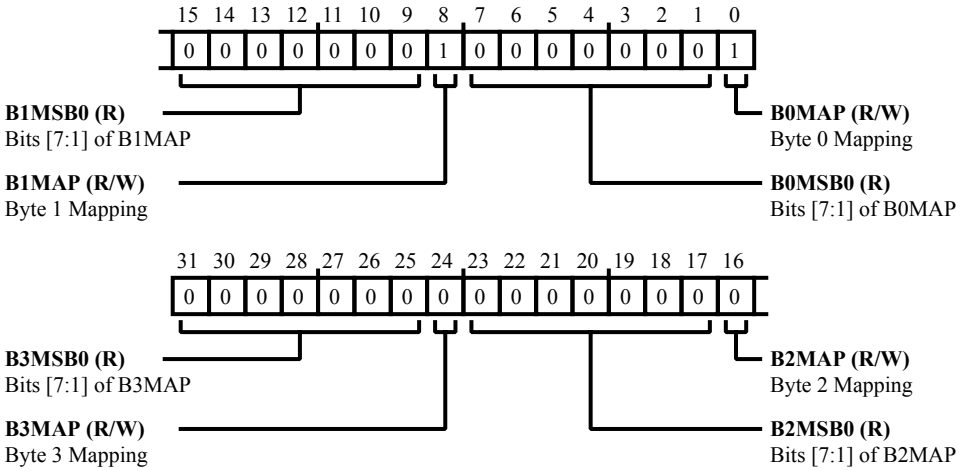

Figure 12-26: PINT_ASSIGN Register Diagram

Table 12-32: PINT_ASSIGN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:25 (R/NW)	B3MSB0	Bits [7:1] of B3MAP.	
24 (R/W)	B3MAP	Byte 3 Mapping.	
		0	B3MAP_PAH. Byte 3 = PA.H
		1	B3MAP_PBH. Byte 3 = PB.H
23:17 (R/NW)	B2MSB0	Bits [7:1] of B2MAP.	
16 (R/W)	B2MAP	Byte 2 Mapping.	
		0	B2MAP_PAL. Byte 2 = PA.L
		1	B2MAP_PBL. Byte 2 = PB.L
15:9 (R/NW)	B1MSB0	Bits [7:1] of B1MAP.	

Table 12-32: PINT_ASSIGN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	B1MAP	Byte 1 Mapping.	
		0	B1MAP_PAH. Byte 1 = PA.H
		1	B1MAP_PBH. Byte 1 = PB.H
7:1 (R/NW)	B0MSB0	Bits [7:1] of B0MAP.	
0 (R/W)	B0MAP	Byte 0 Mapping.	
		0	B0MAP_PAL. Byte 0 = PA.L
		1	B0MAP_PBL. Byte 0 = PB.L

PINT Edge Clear Register

The PINT_EDGE_CLR register permits selecting level-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_CLR enables level sensitivity for the corresponding pin interrupt.

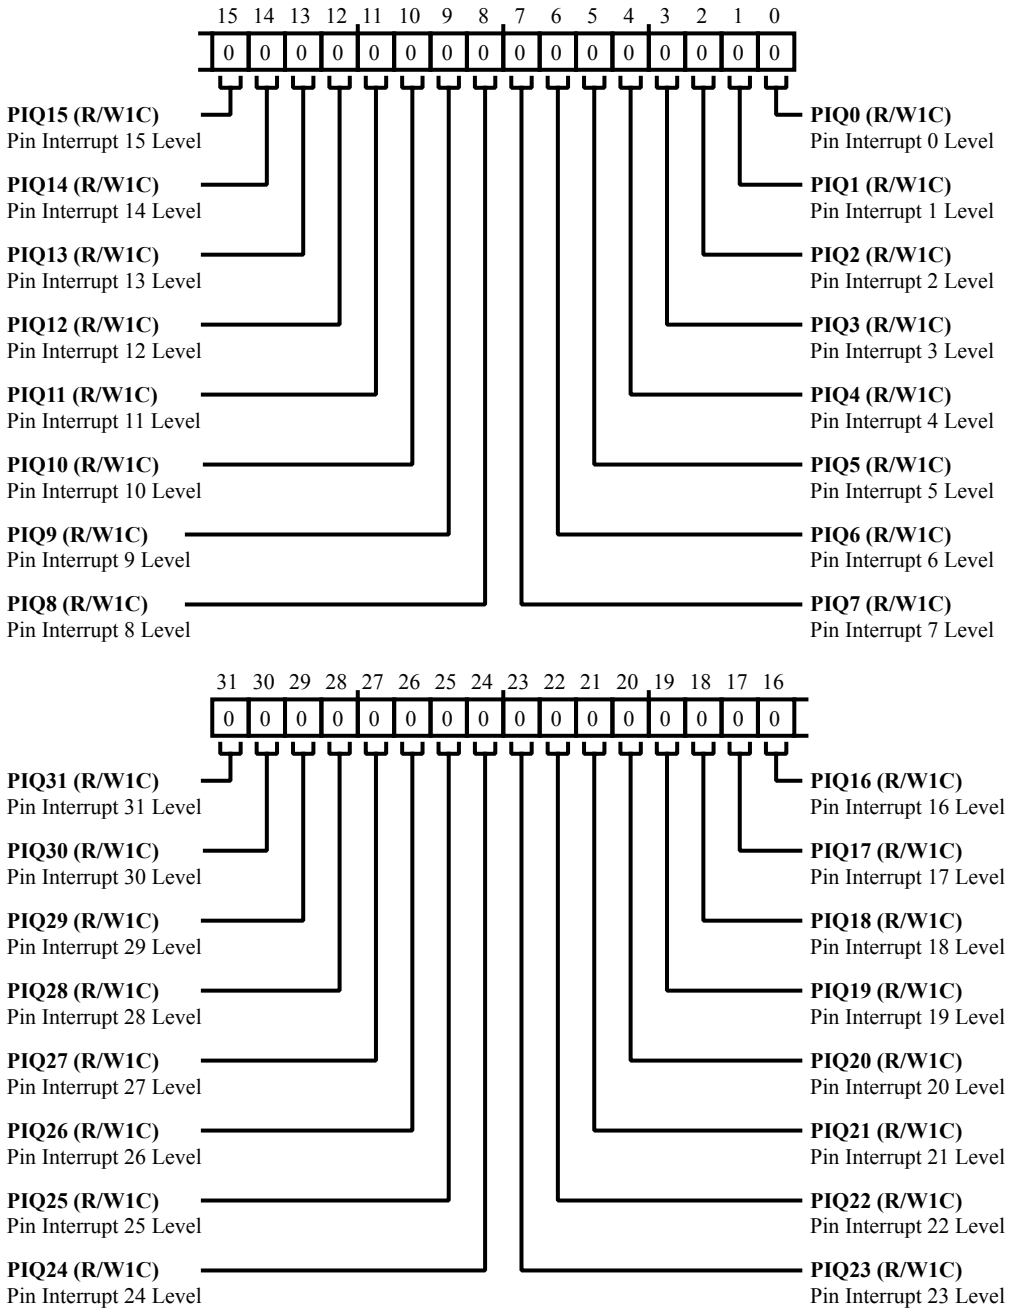

Figure 12-27: PINT_EDGE_CLR Register Diagram

Table 12-33: PINT_EDGE_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Level. Set the PINT_EDGE_CLR.PIQ31 bit to enable level sensitivity.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Level. Set the PINT_EDGE_CLR.PIQ30 bit to enable level sensitivity.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Level. Set the PINT_EDGE_CLR.PIQ29 bit to enable level sensitivity.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Level. Set the PINT_EDGE_CLR.PIQ28 bit to enable level sensitivity.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Level. Set the PINT_EDGE_CLR.PIQ27 bit to enable level sensitivity.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Level. Set the PINT_EDGE_CLR.PIQ26 bit to enable level sensitivity.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Level. Set the PINT_EDGE_CLR.PIQ25 bit to enable level sensitivity.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Level. Set the PINT_EDGE_CLR.PIQ24 bit to enable level sensitivity.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Level. Set the PINT_EDGE_CLR.PIQ23 bit to enable level sensitivity.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Level. Set the PINT_EDGE_CLR.PIQ22 bit to enable level sensitivity.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Level. Set the PINT_EDGE_CLR.PIQ21 bit to enable level sensitivity.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Level. Set the PINT_EDGE_CLR.PIQ20 bit to enable level sensitivity.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Level. Set the PINT_EDGE_CLR.PIQ19 bit to enable level sensitivity.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Level. Set the PINT_EDGE_CLR.PIQ18 bit to enable level sensitivity.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Level. Set the PINT_EDGE_CLR.PIQ17 bit to enable level sensitivity.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Level. Set the PINT_EDGE_CLR.PIQ16 bit to enable level sensitivity.

Table 12-33: PINT_EDGE_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Level. Set the PINT_EDGE_CLR.PIQ15 bit to enable level sensitivity.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Level. Set the PINT_EDGE_CLR.PIQ14 bit to enable level sensitivity.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Level. Set the PINT_EDGE_CLR.PIQ13 bit to enable level sensitivity.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Level. Set the PINT_EDGE_CLR.PIQ12 bit to enable level sensitivity.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Level. Set the PINT_EDGE_CLR.PIQ11 bit to enable level sensitivity.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Level. Set the PINT_EDGE_CLR.PIQ10 bit to enable level sensitivity.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Level. Set the PINT_EDGE_CLR.PIQ9 bit to enable level sensitivity.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Level. Set the PINT_EDGE_CLR.PIQ8 bit to enable level sensitivity.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Level. Set the PINT_EDGE_CLR.PIQ7 bit to enable level sensitivity.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Level. Set the PINT_EDGE_CLR.PIQ6 bit to enable level sensitivity.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Level. Set the PINT_EDGE_CLR.PIQ5 bit to enable level sensitivity.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Level. Set the PINT_EDGE_CLR.PIQ4 bit to enable level sensitivity.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Level. Set the PINT_EDGE_CLR.PIQ3 bit to enable level sensitivity.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Level. Set the PINT_EDGE_CLR.PIQ2 bit to enable level sensitivity.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Level. Set the PINT_EDGE_CLR.PIQ1 bit to enable level sensitivity.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Level. Set the PINT_EDGE_CLR.PIQ0 bit to enable level sensitivity.

PINT Edge Set Register

The PINT_EDGE_SET register permits selecting edge-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_SET enables edge sensitivity for the corresponding pin interrupt.

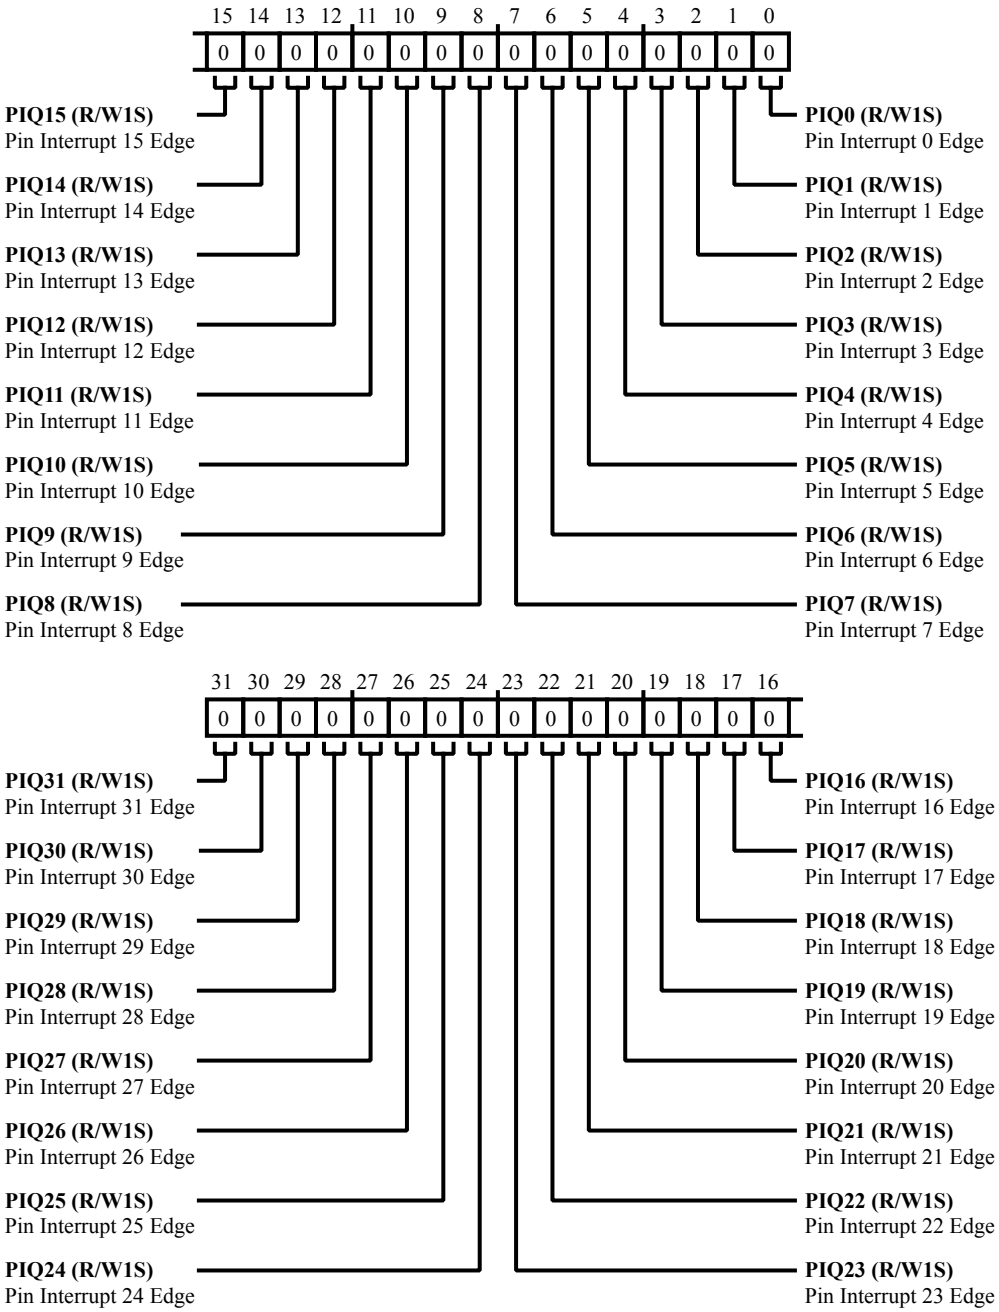

Figure 12-28: PINT_EDGE_SET Register Diagram

Table 12-34: PINT_EDGE_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Edge. Set the `PINT_EDGE_SET.PIQ31` bit to enable edge sensitivity.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Edge. Set the `PINT_EDGE_SET.PIQ30` bit to enable edge sensitivity.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Edge. Set the `PINT_EDGE_SET.PIQ29` bit to enable edge sensitivity.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Edge. Set the `PINT_EDGE_SET.PIQ28` bit to enable edge sensitivity.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Edge. Set the `PINT_EDGE_SET.PIQ27` bit to enable edge sensitivity.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Edge. Set the `PINT_EDGE_SET.PIQ26` bit to enable edge sensitivity.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Edge. Set the `PINT_EDGE_SET.PIQ25` bit to enable edge sensitivity.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Edge. Set the `PINT_EDGE_SET.PIQ24` bit to enable edge sensitivity.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Edge. Set the `PINT_EDGE_SET.PIQ23` bit to enable edge sensitivity.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Edge. Set the `PINT_EDGE_SET.PIQ22` bit to enable edge sensitivity.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Edge. Set the `PINT_EDGE_SET.PIQ21` bit to enable edge sensitivity.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Edge. Set the `PINT_EDGE_SET.PIQ20` bit to enable edge sensitivity.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Edge. Set the `PINT_EDGE_SET.PIQ19` bit to enable edge sensitivity.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Edge. Set the `PINT_EDGE_SET.PIQ18` bit to enable edge sensitivity.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Edge. Set the `PINT_EDGE_SET.PIQ17` bit to enable edge sensitivity.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Edge. Set the `PINT_EDGE_SET.PIQ16` bit to enable edge sensitivity.

Table 12-34: PINT_EDGE_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Edge. Set the PINT_EDGE_SET.PIQ15 bit to enable edge sensitivity.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Edge. Set the PINT_EDGE_SET.PIQ14 bit to enable edge sensitivity.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Edge. Set the PINT_EDGE_SET.PIQ13 bit to enable edge sensitivity.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Edge. Set the PINT_EDGE_SET.PIQ12 bit to enable edge sensitivity.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Edge. Set the PINT_EDGE_SET.PIQ11 bit to enable edge sensitivity.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Edge. Set the PINT_EDGE_SET.PIQ10 bit to enable edge sensitivity.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Edge. Set the PINT_EDGE_SET.PIQ9 bit to enable edge sensitivity.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Edge. Set the PINT_EDGE_SET.PIQ8 bit to enable edge sensitivity.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Edge. Set the PINT_EDGE_SET.PIQ7 bit to enable edge sensitivity.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Edge. Set the PINT_EDGE_SET.PIQ6 bit to enable edge sensitivity.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Edge. Set the PINT_EDGE_SET.PIQ5 bit to enable edge sensitivity.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Edge. Set the PINT_EDGE_SET.PIQ4 bit to enable edge sensitivity.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Edge. Set the PINT_EDGE_SET.PIQ3 bit to enable edge sensitivity.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Edge. Set the PINT_EDGE_SET.PIQ2 bit to enable edge sensitivity.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Edge. Set the PINT_EDGE_SET.PIQ1 bit to enable edge sensitivity.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Edge. Set the PINT_EDGE_SET.PIQ0 bit to enable edge sensitivity.

PINT Invert Clear Register

The PINT_INV_CLR register disables inverting input polarity. Writing 1 to a bit in PINT_INV_CLR disables an inverter for input on the corresponding pin.

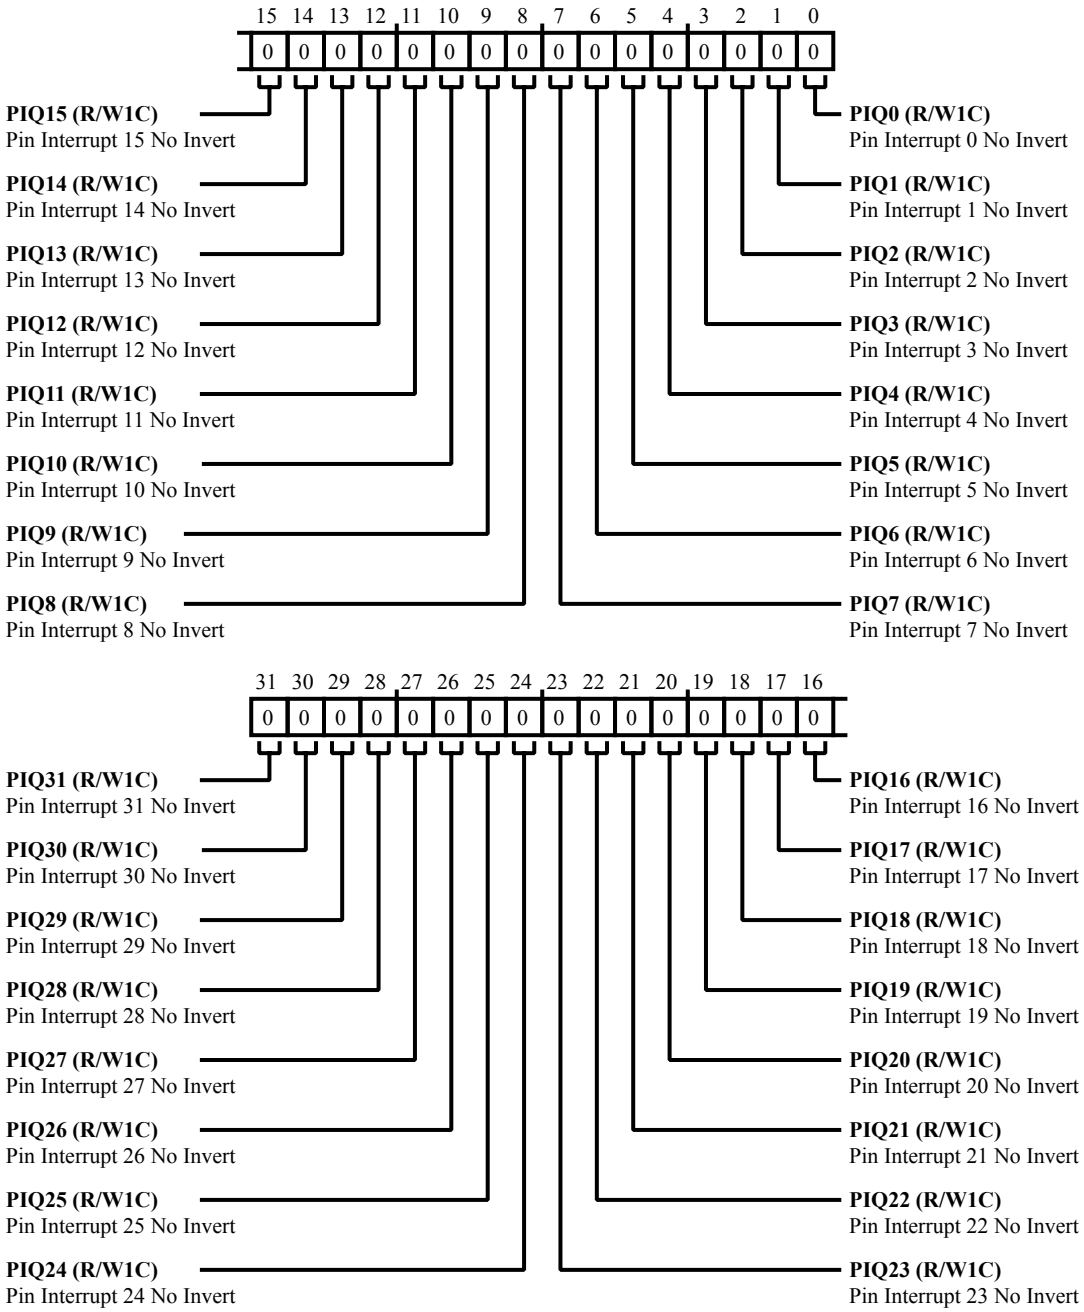

Figure 12-29: PINT_INV_CLR Register Diagram

Table 12-35: PINT_INV_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 No Invert. Set the PINT_INV_CLR.PIQ31 bit to disable inverted input.
30 (R/W1C)	PIQ30	Pin Interrupt 30 No Invert. Set the PINT_INV_CLR.PIQ30 bit to disable inverted input.
29 (R/W1C)	PIQ29	Pin Interrupt 29 No Invert. Set the PINT_INV_CLR.PIQ29 bit to disable inverted input.
28 (R/W1C)	PIQ28	Pin Interrupt 28 No Invert. Set the PINT_INV_CLR.PIQ28 bit to disable inverted input.
27 (R/W1C)	PIQ27	Pin Interrupt 27 No Invert. Set the PINT_INV_CLR.PIQ27 bit to disable inverted input.
26 (R/W1C)	PIQ26	Pin Interrupt 26 No Invert. Set the PINT_INV_CLR.PIQ26 bit to disable inverted input.
25 (R/W1C)	PIQ25	Pin Interrupt 25 No Invert. Set the PINT_INV_CLR.PIQ25 bit to disable inverted input.
24 (R/W1C)	PIQ24	Pin Interrupt 24 No Invert. Set the PINT_INV_CLR.PIQ24 bit to disable inverted input.
23 (R/W1C)	PIQ23	Pin Interrupt 23 No Invert. Set the PINT_INV_CLR.PIQ23 bit to disable inverted input.
22 (R/W1C)	PIQ22	Pin Interrupt 22 No Invert. Set the PINT_INV_CLR.PIQ22 bit to disable inverted input.
21 (R/W1C)	PIQ21	Pin Interrupt 21 No Invert. Set the PINT_INV_CLR.PIQ21 bit to disable inverted input.
20 (R/W1C)	PIQ20	Pin Interrupt 20 No Invert. Set the PINT_INV_CLR.PIQ20 bit to disable inverted input.
19 (R/W1C)	PIQ19	Pin Interrupt 19 No Invert. Set the PINT_INV_CLR.PIQ19 bit to disable inverted input.
18 (R/W1C)	PIQ18	Pin Interrupt 18 No Invert. Set the PINT_INV_CLR.PIQ18 bit to disable inverted input.
17 (R/W1C)	PIQ17	Pin Interrupt 17 No Invert. Set the PINT_INV_CLR.PIQ17 bit to disable inverted input.
16 (R/W1C)	PIQ16	Pin Interrupt 16 No Invert. Set the PINT_INV_CLR.PIQ16 bit to disable inverted input.

Table 12-35: PINT_INV_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 No Invert. Set the PINT_INV_CLR.PIQ15 bit to disable inverted input.
14 (R/W1C)	PIQ14	Pin Interrupt 14 No Invert. Set the PINT_INV_CLR.PIQ14 bit to disable inverted input.
13 (R/W1C)	PIQ13	Pin Interrupt 13 No Invert. Set the PINT_INV_CLR.PIQ13 bit to disable inverted input.
12 (R/W1C)	PIQ12	Pin Interrupt 12 No Invert. Set the PINT_INV_CLR.PIQ12 bit to disable inverted input.
11 (R/W1C)	PIQ11	Pin Interrupt 11 No Invert. Set the PINT_INV_CLR.PIQ11 bit to disable inverted input.
10 (R/W1C)	PIQ10	Pin Interrupt 10 No Invert. Set the PINT_INV_CLR.PIQ10 bit to disable inverted input.
9 (R/W1C)	PIQ9	Pin Interrupt 9 No Invert. Set the PINT_INV_CLR.PIQ9 bit to disable inverted input.
8 (R/W1C)	PIQ8	Pin Interrupt 8 No Invert. Set the PINT_INV_CLR.PIQ8 bit to disable inverted input.
7 (R/W1C)	PIQ7	Pin Interrupt 7 No Invert. Set the PINT_INV_CLR.PIQ7 bit to disable inverted input.
6 (R/W1C)	PIQ6	Pin Interrupt 6 No Invert. Set the PINT_INV_CLR.PIQ6 bit to disable inverted input.
5 (R/W1C)	PIQ5	Pin Interrupt 5 No Invert. Set the PINT_INV_CLR.PIQ5 bit to disable inverted input.
4 (R/W1C)	PIQ4	Pin Interrupt 4 No Invert. Set the PINT_INV_CLR.PIQ4 bit to disable inverted input.
3 (R/W1C)	PIQ3	Pin Interrupt 3 No Invert. Set the PINT_INV_CLR.PIQ3 bit to disable inverted input.
2 (R/W1C)	PIQ2	Pin Interrupt 2 No Invert. Set the PINT_INV_CLR.PIQ2 bit to disable inverted input.
1 (R/W1C)	PIQ1	Pin Interrupt 1 No Invert. Set the PINT_INV_CLR.PIQ1 bit to disable inverted input.
0 (R/W1C)	PIQ0	Pin Interrupt 0 No Invert. Set the PINT_INV_CLR.PIQ0 bit to disable inverted input.

PINT Invert Set Register

The PINT_INV_SET register enables inverting input polarity. Writing 1 to a bit in PINT_INV_SET enables an inverter for input on the corresponding pin.

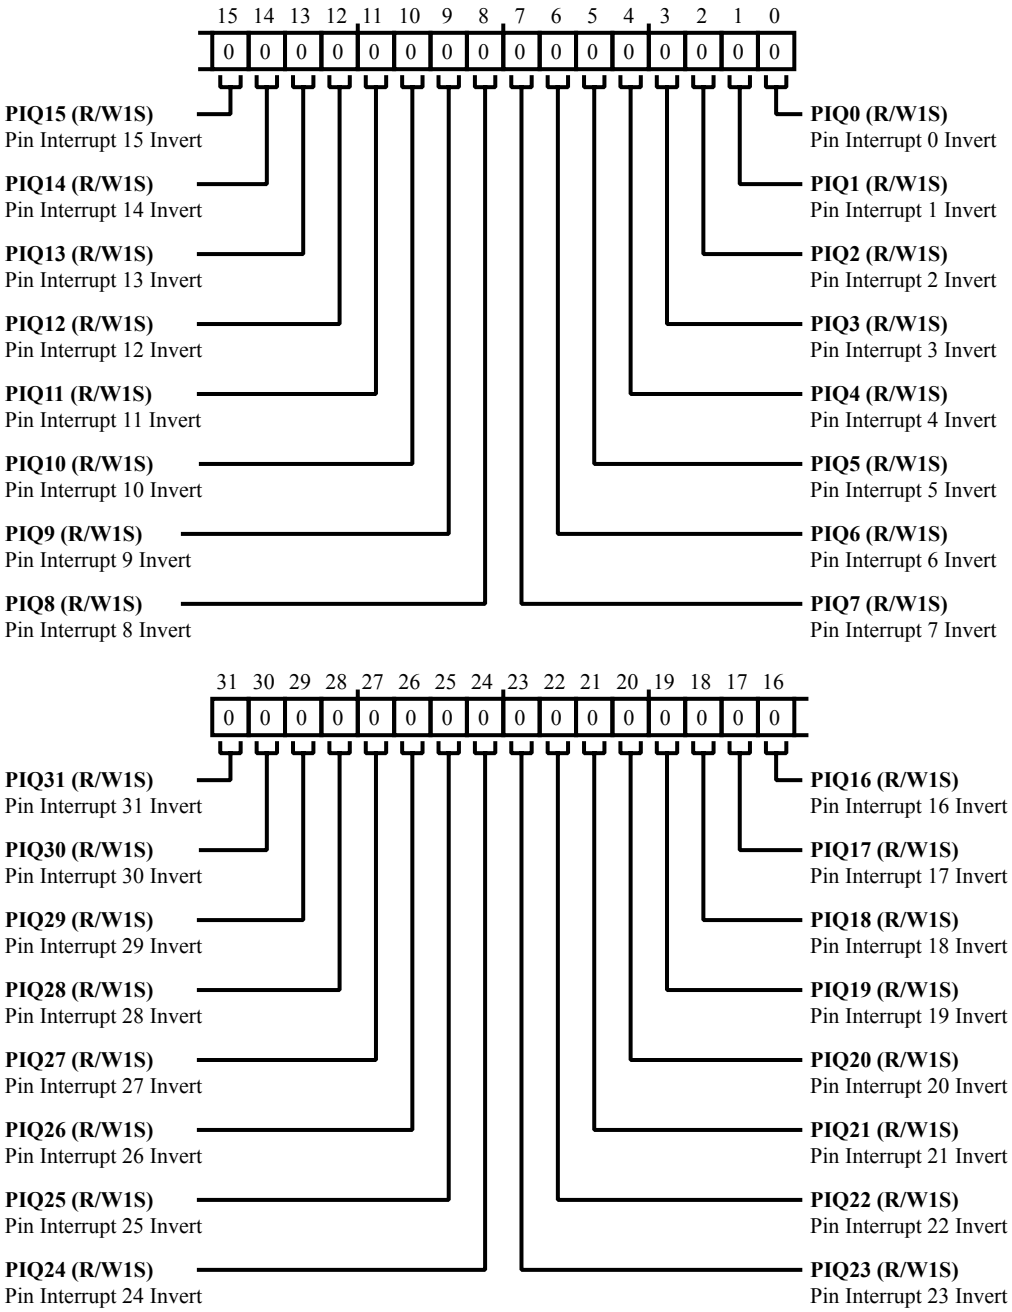

Figure 12-30: PINT_INV_SET Register Diagram

Table 12-36: PINT_INV_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Invert. Set the PINT_INV_SET.PIQ31 bit to enable inverted input.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Invert. Set the PINT_INV_SET.PIQ30 bit to enable inverted input.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Invert. Set the PINT_INV_SET.PIQ29 bit to enable inverted input.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Invert. Set the PINT_INV_SET.PIQ28 bit to enable inverted input.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Invert. Set the PINT_INV_SET.PIQ27 bit to enable inverted input.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Invert. Set the PINT_INV_SET.PIQ26 bit to enable inverted input.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Invert. Set the PINT_INV_SET.PIQ25 bit to enable inverted input.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Invert. Set the PINT_INV_SET.PIQ24 bit to enable inverted input.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Invert. Set the PINT_INV_SET.PIQ23 bit to enable inverted input.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Invert. Set the PINT_INV_SET.PIQ22 bit to enable inverted input.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Invert. Set the PINT_INV_SET.PIQ21 bit to enable inverted input.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Invert. Set the PINT_INV_SET.PIQ20 bit to enable inverted input.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Invert. Set the PINT_INV_SET.PIQ19 bit to enable inverted input.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Invert. Set the PINT_INV_SET.PIQ18 bit to enable inverted input.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Invert. Set the PINT_INV_SET.PIQ17 bit to enable inverted input.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Invert. Set the PINT_INV_SET.PIQ16 bit to enable inverted input.

Table 12-36: PINT_INV_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Invert. Set the PINT_INV_SET.PIQ15 bit to enable inverted input.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Invert. Set the PINT_INV_SET.PIQ14 bit to enable inverted input.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Invert. Set the PINT_INV_SET.PIQ13 bit to enable inverted input.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Invert. Set the PINT_INV_SET.PIQ12 bit to enable inverted input.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Invert. Set the PINT_INV_SET.PIQ11 bit to enable inverted input.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Invert. Set the PINT_INV_SET.PIQ10 bit to enable inverted input.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Invert. Set the PINT_INV_SET.PIQ9 bit to enable inverted input.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Invert. Set the PINT_INV_SET.PIQ8 bit to enable inverted input.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Invert. Set the PINT_INV_SET.PIQ7 bit to enable inverted input.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Invert. Set the PINT_INV_SET.PIQ6 bit to enable inverted input.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Invert. Set the PINT_INV_SET.PIQ5 bit to enable inverted input.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Invert. Set the PINT_INV_SET.PIQ4 bit to enable inverted input.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Invert. Set the PINT_INV_SET.PIQ3 bit to enable inverted input.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Invert. Set the PINT_INV_SET.PIQ2 bit to enable inverted input.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Invert. Set the PINT_INV_SET.PIQ1 bit to enable inverted input.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Invert. Set the PINT_INV_SET.PIQ0 bit to enable inverted input.

PINT Latch Register

The PINT_LATCH register indicates the interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The PINT_LATCH registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either register clears the respective bits in both registers. For interrupt operation, the user may prefer to W1C the PINT_REQ register (address still loaded in Px pointer). In polling mode, it might be cleaner to W1C the PINT_LATCH register.

Whether in edge-sensitive mode or level-sensitive mode, PINT_LATCH bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the PINT_LATCH register functions as latch.

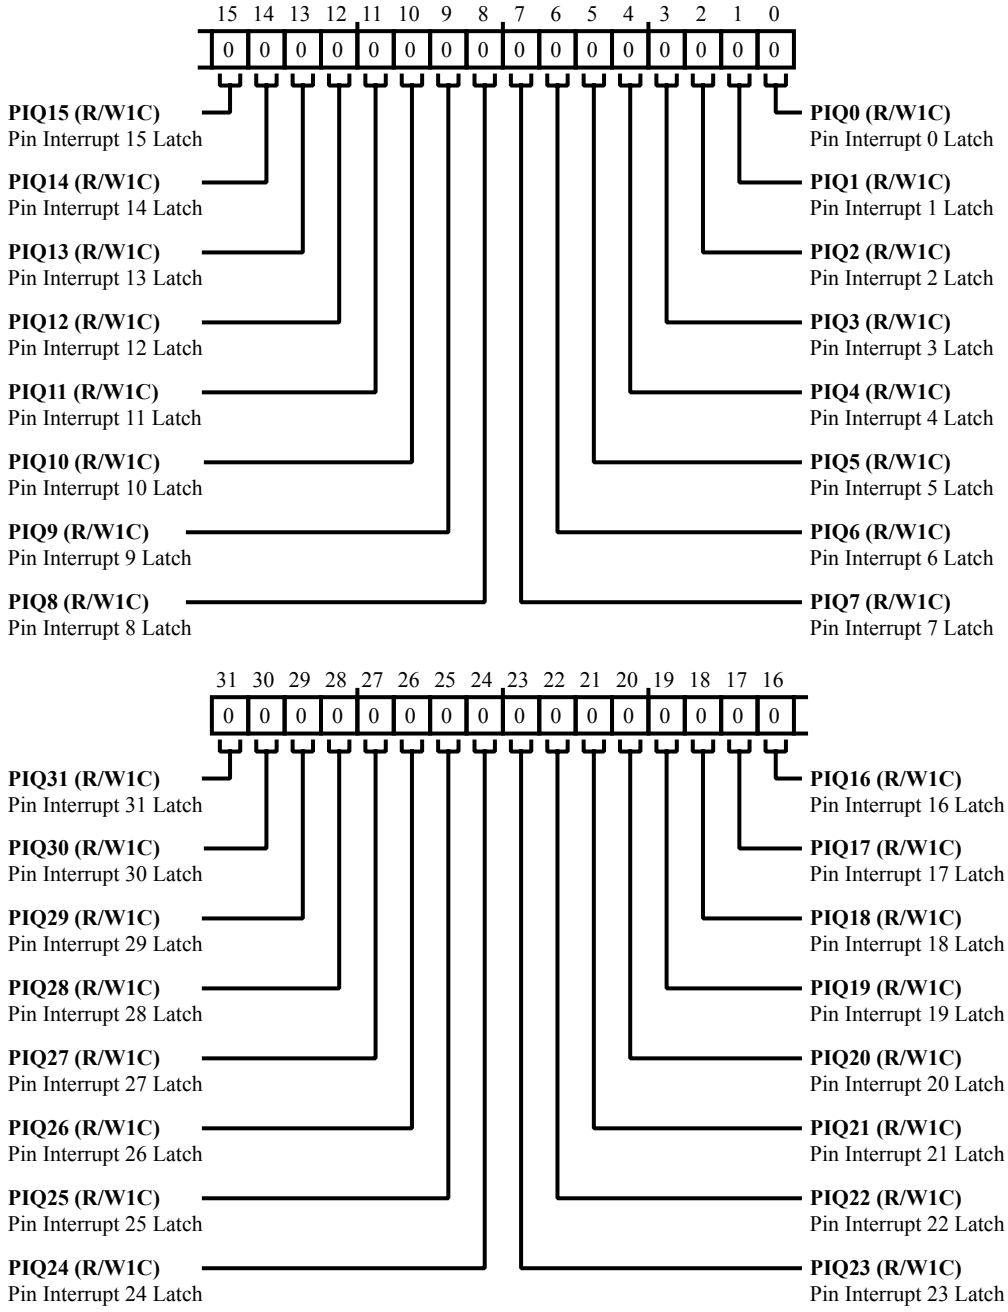

Figure 12-31: PINT_LATCH Register Diagram

Table 12-37: PINT_LATCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Latch. If the `PINT_LATCH.PIQ31` bit is set, the request is latched.

Table 12-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Latch. If the `PINT_LATCH.PIQ30` bit is set, the request is latched.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Latch. If the `PINT_LATCH.PIQ29` bit is set, the request is latched.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Latch. If the `PINT_LATCH.PIQ28` bit is set, the request is latched.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Latch. If the `PINT_LATCH.PIQ27` bit is set, the request is latched.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Latch. If the `PINT_LATCH.PIQ26` bit is set, the request is latched.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Latch. If the `PINT_LATCH.PIQ25` bit is set, the request is latched.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Latch. If the `PINT_LATCH.PIQ24` bit is set, the request is latched.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Latch. If the `PINT_LATCH.PIQ23` bit is set, the request is latched.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Latch. If the `PINT_LATCH.PIQ22` bit is set, the request is latched.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Latch. If the `PINT_LATCH.PIQ21` bit is set, the request is latched.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Latch. If the `PINT_LATCH.PIQ20` bit is set, the request is latched.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Latch. If the `PINT_LATCH.PIQ19` bit is set, the request is latched.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Latch. If the `PINT_LATCH.PIQ18` bit is set, the request is latched.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Latch. If the `PINT_LATCH.PIQ17` bit is set, the request is latched.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Latch. If the `PINT_LATCH.PIQ16` bit is set, the request is latched.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Latch. If the `PINT_LATCH.PIQ15` bit is set, the request is latched.

Table 12-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Latch. If the PINT_LATCH.PIQ14 bit is set, the request is latched.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Latch. If the PINT_LATCH.PIQ13 bit is set, the request is latched.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Latch. If the PINT_LATCH.PIQ12 bit is set, the request is latched.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Latch. If the PINT_LATCH.PIQ11 bit is set, the request is latched.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Latch. If the PINT_LATCH.PIQ10 bit is set, the request is latched.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Latch. If the PINT_LATCH.PIQ9 bit is set, the request is latched.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Latch. If the PINT_LATCH.PIQ8 bit is set, the request is latched.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Latch. If the PINT_LATCH.PIQ7 bit is set, the request is latched.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Latch. If the PINT_LATCH.PIQ6 bit is set, the request is latched.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Latch. If the PINT_LATCH.PIQ5 bit is set, the request is latched.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Latch. If the PINT_LATCH.PIQ4 bit is set, the request is latched.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Latch. If the PINT_LATCH.PIQ3 bit is set, the request is latched.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Latch. If the PINT_LATCH.PIQ2 bit is set, the request is latched.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Latch. If the PINT_LATCH.PIQ1 bit is set, the request is latched.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Latch. If the PINT_LATCH.PIQ0 bit is set, the request is latched.

PINT Mask Clear Register

The PINT_MSK_CLR register permits masking (disabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_CLR masks the corresponding pin interrupt.

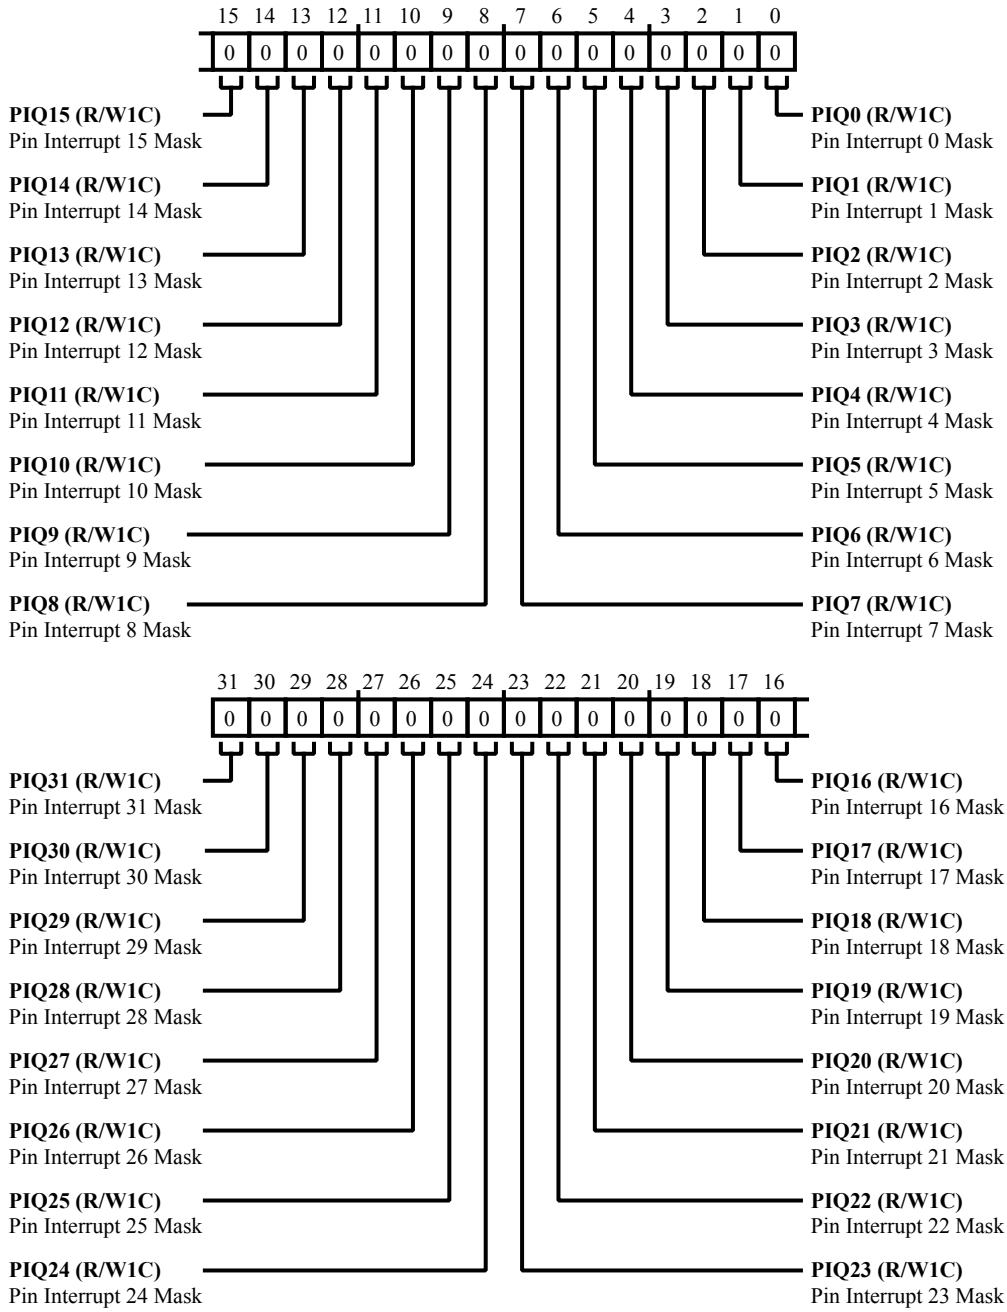

Figure 12-32: PINT_MSK_CLR Register Diagram

Table 12-38: PINT_MSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Mask. Set the PINT_MSK_CLR.PIQ31 bit to disable the interrupt.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Mask. Set the PINT_MSK_CLR.PIQ30 bit to disable the interrupt.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Mask. Set the PINT_MSK_CLR.PIQ29 bit to disable the interrupt.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Mask. Set the PINT_MSK_CLR.PIQ28 bit to disable the interrupt.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Mask. Set the PINT_MSK_CLR.PIQ27 bit to disable the interrupt.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Mask. Set the PINT_MSK_CLR.PIQ26 bit to disable the interrupt.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Mask. Set the PINT_MSK_CLR.PIQ25 bit to disable the interrupt.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Mask. Set the PINT_MSK_CLR.PIQ24 bit to disable the interrupt.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Mask. Set the PINT_MSK_CLR.PIQ23 bit to disable the interrupt.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Mask. Set the PINT_MSK_CLR.PIQ22 bit to disable the interrupt.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Mask. Set the PINT_MSK_CLR.PIQ21 bit to disable the interrupt.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Mask. Set the PINT_MSK_CLR.PIQ20 bit to disable the interrupt.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Mask. Set the PINT_MSK_CLR.PIQ19 bit to disable the interrupt.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Mask. Set the PINT_MSK_CLR.PIQ18 bit to disable the interrupt.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Mask. Set the PINT_MSK_CLR.PIQ17 bit to disable the interrupt.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Mask. Set the PINT_MSK_CLR.PIQ16 bit to disable the interrupt.

Table 12-38: PINT_MSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Mask. Set the PINT_MSK_CLR.PIQ15 bit to disable the interrupt.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Mask. Set the PINT_MSK_CLR.PIQ14 bit to disable the interrupt.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Mask. Set the PINT_MSK_CLR.PIQ13 bit to disable the interrupt.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Mask. Set the PINT_MSK_CLR.PIQ12 bit to disable the interrupt.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Mask. Set the PINT_MSK_CLR.PIQ11 bit to disable the interrupt.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Mask. Set the PINT_MSK_CLR.PIQ10 bit to disable the interrupt.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Mask. Set the PINT_MSK_CLR.PIQ9 bit to disable the interrupt.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Mask. Set the PINT_MSK_CLR.PIQ8 bit to disable the interrupt.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Mask. Set the PINT_MSK_CLR.PIQ7 bit to disable the interrupt.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Mask. Set the PINT_MSK_CLR.PIQ6 bit to disable the interrupt.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Mask. Set the PINT_MSK_CLR.PIQ5 bit to disable the interrupt.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Mask. Set the PINT_MSK_CLR.PIQ4 bit to disable the interrupt.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Mask. Set the PINT_MSK_CLR.PIQ3 bit to disable the interrupt.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Mask. Set the PINT_MSK_CLR.PIQ2 bit to disable the interrupt.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Mask. Set the PINT_MSK_CLR.PIQ1 bit to disable the interrupt.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Mask. Set the PINT_MSK_CLR.PIQ0 bit to disable the interrupt.

PINT Mask Set Register

The PINT_MSK_SET register permits unmasking (enabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_SET unmasks the corresponding pin interrupt.

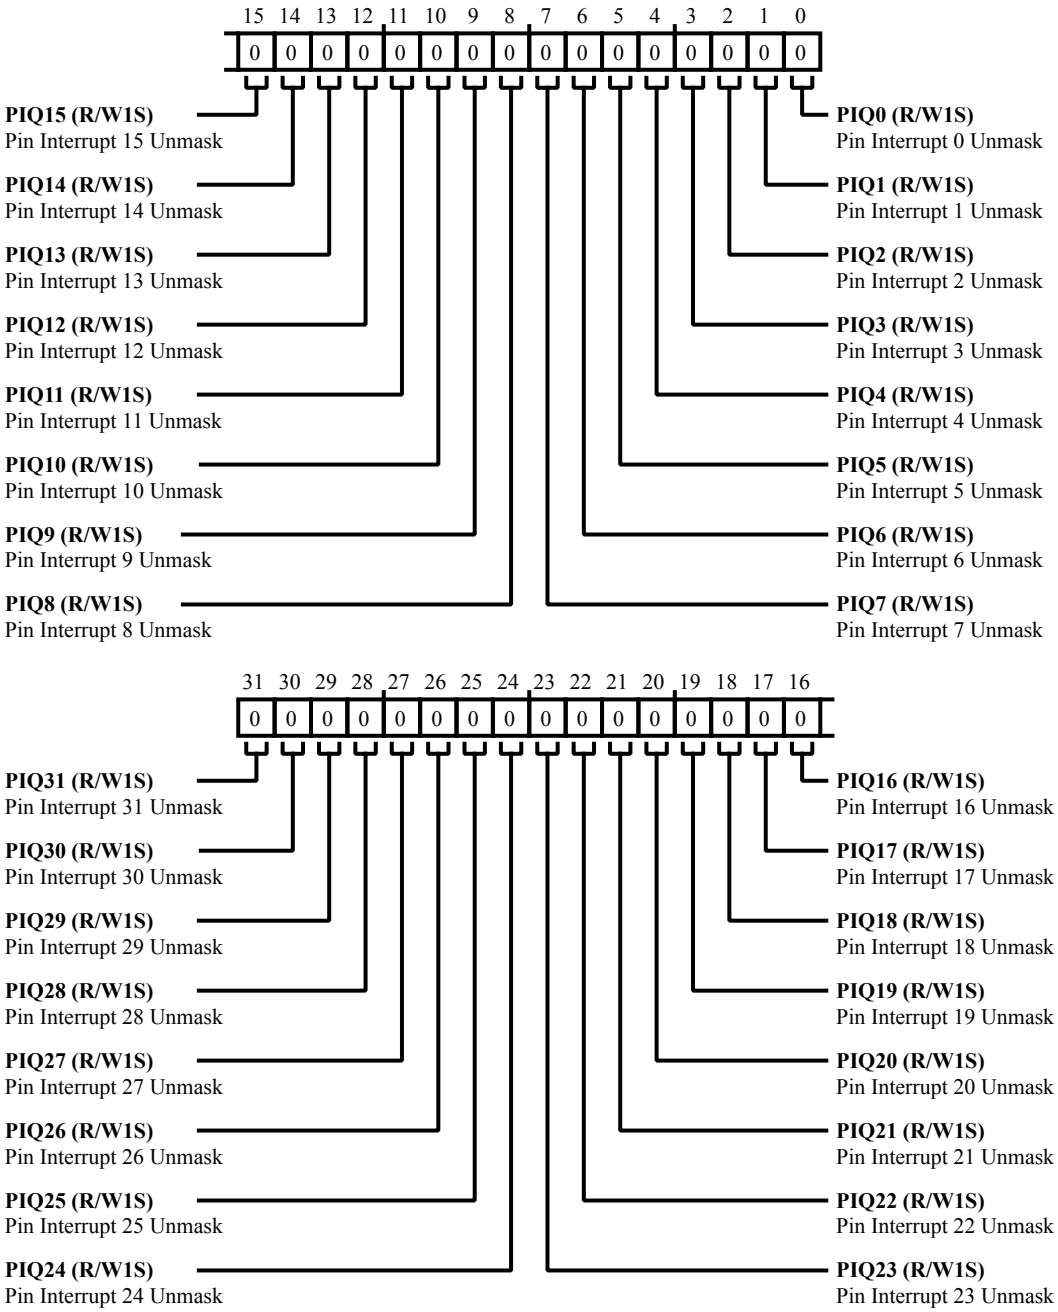

Figure 12-33: PINT_MSK_SET Register Diagram

Table 12-39: PINT_MSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Unmask. Set the PINT_MSK_SET.PIQ31 bit to enable the interrupt.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Unmask. Set the PINT_MSK_SET.PIQ30 bit to enable the interrupt.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Unmask. Set the PINT_MSK_SET.PIQ29 bit to enable the interrupt.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Unmask. Set the PINT_MSK_SET.PIQ28 bit to enable the interrupt.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Unmask. Set the PINT_MSK_SET.PIQ27 bit to enable the interrupt.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Unmask. Set the PINT_MSK_SET.PIQ26 bit to enable the interrupt.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Unmask. Set the PINT_MSK_SET.PIQ25 bit to enable the interrupt.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Unmask. Set the PINT_MSK_SET.PIQ24 bit to enable the interrupt.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Unmask. Set the PINT_MSK_SET.PIQ23 bit to enable the interrupt.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Unmask. Set the PINT_MSK_SET.PIQ22 bit to enable the interrupt.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Unmask. Set the PINT_MSK_SET.PIQ21 bit to enable the interrupt.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Unmask. Set the PINT_MSK_SET.PIQ20 bit to enable the interrupt.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Unmask. Set the PINT_MSK_SET.PIQ19 bit to enable the interrupt.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Unmask. Set the PINT_MSK_SET.PIQ18 bit to enable the interrupt.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Unmask. Set the PINT_MSK_SET.PIQ17 bit to enable the interrupt.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Unmask. Set the PINT_MSK_SET.PIQ16 bit to enable the interrupt.

Table 12-39: PINT_MSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Unmask. Set the PINT_MSK_SET.PIQ15 bit to enable the interrupt.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Unmask. Set the PINT_MSK_SET.PIQ14 bit to enable the interrupt.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Unmask. Set the PINT_MSK_SET.PIQ13 bit to enable the interrupt.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Unmask. Set the PINT_MSK_SET.PIQ12 bit to enable the interrupt.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Unmask. Set the PINT_MSK_SET.PIQ11 bit to enable the interrupt.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Unmask. Set the PINT_MSK_SET.PIQ10 bit to enable the interrupt.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Unmask. Set the PINT_MSK_SET.PIQ9 bit to enable the interrupt.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Unmask. Set the PINT_MSK_SET.PIQ8 bit to enable the interrupt.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Unmask. Set the PINT_MSK_SET.PIQ7 bit to enable the interrupt.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Unmask. Set the PINT_MSK_SET.PIQ6 bit to enable the interrupt.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Unmask. Set the PINT_MSK_SET.PIQ5 bit to enable the interrupt.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Unmask. Set the PINT_MSK_SET.PIQ4 bit to enable the interrupt.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Unmask. Set the PINT_MSK_SET.PIQ3 bit to enable the interrupt.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Unmask. Set the PINT_MSK_SET.PIQ2 bit to enable the interrupt.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Unmask. Set the PINT_MSK_SET.PIQ1 bit to enable the interrupt.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Unmask. Set the PINT_MSK_SET.PIQ0 bit to enable the interrupt.

PINT Pin State Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the PINT_PINSTATE register. While neither input nor output drivers of the pin are enabled, reads of the pin state in PINT_PINSTATE return zero. The PINT_PINSTATE register reports the inverted state of the pin if the signal inverter is activated by the PINT_INV_SET register. The inverter can be enabled on an individual bit-by-bit basis. Every bit in the PINT_INV_SET and PINT_INV_CLR register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

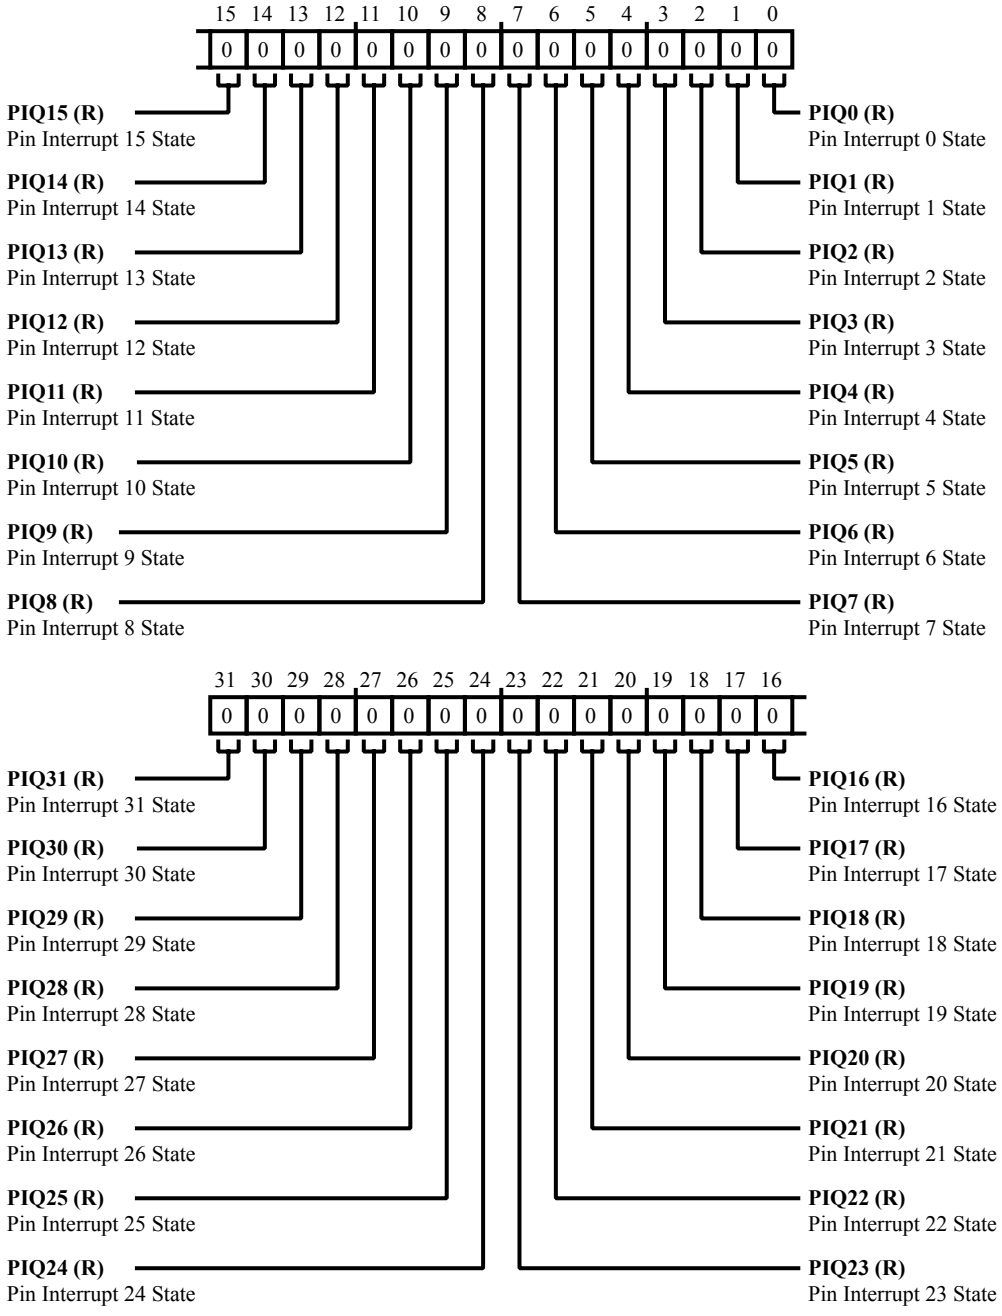

Figure 12-34: PINT_PINSTATE Register Diagram

Table 12-40: PINT_PINSTATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	PIQ31	Pin Interrupt 31 State. A read of the `PINT_PINSTATE.PIQ31` bit returns the pin state.

Table 12-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	PIQ30	Pin Interrupt 30 State. A read of the PINT_PINSTATE.PIQ30 bit returns the pin state.
29 (R/NW)	PIQ29	Pin Interrupt 29 State. A read of the PINT_PINSTATE.PIQ29 bit returns the pin state.
28 (R/NW)	PIQ28	Pin Interrupt 28 State. A read of the PINT_PINSTATE.PIQ28 bit returns the pin state.
27 (R/NW)	PIQ27	Pin Interrupt 27 State. A read of the PINT_PINSTATE.PIQ27 bit returns the pin state.
26 (R/NW)	PIQ26	Pin Interrupt 26 State. A read of the PINT_PINSTATE.PIQ26 bit returns the pin state.
25 (R/NW)	PIQ25	Pin Interrupt 25 State. A read of the PINT_PINSTATE.PIQ25 bit returns the pin state.
24 (R/NW)	PIQ24	Pin Interrupt 24 State. A read of the PINT_PINSTATE.PIQ24 bit returns the pin state.
23 (R/NW)	PIQ23	Pin Interrupt 23 State. A read of the PINT_PINSTATE.PIQ23 bit returns the pin state.
22 (R/NW)	PIQ22	Pin Interrupt 22 State. A read of the PINT_PINSTATE.PIQ22 bit returns the pin state.
21 (R/NW)	PIQ21	Pin Interrupt 21 State. A read of the PINT_PINSTATE.PIQ21 bit returns the pin state.
20 (R/NW)	PIQ20	Pin Interrupt 20 State. A read of the PINT_PINSTATE.PIQ20 bit returns the pin state.
19 (R/NW)	PIQ19	Pin Interrupt 19 State. A read of the PINT_PINSTATE.PIQ19 bit returns the pin state.
18 (R/NW)	PIQ18	Pin Interrupt 18 State. A read of the PINT_PINSTATE.PIQ18 bit returns the pin state.
17 (R/NW)	PIQ17	Pin Interrupt 17 State. A read of the PINT_PINSTATE.PIQ17 bit returns the pin state.
16 (R/NW)	PIQ16	Pin Interrupt 16 State. A read of the PINT_PINSTATE.PIQ16 bit returns the pin state.
15 (R/NW)	PIQ15	Pin Interrupt 15 State. A read of the PINT_PINSTATE.PIQ15 bit returns the pin state.

Table 12-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PIQ14	Pin Interrupt 14 State. A read of the PINT_PINSTATE.PIQ14 bit returns the pin state.
13 (R/NW)	PIQ13	Pin Interrupt 13 State. A read of the PINT_PINSTATE.PIQ13 bit returns the pin state.
12 (R/NW)	PIQ12	Pin Interrupt 12 State. A read of the PINT_PINSTATE.PIQ12 bit returns the pin state.
11 (R/NW)	PIQ11	Pin Interrupt 11 State. A read of the PINT_PINSTATE.PIQ11 bit returns the pin state.
10 (R/NW)	PIQ10	Pin Interrupt 10 State. A read of the PINT_PINSTATE.PIQ10 bit returns the pin state.
9 (R/NW)	PIQ9	Pin Interrupt 9 State. A read of the PINT_PINSTATE.PIQ9 bit returns the pin state.
8 (R/NW)	PIQ8	Pin Interrupt 8 State. A read of the PINT_PINSTATE.PIQ8 bit returns the pin state.
7 (R/NW)	PIQ7	Pin Interrupt 7 State. A read of the PINT_PINSTATE.PIQ7 bit returns the pin state.
6 (R/NW)	PIQ6	Pin Interrupt 6 State. A read of the PINT_PINSTATE.PIQ6 bit returns the pin state.
5 (R/NW)	PIQ5	Pin Interrupt 5 State. A read of the PINT_PINSTATE.PIQ5 bit returns the pin state.
4 (R/NW)	PIQ4	Pin Interrupt 4 State. A read of the PINT_PINSTATE.PIQ4 bit returns the pin state.
3 (R/NW)	PIQ3	Pin Interrupt 3 State. A read of the PINT_PINSTATE.PIQ3 bit returns the pin state.
2 (R/NW)	PIQ2	Pin Interrupt 2 State. A read of the PINT_PINSTATE.PIQ2 bit returns the pin state.
1 (R/NW)	PIQ1	Pin Interrupt 1 State. A read of the PINT_PINSTATE.PIQ1 bit returns the pin state.
0 (R/NW)	PIQ0	Pin Interrupt 0 State. A read of the PINT_PINSTATE.PIQ0 bit returns the pin state.

PINT Request Register

The PINT_REQ register indicates the interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

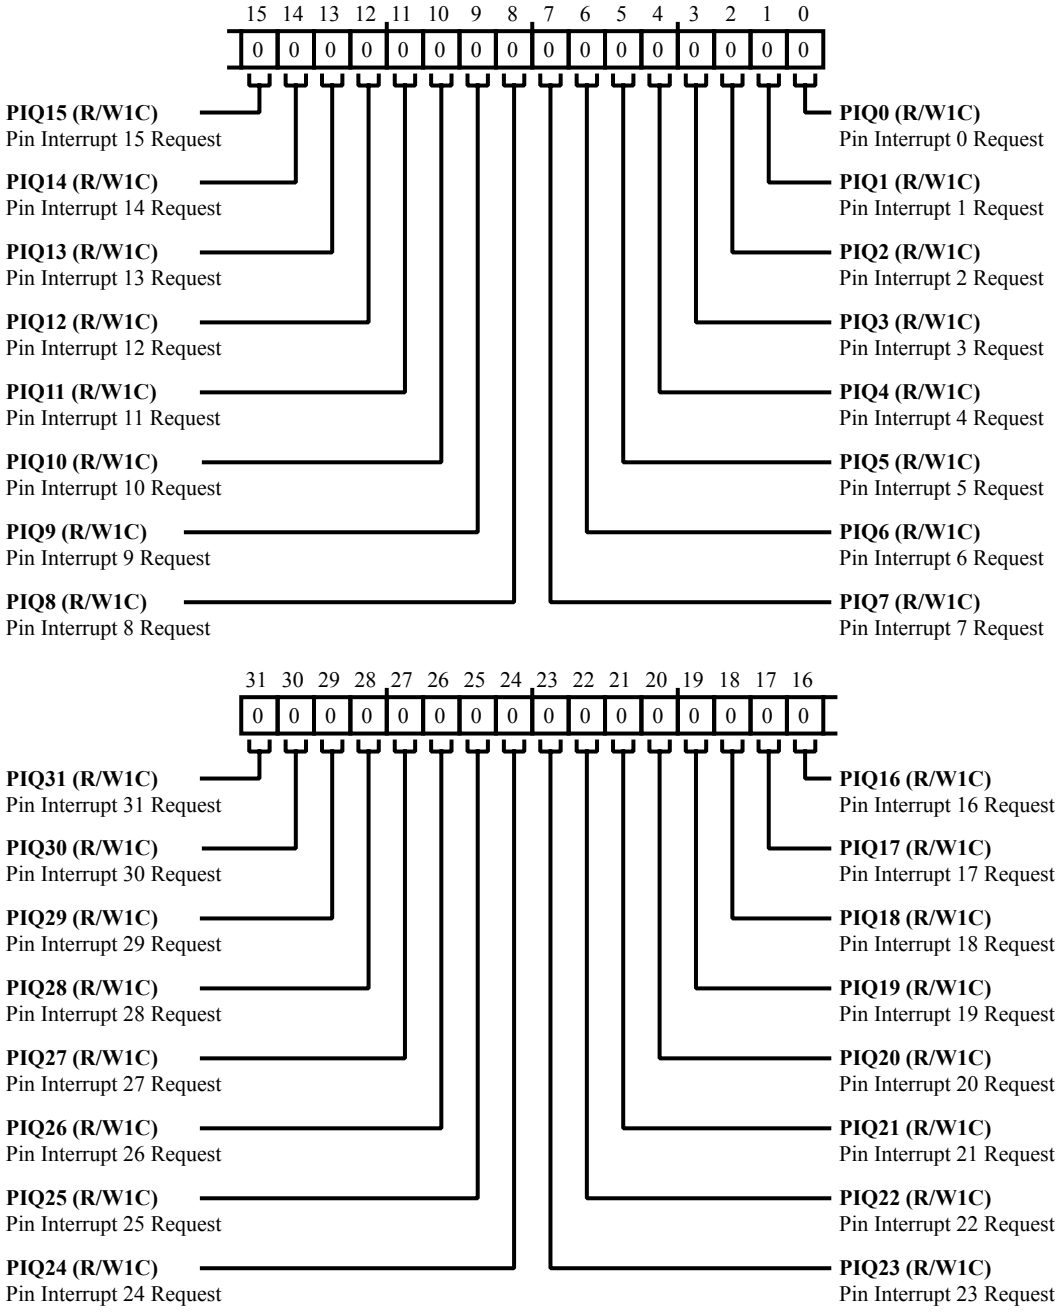

Figure 12-35: PINT_REQ Register Diagram

Table 12-41: PINT_REQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Request. If the `PINT_REQ.PIQ31` bit is set, a request is pending.

Table 12-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Request. If the PINT_REQ.PIQ30 bit is set, a request is pending.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Request. If the PINT_REQ.PIQ29 bit is set, a request is pending.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Request. If the PINT_REQ.PIQ28 bit is set, a request is pending.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Request. If the PINT_REQ.PIQ27 bit is set, a request is pending.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Request. If the PINT_REQ.PIQ26 bit is set, a request is pending.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Request. If the PINT_REQ.PIQ25 bit is set, a request is pending.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Request. If the PINT_REQ.PIQ24 bit is set, a request is pending.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Request. If the PINT_REQ.PIQ23 bit is set, a request is pending.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Request. If the PINT_REQ.PIQ22 bit is set, a request is pending.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Request. If the PINT_REQ.PIQ21 bit is set, a request is pending.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Request. If the PINT_REQ.PIQ20 bit is set, a request is pending.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Request. If the PINT_REQ.PIQ19 bit is set, a request is pending.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Request. If the PINT_REQ.PIQ18 bit is set, a request is pending.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Request. If the PINT_REQ.PIQ17 bit is set, a request is pending.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Request. If the PINT_REQ.PIQ16 bit is set, a request is pending.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Request. If the PINT_REQ.PIQ15 bit is set, a request is pending.

Table 12-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Request. If the `PINT_REQ.PIQ14` bit is set, a request is pending.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Request. If the `PINT_REQ.PIQ13` bit is set, a request is pending.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Request. If the `PINT_REQ.PIQ12` bit is set, a request is pending.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Request. If the `PINT_REQ.PIQ11` bit is set, a request is pending.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Request. If the `PINT_REQ.PIQ10` bit is set, a request is pending.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Request. If the `PINT_REQ.PIQ9` bit is set, a request is pending.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Request. If the `PINT_REQ.PIQ8` bit is set, a request is pending.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Request. If the `PINT_REQ.PIQ7` bit is set, a request is pending.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Request. If the `PINT_REQ.PIQ6` bit is set, a request is pending.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Request. If the `PINT_REQ.PIQ5` bit is set, a request is pending.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Request. If the `PINT_REQ.PIQ4` bit is set, a request is pending.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Request. If the `PINT_REQ.PIQ3` bit is set, a request is pending.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Request. If the `PINT_REQ.PIQ2` bit is set, a request is pending.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Request. If the `PINT_REQ.PIQ1` bit is set, a request is pending.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Request. If the `PINT_REQ.PIQ0` bit is set, a request is pending.

ADSP-2159x_SC591_SC592_SC594 PADS Register Descriptions

Pads Controller (PADS) contains the following registers.

Table 12-42: ADSP-2159x_SC591_SC592_SC594 PADS Register List

Name	Description
PADS_DAI0_0_DS	DAI0 1 to 10 pins DS control
PADS_DAI0_1_DS	DAI0 11 to 20 pins DS control
PADS_DAI0_IE	DAI0 Port Input Enable Control Register
PADS_DAI1_0_DS	DAI1 1 to 10 pins DS control
PADS_DAI1_1_DS	DAI1 11 to 20 pins DS control
PADS_DAI1_IE	DAI1 Port Input Enable Control Register
PADS_DAI[n]_PDE	DAIx Pull-Down Enable
PADS_DAI[n]_PUE	DAIx Pull-Up Enable
PADS_NONPORTS_DS	Non-GPIO Drive Strength Register
PADS_PCFG0	Peripheral PAD Configuration0 Register
PADS_PCFG1	Peripheral Configuration1 Register
PADS_PORTA0_DS	PORTA 0 to 7 pins DS control
PADS_PORTA1_DS	PORTA 8 - 15 pins DS control
PADS_PORTB0_DS	PORTB 0 to 7 pins DS control
PADS_PORTB1_DS	PORTB 8 - 15 pins DS control
PADS_PORTC0_DS	PORTC 0 to 7 pins DS control
PADS_PORTC1_DS	PORTC 8 - 15 pins DS control
PADS_PORTD0_DS	PORTD 0 to 7 pins DS control
PADS_PORTD1_DS	PORTD 8 to 15 pins DS control
PADS_PORTE0_DS	PORTE 0 to 7 pins DS control
PADS_PORTE1_DS	PORTE 8 to 15 pins DS control
PADS_PORTF0_DS	PORTF 0 to 7 pins DS control
PADS_PORTF1_DS	PORTF 8 to 15 pins DS control
PADS_PORTG0_DS	PORTG 0 to 7 pins DS control
PADS_PORTG1_DS	PORTG 8 to 15 pins DS control
PADS_PORTH0_DS	PORTH 0 to 7 pins DS control
PADS_PORTH1_DS	PORTH 8 to 15 pins DS control
PADS_PORTI0_DS	PORTI 0 to 7 pins DS control
PADS_PORT[n]_PDE	PORTx Pull-Down Enable

Table 12-42: ADSP-2159x_SC591_SC592_SC594 PADS Register List (Continued)

Name	Description
PADS_PORT[n]_PUE	PORTx Pull-Up Enable

DAI0 1 to 10 pins DS control

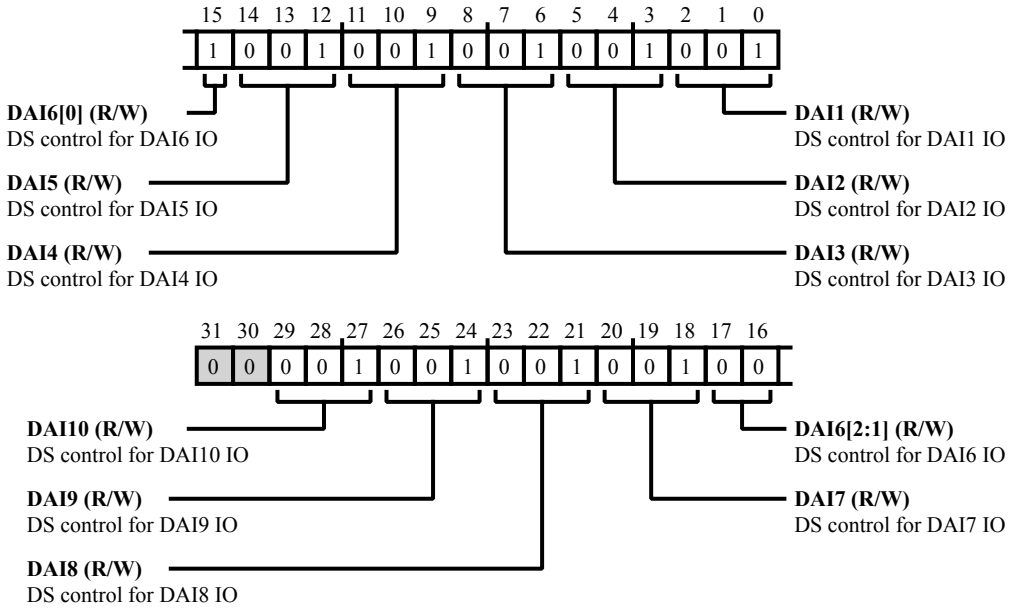

Figure 12-36: PADS_DAI0_0_DS Register Diagram

Table 12-43: PADS_DAI0_0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:27 (R/W)	DAI10	DS control for DAI10 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010. To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
26:24 (R/W)	DAI9	DS control for DAI9 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-43: PADS_DAI0_0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	DAI8	DS control for DAI8 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
20:18 (R/W)	DAI7	DS control for DAI7 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
17:15 (R/W)	DAI6	DS control for DAI6 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
14:12 (R/W)	DAI5	DS control for DAI5 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	DAI4	DS control for DAI4 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-43: PADS_DAI0_0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8:6 (R/W)	DAI3	DS control for DAI3 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	DAI2	DS control for DAI2 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	DAI1	DS control for DAI1 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	DAI12	DS control for DAI12 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	DAI11	DS control for DAI11 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

DAI1 Port Input Enable Control Register

The PADS_DAI1_IE register configures input enable control of the DAI1 (20 pins) pads. If =0 implies input buffer disable and if =1 implies enable.

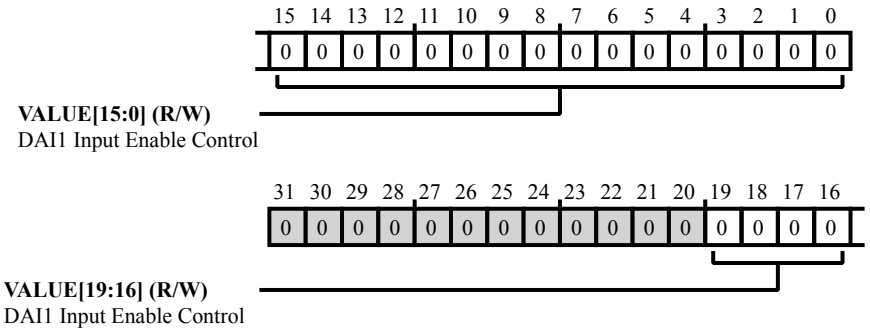

Figure 12-41: PADS_DAI1_IE Register Diagram

Table 12-48: PADS_DAI1_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	VALUE	DAI1 Input Enable Control.

DAIx Pull-Down Enable

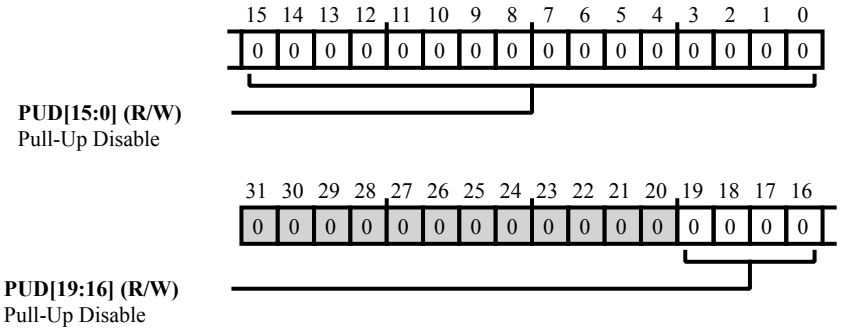

Figure 12-42: PADS_DAI[n]_PDE Register Diagram

Table 12-49: PADS_DAI[n]_PDE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PUD	Pull-Up Disable.

DAIx Pull-Up Enable

The PADS_DAI[n]_PUE register enables the pull-up resistor for DAI pins.

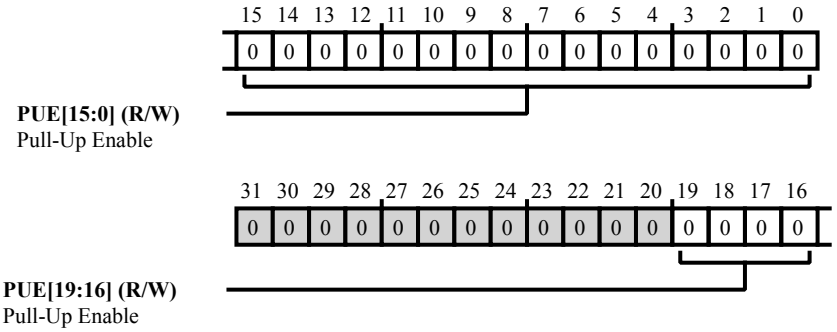

Figure 12-43: PADS_DAI[n]_PUE Register Diagram

Table 12-50: PADS_DAI[n]_PUE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PUE	Pull-Up Enable.

Non-GPIO Drive Strength Register

The PADS_NONPORTS_DS register sets the drive strength and tolerance for the non-GPIO pins. The drive strength is only controlled for pin groups classified by the interface type.

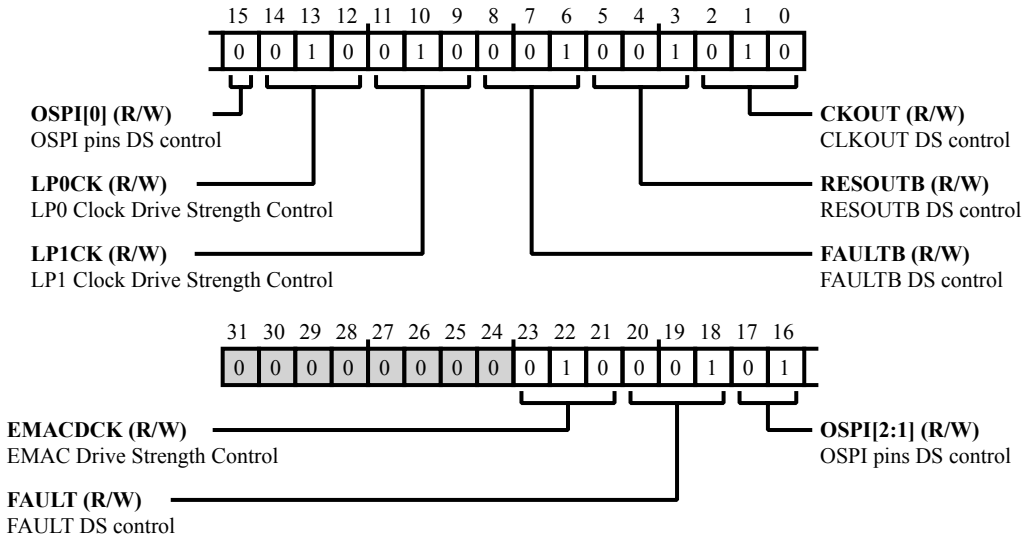

Figure 12-44: PADS_NONPORTS_DS Register Diagram

Table 12-51: PADS_NONPORTS_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	EMACDCK	EMAC Drive Strength Control.	
20:18 (R/W)	FAULT	FAULT DS control.	
17:15 (R/W)	OSPI	OSPI pins DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-51: PADS_NONPORTS_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	LP0CK	LP0 Clock Drive Strength Control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	LP1CK	LP1 Clock Drive Strength Control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
8:6 (R/W)	FAULTB	FAULTB DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	RESOUTB	RESOUTB DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	CKOUT	CLKOUT DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Peripheral PAD Configuration0 Register

The PADS_PCFG0 register provides several configuration options for the pads and multiplexing for peripherals.

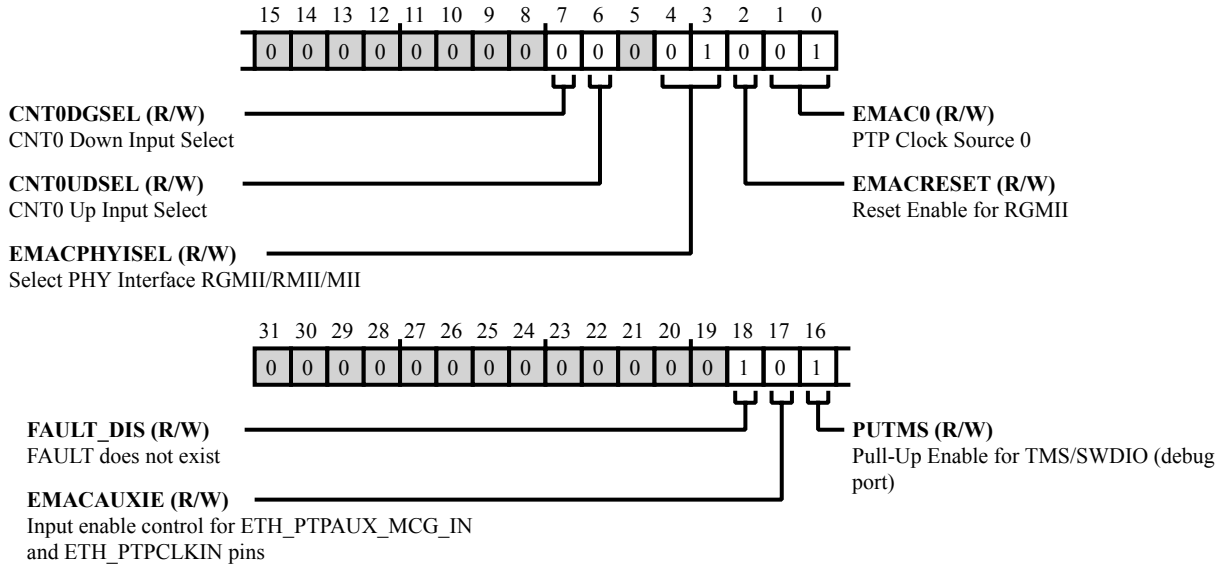

Figure 12-45: PADS_PCFG0 Register Diagram

Table 12-52: PADS_PCFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	FAULT_DIS	FAULT does not exist.	
		0	Disable input
		1	Enable input
17 (R/W)	EMACAUXIE	Input enable control for ETH_PTPAUX_MCG_IN and ETH_PTPCLKIN pins.	
		0	Disable input
		1	Enable input
16 (R/W)	PUTMS	Pull-Up Enable for TMS/SWDIO (debug port).	
		0	Disable pull-up
		1	Enable pull-up
7 (R/W)	CNT0DGSEL	CNT0 Down Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter down and gate.	
		0	GPIO port pins
		1	Trigger connection

Table 12-52: PADS_PCFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CNT0UDSEL	CNT0 Up Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter up and direction.	
		0	GPIO port pins
		1	Trigger connection
4:3 (R/W)	EMACPHYISEL	Select PHY Interface RGMII/RMII/MII.	
		0	MII Interface Selects PHY Interface MII
		1	RGMII Interface Selects PHY Interface RGMII
		2	RMII Interface Selects PHY Interface RMII
		3	Reserved
2 (R/W)	EMACRESET	Reset Enable for RGMII. The PADS_PCFG0.EMACRESET bit asserts the reset on the RGMII interface. To select the PHY interface (RGMII or RMII), set the EMACPHYISEL bit as required and then set PADS_PCFG0.EMACRESET.	
		0	RGMII reset is asserted
		1	RGMII reset reset is deasserted
1:0 (R/W)	EMAC0	PTP Clock Source 0. The PADS_PCFG0.EMAC0 selects the clock source for the PTP Block in EMAC0.	
		0	REFCLK (MII or RMII) or CLKO7 (RGMII)
		1	SCLK0
		2	External PTP clock
		3	SCLK0

Peripheral Configuration1 Register

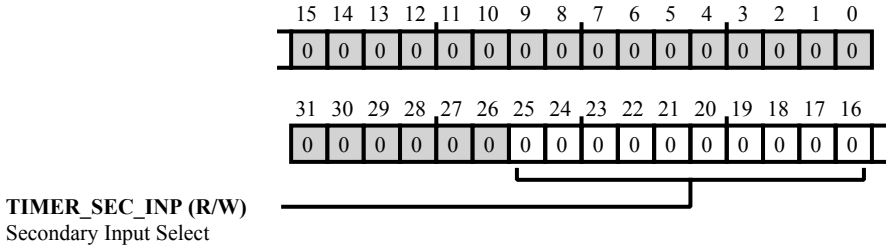

Figure 12-46: PADS_PCFG1 Register Diagram

Table 12-53: PADS_PCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25:16 (R/W)	TIMER_SEC_INP	Secondary Input Select. The `PADS_PCFG1.TIMER_SEC_INP` field selects secondary inputs to timers. '0' on each bit selects (PB_02, PA_02, PA_08, PA_06, PA_11, PB_00, PB_11, PA_14, PA_07, PB_01), '1' on each bit selects (PE_03, PG_09, PG10, PI_05, PF15, PG04, PD_10, PD_04, PD_08, PF_05) respectively on (TIMER0_ACLK4, TIMER0_ACLK3, TIMER0_ACLK2, TIMER0_ACLK1,TIMER0_ACI4, TIMER0_ACI3, TIMER0_ACI2, TIMER0_ACI1, TIMER0_ACI0, TIMER0_CLK)	
		1	bit[0] is '0' then source for TIMER0_CLK is PB_01 else PF_05
		2	bit[1] is '0' then source for TIMER0_ACI0 is PA_07 else PD_08
		4	bit[2] is '0' then source for TIMER0_ACI1 is PA_14 else PD_04
		8	bit[3] is '0' then source for TIMER0_ACI2 is PB_11 else PD_10
		16	bit[4] is '0' then source for TIMER0_ACI3 is PB_00 else PG_04
		32	bit[5] is '0' then source for TIMER0_ACI4 is PA_11 else PF_15
		64	bit[6] is '0' then source for TIMER0_ACLK1 is PA_06 else PG_09
		128	bit[7] is '0' then source for TIMER0_ACLK2 is PA_08 else PI_05
		256	bit[8] is '0' then source for TIMER0_ACLK3 is PA_02 else PG_10

Table 12-53: PADS_PCFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		512	bit[9] is '0' then source for TIMER0_ACLK4 is PB_02 else PE_03

PORTA 0 to 7 pins DS control

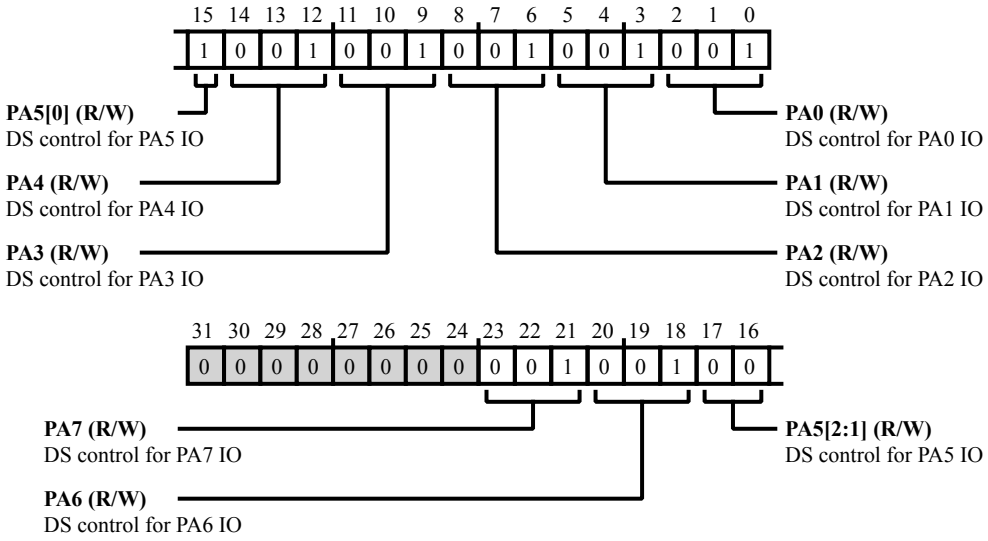

Figure 12-47: PADS_PORTA0_DS Register Diagram

Table 12-54: PADS_PORTA0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	PA7	DS control for PA7 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
20:18 (R/W)	PA6	DS control for PA6 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-54: PADS_PORTA0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	PA5	DS control for PA5 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
14:12 (R/W)	PA4	DS control for PA4 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	PA3	DS control for PA3 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
8:6 (R/W)	PA2	DS control for PA2 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	PA1	DS control for PA1 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-54: PADS_PORTA0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	PA0	DS control for PA0 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

PORTA 8 - 15 pins DS control

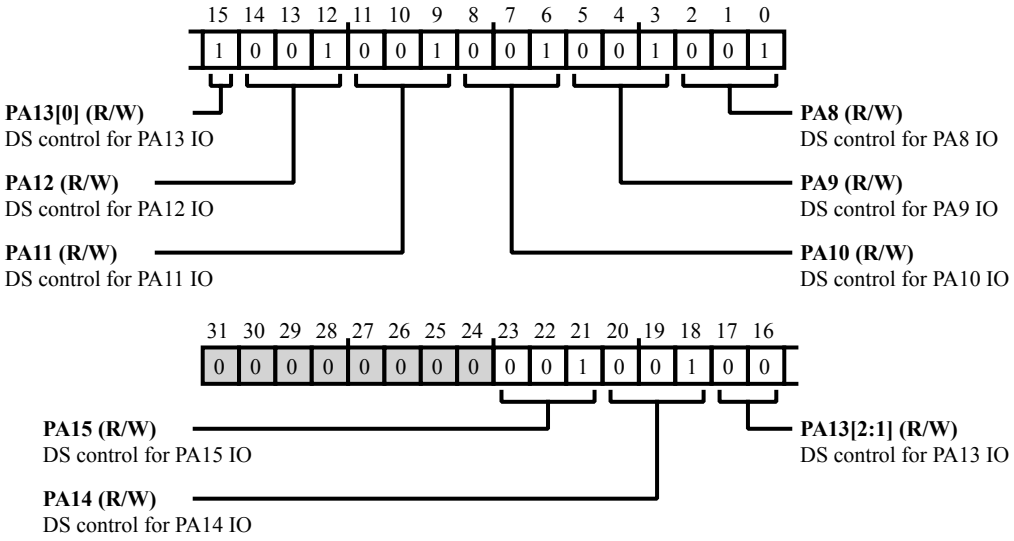

Figure 12-48: PADS_PORTA1_DS Register Diagram

Table 12-55: PADS_PORTA1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	PA15	DS control for PA15 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
20:18 (R/W)	PA14	DS control for PA14 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-55: PADS_PORTA1_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	PA13	DS control for PA13 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
14:12 (R/W)	PA12	DS control for PA12 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	PA11	DS control for PA11 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
8:6 (R/W)	PA10	DS control for PA10 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	PA9	DS control for PA9 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 12-55: PADS_PORTA1_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	PA8	DS control for PA8 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

PORTB 0 to 7 pins DS control

13 Thermal Monitoring Unit (TMU)

The TMU provides on-chip temperature measurement which is important in applications that have substantial power consumption. The TMU is integrated into the processor die and digital infrastructure using an MMR-based system access to measure the die temperature variations in real-time.

TMU Features

The TMU supports the following features:

- On-chip temperature sensing
- Programmable over-temperature and under-temperature limits
- Programmable conversion rate
- Averaging feature available
- Temperature gain and offset correction options
- Uses dedicated channel of HADC for conversion
- Programmable blanking and refresh period for TMU conversion

TMU Functional Description

Following sections provide the functional description of TMU.

TMU Definitions

The following definitions are helpful when using the TMU module.

Thermal Diode

A special type of diode whose electrical properties change with the temperature in a defined way.

DTM

Dynamic thermal management is a set of techniques that adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints.

TMU Block Diagram

The ***Thermal Monitoring Unit Block Diagram*** shows the main block inside TMU.

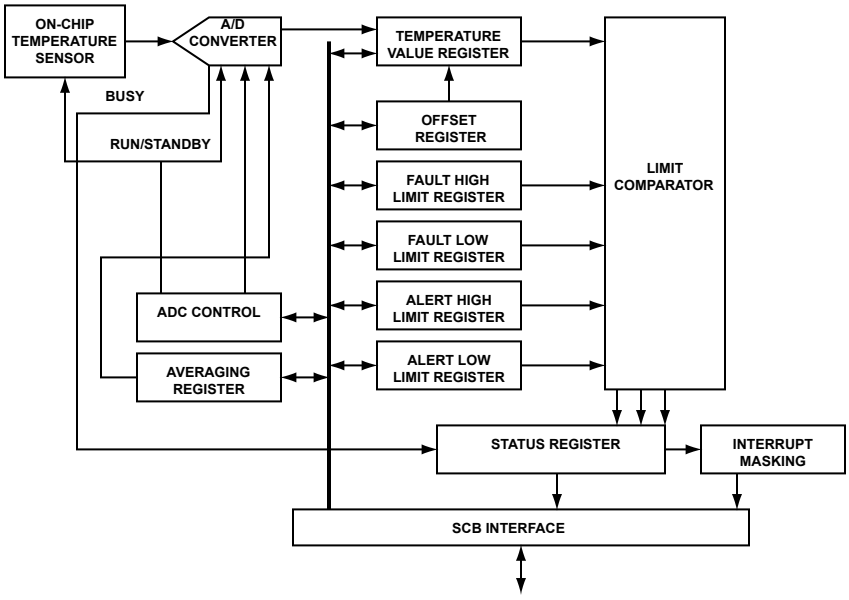

Figure 13-1: Thermal Monitoring Unit Block Diagram

TMU Architectural Concepts

The following sections provide information on the architecture and system integration of the TMU.

System Integration

Dynamic thermal management (DTM) techniques adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints. One of the most important aspects of DTM is to capture the run-time variations in the temperature caused by power consumption variations due to workload changes.

The accuracy of thermal measurements directly affects the efficiency of thermal management as well as the performance of the processor. Temperature estimations lower or higher than the actual temperature may cause late or early activation of DTM techniques.

- Late activation of DTM can result in degraded reliability because the temperature may exceed the designated thresholds.
- Early activation of DTM can have significant impact on performance.

The TMU is an analog thermal sensor that consists of a temperature-sensing diode, a calibrated reference current source, and a current comparator. The sensor placement error is one of the most important sources of inaccuracy in values obtained from thermal sensors.

The TMU module provides the temperature monitoring capability to the chip and implements thermal management in the end system. It provides many features which ensure the minimum load on the software and also minimal or no external components for a flexible temperature monitoring system.

Digital Thermometer

The TMU functions as a digital thermometer with an MMR-based system access. The on-die temperature value is measured and digitized through an A/D converter. The temperature value is stored and updated periodically in an MMR register. The TMU can be configured to generate an interrupt as it crosses the upper temperature limit (`TMU_FLT_LIM_HI` register). A thermal event is also routed to the interrupt port of the sensor. The event is then routed to the SEC, to ensure that core intervention is not required in the event of overheating.

Temperature Sensor Averaging

The temperature sensor averaging feature enhances the accuracy of the temperature measurements. To enable this feature, the `TMU_AVG` bits must be enabled in the control register after power-up. In this mode, the averaging reduces the effect of noise on the temperature result. The temperature is measured each time a conversion is performed. A moving average method is used to determine the result in the temperature value register. The total time to measure a temperature channel is typically 1 ms.

TMU and HADC

The TMU modules uses one of the ADC channels to digitize the temperature reading. Therefore, the HADC module is shared by the TMU. If the TMU is not enabled, the HADC operates at its full throughput. TMU can be enabled periodically or permanently. In periodic enable mode, it is enabled once in a specific refresh period. After enabling, the TMU measures the temperature for a specific blanking period. During the blanking period, the TMU uses the ADC for temperature measurement, so that the ADC is not available for data conversion.

The typical value of blanking period is 21×10^4 system clock (SCLK0) cycles

The typical value of refresh period is 21×10^6 SCLK0 cycles

So, for every 21×10^6 cycles, 21×10^4 cycles are used for temperature measurement. Program these values for blanking period and refresh period through the TMU registers.

When TMU is enabled, the HADC modules is not available for external input conversion. This state is indicated by the `HADC_STAT.TMUHADC_BUSY` status bit. All the requests for HADC conversion are ignored when `HADC_STAT.TMUHADC_BUSY` bit is high.

In the periodic enable mode, the ongoing HADC conversion is completed activating the TMU to measure temperature as shown. If HADC is in autoscan mode, the TMU is activated after completing the ongoing sequence. If HADC is in fixed-conversion mode, all the fixed conversions are completed and followed by TMU activation.

TMU Event Control

The TMU generates different events depending on the state of the TMU temperature measurement and the different thresholds set in thresh hold registers. These events are reported in the TMU_STAT register as shown below. It can generate an event for each of following conditions.

- The fault high limit is configured in the TMU_FLT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The alert high limit is configured in the TMU_ALRT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The fault low limit is configured in the TMU_FLT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.
- The alert low limit is configured in the TMU_ALRT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.

Interrupts and status conditions can be masked (disabled) or unmasked (enabled) by setting and clearing bits in the TMU_IMSK register.

NOTE: Only TMU_FLT_LIM_HI and TMU_ALRT_LIM_HI generate an interrupt to core. Other events only result in status change in the TMU_STAT register.

Status and Error Signals

When the measured temperature value exceeds the high or low limits that are configured in the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and the TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers, corresponding thermal events are triggered.

The fault and alert events are sent to the core through the status register (TMU_STAT). Both the TMU_STAT.FLTHI and TMU_STAT.ALRTHI bits are sticky bits and are cleared by a W1C operation by the core.

The alert and fault registers can be programmed through the MMR bus interface as shown in the TMU block diagram. A write into the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers or the TMU_TEMP register is not allowed when the events are being triggered.

TMU Programming Guidelines

The following section provides basic programming information for the TMU module.

To get the best performance and accuracy from the TMU, intialize the TMU_GAIN, TMU_OFFSET and TMU_AVG registers before enabling the module. Contact Analog Devices, Inc for the current best values to use.

After these registers are programmed, the rest of the TMU initialization can take place. This includes setting up the fault and alert limits and then enabling the TMU.

ADSP-2159x_SC591_SC592_SC594 TMU Register Descriptions

Thermal monitoring unit (TMU) contains the following registers.

Table 13-5: ADSP-2159x_SC591_SC592_SC594 TMU Register List

Name	Description
TMU_ALRT_LIM_HI	Alert High Limit Register
TMU_ALRT_LIM_LO	Alert Low Limit Register
TMU_AVG	Averaging Register
TMU_CNV_BLANK	Temperature conversion blank register
TMU_CTL	TMU Control Register
TMU_FLT_LIM_HI	Fault High Limit Register
TMU_FLT_LIM_LO	Fault Low Limit Register
TMU_GAIN	Gain Value Register
TMU_IMSK	Interrupt Mask Register
TMU_OFFSET	Offset Register
TMU_REFR_CNTR	Temperature Refresh Counter
TMU_STAT	Status Register
TMU_TEMP	Temperature Value Register

Alert High Limit Register

The TMU_ALRT_LIM_HI register sets the temperature alert high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.ALRTHI if the TMU_TEMP value is greater than or equal to TMU_ALRT_LIM_HI. The TMU_ALRT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).

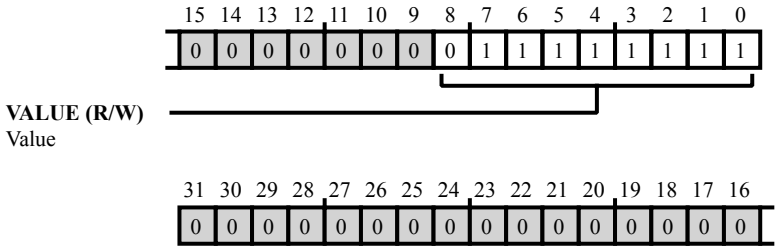

Figure 13-2: TMU_ALRT_LIM_HI Register Diagram

Table 13-6: TMU_ALRT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_ALRT_LIM_HI.VALUE bit field configures the alert temperature high limit as an integer value stored in two's complement format. If the temperature value is greater than or equal to the high-limit the TMU_STAT.ALRTHI bit is set.

Alert Low Limit Register

The TMU_ALRT_LIM_LO register configures the alert temperature low limit.

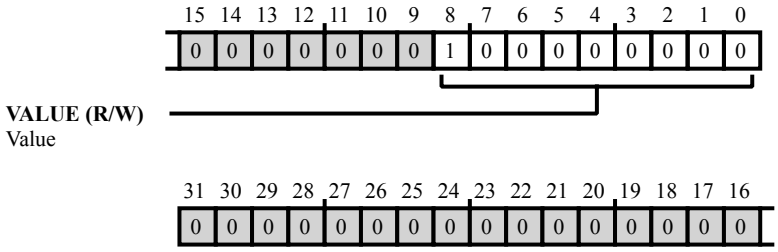

Figure 13-3: TMU_ALRT_LIM_LO Register Diagram

Table 13-7: TMU_ALRT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_ALRT_LIM_LO.VALUE bit field configures the alert temperature low limit as an integer value stored in two's complement format. If the temperature value is less than or equal to the low-limit the TMU_STAT.ALRTLO bit is set.

Averaging Register

The TMU_AVG register enables averaging on the TMU.

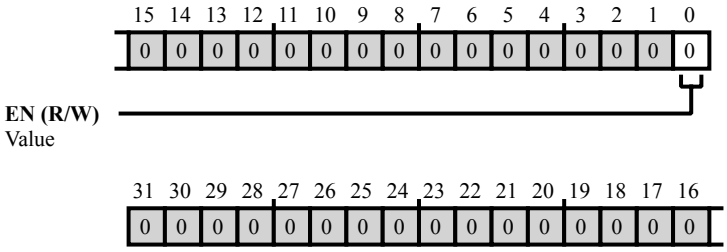

Figure 13-4: TMU_AVG Register Diagram

Table 13-8: TMU_AVG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Value. The TMU_AVG.EN bit enables averaging on the TMU. Averaging is done using the formula (7 x previous_avg_value + current_value)/8. Initially the current_value is taken as previous_avg_value.	
		0	No averaging
		1	Enable averaging

Temperature conversion blank register

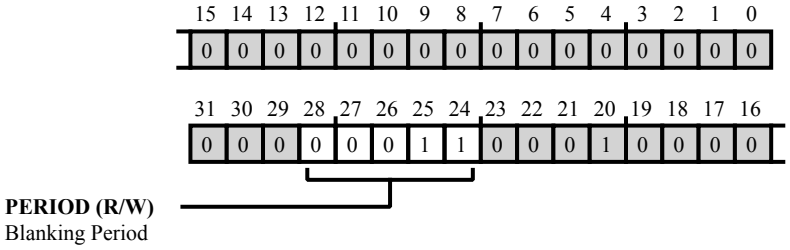

Figure 13-5: TMU_CNV_BLANK Register Diagram

Table 13-9: TMU_CNV_BLANK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:24 (R/W)	PERIOD	Blanking Period. The `TMU_CNV_BLANK.PERIOD` specifies the blanking period. TMU uses the HADC for temperature conversion during this period. The conversion time is calculated as: (CNV_BLANK+1)*50k SCLK cycles. So, the minimum conversion time is 50k SCLK cycles. Default conversion time is 20*10^4 SCLK cycles. For this duration, the system cannot use HADC for data conversion and HADC does take input for data-conversion. The status is indicated by TMUHADC_BUSY bit of the HADC block.

TMU Control Register

The TMU_CTL register contains bits that allow programs to configure and enable the TMU.

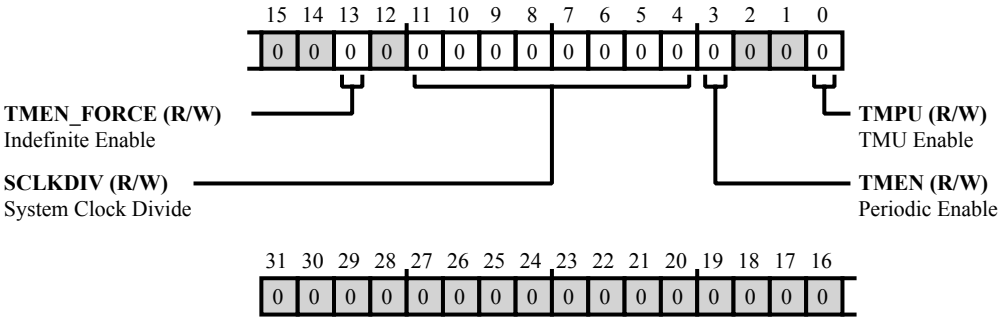

Figure 13-6: TMU_CTL Register Diagram

Table 13-10: TMU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TMEN_FORCE	Indefinite Enable. Asserting the TMU_CTL.TMEN_FORCE bit enables the TMU indefinitely. HADC is always used by the TMU, so the HADC cannot be used to convert channel inputs.	
11:4 (R/W)	SCLKDIV	System Clock Divide. The TMU_CTL.SCLKDIV bit selects the division ratio for the system clock (SCLK). SCLK is divided by (21+4*SCLKDIV). Thus, by default the SCLK is divided by 21.	
3 (R/W)	TMEN	Periodic Enable. Asserting the TMU_CTL.TMEN bit enables the TMU periodically. TMU is enabled once in every refresh period defined by the TMU_REFR_CNTR register. And in each refresh period, TMU measures temperature for the blanking period (Tblank). It is defined by CNV_BLANK bit.	
		0	Disable TMU
		1	Enable TMU periodically
0 (R/W)	TMPU	TMU Enable. The TMU_CTL.TMPU bit enables the TMU. By default, the module is in power-down mode. The peripheral interface is active even in power-down mode (the TMU registers can be read/written).	
		0	Power Down the analog circuitry of TMU
		1	Power Up the analog circuitry of TMU

Fault High Limit Register

The TMU_FLT_LIM_HI register sets the temperature fault high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.FLTHI if the TMU_TEMP value is greater than or equal to TMU_FLT_LIM_HI. The TMU_FLT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).

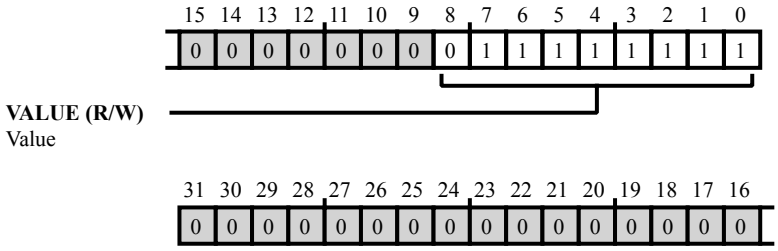

Figure 13-7: TMU_FLT_LIM_HI Register Diagram

Table 13-11: TMU_FLT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_HI.VALUE bit field sets the temperature high limit as an integer in two's complement format. If the limit value is greater than or equal to the high-limit the TMU_STAT.FLTHI bit is set.

Fault Low Limit Register

The TMU_FLT_LIM_LO register configures the fault temperature low limit.

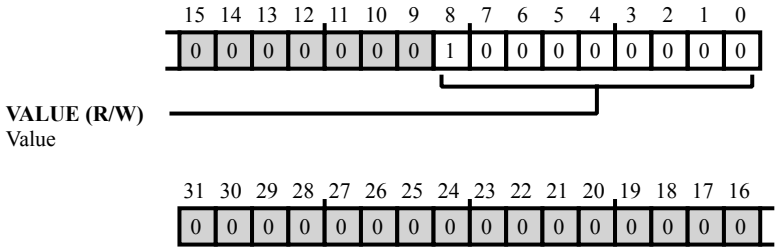

Figure 13-8: TMU_FLT_LIM_LO Register Diagram

Table 13-12: TMU_FLT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_LO.VALUE bit field configures the fault temperature low limit as an integer which is stored in two's complement format. If the temperature value is less than or equal to the low-limit, the TMU_STAT.FLTLO bit is set.

Gain Value Register

The TMU_GAIN register is used to configure the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

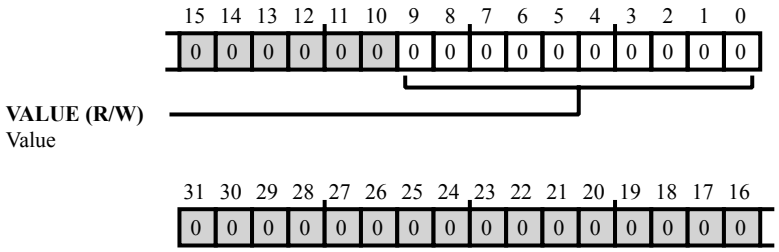

Figure 13-9: TMU_GAIN Register Diagram

Table 13-13: TMU_GAIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Value. The TMU_GAIN.VALUE bit field configures the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

Interrupt Mask Register

The TMU_IMSK register provides bit that are used to mask and unmask the interrupts associated with the TMU module.

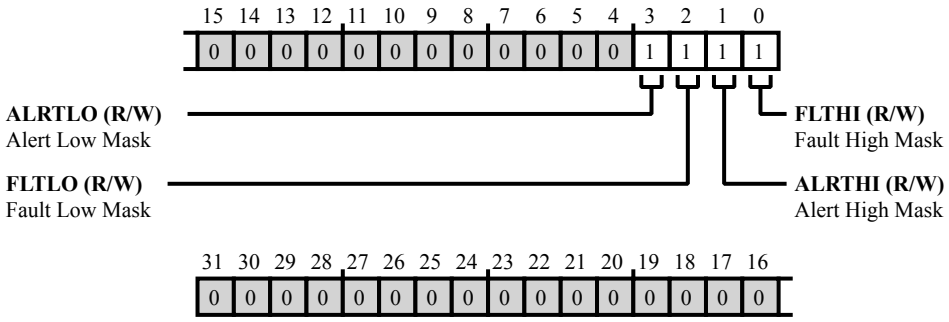

Figure 13-10: TMU_IMSK Register Diagram

Table 13-14: TMU_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ALRTLO	Alert Low Mask. The TMU_IMSK.ALRTLO bit masks or unmasks the alert low status change (TMU_STAT.ALRTLO).	
		0	Unmask alert low status change
		1	Mask alert low status change
2 (R/W)	FLTLO	Fault Low Mask. The TMU_IMSK.FLTLO bit masks or unmasks the fault low status change (TMU_STAT.FLTLO).	
		0	Unmask fault low status change
		1	Mask fault low status change
1 (R/W)	ALRTHI	Alert High Mask. The TMU_IMSK.ALRTHI bit masks or unmasks the alert high status change (TMU_STAT.ALRTHI).	
		0	Unmask alert high status change
		1	Mask alert high status change
0 (R/W)	FLTHI	Fault High Mask. The TMU_IMSK.FLTHI bit masks or unmasks the fault high interrupt (TMU_STAT.FLTHI).	
		0	Unmask fault high interrupt
		1	Mask fault high interrupt

Offset Register

The value programmed in the TMU_OFFSET register is used to correct the offset error in TMU_TEMP register.

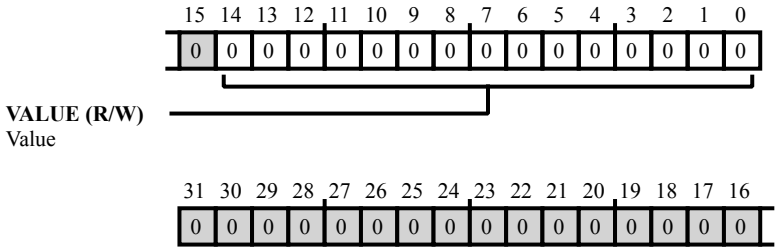

Figure 13-11: TMU_OFFSET Register Diagram

Table 13-15: TMU_OFFSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Value. The TMU_OFFSET.VALUE bit field provides the offset value which is used to correct the offset error in the TMU_TEMP register. This value is in a two's complement fixed point Q7.7 format i.e 8 MSB's represent integer part in 2's complement format. and remaining 7 LSB's represent decimal part. Offset will be applied after multiplying gain.

Temperature Refresh Counter

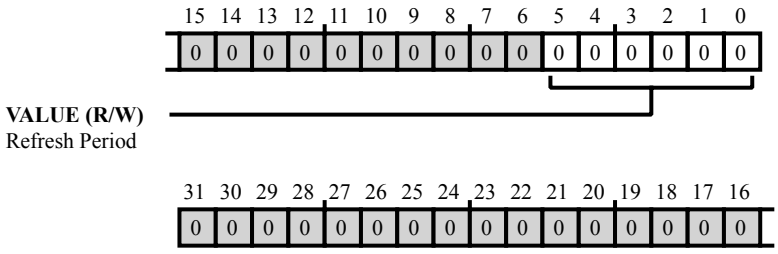

Figure 13-12: TMU_REFR_CNTR Register Diagram

Table 13-16: TMU_REFR_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	VALUE	Refresh Period. The `TMU_REFR_CNTR.VALUE` bit field defines the period to refresh the temperature value. Temperature is refreshed for every (VALUE+1)*(21+4*SCLKDIV)*1M system-clock cycles. SCLKDIV is defined in `TMU_CTL` register. So, by default, the period is 21 million system-clock cycles.

Status Register

The TMU_STAT register bits indicate when an error or fault is detected.

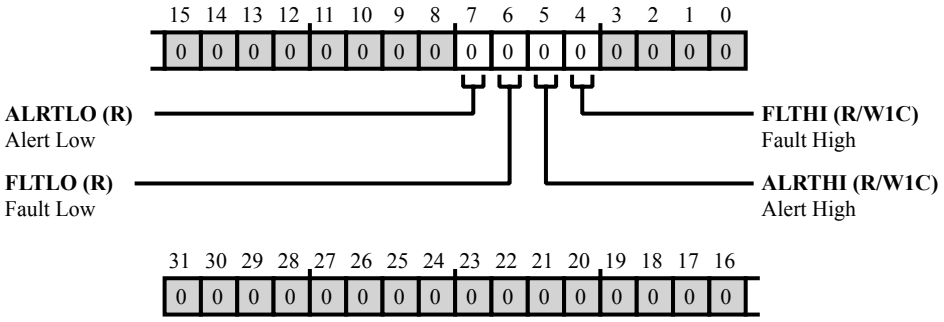

Figure 13-13: TMU_STAT Register Diagram

Table 13-17: TMU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ALRTLO	Alert Low. The TMU_STAT.ALRTLO bit is set when the temperature value is less than or equal to the setting in the TMU_ALRT_LIM_LO register. The bit assertion is masked if TMU_IMSK.ALRTLO is HIGH.
6 (R/NW)	FLTLO	Fault Low. The TMU_STAT.FLTLO bit is set when the temperature value is less than or equal to the setting in the TMU_FLT_LIM_LO register. The bit assertion is masked if TMU_IMSK.FLTLO is HIGH.
5 (R/W1C)	ALRTHI	Alert High. The TMU_STAT.ALRTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. The temperature value register is set to 16'h0D80 (effective temperature value of 27degrees C) when a W1C operation is done on this bit. The bit assertion is masked if TMU_IMSK.ALRTHI is HIGH.
4 (R/W1C)	FLTHI	Fault High. The TMU_STAT.FLTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_FLT_LIM_HI register. The temperature value register is set to 16'h0D80 (effective temperature value of 27 degrees C) when a W1C is done on this bit. The bit assertion is masked if TMU_IMSK.FLTHI is HIGH.

Temperature Value Register

The TMU_TEMP register provides the temperature value from the A/D converter and the status.

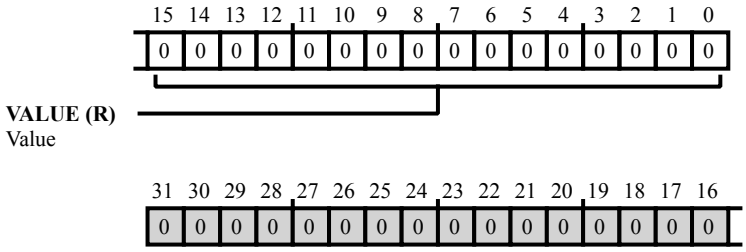

Figure 13-14: TMU_TEMP Register Diagram

Table 13-18: TMU_TEMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Value. The TMU_TEMP.VALUE bit field is the temperature value from A/D converter. This value is stored in two's complement fixed point Q8.7 format where the 9 MSB's represent the integer part in 2's complement, and the remaining 7 LSB's represent the decimal part.

14 Housekeeping ADC (HADC)

The Housekeeping ADC is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

NOTE: HADC is used by the TMU for temperature monitor, so it may be unavailable during temperature conversion. For details, refer to the TMU and HADC section.

HADC Features

The HADC supports following features:

- 12-bit ADC core with built-in sample and hold
- ENOB = 10 bit
- 8 input channels which can be extended to 15 channels by putting an external channel multiplexer
- Throughput rates up to 1 MSPS
- Single ended operation
- External reference nominal at 1.8 V
- Analog input 0 V to 1.8 V.
- Selectable ADC clock frequency through a pre-scaler
- Conversion type adaptable to each application: allows single or continuous conversion with option of auto-scan
- Four channels for the ADSP-21591 and ADSP-21593 processors
- Auto sequencing capability provides up to 8 *auto-conversions* in a single session. Each conversion can be programmed to select any of the available input channels.

HADC Functional Description

The HADC provides the analog to digital conversion capability for general-purpose housekeeping tasks, such as voltage and temperature monitoring. The core of HADC is a 12-bit SAR ADC, providing multiple analog input channels.

The HADC has the following functionality:

Fixed and continuous conversion modes

ADC converts the input channel sequence for a fixed number of times or continuously converts an input channel sequence.

Auto scanning

All the input channels can be sampled in a sequential manner.

Channel sequence programming

The sequence of a channel can be selected by programming the channel mask register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain.

ADSP-2159x_SC591_SC592_SC594 HADC Register List

The Housekeeping ADC (HADC) provides a general purpose, multi-channel successive approximation A-to-D converter. A set of registers governs HADC operations. For more information on HADC functionality, see the HADC register descriptions.

HADC Definitions

The following definitions are helpful when using the HADC module.

Auto-scan

Auto-scan is a feature which allows the multiple channels to be scanned and converted in sequence one after the other.

HADC Wakeup Time

It is the time required by the module after coming out of power down before it can start converting.

Signal-to-Noise and Distortion Ratio (SINAD)

The measured ratio of signal-to-noise and distortion at the output of the ADC. The signal is the rms amplitude of the fundamental. Noise is the sum of all non-fundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio depends on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise and distortion ratio for an ideal N-bit converter with a sine wave input is given by:

Signal-to-(Noise + Distortion) = (6.02 N + 1.76) dB

Total Harmonic Distortion (THD)

The ratio of the rms sum to the harmonics to the fundamental.

Peak Harmonic or Spurious Noise

The ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Typically, the value of this specification is determined by the largest harmonic in the spectrum, but for ADCs where the harmonics are buried in the noise floor, it is a noise peak.

Integral Nonlinearity

The maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints are zero scale, a point 1 LSB below the first code transition, and full scale, a point 1 LSB above the last code transition.

Differential Nonlinearity

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (00...000) to (00...001) from the ideal—that is, GND1 + 1 LSB.

Offset Error Match

The difference in offset error between any two channels.

Gain Error

The deviation of the last code transition (111...110) to (111...111) from the ideal (that is, REFIN – 1 LSB) after the offset error has been adjusted out.

Gain Error Matching

The difference in gain error between any two channels.

Power Supply Rejection Ratio (PSRR)

PSRR is defined as the ratio of the power in the ADC output at full-scale frequency, f, to the power of a 100 mV p-p sine wave applied to the ADC VDD supply of frequency, f_S. The frequency of the input varies from 5 kHz to 25 MHz. PSRR (dB) = 10 log(Pf/Pf_S) where: Pf is the power at frequency, f, in the ADC output. Pf_S is the power at frequency, f_S, in the ADC output.

HADC Block Diagram

The ***HADC Block Diagram*** figure shows the functional blocks within the HADC and the interface to the processor core and the peripherals. The HADC has an internal 8 channel multiplexer that is controlled by a programmable sequencer which selects the desired channel or sequence of channels.

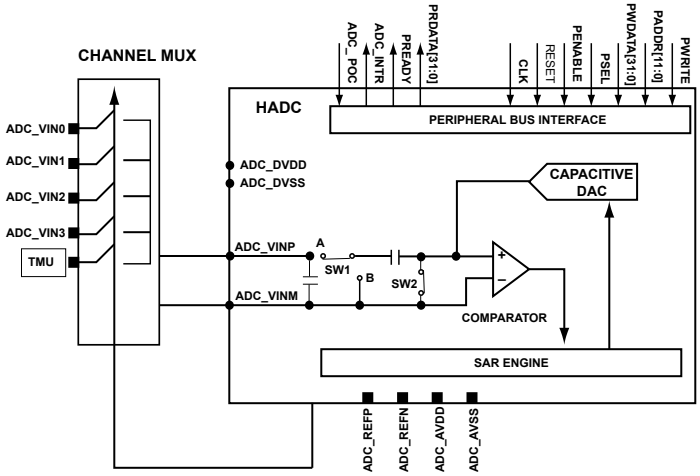

Figure 14-1: HADC Block Diagram

HADC Signal Descriptions

The ***HADC Signal Descriptions*** table provides descriptions of the signals used by the HADC.

Table 14-5: HADC Signal Descriptions

Signal Name	Signal Description
AVDD	ADC I/O supply
AVSS	I/O ground for analog blocks
VREFP	External reference for ADC
VREFN	Ground reference for ADC
VINn	Analog input at channel n

HADC Architectural Concepts

The HADC is based on a 12-bit SAR ADC that provides a simple register-based access model to obtain the results of conversion. The digital front end of the HADC provides a set of registers to configure the mode of operation, sampling frequency, and input channel selection control. The ADC supports multiple input analog channels which can be individually selected or deselected for conversion. The results of each analog channel are stored in a register. The core can access the register to read the conversion results once the conversion is complete. The HADC also provides the interrupts on completion of each channel conversion to avoid polling by the core. The following sections provide more details about the architecture of the HADC.

Converter Operation

The housekeeping ADC is a 12-bit successive approximation ADC based around a capacitive DAC. The ***ADC Acquisition Phase*** figure and the ***ADC Conversion Phase*** figure show simplified schematics of the ADC. The ADC is comprised of control logic, SAR, and a capacitive DAC. The components are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator back into a balanced condition. The ***ADC Conversion Phase*** figure shows the ADC during its acquisition phase. SW2 is closed and SW1 is in Position A. The

comparator is held in a balanced condition and the sampling capacitor acquires the signal on the selected V_{IN} channel.

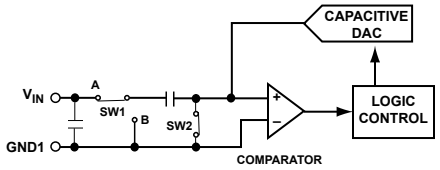

Figure 14-2: ADC Acquisition Phase

When the ADC starts a conversion (see the ***ADC Conversion Phase*** figure), SW2 opens and SW1 moves to Position B, causing the comparator to become unbalanced. The control logic and the capacitive DAC are used to add and subtract fixed amounts of charge to bring the comparator back into a balanced condition. When the comparator is rebalanced, the conversion is complete. The control logic generates the ADC output code.

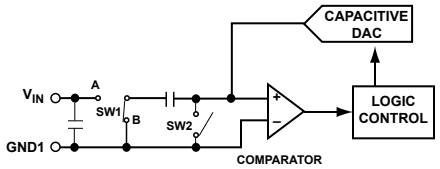

Figure 14-3: ADC Conversion Phase

Auto-Scan

The HADC features auto-scan mode where all the input channels can be sampled in a sequential manner. The number of channels enabled in auto-scan mode can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is set high, that particular channel is masked, and is not included in the auto-scan chain. In this way programs can sample all, none, or a selected set of channels by writing a high or a low for the individual channel. Auto sequencing allows the system to convert the same channel multiple times, allowing programs to perform oversampling algorithms.

For example, if the HADC_CHAN_MSK register bits [3:0] are set to 1101, then channel 0, channel 2 and channel 3 are not included in the auto-scan chain. Whether the conversion is a single or fixed number or continuous depends on the status of HADC_CTL.CONT bit. If this bit is low, the HADC_CTL.FIXEDCNV bits determine the number of sequence conversions.

The maximum number of fixed sequence conversions is 15. By default, the first eight channels of the HADC are enabled and extended channels are masked. An extended channel is the increased number of channels when a single channel of ADC is externally multiplexed, effectively increasing the total number of available channels. The total number of channels supported is 15. The program must configure the HADC_CHAN_MSK register to enable any desired channel.

Channel Sequence Programming

The sequence of a channel can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain. If the program must get the conversion results from a particular channel, then the bit corresponding to that channel should be zero.

Channels 8-15 are virtual channels, in that they can connect an external multiplexer and increase the effective number of channels. As the output of the external multiplexer is routed to channel 7, this channel is not available (or converted) separately when the virtual channels are not masked in the HADC_CHAN_MSK register. The auto-scan section has more details.

ADC Transfer Function

The output coding is straight binary for the analog input channel conversion. The designed code transitions occur at successive LSB values (that is, 1 LSB, 2 LSBs, and so forth). The LSB size is $V_{REF}/4096$ for the HADC. The *ADC Transfer Function* figure shows the ideal transfer characteristic for straight binary coding.

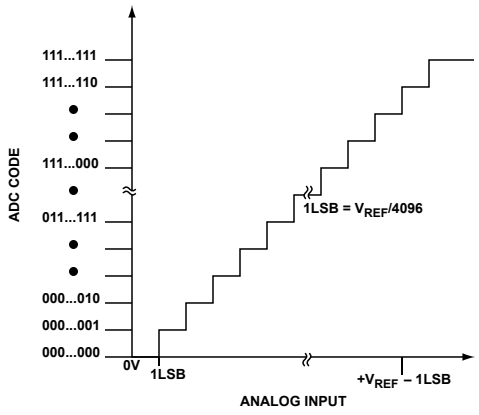

Figure 14-4: ADC Transfer Function

Results

The HADC takes 20 cycles of f_{SAMPLE} for one channel conversion. (The value of the HADC_CTL.FDIV bit field determines f_{SAMPLE}). The time taken to complete one sequence depends on the number of channels in the auto-scan chain. There is a latency of 1 cycle from the time the channel is selected internally to sample to the time the data is ready. After the end of each channel conversion, the data is written into the corresponding data register. An interrupt is generated (if the interrupt mask is not enabled) to signal that the data is ready for that particular channel.

HADC Operating Modes

The HADC has two modes of operation described in the following sections.

Fixed Conversion Mode

In this mode, the ADC converts the input channel sequence for a fixed number of times. The frequency is configured in the HADC_CTL.FIXEDCNV bit field. To use this mode, clear the HADC_CTL.CONT bit.

Continuous Conversion Mode

In this mode ADC continuously converts an input channel sequence, as long as HADC_CTL.STARTCNV bit is held high. To use this mode, set the HADC_CTL.CONT bit.

HADC Event Control

The HADC generates different events depending on the state of the ADC and the status of channel conversions. It can generate an event for each of the following conditions:

- When ADC is ready for conversion
- At the end of sequence conversion
- At the end of each individual channel conversion

Each of these events can generate an interrupt. To generate an interrupt on any desired event, clear the respective bit in the HADC_IMSK register.

HADC Programming Model

Following sections provide some guidelines for HADC programming.

Powering Up the HADC

To power-up the HADC, program the following bits in the HADC_CTL register.

- Deassert the HADC_CTL.PD bit (HADC power down)
- Set the HADC_CTL.NRST bit (Reset)
- Set the HADC_CTL.ENLS bit (Enable level shifters)

After deasserting HADC_CTL.PD, the HADC requires a finite wake-up time (t_{WAKEUP}) before it can start converting. The HADC requires only two f_{SAMPLE} clocks from the assertion of the HADC_CTL.NRST bit before the module is ready to convert. (HADC_CTL.PD is low). Poll the HADC_STAT.RDY bit. A 1 on this bit indicates that the HADC is ready to convert data.

Enabling the HADC

Setting the HADC_CTL.STARTCNV bit enables the HADC. When this bit is kept high, the HADC can work in either continuous or fixed conversion mode. After the HADC_CTL.STARTCNV bit is set =1, the HADC_CHAN_MSK can still be re-programmed, but the new sequence only comes into effect after the current sequence conversion is complete.

ADSP-2159x_SC591_SC592_SC594 HADC Register Descriptions

Housekeeping ADC (HADC) contains the following registers.

Table 14-6: ADSP-2159x_SC591_SC592_SC594 HADC Register List

Name	Description
HADC_CHAN_MSK	Channel Mask Register

Table 14-6: ADSP-2159x_SC591_SC592_SC594 HADC Register List (Continued)

Name	Description
HADC_CTL	Control Register
HADC_DATA[nn]	Channel Data Registers
HADC_IMSK	Interrupt Mask Register
HADC_STAT	Status Register

Channel Mask Register

The HADC_CHAN_MSK register provides bits that mask each channel. The LSB corresponds to channel 0 , the second LSB to channel 1 and so on. If a mask bit is set, the corresponding channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked.

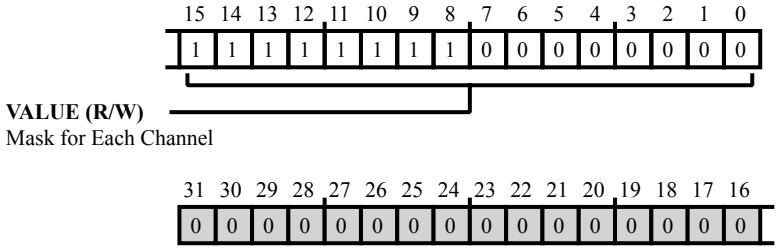

Figure 14-5: HADC_CHAN_MSK Register Diagram

Table 14-7: HADC_CHAN_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Mask for Each Channel. The HADC_CHAN_MSK.VALUE bit field is the mask bit for each channel. The first MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked. The first MSB corresponds to channel 7, the second MSB to channel 6 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked.

Control Register

The HADC_CTL register contains control bits that configure various module settings start or reset the module.

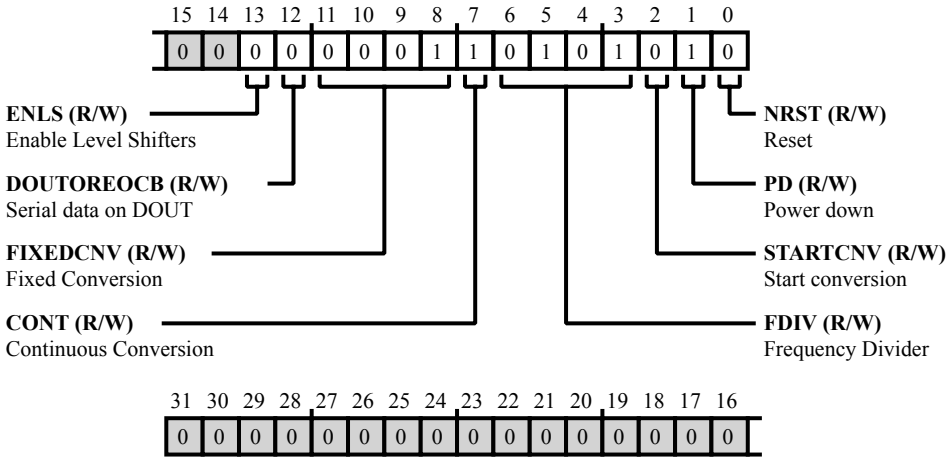

Figure 14-6: HADC_CTL Register Diagram

Table 14-8: HADC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	ENLS	Enable Level Shifters. Setting the HADC_CTL.ENLS bit enables the level shifters, allowing the HADC analog side (which works in the VDD_EXT domain) to work with the digital core and interface is (in the VDD_INT domain).	
		0	Disable down level shifters
		1	Enable down level shifters
12 (R/W)	DOUTOREOCB	Serial data on DOUT. If the HADC_CTL.DOUTOREOCB bit =1, serial data arrives on the EOC_DOUT pin. If this bit =0 (default) it acts as an EOC only if the external multiplexer is connected.	
		0	Reserved
		1	Reserved
11:8 (R/W)	FIXEDCNV	Fixed Conversion. The HADC_CTL.FIXEDCNV bit configures the number of conversions = FIXEDCNV. This value determines how many times a sequence is converted when the HADC is in fixed conversion mode. This only applies when the HADC_CTL.CONT bit =0. Before changing the HADC_CTL.FIXEDCNV bit, clear the HADC_CTL.NRST bit (=0).	

Table 14-8: HADC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CONT	Continuous Conversion. When the HADC_CTL.CONT bit =0, the ADC converts a sequence for a fixed number of times. This number is configured using the HADC_CTL.FIXEDCNV bit field. When the HADC_CTL.CONT bit =1, the ADC continuously converts a given sequence, provided the HADC_CTL.STARTCNV is held high.	
		0	ADC converts sequence for fixed number of times
		1	ADC continuously converts given sequence
6:3 (R/W)	FDIV	Frequency Divider. The HADC_CTL.FDIV bit field configures the f_SAMPLE=f_CLK/(FDIV+1). Select f_CLK and HADC_CTL.FDIV values so that f_SAMPLE is in range of 50 kHz to 22.5 MHz. The minimum value for HADC_CTL.FDIV is 1. Before changing the HADC_CTL.FDIV bits, clear the HADC_CTL.NRST bit.	
2 (R/W)	STARTCNV	Start conversion. The HADC_CTL.STARTCNV bit needs to be set for the ADC to start converting data. If the ADC is running in non continuous mode, it is reset by hardware after the desired number of conversions is completed.	
		0	No action
		1	Start converting
1 (R/W)	PD	Power down. The HADC_CTL.PD bit powers down the analog circuitry of the ADC. After this bit returns to 0 a finite power-up time is required before the ADC can start converting data.	
		0	No action
		1	Power down the analog circuitry of the ADC
0 (R/W)	NRST	Reset. The HADC_CTL.NRST bit resets the ADC.	
		0	Reset the ADC
		1	No action

Channel Data Registers

The HADC_DATA[nn] registers NN ranges from 0-14. Each corresponding to an ADC channel. ADC_DATA_0 corresponds to channel 0, ADC_DATA_1 to channel 1 and so on.

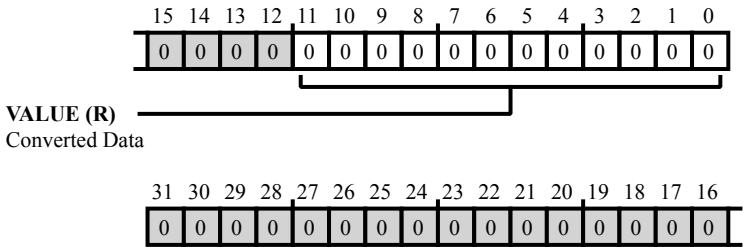

Figure 14-7: HADC_DATA[nn] Register Diagram

Table 14-9: HADC_DATA[nn] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	VALUE	Converted Data. The HADC_DATA[nn].VALUE bit field contains the digital code for the sampled analog value. Each channel has its own data register.

Interrupt Mask Register

The HADC_IMSK register masks (disables) or unmasks (enables) the interrupts as programmed.

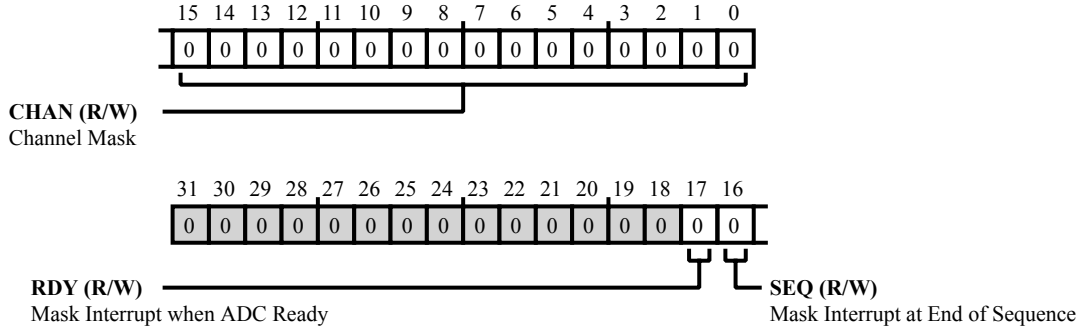

Figure 14-8: HADC_IMSK Register Diagram

Table 14-10: HADC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RDY	Mask Interrupt when ADC Ready. The HADC_IMSK.RDY bit masks the interrupt generated when ADC is ready to convert.	
16 (R/W)	SEQ	Mask Interrupt at End of Sequence. The HADC_IMSK.SEQ bit masks the interrupt which is generated at the end of sequence completion.	
		0	Interrupt is unmasked
		1	Interrupt is masked
15:0 (R/W)	CHAN	Channel Mask. The HADC_IMSK.CHAN bit field provides the interrupt mask bit for each channel. N ranges from 0-15. The MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the bit is SET, interrupt is masked for corresponding channel.	

Status Register

The HADC_STAT register contains bits that provide status information on the HADC module.

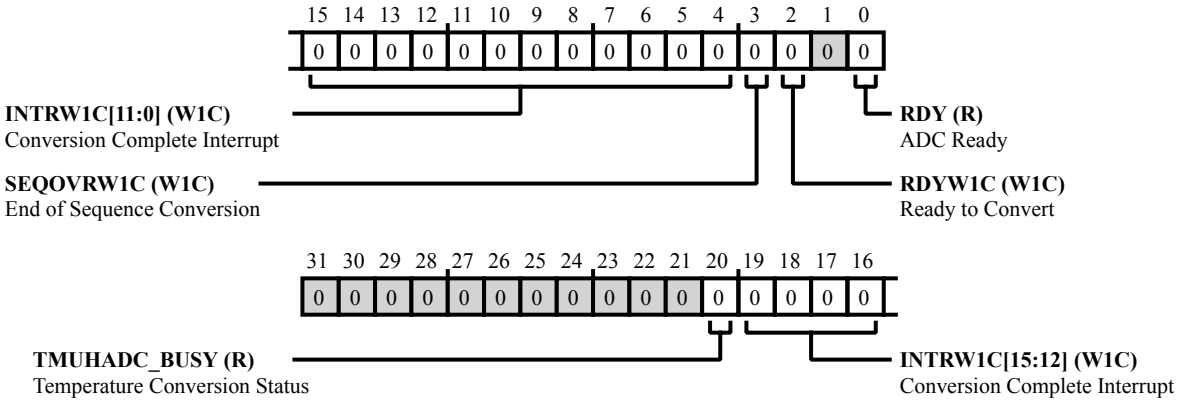

Figure 14-9: HADC_STAT Register Diagram

Table 14-11: HADC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/NW)	TMUHADC_BUSY	Temperature Conversion Status. The HADC_STAT.TMUHADC_BUSY bit, if high, indicates to the system that temperature conversion is ongoing. All ADC conversion requests are ignored.
19:4 (RX/W1C)	INTRW1C	Conversion Complete Interrupt. The HADC_STAT.INTRW1C bit field indicates when the corresponding ADC channel completes conversion. N ranges from 0-15 and the MSB corresponds to channel 15, the second MSB to channel 14 and so on. N ranges from 0-7 and the MSB corresponds to channel 7, the second MSB to channel 6 and so on. These bits are sticky and are W1C.
3 (RX/W1C)	SEQOVRW1C	End of Sequence Conversion. The HADC_STAT.SEQOVRW1C bit indicates the end of a sequence conversion and is a sticky status bit which is W1C.
2 (RX/W1C)	RDYW1C	Ready to Convert. The HADC_STAT.RDYW1C bit is the stick version of the HADC_STAT.RDY bit.
0 (R/NW)	RDY	ADC Ready. The HADC_STAT.RDY bit is set (=1) when the ADC is ready to convert data.

15 Controller Area Network Flexible Data Rate (CANFD)

The controller area network (CAN) protocol is primarily for use as a vehicle serial data bus. It meets the specific requirements of this field, including real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

The CANFD module is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN 2.0 Part B protocol. It supports both standard and extended message frames and long payloads up to 64 bytes, transferred at rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the CANFD module.

NOTE: This document assumes familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN specification from Robert Bosch GmbH.

CANFD Features

Key features of the CANFD module include:

- Full implementation of the CAN FD protocol and the CAN specification 2.0 (Part B) including:
  - Standard data frames
  - Extended data frames
  - Zero to sixty-four bytes data length
  - Programmable bit rate
  - Content-related addressing
- ISO 11898-1 standard compliance
- Flexible mailboxes
  - Configurable data lengths from 0 to 64 bytes
  - Configurable as receive or transmit, supporting standard and extended messages
  - Individual Rx mask registers per mailbox

- Full-featured Rx FIFO
  - Storage capacity for up to six frames
  - Automatic internal pointer handling with DMA support
- Transmission abort capability
- 28 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Independence from the transmission medium (an external transceiver is required)
- Low-power modes, with programmable wakeup on bus activity or matching with received frames (Pretended Networking)
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- Status of synchronization with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Rx FIFO ID filtering, matching incoming IDs against 128 extended, 256 standard, or 512 partial (8 bit) IDs
  - Up to 32 ID filter table elements
- Detection and correction of memory read access errors, with five parity bits for each byte of CANFD memory
- Pretended networking functionality in low-power doze mode

CANFD Functional Description

The CANFD module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system consists of a set of message buffers (MBs) that store configuration and control data, time stamp, message ID, and data. The memory corresponding to the first 38 MBs is configurable to support a FIFO reception scheme with a powerful ID filtering mechanism. The ID filtering mechanism is capable of checking

incoming frames against a table of IDs (up to 128 extended IDs, 256 standard IDs, or 512 8-bit ID slices), with an individual mask register for up to 32 ID filter table elements.

Classical CAN frames support simultaneous reception through a FIFO and mailboxes. CAN FD frames support reception only through mailboxes. For mailbox reception, there is a matching algorithm to store received frames into the MBs that have the same ID programmed in the ID field. There is a masking scheme to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

The CANFD module can also receive and transmit messages in CAN FD format. The MBs are sized to adequately store the quantity of data bytes selected in the MBDSRn fields of the CANFD_FD_CTL register.

The following sections provides listings of the CANFD registers, interrupts, and triggers. It section also provides information on the architectural concepts and functional operation of the CANFD module.

ADSP-2159x_SC591_SC592_SC594 CANFD Register List

CANFD module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification. Features : Flexible DataRate, PretendedNetwork, DMA support, ECC for RAM.

CANFD Architectural Concepts

The following sections provide information about the CANFD architecture.

Block Diagram

The *CANFD Block Diagram* figure shows a block diagram of the CANFD module.

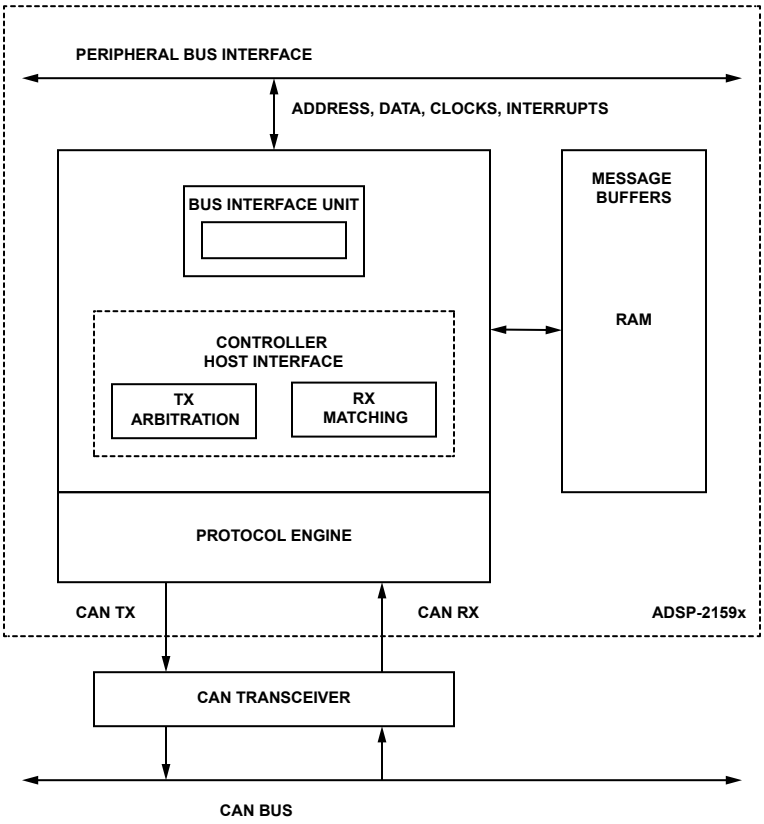

Figure 15-1: CANFD Controller Block Diagram

The CANFD module has the following three submodules and message buffers in an embedded RAM:

Protocol Engine (PE)

The PE submodule manages the serial communication on the CAN bus. It requests RAM access for receiving and transmitting message frames, validates received messages, preforms error handling, and detects CAN FD messages.

Controller Host Interface (CHI)

The CHI submodule handles message buffer selection for reception and transmission, including arbitration, and ID matching algorithms for both flexible data rate (FD) and non-FD message formats.

Bus Interface Unit (BIU)

The BIU submodule controls the access to and from the internal interface bus to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA, and test signals are accessed through the BIU.

Message Buffer (MB)

The CANFD module uses a message buffer structure that represents both extended (29-bit identifier) and standard (11-bit identifier) frames from the CAN specification (Version 2.0, Part B).

Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area for mailboxes is from address offset 0x80 to 0x47F. When CAN FD is enabled, the exact address for each memory byte depends on the size of the payload.

The *Message Buffer Structure 64-Byte Payload* figure shows an example of the message buffer structure with a 64-byte payload.

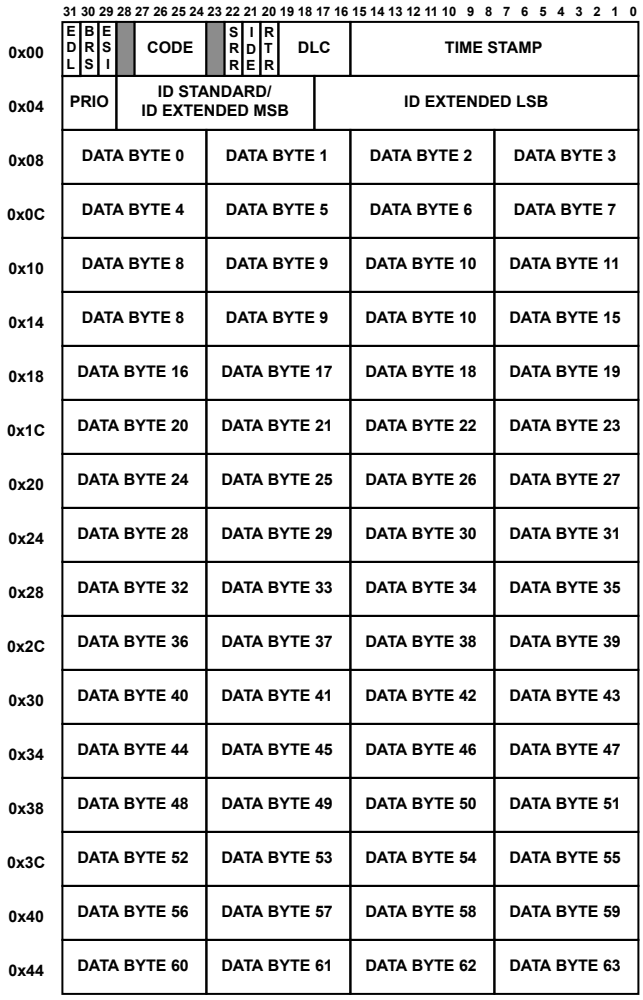

Figure 15-2: Message Buffer Structure 64-Byte Payload

In the example, the first eight bytes of the message buffer is control information associated with the data, followed by the bytes of data in the payload. The control information is defined in the following sections:

Extended Data Length (EDL)

The EDL bit distinguishes between CAN and CAN FD format frames. Do not set EDL when message buffers are configured to RANSWER with code field 0b1010.

Bit Rate Switch (BRS)

The BRS bit defines whether the bit rate is switched inside a CAN FD format frame.

Error State Indicator (ESI)

The ESI bit indicates if the transmitting node is error active or error passive.

Message Buffer Code (CODE)

The CODE field is accessible (read or write) to the processor and the CANFD module, as part of the message buffer matching and arbitration process. The *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables show the encoding.

Table 15-5: Message Buffer Code – Rx Buffer

CODE Description	Rx Code Before New Frame	SRV*1	Rx Code After Successful Reception *2	RRS *3	Comment
0000: INACTIVE – MB is not active.	INACTIVE	N/A	N/A	N/A	MB does not participate in the matching process.
0100: EMPTY – MB is active and empty	EMPTY	N/A	FULL	N/A	When a frame is received successfully, the CODE field is automatically updated to FULL.

Table 15-5: Message Buffer Code – Rx Buffer (Continued)

CODE Description	Rx Code Before New Frame	SRV*1	Rx Code After Successful Reception *2	RRS *3	Comment
0010: FULL – MB is full.	FULL	Yes	FULL	N/A	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching Process.
		No	OVERRUN	N/A	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching Process.
0110: OVERRUN – MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	N/A	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB, the code returns to FULL.
		No	OVERRUN	N/A	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching Process.

Table 15-5: Message Buffer Code – Rx Buffer (Continued)

CODE Description	Rx Code Before New Frame	SRV*1	Rx Code After Successful Reception *2	RRS *3	Comment
1010: RANSWER*4 – A frame was configured to recognize a remote request frame and transmit a response frame in return.	RANSWER	N/A	TANSWER(1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that, an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110). See Matching Process. If the CANFD_CTL2.RRS bit is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		N/A	N/A	1	This code is ignored during matching and arbitration process.
CODE[0]=1; BUSY – CANFD is updating the contents of the MB. The CPU must not access the MB.	BUSY*5	N/A	FULL	N/A	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		N/A	OVERRUN	N/A	

*1 Serviced MB. The MB has been read and unlocked by reading the CANFD_TMR register or other MB.

*2 A frame has a successful reception after it is moved to an MB. See Move Process.

*3 Remote Request Stored bit, see the CANFD_CTL2 register.

*4 Code 1010 is not considered Tx and an MB with this code should not be aborted.

*5 6. For Tx MBs, the BUSY bit is ignored upon read, except when the CANFD_CFG.ABORTEN bit is set. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 15-6: Buffer Message Code – Tx Buffer

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
	INACTIVE	N/A	N/A	MB does not participate in arbitration process.

Table 15-6: Buffer Message Code – Tx Buffer (Continued)

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
1000: INACTIVE – MB is not active.				
1001: ABORT – MB is aborted.	ABORT	N/A	N/A	MB does not participate in arbitration process.
1100: DATA – MB is a Tx Data Frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100: REMOTE – MB is a Tx Remote Request Frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
1110: TANSWER – MB is a Tx Response Frame from an incoming Remote Request Frame.	TANSWER	N/A	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching Process and Arbitration Process.

Substitute Remote Request (SRR)

SRR is a fixed recessive bit, only for the extended format. The SRR bit is set to one for transmission (Tx buffers) and is stored with the value received on the CAN bus for Rx receiving buffers. It is received as either recessive or dominant. If the CANFD module receives this bit as dominant, then it is interpreted as an arbitration loss.

When the bit is set, the recessive value is compulsory for transmission in extended format frames. When it is clear, dominant is not a valid value for transmission in extended format frames.

ID Extended Bit (IDE)

IDE identifies whether the frame format is standard or extended.

When the bit is set, the frame format is extended. When the bit is clear, the frame format is standard.

Remote Transmission Request (RTR)

The RTR bit affects the behavior of remote frames and is part of the reception filter:

When the bit is set, the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx, then incoming remote request frames may be stored. When the RTR bit is clear, the current MB has a data frame to be transmitted. In an Rx MB, it may be considered in matching processes.

See the *Message Buffer Code – Rx Buffer* table, the *Message Buffer Code – Tx Buffer* table, and the description of the `CANFD_CTL2.RRS` bit for additional details.

If the CANFD module transmits RTR as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If RTR is transmitted as 0 (dominant) and received as 1 (recessive), the CANFD treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

NOTE: When configuring CAN FD frames, the RTR bit must be negated.

Length of Data in Bytes (DLC)

The 4-bit DLC field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see Table 59). In reception, DLC is written by the CANFD module, copied from the DLC (Data Length Code) field of the received frame. In transmission, DLC is written by the processor and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field. See the *Data Byte Validity* table.

Free-Running Counter Time Stamp (TIME STAMP)

The 16-bit TIME STAMP field is a copy of the free-running timer, captured for Tx and Rx frames when the beginning of the identifier field appears on the CAN bus.

Local Priority (PRIO)

The 3-bit PRIO field is used only when the CANFD_CFG.LPRIO_EN bit is set and only makes sense for Tx mailboxes. The PRIO field is not transmitted. It is appended to the regular ID to define the transmission priority. See the Arbitration Process section.

Frame Identifier (ID)

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification for both receive and transmit, and the 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification for both receive and transmit.

Data Field (DATA BYTE 0 to 63)

Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the Message Buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE(n) is valid only if n is less than DLC as shown in the *Data Byte Validity* table.

Table 15-7: Data Byte Validity

DLC	Valid Data Bytes
0	None
1	Data Byte 0
2	Data Byte 0 to 1
3	Data Byte 0 to 2
4	Data Byte 0 to 3
5	Data Byte 0 to 4
6	Data Byte 0 to 5
7	Data Byte 0 to 6
8	Data Byte 0 to 7
9	Data Byte 0 to 11

Memory Partition

When CAN FD is enabled, the CANFD RAM can be partitioned in two blocks of 512 bytes. Each block can accommodate a number of message buffers. This depends on the configuration of the size control bit fields in the `CANFD_FD_CTL` register as shown in the *RAM Partition* table.

Table 15-12: RAM Partition

RAM Block	Number of MBs with 8 Bytes*1	Size Control Bit Field	Number of MBs of Different Sizes, per Block
0	0 to 31	CANFD_FD_CTL.MBDSIZR0	MBDSIZR0=00, 32 MBs with 8 bytes payload MBDSIZR0=01, 21 MBs with 16 bytes payload MBDSIZR0=10, 12 MBs with 32 bytes payload, MBDSIZR0=11, 7 MBs with 64 bytes payload
1	32 to 63	CANFD_FD_CTL.MBDSIZR1	MBDSIZR1=00, 32 MBs with 8 bytes payload MBDSIZR1=01, 21 MBs with 16 bytes payload MBDSIZR1=10, 12 MBs with 32 bytes payload MBDSIZR1=11, 7 MBs with 64 bytes payload

*1 default range

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs, and the respective number order may differ from the default configuration of 8 bytes. For example, if Block 0 is configured to 8 bytes payload, Block 1 to 16 bytes, the following table indicates how the message buffers are arranged into RAM.

Table 15-13: RAM Partition Example

RAM Block	Payload Size	Number of MBs in the RAM Block	MB Range
0	CANFD_FD_CTL[MBDSIZR0]=00, 8 bytes payload	32	0 to 31
1	CANFD_FD_CTL[MBDSIZR1]=01, 16 bytes payload	21	32 to 52

Rx FIFO Structure

When the CANFD_CFG.RFEN bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0-5) is used by the Rx FIFO engine.

The region 0x80 to 0x8C contains the output of the FIFO, which must be read by the processor as a message buffer. The FIFO output contains the oldest message that has been received but not yet read. The region 0x90–0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 to 37) depending on the CANFD_CTL2.RFFNUM bit field setting, contains the ID filter table (configurable from 8 to 128 table elements), which specifies filtering criteria for accepting frames into the FIFO. Out of reset, the ID filter

table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for the CANFD_CTL2.RFFNUM bit field setting equal to zero.

The *Rx FIFO Structure* figure shows the Rx FIFO data structure.

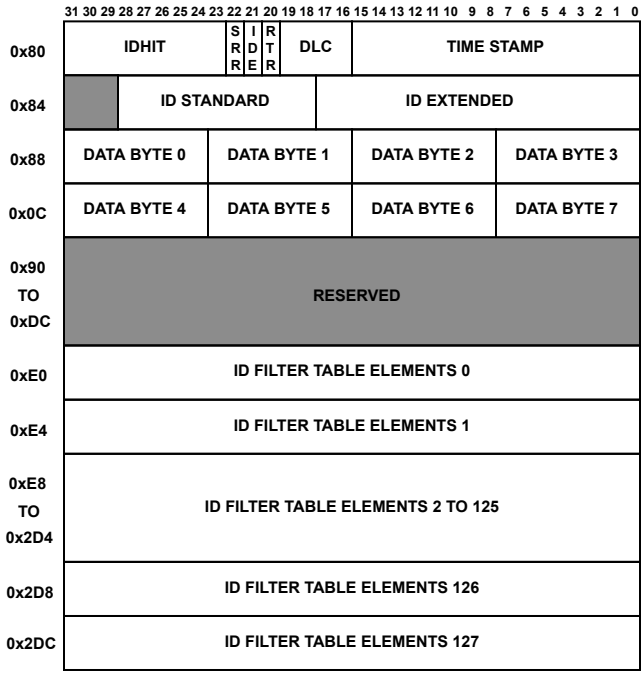

Figure 15-3: Rx FIFO Structure

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the CANFD_CFG.IDAM bit field setting.

The *ID Filter Table Structure* figure shows the three different formats of the ID table elements. All elements of the table must have the same format, as selected by the CANFD_CFG.IDAM bit field.

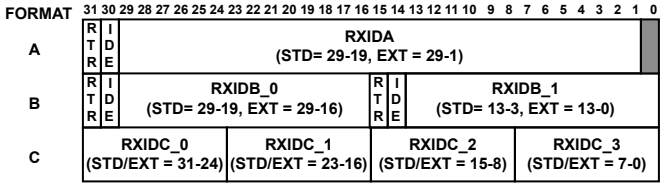

Figure 15-4: ID Filter Table Structure

The *Rx FIFO Filters* table shows the number of Rx FIFO filters configured with the CANFD_CTL2.RFFNUM bit field setting.

Table 15-14: Rx FIFO Filters

CANFD_CTL2.RFFNUM	Number of Rx FIFO Filter Elements	Message Buffers Occupied by Rx FIFO and ID filter table	Remaining Mailboxes	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID filter table elements affected by Rx FIFO global mask
0x0	8	MB 0 to 7	MB 8 to 63	Elements 0 to 7	None
0x1	16	MB 0 to 9	MB 10 to 63	Elements 0 to 9	Elements 10 to 15
0x2	24	MB 0 to 11	MB 12 to 63	Elements 0 to 11	Elements 12 to 23
0x3	32	MB 0 to 13	MB 14 to 63	Elements 0 to 13	Elements 14 to 31
0x4	40	MB 0 to 15	MB 16 to 63	Elements 0 to 15	Elements 16 to 39
0x5	48	MB 0 to 17	MB 18 to 63	Elements 0 to 17	Elements 18 to 47
0x6	56	MB 0 to 19	MB 20 to 63	Elements 0 to 19	Elements 20 to 55
0x7	64	MB 0 to 21	MB 22 to 63	Elements 0 to 21	Elements 22 to 63
0x8	72	MB 0 to 23	MB 24 to 63	Elements 0 to 23	Elements 24 to 71
0x9	80	MB 0 to 25	MB 26 to 63	Elements 0 to 25	Elements 26 to 79
0xA	88	MB 0 to 27	MB 28 to 63	Elements 0 to 27	Elements 28 to 87
0xB	96	MB 0 to 29	MB 30 to 63	Elements 0 to 29	Elements 30 to 95
0xC	104	MB 0 to 31	MB 32 to 63	Elements 0 to 31	Elements 32 to 103
0xD	112	MB 0 to 33	MB 34 to 63	Elements 0 to 31	Elements 32 to 111
0xE	120	MB 0 to 35	MB 36 to 63	Elements 0 to 31	Elements 32 to 119
0xF	128	MB 0 to 37	MB 38 to 63	Elements 0 to 31	Elements 32 to 127

Remote Frame (RTR)

The RTR bit specifies if remote frames are accepted into the FIFO if they match the target ID. If the bit is set, remote frames are accepted and data frames are rejected. If the bit is clear, remote frames are rejected and data frames are accepted.

Extended Frame (IDE)

The IDE bit specifies whether extended or standard frames are accepted into the FIFO if they match the target ID. If the bit is set, extended frames are accepted and standard frames are rejected. If the bit is clear, extended frames are rejected and standard frames are accepted.

Rx Frame Identifier Format A (RXIDA)

Specifies the ID for as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

Rx Frame Identifier Format B (RXIDB_0, RXIDB_1)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

Rx Frame Identifier Format C (RXIDC_1, RXIDC_2, RXIDC_3)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

Identifier Acceptance Filter Hit Indicator (IDHIT)

The 9-bit IDHIT field indicates which identifier acceptance filter is hit by the received message that is in the output of the Rx FIFO. See the Rx FIFO section for more information.

CANFD Processes

The following sections describe the how to transmit and receive CAN and CAN FD frames using the mailbox system.

Transmit Process

To transmit a CAN frame, the processor must prepare a message buffer for transmission by executing the following procedure:

1. Check if the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001) to the CODE field of the control and status (C/S) word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the `CANFD_IFLG1` or `CANFD_IFLG2` register or by the interrupt request if enabled in the respective IMASK bit in the `CANFD_IMSK1` or `CANFD_IMSK2` register. Then, read back the CODE field to check if the transmission was aborted or transmitted (see the Transmission Abort Mechanism section).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the C/S word to activate the MB. When `CANFD_CFG.FDEN` is set, also write the EDL, BRS and ESI bits.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, the CANFD adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission, the value of the `CANFD_TMR` register is written into the TIME STAMP field, the CODE field in the C/S word is updated, both `CANFD_CRC` and `CANFD_FD_CRC` registers are updated, a status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt is generated if allowed by

the corresponding CANFD_IFLAGn bit. The new CODE field after transmission depends on the code that was used to activate the MB. See the *Message Buffer Code – Rx Buffer* table.

When the Abort feature is enabled (CANFD_CFG.ABORTEN is asserted), after the interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore, the processor is not able to update it until the interrupt flag is disabled by the processor. This means that the processor must clear the corresponding CANFD_IFLAGn bit before starting to prepare this MB for a new transmission or reception.

Arbitration Process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones. The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CANFD_CTL2.TXASDLY field value.
- During the error delimiter field of a CAN frame.
- During the overload delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the intermission field.
- When there is a processor write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the intermission field.
- When CHI is in idle state and the processor writes to the C/S word of any MB.
- When CANFD module exits the bus off state.
- Upon leaving freeze mode or low power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the intermission field, the temporary arbitration winner is invalidated and the CANFD module does not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the CANFD_CTL1.LBUF and CANFD_CFG.LPRIOEN bit settings.

Lowest Number Mailbox First

If the CANFD_CTL1.LBUF bit is enabled, the first (lowest number) active Tx mailbox found is the arbitration winner. The CANFD_CFG.LPRIOEN bit has no effect when the CANFD_CTL1.LBUF bit is enabled.

Highest-Priority Mailbox First

If the CANFD_CTL1.LBUF bit is disabled, then the arbitration process searches the active Tx mailbox with the highest priority. This mailbox frame with the highest priority has a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the arbitration value of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the CANFD_CFG.LPRIOEN bit.

Local Priority Disabled

If the CANFD_CFG.LPRIOEN is disabled, local priority is disabled and the arbitration value is built in the exact sequence of bits transmitted in a CAN frame as shown in the *Arbitration Value Priority Disabled* table.

Table 15-15: Arbitration Value Priority Disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

Local Priority Enabled

If the CANFD_CFG.LPRIOEN is enabled, local priority is enabled. In this case, the mailbox PRIO field is included at the very left of the arbitration value as shown in the *Arbitration Value Priority Enabled table.*

Table 15-16: Arbitration Value Priority Enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

As the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values, regardless of the rest of their arbitration values.

NOTE: The PRIO field is not part of the frame on the CAN bus and only affects the internal arbitration process.

Arbitration Completion

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and, after it is done, write access to the C/S word of the corresponding MB is blocked (if CANFD_CFG.ABORTEN is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the processor.
- The CANFD module enters freeze mode or bus off.

- The CANFD module loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration Start and Stop Conditions

The arbitration process is triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During CAN bus off state from TX_ERR_CNT = 124 to 128. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During C/S write by the processor in bus idle mode. The first C/S write starts the arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, the Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and the bus idle state starts, an arbitration process is triggered. In this case, the first and second C/S write in the bus idle state do not restart the arbitration process. It is possible that there is not enough time to finish arbitration in the wait for bus idle state and the next state is idle. In this case, the scan is not interrupted, and it is completed during the bus idle state. During this arbitration, a C/S write does not cause an arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting freeze mode (first bit of the wait for bus idle state). If there is a re- synchronization during wait for bus idle state, the arbitration process restarts.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found when the lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish the Tx arbitration process (for example, when a deactivation was performed near the end of frame). In this case, the arbitration process is pending.
- There is an error or overload flag in the bus.
- There is a low power or freeze mode request in the idle state.

Arbitration is considered pending as described below:

- It was not possible to finish the arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.

- Rx Match has just updated an Rx code to Tx code
- Entering the bus off state.

C/S write during arbitration has the following effect:

- If the C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If the C/S write is performed in an MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

Receive Process

To receive CAN frames into a mailbox, the processor must prepare the mailbox for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx), inactivate the mailbox (See Mailbox Inactivation), preferably with a safe inactivation (See Transmission Abort Mechanism).
2. Write the ID word.
3. Write the EMPTY code (0b0100) to the CODE field of the C/S word to activate the mailbox. No setup is required for the EDL, BRS, and ESI bits; they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (See Move-In) as follows:

1. The received data field (8 bytes at most for classical CAN message format and up to 64 bytes for the CAN FD message format) is stored.
2. The received ID field is stored.
3. The value of the `CANFD_TMR` register at the time of the second bit of the frame identifier field is written into the mailbox TIME STAMP field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the C/S word is updated according to the *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables.
6. A status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register and an interrupt is generated if allowed by the corresponding `CANFD_IMSK1` or `CANFD_IMSK2` register bit.

The recommended procedure for the processor to service (read) the frame received in a mailbox is:

The processor polls for frame reception by checking the status flag bit for the specific mailbox in the respective CANFD_IFLAGn register and not by polling the CODE field of that mailbox. Polling the CODE field does not work because, once a frame is received and the processor services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field does not return to EMPTY. It remains FULL, as explained in the *Message Buffer Code – Rx Buffer* table. If the processor tries to work around this behavior by writing to the C/S word to force

an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

NOTE: Never poll by reading the C/S word directly from the mailboxes. Always read the CANFD_IFLG1 or CANFD_IFLG2 register.

The identifier field of the receive frame is always stored in the matching mailbox. Therefore, the contents of the ID field in a mailbox may change if the match was due to masking.

When the CANFD_CFG.SRXDIS bit is enabled, the CANFD module does not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal is generated. Otherwise, when the CANFD_CFG.SRXDIS bit is disabled, the CANFD module can receive frames transmitted by itself if there is a matching Rx mailbox.

To be able to receive CAN frames through the Rx FIFO, the processor must enable and configure the Rx FIFO during freeze mode (See Rx FIFO). Upon receiving the frames available in Rx FIFO interrupt (see the CANFD_IFLG1.MB05 bit description), the processor services the received frame using the following procedure:

1. Read the C/S word (optional: needed only if a mask was used for the IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the Data field.
4. Read the CANFD_RX_FIFO register (optional).
5. Clear the frames available in Rx FIFO interrupt by writing a one to the CANFD_IFLG1.MB05 bit to release the MB and allow the processor to read the next Rx FIFO entry.

When the CANFD_CFG.DMAEN bit is enabled, upon receiving a frame in the Rx FIFO, the CANFD_IFLG1.MB05 bit generates a DMA request and does not generate a processor interrupt (See Rx FIFO Under DMA Operation). The CANFD_IMSK1 bits in the Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the C/S word (read 0x80 address, optional).
2. Read the ID field (read 0x84 address, optional).
3. Read all data bytes (start read at 0x88 address, optional).
4. Read the last data bytes (read 0x8C address is mandatory).

Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number MB toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. If any CAN protocol error is detected, then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures and depends on conditions described below.

Table 15-17: Matching Architecture

Structure	SMB.RTR	CTRL2.RSS	CTRL2.EACEN	MB.IDE	MB.RTR	MB.ID*1	MB.CODE
Mailbox	0	N/A	0	cmp*2	no_cmp*3	cmp_msk*4	
Mailbox	0	N/A	1	cmp_msk	cmp_msk	cmp_msk	
Mailbox	1	0	N/A	cmp	no_cmp	cmp	
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	
FIFO*5	N/A	N/A	N/A	cmp_msk	cmp_msk	cmp_msk	

*1 1. For mailbox structure, If SMB.IDE is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB.IDE is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on CANFD_CFG.IDAM.

*2 cmp: Compares the Rx SMB contents with the MB contents regardless the masks.

*3 no_cmp: The Rx SMB contents are not compared with the MB contents.

*4 cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.

*5 SMB.IDE and SMB.RTR. are not taken into account when CANFD_CFG.IDAM is format C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the processor and unlocked as described in the Mailbox Lock Mechanism section).

- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation is performed. See the Mailbox Inactivation section.
- The Rx FIFO is not full.

The scan order for mailboxes and the Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by the `CANFD_CFG.IRMQEN` bit. If the `CANFD_CFG.IRMQEN` bit is disabled, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If the `CANFD_CFG.IRMQEN` bit is enabled, the matching winner is selected according to the priority below:

1. The first free-to-receive matched mailbox.
2. The last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and the Rx FIFO by using the`CANFD_CTL2.MRPRIO` bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched for among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for the Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched for in the scan for the Rx FIFO.

If both conditions above are not satisfied and a non free-to-receive matched mailbox is found, then the matching winner determination is conditioned by the `CANFD_CFG.IRMQEN` bit:

- If the `CANFD_CFG.IRMQEN` bit is disabled, the matching winner is the first matched mailbox.
- If the `CANFD_CFG.IRMQEN` bit is enabled, the matching winner is the Rx FIFO if it is a free-to- receive matched structure; otherwise, the matching winner is the last non free-to- receive matched mailbox.

See the *Matching Possibilities and Resulting Reception Structures* table for a summary of matching possibilities.

Table 15-18: Matching Possibilities and Resulting Reception Structures

RFEN	IRMQEN	MRPRIO	Matched in MB[*1]	Matched in FIFO[*2]	Reception Structure	Description
No FIFO, only MB, match is always MB first:						
0	0	X[*3]	None	_[*4]	None	Frame lost by no match

Table 15-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
0	0	X	Free	–	FirstMB	
0	1	X	None	–	None	Frame lost by no match
0	1	X	Free	–	FirstMB	
0	1	X	Not Free	–	LastMB	Overrun
FIFO enabled, no match in FIFO (as if FIFO does not exist):						
1	0	X	None	None	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMB	
1	1	X	Not Free	None	LastMB	Overrun
FIFO enabled, queue disabled:						
1	0	0	X	NotFull	FIFO	
1	0	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	Not Free	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	1	Free	X	FirstMB	
1	0	1	Not Free	X	FirstMB	Overrun
FIFO enabled, queue enabled:						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	Not Free	Full	LastMB	Overrun

Table 15-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	Not Free	NotFull	FIFO	
1	1	1	Not Free	Full	LastMB	Overrun

*1 In the Matched in MB column, the term "None" means the frame has not matched an MB (free-to-receive or non-free-to receive). The term "Free" means the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.

*2 In the Matched in FIFO column, the term "None" means the frame has not matched any filter for the Rx FIFO. It is as if the Rx FIFO does not exist (CANFD_CTL2.RFEN = 0). The term "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it. The term "Full" means that the frame has matched a FIFO filter but the FIFO couldn't store it because the FIFO has no empty slots to receive it.

*3 The X denotes a don't-care condition.

*4 The – denotes a forbidden condition.

If a non-safe mailbox inactivation (See Mailbox Inactivation) occurs during the matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the Rx FIFO is disabled, the `CANFD_CFG.IRMQEN` is enabled, there are two MBs with the same ID, and the CANFD starts receiving messages with that ID. If the two MBs are the second and the fifth in the array, then when the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not “free-to-receive”, so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are “free-to-receive”, so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full-featured FIFO) to allow more time for the processor to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the TIME STAMP field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. The CANFD module supports individual masking per MB. During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a “don't care”. The `CANFD_IMSK1` and `CANFD_IMSK2` registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the CANFD module is in freeze mode; otherwise, they are blocked by hardware.

The CANFD also supports an alternate masking scheme with only four mask registers (CANFD_RX_FIFO_GMSK, CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, and CANFD_RX_15_MSK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when CANFD_CFG.IRMQEN is enabled.

Receive Process Pretending Network Mode

Pretended networking mode adds specific wake up functionality in low power modes (doze mode). When pretended network (PN) mode is enabled by asserting the CANFD_CFG.PNETEN bit, the CANFD module continues processing Rx CAN messages under low power mode, able to detect specific wake up messages by filtering them against ID and payload target values using preselected matching criteria. Wake up functionality is not available for messages in CAN FD format. While in pretended networking mode, CAN FD format messages are ignored.

PN registers are located in the 0x0B00–0x0B7C address range and can only be written only in freeze mode. These registers are used for writing PN configuration (both control and target values) prior entering into pretended networking mode, and for reading wake up flags and the received message ID and data when returning back to normal mode after wake up. The processor waits for the CANFD_CFG.LPMACK bit to be disabled before performing any access to CANFD PN registers.

PN control registers are CANFD_PN_CTL1 and CANFD_PN_CTL2. The control bit fields that configure the filtering criteria are:

- CANFD_PN_CTL1.PLFSEL: Payload filtering selection.
- CANFD_PN_CTL1.IDFSEL: ID filtering selection.
- CANFD_PN_CTL1.FCSEL: Filtering combination selection.

PN target values are:

- CANFD_FLTR_ID1.IDE: IDE target value used to filter the incoming message by its format (standard or extended).
- CANFD_FLTR_ID1.RTR: RTR target value used to filter the incoming message by its type (data or remote frame).
- CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO: Target DLC range used to filter the size of payload part of an incoming message.
- CANFD_FLTR_ID1.VALUE: ID target value used to filter the incoming message ID (equal to, smaller than or equal, greater than or equal, or the lower limit value in an ID range).
- CANFD_FLTR_ID2_IDMSK: ID target value used as the upper limit in an ID range.
- PL1: Payload target value used to filter the incoming message payload (equal to, smaller than or equal, greater than or equal, or the lower limit value in a payload range).
- PL2: Payload target value used as the upper limit in a payload range.

The IDE, RTR, ID, and payload filters have their respective masks. These masks determine which bits are taken into account in equality comparisons (1 in certain mask positions) and which ones are don't care (0 in other mask positions). ID and payload masks are used only for exact ID and/or exact payload comparisons.

The ID of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact ID value by detecting the equality between the ID field of the incoming message and the content of target CANFD_FLTR_ID1 register. The ID mask is used.
- A match with the maximum range of ID; in other words, any message with ID value smaller than or equal to the content of target CANFD_FLTR_ID11 register is accepted. The ID mask is not used.
- A match with the minimum range of ID; in other words, any message with ID value greater than or equal to the content of target CANFD_FLTR_ID1 register is accepted. The ID mask is not used.
- A match inside a range of IDs; in other words, any message with an ID value that is greater than or equal to the content of target CANFD_FLTR_ID1 register and smaller than or equal to the content of target CANFD_FLTR_ID2_IDMSK register is accepted. The ID mask is not used.

The above criteria for ID filtering must be coherent with CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR target values. Only Rx frames that match the respective IDE and RTR bits to the contents of FLT_IDE and FLT_RTR bit fields are compared. When range of IDs is selected (CANFD_PN_CTL1.IDFSEL = 11), both the CANFD_FLTR_ID1.VALUE field and the CANFD_FLTR_ID2_IDMSK register are referred to the same CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR bits.

