

HEWLETT  PACKARD

OPERATING AND SERVICE MANUAL

8672A

SYNTHESIZED SIGNAL GENERATOR

(Including Options 001, 002, 003, 004, and 005)

SERIAL NUMBERS

This manual applies directly to instruments with serial numbers prefixed 1732A and 1733A.

With the changes described in Section VII, this manual also applies to instruments with serial numbers prefixed 1610A, 1701A, 1702A, 1703A, 1704A, 1705A, 1706A, 1707A, 1708A, 1711A, 1712A, 1719A, 1725A and 1731A.

For additional important information about serial numbers, see INSTRUMENT COVERED BY MANUAL in Section I.

FOR REFERENCE PURPOSES ONLY.

SYNTHESIZED SIGNAL GENERATOR

MANUAL IDENTIFICATION

Model Number: 8672A
 Date Printed: March 1978
 Part Number: 08672-90058

This supplement contains important information for correcting manual errors and for adapting the manual to instruments containing improvements made after the printing of the manual.

To use this supplement:

Make all ERRATA corrections

Make all appropriate serial number related changes indicated in the tables below.

Serial Prefix or Number	Make Manual Changes	Serial Prefix or Number	Make Manual Changes
1801A	1	1845A	1 through 9
1816A	1, 2	1905A	1 through 10
1821A	1, 2, 3	1906A	1 through 11
1822A	1 through 4	1913A	1 through 12
1831A	1 through 5	1914A	1 through 13
1833A	1 through 6	1930A	1 through 14
1834A	1 through 7	1940A	1 through 15
1841A	1 through 8	▶ 2002A	1 through 16

▶ NEW ITEM

ERRATA

Page 1-3, Table 1-1 Specifications (2 of 4):

Add the following information to footnote 6:

for Option 008, +8 dBm to -120 dBm from +15°C to +35°C. The RF output level also changes when options are combined. When Options 001 and 008 are combined, the RF output level specification is +10 to -10 dBm. When Options 004 and 008 are combined, the RF output level specification is +7 dBm to -120 dBm. However, when Options 005 and 008 are combined, the RF output level specification is +9 dBm to -10 dBm.

Page 1-6, paragraph 1-49:

Add: If the instrument rack mounting slides are to be mounted in a standard EIA rack, then an adapter (HP Part No. 1494-0023) is needed. The slides without the adapter can be directly mounted in the HP system enclosures.

Page 2-3, paragraph 2-14 continuation:

Change a portion of the fourth line to 23 (binary 10 011);

Page 3-10, Table 3-4:

Change step 4 under Using an External Standard. The last sentence in step 4 should read, "The external reference must be within ± 200 Hz of 10 MHz or ± 100 Hz of 5 MHz for reliable locking to occur."

Page 3-14, Table 3-5 (NOTE):

Change AH2 to AH1

NOTE

Manual change supplements are revised as often as necessary to keep manuals as current and accurate as possible. Hewlett-Packard recommends that you periodically request the latest edition of this supplement. Free copies are available from all HP offices. When requesting copies quote the manual identification information from your supplement, or the model number and print date from the title page of the manual.

ERRATA (Cont'd)

Page 3-17, Table 3-9:

Change the two right-hand column headings to 0 dBm and +10 dBm.

Page 3-19, paragraph 3-53:

Change the statement inside the parentheses to (that is it returns to local).

Page 3-21, Table 3-10, (left hand box under ARGUMENTS and the right of LLC):

Add a comma between digits 2 and 4 RF OFF.

Page 4-3, PROCEDURE, step 8:

Change the third sentence to, "This should occur between 0.517 Vrms and 0.616 Vrms for ambient temperatures between 15°C and 35°C."

Page 4-5, paragraph 4-12, step 5:

Change -2 dBm to +3 dBm.

Page 4-16, paragraph 4-17:

Change the formula in step 5 to $\alpha = 10(P_2 - P_1)/20$.

THIS ONLY
APPLIES
FOR SPECTRUM
ANALYZERS
OTHER THAN
4117 JK

Page 4-17, Paragraph 4-17, AMPLITUDE MODULATION DEPTH METER ACCURACY AND INPUT ACCURACY (Cont'd):

Change step 13 to, "Adjust spectrum analyzer's reference level controls to obtain +500 mVdc on the DVM (V_{DET1})."

Change step 17 to, "To calibrate spectrum analyzer for amplitude modulation level measurement, use the reference level controls to set +282.8 mVdc + V_{OFF} at vertical output (as measured on DVM). For example, if V_{OFF} is -2 mV then set +282.8 mV + (-2 mV) or +280.8 mV at the vertical output. Be sure the trace is peaked on the display when setting the voltage."

Page 4-21 and 4-22, steps 5, 7, and 9:

Change to $300 \text{ Hz} \leq f_0 \leq 1 \text{ kHz}$.

Page 4-26, PROCEDURE, step 8:

Change to "Set the FM deviation switch to the 1 MHz range and tune the test oscillator as accurately as possible to 100 kHz."

Page 4-38, PROCEDURE, Step 11:

Add: Set front panel EXT ALC CAL adjustment fully CW.

Page 4-39, PROCEDURE, Step 13, Program line 30:

Change the note for this line of code to 0 dBm range, +3 dB meter rreading, AM OFF, FM OFF, RF OFF, and EXT XTAL.

Page 4-45, paragraph 4-30, step 6:

In the aging rate equation, change T_2 to T_3 , and T_3 to T_2 .

Page 5-7, paragraph 5-22:

Change Procedure, step 3, to "Verify that in 10 seconds the display drifts less than 360° . A drift of 360° in 10 seconds corresponds to a setting accuracy of 1×10^{-8} . Setting accuracy is not specified for this instrument; the numbers shown are what can typically be obtained."

Page 5-8, PROCEDURE, Step 11:

Change the third sentence to "Adjust 1.61 GHz A3A5R42 (not 1.6) to obtain a DVM reading of $-4.830 \pm 0.001 \text{ Vdc}$."

Page 5-11, PROCEDURE, Step 7 (table of A3A1A2L4 Inductor Values):

Change the HP Part Number of the .68 μH inductor to 9140-0141.

ERRATA (Cont'd)

Page 5-15 and 5-16, Figure 5-4 and PROCEDURE steps 6 and 11:
Change A3A9J3 to A3A9J5 (3 places).

Page 5-29, paragraph 5-36:
Delete (most negative) from step 35.

Page 5-33, PROCEDURE Step 10:
Change program line 70 to CMD "?U3", "K0 = 07 =".

Page 6-2, Table 6-1:
Change A3A8 New Assy Part Number to 86701-60074.

Page 6-13, Table 6-3:
Change A1A8U1 and A1A8U4 to 1826-0502 CD0 IC SWITCH 16-DIP-P.

Page 6-17, Table 6-3:
Change A1A12 to 08672-60118 CD1 same description.
Change A1A11U8 to 08672-80016 CD0 PROM DISPLAY DECODER.

Page 6-19, Table 6-3:
Reverse A1R1 and A1R2 so that A1R1 becomes HP Part Number 2100-3488 RESISTOR-VAR CONTROL C 10K 20% LIN.

Page 6-21, Table 6-3:
Change A2MP4 to 08672-20033.

Page 6-17, Table 6-3:
Change A1A12 to 08672-60118 CD1 same description.
Change A1A11U8 to 08672-80016 CD0 PROM DISPLAY DECODER.

Page 6-25, Table 6-3:
Change A2A4U5 to 1826-0392 CD6 OP AMP GP TO-99.

Page 6-29, Table 6-3:
Change A2A8U24 to 08672-80014 CD8 PROM DIVIDER 2.
Change A2A8U25 to 08672-80015 CD9 PROM DIVIDER 1.

Page 6-31, Table 6-3:
Change A2A10U3 to 08672-80012 CD6 PROM BAND DECODER 2.
Change A2A10U14 to 08672-80013 CD7 PROM BAND DECODER 1.

Page 6-33, Table 6-3:
Delete: Under description for A2A12 "(A2A12W1 Supplied Separately)".
Change A2A11U24 to 08672-80011 CD5 PROM OFFSET.

Page 6-40, Table 6-3:
Change A3A1A2Y1 Description to CRYSTAL QUARTZ 100 MHz Q = $\pm 0.001\%$.

Page 6-51, Table 6-3:
Change A3A7C23 to 0180-0228 CD6 CAPACITOR-FXD 22 UF $\pm 10\%$ 15 VDC TA.

Page 6-52, Table 6-3:
Delete A3A7R47, part number and description, not assigned.
Change A3A7R52 to 0698-3155 CD1 RESISTOR 4.64K 1% .125W F TC=0+—100.

ERRATA (Cont'd)

Page 6-53, Table 6-3:

Change A3A7R73 to 0698-3435 CD0 RESISTOR 38.3 1% .125W F TC=0+—100.

Change A3A7R77 to 0698-3155 CD1 RESISTOR 4.64K 1% .125W F TC=+—100.

Change A3A7R78 to 0757-0316 CD6 RESISTOR 42.2 1% .125W F TC=+—100.

Section VIII, SERVICE (throughout the service sheets' text Table 8-4, Listing of all M and N Numbers and Resulting Frequencies, is erroneously referred to as Table 8-5):

Change to Table 8-4 on the following pages,

Page 8-78, text for SERVICE SHEET 11-A2, paragraph P/O Output Register

Page 8-88, text for SERVICE SHEET 3-A3, paragraph M/N Phase Lock Loop

Page 8-92, text for SERVICE SHEET 5-A3, paragraph M/N Phase Lock Loop

Page 8-94, text for SERVICE SHEET 6-A3, paragraph YTO Phase Lock Loop

Page 8-96, text for SERVICE SHEET 7-A3, paragraph YTO Phase Lock Loop

Page 8-98, text for SERVICE SHEET 8-A3, paragraph YTO Phase Lock Loop

Page 8-100, text for SERVICE SHEET 9-A3, paragraph YTO Phase Lock Loop

Page 8-102, text for SERVICE SHEET 10-A3, paragraph YTO Phase Lock Loop

Page 8-34, SERVICE SHEET 2, PRINCIPLES OF OPERATION, YTO Loop:

Change formula to $f_{20/30} = f_{YTO} \text{ IF} = N(f_{M/N}) - f_0$.

Page 8-37, Figure 8-22 (Service Sheet 2):

Change A9A7 in YTO LOOP SAMPLER block to A3A9U1.

Change 6.999 GHz in YTO LOOP PRETUNE (MAIN COIL DRIVER) block to 6.199 GHz.

Page 8-42, Figure 8-25 (A1A5 ASSEMBLY):

Change R43 to R41 and R41 to R43.

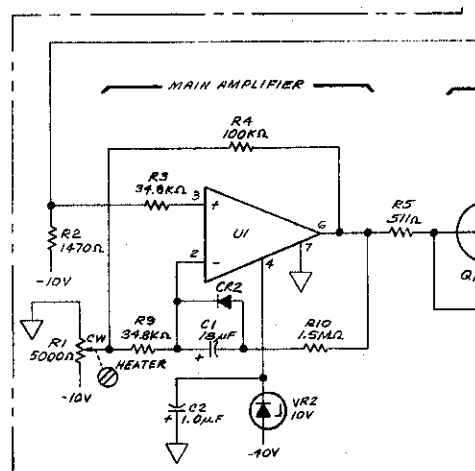

Page 8-44, Figure 8-29:

Reverse the callouts for R41 and R47 (R41 should be R47 and R47 should be R41).

Page 8-45, Figure 8-31 (Service Sheet 2-A1):

Change A1A8C16 to 33 pF.

Change the schematic circuitry around A1A3U1 as shown.

ERRATA (Cont'd)

Page 8-46, SERVICE SHEET 3-A1, TROUBLESHOOTING:
Change to the table shown below.

	Band 1	Band 2	Band 3
HN1	0.2 Vdc	5 Vdc	0.2 Vdc
HN2	0.2 Vdc	0.2 Vdc	5 Vdc
NBAND2	3.6 Vdc	0.2 Vdc	3.6 Vdc
NBAND3	3.6 Vdc	3.6 Vdc	0.2 Vdc
NBAND1	0.2 Vdc	3.6 Vdc	3.6 Vdc
B2	0.01 Vdc	12.1 Vdc	0.01 Vdc
I2	-12 Vdc	-29.6 Vdc	-12 Vdc
G2	-29.7 Vdc	-2.7 to -5.7 Vdc	-29.7 Vdc
I1	-13.2 Vdc	-12.6 Vdc	-12.6 Vdc
B3	0.02 Vdc	0.02 Vdc	12 Vdc
I3	-12 Vdc	-12 Vdc	-29.5 Vdc
G3	-29.7 Vdc	-29.7 Vdc	-4.8 to -7.2 Vdc
BP	0.04 Vdc	0.04 Vdc	14.7 Vdc
SRD BIAS	-6.4 Vdc	+0.2 to -0.3 Vdc	-0.2 to +1.0 Vdc

Page 8-48, Figure 8-35, Component Locations (A1A6 ASSEMBLY):
Exchange reference designator R16 with R17.

Page 8-49, Figure 8-37 (Service Sheet 4-A1):

Change the voltage at TP  to -0.714V.

Page 8-53, Figure 8-43 (Service Sheet 6-A1):

Change in TRANSISTOR AND INTEGRATED CIRCUIT PART NUMBERS box U8 to 08672-80016.

Page 8-55, Figure 8-47 (Service Sheet 7-A1):

Change R15 to R13 (in lower right hand corner of schematic).

Change reference designators of LED displays on right-hand side of schematic. Change A1DS1A to A1DS1, A1DS1B to A1DS2 and A1DS1C to A1DS3.

Change part numbers in TRANSISTOR AND INTEGRATED CIRCUIT PART NUMBERS box for A1DS2, 8 to 1990-0506.

Page 8-56, Figure 8-48:

Change CR3 to CR5, CR5 to CR4, and CR4 to CR3.

ERRATA (Cont'd)

Page 8-57, Figure 8-50 (Service Sheet 8-A1):

Exchange pin numbers on U6E with those on U6F. U6E should be pins 14 and 15 and U6F should be pins 11 and 12.

Exchange pin numbers 4 and 5 on U7A

Change schematic to show A1A9R22, C12, and C25 as being connected to ground 

Page 8-63, Figure 8-59 (Service Sheet 3-A2):

Change, in lower right corner, from 9-A2 to 9-A3.

Page 8-64, Figure 8-60:

Reverse the callouts for S1 and S3 (S1 should be S3 and S3 should be S1).

Page 8-65, Figure 8-62 (Service Sheet 4-A2):

Change U23 pin 9 from NC (no connection) to +5V.

Change parallel poll response S1 to S3 and HP-IB address select S3, S3A, S3B to S1, S1A and S1B.

Change the four-input NOR gate labeled U24B to U25B.

Page 8-71, Figure 8-71 (Service Sheet 7-A2):

Delete, on A2A10U25, the connections between pins 1 and 2, 3 and 4, 5 and 6, 7 and 12. Show pins 2, 4, 5 and 12 as no connection (NC).

Change in TRANSISTOR AND INTEGRATED CIRCUIT PART NUMBERS box

U3 to 08672-80012

U14 to 08672-80013.

Change PIN NUMBERS in INTEGRATED CIRCUIT VOLTAGE AND GROUND CONNECTIONS box for U7-9, 19-23 to +5V(P) -16.

Page 8-73, Figure 8-74 (Service Sheet 8-A2):

Delete polarity indicator symbols at inputs to A2A11U29B pins 1, 2 and 8.

Add polarity indicator symbol at output pin 9 of A2A11U29B.

Page 8-75, Figure 8-77 (Service Sheet 9-A2):

Change in TRANSISTOR AND INTEGRATED CIRCUIT PART NUMBERS box

U24 to 08672-80011.

Page 8-77, Figure 8-80 (Service Sheet 10-A2):

Change in TRANSISTOR AND INTEGRATED CIRCUIT PART NUMBERS box

U24 to 08672-80014

U25 to 08672-80015.

Page 8-79, Figure 8-83 (Service sheet 11-A2):

Change label on P/O A2A8U17 pin 11 to DAC 3200 MHz and label pin 12 NDAC 4800 MHz.

Change labels on P/O A2A12, near right hand side of schematic, XA2A8B pin 29 to DAC 3200 MHz and pin 13 to DAC 4800 MHz.

Change mnemonics on connections between P/O A2A12 and P/O A3A10;

N0 to N1 (XA2A8B pin 28 and P/O J4 pin 7)

N1 to N2 (XA2A8B pin 27 and P/O J4 pin 37)

N2 to N3 (XA2A8C pin 4 and P/O J4 pin 8)

N3 to N4 (XA2A8C pin 6 and P/O J4 pin 38)

N4 to N5 (XA2A8B pin 26 and P/O J4 pin 9)

N5 to N6 (XA2A8B pin 14 and P/O J4 pin 39)

Page 8-83, Figure 8-89 (Service Sheet 13-A2):

Add polarity indicator symbol at U3 pin 9 (Reset).

ERRATA (Cont'd)

Page 8-85, Figure 8-92 (Service Sheet 1-A3):

Change A3A8 10 MHz Reference Oscillator Assembly to 86701-60074.

Page 8-86, Figure 8-93:

Change Q6 to Q9, in lower right-hand corner of figure.

Page 8-88, text for Service Sheet 3-A3:

Change the formula at the bottom of page to $f_M = \left(\frac{A}{M}\right) f_{IF}$

Change under TROUBLESHOOTING, Test Equipment, Digital Voltmeter to HP 3455A.

Page 8-89, Figure 8-98 (Service Sheet 3-A3):

Add to U19 pins 2 and 3, this wired-OR symbol

Page 8-94, Troubleshooting step 6:

Change to — Measure the voltage at U7 pin 4. It should be 0.6 Vdc (high). Pins 1, 8, 9, and 12 should be 0 Vdc. If correct, proceed to step 7. Otherwise, troubleshoot U10, U7 and their associated components.

Page 8-94, Figure 8-105:

Change adjustment 3.8 GHz to 3.2 GHz.

Page 8-95, Figure 8-107 (Service Sheet 6-A3):

Change labels on P/O A3A10 XA3A5 pin 7 to DAC 4800 MHz and pin 8 to DAC 3200 MHz.

Page 8-99, Figure 8-113 (Service Sheet 8-A3):

Change at left side of schematic and in REFERENCE DESIGNATIONS box A3A9J3 to A3A9J5 (2 places).

Page 8-101, Figure 8-116 (Service Sheet 9-A3):

Change the output pin numbers of A3A9A4U5; pin 12 should be pin 3 and pin 3 should be pin 12.

Change at left side of schematic and in REFERENCE DESIGNATIONS box

A3A9J5 to A3A9J3 (2 places).

Page 8-103, Figure 8-119 (Service Sheet 10-A3):

Delete R47 and identify as not assigned.

Change R52 and R77 from 750 to 4640 and show as being connected in parallel.

Change R73 to 38.3 and R78 to 42.2 and show as being connected in series.

Page 8-107, Figure 8-125 (Service Sheet 12-A3):

Add under +5.2V Overvoltage Protection Circuitry, VR4 6.19V next to the zener diode.

Page 8-111/8-112, Table 8-6 (2 of 3):

Change under Board Edge Connectors XA1A6 REF VOLTAGE pin 23 to pin 33.

CHANGE 1

Page 6-32, Table 6-3:

Change A2A11C18 to 0160-0570 CD 9 CAPACITOR-FXD 220 PF $\pm 20\%$ 100 VDC.

Page 6-35, Table 6-3:

Change A3A1A1C39 to 0160-3454 CD 4 CAPACITOR-FXD 220 PF $\pm 10\%$ KVDC.

Page 6-43, Table 6-3:

Change A3A1A5Q7 to 1854-0546 CD 1 TRANSISTOR NPN SI TO-72 PD-200 MW.

Page 8-75, Figure 8-77 (Service Sheet 9-A2):

Change C18 to 220 pF.

CHANGE 2

Page 6-8, Table 6-3:

Change A1A5R68 to 0757-0278 CD9 RESISTOR 1.78K 1% .125 W F TC=0+-100.

Change A1A5R69 to 2100-3351 CD6 RESISTOR TRMR 500 10% C SIDE ADJ 1 TRN.

Page 6-51, Table 6-3:

Change A3A7C23 to 0180-1719 CD 2 CAPACITOR-FXD 22UF $\pm 10\%$ 25 VDC TA.

Page 6-52, Table 6-3:

Add A3A7R47 0757-0420 CD 3 RESISTOR 750 1% .125W F TC=0+-100.

Change A3A7R52 to 0757-0420 CD 3 RESISTOR 750 1% .125W F TC=0+-100.

Page 6-53, Table 6-3:

Change A3A7R73 to 0757-0802 CD 5 RESISTOR 162 1% .5W F TC=0+-100.

Change A3A7R77 to 0757-0420 CD 3 RESISTOR 750 1% .125W F TC=0+-100.

Change A3A7R78 to 0757-0802 CD 5 RESISTOR 162 1% .5W F TC=0+-100.

Page 8-43, Figure 8-27 (Service Sheet 1-A1):

Change R68 to 1780 and R69 to 500 Ω .

Page 8-103, Figure 8-119 (Service Sheet 10-A3):

Add R47, 750 and show as being connected in series with R52 and R77.

Change R52 and R77 to 750.

Change R73 and R78 to 162 and show as being connected in parallel.

CHANGE 3

Page 6-7, Table 6-3:

Change A1A5R31 to 0698-3626 CD 1 RESISTOR 180 5% 2W MO TC=0+-200.

Change A1A5R36 to 0757-0394 CD 0 RESISTOR 51.1 1% .125W F TC=0+-100.

Page 8-43, Figure 8-27 (Service Sheet 1-A1):

Change R31 to 180 Ω and R36 to 51.1 Ω .**CHANGE 4**

Page 6-54, Table 6-3 (under A3A9 Miscellaneous):

Change from 86701-00009 to 86701-00056 CD0 DECK YTO P/L.

Page 6-60, Table 6-3 (under A3 Miscellaneous Parts):

Change from 86701-00020 to 86701-00057 CD1 DIVIDER CENTER 21".

CHANGE 5

Page 1-2, Table 1-1:

Add to FREQUENCY CHARACTERISTICS under Switching Time (CW and AM modes):
 < 15 ms to be within 3 dB of final amplitude level for any frequency change on the same band.

Page 6-8 through 6-10, Table 6-3:

Change the A1A6 Assembly replaceable parts list as shown in this supplement (Part of Change 5).

Page 8-45, Figure 8-31 (Service Sheet 2-A1):

Add the following off page connector to the collector of A1A14 Q1:

(GU) 4-A1

Page 8-48, Figure 8-35:

Change to the component locations diagram as shown in this supplement (Part of Change 5).

Page 8-49, Figure 8-37 (Service Sheet 4-A1):

Change to the schematic diagram as shown in this supplement (Part of Change 5).

Page 8-53, Figure 8-43 (Service Sheet 6-A1):

Change the (HR) 7-A1 offpage connector to 4, 7-A1.

Page 8-111, Table 8-6:

Add pin 8 to column A6 beside signal line mnemonic Coupler Drive to YTM.
 Add pin 7 to column A6 beside signal line mnemonic RF PWR CONT.

A1A6 ASSEMBLY

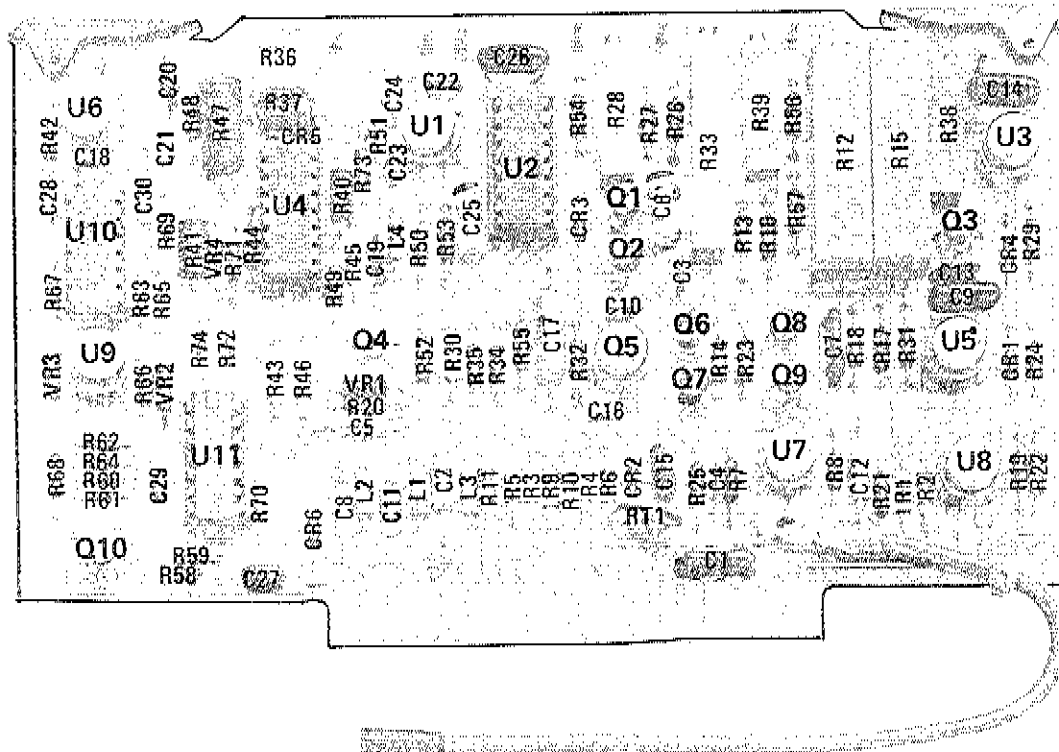

Figure 8-35. A1A6 ALC Detector Assembly Component, Adjustment, and Test Point Locations (Part of Change 5)

Table 6-3. Replaceable Parts (Part of Change 5)

FIG. 8-37 (chg. 5)
Sht 1 of 3

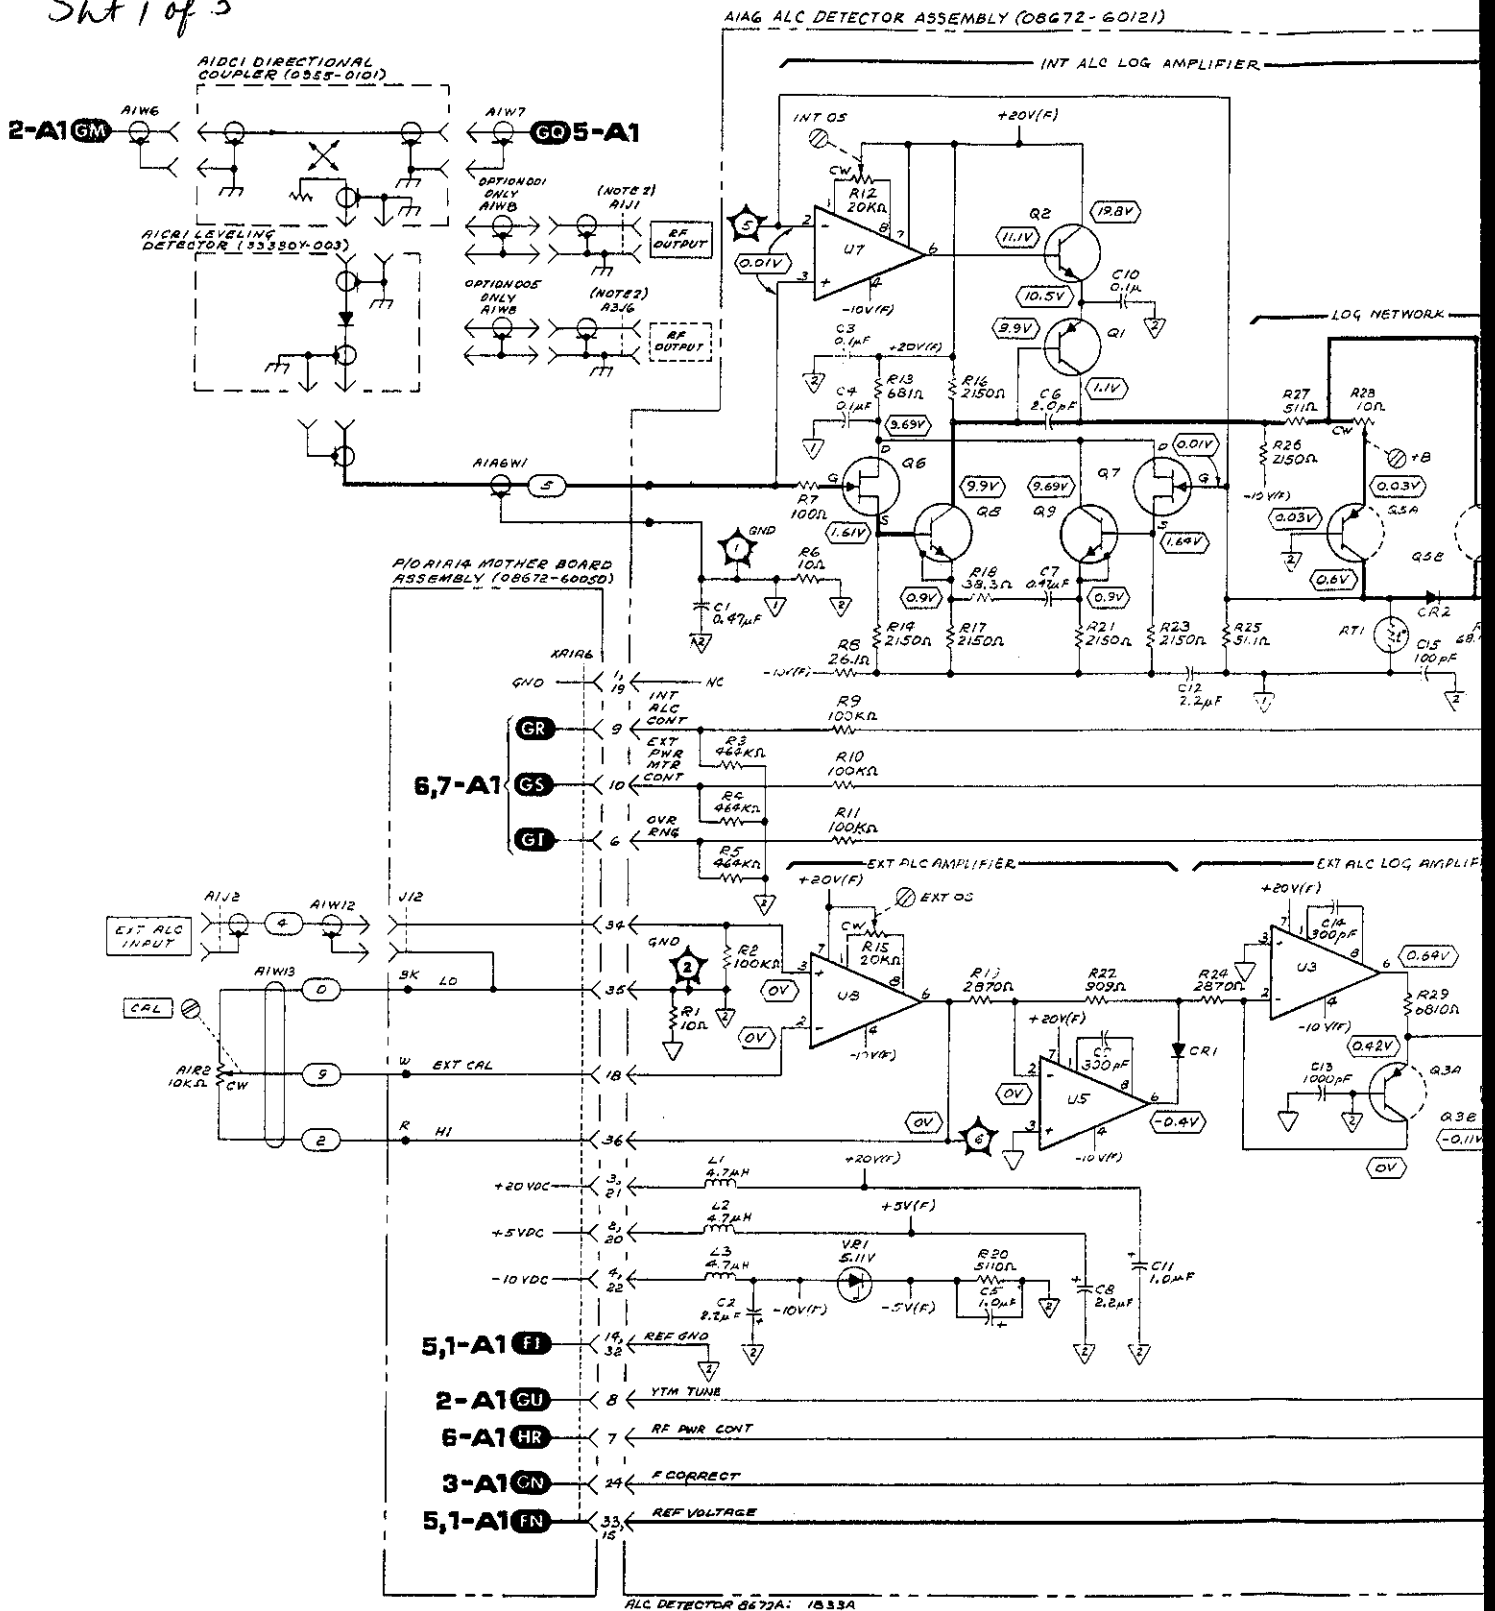

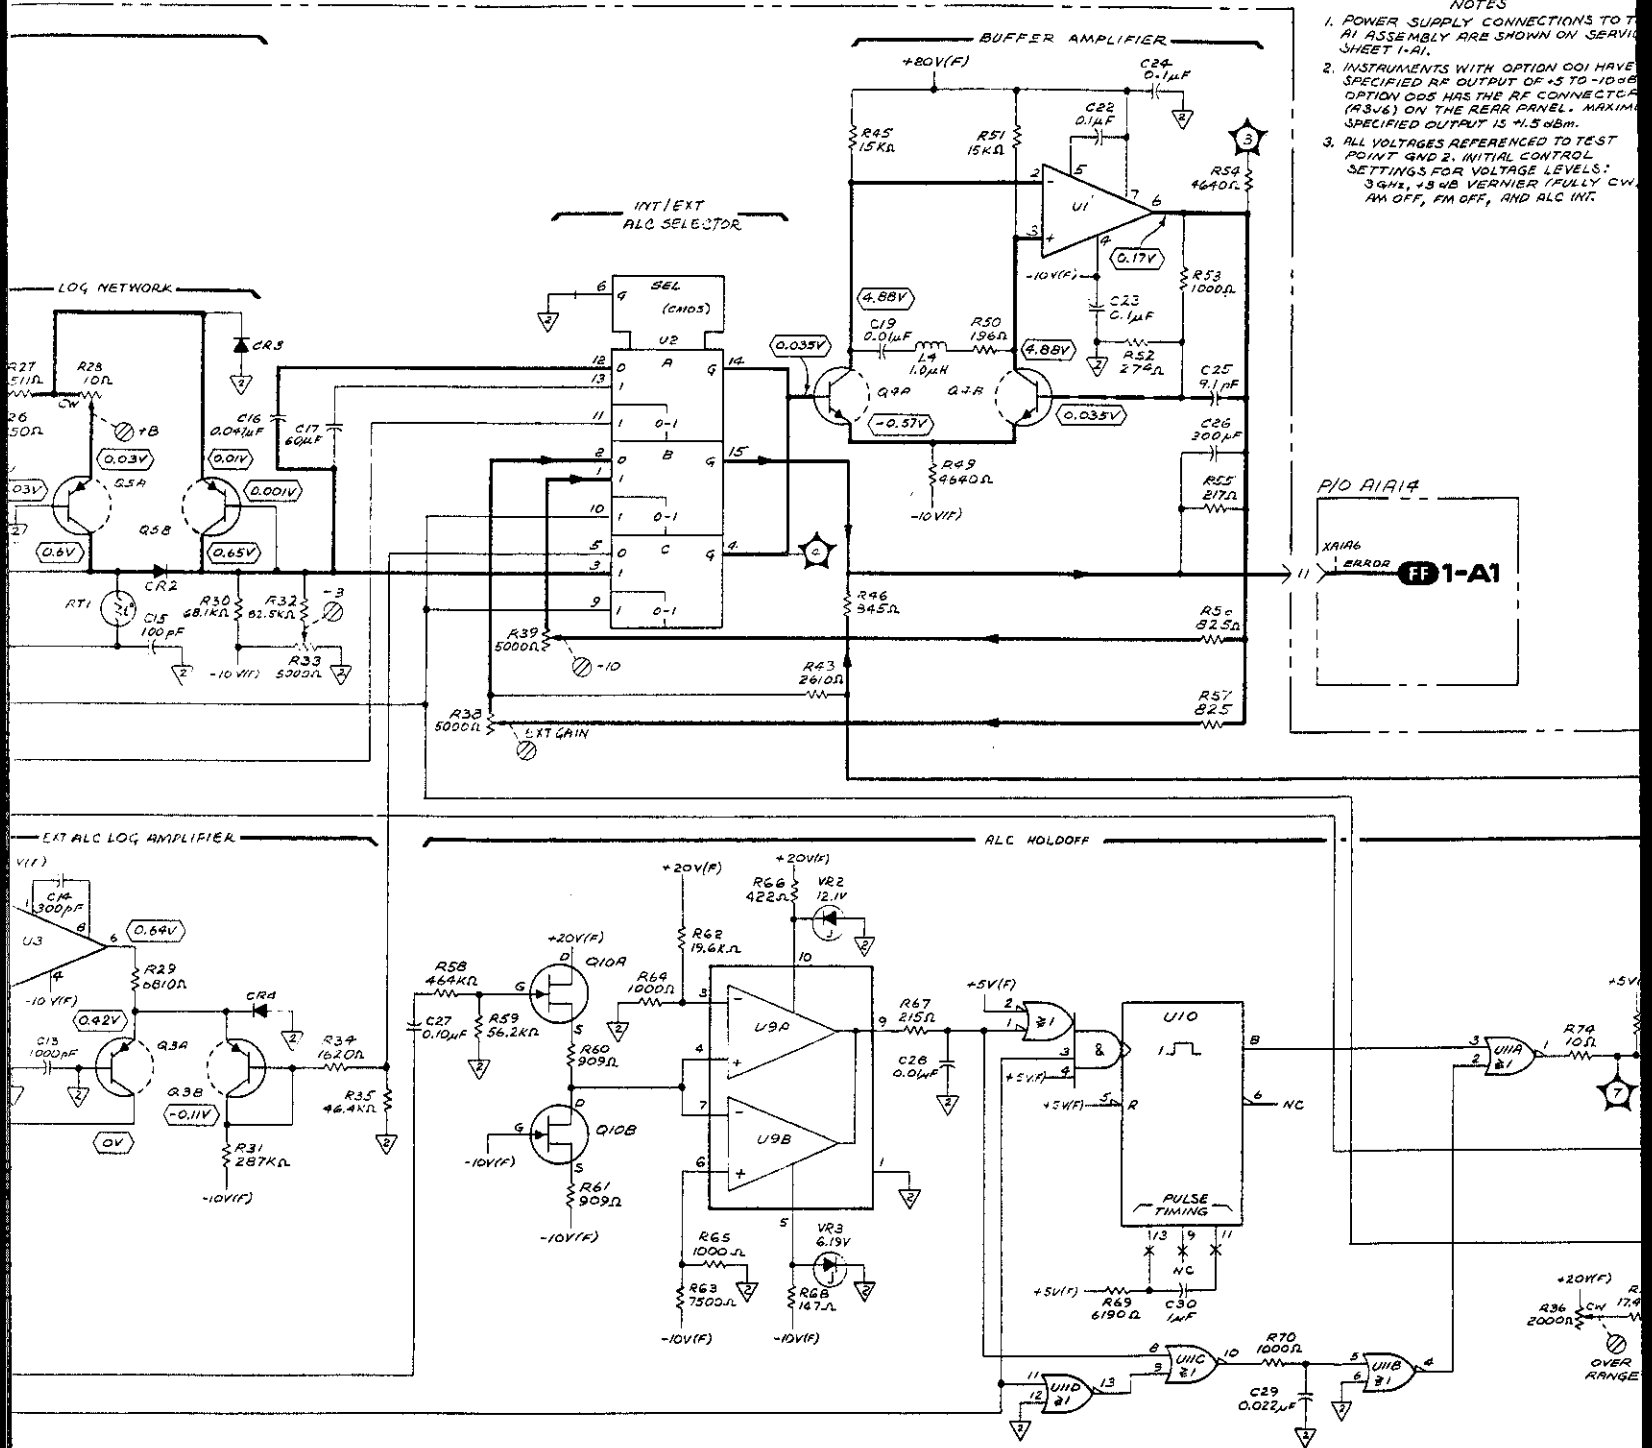

FIG. 8-37 (Chg. 5)
 SHt 2 of 3

- NOTES
1. POWER SUPPLY CONNECTIONS TO THE A1 ASSEMBLY ARE SHOWN ON SERVICE SHEET 1-A1.
 2. INSTRUMENTS WITH OPTION 001 HAVE SPECIFIED RF OUTPUT OF +5 TO -10 dB. OPTION 005 HAS THE RF CONNECTOR (A3V6) ON THE REAR PANEL. MAXIMUM SPECIFIED OUTPUT IS +1.5 dBm.
 3. ALL VOLTAGES REFERENCED TO TEST POINT AND 2. INITIAL CONTROL SETTINGS FOR VOLTAGE LEVELS: 3 SH, 4.5 dB VERNIER (FULLY CW), AM OFF, FM OFF, AND ALC INT.

FIG. 8-37 (chg. 5)
Sht 3 of 3

- NOTES
1. POWER SUPPLY CONNECTIONS TO THE A1 ASSEMBLY ARE SHOWN ON SERVICE SHEET 1-A1.
 2. INSTRUMENTS WITH OPTION 001 HAVE A SPECIFIED RF OUTPUT OF +5 TO -10 dBm; OPTION 005 HAS THE RF CONNECTOR (A3J6) ON THE REAR PANEL. MAXIMUM SPECIFIED OUTPUT IS +1.5 dBm.
 3. ALL VOLTAGES REFERENCED TO TEST POINT QND 2. INITIAL CONTROL SETTINGS FOR VOLTAGE LEVELS: 3 GHz, +3 dB VERNIER (FULLY CW) AM OFF, FM OFF, AND ALC INT.