The ID mask is applied only to the exact ID comparison filtering option (CANFD_PN_CTL1.IDFSEL = 00) to determine which bits are taken into account in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are taken into account in comparison.

Similarly to the ID criteria, 64-bit data or payloads (PL) of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact payload value by detecting the equality between the payload field of the incoming message and the content of PL1 register. The payload mask is used.
- A match with the maximum range of payload; in other words, any message with payload value smaller than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match with the minimum range of payload; in other words,. any message with payload value greater than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match inside a range of payloads; in other words, any message with a payload value that is greater than or equal to the content of PL1 register and smaller than or equal to the content of PL2 register is accepted. The payload mask is not used.

The above criteria for payload filtering must be coherent with CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO limit values. The payload of a Rx incoming message is filtered in accordance to the selected criteria only if the DLC value of the Rx incoming message is inside a DLC range:

- Greater than or equal to the CANFD_FLTR_DLC.LO (lower limit) and
- Lower than or equal to the CANFD_FLTR_DLC.HI (upper limit)

Conversely, a DLC value out of the specified range results in mismatch. By making CANFD_FLTR_DLC.LO = CANFD_FLTR_DLC.HI, only payloads of specified quantity of bytes will be filtered. DLC is not maskable.

When the inside range of payloads option is selected (CANFD_PN_CTL1.PLFSEL = 11), both PL1 and PL2 are considered with the 8-byte data length. All the data bytes excluded by the DLC of the received message are considered with value zero.

Payload mask is only used in the exact match option (CANFD_PN_CTL1.PLFSEL = 00) to select which bits or bytes in the 8-byte data field of both Rx incoming message and the contents of PL1 register are selected for matching. Mask length must be in accordance to the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When a remote frame is received by the CANFD module and the CANFD_PN_CTL1.FCSEL bit is configured to select the payload comparison, the payload filtering is not considered and the comparison results in a mismatch.

Rx incoming messages can also be filtered based upon the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload a predefined quantity of times. This quantity can be configured in the 1 to 255 range. See the CANFD_CTL1 register.
- No message matching the filtering criteria for ID or payload up to a timeout trigger.

  That is, non-reception of a matching message for a defined quantity of time. See the CANFD_CTL2 register.

The CANFD module can generate a wakeup timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag when the counting reaches the predefined timeout value, as specified in the CANFD_PN_CTL2.MATCHTO bit field.

The above filtering criteria can be used together as follows:

- Message ID filtering only.
- Message ID filtering and payload filtering.
- Message ID filtering only occurring N times.
- Message ID filtering and payload filtering occurring N times.

The timeout counter runs concurrently with the reception filtering process. Both engines, timeout counter and message filtering, are independent. If an incoming message matches the selected filter criteria, the timeout counter keeps counting until the processor wakes up.

Conversely, if the timeout counter reaches the target value, then the message filtering process continue to filter incoming messages until the processor wakes up. The CANFD_WUM.MCNT field reports the number of matched messages that occurred under pretended networking mode up to the moment the processor wakes up.

Under pretended networking mode, a wakeup event that occurs sets the respective wake up flag (see the CANFD_WUM register.

- In case of a successful matching in accordance to the selected filtering criteria, the CANFD_WUM.WUMF bit field.
- In case of a timeout trigger, the CANFD_WUM.WTOF bit field.

Either of these flags generates an interrupt to the processor if the respective mask bit is asserted (CANFD_PN_CTL1.WUMFMSK or CANFD_PN_CTL1.WTOFMSK).

There are four wake up message buffers (WMBs) for storing incoming messages in pretended networking mode. Up to four messages can be stored per the CANFD_WMB[n]_ID register. When the CANFD_PN_CTL1.MATCHCNT value is one, just one message is received if matching the filtering criteria, and this message is stored in the CANFD_WMB0 register. If the CANFD_PN_CTL1.MATCHCNT value is between two and four, CANFD_WMB1, CANFD_WMB2, and CANFD_WMB3 are used to store the second, third, and fourth matching messages, respectively. If CANFD_PN_CTL1.MATCHCNT is greater than four, the last four matching messages are stored in the WMBs; respecting the WMB index to indicate the arrival order, the latest is stored in CANFD_WMB3. Only the valid data bytes of the incoming match message is stored in data field of WMBs. The non-valid data bytes are read as zero. In case the of DLC = 0 and RTR = 1, the data field is filled with zero. In any of the above cases, the wake up interrupt is generated just when the filtering criteria is completed and the CANFD_PN_CTL1.WUMFMSK bit is set.

When a non-match wakeup event occurs (timeout or external) and the CANFD_WUM.MCNT value is equal or greater than four, the message stored in WMB0 does not have a valid content. The CANFD_WMB0 is used as the buffer for the current message on the CAN bus. Messages received during pretended networking mode do not have timestamps and respective field in the WMB structure must be ignored.

Under low-power mode (doze or stop), all processes are shut down except for the PN functionality in the PE submodule, which is kept clocked by the oscillator clock. The CANFD continues to receive Rx incoming messages and just compares them against the predefined target values and according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in normal mode, are not performed under pretended networking mode.

Under pretended networking, the CANFD reacts to messages on the CAN bus in the same manner as in normal mode (generates acknowledge bits, detects and counts errors, etc.).

Move Process

There are two types of move process: move-in and move-out.

Move-In

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CANFD_RX_FIFO register. Each Rx SMB has its own move-in process, but only one is performed at a given time as described below. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (See Matching Process) and all of the following conditions are true:

- The CAN bus has reached or let past either of the following:
  - The second bit of the Intermission field next to the frame that carried the message that is in the Rx SMB

    - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process.
- The destination mailbox is not locked by the processor.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time, both are performed and the newest substitutes the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to- be that still does not satisfy all of the aforementioned conditions.

The move-in is canceled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the CANFD itself and the self-reception is disabled (`CANFD_CFG.SRXDIS` bit is enabled)
- Any CAN protocol error is detected.

Note that the pending move-in is not canceled if the CANFD module enters freeze or low-power mode. The pending move-in stays on hold waiting for exit from Freeze or low-power mode and to be unlocked. If an MB is unlocked during freeze mode, the move-in happens immediately.

The move-in process is the execution by the CANFD module of the following steps:

1. Push `CANFD_RX_FIFO.IDHIT` into the `CANFD_RX_FIFO` FIFO if the message is destined to the Rx FIFO.
2. Read all data words from the Rx SMB according to the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox according to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the C/S and ID words from the Rx SMB.
5. Write C/S and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately canceled by the inactivation of the destination mailbox (See Mailbox Inactivation). In this case, the mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO message buffer, in which case the process cannot be canceled.

The BUSY bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the processor that the message buffer content is temporarily incoherent.

Move-Out

The move-out process is the copy of the content from a Tx mailbox to the Tx SMB when a message for transmission is available (See Arbitration Process). The move-out occurs in the following conditions:

- The first bit of intermission field.
- During the bus off state when TX error counter is in the 124 to 128 range.
- During bus idle state.
- During the wait for bus idle state.

The move-out process is not atomic. Only the processor has priority to access the memory concurrently out of bus idle state. In bus idle, the move-out has the lowest priority to the concurrent memory accesses.

Data Coherence

In order to maintain data coherency and proper operation of the CANFD module, the processor must obey the rules described in the Transmit Process and Receive Process sections.

Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the processor if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- The `CANFD_CFG.ABORTEN` bit is enabled.
- The first processor action must be the writing of abort code (1001) into the CODE field of the C/S word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a mailbox that is currently being transmitted or to a mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The CANFD module loses the bus arbitration.
- There is an error during the transmission.
- The CANFD module is put into freeze mode.
- The CANFD enters the bus off state.
- There is an overload frame.

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the respective `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt to the processor is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the respective `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt is (optionally) generated.

If the processor writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. The processor just needs to read the abort code to make sure the active MB was safely inactivated. Although the CANFD_CFG.ABORTEN bit is asserted and the processor wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- The processor checks the corresponding IFLAG and clears it, if asserted.
- The processor writes 1001 into the CODE field of the C/S word.
- The processor waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- The processor reads the CODE field to check if the frame was either transmitted (CODE = 1000) or aborted (CODE = 1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.
- It is necessary to reconfigure the EDL, BRS, and ESI fields of the aborted MB before transmitting it again.

Mailbox Inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the CANFD internal processes, thus allowing the processor to rely on mailbox data coherence after having updated it, even in normal mode.

Inactivation of transmission mailboxes must be performed only when the CANFD_CFG.ABORTEN bit is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated.

To inactivate a mailbox, the processor must update its CODE field to INACTIVE (either 0000 or 1000).

Because the processor is not able to synchronize the CODE field update with the CANFD internal processes, an inactivation has the following consequences:

- A frame on the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

To perform a safe inactivation and avoid the above consequences for Tx mailboxes, the processor must use the transmission abort mechanism .

The inactivation automatically unlocks the mailbox (See Mailbox Lock Mechanism).

NOTE: Message buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region. The processor must maintain data coherency in the FIFO region when the CANFD_CFG.RFEN bit is enabled.

Mailbox Lock Mechanism

Other than mailbox inactivation, the CANFD module has another data coherence mechanism for the receive process. When the processor reads the C/S word of an Rx MB with codes FULL or OVERRUN, the CANFD assumes that the processor wants to read the whole MB in an atomic operation and therefore it sets an internal lock flag for that MB. The lock is released when the processor reads the CANFD_TIMING register (global unlock operation), or when it reads the C/S word of another MB regardless of its code. A processor write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the processor is reading it.

NOTE: The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code other than INACTIVE (0000) or EMPTY (0100). Tx MBs can not be locked. When the CANFD_CFG.IRMQEN bit is disabled, reading the C/S word locked the MB even if it was EMPTY.

If the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and the CANFD module has already received and stored messages into these two MBs. If the processor then attempts to read MB number 5 and at the same time another message with the same ID is arriving, then when the processor reads the C/S word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no “free-to-receive” MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the message in the Rx SMB and there is no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is enabled. If the processor reads the C/S word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is cleared.

NOTE: If the BUSY bit is enabled or if the MB is empty, then reading the C/S word does not lock the MB.

Inactivation takes precedence over locking. If the processor inactivates a locked Rx MB, then the lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB is transferred to the MB. An MB is unlocked when the processor reads the CANFD_TMR register, or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both normal and freeze modes.

An unlock during normal or freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode, and it takes place only when the module resumes to normal or freeze mode.

Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CANFD_CFG.RFEN bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the CANFD module that did not have the FIFO feature.

NOTE: The Rx FIFO must not be enabled when the CAN FD feature is enabled.

The Rx FIFO is 6 messages deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in the Rx FIFO Structure section. The processor can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

The frames available bit (CANFD_IFLG1.MB05)is enabled when there is at least one frame available to be read from the Rx FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the processor reads the message (accessing the output of the FIFO as a message buffer) and the CANFD_RX_FIFO register, then clears the interrupt. If there are more messages in the Rx FIFO, the act of clearing the interrupt updates the output of the FIFO with the next message and updates the CANFD_RX_FIFO register with the attributes of that message, reissuing the interrupt to the processor. Otherwise, the flag remains negated. The output of the Rx FIFO is only valid while the CANFD_IFLG1.MB05 bit enabled.

The Rx FIFO warning bit (CANFD_IFLG1.MB06) is enabled when the number of unread messages in the Rx FIFO is increased to five from four due to the reception of a new message, meaning that the Rx FIFO is almost full. The flag remains enabled until the processor clears it.

The Rx FIFO overflow bit (CANFD_IFLG1.MB07) is enabled when an incoming message is lost because the Rx FIFO is full. The CANFD_IFLG1.MB07 bit is not set when the Rx FIFO is full and the message is captured by a mailbox. The CANFD_IFLG1.MB07 remains set until the processor clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is enabled.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to the CANFD_CTL2.RFFNUM bit setting, that is configurable to one of the following formats:

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE: A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding identifier acceptance filter hit indicator (IDHIT) that can read in the IDHIT field from C/S word. Another way the processor can obtain this information is by accessing the CANFD_RX_FIFO register. The CANFD_RX_FIFO.IDHIT field refers to the message at the output of the FIFO

and is valid while the CANFD_IFLG1.MB05 flag is enabled. The CANFD_RX_FIFO register must be read only before clearing the flag, to guarantee that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the individual mask registers (CANFD_IMSK1 and CANFD_IMSK2), according to the setting of the CANFD_CTL2.RFFNUM bit, allowing very powerful filtering criteria to be defined. If the CANFD_CFG.IRMQEN bit is disabled, then the FIFO filter table is affected by the CANFD_RX_FIFO_GMSK register value.

Rx FIFO Under DMA Operation

The Rx FIFO can support DMA. Using the Rx FIFO with the DMA feature is enabled by enabling both CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits. The DMA controller reads the received message by reading a message buffer structure at the FIFO output port at the 0x80–0x8C address range.

The reset value of the CANFD_CFG.DMAEN bit is zero. When the CANFD_CFG.DMAEN is enabled, the processor must not access the FIFO output port address range. Before enabling the CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CANFD_CFG.DMAEN, the processor must perform a clear FIFO operation.

The Frames available in Rx FIFO bit (CANFD_IFLG1.MB05) is asserted when there is at least one frame available to be read from the FIFO; consequently, a DMA request is generated simultaneously. Upon receiving the request, the DMA controller reads the message (accessing the output of the FIFO as a message buffer). The DMA reading process must end by reading address 0x8C, which clears the CANFD_IFLG1.MB05 bit and updates both the FIFO output with the next message (if FIFO is not empty) and the CANFD_RX_FIFO register with the attributes of the new message. If there are more messages stored in the FIFO, the CANFD_IFLG1.MB05 bit is re-enabled and another DMA request is issued.

NOTE: The CANFD_RX_FIFO register contents cannot be read after the DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080.

The CANFD_IFLG1.MB06 and CANFD_IFLG1.MB07 flags are not used when the DMA feature is enabled.

When the CANFD module is working with DMA, the processor does not receive any Rx FIFO interrupts and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

There is no dedicated DMA channel for reading the CANFD FIFO, however, the MDMA along with the TRU can read from the FIFO RAM. This works by configuring the CANFD module to generate a trigger whenever the CANFD_IFLG1.MB05 bit is set. The MDMA is configured to wait for the trigger from the CANFD module and on receiving the trigger, read from the CANFD FIFO start address at 0x80 offset. Once 16 bytes of FIFO data are read, the CANFD_IFLG1.MB05 bit is cleared.

Only MDMA2 and MDMA6 streams can access the CANFD FIFO.

Clear FIFO Operation

When the CANFD_CFG.RFEN is enabled, the clear FIFO operation is empties the FIFO contents. With the CANFD_CFG.RFEN bit enabled, the clear FIFO occurs when the processor writes a one to the

CANFD_IFLG1.MB01 bit. This operation only can only occur in freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently, the processor must service all FIFO IFLAGs before executing the clear FIFO task.

When the Rx FIFO is working with DMA, the clear FIFO operation clears the CANFD_IFLG1.MB05 flag and the DMA request is canceled.

NOTE: The clear FIFO operation does not clear IFLAGs, except when the CANFD_CFG.DMAEN bit is enabled. When the CANFD_CFG.DMAEN bit is enabled, only the CANFD_IFLG1.MB05 flag is cleared.

CAN Protocol Features

This section describes the CAN protocol related features.

CAN FD Frames

The ISO 11898-1 standard specifies the classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN flexible data rate frame format. The classical frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The flexible data rate frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. The CANFD module can receive and transmit CAN FD messages interleaved with classical CAN messages.

There are three additional control bits in the CAN FD frame:

- The extended data length (EDL) bit enables a longer data payload with different data length coding.
- The bit rate switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The error state indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no remote frames in the CAN FD format. A message configured to transmit a remote frame is always sent out in the classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is cleared. The RTR bit is considered in only in classical CAN frames.

CAN FD messages can be formatted as long frames, in which the data field exceeds 8 bytes and may range from 12 up to 64 bytes. CAN FD messages can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame.

Messages in the classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The *CAN Message Format* figure illustrates the message formats for classical and FD frames with either a standard or extended ID.

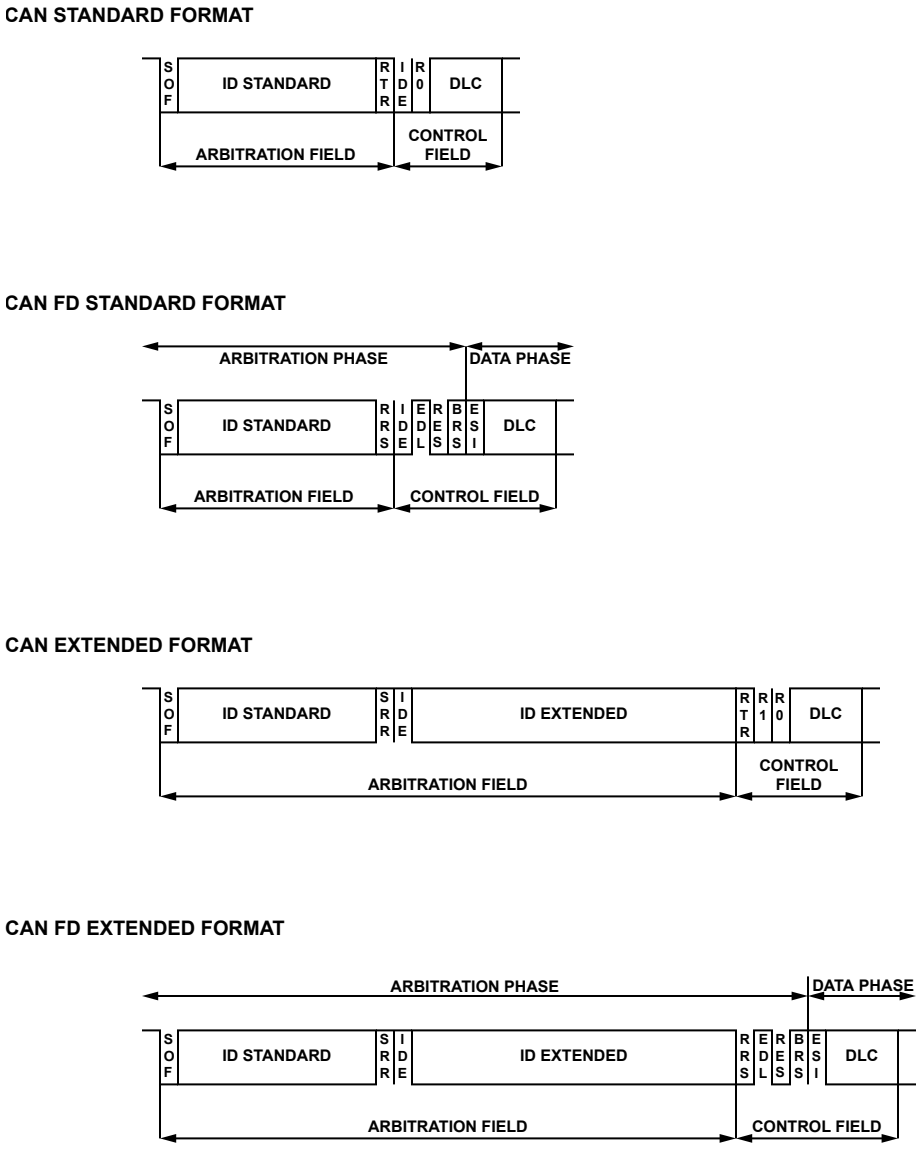

Figure 15-5: CAN Message Format

The ability to receive and transmit CAN FD messages is enabled by the `CANFD_CFG.FDEN` bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value.

CANFD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the start of frame (SOF) bit until the bit rate switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC delimiter until the intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration

phase, the nominal CAN bit timing defined by the CANFD_TIMING register and also by the CANFD_CTL1 register for backward compatibility. Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CANFD_FD_TIMING register.

NOTE: If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and lasts until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use CAN FD frames.

The CANFD_FD_CTL.BRSEN bit enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. When the bit is cleared, the transmission is performed at nominal rate regardless of the BRS bit value. The CANFD_FD_CTL.BRSEN bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC delimiter bit or when an error is detected, whichever occurs first. The *CAN FD Message Bit Rate Switching* figure describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

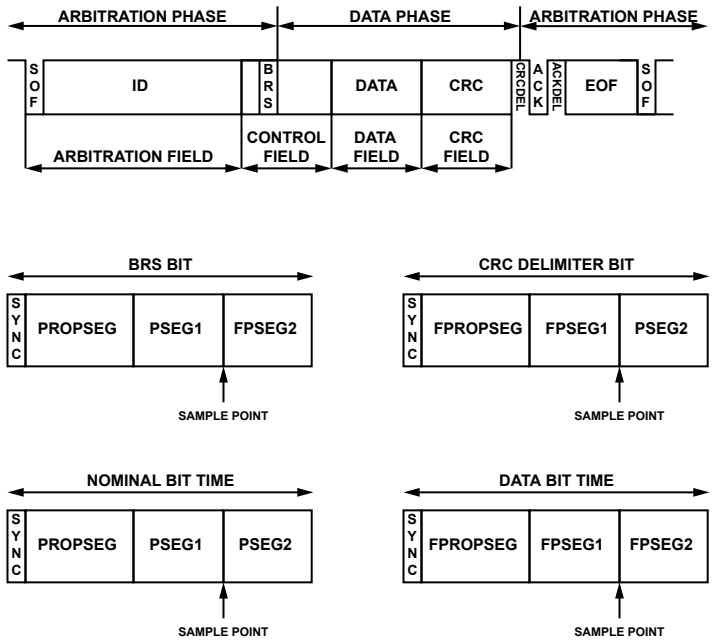

Figure 15-6: CAN FD Message Bit Rate Switching

NOTE: In classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. The CANFD module sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, the CANFD module sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, the CANFD module accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The value of the ESI bit is determined either by the error state of the transmitter at the start of the transmission, if the frame is originated in the CANFD node, or by the original transmitting node if the CANFD module is acting as a gateway for the message. If the transmitter is error passive, the ESI is transmitted recessive; otherwise, it is transmitted dominant.

There are different CRC polynomials for different CAN frame formats:

- The first polynomial, CRC_15, is for all frames in classical CAN format.
- The second, CRC_17, is for frames in CAN FD format with a data field up to 16 bytes long.
- The third, CRC_21, is for frames in CAN FD format with a data field longer than 16 bytes.

Each polynomial results in a hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, the CANFD module decodes the EDL and DLC bits to select the proper CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CANFD_FD_CRC register stores the calculated CRC for the transmitted message, with the adequate length for the type of message, for both CAN FD and non-FD messages. The CANFD_CRC register reports a valid CRC for classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When the CANFD module is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When the CANFD module is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

The CANFD module detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters CANFD_ECR.RXERRCNT and CANFD_ECR.TXERRCNT in the CANFD_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set. The rules for updating the error counters are the same for both CAN FD and non-FD frames.

The error flags CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if the CANFD_CTL1.ERRMSK bit is enabled. The CANFD_ESR1 register has additional error flags (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported with the CANFD_ESR1.FLTCONF bit is the same for both CAN FD and classical CAN frames, and is based on CANFD_ECR.RXERRCNT and

CANFD_ECR.TXERRCNT error counters only. Information contained in CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF counters may be considered as status to help detect the error nature related to the bit rate value. The *CANFD State Related Bit Encoding* table shows how the CANFD state is related to the CANFD_ESR1.SYNC, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, and CANFD_ESR1.RXINPROG bits.

Table 15-19: CANFD State Related Bit Encoding

SYNC	IDLE1	TXINPROG	RXINPROG	CANFD State
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

When the CANFD is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in classical CAN frames. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. The CANFD does not resynchronize while transmitting in the CAN FD data phase.

Transceiver Delay Compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the BRS bit of the message is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled, the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The CANFD module supports an optional transceiver delay compensation (TDC) mechanism that defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism is enabled by the CANFD_FD_CTL.TDCOMPEN bit and is effective only during the data phase of CAN FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC mode is active from the sample point of the BRS bit until the sample point of the CRC delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE: The actual value of the CRC delimiter bit is disregarded by transmitters using the TDC mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during an acknowledge or end of frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit, as shown in the *Transceiver Loop Delay Measurement* figure.

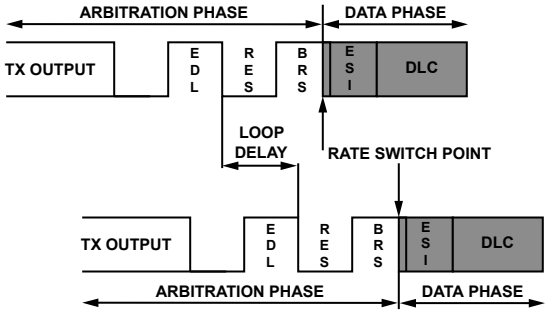

Figure 15-7: Transceiver Loop Delay Measurement

The loop delay is measured in PE clock periods (CANCLK) , from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified with the `CANFD_FD_CTL.TDCOMPOFF` bit. The `CANFD_FD_CTL.TDCOMPVAL` bit field stores the result of this calculation. The `CANFD_FD_CTL.TDCOMPVAL` value saturates at the maximum value of 15 CANCLK when the delay measurement is too long.

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset (`CANFD_FD_CTL.TDCOMPOFF`) shifts the secondary sample point from the edge to an intermediate point inside the bit time (for example, half of the bit time in the data phase), far away from its edges. Therefore, the `CANFD_FD_CTL.TDCOMPOFF` value cannot be larger than the CAN bit duration in the data phase.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on the `CANFD_FD_CTL.TDCOMPVAL` value is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the CANFD module issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, the delay compensation is always disabled. The maximum delay that can be compensated by the transceiver delay compensation during the data phase is 3 CAN bit times - 2 Tq. Beyond this limit, the `CANFD_FD_CTL.TDCOMPFAIL` flag is set to indicate when the TDC mechanism is out of range and unable to compensate the transceiver loop delay.

Remote Frames

A remote frame is a special kind of frame. The processor can program a mailbox to be a remote request frame by configuring the mailbox to transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by the CANFD module, it is treated in one of the following three ways, depending on the `CANFD_CTL2.RRS` and `CANFD_CFG.RFEN` bits:

- If RRS is disabled, the frame ID is compared to the IDs of the transmit message buffers with the CODE field 1010. If there is a matching ID, then this mailbox frame is transmitted. Note that if the matching mailbox has the RTR bit set, then the CANFD module transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is enabled, the frame ID is compared to the IDs of the receive mailboxes with the CODE field 0100, 0010, or 0110. If there is a matching ID, then this mailbox stores the remote frame in the same fashion of a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If RFEN is asserted, the CANFD does not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the FIFO and presented to the processor. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

NOTE: There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. The CANFD receives and transmits remote frames in the classical CAN format.

Overload Frames

The CANFD module transmits overload frames due to the detection of the following CAN bus conditions:

- Detection of a dominant bit in the first/second bit of intermission.
- Detection of a dominant bit at the 7th bit (last) of end of frame field (Rx frames).
- Detection of a dominant bit at the 8th bit (last) of error frame delimiter or overload frame delimiter.

Time Stamp

The value of the CANFD_TMR register is sampled at the beginning of the identifier field on the CAN bus, and is stored at the end of the move-in process in the TIME STAMP field, providing network behavior with respect to time. The free running timer is clocked by the CANFD bit-clock, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The CANFD_TMR register is not incremented during module disable, doze, stop, and freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization.

Protocol Timing

The *CAN Engine Clocking Scheme* figure shows the structure of the clock generation circuitry that prescales the CAND module clock to generate the Sclock.

Figure 15-8: CAN Engine Clocking Scheme

The CANFD module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The CANFD_CTL1 register has fields to control bit timing parameters: CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.RJW.

The CANFD_TIMING register extends the range of the CAN bit timing variables in the CANFD_CTL1 register. The CANFD_TIMING register provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the BRS bit set.

NOTE: When the CAN FD feature is enabled, always set the CANFD_TIMING.BTF bit and configure the CAN bit timing variables in the CANFD_TIMING register.

The CANFD_CTL1.PRESDIV bit field (as well as the extended range CANFD_TIMING.EPRESDIV and CANFD_FD_TIMING.FPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value that generates Sclock. The Sclock period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$Tq = (PRESDIV + 1) / f_{CANCLK}$

The bit rate, which defines the rate at which the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) * Tq

Bit Rate = 1/CAN Bit Time

A bit time is subdivided into three segments:

- SYNC_SEG – Has a fixed length of one time quantum. Signal edges are expected to occur within this segment.
- Time segment 1 – Includes the propagation segment and the phase segment 1 of the CAN standard. Time segment 1 is programmed by setting the CANFD_CTL1.PROPSEG and the CANFD_CTL1.PSEG1 fields so that their sum (plus 2) is in the range of 2 to 16 time quanta. When the CANFD_TIMING.BTF bit is enabled, the CANFD module uses the CANFD_TIMING.EPROPSEG and CANFD_TIMING.EPSEG1 bit fields so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2 – Represents the phase segment 2 of the CAN standard. It can be programmed by setting the CANFD_CTL1.PSEG2 bit field (plus 1) to be 2 to 8 time quanta long. When the CANFD_TIMING.BTF

bit is enabled, the CANFD module configures the CANFD_TIMING.EPSEG2 bit field with a value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses the CANFD_FD_TIMING.FPSEG2 bit field instead, so that the value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the information processing time (IPT), which is 2 time quanta.

See the *Bit Time Segment Example One* figure for an example using CANFD_CTL1 register bit timing variables for classical can format. See the *Bit Time Segment Example Two* figure for an example using CANFD_TIMING and CANFD_FD_TIMING register bit timing variables for CAN FD format. See the *Time Segment Syntax* table for syntax descriptions.

NOTE: For further explanation of the underlying concepts, see the ISO 11898-1 standard and the CAN 2.0A/B protocol specification for bit timing.

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an IPT of 2, which is the value implemented in the CANFD module.

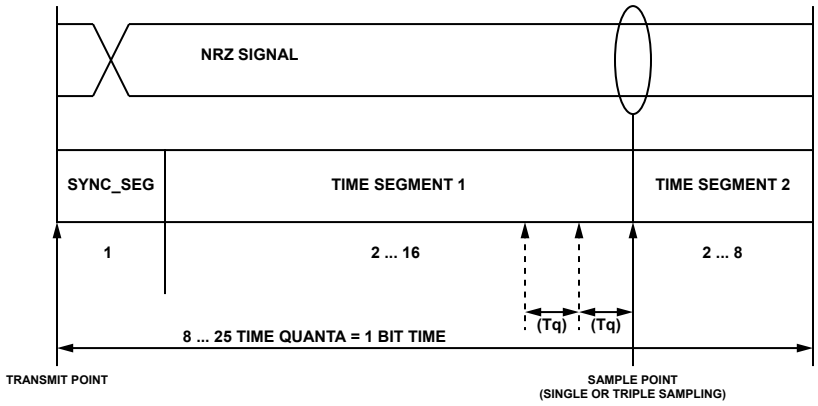

Figure 15-9: Bit Time Segment Example One

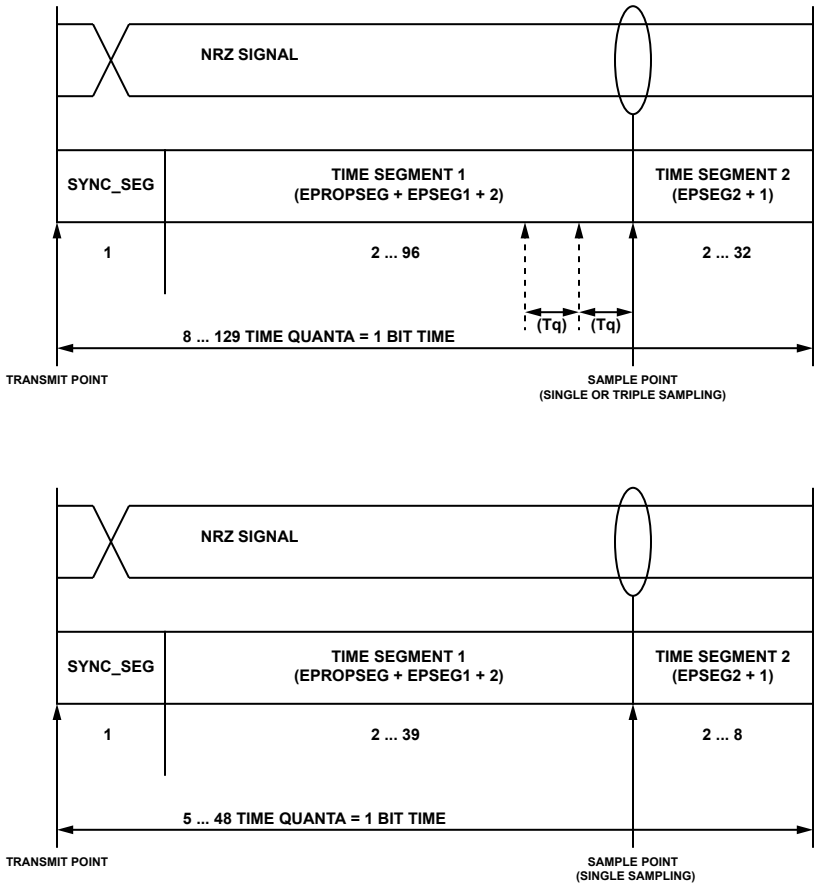

Figure 15-10: Bit Time Segment Example Two

Table 15-20: Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The *BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings* table gives some examples of the CAN compliant segment settings for classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 15-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Resynchronization Jump Width
	2	1 .. 2

Table 15-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings (Continued)

Time Segment 1	Time Segment 2	Resynchronization Jump Width
5 .. 10		
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE: Ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever a CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) is calculated as NumClkBit = (f_{SYS}/f_{CANCLK}) x (PRESDIV + 1) x (PROPSEG + PSEG1 + PSEG2 + 4), where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the PE clock in Hz
- f_{SYS} is the frequency of operation of the system CHI clock in Hz.
- PSEG1 is the `CANFD_CTL1.PSEG1` value.
- PSEG2 is the `CANFD_CTL1.PSEG2` value.
- PROPSEG is the `CANFD_CTL1.PROPSEG` value.
- PRESDIV is the `CANFD_CTL1.PRESDIV` value.

The formula above is also applicable to the alternative CAN bit timing variables described in the `CANFD_TIMING` register and the `CANFD_FD_TIMING` register. For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

Arbitration and Matching Timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

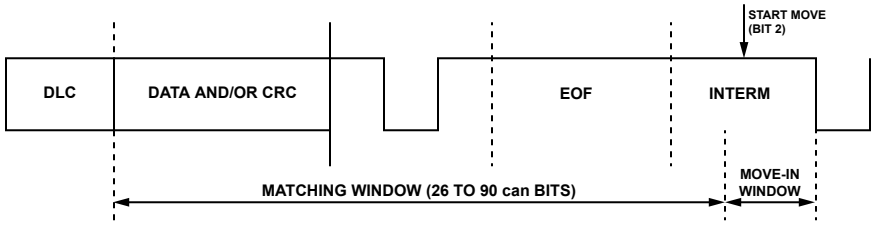

Figure 15-11: Matching and Move-In Time Windows

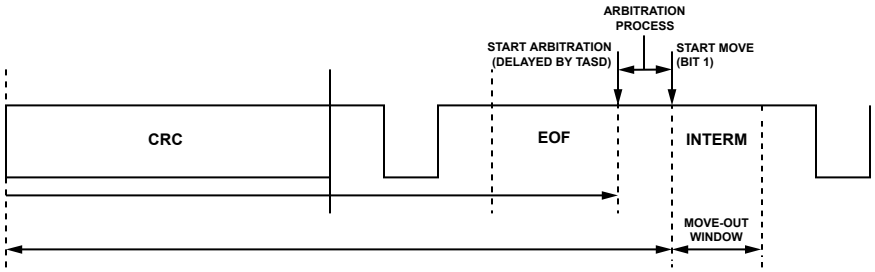

Figure 15-12: Arbitration And Move-out Time Windows

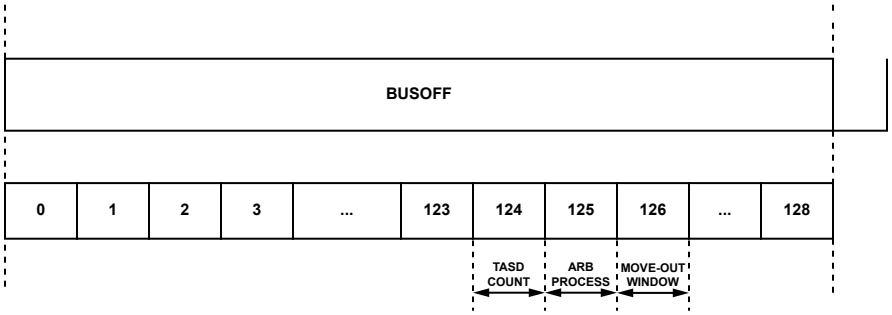

Figure 15-13: Arbitration At The End Of Bus Off And Move-out Time Windows

NOTE: In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the processor or other internal CANFD submodules.

Tx Arbitration Start Delay

The Tx arbitration start delay (`CANFD_CTL2.TXASDLY` bit field) is a variable that indicates the number of CAN bits used by the CANFD to delay the Tx arbitration process start point from the first bit of the CRC field of the current frame.

The `CANFD_CTL2.TXASDLY` bit field can only be written only in freeze mode and is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the processor to reconfigure MBs for transmission after the end of the internal arbitration process, in which the CANFD module finds the winner MB for transmission according to the standard arbitration process. If the arbitration ends before the first bit of the intermission field, then there is a chance the processor reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

The `CANFD_CTL2.TXASDLY` bit field is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as the CAN bit timing variables that determine the CAN bit rate and the number of MBs in use by the matching and arbitration processes.

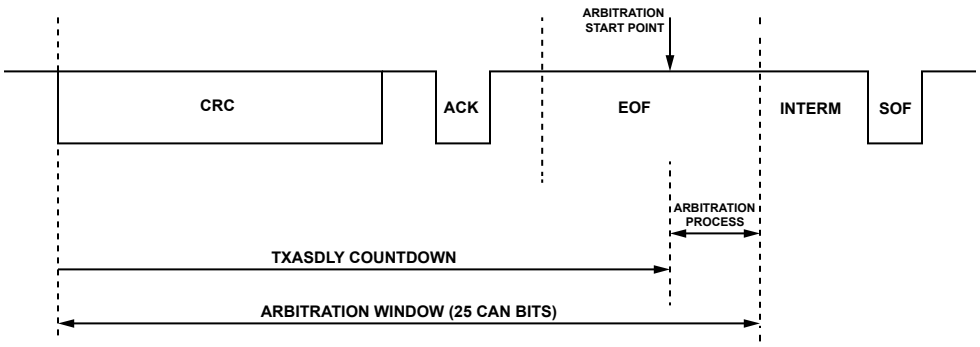

Figure 15-14: Optimal Tx Arbitration Start Point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration is placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If the `CANFD_CTL2.TXASDLY` field is set to zero, the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if the `CANFD_CTL2.TXASDLY` value is close to 24, then the processor can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration, the CANFD module may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal `CANFD_CTL2.TXASDLY` value is calculated as follows:

For CAN FD frames and (MAXMB + 1) $\leq NMB_{END}$, TXASDLY = 31 – ((2*(MAXMB + 1) + 4)/$CPCB_N$)

For CAN FD frames and (MAXMB + 1) > NMB_{END}, TXASDLY = 22 – ((2*(MAXMB + 1) - NMB_{END})/ $CPCB_F$)

For non-FD frames, TXASDLY = 25 – (((2*(MAXMB + 1) + 4)) / CPCB) where:

NMB_{END} = ((9 * CPCBN) - 4) / 2

$BITRATE_N$= f_{CANCLK} / ([1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] x (EPRESDIV + 1))

$BITRATE_F$= f_{CANCLK} / ([1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] x (FPRESDIV + 1))

$CPCB_N$ = f_{SYS} / $BITRATE_N$

$CPCB_F$ = f_{SYS} / $BITRATE_F$

CPCB = $CPCB_N$

- MAXMB is the `CANFD_CFG.MAXMB` value.

- NMBEND is the number of MBs that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame.
- BITRATEN is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- BITRATEF is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- CPCBN is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- CPCBF is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the `CANFD_TIMING.EPSEG1` or `CANFD_CTL1.PSEG1` value.
- EPSEG2 is the `CANFD_TIMING.EPSEG2` or `CANFD_CTL1.PSEG2` value.
- EPROPSEG is the `CANFD_TIMING.EPROPSEG` or `CANFD_CTL1.PROPSEG` value.
- EPRESDIV is the `CANFD_TIMING.EPRESDIV` or `CANFD_CTL1.PRESDIV` value.
- FPSEG1 is the `CANFD_FD_TIMING.FPSEG1` value.
- FPSEG2 is the `CANFD_FD_TIMING.FPSEG2` value.
- FPROPSEG is the `CANFD_FD_TIMING.FPROPSEG` value.
- FPRESDIV is the `CANFD_FD_TIMING.FPRESDIV` value.

NOTE: The f_{SYS} and f_{CANCLK} is same clocked from CDU CLKO4.

The following table give the TXASDLY value calculated for some configuration cases.

- f_{CANCLK} = 40 MHz
- Bit rate in arbitration phase = 1 Mbaud

Table 15-22: TXASDLY Values For Case Example

Number of MBs	TXASDLY Value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

CANFD Clock Domains and Restrictions

When doing matching and arbitration, the CANFD module needs to scan the entire MB memory during the time slot of one CAN frame, comprising a number of CAN bits. In order to have sufficient time to do that, there must be a minimum number of peripheral clocks per CAN bit, as specified in the *CAN Bit Minimum Peripheral Clock* table.

Table 15-23: CAN Bit Minimum Peripheral Clock

Number of Mailboxes	**CANFD_CFG.RFEN** Bit Value	Minimum Peripheral Clocks per CAN Bit
16	0	16
32	0	16
64	0	25
96	0	37
128	0	49
16	1	16
32	1	17
64	1	30

For the classical CAN frame format, the minimum number of peripheral clocks per CAN bit specified in the *TXASDLY Values For Case Example* table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the CANFD_CTL1 register or the CANFD_TIMING register. The time quantum (Tq) is defined in the Protocol Timing section. The minimum number of time quanta per CAN bit must be 8, so the CAN clock frequency is at least 8 times the CAN bit rate.

For the CAN FD frame format, the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNom-Bit) is calculated with the following equation:

NumClkNomBit =(fSYS/fCANCLK) X (PRESDIV + 1) X (PROPSEG + PSEG1 + PSEG2 + 4)

= fSYS/NomBitRate

where PRESDIV, PSEG1 and PSEG2 are CAN bit time values in the CANFD_CTL1 register. Alternatively, the EPRESDIV, EPSEG1 and EPSEG2 values in the CANFD_TIMING register can be used instead. NumClkNomBit is also calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate).

The number of CAN bits in the data phase of a FD frame with the BRS bit set depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frame Fast CAN Bits* table. The less the number of data bytes, the less the number of fast CAN bits, and less time is available for the CANFD module to scan the whole MB memory during the internal matching and arbitration processes.

Table 15-24: CAN FD Frame Fast CAN Bits

Minimum Data Bytes	DLC Field	Number of Fast Bits
0	0x0	21
1	0x1	29
2	0x2	37
3	0x3	45
4	0x4	53
5	0x5	61
6	0x6	69
7	0x7	77
8	0x8	85
12	0x9	117
16	0xA	149
20	0xB	186
24	0xC	218
32	0xD	282
48	0xE	410
64	0xF	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is calculated so that enough time is available for the CANFD module to scan the MB memory during reception and transmission. The equation below calculates this constraint:

MinNumClkFastBit = ((8.5 x MaxNumOfMb) + 64 - (9 x NumClkNomBit)) / NumOfFastBits

where MaxNumOfMb is the maximum number of available mailboxes defined in the `CANFD_CFG.MAXMB` bit field.

The clock domain crossing circuit between the CHI and PE submodules also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the following equation:

MinNumClkFastBit = 3 x (1 + (f_{SYS}/f_{CANCLK}))

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above:

MinNumClkFastBit = Maximum (MinNumClkFastBit , MinNumClkFastBit)

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) is calculated as follows:

DataBitRate = f_{CANCLK} / (ROUNDUP ((MinNumClkFastBit x f_{CANCLK}) / f_{SYS}

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by the CANFD module in CAN FD mode. In addition, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of CANFD variables, an consider an application example with the peripheral and oscillator clock frequencies set to 50 MHz.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as follows: NumClkNomBit = (50 x 10^6)/(1 x 10^6) = 50
2. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated as follows:

   MinNumClkFastBit = ((8.5 X 96) + 64 - (9 X 50)) / 85 = 5.06

   MinNumClkFastBit = 3 x (1 + 50/50) = 6.0

   MinNumClkFastBit = Maximum (5.06 , 6.0) = 6.0

As demonstrated in this example, even though the oscillator clock frequency (50 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific CANFD configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the $MinNumClkFastBit_B$ limit.

The *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table shows the maximum data rate for CAN FD according to the clock frequencies, payload size, and number of available mailboxes. As shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table, for some cases, if the number of available mailboxes is reduced, the CANFD module achieves a data rate up to 8 Mbps.

Table 15-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	128	8.0
60	12	128	8.0

Table 15-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase (Continued)

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

CANFD Operating Modes

The CANFD module has functional modes and low-power modes.

CAUTION: The CANFD does not support the permanent dominant failure on the CAN bus line. If a low-power request or freeze mode request is done during a permanent dominant, the corresponding acknowledge can never be asserted.

The CANDFD module has the following main functional modes:

- Normal Mode
- Freeze Mode
- Loop-Back Mode
- Listen-Only Mode
- CAN FD Active Mode

For low-power operation, the CANDFD module has the following modes:

- Module Disable Mode
- Doze Mode
- Stop Mode
- Pretended Network Mode

NOTE: The CANFD does not support the permanent dominant failure on the CAN bus line. If there is a low-power request or freeze mode request during a permanent dominant, the corresponding acknowledge will not be asserted.

Normal Mode

In normal mode, the CANFD module operates by receiving and transmitting message frames. In this mode, errors are handled normally and all CAN protocol functions are enabled.

Freeze Mode

In freeze mode, there is no transmission or reception of frames and synchronicity to the CAN bus is lost. Freeze mode is enabled by setting the CANFD_CFG.FRZ bit.

Freeze mode is requested either by the processor by enabling the CANFD_CFG.HALT bit or when it is put into debug mode. In both cases, when the CANFD_CFG.FRZ bit is enabled, the CANFD module must not be in a low-power mode. Freeze mode is also requested through the automatic assertion of both the CANFD_CFG.HALT and CANFD_CFG.FRZACK bits when the CANFD_MEC.NCERRFRZEN bit is set and a non-correctable error is detected in a memory read access performed by CANFD internal processes. The acknowledgement is obtained through the assertion by the CANFD_CFG.FRZACK bit. The CANFD module is only in freeze mode when both the request and acknowledge conditions are satisfied.

In response to a freeze mode request, the CANFD module performs the following operations:

- Waits to be in either the intermission, passive error, bus off, or idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent going to freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the CANFD_ECR register, which is read-only in other modes.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.FRZACK bits.

After requesting freeze mode, wait for the CANFD_CFG.FRZACK bit to be set before executing any other action, or the CANFD module will not operate properly.

To exit freeze mode, disable the CANFD_CFG.FRZ bit, remove the processor from debug mode, or disable the CANFD_CFG.HALT bit.

The CANFD_CFG.FRZACK bit is disabled after the PE recognizes the negation of the freeze request. Once out of freeze mode, the CANFD module tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

Loop-Back Mode

The CANFD module enters loop-back mode when the CANFD_CTL1.LBEN is set. In loop-back mode, the CANFD module performs an internal loop back for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic ‘1’). The CANFD module behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

Listen-Only Mode

The CANFD module enters listen-only mode when the CANFD_CTL1.LOMEN bit is enabled. In listen-only mode, transmission is disabled, all error counters are frozen, and the CANFD module operates in a CAN error passive mode. The module only receives messages acknowledged by another CAN station. If the CANFD detects a message that has not been acknowledged, it flags a BIT0 error (without changing the receive error counter), as if it were trying to acknowledge the message.

CAN FD Active Mode

In CAN FD active mode, the CANFD module can transmit and receive all messages formatted according to the CAN FD protocol and CAN 2.0 (protocol 2.0) in an interleaved fashion. The CANFD module is put into CAN FD active mode by setting the CANFD_CFG.FDEN bit when in freeze mode.

Module Disable Mode

The module disable mode is a low-power mode normally used to temporarily disable a complete CANFD block, with no power consumption. To enter module disable mode, enable the CANFD_CFG.DIS bit. Once the processor is in module disable mode, the CANFD_CFG.LPMACK bit is set.

Do not use module disable mode under pretended networking mode. Disable the CANFD_CFG.DIS bit and wait for CANFD_CFG.LPMACK bit to clear before enabling the CANFD_CFG.PNETEN bit.

If the CNAFD module is disabled during transmission or reception, it will perform the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the module disable mode.

To exit module disable mode, disable the CANFD_CFG.DIS bit. If the CANFD module is disabled during freeze mode, it sends a requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

Doze Mode

The doze mode is a system low-power mode in which the processor bus is kept alive and a global doze mode request is sent to all peripherals asking them to enter low-power mode. Before sending a global doze mode request, set the CANFD_CFG.DOZEN bit. The global doze request is set with the MISCREG_CAN_SYSCTL.CAN1_IPG_DOZE or MISCREG_CAN_SYSCTL.CAN0_IPG_DOZE bit. Once the processor requests the doze mode, the CANFD_CFG.LPMACK bit is set.

To exit doze mode, disable the CANFD_CFG.DOZEN bit or clear the IPG_DOZE bits in the MISCREG_CAN_SYSCTL register. The CANFD module will also exit doze mode when activity is detected on the CAN bus and the self wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

If the doze mode is triggered during freeze mode, the CANFD module requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

If doze mode is triggered during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the doze mode.

Exiting Doze mode is done in one of the following ways:

- Disabling the doze mode request in the MISCREG_CAN_SYSCTL register.
- Disabling the CANFD_CFG.DOZEN bit.
- When the CANFD module detects activity on the CAN bus and the self wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

If the self wake up mechanism is enabled at the time that the CANFD module entered doze mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module clears the CANFD_CFG.DOZEN bit, requests to resume clocks, and disables the CANFD_CFG.LPMACK bit after the CAN PE recognizes the doze mode is disabled.

The CANFD module also sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. The CANFD module then waits for 11 consecutive recessive bits to

synchronize to the CAN bus. As a consequence, the CANFD module does not receive the frame that woke it up. The *Wake Up From Doze Mode* table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon wakeup from the doze mode.

Table 15-26: Wake Up From Doze Mode

SLFWAKEN	WAKINT	WAKMSK	CANFD Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in doze mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Stop Mode

The stop mode is a system low-power mode in which all clocks are stopped for maximum power savings. A global stop request is set with the MISCREG_CAN_SYSCTL.CAN0_IPG_STOP or MISCREG_CAN_SYSCTL.CAN1_IPG_STOP bit. Once the processor is in the stop mode, the CANFD_CFG.LPMACK bit is set.

If the CANFD module receives a global stop mode request during freeze mode, it sets the CANFD_CFG.LPMACK bit, clears the CANFD_CFG.FRZACK bit, and then sends the stop acknowledge signal to the processor to shut down the clocks globally.

If stop mode is requested during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.
- Sends a stop acknowledge signal to the processor to shut down the clocks globally.

Stop mode is exited when the processor resumes the clocks and removes the stop mode request, or when activity is detected on the CAN bus and the self wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

If the self wake up mechanism is enabled at the time that the CANFD module entered stop mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. Upon receiving the interrupt, the processor resumes the clocks and removes the stop mode request. The CANFD module then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, the CANFD module does not receive the frame that woke it up. The *Wakeup From Stop Mode*table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon wakeup from the stop mode. Note that wakeup from the stop mode only works when both bits are asserted.

Table 15-27: Wakeup From Stop Mode

SLFWAKEN	WAKINT	WAKMSK	Chip Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in stop mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Pretended Network Mode

Pretended networking is a special low-power mode used to receive wake up messages with low power consumption. Pretended networking mode can be selected to operate together with doze mode. Before entering low-power mode, the CANFD_CFG.PNETEN bit must be asserted. Once in low-power mode, the CHI submodule clocks are shut down and the PE submodule is kept clocked, so that the receive process is still active to filter incoming messages as defined by the configuration.

Pretended networking is a special low-power mode used to receive wake up messages with low power consumption. Pretended networking mode can be selected to operate together with doze mode. Before entering low-power mode, the CANFD_CFG.PNETEN bit must be asserted. Once in low-power mode, the CHI submodule clocks are shut down and the PE submodule is kept clocked, so that the receive process is still active to filter incoming messages as defined by the configuration.

Upon detecting a wakeup event, a wake up interrupt is issued to the system. When the CANFD_CFG.PNETEN bit is enabled, the processor disables the self wake up feature by disabling the CANFD_CFG.SLFWAKEN bit. Wake up from matched message or time-out in pretended networking modes happens only when pretended networking mode is used along with doze mode. Wakeup is not supported in stop mode.

To enter pretended networking mode, the CANFD must be in normal mode and not in freeze or module disable mode. Under pretended networking mode, the CANFD module stays synchronized with the CAN bus in doze mode. When doze is requested, the CANFD module performs the following operations:

- Waits to be in the idle state, or else waits for the third bit of intermission, and then checks it to be recessive.
- Sets the CANFD_CFG.LPMACK bit.
- Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

The CANFD module exits pretended networking mode in the following ways:

- The processor removes the doze mode request.
- The processor disables the CANFD_CFG.DOZEN bit.

The CANFD will wait until bus idle or the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit.

The above exit methods are triggered either by the CANFD module detecting a wake up event and issuing the respective interrupt, or by the processor itself upon being woken up. The CANFD will wait until the bus idle state or until the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit and resume normal mode. This procedure ensures that the CANFD module is synchronized to the CAN bus after exiting pretended networking mode. The processor must wait for the CANFD_CFG.LPMACK bit to be disabled before performing any access to the CANFD.

CANFD Event Control

The following section describe how the CANFD module generates and controls events.

Interrupts

The CANFD module has many interrupt sources: interrupts due to MBs and interrupts due to the OR'd interrupts from MBs, bus off, bus off done, error, error fast (errors detected in the data phase of CAN FD format messages with the CANFD_FD_CTL.BRSEN bit set), wake up, wake up match, wake up timeout, Tx warning, and Rx warning states.

Each one of the MBs can be an interrupt source if the corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CANFD_IFLG1 and CANFD_IFLG2 registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the processor writes it to 1 (unless another interrupt is generated at the same time).

NOTE: The processor must only clear the bit causing the current interrupt, so bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause the accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CANFD_CFG.RFEN = 1) and DMA is disabled (CANFD_CFG.DMAEN = 0), the interrupts corresponding to MBs 0 to 7 have different meanings:

- Bit 7 of the CANFD_IFLG1 register becomes the “FIFO Overflow” flag.
- Bit 6 of the CANFD_IFLG1 register becomes the “FIFO Warning” flag.
- Bit 5 of the CANFD_IFLG1 register becomes the “Frames Available in FIFO” flag.
- Bit 4-0 of the CANFD_IFLG1 register are unused.

If both Rx FIFO and DMA are enabled (CANFD_CFG.RFEN =1 and CANFD_CFG.DMAEN = 1), the CANFD does not generate any FIFO interrupt. Bit 5 of the CANFD_IFLG1 register still indicates “Frames Available in FIFO” and generates a DMA request. Bits 7, 6, and 4–0 are unused.

NOTE: The Rx FIFO cannot be enabled when the CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR’d together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the processor must read the CANFD_IFLG1 and CANFD_IFLG2 registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for bus off, bus off done, error, error fast, wake up, Tx warning ,and Rx warning generate interrupts like the MB interrupt sources, and are read from the CANFD_ESR1 register. The bus off, error, Tx warning, and Rx warning interrupt mask bits are located in the CANFD_CTL1 register; the wake up interrupt mask bit is located in CANFD_CFG register.

The interrupt sources for pretended networking (wake up by match flag and wake up by timeout flag) are read in the CANFD_WUM register and the respective interrupts masks bits are located in CANFD_PN_CTL1 register.

Bus Interface

The processor accesses to CANFD registers are subject to the following rules:

- Read and write accesses to reserved address space result in access errors.
- Write accesses to positions with bits that are all currently read-only results in access errors.

  If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to the register and bit descriptions for details.
- Read and write accesses to unimplemented address space results in access errors.
- Read and write accessed to RAM located positions during low-power modes results in access errors.
- If CANFD_CFG.MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Reserved words within RAM cannot be used.

  For example, suppose the CANFD RAM can support up to 16 MBs, the CANFD_CTL2.RFFNUM bit field is 0x0, and the CANFD_CFG.MAXMB bit field is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB.

The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one individual mask and the available memory in the mask registers space is from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF, there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on the `CANFD_CFG.MAXMB` bit field.

Detection and Correction of Memory Errors

The CANFD module supports detection and correction of errors in memory read accesses. Each byte of CANFD memory is associated with five parity bits, which ensures a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors), and errors in 2 bits can be detected but not corrected (non-correctable errors). Errors in more than 2 bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

The CANFD module detects a non-correctable error in the event either an all-zeros or an all-ones read occurs and updates the `CANFD_ERR_RSYN` register. The `CANFD_ERR_RSYN` register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

The *Syndrome Definition* table shows the SYNDn field in the `CANFD_ERR_RSYN` register, indicates the type of error, and the bit in byte (n) affected by the error. Each BEn field in the `CANFD_ERR_RSYN` register indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported as described in the Error Indication and Error Reporting sections.

Table 15-28: Syndrome Definition

SYNDn	Type	Bit Affected
0x00	N/A	None (no error)
0x01	Code	0
0x02	Code	1
0x04	Code	2
0x07	Data	5
0x08	Code	3
0x0E	Data	7
0x10	Code	4
0x13	Data	2
0x15	Data	6
0x16	Data	1
0x19	Data	3
0x1A	Data	4

Table 15-28: Syndrome Definition (Continued)

SYNDn	Type	Bit Affected
0x1C	Data	0
0x06	N/A	All-zeros non-correctable error
0x1F	N/A	All-ones non-correctable error
All others	N/A	Non-correctable error

Memory errors are indicated to the host through the CANFD_ERR_STAT register and bus transfer errors, and reported through the CANFD_ERR_RADDR,CANFD_ERR_RDAT, and CANFD_ERR_RSYN registers.

The error detection and correction mechanism is activated by the CANFD_MEC.ECCDIS bit. When error detection and correction is disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated to the data.

NOTE: All CANFD memory must be initialized before operation in order for the parity bits in memory to properly update. The CANFD_CTL2.WRMFRZEN bit grants write access to all memory positions that require initialization, ranging from 0x080 to 0xADF (and from 0xF28 to 0xFFF when the CAN FD feature is enabled). The CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers also need to be initialized. The CANFD_CFG.RFEN bit must not be set during memory initialization. The *Identifier Acceptance Filter Fields for Global Bits* table shows the configurations for the CANFD_RX_FIFO_GMSK register.

Table 15-29: Identifier Acceptance Filter Fields for Global Mask Bits

Rx FIFO ID Filter Table Element Format **CANFD_CFG.IDAM**	Identifier Acceptance Filter Fields **CANFD_RX_FIFO_GMSK.VALUE**					
RTR	IDE	RXIDA	RXIDB	RXIDC	Reserved	
A	VALUE[31]	VALUE[30]	VALUE[29:1]	N/A	N/A	VALUE[0]
B	VALUE[31], VALUE[15]	VALUE[30], VALUE[14]	N/A	VALUE[29:16], VALUE[13:0]	N/A	N/A
C	N/A	N/A	N/A	N/A	VALUE[31:24], VALUE[23:16], VALUE[15:8], VALUE[7:0]	N/A

To avoid accidentally changing the critical error correction configuration, use the following protocol to enable the CANFD_MEC register update:

1. By default, the CANFD_CTL2.ECRWREN bit is zero and the CANFD_MEC.ECRWRDIS bit is one.

2. Set the CANFD_CTL2.ECRWREN bit.
3. Clear the CANFD_MEC.ECRWRDIS bit.
4. All writes to the CANFD_MEC register must keep the CANFD_MEC.ECRWRDIS bit cleared.
5. After configuration is done, lock the CANFD_MEC register by either setting the CANFD_MEC.ECRWRDIS bit or clearing the CANFD_CTL2.ECRWREN bit.

Sources of Memory Access

The CANFD memory can be accessed by two major sources (or requesters):

- Host (processor): The largest word accessed is 32 bits wide.
- CANFD internals processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): The largest word accessed is 64 bits wide.

The way that non-correctable errors are indicated and reported depends on the source of access.

Error Indication

Memory errors are indicated by the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, and CANFD_ERR_STAT.CEI flag bits. Non-correctable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by CANFD internal processes. The CANFD makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag raises an interrupt unless it is masked in the CANFD_MEC register. If both non-correctable and correctable errors are found in different bytes of the same read operation, both flags are set.

A non-correctable error detected in host access is also indicated as a bus transfer error. A bus wait request asserts to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the CANFD_ERR_STAT.HNCEI bit is not masked, the same non-correctable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in the CANFD_ERR_STAT register. The overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. The recommended handling sequence for error indication is as follows:

1. Get the error report information from the report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN.
2. Use the error report information to take proper measures in the application.
3. Clear the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, CANFD_ERR_STAT.CEI flag bits.
4. If the overrun flag is active:
    a. Alert that application that at least one error could not be handled.

b. Clear the overrun flag bit.

The CANFD internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words, the interrupt and overrun flags are set simultaneously.

Error Reporting

The report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN provide detailed information about the address read, raw data, and syndrome read with error and indicated by the flags.

The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If any of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error, or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in the CANFD_ERR_RADDR register.

The address reported in the CANFD_ERR_RADDR register and defined in the CANFD_ERR_IADDR register are not the same as those listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the Error Injection section.

Addresses reported when reading memory portions organized as FIFOs, such as the CANFD_RX_FIFO register, refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To ensure coherence of the error report registers, turn off the report update by setting the CANFD_MEC.RERDIS bit before reading the report registers.

Response to Errors

Correctable errors have no effect on CANFD operation because affected data is corrected before use by the host or CANFD internal processes.

For host-initiated reads, a non-correctable error affects the host, but does not affect CANFD operation.

Non-correctable errors detected on memory reads requested by the CANFD internal processes result in incorrect operation depending on the state of the CANFD_MEC.NCERRFRZEN bit, as follows:

- During reception (either matching or move-in processes), when a non-correctable error occurs, an incorrect destination is selected to store the incoming frame, a corrupted frame is stored in the correct destination, or both. If the CANFD_MEC.NCERRFRZEN is set, the CANFD module stops operation automatically and enters freeze mode to prevent corrupted data from being treated as valid by CANFD internal processes. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD continues working and a corrupted frame is received.

- During the arbitration process, when a non-correctable error occurs, either a non-highest priority Tx message buffer is mistakenly selected for transmission or the data is corrupted. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the move-out. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD proceeds to move-out with a corrupted frame that will transmit on the CAN bus.
- During the move-out process, when a non-correctable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the transmission. If the CANFD_MEC.NCERRFRZEN bit is cleared, the corrupted frame is transferred from the Tx SMB to the PE submodule and transmits on the CAN bus.
- A non-correctable error can be detected beyond the move-out process, when Tx data is read from the Tx SMB (buffer located in RAM) to be transferred to the PE submodule for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus. To prevent the frame from being successfully received by the external nodes, the CANFD module inverts all bits in the CRC field (CRC sequence plus CRC Delimiter), and transmits an error flag just after CRC delimiter as a result of self-detecting a bit1 error and a form error due to the CRC field inversion. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode just after the error frame. If the CANFD_MEC.NCERRFRZEN bit is negated, the CANFD module attempts to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission. In the event the non-correctable error persists, the CANFD module eventually reaches the bus off state because of consecutive error detections. The CANFD_ECR.TXERRCNT field is updated every time the CANFD module inverts the CRC field causing errors as described above.

When the CANFD_MEC.NCERRFRZEN bit is set and the CANFD module enters freeze mode, only the host processor can cause then CANFD to exit freeze mode and resume normal mode. Assertion of the CANFD_MEC.NCERRFRZEN bit is the only way to prevent corrupted frames from transmitting on the CAN bus up to the move-out internal process.

The error report registers provide information to the application for customized handling of these situations.

Error Injection

The error injection registers CANFD_ERR_IADDR, CANFD_ERR_IDP, and CANFD_ERR_IPP are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers.

The *Error Injection Address Mapping* table shows the relationship between the error injection addresses and the ones in the module memory map. Use this table to convert from the memory map address to the correct location in the physical CANFD RAM.

NOTE: Where pairs of values are provided in the table, the first is the address when the CANFD_CFG.FDEN bit is disabled and the second is when the CANFD_CFG.FDEN bit is enabled.

Table 15-30: Error Injection Address Mapping

RAM Contents	Injection Address	Memory Map
CANFD registers	Not mapped	N/A
MBs	0x0000	0x0080
Reserved	N/A	0x0480
RXIMRs	0x0400	0x0880
Reserved	N/A	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84
RXFIR_2	0x0508	0x0A88
RXFIR_3	0x050C	0x0A8C
RXFIR_4	0x0510	0x0A90
RXFIR_5	0x0514	0x0A94
Reserved	N/A	0x0A98
CANFD_RX_MB_GMSK	0x0520	0x0010

CANFD_RX_14_MSK	0x0528	0x0014
CANFD_RX_15_MSK	0x052C	0x0018
Tx_SMB	0x0530	0x0AB0 / 0x0F28
Rx_SMB0	0x0540 / 0x0578	0x0AC0 / 0x0F70
Rx_SMB1	0x0550 / 0x05C0	0x0AD0 / 0x0FB8
ECC registers	Not mapped	0x0AE0
Pretended networking registers	Not mapped	0x0B00
CAN FD registers	Not mapped	0x0C00
Reserved	N/A	0x0C0C

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in the CANFD_ERR_IDP and CANFD_ERR_IPP registers. Injection can be selected specifically for memory accesses requested by host or by CANFD internal processes.

In case of accesses larger than 32 bits, the CANFD_MEC.EXTERRIEN bit extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE: It is very unlikely, but error injection may correct a bit with an error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the CANFD_MEC.HAERRIEN and CANFD_MEC.IAERRIEN bits must be cleared while configuring the memory injection.

CANFD Programming Model

Following sections provide some guidelines for CANFD programming.

Initialization

The CANFD module is reset in one of the three following ways:

- A chip level hard reset, that resets all memory mapped registers asynchronously.
- Setting the CANFD_CFG.SOFTRST bit , which resets some of the memory mapped registers synchronously. The *Register Reset States* table shows the registers affected by a soft reset.
- Chip level soft reset, which has the same effect as setting the CANFD_CFG.SOFTRST bit.

Soft reset is synchronous and has to follow an internal request and acknowledge procedure across clock domains and takes time to fully propagate the effects. The the CANFD_CFG.SOFTRST bit remains set while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. Exit the low-power mode and resume the clocks before applying a soft reset.

Table 15-31: Register Reset States

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_TIMING	Yes	No
CANFD_CRC	Yes	Yes
CANFD_CTL1	Yes	No
CANFD_PN_CTL1	Yes	Yes
CANFD_CTL2	Yes	No
CANFD_PN_CTL2	Yes	Yes
CANFD_ECR	Yes	Yes
CANFD_ERR_IADDR	Yes	Yes
CANFD_ERR_IDP	Yes	Yes
CANFD_ERR_IPP	Yes	Yes
CANFD_ERR_STAT	Yes	Yes
CANFD_ESR1	Yes	Yes
CANFD_ESR2	Yes	Yes

Table 15-31: Register Reset States (Continued)

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_FD_TIMING	Yes	No
CANFD_FD_CRC	Yes	Yes
CANFD_FD_CTL	Yes	No
CANFD_FLTR_DLC	Yes	Yes
CANFD_FLTR_ID1	Yes	Yes
CANFD_FLTR_ID2_IDMSK	Yes	Yes
CANFD_IFLG1	Yes	Yes
CANFD_IFLG2	Yes	Yes
CANFD_IMSK1	Yes	Yes
CANFD_IMSK2	Yes	Yes
CANFD_CFG	Yes	Yes

CANFD_FLTR_DATA1_HI	Yes	Yes
CANFD_FLTR_DATA1_LO	Yes	Yes
CANFD_FLTR_DATA2_DMSK_HI	Yes	Yes
CANFD_FLTR_DATA2_DMSK_LO	Yes	Yes
CANFD_ERR_RADDR	Yes	Yes
CANFD_ERR_RDAT	Yes	Yes
CANFD_ERR_RSYN	Yes	Yes
CANFD_RX_14_MSK	No	No
CANFD_RX_15_MSK	No	No
CANFD_RX_FIFO_GMSK	No	No
CANFD_RX_FIFO	No	No
CANFD_RX_IMSK[n]	No	No
CANFD_RX_MB_GMSK	No	No
CANFD_TMR	Yes	Yes
CANFD_WMB[n]_DATA_HI	Yes	No
CANFD_WMB[n]_DATA_LO	Yes	No
CANFD_WMB[n]_ID	Yes	No
CANFD_WMB[n]_STAT	Yes	No
CANFD_WUM	Yes	Yes

Note that the MBs and the Rx individual mask registers are not affected by reset, so they are not automatically initialized.

CANFD Initialization Sequence

For any configuration change or initialization, the CANFD must be is put into freeze mode. The following steps are a generic initialization sequence applicable to the CANFD module:

1. Initialize the Module Configuration Register (CANFD_CFG):
    - Enable the individual filtering per MB and reception queue features by setting the CANFD_CFG.IRMQEN bit.
    - Enable the warning interrupts by setting the CANFD_CFG.WRNEN bit.
    - Optionally disable frame self reception by setting the CANFD_CFG.SRXDIS bit.
    - Enable the Rx FIFO by setting the CANFD_CFG.RFEN bit.
    - If Rx FIFO is enabled and DMA is required, set the CANFD_CFG.DMAEN bit.
    - If Pretended Networking mode is required, set the CANFD_CFG.PNETEN bit.
    - Enable the abort mechanism by setting the CANFD_CFG.ABORTEN bit.
    - Enable the local priority feature by setting the CANFD_CFG.LPRIOEN bit.
2. Initialize the Control 1 Register (CANFD_CTL1) and optionally the CAN Bit Timing Register (CANFD_TIMING). Also, initialize the CAN FD CAN Bit Timing Register (CANFD_FD_TIMING):
    - Determine the bit timing parameters: CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, CANFD_CTL1.RJW.
    - Optionally determine the extended bit timing parameters: CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, CANFD_TIMING.ERJW.
    - Determine the CAN FD bit timing parameters: CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, CANFD_FD_TIMING.FRJW.
    - Determine the bit rate by programming the CANFD_CTL1.PRESDIV field and optionally the CANFD_TIMING.EPRESDIV field.
    - Determine the CAN FD bit rate by programming the CANFD_FD_TIMING.FPRESDIV field. Determine the internal arbitration mode (CANFD_CTL1.LBUF bit).
3. Initialize the Message Buffers:
    - Initialize the C/S word of all MBs.
    - If the Rx FIFO is enabled, initialize the ID filter table.
    - Initialize other entries in each MB.
4. Initialize the individual masks in the CANFD_IMSK1 and CANFD_IMSK2 registers.

5. Set required interrupt mask bits in the CANFD_IMSK1 and CANFD_IMSK2 registers (for all MB interrupts), in the CANFD_CFG register for the wake up interrupt, and in the CANFD_CTL1 and CANFD_CTL2 registers for the bus off and error interrupts.
6. If pretended networking mode is enabled, configure the necessary registers for selective wake up.
7. Disable the CANFD_CFG.HALT bit.

After the last step listed, the CANFD module attempts to synchronize to the CAN bus.

Pretended Network - Doze Mode

Complete the following sequence to enter the pretended networking mode in doze mode:

1. Set the CANFD_CFG.PNETEN bit to enable the controller to enter the pretended networking mode, when one of the low power modes is requested.
2. Clear the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Doze mode.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.

Pretended Network - Stop Mode

Complete the following sequence to enter the pretended networking mode in stop mode:

1. Set the the CANFD_CFG.PNETEN bit to enable the controller to enter pretended networking mode, when one of the low power modes is requested.
2. Clear the the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Stop mode. Keep CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT bits set to keep the clock to register block running.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
7. Disable CANFD register clocks by clearing bits CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT for CANFD0/CANFD1 respectively.

ADSP-2159x_SC591_SC592_SC594 CANFD Register Descriptions

Controller Access Network with Flexible Data Rate (CANFD) (CANFD) contains the following registers.

Table 15-32: ADSP-2159x_SC591_SC592_SC594 CANFD Register List

Name	Description
CANFD_TIMING	Can Bit Timing Register
CANFD_CRC	CRC Register
CANFD_CTL1	Control 1 Register
CANFD_PN_CTL1	Pretended Networking Control1 Register
CANFD_CTL2	Control 2 Register
CANFD_PN_CTL2	Pretended Networking Control2 Register
CANFD_ECR	Error Counter Register
CANFD_ERR_IADDR	Error Injection Address Register
CANFD_ERR_IDP	Error Injection Data Pattern Register
CANFD_ERR_IPP	Error Injection Parity Pattern Register
CANFD_ERR_STAT	Error Status Register
CANFD_ESR1	Error and Status 1 Register
CANFD_ESR2	Error and Status 2 Register
CANFD_FD_TIMING	CANFD Bit Timing Register
CANFD_FD_CRC	CANFD CRC Register
CANFD_FD_CTL	CANFD Control Register
CANFD_FLTR_DLC	Pretended Networking DLC Filter Register
CANFD_FLTR_ID1	Pretended Networking ID Filter1 Register
CANFD_FLTR_ID2_IDMSK	Pretended Networking ID Filter2 / IDMask Register
CANFD_IFLG1	Mailbox Interrupt Flag 1 Register
CANFD_IFLG2	Mailbox Interrupt Flag 2 Register
CANFD_IMSK1	Mailbox Interrupt Mask 1 Register
CANFD_IMSK2	Mailbox Interrupt Mask 2 Register
CANFD_CFG	Module Configuration Register
CANFD_MEC	Memory Error Control Register
CANFD_FLTR_DATA1_HI	Pretended Networking Payload Low Filter2 Register
CANFD_FLTR_DATA1_LO	Pretended Networking Payload Low Filter1 Register

Table 15-32: ADSP-2159x_SC591_SC592_SC594 CANFD Register List (Continued)

Name	Description
CANFD_FLTR_DATA2_DMSK_HI	Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register
CANFD_FLTR_DATA2_DMSK_LO	Pretended Networking Payload Low Filter2 / Payload Low Mask Register
CANFD_ERR_RADDR	Error Report Address Register
CANFD_ERR_RDAT	Error Report Data Register
CANFD_ERR_RSYN	Error Report Syndrome Register
CANFD_RX_14_MSK	Receive Mailbox14 Mask Register
CANFD_RX_15_MSK	Receive Mailbox15 Mask Register
CANFD_RX_FIFO_GMSK	Receive FIFO Global Mask Register
CANFD_RX_FIFO	Receive FIFO Information Register
CANFD_RX_IMSK[n]	Receive Individual Mask Register
CANFD_RX_MB_GMSK	Receive Mailbox Global Mask Register
CANFD_TMR	Free Running Timer Register
CANFD_WMB[n]_DATA_HI	Wakeup Message Buffer Data 4-7 Register
CANFD_WMB[n]_DATA_LO	Wakeup Message Buffer Data 0-3 Register
CANFD_WMB[n]_ID	Wakeup Message ID Buffer Register
CANFD_WMB[n]_STAT	Wakeup Message Buffer Control/Status Register
CANFD_WUM	Pretended Networking Wakeup Match Register

Can Bit Timing Register

The CANFD_TIMING register is an alternative way to store the CAN bit timing variables described in the CANFD_CTL1 register. The CANFD_TIMING.EPRESDIV, CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.ERJW bit fields are extended versions of the CANFD_CTL1 register CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2 and CANFD_CTL1.RJW bit fields respectively.

The CANFD_TIMING.BTF bit selects the use of the timing variables defined in the CANFD_TIMING register. The contents of the CANFD_TIMING register are not affected by a soft reset.

NOTE: The CAN bit variables in the CANFD_CTL1 and CANFD_TIMING registers are stored in the same register.

NOTE: When the CAN FD feature is enabled (CANFD_CFG.FDEN is set), always set CANFD_TIMING.BTF.

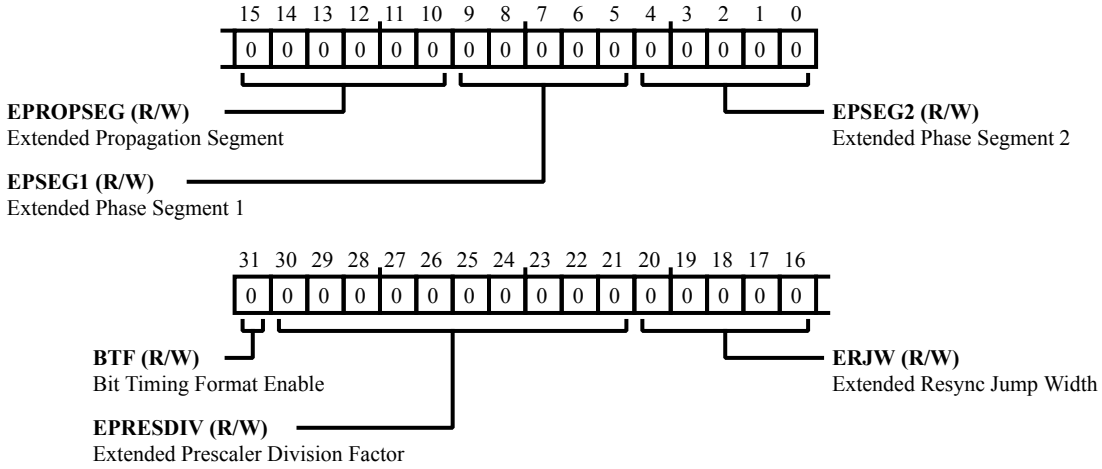

Figure 15-15: CANFD_TIMING Register Diagram

Table 15-33: CANFD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BTF	Bit Timing Format Enable. The CANFD_TIMING.BTF bit enables the use of the extended CAN bit timing fields in the CANFD_TIMING register to replace the CAN bit time variables defined in the CANFD_CTL1 register. The CANFD_TIMING.BTF bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 15-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30:21 (R/W)	EPRESDIV	Extended Prescaler Division Factor. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The CANFD_TIMING.EPRESDIV bit field extends the CANFD_CTL1.PRESDIV value range. Sclock frequency = PE clock frequency / (EPRESDIV + 1) The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPRESDIV bit field has no effect. The CANFD_TIMING.EPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.
20:16 (R/W)	ERJW	Extended Resync Jump Width. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.ERJW bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. The CANFD_TIMING.ERJW bit field extends the CANFD_CTL1.RJW value range. Resync Jump Width = ERJW + 1 One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.ERJW bit field has no effect. The CANFD_TIMING.ERJW bit field can only be written in freeze mode and is blocked by hardware in other modes.
15:10 (R/W)	EPROPSEG	Extended Propagation Segment. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPROPSEG bit field defines the length of the propagation segment in the bit time. The CANFD_TIMING.EPROPSEG bit field extends the CANFD_CTL1.PROPSEG value range. Propagation Segment Time = (EPROPSEG + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPROPSEG bit field has no effect. The CANFD_TIMING.EPROPSEG bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 15-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	EPSEG1	Extended Phase Segment 1. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG1 bit field defines the length of phase segment 1 in the bit time. The CANFD_TIMING.EPSEG1 bit field extends the CANFD_CTL1.PSEG1 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG1 bit field has no effect. The CANFD_TIMING.EPSEG1 bit field can only be written in freeze mode and is blocked by hardware in other modes.
4:0 (R/W)	EPSEG2	Extended Phase Segment 2. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG2 bit field defines the length of phase segment 2 in the bit time. The CANFD_TIMING.EPSEG2 bit field extends the CANFD_CTL1.PSEG2 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG2 bit field has no effect. The CANFD_TIMING.EPSEG2 bit field can only be written in freeze mode and is blocked by hardware in other modes.

CRC Register

The CANFD_CRC register provides information about the CRC of transmitted messages for non-FD messages. For messages in CAN FD format that require either 17 or 21 bits, the CANFD_CRC register only reports the 15 low order bits of CRC calculations. For CAN FD format frames, the CANFD_FD_CRC register must be used. The CANFD_CRC register updates at the same time the Tx Interrupt Flag is set.

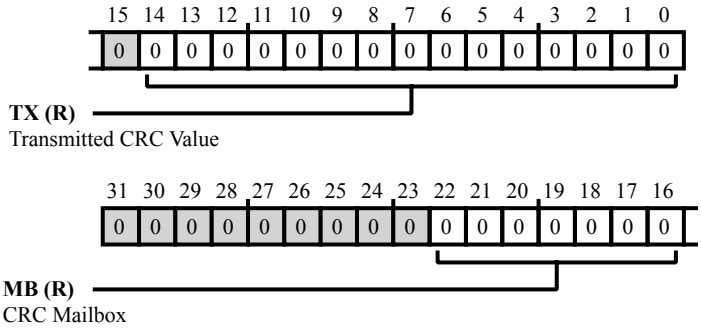

Figure 15-16: CANFD_CRC Register Diagram

Table 15-34: CANFD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	MB	CRC Mailbox. The CANFD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the CANFD_CRC.TX field.
14:0 (R/NW)	TX	Transmitted CRC Value. The CANFD_CRC.TX bit field indicates the CRC value of the last transmitted message for non-FD frames. For CAN FD frames, the CRC value is reported in the CANFD_FD_CRC register.

Control 1 Register

The CANFD_CTL1 register is defined for specific CANFD control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, loop-back mode, listen-only mode, bus off recovery behavior, and interrupt enabling (bus off, error, warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) are also configurable in the CANFD_TIMING register, which extends the range of all these variables. If the CANFD_TIMING.BTF bit is set, the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of the The CANFD_CTL1 register become read-only.

NOTE: When the CAN FD feature is enabled, do not use the CANFD_CTL1.PRESDIV, CANFD_CTL1.RJW, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.PROPSEG fields of the CANFD_CTL1 register for CAN bit timing. Instead, use the CANFD_TIMING.EPRESDIV, CANFD_TIMING.ERJW, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.EPROPSEG fields of the CANFD_TIMING register.

The contents of the CANFD_CTL1 register are not affected by a soft reset.

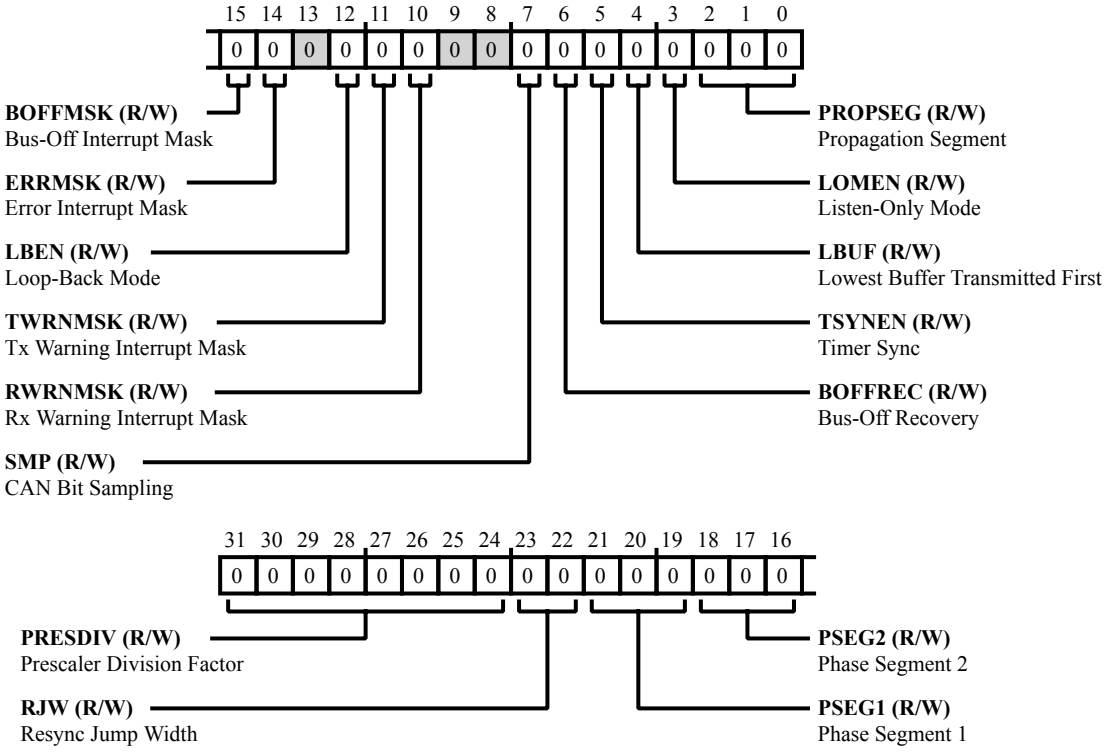

Figure 15-17: CANFD_CTL1 Register Diagram

Table 15-35: CANFD_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PRESDIV	Prescaler Division Factor. The CANFD_CTL1.PRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (SCLOCK) frequency. The SCLOCK period defines the time quantum of the CAN protocol. For the reset value, the SCLOCK frequency is equal to the PE clock frequency. The maximum value of PRESDIV is 0xFF, which gives a minimum SCLOCK frequency equal to the PE clock frequency divided by 256. The CANFD_CTL1.PRESDIV bit can only be written in freeze mode and is blocked by hardware in other modes. SCLOCK Frequency = PE Clock Frequency / (PRESDIV + 1)	
23:22 (R/W)	RJW	Resync Jump Width. The CANFD_CTL1.RJW bit field defines the maximum number of time quanta that a bit time can change with one re-synchronization. One time quantum is equal to the SCLOCK period. The valid programmable values for the CANFD_CTL1.RJW bits are 03. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Resync Jump Width = RJW + 1	
21:19 (R/W)	PSEG1	Phase Segment 1. The CANFD_CTL1.PSEG1 bit field defines the length of the phase segment 1 of the bit time. The valid programmable values are 07. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) Time-Quanta	
18:16 (R/W)	PSEG2	Phase Segment 2. The CANFD_CTL1.PSEG2 bit field defines the length of phase segment 2 of the bit time. The valid programmable values are 17. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) Time-Quanta	
15 (R/W)	BOFFMSK	Bus-Off Interrupt Mask. The CANFD_CTL1.BOFFMSK bit provides a mask for the bus off interrupt (CANFD_ESR1.BOFFINT).	
		0	Disable
		1	Enable

Table 15-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ERRMSK	Error Interrupt Mask. The CANFD_CTL1.ERRMSK bit provides a mask for the error interrupt (CANFD_ESR1.ERRINT).	
		0	Disable
		1	Enable
12 (R/W)	LBEN	Loop-Back Mode. The CANFD_CTL1.LBEN bit configures the CANFD module to operate in loop-back mode. In loop-back mode, the CANFD modules performs an internal loop back to use for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). The CANFD module behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD module ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. The CANFD_CTL1.LBEN bit can only be written in freeze mode and is blocked by hardware in other modes. Note that in loop-back mode, the CANFD_CFG.SRXDIS bit cannot be asserted, because it impedes the self reception of a transmitted message. Also, note that the CANFD_FD_CTL.TDCOMPEN bit must be 0 (transceiver delay compensation feature disabled) when the CANFD_CTL1.LBEN bit is asserted.	
11 (R/W)	TWRNMSK	Tx Warning Interrupt Mask. The CANFD_CTL1.TWRNMSK bit provides a mask for the Tx warning interrupt (CANFD_ESR1.TXWRNINT) The CANFD_CTL1.TWRNMSK bit is read as zero when CAN_MCR.WRNEN is negated. The CANFD_CTL1.TWRNMSK bit can only be written when the CANFD_CFG.WRNEN bit is enabled.	
		0	Tx Warning Interrupt Disabled
		1	Tx Warning Interrupt Enabled

Table 15-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	RWRNMSK	Rx Warning Interrupt Mask. The CANFD_CTL1.RWRNMSK bit provides a mask for the Rx warning interrupt (CANFD_ESR1.RXWRNINT) The CANFD_CTL1.RWRNMSK bit is read as zero when the CANFD_CFG.WRNEN bit is negated. It can only be written only if the CANFD_CFG.WRNEN bit is enabled.	
		0	Rx Warning Interrupt Disabled
		1	Rx Warning Interrupt Enabled
7 (R/W)	SMP	CAN Bit Sampling. The CANFD_CTL1.SMP bit defines the sampling mode of CAN bits at the Rx input. When the CANFD_CTL1.SMP bit is disabled, one sample determines the bit value. When it is enabled three samples determine the value of the received bit: the regular sample (sample point) and the two preceding samples; a majority rule is used. The CANFD_CTL1.SMP bit can only be written in freeze mode and is blocked by hardware in other modes. Note that for proper operation, when enabling CAN bit sampling, guarantee a minimum value of 2 time quanta in the CANFD_CTL1.PSEG1 (or CANFD_TIMING.EPSEG1) bit field. SMP cannot be asserted when CAN FD is enabled (CANFD_CFG.FDEN = 1).	
		0	Disable
		1	Enable

Table 15-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	BOFFREC	Bus-Off Recovery. The CANFD_CTL1.BOFFREC bit defines how the CANFD module recovers from bus off state. When the CANFD_CTL1.BOFFREC bit is enabled, automatic recovering from the bus off state occurs according to the CAN Specification 2.0B. When the CANFD_CTL1.BOFFREC bit is disabled, automatic recovering from the bus off state is disabled and the CANFD module remains in the bus off state until the CANFD_CTL1.BOFFREC bit is enabled by software. If this occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then the bus off recovery happens as if the CANFD_CTL1.BOFFREC bit was never disabled. If the bit is enabled after 128 sequences of 11 recessive bits occurred, then the CANFD module will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After being enabled, the CANFD_CTL1.BOFFREC bit can be disabled again during the bus off state, but it will be effective only the next time the CANFD module enters the bus off state. If CANFD_CTL1.BOFFREC bit was enabled when the CANFD module entered the bus off state, disabling the CANFD_CTL1.BOFFREC bit during the bus off state will not be effective for the current bus off recovery.	
		0	Enable
		1	Disable
5 (R/W)	TSYNEN	Timer Sync. The CANFD_CTL1.TSYNEN bit enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. The timer sync feature provides a means to synchronize multiple CANFD stations with a special SYNC message (global network time). If the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the first available mailbox, according to the CANFD_CTL2.RFFNUM setting, is used for timer synchronization instead of MB0. The CANFD_CTL1.TSYNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 15-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	LBUF	Lowest Buffer Transmitted First. The CANFD_CTL1.LBUF bit defines the ordering mechanism for message buffer transmission. When the CANFD_CTL1.LBUF bit is enabled, the lowest number buffer is transmitted first and when it is disabled the buffer with highest priority is transmitted first. When the CANFD_CTL1.LBUF bit is enabled, the CANFD_CFG.LPRIOEN bit does not affect the arbitration priority. The CANFD_CTL1.LBUF bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
3 (R/W)	LOMEN	Listen-Only Mode. The CANFD_CTL1.LOMEN bit configures the CANFD module to operate in listen-only mode. When the CANFD_CTL1.LOMEN is enabled to be in listen-only mode, transmission is disabled, all error counters in the CANFD_ECR register are frozen, and the CANFD module operates in the CAN error passive mode. Only messages acknowledged by another CAN station will be received. If the CANFD module detects a message that has not been acknowledged, it flags a BIT0 error without changing the receive error counter (CANFD_ECR.RXERRCNT), as if it were trying to acknowledge the message. Listen-Only mode is acknowledged by the state of the CANFD_ESR1.FLTCONF bit field indicating a passive error. There can be some delay between the Listen-Only mode request and acknowledge. The CANFD_CTL1.LOMEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
2:0 (R/W)	PROPSEG	Propagation Segment. The CANFD_CTL1.PROPSEG bit field defines the length of the propagation segment in the bit time. The valid programmable values are 07. The CANFD_CTL1.PROPSEG bit can only be written in freeze mode and is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) Time-Quanta. Time-Quantum = One SCLOCK Period.	

Pretended Networking Control1 Register

The CANFD_PN_CTL1 register contains control bits for pretended networking mode filtering selection. Configure this register with the filter criteria to receive wakeup messages. Bits other than CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK can only be written in freeze mode.

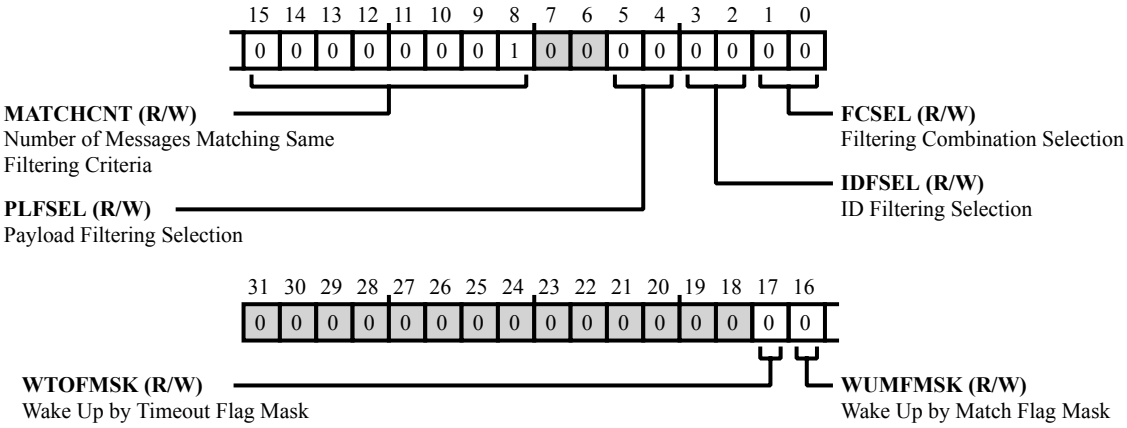

Figure 15-18: CANFD_PN_CTL1 Register Diagram

Table 15-36: CANFD_PN_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	WTOFMSK	Wake Up by Timeout Flag Mask. The CANFD_PN_CTL1.WTOFMSK bit masks the generation of a wakeup event originated by a timeout:	
		0	Timeout Event Disabled
		1	Timeout Event Enabled
16 (R/W)	WUMFMSK	Wake Up by Match Flag Mask. The CANFD_PN_CTL1.WUMFMSK bit masks the generation of a wakeup event originated by a successfully filtered Rx message.	
		0	Wakeup match disabled
		1	Wakeup match enabled

Table 15-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	MATCHCNT	Number of Messages Matching Same Filtering Criteria. The CANFD_PN_CTL1.MATCHCNT bit field defines the number of times a given message must match the predefined filtering criteria for ID and/or PL before generating a wakeup event. This quantity is configured in the 1 to 255 range. For example, if the received message must match the predefined filtering criteria for ID and/or PL once before generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0x01; if it must match twice before generating a wakeup event, the bit field value is 0x02; and if it must match 255 times generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0xFF.	
5:4 (R/W)	PLFSEL	Payload Filtering Selection. The CANFD_PN_CTL1.PLFSEL bit field selects the level of payload filtering to be applied when the CANFD module is under pretended networking mode. Filtering does not accept remote messages (RTR=1) when payload filtering is active.	
		0	Match the payload contents against an exact target value
		1	Match if a payload value is greater than or equal to a specific target value
		2	Match if a payload value is less than or equal to a specific target value
		3	Match if a payload value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit
3:2 (R/W)	IDFSEL	ID Filtering Selection. The CANFD_PN_CTL1.IDFSEL bit field selects the level of ID filtering to be applied when the CANFD module is under pretended networking mode. In ID filtering, if the CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are set, the IDE and RTR bits are also considered part of the reception filter.	
		0	Match the ID contents against an exact target value
		1	Match if the ID value is greater than or equal to a specific target value
		2	Match if the ID value is less than or equal to a specific target value
		3	Match if the ID value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit

Table 15-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	FCSEL	Filtering Combination Selection. The `CANFD_PN_CTL1.FCSEL` bit field selects elects the filtering criteria to be applied when the CANFD module is in pretended networking mode.	
		0	Message ID filtering only
		1	Message ID filtering and payload filtering
		2	Message ID filtering occurring a specified number of times
		3	Message ID filtering and payload filtering a specified number of times

Control 2 Register

The CANFD_CTL2 register complements CANFD_CTL1, providing control bits for memory write accesses in freeze mode, for extending FIFO filter quantity, and for adjusting the operation of internal CANFD processes like matching and arbitration.

The contents of the CANFD_CTL2 register are not affected by soft reset.

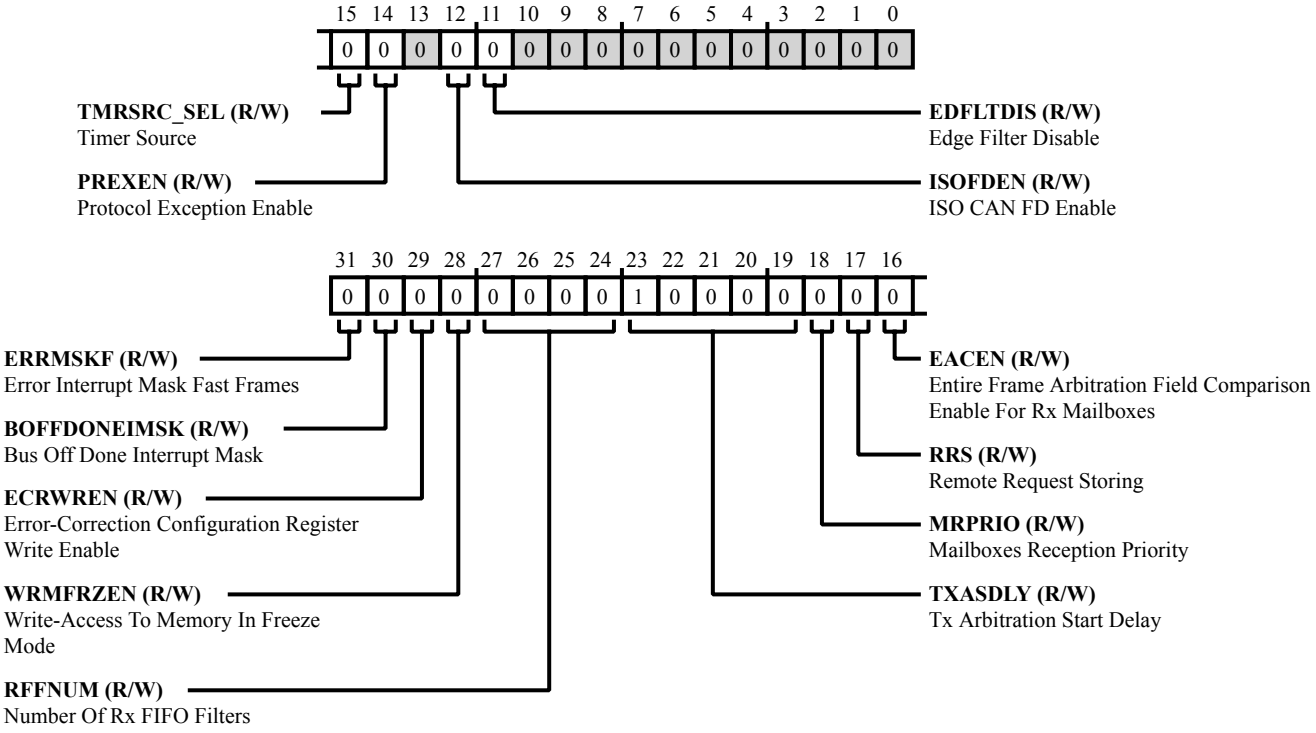

Figure 15-19: CANFD_CTL2 Register Diagram

Table 15-37: CANFD_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ERRMSKF	Error Interrupt Mask Fast Frames. The CANFD_CTL2.ERRMSKF bit is the error interrupt mask for errors detected in the data phase of fast CAN FD frames. It provides a mask for the CANFD_ESR1.ERRINTF interrupt. When the CANFD_CTL2.ERRMSKF bit is set, the error interrupt is enabled. When the bit is cleared the error interrupt is disabled.

Table 15-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	BOFFDONEIMSK	Bus Off Done Interrupt Mask. The CANFD_CTL2.BOFFDONEIMSK bit provides a mask for the bus off done interrupt in the CANFD_ESR1 register. When the CANFD_CTL2.BOFFDONEIMSK bit is set, the bus off done interrupt is enabled. When the bit is cleared the bus off done interrupt is disabled.
29 (R/W)	ECRWREN	Error-Correction Configuration Register Write Enable. The CANFD_CTL2.ECRWREN bit enables the MECR register to be updated. Setting the CANFD_CTL2.ECRWREN bit is set, enables updates. Clearing the bit disables updates. The CANFD_CTL2.ECRWREN bit is automatically set to zero if the protocol described in the Detection and Correction of Memory Errors section of the CANFD chapter is not followed.
28 (R/W)	WRMFRZEN	Write-Access To Memory In Freeze Mode. The CANFD_CTL2.WRMFRZEN bit enables unrestricted write access to the CANFD memory in freeze mode. Clear the CANFD_CTL2.WRMFRZEN bit to maintain the write access restrictions. Set the CANFD_CTL2.WRMFRZEN bit to enable unrestricted write access to the CANFD memory. The CANFD_CTL2.WRMFRZEN bit can only be written in freeze mode and has no effect out of freeze mode. The CANFD_CFG.RFEN bit must not be set during CANFD memory initialization.

Table 15-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27:24 (R/W)	RFFNUM	Number Of Rx FIFO Filters. The CANFD_CTL2.RFFNUM bit field defines the number of Rx FIFO filters. For more details, see the Number of Rx FIFO Filters table in the CANFD chapter. The maximum selectable number of filters is a function of configuration parameter NUMBER_OF_MB. Do not program the CANFD_CTL2.RFFNUM bit field with values that make the number of message buffers occupied by the Rx FIFO and ID Filter exceed the number of mailboxes present, defined by the CANFD_CFG.MAXMB bit field. Each group of eight filters occupies a memory space equivalent to two message buffers, which means that as more filters are implemented fewer mailboxes are available. Considering that the Rx FIFO occupies the memory space originally reserved for MB05, program the CANFD_CTL2.RFFNUM bit with a value corresponding to a number of filters not greater than the number of available memory words. Calculate this as follows: (SETUP_MB - 6) 4 where SETUP_MB is the lower value between parameter NUMBER_OF_MB and register field CANFD_CFG.MAXMB. The number of remaining mailboxes available is (SETUP_MB - 8) - (RFFN 2) If the number of Rx FIFO filters programmed through the CANFD_CTL2.RFFNUM bit field exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. Note that the number of the last remaining available mailbox is defined by the least value between (NUMBER_OF_MB - 1) and the CANFD_CFG.MAXMB field. If the individual Rx mask registers are not enabled, all Rx FIFO filters are affected by the Rx FIFO global mask. The CANFD_CTL2.RFFNUM bit field can only be written in freeze mode as it is blocked by hardware in other modes.
23:19 (R/W)	TXASDLY	Tx Arbitration Start Delay. The CANFD_CTL2.TXASDLY bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on the CAN bus. The CANFD_CTL2.TXASDLY bit field can only be written in freeze mode and it is blocked by hardware in other modes.
18 (R/W)	MRPRIO	Mailboxes Reception Priority. The CANFD_CTL2.MRPRIO bit defines the mailboxes reception priority. If the CANFD_CTL2.MRPRIO bit is set, the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. If the bit is cleared, matching starts from Rx FIFO and continues on mailboxes. The CANFD_CTL2.MRPRIO bit can only be written only in freeze mode and it is blocked by hardware in other modes.

Table 15-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RRS	Remote Request Storing. If the CANFD_CTL2.RRS bit is set, a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion of a data frame. No automatic remote response frame is generated. If the CANFD_CTL2.RRS bit is is cleared, the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE=0b1010 is found with the same ID. The CANFD_CTL2.RRS bit can only be written in freeze mode and it is blocked by hardware in other modes.	
16 (R/W)	EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes. The CANFD_CTL2.EACEN bit controls the comparison of IDE and RTR bits within Rx mailboxes filters with their corresponding bits in the incoming frame by the matching process. The CANFD_CTL2.EACEN bit does not affect matching for the Rx FIFO. When the CANFD_CTL2.EACEN bit is set it enables the comparison of both the IDE and RTR bits of an Rx mailbox filter with the corresponding bits of the incoming frame. Mask bits do apply. When the CANFD_CTL2.EACEN bit is cleared the IDE bit of the Rx mailbox filter is always compared and RTR is never compared, regardless of mask bits. EACEN can be only written only in freeze mode and it is blocked by hardware in other modes.	
15 (R/W)	TMRSRC_SEL	Timer Source. The CANFD_CTL2.TMRSRC_SEL bit selects the time tick source used for incrementing the free running timer counter. When the CANFD_CTL2.TMRSRC_SEL bit is set, the free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus or a different value as required. When the CANFD_CTL2.TMRSRC_SEL bit is cleared, the free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. The CANFD_CTL2.TMRSRC_SEL bit can only be written in freeze mode.	
14 (R/W)	PREXEN	Protocol Exception Enable. The CANFD_CTL2.PREXEN bit enables the protocol exception feature. The CANFD_CTL2.PREXEN bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 15-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ISOFDEN	ISO CAN FD Enable. The `CANFD_CTL2.ISOFDEN` bit controls ISO CAN FD compliant operation. Setting the bit enables ISO CAN FD compliant operation by enabling the following features, which are part of the ISO 11898 standard and not included in the original (Bosch) CAN FD protocol specification: The count of variable stuff bits inserted from the Start of Frame bit to the last bit of Data field. Also, the modulo 8 count of variable stuff bits plus the respective parity bit (even parity calculated over the 3-bit modulo 8 count) are combined as the 4-bit Stuff Count field and inserted before the CRC sequence field. CRC calculation extends beyond the end of data field and takes the stuff count field bits into account. Clearing the `CANFD_CTL2.ISOFDEN` bit disables ISO CAN FD specific features (non-ISO CAN FD operation). The `CANFD_CTL2.ISOFDEN` bit is only writable in freeze mode.	
11 (R/W)	EDFLTDIS	Edge Filter Disable. The `CANFD_CTL2.EDFLTDIS` bit controls the edge filter used during the bus integration state. When the edge filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. The `CANFD_CTL2.EDFLTDIS` bit is only writable in freeze mode.	
		0	Enable
		1	Disable

Pretended Networking Control2 Register

The CANFD_PN_CTL2 register contains configuration bits for the timeout value under pretended networking mode. Only write to this register in freeze mode.

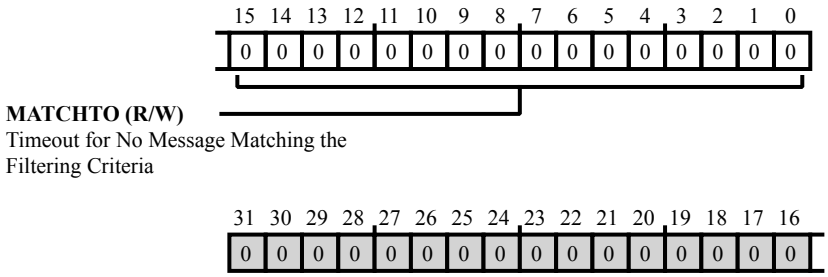

Figure 15-20: CANFD_PN_CTL2 Register Diagram

Table 15-38: CANFD_PN_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MATCHTO	Timeout for No Message Matching the Filtering Criteria. The CANFD_PN_CTL2.MATCHTO bit field defines a timeout value that generates a wakeup event when the CANFD_CFG.PNETEN bit is enabled. If the timeout counter reaches the target value when the CANFD module is in pretended networking mode, a wakeup event is generated. The timeout limit value is configured from 1 to 65535 to control an internal 16-bit up-count timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, with a period 64 times the CAN bit time unit. When the CANFD_PN_CTL2.MATCHTO bit field is 0x0000, the timeout is disabled.

Error Counter Register

The CANFD_ECR register has four 8-bit fields reflecting the value of the CANFD error counters:

•Transmit error counter (CANFD_ECR.TXERRCNT field)

•Receive error counter (CANFD_ECR.RXERRCNT field)

•Transmit error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.TXERRCNTF field)

•Receive error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.RXERRCNTF field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. The TXERRCNTF and RXERRCNT_FAST counters only count the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The fault confinement state (CANFD_ESR1.FLTCONF) is only updated based on the TXERRCNT and RXERRCNT counters. The TXERRCNT and RXERRCNT counters can only be written in freeze mode. The TXERRCNTF and RXERRCNT_FAST counters are read-only except in freeze mode, where the processor can write a zero value. The rules for incrementing and decrementing these counters are described in the CAN protocol and are completely implemented in the CANFD module.

The basic rules for the CANFD bus state transitions are as follows:

• If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the CANFD_ESR1.FLTCONF field updates to reflect the error passive state.

• If the CANFD state is error passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the CANFD_ESR1.FLTCONF field updates to reflect the error active state.

• If the value of TXERRCNT increases to be greater than 255, the CANFD_ESR1.FLTCONF field updates to reflect the bus off state and an interrupt may be issued. The value of TXERRCNT is then reset to zero.

• If the CANFD is in the bus off state, then TXERRCNT is cascaded together with another internal counter to count the 128 occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing TXERRCNT. When TXERRCNT reaches the value of 128, the CANFD_ESR1.FLTCONF field is updated to be error active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNTF counter is frozen during bus off.

• If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the CANFD_ESR1.ACKERR bit). After the transition to the error passive state, TXERRCNT is no longer incremented by acknowledge errors. Therefore, the device never goes to the bus off state.

• If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to the error active state.

• The TXERRCNTF and RXERRCNT_FAST error counters values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as the TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen while the CANFD is in the bus off state. They are reset when the CANFD leaves the bus off state and restart counting once the CANFD resumes to the error active state.

• When the CANFD module is in pretended networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors and error flags are stored. TXERRCNT and TXERRCNTF preserve their values and do not change since no transmission occurs under pretended networking mode. Error counters and error flags that changed values while in pretended networking mode are updated in the CANFD_ECR and CANFD_ESR1 registers when the CANFD module resumes normal mode. The FAST error flags in the CANFD_ESR1 register are not set if the CANFD is in pretended networking mode.

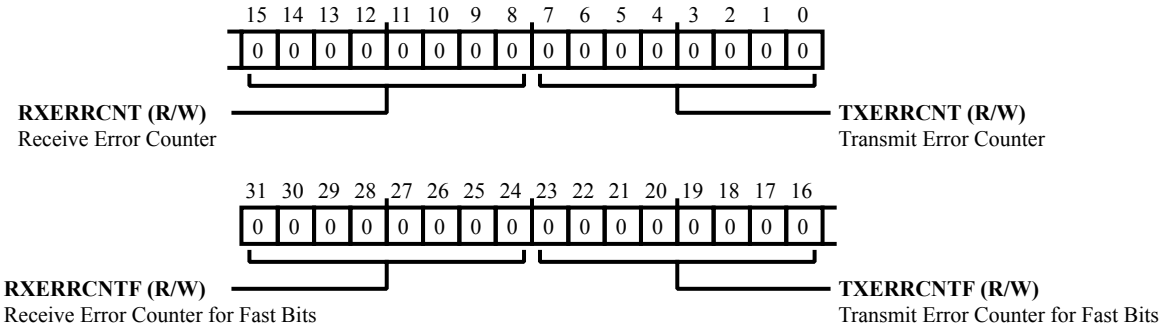

Figure 15-21: CANFD_ECR Register Diagram

Table 15-39: CANFD_ECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RXERRCNTF	Receive Error Counter for Fast Bits. The CANFD_ECR.RXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.RXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.
23:16 (R/W)	TXERRCNTF	Transmit Error Counter for Fast Bits. The CANFD_ECR.TXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.TXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.

Table 15-39: CANFD_ECR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	RXERRCNT	Receive Error Counter. The `CANFD_ECR.RXERRCNT` bit field is for all errors detected in received messages. The `CANFD_ECR.RXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.
7:0 (R/W)	TXERRCNT	Transmit Error Counter. The `CANFD_ECR.TXERRCNT` bit field is for all errors detected in transmitted messages. The `CANFD_ECR.TXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.

Error Injection Address Register

The CANFD_ERR_IADDR register holds the address where a memory read error is injected.

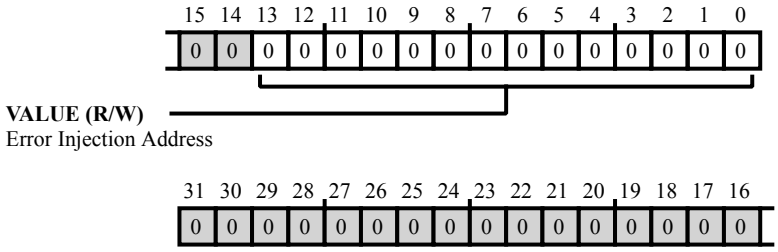

Figure 15-22: CANFD_ERR_IADDR Register Diagram

Table 15-40: CANFD_ERR_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	VALUE	Error Injection Address. The CANFD_ERR_IADDR.VALUE bit field defines the physical RAM address where a memory read error is to be injected. See the Error Injection Address Mapping table in the CANFD chapter for more details. Note that the two least significant bits are always read as zero.

Error Injection Data Pattern Register

The CANFD_ERR_IDP register holds the error pattern injected in the data word that is read from memory.

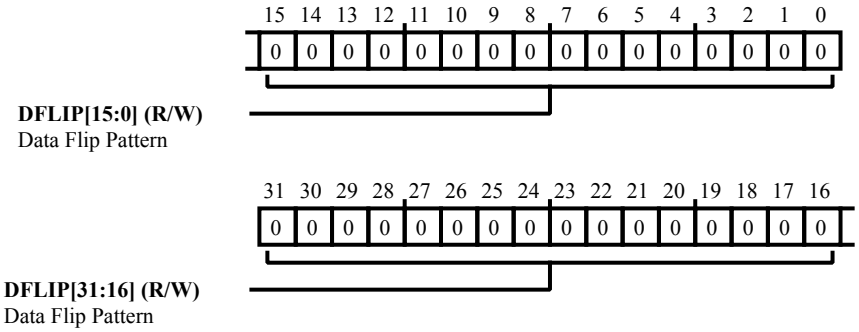

Figure 15-23: CANFD_ERR_IDP Register Diagram

Table 15-41: CANFD_ERR_IDP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DFLIP	Data Flip Pattern. The CANFD_ERR_IDP.DFLIP bit field determines the data flip pattern. Bits set to one in the flip pattern cause the corresponding data bit in the word read from memory to invert.

Error Injection Parity Pattern Register

The CANFD_ERR_IPP register holds the error pattern that is injected in the parity bits read from memory along with data word. Bits set to one in the flip pattern cause the corresponding parity bit, in the word read from memory, to invert.

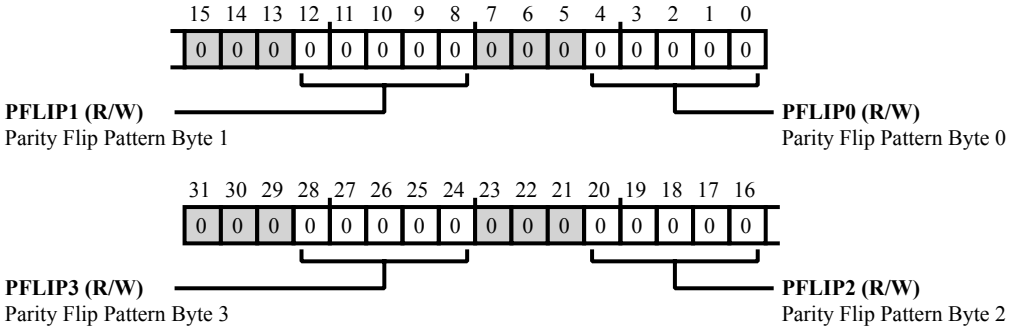

Figure 15-24: CANFD_ERR_IPP Register Diagram

Table 15-42: CANFD_ERR_IPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:24 (R/W)	PFLIP3	Parity Flip Pattern Byte 3. The CANFD_ERR_IPP.PFLIP3 bit field is for the parity flip pattern for byte 3 (most significant).
20:16 (R/W)	PFLIP2	Parity Flip Pattern Byte 2. The CANFD_ERR_IPP.PFLIP2 bit field is for the parity flip pattern for byte 2.
12:8 (R/W)	PFLIP1	Parity Flip Pattern Byte 1. The CANFD_ERR_IPP.PFLIP1 bit field is for the parity flip pattern for byte 1.
4:0 (R/W)	PFLIP0	Parity Flip Pattern Byte 0. The CANFD_ERR_IPP.PFLIP0 bit field is for the parity flip pattern for byte 0 (least significant).

Error Status Register

The CANFD_ERR_STAT register holds the status bits of the error correction and detection operations. Clear these flags by writing them with a one. Writing a zero to the flags has no effect.

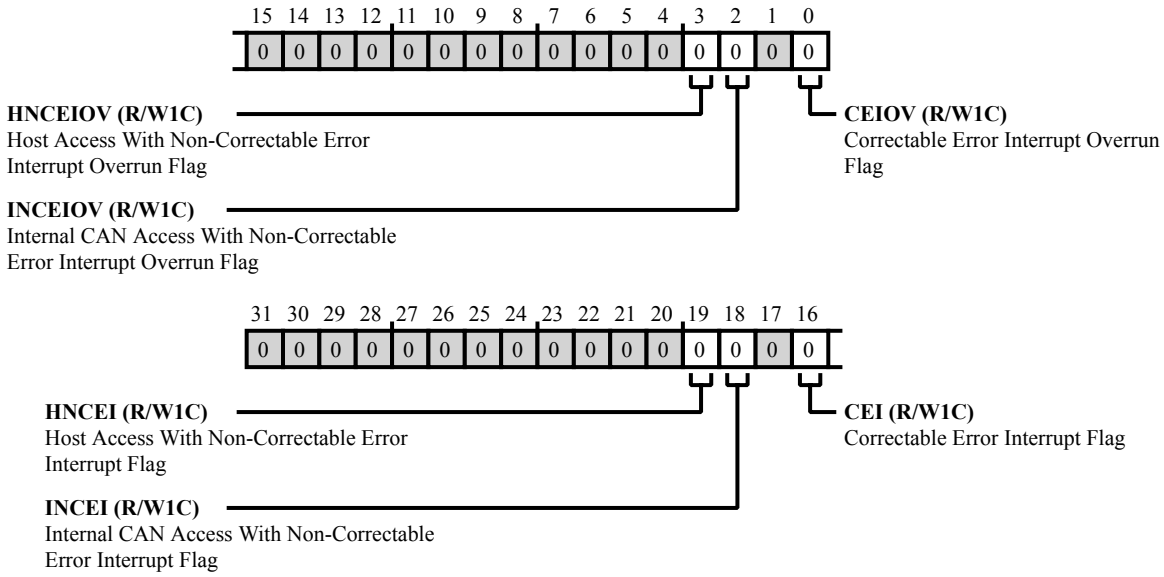

Figure 15-25: CANFD_ERR_STAT Register Diagram

Table 15-43: CANFD_ERR_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	HNCEI	Host Access With Non-Correctable Error Interrupt Flag. The CANFD_ERR_STAT.HNCEI bit indicates if a non-correctable error is detected in a host access. If the CANFD_ERR_STAT.HNCEI bit is set, a non-correctable error was detected in a memory read initiated by the host. A bus transfer error is asserted for that access. If the CANFD_MEC.HNCIMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.HNCEI bit is cleared, no non-correctable errors were detected in host accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected

Table 15-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	INCEI	Internal CAN Access With Non-Correctable Error Interrupt Flag. The `CANFD_ERR_STAT.INCEI` bit indicates if a non-correctable error is detected in a CAN access. If the `CANFD_ERR_STAT.INCEI` bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process. A bus transfer error is asserted for that access. If the `CANFD_MEC.INCEMSK` bit is set, the interrupt is asserted. If the `CANFD_ERR_STAT.INCEI` bit is cleared, no non-correctable errors were detected in CAN accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected
16 (R/W1C)	CEI	Correctable Error Interrupt Flag. The `CANFD_ERR_STAT.CEI` bit indicates if a correctable error is detected. If the `CANFD_ERR_STAT.CEI` bit is set, a correctable error was detected in a memory read. If the `CANFD_MEC.CEIMSK` bit is set, the interrupt is asserted. If the `CANFD_ERR_STAT.CEI` bit is cleared, no correctable errors were detected so far.	
		0	No Correctable Error Detected
		1	Correctable Error Detected
3 (R/W1C)	HNCEIOV	Host Access With Non-Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.HNCEIOV` bit indicates if an overrun on non-correctable error is detected in a host access. If the `CANFD_ERR_STAT.HNCEIOV` bit is set, a non-correctable error was detected in a memory read initiated by the host when the `CANFD_ERR_STAT.HNCEI` bit is set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.HNCEIOV` bit is cleared, no overrun on non-correctable errors were detected in a host access.	
		0	No Overrun Detected
		1	Overrun Detected

Table 15-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	INCEIOV	Internal CAN Access With Non-Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.INCEIOV` bit indicates if an overrun on non-correctable error is detected in a CAN access. If the `CANFD_ERR_STAT.INCEIOV` bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process when the `CANFD_ERR_STAT.INCEI` bit is set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.INCEIOV` bit is cleared, no overrun on non-correctable errors were detected in a CAN access.	
		0	No Overrun Detected
		1	Overrun Detected
0 (R/W1C)	CEIOV	Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.CEIOV` bit indicates if an overrun on correctable errors is detected. If the `CANFD_ERR_STAT.CEIOV` bit is set, a overrun on a correctable error was detected in a memory read while the `CANFD_ERR_STAT.CEI` bit was set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.CEIOV` bit is cleared, no overrun on correctable errors were detected.	
		0	No Overrun Detected
		1	Overrun Detected

Error and Status 1 Register

The CANFD_ESR1 register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the processor.

The reported error conditions are:

• CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR, for errors detected in CAN frames of any format.

• CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF for errors detected in the data phase of CAN FD frames with the BRS bit set.

An error detected in a single CAN frame is reported by one or more error flags. Error reporting is cumulative in case additional error events occur in subsequent frames before the processor reads the CANFD_ESR1 register.

CANFD_ESR1.TXWRN, CANFD_ESR1.RXWRN, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, CANFD_ESR1.FLTCONF, CANFD_ESR1.RXINPROG, and CANFD_ESR1.SYNC are status bits.

CANFD_ESR1.BOFFINT, CANFD_ESR1.BOFFDONEINT, CANFD_ESR1.ERRINT, CANFD_ESR1.ERRINTF, CANFD_ESR1.WAKINT,CANFD_ESR1.TXWRNINT, and CANFD_ESR1.RXWRNINT are interrupt bits. When servicing interrupt requests generated by these bits use the following procedure:

• Read the CANFD_ESR1 register to capture all error condition and status bits. This action clears the respective bits set since the last read access.

• Write 1 to clear the interrupt bit that triggered the interrupt request.

• Write 1 to clear the CANFD_ESR1.ERROVR bit if it is set.

Starting from all error flags cleared, a first error event sets either the CANFD_ESR1.ERRINT or the CANFD_ESR1.ERRINTF bits (provided the corresponding mask bit is asserted). If other error events in subsequent frames occur before the processor services the interrupt request, the CANFD_ESR1.ERROVR bit is set to indicate that errors from different frames have accumulated.

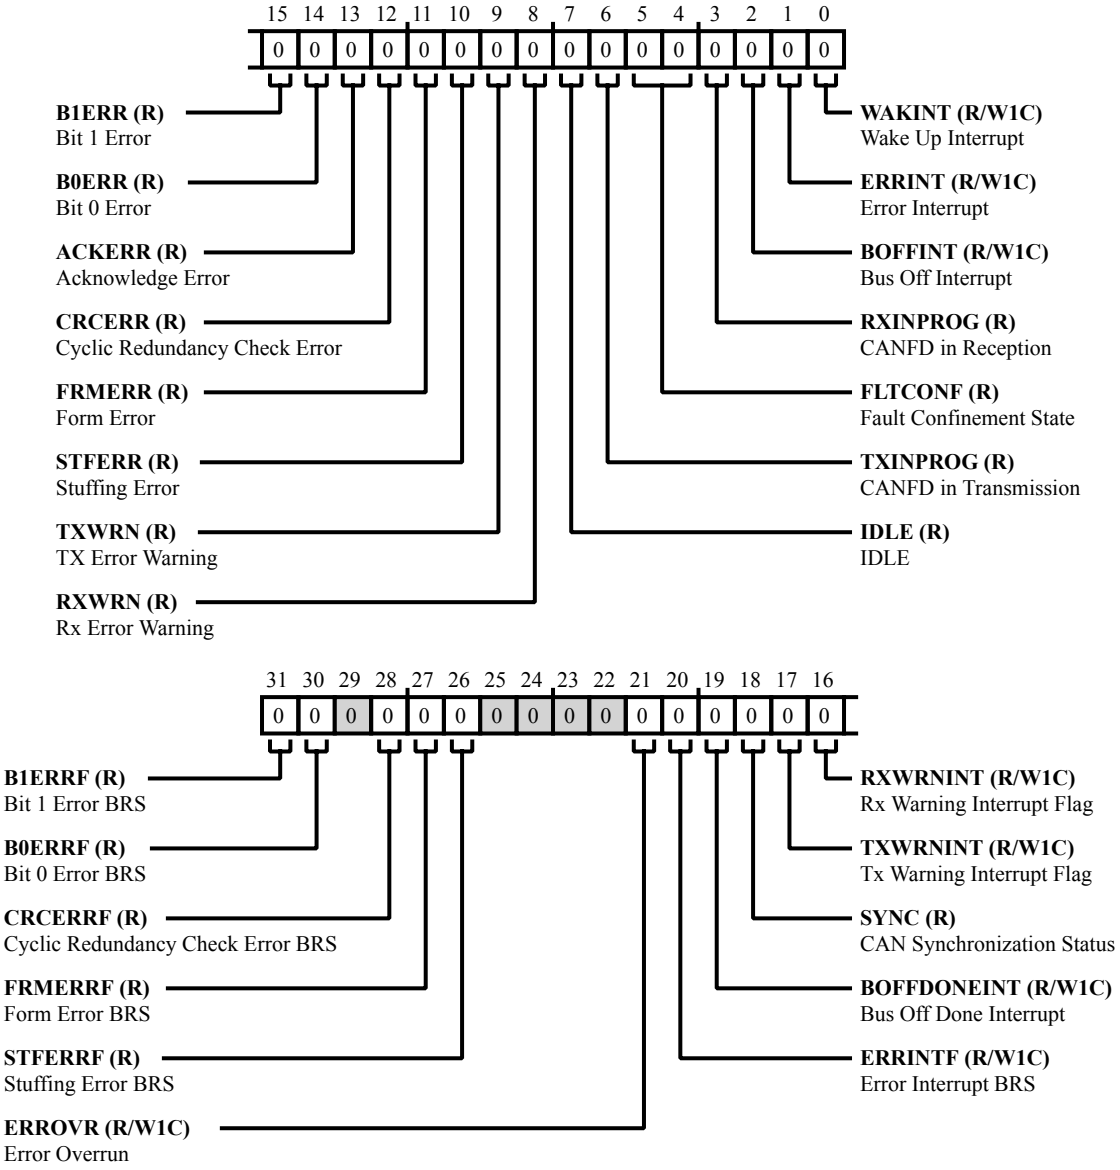

Figure 15-26: CANFD_ESR1 Register Diagram

Table 15-44: CANFD_ESR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	B1ERRF	Bit 1 Error BRS. The CANFD_ESR1.B1ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B1ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
30 (R/NW)	B0ERRF	Bit 0 Error BRS. The CANFD_ESR1.B0ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B0ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
28 (R/NW)	CRCERRF	Cyclic Redundancy Check Error BRS. The CANFD_ESR1.CRCERRF bit indicates if a CRC error is detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set. The calculated CRC is different from the received CRC. When the CANFD_ESR1.CRCERRF bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
27 (R/NW)	FRMERRF	Form Error BRS. The CANFD_ESR1.FRMERRF bit indicates that a form error is detected by the receiver node in the data phase of CAN FD frames with the BRS bit set. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERRF bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	STFERRF	Stuffing Error BRS. The CANFD_ESR1.STFERRF bit indicates that a stuffing error is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.STFERRF bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
21 (R/W1C)	ERROVR	Error Overrun. The CANFD_ESR1.ERROVR bit indicates that an error condition occurred when any error flag is already set. When the CANFD_ESR1.ERROVR bit is enabled an overrun has occurred. When it is disabled, an overrun has not occurred. Clear the CANFD_ESR1.ERROVR bit by writing a one to it.	
		0	Disable
		1	Enable
20 (R/W1C)	ERRINTF	Error Interrupt BRS. The CANFD_ESR1.ERRINTF bit indicates an error interrupt is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.ERRINTF bit is enabled it indicates setting the of any error bit detected in the data phase of CAN FD frames with the BRS bit set. When it is disabled, there is no such occurrence. The CANFD_ESR1.ERRINTF bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, or CANFD_ESR1.STFERRF) is set. If the CANFD_CTL2.ERRMSKF is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.ERRINTF bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	BOFFDONEINT	Bus Off Done Interrupt. When the CANFD_ESR1.BOFFDONEINT bit is enabled it indicates the CANFD module has completed the bus off process. When it is disabled, there is no such occurrence. The CANFD_ESR1.BOFFDONEINT bit is set when the Tx Error Counter (CANFD_ECR.TXERRCNT) finishes counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave bus off mode. If the CANFD_CTL2.BOFFDONEIMSK is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.BOFFDONEINT bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
18 (R/NW)	SYNC	CAN Synchronization Status. The CANFD_ESR1.SYNC bit is a read-only flag that indicates whether the CANFD module is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the CANFD module. When the CANFD_ESR1.SYNC bit is enabled, the CANFD module is synchronized to the CAN bus. When it is disabled, the CANFD module is not synchronized to the CAN bus.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	TXWRNINT	Tx Warning Interrupt Flag. When the CANFD_ESR1.TXWRNINT bit is enabled, the Tx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.TXWRNINT bit is set when the CANFD_ESR1.TXWRN bit transitions from 0 to 1, meaning that the Tx error counter reached 96. If the CANFD_CTL1.TWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.TXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.TXWRNINT flag is masked. The processor must clear the CANFD_ESR1.TXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.TXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.TXWRNINT bit is not generated during the bus off state and is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.TXWRNINT bit does not update.	
		0	Disable
		1	Enable
16 (R/W1C)	RXWRNINT	Rx Warning Interrupt Flag. When the CANFD_ESR1.RXWRNINT bit is enabled, it indicates that the Rx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.RXWRNINT bit is set when the CANFD_ESR1.RXWRN bit transitions from 0 to 1, meaning that the Rx error counter reached 96. If the CANFD_CTL1.RWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.RXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.RXWRNINT flag is masked. The processor must clear the CANFD_ESR1.RXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.RXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.RXWRNINT bit is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.RXWRNINT bit does not update to reflect the Rx error counter state.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	B1ERR	Bit 1 Error. The CANFD_ESR1.B1ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B1ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B1ERR bit updates when the CANFD module returns to normal mode from pretended networking mode. Note that the CANFD_ESR1.B1ERR bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.	
		0	Disable
		1	Enable
14 (R/NW)	B0ERR	Bit 0 Error. The CANFD_ESR1.B0ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B0ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B0ERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
13 (R/NW)	ACKERR	Acknowledge Error. The CANFD_ESR1.ACKERR bit indicates an acknowledge error is detected by the transmitter node (a dominant bit detected during the ACK SLOT) When the CANFD_ESR1.ACKERR bit is enabled an ACK error occurred since the last read of this register.When the bit is disabled, there is no such occurrence. The CANFD_ESR1.ACKERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/NW)	CRCERR	Cyclic Redundancy Check Error. The CANFD_ESR1.CRCERR bit indicates if a CRC error is detected by the receiver node in a non-FD message or in the arbitration or data phase of a frame in CAN FD format (the calculated CRC is different from the received CRC) When the CANFD_ESR1.CRCERR bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.CRCERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
11 (R/NW)	FRMERR	Form Error. The CANFD_ESR1.FRMERR bit indicates that a form error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERR bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.FRMERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
10 (R/NW)	STFERR	Stuffing Error. The CANFD_ESR1.STFERR bit indicates that a stuffing error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. When the CANFD_ESR1.STFERR bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.STFERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	TXWRN	TX Error Warning. The CANFD_ESR1.TXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.TXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.TXWRN bit is only affected by the CANFD_ECR.TXERRCNT value. It does not update during freeze mode.	
		0	Disable
		1	Enable
8 (R/NW)	RXWRN	Rx Error Warning. The CANFD_ESR1.RXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.RXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.RXWRN bit is only affected by the CANFD_ECR.RXERRCNT value. It does not update during freeze mode. It updates when the CANFD returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
7 (R/NW)	IDLE	IDLE. The CANFD_ESR1.IDLE bit indicates when the CAN bus is in the IDLE state. When the CANFD_ESR1.IDLE bit is enabled, the CAN bus is IDLE. When it is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
6 (R/NW)	TXINPROG	CANFD in Transmission. The CANFD_ESR1.TXINPROG bit indicates if the CANFD module is transmitting a message. When the CANFD_ESR1.TXINPROG bit is enabled, the CANFD module is transmitting a message. When it is disabled, the CANFD module is not transmitting a message.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	FLTCONF	Fault Confinement State. The CANFD_ESR1.FLTCONF bit field indicates the fault confinement state of the CANFD module. If the CANFD_CTL1.LOMEN bit is enabled, after some delay that depends on the CAN bit timing, the CANFD_ESR1.FLTCONF bit field will indicate the error passive state. The same delay affects how the CANFD_ESR1.FLTCONF bit field reflects an update to the CANFD_ECR register by the processor. It may take up to one CAN bit time to get them coherent again. The CANFD_ESR1.FLTCONF bit field is affected by soft reset. However, if the CANFD_CTL1.LOMEN bit is enabled, the CANFD_ESR1.FLTCONF reset value lasts just one CAN bit. After this time, the CANFD_ESR1.FLTCONF bit field indicates the error passive state.	
		0	Error Active
		1	Error Passive
		2	Bus Off
		3	Bus Off
3 (R/NW)	RXINPROG	CANFD in Reception. The CANFD_ESR1.RXINPROG bit indicates if the CANFD module is receiving a message. When the CANFD_ESR1.RXINPROG bit is enabled the CANFD module is receiving a message and when it is disabled the CANFD module is not receiving a message.	
		0	Disable
		1	Enable
2 (R/W1C)	BOFFINT	Bus Off Interrupt. The CANFD_ESR1.BOFFINT bit is enabled when the CANFD module enters the bus off state. If the corresponding mask bit (CAN_CTRL1.BOFFMSK) is set, an interrupt is generated to the processor. When the CANFD_ESR1.BOFFINT bit is disabled, there is no such occurrence. The CANFD_ESR1.BOFFINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Table 15-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ERRINT	Error Interrupt. The CANFD_ESR1.ERRINT bit indicates that at least one of the error bits (CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, or CANFD_ESR1.STFERR) is set. If the corresponding mask bit (CANFD_CTL1.ERRMSK) is set, an interrupt is generated to the processor. The CANFD_ESR1.ERRINT bit is cleared by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
0 (R/W1C)	WAKINT	Wake Up Interrupt. The CANFD_ESR1.WAKINT bit applies when the CANFD module is in low-power mode under a self wake up mechanism (doze or stop mode). When the CANFD_ESR1.WAKINT bit is enabled it indicates a recessive-to-dominant transition was received on the CAN bus. When a recessive-to-dominant transition is detected on the CAN bus and the CANFD_CFG.WAKMSK bit is set, an interrupt is generated to the processor. This bit is cleared by writing it to one. When the bit is disabled, there is no such occurrence. When the CANFD_CFG.SLFWAKEN bit is disabled, the CANFD_ESR1.WAKINT flag is masked. The processor must clear the CANFD_ESR1.WAKINT flag before disabling the CANFD_CFG.SLFWAKEN bit. Otherwise, he CANFD_ESR1.WAKINT is set when the CANFD_CFG.SLFWAKEN bit is set again. Writing zero has no effect. The CANFD_ESR1.WAKINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Error and Status 2 Register

The CANFD_ESR2 register reports general status information.

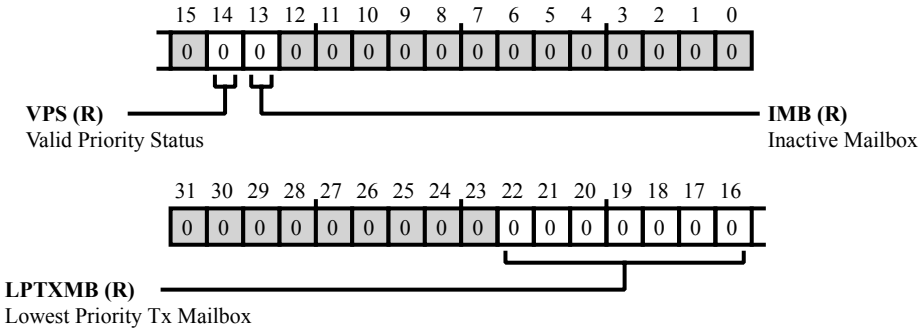

Figure 15-27: CANFD_ESR2 Register Diagram

Table 15-45: CANFD_ESR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	LPTXMB	Lowest Priority Tx Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field indicates the lowest number inactive mailbox, per the CANFD_ESR2.IMB bit. If there is no inactive mailbox, then the mailbox indicated depends on the CANFD_CTL1.LBUF bit value. If the CANFD_CTL1.LBUF bit bit is cleared, the mailbox indicated is the one that has the greatest arbitration value. If the CANFD_CTL1.LBUF bit bit is set, the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted, it is not considered in the CANFD_ESR2.LPTXMB bit field calculation. If the CANFD_ESR2.IMB bit is not set and a frame is transmitted successfully, the CANFD_ESR2.LPTXMB bit field is updated with the mailbox number.

Table 15-45: CANFD_ESR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	VPS	Valid Priority Status. The CANFD_ESR2.VPS bit indicates whether the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB contents are currently valid. If the CANFD_ESR2.VPS bit is set, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are valid. If the bit is cleared, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are invalid. The CANFD_ESR2.VPS bit is set upon every complete Tx arbitration process unless the processor writes to the C/S word of a mailbox that has already been scanned (is behind Tx Arbitration Pointer during the Tx arbitration process). If there is no inactive mailbox and only one Tx mailbox that is being transmitted, then the CANFD_ESR2.VPS bit is not set. The CANFD_ESR2.VPS bit is cleared upon the start of every Tx arbitration process or upon a write to the C/S word of any mailbox. Note that the CANFD_ESR2.VPS bit is not affected by any processor write into the C/S of a MB that is blocked by the abort mechanism. When the CANFD_CFG.ABORTEN bit is set, the abort code write into the C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with the interrupt flag set is blocked.
13 (R/NW)	IMB	Inactive Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.IMB bit indicates whether there is any inactive mailbox (CODE field is either 0b1000 or 0b0000). If the CANFD_ESR2.IMB bit is set and the CANFD_ESR2.VPS bit is set and there is at least one inactive mailbox. The CANFD_ESR2.LPTXMB bit field content is the number of the first one. If the CANFD_ESR2.IMB bit is cleared and the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field is not an inactive mailbox. The CANFD_ESR2.IMB bit is set during arbitration, if a CANFD_ESR2.LPTXMB value is found and it is inactive. The CANFD_ESR2.IMB bit is also set if CAN_ESR2.MB is not set and a frame is transmitted successfully. The CANFD_ESR2.IMB bit is cleared at the start of arbitration. Note that if an MB is successfully transmitted and The CANFD_ESR2.IMB bit is zero (no inactive mailbox), then the CANFD_ESR2.VPS and CANFD_ESR2.IMB bits are set and the index related to the MB just transmitted is loaded into the CANFD_ESR2.LPTXMB bit field.

CANFD Bit Timing Register

The CANFD_FD_TIMING register stores the CAN bit timing variables for use in the data phase of CAN FD messages when the CANFD_FD_CTL.BRSEN bit is set, compatible with CAN FD specification. The CANFD_FD_TIMING.FPRESDIV, CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, and CANFD_FD_TIMING.FRJW bit fields define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of the CANFD_FD_TIMING register are not affected by soft reset.

Note that the sum of values in the CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields must be at least two time quanta.

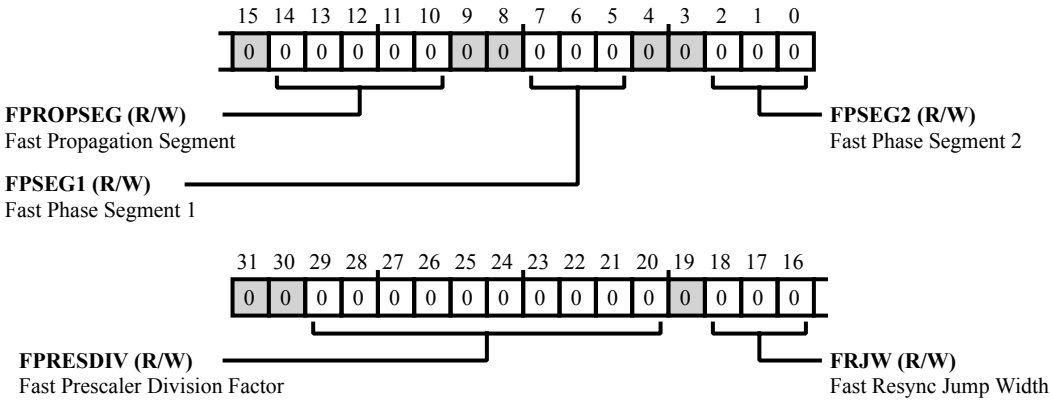

Figure 15-28: CANFD_FD_TIMING Register Diagram

Table 15-46: CANFD_FD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:20 (R/W)	FPRESDIV	Fast Prescaler Division Factor. The CANFD_FD_TIMING.FPRESDIV bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. This is in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (FPRESDIV + 1). To minimize errors when processing FD frames, use the same value for the CANFD_FD_TIMING.FPRESDIV and CANFD_CTL1.PRESDIV bit fields The CANFD_FD_TIMING.FPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 15-46: CANFD_FD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/W)	FRJW	Fast Resync Jump Width. The `CANFD_FD_TIMING.FRJW` bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Resync Jump Width = FSJW + 1. One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FRJW` bit field can only be written in freeze mode and is blocked by hardware in other modes.
14:10 (R/W)	FPROPSEG	Fast Propagation Segment. The `CANFD_FD_TIMING.FPROPSEG` bit field defines the length of the propagation segment in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Propagation Segment Time = FPROPSEG Time-Quanta One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FPROPSEG` bit field can only be written in freeze mode and is blocked by hardware in other modes.
7:5 (R/W)	FPSEG1	Fast Phase Segment 1. The `CANFD_FD_TIMING.FPSEG1` bit field defines the length of phase segment 1 in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 1 = (FPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.
2:0 (R/W)	FPSEG2	Fast Phase Segment 2. The `CANFD_FD_TIMING.FPSEG2` bit field defines the length of phase segment 2. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 2 = (FPSEG2 + 1) Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.

CANFD CRC Register

The CANFD_FD_CRC register provides information about the CRC of transmitted messages. The CANFD module uses different CRC polynomials for different frame formats as follows:

·The CRC_15 polynomial is used for all frames in CAN format.

·The CRC_17 polynomial is used for frames in CAN FD format with a data field up to sixteen bytes.

·The CRC_21 polynomial is used for frames in CAN FD format with a data field longer than sixteen bytes.

Each polynomial shown below results in a Hamming distance of 6. The CANFD_FD_CRC register updates when the Tx interrupt flag is asserted.

CRC_15 = 0xC599:(x^15+x^14+x^10+x^8+x^7+x^4+x^3+1)

CRC_17 = 0x3685B:(x^17+x^16+x^14+x^13+x^11+x^6+x^4+x^3+x^1+1)

CRC_21 = 0x302899:(x^21+x^20+x^13+x^11+x^7+x^4+x^3+1)

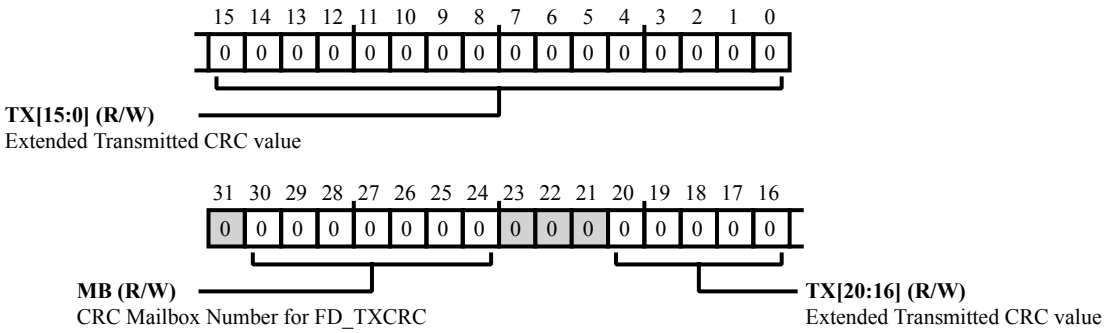

Figure 15-29: CANFD_FD_CRC Register Diagram

Table 15-47: CANFD_FD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:24 (R/W)	MB	CRC Mailbox Number for FD_TXCRC. The CANFD_FD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames.

Table 15-47: CANFD_FD_CRC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:0 (R/W)	TX	Extended Transmitted CRC value. The `CANFD_FD_CRC.TX` bit field contains the CRC value calculated over the most recent transmitted message. There are different CRC polynomials for different frame formats. All frames in CAN format use a 15-bit polynomial, CRC_15. CRC_17 is for frames in CAN FD format with a data field up to sixteen bytes long. The 21-bit polynomial, CRC_21, is for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as the `CANFD_CRC` register.

CANFD Control Register

The CANFD_FD_CTL register contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks).

When 8 bytes of payload is selected, block R0 allocates MB0 to MB31 and block R1 allocates MB32 to MB63.

When more than 8 bytes of payload is selected, the maximum number of MBs in a block is limited as described as follows:

Payload Size => Maximum Number of Message Buffers per RAM Block

8 bytes => 32

16 bytes => 21

32 bytes => 12

64 bytes => 7

Note that one memory block fits exactly 32 MBs with 8 bytes payload. For the other options of payload sizes, empty memory may exist between last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of CANFD_FD_CTL register are not affected by soft reset.

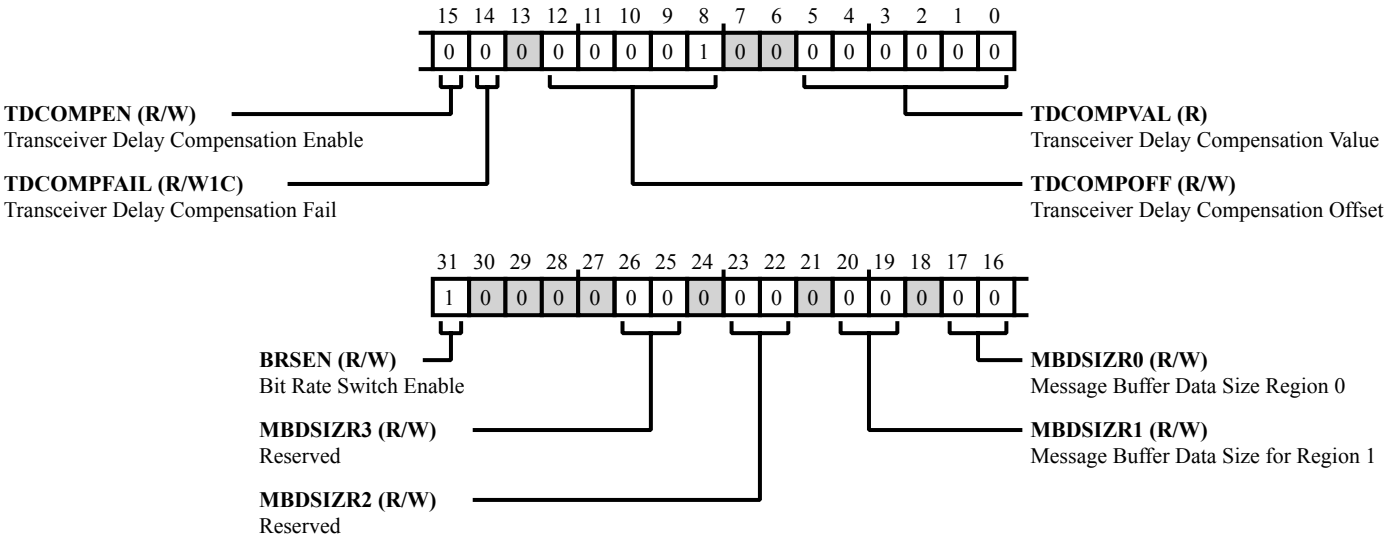

Figure 15-30: CANFD_FD_CTL Register Diagram

Table 15-48: CANFD_FD_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BRSEN	Bit Rate Switch Enable. The CANFD_FD_CTL.BRSEN bit enables the effect of the bit rate switch (BRS) bit during the data phase of Tx messages. When the CANFD_FD_CTL.BRSEN bit is set, if the BRS bit in the Tx MB is recessive, the CANFD module transmits a frame with bit rate switching. When the CANFD_FD_CTL.BRSEN bit is clear, the BRS bit in the Tx MB has no effect and the CANFD module transmits a frame with the nominal rate. The processor can write the CANFD_FD_CTL.BRSEN bit any time, however, the effect only becomes active when the CAN bus is in the wait for bus idle, bus idle, bus off state, or when the current frame under reception or transmission reaches the inter-frame space. By negating the CANFD_FD_CTL.BRSEN bit, the processor can force all bits in CAN FD messages to be transmitted with a nominal bit rate, despite the value in the BRS bit of the Tx MBs.	
		0	Nominal Rate
		1	Bit Rate Switching
26:25 (R/W)	MBDSIZR3	Reserved. Message Buffer Data Size for Region 3 Selects the data size for the region R3 of message buffers allocated in RAM: 00: Selects 8 bytes per message buffer. 01: Selects 16 bytes per message buffer. 10: Selects 32 bytes per message buffer. 11: Selects 64 bytes per message buffer. MBDSR3 can be written in Freeze mode only.	
23:22 (R/W)	MBDSIZR2	Reserved. Message Buffer Data Size for Region 2 Selects the data size for the region R2 of message buffers allocated in RAM: 00: Selects 8 bytes per message buffer. 01: Selects 16 bytes per message buffer. 10: Selects 32 bytes per message buffer. 11: Selects 64 bytes per message buffer. MBDSR2 can be written in Freeze mode only.	
20:19 (R/W)	MBDSIZR1	Message Buffer Data Size for Region 1. The CANFD_FD_CTL.MBDSIZR1 bit field selects the data size for the region R1 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR1 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer

Table 15-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	MBDSIZR0	Message Buffer Data Size Region 0. The CANFD_FD_CTL.MBDSIZR0 bit field selects the data size for the region R0 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR0 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
15 (R/W)	TDCOMPEN	Transceiver Delay Compensation Enable. The CANFD_FD_CTL.TDCOMPEN bit enables or disables the TDC feature. The CANFD_FD_CTL.TDCOMPEN bit can only be written in freeze mode. Note that when loop-back mode is enabled (CANFD_CTL1.LBEN), the CANFD_FD_CTL.TDCOMPEN bit must be disabled.	
		0	Disable
		1	Enable
14 (R/W1C)	TDCOMPFAIL	Transceiver Delay Compensation Fail. The CANFD_FD_CTL.TDCOMPFAIL bit indicates when the transceiver delay compensation (TDC) mechanism is out of range. When the TDC is out of range it is unable to compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. The CANFD_FD_CTL.TDCOMPFAIL bit is set the first time the CANFD module detects the out of range condition. To clear the CANFD_FD_CTL.TDCOMPFAIL bit, write a one to it.	
		0	Measured loop delay is in range
		1	Measured loop delay is out of range
12:8 (R/W)	TDCOMPOFF	Transceiver Delay Compensation Offset. The CANFD_FD_CTL.TDCOMPOFF bit field contains the offset value that must be added to the loop delay of the measured transceiver. This defines the position of the delayed comparison point when bit rate switching is active. The CANFD_FD_CTL.TDCOMPOFF bit field can only be written in freeze mode. The bit field value is defined in PE clock periods and must be smaller than the CAN bit duration in the data bit rate. Do not set the CANFD_FD_CTL.TDCOMPOFF bit field to zero.	

Table 15-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/NW)	TDCOMPVAL	Transceiver Delay Compensation Value. The `CANFD_FD_CTL.TDCOMPVAL` bit field contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the value in the `CANFD_FD_CTL.TDCOMPOFF` bit field. This value is an integer multiple of the PE clock period.

Pretended Networking DLC Filter Register

The CANFD_FLTR_DLC register contains the DLC inside range target values (CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO) for filtering incoming messages. The DLC range is only for payload filtering. The CANFD_FLTR_DLC register can only be written in freeze mode.

Note that when a fixed quantity of data bytes is required, both the CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO bit fields must have the same value; otherwise, a range of DLC is considered for filtering.

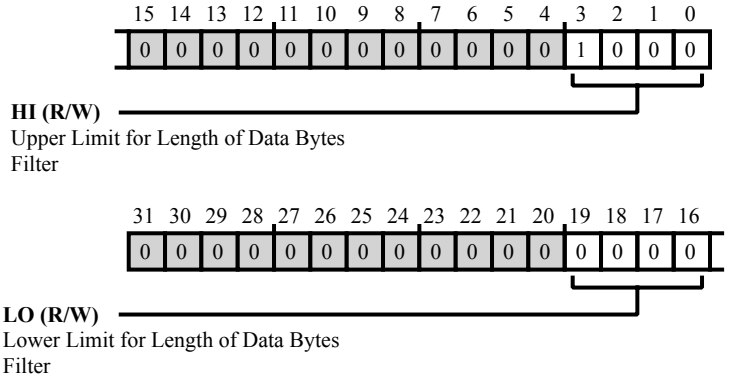

Figure 15-31: CANFD_FLTR_DLC Register Diagram

Table 15-49: CANFD_FLTR_DLC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	LO	Lower Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.LO bit field specifies the lower limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.LO bit field is part of payload reception filter.
3:0 (R/W)	HI	Upper Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.HI bit field specifies the upper limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.HI bit field is part of payload reception filter.

Pretended Networking ID Filter1 Register

The CANFD_FLTR_ID1 register contains the FLT_ID1 target value and the IDE and RTR target values for filtering the incoming message ID. This register is for equal to, smaller than, greater than comparisons, or as the lower limit value in an ID range detection. The CANFD_FLTR_ID1 register is only written in freeze mode.

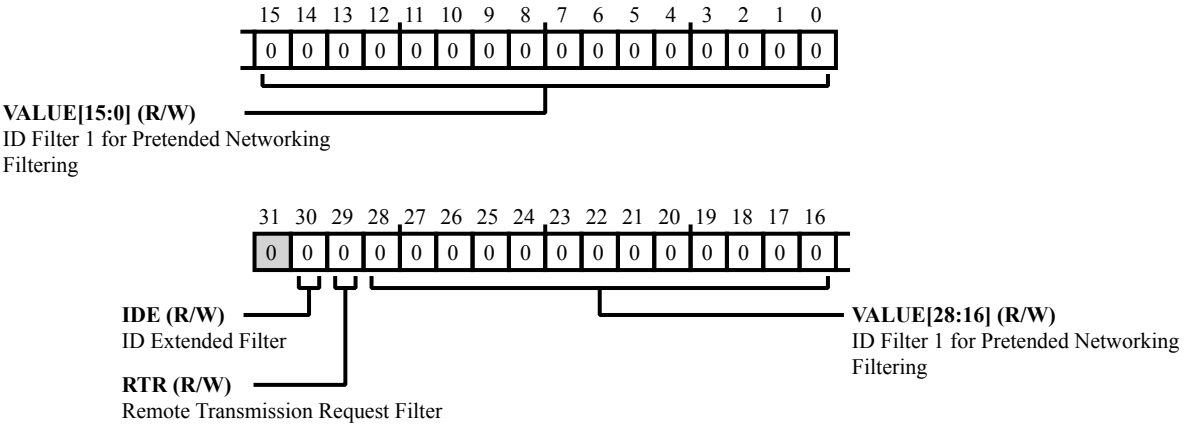

Figure 15-32: CANFD_FLTR_ID1 Register Diagram

Table 15-50: CANFD_FLTR_ID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Filter. The CANFD_FLTR_ID1.IDE bit identifies if the frame format is standard or extended. It is part of the ID reception filter.	
		0	Accept standard frame format
		1	Accept extended frame format
29 (R/W)	RTR	Remote Transmission Request Filter. The CANFD_FLTR_ID1.RTR bit identifies if the frame is remote. It is part of the ID reception filter.	
		0	Reject remote frame (accept data frame)
		1	Accept remote frame
28:0 (R/W)	VALUE	ID Filter 1 for Pretended Networking Filtering. The CANFD_FLTR_ID1.VALUE bit field defines either the 29 bits of a extended frame format, considering all bits, or the 11 bits of a standard frame format, considering just the 11 leftmost bits.	

Pretended Networking ID Filter2 / IDMask Register

The CANFD_FLTR_ID2_IDMSK register contains the FLT_ID2 target value for use as the upper limit value in ID range detection. When exact ID filtering criteria is selected, the CANFD_FLTR_ID2_IDMSK register is also for storing the ID mask. The CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are for ID filtering (exact and range) as part of the ID reception filter.

The CANFD_FLTR_ID2_IDMSK register can only be written in freeze mode.

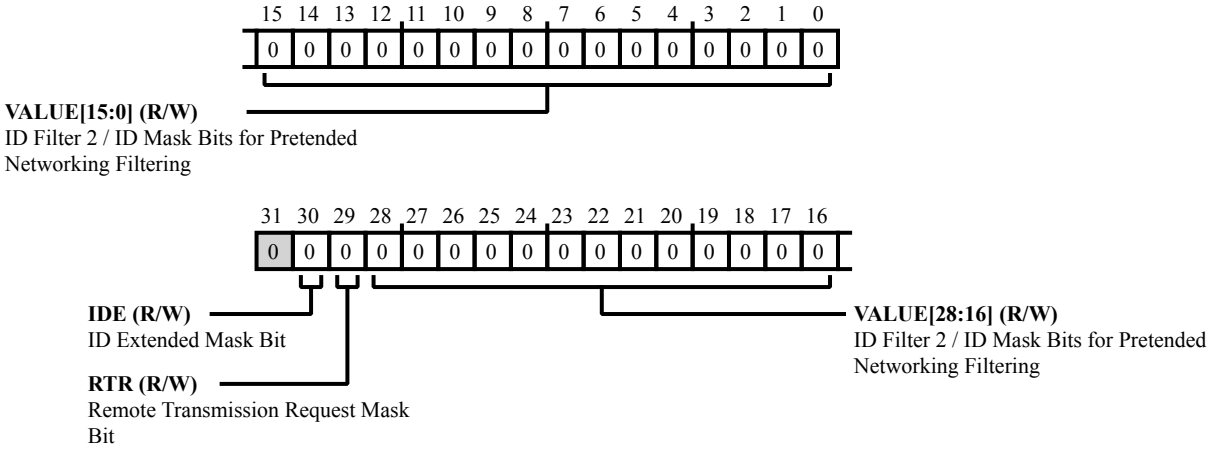

Figure 15-33: CANFD_FLTR_ID2_IDMSK Register Diagram

Table 15-51: CANFD_FLTR_ID2_IDMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Mask Bit. The CANFD_FLTR_ID2_IDMSK.IDE bit indicates whether the frame format (standard/extended) is used as part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.IDE bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a dont care.	
		0	Don't Care
		1	Checked
29 (R/W)	RTR	Remote Transmission Request Mask Bit. The CANFD_FLTR_ID2_IDMSK.RTR bit indicates if the frame type (data/remote) is part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.RTR bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a dont care.	
		0	Don't Care
		1	Checked

Table 15-51: CANFD_FLTR_ID2_IDMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	VALUE	ID Filter 2 / ID Mask Bits for Pretended Networking Filtering. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field defines the ID filter value (FLT_ID2). In extended frame format, use all 29 bits (FLT_ID2[28:0]) in the field. In standard frame format, use the upper 11 bits (FLT_ID2[28:18]) and the lower 18 bits (FLT_ID2[17:0]) have no meaning. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field can also be IDMASK in exact ID filtering to define the mask value. In extended frame format, use all 29 bits (IDMASK[28:0]) in the field. In standard frame format, use the upper 11 bits (IDMASK[28:18]) and the lower 18 bits (IDMASK[17:0]) have no meaning.

Mailbox Interrupt Flag 1 Register

The CANFD_IFLG1 register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding bit in the CANFD_IFLG1 register. If the corresponding bit in the CANFD_IMSK1 register is set, an interrupt is generated. The interrupt flag must be cleared by writing a 1 to it. Writing a zero has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG1 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

There is an exception is when DMA for Rx FIFO is enabled, as described below.

Rx FIFO:

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the CANFD_CFG.RFEN bit is set and the CANFD_CFG.DMAEN bit is cleared, the function of the 8 least significant interrupt flags changes as follows: • BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO.

• BUF0I is used to empty the FIFO.

• BUF4I to BUF1I are reserved.

Before setting the CANFD_CFG.RFEN bit, the processor must service the IFLAG bits asserted in the Rx FIFO region or these IFLAG bits will mistakenly show the related MBs now belonging to the FIFO as having contents to be serviced. When the CANFD_CFG.RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when a CANFD_CTL2.RFFNUM value is selected extending Rx FIFO filters beyond MB7. For example, when the CANFD_CTL2.RFFNUM value is 0x8, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

The Rx FIFO must be disabled when the CANFD_CFG.FDEN bit is enabled.

Rx FIFO with DMA:

When both the CANFD_CFG.RFEN bit and the CANFD_CFG.DMAEN bits are set (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation:

• BUF7I, BUF6I, and BUF4I–BUF1I are not used.

• BUF5I indicates operating condition of FIFO.

• BUF5I does not generate a CPU interrupt, but generates a DMA request.

• BUF0I is used to empty FIFO.

The CANFD_IMSK1 register bits in the Rx FIFO region are not considered when the CANFD_CFG.DMAEN bit is asserted. In addition, the processor must not clear the flag BUF5I when DMA is enabled. Before setting the CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. When the CANFD_CFG.DMAEN bit is cleared, the FIFO must be empty.

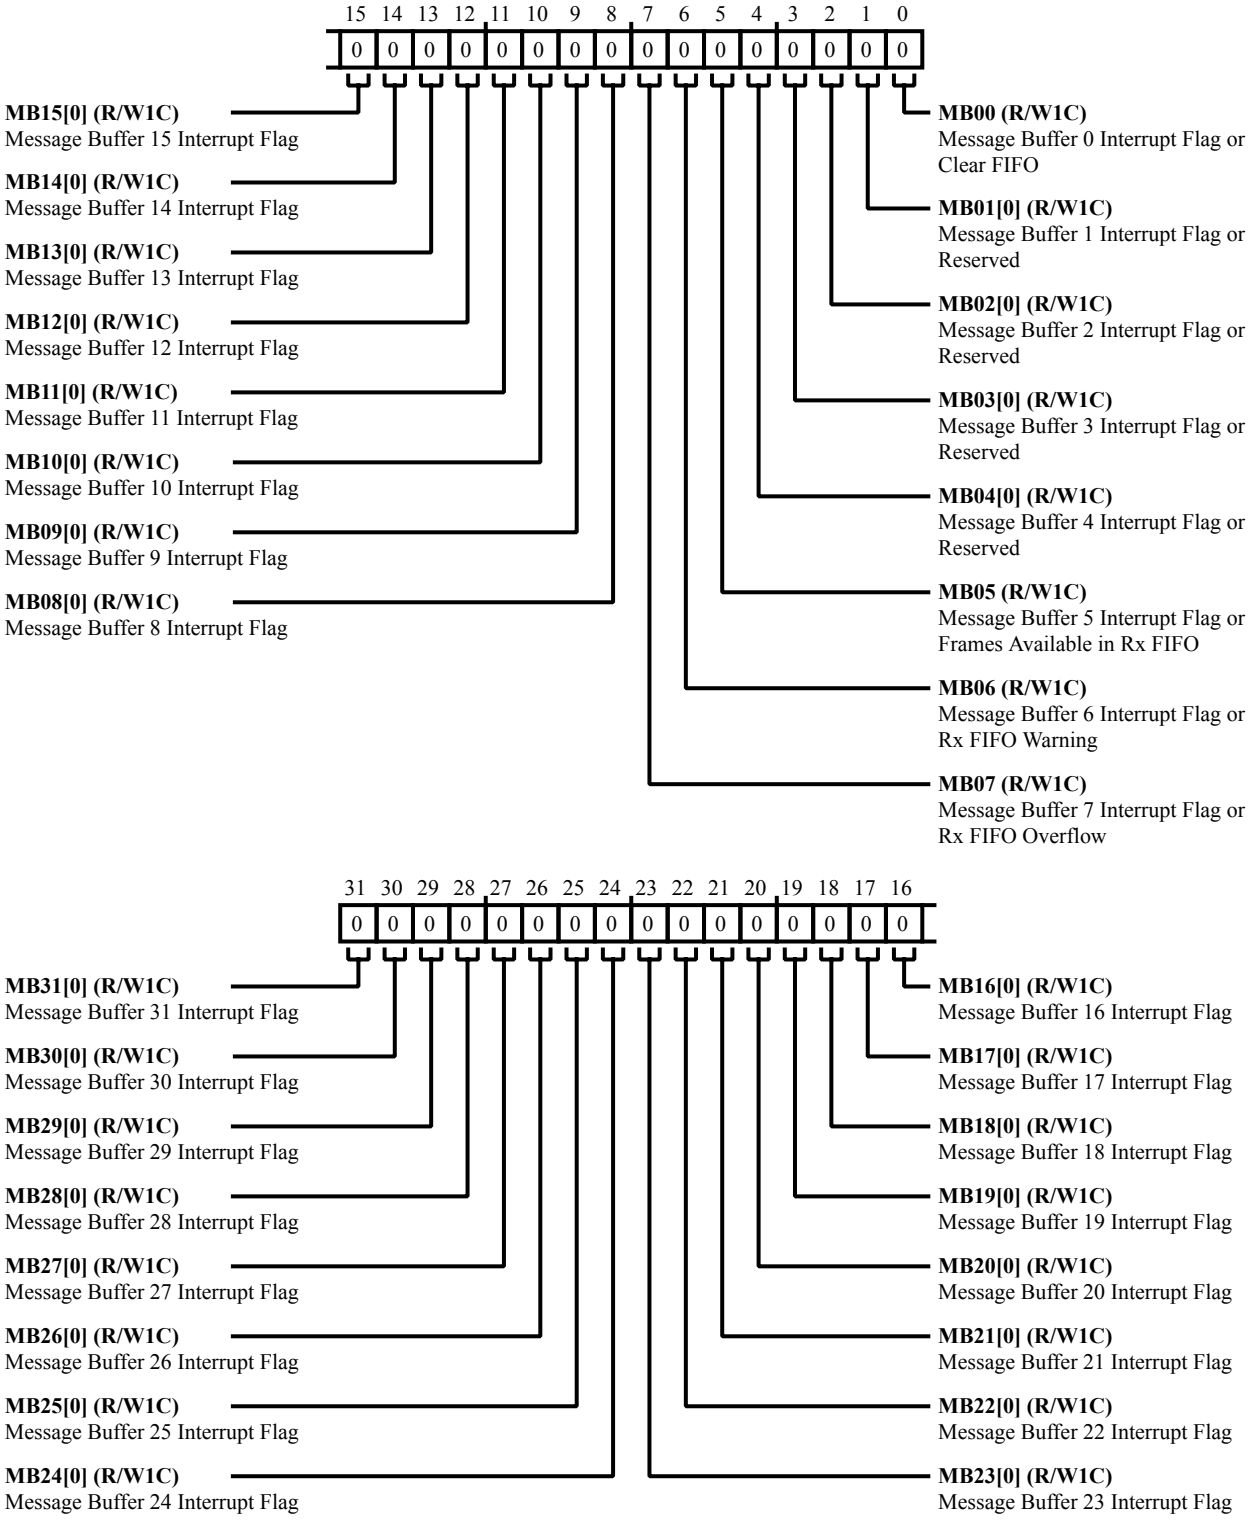

Figure 15-34: CANFD_IFLG1 Register Diagram

Table 15-52: CANFD_IFLG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MB31	Message Buffer 31 Interrupt Flag. The CANFD_IFLG1.MB31 bit flags the CANFD module message buffer interrupt for MB31. When the CANFD_IFLG1.MB31 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
30 (R/W1C)	MB30	Message Buffer 30 Interrupt Flag. The CANFD_IFLG1.MB30 bit flags the CANFD module message buffer interrupt for MB30. When the CANFD_IFLG1.MB30 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
29 (R/W1C)	MB29	Message Buffer 29 Interrupt Flag. The CANFD_IFLG1.MB29 bit flags the CANFD module message buffer interrupt for MB29. When the CANFD_IFLG1.MB29 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
28 (R/W1C)	MB28	Message Buffer 28 Interrupt Flag. The CANFD_IFLG1.MB28 bit flags the CANFD module message buffer interrupt for MB28 When the CANFD_IFLG1.MB28 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
27 (R/W1C)	MB27	Message Buffer 27 Interrupt Flag. The CANFD_IFLG1.MB27 bit flags the CANFD module message buffer interrupt for MB27. When the CANFD_IFLG1.MB27 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W1C)	MB26	Message Buffer 26 Interrupt Flag. The CANFD_IFLG1.MB26 bit flags the CANFD module message buffer interrupt for MB26. When the CANFD_IFLG1.MB26 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
25 (R/W1C)	MB25	Message Buffer 25 Interrupt Flag. The CANFD_IFLG1.MB25 bit flags the CANFD module message buffer interrupt for MB25. When the CANFD_IFLG1.MB25 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
24 (R/W1C)	MB24	Message Buffer 24 Interrupt Flag. The CANFD_IFLG1.MB24 bit flags the CANFD module message buffer interrupt for MB24. When the CANFD_IFLG1.MB24 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
23 (R/W1C)	MB23	Message Buffer 23 Interrupt Flag. The CANFD_IFLG1.MB23 bit flags the CANFD module message buffer interrupt for MB23. When the CANFD_IFLG1.MB23 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
22 (R/W1C)	MB22	Message Buffer 22 Interrupt Flag. The CANFD_IFLG1.MB22 bit flags the CANFD module message buffer interrupt for MB22. When the CANFD_IFLG1.MB22 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W1C)	MB21	Message Buffer 21 Interrupt Flag. The CANFD_IFLG1.MB21 bit flags the CANFD module message buffer interrupt for MB21. When the CANFD_IFLG1.MB21 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
20 (R/W1C)	MB20	Message Buffer 20 Interrupt Flag. The CANFD_IFLG1.MB20 bit flags the CANFD module message buffer interrupt for MB20. When the CANFD_IFLG1.MB20 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
19 (R/W1C)	MB19	Message Buffer 19 Interrupt Flag. The CANFD_IFLG1.MB19 bit flags the CANFD module message buffer interrupt for MB19. When the CANFD_IFLG1.MB19 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
18 (R/W1C)	MB18	Message Buffer 18 Interrupt Flag. The CANFD_IFLG1.MB18 bit flags the CANFD module message buffer interrupt for MB18. When the CANFD_IFLG1.MB18 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
17 (R/W1C)	MB17	Message Buffer 17 Interrupt Flag. The CANFD_IFLG1.MB17 bit flags the CANFD module message buffer interrupt for MB17. When the CANFD_IFLG1.MB17 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W1C)	MB16	Message Buffer 16 Interrupt Flag. The `CANFD_IFLG1.MB16` bit flags the CANFD module message buffer interrupt for MB16. When the `CANFD_IFLG1.MB16` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
15 (R/W1C)	MB15	Message Buffer 15 Interrupt Flag. The `CANFD_IFLG1.MB15` bit flags the CANFD module message buffer interrupt for MB15. When the `CANFD_IFLG1.MB15` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
14 (R/W1C)	MB14	Message Buffer 14 Interrupt Flag. The `CANFD_IFLG1.MB14` bit flags the CANFD module message buffer interrupt for MB14. When the `CANFD_IFLG1.MB14` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
13 (R/W1C)	MB13	Message Buffer 13 Interrupt Flag. The `CANFD_IFLG1.MB13` bit flags the CANFD module message buffer interrupt for MB13. When the `CANFD_IFLG1.MB13` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
12 (R/W1C)	MB12	Message Buffer 12 Interrupt Flag. The `CANFD_IFLG1.MB12` bit flags the CANFD module message buffer interrupt for MB12. When the `CANFD_IFLG1.MB12` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	MB11	Message Buffer 11 Interrupt Flag. The `CANFD_IFLG1.MB11` bit flags the CANFD module message buffer interrupt for MB11. When the `CANFD_IFLG1.MB11` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
10 (R/W1C)	MB10	Message Buffer 10 Interrupt Flag. The `CANFD_IFLG1.MB10` bit flags the CANFD module message buffer interrupt for MB10. When the `CANFD_IFLG1.MB10` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
9 (R/W1C)	MB09	Message Buffer 9 Interrupt Flag. The `CANFD_IFLG1.MB09` bit flags the CANFD module message buffer interrupt for MB09. When the `CANFD_IFLG1.MB09` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
8 (R/W1C)	MB08	Message Buffer 8 Interrupt Flag. The `CANFD_IFLG1.MB08` bit flags the CANFD module message buffer interrupt for MB08. When the `CANFD_IFLG1.MB08` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	MB07	Message Buffer 7 Interrupt Flag or Rx FIFO Overflow. The CANFD_IFLG1.MB07 bit flags the CANFD module message buffer interrupt for MB7 or Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is disabled, MB7 completed transmission or reception. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is enabled, there is an Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is enabled, there is no occurrence of Rx FIFO overflow. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB07 bit flags the interrupt for MB7. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB07 bit represents the Rx FIFO overflow. In this case, the CANFD_IFLG1.MB07 bit indicates that a message was lost because the Rx FIFO is full. Note that the CANFD_IFLG1.MB07 bit is not asserted when the Rx FIFO is full and the message was captured by a mailbox. Note that the CANFD_IFLG1.MB07 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
6 (R/W1C)	MB06	Message Buffer 6 Interrupt Flag or Rx FIFO Warning. The CANFD_IFLG1.MB06 bit flags the CANFD module message buffer interrupt for MB6 or Rx FIFO warning. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is disabled, MB6 completed transmission or reception. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO is almost full. When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is enabled, the Rx FIFO is not almost full. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB06 bit flags the interrupt for MB6. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB06 bit represents the Rx FIFO warning. In this case, BUF6I indicates when the number of unread messages in the Rx FIFO increases from 4 to 5 due to the reception of a new message, meaning that the Rx FIFO is almost full. Note that if the CANFD_IFLG1.MB06 bit is cleared while the number of unread messages is greater than 4, the CANFD_IFLG1.MB06 bit is not asserted again until the number of unread messages in the Rx FIFO decreases to 4 or less. Note that the CANFD_IFLG1.MB06 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	MB05	Message Buffer 5 Interrupt Flag or Frames Available in Rx FIFO. The CANFD_IFLG1.MB05 bit flags the CANFD module message buffer interrupt for MB5 or Rx FIFO frames available. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is disabled, MB5 completed transmission or reception. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO has frames available. BUF5I generates a DMA request when both the CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits are set. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is enabled, no frames are available in the Rx FIFO. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), CANFD_IFLG1.MB05 bit flags the interrupt for MB5. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB05 bit represents the frames available in the Rx FIFO and indicates that at least one frame is available to be read from the Rx FIFO. When the CANFD_CFG.DMAEN bit is set, the CANFD_IFLG1.MB05 bit generates a DMA request and the processor must not clear the CANFD_IFLG1.MB05 bit by writing one to it. Note that the CANFD_IFLG1.MB05 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
4 (R/W1C)	MB04	Message Buffer 4 Interrupt Flag or Reserved. The CANFD_IFLG1.MB04 bit flags the interrupt for MB4, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB04 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB04 bit is reserved. Note that the CANFD_IFLG1.MB04 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is is changed by a processor write.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W1C)	MB03	Message Buffer 3 Interrupt Flag or Reserved. The CANFD_IFLG1.MB03 bit flags the interrupt for MB3, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB03 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB03 bit is reserved. Note that the CANFD_IFLG1.MB03 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is is changed by a processor write.
2 (R/W1C)	MB02	Message Buffer 2 Interrupt Flag or Reserved. The CANFD_IFLG1.MB02 bit flags the interrupt for MB2, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB02 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB02 bit is reserved. Note that the CANFD_IFLG1.MB02 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is is changed by a processor write.
1 (R/W1C)	MB01	Message Buffer 1 Interrupt Flag or Reserved. The CANFD_IFLG1.MB01 bit flags the interrupt for MB1, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB01 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB01 bit is reserved. Note that the CANFD_IFLG1.MB01 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is is changed by a processor write.

Table 15-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	MB00	Message Buffer 0 Interrupt Flag or Clear FIFO. The CANFD_IFLG1.MB00 bit flags the interrupt for MB0, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB00 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB00 bit triggers the clear FIFO operation. This operation empties FIFO contents. Before performing this operation, the processor must service all FIFO related IFLAGs. When the CANFD_CFG.DMAEN bit is is set (DMA is enabled), this operation also clears the CANFD_IFLG1.MB05 flag and consequently aborts the DMA request. The clear FIFO operation occurs when the processor writes a one to the CANFD_IFLG1.MB00 bit, which is only allowed in freeze mode and is blocked by hardware in other conditions.