P/O Figure 8-77. P/O Timing and Control Schematic Diagram (Part of Change 6)

CHANGE 7

Page 6-31, Table 6-3:

Change A2A10U24 to 1820-0946 CD 4 IC GATE CMOS NOR QUAD 2-INP.

Page 8-71, Figure 8-71 (Service Sheet 7-A2):

In the table of Transistor and Integrated Circuit Part Numbers:

Delete U24.

Add U24 1820-0946.

CHANGE 8

Page 6-37, Table 6-3:

Change A3A1A2C8 to 0160-2257 CD3 CAPACITOR-FXD 10 PF ±5% 500 VDC CER 0±60.

Page 6-38, Table 6-3:

Change A3A1A2L4 to 9100-2254 CD3 COIL-MLD 390 NH 10% Q=35 .095D x .25LG -NOM

CHANGE 8 (Cont'd)

Page 6-48, Table 6-3:

Change A3A5R13 to 2100-1657 CD1 RESISTOR-TRMR 1K 5% WW SIDE-ADJ 22-TRN
 Change A3A5R16 to 0699-0271 CD8 RESISTOR 715 1% .125W F TC-0±100.

Page 6-49, Table 6-3:

Change A3A5R52 to 0698-6360 CD6 RESISTOR 10K .1% .125W F TC-0±25.
 Change A3A5VR1 to 1902-0692 CD1 DIODE-ZNR 6.3V 1% DO-7 PD=.4W TC = .001%.

Page 6-53, Table 6-3:

Change A3A9J1 through J6 to 1250-0691 CD7 CONNECTOR-RF SMB M SGL-HOLE-FR 50-OHM.

Page 8-87, Figure 8-95 (Service Sheet 2-A3):

Change A3A1A2C8 to 10.0 pF.
 Change A3A1A2L4 to 0.39 μ H.

Page 8-95, Figure 8-107 (Service Sheet 6-A3):

Change A3A5VR1 to 6.3V.
 Change A3A5R13 to 1K Ω .
 Change A3A5R16 to 715 Ω .
 Change A3A5R52 to 10K Ω .

CHANGE 9

Page 1-2, Table 1-1:

Change under SPECTRAL PURITY CHARACTERISTICS Single-Sideband Phase Noise (1 Hz BW, CW mode), as shown:

Frequency Range (GHz)	SSB Phase Noise Ratio (in 1 Hz BW, CW mode) at Specified Offset Frequency*				
	10 Hz	100 Hz	1 kHz	10 kHz	100 kHz
2.0-6.2	-58dB	-70dB	-78dB	-86dB	-110dB
6.2-12.4	-52dB	-64dB	-72dB	-80dB	-104dB
12.4-18.0	-48dB	-60dB	-68dB	-76dB	-100dB

Page 4-22, paragraph 4-20:

Change the SPECIFICATION table as shown in the above table.

Page 4-23, PROCEDURE steps 6 and 8:

Change 60 to 58.
 Change 57.6 to 55.6 dB down.
 Change 54 to 52.
 Change 51.6 to 49.6 dB down.

Page 4-24, PROCEDURE steps 10, 12, and 20:

Change 50 to 48.
 Change 47.6 to 45.6 dB down
 Change 75 to 78
 Change 60.8 to 62.8 dB down
 Change 69 to 72.
 Change 54.8 to 56.8 dB down.
 Change 65 to 68.
 Change 50.8 to 52.8 dB down.

CHANGE 9 (Cont'd)

Page 4-24, PROCEDURE steps 10, 12, and 20: (Cont'd)

Change 61.8 to 58.8 dB down

Change 55.8 to 52.8 dB down

Change 51.8 to 48.8 dB down

Page 4-25, PROCEDURE step 22:

Change 71.8 to 72.8 dB down

Change 65.8 to 66.8 dB down

Change 61.8 to 62.8 dB down

Page 4-47, Table 4-4 (Para. No. 4-20):

Change per the following:

	Test	Results Min	
2.0-6.2 GHz	10 Hz	-58 dBc	55.6 dB down
	100 Hz	-70 dBc	62.8 dB down
	1 kHz	-78 dBc	60.8 dB down
	10 kHz	-86 dBc	58.8 dB down
	100 kHz	-110 dBc	72.8 dB down
6.2-12.4 GHz	10 Hz	-52 dBc	49.6 dB down
	100 Hz	-64 dBc	56.8 dB down
	1 kHz	-72 dBc	54.8 dB down
	10 kHz	-80 dBc	52.8 dB down
	100 kHz	-104 dBc	66.8 dB down

Page 4-48, Table 4-4 (Par. No. 4-20):

Change per the following:

	Test	Results Min	
12.4-18.0 GHz	10 Hz	-48 dBc	45.6 dB down
	100 Hz	-60 dBc	52.8 dB down
	1 kHz	-68 dBc	50.8 dB down
	10 kHz	-76 dBc	48.8 dB down
	100 kHz	-100 dBc	62.8 dB down

CHANGE 10

Page 6-25, Table 6-3:

Change A2A4R23 to 0757-0819 CD4 RESISTOR 909 1% 0.5W F TC=0±100.

Page 8-61, Figure 8-56 (Service Sheet 2-A2):

Change R23 to 909Ω.

CHANGE 11

Page 6-5, Table 6-3:

Add A1A1C3 0160-0174 CD9 CAPACITOR-FXD 0.47 μ F +80 -20% 25 VDC CER.

Page 6-52, Table 6-3:

Change A3A7Q3 to 1854-0401 CD7 TRANSISTOR NPN SI TO-72 PD = 175 mW.

Page 8-57, Figure 8-50 (Service Sheet 8-A1):

Add at left side of schematic, capacitor 0.47 μ F, from the shield of A1W18 to ground, and label the capacitor A1A1C3.

Page 8-103, Figure 8-119 (Service Sheet 10-A3):

Change, in table of TRANSISTOR and INTEGRATED CIRCUIT PART NUMBERS, Q3 to 1854-0401.

CHANGE 12

Page 6-54, Table 6-3:

Change A3A9W1 to 86701-20064 CD2

Change A3A9W2 to 86701-20066 CD4

Change A3A9W3 to 86701-20065 CD3

Change under A3A9 MISCELLANEOUS, 86701-00009 to 86701-00058 CD2 DECK YTO PHASE LOCK

Change A3A9A1 to 0955-0098 CD1 (same description).

Page 8-103, Figure 8-119 (Service Sheet 10-A3):

Change A3A9A1 Directional Coupler to 0955-0098.

CHANGE 13

Page 6-43, Table 6-3:

Change A3A1A5Q5 to 1854-0686 CD 0 TRANSISTOR NPN SI TO-72 PD=200 MW FT 4 GHz.

Add A3A1A5R42 0698-7205 CD 0 RESISTOR 51.1 1% .05W F TC=0 \pm 100.

Page 8-93, Figure 8-104 (Service Sheet 5-A3):

Add a resistor from the collector of Q5 to ground and label it R42 51.1 Ω .

Change in table of TRANSISTOR and INTEGRATED CIRCUIT PART NUMBERS Q5 to 1854-0686. Also change Q1,3-9 to read Q1,3,4,6-9.

CHANGE 14

Page 6-21, Table 6-3:

Change A2A1C2 to 0160-0573 CD2 CAPACITOR-FXD 4700PF \pm 20% 100 VDC CER.

Page 8-81, Figure 8-86 (Service Sheet 12-A2):

Change C2 to 4700 pF.

CHANGE 15

Page 6-7, Table 6-3, Replaceable Parts:

Change A1A5CR6 to 1901-0539.

► **CHANGE 16**

Page 6-8 through 6-10, Table 6-3:

Change the A1A6 assembly replaceable parts list as shown in this supplement (Part of Change 16).

Page 8-48, Figure 8-35:

Change to the component locations diagram as shown in this supplement (Part of Change 16).

Page 8-49, Figure 8-37 (service Sheet 4-A1):

Change to the schematic diagram as shown in this supplement (Part of Change 16).

ADJUSTMENTS

5-33. 20/30 MHz (LFS) Loop Divider Bias Adjustments (Cont'd)

7. Connect the equipment as shown in Figure 5-11.
8. Center A2A5R4 (CLK BIAS ADJ).
9. Observe the clock signal on the oscilloscope display.
10. Adjust A2A5R4 to obtain a stable clock frequency.
11. Reduce the signal generator output level while readjusting A2A5R4 to obtain a stable clock signal at the lowest possible signal.
12. Verify that a stable clock signal is obtained with an input signal of -10 dBm or less.
13. Disconnect the test equipment and reinstall A2A5 in its cavity. Reconnect the cable to A2A5J1.

5-34. A2A4 Assembly Notch Filter Adjustment

REFERENCE: Service Sheet 2-A2.

DESCRIPTION: A 7985 Hz signal is passed through the 8 kHz notch filter. The adjustable components are set for the minimum signal transfer.

- NOTES
1. POWER SUPPLY CONNECTIONS TO THE A1 ASSEMBLY ARE SHOWN ON SERVICE SHEET 1-A1.
 2. INSTRUMENTS WITH OPTION 001 HAVE A SPECIFIED RF OUTPUT OF +5 TO -10 dBm; OPTION 005 HAS THE RF CONNECTOR (A3J6) ON THE REAR PANEL. MAXIMUM SPECIFIED OUTPUT IS +1.5 dBm.
 3. ALL VOLTAGES REFERENCED TO TEST POINT AND 2. INITIAL CONTROL SETTINGS FOR VOLTAGE LEVELS: 3GHz, +3 dB VERNIER (FULLY CW) AM OFF, FM OFF, AND ALC INT.

SAFETY CONSIDERATIONS

GENERAL

This product and related documentation must be reviewed for familiarization with safety markings and instructions before operation. This product has been designed and tested in accordance with international standards.

SAFETY SYMBOLS

Instruction manual symbol: the product will be marked with this symbol when it is necessary for the user to refer to the instruction manual (refer to Table of Contents).

Indicates hazardous voltages.

Indicates earth (ground) terminal.

WARNING

The WARNING sign denotes a hazard. It calls attention to a procedure, practice, or the like, which, if not correctly performed or adhered to, could result in personal injury. Do not proceed beyond a WARNING sign until the indicated conditions are fully understood and met.

CAUTION

The CAUTION sign denotes a hazard. It calls attention to an operating procedure, practice, or the like, which, if not correctly performed or adhered to, could result in damage to or destruction of part or all of the product. Do not proceed beyond a CAUTION sign until the indicated conditions are fully understood and met.

SAFETY EARTH GROUND

This is a Safety Class I product (provided with a protective earthing terminal). An uninterruptible safety earth ground must be provided from the main power source to the product input wiring terminals, power cord, or supplied power cord set. Whenever it is likely that the protection has been impaired, the product must be made inoperative and be secured against any unintended operation.

BEFORE APPLYING POWER

Verify that the product is configured to match the available main power source per the input power configuration instructions provided in this manual.

If this product is to be energized via an auto-transformer make sure the common terminal is connected to the neutral (grounded side of mains supply).

SERVICING

WARNINGS

Any servicing, adjustment, maintenance, or repair of this product must be performed only by qualified personnel.

Adjustments described in this manual may be performed with power supplied to the product while protective covers are removed. Energy available at many points may, if contacted, result in personal injury.

Capacitors inside this product may still be charged even when disconnected from its power source.

To avoid a fire hazard, only fuses with the required current rating and of the specified type (normal blow, time delay, etc.) are to be used for replacement.

Figure 1-1. HP Model 8672A and Accessories Supplied.

SECTION I

GENERAL INFORMATION

1-1. INTRODUCTION

1-2. This manual contains information pertinent to installation, operation, testing, adjusting, and servicing the Hewlett-Packard Model 8672A Synthesized Signal Generator. The Model 8672A will generally be referred to as the Synthesizer throughout this manual.

1-3. Information pertaining to the Hewlett-Packard Interface Bus (HP-IB) as it relates to the Synthesizer is found in various sections of this manual. Section VIII contains a diagnostic program for checkout of HP-IB functions. A remote operator's check is also found in Section VIII.

1-4. Figure 1-1 shows the Synthesizer with all supplied accessories.

1-5. Packaged with this manual is an Operating Information Supplement. This is simply a copy of the first three sections of this manual. This supplement should stay with the instrument for use by the operator. Additional copies may be ordered separately through your nearest Hewlett-Packard office. The part number is listed on the title page of this manual.

1-6. On the title page of this manual, below the manual part number, is a "Microfiche" part number. This number may be used to order 100 x 150 mm (4 x 6-inch) microfilm transparencies of the manual. Each microfiche contains up to 96 photo-duplicates of the manual pages. The microfiche package also includes the latest Manual Changes supplement as well as all pertinent Service Notes.

1-7. SPECIFICATIONS

1-8. Instrument specifications are listed in Table 1-1. These specifications are the performance standards, or limits against which the instrument may be tested.

1-9. SAFETY CONSIDERATIONS

1-10. This product is a Safety Class I instrument (provided with a protective earth terminal). The instrument and manual should be reviewed for safety markings and instructions before operation.

1-11. The Synthesizer and all related documentation must be reviewed for familiarization with safety markings and instructions before operation. Refer to the Safety Considerations page found at

the beginning of this manual for a summary of the safety information.

1-12. Safety information pertinent to the task at hand (installation, operation, performance testing, adjustments, or service) is found throughout this manual.

1-13. INSTRUMENTS COVERED BY MANUAL

1-14. **Options.** Electrical options 001, 002, 003, 004, 005 and various mechanical options are documented in this manual. The differences are noted under the appropriate paragraph such as Options in Section I, the Replaceable Parts List and the schematic diagrams.

1-15. **Serial Numbers.** Attached to this instrument is a serial number plate. The serial number is in the form 1234A00123. The first four digits and the letter comprise the serial prefix. The last five digits form the sequential suffix that is unique to each instrument. The contents of this manual apply directly to instruments having the same serial number prefix(es) as listed under SERIAL NUMBERS on the title page.

1-16. For information concerning a serial number prefix not listed on the title page or in the Manual Changes supplement, contact your nearest Hewlett-Packard office.

1-17. MANUAL CHANGE SUPPLEMENTS

1-18. An instrument manufactured after the printing of this manual may have a serial prefix that is not listed on the title page. This unlisted serial prefix indicates that the instrument is different from those documented in this manual. The manual for this instrument is supplied with a yellow Manual Change supplement that contains "change information" that documents the differences.

1-19. In addition to change information, the supplement may contain information for correcting errors in the manual. To keep this manual as current and accurate as possible, Hewlett-Packard recommends that you periodically request the latest Manual Changes supplement. The supplement for this manual is keyed to this manual's print date and part number, both of which appear on the title page. Complimentary copies of the supplement are available from Hewlett-Packard.

Table 1-1. Specifications (1 of 4)

SPECIFICATIONS

FREQUENCY CHARACTERISTICS

Range: 2.0 to 18.0 GHz (overrange to 18.599 997 GHz)

Resolution: 1 kHz, 2.0–6.199 999 GHz
 2 kHz, 6.2–12.399 998 GHz
 3 kHz, 12.400 002–18.0 GHz

Time Base:

Internal: 10 MHz; Aging Rate is $< 5 \times 10^{-10}$ /day after 30 day warmup^{1,2}.

External: 5 or 10 MHz; 0.1 to 1 Vrms nominal into 50 ohms³.

Reference Outputs: 10 MHz and 100 MHz, 0.2 Vrms nominal into 50 ohms.

Frequency Accuracy: same as time base².

Switching Time (CW and AM modes): < 15 ms to be within 1 kHz frequencies from 2–6.2 GHz, within 2 kHz from 6.2 to 12.4 GHz, and within 3 kHz from 12.4–18 GHz.

SPECTRAL PURITY CHARACTERISTICS

Harmonics (up to 18 GHz): < -25 dBc.

Sub-harmonics and Multiplies (up to 18 GHz): < -25 dBc.

Power Line Related and Spurious: (Due to fan rotation; within 5 Hz below line frequency and multiples):

Option 003 only (400 Hz operation)

Spurious (CW and AM modes⁴):

Non-harmonically related: < -70 dBc, 2.0–6.2 GHz
 < -64 dBc, 6.2–12.4 GHz
 < -60 dBc, 12.4–18.0 GHz

Power Line Related and Spurious: (Due to fan rotation within 5 Hz below line frequency and multiples):

Carrier (F _c) Frequency Range (GHz)	Power Line Related and Spurious Levels at Frequency Offset (f _o) from Carrier (F _c)		
	f _o < 2 kHz	2 kHz ≤ f _o ≤ 8 kHz	f _o > 8 kHz
2.0–6.2	-40 dBc	-50 dBc	-65 dBc
6.2–12.4	-34 dBc	-44 dBc	-59 dBc
12.4–18	-30 dBc	-40 dBc	-55 dBc

Except Option 003 Instruments (400 Hz operation)

Carrier(F _c) Frequency Range (GHz)	Power Line Related and Spurious Levels At Frequency Offset (f _o) From Carrier (F _c)		
	f _o < 300 Hz	300 Hz ≤ f _o ≤ 1 kHz	f _o > 1 kHz
2.0–6.2	-50 dBc	-60 dBc	-65 dBc
6.2–12.4	-44 dBc	-54 dBc	-59 dBc
12.4–18.0	-40 dBc	-50 dBc	-55 dBc

Single-Sideband Phase Noise (1 Hz BW, CW mode):

Frequency Range (GHz)	SSB Phase Noise Ratio (in 1 Hz BW, CW mode) at Specified Offset Frequency*				
	10 Hz	100 Hz	1 kHz	10 kHz	100 kHz
2.0–6.2	-60 dB	-68 dB	-78 dB	-89 dB	-109 dB
6.2–12.4	-54 dB	-62 dB	-72 dB	-83 dB	-103 dB
12.4–18.0	-50 dB	-58 dB	-68 dB	-79 dB	-99 dB

*dB referenced to carrier (dBc)

¹ Reference is kept at operating temperature in STAND-BY mode with the instrument connected to Mains power. For instruments disconnected from Mains power less than 24 hours, the aging rate is $< 5 \times 10^{-10}$ /day after a 24 hour warmup.

² Overall accuracy of the internal reference oscillator is a function of time base calibration \pm aging rate \pm temperature effects \pm line voltage effects. Typical temperature and line voltage effects are $< 1 \times 10^{-10}$ /°C and $< 5 \times 10^{-10}$ /+5% -10% line voltage change.

³ Stability and spectral purity will be partially determined by characteristics of external reference oscillator.

⁴ External FM signals at rates < 100 kHz must be disconnected.

Table 1-1. Specifications (2 of 4)

RF OUTPUT CHARACTERISTICS

Level: +3 to -120 dBm, +15°C to +35°C^{5,6}

Total Indicated Meter Accuracy (+15°C to +35°C):^{7, 8, 9}

Frequency Range (GHz)	Indicated Meter Accuracy at OUTPUT LEVEL RANGE Switch Setting			
	0 dBm (No Attenuation)	-10 dBm	-20 dBm	-30 dBm and Below
2.0-6.2	± 1.75 dB	±2.25 dB	±2.45 dB	± 1.75 dB ±0.3 dB/10 dB step below 0 dBm range
6.2-12.4	± 2.0 dB	±2.5 dB	±2.7 dB	± 2.0 dB ±0.3 dB/10 dB step below 0 dBm range
12.4-18.0	±2.25 dB	±2.85 dB	±3.05 dB	±2.25 dB ±0.4 dB/10 dB step below 0 dBm range

Remote Programming Accuracy^{7, 8}: 0.75 dB better than meter accuracy indicated above.

Flatness (0 dBm range, +15°C to +35°C)^{7,9}: ±0.75 dB, 2.0-6.2 GHz
 ±1.00 dB, 2.0-12.4 GHz
 ±1.25 dB, 2.0-18.0 GHz

Output Level Switching Time: < 20 ms^{7,10}.

Impedance: 50 ohms

Source SWR:¹¹ <2.5

⁵ Additional power available on +10 dBm range (overrange), but for power settings above +3 dBm spurious oscillations may degrade performance.

⁶ For Option 001 instruments, RF output level specification changes to +5 to -10 dBm from +15 to +35°C; for Option 004, +2.0 dBm max.; Option 005, +4 to -10 dBm from +15 to +35°C.

⁷ Applies for internal leveling only.

⁸ Specification includes allowances for meter accuracy (typically ±0.50 dB), detector linearity, temperature, flatness, attenuator accuracy and measurement uncertainty. All but the attenuator accuracy and the measurement error can be calibrated out with a power meter at fixed vernier settings.

⁹ For Option 004 and 005 instruments, total indicated meter accuracy and flatness are degraded by an additional ±0.25 dB.

¹⁰ Typically < 10 ms for any change on same output level range.

¹¹ On the 0 dBm and -10 dBm output level range, specification applies only at the RF output frequency.

Table 1-1. Specifications (3 of 4)

AMPLITUDE MODULATION CHARACTERISTICS

Depth (for meter readings 0 dBm and below, +15°C to +35°C):¹²

- 0-75% from 2.0-6.2 GHz
- 0-60% from 6.2-12.4 GHz
- 0-50% from 12.4-18.0 GHz

Rates (3 dB bandwidth):

10 Hz-100 kHz.

Frequency Response (100 Hz-10 kHz rates):

± 0.25 dB.

Sensitivity (percent AM per Vpk):

30%/V and 100%/V ranges. Maximum input 1 Vpk into 600 ohms nominal.¹³

Distortion (for rates less than 10 kHz and meter readings 0 dB and below, +15°C to +35°C):

- <3% at 30% depth
- <4% at 50% depth
- <5% at 75% depth

Indicated Meter Accuracy (100 Hz-10 kHz rates): ±5% of range.

Accuracy Relative to EXT AM Input Level (100 Hz-10 kHz rates): ±10% of range.

Incidental φM (Rates ≤ 10 kHz, 30% Depth):

- < 0.5 Rad, 2.0-6.2 GHz
- < 1.5 Rad, 6.2-12.4 GHz
- < 1.0 Rad, 12.4-18.0 GHz

Incidental FM:

Incidental φM x f_{mod}.

FREQUENCY MODULATION CHARACTERISTICS

Peak Deviation (maximum): The smaller of 10 MHz or f_{mod} x 5, 2.0-6.2GHz; 10 MHz or f_{mod} x 10, 6.2-12.4 GHz; 10 MHz or f_{mod} x 15, 12.4-18.0 GHz

Rates (3 dB bandwidth typical): 30, 100 kHz/V ranges, 50 Hz to 10 MHz; 300 kHz/V and 1, 3, 10 MHz/V ranges, 1 kHz to 10 MHz.

Frequency Response (relative to 100 kHz rate):

- ±2.0 dB, 100 Hz-3 MHz, 30 and 100 kHz/V ranges.
- ±2.0 dB, 3 kHz-3 MHz, 300 kHz/V and 1, 3, 10 MHz/V ranges.

Sensitivity (peak deviation per Vpk):

30, 100, 300 kHz/V and 1, 3, 10 MHz/V ranges, maximum input 1 Vpk into 50 ohms nominal.¹⁴

Harmonic and Non-Harmonic Distortion:¹⁵ <12% for rates < 3 kHz, decreasing linearly with frequency to 5% at 20 kHz rate. < 5% for 20 to 100 kHz rates.

Residual FM in FM and CW Modes (noise and power line related)¹⁶:

Mode/Range	Residual FM in Post Detection Bandwidth	
	20 Hz-1 kHz	20 Hz-3 kHz
CW and 30 kHz/V thru 3 MHz/V ranges	6 Hz-rms	12 Hz-rms
10 MHz/V range	10 Hz-rms	20 Hz-rms

Indicated Meter Accuracy (at 100 kHz rate):¹⁷

- ±10% of full scale at +15°C to +35°C.
- ±15% of full scale at 0 to +55°C.

Accuracy Relative to External Input Level (at 100 kHz rate):¹⁷ ±7% of range at +15°C to +35°C

±10% of range at 0 to +55°C.

Incidental AM (rates ≤100 kHz, peak deviation ≤1 MHz): < 10%.

¹² The meter reading of output power level when using AM is carrier level only (i.e., does NOT include power in AM sidebands).

¹³ 1.0V peak gives maximum depth on each range. AM depth is linearly controlled by varying input level between 0 and 1 Vpk.

¹⁴ 1 Vpk gives maximum deviation on each range. Peak deviation is linearly controlled by varying input level between 0 and 1 Vpk.

¹⁵ For certain FM modulating frequencies, spurious FM signals (non-harmonic distortion) may occur. After demodulation in an external FM discriminator, the contribution to distortion of these spurious FM signals is typically less than 0.6%.

¹⁶ Residual FM doubles in 6.2-12.4 GHz range; triples in 12.4-18.0 GHz range.

¹⁷ For FM rates other than 100 kHz, add FM frequency response specification.

Table 1-1. Specifications (4 of 4)

REMOTE PROGRAMMING CHARACTERISTICS	
<p>Frequency: Programmable over full range (up to 18.599 997 GHz) with same resolution as in manual mode.</p> <p>Output Level: Programmable in 1 dB steps, +3 to -120 dBm, plus the 10 dB of overrange.</p>	<p>AM Modulation: OFF, 30%/Vpk, and 100%/Vpk ranges.</p> <p>FM Modulation: OFF; 30, 100, 300 kHz/Vpk; 1, 3, 10 MHz/Vpk ranges.</p> <p>Other: RF ON, RF OFF, ALC INT, ALC EXT XTAL, ALC EXT, PWR MTR.</p> <p>Programming Format: HP-IB (Hewlett-Packard Interface Bus).</p>
GENERAL CHARACTERISTICS	
<p>Operating Temperature Range: 0° to 55°C.</p> <p>Leakage: Meets radiated and conducted limits of MIL-I-6181D.</p>	<p>Power: 100, 120, 220, or 240V, +5%, -10% 48-66 Hz 300 VA maximum.</p> <p>Net Weight: 27.2 kg (60 lb).</p> <p>Dimensions: 600 mmD x 425 mmW x 133 mmH (23-5/8" x 16-3/4" x 5-1/4").</p>

1-20. DESCRIPTION

1-21. The HP Model 8672A Synthesized Signal Generator has a frequency range of 2000 to 18 000 MHz. The output is leveled and calibrated from +3 to -120 dBm. AM and/or FM modulation modes can be selected. The frequency, output level, modulation modes, and most other modes or functions can be remotely controlled using the HP-IB programming format.

1-22. Frequency

1-23. Frequencies from 2000 to 18 000 MHz (overrange to 18 599.997 MHz) can be tuned from the front panel. Minimum resolution is 1 kHz from 2000 to 6199.999 MHz, 2 kHz from 6200 to 12 399.998 MHz and 3 kHz from 12 400.002 to 18 000 MHz. Tuning resolutions of 100 MHz, 1 MHz, 10 kHz, or 1 kHz minimum are selected by front panel pushbuttons.

1-24. Frequency stability is dependent on the time base, either an internal or external oscillator. The internal crystal oscillator operates at 10 MHz while an external oscillator must operate at 5 or 10 MHz. The heart of the Synthesizer, a YIG tuned oscillator (YTO), is phase-locked to the time base oscillator.

1-25. Output Level

1-26. The output of the Synthesizer is exceptionally flat due to the action of the internal auto-

matic leveling control (ALC) loop. The accuracy of the total indicated output level (the sum of the front panel meter reading and the attenuator range) is increased.

1-27. The OUTPUT LEVEL VERNIER controls the output level as indicated by the front panel meter (+3 to -10 dB). The OUTPUT LEVEL RANGE switch sets the attenuation of the output level in twelve 10 dB steps (0 to -110 dBm). The +10 dBm range (overrange) is also controlled by the OUTPUT LEVEL RANGE switch.

1-28. Modulation Modes

1-29. AM and FM modes are possible with externally generated modulation signals. AM depth and FM peak deviation are linearly controlled by the external input voltage up to 1.0 volt-peak maximum.

1-30. Useable AM depths up to 50% can be set using the front panel meter across the entire frequency range. Usable depths to 60% can be set below 12 400 MHz; to 75% below 6200 MHz. Usable modulation rates lie between 10 Hz and 100 kHz.

1-31. FM peak deviation can be set using the front panel meter. At output frequencies below 6200 MHz, peak deviation is limited to 10 MHz or five times the modulation frequency, whichever

is lower. From 6200 to 12 400 MHz, peak deviation is limited to the lesser of 10 MHz or ten times the modulation frequency; from 12 400 to 18 000 MHz the lesser of 10 MHz or fifteen times the modulation frequency. Usable modulation rates fall between 50 Hz and 10 MHz. Six ranges of deviation sensitivity are switch selectable.

1-32. Miscellaneous Outputs and Indicators

1-33. The front panel meter indicates output level, AM depth, or FM peak deviation. The meter mode is selected by a front panel switch.

1-34. External leveling is selected by a front panel switch. A power meter or crystal detector may be used as the leveling loop detector.

1-35. Phase-locked reference outputs of 10 and 100 MHz are available on the rear panel.

1-36. Six front panel status indicators make the Synthesizer operation easier and aids in reducing possible operator error.

1-37. Remote Operation

1-38. The Synthesizer is fully programmable via the Hewlett-Packard Interface Bus. In the remote mode all front panel controls are disabled except the LINE and METER MODE switches.

1-39. The output level is selected in 1 dB steps. The programmed output level is more accurate than can be obtained in the local mode. This occurs because the output level is set by programming rather than being set by monitoring the meter reading. The meter reading may be in error due to meter nonlinearity.

1-40. OPTIONS

1-41. Electrical Options

1-42. **Option 001.** The RF Output connector is mounted on the front panel but the internal attenuator is omitted. The specified output level is +5 to -10 dBm.

1-43. **Option 002.** The internal 10 MHz crystal reference is omitted.

1-44. **Option 003.** A special fan allows operation from 400 Hz power Mains.

1-45. **Option 004.** The Synthesizer's RF output connector is located on the rear panel. Maximum output power is +2.0 dBm. Total indicated level accuracy and flatness is degraded by ± 0.25 dB.

1-46. **Option 005.** The Synthesizer's RF output connector is located on the rear panel and the attenuator is omitted. The specified output power is +4.0 to -10 dBm. Total indicated level accuracy and flatness is degraded by ± 0.25 dB.

1-47. Mechanical Options

1-48. The following options may have been ordered and received with the Synthesizer. If they were not received with the original shipment and are now required, they must be ordered from your nearest Hewlett-Packard office using the part number included in each of the following paragraphs.

1-49. **Chassis Slide Mount Kit.** This kit is extremely useful when the Synthesizer is rack mounted. Access to internal circuits and components, or the rear panel is possible without removing the Synthesizer from the rack. Order HP part number 1494-0017. When this kit comes with the Synthesizer, it is identified as Option 006.

1-50. **Front Handle Kit.** Ease of handling is increased with the front panel handles. Order HP part number 5061-0089.

1-51. **Rack Flange Kit.** The Synthesizer can be solidly mounted to the instrument rack using this kit. Order HP part number 5061-0077.

1-52. **Rack Flange and Front Handle Combination Kit.** This kit is not a front handle kit and rack flange kit packaged together. The combination is made up of a unique part which includes both functions. Order HP part number 5061-0083.

1-53. COMPATIBILITY

1-54. The Synthesizer is compatible with HP-IB as indicated by the following code: AH1, C0, DC1, DT0, L4, LE0, PP2, RL2, SH1, SR1, T6 and TE0. An explanation of the compatibility code may be found in the IEEE Standard 488-1975, "IEEE Standard Digital Interface for Programmable Instrumentation."

1-55. For more detailed information relating to programmable control of the Synthesizer, refer to Section III in this manual.

1-56. SELECTING THE HP-IB ADDRESS

1-57. The HP-IB address switches are located within the Synthesizer. The switches represent a two-digit octal number. This number corresponds to talk and listen address characters which an HP-IB

controller is capable of generating. A table in Section II shows all HP-IB talk and listen addresses. Refer to the paragraph entitled HP-IB Address and Parallel Poll Response Selection in Section II.

1-58. ACCESSORIES SUPPLIED

1-59. The accessories supplied with the Synthesizer are shown in Figure 1-1.

a. The line power cable may be supplied in several combinations of plugs. Refer to Power Cables in Section II.

b. Fuses with a 3.0A rating for 100/120 Vac (HP 2110-0003) and a 1.5A rating for 220/240 Vac (HP 2110-0043) are supplied. One fuse is factory installed according to the voltage available in the country of destination. Refer to Line Voltage Selection in Section II.

c. There are four extender boards supplied which aid in performance testing, adjusting, and troubleshooting the instrument.

1. One 30-pin (15 x 2) extender board, HP part number 08672-60117.
2. Two 36-pin (18 x 2) extender boards, HP part number 08672-60020.
3. One 3-section, 30-pins (15 x 2) per section, extender board, HP part number 08672-60016 (for use in the A2 Assembly).

1-60. EQUIPMENT REQUIRED BUT NOT SUPPLIED

1-61. For Option 002 instruments which lack an internal frequency standard, an external reference must be used. The performance of the external reference should at least match the specifications and, in particular, the frequency accuracy¹ and spectral purity of the HP Model 10544C Crystal Oscillator. When using an external oscillator, microphonics or line related spurious signals may increase.

1-62. An external signal source is required if amplitude or frequency modulation is desired. For AM, the source should have a variable output of 0 to 1 Vpk into 600 ohms, modulation rates up to 100 kHz, and distortion of <1%. For FM, the source should have a variable output of 0 to 1 Vpk into 50 ohms, modulation rates up to 10 MHz, and distortion of <1%. The HP 651B and 654A function generators are adequate for modulating the Synthesizer and meet the stated requirements.

1-63. A remotely programmable audio source would be convenient for full remote control of modulation levels and rates.

1-64. EQUIPMENT AVAILABLE

1-65. The Synthesizer has an HP-IB interface and can be used with any HP-IB compatible computing controller or computer for automatic systems applications.

1-66. The 11712A Support Kit is available to aid the user in maintaining and servicing the Synthesizer. It consists of cables, adaptors, terminations, prerecorded programs, extender boards and a test extender board.

1-67. The prerecorded programs are on tape cassettes and are for use with the HP 9830A Computing Controller. The Output Register Test Board is intended to aid in troubleshooting the frequency control circuits.

1-68. Refer to the 11712A Support Kit operating manual for additional information. It may be ordered through your nearest Hewlett-Packard office.

1-69. RECOMMENDED TEST EQUIPMENT

1-70. Table 1-2 lists the test equipment and accessories recommended for use in testing, adjusting, and servicing the Synthesizer. If any of the recommended equipment is unavailable, instruments with equivalent minimum specifications may be used.

¹ Frequency Accuracy: needed 1 ppm; minimum requirement 10 ppm.

Table 1-2. Recommended Test Equipment (1 of 3)

Instrument	Critical Specifications	Recommended Model	Use*
Adapter (2 required)	APC-7 to Type-N Male Frequency Range: 2-18 GHz	HP 11525A	P
Amplifier, 40 dB	Frequency Range, 5 Hz to 10 kHz Gain: 40 dB (x100) into open circuit	HP 465A	P
Analyzer, Logic State	8-bit display Triggerable	HP 1601A	T
Analyzer, Spectrum	Frequency response: to 40 kHz Bandwidth: 1 Hz minimum Frequency Span Per Division: 5 Hz minimum Amplitude Range: 0 to -70 dB	HP 3580A	P
Analyzer, Spectrum	Frequency Range: 10 kHz-100 MHz Frequency Span: 0.1-100 MHz Resolution Bandwidth: 30 Hz-300 kHz Amplitude Range: +10 to -90 dBm Vertical Sensitivity: 2 dB per division minimum	HP 8553B/8552B/141T	A,T
	Frequency Range: 1 kHz-200 kHz Frequency Span: 0-50 kHz	HP 8556A	P,A,T
	Frequency Range: 2-18 GHz Frequency Span: 50 kHz to 200 MHz per division Resolution Bandwidth: 30 Hz-300 kHz Amplitude Range: +10 to -90 dBm Vertical Sensitivity: 2 dB per division minimum	HP 8565A	P,A,T
Attenuator	3 dB 10 dB	HP 8491A, Opt.003 HP 8491A, Opt.010	A P
Cable, Semi-rigid	50Ω 3.6 mm (0.141") diameter with compatible SMA connector	Locally fabricated	P
Cable, HP-IB Interconnect	HP-IB Compatible	HP 10631A	P,A,T
Cable, Special Interconnect	Special (see Figure 1-3)	Locally fabricated	A
Controller, HP-IB	HP-IB Compatible	HP 9830A	P,A,T
Counter, Frequency	Range: 20 kHz to 18 GHz range Resolution: 10 Hz	HP 5340A	P,A,T
Coupler, Directional	24 dB directivity minimum, 2 to 18 GHz	HP 11691D	P,T
* P = Performance Testing, A = Adjustments, T = Troubleshooting			

Table 1-2. Recommended Test Equipment (2 of 3)

Instrument	Critical Specifications	Recommended Model	Use*
Current Probe, AC	Frequency Range: 2–35 MHz	HP 1110A	A
Detector, Crystal	Type-N connector, 2–18 GHz range	HP 8470B, Opt. 012	P,A,T
Discriminator, FM	RF Input: 10 kHz to 10 MHz Audio Frequency Response: to 1 MHz Sensitivity: 0.01V	HP 5210A	P
Low Pass Filters	1 MHz — Butterworth 10 kHz — Butterworth	Included with HP 5210A Included with HP 5210A	P P
Shorting Board		Included with HP 5210A	P
Filter, Low Pass	1 kHz Butterworth, 50 ohms Connectors: BNC male/BNC female	CIR-Q-TEL FLT/21B-1K-5/50-3A/4B	P
	3 kHz Butterworth, 50 ohms Connectors: BNC male/BNC female	CIR-Q-TEL FLT/21B-3K-5/50-3A/3B	P
	15 kHz Special (see Figure 1-2)	Locally fabricated	P
Mixer, Double Balanced	2–18 GHz response	RHG DM1-18	P,A
Oscillator, Sweep	Center Frequency: 150–200 MHz Center Frequency Resolution: 0.1 MHz Sweep Range: 10 and 200 MHz	HP 86220A/8620C	A
Oscillator, Test	Level: 1 Vpk minimum Range: 10 kHz to 1 MHz	HP 651B	P,A,T
Oscilloscope	Vertical Amplifier response: Dc to 50 MHz Vertical Amplifier Sensitivity: 0.05 to 0.5V/ division Dual Channel External Triggering Horizontal Input	HP 180C/1801A/1821A	P,A,T
	Storage	HP 181A	P
Divide-by-10 Probe	Compatible with 1801A	HP 10001A	A
Pads, Foam (2 required)	43 x 58 cm (17 x 23 inches) 5 cm (2 in.) thick		P
Power Meter	Frequency Range: 2–18 GHz Accuracy: ± 0.2 dB Range: +17 to –25 dBm into 50 ohms	HP 436A/8481A	P,A,T
	Range: –20 dBm to –60 dBm into 50 ohms	HP 8484A	P
Resistor	100 Ω	HP 0698-7212	P
* P = Performance Testing, A = Adjustments, T = Troubleshooting			

Table 1-2. Recommended Test Equipment (3 of 3)

Instrument	Critical Specifications	Recommended Model	Use*
Short	APC-7	HP 11565A	P
Signal Generator, Synthesized	RF Source: 2-18 GHz phase locked Frequency Resolution: 1 kHz Maximum Output: +7 dBm minimum at specific frequencies	HP 8672A	P,A
Signal Generator, RF	-5 to -20 dBm at 240 MHz	HP 8654A	A
Standard, Frequency	Long Term Stability: $<1 \times 10^{-10}$ /24 hours	HP 5065A	P
Supply, Power	0 to -40 Vdc	HP 6202B	A
Termination, Feedthru	50Ω connectors: BNC male/BNC female 600Ω connectors: BNC male/BNC female	HP 11048C HP 11095A	P,T P,A,T
Termination	50Ω 50Ω; APC-7	HP 1250-0207 HP 909A Opt. 12	A P
Voltmeter, Digital	Range: +22 to -40 Vdc; 0 to 1 Vrms Resolution: 0.001 Vdc; 1 μVrms Frequency Response: 100 kHz minimum	HP 3455A	P,A,T
Voltmeter, AC	Range: +10 to -60 dB Frequency Response: 1-50 kHz	HP 400E	A,T
Voltmeter, RMS	Range: to 100 mVrms Resolution: 0.01 mVrms Frequency Response: to 10 kHz	HP 3400A	P

*P = Performance Testing, A = Adjustments, T = Troubleshooting

Figure 1-3. Special Interconnect Cable

SECTION II INSTALLATION

2-1. INTRODUCTION

2-2. This section provides the information needed to install the Synthesizer. Included is information pertinent to initial inspection, power requirements, line voltage selection, power cables, interconnection, environment, instrument mounting, storage and shipment.

2-3. INITIAL INSPECTION

WARNING

To avoid hazardous electrical shock, do not perform electrical tests when there are signs of shipping damage to any portion of the outer enclosure (covers, panels, meters).

2-4. Inspect the shipping container for damage. If the shipping container or cushioning material is damaged, it should be kept until the contents of the shipment have been checked for completeness and the instrument has been checked mechanically and electrically. The contents of the shipment should be as shown in Figure 1-1. Procedures for checking electrical performance are given in Section IV. If the contents are incomplete, if there is mechanical damage or defect, or if the instrument does not pass the electrical performance test, notify the nearest Hewlett-Packard office. If the shipping container is damaged, or the cushioning material shows signs of stress, notify the carrier as well as the Hewlett-Packard office. Keep the shipping materials for the carrier's inspection.

2-5. PREPARATION FOR USE

2-6. Power Requirements

2-7. The Synthesizer requires a power source of 100, 120, 220, or 240 Vac, +5% to -10%, 48 to 60 Hz single phase (for Option 003 instruments, 400 Hz single phase and 120 Vac, +5%, -10% only). Power consumption is approximately 300 volt-amperes.

WARNINGS

This is a Safety Class I product (provided with a protective earthing terminal). An uninterruptible safety earth

ground must be provided from the main power source to the product input wiring terminals, power cord, or supplied power cord set. Whenever it is likely that the protection has been impaired, the product must be made inoperative and be secured against any unintended operation.

If this instrument is to be energized via an autotransformer for voltage reduction, make sure the common terminal is connected to the earthed pole of the power source.

2-8. Line Voltage and Fuse Selection

CAUTION

BEFORE PLUGGING THIS INSTRUMENT into the Mains (line) voltage, be sure the correct voltage and fuse have been selected.

Figure 2-1. Line Voltage and Fuse Selection

2-9. Verify that the line voltage selection card and the fuse are matched to the power source. Refer to Figure 2-1, Line Voltage and Fuse Selection.

2-10. Power Cable

WARNING

BEFORE CONNECTING THIS INSTRUMENT, the protective earth terminals of this instrument must be connected to the protective conductor of the (Mains) power cord. The Mains plug shall only be inserted in a socket outlet provided with a protective earth contact. The protective action must not be negated by the use of an extension cord (power cable) without a protective conductor (grounding).

2-11. This instrument is equipped with a three-wire power cable. When connected to an appropriate ac power receptacle, this cable grounds the instrument cabinet. The type of power cable plug shipped with each instrument depends on the country of destination. Refer to Figure 2-2 for the part numbers of the power cable available.

2-12. HP-IB Address and Parallel Poll Response Selection

2-13. In the Synthesizer, the HP-IB talk and listen addresses and the parallel poll sense and response line are switch selectable. The following procedure explains how the switches are to be set. Refer to Table 2-1 for a listing of the talk and listen address.

2-14. To change the HP-IB address or to select a different parallel poll response, the top cover of the Synthesizer and the internal A2 Assembly's cover must be removed.

- a. Disconnect the line (Mains) power cable.
- b. Remove any HP-IB cables or connectors from the HP-IB connector.
- c. Remove the Synthesizer's top cover and the A2 Assembly's protective cover. Refer to the Disassembly and Reassembly Procedures in Section VIII.
- d. If the parallel poll sense or response switches are to be changed, remove the A2A9 Board Assembly.
- e. Select the new address as shown in Table 2-1. The location of the switches are shown on

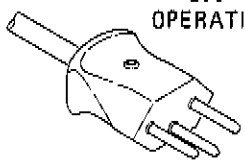

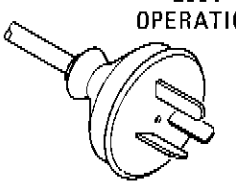

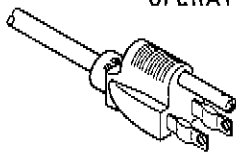

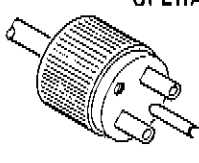

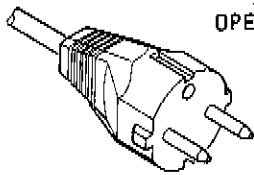

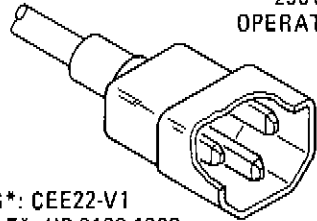

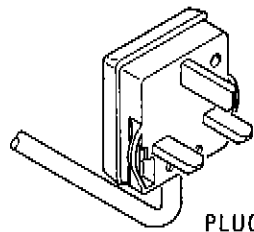

<p>250V OPERATION</p>  <p>PLUG*: SEV 1011.1959-24507 TYPE 12 CABLE*: HP 8120-2104</p>	<p>250V OPERATION</p>  <p>PLUG*: NZSS 198/AS C112 CABLE*: HP 8120-1369</p>	<p>125V OPERATION</p>  <p>PLUG*: NEMA 5-15P CABLE*: 8120-1378</p>	<p>250V OPERATION</p>  <p>PLUG*: NEMA G-15P CABLE*: HP 8120-0698</p>

<p>*The number shown for the plug is the industry identifier for the plug only. The number shown for the cable is an HP part number for a complete cable including the plug.</p>			

Figure 2-2. Power Cable and Mains Plug Part Numbers

HP-IB Address and Parallel Poll Response Selection (cont'd)

Figure 2-3. The HP-IB ADDRESS SELECT switch settings (for S2 and S3) are in the octal code. For example, the factory selected addresses are set to 23 (binary 01 011; equivalent to bits b5 through b1 on the table). Therefore, the listen address is '3' and the talk address is 'S'.

f. The PARALLEL POLL SENSE switch (S4) is set to either the OFF, 0 (zero) or 1 (one) position. In the zero position, the less positive level indicates an affirmative response to the poll.

g. The PPR (Parallel Poll Response) switch (S1) is set to select one-of-eight lines (one of 1 through 8). The selected line passes the Synthesizer's response to the parallel poll to the HP-IB controller.

h. Re-install the A2A9 Assembly.

i. Replace the A2 Assembly's internal cover and the Synthesizer's top cover.

j. Connect the line (Mains) power cable to the Line Power Module; connect the HP-IB cable to the HP-IB connector.

2-15. Interconnections

2-16. Interconnection data for the Hewlett-Packard Interface Bus is provided in Figure 2-4.

2-17. Mating Connectors

2-18. **Interface Connector.** The HP-IB mating connector is shown in Figure 2-4.

2-19. **Coaxial Connectors.** Coaxial mating connectors used with the Synthesizer should be 50-ohm Type-N male connectors that are compatible with those specified in US MIL-C-39012.

2-20. Operating Environment

2-21. The operating environment should be within the following limitations:

Temperature	0°C to +55°C
Humidity	< 95% relative
Altitude	< 4570 metres (15 000 feet)

NOTE

RF Output accuracy, flatness and maximum power will meet specifications only between 15 and 35°C.

2-22. Bench Operation

2-23. The instrument cabinet has plastic feet and fold-away tilt stands for convenience in bench operation. (The plastic feet are shaped to ensure self-aligning of the instruments when stacked.) The tilt stands raise the front of the instrument for easier viewing of the control panel.

Figure 2-3. Location of HP-IB Address and Parallel Poll Switches

Logic Levels

The Hewlett-Packard Interface Bus logic levels are TTL compatible, i.e., the true (1) state is 0.0 Vdc to +0.4 Vdc and the false (0) state is +2.5 Vdc to +5.0 Vdc.

Programming and Output Data Format

Refer to Section III, Operation.

Mating Connector

HP 1251-0293; Amphenol 57-30240.

Mating Cables Available

HP 10631A, 0.9 metres (3 ft.), HP 10631B, 1.8 metres (6 ft.)
 HP 10631C, 3.7 metres (12 ft.)

Cabling Restrictions

1. A Hewlett-Packard Interface Bus System may contain no more than 1.8 metres (6 ft.) of connecting cable per instrument.
2. The maximum accumulative length of connecting cable for any Hewlett-Packard Interface Bus System is 20.0 metres (65.6 ft.)

2-24. Rack Mounting

WARNING

The Synthesizer is heavy for its size (27.2 kg, 60 lb). Care must be exercised when lifting to avoid personal injury. Use equipment slides when rack mounting.

2-25. Rack Mounting information is provided with the rack mounting kits. If the kits were not ordered with the instrument as options, they may be ordered through the nearest Hewlett-Packard

office. Refer to the paragraph entitled Options in Section I.

2-26. STORAGE AND SHIPMENT

2-27. Environment

2-28. The instrument should be stored in a clean dry environment. The following environmental limitations apply to both storage and shipment:
 Temperature -55°C to +75°C
 Humidity < 95% relative
 Altitude < 15 300 metres (50 000 feet)

2-29. Packaging

2-30. Original Packaging. Containers and materials identical to those used in factory packaging are available through Hewlett-Packard offices. If the instrument is being returned to Hewlett-Packard for servicing, attach a tag indicating the type of service required, return address, model number, and full serial number. Also mark the container **FRAGILE** to assure careful handling. In any correspondence refer to the instrument by model number and full serial number.

2-31. Other Packaging. The following general instructions should be used for re-packaging with commercially available materials:

a. Wrap the instrument in heavy paper or plastic. (If shipping to a Hewlett-Packard office or

service center, attach a tag indicating the service required, return address, model number, and full serial number.)

b. Use a strong shipping container. A double-wall carton made of 2.4 MPa (350 psi) test material is adequate.

c. Use enough shock-absorbing material (75 to 100 mm layer; 3 to 4 inches) around all sides of instrument to provide firm cushion and prevent movement in the container. Protect the control panel with cardboard.

d. Seal the shipping container securely.

e. Mark the shipping container **FRAGILE** to assure careful handling.

SECTION III OPERATION

3-1. INTRODUCTION

3-2. This section explains how to operate the Synthesizer. Included in this section are descriptions of all front and rear panel controls, connectors and indicators, operator's checks, operating instructions, and operator's maintenance.

3-3. Local operating instructions begin with paragraph 3-10. Remote operation with the Hewlett-Packard Interface Bus (HP-IB) is explained beginning with paragraph 3-16.

3-4. PANEL FEATURES

3-5. The front and rear panel features of the Synthesizer are shown in Figures 3-1 and 3-2 and are described in Tables 3-1 and 3-2. The tables contain detailed descriptions of the controls, connectors, and indicators.

3-6. OPERATOR'S MAINTENANCE

3-7. The only maintenance the operator should normally perform is the replacement of the primary power fuse (F1) located in the Line Power Module Assembly ⑨ (A3A11) shown in Figure 3-2 and the mechanical zero adjustment ⑳ of the meter shown in Figure 3-1. For instructions on how to change the fuse, refer to Section II, Line Voltage Selection.

3-8. Mechanical Meter Zeroing

3-9. To mechanically zero the front panel meter ② (see Figure 3-1), set the LINE switch ⑫ to the STANDBY position and place the Synthesizer in its normal operating position. Turn the mechanical zeroing adjustment clockwise to move the needle up scale or counter-clockwise to move the needle down scale. The zero point is located at the left end of the 0-1 or the 0-3 scales. DO NOT zero on the left end of the top dB scale at -10 as this is not the proper zeroing point.

3-10. LOCAL OPERATION

WARNINGS

Before the instrument is switched on, all protective earth terminals, extension

cords, auto-transformers and devices connected to it should be connected to a protective earth grounded socket. Any interruption of the protective earth grounding will cause a potential shock hazard that could result in personal injury.

Only fuses with the required rated current and specified type should be used. Do not use repaired fuses or short circuited fuseholders. To do so could cause a shock or fire hazard.

CAUTION

Before the instrument is switched on, it must be set to the voltage of the power source, or damage to the instrument may result.

3-11. A procedure for verifying the major functions of the Synthesizer is provided in Tables 3-3 and 3-4. The procedure is divided into two parts: Local Operator's Checks and Local Operating Instructions. The Local Operator's Checks should be performed first to verify proper operation of the Synthesizer. The Local Operating Instructions explain how to set and use the Synthesizer's controls.

3-12. LOCAL OPERATOR'S CHECK

3-13. Table 3-3 provides general instructions for checking the operation of the Synthesizer via the front and rear panel controls.

3-14. LOCAL OPERATING INSTRUCTIONS

3-15. Table 3-4 provides general instructions for operating the Synthesizer via the front and rear panel controls.

WARNING

Any interruption of the protective (grounding) conductor (inside or outside the instrument) or disconnecting the protective earth terminal is likely to make this instrument dangerous. Intentional interruption is prohibited.

FIG. 3-1
SWT 2 of 2

Figure 3-1. Front Panel Connectors, Controls, Switches, and Displays.

Table 3-1. Front Panel Features (1 of 2)

FRONT PANEL FEATURES

- 1** **RANGE dBm:** LED display indicates the sign and selected range of the RF output in 10 dB steps from -110 to +10 dBm. RANGE is determined by the setting of the OUTPUT LEVEL RANGE selector **24** or remotely programmed.
- 2** **Meter:** automatically ranges to one of three scales, read according to position of METER MODE selector **28**.
- LEVEL:** -10 to +3 dB scale indication. LEVEL is determined by the setting of the OUTPUT LEVEL VERNIER control **20** or remotely programmed and read relative to the RANGE dBm **1** level displayed.
- AM:** 0 to 3 scale is read 0 to 30% and the 0 to 1 scale is read 0 to 100% depending on the setting of the AM selector **15** and displayed by the AM annunciator **5**.
- FM:** 0 to 3 scale is read 0 to 0.03 MHz, 0 to 0.3 MHz, and 0 to 3 MHz; and the 0 to 1 scale read 0 to 0.1 MHz, 0 to 1.0 MHz, and 0 to 10 MHz. Depends on the position of the FM DEVIATION MHz selector **18** and is displayed by the FM annunciator **6**.
- 3** **RF annunciator:** ON-OFF indicates when the RF OUTPUT **26** is enabled or disabled, controlled by the RF switch **27** or remotely programmed.
- OVER RANGE:** indicates when the +10 dBm range is selected or remotely programmed.
- 4** **ALC annunciator:** indicates whether the ALC (Automatic Level Control) is INT (internal), external XTAL (crystal), or external MTR (Power Meter) as determined by the position of the ALC selector **17**. LEV UNCAL indicates an unlevelled output or an illegal range was programmed remotely (<-110 dBm).
- 5** **AM annunciator:** indicates OFF, 30%, or 100% modulation range as determined by the AM selector **15** or as remotely programmed.
- 6** **FM annunciator:** indicates OFF, 0.03, 0.1, 0.3, 1, 3, and 10 MHz deviation range for 1 Vpk. Deviation range is determined by the position of the FM DEVIATION MHz selector **18** or remotely programmed. OVER MOD indicates an input signal greater than 1 Vpk at the FM INPUT connector **16** or that the modulation index is greater than 5, 10, or 15 depending on the band.
- 7** **FREQUENCY MHz:** LED display indicates the selected frequency.
- 8** **Frequency Resolution Light Bars:** indicate the frequency tuning resolution selected by the FREQUENCY RESOLUTION keys **13**. The first light bar indicates 100 MHz resolution, the second indicates 1 MHz, the third indicates 10 kHz, and the fourth indicates 1 kHz resolution. The light bars to the left of the one selected will also light.
- 9** **STATUS Block:** annunciators display the internal conditions of the Synthesizer.
- OVEN:** when lit, indicates that the crystal oven is not up to operating temperature.
- OUT OF RANGE:** when lit, indicates an out of range (illegal) frequency has been remotely programmed.
- REMOTE:** when lit, indicates the Synthesizer is set to remote operation by an HP-IB controller.
- STANDBY:** when lit, indicates that power is applied but the LINE switch **12** is in the STANDBY position.
- NOT PHASE LOCKED:** indicates that one or more of the phase lock loops are unlocked or the RF switch **27** is in the OFF position.
- INTERNAL REF OFF:** when lit, indicates when the rear panel INT-EXT switch **27** (see Figure 3-2) is in the EXT position.
- HOLD key:** disables the TUNING control **14** on the front panel and extinguishes the Frequency Resolution Light Bars **8**.
- PRESET key (3 GHz):** sets frequency to 3 GHz and extinguishes the Frequency Resolution Light Bars **8**.

Table 3-1. Front Panel Features (2 of 2)

- 12 LINE switch:** applies power to the Synthesizer when set to the ON position; power is supplied to the crystal oven and the battery charger circuit in the STANDBY position.
- 13 FREQUENCY RESOLUTION pushbuttons:** selects tuning resolution in 100 MHz, 1 MHz, 10 kHz, or 1, 2, or 3 kHz steps (depending on the frequency selected). The HOLD switch **10** clears any frequency resolution selected.
- 14 TUNING control:** changes the Synthesizer's output frequency by the increments selected by the FREQUENCY RESOLUTION selectors **13**.
- 15 AM function switch:** selects OFF, 30%/V, or 100%V modulation by a signal applied to the AM INPUT connector **19**. The selected range is displayed on the AM annunciator **5**. Modulation percentage is read on the Meter **2** when the METER MODE selector **28** is set to AM. AM may be remotely programmed.
- 16 FM INPUT connector:** accepts a maximum 1 Vpk external modulation signal (50Ω source impedance). Deviation varies linearly with the input signal. Deviation ranges are controlled by the FM DEVIATION switch **18** or remotely programmed.
- 17 ALC switch:** selects either internal (INT) leveling, external crystal (XTAL), or external power meter (PWR MTR) leveling. The external leveling device (crystal or power meter) may have either a positive or negative output. The ALC selector can be remotely programmed.
- 18 FM DEVIATION MHz switch:** selects the meter scale and peak deviation that is obtained with a signal applied to the FM INPUT connector **16**. The peak deviation range is displayed on the FM annunciator **6** and the actual peak deviation is read from the selected scale on the Meter **2**. The FM DEVIATION MHz selector can be remotely programmed.
- 19 AM INPUT connector:** accepts a maximum 1 Vpk external modulation signal (600 ohm impedance). A 1 Vpk signal develops full scale modulation as selected by the AM selector **15** or as programmed remotely. Percent modulation varies linearly with the input signal.
- 20 OUTPUT LEVEL VERNIER:** adjusts the RF output level over the range of +3 to -10 dB, relative to the Output Level Range as read on the Meter **2**. The Vernier function is programmable in 1 dB steps.
- 21 EXT ALC INPUT connector:** accepts positive or negative leveling signals from either a power meter or crystal detector as selected by the ALC selector **17**.
- 22 Mechanical Meter Zero:** sets meter suspension so the Meter **2** indicates zero when power is removed from the Synthesizer and the Synthesizer is in its normal operating position.
- 23 CAL control:** adjusts the ALC gain to match the external leveling device in use. The CAL control must be returned to the fully clockwise position when the Synthesizer is returned to internal leveling.
- 24 OUTPUT LEVEL RANGE:** selects the RF output level range in 10 dB steps from +10 to -110 dBm. The selected range is displayed by the RANGE dBm LED readout **1**. The range may also be programmed remotely.
- 25 PEAK-NORM control:** generally left in the NORM detented position (fully clockwise). It is used to peak the RF output at a particular frequency in the band at the expense of power at other frequencies.
- 26 RF OUTPUT connector:** 50 ohm type-N female connector supplies the RF output over the entire frequency range of 2 to 18 GHz.
- 27 RF switch:** completely turns off the RF output when in the OFF position. This condition is displayed in the RF annunciator **3** and causes the NOT PHASE LOCKED annunciator in the STATUS Block **9** to illuminate. When the ON position is selected, the Synthesizer returns to normal operation. The functions of the RF switch are programmable.
- 28 METER MODE switch:** selects either LEVEL, AM, or FM to be displayed on the meter **2**.

Table 3-2. Rear Panel Features

- 1 **HP-IB CONNECTOR:** connects the Synthesizer to the Hewlett-Packard Interface Bus for remote operation. When in remote operation, the STATUS Block (see Figure 3-1) 9 REMOTE annunciator illuminates.
- 2 **100 MHz OUT (A3J7):** 0 dBm (nominal) into 50 ohms, can be used as an external timebase and for troubleshooting.
- 3 **RF OUT (A3J6):** only for Options 004 and 005, 50 ohm type N output connector (see Table 1-1 for Option information).
- 4 **10 MHz OUT (A3J8):** 0 dBm (nominal) into 50 ohms, can be used as an external timebase and for troubleshooting.
- 5 **FREQ. STANDARD Output (A3J9):** 10.000 MHz into 50 ohms at +7 dBm (nominal) from the internal frequency standard except when INT/EXT switch 6 is in the EXT position.
- 6 **FREQ STANDARD INT/EXT switch:** normally left in the INT position. Removes power from internal frequency standard when in the EXT position.
- 7 **Jumper (A3W3):** normally connects the Internal Frequency Standard Output (A3J9) to the External Frequency Standard Input (A3J10).
- 8 **FREQ STANDARD Input (A3J10):** normally connected by A3W3 to A3J9. Also used to connect an external frequency standard of 5 or 10 MHz at 0 dBm to the Synthesizer.
- 9 **Line Power Module:** permits operation from 100, 120, 220, or 240 Vac. The number visible in the window displays the nominal line (Mains) voltage for which the Synthesizer is set (see Figure 2-1). The protective grounding conductor connects to the Synthesizer through this module. The line power fuse (A3F1) is part of this module and is the only part to be changed by the operator.

Figure 3-2. Rear Panel Connectors, Switches, and Displays

Table 3-3. Local Operator's Checks (1 of 4)

INITIAL CONDITIONS

1. Check that the LINE switch **12** is in STANDBY and remove the power cable from the Line Power Module **9** (see Figure 3-2).
2. Check that Line Power Module **9** (see Figure 3-2) is set to the nominal line voltage to be used and that the fuse is the correct value and type.
3. Set the front panel controls and switches as follows:

15 AM selector	OFF
17 ALC selector	INT
18 FM DEVIATION MHz selector	OFF
20 OUTPUT LEVEL VERNIER control	fully ccw
24 OUTPUT LEVEL RANGE control	fully ccw
25 PEAK-NORM switch	NORM (detented)
27 RF switch	OFF
28 METER MODE selector	LEVEL
4. Set the rear panel controls and cables as follows:

6 FREQ STANDARD INT/EXT switch	INT
7 Jumper (A3W3)	Connects A3J9 to A3J10

OPERATION

1. Set the LINE switch **9** to ON and check for the following conditions:

1 RANGE dBm display	-110 dBm
3 RF annunciator	OFF
4 ALC annunciator	INT and LEV UNCAL
5 AM annunciator	OFF
6 FM annunciator	OFF
7 FREQUENCY MHz display	some frequency between 2-18.6 GHz (if frequency display is not stable, press PRESET (3 GHz) 11)
8 Frequency Resolution Light Bars	extinguished
9 STATUS annunciators	
OVEN	may be lit and will extinguish when the reference oscillator oven operating temperature is reached.
NOT PHASE LOCKED	illuminated
2. Press PRESET (3 GHz) key **11** and FREQUENCY display **7** should now indicate 3000.000 MHz.

Table 3-3. Local Operator's Checks (2 of 4)

OPERATION (Cont'd)

3. Press one at a time, the four FREQUENCY RESOLUTION keys **13** and the Frequency Resolution Light Bars **8** should light one at a time and remain lit. Rotate the TUNING control **14** clockwise and then counter-clockwise and note that the digits displayed in the FREQUENCY display **8** increase and then decrease in order as the TUNING control **14** is turned. Perform this step as each of the four FREQUENCY RESOLUTION keys **13** are pressed. The first key on the left produces resolution in 100 MHz steps, the second key 1 MHz steps, the third key 10 kHz steps, and the fourth key 1 kHz, 2 kHz, or 3 kHz steps, depending upon the frequency band. Pressing the fourth key first will cause all four of the Frequency Light Bars **8** to light and will produce the highest tuning resolution. Pressing the HOLD **10** pushbutton causes the Light Bars **8** to extinguish and prevents the TUNING control **14** from changing the frequency displayed.
4. Connect the microwave frequency counter to the Synthesizer as shown in Figure 3-3.
5. Set the RF switch **27** to ON. The ALC Block **4** annunciator LEV UNCAL should extinguish. If the STATUS Block **9** annunciator OVEN is extinguished, the NOT PHASE LOCKED annunciator should also extinguish. The Meter **2** should indicate -10 dB.

Figure 3-3. Operator's Frequency and Modulation Checks Test Setup

6. Turn the OUTPUT LEVEL RANGE control **24** clockwise through each of the thirteen positions (-110 to $+10$ dBm). At the 0 and $+10$ dBm positions and any other positions of interest, vary the OUTPUT LEVEL VERNIER control **20** from -10 to $+3$ dB. In the $+10$ dBm range, the VERNIER's range is specified only to $+3$ dBm output level but some Synthesizers may deliver more power. The RF Block **3** annunciator OVER RANGE lights when the $+10$ dBm range is selected. If the desired power cannot be produced, the ALC Block **4** annunciator LEV UNCAL is illuminated.

Table 3-3. Local Operator's Checks (3 of 4)

OPERATION (Cont'd)

7. Note the frequency on the FREQUENCY MHz display 7. Set the LINE switch 12 to the STANDBY position. The STATUS Block 9 annunciator STANDBY should light. Leave the Synthesizer in the standby condition for several seconds.
8. Set the LINE switch 12 to ON. The FREQUENCY MHz display 7 should display the same frequency as was displayed in step 7. The STATUS Block 9 annunciator STANDBY should extinguish.
9. Apply power to the test oscillator, set the frequency to 10 kHz and the output level to 0 Vrms. Connect the test setup as shown in Figure 3-3.
10. Set the METER MODE selector 28 to AM and the AM selector 15 to 100%. The AM annunciator 5 100% should be lit.
11. Increase the output of the test oscillator slowly from 0.0 to approximately 0.8 Vrms. As the Meter 2 approaches full scale, the ALC Block 4 annunciator LEV UNCAL should illuminate.
12. Set the AM selector 15 to OFF, reduce the test oscillator's output to 0 Vrms, and remove the cable from the AM INPUT connector 19.
13. Set the test oscillator's frequency to 100 kHz.
14. Set the METER MODE selector 28 to FM and the FM DEVIATION MHz selector 18 to 3. The FM annunciator 6 3 will light.
15. Increase the test oscillator's output from 0 Vrms to approximately 0.5 Vrms. The FM annunciator 6 OVERMOD will light when there is excessive deviation or an input signal greater than 1 Vpk.
16. Disconnect the test setup.
17. Set the ALC selector 17 to INT, METER MODE selector 28 to LEVEL, and the OUTPUT LEVEL RANGE control 24 to -10 dBm shown in the RANGE dBm display 1. Adjust the OUTPUT LEVEL VERNIER control 20 for 0 dB on the Meter 2. This will develop a -10 dBm level at the RF OUTPUT connector 26.
18. Set the RF switch 27 to OFF and the ALC selector 17 to PWR MTR. Connect a power meter and power sensor as shown in Figure 3-4. The Recorder Output from the power meter may be either positive or negative polarity.

NOTE

The HP Model 436A Power Meter must be set to RANGE HOLD mode for use in this test setup.

Table 3-3. Local Operator's Checks (4 of 4)

OPERATION (Cont'd)

19. Set the RF switch 27 to ON. Adjust the CAL control 23 for a steady indication of the Meter 2. This adjusts the loop gain and prevents unwanted oscillations. The ALC Block 2 annunciator LEV UNCAL lights when oscillations occur or the loop opens, causing unleveling to occur.
20. Set the RF switch 27 to OFF. Disconnect the power meter and power sensor.
21. Connect a crystal detector as shown in Figure 3-4. Set the ALC selector 17 to XTAL.

NOTE

The output voltage from the crystal detector may be either negative or positive polarity.

22. Set the RF switch 27 to ON and adjust the CAL control 23 for a steady indication on the Meter 2.
23. Set the RF switch 27 to OFF. Disconnect the test setup.

Figure 3-4. Operator's External ALC Checks Test Setup

Table 3-4. Local Operating Instructions (1 of 4)

SETTING FREQUENCY AND OUTPUT LEVEL

1. Be sure the Synthesizer is set to local. Make sure the internal reference is selected or an external reference is connected to A3J10.

2. Set front panel controls and switches to the following positions:
 - 12 LINE switch ON
 - 13 FREQUENCY RESOLUTION keys to resolution desired and displayed on Frequency Resolution Light Bars 8
 - 14 TUNING control to frequency desired as displayed on Frequency readout 7
 - 10 HOLD pushbutton press pushbutton, the frequency desired is not held
 - 24 OUTPUT LEVEL RANGE control 00 on RANGE dBm display 1
 - 27 RF switch ON
 - 20 OUTPUT LEVEL VERNIER control 0 dB on Meter 2

This sets a power level of 0 dBm at the RF OUTPUT connector 26 .

3. Set the OUTPUT LEVEL RANGE control 24 to indicate -10 dBm in the RANGE dBm display 1 . Adjust the OUTPUT LEVEL VERNIER control 20 to indicate -5 dB on the Meter 2 . This sets an output power level of -15 dBm at the RF OUTPUT connector 26 .

$$-10 \text{ dBm} + (-5 \text{ dB}) = -15 \text{ dBm}$$

The indication on the Meter 2 plus the reading on the RANGE dBm display 1 equals the power level at the RF OUTPUT connector 26 .

Table 3-4. Local Operating Instructions (2 of 4)

USING AN EXTERNAL STANDARD

1. On the rear panel (see Figure 3-2), remove Jumper **7** (A3W3) from the FREQ STANDARD EXT connector **8** (A3J10), and set the FREQ STANDARD INT/EXT switch **6** to EXT.
2. Connect an external frequency standard of 5 or 10 MHz, 0 dBm (nominal) into 50 ohms impedance to the FREQ STANDARD EXT connector **8**.
3. Set the LINE **12** switch to ON and the RF switch **27** to ON.
4. The front panel display should indicate as follows:
 STATUS annunciator. INTERNAL REF OFF
 The NOT PHASE LOCKED annunciator may light if the external reference is not of sufficient accuracy in frequency or has an insufficient power level. The external reference must be within ± 200 Hz of 10 MHz for reliable locking to occur.
5. The Synthesizer may now be used for any of its normal operations.

SETTING AMPLITUDE MODULATION

1. Set front panel (see Figure 3-1) controls and switches as follows:
28 METER MODE selector AM
2. Connect an oscillator with a 600 ohm output impedance to the AM INPUT connector **19**. Set the oscillator's output to 0 Vrms and to the modulation frequency desired.
3. Set the AM Function switch **15** to 30% or 100%. The Meter **2** should indicate 0% on the 0 to 3 scale, or 0% on the 0 to 10 scale.
4. Set the OUTPUT LEVEL VERNIER control **20** and the OUTPUT LEVEL RANGE control **24** to the level desired from the RF OUTPUT connector **26**.
5. Increase the oscillator's output until the desired percent modulation between 0 to 30% (full scale) is reached. Full scale is 1 Vpk.
6. Reduce the oscillator's output to 0 Vrms.

Table 3-4. Local Operating Instructions (3 of 4)

SETTING FREQUENCY MODULATION

1. Set front panel (see Figure 3-1) controls and switches as follows:
 - 28 METER MODE selector FM
2. Connect a modulation source with a 50 ohm output impedance to the FM INPUT connector 16 .
Set the oscillator's output to 0 Vrms and to the modulation frequency desired.
3. Set the FM DEVIATION MHz selector 18 to the desired deviation range. The peak deviation is shown on the Meter 2 . The 0.03, 0.3, and 3 ranges are indicated on the Meter 2 on the 0 to 3 scale and the 0.1, 1, and 10 ranges are indicated on the 0 to 1.0 scale.
4. An FM input of 1.0 Vpk (0.707 Vrms) represents full scale modulation voltage. Set the input level to obtain the desired deviation.
5. The FM annunciator 6 OVERMOD and the STATUS Block 9 annunciator NOT PHASE-LOCKED will light to indicate that an over modulation condition exists. This can occur if an input signal of greater than 1 Vpk or if the maximum allowable modulation index is exceeded.

SETTING EXTERNAL ALC WITH A POWER METER OR CRYSTAL DETECTOR

1. Set front panel (see Figure 3-1) controls and switches as follows:
 - 25 PEAK-NORM control NORM (detented)
 - 27 RF switch ON
 - 28 Meter Mode selector LEVEL
2. Set the LINE switch 12 to ON and set the OUTPUT LEVEL VERNIER control 20 and the OUTPUT LEVEL RANGE control 24 for -10 dBm output.
3. Connect the external leveling crystal detector (XTAL) or a power meter (PWR MTR) to sense the RF signal level at the point to be leveled. The leveling device may produce either a positive or negative polarity output voltage. The Synthesizer automatically produces the proper polarity signal to use with the ALC loop.
 - 4a. If using a crystal detector, connect the detectors output to the EXT ALC INPUT connector 21 .
Set the ALC selector 17 to XTAL.
 - 4b. If using a power meter, connect the Recorder Output to the EXT ALC INPUT connector 17 . Set the ALC selector 21 to PWR MTR.

Table 3-4. Local Operating Instructions (4 of 4)

SETTING EXTERNAL ALC WITH A POWER METER OR CRYSTAL DETECTOR (Cont'd)

NOTE

If the HP 436A Power Meter is to be used, set the Synthesizer's output level to -1 dBm with the ALC selector 17 set to INT. Depress the RANGE HOLD pushbutton on the 436A. If the RANGE HOLD pushbutton is not depressed, the power meter may slowly oscillate due to autoranging.

5. Set the OUTPUT LEVEL RANGE control 24 and the VERNIER control 20 for the desired power level.
6. Adjust the CAL control 23 to obtain a stable, leveled power output 10 dB below the output level indicated by the RANGE dBm display 1 and the indication on the Meter 2. The 10 dB offset places the ALC loop in the center of its dynamic range.

3-16. REMOTE (HP-IB) OPERATION

3-17. The Synthesizer can be operated through the Hewlett-Packard Interface Bus (HP-IB). For further information about the HP-IB, refer to IEEE Standard 488-1975, the Hewlett-Packard catalog, and the booklet "Improving Measurements in Engineering and Manufacturing" (HP Part No. 5952-0058). Synthesizer compatibility, programming, and data format is described in the paragraphs which follow.

3-18. Synthesizer Talk and Listen address, and Parallel and Serial Poll response selection is described in Section II.

3-19. For Synthesizer remote checkout and troubleshooting, refer to the Remote Operator's Check and the HP-IB Diagnostic Program in Section VIII. The Remote Operator's Check verifies that the Synthesizer's functions can be programmed while the HP-IB Diagnostic Program tests the Bus functions of the Synthesizer.

3-20. Compatibility

3-21. The Synthesizer is fully programmable with the HP-IB. Front panel functions except the LINE switch **12**, (see Figure 3-1). METER MODE selector **28**, PEAK-NORMAL control **25**, and CAL control **23** can be programmed.

3-22. The programming capability of the Synthesizer will be described in terms of the twelve bus messages found in Table 3-5.

3-23. Local/Remote and Remote/Local Mode Changes

3-24. The Synthesizer can communicate over the bus when in remote or local. In remote, the Synthesizer's front panel controls are disabled and the Synthesizer can be addressed to talk or listen. When addressed to listen, the Synthesizer will respond to the Data, Clear (SDC), Local, and Clear Lockout/Set Local. When addressed to talk, the Synthesizer automatically stops listening and sends a status byte over the eight data lines. Also, the Synthesizer can send a service request (SRQ) and respond to serial and parallel polls and the Abort message. In local, the Synthesizer is fully controlled by the front panel, but it will respond to serial or parallel polls, its talk address, and it will send a service request (SRQ).

3-25. Addressing. The Synthesizer interprets the byte on the bus' eight data lines as an ASCII ad-

dress or command if the remote enable line (REN) is true and the bus is in the command mode: attention line (ATN) true and interface clear line (IFC) false. The Synthesizer's talk and listen addresses are switch selectable as described in Section II. Referring to Table 2-1, characters in columns 2 or 3 are valid listen addresses, characters in columns 4 and 5 are talk addresses, and characters in column 1 are commands: device clear (DC), serial poll enable (SPE), and serial poll disable (SPD).

3-26. Programming the Local to Remote Mode Change. The Synthesizer will switch to remote only when addressed to listen. When first switched to remote, the REMOTE lamp lights and the VERNIER resets to -10 dB. Nothing else will change from the front panel control settings until the Synthesizer receives a data message string. Once in remote, the synthesizer can be unaddressed with the universal Unlisten address or Abort message, addressed to talk, re-addressed to listen, or programmed to return to local.

3-27. Programming the Remote to Local Mode Change. The Synthesizer will return to local when the Local or Clear Lockout/Set Local messages are sent by the controller. The Clear Lockout/Set Local message sets the remote enable line (REN) false.

3-28. Data Messages

3-29. The Synthesizer communicates on the bus primarily with data messages. It responds to data messages that program frequency, output level, modulation and ALC configuration. It sends a byte that describes its status. Data messages consist of one or more bytes sent over the bus' 8 data lines when the bus is in the data mode (attention line [ATN] false). The Synthesizer receives data messages when addressed to listen and sends a status byte when addressed to talk.

3-30. Receiving Data Messages

3-31. The Synthesizer will receive Data messages when addressed to listen. The Data message string, or program string, consists of one or more ASCII characters, arranged as a program code followed by arguments. They need not be on the same program line.

3-32. Data Input Format. The program string syntax is as shown in Example 1. For example, to program the four functions for 12.596365 GHz, -94 dBm AM and FM OFF, and ALC internal normal, use the program codes and arguments in Table 3-10 and write the string as in Example 2.

Table 3-5. Message Reference Table

Message and Identification	Applicable	Command and Title	Response
Data	Yes	T6 Talker, L4 Listener, AH1 Acceptor Handshake SH1 Source Handshake	Synthesizer changes frequency output level, modulation, and ALC.
Trigger (DT0)	No	Device Trigger	Synthesizer does not respond to a Device Trigger.
Clear (DC1)	Yes	DCL Device Clear	The Synthesizer responds to a DCL or SDC command by setting frequency to 3 GHz, Modulation to off, RF off, and ALC to Internal.
	Yes	SDC Selected Device Clear	
Remote (RL2)	Yes	REN Remote Enable	Synthesizer goes to remote when the REN line is true and the Synthesizer is first addressed to listen.
Local (RL2)	Yes	GTL Go to Local	Synthesizer goes to local when a GTL command is received. The frequency does not change but the front panel controls determine the other functions.
Local Lockout (RL2)	No	LLO Local Lockout	Synthesizer does not respond to the LLO command.
Clear Lockout/ Set Local (RL2)	Yes	REN Remote Disable	Synthesizer goes to local when REN goes false.
Pass Control/ Take Control (C0)	No	Controller	The Synthesizer cannot act as a controller.
Require Service (SR1)	Yes	SRQ Service Request	The Synthesizer sets SRQ line true when when unlocked, unleveled, FM overmodulated or out of range (freq.).
Status Byte	Yes	SPE Serial Poll Enable	The Synthesizer responds to a serial poll by sending a status byte.
	Yes	SPD Serial Poll Disable	
Status Bit (PP2)	Yes	PP Parallel Poll	The Synthesizer responds to a parallel poll by sending a status bit on a switch selected data line.
Abort	Yes	IFC Interface Clear	The synthesizer stops listening or talking.

NOTE

Complete HP-IB capability as defined in IEEE Std. 488 is DC1, RL2, SR1, PP2, T6, L4, AH2, SH1, DT0, C0.

Receiving Data Messages (Cont'd)

EXAMPLE 1

EXAMPLE 2

The Synthesizer ignores spaces, commas, decimal points, carriage returns, and line feeds. Paragraph 3-37 has more information on program codes. All functions may be programmed together as shown or separately as will be described in detail in the following paragraphs.

3-33. Programming Frequency. The Synthesizer accepts any frequency within its range to 8 significant digits. Above 6.2 GHz the 1 kHz digit is rounded up or down to be compatible with the 2 kHz or 3 kHz resolution. Use Figure 3-5 and Table 3-6 to write the program string with the following syntax:

Table 3-6. Frequency Program Codes and Arguments

	Program Codes		Arguments
FREQUENCY	10 GHz	P	0 THROUGH 9
	1 GHz	Q	
	1 MHz	T	
	100 kHz	U	
	10 kHz	V	
	1 kHz	W	
	EXECUTE	Z	

Within the Synthesizer, frequency information is stored in two blocks of four digits each. One block is for the 10 GHz through 10 MHz digits; the other block is for the 1 MHz through 1 kHz digits. Programming within one block does not change the other block unless it is necessary for the Synthesizer to round off the 1 kHz digit for frequencies above 6.2 GHz. Figure 3-5 illustrates this; use it as a guide to make Frequency programming easier.

Figure 3-5. Frequency Programming

Receiving Data Messages (Cont'd)

3-34. Programming Output Level. The 0 to -110 dBm positions of the Synthesizer's RANGE switch, and the Functions of the VERNIER control are programmed with the output level string. The VERNIER control's function is programmed in 1 dB steps from +3 to -10 dB. RANGE is programmed in 10 dB steps, and the +10 dB position (over-range) of the RANGE switch is programmed with the ALC code and argument (see paragraph 3-36). Although it is possible to program the +10 dB range with 10 dB step attenuation (RANGE) it is unnecessary and should not be done¹. The output level program string consists of the program codes for RANGE and VERNIER each followed by an argument (Table 3-7) as shown.

¹ For the Synthesizer to achieve a +10 dBm output level, the RANGE and VERNIER arguments must be set for 0 dBm.

Table 3-7. Output Level

	Program Codes	Arguments
Output Level Range	K	0 dBm 0
		-10 1
		-20 2
		-30 3
		-40 4
		-50 5
		-60 6
		-70 7
		-80 8
		-90 9
		-100 :
		-110 ;
Output Level Vernier	L	+3 dB 0
		+2 1
		+1 2
		0 3
		-1 4
		-2 5
		-3 6
		-4 7
		-5 8
		-6 9
		-7 :
		-8 ;
-9 <		
-10 =		

Receiving Data Messages (Cont'd)

3-35. Programming Modulation. The Synthesizer accepts codes and arguments (Table 3-8) for two ranges of AM and six ranges of FM. The two modulation types can be used separately or together. Program string syntax is as follows:

3-36. Programming ALC. The ALC program string controls the functions of the RF ON-OFF switch, the ALC selector switch, and the +10 dBm position of the output level RANGE switch. The string consists of the program code, which is O (the letter O), followed by a single argument representing the desired combination of the switch positions. Each switch position has a numerical weight. Compute the argument by adding the weights (use the equal sign [=] for a weight of 13, and the question mark [?] for a weight of 17).

Table 3-8. Modulation

	Program Codes	Arguments
AM	M	OFF 0 or 1
		100% 2
		30% 3
FM	N	OFF 6 or 7
		30 kHz 5
		100 kHz 4
		300 kHz 3
		1 MHz 2
		3 MHz 1
10 MHz 0		

Weighting is as follows:

RF ON-OFF switch; ALC switch; RANGE switch;

OFF = 0 INT = 0 0 dBm = 0

ON = 1 XTAL = 4 +10 dBm = 2

 MTR = 12

Note that for the Synthesizer to achieve a +10 dBm RF output level, the output level RANGE and VERNIER arguments must be set for 0 dBm and the ALC argument must be appropriate for +10 dBm output. With RF OFF, combinations of the other two switches results in arguments of 0, 2, 4, 6, or 8. For RF ON, possible arguments are in the following table:

Table 3-9. ALC Arguments (with RF ON)

ALC switch \ RANGE switch	0 dB	+10 dB
	INT	1
XTAL	5	7
MTR	=	?

In general, an even argument results in the RF ON-OFF switch being set OFF, while an odd argument results in RF ON with the other switch combinations as shown in the table.

3-37. Optional Program Codes. The Synthesizer interprets any ASCII character in columns 4 and 5 of Table 2-1 as a program code. The two columns are equivalent; for example, it will respond the same way to "Z" as it does to "J". The Synthesizer ignores all other characters.