Mailbox Interrupt Flag 2 Register

The CANFD_IFLG2 register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective bit in the CANFD_IFLG2 bit. If the corresponding bit is set, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG2 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

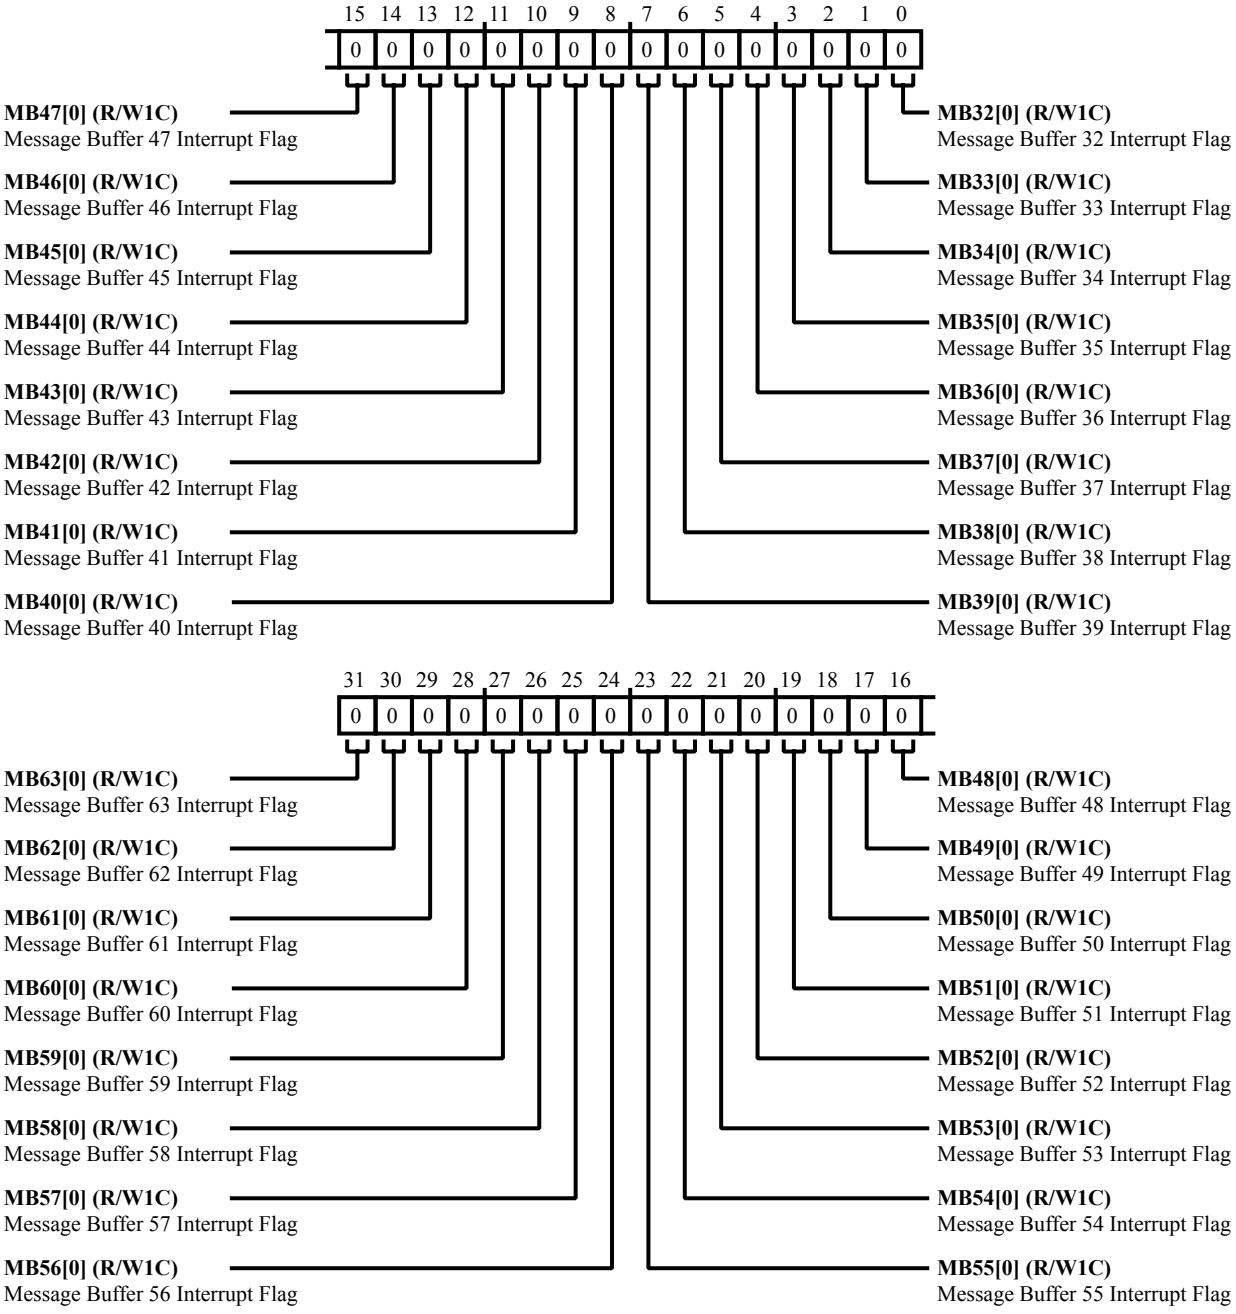

Figure 15-35: CANFD_IFLG2 Register Diagram

Table 15-53: CANFD_IFLG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MB63	Message Buffer 63 Interrupt Flag. The CANFD_IFLG2.MB63 bit flags the CANFD module message buffer interrupt for MB63. When the CANFD_IFLG2.MB63 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
30 (R/W1C)	MB62	Message Buffer 62 Interrupt Flag. The CANFD_IFLG2.MB62 bit flags the CANFD module message buffer interrupt for MB62. When the CANFD_IFLG2.MB62 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
29 (R/W1C)	MB61	Message Buffer 61 Interrupt Flag. The CANFD_IFLG2.MB61 bit flags the CANFD module message buffer interrupt for MB61. When the CANFD_IFLG2.MB61 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
28 (R/W1C)	MB60	Message Buffer 60 Interrupt Flag. The CANFD_IFLG2.MB60 bit flags the CANFD module message buffer interrupt for MB60. When the CANFD_IFLG2.MB60 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
27 (R/W1C)	MB59	Message Buffer 59 Interrupt Flag. The CANFD_IFLG2.MB59 bit flags the CANFD module message buffer interrupt for MB59. When the CANFD_IFLG2.MB59 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
26 (R/W1C)	MB58	Message Buffer 58 Interrupt Flag. The CANFD_IFLG2.MB58 bit flags the CANFD module message buffer interrupt for MB58. When the CANFD_IFLG2.MB58 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 15-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W1C)	MB57	Message Buffer 57 Interrupt Flag. The `CANFD_IFLG2.MB57` bit flags the CANFD module message buffer interrupt for MB57. When the `CANFD_IFLG2.MB57` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
24 (R/W1C)	MB56	Message Buffer 56 Interrupt Flag. The `CANFD_IFLG2.MB56` bit flags the CANFD module message buffer interrupt for MB56. When the `CANFD_IFLG2.MB56` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
23 (R/W1C)	MB55	Message Buffer 55 Interrupt Flag. The `CANFD_IFLG2.MB55` bit flags the CANFD module message buffer interrupt for MB55. When the `CANFD_IFLG2.MB55` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
22 (R/W1C)	MB54	Message Buffer 54 Interrupt Flag. The `CANFD_IFLG2.MB54` bit flags the CANFD module message buffer interrupt for MB54. When the `CANFD_IFLG2.MB54` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
21 (R/W1C)	MB53	Message Buffer 53 Interrupt Flag. The `CANFD_IFLG2.MB53` bit flags the CANFD module message buffer interrupt for MB53. When the `CANFD_IFLG2.MB53` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
20 (R/W1C)	MB52	Message Buffer 52 Interrupt Flag. The `CANFD_IFLG2.MB52` bit flags the CANFD module message buffer interrupt for MB52. When the `CANFD_IFLG2.MB52` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 15-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W1C)	MB51	Message Buffer 51 Interrupt Flag. The CANFD_IFLG2.MB51 bit flags the CANFD module message buffer interrupt for MB51. When the CANFD_IFLG2.MB51 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
18 (R/W1C)	MB50	Message Buffer 50 Interrupt Flag. The CANFD_IFLG2.MB50 bit flags the CANFD module message buffer interrupt for MB50. When the CANFD_IFLG2.MB50 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
17 (R/W1C)	MB49	Message Buffer 49 Interrupt Flag. The CANFD_IFLG2.MB49 bit flags the CANFD module message buffer interrupt for MB49. When the CANFD_IFLG2.MB49 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
16 (R/W1C)	MB48	Message Buffer 48 Interrupt Flag. The CANFD_IFLG2.MB48 bit flags the CANFD module message buffer interrupt for MB48. When the CANFD_IFLG2.MB48 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
15 (R/W1C)	MB47	Message Buffer 47 Interrupt Flag. The CANFD_IFLG2.MB47 bit flags the CANFD module message buffer interrupt for MB47. When the CANFD_IFLG2.MB47 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
14 (R/W1C)	MB46	Message Buffer 46 Interrupt Flag. The CANFD_IFLG2.MB46 bit flags the CANFD module message buffer interrupt for MB46. When the CANFD_IFLG2.MB46 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 15-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	MB45	Message Buffer 45 Interrupt Flag. The `CANFD_IFLG2.MB45` bit flags the CANFD module message buffer interrupt for MB45. When the `CANFD_IFLG2.MB45` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
12 (R/W1C)	MB44	Message Buffer 44 Interrupt Flag. The `CANFD_IFLG2.MB44` bit flags the CANFD module message buffer interrupt for MB44. When the `CANFD_IFLG2.MB44` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
11 (R/W1C)	MB43	Message Buffer 43 Interrupt Flag. The `CANFD_IFLG2.MB43` bit flags the CANFD module message buffer interrupt for MB43. When the `CANFD_IFLG2.MB43` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
10 (R/W1C)	MB42	Message Buffer 42 Interrupt Flag. The `CANFD_IFLG2.MB42` bit flags the CANFD module message buffer interrupt for MB42. When the `CANFD_IFLG2.MB42` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
9 (R/W1C)	MB41	Message Buffer 41 Interrupt Flag. The `CANFD_IFLG2.MB41` bit flags the CANFD module message buffer interrupt for MB41. When the `CANFD_IFLG2.MB41` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
8 (R/W1C)	MB40	Message Buffer 40 Interrupt Flag. The `CANFD_IFLG2.MB40` bit flags the CANFD module message buffer interrupt for MB40. When the `CANFD_IFLG2.MB40` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 15-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	MB39	Message Buffer 39 Interrupt Flag. The `CANFD_IFLG2.MB39` bit flags the CANFD module message buffer interrupt for MB39. When the `CANFD_IFLG2.MB39` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
6 (R/W1C)	MB38	Message Buffer 38 Interrupt Flag. The `CANFD_IFLG2.MB38` bit flags the CANFD module message buffer interrupt for MB38. When the `CANFD_IFLG2.MB38` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
5 (R/W1C)	MB37	Message Buffer 37 Interrupt Flag. The `CANFD_IFLG2.MB37` bit flags the CANFD module message buffer interrupt for MB37. When the `CANFD_IFLG2.MB37` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
4 (R/W1C)	MB36	Message Buffer 36 Interrupt Flag. The `CANFD_IFLG2.MB36` bit flags the CANFD module message buffer interrupt for MB36. When the `CANFD_IFLG2.MB36` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
3 (R/W1C)	MB35	Message Buffer 35 Interrupt Flag. The `CANFD_IFLG2.MB35` bit flags the CANFD module message buffer interrupt for MB35. When the `CANFD_IFLG2.MB35` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
2 (R/W1C)	MB34	Message Buffer 34 Interrupt Flag. The `CANFD_IFLG2.MB34` bit flags the CANFD module message buffer interrupt for MB34. When the `CANFD_IFLG2.MB34` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 15-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1C)	MB33	Message Buffer 33 Interrupt Flag. The `CANFD_IFLG2.MB33` bit flags the CANFD module message buffer interrupt for MB33. When the `CANFD_IFLG2.MB33` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
0 (R/W1C)	MB32	Message Buffer 32 Interrupt Flag. The `CANFD_IFLG2.MB32` bit flags the CANFD module message buffer interrupt for MB32. When the `CANFD_IFLG2.MB32` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Mailbox Interrupt Mask 1 Register

The CANFD_IMSK1 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB. The CANFD_IMSK1 register contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

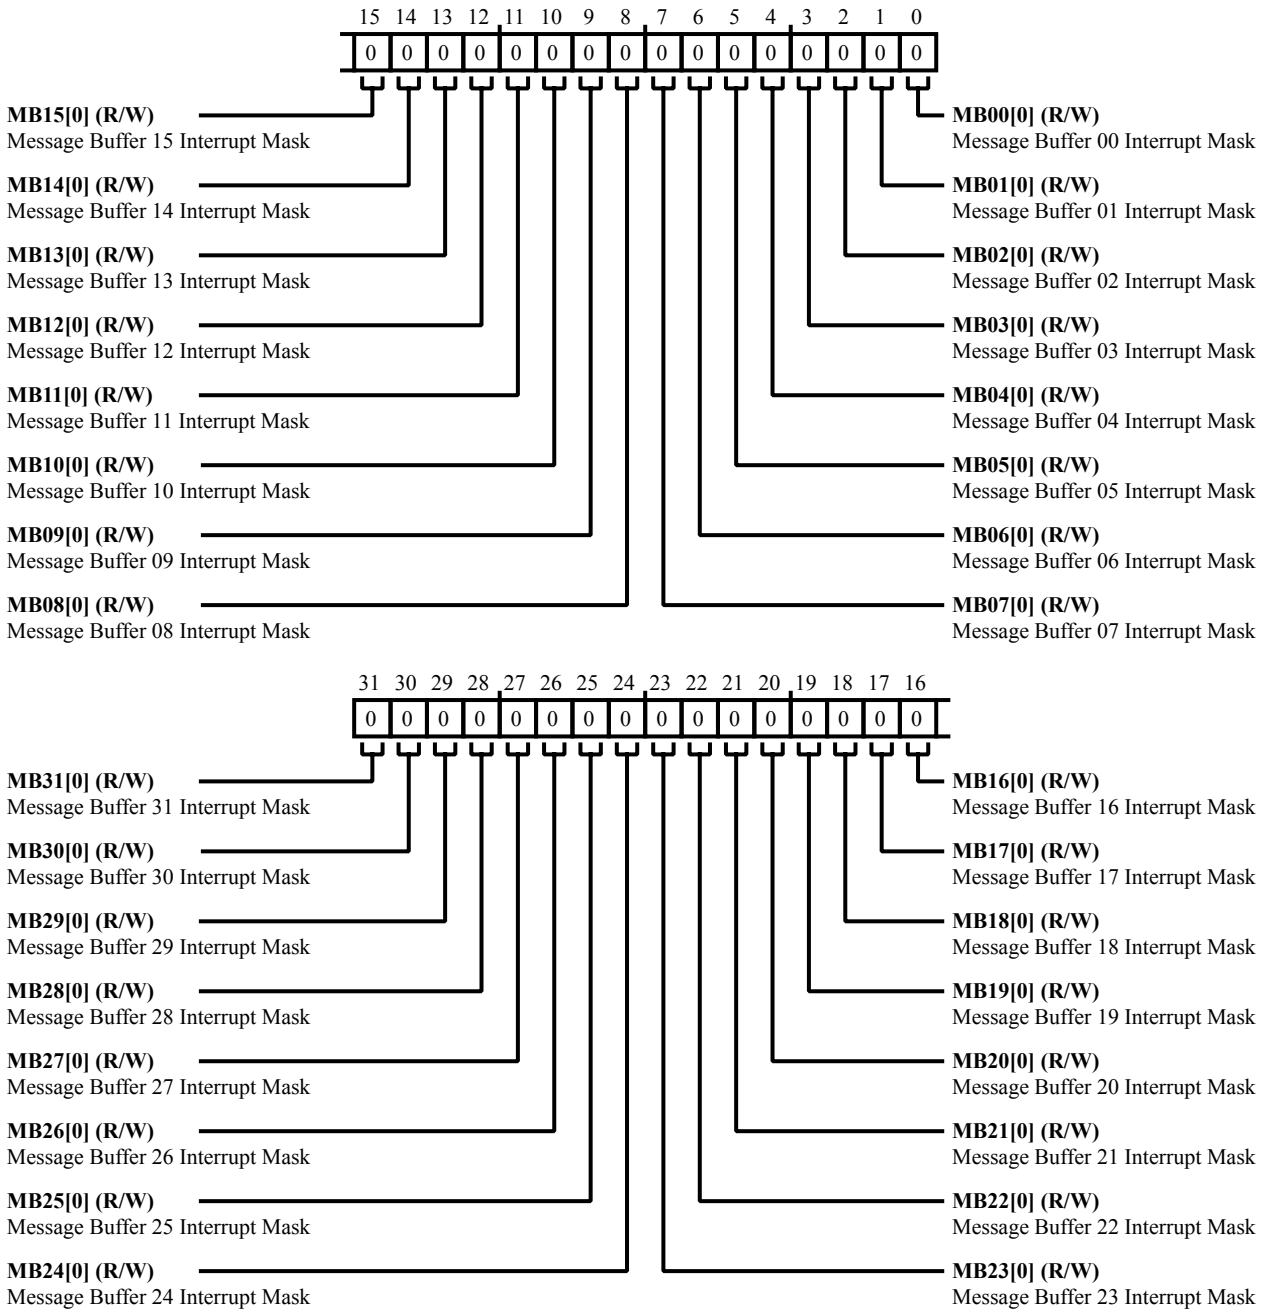

Figure 15-36: CANFD_IMSK1 Register Diagram

Table 15-54: CANFD_IMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MB31	Message Buffer 31 Interrupt Mask. The CANFD_IMSK1.MB31 bit is the CANFD module message buffer interrupt for MB31. When the CANFD_IMSK1.MB31 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
30 (R/W)	MB30	Message Buffer 30 Interrupt Mask. The CANFD_IMSK1.MB30 bit is the CANFD module message buffer interrupt for MB30. When the CANFD_IMSK1.MB30 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
29 (R/W)	MB29	Message Buffer 29 Interrupt Mask. The CANFD_IMSK1.MB29 bit is the CANFD module message buffer interrupt for MB29. When the CANFD_IMSK1.MB29 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
28 (R/W)	MB28	Message Buffer 28 Interrupt Mask. The CANFD_IMSK1.MB28 bit is the CANFD module message buffer interrupt for MB28. When the CANFD_IMSK1.MB28 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
27 (R/W)	MB27	Message Buffer 27 Interrupt Mask. The CANFD_IMSK1.MB27 bit is the CANFD module message buffer interrupt for MB27. When the CANFD_IMSK1.MB27 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	MB26	Message Buffer 26 Interrupt Mask. The CANFD_IMSK1.MB26 bit is the CANFD module message buffer interrupt for MB26. When the CANFD_IMSK1.MB26 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
25 (R/W)	MB25	Message Buffer 25 Interrupt Mask. The CANFD_IMSK1.MB25 bit is the CANFD module message buffer interrupt for MB25. When the CANFD_IMSK1.MB25 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
24 (R/W)	MB24	Message Buffer 24 Interrupt Mask. The CANFD_IMSK1.MB24 bit is the CANFD module message buffer interrupt for MB24. When the CANFD_IMSK1.MB24 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
23 (R/W)	MB23	Message Buffer 23 Interrupt Mask. The CANFD_IMSK1.MB23 bit is the CANFD module message buffer interrupt for MB23. When the CANFD_IMSK1.MB23 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
22 (R/W)	MB22	Message Buffer 22 Interrupt Mask. The CANFD_IMSK1.MB22 bit is the CANFD module message buffer interrupt for MB22. When the CANFD_IMSK1.MB22 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	MB21	Message Buffer 21 Interrupt Mask. The CANFD_IMSK1.MB21 bit is the CANFD module message buffer interrupt for MB21. When the CANFD_IMSK1.MB21 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
20 (R/W)	MB20	Message Buffer 20 Interrupt Mask. The CANFD_IMSK1.MB20 bit is the CANFD module message buffer interrupt for MB20. When the CANFD_IMSK1.MB20 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
19 (R/W)	MB19	Message Buffer 19 Interrupt Mask. The CANFD_IMSK1.MB19 bit is the CANFD module message buffer interrupt for MB19. When the CANFD_IMSK1.MB19 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
18 (R/W)	MB18	Message Buffer 18 Interrupt Mask. The CANFD_IMSK1.MB18 bit is the CANFD module message buffer interrupt for MB18. When the CANFD_IMSK1.MB18 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
17 (R/W)	MB17	Message Buffer 17 Interrupt Mask. The CANFD_IMSK1.MB17 bit is the CANFD module message buffer interrupt for MB17. When the CANFD_IMSK1.MB17 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	MB16	Message Buffer 16 Interrupt Mask. The CANFD_IMSK1.MB16 bit is the CANFD module message buffer interrupt for MB16. When the CANFD_IMSK1.MB16 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
15 (R/W)	MB15	Message Buffer 15 Interrupt Mask. The CANFD_IMSK1.MB15 bit is the CANFD module message buffer interrupt for MB15. When the CANFD_IMSK1.MB15 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
14 (R/W)	MB14	Message Buffer 14 Interrupt Mask. The CANFD_IMSK1.MB14 bit is the CANFD module message buffer interrupt for MB14. When the CANFD_IMSK1.MB14 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
13 (R/W)	MB13	Message Buffer 13 Interrupt Mask. The CANFD_IMSK1.MB13 bit is the CANFD module message buffer interrupt for MB13. When the CANFD_IMSK1.MB13 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
12 (R/W)	MB12	Message Buffer 12 Interrupt Mask. The CANFD_IMSK1.MB12 bit is the CANFD module message buffer interrupt for MB12. When the CANFD_IMSK1.MB12 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	MB11	Message Buffer 11 Interrupt Mask. The CANFD_IMSK1.MB11 bit is the CANFD module message buffer interrupt for MB11. When the CANFD_IMSK1.MB11 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
10 (R/W)	MB10	Message Buffer 10 Interrupt Mask. The CANFD_IMSK1.MB10 bit is the CANFD module message buffer interrupt for MB10. When the CANFD_IMSK1.MB10 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
9 (R/W)	MB09	Message Buffer 09 Interrupt Mask. The CANFD_IMSK1.MB09 bit is the CANFD module message buffer interrupt for MB09. When the CANFD_IMSK1.MB09 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
8 (R/W)	MB08	Message Buffer 08 Interrupt Mask. The CANFD_IMSK1.MB08 bit is the CANFD module message buffer interrupt for MB08. When the CANFD_IMSK1.MB08 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
7 (R/W)	MB07	Message Buffer 07 Interrupt Mask. The CANFD_IMSK1.MB07 bit is the CANFD module message buffer interrupt for MB07. When the CANFD_IMSK1.MB07 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	MB06	Message Buffer 06 Interrupt Mask. The CANFD_IMSK1.MB06 bit is the CANFD module message buffer interrupt for MB06. When the CANFD_IMSK1.MB06 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
5 (R/W)	MB05	Message Buffer 05 Interrupt Mask. The CANFD_IMSK1.MB05 bit is the CANFD module message buffer interrupt for MB05. When the CANFD_IMSK1.MB05 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
4 (R/W)	MB04	Message Buffer 04 Interrupt Mask. The CANFD_IMSK1.MB04 bit is the CANFD module message buffer interrupt for MB04. When the CANFD_IMSK1.MB04 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
3 (R/W)	MB03	Message Buffer 03 Interrupt Mask. The CANFD_IMSK1.MB03 bit is the CANFD module message buffer interrupt for MB03. When the CANFD_IMSK1.MB03 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
2 (R/W)	MB02	Message Buffer 02 Interrupt Mask. The CANFD_IMSK1.MB02 bit is the CANFD module message buffer interrupt for MB02. When the CANFD_IMSK1.MB02 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 15-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	MB01	Message Buffer 01 Interrupt Mask. The `CANFD_IMSK1.MB01` bit is the CANFD module message buffer interrupt for MB01. When the `CANFD_IMSK1.MB01` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK1` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG1` register is set.
0 (R/W)	MB00	Message Buffer 00 Interrupt Mask. The `CANFD_IMSK1.MB00` bit is the CANFD module message buffer interrupt for MB00. When the `CANFD_IMSK1.MB00` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK1` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG1` register is set.

Mailbox Interrupt Mask 2 Register

The CANFD_IMSK2 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. The CANFD_IMSK2 register contains one interrupt mask bit per buffer, enabling the processor to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

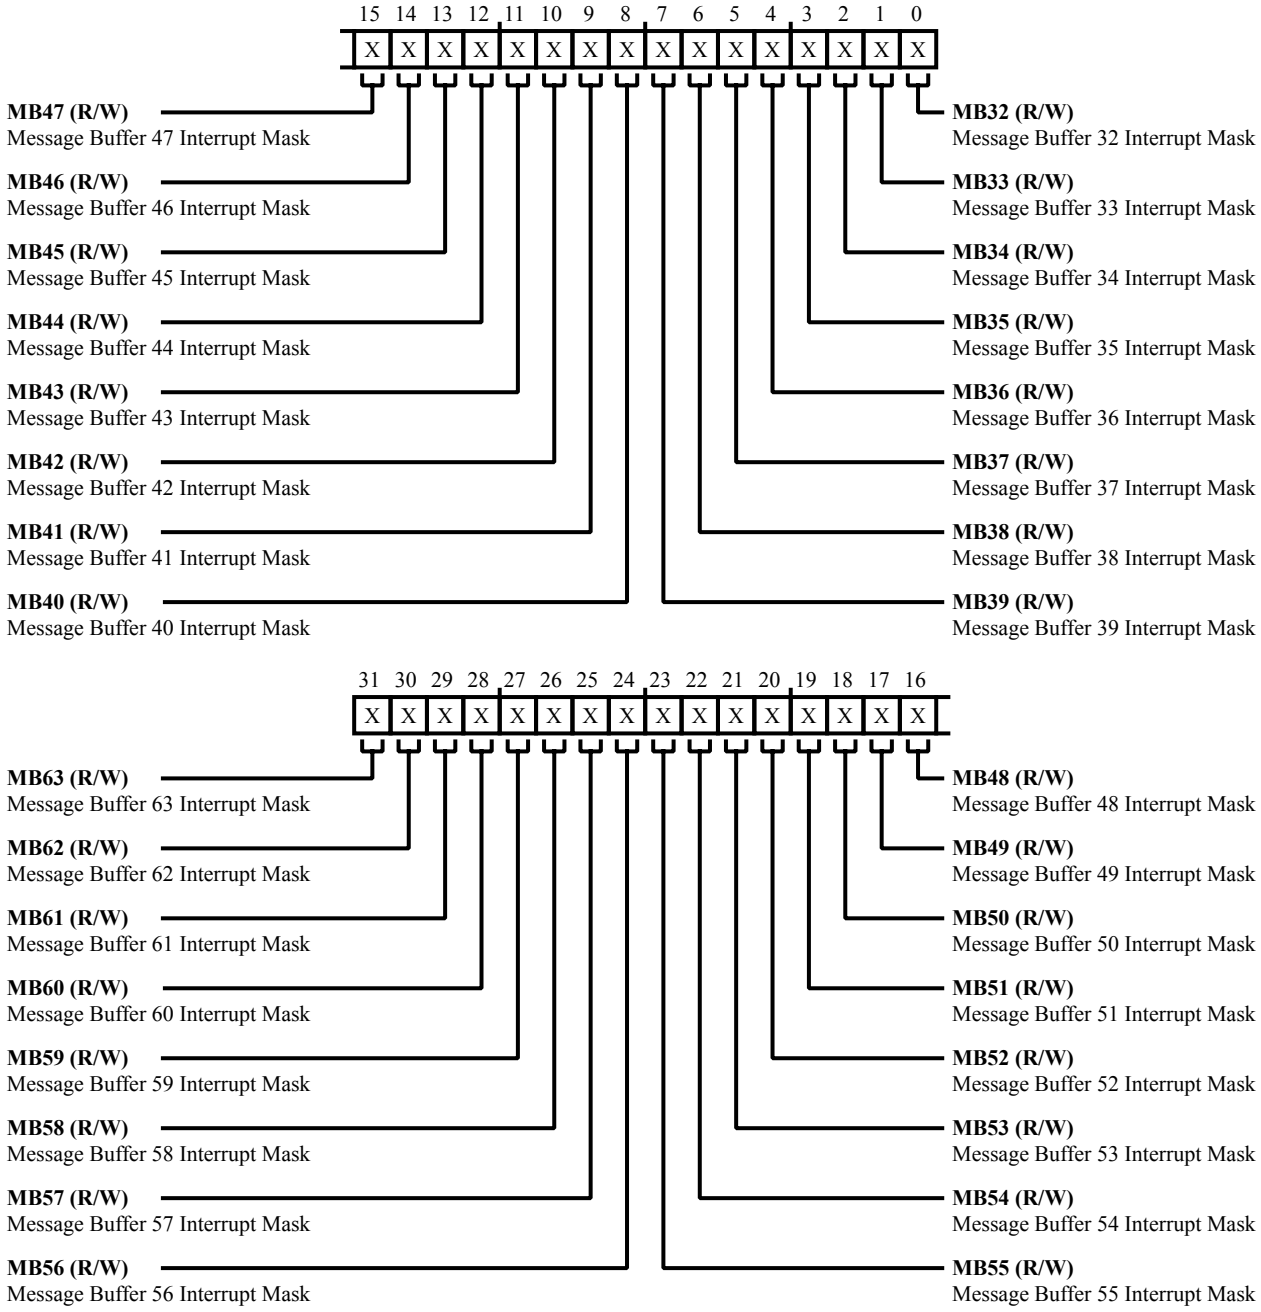

Figure 15-37: CANFD_IMSK2 Register Diagram

Table 15-55: CANFD_IMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MB63	Message Buffer 63 Interrupt Mask. The CANFD_IMSK2.MB63 bit is the CANFD module message buffer interrupt for MB63. When the CANFD_IMSK2.MB63 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
30 (R/W)	MB62	Message Buffer 62 Interrupt Mask. The CANFD_IMSK2.MB62 bit is the CANFD module message buffer interrupt for MB62. When the CANFD_IMSK2.MB62 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
29 (R/W)	MB61	Message Buffer 61 Interrupt Mask. The CANFD_IMSK2.MB61 bit is the CANFD module message buffer interrupt for MB61. When the CANFD_IMSK2.MB61 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
28 (R/W)	MB60	Message Buffer 60 Interrupt Mask. The CANFD_IMSK2.MB60 bit is the CANFD module message buffer interrupt for MB60. When the CANFD_IMSK2.MB60 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
27 (R/W)	MB59	Message Buffer 59 Interrupt Mask. The CANFD_IMSK2.MB59 bit is the CANFD module message buffer interrupt for MB59. When the CANFD_IMSK2.MB59 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	MB58	Message Buffer 58 Interrupt Mask. The CANFD_IMSK2.MB58 bit is the CANFD module message buffer interrupt for MB58. When the CANFD_IMSK2.MB58 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
25 (R/W)	MB57	Message Buffer 57 Interrupt Mask. The CANFD_IMSK2.MB57 bit is the CANFD module message buffer interrupt for MB57. When the CANFD_IMSK2.MB57 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
24 (R/W)	MB56	Message Buffer 56 Interrupt Mask. The CANFD_IMSK2.MB56 bit is the CANFD module message buffer interrupt for MB56. When the CANFD_IMSK2.MB56 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
23 (R/W)	MB55	Message Buffer 55 Interrupt Mask. The CANFD_IMSK2.MB55 bit is the CANFD module message buffer interrupt for MB55. When the CANFD_IMSK2.MB55 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
22 (R/W)	MB54	Message Buffer 54 Interrupt Mask. The CANFD_IMSK2.MB54 bit is the CANFD module message buffer interrupt for MB54. When the CANFD_IMSK2.MB54 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	MB53	Message Buffer 53 Interrupt Mask. The CANFD_IMSK2.MB53 bit is the CANFD module message buffer interrupt for MB53. When the CANFD_IMSK2.MB53 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
20 (R/W)	MB52	Message Buffer 52 Interrupt Mask. The CANFD_IMSK2.MB52 bit is the CANFD module message buffer interrupt for MB52. When the CANFD_IMSK2.MB52 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
19 (R/W)	MB51	Message Buffer 51 Interrupt Mask. The CANFD_IMSK2.MB51 bit is the CANFD module message buffer interrupt for MB51. When the CANFD_IMSK2.MB51 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
18 (R/W)	MB50	Message Buffer 50 Interrupt Mask. The CANFD_IMSK2.MB50 bit is the CANFD module message buffer interrupt for MB50. When the CANFD_IMSK2.MB50 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
17 (R/W)	MB49	Message Buffer 49 Interrupt Mask. The CANFD_IMSK2.MB49 bit is the CANFD module message buffer interrupt for MB49. When the CANFD_IMSK2.MB49 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	MB48	Message Buffer 48 Interrupt Mask. The CANFD_IMSK2.MB48 bit is the CANFD module message buffer interrupt for MB48. When the CANFD_IMSK2.MB48 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
15 (R/W)	MB47	Message Buffer 47 Interrupt Mask. The CANFD_IMSK2.MB47 bit is the CANFD module message buffer interrupt for MB47. When the CANFD_IMSK2.MB47 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
14 (R/W)	MB46	Message Buffer 46 Interrupt Mask. The CANFD_IMSK2.MB46 bit is the CANFD module message buffer interrupt for MB46. When the CANFD_IMSK2.MB46 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
13 (R/W)	MB45	Message Buffer 45 Interrupt Mask. The CANFD_IMSK2.MB45 bit is the CANFD module message buffer interrupt for MB45. When the CANFD_IMSK2.MB45 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
12 (R/W)	MB44	Message Buffer 44 Interrupt Mask. The CANFD_IMSK2.MB44 bit is the CANFD module message buffer interrupt for MB44. When the CANFD_IMSK2.MB44 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	MB43	Message Buffer 43 Interrupt Mask. The CANFD_IMSK2.MB43 bit is the CANFD module message buffer interrupt for MB43. When the CANFD_IMSK2.MB43 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
10 (R/W)	MB42	Message Buffer 42 Interrupt Mask. The CANFD_IMSK2.MB42 bit is the CANFD module message buffer interrupt for MB42. When the CANFD_IMSK2.MB42 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
9 (R/W)	MB41	Message Buffer 41 Interrupt Mask. The CANFD_IMSK2.MB41 bit is the CANFD module message buffer interrupt for MB41. When the CANFD_IMSK2.MB41 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
8 (R/W)	MB40	Message Buffer 40 Interrupt Mask. The CANFD_IMSK2.MB40 bit is the CANFD module message buffer interrupt for MB40. When the CANFD_IMSK2.MB40 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
7 (R/W)	MB39	Message Buffer 39 Interrupt Mask. The CANFD_IMSK2.MB39 bit is the CANFD module message buffer interrupt for MB39. When the CANFD_IMSK2.MB39 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	MB38	Message Buffer 38 Interrupt Mask. The CANFD_IMSK2.MB38 bit is the CANFD module message buffer interrupt for MB39. When the CANFD_IMSK2.MB38 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
5 (R/W)	MB37	Message Buffer 37 Interrupt Mask. The CANFD_IMSK2.MB37 bit is the CANFD module message buffer interrupt for MB37. When the CANFD_IMSK2.MB37 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
4 (R/W)	MB36	Message Buffer 36 Interrupt Mask. The CANFD_IMSK2.MB36 bit is the CANFD module message buffer interrupt for MB36. When the CANFD_IMSK2.MB36 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
3 (R/W)	MB35	Message Buffer 35 Interrupt Mask. The CANFD_IMSK2.MB35 bit is the CANFD module message buffer interrupt for MB35. When the CANFD_IMSK2.MB35 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
2 (R/W)	MB34	Message Buffer 34 Interrupt Mask. The CANFD_IMSK2.MB34 bit is the CANFD module message buffer interrupt for MB34. When the CANFD_IMSK2.MB34 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 15-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	MB33	Message Buffer 33 Interrupt Mask. The `CANFD_IMSK2.MB33` bit is the CANFD module message buffer interrupt for MB33. When the `CANFD_IMSK2.MB33` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK2` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG2` register is set.
0 (R/W)	MB32	Message Buffer 32 Interrupt Mask. The `CANFD_IMSK2.MB32` bit is the CANFD module message buffer interrupt for MB32. When the `CANFD_IMSK2.MB32` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK2` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG2` register is set.

Module Configuration Register

The CANFD_CFG register configures the operation modes and settings for the CANFD module. This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

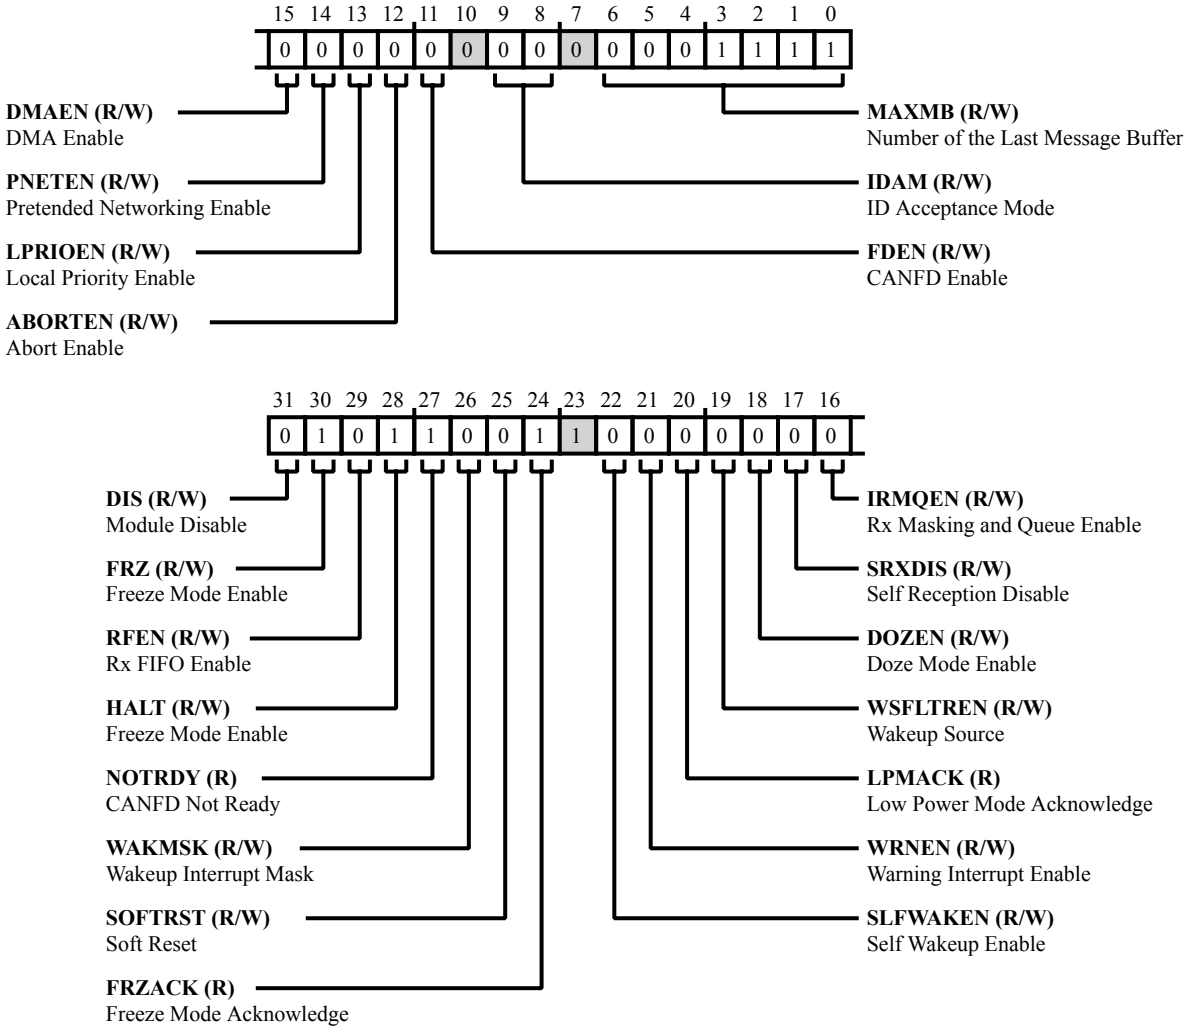

Figure 15-38: CANFD_CFG Register Diagram

Table 15-56: CANFD_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DIS	Module Disable. The CANFD_CFG.DIS bit disables or enables the CANFD module. When the CANFD_CFG.DIS bit is set, the CANFD module disables the clocks to the PE and CHI submodules. This bit is not affected by a soft reset.	
		0	Enable
		1	Disable
30 (R/W)	FRZ	Freeze Mode Enable. The CANFD_CFG.FRZ bit specifies the CANFD module behavior when the CANFD_CFG.HALT bit is set or when there is a debug mode request at the chip level. When the CANFD_CFG.FRZ bit is set, the CANFD module enters freeze mode. Negation of the CANFD_CFG.FRZ bit causes the CANFD module to exit from freeze mode. The CANFD_CFG.FRZ bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
29 (R/W)	RFEN	Rx FIFO Enable. The CANFD_CFG.RFEN bit enables the Rx FIFO. When the CANFD_CFG.RFEN bit is set, do not use MBs 05 for normal reception and transmission. The corresponding memory region (0x800xDC) is used by the FIFO engine and additional MBs (up to 32, depending on the CANFD_CTL2.RFFNUM bit setting) are used as Rx FIFO ID filter table elements. The CANFD_CFG.RFEN bit also impacts the minimum number of peripheral clocks per CAN bit. The CANFD_CFG.RFEN bit can only be written in freeze mode because it is blocked by hardware in other modes. Note that the CANFD_CFG.RFEN bit cannot be set when the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	HALT	Freeze Mode Enable. Setting the CANFD_CFG.HALT bit puts the CANFD module into freeze mode. The processor clears the CANFD_CFG.HALT bit after initializing the message buffers, the CANFD_CTL1 register, and the CANFD_CTL2 register. The CANFD module does not receive or transmit data before the CANFD_CFG.HALT bit is cleared. The CANFD module cannot enter freeze mode while it is in a low-power mode. The CANFD_CFG.HALT bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
27 (R/NW)	NOTRDY	CANFD Not Ready. The CANFD_CFG.NOTRDY bit is a read-only bit that indicates the CANFD module is either in module disable, doze, stop, or freeze mode. The CANFD_CFG.NOTRDY bit is negated once the CANFD module exits these modes. Soft reset does not affect the CANFD_CFG.NOTRDY bit.	
		0	Normal, Listen-Only, or Loop-Back Mode
		1	Module Disable, Doze, Stop, or Freeze Mode
26 (R/W)	WAKMSK	Wakeup Interrupt Mask. The CANFD_CFG.WAKMSK bit enables the wakeup interrupt using the self wakeup mechanism.	
		0	Disable
		1	Enable
25 (R/W)	SOFTRST	Soft Reset. When the CANFD_CFG.SOFTRST bit is set, the internal state machines and some of the memory mapped registers of the CANFD module reset. For the processor to directly assert a soft reset, write to the CANFD_CFG.SOFTRST bit. A soft reset can also occur when a global soft reset is requested at the chip level. Soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, so it takes time to fully propagate the effect. The CANFD_CFG.SOFTRST bit remains set while reset is pending and is automatically negated when the reset completes. Poll the CANFD_CFG.SOFTRST bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low-power mode. Remove the CANFD module from low-power mode before applying soft reset. A soft reset does not affect the CANFD_CFG.SOFTRST bit.	

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	FRZACK	Freeze Mode Acknowledge. The CANFD_CFG.FRZACK bit is a read-only bit that indicates the CANFD module is in freeze mode and the prescaler is stopped. A freeze mode request is only granted after the current transmission or reception processes completes. Poll the CANFD_CFG.FRZACK bit in software to know when the CANFD module enters freeze mode. If a freeze mode request is negated, the CANFD_CFG.FRZACK bit is negated after the CANFD module prescaler is running again. If freeze mode is requested while the CANFD module is in a low-power mode, the CANFD_CFG.FRZACK bit sets only when the module exits the low-power mode. Soft reset does not affect the CANFD_CFG.FRZACK bit. Note that the CANFD_CFG.FRZACK bit is set within 178 CAN bits of the freeze mode request. It is negated within 2 CAN bits after a freeze mode request removal.	
		0	No Freeze Mode Prescaler is running.
		1	Freeze Mode The prescaler stopped.
22 (R/W)	SLFWAKEN	Self Wakeup Enable. The CANFD_CFG.SLFWAKEN bit enables the self wakeup feature when the CANFD module is in a low-power mode other than module disable. When the self wakeup feature is enabled, the CANFD module monitors the bus for a wakeup event (a recessive-to-dominant transition). If a wake up event is detected during doze mode, the CANFD module requests resumption of the clocks and when the CANFD_CFG.SLFWAKEN bit is enabled generates a wakeup interrupt to the processor. If a wakeup event is detected during stop mode, the CANFD module, when the CANFD_CFG.SLFWAKEN bit is enabled, generates a wake up interrupt to the processor so that it can exit stop mode globally and the CANFD module can request to resume the clocks. When the CANFD module is in a low-power mode other than module disable, the CANFD_CFG.SLFWAKEN bit cannot be written as it is blocked by hardware. Disable self wakeup when pretended networking mode is set.	
		0	Disable
		1	Enable

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	WRNEN	Warning Interrupt Enable. The CANFD_CFG.WRNEN bit enables the generation of the TWRNINT and RWRNINT flags in the CANFD_ESR1 register. If the CANFD_CFG.WRNEN bit is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters. No warning interrupt is generated. The CANFD_CFG.WRNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
20 (R/NW)	LPMACK	Low Power Mode Acknowledge. The CANFD_CFG.LPMACK bit is a read-only bit that indicates that the CANFD module is in a low-power mode (module disable, doze, or stop). The module can only enter a low-power mode when all current transmission or reception processes have finished. Poll the CANFD_CFG.LPMACK bit to know when the CANFD module is in low-power mode. The CANFD_CFG.LPMACK bit is not affected by soft reset. Note that the CANFD_CFG.LPMACK bit is set within 180 CAN bits of the low-power mode request by the processor. It is negated within 2 CAN bits after removing the low-power mode request. When the CANFD module is in pretended networking mode, the CANFD_CFG.LPMACK bit is negated within 180 CAN bits from the removal of the low-power mode request.	
		0	Disable Not in low-power mode
		1	Enable In low-power mode
19 (R/W)	WSFLTREN	Wakeup Source. The CANFD_CFG.WSFLTREN bit controls whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. When enabled, the CANFD module uses the filtered Rx input to detect recessive-to-dominant edges on the CAN bus. When disabled the CANFD module uses the unfiltered Rx input to detect recessive-to-dominant edges on the CAN bus. The CANFD_CFG.WSFLTREN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	DOZEN	Doze Mode Enable. The CANFD_CFG.DOZEN bit controls whether the CANFD module can enter low-power mode when doze mode is requested at the chip level. When the CANFD_CFG.DOZEN bit is set the CANFD module can enter low-power mode and when it is cleared the module cannot. The CANFD_CFG.DOZEN bit is automatically reset when the CANFD module wakes up from doze mode upon detecting activity on the CAN bus (CANFD_CFG.SLFWAKEN enabled).	
		0	Disable
		1	Enable
17 (R/W)	SRXDIS	Self Reception Disable. The CANFD_CFG.SRXDIS bit controls whether the CANFD module can receive frames transmitted from itself. When the CANFD_CFG.SRXDIS bit is set, frames transmitted by the CANFD module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. The CANFD_CFG.SRXDIS bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Enable
		1	Disable
16 (R/W)	IRMQEN	Rx Masking and Queue Enable. The CANFD_CFG.IRMQEN bit controls whether the Rx matching process is based on individual masking and queue or on a masking scheme with the CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_CFG.IRMQEN bit can only be written in freeze mode and is blocked by hardware in other modes. For backward compatibility, when CANFD_CFG.IRMQEN is disabled, reading a C/S word locks the MB even when it is empty.	
		0	Disable
		1	Enable

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	DMAEN	DMA Enable. The CANFD_CFG.DMAEN bit enables or disables the DMA feature. The DMA feature is only for use with the Rx FIFO and the CANFD_CFG.RFEN bit must be set. When both the CANFD_CFG.DMAEN and CANFD_CFG.RFEN bits are set, CANFD_IFLG1.MB05 generates the DMA request and no Rx FIFO interrupt is generated. The CANFD_CFG.DMAEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
14 (R/W)	PNETEN	Pretended Networking Enable. The CANFD_CFG.PNETEN bit enables the pretended networking mode. When pretended networking is enabled, the PE submodule is kept operational in doze mode and stop mode. It is able to process Rx message filtering as defined by the pretended networking configuration registers. The CANFD_CFG.PNETEN bit can be only be written in freeze mode.	
		0	Disable
		1	Enable
13 (R/W)	LPRIOEN	Local Priority Enable. The CANFD_CFG.LPRIOEN bit controls whether the local priority feature is enabled and is provided for backward compatibility with legacy applications. Local priority expands the arbitration ID. With this expanded ID concept, the arbitration process is based on the full 32-bit word, but the actual transmitted ID still has 11 bits for standard frames and 29 bits for extended frames. The CANFD_CFG.LPRIOEN bit can only be written only in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ABORTEN	Abort Enable. The CANFD_CFG.ABORTEN bit enables the Tx abort mechanism. The Tx abort mechanism ensures a safe procedure for aborting a pending transmission, so that no frame is sent on the CAN bus without notification. The CANFD_CFG.ABORTEN bit can only be written only in freeze mode and is blocked by hardware in other modes. Note that when the CANFD_CFG.ABORTEN bit is set, the abort mechanism must only be used for updating mailboxes configured for transmission. Writing the abort code into Rx mailboxes can cause unpredictable results when the CANFD_CFG.ABORTEN bit is enabled.	
		0	Disable
		1	Enable
11 (R/W)	FDEN	CANFD Enable. The CANFD_CFG.FDEN bit enables CAN with Flexible Data rate (CAN FD) operation. When the CANFD_CFG.FDEN bit is enabled, the CANFD module can receive and transmit messages in both CAN FD and CAN 2.0 formats. When it is disabled, the CANFD module can only receive and transmit messages in CAN 2.0 format. The CANFD_CFG.FDEN bit can only be written in freeze mode only. Note that the CANFD_CFG.RFEN bit cannot be set if the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable
9:8 (R/W)	IDAM	ID Acceptance Mode. The CANFD_CFG.IDAM bit field identifies the format of the Rx FIFO ID Filter Table elements (ID Acceptance Mode). All elements of the table are configured at the same time by the CANFD_CFG.IDAM bit field (they are all the same format). The CANFD_CFG.IDAM bit field can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Format A There is one full ID (standard and extended) per ID filter table element.
		1	Format B There are two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element.
		2	Format C There are four partial 8-bit standard IDs per ID Filter Table element.
		3	Format D All frames are rejected.

Table 15-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	MAXMB	Number of the Last Message Buffer. The CANFD_CFG.MAXMB bit field defines the number of the last message buffer that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 message buffer configuration. The CANFD_CFG.MAXMB bit field can only be written in freeze mode and is blocked by hardware in other modes. Note that the CANFD_CFG.MAXMB bit field must be programmed with a value smaller than or equal to the number of available message buffers. Additionally, the definition of the CANFD_CFG.MAXMB bit value must take into account the region of MBs occupied by Rx FIFO and the ID filters table space defined by the CANFD_CTL2.RFFNUM bit. The CANFD_CFG.MAXMB bit field impacts the minimum number of peripheral clocks per CAN bit.

Memory Error Control Register

The CANFD_MEC register contains control bits for memory error detection and correction (ECC).

Note that when the CANFD_CTL2.ECRWREN bit is disabled, writes to the CANFD_MEC register are blocked, with the exception of the CANFD_MEC.ECRWRDIS bit.

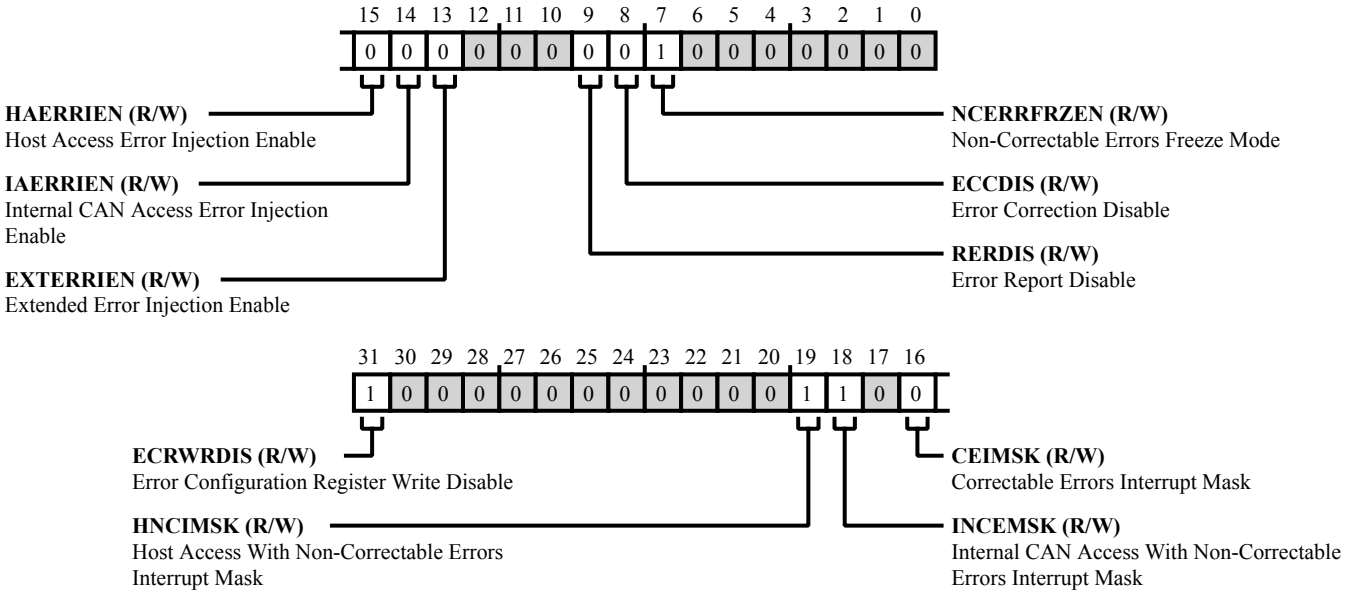

Figure 15-39: CANFD_MEC Register Diagram

Table 15-57: CANFD_MEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ECRWRDIS	Error Configuration Register Write Disable. The CANFD_MEC.ECRWRDIS bit disables writes to the CANFD_MEC register. The CANFD_MEC.ECRWRDIS bit is automatically set to 1 (disabled) when the CANFD_CTL2.ECRWREN bit is enabled. See the protocol described in the Detection and Correction of Memory Errors section of the CANFD chapter.	
		0	Enable
		1	Disable
19 (R/W)	HNCIMSK	Host Access With Non-Correctable Errors Interrupt Mask. The CANFD_MEC.HNCIMSK bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the host.	
		0	Disable
		1	Enable

Table 15-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	INCEMSK	Internal CAN Access With Non-Correctable Errors Interrupt Mask. The `CANFD_MEC.INCEMSK` bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
16 (R/W)	CEIMSK	Correctable Errors Interrupt Mask. The `CANFD_MEC.CEIMSK` bit enables the interrupt in case of correctable errors detected in memory reads issued by the host or CANFD module internal processes.	
		0	Disable
		1	Enable
15 (R/W)	HAERRIEN	Host Access Error Injection Enable. The `CANFD_MEC.HAERRIEN` bit enables the injection of errors for memory reads issued by the host.	
		0	Disable
		1	Enable
14 (R/W)	IAERRIEN	Internal CAN Access Error Injection Enable. The `CANFD_MEC.IAERRIEN` bit enables the injection of errors for memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
13 (R/W)	EXTERRIEN	Extended Error Injection Enable. Memory accesses performed by internal CANFD processes are 64-bit accesses. The `CANFD_MEC.EXTERRIEN` bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. When the `CANFD_MEC.EXTERRIEN` bit is enabled, the error injection is applied to the 64-bit word. When the bit is disabled, error injection is only applied to the 32-bit word. See the descriptions of the `CANFD_ERR_IDP` and `CANFD_ERR_IPP` registers.	
		0	Disable
		1	Enable

Table 15-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RERDIS	Error Report Disable. The `CANFD_MEC.RERDIS` bit disables the update of the error report registers. When the the error report registers are disabled, the update of error-related flags and the generation of bus transfer errors are still active. Note that when reading the report registers, the `CANFD_MEC.RERDIS` bit must be set to ensure coherence on the consecutive register reads.	
		0	Enable
		1	Disable
8 (R/W)	ECCDIS	Error Correction Disable. The `CANFD_MEC.ECCDIS` bit disables the memory detection and correction mechanism. In addition to disabling the error report mechanism, when the `CANFD_MEC.ECCDIS` bit is set, the update of the error-related flags and generation of bus transfer errors also stops. The parity bits continue to be calculated and written into memory on write transactions.	
		0	Enable
		1	Disable
7 (R/W)	NCERRFRZEN	Non-Correctable Errors Freeze Mode. The `CANFD_MEC.NCERRFRZEN` bit determines the response when a non-correctable error is detected in a memory read performed by CANFD module internal processes. Enabling the `CANFD_MEC.NCERRFRZEN` bit puts the CANFD module in freeze mode, preventing corrupted data from being treated as valid by CANFD internal processes. Disabling the bit maintains normal operation.	
		0	Disable
		1	Enable

Pretended Networking Payload Low Filter2 Register

The CANFD_FLTR_DATA1_HI register contain Payload Filter 1 high order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_HI register can only be written in freeze mode.

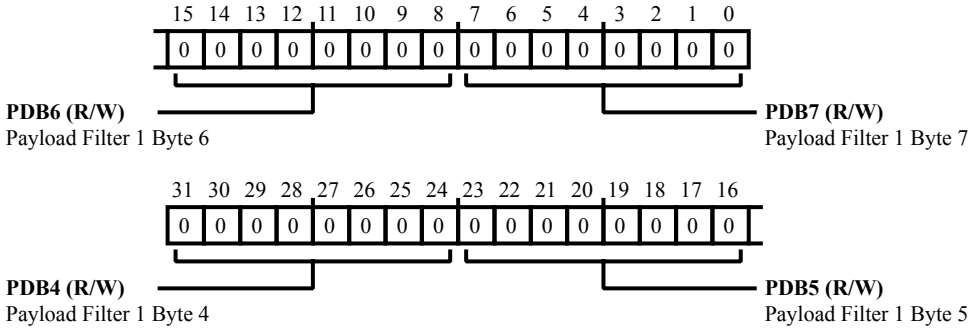

Figure 15-40: CANFD_FLTR_DATA1_HI Register Diagram

Table 15-58: CANFD_FLTR_DATA1_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 1 Byte 4. The CANFD_FLTR_DATA1_HI.PDB4 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 1 Byte 5. The CANFD_FLTR_DATA1_HI.PDB5 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 1 Byte 6. The CANFD_FLTR_DATA1_HI.PDB6 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 1 Byte 7. The CANFD_FLTR_DATA1_HI.PDB7 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter1 Register

The CANFD_FLTR_DATA1_LO register contain Payload Filter 1 low order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_LO register can only be written in freeze mode.

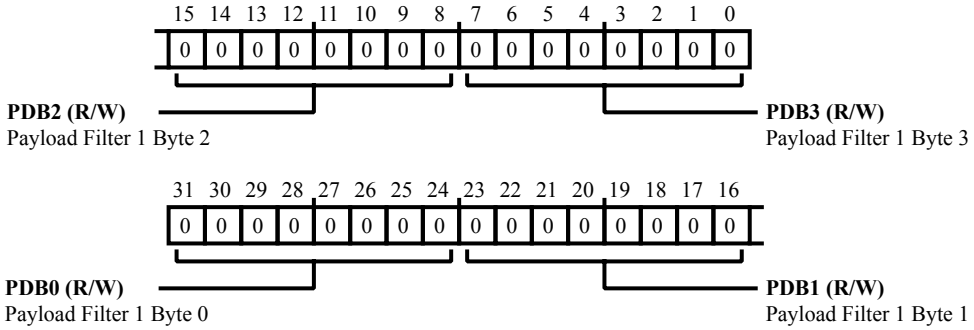

Figure 15-41: CANFD_FLTR_DATA1_LO Register Diagram

Table 15-59: CANFD_FLTR_DATA1_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 1 Byte 0. The CANFD_FLTR_DATA1_LO.PDB0 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 1 Byte 1. The CANFD_FLTR_DATA1_LO.PDB1 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 1 Byte 2. The CANFD_FLTR_DATA1_LO.PDB2 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 1 Byte 3. The CANFD_FLTR_DATA1_LO.PDB3 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 3.

Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register

The CANFD_FLTR_DATA2_DMSK_HI register has two functions:

·It contains the high order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

·When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_HI register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_HI register is not used. It can only be written in freeze mode.

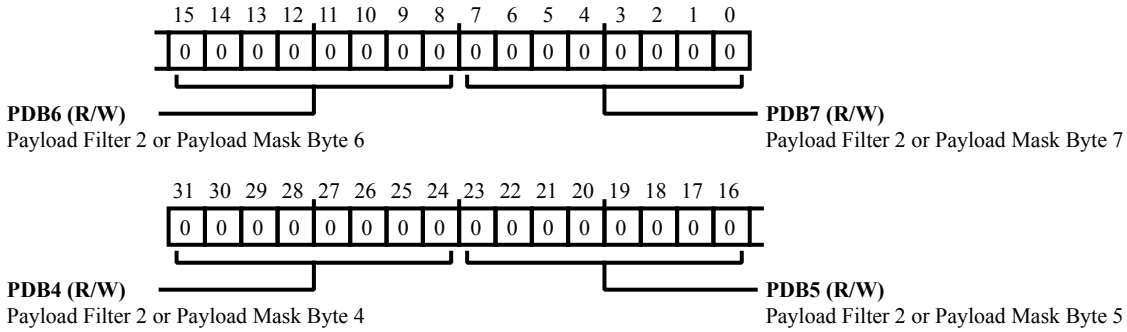

Figure 15-42: CANFD_FLTR_DATA2_DMSK_HI Register Diagram

Table 15-60: CANFD_FLTR_DATA2_DMSK_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 2 or Payload Mask Byte 4. The CANFD_FLTR_DATA2_DMSK_HI.PDB4 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 2 or Payload Mask Byte 5. The CANFD_FLTR_DATA2_DMSK_HI.PDB5 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 2 or Payload Mask Byte 6. The CANFD_FLTR_DATA2_DMSK_HI.PDB6 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 2 or Payload Mask Byte 7. The CANFD_FLTR_DATA2_DMSK_HI.PDB7 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter2 / Payload Low Mask Register

The CANFD_FLTR_DATA2_DMSK_LO register has two functions:

·It contains the low order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

·When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_LO register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_LO register is not used. It can only be written in freeze mode.

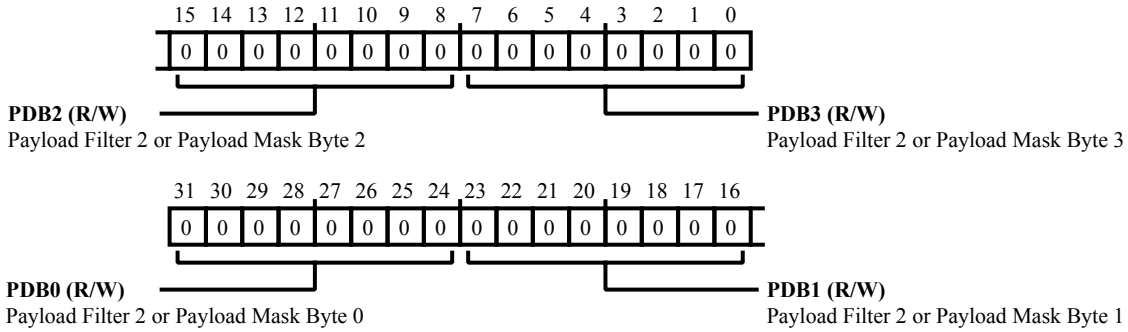

Figure 15-43: CANFD_FLTR_DATA2_DMSK_LO Register Diagram

Table 15-61: CANFD_FLTR_DATA2_DMSK_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 2 or Payload Mask Byte 0. The CANFD_FLTR_DATA2_DMSK_LO.PDB0 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 2 or Payload Mask Byte 1. The CANFD_FLTR_DATA2_DMSK_LO.PDB1 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 2 or Payload Mask Byte 2. The CANFD_FLTR_DATA2_DMSK_LO.PDB2 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 2 or Payload Mask Byte 3. The CANFD_FLTR_DATA2_DMSK_LO.PDB3 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 3.

Error Report Address Register

The CANFD_ERR_RADDR register reports the address of an access with an error (correctable or non-correctable) and reports the identification of the source of that access.

The address is 32-bit aligned. Non-aligned accesses, where the CANFD_ERRADDR[1:0] bits are non-zero, are reported with the address aligned and the data in the CANFD_ERR_RDAT register shifted accordingly. If there is an error in an access that is larger than 32 bits (as performed by CANFD internal processes), the address of the 32-bit word with the error is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

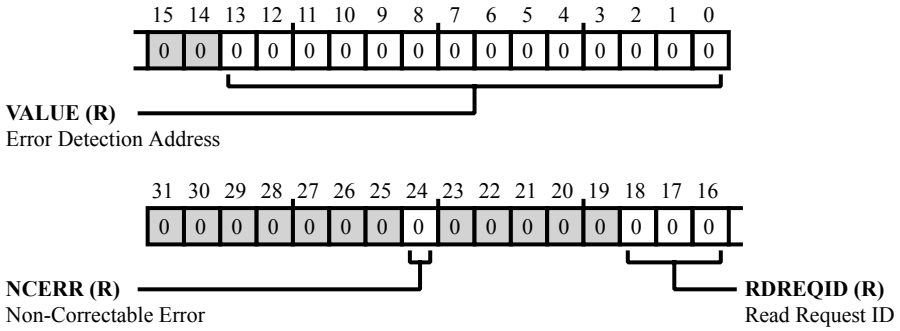

Figure 15-44: CANFD_ERR_RADDR Register Diagram

Table 15-62: CANFD_ERR_RADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	NCERR	Non-Correctable Error. The CANFD_ERR_RADDR.NCERR bit indicates that a report is due to an non-correctable error. When the CANFD_ERR_RADDR.NCERR bit is set, it is reporting a non-correctable error. When it is cleared, it is reporting a correctable-error.	
18:16 (R/NW)	RDREQID	Read Request ID. The CANFD_ERR_RADDR.RDREQID bit field identifies the details of a memory read request.	
		0	Move-Out CANFD Access
		1	Move-In CANFD Access
		2	TX Arbitration
		3	Rx Matching
		4	Move-Out Host Access
		5	Reserved
		6	Reserved
		7	Reserved

Table 15-62: CANFD_ERR_RADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	VALUE	Error Detection Address. The `CANFD_ERR_RADDR.VALUE` bit field contains the address where the error was detected in the $ See the description of the Error Injection Address Register (CAN_ERRIAR).

Error Report Data Register

The CANFD_ERR_RDAT register reports the raw data (unmodified by the ECC logic correction) read from the memory with the error. The value reported does not represent the transient values of the BUSY bit when reading a message buffer.

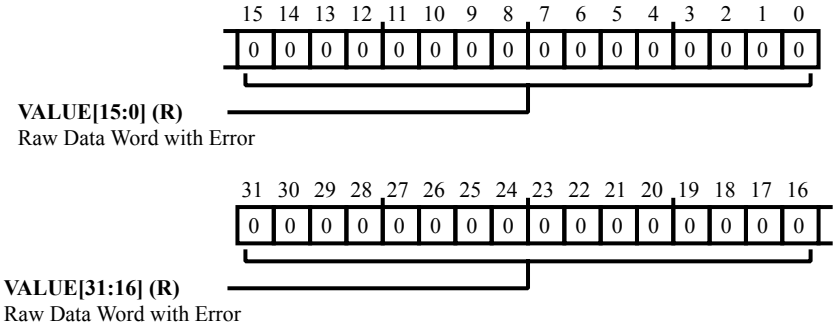

Figure 15-45: CANFD_ERR_RDAT Register Diagram

Table 15-63: CANFD_ERR_RDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Raw Data Word with Error. The CANFD_ERR_RDAT.VALUE bit field contains the raw data word read from memory with error. This data word is unmodified by the correction performed by ECC logic and does not represent the transient values of the BUSY bit when reading the message buffer.

Error Report Syndrome Register

The CANFD_ERR_RSYN register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. The CANFD_ERR_RSYN.SYND3 bit field corresponds to the most significant byte in the data word read from memory and the CANFD_ERR_RSYN.SYND0 bit field corresponds to the least significant.

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported.

See the Detection and Correction of Memory Errors section of the CANFD chapter for more details.

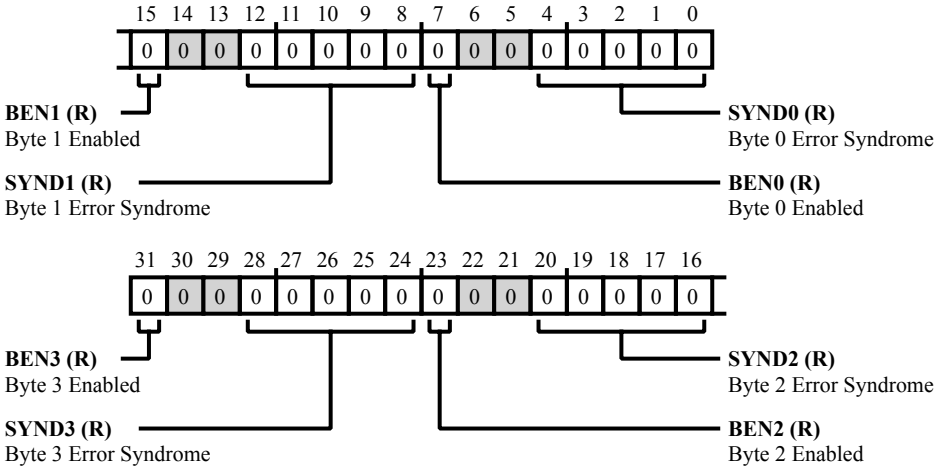

Figure 15-46: CANFD_ERR_RSYN Register Diagram

Table 15-64: CANFD_ERR_RSYN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	BEN3	Byte 3 Enabled. The CANFD_ERR_RSYN.BEN3 bit indicates if byte 3 (most significant) was read. If the CANFD_ERR_RSYN.BEN3 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
28:24 (R/NW)	SYND3	Byte 3 Error Syndrome. The CANFD_ERR_RSYN.SYND3 bit field contains the error syndrome for byte 3. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND3 bit field.	

Table 15-64: CANFD_ERR_RSYN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/NW)	BEN2	Byte 2 Enabled. The CANFD_ERR_RSYN.BEN2 bit indicates if byte 2 was read. If the CANFD_ERR_RSYN.BEN2 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
20:16 (R/NW)	SYND2	Byte 2 Error Syndrome. The CANFD_ERR_RSYN.SYND2 bit field contains the error syndrome for byte 2. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND2 bit field.	
15 (R/NW)	BEN1	Byte 1 Enabled. The CANFD_ERR_RSYN.BEN1 bit indicates if byte 1 was read. If the CANFD_ERR_RSYN.BEN1 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
12:8 (R/NW)	SYND1	Byte 1 Error Syndrome. The CANFD_ERR_RSYN.SYND1 bit field contains the error syndrome for byte 1. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND1 bit field.	
7 (R/NW)	BEN0	Byte 0 Enabled. The CANFD_ERR_RSYN.BEN0 bit indicates if byte 2 (least significant) was read. If the CANFD_ERR_RSYN.BEN0 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
4:0 (R/NW)	SYND0	Byte 0 Error Syndrome. The CANFD_ERR_RSYN.SYND0 bit field contains the error syndrome for byte 0 (least significant). The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND0 bit field.	

Receive Mailbox14 Mask Register

The CANFD_RX_14_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_14_MSK register has no effect.

The CANFD_RX_14_MSK register is used to mask the filter fields of message buffer 14.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

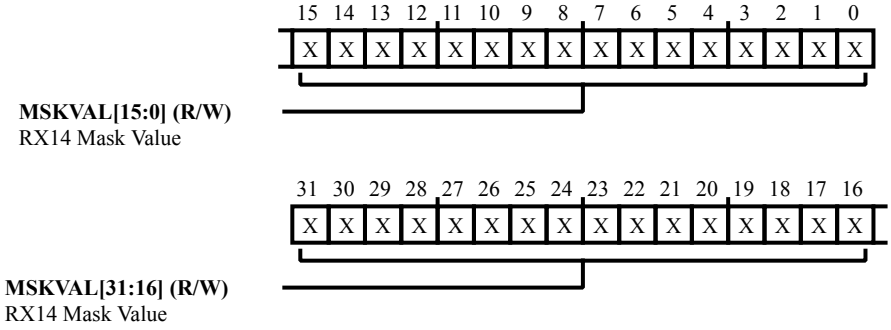

Figure 15-47: CANFD_RX_14_MSK Register Diagram

Table 15-65: CANFD_RX_14_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX14 Mask Value. In the CANFD_RX_14_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 14 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive Mailbox15 Mask Register

The CANFD_RX_15_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_15_MSK register has no effect.

The CANFD_RX_15_MSK register is used to mask the filter fields of message buffer 15.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

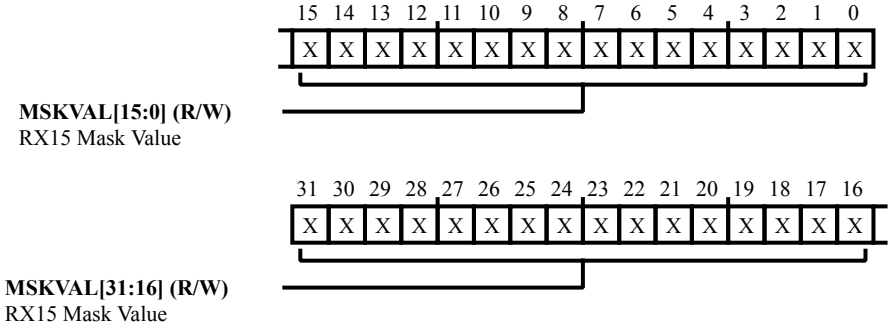

Figure 15-48: CANFD_RX_15_MSK Register Diagram

Table 15-66: CANFD_RX_15_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX15 Mask Value. In the CANFD_RX_15_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 15 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive FIFO Global Mask Register

The CANFD_RX_FIFO_GMSK register is located in RAM.

If the Rx FIFO is enabled, the CANFD_RX_FIFO_GMSK register is used to mask the Rx FIFO ID filter table elements that do not have a corresponding CANFD_RX_IMSK according to the CANFD_CTL2.RFFNUM bit field setting.

The CANFD_RX_FIFO_GMSK register can only be written in freeze mode as it is blocked by hardware in other modes.

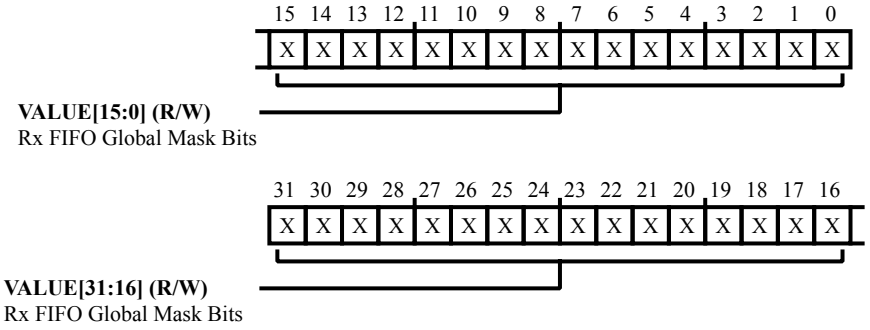

Figure 15-49: CANFD_RX_FIFO_GMSK Register Diagram

Table 15-67: CANFD_RX_FIFO_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Rx FIFO Global Mask Bits. The CANFD_RX_FIFO_GMSK.VALUE bits mask the ID filter table elements bits in a perfect alignment. If the CANFD_RX_FIFO_GMSK.VALUE bit is set, the corresponding bit in the filter is checked. If it is clear, the corresponding bit in the filter is a dont care. See the Identifier Acceptance Filter Fields for Global Mask Bits table in the CANFD chapter.

Receive FIFO Information Register

The CANFD_RX_FIFO register provides information on the Rx FIFO.

The CANFD_RX_FIFO register is the port through which the processor accesses the output of the RXFIR FIFO located in RAM. The CANFD_RX_FIFO register is written by the CANFD module whenever a new message is moved into the Rx FIFO and the register output is updated whenever the output of the Rx FIFO is updated with the next message.

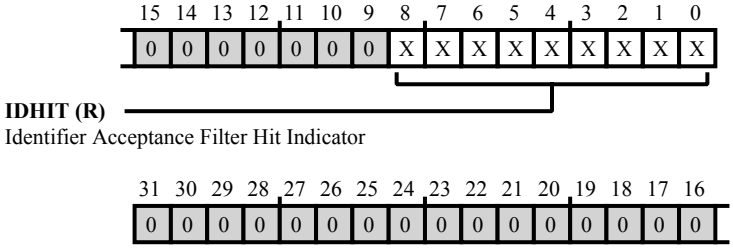

Figure 15-50: CANFD_RX_FIFO Register Diagram

Table 15-68: CANFD_RX_FIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	IDHIT	Identifier Acceptance Filter Hit Indicator. The CANFD_RX_FIFO.IDHIT bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. The CANFD_RX_FIFO.IDHIT bit field is valid only while the CANFD_IFLG1.MB05 bit is set.

Receive Individual Mask Register

The CANFD_RX_IMSK[n] registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CANFD_CFG.RFEN is disabled), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CANFD_CFG.RFEN is enabled), an individual mask is provided for each Rx FIFO ID Filter table element on a one-to-one correspondence depending on the setting of the CANFD_CTL2.RFFNUM bit.

The CANFD_RX_IMSK0 register stores the individual mask associated with either MB0 or ID Filter Table Element 0, CANFD_RX_IMSK1 stores the individual mask associated with either MB1 or ID Filter Table Element 1, and so on.

The CANFD_RX_IMSK[n] registers are only be accessed by the processor while the CANFD is in freeze mode and are otherwise blocked by hardware.

The CANFD_RX_IMSK[n] registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

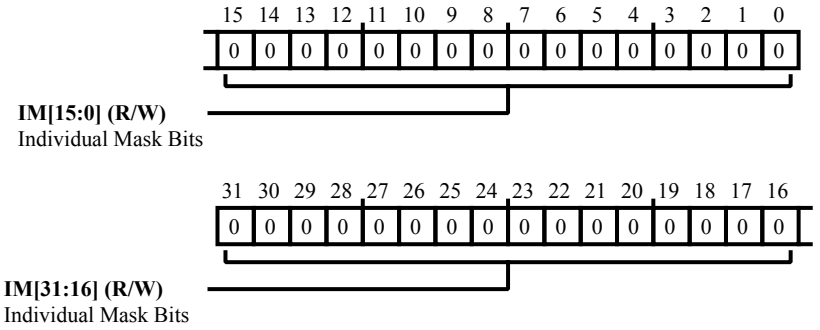

Figure 15-51: CANFD_RX_IMSK[n] Register Diagram

Table 15-69: CANFD_RX_IMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	IM	Individual Mask Bits. The CANFD_RX_IMSK[n].IM bits masks the corresponding bit in both the mailbox filter and Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the CANFD_RX_MB_GMSK register description. For Rx FIFO ID filter table elements, see the CANFD_RX_FIFO_GMSK register description. If a bit in the CANFD_RX_IMSK[n].IM field is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a don't care.

Receive Mailbox Global Mask Register

The CANFD_RX_MB_GMSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is disabled, the CANFD_RX_MB_GMSK register is always in effect (the bits in the MG field will mask the mailbox filter bits).

When the CANFD_CFG.IRMQEN bit is enabled, the CANFD_RX_MB_GMSK register has no effect (the bits in the MG field will not mask the mailbox filter bits).

The CANFD_RX_MB_GMSK register is used to mask the filter fields of all Rx MBs, excluding MBs 14–15, which have individual mask registers.

The CANFD_RX_MB_GMSK register can only be written in freeze mode and is blocked by hardware in other modes.

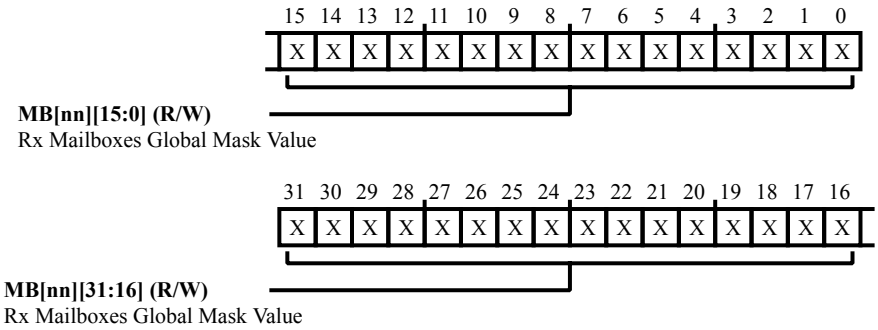

Figure 15-52: CANFD_RX_MB_GMSK Register Diagram

Table 15-70: CANFD_RX_MB_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	MB[nn]	Rx Mailboxes Global Mask Value. For all CANFD_RX_MB_GMSK.MB[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running. The bits in the CANFD_RX_MB_GMSK.MB[nn] bit field mask the mailbox filter bits. If a bit in the field is a zero, the corresponding bit in the filter is a don't care. If the bit is a one, the corresponding bit in the filter is checked. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant bits affect the fields RTR and IDE, which are located in the control and status (C/S) word of the mailbox. For more details on this bit field, see the Mailbox Global Filter Field Mask table in the CANFD chapter.	
		0	Don't Care
		1	Checked

Free Running Timer Register

The CANFD_TMR register is a 16-bit free running counter. The timer starts from 0x0 after reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, the timer increments by one for each bit that is received or transmitted. When there is no message on the bus, the timer counts using the previously programmed baud rate. The timer is not incremented during module disable, doze, stop, pretended networking, and freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after the successful reception or transmission of a message.

If the CANFD_CTL1.TSYNEN bit is enabled, the timer is reset whenever a message is received in the first available mailbox, according to the CANFD_CTL2.RFFNUM setting.

The processor can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure.

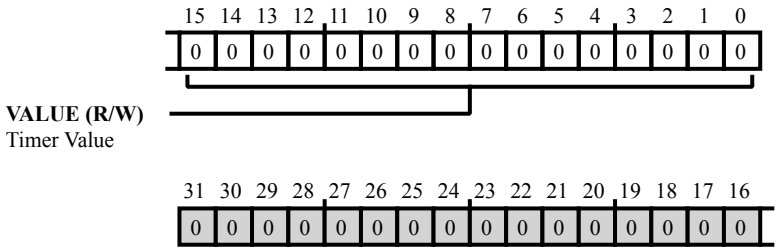

Figure 15-53: CANFD_TMR Register Diagram

Table 15-71: CANFD_TMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Timer Value. The CANFD_TMR.VALUE bit field contains the free-running counter value.

Wakeup Message Buffer Data 4-7 Register

The CANFD_WMB[n]_DATA_HI registers are the wakeup message buffer data 4-7 registers. Each of the four wake up message buffers contains a register to store the data bytes 4 to 7 of the payload information of an incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB4C for WMB0, 0xB5C for WMB1, 0xB6C for WMB2, and 0xB7C for WMB3.

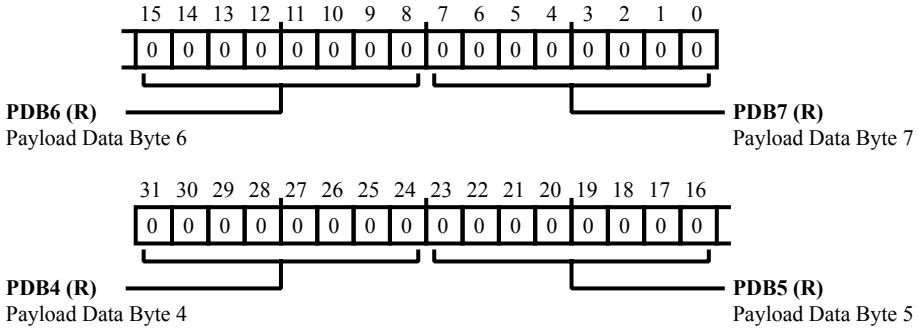

Figure 15-54: CANFD_WMB[n]_DATA_HI Register Diagram

Table 15-72: CANFD_WMB[n]_DATA_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB4	Payload Data Byte 4. The CANFD_WMB[n]_DATA_HI.PDB4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB5	Payload Data Byte 5. The CANFD_WMB[n]_DATA_HI.PDB5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB6	Payload Data Byte 6. The CANFD_WMB[n]_DATA_HI.PDB6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB7	Payload Data Byte 7. The CANFD_WMB[n]_DATA_HI.PDB7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Wakeup Message Buffer Data 0-3 Register

The CANFD_WMB[n]_DATA_LO registers are the wakeup message buffer data 0-3 registers. Each of the four wake up message buffers contains a register to store the data bytes 0 to 3 of the payload information of an incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB48 for WMB0, 0xB58 for WMB1, 0xB68 for WMB2, and 0xB78 for WMB3.

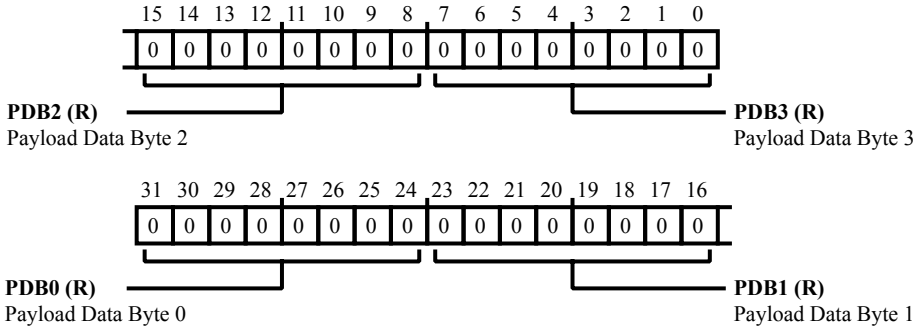

Figure 15-55: CANFD_WMB[n]_DATA_LO Register Diagram

Table 15-73: CANFD_WMB[n]_DATA_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB0	Payload Data Byte 0. The CANFD_WMB[n]_DATA_LO.PDB0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB1	Payload Data Byte 1. The CANFD_WMB[n]_DATA_LO.PDB1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB2	Payload Data Byte 2. The CANFD_WMB[n]_DATA_LO.PDB2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB3	Payload Data Byte 3. The CANFD_WMB[n]_DATA_LO.PDB3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Wakeup Message ID Buffer Register

The CANFD_WMB[n]_ID registers are the wakeup message ID buffers. Each of the four wake up message buffers contains a register to store the ID information of an incoming Rx message.

Note that the ID registers are located at 0xB44 for WMB0, 0xB54 for WMB1, 0xB64 for WMB2, and 0xB74 for WMB3.

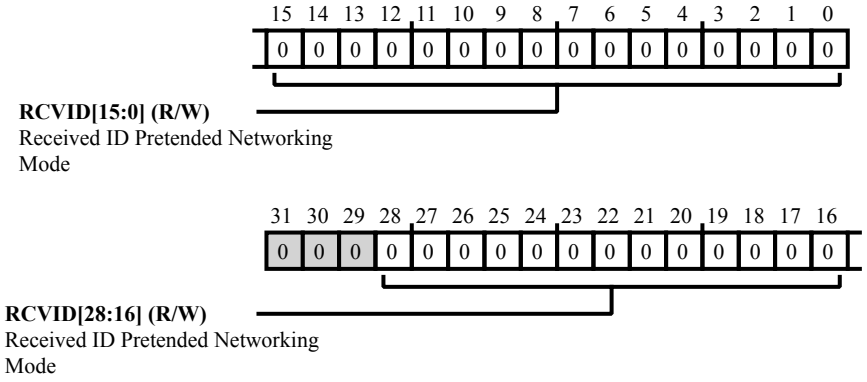

Figure 15-56: CANFD_WMB[n]_ID Register Diagram

Table 15-74: CANFD_WMB[n]_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	RCVID	Received ID Pretended Networking Mode. The CANFD_WMB[n]_ID.RCVID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only. In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Wakeup Message Buffer Control/Status Register

The CANFD_WMB[n]_STAT registers are the for wakeup message buffer control and status information. Each of the four wake up message buffers contains a register to store the control status information (IDE, RTR and DLC fields) of an incoming Rx message.

Note that the control status registers are located at 0xB40 for WMB0, 0xB50 for WMB1, 0xB60 for WMB2, and 0xB70 for WMB3.

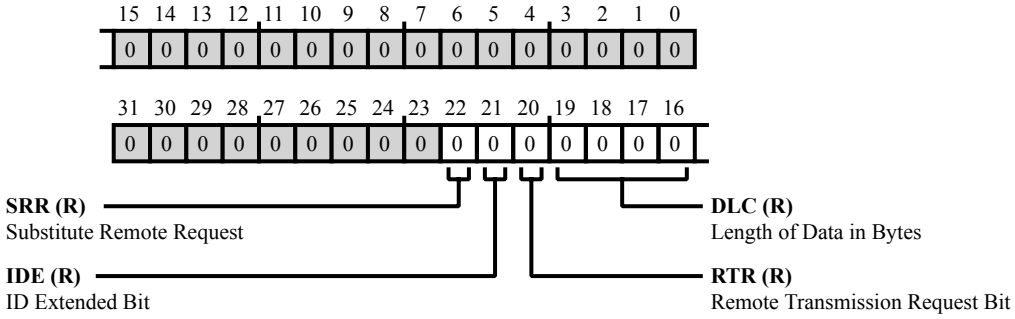

Figure 15-57: CANFD_WMB[n]_STAT Register Diagram

Table 15-75: CANFD_WMB[n]_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB[n]_STAT.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB[n]_STAT.IDE bit identifies is the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request Bit. The CANFD_WMB[n]_STAT.RTR bit identifies if the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data in Bytes. The CANFD_WMB[n]_STAT.DLC bit field represents the length (in bytes) of the Rx data received when the CANFD module is in pretended networking mode. The CANFD_WMB[n]_STAT.DLC bit field is written by the CANFD module, copied from the data length code (DLC) field of the received frame. The DLC field indicates which data bytes are valid.	

Pretended Networking Wakeup Match Register

The CANFD_WUM register contains wake up information related to the matching processes performed while the CANFD module receives frames under pretended networking mode.

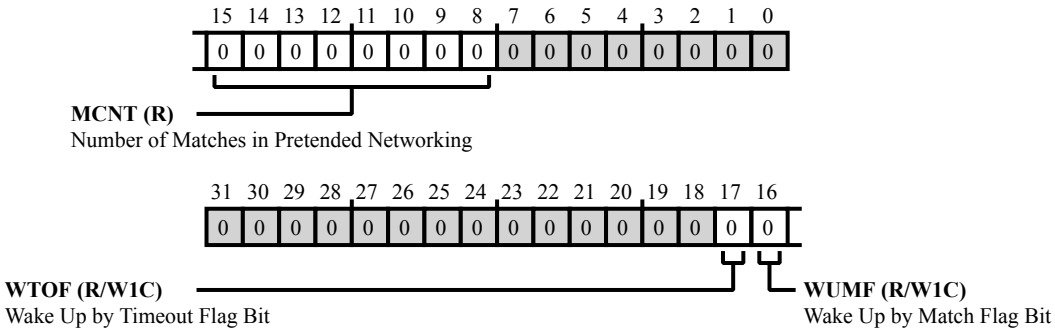

Figure 15-58: CANFD_WUM Register Diagram

Table 15-76: CANFD_WUM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	WTOF	Wake Up by Timeout Flag Bit. The CANFD_WUM.WTOF bit indicates if the CANFD module detects a timeout event during a time interval defined by the CANFD_PN_CTL2.MATCHTO bit field. WTOF generates a wakeup event if the CANFD_PN_CTL1.WTOFMSK enabled.	
		0	No event detected
		1	Wakeup event detected
16 (R/W1C)	WUMF	Wake Up by Match Flag Bit. The CANFD_WUM.WUMF bit indicates whether the CANFD module detects a matching Rx incoming message passing the filtering criteria specified in the CANFD_PN_CTL1 register. WUMF generates a wakeup event if the CANFD_PN_CTL1.WUMFMSK bit is enabled.	
		0	No event detected
		1	Wakeup event detected
15:8 (R/NW)	MCNT	Number of Matches in Pretended Networking. The CANFD_WUM.MCNT bit field reports the number of times a given message matches the predefined filtering criteria for ID and/or PL before a wake up event. The CANFD_WUM.MCNT bit field is reset by the CANFD module when it enters pretended networking mode. This bit field and is not affected by a soft reset.	

ADSP-2159x_SC591_SC592_SC594 MISCREG Register Descriptions

Misc registers for module are for integration purpose (MISCREG) contains the following registers.

Table 15-77: ADSP-2159x_SC591_SC592_SC594 MISCREG Register List

Name	Description
MISCREG_CAN_SYSCTL	
MISCREG_PFB_L2CC_EXCL_CTL	
MISCREG_PLL2_CONTROL	
MISCREG_SH0_PFB_RANGE_SELECT	Prefetch Range Selection Register
MISCREG_SH1_PFB_RANGE_SELECT	Prefetch Range Selection Register
MISCREG_SHARC_BRIDGE_REMAP	

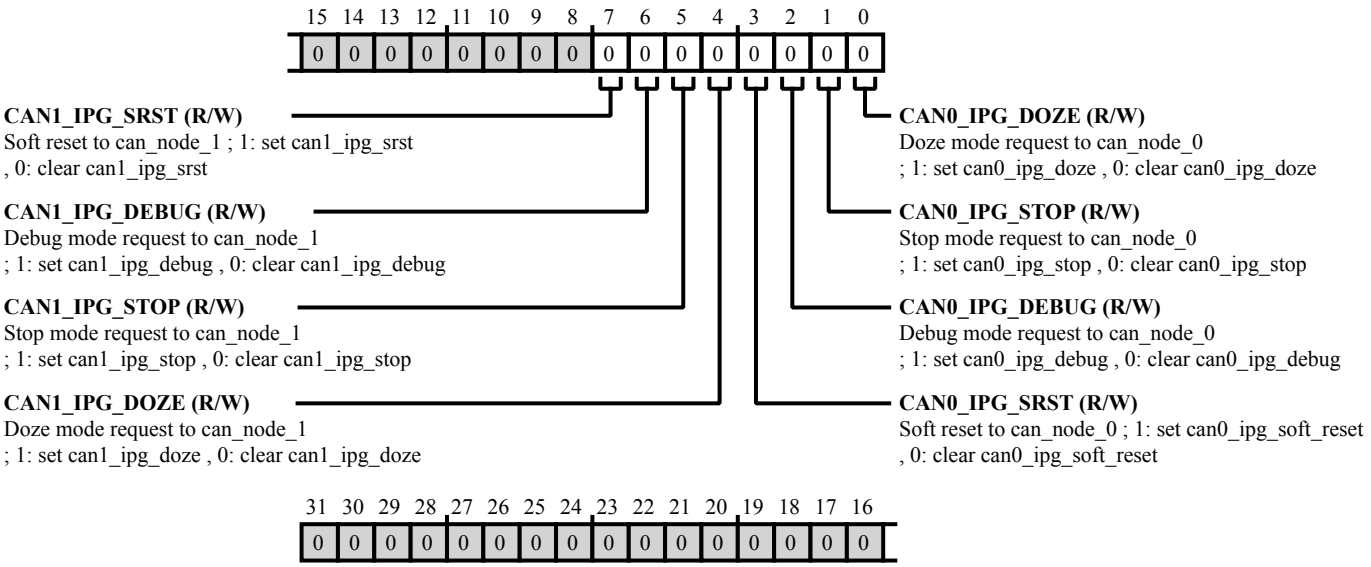

Figure 15-59: MISCREG_CAN_SYSCTL Register Diagram

Table 15-78: MISCREG_CAN_SYSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W)	CAN1_IPG_SRST	Soft reset to can_node_1 ; 1: set can1_ipg_srst , 0: clear can1_ipg_srst. Soft reset to can_node_1 ; 1: set can1_ipg_srst , 0: clear can1_ipg_srst
6 (R/W)	CAN1_IPG_DEBUG	Debug mode request to can_node_1 ; 1: set can1_ipg_debug , 0: clear can1_ipg_debug. Debug mode request to can_node_1 ; 1: set can1_ipg_debug , 0: clear can1_ipg_debug
5 (R/W)	CAN1_IPG_STOP	Stop mode request to can_node_1 ; 1: set can1_ipg_stop , 0: clear can1_ipg_stop. Stop mode request to can_node_1 ; 1: set can1_ipg_stop , 0: clear can1_ipg_stop
4 (R/W)	CAN1_IPG_DOZE	Doze mode request to can_node_1 ; 1: set can1_ipg_doze , 0: clear can1_ipg_doze. Doze mode request to can_node_1 ; 1: set can1_ipg_doze , 0: clear can1_ipg_doze
3 (R/W)	CAN0_IPG_SRST	Soft reset to can_node_0 ; 1: set can0_ipg_soft_reset , 0: clear can0_ipg_soft_reset. Soft reset to can_node_0 ; 1: set can0_ipg_soft_reset , 0: clear can0_ipg_soft_reset
2 (R/W)	CAN0_IPG_DEBUG	Debug mode request to can_node_0 ; 1: set can0_ipg_debug , 0: clear can0_ipg_debug. Debug mode request to can_node_0 ; 1: set can0_ipg_debug , 0: clear can0_ipg_debug
1 (R/W)	CAN0_IPG_STOP	Stop mode request to can_node_0 ; 1: set can0_ipg_stop , 0: clear can0_ipg_stop. Stop mode request to can_node_0 ; 1: set can0_ipg_stop , 0: clear can0_ipg_stop

Table 15-78: MISCREG_CAN_SYSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	CAN0_IPG_DOZE	Doze mode request to can_node_0 ; 1: set can0_ipg_doze , 0: clear can0_ipg_doze. Doze mode request to can_node_0 ; 1: set can0_ipg_doze , 0: clear can0_ipg_doze

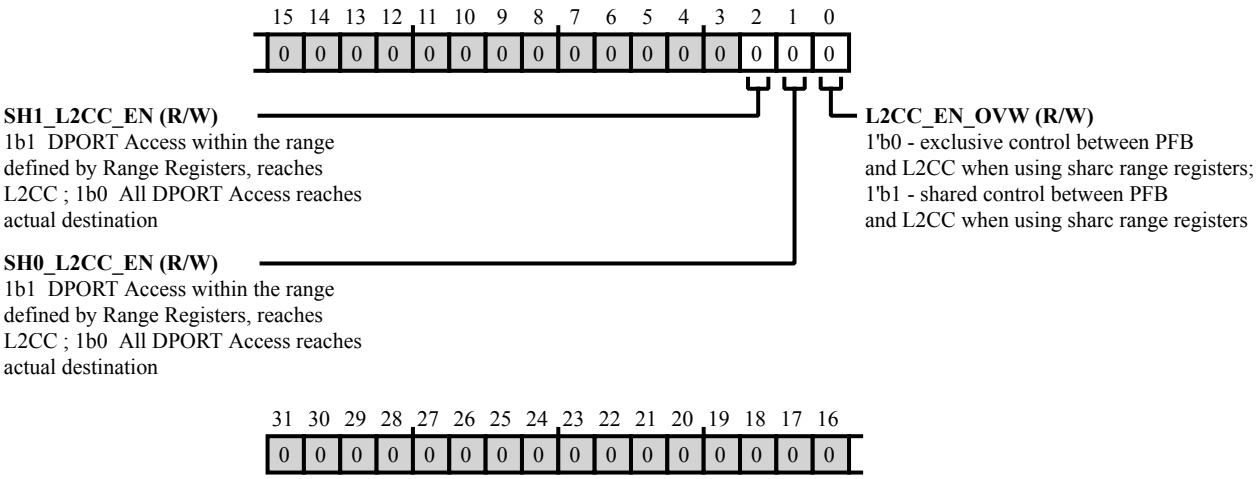

Figure 15-60: MISCREG_PFB_L2CC_EXCL_CTL Register Diagram

Table 15-79: MISCREG_PFB_L2CC_EXCL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	SH1_L2CC_EN	1b1 DPORT Access within the range defined by Range Registers, reaches L2CC ; 1b0 All DPORT Access reaches actual destination.
1 (R/W)	SH0_L2CC_EN	1b1 DPORT Access within the range defined by Range Registers, reaches L2CC ; 1b0 All DPORT Access reaches actual destination.
0 (R/W)	L2CC_EN_OVW	1'b0 - exclusive control between PFB and L2CC when using sharc range registers; 1'b1 - shared control between PFB and L2CC when using sharc range registers.

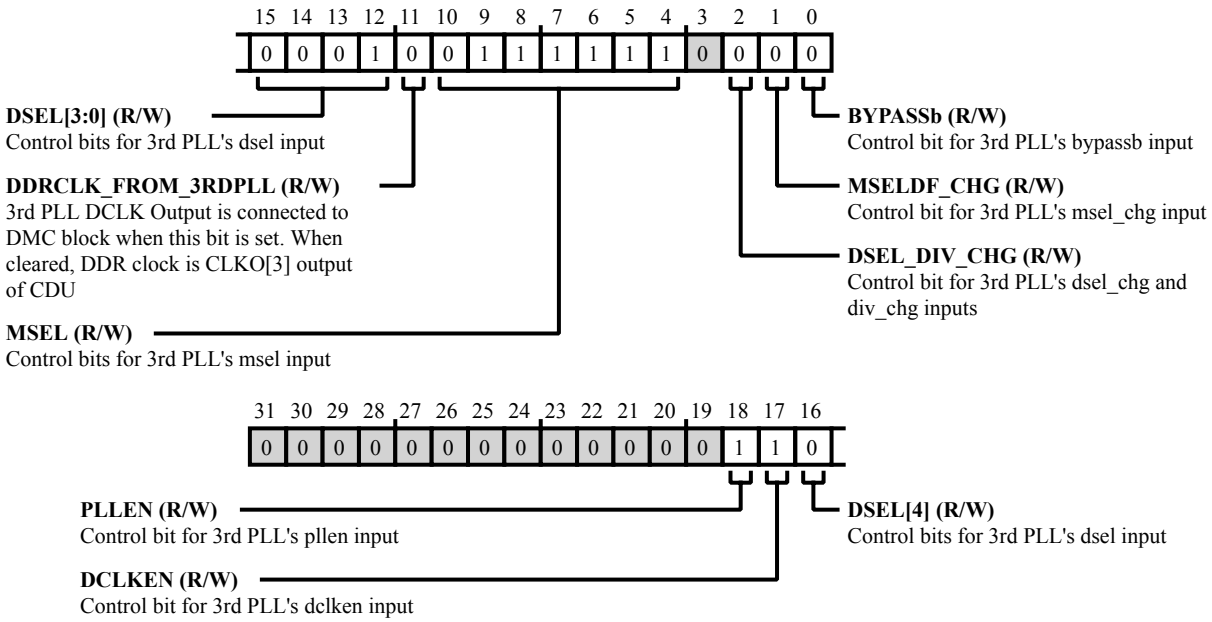

Figure 15-61: MISCREG_PLL2_CONTROL Register Diagram

Table 15-80: MISCREG_PLL2_CONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	PLLEN	Control bit for 3rd PLL's pllen input. Internal signal from Dynamic Power Management Unit (DPM) which enables/disables the PLL system (e.g. in Active mode, during BYPASS.)
17 (R/W)	DCLKEN	Control bit for 3rd PLL's dclken input. Enables DCLK clock buffer
16:12 (R/W)	DSEL	Control bits for 3rd PLL's dsel input. Selects DCLK divide ratio
11 (R/W)	DDRCLK_FROM_3RDPLL	3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU. 3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU
10:4 (R/W)	MSEL	Control bits for 3rd PLL's msel input. The `MISCREG_PLL2_CONTROL.MSEL` selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL * 2 Where the value of MSEL is between 1 and 127.

Table 15-80: MISCREG_PLL2_CONTROL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	DSEL_DIV_CHG	Control bit for 3rd PLL's dsel_chg and div_chg inputs. Signal from PCU indicating a DDR clock frequency change
1 (R/W)	MSELDF_CHG	Control bit for 3rd PLL's msel_chg input. Signal from PLL Control Unit indicating a frequency change resulting from a change in either the DF or MSEL bits.
0 (R/W)	BYPASSB	Control bit for 3rd PLL's bypassb input. Active-low control bit to bypass the PLL which forces CLKIN on all output clocks

Prefetch Range Selection Register

Prefetching can be disabled for up to sixteen address ranges by setting the appropriate bit in the MISCREG_SH0_PFB_RANGE_SELECT register. The MISCREG_SH0_PFB_RANGE_SELECT[31:16] bits control the range selection for the instruction cache, and MISCREG_SH0_PFB_RANGE_SELECT[15:0] bits control the range selection for the data cache.

16 Watchdog Timer (WDOG)

The processor has a 32-bit watchdog timer that can be used to verify system reliability by generating an event to the processor core when the watchdog expires before software updates it.

WDOG Features

The watchdog timer has the following features:

- Programmable 32-bit watchdog count value
- 8-bit disable bit pattern
- General-purpose core event generation

The watchdog timer can supervise system software stability by periodically reloading it to prevent expiration of the downward-counting timer (such that the count never becomes 0). When used in this fashion, an expiring timer can indicate the system software is not running normally.

Expiration of the WDOG counter generates a general-purpose interrupt, which can be used in a variety of ways:

- as an interrupt vector sent through the System Event Controller (SEC) to the core to be serviced by a handler function, providing full software control of device resources (for example, GPIO management and reset control).
- as a fault condition through the SEC to provide hardware-automated:
    - signalling of the fault condition on external pins to the system,
    - system reset requests to the Reset Control Unit (RCU), and/or
    - trigger outputs (SEC0_FAULT trigger requester) through the Trigger Routing Unit (TRU) to initiate activities in a variety of potential trigger completers (for example, GPIO control).

To facilitate debugging, the watchdog timer does not decrement (even if enabled) when the processor is in emulation mode.

WDOG Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK0_0 cycle. If it reaches zero, the watchdog expiration event is generated, which can be used in many ways.

To start the watchdog timer:

1. Program the watchdog timeout period (in SCLK0_0 cycles) in the WDOG_CNT register. With the watchdog disabled, this write also preloads the WDOG_STAT register.
2. Enable the watchdog timer by writing any value other than 0xAD to the WDOG_CTL.WDEN field.

Once the watchdog is enabled, writes to the WDOG_CNT register are ignored. The counter begins decrementing, and the current counter value can be read from the 32-bit WDOG_STAT register at any time.

To prevent the counter from expiring, software must "kick" the watchdog by writing any value to the WDOG_STAT register while the current count is non-zero. While the value written is irrelevant and ignored, this action resets the current counter in the WDOG_STAT register to the programmed WDOG_CNT value, and decrementing continues. The internal counter continues decrementing until it reaches zero, at which point the expiration event is generated, and the WDOG_CTL.WDRO rollover bit is set.

Watchdog operation continues in this manner unless disabled by explicitly writing 0xAD to the WDOG_CTL.WDEN field.

The watchdog expiration event can be used in a variety of ways, as listed below.

- The watchdog expiration event itself is one of numerous interrupt sources that is managed by the System Event Controller. Like other peripheral sources, this event can be used to cause a vector to a handler function that executes based on interrupt priority.
- The watchdog expiration event can be used to initiate automated hardware response through the SEC Fault Interface (SFI).

For this, the WDOG expiry has to be configured as the fault source in the SEC. Then the response to the WDOG expiry can be set to any of the below:

- Signalling through the external fault pin.
- System reset
- Trigger outputs to numerous potential trigger completers.

For further details on how watchdog expiration event can be used with the SFI, see Configuring the WDOG Expiry Event to Issue a System Reset.

ADSP-2159x_SC591_SC592_SC594 WDOG Register List

The Watchdog Timer unit (WDOG) provides a software-based watchdog timer that can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. A set of registers governs WDOG operations. For more information on WDOG functionality, see the WDOG register descriptions.

WDOG Block Diagram

The ***Watchdog Timer Block Diagram*** figure shows the detailed block diagram for the watchdog timer.

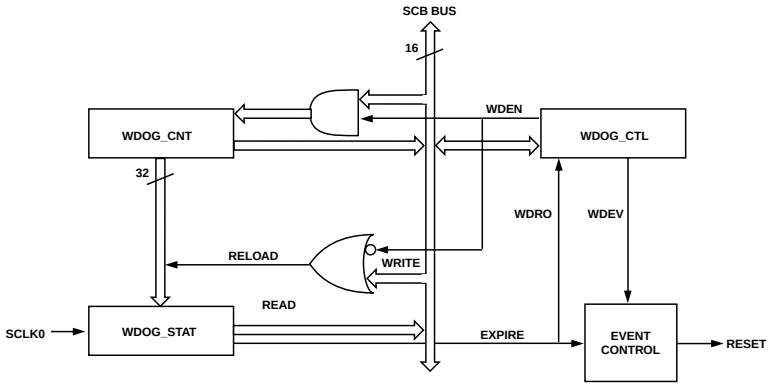

Figure 16-1: Watchdog Timer Block Diagram

Internal Interface

The system clock (SCLK0) clocks the watchdog timer. The registers are accessed through the 16-bit peripheral MMR access bus. 32-bit read/write operations always access the 32-bit `WDOG_CNT` and `WDOG_STAT` registers. Hardware ensures that those accesses are atomic. When the counter expires, the WDOG expiration event is generated.

External Interface

The watchdog timer does not directly interact with any external pins.

ADSP-2159x_SC591_SC592_SC594 WDOG Register Descriptions

Watchdog Timer Unit (WDOG) contains the following registers.

Table 16-5: ADSP-2159x_SC591_SC592_SC594 WDOG Register List

Name	Description
`WDOG_CNT`	Count Register
`WDOG_CTL`	Control Register
`WDOG_STAT`	Watchdog Timer Status Register
`WDOG_WIN`	Watchdog Timer Window Register

Count Register

The WDOG_CNT register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the WDOG_CNT register can be updated only when the WDOG timer is disabled. A write to the WDOG_CNT register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

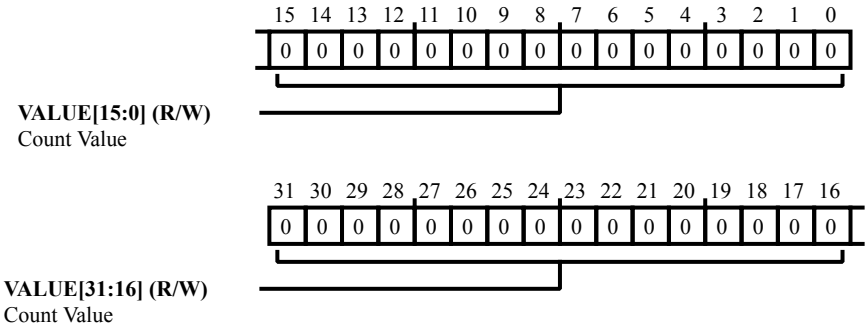

Figure 16-2: WDOG_CNT Register Diagram

Table 16-6: WDOG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Count Value. The WDOG_CNT.VALUE bit field holds the programmable, unsigned count value.

Control Register

The WDOG_CTL register controls the watchdog timer. This register supports enabling/disabling the watchdog timer and supports checking the timer rollover status. Note that when the processor is in emulation mode, the watchdog timer counter will not decrement even if it is enabled.

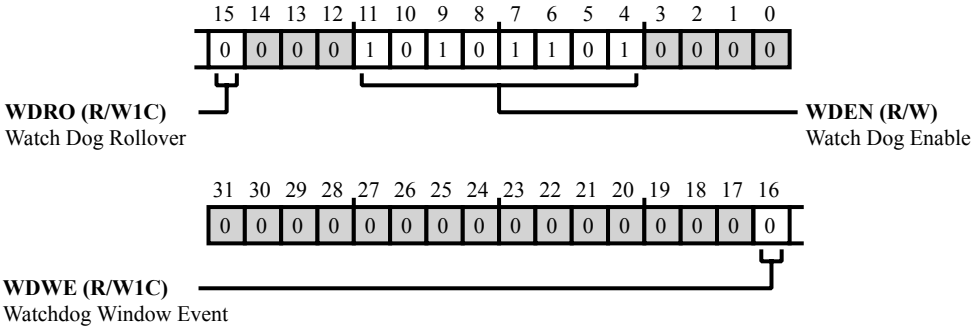

Figure 16-3: WDOG_CTL Register Diagram

Table 16-7: WDOG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	WDWE	Watchdog Window Event. Software can determine whether the timer has been serviced unexpectedly early by interrogating the WDOG_CTL.WDWE status bit. This is a sticky bit that is set whenever the watchdog is serviced and the WDOG_STAT value is greater than the WDOG_WIN value. It is cleared only by disabling the watchdog timer and by writing a 1 to the bit.	
		0	Window Event has not occurred
		1	Window Event has occurred
15 (R/W1C)	WDRO	Watch Dog Rollover. Software can determine whether the timer has rolled over by interrogating the WDOG_CTL.WDRO status bit. This is a sticky bit that is set whenever the watch dog timer count reaches 0 and cleared only by disabling the watch dog timer and then writing a 1 to the bit.	
		0	WDT Has Not Expired
		1	WDT Has Expired
11:4 (R/W)	WDEN	Watch Dog Enable. The WDOG_CTL.WDEN field is used to enable and disable the watchdog timer. Writing any value other than the disable value into this field enables the watchdog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watchdog timer.	
		173	Counter Disabled. All other values mean that the counter is enabled.

Watchdog Timer Status Register

The WDOG_STAT register contains the current count value of the watchdog timer. Reads of this register return the current count value. When the watchdog timer is enabled, the WDOG_STAT register is decremented by 1 on each SCLK0 cycle. When the count value reaches 0, the watchdog timer stops counting, and the expiry event is generated. The WDOG_STAT register is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in this register but are instead copied from the WDOG_CNT register. This copy process can happen in two ways:

- While the watchdog timer is disabled, writing the WDOG_CNT register pre-loads the WDOG_STAT register.
- While the watchdog timer is enabled, writing the WDOG_STAT register loads it with the value in the WDOG_CNT register.
- While the watchdog timer is disabled, writing to the WDOG_STAT register also reloads it with the value in the WDOG_CNT register.

When the processor executes a write (of an arbitrary value) to the WDOG_STAT register, the value in the WDOG_CNT register is copied into the WDOG_STAT register. Typically, software sets the value of WDOG_CNT at initialization, then periodically writes to the WDOG_STAT register before the watchdog timer expires. This reloads the watchdog timer with the value from WDOG_CNT and prevents generation of the expiry event.

If the program does not reload the counter before SCLK0 x count register cycles, an expiry event is generated, and the WDOG_CTL.WDRO bit is set. When this happens, the counter stops decrementing and remains at zero. If the counter is enabled with a zero loaded to the counter, the WDOG_CTL.WDRO bit is set immediately and the counter remains at zero and does not decrement.

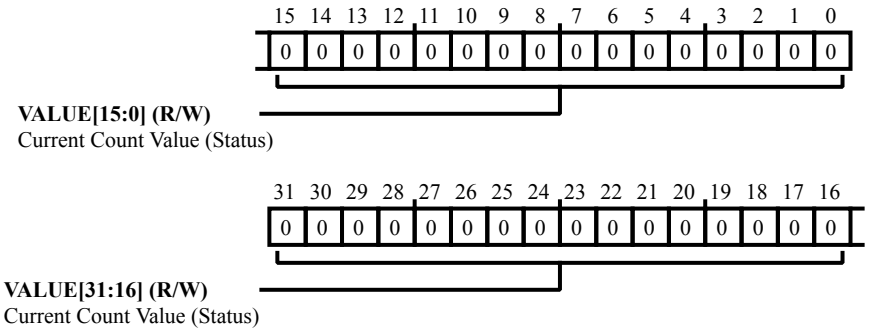

Figure 16-4: WDOG_STAT Register Diagram

Table 16-8: WDOG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Current Count Value (Status). The `WDOG_STAT.VALUE` bit field contains the current count value of the watchdog timer.

Watchdog Timer Window Register

Watchdog window register holds the unsigned window value programmed. The window register can be programmed while the WDOG is disabled; any write to the register when WDOG is enabled doesn't alter the contents of the register. When the WDOG is enabled and the core services the WDOG by doing a write to `WDOG_STAT` register while the `WDOG_STAT` value is greater than `WDOG_WIN`, the WDWE event is generated and also the counter stops decrementing.

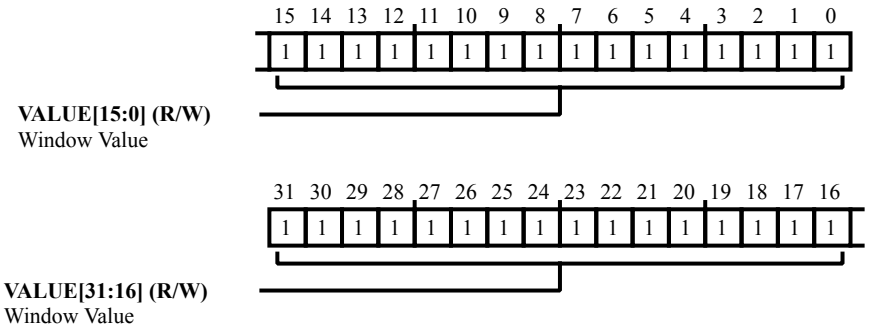

Figure 16-5: WDOG_WIN Register Diagram

Table 16-9: WDOG_WIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Window Value. The `WDOG_WIN.VALUE` bit field contains the unsigned window value.

17 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows various I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The link ports of the processor support 8-bit wide data transfers. The link port pins are multiplexed in the GPIO ports. For information on processor multiplexing, see the data sheet for the specific processor.

Link ports can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors.

NOTE: Reference to CLKO8 in this chapter can be considered as OCLK0_0.

LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with eight data signals (`LP_D0` - `LP_D7`), an acknowledge signal (`LP_ACK`), and a clock signal (`LP_CLK`).
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple processors.
- Pack data into 32-bit words. The processor can directly read this data or transfer it through DMA to or from on-chip memory.
- Support for data buffering through a 2-deep FIFO for transmit and a 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- A dedicated DMA channel.
- Support for data transfer in 2-bit mode (DDR/non-DDR only) and 4-bit mode (DDR/non-DDR)

LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

ADSP-2159x_SC591_SC592_SC594 LP Register List

The Link Port LP is an 8-bit wide parallel port that can connect to another processor's LP or another LP-compatible device. This port allows a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers governs LP operations. For more information on LP functionality, see the LP register descriptions.

Block Diagram

The ***Link Port Block Diagram*** shows the block diagram of a link port.

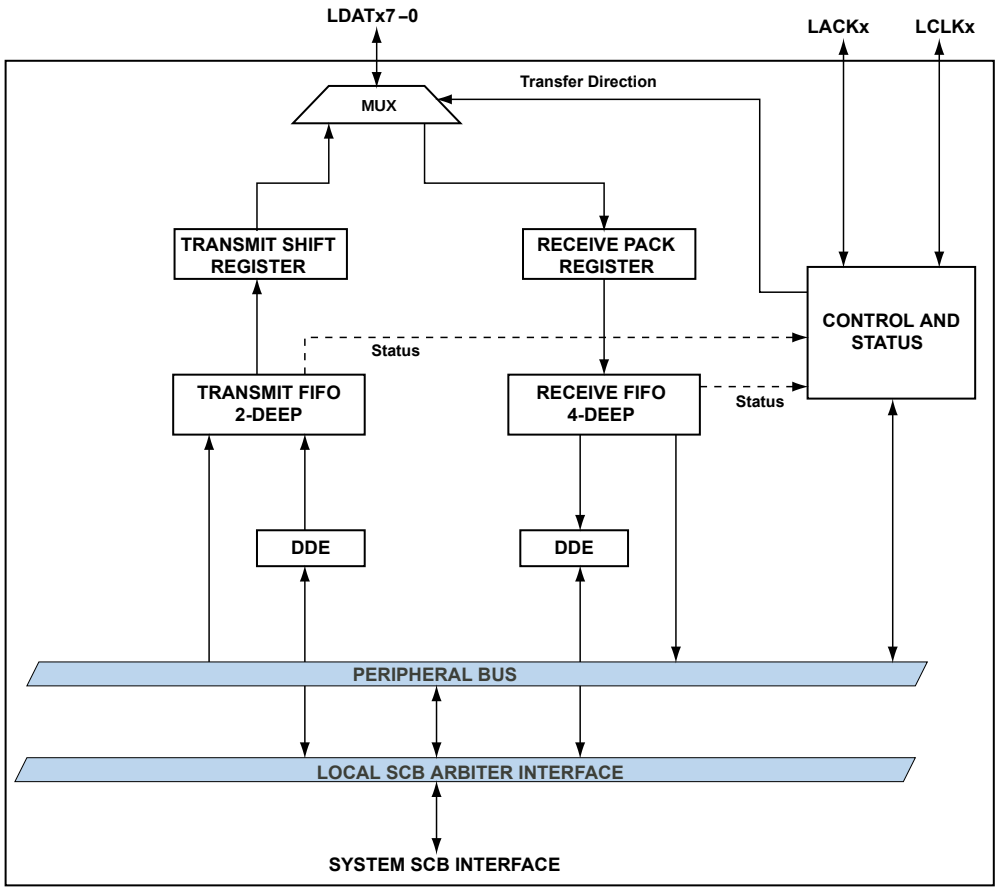

Figure 17-1: Link Port Block Diagram

External Connections

As shown in the ***Link Port Pin Connections*** figure, a link port has eight data lines (LP_D0 – LP_D7), a clock line (LP_CLK), and an acknowledge line (LP_ACK). A link port can act as either a transmitter or a receiver but not both at the same time.

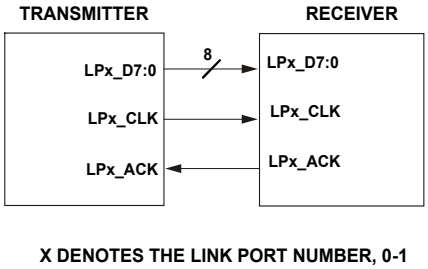

Figure 17-2: Link Port Pin Connections

Use external pull-downs for the LP_CLK and LP_ACK pins so that the link port can enable the transmitter and receiver, irrespective of the state of the other.

Internal Blocks

As shown in the block diagram, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. The core MMR access bus interfaces with these FIFOs. The distributed DMA engines (DDE) use the system cross bar (SCB) interface to access the FIFO. The link port uses the LP_CTL.TRAN bit to determine whether the module is enabled for transmit or receive operation.

Architectural Concepts

The following sections describe the architectural concepts of the link port.

- Link Port Protocol
- FIFO Buffers
- Handshake for Link Port Enable Process
- Clocking
- Multi-Processor Connectivity

Link Port Protocol

A link port transmitted word consists of 4 bytes and the communication proceeds as follows.

1. The transmitter asserts the link port clock (LP_CLK) with each byte of data. The receiver uses the falling edge of LP_CLK driven by the transmitter to latch the byte.
2. When the receiver is ready to accept another word in the receive buffer it asserts the acknowledge signal, LP_ACK.

3. The transmitter samples LP_ACK driven by the receiver at the beginning of each word transmission. If LP_ACK is deasserted, then the transmitter does not transmit the next word.
4. The transmitter leaves LP_CLK high and continues to drive the first byte of the next word until LP_ACK is asserted.
5. When this assertion occurs, the transmitter drives LP_CLK low. The transmission of the next word starts. If the transmit buffer is empty, LP_CLK remains low until the buffer refills, regardless of the state of LP_ACK.

The LP_ACK signal can deassert when it anticipates that the buffer could fill. The receiver reasserts the LP_ACK signal as soon as the internal DMA grant signal has occurred or the core reads the receive buffer. Either of these actions frees a buffer location.

NOTE: The LP_ACK signal inhibits transmission of the next word and not of the current byte.

The LP_ACK signal provides a handshake between the receiver and transmitter in the following configurations.

- When configured as a transmitter, the port drives both the data and the clock while LP_ACK is three-stated. In this mode, LP_CLK is always synchronous with OCLK0_0.
- When configured as a receiver, the link port drives the acknowledge signal and the data and clock lines are three-stated. In this case, the external LP_CLK signal can either be synchronous or asynchronous with OCLK0_0.
- When the link port is disabled, the data, clock, and acknowledge signals are three-stated.

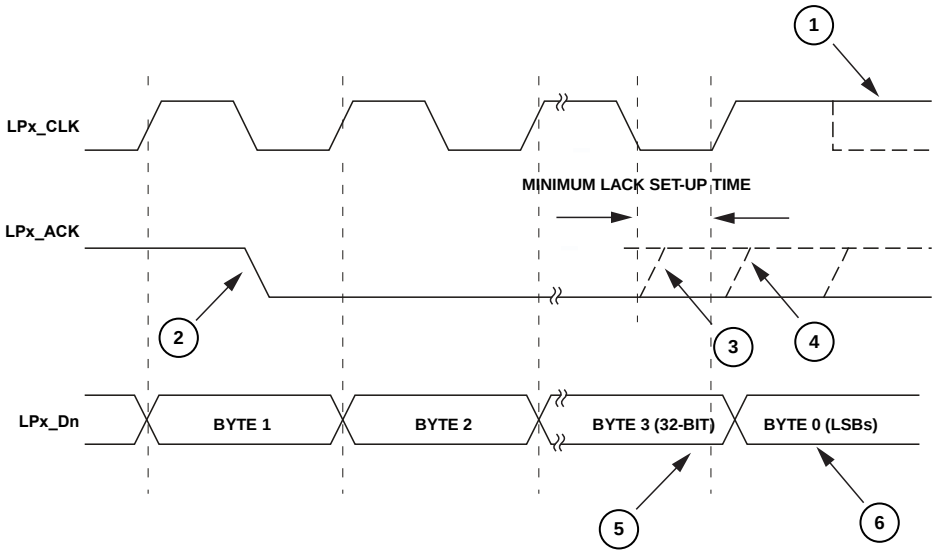

Figure 17-3: Link Port Communication and Handshake Waveform

The following list describes the stages shown in the ***Link Port Communication and Handshake Waveform*** figure.

1. LP_CLK stays high at byte 0 when LP_ACK is sampled low on the previous LP_CLK rising edge. LP_CLK high indicates a stall.
2. The LP_ACK signal can deassert after byte 0.

3. The LP_ACK signal reasserts as soon as the link buffer is not full (depending on Rx FIFO conditions).
4. The transmitter samples LP_ACK to determine whether to transmit the next word.
5. The receiver accepts the remaining word even if LP_ACK is deasserted. The transmitter does not send the following word.
6. Transmission of data for next word is held until LP_ACK is asserted.

The transmitter samples the LP_ACK signal. If the signal is high, the transmitter gives out the falling edges of LP_CLK for data sampling. The LP_ACK signal is first sampled at the rising edge of OCLK0_0. One more OCLK0_0 stage synchronizes the signal further. This synchronized signal is given to the subsequent logic. The LP_CLK falling edge is aligned with OCLK0_0 falling edge in a 1:1 clock ratio mode and with the OCLK0_0 rising edge for the rest of the clock ratios. The following figures explain how the synchronization is maintained between the LP_ACK and LP_CLK signals.

In the following figure, synchronizing time is guaranteed to be 1.5 OCLK0_0 cycles.

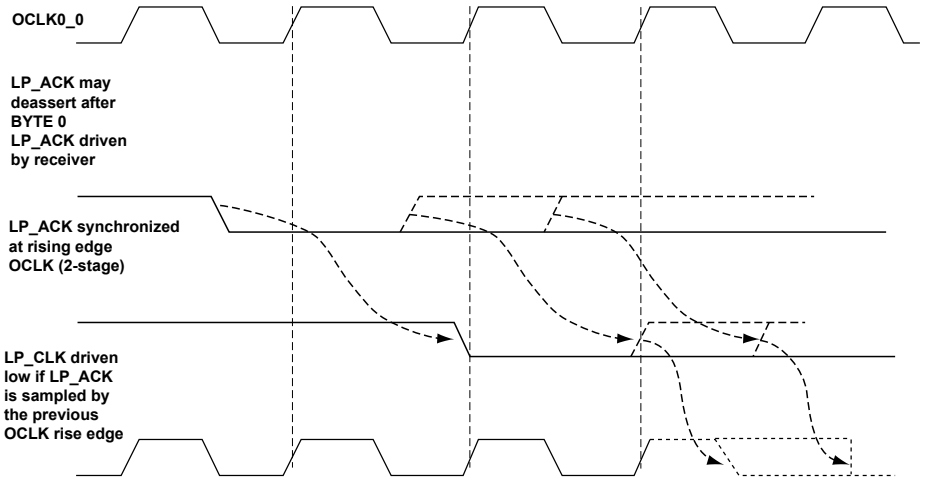

Figure 17-4: LP_ACK Synchronization for OCLK0_0:LP_CLK=1:1

In the following figure, synchronizing time is guaranteed to be 2 OCLK0_0 cycles.

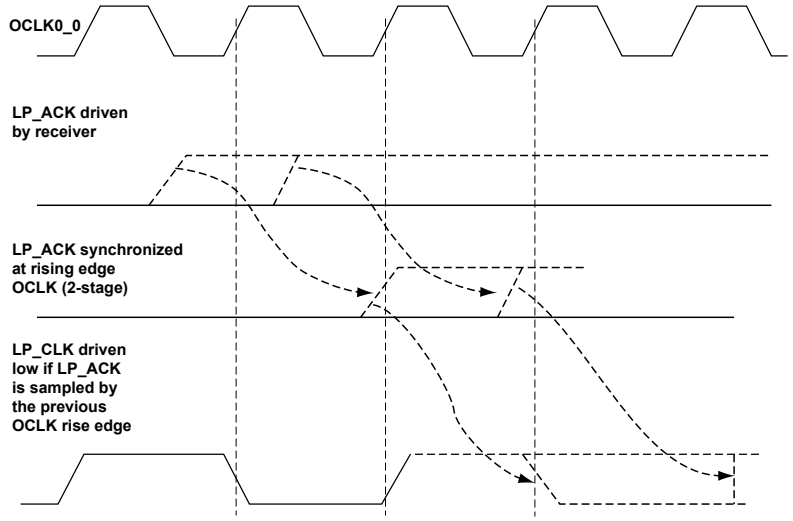

Figure 17-5: LP_ACK Synchronization for OCLK0_0: LP_CLK=1:2, 1:4 and Up

The link port uses the value programmed in the LP_DIV register at the transmitter to determine the frequency of the link port clock (LP_CLK). However, the signal appearing on the LP_CLK pin is also dependent on the status of the LP_ACK pin driven by the receiver. The ***Relationship Between Internal Link Port Clock and Link Port Clock at the Pins*** figure shows this relationship.

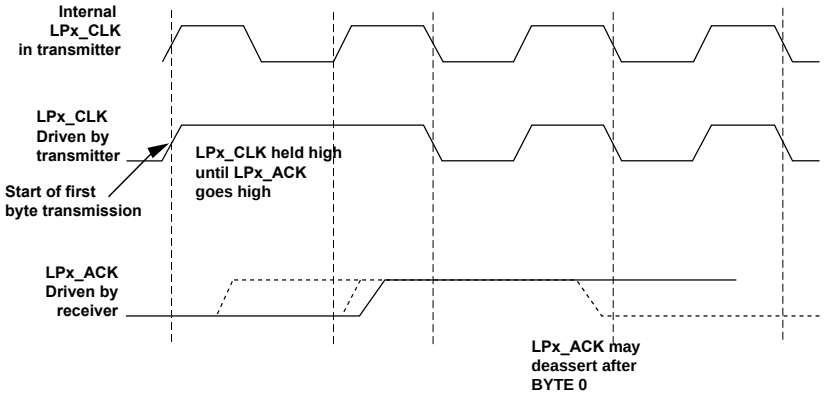

Figure 17-6: Relationship Between Internal Link Port Clock and Link Port Clock at the Pins

FIFO Buffers

When a link port is configured as transmitter, the link port uses a 2-deep FIFO buffer. A shift register unpacks the single 32-bit word to four 8-bit data bytes. As the FIFO has space for more data, the link port makes a new DMA request. If the FIFO becomes empty, the LP_CLK signal is deasserted. The core can access FIFO through the LP_TX register.

The core or DMA makes three writes (2-stage FIFO and 1 shift register) to the transmit buffer before it signals a full condition. The link port uses the LP_STAT.FFST bit field to reflect the status of the FIFO but not the shift register full or empty condition. However, the program can poll the LP_STAT.LPBS bit to discover whether the link

port is driving data from the shift register to the pins. The LP_STAT.LPBS bit is also set when receiver has held off transmission by driving LP_ACK low.

NOTE: When the 2-deep FIFO and the output shift-register overflow, any further write to the link port buffer overwrites the input stage of the FIFO.

NOTE: The core can also read the transmit FIFO through the data LP_TX register.

NOTE: If the transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition is signaled after two writes.

The transmit buffer registers have shadow registers. Using these shadow registers, both stages of the 2-deep FIFO can be read without updating the status registers. The LP_TXIN_SHDW register corresponds to the input stage of the FIFO. The LP_TXOUT_SHDW register corresponds to the output stage of the FIFO as shown in the ***Transmit FIFO path*** figure.

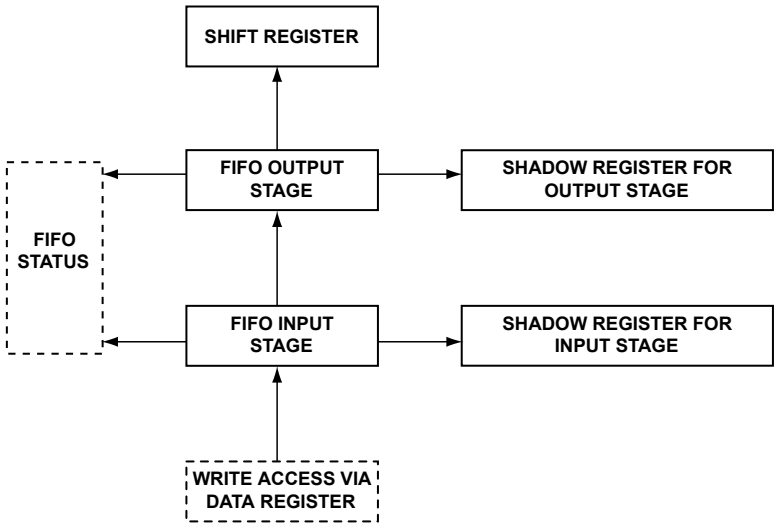

Figure 17-7: Transmit FIFO path

When a link port is configured as receiver, data transfers to the core or DMA from the full 4-deep receive FIFO. An internal packing register packs data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. The link port uses the LP_STAT.FFST bits to reflect the status of the 4-deep read buffer FIFO. The core can access this FIFO through the LP_RX register.

NOTE: When receive FIFO overflows (LP_STAT.ROVF bit=1), any further data from the transmitter is lost. Only the data retained in the receive FIFO can be retrieved further.

The receiver drives the LP_ACK output signal low, after the first byte of data for the next-to-last empty slot (in the 4-deep FIFO) is received. This functionality prevents data loss due to the transmitter starting transmission of the next word before the LP_ACK signal reaches the transmitter. (The timing is due to the larger delay in synchronization.) This functionality guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. The ***LACK Generation Based on Receive FIFO Status*** figure

shows how FIFO slots influence the acknowledge signal generation. The grayed sections show received data. The white sections show empty locations where the decision to pull LP_ACK high is taken.

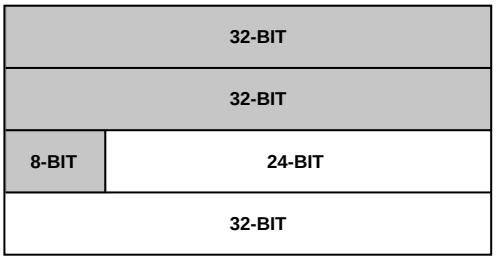

Figure 17-8: LACK Generation Based on Receive FIFO Status

NOTE: The link port uses a 4-deep receive FIFO only under a worst case situation, as mentioned. In all other cases, respond as if the FIFO has only a 3-deep stage. The LP_ACK signal is pulled high before the last stage of the FIFO.

The link port has memory-mapped buffers for both receive and transmit operations. A JTAG-based emulator can read the FIFO which can cause unexpected problems in data transfers. This activity can only happen during an emulation event (typically hitting a breakpoint or single-stepping). The emulator issues core reads through JTAG. To work around this issue, see the tools documentation for more information.

Handshake for Link Port Enable Process

In a link port-based system, the transmitter and the receiver can be enabled at different times. Use external pull-downs for the LP_CLK and LP_ACK signals.

If the receiver is enabled before the transmitter, the external pull-down holds the LP_CLK signal of the transmitter low. The receiver is held off. The receiver can wait for a rising edge on the LP_CLK signal to assert its receive service request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after the application enables it.

If the transmitter is enabled before the receiver, the external pull-down holds the LP_ACK signal of the receiver low. Transmission is held off. Refer to the ***Enable the Transmitter Before the Receiver*** figure. The transmitter can wait for a rising edge on the LP_ACK signal to assert its transmit service request interrupt. This rising edge is asserted as soon as the receiver is enabled after the hardware drives the LP_ACK high.

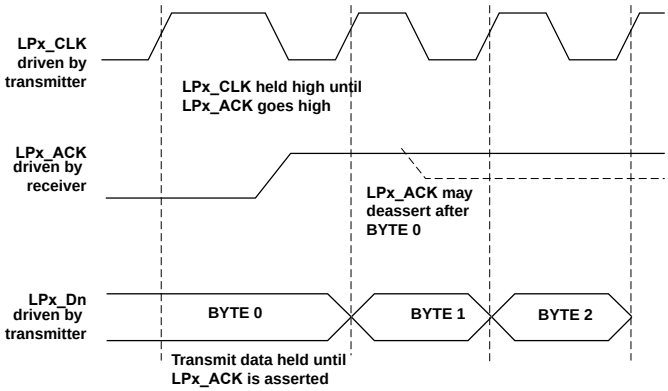

Figure 17-9: Enable the Transmitter Before the Receiver

NOTE: Service request interrupts or status are asserted only when the link port (receiver or transmitter) is disabled.

Clocking

The link port clock (LP_CLK) is derived from the internal system clock (OCLK0_0). The link port clock to system clock ratio can be configured in the LP_DIV register. This value applies to the transmitter only. The receiver can operate at any asynchronous frequency up to the maximum frequency, independent of the ratio programmed. The following formula describes the relationship between the frequency of the link port clock, the OCLK0_0 frequency, and the LP_DIV value.

- $f_{LP\_CLK} = f_{OCLK0\_0}$< or = $f_{LP\_CLK\text{-}MAX}$ if DIV = 0
- $f_{LP\_CLK} = f_{OCLK0\_0}/(2 \times DIV)$ if DIV > 0

Where: f_{LP_CLK} = link clock frequency, $f_{LP\_CLK\text{-}MAX}$ = link clock maximum frequency, and f_{OCLK0_0} = system clock frequency.

While programming the LP_DIV register to select the clock ratio, ensure that the LP_CLK frequency does not exceed the maximum frequency supported for the device. For supported frequencies, see the product-specific data sheet.

NOTE: The Drive Strength (DS) value must be changed to b(010) for the LPCLK pin to operate the link port at the maximum frequency of 125 MHz. Refer the PADS_PORTB0_DS and PADS_PORTC0_DS register bit descriptions for details.

Multi-Processor Connectivity

Link ports can operate independently, allowing glueless connection with external processors. Link ports have dedicated DMA channels, allowing independent data transfers. The following group of figures shows some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

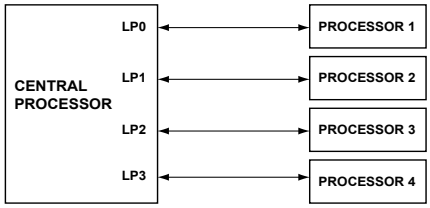

Figure 17-10: Central Processor-Based Model

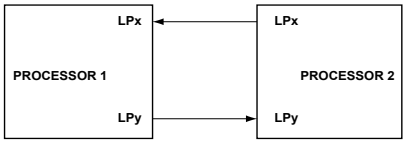

Figure 17-11: Link Port Full-Duplex Transfer Model

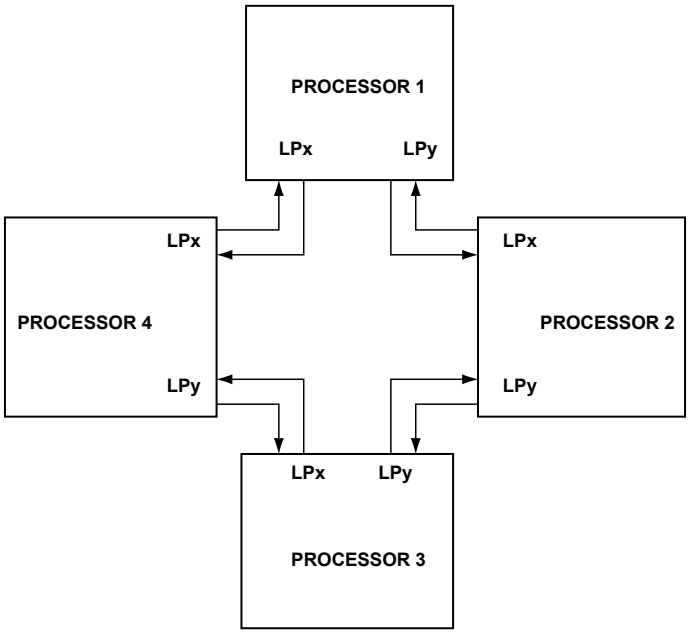

Figure 17-12: Link Port Ring Model

The link port protocol does not include built-in support for multiple requesters. However, there can be situations where multiple devices try to become the bus requester at the same time. Multi-requester conflicts can be resolved using token passing. In token passing, the token is a software flag that passes between processors.

At reset, the token is set to reside in the link port of one device, making it the requester and the transmitter. When a receiver (completer) wants to become the requester, it can assert its `LP_ACK` signal to get the attention of the requester. The requester knows, through the software protocol, whether to respond with actual data or whether the token is requested. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag.

Simultaneously, the completer sets its token and can thereafter transmit. The token release word can be any user-defined value. Because the transmitter and receiver expect a code word, this word does not need to be exclusive of

normal data transmission. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the completer examines the data sent back and if it is the token release word, the completer sets its token, and can thereafter transmit.

The link port protocol includes handshake mechanism to inform the other end of transfer (transmit or receive) of an enable instance. However, it does not support handshakes to inform a disable instance, while a chunk of data transfers. The application must assume the disabled state of the other end, and take appropriate action.

For example, in a multi-processing environment, a receiver did not read its full FIFO for an extended time due to internal bus arbitrations. The transmitter can require software or a peripheral timer-based timeout to inform the application that the LP_ACK signal is low for an extended time period.

LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The following sections explain the data transfer modes, using the core and using DMA.

- Core Data Transfers
- DMA Data Transfers

LP Data Transfer Modes

This section describes link port DMA and core data transfers.

Core Data Transfers

If DMA is disabled for a link port buffer, the processor core can write or read internal FIFO buffers as a memory-mapped register through the MMR access bus. In order to avoid FIFO overflow or underflow, the core can access the FIFO registers in one of the two following ways.

1. Access link port registers using an interrupt service routine (ISR) mapped to the data request interrupt of the link port. The interrupt request remains high only if the FIFO is accessible (if the FIFO is not full in transmit mode and not empty in receive mode).
2. Poll the FIFO status bits of the LP_STAT register. Write to the transmit FIFO if not full or read from the receive FIFO if not empty.

DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA-related activity is explained in the following steps.

1. Data Receive – Once the DMA channel and link port module are configured and enabled, the external device begins writing data to the FIFO through the data pins of the link port. The FIFO detects this activity and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. Data Transmit – Once the DMA channel and link port module are configured and enabled, setting the LP_CTL.EN bit automatically asserts a DMA request when the transmit FIFO is empty. After the request is granted, DMA fills the FIFO. The external device begins reading data from the FIFO through the data pins of

the link port. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

LP Event Control

This section describes how the link port uses interrupts and status signals.

Interrupt Signals

Each link port has two dedicated interrupt lines registered with the system event controller—a data request interrupt and a status interrupt. Data request interrupts are asserted based on FIFO conditions for data transfer. Status interrupts are asserted when a service request status or an overflow status is set. The following list explains each of these interrupts.

- ***Data Request Interrupt.*** Asserted if the FIFO is not full in transmission mode and the FIFO is not empty in reception mode. This functionality serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is based on the `LP_STAT.FFST` (status bit of the link port buffer).
- ***Link Port Transmit Service Request Interrupt (LTRQ)***. Allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, the transmit service request interrupt is enabled by setting the `LP_CTL.TRQMSK` bit. When set, an external receiver can indicate to the disabled transmitter that it must receive data through the connected link port. The receiver does so by driving a high level on the `LP_ACK` line. When the `LP_ACK` of the disabled transmitter link port is detected high, a `LP_STAT.LTRQ` interrupt is generated. The transmitter can enable itself for data transfer with the receiver. The link port needs a pull-down on `LP_ACK` for this feature to function properly.
- ***Link Port Receive Service Request Interrupt (LRRQ)***. When a link port is configured as receiver, this interrupt is enabled by setting the `LP_CTL.RRQMSK` bit. When set, an external transmitter can indicate to the disabled receiver that it must receive data through the connected link port. The transmitter does so by driving out the first data. When the `LP_CLK` of the disabled receiver link port is detected high, a `LP_STAT.LRRQ` interrupt is generated. The receiver can further enable itself for data transfer with the transmitter. The link port needs a pull-down on the `LP_CLK` signal for this feature to function properly.
- ***Link Port Receive Overflow Interrupt (LPOVF)***. Generated when the receiver FIFO overflows and is enabled by setting the `LP_CTL.ROVFMSK` bit. This interrupt can happen if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` signal causing the receive FIFO to overflow.

Enabling Link Port Interrupts

A data request interrupt is fed to the system event controller directly and can be controlled separately from the application.

To mask the interrupt, set the mask bits in `LP_CTL` register corresponding to service interrupts and the overflow interrupt. These interrupts are OR'ed and fed to the SIC as a single `LP_STAT` interrupt. These interrupts are latched and stored in the associated bits of `LP_STAT` register. If an `LP_STAT` interrupt occurs, in the ISR, programs

can read the LP_STAT register bits to determine the type of interrupt. These bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

Status and Error Signals

This section explains the various status signals in the LP_STAT register.

- ***Transfer Status signals***. The link port uses the bus status bit (LP_STAT.LPBS) to give the status of the bus condition (busy or idle), when the link port is configured as transmitter. The LP_STAT.LPBS is high if the link port drives data into the link port pins. Programs can poll this bit after polling the LP_STAT.FFST bit to disable the link port safely.

  The link buffer status (LP_STAT.FFST) field directly indicates the status of the FIFO (including empty or full conditions) during data transfer. Software can poll this field in the LP_STAT register before writing to the FIFO (in case of transmission) or reading from the FIFO (in case of reception). The LP_STAT.FFST bit is automatically cleared when the link port is disabled.

- ***Transfer Request Status signals***. The link port uses the receive request status (LP_STAT.LRRQ) bit to indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter). The link port uses the transmit request status (LP_STAT.LTRQ) bit to indicate that an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll these bits to enable the transmitter or receiver accordingly.

- ***Error Status signals***. In receive mode 32-bit data is received in four chunks of 8-bit data. This data is then packed to a single 32-bit data before loading the FIFO. The link buffer error status (LP_STAT.LPACK) bit is high during this packing process and goes low after packing.

  The link port overflow status (LP_STAT.ROVF) bit is set when the receive FIFO overflows. This event can occur if the transmitter continues to transmit data even though the receiver has deasserted LP_ACK causing the receiver FIFO to overflow.

LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- Setting Up a DMA Transmit Operation
- Setting Up a DMA Receive Operation
- Setting Up a Core Transmit Operation
- Setting Up a Core Receive Operation

Setting Up a DMA Transmit Operation

This following procedure describes the typical steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.

2. Configure the drive strength value to b(010) for the link port clock pins to operate the link port at maximum frequency (PADS_PORTB0_DS and PADS_PORTC0_DS registers).
3. Install interrupt handlers for DMA and for transfer status (service request interrupt).
4. Configure the link port to transmit by setting the LP_CTL bit and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit.
5. Program the link port clock divider by writing a value to the LP_DIV register.
6. If using DMA stop mode or auto buffer mode, program the appropriate DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation and memory read).
7. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
8. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
9. Enable DMA by setting the DMA_CFG.EN bit.
10. Enable the link port by setting the LP_CTL.EN bit.
11. Wait for DMA to assert a transfer completion interrupt.
12. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit.

Setting Up a DMA Receive Operation

This section describes the typical steps for using the link ports in DMA receive mode.

1. Enable the link port pins in GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port for reception (clear the LP_CTL.TRAN bit) and enable the receive request interrupt mask by setting the LP_CTL.RRQMSK bit.
4. If using DMA stop mode or auto buffer mode, program the DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE=1, DMA_CFG.MSIZE=4, interrupt generation and memory write).
5. If using DMA array mode or list mode, create DMA configuration data structures filled with components.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation, memory write and fetch =4/5) and DMA_DSCPTR_NXT register (if list mode). Further, program

DMA configuration register (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, Memory Write and Fetch =4/5) and program the DMA_DSCPTR_NXT register (if list mode).

6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for the receive service request interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
8. Enable DMA by setting the DMA_CFG.EN bit.
9. Enable the link port by setting the LP_CTL.EN bit.
10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit of the DMA status register.

Setting Up a Core Transmit Operation

This section describes the typical steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Configure the drive strength value to b(010) for the link port clock pins to operate the link port at maximum frequency (PADS_PORTB0_DS and PADS_PORTC0_DS registers).
3. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC.
4. Configure the link port for transmission by setting the LP_CTL.TRAN bit) and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit).
5. Program the link port clock divider by writing a value in to the LP_DIV register.
6. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
7. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
8. Enable the link port by setting the LP_CTL.EN bit.
9. The data request interrupt is asserted whenever there is free space in the FIFO. The application can write to the LP_TX register based on the FIFO conditions (half or empty) reflected in the LP_STAT.FFST bit field.

Setting Up a Core Receive Operation

This section describes the typical steps for using the link ports in processor core-based reception.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC).

3. Configure link port for reception (clear LP_CTL.TRAN bit). Enable the receive request interrupt mask bit (set LP_CTL.RRQMSK).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. The application can wait for receive service request interrupt to be asserted.
5. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
6. Enable the link port by setting the LP_CTL.EN bit.
7. The data request interrupt is asserted whenever there is free space in the FIFO. The application can read from the LP_RX register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the LP_STAT.FFST bit field.

ADSP-2159x_SC591_SC592_SC594 LP Register Descriptions

Link Port (LP) contains the following registers.

Table 17-6: ADSP-2159x_SC591_SC592_SC594 LP Register List

Name	Description
LP_CTL	Control Register
LP_DIV	Clock Divider Value Register
LP_RX	Receive Buffer Register
LP_STAT	Status Register
LP_TX	Transmit Buffer Register
LP_TXIN_SHDW	Shadow Input Transmit Buffer Register
LP_TXOUT_SHDW	Shadow Output Transmit Buffer Register

Control Register

The LP_CTL register provides LP interrupt masking, selection of transfer direction, and link port enable.

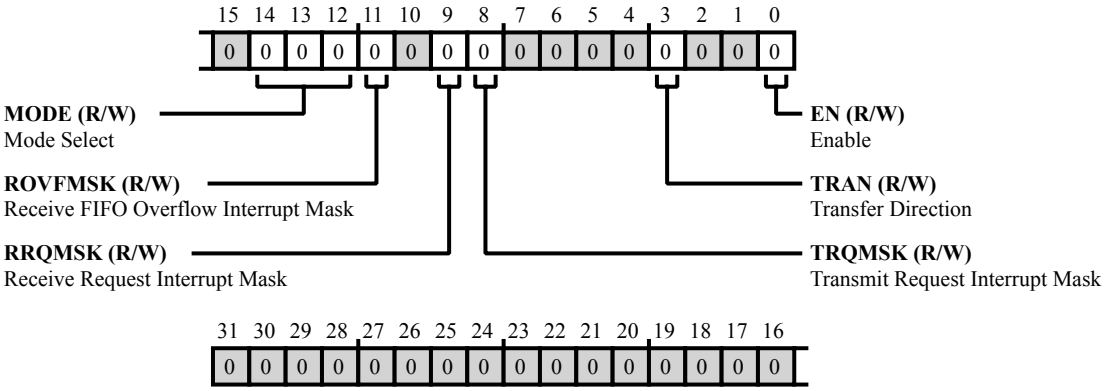

Figure 17-13: LP_CTL Register Diagram

Table 17-7: LP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	MODE	Mode Select. The LP_CTL.MODE field indicates the mode of operation: Single Data Rates (SDR) of 2 bit and 4 bit, Double Data Rates (DDR) of 2 bit, 4 bit, and 8 bit. Note that the LRRQ interrupt is not supported in DDR mode. The LP receiver must be enabled by the user before starting the LP transmitter. For LP DDR mode, the value of LP DDR clock should be twice that of LP clock. CDU CLKO9 is used for the LP DDR clock.	
		0	8 bit SDR The default mode. (D0, D1, D2, D3, D4, D5, D6 and D7 data pins used)
		1	4 bit SDR (D0, D1, D2 and D3 data pins are used)
		2	2 bit SDR (D0 and D1 data pins are used)
		4	Reserved
		5	4 bit DDR (D0, D1, D2 and D3 data pins are used)
		6	2 bit DDR (D0 and D1 data pins are used)
11 (R/W)	ROVFMSK	Receive FIFO Overflow Interrupt Mask.	
		0	Mask Disable Receive FIFO Overflow Interrupt
		1	Unmask Enable Receive FIFO Overflow Interrupt

Table 17-7: LP_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RRQMSK	Receive Request Interrupt Mask. Link Port Receive Request Mask	
		0	Mask Disable Receive Request interrupt.
		1	Unmask Enable Receive Request interrupt.
8 (R/W)	TRQMSK	Transmit Request Interrupt Mask. Link Port Transmit Request Mask	
		0	Mask Disable Transmit Request interrupt.
		1	Unmask Enable Transmit Request interrupt.
3 (R/W)	TRAN	Transfer Direction. The `LP_CTL.TRAN` bit selects the transfer direction as transmit (if set) or receive (if cleared) for link buffer.	
		0	Receive Direction transfer is receive
		1	Transmit Direction transfer is transmit
0 (R/W)	EN	Enable. The `LP_CTL.EN` enables or disables the link port. When the processor disables the port (`LP_CTL.EN` transitions from high to low), the processor clears the corresponding `LP_STAT` bits.	
		0	Disable Disable linkport
		1	Enable linkport Enable linkport

Clock Divider Value Register

The LP_DIV register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (CLKO8). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

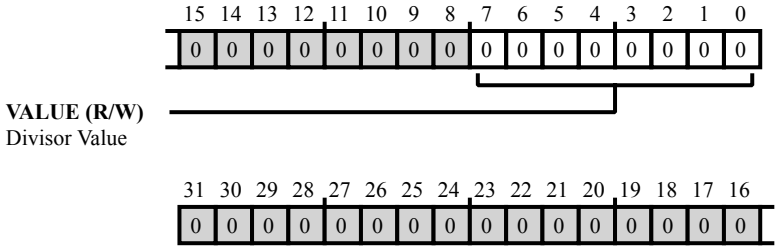

Figure 17-14: LP_DIV Register Diagram

Table 17-8: LP_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Divisor Value. The LP_DIV.VALUE bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (CLKO8). The LP_DIV.VALUE should be programmed prior to LP enable. For LP_DIV.VALUE = 0, LCLK = CLKO8 For LP_DIV.VALUE = xxxxxxxx, LCLK = CLKO8 / (2 x DIV)

Receive Buffer Register

The LP_RX register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

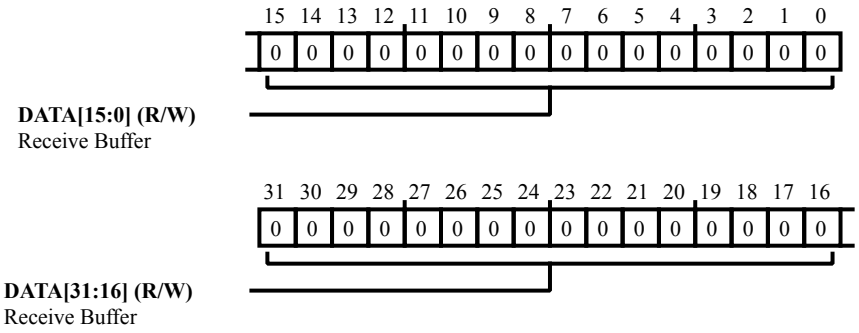

Figure 17-15: LP_RX Register Diagram

Table 17-9: LP_RX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Receive Buffer.

Status Register

The LP_STAT register provides status information on link port interrupts, FIFO, buses, and receive/transmit requests.

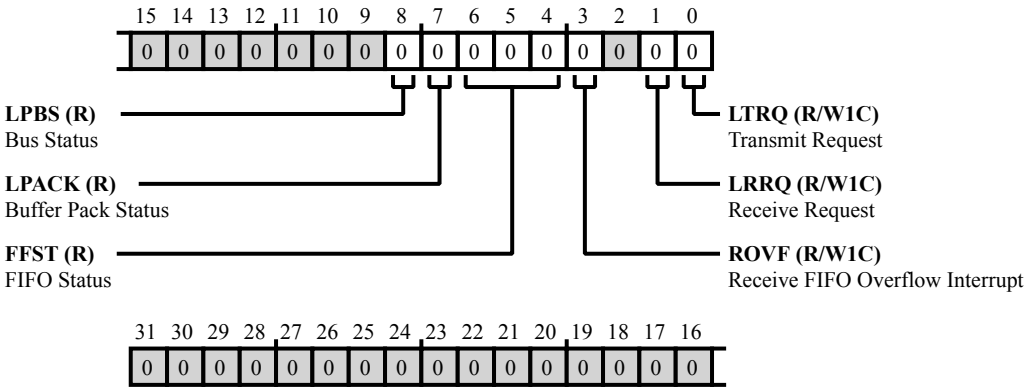

Figure 17-16: LP_STAT Register Diagram

Table 17-10: LP_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	LPBS	Bus Status. The LP_STAT.LPBS bit indicates the LPDAT bus status. LP_STAT.LPBS is kept high if data is being driven by the link port into the LP_D[n] pins.	
		0	Link port bus is idle
		1	Link port bus is busy
7 (R/NW)	LPACK	Buffer Pack Status. The LP_STAT.LPACK bit indicates packing status. In receive mode, 32-bit data is received in 4 blocks of 8-bit data. Then, the data is packed to get a single 32-bit data before loading the FIFO. The LP_STAT.LPACK bit is high during this packing process and goes low after packing. In transmit mode, 32-bit data in the FIFO is unpacked to 4 blocks of 8-bit data before sending. The LP_STAT.LPACK is high during unpacking.	
		0	Packing Complete Packing done
		1	Packing Incomplete Packing is in progress
6:4 (R/NW)	FFST	FIFO Status. The LP_STAT.FFST bits indicate the FIFO status. These bits are cleared when the LP is disabled.	
		0	TX - Empty; RX - Empty Link buffer (TX OR RX) empty

Table 17-10: LP_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	TX - Reserved ; RX - Has 1 data word RX has 1 word of data. TX reserved
		2	TX - Reserved; RX - Has 2 data words RX has 2 word of data. TX reserved.
		3	TX - Reserved; RX - Has 3 data words RX has 3 word of data. TX reserved.
		4	TX - One Word; RX -Has 4 data words RX has 4 word of data. TX 1 word of data.
		5	Reserved
		6	TX - FIFO Full; RX - Reserved RX reserved. TX reserved.
		7	Reserved
3 (R/W1C)	ROVF	Receive FIFO Overflow Interrupt. This interrupt is generated when the receiver FIFO overflows. This overflow may happen if the transmitter continues to transmit data even though the receiver has de-asserted the `LP_ACK` pin.	
1 (R/W1C)	LRRQ	Receive Request. The LP generates this interrupt when the `LP_CLK` pin of a disabled link port (the receiver) is forced high by another link port (the transmitter). Note that the LRRQ interrupt is not supported in DDR mode.	
0 (R/W1C)	LTRQ	Transmit Request. The LP generates this interrupt when the `LP_ACK` pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).	

Transmit Buffer Register

The LP_TX register buffers the transmit data flow through the LP. The transmit buffer is two words deep. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the link port interface from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the LP_CLK signal. For more information on LP buffer features and operations, see the LP functional description.

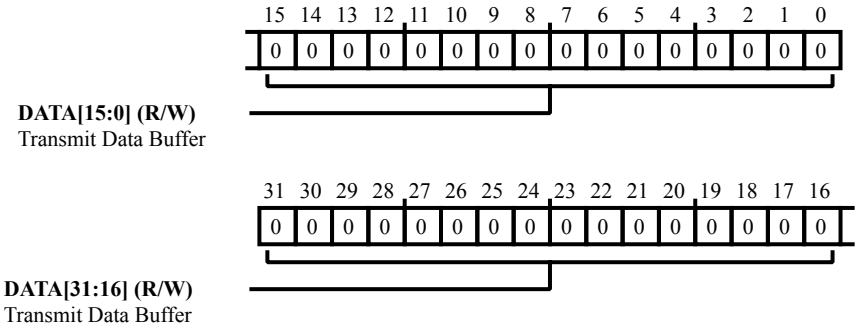

Figure 17-17: LP_TX Register Diagram

Table 17-11: LP_TX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit Data Buffer.

Shadow Input Transmit Buffer Register

The LP_TXIN_SHDW register contains the same data as the input stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

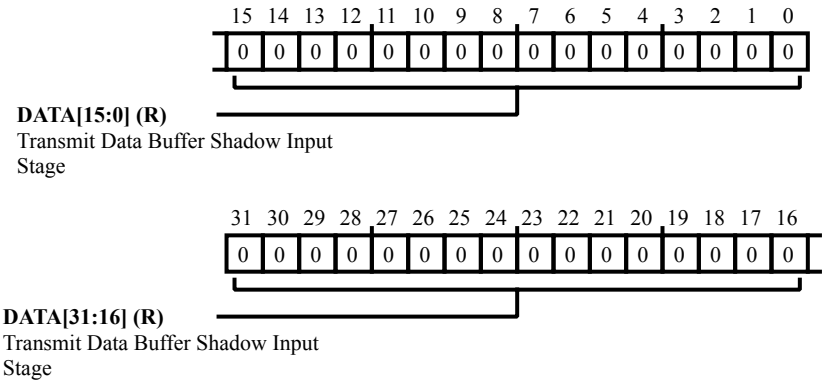

Figure 17-18: LP_TXIN_SHDW Register Diagram

Table 17-12: LP_TXIN_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Buffer Shadow Input Stage.

Shadow Output Transmit Buffer Register

The LP_TXOUT_SHDW register contains the same data as the output stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

Table 17-13: LP_TXOUT_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Output Shadow Register.

18 Pulse Density Modulation (PDM) Microphone Interface

The pulse density modulation (PDM) microphone interface converts digital PDM microphone data to I^2S/TDM format. The microphone data in I^2S/TDM format is then routed internally to the SPORT/ASRC or externally via the DAI pins. Each DAI unit has one PDM interface.

PDM Features

The PDM interface includes the following features:

- Four channels of PDM audio inputs from digital microphones
- 16×, 32×, or 64× decimation ratio of PDM to pulse code modulation (PCM) audio data
- 24-bit resolution to support high sound pressure level (SPL) microphones
- 126 dB A-weighted SNR
- 4 kHz to 192 kHz output sampling rate
- Bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate

  NOTE: Refer to the product data sheet for the maximum BCLK frequency.
- Automatic PDM clock generation
- Slave I^2S or TDM output interface
- Supports up to 16 TDM slots
- Configurable TDM slot routing and sizes

PDM Functional Description

The following are the typical connections for the PDM module:

- PDM interface – PDM clock (PDM_CLK0) and PDM data (PDM_DAT0 and PDM_DAT1) are typically routed to DAI pins via the Signal Routing Unit (SRU) which is in turn connected to a PDM data source, for example, PDM microphones.
- Slave I^2S/TDM interface – Bit clock (BCLK), frame sync (LRCLK), and serial data (SDATA) signals are typically routed internally to the SPORT via the SRU in order for the microphone data to reach memory in PCM format.
- Control registers - All PDM related control registers are included in the DAI MMR system.

Pulse Density Modulation interface block

Table 18-1: ADSP-2159x_SC591_SC592_SC594 PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Block Diagram

The *PDM Interface Block Diagram* figure illustrates the interconnection of PDM block in the DAI subsystem.

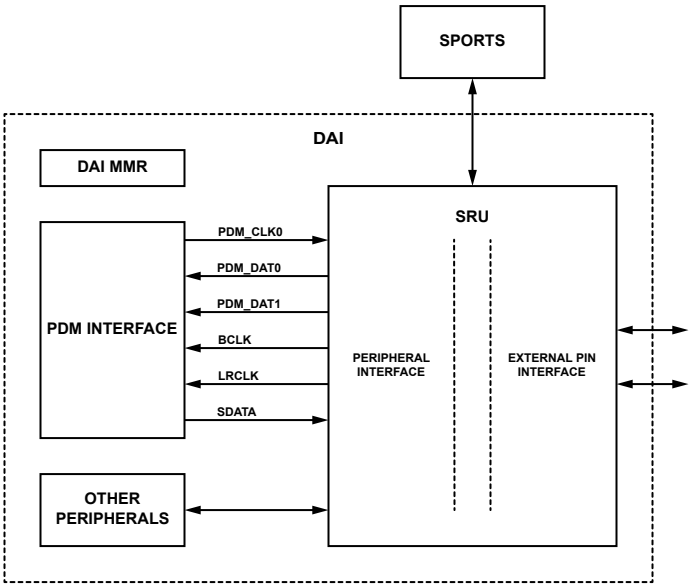

Figure 18-1: PDM Interface Block Diagram

PDM Architectural Concepts

The PDM interface provides up to four channels of decimation from a 1-bit PDM source to a 24-bit PCM audio stream. The down sampling ratio is typically 64 × f_S, where f_S is the PCM output sampling rate. The down sampling ratio can also be set at 32 × f_S or 16 × f_S, to facilitate higher output sampling rates. All channels decimate at the same ratio. The 24-bit down-sampled PCM audio data is output via standard stereo (I^2S, left justified, right justified) or TDM format. The input sources for the PDM interface can be any device that has a slave PDM output, such as a digital microphone.

Internally, there are four channels. The *PDM Channel Mapping* table details the mapping of the PDM_DATx input pins to the internal channels. If a channel is not in use, the associated PDM_DATx pin can be disabled to save power.

Table 18-2: PDM Channel Mapping

Input Pin	PDM_CLK Edge	Internal Channel
PDM_DAT0	Falling	0
PDM_DAT0	Rising	1
PDM_DAT1	Falling	2
PDM_DAT1	Rising	3

PDM Initialization and Clocking

After I^2S clocks are applied, there are 16 full frame sync cycles of initialization time before the PDM clocks start. Once the PDM clocks start running, 48 additional frame sync cycles elapse before the PDM data is driven on the SDATA pin.

During normal operation, if the bit clock or frame sync is removed then the PDM clock output stops immediately and the PDM interface enters a lower power state. If the clocks resume, the PDM interface relocks to the bit clock and frame sync signals and adjusts the PDM clock output accordingly. The length of time before the PDM clock outputs resume is 4 frames ± 1 frame to lock to the incoming signal. If the format of the clock signals change, the PDM interface detects this change at the end of the frame and stops the PDM clock outputs. Then, the device reconfigures and resumes sending PDM clocks with no user intervention. Again, the PDM clock outputs resume after 4 frames ±1 frame to lock to the incoming signal.

The PDM interface requires a clock rate that is a minimum of 64× the frame sync sample rate. Bit clock rates of 128×, 192×, 256×, 384×, and 512× the frame sync rate are also supported. The PDM interface automatically detects the ratio between the bit clock and frame sync signals and generates a PDM clock output at 64 × the frame synce rate by default. If lower decimation ratios are selected in the `PDM_CTL0` register, the PDM output clock rate corresponds to the configuration set in the `PDM_CTL0.DEC_RATIO` bit field. The minimum sampling rate is 4 kHz and the maximum sampling rate is 192 kHz. The PDM clock range is 256 kHz to 6.144 MHz. Internally, all processing is done at the PDM clock rate.

SPORT Interface

The PDM interface supports I^{2}S and TDM serial output formats. It supports up to 16 TDM slots, with slot widths of 16, 24, or 32-bits. Internal channels are connected to output slots by configuring the appropriate channel slot bit fields in the PDM_SP_CTL1 register. By defult, each channel is routed to the slot with the same number. For example, the reset value of the PDM_SP_CTL1.CH3_SLOT bit field is 0x0011, connecting channel 3 to slot 3.

Each channel has a drive select bit: PDM_SP_CTL1.CH0_DRV, PDM_SP_CTL1.CH1_DRV, PDM_SP_CTL1.CH2_DRV, or PDM_SP_CTL1.CH3_DRV. If the drive select bit is set to one, the channel is driven on the serial port in the appropriate output slot; and if it is cleared to zero, the channel does does not drive (tristate high impedance mode). Note that this feature is useful only when the SPORT data is driven out of the processor via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

It is possible to erroniously configure more than one chanel to drive on a single TDM slot. There is no cross-checking of register settings to prevent this configuration, but it will not damage the device. In this case, only the data from the the lowest channel number is driven into the slot and the data from the higher channels will not be driven.

The PDM_SP_CTL0.SAI_MODE bit configures the SPORT interface mode. The two modes are stereo and TDM. The primary difference between these two modes is the format of the frame sync clock that is expected and the polarity of the active edge of the clock.

With the PDM_SP_CTL0.SAI_MODE bit and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in stereo mode with the clock polarity set to normal. In this mode, there must be only two channels of data sent. The frame starts with the falling edge of the frame sync, with an expected cycle of 50% high and 50% low. Channel 0 sends out data when the clock is low. As soon as the frame sync goes high the data from channel 0 stops and channel 1 begins sending data. Both edges of the frame sync clock are used. If the duty cycle is not 50/50, there may be errors in the resulting data. In this mode of operation, the PDM interface does not expect 32-bit clock transitions for each channel. All bit clock to frame sync ratios are supported.

With the PDM_SP_CTL0.SAI_MODE bit set to one and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in TDM mode with the clock polarity set to normal. In this mode, it is possible to can transmit anywhere from one channel to as many as four channels spread out across 16 data slots in TDM-16 format.

The PDM interface supports bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate. The BCLK frequency, however must not exceed the maximum value specified in the data sheet. These bit clock rates are combined with the three different TDM slot sizes of 16-bit, 24-bit, or 32-bit slots, selected by the PDM_SP_CTL0.CH0_SLOT_WIDTH bit field. Note that as soon as the next frame sync edge is detected, the PDM interface restarts from slot 0 and any unreceived data from the previous frame is lost. This is how to achieve unusual TDM formats like TDM-5 or TDM-10. In addition, there is only support for TDM-16 or less for placing data into a TDM slot. Data cannot be placed into slots above 16, however it is possible to configure the PDM interface to tristate all unused TDM slots, which includes all the slots above the first 16 slots for modes that have more than 16 slots.

In TDM mode, the frame sync is expected to be a positive going pulse that is at least one-bit clock period wide. A falling edge is not necessary, it is only important that the signal is low long enough to meet the timing specification

for a read before transitioning from low to high. The frame starts with the rising edge of this pulse. The data is clocked out according to the slot width and using the data format specified in the PDM_SP_CTL0 register. The PDM interface continues to send data until all active channels are sent and then the device waits for the next frame sync clock edge to start sending the next set of frame samples.

In TDM-8 format, when the PDM interface is set to output channel 0 through channel 3 into slot 0 to slot 3, the PDM interface can tristate for the remainder of the frame. This allows another PDM to output four channels onto slot 4 thorugh slot 7. These slots do not have to be consecutive and the two devices can be configured to interleave their respective data. The serial port can be set up to drive only when there is data to drive into a data slot. If all eight channels are not in use, configuring the the drive select bit in the PDM_SP_CTL1 for the unused channels will assign those slots to drive or tristate in the TDM data stream. Note that this feature is useful only when the SPORT data is driven out of the chip via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

To invert the IRCLK polarity, set the PDM_SP_CTL0.LRCLK_POL bit to one. With inverted clock polarity in stereo mode, channel 0 is sent out when the frame sync is high, so the start of the frame is a low to high transition. With inverted clock polarity in TDM mode, the frame sync pulse is negative so the frame starts with the high to low transition.

Configure the PDM_SP_CTL0.DATA_FORMAT bit field to align data within the 32-bit data slot. There is support for left justified mode, delayed by one-bit clock period; and right justified modes for 24-bit, 20-bit, and 16-bit data word sizes.

SPORT Timing

The *Stereo Mode* figure is a timing diagram for I^{2}S mode with 24-bit data.

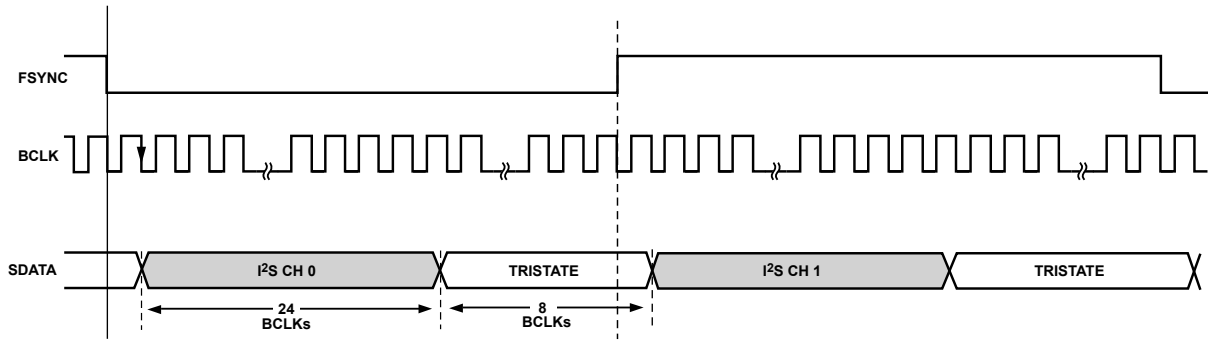

Figure 18-2: Stereo Mode

The *TDM4 Mode Four Channel* figure is a timing diagram for TDM4 mode with default channel assignments, 24-bit data, and 32-bit slots, and normal polarity clocks.

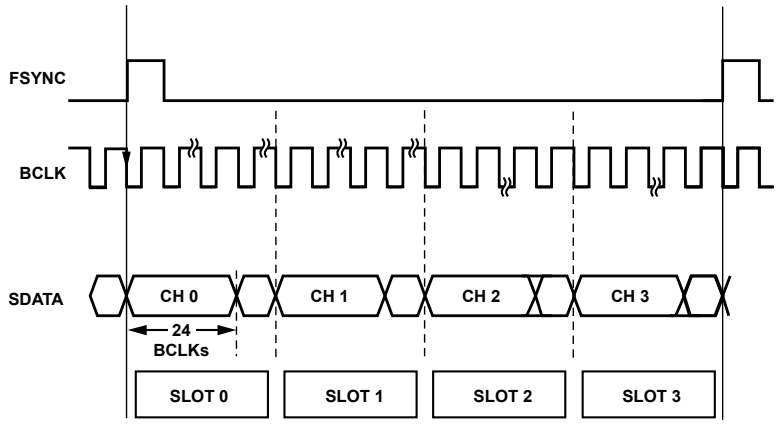

Figure 18-3: TDM4 Four Channel

The ***TDM4 Mode Two Channel*** figure is a timing diagram that shows TDM4 mode with only two channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

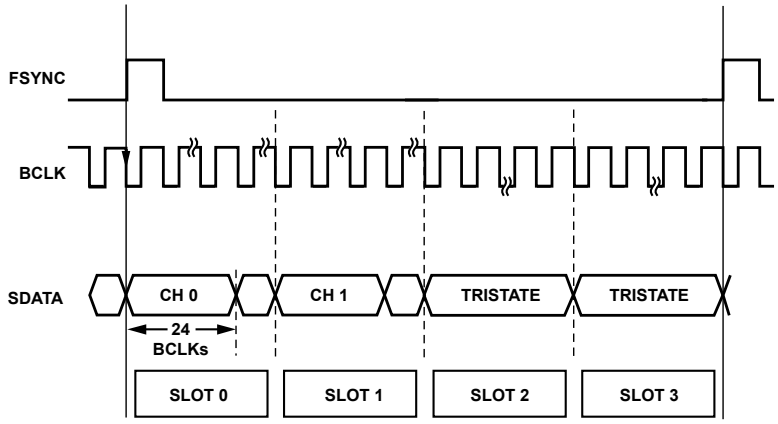

Figure 18-4: TDM4 Two Channel

The ***TDM8 Mode Four Channel*** figure is a timing diagram that shows TDM8 mode with all the four channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

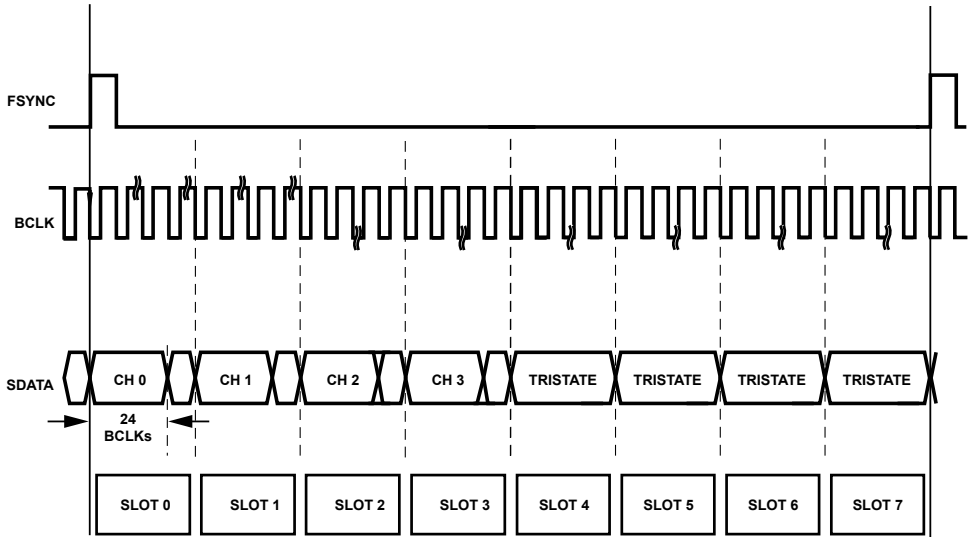

Figure 18-5: TDM8 Four Channels

The *TDM2 Mode Two Channel* figure is a timing diagram that shows TDM2 mode with two channels enabled, 24-bit data delayed by one BCLK, 32-bit slots, and normal polarity clocks.

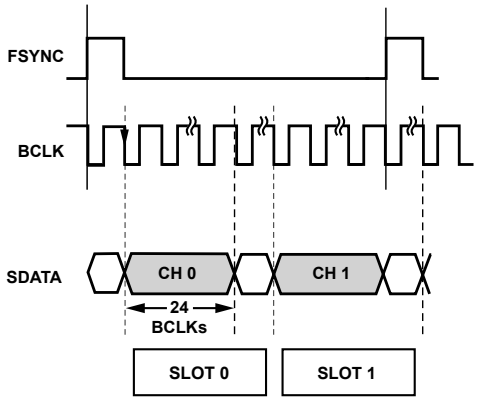

Figure 18-6: TDM2 Two Channels

High Pass Filter

There is a first order high-pass filter in the signal path. It is disabled by default and can be enabled by setting the `PDM_HPF_CTL.EN` bit. To adjust the cutoff frequency, configure the `PDM_HPF_CTL.FC` bit field. The settings are relative to the output sampling rate.