3-38. Abbreviated Program String. The Synthesizer accepts and processes the characters of a pro-

Receiving Data Messages (Cont'd)

gram string in a left to right sequence. It also automatically counts program codes in the sequence shown in Table 2-1 columns 4 and 5. This sequence is equivalent to the program string order shown in paragraph 3-32. If done in that sequence, program strings for level, modulation, and ALC can be written like those for frequency. The program string will consist of the program code for the first function being programmed followed by arguments for all functions as shown below:

3-39. Programming Execution Time. Programming execution time is determined by two parameters: the rate at which data can be input into the Synthesizer over the interface and the time it takes the Synthesizer to reach the desired output state. The Synthesizer can typically accept data at rates up to 80 kbytes/second. This is generally a much shorter time than it then takes the Synthesizer to reach the desired output state. If the controller and all other instruments on the bus are fast enough, data transfer is then only a small fraction of the total program execution time. Typical execution times for the various functions of the Synthesizer are as follows:

a. Frequency Switching. The time it takes to switch from one frequency to the next depends on the largest frequency digit being changed. Generally, the smaller the digit being changed, the shorter the switching time. Typical switching times by largest digit being changed on the 2.0 to 6.2 GHz band are shown in Figure 3-6 below. For higher bands, actual digits being changed must be determined by dividing the output frequency by 2 (6.2 to 12.4 GHz band), or by 3 (12.4 to 18 GHz band). If FM is on during a frequency change, switching time will increase.

Largest Digit Changed	100 MHz	10 MHz	1 MHz	100 kHz	10 kHz	1 kHz
Time to be Within 1 kHz	10 ms	10 ms	10 ms	5 ms	3 ms	1.5 ms

b. Output Level Programming

- Output range switching (10 dB steps) <20 ms
- Output vernier switching (1 dB steps) <10 ms
- RF ON/OFF switch ON <30 ms
- RF ON/OFF switch OFF < 5 ms

c. Modulation Programming

- FM range change and frequency change in FM mode <50 ms
- AM range change <15 ms

Figure 3-6. Typical frequency switching time showing WORST CASE lock and settling times

3-40. Sending Data Messages

3-41. The Synthesizer sends a status byte when addressed to talk. This byte is the Synthesizer's response to a serial poll which will be explained in paragraph 3-59. The Synthesizer will talk when in local as well as remote.

3-42. Receiving the Trigger Message

3-43. The Synthesizer doesn't respond to the Trigger message.

3-44. Receiving the Clear Message

3-45. The Synthesizer responds to the Clear message by setting the frequency to 3 GHz, ALC to internal, RF power off, and modulation off. This message can take two forms: Device Clear, which the Synthesizer responds to when not addressed, and Selected Device Clear which the Synthesizer responds to when addressed to listen. The Device Clear messages do not affect addressing.

3-46. Receiving the Remote Message

3-47. The Synthesizer is enabled to go into remote when the controller sends the Remote message, but does not actually switch to remote until first addressed to listen. The Remote message is the means by which the controller sets the remote enable line (REN) true. Some controllers send this message automatically when first turned on or reset.

3-48. Receiving the Local Message

3-49. The Synthesizer returns to local front panel control when it receives the Local message. The frequency will not change from the last programmed value but the other functions will correspond to the front panel control settings.

3-50. Receiving the Local Lockout Message

3-51. The Synthesizer does not respond to the Local Lockout message.

3-52. Receiving the Clear Lockout/Set Local Message

3-53. The Synthesizer responds to the Clear Lockout/Set Local message in the same way as to the Local message (that is if returns to local). The Synthesizer need not be addressed to listen. This message sets the REN line false.

3-54. Receiving the Pass Control Message

3-55. The Synthesizer does not respond to the Pass Control message as it cannot act as a controller.

3-56. Sending the Require Service Message

3-57. The Synthesizer sends the Require Service message to the controller when one of the following conditions exists for more than 50 ms:

- 1) Not phase-locked with RF power on.
- 2) Frequency programmed out of range.
- 3) RF power level uncalibrated with RF power on.
- 4) FM overmodulated with RF power on.

The Synthesizer sends this message by setting the service request line (SRQ) true. It will request service in local or remote whether or not it is addressed.

3-58. Sending the Status Byte Message

3-59. The Synthesizer sends the status byte when addressed to talk. This byte is the Synthesizer's response to a serial poll. The Synthesizer responds to a serial poll when the controller sends a serial poll enable command (SPE), then addresses the Synthesizer to talk. The SPE command enables the Synthesizer to clear the service request (SRQ) when addressed to talk. Also, when the Synthesizer receives its talk address, bit 7 of the status byte is latched. The Controller can then determine the status of the Synthesizer by converting the status byte to a decimal value. Status byte coding is as follows:

STATUS BYTE

Bit Number	8	7	6	5	4	3	2	1
Decimal Value	128	64	32	16	8	4	2	1
Function	CRYSTAL OVEN COLD	RSV REQUEST SERVICE	OUT OF RANGE (frequency)	RF OFF	NOT PHASE LOCKED	LEV UNCAL	FM OVER- MOD	+10 dBm OVER- RANGE

Sending the Status Byte Message (Cont'd)

3-60. The RSV (Request Service) bit is true whenever any of the four conditions that cause a request for service exists (even during the first 50 ms after a programming change). Once the Synthesizer is addressed to talk, the RSV line is latched even though the Synthesizer's need for service may have changed.

3-61. The status byte is useful for determining when a given programming change has been executed. For example, if the Synthesizer is addressed to talk immediately after a frequency change, the status byte can be used to determine when the Synthesizer has re-acquired lock. A frequency change might be followed by a status byte sequence of 72, 72, and then 64, indicating the Synthesizer is now locked.

3-62. Sending the Status Bit Message

3-63. The Synthesizer outputs a status bit on one of the Bus data lines in response to a parallel/poll

(see controller manual). The line is switch selectable (see Section II) as is the level of the bit's logic. The status bit represents one bit of the status byte.

3-64. Receiving the Abort Message

3-65. The Synthesizer stops talking or listening when it receives the Abort Message.

3-66. Programming Quick Reference Guide

3-67. Table 3-10 shows program string syntax, program codes and arguments, and the status byte. All possible program codes (including equivalent duplicates) are shown, but the recommended codes are indicated with boldface type.

3-68. Programming Examples

3-69. Figure 3-7 is a flowchart showing how to program all of the Synthesizer functions and the twelve bus messages in HPL (9825 computing controller), and BASIC (9830 computing controller).

Table 3-10. Programming Quick Reference Guide

PROGRAM STRING SYNTAX

SECTION IV PERFORMANCE TESTS

4-1. INTRODUCTION

4-2. The procedures in this section test the instrument's electrical performance using the specifications of Table 1-1 as the performance standards. All tests can be performed without access to the interior of the instrument. A simpler operational test is included in Section III under Operator's Checks.

NOTES

For ease of testing, the Frequency and Output Level Switching Time tests may be performed with top covers removed.

If the performance tests are to be considered valid the following conditions must be met:

- a. *The Synthesizer must have a 1-hour warmup.*
- b. *The line voltage must be within +5% and -10% of nominal.*
- c. *The ambient temperature must be +15°C to +35°C for the Output Level Flatness and RF Output Level and Accuracy tests.*

Before aging rate tests are performed, the Synthesizer must 1) have a 30 day warm-up if it has been disconnected from the Mains power for more than 24 hours or 2) the Synthesizer must have a 24 hour warm-up if it has been disconnected from the Mains power for less than 24 hours.

4-3. EQUIPMENT REQUIRED

4-4. Equipment required for the performance tests is listed in the Recommended Test Equipment table in Section I. Any equipment that satisfies the critical specifications given in the table may be substituted for the recommended model(s).

4-5. TEST RECORD

4-6. Results of the performance tests may be tabulated on the Test Record at the end of the procedures. The Test Record lists all of the tested specifications and their acceptable limits. The results recorded at incoming inspection can be used for comparison in periodic maintenance and troubleshooting and after repairs or adjustments.

4-7. CALIBRATION CYCLE

4-8. This instrument requires periodic verification of performance. Depending on the use and environmental conditions, the instrument should be checked using the following performance tests at least every six months after the first year.

4-9. ABBREVIATED PERFORMANCE TESTING

4-10. Performing the Operational Verification checks is suggested as an alternative to a complete verification of the specifications listed in Table 1-1. These checks give reasonable assurance that the Synthesizer is performing properly.

PERFORMANCE TESTS

4-11. OPERATIONAL VERIFICATION CHECKS

DESCRIPTION: This procedure checks the Synthesizer to give reasonable assurance that it is working properly by performing selected tests of all major functions. As each step is completed it may be checked off on Table 4-1. If remote verification is required, the Remote Operator's Check in Section VIII is recommended.

EQUIPMENT:

Spectrum Analyzer	8565A
Power Meter	436A/8481A
Test Oscillator	651B
Digital Voltmeter	3455A
Frequency Counter	5340A

- PROCEDURE:**
1. Connect the Synthesizer to the Mains power and allow sufficient warm-up time for the OVEN annunciator to go out.
 2. Connect the power meter to the Synthesizer's RF OUTPUT. Set the Synthesizer's controls for 2 GHz, OUTPUT LEVEL RANGE to 0 dBm, OUTPUT LEVEL VERNIER control fully clockwise, the ALC switch to either XTAL or PWR MTR position and the METER mode switch should be in the LEVEL position. Under these conditions the Synthesizer should deliver maximum power, the panel meter should indicate zero and the LVL UNCAL annunciator should be lighted.

Figure 4-1. Typical Maximum Power Available on the +10 dBm Range (over-range)

3. Tune from 2 to 18.0 GHz in 100 MHz steps. The power should remain above +3 dBm over the entire frequency range. Figure 4-1 shows a typical output level curve. Be sure the NOT PHASE LOCKED annunciator is off before making power measurements.

PERFORMANCE TESTS

4-11. OPERATIONAL VERIFICATION CHECKS (Cont'd)

4. Set the ALC switch to INT. Adjust the VERNIER control to obtain a meter reading of 0 dBm. Tune in 100 MHz steps from 2 to 18.0 GHz. The LVL UNCAL annunciator is not lighted and the total power variation should be within the following limits.
2—6.2 GHz ± 0.75 dB
6.2—12.4 GHz ± 1 dB
12.4—18.0 GHz ± 1.25 dB
5. Set the Synthesizer frequency to 2 GHz and adjust the VERNIER control to obtain 0 dBm as indicated on the power meter.
6. Connect the spectrum analyzer to the Synthesizer's RF OUTPUT in place of the power meter. Tune the spectrum analyzer to observe the 2 GHz signal. Adjust the spectrum analyzer's log reference level to place the signal at the top graticule line.
7. Change the Synthesizer's OUTPUT LEVEL RANGE switch from 0 dBm to -80 dBm in 10 dB steps. Verify that the change per step is, in fact, 10 dB. This is to assure that each section of the output attenuator is switching properly and does not rigorously test operation to specifications.
8. Set the OUTPUT LEVEL RANGE to -10 dBm, the meter switch to FM and connect a 100 kHz signal from a test oscillator's 50 ohm output to the FM INPUT connector. Set the FM DEVIATION switch to the 0.3 MHz range. Adjust the test oscillator's output level to obtain the first Bessel null of the carrier. This should occur between 0.658 Vrms and 0.757 Vrms for ambient temperatures between 15°C and 35°C. The front panel meter should indicate between 210 and 270 kHz deviation.
9. Set the FM DEVIATION switch to OFF and disconnect the input signal. Set the METER MODE switch to AM, set the AM function switch to the 100% range and connect a 10 kHz signal (from the 600 ohm output of the test oscillator) to the AM INPUT connector. Set the spectrum analyzer vertical sensitivity per division switch to 2 dB log. Adjust the log reference level to place the carrier on the top graticule line.
10. Adjust the test oscillator's output level to place the first sidebands 10 dB below the carrier. This should occur at a test oscillator output level between 0.416 Vrms and 0.478 Vrms. The meter should indicate between 53.25% and 73.25% (63.25% nominal) for ambient temperatures between 15°C and 35°C.
11. If any of the steps in this procedure seem to have failed, perform the related performance tests or refer to the service information in Section VIII as necessary.

PERFORMANCE TESTS

4-11. OPERATIONAL VERIFICATION CHECKS (Cont'd)

Table 4-1. Record of Operational Verification Checks

Step	Description	Results
1.	OVEN annunciator is not lighted.	_____
2.	Panel meter indicates zero (LEVELED) LVL UNCAL ANNUNCIATOR IS LIGHTED.	_____ _____
3.	The NOT PHASE LOCKED annunciator is not lighted.	_____
4.	The LVL UNCAL annunciator is not lighted. Power variation (leveled flatness) is: ±0.75 dB maximum from 2.0 to 6.2 GHz ±1.00 dB maximum from 6.2 to 12.4 GHz ±1.25 dB maximum from 12.4 to 18.0 GHz	_____ _____ _____ _____
7.	OUTPUT LEVEL change is about 10 dB for each OUTPUT LEVEL RANGE switch setting from 0 to -80 dBm.	_____
8.	Frequency Modulation drive voltage is within tolerance. Frequency Modulation metering accuracy is within tolerance.	_____ _____
10.	Amplitude Modulation drive voltage is within tolerance Amplitude Modulation metering accuracy is within tolerance.	_____ _____

4-12. OUTPUT LEVEL FLATNESS

SPECIFICATION: (0 dBm range; +15°C to +35°C)
±0.75 dB, 2.0 to 6.2 GHz
±1.00 dB, 2.0 to 12.4 GHz
±1.25 dB, 2.0 to 18.0 GHz

For Options 004 and 005 instruments, flatness is degraded by an additional ±0.25 dB.
Applies for internal leveling only.

DESCRIPTION: A power meter is used to measure the output power as the Synthesizer frequency is tuned across the range of 2 GHz to 18 GHz. The test may be performed in either the remote or local mode.

EQUIPMENT: Power Meter/Sensor HP 436A/8481A

PERFORMANCE TESTS

4-12. OUTPUT LEVEL FLATNESS (Cont'd)

- PROCEDURE:
1. Calibrate and zero the power meter.
 2. Press the Synthesizer's PRESET (3 GHz) pushbutton.
 3. Set the OUTPUT LEVEL RANGE switch to 0 dBm.
 4. Connect the power sensor to the RF OUTPUT connector.
 5. Adjust the OUTPUT LEVEL VERNIER control for a level of -2 dBm as indicated by the power meter. DO NOT change the VERNIER CONTROL setting until this procedure is completed.
 6. Tune the Synthesizer in 1 MHz steps over the frequency range. Record the maximum and minimum power outputs. BE SURE to change the power meter's calibration factor as the frequency is changed.

NOTE

The plus and minus specification for output power is not referenced to a particular frequency. The specification rather, represents the total power variation over the entire frequency range.

2.0 - 6.2 GHz	± 0.75 dB	Minimum _____	
		Maximum _____	
		Total Variation _____	1.50 dB
2.0 - 12.4 GHz	± 1.00 dB	Minimum _____	
		Maximum _____	
		Total Variation _____	2.00 dB
2.0 - 18.0 GHz	± 1.25 dB	Minimum _____	
		Maximum _____	
		Total Variation _____	2.50 dB

7. If the Output Level flatness is not within the required tolerance, perform the ALC adjustments in Section V.

4-13. HARMONICS AND SUBHARMONICS

SPECIFICATIONS: All harmonics up to 18 GHz and subharmonics and multiples up to 18 GHz shall be better than -25 dBc.

DESCRIPTION: A comparison of amplitude levels of the harmonics and subharmonics to the fundamental signal are to be made. A reference level for the Synthesizer's carrier signal is established by viewing the output on the spectrum analyzer's display. The Synthesizer is then tuned to another frequency so that a harmonic or subharmonic of this new signal is viewed on the display and is compared to the carrier signal level. Various signals are viewed to verify proper performance.

PERFORMANCE TESTS

4-13. HARMONICS AND SUBHARMONICS (Cont'd)

EQUIPMENT: Spectrum Analyzer HP 8565A

- PROCEDURE:
1. Set the Synthesizer's OUTPUT LEVEL RANGE switch to 0 dBm and VERNIER control for a meter reading of +3 dB. Tune to 4000 Hz.
 2. Connect the Synthesizer's RF OUTPUT to the spectrum analyzer's RF input.
 3. Set the spectrum analyzer's control to display the fundamental signal. Set the resolution bandwidth to 10 kHz and the input attenuation to 40 dB. Adjust the log reference level to set the signal at the top graticule line of the display.
 4. Tune the Synthesizer's frequency to 2000 MHz. The second harmonic signal viewed on the analyzer's display should be greater than 25 dB below the reference. Record the harmonic signals amplitude.
25 dB _____
 5. Tune the Synthesizer and spectrum analyzer to 6000 MHz. Adjust the analyzer's log reference level to set the fundamental signal to the top graticule line.
 6. Tune the Synthesizer to 3000 MHz. The second harmonic should be greater than 25 dB below the reference. Record the signal level.
25 dB _____
 7. Tune the Synthesizer to 2000 MHz. The third harmonic should be greater than 25 dB below reference. Record the signal level.
25 dB _____
 8. Tune the Synthesizer and spectrum analyzer to 4133.334 MHz. Adjust the log reference level to set fundamental signal to the top graticule line.
 9. Tune the Synthesizer to 8266.668 MHz. The $\frac{1}{2}f$ subharmonic (fundamental feedthrough) on the spectrum analyzer should be greater than 25 dB down. Record the signal level.
25 dB _____
 10. Tune the Synthesizer to 12 400.002 MHz. The $\frac{1}{3}f$ subharmonic should be greater than 25 dB down. Record the signal level.
25 dB _____
 11. Tune the Synthesizer and spectrum analyzer to 8266.668 MHz. Adjust the log reference level to set the fundamental signal to the top graticule line.
 12. Tune the Synthesizer to 12 400.002 MHz. The $\frac{2}{3}f$ subharmonic should be greater than 25 dB down. Record the signal level.
25 dB _____

NOTE

This procedure may be repeated at any frequency of interest within the specification limits of 2000 MHz to 18 000 MHz.

13. If the harmonics and subharmonics are not within tolerance, perform the VTM and ALC adjustments in Section V.

PERFORMANCE TESTS

4-14. SWR

SPECIFICATIONS: Impedance: 50 ohms

SWR: <2.5. On 0 dBm and -10 dBm output level ranges specification applies only at the RF output frequency.

DESCRIPTION: The insertion loss of the directional coupler is measured. From the insertion loss and the SWR specification, the maximum allowable power variation is calculated (assuming that the Synthesizer is operating into a short circuit). The Synthesizer is then operated into a short and the power variation is measured and compared with the calculated limits.

Figure 4-2. SWR Test Setup

EQUIPMENT:	10 dB Attenuator	HP 8491B Option 010
	Adapter, APC-7 to Type-N Male (2 req'd)	HP 11525A
	50 Ohm Termination, APC-7	HP 909A Option 12
	Short, APC-7	HP 11565A
	Directional Coupler	HP 11691D
	Power Meter/Sensor	HP 436A/8484A

- PROCEDURE:
1. Set Synthesizer's controls for an output of 3 GHz at -12 dBm, connect the 10 dB attenuator to Synthesizer's RF OUTPUT connector and measure the power output with the power meter. See Figure 4-2, Step 1.

3 GHz _____ dBm

NOTE

For reliable results, DO NOT CHANGE the Synthesizer's OUTPUT LEVEL RANGE switch or VERNIER control settings for the remainder of this test.

PERFORMANCE TESTS

4-14. SWR (Cont'd)

2. Repeat the measurement at 3 GHz intervals to 18 GHz.

6 GHz _____ dBm
 9 GHz _____ dBm
 12 GHz _____ dBm
 15 GHz _____ dBm
 18 GHz _____ dBm

3. Connect the equipment as shown in Figure 4-2 (step 3).

4. Measure the power at the same frequencies as in steps 1 and 2.

3 GHz _____ dBm
 6 GHz _____ dBm
 9 GHz _____ dBm
 12 GHz _____ dBm
 15 GHz _____ dBm
 18 GHz _____ dBm

5. Compute the insertion loss (I) of the directional coupler and adapters for each frequency (step 1 or 2 minus step 4).

3 GHz _____ dB
 6 GHz _____ dB
 9 GHz _____ dB
 12 GHz _____ dB
 15 GHz _____ dB
 18 GHz _____ dB

6. Calculate the gain of the coupler and the ratio of maximum to minimum power for SWR of 2.5 at each listed frequency. Use the following formulas:

$$G = 10^{(-I/20)}$$

$$R = \frac{1 + G^2 / 2.32}{1 - G^2 / 2.32}$$

Where G = gain of Coupler

I = insertion loss (recorded in step 5)

R = ratio of maximum to minimum power.

PERFORMANCE TESTS

4-14. SWR (Cont'd)

- 3 GHz G = _____ R = _____
- 6 GHz G = _____ R = _____
- 9 GHz G = _____ R = _____
- 12 GHz G = _____ R = _____
- 15 GHz G = _____ R = _____
- 18 GHz G = _____ R = _____

7. Convert the ratio R to the maximum variation allowable (in dB) by using the formula:

$$S = 20 \log_{10} R$$

Where S = maximum variation (dB)
and R = ratio of maximum to minimum power.

- 3 GHz S = _____
- 6 GHz S = _____
- 9 GHz S = _____
- 12 GHz S = _____
- 15 GHz S = _____
- 18 GHz S = _____

8. Connect equipment as shown in Figure 4-2 (step 8).
9. To verify the Synthesizer's SWR, slowly tune around 3 GHz to find the minimum and maximum power indications. Record the power indications and figure the variation.

	MAXIMUM		MINIMUM		VARIATION
3 GHz	_____ dBm	—	_____ dBm	=	_____
6 GHz	_____ dBm	—	_____ dBm	=	_____
9 GHz	_____ dBm	—	_____ dBm	=	_____
12 GHz	_____ dBm	—	_____ dBm	=	_____
15 GHz	_____ dBm	—	_____ dBm	=	_____
18 GHz	_____ dBm	—	_____ dBm	=	_____

10. Repeat the search for maxima and minima at the other frequencies. The variation at each frequency should be less than the value of S computed in step 7.

If the SWR specification is not within tolerance, refer to the troubleshooting information in Section VIII, Service Sheet 4.

PERFORMANCE TESTS

4-15. FM ACCURACY

SPECIFICATION: FM indicated meter accuracy (at 100 kHz rate): $\pm 10\%$ full scale at $+15$ to $+35^\circ\text{C}$; $\pm 15\%$ of full scale from 0 to 55°C .

FM accuracy relative to external input level (at 100 kHz rate): $\pm 7\%$ range at $+15$ to $+35^\circ\text{C}$; $\pm 10\%$ of range from 0 to 55°C .

NOTE

For FM rates other than 100 kHz, add the FM frequency response specification.

DESCRIPTION: With the FM rate fixed, the FM peak deviation is varied to produce a carrier null. Because the FM rate is fixed, the peak deviation is known at the null. The meter indication of peak deviation and the modulation drive level should be within their specified tolerances.

Figure 4-3. FM Accuracy Test Setup

EQUIPMENT:

Frequency Counter	HP 5340A
Test Oscillator	HP 651B
Digital Voltmeter	HP 3455A
Spectrum Analyzer	HP 8565A

PROCEDURE:

1. Connect the equipment as shown in Figure 4-3.
2. Set the test oscillator's output to 100 kHz as accurately as possible.
3. Tune the Synthesizer to 3000 MHz at -10 dBm. Adjust the spectrum analyzer controls for a clear display of the carrier.
4. Set the Synthesizer's FM DEVIATION switch to the 0.3 MHz range; set the METER MODE switch to FM.

PERFORMANCE TESTS

4-15. FM ACCURACY (Cont'd)

5. Adjust the test oscillator's output level to obtain a carrier null. (This should occur near 0.56 Vrms.)
6. The Synthesizer's front panel meter should read between 2.10 and 2.70 (240 kHz peak deviation). Record the reading.
210 _____ 270 kHz-pk
7. The DVM should read between 0.53 and 0.61 Vrms. Record the level.
0.53 _____ 0.61 Vrms
8. If the FM Accuracy is not within tolerance, perform the FM Driver Adjustment and the FM Adjustments in Section V.

4-16. AM DISTORTION

SPECIFICATION: For rates less than 10 kHz, for meter readings 0 db and below and from +15°C to +35°C.
 less than 3% at 30% depth
 less than 4% at 50% depth
 less than 5% at 75% depth.

DESCRIPTION: The amplitude modulated output of the Synthesizer is detected by a spectrum analyzer (zero frequency span per division). The distortion present on the detected signal (at the vertical output) is displayed on a low frequency spectrum analyzer.

Figure 4-4. AM Distortion Test Setup

EQUIPMENT:
 Spectrum Analyzer HP 8565A
 Spectrum Analyzer
 (Low Frequency) HP 3580A
 Test Oscillator HP 651B

PROCEDURE: 1. Set the test oscillator's controls to 1 kHz at approximately 0.7 Vrms.

PERFORMANCE TESTS

4-16. AM DISTORTION (Cont'd)

2. Tune the Synthesizer to 3000 MHz at an OUTPUT LEVEL of -10 dBm.
3. Set the Synthesizer's AM function switch to 30% and the METER MODE switch to AM.
4. Connect the test oscillator's 600 ohm output to the Synthesizer's AM input. Adjust the level as needed to obtain a meter reading of 30% AM.
5. Connect the Synthesizer's RF OUTPUT to the spectrum analyzer's input.
6. Set the spectrum analyzer's input attenuation to 30 dB and tune to center the 3000 MHz signal.
7. Set the resolution bandwidth to 300 kHz, frequency span to zero, vertical display to linear, trigger to video and video filter off.
8. Adjust the spectrum analyzer's vertical sensitivity controls to place the demodulated waveform near top of the display.
9. Connect the low frequency spectrum analyzer's input to the spectrum analyzer's vertical output connector.
10. Set the low frequency analyzer's controls to observe the fundamental and three harmonics of the detected signal.
11. Record the AM harmonic levels relative to the fundamental (dB down) as measured on the low frequency analyzer's display.

Percentage Distortion at 30% AM Depth

Harmonic	AM Harmonic Levels (dB down from fundamental)	Power Ratio
second	_____	_____
third	_____	_____
fourth	_____	_____
total		_____

12. To determine the percentage distortion, first convert each significant harmonic level from dB down from the fundamental to the power ratio using Table 4-2. Then add the power ratios. Use the table to convert from the total power ratio to percent distortion. The distortion level should be less than 3%. Record the level. _____ 3%
 13. Set the Synthesizer's AM function switch to 100%.
 14. Adjust the test oscillator's output level to obtain a meter reading of 50% AM.
-

PERFORMANCE TESTS

4-16. AM DISTORTION (Cont'd)

15. Adjust the spectrum analyzer's vertical sensitivity controls to place the demodulated waveform near the top of the display.
16. Set the low frequency spectrum analyzer's controls to observe the fundamental and three harmonics of the detected signal.
17. Record the AM harmonic levels relative to the fundamental.

Percentage Distortion at 50% AM Depth

Harmonic	Harmonic Levels (dB down from Fundamental)	Power Ratio
second	_____	_____
third	_____	_____
fourth	_____	_____
total		_____

18. Using Table 4-2 determine the total power ratio of the harmonics as in step 12. The distortion should be less than 4%. Record the level.

_____ 4%

19. Adjust the test oscillator's output level to obtain a meter reading of 75% AM.
20. Adjust the spectrum analyzer's vertical sensitivity controls to place the demodulated waveform near the top of the display.
21. Set the low frequency spectrum analyzer's controls to observe the fundamental and three harmonics of the detected signal.
22. Record the AM harmonic levels relative to the fundamental.

Percentage Distortion at 75% AM Depth

Harmonic	Harmonic Levels (dB down from Fundamental)	Power Ratio
second	_____	_____
third	_____	_____
fourth	_____	_____
total		_____

23. Using Table 4-2 determine the total power ratio of the harmonics as in step 12. The distortion should be less than 5%. Record the level.

_____ 5%

24. If the AM Distortion is not within tolerance, refer to the troubleshooting information in Section VIII. Service Sheet 4.

PERFORMANCE TESTS

4-16. AM DISTORTION (Cont'd)

Table 4-2. Harmonic Level versus Percentage Distortion

Ratio to Fundamental (dB)	Power Ratio	Distortion (%)	Ratio to Fundamental (dB)	Power Ratio	Distortion (%)

PERFORMANCE TESTS

4-17. AMPLITUDE MODULATION DEPTH, METER ACCURACY, AND INPUT ACCURACY

SPECIFICATIONS: AM Depth for meter readings of 0 dB and below. The power specified is carrier power only (i.e., does not include the power in the AM sidebands).

- 0-75%, 2.0-6.2 GHz
- 0-60%, 6.2-12.4 GHz
- 0-50%, 12.4-18.0 GHz

Sensitivity (percent AM per Vpk): 30%/V and 100%/V ranges. Maximum input 1.0 Vpeak into 600 ohms nominal (1.0 Vpeak gives maximum depth on each range. AM depth is linearly controlled by varying input level between 0 and 1 volt peak.)

Indicated Meter Accuracy (100 Hz to 10 kHz rates): ±5% of range.

Accuracy Relative to EXT AM Input Level (100 Hz to 10 kHz rates): ±10% of range.

DESCRIPTION: The specified parameters are tested by measuring the modulation level and comparing it to the modulation level meter reading and input drive voltage. A spectrum analyzer is used to detect the modulation signal in the zero scan mode. The analyzer's vertical output is calibrated to provide an accurate measure of AM level (% AM is half the vertical output voltage in mVrms).

Figure 4-5. Amplitude Modulation Depth Meter Accuracy and Input Accuracy Test Setup

EQUIPMENT:	Spectrum Analyzer	HP 8565A
	Digital Voltmeter	HP 3455A
	Test Oscillator	HP 651B
	Power Meter	HP 436A/8484A

- PROCEDURE:
1. Set the Synthesizer's controls as follows:
 - METER MODE switch LEVEL
 - RF switch ON
 - OUTPUT LEVEL RANGE switch . . . -30 dBm
 - OUTPUT LEVEL VERNIER control (adjusted for meter reading). +3 dB
 - ALC mode switch INT
 - AM function switch OFF
 - FM DEVIATION switch OFF

PERFORMANCE TESTS

4-17. AMPLITUDE MODULATION DEPTH METER ACCURACY AND INPUT ACCURACY (Cont'd)

NOTE

Do not change the VERNIER control setting for the remainder of this test.

2. Press the PRESET (3 GHz) pushbutton.
3. Connect the power meter to the Synthesizer's RF OUTPUT connector. Record the output power.
 $P_1 = \text{_____ dBm}$
4. Set the Synthesizer's OUTPUT LEVEL RANGE switch to -50 dBm. Record the output power.
 $P_2 = \text{_____ dBm}$
5. Calculate a value for α using the following formula or look up the value in Table 4-3.

$$\alpha = 10^{(P_2 - P_1)/20} \approx 10^{-1}$$

Table 4-3. Modulation Index

$P_2 - P_1$	Alpha (α)	$P_2 - P_1$	Alpha (α)
-18.0	0.1259	-20.0	0.1000
-18.1	0.1245	-20.1	0.0989
-18.2	0.1230	-20.2	0.0977
-18.3	0.1216	-20.3	0.0966

		-22.0	0.0794

NOTE!
THIS TEST CALLS OUT 8565A
BUT ONLY WORKS AS WRITTEN
PERFORMANCE TESTS WITH 141T

4-17. AMPLITUDE MODULATION DEPTH METER ACCURACY AND INPUT ACCURACY (Cont'd)

6. Set the spectrum analyzer's controls for a center frequency of 3 GHz, frequency span per division 20 kHz, resolution bandwidth 300 kHz, input attenuation 30 dB, vertical sensitivity linear, and set the tuning stabilizer to on. Set the video filter to off.
7. Connect the Synthesizer's RF OUTPUT to the spectrum analyzer's RF input. Connect the Synthesizer's AM INPUT to the test oscillator's 600Ω output through a coaxial tee.
8. Reset the Synthesizer's OUTPUT LEVEL RANGE switch to -30 dBm.
9. Connect the DVM to the spectrum analyzer's vertical output.
10. Fine tune the spectrum analyzer to center the signal on the display.
11. Set the spectrum analyzer to zero scan.
12. Fine tune the analyzer to peak the signal on the display.
13. Adjust the spectrum analyzer's reference level controls to obtain -500 mVdc on the DVM (V_{DET1}).
14. Decrease the Synthesizer's RF output power by 20 dB. Note DVM reading.

$$V_{DET2} = +35.9 \text{ mVdc}$$

15. Calculate the offset voltage from the following expressions:

$$V_{OFF} = \frac{V_{DET2} - \alpha V_{DET1}}{1 - \alpha} = +95.44 \text{ mV}$$

where V_{OFF} = offset voltage

V_{DET1} = detected dc voltage at V_{RF1}

V_{DET2} = detected dc voltages at V_{RF2}

α = ratio of V_{RF2} to V_{RF1}

V_{RF1} = RF OUTPUT voltage

V_{RF2} = attenuated RF OUTPUT voltage

16. Set the Synthesizer's OUTPUT LEVEL RANGE to -30 dBm.
17. To calibrate the spectrum analyzer for amplitude modulation level measurement, use the reference level controls to set -282.8 mVdc (V_{OFF} at vertical output (as measured on DVM). For example, if V_{OFF} is +33 mV then set -282.8 mV + (+33 mV) or -249.8 mV at the vertical output. Be sure the trace is peaked on the display when setting the voltage.

8565 + 8566 USE +500mV, +282.8mV

PERFORMANCE TESTS

4-17. AMPLITUDE MODULATION DEPTH METER ACCURACY AND INPUT ACCURACY (Cont'd)

- Set the DVM to measure mVrms. The AM depth may now be calculated according to the following expression:

$$\text{AM Depth (\%)} = \frac{\text{DVM Reading (mVrms)}}{2}$$

- Set the Synthesizer's METER MODE switch to AM and AM switch to 100%.
- Set the test oscillator's controls to obtain an AM meter reading of 75% at a 1 kHz rate. Record the DVM reading in the table.

Detected AM Signal

AM METER
ACCY ± 5% →

AM Level	Synthesizer RF Output (MHz)	DVM Reading (mVrms)		
		Min.	Actual	Max.
75%	3 000	140	158	160
60%	7 000	110		130
50%	13 000	90		110

- Adjust the test oscillator's output level control for a DVM reading of 150 mVrms (75% AM level).
- Connect the DVM input to the open port of the coaxial tee. Measure and record the modulation drive signal.

AM Drive Signal

EXT AM DRIVE
INPUT ACCY ± 10% →

AM Level	Preset DVM Level (mVrms)	DVM Reading (mVrms)		
		Min.	Actual	Max.
75%	150	460		601
60%	120	354		495
50%	100	283		424

- Repeat steps 6 through 19 using a Synthesizer output of 7000 MHz and an AM level of 60%. Record the DVM readings in the tables.

PERFORMANCE TESTS

4-17. AMPLITUDE MODULATION DEPTH METER ACCURACY AND INPUT ACCURACY (Cont'd)

24. Repeat steps 6 through 19 using a Synthesizer output of 13 000 MHz and an AM level of 50%. Record the DVM readings in the tables.
25. Connect the DVM to the spectrum analyzer's vertical output.
26. Set the Synthesizer's AM switch to 30%.
27. Set the test oscillator's output level controls to obtain an AM meter reading of 30%. Verify that the DVM reading is 60.0 ± 3.0 Vrms.
- 57.0 _____ 63.0 mVrms
28. Connect the DVM input to the open port of the coaxial tee. Verify that the DVM reading is 707 ± 71 mVrms.
- 636 _____ 778 mVrms
29. If the meter accuracy is not within tolerance, perform the AM Meter Adjustment in Section V. If the input accuracy is not within tolerance, refer to the troubleshooting information in Section VIII, Service Sheet 4.

4-18. NON-HARMONICALLY RELATED SPURIOUS (CW AND AM MODES)

SPECIFICATION: < -70 dB, 2.0-6.2 GHz
 < -64 dB, 6.2-12.4 GHz
 < -60 dB, 12.4-18.0 GHz

External FM modulation signals at rates <100 kHz must be disconnected.

DESCRIPTION: The spectrum analyzer is calibrated by setting the carrier to the top graticule line. The Synthesizer's RF output level is increased. The spectrum analyzer is tuned to any frequency between 2 and 18 GHz in search of spurious signals.

NOTE

The non-harmonically related spurious signals will always increase in amplitude above 6.2 GHz due to multiplication in the YIG tuned multiplier. The increase is determined by a strict mathematical relationship. Therefore, if the specification is met in the range 2-6.2 GHz, it will always meet the less stringent specification in the multiplied ranges, that is, from 6.2-18.0 GHz.

PERFORMANCE TESTS

4-18. NON-HARMONICALLY RELATED SPURIOUS (CW AND AM MODES) (Cont'd)

EQUIPMENT: Spectrum Analyzer HP 8565A

- PROCEDURE:
1. Connect the Synthesizer's RF OUTPUT to the spectrum analyzer's input.
 2. Set the Synthesizer's OUTPUT LEVEL controls for -47 dBm (-50 dBm RANGE and a $+3$ dB meter reading); tune to 3000 MHz.
 3. Tune the spectrum analyzer's center frequency to view the carrier. Set frequency to 10 kHz per division, resolution bandwidth to 1 kHz and sweep time as needed to maintain spectrum analyzer calibration. Set the video filter to 100 Hz (0.1 times the resolution bandwidth).
 4. Adjust the reference level control to place the carrier at the top graticule line.
 5. Increase the Synthesizer's output power to $+3$ dBm. Do not readjust the spectrum analyzer amplitude calibration.
 6. Tune the spectrum analyzer to any desired frequency in search of non-harmonically related spurious signals. Verify that any signals found are non-harmonically related and not generated by the spectrum analyzer. Verify that the spurious signals are below specified limits.
 7. If the non-harmonically related spurious are not within tolerance, refer to the troubleshooting information in Section VIII, Service Sheet 1.

4-19. POWER LINE RELATED SPURIOUS (CW AND AM MODES)

SPECIFICATION: Due to fan rotation within 5 Hz below line frequency and multiples, except Option 003 instruments (400 Hz operation):

Center Frequency Range (F_c)	Power Line Related and Spurious Levels at frequency offset (f_o) from carrier (F_c)		
	$f_o < 300$ Hz	$300 \text{ Hz} \leq f_o \leq 1 \text{ kHz}$	$f_o > 1 \text{ kHz}$
2.0–6.2 GHz	-50 dBc	-60 dBc	-65 dBc
6.2–12.4 GHz	-44 dBc	-54 dBc	-59 dBc
12.4–18.0 GHz	-40 dBc	-50 dBc	-55 dBc

NOTE

For Option 003 instrument (400 Hz operation) refer to Table 1-1.

DESCRIPTION: The Unit Under Test is isolated from vibration on a two-inch thick foam pad. The primary power source is separate from the power source for the reference unit and spectrum analyzer. The outputs of the Unit Under Test and reference unit are mixed together. The IF output is connected to the input of the low frequency spectrum analyzer. The line related sidebands are observed on the analyzer display.

PERFORMANCE TESTS

4-19. POWER LINE RELATED SPURIOUS (CW AND AM MODES) (Cont'd)

Figure 4-6. Power Line Related Spurious Test Setup

NOTE

The Unit Under Test must be operated at a line (Mains) power frequency different than that of the reference unit and spectrum analyzer. This avoids the summing of the power line spurious signals.

EQUIPMENT:	Synthesized Signal Generator	HP 8672A
	Mixer	RHG DM1-18
	Spectrum Analyzer	HP 3580A
	Foam Pads	" "

- PROCEDURE:
1. Set the Unit Under Test to 3000 MHz at -20 dBm with all modulation off.
 2. Set the reference unit to 3000.020 MHz at 0 dBm.
 3. Set the spectrum analyzer controls for a start frequency of 20 kHz, frequency span per division 50 Hz, and resolution bandwidth 3 Hz.
 4. Connect the equipment as shown in Figure 4-6.
 5. Adjust the spectrum analyzer to set the 20 kHz signal to the top graticule line on the display. Verify that the line related harmonics of the Unit Under Test are below the values shown in the table. Record the highest spurious level on each offset band.

2.0-6.2 GHz	$f_o < 300 \text{ Hz}$	50 dB down	_____
	$300 \text{ Hz} < f_o < 1 \text{ kHz}$	60 dB down	_____

PERFORMANCE TESTS

4-19. POWER LINE RELATED SPURIOUS (CW AND AM MODES) (Cont'd)

6. Change the spectrum analyzer's frequency span per division to 500 Hz. Measure and record the spurious signal levels.

2.0–6.2 GHz $f_o > 1$ kHz 65 dB down _____

7. Tune the Unit Under Test and reference unit to 7000 and 7000.020 respectively. Change the spectrum analyzer's frequency span per division to 50 Hz. Measure and record the spurious signal levels.

6.2–12.4 GHz $f_o < 300$ Hz 44 dB down _____

300 Hz $< f_o < 1$ kHz 54 dB down _____

8. Repeat step 6.

6.2–12.4 GHz $f_o > 1$ kHz 59 dB down _____

9. Repeat step 7 at 16 000 and 16 000.020 MHz respectively.

12.4–18.0 GHz $f_o < 300$ Hz 40 dB down _____

300 Hz $< f_o < 1$ kHz 50 dB down _____

10. Repeat step 6.

12.4–18.0 GHz $f_o > 1$ kHz 55 dB down _____

11. If the power supply related spurious are not within tolerance, refer to Section VIII, Service Sheet 12-A3 for troubleshooting information.

4-20. SINGLE-SIDEBAND PHASE NOISE RATIO

SPECIFICATION:

Frequency Range (GHz)	Single Sideband Phase Noise Ratio (in 1 Hz Bandwidth and CW Mode) at Specified Offset Frequency				
	10 Hz	100 Hz	1 kHz	10 kHz	100 kHz
2.0–6.2	–60 dBc	–68 dBc	–78 dBc	–89 dBc	–109 dBc
6.2–12.4	–54 dBc	–62 dBc	–72 dBc	–83 dBc	–103 dBc
12.4–18.0	–50 dBc	–58 dBc	–68 dBc	–79 dBc	–99 dBc

DESCRIPTION: The RF outputs of two synthesizers are mixed together to obtain a 40 kHz or 200 kHz IF signal. The noise sidebands are observed on a spectrum analyzer. Correction factors are applied to compensate for the use of bandwidths wider than 1 Hz and for using the spectrum analyzer.