The *HPF Cutoff Frequence Selection* table shows the setting and the cutoff frequency for common sampling rates.

Table 18-3: HPF Cutoff Frequencey Selections

PDM_HPF_CTL.HPF_FC	Multipication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)
0101	0.00505	242.4	161.6
1001	0.00251	120.48	80.32

Table 18-3: HPF Cutoff Frequencey Selections (Continued)

PDM_HPF_CTL.HPF_FC	Multipication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)
0111	0.00125	60	40
1000	0.000623	29.904	19.936
1001	0.000311	14.928	9.952

1011	0.0000777	3.7296	2.4864
1100	0.0000389	1.8672	1.2448
1101	0.0000194	0.9312	0.6208
1110	0.00000971	0.46608	0.31072
1111	0.00000468	0.23328	0.15552

PDM Programming Model

The following section provides information on configuring the PDM interface.

Configuring the PDM Interface

Use the following steps to configure the PDM interface:

Optional high pass filter configuration:

- Configure the `PDM_HPF_CTL` register to enable the high pass filter using the `PDM_HPF_CTL.EN` bit and set the cutoff frequency by programming the `PDM_HPF_CTL.FC` bit field.

1. Configure `PDM_SP_CTL0` register to set the following parameters:
    a. SPORT mode (Stereo/TDM) with the `PDM_SP_CTL0.SAI_MODE` bit
    b. SPORT data format (BCLK delay) with `PDM_SP_CTL0.DATA_FORMAT` bit field
    c. SPORT slot width (16, 24, or 32 bits) with `PDM_SP_CTL0.CH0_SLOT_WIDTH` bit field – applicable only for the TDM mode
    d. BCLK capture edge (rising/falling) with the `PDM_SP_CTL0.BCLK_POL` bit
    e. LRCLK polarity (normal/inverted) with the `PDM_SP_CTL0.LRCLK_POL` bit
2. Configure the `PDM_SP_CTL1` register to set the following parameters:
    a. PDM to SPORT channel slot mapping with serial port channel slot bit fields (CHx_SLOT)
    b. To select if the PDM channel will get driven to the associated SPORT channel slot with the serial port channel drive select bit (CHx_DRV).

3. Configure the PDM_CTL0 register to configure the decimation ratio with the PDM_CTL0.DEC_RATIO bit field and finally enable the PDM clock with the PDM_CTL0.CLK0_EN bit.

Software Reset

The PDM_RESET.SOFT bit is set to perform a soft reset of the PDM block. Setting this bit resets internal bit clock counters and audio data, but it does not reset the PDM register settings. This bit is self-clearing.

ADSP-2159x_SC591_SC592_SC594 PDM Register Descriptions

Pulse Density Modulation interface block (PDM) contains the following registers.

Table 18-4: ADSP-2159x_SC591_SC592_SC594 PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Control Register

The PDM_CTL0 register (read/write) controls the channel activation, clock enable and Decimation ratio.

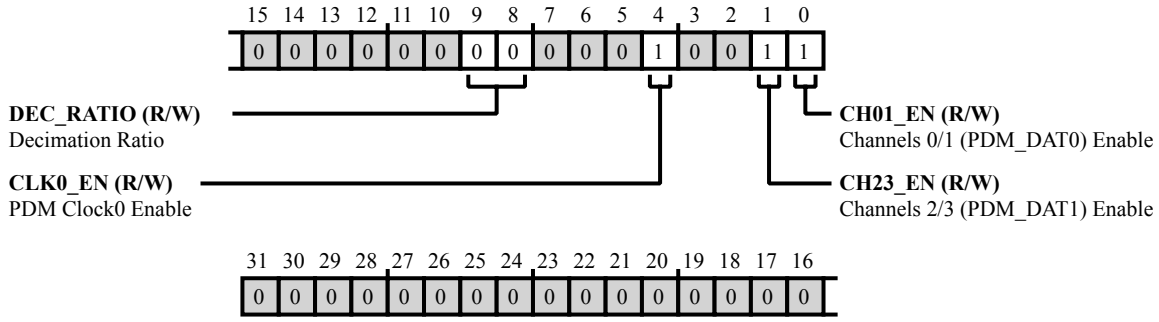

Figure 18-7: PDM_CTL0 Register Diagram

Table 18-5: PDM_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	DEC_RATIO	Decimation Ratio.	
		0	64 times decimation
		1	32 times decimation
		2	16 times decimation
4 (R/W)	CLK0_EN	PDM Clock0 Enable.	
		0	PDM_CLK0 output disabled
		1	PDM_CLK0 output enabled
1 (R/W)	CH23_EN	Channels 2/3 (PDM_DAT1) Enable.	
		0	PDM channels 2/3 disabled
		1	PDM channels 2/3 enabled
0 (R/W)	CH01_EN	Channels 0/1 (PDM_DAT0) Enable.	
		0	PDM channels 0/1 disabled
		1	PDM channels 0/1 enabled

High Pass Filter Control Register

The PDM_HPF_CTL register (read/write) controls the High Pass Filter.

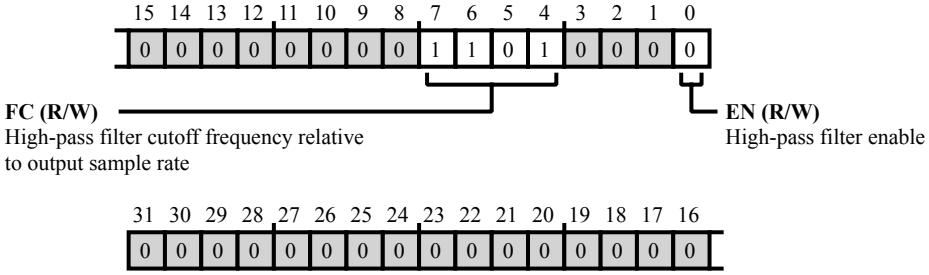

Figure 18-8: PDM_HPF_CTL Register Diagram

Table 18-6: PDM_HPF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/W)	FC	High-pass filter cutoff frequency relative to output sample rate.	
		0	Reserved
		1	Reserved
		2	Reserved
		3	Reserved
		4	Reserved
		5	0.00505
		6	0.00251
		7	0.00125
		8	0.000623
		9	0.000311
		10	0.000155
		11	0.0000777
		12	0.0000389
		13	0.0000194
		14	0.00000971
		15	0.00000486
0 (R/W)	EN	High-pass filter enable.	
		0	High Pass Filter Off
		1	High Pass Filter On

Software Reset Register

The PDM_RESET register (read/write) controls the software reset operations.

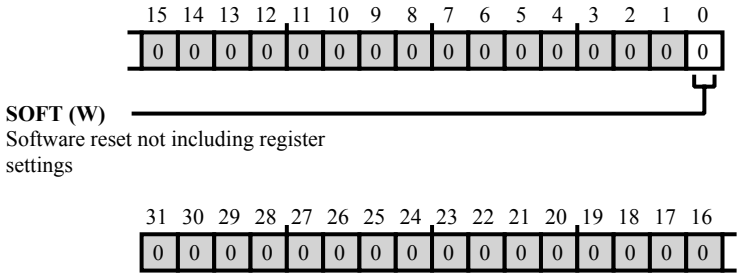

Figure 18-9: PDM_RESET Register Diagram

Table 18-7: PDM_RESET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (RX/W)	SOFT	Software reset not including register settings.	
		0	N/A
		1	Write once to soft reset

Serial Port Control0 Register

The PDM_SP_CTL0 register (read/write) controls serial port mode, data format and slot width.

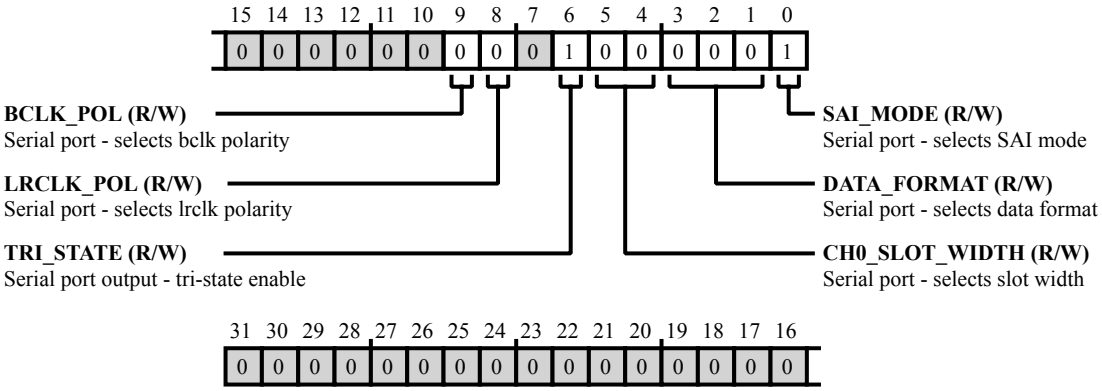

Figure 18-10: PDM_SP_CTL0 Register Diagram

Table 18-8: PDM_SP_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	BCLK_POL	Serial port - selects bclk polarity.	
		0	Capture on rising edge
		1	Capture on falling egde
8 (R/W)	LRCLK_POL	Serial port - selects lrclk polarity.	
		0	Normal Polarity
		1	Inverted Polarity
6 (R/W)	TRI_STATE	Serial port output - tri-state enable.	
		0	tri-state disabled
		1	tri-state enabled
5:4 (R/W)	CH0_SLOT_WIDTH	Serial port - selects slot width.	
		0	32 BCLK's per slot
		1	16 BCLK's per slot
		2	24 BCLK's per slot
3:1 (R/W)	DATA_FORMAT	Serial port - selects data format.	
		0	Typical I2S mode, delay by 1
		1	Left Justified,delay by 0
		2	Delay by 8
		3	Delay by 12

Table 18-8: PDM_SP_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Delay by 16
0 (R/W)	SAI_MODE	Serial port - selects SAI mode.	
		0	STEREO (I2S, LJ, RJ)
		1	TDM

Serial Port Control1 Register

The PDM_SP_CTL1 register (read/write) controls the mapping of channel 0/1/2/3 to TDM slots.

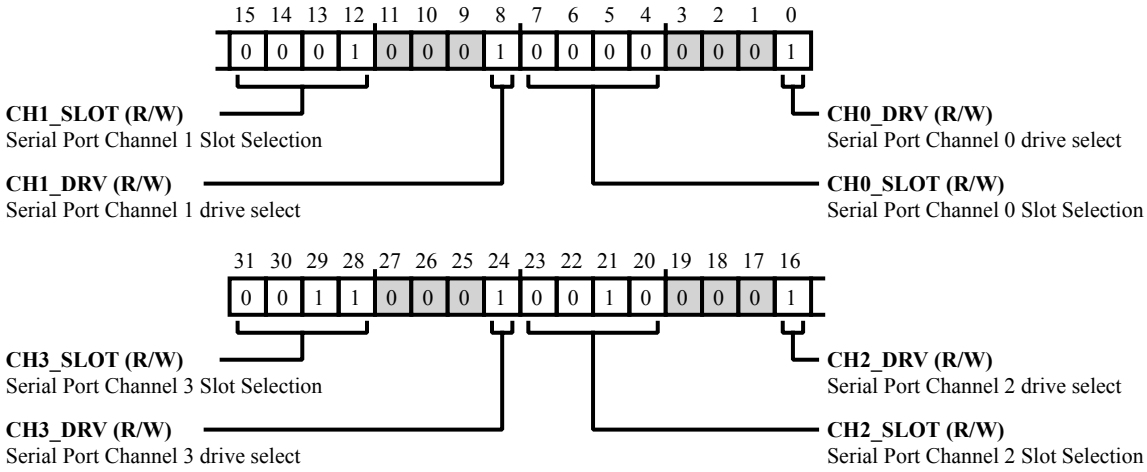

Figure 18-11: PDM_SP_CTL1 Register Diagram

Table 18-9: PDM_SP_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/W)	CH3_SLOT	Serial Port Channel 3 Slot Selection.	
		0	Map channel to TDM slot 0/I2S Left
		1	Map channel to TDM slot 1/I2S Right
		2	Map channel to TDM slot 2
		3	Map channel to TDM slot 3
		4	Map channel to TDM slot 4
		5	Map channel to TDM slot 5
		6	Map channel to TDM slot 6
		7	Map channel to TDM slot 7

		11	Map channel to TDM slot 11
		12	Map channel to TDM slot 12
		13	Map channel to TDM slot 13
		14	Map channel to TDM slot 14
		15	Map channel to TDM slot 15
0 (R/W)	CH0_DRV	Serial Port Channel 0 drive select. This determines whether the associated channel gets driven in its assigned slot or not.	
		0	Channel will not be driven on serial port
		1	Channel will be driven on serial port in selected output slot.

19 Universal Serial Bus Controller (USBC)

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players. It allows these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB device-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 specification.

USBC Features

The USB OTG controller provides the following features:

- Complies with the On-The-Go Supplement to the USB 2.0 Specification (revision 2.0)
- Supports high speed (HS, 480 Mbps), full speed (FS, 12 Mbps) and low speed (LS, 1.5 Mbps) rates
- Provides scatter/gather DMA mode access support on the application side
- Provides ULPI interface support on the MAC PHY
- Supports up to 12 bidirectional endpoints including control endpoint 0
- Supports Session Request Protocol (SRP)
- Supports Host Negotiation Protocol (HNP)
- Supports up to 16 host channels. In host mode, when the number of device endpoints to be supported is more than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Includes automatic ping capabilities
- Supports the keep-alive in low speed mode and SOFs in high and full speed modes

The application interface uses the bus to support the following:

- Bus completer interface for accessing Control and Status Registers (CSRs). (Access to FIFO and queues is not supported).
    - Bus requester interface for data FIFO access

  - Supports 32-bit data on the AHB bus
  - Supports little endian mode
  - Supports INCR4, INCR8, INCR16, INCR, and single transfers on the bus completer interface
  - Supports error and okay bus responses on the bus requester interface. The bus completer interface supports only an okay response. An error response is generated on the bus completer interface when the transfer size (HSIZE) is not equal to 32 bits.
  - Software-selectable bus burst type on bus requester interface in DMA mode
- When INCR4 is chosen, the core uses INCR/INCR4 or single
- When INCR8 is chosen, the core normally uses INCR8. However, at the beginning and at the end of a transfer, it can use INCR or single, depending on the size of the transfer.
- When INCR16 is chosen, the core normally uses INCR16. However, at the beginning and at the end of a transfer, it can use INCR or single, depending on the size of the transfer.
- Handles the fixed burst address alignment. For example, INCR16 is used only when lower addresses [5:0] are all 0.
- Generates bus busy cycles on the bus requester interface
- Supports the 1KB boundary breakup

The MAC PHY interface supports the ULPI interface and 8-bit SDR

The system memory architecture has the following features:

- Supports internal DMA mode for the system memory architecture
- Provides descriptor-based scatter/gather DMA operation

Supports Non-DWORD alignment:

- In host mode, supports scatter/gather DMA mode, IN and OUT transfers - Non-DWORD alignment of buffer addresses
- In device mode, supports scatter/gather DMA mode, IN and OUT transfers - Non-DWORD alignment of buffer addresses

NOTE: Non-DWORD alignment support is available only for buffer addresses and not for descriptors.

The internal memory features:

- Support for a dedicated transmit FIFO for each of the device IN endpoints. Each FIFO can hold multiple packets.
- An interface for remote memory support used to signal the core of a DMA write complete event on the system
- Support for packet-based, dynamic FIFO memory allocation for endpoints for small FIFOs, and flexible, efficient use of RAM.

- Support to change the FIFO memory size of an endpoint during transfers
- Support for endpoint FIFO sizes that are not powers of 2, to allow the use of contiguous memory locations.
- Optional support for transmit and receive thresholding in DMA mode (in device mode). Thresholding and threshold length are selectable through global registers.

USBC Functional Description

The USB OTG controller includes the following interfaces:

- *Bus completer and data RAM* – the bus completer provides the microcontroller with read and write access to the CSRs of the core. The data RAM interface connects to single port RAM (SPRAM) for transaction data storage which is 4096 deep.
- *USB 2.0 PHYs and serial transceiver* – The USB OTG core supports the ULPI PHY interface (Revision 1.1). The ULPI PHY is unidirectional, with 8-bit SDR (single data rate).
- Internal DMA controller (bus requester) – enables the core to act as a requester on the bus to transfer data to and from the bus.
- PHY control interfaces to ULPI PHY registers.
- Descriptor-based scatter/gather DMA controller for device and host mode. (Descriptor-based congruent-sequential DMA is not supported).
- The core supports the scatter/gather DMA operation in both device and host mode.

NOTE: Hubs (split transfers) are not supported in the host scatter/gather DMA mode of operation. Split transfers are supported only in host buffer DMA (internal DMA) mode of operation.

ADSP-2159x_SC591_SC592_SC594 USBC Register List

The Universal Serial Bus Controller (USBC) is a multi-point high-speed dual-role USB 2.0-compliant controller. The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On- The-Go (OTG) supplement to the USB 2.0 Specification. A set of registers governs USBC operations. For more information on USBC functionality, see the USB controller register descriptions.

USBC Block Diagram

The ***USBC Block Diagram*** shows the USB OTG controller in a typical system.

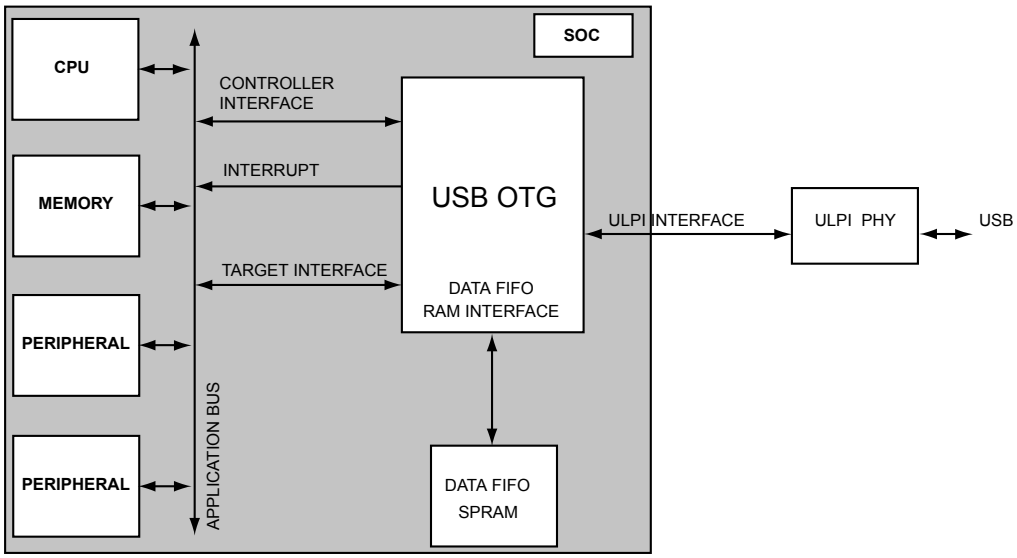

Figure 19-1: USBC Block Diagram

USBC Definitions

A list of common USB terms and their definitions as used in this specification and based on the USB controller follows:

'A' Device

The USB device with a mini-A plug inserted into its receptacle. The A device always supplies power to VBUS.

'B' Device

The USB device with a standard-B or mini-B plug inserted into its receptacle. The B device starts a session as the peripheral.

Bidirectional endpoint

An endpoint that can concurrently support both receive and transfer packets.

Control endpoint

An endpoint used only for transfer of USB control packets for setup and configuration. In all USB devices, the control endpoint refers to the bidirectional endpoint 0.

Dual role device

A USB device that can operate either as the USB host in an OTG session or as a traditional USB peripheral.

Endpoint

A single physical communication channel for USB, implemented as a FIFO and control logic for that endpoint. Each endpoint has an associated USB transfer type, maximum packet size, bandwidth requirement, endpoint number, and (often) a fixed transfer direction.

Frame

A regular, fixed 1 ms (LS and FS) / 125 us timeslot that can contain several transactions. The transfer type determines the permissible transactions for a given endpoint.

HNP

Host negotiation protocol. Part of the USB OTG supplement that allows the host function to be transferred between two connected dual role devices.

Packet

The lowest level of data exchange on USB. The transfer type and buffer size of the USB peripheral determine the size.

PHY

The PHY is a transceiver circuit that implements the physical layer of USB. For full speed USB OTG, this circuit includes line drivers and receivers, pull-up, or pull-down resistors as well as device ID and VBUS level detection.

Session

A period during which USB transfers take place within an OTG connection. The A device (drives VBUS) or B device (initiates SRP) can initiate this period. VBUS is powered during a session.

SRP

Session request protocol. Part of the USB OTG supplement that allows a B device to turn on VBUS and initiate a USB session.

Transaction

Collection of one or more packets in sequence

Transfer

Collection of one or more transactions in sequence

Unidirectional endpoint

Endpoint with its direction fixed in a single direction (for example, it can only receive packets from the USB) in both host and peripheral modes.

Transmit and Receive FIFOs

A transmit and receive FIFO interface on the USB OTG core is used to move data in and out of the data FIFO RAM. These movements are classified as periodic (for isochronous and interrupt transfers) or non-periodic (for bulk and control transfers). The interface has

- A single receive FIFO for all host IN and device OUT transfers
- Dedicated Tx FIFO for each IN endpoint for periodic /non-periodic device IN transfers

Restrictions

The USBC modules has some restrictions for response time and thresholding.

Response Time Restriction

For the controller as a device, there is a worst-case response time for any tokens that follow an isochronous OUT transaction. This worst-case response time depends on the bus clock frequency. The controller registers are in the bus domain; the controller does not accept another token before updating these register values. The worst case is for

any token following an isochronous OUT. For an isochronous transaction, there is no handshake and the next token can come sooner than expected. When the bus clock is the same as the PHY clock, this worst-case value is seven PHY clocks. When the bus clock is faster, this value is smaller.

If this worst-case condition occurs:

- For bulk/interrupt tokens, the controller responds with a NAK and drops the isochronous and setup tokens. The host interprets this event as a time-out condition for SETUP and retries the SETUP packet.
- For isochronous transfers, the controller sets the `USBC_ISTAT.INCOMPLP` interrupt to inform the application that isochronous IN/OUT packets were dropped.

At the system level, this limitation can reduce the performance of the device controller because the controller drops or sends NAK to the token which is sent by the host too close to end of the preceding isochronous OUT token. For bulk, interrupt, and control transactions, the system recovers as the host retires the token; the transactions will eventually complete. For isochronous transactions, the host proceeds to the next transaction scheduled for the next interval.

A significant performance degradation occurs in the following cases:

- The device is connected to a host which is capable of consistently sending a token within 88-96 bit times, that is, six to seven PHY clocks from the end of the preceding isochronous OUT token.
- The device is connected to a host through multiple layers of hubs such that the interpacket gap between an isochronous OUT token and the following token shrinks to less than seven PHY clocks.

However, the system does not stop responding or enter an unrecoverable state. It has been observed that the USB host implementation is unable to send tokens with the worst-case inter-packet gap of 88-96 bit times.

Thresholding

When enabling thresholding, the bus must run at 60 MHz or faster. Do not enable the `USBC_THR_CTL_D.RXTHREN` bit because it may cause issues in the RxFIFO (especially during error conditions such as Rx error and babble).

USBC Architectural Concepts

The USB controller operates in either of two USB operation modes (device or host mode) at a given time.

In device mode, the USB controller encodes, decodes, checks, and directs all USB packets sent and received, responding appropriately to host requests. Data is transferred from the processor core memory into the Tx FIFOs of the device onto USB as IN packets. In the other direction, USB OUT packets are received into the Rx FIFOs (having been sent from the host) and transferred to system memory for processing or storage. In peripheral mode, the USB controller acts as a completer device to another USB host; either a personal computer or another OTG host controller.

When operating in host mode, the USB controller uses simple hosting capabilities to requester point-to-point connections with another USB peripheral, initiating transfers on the bus for the peripheral to respond. USB IN packets

are received into the Rx FIFOs for transfer into the processor core memory. Data written into Tx FIFOs is transmitted onto the bus as USB OUT packets. In this mode, the USB controller encodes, decodes, and checks USB packets sent and received. The controller automatically schedules isochronous and interrupt transfers from the endpoint buffers. It performs one transaction every *n* frames, where n represents the polling interval programmed for the endpoint.

Any of the endpoints can be programmed to be written to or read from using the DMA requester channels. This configuration provides the most efficient means of transferring data between the controller and on-chip memory.

The USB provides two top-level maskable interrupts, each of which can be sourced from any or all of transmit endpoint status, receive endpoint status or global USB status.

The RAM interface of the USB controller supports a single block of synchronous single-port RAM used to buffer the USB packets.

ATTENTION: Check the processor data sheet for requirements regarding minimum system clock frequency needed for proper USB operation.

System Level Architecture

The following sections describe the system level architecture.

Bus Interface Unit (BIU)

The bus interface unit (BIU) includes the completer bus interface unit (BIUS) and the requester bus interface unit (BIUM).

Requester Bus Interface Unit (BIUM)

The internal DMA controller translates internal DMA requests into bus requester requests. The DMA address, transfer count, and packet count registers reside in the CSR block. The address of the selected channel is given as an input to the internal DMA controller. The BIUM converts the internal DMA request cycles into bus cycles. Characteristics of this interface include the following:

- Fully AMBA 2.0-compliant bus requester —No restrictions
- SINGLE, INCR, INC4, INC8, or INC8 burst types. When INC4, INC8, or INC16 is chosen, SINGLE and INCR cycles can happen due to a split, retry, or early termination.

  The USBC core uses INCR in the following scenarios:

  - Remaining data transfers (when the data length is not a direct multiple of the burst length, the remaining data is sent using INCR burst type).
- Handles bus ERROR condition
- Inserts busy cycle when needed by the application
- Handles bus 1 KB boundary breaking

- Data bus and address bus (of the bus requester) are 32 bits wide. The USBC core generates transfer with HSIZE = 2 (DWORD) and 0 (BYTE).

Completer Bus Interface Unit (BIUS)

The bus completer interface unit converts bus cycles to CSR write/read, data FIFO read/write, and DFIFO push/pop signals. DFIFO read and write access is made available only for testing purposes. The read, write, push, and pop signals are active high for one clock.

The wait states for different accesses are:

- Zero wait states on writes to the CSR, except when the state machine is busy with a previous push to DFIFO or write data RAM
- Zero wait states on pushes to DFIFO, one additional wait state when the USB accesses the FIFO RAM
- Zero wait states on debug writes to DFIFO, one additional wait state when the USB accesses the FIFO RAM
- One wait state on reads to CSR registers
- One initial wait state on NSEQ pop access and no subsequent wait states on NSEQ/SEQ back-to-back pops to DFIFO; one additional wait state when the USB accesses the FIFO RAM.
- Two wait states on software debug reads to DFIFO, one additional wait state when the USB accesses the FIFO RAM (debug access to DFIFO is not optimized to save area)

The BIUS is:

- Fully AMBA 2.0 compliant bus completer with no restrictions
- Supports INCR4, INCR8, INCR16, INCR and SINGLE transfers
- Supports busy and early terminations
- CSR and DFIFO reads/writes must always be 32-bit; 8- and 16-bit write accesses commit unknown values to the DFIFO.
- Generates OKAY responses only
- Does not generate SPLIT, RETRY, or ERROR responses

To make the software transparent to the hardware implementation, one 4 KB region is mapped to each device endpoint or host channel. The controller has:

- One common Rx FIFO, used in host and device modes
- Separate IN endpoint transmit FIFO for each device mode IN endpoints in a dedicated transmit FIFO operation
- The FIFO SPRAM is also used for storing some register values to save gates. In scatter/gather DMA mode, four SPRAM locations (four 35-bit words) are reserved for this reason.
- In DMA mode, one SPRAM location (one 35-bit word) is used for storing the DMA address

Within the controller:

- Writes to any non-periodic IN endpoint or OUT channel are mapped to the non-periodic Tx FIFO

In device mode, a write access to an IN endpoint is mapped to the corresponding endpoint Tx FIFO. The USBC_CTL_IEP0_D[30:27] field maps an endpoint to a specific device periodic FIFO).

When USBC_CTL_IEP[n]_D.TXFNUM = 0, the endpoint is mapped to a common non-periodic Tx FIFO. Otherwise, it is mapped to the FIFO number selected by these fields. Hardware maintains the non-periodic Tx queue and host mode Tx periodic queues for internal operation. For debugging, software can read the top of the queue information. Because the read domain of these queues is in the PHY domain, no debug pop access is provided to these queues, saving area; access is provided only to the top of the queue.

NOTE: In device mode, each periodic IN endpoint has a separate buffer allocated, holding only one packet at a time. Therefore, there is no device mode periodic queue. Limiting to one packet shrinks the individual FIFO controller, saving area.

The ***Host FIFO Address Mapping*** figure shows FIFO mapping in host mode.

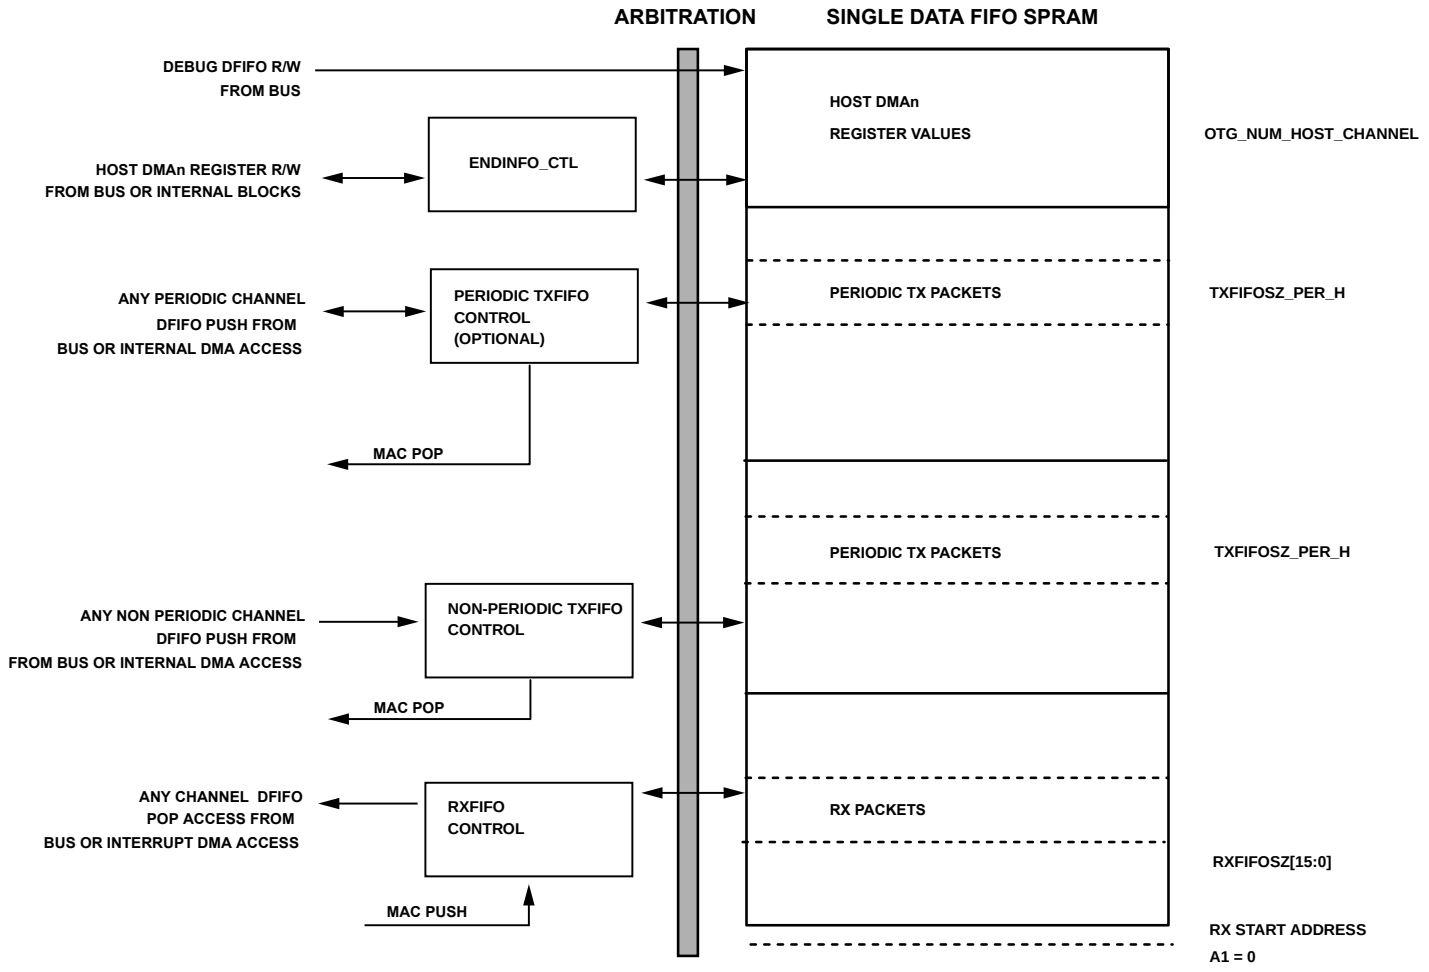

Figure 19-2: Host FIFO Address Mapping

The ***Device FIFO Address Mapping*** figure shows FIFO mapping in device mode.

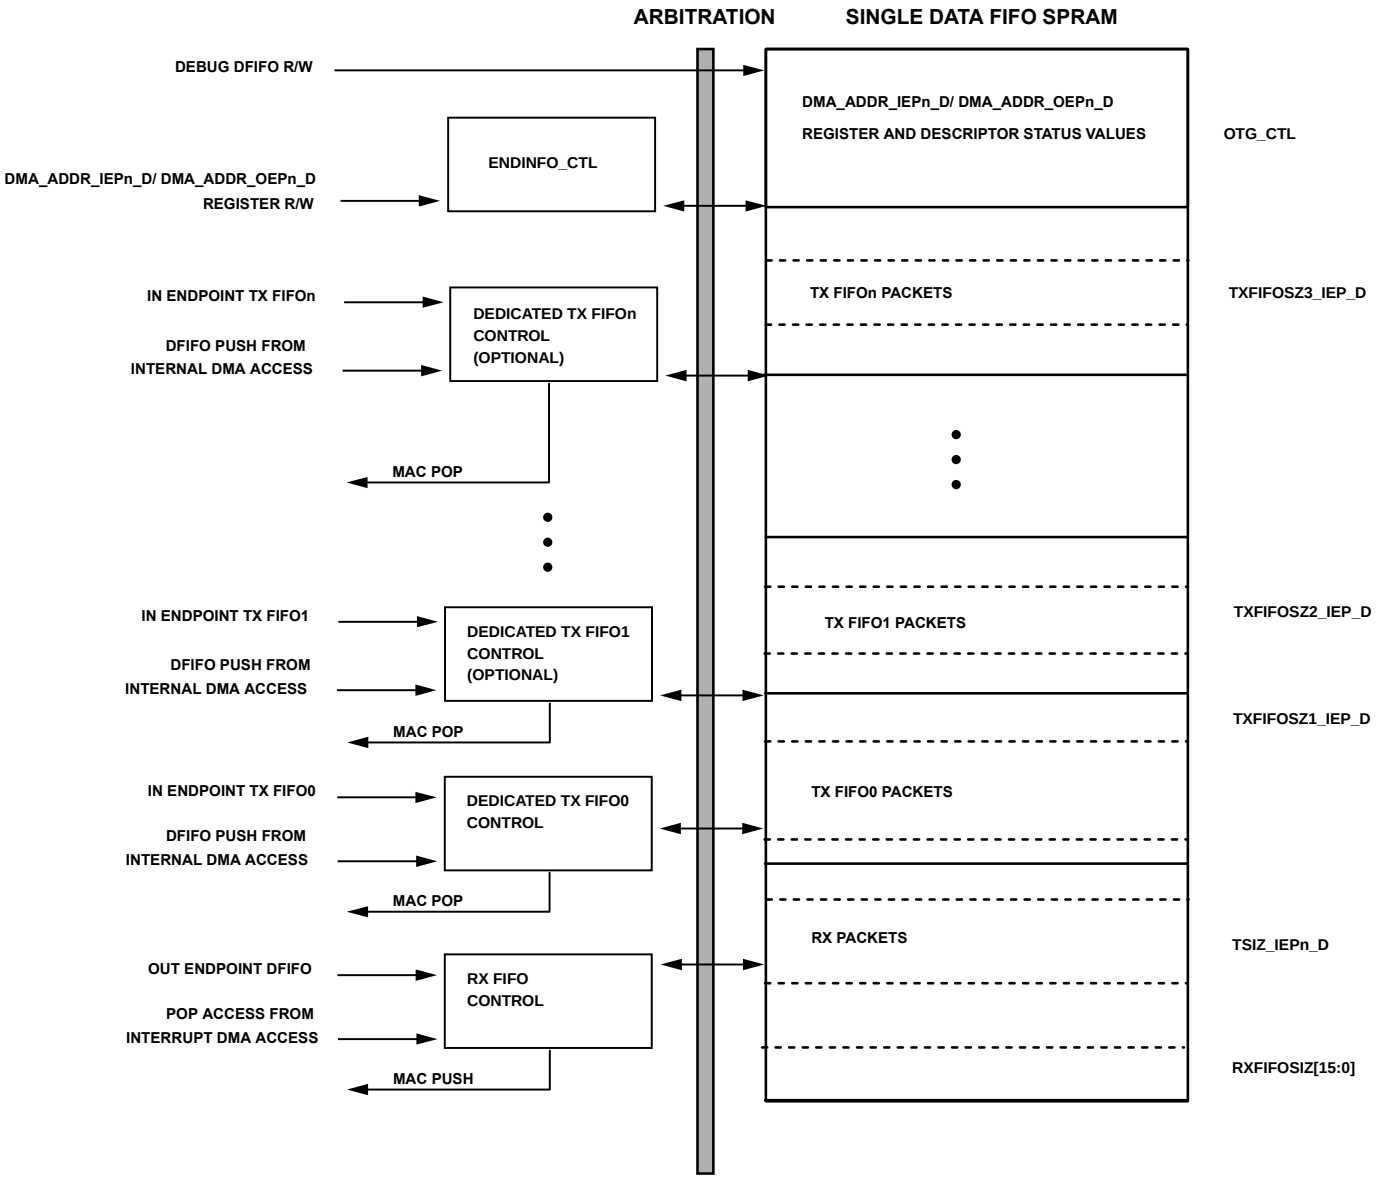

Figure 19-3: Device FIFO Address Mapping

Internal DMA Controller

The USB OTG provides an internal DMA mode of operation.The internal DMA controller has two modes of operation: buffer DMA mode and scatter/gather DMA mode.

The *USBC Internal DMA Control Block Diagram* shows the internal DMA controller mode.

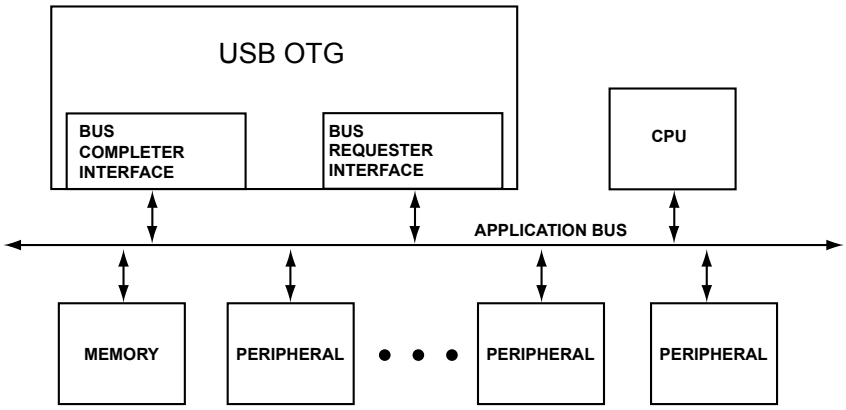

Figure 19-4: USBC Internal DMA Control Block Diagram

Host Architecture

The host uses one transmit FIFO for all non-periodic OUT transactions. The transmit FIFO is used as a transmit buffer to hold the data (payload of the transmit packet) to be transmitted over the USB port. The host pipes the USB transactions through request queues. Each entry in the request queue holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written into the queue determines the sequence of transactions on the USB. The host processes the non-periodic request queue, at the beginning of each (micro) frame.

The host uses one receive FIFO for all non-periodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to system memory. The status of each packet received also goes into the FIFO. The status entry holds the IN channel number (along with other information such as received byte count and validity status) to perform a transaction on the bus.

The ***System Level Host BIU Block Diagram*** shows the bus interface architecture of the USB OTG controller in host mode.

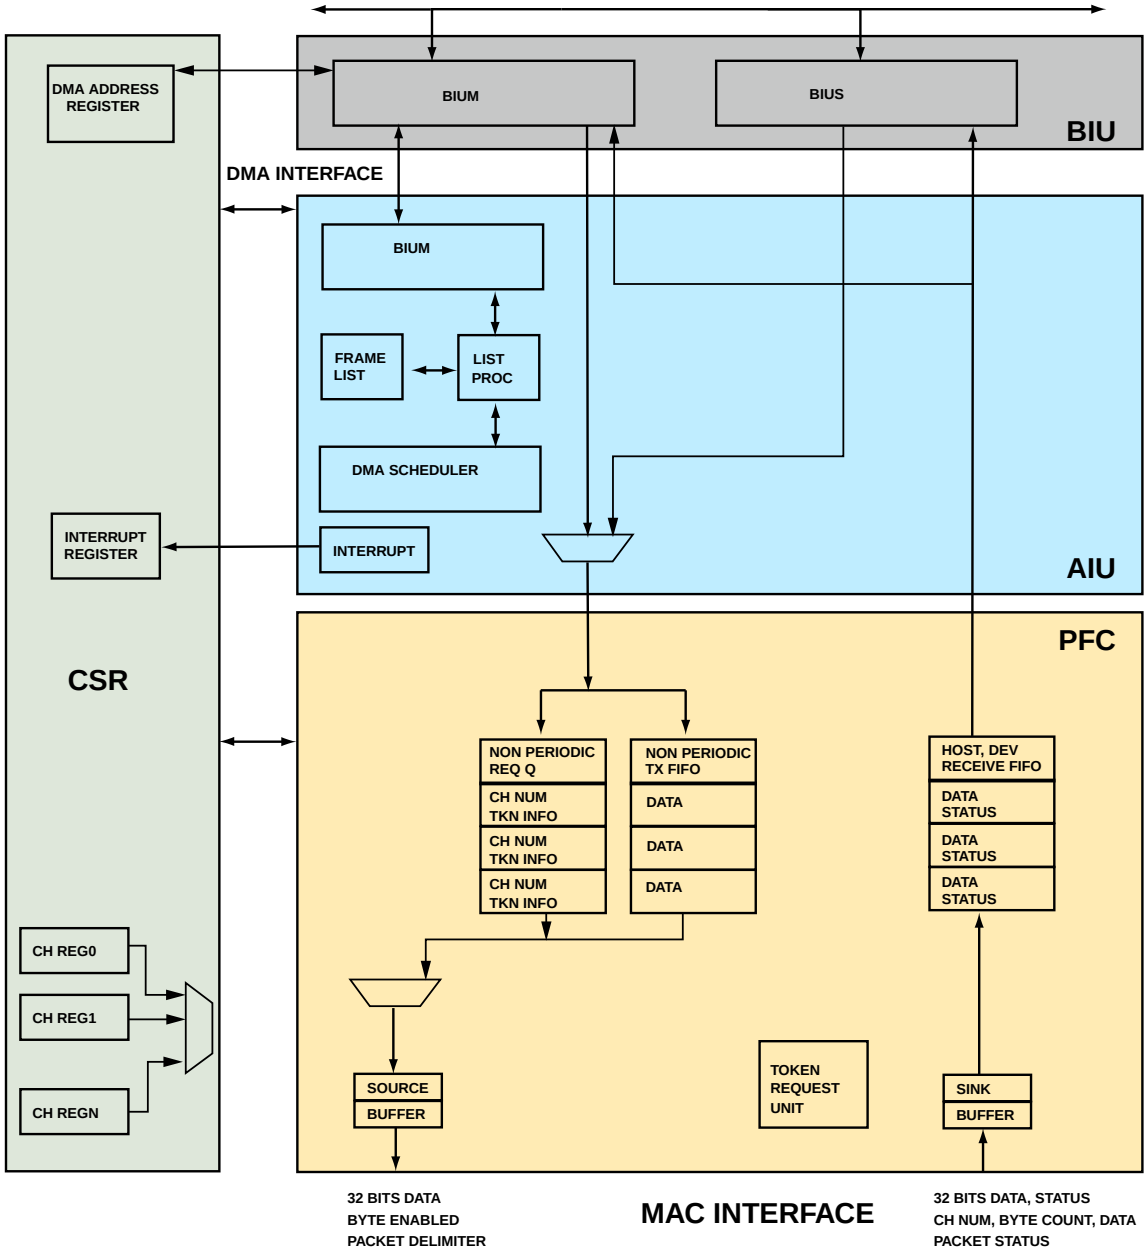

Figure 19-5: System Level Host BIU Block Diagram

Device Architecture

In device mode, the USB OTG core uses a dedicated transmit FIFO operation or a single receive FIFO. The ***System Level Device BIU Block Diagram*** shows the bus interface architecture of the USB OTG controller in device mode.

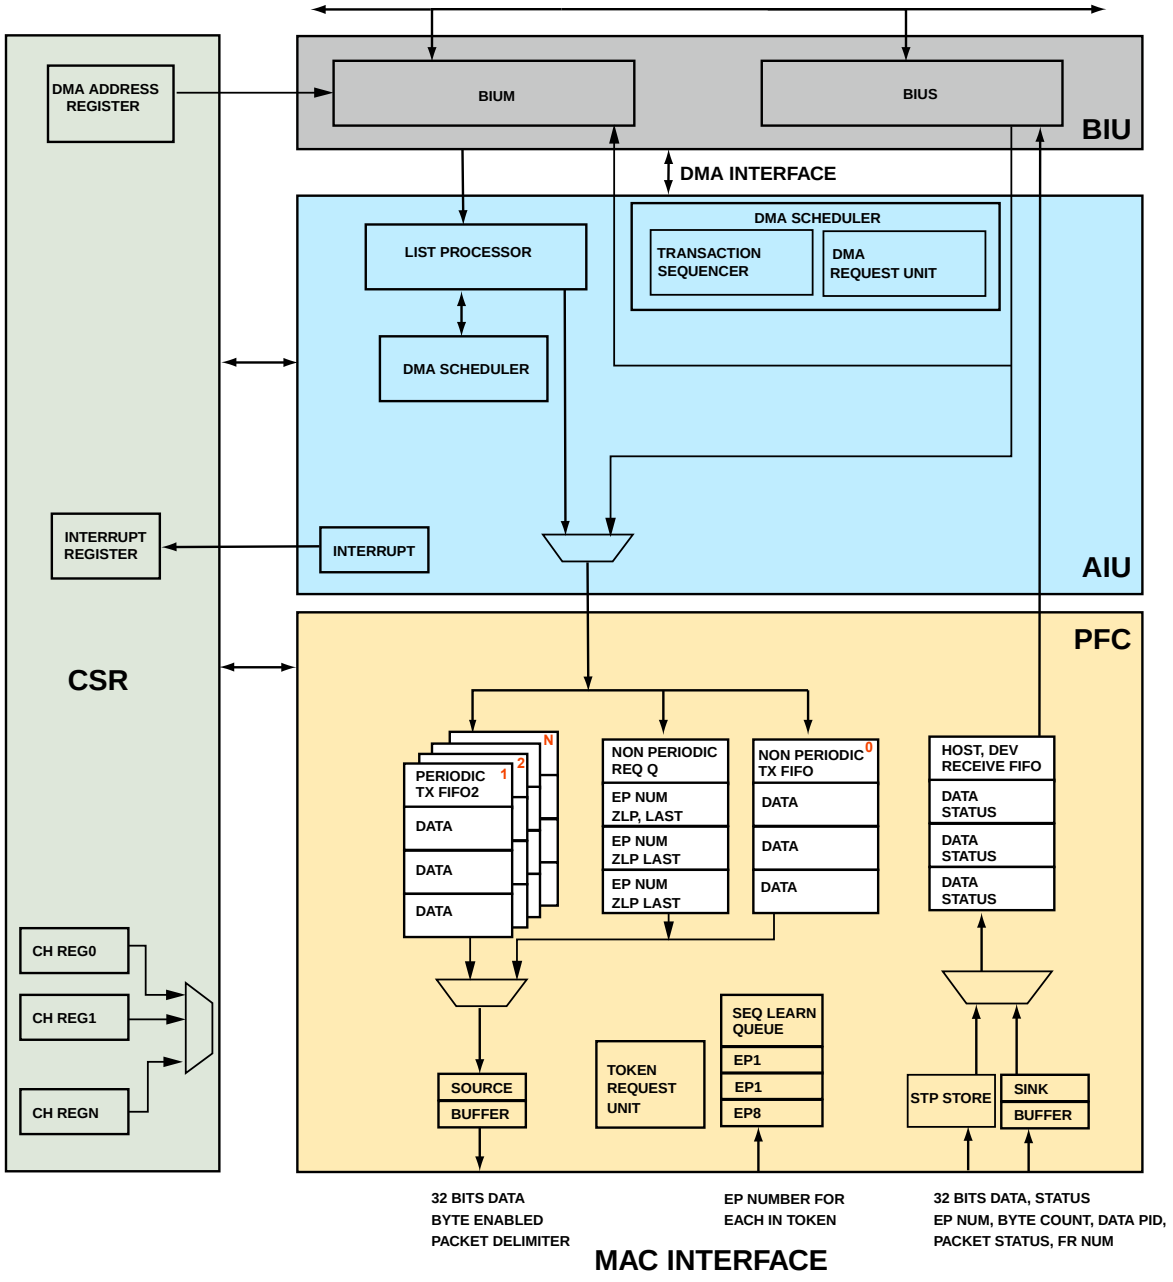

Figure 19-6: System Level Device BIU Block Diagram

Dedicated Transmit FIFO Operation

In a dedicated transmit FIFO operation, the USB OTG core uses individual transmit FIFOs for each IN endpoint. The core also supports thresholding in the transmit and receive directions when DMA mode is selected. For transmit mode, there are separate controls to enable thresholding for isochronous and non-isochronous transfers. Support is also provided for two different threshold values for the bus and the MAC on the transmit side.

When thresholding is enabled, the core can be configured to have a less-than-one packet sized FIFO. The core internally handles an underrun condition during transmit and corrupts the packet (inverts the CRC) on the USB.

During a receive operation with thresholding, when a packet ends up in a FIFO overflow condition, the core NAKs the OUT packet and internally rewinds the pointers. When thresholding is enabled, the best practice is to have a FIFO size two times the threshold value. If packet transmission results in an underrun condition (eventually resulting in packet corruption on the USB), the host can time out the endpoint after three consecutive errors.

Single Receive FIFO Operation

The OTG device uses a single receive FIFO to receive data for all the OUT endpoints. The receive FIFO holds the status of the received data packet, such as byte count, data PID, and the validity of the received data. The DMA or the application reads the data out of the receive FIFO as it is received.

Control and Status Registers (CSR)

The CSR block resides in the bus clock domain and contains all registers except the power and clock gating control register (`USBC_PWR_CTL`) and the core interrupt register (`USBC_ISTAT`[31:29]). These register bits must be active in power down mode, and hence are implemented in the BIUS module. The bus completer interface unit can write and read registers, and the core can set or reset the interrupt and status bits. The interrupts have priority over bus completer interface updates. For example, when a bus completer interface access tries to clear an interrupt bit when the core is setting the same interrupt bit, the interrupt bit is set and the bus write to that bit is ignored.

Because the core does not check byte enables, all register accesses are 32 bits.

Even though bus completer writes have only the granularity of byte writes, each interrupt bit in an interrupt register is controlled separately. Thus, the bus completer interface can clear an interrupt bit when the core is setting a different interrupt bit, but no read modify byte write (which could cause erroneous interrupt behaviors) is performed.

All implemented registers are 32 bits wide, and only those registers required by the configuration are implemented. For example, when the core is configured for only two endpoints, then registers corresponding to endpoints 3–15 are not implemented. In addition, because the core can be only be either in host or device mode at a given time, the host and device registers use the same physical registers to save area. Writes to unimplemented registers are ignored and reads from them return an unknown value. Cycles complete gracefully with an OK response. When device mode registers are accessed during host mode and conversely, the mode mismatch interrupt (`USBC_ISTAT.MODEMIS`) is set, write data is ignored, and read data returns an unknown value.

Application Interface Unit (AIU)

The application Interface Unit (AIU) consists of the following interfaces:

- Bus requester
- Bus completer
- Packet FIFO ontroller
- Control and status registers

The AIU is responsible for the following functions.

- Generating and writing the delimiter (byte enables and last DWORD indicator) into the transmit FIFOs (based on FIFO number) for transmit packets in device (IN) and host (OUT) modes
- Writing a token into the request queue (periodic/non-periodic) for transmit transactions in device and host modes
- Writing a token into the request queue for receive (IN) transactions (only in host mode)
- Selecting the periodic or non-periodic request queue based on the type of transaction. When the channel or endpoint type indicates a periodic transaction, the periodic queue is selected.
- Generating interrupts for both transmit and receiving operations in device and host modes
- Address decoding for selecting the appropriate transmit FIFOs and queues
- Generating DMA interface signals to access an internal DMA controller for data transfer
- Round-robin arbitration among periodic and non-periodic channels and endpoints. Higher priority is always given to periodic channels or endpoints .
- Transmit/receive threshold handling (when transmit thresholding is enabled)
- Rewinding logic for DMA address and transfer size during an underrun or overflow condition (when thresholding is enabled)

DMA Scheduler (DSCH)

The DSCH is responsible for interfacing to an internal DMA. It controls the transfer of data packets between the system memory and the OTG core.

The DMA scheduler includes the following:

- *Arbiter* – This logic provides the sequence in which the channels/endpoints are to be processed in DMA mode. In host mode, the arbiter provides round-robin arbitration among periodic and non-periodic channels. Periodic channels are processed with higher priority.

  In device mode, when a threshold is enabled, the priority is as follows:

  1. Any transmit endpoint which is active on the USB
  2. Any receive data in a receive FIFO
  3. Round-robin arbitration on periodic transmit endpoints
  4. Round-robin arbitration on non-periodic transmit endpoints. In device mode when thresholding is not enabled, round robin arbitration is used for periodic and non-periodic IN endpoints with priority given to periodic IN endpoints.

- *DMA Request State Machine* – The state machine is responsible for the following:
  - Requesting the internal DMA for data fetch (from system memory to transmit FIFO, one maximum packet size or last packet size at a time)

- Writing the OUT request token into the request queue at the end of data fetch in host mode.
- Writing the IN request token into the request queue in host mode
- Requesting the internal DMA for data update (from the receive FIFO to system memory, one maximum packet size or last packet size at a time)
- Writing the request queue for ping, complete split, zero-length packet, or disable channel requests for the host

Periodic FIFO Control (PFC)

The PFC includes periodic and non-periodic transmit FIFOs and an endpoint information controller.

Periodic Transmit Data FIFO

The periodic transmit data FIFO stores periodic transmit data. There are different periodic FIFO structures in device and host modes.

Device Mode

There are no periodic or non-periodic FIFOs. FIFOs are implemented based on the number of IN endpoints and the application chooses a specific FIFO for an IN endpoint when enabling an endpoint. The following periodic IN endpoint characteristics remain valid in a dedicated transmit FIFO operation:

- The BIUS or the DMA interface unit writes data into a dedicated FIFO; the MAC reads the data from it.
- Each FIFO holds data for a single periodic IN endpoint. For high-bandwidth endpoints, this FIFO can hold in a single micro frame only the data to be transmitted, which can be no more than three maximum-packet-size packets.
- A whole packet must be in the FIFO before it can be transmitted on the USB, when thresholding is not enabled.
- When thresholding is enabled, the core starts transmitting on the USB in response to an IN token, when there is at least one MAC threshold amount of data available in the FIFO. For high-bandwidth periodic IN endpoints, the core can transmit one packet that is already available in the FIFO, while a second packet is being pushed into the FIFO.

Host Mode

Host mode periodic OUT transfers are not supported.

Non-Periodic Transmit Data FIFO

The non-periodic transmit data FIFO stores the data to be transmitted on all non-periodic IN endpoints in device mode and OUT channels in host mode. A non-periodic request queue associated with this FIFO stores endpoint or channel-related information.

- The BIUS or the DMA interface unit writes data to this FIFO; the MAC reads this data from it.

- In device mode, for each data packet in the data FIFO, there is a corresponding endpoint number and IN data packet type information entry in the request queue.
- In host mode, for each data packet in the data FIFO, there is a corresponding channel number and token-related control information entry in the request queue.
- The request queue also holds IN token entries in host mode (even though there is no associated data in the data FIFO).
- The depth of the non-periodic request queue is eight packets; it is implemented using flip-flops.
- Since dynamic FIFO sizing is enabled, the data FIFO RAM size and start address must be programmed in the CSRs.
- The data FIFO is 35 bits wide:
    - Bits [34:32]: A 4-bit byte enable, and a 1-bit packet delimiter are encoded into 3 bits and stored in external RAM. This reduces the data width in the external data RAM.
    - Encoding is as follows:
        - 3'b100: Last DWORD of the packet, all 4 bytes are valid
        - 3'b011: Last DWORD of the packet, bytes 0, 1, and 2 are valid
        - 3'b010: Last DWORD of the packet, bytes 0, and 1 are valid
        - 3'b001: Last DWORD of the packet, only byte 0 is valid
        - 3'b111: Non-last DWORD of a packet, all 4 bytes are valid
- Bits [31:0]: Data
- The request queue is 7 bits wide:
    - Host Mode:
        - Bits [6:3]: Channel number
        - Bits [2:0]: Token-related control information
    - Device Mode:
        - Bits [6:3]: IN endpoint number
        - Bit [2]: Not used
        - Bit [1]: Indicates a zero-length data packet
        - Bit [0]: Not used

Dedicated Transmit FIFO Operation

In host mode, the FIFO architecture is the same as in non-periodic transmit FIFO operation.

In device mode, there are no periodic or non-periodic FIFOs. FIFOs are implemented based on the number of IN endpoints (OTG_NUM_IN_EPS) (`USBC_HWCFG2.NDEVEPS`), and the application chooses a specific FIFO for an IN endpoint when it enables an endpoint. The following non-periodic IN endpoint characteristics remain valid in dedicated transmit FIFO mode:

- There are no queues associated with device mode FIFOs.
- If dynamic FIFO sizing is enabled, the data FIFO RAM size and the start address must be programmed in the CSRs
- The data FIFO is 35 bits wide. Bits 31:0 are data, and bits 34:32 are byte enables and packet delimiter encoding.

  Bits 34:32 are decoded below:

  - 3'b100 - Last DWORD of the packet, all 4 bytes valid
  - 3'b011 - Last DWORD of the packet, bytes 0, 1, 2 valid
  - 3'b010 - Last DWORD of the packet, bytes 0, 1 are valid
  - 3'b001 - Last DWORD of the packet, only byte 0 is valid
  - 3'b111 - Non last DWORD of a packet, all 4 bytes valid. 4-bit byte enables and 1-bit packet delimiter are encoded into 3 bits before storing into the external RAM. This reduces the data width in the external data RAM .

Receive Data FIFO

This FIFO stores data and status received on all OUT endpoints in device mode and all IN endpoints in host mode.

- The MAC writes data into this FIFO, and the BIUS or DMA interface unit reads this data from it.
- This FIFO can hold multiple OUT packets belonging to different endpoints or channels
- For each data OUT packet received on the USB, there is an associated status that indicates the byte count, packet status, and endpoint or channel number of the received packet.
- Data packets received with errors are flushed, so the BIUS and DMA interface unit never receive a corrupted data packet.
- Setup data packets received by the MAC in device mode are also written to the receive FIFO.
- Space is reserved in the receive data FIFO to store setup packets and related status information, based on the control endpoint supported by the device. The core never uses this reserved space to store any other type of data. This ensures that there is always enough space in the receive data FIFO to store setup data packets.
- If the device supports n endpoints, (4 * n + 6) DWORDs of space are allocated for receiving setup data packets. The extra 6 DWORDs are allocated to accommodate any back-to-back setup data packets sent by the USB host.
- The data FIFO is 35 bits wide:

- Bits [34:32]: Unused
- Bits [31:0]: data word
- Device mode status:
  - Bits [24:21]: 4 LSBs of the frame number in which the packet was received
  - Bits [20:17]: Packet status
  - Bits [16:15]: Data PID
  - Bits [14:4]: Byte count
  - Bits [3:0]: Endpoint number
- Host mode status:
  - Bits [20:17]: Packet status
  - Bits [16:15]: Data PID
  - Bits [14:4]: Byte count
  - Bits [3:0]: Channel number

Endpoint Information Controller (EPINFO_CTL)

The EPINFO_CTL manages the stored values in the last few locations of the SPRAM. The SPRAM Allocation table shows the space allocated for scatter/gather DMA.

Table 19-3: SPRAM Allocation

Mode	SPRAM Space Allocation (EP_LOC_CNT)
Host	Four locations per channel are used in SPRAM to store the base descriptor address, current descriptor address, current buffer pointer, and the status quadlet. For example, if there are ten channels, the last forty locations are reserved for storing these values.
Device	Four locations per endpoint direction are used in SPRAM to store the base descriptor address, current descriptor address, current buffer pointer and the status quadlet. The application writes data to the base descriptor address. When the application reads the location where it wrote the base descriptor address, it receives the current descriptor address. For example, if there are ten bidirectional endpoints, the last 80 locations are reserved for storing these values.

Media Access Controller (MAC)

The Media Access Controller (MAC) module handles USB transactions, and device, host, and OTG protocols. This section discusses the MAC components, transaction and protocol handling.

MAC Components

The *MAC Block Diagram* shows the major MAC module components.

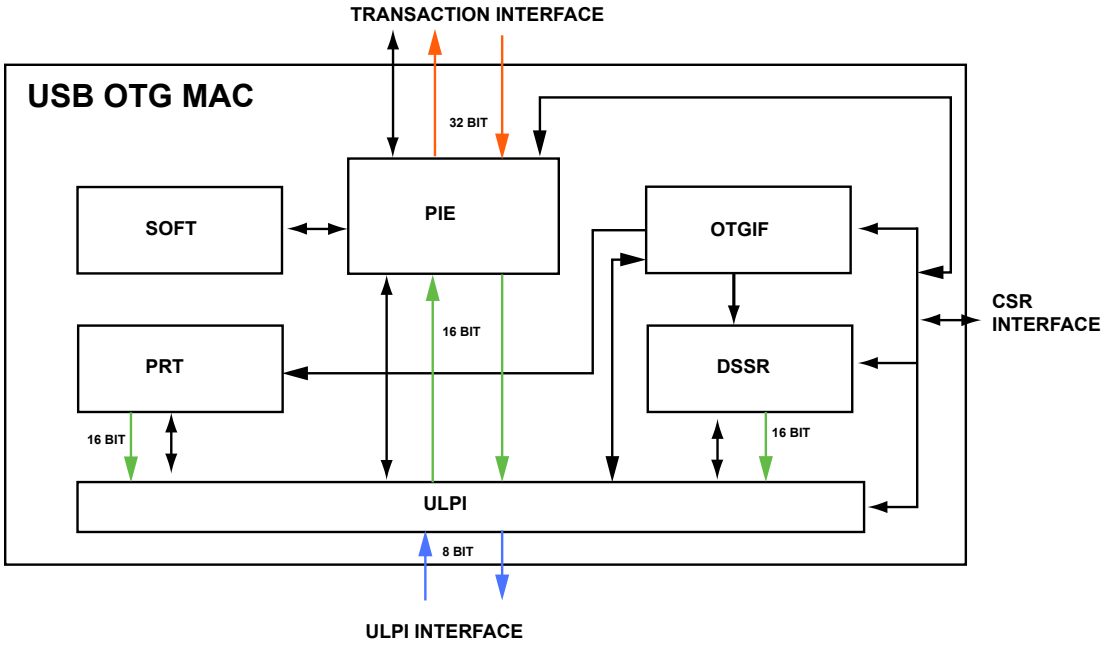

Figure 19-7: MAC Block Diagram

The MAC major blocks include

- *Device Speed enumeration, Suspend, and Resume block (DSSR)* – This block performs the speed enumeration, suspend, resume and remote wakeup functions. The DSSR block is only active in device mode.
- *Parallel Interface Engine (PIE)* –This block is responsible for token, data, and handshake packet generation and reception, and PID and CRC checking and generation. It generates handshake and data packets based on data integrity and on CSR control and FIFO status information. The PIE also handles the data transfer to and from the FIFO, and the status update to the PFC and AIU.
- *SOF tracker (SOFT)* – This block tracks SOF packets and generates SOF interrupts in device mode. It handles missing SOFs and delayed SOFs to keep the frame number synchronization between the host and the device.
- *Port (PRT)* – The port block is only active in host mode. It is responsible for connect and disconnect detection, USB reset and speed enumeration, suspend and resume generation, remote wakeup detection, SOF generation, and high-speed test mode handling.
- *OTG Interface (OTGIF)* – The OTG interface block handles SRP and HNP. These OTG protocols are implemented either through the regular ULPI interface or the I^2C interface (for USB 1.1 serial transceivers only).
- *ULPI Interface* – The block converts data widths for the 8-bit PHY interface and multiplexes output signals to the PHY from multiple blocks.

USB Transaction Handling

The USB handles transactions differently in device and host modes.

Device Mode

In device mode, the MAC decodes and checks the integrity of token packets as it receives them from the host. If the received token is a valid OUT or setup token, the MAC waits and checks the PID of the following data packet. It then writes the data to the Rx FIFO (when it is available). After the packet is completed, the MAC checks the data integrity, sends the appropriate handshake when required to the host, and writes the transaction status to the receiving status queue. If the OUT token is received and the Rx FIFO is not available, the MAC sends the host a NAK handshake. If the received token is a valid ping token, the MAC sends the appropriate handshake, based on the FIFO status and CSR control information. If an IN token is received and the data is available in the FIFO, the MAC reads the data, builds the data packet and sends it. It waits for a handshake packet, if any, from the host, and then updates the transaction status to the PFC. If an IN token is received and the data is not available in the FIFO, the MAC sends the host a NAK handshake.

Host Mode

In host mode, the MAC receives a token request from the AIU to start a USB transaction. After receiving a token request, the MAC builds and sends the requested token packet. For OUT or setup transactions, the MAC reads data from the Tx FIFO, builds and sends a data packet. It waits for a handshake packet, if any, from the device, and updates the transaction status to the AIU. For an IN or ping transaction, the MAC waits for a data or handshake packet from the device. If it receives a handshake packet, the MAC updates the status to the AIU. If it receives a data packet with the correct PID, the MAC writes the data into the Rx FIFO, checks the integrity of the data, sends a handshake packet, when required, to the device, then updates the status to the AIU.

Host Protocol Handling

In host mode, the MAC detects the device connect and disconnect, handles the USB reset and speed enumeration process, initiates USB suspend and resume, detects remote wakeup, generates SOF packets, and handles high-speed test modes.

Device Protocol Handling

In device mode, the MAC handles the USB reset sequence and speed enumeration process to determine the USB operating speed. The MAC detects USB suspend and resume signaling from the host, initiates remote wakeup, handles soft connect and disconnect, decodes and tracks SOF packets, and handles high-speed test modes.

OTP Protocol Handling

The MAC handles Host Negotiation Protocol (HNP) for host and peripheral role swapping. It handles the Session Request Protocol (SRP), which allows an A-device to turn off VBUS to save power when the USB bus is used. It also provides a means for a B-device to request the A-device to activate VBUS.

ADSP-2159x_SC591_SC592_SC594 USBC Register Descriptions

USB Controller (USBC) contains the following registers.

Table 19-4: ADSP-2159x_SC591_SC592_SC594 USBC Register List

Name	Description
USBC_ISTAT_D	Device All Endpoint Interrupt Status Register
USBC_IMSK_D	Device All Endpoint Interrupt Mask Register
USBC_CFG_D	Device Configuration Register
USBC_CTL_D	Device Control Register

Device All Endpoint Interrupt Status Register

When a significant event occurs on an endpoint, the `USBC_ISTAT_D` register interrupts the application using the `USBC_ISTAT.OEPINT` or `USBC_ISTAT.IEPINT` register. There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used.

Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint n Interrupt register (`USBC_ISTAT_IEP[n]_D`/ `USBC_ISTAT_OEP[n]_D`).

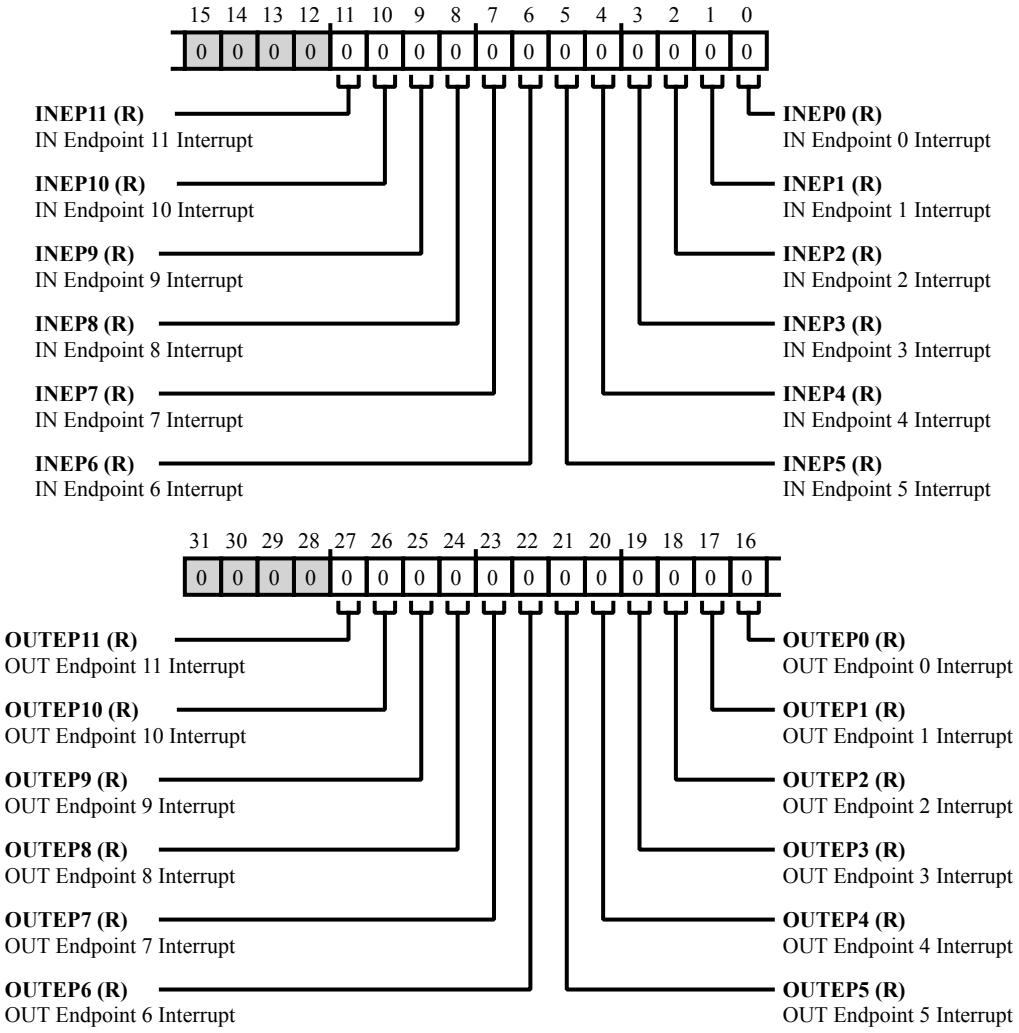

Figure 19-8: USBC_ISTAT_D Register Diagram

Table 19-5: USBC_ISTAT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/NW)	OUTEP11	OUT Endpoint 11 Interrupt. The `USBC_ISTAT_D.OUTEP11` bit enables the interrupt request for the OUT endpoint.
26 (R/NW)	OUTEP10	OUT Endpoint 10 Interrupt. The `USBC_ISTAT_D.OUTEP10` bit enables the interrupt request for the OUT endpoint.
25 (R/NW)	OUTEP9	OUT Endpoint 9 Interrupt. The `USBC_ISTAT_D.OUTEP9` bit enables the interrupt request for the OUT endpoint.
24 (R/NW)	OUTEP8	OUT Endpoint 8 Interrupt. The `USBC_ISTAT_D.OUTEP8` bit enables the interrupt request for the OUT endpoint.
23 (R/NW)	OUTEP7	OUT Endpoint 7 Interrupt. The `USBC_ISTAT_D.OUTEP7` bit enables the interrupt request for the OUT endpoint.
22 (R/NW)	OUTEP6	OUT Endpoint 6 Interrupt. The `USBC_ISTAT_D.OUTEP6` bit enables the interrupt request for the OUT endpoint.
21 (R/NW)	OUTEP5	OUT Endpoint 5 Interrupt. The `USBC_ISTAT_D.OUTEP5` bit enables the interrupt request for the OUT endpoint.
20 (R/NW)	OUTEP4	OUT Endpoint 4 Interrupt. The `USBC_ISTAT_D.OUTEP4` bit enables the interrupt request for the OUT endpoint.
19 (R/NW)	OUTEP3	OUT Endpoint 3 Interrupt. The `USBC_ISTAT_D.OUTEP3` bit enables the interrupt request for the OUT endpoint.
18 (R/NW)	OUTEP2	OUT Endpoint 2 Interrupt. The `USBC_ISTAT_D.OUTEP2` bit enables the interrupt request for the OUT endpoint.
17 (R/NW)	OUTEP1	OUT Endpoint 1 Interrupt. The `USBC_ISTAT_D.OUTEP1` bit enables the interrupt request for the OUT endpoint.
16 (R/NW)	OUTEP0	OUT Endpoint 0 Interrupt. The `USBC_ISTAT_D.OUTEP0` bit enables the interrupt request for the OUT endpoint.

Table 19-5: USBC_ISTAT_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	INEP11	IN Endpoint 11 Interrupt. The `USBC_ISTAT_D.INEP11` bit enables the interrupt request for the IN endpoint.
10 (R/NW)	INEP10	IN Endpoint 10 Interrupt. The `USBC_ISTAT_D.INEP10` bit enables the interrupt request for the IN endpoint.
9 (R/NW)	INEP9	IN Endpoint 9 Interrupt. The `USBC_ISTAT_D.INEP9` bit enables the interrupt request for the IN endpoint.
8 (R/NW)	INEP8	IN Endpoint 8 Interrupt. The `USBC_ISTAT_D.INEP8` bit enables the interrupt request for the IN endpoint.
7 (R/NW)	INEP7	IN Endpoint 7 Interrupt. The `USBC_ISTAT_D.INEP7` bit enables the interrupt request for the IN endpoint.
6 (R/NW)	INEP6	IN Endpoint 6 Interrupt. The `USBC_ISTAT_D.INEP6` bit enables the interrupt request for the IN endpoint.
5 (R/NW)	INEP5	IN Endpoint 5 Interrupt. The `USBC_ISTAT_D.INEP5` bit enables the interrupt request for the IN endpoint.
4 (R/NW)	INEP4	IN Endpoint 4 Interrupt. The `USBC_ISTAT_D.INEP4` bit enables the interrupt request for the IN endpoint.
3 (R/NW)	INEP3	IN Endpoint 3 Interrupt. The `USBC_ISTAT_D.INEP3` bit enables the interrupt request for the IN endpoint.
2 (R/NW)	INEP2	IN Endpoint 2 Interrupt. The `USBC_ISTAT_D.INEP2` bit enables the interrupt request for the IN endpoint.
1 (R/NW)	INEP1	IN Endpoint 1 Interrupt. The `USBC_ISTAT_D.INEP1` bit enables the interrupt request for the IN endpoint.
0 (R/NW)	INEP0	IN Endpoint 0 Interrupt. The `USBC_ISTAT_D.INEP0` bit enables the interrupt request for the IN endpoint.

Device All Endpoint Interrupt Mask Register

The USBC_IMSK_D register works with the USBC_ISTAT_D register to interrupt the application when an event occurs on a device endpoint. However, the USBC_ISTAT_D register bit that corresponds to the interrupt is still set.

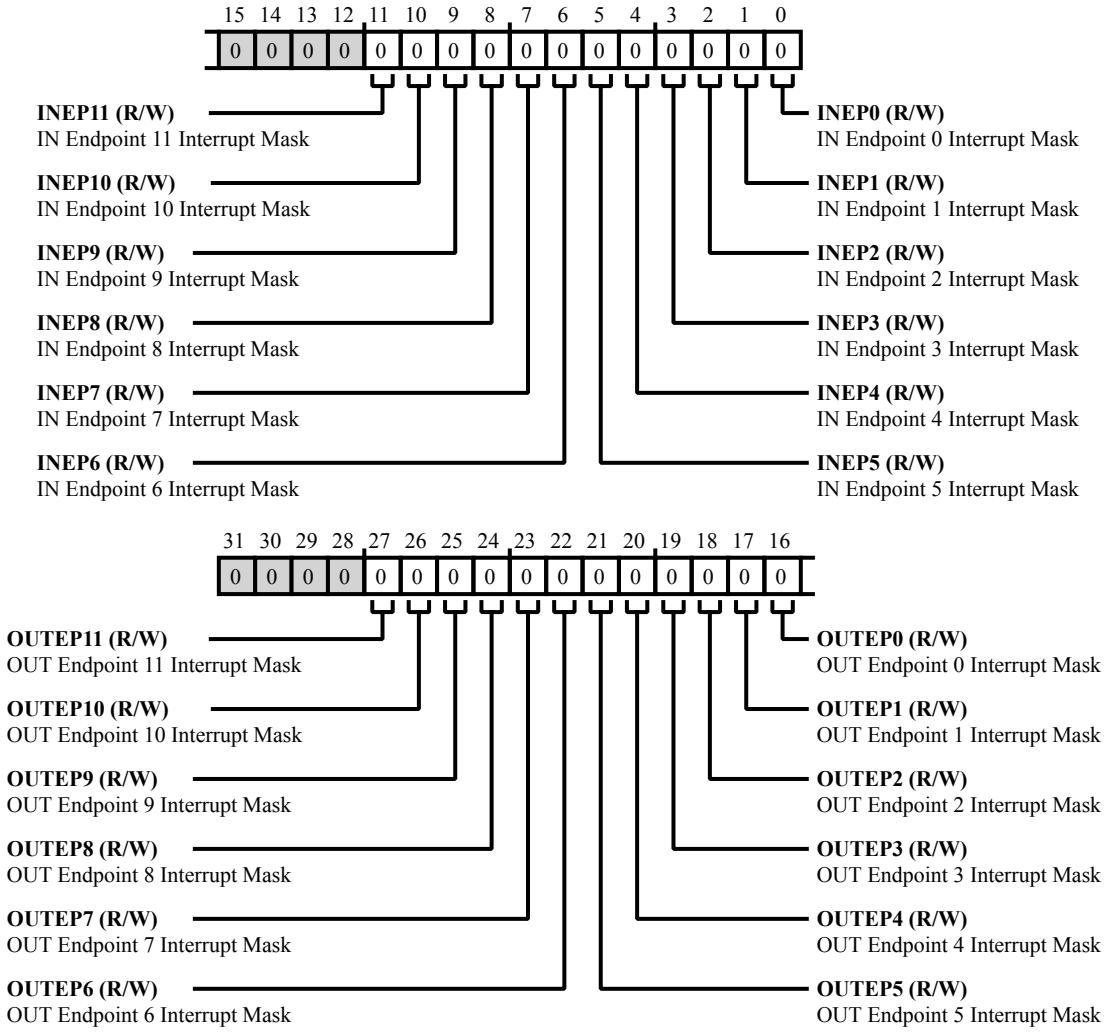

Figure 19-9: USBC_IMSK_D Register Diagram

Table 19-6: USBC_IMSK_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W)	OUTEP11	OUT Endpoint 11 Interrupt Mask. The USBC_IMSK_D.OUTEP11 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.

Table 19-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	OUTEP10	OUT Endpoint 10 Interrupt Mask. The USBC_IMSK_D.OUTEP10 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
25 (R/W)	OUTEP9	OUT Endpoint 9 Interrupt Mask. The USBC_IMSK_D.OUTEP9 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
24 (R/W)	OUTEP8	OUT Endpoint 8 Interrupt Mask. The USBC_IMSK_D.OUTEP8 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
23 (R/W)	OUTEP7	OUT Endpoint 7 Interrupt Mask. The USBC_IMSK_D.OUTEP7 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
22 (R/W)	OUTEP6	OUT Endpoint 6 Interrupt Mask. The USBC_IMSK_D.OUTEP6 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
21 (R/W)	OUTEP5	OUT Endpoint 5 Interrupt Mask. The USBC_IMSK_D.OUTEP5 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
20 (R/W)	OUTEP4	OUT Endpoint 4 Interrupt Mask. The USBC_IMSK_D.OUTEP4 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
19 (R/W)	OUTEP3	OUT Endpoint 3 Interrupt Mask. The USBC_IMSK_D.OUTEP3 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
18 (R/W)	OUTEP2	OUT Endpoint 2 Interrupt Mask. The USBC_IMSK_D.OUTEP2 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
17 (R/W)	OUTEP1	OUT Endpoint 1 Interrupt Mask. The USBC_IMSK_D.OUTEP1 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
16 (R/W)	OUTEP0	OUT Endpoint 0 Interrupt Mask. The USBC_IMSK_D.OUTEP0 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.

Table 19-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	INEP11	IN Endpoint 11 Interrupt Mask. The `USBC_IMSK_D.INEP11` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
10 (R/W)	INEP10	IN Endpoint 10 Interrupt Mask. The `USBC_IMSK_D.INEP10` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
9 (R/W)	INEP9	IN Endpoint 9 Interrupt Mask. The `USBC_IMSK_D.INEP9`bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
8 (R/W)	INEP8	IN Endpoint 8 Interrupt Mask. The `USBC_IMSK_D.INEP8`bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
7 (R/W)	INEP7	IN Endpoint 7 Interrupt Mask. The `USBC_IMSK_D.INEP7` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
6 (R/W)	INEP6	IN Endpoint 6 Interrupt Mask. The `USBC_IMSK_D.INEP6` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
5 (R/W)	INEP5	IN Endpoint 5 Interrupt Mask. The `USBC_IMSK_D.INEP5` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
4 (R/W)	INEP4	IN Endpoint 4 Interrupt Mask. The `USBC_IMSK_D.INEP4` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
3 (R/W)	INEP3	IN Endpoint 3 Interrupt Mask. The `USBC_IMSK_D.INEP3` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
2 (R/W)	INEP2	IN Endpoint 2 Interrupt Mask. The `USBC_IMSK_D.INEP2` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
1 (R/W)	INEP1	IN Endpoint 1 Interrupt Mask. The `USBC_IMSK_D.INEP1` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.

Table 19-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	INEP0	IN Endpoint 0 Interrupt Mask. The `USBC_IMSK_D.INEP0` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.

Device Configuration Register

The USBC_CFG_D register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

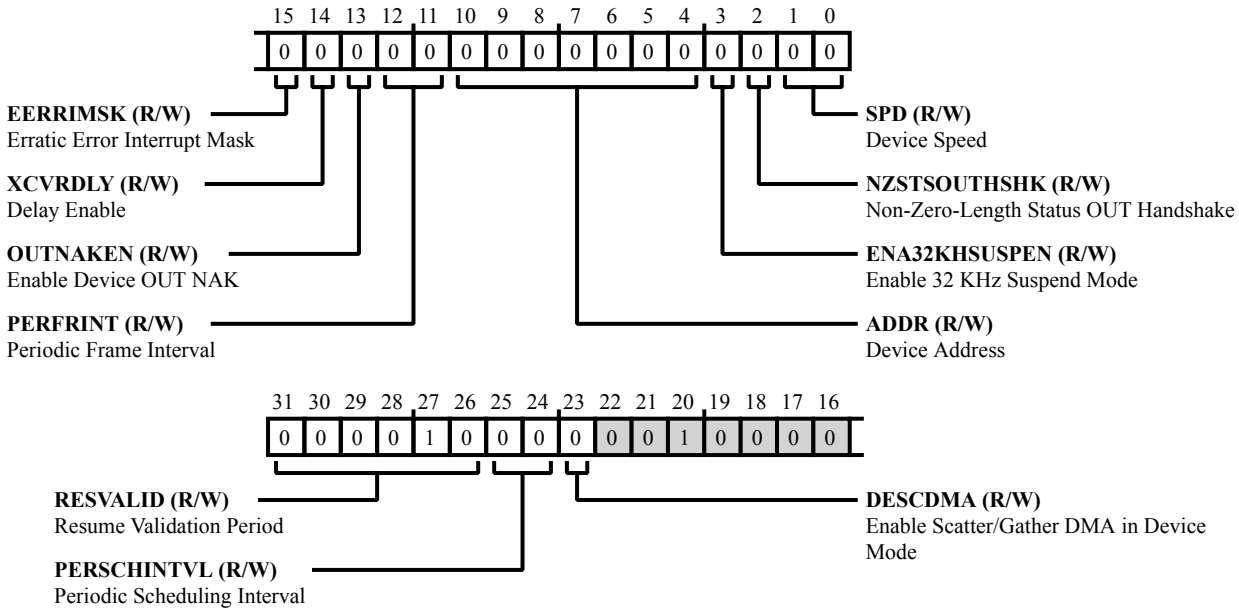

Figure 19-10: USBC_CFG_D Register Diagram

Table 19-7: USBC_CFG_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:26 (R/W)	RESVALID	Resume Validation Period. The USBC_CFG_D.RESVALID field controls the resume period when the core resumes after suspend. The core counts for USBC_CFG_D.RESVALID clock cycles to detect a valid resume. The USBC_CFG_D.RESVALID field is effective only when USBC_CFG_D.ENA32KHSUSPEN is set.

Table 19-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	PERSCHINTVL	Periodic Scheduling Interval. The USBC_CFG_D.PERSCHINTVL field must be programmed for scatter/gather DMA mode. The USBC_CFG_D.PERSCHINTVL field specifies the amount of time the internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50, or 75% of (micro)frame. When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data. When no periodic endpoints are active, the internal DMA engine services the non-periodic endpoints and ignores this field. After the specified time within a (micro)frame, the DMA switches to fetching for non-periodic endpoints.	
		0	25% of microframe
		1	50% of microframe
		2	75% of microframe
		3	Reserved
23 (R/W)	DESCDMA	Enable Scatter/Gather DMA in Device Mode. When the scatter/gather DMA option is selected during configuration, the application can set the USBC_CFG_D.DESCDMA bit during initialization to enable the scatter/gather DMA operation. Note: This bit must be modified only once after a reset. The following combinations are available for programming: Slave mode: USBC_AHB_CFG.DMAEN=0, USBC_CFG_D.DESCDMA=0 Invalid: USBC_AHB_CFG.DMAEN=0, USBC_CFG_D.DESCDMA=1 Buffered DMA mode: USBC_AHB_CFG.DMAEN=1, USBC_CFG_D.DESCDMA=0 Scatter/gather DMA mode: USBC_AHB_CFG.DMAEN=1, USBC_CFG_D.DESCDMA=1	
15 (R/W)	EERRIMSK	Erratic Error Interrupt Mask. The USBC_CFG_D.EERRIMSK bit unmasks (enables) or masks (disables) the interrupt request for early suspend on erratic error.	
14 (R/W)	XCVRDLY	Delay Enable. The USBC_CFG_D.XCVRDLY bit enables or disables the delay between xcvr_sel and txvalid during device chirp.	

Table 19-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	OUTNAKEN	Enable Device OUT NAK. The `USBC_CFG_D.OUTNAKEN` bit enables setting NAK for bulk OUT endpoints after the transfer is completed for device mode descriptor DMA. The `USBC_CFG_D.OUTNAKEN` bit is one time programmable after reset like any other `USBC_CFG_D` register bits.	
		0	Disable
		1	Enable
12:11 (R/W)	PERFRINT	Periodic Frame Interval. The `USBC_CFG_D.PERFRINT` field indicates the time within a (micro)frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine when all the isochronous traffic for that (micro)frame is complete.	
		0	80% of the microframe interval
		1	85% of the microframe interval
		2	90% of the microframe interval
		3	95% of the microframe interval
10:4 (R/W)	ADDR	Device Address. The `USBC_CFG_D.ADDR` field must be programmed after every SetAddress control command.	
3 (R/W)	ENA32KHSUSPEN	Enable 32 KHz Suspend Mode. The `USBC_CFG_D.ENA32KHSUSPEN` bit can be set only when the FS PHY interface is selected. Otherwise, this bit needs to be cleared. If the FS PHY interface is chosen and this bit is set, the PHY clock during suspend must be switched from 48 MHz to 32 KHz.	
2 (R/W)	NZSTSOUTHSHK	Non-Zero-Length Status OUT Handshake. The `USBC_CFG_D.NZSTSOUTHSHK` field selects the handshake that the core sends upon receiving a non-zero length data packet during the OUT transaction of a control transfer's status stage.	
		0	Send the received OUT packet to the application (zero length or non-zero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the Device Endpoint Control register.
		1	Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.

Table 19-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPD	Device Speed. The `USBC_CFG_D.SPD` bit indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the connect sequence is completed, and is based on the speed of the USB host to which the core is connected.	
		0	High Speed USB 2.0. PHY clock is 30 Mhz or 60 Mhz.
		1	Full Speed USB 2.0. PHY clock is 30 Mhz or 60 Mhz.
		2	Low Speed USB 1.1 Transceiver clock is 6 Mhz.
		3	Full Speed USB 1.1. Transceiver clock is 48 MHz.

Device Control Register

In device mode, the USBC_CTL_D register controls global functions such as wakeup and soft disconnect.

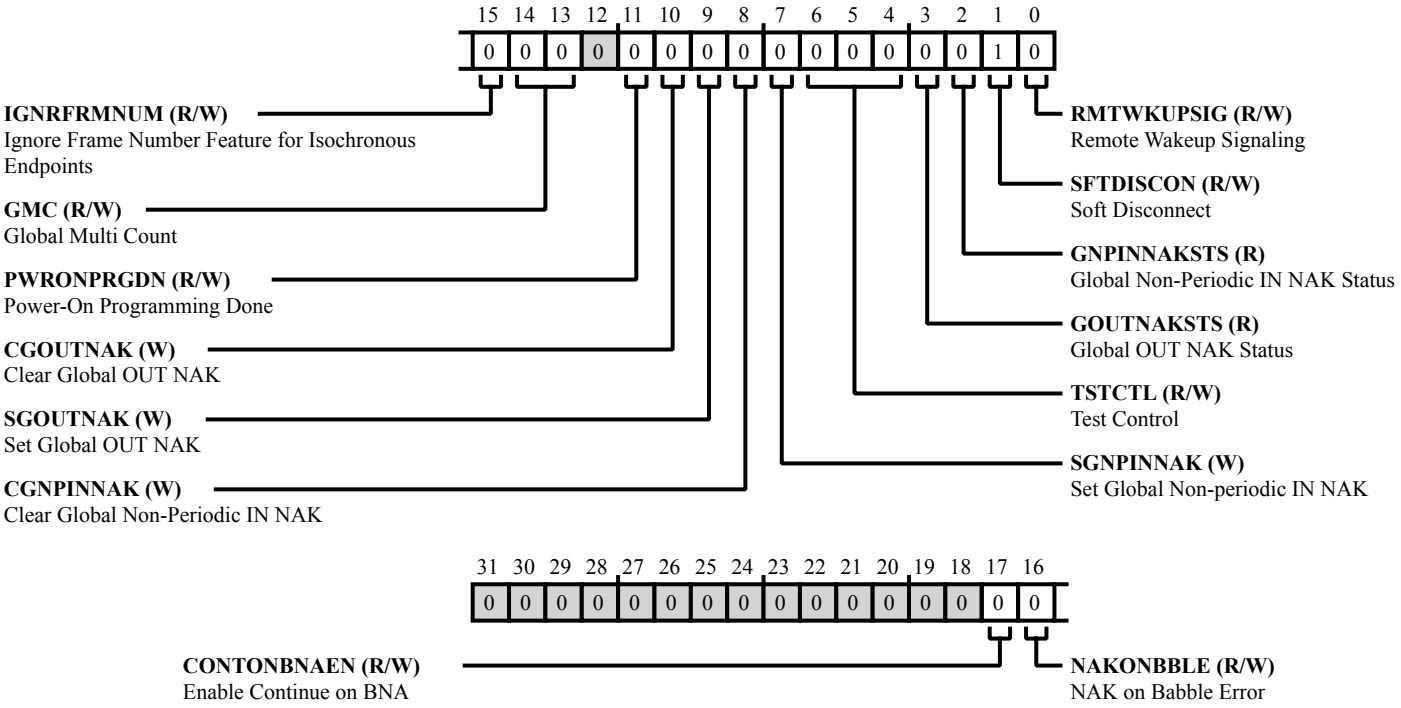

Figure 19-11: USBC_CTL_D Register Diagram

Table 19-8: USBC_CTL_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	CONTONBNAEN	Enable Continue on BNA. The USBC_CTL_D.CONTONBNAEN bit enables the core to continue on BNA for bulk OUT endpoints. With this feature enabled, when a bulk OUT or INTR OUT endpoint receives a BNA interrupt, the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. After receiving a BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the DOEPDMA descriptor or from the descriptor that received the BNA interrupt. The USBC_CTL_D.CONTONBNAEN bit is a one-time programmable after reset bit (like the other USBC_CTL_D register bits).	
		0	Process from the DOEPDMA descriptor
		1	Process from the descriptor that received the BNA interrupt

Table 19-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NAKONBBLE	NAK on Babble Error. When set (=1), the USBC_CTL_D.NAKONBBLE bit enables NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received.
15 (R/W)	IGNRFRMNUM	Ignore Frame Number Feature for Isochronous Endpoints. The USBC_CTL_D.IGNRFRMNUM bit controls the Periodic Transfer Interrupt (PTI) feature. When USBC_CTL_D.IGNRFRMNUM is set (=1), the core transmits the packets only in the frame number in which they are intended to be transmitted. When USBC_CTL_D.IGNRFRMNUM is cleared, the core ignores the frame number, sending packets immediately as the packets are ready. Note: Do not set (=1) the USBC_CTL_D.IGNRFRMNUM bit when the core is operating in threshold mode. This feature does not apply to high speed, high bandwidth transfers. When the USBC_CTL_D.IGNRFRMNUM bit is set (=1), there must be only one packet per descriptor. In scatter/gather DMA mode, if USBC_CTL_D.IGNRFRMNUM bit is enabled, the packets are not flushed when a ISOC IN token is received for an elapsed frame. In PTI mode, the application receive a transfer complete interrupt after transfers for multiple (micro)frames are completed.
14:13 (R/W)	GMC	Global Multi Count. The USBC_CTL_D.GMC field indicates the number of packets to be serviced for the endpoint before moving to the next endpoint. It applies only to non-periodic endpoints. The USBC_CTL_D.GMC bit must be programmed only once after initialization. The value of this field automatically changes to 2'h1 when USBC_CFG_D.DESCDMA = 1. 0 – Invalid 1 – 1 packet 2 – 2 packets 3 – 3 packets
11 (R/W)	PWRONPRGDN	Power-On Programming Done. Th USBC_CTL_D.PWRONPRGDN bit indicates that register programming is completed after a wakeup from power down mode.
10 (RX/W)	CGOUTNAK	Clear Global OUT NAK. A write to the USBC_CTL_D.CGOUTNAK field clears the global OUT NAK.

Table 19-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (RX/W)	SGOUTNAK	Set Global OUT NAK. A write to the USBC_CTL_D.SGOUTNAK field sets the global OUT NAK. The application uses this bit to send a NAK handshake on all OUT endpoints. The application must set the this bit only after making sure that the USBC_ISTAT.GOUTNAKEFF bit is cleared (=0).	
8 (RX/W)	CGNPINNAK	Clear Global Non-Periodic IN NAK. A write to the USBC_CTL_D.CGNPINNAK field clears the global non-periodic IN NAK.	
7 (RX/W)	SGNPINNAK	Set Global Non-periodic IN NAK. A write to the USBC_CTL_D.SGNPINNAK field sets the global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints. The core can also set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must set this bit only after ensuring that after making sure that the USBC_ISTAT.GINNAKEFF bit is cleared (=0).	
6:4 (R/W)	TSTCTL	Test Control. The USBC_CTL_D.TSTCTL field indicates the test mode state.	
		0	Test mode disabled
		1	Test_J mode. In this mode, the USB controller transmits a continuous J on the bus.
		2	Test_K mode. In this mode, the USB controller transmits a continuous K on the bus.
		3	Test_SE0 NAK mode
		4	Test_Packet mode
		5	Test_Force_Enable mode
3 (R/NW)	GOUTNAKSTS	Global OUT NAK Status. The USBC_CTL_D.GOUTNAKSTS bit indicates whether a handshake is sent based on the FIFO status and the NAK and STALL bit settings or sends a NAK handshake on all packets, except on SETUP transactions. No data is written to the RxFIFO (irrespective of space availability). All isochronous OUT packets are dropped	
		0	Send handshake
		1	Send NAK handshake

Table 19-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	GNPINNAKSTS	Global Non-Periodic IN NAK Status. The `USBC_CTL_D.GNPINNAKSTS` bit indicates whether a handshake is sent out based on the data availability in the transmit FIFO or an NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.	
		0	Handshake based on available data
		1	NAK Handshake
1 (R/W)	SFTDISCON	Soft Disconnect. The `USBC_CTL_D.SFTDISCON` bit signals the controller to do a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. The following is the minimum duration under various conditions for which this bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application adds some extra delay to the specified minimum duration. For high speed, if the device state is suspended, the minimum duration is 1 ms + 2.5 us. If the device state is idle, the minimum duration is 3 ms + 2.5 us. If the device state is not idle or suspended (performing transactions), the minimum duration 125 us For full speed/low speed, if the device state is suspended, the minimum duration is 1 ms + 2.5 us. if the device state is idle, the minimum duration is 2.5 us. if the device state is not idle or suspended (performing transactions), the minimum duration 125 us. Note: This bit can be also used for ULPI/FS serial interfaces. This bit is not impacted by a soft reset.	
		0	Normal Operation When this bit is cleared after a soft disconnect, the controller generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.
		1	The controller generates a device disconnect event to the USB host.

Table 19-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	RMTWKUPSIG	Remote Wakeup Signaling. When the `USBC_CTL_D.RMTWKUPSIG` bit is set (=1), the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1-15 ms after setting it. If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears the `USBC_CTL_D.RMTWKUPSIG` bit 50 ms after being set by the application.

Device Control IN Endpoint 0 Control Register

In device mode, the USBC_CTL_IEP0_D register controls IN endpoint 0.

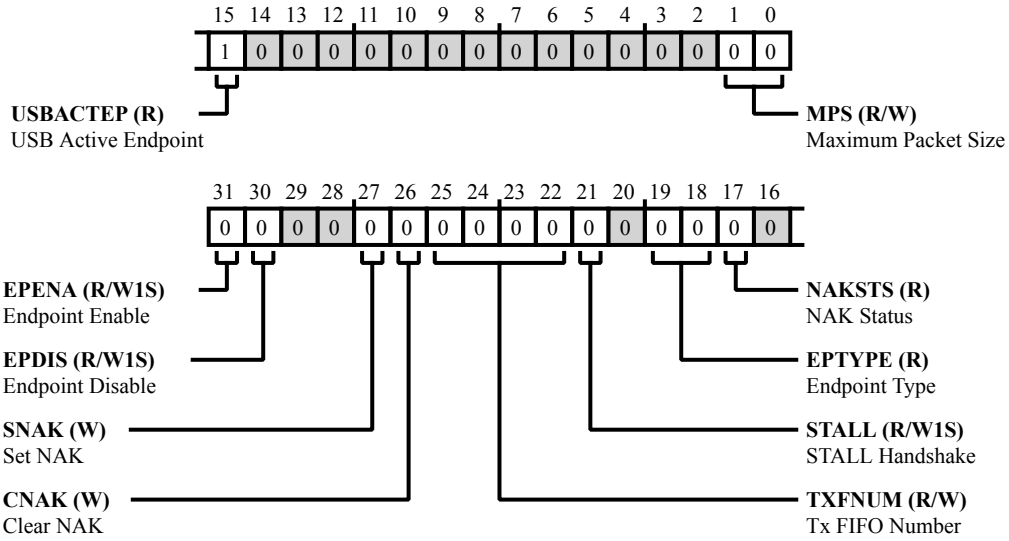

Figure 19-12: USBC_CTL_IEP0_D Register Diagram

Table 19-9: USBC_CTL_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. The USBC_CTL_IEP0_D.EPENA bit indicates that the descriptor structure and data buffer with data ready for transmission is configured.
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_IEP0_D.EPDIS bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_IEP0_D.EPDIS bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_IEP0_D.SNAK bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_IEP0_D.CNAK bit clears the NAK bit for the endpoint.

Table 19-9: USBC_CTL_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:22 (R/W)	TXFNUM	Tx FIFO Number. The `USBC_CTL_IEP0_D.TXFNUM` field indicates the FIFO number that is assigned to the IN endpoint.	
21 (R/W1S)	STALL	STALL Handshake. The application sets (=1) the `USBC_CTL_IEP0_D.STALL` bit, and the core clears (=0) it, when a SETUP token is received for the endpoint. If a NAK bit, the global non-periodic IN NAK, or global OUT NAK is set along with this bit, the `USBC_CTL_IEP0_D.STALL` bit takes priority.	
19:18 (R/NW)	EPTYPE	Endpoint Type. The `USBC_CTL_IEP0_D.EPTYPE` bit is hardcoded to 00 for control.	
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_IEP0_D.NAKSTS` bit is set, either by the application or core, the core stops transmitting data, even when there is data available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Core is transmitting non-NAK handshakes based on FIFO status
		1	Core is transmitting NAK handshakes on the endpoint
15 (R/NW)	USBACTEP	USB Active Endpoint. The `USBC_CTL_IEP0_D.USBACTEP` bit is always set (= 1), indicating that control endpoint 0 is active in all configurations and interfaces.	
1:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CTL_IEP0_D.MPS` field indicates the maximum packet size (in bytes) for the current logical endpoint. The field applies to IN and OUT endpoints.	
		0	64 bytes
		1	32 bytes
		2	16 bytes
		3	8 bytes

Device Control IN Endpoint n Control Register

In device mode, the `USBC_CTL_IEP[n]_D` register controls IN endpoint n.

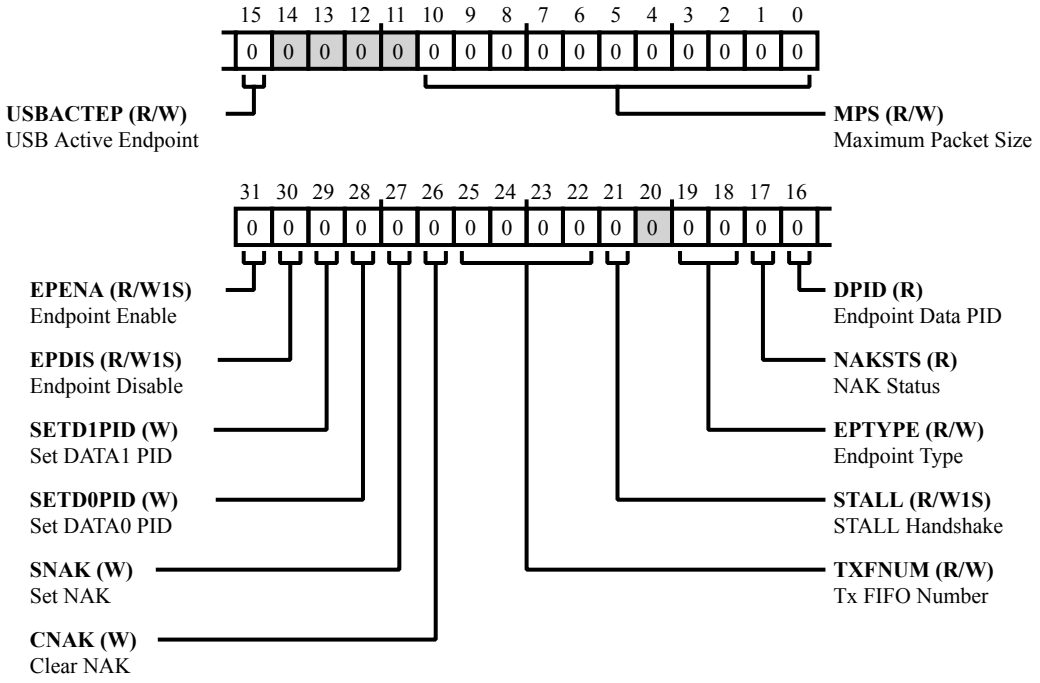

Figure 19-13: USBC_CTL_IEP[n]_D Register Diagram

Table 19-10: USBC_CTL_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When scatter/gather DMA mode is enabled for IN endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoints, it indicates that the descriptor structure and data buffer to receive data is set up. When scatter/gather DMA mode is enabled, such as for buffer-pointer based DMA mode: For IN endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that data is ready to be transmitted on the endpoint. For OUT endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the `USBC_CTL_IEP[n]_D.EPENA` bit before setting any of the following interrupts on this endpoint: SETUP Phase Done, Endpoint Disabled, Transfer Completed. Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory.

Table 19-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_IEP[n]_D.EPDIS bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_IEP[n]_D.EPDIS bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint. The USBC_CTL_IEP[n]_D.EPDIS bit applies to IN and OUT endpoints.
29 (RX/W)	SETD1PID	Set DATA1 PID. The USBC_CTL_IEP[n]_D.SETD1PID bit applies to interrupt and bulk IN and OUT endpoints only.The USBC_CTL_IEP[n]_D.SETD1PID bit applies to both for scatter/gather DMA mode and non scatter/gather DMA mode. Writing to the USBC_CTL_IEP[n]_D.SETD1PID bit sets the Endpoint Data PID (DPID) field in this register to DATA1. In non scatter/gather DMA mode, set odd (micro)frame (SetOddFr). SetOddFr applies to isochronous IN and OUT endpoints only. Writing to the USBC_CTL_IEP[n]_D.SETD1PID bit sets the even and odd (micro)Frame (EO_FrNum) field to odd (micro)frame. The USBC_CTL_IEP[n]_D.SETD1PID bit is not applicable for scatter/gather DMA mode for isochronous endpoints.
28 (RX/W)	SETD0PID	Set DATA0 PID. The USBC_CTL_IEP[n]_D.SETD0PID bit applies to interrupt/bulk IN and OUT endpoints only. A write to the USBC_CTL_IEP[n]_D.SETD0PID bit sets the endpoint data PID (DPID) field in this register to DATA0. The USBC_CTL_IEP[n]_D.SETD0PID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. In non-scatter/gather DMA mode: Set even (micro)frame (SetEvenFr) SetEvenFr applies to isochronous IN and OUT endpoints only. A write to the USBC_CTL_IEP[n]_D.SETD0PID bit sets the even/odd (micro)frame (EO_FrNum) field to even (micro)frame. When scatter/gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_IEP[n]_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_IEP[n]_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.

Table 19-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (RX/W)	CNAK	Clear NAK. A write to the `USBC_CTL_IEP[n]_D.CNAK` bit clears the NAK bit for the endpoint.	
25:22 (R/W)	TXFNUM	Tx FIFO Number. The `USBC_CTL_IEP[n]_D.TXFNUM` field indicates the FIFO number that is assigned to the IN endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	
21 (R/W1S)	STALL	STALL Handshake. The `USBC_CTL_IEP[n]_D.STALL` bit indicates a handshake stall. The application sets (=1) the `USBC_CTL_IEP[n]_D.STALL` bit to stall all tokens from the USB host to this endpoint. If a NAK, global non-periodic IN NAK, or global OUT NAK bit is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. The `USBC_CTL_IEP[n]_D.STALL` bit applies to non-control, non-isochronous IN and OUT endpoints only. The application can only set the `USBC_CTL_IEP[n]_D.STALL` bit, and the core clears it, when a SETUP token is received for this endpoint. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
19:18 (R/W)	EPTYPE	Endpoint Type. The `USBC_CTL_IEP[n]_D.EPTYPE` bit indicates the transfer type supported by this logical endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt

Table 19-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_IEP[n]_D.NAKSTS` bit is set, either by the application or core, the core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Core is transmitting non-NAK handshakes based on the FIFO status
		1	Core is transmitting NAK handshakes on the endpoint
16 (R/NW)	DPID	Endpoint Data PID. The `USBC_CTL_IEP[n]_D.DPID` field applies to interrupt/bulk IN and OUT endpoints only. The `USBC_CTL_IEP[n]_D.DPID` field indicates the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 The `USBC_CTL_IEP[n]_D.DPID` field applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-scatter/gather DMA mode, the `USBC_CTL_IEP[n]_D.DPID` field applies to isochronous IN and OUT endpoints only. The `USBC_CTL_IEP[n]_D.DPID` field indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro)frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro)frame When scatter/gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.	

Table 19-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	USBACTEP	USB Active Endpoint. `USBC_CTL_IEP[n]_D.USBACTEP` bit indicates whether this endpoint is active in the current configuration and interface. The core clears the `USBC_CTL_IEP[n]_D.USBACTEP` bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.
10:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CTL_IEP[n]_D.MPS` field indicates the maximum packet size (in bytes) for the current logical endpoint. This value is in bytes.

Device Control IN Endpoint 0 DMA Address Register

In device mode, the USBC_DMA_ADDR_IEP0_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_IEP0_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_IEP0_D register indicates the base pointer for the descriptor list.

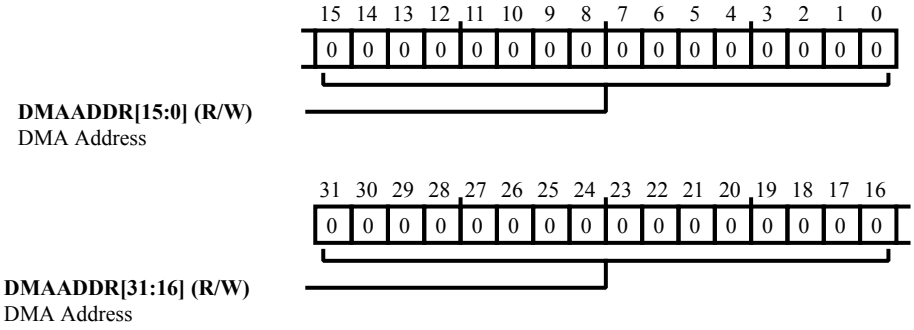

Figure 19-14: USBC_DMA_ADDR_IEP0_D Register Diagram

Table 19-11: USBC_DMA_ADDR_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. This USBC_DMA_ADDR_IEP0_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten.

Device IN Endpoint 0 Buffer Address Register

In device mode, the USBC_DMA_BADDR_IEP0_D register indicates the buffer address for IN endpoint 0. It is updated when the data transfer for the endpoint 0 is in progress.

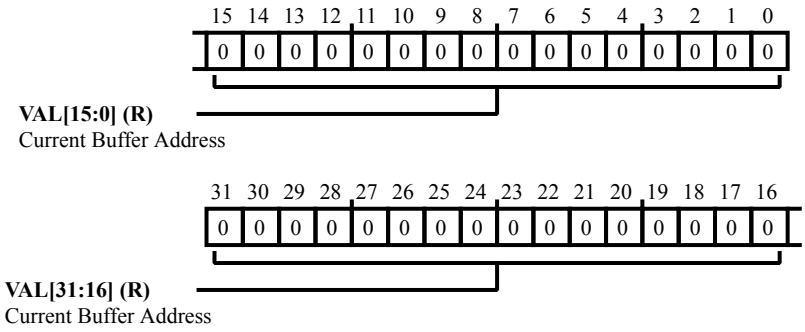

Figure 19-15: USBC_DMA_BADDR_IEP0_D Register Diagram

Table 19-12: USBC_DMA_BADDR_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VAL	Current Buffer Address. The USBC_DMA_BADDR_IEP0_D.VAL field holds the current buffer address.

Device Control IN Endpoint n DMA Buffer Address Register

In device mode, the USBC_DMA_BADDR_IEP[n]_D register indicates the buffer address for IN endpoint n. It is updated when the data transfer for the corresponding endpoint is in progress.

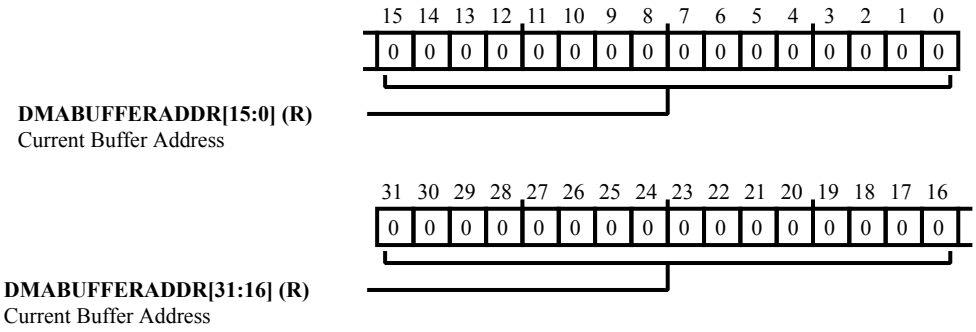

Figure 19-16: USBC_DMA_BADDR_IEP[n]_D Register Diagram

Table 19-13: USBC_DMA_BADDR_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_IEP[n]_D.DMABUFFERADDR field holds the current buffer address. This field is present only in scatter/gather DMA mode. Otherwise, this field is reserved.

Device Control IN Endpoint n DMA Address Register

The USBC_DMA_ADDR_IEP[n]_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_IEP[n]_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_IEP[n]_D register indicates the base pointer for the descriptor list.

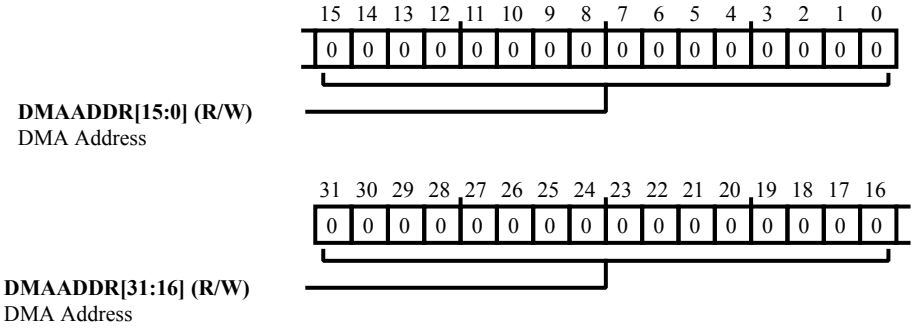

Figure 19-17: USBC_DMA_ADDR_IEP[n]_D Register Diagram

Table 19-14: USBC_DMA_ADDR_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_IEP[n]_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten.

Device IN Endpoint FIFO Empty Interrupt Mask Register

The USBC_IMSK_IEP_FEMPT_D register is valid only in dedicated FIFO operation (OTG_EN_DED_TX_FIFO = 1). This register is used to control the IN endpoint FIFO empty interrupt generation.

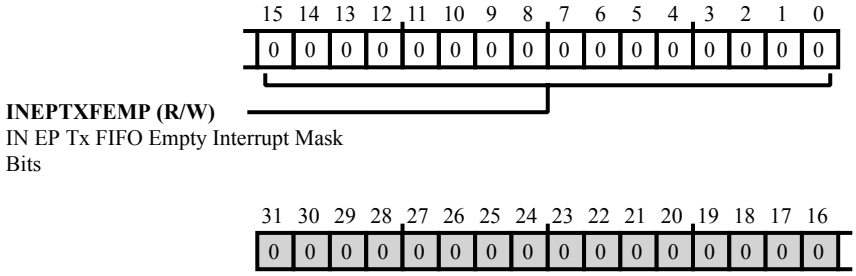

Figure 19-18: USBC_IMSK_IEP_FEMPT_D Register Diagram

Table 19-15: USBC_IMSK_IEP_FEMPT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	INEPTXFEMP	IN EP Tx FIFO Empty Interrupt Mask Bits. The USBC_IMSK_IEP_FEMPT_D.INEPTXFEMP field acts as mask bits for the TXFEMP interrupt in the USBC_ISTAT_IEP[n]_D register; one bit per IN Endpoint. For example, bit 0 for IN endpoint 0, bit 15 for IN endpoint 15.

Device Control IN Endpoint 0 Interrupt Control Register

The USBC_ISTAT_IEP0_D register indicates the status of an endpoint with respect to USB- and bus-related events. The application must read this register when USBC_ISTAT.OEPINT or USBC_ISTAT.IEPINT is set. Before the application can read this register, it must first read the USBC_ISTAT_D register to get the exact endpoint number for the Device Endpoint n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USBC_ISTAT_D and USBC_ISTAT registers.

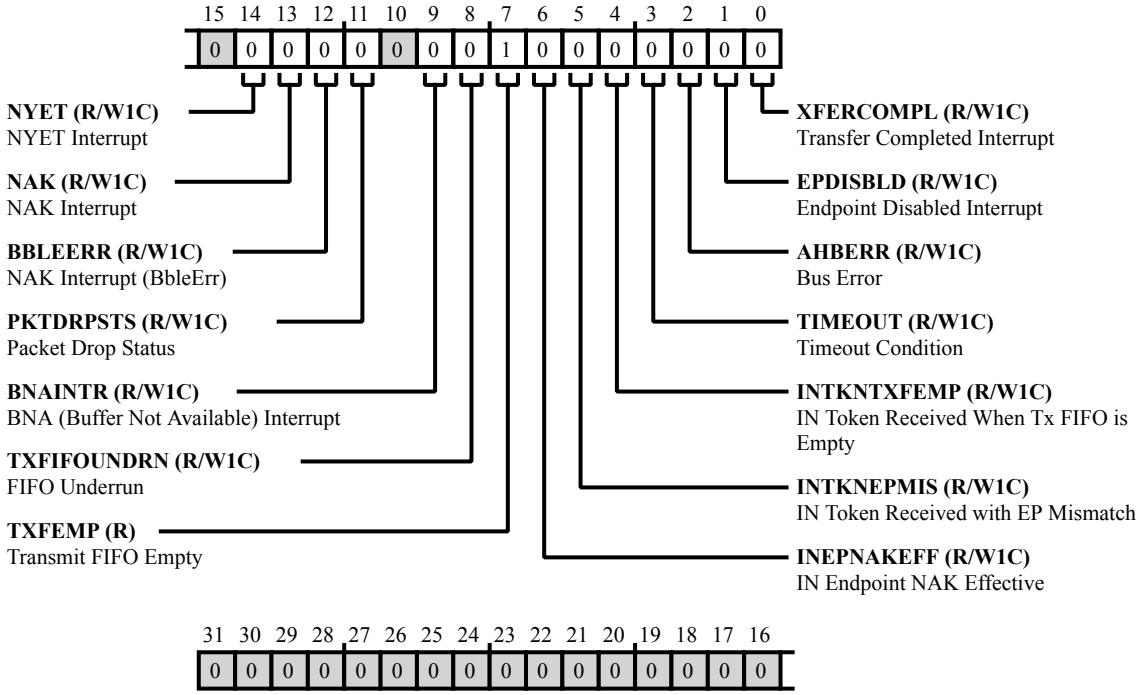

Figure 19-19: USBC_ISTAT_IEP0_D Register Diagram

Table 19-16: USBC_ISTAT_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt. The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints, the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates the NAK interrupt when babble is received for the endpoint.

Table 19-16: USBC_ISTAT_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit indicates to the application that an ISOC OUT packet has been dropped. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit does not have an associated mask bit and does not generate an interrupt. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA (Buffer Not Available) Interrupt. The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	TXFIFOUNDRN	FIFO Underrun. The USBC_ISTAT_IEP0_D.TXFIFOUNDRN bit applies to IN endpoints only. The core generates this interrupt when it detects a transmit FIFO underrun condition in threshold mode for this endpoint.
7 (R/NW)	TXFEMP	Transmit FIFO Empty. This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the USBC_AHB_CFG.NPTXFELVL bit. The USBC_ISTAT_IEP0_D.TXFEMP bit is valid only for IN endpoints.
6 (R/W1C)	INEPNAKEFF	IN Endpoint NAK Effective. The USBC_ISTAT_IEP0_D.INEPNAKEFF bit applies to periodic IN endpoints only. The USBC_ISTAT_IEP0_D.INEPNAKEFF bit can be cleared when the application clears the IN endpoint NAK by writing to the USBC_CTL_IEP[n]_D.CNAK bit. This interrupt indicates that the core has sampled the NAK bit. Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.
5 (R/W1C)	INTKNEPMIS	IN Token Received with EP Mismatch. The USBC_ISTAT_IEP0_D.INTKNEPMIS bit indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. The USBC_ISTAT_IEP0_D.INTKNEPMIS bit applies to non-periodic IN endpoints only.

Table 19-16: USBC_ISTAT_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	INTKNTXFEMP	IN Token Received When Tx FIFO is Empty. The USBC_ISTAT_IEP0_D.INTKNTXFEMP bit indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. The USBC_ISTAT_IEP0_D.INTKNTXFEMP bit applies to non-periodic IN endpoints only.
3 (R/W1C)	TIMEOUT	Timeout Condition. The USBC_ISTAT_IEP0_D.TIMEOUT bit indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. In shared TX FIFO mode, the USBC_ISTAT_IEP0_D.TIMEOUT bit applies to non-isochronous IN endpoints only. In dedicated FIFO mode, the USBC_ISTAT_IEP0_D.TIMEOUT bit applies only to control IN endpoints. In scatter/gather DMA mode, the timeout interrupt is not asserted.
2 (R/W1C)	AHBERR	Bus Error. The USBC_ISTAT_IEP0_D.AHBERR bit bus error during a bus read/write. It applies only in internal DMA mode. The application can read the corresponding endpoint DMA address register to get the error address. The USBC_ISTAT_IEP0_D.AHBERR bit applies to IN and OUT endpoints.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The USBC_ISTAT_IEP0_D.EPDISBLD bit indicates that the endpoint is disabled per the application's request. The USBC_ISTAT_IEP0_D.EPDISBLD bit applies to IN and OUT endpoints.
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The USBC_ISTAT_IEP0_D.XFERCOMPL field applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When scatter/gather DMA mode is disabled, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device Control IN Endpoint n Interrupt Control Register

The USBC_ISTAT_IEP[n]_D register indicates the status of an endpoint with respect to USB- and bus-related events. This register exists for endpoint [n] when the USBC_HWCFG.EPDIR bit is 0 or 1 for that endpoint.

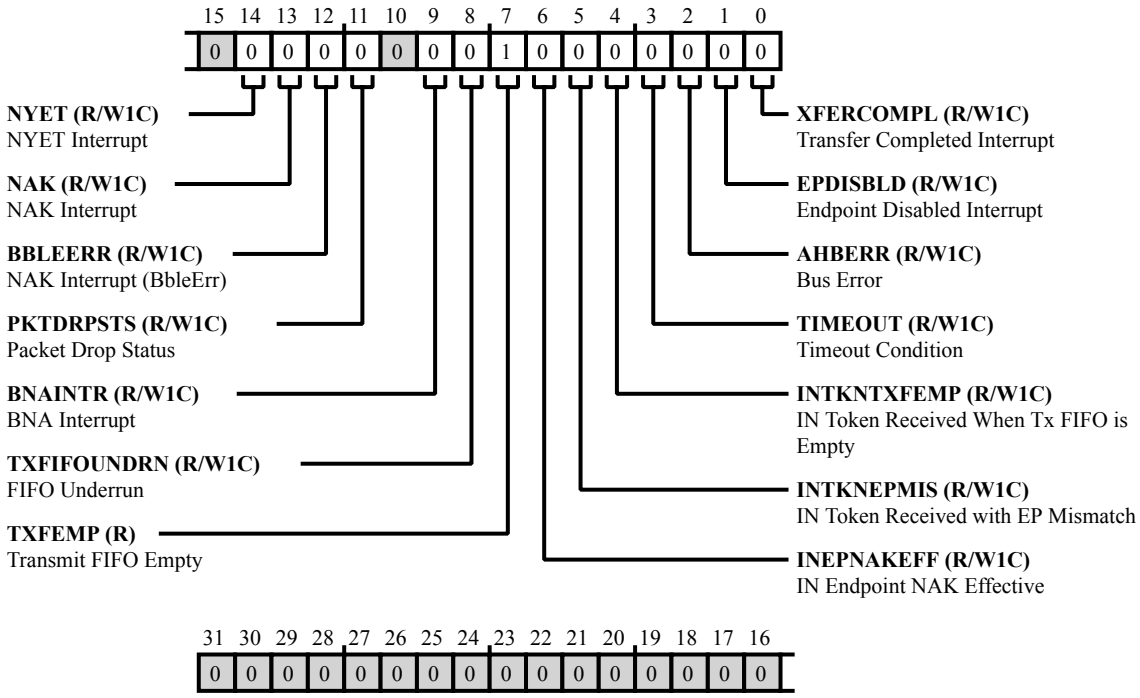

Figure 19-20: USBC_ISTAT_IEP[n]_D Register Diagram

Table 19-17: USBC_ISTAT_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates USBC_ISTAT_IEP[n]_D.NYET (NYETInterrupt) when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt. The core generates the USBC_ISTAT_IEP[n]_D.NAK (NAKInterrupt) when a NAK is transmitted or received by the device. In case of isochronous IN endpoints, the interrupt is generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates the USBC_ISTAT_IEP[n]_D.BBLEERR interrupt when babble is received for the endpoint.

Table 19-17: USBC_ISTAT_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_IEP[n]_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_IEP[n]_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA Interrupt. The core generates the BNA (Buffer Not Available) interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	TXFIFOUNDRN	FIFO Underrun. The `USBC_ISTAT_IEP[n]_D.TXFIFOUNDRN` bit applies to IN endpoints only. The `USBC_ISTAT_IEP[n]_D.TXFIFOUNDRN` bit is valid only when thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint.
7 (R/NW)	TXFEMP	Transmit FIFO Empty. The `USBC_ISTAT_IEP[n]_D.TXFEMP` bit is valid only for IN endpoints. This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the `USBC_AHB_CFG.NPTXFELVL` bit.
6 (R/W1C)	INEPNAKEFF	IN Endpoint NAK Effective. The `USBC_ISTAT_IEP[n]_D.INEPNAKEFF` bit applies to periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INEPNAKEFF` bit can be cleared when the application clears the IN endpoint NAK by writing to `USBC_CTL_IEP[n]_D.CNAK`. This interrupt indicates that the core has sampled the NAK bit. When set (either by the application or by the core), the interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.
5 (R/W1C)	INTKNEPMIS	IN Token Received with EP Mismatch. The `USBC_ISTAT_IEP[n]_D.INTKNEPMIS` bit applies to non-periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INTKNEPMIS` bit indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Table 19-17: USBC_ISTAT_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	INTKNTXFEMP	IN Token Received When Tx FIFO is Empty. The `USBC_ISTAT_IEP[n]_D.INTKNTXFEMP` bit applies to non-periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INTKNTXFEMP` bit indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.
3 (R/W1C)	TIMEOUT	Timeout Condition. The `USBC_ISTAT_IEP[n]_D.TIMEOUT` bit indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. In dedicated FIFO mode, the `USBC_ISTAT_IEP[n]_D.TIMEOUT` bit applies only to control IN endpoints. In scatter/gather DMA mode, the timeout interrupt is not asserted.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_IEP[n]_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_IEP[n]_D.AHBERR` bit is set (=1) when there is a bus error during a bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_IEP[n]_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_IEP[n]_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When scatter/gather DMA mode is disabled, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device IN Endpoint Common Interrupt Mask Register

The USBC_IMASK_IEP_D register works with each of the Device IN Endpoint Interrupt (USBC_ISTAT_IEP[n]_D) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the USBC_ISTAT_IEP[n]_D register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

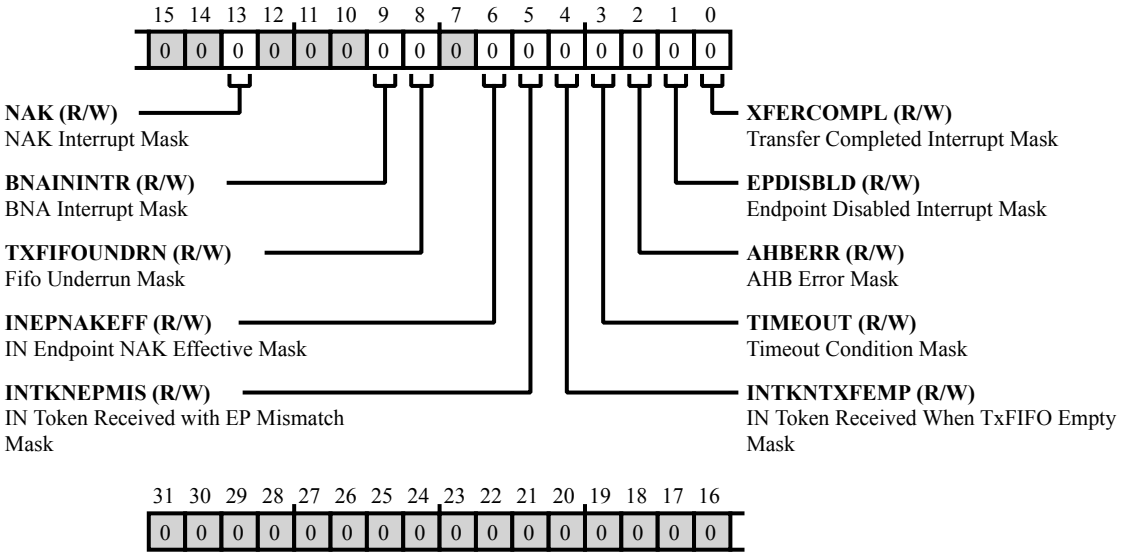

Figure 19-21: USBC_IMASK_IEP_D Register Diagram

Table 19-18: USBC_IMASK_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	NAK	NAK Interrupt Mask.
9 (R/W)	BNAININTR	BNA Interrupt Mask.
8 (R/W)	TXFIFOUNDRN	Fifo Underrun Mask.
6 (R/W)	INEPNAKEFF	IN Endpoint NAK Effective Mask.
5 (R/W)	INTKNEPMIS	IN Token Received with EP Mismatch Mask.
4 (R/W)	INTKNTXFEMP	IN Token Received When TxFIFO Empty Mask.

Table 19-18: USBC_IMASK_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TIMEOUT	Timeout Condition Mask. Timeout Condition Mask (TimeOUTMsk) (Non-isochronous endpoints)
2 (R/W)	AHBERR	AHB Error Mask.
1 (R/W)	EPDISBLD	Endpoint Disabled Interrupt Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Interrupt Mask.

Device Control IN Endpoint 0 Transfer Size Register

The application must modify the USBC_TSIZ_IEP0_D register before enabling endpoint 0. Once endpoint 0 is enabled using endpoint enable bit (USBC_CTL_IEP0_D.EPENA /USBC_CTL_OEP0_D.EPENA), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1-15.

When scatter/gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when scatter/gather DMA mode is enabled, the core returns all zeros.

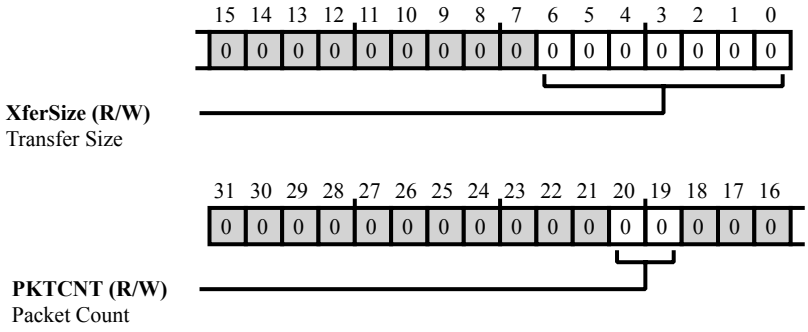

Figure 19-22: USBC_TSIZ_IEP0_D Register Diagram

Table 19-19: USBC_TSIZ_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_IEP0_D.PKTCNT field indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0. For IN endpoints, the USBC_TSIZ_IEP0_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO. For OUT endpoints, the USBC_TSIZ_IEP0_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.

Table 19-19: USBC_TSIZ_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	XFERSIZE	Transfer Size. The `USBC_TSIZ_IEP0_D.XFERSIZE` field contains the transfer size in bytes for the current endpoint. The transfer size (XferSize) = Sum of buffer sizes across all descriptors in the list for the endpoint. In buffer DMA, the core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. For IN endpoints, the core decrements the `USBC_TSIZ_IEP0_D.XFERSIZE` field every time a packet from the external memory is written to the TxFIFO. For OUT endpoints, the core decrements the `USBC_TSIZ_IEP0_D.XFERSIZE` field every time a packet is read from the RxFIFO and written to the external memory.

Device Control IN Endpoint n Transfer Size Register

The USBC_TSIZ_IEP[n]_D register indicates the Device IN Endpoint n transfer size.

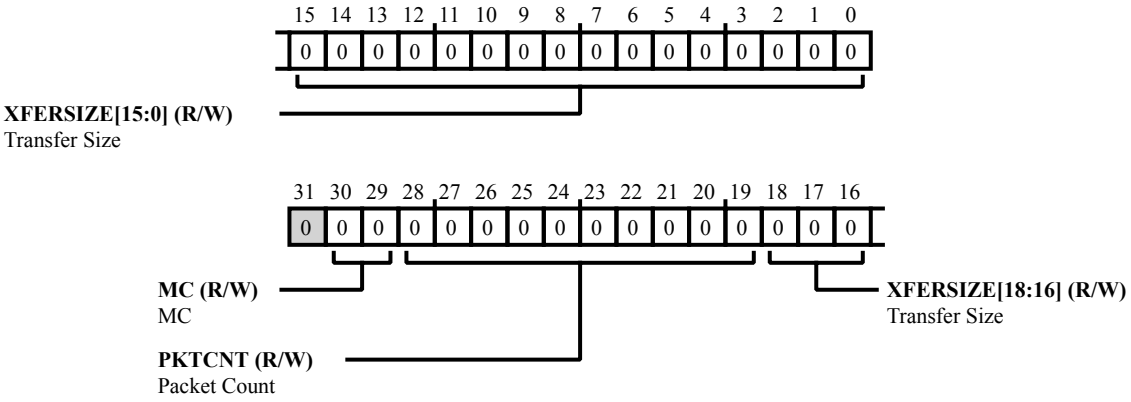

Figure 19-23: USBC_TSIZ_IEP[n]_D Register Diagram

Table 19-20: USBC_TSIZ_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	MC	MC. For periodic IN endpoints, the USBC_TSIZ_IEP[n]_D.MC field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. For non-periodic IN endpoints, the USBC_TSIZ_IEP[n]_D.MC field is valid only in internal DMA mode. It specifies the number of packets the core must fetch for an IN endpoint before it switches to the next endpoint. The USBC_TSIZ_IEP[n]_D.MC field applies to IN endpoints only.	
		0	Reserved
		1	1 packet
		2	2 packets
		3	3 packets
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_IEP[n]_D.PKTCNT field indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0. The USBC_TSIZ_IEP[n]_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.	

Table 19-20: USBC_TSIZ_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:0 (R/W)	XFERSIZE	Transfer Size. The `USBC_TSIZ_IEP[n]_D.XFERSIZE` field indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be configured to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

Device IN Endpoint 1 Transmit FIFO Size Register

The USBC_TXFIFOSZ1_IEP_D register holds the size and memory start address of IN endpoint Tx FIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ1_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 3.

For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_PER_H register for programming the size and memory start address.

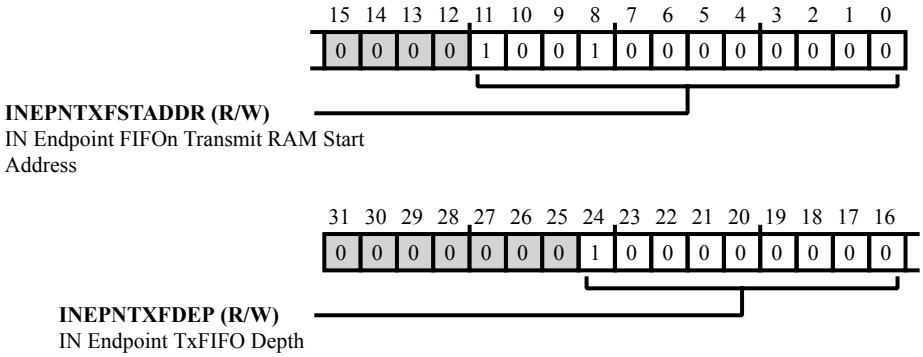

Figure 19-24: USBC_TXFIFOSZ1_IEP_D Register Diagram

Table 19-21: USBC_TXFIFOSZ1_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ1_IEP_D.INEPNTXFDEP field indicates the IN endpoint TxFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 Programmed values must not exceed the power-on value.
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. The USBC_TXFIFOSZ1_IEP_D.INEPNTXFSTADDR field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 3). The power-on reset value of the USBC_TXFIFOSZ1_IEP_D register is specified as the largest Rx data FIFO depth.

Device IN Endpoint 2 Transmit FIFO Size Register

The USBC_TXFIFOSZ2_IEP_D register is valid only in dedicated FIFO mode (OTG_EN_DED_TX_FIFO=1). It holds the size and memory start address of IN endpoint TxFIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ2_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 15. For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_NP register for programming the size and memory start address.

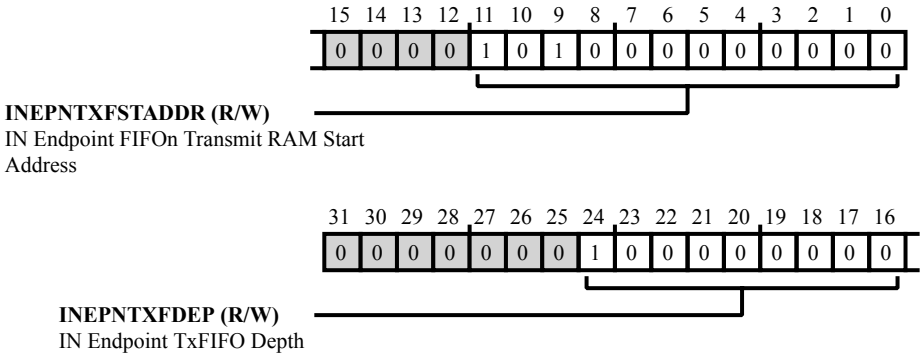

Figure 19-25: USBC_TXFIFOSZ2_IEP_D Register Diagram

Table 19-22: USBC_TXFIFOSZ2_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ2_IEP_D.INEPNTXFDEP field indicates the IN endpoint TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value of the USBC_TXFIFOSZ2_IEP_D register is specified as the largest IN endpoint FIFO number depth Programmed values must not exceed the power-on value.

Table 19-22: USBC_TXFIFOSZ2_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. This `USBC_TXFIFOSZ2_IEP_D.INEPNTXFSTADDR` field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 15). The power-on reset value of the `USBC_TXFIFOSZ2_IEP_D` register is specified as the largest Rx data FIFO depth. The power-on reset value of the register is calculated according to the following formula: OTG_RX_DFIFO_DEPTH + SUM of OTG_TX_DINEP_DFIFO_DEPTH_'i' (where x = 0 to n 1) If at POR the calculated value (C) exceeds 65535, then the reset value becomes reset value(A) = (C 65536). For example: If the start address of IN endpoint FIFO 1 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 and the start address of IN endpoint FIFO 2 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 + OTG_TX_DINEP_DFIFO_DEPTH_ 1. Programmed values must not exceed the power-on value.

Device IN Endpoint 3 Transmit FIFO Size Register

The USBC_TXFIFOSZ3_IEP_D register is valid only in dedicated FIFO mode (OTG_EN_DED_TX_FIFO=1). It holds the size and memory start address of IN endpoint TxFIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ3_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 15. For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_NP register for programming the size and memory start address.

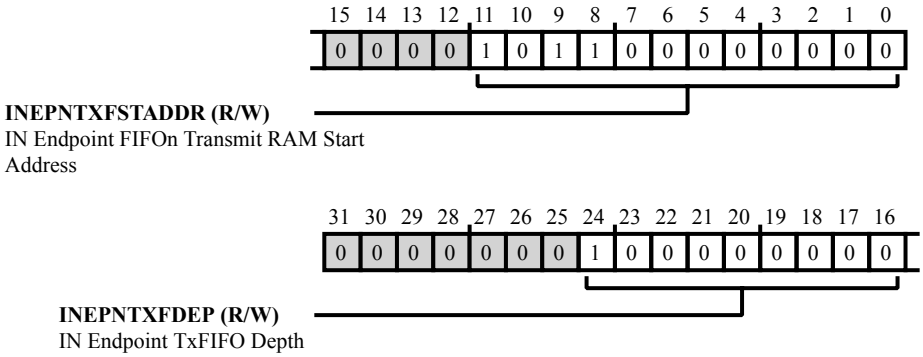

Figure 19-26: USBC_TXFIFOSZ3_IEP_D Register Diagram

Table 19-23: USBC_TXFIFOSZ3_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ3_IEP_D.INEPNTXFDEP field indicates the IN endpoint TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value of the USBC_TXFIFOSZ3_IEP_D register is specified as the largest IN endpoint FIFO number depth. Programmed values must not exceed the power-on value.

Table 19-23: USBC_TXFIFOSZ3_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. The `USBC_TXFIFOSZ3_IEP_D.INEPNTXFSTADDR` field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 15). The power-on reset value of the `USBC_TXFIFOSZ3_IEP_D` register is specified as the largest Rx data FIFO depth. The power-on reset value of the register is calculated according to the following formula: OTG_RX_DFIFO_DEPTH + SUM of OTG_TX_DINEP_DFIFO_DEPTH_'i' (where x = 0 to n 1) If at POR the calculated value (C) exceeds 65535, then the reset value becomes reset value(A) = (C 65536). For example: If the start address of IN endpoint FIFO 1 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 and the start address of IN endpoint FIFO 2 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 + OTG_TX_DINEP_DFIFO_DEPTH_ 1. If Enable Dynamic FIFO Sizing is deselected in coreConsultant (OTG_DFIFO_DYNAMIC = 0), this field is read-only and read value is the power-on reset value. Programmed values must not exceed the power-on value.

Device OUT Endpoint 0 Control Register

In device mode, the USBC_CTL_OEP0_D register controls OUT endpoint 0.

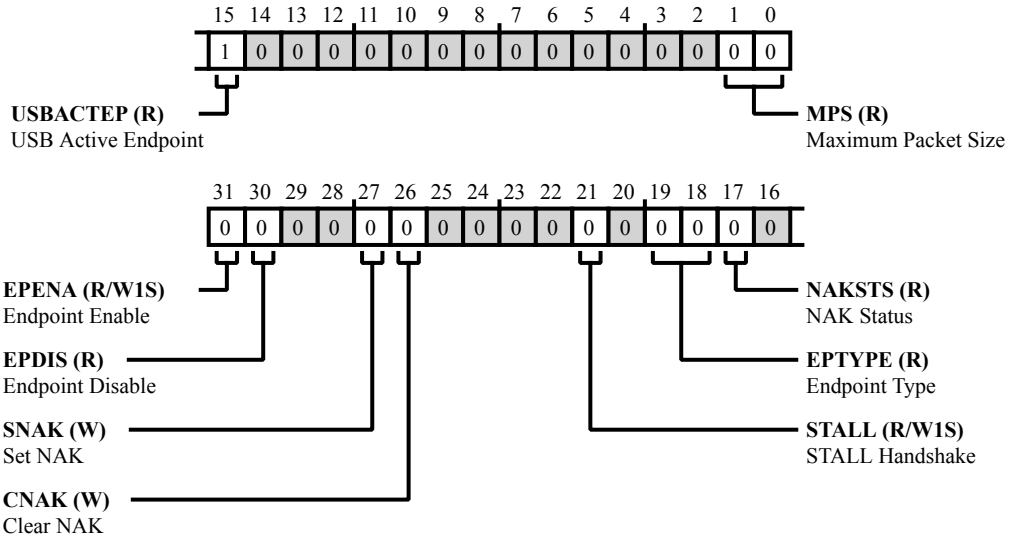

Figure 19-27: USBC_CTL_OEP0_D Register Diagram

Table 19-24: USBC_CTL_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When Scatter/Gather DMA mode is enabled, for OUT endpoints, the USBC_CTL_OEP0_D.EPENA bit indicates that the descriptor structure and data buffer to receive data is set up. When Scatter/Gather DMA mode is disabled (such as for buffer-pointer based DMA mode), the USBC_CTL_OEP0_D.EPENA bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the USBC_CTL_OEP0_D.EPENA bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: In DMA mode, the USBC_CTL_OEP0_D.EPENA bit must be set for the core to transfer SETUP data packets into memory.
30 (R/NW)	EPDIS	Endpoint Disable. The application cannot disable control OUT endpoint 0.

Table 19-24: USBC_CTL_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_OEP0_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_OEP0_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint.	
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_OEP0_D.CNAK bit clears the NAK bit for the endpoint.	
21 (R/W1S)	STALL	STALL Handshake. The application can only set the USBC_CTL_OEP0_D.STALL bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is Set along with the USBC_CTL_OEP0_D.STALL bit, the STALL bit takes priority. Irrespective of the configuration of the USBC_CTL_OEP0_D.STALL bit, the core always responds to SETUP data packets with an ACK handshake.	
19:18 (R/NW)	EPTYPE	Endpoint Type. The USBC_CTL_OEP0_D.EPTYPE field is hardcoded to 2'b00 for control.	
17 (R/NW)	NAKSTS	NAK Status. The USBC_CTL_OEP0_D.NAKSTS bit indicates whether the core is transmitting non-NAK handshakes based on the FIFO status or transmitting NAK handshakes on this endpoint. When either the application or the core sets the USBC_CTL_OEP0_D.NAKSTS bit, the core stops receiving data, even if there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Transmit non-NAK handshakes
		1	Transmit NAK handshakes
15 (R/NW)	USBACTEP	USB Active Endpoint. The USBC_CTL_OEP0_D.USBACTEP bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.	
1:0 (R/NW)	MPS	Maximum Packet Size. The USBC_CTL_OEP0_D.MPS field indicates the maximum packet size for control OUT endpoint 0. It is the same size that is programmed in control IN Endpoint 0.	
		0	64 Bytes
		1	32 Bytes
		2	16 Bytes
		3	8 Bytes

Device OUT Endpoint n Control Register

In device mode, the `USBC_CTL_OEP[n]_D` register controls OUT endpoint n.

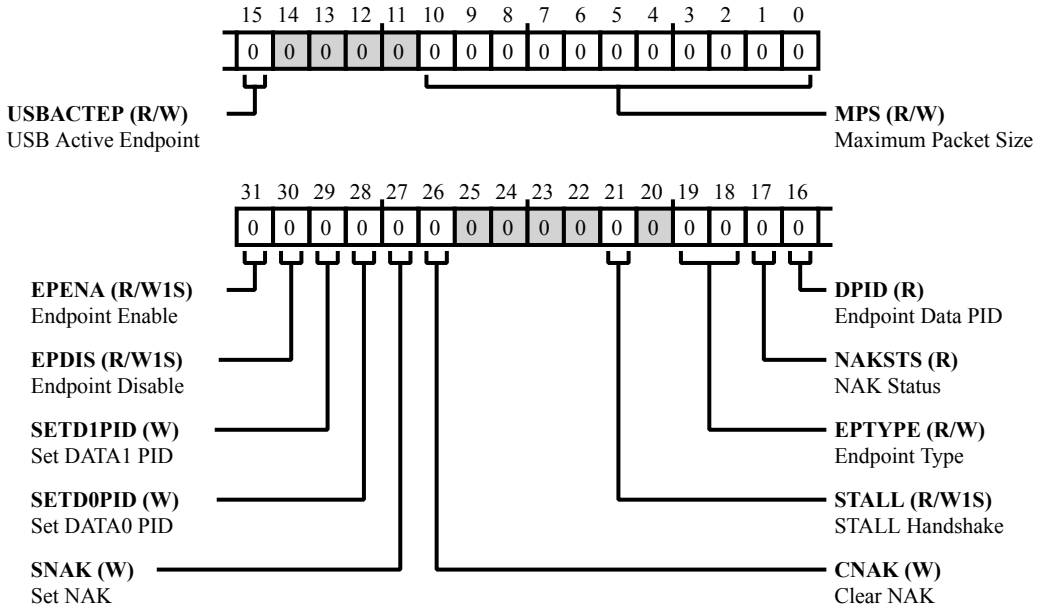

Figure 19-28: USBC_CTL_OEP[n]_D Register Diagram

Table 19-25: USBC_CTL_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When Scatter/Gather DMA mode is enabled: For IN endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the descriptor structure and data buffer with data ready to transmit is configured. For OUT endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the descriptor structure and data buffer to receive data is configured. When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: For IN endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that data is ready to be transmitted on the endpoint. For OUT endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the USBC_CTL_OEP[n]_D.EPENA bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Applies to IN and OUT endpoints. Note: For control endpoints in DMA mode, the USBC_CTL_OEP[n]_D.EPENA bit must be configured to be able to transfer SETUP data packets in memory.
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_OEP[n]_D.EPDIS bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_OEP[n]_D.EPDIS bit before setting the Endpoint Disabled interrupt. The application must set the USBC_CTL_OEP[n]_D.EPDIS bit only if Endpoint Enable is already set for this endpoint. Applies to IN and OUT endpoints.
29 (RX/W)	SETD1PID	Set DATA1 PID. In non scatter-gather DMA mode, the bit sets the odd (micro)frame (SetOddFr). Writing to the bit sets the even and odd (micro)frame (EO_FrNum) field to odd (micro)frame. Applies to isochronous IN and OUT endpoints only.

Table 19-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RX/W)	SETD0PID	Set DATA0 PID. A write to the USBC_CTL_OEP[n]_D.SETD0PID bit sets the endpoint data PID (DPID) field in this register to DATA0. The USBC_CTL_OEP[n]_D.SETD0PID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. In non-scatter/gather DMA mode: Set even (micro)frame (SetEvenFr). The SetEvenFr applies to isochronous IN and OUT endpoints only. A write to the USBC_CTL_OEP[n]_D.SETD0PID bit sets the even/odd (micro)frame (EO_FrNum) field to even (micro)frame. When scatter/gather DMA mode is enabled, the USBC_CTL_OEP[n]_D.SETD0PID bit is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. The USBC_CTL_OEP[n]_D.SETD0PID bit applies to interrupt/bulk IN and OUT endpoints only.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_OEP[n]_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_OEP[n]_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set the USBC_CTL_OEP[n]_D.SNAK bit for an endpoint after a SETUP packet is received on that endpoint.
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_OEP[n]_D.CNAK bit clears the NAK bit for the endpoint.
21 (R/W1S)	STALL	STALL Handshake. For non-control, non-isochronous IN and OUT endpoints: The application sets the USBC_CTL_OEP[n]_D.STALL bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear the USBC_CTL_OEP[n]_D.STALL bit, never the core. For control endpoints: The application can only set the USBC_CTL_OEP[n]_D.STALL bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's configuration, the core always responds to SETUP data packets with an ACK handshake.

Table 19-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:18 (R/W)	EPTYPE	Endpoint Type. The `USBC_CTL_OEP[n]_D.EPTYPE` field indicates the transfer type supported by this logical endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_OEP[n]_D.NAKSTS` bit is set, either by the application or core, the core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the Tx FIFO. For isochronous IN endpoints: The core sends out a zero length data packet, even if there data is available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Transmit non NAK handshakes
		1	Transmit NAK handshakes

Table 19-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/NW)	DPID	Endpoint Data PID. The USBC_CTL_OEP[n]_D.DPID bit applies to interrupt/bulk IN and OUT endpoints only. The USBC_CTL_OEP[n]_D.DPID bit indicates the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID bits of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 The USBC_CTL_OEP[n]_D.DPID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-scatter/gather DMA mode, the USBC_CTL_OEP[n]_D.DPID bit applies to isochronous IN and OUT endpoints only. The USBC_CTL_OEP[n]_D.DPID bit indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro)frame number in which it intends to transmit/ receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro)frame When scatter/gather DMA mode is enabled, the USBC_CTL_OEP[n]_D.DPID bit is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.
15 (R/W)	USBACTEP	USB Active Endpoint. The USBC_CTL_OEP[n]_D.USBACTEP bit indicates whether this endpoint is active in the current configuration and interface. The core clears the USBC_CTL_OEP[n]_D.USBACTEP bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.
10:0 (R/W)	MPS	Maximum Packet Size. The USBC_CTL_OEP[n]_D.MPS field indicates the maximum packet size for the current logical endpoint. This value is in bytes.

Device OUT Endpoint 0 DMA Address Register

In device mode, the USBC_DMA_ADDR_OEP0_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_OEP0_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_OEP0_D register indicates the base pointer for the descriptor list.

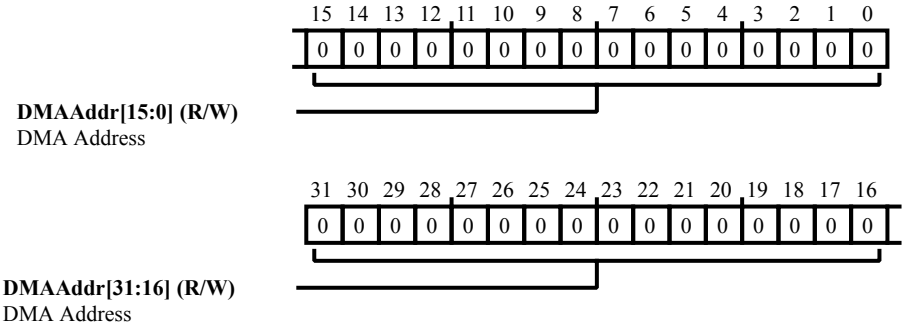

Figure 19-29: USBC_DMA_ADDR_OEP0_D Register Diagram

Table 19-26: USBC_DMA_ADDR_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_OEP0_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to- back, the SETUP data packet in the memory is overwritten.

Device OUT Endpoint 0 Buffer Address Register

In device mode, the USBC_DMA_BADDR_OEP0_D register indicates the buffer address for OUT endpoint 0. It is updated when the data transfer for the endpoint 0 is in progress.

The USBC_DMA_BADDR_OEP0_D register is available only in scatter/gather DMA mode and is otherwise reserved.

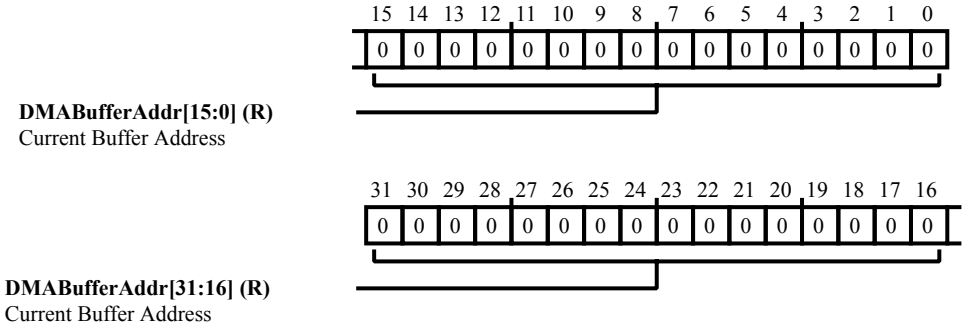

Figure 19-30: USBC_DMA_BADDR_OEP0_D Register Diagram

Table 19-27: USBC_DMA_BADDR_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_OEP0_D.DMABUFFERADDR bit filed contains the current buffer address.

Device OUT Endpoint n Buffer Address Register

In device mode, the USBC_DMA_BADDR_OEP[n]_D register indicates the buffer address for OUT endpoint n. It is updated when the data transfer for the corresponding endpoint is in progress.

The USBC_DMA_BADDR_OEP[n]_D register is available only in scatter/gather DMA mode and is otherwise reserved.

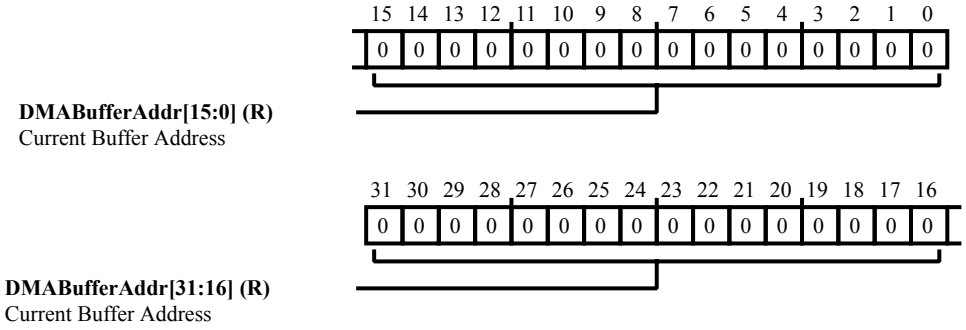

Figure 19-31: USBC_DMA_BADDR_OEP[n]_D Register Diagram

Table 19-28: USBC_DMA_BADDR_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_OEP[n]_D.DMABUFFERADDR bit filed contains the current buffer address.

Device OUT Endpoint n DMA Address Register

The USBC_DMA_ADDR_OEP[n]_D register indicates the DWORD-aligned address. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_OEP[n]_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_OEP[n]_D register indicates the base pointer for the descriptor list.

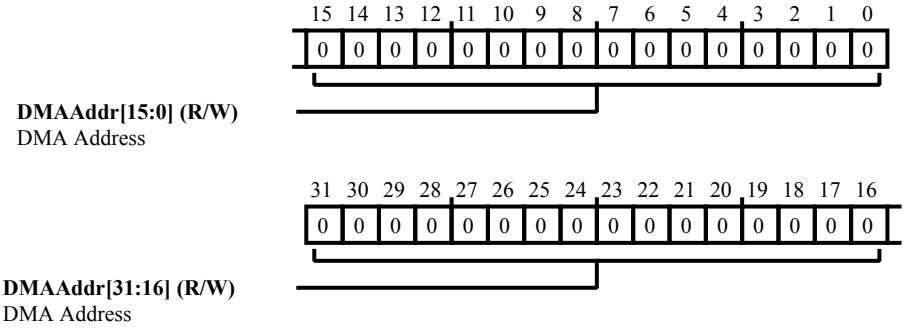

Figure 19-32: USBC_DMA_ADDR_OEP[n]_D Register Diagram

Table 19-29: USBC_DMA_ADDR_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_OEP[n]_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to- back, the SETUP data packet in the memory is overwritten.

Device OUT Endpoint 0 Interrupt Register

The USBC_ISTAT_OEP0_D register is the device OUT endpoint 0 interrupt register.

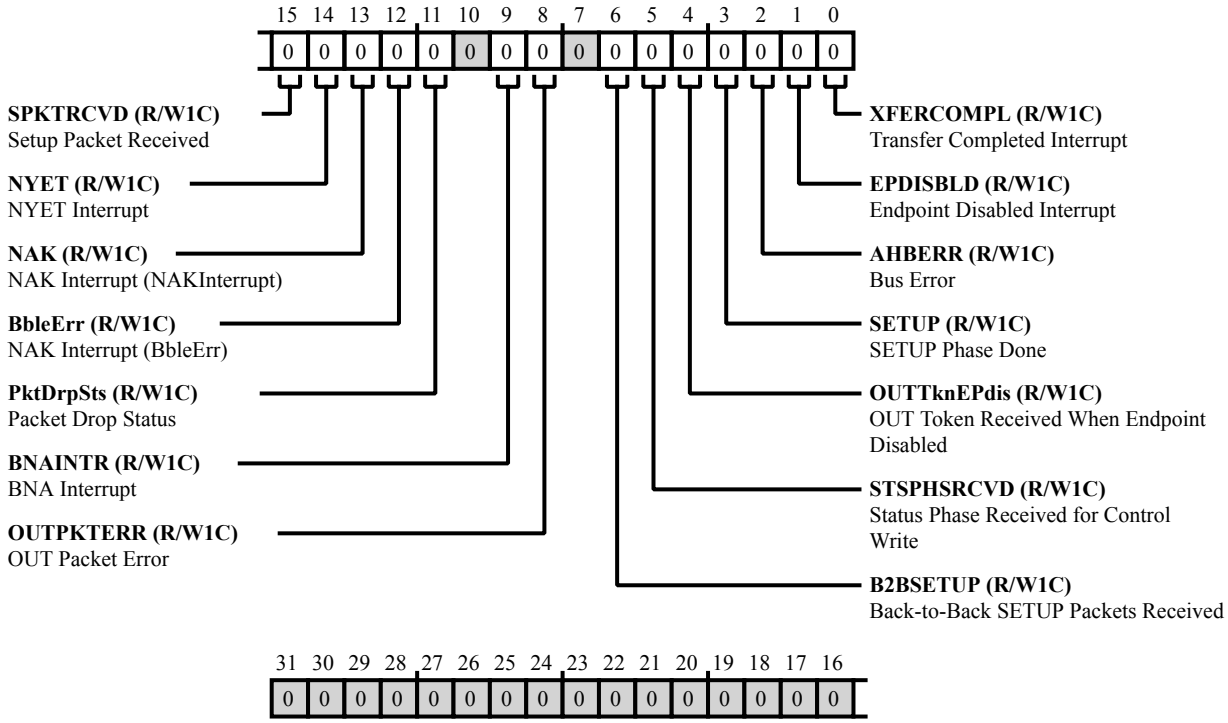

Figure 19-33: USBC_ISTAT_OEP0_D Register Diagram

Table 19-30: USBC_ISTAT_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SPKTRCVD	Setup Packet Received. The USBC_ISTAT_OEP0_D.SPKTRCVD bit applies to control OUT endpoints in only in the buffer DMA mode. Set by the controller, the USBC_ISTAT_OEP0_D.SPKTRCVD bit indicates that this buffer holds 8 bytes of setup data. There is only one SETUP packet per buffer. On receiving a SETUP packet, the controller closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Note: Because of the above behavior, the controller can receive any number of back to back setup packets and one buffer for every SETUP packet is used.	
		0	No SETUP packet received
		1	SETUP packet received

Table 19-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt (NAKInterrupt). The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates this interrupt when babble is received for the endpoint.
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_OEP0_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_OEP0_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA Interrupt. The `USBC_ISTAT_OEP0_D.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates the BNA (Buffer Not Available) interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	OUTPKTERR	OUT Packet Error. The `USBC_ISTAT_OEP0_D.OUTPKTERR` bit applies to OUT endpoints only. This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet.
6 (R/W1C)	B2BSETUP	Back-to-Back SETUP Packets Received. The `USBC_ISTAT_OEP0_D.B2BSETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP0_D.B2BSETUP` bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Table 19-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	STSPHSRCVD	Status Phase Received for Control Write. This interrupt is valid only for control OUT endpoints and only in scatter/gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase. This is applicable only in case of scatter/gather DMA mode.
4 (R/W1C)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled. The `USBC_ISTAT_OEP0_D.OUTTKNEPDIS` bit applies only to control OUT endpoints. The `USBC_ISTAT_OEP0_D.OUTTKNEPDIS` bit indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.
3 (R/W1C)	SETUP	SETUP Phase Done. The `USBC_ISTAT_OEP0_D.SETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP0_D.SETUP` bit indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_OEP0_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP0_D.AHBERR` bit is generated only in internal DMA mode when there is a bus error during an bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_OEP0_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP0_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.

Table 19-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_OEP0_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_OEP0_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_OEP0_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. Note: In DMA mode, this bit must be set for the core to transfer SETUP data packets into memory. When scatter/gather DMA mode is disabled, the bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device OUT Endpoint n Interrupt Register

The USBC_ISTAT_OEP[n]_D register is the device OUT endpoint n interrupt register.

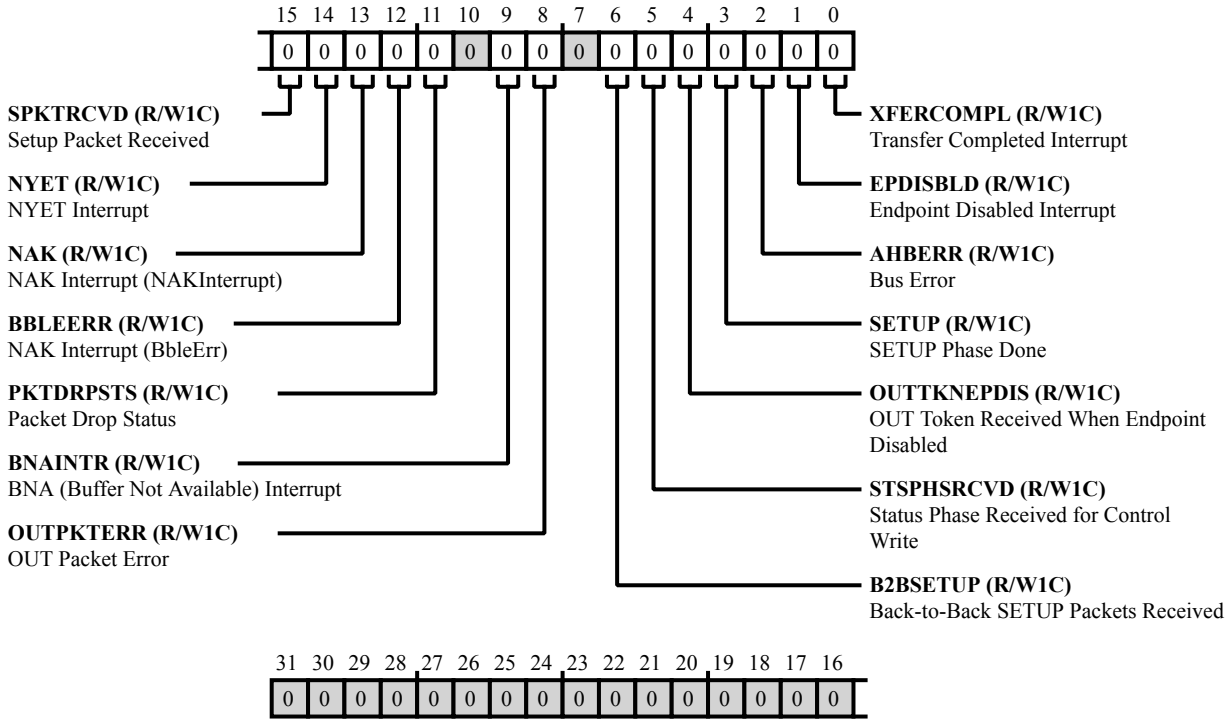

Figure 19-34: USBC_ISTAT_OEP[n]_D Register Diagram

Table 19-31: USBC_ISTAT_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SPKTRCVD	Setup Packet Received. The USBC_ISTAT_OEP[n]_D.SPKTRCVD bit applies to control OUT endpoints in only in the buffer DMA mode. Set by the controller, the USBC_ISTAT_OEP[n]_D.SPKTRCVD bit indicates whether the SETUP packet has been received. The buffer holds 8 bytes of SETUP data. There is only one SETUP packet per buffer. On receiving a SETUP packet, the controller closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Note: Because of the above behavior, the controller can receive any number of back-to-back SETUP packets and one buffer for every SETUP packet is used.	
		0	No SETUP packet received
		1	SETUP Packet Received

Table 19-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt (NAKInterrupt). The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates this interrupt when babble is received for the endpoint.
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_OEP[n]_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_OEP[n]_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA (Buffer Not Available) Interrupt. The `USBC_ISTAT_OEP[n]_D.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	OUTPKTERR	OUT Packet Error. The `USBC_ISTAT_OEP[n]_D.OUTPKTERR` bit applies to OUT endpoints only. This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet.
6 (R/W1C)	B2BSETUP	Back-to-Back SETUP Packets Received. The `USBC_ISTAT_OEP[n]_D.B2BSETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP[n]_D.B2BSETUP` bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Table 19-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	STSPHSRCVD	Status Phase Received for Control Write. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit is valid only for control OUT endpoints and only in scatter/gather DMA mode. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit indicates an interrupt that is generated after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit is applicable only in case of scatter/gather DMA mode.
4 (R/W1C)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled. The `USBC_ISTAT_OEP[n]_D.OUTTKNEPDIS` bit applies only to control OUT endpoints. The `USBC_ISTAT_OEP[n]_D.OUTTKNEPDIS` bit indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.
3 (R/W1C)	SETUP	SETUP Phase Done. The `USBC_ISTAT_OEP[n]_D.SETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP[n]_D.SETUP` bit indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_OEP[n]_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP[n]_D.AHBERR` bit is generated when there is a bus error during an bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_OEP[n]_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP[n]_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.

Table 19-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. Note: In DMA mode, this bit must be set for the core to transfer SETUP data packets into memory. When scatter/gather DMA mode is disabled, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device OUT Endpoint Common Interrupt Mask Register

The USBC_IMASK_OEP_D register works with each of the device OUT endpoint interrupt (USBC_ISTAT_OEP[n]_D) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the USBC_ISTAT_OEP[n]_D register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

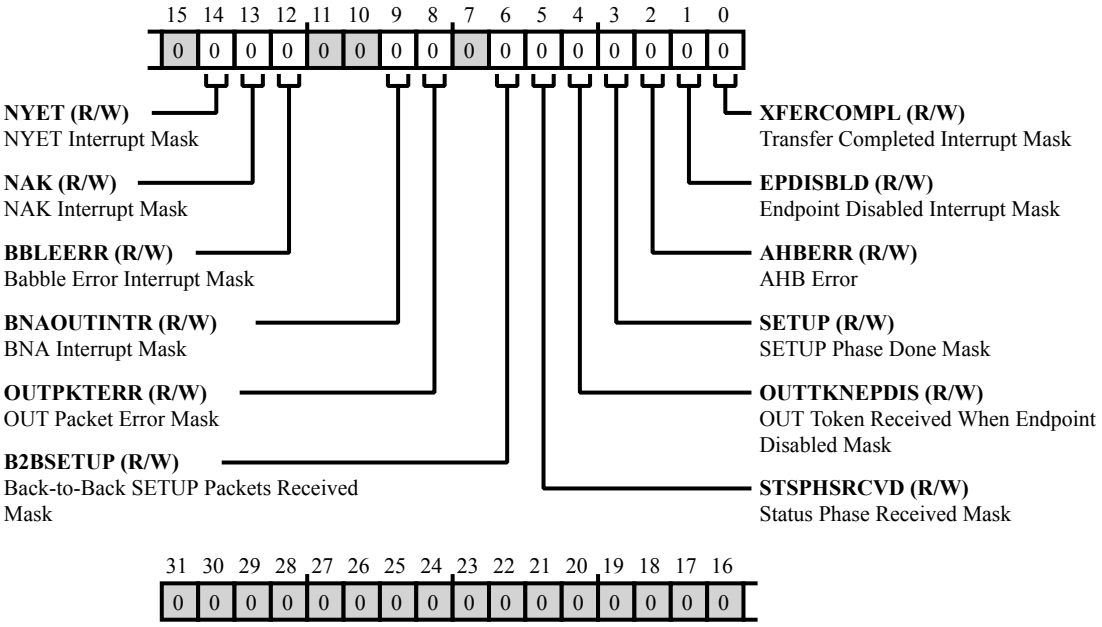

Figure 19-35: USBC_IMASK_OEP_D Register Diagram

Table 19-32: USBC_IMASK_OEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	NYET	NYET Interrupt Mask.
13 (R/W)	NAK	NAK Interrupt Mask.
12 (R/W)	BBLEERR	Babble Error Interrupt Mask.
9 (R/W)	BNAOUTINTR	BNA Interrupt Mask. BNA interrupt Mask (BnaOutIntrMsk)
8 (R/W)	OUTPKTERR	OUT Packet Error Mask.

Table 19-32: USBC_IMASK_OEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	B2BSETUP	Back-to-Back SETUP Packets Received Mask. The `USBC_IMASK_OEP_D.B2BSETUP` bit only applies to control OUT endpoints.
5 (R/W)	STSPHSRCVD	Status Phase Received Mask. The `USBC_IMASK_OEP_D.STSPHSRCVD` bit only applies to control OUT endpoints.
4 (R/W)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled Mask. The `USBC_IMASK_OEP_D.OUTTKNEPDIS` bit only applies to control OUT endpoints.
3 (R/W)	SETUP	SETUP Phase Done Mask. The `USBC_IMASK_OEP_D.SETUP` bit only applies to control endpoints.
2 (R/W)	AHBERR	AHB Error.
1 (R/W)	EPDISBLD	Endpoint Disabled Interrupt Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Interrupt Mask.

Device OUT Endpoint 0 Transfer Size Register

The USBC_TSIZ_OEP0_D register holds the transfer size of OUT endpoint 0 implemented in device mode.

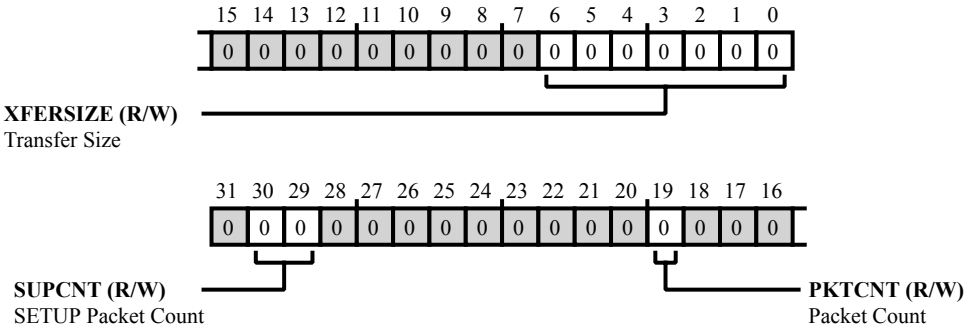

Figure 19-36: USBC_TSIZ_OEP0_D Register Diagram

Table 19-33: USBC_TSIZ_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	SUPCNT	SETUP Packet Count. The USBC_TSIZ_OEP0_D.SUPCNT field specifies the number of back-to-back SETUP data packets the endpoint can receive.	
		0	Reserved
		1	1 packet
		2	2 packets
		3	3 packets
19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_OEP0_D.PKTCNT field is decremented to zero after a packet is written into the Rx FIFO.	
6:0 (R/W)	XFERSIZE	Transfer Size. The USBC_TSIZ_OEP0_D.XFERSIZE field indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements the USBC_TSIZ_OEP0_D.XFERSIZE field every time a packet is read from the Rx FIFO and written to the external memory.	

Device OUT Endpoint n Transfer Size Register

The USBC_TSIZ_OEP[n]_D register holds the transfer size of OUT endpoint n implemented in device mode.

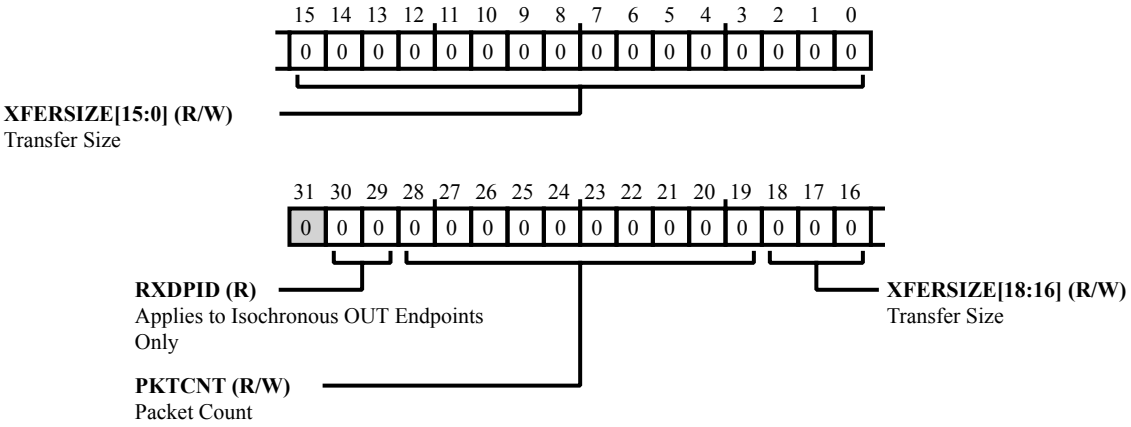

Figure 19-37: USBC_TSIZ_OEP[n]_D Register Diagram

Table 19-34: USBC_TSIZ_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/NW)	RXDPID	Applies to Isochronous OUT Endpoints Only. The USBC_TSIZ_OEP[n]_D.RXDPID field indicates the data PID received in the last packet for this endpoint.	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_OEP[n]_D.PKTCNT field is decremented to zero after a packet is written into the Rx FIFO.	
18:0 (R/W)	XFERSIZE	Transfer Size. The USBC_TSIZ_OEP[n]_D.XFERSIZE field indicates the transfer size in bytes for endpoint n. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	

Device Status Register

The USBC_STAT_D register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the USBC_ISTAT_D register.

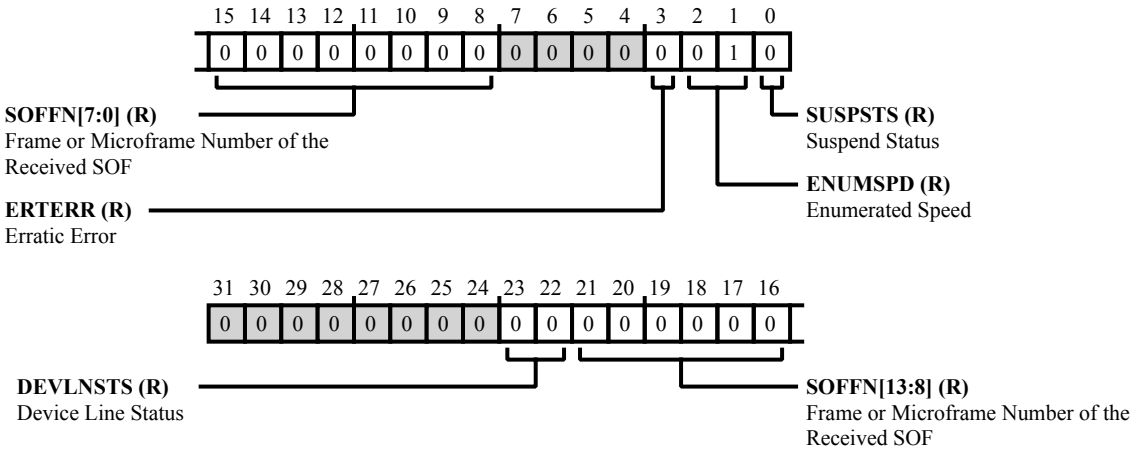

Figure 19-38: USBC_STAT_D Register Diagram

Table 19-35: USBC_STAT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/NW)	DEVLNSTS	Device Line Status. The USBC_STAT_D.DEVLNSTS field indicates the current logic level USB data lines.	
		0	Logic Level of D+
		1	Logic Level of D-
21:8 (R/NW)	SOFFN	Frame or Microframe Number of the Received SOF. When the core is operating at high speed, the USBC_STAT_D.SOFFN field contains a microframe number. When the core is operating at full or low speed, this field contains a frame number. Note: This register may return a non-zero value if read immediately after power-on reset. In case the register bit reads non-zero immediately after power-on reset, it does not indicate that SOF has been received from the host. The read value of this interrupt is valid only after a valid connection between host and device is established.	