PERFORMANCE TESTS

4-20. SINGLE-SIDEBAND PHASE NOISE RATIO (Cont'd)

Figure 4-7. Single-Sideband Phase Noise Ratio Test Setup

EQUIPMENT:	Synthesized Signal Generator	HP 8672A
	Spectrum Analyzer (5 Hz–50 kHz)	HP 3580A
	Spectrum Analyzer (20 Hz–300 kHz)	HP 8556A/8552B/141T
	Mixer	RHG DM1-18

NOTE

The signal-to-phase noise ratio as measured with the spectrum analyzer is reduced by the 2.4 dB noise correction factor. This correction is necessary due to the spectrum analyzer characteristics.

- PROCEDURE:
1. Set the 5 Hz–50 kHz spectrum analyzer's start frequency to 40 kHz, bandwidth 1 Hz, frequency span per division 5 Hz.
 2. Connect the equipment as shown in Figure 4-7.
 3. Set the Unit Under Test to 6100 MHz at –20 dBm.
 4. Set the reference unit to 6100.040 MHz at +3 dBm.
 5. Set the spectrum analyzer controls so the peak of the 40 kHz signal is at the top graticule line.
 6. Observe the noise level 10 Hz from the carrier. It should be greater than 60 dB below the carrier. Record the measured level. 57.6 dB down _____
 7. Change the center frequency of the Unit Under Test and the reference unit to 12 200 MHz and 12 200.040 MHz respectively.
 8. Observe the noise level 10 Hz from the carrier. It should be greater than 54 dB below the carrier. Record the measured level. 51.6 dB down _____
 9. Change the center frequencies to 18 000 MHz and 18 000.040 MHz.

PERFORMANCE TESTS

4-20. SINGLE-SIDEBAND PHASE NOISE RATIO (Cont'd)

10. Observe the noise level 10 Hz away from the carrier. It should be greater than 50 dB below the carrier.
47.6 dB down _____
11. Set the spectrum analyzer controls for a bandwidth of 3 Hz and frequency span per division of 20 Hz. (The use of a 3 Hz bandwidth requires a 4.77 dB correction in the measured noise level, that is, the actual noise level in a 1 Hz bandwidth is 4.77 dB lower than the noise measured in a 3 Hz bandwidth.)
12. Repeat steps 3 through 10 except observe the noise 100 Hz from the carrier. Record the measured levels. (The specification limits include the correction factors.)
- | | |
|------------|--------------------|
| 6100 MHz | 60.8 dB down _____ |
| 12 200 MHz | 54.8 dB down _____ |
| 18 000 MHz | 50.8 dB down _____ |
13. For the remainder of the procedure, use the 20 Hz–300 kHz spectrum analyzer. Set the analyzer's bandwidth to 30 Hz and frequency span per division to 200 Hz. The 30 Hz bandwidth requires a 14.77 dB correction.
14. Set the frequency of the Unit Under Test to 6100 MHz; change the reference oscillator frequency to 6100.200 MHz.
15. Tune the spectrum analyzer to place the 200 kHz IF signal at the left edge of the display. Set the spectrum analyzer controls to place the peak of the 200 kHz signal at the top graticule line. Increase the log reference level control to move the peak of the carrier 20 dB above the top graticule line.
16. Observe the noise level 1 kHz from the carrier. The corrected level should be greater than 75 dB down. Record the measured level.
60.8 dB down _____
17. Change the Unit Under Test and reference unit frequencies to 12 200 MHz and 12 200.200 MHz respectively. The corrected noise level 1 kHz from the carrier should be greater than 69 dB down. Record the measured level.
54.8 dB down _____
18. Change the center frequencies to 18 000 MHz and 18 000.200 MHz. The corrected noise level 1 kHz from the carrier should be greater than 65 dB down. Record the measured level.
50.8 dB down _____
19. Set the spectrum analyzer controls for a bandwidth of 300 Hz and a frequency span per division of 2 kHz. The correction for the 300 kHz bandwidth is 24.77 dB.
20. Repeat steps 14 through 18 except observe the noise 10 kHz from the carrier and add the 24.77 dB correction factor. Record the measured levels.
- | | |
|------------|--------------------|
| 6100 MHz | 61.8 dB down _____ |
| 12 200 MHz | 55.8 dB down _____ |
| 18 000 MHz | 51.8 dB down _____ |
-

PERFORMANCE TESTS

4-20. SINGLE-SIDEBAND PHASE NOISE RATIO (Cont'd)

21. Set the spectrum analyzer controls for a bandwidth of 3 kHz and frequency span per division of 20 kHz. The correction factor is 34.77 dB.
22. Repeat steps 14 through 18 except observe the noise 100 kHz from the carrier and add the 34.77 dB correction factor. Record the measured levels.

6100 MHz	71.8 dB down _____
12 200 MHz	65.8 dB down _____
18 000 MHz	61.8 dB down _____

23. If the Single-Sideband Phase Noise Ratio is out of tolerance, perform the following adjustments in Section V: YTO Driver, VCXO, M/N Loop, 20/30 Loop VCO, YTO Sampler, YTO Phase Detector, YTO Offset and FM Overmodulation and FM Driver.

4-21. FM FREQUENCY RESPONSE

SPECIFICATION: (Relative to 100 kHz)

For 30 and 100 kHz/V ranges, ± 2.0 dB from 100 Hz to 3 MHz

For 300 kHz and 1.3 and 10 MHz/V ranges, ± 2.0 dB from 3 kHz to 3 MHz.

DESCRIPTION:

The test oscillator is tuned to 100 kHz and the output level is adjusted to obtain the first carrier (Bessel) null ($\beta = 2.404$). The output level and the 100 kHz rate are the references for later calculations. At other modulation rates, the output level is set and measured for the first carrier null. The measured voltage and the rate are then compared to the established reference to determine frequency response.

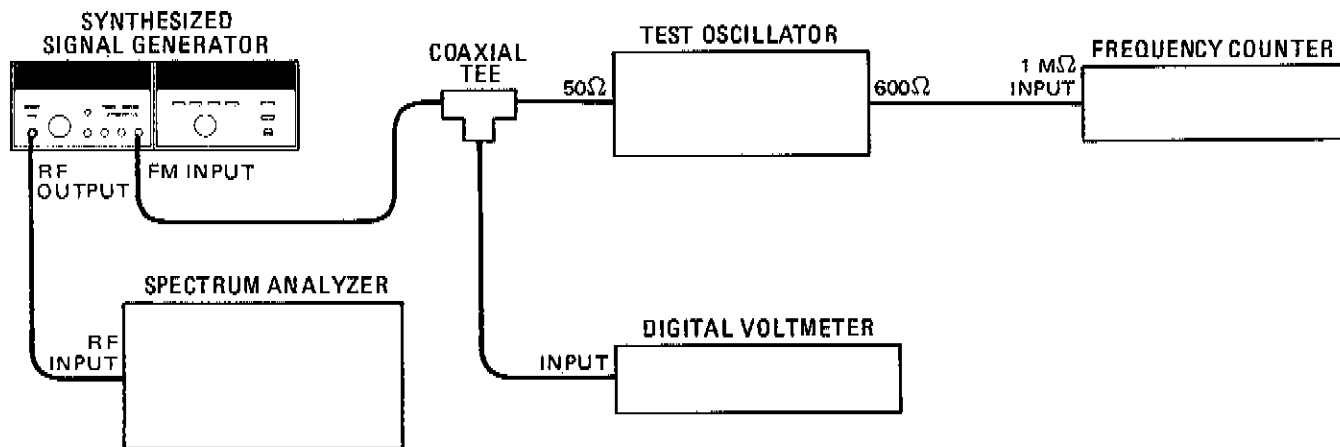

Figure 4-8. FM Frequency Response Test Setup

EQUIPMENT:

Digital Voltmeter	HP 3455A
Frequency Counter	HP 5340A
Spectrum Analyzer	HP 8565A
Test Oscillator	HP 651B

PERFORMANCE TESTS

4-21. FM FREQUENCY RESPONSE (Cont'd)

- PROCEDURE:
1. Connect the equipment as shown in Figure 4-8.
 2. Tune the Synthesizer's controls to 3 GHz at 0 dBm. Adjust the spectrum analyzer's controls to display the RF signal. Set the scan width to 100 kHz per division initially. Set the other controls as needed for a calibrated display. (It will be necessary to change the scan width for later measurements).
 3. Set the FM deviation switch to the 10 MHz range and tune the test oscillator as accurately as possible to 100 kHz.
 4. Adjust the test oscillator output voltage to obtain the first carrier (bessel) null ($\beta = 2.404$). Record the voltage indicated on the digital voltmeter in the table. (The voltage should be approximately 0.17 Vrms).
 5. Tune the test oscillator to 3 kHz (f_x) and adjust the output voltage (V_x) to obtain the first carrier null. Record the measured frequency and voltage in the table.
 6. Repeat step 5 for each of the remaining frequencies listed in the following table.

Frequency (in kHz)	Measured Frequency (f_x ; in kHz)	Measured Voltage V_x (mVrms)	Calculated Response (in dB)
3	_____	_____	_____
30	_____	_____	_____
100	100.0	_____	0
300	_____	_____	_____
1000	_____	_____	_____
3000	_____	_____	_____

7. Use the following equation to calculate the flatness of the FM circuits:

$$dB = 20 \log \frac{V_x}{V_{100 \text{ kHz}}} - 20 \log \frac{f_x}{100 \text{ kHz}}$$

where dB = the calculated frequency response

V_x = the voltage measured at f_x

$V_{100 \text{ kHz}}$ = the reference voltage measured at 100 kHz

f_x = the measured frequency.

8. If the FM frequency response is not within the required tolerance, perform the FM Driver Adjustment and the FM Adjustment in Section V.

PERFORMANCE TESTS

4-22. FM HARMONIC AND NON-HARMONIC DISTORTION

SPECIFICATION: Less than 12% for rates less than 3 kHz decreasing linearly with frequency to 5% at 20 kHz. Less than 5% for 20 to 100 kHz rates.

NOTE

For certain FM Modulating frequencies, spurious FM signals (non-harmonic distortion) may occur. After demodulation in an external FM discriminator, the contribution to distortion of those spurious FM signals is typically less than 0.6%.

DESCRIPTION: The frequency modulated RF output of the Unit Under Test is mixed with an unmodulated signal which is offset by 9 MHz. The 9 MHz IF signal is demodulated. The harmonics of the demodulated signal are viewed on a low frequency spectrum analyzer. The total distortion is computed using Table 4-2, Harmonic Level Versus Percentage Distortion.

Figure 4-9. FM Distortion Test Setup

EQUIPMENT:	Synthesized Signal Generator	HP 8672A
	Test Oscillator	HP 651B
	Mixer	RHG DM1-18
	FM Discriminator	HP 5210A
	1 MHz Low Pass Filter (for HP 5210A)	Refer to HP 5210A Operating and Service Manual
	Spectrum Analyzer	HP 8556A/8552B/141T
	Termination, 50Ω FeedThru	HP 11048C
	Resistor, 100Ω	HP 0698-7212

PERFORMANCE TESTS

4-22. FM HARMONIC AND NON-HARMONIC DISTORTION (Cont'd)

- PROCEDURE:**
1. Set the controls of the Unit Under Test to 3000 MHz at +3 dBm (+7 dBm maximum or maximum level power available).
 2. Set the reference unit's controls to 3009 MHz at 0 dBm.
 3. Set the test oscillator's controls to 100 kHz at 0.35 V_{rms}.
 4. Connect the equipment as shown in Figure 4-9. Be sure that the Unit Under Test is connected to the mixer's LO port. Be sure the 1 MHz Low Pass filter is installed in the FM Discriminator.
 5. Set the FM Deviation switch of the Unit Under Test to 1 MHz. Verify that the meter (with the METER MODE switch in the FM position) reads about 500 kHz peak deviation.
 6. Set the FM discriminator's controls to the 10 MHz frequency range and 0.01 volt sensitivity range.
 7. Adjust the spectrum analyzer's controls to view the recovered modulation and harmonics.
 8. To determine the total distortion, first convert each significant harmonic or spurious level from dB below the fundamental to the power ratio using Table 4-2, add the power ratios and convert the sum to percent distortion.

Example:

2nd harmonic:	30 dB down = .001
3rd harmonic:	45 dB down = .0000316
4th harmonic:	39 dB down = .0001259
5th harmonic:	60 dB down = .0000010
Significant Spurious Level:	57 dB down = <u>.0000020</u>
	.0011605 = 3.4%

or 3.4% distortion

The total distortion should be less than 5%. Record the level.

9. If the FM distortion is not within the required tolerance, perform the FM Driver Adjustments in Section V. Then, if necessary, refer to Service Sheet 8-A1 or 10-A3 for troubleshooting information.

4-23. RESIDUAL FM IN FM AND CW MODES**SPECIFICATION:** Noise and power line related

In CW and 30 kHz/V thru 3 MHz/V ranges

6 Hz-rms in 20 Hz—1 kHz post detection bandwidth

12 Hz-rms in 20 Hz—3 kHz post detection bandwidth

In 10 MHz/V range

10 Hz-rms in 20 Hz—1 kHz post detection bandwidth

20 Hz-rms in 20 Hz—3 kHz post detection bandwidth

Residual FM doubles in the 6.2—12.4 GHz range; triples in the 12.4—18.0 GHz range.

PERFORMANCE TESTS

4-23. RESIDUAL FM IN FM AND CW MODES (Cont'd)

DESCRIPTION: The RF output of the Unit Under Test is mixed with the RF output of the reference unit. The IF signal is demodulated and filtered. The filtered output is measured in rms volts and is proportional to the residual FM.

Figure 4-10. Residual FM in FM and CW Modes Test Setup

EQUIPMENT:	FM Discriminator	HP 5210A
	40 dB Amplifier	HP 465A
	Low Pass Filter (3 kHz)	CIR-Q-TEL FLT/21B-3K-5/50-3A/3B
	Low Pass Filter (1 kHz)	CIR-Q-TEL FLT/21B-1K-5/50-3A/3B
	Digital Voltmeter	HP 3455A
	Synthesized Signal Generator	HP 8672A
	Mixer	RHG DM 1-18
	50Ω Feedthru Termination	HP 11048C
	RMS Voltmeter	HP 3400A

PROCEDURE:

NOTE

The shorting board and 10 kHz filter are supplied with the FM Discriminator.

1. Install a shorting board in the FM discriminator. Set the sensitivity switch to calibrate position; set the range switch to 100 kHz.
2. Connect the digital voltmeter to the discriminator output.
3. Adjust the rear panel gain control for a discriminator output of 1.00 Vdc.

PERFORMANCE TESTS

4-23. RESIDUAL FM IN FM AND CW MODES (Cont'd)

4. Set the controls of the Unit Under Test as follows:
 METER MODE switch LEVEL
 RF switch ON
 OUTPUT LEVEL RANGE switch -30 dBm
 OUTPUT LEVEL VERNIER control
 (adjusted for meter reading) +3 dB
 ALC mode switch INT
 AM function switch OFF
 FM DEVIATION switch OFF
 PRESET (3 GHz) pushbutton press
5. Set the controls of the reference unit to 3000.1 MHz at +7 dBm maximum or maximum leveled power available.
6. Install a 10 kHz Butterworth low pass filter in the FM discriminator.
7. Connect the equipment as shown in Figure 4-10.
8. Connect a 3 kHz low pass filter to the amplifier output.
9. Set the Synthesizer's FM DEVIATION switch to each range in turn. Allow time for the voltage reading to settle. Measure the voltage for each range and record it in the following table. Be sure each reading is within the required tolerance. (The measurement sensitivity is 0.354 mVrms/Hz-rms).
10. Install a 1 kHz low pass filter and repeat step 9.

NOTES

This test may be performed at any desired frequency. The frequency of the reference unit must be 0.1 MHz greater than that of the Unit Under Test. If the frequency of the Unit Under Test is between 6.2 and 12.4 GHz, the specified residual FM doubles. From 12.4 to 18.0 the residual FM triples.

The test setup calibration can be checked by applying a 1 kHz signal to the FM input and adjusting the level to obtain 5 kHz peak deviation. The rms voltmeter should read 1.77 Vrms.

FM Range	Residual FM in Post Detection Bandwidth			
	20 Hz-1 kHz		20 Hz-3 kHz	
	Actual	Max	Actual	Max
CW (OFF)	_____	2.12 mVrms	_____	4.24 mVrms
0.03 MHz	_____	2.12 mVrms	_____	4.24 mVrms
0.1 MHz	_____	2.12 mVrms	_____	4.24 mVrms
0.3 MHz	_____	2.12 mVrms	_____	4.24 mVrms
1 MHz	_____	2.12 mVrms	_____	4.24 mVrms
3 MHz	_____	2.12 mVrms	_____	4.24 mVrms
10 MHz	_____	3.53 mVrms	_____	7.06 mVrms

PERFORMANCE TESTS

4-23. RESIDUAL FM IN FM AND CW MODES (Cont'd)

11. If the residual FM is not within the required tolerance, perform the Single-Sideband Phase Noise Ratio Performance Test.

4-24. RF OUTPUT LEVEL AND ACCURACY

SPECIFICATION: Output Level: +3 to -120 dBm into 50 ohms, +15 to +35°C. Additional power available on +10 dBm range (overrange), but for power settings above +3 dBm, spurious oscillations may degrade performance.

For Option 001 instruments, specified RF output power is +5 to -10 dBm; for Option 004 instruments, maximum is +2.0 dBm; for Option 005 instruments +4.0 to -10 dBm.

For Options 004 and 005 instruments, total indicated meter accuracy is degraded by an additional ± 0.25 dB.

Total Indicated Meter Accuracy: Applies for Internal Leveling only.

Frequency Range	Indicated Meter Accuracy (at OUTPUT LEVEL RANGE switch settings)*			
	0 dBm	-10 dBm	-20 dBm	-30 dBm and Below
2.0-6.2 GHz	± 1.75 dB	± 2.25 dB	± 2.45 dB	± 1.75 dB ± 0.30 dB per 10 dB step below 0 dBm range
6.2-12.4 GHz	± 2.00 dB	± 2.50 dB	± 2.70 dB	± 2.00 dB ± 0.30 dB per 10 dB step below 0 dBm range
12.4-18.0 GHz	± 2.25 dB	± 2.85 dB	± 3.05 dB	± 2.25 dB ± 0.40 dB per 10 dB step below 0 dBm range

*Specification includes allowances for meter accuracy (typically ± 0.5 dB), detector linearity, temperature, flatness, attenuator accuracy, and measurement uncertainty. All but the attenuator accuracy and measurement uncertainty can be calibrated out with a power meter at fixed vernier settings.

DESCRIPTION: A power meter is used to measure the Synthesizer's RF output level down to the -60 dBm range. All ranges below -60 dBm are checked by measuring the accuracy relative to the level measured at -60 dBm.

PERFORMANCE TESTS

4-24. RF OUTPUT LEVEL AND ACCURACY (Cont'd)

Figure 4-11. RF Output Level and Accuracy Test Setup

EQUIPMENT:	Synthesized Signal Generator	HP 8672A
	Power Meter/Power Sensor	HP 436A/8481A and 8484A
	Mixer	RHG DM1-18
	Spectrum Analyzer	HP 8556A/8552B/141T
	50 Ohm Feedthru Termination	HP 11048C
	40 dB Amplifier	HP 465A
	Semi-Rigid Coaxial Cable	Locally Fabricated

- PROCEDURE:
1. Set the controls of the Unit Under Test as follows:

PRESET (3 GHz) pushbutton	press for 3000 MHz
METER MODE switch	LEVEL
RF switch	ON
ALC	INT
Output LEVEL RANGE switch	0 dBm
Output LEVEL VERNIER control (adjust for meter reading)	0 dB
AM	OFF
FM	OFF

DO NOT CHANGE the VERNIER control setting for the remainder of this test.
 2. Connect the power sensor (HP 8481A) to the power meter and press the power meter's zeroing pushbutton. Calibrate the power meter/sensor.

PERFORMANCE TESTS

4-24. RF OUTPUT LEVEL AND ACCURACY (Cont'd)

3. Connect the power sensor to the RF OUTPUT connector of the Unit Under Test.
4. In the following steps, set the power meter's calibration factor switch as required. As indicated in the table and the following steps, measure and record the power level of the Unit Under Test.
5. Set the OUTPUT RANGE switch of the Unit Under Test to -10 and -20 dBm. Record the measured levels.
6. Set the OUTPUT RANGE switch to 0 dBm and repeat steps 4 and 5 at 8000 and $18\ 000$ MHz.
7. Replace the power sensor with the more sensitive model (HP 8484A).
8. Rezero and recalibrate the power meter system.
9. Connect the power sensor to the RF OUTPUT connectors of the Unit Under Test.
10. Measure and record the output levels at OUTPUT LEVEL RANGE switch settings of -30 to -60 dBm at frequencies of 3000 , 8000 , and $18\ 000$ MHz. Be sure to reset the calibration factor switch as required.

NOTE

This test may be performed at any frequency from 2–18 GHz.

Output Level Range (dBm)	Measured Output Level (dBm) at Frequency (f_o)								
	$2.0\ \text{GHz} \leq f_o < 6.2\ \text{GHz}$			$6.2\ \text{GHz} \leq f_o < 12.4\ \text{GHz}$			$12.4\ \text{GHz} \leq f_o \leq 18.0\ \text{GHz}$		
	Min	Measured	Max	Min	Measured	Max	Min	Measured	Max
0	-1.75	_____	+1.75	-2.00	_____	+2.00	-2.25	_____	+2.25
-10	-12.25	_____	-7.75	-12.50	_____	-7.50	-12.85	_____	-7.15
-20	-22.45	_____	-17.55	-22.70	_____	-17.30	-23.05	_____	-16.95

-50	-53.25	_____	-46.75	-53.50	_____	-46.50	-54.25	_____	-45.75
-60	-63.55	_____	-56.45	-63.80	_____	-56.20	-64.65	_____	-55.35

11. Disconnect the power meter. Connect the other equipment shown in Figure 4-11. If necessary, paint the non-movable seams of the Type-N to Sealectro connectors and semi-rigid cables with a conductive coating.¹

¹From the Sel. Rex Company, Conductive Coating, part number LO2-1068, HP part number 6010-0006.

PERFORMANCE TESTS

4-24. RF OUTPUT LEVEL AND ACCURACY (Cont'd)

NOTES

The remainder of this test does not make absolute power measurements. The test does give reasonable assurance that the output level accuracy in the lower ranges meets the performance standards.

The semi-rigid cables used in this test may easily be twisted or bent. Stressing these cables in any way may affect the measurement capability of the system.

12. Press the PRESET pushbutton of the Unit Under Test.
13. Tune the reference unit to 3000.020 MHz at +7 dBm or maximum leveled power available.
14. Adjust the spectrum analyzer's vertical sensitivity controls so the amplitude of the IF signal (20 kHz) is set to the center horizontal graticule as a reference level (2 dB per division sensitivity). Note the vertical sensitivity control setting. Set the resolution bandwidth to 300 Hz or less.
15. Decrease the OUTPUT LEVEL RANGE switch setting of the Unit Under Test in 10 dB steps down to the lowest range. For each range, readjust the spectrum analyzer's vertical sensitivity controls to bring the displayed level back to the reference graticule. Record the difference from the reference level (step 14).
16. Tune the Unit Under Test to 8000 MHz; reference unit to 8000.020 MHz. Repeat steps 14 and 15.
17. Tune the Unit Under Test to 18 000 MHz; reference unit to 18 000.020 MHz. Repeat steps 14 and 15.

Output Level Range (dBm)	Output Level (dB down from level at -60 dBm range) at Frequency (f_o)								
	2.0 GHz $\leq f_o < 6.2$ GHz			6.2 GHz $\leq f_o < 12.4$ GHz			12.4 GHz $\leq f_o \leq 18.0$ GHz		
	Min	Measured	Max	Min	Measured	Max	Min	Measured	Max
-70	9.7	_____	10.3	9.7	_____	10.3	9.6	_____	10.4
-80	19.4	_____	20.6	19.4	_____	20.6	19.2	_____	20.8
-90	29.1	_____	30.9	29.1	_____	30.9	28.8	_____	31.2
-100	38.8	_____	41.2	38.8	_____	41.2	38.4	_____	41.6
-110	48.5	_____	51.5	48.5	_____	51.5	48.0	_____	52.0

18. If the RF output level and accuracy are not within tolerance, perform the ALC Adjustment procedure in Section V.

PERFORMANCE TESTS

4-25. INCIDENTAL PHASE AND FREQUENCY MODULATION

SPECIFICATION: At rates ≤ 10 kHz and 30% AM depth, incidental FM shall be:

- less than 5 kHz (0.5 radians) from 2.0 to 6.2 GHz
- less than 15 kHz (1.5 radians) from 6.2 to 12.4 GHz
- less than 10 kHz (1.0 radians) from 12.4 to 18 GHz.

DESCRIPTION: The RF outputs of two Synthesizers are mixed and the IF is monitored on an oscilloscope and spectrum analyzer. The Unit Under Test is amplitude modulated to establish a reference level on the spectrum analyzer at a synchronized phase difference of 90° (minimum measurement sensitivity to incidental phase and frequency modulation). The synthesizers' outputs are synchronized to a phase difference of 0° (maximum measurement sensitivity to incidental phase and frequency modulation). The measurement level is compared to the AM reference level.

Figure 4-12. Incidental Phase and Frequency Modulation Test Setup

EQUIPMENT:	Synthesized Signal Generator	HP 8672A
	Mixer	RHG DM1-18
	Test Oscillator	HP 651B
	Oscilloscope	HP 180C/1801A/1821A
	Spectrum Analyzer	HP 3580A
	Low Pass Filter (15 kHz)	(See Figure 1-3)

- PROCEDURE:
1. Set the controls of the Unit Under Test as follows:
 - METER MODE switch LEVEL
 - RF switch ON

PERFORMANCE TESTS

4-25. INCIDENTAL PHASE AND FREQUENCY MODULATION (Cont'd)

OUTPUT LEVEL RANGE switch -20 dBm
 OUTPUT LEVEL VERNIER control
 (adjusted for meter reading) +3 dB
 ALC mode switch INT
 AM function switch OFF
 FM function switch OFF

2. Press the PRESET (3 GHz) pushbutton.
3. Set the reference unit controls for 3000.008 MHz at +3 dBm.
4. Connect the equipment as shown in Figure 4-12.
5. Adjust the oscilloscope's controls to obtain an 8 vertical division display of the 8 kHz IF signal.
6. Tune the reference unit to 3000.001 MHz.
7. Tune the reference unit to 3000.000 MHz to obtain a dc level within $\pm 1/10$ division of top graticule line.
8. Repeat steps 5 and 6 as often as necessary to end up within $\pm 1/10$ division. This may be quite difficult since the display is moving at a 1 kHz rate.
9. Set test oscillator's controls to 10 kHz at 0.34 Vrms.
10. Set the Unit Under Test AM function switch to 100%. Adjust the test oscillator output to obtain a display of 3.87 division peak-to-peak (48.5% AM).

NOTE

Do not adjust the test oscillator's controls for the duration of this test.

11. Adjust the spectrum analyzer controls for a convenient 0 dB reference level at 10 kHz.
12. Set Unit Under Test AM switch to OFF.
13. Tune the reference unit to 3000.001 MHz.
14. Retune the reference unit to 3000.000 MHz to obtain a dc level within $\pm 1/10$ division of the center graticule line.
15. Repeat steps 13 and 14 until the required tolerance is achieved.
16. Set the Unit Under Test AM switch to ON.
17. Measure and record the level indicated by the spectrum analyzer. The signal should be ≥ 5 dB below the reference level.

5 dB down _____

18. If the incidental phase and frequency modulation is not within tolerance, refer to Service Sheet 4 in Section VIII for troubleshooting information.
-

PERFORMANCE TESTS

4-26. FREQUENCY SWITCHING TIME

SPECIFICATION: (CW and AM modes)

Less than 15 ms to be within 1 kHz for frequencies 2–6.2 GHz; within 2 kHz from 6.2–12.4 GHz; within 3 kHz from 12.4–18 GHz.

DESCRIPTION: The measurement system is connected so the oscilloscope is triggered at the execute frequency change command. The mixer output is viewed on the oscilloscope display. Switching is completed when the displayed frequency settles to the minimum resolution (1, 2, or 3 kHz), the difference between the Synthesizers' outputs.

Figure 4-13. Frequency Switching Time Test Setup

EQUIPMENT:	HP-IB Controller	HP 9830A
	Synthesized Signal Generator	HP 8672A
	HP-IB Interconnect Cable	HP 10631A
	Mixer	RHG DM1-18
	Oscilloscope	HP 180C/1801A/1821A

WARNING

This test may be performed with power supplied and protective covers removed. If the covers are removed, this test should be performed only by service-trained personnel who are aware of the hazards involved (for example, fire and electrical shock).

PERFORMANCE TESTS

4-26. FREQUENCY SWITCHING TIME (Cont'd)**NOTE**

The necessity of removing the Synthesizer's covers to perform this test is eliminated if the oscilloscope's trigger input is connected to pin 6 of the HP-IB Interconnect Cable. In this case, proceed immediately to step 8.

- PROCEDURE:**
1. Disconnect the line (Mains) power cable from the Synthesizer's rear panel.
 2. Remove the two rear panel standoffs which are in contact with the top cover.
 3. Loosen the screw at the center of the top cover's rear lip. Slide the cover toward the rear. Remove the cover.
 4. Remove the screw which holds the A2 Assembly's protective cover in place. The screw is located near the right rear corner of the instrument.
 5. Lift and remove the cover while sliding it toward the rear of the instrument.
 6. Reconnect the line (Mains) power cable to the rear panel power module.
 7. Connect the oscilloscope's triggered vertical input to A2A7TP1. (This test point pulses high when the frequency execute command is accepted by the Synthesizer.
 8. Connect the Synthesizer and HP-IB controller together with a HP-IB Interconnect Cable.
 9. Set the oscilloscope controls to alternate B display, sweep time per division 2 ms, sweep mode normal/internal, and positive slope.

NOTE

The following programs are for the HP 9830A Calculator. For use with any other HP-IB controller, the program may need to be modified.

10. Load and run the following HP-IB controller program. This program is used to set the oscilloscope for reliable triggering on the pulse at A2A7TP1.

```

10 OUTPUT (13,20)1280,7531
20 FORMAT 2B
30 CMD "?U3", "Z1Z1Z1Z1Z1Z1Z1Z1Z1Z1"
40 GOTO 30
50 END

```

Frequency Execute

11. Connect the remaining equipment as shown in Figure 4-13.
12. Set the frequency of the reference unit to 2100.001 MHz at +5 dBm.

PERFORMANCE TESTS

4-26. FREQUENCY SWITCHING TIME (Cont'd)

13. Load and run the following program. The Synthesizer's initial conditions are set. Then this program will continue switching between output frequencies of 18 GHz and 2.1 GHz until the stop key is pressed.

```

10 OUTPUT (18,20)1280,768;
20 FORMAT 2B
30 CMD "?US","K00075"
40 CMD "", "P18000000Z1"
50 WAIT 30
60 CMD "", "A2100000Z1"
70 WAIT 10
80 GOTO 40
90 END

```

0 dBm range, 0 dB meter reading, AM OFF, FM OFF, RF OFF, and EXT XTAL.

18 000.000 MHz, frequency execute.

2100.000 MHz, frequency execute

NOTE

Lines 50 and 70 are included to stabilize the oscilloscope's display.

14. Measure the switching time by observing the signal on the oscilloscope display. (The Frequency Execute program code triggers the oscilloscope's horizontal sweep. Therefore, the timing begins at the display's left graticule. The timing ends at the last phase reversal as the IF signal settles into a steady frequency. Refer to Figure 4-13. This should occur in less than 15 ms. Record the switching time.

_____ 15 ms

15. Interchange lines 40 and 60 of the program.
16. Tune the reference unit to 17 999.997 MHz.
17. Rerun the program. Record the switching time to the last phase reversal.

_____ 15 ms

18. If the frequency switching time is not within tolerance, refer to Section VIII Service Sheet 1 for troubleshooting information.

4-27. OUTPUT LEVEL SWITCHING TIME

SPECIFICATION: <20 ms (typically <10 ms for any change on the same output level range). Applies for internal leveling only.

DESCRIPTION: The measuring system is set up to trigger the oscilloscope at the instant the change output level command is given. The RF output is detected and coupled to the oscilloscope's vertical input. The time to complete switching (which includes settling time) is viewed on the oscilloscope display.

PERFORMANCE TESTS

4-27. OUTPUT LEVEL SWITCHING TIME (Cont'd)

WARNING

This test may be performed with power supplied and protective covers removed. If the covers are removed, this test should be performed only by service-trained personnel who are aware of the hazards involved (for example, fire and electrical shock).

NOTE

The necessity of removing the Synthesizer's covers to perform this test is eliminated if the oscilloscope's trigger input is connected to pin 6 of the HP-IB cable. In this case, proceed immediately to step 8.

- PROCEDURE:
1. Disconnect the line (Mains) power cable from the Synthesizer's rear panel.
 2. Remove the two rear panel standoffs which are in contact with the top cover.
 3. Loosen the screw at the center of the top cover's rear lip. Slide the cover toward the rear. Remove the cover.

PERFORMANCE TESTS

4-27. OUTPUT LEVEL SWITCHING TIME (Cont'd)

4. Remove the screw which holds the A2 Assembly's protective cover in place. The screw is located near the right rear corner of the instrument.
5. Lift the cover while sliding it toward the rear of the instrument.
6. Remove the A2A9 Remote Interface Assembly. Reinstall it on a 30 pin extender board.
7. Reconnect the line (Mains) power cable to the rear panel power module. Allow the Synthesizer to warm up until the OVEN status light goes out.
8. Connect the rest of the equipment as shown in Figure 4-14.
9. Connect the oscilloscope's triggered input to A2A9 U14-pin 15, or pin 6 of the HP-IB Interconnect Cable. Set the oscilloscope to trigger on the negative going edge of the DAV (Data Valid) pulse.
10. Set the oscilloscope to 5 ms per division, persistence to maximum and input sensitivity as required.
11. Load and run the following HP-IB controller program.