Table 19-35: USBC_STAT_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	ERTERR	Erratic Error. The core sets the USBC_STAT_D.ERTERR bit to report any erratic errors (due to PHY error) seen on the ULPI. Due to erratic errors, the USBC_otg core goes into a SUSPEND state and an interrupt is generated to the application with the USBC_ISTAT.ERLYSUSP bit. If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recovery.	
2:1 (R/NW)	ENUMSPD	Enumerated Speed. The USBC_STAT_D.ENUMSPD field indicates the speed at which the controller has come up after speed detection through a connect or reset sequence. Low speed is not supported for devices using a ULPI PHY.	
		0	High speed. PHY clock is running at 30 or 60 Mhz.
		1	Full speed. PHY clock is running at 30 or 60 Mhz.
		2	Low speed. PHY clock is running at 6 Mhz.
		3	Full speed. PHY clock is running at 48 Mhz.
0 (R/NW)	SUSPSTS	Suspend Status. In device mode, the USBC_STAT_D.SUSPSTS bit is set (=1) as long as a SUSPEND condition is detected on the USB. The core enters the SUSPEND state when there is no activity on the linestate signal for an extended period of time. The core comes out of the suspend under the following conditions : - If there is any activity on the linestate signal, or - If the application writes to the Remote Wakeup Signaling bit in the USBC_CTL_D register. When the core comes out of the suspend, the USBC_STAT_D.SUSPSTS bit is cleared (=0).	

Device Threshold Control Register

The USBC_THR_CTL_D register indicates the device threshold control information.

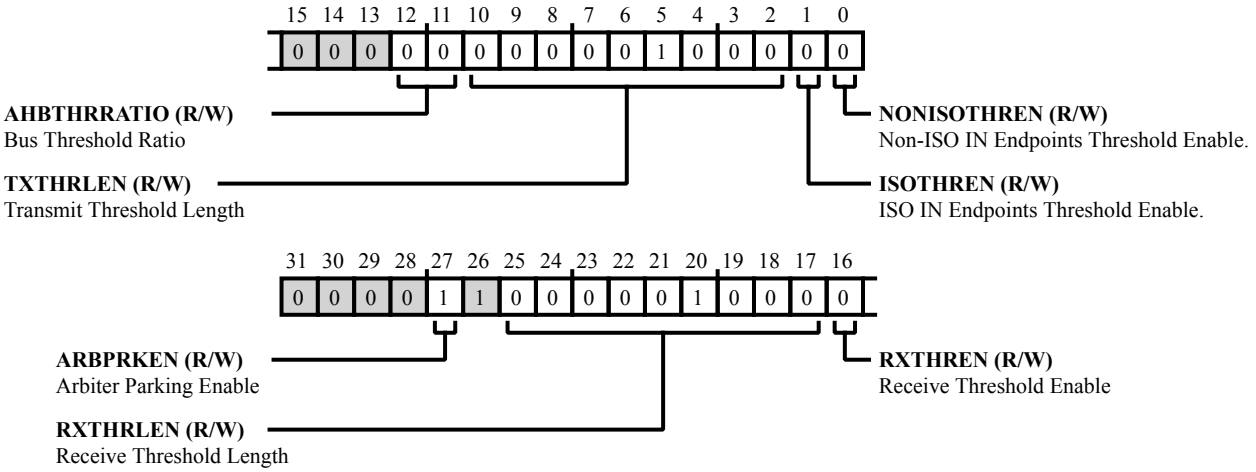

Figure 19-39: USBC_THR_CTL_D Register Diagram

Table 19-36: USBC_THR_CTL_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W)	ARBPRKEN	Arbiter Parking Enable. The USBC_THR_CTL_D.ARBPRKEN bit controls internal DMA arbiter parking for IN endpoints. If thresholding is enabled and the USBC_THR_CTL_D.ARBPRKEN bit is set (=1), the arbiter parks on the IN endpoint for which there is a token received on the USB. This avoids getting into underrun conditions. By default, arbiter parking is enabled.
25:17 (R/W)	RXTHRLEN	Receive Threshold Length. The USBC_THR_CTL_D.RXTHRLEN field specifies receive thresholding size in DWORDS. The USBC_THR_CTL_D.RXTHRLEN field also specifies the amount of data received on the USB before the core can start transmitting on the bus. The threshold length has to be at least eight DWORDS. The recommended value for ThrLen must be the same as USBC_AHB_CFG.HBSTLEN.
16 (R/W)	RXTHREN	Receive Threshold Enable. When the USBC_THR_CTL_D.RXTHREN bit is set, the core enables thresholding in the receive direction. Note: Do not enable the USBC_THR_CTL_D.RXTHREN bit, because it may cause issues in the RxFIFO, especially during error conditions such as RxError and Babble.

Table 19-36: USBC_THR_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12:11 (R/W)	AHBTHRRATIO	Bus Threshold Ratio. The USBC_THR_CTL_D.AHBTHRRATIO field defines the ratio between the bus threshold and the MAC threshold for the transmit path only. The bus threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the bus and the MAC threshold must be DWORD-aligned. The application must program USBC_THR_CTL_D.TXTHRLEN and the USBC_THR_CTL_D.AHBTHRRATIO bits to make the bus threshold value DWORD aligned. If the bus threshold value is not DWORD aligned, the core might not behave correctly. When programming the USBC_THR_CTL_D.TXTHRLEN and USBC_THR_CTL_D.AHBTHRRATIO, the application must ensure that the minimum bus threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements.	
		0	MAC threshold
		1	MAC threshold/2
		2	MAC threshold/4
		3	MAC threshold/8
10:2 (R/W)	TXTHRLEN	Transmit Threshold Length. The USBC_THR_CTL_D.TXTHRLEN field specifies the transmit thresholding size in DWORDS. It also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length must be at least eight DWORDS when the value of USBC_THR_CTL_D.AHBTHRRATIO is zero. When the USBC_THR_CTL_D.AHBTHRRATIO bit field is non zero, the application must ensure that the bus threshold value does not go below the recommended eight DWORD. The USBC_THR_CTL_D.TXTHRLEN field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for the USBC_THR_CTL_D.TXTHRLEN field is the same as the programmed bus burst length in the USBC_AHB_CFG.HBSTLEN field.	
1 (R/W)	ISOTHREN	ISO IN Endpoints Threshold Enable.. When the USBC_THR_CTL_D.ISOTHREN bit is set, the core enables thresholding for isochronous IN endpoints.	
0 (R/W)	NONISOTHREN	Non-ISO IN Endpoints Threshold Enable.. When the USBC_THR_CTL_D.NONISOTHREN bit is set, the core enables thresholding for non Isochronous IN endpoints.	

Device Control IN Endpoint Transmit FIFO Status Register

The USBC_TXFSTAT_IEP0_D register indicates the amount of free space available in the endpoint Tx FIFO.

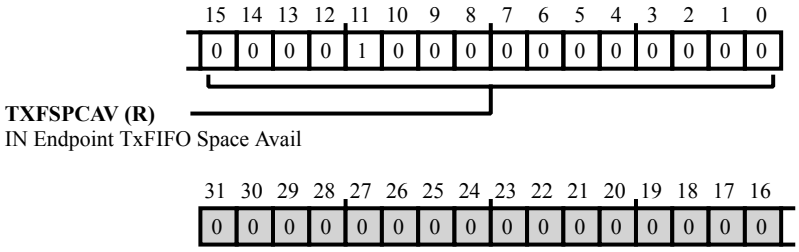

Figure 19-40: USBC_TXFSTAT_IEP0_D Register Diagram

Table 19-37: USBC_TXFSTAT_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXFSPCAV	IN Endpoint TxFIFO Space Avail. The USBC_TXFSTAT_IEP0_D.TXFSPCAV field indicates the amount of free space available in the endpoint TxFIFO. Values are in terms of 32-bit words. - 16'h0: Endpoint TxFIFO is full - 16'h1: 1 word available - 16'h2: 2 words available - 16'hn: n words available (where 0 n 32,768) - 16'h8000: 32,768 words available - Others: Reserved

Device Control IN Endpoint Transmit FIFO Status Register

In device mode, the USBC_TXFSTAT_IEP[n]_D register indicates the status of the Tx FIFO in the endpoint.

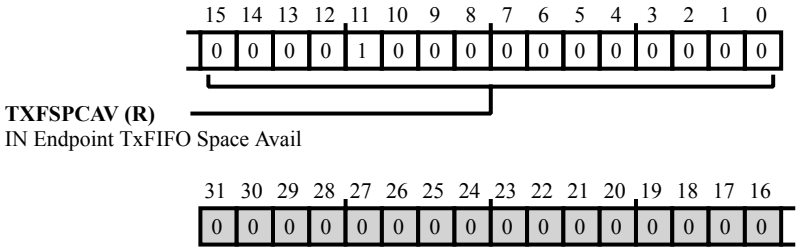

Figure 19-41: USBC_TXFSTAT_IEP[n]_D Register Diagram

Table 19-38: USBC_TXFSTAT_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXFSPCAV	IN Endpoint TxFIFO Space Avail. The USBC_TXFSTAT_IEP[n]_D.TXFSPCAV field indicates the amount of free space available in the endpoint TxFIFO. Values are in terms of 32-bit words. - 16'h0: Endpoint TxFIFO is full - 16'h1: 1 word available - 16'h2: 2 words available - 16'hn: n words available (where 0 n 32,768) - 16'h8000: 32,768 words available - Others: Reserved

Device VBUS Discharge Time Register

The USBC_VBUSDIS_D register specifies the VBUS discharge time after VBUS pulsing during SRP.

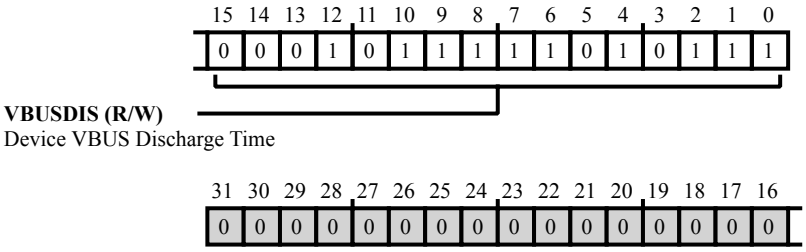

Figure 19-42: USBC_VBUSDIS_D Register Diagram

Table 19-39: USBC_VBUSDIS_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VBUSDIS	Device VBUS Discharge Time. The USBC_VBUSDIS_D.VBUSDIS bit indicates the VBUS discharge time after VBUS pulsing during SRP. This value equals (VBUS discharge time in PHY clocks) / 1,024. The value used depends whether the PHY is operating at 30 MHz (16-bit data width) or 60 MHz (8-bit data width). Depending on the VBUS load, this value can need adjustment.

Device VBUS Pulsing Time Register

The USBC_VBUSPULSE_D register indicates the pulsing time during SRP.

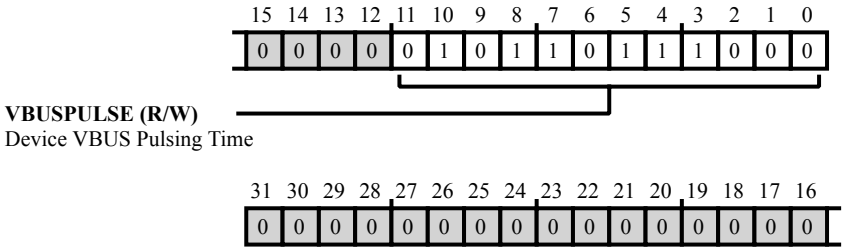

Figure 19-43: USBC_VBUSPULSE_D Register Diagram

Table 19-40: USBC_VBUSPULSE_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	VBUSPULSE	Device VBUS Pulsing Time. The USBC_VBUSPULSE_D.VBUSPULSE field specifies the VBUS pulsing time during SRP. This value equals (VBUS pulsing time in PHY clocks) / 1,024. The value used depends whether the PHY is operating at 30 MHz (16-bit data width) or 60 MHz (8-bit data width).

Bus Configuration Register

The USBC_AHB_CFG register can be used to configure the core after power-on or a change in mode. This register mainly contains bus system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the bus or the USB.

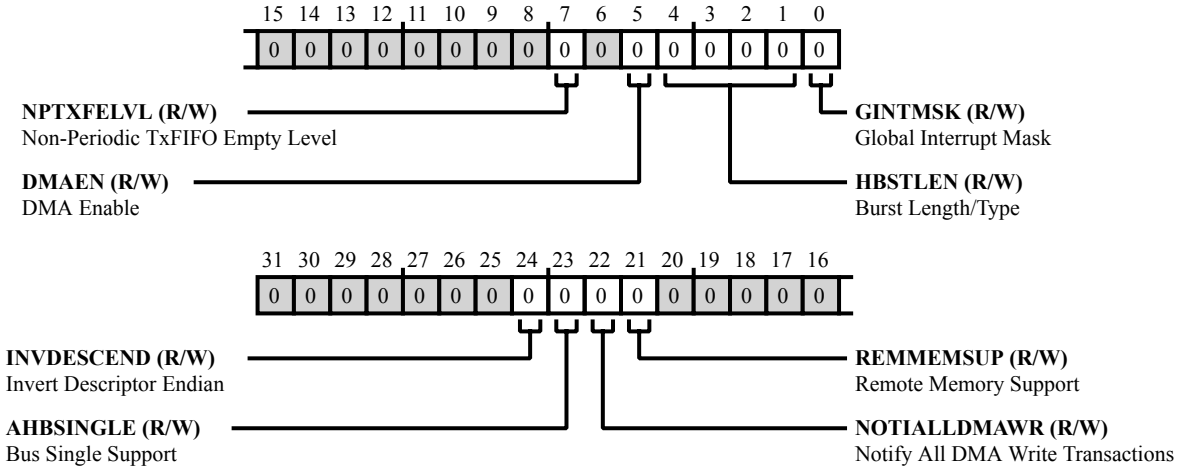

Figure 19-44: USBC_AHB_CFG Register Diagram

Table 19-41: USBC_AHB_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	INVDESCEND	Invert Descriptor Endian. The USBC_AHB_CFG.INVDESCEND bit is applicable in host and device modes. The USBC_AHB_CFG.INVDESCEND bit indicates whether the byte order function (endian) of the bus requester is the same as the descriptor or is inverted.	
		0	Endian configuration is the same as the bus requester
		1	Endian configuration is the opposite of the bus requester. If the byte order function of the bus requester is big endian, the descriptor is little endian. If the the byte order function of bus requester is little endian, the descriptor is big endian.

Table 19-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	AHBSINGLE	Bus Single Support. When the core is operating in DMA mode, the USBC_AHB_CFG.AHBSINGLE bit supports single transfers for the remaining data in a transfer. It determines whether the remaining data is sent in an INCR burst size or a single burst size. The USBC_AHB_CFG.AHBSINGLE bit is active in both host and device modes. Note: If this feature is enabled, the bus RETRY and SPLIT transfers still have INCR burst type. Enable this feature when the bus responder connected to the core does not support INCR burst (and when Split, and Retry transactions are not being used in the bus). 0 – INCR Burst Size 1 – Single Burst Size
22 (R/W)	NOTIALLDMAWR	Notify All DMA Write Transactions. The USBC_AHB_CFG.NOTIALLDMAWR bit is applicable in host and device modes. The USBC_AHB_CFG.NOTIALLDMAWR bit is programmed to enable the system DMA Done functionality for all the DMA write Transactions corresponding to the channel/endpoint. The USBC_AHB_CFG.NOTIALLDMAWR bit is valid only when USBC_AHB_CFG.REMMEMSUP = 1 and USBC_AHB_CFG.NOTIALLDMAWR = 1. The core asserts dma request for all the DMA write transactions on the bus interface. The core waits for system dma done signal for all the DMA write transactions in order to complete the transfer of a particular channel/endpoint. When USBC_AHB_CFG.NOTIALLDMAWR = 0, the core asserts dma request signal only for the last transaction of DMA write transfer corresponding to a particular channel/endpoint. Similarly, the core waits for system dma done signal only for that transaction of DMA write to complete the transfer of a particular channel/endpoint.
21 (R/W)	REMMEMSUP	Remote Memory Support. The USBC_AHB_CFG.REMMEMSUP bit is applicable in host and device modes. The USBC_AHB_CFG.REMMEMSUP bit is programmed to enable the functionality to wait for the system DMA Done signal for the DMA write transfers. When USBC_AHB_CFG.REMMEMSUP = 1, the dma request output signal is asserted when the DMA starts write transfer to the external memory. When the core is done with the transfers it asserts dma done signal to flag the completion of DMA writes from the controller. The core then waits for system dma done signal from the system to proceed further and complete the data transfer corresponding to a particular channel/endpoint. When USBC_AHB_CFG.REMMEMSUP = 0, the dma request and dma done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as the DMA write transfer is done at the core boundary and it does not wait for the system dma done signal to complete the DATA transfers.

Table 19-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	NPTXFELVL	Non-Periodic TxFIFO Empty Level. The USBC_AHB_CFG.NPTXFELVL bit is applicable in host and device modes. In host mode and with shared FIFO and device mode: - 1'b0: the USBC_ISTAT.NPTXFEMP interrupt indicates that the non-periodic TxFIFO is half empty. - 1'b1: the USBC_ISTAT.NPTXFEMP interrupt indicates that the non-periodic TxFIFO is completely empty. In dedicated FIFO in device mode: - 1'b0: the USBC_ISTAT_IEP[n]_D.TXFEMP interrupt indicates that the IN endpoint TxFIFO is half empty. - 1'b1: the USBC_ISTAT_IEP[n]_D.TXFEMP interrupt indicates that the IN endpoint TxFIFO is completely empty.	
		0	TxFIFO half empty: device mode and host mode with shared FIFO USBC_ISTAT.NPTXFEMPinterrupt / device mode with dedicated FIFO USBC_ISTAT_IEP[n]_D.TXFEMP interrupt
		1	TxFIFO completely empty: device mode and host mode with shared FIFO USBC_ISTAT.NPTXFEMP interrupt / device mode with dedicated FIFO USBC_ISTAT_IEP[n]_D.TXFEMP interrupt
5 (R/W)	DMAEN	DMA Enable. The USBC_AHB_CFG.DMAEN bit is applicable in host and device modes. The USBC_AHB_CFG.DMAEN bit is always 0 when bus responder only mode has been selected. Reset: 1'b0	
4:1 (R/W)	HBSTLEN	Burst Length/Type. The USBC_AHB_CFG.HBSTLEN bit field indicates the burst length. It is applicable in host and device modes.	
		0	Single
		1	INCR
		2	Reserved
		3	INCR4
		4	Reserved
		5	INCR8
		6	Reserved
		7	INCR16

Table 19-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	GINTMSK	Global Interrupt Mask. The application uses the `USBC_AHB_CFG.GINTMSK` bit to mask or unmask the interrupt line assertion to itself. Irrespective of the configuration of the `USBC_AHB_CFG.GINTMSK` bit, the interrupt status registers are updated by the controller. The `USBC_AHB_CFG.GINTMSK` bit is applicable in host and device modes.	
		0	Mask
		1	Unmask

DFIFO Configuration Register

The USBC_DFIFO_CFG register represents the global DFIFO configuration.

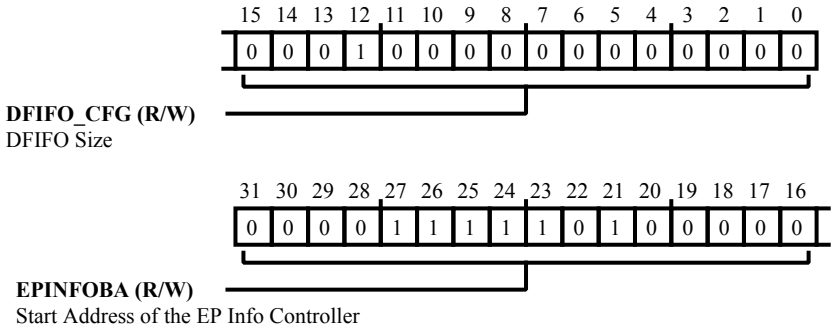

Figure 19-45: USBC_DFIFO_CFG Register Diagram

Table 19-42: USBC_DFIFO_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	EPINFOBA	Start Address of the EP Info Controller. The USBC_DFIFO_CFG.EPINFOBA field provides the start address of the EP info controller.
15:0 (R/W)	DFIFO_CFG	DFIFO Size. The USBC_DFIFO_CFG.DFIFO_CFG field is for dynamic programming of the DFIFO Size. This value takes effect only when the application programs a non zero value to this register. The value programmed must conform to the guidelines described in 'FIFO RAM Allocation'. The core does not have any corrective logic if the FIFO sizes are programmed incorrectly.

User Hardware Configuration 1 Register

The USBC_HWCFG1 register contains the logical endpoint direction(s).

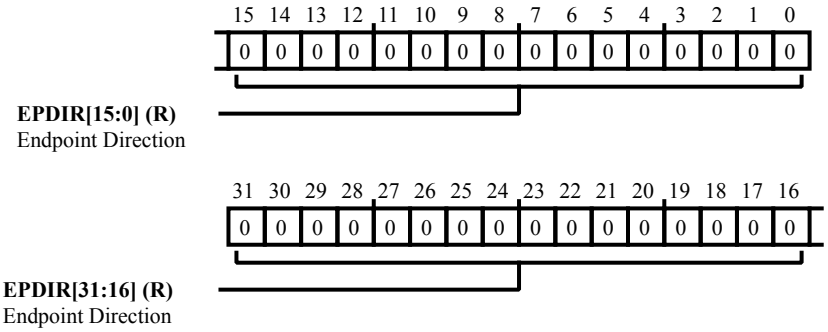

Figure 19-46: USBC_HWCFG1 Register Diagram

Table 19-43: USBC_HWCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	EPDIR	Endpoint Direction. The USBC_HWCFG1.EPDIR field uses two bits per endpoint to determine the endpoint direction. Endpoint - Bits [31:30]: Endpoint 15 direction - Bits [29:28]: Endpoint 14 direction ... - Bits [3:2]: Endpoint 1 direction - Bits[1:0]: Endpoint 0 direction (always BIDIR)	
		0	BIDIR (IN and OUT) endpoint
		1	IN endpoint
		2	OUT endpoint
		3	Reserved

User Hardware Configuration 2 Register

The USBC_HWCFG2 register contains configuration options.

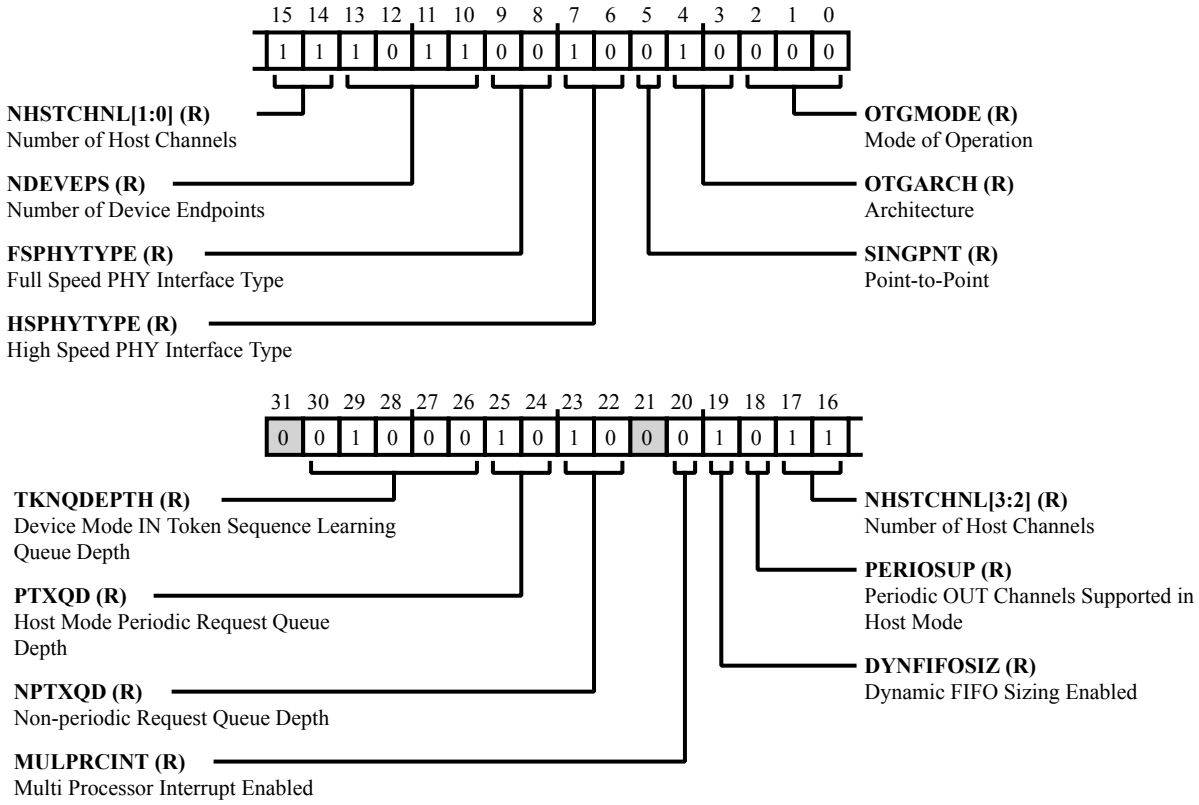

Figure 19-47: USBC_HWCFG2 Register Diagram

Table 19-44: USBC_HWCFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:26 (R/NW)	TKNQDEPTH	Device Mode IN Token Sequence Learning Queue Depth. The USBC_HWCFG2.TKNQDEPTH field indicates the device mode IN token sequence learning queue depth. The depth can range from 0 to 30.	
25:24 (R/NW)	PTXQD	Host Mode Periodic Request Queue Depth. The USBC_HWCFG2.PTXQD field indicates the host mode periodic request queue depth.	
		0	2
		1	4
		2	8
		3	16

Table 19-44: USBC_HWCFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/NW)	NPTXQD	Non-periodic Request Queue Depth. The `USBC_HWCFG2.NPTXQD` field indicates the non-periodic request queue depth.	
		0	2
		1	4
		2	8
		3	Reserved
20 (R/NW)	MULPRCINT	Multi Processor Interrupt Enabled. The `USBC_HWCFG2.MULPRCINT` bit indicates if the multiprocessor interrupt is enabled.	
		0	No
		1	Yes
19 (R/NW)	DYNFIFOSIZ	Dynamic FIFO Sizing Enabled. The `USBC_HWCFG2.DYNFIFOSIZ` bit indicates if dynamic FIFO sizing is enabled.	
18 (R/NW)	PERIOSUP	Periodic OUT Channels Supported in Host Mode. The ${.::} field indicates if the periodic OUT channel is supported in host mode.	
		0	No
		1	Yes
17:14 (R/NW)	NHSTCHNL	Number of Host Channels. The `USBC_HWCFG2.NHSTCHNL` field indicates the number of host channels supported by the core in host mode. The range of this field is 0-15: 0 specifies 1 channel, 15 specifies 16 channels.	
13:10 (R/NW)	NDEVEPS	Number of Device Endpoints. The `USBC_HWCFG2.NDEVEPS` field indicates the number of device endpoints supported by the core in device mode. The range of this field is 0-15.	
9:8 (R/NW)	FSPHYTYPE	Full Speed PHY Interface Type. The `USBC_HWCFG2.FSPHYTYPE` field indicates the type of full speed PHY interface.	
		0	Full speed interface not supported
		1	Dedicated full speed interface
		2	FS pins shared with UTMI+ pins
		3	FS pins shared with ULPI pins

Table 19-44: USBC_HWCFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	HSPHYTYPE	High Speed PHY Interface Type. The `USBC_HWCFG2.HSPHYTYPE` field indicates the type of high speed PHY interface.	
		0	High speed interface is not supported
		1	UTMI+
		2	ULPI
		3	UTMI+ and ULPI
5 (R/NW)	SINGPNT	Point-to-Point. The `USBC_HWCFG2.SINGPNT` bit indicates whether the application is a single point application with hub and split support or a multipoint application with no hub and split support.	
		0	Multipoint Application
		1	Single Point Application
4:3 (R/NW)	OTGARCH	Architecture. The `USBC_HWCFG2.OTGARCH` field indicates the architecture.	
		0	Responder Only
		1	External DMA
		2	Internal DMA
		3	Reserved
2:0 (R/NW)	OTGMODE	Mode of Operation. The `USBC_HWCFG2.OTGMODE` field indicates the mode of operation.	
		0	HNP and SRP Capable OTG (Host and Device)
		1	SRP Capable OTG (Host and Device)
		2	Non-HNP and Non-SRP Capable OTG (Host and Device)
		3	SRP Capable Device
		4	Non-OTG Device
		5	SRP Capable Host
		6	Non-OTG Host
		7	Reserved

User Hardware Configuration 3 Register

The USBC_HWCFG3 register contains configuration options.

Table 19-45: USBC_HWCFG3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	DFIFOD	DFIFO Depth. The USBC_HWCFG3.DFIFOD field indicates the DFIFO depth. This value is in terms of 32-bit words, with a minimum value is 32 and a maximum value is 32,768.	
15 (R/NW)	LPMMODE	LPM Mode Enable. The USBC_HWCFG3.LPMMODE bit enables the LPM mode of operation.	
9 (R/NW)	PHYCTLSUP	Vendor Control Interface Support. The USBC_HWCFG3.PHYCTLSUP bit indicates whether the vendor control interface is available on the core.	
		0	Not available
		1	Available
7 (R/NW)	OTGEN	OTG Function Enabled. The application uses the USBC_HWCFG3.OTGEN bit to indicate the OTG capabilities of the controller.	
		0	Not OTG capable
		1	OTG capable
6:4 (R/NW)	PKTSZWDTH	Width of Packet Size Counters. The USBC_HWCFG3.PKTSZWDTH field indicates the width of the transfer size counters.

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	4 Bits
		1	5 Bits
		2	6 Bits
		3	7 Bits
		4	8 Bits
		5	9 Bits
		6	10 Bits
3:0 (R/NW)	XFSIZWDTH	Width of Transfer Size Counters. The `USBC_HWCFG3.XFSIZWDTH` field indicates the width of the transfer size counters.	
		0	11 Bits
		1	12 Bits
		2	13 Bits
		3	14 Bits
		4	15 Bits
		5	16 Bits
		6	17 Bits
		7	18 Bits
		8	19 Bits

User Hardware Configuration 4 Register

The USBC_HWCFG4 register contains configuration options.

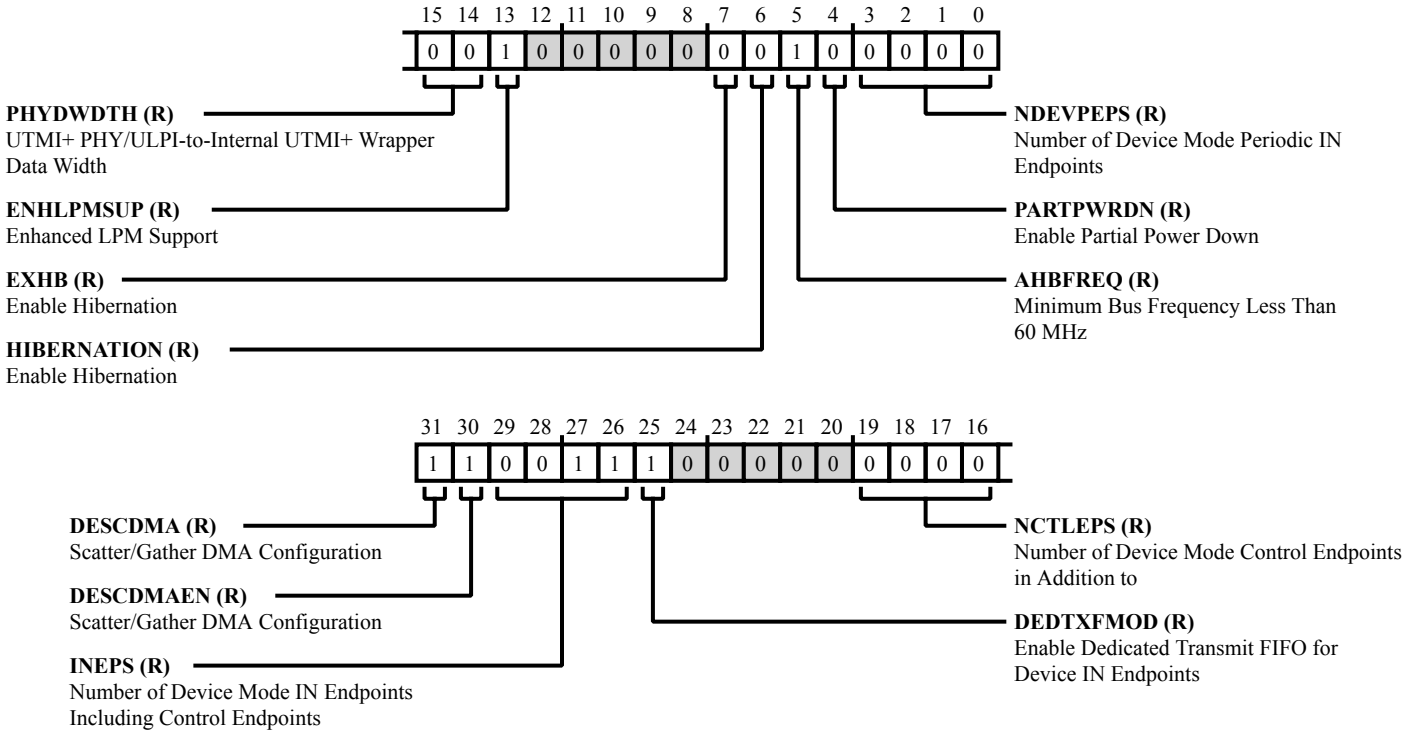

Figure 19-49: USBC_HWCFG4 Register Diagram

Table 19-46: USBC_HWCFG4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	DESCDMA	Scatter/Gather DMA Configuration. The USBC_HWCFG4.DESCDMA bit enables dynamic scatter/gather DMA configuration.	
		0	Disable
		1	Enable
30 (R/NW)	DESCDMAEN	Scatter/Gather DMA Configuration. The USBC_HWCFG4.DESCDMAEN bit enables scatter/gather DMA configuration.	
		0	Non scatter/gather DMA
		1	Scatter/gather DMA
29:26 (R/NW)	INEPS	Number of Device Mode IN Endpoints Including Control Endpoints. The USBC_HWCFG4.INEPS field indicates the number of device mode IN endpoints (including control endpoints).	

Table 19-46: USBC_HWCFG4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	1 IN Endpoint
		1	2 IN Endpoints
		2	3 IN Endpoints
		3	4 IN Endpoints
		4	5 IN Endpoints
		5	6 IN Endpoints
		6	7 IN Endpoints
		7	8 IN Endpoints
		8	9 IN Endpoints
		9	10 IN Endpoints
		10	11 IN Endpoints
		11	12 IN Endpoints
		12	13 IN Endpoints
		13	14 IN Endpoints
		14	15 IN Endpoints
		15	16 IN Endpoints
25 (R/NW)	DEDTXFMOD	Enable Dedicated Transmit FIFO for Device IN Endpoints. The `USBC_HWCFG4.DEDTXFMOD` bit enables a dedicated transmit FIFO for device IN endpoints (DedFifoMode).	
		0	Disable
		1	Enable
19:16 (R/NW)	NCTLEPS	Number of Device Mode Control Endpoints in Addition to. Endpoint 0 (NCTLEPS) Range: 0-15	
15:14 (R/NW)	PHYDWDTH	UTMI+ PHY/ULPI-to-Internal UTMI+ Wrapper Data Width. When a ULPI PHY is used, an internal wrapper converts ULPI to UTMI+.	
		0	8 bits
		1	16 bits
		2	8/16 bits, software selectable
		3	Reserved

Table 19-46: USBC_HWCFG4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	ENHLPMSUP	Enhanced LPM Support. The `USBC_HWCFG4.ENHLPMSUP` bit indicates that the controller supports the following behavior: L1 entry behavior is based on FIFO status: - TX FIFO - Accept L1 request even if ISOC OUT TX FIFO is not empty. - Reject L1 request if non-periodic TX FIFO is not empty. - Ensure application can flush the TX FIFO while the controller is in L1. - RX FIFO - Accept L1 request even if RX FIFO (common to periodic and non-periodic) is not empty. - Accept L1 request but delay SLEEPM assertion until RX SINK buffer is empty. Prevent L1 entry if a control transfer is in progress on any control Endpoint. Ability to Flush TxFIFO even if PHY Clock is gated.	
7 (R/NW)	EXHB	Enable Hibernation. The `USBC_HWCFG4.EXHB` bit enables extended hibernation.	
		0	Disable
		1	Enable
6 (R/NW)	HIBERNATION	Enable Hibernation. The `USBC_HWCFG4.HIBERNATION` bit enables hibernation.	
		0	Disable
		1	Enable
5 (R/NW)	AHBFREQ	Minimum Bus Frequency Less Than 60 MHz. The `USBC_HWCFG4.AHBFREQ` bits indicates whether the minimum bus frequency is less than 60 MHz.	
		0	No
		1	Yes
4 (R/NW)	PARTPWRDN	Enable Partial Power Down. The `USBC_HWCFG4.PARTPWRDN` bit enables or disables partial power down.	
		0	Disable
		1	Enable
3:0 (R/NW)	NDEVPEPS	Number of Device Mode Periodic IN Endpoints. The `USBC_HWCFG4.NDEVPEPS` field indicates the number of periodic IN endpoints (0-15).	

Interrupt Mask Register

The USBC_IMSK register works with the Interrupt Register (USBC_ISTAT) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the USBC_ISTAT register bit corresponding to that interrupt is still set.

Note: The fields of this register change depending on host or device mode.

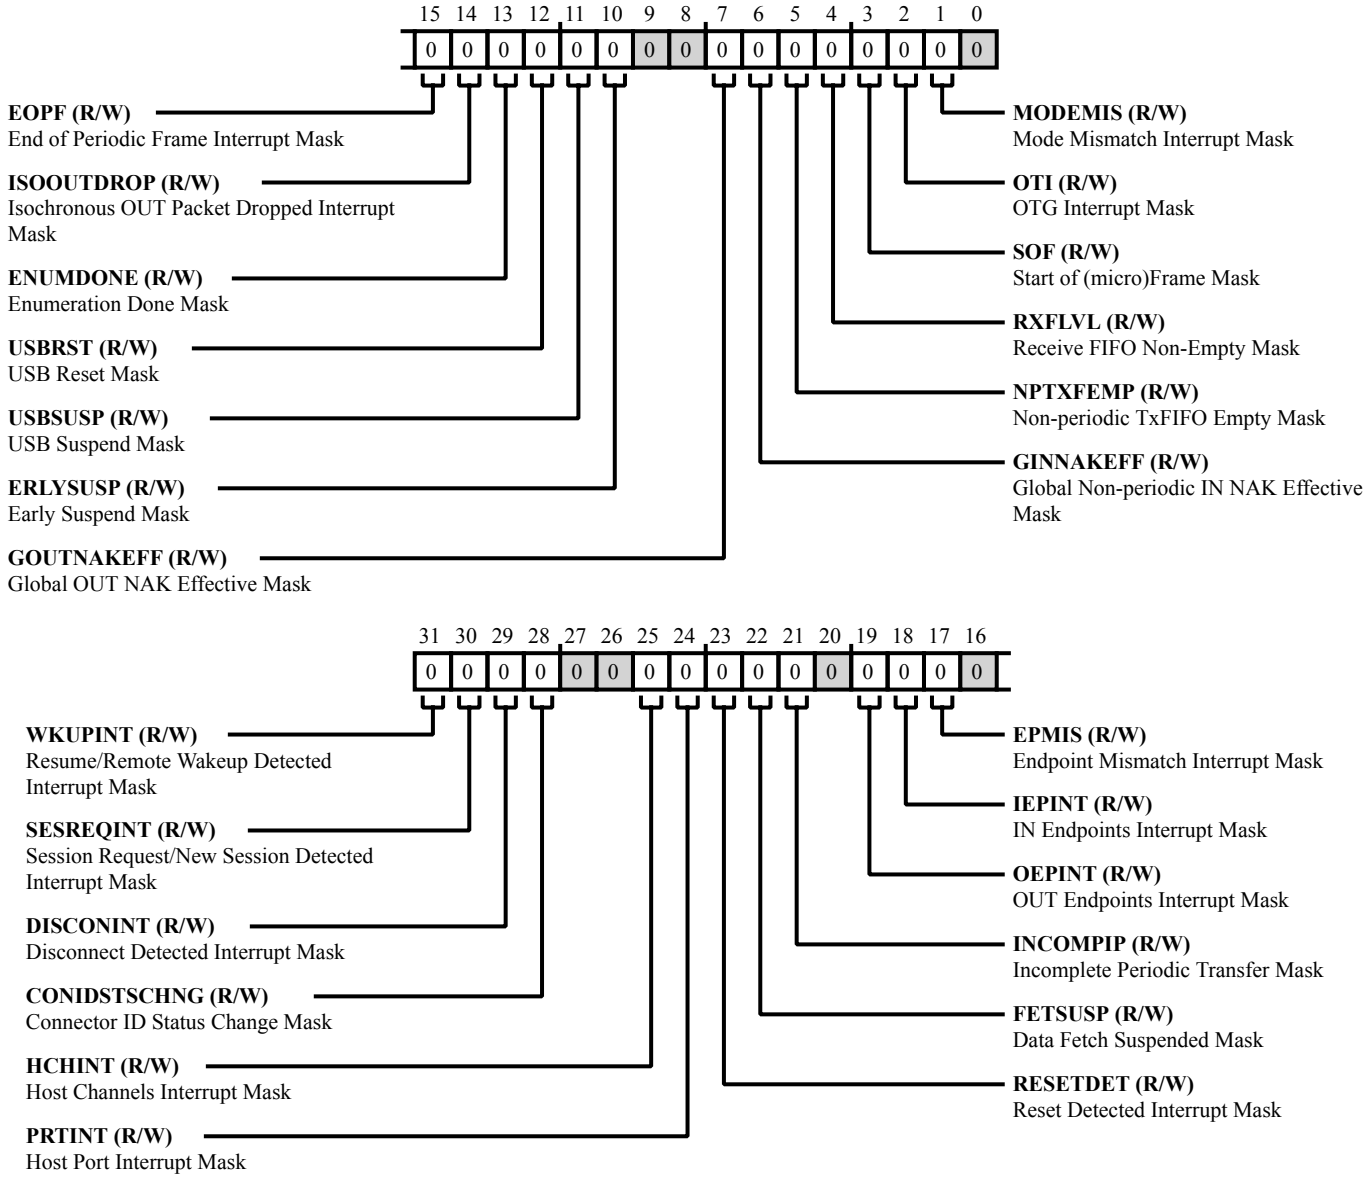

Figure 19-50: USBC_IMSK Register Diagram

Table 19-47: USBC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	WKUPINT	Resume/Remote Wakeup Detected Interrupt Mask. Mode: Host and Device The WakeUp bit is used for LPM state wake up in a way similar to that of wake up in suspend state.
30 (R/W)	SESREQINT	Session Request/New Session Detected Interrupt Mask. Mode: Host and Device
29 (R/W)	DISCONINT	Disconnect Detected Interrupt Mask. Mode: Host and Device Disconnect Detected Interrupt Mask (DisconnIntMsk)
28 (R/W)	CONIDSTSCHNG	Connector ID Status Change Mask. Mode: Host and Device Connector ID Status Change Mask (ConIDStsChngMsk)
25 (R/W)	HCHINT	Host Channels Interrupt Mask. Mode: Host only
24 (R/W)	PRTINT	Host Port Interrupt Mask. Mode: Host only
23 (R/W)	RESETDET	Reset Detected Interrupt Mask. Mode: Device only
22 (R/W)	FETSUSP	Data Fetch Suspended Mask. Mode: Device only
21 (R/W)	INCOMPIP	Incomplete Periodic Transfer Mask. Mode: Host only Incomplete Isochronous OUT Transfer Interrupt Mask (incompISOOUTMsk) Mode: Device only
19 (R/W)	OEPINT	OUT Endpoints Interrupt Mask. Mode: Device only
18 (R/W)	IEPINT	IN Endpoints Interrupt Mask. Mode: Device only
17 (R/W)	EPMIS	Endpoint Mismatch Interrupt Mask. Mode: Device only
15 (R/W)	EOPF	End of Periodic Frame Interrupt Mask. Mode: Device only
14 (R/W)	ISOOUTDROP	Isochronous OUT Packet Dropped Interrupt Mask. Mode: Device only
13 (R/W)	ENUMDONE	Enumeration Done Mask. Mode: Device only

Table 19-47: USBC_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	USBRST	USB Reset Mask. Mode: Device only
11 (R/W)	USBSUSP	USB Suspend Mask. Mode: Device only
10 (R/W)	ERLYSUSP	Early Suspend Mask. Mode: Device only
7 (R/W)	GOUTNAKEFF	Global OUT NAK Effective Mask. Mode: Device only
6 (R/W)	GINNAKEFF	Global Non-periodic IN NAK Effective Mask. Mode: Device only,
5 (R/W)	NPTXFEMP	Non-periodic TxFIFO Empty Mask. Mode: Host and Device
4 (R/W)	RXFLVL	Receive FIFO Non-Empty Mask. Mode: Host and Device
3 (R/W)	SOF	Start of (micro)Frame Mask. Mode: Host and Device
2 (R/W)	OTI	OTG Interrupt Mask. Mode: Host and Device
1 (R/W)	MODEMIS	Mode Mismatch Interrupt Mask. Mode: Host and Device

Interrupt Status Register

The USBC_ISTAT register interrupts the application for system-level events in the current mode (device mode or host mode). Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1'b1 into the bit.

The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the USBC_ISTAT register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Note: Read the reset value of USBC_ISTAT.CURMOD only after the following conditions:

If IDDIG_FILTER is disabled, read only after PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

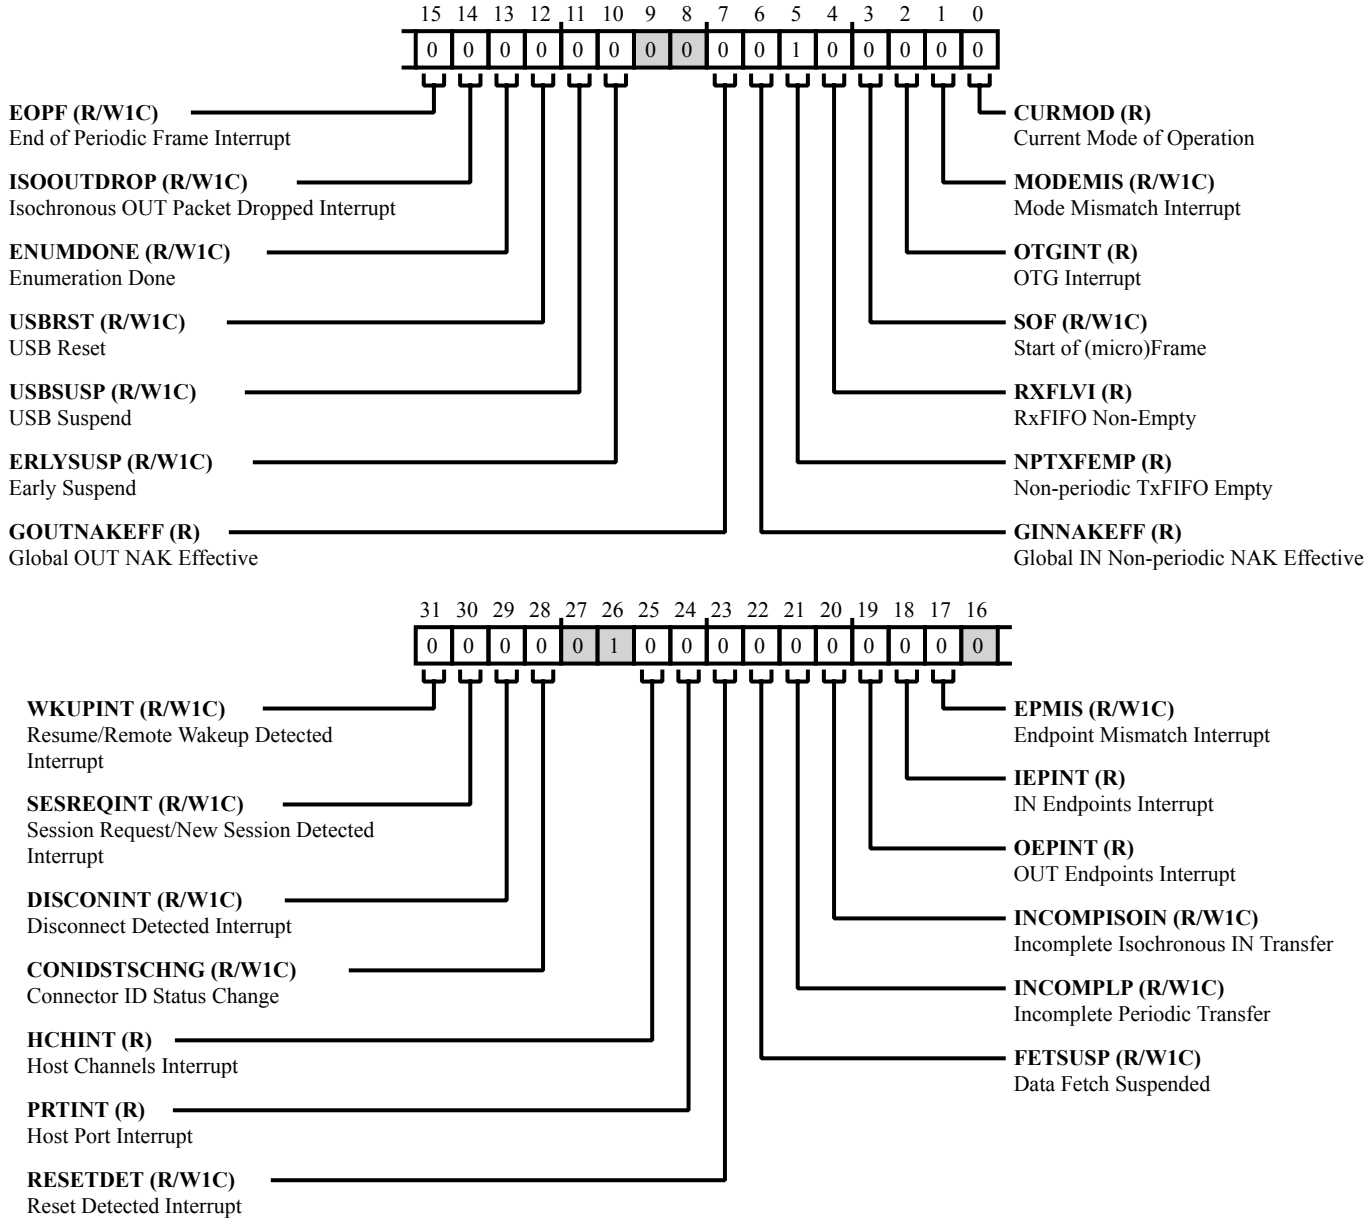

Figure 19-51: USBC_ISTAT Register Diagram

Table 19-48: USBC_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	WKUPINT	Resume/Remote Wakeup Detected Interrupt. The USBC_ISTAT.WKUPINT bit is applicable in host and device mode. Wakeup interrupt during Suspend(L2) or LPM(L1) state. During Suspend(L2): In device mode, the USBC_ISTAT.WKUPINT bit is set only when a host-initiated resume is detected on the USB. In host mode, the USBC_ISTAT.WKUPINT bit is set only when a device-initiated remote wakeup is detected on USB. During LPM(L1): In device mode, the USBC_ISTAT.WKUPINT bit is set for either host-initiated resume or device-initiated remote wakeup on USB. In host mode, the USBC_ISTAT.WKUPINT bit is set for either host-initiated resume or device-initiated remote wakeup on USB.
30 (R/W1C)	SESREQINT	Session Request/New Session Detected Interrupt. The USBC_ISTAT.SESREQINT bit is applicable in host and device mode.
29 (R/W1C)	DISCONINT	Disconnect Detected Interrupt. The USBC_ISTAT.DISCONINT bit is applicable in host mode. Disconnect Detected Interrupt (DisconnInt) The USBC_ISTAT.DISCONINT bit is set (=1) when a device disconnect is detected.
28 (R/W1C)	CONIDSTSCHNG	Connector ID Status Change. The USBC_ISTAT.CONIDSTSCHNG bit is applicable in host and device mode. The core sets the USBC_ISTAT.CONIDSTSCHNG bit when there is a change in connector ID status.
25 (R/NW)	HCHINT	Host Channels Interrupt. The USBC_ISTAT.HCHINT bit is applicable in host mode. The core sets the USBC_ISTAT.HCHINT bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the USBC_ISTAT_H register to determine the exact number of the channel on which the interrupt occurred, and Then read the corresponding USBC_ISTAT[n]_H register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the USBC_ISTAT[n]_H register to clear this bit.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/NW)	PRTINT	Host Port Interrupt. The USBC_ISTAT.PRTINT bit is applicable in host mode. The core sets the USBC_ISTAT.PRTINT bit to indicate a change in port status of one of the controller ports in host mode. The application must read the USBC_PORT_CTL_H register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host Port Control and Status register to clear the USBC_ISTAT.PRTINT bit.
23 (R/W1C)	RESETDET	Reset Detected Interrupt. The USBC_ISTAT.RESETDET bit is applicable in device mode. In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in Suspend. In host mode, this interrupt is not asserted.
22 (R/W1C)	FETSUSP	Data Fetch Suspended. The USBC_ISTAT.FETSUSP bit is applicable in device mode. This interrupt indicates that the core has stopped fetching data. For IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application: - Sets a global non-periodic IN NAK handshake - Disables IN endpoints - Flushes the FIFO - Determines the token sequence from the IN token sequence learning queue - Re-enables the endpoints - Clears the global non-periodic IN NAK handshake If the global non-periodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received. The core generates an 'IN token received when FIFO empty' interrupt. The USBC_otg then sends the host a NAK response. To avoid this scenario, the application can check the USBC_ISTAT.FETSUSP interrupt, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the IN token received when FIFO empty interrupt when clearing a global IN NAK handshake.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W1C)	INCOMPLP	Incomplete Periodic Transfer. The USBC_ISTAT.INCOMPLP bit is applicable in host and device mode. In host mode, the core sets the USBC_ISTAT.INCOMPLP bit when there are incomplete periodic transactions still pending which are scheduled for the current microframe. Incomplete Isochronous OUT Transfer (incompISOOUT) In device mode, the core sets (=1) the USBC_ISTAT.INCOMPLP bit to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current microframe. The USBC_ISTAT.INCOMPLP bit is set along with the USBC_ISTAT.EOPF bit.
20 (R/W1C)	INCOMPISOIN	Incomplete Isochronous IN Transfer. The USBC_ISTAT.INCOMPISOIN bit is applicable in device mode. The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. Note: This interrupt is not asserted in scatter/gather DMA mode.
19 (R/NW)	OEPINT	OUT Endpoints Interrupt. The USBC_ISTAT.OEPINT bit is applicable in device mode. The controller sets the USBC_ISTAT.OEPINT bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the USBC_ISTAT_D register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding USBC_ISTAT_OEP[n]_D register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding USBC_ISTAT_OEP[n]_D register to clear the USBC_ISTAT.OEPINT bit.
18 (R/NW)	IEPINT	IN Endpoints Interrupt. The USBC_ISTAT.IEPINT bit is applicable in device mode. The core sets the USBC_ISTAT.IEPINT bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the USBC_ISTAT_D register to determine the exact number of the IN endpoint on the USBC_ISTAT_IEP[n]_D register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding USBC_ISTAT_IEP[n]_D register to clear the USBC_ISTAT.IEPINT bit.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W1C)	EPMIS	Endpoint Mismatch Interrupt. The USBC_ISTAT.EPMIS bit is applicable in device mode. Note: This interrupt is valid only in shared FIFO operation. The USBC_ISTAT.EPMIS bit indicates that an IN token has been received for a non-periodic endpoint, but the data for another endpoint is present in the top of the non-periodic transmit FIFO and the IN endpoint mismatch count programmed by the application has expired.
15 (R/W1C)	EOPF	End of Periodic Frame Interrupt. The USBC_ISTAT.EOPF bit is applicable in device mode. The USBC_ISTAT.EOPF bit indicates that the period specified in the USBC_CFG_D.PERFRINT field has been reached in the current microframe.
14 (R/W1C)	ISOOUTDROP	Isochronous OUT Packet Dropped Interrupt. The USBC_ISTAT.ISOOUTDROP bit is applicable in device mode. The controller sets the USBC_ISTAT.ISOOUTDROP bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint.
13 (R/W1C)	ENUMDONE	Enumeration Done. The USBC_ISTAT.ENUMDONE bit is applicable in device mode. The core sets the USBC_ISTAT.ENUMDONE bit to indicate that speed enumeration is complete. The application must read the USBC_STAT_D register to obtain the enumerated speed.
12 (R/W1C)	USBRST	USB Reset. The USBC_ISTAT.USBRST bit is applicable in device mode. The controller sets the USBC_ISTAT.USBRST bit to indicate that a reset is detected on the USB.
11 (R/W1C)	USBSUSP	USB Suspend. The USBC_ISTAT.USBSUSP bit is applicable in device mode. The controller sets the USBC_ISTAT.USBSUSP bit to indicate that a suspend was detected on the USB. The controller enters the suspended state when there is no activity on the linestate signal for an extended period of time.
10 (R/W1C)	ERLYSUSP	Early Suspend. The USBC_ISTAT.ERLYSUSP bit is applicable in device mode. The controller sets the USBC_ISTAT.ERLYSUSP bit to indicate that an idle state has been detected on the USB for 3 ms.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	GOUTNAKEFF	Global OUT NAK Effective. The USBC_ISTAT.GOUTNAKEFF bit is applicable in device mode. The USBC_ISTAT.GOUTNAKEFF bit indicates that the USBC_CTL_D.SGOUTNAK bit, set by the application, has taken effect in the core. The USBC_ISTAT.GOUTNAKEFF bit can be cleared by writing to the USBC_CTL_D.CGOUTNAK bit.
6 (R/NW)	GINNAKEFF	Global IN Non-periodic NAK Effective. The USBC_ISTAT.GINNAKEFF bit is applicable in device mode. The USBC_ISTAT.GINNAKEFF bit indicates that the USBC_CTL_D.SGNPINNAK bit, set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. The USBC_ISTAT.GINNAKEFF bit can be cleared by clearing the USBC_CTL_D.CGNPINNAK bit. This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.
5 (R/NW)	NPTXFEMP	Non-periodic TxFIFO Empty. The USBC_ISTAT.NPTXFEMP bit is applicable in host and device mode. The USBC_ISTAT.NPTXFEMP bit indicates that an interrupt is asserted when the non-periodic TxFIFO is either half or completely empty, and there is space for at least one Entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the USBC_AHB_CFG.NPTXFELVL bit. In host mode, the application can use the USBC_ISTAT.NPTXFEMP bit In device mode, the application uses uses USBC_ISTAT_IEP[n]_D.TXFEMP.
4 (R/NW)	RXFLVI	RxFIFO Non-Empty. The USBC_ISTAT.RXFLVI bit is applicable in host and device mode. The USBC_ISTAT.RXFLVI bit indicates that there is at least one packet pending to be read from the RxFIFO.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W1C)	SOF	Start of (micro)Frame. The USBC_ISTAT.SOF bit is applicable in host and device mode. In host mode, the core sets the USBC_ISTAT.SOF bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to the USBC_ISTAT.SOF bit to clear the interrupt. In device mode, the controller sets the USBC_ISTAT.SOF bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. The USBC_ISTAT.SOF bit can be set only by the core; the application must write 1 to clear it. Note: This register may return 1'b1 if read immediately after power-on reset. If the register bit reads 1'b1 immediately after power-on reset, it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.
2 (R/NW)	OTGINT	OTG Interrupt. The USBC_ISTAT.OTGINT bit is applicable in host and device mode. The controller sets the USBC_ISTAT.OTGINT bit to indicate an OTG protocol event. The application must read the USBC_OTG_IRQ register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the USBC_OTG_IRQ register to clear thE USBC_ISTAT.OTGINT bit.
1 (R/W1C)	MODEMIS	Mode Mismatch Interrupt. The USBC_ISTAT.MODEMIS bit is applicable in host and device mode. The core sets the USBC_ISTAT.MODEMIS bit when the application is trying to access: - A host mode register, when the controller is operating in device mode - A device mode register, when the controller is operating in host mode The register access is completed on the bus with an OKAY response, but is ignored by the controller internally and does not affect the operation of the controller. The USBC_ISTAT.MODEMIS bit can be set only by the core; the application should write 1 to clear it.

Table 19-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	CURMOD	Current Mode of Operation. The `USBC_ISTAT.CURMOD` bit is applicable in host and device mode. Current Mode of Operation (CurMod) The `USBC_ISTAT.CURMOD` bit indicates the current mode. Note: The reset value of this register field can be read only after the PHY clock is stable.	
		0	Device mode
		1	Host mode

Non-periodic Transmit FIFO Size Register

The application can program the RAM size and the memory start address for the non-periodic TxFIFO.

Note: The fields of the USBC_TXFIFOSZ_NP register change depending on host or device mode.

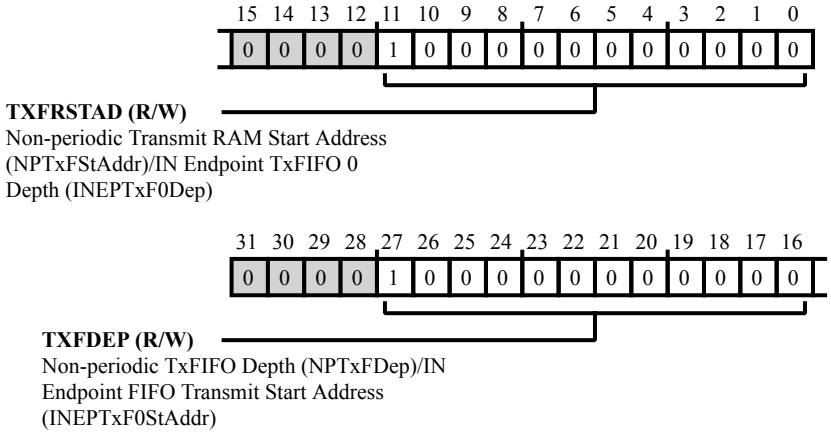

Figure 19-52: USBC_TXFIFOSZ_NP Register Diagram

Table 19-49: USBC_TXFIFOSZ_NP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/W)	TXFDEP	Non-periodic TxFIFO Depth (NPTxFDep)/IN Endpoint FIFO Transmit Start Address (INEPTxF0StAddr). In host mode, this field contains the Non-periodic TxFIFO Depth (NPTxFDep). In device mode, this field contains the IN Endpoint FIFO Transmit Start Address (INEPTxF0StAddr). Programmed values must not exceed the power-on value. The power-on reset value of this field is 2048.
11:0 (R/W)	TXFRSTAD	Non-periodic Transmit RAM Start Address (NPTxFStAddr)/IN Endpoint TxFIFO 0 Depth (INEPTxF0Dep). In host mode, this field is Non-periodic Transmit RAM Start Address (NPTxFStAddr). In device mode, this field is IN Endpoint TxFIFO 0 Depth (INEPTxF0Dep). This value is in terms of 32-bit words. The minimum value is 16, the maximum value is 32,768, and the reset value is 256.

Non-periodic Transmit FIFO/Queue Status Register

In device mode, the USBC_TXFIFO_STAT_NP register is valid only in shared FIFO operation.

The read-only USBC_TXFIFO_STAT_NP register contains the free space information for the non-periodic TxFIFO and the non-periodic transmit request queue.

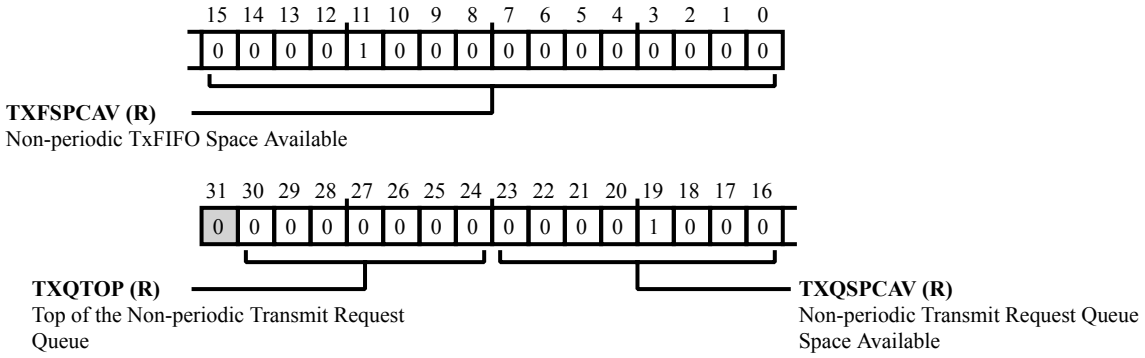

Figure 19-53: USBC_TXFIFO_STAT_NP Register Diagram

Table 19-50: USBC_TXFIFO_STAT_NP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:24 (R/NW)	TXQTOP	Top of the Non-periodic Transmit Request Queue. Entry in the Non-periodic Tx Request Queue that is currently being processed by the MAC. - Bits [30:27]: Channel/endpoint number - Bits [26:25]: - 2'b00: IN/OUT token -- 2'b01: Zero-length transmit packet (device IN/host OUT) -- 2'b10: PING/CSPLIT token -- 2'b11: Channel halt command - Bit [24]: Terminate (last Entry for selected channel/endpoint)	
23:16 (R/NW)	TXQSPCAV	Non-periodic Transmit Request Queue Space Available. The USBC_TXFIFO_STAT_NP.TXQSPCAV bit field indicates the amount of free space available in the non-periodic transmit request queue. This queue holds both IN and OUT requests in host mode. Device mode has only IN requests. Values are in terms of 32-bit words.	
		0	Queue Full
		1	1 Location Available
		2	2 Locations Available

Table 19-50: USBC_TXFIFO_STAT_NP Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Locations Available
		4	4 Locations Available
		5	5 Locations Available
		6	6 Locations Available
		7	7 Locations Available
		8	8 Locations Available
15:0 (R/NW)	TXFSPCAV	Non-periodic TxFIFO Space Available. The `USBC_TXFIFO_STAT_NP.TXFSPCAV` bit field indicates the amount of free space available in the Non-periodic TxFIFO. Values are in terms of 32-bit words. 16'hn: n words available, where 0 <= n <= 32,768) reserved where n > 32,768, and full where n = 0.	
		0	TxFIFO Full

OTG Control and Status Register

The USBC_OTG_CTL register controls the behavior and reflects the status of the OTG function of the controller.

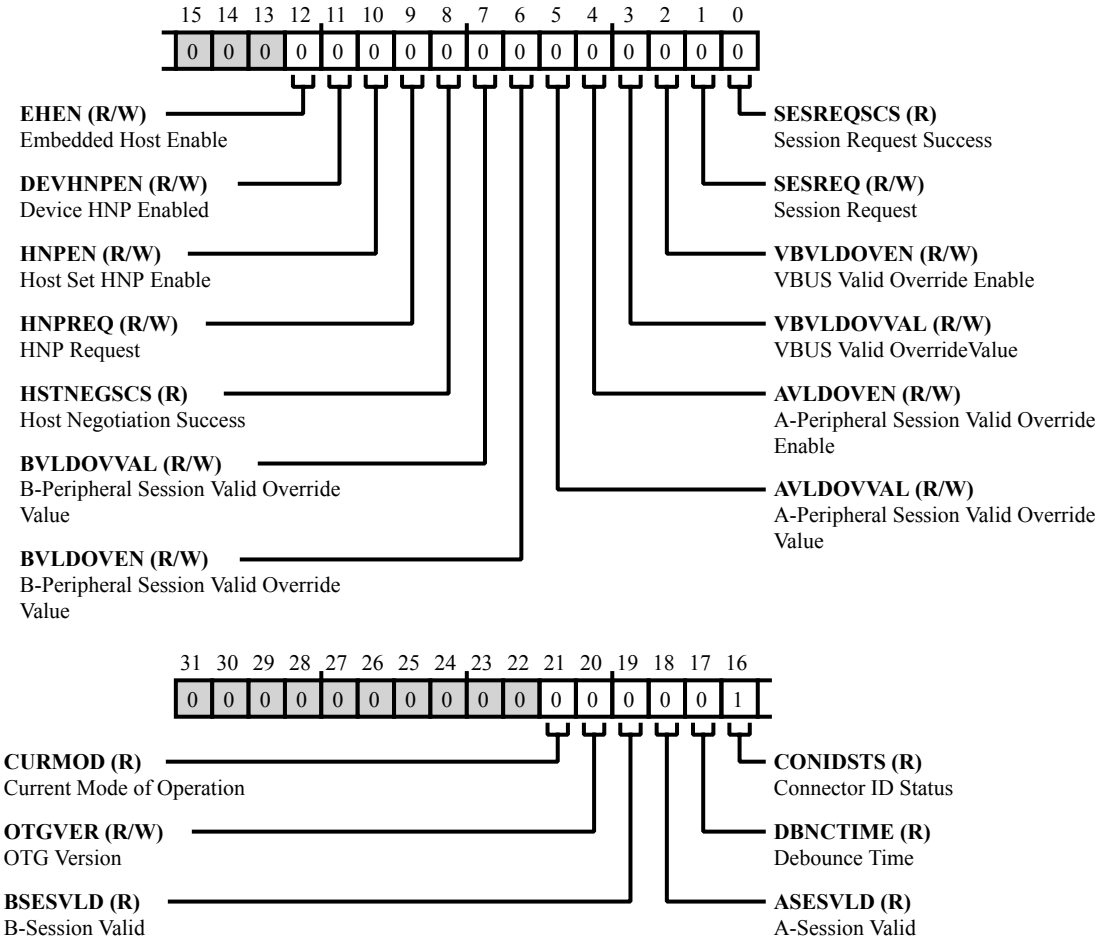

Figure 19-54: USBC_OTG_CTL Register Diagram

Table 19-51: USBC_OTG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/NW)	CURMOD	Current Mode of Operation. Current Mode of Operation (CurMod) Mode: Host and Device The USBC_OTG_CTL.CURMOD bit indicates the current mode. Reset:1'b0 Note: The reset value of this register field can be read only after the PHY clock is stable.	
		0	Host Mode
		1	Device Mode

Table 19-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	OTGVER	OTG Version. The USBC_OTG_CTL.OTGVER bit indicates the OTG revision.	
		0	OTG Version 1.3: Core supports data line pulsing and VBus pulsing for SRP
		1	OTG Version 2.0: Core supports only data line pulsing for SRP
19 (R/NW)	BSESVLD	B-Session Valid. Mode: Device only The USBC_OTG_CTL.BSESVLD bit indicates the device mode transceiver status. In OTG mode, the USBC_OTG_CTL.BSESVLD bit is used to determine if the device is connected or disconnected. Note:The reset value of the USBC_OTG_CTL.BSESVLD bit is 1'b0. - The reset value of this register field can be read only after the PHY clock is stable.	
		0	B-session is not valid
		1	B-session is valid
18 (R/NW)	ASESVLD	A-Session Valid. Mode: Host only The USBC_OTG_CTL.ASESVLD bit indicates the host mode transceiver status. Note:The reset value of the USBC_OTG_CTL.ASESVLD bit is 1'b0.	
		0	A-session is not valid
		1	A-session is valid
17 (R/NW)	DBNCTIME	Debounce Time. Mode: Host only The USBC_OTG_CTL.DBNCTIME bit indicates the debounce time of a detected connection.	
		0	Long debounce time, used for physical connections (100 ms + 2.5 micro-sec)
		1	Short debounce time, used for soft connections (2.5 micro-sec)

Table 19-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CONIDSTS	Connector ID Status. Mode: Host and Device The `USBC_OTG_CTL.CONIDSTS` bit indicates the connector ID status on a connect event. Note: The reset value of this register field can be read only after the PHY clock is stable	
		0	The core is in A-Device mode
		1	The core is in B-Device mode
12 (R/W)	EHEN	Embedded Host Enable. Mode: SRP Capable Host The `USBC_OTG_CTL.EHEN` bit is used to select between OTG A device state machine and embedded host state machine.	
		0	OTG A Device state machine is selected
		1	Embedded Host State Machine is selected
11 (R/W)	DEVHNPEN	Device HNP Enabled. Mode: HNP Capable OTG Device The application sets the `USBC_OTG_CTL.DEVHNPEN` bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.	
		0	HNP Not Enabled
		1	HNP Enabled
10 (R/W)	HNPEN	Host Set HNP Enable. Mode: HNP Capable OTG Host The application sets the `USBC_OTG_CTL.HNPEN` bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.	
		0	Host Set HNP is not enabled
		1	Host Set HNP is enabled

Table 19-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	HNPREQ	HNP Request. Mode: HNP Capable OTG Device The application sets the USBC_OTG_CTL.HNPREQ bit to initiate an HNP request to the connected USB host. The application can clear the USBC_OTG_CTL.HNPREQ bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (USBC_OTG_IRQ.HNEGSSTSCHG) is set. The controller clears the USBC_OTG_CTL.HNPREQ bit when the USBC_OTG_IRQ.HNEGSSTSCHG bit is cleared.	
		0	No HNP request
		1	HNP request
8 (R/NW)	HSTNEGSCS	Host Negotiation Success. Mode: HNP-capable Device The controller sets the USBC_OTG_CTL.HSTNEGSCS bit when host negotiation is successful. The controller clears the USBC_OTG_CTL.HNPREQ bit is set.	
		0	Host negotiation failure
		1	Host negotiation success
7 (R/W)	BVLDOVVAL	B-Peripheral Session Valid Override Value. Mode: Device only The USBC_OTG_CTL.BVLDOVVAL bit is used to set Override value for Bvalid signal when the USBC_OTG_CTL.BVLDOVEN bit is set.	
		0	Bvalid value is 0
		1	Bvalid value is 1
6 (R/W)	BVLDOVEN	B-Peripheral Session Valid Override Value. Mode: Device only The USBC_OTG_CTL.BVLDOVEN bit is used to enable/disable the software to override the Bvalid signal using the USBC_OTG_CTL.BVLDOVVAL bit.	
		0	Override is disabled and bvalid signal from the respective PHY selected is used internally by the force
		1	Internally Bvalid received from the PHY is overridden

Table 19-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	AVLDOVVAL	A-Peripheral Session Valid Override Value. Mode: Host only The `USBC_OTG_CTL.AVLDOVVAL` bit is used to set override value for the Avalid signal when the `USBC_OTG_CTL.AVLDOVEN` bit is set.	
		0	Avalid value is 0
		1	Avalid value is 1
4 (R/W)	AVLDOVEN	A-Peripheral Session Valid Override Enable. Mode: Host only The `USBC_OTG_CTL.AVLDOVEN` bit is used to enable/disable the software to override the Avalid signal using the `USBC_OTG_CTL.AVLDOVVAL` bit.	
		0	Override is disabled and Avalid signal from the respective PHY selection is used internally by the core
		1	Internally Avalid received from the PHY is overridden
3 (R/W)	VBVLDOVVAL	VBUS Valid OverrideValue. Mode: Host only The `USBC_OTG_CTL.VBVLDOVVAL` bit is used to set override value for vbusvalid signal when the `USBC_OTG_CTL.VBVLDOVEN` is set.	
		0	vbusvalid value is 0
		1	vbusvalid value is 1
2 (R/W)	VBVLDOVEN	VBUS Valid Override Enable. Mode: Host only The `USBC_OTG_CTL.VBVLDOVEN` bit is used to enable/disable the software to override the Bvalid signal using the `USBC_OTG_CTL.VBVLDOVVAL` bit.	
		0	Override is disabled and bvalid signal from the respective PHY selected is used internally by the controller
		1	Internally Bvalid received from the PHY is overridden

Table 19-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SESREQ	Session Request. Mode: Device only The application sets the USBC_OTG_CTL.SESREQ bit to initiate a session request on the USB. The application can clear the USBC_OTG_CTL.SESREQ bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (USBC_OTG_IRQ.HNEGSSTSCHG) is set. The core clears the USBC_OTG_CTL.SESREQ bit when the USBC_OTG_IRQ.HNEGSSTSCHG bit is cleared. If you use the USB 1.1 Full-Speed Serial Transceiver interface to initiate the session request, the application must wait until the VBUS discharges to 0.2 V, after the B-Session Valid bit in this register (USBC_OTG_CTL.BSESVLD) is cleared. This discharge time varies between different PHYs and can be obtained from the PHY vendor.	
		0	No session request
		1	Session request
0 (R/NW)	SESREQSCS	Session Request Success. Mode: Device only The core sets the USBC_OTG_CTL.SESREQSCS bit when a session request initiation is successful.	
		0	Failure
		1	Success

OTG Interrupt Register

The application reads the USBC_OTG_IRQ register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

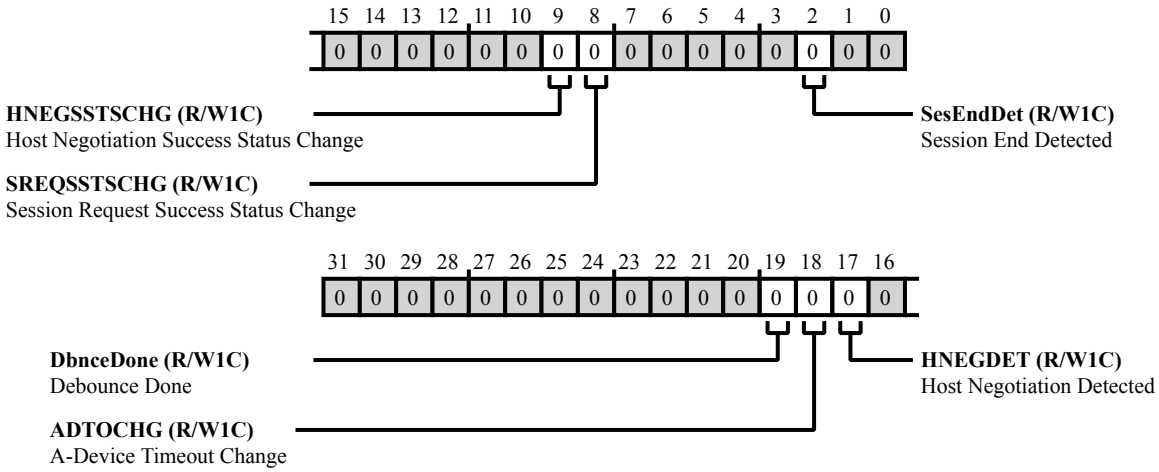

Figure 19-55: USBC_OTG_IRQ Register Diagram

Table 19-52: USBC_OTG_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W1C)	DBNCEDONE	Debounce Done. Mode: Host only The core sets the USBC_OTG_IRQ.DBNCEDONE bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable (USBC_CFG.HNPCAP) or SRP Capable (${.:GUSBCFG:SRPCap) is set. This bit can be set only by the core and the application should write 1 to clear it.
18 (R/W1C)	ADTOCHG	A-Device Timeout Change. Mode: Host and Device The core sets the USBC_OTG_IRQ.ADTOCHG bit to indicate that the A-device has timed out while waiting for the B-device to connect. This bit can be set only by the core and the application should write 1 to clear it.
17 (R/W1C)	HNEGDET	Host Negotiation Detected. Mode:Host and Device The core sets the USBC_OTG_IRQ.HNEGDET bit when it detects a host negotiation request on the USB. This bit can be set only by the core and the application should write 1 to clear it.

Table 19-52: USBC_OTG_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W1C)	HNEGSSTSCHG	Host Negotiation Success Status Change. Mode: Host and Device The core sets the `USBC_OTG_IRQ.HNEGSSTSCHG` bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit (`USBC_OTG_CTL.HSTNEGSCS`) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it.
8 (R/W1C)	SREQSSTSCHG	Session Request Success Status Change. Mode: Host and Device The core sets the `USBC_OTG_IRQ.SREQSSTSCHG` bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (`USBC_OTG_CTL.SESREQSCS`) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it.
2 (R/W1C)	SESENDDET	Session End Detected. Mode: Host and Device This bit can be set only by the core and the application should write 1 to clear it.

PHY Interface Control Register

The application can use the USBC_PHYIF_CTL register to access PHY registers.

The application sets the USBC_PHYIF_CTL register for PHY register access. The application polls the VStatus Done bit in USBC_PHYIF_CTL register for the completion of the PHY register access.

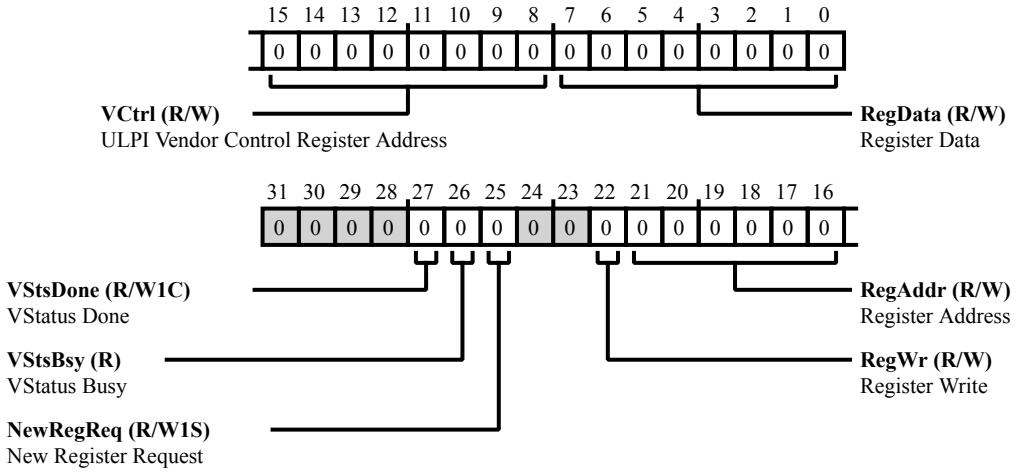

Figure 19-56: USBC_PHYIF_CTL Register Diagram

Table 19-53: USBC_PHYIF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W1C)	VSTSDONE	VStatus Done. The core sets the USBC_PHYIF_CTL.VSTSDONE bit when the vendor control access is done. This bit is cleared by the core when the application sets the New Register Request bit (USBC_PHYIF_CTL.NEWREGREQ).
26 (R/NW)	VSTSBSY	VStatus Busy. The core sets the USBC_PHYIF_CTL.VSTSBSY bit when the vendor control access is in progress and clears this bit when done.
25 (R/W1S)	NEWREGREQ	New Register Request. The application sets the USBC_PHYIF_CTL.NEWREGREQ bit for a new vendor control access.
22 (R/W)	REGWR	Register Write. Set the USBC_PHYIF_CTL.REGWR bit for register writes and clear it for register reads.
21:16 (R/W)	REGADDR	Register Address. The 6-bit PHY register address for immediate PHY Register set access. Set the USBC_PHYIF_CTL.REGADDRfield to 0x2F for Extended PHY Register set access.

Table 19-53: USBC_PHYIF_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	VCTRL	ULPI Vendor Control Register Address. The 4-bit register address a vendor defined 4-bit parallel output bus. Bits 11:8 of this field are placed on utmi_vcontrol[3:0]. ULPI Extended Register Address (ExtRegAddr) The 6-bit PHY extended register address.
7:0 (R/W)	REGDATA	Register Data. The `USBC_PHYIF_CTL.REGDATA` bit field contains the write data for register write. Read data for register read is valid when the `USBC_PHYIF_CTL.VSTSDONE` bit is set.

Reset Register

The USBC_RST_CTL register resets various hardware features inside the controller.

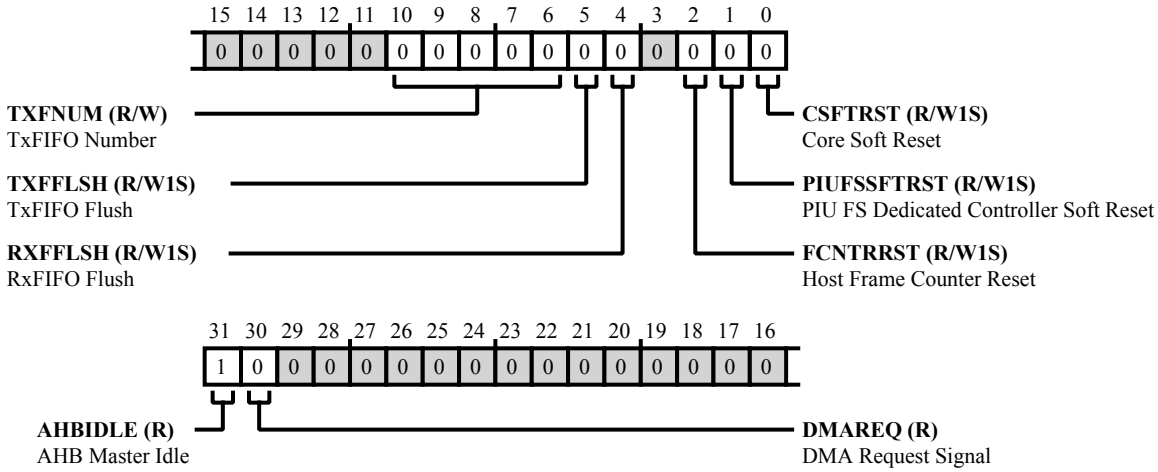

Figure 19-57: USBC_RST_CTL Register Diagram

Table 19-54: USBC_RST_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	AHBIDLE	AHB Master Idle. Mode: Host and Device The USBC_RST_CTL.AHBIDLE bit indicates that the bus master state machine is in the IDLE condition.	
30 (R/NW)	DMAREQ	DMA Request Signal. Mode: Host and Device The USBC_RST_CTL.DMAREQ bit indicates that the DMA request is in progress. Used for debug.	
10:6 (R/W)	TXFNUM	TxFIFO Number. Mode: Host and Device This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit.	
		0	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO flush in device mode when in shared FIFO operation Tx FIFO 0 flush in device mode when in dedicated FIFO mode

Table 19-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 1 flush in device mode when in shared FIFO operation Tx FIFO 1 flush in device mode when in dedicated FIFO mode
		2	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 2 flush in device mode when in shared FIFO operation Tx FIFO 2 flush in device mode when in dedicated FIFO mode
		3	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 3 flush in device mode when in shared FIFO operation Tx FIFO 3 flush in device mode when in dedicated FIFO mode
		4	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 4 flush in device mode when in shared FIFO operation Tx FIFO 4 flush in device mode when in dedicated FIFO mode
		5	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 5 flush in device mode when in shared FIFO operation Tx FIFO 5 flush in device mode when in dedicated FIFO mode
		6	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 6 flush in device mode when in shared FIFO operation Tx FIFO 6 flush in device mode when in dedicated FIFO mode
		7	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 7 flush in device mode when in shared FIFO operation Tx FIFO 7 flush in device mode when in dedicated FIFO mode

Table 19-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		8	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 8 flush in device mode when in shared FIFO operation Tx FIFO 8 flush in device mode when in dedicated FIFO mode
		9	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 9 flush in device mode when in shared FIFO operation Tx FIFO 9 flush in device mode when in dedicated FIFO mode
		10	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 10 flush in device mode when in shared FIFO operation Tx FIFO 10 flush in device mode when in dedicated FIFO mode
		11	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 11 flush in device mode when in shared FIFO operation Tx FIFO 11 flush in device mode when in dedicated FIFO mode
		12	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 12 flush in device mode when in shared FIFO operation Tx FIFO 12 flush in device mode when in dedicated FIFO mode
		13	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 13 flush in device mode when in shared FIFO operation Tx FIFO 13 flush in device mode when in dedicated FIFO mode
		14	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 14 flush in device mode when in shared FIFO operation Tx FIFO 14 flush in device mode when in dedicated FIFO mode

Table 19-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		15	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 15 flush in device mode when in shared FIFO operation Tx FIFO 15 flush in device mode when in dedicated FIFO mode
		16	Flush all transmit FIFOs in device or host mode
5 (R/W1S)	TXFFLSH	TxFIFO Flush. Mode: Host and Device The USBC_RST_CTL.TXFFLSH bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: - Read the NAK Effective Interrupt to ensure the core is not reading from the FIFO. - Write the USBC_RST_CTL.AHBIDLE bit to ensure the core is not writing anything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower of PHY or bus clock.	
4 (R/W1S)	RXFFLSH	RxFIFO Flush. Mode: Host and Device The application can flush the entire RxFIFO using the USBC_RST_CTL.RXFFLSH bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to the USBC_RST_CTL.RXFFLSH bit after checking that the controller is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the USBC_RST_CTL.RXFFLSH bit is cleared before performing any other operations. This bit requires eight clocks (slowest of PHY or bus clock) to clear.	
2 (R/W1S)	FCNTRRST	Host Frame Counter Reset. Mode: Host only The application writes to the USBC_RST_CTL.FCNTRRST bit to reset the (micro)frame number counter inside the core. When the (micro)frame counter is reset, the subsequent SOF sent out by the core has a (micro)frame number of 0. When application writes 1 to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles.	

Table 19-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1S)	PIUFSSFTRST	PIU FS Dedicated Controller Soft Reset. Mode: Host and Device The USBC_RST_CTL.PIUFSSFTRST bit resets the PIU FS dedicated controller. All module state machines in FS dedicated controller of the PIU are reset to the IDLE state. The bit is used to reset the FS dedicated controller in PIU in case of any PHY errors like loss of activity or babble error resulting in the PHY remaining in RX state for more than one frame boundary. The USBC_RST_CTL.PIUFSSFTRST bit is a self clearing bit and core clears this bit after all the necessary logic is reset in the core.
0 (R/W1S)	CSFTRST	Core Soft Reset. Mode: Host and Device Resets the hclk and phy_clock domains as follows: - Clears the interrupts and all the CSR registers except the following register bits: USBC_PWR_CTL.RSTPDWNMODULE, USBC_CFG.FRCDEVMOD, USBC_CFG.FRCHSTMOD, , USBC_CFG.PHYSEL, USBC_CFG.FSINTF, USBC_CFG.ULPI_UTMI_SEL, USBC_CFG.PHYIF, USBC_CFG.TXENDDLY, USBC_CFG.TSDLPULSE, USBC_CFG.CLKSUSM, USBC_CFG.AUTORES, USBC_CFG_H.PCLKSEL, USBC_CFG_D.SPD, and USBC_CTL_D.SFTDISCON: - All module state machines: - All module state machines (except the bus completer unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed.: - Any transactions on the bus requester are terminated as soon as possible, after gracefully completing the last data phase of a bus transfer. Any transactions on the USB are terminated immediately.: The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (bus requester is IDLE) before starting any operation. Typically software reset is used during software development and also when dynamically changing the PHY selection bits in the USB configuration registers listed above. When the PHY is changed, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

Receive FIFO Size Register

The USBC_RXFIFOSZ register indicates the RAM size that must be allocated to the RxFIFO.

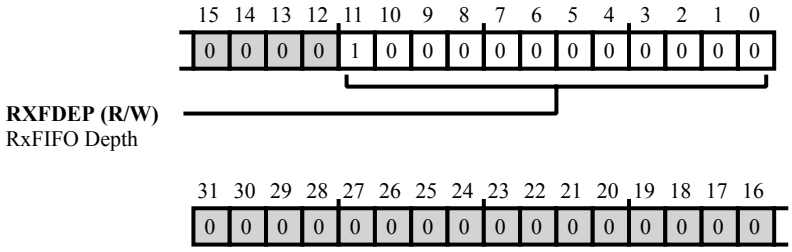

Figure 19-58: USBC_RXFIFOSZ Register Diagram

Table 19-55: USBC_RXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	RXFDEP	RxFIFO Depth. Mode: Host and Device The USBC_RXFIFOSZ.RXFDEP field indicates the RxFIFO depth. This value is in terms of 32-bit words. - Minimum value is 16 - Maximum value is 32,768 The power-on reset value of this register is specified as the largest Rx data FIFO depth The reset value is 2048.

Receive Status Read/Pop Register

A read to the USBC_RXDATA_STAT register returns the contents of the top of the receive FIFO and additionally pops the top data entry out of the RxFIFO.

The receive status contents must be interpreted differently in host and device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 32'h0000_0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (USBC_ISTAT.RXFLVI) is asserted.

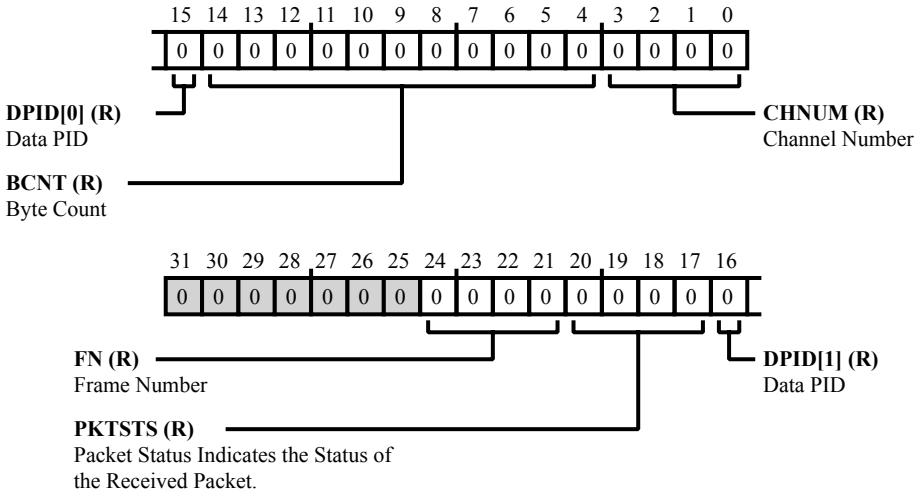

Figure 19-59: USBC_RXDATA_STAT Register Diagram

Table 19-56: USBC_RXDATA_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:21 (R/NW)	FN	Frame Number. Mode: Device only The USBC_RXDATA_STAT.FN bit field is the least significant 4 bits of the (micro)Frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Table 19-56: USBC_RXDATA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20:17 (R/NW)	PKTSTS	Packet Status Indicates the Status of the Received Packet.. In host mode, - 4'b0010: IN data packet received - 4'b0011: IN transfer completed (triggers an interrupt) - 4'b0101: Data toggle error (triggers an interrupt) - 4'b0111: Channel halted (triggers an interrupt) - Others: Reserved Reset:4'b0 In device mode, - 4'b0001: Global OUT NAK (triggers an interrupt) - 4'b0010: OUT data packet received - 4'b0011: OUT transfer completed (triggers an interrupt) - 4'b0100: SETUP transaction completed (triggers an interrupt) - 4'b0110: SETUP data packet received - Others: Reserved Reset:4'h0	
16:15 (R/NW)	DPID	Data PID. In host mode, the `USBC_RXDATA_STAT.DPID` bit field indicates the data PID of the received packet. In device mode, the `USBC_RXDATA_STAT.DPID` bit field indicates the data PID of the received OUT data packet. Reset: 2'h0	
		0	DATA0
		1	DATA1
		2	DATA2
		3	MDATA
14:4 (R/NW)	BCNT	Byte Count. In host mode, the `USBC_RXDATA_STAT.BCNT` bit indicates the byte count of the received IN data packet. In device mode, the `USBC_RXDATA_STAT.BCNT` bit indicates the byte count of the received data packet.	

Table 19-56: USBC_RXDATA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/NW)	CHNUM	Channel Number. Mode: Host only The `USBC_RXDATA_STAT.CHNUM` bit indicates the channel number to which the current received packet belongs. Endpoint Number (EPNum) Mode: Device only The `USBC_RXDATA_STAT.CHNUM` bit indicates the endpoint number to which the current received packet belongs.

Receive Status Debug Read Register

A read to the USBC_RXDBG_STAT register returns the contents of the top of the receive FIFO.

The receive status contents must be interpreted differently in Host and device modes. The core ignores the receive status read when the receive FIFO is empty and returns a value of 32'h0000_0000.

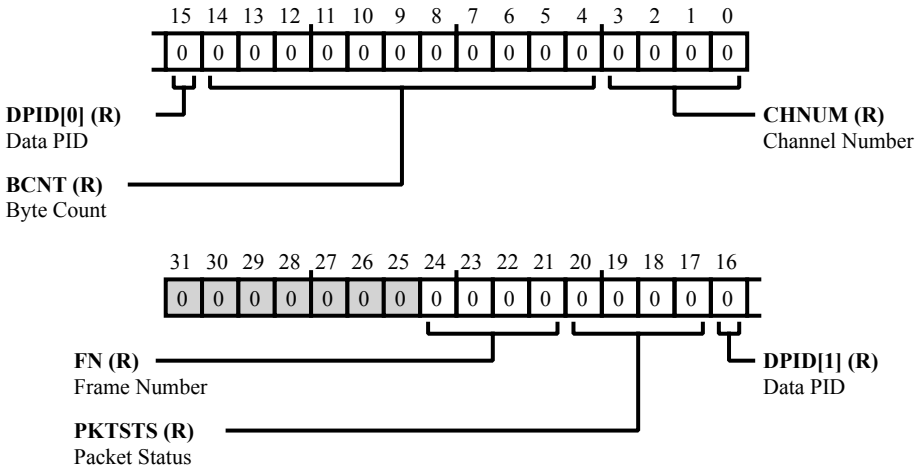

Figure 19-60: USBC_RXDBG_STAT Register Diagram

Table 19-57: USBC_RXDBG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:21 (R/NW)	FN	Frame Number. Mode: Device only The USBC_RXDBG_STAT.FN field is the least significant 4 bits of the (micro)frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Table 19-57: USBC_RXDBG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20:17 (R/NW)	PKTSTS	Packet Status. In host mode, the USBC_RXDBG_STAT.PKTSTSfield indicates the status of the received packet. - 4'b0010: IN data packet received - 4'b0011: IN transfer completed (triggers an interrupt) - 4'b0101: Data toggle error (triggers an interrupt) - 4'b0111: Channel halted (triggers an interrupt) - Others: Reserved Reset:4'b0 In device mode, - 4'b0001: Global OUT NAK (triggers an interrupt) - 4'b0010: OUT data packet received - 4'b0011: OUT transfer completed (triggers an interrupt) - 4'b0100: SETUP transaction completed (triggers an interrupt) - 4'b0110: SETUP data packet received - Others: Reserved Reset:4'h0	
16:15 (R/NW)	DPID	Data PID. In host mode, the USBC_RXDBG_STAT.DPID field indicates the data PID of the received packet. In device mode, the USBC_RXDBG_STAT.DPID field indicates the data PID of the received OUT data packet. Reset: 2'h0	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA
14:4 (R/NW)	BCNT	Byte Count. In host mode, the USBC_RXDBG_STAT.BCNT field indicates the byte count of the received IN data packet. In device mode, the USBC_RXDBG_STAT.BCNT field indicates the byte count of the received data packet.	

Table 19-57: USBC_RXDBG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/NW)	CHNUM	Channel Number. Mode: Host only The `USBC_RXDBG_STAT.CHNUM` field indicates the channel number to which the current received packet belongs. Endpoint Number (EPNum) Mode: Device only The `USBC_RXDBG_STAT.CHNUM` field indicates the endpoint number to which the current received packet belongs.

Module ID Register

The USBC_MODID register (read-only) contains the module ID.

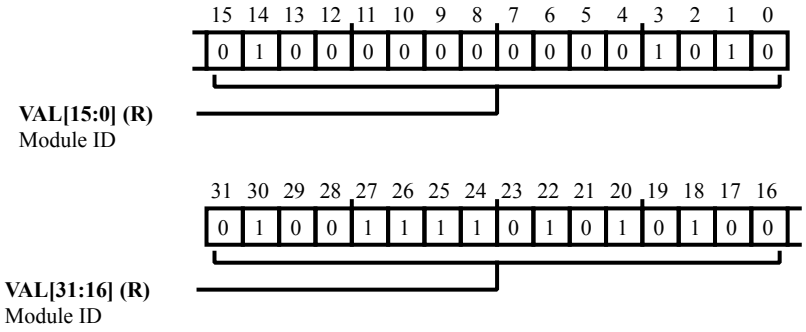

Figure 19-61: USBC_MODID Register Diagram

Table 19-58: USBC_MODID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VAL	Module ID. Module ID of the controller being used currently.

USB Configuration Register

The USBC_CFG register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the bus or the USB. Do not make changes to this register after the initial programming.

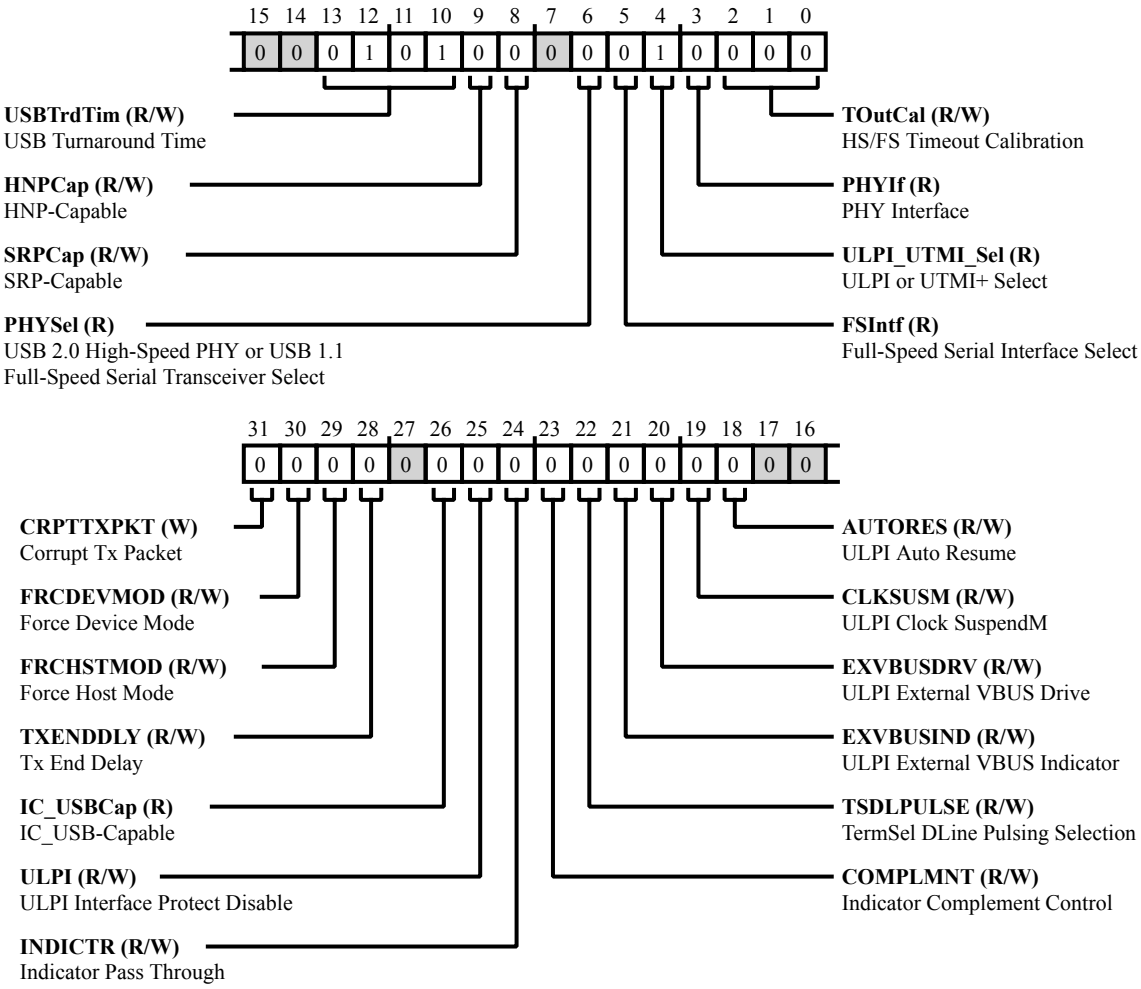

Figure 19-62: USBC_CFG Register Diagram

Table 19-59: USBC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RX/W)	CRPTTXPKT	Corrupt Tx Packet. Mode: Host and device The USBC_CFG.CRPTTXPKT bit is for debug purposes only. Never set this bit to 1. The application should always write zero to this bit.

Table 19-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	FRCDEVMOD	Force Device Mode. Mode:Host and device Writing a 1 to the `USBC_CFG.FRCDEVMOD` bit forces the controller to device mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect.	
		0	Normal Mode
		1	Force Device Mode
29 (R/W)	FRCHSTMOD	Force Host Mode. Mode: Host and device Writing a 1 to the `USBC_CFG.FRCHSTMOD` bit forces the core to host mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect.	
		0	Normal Mode
		1	Force Host Mode
28 (R/W)	TXENDDLY	Tx End Delay. Mode: Device only Writing a one to the `USBC_CFG.TXENDDLY` bit enables the controller to follow the TxEndDelay timings as per UTMI+ specification 1.05 section 4.1.5 for opmode signal during remote wakeup.	
		0	Normal Mode
		1	Tx End Delay
26 (R/NW)	IC_USBCAP	IC_USB-Capable. Mode: Host and Device The application uses the `USBC_CFG.IC_USBCAP` bit to control the core's IC_USB capabilities.	
		0	IC_USB PHY Interface Not Selected
		1	IC_USB PHY Interface Selected
25 (R/W)	ULPI	ULPI Interface Protect Disable. Mode: Host only Controls circuitry built into the PHY for protecting the ULPI interface when the link tri-states STP and data. Any pull-ups or pull-downs employed by this feature can be disabled.	
		0	Enable Interface Protect Circuit
		1	Disable Interface Protect Circuit

Table 19-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	INDICTR	Indicator Pass Through. Mode: Host only Controls whether the complement output is qualified with the internal Vbus valid comparator before being used in the Vbus state in the RX CMD.	
		0	Complement Output Signal Qualified with Internal VbusValid Comparator
		1	Complement Output Signal Not Qualified with Internal VbusValid Comparator
23 (R/W)	COMPLMNT	Indicator Complement Control. Mode: Host only The `USBC_CFG.COMPLMNT` bit controls the PHY to invert the ExternalVbusIndicator input signal, generating the complement output.	
		0	Do Not Invert ExternalVbusIndicator Signal
		1	Invert ExternalVbusIndicator Signal
22 (R/W)	TSDLPULSE	TermSel DLine Pulsing Selection. Mode: Device only The `USBC_CFG.TSDLPULSE` bit selects utmi_termselect to drive data line pulse during SRP.	
		0	Data Line Pulsing Using utmi_txvalid (Default)
		1	Data Line Pulsing Using utmi_termsel
21 (R/W)	EXVBUSIND	ULPI External VBUS Indicator. Mode: Host only The `USBC_CFG.EXVBUSIND` bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator.	
		0	Internal VBUS Valid Comparator
		1	External VBUS Valid Comparator
20 (R/W)	EXVBUSDRV	ULPI External VBUS Drive. Mode: Host only The `USBC_CFG.EXVBUSDRV` bit selects between internal or external supply to drive 5V on VBUS, in ULPI PHY.	
		0	Internal Charge Pump (Default)
		1	External Supply

Table 19-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	CLKSUSM	ULPI Clock SuspendM. Mode: Host and Device The `USBC_CFG.CLKSUSM` bit sets the ClockSuspendM bit in the interface control register on the PHY. This bit applies only in serial or carkit modes.	
		0	PHY powers down internal clock during suspend
		1	PHY does not power down internal clock
18 (R/W)	AUTORES	ULPI Auto Resume. Mode: Host and Device The `USBC_CFG.AUTORES` bit sets the AutoResume bit in the interface control register on the PHY.	
		0	PHY does not use AutoResume feature
		1	HY uses AutoResume feature
13:10 (R/W)	USBTRDTIM	USB Turnaround Time. Mode: Device only The `USBC_CFG.USBTRDTIM` bit field the turnaround time in PHY clocks. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). This must be programmed as follows: - 4'h5: When the MAC interface is 16-bit UTMI - 4'h9: When the MAC interface is 8-bit UTMI Note: The previous values are calculated for the minimum bus frequency of 30 MHz. USB turnaround time is critical for certification where long cables and 5-Hubs are used. If the bus needs to run at less than 30 MHz and the USB turnaround time is not critical, these bits can be programmed to a larger value.	
9 (R/W)	HNPCAP	HNP-Capable. Mode: Host and Device The `USBC_CFG.HNPCAP` bit is for configuring the controller HNP capabilities. If HNP functionality is disabled by the software, the OTG signals on the PHY domain must be tied to the appropriate values.	
		0	HNP Capability Disabled
		1	HNP Capability Enabled

Table 19-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SRPCAP	SRP-Capable. Mode: Host and Device The `USBC_CFG.SRPCAP` bit is for configuring the controller SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. If SRP functionality is disabled by the software, the OTG signals on the PHY domain must be tied to the appropriate values.	
		0	SRP Capability Disabled
		1	SRP Capability Enabled
6 (R/NW)	PHYSEL	USB 2.0 High-Speed PHY or USB 1.1 Full-Speed Serial Transceiver Select. Mode: Host and Device The application uses the `USBC_CFG.PHYSEL` bit to select either a high-speed UTMI+ or ULPI PHY, or a full-speed transceiver. This bit is always 0, with read only access.	
		0	USB 2.0 high-speed UTMI+ or ULPI PHY
		1	USB 1.1 full-speed serial transceiver
5 (R/NW)	FSINTF	Full-Speed Serial Interface Select. Mode: Host and Device The application uses the `USBC_CFG.FSINTF` bit to select either a unidirectional or bidirectional USB 1.1 full-speed serial transceiver interface.	
		0	6-pin unidirectional full-speed serial interface
		1	3-pin bidirectional full-speed serial interface
4 (R/NW)	ULPI_UTMI_SEL	ULPI or UTMI+ Select. Mode: Host and Device The application uses the `USBC_CFG.ULPI_UTMI_SEL` bit to select either a UTMI + interface or ULPI Interface.	
		0	UTMI+ Interface
		1	ULPI Interface
3 (R/NW)	PHYIF	PHY Interface. Mode: Host and Device The application uses this bit to configure the core to support a ULPI PHY with an 8- or 16-bit interface.	
		0	8 bits
		1	16 bits

Table 19-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	TOUTCAL	HS/FS Timeout Calibration. Mode: Host and Device The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are as follows: High-speed operation: - One 30-MHz PHY clock = 16 bit times - One 60-MHz PHY clock = 8 bit times Full-speed operation: - One 30-MHz PHY clock = 0.4 bit times - One 60-MHz PHY clock = 0.2 bit times - One 48-MHz PHY clock = 0.25 bit times

Host All Channels Interrupt Register

When a significant event occurs on a channel, the USBC_ISTAT_H register interrupts the application using the USBC_ISTAT.HCHINT bit. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel n interrupt register.

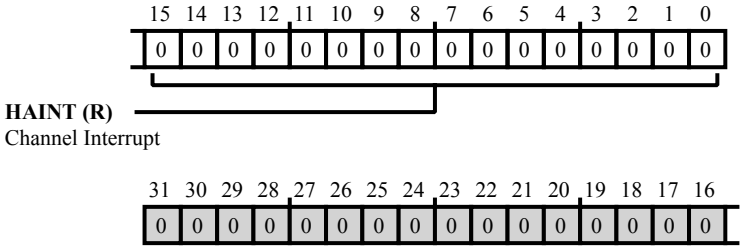

Figure 19-63: USBC_ISTAT_H Register Diagram

Table 19-60: USBC_ISTAT_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	HAINT	Channel Interrupt. Channel Interrupt for channel no.

Host All Channels Interrupt Mask Register

The USBC_IMSK_H register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

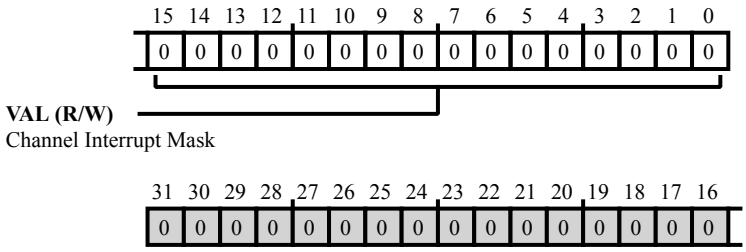

Figure 19-64: USBC_IMSK_H Register Diagram

Table 19-61: USBC_IMSK_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VAL	Channel Interrupt Mask. One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

Host Channel n Characteristics Register

The USBC_CHAR[n]_H register indicates the characteristics of the host channel n.

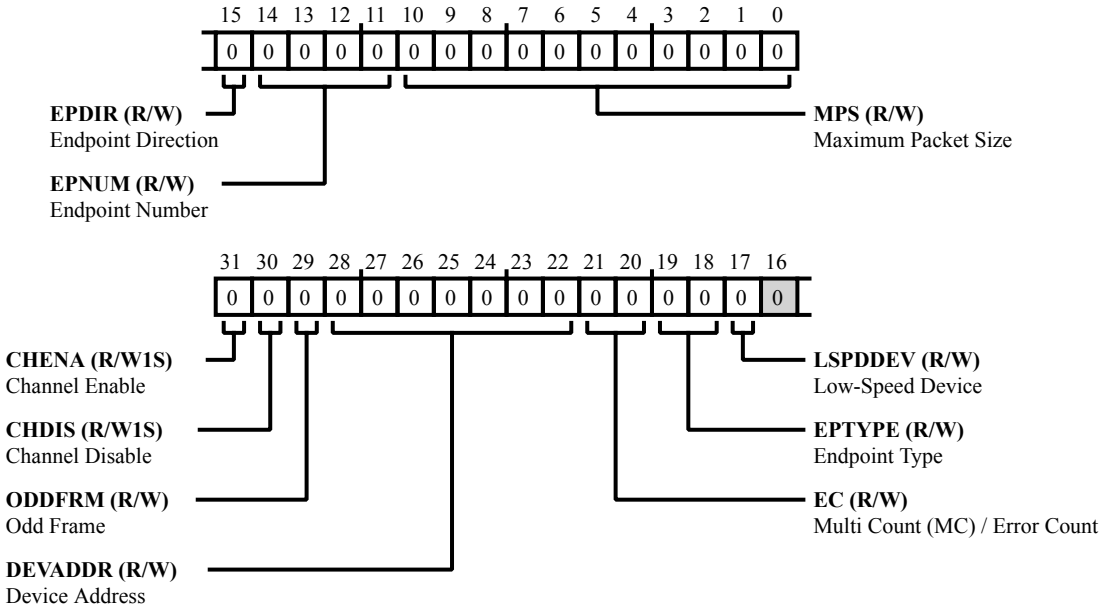

Figure 19-65: USBC_CHAR[n]_H Register Diagram

Table 19-62: USBC_CHAR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	CHENA	Channel Enable. When scatter/gather mode is enabled, the USBC_CHAR[n]_H.CHENA bit indicates that: - 1'b0: the descriptor structure is not yet ready. - 1'b1: the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When scatter/gather mode is disabled, the USBC_CHAR[n]_H.CHENA bit set by the application and cleared by the OTG host. - 1'b0: Channel disabled - 1'b1: Channel enabled
30 (R/W1S)	CHDIS	Channel Disable. The application sets the USBC_CHAR[n]_H.CHDIS bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the channel disabled interrupt before treating the channel as disabled.

Table 19-62: USBC_CHAR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	ODDFRM	Odd Frame. The USBC_CHAR[n]_H.ODDFRM bit is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. The USBC_CHAR[n]_H.ODDFRM bit is applicable for only periodic (isochronous and interrupt) transactions.	
		0	Even (micro)frame
		1	Odd (micro)frame
28:22 (R/W)	DEVADDR	Device Address. The USBC_CHAR[n]_H.DEVADDR field selects the specific device serving as the data source or sink.	
21:20 (R/W)	EC	Multi Count (MC) / Error Count. When the Split Enable bit of the Host Channel-n Split Control register (USBC_SPLT_CTL[n]_H.SPLTENA) is reset (=0), the USBC_CHAR[n]_H.EC field indicates to the host the number of transactions that must be executed per micro-frame for this periodic endpoint. For non periodic transfers, the USBC_CHAR[n]_H.EC field is used only in DMA mode and specifies the number packets to be fetched for this channel before the internal DMA engine changes arbitration. When the USBC_SPLT_CTL[n]_H.SPLTENA is set (=1), the USBC_CHAR[n]_H.EC field indicates the number of immediate retries to be performed for a periodic split transactions on transaction errors. The USBC_CHAR[n]_H.EC bit field must be set to at least 2'b01.	
		0	Reserved
		1	1
		2	2
		3	3
19:18 (R/W)	EPTYPE	Endpoint Type. The USBC_CHAR[n]_H.EPTYPE field indicates the transfer type selected.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
17 (R/W)	LSPDDEV	Low-Speed Device. The USBC_CHAR[n]_H.LSPDDEV bit is set by the application to indicate that this channel is communicating to a low-speed device.	

Table 19-62: USBC_CHAR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EPDIR	Endpoint Direction. The `USBC_CHAR[n]_H.EPDIR` bit indicates whether the transaction is IN or OUT.	
		0	Out
		1	In
14:11 (R/W)	EPNUM	Endpoint Number. The `USBC_CHAR[n]_H.EPNUM` field indicates the endpoint number on the device serving as the data source or sink.	
10:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CHAR[n]_H.MPS` field indicates the maximum packet size of the associated endpoint.	

Host Channel n DMA Buffer Address Register

The USBC_DMA_BADDR[n]_H register holds the current buffer address. It is present only for scatter/gather DMA. It is implemented in RAM instead of a flop-based implementation. The USBC_DMA_BADDR[n]_H register is updated during the data transfer for the corresponding end point.

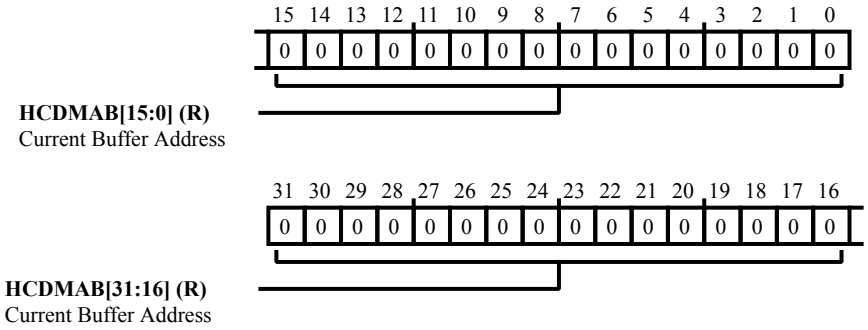

Figure 19-66: USBC_DMA_BADDR[n]_H Register Diagram

Table 19-63: USBC_DMA_BADDR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	HCDMAB	Current Buffer Address. The USBC_DMA_BADDR[n]_H.HCDMAB bit field indicates the current buffer address. The USBC_DMA_BADDR[n]_H register is present only in scatter/gather DMA mode. This field is reserved in other modes.

Host Channel n DMA Address Register

The USBC_DMA_ADDR[n]_H register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.This register is incremented on every bus transaction.

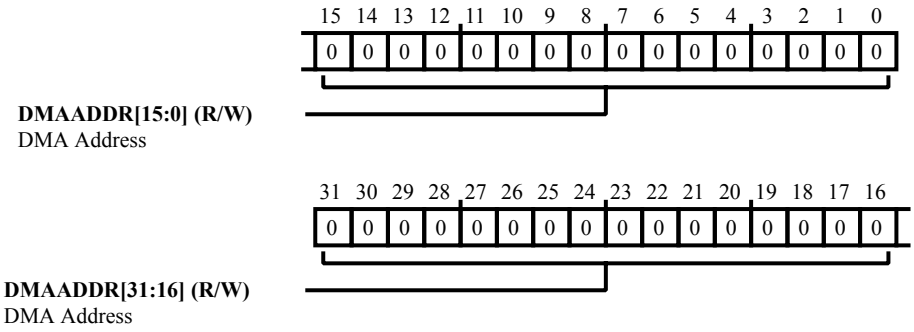

Figure 19-67: USBC_DMA_ADDR[n]_H Register Diagram

Table 19-64: USBC_DMA_ADDR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. In buffer DMA mode: [31:0]: DMA Address (DMAAddr) The USBC_DMA_ADDR[n]_H.DMAADDR field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. For control endpoints, the USBC_DMA_ADDR[n]_H.DMAADDR field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every bus transaction. The application can give only a DWORD-aligned address. When scatter/gather DMA mode is not enabled, the application programs the start address value in the USBC_DMA_ADDR[n]_H.DMAADDR field. When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR[n]_H.DMAADDR field indicates the base pointer for the descriptor list.

Host Configuration Register

The USBC_CFG_H register is the host configuration register.

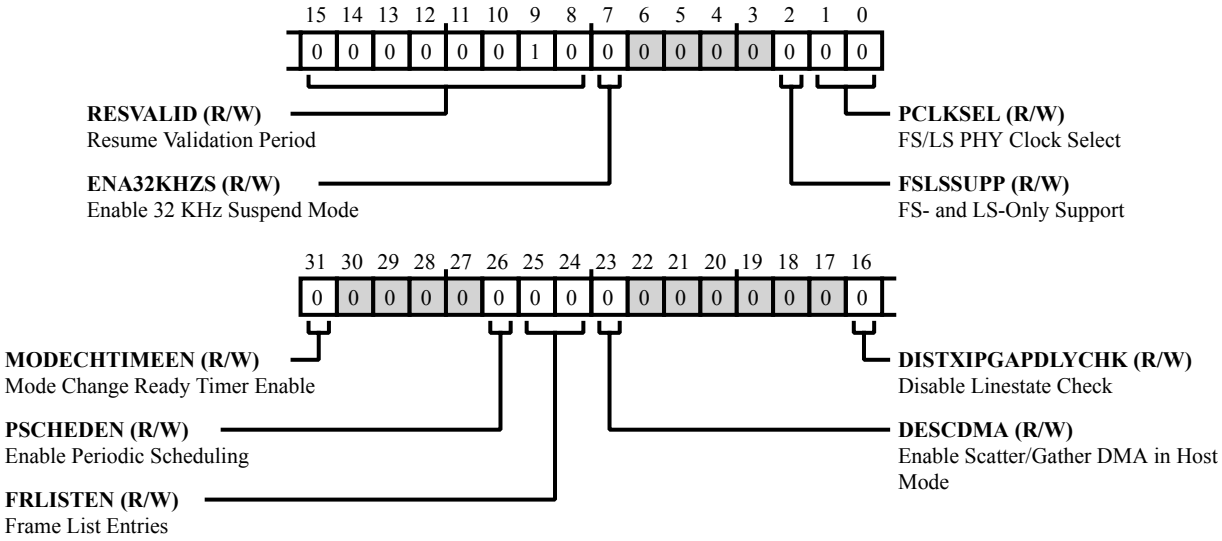

Figure 19-68: USBC_CFG_H Register Diagram

Table 19-65: USBC_CFG_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MODECHTIMEEN	Mode Change Ready Timer Enable. The USBC_CFG_H.MODECHTIMEEN bit is used to enable/disable the host core to wait 200 PHY clock cycles at the end of resume to change the opmode signal to the PHY to 00 after suspend or LPM.	
		0	Host core waits for either 200 PHY clock cycles or a line state of SE0 at the end of resume, to the change the op-mode from 2'b10 to 2'b00
		1	Host core only waits for a line state of SE0 at the end of resume, to change the opmode from 2'b10 to 2'b0
26 (R/W)	PSCHEDEN	Enable Periodic Scheduling. The USBC_CFG_H.PSCHEDEN bit applies in host DMA mode only. The USBC_CFG_H.PSCHEDEN bit enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. When the USBC_CFG_H.PSCHEDEN bit is set, the core will get ready to start scheduling periodic channels. When the USBC_CFG_H.PSCHEDEN bit is reset, the core will get ready to stop scheduling periodic channels.	

Table 19-65: USBC_CFG_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	FRLISTEN	Frame List Entries. The USBC_CFG_H.FRLISTEN field specifies the number of entries in the frame list. The USBC_CFG_H.FRLISTEN field is valid only in scatter/gather DMA mode.	
		0	8 Entries
		1	16 Entries
		2	32 Entries
		3	64 Entries
23 (R/W)	DESCDMA	Enable Scatter/Gather DMA in Host Mode. The application can set the USBC_CFG_H.DESCDMA bit during initialization to enable the scatter/gather DMA operation. Note: The USBC_CFG_H.DESCDMA bit must be modified only once after a reset. The following combinations are available for programming: - USBC_AHB_CFG.DMAEN = 0, USBC_CFG_H.DESCDMA = 0 => Slave mode - USBC_AHB_CFG.DMAEN = 0, USBC_CFG_H.DESCDMA = 1 => Invalid - USBC_AHB_CFG.DMAEN = 1, USBC_CFG_H.DESCDMA = 0 => Buffered DMA mode - USBC_AHB_CFG.DMAEN = 1, USBC_CFG_H.DESCDMA = 1 => Scatter/Gather DMA mode	
16 (R/W)	DISTXIPGAPDLYCHK	Disable Linestate Check. The USBC_CFG_H.DISTXIPGAPDLYCHK field applies only in HS mode of operation. When enabled, the controller implements counter based logic to detect the end of token transmission, otherwise controller monitors the linestate for end of token transmission, to start the token-to-token and token-to-data interpacket delay counter.	
15:8 (R/W)	RESVALID	Resume Validation Period. The USBC_CFG_H.RESVALID field is effective only when USBC_CFG_H.ENA32KHZS is set (=1). The USBC_CFG_H.RESVALID field controls the resume period when the core resumes from suspend. The core counts for USBC_CFG_H.RESVALID number of clock cycles to detect a valid resume when this is set.	
7 (R/W)	ENA32KHZS	Enable 32 KHz Suspend Mode. The USBC_CFG_H.ENA32KHZS bit can be set only in FS PHY interface is selected. Otherwise, this bit needs to be set to zero.	

Table 19-65: USBC_CFG_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	FSLSSUPP	FS- and LS-Only Support. The USBC_CFG_H.FSLSSUPP bit controls the core's enumeration speed. Using this bit, the application can make the core enumerate as a full speed host, even if the connected device supports high speed traffic. Do not make changes to this field after initial programming.	
		0	HS/FS/LS based on maximum speed suported by the connected device
		1	FS/LS only, even if the connected device can support high speed.
1:0 (R/W)	PCLKSEL	FS/LS PHY Clock Select. The USBC_CFG_H.PCLKSEL field selects the full speed and low speed PHY clock rates. When the core is in full-speed host mode: 0: PHY clock is running at 30/60 MHz 1: PHY clock is running at 48 MHz Others: Reserved When the core is in low speed host mode 00: PHY clock is running at 30/60 MHz. When the ULPI PHY low power mode is not selected, use 30/60 MHz. 01: PHY clock is running at 48 MHz. When the ULPI PHY low power mode is selected, use 48 MHz if the PHY supplies a 48 MHz clock during low speed mode. 10: PHY clock is running at 6 MHz. In USB 1.1 FS mode, use 6 MHz when the ULPI PHY low power mode is selected and the PHY supplies a 6 MHz clock during LS mode. If a 6 MHz clock is selected during LS mode, a soft reset is required. 11: Reserved Notes: When core in FS mode, the internal and external clocks have the same frequency. When core in LS mode, If USBC_CFG_H.PCLKSEL = 00: Internal and external clocks have the same frequency If USBC_CFG_H.PCLKSEL = 10: Internal clock is the divided by eight version of external 48 MHz clock	

Host Channel n Interrupt Mask Register

The USBC_IMSK[n]_H register reflects the mask for each channel status.

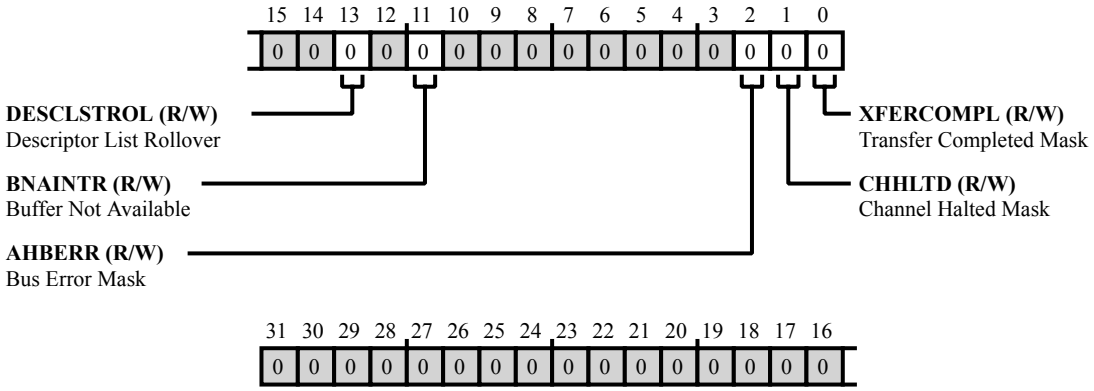

Figure 19-69: USBC_IMSK[n]_H Register Diagram

Table 19-66: USBC_IMSK[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	DESCLSTROL	Descriptor List Rollover. This bit is valid only when Scatter/Gather DMA mode is enabled.
11 (R/W)	BNAINTR	Buffer Not Available. This bit indicates that the buffer is not available. It is valid only when scatter/gather DMA mode is enabled.
2 (R/W)	AHBERR	Bus Error Mask. In scatter/gather DMA mode for host, interrupts will not be generated due to the corresponding bits set in HCINTn.
1 (R/W)	CHHLTD	Channel Halted Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Mask.

Host Channel n Interrupt Status Register

The USBC_ISTAT[n]_H register indicates the status of an endpoint with respect to USB and bus related events. The application must read this register when the USBC_ISTAT.HCHINT bit is set.

Before the application can read this register, it must first read the USBC_ISTAT_H register to get the exact channel number for the Host Channel n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USBC_ISTAT_H and USBC_ISTAT registers.

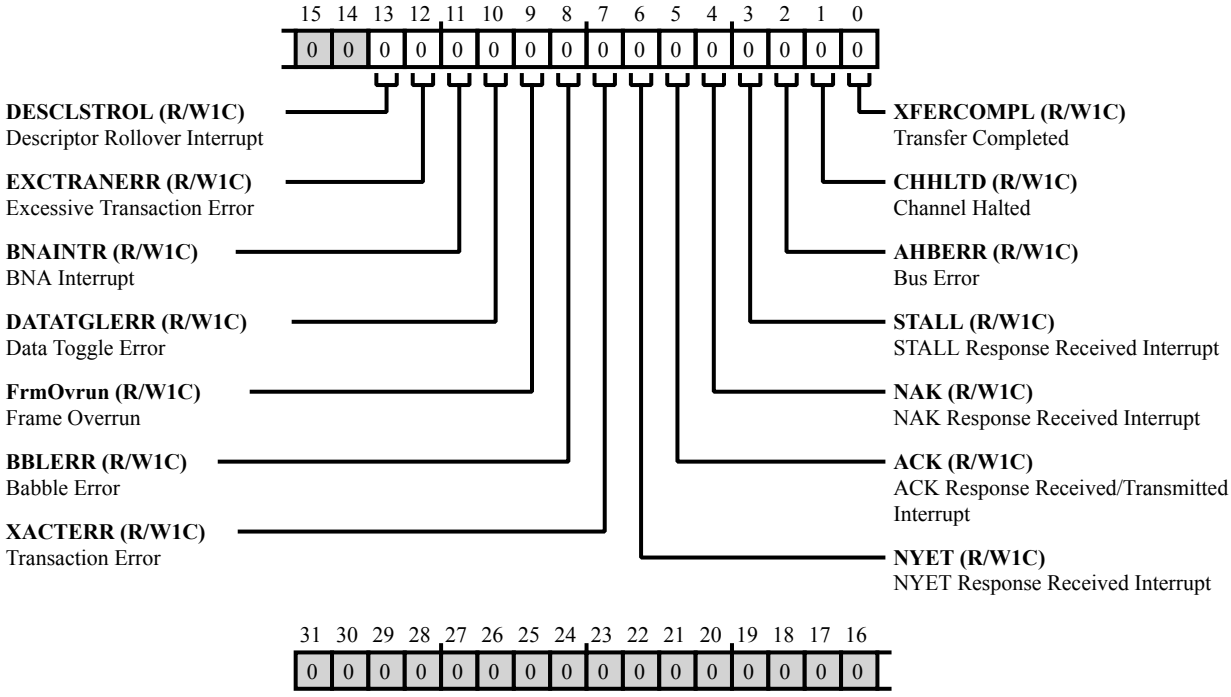

Figure 19-70: USBC_ISTAT[n]_H Register Diagram

Table 19-67: USBC_ISTAT[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	DESCLSTROL	Descriptor Rollover Interrupt. The USBC_ISTAT[n]_H.DESCLSTROL bit is valid only when scatter/gather DMA mode is enabled. The core sets the USBC_ISTAT[n]_H.DESCLSTROL bit when the corresponding channel's descriptor list rolls over. For non scatter/gather DMA mode, the USBC_ISTAT[n]_H.DESCLSTROL bit is reserved.

Table 19-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W1C)	EXCTRANERR	Excessive Transaction Error. The `USBC_ISTAT[n]_H.EXCTRANERR` bit is valid only when scatter/gather DMA mode is enabled. The core sets this bit when three consecutive transaction errors occurred on the USB bus. The `USBC_ISTAT[n]_H.EXCTRANERR` bit is not generated for isochronous channels. For non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.EXCTRANERR` bit is reserved.
11 (R/W1C)	BNAINTR	BNA Interrupt. The `USBC_ISTAT[n]_H.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA (Buffer Not Available) is not generated for isochronous channels. For non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.BNAINTR` bit is reserved.
10 (R/W1C)	DATATGLERR	Data Toggle Error. The `USBC_ISTAT[n]_H.DATATGLERR` bit can be set only by the core and the application should write 1 to clear it. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.DATATGLERR` bit is masked in the core.
9 (R/W1C)	FRMOVRUN	Frame Overrun. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.FRMOVRUN` bit is masked in the core. The `USBC_ISTAT[n]_H.FRMOVRUN` bit bit can be set only by the core and the application should write 1 to clear it.
8 (R/W1C)	BBLERR	Babble Error. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.BBLERR` bit is masked in the core. The `USBC_ISTAT[n]_H.BBLERR` bit can be set only by the core and the application should write 1 to clear it.
7 (R/W1C)	XACTERR	Transaction Error. The `USBC_ISTAT[n]_H.XACTERR` bit indicates one of the following errors occurred on the USB: CRC check failure, Timeout, Bit stuff error, or False EOP. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.XACTERR` bit is masked in the core. The `USBC_ISTAT[n]_H.XACTERR` bit can be set only by the core and the application should write 1 to clear it.

Table 19-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W1C)	NYET	NYET Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.NYET` bit is masked in the core. The `USBC_ISTAT[n]_H.NYET` bit can be set only by the core and the application should write 1 to clear it.
5 (R/W1C)	ACK	ACK Response Received/Transmitted Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.ACK` bit is masked in the core. The `USBC_ISTAT[n]_H.ACK` bit can be set only by the core and the application should write 1 to clear it.
4 (R/W1C)	NAK	NAK Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.NAK` bit is masked in the core. The `USBC_ISTAT[n]_H.NAK` bit can be set only by the core and the application should write 1 to clear it.
3 (R/W1C)	STALL	STALL Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.STALL` bit is masked in the core. The `USBC_ISTAT[n]_H.STALL` bit can be set only by the core and the application should write 1 to clear it.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT[n]_H.AHBERR` bit is generated only in internal DMA mode when there is a bus error during a bus read/write. The application can read the corresponding channel's DMA address register to get the error address.
1 (R/W1C)	CHHLTD	Channel Halted. In non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.CHHLTD` bit indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In scatter/gather DMA mode, the `USBC_ISTAT[n]_H.CHHLTD` bit indicates that transfer completed due to any of the following: EOL being set in descriptor Bus error Excessive transaction errors Babble Stall

Table 19-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed. The `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that the transfer completed normally without any errors. The `USBC_ISTAT[n]_H.XFERCOMPL` bit can be set only by the core and the application should write 1 to clear it. For scatter/gather DMA mode, the `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that current descriptor processing completed with an IOC bit set in its descriptor. In non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that transfer completed normally without any errors.

Host Channel n Split Control Register

The USBC_SPLT_CTL[n]_H register controls split transactions for a channel.

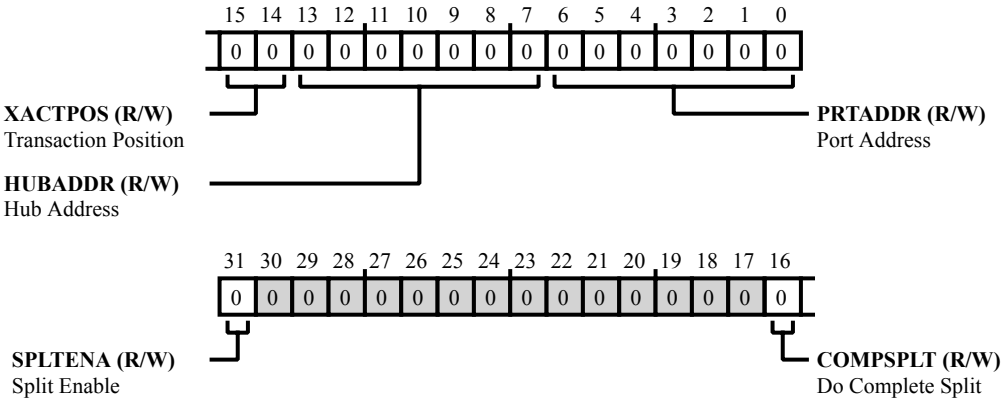

Figure 19-71: USBC_SPLT_CTL[n]_H Register Diagram

Table 19-68: USBC_SPLT_CTL[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	SPLTENA	Split Enable. When set (=1), the USBC_SPLT_CTL[n]_H.SPLTENA bit enables the channel to perform split transactions.	
16 (R/W)	COMPSPLT	Do Complete Split. The USBC_SPLT_CTL[n]_H.COMPSPLT bit enables the request to the OTG host to perform a complete split transaction.	
15:14 (R/W)	XACTPOS	Transaction Position. The USBC_SPLT_CTL[n]_H.XACTPOS field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.	
		0	Mid. The middle payload of the transaction (which is larger than 188 bytes).
		1	End. The last payload of the transaction (which is larger than 188 bytes).
		2	Begin. The first data payload of the transaction (which is larger than 188 bytes).
		3	All. The entire data payload is the transaction (which is less than or equal to 188 bytes).
13:7 (R/W)	HUBADDR	Hub Address. The USBC_SPLT_CTL[n]_H.HUBADDR field holds the device address of the transaction translator's hub.	

Table 19-68: USBC_SPLT_CTL[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRTADDR	Port Address. The `USBC_SPLT_CTL[n]_H.PRTADDR` field indicates the port number of the recipient transaction translator.

Host Channel n Transfer Size Register

The USBC_TSIZ[n]_H register represents the host channel n transfer size register.

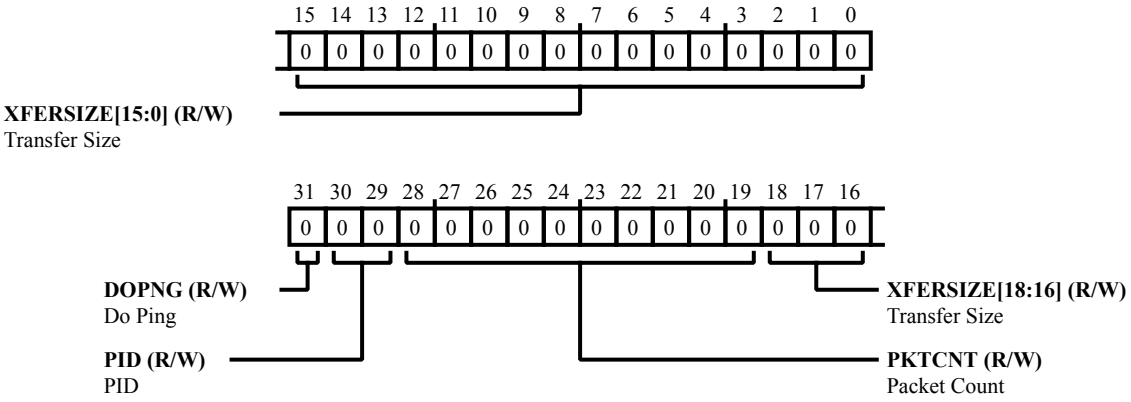

Figure 19-72: USBC_TSIZ[n]_H Register Diagram

Table 19-69: USBC_TSIZ[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DOPNG	Do Ping. The USBC_TSIZ[n]_H.DOPNG bit is used only for OUT transfers. Setting the USBC_TSIZ[n]_H.DOPNG bit (=1) directs the host to do PING protocol. Note: Do not set USBC_TSIZ[n]_H.DOPNG bit for IN transfers. If the USBC_TSIZ[n]_H.DOPNG bit is set for for IN transfers, it disables the channel.	
30:29 (R/W)	PID	PID. The USBC_TSIZ[n]_H.PID field indicates the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA (non-control) / SETUP (control)
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ[n]_H.PKTCNT field indicates the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.	

Table 19-69: USBC_TSIZ[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:0 (R/W)	XFERSIZE	Transfer Size. For an OUT, the `USBC_TSIZ[n]_H.XFERSIZE` field is the number of data bytes the host sends during the transfer. For an IN, the `USBC_TSIZ[n]_H.XFERSIZE` field is the buffer size that the application has reserved for the transfer. The `USBC_TSIZ[n]_H.XFERSIZE` field must be programmed as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). Scatter/Gather DMA Mode: [18:16]: Reserved [15:8]: NTD (Number of Transfer Descriptors) (Non Isochronous) This value is in terms of number of descriptors. Maximum number of descriptor that can be present in the list is 64. The values can be from 0 to 63. 0 1 descriptor 63 64 descriptors This field indicates the total number of descriptors present in that list. The core will wrap around after servicing NTD number of descriptors for that list. (Isochronous) This field indicates the number of descriptors present in that list microframe. The possible values for FS are 1 - 2 descriptors 3 - 4 descriptors 7 - 8 descriptors 15 - 16 descriptors 31 - 32 descriptors 63 - 64 descriptors The possible values for HS are 7 - 8 descriptors 15 - 16 descriptors 31 - 32 descriptors 63 - 64 descriptors 127 - 128 descriptors 255 - 256 descriptors [7:0]: SCHED_INFO (Schedule information) Every bit in this 8 bit register indicates scheduling for that microframe. Bit 0 indicates scheduling for 1st microframe and bit 7 indicates scheduling for 8th microframe in that frame. A value of 8b11111111 indicates that the corresponding interrupt channel is scheduled to issue a token every microframe in that frame. A value of 8b10101010 indicates that the corresponding interrupt channel is scheduled to issue a token every alternate microframe starting with second microframe. Note that this field is applicable only for

Host Frame Interval Register

The USBC_FIR_H register indicates the frame interval. It also control the the reloading of the USBC_FIR_H register during runtime.

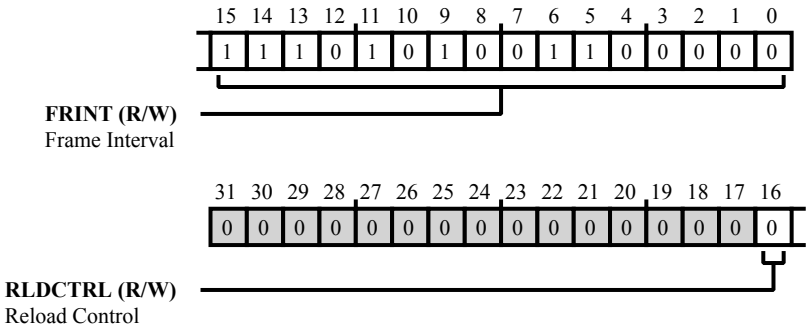

Figure 19-73: USBC_FIR_H Register Diagram

Table 19-70: USBC_FIR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	RLDCTRL	Reload Control. The USBC_FIR_H.RLDCTRL bit enables dynamic reloading of the USBC_FIR_H register during runtime. The USBC_FIR_H.RLDCTRL bit must be programmed during initial configuration and its value should not be changed during runtime.	
		0	Disable
		1	Enable
15:0 (R/W)	FRINT	Frame Interval. The USBC_FIR_H.FRINT field specifies the interval between two consecutive SPFs (FS) or micro-SOFs (HS) or keep-alive tokens (HS). The field contains the number of PHY clocks that constitute the required frame interval. The default value set in the USBC_FIR_H.FRINT field is for full-speed operation when the PHY clock frequency is 60 MHz. The application can write a value to this register only after the USBC_PORT_CTL_H.ENA bit is set (=1). If no value is programmed, the core calculates the value based on the PHY clock specified in the USBC_CFG_H.PCLKSEL field. Do not change the value of USBC_FIR_H.FRINT field after the initial configuration. 125 s * (PHY clock frequency for HS) 1 ms * (PHY clock frequency for FS/LS)	

Host Frame List Base Address Register

The USBC_FL_BADDR_H register holds the starting address of the frame list information. This register is used only for isochronous and interrupt channels.

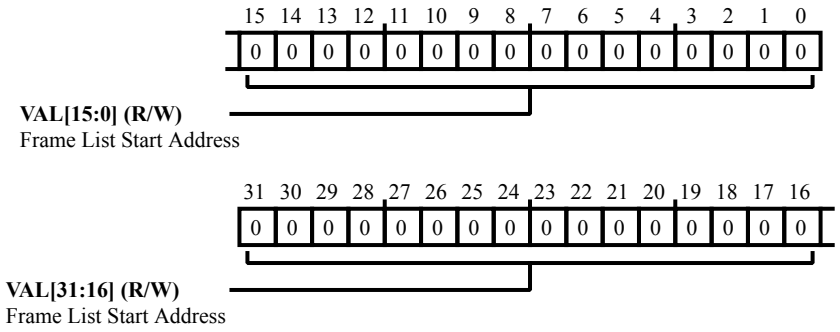

Figure 19-74: USBC_FL_BADDR_H Register Diagram

Table 19-71: USBC_FL_BADDR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Frame List Start Address.

Host Frame Number/Frame Time Remaining Register

The USBC_FNUM_H register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current (micro)frame.

Note: Read the reset value of this register only after the following conditions:

If IDDIG_FILTER is disabled, read only when the PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

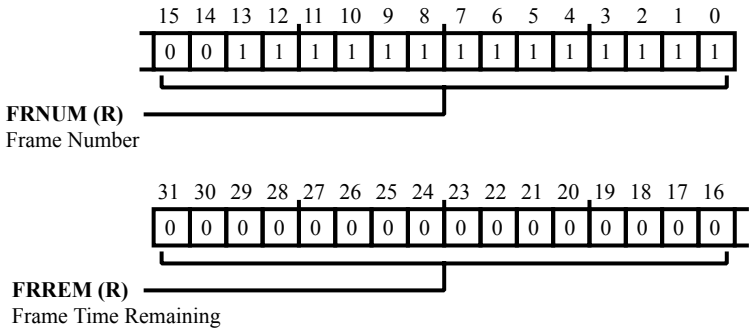

Figure 19-75: USBC_FNUM_H Register Diagram

Table 19-72: USBC_FNUM_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	FRREM	Frame Time Remaining. The USBC_FNUM_H.FRREM field indicates the amount of time remaining in the current microframe (HS) or frame (FS/LS), in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, the USBC_FNUM_H.FRREM field is reloaded with the value in the frame interval register and a new SOF is transmitted on the USB.
15:0 (R/NW)	FRNUM	Frame Number. The USBC_FNUM_H.FRNUM field increments when a new SOF is transmitted on the USB. It is reset to 0 when it reaches 16'h3FFF.

Host Port Control and Status Register

The USBC_PORT_CTL_H register is available only in host mode. Currently, the OTG host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port.

The R_SS_WC bits in this register can trigger an interrupt to the application through the USBC_ISTAT.PRTINT bit. On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

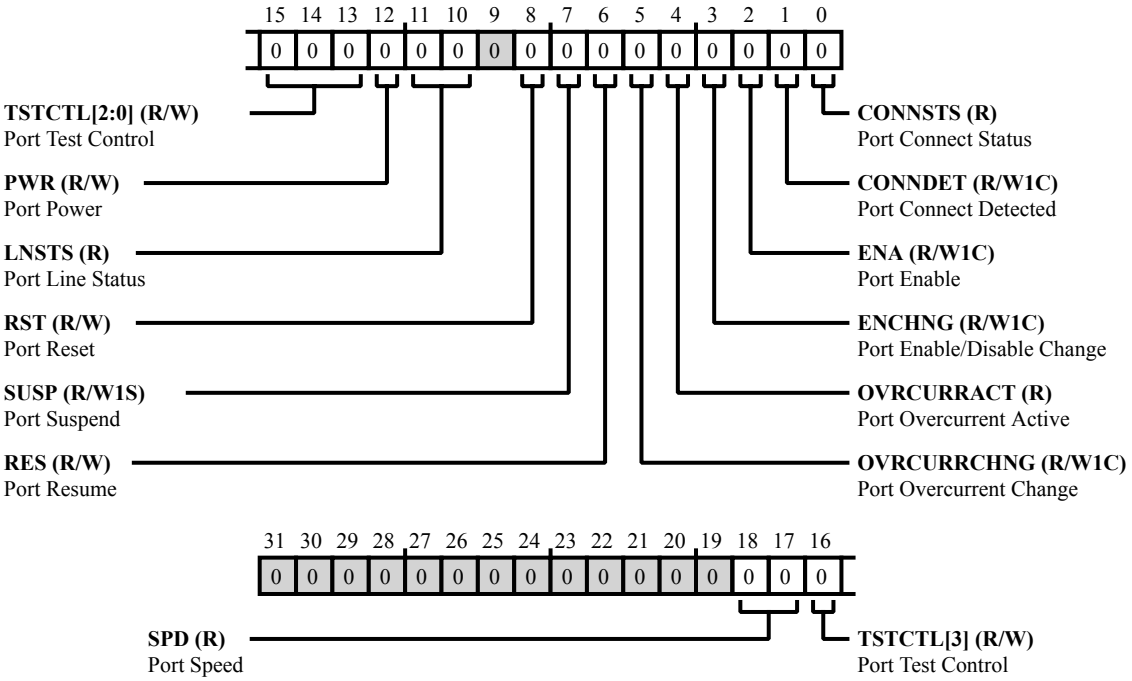

Figure 19-76: USBC_PORT_CTL_H Register Diagram

Table 19-73: USBC_PORT_CTL_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:17 (R/NW)	SPD	Port Speed. The USBC_PORT_CTL_H.SPD field indicates the speed of the device attached to this port.	
		0	High speed
		1	Full speed
		2	Low speed
		3	Reserved

Table 19-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16:13 (R/W)	TSTCTL	Port Test Control. The application writes a nonzero value to the `USBC_PORT_CTL_H.TSTCTL` field to put the port into a test mode, and the corresponding pattern is signaled on the port. To move the USBC_otg controller to test mode, this field must be set. Complete the following steps to move the USBC_otg core to test mode: 1. Power on the core. 2. Load the USBC_otg driver. 3. Connect an HS device and enumerate to HS mode. 4. Access the `USBC_PORT_CTL_H` register to send test packets. 5. Remove the device and connect to fixture (OPT) port. The USBC_otg host core continues sending out test packets. 6. Test the eye diagram.	
		0	Test mode disabled
		1	Test_J mode
		2	Test_K mode
		3	Test_SEO_NAK mode
		4	Test_Packet mode
		5	Test_Force_Enable
		6	Reserved
		7	Reserved
		8	Reserved
		9	Reserved
		10	Reserved
		11	Reserved
		12	Reserved
		13	Reserved
		14	Reserved
		15	Reserved

Table 19-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PWR	Port Power. The USBC_PORT_CTL_H.PWR bit controls power to the port (write 1 to set to 1 and write 0 to set to 0). The core can clear the USBC_PORT_CTL_H.PWR field bit on an overcurrent condition. Note: The USBC_PORT_CTL_H.PWR bit is interface independent. The application needs to program the USBC_PORT_CTL_H.PWR bit for all interfaces.	
		0	Power off
		1	Power on
11:10 (R/NW)	LNSTS	Port Line Status. The USBC_PORT_CTL_H.LNSTS field indicates the current logic level USB data lines Bit [10]: Logic level of D+ Bit [11]: Logic level of D-	
8 (R/W)	RST	Port Reset. When the application sets the USBC_PORT_CTL_H.RST bit, a reset sequence is started on this port. The application must time the reset period and clear the USBC_PORT_CTL_H.RST bit after the reset sequence is complete. The application must leave the USBC_PORT_CTL_H.RST bit set for at least a minimum duration mentioned below to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard. The USBC_PORT_CTL_H.RST bit is cleared by the core even if there is no device connected to the host. High speed: 50 ms Full speed/low speed: 10 ms	
		0	Port not in reset
		1	Port in reset

Table 19-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1S)	SUSP	Port Suspend. The application sets the USBC_PORT_CTL_H.SUSP bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY. The USBC_PORT_CTL_H.SUSP bit indicates the current suspend status of the port. The USBC_PORT_CTL_H.SUSP bit is cleared by the core after a remote wakeup signal is detected or the application sets the port reset bit or port resume bit in this register or the (USBC_ISTAT.WKUPINT or USBC_ISTAT.DISCONINT bit. The USBC_PORT_CTL_H.SUSP bit is cleared by the core even if there is no device connected to the host.	
		0	Port not in suspend mode
		1	Port in suspend mode
6 (R/W)	RES	Port Resume. The application sets the USBC_PORT_CTL_H.RES bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the USBC_ISTAT.WKUPINT bit, the core starts driving resume signaling without application intervention and clears the USBC_PORT_CTL_H.RES bit when it detects a disconnect condition. When LPM is enabled, In L1 state the behavior of the USBC_PORT_CTL_H.RES bit is as follows: The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal. If the core detects a USB remote wakeup sequence, as indicated by the Port L1Resume/Remote L1Wakeup Detected Interrupt bit of the core Interrupt register the (USBC_ISTAT.L1WkUpInt), the core starts driving resume signaling without application intervention and clears the USBC_PORT_CTL_H.RES bit at the end of resume. This bit can be set by both core or application and also cleared by core or application. The USBC_PORT_CTL_H.RES bit is cleared by the core even if there is no device connected to the host.	
		0	No resume driven
		1	Resume driven
5 (R/W1C)	OVRCURRCHNG	Port Overcurrent Change. The core sets the USBC_PORT_CTL_H.OVRCURRCHNG bit when the status of the the USBC_PORT_CTL_H.OVRCURRACT bit changes. The USBC_PORT_CTL_H.OVRCURRCHNG bit can be set only by the core and the application should write 1 to clear it.	

Table 19-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	OVRCURRACT	Port Overcurrent Active. The USBC_PORT_CTL_H.OVRCURRACT bit indicates the overcurrent condition of the port.	
		0	No overcurrent condition
		1	Overcurrent condition
3 (R/W1C)	ENCHNG	Port Enable/Disable Change. The core sets the USBC_PORT_CTL_H.ENCHNG bit when the status of the USBC_PORT_CTL_H.ENA bit changes. The USBC_PORT_CTL_H.ENCHNG bit can be set only by the core and the application should write 1 to clear it.	
2 (R/W1C)	ENA	Port Enable. The USBC_PORT_CTL_H.ENA bit enables the port. A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set the USBC_PORT_CTL_H.ENA bit by a register write. It can only clear the USBC_PORT_CTL_H.ENA bit to disable the port by writing 1. This bit does not trigger any interrupt to the application.	
		0	Disable
		1	Enable
1 (R/W1C)	CONNDET	Port Connect Detected. The core sets the USBC_PORT_CTL_H.CONNDET bit when a device connection is detected to trigger an interrupt to the application using the USBC_ISTAT.PRTINT bit. The USBC_PORT_CTL_H.CONNDET bit can be set only by the core and the application should write 1 to clear it. The application must write a 1 to this bit to clear the interrupt.	
0 (R/NW)	CONNSTS	Port Connect Status. The USBC_PORT_CTL_H.CONNSTS bit indicates whether a device is connected to the port.	
		0	No device attached to port
		1	Device attached to port

Host Periodic Transmit FIFO Size Register

The USBC_TXFIFOSZ_PER_H register holds the size and the memory start address of the periodic TxFIFO.

Note: Read the reset value of this register only after the following conditions:

If IDDIG_FILTER is disabled, read only after PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

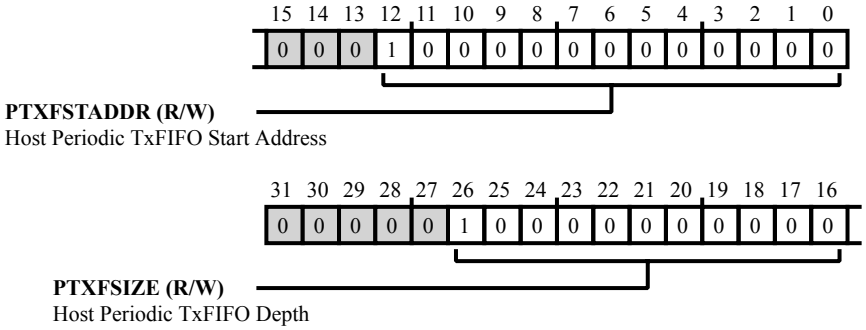

Figure 19-77: USBC_TXFIFOSZ_PER_H Register Diagram

Table 19-74: USBC_TXFIFOSZ_PER_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26:16 (R/W)	PTXFSIZE	Host Periodic TxFIFO Depth. The USBC_TXFIFOSZ_PER_H.PTXFSIZE field indicates the host periodic TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value is specified as the largest host mode periodic Tx Data FIFO depth. Programmed values must not exceed the power-on value.
12:0 (R/W)	PTXFSTADDR	Host Periodic TxFIFO Start Address.

Power and Clock Gating Control Register

The USBC_PWR_CTL register controls power down, sleep, and clock stopping features.

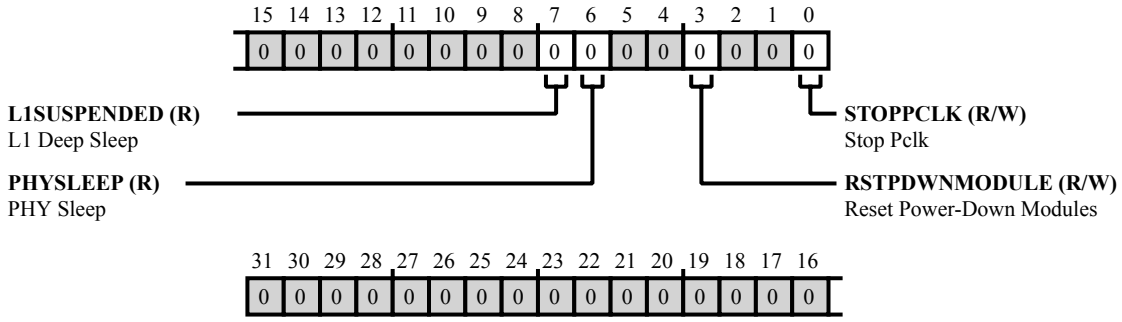

Figure 19-78: USBC_PWR_CTL Register Diagram

Table 19-75: USBC_PWR_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	L1SUSPENDED	L1 Deep Sleep. The USBC_PWR_CTL.L1SUSPENDED bit indicates that the PHY is in deep sleep when in L1 state.
6 (R/NW)	PHYSLEEP	PHY Sleep. The USBC_PWR_CTL.PHYSLEEP indicates that the PHY is in a sleep state.
3 (R/W)	RSTPDWNMODULE	Reset Power-Down Modules. The USBC_PWR_CTL.RSTPDWNMODULE bit is valid only in Partial Power-Down mode. - The application sets this bit when the power is turned off. - The application clears this bit after the power is turned on and the PHY clock is up. Note: The R/W of all core registers are possible only when this bit is set to 1b0.
0 (R/W)	STOPPCLK	Stop Pclk. The USBC_PWR_CTL.STOPPCLK bit stops the PHY clock (phy_clk), when set (=1) and the USB is suspended, the session is not valid, or the device is disconnected. The USBC_PWR_CTL.STOPPCLK bit, when clear (=0), the USB resumes or a new session starts.

20 Serial Peripheral Interface (SPI)

The serial peripheral interface is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

With a range of configurable options, the SPI ports provide a glueless hardware interface with other SPI-compatible devices in master mode, slave mode, and multimaster environments. The SPI peripheral includes programmable baud rates, clock phase, and clock polarity. The peripheral can operate in a multimaster environment by interfacing with several other devices, acting as either a master device or a slave device. In a multimaster environment, the SPI peripheral uses open-drain outputs to avoid data bus contention. The flow control features enable slow slave devices to interface with fast master devices by providing an SPI ready pin which flexibly controls the transfers.

NOTE: SPI peripherals on the processor operate in the CLKO6 domain. For more details on CLKO6 programming, refer the *Clock Generation Unit (CGU)* chapter.

SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- 8, 16-bit and 32-bit word sizes
- Programmable baud rate, clock phase, and polarity
- Programmable interframe latency
- Flow control
- Support for Fast and DIOM modes
- SPI1 and SPI2 support quad mode. Memory-mapped mode is supported by SPI2 only.
- Independent receive and transmit DMA channels

- Burst transfer mode for non-DMA write accesses

SPI Functional Description

This section provides information on the function of the SPI module.

Shift register functionality

The SPI is essentially a shift register that serially transmits and receives data bits to or from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

Master slave functionality

During a data transfer, one SPI system acts as the link master which controls the data flow. The other system acts as the slave, which has data shifted into and out of it by the master. Different devices can take turn being masters, and one master can simultaneously shift data into multiple slaves (broadcast mode). However, only one slave can drive its output to write data back to the master at any given time. This rule must be enforced in the broadcast mode. Several slaves can be selected to receive data from the master in this mode. But only one slave can be enabled to send data back to the master.

Enhanced operating modes

SPI supports enhanced modes of operation like fast mode, DIOM, and Quad-SPI, and optional flow control. In fast mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both MOSI and MISO are configured as input or output pins, and 2 bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI_D3:0 are configured as input or output pins and 4 bits are shifted in or out on each receive or transmit edge. A slower slave can use flow control to stall a faster master device.

Single and multi-master use

The SPI can be used in a single master as well as multi-master environment. The `SPI_MOSI`, `SPI_MISO`, and the `SPI_CLK` signals are all tied together in both configurations. SPI transmission and reception can be enabled simultaneously or individually, depending on `SPI_RXCTL` and `SPI_TXCTL` settings. In broadcast mode, several slaves can be enabled to receive, but only one slave must be in transmit mode and driving the `SPI_MISO` line.

ADSP-2159x_SC591_SC592_SC594 SPI Register List

The Serial Peripheral Interface (SPI) provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments. The SPI's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers governs SPI operations. For more information on SPI functionality, see the SPI register descriptions.

Table 20-1: ADSP-2159x_SC591_SC592_SC594 SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register

SPI Block Diagram

The ***SPI Controller Block Diagram*** illustrates the blocks of the SPI module. The module is comprised of three primary parts:

- SPI core contains the receive and transmit FIFOs and their associated shift registers
- Control blocks contain the synchronizer and logic to control the data flow through the data pipelines
- Register block

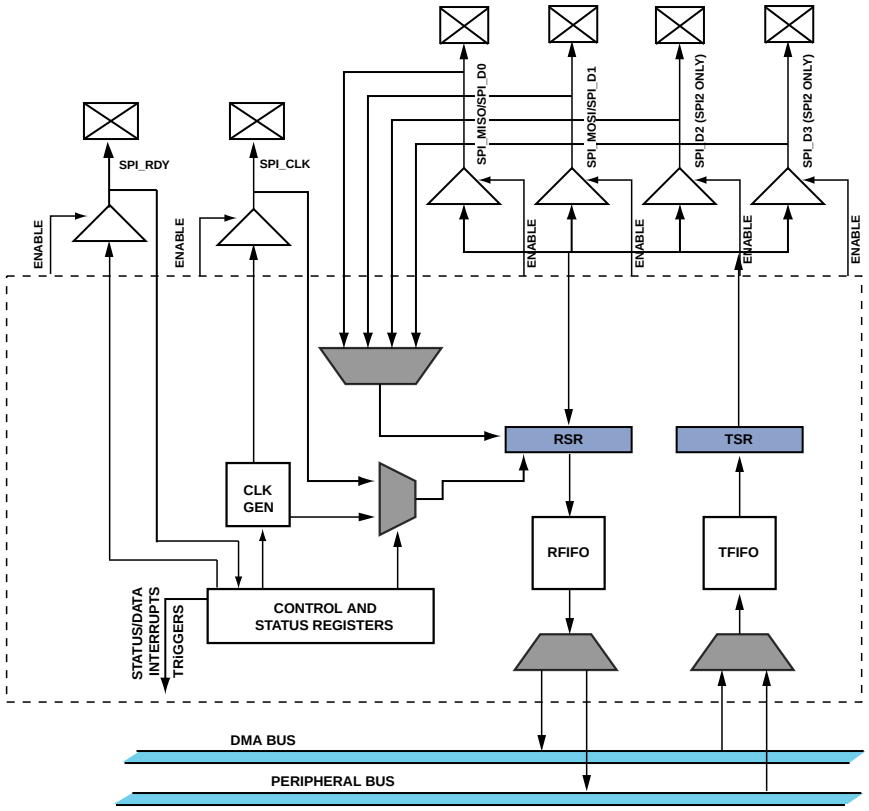

Figure 20-1: SPI Controller Block Diagram, Quad Mode

Transfer Protocol

The SPI module implements two channels that are independent of each other. The SPI module uses the SPI_RXCTL and SPI_TXCTL dedicated control registers to control these channels. Except in dual and quad modes, SPI can enable and use both channels simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the SPI_CTL.CPOL and SPI_CTL.CPHA bits.

The ***SPI Transfer Protocol*** figures demonstrate the two basic transfer formats as defined by the CPHA bit. Two waveforms are shown for SPI_CLK; one for SPI_CTL.CPOL=0 and the other for SPI_CTL.CPOL=1. The diagrams can be interpreted as master or slave timing diagrams since the SPI_CLK, SPI_MISO, and SPI_MOSI pins are directly connected between the master and the slave. The SPI_MISO signal is the output from the slave (slave transmission), and the SPI_MOSI signal is the output from the master (master transmission). The master generates the SPI_CLK signal. The SPI_SS signal is the slave device select input to the slave from the master. The diagrams represent an 8-bit transfer (SPI_CTL.SIZE=0) with the MSB first (SPI_CTL.LSBF=0). Any combination of the SPI_CTL.SIZE and SPI_CTL.LSBF bits is permissible. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase could be identical for the master device and the slave device involved in the communication link. The transfer format from the master can be changed between transfers to adjust for various requirements of a slave device.

The SPI module uses the SPI_CTL.ASSEL bit to determine when the SPI hardware or software control the SPI_SEL[n] line. When SPI_CTL.ASSEL=1, the slave select line must be set to the polarity set in the SPI_CTL.SELST field between each serial transfer. The actual behavior of SPI_SEL[n] also depends on the parameters programmed into the SPI_DLY register. The SPI hardware logic automatically controls this functionality. When SPI_CTL.ASSEL=0, SPI_SEL[n] can either remain active between successive transfers or be inactive. The software must control this activity through manipulation of the SPI_SLVSEL register.

The ***SPI Transfer Protocol*** pair of figures illustrates the case when SPI_CTL.ASSEL = 1 and the SPI_SEL[n] line is inactive between frames. If ASSEL = 0, the SPI_SEL[n] line can remain active between frames; however, the first bit is only driven when an active transition of SPI_CLK occurs.

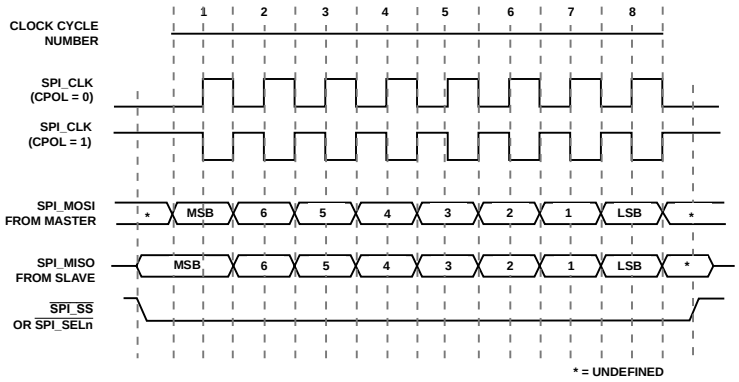

Figure 20-2: SPI Transfer Protocol for CPHA=0

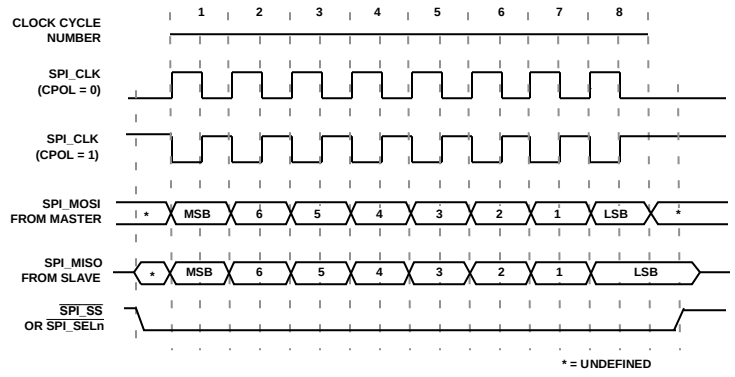

Figure 20-3: SPI Transfer Protocol for CPHA=1

Clock Considerations

The SPI_CLK signal is a gated clock that is only active during data transfers, for the time of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In dual-I/O mode, it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be derived using both even and odd dividers from CLKO6.

For master devices, the SPI uses the SPI_CLK register value to determine the clock rate, whereas this value is ignored for slave devices.

When the SPI controller is a master, SPI_CLK is an output signal. Conversely, when the SPI controller is a slave, SPI_CLK is an input signal. Slave devices ignore the SPI clock when the slave select input is driven inactive. The SPI uses the SPI_CLK signal to shift out and shift in the data driven onto the SPI_MISO and SPI_MOSI lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the SPI_CTL register and define the transfer format.

Controlling Delay Between Frames

The ***SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing using the SPI_DLY.LEADX and SPI_DLY.LAGX programming. The SPI uses the SPI_DLY.LAGX bits to control the timing between the slave select (SPI_SS) signal assertion and the first SPI_CLK edge. The SPI uses the SPI_DLY.LEADX bits to control the timing between the last SPI_CLK edge and deassertion of the SPI_SS signal. The lead and lag timing can be extended by a 1 SPI_CLK duration to ease timing restrictions on the slave device.

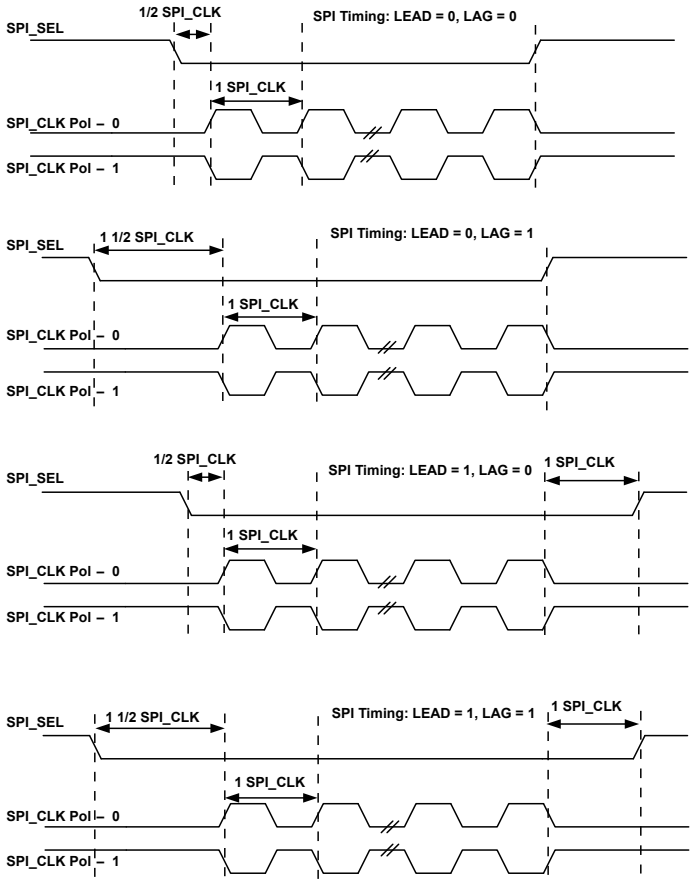

Figure 20-4: SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)

The ***SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing with STOP programming. The SPI module uses this timing to insert multiples of `SPI_CLK` period delays between transfers. The `SPI_SS` line is deasserted for the duration specified in the `SPI_DLY.STOP` bit field, assuming the `SPI_CTL.SELST` bit is configured for deassertion between transfers.

If the `SPI_DLY.STOP` bit =0, the master operates in a *continuous mode*. This mode causes an immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the slave select line is continuously asserted.

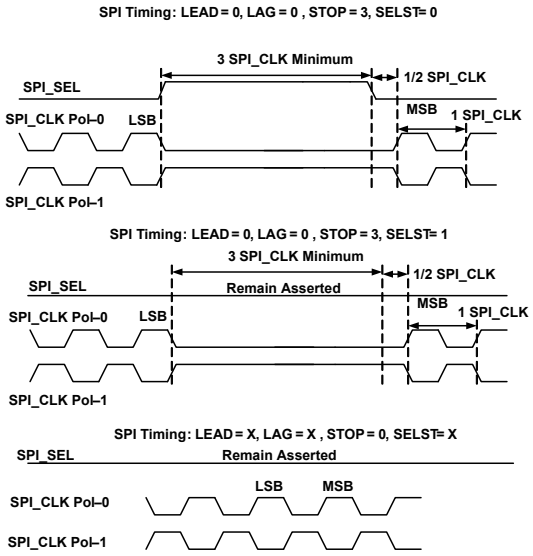

Figure 20-5: SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)

When the SPI_DLY.STOP bit =0 and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the SPI uses the SPI_CTL.SELST bit to determine the state of the slave select pin. The SPI uses the SPI_DLY.LEADX and SPI_DLY.LAGX bits to determine the timing between SPI_CLK edges and the slave select line.

Flow Control

In master mode, the slave device must drive the SPI_RDY pin. The pin acts as an input signal. The slave can deassert the SPI_RDY pin to stop the master from initiating any new transfer. If SPI_RDY is deasserted in the middle of a transfer, the current transfer continues, and the next transfer will not start unless the slave asserts the SPI_RDY signal. Whenever the slave deasserts SPI_RDY and stalls the master, the SPI controller goes into a waiting state, and the SPI_STAT.FCS bit is set. When the slave asserts SPI_RDY, the SPI controller resumes operation, and the SPI_STAT.FCS bit is cleared.

In slave mode, the SPI_RDY pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. The SPI uses the SPI_CTL.FCCH bit to control this configuration. If flow control is configured on the TX channel, as the SPI_TFIFO status nears the empty condition, the SPI_RDY pin is deasserted. If flow control is configured on the RX channel, as the SPI_RFIFO status nears the full condition, the SPI_RDY pin is deasserted. The SPI uses the SPI_CTL.FCWM bits to control the FIFO status at which SPI_RDY deassertion takes place. Flow control in slave mode is purely based on the FIFO status and does not depend on the word counters.

The ***SPI Flow Control Timing in Master Mode*** figure illustrates this timing.

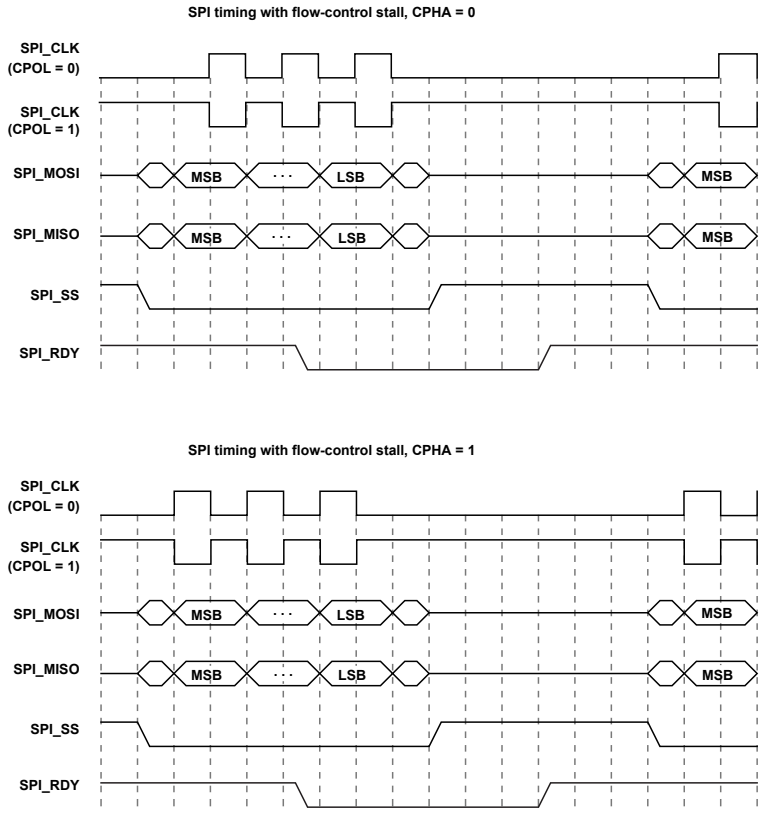

Figure 20-6: SPI Flow Control Timing in Master Mode.

Slave Select Operation

If the SPI is in slave mode, $\overline{\texttt{SPI\_SS}}$ acts as the slave select input. When SPI is enabled as a master, $\overline{\texttt{SPI\_SS}}$ can serve as an error detection input for the SPI in a multi-master environment. The SPI_CTL.PSSE bit enables this feature. When SPI_CTL.PSSE=1, the $\overline{\texttt{SPI\_SS}}$ input is the master mode error input. Otherwise, $\overline{\texttt{SPI\_SS}}$ is ignored.

The $\overline{\texttt{SPI\_SS}}$ signal is an active-low signal. The master asserts the signal during the transfer. The signal can be deasserted or remain asserted between transfers. When $\overline{\texttt{SPI\_SS}}$ is deasserted, SPI_CLK and inputs are ignored, and outputs are three-stated.

The slave select bits (SPI_SLVSEL.SSEL1 – SPI_SLVSEL.SSEL7) are used in a multiple-slave SPI environment. For example, if there are eight SPI devices in the system including a processor master, the master processor can support the SPI mode transactions across the other seven devices. This configuration requires only one master processor in this multi-slave environment.

For example, assume that the SPI of the processor is the master. The SPI_SLVSEL.SSEL1 – SPI_SLVSEL.SSEL7 bits on the processor can be connected to the slave select pin of each slave device. In this configuration, the slave select bits can be used in three ways. In cases 1 and 2, the processor is the master and the seven microcontrollers or peripherals with SPI interfaces are slaves. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all slave select bits are set.