NOTE

The following program is for use in the HP 9830A Calculator. For use with any other HP-IB controller, the program must be modified.

```

3000,000 MHz, frequency execute, 0 dB meter reading, AM OFF, FM OFF, RF ON and EXT XTAL.

F is a counter; repeats sub-routine (lines 60 through 110) 50 times.

Attenuation 0 dBm range, ready to reset attenuation.

Resets attenuation to -110 dBm range.

NOTES

Lines 80 and 100 are included to stabilize the oscilloscope's display.

When the oscilloscope is set to trigger on the negative-going edge of the DAV pulse, the switching time from the maximum attenuation range to the 0 dBm range is displayed.

PERFORMANCE TESTS

4-27. OUTPUT LEVEL SWITCHING TIME (Cont'd)

12. When the STOP command (step 40) is reached, erase the oscilloscope display and press CONTINUE EXECUTE to complete the program. The time required to switch should be less than 20 ms. Record the slowest switching time shown on the oscilloscope display.

_____ 20 ms

13. If the output level switching time is not within the required tolerance, refer to Section VIII Service Sheet 4 for troubleshooting information.

4-28. AM RATES

SPECIFICATION: For 3 dB bandwidth: 10 Hz to 100 kHz.

DESCRIPTION: The Synthesizer is modulated with a signal of fixed amplitude at various frequencies. A loaded crystal detector is used to demodulate the microwave signal and the amplitude of the recovered modulation is observed on an oscilloscope.

Figure 4-15. AM Rate Test Setup

EQUIPMENT:

Crystal Detector	HP 8470B Option 012
Oscilloscope	HP 180C/1801A/1821A
Test Oscillator	HP 651B
600 Ω Feedthru Termination	HP 11095A

- PROCEDURE:**
1. Connect the equipment as shown in Figure 4-15.
 2. Set the Synthesizer's AM function switch to 30%, OUTPUT LEVEL to 0 dBm, and tune to 3000 MHz.
 3. Set the test oscillator output to 10 kHz and adjust the output amplitude to obtain an indicated 30% AM on the Synthesizer's front panel meter.
 4. Set the oscilloscope to obtain a 5 division peak-to-peak display of the demodulated waveform. The 5 division display represents the nominal 0 dB point. A 3.5 division display is 3 dB down, and a 7 division display is 3 dB greater.

PERFORMANCE TESTS

4-28. AM RATES (Cont'd)

- Vary the test oscillator's frequency over the range of 10 Hz to 100 kHz while observing the signal amplitude on the oscilloscope. The signal should remain within the 3.5 to 7.0 division limits.

Maximum amplitude _____ 7.0 div.

Minimum amplitude 3.5 div. _____

NOTE

This test may be performed at any desired output frequency.

- If the AM bandwidth is not within the required tolerance, perform the AM Bandwidth Adjustment in Section V.

4-29. INCIDENTAL AM

SPECIFICATION: Less than 10% at rates less than or equal to 100 kHz and peak deviation less than or equal to 1 MHz.

DESCRIPTION: A reference is established by modulating the Synthesizer at 10% AM (the maximum allowable incidental AM). The detected signal is measured with a voltmeter. The Synthesizer is frequency modulated while the detected AM level is compared to the reference level.

Figure 4-16. Incidental AM Test Setup

EQUIPMENT:	Crystal Detector	HP 8470B Option 012
	Digital Voltmeter	HP 3455A
	Test Oscillator	HP 651B
	50Ω Feedthru Termination	HP 11048C

- PROCEDURE:**
- Connect the equipment as shown in Figure 4-16.
 - Set the Synthesizer's AM function switch to 30% and the METER MODE switch to AM.

PERFORMANCE TESTS

4-29. INCIDENTAL AM (Cont'd)

3. Adjust the test oscillator's controls for an indicated 10% AM level at a 10 kHz rate.
4. Record the detected level of AM as indicated by the digital voltmeter.
Reference Level _____ Vrms
5. Set the Synthesizer's AM function switch to OFF; set the FM Deviation switch to 1 MHz.
6. Set the test oscillator's frequency to 100 kHz.
7. Vary the test oscillator's amplitude between 0 and 0.35 Vrms. Verify that the DVM reading is less than the level recorded in step 4. Record the maximum level.
_____ Vrms
8. If the incidental AM is not within the required tolerance, refer to Section VIII, Service Sheet 4 for troubleshooting information.

4-30. INTERNAL TIME BASE AGING RATE

SPECIFICATION: Less than 5×10^{-10} per day after 30 day warmup. For instruments disconnected from Mains power less than 24 hours, the aging rate is $< 5 \times 10^{-10}$ per day after a 24 hour warmup.

DESCRIPTION: A reference signal from the Synthesizer (10 MHz OUT) is connected to the oscilloscope's vertical input. A frequency standard (with long term stability greater than 1×10^{-10}) is connected to the trigger input. The time required for a specific phase change is measured immediately and after a period of time. The aging rate is inversely proportional to the absolute value of the difference in the measured times.

Figure 4-17. Internal Time Base Aging Rate Test Setup

EQUIPMENT:

Frequency Standard	HP 5065A
Oscilloscope	HP 180C/1801A/1821A
50Ω Feedthru Termination	HP 11048C

NOTE

Be sure the Synthesizer has had 30 days to warm up before beginning this test. If the Synthesizer was disconnected from the power line for less than 24 hours, only a 24 hour warm-up is needed.

- PROCEDURE:**
1. Set the rear panel **FREQ REFERENCE INT-EXT** switch to the **INT** position.

PERFORMANCE TESTS

4-30. INTERNAL TIME BASE AGING RATE (Cont'd)

2. Connect the equipment as shown in Figure 4-17.
3. Adjust the oscilloscope controls for a stable display of the 100 MHz Synthesizer output.
4. Measure the time required for a phase change of 360° . Record the time (T_1) in seconds.

$$T_1 = \text{_____ s}$$

5. Wait for a period of time (from 3 to 24 hours) and re-measure the phase change time. Record the period of time between measurements (T_2) in hours and the new phase change time (T_3) in seconds.

$$T_2 = \text{_____ h}$$

$$T_3 = \text{_____ s}$$

6. Calculate the aging rate from the following equation:

$$\text{Aging Rate} = \left| \left(\frac{1 \text{ cycle}}{f} \right) \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \left(\frac{T}{T_3} \right) \right|$$

where: 1 cycle = the phase change reference for the time measurement (in this case, 360°)

f = Synthesizer's reference output frequency (10 MHz)

T = specified time for aging rate (24h)

T_1 = initial time measurement (s) for a 360° (1 cycle) change

T_2 = time between measurements (h)

T_3 = final time measurement (s) for a 360° (1 cycle) change

for example:

$$\text{if } T_1 = 351\text{s}$$

$$T_2 = 3\text{h}$$

$$T_3 = 349\text{s}$$

then:

$$\begin{aligned} \text{Aging Rate} &= \left| \left(\frac{1 \text{ cycle}}{10 \text{ MHz}} \right) \left(\frac{1}{351\text{s}} - \frac{1}{349\text{s}} \right) \left(\frac{24\text{h}}{3\text{h}} \right) \right| \\ &= 1.306 \times 10^{-11} \end{aligned}$$

7. Verify that the aging rate is less than 5×10^{-10} .

NOTE

If the absolute frequencies of the frequency standard and the Synthesizer's reference oscillator are extremely close, the measurement time in steps 5 and 6 (T_1 and T_3) can be reduced by measuring the time required for a phase change of something less than 360° . Change 1 cycle in the formula (i.e., $180^\circ = 1/2$ cycle, $90^\circ = 1/4$ cycle).

8. If the aging rate is not within the required tolerance, refer to Section VIII, Service Sheet 2 for troubleshooting information. Be sure sufficient warm-up time has been allowed.

SECTION V ADJUSTMENTS

5-1. INTRODUCTION

5-2. This section contains adjustments and checks that assure peak performance of the Synthesizer. This instrument should be readjusted after repair or failure to pass a performance test. Allow a 30 minute warm-up prior to performing the adjustments.

5-3. The order in which the adjustments are made is critical. Prior to making any adjustments, refer to the paragraph entitled Related Adjustments.

5-4. Determining the adjustments to be performed after a component failure and subsequent repair or a performance test failure is important. This will help keep the adjustment time to a minimum. After the repair and/or adjustment, performance tests are usually required to verify proper performance. Refer to the paragraph entitled Related Adjustments.

5-5. SAFETY CONSIDERATIONS

5-6. This section contains information, cautions and warnings which must be followed for your protection and to avoid damage to the equipment.

WARNINGS

Maintenance described in this section is performed with power supplied to the instrument and with protective covers removed. Maintenance should be performed only by service trained personnel who are aware of the hazard involved (for example, fire and electrical shock). Where maintenance can be performed without power applied, the power should be removed.

A pin-to-pin voltage difference of 60 Vdc may be found on many of the Synthesizer's circuit board connectors. Be careful while working on the circuit boards with power supplied to the instrument.

If a circuit board is placed on an extender board, the possibility of coming in

contact with 60 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

5-7. EQUIPMENT REQUIRED

5-8. Each adjustment procedure contains a list of required test equipment and accessories. The test equipment is identified by callouts in the test setup diagrams included with each procedure.

5-9. If substitutions must be made for the specified test equipment, refer to Table 1-2 for the minimum specifications. It is important that the test equipment meet the critical specifications listed in the table if the Synthesizer is to meet its performance requirements.

5-10. The HP 11712A Service Kit is an accessory item available from Hewlett-Packard for use in maintaining the Synthesizer.

5-11. FACTORY SELECTED COMPONENTS

5-12. Factory selected components are identified on the schematics and parts list by an asterisk which follows the reference designator. The normal value or range of the components are shown. The manual change sheets will provide updated information pertaining to the selected components. Table 5-1 lists the reference designator, the criterion used for selecting a particular value, the normal value range, and the service sheet where the component part is shown.

5-13. RELATED ADJUSTMENTS

5-14. If all the adjustments are to be performed, they should be done in order with the exception of the A2 Assembly Adjustments. These adjustments should be performed after the M/N Loop Adjustments and before the YTO Sampler Adjustments.

5-15. In the event of a performance test or component failure, it must be determined if an adjustment procedure should be performed or if the instrument should be repaired. Tables 5-2 and 5-3 indicate the required action in either case.

RELATED ADJUSTMENTS (Cont'd)

5-16. After the instrument is repaired and/or adjusted, performance test(s), a frequency check and verification of phase lock or all of these things must be done to verify proper performance of the Synthesizer. Tables 5-2 and 5-3 contain the necessary information that provides assurance of proper performance.

5-17. Prior to performing the adjustment procedures, refer to the disassembly procedures in Sec-

tion VIII. These procedures cover the removal of the top and bottom covers, the internal A1 and A2 assembly covers, and the A3A9 YTO Loop Assembly.

5-18. ADJUSTMENT LOCATIONS

5-19. The last foldouts in this manual contain figures that show the locations of assemblies, adjustments, test points and chassis parts.

Table 5-1. Factory Selected Components

Reference Designator	Service Sheet	Range of Values	Basis of Selection
A1A13R1	1-A1	100 k Ω to 1 M Ω	Matched to the A1A13A1 Preamplifier at the factory.
A3A1A2C8	2-A3	0 to 8 pF	Centers the frequency adjustment range of A3A1A2C4 about 100 MHz.
A3A1A2L4	2-A3	0.22 to 0.68 μ H	Centers the adjustment range of A3A1A2C4 around 100 MHz. Refer to the VCXO Adjustment procedure.
A3A1A2R67, R68 and R69	2-A3	Refer to Table 5-4.	Required change in attenuation necessary for a -10 dBm output level of the 400 MHz signal. Refer to the VCXO Adjustment procedure.
A3A7C19	10-A3	160 or 220 pF	Matched to the part number of A3A9A3 2.0-6.2 GHz YTO Assembly. 160 pF with HP 5086-7131; 220 pF with HP 5086-7242.
A3A7C48	7-A3	3.9 to 5.6 pF	For the 100 kHz or lower FM deviation range. Using the FM Frequency Response Test Setup (test oscillator and spectrum analyzer only). Set the test oscillator's controls to the spectrum analyzer's display of the first FM sidebands are 30 dB down from carrier at 1 MHz. At 3.16 MHz the sidebands should be 40 dB down; at 10 MHz, 50 dB down. If the response is peaking, insert a smaller value capacitor. If the response is rolling off, insert a larger value capacitor.
A3A7R61, R65 and R75	10-A3	R61: 1620 or 1960 Ω R75: 1780 or 2150 Ω R65: 3.16 to 11.0 k Ω	Normal values for sensitivity of 10 MHz-pk/Vrms from front panel; R61, 1960 Ω ; R75, 1820 Ω ; R65, 5110 Ω . If sensitivity is low, change R75 to 2150 Ω ; R65 to 3830 Ω . If sensitivity is high, change R61 to 1620 Ω ; R75 to 1780 Ω ; R65 to 9090 Ω . Measure the dc voltage on the emitter of Q5. If more negative with -8.0 Vdc, reduce the value of R65; if more positive than -0.5 Vdc, increase the value of R65.
A3A7R67	10-A3	75 or 178 Ω	Matched to the part number of A3A9A3 2.0-6.2 GHz YTO Assembly: 178 Ω with HP 5086-7131; 75 Ω with HP 5086-7242.
A3A9A4R20	9-A3	348 Ω to 1.21 k Ω	YTO Loop gain crossover of 20 \pm 2 kHz. Refer to the YTO Loop Phase Detector Adjustment.

Table 5-2. Performance Test Failure and Required Action (1 of 2)

Performance Test Failure ¹	Adjustment or Repair	Repeat Performance Test(s)
Output Level Flatness —or— RF Output Level and Accuracy	ALC Adjustments Output Attenuator or Output Cable malfunction.	Output Level Flatness. RF Output Level and Accuracy. All AM Tests.
SWR	Refer to Section VIII for repair information (no adjustment). Output attenuator or cable malfunction.	SWR
Harmonics and Subharmonics	YTM and ALC Adjustments or YTM failure.	Output Level Flatness. RF Output Level and Accuracy. Harmonics and Subharmonics.
Non-Harmonically Related Spurious	This problem may occur anywhere in the instrument. Isolate the defective component and make adjustments as required (see Table 5-3).	Non-Harmonically Related Spurious. Other tests are as required.
Power Line Related Spurious	Refer to Section VIII, SS12-A3.	Power Line Related Spurious.
Single-Sideband Phase Noise Ratio	YTO Driver VCXO, M/N Loop, 20/30 Loop VCO, 20/30 Loop Bias, YTO Sampler, YTO Phase Detector, YTO Offset and FM Overmodulation, and FM Driver Adjustments.	Check for phase lock. Single-Sideband Phase Noise Ratio. All FM tests.
AM Distortion	Repair of AM or ALC circuits required. ² Adjustment (if any) related to repair.	Related to Repair.
AM Depth Meter Accuracy, and Input Accuracy	For incorrect meter accuracy, perform the AM Meter Adjustment; for incorrect input accuracy, troubleshoot the AM and ALC circuits.	AM Depth Meter Accuracy and Input Accuracy.
AM Rates (3 dB Bandwidth)	AM Bandwidth Adjustment	AM Rate (3 dB Bandwidth).
Incidental Phase and Frequency Modulation	Repair AM, YTM, or ALC circuits (see Table 5-3).	Related to Repair.
FM Accuracy —or— FM Frequency Response	FM Driver Adjustment FM Adjustments	All FM tests.
FM Distortion	First perform FM Driver Adjustments; then, if necessary, repair FM Driver or FM Input Circuits (see Table 5-3).	All FM tests.
Residual FM in FM and CW Modes	Check FM Driver for hum, noise or ground loops. Check the YTO Loop for "solid" phase lock.	Single-Sideband Phase Noise Ratio.

¹ If the output frequency is incorrect or any of the phase lock loops are unlocked, make the appropriate adjustments and (if necessary) refer to Section VIII for repair information. After adjustment or repair, check for the correct frequency and verify that the phase lock loops are locked. Perform the single-sideband phase noise ratio test.

² Excessive AM distortion (clipping) in the +10 dBm OUTPUT LEVEL RANGE may occur. Reducing the output level by setting the range to 0 dBm or turning the VERNIER ccw should reduce the AM distortion to an acceptable level.

Table 5-2. Performance Test Failure and Required Action (2 of 2)

Performance Test Failed ¹	Adjustment or Repair	Repeat Performance Test(s)
Incidental AM	Repair or adjust the YTM and ALC circuits (see Table 5-3).	Output Level Flatness. RF Output Level Accuracy. Harmonics and Sub-Harmonics. Incidental AM.
Frequency Switching Time	Repair or adjust the YTO Loop or the remote programming circuit boards A2A7 and A2A9.	Frequency Switching Time.
Output Level Switching Time	Repair the output attenuator driver; replace the output attenuator	Output Level Switching Time.
Internal Time Base Aging Rate	Replace A3A8 or repair power supply. ²	Internal Time Base Aging Rate.
¹ If the output frequency is incorrect or any of the phase lock loops are unlocked, make the appropriate adjustments and (if necessary) refer to Section VIII for repair information. After adjustment or repair, check for the correct frequency and verify that the phase lock loops are locked. Perform the single-sideband phase noise ratio test.		
² Be sure sufficient warm-up time has been allowed. It may require up to 30 days.

ADJUSTMENTS

5-20. A3 RF SOURCE ASSEMBLY ADJUSTMENTS

5-21. Power Supply Adjustments

REFERENCE: Service Sheets 11-A3, 12-A3, and 13-A3.

DESCRIPTION: Adjust the +22 volt and +20 volt power supplies to their required tolerance. Check the remaining supply voltages for which the +20 volt supply is the reference (+11V, +5.2V, -5.2V, -10V, and -40V).

EQUIPMENT: Digital Voltmeter HP 3455A

- PROCEDURE:
1. Remove the Synthesizer's top cover.
 2. Set the LINE switch to ON; set the rear panel FREQ STANDARD INT/EXT switch to INT.
 3. Connect the DVM input to A3A2TP1.
 4. Adjust +22 ADJ A3A2R5 for a DVM reading of $+22.00 \pm 0.02$ Vdc.
 5. Connect the DVM input to A3A3TP5.
 6. Set +20 ADJ A3A3R50 for a DVM reading of $+20.0 \pm 0.001$ Vdc.
 7. Check the following power supplies as shown in the table. If any voltages are incorrect, try resetting A3A3R50 for the correct +20V, +5.2V, -5.2V, -10V, and -40 Vdc levels. All voltages should be within tolerance. If necessary refer to troubleshooting information in Section VIII. Repair the supply in question and recheck the voltage.

Power Supply	Test Point	Power Supply Voltage (Vdc)	
		Min.	Max.
+11 Vdc	A3A3TP6	+9.9	+12.1
+5.2 Vdc	A3A3TP2	+5.1	+5.3
-5.2 Vdc	A3A4TP5	-5.1	-5.3
-10 Vdc	A3A4TP4	-9.8	-10.2
-40 Vdc	A3A4TP1	-39.00	-40.60

8. Perform the performance tests as required by 1) the test failure that led to this adjustment procedure or 2) the assembly that was repaired that led to this adjustment procedure.

ADJUSTMENTS

5-22. 10 MHz Reference Oscillator Adjustment

REFERENCE: Service Sheet 1-A3.

DESCRIPTION: Connect reference signal from the Synthesizer (10 MHz OUT) to the oscilloscope's vertical input. A frequency standard (with long term stability greater than 1×10^{-10}) is connected to the trigger input. Adjust the A3A8 Assembly's FREQ adjustment for a minimum drift rate.

Figure 5-1. 10 MHz Reference Oscillator Adjustment Test Setup

EQUIPMENT: Frequency Standard HP 5065A
 Oscilloscope HP 180C/1801A/1821A
 50Ω Feedthru Termination HP 11048C

NOTE

Be sure the Synthesizer has had 30-minutes to warm up before performing the adjustment. Verify that the oven and phase lock status indicators are not lit. If necessary, refer to the troubleshooting information in Section VIII.

- PROCEDURE:
1. Set the rear panel FREQ REFERENCE INT EXT switch to the INT position.
 2. Set the FREQ adjustment (on the A3A8 Assembly) so the signal, as observed on the oscilloscope display, is not drifting.
 3. Verify that in 10 seconds the display drifts less than 1 division. If necessary, repeat steps 2 and 3.

ADJUSTMENTS

5-23. Digital-to-Analog Converter Adjustment

REFERENCE: Service Sheet 6-A3.

DESCRIPTION: The adjustments set the analog output voltages with respect to the digital frequency inputs. Adjustments are made at certain selected frequencies of which some are below the low frequency limit of the Synthesizer (2000 MHz). These frequencies are selected by shorting the test point pair A2A8TP1 and tuning to the specified frequencies.

EQUIPMENT: Digital Voltmeter HP 3455A

- PROCEDURE:
1. Set the Synthesizer's controls as follows:
 - RF switch ON
 - ALC mode switch INT
 - TUNING control (adjust for frequency of) . . 4800.000 MHz
 2. Press the HOLD key.
 3. Connect the DVM ground lead to the reference ground, A3A6TP5. (The ground lead remains connected here for the remainder of this procedure). Be sure the A3A6 assembly is properly installed in the instrument.
 4. Attach the DVM test lead to A3A5TP4. Set Ref Adj (Reference Buffer output) A3A5R13 for a DVM reading of -6.50 ± 0.07 Vdc.
 5. Check the output voltages of the Reference Buffers at A3A5TP1 ($+10.75 \pm 0.25$ Vdc) and A3A5TP2 ($+10.00 \pm 0.15$ Vdc). Make repairs if necessary.
 6. Connect the DVM to the YTO Pretune Output, A3A5TP3.
 7. Short the test point pair, A2A8TP1, with an alligator clip. Adjust 1.6 GHz A3A5R4 (not 1.61) to obtain -4.800 ± 0.001 Vdc. Obtain an accuracy of ± 0.0001 Vdc if possible in this and succeeding steps.
 8. Remove the clip from A2A8TP1. Adjust 4.8 GHz A3A5R3 to obtain a reading of -14.400 ± 0.001 Vdc.
 9. Tune to 4900.000 MHz and short the test point pair A2A8TP1 with the clip. Adjust 1.7 GHz A3A5R29 to obtain -5.100 ± 0.001 Vdc.
 10. Repeat steps 7, 8, and 9 until all voltages are within 0.001 Vdc of the specified value.
 11. Tune the frequency to 4810.000 MHz. Verify that the clip is connected to A2A8TP1. Adjust 1.61 GHz A3A5R42 (not 1.61) to obtain a DVM reading of -4.830 ± 0.001 Vdc.
 12. Tune to 5000.000 MHz. Adjust 1.8 GHz A3A5R24 to obtain -5.400 ± 0.001 Vdc.
 13. Remove the alligator clip. Tune to 2000.000 MHz. Adjust 2.0 GHz A3A5R22 to obtain -6.000 ± 0.001 Vdc.
-

ADJUSTMENTS

5-23. Digital-to-Analog Converter Adjustment (Cont'd)

- 14. Tune to 2400.000 MHz. Adjust 2.4 GHz A3A5R20 to obtain -7.200 ± 0.001 Vdc.
- 15. Tune to 3200.000 MHz. Adjust 3.2 GHz A3A5R18 to obtain -9.600 ± 0.001 Vdc.
- 16. At each frequency listed in the table, check the YTO Pretune voltage at A3A5TP3 with the clip attached to the test point pair A2A8TP1.

Synthesizer Frequency	Voltage at A3A5TP3 (Vdc)
4.801 GHz	-4.803 ± 0.001
4.802 GHz	-4.806 ± 0.001
4.804 GHz	-4.812 ± 0.001
4.808 GHz	-4.824 ± 0.001
4.810 GHz	-4.880 ± 0.001
4.820 GHz	-4.860 ± 0.001
4.840 GHz	-4.920 ± 0.001
4.880 GHz	-5.040 ± 0.001

- 17. Tune to 4910.000 MHz. At A3A5TP3 the YTO Pretune voltage should be -5.130 ± 0.002 Vdc with the clip in place and -14.730 ± 0.002 Vdc with the clip removed. If necessary repeat the procedure. Then if the voltage tolerance cannot be met, refer to Section VIII for troubleshooting information.
- 18. Remove the DVM and clip lead.

5-24. YTO Driver Adjustment

REFERENCE: Service Sheet 7-A3.

DESCRIPTION: When the fundamental output of the Synthesizer is set to the maximum and minimum frequencies, the YTO Driver's gain and offset current are set to give specified YTO output frequencies.

EQUIPMENT: Frequency Counter HP 5340A

PROCEDURE: 1. Set the Synthesizer's RF switch to ON.

NOTE

All boards must be installed in the instrument before these adjustments are made.

ADJUSTMENTS

5-24. YTO Driver Adjustment (Cont'd)

2. Connect the frequency counter to the RF OUTPUT connector A1J1.
3. Connect the reference ground A3A6TP5 to YTO Tune 1) A3A7TP2 with a jumper wire.
4. Tune the Synthesizer to 2000.000 MHz. Set 2 GHz Adj A3A6R34 to obtain 2000.0 ± 0.1 MHz on the frequency counter.
5. Tune the Synthesizer to 6199.000 MHz. Set 6.199 GHz Adj A3A6R25 to obtain 6199.0 ± 0.1 MHz on the frequency counter.
6. Repeat steps 4 and 5 as required to obtain the required tolerance at both frequencies.
7. Disconnect A3A6TP5 from A3A7TP2.
8. Verify that the frequency output is accurate to 1 kHz and that the phase lock loops are locked before performing the Single-Sideband Phase Noise Ratio performance test in Section IV.

5-25. Voltage Controlled Crystal Oscillator (VCXO) Adjustment

REFERENCE: Service Sheet 2-A3.

DESCRIPTION: The open loop frequency and maximum power output of the 100 MHz VCXO is centered around 100 MHz. The output is set as close as practical to 100 MHz. The 400 MHz signal is adjusted for maximum 400 MHz output and minimum spurious output. The attenuator is selected to provide a 400 MHz output of -10 dBm.

Figure 5-2. VCXO Adjustment Test Setup

ADJUSTMENTS

5-25. Voltage Controlled Crystal Oscillator (VCXO) Adjustment (Cont'd)

EQUIPMENT: Frequency Counter HP 5340A
 Spectrum Analyzer HP 8565A
 Power Supply HP 6202B
 Power Meter HP 436A/8481A
 Digital Voltmeter HP 3455A

- PROCEDURE:
1. Connect the frequency counter to A3A1A2J2 in place of the termination; connect the spectrum analyzer to A3A1A2J1 in place of the gray-orange-white cable.
 2. Set the output of a low voltage power supply to -8.00 ± 0.01 Vdc. Connect the positive lead to ground and the negative lead to A3A1A2TP1 TUNE.
 3. Tune the 100 MHz Adj A3A1A2C4 for the maximum 100 MHz signal level as viewed on the spectrum analyzer display.
 4. Tune the 100 MHz Adj to increase the frequency (and decrease the amplitude) until the oscillation stops on the high frequency side; then tune the 100 MHz Adj to decrease the frequency until the oscillation stops. If the VCXO does not stop oscillating at the high end, decrease the value of A3A1A2C8 by 1 pF from its present value. If it does not stop at the low end, increase the value of A3A1A2C8 by 1 pF. If a change is necessary, repeat this step.
 5. Adjust the 100 MHz Adj to obtain the maximum signal level as viewed on the spectrum analyzer display. Slowly tune to a higher frequency until the power drops by 1 dB. Record Δf_1 , that is, how far the 1 dB point is above 100 MHz. Use the frequency counter to make the measurements to 10 Hz resolution.
 6. Tune to a lower frequency until the power is decreased 1 dB on the other side of the peak. Record Δf_2 , that is, how far the 1 dB point is below 100 MHz.
 7. The VCXO centering about 100 MHz is correct if $0.5 \leq \frac{\Delta f_1}{\Delta f_2} \leq 2$.
- If the ratio is less than 0.5, decrease A3A1A2L4 one value to increase the center frequency. If the ratio is greater than 2, increase A3A1A2L4 one value to decrease center frequency. Refer to the following table for the inductor values.

A3A1A2L4 Inductor Values

Value	HP Part Number
0.68 μ H	9100-0141
0.56 μ H	9100-2256
0.47 μ H	9100-2255
0.39 μ H	9100-2254
0.33 μ H	9100-0368
0.27 μ H	9100-2252
0.22 μ H	9100-2251

8. If the inductor value is changed, repeat steps 3 through 7.

ADJUSTMENTS

5-25. Voltage Controlled Crystal Oscillator (VCXO) Adjustment (Cont'd)

9. Adjust the 100 MHz Adj to obtain a VCXO output of 100 MHz \pm 100 Hz.
10. Connect the spectrum analyzer to the 400 MHz output. Set the spectrum analyzer's controls for a center frequency of 500 MHz, frequency span per division 100 MHz and vertical sensitivity per division 10 dB log. Adjust the 400 MHz A3A1A2C3, C2 and C1 adjustments in that order to obtain the maximum 400 MHz signal with the lowest harmonic levels possible.
11. Check the various harmonics of 100 MHz relative to the 400 MHz level. 200 and 800 MHz should be greater than 25 dB down; 100, 300, 500, 600, 700, and 900 MHz should be greater than 40 dB down. If necessary, repeat steps 10 and 11.
12. Connect the power meter to the 400 MHz Output (the gray-red-white cable) after disconnecting it from A3A1A5J1. The power should be -10 to -11 dBm. If the power is incorrect, select the values of A3A1A2R67, R68 and R69 from the Table of Attenuator Resistor Values to obtain the proper power level. The attenuation should always be at least 3 dB or greater.

Attenuator Resistor Values

Attenuation (dB)	Resistors (ohms)		
	R67	R68	R69
3	261	17.8	261
4	215	23.7	215
5	178	31.6	178
6	147	38.3	147
7	133	46.4	133
8	121	51.1	121
9	110	61.9	110

13. If the amount of attenuation is changed, recheck the harmonic levels.
14. Verify that the frequency output is accurate to 1 kHz and that the phase locked loops are locked before performing the Single Sideband Phase Noise Ratio test.

5-26. M/N Loop Adjustments

REFERENCE: Service Sheet 4-A3.

DESCRIPTION: The M/N loop frequency is set to track tuning voltage across the frequency range. The output level is set and checked to ensure an adequate R.F. output level across the band.

ADJUSTMENTS

5-26. M/N Loop Adjustments (Cont'd)

Figure 5-3. M/N Loop Adjustment Test Setup

EQUIPMENT:	Digital Voltmeter	HP 3455A
	Frequency Counter	HP 5340A
	Spectrum Analyzer	HP 8565A
	Power Supply	HP 6202B

- PROCEDURE:
1. Set the Synthesizer controls as follows:

RF Switch	ON
TUNING control	6090.000 MHz
FREQ REFERENCE INT-EXT switch	INT
 2. Connect the equipment as shown in Figure 3.
 3. Verify that the M/N output frequency is exactly 197.419 MHz ± 1 count.

NOTE

The adjustment screws for A3A1A4C1 and C5 are held in place by lock nuts. After making the adjustment, tighten the lock nuts and recheck the frequency and level.

WARNING

Because this circuit board is being placed on an extender board, the possibility of coming in contact with 60 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

4. Remove the A3A1A4/A5 Assembly and place it on a 30-pin extender board.

ADJUSTMENTS

5-26. M/N Loop Adjustments (Cont'd)

5. Connect the spectrum analyzer input to the M/N VCO output A3A1A4W1 (white coax).

CAUTION

Do not apply a positive voltage to A3A1A4TP1. A positive voltage will forward bias the VCO tuning diodes and may destroy them.

6. Connect the positive output of a power supply to ground; connect the negative output to the A3A1A4TP1 TUNE. Set the power supply for -35.0 ± 0.5 Vdc.

NOTE

The adjustment screws for A3A1A4A1C1 and C5 are held in place by lock nuts. After making the adjustment, tighten the lock nuts and recheck the frequency and level.

7. Release the lock nut for the PWR adjustment A3A1A4A1C5. Adjust A3A1A4A1C5 for an output level of 0 ± 2 dBm. Tighten the lock nut.
8. Slowly reduce the dc voltage at A3A1A4TP1 while monitoring the VCO output power on the spectrum analyzer. The output power should be greater than -2 dBm between 395 MHz (-35 Vdc) and 355 MHz (-2.3 Vdc).
9. Set FREQ ADJ A3A1A4A1C1 for a voltage level of -35.0 ± 0.5 Vdc.
10. Tune the Synthesizer frequency to 2100.000 MHz. Verify that the M/N output frequency is 177.500 MHz and the tuning voltage is -2.4 ± 0.7 Vdc.
11. Remove the power supply connection to A3A1A4TP1. Set the LINE switch to STANDBY; then install the A3A1A4/A5 assembly.

NOTE

If required, proceed to the 20/30 MHz Loop VCO Pre-tune Adjustments.

12. Verify that the frequency output is accurate to 1 kHz and that the phase lock circuits are locked before performing the Single-Sideband Phase Noise Ratio performance test in Section IV.

5-27. YTO Loop Sampler Adjustments

REFERENCE: Service Sheet 8-A3.

DESCRIPTION: The sampler is driven by a sweep oscillator and the dc output is monitored with an oscilloscope. The sampler driver circuit is adjusted for maximum amplitude and flatness over the range of the M/N Loop. The Sampler's IF preamplifier is adjusted for correct output level and the frequency response is checked.

ADJUSTMENTS

5-27. YTO Loop Sampler Adjustments (Cont'd)

Figure 5-4. YTO Loop Sampler Adjustment Test Setup

EQUIPMENT:	Oscilloscope (with divide-by-10 probe)	HP 180C/1801A/1821A
	Sweep Oscillator	HP 86220A/8620C
	Spectrum Analyzer	HP 8553B/8552B/141T
	Frequency Counter	HP 5340A

- PROCEDURE:
1. Set the Synthesizer's RF switch to OFF and disconnect the power cord.
 2. Remove the Synthesizer's top and bottom covers and place the A3A9 Assembly into the test position. See the disassembly procedures in Section VIII.
 3. Remove the right side cover of A3A9.
 4. Connect a 50 ohm termination to the A3A9A1 Directional Coupler.
 5. Set the sweep oscillator's controls for a leveled output level of 0 dBm, center frequency range of 187.5 ± 1.0 MHz (measured by frequency counter) and a sweep range of $200 \text{ MHz} \pm 100 \text{ MHz}$.
 6. Connect the equipment as shown in Figure 5-4. The sweep oscillator's RF output is connected to the M/N LOOP SIGNAL connector, A3A9J3, in place of the white-orange cable.
 7. Adjust A3A9A5C1 and C2 (with an insulated adjustment tool) to get an oscilloscope display similar to Figure 5-5. Tune for maximum negative voltage and flatness over the center two divisions. The minimum change from the reference level to the maximum negative voltage should be 0.4 volts.

ADJUSTMENTS

5-27. YTO Loop Sampler Adjustments (Cont'd)

Figure 5-5. Typical Swept Frequency Response at A3A9A5TP1
(frequency span per division 20 MHz)

8. Short A3A7TP2 to ground. Set the Synthesizer's RF switch to ON and tune to 2100 MHz. Disconnect the grey cable from the phase detector output A3A9J6. Remove the oscilloscope's probe from A3A9A5TP1.
9. Connect the spectrum analyzer's input directly to the IF OUT A3A9J2.
10. Set the sweep oscillator's controls for a center frequency of 177.5 ± 1.0 MHz; set the sweep width to 10 MHz.
11. Connect the sweep oscillator's output to the M/N LOOP SIGNAL input A3A9J3.
12. Set the spectrum analyzer's controls for a 0 to 100 MHz frequency span. Set the other controls to display the swept IF signal. The fundamental, second and third harmonics should be visible at 30, 60 and 90 MHz. Tune the sweep oscillator slightly to align the signals on the display.
13. Adjust the IF GAIN A3A9A5R1 so that the displayed IF signal at 30 MHz is $+2 \pm 1$ dBm.
14. Slowly tune the sweep oscillator's center frequency from 174 to 181 MHz and observe the fundamental's output level. Verify that the allowable level variation is not exceeded or that the power does not drop below the stated level over the frequency range.
 - a. From 20 to 30 MHz, +2 to +6 dBm.
 - b. From 6 to 20 MHz, -3 dBm.
 - c. From 30 to 70 MHz, -10 dBm.

ADJUSTMENTS

5-27. YTO Loop Sampler Adjustments (Cont'd)

15. Return the Synthesizer to normal operation by:
 - a. disconnecting the sweep generator;
 - b. reconnecting the gray cable to A3A9J6 and the white-orange cable to A3A9J3;
 - c. reversing the instructions of steps 4, 3, 2, and 1.
16. Verify that the frequency output is accurate to ± 1 kHz and that the phase lock circuits are locked before performing the Single-Sideband Phase Noise Ratio test.

5-28. YTO Loop Offset and FM Overmodulation Adjustments

REFERENCE: Service Sheet 9-A3.

DESCRIPTION: In order to operate the YTO loop phase-detector in the linear region, the loop offset must be set 1 radian from the detector's zero crossover point. A drive signal of 1 radian-peak is connected at the FM INPUT connector while the phase detector output is monitored with an oscilloscope. The loop offset adjustment is set so that foldover at the peak of the phase detector output signal just begins. To set the FM overmodulation threshold, the FM input level is set for a modulation index of 6.5. The adjustment is set to a position that just lights the front panel OVERMOD annunciator.

Figure 5-6. YTO Loop Offset and FM Overmodulation Test Setup

EQUIPMENT: Oscilloscope HP 180C/1801A/1821A
 Spectrum Analyzer HP 8565A
 Test Oscillator HP 651B

PROCEDURE: 1. Set the Synthesizer's FM Deviation switch to 10 MHz and press the PRESET (3 GHz) pushbutton.
 2. Tune the test oscillator to 100 kHz.

ADJUSTMENTS

5-28. YTO Loop Offset and FM Overmodulation Adjustments (Cont'd)

3. Connect the equipment as shown in Figure 5-6.
4. Adjust the spectrum analyzer's controls to display the carrier and the 100 kHz sidebands.
5. Adjust the test oscillator's output level for the first carrier null as observed on the spectrum analyzer's display. Record the test oscillator's output level as measured with the oscilloscope. _____ Vrms
6. Divide the measured value by 2.4. Readjust the test oscillator's output level to the computed level.
7. Connect the oscilloscope to A3A9A4TP1 through a divide-by-ten probe. Adjust the oscilloscope's controls to view the 100 kHz signal.
8. Set the YTO loop offset adjustment OFST A3A9A4R53 so the sinusoidal waveform just begins to fold over. Refer to Figure 5-7.

NOTE

There may be two settings of A3A9A4R53 which give the proper offset. Use the position closer to the center of the adjustment range.

Figure 5-7. YTO Loop Offset Adjustment Waveforms

9. Disconnect the oscilloscope's probe.
10. Adjust the test oscillator's output level for the second carrier null as observed on the spectrum analyzer's display. Record the test oscillator's output level. _____ Vrms
11. Multiply the measured value by 1.18. Readjust the test oscillator's output level to the computed level.
12. Set the FM overmodulation adjustment OMOD A3A9A4R30 to the full clockwise position. Slowly rotate the adjustment counterclockwise until the front panel OVERMOD annunciator is illuminated.
13. Verify that the output frequency is accurate to ± 1 kHz and that the phase lock loop circuits are phase locked before performing the Single-Sideband Phase Noise Ratio test.

ADJUSTMENTS

5-29. YTO Loop Phase Detector Adjustment

REFERENCE: Service Sheet 9-A3.

DESCRIPTION: The gain-crossover frequency of the YTO Phase Locked loop is measured and adjusted using a low frequency spectrum analyzer and tracking generator.

Figure 5-8. YTO Loop Phase Detector Adjustment Test Setup

EQUIPMENT: Spectrum Analyzer (with tracking generator) . . . HP 8556A/8552B/141T
 AC Current Probe HP 1110A
 Special Interconnect Cable (See Figure 1-3).

PROCEDURE: 1. Set the Synthesizer RF switch to ON.
 2. Connect the equipment as shown in Figure 5-8. The special interconnect cable is inserted between A3W16 (gray cable) and A3A9J6 (YTO Tune 1).

NOTE

When clipping the current probe around the special cable's center conductor, do not allow the metal surface to come in contact with the center conductor connection of the SMA connectors.

3. Set the spectrum analyzer to scan from 0 to 50 kHz, vertical sensitivity per division to 2 dB, scan mode to single, and set the display's variable persistence to maximum.
4. Press the single sweep pushbutton.
5. Move the spectrum analyzer's input to the cable side (A3W16) of the special cable.
6. Press the single sweep pushbutton. Check that the gain-crossover frequency is 20 ± 2 kHz. If the gain-crossover frequency is not correct, A3A9A4R20 must be changed to set the correct frequency. Refer to Figure 5-8.

ADJUSTMENTS

5-29. YTO Loop Phase Detector Adjustment (Cont'd)

$$R_2 = R_1 \left(\frac{F_1}{F_2} \right)$$

where R_2 = required value for R20

R_1 = present value of R20

F_1 = measured frequency

F_2 = required frequency (20 kHz)

for example, if

$$R_1 = 619\Omega$$

and $F_1 = 25 \text{ kHz}$

$$\text{then } R_2 = 619 \frac{25 \text{ kHz}}{20 \text{ kHz}}$$

$$R_2 = 773\Omega \text{ or } 750\Omega \text{ (closest value)}$$

7. Install R20 and recheck the gain-crossover frequency.

18 _____ 22 kHz

NOTE

The other loop parameters, phase margin and loop gain, may be checked if the loop does not operate correctly. Loop gain is checked at 1 kHz and should be approximately 40 dB. Phase margin is checked by disconnecting the input to the ac probe, shorting the input, and pressing the single sweep pushbutton. Phase margin should be approximately 45° and is calculated by the following expression:

$$\theta = \cos^{-1} \left[1 - \frac{10^{\left(\frac{A}{10}\right)}}{2} \right]$$

where θ = phase margin

and A = ratio (in dB) of the induced voltage to the gain-crossover.
(Gain-crossover is the reference, therefore the ratio is negative.)

Figure 5-9. Spectrum Analyzer Display of Phase Locked-Loop Gain

ADJUSTMENTS

5-29. YTO Loop Phase Detector Adjustment (Cont'd)

8. Reinstall the A3A9 Assembly after replacing the covers. Refer to the appropriate procedures in Section VIII.
9. Verify that the output frequency is accurate to ± 1 kHz and that the phase lock loop circuits are phase locked before performing the Single-Sideband Phase Noise Ratio test.

5-30. FM Driver Adjustment

REFERENCE: Service Sheet 10-A3.

DESCRIPTION: The dc offset of the FM integrator amplifier is set as close to zero volts as possible. Any FM signal present on the error signal line of the YTO phase-locked loop is nulled at both high and low FM driver sensitivity.

Figure 5-10. FM Driver Adjustment Test Setup

EQUIPMENT: Oscilloscope HP 180C/1801A/1821A
 Test Oscillator HP 651B

- PROCEDURE:
1. Set the FM DEVIATION switch to 0.1 MHz.
 2. Connect the oscilloscope to A3A7TP3.
 3. Set OFST (offset adjust) A3A7R28 for 0.0 ± 0.1 Vdc.
 4. Set the FM DEVIATION switch to 10 MHz.
 5. Verify a voltage level of 0 ± 2 Vdc at A3A7TP3.
 6. Set the RF switch to ON.
 7. Set the test oscillator controls for an output of 1.5 mVrms at 5 kHz.
 8. Connect the oscilloscope to A3A7TP2; connect the test oscillator output to the FM INPUT. The signal displayed by the oscilloscope will generally be less than 20 mV_{p-p}.
 9. Set GAIN A3A7R40 to null any FM signal present at A3A7TP2.
 10. Set FM DEVIATION MHz switch to 0.1 MHz and test oscillator output level to 0.15 Vrms.
 11. Set -40 GN (-40 Gain) A3A7R46 to null any FM signal present at A3A7TP2.
 12. Verify that the output frequency is accurate to ± 1 kHz and that the phase locked loops are phase locked before performing the Single-Sideband Phase Noise Ratio test.

 ADJUSTMENTS

5-31. A2 CONTROLLER ASSEMBLY ADJUSTMENTS

5-32. 160–240 MHz (20/30 MHz or LFS Loop) VCO Pretune Adjustments

REFERENCE: Service Sheet 3-A2.

DESCRIPTION: If any oscillator components have been replaced, the low and high frequency limits of the oscillator must be checked to insure proper operation. The oscillator coil is moved closer to or away from the circuit board in order to set the low and high frequency limits.

EQUIPMENT: Frequency Counter HP 5340A

NOTE

This procedure need be performed only if major repair has been done to the oscillator.

- PROCEDURE:
1. Set the LINE ON-STANDBY switch to STANDBY.
 2. Remove the screws which hold the A2A3 VCO assembly in place.

WARNING

Because this circuit board is being placed on an extender board, the possibility of coming in contact with 60 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

3. Remove the A2A3 Assembly, place it on an extender board, and reinstall the assembly.
4. Remove the green cable A3W14 which is connected to the 20/30 MHz OUTPUT A2A3J1. Connect the frequency counter output to A2A3J1.
5. Set the LINE ON-STANDBY switch to ON.
6. Set A2A3S1 (FREQ TEST SWITCH) to the TEST HIGH FREQ position. The frequency should be greater than 30.5 MHz.
7. If the frequency is less than 30.4 MHz, the oscillator coil must be moved closer to the circuit board. The oscillator cover must be removed before adjusting the coil.

NOTE

The oscillator coil is normally mounted parallel to the circuit board with the bottom threads approximately 1.3 mm (0.050 inch) above the board.

8. Replace the oscillator cover and recheck the frequency.
 9. Set A2A3S1 to the TEST LOW FREQ position. Verify a frequency reading of less than 19.5 MHz. If necessary, remove the cover, reset the coil, replace the cover and repeat steps 6 through 9.
 10. Set A2A3S1 to the NORMAL position.
 11. Reinstall A2A3 in its cavity and reconnect the green cable to A2A3J1.
-

ADJUSTMENTS

5-33. 20/30 MHz (LFS) Loop Divider Bias Adjustments

REFERENCE: Service Sheet 1-A2.

DESCRIPTION: A clock signal derived from an external RF signal source is monitored with an oscilloscope. The RF signal level is slowly reduced and the CLK BIAS ADJ is set to obtain a stable clock signal. The RF input is reduced to the minimum level that provides a stable signal.

Figure 5-11. 20/30 MHz Loop Divider Bias Adjustment Test Setup

EQUIPMENT: Oscilloscope HP 180C/1801A/1821A
 Signal Generator HP 8654A

- PROCEDURE:
1. Disconnect the Mains power cable and set the LINE ON-STANDBY switch to STANDBY.
 2. Remove the screws that hold the A2A5 20/30 MHz Divider Assembly in place.

WARNING

Because this circuit board is being placed on an extender board, the possibility of coming in contact with 60 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

3. Remove the A2A5 Assembly, place it on an extender board, and reinstall the assembly.
4. Connect the power cable to the power module. Set the LINE ON-STANDBY switch to ON.
5. Set the signal generator controls for cw output of -5 dBm at 240 MHz.
6. Remove the red cable A2W2 from the 160-240 MHz INPUT A2A5J1.

ADJUSTMENTS

5-33. 20/30 MHz (LFS) Loop Divider Bias Adjustments (Cont'd)

7. Connect the equipment as shown in Figure 5-11.
8. Center A2A5R4 (CLK BIAS ADJ).
9. Observe the clock signal on the oscilloscope display.
10. Adjust A2A5R4 to obtain a stable clock frequency.
11. Reduce the signal generator output level while readjusting A2A5R4 to obtain a stable clock signal at the lowest possible signal.
12. Verify that a stable clock signal is obtained with an input signal of -10 dBm or less.
13. Disconnect the test equipment and reinstall A2A5 in its cavity. Reconnect the cable to A2A5J1.

5-34. A2A4 Assembly Notch Filter Adjustment

REFERENCE: Service Sheet 2-A2.

DESCRIPTION: A 7985 Hz signal is passed through the 8 kHz notch filter. The adjustable components are set for the minimum signal transfer.

Figure 5-12. A2A4 Assembly Notch Filter Adjustment Test Setup

EQUIPMENT:	Test Oscillator	HP 651B
	Frequency Counter	HP 5340A
	AC Voltmeter	HP 400E
	3 dB Attenuator	HP 8491A Option 003

ADJUSTMENTS

5-34. A2A4 Assembly Notch Filter Adjustment (Cont'd)

PROCEDURE: 1. Set the LINE ON-STANDBY switch to STANDBY.

WARNING

Because this circuit board is being placed on an extender board, the possibility of coming in contact with 60 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

2. Remove the A2A4 Assembly.
3. Unsolder the input end (top) of A2A4R28 (refer to the component location diagram).
4. Install the circuit board on an extender board.
5. Connect the equipment as shown in Figure 5-12. The leads from the 3 dB attenuator should be as short as possible. Clip the ground wire to the negative side of A2A4C4.
6. Set the test oscillator's controls for 1 kHz and an AC voltmeter indication of +10 dBm.
7. Set the test oscillator as close to 7985 Hz as possible.
8. Adjust A2A4L3 and L4 to minimize the meter reading. The indication must be less than -50 dBm.
9. Resolder A2A4R28, reinstall the A2A4 Assembly, and replace the top cover.

NOTE

If required, proceed to the YTO Loop Sampler Adjustments.

5-35. A1 RF OUTPUT ASSEMBLY ADJUSTMENTS**5-36. YTM Adjustments**

REFERENCE: Service Sheet 2-A1 and 3-A1.

DESCRIPTION: The injected input from the test oscillator causes the YTM to sweep across a band that is centered at the Synthesizer's RF output frequency. The RF output is detected and the swept response is viewed on the oscilloscope's display. The adjustments align the YTM tuning with respect to the RF output. Final adjustments set the power output level.

ADJUSTMENTS

5-36. YTM Adjustments (Cont'd)

Figure 5-13. YTM Adjustments Test Setup

EQUIPMENT:	Oscilloscope	HP 180C/1801A/1821A
	Test Oscillator	HP 651B
	Crystal Detector	HP 8470B Option 012
	600Ω Feedthru Termination	HP 11095A
	Power Meter/Sensor	HP 436A/8481A
	Digital Voltmeter	HP 3455A

- PROCEDURE:
1. Set the LINE switch to STANDBY.
 2. Adjust the front panel meter's mechanical zero adjustment for a meter indication of exactly zero (0).
 3. Remove the Synthesizer's top cover and the A1 Assembly's cover by following the disassembly instructions found in Section VIII.
 4. Set the Synthesizer's controls as follows:

LINE switch	ON
METER MODE Switch	LEVEL
RF Switch	ON
ALC Mode Switch	PWR MTR
OUTPUT LEVEL RANGE Switch	0 dBm
AM Function Switch	OFF

 ADJUSTMENTS

5-36. YTM Adjustments (Cont'd)

FM DEVIATION Switch OFF
 PRESET (3 GHz) pushbutton press
 RF OUTPUT PEAK-NORM Control NORM

5. Allow 30 minutes warmup.
6. Connect the "HIGH" input lead of the DVM to the +12.4V test point on A1A8; connect the "LOW" input lead to the GND test point on A1A8.
7. Adjust +12.4V A1A8R64 for $+12.400 \pm 0.005$ Vdc.

NOTE

The following two steps need be done only after replacing the A1A3 YTM Assembly.

8. Connect the "HIGH" input lead of the DVM to +C.S. test point on the A1A8 Assembly. (The "LOW" input lead remains as is.)
9. Adjust BD1 LO A1A8R46 for $+8.0 \pm 0.2$ Vdc.
10. Tune to 2000 MHz.
11. Center BIAS adjust A1A7R31 and PWR adjust A1A7R29.
12. Set the test oscillator's controls for an output of 60 Hz at 700 mVrms (open circuit).
13. Set the oscilloscope's vertical controls to 0.1 volt per division with dc coupling; set the horizontal controls for external sweep with the magnifier to X10.
14. Connect the equipment as shown in Figure 5-13.
15. Adjust the oscilloscope's horizontal sensitivity to obtain a 6 division sweep that is centered horizontally. Set polarity to -UP.
16. Set BD1 LO A1A8R46 to center the YTM response as shown in Figure 5-14A.
17. Tune to 6000 MHz; adjust BD1 HI A1A8R20 to center the YTM response.
18. Tune from 6000 to 2000 MHz. Verify that the YTM response remains reasonably well centered across the band.
19. Tune to 6500 MHz; adjust BD2 LO A1A8R47 to set the peak of the YTM response about 1 division to the right of center. Refer to Figure 5-14B.
20. Tune to 11 500 MHz; adjust BD2 HI A1A8R16 to set the response as shown in Figure 5-14B.

ADJUSTMENTS

5-36. YTM Adjustments (Cont'd)

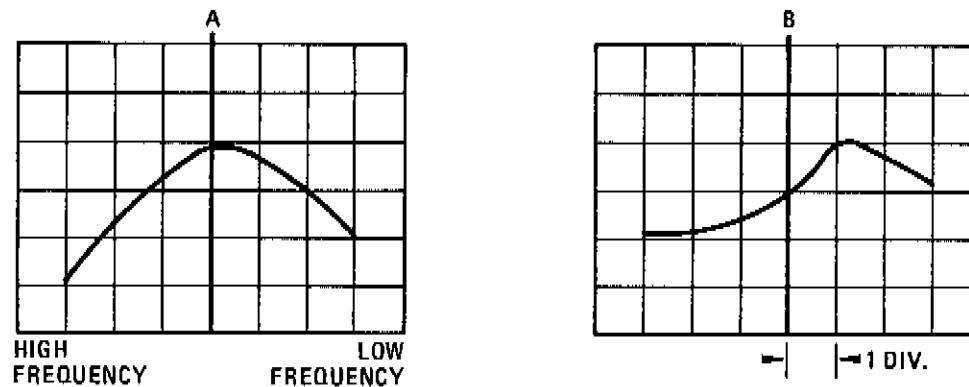

Figure 5-14. Typical YTM Response

21. Tune from 12 300 to 6200 MHz. Verify that the peak YTM response stays to the right of center (at times may be very nearly centered) across the entire range.

NOTE

If necessary, iterate the BD2 LO and BD2 HI adjustments to keep the peak response to the right of center (especially important above 9000 MHz).

22. Tune to 13 000 MHz; adjust BD3 LO A1A8R41 to set the YTM response peak 0.4 divisions to the right of center.
23. Tune to 16 000 MHz; adjust BD3-16 A1A8R11 to set the YTM response peak 0.4 divisions to the right of center.
24. Tune to 17 000 MHz; adjust BD3-17 A1A8R17 to center the response.
25. Tune to 18 000 MHz; adjust BD3-18 A1A8R23 to center the response.
26. Tune to 18 599 MHz; adjust BD3-18.6 A1A8R32 to center the response.
27. Tune from 12.4 GHz to 16 GHz to assure the response peak remains to the right of center. If necessary, iterate BD3 LO and BD3-16 to obtain the required response. End iteration with BD3-16.
28. Tune from 16 000 to 18 000 MHz to assure the response peak remains approximately centered across the band. If not iterate between BD3-16, BD3-17, and BD3-18 to obtain the required response. The last adjustment should be made on BD3-18.

ADJUSTMENTS

5-36. YTM Adjustments (Cont'd)

29. Tune from 18 000 to 18 599 MHz to assure the response peak remains approximately centered. Iterate BD3-18 and BD3-18.6 if necessary to obtain the required response. The last adjustment should be made to the BD3-18.6 adjustment.
30. Remove the signal from the A1A8 SENSE test point.
31. Connect the power sensor to the RF OUTPUT connector; tune to 11 500 MHz.
32. Adjust PWR A1A7R29 to obtain the maximum output power. Readjust A1A7R29 to reduce the power output 0.5 dB.
33. Set the Synthesizer's ALC mode switch to INT; set the OUTPUT LEVEL RANGE switch to 0 dBm.
34. Set the OUTPUT LEVEL VERNIER control for a -10 dBm reading on the power meter.
35. Connect the DVM to A1A5TP6; adjust BIAS A1A7R31 to obtain the maximum (most negative) DVM reading.
36. The voltage at the A1A7 BIAS test point should be -0.45 ± 0.1 Vdc.

5-37. ALC Adjustments

REFERENCE: Service Sheets 1-A1, 3-A1, 4-A1 and 5-A1.

DESCRIPTION: Various adjustments are made while monitoring the output power level. First, the AM balance is set by adjusting the AM BAL for the same power level in and out of the AM mode. The front panel meter is calibrated in the RF level mode. The overrange adjustment is set to obtain the same RF level in and out of the overrange mode. The programmed tracking of RF output level (1 dB steps) is set. The maximum flatness of high frequency bands is adjusted relative to a band 1 reference.

EQUIPMENT: Digital Voltmeter HP 3455A
 Power Meter/Sensor HP 436A/8481A
 HP-IB Controller HP 9830A

- PROCEDURE:
1. Set the LINE switch to STANDBY; set the front panel meter's mechanical zero adjustment for a meter indication of exactly zero (0).
 2. Set the ALC mode switch to INT and set the front panel RF OUTPUT PEAK control to NORM.
 3. Preset the following adjustable components as follows:

MET CAL	A1A5R69,	center
GAIN X1	A1A5R23,	full ccw
GAIN X2	A1A5R21,	full ccw
GAIN X3	A1A5R17,	full ccw
Slope 10 GHz	A1A7R18,	full ccw
Slope 18 GHz	A1A7R4,	center

 ADJUSTMENTS

5-37. ALC Adjustments (Cont'd)

4. Tune to 4000 MHz and set the OUTPUT LEVEL RANGE switch to 0 dBm. Set the VERNIER control for a meter reading of -4 dBm.
5. Connect the DVM to A1A5TP4 (positive lead) and A1A5 GND test points.
6. Adjust OS (offset) A1A5R3 to obtain $+130.0 \pm 0.5$ mVdc. The ALC loop must be leveled (LEV UNCAL lamp off).
7. Connect the power meter to the RF OUTPUT connector.
8. Adjust the OUTPUT LEVEL VERNIER control for a power meter reading of 0 dBm.
9. Set the AM switch to OFF. Measure and record the output power level. _____ dBm
10. Set the AM switch to 30%. Adjust AM BAL A1A5R54 for the same output power as measured in step 9.
11. Set the AM switch to OFF.
12. Connect the HP-IB controller to the Synthesizer.
13. Load and run the following program. Thirty-two seconds is allowed for each adjustment. When the adjustment is complete, press any alphanumeric key to advance to the next step. Some adjustments are iterative. The program will continue to loop until told to do otherwise.

NOTE

The following program is intended for use with the HP 9830A Calculator. For use with any other HP-IB controller the program may need to be modified.

```

10 DIM A$(20)

14. Set the OUTPUT LEVEL RANGE switch to 0 dBm; Adjust the OUTPUT RANGE VERNIER to exactly 0 dBm. Record the power meter reading.
_____ dBm.
15. Tune the Synthesizer to 10 000 MHz and adjust Slope 10 GHz A1A7R18 for the same power reading recorded in step 14.
16. Tune to 18 000 MHz and adjust Slope 18 GHz A1A7R4 for the same power reading recorded in step 14.
17. Tune between 8000 and 12 000 MHz (1 MHz tuning resolution).
18. Adjust Slope 10 GHz A1A7R18 to make the power variation symmetrical about 0 dBm.
19. Tune between 17 000 and 18 000 MHz and adjust Slope 18 GHz A1A7R4 to make the variation symmetrical about 0 dBm.
20. Tune from 2000 to 18 000 MHz to ensure flatness is within specification. Reset the power meter's calibration factor switch as needed.

5-38. External Leveling Adjustments

REFERENCE: Service Sheet 4-A1.

DESCRIPTION: These adjustments are made to minimize dc offset and to center the operating range of the external leveling circuitry.

EQUIPMENT: Digital Voltmeter HP 3455A
 Power Meter/Sensor HP 436A/8481A
 50 Ohm Termination HP 1250-0207
 HP-IB Controller HP 9830A

- PROCEDURE:
1. Tune to 4000 MHz.
 2. Center the EXT ALC INPUT CAL control.
 3. Place a 50 ohm BNC termination on the EXT ALC INPUT connector.
 4. Connect the DVM to A1A6TP6 and A1A6 GND2.
 5. Adjust EXT OS (external offset) A1A6R13 for 0.0 ± 0.1 mVdc.
 6. Disconnect the DVM and 50 ohm termination.
 7. Connect the power sensor to the RF OUTPUT connector; connect the power meter's recorder output to the EXT ALC INPUT.

NOTE

Because the HP 436A has automatic ranging, this procedure will work properly only when the range hold switch is activated on the 0 dBm range.

ADJUSTMENTS

5-38. External Leveling Adjustments (Cont'd)

ADJUSTMENTS

5-39. AM Bandwidth Adjustment

REFERENCE: Service Sheet 1-A1.

DESCRIPTION: The bandwidth of the AM circuit is set. A reference level is established on the spectrum analyzer display. The maximum specified AM drive frequency is set for each frequency band. The center frequency is tuned across the band to determine worst case sensitivity. The AM gain adjustment is set to a predetermined level for each band.

EQUIPMENT: Spectrum Analyzer HP 8553B/8552B/141T
 Test Oscillator HP 651B

- PROCEDURE:
1. Set the Synthesizer's controls for an output of -110 dBm (-110 dBm range; 0 dBm meter reading) at 2000 MHz. Set the AM function switch to 100% .
 2. Set the test oscillator controls for an output of 0.5 Vrms at 10 kHz.
 3. Connect the spectrum analyzer's input to A1A6TP3; connect the test oscillator's 600Ω output to the AM INPUT connector.
 4. Set the spectrum analyzer controls to view the 10 kHz signal.

NOTE

Do not be concerned about the high harmonic content observed on the spectrum analyzer display.

5. To establish a reference level for the modulation signal, set the peak of the 10 kHz signal to the center horizontal graticule line using the vertical sensitivity range and vernier controls (2 dB log per division). DO NOT disturb the vertical sensitivity controls or test oscillator amplitude controls for the remainder of this test.
 6. Tune the test oscillator to 500 kHz.
 7. Tune the spectrum analyzer to display the 500 kHz signal.
 8. Tune the Synthesizer from 2000 to 6199 MHz in 1 MHz steps to find the frequency that yields the lowest level (AM sensitivity). Note the frequency and level.
 9. Set the VERNIER control for a meter reading of -10 dBm. Tune from 2000 to 6199 MHz in 1 MHz steps. Note the frequency and level of the lowest level (AM sensitivity).
 10. Tune to the frequency of lowest AM sensitivity as determined in steps 8 and 9.
 11. Set GAIN X1 A1A5R23 for a displayed signal 2.0 ± 0.5 dB below the reference graticule.
 12. Tune the test oscillator and spectrum analyzer to 100 kHz.
 13. Tune the Synthesizer from 6200 to $12\ 399$ MHz in 1 MHz steps to find the frequency of lowest modulation sensitivity.
 14. Set the VERNIER control for a meter reading of 0 dBm. Tune from 6200 to $12\ 399$ MHz in 1 MHz steps. Note the frequency and level.
-

ADJUSTMENTS

5-39. AM Bandwidth Adjustment (Cont'd)

15. Set GAIN X2 A1A5R20 for a displayed signal 2.0 ± 0.5 dB below the reference graticule.
16. Tune the synthesizer from 12 400 to 18 000 MHz (1 MHz steps) to find the frequency of lowest modulation sensitivity.
17. Set GAIN X3 A1A5R14 for a displayed signal amplitude 2.0 ± 0.5 dB below the reference graticule.

5-40. AM Meter Adjustment

REFERENCE: Service Sheet 8-A1.

DESCRIPTION: The Unit Under Test RF output is mixed with the output of the reference unit. The 10 MHz IF signal is connected to the oscilloscope's vertical input. The test oscillator's output is used to drive the AM circuits in the Unit Under Test and the horizontal amplifiers in the oscilloscope. The resultant oscilloscope display is a trapezoidal waveform from which AM depth is easily calculated.

Figure 5-15. AM Meter Adjustment Test Setup

EQUIPMENT:	Synthesized Signal Generator . . .	HP 8672A
	Mixer	RHG DM1-18
	Test Oscillator	HP 651B
	Oscilloscope	HP 180C/1801A/1821A

ADJUSTMENTS

5-40. AM Meter Adjustment (Cont'd)

- PROCEDURE:
1. Set the test oscillator's controls to 10 kHz at 0.35 Vrms.
 2. Set the controls of the Unit Under test in the following order:

METER MODE switch	LEVEL
RF Switch	ON
OUTPUT LEVEL RANGE switch	-20 dBm
OUTPUT LEVEL VERNIER control for meter reading of	0 dB
ALC mode switch	INT
AM function switch	100%
FM DEVIATION switch	OFF
PRESET (3 GHz)	press
METER MODE switch	AM
 3. Set the controls of the reference unit for an output of +8 dBm (or maximum leveled output) at 3010 MHz.
 4. Set the oscilloscope's controls to display the trapezoidal modulation signal as shown in Figure 5-15.
 5. Adjust the test oscillator's output voltage so that voltage A is 2 divisions and voltage B is 6 divisions.
 6. Adjust AM MTR A1A9R69 to obtain a front panel meter reading of 50% AM depth.

5-41. AM Meter Adjustment – Alternate Procedure

REFERENCE: Service Sheet 8-A1.

DESCRIPTION: The Synthesizer's amplitude modulated output is input to a spectrum analyzer. The meter drive circuit is set to read the same AM depth as indicated on the analyzer's display.

EQUIPMENT: Spectrum Analyzer HP 8565A
 Test Oscillator HP 651B

- PROCEDURE:
1. Set the test oscillator's controls to 10 kHz and 0.35 Vrms.
 2. Set the Synthesizer's controls in order as follows:

METER MODE switch	LEVEL
RF switch	ON
OUTPUT LEVEL RANGE switch	0 dBm
OUTPUT LEVEL VERNIER control for meter reading of	0 dB
ALC mode switch	INT
AM function switch	100%
FM DEVIATION switch	OFF
PRESET (3 GHz)	press
METER mode switch	AM
-

ADJUSTMENTS

5-41. AM Meter Adjustment – Alternate Procedure (Cont'd)

3. Connect the spectrum analyzer's RF input to the Synthesizer's RF OUTPUT; connect the test oscillator's 600 ohm output to the Synthesizer's AM INPUT.
4. Adjust the spectrum analyzer's controls to view the carrier and AM sidebands on the display. Set the frequency span per division to 10 kHz; vertical sensitivity per division 2 dB.
5. Adjust the test oscillator output voltage to obtain AM sidebands that are 12 dB down from carrier. Ignore the distortion sidebands.
6. Adjust AM MTR A1A9R69 to obtain a front panel meter reading of 50% AM depth.

5-42. FM Adjustments

REFERENCE: Service Sheet 8-A1.

DESCRIPTION: The RF signal is viewed on the spectrum analyzer's display. With a preset modulation drive input, the FM gain is set for modulation index of 2.40 (first carrier null). The modulation drive is set for a level which will cause FM deviation equal to a full scale meter reading. The meter drive adjustment is set accordingly. The modulation drive is set to a level which will cause overmodulation and the FM overmodulation control is set to cause the OVERMOD annunciator to be illuminated.

Figure 5-16. FM Adjustments Test Setup

 ADJUSTMENTS

5-42. FM Adjustments (Cont'd)

EQUIPMENT:	Spectrum Analyzer	HP 8565A
	Test Oscillator	HP 651B
	Frequency Counter	HP 5340A
	Digital Voltmeter	HP 3455A

- PROCEDURE:
1. Set the controls of the unit under test in order as follows:

METER MODE switch	LEVEL
RF switch	ON
ALC mode switch	INT
OUTPUT LEVEL RANGE switch	-20 dBm
OUTPUT LEVEL VERNIER control for a meter reading of	0 dB
AM function switch	OFF
FM DEVIATION switch	0.3 MHz
PRESET (3 GHz)	press PRESET
 2. Set METER MODE switch to FM.
 3. Connect the equipment as shown in Figure 5-16.
 4. Set the test oscillator's controls to 100 kHz at 0.5668 Vrms.
 5. Set FM OMOD A1A9R34 to its full clockwise position.
 6. Set the spectrum analyzer's controls as follows: center frequency 3000 MHz, frequency span per division 100 kHz and resolution bandwidth 10 kHz. Other controls are adjusted to provide a good display of the signal.
 7. Adjust FM GAIN A1A9R37 for the first carrier null.

NOTE

If it is impossible to adjust the FM GAIN for the first carrier null refer to Table 5-1. Check the values of selected components A3A7R61, 75 and 65.

8. Set the test oscillator's output level to 0.707 Vrms.
9. Adjust FM MTR A1A9R21 for a full scale front panel meter reading on the Unit Under Test.
10. Set the test oscillator's output to 100.00 ± 0.05 kHz and 0.7425 Vrms.
11. Slowly adjust FM OMOD A1A9R34 until the front panel OVERMOD annunciator is illuminated.
12. Reduce the test oscillator's output to 0.707 Vrms; verify that the OVERMOD annunciator is off.

SECTION VI REPLACEABLE PARTS

6-1. INTRODUCTION

6-2. This section contains information for ordering parts. Table 6-2 lists abbreviations used in the parts list and throughout the manual. Table 6-3 lists all replaceable parts in reference designator order. Table 6-4 contains the names and addresses that correspond to the manufacturer's code numbers.

6-3. EXCHANGE ASSEMBLIES

6-4. Table 6-1 lists assemblies within the instrument that may be replaced on an exchange basis, thus affording a considerable cost saving. Exchange, factory-repaired and tested assemblies are available only on a trade-in basis; therefore, the defective assemblies must be returned for credit. For this reason, assemblies required for spare parts stock must be ordered by the new assembly part number.

6-5. ABBREVIATIONS

6-6. Table 6-2 lists abbreviations used in the parts list, schematics and throughout the manual. In some cases, two forms of the abbreviation are used, one all in capital letters, and one partial or no capitals. This occurs because the abbreviations in the parts list are always all capitals. However, in the schematics and other parts of the manual, other abbreviation forms are used with both lower case and upper case letters.

6-7. REPLACEABLE PARTS LIST

6-8. Table 6-3 is the list of replaceable parts and is organized as follows:

- a. Electrical assemblies and their components in alpha-numercial order by reference designation.
- b. Chassis-mounted parts in alpha-numerical order by reference designation.
- c. Miscellaneous parts.

6-9. The information given for each part consists of the following:

- a. The Hewlett-Packard part number.

- b. Part number check digit (CD).
- c. The total quantity (Qty) in the major assembly (A1, A2, or A3).
- d. The description of the part.
- e. A typical manufacturer of the part in a five-digit code.
- f. The manufacturer's number for the part.

6-10. The total quantity for each part is given only once — at the first appearance of the part number in the list for each major assembly.

NOTE

Total quantities for optional assemblies are totaled by assembly and not integrated into the standard list.

6-11. ORDERING INFORMATION

6-12. To order a part listed in the replaceable parts table, quote the Hewlett-Packard Part number (with the check digit) indicate the quantity required, and address the order to the nearest Hewlett-Packard office. The check digit will ensure accurate and timely processing of your order.

6-13. To order a part that is not listed in the replaceable parts table, include the instrument model number, instrument serial number, description and function of the part, and the number of parts required. Address the order to the nearest Hewlett-Packard office.

6-14. SPARE PARTS KIT

6-15. Stocking spare parts for an instrument is often done to ensure quick return to service after a malfunction occurs. Hewlett-Packard has a "Spare Parts Kit" available for this purpose. The kit consists of selected replaceable assemblies and components for this instrument. The contents of the kit and the "Recommended Spares" list are based on failure reports and repair data, and provides parts support for one year. A complimentary "Recommended Spares" list for this instrument may be obtained on request and the "Spare Parts Kit" may be ordered through your nearest Hewlett-Packard office.

Table 6-1. Part Numbers for Exchange Assemblies

Reference Designation	Description	Part Number*	
		Exchange Assy	New Assy
A1A8	YTM	5086-6151	5086-7151
A1AT1	Programmable Attenuator Assembly	08672-60111	08672-60114
A3A1A4	M/N VCO Assembly	86701-60071	86701-60065
A3A8	10 MHz Reference Oscillator Assembly	86701-60072	86701-60067
A3A9A3	YTO	5086-6131	5086-7131

*When ordering extra assemblies for spare parts stock, use new assembly part number only. Exchange orders require return of the defective part.

Table 6-2. Reference Designations and Abbreviations (1 of 2)

REFERENCE DESIGNATIONS

A assembly	E miscellaneous electrical part	P electrical connector (movable portion); plug	U integrated circuit; microcircuit
AT attenuator; isolator; termination	F fuse	Q transistor: SCR; triode thyristor	V electron tube
B fan; motor	FL filter	R resistor	VR voltage regulator; breakdown diode
BT battery	H hardware	RT thermistor	W cable; transmission path; wire
C capacitor	HY circulator	S switch	X socket
CP coupler	J electrical connector (stationary portion); jack	T transformer	Y crystal unit (piezo-electric or quartz)
CR diode; diode thyristor; varactor	K relay	TB terminal board	Z tuned cavity; tuned circuit
DC directional coupler	L coil; inductor	TC thermocouple	
DL delay line	M meter	TP test point	
DS annunciator; signaling device (audible or visual); lamp; LED	MP miscellaneous mechanical part		

ABBREVIATIONS

A ampere	COEF coefficient	EDP electronic data processing	INT internal

SECTION VII MANUAL CHANGES

7-1. INTRODUCTION

7-2. This section contains manual change instructions for backdating this manual for HP Model 8672A Synthesized Signal Generators having serial number prefixes lower than 1732A or 1733A. This section also contains instrument modification suggestions and procedures that are recommended to improve the performance and reliability of your generator.

7-3. MANUAL CHANGES

7-4. To adapt this manual to your instrument, refer to Table 7-1 and make all of the manual

changes listed opposite your instrument's serial number prefix. The manual changes are listed in serial number prefix sequence and should be made in the sequence listed. Table 7-2 is a summary of changes by component.

7-5. If your instrument's serial number prefix is not listed on the title page of this manual or in Table 7-1, it may be documented in a MANUAL CHANGES supplement. For additional important information about serial number coverage, refer to INSTRUMENTS COVERED BY MANUAL in Section I.

Table 7-1. Manual Changes by Serial Number Prefix

Serial Prefix or Number	Make Manual Changes	Serial Prefix or Number	Make Manual Changes
1610A	M,L,K,J,I,H,G,F,E,D,C,B,A	1707A	M,L,K,J

CHANGE A

Table 6-3:

Change A3A7C19 to 0160-0134, CAPACITOR-FXD 220 pF $\pm 5\%$ 300 WVDC MICA.
Change A3A7R42 and R43 to 0698-3155, RESISTOR 4.64K 1% .125W F TC=0 \pm 100.
Change A3A7R55 to 0757-0416, RESISTOR 511 1% .125W F TC=0 \pm 100.
Change A3A7R61* and R75 to 0698-0083, RESISTOR 1.96K 1% .125W F TC=0 \pm 100.
Change A3A7R65 to 0757-0439, RESISTOR 6.81K 1% .125W F TC=0 \pm 100.
Change A3A7R67 to 0757-0398, RESISTOR 75 1% .125W F TC=0 \pm 100.

Service Sheet 10-A3:

Change the following:

A3A7C19 to 220 pF.
A3A7R65 to 6810 ohms.
A3A7R67 to 75 ohms.
A3A7R42 to 4640 ohms.
A3A7R43 to 4640 ohms.
A3A7R55 to 511 ohms.
A3A7R61 to 1960 ohms.
A3A7R75 to 1960 ohms.

CHANGE B

Table 6-3:

Delete A3A9A5R41
Add A3A9A5E1.

Service Sheet 8-A3:

Add A3A9A5E1 in place of A3A9A5R41 (21.5 ohms).

CHANGE C

Table 6-3:

Add A3A9A4CR10, 1901-0535, Diode-Schottky.
Delete A3A9A4R57.

Change the following A3A9A4 Components:

R37 and R38, 0698-0083 RESISTOR 1.96K 1% .125W F TC=0 \pm 100.
R54, 0698-7249, RESISTOR 3.48K 1% .05W F TC=0 \pm 100.
R55, 0698-7241, RESISTOR 1.62K 1% .05W F TC=0 \pm 100.

Service Sheet 9-A3:

The following changes are to be made to the A3A9A4 assembly:

Delete R57.
Change R37 and R38 to 1.96K ohms.
Change R54 to 3480 ohms.
Change R55 to 1628 ohms.
Add CR10, connected between U7 pin 12 and ground.

CHANGE D

Table 6-3:

Change the following A3A7 resistors as follows:

- R42, 0698-3151, RESISTOR 4.64K 1% .125W F TC=0±100.
- R43, 0757-0279, RESISTOR 3.16K 1% .125W F TC=0±100.
- R55, 0698-3445, RESISTOR 348Ω 1% .125W F TC=0±100.
- R65*, 0698-3151, RESISTOR 4.64K 1% .125W F TC=0±100.
- R71, 0686-1825, RESISTOR, 1.8K 5% .5W CC TC=0+647.

Service Sheet 10-A3:

Change the following A3A7 resistors:

- R42 to 4640 ohms.
- R43 to 3160 ohms.
- R55 to 511 ohms.
- R65* to 6810 ohms.
- R71 to 1800 ohms.

CHANGE E

Table 6-3:

- Change A3A1A5C3 to 0160-2251, CAPACITOR-FXD 5.6 pF ±0.25 pF 500 WVDC CER.
- Add A3A1A5C6, 0160-3878, CAPACITOR-FXD 1000 pF ±20% 100 WVDC CER.
- Delete A3A1A5R40.
- Delete A3A1A5R41.
- Change A3A1A5R4, 0698-7212, RESISTOR 100 1% 0.05W F TC=0±100.
- Change A3A1A5R36, 0698-7222, RESISTOR 261 1% 0.05W F TC=0±100.
- Add A3A1A5C38, 0160-2238, CAPACITOR-FXD 1.5 pF ±0.25 pF 500 WVDC CER.
- Add A3A1A5C39, 0160-2260, CAPACITOR-FXD 13 pF ±5% 500 WVDC CER.
- Add A3A1A5L3 and L12, 9100-0346, COIL-FXD MOLDED RF CHOKE 0.05 μH 20%

Service Sheet 5-A3:

- Change A3A1A5R36 to 82.5 ohms.
- Add A3A1A5C38.
- Change A3A1A5R40 to A3A1A5L12 0.05 μH.
- Change A3A1A5R41 to A3A1A5C39, 13 pF.
- Change A3A1A5R4 to 100 ohms.
- Change A3A1A5C3 to 5.6 pF.
- Add A3A1A5L3, 50 nH, connected from the collector of Q5 to ground.
- Add A3A1A5C6; 1000 pF, connected from the collector of Q5 to the LO input of U1.

CHANGE F

Table 6-3:

- Change A3A9A5Q4 to 1855-0218, TRANSISTOR-MOSFET DUAL-GATE N-CHAN E-MODE.

Service Sheet 8-A3:

- Change the part number of A3A9A5Q4 to 1855-0218.

CHANGE G

Paragraph 5-24:

- Change step 2 to "Connect -10 Vdc from a low voltage power supply to the TUNE test point A3A1A2TP1.

CHANGE G (Cont'd)

Table 6-3:

- Change A3A1A1R51 to 0698-3136, RESISTOR 17.8K 1% 0.125W F TC=0±100.
- Change A3A1A1R75 to 0698-7247, RESISTOR 2.87K 1% 0.05W F TC=0±100.
- Change A3A1A1VR2 to 1902-0184, DIODE-ZNR 16.2V 5% D0-7 PD=0.4W TC=+0.066%.
- Change A3A1A2Y1 to 0410-0482.
- Delete A3A3C15.
- Change A3A4C12 to 0160-3460, CAPACITOR-FXD 0.05 μ F +80% 100 WVDC CER.

Service Sheet 2 text (troubleshooting):

- Change the last sentence of the first paragraph to "This is normally -10 Vdc when the loop is locked."

Service Sheet 2:

- Change the A3A1A1 TUNE VOLTAGE to "-5 to -40 Vdc, -10 Vdc nominal."

Service Sheet 1-A3:

- Change the TUNE VOLTAGE to "-10 Vdc nominal."
- Change the value of A3A1A1R51 to 17.8K and A3A1A1R75 to 2870 ohms.
- Change the rated value of A3A1A1VR2 to 16.2V.

Service Sheet 2-A3:

- Change the TUNE VOLTAGE to "-5 to -40 Vdc, -10 Vdc nominal."

Figure 8-121 (Service Sheet 13-A3):

- Delete A3A3C15.
- Change the value of A3A4C12 to 0.05 μ F.

CHANGE H

Table 6-3:

- Change A3A1A4A2R4 to 0698-3150, RESISTOR 2.37K 1% 0.125W F TC=0±100.

Service Sheet 4-A3:

- Change the value of A3A1A4A2R4 to 2370 ohms.

CHANGE I

Table 1-1:

- Change the FREQUENCY MODULATION CHARACTERISTICS, Frequency Response (relative to 100 kHz rate) to
 - "±1.5 dB, 100 Hz -3 MHz, 30 and 100 kHz/V ranges;
 - ±1.5 dB, 3 kHz -3 MHz, 300 kHz/V and 1, 3, 10 MHz/V ranges."

Table 4-3:

- Change the specification for FM FREQUENCY RESPONSE to "±1.5 dB from 100 Hz to 3 MHz."

CHANGE J

Table 6-3:

- Change A2A1C1 to 0180-0197, CAPACITOR-FXD 2.2 UF ±10% 20 VDC TA.
- Delete A2A3R34.
- Change A2A3C12 to 0160-2200, CAPACITOR-FXD 43 pF ±5% 300 WVDC MICA.

CHANGE J (Cont'd)

Service Sheet 3-A2:

Change the part number for A3A1A5Q5, Q6, Q8 and Q9 to 1854-0345.

SECTION VIII SERVICE

8-1. INTRODUCTION

8-2. This section provides information on service related subjects. Safety considerations include warnings and cautions to be observed while servicing the instrument. The arrangement of the principles of operation and troubleshooting is explained. Repair information such as non-repairable items, module exchange and disassembly and reassembly procedure are included.

8-3. The service sheets are in the foldout section. Each service sheet includes a block or schematic diagram, with accompanying principles of operation and troubleshooting information. Usually a component location diagram is also included. Figure 8-1 Schematic Diagram Notes provides general information which relates to block and schematic diagram symbols.

8-4. Other pertinent service information is included throughout the section.

8-5. SAFETY CONSIDERATIONS

8-6. This section contains warnings and cautions which must be followed for your protection and to avoid damage to the equipment.

WARNING

Maintenance described herein is performed with power supplied to the instrument and with protective covers removed. Such maintenance should be performed only by service-trained personnel who are aware of the hazards involved. Where maintenance can be performed without power supplied, the power should be removed.

8-7. Any adjustment, maintenance, and repair of the opened instrument under voltage should be avoided as much as possible and, when inevitable, should be carried out only by a skilled person who is aware of the hazard involved.

8-8. Capacitors inside the instrument may still be charged even if the instrument has been disconnected from its source of supply.

8-9. Make sure that only fuses with the required rated current and of the specified type (normal blow, time delay, etc.) are used for replacement. The use of repaired fuses and the short-circuiting of fuseholders must be avoided.

8-10. Whenever it is likely that this protection has been impaired, the instrument must be made inoperative and be secured against any unintended operation.

8-11. PRINCIPLES OF OPERATION

8-12. The operation of the Synthesizer is explained on each service sheet. Overall operation, in terms of interaction of the major assemblies, is found on Service Sheet 1. Each major assembly is broken down into sections (groups of assemblies) on Service Sheets 2, 3 and 4. Remaining service sheets review the section operating information and explain the assembly operation to the stage (group of components) level.

8-13. TROUBLESHOOTING

NOTE

If the Synthesizer malfunctions, begin troubleshooting on Service Sheet 1.

8-14. Arrangement in Manual

8-15. The troubleshooting information for the Synthesizer is found on each service sheet. If the Synthesizer malfunctions, begin troubleshooting with Service Sheet 1 to isolate the defect to a major assembly. On Service Sheets 2, 3, and 4, troubleshoot to the section level (a logical group of assemblies). Next, isolate the defective assembly by following the information on the key Service Sheet for the section. With the remaining information on the key service sheet (which applies to the assembly) on the remaining service sheets, isolate the defective stage. Continue troubleshooting to defective component.

8-16. Supplemental Troubleshooting Aids

8-17. The HP-IB Diagnostic Program may verify that the HP-IB input to the Synthesizer is operat-

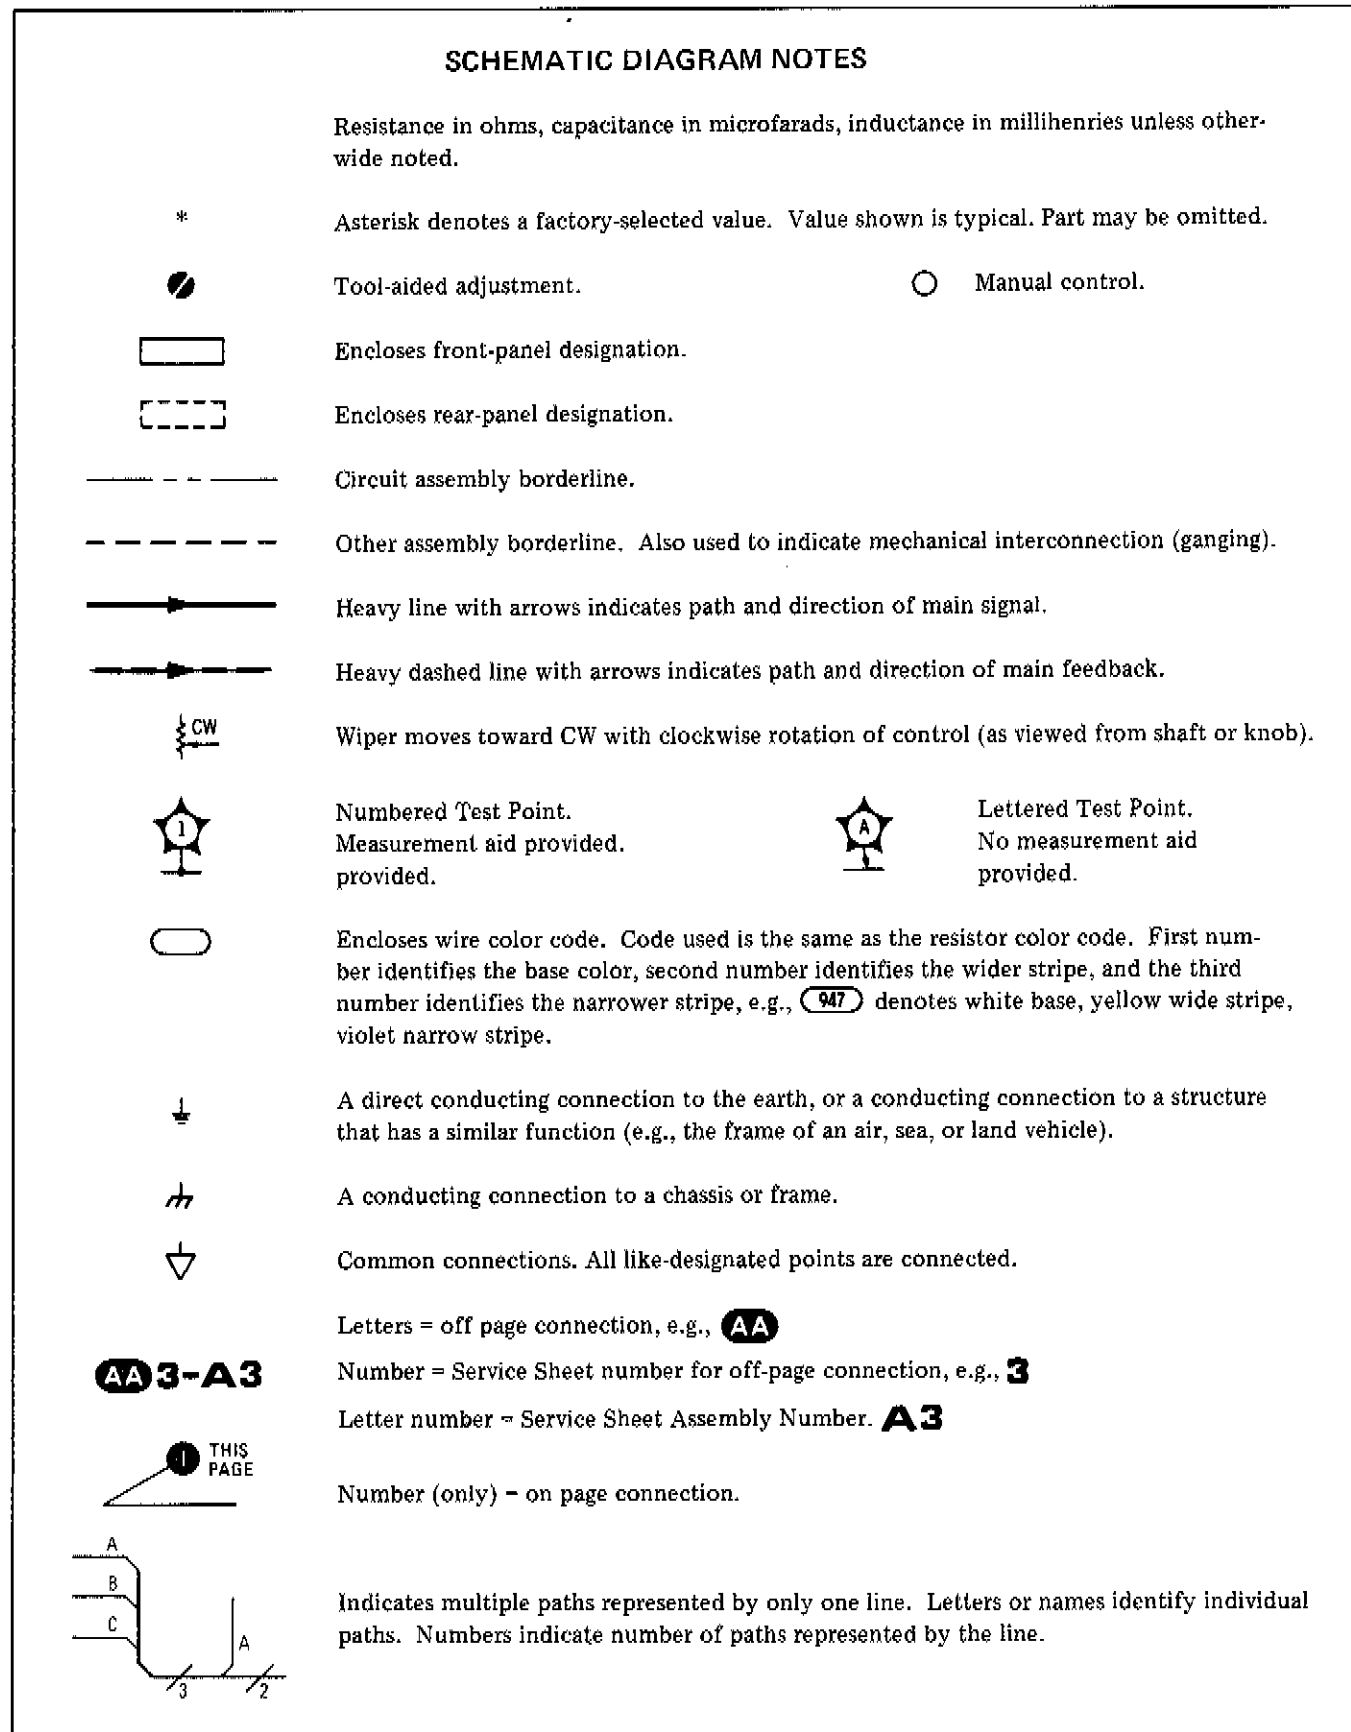

Figure 8-1. Schematic Diagram Notes (1 of 3)

SCHEMATIC DIAGRAM NOTES

Coaxial or shielded cable.

Relay contact moves in direction of arrow when energized.

Indicates a pushbutton switch with a momentary (ON) position.

Indicates a ganged 2-section 4-position rotary switch.

Indicates a Schottky (hot-carrier) diode.

Dual Transistors -- Physical location of the pins is as shown.