2. Receive and transmit from one SPI device by enabling only one slave SPI device at a time.
3. If all the slaves are also processors, then the requester can receive data from only one processor at a time. (The functionality is enabled by clearing the SPI_CTL.EMISO bit in the six other slave processors.) The requestor can transmit broadcast data to all seven at the same time. This MISO enabling feature is available in some other microcontrollers. Therefore, it is possible to use the MISO enabling feature with any other SPI device that includes this functionality.

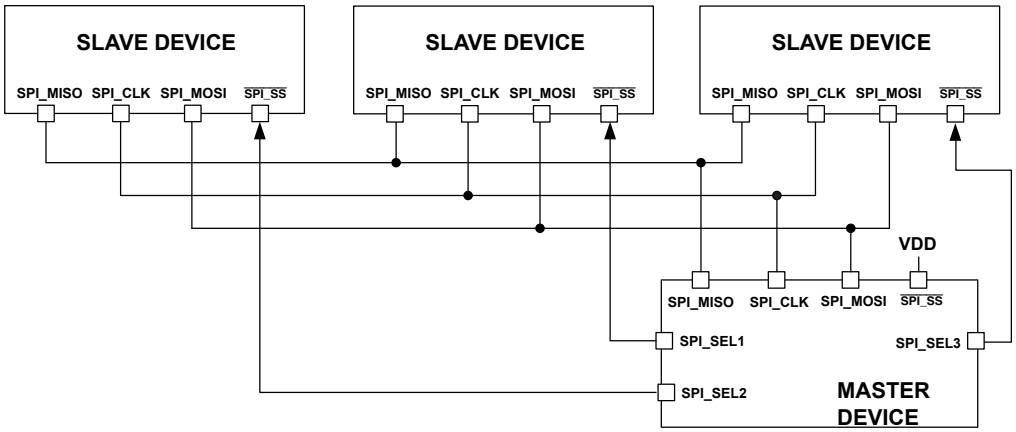

Figure 20-7: Single-Master, Multiple-Slave Configuration

Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a master or a slave.
2. The state of the SPI_CTL.ASSEL bit, which selects between hardware and software control over SPI_SLVSEL.

When SPI_CTL.CPHA=0, the enabled slave select outputs are driven active. However, the SPI_CLK signal remains inactive for the first half of the first cycle of SPI_CLK. For a slave with SPI_CTL.CPHA=0, the transfer starts as soon as the SPI_SS input goes low.

When SPI_CTL.CPHA=1, a transfer starts with the first active edge of SPI_CLK for both slave and master devices. For a master device, a transfer is complete after it sends the last data and simultaneously receives the last data bit. A transfer for a slave device ends after the last sampling edge of SPI_CLK. If SPI_CTL.ASSEL=1, the hardware maintains responsibility for toggling SPI_SS between frames. If SPI_CTL.ASSEL=0, software controls the SPI_SS line and can keep it active between frames.

The SPI_STAT.RFE bit defines when the receive buffer can be read, indicating that SPI_RFIFO is not empty. The SPI_STAT.TFF bit defines when the transmit buffer can be written, indicating that the SPI_TFIFO is not full. The end of a single word transfer occurs when the SPI_STAT.RFE bit is cleared. The status indicates that a new word has been received and written into the receive FIFO. The SPI_STAT.RFE bit remains cleared as long as the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the SPI_STAT.SPIF bit is also available for polling. This bit can have a slightly different behavior from other commercially available devices.

In master mode with the SPI_CTL.ASSEL bit cleared, software manually asserts the required slave select signal before starting the transaction. After all data transfers, software typically releases the slave select line.

When the receive or transmit word counters are enabled in the SPI_TXCTL or SPI_RXCTL registers, the SPI generates a finish interrupt at the end of the transfer. It signals the end of all transfers related to that transaction.

Transmit Operation in Non-DMA Mode

The transmit operation in non-DMA mode is enabled through the SPI_TXCTL.TEN bit. It can be enabled independently from the receive operation, and the transmit channel can become the initiating channel based on the SPI_TXCTL.TTI bit setting.

Transmit underrun is not possible in this mode, as no new transfer initiates unless the transmit FIFO is empty (in the case that SPI_TXCTL.TTI =1). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This event can occur if SPI_TXCTL.TTI =1 and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt request is signaled once the transmit channel has been enabled and the transmit FIFO is not full. The SPI uses the SPI_TXCTL.TDR bit setting to control the frequency of the interrupt request.

Receive Operation in Non-DMA Mode

The receive operation in non-DMA mode is enabled through the SPI_RXCTL.REN bit. It can be enabled independently from the transmit operation, and the receive channel can become the initiating channel based on the SPI_RXCTL.RTI bit setting.

Receive overflow is not possible in this mode, as no new transfer initiates when the receive FIFO is full (in the case of SPI_RXCTL.RTI =1). A transmit underrun can occur (SPI_TXCTL.TDU bit) when no valid data is in the SPI_TFIFO register when a transfer is initiated. This event can occur if SPI_RXCTL.RTI =1 and the transmit channel is enabled in a non-initiating capacity.

An SPI receive interrupt request is signaled once the receive channel has been enabled and there is data waiting to be read. The SPI uses the SPI_RXCTL.RDR bit setting to control the frequency of the interrupt request.

Dual I/O Mode

In Dual I/O mode, the SPI_MISO and SPI_MOSI pins are configured to operate in the same direction which doubles bandwidth. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends the first bit on the SPI_MOSI pin and the second bit on the SPI_MISO pin. If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt request generation is unaffected by dual I/O mode. However, the interrupt service interval is reduced, since the individual transfer latency is halved.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

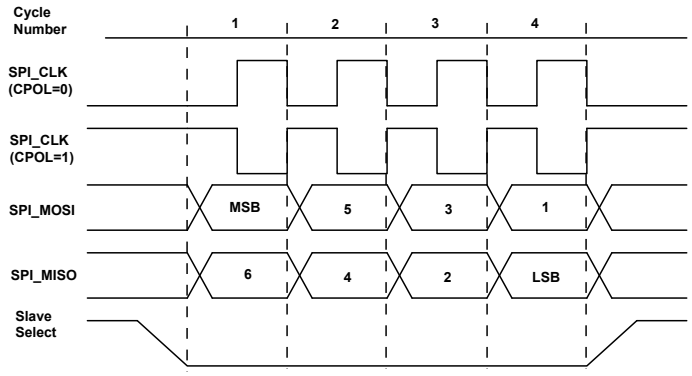

Figure 20-8: Dual I/O Mode Transfer Protocol for CPHA=0, SOSI=1, 8-Bit Transfer, LSBF=0.

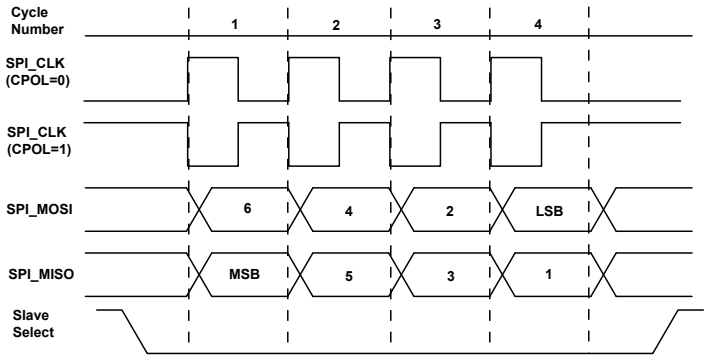

Figure 20-9: Dual I/O Mode Transfer Protocol for CPHA=1, SOSI=0, 8-Bit Transfer, LSBF=0.

Quad I/O Mode (SPI2 only)

In quad SPI mode, the SPI_MISO and SPI_MOSI pins, in tandem with the SPI_D2 and SPI_D3 pins, are configured to operate in the same direction. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends:

- The first bit on the SPI_MOSI pin
- The second bit on the SPI_MISO pin
- The third bit on the SPI_D2 pin
- The fourth bit on the SPI_D3 pin

If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled as either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt generation is unaffected by quad SPI mode.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

While using dual or quad I/O mode for communicating with flash devices, program the SPI_CTL.CPHA and the SPI_CTL.CPOL bits =1. This programming avoids bus contention during read operations, because the flash device starts driving out the bits immediately after dummy cycles in read header.

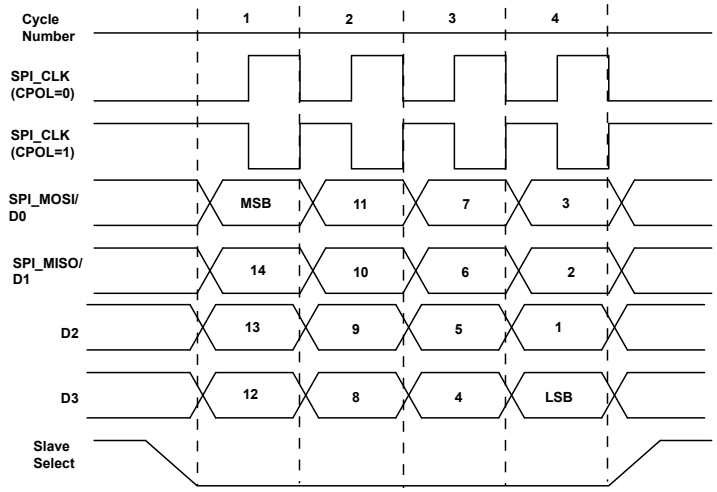

Figure 20-10: Quad Mode Timing for CPHA=0, SOSI=1, 16-Bit Transfer, LSBF=0.

NOTE: The SPI does support quad SPI 8-bit transfer in slave continuous mode of operation with an CLKO6:SPI_CLK ratio of less than 1:2. A minimum of 2 CLKO6 cycles is required between transfers in 8-bit quad SPI slave mode with an CLKO6:SPI_CLK ratio of less than 1:2.

Fast Mode

Fast mode is similar to the normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in master mode operation only. When the SPI operates in fast mode, the slave drives the data for one full cycle.

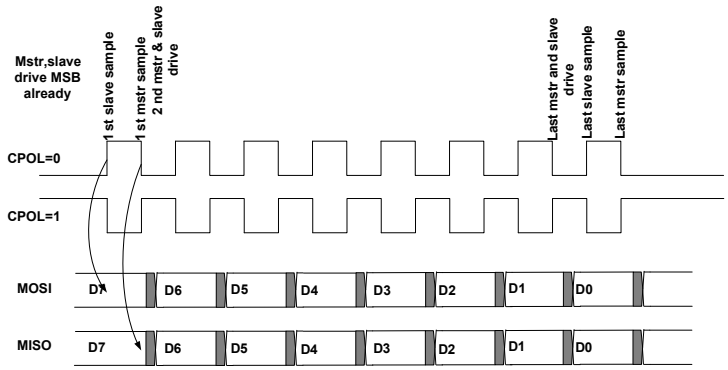

Figure 20-11: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 0

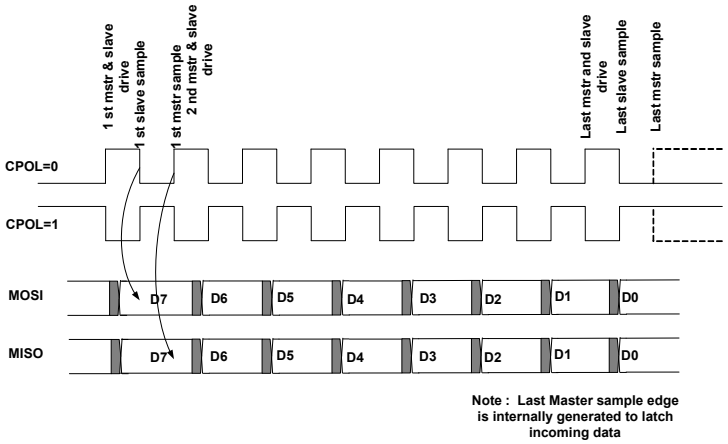

Figure 20-12: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 1

Memory-Mapped Mode (SPI2 only)

The SPI supports direct memory-mapped read accesses from a SPI memory device, enabled by setting the `SPI_CTL.MMSE` bit. This mode allows for direct execution of instructions from a SPI memory device without the need for a low-level software driver, as hardware handles all overhead tasks (for example, transmission of the read header, pin turnaround timing, and receive data sizing). The SPI features configurable options in the memory-mapped read header register (`SPI_MMRDH`) to provide compatibility with a wide range of SPI memory devices.

In non-memory-mapped mode, the software is responsible for providing the command and required dummy words for the read response, whereas this is all handled by hardware when the SPI is in memory-mapped mode. The memory of the SPI device is accessible directly through reads of the processor address space. The read accesses can be code or data accesses in core mode or when using memory DMA (MDMA). These accesses allow code to execute directly from SPI memory devices (true eXecute-In-Place operations), and the contents can be cached to improve performance. It is not necessary to access the SPI data buffer registers nor poll status bits; however, the hardware does not support peripheral DMA accesses nor write operations to the SPI memory space.

The ***Types of Operations*** table is a comparison of the permitted operations in the non-memory-mapped and memory-mapped modes supported by the SPI controller.

Table 20-6: Types of Operations

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
Core data write	Yes	No
Core data read	Yes	Yes
Code fetch: Execute-In-Place (XIP)	No	Yes
Read/Write accesses using SPI Peripheral DMA	Yes	No
Read/Write accesses by other peripheral DMA channels	No	No
MDMA read*	No	Yes

Table 20-6: Types of Operations (Continued)

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
MDMA write	No	No

NOTE: MDMA read* - Only standard bandwidth MDMA (MDMA0 and MDMA1) and Enhanced Bandwidth MDMA (MDMA2) can be used for accessing flash address space in memory mapped mode. The maximum bandwidth MDMA (MDMA3) cannot access flash address space.

Memory-Mapped Description of Operation

Memory-mapped mode is enabled by setting the `SPI_CTL.MMSE` bit. When enabled, the SPI (if ready) accepts the read requests through a dedicated on-chip slave interface. The memory subsystem master drives this dedicated interface through the SCB fabric.

In a typical scenario, the memory subsystem master issues read requests to the fabric, and the fabric routes these requests to the slave port of the SPI peripheral. The master describes the read access using a number of parameters such as starting address, transfer size, and burst type. The SPI responds to this read access request when it is ready for a new transfer. It loads the opcode, a specified number of address bytes, and an optional mode byte into the transmit FIFO. The SPI memory state machine begins when both the transmit and receive channels of the SPI are enabled with:

- the transmit transfer initiation bit is set (`SPI_TXCTL.TTI`=1), *and*
- the receive initiation bit is cleared (`SPI_RXCTL.RTI`=0)

The SPI memory read sequence starts with the assertion of $\overline{\texttt{SPI\_SEL1}}$. If the SPI memory state machine is in the reset state, it looks for a command. The SPI hardware then sends the specific 8-bit read command (which can be optionally skipped), followed by the SPI memory read address. After this, a dummy period is inserted, in which a mode byte is optionally sent and the pins are held or three-stated during the dummy clocking period.

NOTE: This read header is transmitted over the SPI standard protocol pins (`SPI_CLK`, `SPI_MOSI`, `SPI_MISO`, $\overline{\texttt{SPI\_SEL1}}$) or over the extended SPI protocol pins (`SPI_CLK`, `SPI_MOSI`, `SPI_MISO`, `SPI_D2`, `SPI_D3`, $\overline{\texttt{SPI\_SEL1}}$), based on the `SPI_MMRDH.CMDPINS`, `SPI_MMRDH.ADRPINS`, and `SPI_CTL.MIOM` bit settings. SPI memory devices usually support communication in MSB-first mode. In dual mode, the SPI typically uses `SPI_MISO` as IO1 and `SPI_MOSI` as IO0. In quad mode, the SPI typically uses `SPI_D3` pin as IO3, `SPI_D2` as IO2, `SPI_MISO` as IO1, and `SPI_MOSI` as IO0.

When all I/O data pins are three-stated, the SPI continues clocking the SPI memory device, which drives out the data bits at the addressed location, until all bytes are received. The SPI hardware reads the data as configured by the `SPI_CTL.MIOM` bit setting. Upon reception of the last byte, the SPI typically deasserts $\overline{\texttt{SPI\_SEL1}}$ to prepare for the next requested read header.

Application code must ensure that the opcode sent is consistent with multiple I/O programming and that the parameters specified in the memory-mapped read header register are consistent with flash read access timing.

The *SPI Memory-Mapped Register Operations Flow* diagram shows how the fields of the SPI_MMRDH register determine the read header while initiating transfers in memory-mapped mode.

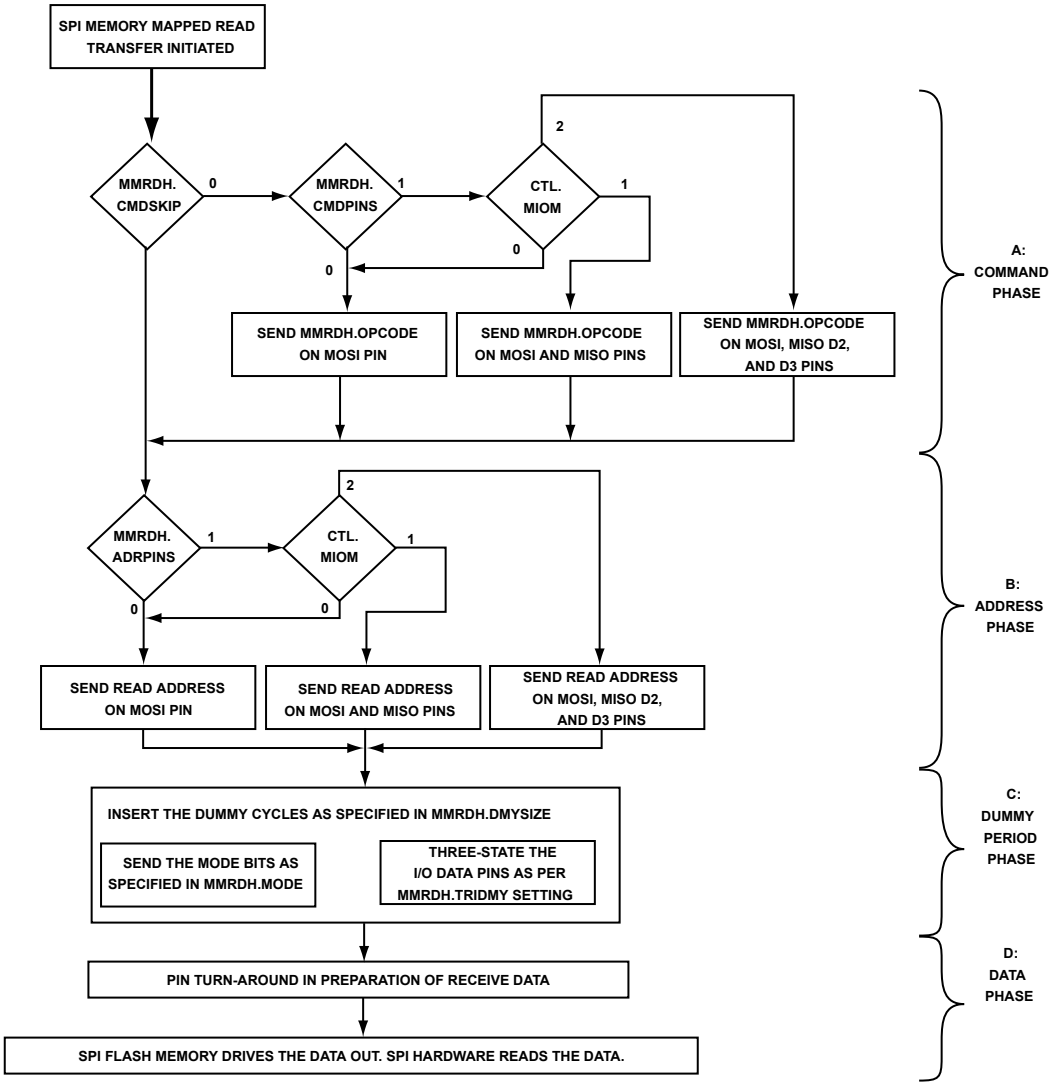

Figure 20-13: SPI Memory-Mapped Register Operations Flow

Memory-Mapped Architectural Concepts

In memory-mapped mode, the SPI accepts read requests through a dedicated on-chip slave interface. The SPI (if ready) accepts these requests and begins the process of assembling the read header based on access attributes described in both the SPI_MMRDH register and the internal bus request. After the read header transmission is complete, a pin turnaround period is timed and the receiver is enabled. The SPI continues clocking the SPI memory device until all bytes are received.

The SPI memory-mapped hardware accommodates various memory devices with different read timing. The capabilities include extra mode bits, flexible dummy period timing, and three-state control, as configured in the SPI_MMRDH register.

The *Memory-Mapped Protocol* figure shows the protocol for the SPI controller in memory-mapped mode.

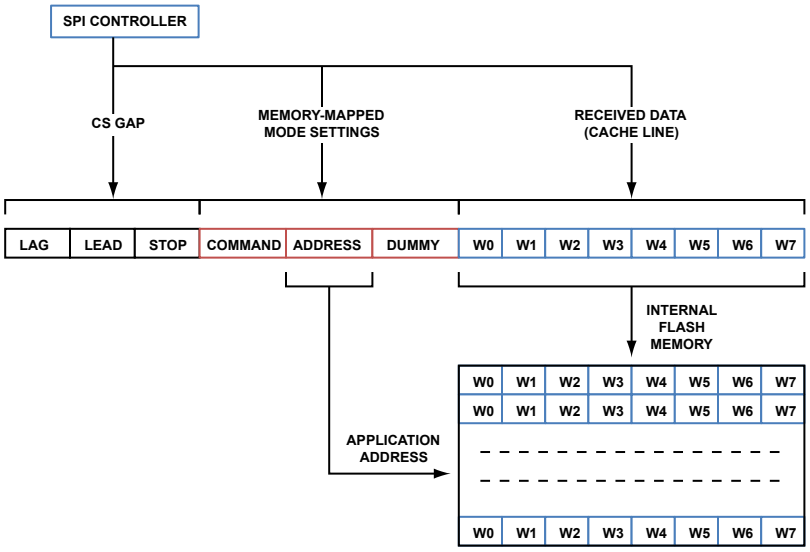

Figure 20-14: Memory-Mapped Protocol

As shown in the figure, the COMMAND field (`SPI_MMRDH.OPCODE`) is transmitted upon assertion of the `SPI_SEL[n]` signal. The SPI memory interprets this 8-bit value as a read command. Any 8-bit read opcode whose timing is compliant with the processor SPI and features provided by memory-mapped hardware is allowed, the most common being:

- Standard Read (0x03)
- Fast Read (0x0B)
- Fast Read Dual Output (0x3B)
- Fast Read Dual I/O (0x6B)
- Fast Read Quad Output (0xBB)
- Fast Read Quad I/O (0xEB)

NOTE: The SPI hardware does not validate the content of the `SPI_MMRDH.OPCODE` field prior to transmitting.

DMYSIZE (Number of Dummy Bytes)

When operating at a high clock frequency in multi-IO modes, most flash devices require some dummy clocks after the address bits. These dummy clock cycles allow the internal circuits of the device extra time for setting up the initial address. These bits specify the number of bytes separating address transmission and read data return.

The number of dummy cycles required varies per manufacturer, the read command used, and the SPI access time. The SPI hardware allows dummy cycles to be programmed in bytes in the `SPI_MMRDH.DMYSIZE` field, the value of which is a function of the number of pins used to transmit the address (`SPI_MMRDH.ADRPINS`), as shown in the *Pins Used to Transmit the Address (ADRPINS)* table.

Table 20-7: Pins Used to Transmit the Address (ADRPINS)

	Dummy clock cycles		
SPI_MMRDH.DMYSIZE	(**SPI_MMRDH.ADRPINS**=0, **SPI_CTL.MIOM**=x) Dummy bytes elapse over 1-pin	(**SPI_MMRDH.ADRPINS**=1, **SPI_CTL.MIOM**=1) Dummy bytes elapse over 2-pins	(**SPI_MMRDH.ADRPINS**=1, MIOM=2) Dummy bytes elapse over 4-pins
000	0	0	0
001	8	4	2
010	16	8	4
011	24	12	6
100	32	16	8
101	40	20	10
110	48	24	12
111	56	28	14

This dummy clocking period allows the mode bits to be sent, the pins to be three-stated, and the pins to be turned around in preparation for the receive data.

Memory-Mapped Read Accesses

The SPI hardware supports the most commonly used read operations.

- Two standard SPI reads (read and read fast), which use the unidirectional SPI_MOSI and SPI_MISO pins in addition to SPI_SEL[n] and SPI_CLK
- Four extended SPI multiple I/O reads: dual output, quad output, dual I/O, and quad I/O reads

The ***SPI Read Operations*** table and ***SPI Flash Fast Read Sequence*** figures summarize the types of read operations. Program each read operation in a way that is compatible with the description given in the SPI flash data sheet.

Table 20-8: SPI Read Operations

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Read	0x03	1	1	Zero	No	No	1
Fast Read	0x0B	1	1	Non-Zero	Yes	No	1
Dual Output Read	0x3B	1	1	Non-Zero	Yes	Yes(IO0-1)	2
Quad Output Read	0x6B	1	1	Non-Zero	Yes	Yes(IO0-3)	4
Dual I/O Read	0xBB	1, 2	2	Non-Zero	Yes	Yes (IO0-1)	2
Quad I/O Read	0xEB	1, 4	4	Non-Zero	Yes	Yes (IO0-3)	4

Some memory devices also support word quad I/O read (0xE7) and octal quad I/O read (0xE3) operations. These operations require fewer dummy cycles than normal quad I/O read operations.

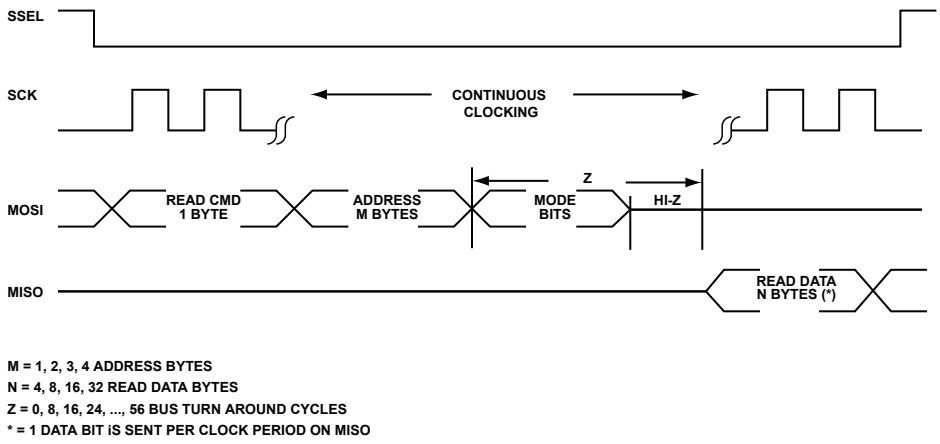

Figure 20-15: SPI Flash Fast Read Sequence

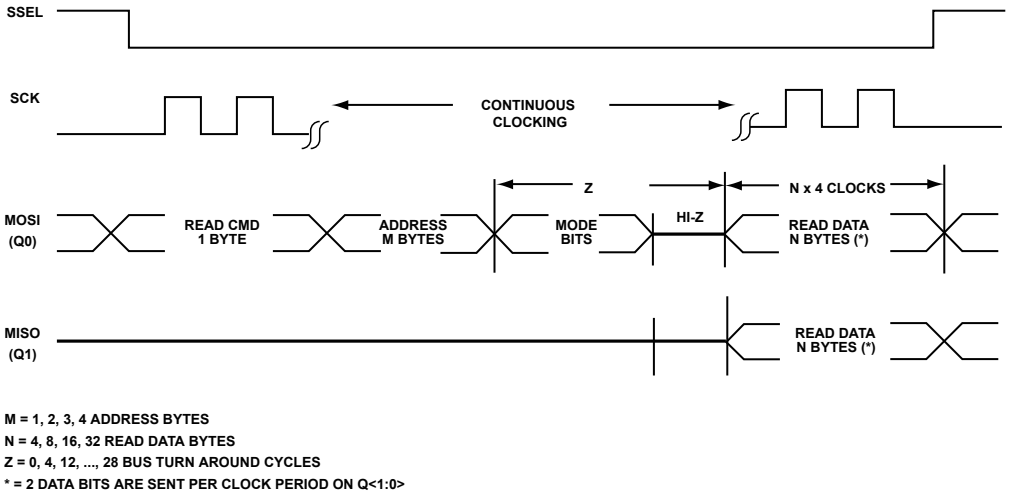

Figure 20-16: SPI Flash Fast Read (Dual Output) Sequence

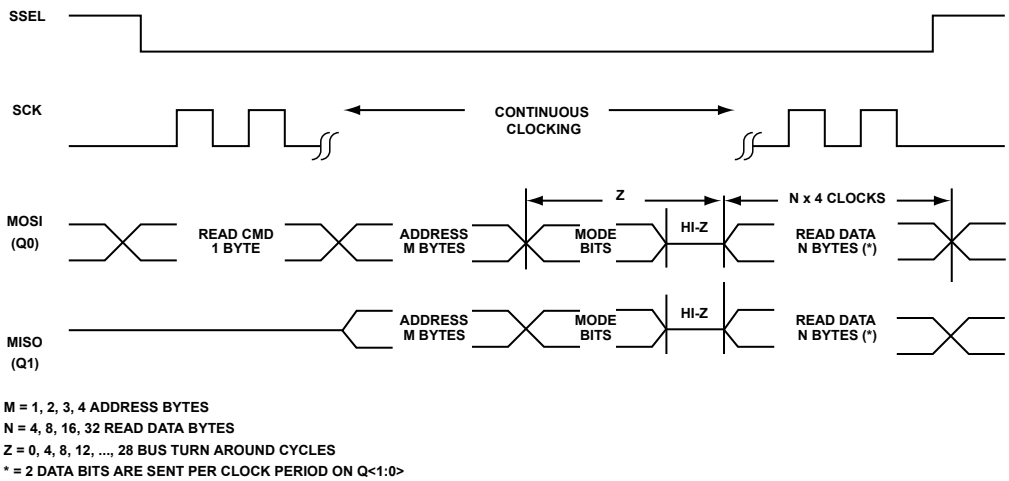

Figure 20-17: SPI Flash Fast Read (Dual I/O) Sequence

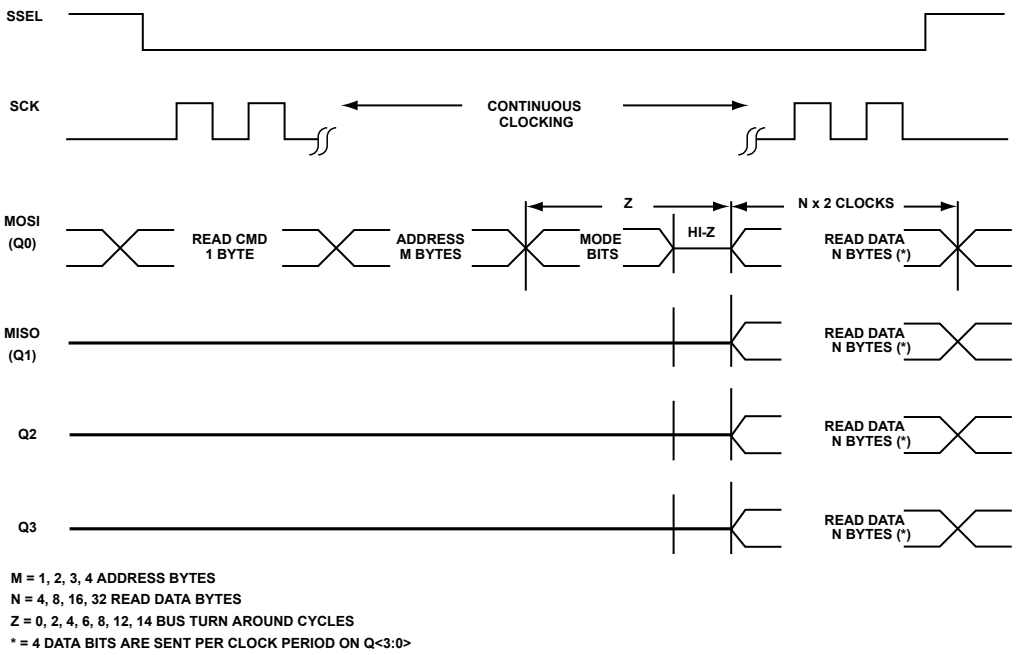

Figure 20-18: SPI Flash Quad Output Read Sequence

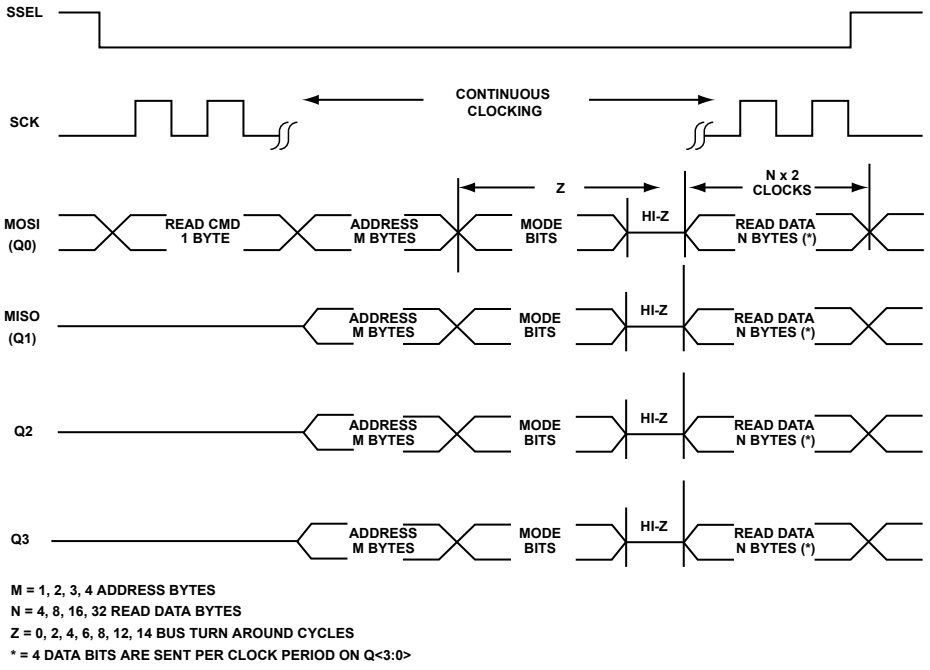

Figure 20-19: SPI Flash Quad I/O Read Sequence

SPI memory-mapped reads can be made cacheable in the core's internal memory by properly configuring the region as cacheable memory without bypass (see the related core's cache configuration documentation for details). In the figures, the number of read data bytes (N) is based on the following:

- For an instruction fetch by core (when in XIP mode); the number of instruction bytes to be fetched depends on the cache line size of the cache.

- For a data fetch by the core (data read), the number of data bytes to be fetched depends on the cache line size of the cache.

Although the minimum size of a memory-mapped data read transfer is 4 bytes, applications can fetch a single byte or a 2-byte data. (For example, it can fetch an unsigned char or short access in C code). In this case, only the required bytes are provided to the core and the other bytes are cached.

The on-chip memory subsystem master provides a starting address for the burst and the SPI hardware issues this address as part of the read header. The address provided is N-byte aligned. For example, to read the 30th byte from SPI memory, then the typical address to provide is:

- 28 (0x0000_001C) for a 32-bit cache line
- 24 (0x0000_0018) for a 64-bit cache line
- 16 (0x0000_0010) for a 128-bit cache line
- 0 (0x0000_0000) for a 256-bit cache line

The read data is returned to the memory subsystem in the order provided by the SPI memory. There can be considerable delay for the expected data provided to the master.

To minimize this delay, the wrap feature can be used where the memory subsystem provides the address of the critical word.

- For MDMA reads, the number of read data bytes (N) is always equal to 4 bytes. The MDMA read does not depend on the cache setting. For MDMA reads, limit the `DMA_CFG.MSIZE` field to 1, 2 or 4 bytes. The address provided by the memory subsystem master to the SPI hardware is always 4 byte-aligned.

Memory-Mapped High-Performance Features

In addition to automating the SPI memory read accesses, the memory-mapped hardware also provides some features to improve SPI memory fetches and increase the system performance. The following sections describe these features.

Merged Read Accesses

It is common for the memory subsystem to fetch two or more cache lines from consecutive addresses (the address sequencing is linear without any jumps). To take advantage of this situation, the SPI memory-mapped hardware provides a feature called merging. Enable merging by setting the `SPI_MMRDH.MERGE` bit.

When enabled, the hardware compares the address of an incoming read request to the address of a request the SPI memory is actively servicing. It can decide to merge two accesses when the address for the second access is incremental. For example, if the first address of a 32-byte cache line fetch is 0x0000_0000 and the second fetch is to address 0x0000_0020, then these two accesses can be merged. Merging increases efficiency and overall fetch bandwidth by eliminating the read header for those accesses which only require continuation of the SPI clock.

Wrap Around Accesses

Many SPI flash memory devices support wrapping which is used to enhance critical word fetching of cache lines. In this mode, the SPI device automatically wraps the read address to the base of a cache line once the end of the cache line is reached.

Wrap around accesses are enabled by setting the SPI_MMRDH.WRAP bit.

Some flash devices require programs to send a ***Set Wrap*** command to place the device in wrap mode. Other flash devices provide a configuration register which must be programmed to set the flash in wrap mode. Since the SPI memory-mapped hardware does not support any write operations to flash, perform this step in non-memory-mapped mode (SPI_CTL.MMSE=0) by accessing the SPI registers.

Data access is limited to 8-byte, 16-byte, or 32-byte sections of flash page in wrap mode. The Arm core uses the Wrap 4 access (64-bit data) for L1 cache. The Arm core uses Wrap 4 and Wrap 8 accesses (64-bit data) for L2 cache. The cores use the Wrap 8 accesses for unaligned accesses. During the read request to the SPI memory-mapped hardware, the memory subsystem master of the processor provides the address of a critical word instead of the line base. The read-data starts at the address specified in the instruction. Once it reaches the end boundary of the 8, 16, or 32-byte section, the output automatically wraps around to the beginning boundary to the line base address. The data fetch continues. It is not necessary to deassert the SPI SPI_SEL[n] signal or resend the read header to wrap to the cache line base when servicing misaligned cache fill requests.

The ***Byte Sequence in Wrap Modes*** table shows byte sequences in various wrap modes.

Table 20-9: Byte Sequence in Wrap Modes

Starting Address	8-Byte Wrap (cache_line = 8 byte)
0	0-1-2- . . . -6-7
1	1-2- 3-. . . -7-0
7	7-0-1- . . . -5-6
15	15-8-9- . . . -13-14
31	31-24-25-. . . .-29-30

The burst with wrap feature allows applications to fetch a critical address quickly. Applications then fill the cache afterwards within a fixed length (8/16/32-byte) of data without issuing multiple read commands. Certain applications can benefit from this feature to improve cache fill efficiency and overall performance of system code execution.

NOTE: Do not use the merge and wrap feature together. Using wrap bursts can unintentionally disable merging (merging cannot occur for unaligned wrapping bursts). A wrap burst can start fetching data words in the middle of the cache line and cannot be merged with the next access.

Execute-In-Place (XIP, SPI2 only)

Execute-In-Place, most commonly known as XIP, allows software code to execute directly from an SPI flash device rather than downloading the code and executing it out of RAM. XIP, also known as Command Skip mode, is a general term and can be applied to fetching data as well.

There is a difference between XIP mode and standard mode. In XIP mode, after the SPI memory device is selected (CS# =LOW), the memory device does not decode the first input byte as command code. Instead, it expects the read header to directly start with address bytes. In standard mode, the memory decodes the first input byte it receives as a command code.

The XIP mode dramatically reduces random access time for applications that require fast code execution without shadowing the memory content on a RAM. The SPI memory-mapped hardware provides a control bit, SPI_MMRDH.CMDSKIP to skip the command from read header.

Some SPI memory devices require configuration of their control register to enable the XIP mode of operation, using the non-memory-mapped mode of the processor SPI. Typically, during the dummy cycle period, the mode bits are used to confirm the XIP operation and the SPI_MMRDH.MODE field must be set appropriately. A dummy memory-mapped access may be needed before setting the SPI_MMRDH.CMDSKIP bit in order to set the SPI memory device in Command Skip mode.

For more details about how to configure SPI memories into XIP mode, refer to the device data sheet.

NOTE: When configuring the flash to XIP mode from the SHARC+ core, ensure that the routine that configures flash to XIP is not routed through the L2CC. This is accomplished by first configuring the flash to XIP mode, then enabling the L2CC from the core.

Memory-Mapped Mode Error Status Bits

The SPI memory-mapped hardware provides bits in the SPI_STAT register to report errors. It provides these bits for notification only and their state has no effect on SPI operations. The status register bits are sticky. A W1C (write-1-to-clear) operation clears the bits.

- Memory-Mapped Write Error (SPI_STAT.MMWE). This bit is set (=1) if an attempt is made to write to address space that is reserved for memory-mapped SPI memory. The SPI memory-mapped hardware does not support automated write access to SPI memory space.
- Memory-Mapped Read Error (SPI_STAT.MMRE). This bit is set (=1) if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (SPI_CTL.MMSE =0).
- Memory-Mapped Access Error (SPI_STAT.MMAE). This bit is set (=1) if an attempt is made to access either the TX or RX FIFO while memory-mapped access of SPI memory is enabled. In this case, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric reports an error. Legacy methods include any direct access made to the TX and RX FIFOs, whether by DMA or processor MMR.
- Memory-Mapped Write Error Mask (SPI_CTL.MMWEM) bit specifies whether an error response is returned to the fabric on write attempts to address space that is reserved for memory-mapped SPI memory reads. Regardless of whether a write error response is masked using this bit, the memory-mapped write error (SPI_STAT.MMWE) sticky notification bit is still set.

  NOTE: Unlike other bits in the SPI_STAT register, these memory-mapped mode error bits do not have associated bits in the SPI interrupt mask (SPI_IMSK) and SPI interrupt condition (SPI_ILAT) registers.

The memory-mapped top register (SPI_MMTOP) is used to specify the upper limit of the SPI memory address. The memory-mapped accesses to SPI memory addresses equal to or above this range are considered illegal. The accesses are blocked and a bus error response is generated.

This register is useful to block the invalid SPI memory address accesses. Some SPI memory vendors do not clearly specify (guarantee) that overrange address bits are ignored (address spaces can be wrapped).

Memory-Mapped Programming Guidelines

Setting the SPI_CTL.MMSE bit enables SPI memory-mapped mode. When enabled, the SPI interface is forced to be consistent with SPI memory requirements regardless the settings of certain control bits. The following tables specify typical settings for configuring the SPI in memory-mapped mode:

Table 20-10: SPI Control (SPI_CTL) Register

Bits	Typical values to set	Description	Comments
SPI_CTL.MSTR	1	Master mode enable	
SPI_CTL.PSSE	0	Protected slave select enable	
SPI_CTL.ODM	0	Open-drain mode enable	
SPI_CTL.CPHASPI_CTL.CPOL	0–0 or 1–1	SPI mode of communication	Flash dependent, usually SPI flash supports mode-0 (CPHA=CPOL=0) and mode-3 (CPHA=CPOL=1)
SPI_CTL.ASSEL	1	Hardware slave select pin control	
SPI_CTL.SELST	1	Slave select asserted between transfers	
SPI_CTL.EMISO	1	MISO pin enable	
SPI_CTL.SIZE	2	32-bit transfer size	
SPI_CTL.LSBF	0	MSB bit first mode	Flash dependent, usually SPI flash communicates in MSB bit first mode
SPI_CTL.FCEN SPI_CTL.FCCH SPI_CTL.FCPL SPI_CTL.FCWM	0	Hardware flow control related bits	
SPI_CTL.FMODE	1	Fast mode enable	Typically set to 1 for full cycle timing, 0 only works at low speed
SPI_CTL.SOSI	0	Treat SPI_MOSI pin as IO0 pin.	

Table 20-11: SPI Receive Control Register

Bits	Typical values to set	Description
SPI_RXCTL.REN	1	Receive channel enable
SPI_RXCTL.RTI	0	Receive transfer initiation disable
SPI_RXCTL.RWCEN	0	Receive word counter disable

Table 20-11: SPI Receive Control Register (Continued)

Bits	Typical values to set	Description
SPI_RXCTL.RDR	0	Receive data request disable
SPI_RXCTL.RDO	0	Discard incoming data if RFIFO is full
SPI_RXCTL.RRWM	0	Receive FIFO regular watermark
SPI_RXCTL.RUWM	0	Receive FIFO urgent watermark disable

Table 20-12: SPI Transmit Control Register

Bits	Typical values to set	Description
SPI_TXCTL.TEN	1	Transmit channel enable
SPI_TXCTL.TTI	1	Transmit transfer initiation disable
SPI_TXCTL.TWCEN	0	Transmit word counter disable
SPI_TXCTL.TDR	0	Transmit data request disable
SPI_TXCTL.TDU	0	Send last word when TFIFO is empty
SPI_TXCTL.TRWM	0	Transmit FIFO regular watermark
SPI_TXCTL.TUWM	0	Transmit FIFO urgent watermark disable

Table 20-13: SPI DLY Control Register

Bits	Typical values to set	Description	Comments See Flash data sheet for CS (for example. SSEL) timing specs
SPI_DLY.LAGX	1	Extended lag timing	
SPI_DLY.LEADX	1	Extended lead timing	
SPI_DLY.STOP	3	Stop bit between the transfers	Can be set to 1 at lower SPI clock frequencies.

The multiple I/O mode (SPI_CTL.MIOM) bits are partially ignored:

- The command (opcode) is transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.CMDPINS bit setting.
- The address is then transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.ADRPINS bit setting.
- The data is always read with the number of pins specified by the SPI_CTL.MIOM bits.

NOTE: Set the SPI module enable bits SPI_CTL.EN last after configuring all registers.

Use the following programming guidelines for memory-mapped mode:

- The SPI memory-mapped hardware does not check the flash status before initiating the access. It assumes that SPI memory is always able to respond to a read access. Befor enabling memory-mapped mode (for example, setting the `SPI_CTL.MMSE` bit) ensure that SPI flash is ready for a read access. When using non-memory-mapped mode, a write-complete status can be examined prior to enabling the SPI in memory-mapped mode. (See the write in progress bit in the SPI flash memory status register.) Also, immediately after initial power-up, SPI memory devices can be inaccessible for a vendor-specified period.
- When SPI is enabled in memory-mapped mode, attempts to communicate with the SPI device using legacy methods are blocked. Legacy methods include any direct access made to the transmit or receive FIFOs, whether initiated by DMA or by a processor MMR access.
- To use some of the features offered by SPI memory devices, programs can first configure the SPI memory device by setting its control word or sending some commands. Since SPI memory-mapped hardware does not allow any type of SPI write operations, configure the SPI in non-memory-mapped mode prior to enabling memory-mapped mode.
- The memory-mapped hardware does not interpret the opcode. It does not check the validity of the timing that is specified in the `SPI_MMRDH` register for a particular opcode. Programs must set the fields of the `SPI_MMRDH` register to be consistent with the read-type selected.
- When the core requests the data or code fetch, the memory-mapped transfer depends on cache settings. The cache configuration register in the SPI memory device must be appropriately configured before enabling memory-mapped mode. Some of the high performance modes like merge, wrap, and transfer size depend on cache parameters.
- SPI memory-mapped MDMA reads do not support wrapping. For MDMA reads, limit the `DMA_CFG.MSIZE` field to 1 byte, 2 bytes or 4 bytes.
- There is not always tool support to change the SPI memory-mapped hardware setting or cache settings on-the-fly. Changing these settings can optimize the performance of code that accesses SPI memory in memory-mapped mode. It is expected that the SPI memory, SPI peripheral, and cache are programmed to one specific set of control settings for the whole application. Profiling or benchmarking of the actual application can be done to find the setting that works best.

SPI Interrupt Signals

The SPI controller supports three types of interrupt request signals that correspond to data, status, and error conditions.

Data Interrupts

The SPI peripheral supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the peripheral interfaces with separate read and write interfaces with DMA, the read and write data interrupts are independent. When the DMA channels are not used, the interrupts are routed directly to the system event controller. The interrupts occupy the same vector locations as the corresponding DMA channels.

Each of the data interrupt requests can be individually controlled. Program the SPI_RXCTL.RDR and SPI_TXCTL.TDR bit fields for receive and transmit, respectively. When receive is enabled, the RX interrupt request is issued whenever there is data available in the receive datapath for reading. (The event occurs according to the SPI_RXCTL.RDR bit setting.) When transmit is enabled, the TX interrupt request is issued whenever the transmit datapath can be written. (The event occurs according to the SPI_TXCTL.TDR setting.) DMA data interrupts are compatible with second-generation DMA to incorporate urgent data requests and transfer finish interrupt requests apart from the usual data request interrupts. Transmit interrupt requests operate independently from the word counter-value in the SPI_TWC register.

Status Interrupts

The SPI controller supports several status interrupt requests to indicate different conditions of the receiver and transmitter. All status interrupt requests can be masked. Status interrupt requests are signaled directly through a single SPI status IRQ line. The line cannot be combined with the SPI error IRQ line for some processors. The ***SPI Status Interrupts*** table describes the status interrupt requests that are available for the SPI controller.

Table 20-14: SPI Status Interrupts

SPI_STAT Bit	Description
SPI_STAT.RUWM	Receive FIFO urgent watermark interrupt request. Issued when the level of the RFIFO breaches the watermark set in the SPI_RXCTL.RUWM field. It is cleared when the level of the RFIFO reaches the watermark set in the SPI_RXCTL.RRWM field. If the RX channel is configured in DMA mode, SPI_RXCTL.RUWM is multiplexed with the data request.
SPI_STAT.TUWM	Transmit FIFO urgent watermark interrupt request. Issued when the level of the TFIFO breaches the watermark set using the SPI_TXCTL.TUWM bit. It is cleared when the level of the TFIFO reaches the watermark set in the SPI_TXCTL.TRWM field. If the TX channel is configured in DMA mode, SPI_STAT.TUWM is multiplexed with the data request.
SPI_STAT.TS	Transmit start interrupt request. Issued when the start of a transmit burst is detected by loading of the SPI_TWC register with the contents of the SPI_TWCR register.
SPI_STAT.RS	Receive start interrupt request. Issued when the start of a receive burst is detected by the loading of SPI_RWC with the contents of SPI_RWCR.
SPI_STAT.TF	Transmit finish interrupt request. Issued when a transmit burst completes (SPI_TWC decrements to zero).
SPI_STAT.RF	Receive finish interrupt request. Issued when a receive burst completes (SPI_RWC decrements to zero).

Error Conditions

The SPI controller supports interrupt requests upon several different error conditions. All interrupt requests are maskable. The individual error indications combine into a single SPI error IRQ signal, which can be multiplexed on some processors with the aggregated SPI status IRQ signal. The ***SPI Error Interrupts*** table details the possible error indications.

Error conditions arise depending on which of the channels (transmit or receive) are enabled. If a channel is disabled, all errors related to it are ignored. When both channels are enabled, errors from both channels are enabled.

Table 20-15: SPI Error Interrupts

Bit	Description
SPI_STAT.MF	Mode fault. Signaled when another device also tries to be a master in a multi-master system and drives the SPI_SS input low. This error is signaled in master mode operation.
SPI_STAT.TUR	Transmission error. Signaled when an underflow condition occurs on the transmit channel. This event occurs when a new transfer starts but SPI_TFIFO is empty. This error does not occur in master transmit initiating mode since SPI_TFIFO *Not Empty* is one of the conditions for transfer initiation.
SPI_STAT.ROR	Reception error. Signaled when an overflow condition occurs on the receive channel. This event occurs when a new data word is received, but the SPI_RFIFO is full. This error condition does not occur in master receive initiating mode since SPI_RFIFO *Not Full* is one of the conditions for transfer initiation.
SPI_STAT.TC	Transmit collision error. Signaled when loading data to the transmit shift register happens near the first transmitting edge of SPI_CLK. In slave mode of operation, the SPI controller is unaware of when the next transfer starts. Loading of data to the transmit shift register can happen just after the transmitting edge. This event results in the setup time not being met for the first bit transmitted. The transmitted data is corrupt. In SPI_CTL.CPHA 1 mode, the first SPI_CLK edge is taken as the first transmitting edge. If SPI_CTL.CPHA =0, then the last SPI_CLK edge of the last transmission (SPI_CTL.SELST =1) or slave select deassertion (SPI_CTL.SELST =0) is taken as the first transmitting edge. This error is signaled only in the slave mode of operation. In master mode of operation, loading of data happens before the first transmitting edge of SPI_CLK.

SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

Programming Guidelines

It is acceptable to program SPI_RXCTL and SPI_TXCTL registers after programming the SPI_CTL register. However, program the initiating mode register and its counter-register, if enabled, after the non-initiating mode register. For example, if transmit is the initiating mode and receive is the non-initiating mode, then program the SPI_RXCTL and SPI_RWC registers before the SPI_TXCTL and SPI_TWC registers. If enabling both transmit and receive in initiating mode, enable the SPI_CTL register after programming both the SPI_RXCTL and SPI_TXCTL registers.

These programming guidelines prevent SPI from starting a transfer when SPI registers are not fully programmed. Other ways of programming are also allowed as long as the initiating conditions prevent the start of communication until after programming of SPI registers is complete.

Avoid data corruption when changing the SPI module configuration. Do not change the configuration during a data transfer. Additionally, change the clock polarity only when no slave is selected. However, an exception to this rule exists. When an SPI communication link consists of a single master and slave, SPI_CTL.ASSEL = 0. The slave select input of the slave is permanently tied low. In this case, the slave is always selected. Avoid data corruption by enabling the slave only after both the master and slave devices are configured.

The module supports 8, 16-bit and 32-bit word sizes. To ensure correct operation, configure both the master and slave with the same word size.

Master Operation in Non-DMA Modes

This section describes the operation of the SPI as a master in non-DMA mode.

1. Write to the SPI_SLVSEL register, setting one or more of the SPI select enable bits. This operation ensures that the desired slaves are properly deselected while the master is configured.
2. The SPI_RXCTL.RTI and SPI_TXCTL.TTI bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the SPI_CLK, SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. This operation enables the device as a master and configures the SPI system. It specifies the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

   ADDITIONAL INFORMATION: If SPI_RXCTL.RTI is enabled and SPI_TXCTL.TTI is not, write to the SPI_RXCTL register after writing into SPI_CTL, SPI_TXCTL, and SPI_TFIFO registers to prevent a transmit underrun for the first transfer.
4. If SPI_CTL.ASSEL=0, activate the desired slaves by clearing one or more of the SPI_SLVSEL flag bits. Otherwise, the SPI hardware performs slave activation.
5. The SPI controller then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. Before a shift, the shift register is loaded with the contents of the SPI_TFIFO register. At the end of the transfer, the contents of the shift register are loaded into SPI_RFIFO.
6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows usage of available channel resources for receives or transmits simultaneously with the initiating channel.

Slave Operation in Non-DMA Modes

When a device is enabled as a slave in a non-DMA mode, a transition of the $\overline{\text{SPI\_SS}}$ select signal to the active state (low) triggers the the start of a transfer. Or, the first active edge of SPI_CLK triggers the start, depending on the state of SPI_CTL.CPHA bit. The interface operates in the following manner.

1. The core writes to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. The operation defines the mode of the serial link to be the same as the mode setup in the SPI master.
2. To prepare for the data transfer, the core writes data to be transmitted into SPI_TFIFO.
3. Once the $\overline{\text{SPI\_SS}}$ falling edge is detected, the slave starts sending data on active SPI_CLK edges and sampling data on inactive SPI_CLK edges.
4. Reception or transmission continues until $\overline{\text{SPI\_SS}}$ is released or until the slave has received the proper number of clock cycles.

5. The slave device continues to receive or transmit with each new falling edge transition on SPI_SS or active SPI_CLK edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.

Configuring DMA Master Mode

The SPI interface supports a write DMA channel and a read DMA channel. It can use these functions individually or in a lock-step manner in duplex mode (SPI_TXCTL.TTI= SPI_RXCTL.RTI=1).

1. Write to the appropriate DMA registers to enable the SPI DMA channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_SLVSEL register, setting one or more of the SPI flag select bits.
3. Write to the SPI_CLK and SPI_CTL registers, enabling the device as a master and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, and so forth.
4. Write to SPI_RXCTL to configure SPI master receive mode, or write to SPI_TXCTL to configure SPI master transmit mode.
5. Finally, write to the SPI_RXCTL.REN bit to enable the receive channel, or write to SPI_TXCTL.TEN to enable the transmit channel.
6. If the SPI_RXCTL.RTI bit is enabled, a receive transfer is initiated upon enabling SPI_CTL.EN bit. If the receive word counter is enabled (SPI_RXCTL.RWCEN), then the SPI_RWC register must be non-zero for a transfer to initiate.

   ADDITIONAL INFORMATION: If enabling both receive and transmit DMA channels, but not enabling SPI_TXCTL.TTI, write to the SPI_RXCTL register after writing the SPI_CTL and SPI_TXCTL registers. In this way, a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the receive shift register and writes to the SPI receive FIFO. The SPI then requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the SPI receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, when SPI_RWC does not become zero while SPI_RXCTL.RWCEN=1.
7. If SPI_TXCTL.TTI is enabled, the SPI controller requests DMA reads from memory as long as there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the SPI_TWC register is non-zero when SPI_TXCTL.TWCEN=1, the SPI continues to initiate transfers until disabled.
8. If both the SPI_TXCTL.TTI and SPI_RXCTL.RTI bits are enabled, the SPI controller requests a DMA read from memory. However, there must be space for more data in the transmit pipe and the number of words written into the SPI must be less than SPI_TWC if SPI_TXCTL.TWCEN=1. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

   ADDITIONAL INFORMATION: As the SPI writes data from the transmit FIFO into the transmit shift register, it initiates a transfer on the SPI link. Data received from the transfer is moved from the SPI receive shift register to the receive FIFO. The SPI controller requests a write from DMA to memory. Upon a DMA grant,

the DMA engine reads a word from the receive FIFO and writes to memory. Transfer continues to be initiated as long as both receives and transmits can accommodate new data.

9. If the receive pipe fills up due to unavailability of DMA grants, the transmit pipe stalls until the pipe is drained. If the transmit pipe fills up, the SPI stops requesting for DMA writes. If the value in SPI_RWC expires, further write-requests to DMA stop. However, data already written into the transmit FIFO is sent, and read requests to DMA continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. For receive transfers, the value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer. For transmit transfers, the value in the SPI_TFIFO register is loaded into the shift register at the start of the transfer.

Configuring DMA Slave Mode Operation

This mode occurs when the SPI is enabled as a slave and the DMA engine is configured to transmit or receive data. A transition of the SPI_SS signal to the active-low state triggers the start of a transfer. Or, the first active edge of SPI_CLK triggers the start of a transfer, depending on the state of the SPI_CTL.CPHA bit. The following steps illustrate the SPI receive or transmit DMA sequence in an SPI slave (in response to a master command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers to define the mode of the serial link to be the same as the mode configured in the SPI master.
3. If the receive channel is enabled (SPI_RXCTL.REN is asserted), the following actions occur:
    a. Once the slave select input is active, the slave starts receiving and transmitting data on active SPI_CLK edges.
    b. The value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer.
    c. Once SPI_RFIFO has valid data, it requests a write from DMA to memory.
    d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
    e. As long as there is data in the receive FIFO, the SPI slave continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory. The SPI slave continues receiving words on active SPI_CLK edges as long as the SPI_SS input is active.
    f. If the data collected in the receive pipe breaches the set level, and the DMA engine cannot keep up with the receive rate, the slave can deassert the SPI_RDY signal. This signaling throttles the master. The receive pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the SPI can use the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten into the receive FIFO (when SPI_CTL.FCEN is inactive).
4. If the transmit channel is enabled (SPI_TXCTL.TEN is asserted), the following actions occur:

a. The SPI requests a DMA read from memory.

b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.

d. Once the slave select input is active, the slave starts receiving and transmitting data on active SPI_CLK edges.

e. As long as there is room in the transmit FIFO, the SPI slave continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO. The SPI slave continues transmitting words on active SPI_CLK edges as long as the SPI_SS input is active.

f. If the number of outstanding data entries in the transmit pipe breaches the level set and the DMA cannot keep up with the transmit rate, the slave deasserts the SPI_RDY signal. This signaling throttles the master. The transmit pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA fills the transmit FIFO. Alternately, the SPI_TXCTL.TDU bit decides the state of the transmit data (when SPI_CTL.FCEN is deasserted).

5. If both receive and transmit channels are enabled, the following actions occur after the actions for each channel. Transfers continue as long as both receive and transmit channels can accommodate new data.

a. If the receive pipe fills up due to the unavailability of DMA grant, the SPI interface stalls the master by asserting the SPI_RDY pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI uses the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten in the receive FIFO (when SPI_CTL.FCEN is deasserted).

b. If the transmit pipe fills up, the SPI stops requesting DMA writes until the pipe clears.

c. If there is an underflow problem in the transmit pipe, the slave stalls the master by deasserting SPI_RDY while the DMA fills the transmit FIFO. Alternately, the SPI uses the SPI_TXCTL.TDU bit to decide the state of the transmit data (when SPI_CTL.FCEN is deasserted).

ADSP-2159x_SC591_SC592_SC594 SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

Table 20-16: ADSP-2159x_SC591_SC592_SC594 SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register

Table 20-16: ADSP-2159x_SC591_SC592_SC594 SPI Register List (Continued)

Name	Description
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header
SPI_MMTOP	SPI Memory Top Address
SPI_RFIFO	Receive FIFO Data Register
SPI_RWC	Received Word Count Register
SPI_RWCR	Received Word Count Reload Register
SPI_RXCTL	Receive Control Register
SPI_SLVSEL	Slave Select Register
SPI_STAT	Status Register
SPI_TFIFO	Transmit FIFO Data Register
SPI_TWC	Transmitted Word Count Register
SPI_TWCR	Transmitted Word Count Reload Register
SPI_TXCTL	Transmit Control Register

Clock Rate Register

The SPI_CLK register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SPI clock) and the system clock (CLKO6).

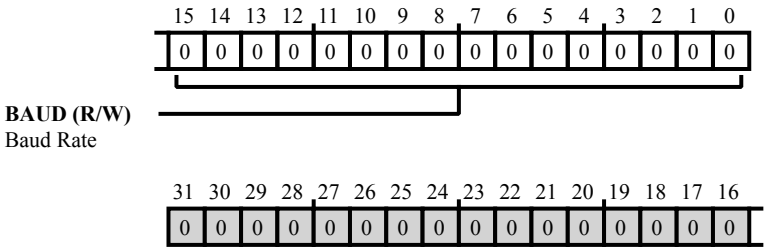

Figure 20-20: SPI_CLK Register Diagram

Table 20-17: SPI_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	BAUD	Baud Rate. The SPI_CLK.BAUD bits set the SPI baud rate according to the formula: BAUD = (CLKO6 / SPI Clock) - 1

Control Register

The SPI_CTL register enables the SPI and configures settings for operating modes, communication protocols, and buffer operations.

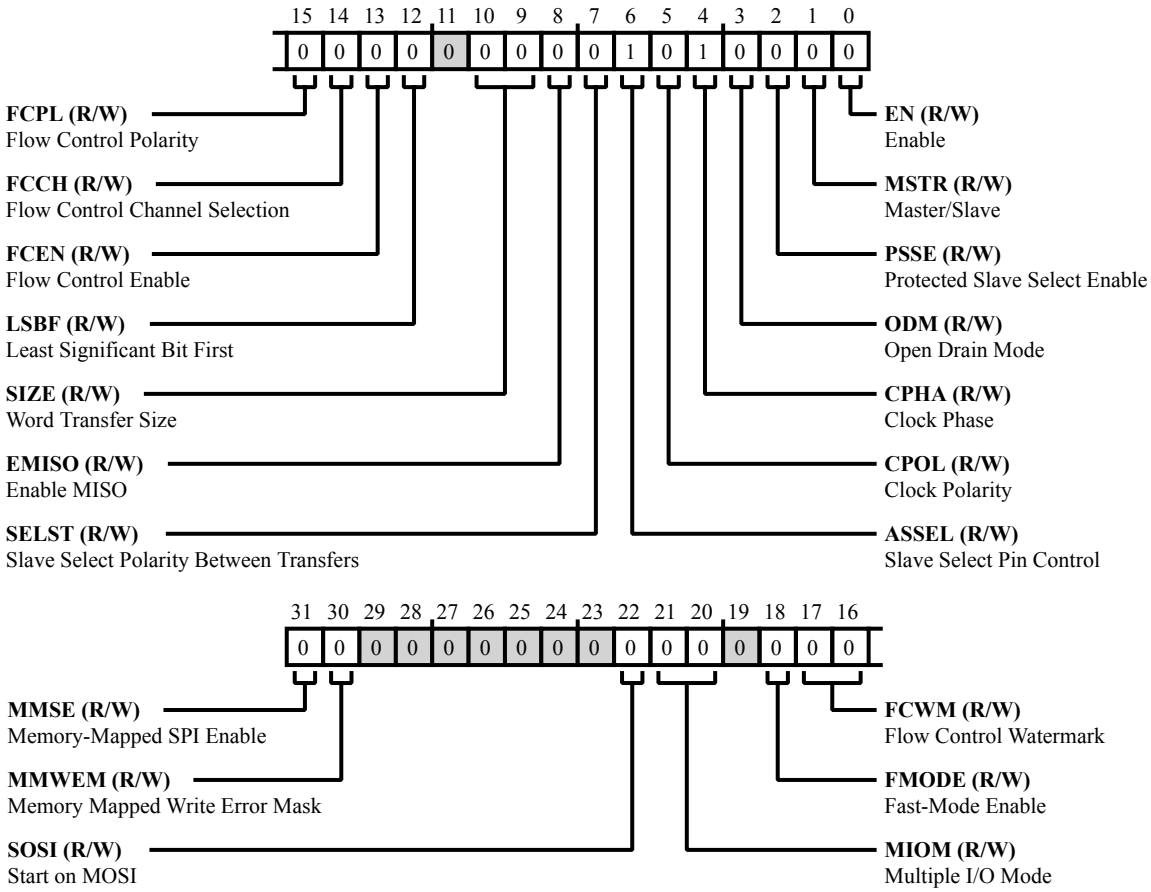

Figure 20-21: SPI_CTL Register Diagram

Table 20-18: SPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MMSE	Memory-Mapped SPI Enable. When the SPI_CTL.MMSE bit is asserted, communication to an SPI memory device is automated such that the memory it contains is accessible directly through the read of processor address space assigned to it. (As far as the SPI peripheral is concerned, this includes all read accesses received by the SPI peripherals system crossbar slave port.) Note that when memory-mapped access of SPI memory is enabled, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses are generated. Legacy methods include any direct access made to the Tx and Rx FIFOs, whether initiated by DMA or processor MMR access.	
		0	Hardware automated access of memory-mapped SPI memory disabled.
		1	Hardware-automated access of memory-mapped SPI memory enabled.
30 (R/W)	MMWEM	Memory Mapped Write Error Mask. The SPI_CTL.MMWEM bit specifies whether an error response is returned to the fabric upon write attempts to address space reserved for memory-mapped reads of SPI memory.	
		0	Write error response returned upon write attempts to memory-mapped SPI memory
		1	Write error response masked (not returned) upon write attempts to memory-mapped SPI memory
22 (R/W)	SOSI	Start on MOSI. The SPI_CTL.SOSI bit is valid only when SPI_CTL.MIOM is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes. In DIOM, by default, (SPI_CTL.SOSI =0) SPI sends the first bit on the SPI_MISO pin and the second bit on the SPI_MOSI pin. In QIOM, by default, the SPI sends the first bit on the SPI_D3 pin, the second bit on the SPI_D2 pin, the third bit on the SPI_MISO pin and the fourth bit on the SPI_MOSI pin. This order can be reversed by setting the SPI_CTL.SOSI bit. When this bit is set, the SPI sends the first bit on the SPI_MOSI pin. The first bit referred to here depends on the SPI_CTL.LSBF bit setting (MSB bit or LSB bit).	
		0	Start on MISO (DIOM) or start on SPI_D3
		1	Start on MOSI

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	MIOM	Multiple I/O Mode. The SPI_CTL.MIOM bits enable SPI operation in dual I/O mode (DIOM) or quad I/O mode (QIOM). These bits can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	No MIOM (disabled)
		1	DIOM operation
		2	QIOM operation
		3	Reserved
18 (R/W)	FMODE	Fast-Mode Enable. The SPI_CTL.FMODE bit enables fast mode operation for SPI receive transfers. SPI transmit operations in fast mode are the same as normal mode.	
		0	Disable
		1	Enable
17:16 (R/W)	FCWM	Flow Control Watermark. The SPI_CTL.FCWM bits select the watermark level of the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer) that triggers flow control operation. These bits are applicable only when the SPI is a slave (SPI_CTL.MSTR = 0) and flow control is enabled (SPI_CTL.FCEN =1). When the watermark condition is met, the SPI slave deasserts the SPI_RDY pin.	
		0	TFIFO empty or RFIFO full
		1	TFIFO 75% or more empty, or RFIFO 75% or more full
		2	TFIFO 50% or more empty, or RFIFO 50% or more full
		3	Reserved
15 (R/W)	FCPL	Flow Control Polarity. The SPI_CTL.FCPL bit selects flow control polarity for the SPI_RDY pin when flow control is enabled. When the SPI_RDY pin is active, the SPI is indicating it is ready for data transfer.	
		0	Active-low RDY
		1	Active-high RDY

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	FCCH	Flow Control Channel Selection. The SPI_CTL.FCCH bit selects whether the SPI applies flow control to the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer). This bit is applicable only when the SPI is a slave and flow control is enabled.	
		0	Flow control on RX buffer
		1	Flow control on TX buffer
13 (R/W)	FCEN	Flow Control Enable. The SPI_CTL.FCEN bit enables SPI flow control operation, which permits slow slave devices to interface with fast master devices. This bit controls the operation of the SPI_RDY pin. Note that options for flow control operation are available using the SPI_CTL.FCCH, SPI_CTL.FCPL, and SPI_CTL.FCWM bits.	
		0	Disable
		1	Enable
12 (R/W)	LSBF	Least Significant Bit First. The SPI_CTL.LSBF bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit can only be changed when the SPI is disabled.	
		0	MSB sent/received first (big endian)
		1	LSB sent/received first (little endian)
10:9 (R/W)	SIZE	Word Transfer Size. The SPI_CTL.SIZE bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the master and slave must be configured with the same word size. This bit can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	8-bit word
		1	16-bit word
		2	32-bit word
		3	Reserved
8 (R/W)	EMISO	Enable MISO. The SPI_CTL.EMISO bit enables master-in-slave-out (MISO) mode. This SPI mode is applicable only when the SPI is a slave.	
		0	Disable
		1	Enable

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SELST	Slave Select Polarity Between Transfers. The SPI_CTL.SELST bit selects the state (polarity) for the $\overline{\text{SPI\_SEL[n]}}$ pin between SPI transfers when the SPI is a master and hardware slave select assertion is enabled (SPI_CTL.ASSEL =1). In slave mode, this bit affects the detection of both transmit collision (SPI_STAT.TC and underrun (SPI_STAT.TUR) errors.	
		0	Deassert slave select (high)
		1	Assert slave select (low)
6 (R/W)	ASSEL	Slave Select Pin Control. The SPI_CTL.ASSEL bit selects whether the SPI hardware sets the $\overline{\text{SPI\_SEL[n]}}$ pin output value (ignoring the slave select SPI_SLVSEL.SSEL1 - SPI_SLVSEL.SSEL7 bits) or whether software control of the slave select bits set the $\overline{\text{SPI\_SEL[n]}}$ pin output value. This feature is applicable only when the SPI is a master. When hardware control is enabled, the $\overline{\text{SPI\_SEL[n]}}$ pin output is asserted during the transfers, and the pin polarity between transfers is selected by the SPI_CTL.SELST bit. When software control is enabled, the $\overline{\text{SPI\_SEL[n]}}$ pin output value is set through software control of the slave select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers.	
		0	Software slave select control
		1	Hardware slave select control
5 (R/W)	CPOL	Clock Polarity. The SPI_CTL.CPOL bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (SPI_CLK). This bit works with the SPI_CTL.CPHA bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	Active-high SPI CLK
		1	Active-low SPI CLK
4 (R/W)	CPHA	Clock Phase. The SPI_CTL.CPHA bit selects whether the SPI starts toggling the signal for the SPI clock (SPI_CLK) from the start of the first data bit or from the middle of the first data bit. The SPI_CTL.CPHA bit works with the SPI_CTL.CPOL bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	SPI CLK toggles from middle
		1	SPI CLK toggles from start

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ODM	Open Drain Mode. The SPI_CTL.ODM bit configures the data output pins (SPI_MOSI and SPI_MISO) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-master or multi-slave SPI systems. When SPI_CTL.ODM is enabled and the SPI is a master, the SPI three-states the SPI_MOSI pin when the data driven out on MOSI is a logic-high. The SPI does not three-state the SPI_MOSI pin when the driven data is a logic-low. When SPI_CTL.ODM is enabled and the SPI is a slave, the SPI three-states the SPI_MISO pin when the data driven out on SPI_MISO is a logic-high. Note that an external pull-up resistor is required on both the SPI_MOSI and SPI_MISO pins when SPI_CTL.ODM is enabled.	
		0	Disable
		1	Enable
2 (R/W)	PSSE	Protected Slave Select Enable. The SPI_CTL.PSSE bit enables the $\overline{\text{SPI\_SS}}$ pin to provide error detection input in a multi-master environment when the SPI is in master mode. If some other device in the system asserts the $\overline{\text{SPI\_SS}}$ pin while SPI is enabled as master (and SPI_CTL.PSSE is enabled), this condition causes a mode fault error.	
		0	Disable
		1	Enable
1 (R/W)	MSTR	Master/Slave. The SPI_CTL.MSTR bit toggles the SPI between master mode and slave mode. This bit can only be changed when the SPI is disabled.	
		0	Slave
		1	Master
0 (R/W)	EN	Enable. The SPI_CTL.EN bit enables SPI operation.	
		0	Disable SPI module
		1	Enable

Delay Register

The SPI_DLY register selects a transfer delay and the lead/lag timing between slave select signals and SPI clock edge assertion/deassertion.

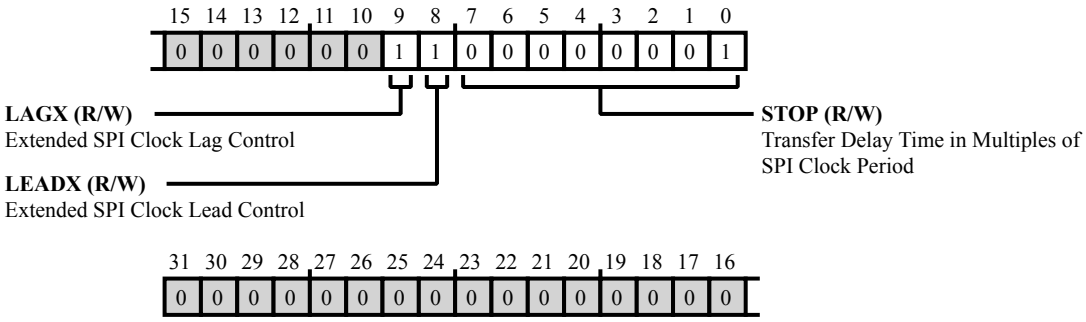

Figure 20-22: SPI_DLY Register Diagram

Table 20-19: SPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	LAGX	Extended SPI Clock Lag Control. The SPI_DLY.LAGX bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the slave select (SPI_SEL[n]) assertion and first SPI clock edge.	
		0	Disable
		1	Enable
8 (R/W)	LEADX	Extended SPI Clock Lead Control. The SPI_DLY.LEADX bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the slave select (SPI_SEL[n]) deassertion and last SPI clock edge.	
		0	Disable
		1	Enable
7:0 (R/W)	STOP	Transfer Delay Time in Multiples of SPI Clock Period. The SPI_DLY.STOP bits select a delay (number of stop bits in multiples of SPI clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The SPI_DLY.STOP bits can be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0).	

Masked Interrupt Condition Register

The SPI_ILAT register latches interrupts, queuing the interrupt requests for service. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in SPI_ILAT.

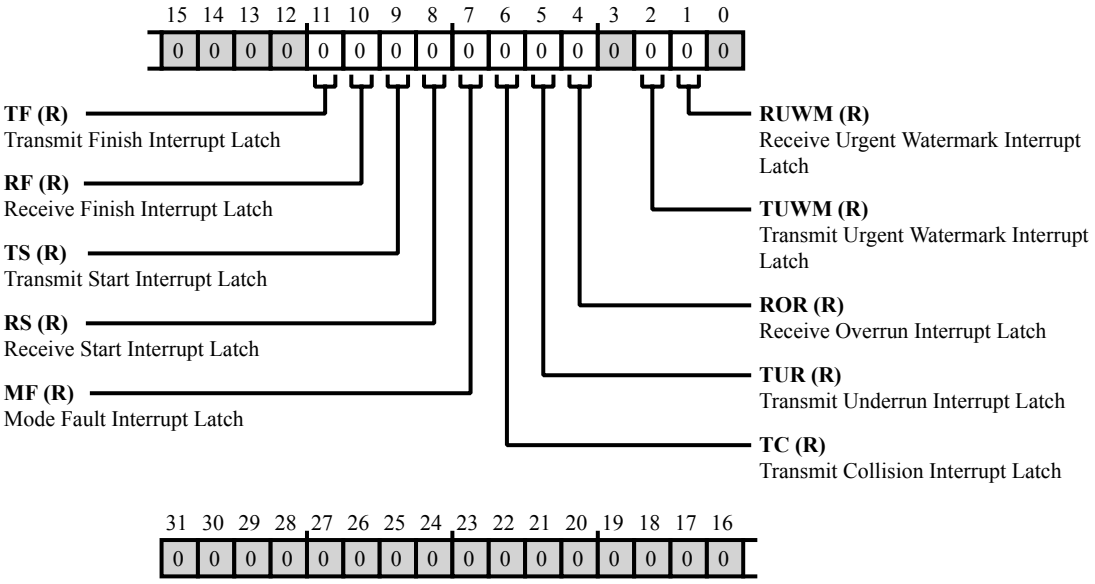

Figure 20-23: SPI_ILAT Register Diagram

Table 20-20: SPI_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
10 (R/NW)	RF	Receive Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
9 (R/NW)	TS	Transmit Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
8 (R/NW)	RS	Receive Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Table 20-20: SPI_ILAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	MF	Mode Fault Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
6 (R/NW)	TC	Transmit Collision Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
5 (R/NW)	TUR	Transmit Underrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
4 (R/NW)	ROR	Receive Overrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Masked Interrupt Clear Register

The SPI_ILAT_CLR register permits clearing individual mask bits in the SPI_ILAT register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_ILAT_CLR register to clear the corresponding bit in the SPI_ILAT register.

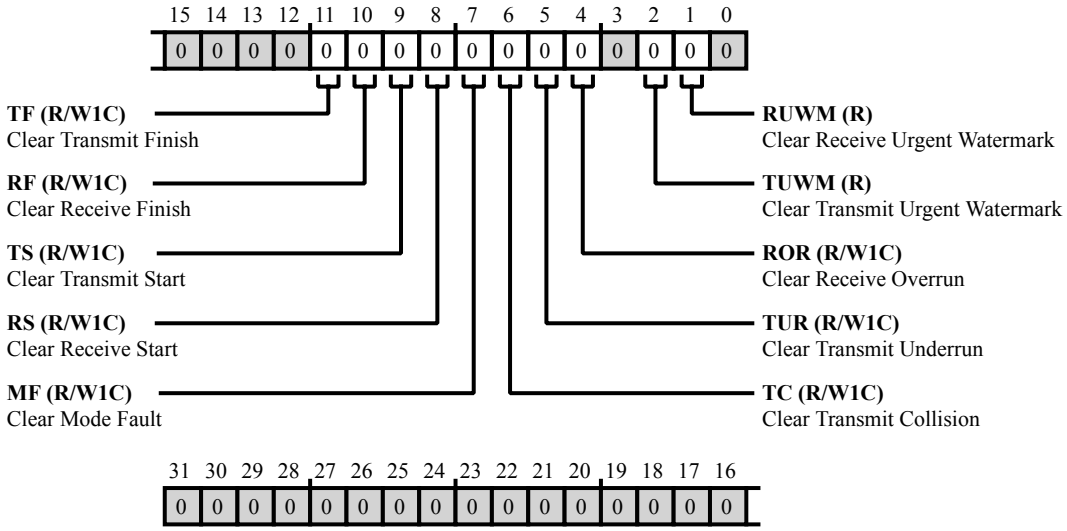

Figure 20-24: SPI_ILAT_CLR Register Diagram

Table 20-21: SPI_ILAT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_ILAT_CLR.TF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_ILAT_CLR.RF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_ILAT_CLR.TS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 20-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_ILAT_CLR.RS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_ILAT_CLR.MF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_ILAT_CLR.TC bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_ILAT_CLR.TUR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_ILAT_CLR.ROR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
2 (R/NW)	TUWM	Clear Transmit Urgent Watermark. The SPI_ILAT_CLR.TUWM bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 20-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	RUWM	Clear Receive Urgent Watermark. The `SPI_ILAT_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_ILAT` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Register

The SPI_IMSK register unmasks (enables) or masks (disables) SPI interrupt requests. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in the SPI_ILAT register, queuing the interrupt request for service.

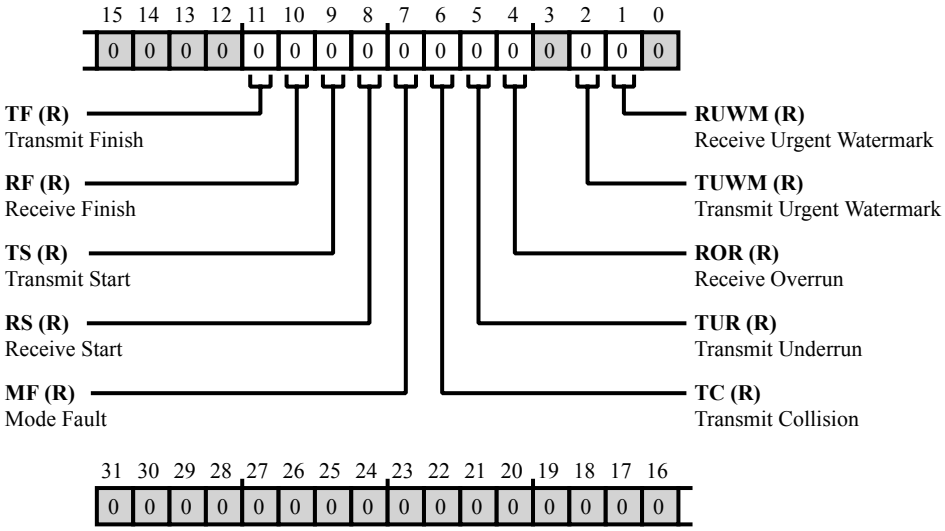

Figure 20-25: SPI_IMSK Register Diagram

Table 20-22: SPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish. The SPI_IMSK.TF bit unmasks (enables) or masks (disables) the TF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
10 (R/NW)	RF	Receive Finish. The SPI_IMSK.RF bit unmasks (enables) or masks (disables) the RF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
9 (R/NW)	TS	Transmit Start. The SPI_IMSK.TS bit unmasks (enables) or masks (disables) the TS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Table 20-22: SPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	RS	Receive Start. The SPI_IMSK.RS bit unmasks (enables) or masks (disables) the RS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
7 (R/NW)	MF	Mode Fault. The SPI_IMSK.MF bit unmasks (enables) or masks (disables) the MF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
6 (R/NW)	TC	Transmit Collision. The SPI_IMSK.TC bit unmasks (enables) or masks (disables) the TC interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
5 (R/NW)	TUR	Transmit Underrun. The SPI_IMSK.TUR bit unmasks (enables) or masks (disables) the TUR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
4 (R/NW)	ROR	Receive Overrun. The SPI_IMSK.ROR bit unmasks (enables) or masks (disables) the ROR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark. The SPI_IMSK.TUWM bit unmasks (enables) or masks (disables) the TUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark. The SPI_IMSK.RUWM bit unmasks (enables) or masks (disables) the RUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Interrupt Mask Clear Register

The SPI_IMSK_CLR register permits clearing individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_IMSK_CLR register to clear the corresponding bit in the SPI_IMSK register.

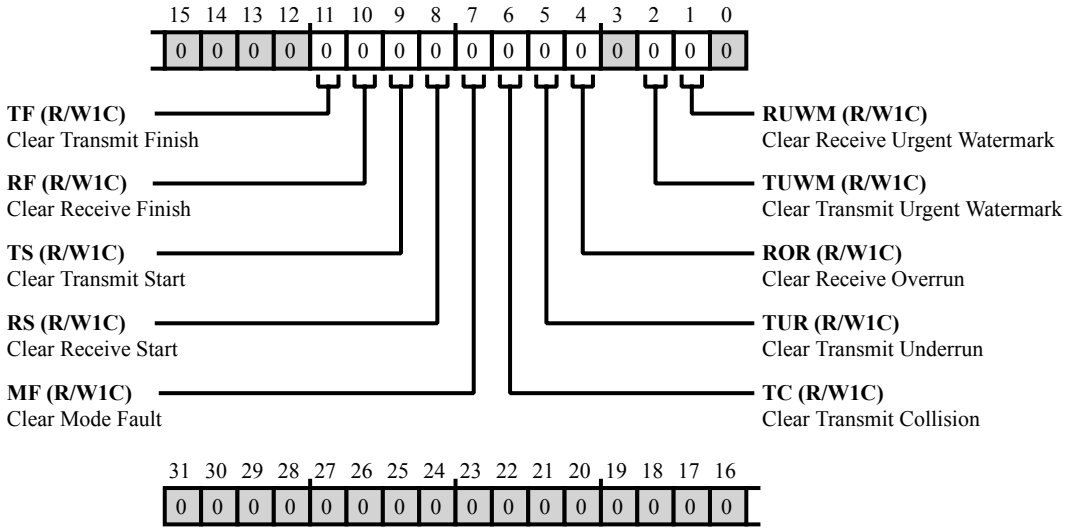

Figure 20-26: SPI_IMSK_CLR Register Diagram

Table 20-23: SPI_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_IMSK_CLR.TF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_IMSK_CLR.RF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_IMSK_CLR.TS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 20-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_IMSK_CLR.RS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_IMSK_CLR.MF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_IMSK_CLR.TC bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_IMSK_CLR.TUR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_IMSK_CLR.ROR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
2 (R/W1C)	TUWM	Clear Transmit Urgent Watermark. The SPI_IMSK_CLR.TUWM bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 20-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RUWM	Clear Receive Urgent Watermark. The `SPI_IMSK_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Set Register

The SPI_IMSK_SET register permits setting individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-set on a bit in the SPI_IMSK_SET register to set the corresponding bit in the SPI_IMSK register.

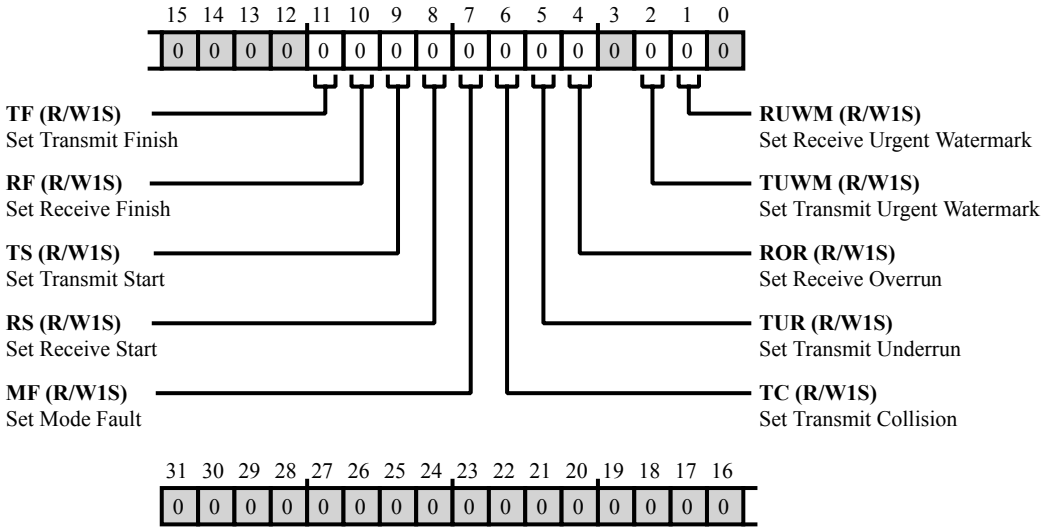

Figure 20-27: SPI_IMSK_SET Register Diagram

Table 20-24: SPI_IMSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1S)	TF	Set Transmit Finish. The SPI_IMSK_SET.TF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
10 (R/W1S)	RF	Set Receive Finish. The SPI_IMSK_SET.RF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
9 (R/W1S)	TS	Set Transmit Start. The SPI_IMSK_SET.TS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 20-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1S)	RS	Set Receive Start. The SPI_IMSK_SET.RS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
7 (R/W1S)	MF	Set Mode Fault. The SPI_IMSK_SET.MF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
6 (R/W1S)	TC	Set Transmit Collision. The SPI_IMSK_SET.TC bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
5 (R/W1S)	TUR	Set Transmit Underrun. The SPI_IMSK_SET.TUR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
4 (R/W1S)	ROR	Set Receive Overrun. The SPI_IMSK_SET.ROR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
2 (R/W1S)	TUWM	Set Transmit Urgent Watermark. The SPI_IMSK_SET.TUWM bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 20-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	RUWM	Set Receive Urgent Watermark. The `SPI_IMSK_SET.RUWM` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit

Memory Mapped Read Header

The SPI_MMRDH register enables the use of memory-mapped mode. This mode allows direct memory-mapped read accesses of an SPI memory device and is primarily used to directly execute instructions from an SPI FLASH memory without using a low-level software driver. All overhead tasks such as transmission of the read header, pin turnaround timing and receive data sizing are handled in hardware.

The memory-mapped access mode is enabled by setting the SPI_CTL.MMSE bit. The features within the SPI_MMRDH register include a command skip mode, variable length byte addressing, and independent multi-pin support for command transmission, address transmission and data reception. In addition, the command opcode and mode bytes are fully programmable.

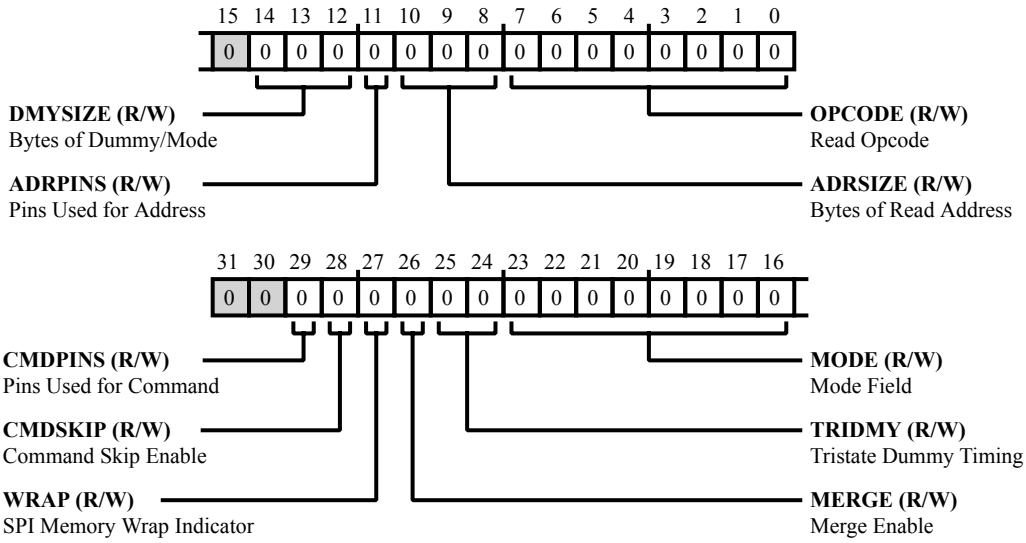

Figure 20-28: SPI_MMRDH Register Diagram

Table 20-25: SPI_MMRDH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CMDPINS	Pins Used for Command. The SPI_MMRDH.CMDPINS bit specifies the number of pins to be used for command transmission. This bit must be set consistent with the expectations established by the read opcode. Hardware does not interpret SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior. When cleared, it overrides the SPI_CTL.MIOM bits. When set, it uses bits specified by the SPI_CTL.MIOM bit setting.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMDSKIP	Command Skip Enable. The SPI_MMRDH.CMDSKIP bit enables command skip mode where the address is sent first and the OPCODE field is not sent (SPI_MMRDH.CMDSKIP bit =1). This mode is useful for supporting XIP (Execute-In-Place) operation where only the address is sent and the same read command is assumed. The SPI flash device must be primed with an initial read command, before the SPI_MMRDH.CMDSKIP bit is set.	
		0	OPCODE field is sent first followed by address
		1	OPCODE field is not sent; address is sent first
27 (R/W)	WRAP	SPI Memory Wrap Indicator. The SPI_MMRDH.WRAP bit must be set by software if software places a connected SPI memory device into a 8-byte, 16-byte or 32-byte wrap mode based on the ILINE and DLINE field setting of the cache configuration register address wrap mode. Software achieves this by transmitting a vendor specified command to the SPI memory device while the SPI_CTL.MMSE bit =0. If the SPI_MMRDH.WRAP bit =1, the SPI does not need to deassert the SPI slave select signal and resend the read header in order to wrap to the cache line base when servicing misaligned cache fill requests. Although this improves cache fill efficiency, it requires that the SPI deassert the SPI slave select pin and resend the read header whenever a DMA burst requests crosses 32 byte alignments. Setting this bit improves cache throughput but decreases DMA throughput.	
		0	SPI Memory auto increments address purely sequentially
		1	SPI Memory auto increments address but wraps within 32 Byte lines
26 (R/W)	MERGE	Merge Enable. When the SPI_MMRDH.MERGE bit is set, SPI hardware combines the two successive transfers. This increases the throughput rate when accessing a large number of sequential memory locations. For more information refer to the Merged Read Accesses section.	

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRIDMY	Tristate Dummy Timing. The SPI_MMRDH.TRIDMY bits specify whether and when output pins are three-stated during the interval of time specified by the SPI_MMRDH.DMYSIZE bits. Output pins potentially three-stated include all pins which were used to transmit the address	
		0	Tristate outputs immediately
		1	Tristate outputs after 4 bits of dummy/mode are transmitted
		2	Tristate outputs after 8 bits of dummy/mode are transmitted
		3	Never tristate outputs (previously specified output state is held)
23:16 (R/W)	MODE	Mode Field. These bits specify up to a leading byte to be transmitted during the interval of time specified by the SPI_MMRDH.DMYSIZE bit field. This first byte, or a portion of it, is interpreted as mode bits when certain opcodes are used in conjunction with certain SPI memory devices. Mode bits are sent using the same number of pins which were used to transmit the address. Once sent, output pins will be held in their final resultant state until the conclusion of all dummy byte periods, unless three-stating the outputs is specified first by the SPI_MMRDH.TRIDMY bits.	
14:12 (R/W)	DMYSIZE	Bytes of Dummy/Mode. The SPI_MMRDH.DMYSIZE bit field specifies the number of bytes separating address transmission and read data return. Dummy bytes elapse assuming dummy bits are transmitted using the same number of pins which were used to transmit address.	
		0	0 Bytes
		1	1 Bytes
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
		5	5 Bytes
		6	6 Bytes
		7	7 Bytes

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ADRPINS	Pins Used for Address. The SPI_MMRDH.ADRPINS bit specifies the number of pins to be used for address transmission. This bit must be set consistent with expectations established by read opcode. Hardware does not interpret the SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits
10:8 (R/W)	ADRSIZE	Bytes of Read Address. The SPI_MMRDH.ADRSIZE bit field defines the number of bytes used to specify the read address. The read address is sent immediately following the transmission of opcode. Unlike opcode bits, address bits may be sent using either one or multiple pins. The number of pins is selected using the SPI_MMRDH.ADRPINS bit. The address sent to a connected SPI memory device is an echo of the read address received by the SPI peripheral slave port. The least significant bytes of address are sent when the entire address is not sent.	
		0	1 Byte
		1	1 Byte
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
7:0 (R/W)	OPCODE	Read Opcode. The SPI_MMRDH.OPCODE bit field specifies the initial bits transmitted in response to a read request of SPI memory. Although any opcode may be sent, values 0x03, 0x0B, 0x3B, 0x6B, 0xBB, and 0xEB are likely to be the most commonly used. SPI_MMRDH.OPCODE is sent by the SPI without interpretation; the states of these bits have no effect beyond specifying what is initially shifted across the SPI interface.	

SPI Memory Top Address

The SPI_MMTOP register specifies the top populated address of a connected SPI memory device.

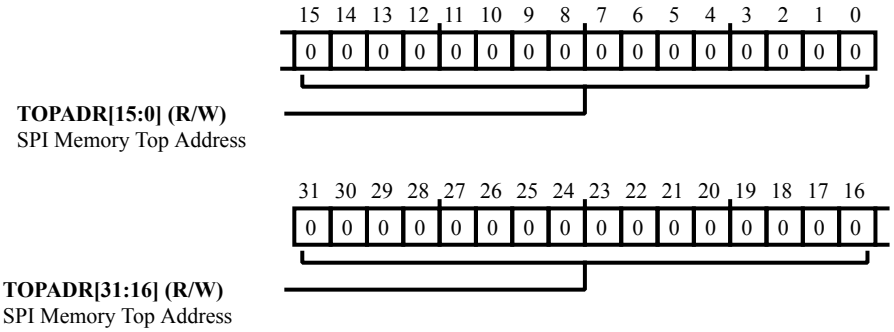

Figure 20-29: SPI_MMTOP Register Diagram

Table 20-26: SPI_MMTOP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TOPADR	SPI Memory Top Address. The SPI_MMTOP.TOPADR bit field specifies the top populated address of a connected SPI memory device. Attempts to access SPI memory are not blocked if this address is exceeded and an error is generated as part of the read response.

Receive FIFO Data Register

The SPI_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI master stops initiating new transfers on the SPI if SPI_RXCTL.RTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI_RFIFO is full, the data in the receive FIFO is invalid. The SPI indicates this condition with receive overrun (SPI_STAT.ROR) error. This condition is possible when SPI_RXCTL.RTI =0 and SPI_RXCTL.REN =1 for a master, or for a slave that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

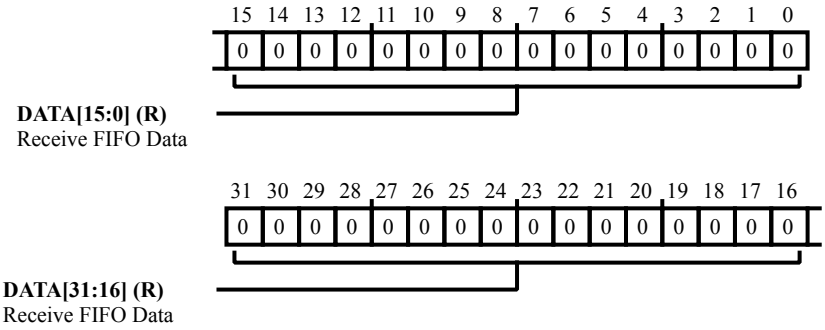

Figure 20-30: SPI_RFIFO Register Diagram

Table 20-27: SPI_RFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Receive FIFO Data. The SPI_RFIFO.DATA bit field contains the FIFO receive data.

Received Word Count Register

The SPI_RWC register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in SPI_RWC, enable the receive word counter (SPI_RXCTL.RWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (SPI_ILAT.RF). In DMA mode, the SPI uses the SPI_RWC register to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_RWC registers should match the word count in the DMA configuration. The SPI_RWC register maintains the number of frames to be received in a transfer. The SPI_RWC should only be changed when the counter is disabled.

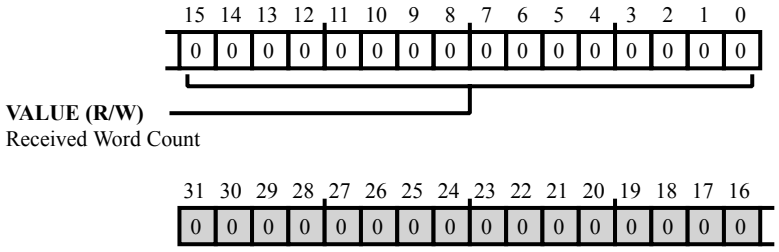

Figure 20-31: SPI_RWC Register Diagram

Table 20-28: SPI_RWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count. The SPI_RWC.VALUE bits hold the receive transfer word count.

Received Word Count Reload Register

The SPI_RWCR register holds the receive word count value that the SPI loads into the SPI_RWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_RWCR register should only be changed when the counter is disabled.

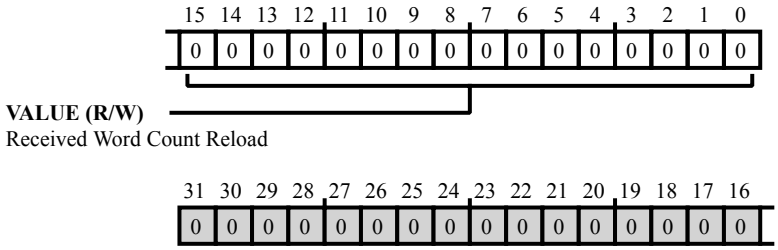

Figure 20-32: SPI_RWCR Register Diagram

Table 20-29: SPI_RWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count Reload. The SPI_RWCR.VALUE bits hold the receive transfer word count reload value.

Receive Control Register

The SPI_RXCTL register enables the SPI receive channel, initiates receive transfers, and configures SPI_RFIFO buffer watermark settings.

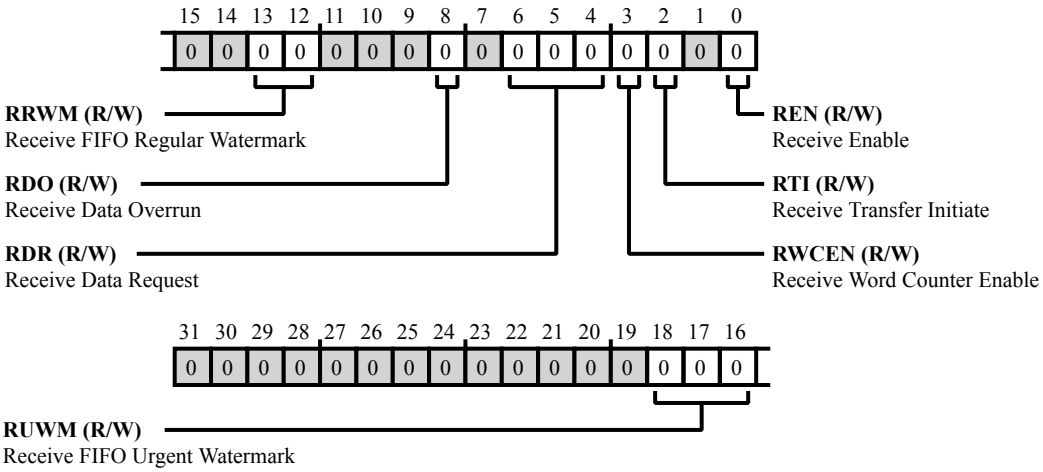

Figure 20-33: SPI_RXCTL Register Diagram

Table 20-30: SPI_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RUWM	Receive FIFO Urgent Watermark. The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Disabled
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
		5	Reserved
		6	Reserved
		7	Reserved

Table 20-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	RRWM	Receive FIFO Regular Watermark. The SPI_RXCTL.RRWM bits select the receive FIFO (SPI_RFIFO) watermark level for regular data bus requests. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Empty RFIFO
		1	RFIFO less than 25% full
		2	RFIFO less than 50% full
		3	RFIFO less than 75% full
8 (R/W)	RDO	Receive Data Overrun. The SPI_RXCTL.RDO bit selects handling for receive data requests when the receive buffer (SPI_RFIFO) is full. If enabled and SPI_RFIFO is full, the SPI overwrites old data in the buffer with incoming data. If disabled and SPI_RFIFO is full, the SPI keeps old data in the buffer and discards incoming data.	
		0	Discard incoming data if SPI_RFIFO is full
		1	Overwrite old data if SPI_RFIFO is full
6:4 (R/W)	RDR	Receive Data Request. The SPI_RXCTL.RDR bits select receive FIFO (SPI_RFIFO) watermark conditions that direct the SPI to generate a receive data request.	
		0	Disabled
		1	Not empty RFIFO
		2	25% full RFIFO
		3	50% full RFIFO
		4	75% full RFIFO
		5	Full RFIFO
		6	Reserved
		7	Reserved
3 (R/W)	RWCEN	Receive Word Counter Enable. The SPI_RXCTL.RWCEN bit enables the decrement of the SPI_RWC register when the count is not zero and SPI_RXCTL.RTI is enabled. Enabling SPI_RXCTL.RWCEN prevents receive overrun errors from occurring. The SPI_RXCTL.RWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 20-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RTI	Receive Transfer Initiate. The SPI_RXCTL.RTI bit enables initiation of receive transfers if the receive FIFO (SPI_RFIFO) is not full. The bit also enables this initiation if SPI_RWC is not zero when SPI_RXCTL.RWCEN is enabled. Enabling SPI_RXCTL.RTI prevents receive overrun errors from occurring. The SPI_RXCTL.RTI bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	REN	Receive Enable. The SPI_RXCTL.REN bit enables SPI receive channel operation.	
		0	Disable
		1	Enable

Slave Select Register

The SPI_SLVSEL register enables the SPI_SEL[n] pins for output and indicates the state (high or low) of these pins when enabled.

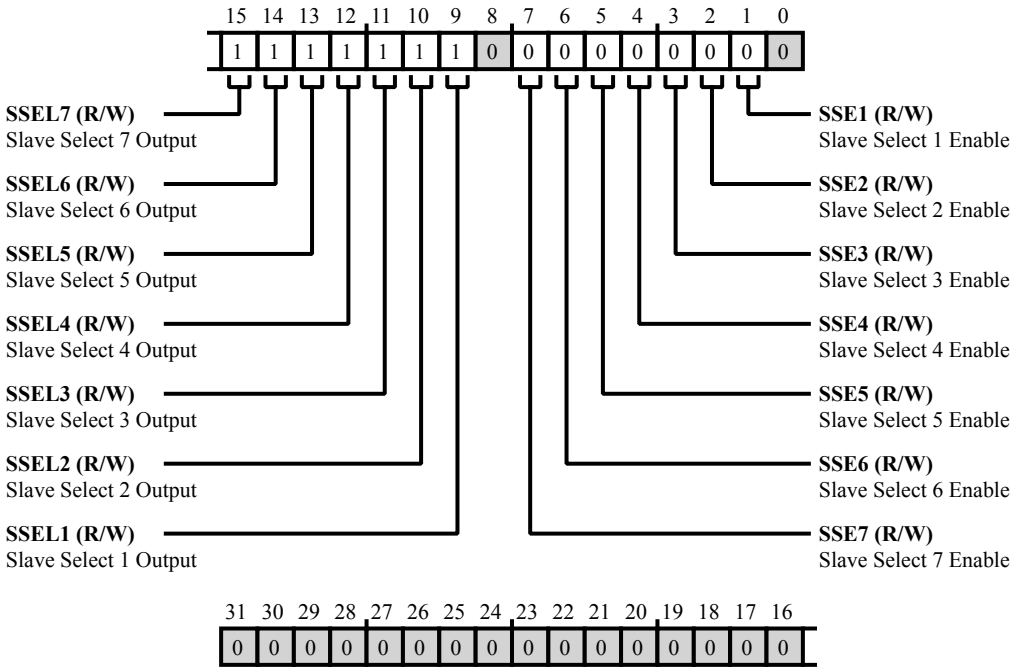

Figure 20-34: SPI_SLVSEL Register Diagram

Table 20-31: SPI_SLVSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SSEL7	Slave Select 7 Output. The SPI_SLVSEL.SSEL7 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
14 (R/W)	SSEL6	Slave Select 6 Output. The SPI_SLVSEL.SSEL6 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High

Table 20-31: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	SSEL5	Slave Select 5 Output. The SPI_SLVSEL.SSEL5 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
12 (R/W)	SSEL4	Slave Select 4 Output. The SPI_SLVSEL.SSEL4 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
11 (R/W)	SSEL3	Slave Select 3 Output. The SPI_SLVSEL.SSEL3 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
10 (R/W)	SSEL2	Slave Select 2 Output. The SPI_SLVSEL.SSEL2 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
9 (R/W)	SSEL1	Slave Select 1 Output. The SPI_SLVSEL.SSEL1 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
7 (R/W)	SSE7	Slave Select 7 Enable. The SPI_SLVSEL.SSE7 bit enables the related SPI_SEL[n] pin for output. If disabled, the SPI three-states the related SPI_SEL[n] pin.	
		0	Disable
		1	Enable

Table 20-31: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SSE6	Slave Select 6 Enable. The SPI_SLVSEL.SSE6 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
5 (R/W)	SSE5	Slave Select 5 Enable. The SPI_SLVSEL.SSE5 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
4 (R/W)	SSE4	Slave Select 4 Enable. The SPI_SLVSEL.SSE4 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
3 (R/W)	SSE3	Slave Select 3 Enable. The SPI_SLVSEL.SSE3 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
2 (R/W)	SSE2	Slave Select 2 Enable. The SPI_SLVSEL.SSE2 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
1 (R/W)	SSE1	Slave Select 1 Enable. The SPI_SLVSEL.SSE1 bit enables the related $\overline{\text{SPI\_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable

Status Register

The SPI_STAT register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the SPI_IMSK register, the interrupt request is latched into the corresponding bit in the SPI_ILAT register.

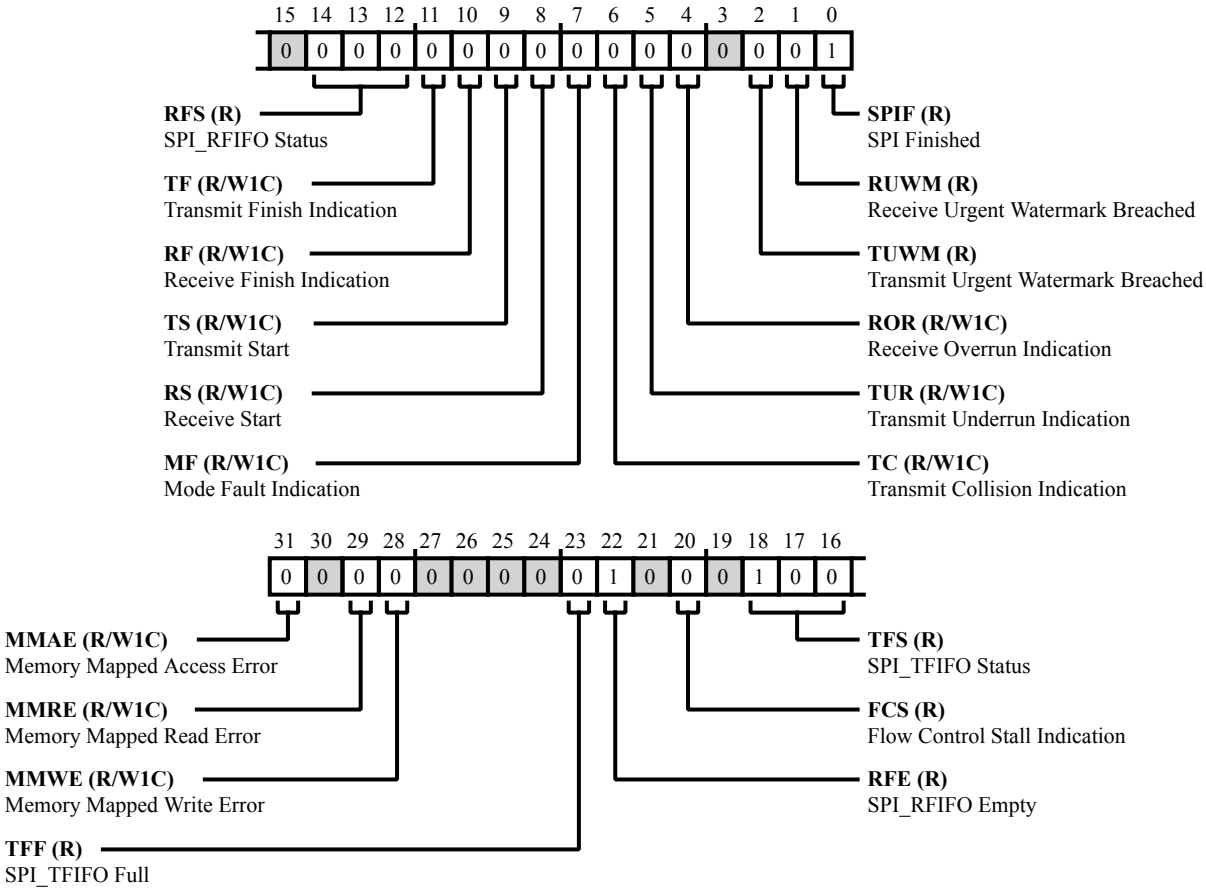

Figure 20-35: SPI_STAT Register Diagram

Table 20-32: SPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MMAE	Memory Mapped Access Error. The SPI_STAT.MMAE bit =1 if an attempt is made to access either the Tx or Rx FIFO while memory-mapped access of SPI memory is enabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMAE bit =0 when a 1 is written to it. The SPI_STAT.MMAE bit is provided for software notification only. Its state has no further effect.

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W1C)	MMRE	Memory Mapped Read Error. The SPI_STAT.MMRE bit =1 if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMRE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
28 (R/W1C)	MMWE	Memory Mapped Write Error. The SPI_STAT.MMWE bit =1 if an attempt is made to write address space reserved for memory-mapped SPI memory. The SPI_STAT.MMWE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
23 (R/NW)	TFF	SPI_TFIFO Full. The SPI_STAT.TFF bit indicates whether the SPI_TFIFO is full or not full.	
		0	Not full Tx FIFO
		1	Full Tx FIFO
22 (R/NW)	RFE	SPI_RFIFO Empty. The SPI_STAT.RFE bit indicates whether the SPI_RFIFO is empty or not empty.	
		0	Rx FIFO not empty
		1	Rx FIFO empty
20 (R/NW)	FCS	Flow Control Stall Indication. The SPI_STAT.FCS bit indicates whether a slave has deasserted the SPI_RDY pin to stall the SPI master while the slave is unable to service the SPI masters request. This bit is valid only when the SPI is a master (SPI_CTL.MSTR =1) and flow control is enabled (SPI_CTL.FCEN =1).	
		0	No Stall (RDY pin asserted)
		1	Stall (RDY pin deasserted)
18:16 (R/NW)	TFS	SPI_TFIFO Status. The SPI_STAT.TFS bits indicate the status of the SPI_TFIFO. The SPI uses this status when evaluating transmit watermark conditions.	
		0	Full TFIFO
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/NW)	RFS	SPI_RFIFO Status. The SPI_STAT.RFS bits indicate the status of the SPI_RFIFO. The SPI uses this status when evaluating receive watermark conditions.	
		0	Empty RFIFO
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
11 (R/W1C)	TF	Transmit Finish Indication. The SPI_STAT.TF bit indicates that the SPI has detected the finish of a transmit burst transfer (the SPI_TWC count decrements to zero). This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit finish detected
10 (R/W1C)	RF	Receive Finish Indication. The SPI_STAT.RF bit indicates that the SPI has detected the finish of a receive burst transfer (the SPI_RWC count decrements to zero). This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive finish detected
9 (R/W1C)	TS	Transmit Start. The SPI_STAT.TS bit indicates that the SPI has detected the start of a transmit burst transfer. A transmit bursts starts with the load of SPI_TWC from the SPI_TWCR. This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit start detected
8 (R/W1C)	RS	Receive Start. The SPI_STAT.RS bit indicates that the SPI has detected the start of a receive burst transfer. A receive bursts starts with the load of SPI_RWC from the SPI_RWCR. This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive start detected

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	MF	Mode Fault Indication. The SPI_STAT.MF bit, when SPI is a master and SPI_CTL.PSSE is enabled, indicates that multiple masters have asserted slave select inputs.	
		0	No status
		1	Mode fault occurred
6 (R/W1C)	TC	Transmit Collision Indication. The SPI_STAT.TC bit, when SPI is a slave, indicates that the load of data into the shift register has occurred too close to the first transmitting edge of the SPI clock.	
		0	No status
		1	Transmit collision occurred
5 (R/W1C)	TUR	Transmit Underrun Indication. The SPI_STAT.TUR bit, when the transmit FIFO (SPI_TFIFO) is empty, indicates that the last word in the transmit FIFO has been re-sent as transmit data. Alternately, it indicates that zero has been sent as transmit data.	
		0	No status
		1	Transmit underrun occurred
4 (R/W1C)	ROR	Receive Overrun Indication. The SPI_STAT.ROR bit, when the receive FIFO (SPI_RFIFO) is full, indicates that a word in the receive FIFO has been overwritten with incoming receive data. Alternately, it indicates that incoming receive data has been discarded.	
		0	No status
		1	Receive overrun occurred
2 (R/NW)	TUWM	Transmit Urgent Watermark Breached. The SPI_STAT.TUWM bit indicates that the transmit urgent watermark (SPI_TXCTL.TUWM) has been reached. This condition is cleared when the transmit FIFO fills enough to reach the transmit regular watermark (SPI_TXCTL.TRWM).	
		0	Tx regular watermark reached
		1	Tx urgent watermark breached
1 (R/NW)	RUWM	Receive Urgent Watermark Breached. The SPI_STAT.RUWM bit indicates that the receive urgent watermark (SPI_RXCTL.RUWM) has been reached. This condition is cleared when the receive FIFO empties enough to reach the receive regular watermark (SPI_RXCTL.RRWM).	
		0	Rx regular watermark reached
		1	Rx urgent watermark breached

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SPIF	SPI Finished. The `SPI_STAT.SPIF` bit indicates that a single word transfer is complete.	
		0	No status
		1	Completed single word transfer

Transmit FIFO Data Register

The SPI_TFIFO register has an interface to the transmit shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_TFIFO register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI master stops initiating new transfers on the SPI if SPI_TXCTL.TTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after SPI_TFIFO is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (SPI_STAT.TUR). This condition is possible when SPI_TXCTL.TTI =0 and SPI_TXCTL.TEN =1 for a master, or for a slave that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

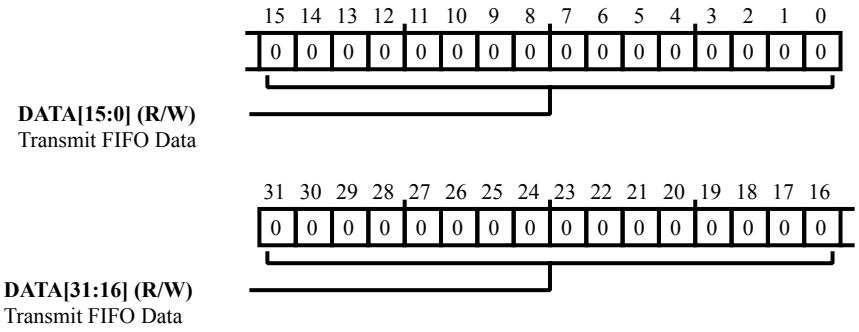

Figure 20-36: SPI_TFIFO Register Diagram

Table 20-33: SPI_TFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit FIFO Data. The SPI_TFIFO.DATA bit field contains the FIFO transmit data.

Transmitted Word Count Register

The SPI_TWC register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in SPI_TWC, enable the transmit word counter (SPI_TXCTL.TWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt request. In DMA mode, the SPI uses the SPI_TWC to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_TWC registers should match the word count in the DMA configuration. The SPI_TWC maintains the number of frames to be transmitted in a transfer. The SPI_TWC should only be changed when the counter is disabled.

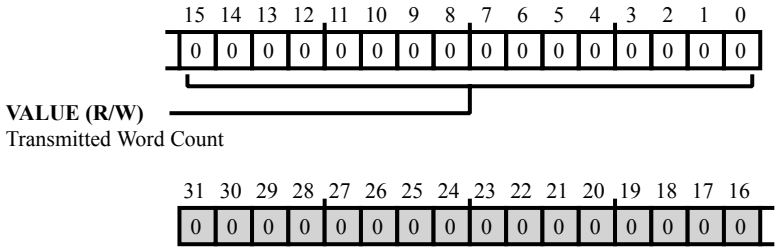

Figure 20-37: SPI_TWC Register Diagram

Table 20-34: SPI_TWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count. The SPI_TWC.VALUE bits hold the transmit transfer word count.

Transmitted Word Count Reload Register

The SPI_TWCR register holds the transmit word count value that the SPI loads into the SPI_TWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_TWCR should only be changed when the counter is disabled.

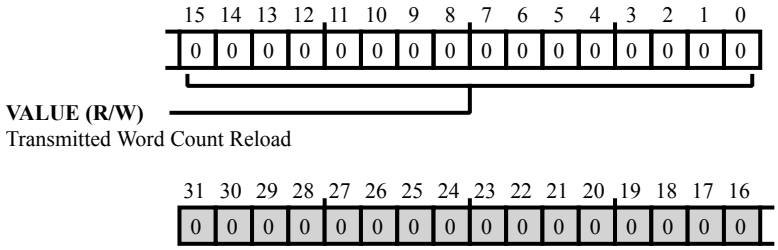

Figure 20-38: SPI_TWCR Register Diagram

Table 20-35: SPI_TWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count Reload. The SPI_TWCR.VALUE bits hold the transmit transfer word count reload value.

Transmit Control Register

The SPI_TXCTL register enables the SPI transmit channel, initiates transmit transfers, and configures SPI_TFIFO buffer watermark settings.

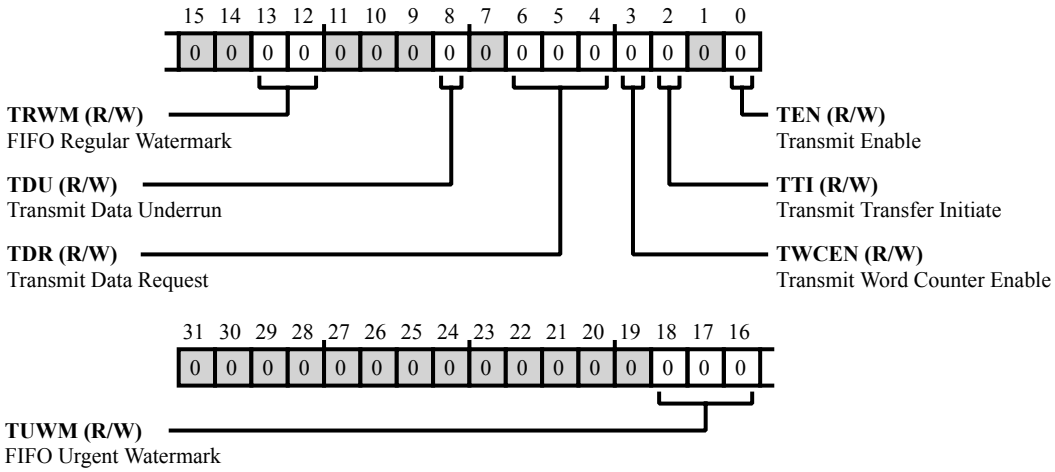

Figure 20-39: SPI_TXCTL Register Diagram

Table 20-36: SPI_TXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	TUWM	FIFO Urgent Watermark. The SPI_TXCTL.TUWM bits select the transmit FIFO (SPI_TFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.TUWM interrupt request. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Disabled
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 20-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	TRWM	FIFO Regular Watermark. The SPI_TXCTL.TRWM bits select the transmit FIFO (SPI_TFIFO) watermark level for regular data bus requests. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Full TFIFO
		1	TFIFO less than 25% empty
		2	TFIFO less than 50% empty
		3	TFIFO less than 75% empty
8 (R/W)	TDU	Transmit Data Underrun. The SPI_TXCTL.TDU bit selects handling for transmit data requests when the transmit buffer (SPI_TFIFO) is empty. If enabled and SPI_TFIFO is empty, the SPI transmits zero as data. If disabled and SPI_TFIFO is empty, the SPI transmits the last word in the buffer as data.	
		0	Send last word when SPI_TFIFO is empty
		1	Send zeros when SPI_TFIFO is empty
6:4 (R/W)	TDR	Transmit Data Request. The SPI_TXCTL.TDR bits select transmit FIFO (SPI_TFIFO) watermark conditions that direct the SPI to generate a transmit status interrupt request.	
		0	Disabled
		1	Not full TFIFO
		2	25% empty TFIFO
		3	50% empty TFIFO
		4	75% empty TFIFO
		5	Empty TFIFO
3 (R/W)	TWCEN	Transmit Word Counter Enable. The SPI_TXCTL.TWCEN bit enables the decrement of the transmit word count (SPI_TWC) register when the count is not zero and SPI_TXCTL.TTI is enabled. Enabling SPI_TXCTL.TWCEN prevents transmit underrun errors from occurring. The SPI_TXCTL.TWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 20-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	TTI	Transmit Transfer Initiate. The SPI_TXCTL.TTI bit enables initiation of transmit transfers if the transmit FIFO (SPI_TFIFO) is not empty. The bit also enables this initiation if SPI_TWC is not zero when SPI_TXCTL.TWCEN is enabled. Enabling SPI_TXCTL.TTI prevents transmit underrun errors from occurring. The SPI_TXCTL.TTI bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	TEN	Transmit Enable. The SPI_TXCTL.TEN bit enables SPI transmit channel operation.	
		0	Disable
		1	Enable

21 Octal Serial Peripheral Interface (OSPI)

The Octal Serial Peripheral Interface (OSPI) controller provides access to serial flash devices. It is designed to access flash devices with its modes enabling efficient communication, with minimum overhead on software. Standard SPI is supported along with high performance dual, quad, and octal SPI modes where data can be transferred on up to 8 data pins. Along with normal mode of operation in single transfer (STR) mode, the OSPI controller supports dual transfer rate (DTR) mode, where data, address, and commands are transferred on both edges of the serial clock. With direct access mode support, any read/write to the OSPI memory space triggers a read/write to flash memory.

Direct read accesses using core and DMA are possible, with the latter minimizing software overhead. The OSPI controller also provides Software Triggered Instruction Generation (STIG) mode, which can be used to erase the data on flash devices and access volatile and nonvolatile configuration registers, legacy flash status register, and other status/protection registers.

The OSPI provides a glueless hardware interface with SPI flash devices. The OSPI peripheral includes programmable baud rates, clock phase, clock polarity, separate dummy cycles for read and write accesses, data sampling control, programmable page size/block size, and so on. With this independent control of how many lines to use for command, address, and data allows to virtually interface any flash device with the processor through OSPI controller.

The OSPI also provides support for DQS when sampling data to improve read data capture and PHY mode support to enable high-speed data transfers.

OSPI Features

The OSPI controller supports the following features:

- Full-duplex, synchronous, serial interface
- Memory mapped direct mode operation for performing flash data transfers
- STIG mode operation to issue flash commands
- Automatic flash status polling support for flash program through direct access mode
- XIP (Execute in Place) support
- Support for single, dual, quad, or octal modes of operation
- Support for DDR mode and DTR protocol (including Octal DDR protocol)

- Up to 16-bit data transfer in each SPI clock cycle
- Programmable baud rate, clock phase, and polarity
- Programmable interrupt generation
- Programmable chip select control timing
- Programmable dummy cycles for read and write operations
- Tune data capture mechanism to improve high speed operation
- Programmable write protected regions to block system writes
- Support for DQS to sample the data to improve read data capturing
- PHY mode support to allow the high speed data transfers

OSPI Functional Description

ADSP-2159x_SC591_SC592_SC594 OSPI Register List

The OSPI is an Octal SPI controller. It contains the following registers.

Table 21-1: ADSP-2159x_SC591_SC592_SC594 OSPI Register List

Name	Description
OSPI_CTL	Octal SPI Control Register
OSPI_DLY	Device Delay Register
OSPI_DRICTL	Device Read Instruction Control Register
OSPI_DWICTL	Device Write Instruction Control Register
OSPI_DSCTL	Device Size Control Register
OSPI_DLLOB_LWR	DLL Observable Register (Lower)
OSPI_DLLOB_UP	DLL Observable Register (Upper)
OSPI_FCA	Flash Command Address Register
OSPI_FCCTL	Flash Command Control Register
OSPI_FCMCTL	Flash Command Control Memory Register
OSPI_FCRD_LWR	Flash Command Read Data Register (Lower)
OSPI_FCRD_UP	Flash Command Read Data Register (Upper)
OSPI_FCWD_LWR	Flash Command Write Data Register (Lower)
OSPI_FCWD_UP	Flash Command Write Data Register (Upper)
OSPI_IMSK	Interrupt Mask Register
OSPI_ISTAT	Interrupt Status Register

Table 21-1: ADSP-2159x_SC591_SC592_SC594 OSPI Register List (Continued)

Name	Description
OSPI_WRPROT_LWR	Lower Write Protection Register
OSPI_MBCTL	Mode Bit Control Register
OSPI_MODID	Module ID Register
OSPI_POLLEXP	Polling Expiration Register
OSPI_OE_LWR	Opcode Extension Register (Lower)
OSPI_OE_UP	Opcode Extension Register (Upper)
OSPI_PHYCTL	PHY Control Register
OSPI_PHYMCTL	PHY DLL Master Control Register
OSPI_POLSTAT	Polling Flash Status Register
OSPI_RDC	Read Data Capture Register
OSPI_REMAPADDR	Remap Address Register
OSPI_WRPROT_UP	Upper Write Protection Register
OSPI_WRPROT_CTL	Write Protection Control Register
OSPI_WCCTL	Write Completion Control Register

ADSP-2159x_SC591_SC592_SC594 OSPI Interrupt List

Table 21-2: ADSP-2159x_SC591_SC592_SC594 OSPI Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
137	OSPI0_INT	OSPI0 Error	Level	

OSPI Block Diagram

The OSPI module is comprised of:

- Low level SPI protocol controller
- Internal transmit/receive FIFOs
- DAC
- STIG controller
- Register interface

The ***OSPI Controller Block Diagram*** shows the OSPI controller functional blocks.

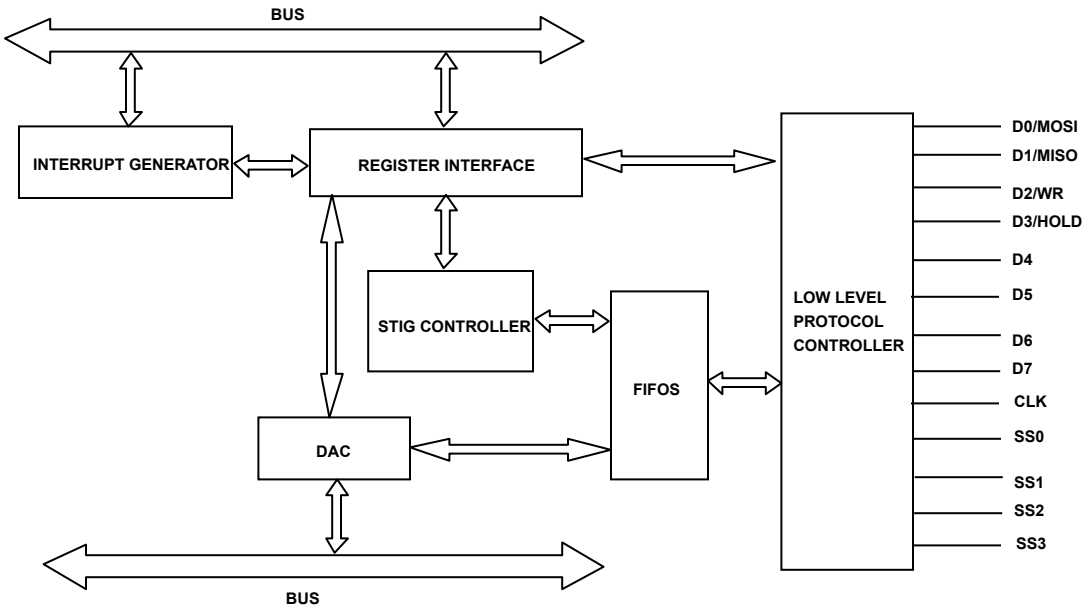

Figure 21-1: OSPI Controller Block Diagram

Architectural Concepts

There are two clock sources for the OSPI controller and one generated clock for clocking external flash device.

The SYSCLK is the main system clock used to transfer data over the AHB bus between the controller (core/DMA) and the OSPI controller. The SCLK0_0 clock is used to access the OSPI controller registers to perform basic configuration of the controller and interrupt handling. The OSPI_REFCLK, is used to serialize the data and drive the OSPI interface. The external clock driven on the OSPI_CLK pin, which is synchronous to the reference clock, is derived from the OSPI_REFCLK and divided using internal baud rate dividers. Using the OSPI_REFCLK clock, allows the core to decouple the frequency of the SPI flash device from system clocks, thereby providing a flexible clocking solution.

The OSPI controller supports two independent controllers (to support different types of flash accesses):

- Direct Access Controller (DAC)
- Software Triggered Instruction Generator (STIG)

The high-level architecture of the OSPI controller is divided into two blocks. The first is the high-level OSPI controller that interfaces with the rest of the SoC. It also queues flash transactions based on data from AHB and APB bus interfaces. The second module is the low-level SPI Protocol Controller. It is used for serializing data from high-level OSPI controller and translating them into the SPI transfer protocol where there are two possible data paths. The first path preserves backward compatibility with the previous SoCs. This path bypasses the PHY module. Use this path when there is no strict requirement for high performance (clock divider is greater or equal 4).

The second data path is through the PHY Module and is for dividers lower than 4. The configuration is set by software. The controller waits for a valid direct access from the AHB bus (which runs off SYSCLK) or for a software triggered read from the APB bus. When such an event occurs, the corresponding internal controller is selected

(DAC or STIG). The flash command generator block arbitrates between accesses and forwards control into the low-level SPI module. This block works on the reference clock. Transmit data is synchronized internally to the TX FIFO and then serialized to the SPI interface. When the direction of transfer changes and the device returns data to the controller, data is read into the RX FIFO and then synchronized to the internal clocks. The SPI control logic selects the source of the data path (with or without PHY) based on the register configuration. The reference clock and the associated delayed variants are relevant for this transfer type when the PHY mode is enabled.

Direct Access Controller (DAC)

Direct access refers to the operation where AHB bus accesses targeted to the OSPI memory mapped space of processor directly triggers a read/write on flash memory. It is memory mapped and used to access and directly execute the code from external flash memory. When DAC is enabled through the `OSPI_CTL.DACEN` field, any incoming AHB access is serviced by the DAC. Direct accesses can be launched by accessing the OSPI memory address space using core or via one of the MDMA channels. In memory mapped mode, communication to a flash device is automated. The flash memory is accessible directly through reads/write of the processor address space. This access allows code to execute directly from flash devices (true XIP operations). The content can be cached for good performance.

When servicing AHB reads, the DAC sends an additional access downstream apart from the one issued by the AHB in single AHB burst. This is invisible from the system interface. It is a predicted read and ensures that the SPI core operates with maximum bandwidth. The AHB burst not defined by the AMBA specification. It is defined as follows:

- The first access of the AHB burst is defined by:

  An AHB access that is non-sequential (based on address comparison).

  An AHB access that is non-sequential or sequential when the downstream modules are idle.
- The last access of the AHB burst is defined by an AHB access that is sequential and precedes a new burst.
- Size of the AHB burst is the number of AHB accesses (first access to last access).
- The number of DAC requests per AHB burst is equal to the size of the AHB burst + 1.

When AHB clock is slower than the SPI data rate, the sequential read transfer may be interrupted on the SPI side and continues after the AHB clock accepts the last data. The limiting value gets narrower as the SPI clock divider and AHB access size decrease and the number of data IOs (single, dual, quad, or octal) increase. If the system cannot meet the SPI data rate, use higher SPI clock divider. This decreases the SPI data rate, but prevents OSPI accesses to external flash to break in between and pass the *Opcode-Address-Dummy* sequence each time. This increases the overall performance by keeping the data transfer continuous.

The controller is designed to work at high data rates. This predicted read results in redundant data during mixed AHB accesses on slow system data rate. Mixed accesses implies that direct AHB sequence of single non-sequential access following few sequential accesses. The predicted read cannot be dropped because of SPI transfer interruption. It is sent as a separate SPI transaction which creates redundant data on the interface for one access. To avoid this issue, drop this data by system or introduce wait states on AHB before issuing a non-sequential direct AHB access.

For bus writes, the DAC triggers a sequence of write commands that mimic the way reads are processed, though the number of DAC write requests are equal to the number of bus write requests received. The bus controller ensures

that flash bursts do not break the flash page boundary. When a page boundary is detected, only the number of byte accesses up to that boundary are forwarded. A sequential direct write request that crosses a page boundary must be detected as non-sequential, causing the controller to force the flash device to enter a self-timed page program cycle. The controller supports splitting the writes crossing the page boundaries only for word-aligned addresses.

The external bus controller supplying data for writes must guarantee write data for a particular page that can be provided to the controller in a timely fashion to avoid downstream starvation. If there is a large delay in the system issuing a sequential write, flash write cycle may be prematurely initiated, reducing the device life time.

Flash erase operations, which may be required before a page write, are triggered by software using the STIG. Once a page program cycle has been started, the OSPI controller automatically polls for write cycle to complete before allowing any bus accesses to complete. This is achieved by holding the subsequent AHB direct accesses in wait state.

For memory mapped accesses using the DAC, the flash memory is accessible using the address space 0x60000000 – 0x7FFFFFFF, as indicated in the processor datasheet. Since both SPI2 and OSPI controllers can accesses this space in memory mapped mode, there are control bits in the `SCB5_SPI2_OSPI_REMAP` register to control which controller is able to access this flash memory mapped space. Either OSPI or SPI2 can exclusively access whole of the flash memory space or there is an option to divide this space between OSPI and SPI2.

If the `SCB5_SPI2_OSPI_REMAP` register = 0x0, the entire flash memory mapped space is only accessible by the SPI2 controller. Do not try to access this space with the OSPI controller.

If the `SCB5_SPI2_OSPI_REMAP` register = 0x1, the entire flash memory mapped space is only accessible by the OSPI controller. Do not try to access this space with the SPI2 controller.

If the `SCB5_SPI2_OSPI_REMAP` register = 0x2, the flash memory mapped space is divided between the OSPI and SPI2 controllers. The flash memory mapped space (0x60000000 - 0x602FFFFF) is only accessible by SPI2 and the flash memory mapped space (0x60300000 - 0x7FFFFFFF) is only accessible by OSPI. This option is only valid for the ADSP-SC59x/2159x HPC package.

Software Triggered Instruction Generator (STIG)

DAC is primarily used to transfer data. To access the volatile and nonvolatile configuration registers, the legacy Flash SPI Status register, other status/protection registers and perform erase operations, a separate software controller is required.

The STIG is controlled using the `OSPI_FCCTL` register by setting up the command to issue to the flash device. This is a generic controller used to perform instructions that the flash device supports from the extended SPI protocol. The STIG controller command is sent to the flash device and written to the software in the `OSPI_FCCTL.OPCODE` field. This is different from the `OSPI_DRICTL.OPCODERD` and `OSPI_DWICTL.OPCODEWR` fields, as these fields do not impact the STIG operation.

Configuring instructions that are not compliant with the flash specifications can cause unpredicted behavior of the controller. Bit 0 is used to trigger the command, bit 1 used by software to poll the status of the command execution. For reads, when the command has been serviced (bit 1 toggles from 1 to 0), up to 8 bytes of read data is placed in the `OSPI_FCRD_LWR` and `OSPI_FCRD_UP` registers. For writes, data must be placed in the `OSPI_FCWD_LWR` and `OSPI_FCWD_UP` registers. The STIG completion request can be also checked by the corresponding interrupt.

The interrupt indicates that the controller is ready to accept a new STIG request. The STIG completion request is not equivalent to completion on the SPI side. For example, if STIG is configured to the data command only on transmit, data is taken from the corresponding STIG register fields and put into TX FIFO. As all write bytes are known, another STIG can be queued before completing serialization of the current one.

There are few commands that require more data to read than 8 bytes (for example, READ ID command). Additional STIG memory bank is implemented to accommodate this data, if required. The STIG memory bank is controlled by the OSPI_FCMCTL register. If enabled, the number of bytes to read in the STIG is extended to 16 bytes, as defined in the OSPI_FCMCTL.RDSZ field. There are few commands (excluding read arrays that are not intended to be handled in STIG mode, but in Direct Access Mode) that return more than 8 bytes to the controller.

If the number of read bytes in the STIG, as defined in the OSPI_FCMCTL.RDSZ field, exceeds the memory bank depth, the remaining data overwrites the STIG memory bank locations starting from its first address. When memory bank is enabled, the OSPI_FCRD_LWR and OSPI_FCRD_UP registers keep the last 8 bytes read from the flash device by the STIG. For example, to get a single byte from the last eight bytes of a long continuous read SPI data chain, there is no need to access the STIG memory bank as data can be obtained from the OSPI_FCRD_LWR and OSPI_FCRD_UP registers. To access more data, STIG memory bank data request must be triggered. It is controlled by the OSPI_FCMCTL register and works analogously to trigger the STIG. Bit 0 (OSPI_FCMCTL.TRIGREQ) is used to trigger the command. Bit 1 (OSPI_FCMCTL.BNKREQ) used by software to poll the status of the command execution. When bit 1 toggles from 1 to 0, the data byte (OSPI_FCMCTL.BNKDATA) from the corresponding address (OSPI_FCMCTL.BNKADDR) is valid. The address must be set before triggering the STIG memory bank access. Each consecutive STIG access overwrites the previous one so that the data in the bank fits into byte index fetched by the last STIG access configured to use the memory bank (first incoming byte equals first address of the memory bank, second one equals the second address and so on).

Servicing STIG Request

The OSPI controller determines the number of bytes in the OSPI_FCCTL register to be sent to the flash device, when there is a STIG request. The OSPI_FCCTL.OPCODE field indicates the instruction to be sent and is always pushed first. If there is an address to send, the address (size is also programmed in the same register) is sent next. The address is stored in the OSPI_FCA register. If there are dummy cycles (size of which is also programmed in the OSPI_FCCTL register), they are sent next.

For write data (size of which is also programmed in the OSPI_FCCTL register), up to 8 bytes can be sent (as stored in the OSPI_FCWD_LWR and OSPI_FCWD_UP registers). When read data is collected from the flash device, the OSPI controller stores it in the OSPI_FCRD_LWR and OSPI_FCRD_UP registers.

Arbitration Between DAC and STIG Access

When multiple controllers are simultaneously active, a simple, fixed priority arbitration scheme is used to arbitrate between each interface and to access the external flash.

The fixed priority is defined as follows, highest priority first:

1. Direct Access Write
2. STIG Access

3. Direct Access Read

When one controller is servicing the request, the other controller is back pressured while waiting to be serviced.

Auto Polling for DAC Write Access

For DAC write accesses, which initiate flash program operation, the OSPI controller provides an option to automatically poll the flash status for program completion. When a flash write operation is triggered through DAC, the OSPI controller sends the write data up to page size defined in the OSPI_DSCTL.PGSZ field. Once a page boundary is reached, the DAC stops sending data to the flash device as the flash device enters the program mode. Once the device is in program mode, the OSPI controller can automatically send the flash status read commands to check the state of the flash.

The OSPI_WCCTL register defines the setting to poll the flash device correctly. By default, it is configured to poll bit 0 of the Device STATUS register (using opcode 0x05), which is common across all devices to indicate Write in Progress (WIP). However, in some devices (such as Micron devices, where size is > 512 MB), it is required that the controller polls a different bit of a different device register. This means the controller must issue a different command during this polling phase. For example, in Micron N25Q devices, it is bit 7 of the FLAG STATUS register (opcode 0x70) instead of bit 0 of the STATUS register that must be polled. For this reason, the OSPI_WCCTL register has been provided for software to determine the bit and the opcode to use to poll for write completion, and also the number of successive valid polls that should take place.

To ensure that the bandwidth of the device is not affected by continuous read status SPI transactions, prolong the delay between the successive flash status read command by programming the OSPI_WCCTL.REPDLY field. This feature is implemented to free up the SPI bandwidth, if required. However, defining this delay is not always desired as the ready bit indication can come later what impacts the overall performance. This register must be setup while the controller is idle.

When the OSPI controller starts to service a STIG request, it sets the OSPI_FCCTL.STAT bit to indicate a command execution is in progress. When the OSPI controller is in the auto polling state, servicing a STIG request is different. Several devices are inaccessible after a program operation until the device has completed that write. Few of them have a possibility to suspend the programming page. It can be controlled by the OSPI_POLSTAT.STAT bit, which indicates active auto polling phase. After requesting a STIG, the OSPI controller issues an appropriate opcode to memory. While servicing a STIG (in auto polling phase), the OSPI_FCCTL.STAT bit remains steady and other parts of transfer such as address or dummy bits are disabled (to issue program suspend command, only opcode is needed).

SPI Command Translation

Requests issued by the DAC or STIG are translated into a sequence of byte transfers to send downstream (before serializing the flash device). These sequences depend on the requested transfer, except the following example (1-byte non-sequential read):

INSTRUCTION OPCODE > ADDRESS > MODEBYTE > DUMMY CYCLES > 1-DATA BYTE

NOTE: During data phase mode, data programmed in the OSPI_MBCTL register is driven on pins. If mode data is not enabled, the address phase is followed directly by dummy cycles. During the dummy cycle phase the

OSPI data pins (D0-D7) are three-stated (High-z). To ensure the correct signal level on the data pins during this phase, external pull-ups can be used on data pins.

For sequential accesses, an extra data byte per read is pushed to the flash device on the back of the above sequence, assuming that it can be done without any gap between each transferred byte.

The actual sequence sent to the flash device depends on the requested transfers (non-sequential or sequential), whether the device is configured in XIP mode or not, and the state of the OSPI_DRICTL and OSPI_DWICTL registers. For writes, the write enable latch (WEL) within the flash device must be high before a write sequence can be issued.

The OSPI controller automatically issues a WEL command before triggering a write command via the DAC (the program need not perform this operation). To increase flexibility and performance, turn off this feature by setting the OSPI_DWICTL.WELDIS bit. The opcode for WEL is 0x06 and common between the devices. However, the WEL operation is programmed using the OSPI_OE_LWR.XRDBYT/OSPI_OE_UP.FSTBYTWEL bits and (optionally) the OSPI_OE_LWR.XWRBYT/OSPI_OE_UP.XBYTWEL bits (flash device requires 2-byte command code for WEL).

When write requests from the DAC are not received and all outstanding requests have been sent, the flash device automatically starts the page program write cycle. Any incoming request at this time is held in wait state until the cycle is completed. The OSPI controller automatically polls the flash device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the Read Status Register (RDSR) opcode to the flash device and waiting until the device indicates that the write cycle is completed (the Write in Progress bit is cleared to zero and WEL bit is cleared to zero or device ready bit is set to one). The WREN and RDSR device instructions are only sent by the controller. For other specific instruction that the user determines must be sent to the device (for example, if the device needs to be unprotected before a write command is issued), has to be separately handled by issuing flash commands via the STIG.

Hold and Reset Control

There is an option to trigger hold and reset features on the I/Os of the flash device. The hold functionality is common across the devices and takes an alternative function of the DQ3 pin (applicable when device does not operate in quad SPI or DDR modes). The transfer can be held and resumed by the OSPI_CTL.HLD bit. Devices with hold feature on DQ3 need another dedicated pin for hardware reset. Devices without hold feature have an alternative reset on the DQ3 pin, which makes the additional reset pin redundant. The controller supports both variants. The OSPI_CTL.RSTCFG field allows the user to configure the hardware reset solution implemented in the device. After configuration, it is possible to trigger hold or reset features using I/Os (OSPI_CTL.HLD or OSPI_CTL.RST bits).

NOTE: The OSPI controller does not support dedicated reset pin to control the reset of flash devices. Flash devices with reset functionality on DQ3 can be controlled directly via OSPI controller.

After hold activation, the controller is in waiting state. Any other operations must not be requested before de-asserting the OSPI_CTL.HLD bit. The hold feature is useful when any SPI transaction needs to be prolonged to adjust it into specific point in time. To check if the hold request is suspended, the OSPI_CTL.IDLE bit can be polled

for. If SPI is not in the idle state, the transfer is suspended. Software must reset the OSPI_CTL.HLD bit before any new SPI transaction. In case hold request is set before starting any transfer, it will be in hold state after it starts.

Hardware reset must be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling the OSPI_CTL.IDLE bit. If the controller is in the idle state and no other transfer requests are queued, hardware reset can be triggered. Reset feature is useful when any write, program, or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to inactive. Triggering hold or reset on the DQ3 pin at the time the device is configured to work in Quad SPI or DDR mode, overwrites transfer data on the DQ3 with 0. This behaviour is considered as a software error. Ensure that the flash device is introduced to suitable SPI Mode (by polling its Configuration Register) before triggering alternative DQ3 function.

Flash Instruction Type Support

To send correct read and write opcodes, software must initialize the OSPI_DRICTL and OSPI_DWICTL registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the flash (default is basic read and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad, or octal pins for address and data transfers.

To ensure that the controller can operate from a reset state, the registers are reset to an opcode compatible with single I/O standard SPI devices. Though it is applicable for both reads and writes, the OSPI_DRICTL.INSTRTYP field appears only once (not included in the OSPI_DWICTL register). If software sets this to any value other than 0, the OSPI_DRICTL.ADDRTRNSFR/OSPI_DWICTL.ADDRTRNSFR/ OSPI_DRICTL.DATATRNSFR/OSPI_DWICTL.DATATRNSFR bits become don't care. It is made available to allow software to support less common flash instructions, where opcode, address, and data are sent on 2 or 4 data lines (opcode from several instructions are sent serially to the flash device, even for dual/quad instructions).

Dual Data Rate (DDR) Operations

The OSPI controller supports DDR mode of operation, in which some or all transfer phases happen in DDR mode, where the I/O lines are driven/sampled on both rising and falling edges of the clock.

In DDR mode, the OSPI controller supports the following modes:

- Dual Transfer Rate (DTR) mode, where command is driven in SDR mode and address/dummy cycles/data are driven in DDR mode.
- DTR protocol mode, where everything including command is driven in DDR mode.

For DTR mode, there are specific commands which are recognized by the flash as DTR commands. These are DTR Read commands which can be handled in STR Protocol (but in DTR Mode). This is achieved by setting the OSPI_CTL.DTREN bit to 0 and OSPI_DRICTL.DDREN bit to 1.

For DTR protocol mode, all normal commands can be sent in DDR fashion, provided the flash is already configured in a mode to accept the commands in DDR mode. Support for DTR protocol provides significant enhancement. This is enabled in the OSPI controller by setting the OSPI_DRICTL.DDREN bit to 1. It allows the device to work in DTR mode for each possible command (not only DTR read ones). It can also handle opcode phase in DTR mode, which improves the overall performance.

There are several devices (for example, Micron N25Q512A) that can hande read operations in DTR mode. They can issue and capture data on both rising and falling edges while working with a dedicated command type. This enables the controller to maintain same throughput twice the lower frequency of SPI_CLK for STR mode.

In MT25Q family of Micron devices, DTR protocol is implemented. It enables device to handle all commands in DTR mode. DTR Read commands detect DTR mode based on dedicated opcode. Therefore, opcode has to be sent as STR. When DTR protocol is enabled, the device does not need opcode to detect edge mode, as it can recognize based on the volatile or nonvolatile bit in the flash configuration register.

The ***Read Configuration Examples*** table illustrates how software must configure the controller for selected specific read and write instruction supported by the different devices.

Table 21-3: Read Configuration Examples

Command	Opcode (Number of Lanes/ Edge Mode)	Address/ Dummy/ Mode (Number of Lanes/ Edge Mode)	Data (Number of Lanes/ Edge mode)	Instruction Type `OSPI_DRICTL.INSTRTYP`	Address Transfer Type `OSPI_DRICTL.ADDRTRNSFR`	Data Transfer Type `OSPI_DRICTL.DATATRNSFR`	DDR Bit Enable `OSPI_DRICTL.DDREN`
READ	1/SDR	1/SDR	1/SDR	0	0	0	0
FAST_READ	1/SDR	1/SDR	1/SDR	0	0	0	0
DTR FAST_READ	1/SDR	1/DDR	1/DDR	0	0	0	1
DOR (Dual output Fast Read)	1/SDR	1/SDR	2/SDR	0	0	1	0
DTR DOR (Dual output Fast Read)	1/SDR	1/DDR	2/DDR	0	0	1	1
DIOR (Dual I/O Fast Read)	1/SDR	2/SDR	2/SDR	0	1	1	0
DTR DIOR (Dual I/O Fast Read)	1/SDR	2/DDR	2/DDR	0	1	1	1
QOR (Quad output Fast Read)	1/SDR	1/SDR	4/SDR	0	0	2	0
DTR QOR (Quad output Fast Read)	1/SDR	1/DDR	4/DDR	0	0	2	1
QIOR (Quad I/O Fast Read)	1/SDR	4/SDR	4/SDR	0	2	2	0

Table 21-3: Read Configuration Examples (Continued)

Command	Opcode (Number of Lanes/ Edge Mode)	Address/ Dummy/ Mode (Number of Lanes/ Edge Mode)	Data (Number of Lanes/ Edge mode)	Instruction Type `OSPI_DRICTL.INSTRTYP`	Address Transfer Type `OSPI_DRICTL.ADDRTRNSFR`	Data Transfer Type `OSPI_DRICTL.DATATRNSFR`	DDR Bit Enable `OSPI_DRICTL.DDREN`
DTR QIOR (Quad I/O Fast Read)	1/SDR	4/DDR	4/DDR	0	2	2	1
OOR (Octal output Fast Read)	1/SDR	1/SDR	8/SDR	0	0	3	0
DTR OOR (Octal output Fast Read)	1/SDR	1/DDR	8/DDR	0	0	3	1
OIOR (Octal I/O Fast Read)	1/SDR	8/SDR	8/SDR	0	3	3	0
DTR OIOR (Octal I/O Fast Read)	1/SDR	8/DDR	8/DDR	0	3	3	1
DCFR (Dual Command Fast Read)	2/SDR	2/SDR	2/SDR	1	don't care	don't care	0
DTR DCFR (Dual Command Fast Read)	2/SDR	2/DDR	2/DDR	1	don't care	don't care	1
QCFR (Quad Command Fast Read)	4/SDR	4/SDR	4/SDR	2	don't care	don't care	0
DTR QCFR (Quad Command Fast Read)	4/SDR	4/DDR	4/DDR	2	don't care	don't care	1
OCFR (Octal Command Fast Read)	8/SDR	8/SDR	8/SDR	3	don't care	don't care	0
DTR OCFR (Octal Command Fast Read)	8/SDR	8/DDR	8/DDR	3	don't care	don't care	1

NOTE: This data is applicable for 3-byte and 4-byte address variants of the commands.

In DTR protocol, all transfer phases (including opcode) take DDR edge mode independent of the command under execution. DTR protocol is enabled by the OSPI_CTL.DTREN bit. It has higher priority than the OSPI_DRICTL.DDREN bit. Therefore, if the OSPI_CTL.DTREN bit is set, irrespective of value programmed in the OSPI_DRICTL.DDREN bit, all command, address, dummy cycles, and data are transferred in DDR mode.

Table 21-4: Write Configuration Examples

Command	Opcode (Number of Lanes)	Address/ Dummy/Mode (Number of Lanes)	Data (Number of Lanes)	Instruction OSPI_DRICTL.INSTRTYP	Address Transfer Type OSPI_DWICTL.ADDRTRNSFR	Data Transfer Type OSPI_DWICTL.DATATRNSFR
PP (Page Program)	1	1	1	0	0	0
DIFP (Dual Input Fast Program)	1	1	2	0	0	1
DIEFP (Dual Input Extended Fast Program)	1	2	2	0	1	1
QIFP (Quad Input Fast Program)	1	1	4	0	0	2
QIEFP (Quad Input Extended Fast Program)	1	4	4	0	2	2
OIFP (Octal Input Fast Program)	1	1	8	0	0	3
OIEFP (Octal Input Extended Fast Program)	1	8	8	0	3	3
DCPP (Dual Command Page Program)	2	2	2	1	don't care	don't care
QCPP (Quad Command Page Program)	4	4	4	2	don't care	don't care
OCPP (Octal Command Page Program)	8	8	8	3	don't care	don't care

NOTE: This data is applicable for both 3-byte or 4-byte address variants of the commands.

In DTR protocol, all transfer phases (including opcode) take DDR edge mode independent of the command under execution.

Data Sampling

The OSPI provides flexibility to configure the sampling point of read data with the SPI clock to meet setup and hold timings of the flash devices when operating at higher speed. The OSPI_RDC register provides an option to control the sampling point. In OSPI controller, data received on the OSPI pins is sampled by internal reference clock (OSPI_REFCLK). In STR mode, by default (when the OSPI_RDC.DLYRD = 0), the incoming data is on the first falling edge of the OSPI_REFCLK in second half of SPI clock. In DTR mode, it is on the first falling edge of the OSPI_REFCLK in second quarter of SPI clock.

The OSPI_RDC.SMPLEDG bit selects the edge of the OSPI_REFCLK, in which data from flash memory are sampled. This increases the sampling resolution by two times. The OSPI_RDC.DLYRD field controls the additional number of OSPI_REFCLK cycles that must be applied to the internal read data capture circuit. Large clock-to-out delay of the flash memory, trace delays, and other device delays may impose an upper limit on the flash clock frequency which is less for the flash memory to operate. To compensate this, software must set this register to a value that guarantees robust data captures.

For example, if baud divider (OSPI_CTL.BAUD field) is programmed to 7, it results in divider of 16. Therefore, SPI_CLK: OSPI_REFCLK = 16:1 (every 1 SPI_CLK cycle has 16 OSPI_REFCLK cycles). Assuming that the OSPI_RDC.DLYRD bits are programmed to X,

In STR mode of operation, received data is captured on:

- (16/2) + X^{th} falling edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 0
- (16/2) + X^{th} rising edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 1

In DTR mode of operation, received data is captured on:

- (16/4) + X^{th} falling edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 0
- (16/4) + X^{th} rising edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 1

To improve the hold timing during transfers in DTR mode, the OSPI_RDC.DDRDLYRD delays the transmitted data by programmable number of OSPI_REFCLK cycles.

NOTE: The OSPI interface for Octal DTR mode may not work at higher frequencies for flash devices that require DQS.

PHY Module Architecture

The PHY Module is divided into the following four sub-blocks:

- Data Transmitter

  The data transmitter serializes the transmit data to assign complaint signal values into the controller output interface. The input data size is 2-bytes in order to cover the octal DDR scenario where two bytes are sent within a single reference clock cycle. The configuration interface covers selected SPI protocols (single, dual, quad, or octal) or command types (DDR, SDR). These values are necessary to calculate the number of bits that fit into a clock cycle and consequently what set value must be set by the hardware.

- Data Receiver

  The data receiver block samples data from flash device.

- Delay Line Module

  The delay line module block provides an appropriate delay for the input clock to ensure correct data transmitting and sampling. This block contains two separate delay paths for the OSPI clock, one feeding the external FLASH device and the other feeding the internal PHY sampling clock used for capturing data from the device when the PHY mode is enabled. Delay line values are configurable in software.

- Clock Arbiter

  The clock arbiter handles gating the clock logic for clocks forwarded to the DLL inputs.

The PHY Module Block Diagram shows the sub-blocks in the PHY module. The sections following the diagram describe the architecture of the sub-blocks in more detail.

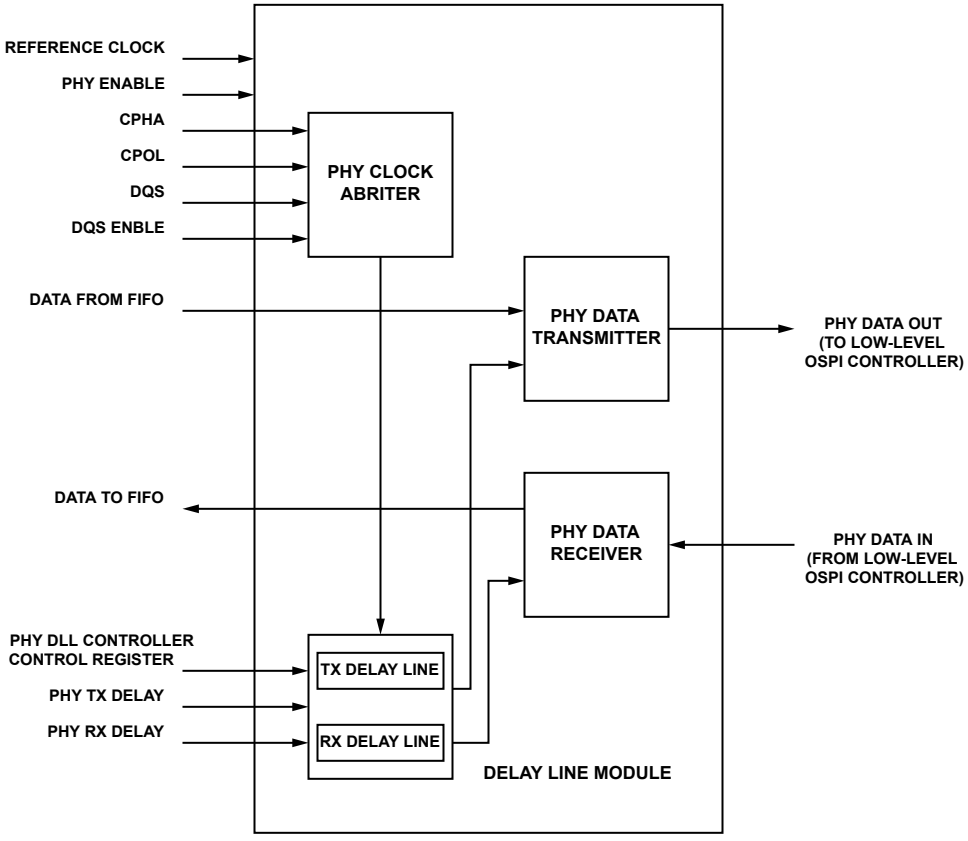

Figure 21-2: PHY Module Block Diagram

PHY Data Transmitter

The data transmitter latches queued data to transmit on both the negative and positive edges of the reference clock. Then data is chopped to fit into the output interface. With the PHY module, in the last stage of the TX data path data from both edges are connected, forwarded back to the low-level OSPI controller, and then put on the OSPI

controller outputs if the PHY enable bit is asserted. Otherwise, the controller outputs generated by the low-level OSPI controller are selected.

PHY Data Receiver

In the data receiver module, data is sampled on both edges of the delayed reference clock (sampling clock) ensuring a wide range of the sampling window. Read data is gathered in shift registers and then merged into a byte-sized input FIFO. Data reception is programmable to work either with the delayed reference clock or with the DQS input signal from the flash device.

Delay Line Module

Due to the asynchronous nature of flash devices, it is important to address the timing requirements for capturing and receiving data between the controller and the flash. The PHY module contains logic to meet the timing requirements. The delay compensation circuit is designed with the following features:

- Programmable OSPI clock delay specified as a percentage of a clock cycle
- Programmable sampling clock delay specified as a percentage of a clock cycle
- Delay compensation circuit re-sync circuitry activated during refresh cycles to compensate for temperature and voltage drift

The delay compensation circuitry relies on a controller/target approach. The controller delay line is used to determine how many delay elements constitute a complete cycle. This count, along with the programmable fractional delay settings, determines the actual number of delay elements to program into the target delay lines. The controller and target delay lines are identical. This approach allows the memory controller to observe a clock and then delay other signals by a fixed percentage of that clock.

DLL Locking is controlled through the register interface. When the DLL is reset, the controller DLL performs a locking procedure starting with the DLL start point value in the `OSPI_PHYMCTL.INITDLY` bit field and the current frequency of operation. The DLL start point value must not exceed a delay of 1 and 1/4 cycles of delay, when calculated by estimating the worst case timing through a delay element at the highest frequency the DLL will be operating at. For example, if the maximum operating frequency is 200 MHz (period of 5 ns) and the worst case delay element has a 85 ps delay, then program the DLL start point to 5 / 0.085 = 58.8 = 59 elements = 0x3B.

With this setting, the controller DLL is will correctly lock for all frequencies below 200 MHz and in any process corner. If the delay provided by the delay line is enough to cover a full clock cycle, the controller DLL is in full clock mode. In this case, the DLL lock value in the `OSPI_DLLOB_LWR.LWRLOCK` bit field reports the number of delay element in one full clock cycle. The target delay line fractional setting uses this number to determine the number of delay elements to add to the target delay lines. For example, if the DLL lock value = 50 = 0x32, then the target delay line percentage = 25% = 0x20, and the target delay line delay value = 50 × 0.25 = 12.5 elements. The DLL Module will round the calculated value into an integer number of delay elements.

If the frequency of operation is such that the delay line is not long enough to accommodate a full cycle of delay, the controller DLL will automatically detect this and switch to half clock mode. In this mode, the controller DLL attempts to lock when the delay in the delay line reaches a half-clock cycle. If lock is achieved in half clock mode, the

target delay lines are automatically adjusted to program a fractional delay of a full cycle. There is no need to change the target delay settings based upon the lock mode of the controller DLL. For example, if the DLL lock value = 50 = 0x32, then the target delay line percentage = 25% = 0x20, and the target delay line delay value = (50 2) × 0.25 = 25 elements. Do not work in half clock mode when using a loop-back sampling method or when the SPI clock is configured to SPI Mode 3 (CPHA =1, CPOL =1).

If the frequency of operation is such that the delay line is not long enough to capture a half-clock cycle of delay, the controller DLL will indicate lock and set the number of delays to the maximum length of the delay line. This is called saturation mode. There is no need to change the target delay settings in this mode. The target delay settings will be fixed at the fractional delay based upon the maximum delay of the delay line times 2. For example, if the DLL lock value = MAX = 128 = 0x80, and the target delay line percentage = 25% = 0x20, then the target delay line delay value = (128 × 2) × 0.25 = 64 elements.

PHY Clock Arbiter

The OSPI clock is generated only when the SPI control logic FSM indicates that an SPI transfer is ongoing. Conversely, the reference clock is continuously generated. This module generates a sampling clock that is ready to pass through the RX delay line. It is generated when read data phase of SPI transfer is detected based on information from the SPI control module. The sampling clock is optionally sourced from DQS or loop-back input.

PHY Pipeline Mode

The PHY pipeline mode is for a direct read mode of operation. The flash command generator pipelines and puts a few expected sequential accesses into the TX FIFO causing the CS to stay active since the low-level OSPI controller controls the internal TX FIFO fill level. To correctly trigger a direct read in pipeline mode, first poll the `OSPI_CTL.IDLE` bit to determine that the TX FIFO is empty. The sequential data transfer is interrupted when non-sequential access occur or too many wait states are introduced by the SPB controller to keep the flash transaction continuous. Introducing wait states slows down the system data rate.

Enable this mode when following conditions are met:

- SYSCLK > 1.1 × OSPI_REFCLK

  NOTE: In PHY mode the reference clock is taken from the CDU CLKO10

- Accesses are only 32-bits in size

Programming Concepts

Software configures the OSPI controller before communicating with the flash device. The static configuration bits must be setup before the OSPI controller is enabled using the `OSPI_CTL.EN` field. To change the controller configuration, disable it before reconfiguring.

Configuring OSPI after Reset

The OSPI controller comes up with a state that is suitable to perform basic reads and writes using the DAC. Basic read (opcode 0x03) and write (opcode 0x02) instructions are supported by all target devices. The controller also wakes up with a baud rate divider setting of 32. Assuming that the reference clock operates at 500 MHz after reset, the effective SPI clock is 15.625 MHz. This must be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the OSPI_DSCTL register must be modified to the appropriate size. If software wants writes to the device and the number of bytes per device page is not equal to 256, the OSPI_DSCTL register must also be modified. The software must enable the write protect feature prior to enabling the OSPI controller. This blocks any AHB writes from taking effect. The OSPI_WRPROT_LWR, OSPI_WRPROT_UP, OSPI_WRPROT_CTL, and OSPI_DSCTL.PGSZ fields must be setup.

After reset, software can read from and write to the flash device. Enabling/disabling the controller and DAC is achieved by writing to the corresponding OSPI_CTL register fields. Maintain the default values of the baud rate divisor and default state of the OSPI_CTL.CPOL/ OSPI_CTL.CPHA bits. A write data value of 0x00780081 is recommended.

Programming Dummy Cycles

When programming the dummy cycles for OSPI reads (DAC and STIG-initiated reads) from the flash device, mode data should be considered as it impacts the actual number of dummy cycles seen on the bus. If mode data is not enabled, then the number of dummy cycles is that same as those set in dummy cycles field, respectively, for STIG or DAC operation.

However, if mode data is enabled, then in addition to the programmed number of dummy cycles, a few extra cycles are needed to transmit out the mode data. The number of cycles added depends on the bus mode of the OSPI. For example, if the address phase of the command is configured to be sent on a single line in STR mode, then the mode bits consume eight cycles. If the address phase of the command is configured to be sent on four lines in DTR mode, then the mode bits consume one cycle. These extra cycles should be considered when configuring the dummy cycles for the controller so the overall dummy clock cycles match the dummy cycles provided in flash data sheet.

Configuring OSPI for Optimal Use

Software must accurately configure the controller to optimally access the flash.

To configure the controller:

1. Wait until pending STIG are completed or poll the OSPI_CTL.IDLE field.
2. Disable the OSPI_CTL.DACEN field. The OSPI controller can be completely disabled using the OSPI_CTL.EN field.
3. Update the OSPI_DLY register. This register allows the user to tweak how the chip select is driven after each flash access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become critical. The numbers programmed in this register are based on the period of OSPI_REFCLK.

For example, an ATMEL device needs 50 ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller providea a minimum of 1 SCLK period. When the device is operating at 50 MHz, the SCLK period is only 20 ns. Therefore, additional 30 ns are required. As the register defines the number of OSPI_REFCLK cycles to add, if OSPI_REFCLK is running at 500 MHz (2 ns period), user must program a value of at least 15 to the `OSPI_DLY.DSRT` bits. This delay can be extended during auto-polling phase. Polling repetition delay can be defined in the `OSPI_WCCTL.REPDLY` field.

4. Update the `OSPI_DSCTL` register. The number of bytes per page is required to perform any write operation on flash. The number of bytes per device block is only required if the write protect feature is used.
5. Setup and enable the write protection registers (`OSPI_WRPROT_LWR`, `OSPI_WRPROT_UP`, and `OSPI_WRPROT_CTL`), if write protection features are required.
6. Enable the required interrupts using the `OSPI_IMSK` register.
7. Update the `OSPI_REMAPADDR` register to remap the DAC addresses to different address in flash.
8. Set the baud rate divisor in the `OSPI_CTL.BAUD` to define the required clock frequency of the target device.
9. Select the appropriate chip select signal to use through the `OSPI_CTL.BAUD` bits.
10. Update the `OSPI_RDC` register. This register delays when read data is captured and helps when read data path from the device to the controller is long and the device clock frequency is high.
11. Enable the OSPI controller and DAC using the `OSPI_CTL` register.

Configuring OSPI for DAC Read Operation

1. Configure the `OSPI_DRICTL` register:
    a. Program the desired opcode for Read command (0xBB for Dual SPI read).
    b. Configure th instruction type, address transfer type, and data transfer type as per the opcode.
    c. Configure the dummy cycles for the selected command opcode depending on the flash device.
    d. Set the Mode bit Enable if the mode data needs to be transferred during dummy cycles phase.
    e. Set the DDR enable bit if the command works in DTR mode.
2. If the operation requires dual opcode, set the `OSPI_CTL.OPCODEEN` bit.
3. Update the second byte for read opcode in the `OSPI_OE_LWR.XRDBYT` field.
4. To operate in DTR protocol mode, set the `OSPI_CTL.DTREN` bit.

   If this bit is set, the `OSPI_DRICTL.DDREN` bit has no effect and all phases of command including the opcode are done in DDR mode.
5. Update the `OSPI_DSCTL.ADDRSZ` field.
6. Update the `OSPI_MBCTL.MODE` field.

7. Enable the DAC mode using the OSPI_CTL.DACEN bit, if not enabled.
8. Start the read transfer by accessing the OSPI memory mapped space through core or MDMA accesses. Any access to address 0x60000000 will access the flash address 0x0 if address remapping is 0.
9. If using MDMA for the transfer, wait for the DMA to complete.

NOTE: For accesses through core, software need not check FIFO levels. All the FIFOs are internally maintained by DAC.

Configuring OSPI for DAC Write Operation

1. Configure the OSPI_DWICTL register:
   a. Program the desired opcode for write command like 0x02 for single SPI page program.
   b. Configure the address transfer type and data transfer type as per the opcode.
   c. Configure the dummy cycles for selected command opcode depending on the flash device.
2. Update the OSPI_DRICTL.INSTRTYP field as per the selected opcode.
3. Clear the OSPI_DWICTL.WELDIS bit to manually send the WEL (Write Enable) instruction to flash. Else, the controller automatically issues WEL to flash before sending any write command to flash.

   If WEL command for flash under use is not 0x06, update the OSPI_OE_UP.FSTBYTWEL field.
4. If the operation requires dual opcode, set the OSPI_CTL.OPCODEEN bit.
5. Update the second byte for read opcode in the OSPI_OE_LWR.XWRBYT field.
6. Update the number of address bytes the command expects in the OSPI_DSCTL.ADDRSZ field.
7. As the controller supports the automatic polling for write operation complete, update the OSPI_WCCTL register accordingly to enable the automatic polling for flash program operation complete.
   a. Enable the automatic polling by clearing the OSPI_WCCTL.DIS bit.
   b. Update Polling opcode and define polling bit index and polarity as per the flash device.
   c. Update polling count and polling repetition delay.
   d. Optionally, update the OSPI_POLLEXP register if polling expiration is enabled.
8. Enable the DAC mode using the OSPI_CTL.DACEN, if not enabled.
9. Start the read transfer by accessing the OSPI memory mapped space through core or MDMA accesses. Any access to address 0x60000000 will access the flash address 0x0 if address remapping is 0.
10. Wait for the DMA to complete, if using MDMA for the transfer.

NOTE: For accesses through core, software need not check FIFO levels. All FIFOs are internally maintained by DAC.

Issuing STIG Command

This is a typical method that software uses to access the flash device registers and perform erase operations. It can also be used to access the flash array (though only 8 data bytes can be read or written at a time), as defined in the OSPI_FCRD_LWR, OSPI_FCWD_LWR, OSPI_FCRD_UP and, OSPI_FCWD_UP registers.

To issue a STIG command:

1. Set the OSPI_IMSK.STIGREQ_MSK bit to enable the STIG command completion interrupt.
2. Update the OSPI_FCCTL.OPCODE and OSPI_FCCTL.DMY bits, as per the flash command that need to be executed via STIG.
3. Clear the OSPI_FCCTL.STIGBNKEN bit.
4. Set the OSPI_FCCTL.ADDREN bit, if the command requires the address to be driven.

   If set:

   a. Update the OSPI_FCCTL.ADDRSZ field according to the number of address bytes expected by the command.

   b. Update the OSPI_FCA register with the desired flash address.
5. If command expects the data to be sent to flash, set the OSPI_FCCTL.WREN bit.

   If set:

   a. Update the OSPI_FCCTL.WRSZ field according to the number of data bytes to be sent to flash.

   b. Update the OSPI_FCWD_LWR and OSPI_FCWD_UP registers with data to be sent to flash.
6. If command expects the data to be received from the flash, set the OSPI_FCCTL.RDEN bit.

   If set, update the OSPI_FCCTL.RDSZ field according to the number of data bytes to expected from flash.
7. Update the OSPI_FCCTL.MODEEN bit, if the mode data are sent during dummy cycles.

   If set, update the OSPI_MBCTL.MODE field with desired mode data.
8. Set the OSPI_FCCTL.EXE bit to execute the STIG command.
9. Set the OSPI_ISTAT.STIGREQ bit (or wait for interrupt if enabled) indicating that the STIG command execution is completed.
10. If command expects the data to be received from the flash, read the data from the OSPI_FCWD_LWR and OSPI_FCWD_UP registers.

NOTE: Do not set the OSPI_FCCTL.WREN and OSPI_FCCTL.RDEN bits simultaneously. A given command can either read data or send data to the flash, but not both at the same time.

With normal STIG command, only 8 bytes can be read at a time, but with support of STIG memory bank up to 16 bytes can be read in to STIG memory bank. This is controlled by the OSPI_FCCTL.STIGBNKEN bit and

OSPI_FCMCTL register. Commands issued using this interface have a higher priority than all other read accesses coming from AHB, and interrupts any read commands being requested by the DAC.

To issue a STIG memory bank read command:

1. Set the OSPI_IMSK.STIGREQ_MSK bit to enable STIG command completion interrupt.
2. Update the OSPI_FCCTL.OPCODE and OSPI_FCCTL.DMY bits as per the flash command that need to be executed via STIG.
3. Set the OSPI_FCCTL.STIGBNKEN bit.
4. Set the OSPI_FCCTL.ADDREN bit, if the command requires the address to be driven.

   If set:

   a. Update the OSPI_FCCTL.ADDRSZ field according to the number of address bytes expected by the command.

   b. Update the OSPI_FCA register with the desired flash address.
5. Update the OSPI_FCCTL.MODEEN bit, if the mode data are sent during dummy cycles.

   If set, update the OSPI_MBCTL.MODE field with the desired mode data.
6. Set the OSPI_FCCTL.EXE bit to execute the STIG command.
7. Set the OSPI_ISTAT.STIGREQ bit (or wait for interrupt if enabled) indicating that the STIG command execution is completed.

At this stage, 16 bytes of data read from the flash device are available in the STIG memory bank. To access this data, a STIG memory bank read has to be issued. Each read can read one byte form STIG memory bank at a time. To read all data, 16 reads must be issued.

To read a data byte from STIG memory bank:

1. Set the OSPI_FCMCTL.BNKADDR field. This can be any value from 0 to 16.
2. Set the OSPI_FCMCTL.TRIGREQ bit to trigger the STIG memory bank read.
3. Poll the OSPI_FCMCTL.BNKREQ bit to clear.
4. Read the requested data byte from the OSPI_FCMCTL.BNKDATA.

Entering XIP mode

The controller supports XIP operations to minimize the latency for back-to-back reads or code execution.

If the flash device comes in XIP on power up, software cannot discover the state of XIP from POR via the Flash Status Register reads. The only operation of a flash device when XIP mode is enabled, is an XIP read. In such cases, software must be aware that if flash enters XIP from POR, the OSPI_MBCTL.MODE and OSPI_CTL.XIPIMM fields must be set. This makes the controller to enter XIP mode immediately and start communicating with the flash

device in XIP mode on next read issued. Therefore, it does not require the read opcode to be transferred. To exit XIP mode, this bit must be set to 0. This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited.

`OSPI_CTL.XIPRD`: If it is not known that the flash device enters XIP from POR, and XIP from POR may be supported by the attached flash device, software can attempt to exit the XIP mode by issuing an XIP exit command using a STIG command. For this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

XIP mode is supported in several flash devices. However, flash manufacturers do not have a consistent standard approach. Most of them use signature bits that are sent to the device immediately following the address bytes. Few of them (such as Micron devices) use signature bits and require a flash device configuration register write to enable XIP.

The following section describes how software ensures entry into XIP mode for the flash devices compliant with the OSPI controller.

Micron N25Q, MT25Q, and MT35X Devices

XIP mode must first be enabled by setting the corresponding field of VCR within the flash device. The VCR can be written to using the `OSPI_FCCTL` register to issue a VCR write command.

1. Disable the DAC using the `OSPI_CTL.DACEN` bit to ensure that no new AHB read accesses are sent to the flash device.
2. Use STIG mode to issue a VCR write to flash memory.
3. Set XIP mode bits in the `OSPI_MBCTL.MODE` field to 8'b00000000.
4. Enable the OSPI controller XIP mode by setting the `OSPI_CTL.XIPRD` bit.
5. Re-enable the DAC.

Micron (Supporting Basic XIP Mode), Winbond, Spansion Devices

1. Disable the DAC using the `OSPI_CTL.DACEN` bit to ensure that no new AHB read accesses are sent to the flash device.
2. Set XIP mode bits in the `OSPI_MBCTL.MODE` to:
   - 8'b10000000, for Micron devices supporting basic XIP mode
   - 8'b00100000, for Winbond devices
   - 8'b10100000, for Spansion devices
3. Enable XIP mode by setting the `OSPI_CTL.XIPRD` bit.
4. Reenable the DAC.

Using PHY Mode

The OSPI PHY mode extends the architecture of the OSPI flash controller to allow the interfacing of high-speed flash devices and ensure the reliable data transfers at high speed. For non-PHY operations, the controller assumes that OSPI transfer clock is at least 4 times lower than the reference clock to ensure correct data transactions in SDR mode and 8 times lower for DDR transactions. This provides comfortable regulation of data synchronization but it is not effective from a dynamic power efficiency standpoint.

The PHY mode allows transfers at speeds that match the increasing reference clocks of emerging higher performance flash devices, including frequencies close to 200 MHz. The PHY module works with the OSPI flash controller to enable DDR or SDR transfers at the device frequencies. For example, if a given flash device operates at 200 MHz, the reference clock is also 200 MHz, eliminating the need for high speed peripheral clocks.

The default reference clock (OSPI_REFLK) for OSPI is SYSCLK, but to enable support for PHY mode the reference clock is selected from one of the options from CDU output clock 10 (Refer to the CDU chapter). By default, it is connected to SYSCLK which is suitable for non-PHY mode of operation. For PHY mode, the reference clock (OSPI_REFLK) is either SCLK0_0 or SCLK1_1.

To configure PHY mode, first implement the procedure described in the Configuring OSPI for Optimal Use section and then proceed with the following steps based on the DLL mode configuration:

DLL Bypass Mode

1. Enable the PHY mode by setting the `OSPI_CTL.PHYEN` bit and enable the DDR protocol with the `OSPI_CTL.DTREN` bit.

   NOTE: Ensure that the device is configured to work in DDR Protocol (do not confuse with DDR commands).

2. Calibrate the software using the following sub steps:

   a. Calculate how many delay elements are necessary to shift the reference clock period by 25% and program this value in the `OSPI_PHYCTL.TXDLY` bit field. This is the best case for DDR transfers from the set-up/hold timing standpoint. The delay may vary slightly in a real design.

   b. Resynchronize the DLLs by setting the `OSPI_PHYCTL.RESYNC` bit. If this has already been set by a previous resynchronization, toggle the bit to 0 and then back to 1 to trigger the re-synchronization DLL logic.

   c. Enable the PHY bypass mode by setting the `OSPI_PHYMCTL.BYPCTL` bit.

   d. Trigger a read request from a location where the value is predictable. Depending on the device, this is the parameter page, ID, status, data from the OTP region, or data from the location of the flash array.

   e. Check for data correctness by incrementing the value of the RX clock delay using the `OSPI_PHYCTL.RXDLY` bit field, resynchronizing the DLLs, triggering a valid read request, and then checking for the correct data and store information. Continue to check until the range boundary of the RX clock delay is achieved and then proceed to the next step.

3. Set the RX clock delay value with one from the middle of valid range based on the information in storage.
4. Resynchronize the DLLs
5. Set the device read instruction register for Octal Read DDR Configuration. Configure each transfer phase to work in octal mode and set the number of dummy cycles to a minimum of the number specified in the documentation of the device. More dummy cycles may be set to accommodate additional read path delays in actual systems data.
6. Enable pipeline mode by setting the `OSPI_CTL.PIPEPHYEN` bit.
7. Perform a sequential read of data consistent with the conditions indicated in the PHY Pipeline Mode section.
8. Poll for IDLE with the `OSPI_CTL.IDLE` bit and when it is asserted to high trigger the next transfer request.

DLL Controller Mode

1. Enable the PHY mode by setting the `OSPI_CTL.PHYEN` bit and enable the DDR protocol with the `OSPI_CTL.DTREN` bit.

   NOTE: Ensure that the device is configured to work in DDR protocol (do not confuse with DDR commands).

2. Calibrate the software using the following sub steps:
   a. Drive the `OSPI_CTL.RST` bit low to reset the DLL.
   b. Calculate initial delay value for the controller DLL according to the PHY DLL controller control register bits[6:0] and write this value into the `OSPI_PHYMCTL.INITDLY` bit field.
   c. Set DLL reset bit (`OSPI_CTL.RST`) back to high. The controller delay line automatically starts the locking procedure with the configuration given once the DLL module is in reset state.
   d. Poll the `OSPI_DLLOB_LWR.LOCK` bit. When it is set, the lock is done.
   e. Resynchronize the DLLs by setting the `OSPI_PHYCTL.RESYNC` bit. If this has already been set by a previous resynchronization, toggle the bit to 0 and then back to 1 to trigger the re-synchronization DLL logic.
   f. Set the TX DLL delay bit field (`OSPI_PHYCTL.TXDLY`) and the RX DLL delay bit field (`OSPI_PHYCTL.RXDLY`) to the current percentage clock offsets. Wait 20 reference clock cycles for the new configuration to propagate before triggering the next SPI transfer.
   g. Trigger a read request from a location where the value is predictable. Depending on the device, this is the parameter page, ID, status, data from the OTP region, or data from the location of the flash array.
   h. Check for data correctness by incrementing the value of the RX clock delay using the `OSPI_PHYCTL.RXDLY` bit field, resynchronizing the DLLs, triggering a valid read request, and then checking for the correct data and store information. Continue to check until the range boundary of the RX clock delay is achieved and then proceed to the next step.

3. Set the RX clock delay value with one from the middle of valid range based on the information in storage.
4. Resynchronize the DLLs
5. Set the device read instruction register for octal read DDR configuration. Configure each transfer phase to work in octal mode and set the number of dummy cycles to a minimum of the number specified in the documentation of the device. More dummy cycles may be set to accommodate additional read path delays in actual systems data.
6. Enable pipeline mode by setting the `OSPI_CTL.PIPEPHYEN` bit.
7. Perform a sequential read of data consistent with the conditions indicated in the PHY pipeline Mode section.
8. Poll for IDLE with the `OSPI_CTL.IDLE` bit and when it is asserted to high trigger the next transfer request.

ADSP-2159x OSPI Register Descriptions

Octal SPI (OSPI) contains the following registers.

Table 21-5: ADSP-2159x OSPI Register List

Name	Description
OSPI_CTL	Octal SPI Control Register
OSPI_DLY	Device Delay Register
OSPI_DRICTL	Device Read Instruction Control Register
OSPI_DWICTL	Device Write Instruction Control Register
OSPI_DSCTL	Device Size Control Register
OSPI_DLLOB_LWR	DLL Observable Register (Lower)
OSPI_DLLOB_UP	DLL Observable Register (Upper)
OSPI_FCA	Flash Command Address Register
OSPI_FCCTL	Flash Command Control Register
OSPI_FCMCTL	Flash Command Control Memory Register
OSPI_FCRD_LWR	Flash Command Read Data Register (Lower)
OSPI_FCRD_UP	Flash Command Read Data Register (Upper)
OSPI_FCWD_LWR	Flash Command Write Data Register (Lower)
OSPI_FCWD_UP	Flash Command Write Data Register (Upper)
OSPI_IMSK	Interrupt Mask Register
OSPI_ISTAT	Interrupt Status Register
OSPI_WRPROT_LWR	Lower Write Protection Register
OSPI_MBCTL	Mode Bit Control Register
OSPI_MODID	Module ID Register

Table 21-5: ADSP-2159x OSPI Register List (Continued)

Name	Description
OSPI_POLLEXP	Polling Expiration Register
OSPI_OE_LWR	Opcode Extension Register (Lower)
OSPI_OE_UP	Opcode Extension Register (Upper)
OSPI_PHYCTL	PHY Control Register
OSPI_PHYMCTL	PHY DLL Master Control Register
OSPI_POLSTAT	Polling Flash Status Register
OSPI_RDC	Read Data Capture Register
OSPI_REMAPADDR	Remap Address Register
OSPI_WRPROT_UP	Upper Write Protection Register
OSPI_WRPROT_CTL	Write Protection Control Register
OSPI_WCCTL	Write Completion Control Register

Octal SPI Control Register

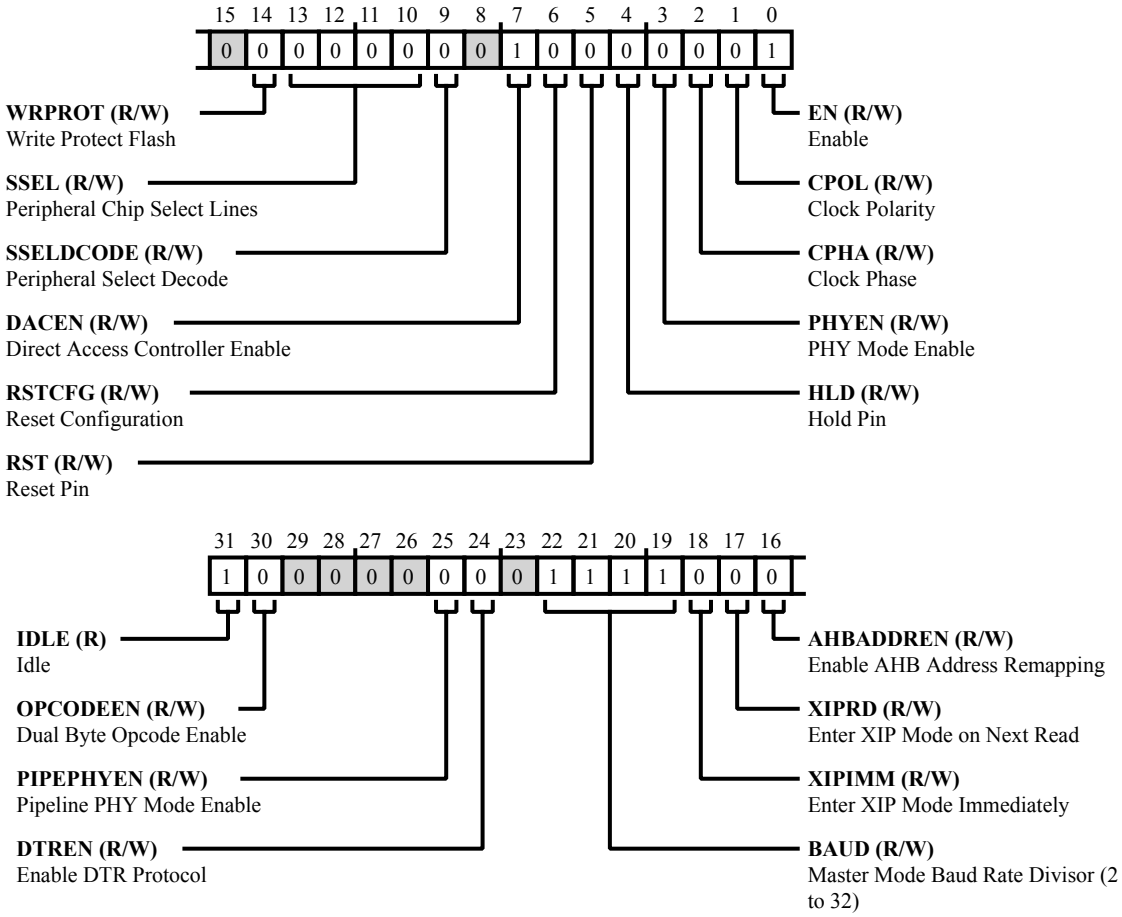

Figure 21-3: OSPI_CTL Register Diagram

Table 21-6: OSPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	IDLE	Idle. Serial interface and low level SPI pipeline is idle. This is a status read-only bit. Note: This is a re-timed signal. There is an inherent delay in generating this signal.
30 (R/W)	OPCODEEN	Dual Byte Opcode Enable. The `OSPI_CTL.OPCODEEN` bit is set if the target Flash device supports dual byte opcode (Macronix MX25). It is applicable for Octal I/O mode or protocol only. It should be set back to low if the device is configured to work in another SPI Mode. If enabled, the supplementing bytes are taken from the `OSPI_OE_LWR` and `OSPI_OE_UP` registers.

Table 21-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	PIPEPHYEN	Pipeline PHY Mode Enable. The `OSPI_CTL.PIPEPHYEN` bit is relevant only for configuration with PHY module. It is asserted to 1 between consecutive PHY pipeline reads transfers and deasserted to 0 otherwise.	
24 (R/W)	DTREN	Enable DTR Protocol. The `OSPI_CTL.DTREN` bit enables the DTR protocol. It must be set if the device is configured to work in DTR protocol.	
22:19 (R/W)	BAUD	Master Mode Baud Rate Divisor (2 to 32). The `OSPI_CTL.BAUD` bit field selects the baud rate divisor. SPI Baud Rate = (Master Reference Clock)/ Baud Rate Divisor where, Baud Rate Divisor is: 4'b0000 = /2 4'b0001 = /4 4'b0010 = /6 4'b0011 = /8 4'b0100 = /10 ... 4'b1111 = /32	
18 (R/W)	XIPIMM	Enter XIP Mode Immediately. If XIP is enabled, setting to 0 causes the controller to exit XIP mode on the next read instruction. If set to 1, operate the device in XIP mode immediately. Use this register when the external device wakes up in XIP mode (as per the contents of its non-volatile configuration register). The controller assumes the next read instruction is passed to the device as an XIP instruction, and therefore does not require the read opcode to be transferred. Note: To exit XIP mode, this bit should be set to 0. This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting this bit (to ensure that XIP mode is exited).	
		0	If XIP is enabled, it causes the controller to exit XIP mode on the next read instruction
		1	Operate the device in XIP mode immediately

Table 21-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	XIPRD	Enter XIP Mode on Next Read. If XIP is enabled, setting to 0 causes the controller to exit XIP mode on the next read instruction. If XIP is disabled, setting to 1 informs the controller that the device is ready to enter XIP on the next read instruction. The controller sends the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register after the controller ensures that the Flash device is configured to enter XIP mode. Note: To exit XIP mode, this bit should be set to 0. This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting this bit (to ensure that XIP mode is exited).	
		0	If XIP is enabled, it cause the controller to exit XIP mode on the next read instruction
		1	If XIP is disabled, this setting informs the controller that the device is ready to enter XIP on the next read instruction
16 (R/W)	AHBADDREN	Enable AHB Address Remapping. The `OSPI_CTL.AHBADDREN` bit enables AHB address remapping (Direct Access Mode only). When set to 1, the incoming AHB address will be adapted and sent to the Flash device as (address + N), where N is the value stored in the remap address register.	
14 (R/W)	WRPROT	Write Protect Flash. The `OSPI_CTL.WRPROT` bit, when set (=1), drives the Write Protect pin of the Flash. This is resynchronized to the generated memory clock, as necessary.	
13:10 (R/W)	SSEL	Peripheral Chip Select Lines. The `OSPI_CTL.SSEL` bit field indicates the peripheral chip select line. If `OSPI_CTL.SSELDCODE` = 0, ss[3:0] is output: ss[3:0] ..... SSEL[3:0] 4'bxxx0.....1110.....SSEL0 selected 4'bxx01.....1101.....SSEL1 selected 4'bx011.....1011.....SSEL2 selected 4'b0111.....0111.....SSEL3 selected 4'b1111.....1111.....No peripheral selected If `OSPI_CTL.SSELDCODE` = 1, ss[3:0] directly drives SSEL[3:0].	

Table 21-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SSELDCODE	Peripheral Select Decode. The OSPI_CTL.SSELDCODE bit indicates the peripheral select decode.	
		0	Only one of the 4 selects n_ss_out [3:0] is active
		1	Allows external 4:16 decode (n_ss_out = ss)
7 (R/W)	DACEN	Direct Access Controller Enable. The OSPI_CTL.DACEN bit enables the Direct Access Controller. When the Direct Access Controller and Indirect Access Controller are disabled, all AHB requested are completed with an error response.	
		0	Disable Direct Access Controller once current transfer of the data word is complete
		1	Enable Direct Access Controller
6 (R/W)	RSTCFG	Reset Configuration. The OSPI_CTL.RSTCFG bit indicates the reset pin configuration.	
		0	Reset Feature on DQ3 Pin of the Device
		1	Reset Feature on Dedicated Pin of the Device (Controlling the 5th bit Influences the Output)
5 (R/W)	RST	Reset Pin. The OSPI_CTL.RST bit, when set (=1), drives the Reset pin of the Flash and is reset to deactivate the Reset pin.	
4 (R/W)	HLD	Hold Pin. The OSPI_CTL.HLD bit, when set (=1), drives the Hold pin of the Flash and reset to deactivate the Hold pin.	
3 (R/W)	PHYEN	PHY Mode Enable. When the OSPI_CTL.PHYEN bit is enabled, the controller is informed that PHY module is to be used for handling SPI transfers. This bit is relevant only for configuration with PHY module.	
2 (R/W)	CPHA	Clock Phase. The OSPI_CTL.CPHA bit selects the clock phase.	
		0	SPI clock is active outside the word
		1	SPI clock is inactive outside the word
1 (R/W)	CPOL	Clock Polarity. The OSPI_CTL.CPOL bit selects clock polarity outside SPI word.	
		0	OSPI clock is quiescent low
		1	OSPI clock is quiescent high

Table 21-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The `OSPI_CTL.EN` bit enables OSPI operation.	
		0	Disable OSPI Module
		1	Enable OSPI Module

Device Delay Register

This register introduces relative delays in the generation of the master output signals. All timings are defined in cycles of the SPI REFERENCE CLOCK/ext_clk.

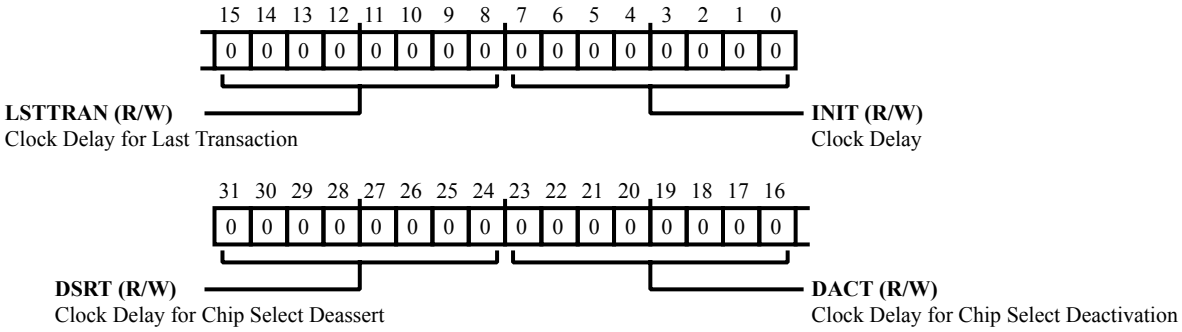

Figure 21-4: OSPI_DLY Register Diagram

Table 21-7: OSPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	DSRT	Clock Delay for Chip Select Deassert. Delay in master reference clocks for the length that the master mode chip select outputs are de-asserted between transactions. The minimum delay is always SCLK period to ensure the chip select is not asserted again within an SCLK period.
23:16 (R/W)	DACT	Clock Delay for Chip Select Deactivation. Delay in master reference clocks between one chip select being de-activated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.
15:8 (R/W)	LSTTRAN	Clock Delay for Last Transaction. Delay in master reference clocks between last bit of current transaction and de-asserting the device chip select (n_ss_out). By default, the chip select is de-asserted on the cycle following the completion of the current transaction.
7:0 (R/W)	INIT	Clock Delay. Clock delay with n_ss_out. Delay in master reference clocks between setting n_ss_out low and first bit transfer.

Device Read Instruction Control Register

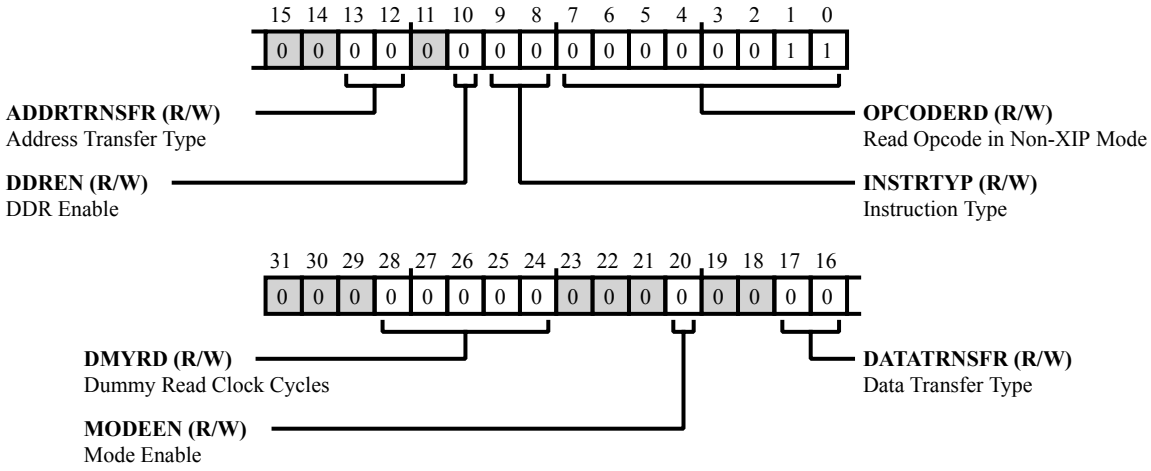

Figure 21-5: OSPI_DRICTL Register Diagram

Table 21-8: OSPI_DRICTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28:24 (R/W)	DMYRD	Dummy Read Clock Cycles. Number of dummy clock cycles required by the device for a read instruction.	
20 (R/W)	MODEEN	Mode Enable. This field is set to 1 to ensure that the `OSPI_MBCTL.MODE` bits are sent following the address bytes.	
17:16 (R/W)	DATATRNSFR	Data Transfer Type. Data transfer type for standard SPI modes.	
		0	SIO Mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Used for Dual Input/Output instructions. For data transfers, DQ0 and DQ1 are used as both inputs and outputs.
		2	Used for Quad Input/Output instructions. For data transfers, DQ0, DQ1, DQ2, and DQ3 are used as both inputs and outputs.
		3	Used for Quad Input/Output instructions. For data transfers, DQ[7:0] are used as both inputs and outputs.

Table 21-8: OSPI_DRICTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	ADDRTRNSFR	Address Transfer Type. Address transfer type for standard SPI modes.	
		0	Addresses can be shifted to the device on DQ0 only.
		1	Addresses can be shifted to the device on DQ0 and DQ1 only.
		2	Addresses can be shifted to the device on DQ0, DQ1, DQ2, and DQ3.
		3	Addresses can be shifted to the device on DQ [7:0]
10 (R/W)	DDREN	DDR Enable. It checks if the opcode from the `OSPI_DRICTL.OPCODERD` field is compliant with one of the DDR read commands. Set this field to 1 when opcode from bits 7 to 0 is compliant with DDR command. Master output data is issued by the controller in DDR fashion starting of the address SPI transfer phase. It is not applicable for STIG Mode.	
9:8 (R/W)	INSTRTYP	Instruction Type. Instruction Type.	
		0	Use standard SPI mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Use DIO-SPI mode. Instruction sent on DQ0 and DQ1.
		2	Use QIO-SPI mode. Instruction sent on DQ0, DQ1, DQ2, and DQ3.
		3	Use OIO-SPI mode. Instruction sent on DQ[7:0].
7:0 (R/W)	OPCODERD	Read Opcode in Non-XIP Mode. Read Opcode to use when not in XIP mode.	

Device Write Instruction Control Register

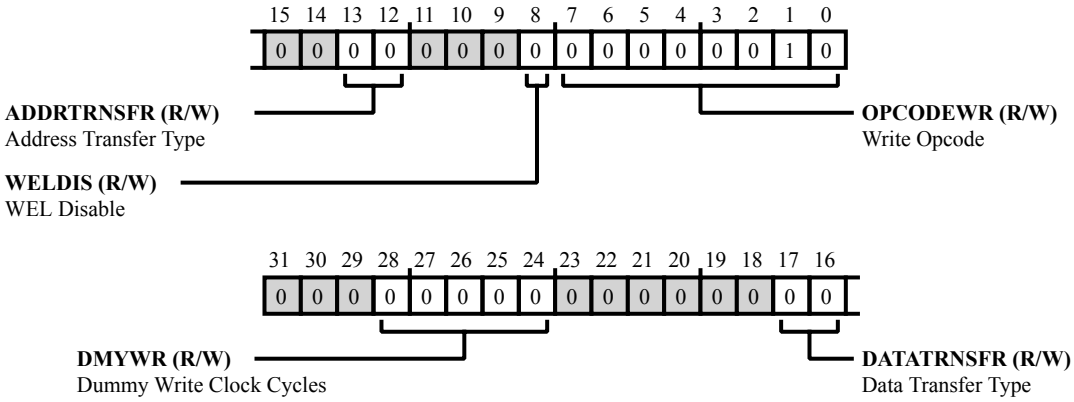

Figure 21-6: OSPI_DWICTL Register Diagram

Table 21-9: OSPI_DWICTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28:24 (R/W)	DMYWR	Dummy Write Clock Cycles. Number of dummy clock cycles required by the device for write instruction.	
17:16 (R/W)	DATATRNSFR	Data Transfer Type. Data transfer type for standard SPI modes.	
		0	SIO Mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Used for Dual Input/Output instructions. For data transfers, DQ0 and DQ1 are used as both inputs and outputs.
		2	Used for Octal Input/Output Instructions. For data transfers, DQ0, DQ1, DQ2, and DQ3 are used as both inputs and outputs.
		3	Used for Octal Input/Output instructions. For data transfers, DQ[7:0] are used as both inputs and outputs.

Table 21-9: OSPI_DWICTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	ADDRTRNSFR	Address Transfer Type. Address transfer type for standard SPI modes.	
		0	Addresses can be shifted to the device on DQ0 only.
		1	Addresses can be shifted to the device on DQ0 and DQ1.
		2	Addresses can be shifted to the device on DQ0, DQ1, DQ2, and DQ3.
		3	Addresses can be shifted to the device on DQ [7:0].
8 (R/W)	WELDIS	WEL Disable. This is to turn off automatic issuing of WEL command before write operation for DAC or INDAC.	
7:0 (R/W)	OPCODEWR	Write Opcode.	

Device Size Control Register

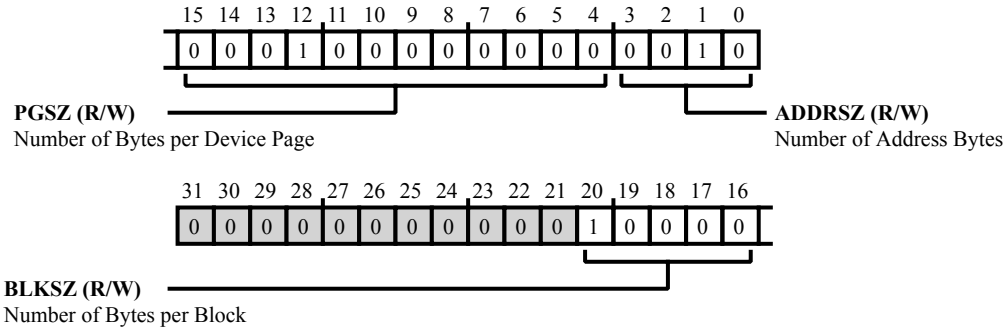

Figure 21-7: OSPI_DSCTL Register Diagram

Table 21-10: OSPI_DSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:16 (R/W)	BLKSZ	Number of Bytes per Block. The controller uses this field to perform write protection logic. The number of bytes per block must be a power of 2. 0: 1 byte 1: 2 bytes 3: 8 bytes ... 16: 65535 bytes and so on
15:4 (R/W)	PGSZ	Number of Bytes per Device Page. The controller uses this field to perform flash writes up to and across page boundaries.
3:0 (R/W)	ADDRSZ	Number of Address Bytes. Defines the address size for DAC mode. A value of 0 indicates 1 byte.

DLL Observable Register (Lower)

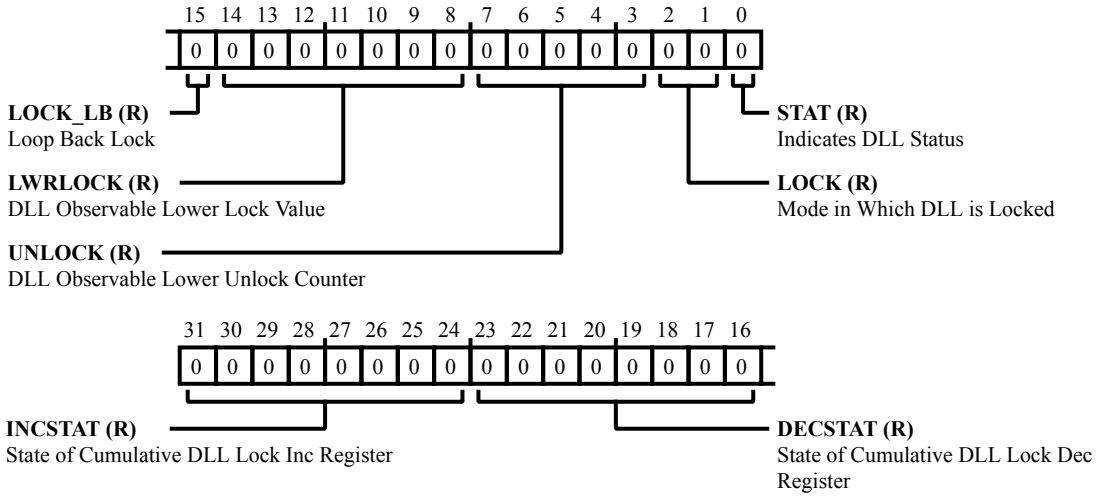

Figure 21-8: OSPI_DLLOB_LWR Register Diagram

Table 21-11: OSPI_DLLOB_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	INCSTAT	State of Cumulative DLL Lock Inc Register. Holds the state of the cumulative dll_lock_inc register.
23:16 (R/NW)	DECSTAT	State of Cumulative DLL Lock Dec Register. Holds the state of the cumulative dll_lock_dec register.
15 (R/NW)	LOCK_LB	Loop Back Lock. This bit indicates that lock of loop back is done.
14:8 (R/NW)	LWRLOCK	DLL Observable Lower Lock Value. Reports the DLL encoder value from the master DLL to slave DLLs.
7:3 (R/NW)	UNLOCK	DLL Observable Lower Unlock Counter. Reports the number of increments or decrements required for the master DLL to complete the locking process.
2:1 (R/NW)	LOCK	Mode in Which DLL is Locked. Defines the mode in which the DLL has achieved the lock.
0 (R/NW)	STAT	Indicates DLL Status.

DLL Observable Register (Upper)

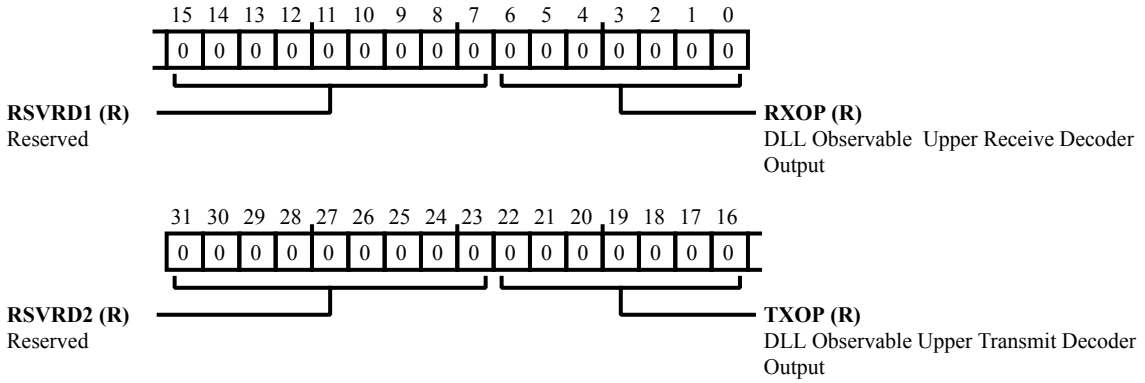

Figure 21-9: OSPI_DLLOB_UP Register Diagram

Table 21-12: OSPI_DLLOB_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:23 (R/NW)	RSVRD2	Reserved. Unused.
22:16 (R/NW)	TXOP	DLL Observable Upper Transmit Decoder Output. Holds the encoded value for the TX delay line for this slice.
15:7 (R/NW)	RSVRD1	Reserved. Unused.
6:0 (R/NW)	RXOP	DLL Observable Upper Receive Decoder Output. Holds the encoded value for the RX delay line for this slice.

Flash Command Address Register

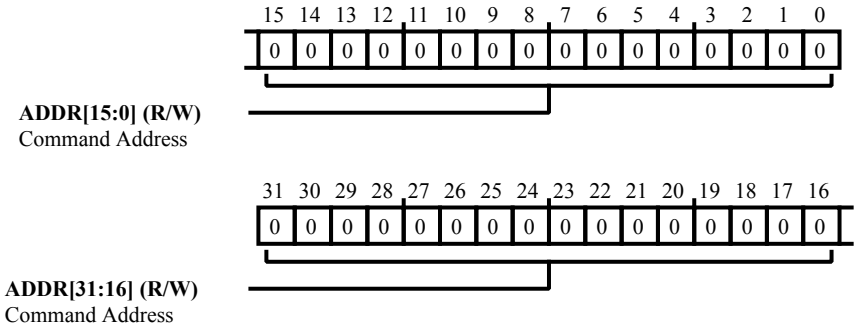

Figure 21-10: OSPI_FCA Register Diagram

Table 21-13: OSPI_FCA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Command Address. It is the address used by the command specified in the `OSPI_FCCTL.OPCODE` field. This must be setup before triggering the STIG command using the `OSPI_FCCTL.EXE` field.

Flash Command Control Register

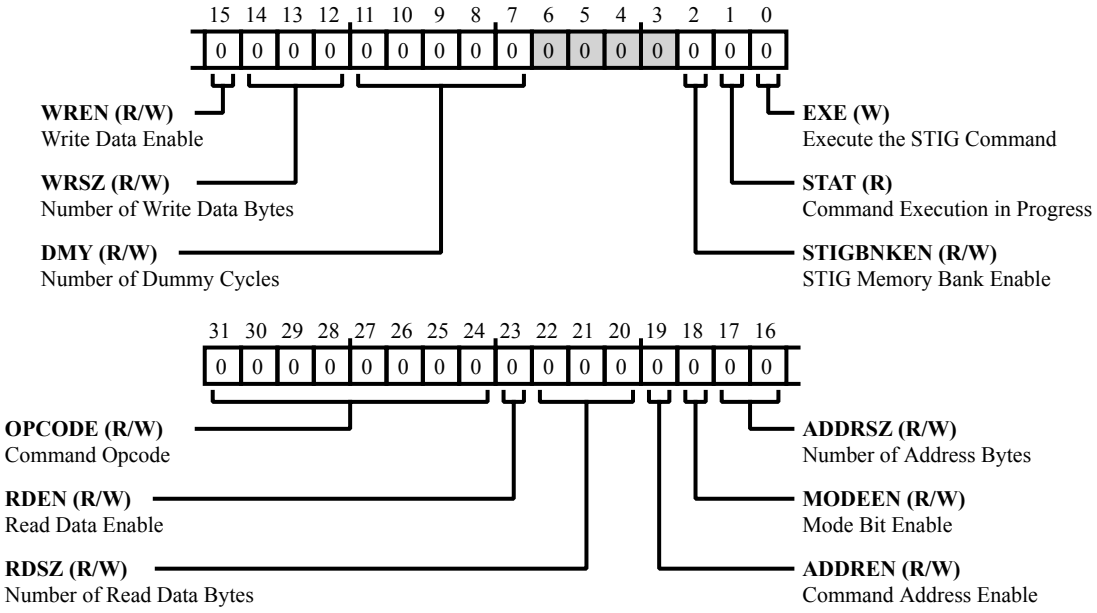

Figure 21-11: OSPI_FCCTL Register Diagram

Table 21-14: OSPI_FCCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	OPCODE	Command Opcode. This field must be set before triggering the STIG command. For example, 0x20 maps to sub sector erase. Writing to the `OSPI_FCCTL.EXE` launches the command. Note: Using this approach, to issue commands to the device will make use of the instruction type of the `OSPI_DRICTL` and `OSPI_DWICTL` registers.	
		0	Command opcode, command address, command dummy bytes, and command data are serially transferred.
		1	Command opcode, command address, command dummy bytes, and command data are transferred in parallel using DQ0 and DQ1 pins.
		2	Command opcode, command address, command dummy bytes, and command data are transferred in parallel using DQ0 , DQ1, and DQ2 pins.
		3	Reserved
23 (R/W)	RDEN	Read Data Enable. Set to 1 if the command specified in the `OSPI_FCCTL.OPCODE` requires read data bytes to be received from the device.	

Table 21-14: OSPI_FCCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:20 (R/W)	RDSZ	Number of Read Data Bytes. Up to 8 data bytes can be read using this command. Set this field to 0 for 1 byte and 7 for 8 bytes.
19 (R/W)	ADDREN	Command Address Enable. Set to 1 if the command specified in the `OSPI_FCCTL.OPCODE` field requires an address. This must be set before triggering the command via writing a 1 to the execute field.
18 (R/W)	MODEEN	Mode Bit Enable. Set this field to 1 to ensure the `OSPI_MBCTL.MODE` field is sent following the address bytes.
17:16 (R/W)	ADDRSZ	Number of Address Bytes. Set to the number of address bytes required (the address itself is programmed in the `OSPI_FCA` register. This must be setup before triggering the command via bit 0 of this register.
		0 — 1 address byte
		1 — 2 address bytes
		2 — 3 address bytes
		3 — 4 address bytes
15 (R/W)	WREN	Write Data Enable. Set to 1 if the command specified in the `OSPI_FCCTL.OPCODE` field requires write data bytes to be sent to the device.
14:12 (R/W)	WRSZ	Number of Write Data Bytes. Up to 8 data bytes may be written using this command. Set to 0 for 1 byte, 7 for 8 bytes.
11:7 (R/W)	DMY	Number of Dummy Cycles. Set to the number of dummy cycles required. This should be setup before triggering the command via the `OSPI_FCCTL.EXE` field.
2 (R/W)	STIGBNKEN	STIG Memory Bank Enable. This bit must be asserted high before triggering the flash memory bank transfer. It must be de-asserted before triggering any other operation. This is set before triggering the command via `OSPI_FCCTL.EXE` field.
1 (R/NW)	STAT	Command Execution in Progress.
0 (RX/W)	EXE	Execute the STIG Command.

Flash Command Control Memory Register

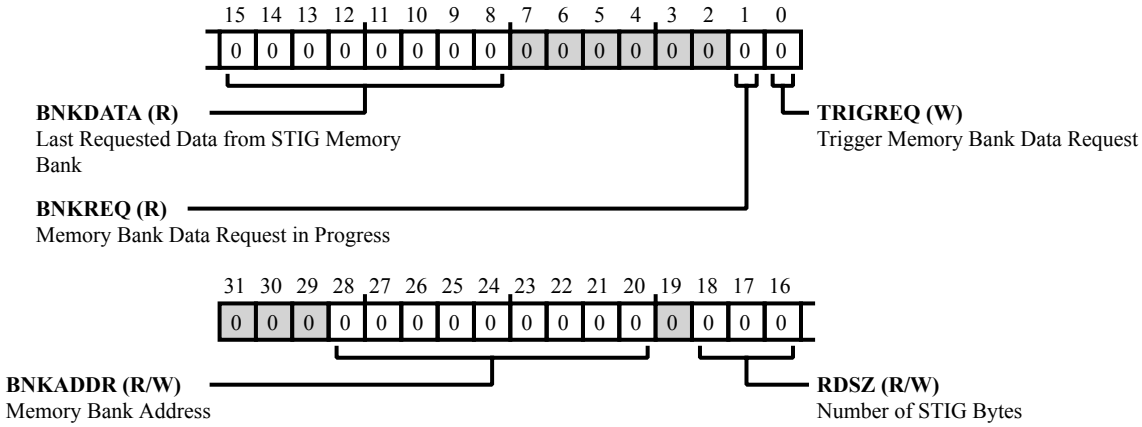

Figure 21-12: OSPI_FCMCTL Register Diagram

Table 21-15: OSPI_FCMCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:20 (R/W)	BNKADDR	Memory Bank Address. The address of the memory bank from which data is read.
18:16 (R/W)	RDSZ	Number of STIG Bytes. It defines the number of read bytes for the extended STIG.
15:8 (R/NW)	BNKDATA	Last Requested Data from STIG Memory Bank.
1 (R/NW)	BNKREQ	Memory Bank Data Request in Progress.
0 (RX/W)	TRIGREQ	Trigger Memory Bank Data Request.

Flash Command Read Data Register (Lower)

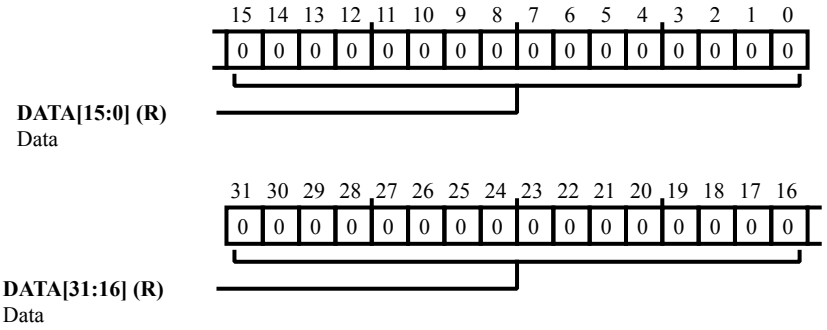

Figure 21-13: OSPI_FCRD_LWR Register Diagram

Table 21-16: OSPI_FCRD_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Data. This is the data that is returned by the flash device for any status or configuration read operation carried out by triggering the STIG event in the `OSPI_FCCTL` register. The register is valid when the `OSPI_FCCTL.STAT` bit is low.

Flash Command Read Data Register (Upper)

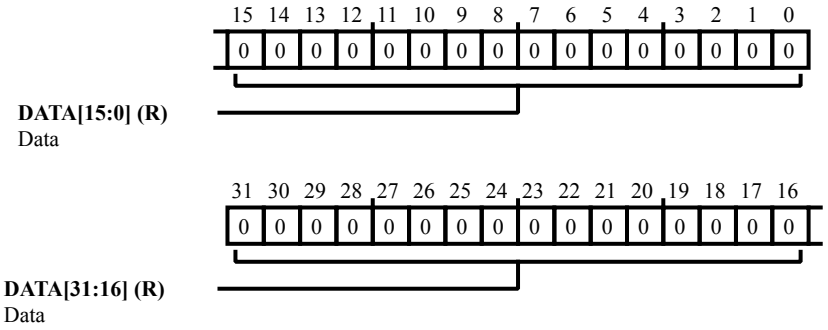

Figure 21-14: OSPI_FCRD_UP Register Diagram

Table 21-17: OSPI_FCRD_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Data. This is the data that is returned by the flash device for any status or configuration read operation carried out by triggering the STIG event in the `OSPI_FCCTL` register. The register is valid when the `OSPI_FCCTL.STAT` bit is low

Flash Command Write Data Register (Lower)

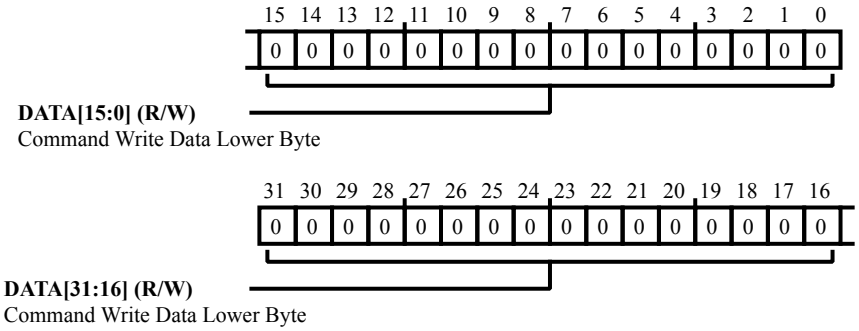

Figure 21-15: OSPI_FCWD_LWR Register Diagram

Table 21-18: OSPI_FCWD_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Command Write Data Lower Byte. It is the data written to the flash for any status or configuration write operation carried out by triggering the STIG event in the `OSPI_FCCTL` register. This must be setup before triggering the command using the `OSPI_FCCTL.EXE` field.

Flash Command Write Data Register (Upper)

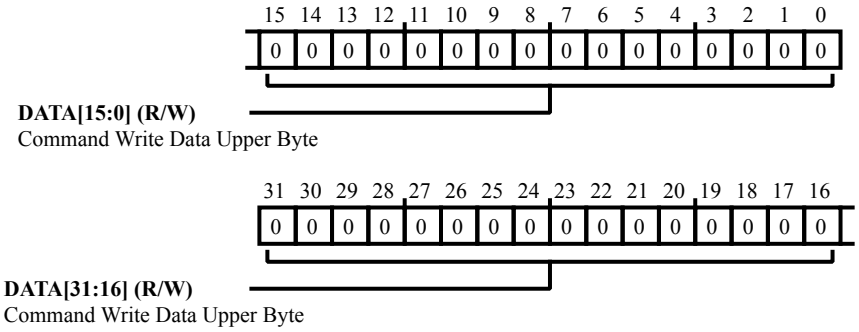

Figure 21-16: OSPI_FCWD_UP Register Diagram

Table 21-19: OSPI_FCWD_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Command Write Data Upper Byte. It is the data written to the flash for any status or configuration write operation carried out by triggering the event in the `OSPI_FCCTL` register. This must be setup before triggering the command using the `OSPI_FCCTL.EXE` field.

Interrupt Mask Register

This register allows the user to mask/unmask particular interrupt sources. This register must be setup when the controller is idle.

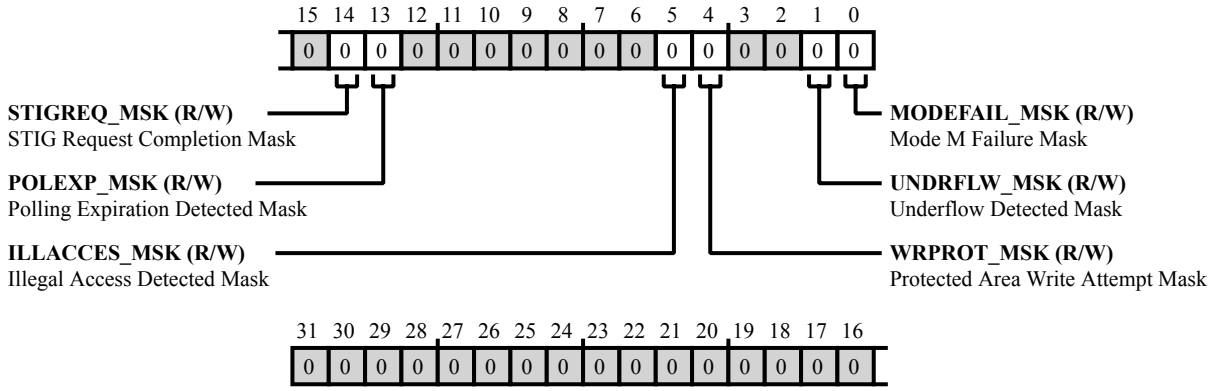

Figure 21-17: OSPI_IMSK Register Diagram

Table 21-20: OSPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	STIGREQ_MSK	STIG Request Completion Mask.
13 (R/W)	POLEXP_MSK	Polling Expiration Detected Mask.
5 (R/W)	ILLACCES_MSK	Illegal Access Detected Mask.
4 (R/W)	WRPROT_MSK	Protected Area Write Attempt Mask.
1 (R/W)	UNDRFLW_MSK	Underflow Detected Mask.
0 (R/W)	MODEFAIL_MSK	Mode M Failure Mask.

Interrupt Status Register

The status fields in this register are set when the described event occurs, and the interrupt is enabled in the OSPI_IMSK register. If any of these bit fields are set, the interrupt output is asserted high. The fields are each cleared by writing a 1 to the field.

Note: Bit fields [10:6] are valid only when legacy SPI mode is active.

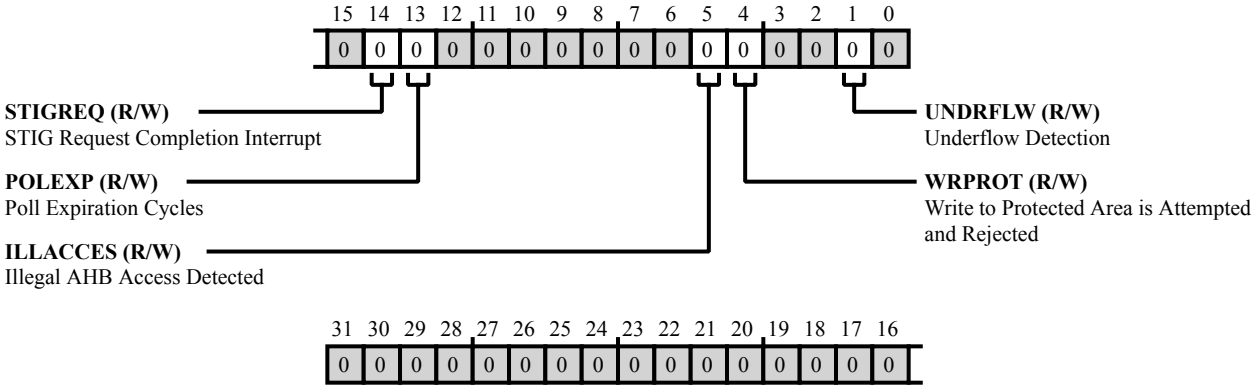

Figure 21-18: OSPI_ISTAT Register Diagram

Table 21-21: OSPI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	STIGREQ	STIG Request Completion Interrupt. The controller is ready to get another STIG request.	
13 (R/W)	POLEXP	Poll Expiration Cycles. The maximum number of programmed polls cycles is expired.	
5 (R/W)	ILLACCES	Illegal AHB Access Detected. AHB wrapping bursts and the use of SPLIT/RETRY accesses cause this error interrupt to trigger.	
4 (R/W)	WRPROT	Write to Protected Area is Attempted and Rejected.	
1 (R/W)	UNDRFLW	Underflow Detection. Underflow is detected.	
		0	No underflow is detected.
		1	underflow is detected and an attempt to transfer data is made when the small TX FIFO is empty. This may occur when AHB write data is slowly provided to keep up with the requested write operation.

Lower Write Protection Register

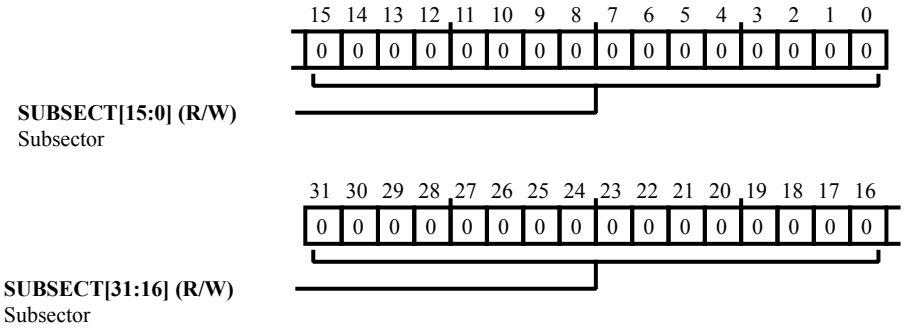

Figure 21-19: OSPI_WRPROT_LWR Register Diagram

Table 21-22: OSPI_WRPROT_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SUBSECT	Subsector. It defines the lower end of the address range to be protected. The address to be programmed must be OSPI memory map address (starting from 0x60000000) shifted by the value in the `OSPI_DSCTL.BLKSZ`. For example, if lower address of flash to be protected is 0x100 and the `OSPI_DSCTL.BLKSZ`= 4, the value to be programmed in this register must be 0x60000100 >> 4, which is 0x06000010.

Mode Bit Control Register

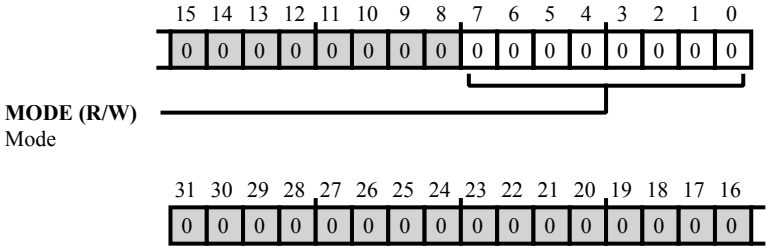

Figure 21-20: OSPI_MBCTL Register Diagram

Table 21-23: OSPI_MBCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MODE	Mode. These bits are sent to the device following the address bytes if mode bit transmission is enabled.

Module ID Register

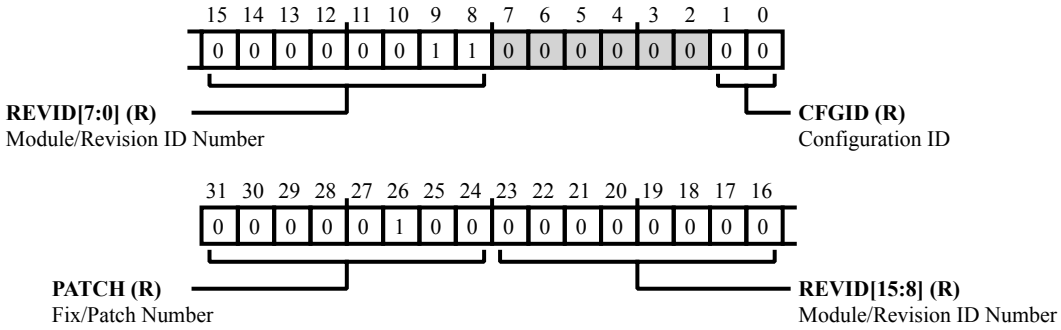

Figure 21-21: OSPI_MODID Register Diagram

Table 21-24: OSPI_MODID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/NW)	PATCH	Fix/Patch Number. Fix/patch number related to the `OSPI_MODID.REVID` field.	
23:8 (R/NW)	REVID	Module/Revision ID Number.	
1:0 (R/NW)	CFGID	Configuration ID. Configuration ID number.	
		0	Reserved
		1	Reserved
		2	Reserved
		3	Reserved

Polling Expiration Register

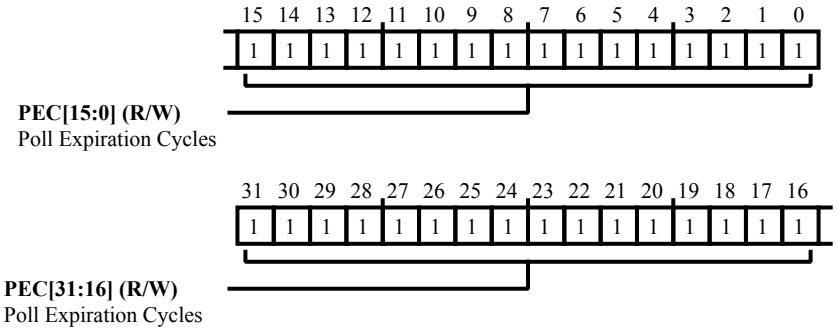

Figure 21-22: OSPI_POLLEXP Register Diagram

Table 21-25: OSPI_POLLEXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PEC	Poll Expiration Cycles. It defines the number of polls cycles before expiration.

Opcode Extension Register (Lower)

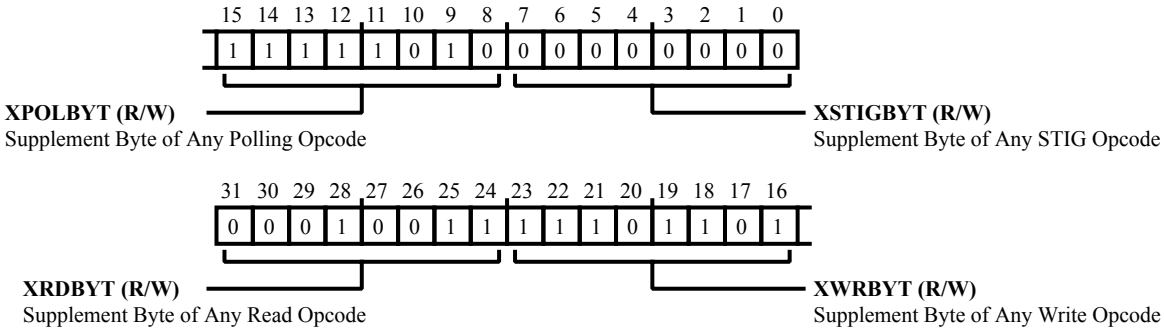

Figure 21-23: OSPI_OE_LWR Register Diagram

Table 21-26: OSPI_OE_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	XRDBYT	Supplement Byte of Any Read Opcode.
23:16 (R/W)	XWRBYT	Supplement Byte of Any Write Opcode.
15:8 (R/W)	XPOLBYT	Supplement Byte of Any Polling Opcode.
7:0 (R/W)	XSTIGBYT	Supplement Byte of Any STIG Opcode.

Opcode Extension Register (Upper)

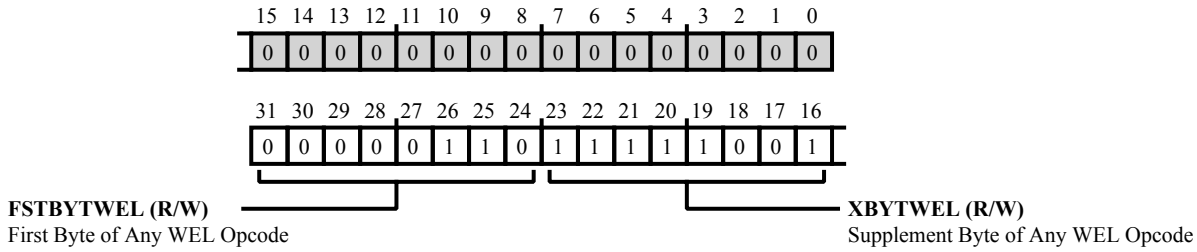

Figure 21-24: OSPI_OE_UP Register Diagram

Table 21-27: OSPI_OE_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	FSTBYTWEL	First Byte of Any WEL Opcode.
23:16 (R/W)	XBYTWEL	Supplement Byte of Any WEL Opcode.

PHY Control Register

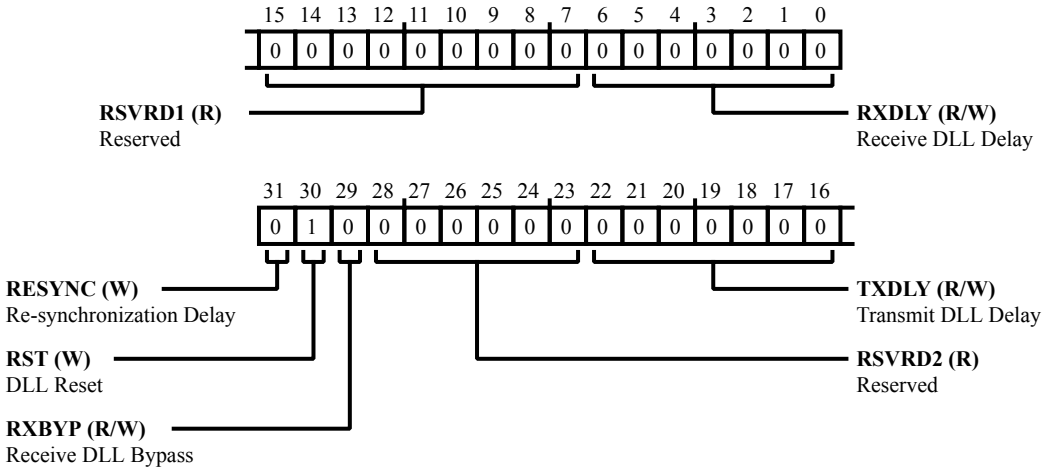

Figure 21-25: OSPI_PHYCTL Register Diagram

Table 21-28: OSPI_PHYCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RX/W)	RESYNC	Re-synchronization Delay. This bit is used for re-synchronization delay lines to update them with values from the `OSPI_PHYCTL.RXDLY` and `OSPI_PHYCTL.TXDLY` fields.
30 (RX/W)	RST	DLL Reset. This bit is used for reset of Delay Lines by software.
29 (R/W)	RXBYP	Receive DLL Bypass. This field determines if RX DLL is bypassed.
28:23 (R/NW)	RSVRD2	Reserved. Unused.
22:16 (R/W)	TXDLY	Transmit DLL Delay. This field determines the number of delay elements to insert on data path between ref_clk and spi_clk.
15:7 (R/NW)	RSVRD1	Reserved. Unused.
6:0 (R/W)	RXDLY	Receive DLL Delay. This field determines the number of delay elements to insert on data path between ref_clk and rx_dll_clk.

PHY DLL Master Control Register

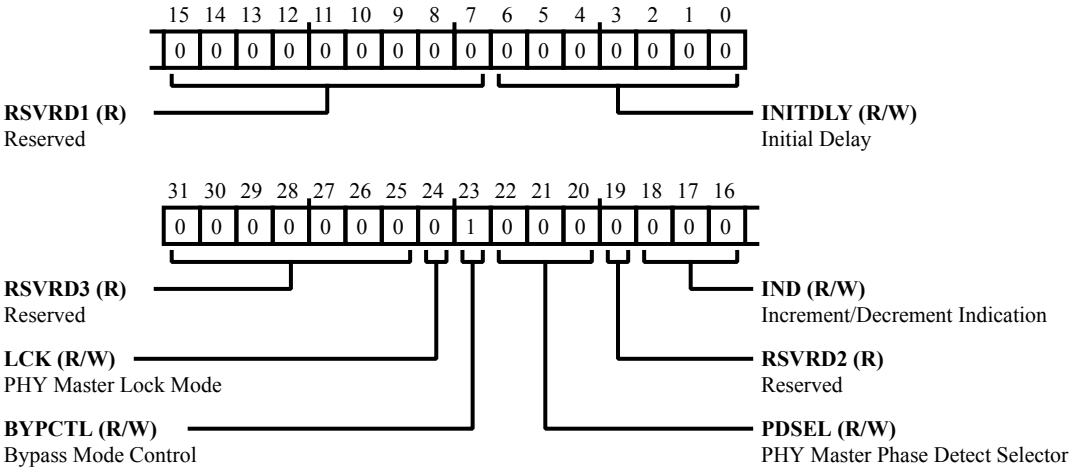

Figure 21-26: OSPI_PHYMCTL Register Diagram

Table 21-29: OSPI_PHYMCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:25 (R/NW)	RSVRD3	Reserved. Unused.
24 (R/W)	LCK	PHY Master Lock Mode. Determines if the master delay line locks on a full cycle or half cycle of delay.
23 (R/W)	BYPCTL	Bypass Mode Control. Controls the bypass mode of the master and slave DLLs
22:20 (R/W)	PDSEL	PHY Master Phase Detect Selector. Selects the number of delay elements to be inserted between the phase detect flip-flops.
19 (R/NW)	RSVRD2	Reserved. Unused.
18:16 (R/W)	IND	Increment/Decrement Indication. Indicates the number of consecutive increment or decrement indications.
15:7 (R/NW)	RSVRD1	Reserved. Unused.
6:0 (R/W)	INITDLY	Initial Delay. This value is the initial delay value for the DLL.

Polling Flash Status Register

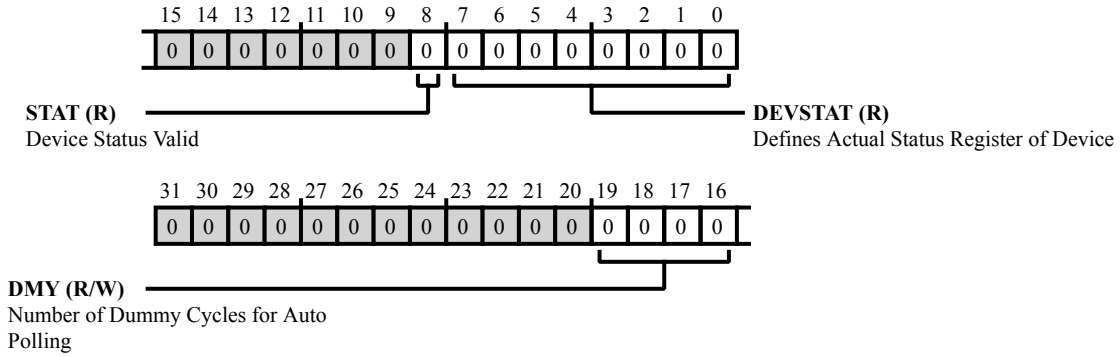

Figure 21-27: OSPI_POLSTAT Register Diagram

Table 21-30: OSPI_POLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	DMY	Number of Dummy Cycles for Auto Polling. This field enables the user to define additional dummy cycles for read status during the auto-polling state. It may be necessary to add some cycles if the external delay of read data path shifts it outside the defined clock cycle.
8 (R/NW)	STAT	Device Status Valid. This bit is set when value in bits from 7 to 0 is valid.
7:0 (R/NW)	DEVSTAT	Defines Actual Status Register of Device.

Read Data Capture Register

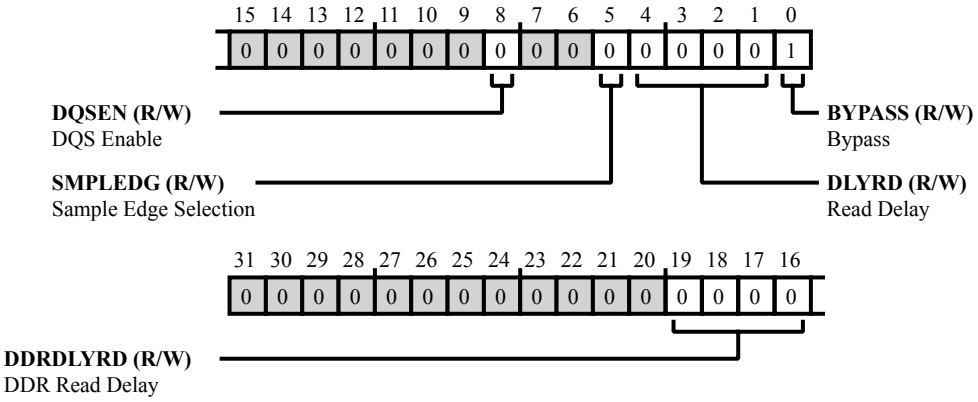

Figure 21-28: OSPI_RDC Register Diagram

Table 21-31: OSPI_RDC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	DDRDLYRD	DDR Read Delay. Delay the transmitted data by the number of ref_clk cycles.This field is relevant only when DDR read Command is executed. Else, it can be ignored.	
8 (R/W)	DQSEN	DQS Enable. If this bit is enabled, the signal from DQS input is driven into RX DLL and is used for data capturing in PHY Mode instead of internally generated gated ref_clk.	
5 (R/W)	SMPLEDG	Sample Edge Selection. Select the edge on which data outputs from flash memory has to be sampled.	
		0	Data outputs from Flash are sampled on falling edge of the ref_clk.
		1	Data outputs from Flash are sampled on rising edge of the ref_clk.
4:1 (R/W)	DLYRD	Read Delay. Delay the read data capturing logic by the programmed number of SYSCLK cycles.	
0 (R/W)	BYPASS	Bypass. Bypass the adapted loop back clock circuit.	
		0	Enable the adapted loop back clock circuit.
		1	Disable the adapted loop back clock circuit.

Remap Address Register

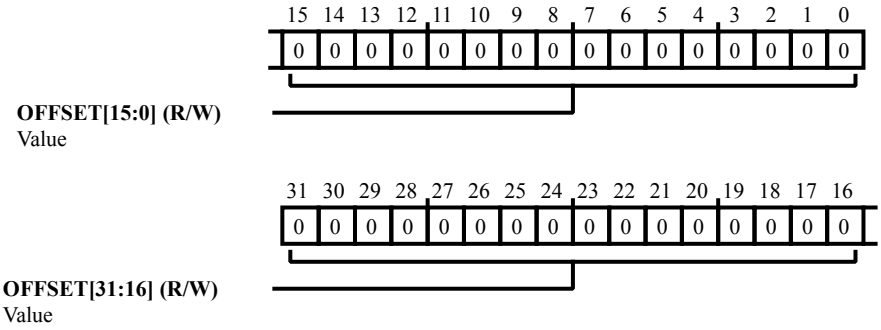

Figure 21-29: OSPI_REMAPADDR Register Diagram

Table 21-32: OSPI_REMAPADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	OFFSET	Value. Used to remap an incoming AHB address to a different address used by the Flash.

Upper Write Protection Register

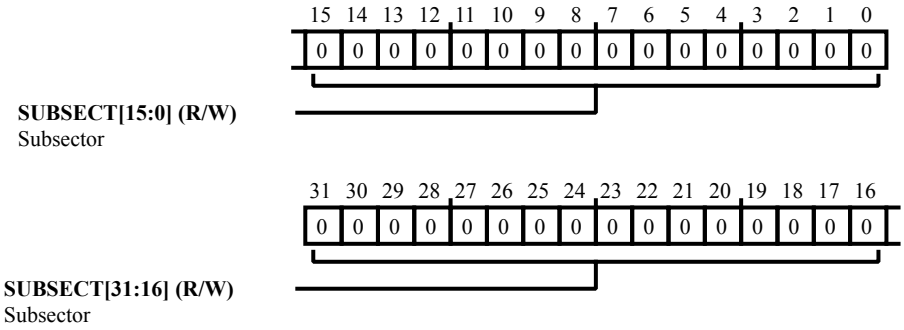

Figure 21-30: OSPI_WRPROT_UP Register Diagram

Table 21-33: OSPI_WRPROT_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SUBSECT	Subsector. It defines the upper end of the address range to be protected. The address to be programmed must be OSPI memory map address (starting from 0x60000000) shifted by the value in the `OSPI_DSCTL.BLKSZ`. For example, if upper address of flash to be protected is 0x100 and the `OSPI_DSCTL.BLKSZ`= 4, the value to be programmed in this register must be 0x60000100 >> 4, which is 0x06000010.

Write Protection Control Register

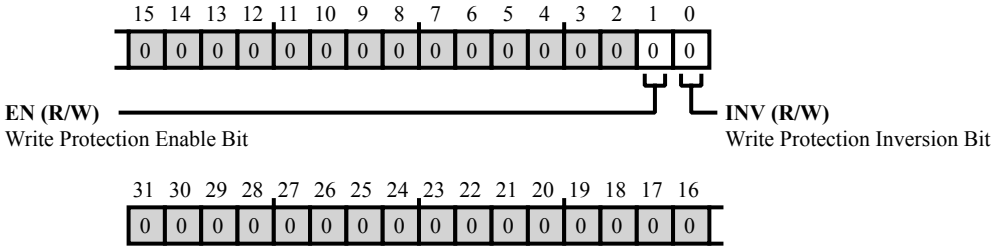

Figure 21-31: OSPI_WRPROT_CTL Register Diagram

Table 21-34: OSPI_WRPROT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	EN	Write Protection Enable Bit. When set to 1, any AHB write access with an address within the protection region defined in the lower and upper write protection registers is rejected. An AHB error response is generated and an interrupt source triggered. When set to 0, the protection region is disabled.
0 (R/W)	INV	Write Protection Inversion Bit. When set to 1, the protection region defined in the lower and upper write protection registers is inverted meaning it is the region that the system is permitted to write to. When set to 0, the protection region defined in the lower and upper write protection registers is the region that the system is not permitted to write to.

Write Completion Control Register

This register defines how the controller polls the device following a write transfer.

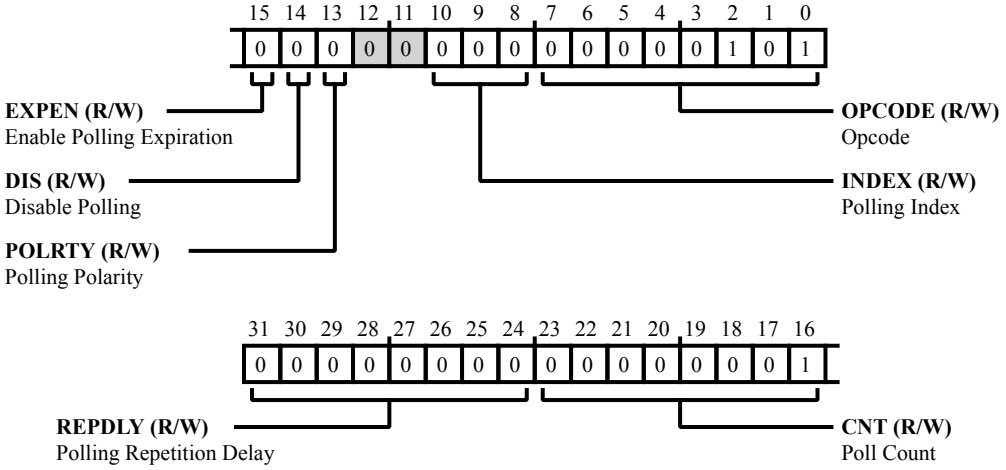

Figure 21-32: OSPI_WCCTL Register Diagram

Table 21-35: OSPI_WCCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	REPDLY	Polling Repetition Delay. Defines the additional delay required to ensure that the Chip Select is de-asserted during auto polling phase.	
23:16 (R/W)	CNT	Poll Count. Defines the number of times the controller should expect to see a true result from polling in successive reads of the device register.	
15 (R/W)	EXPEN	Enable Polling Expiration. It is set to 1 to enable auto polling expiration.	
14 (R/W)	DIS	Disable Polling. It switches off automatic polling function.	
13 (R/W)	POLRTY	Polling Polarity. Defines the polling polarity.	
		0	Write transfer to the device will be complete if the polled bit is 0.
		1	Write transfer to the device will be complete if the polled bit is 1.

Table 21-35: OSPI_WCCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10:8 (R/W)	INDEX	Polling Index. Defines the bit index that must be polled. A value of 010 means that bit 2 of the returned data is polled for. A value of 111 means that bit 7 of the returned data is polled for.
7:0 (R/W)	OPCODE	Opcode. Defines the opcode that must be issued by the controller when it is automatically polling for device program completion. This command is issued followed all device write operations. By default, this polls the standard device status register using opcode 0x05.

22 Universal Asynchronous Receiver/Transmitter (UART)

The UART module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

The UART module supports partial modem status and control functionality to allow for hardware flow control.

The UART is a DMA-capable peripheral with separate transmit and receive DMA controller channels. The use of DMA requires minimal software intervention as the DMA engine moves the data. The UART can also use a programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling.

The UART can use one of the peripheral timers for a hardware-assisted auto-baud detection mechanism. The timers are external to the UART.

NOTE: The UARTs (UART0, UART1, UART2, and UART3) operate in the SCLK0 domain.

UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Extra 8-stage receive FIFO with programmable threshold interrupt request
- Flexible transmit and receive interrupt request timing

- Three interrupt outputs for receive, transmit, and status
- Independent DMA operation for receive and transmit
- Programmable automatic request to send (RTS)/clear to send (CTS) hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loopback
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

Table 22-1: UART Specifications

Feature	Availability
Protocol	
Controller-Capable	Yes
Target-Capable	Yes
Transmission Simplex	Yes
Transmission Half-Duplex	Yes
Transmission Full-Duplex	Yes
Access Type	
Data Buffer	Yes
Core Data Access	Yes
DMA Data Access	Yes
DMA Channels	2 (per UART Port)

UART Block Diagram

The ***UART Block Diagram*** figure shows a simplified block diagram of one UART module and how it interconnects to the processor system.

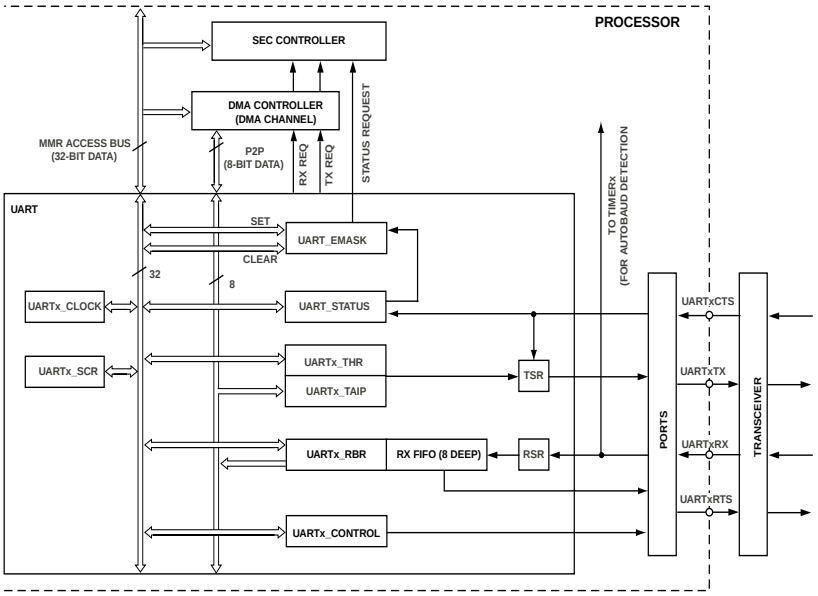

Figure 22-1: UART Block Diagram

UART Architectural Concepts

The following sections provide information about the UART architecture.

Internal Interface

The UART is a DMA-capable peripheral with support for separate transmit and receive DMA controller channels. It operates in either DMA or programmed core modes. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data. The `UART_RBR` and `UART_THR` registers also connect to one of the peripheral DMA buses.

All UART registers are 32 bits wide and the registers connect to the peripheral MMR bus. Not all MMRs can be used and unused bits are zero-filled. The UART has three interrupt outputs described as follows.

- The transmit and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC).
- The status interrupt output connects directly to the SEC. On many processors, the alternative capture input (`(TIMER_ACI[nn])`) of one of the GP timers also senses the `UART_RX` pin. When configured in capture mode, the processor can then use the GP timer to detect the bit rate of the received signal.

External Interface

Each UART features a `UART_RX` (receive) pin and a `UART_TX` (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full-duplex or half-duplex standards. For example, EIA-232, EIA-422, 4-wire EIA-485 for full-duplex or 2-wire EIA-485, LIN for half-duplex. Additionally, the UART features a pair of clear-to-send, input pins (`UART_CTS`),

and request-to-send, output pins (UART_RTS) for hardware flow control. UART signals are multiplexed with other functions at the pin level.

Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, the UART features a UART_RTS/UART_CTS hardware flow control mechanism. The UART_RTS signal is an output that connects to the UART_CTS input of the communication partner. If data transfer is bidirectional, the figure shows the ***UART Hardware Flow Control*** handshake.

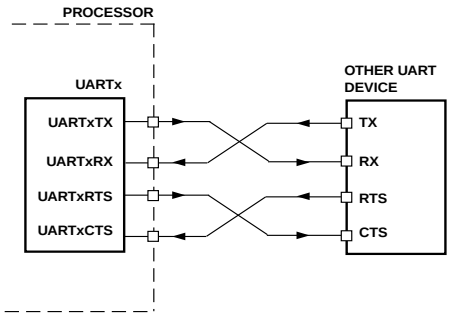

Figure 22-2: UART Hardware Flow Control

In both DMA and core mode, the receiver can deassert the UART_RTS signal to indicate that its receive buffer is almost full. Continued data transfers can cause an overrun error. The transmitter pauses when the UART_CTS input is in a deasserted state. In this state, the transmitter completes transmission of the data currently held in the transmit shift register (UART_TSR) but it does not continue with the data in the transmit hold register (UART_THR). If the UART_CTS pin is asserted again, the transmitter resumes and loads the content of UART_THR register into the UART_TSR register.

Bit Rate Generation

The peripheral clock (SCLK0) and the 16-bit divisor in the UART_CLK register characterize the sample clock. The UART uses the UART_CTL.EN bit to enable the clock. By default, every serial bit is oversampled 16 times. The bit clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the UART_CLK.EDBO bit is set, so that the following equation applies:

$$\text{Bit Rate} = \text{SCLK0}/(16^{(1-\text{EDBO})} \times \text{Divisor})$$

The ***UART Bit Rate Examples with 100 MHz SCLK*** table provides example divide factors required to support standard baud rates at an SCLK0 of 100 MHz.

Table 22-7: UART Bit Rate Examples with 100 MHz SCLK0

Bit Rate (bits/sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
2400	2604	2400.15	0.006	41667	2399.98	0.001
4800	1302	4800.31	0.006	20833	4800.08	0.002

Table 22-7: UART Bit Rate Examples with 100 MHz SCLK0 (Continued)

Bit Rate (bits/ sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
9600	651	9600.61	0.006	10417	9599.69	0.003
19200	326	19171.78	0.147	5208	19201.23	0.006
38400	163	38343.56	0.147	2604	38402.46	0.006
57600	109	57339.45	0.452	1736	57603.69	0.006
115200	54	115740.74	0.469	868	115207.37	0.006
921600	7	892857.14	3.119	109	917431.19	0.452
1500000	4	1562500	4.167	67	1492537.31	0.498
3000000	2	3125000	4.167	33	3030303.03	1.01
6250000	1	6250000	0	16	6250000	0

NOTE: Properly select the SCLK0 frequencies. Even multiples of bit rate decrease the error percentage.

Setting the bit clock equal to the sample clock (`UART_CLK.EDBO` =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. Use `UART_CLK.EDBO` mode only when bit rate accuracy is not acceptable in the `UART_CLK.EDBO`=0 mode.

The `UART_CLK.EDBO`=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.

Autobaud Detection

At the chip level, the $\overline{\texttt{UART\_RX}}$ pin is typically routed to an alternate capture input (`TIMER_ACI[nn]`) of a general-purpose timer. When working in width capture mode, the processor uses this general-purpose timer to detect the bit rate applied to the $\overline{\texttt{UART\_RX}}$ pin automatically by an external device. It often uses the capture capabilities of the timer to supervise the bit rate at run time. If the UART communicates with any device supplied by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically, as required.

Often, the processor uses autobaud detection for initial bit rate negotiations where it is most likely a completer device waiting for the host to send a predefined autobaud character. This situation is common for UART booting. Do not enable the `UART_CTL.EN` bit while autobaud detection is in-process, to prevent the UART from starting a receive operation with incorrect bit rate matching. Alternatively, set the `UART_CTL.LOOP_EN` bit to disconnect the UART from its $\overline{\texttt{UART\_RX}}$ pin.

A software routine can detect the pulse widths of serial stream bit cells. The sample base of the timer is synchronous with the UART operation (all derived from the same SCLK0). The UART uses pulse widths to calculate the bit rate divider as follows:

Divisor = `TIMER_TMR[n]_WID`/($16^{(1-\text{EDBO})}$ × Number of captured UART bits)

To increase the number of timer counts and the resolution of the captured signal, do not measure just the pulse width of a single bit. Instead, enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown in the ***Autobaud Detection*** figure.

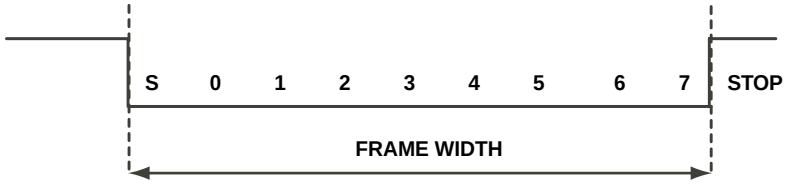

Figure 22-3: Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula:

Divisor = `TIMER_TMR[n]_WID`/($16^{(1-EDBO)}$ × 9)

NOTE: For processor-specific mapping of timer alternate capture inputs to the UARTs of the processor, see "Width Capture (WIDCAP) Mode" in the "*General-Purpose Timer (TIMER)*" chapter.

Real receive signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection does not always return adequate results without extra conditioning of the analog signal. Measure signal periods to work around this issue.

For example, predefine the ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the ***Autobaud Detection Character 0x40*** figure, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula:

Divisor = `TIMER_TMR[n]_PER`/($16^{(1-EDBO)}$ × 8)

or:

- Divisor = `TIMER_TMR[n]_PER`>> 7, if `UART_CLK.EDBO`=0
- Divisor = `TIMER_TMR[n]_PER`>> 3, if `UART_CLK.EDBO`=1

The ***Autobaud Detection Character 0x40*** figure shows the ASCII “@” (0x40) detection character.

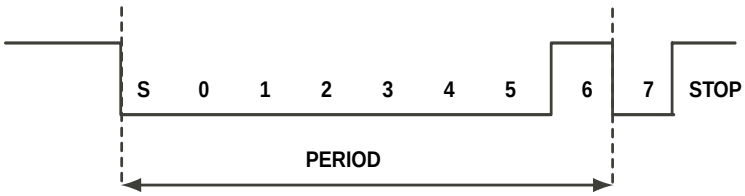

Figure 22-4: Autobaud Detection Character 0x40

UART Debug Features

The UART can automatically calculate and transmit a parity bit. The ***UART Parity*** table summarizes parity behavior assuming 8-bit data words (`UART_CTL.WLS`=b#11).

Table 22-8: UART Parity

PEN	STP	EPS	Data (hex)	Data (binary, LSB first)	Parity
0	x	x	x	x	None
1	0	0	0x60	0000 0110	1
1	0	0	0x57	1110 1010	0
1	0	1	0x60	0000 0110	0
1	0	1	0x57	1110 1010	1
1	1	0	x	x	1
1	1	1	x	x	0

The two force error bits, UART_CTL.FPE and UART_CTL.FFE, are intended for test purposes. They are useful for debugging software, especially in loopback mode.

The UART can be set to internal loopback mode (UART_CTL.LOOP_EN=1). Loopback mode disconnects the input of the receiver from the receive pin and internally redirects the transmit output to the receiver. The transmit pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to deassert, disconnects the UART_STAT.CTS bit from the UART_CTS input pin, and connects the internal version of UART_RTS to the UART_STAT.CTS bit.

Additionally, the UART_TX pin can be forced to zero asynchronously using the UART_CTL.SB bit.

UART Operating Modes

The following sections describe the main operating modes of the UART.

- UART Mode
- IrDA SIR Mode
- Multi-Drop Bus Mode

UART Mode

The UART mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5–8 data bits
- Address bit (available in MDB mode only)
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits valid only in 5-bit word length)

The UART_CTL register controls the format of received and transmitted character frames. Data is always transmitted and received with the least significant bit (LSB) first.

The ***Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)*** figure shows a typical physical bit stream measured on a UART_TX pin.

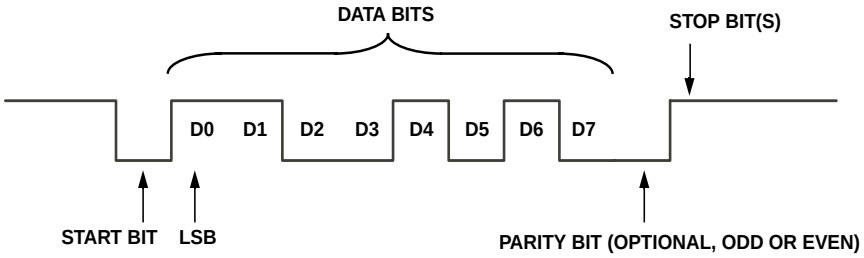

Figure 22-5: Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)

IrDA SIR Mode

The UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. The UART does not support pulse position modulation.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the UART uses a 16x clock to determine an IrDA pulse sample window, from which it recovers the RZI modulated NRZ code.

NOTE: The UART_CLK.EDBO bit is not valid in IrDA mode. Clear (=0) this bit in this mode.

Multi-Drop Bus Mode

The UART uses a protocol for point-to-point connections as well as in networks where the EIA-485 standard is representative of UART-based bus systems. The EIA-232 standard defines point-to-point connections. In such networks, node addressing is important.

In a multidrop bus (MDB) network, for example, an address bit enhances the UART frame. The address bit is inserted between the data bits and the optional parity bit. To configure the UART for MDB mode, set the mode of operation bits (UART_CTL.MOD [5:4]) to 01.

By convention, the address bit is transmitted low for regular data bytes. When set, it marks special address bytes that require the attention of all nodes on the network.

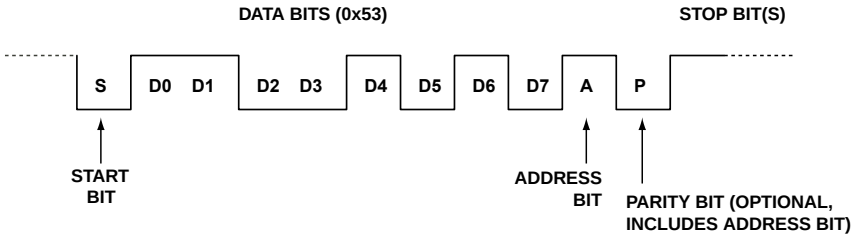

Figure 22-6: UART Frame with Address Bit

All transmit operations are processed through the transmit buffer register (UART_THR), so all DMA data transmissions clear the address bit. If data is written to the transmit address or insert pulse register (UART_TAIP) instead, the same transmit operation is initiated with the only exception that the address bit is sent high.

The UART uses the UART_STAT.ADDR bit of the receiver to signal whether the previously received frame had the address bit set or not. Hardware updates it every time a new frame is received. When the enable address word interrupt bit (UART_IMSK.EAWI) is set, the reception of an address byte triggers a special status interrupt request.

The address sticky bit (UART_STAT.ASTKY) is the sticky version of the UART_STAT.ADDR bit. Hardware sets it whenever the UART_STAT.ADDR bit is set. Software can clear the UART_STAT.ASTKY bit with a W1C operation.

In MDB mode, only address bytes progress to the receive FIFO by default. Data bytes are gated unless the UART_STAT.ASTKY bit is set. The receiver ignores all traffic on the UART bus. This way, the processor can go into low-power mode and interrupt activity does not load the processor every time a frame is transmitted on the UART bus. If, however, an address frame is transmitted, the receiver immediately samples all further traffic. A software routine can analyze the received data, decide whether it was of relevance for the local network node, and W1C the UART_STAT.ASTKY bit if it was not.

Software can overrule of the hardware address frame detection by setting the UART_STAT.ADDR bit and (indirectly) the UART_STAT.ASTKY bit with a W1S operation.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5–8 data bits
- Address bit
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits are valid only in 5-bit word length)

NOTE: If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

UART Data Transfer Modes

The UART can transfer data using both the core and DMA. Receive and transmit paths operate independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The UART_THR register buffers the transmit shift register (UART_TSR) and the UART_RBR register buffers the receive shift register (UART_RSR).

UART Mode Transmit Operation (Core)

In core mode, the processor core moves data to and from the UART. A write to the UART_THR register initiates the transmit operation. If no former operation is pending, the UART_THR register passes the data immediately to the

UART_TSR register. There, it is shifted out at the bit rate characterized by the UART_CLK register, with start, stop, and parity bits appended as defined by the UART_CTL register.

The UART_THR register and the UART_TSR register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) always transmits first. This bit is bit 0 of the value written to the UART_THR register.

UART Mode LIN Break Command

Some UART-based protocols demand synchronization methods that are not native to standard UART implementations. For example, the Local Interconnect Network (LIN) protocol requires a low-pulse of well-defined transmit length as a prologue to every multi-byte message. Its length must be at least 13 bit-times.

With previous UARTs, there were two options to implement this protocol:

- A null byte is transmitted with a temporarily lowered bit rate, or
- A software counter generates the period and the asynchronous set break (SB) mechanisms pull the transmit pin low

Since both methods have their disadvantages, the newer UART introduces a new inter-frame gap technique.

The feature is not available in MDB or IrDA operating modes. However, in standard UART mode (bits UART_CTL.MOD [5:4] =00), a write to the UART_TAIP register initiates the transmission of an inter-frame pulse. If the transmit buffer is not empty, the UART first transmits all bytes in the queue. It only initiates with pulse generation after the last stop bit of the last byte has been shifted out.

The value written into the UART_TAIP register defines the nature and the duration of the transmitted pulse. Bits [6:0] control the duration in bit-times and bit [7] controls the value (duration = UART_TAIP[6:0] / UART_CLK[15:0]). If UART_TAIP[7] is set, and an active high pulse is issued, the number of stop bits is extended. If UART_TAIP[7] is cleared, a low pulse is generated. Invert the polarity using the UART_CTL.FCPOL bit. Writing a value of 13 into the UART_TAIP register generates the break command as required by the LIN protocol.

NOTE: If the UART_CTL.TPOLC bit is enabled, an inverted most-significant bit can be transmitted.

NOTE: If another transmission is pending (in the UART_TSR register), the UART_TAIP initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap precedes transmission of the number of stop bits as set in the UART_CTL.STB and UART_CTL.STBH bit fields.

The UART receiver can detect break commands through the break indicator (UART_STAT.BI) flag. This flag reports that an entire UART frame has been received in low state. It does not report whether the duration of the received low pulse was exact or at least 13 bit-times as LIN controllers transmit. Typically, the break indicator meets LIN requirements. The processor can use GP timers to determine the pulse width more precisely, if necessary.

Each $\overline{\text{UART\_RX}}$ pin is also routed to a GP timer through its alternate capture input (TACI). This functionality is not only useful for bit rate detection (*autobaud*) but also helps to measure the pulse widths precisely on the $\overline{\text{UART\_RX}}$ input. Additionally, the GP timers can issue an interrupt request or a fault condition when the received

pulse width is shorter than a bit time or longer than the worst-case break condition. The windowed watchdog width mode of the GP timers controls this functionality.

UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration except that one valid stop bit is always sufficient. The UART_CTL.STB and UART_CTL.STBH bits have no impact on the receiver.

The UART receiver senses the falling edges of the receive input. When it detects an edge, the receiver starts sampling the input according to settings in the UART_CLK register. The receiver samples the start bit (majority sampling) close to its midpoint. If sampled low, it assumes a valid start condition. Otherwise, it discards the detected falling edge.

After detection of the start bit, the received word is shifted into the UART_RSR register.

After the corresponding stop bit is received, the content of the UART_RSR register is transferred to the 8-deep receive FIFO and is accessible by reading the UART_RBR register.

The receive FIFOs and the UART_RBR register act as a 9-stage receive buffer. If the stop bit of the ninth word is received before software reads the UART_RBR register, an overrun error is reported. Overruns protect data in the UART_RBR register and the receive FIFO from being overwritten by further data until the software clears the UART_STAT.OE bit. However, the data in the UART_RSR register is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver oversamples every bit 16 times and makes a majority-decision based on the middle three samples. This functionality improves immunity against noise and hazards on the line. The receiver disregards spurious pulses of less than two times the sampling clock period.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set to 1, the receiver samples bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy as required at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception starts when the UART receiver detects a falling edge on the $\overline{\text{UART\_RX}}$ input pin. The receiver attempts to see a start bit. The data is shifted into the UART_RSR register. After the ninth sample of the first, the receiver processes the stop bit and copies the received data to the 8-stage receive FIFO. The UART_RSR recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is typically asynchronous to the data rate of the transmitter, the sampling point can drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the UART_CTL.RPOLC bit.

NOTE: The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately acts (status update). It then prepares for new falling edge detection (start detection).

IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the UART_CTL.TPOLC bit is configured for active-low operation. In this configuration, a zero is transmitted as a high pulse of 16 UART clock periods and a one is transmitted as a low pulse for 16 UART clock periods. Then, six UART clock periods delay the leading edge of the pulse. Similarly, eight UART clock periods truncate the trailing edge of the pulse. For a 16-cycle UART clock period, this operation results in the final representation of the original zero as a high pulse of only 3/16 clock periods. The ***IrDA Transmit Pulse*** figure shows how the pulse is centered around the middle of the bit time. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the ***IrDA Transmit Pulse*** figure, the error terms associated with the bit rate generator are small and well within the tolerance of most infrared transceiver specifications.

NOTE: In IrDA mode, writes to the UART_TAIP register are equivalent to writes to the UART_THR register.

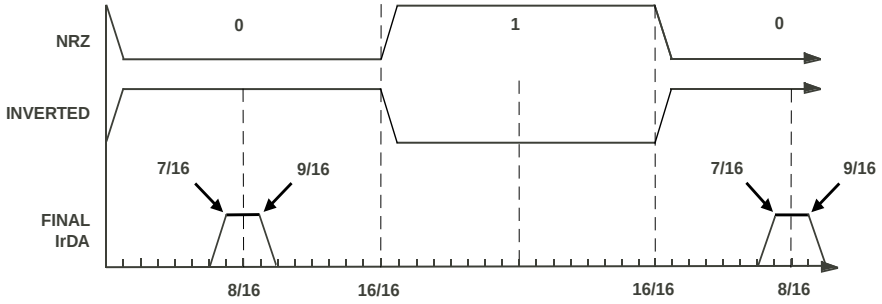

Figure 22-7: IrDA Transmit Pulse

IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. The receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time the receiver detects an initial pulse. If the pulse is absent when the counter expires, the receiver interprets it as a glitch. Otherwise, the receiver interprets it as a zero. This assessment is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK0) period. Appropriate shielding avoids sources outside of the chip and not part of the transmitter. The only other source of a glitch is the transmitter itself. The processor relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results can occur. The 4-bit counter adds an extra level of protection at a minimal cost.

NOTE: Because SCLK0 can change across systems, the longest glitch tolerated is inversely proportional to the SCLK0 frequency.

A counter that is clocked at the 16x bit-time sample clock determines the receive sampling window. The sampling window is resynchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit. The ***IrDA Receiver Pulse Detection*** figure provides examples of each polarity type.

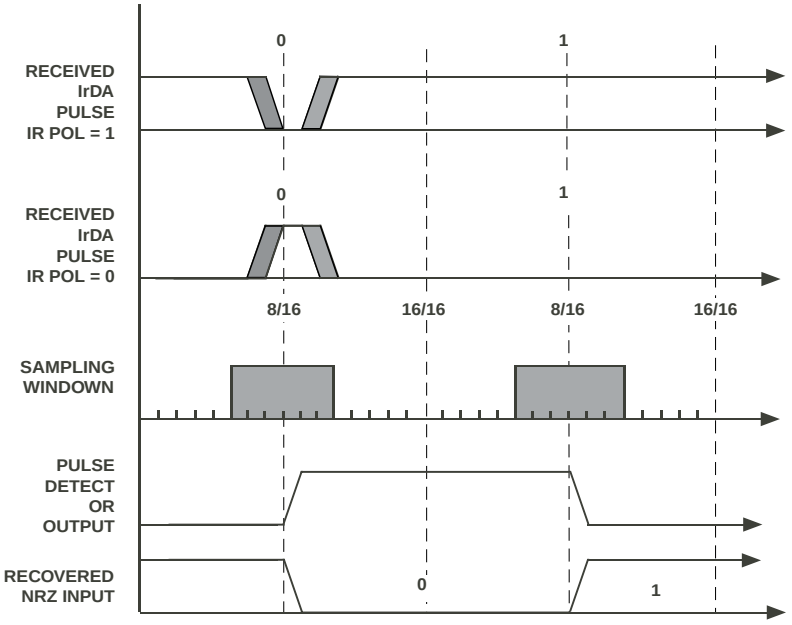

Figure 22-8: IrDA Receiver Pulse Detection

MDB Transmit Operation

In MDB mode, receive and transmit paths operate independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the UART_THR or UART_TAIP registers. A write to the UART_THR register transmits the written word with the appending address bit set low. A write to the UART_TAIP register transmits the written word with the appended address bit set high. The data is moved into the UART_TSR register, where it is shifted out at the bit rate programmed by the UART_CLK register, with start, stop, address, and parity bits appended, as required.

If DMA is enabled, the DMA engine always writes the data into the UART_THR register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the UART_CTL.TPOLC bit.

MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the UART_RSR register at the programmed bit.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set, the receiver samples the bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy needed at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the UART_RSR register is transferred to the receive FIFO and accessible through the UART_RBR register.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit.

DMA Mode

In DMA mode, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just has to set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the bus activity and arbitration mechanism determine the latency. The processor loading and interrupt priorities do not determine the latency.

To enable UART DMA, first set up the system DMA control registers. Then, enable the UART_IMSK.ERBFI or UART_IMSK.ETBEI interrupts. This sequence is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit. The status interrupt for the UART goes directly to the system event controller (SEC), bypassing the DMA unit completely.

For transmit DMA, programs must set the DMA_CFG.SYNC bit. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART transmit DMA interrupt service routine can disable the DMA or to clear the UART_IMSK.ETBEI control bit only when the DMA_CFG.SYNC bit is set. Otherwise, up to four data bytes can be lost.

When the UART_IMSK.ETBEI bit is set, an initial transmit DMA request is issued immediately. The program then clears the UART_IMSK.ETBEI bit through the DMA service routine.

In DMA transmit mode, the UART_IMSK.ETBEI bit enables the peripheral request to the DMA FIFO. The DMA_CFG.EN bit enables the strobe on the memory side. If the DMA count is less than the DMA FIFO depth, which is 4, then the DMA interrupt can be requested before the UART_IMSK.ETBEI bit is set. If this behavior is unwanted, set the DMA_CFG.SYNC bit.

Regardless of the DMA_CFG.SYNC setting, the DMA stream has not left the UART transmitter completely at the time the interrupt request is generated. Transmission can abort in the middle of the stream, causing data loss, when the UART clock was disabled without extra synchronization with the UART_STAT.TEMT bit.

The UART provides functionality to avoid resource-consuming polling of the UART_STAT.TEMT bit. The UART_IMSK_SET.EDTPTI bit enables the UART_STAT.TEMT bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the DMA_CFG.INT bit cleared and set the UART_IMSK_SET.EDTPTI bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the UART_STAT.TEMT event triggers a DMA interrupt after the last word of the DMA has left the UART transmit buffers. If DMA_CFG.INT and UART_IMSK.EDTPTI are set, when finishing STOP mode, the DMA requests two interrupts.

The DMA of the UART module supports 8-bit and 16-bit operation, but not 32-bit operation. It does not support sign-extension.

Mixing DMA and Core Modes

Switching from DMA mode to core operation dynamically requires some consideration, especially for transmit operations. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the transmit DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The transmit DMA interrupt service routine is not yet permitted to disable the DMA_CFG.EN bit. The interrupt is requested when the DMA_STAT.IRQDONE bit is set. The DMA_STAT.RUN bit, however, remains set until the data has completely left the transmit DMA FIFO.

When planning to switch from a DMA to core mode, set the DMA_CFG.SYNC bit in the word of the last descriptor or work unit before handing over control. Then, after the interrupt request occurs, software can write new data into the UART_THR register as soon as the UART_STAT.THRE bit permits. If the DMA_CFG.SYNC bit cannot be set, software can poll the DMA_STAT.RUN bit instead. Alternatively, using the UART_IMSK.EDTPTI bit can avoid expensive status bit polling.

When switching from core to DMA operation, ensure that the first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the UART_STAT.TEMT bit is high, pulse the UART_IMSK.ETBEI bit to initiate DMA transmission.

Setting Up Hardware Flow Control

The following steps show how to set up UART hardware flow control:

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART\_CTS}}$ and $\overline{\text{UART\_RTS}}$ polarity through the UART_CTL.FCPOL bit.

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the $\overline{\text{UART\_RTS}}$ pin is not driven. Some applications require a resistor to pull the UART_RTS signal to either state during reset.

UART Event Control

Status flags in the UART_STAT register are available to signal data reception, parity, and error conditions, if necessary.

DMA and Interrupt Multiplexing

See the *Direct Memory Access (DMA)* chapter for information on DMA multiplexing. Several interrupts and DMA channels in the UART can be multiplexed.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Masks

Each UART features a set of interrupt mask registers: UART_IMSK, UART_IMSK_SET, and UART_IMSK_CLR. The UART_IMSK register supports read/write operations. Writing ones to the UART_IMSK_SET register enables interrupts, writing ones to the UART_IMSK_CLR register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupt requests independently and easily.

The UART module uses the UART_IMSK registers to enable requests for system handling of empty or full states of data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits in this register are normally set.

Each UART module has three interrupt outputs. It uses one for transmission, one for reception, and one for reporting status events. The UART module routes transmit and receive requests through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. A DMA channel must be associated with the UART module to enable transmit and receive interrupts. Otherwise, transmit and receive requests cannot be forwarded.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt request output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Servicing

Interrupt service routines (ISRs) perform UART writes and reads. Separate interrupt lines are provided for transmit, receive, and status. The UART_IMSK register group enables the independent interrupts individually. To enable UART transmit interrupts, set the UART_CTL.EN bit.

The ISRs evaluate the status bits in the UART_STAT register to determine the signaling interrupt source. The system event controller for the processor assigns and unmasks interrupts. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, use the UART_IMSK.ERFCI status interrupt as an alternative to the regular UART_IMSK.ERBFI receive interrupt. Hardware must ensure that at least two (if UART_CTL.RFIT=0) or four (if UART_CTL.RFIT=1) words are available in the receive buffer by the time the interrupt is requested.

Transmit Interrupts

The UART module uses the UART_IMSK_SET.ETBEI bit to enable transmit interrupt requests.

The UART_THR and UART_TAIP registers are the same physical register, and both affect the signaling of the UART_STAT.TEMT, UART_STAT.TFI, and UART_STAT.THRE bits similarly.

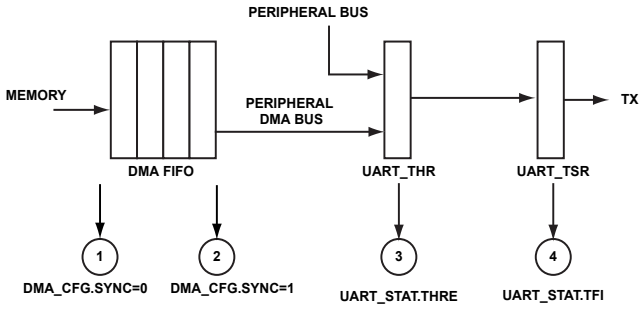

Figure 22-9: Transmit Interrupts

The UART module asserts the transmit request along with the `UART_STAT.THRE` bit, indicating that the transmit buffer is ready for new data. The `UART_STAT.THRE` bit resets to 1. When the `UART_IMSK_SET.ETBEI` bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Set the `UART_IMSK_SET.ETBEI` bit and let the interrupt service routine load the first character from memory and write it to the `UART_THR` register in the normal manner. ISRs can clear the `UART_IMSK.ETBEI` bit through the `UART_IMSK_CLR` register when the string transmission has completed.

Hardware clears the `UART_STAT.THRE` bit when new data is written to the `UART_THR` register. These write operations also clear the transmit interrupt request. However, they also initiate further transmission. If continued transmission is undesirable, the UART module can alternatively clear the transmit request through the `UART_IMSK_CLR.ETBEI` bit register. Transfers of data from the `UART_THR` register to the `UART_TSR` register reset this status flag in the `UART_STAT` register.

ISRs can interrogate the `UART_STAT.TEMT` bit to discover any ongoing transmission. The sticky counterpart of the `UART_STAT.TEMT` bit, `UART_STAT.TFI`, indicates when the transmit buffer has drained and can trigger a status interrupt. When data is pending in either one of these registers, the `UART_STAT.TEMT` flag is low. As soon as all data has left the `UART_TSR` register, the `UART_STAT.TEMT` bit goes high again and indicates that all pending transmit operations (including stop bits) have finished. Then, it is safe to disable the `UART_CTL.EN` bit or to three-state off-chip line drivers. Then, the UART module can generate an interrupt either through the status interrupt channel when the `UART_IMSK.ETFI` bit is set, or through the DMA controller when enabled by the `UART_IMSK.EDTPTI` bit.

When enabled by the `UART_IMSK.ETBEI` bit, the `UART_STAT.THRE` flag requests data along the peripheral command lines to the DMA controller (referred to as TXREQ). This signal is routed through the DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA controller simply forwards it to the SEC. Alternatively the `UART_IMSK.ETXS` bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, the UART module can poll the status flags to determine when data is ready to move. Because polling is processor intensive, it is not typically used in real-time signal processing environments. Since read operations from `UART_STAT` registers have no side effects, different software threads can interrogate these registers without mutual impacts.

Polling the SEC_SSTAT[n] register without enabling the interrupts by the SEC_CCTL[n] register is an alternate method of operation to consider. Software can write up to two words into the UART_THR register before enabling the UART clock. As soon as the UART_CTL.EN bit is set, the UART module sends those two words.

Receive Interrupts

The UART module uses the UART_IMSK_SET.ERBFI bit to enable receive interrupt requests. If set, the UART_STAT.DR flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the UART_RBR register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the UART_IMSK.ERXS bit can redirect the receive interrupts to the UART status interrupt. When software reads the UART_RBR register, hardware clears the UART_STAT.DR bit again, which, in turn, clears the receive interrupt request.

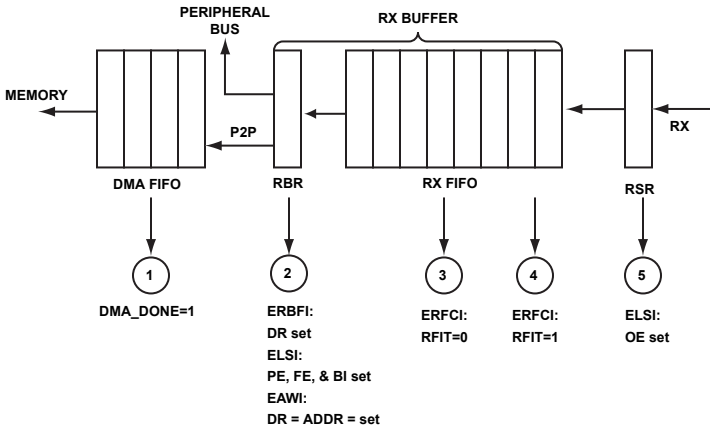

Figure 22-10: Receive Interrupts

Hardware updates the following:

- UART_STAT.DR bits
- UART_STAT.ADDR bits
- UART_STAT.ASTKY bits
- UART_STAT.PE bits
- UART_STAT.FE bits
- UART_STAT.BI bits
- UART_RBR register

The UART_STAT.OE bit is updated as soon as an overflow condition occurs (for example when a stop bit for a frame is received and the receive FIFO is full). When software does not read the UART_RBR register in time, the received data is protected from being overwritten by new data until software clears the UART_STAT.OE bit. Only the content of the UART_RSR register can be overwritten in the overrun case.

The UART module uses the UART_STAT.RFCS bit to monitor the state of the 8-deep receive FIFO. It uses the UART_CTL.RFIT bit to control the behavior of the buffer. If UART_CTL.RFIT is zero, the UART_STAT.RFCS bit is set when the receive buffer holds four or more words. If UART_CTL.RFIT is set, the UART_STAT.RFCS bit is set when the receive buffer holds seven or more words. Hardware clears the UART_STAT.RFCS bit when a core or DMA reads the UART_RBR register and when the buffer is flushed below the level of four (UART_CTL.RFIT=0) or seven (UART_CTL.RFIT=1). If the associated interrupt bit UART_IMSK.ERFCI is enabled, a status interrupt request is reported when the UART_STAT.RFCS bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. The bit enables status interrupt requests.

The controller detects the following error conditions, shown with their associated bits in the UART_STAT register.

- Overrun error (UART_STAT.OE bit)
- Parity error (UART_STAT.PE bit)
- Framing error or invalid stop bit (UART_STAT.FE bit)
- Break indicator (UART_STAT.BI bit)

Status Interrupts

The UART module uses status interrupt channels for the following purposes:

- Line status interrupt requests
- Flow control interrupt requests
- Receive FIFO threshold interrupt requests
- Transmission finished interrupt request

The UART module uses the UART_IMSK.ELSI bit to enable the line status interrupts. If set, the status interrupt request is asserted with one of the UART_STAT.BI, UART_STAT.FE, UART_STAT.PE, or UART_STAT.OE receive errors bits. A W1C operation to the UART_STAT register clears the error bits. Once all error conditions are cleared, the interrupt request deasserts.

The UART module uses the UART_IMSK_SET.ERFCI bit to enable the receive FIFO count interrupt. If set, a status interrupt request is generated when the UART_STAT.RFCS is active. The UART_STAT.RFCS bit indicates a receive buffer threshold level. If the UART_CTL.RFIT bit is cleared, software can safely read two words out of the UART_RBR register by the time the UART_STAT.RFCS interrupt occurs.

If the UART_CTL.RFIT bit is set, software can safely read four words. The interrupt request and the UART_STAT.RFCS bit are cleared when the UART_RBR is read enough of times, so that the receive buffer drains below the threshold of two (UART_CTL.RFIT=0) or four (UART_CTL.RFIT=1). Because in DMA mode a status service routine may not be permitted to read UART_RBR, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The UART module uses the UART_IMSK_SET.EDSSI bit to enable the flow control interrupts. If active, a status interrupt is generated when the sticky UART_STAT.SCTS bit register is set, indicating that the UART_CTS input of the transmitter been reasserted. A W1C operation to the UART_STAT.SCTS bit clears the interrupt request.

The UART module uses the UART_IMSK_SET.ETFI bit to enable the transmission finished interrupt. If active, a status interrupt request is asserted when the UART_STAT.TFI bit is set. The UART_STAT.TFI is the sticky version of the UART_STAT.TEMT bit, indicating that a byte that started transmission has finished. A W1C operation to the UART_STAT.TFI bit clears the interrupt request.

Multi-Drop Bus Events

Several status bits and interrupt features in the UART_STAT and UART_IMSK registers facilitate efficient data handling in multi-drop bus mode. These features include the address (UART_STAT.ADDR) bit, the address sticky (UART_STAT.ASTKY) bit and the enable address word interrupt (UART_IMSK.EAWI). One of the key features of the multi-drop bus protocol is its address bit. The address bit signifies to the completer that the requester is transmitting an address word (all read it) or a data word (only the addressed target reads its). The UART hardware provides an efficient method of handling the situation described with the use of UART_STAT.ASTKY bit.

NOTE: The UART module uses the UART_STAT.ASTKY bit in multi-drop bus mode to indicate when an address operation for a peripheral is occurring. The UART_STAT.ASTKY bit is a sticky version of the UART_STAT.ADDR bit. Hardware sets the bit whenever the UART_STAT.ADDR bit is set. Only software clears it with a W1C operation. With the UART_STAT.ASTKY bit set, words are received irrespective of the mode bit or address bit setting. With the UART_STAT.ASTKY bit cleared, only address words (mode bit =1) are received and words with mode bit =0 are ignored in MDB mode. This bit does not affect reception in non-MDB modes. (Words with mode bit =0 are not moved from the UART_RSR register to the receive FIFO.)

UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

Detecting Autobaud

To detect Autobaud:

1. Ensure that the timer is disabled.
2. Configure the following bits: UART_CTL.MOD =00, UART_CTL.LOOP_EN =1, UART_CTL.WLS =11 (8-bit data), and UART_CTL.EN =1
3. Configure the following bits: TIMER_TMR[n]_CFG.TMODE =1101, TIMER_TMR[n]_CFG.OUTDIS =1, TIMER_TMR[n]_CFG.IRQMODE =10 and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.

   The bit rate can be derived from the timer period register value according to the formula provided in the Autobaud Detection section.

Using Common Initialization Steps

When using the core or the DMA to execute transfers, the following steps are common to all UART modes.

1. All UART signals are multiplexed and compete with other functions at pin level. First, program the port registers according to the guidelines in the PORT chapter.
2. Program the UART_CLK register. Refer to Bit Rate Generation topic.
3. Program the UART_CTL register and enable the UART clock.

Using Core Transfers

Write data into the UART_THR register, when the UART_STAT.THRE bit is set, to initiate a core transmit operation. If the UART_STAT.DR bit is set, received data can be read from the UART_RBR register.

Using DMA Transfers

1. Make sure that the UART_IMSK.ETBEI or the UART_IMSK.ERBFI bits are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the UART_IMSK.ETBEI or UART_IMSK.ERBFI bits to start the transfer.

Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC)
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART\_CTS}}$ and $\overline{\text{UART\_RTS}}$ polarity through the UART_CTL.FCPOL bit.

ADSP-2159x_SC591_SC592_SC594 UART Register Descriptions

UART (UART) contains the following registers.

Table 22-9: ADSP-2159x_SC591_SC592_SC594 UART Register List

Name	Description
UART_CLK	Clock Rate Register

Table 22-9: ADSP-2159x_SC591_SC592_SC594 UART Register List (Continued)

Name	Description
UART_CTL	Control Register
UART_IMSK	Interrupt Mask Register
UART_IMSK_CLR	Interrupt Mask Clear Register
UART_IMSK_SET	Interrupt Mask Set Register
UART_RBR	Receive Buffer Register
UART_RSR	Receive Shift Register
UART_RXCNT	Receive Counter Register
UART_SCR	Scratch Register
UART_STAT	Status Register
UART_TAIP	Transmit Address/Insert Pulse Register
UART_THR	Transmit Hold Register
UART_TSR	Transmit Shift Register
UART_TXCNT	Transmit Counter Register

Clock Rate Register

The UART_CLK register divides the system clock (SCLK0) down to the bit clock.

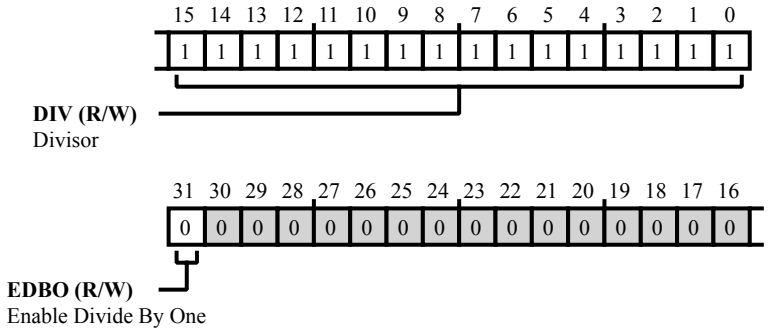

Figure 22-11: UART_CLK Register Diagram

Table 22-10: UART_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EDBO	Enable Divide By One. The UART_CLK.EDBO bit enables the bypassing of the divide-by-16 prescaler in bit clock generation. This functionality improves bit rate granularity, especially at high bit rates. Do not set this bit in IrDA mode. Note: Properly select the SCLK frequencies. Even multiples of bit rate decrease the error percentage. Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. The disadvantage is that the power dissipation is higher and sample points are not always accurate. Therefore, use UART_CLK.EDBO=1 mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode. The UART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.	
		0	Bit clock prescaler = 16
		1	Bit clock prescaler = 1
15:0 (R/W)	DIV	Divisor. The UART_CLK.DIV provides the divisor for the UART's clock bit rate calculation. The bit rate is defined by: Bit Rate = SCLK0 / ($16^{(1-EDBo)}$ x UART_CLK.DIV)	

Control Register

The UART_CTL register provides enable and disable control for UART and IrDA mode of operation. It also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

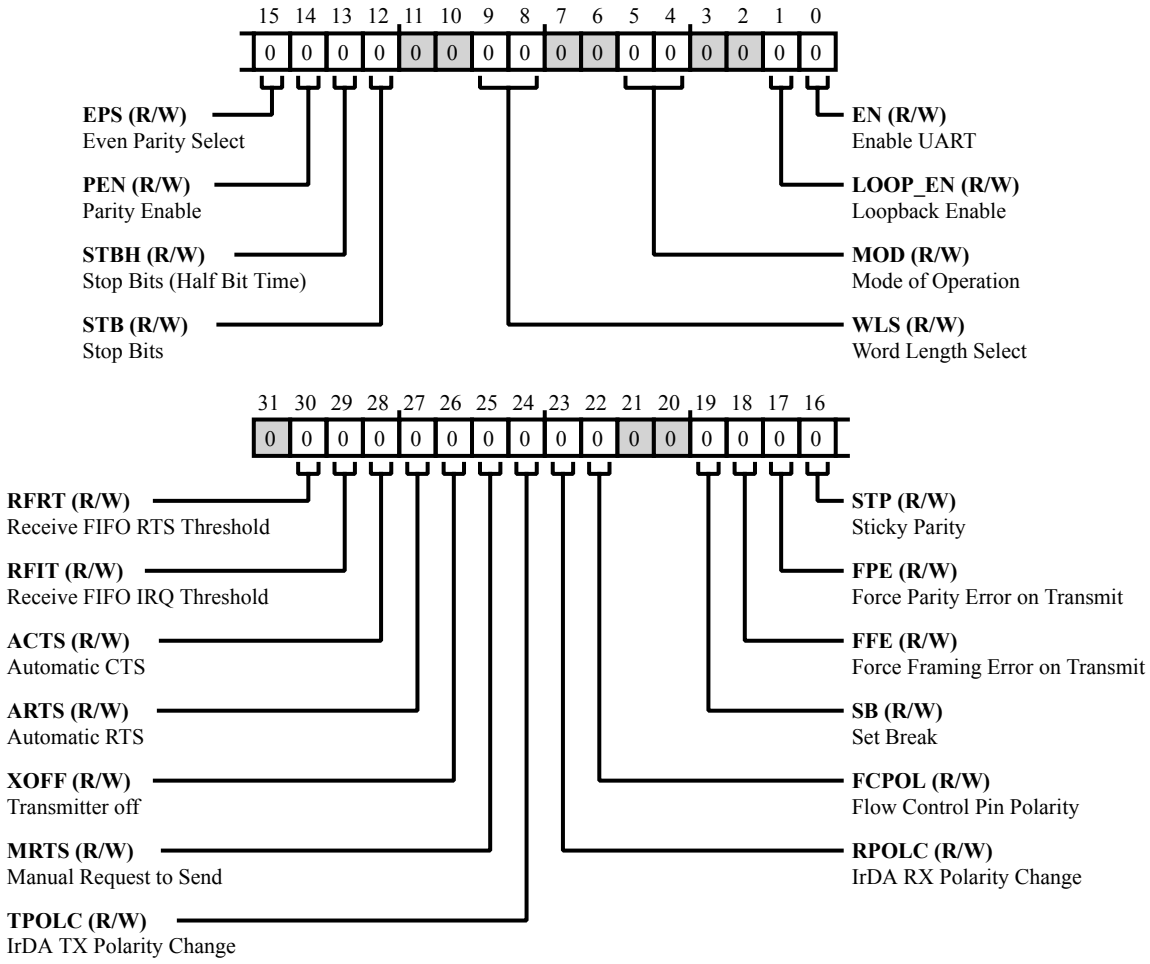

Figure 22-12: UART_CTL Register Diagram

Table 22-11: UART_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RFRT	Receive FIFO RTS Threshold. The UART_CTL.RFRT bit controls UART_RTS pin assertion and deassertion timing. This bit is ignored if UART_CTL.ARTS is cleared. If set, the UART_RTS pin is deasserted when the receive buffer already holds seven words and an eighth start bit is detected. It is reasserted when the FIFO contains seven words or less. If cleared, the UART_RTS pin is deasserted when the RX buffer already holds four words and a fifth start bit is detected. The UART_RTS pin is reasserted when the RX buffer contains no more than 4 words.	
		0	Deassert RTS if RX FIFO word count > 4; assert if <= 4
		1	Deassert RTS if RX FIFO word count > 7; assert if <= 7
29 (R/W)	RFIT	Receive FIFO IRQ Threshold. The UART_CTL.RFIT bit controls the timing of the UART_STAT.RFCS bit. If UART_CTL.RFIT is cleared, the receive threshold is two. If UART_CTL.RFIT is set, the threshold is four words in the receive buffer.	
		0	Set RFCS=1 if RX FIFO count >= 4
		1	Set RFCS=1 if RX FIFO count >= 7
28 (R/W)	ACTS	Automatic CTS. The UART_CTL.ACTS bit must be set to enable the UART_CTS input pin for UART_TX handshaking. If enabled, the UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL is set) or complement value (if UART_CTL.FCPOL is cleared) of the UART_CTS input pin. The UART_STAT.CTS bit can be used to determine whether the external device is ready to receive data (if UART_STAT.CTS is set) or whether it is busy (if UART_STAT.CTS is cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART_TX line transmits data whenever there is data to send, regardless of the value of UART_CTS. Software can pause ongoing transmission by setting the UART_CTL.XOFF bit.	
		0	Disable TX handshaking protocol
		1	Enable TX handshaking protocol
27 (R/W)	ARTS	Automatic RTS. The UART_CTL.ARTS bit must be set to enable the UART_RTS input pin for UART_TX handshaking. If set, the hardware guarantees a minimal UART_RTS pin deassertion pulse width of at least the number of data bits defined by the UART_CTL.WLS bit field. If cleared, the UART_RTS pin is not generated automatically by hardware. The UART_RTS pin can still be manually controlled by the UART_CTL.MRTS bit, and software is responsible for UART_RTS pulse width control (if needed).	
		0	Disable RX handshaking protocol.
		1	Enable RX handshaking protocol.

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	XOFF	Transmitter off. The UART_CTL.XOFF bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the UART_CTL.XOFF bit is ignored if the UART_CTL.ACTS bit is set.	
		0	Transmission ON, if ACTS=0
		1	Transmission OFF, if ACTS=0
25 (R/W)	MRTS	Manual Request to Send. The UART_CTL.MRTS bit controls the state of the UART_RTS output pin when the UART_CTL.ARTS bit is cleared. When UART_CTL.MRTS is cleared, the UART deasserts the UART_RTS pin, signaling to the external device that the UART is not ready to receive. When UART_CTL.MRTS is set, the UART asserts the UART_RTS pin, signaling to the external device that the UART is ready to receive.	
		0	Deassert RTS pin when ARTS=0
		1	Assert RTS pin when ARTS=0
24 (R/W)	TPOLC	IrDA TX Polarity Change. The UART_CTL.TPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_TX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_TX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low TX polarity setting
		1	Active-high TX polarity setting
23 (R/W)	RPOLC	IrDA RX Polarity Change. The UART_CTL.RPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_RX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_RX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low RX polarity setting
		1	Active-high RX polarity setting

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	FCPOL	Flow Control Pin Polarity. The UART_CTL.FCPOL bit selects the polarities of the UART_CTS and UART_RTS pins. When the UART_CTL.FCPOL bit is cleared, the UART_RTS and UART_CTS pins are active low, and the UART is halted when the UART_RTS and UART_CTS pin state is high. When UART_CTL.FCPOL bit is set, the UART_RTS and UART_CTS pins are active high, and the UART is halted when the UART_RTS and UART_CTS pin state is low.	
		0	Active low CTS/RTS
		1	Active high CTS/RTS
19 (R/W)	SB	Set Break. If set, the UART_CTL.SB bit forces the UART_TX pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the UART_TX pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if UART_CTL.TPOLC is cleared, drive UART_TX pin low; or if UART_CTL.TPOLC is set, drive UART_TX pin high.)	
		0	No force
		1	Force TX pin to 0
18 (R/W)	FFE	Force Framing Error on Transmit. The UART_CTL.FFE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force error
17 (R/W)	FPE	Force Parity Error on Transmit. The UART_CTL.FPE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force parity error

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	STP	Sticky Parity. The UART_CTL.STP bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by UART_CTL.STP cleared and UART_CTL.EPS set. Then, the count of logical-1 bits must be a even value. If the UART_CTL.STP bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted UART_CTL.EPS bit.	
		0	No forced parity
		1	Force (Stick) parity to defined value (if PEN=1)
15 (R/W)	EPS	Even Parity Select.	
		0	Odd parity
		1	Even parity
14 (R/W)	PEN	Parity Enable. The UART_CTL.PEN bit enables parity transmission and parity check. The UART_CTL.PEN bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the UART_CTL.STP and UART_CTL.EPS control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they do not match. If the UART_CTL.PEN bit is cleared, the UART_CTL.STP and the UART_CTL.EPS bits are ignored.	
		0	Disable
		1	Enable parity transmit and check
13 (R/W)	STBH	Stop Bits (Half Bit Time).	
		0	0 half-bit-time stop bit
		1	1 half-bit-time stop bit
12 (R/W)	STB	Stop Bits. The UART_CTL.STB bit controls how many stop bits are appended to transmitted data.	
		0	1 stop bit
		1	2 stop bits

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	WLS	Word Length Select. The UART_CTL.WLS field determines whether the transmitted and received UART word consists of 5, 6, 7, or 8 data bits.	
		0	5-bit word
		1	6-bit word
		2	7-bit word
		3	8-bit word
5:4 (R/W)	MOD	Mode of Operation. The UART_CTL.MOD selects the UART operation mode (UMOD).	
		0	UART mode
		1	MDB mode
		2	IrDA SIR mode
1 (R/W)	LOOP_EN	Loopback Enable. The UART_CTL.LOOP_EN bit enables UART loopback mode. When set, this bit disconnects the input of the receiver from the UART_RX pin, and internally redirects the transmit output to the receiver. The UART_TX pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to its deassertive state, disconnects the UART_CTS bit from the UART_CTS input pin, and directly connects the UART_CTL.MRTS bit to the UART_STAT.CTS bit. In loopback mode, setting the UART_CTL.MRTS bit sets the UART_STAT.CTS bit and enables the transmitter of the UART. Clearing the UART_CTL.MRTS bit clears the UART_STAT.CTS bit and disables the transmitter of the UART.	
		0	Disable
		1	Enable
0 (R/W)	EN	Enable UART. The UART_CTL.EN enables the UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.	
		0	Disable
		1	Enable

Interrupt Mask Register

The UART_IMSK register indicates the interrupt mask status (unmasked, if set, or masked, if cleared) of the UART status interrupt requests. This register is not a data register. Instead, it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to the UART_IMSK_SET register enables (unmasks) interrupt requests, and writing ones to the UART_IMSK_CLR register disables (masks) them. Reads from either register return the enabled bits.

The UART_IMSK register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of the data inventory state using interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle the data transmit, data receive, and line status events independently, regardless of whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the UART_IMSK.ELSI bit to reroute the transmit and receive interrupts to the status interrupt request output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available for receive and transmit operations. Line error handling can be configured independently from the receive or transmit setup.

The DMA of the UART is enabled by first setting up the system DMA control registers and then enabling the UART_IMSK.ERBFI and UART_IMSK.ETBEI interrupts. This configuration is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit(s). However, the error interrupt for the UART goes directly to the system interrupt handling unit(s), bypassing the DMA unit completely.

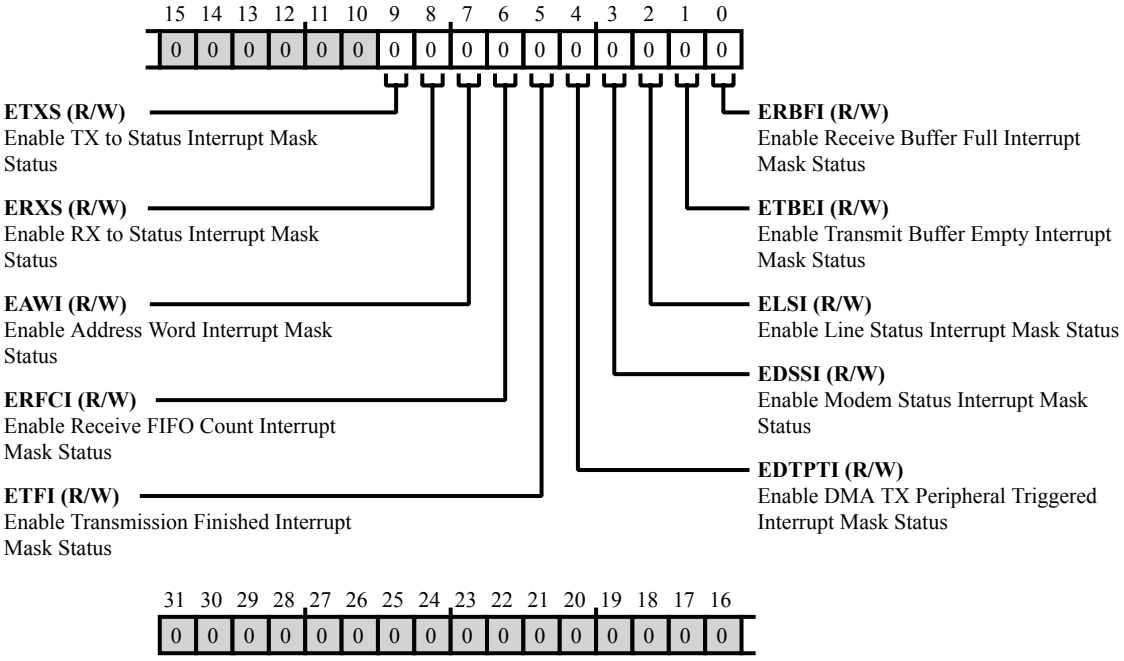

Figure 22-13: UART_IMSK Register Diagram

Table 22-12: UART_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ETXS	Enable TX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETXS` bit indicates re-direction of the TX interrupt requests to status interrupt output. If cleared, TX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
8 (R/W)	ERXS	Enable RX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERXS` bit indicates re-direction of RX interrupt requests to status interrupt output. If cleared, RX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 22-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EAWI	Enable Address Word Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EAWI bit indicates generation of a status interrupt request when an Address word in MDB-mode is present in the UART_RBR. A received word is an address word if the UART_STAT.ADDR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
6 (R/W)	ERFCI	Enable Receive FIFO Count Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERFCI bit indicates enabling of the receive buffer threshold interrupt request if signaled by the UART_STAT.RFCS bit. Read the UART_RBR register sufficient times to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
5 (R/W)	ETFI	Enable Transmission Finished Interrupt Mask Status. If set (interrupt unmasked) the UART_IMSK.ETFI bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the UART_STAT.TFI. The UART_IMSK.ETFI interrupt can be used to avoid expensive polling of the UART_STAT.TEMT bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the UART_STAT.TFI bit to clear the interrupt request. In DMA operation, the UART_IMSK.ETFI bits functionality might be preferred.	
		0	Interrupt is masked
		1	Interrupt is unmasked
4 (R/W)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDTPTI bit indicates enabling of the DMA completion interrupt request to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt request by the time the UART_STAT.TEMT bit goes high after the last DMA data word is transmitted. When UART_IMSK.EDTPTI is set, usually the DMA_CFG.INT field is cleared to 00 in a STOP mode DMA. This set up suppresses the normal completion interrupt request, and the UART_STAT.TEMT event is signaled through the DMA controller and triggers the DMA interrupt. If both (DMA_CFG.INT not 00 and UART_IMSK.EDTPTI set), two interrupts are requested at the end of a STOP mode DMA.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 22-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	EDSSI	Enable Modem Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDSSI bit indicates enabling of a modem status interrupt request on the same status interrupt channel when the UART_STAT.SCTS bit is set. This indicates UART_CTS pin re-assertion. Write-1-to-clear (W1C) the UART_STAT.SCTS bit to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
2 (R/W)	ELSI	Enable Line Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ELSI bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the UART_STAT.OE, UART_STAT.PE, UART_STAT.FE, and UART_STAT.BI interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling UART_IMSK.ELSI disables the RX/TX interrupt channels and negates the UART_IMSK.EDTPTI bit.	
		0	Interrupt is masked
		1	Interrupt is unmasked
1 (R/W)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ETBEI bit indicates generation of a TX interrupt request if the UART_STAT.THRE bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
0 (R/W)	ERBFI	Enable Receive Buffer Full Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERBFI indicates generation of an RX interrupt request if the UART_STAT.DR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Interrupt Mask Clear Register

The UART_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

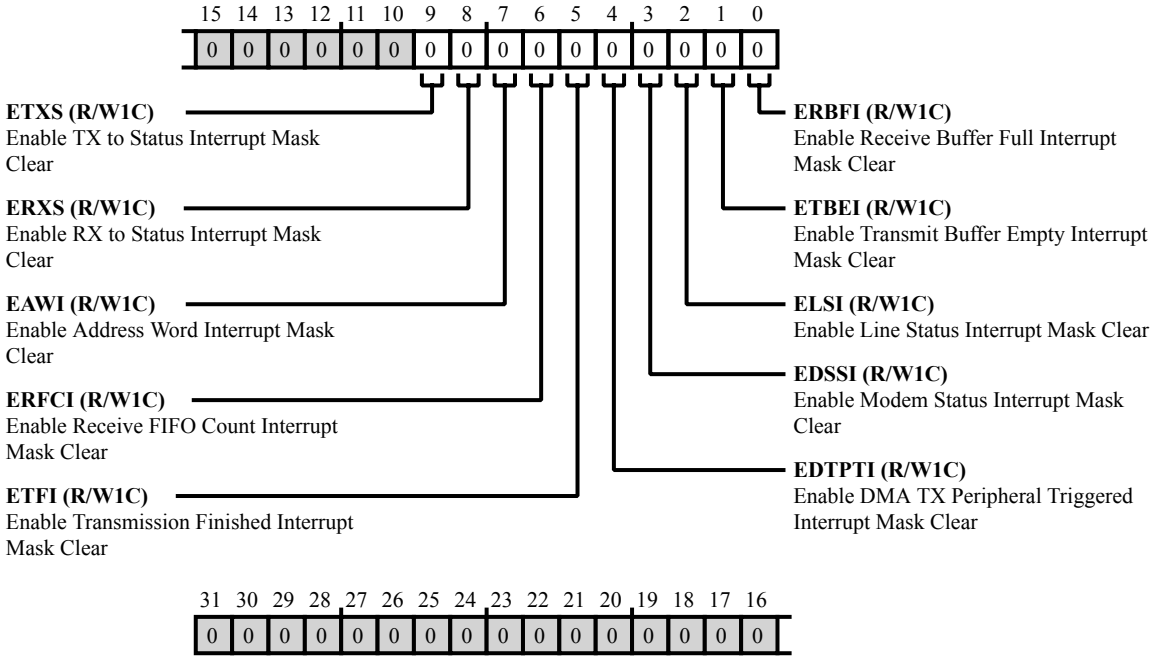

Figure 22-14: UART_IMSK_CLR Register Diagram

Table 22-13: UART_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ETXS	Enable TX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
8 (R/W1C)	ERXS	Enable RX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
7 (R/W1C)	EAWI	Enable Address Word Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Table 22-13: UART_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERFCI	Enable Receive FIFO Count Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
5 (R/W1C)	ETFI	Enable Transmission Finished Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
4 (R/W1C)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
3 (R/W1C)	EDSSI	Enable Modem Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
2 (R/W1C)	ELSI	Enable Line Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
1 (R/W1C)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
0 (R/W1C)	ERBFI	Enable Receive Buffer Full Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Interrupt Mask Set Register

The UART_IMSK indicates interrupt request mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

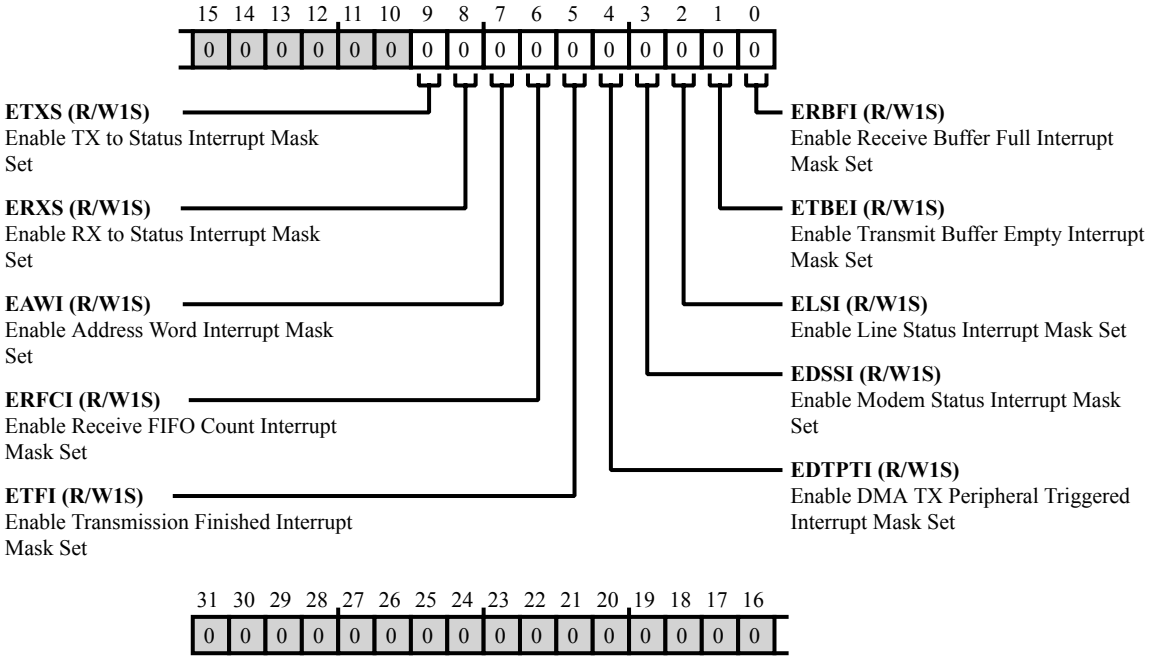

Figure 22-15: UART_IMSK_SET Register Diagram

Table 22-14: UART_IMSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1S)	ETXS	Enable TX to Status Interrupt Mask Set.	
		0	No action

		0	No action
		1	Unmask interrupt
0 (R/W1S)	ERBFI	Enable Receive Buffer Full Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt

Receive Buffer Register

The read-only UART_RBR register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the UART_STAT.DR bit.

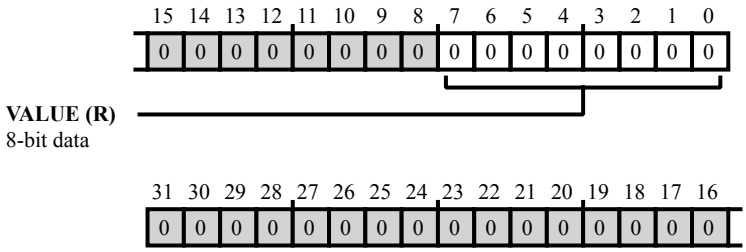

Figure 22-16: UART_RBR Register Diagram

Table 22-15: UART_RBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	8-bit data.

Receive Shift Register

The read only UART_RSR register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the UART_RSR contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

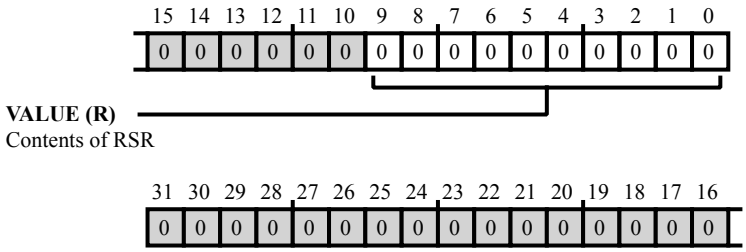

Figure 22-17: UART_RSR Register Diagram

Table 22-16: UART_RSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	VALUE	Contents of RSR.

Receive Counter Register

The UART_RXCNT register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

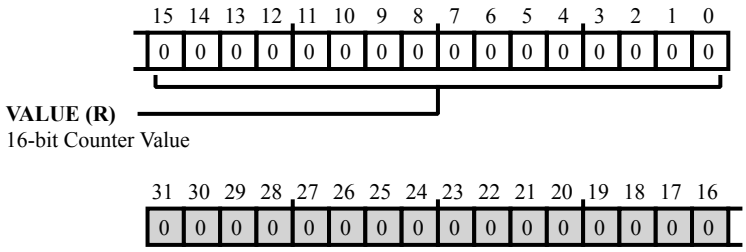

Figure 22-18: UART_RXCNT Register Diagram

Table 22-17: UART_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

Scratch Register

The UART_SCR registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

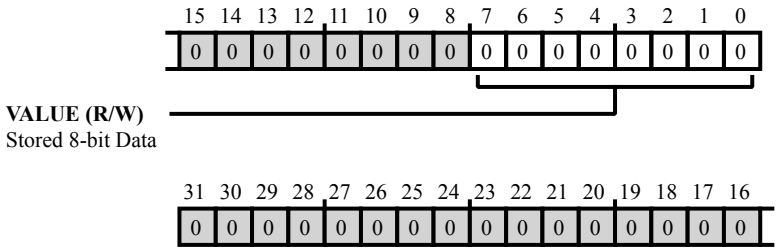

Figure 22-19: UART_SCR Register Diagram

Table 22-18: UART_SCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Stored 8-bit Data.

Status Register

The UART_STAT register contains the UART line status and UART modem status, as indicated by the current states of the UART's UART_CTS pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

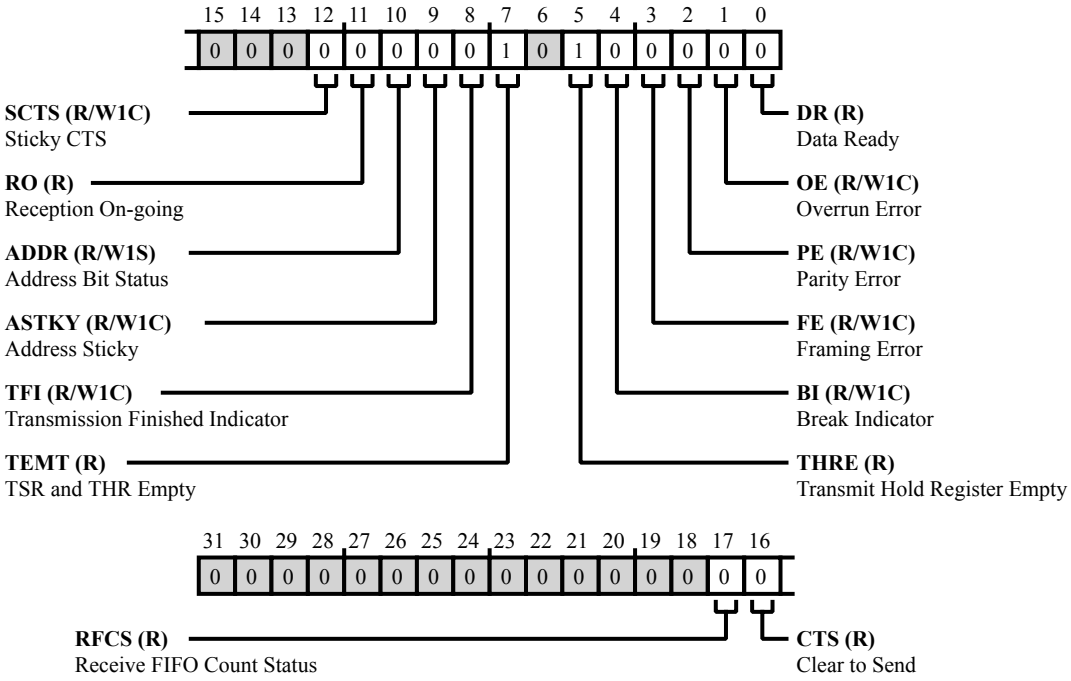

Figure 22-20: UART_STAT Register Diagram

Table 22-19: UART_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RFCS	Receive FIFO Count Status. The UART_STAT.RFCS bit is set when the receive buffer holds more or equal entries than a certain threshold. The threshold is controlled by the UART_CTL.RFIT bit. If UART_CTL.RFIT is cleared, the threshold is four entries. If UART_CTL.RFIT is set, the threshold is seven entries. The UART_STAT.RFCS bit is cleared when the UART_RBR register is read sufficient times until the buffer is drained below the threshold. The UART_STAT.RFCS bit can trigger a status interrupt request if enabled by the UART_IMSK_SET.ERFCI bit.	
		0	RX FIFO has less than 4 (7) entries when RFIT=0 (1)
		1	RX FIFO has at least 4 (7) entries when RFIT=0 (1)

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CTS	Clear to Send. The UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL set) or the complement value (if UART_CTL.FCPOL cleared) of the UART_CTS input pin. The UART_CTL.ACTS bit must be set to enable this feature. The core can read the value of the UART_STAT.CTS bit to determine whether the external device is ready to receive (UART_STAT.CTS set) or if it is busy (UART_STAT.CTS cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of UART_STAT.CTS. When UART_CTL.ACTS is cleared, the software can pause transmission temporarily by setting the XOFF bit. Note that in loopback mode (UART_CTL.LOOP_EN set), the UART_STAT.CTS bit is disconnected from the UART_CTS input pin. Instead, the bit is directly connected to the UART_CTL.MRTS bit.	
		0	Not clear to send (External device not ready to receive)
		1	Clear to send (External device ready to receive)
12 (R/W1C)	SCTS	Sticky CTS. The UART_STAT.SCTS bit is a sticky bit that is set when UART_STAT.CTS transitions from 0 to 1. The UART_STAT.SCTS bit is cleared by software with a W1C operation. This bit can trigger a line status interrupt request if enabled by the UART_IMSK_SET.EDSSI bit.	
		0	CTS has not transitioned from low to high
		1	CTS has transitioned from low to high
11 (R/NW)	RO	Reception On-going.	
		0	No data reception in progress
		1	Data reception in progress
10 (R/W1S)	ADDR	Address Bit Status. The UART_STAT.ADDR bit is used to mirror the address bit of the word in UART_RBR in multi-drop bus protocol, and is enabled only in MDB mode. The UART_STAT.ADDR bit is updated by hardware upon detecting a received word with the address bit in UART_RBR set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.	
		0	Address bit is low
		1	Address bit is high

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ASTKY	Address Sticky. The UART_STAT.ASTKY bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the UART_STAT.ADDR bit and is set by hardware when setting the UART_STAT.ADDR bit. The UART_STAT.ASTKY bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the UART_STAT.ASTKY bit set, words will be received irrespective of the UART_CTL.MOD bit or UART_STAT.ADDR bit selection. With the UART_STAT.ASTKY bit cleared, only address words (UART_CTL.MOD bit set) will be received and words with UART_CTL.MOD bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The UART_STAT.ASTKY bit does not affect reception in non-MDB modes.	
		0	ADDR bit has not been set
		1	ADDR bit has been set
8 (R/W1C)	TFI	Transmission Finished Indicator. The UART_STAT.TFI bit is a sticky version of the UART_STAT.TEMT bit. While UART_STAT.TEMT is automatically cleared by hardware when new data is written to the UART_THR register, the sticky UART_STAT.TFI bit remains set, until it is cleared by software (W1C). The UART_STAT.TFI bit enables more flexible transmit interrupt request timing.	
		0	TEMT did not transition from 0 to 1
		1	TEMT transition from 0 to 1
7 (R/NW)	TEMT	TSR and THR Empty. The UART_STAT.TEMT bit indicates that the UART_THR and UART_TAIP registers and the UART_TSR register are empty. In this case, the program is permitted to write to the UART_THR and UART_TAIP registers twice without losing data. The UART_STAT.TEMT bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the UART_CTL.EN bit or to three-state the off-chip line driver.	
		0	Not empty TSR/THR
		1	TSR/THR Empty

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	THRE	Transmit Hold Register Empty. The UART_STAT.THRE bit indicates that the UART transmit channel is ready for new data and software can write to the UART_THR and UART_TAIP registers. Writes to the UART_THR and UART_TAIP registers clear the UART_STAT.THRE. The bit is set again when the UART_THR and UART_TAIP registers are empty and ready to accept data.	
		0	Not empty THR/TAIP
		1	Empty THR/TAIP
4 (R/W1C)	BI	Break Indicator. The UART_STAT.BI bit indicates that the first stop bit is sampled low and the entire data word, including parity bit, consists of low bits only. (This condition indicates that UART_RX was held low for more than the maximum word length.) The UART_STAT.BI bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The bit is sticky and can be cleared by W1C operations.	
		0	No break interrupt
		1	Break interrupt this indicates UARTxRX was held low(RPOLC=0) / high (RPOLC=1) for more than the maximum word length
3 (R/W1C)	FE	Framing Error. The UART_STAT.FE bit indicates that the first stop bit is sampled. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.FE bit is sticky and can be cleared by W1C operations. Note that invalid stop bits can be simulated by setting the UART_CTL.FFE bit.	
		0	No error
		1	Invalid stop bit error
2 (R/W1C)	PE	Parity Error. The UART_STAT.PE bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.PE bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the UART_CTL.FPE bit.	
		0	No parity error
		1	Parity error

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	OE	Overrun Error. The UART_STAT.OE bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the UART_RBR register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the UART_RBR and receive FIFO are protected from being overwritten by new data until the UART_STAT.OE bit is cleared by software. The content of the UART_RSR register is lost as soon as the overrun occurs. The UART_STAT.OE bit is sticky and can be cleared by W1C operations.	
		0	No overrun
		1	Overrun error
0 (R/NW)	DR	Data Ready. The UART_STAT.DR bit indicates that data is available in the receiver and can be read from the UART_RBR register. The bit is set by hardware when the receiver detects the first valid stop bit. The bit is cleared by hardware when the UART_RBR register is read.	
		0	No new data
		1	New data in RBR

Transmit Address/Insert Pulse Register

The UART_TAIP register and the UART_THR register share the same physical register, but UART_TAIP has different effect than the UART_THR register when UART_TAIP is written to in MDB and UART modes.

In MDB mode, data written to the UART_TAIP register is transmitted as an address frame (as with the UART_CTL.MOD bit set).

In UART mode, a write to UART_TAIP causes a pulse of value UART_TAIP [7] for a duration of UART_TAIP [6:0] x bit time. (There is additional inversion if the UART_CTL.TPOLC bit is set).

Bit time is defined by the UART_CLK register. The transmission of the pulse is followed by stop bit transmission as specified by the UART_CTL.STB and UART_CTL.STBH bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to UART_TAIP is treated the same as writes to UART_THR.

Accesses to the UART_TAIP register have the same affects as the UART_THR register with respect to the UART_STAT.THRE, UART_STAT.TEMT, and UART_STAT.TFI flags.

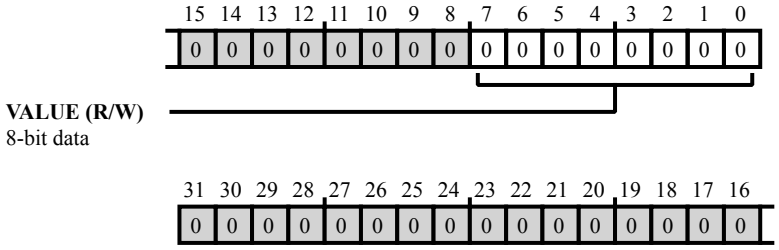

Figure 22-21: UART_TAIP Register Diagram

Table 22-20: UART_TAIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8-bit data.

Transmit Hold Register

The write-only UART_THR register is the UART's transmit buffer. The UART_STAT.THRE bit indicates whether data can be written to UART_THR. Writes to this register automatically propagate to the internal UART_TSR register as soon as UART_TSR is ready. Then, transmit operation is initiated immediately.

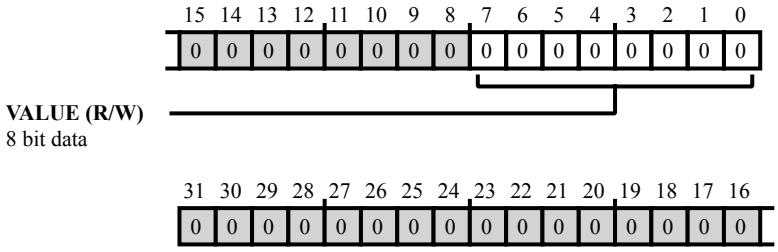

Figure 22-22: UART_THR Register Diagram

Table 22-21: UART_THR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8 bit data.

Transmit Shift Register

The read only UART_TSR register which returns the content of the UART's transmit shift register.

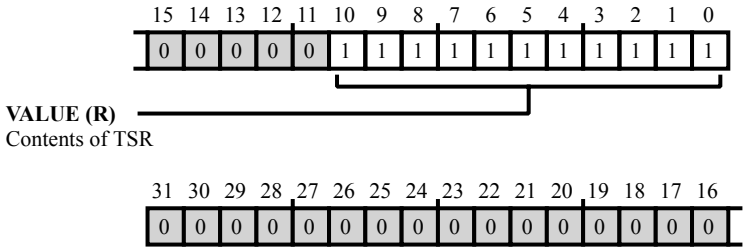

Figure 22-23: UART_TSR Register Diagram

Table 22-22: UART_TSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Contents of TSR.

Transmit Counter Register

The UART_TXCNT read only register returns the content of 16-bit counter in the UART transmitter. This count is used for baud rate clock generation (the lower [15:0] is the count data).

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

23 Enhanced Parallel Peripheral Interface (EPPI)

The Enhanced Parallel Peripheral Interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCDs, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has two DMA channels associated with it. Moreover, in some modes, an EPPI can use an extra DMA channel.

EPPI Features

The EPPI module supports the following features.

- Programmable data length from 8 bits to up to 24 bits per clock cycle (depending on the product model)
- Bidirectional and half-duplex port
- Internal or external clock source
- Clock gating by an external device asserting the clock gating control signal
- Various framed and non-framed operating modes, as well as internal or external frame syncs
- Various general-purpose modes with 0, 1, 2, and 3 frame sync modes for both receive and transmit
- Ignores premature external frame syncs for data consistency
- SMPTE274M and SMPTE 296M high definition format support
- ITU-656, SMPTE 296M and SMPTE 274M status word error detection and correction for ITU-656 receive modes
- ITU-656, SMPTE 296M and SMPTE 274M receive modes – active video only, vertical blanking only, and entire field
- ITU-656, SMPTE 296M and SMPTE 274M preamble and status word decode
- Optional packing and unpacking of data to or from 32 bits from or to 8, 16 bits and 24 bits. If packing or unpacking is enabled, endianness can be altered to change the order of packing or unpacking of bytes/words
- Optional sign extension or zero-fill and alternate even or odd data sample filter for receive modes

- RGB888 to RGB666 or RGB565 conversion for transmit modes
- 4:2:2 YCrCb data Tx/Rx interleaving or de-interleaving modes
- Configurable LCD data enable (DEN) output available on frame sync 3
- Delayed start of PPI frame syncs
- Data clipping and mirroring
- Horizontal and vertical windowing for general purpose 2 and 3 frame sync modes
- Preamble, blanking and stripping support
- Multiplexing dual input

EPPI Functional Description

The EPPI has the following functionality.

RGB data formats

For transmit modes, the EPPI can convert RGB888 data in memory to either RGB565 or RGB666 at the output using bits in the Control register.

Data clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. This functionality is used for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes.

Data mirroring

A data mirroring feature is available which mirrors the EPPI data bits 15–0. This functionality is available in both transmit and receive modes.

Windowing

The EPPI supports windowing for general-purpose input modes.

Preamble, blanking and stripping support

The EPPI can embed blanking information and clip active data to be transmitted. This functionality is available for single channel data, interleaved data, and parallel data and supports data lengths equal to 16 bits, 20 bits or 24 bits.

ADSP-2159x_SC591_SC592_SC594 EPPI Register List

The EPPI is a half-duplex, bidirectional parallel port. It comprises a clock pin, 3 frame sync pins, and a set of data pins. For more information on EPPI functionality, see the EPPI register descriptions.

Table 23-1: ADSP-2159x_SC591_SC592_SC594 EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

20	EPPI0_CH1_DMA	EPPI0 Channel 1 DMA	Pulse

RGB Data Formats

For transmit modes, the EPPI can convert RGB888 data in memory to RGB666 at the output when the EPPI_CTL.RGBFMTEN bit is set and the EPPI_CTL.DLEN value is equal to 18 bits. Similarly, the EPPI can convert RGB888 data in memory to RGB565 at the output when the EPPI_CTL.RGBFMTEN bit is set and EPPI_CTL.DLEN is equal to 16 bits.

This conversion is performed as follows:

- If EPPI_CTL.PACKEN =1, the EPPI first unpacks according to the EPPI_CTL.SWAPEN bit setting, and the three 32-bit data words from the DMA are broken into four 24-bit data words to be transmitted out, as described earlier.
- If EPPI_CTL.PACKEN =0, the EPPI takes the lower 24 bits of the 32-bit DMA as the data to be transmitted. Then, the EPPI truncates this 24-bit data word to the required data width. It removes the lower 2 bits of G and the lower 2 bits or 3 bits of R and B.

Data Clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. It uses these registers for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes. All data values for odd samples which are less than the value in the EPPI_ODDCLIP.LOWODD bit field are replaced with the value in the EPPI_ODDCLIP.LOWODD field. All data values for even samples which are less than the value in the EPPI_EVENCLIP.LOWEVEN field are replaced with the value in the EPPI_EVENCLIP.LOWEVEN field.

In the same manner, all data values for odd samples which are more than the value in the EPPI_ODDCLIP.HIGHODD bit field are replaced with the value in the EPPI_ODDCLIP.HIGHODD field. All data values for even samples which are more than the values in the EPPI_EVENCLIP.HIGHEVEN field are replaced with the values in the EPPI_EVENCLIP.HIGHEVEN field.

Depending on the programmed EPPI length, only the corresponding bits (least aligned) are considered for clipping. For example, if the EPPI is programmed in 10-bit mode, bits 9:0 and bits 25:16 constitute the clipping thresholds. The higher bits are ignored. The EPPI supports 8-bit, 10-bit, 12-bit, and 16-bit clipping thresholds.

For the 4:2:2 YCrCb color space, Luma and Chroma typically have different lower and upper thresholds. Separate thresholds can be required for even and odd data samples. For monochrome (Y only) or some non-video clipping applications, the value in the EPPI_ODDCLIP.LOWODD field can be the same as the value in the EPPI_EVENCLIP.LOWEVEN field. The value in the EPPI_ODDCLIP.HIGHODD field can be the same as the value in the EPPI_EVENCLIP.HIGHEVEN field.

In GP 0 FS mode with internal blanking generation, clipping is valid only for the active video part of the transmitted data. ITU-R 656 preambles, status words, and blanking data bypass the clipping logic.

If the EPPI is programmed in 16 or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the YDATA (luma data) gets the clipping threshold levels of the EPPI_EVENCLIP register. The CDATA (chroma data) gets the clipping threshold levels of the EPPI_ODDCLIP register.

The clipping registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

Data Mirroring

To increase the pin multiplexing options for the EPPI data pins, a data mirroring feature is available which mirrors the EPPI data bits 15:0. This feature is available in both transmit and receive modes. It is enabled by setting the EPPI_CTL.DMIRR bit.

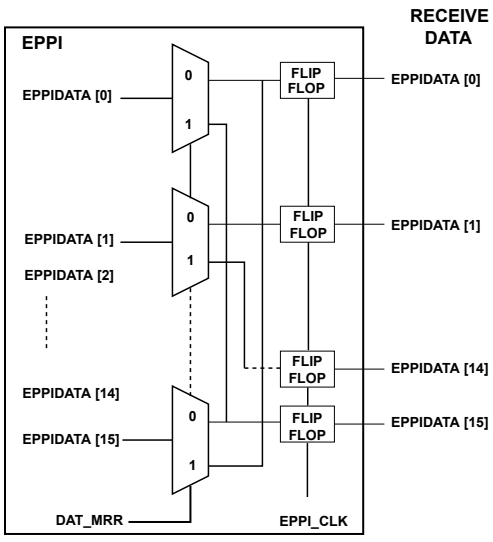

Figure 23-1: Data Mirroring Receive

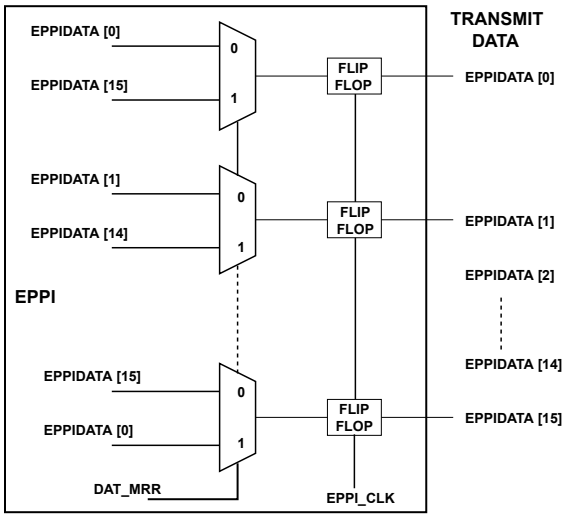

Figure 23-2: Data Mirroring Transmit

Windowing

The EPPI supports windowing for general-purpose input modes. The module can be configured to bring in a region of interest instead of the entire frame of data, which helps reduce bandwidth requirements.

Preamble, Blanking and Stripping Support

The EPPI supports embedding blanking information and clipping of active data for transmission. This functionality is available for single-channel data, interleaved data, and parallel data and supports a data length (`EPPI_CTL.DLEN`) of 16, 20 bits or 24 bits.

Support of preamble generation or detection and stripping of blanking information is also provided for ITU656 mode and the SMPTE 274M and 296M HD formats. The ***Video Mode Comparison*** table shows the SMPTE standards in comparison with the ITU656 modes. Preambles for SMPTE and ITU656 modes are identical. Extension of preamble to 12 bits is also supported.

Table 23-5: Video Mode Comparison

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
ITU656 (NTSC)	30	1716x525	720x480	27.02	Y-C interleaved
ITU656 (PAL)	25	1728x625	720x576	27.00	Y-C interleaved
SMPTE 296M	30	3300x750	1280x720	74.25	Y,C separate
	60	1650x750	1280x720	74.25	Y,C separate

Table 23-5: Video Mode Comparison (Continued)

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
SMPTE 274M	30	2200x1125	1920x1080	74.25	Y,C separate
	60	2200x1125	1920x1080	148.50	Y,C separate
	25	2640x1125	1920x1080	74.25	Y,C separate
	50	2640x1125	1920x1080	148.50	Y,C separate
	24	2750x1125	1920x1080	74.25	Y,C separate

See the clock operating conditions section of the data sheet for the maximum sampling frequency for this product.

EPPI Definitions

The following definitions are helpful when using the EPPI module.

ITU-R BT.-656

Description of a digital video protocol for interfaces and data stream format required to send uncompressed PAL or NTSC standard definition TV (525 or 625 lines) signals.

YUV422

YUV is a color space where luminance (Y) and chrominance (UV) components define the pixels. The suffix signifies how the chrominance components have been decimated and provide formatting information. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component is available. Typical YUV422 formatting interleaves the luminance and chrominance (for example, U1Y1V1Y2U2Y3V2Y4).

RGB888

RGB is a color space where three color values, one red (R), one green (G) and one blue (B), define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green, and blue value is 8 bits.

RGB565

RGB is a color space where three color values, one red (R), one green (G) and one blue (B) define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB565 means that the red (R) and blue (B) are 5 bits each while the green (G) is 6 bits. When packed together, each RGB565 pixel can be represented in a 16-bit data word. LCD display panels commonly use this format.

SMPTE 274M

An HD standard defining the spatial resolution (image sample structure) and frame rates for 1920x1080.

SMPTE 296M

An HD standard for defining the spatial resolution (image sample structure) and frame rates fro 1280x720.

EPPI Block Diagram

The ***EPPI Block Diagram*** figure shows the functional blocks within the EPPI.

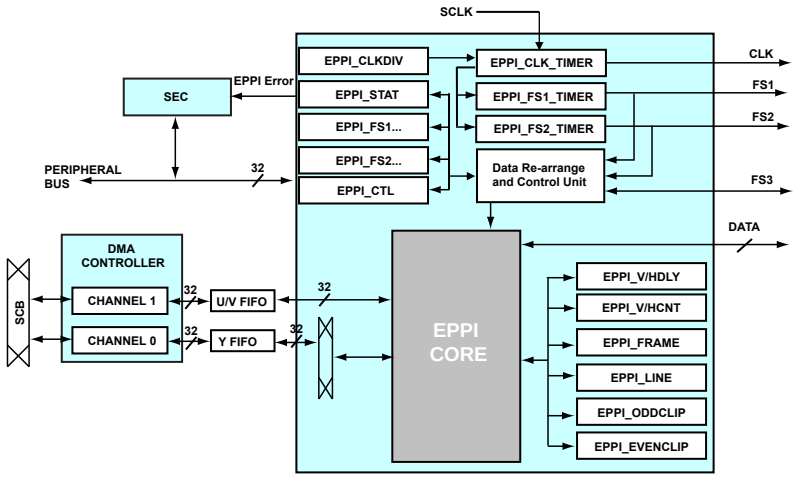

Figure 23-3: EPPI Block Diagram

EPPI Architectural Concepts

The following sections describe the architectural concepts.

- Reset Operation
- Frame Sync Polarity and Sampling Edge
- Direct Memory Access (DMA)
- EPPI Clock

Reset Operation

On a hardware reset, the entire EPPI is reset. All MMRs return to their default values. EPPI interrupt and DMA requests become inactive and internally generated `EPPI_CLK` and frame syncs are aborted.

In software, write 0 to the `EPPI_CTL.EN` bit to reset and reconfigure the EPPI. When disabled in this manner, only the `EPPI_STAT` register is cleared to its reset value. Interrupts and DMA requests become inactive and internally generated clock and frame syncs are aborted.

Frame Sync Polarity and Sampling Edge

The EPPI_CTL.POLS and EPPI_CTL.POLC bits provide a mechanism to select the active level of the frame syncs and the sampling or driving edge of the EPPI clock, respectively. This functionality allows the EPPI to connect to data sources and receivers with a wide array of control signal polarities. Often, the remote data source or receiver also offer configurable signal polarities. In these cases, the EPPI_CTL.POLS and EPPI_CTL.POLC bits add flexibility.

Table 23-6: Frame Sync Polarity Selections and Frame Sync Pin States

Bit Setting	Frame Sync 2	Frame Sync 1
POLS = b#00	Active high	Active high
POLS = b#01	Active high	Active low
POLS = b#10	Active low	Active high
POLS = b#11	Active low	Active low

Table 23-7: Clock Polarity Selections and Receive/Transmit Pin States

	Receive		Transmit	
Bit Setting	Sample Data	Sample/Drive Syncs	Drive Data	Sample/Drive Syncs
POLC = b#00	Falling edge	Falling edge	Rising edge	Rising edge
POLC = b#01	Falling edge	Rising edge	Rising edge	Falling edge
POLC = b#10	Rising edge	Falling edge	Falling edge	Rising edge
POLC = b#11	Rising edge	Rising edge	Falling edge	Falling edge

Direct Memory Access (DMA)

The EPPI has a native DMA controller with two channels. A local arbiter arbitrates between these channels and requests are forwarded to the system crossbar. The EPPI has one connection to the fabric.

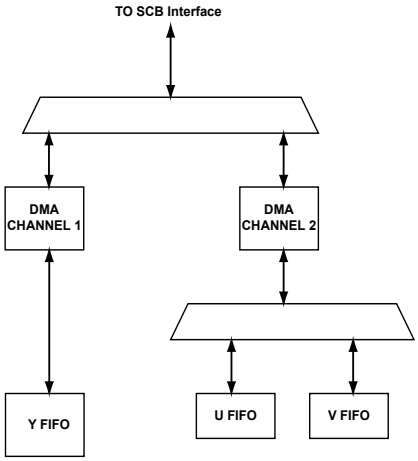

Figure 23-4: EPPI DMA Interface

The EPPI must be used with DMA. Configuring the EPPI DMA channels is a necessary step toward using the EPPI interface. The channels can be configured for either transmit or receive operation, and have a maximum throughput of (EPPI_CLK) x (32 bits/transfer). In modes where data lengths permit, packing can increase transfer bandwidth.

The DMA engine generates interrupts at the completion of a row, frame, or partial-frame transfer. The DMA engine also coordinates the source or destination point for the data that is transferred through the EPPI.

The 2D DMA capability allows the processor to be interrupted at the end of a line or after a frame of video is transferred, or if a DMA error occurs. The DMA_XCNT and DMA_YCNT registers allow for flexible data interrupt points. For example, assume the DMA_XMOD = DMA_YMOD =1. If a data frame contains 320 × 240 bytes (240 rows of 320 bytes each), the following conditions hold.

- Setting DMA_XCNT =320, DMA_YCNT = 240, and DMA_CFG.INT =1 interrupts on every row transferred, for the entire frame.
- Setting DMA_XCNT =320, DMA_YCNT =240, and DMA_CFG.INT =2 interrupts only on the completion of the frame (when 240 rows of 320 bytes have been transferred).
- Setting DMA_XCNT =38,400 (320 x 120), DMA_YCNT =2, and DMA_CFG.INT =1 causes an interrupt when half of the frame is transferred, and again when the whole frame is transferred.

The following is the general procedure for setting up DMA operation with the EPPI.

1. Configure the DMA registers as appropriate for the desired DMA operating mode.
2. Enable the DMA channel for operation.
3. Configure appropriate EPPI registers.
4. Enable the EPPI by writing 1 to the EPPI_CTL.EN bit.

EPPI Clock

The EPPI can be supplied with an external clock, or the clock can be generated internally and supplied to external devices. For information on the maximum PPI_CLK specification in internal and external clock modes, see the product-specific data sheet.

When using an external EPPI_CLK, there can be up to two cycles latency before valid data is received or transmitted.

The internal clock can be generated from SCLK0 when the EPPI_CTL.ICLKGEN bit is set. The value in the EPPI_CLKDIV register determines the generated clock frequency. The internally generated EPPI clock frequency is:

$f_{PCLK} = f_{SCLK0}/(EPPI\_CLKDIV + 1)$

where:

f_{PCLK} – frequency of internally generated EPPI clock

f_{SCLK} – frequency of SCLK0

EPPI_CLKDIV – Clock division value programmed in the EPPI_CLKDIV register.

The ***Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock*** table gives a few examples.

Table 23-8: Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock

CLKDIV15–0	EPPI/SCLK0 Clock Ratio
0x0002	1:3
0x0003	1:4
0x0004	1:5
0x0005	1:6
...	...

EPPI Operating Modes

The EPPI supports various receive and transmit modes of operation which include the detection and generation of preamble data. Specifically, the EPPI supports data formats described in the specifications ITU656, SMPTE 274M and SMPTE 296M. In addition to these modes, the EPPI also supports general-purpose receive and transmit using up to three frame syncs (FS).

The control register (EPPI_CTL) includes most of the bits used for configuring operating modes. The “Register Descriptions” section of this chapter provides complete descriptions of these bits.

ITU-R 656 Modes

The EPPI supports three input modes and one output mode for ITU-R 656 framed data. This section describes these modes.

ITU-R 656 Background

In ITU-R 656 mode, the horizontal (H), vertical (V), and field (F) signals are sent as an embedded part of the video data stream. The signals are sent in a series of bytes that form a control word. ITU-R 656 was formerly known as CCIR-656.

The letter H is used to distinguish between the *start of active video* (SAV) and *end of active video* (EAV) signals. These signals indicate the beginning and end of active video data in each line. The SAV occurs on a 1-to-0 transition of H, and EAV occurs on a 0-to-1 transition of H. The space between EAV and SAV is filled with horizontal blanking data. Therefore, H = 1 during the horizontal blanking portion of the data stream, and H = 0 during the active video portion of the data stream.

The letter V is used to denote the vertical blanking portion of the data stream. A transition in V can occur only in the EAV sequence. When V = 1, the data stream contains vertical blanking data, and when V = 0, the data stream contains active video data.

The letter F is used to distinguish Field 1 from Field 2. Interlaced video has two fields in a frame of data. It requires each field to be handled uniquely, and alternate rows of each field combined to create the actual video image.

For interlaced video, F = 0 represents Field 1 (*Odd Field*) and F = 1 represents Field 2 (*Even Field*). Progressive video makes no distinction between Field 1 and Field 2, and F is always 0 for progressive video. Interlaced video requires each field to be handled uniquely because alternate rows of each field combine to create the actual video image.

An entire field of video is comprised of active video plus horizontal blanking (the space between an EAV and SAV code) and vertical blanking (the space where V = 1). A field of video commences on a transition of the F bit.

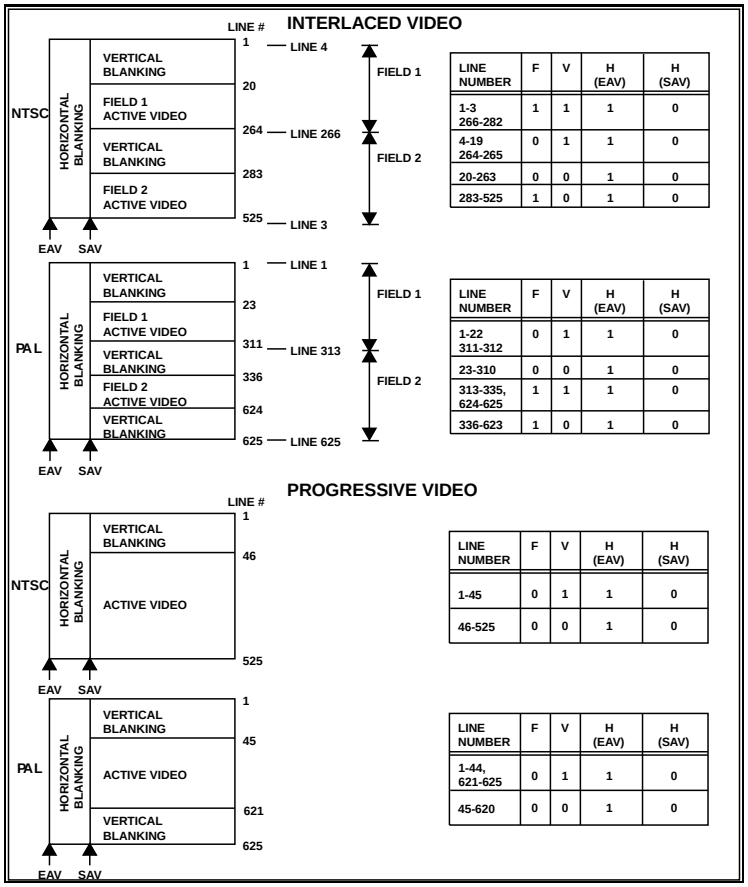

Figure 23-5: Typical Video Frame Partitioning for NTSC/PAL Systems in Interlaced and Progressive ITU-R BT.656 Systems

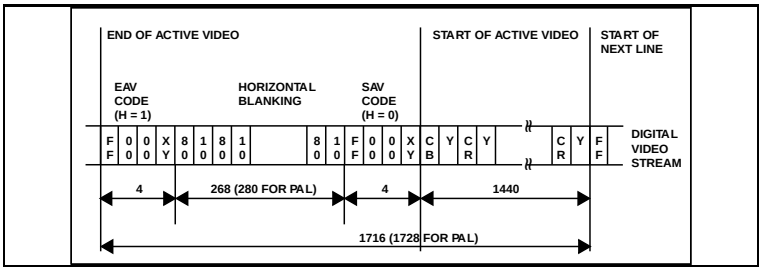

Figure 23-6: ITU-R 656 8-Bit Parallel Data Stream from NTSC (PAL) Systems

NOTE: Refer to the ***Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video*** table. There is a defined preamble of three data elements (for example, in the case of 8-bit video: 0xFF, 0x00, 0x00), followed by the XY status word. The status word contains four protection bits for error detection and correction excluding the

F (field), V (vertical blanking), and H (horizontal blanking) bits. F and V are only allowed to change as part of EAV sequences (that is, transition from H = 0 to H = 1).

The bit definitions are as follows:

- F = 0 for field 1
- F = 1 for field 2
- V = 1 during vertical blanking
- V = 0 when not in vertical blanking
- H = 0 at SAV
- H = 1 at EAV
- P3 = V XOR H
- P2 = F XOR H
- P1 = F XOR V
- P0 = F XOR V XOR H

P3–P0 are protection bits that enable 1-bit and 2-bit error detection, and 1-bit error correction at the receiver. The EPPI corrects the error if it detects 1-bit errors in F, V, or H. Errors in the protection bits themselves are detected but not corrected.

Table 23-9: Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video

	8-Bit Data								10-Bit Data	
	D9 (MSB	D8	D7	D6	D5	D4	D3	D2	D1	D0
Preamble	1	1	1	1	1	1	1	1	1	1
	0	0	0	0	0	0	0	0	0	0
	0	0	0	0	0	0	0	0	0	0
Control Byte	1	F	V	H	P3	P2	P1	P0	0	0

The EPPI_STAT register contains 2 bits, EPPI_STAT.ERRDET and EPPI_STAT.ERRNCOR, that are used to report the status of error detected and error not corrected, respectively.

The EPPI_STAT.ERRDET bit is set whenever an error is detected in the status word. However, this bit does not generate an interrupt. The EPPI_STAT.ERRNCOR bit is set when more than a 1-bit error is detected in the status word. An interrupt is generated when the EPPI_STAT.ERRNCOR bit is set. It can be cleared by clearing the EPPI_STAT.ERRNCOR and EPPI_STAT.ERRDET bits. Both bits are sticky and W1C.

In many applications, video streams other than the standard NTSC/PAL formats (for example, CIF, QCIF) can be employed. The processor interface is flexible enough to accommodate different row and field lengths. In general, as

long as the incoming video has the proper EAV/SAV codes, the EPPI can read it in. A CIF image could be formatted to be 656-compliant, where EAV and SAV values define the range of the image for each line. The V and F codes are used to delimit fields and frames.

The following sections provide descriptions of EPPI operations.

Table 23-10: Operating Modes and Generic EPPI Operation

		How to configure	Useful for	How to configure in ITU R 656 Tx Mode

	Rx	DIR = 0 XFRTYPE = b#11 FSCFG = b#11		

ITU-R 656 Input Modes

In the ITU-R 656 input modes, the video source provides the clock or the system supplies it externally.

As shown in the ***ITU-R 656 Input Submodes*** figure and described in the following sections, there are three submodes supported for ITU-R 656 inputs: entire field, active video only, and vertical blanking interval only.

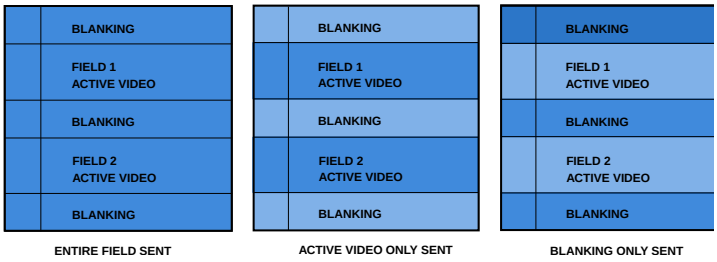

Figure 23-7: ITU-R 656 Input Submodes

Entire Field

In this mode, the EPPI reads the entire incoming bit stream. This stream includes active video as well as control byte sequences and ancillary data that can be embedded in horizontal and vertical blanking intervals.

Data transfer starts immediately after Field 1 synchronization occurs. The transfer does not include the first EAV code that contains the F = 0 assignment for interlaced video or the V = 0 assignment for progressive video.

Active Video

The EPPI uses this mode when only the active video portion of a field is of interest. The EPPI ignores (does not read in) all data between EAV and SAV, as well as all data present when V = 1. Furthermore, the control byte sequences are not stored to memory. The EPPI filters the sequences. After the start of Field 1 synchronizes, the EPPI ignores incoming samples until it sees an SAV.

In active video mode, programs must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. Programs must specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.

In this mode, any input data sequence that is considered part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appear in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually and not be tagged along with the preamble sequence FF, 00, 00. This functionality also applies to vertical blanking interval mode.

Vertical Blanking Interval (VBI)

In this mode, data transfer is only active while V = 1 is in the control byte sequence. This functionality indicates that the video source is in the midst of the vertical blanking interval (VBI), which is sometimes used for ancillary data transmission. The ITU-R 656 recommendation specifies the format for these ancillary data packets, but the EPPI is not equipped to decode the packets themselves. Software must handle this task. Horizontal blanking data is logged where it coincides with the rows of the VBI.

The VBI is split into two regions within each field. The EPPI considers these two separate regions as one contiguous space. However, frame synchronization begins at the start of Field 1, which does not necessarily correspond to the

start of vertical blanking. For instance, in 525/60 systems, the start of Field 1 (F = 0) corresponds to line 4 of the VBI.

In VBI mode, the program must specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. The program must specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.

In this mode, any input data sequence that is considered as part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appears in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually, and not be tagged along with the preamble sequence FF, 00, 00. This functionality applies to active video mode too.

ITU-R 656 Output in General-Purpose Transmit Modes

In GP transmit mode, the EPPI frames an ITU-R 656 output stream with the proper preambles and blanking intervals by setting the EPPI_CTL.BLANKGEN bit. The EPPI fetches active data from memory through the DMA channel, saving DMA bandwidth. The EPPI generates and embeds the proper preamble, status word (EAV and SAV sequences), and blanking data along with the active video from memory. Program the EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF, and EPPI_FS1_WLHB registers to perform the desired functions. The EPPI can also drive out the frame syncs using the EPPI_CTL.FSCFG bit setting.

The ***16-Bit Transmit with Internal Blanking Generation*** figure shows the bit stream format in 16-bit transmit modes with blanking generation (EPPI_CTL.BLANKGEN enabled). Each 16-bit data sample consists of 8-bit luma (Y) and 8-bit chroma (Cr or Cb) components. During transmission, the chroma data and blanking bytes of value 0x80 are placed on the upper half (MSBs) of the data lines. The luma data and blacking bytes of value 0x10 are placed on the lower half (LSBs) of the data lines.

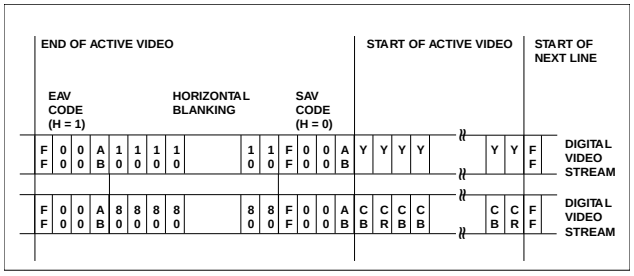

Figure 23-8: 16-Bit Transmit with Internal Blanking Generation

The ***Generated Blanking Preamble Sequence*** figure shows the data transmitted by the EPPI in this mode. After the EPPI is enabled, and if the EPPI FIFO is not empty, the transmission starts by sending out an EAV sequence for a vertical blanking line. For interlaced video, F starts at 1. For progressive video, F is always 0.

NOTE: Internal blanking generation functionality is valid only when the data length is 8, 10, or 16 bits and when the EPPI is in GP transmit modes. The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

The internal blanking generation functionality of the ITU-R 656 output mode can also be bypassed by clearing the EPPI_CTL.BLANKGEN bit. (For example, if sending ancillary data in the blanking interval). The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

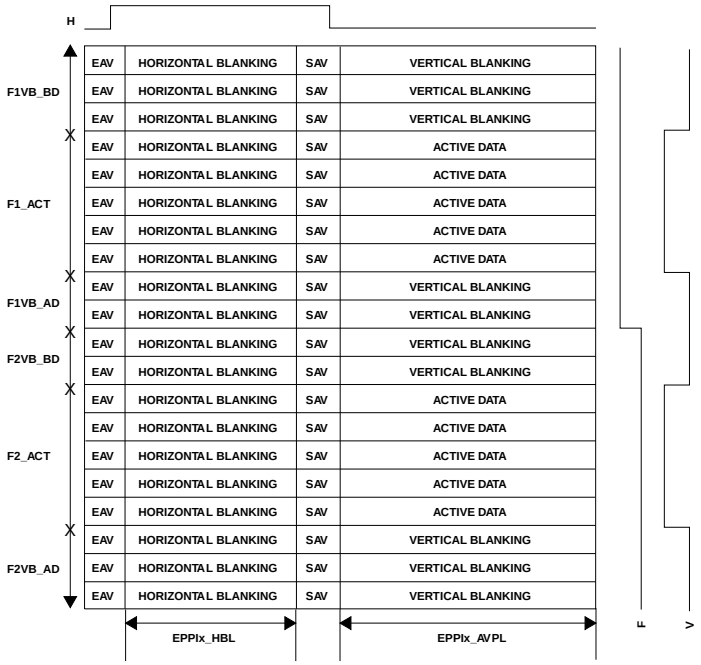

Figure 23-9: Generated Blanking Preamble Sequence

Frame Synchronization in ITU-R 656 Modes

For interlaced video, the start of frame synchronization occurs when a high-to-low transition is detected in F, the field indicator. For progressive video, the start of frame synchronization occurs when a high-to-low transition is detected in V, the vertical blanking indicator. These transitions in F and V can occur only in the EAV sequence. A start of line is detected on a low-to-high transition in H, the horizontal blanking indicator, which occurs in the EAV sequence as well.

For interlaced video, the start of frame corresponds to the start of field 1. Therefore, up to two fields can be ignored before the EPPI receives data. (For example, if field 1 started before the EPPI-to-camera channel was established). For progressive video, the start of frame corresponds to the start of active video.

Because all H and V signaling is embedded in the data stream in ITU-R 656 modes, the EPPI ignores the count registers (`EPPI_HCNT`, `EPPI_VCNT`). However, the EPPI still uses the `EPPI_FRAME` register to check for synchronization errors. Therefore, program this MMR with the number of lines expected in each frame of video.

The EPPI monitors the number of EAV-to-SAV transitions that occur from the start of a frame until it decodes the end of frame condition. (For example, a transition from F = 1 to F = 0 for interlaced video and a transition from V = 1 to V = 0 for progressive video).

At the end of frame condition, the actual number of lines processed is compared against the value in `EPPI_FRAME`. If there is a mismatch, a frame track error is asserted in the `EPPI_STAT` register. For example, if an SAV transition was missed, the current field only has NUM_ROWS – 1 rows. But, resynchronization occurs at the start of the next frame. When the EPPI receives the entire field, the field status bit is toggled in the `EPPI_STAT` register. This way, an interrupt service routine (ISR) can discern which field was previously read in.

General-Purpose EPPI Modes

The general-purpose (GP) EPPI modes accommodate a wide variety of data capture and transmission applications.

Each EPPI has three bidirectional frame sync pins. The EPPI internally generates frame syncs, or an external device communicating with the EPPI generates them.

GP modes differ based on the number of frame syncs used and the EPPI supports GP 0 FS—GP 3 FS modes.

All the GP modes, except 0 FS mode, support horizontal windowing. GP modes with 2 and 3 frame syncs also support vertical windowing.

For GP transmit modes with internal clock or frame syncs, the EPPI starts generating the clock or frame syncs only when the EPPI FIFO is full for the first time. For GP 0 FS transmit mode, the EPPI only starts transmitting when the EPPI FIFO is full for the first time.

General-Purpose 0 Frame Sync Mode

This mode is useful for applications where periodic frame syncs are not used to frame the data.

After the initial trigger, the EPPI receives or transmits data samples on every clock cycle. However, if the `EPPI_CTL.SKIPEN` bit is set for receive mode, the EPPI receives only alternate data samples.

The `EPPI_LINE`, `EPPI_FRAME`, `EPPI_HCNT`, `EPPI_HDLY`, `EPPI_VCNT`, and `EPPI_VDLY` registers are not valid for GP 0 FS mode. Therefore, windowing is not possible in this mode. Also, line and frame track errors are not applicable in this mode.

GP 0 FS receive mode is further divided into two submodes; internal trigger (`EPPI_CTL.FLDSEL` bit =0) and external trigger (`EPPI_CTL.FLDSEL` bit =1). The submodes are based on how the processor initiates data transmission or reception. GP 0 FS transmit mode is always internally triggered. DMA handles all subsequent data manipulation.

- ***Frame synchronization in GP 0 FS external trigger mode.*** When the EPPI is programmed in external trigger mode, it does not generate the `EPPI_FS1` signal and the external device must provide a trigger. The EPPI starts receiving the data as soon as an `EPPI_FS1` signal assertion is detected. After that, the DMA handles all subsequent data manipulation and any activity on `EPPI_FS1` is ignored.
- ***Frame synchronization in GP 0 FS internal trigger mode.*** When the EPPI is programmed in internal trigger mode, it starts receiving or transmitting data as soon as the EPPI clock is enabled and synchronized. There can be up to four PPI clock cycles of latency before valid data is received or transmitted.

General-Purpose 1 Frame Sync Mode

This mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

The `EPPI_FRAME`, `EPPI_VDLY`, and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not available.

General-Purpose 2 Frame Sync Mode

This mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC signal can be connected to EPPI_FS1 and the VSYNC signal can be connected to EPPI_FS2.

Data Enable in General-Purpose 2 Frame Sync Transmit Mode

The EPPI_FS3 pin functions as a data enable (DEN) pin, when EPPI is configured in GP 2 FS transmit mode and generating the frame sync internally. The bits EPPI_CTL.MUXSEL and EPPI_CTL.CLKGATEN are not enabled. The functionality of the DEN pin is described in the following two cases.

Case 1

Blanking generation is configured using the EPPI_CTL.BLANKGEN bit. EPPI data length (EPPI_CTL.DLEN bit) is configured for 8, 10, or 16-bit transfers. The EPPI_FS3 pin asserts during the *active data* regions, aligned with EPPI_CLK according to the clock polarity (EPPI_CTL.POLC bit) settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The pin EPPI_FS3 is driven out on the same EPPI clock edge that drives out data. The frame sync polarity (EPPI_CTL.POLS) setting does not apply here—EPPI_FS3 is always active high in this mode.

Case 2

Blanking generation (EPPI_CTL.BLANKGEN =0) is disabled. Or blanking generation is enabled, but the EPPI data length (EPPI_CTL.DLEN bit) is configured for a transfer size other than 8, 10, or 16 bits. The EPPI_FS3 pin asserts at the start of the active data region on each line, aligned with EPPI_CLK according to the EPPI_CTL.POLC bit settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The EPPI_FS3 signal is driven out on the same EPPI clock edge that drives out data.

The EPPI_CTL.POLS bit setting does not apply for case 2. The EPPI_FS3 signal is always active high in this mode. Once asserted, EPPI_FS3 stays asserted for the number of clock cycles per line configured in the EPPI_HCNT register, then it deasserts. This behavior on each line continues for the total number of lines programmed in the EPPI_VCNT register per frame. The behavior repeats at the start of subsequent video frames.

In case 2, if transmission of valid data is held off due to delays programmed in the EPPI_HDLY or EPPI_VDLY registers, the assertion of EPPI_FS3 is also held off. The delay is on a per-line or per-frame basis.

General-Purpose 3 Frame Sync Mode

This mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to the EPPI_FS1 pin, VSYNC connects to the EPPI_FS2 pin, and FIELD connects to the EPPI_FS3 pin.

GP 3 FS mode is similar in operation to GP 2 FS mode. However, the start of frame synchronization in GP 3 FS also considers the state of the EPPI_FS3 pin. All the windowing register settings (EPPI_FRAME, EPPI_LINE, EPPI_HDLY, EPPI_HCNT, EPPI_VDLY, and EPPI_VCNT registers), as well as data reception or transmission and error generation are the same as for GP 2 FS mode. In addition, for GP 3 FS mode with internal frame syncs, the EPPI_CTL.FLDSEL bit setting specifies the condition under which the transfer begins.

The EPPI generates the EPPI_FS3 signal and toggles during every assertion of EPPI_FS2 or a combination of EPPI_FS2 and EPPI_FS1. The toggle depends on the EPPI_CTL.FLDSEL bit setting. The EPPI skips an EPPI_FS2 signal when the EPPI_FS3 value is high. Because of this condition, program the EPPI_FS2 period value to half of the total number of pixels in the frame as in GP 3 FS mode. When in GP 2 FS mode, program the EPPI_FS2 period with the value equal to the number of pixels per frame.

Supported Data Formats

The following sections describe EPPI receive and transmit data formats.

Receive Data Formats

The ***EPPI Receive Data Formats*** table provides information about EPPI configuration for specific use models for receive data.

Table 23-11: EPPI Receive Data Formats

Input Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1 – Four EPPI words are packed to 32-bit DMA data. EPPI_CTL.PACKEN =0 – Each EPPI word is sent as 8-bit data on the 32-bit DMA bus. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Gives I (in phase) and Q (quadrature) components. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 23-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
10	NTSC/PAL data	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1. EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 10-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 SEPPI_CTL.SUBSPLTODD = 0 since there are only two components.
12	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 12-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.
14	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 23-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB565 sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are packed to a 32-bit DMA data. EPPI_CTL.RGBFMTEN is valid only in transmit modes. So, RGB565 cannot be byte aligned in memory. EPPI_CTL.PACKEN =0. Each EPPI word is sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 16-bit case with EPPI_CTL.PACKEN =1
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =0.
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =0.

Transmit Data Formats

The ***EPPI Transmit Data Formats*** table provides information about EPPI configuration for specific use models for transmit data.

Table 23-12: EPPI Transmit Data Formats

Output Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	Serial RGB for lower-resolution LCDs	No splitting possible. EPPI_CTL.PACKEN =1. The 32-bit DMA data is unpacked to drive four EPPI words. EPPI_CTL.PACKEN =0. The lowest 8 bits of the DMA data is driven on the EPPI data and the rest of the 24 bits are discarded. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1.
10	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.

Table 23-12: EPPI Transmit Data Formats (Continued)

Output Data Width	Use Model	Splitting/Packing Options
12	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
14	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	RGB565 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the LSBs from each component to drive out RGB565 data.
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD = 0
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1
18	RGB666 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the 2 LSBs from each component to drive out RGB666 data.

Data Transfer Modes

The following sections describe EPPI data transfer modes, including receive or transmit data packing, sign extension, zero fill, receive or transmit split modes, clock gating, delayed start, and data consistency management.

Data Packing for Receive Modes

For receive modes, if the EPPI_CTL.PACKEN bit =1 and the DMA is 32 bits, the EPPI packs the incoming data into 32-bit words based on the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings. When EPPI_CTL.SWAPEN =0, the EPPI puts the first data in the least significant bits and when EPPI_CTL.SWAPEN =1, the EPPI puts the first data in the most significant bits. The packing options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, four 8-bit words can be packed into one 32-bit word.
- When EPPI_CTL.DLEN =16, two 16-bit words can be packed into one 32-bit word.
- For EPPI_CTL.DLEN values that are more than 8 bits but less than 16 bits, two such words are either sign-extended or zero-filled to 16 bits, and packed into one 32-bit word.
- When EPPI_CTL.DLEN =18, the EPPI sign-extends or zero-fills the 18-bit data to 24 bits and packs four 24-bit words into three 32-bit words.

- When EPPI_CTL.DLEN =24, the EPPI packs four 24-bit words into three 32-bit words.

When EPPI_CTL.PACKEN =0, the EPPI receives the incoming data and sends it on the bus as-is. If EPPI_CTL.DLEN is less than or equal to 16 bits, the DMA is a 16-bit DMA; otherwise it is a 32-bit DMA.

Data Packing for Transmit Modes

For transmit modes, if the EPPI_CTL.DLEN bit =1 and the DMA is a 32-bit DMA, the EPPI unpacks the 32-bit word according to the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings.

If EPPI_CTL.SWAPEN =1, the EPPI transmits the most significant bits as the first data, and if EPPI_CTL.SWAPEN =0, the EPPI transmits the least significant bits as the first data. The unpacking options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, the EPPI transmits one 32-bit word from memory as four 8-bit data words.
- For EPPI_CTL.DLEN values greater than 8 bits but less than or equal to 16 bits, the EPPI transmits one 32-bit word from memory as two 16-bit data words.
- When EPPI_CTL.DLEN =18 or 24, the EPPI transmits three 32-bit words from memory as four data words.

Sign-Extended and Zero-Filled Data

The following list describes the bit settings and functionality for sign-extending and zero-filling data.

- For EPPI_CTL.DLEN equal to 10, 12 or 14, data is zero-filled or sign-extended to 16 bits.
- For EPPI_CTL.DLEN equal to 18 bits, data is zero-filled or sign-extended to 24 bits if packing is enabled, and zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 24 bits, data is zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 8 bits, data is zero-filled or sign-extended to 16 bits if packing is disabled.
- If EPPI_CTL.SIGNEXT =1, then the data is sign-extended, otherwise it is zero-filled.

Split Receive Modes

The control register has three control bits for split receive modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI splits the incoming data stream into two substreams, an even stream, and an odd stream, and packs them separately.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. When EPPI_CTL.SUBSPLTODD =1, the EPPI subsplits the odd substream, and packs the streams separately.
- The EPPI_CTL.DMACFG bit is also available only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Split Transmit Modes

The EPPI_CTL register has three control bits for split transmit modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. The DMA is always a 32-bit DMA. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI receives the Luma (Y3Y2Y1Y0) and interleaved Chroma (Cr1Cb1Cr0Cb0) data as 32 bits from the DMA channel. The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. In this case, if EPPI_CTL.SUBSPLTODD =1, the EPPI receives the Luma (Y3Y2Y1Y0) and deinterleaved Chroma (Cb3Cb2Cb1Cb0 and Cr3Cr2Cr1Cr0). The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit. (The EPPI does not decimate the chroma data when formatting it into 4:2:2.)
- The EPPI_CTL.DMACFG bit is also valid only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Clock Gating

In ITU-R BT.656 and GP 0/1/2 FS modes, EPPI_FS3 becomes a clock-gating input. This functionality is valid for both internally and externally sourced EPPI_CLK, in both receive and transmit modes. This clock gating signal must be synchronous with EPPI_CLK. The external device on the rising edge of EPPI_CLK must drive the clock gating signal. Its function is to hold the sync and data lines in their current state until EPPI_FS3 is driven low. There are no additional latency cycles upon coming out of clock gating mode.

If clock gating is not required, the EPPI_FS3 pin must either be tied to ground, or configured to operate as another of its multiplexed functions.

In GP 2 FS transmit mode with internally generated frame syncs, the EPPI_FS3 pin functions as a data enable signal.

Support for Delayed Start of EPPI Frame Syncs

The EPPI supports a delayed start of the EPPI_FS1 and EPPI_FS2 frame syncs. The EPPI_FS1_DLY and EPPI_FS2_DLY registers are programmable registers corresponding to EPPI_FS1 (HSYNC) and EPPI_FS2 (VSYNC).

The delay programmed in these registers applies to the first active edge of the internally generated frame sync. The delay starts from the first EPPI_CLK edge. The delay counter runs only for the first time and then shuts off until the EPPI is reenabled. (The delay counter is the period counter itself, since they do not run together.) Program the delay registers prior to the first EPPI_CLK edge (similar to the width and period registers). The ***EPPI Delayed Frame Sync Generation*** figure shows the functioning of EPPI_FS1 and EPPI_FS2.

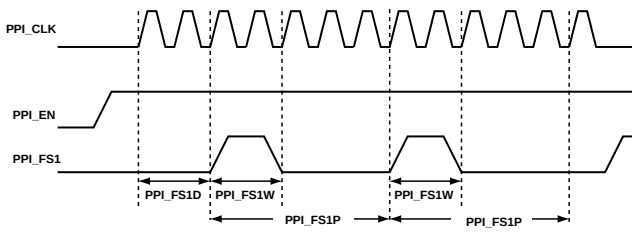

Figure 23-10: EPPI Delayed Frame Sync Generation

Ignoring Premature External Frame Syncs for Data Consistency

Once a frame has started with a VSYNC followed by an HSYNC (or both coming together), a line is tracked. When the count expires, the state machine waits at the end of line for an HSYNC to come. With the arrival of the HSYNC, the state machine starts tracking the next line, and so on.

The number of lines tracked is counted separately. Once the end of a frame is reached, the state machine waits there for the next VSYNC/HSYNC combination. The next frame starts once they are sampled. Unfortunately, every incoming FS (VSYNC or HSYNC) resets the respective counters and the tracking starts all over (even if the FS signals are premature). The result is incomplete data (or frames) to enter into memory through the PxP interface.

To correct this problem, the EPPI waits for a frame or line completion before considering any incoming FS as valid.

- Single FS mode and line tracking in dual FS mode – When a line is in progress, when HSYNC is detected prematurely, it is ignored. A line track underflow event is generated.
- Dual FS mode – If a VSYNC is received when a frame is in progress, it is ignored. A frame track underflow error (`EPPI_STAT.FTERRUNDR`) is generated.

Ignoring the FS ensures that once a frame starts, the amount of data that goes into the memory/PxP interface corresponds exactly to the programmed data size in a frame.

NOTE: Even if the premature FS is a valid FS, the state machine loses at most one frame and it recovers in the subsequent FS. The FS to number of data going into the memory relationship is always maintained as programmed.

When data underflow errors occur at the DMA interface, the EPPI does the following.

- If a premature line sync is detected, an LT underflow error is generated (`EPPI_STAT.LTERRUNDR` =1). All further line track errors are ignored until the EPPI detects the next valid line sync.
- If a premature frame sync is detected, an FT underflow error is generated (`EPPI_STAT.FTERRUNDR` =1). All further frame track and line track errors are ignored until the EPPI detects the next valid frame sync.

EPPI Event Control

The following sections describe how EPPI manages events.

EPPI Status, Error, and Interrupt Signals

The EPPI generates error interrupts (flagged in the EPPI_STAT register) when any one of the following error conditions occur.

- EPPI_STAT.YFIFOERR (YFIFO underflow or overflow)
- EPPI_STAT.CFIFOERR (CFIFO underflow or overflow)
- EPPI_STAT.LTERROVR (line track overflow error)
- EPPI_STAT.LTERRUNDR (line track underflow error)
- EPPI_STAT.FTERROVR (frame track overflow error)
- EPPI_STAT.FTERRUNDR (frame track underflow error)
- EPPI_STAT.ERRNCOR (ITU preamble error not corrected)

A W1C (write-1-to-clear) operation clears the error conditions. Each of the individual conditions which cause an EPPI error interrupt can be masked. The interrupt mask register (EPPI_IMSK) allows the masking of individual conditions which cause error interrupts.

There is only one interrupt line from each EPPI so all interrupts are internally OR'ed and sent as a single interrupt to the core. The EPPI_STAT register must then be read to discover specific errors. The following sections describe these errors in detail.

Frame and Line Track Errors

In external frame sync mode, the EPPI uses line track error (EPPI_STAT.LTERROVR and EPPI_STAT.LTERRUNDR) and frame track error (EPPI_STAT.FTERROVR and EPPI_STAT.FTERRUNDR) status bits to monitor the line and frame synchronization errors. The EPPI updates the bits when there is a mismatch detected in the HSYNC and VSYNC as compared to the programmed values in EPPI_LINE and EPPI_FRAME count registers.

Line Track Errors

The line track overflow (EPPI_STAT.LTERROVR) and underflow errors (EPPI_STAT.LTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them and not at the next frame sync.

- If the frame sync has not arrived when the EPPI_LINE counter expires, then the EPPI_STAT.LTERROVR error is generated.
- When the EPPI_LINE counter is running and a frame sync is detected, the EPPI_STAT.LTERRUNDR error is generated. A W1C operation clears boths interrupts.

Frame Track Errors

The frame track overflow (EPPI_STAT.FTERROVR) and underflow errors (EPPI_STAT.FTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them. When the EPPI_FRAME.VALUE counter expires, the EPPI_STAT.FTERROVR error is reported before the next frame sync arrives.

When the EPPI_FRAME counter is running and a frame sync is detected, then an EPPI_STAT.FTERRUNDR is reported.

Both errors generate an error interrupt. Perform a W1C operation to clear the interrupts at their respective locations in the status register.

A premature frame sync results in a frame track under run error. But, the error is logged (register bit set) only after the subsequent blanking period (if any) elapses.

Preamble Error Not Corrected Error

The EPPI supports data embedded frame syncs in ITU and SMPTE formats. In these formats, the module can receive an erroneous preamble which is not correctable. The EPPI_STAT.ERRNCOR error signals when this event occurs.

EPPI Programming Model

The following sections describe programming techniques, including receiving or transmitting ITU-R 656 frames; configuring transfers in GP0, GP1, GP2, and GP3 modes; and managing EPPI mode configurations.

Receiving ITU-R 656 Frames

The EPPI supports the reception of ITU-R 656 compliant frames.

1. Configure the EPPI to receive either full ITU-R 656 frame, active video, or blanking information by configuring the EPPI_CTL.XFRTYPE bits.
2. In both active video mode and in VBI (vertical blanking information) mode, specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. Specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.
3. Configure DMA descriptors to move the data to memory.
4. Enable DMA.
5. Enable the EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Depending on the EPPI configuration, either the full ITU-R 656 frame is moved to memory or only the active video or only the blanking information.

Transmitting ITU-R 656 Frames in GP Transmit Modes

The EPPI can take active video from memory and generate the proper preambles and blanking information to produce valid ITU-R 656 video frames for transmission.

1. Provide active data frame in memory.
2. Set the EPPI_CTL.BLANKGEN bit so the EPPI generates blanking information.
3. Configure the EPPI_FS1_WLHB, EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF registers accordingly.
4. Configure the rest of the EPPI settings.
5. Configure DMA to fetch active frame data from memory buffers.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The EPPI takes the active data from memory, generates the blanking information, and transmits an ITU-R 656 frame

Configuring Transfers in GP 0 FS Mode

The EPPI can be configured to not use periodic frame syncs to frame the data.

1. Configure the EPPI to operate in GP 0 FS mode by setting EPPI_CTL.XFRTYPE = b#11 and EPPI_CTL.FSCFG = b#00.
2. When receiving, configure the EPPI to trigger on internally or externally by setting the EPPI_CTL.FLDSEL field appropriately. When transmitting, the EPPI always generates a trigger internally.
3. Configure DMA to move the data to or from memory.
4. Enable DMA.
5. Enable EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The DMA descriptions control the amount of data transferred. The frame syncs from the EPPI do not control the amount.

Configuring Transfers in GP 1 FS Mode

The GP 1 FS mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

NOTE: The EPPI_FRAME, EPPI_VDLY, and EPPI_VCNT registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

1. Configure GP 1 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#01. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_LINE register to contain the number clock cycles expected between two assertions of the EPPI_FS1 signal to monitor the line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
3. Program the EPPI_HDLY register to contain the number of clock cycles to wait after the assertion of EPPI_FS1. For example, the start of frame.
4. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each frame.
5. Configure DMA to move the data to or from memory.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then, switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line.

Configuring Transfers in GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC connects to the EPPI_FS1 signal and VSYNC connects to the EPPI_FS2 signal.

1. Configure the EPPI to operate in GP 2 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#10. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_FRAME register to contain the number of expected lines per frame. The value can be equal to the number of EPPI_FS1 signal assertions expected between the start of each frame sync. The EPPI uses the value to monitor frame track errors. Program the EPPI_FRAME register before the EPPI_VCNT register.
3. Program the EPPI_LINE register to contain the number of clock cycles expected between two assertions of the EPPI_FS1 signal to monitor line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
4. Program the EPPI_HDLY register to configure the number of clock cycles to wait after the assertion of the EPPI_FS1 signal. (For example, the start of the line).
5. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each line.

6. Program the EPPI_VDLY register to contain the number of lines to wait after the start of frame is detected.
7. Program the EPPI_VCNT register to contain the number of lines to receive or transmit.
8. If setting up the EPPI for transmit, the data enable (DEN) pin behaves according to the enabling of the blanking generation and the data length setting (DLEN). See Data Enable in General-Purpose 2 Frame Sync Transmit Mode for more details.
9. Enable DMA.
10. Enable the EPPI.
11. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame.

Configuring Transfers in GP 3 FS Mode

GP 3 FS mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to EPPI_FS1, VSYNC connects to EPPI_FS2, and FIELD connects to EPPI_FS3.

1. Configure the EPPI to operate in GP 3 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#11. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Configure the windowing registers according to steps in GP 2 FS mode.
3. Enable DMA.
4. Enable the EPPI.
5. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame. Operation and result are similar to operation in GP 2 FS mode but the EPPI also uses the EPPI_FS3 signal.

Configuring the EPPI to Use the Windowing Feature

Windowing is a useful feature for applications where the region of interest is smaller than the active video stream (for example, sensor calibration, auto-focusing, and others). It can result in significant DMA bandwidth reduction. The EPPI supports windowing for GP input modes.

1. Program the EPPI_FRAME register with the number of lines the frame contains.

2. Program the EPPI_LINE register with the number of samples per line in the frame.
3. Program the EPPI_VDLY register with the number of lines to wait after the start of a new frame before starting to read or transmit data.
4. Program the EPPI_VCNT register with the number of lines to read in or write out after EPPI_VDLY number of lines from the start of the frame.
5. Program the EPPI_HDLY register with the number of clock cycles to delay after the assertion of EPPI_FS1 is detected for the start of a new line.
6. Program the EPPI_HCNT register with the number of samples to read in or write out after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1.

EPPI Mode Configuration

This section describes EPPI mode configurations, including support for all EPPI transmit and receive modes.

Configuring 8-Bit Receive Mode

For 8-bit non-split receive mode and if EPPI_CTL.PACKEN =1, the EPPI packs 4 bytes of incoming data into a 32-bit word. Alternate even or odd samples can be skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

Table 23-13: 8-Bit Receive Mode with Packing Enabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0x11						
0x22						
0x33						
0x44	0x4433 2211	0x1122 3344				
0x55						
0x66						
0x77			0x7755 3311		0x1133 5577	
0x88	0x8877 6655	0x5566 7788		0x8866 4422		0x2244 6688
0x99						
0xAA						
0xBB						

Table 23-13: 8-Bit Receive Mode with Packing Enabled (Continued)

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0xCC	0xCCBB AA99	0x99AA BBCC				
0xDD

0xFF			0xFFDD BB99		0x99BB DDFF	
0x00	0x00FF EEDD	0xDDE EFF00		0x00EE CCAA		0xAACC EE00

If `EPPI_CTL.PACKEN`=0, the DMA is a 16-bit DMA and the EPPI either sign-extends or zero-fills the bytes of incoming data into a 16-bit word. The `EPPI_CTL.SWAPEN` bit has no effect if `EPPI_CTL.PACKEN`=0.

Table 23-14: 8-Bit Receive Mode with Packing Disabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=1	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=X SIGNEXT=1

0xBB	0x00BB	0xFFBB		0xFFBB

Configuring 10/12/14-Bit Receive Modes

For 10, 12, or 14-bit non-split receive modes, the EPPI first either zero-fills or sign-extends the incoming data into a 16-bit word. The action depends on the setting of the `EPPI_CTL.SIGNEXT` bit. If `EPPI_CTL.PACKEN` =1, the EPPI then packs two of these words into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Configuring 16-Bit Receive Mode

For 16-bit non-split receive mode, if `EPPI_CTL.PACKEN` =1, the EPPI packs two 16-bit incoming data into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and

EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

0x8888	0x8888		0x8888

Configuring 18-Bit Receive Mode

For 18-bit non-split receive mode, if EPPI_CTL.PACKEN =0, the EPPI zero-fills or sign-extends the incoming data into a 32-bit word. If EPPI_CTL.PACKEN =1, the EPPI first zero-fills or sign-extends the incoming data to 24 bits, and then packs four such 24-bit data words into three 32-bit words. Alternate even or odd samples can be

skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The EPPI_CTL.SWAPEN bit has no effect.

Table 23-21: 18-bit Receive Mode with Packing Disabled

Configuring 8-Bit Split Receive Mode

For 8-bit split receive mode, the EPPI_CTL.PACKEN and EPPI_CTL.SIGNEXT bits are not valid. The EPPI always packs 4 bytes of data into one 32-bit word.

Table 23-23: 8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0

When the bits settings are `EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =1 and `EPPI_CTL.DMACFG` =0, the EPPI packs the second Chroma component sent over the DMA bus completely before the Luma component. However, it is intentionally held until that previous word is moved out. This functionality allows the separation of Luma and Chroma values into individual buffers when using 2D-DMA. The second Chroma component is U0U1U2U3 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0*** and ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** tables. The Luma component is Y4Y5Y6Y7 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** table.

Configuring 10/12/14/16-Bit Split Receive Mode with SPLTWRD=0

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. For 10, 12, or 14-bit split receive modes, the EPPI first either sign-extends or zero-fills the incoming data into a 16-bit word. The EPPI then packs two of these words into one 32-bit word to send to the DMA.

Configuring 16-Bit Split Receive Mode with SPLTWRD=1

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. The `EPPI_CTL.SPLTWRD` bit is only valid when the `EPPI_CTL.DLEN` bit =16 bits.

Table 23-27: 16-bit Split Receive Mode with SPLTWRD = 1, SKIPEN = 0 and SWAPEN = 0

Pin Data (16 bits)	SPLTEO=1 SUBSPLTODD=0 SWAPEN=0 SKIPEN=0 SKIPEO=X			SPLT_EVEN_ODD=1 SUBSPLTODD=1 SWAPEN=0 SKIPEN=0 SKIPEO=X

Configuring 8-Bit Transmit Mode

For 8-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into 4 bytes to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the lower 8 bits. The `EPPI_CTL.SWAPEN` bit has no effect when `EPPI_CTL.PACKEN` =0.

Table 23-28: 8-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x11223344	0x44	0x11
0x55667788	0x33	0x22
	0x22	0x33
	0x11	0x44
	0x88	0x55
	0x77	0x66
	0x66	0x77

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x34
0x2345	0x45
0x3456	0x56

Configuring 10/12/14-Bit Transmit Modes

For 10, 12, or 14-bit non-split transmit modes, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words. The EPPI then transmits the required LSBs from each data word. The EPPI transmits either the most significant word or the least significant word as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the required LSBs. The `EPPI_CTL.SWAPEN` bit has no effect when the `EPPI_CTL.PACKEN` bit =0.

Table 23-30: 10-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x222	0x111
0x3333 4444	0x111	0x222
	0x044	0x333
	0x333	0x044

Table 23-31: 10-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x234
0x2345	0x345
0x3456	0x056
0x4567	0x167

Configuring 16-Bit Transmit Mode

For 16-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If the `EPPI_CTL.PACKEN` bit =0, the DMA is a 16-bit DMA and the EPPI transmits the data as is. The `EPPI_CTL.SWAPEN` has no effect when `EPPI_CTL.PACKEN` bit =0.

Table 23-32: 16-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x2222	0x1111
0x3333 4444	0x1111	0x2222
	0x4444	0x3333
	0x3333	0x4444

Table 23-33: 16-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x1234
0x2345	0x2345
0x3456	0x3456

Configuring 18-Bit Transmit Mode

For 18-bit transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory. In this mode, when `EPPI_CTL.RGBFMTEN` is set, the least significant 2 bits of R, G, and B are dropped.

Table 23-34: 18-bit Transmit Mode with Packing Enabled

DMA Data	Pin Data (18-bits)	
	RGBFMTEN=0	RGBFMTEN=1
0x0123 4567	0x3 4567	0x0 8459
0x89AB CDEF	0x1 EF01	0x3 3EC0
0x0123 4567	0x3 89AB	0x1 98AA
	0x1 2345	0x0 0211

Table 23-35: 18-bit Transmit Mode with Packing Disabled

Configuring 10/12/14/16-Bit Transmit Mode with SPLTWRD=0

For 16-bit split transmit mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. For 10, 12, or 14-bit split transmit modes, the EPPI first unpacks the data in the same way as for 16-bit transmit mode. But, the EPPI transmits only the required number of LSBs.

Table 23-40: 16-bit Split Transmit Mode with SPLTEO = 1, SUBSPLTODD = 0, and SWAPEN = 0

EPPI Programming Concepts

This section provides information on SMPTE programming.

SMPTE Modes Programming

The programming model of SMPTE modes is similar to ITU Modes. All programming modes pertaining to ITU modes like XFRTYPE, FSCFG, FLDSEL, and BLANKGEN hold true for SMPTE modes as well. The only difference is that since ITU modes use Y-Cr/Cb interleaved data and SMPTE use parallel Y-Cr/Cb data, SPLTWRD could be set while operating in SMPTE modes. The ***Programming Modes for SMPTE Formats*** table describes the programming modes for different SMPTE formats.

Table 23-46: Programming Modes for SMPTE Formats

SMPTE Format	SMPTE Channel Width	EPPI Input Bit Width	EPPI Mode	Remarks
296M	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported
	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported

ADSP-2159x_SC591_SC592_SC594 EPPI Register Descriptions

Enhanced Parallel Peripheral Interface (EPPI) contains the following registers.

Table 23-47: ADSP-2159x_SC591_SC592_SC594 EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

Clock Divide Register

The EPPI_CLKDIV register provides the divisor for EPPI internal clock generation. The generated clock frequency is given by following formula:

EPPI_CLK = (SCLK0) / (EPPI_CLKDIV + 1)

Note that a value of 0xFFFF is invalid for the EPPI_CLKDIV register.

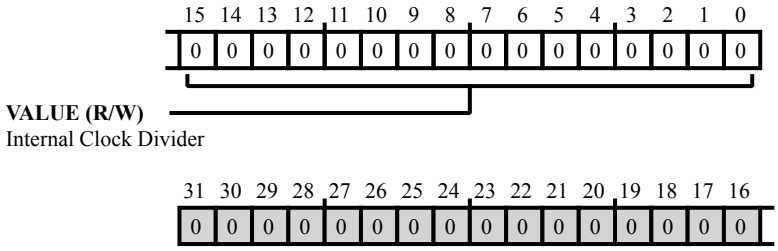

Figure 23-11: EPPI_CLKDIV Register Diagram

Table 23-48: EPPI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Internal Clock Divider.

Control Register

The EPPI_CTL register configures the EPPI for operating mode, control signal polarities, and data width of the port.

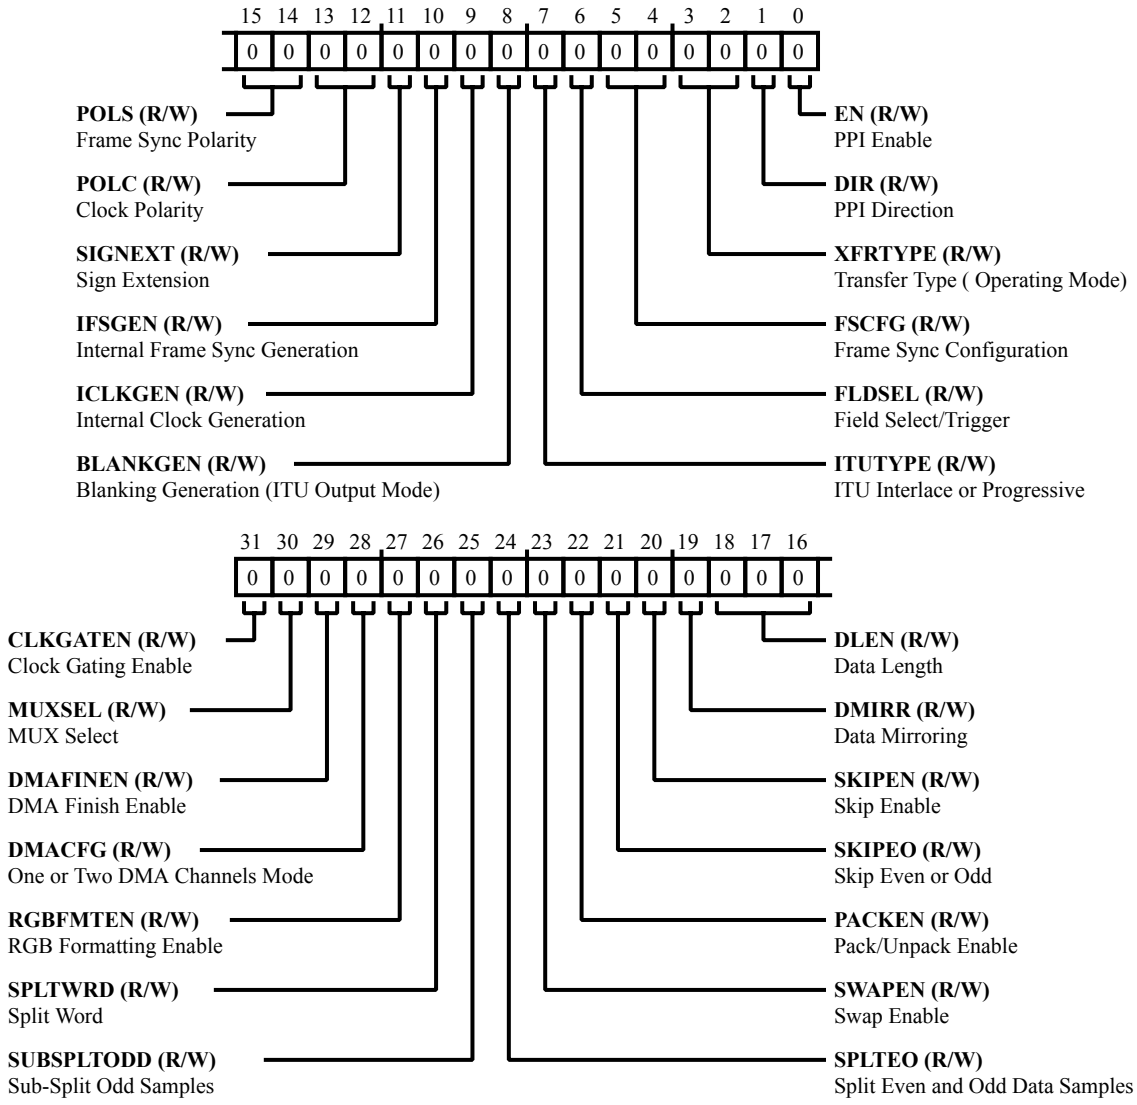

Figure 23-12: EPPI_CTL Register Diagram

Table 23-49: EPPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKGATEN	Clock Gating Enable. The EPPI_CTL.CLKGATEN bit enables using the EPPI_FS3 pin as a clock gating pin. When EPPI_CTL.CLKGATEN is set, the EPPI_FS3 pin acts as a clock gating signal, and both the internal and external clock are gated. Note that the EPPI_FS3 pin gating signal is active low, and the EPPI_CTL.CLKGATEN selection is ignored if EPPI_CTL.MUXSEL is set or EPPI_CTL.FSCFG equals 0x3.	
		0	Disable
		1	Enable
30 (R/W)	MUXSEL	MUX Select. The EPPI_CTL.MUXSEL bit enables multiplexing of a primary and alternate camera using the EPPI main data and clock lines. For more information on this feature, see the EPPI functional description.	
		0	Normal Operation
		1	Multiplexed Operation
29 (R/W)	DMAFINEN	DMA Finish Enable. The EPPI_CTL.DMAFINEN bit selects whether or not the EPPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.	
		0	No Finish Command
		1	Enable Send Finish Command
28 (R/W)	DMACFG	One or Two DMA Channels Mode. The EPPI_CTL.DMACFG bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.DMACFG is set, the EPPI uses two DMA channels. And, if EPPI_CTL.DMACFG is cleared, the EPPI uses only one DMA channel.	
		0	PPI Uses One DMA Channel
		1	PPI Uses Two DMA Channels
27 (R/W)	RGBFMTEN	RGB Formatting Enable. For 16- or 18-bit transmit modes only, the EPPI_CTL.RGBFMTEN bit enables conversion of RGB888 from memory into RGB666 output data (18-bit transmit) or enables conversion of RGB888 from memory into RGB565 output data (16-bit transmit). Note that EPPI_CTL.SPLTEO and EPPI_CTL.RGBFMTEN should never be set simultaneously.	
		0	Disable RGB Formatted Output
		1	Enable RGB Formatted Output

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	

26 (R/W)	SPLTWRD	Split Word.
		The EPPI_CTL.SPLTWRD bit selects split word data placement when the data length (EPPI_CTL.DLEN) selects 16-, 20-, or 24-bit data words. For all other EPPI_CTL.SPLTWRD values, the set or clear selections for EPPI_CTL.SPLTWRD produce the same result (act as though EPPI_CTL.SPLTWRD is cleared). For EPPI_CTL.SPLTWRD set, the EPPI_CTL.DLEN values below result in the following combinations of split words:
		`DLEN  Cr/Cb data  Y data`
		`16  PPI_DATA[15:8]  PPI_DATA[7:0]`
		`20  PPI_DATA[19:10]  PPI_DATA[9:0]`
		`24  PPI_DATA[23:12]  PPI_DATA[11:0]`	

		0	PPI_DATA has (DLEN-1) bits of Y or Cr or Cb
		1	PPI_DATA Contains 2 Elements per Word
25 (R/W)	SUBSPLTODD	Sub-Split Odd Samples. The EPPI_CTL.SUBSPLTODD bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.SUBSPLTODD is set, the EPPI sub-splits the odd sub-stream, and packs them separately.	
		0	Disable
		1	Enable
24 (R/W)	SPLTEO	Split Even and Odd Data Samples. If EPPI_CTL.SPLTEO is set, the EPPI splits the incoming data stream into two sub-streams, an even stream and an odd stream, and packs them separately.	
		0	Do Not Split Samples
		1	Split Even/Odd Samples
23 (R/W)	SWAPEN	Swap Enable. The EPPI_CTL.SWAPEN selects whether or not to swap the order of the first data (most-significant bits versus least-significant bits) of the DMA word. For receive modes, the EPPI puts the first data in the most significant bits (if set) or puts the first data in the least significant bits (if cleared) of the DMA word. For transmit modes, the EPPI transmits the most significant bits in the DMA word as the first data (if set) or transmits the least significant bits in the DMA word as the first data (if cleared).	
		0	Disable
		1	Enable

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	PACKEN	Pack/Unpack Enable. The EPPI_CTL.PACKEN select whether or not packing is enabled (for receive modes) and unpacking is enabled (for transmit modes). When this bit is set, EPPI transfer DMA is 32-bits wide. When this bit is cleared and the EPPI_CTL.DLEN is less than or equal to 16 bits, EPPI transfer DMA is 16-bits wide. For receive modes, if this bit is set, then the EPPI packs the incoming data into 32-bit words. If this bit is cleared, then the EPPI does not do any packing. For transmit modes, if this bit is set, then the EPPI always unpacks the 32-bit data from DMA. If this bit is not set, the EPPI does not do any unpacking.	
		0	Disable
		1	Enable
21 (R/W)	SKIPEO	Skip Even or Odd. The EPPI_CTL.SKIPEO bit selects whether even (if set) or odd (if cleared) samples are skipped if sample skipping is enabled (EPPI_CTL.SKIPEN is set). This feature only is useful for receive modes.	
		0	Skip Odd Samples
		1	Skip Even Samples
20 (R/W)	SKIPEN	Skip Enable. The EPPI_CTL.SKIPEN bit enables skipping alternate samples. This feature only is useful for receive modes.	
		0	No Samples Skipping
		1	Skip Alternate Samples
19 (R/W)	DMIRR	Data Mirroring. The EPPI_CTL.DMIRR field enables mirroring (bit reversing) of the data coming in or going out on the EPPI data pins. Pin Data PPI Data (DAT_MRR=0) PPI Data (DAT_MRR=1) 15 15 0 14 14 1 .... 1 1 14 0 0 15	
		0	No Data Mirroring
		1	Data Mirroring
18:16 (R/W)	DLEN	Data Length. The EPPI_CTL.DLEN bits select the data length for the EPPI. Note that the 20 bits data length selection is valid only for SMPTE modes (EPPI_CTL.SPLTWRD set).	

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	8 bits
		1	10 bits
		2	12 bits
		3	14 bits
		4	16 bits
		5	18 bits
		6	20 bits
		7	24 bits
15:14 (R/W)	POLS	Frame Sync Polarity. The `EPPI_CTL.POLS` selects whether the frame syncs' polarity is active low versus active high.	
		0	FS1 and FS2 are active high
		1	FS1 is active low. FS2 is active high
		2	FS1 is active high. FS2 is active low
		3	FS1 and FS2 are active low
13:12 (R/W)	POLC	Clock Polarity. The `EPPI_CTL.POLC` selects the rising versus falling edge for sampling data and sampling/driving syncs.	
		0	Clock/Sync Polarity Mode 0. For receive mode: Sample data on falling edge and sample/drive syncs on falling edge. For transmit mode: Drive data on rising edge and sample/drive syncs on rising edge.
		1	Clock/Sync Polarity Mode 1. For receive mode: Sample data on falling edge and sample/drive syncs on rising edge. For transmit mode: Drive data on rising edge and sample/drive syncs on falling edge.
		2	Clock/Sync Polarity Mode 2. For receive mode: Sample data on rising edge and sample/drive syncs on falling edge. For transmit mode: Drive data on falling edge and sample/drive syncs on rising edge.
		3	Clock/Sync Polarity Mode 3. For receive mode: Sample data on rising edge and sample/drive syncs on rising edge. For transmit mode: Drive data on falling edge and sample/drive syncs on falling edge.

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SIGNEXT	Sign Extension. The EPPI_CTL.SIGNEXT select whether (for receive modes when EPPI_CTL.DLEN selecting 16 bit data length) the data is sign extended or zero filled. Not that EPPI_CTL.SPLTWRD is removed from this shared bit.	
		0	Zero Filled
		1	Sign Extended
10 (R/W)	IFSGEN	Internal Frame Sync Generation. The EPPI_CTL.IFSGEN bit selects whether the frame syncs are generated internally or are supplied by an external device.	
		0	External Frame Sync
		1	Internal Frame Sync
9 (R/W)	ICLKGEN	Internal Clock Generation. The EPPI_CTL.ICLKGEN bit selects whether the EPPI_CLK is generated internally or is supplied by an external device.	
		0	External Clock
		1	Internal Clock
8 (R/W)	BLANKGEN	Blanking Generation (ITU Output Mode). The EPPI_CTL.BLANKGEN enables ITU output with internal blanking. In GP 8, 10 transmit bit modes (when EPPI_CTL.SPLTWRD is cleared) and 16-, 20-, and 24-bit transmit modes (when EPPI_CTL.SPLTWRD is set), EPPI_CTL.BLANKGEN selects whether or not the EPPI generates blanking and generates preamble and insertion with active data from memory.	
		0	Disable
		1	Enable
7 (R/W)	ITUTYPE	ITU Interlace or Progressive. The EPPI_CTL.ITUTYPE selects interlaced or progressive operation for ITU656 mode. This selection is valid for both TX and RX modes.	
		0	Interlaced
		1	Progressive

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	FLDSEL	Field Select/Trigger. The EPPI_CTL.FLDSEL bits configure the EPPI field and trigger selection. These are valid for GP modes (EPPI_CTL.XFRTYPE =0x3) and ITU656 active video mode (EPPI_CTL.XFRTYPE cleared).	
		0	Field Mode 0. Read field 1 (for ITU656 active video mode). Set internal trigger (for GP RX mode). FS3 is toggled on FS2 assertion followed by FS1 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
		1	Field Mode 1 Read field 1 and field 2 (ITU656 active video mode). Set external trigger (GP RX mode). FS3 is toggled on FS2 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
5:4 (R/W)	FSCFG	Frame Sync Configuration. The EPPI_CTL.FSCFG bits configure the EPPI frame syncs. These are valid only for GP modes (EPPI_CTL.XFRTYPE =0x3). The output of the frames syncs also depends on whether the EPPI transfer direction is transmit and the EPPI is in ITU output mode (EPPI_CTL.BLANKGEN is set).	
		0	Sync Mode 0. FS0 driven in GP mode. FS0 not driven in ITU output mode.
		1	Sync Mode 1. FS1 driven in GP mode. HSYNC driven on FS1 in ITU output mode.
		2	Sync Mode 2. FS2 driven in GP mode. HSYNC driven on FS1 and VSYNC driven on FS1 in ITU output mode.
		3	Sync Mode 3. FS3 driven in GP mode. HSYNC driven on FS1, VSYNC driven on FS2, and FIELD driven on FS3 in ITU output mode.

Table 23-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	XFRTYPE	Transfer Type (Operating Mode). The `EPPI_CTL.XFRTYPE` bits select the EPPI operating mode. In receive mode (`EPPI_CTL.DIR` cleared), the EPPI modes include ITU656 active video only mode, ITU656 entire field mode, ITU656 vertical blanking only mode, and non-ITU656 mode (GP mode). For transmit mode (`EPPI_CTL.DIR` set), the `EPPI_CTL.XFRTYPE` bits have no effect, and the EPPI (in transmit mode) is always in GP mode.	
		0	ITU656 Active Video Only Mode
		1	ITU656 Entire Field Mode
		2	ITU656 Vertical Blanking Only Mode
		3	Non-ITU656 Mode (GP Mode)
1 (R/W)	DIR	PPI Direction. The `EPPI_CTL.DIR` bit selects whether the EPPI is in receive mode (if cleared) or in transmit mode (if set).	
		0	Receive Mode
		1	Transmit Mode
0 (R/W)	EN	PPI Enable. The `EPPI_CTL.EN` bit enables or disables the EPPI.	
		0	Disable
		1	Enable

Control Register 2 Register

The EPPI_CTL2 register controls HSYNC finish signal generation.

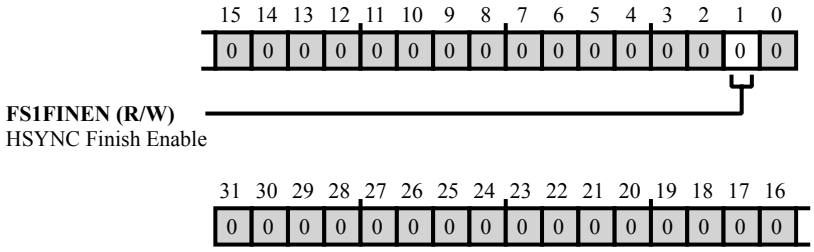

Figure 23-13: EPPI_CTL2 Register Diagram

Table 23-50: EPPI_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FS1FINEN	HSYNC Finish Enable. The EPPI_CTL2.FS1FINEN bit selects whether (if set) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a LINE is received completely or (if cleared) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely. Note that the EPPI_CTL.DMAFINEN bit must be set for the EPPI to generate either of the finish commands.	
		0	Finish sent after frame RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely
		1	Finish sent after frame/line RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.

Clipping Register for EVEN (Luma) Data Register

The EPPI_EVENCLIP register selects the clipping threshold for luma data, which provides clipping of individual video components.

The high even and low even spaces in EPPI_EVENCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

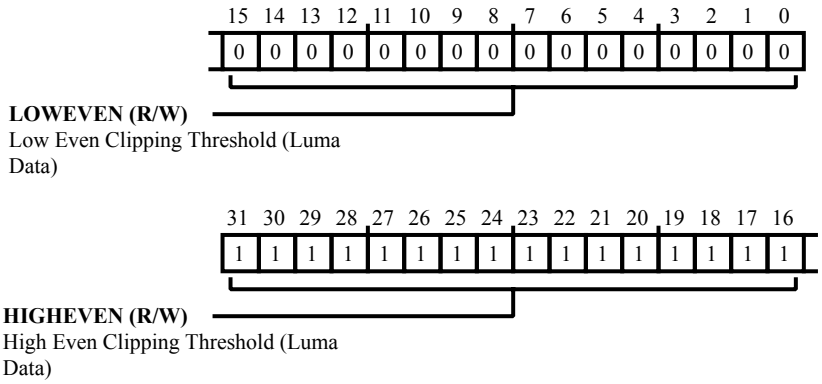

Figure 23-14: EPPI_EVENCLIP Register Diagram

Table 23-51: EPPI_EVENCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHEVEN	High Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.HIGHEVEN bit field selects the clipping threshold for luma data. The high even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWEVEN	Low Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.LOWEVEN bit field selects the clipping threshold for luma data. The low even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Lines Per Frame Register

The EPPI_FRAME register tracks the frame track overflow and underflow errors. This register should be programmed with the number of lines expected per frame. Any write to the EPPI_FRAME register will also write the same value to the EPPI_VCNT register. But, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_FRAME register should be programmed before the EPPI_VCNT register.

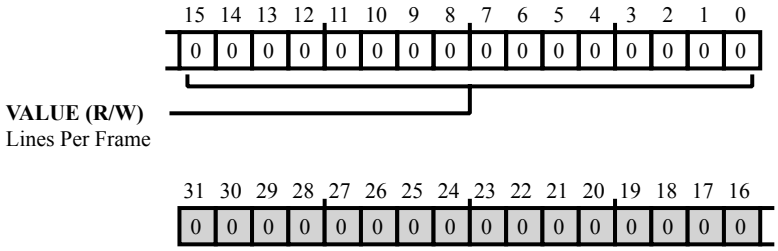

Figure 23-15: EPPI_FRAME Register Diagram

Table 23-52: EPPI_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Lines Per Frame. The EPPI_FRAME.VALUE holds the number of lines expected per frame of data.

Frame Sync 1 Delay Value Register

The EPPI_FS1_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after the EPPI is enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

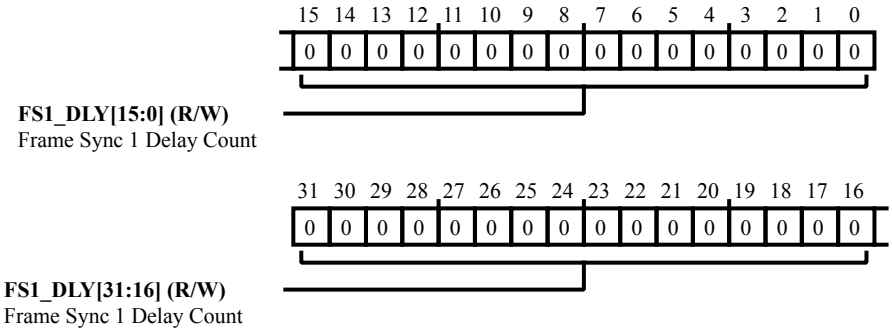

Figure 23-16: EPPI_FS1_DLY Register Diagram

Table 23-53: EPPI_FS1_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS1_DLY	Frame Sync 1 Delay Count. The EPPI_FS1_DLY.FS1_DLY bit field selects the delay count.

FS1 Period Register / EPPI Active Samples Per Line Register

The EPPI_FS1_PASPL register content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL register is used for the generation of frame sync 1. The register contains the period required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of active video or vertical blanking samples per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for this register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_PASPL register as containing 1.

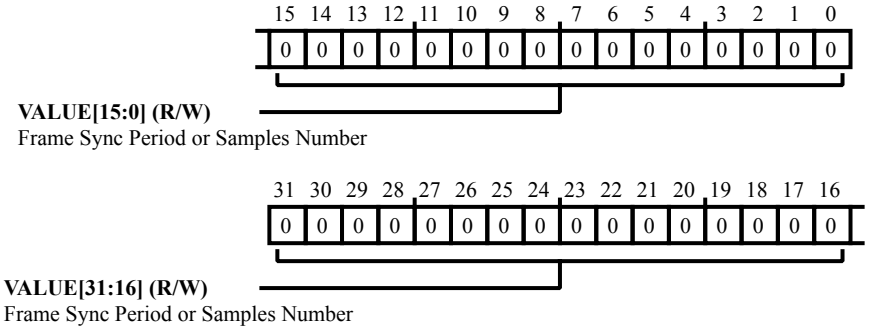

Figure 23-17: EPPI_FS1_PASPL Register Diagram

Table 23-54: EPPI_FS1_PASPL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Period or Samples Number. In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL.VALUE bit field is used for the generation of frame sync 1 and contains the period required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this bit field contains the number of samples of active video or vertical blanking samples per line.

FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register

The EPPI_FS1_WLHB register's content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2 or 3 FS modes, EPPI_FS1_WLHB is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of horizontal blanking per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for the EPPI_FS1_WLHB register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_WLHB register as containing 1.

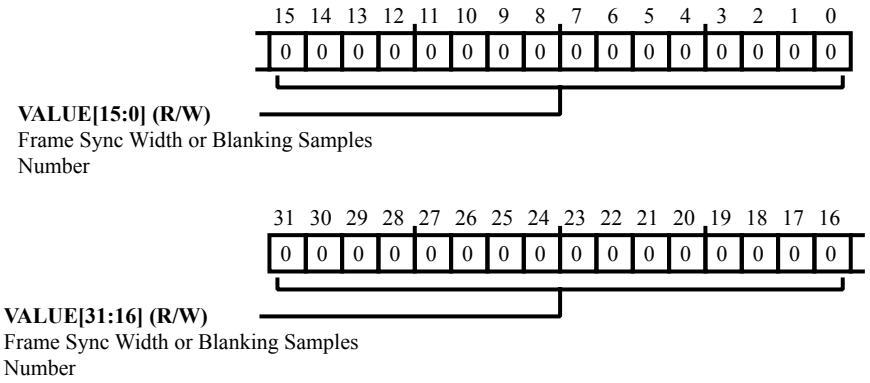

Figure 23-18: EPPI_FS1_WLHB Register Diagram

Table 23-55: EPPI_FS1_WLHB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Width or Blanking Samples Number. The EPPI_FS1_WLHB.VALUE bit field content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode. In GP 1, 2 or 3 FS modes, the EPPI_FS1_WLHB.VALUE bit field is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with EPPI_CTL.BLANKGEN set, this bit field contains the number of samples of horizontal blanking per line.

Frame Sync 2 Delay Value Register

The EPPI_FS2_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after EPPI enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with the value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

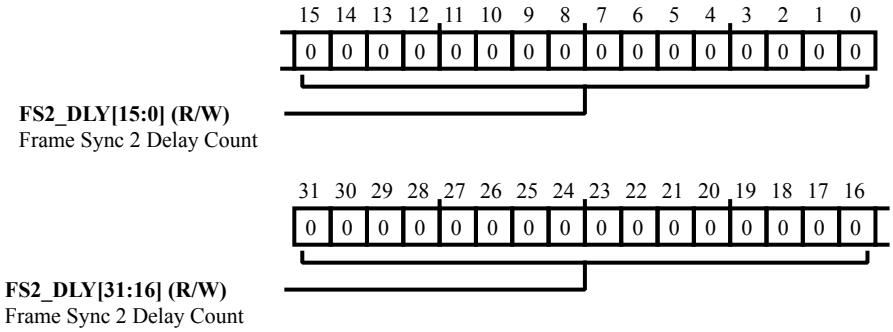

Figure 23-19: EPPI_FS2_DLY Register Diagram

Table 23-56: EPPI_FS2_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS2_DLY	Frame Sync 2 Delay Count. The EPPI_FS2_DLY.FS2_DLY bit field selects the delay count.

FS2 Period Register / EPPI Active Lines Per Field Register

The EPPI_FS2_PALPF register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, EPPI_FS2_PALPF is used for the generation of frame sync 2. This register contains the period required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of lines of active video per field.

Note that a value of 0 for the EPPI_FS2_PALPF.F1ACT or EPPI_FS2_PALPF.F2ACT bits is illegal. If either is programmed as 0, the EPPI regards the 0 value fields as containing 1.

Also, note that for progressive video, the EPPI_FS2_PALPF.F2ACT bit is ignored.

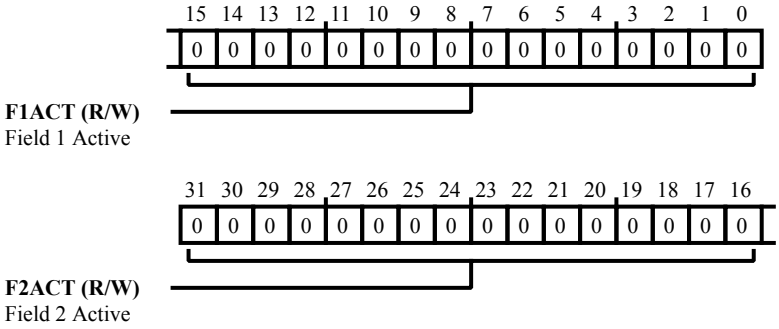

Figure 23-20: EPPI_FS2_PALPF Register Diagram

Table 23-57: EPPI_FS2_PALPF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	F2ACT	Field 2 Active. The EPPI_FS2_PALPF.F2ACT bit field contains the number of lines of active data in field 2.
15:0 (R/W)	F1ACT	Field 1 Active. The EPPI_FS2_PALPF.F1ACT bit field contains the number of lines of active data in field 1.

FS2 Width Register / EPPI Lines Of Vertical Blanking Register

The EPPI_FS2_WLVB register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, the EPPI_FS2_WLVB register is used for the generation of frame sync 2. The register contains the width required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number or lines of vertical blanking.

Note that for progressive video, the EPPI_FS2_WLVB.F2VBBD and EPPI_FS2_WLVB.F2VBAD bits are ignored.

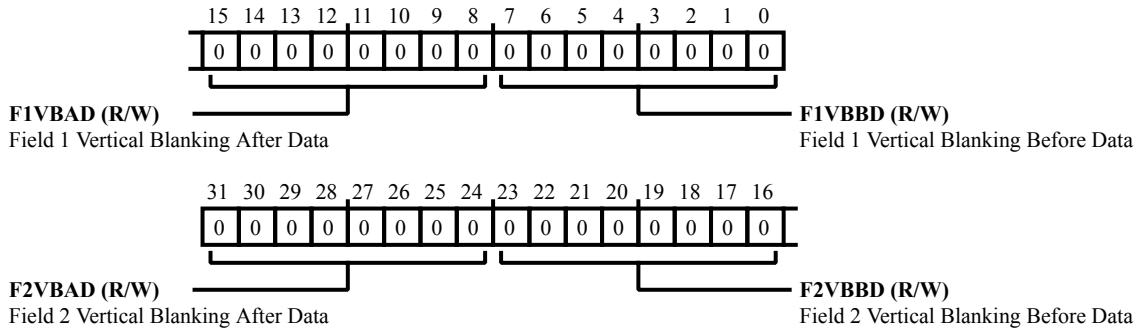

Figure 23-21: EPPI_FS2_WLVB Register Diagram

Table 23-58: EPPI_FS2_WLVB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	F2VBAD	Field 2 Vertical Blanking After Data. The EPPI_FS2_WLVB.F2VBAD bit field contains the number of lines of vertical blanking after field 2.
23:16 (R/W)	F2VBBD	Field 2 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F2VBBD bit field contains the number of lines of vertical blanking before field 2.
15:8 (R/W)	F1VBAD	Field 1 Vertical Blanking After Data. The EPPI_FS2_WLVB.F1VBAD bit field contains the number of lines of vertical blanking after field 1.
7:0 (R/W)	F1VBBD	Field 1 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F1VBBD bit field contains the number of lines of vertical blanking before field 1.

Horizontal Transfer Count Register

The EPPI_HCNT register holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1. Any write to the EPPI_LINE register modifies the EPPI_HCNT register. But, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_HCNT register should be programmed after the EPPI_LINE register.

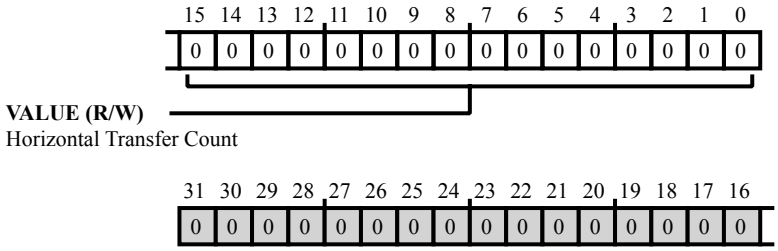

Figure 23-22: EPPI_HCNT Register Diagram

Table 23-59: EPPI_HCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Transfer Count. The EPPI_HCNT.VALUE holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the last assertion of EPPI_FS1.

Horizontal Delay Count Register

The EPPI_HDLY register contains the number of clock cycles to delay after the assertion of EPPI_FS1 is detected before starting to read or write data.

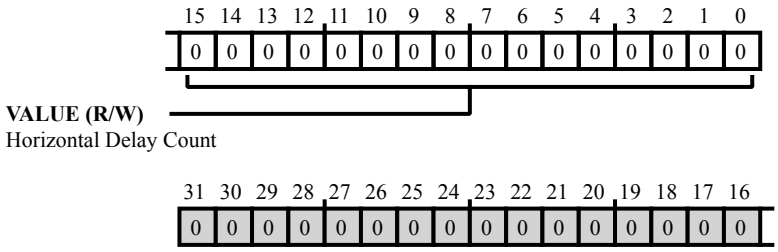

Figure 23-23: EPPI_HDLY Register Diagram

Table 23-60: EPPI_HDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Delay Count. The EPPI_HDLY.VALUE holds the number of EPPI_CLK cycles to delay after assertion of EPPI_FS1 before starting to read or write data.

Interrupt Mask Register

The EPPI_IMSK register permits the masking (if associated bit is set) of EPPI error interrupts for YFIFO underflow or overflow, CFIFO underflow or overflow, line track overflow error, line track underflow error, frame track overflow error, frame track underflow error, and ERR_NCOR (ITU preamble error not corrected. These conditions are flagged in the EPPI_STAT register and cleared by write-1-to-clear.

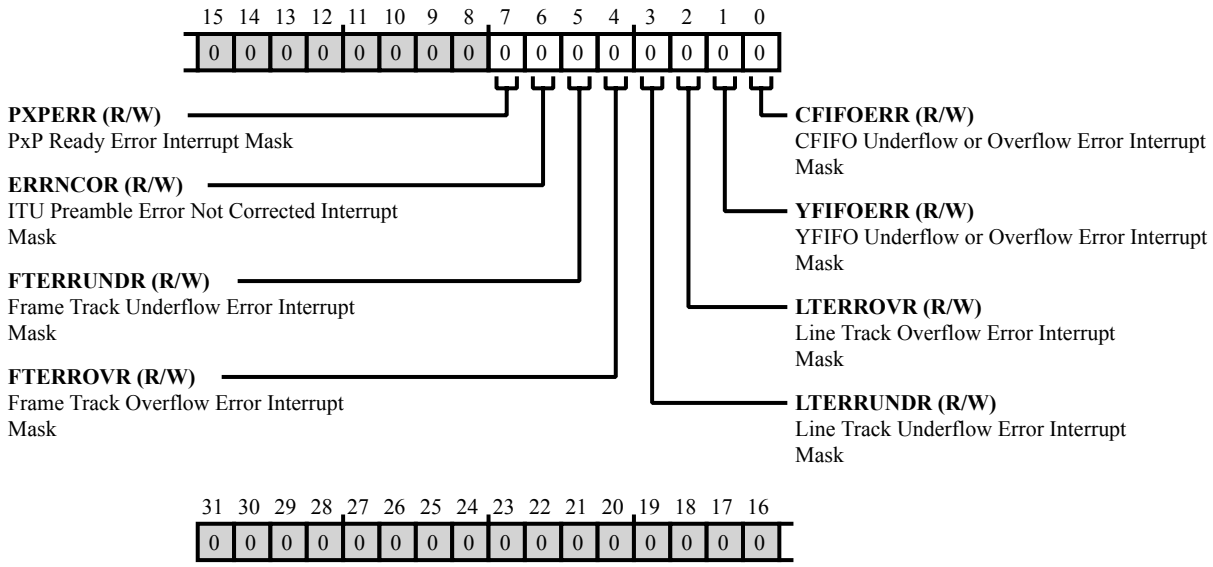

Figure 23-24: EPPI_IMSK Register Diagram

Table 23-61: EPPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PXPERR	PxP Ready Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
6 (R/W)	ERRNCOR	ITU Preamble Error Not Corrected Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
5 (R/W)	FTERRUNDR	Frame Track Underflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
4 (R/W)	FTERROVR	Frame Track Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt

Table 23-61: EPPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	LTERRUNDR	Line Track Underflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
2 (R/W)	LTERROVR	Line Track Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
1 (R/W)	YFIFOERR	YFIFO Underflow or Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
0 (R/W)	CFIFOERR	CFIFO Underflow or Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt

Samples Per Line Register

The EPPI_LINE register tracks the line track overflow and underflow errors. This register should be programmed with the number of samples expected per line. Any write to the EPPI_LINE register will also write the same value to the EPPI_HCNT register. However, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_LINE register should be programmed before the EPPI_HCNT register.

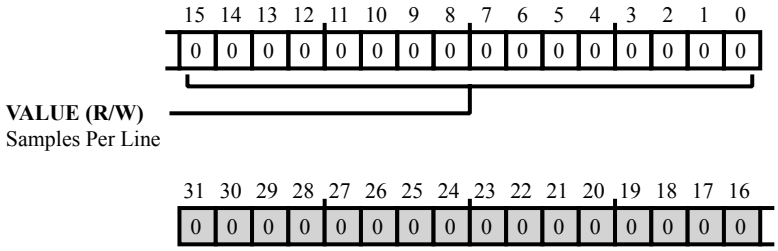

Figure 23-25: EPPI_LINE Register Diagram

Table 23-62: EPPI_LINE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Samples Per Line. The EPPI_LINE.VALUE holds the number of samples expected per line.

Clipping Register for ODD (Chroma) Data Register

The EPPI_ODDCLIP register selects the clipping threshold for chroma data, which provides clipping of individual video components.

The high odd and low odd spaces in EPPI_ODDCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

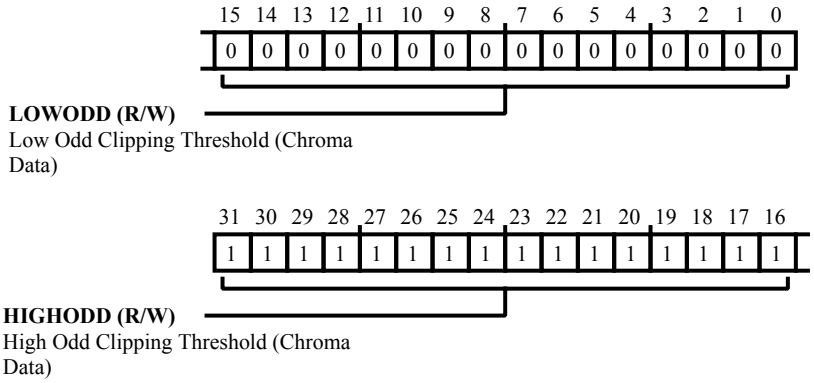

Figure 23-26: EPPI_ODDCLIP Register Diagram

Table 23-63: EPPI_ODDCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHODD	High Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.HIGHODD bit field selects the clipping threshold for luma data. The high odd spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWODD	Low Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.LOWODD bit field selects the clipping threshold for luma data. The low add spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Status Register

The EPPI_STAT register contains bits that provide information about the current operating state of the EPPI.

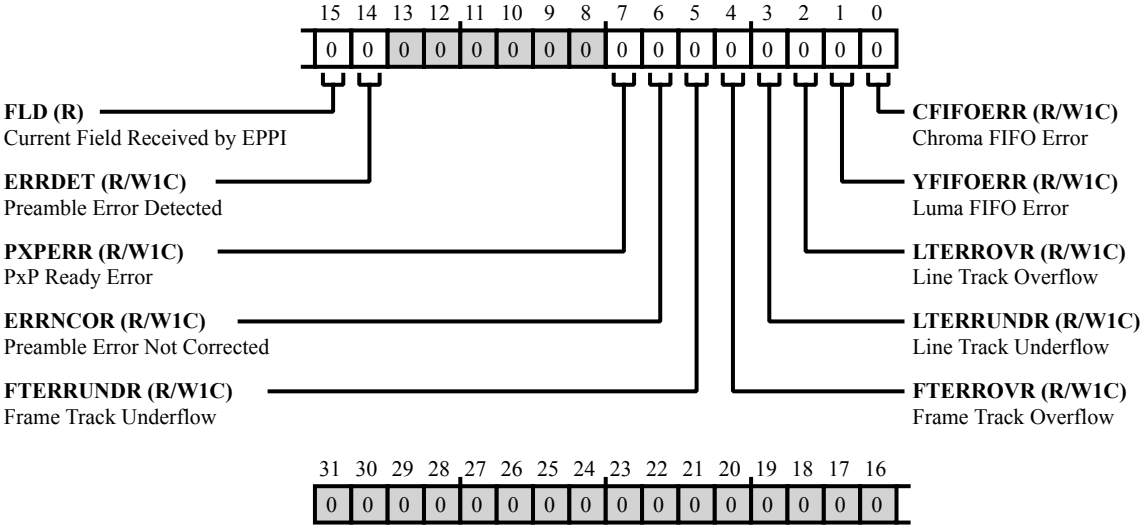

Figure 23-27: EPPI_STAT Register Diagram

Table 23-64: EPPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	FLD	Current Field Received by EPPI. The EPPI_STAT.FLD bit indicates whether the current field being received by the PPI is field 1 (if clear) or field 2 (if set).	
		0	Field 1
		1	Field 2
14 (R/W1C)	ERRDET	Preamble Error Detected. The EPPI_STAT.ERRDET bit is useful only in ITU receive modes and indicates if an error has been detected in the status word of EAV or SAV sequences (if set) or not (if clear).	
		0	No Preamble Error Detected
		1	Preamble Error Detected
7 (R/W1C)	PXPERR	PxP Ready Error. The EPPI_STAT.PXPERR bit is valid only in the RX mode. This bit indicates whether the incoming PPI data overflows the PxP interface (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	

Table 23-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERRNCOR	Preamble Error Not Corrected. The EPPI_STAT.ERRNCOR bit is useful only in the ITU receive modes and indicates if an error in the status word of EAV or SAV sequences can not be cleared (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No uncorrected preamble error has occurred
		1	Preamble error detected but not corrected
5 (R/W1C)	FTERRUNDR	Frame Track Underflow. The EPPI_STAT.FTERRUNDR bit indicates whether a frame track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
4 (R/W1C)	FTERROVR	Frame Track Overflow. The EPPI_STAT.FTERROVR bit indicates whether a frame track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
3 (R/W1C)	LTERRUNDR	Line Track Underflow. The EPPI_STAT.LTERRUNDR bit indicates whether a line track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
2 (R/W1C)	LTERROVR	Line Track Overflow. The EPPI_STAT.LTERROVR bit indicates whether a line track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Table 23-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	YFIFOERR	Luma FIFO Error. For RX modes, the `EPPI_STAT.YFIFOERR` bit indicates whether the Luma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the Luma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
0 (R/W1C)	CFIFOERR	Chroma FIFO Error. For RX modes, the `EPPI_STAT.CFIFOERR` bit indicates whether the chroma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the chroma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Vertical Transfer Count Register

The EPPI_VCNT register holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame. Any write to the EPPI_FRAME register modifies the EPPI_VCNT register. However, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_VCNT register should be programmed after the EPPI_FRAME register.

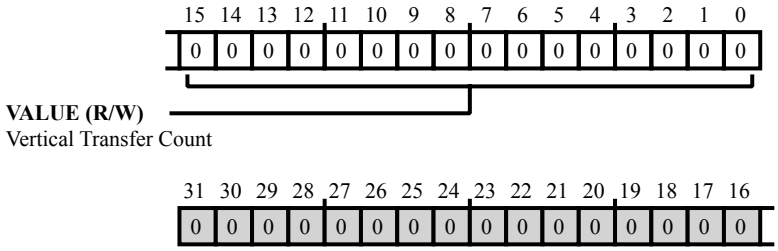

Figure 23-28: EPPI_VCNT Register Diagram

Table 23-65: EPPI_VCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Transfer Count. The EPPI_VCNT.VALUE holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame.

Vertical Delay Count Register

The EPPI_VDLY register contains the number of lines to wait after the start of a new frame before starting to read/transmit data.

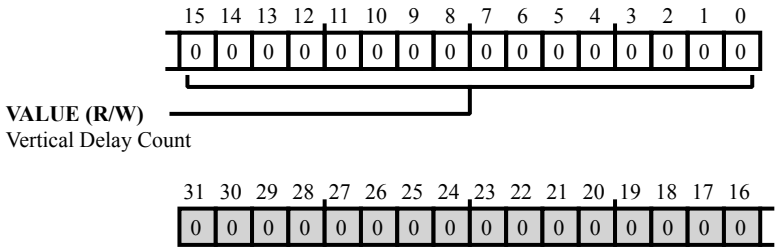

Figure 23-29: EPPI_VDLY Register Diagram

Table 23-66: EPPI_VDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Delay Count. The EPPI_VDLY.VALUE holds the number of lines to wait after the start of a new frame before starting to read/transmit data.

24 General-Purpose Timer (TIMER)

The general-purpose timer (GP Timer) module serves as a collection of system timers that support various system-level functions. These functions include:

- Synchronized PWM waveform output capability
- External signal capture
- External event count
- General time-base functionality

Additionally, interrupt requests can be generated upon completion of timer events. Moreover, GP timers can act both as trigger requesters and trigger completers.

GP Timer Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed watchdog mode
- Pulse-width count and capture (WDTH_CAP) mode
- External Event (EXT_CLK) mode
- Pulse-width modulation (PWM_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values

- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output

ADSP-2159x_SC591_SC592_SC594 TIMER Register List

The General-Purpose Timer block (TIMER) provides timers that may be used for external event capture and measurement, system timing, and PWM waveform generation. A set of registers governs TIMER operations. For more information on TIMER functionality, see the TIMER register descriptions.

Table 24-1: ADSP-2159x_SC591_SC592_SC594 TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register

Timer Block Diagram

The Timer block diagram figure shows all of the possible clock sources.

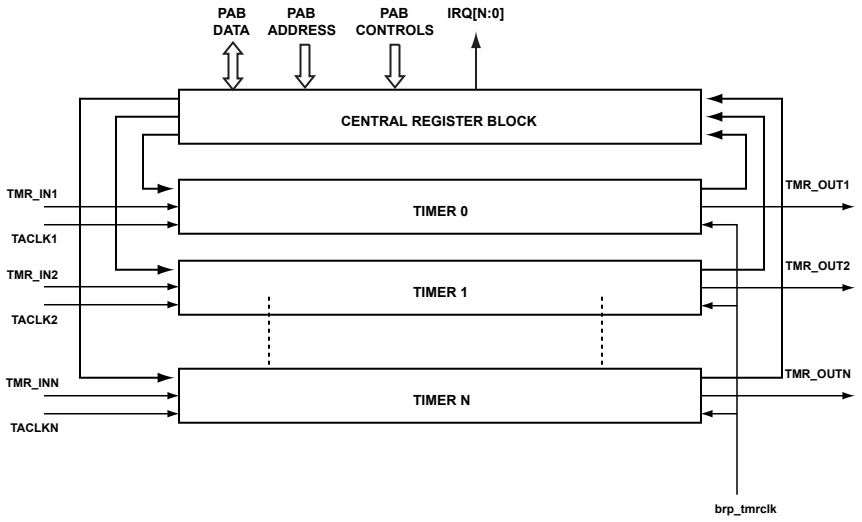

Figure 24-1: Timer Block Diagram

Internal Interface

The processor core always accesses the timer registers through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has a dedicated data interrupt request. There is also one common timer status and error interrupt request output that connects to the system event

controller. Whenever a data interrupt request is generated, a data trigger requester pulse is also driven out, if enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a trigger completer.

In total, the GP timer module can have up to (N + 1) interrupt request output lines and N data trigger lines.

Internal Timer Connections

The Timers support alternate inputs for the clock/capture (see External Interface). Some signals have internal default alternate connections according to the ***Timer Signal Routing*** table.

Table 24-5: Timer Signal Routing

Timer Signal	Connection
TM0_ACLK0	SYS_CLKIN0
TM0_ACI5	DAI0_PB04
TM0_ACLK5	DAI0_PB03
TM0_ACI6	DAI1_PB04
TM0_ACLK6	DAI1_PB03
TM0_ACI07	CNT0_TO
TM0_ACLK7	SYS_CLKIN1
TM0_ACI8	DAI0_PB06
TM0_ACLK8	DAI0_PB05
TM0_ACI9	DAI1_PB06
TM0_ACLK9	DAI1_PB05
TM0_ACI14	DAI0 Group C
TM0_ACI15	DAI1 Group C

External Interface

Each GP timer module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in the data sheet for the processor.

Every timer has one main input/output signal (`TIMER_TMR[nn]`) and, usually, one auxiliary input pin, used as an alternate capture input (`TIMER_ACI[nn]`). Each timer can either run with a time base of SCLK0 or can reference an external clock on one of two (`TIMER_ACLK[nn]`) pins. The TMR_ALT_CLK0 signal maps to individual alternate clock ((`TIMER_ACLK[nn]`) pins for one or more timers. For instance, a TM_ACLK3 pin would provide an alternate site to supply an external signal that would serve as reference clock for TMR3. Likewise, the TMR_ALT_CLK1 signal from each timer unit connects together internally to provide a single global timer clock pin (`TIMER_CLK`) for the GP timer module. It is used as an additional time base.

GP Timer Operating Modes

The following sections provide information on the various operating modes of the GP timer.

General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only TIMER_TMR[n]_CNT register. Once the module enables a timer, it loads the timer TIMER_TMR[n]_CNT register with a starting value.

A timer can operate in one of several different modes, configured through the TIMER_TMR[n]_CFG register for that timer. These modes are: PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT, and IDLE. The ***Timer Mode Descriptions*** table summarizes the modes.

Table 24-6: Timer Mode Descriptions

Timer Mode	Description
PWMOUT	Generates single or continuous PWM waveforms with programmable pulse width, period, and delay
EXTCLK	Counts edges of an externally applied waveform
WIDCAP	Captures pulse width or period of an externally applied waveform
WATCHDOG	Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt when it falls inside or outside of that window
PININT	Can generate an interrupt request on an active edge applied to a timer pin
IDLE	Idle; no activity

Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the double-buffered period, pulse width, and delay registers. These values are then ready for use in the first timer period. When a timer is already running, software can write new values to the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers. The written values are buffered and do not update into the registers until the end of the current period. (The update occurs when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_PER register.)

If new values are not written to these registers, the value from the previous period is reused. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. Values written to the period, pulse width, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width, or delay value. Written values are not readback until they become active.

The usage of the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers varies, depending on the mode of the timer specified by the TIMER_TMR[n]_CFG.TMODE bits. See the ***Usage of the Period, Width, and Delay Registers in Different Timer Modes*** table for more information.

Table 24-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
IDLE	Not writable	Not writable	Not writable
WATCHDOG	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.	Read-only. Retains value of last measured width or period of the input signal.	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.
WIDCAP	Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.	Read-only. Width value captured at the appropriate time and updated from its buffer register simultaneously with the Period register.	Not used
PWMOUT	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.
EXTCLK	Can be updated on-the-fly.	Not used	Not used
PININT	Not used	Not used	Not used

If any of the period, pulse width, and delay registers are not used, then programs cannot write into that register. For example, in WIDCAP mode, the delay registers are not used. So, the program is not allowed to write any value to the TIMER_TMR[n]_DLY register. To prevent undesired operation, program the TIMER_TMR[n]_CFG.TMODE bits before programming the period, width, or delay registers.

If a program changes the TIMER_TMR[n]_CFG.TMODE bits from a status register to writable register (for example in PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWMOUT mode with small periods, there may not be enough time between updates from the buffer registers to write these registers. The next period can use one old value and one new value. To prevent (width + pulse delay) > period errors, write the width and delay registers before the period register when decreasing the values. Write the period register before the width and delay registers when increasing the value.

Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TIMER_TMR[nn] pin. This mode is frequently used to implement a precise delay, often with generating an output trigger. The timer module uses the value in the TIMER_TMR[n]_DLY register to control the assertion of a pulse. The value in the TIMER_TMR[n]_WID register defines the pulse width. The TIMER_TMR[n]_PER is not used and cannot be written in this mode. After completion of the pulse, the timer is automatically stopped, and optionally generates an interrupt. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control pulse polarity.

The timer can be configured to generate a data interrupt request after satisfying various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is not necessary to clear the relevant TIMER_RUN bit to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding TIMER_RUN bit is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate TIMER_RUN bit, and wait for the timer to stop. Then, write another 1 to the same TIMER_RUN bit.

Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates a repetitive pulse with a well-defined period, duty cycle, and pulse position. The TIMER_TMR[n]_DLY, TIMER_TMR[n]_PER, and TIMER_TMR[n]_WID registers are programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in the TIMER_TMR[n]_PER register. Initially, the TIMER_TMR[nn] pin remains in a deasserted state. The pin toggles to an asserted state when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_DLY register.

The timer can control the assertion sense of the TIMER_TMR[nn] pin with the TIMER_TMR[n]_CFG.PULSEHI bit. The TIMER_TMR[nn] pin holds this value for the number of clock cycles specified in the TIMER_TMR[n]_WID register. Then, the pin deasserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

The timer can be configured to generate a data interrupt request after satisfying any of various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is important to guarantee that the programmed period is greater than or equal to the sum of width and delay. Similarly, delay must be less than period. Violating either of these criteria results in an unpredictable waveform on the TIMER_TMR[nn] pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TIMER_TMR[nn] pin is achieved by setting TIMER_TMR[n]_PER to 2 and TIMER_TMR[n]_WID to 1. This operation makes the TIMER_TMR[nn] pin toggle each SCLK0 clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%.

When the TIMER_STOP_CFG.TMR[nn] bit of a timer is 0, the timer treats a stop operation as a stop-is-pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This funtionality prevents truncation of the current pulse and unwanted PWM patterns at the TIMER_TMR[nn] pin. The processor can determine when the timer stops running by polling the corresponding TIMER_RUN.TMR[nn] bit until it reads 0 or by waiting for the last interrupt (if enabled).

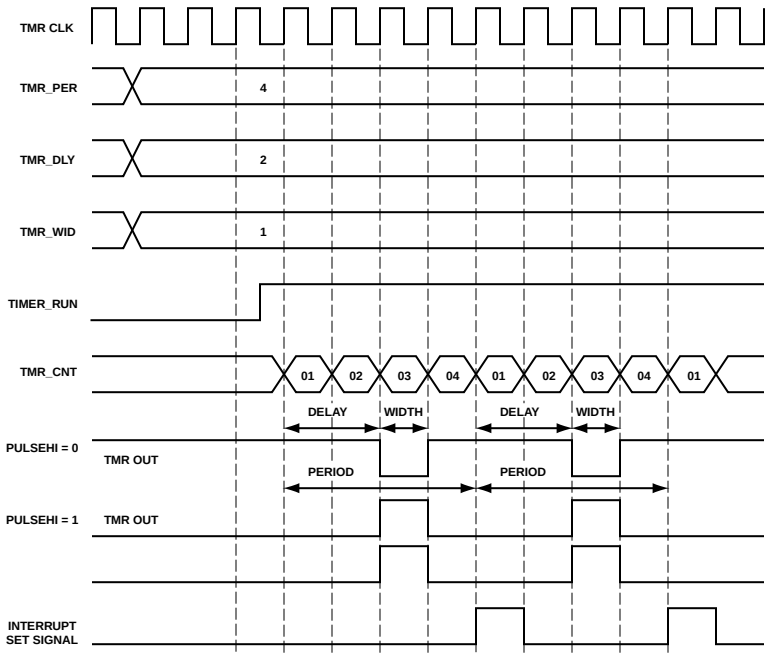

Figure 24-2: Signal Generation in Continuous PWMOUT Mode

The TIMER_TMR[n]_CFG register cannot be reconfigured until after the timer stops and the TIMER_RUN register reads 0.

Programs can force a timer to stop immediately in PWMOUT mode by writing a 1 to the TIMER_STOP_CFG register followed by writing a 1 to the TIMER_RUN_CLR register. (Or, a program can stop a timer by writing a 0 to the appropriate TIMER_RUN.TMR[nn] bit.) This operation stops the timer whether the pending stop is waiting for the end of the current period or the end of the current pulse width. The timer can use this feature to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, as it can corrupt the PWM pattern generated at the TIMER_TMR[nn] pin, though after such a stop the pin deasserts automatically. Each timer samples its TIMER_RUN.TMR[nn] bit at the end of each period. It stops cleanly at the end of the first period after the TIMER_RUN.TMR[nn] bit is low. A timer that is disabled and then restarted (before the end of the current period), continues to run as if nothing happened. Typically, the program disables a PWMOUT timer and then waits for it to stop itself.

Width Capture (WIDCAP) Mode

The timer uses WIDCAP mode, often called capture mode, to measure pulse widths on the TIMER_TMR[nn] or (TIMER_ACI[nn]) inputs. The polarity (active high or low) of the input signal can be selected with the TIMER_TMR[n]_CFG.PULSEHI bit. The ***Timer Signal Flow in Width Capture Mode*** figure shows the control signal flow for WIDCAP_CAP mode.

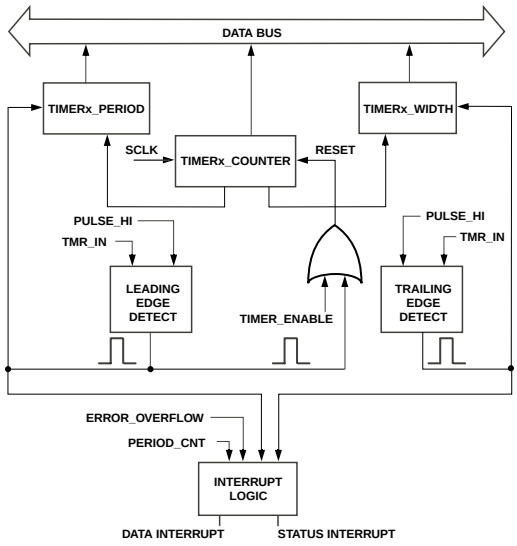

Figure 24-3: Timer Signal Flow in Width Capture Mode

NOTE: SCLK in the ***Timer Signal Flow in Width Capture Mode*** figure is SCLK0.

In this mode, the timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select between the `TIMER_TMR[nn]` or (`TIMER_ACI[nn]`) input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its `TIMER_TMR[n]_CNT` register to 0x0000 0001. It does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its period buffer register. The `TIMER_TMR[n]_CNT` register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, programs can measure both the pulse width and the pulse period of a waveform. The timer does not use the `TIMER_TMR[n]_DLY` register in this mode. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to control the definition of leading edge and trailing edge of the `TIMER_TMR[nn]` /(`TIMER_ACI[nn]`) pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The `TIMER_TMR[n]_PER` register is updated from the period buffer register.
2. The `TIMER_TMR[n]_WID` register is updated from the width buffer register.
3. The `TIMER_DATA_ILAT.TMR[nn]` bit is set (if enabled).
4. A timer data trigger pulse is generated (if enabled).

The `TIMER_TMR[n]_CFG.TMODE` bit 0 controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The `TIMER_STAT_ILAT` register is not set at a

measurement report. A measurement report occurs, at most, once per input signal period. The current TIMER_TMR[n]_CNT value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively. But, these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt request to signal that the TIMER_TMR[n]_PER and the TIMER_TMR[n]_WID registers are ready to be read.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1011, the measurement report occurs just after the width buffer register captures its value at a falling edge. Then, the TIMER_TMR[n]_WID register reports the pulse width measured in the pulse that has ended, but the TIMER_TMR[n]_PER register reports the pulse period measured at the end of the previous period. If only the first trailing edge has occurred, then the first period value has not yet been measured at the first measurement report. So, the period value is not valid. A read of the TIMER_TMR[n]_PER value in this case returns 0. See the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure for more information.

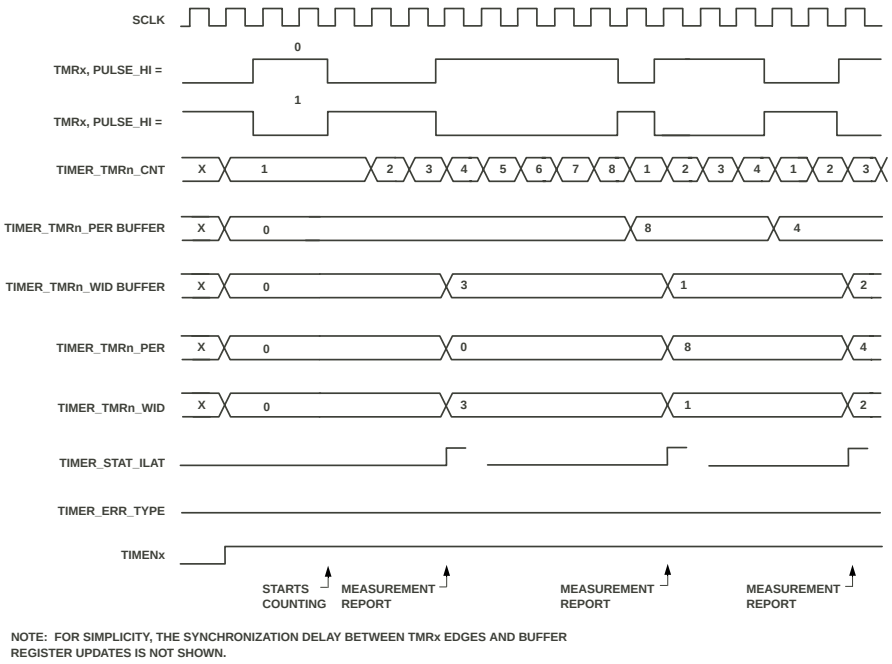

Figure 24-4: Example of Width Capture Deasserted Mode (TMODE=b#1011)

NOTE: SCLK in the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure is SCLK0.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1010, the measurement report occurs just after the period buffer register captures its value at a leading edge. Then, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers report the pulse period and pulse width measured in the period that has ended. Refer to the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure for more information.

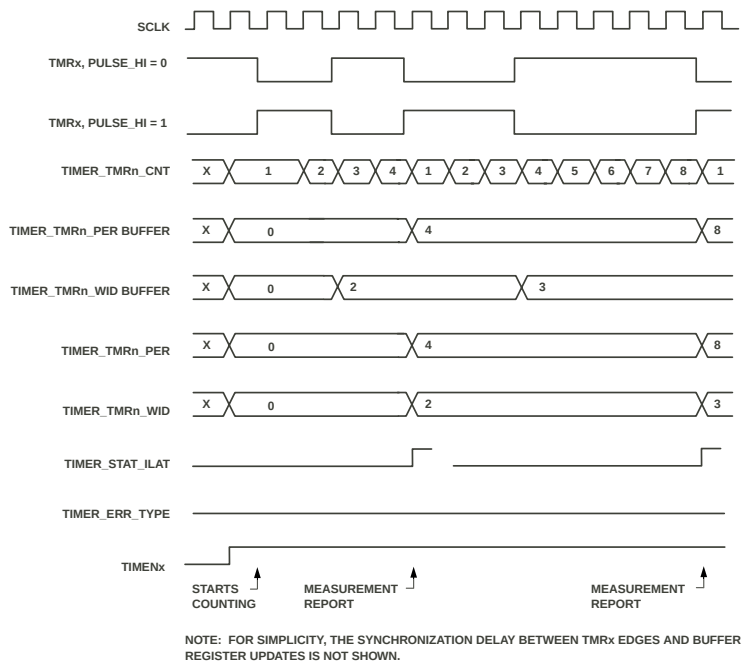

Figure 24-5: Example of Width Capture Asserted Mode (TMODE=b#1010)

NOTE: SCLK in the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure is SCLK0.

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set `TIMER_TMR[n]_CFG.TMODE` = b#1011. If `TIMER_TMR[n]_CFG.TMODE` = b#1010 for this case, no period value is captured in the period buffer register. Instead, the timer genererates an error report interrupt request (if enabled) when the `TIMER_TMR[n]_CNT` range is exceeded and the counter wraps around. In this case, both the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers read 0 (because no measurement report occurred to copy the value captured in the width buffer register to the `TIMER_TMR[n]_WID` register).

If using the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010 mode to measure the width of a single pulse, programs can disable the timer after taking the interrupt that ends the measurement interval. If desired, restart the timer as appropriate in preparation for another measurement. This procedure prevents the timer from free-running after the width measurement and logging errors generated by the timer count overflowing.

Width Capture Mode Overflow

A timer status interrupt request (when enabled) is generated when the `TIMER_TMR[n]_CNT` register wraps around from 0xFFFF FFFF to 0 in the absence of a leading edge. At that point, the `TIMER_STAT_ILAT` bit is set and the `TIMER_ERR_TYPE` bits change to indicate a count overflow due to a period greater than the range of the counter. This indication is referred to as an error report. A data interrupt request in WIDCAP mode indicates that a new measurement is ready to be read (a measurement report). Similarly, an interrupt request on the timer status interrupt line (shared interrupt request for all timers) indicates an overflow error when generated in this mode.

The `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are never updated at the time an overflow error is signaled. If the timer overflows and the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are not updated. If the timer overflows and the

TIMER_TMR[n]_CFG.TMODE bit =b#1011, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers are updated only if a trailing edge is detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupt requests to measure input signal periods longer than 0xFFFF FFFF. Each error report interrupt request adds a full 2^{32}SCLK0 counts to the total for the period, but the width is ambiguous. Ensure that if software monitors only the status interrupt request, then status interrupt requests from all other timers are masked.

Refer to the ***Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)*** figure. The period is 0x1 0000 0004, but the pulse width could be either 0x0 0000 0002 or 0x1 0000 0002.

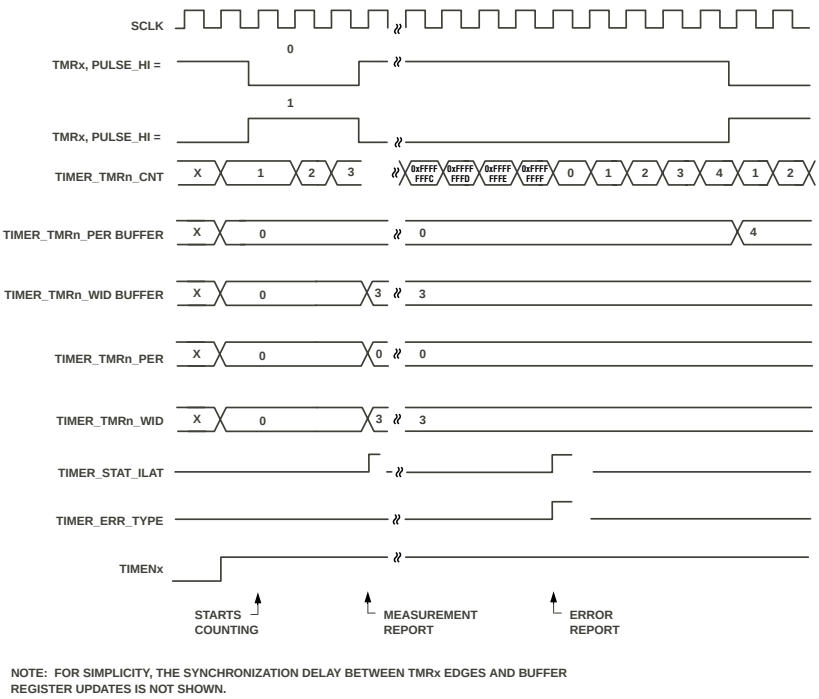

Figure 24-6: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0.

The waveform applied to the TIMER_TMR[nn] (or (TIMER_ACI[nn])) pin is not required to have a 50% duty cycle. The minimum input low time is little more than one SCLK0 period. The minimum input high time is a little more than one SCLK0 period. (Refer to the product data sheet for details.) The maximum TIMER_TMR[nn] input frequency is less than SCLK0/2, with a 50% duty cycle. Under these conditions, the WIDCAP mode timer measures: period =2 and pulse width =1.

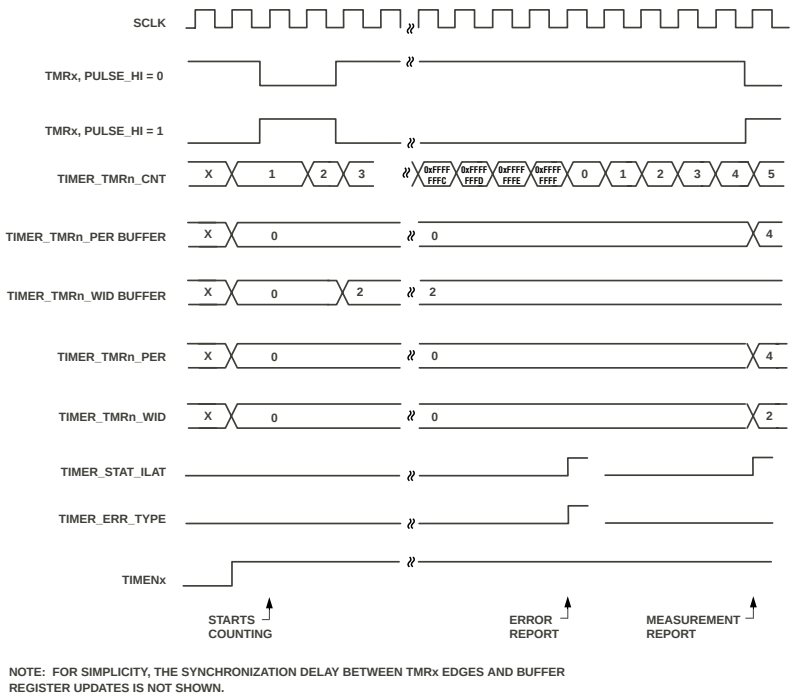

Figure 24-7: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1011)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0.

Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from one of the `TIMER_TMR[nn]` pins or the `TIMER_ACI[nn]` pins. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt request appropriately. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to select polarity of the input signal.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet.

Windowed Watchdog Width Mode

In windowed watchdog width mode, the timer counter monitors the pulse width of an input signal on one of the `TIMER_TMR[nn]` pins or one of the alternate clock pins (`TIMER_ACLK[nn]`). Program the minimum pulse width (p_{MIN}) in the `TIMER_TMR[n]_DLY` register and the maximum pulse width (p_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0 or alternate clock). The timer can generate an interrupt if the deasserting pulse edge occurs:

- Inside the window (p_{MIN} < pulse width ≤ p_{MAX}), or
- Outside the window (pulse width ≤ p_{MIN} or pulse width > p_{MAX})

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. Any pulse that is already active when the timer is enabled is ignored.

With the TIMER_TMR[n]_CFG.IRQMODE bit =b#11, the timer generates an interrupt if the timed pulse width exceeds p_{MAX}, or if the pulse width is less than p_{MIN}. After attaining p_{MAX}, the pulse stays at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting TIMER_TMR[n]_CFG.IRQMODE =b#10.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the TIMER_TMR[n]_WID register. During the inactive portion of the input signal, the internal counter does not increment. The ***Watchdog Width Mode Timing*** figure shows the signal flow in this mode.

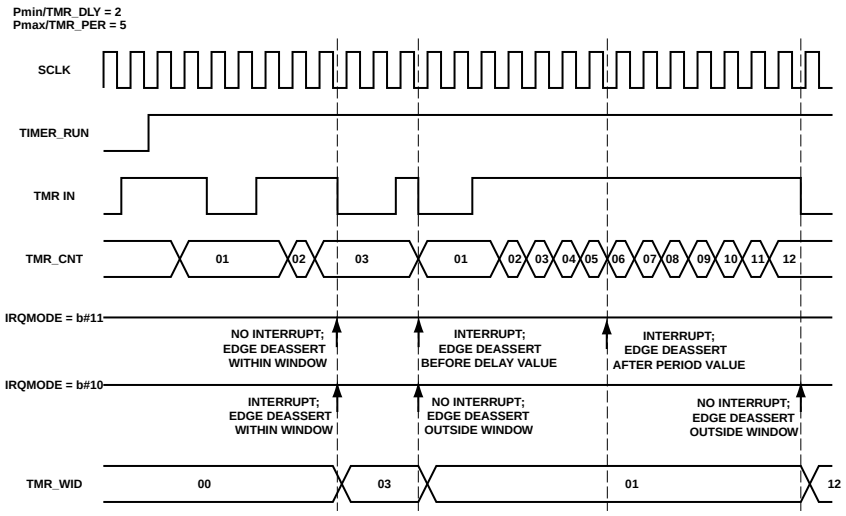

Figure 24-8: Watchdog Width Mode Timing

NOTE: SCLK in the ***Watchdog Width Mode Timing*** figure is SCLK0.

To check only the upper limit on pulse width (p_{MAX} but not p_{MIN}), then program p_{MIN} as 0 or 1. In such a case, it is better to use TIMER_TMR[n]_CFG.IRQMODE =b#11. With TIMER_TMR[n]_CFG.IRQMODE = b#10, a pulse width of 1 clock cycle results in an interrupt. For details, see the ***Windowed Watchdog Width Mode Interpretation*** table.

Table 24-8: Windowed Watchdog Width Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE= b#10	IRQMODE= b#11	Error Interrupt?
0 or 1	Anything ≥ 1	PW = 1	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
> 1 but ≤ (Period -1)	Anything > 1	PW ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < PW≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
≥ Period	-	PW ≤ TMR_PER	Undefined	Undefined	No Error Interrupt
	-	PW > TMR_PER	Undefined	Undefined	b#11 Error Type
-	0	-	Undefined	Undefined	b#10 Error Type

Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising or falling edges of an input signal on one of the `TIMER_TMR[nn]` or `TIMER_ACI[nn]` pins. Program the required minimum number of clock cycles (t_{MIN}) in the `TIMER_TMR[n]_DLY` register and the required maximum allowed number of clock cycles (t_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0) or alternate time clock (`TIMER_ACLK[nn]`). The timer can generate an interrupt when two consecutive occurrences of an active edge are:

- Within a specified window (t_{MIN} < Pulse Period ≤ t_{MAX}), or
- Outside a specified window (pulse width ≤ (t_{MIN} or t_{MAX} < pulse width)

When the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11 and the pulse period > t_{MAX} or is ≤ t_{MIN}, the timer generates an interrupt (if unmasked). After attaining the t_{MAX} value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified

window condition, by setting `TIMER_TMR[n]_CFG.IRQMODE` =b#10. Refer to the ***Watchdog Period Mode Timing*** figure for timer functionality in period watchdog mode.

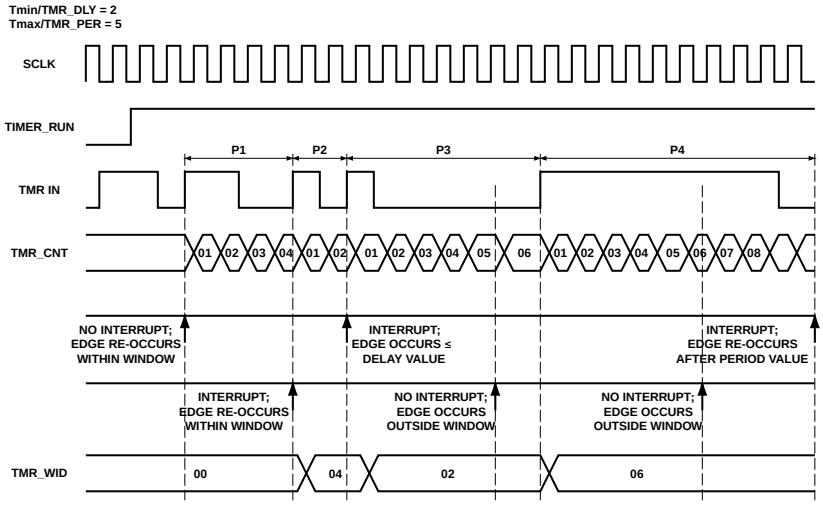

Figure 24-9: Watchdog Period Mode Timing

NOTE: SCLK in the ***Watchdog Period Mode Timing*** figure is SCLK0.

To check only the upper limit on period (the t_{MAX} value, not the t_{MIN} value), program t_{MIN} as 0 or 1. For details, refer to the ***Windowed Watchdog Period Mode Interpretation*** table.

Table 24-9: Windowed Watchdog Period Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
0 or 1	Anything ≥ 2	Pulse Period ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse period crosses Pmax (Period Register) value	No Error Interrupt
> 1 but ≤ Period -1	Anything ≥ 2	Pulse Period ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < Pulse Period ≤TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) value	No Error Interrupt

Table 24-9: Windowed Watchdog Period Mode Interpretation (Continued)

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
≥ Period	-	Pulse Period < TMR_PER	Undefined	Undefined	No Error Interrupt
		Pulse Period ≥ TMR_PER	Undefined	Undefined	b#11 Error Type
-	0 or 1	-	Undefined	Undefined	b#10 Error Type

Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the TIMER_TMR[nn] pin or the (TIMER_ACI[nn]) pin can cause an edge-based interrupt, if enabled. (The timer uses the TIMER_TMR[n]_CFG.TINSEL register to select the pin). The event on the input pin can set the TIMER_DATA_ILAT.TMR[nn] bit and issue a system interrupt request. Program the TIMER_TMR[n]_CFG.PULSEHI bit to change active edge polarity.

Since the interrupt request is generated in the SCLK0 clock domain, the width of the input signal must be more than one SCLK0 period. Along with generating the interrupt request, the timer also generates a trigger pulse (configured using the TIMER_TRG_MSK register). Due to the configuration of polarity, glitches can cause the generation of an undesired interrupt request at the input. To avoid this problem, programs must ensure that interrupt requests are unmasked only after configuring the desired polarity.

External Clock (EXTCLK) Mode

The timer uses EXTCLK mode, sometimes referred to as the counter mode, to count external events (signal edges), on either the TIMER_TMR[nn] or (TIMER_ACI[nn]) input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to SCLK0. The current count in the TIMER_TMR[n]_CNT register represents the number of leading-edge events detected. The TIMER_TMR[n]_PER register is programmed with the value of the maximum timer external count before stopping or issuing an interrupt request or trigger.

The TIMER_TMR[n]_CFG.PULSEHI bit determines the polarity of the leading edge on the input pin. The timer uses the TIMER_TMR[n]_CFG.TINSEL bit to select whether the event is counted on the TIMER_TMR[nn] or on the (TIMER_ACI[nn]) pin. The TIMER_STAT_ILAT.TMR[nn] and TIMER_ERR_TYPE bits are set if *one* of these conditions is met:

- TIMER_TMR[n]_CNT wraps around from 0xFFFF FFFF to 0
- The period = 0 at startup
- TIMER_TMR[n]_CNT register rolls over (from count = period to count = 0x1)

The TIMER_TMR[n]_WID and TIMER_TMR[n]_DLY registers are unused in this mode and must not be written.

The ***EXTCLK Mode Control Flow*** figure shows a flow diagram for EXTCLK mode.

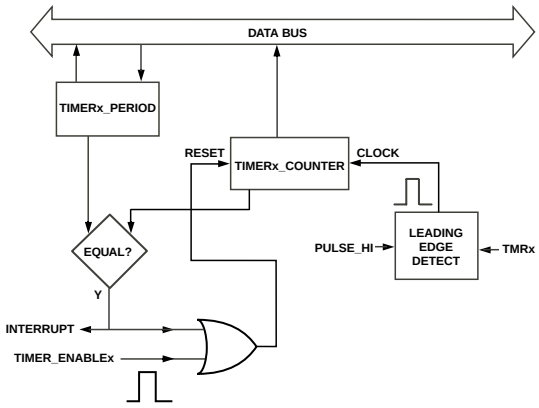

Figure 24-10: EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet. Program the period to any value from 1 to (2^{32} – 1), inclusive.

After the timer has started, it resets the `TIMER_TMR[n]_CNT` register to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TIMER_TMR[n]_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After the `TIMER_TMR[n]_CNT` register reaches the value programmed in the `TIMER_TMR[n]_PER` register, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading-edge reloads the `TIMER_TMR[n]_CNT` register with 0x1, and the timer continues counting until it is disabled.

GP Timer Programming Concepts

Using the features, operating modes, and event control for the GP timer to their greatest potential requires an understanding of some GP timer-related concepts.

Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and delay settings for each of the first three timer periods after the timer starts.

1. Program the first set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.
2. Enable the timer using the `TIMER_RUN` register.
3. Immediately program the second set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values, as needed.
4. Wait for the first timer interrupt request.
5. Program the third set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.

Each new setting is then programmed when the preceding timer interrupt request is received.

Configuring, Enabling, and Disabling One or More Timers

1. Configure the relevant timers for the operating mode and other properties using the TIMER_TMR[n]_CFG register.
2. Write a 1 to the representative TIMER_RUN.TMR[nn] bit. Or, use the TIMER_RUN_SET register to avoid disturbing the settings of other timers that are not going through configuration.

   The timer is enabled and operating.
3. To stop one or more timers, first program the TIMER_STOP_CFG register to determine whether to stop immediately or gracefully upon receiving a stop command.

   ADDITIONAL INFORMATION: PWMOUT modes are the only modes where a timer can be configured for graceful termination.
4. Write a 0 to the representative TIMER_RUN.TMR[nn] bits to stop the timer according to their TIMER_STOP_CFG settings. Alternately, write a 1 to the appropriate TIMER_RUN_CLR.TMR[nn] bits to avoid disturbing the settings of other timers that are not terminating.

   The timers stop.

Configuring Timer Data and Status Interrupts

1. Configure the TIMER_TMR[n]_CFG.IRQMODE bit field with the desired interrupt properties.
2. Unmask the interrupt source.
3. Set the TIMER_TMR[n]_CFG.IRQMODE field but leave the interrupt masked at the system level to poll the TIMER_DATA_ILAT.TMR[nn] bit of the timer without generating an interrupt.
4. Use the TIMER_STAT_IMSK register to generate interrupt requests by overflow or error conditions (incorrect programming values). The timer uses the TIMER_STAT_ILAT.TMR[nn] bits to report interrupt errors, when the timer status interrupt source is unmasked.
5. To poll the TIMER_STAT_ILAT.TMR[nn] bit of the timer without generating an interrupt, unmask the corresponding bit in the TIMER_STAT_IMSK register, but leave the interrupt masked at the system level.

Configuring the Timer as a Trigger Completer

The timer can be configured to either start or stop or toggle between these two states on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.SLAVETRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =1 then the trigger pulse starts timer, if it is stopped.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =0 then the trigger pulse stops timer, if it is running.
- When TIMER_TMR[n]_CFG.TGLTRIG bit =0, the trigger pulse has no effect when the timer is already in the requested state.

If TIMER_TMR[n]_CFG.TGLTRIG bit is 1, the trigger pulse starts the timer if it is stopped, or stops the timer if it is running. The TIMER_TMR[n]_CFG.SLAVETRIG bit has no effect on trigger mechanism. In continuous PWMOUT mode, the timer stops gracefully or abruptly depending on the stop mechanism programmed in the TIMER_STOP_CFG_CLR register. In other modes, the timer stops immediately.

Ordered Trigger Toggle Mode

The timer can be configured to either start or stop the timer on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.ORDTGLTRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 0, then the input trigger pulse on trigger completer 0 or trigger completer 1 starts the timer if it is stopped, or stops the timer if it is running.
- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 1, then the input trigger pulse on trigger completer 0 starts timer if it is stopped. If the timer is running, it stops when the input trigger pulse on trigger completer 1 is detected.

  Trigger completer 0 cannot toggle the timer from the run to halt state. Trigger completer 1 cannot toggle the timer from the halt to run state.

NOTE: The timer state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET, and TIMER_RUN_CLR registers in this mode.

Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width, and delay registers simultaneously across more than one timer.

1. Enable the appropriate broadcast bits (TIMER_TMR[n]_CFG.BPEREN, TIMER_TMR[n]_CFG.BWIDEN are TIMER_TMR[n]_CFG.BDLYEN) for the timers involved in the broadcast. The use of these bits depends on which broadcast registers the timer uses (TIMER_BCAST_PER, TIMER_BCAST_WID, or TIMER_BCAST_DLY).
2. Program the TIMER_BCAST_PER register (for example), to broadcast the period setting across the multiple timers enabled.

   The enabled timers load their TIMER_TMR[n]_PER registers with the value specified in the TIMER_BCAST_PER register.
3. Repeat Step 2 as needed for the TIMER_BCAST_WID and TIMER_BCAST_DLY register settings.

Timer Illegal States

The following sections use these definitions:

- Startup. The first clock period during which the timer counter is running after the timer is started by writing the TIMER_RUN register.
- Rollover. The time when the current count in TIMER_TMR[n]_CNT matches the value in TIMER_TMR[n]_PER and the counter is reloaded with the value 1.
- Overflow. The timer counter was incremented instead of doing a rollover when it was holding the maximum count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so it erroneously loads a new value of 0x0000 0000.
- Unchanged. No new error.

When the TIMER_ERR_TYPE register is designated unchanged, it displays the previously reported error code orb# 00 when there has been no error since this timer was enabled.

When the TIMER_STAT_ILAT register is unchanged, it reads 0 when there has been no error or overflow since this timer was enabled. Or, it reads 0 if software has performed a W1C to clear any previous error. If software has not acknowledged a previous error, the TIMER_STAT_ILAT register reads 1. Software can read the TIMER_STAT_ILAT register to check for errors. If a particular bit of a timer is set in this register, software can then read the TIMER_ERR_TYPE register for more information. Once detected, software can W1C the appropriate TIMER_STAT_ILAT bit to acknowledge the error.

Read the following tables as:

- In mode __ at event __,
- if TIMER_TMR[n]_PER is __ and TIMER_TMR[n]_WID is __ and TIMER_TMR[n]_DLY is __,
- then TIMER_ERR_TYPE is __ and TIMER_STAT_ILAT is __.

Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases can cause unwanted behavior of the TIMER_TMR[nn] pins.

NOTE: For PININT mode, the timer does not use error functionality.

Continuous PWMOUT Mode

Table 24-10: Startup Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)

ADSP-2159x_SC591_SC592_SC594 TIMER Register Descriptions

General-Purpose Timer Block (TIMER) contains the following registers.

Table 24-22: ADSP-2159x_SC591_SC592_SC594 TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register
TIMER_STAT_ILAT	Status Interrupt Latch Register
TIMER_STAT_IMSK	Status Interrupt Mask Register
TIMER_STOP_CFG	Stop Configuration Register
TIMER_STOP_CFG_CLR	Stop Configuration Clear Register
TIMER_STOP_CFG_SET	Stop Configuration Set Register
TIMER_TMR[n]_CFG	Timer n Configuration Register

Table 24-22: ADSP-2159x_SC591_SC592_SC594 TIMER Register List (Continued)

Name	Description
TIMER_TMR[n]_CNT	Timer n Counter Register
TIMER_TMR[n]_DLY	Timer n Delay Register
TIMER_TMR[n]_PER	Timer n Period Register
TIMER_TMR[n]_WID	Timer n Width Register
TIMER_TRG_IE	Trigger Slave Enable Register
TIMER_TRG_MSK	Trigger Master Mask Register

Broadcast Delay Register

For timers with TIMER_TMR[n]_CFG.BDLYEN enabled, a write to the TIMER_BCAST_DLY register concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_DLY register.

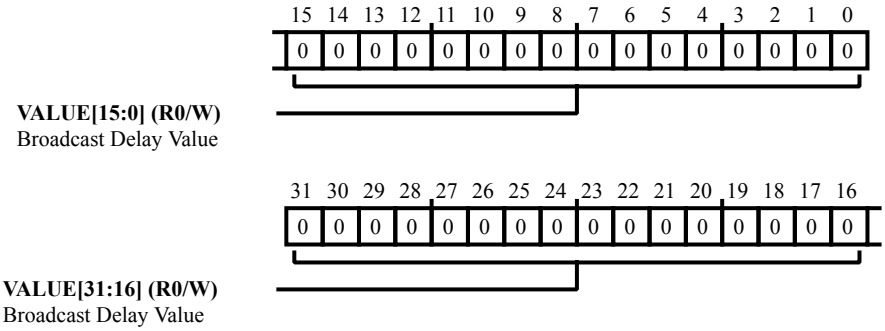

Figure 24-11: TIMER_BCAST_DLY Register Diagram

Table 24-23: TIMER_BCAST_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Delay Value. A write to the TIMER_BCAST_DLY.VALUE bit field concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Broadcast Period Register

For timers with TIMER_TMR[n]_CFG.BPEREN enabled, a write to the TIMER_BCAST_PER register concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of TIMER_BCAST_PER returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_PER register.

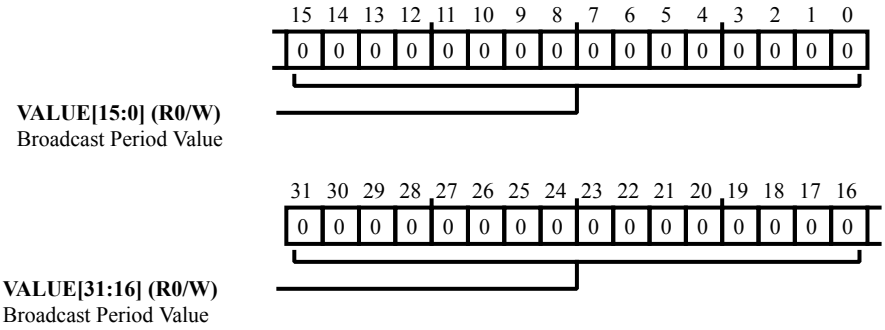

Figure 24-12: TIMER_BCAST_PER Register Diagram

Table 24-24: TIMER_BCAST_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Period Value. A write to the TIMER_BCAST_PER.VALUE bit field concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of the TIMER_BCAST_PER.VALUE bit fields returns 0x0000 0000, and no bus error is generated.

Broadcast Width Register

For timers with TIMER_TMR[n]_CFG.BWIDEN enabled, a write to the TIMER_BCAST_WID register concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_WID register.

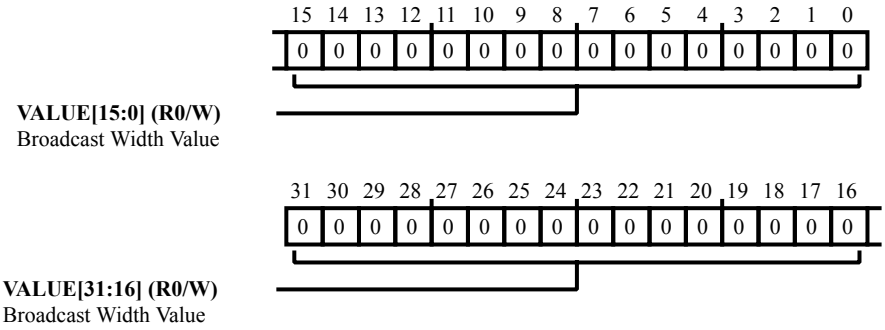

Figure 24-13: TIMER_BCAST_WID Register Diagram

Table 24-25: TIMER_BCAST_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Width Value. A write to the TIMER_BCAST_WID.VALUE bit field concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Data Interrupt Latch Register

The TIMER_DATA_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER_DATA_IMSK register and generated according to the conditions selected by the TIMER_TMR[n]_CFG.IRQMODE bits. If a bit in TIMER_DATA_ILAT is already set and the corresponding interrupt is masked in TIMER_DATA_IMSK, the latch holds its old value, leaving the interrupt request asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER_DATA_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

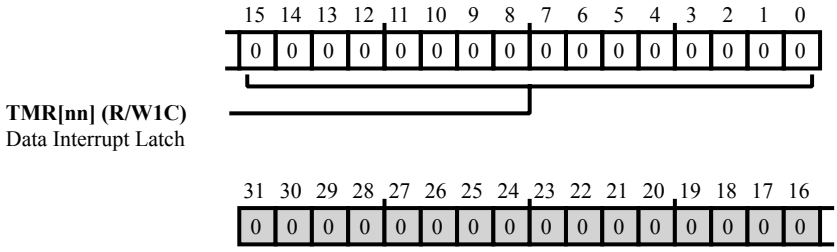

Figure 24-14: TIMER_DATA_ILAT Register Diagram

Table 24-26: TIMER_DATA_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Data Interrupt Latch. For all TIMER_DATA_ILAT.TMR[nn] bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding TIMER_TMR[n]_CFG.IRQMODE bit has occurred).

Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The TIMER_DATA_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_DATA_IMSK register is 0xFFFF, masking these interrupts after reset.

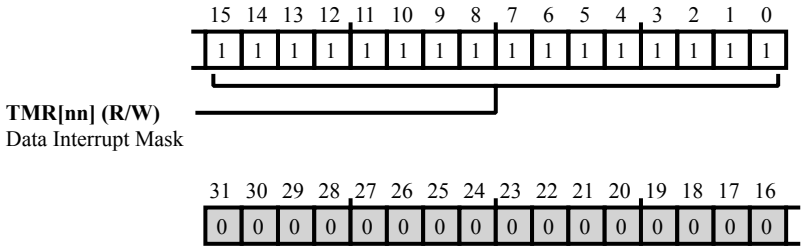

Figure 24-15: TIMER_DATA_IMSK Register Diagram

Table 24-27: TIMER_DATA_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Data Interrupt Mask. For all TIMER_DATA_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request.

Error Type Status Register

The TIMER_ERR_TYPE register contains error type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error request interrupt is latched in the TIMER_STAT_ILAT register, the corresponding TERRx bits in the TIMER_ERR_TYPE register are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on the TIMER_ERR_TYPE register.

Run Register

The TIMER_RUN allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration TIMER_STOP_CFG register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the TIMER_RUN_CLR register.

Reading the TIMER_RUN register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the TIMER_RUN register is not used in PININT mode. PININT mode starts as soon as the TIMER_TMR[n]_CFG.TMODE bits are set to 111.

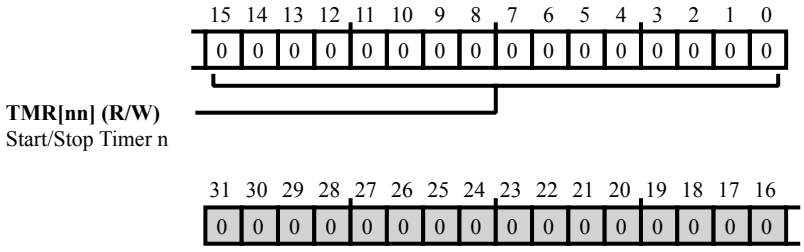

Figure 24-17: TIMER_RUN Register Diagram

Table 24-29: TIMER_RUN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Start/Stop Timer n. For all TIMER_RUN.TMR[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running.

Run Clear Register

The TIMER_RUN_CLR register is an alias register, providing a mechanism to clear a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To stop a particular timer, software must write a 1 into the corresponding TIMER_RUN_CLR bit. Writing a 0 has no effect. Because TIMER_RUN_CLR is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_CLR returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the TIMER_STOP_CFG register.

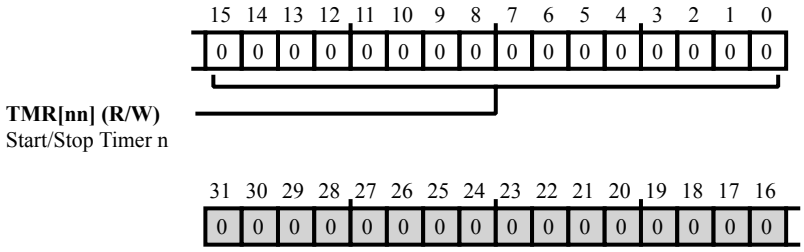

Figure 24-18: TIMER_RUN_CLR Register Diagram

Table 24-30: TIMER_RUN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	RUN Clear Alias. For all TIMER_RUN_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the TIMER_RUN register). Using TIMER_RUN_CLR to clear start/stop bits permits stopping specific timers without influencing run status of other timers.

Run Set Register

The TIMER_RUN_SET register is an alias register, providing a mechanism to set a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To start a particular timer, software must write a 1 into the corresponding TIMER_RUN_SET bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into TIMER_RUN_SET. Because TIMER_RUN_SET is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_SET returns 0x0000.

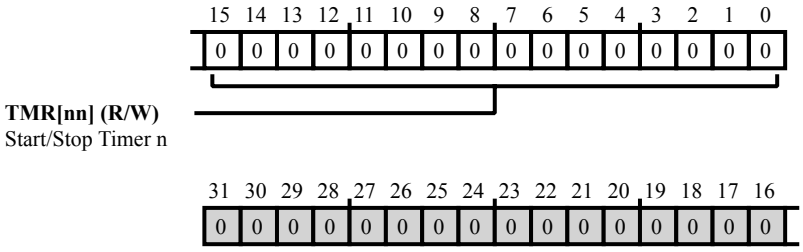

Figure 24-19: TIMER_RUN_SET Register Diagram

Table 24-31: TIMER_RUN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	RUN Set Alias. For all TIMER_RUN_SET.TMR[nn] bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the TIMER_RUN register). Using TIMER_RUN_SET to set start/stop bits permits starting specific timers without influencing the run status of other timers.

Status Interrupt Latch Register

The TIMER_STAT_ILAT holds the latched interrupt status for error interrupt requests, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the TIMER_STAT_ILAT register provide information regarding each timer interrupt request source.

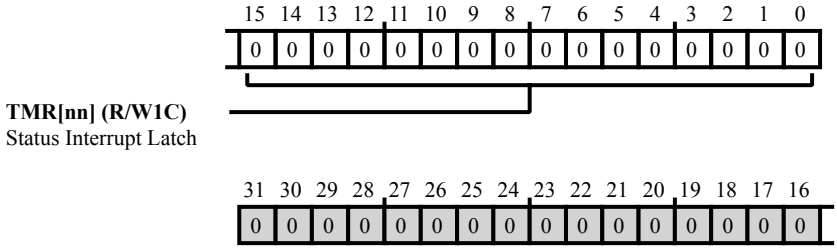

Figure 24-20: TIMER_STAT_ILAT Register Diagram

Table 24-32: TIMER_STAT_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Status Interrupt Latch. For all TIMER_STAT_ILAT.TMR[nn] bits, status of 0 indicates no error interrupt request is latched, and status of 1 indicates a timer counter overflow or programming error interrupt request is latched.

Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the system event controller. The TIMER_STAT_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_STAT_IMSK register is 0xFFFF, masking these interrupts after reset.

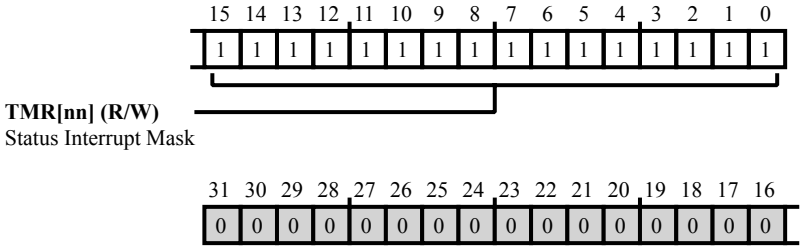

Figure 24-21: TIMER_STAT_IMSK Register Diagram

Table 24-33: TIMER_STAT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Status Interrupt Mask. For all TIMER_STAT_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request.

Stop Configuration Register

The TIMER_STOP_CFG register selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in TIMER_RUN or a write =1 to the corresponding bit in TIMER_RUN_CLR. A read of TIMER_STOP_CFG returns the last value written.

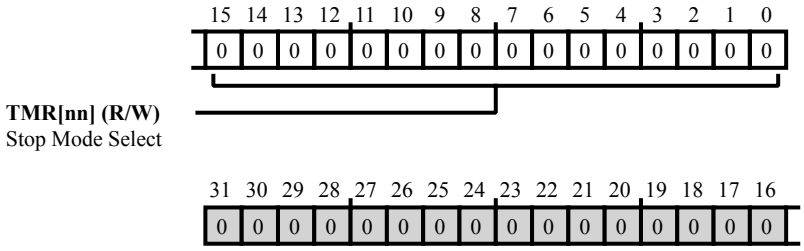

Figure 24-22: TIMER_STOP_CFG Register Diagram

Table 24-34: TIMER_STOP_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Stop Mode Select. For all TIMER_STOP_CFG.TMR[nn] bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop.

Stop Configuration Clear Register

This is an alias register, providing a mechanism to clear a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To clear a bit in TIMER_STOP_CFG, software must write a 1 to the corresponding bit of TIMER_STOP_CFG_CLR register. Writing a zero has no effect. Because the TIMER_STOP_CFG_CLR register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_CLR register returns 0x0000.

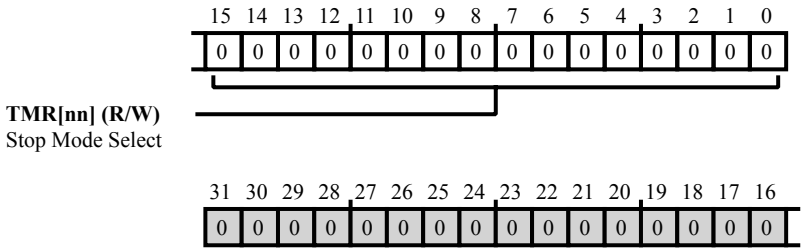

Figure 24-23: TIMER_STOP_CFG_CLR Register Diagram

Table 24-35: TIMER_STOP_CFG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	STOP_CFG Clear Alias. For all TIMER_STOP_CFG_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To set a bit in the TIMER_STOP_CFG register, software must write a 1 to the corresponding bit of the TIMER_STOP_CFG_SET register. Writing a zero has no effect. Because the TIMER_STOP_CFG_SET register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_SET register returns 0x0000.

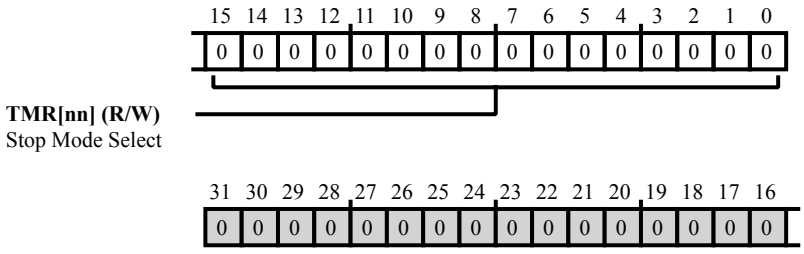

Figure 24-24: TIMER_STOP_CFG_SET Register Diagram

Table 24-36: TIMER_STOP_CFG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	STOP_CFG Set Alias. For all TIMER_STOP_CFG_SET.TMR[nn] bits, write =0 has no effect, and write =1 for abrupt stop (setting the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_SET to set stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Timer n Configuration Register

Each timer has a TIMER_TMR[n]_CFG register that specifies its operating mode. Only write to a TIMER_TMR[n]_CFG register when the corresponding timer is not running.

After disabling a timer operating in PWMOUT mode, verify that the timer has stopped running by checking the start/stop status of the timer in the TIMER_RUN register before writing to the timer's TIMER_TMR[n]_CFG register.

Note that a timer's TIMER_TMR[n]_CFG register may be read at any time.

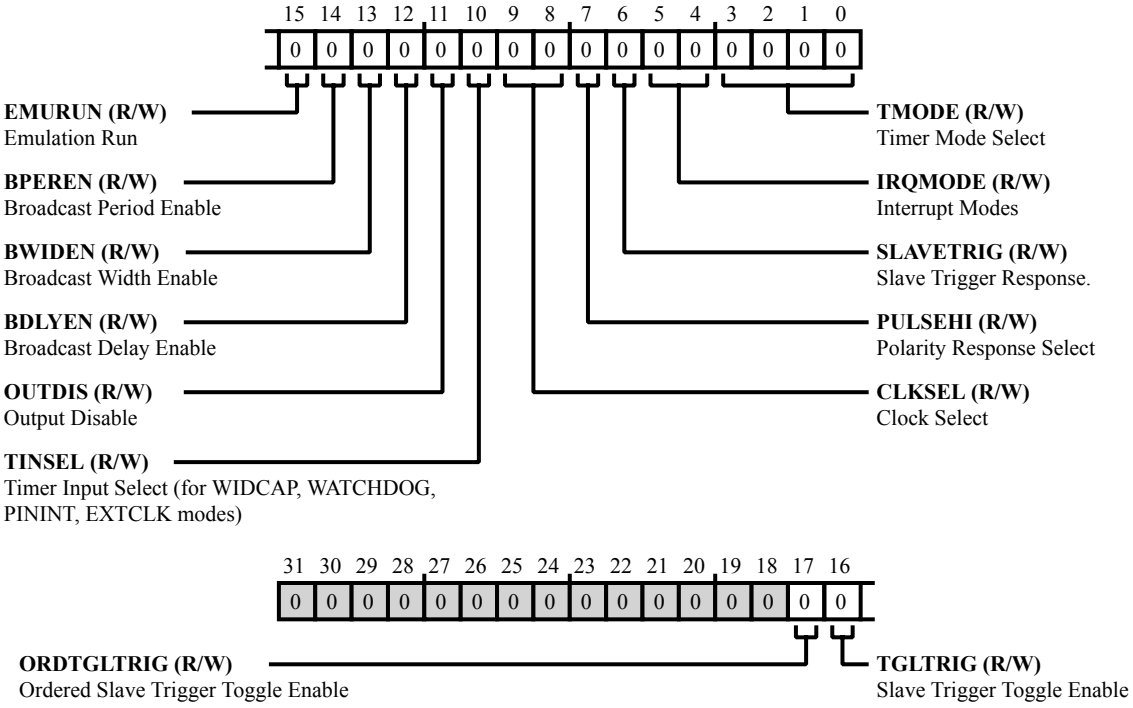

Figure 24-25: TIMER_TMR[n]_CFG Register Diagram

Table 24-37: TIMER_TMR[n]_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ORDTGLTRIG	Ordered Slave Trigger Toggle Enable. The TIMER_TMR[n]_CFG.ORDTGLTRIG bit controls ordered slave trigger toggle mode. The timer(slave) state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET and TIMER_RUN_CLR registers when this bit is enabled.	
		0	No effect
		1	Trigger pulse on Trigger Slave 0 starts the timer if it in halt state and trigger pulse in Trigger Slave 1 stops the timer if it is running
16 (R/W)	TGLTRIG	Slave Trigger Toggle Enable. The TIMER_TMR[n]_CFG.TGLTRIG bit stops the timer if it is running and starts the timer if it is halted (in the stop state). If the TIMER_TMR[n]_CFG.TGLTRIG bit is set, then the setting of the TIMER_TMR[n]_CFG.SLAVETRIG bit is ignored.	
		0	Slave Trigger Response Depends on SLAVETRIG Bit Setting
		1	Slave Trigger Toggles Timer State
15 (R/W)	EMURUN	Emulation Run. The TIMER_TMR[n]_CFG.EMURUN bit causes the timer to run (count) during emulation.	
		0	Stop Timer During Emulation
		1	Run Timer During Emulation
14 (R/W)	BPEREN	Broadcast Period Enable. The TIMER_TMR[n]_CFG.BPEREN bit enables updates to the TIMER_TMR[n]_PER register simultaneously across more than one timer.	
		0	Disable Broadcast to PER Register
		1	Enable Broadcast to PER Register
13 (R/W)	BWIDEN	Broadcast Width Enable. The TIMER_TMR[n]_CFG.BWIDEN bit enables updates to the TIMER_TMR[n]_WID register simultaneously across more than one timer.	
		0	Disable Broadcast to WID Register
		1	Enable Broadcast to WID Register

Table 24-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BDLYEN	Broadcast Delay Enable. The `TIMER_TMR[n]_CFG.BDLYEN` bit enables updates to the `TIMER_TMR[n]_DLY` register simultaneously across more than one timer.	
		0	Disable Broadcast to DLY Register
		1	Enable Broadcast to DLY Register
11 (R/W)	OUTDIS	Output Disable. The `TIMER_TMR[n]_CFG.OUTDIS` bit enables or disables the timer pin output buffer.	
		0	Enable TMR Pin Output Buffer
		1	Disable TMR Pin Output Buffer
10 (R/W)	TINSEL	Timer Input Select (for WIDCAP, WATCHDOG, PININT, EXTCLK modes).	
		0	Use TMR Pin Input
		1	Use TMR Alternate Capture Input
9:8 (R/W)	CLKSEL	Clock Select. The `TIMER_TMR[n]_CFG.CLKSEL` bit field selects the TIMER clock to use.	
		0	Use SCLK0
		1	Use TMR_ALT_CLK0 as TMR Clock
		3	Use TMR_ALT_CLK1 as TMR Clock
7 (R/W)	PULSEHI	Polarity Response Select. The `TIMER_TMR[n]_CFG.PULSEHI` bit defines specific behaviors of the timer based on the operating mode. For more information, see the specific operating mode in the Programming Concepts section.	
		0	Negative Response or Pulse. A Negative Edge Response or Negative Action Pulse on the TMR pin.
		1	Positive Response or Pulse. A Positive Edge Response or Positive Action Pulse on the TMR pin.
6 (R/W)	SLAVETRIG	Slave Trigger Response.. The `TIMER_TMR[n]_CFG.SLAVETRIG` bit controls the trigger response. The trigger pulse has no effect (to stop or start the timer) if the timer is already in the requested state.	
		0	Pulse Stops Timer if it is Running
		1	Pulse Starts Timer if it is Stopped

Table 24-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	IRQMODE	Interrupt Modes. The TIMER_TMR[n]_CFG.IRQMODE bit field selects the interrupt request mode. Note that any mismatched combination of the TIMER_TMR[n]_CFG.IRQMODE and the TIMER_TMR[n]_CFG.TMODE bits results in no interrupt being generated. In WIDCAP modes, the position of the interrupt is controlled with the TIMER_TMR[n]_CFG.TMODE bit, and the TIMER_TMR[n]_CFG.IRQMODE bit is ignored. Whenever an interrupt is generated, a trigger master pulse is also generated, if enabled in the TIMER_TRG_MSK register.	
		0	Active Edge Mode. The timer generates an interrupt at every active edge. The active edge polarity depends on the state of the TIMER_TMR[n]_CFG.PULSEHI bit. Valid for PININT mode only.
		1	Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_DLY register. This mode is valid for all PWMOUT modes.
		2	Width Plus Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_WID register plus the value in the TIMER_TMR[n]_DLY register. (PWMOUT modes only) The timer generates an interrupt if the deasserting edge is within the specified window. (WATCHDOG modes only)
		3	Period Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_PER register. (Continuous PWMOUT and EXTCLK modes only) The timer generates an interrupt if the deasserting edge is outside the specified window.(WATCHDOG modes only)
3:0 (R/W)	TMODE	Timer Mode Select. The TIMER_TMR[n]_CFG.TMODE bit field selects the operating mode of each timer.	
		0-7	Idle Mode
		8	Period Watchdog Mode
		9	Width Watchdog Mode

Table 24-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		10	Measurement Report at Asserting Edge of Waveform
		11	Measurement Report at Deasserting Edge of Waveform
		12	Continuous PWMOUT Mode
		13	Single Pulse PWMOUT Mode
		14	EXTCLK Mode
		15	PININT (pin interrupt) Mode

Timer n Counter Register

The TIMER_TMR[n]_CNT register holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The TIMER_TMR[n]_CNT register is read-only and may be read at any time (whether the timer is running or stopped). Reading the TIMER_TMR[n]_CNT register returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK0, the TMR or alternate capture input pins, ACLK[n]. The counter retains its value after the timer is disabled.

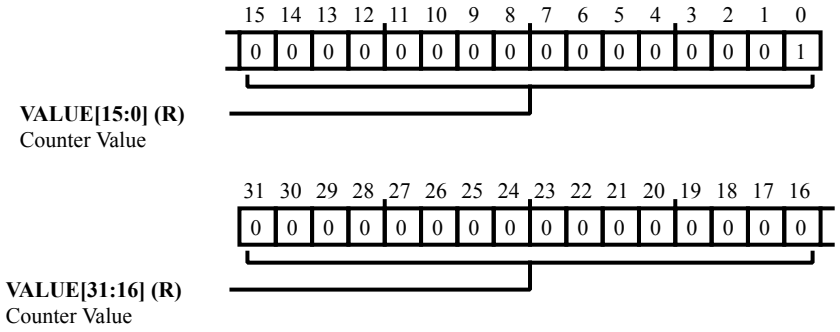

Figure 24-26: TIMER_TMR[n]_CNT Register Diagram

Table 24-38: TIMER_TMR[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Counter Value. The TIMER_TMR[n]_CNT.VALUE bit field holds the current timer count.

Timer n Delay Register

The TIMER_TMR[n]_DLY register holds the delay value for the corresponding timer. This register's use is based on the selected timer mode.

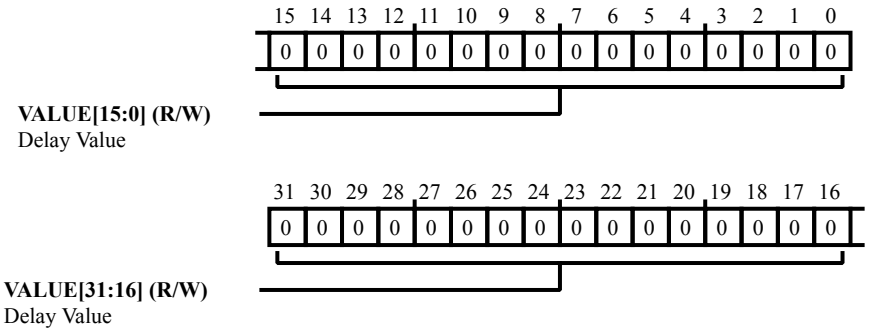

Figure 24-27: TIMER_TMR[n]_DLY Register Diagram

Table 24-39: TIMER_TMR[n]_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Value. The TIMER_TMR[n]_DLY.VALUE bit field holds the delay value for the corresponding timer.

Timer n Period Register

The TIMER_TMR[n]_PER register holds the period value for the corresponding timer. This register's use is based on the selected timer mode.

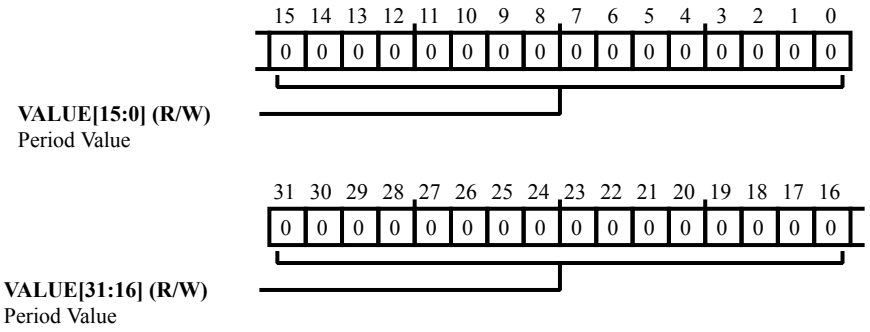

Figure 24-28: TIMER_TMR[n]_PER Register Diagram

Table 24-40: TIMER_TMR[n]_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Period Value. The TIMER_TMR[n]_PER.VALUE bit field holds the period value for the corresponding timer.

Timer n Width Register

The TIMER_TMR[n]_WID register holds the width value for the corresponding timer. This register's use is based on the selected timer mode.

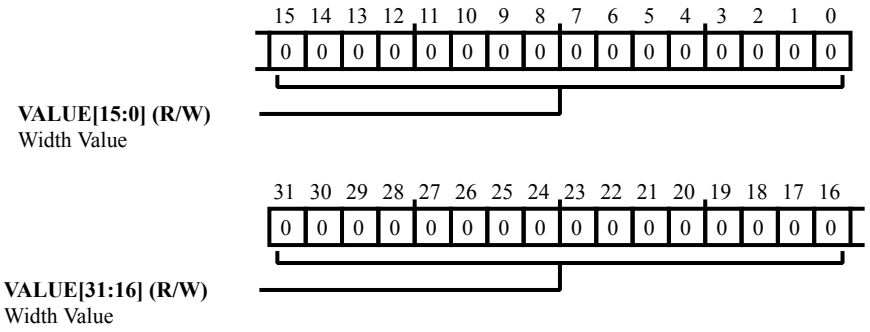

Figure 24-29: TIMER_TMR[n]_WID Register Diagram

Table 24-41: TIMER_TMR[n]_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Width Value. The TIMER_TMR[n]_WID.VALUE bit field holds the width value for the corresponding timer.

Trigger Slave Enable Register

As a trigger slave, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_IE contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the TIMER_TRG_IE register is 0xFFFF, masking these triggers after reset.

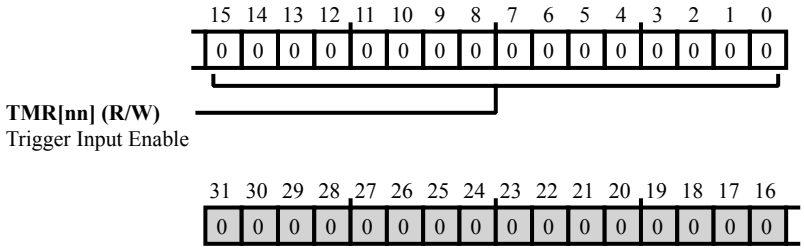

Figure 24-30: TIMER_TRG_IE Register Diagram

Table 24-42: TIMER_TRG_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Input Enable. For all TIMER_TRG_IE.TMR[nn] bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input.

Trigger Master Mask Register

As a trigger master, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_MSK register contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the TIMER_TRG_MSK register is 0xFFFF, masking these triggers after reset.

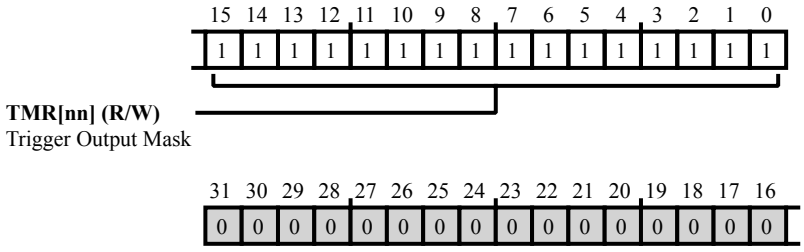

Figure 24-31: TIMER_TRG_MSK Register Diagram

Table 24-43: TIMER_TRG_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Output Mask. For all TIMER_TRG_MSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output.

25 General-Purpose Counter (CNT)

The GP counter converts pulses from incremental position encoders into data that is representative of the actual position of the pulse. This conversion is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero-position input (zero marker). The GP counter can use the zero position input feature to establish a reference point for verifying that the acquired position does not drift over time. In addition, the GP counter can use the incremental position information to determine speed, if the time intervals are measured.

The GP counter provides flexible ways to establish position information. When used with the GP timer block, the GP counter can allow for the acquisition of coherent position or time stamp information that enables speed calculation.

GP Counter Features

The GP counter includes the following features:

- 32-bit up or down counter
- Quadrature encode mode (Gray code)
- Binary encoder mode
- Alternative frequency-direction mode
- Timed direction and up or down counting modes
- Zero marker or push-button support
- Capture event timing in association with GP Timer
- Boundary comparison and boundary setting features

GP Counter Functional Description

The ***GP Counter Block Diagram*** shows a block diagram of the GP counter. The `CNT_UD` and `CNT_DG` pins accept various forms of incremental inputs. The 32-bit counter processes the inputs. The GP counter uses the `CNT_ZM` pin to sense the pressing of a push button.

NOTE: When enabled, the GP counter requires 3 SCLK0 cycles of initialization before recognizing valid toggles on its input pins.

The three input pins can be filtered (debounced) before the GP counter evaluates them.

The GP counter features a flexible boundary comparison. In all of the operating modes, the counter can be compared to an upper and lower limit. It takes various actions when reaching these limits.

The GP counter has a flexible input selection. Apart from accepting inputs from the CNT0_UD and CNT0_DG and PORT pins, the counter can be configured to accept trigger inputs by setting PADS_PCFG0.CNT0UDSEL and PADS_PCFG0.CNT0DGSEL bits. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

The module can optionally generate an interrupt request to the system through its IRQ line. On many processors, a GP timer module can use an output to generate time stamps on certain events.

ADSP-2159x_SC591_SC592_SC594 CNT Register List

The GP Counter (CNT) provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial encoders.

The CNT converts pulses from incremental position encoders into data that is representative of the actual position. To complete this task, the CNT integrates (counts) pulses on one or two inputs. Because integration provides relative position, a zero position input (zero marker) is usually provided that establishes a reference point, verifying that the acquired position does not drift over time. The incremental position information may also be used to determine speed, if the relevant time intervals are measured. The CNT provides flexible ways to establish position information. When used in conjunction with the General-purpose Timer (TIMER), the CNT allows acquisition of coherent position/time stamp information, enabling speed calculation.

A set of registers govern CNT operations. For more information on CNT functionality, see the CNT register descriptions.

GP Counter Operating Modes

The GP counter has the following five modes of operation.

1. Quadrature Encoder
2. Binary Encoder
3. Up/Down Counter
4. Direction Counter
5. Timed Direction

With the exception of the timed direction mode, the GP counter can operate with the GP timer block to capture additional timing information (time stamps) associated with events detected by this block.

Quadrature Encoder Mode

In this mode, the CNT_UD and CNT_DG inputs expect a quadrature-encoded signal that is interpreted as a two-bit Gray code. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Quadrature Events and Counting Mechanism*** table. Optionally, an interrupt is generated when both inputs

change within one SCLK0 cycle. Gray coding prohibits such transitions. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 25-5: Quadrature Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG, CUD Inputs	00	01	11	10	00	01	11	10	00

It is possible to reverse the count direction of the Gray-coded signal by enabling the polarity inverter of either the CNT_UD pin or the CNT_DG pin. Inverting both pins does not alter the behavior. The GP counter can enable this feature with the CNT_CFG.CDGINV and CNT_CFG.CUDINV bits.

As an example, the CNT_DG and CNT_UD inputs are 00 and the next transition is to 01. These inputs normally change the counter in increments as shown in the table. If the CNT_UD polarity is inverted, this condition generates a received input of 01 followed by 00. The results is a decrement of the counter, altering the behavior of the connected hardware.

Binary Encoder Mode

This mode is almost identical to quadrature encoder mode, with the exception that the CNT_UD: CNT_DG inputs expect a binary-encoded signal. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Binary Events and Counting Mechanism*** table. Optionally, an interrupt is generated when the detected code steps by more than 1 (in binary arithmetic) within one SCLK0 cycle. Such transitions are erroneous. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 25-6: Binary Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG:CUD Inputs	00	01	10	11	00	01	10	11	00

Reversing the CNT_UD and CNT_DG pin polarity has a different effect in binary encoder mode than for the quadrature encoder mode. Inverting the polarity of the CNT_UD pin only, or inverting both the CNT_UD and CNT_DG pins, results in reversing the count direction.

Up/Down Counter Mode

In this mode, the counter increments or decrements at every active edge of the input pins. The GP counter uses the CNT_CFG.CUDINV bit to select an active edge and has the following results.

- If the GP counter module detects an active edge at the CNT_UD input, the counter increments.
- If the GP counter module detects an active edge at the CNT_DG input, the counter decrements.
- If simultaneous edges occur on the CNT_DG and CNT_UD pins, the counter remains unchanged, and both up-count and down-count events are signaled in the CNT_STAT register.

Direction Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the CNT_DG input pin. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity.

If the GP counter detects an active edge at the CNT_DG input, the counter value changes by one in the selected direction.

Timed Direction Mode

In this mode, the counter is incremented or decremented at each SCLK0 cycle. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity. The CNT_DG pin can be used to gate the clock. The GP counter uses the CNT_CFG.CDGINV bit to select the polarity.

GP Counter Programming Model

The following sections provide information for programming the interface.

GP Counter General Programming Flow

The following are general guidelines for configuring and enabling the GP counter.

1. Initialize (but do not enable) the GP counter for the desired mode and settings through the CNT_CFG register.
2. Usually, events of interest are processed using interrupts rather than by polling status bits. In this case, clear all status bits and activate the interrupt generation requests with the CNT_IMSK register.
3. Configure interrupts at the system level to insure desired interrupt signaling to the system.
4. If timing information is required, set up the relevant GP Timer in width capture mode.
5. Finally, enable interrupt requests and the GP Counter itself using the CNT_IMSK and CNT_CFG registers, respectively.

GP Counter Mode Configuration

The GP counter can use the CNT_ZM input pin to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes:

- Push-button mode
- Zero-marker-zeros-counter mode
- Zero-marker-error mode
- Zero-once mode

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

Configuring Zero-Marker-Zeros-Counter Mode

The following provides information on configuring zero-marker-zeros-counter mode for the GP counter.

1. Set CNT_IMSK.CZMZ to enable CNT_CNTR. The zero marker interrupt zeroes the counter.
2. Set CNT_CFG.ZMZC to enable ZMZC mode.
3. Select the active edge polarity through the CNT_CFG.CZMINV bit.
4. Proceed with any other desired configuration steps and enable the peripheral.

This configuration causes an active level at the CNT_ZM pin to clear the CNT_CNTR register and keep it cleared until the CNT_ZM pin is deactivated. In addition, the CNT_STAT.CZMZ bit is set.

Configuring Zero-Marker-Error Mode

The GP counter uses this mode to detect discrepancies between counter-value and the zero marker output of certain rotary encoder devices.

1. Set the CNT_STAT.CZME bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

When the GP counter detects an active edge at the CNT_ZM input pin, it compares the four LSBs of the CNT_CNTR register to zero. If they are not zero, the GP counter uses CNT_STAT.CZME bit to signal a mismatch.

Configuring Zero-Once Mode

The GP counter uses this mode to perform an initial reset of the counter-value when it detects an active zero marker. After that, the zero marker is ignored (the counter is no longer reset).

1. Set the CNT_CMD.W1ZMONCE bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Ensure that at least one of the following bits is enabled: CNT_IMSK.CZM, CNT_IMSK.CZME, CNT_IMSK.CZMZ.

4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_CNTR register and the CNT_CMD.W1ZMONCE bit are cleared on the next active edge of the CNT_ZM pin. Now the CNT_CMD.W1ZMONCE bit can be read to check whether the event has already occurred.

Configuring Boundary Auto-Extend Mode

In this mode, hardware modifies the boundary registers (CNT_MIN and CNT_MAX) whenever the CNT_CNTR value reaches either of them. The GP counter uses this mode to monitor the widest angle a thumb wheel even if the software did not generate interrupts.

1. Initialize CNT_CNTR with the desired value.
2. Set both CNT_MIN and CNT_MAX to this same value.
3. Configure the CNT_CFG.BNDMODE field for auto extend mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_MAX register is loaded with the current CNT_CNTR value when the latter increments beyond the CNT_MAX value. Similarly, the CNT_MIN register is loaded with the CNT_CNTR value when the latter decrements below the CNT_MIN value. The CNT_STAT.MAXC and CNT_STAT.MINC status bits are set when the CNT_CNTR value matches the respective boundary register value.

Configuring Boundary Capture Mode

In this mode, the CNT_CNTR value is latched into the CNT_MIN register at one detected edge of the CNT_ZM input pin, and latched into the CNT_MAX boundary register at the opposite edge.

1. To capture the CNT_ZM pin rising edge into CNT_MIN and the falling edge into CNT_MAX, program CNT_CFG.CZMINV for active high polarity. Conversely, to capture the CNT_ZM pin falling edge into CNT_MIN and the rising edge into CNT_MAX, program CNT_CFG.CZMINV for active low polarity.
2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary capture mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_STAT.MAXC and CNT_STAT.MINC status bits report the capture event, depending on how interrupt masks are configured.

Configuring Boundary Compare and Boundary Zero Modes

In these modes, the two boundary registers (CNT_MAX and CNT_MIN) are compared to the value in the CNT_CNTR register.

1. Program CNT_MAX and CNT_MIN registers with appropriate upper and lower range values.

2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary compare mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

If after incrementing, CNT_CNTR = CNT_MAX, then the CNT_STAT.MAXC bit is set. Similarly if after decrementing, CNT_CNTR = CNT_MIN, then the CNT_STAT.MINC bit is set.

Additionally, for boundary zero mode, the counter-value in CNT_CNTR is set to zero. The CNT_STAT.MAXC and CNT_STAT.MINC bits are not set when software updates the CNT_MAX or CNT_MIN registers.

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

GP Counter Programming Concepts

Using the features, operating modes, and event control for the GP counter to their greatest potential requires an understanding of some GP counter-related concepts. Some key aspects to consider are input noise filtering and capturing timing information.

CNT Input Noise Filtering

In all modes, the three input pins can be filtered to present clean signals to the GP counter logic. The GP counter uses the CNT_CFG.DEBEN bit to enable or disable this filtering. The ***Programmable Noise Filtering*** figure shows the filtering operation for the CNT_UD pin.

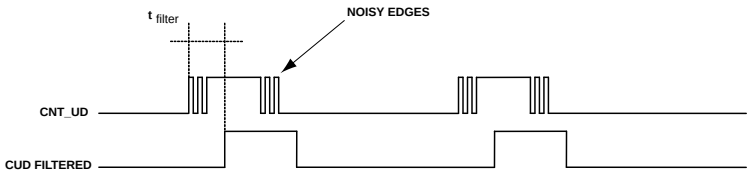

Figure 25-1: Programmable Noise Filtering

The CNT module implements the filtering mechanism using counters for each GP counter pin, where each counter is initialized from the CNT_DEBNCE.DPRESCALE field. When a transition is detected on a pin, the corresponding counter starts counting up to the programmed number of SCLK0 cycles. The state of the pin is latched after time t_{filter} and passed on to the GP counter logic.

The following formula determines the time t_{filter}, given SCLK0 and the CNT_DEBNCE.DPRESCALE value, where lower values of CNT_DEBNCE.DPRESCALE result in shorter debounce delays:

$t_{filter} = 128 \times (2^{DPRESCALE} \times SCLK0)$

Capturing Counter Interval and CNT_CNTR Read Timing

When the count speed is low, it is often useful to capture the time elapsed since the last count event. Program the TIMER_TMR[n]_CFG register of the associated GP timer in a width capture mode with the following bit settings.

- TIMER_TMR[n]_CFG.PULSEHI = 0
- TIMER_TMR[n]_CFG.TMODE = b#1011
- TIMER_TMR[n]_CFG.TINSEL = 1

The ***Capture Intervals*** figure shows and the following list describe the operation of the GP counter and the GP timer in this mode.

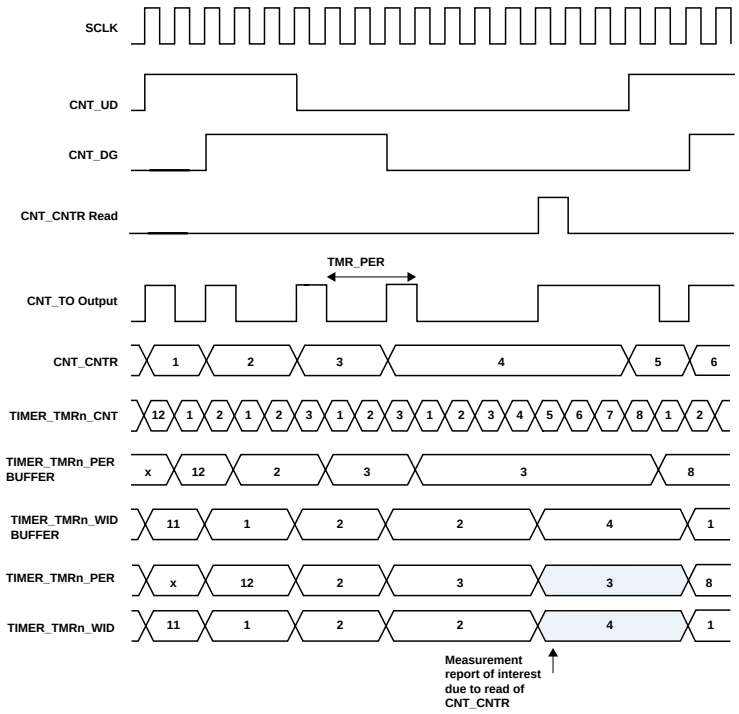

Figure 25-2: Capture Intervals

NOTE: SCLK in the ***Capture Intervals*** figure is SCLK0.

1. The CNT_TO signal generates a pulse every time a count event occurs. In addition, when the processor reads the CNT_CNTR register, the CNT_TO signal presents a pulse which is extended (high) until the next count event.
2. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from falling edge to falling edge, because TIMER_TMR[n]_CFG.PULSEHI = 0) of the CNT_TO signal.

3. The TIMER_TMR[n]_WID register is updated with the pulse width (the portion where CNT_TO is low, again because TIMER_TMR[n]_CFG.PULSEHI = 0).
4. Both registers are updated at every rising edge of the CNT_TO signal (because TIMER_TMR[n]_CFG.TMODE= b#011).

The TIMER_TMR[n]_PER register contains the period between the last two count events. The TIMER_TMR[n]_WID register contains the time since the last count event and the read of the CNT_CNTR register, both measured in SCLK0 cycles.

Read the CNT_CNTR register to latch the two time measurements, providing a coherent triplet of information to calculate speed and position.

NOTE: Speed restrictions apply to the use of the CNT_TO signal. Therefore, programs must not operate at count event rates that are high. For instance, if CNT_CNTR is incremented or decremented every SCLK0 cycle (timed direction mode), the CNT_TO signal is not valid.

Capturing Time Interval Between Successive Counter Events

When the required timing information is the interval between successive count events, program the associated timer in a width capture mode. Set the TIMER_TMR[n]_CFG bit of TIMER_TMR[n]_CFG.PULSEHI = 1, TIMER_TMR[n]_CFG.TMODE = b#1010 and TIMER_TMR[n]_CFG.TINSEL = 1. Typically, this information is sufficient if the speed of GP counter events does not to reach low values.

The ***Period Register Timing*** figure shows the operation of the GP counter and the GP timer in this mode.

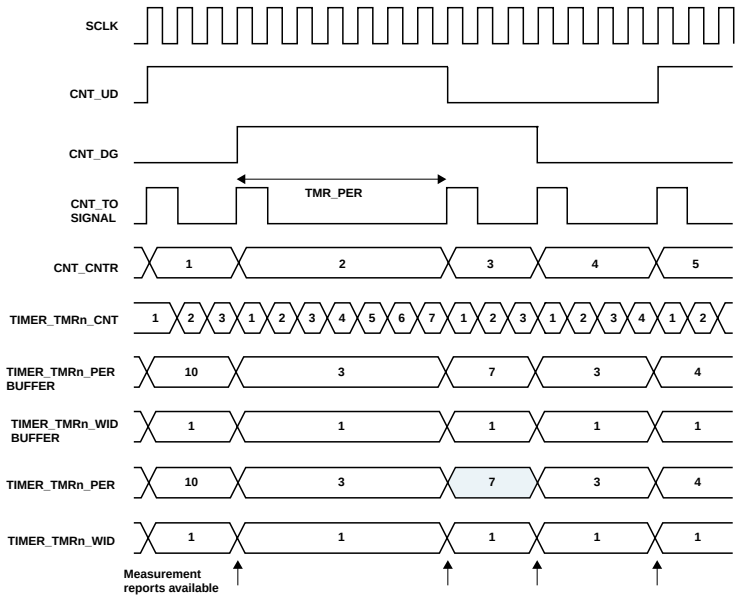

Figure 25-3: Period Register Timing

NOTE: SCLK in the ***Period Register Timing*** figure is SCLK0.

The CNT_TO signal generates a pulse every time a count event occurs. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from rising edge to rising edge) of the CNT_TO signal. The TIMER_TMR[n]_PER register is updated at every rising edge of the CNT_TO signal and contains the number of SCLK0 cycles that have elapsed since the previous rising edge.

Incidentally, the TIMER_TMR[n]_WID register is also updated at the same time, but is generally of no interest in this mode of operation. If no reads of the CNT_CNTR register occur between counter events, the TIMER_TMR[n]_WID register only contains the width of the CNT_TO pulse. If a read of CNT_CNTR has occurred between events, the TIMER_TMR[n]_WID register contains the time between the read of CNT_CNTR and the next event.

This mode can also be used with TIMER_TMR[n]_CFG.PULSEHI = 0. In this case, the period of CNT_TO is measured between falling edges. It results in the same values as in the previous case, only the latching occurs one SCLK0 cycle later.

GP Counter Event Control

Eleven events can be signaled to the processor using status information and optional interrupt requests. The GP counter uses the respective bits in the CNT_IMSK register to enable the interrupt requests. It uses dedicated bits in the CNT_STAT register to report events. When an interrupt request from the GP counter is serviced, the application software is responsible for correct interpretation of the events. It is recommended to logically AND the content of the CNT_IMSK and CNT_STAT registers to identify pending interrupt requests.

Perform a write-one-to-clear (W1C) operation to the CNT_STAT register to clear the interrupt requests. Hardware does not clear the status bits automatically, unless the counter module is disabled.

The following sections describe the events associated with the GP counter.

Illegal Gray and Binary Code Events

When illegal transitions occur in quadrature encoder or binary encoder modes, the CNT_STAT.IC bit is set. If enabled by the CNT_STAT.IC bit, the counter module generates an interrupt request. Set the CNT_STAT.IC bit only in the quadrature encoder or binary encoder modes.

Up/Down Count Events

The GP counter uses the CNT_STAT.UC bit to indicate whether the counter has been incremented. Similarly, the CNT_STAT.DC bit reports decrements. The two events are independent. For instance, if the counter increments by one and then decrements by two, both bits remain set, even though the resulting counter-value shows a decrement by one.

In up/down counter mode, hardware can detect simultaneous active edges on the CNT_UD and CNT_DG inputs. In that case, the CNT_CNTR remains unchanged, but both the CNT_STAT.UC and CNT_STAT.DC bits are set. Interrupt requests for these events can be enabled through the CNT_IMSK.UC and CNT_IMSK.DC bits. Use this feature carefully when the counter is clocked at high rates. This suggestion is especially critical when the counter operates in DIR_TMR mode, as interrupts are generated every SCLK0 cycle.

These events can also be used for more push buttons, when GP counter features are unnecessary. When up/down counter mode is enabled, the GP counter can use these count events to report interrupts from push buttons that connect to the CNT_UD and CNT_DG inputs.

Zero-Count Events

The CNT_STAT.CZERO status bit indicates that the CNT_CNTR has reached a value equal to 0x0000 0000 after an increment or decrement. This bit is not set when the counter value is set to zero by a write to CNT_CNTR or by setting the CNT_CMD.W1LCNTZERO bit. If enabled by the CNT_IMSK.CZERO bit, the GP counter module generates an interrupt request.

Overflow Events

There are two status bits that indicate whether the signed counter-register has overflowed from a positive to a negative value or conversely. The CNT_STAT.COV31 bit reports that the 32-bit CNT_CNTR register has either incremented from 0x7FFF FFFF to 0x8000 0000, or decremented from 0x8000 0000 to 0x7FFF FFFF.

If enabled by the CNT_IMSK.COV31 bit, an interrupt request is generated. Similarly, in applications where only the lower 16 bits of the counter are of interest, the CNT_STAT.COV15 status bit reports counter transitions from 0xXXXX 7FFF to 0xXXXX 8000, or from 0xXXXX 8000 to 0xXXXX 7FFF. If enabled by the CNT_IMSK.COV15 bit, an interrupt request is generated.

Boundary Match Events

The CNT_STAT.MINC and CNT_STAT.MAXC status bits report boundary events as described in Configuring Boundary Capture Mode. These bits are not set if the software updates the CNT_CNTR, CNT_MAX, or CNT_MIN registers or writes to the CNT_CMD register. The CNT_IMSK.MINC and CNT_IMSK.MAXC bits enable interrupt request generation on boundary events.

Zero Marker Events

The CNT_STAT.CZM, CNT_STAT.CZME, and CNT_STAT.CZMZ bits are associated with zero marker events, as described in Configuring GP Counter Push-Button Operation. Each of these events can optionally generate an interrupt request, when enabled by the corresponding CNT_IMSK.CZM, CNT_IMSK.CZME and CNT_IMSK.CZMZ bits.

ADSP-2159x_SC591_SC592_SC594 CNT Register Descriptions

CNT (CNT) contains the following registers.