NSTOR

Signals that are active-low, are identified by the letter N followed by a signal mnemonic (such as NSTOR).

STOR

Signals that are active-high are identified by a signal mnemonic (such as STOR).

Identification of logic families is as shown (in this case, ECL). For more information on logic symbols, refer to the paragraph entitled Logic Symbols in Section VIII.

Figure 8-1. Schematic Diagram Notes (2 of 3)

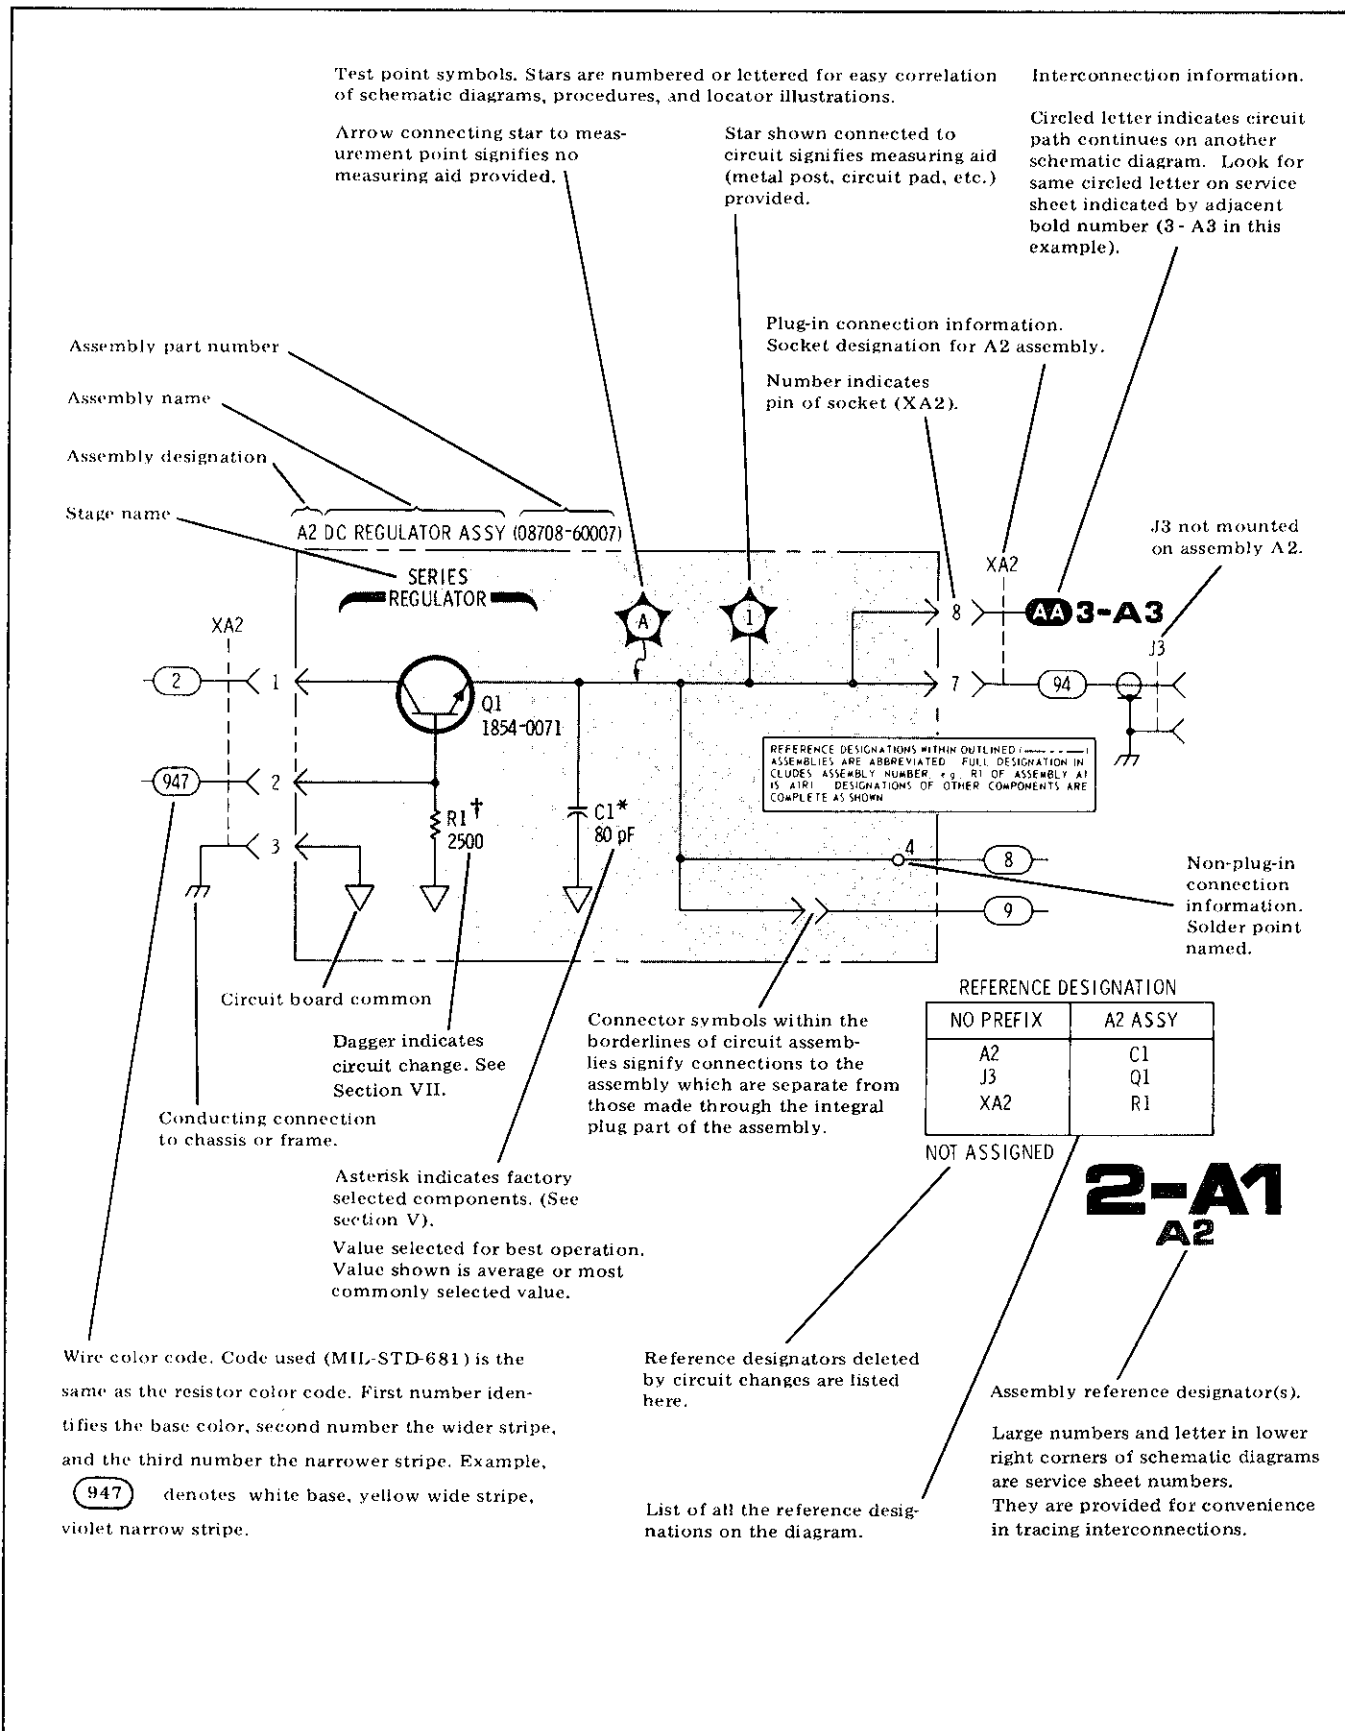

Figure 8-1. Schematic Diagram Notes (3 of 3)

Supplemental Troubleshooting Aids (Cont'd)

ing properly. The program will not isolate a remote problem but it may give some indication of what the actual problem is. A remote operator's check, found near the last page of this manual, checks the various functions of the Synthesizer when the HP-IB controller and bus are operating correctly.

8-18. An Operational Verification Check, located before the performance tests in Section IV, may be used to check the performance of the instrument without an excessive outlay of time.

8-19. Table 5-2 (in Section V) may aid in isolating a circuit defect in the event of a performance test failure.

8-20. RECOMMENDED TEST EQUIPMENT

8-21. Test equipment and test equipment accessories required to maintain the Synthesizer are listed in Table 1-2. Equipment other than that listed may be used if it meets the listed critical specifications.

8-22. SERVICE AIDS

8-23. **Pozidriv Screwdrivers.** Many screws in the instrument appear to be Phillips, but are not. To avoid damage to the screw slots, Pozidriv screwdrivers should be used.

8-24. **Blade Tuning Tools.** For adjustments requiring a non-metallic tuning tool, use the J.F.D., Model No. 5284 (HP 8710-1010). In situations not requiring non-metallic tuning tools, an ordinary small screwdriver or other suitable tool is sufficient. No matter what tool is used, never try to force any adjustment control in this instrument. This is especially critical when adjusting variable inductors or capacitors.

8-25. **Part Location Aids.** The locations of some chassis-mounted parts and the major assemblies are shown on or near the last foldout of this manual. The locations of individual components mounted on printed circuit boards or other assemblies are shown on the service sheet.

8-26. **Servicing Aids on Printed Circuit Boards.** The servicing aids include test points, transistor and integrated circuit designations, adjustment callouts, and assembly stock numbers.

8-27. REPAIR

8-28. After a circuit board is repaired, it is recommended that the area surrounding the new component be sprayed with a protective coating.*

8-29. Factory Selected Components

8-30. Some component values are selected at the time of final checkout at the factory (see Table 5-1). Usually these values are not extremely critical; they are selected to provide optimum compatibility with associated components. These components are identified on individual schematics by an asterisk (*). The recommended procedure for replacing a factory-selected part is as follows:

a. Try the original value, then perform the calibration test specified for the circuit in the performance and adjustment sections of this manual.

b. If calibration cannot be accomplished, try the typical value shown in the parts list and repeat the test.

c. If the test results are still not satisfactory, substitute various values within the tolerance specified in Table 5-1 until the desired result is obtained.

8-31. Non-Field Repairable Assemblies

8-32. A few of the Synthesizer's assemblies must be replaced if they malfunction. If they are repairable, they may be returned to the factory under the Module Exchange Program (refer to the next paragraph). The following assemblies are not repairable:

A1A13	YTM Assembly
A1A12	Power Amplifier (if the power amplifier is defective, replace the entire A1A12 Assembly).
A1A13A1	Preamplifier Assembly (if defective, replace the entire A1A13 Assembly).
A1AT2	Isolator
A1AT3	Pin Modulator
A1CR1	Leveling Detector
A1DC1	Directional Coupler
A1FL1	High Pass Filter
A2A2	Rotary Pulse Generator
A3A9U1	Sampler 2-6.5 GHz
A3A9A1	Directional Coupler Assembly
A3A9A2	YTO Interconnect Assembly
A3A9A6	Attenuator Assembly, 15 dB
A3A9A7	6.3 GHz Low Pass Filter Assembly
A3A11	Power Line Module

*Such as "Krylon" No. 1301 by Borden Inc., Department CP Columbus, Ohio 43215.

8-33. Module Exchange Program

8-34. The restored assemblies listed below may be ordered as replacements under the Module Exchange Program.

A1AT1	Programmable Attenuator Assembly
A1A3	YTM Assembly
A3A1A4	M/N VCO Assembly (if A3A1A4A1 is defective, replace the entire assembly).
A3A8	10 MHz Reference Oscillator Assembly
A3A9A3	2–6.2 GHz YTO Assembly

Refer to Section VI for ordering information.

8-35. After Service Product Safety Checks

8-36. Visually inspect interior of instrument for any signs of abnormal internally generated heat, such as discolored printed circuit boards or components, damaged insulation, or evidence of arcing. Determine and remedy cause of any such condition.

8-37. Using a suitable ohmmeter, check resistance from instrument enclosure to ground pin on power cable plug. The reading must be less than one-half ohm. Flex the power cable while making this measurement to determine whether intermittent discontinuities exist.

8-38. Check any front or rear panel terminals marked as ground, using the procedure in paragraph 8-37.

8-39. Check resistance from instrument enclosure to the line and neutral (tied together) with the power switch on and the power source disconnected. The minimum acceptable resistance is two megohms.

8-40. Check line fuse (A3F1) to verify that a correctly rated fuse is installed (refer to Section II).

8-41. Disassembly and Reassembly Procedures**WARNINGS**

Maintenance described herein is performed with power supplied to the instrument and with protective covers removed. Such maintenance should be performed only by service-trained personnel who are aware of the hazards involved. Where maintenance can be performed without power supplied, the power should be removed.

A pin-to-pin voltage difference of 60 Vdc may be found on many of the Synthesizer's circuit board connectors. This voltage could cause personal injury if contacted. Be careful while working on the circuit boards with power supplied to the instrument.

If a circuit board is placed on an extender board, the possibility of coming in contact with 60 Vdc is greatly increased. This voltage could cause personal injury if contacted. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

8-42. Before performing any of the following disassembly or reassembly procedures, the following steps must be performed.

- a. Set the LINE switch to STANDBY.
- b. Remove the Line Power Cable from the Line Module (A3A11).

8-43. **Top Cover Removal.** To remove the top cover from the Synthesizer, follow the steps as listed below:

- a. Remove the two plastic feet from the rear of the top cover by removing the Pozidriv screw from each foot (see Figure 8-2).
- b. Unscrew the Pozidriv screw at the middle of the rear edge of the top cover (see Figure 8-2). This is a captive screw and will cause the top cover to pull away from the front frame. Captive screw part number HP 0560-1171; clip part number HP 0510-0043.
- c. Lift the top cover off the Synthesizer.

8-44. **A1 Assembly Protective Cover Removal.** To remove the protective cover, follow the steps listed below:

- a. Remove the eight Pozidriv screws from the protective cover.
- b. Move the cables toward the rear of the Synthesizer. Lift the protective cover from the A1 Assembly.

8-45. **A2 Assembly Protective Cover Removal.** To remove the protective cover, follow the steps as

Disassembly and Reassembly Procedures (Cont'd)

listed below:

a. Remove the Pozidriv screw at the rear of the protective cover.

b. Lift up the rear portion of the protective cover and slide towards the rear of the Synthesizer to allow the front edge pins to disengage from the guide slots.

8-46. Bottom Cover Removal. To remove the bottom cover from the Synthesizer, follow the steps as listed below:

a. Place the Synthesizer upside down.

b. Remove the two plastic feet from the rear of the bottom cover by removing the Pozidriv screw from each foot (see Figure 8-2).

c. Unscrew the Pozidriv screw at the middle of the rear edge of the bottom cover (see Figure 8-2). This is a captive screw and will cause the front edge of the bottom cover to pull away from the front frame. Captive screw part number is HP 0570-1171; clip part number is HP 0510-0043.

d. Lift the bottom cover off the Synthesizer.

8-47. Front Panel Removal. To remove either the A1 or A2 Assembly Front Panel, follow the steps as listed below:

a. Place the Synthesizer upside down.

b. Remove the plastic foot on the A2 Assembly side of the instrument.

c. Remove the two Pozidriv screws from the bottom edge of the front frame over the front panel.

d. Place the Synthesizer with top side up.

e. Remove the top plastic trim strip from the front frame.

f. Remove the two Pozidriv screws from the top edge of the front frame over the front panel.

g. Carefully, pull the front panel outward to clear the front frame (see Figure 8-3).

h. Disconnect the cables and the wiring as necessary to free the front panel.

i. Remove the two Pozidriv screws from the hinge and remove the front panel.

8-48. Fan Removal and Replacement. To remove the fan from the Synthesizer, follow the steps listed on page 8-9.

WARNING

The fan and fan relay always have 120 Vac across the terminals if the instrument is connected to the Mains (line) voltage. BE SURE the instrument is disconnected before removing the fan.

Figure 8-2. Rear Panel of the Synthesizer

Figure 8-3. A1 and A2 Assembly Front Panel Fully Extended

Disassembly and Reassembly Procedures (Cont'd)

a. Remove the bottom cover from the Synthesizer as in paragraph 8-46.

b. Remove two Pozidriv screws from the fan cowl and remove the cowl.

c. Remove the clear plastic protective cover from the bottom of the Synthesizer by removing the five white circled screws (see Figure 8-4).

d. Remove the plastic clamp holding the three wires going to the fan from the Mother Board.

e. Unsolder the two black (06 and 09) wires from the Mother Board. Remove the screw from the ground wire.

f. Pull the three wires out of the rear frame going to the fan.

g. Remove the four nuts and lockwashers from the fan mounting brackets.

h. Carefully remove the fan from the mounting bracket. Do not lose any of the hardware.

i. Before replacing the fan, check to see that the magnetic shield is securely in place on the blade side of the fan motor.

j. Reassemble the fan in the reverse order. When tightening the four nuts and lockwashers, be careful that the four rubber shock mounts do not twist with the nuts as they are tightened. Be sure the wires go around the outside of the fan strut (away from the fan blade).

WARNING

BE SURE to replace the A3 Assembly's protective plastic cover before replacing the bottom cover. This cover is intended to provide protection from electrical shock when the bottom cover is removed.

k. Replace the cable clamp and MAKE SURE that the plastic protective cover is replaced before replacing the bottom cover.

8-49. Rear Panel Removal. To remove the rear panel for access to the Line Module (A3A11), fan relay (A3K1), transistors (A3Q1-Q4), and the rear panel coax connectors, follow the steps listed below:

a. Remove the top cover as in paragraph 8-43.

b. Remove the two Pozidriv screws from the top of the rear frame and the three screws from over the heat sink (see Figure 8-2).

c. Push the top of the panel outward. The transistors (A3Q1-Q4) can be replaced by removing the two Pozidriv screws holding them in place.

8-50. A3A1 M/N Loop Assembly Removal. To remove the A3A1 Assembly from the Synthesizer follow the steps as listed below:

a. Remove the top and bottom covers as in paragraphs 8-43 and 8-46.

b. Set the Synthesizer on its right side.

c. Remove the five coaxial cables from the A3A1 Assembly to free it from the other assemblies.

d. Remove the eight Pozidriv screws labeled B from the Mother Board, noting the sizes of each. These screws can be removed without removing the protective cover from the bottom of the Synthesizer.

e. Hold the A3A1 Assembly while removing the last screw. Then lift the assembly away from the Mother Board.

8-51. A3A9 YTO Loop Assembly Removal. To remove the A3A9 YTO Loop Assembly from the Synthesizer, follow the steps as listed below:

a. Remove the top and bottom covers as in paragraphs 8-43 and 8-46.

b. Remove the Pozidriv screw labeled "A" from the top of the A3A9 Assembly.

c. Disconnect the semi-rigid coax (A1W1) from A3A9A1J1. Loosen the cable at A1A13A1J1 and rotate it up and away from A3A9.

d. Remove the two Pozidriv screws labeled A from the bottom of the A3A9 Assembly through the Mother Board (see Figure 8-4).

e. Lift the assembly out until it clears the surrounding assemblies. Hook the front edge of the assembly over the front edge of the A3 Assembly as shown in Figure 8-5.

Figure 8-4. Bottom of the Synthesizer

Dissassembly and Reassembly Procedures (Cont'd)

f. Secure the assembly into place by tightening the captive thumb screw into the pressed-in nut.

g. Connect a test cable from A3A9A1J1 to A1A11J1 for troubleshooting and testing purposes.

CAUTION

When reinstalling the A3A9 Assembly, be careful not to crush or pinch the coaxial or flat ribbon cables.

8-52. A1 Assembly Removal. To remove the A1 Assembly from the Synthesizer, follow the steps listed below:

- a. Remove the top cover.
- b. Disconnect A1W1 from A1A13A1J1; loosen the cable at A3A9A1J1. Rotate the cable up and away from the A1 Assembly.
- c. Remove the protective cover from the A1 Assembly.
- d. Remove the A1A7, A1A8, and A1A9 boards.

Figure 8-5. A3A9 Assembly in Service Position

Disassembly and Reassembly Procedures (Cont'd)

e. Disconnect the FM SIG (brown) and the YTM TUNE (yellow) coax connectors.

f. Set the Synthesizer on its right side with the A1 assembly up.

g. Remove the front frame top trim strip.

h. Remove the two Pozidriv screws from the top of the front frame.

i. Remove the trim strip from the bottom of the front frame.

j. Remove two Pozidriv screws from the bottom of the front frame.

k. Remove the two Pozidriv screws from the siderail handle. Lift the handle's end pieces from the side cover. Push the side cover toward the rear of the instrument and remove it.

l. Remove the six Pozidriv screws that secure the A1 Assembly to the siderail. Remove the two Pozidriv screws that secure the A1 and A2 assemblies to the center rail.

m. Pull forward on the brace in the A1 Assembly and it should start to slide out of the Synthesizer. Place the two coaxial cables so they clear the A1 Assembly.

8-53. A1A13A1 Preamplifier Assembly Removal. To remove the preamplifier assembly follow the procedure listed below.

Disassembly and Reassembly Procedures (Cont'd)

- a. Remove the A1 Assembly.
- b. Set the A1 Assembly on its right side.
- c. Remove the three screws which hold the A1A12 Power Amplifier Assembly bracket in place. These screws are located on the bottom of the A1 Assembly nearest the rear panel.
- d. Set the A1 Assembly upright.
- e. Remove the blue cable that is connected to the A1AT3 Pin Modulator.
- f. Remove the semi-rigid cable at the Pre-amplifier output. Loosen the cable at the modulator input and rotate it down toward the power amplifier.
- g. On the rear panel of the A1 Assembly, remove the four screws that secure the Preamplifier.
- h. Remove four screws (two to each multi-pin connector).

CAUTION

Do not let the coaxial connector jacks drag across the circuit board while removing the Preamplifier.

After removing the Preamplifier, tip it back so the inductor beads won't be lost.

- i. Pull the A1A13 circuit board forward and remove the Preamplifier by sliding it up and between the chassis and circuit board.

NOTE

When re-installing the Preamplifier, position it so the pins will plug into the board correctly.

8-54. A1A2 Power Amplifier Assembly Removal. To remove the Power Amplifier Assembly, follow the procedure below.

- a. Remove the A1 Assembly.
- b. Set the A1 Assembly on its right side.
- c. Remove the three screws that hold the Power Amplifier bracket in place. These screws are

on the bottom of the A1 Assembly nearest the rear panel.

- d. Set the A1 Assembly upright.
- e. Remove both semi-rigid coaxial cables that are connected to the Power Amplifier Assembly.
- f. Remove the flat-ribbon cable connector with a standard blade screwdriver.
- g. Loosen the cable at the A1AT1 Pin Modulator output and move the other end away from the Power Amplifier.
- h. Loosen the cable at the input to the A1AT2 Isolator. Raise the opposite end of the cable and re-tighten the connector slightly.
- i. Slide the Power Amplifier Assembly and bracket out the right side of the A1 Assembly.

8-55. A1AT2 Isolator Removal. To remove the Isolator, follow the procedure below.

- a. Remove the Synthesizer's top and bottom covers. (Refer to the appropriate procedures.)
- b. Position the Synthesizer with the top side up.
- c. Remove the A1 Assembly's protective cover. (Refer to the appropriate procedure.)
- d. Disconnect the semi-rigid coaxial cables from the Isolator.
- e. Set the Synthesizer on its right side.
- f. Remove the four nuts that secure the Isolator with a 5/16-inch nut driver.
- g. Lift the Isolator; slide it toward the rear and top of the A1 Assembly.

NOTE

When replacing the Isolator, make sure the rubberized RF Shield that surrounds the Isolator is folded flat underneath. Be sure the RF Shield between the Isolator and A1AT1 Programmable Attenuator is not wrinkled.

8-56. A1AT1 Programmable Attenuator Removal. The following procedure explains how to remove the Attenuator.

Disassembly and Reassembly Procedures (Cont'd)

- a. Remove the Synthesizer's top cover. (Refer to the appropriate procedure.)
- b. Remove the left side cover.
- c. Set the Synthesizer with its top up.
- d. Disconnect the semi-rigid coaxial cable at the Attenuator's input and output.
- e. Remove the semi-rigid coaxial cable that is connected to the A1DC1 Directional Coupler.
- f. Remove the two panhead Pozidriv screws through the left side frame that secure the Attenuator.

NOTE

While removing the Attenuator, be sure the surrounding rubberized RF Shield does not wrinkle or move.

- g. Remove the large gray cable from its clamp. The clamp is located above the Attenuator at the rear of the A1 Assembly.
- h. Slide the rear of the Attenuator up. Be careful not to put excessive pressure on the gray cable's connector.
- i. Continue to slide the Attenuator up and out of the A1 Assembly.
- j. To remove the gray cable's connector from the Attenuator, press on the top and bottom of the connector (close to Attenuator) and pull away.

NOTES

The following items must be considered for re-installing the Attenuator.

1. *The screws cannot be inserted into the Attenuator if the conductor rubber pad has moved.*
2. *The semi-rigid cable must be connected to the directional coupler before connecting it to the Attenuator.*
3. *Connect the semi-rigid cable to the Attenuator output jack.*
4. *Insert the large gray cable in its clamp.*

8-57. A1A3 YTM and A1FL1 High Pass Filter Removal. The following procedure explains how the YTM and filter are removed.

- a. Remove the Synthesizer's top and bottom covers. (Refer to the appropriate procedures.)
- b. Remove the A1 Assembly protective cover. (Refer to the appropriate procedure.)
- c. Open the A1 Assembly front panel. (Refer to the appropriate procedure.)
- d. Set the instrument on its right side.
- e. Remove the two Pozidriv screws that secure the YTM.
- f. Set the Synthesizer with its top up.
- g. Remove the semi-rigid coaxial cable connector at the A1AT2 Isolator output.
- h. Disconnect the cable connected at the YTM output.
- i. Loosen the connector of the same cable at the Directional Coupler input. Rotate the cable up and away from the YTM.
- j. Tip the front of the YTM up. Reach through the front panel opening and remove the screw that holds the cable clamp.
- k. To remove the flat ribbon cable connector, push the red tabs back and pull the connector straight up.
- l. Pass the YTM and High Pass Filter out through the front panel opening.

8-58. Battery Replacement. To replace the batteries, follow the steps listed below:

- a. Remove top cover.
- b. Grasp the top of the battery holder's clip and pull forward until it slips off.
- c. Grip the battery pack on both sides with your fingers and pull straight out.
- d. Position the new battery pack so the metal strips press against the flexible contacts of the battery holder.

Disassembly and Reassembly Procedures (Cont'd)

e. Slip the small end of the battery clip over the bottom end of the battery holder. Snap the top end of the clip into place.

8-59. LOGIC SYMBOLS

8-60. The logic symbols used in this manual are based on the American National Standard ANSI Y32.14-1973, "Graphic Symbols for Logic Diagrams (Two-State Devices)." The following summary should settle most questions of interpretation.

8-61. Qualifiers

8-62. Qualifiers are that portion of the symbol (either rectangular or distinctively shaped) that denotes the logic function. Refer to Figure 8-6.

8-63. Indicator Symbols

8-64. Indicator symbols identify the active state or level of a symbol's input or output. The more positive level is the high state; the less positive is the low state. Refer to Figure 8-8.

Figure 8-6. Qualifiers

8-65. Contiguous Blocks

8-66. Two symbols may share a common boundary parallel or perpendicular to the direction of signal flow. Note that in the examples shown in Figure 8-7, there is generally no logic connection across a horizontal line; however, there is always a logic connection across a vertical line. An exception to this is the Common Control Block (Figure 8-12) where there is a logic connection across a horizontal line.

8-67. Dependency Notation

8-68. Dependency Notation is a way to simplify symbols for complex IC elements by defining the

existence of an AND relationship between inputs, or by the AND, OR, control, or free (switch) conditioning of an output by an input without actually showing all the elements and interconnections involved. The examples of Figure 8-9 and 8-10 use the letter "C" for control, "G" for gate (AND), "V" for OR and "F" for free. The dependent input or output is labeled with a number that is either prefixed (e.g., 1X) or subscripted (e.g., X₁). They both mean the same thing. Note that many times a controlled line may already be labeled with a number; as for example, a coder. In this case, the controlling or gating input will be labeled with a letter. See Figure 8-11.

Figure 8-7. Contiguous Blocks

Figure 8-8. Indicator Symbols

Figure 8-9. AND Dependency Notation

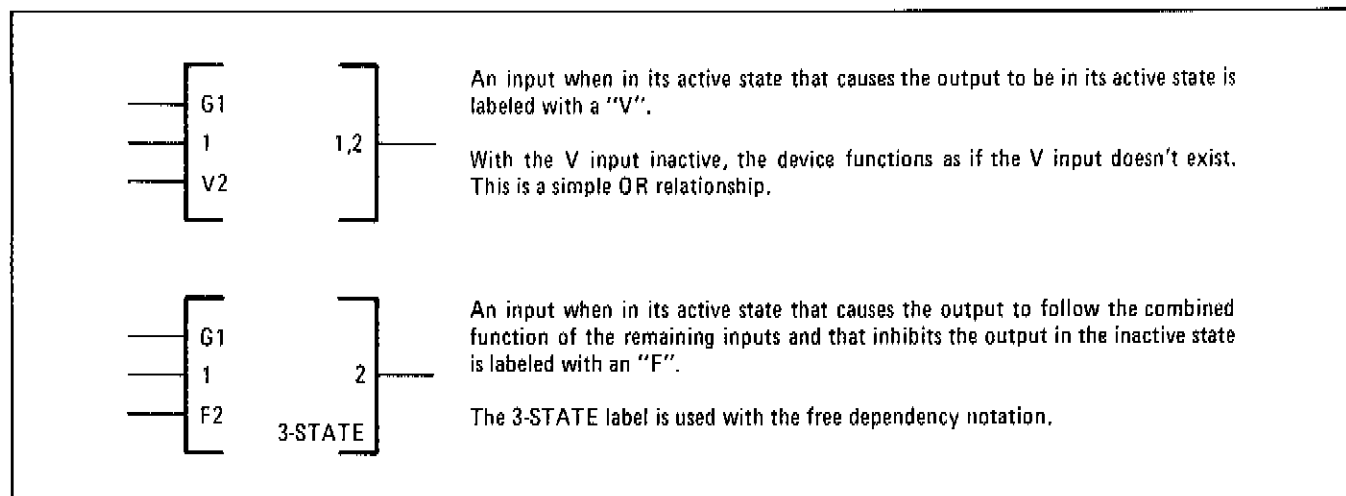

Figure 8-10. OR and Free Dependency Notation

Figure 8-11. AND Dependency Notation, Coder Example Using Letters

8-69. Common Control Block

8-70. The Control Block is used in conjunction with an array of related symbols in order to group common logic lines. Figure 8-12 shows how the Control Block is usually represented. Figure 8-13 shows a quad D-Type flip-flop with reset. This can be redrawn by combining what is shown in Figures 8-12 and 8-13 about Contiguous Blocks and Common Control Blocks. The result is shown in Figure 8-14. Note that the more complex representation shown in Figure 8-13 might be used when the flip-flops are functionally scattered around the schematic (not used as a quad unit).

Figure 8-12. Common Control Block

Figure 8-13. Quad D-Type Latch (Individual)

Figure 8-14. Quad D-Type Latch (Combined)

8-71. Complex Devices

Figures 8-15 through 8-17 show how the basic symbols can be combined in various ways to illustrate the behavior of fairly complex devices.

8-72. Quad D-Type Latch. Refer to Figure 8-15. The register control block is used to illustrate a quad D-type latch. There is a common active-low reset (R), and a common edge-triggered control input (C). Since there is only one dependency relationship, the controlling input is not numbered and the controlled function (D) is subscripted with a C.

Figure 8-15. Quad D-Type Latch Example

Complex Devices (Cont'd)

8-73. Multiplexer. The multiplexer block is used to simplify the AND portion of a quad AND-OR select gate. When G1 is high, the data presented at the "1" inputs are gated through. When G2 is high, the data presented at the "2" inputs are gated through.

Figure 8-16. Multiplexer (AND-OR Selected) Example

8-74. Shift Register Control Block. The shift register control block is used to show common inputs to a bidirectional shift register. Notice that " $\rightarrow m$ " means shift the contents to the right or down by "m" units. And " $\leftarrow m$ " means shift the contents to the left or up by "m" units. Note: If $m=1$, "m" may be omitted. Inputs "a" and "b" are each single IC pins that have two functions. Input "a" enables one of the inputs to the top D-type flip flop (1D), and also shifts the register contents down one unit. Input "b" enables one of the inputs to the bottom flip-flop (2D), and also shifts the register contents up one unit. Input "c" loads all four flip-flops in parallel (3D). Input "d" is a common reset. The output delay indicator is used because the outputs change state when the control input returns to its inactive state.

8-75. Up-Down Counter Control Block. The counter control block (Figure 8-18) is used to show the common inputs to a Presettable Decade Up/Down Counter. Notice that " $+m$ " means count up (increment the count) by "m"; " $-m$ " means count down by "m". Note that if $m=1$, "m" may be omitted. Since the D-type flip-flops are master-slave, the output delay indicator is used. The " $=9$,

$+1$ " and " $=0,-1$ " notation defines when the carry and borrow outputs are generated. They also define it as a decade counter; a binary counter would have carry indicated with " $=15, +1$ ". Flip-flop weighting is indicated in parenthesis.

SERVICE SHEET 1
PRINCIPLES OF OPERATION

The HP Model 8672A Synthesized Signal Generator consists of the A3 RF Source Assembly, A2 Controller Assembly and the A1 RF Output Assembly. Figure 8-19 is a simplified block diagram. The Overall Troubleshooting Block Diagram shows the interconnections between the major assemblies. Figure 8-20 shows the physical location of these assemblies in the Synthesizer.

The Synthesizer's RF output signal is generated in the YTO Loop of the A3 RF Source Assembly. Through the interconnection of the phase lock loops, the output signal is phase locked to the time base. The power supplies are also part of the A3 Assembly.

Digital signals from the A2 Controller Assembly are input to the loop circuits to control the RF output frequency. The frequency may be tuned from the front panel or programmed through the HP-IB Interface. The RF signal from the YTO is passed through an amplifier, PIN modulator, YIG-tuned multiplier, and stepped attenuator in the A1 RF Output Assembly. An ALC loop controls the level and provides amplitude modulation. The

attenuator's output is connected to the front panel RF Output jack. The frequency and amplitude modulation modes are selected by circuits within the A1 Assembly. The FM is added to the carrier in the A3 Assembly's YTO Loop.

In the local mode, the control signals are input from the front panel. Programmed inputs come through the HP-IB Interface to control frequency, RF level functions, and modulation.

The front panel annunciators indicate the Synthesizer's operating mode and status. Table 8-2 lists the status and explains the functions monitored.

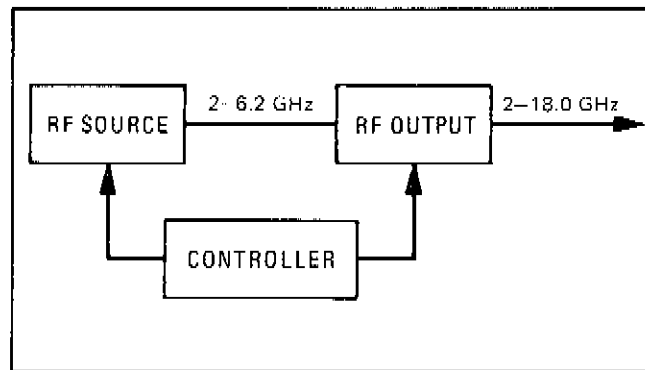

Figure 8-19. Synthesizer's Simplified Block Diagram

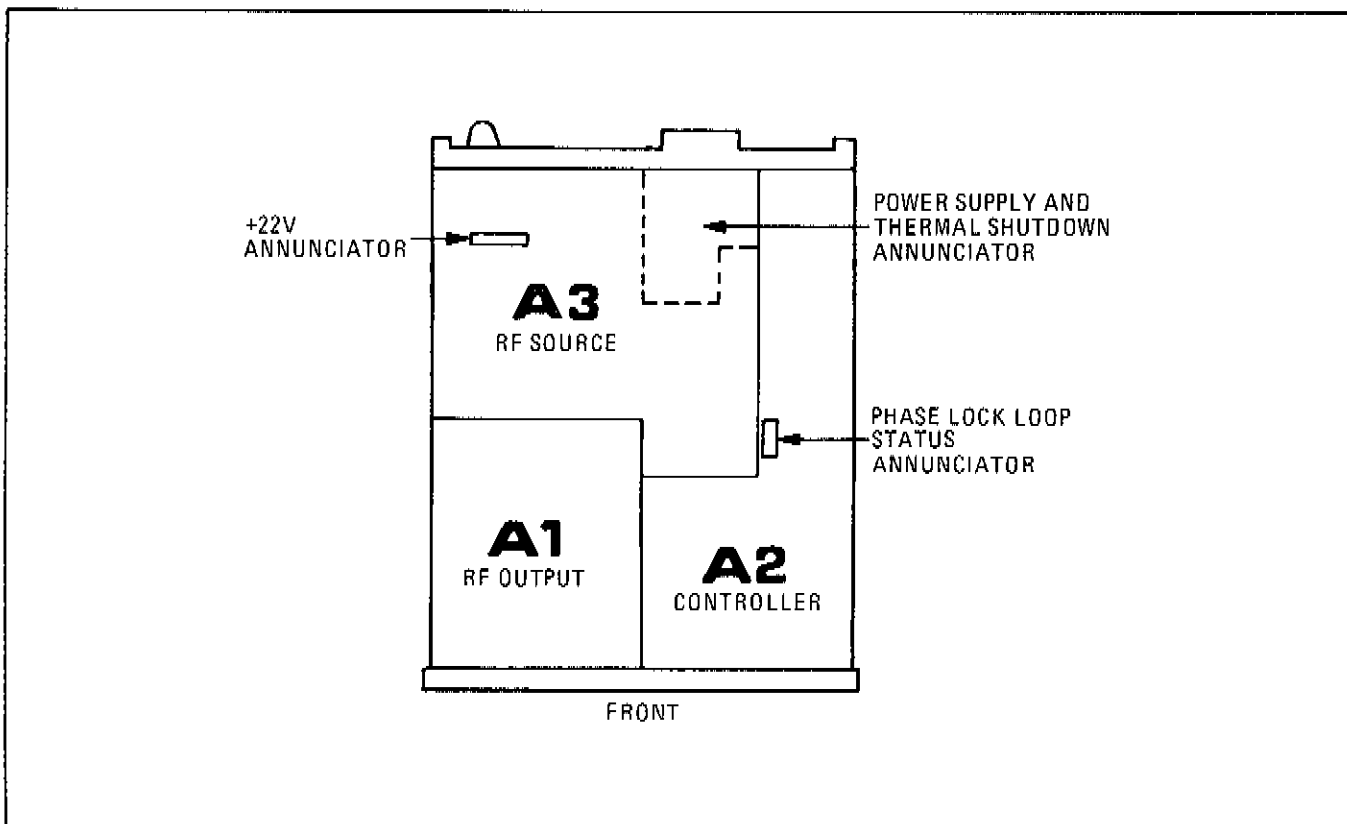

Figure 8-20. Major Assembly Locations

Table 8-2. Front Panel Status Annunciators

Annunciator		Purpose
Name	Location	
OVEN	A2	Monitors the reference oven in the A3 Assembly. Indicates oven temperature is not stabilized.
OUT OF RANGE	A2	Indicates that an incorrect frequency has been programmed.
REMOTE	A2	Indicates that the Synthesizer is in the remote mode.
STANDBY	A2	Indicates that the LINE switch is set to STANDBY.
NOT PHASE-LOCKED	A2	Indicates that one or more of the loops are not phase-locked. Refer to the Phase Lock Loop Status Annunciators.
INT REFERENCE OFF	A2	Indicates that the rear panel FREQ REF switch is set to EXT.
FM OVER MOD	A1	Indicates that the maximum FM deviation (A3) or maximum input drive (A1) has been exceeded.
ALC LEV UNCAL	A1	Indicates that the ALC (leveling) circuit is not providing a leveled output or that the range attenuator was programmed to a power level below its range.

TROUBLESHOOTING

Begin troubleshooting by following Table 8-3, Overall Troubleshooting. The table is designed to isolate a malfunction to one of the three major assemblies. Begin troubleshooting with step 1. This is important since the table assumes that all measurements and indications are normal. When a malfunction is isolated by using the table, turn to the service sheet indicated for further troubleshooting information.

The following information can also be used to isolate a malfunction to the major assembly level or it can be used as supplemental information to the table.

Refer to Overall Troubleshooting Block Diagram. Examine the front and rear panel switches and annunciators or program specific functions and examine their annunciators. A switch or programmed function normally will effect only one annunciator. Some will also change the status annunciators listed in the Front Panel Status Annunciators' table. Check to see that those related to the malfunction respond properly to the switch setting or programmed function. For detailed information on the annunciator response to switch settings, refer to the figures showing the front and

rear panel controls, connectors and indicators in Section III.

Problems indicated by the NOT PHASE LOCKED annunciator can be further isolated by removing the instrument's top cover. (Refer to the Disassembly and Reassembly procedures in this section.) View the phase-locked loop annunciators which are located on the A2 assembly (refer to Figure 8-19). If the entire instrument seems to be off or if the STANDBY annunciator does not change with the LINE switch being set to ON, check the rear panel fuse and the power supply and thermal shutdown annunciators. Also check the +22V annunciator.

The next step is to measure main signal paths that lead to a malfunction in one of the major assemblies. Refer to the Overall Troubleshooting Block Diagram. When a problem is isolated to a major assembly, refer to the troubleshooting information on the appropriate service sheet.

The following table is designed to isolate a malfunction to one of three major assemblies. Begin troubleshooting with step 1. This is important, since the table is set up assuming that all previous steps are normal. When a malfunction is located in the table, turn to the service sheet indicated for further troubleshooting information.

Table 8-3. Overall Troubleshooting (1 of 3)

INITIAL CONDITIONS

1. Check that the LINE switch is in STANDBY and remove the Power Cable from the Line Module (A3A11).
2. Set the voltage selection card in the Line Module (A3A11) for the nominal line voltage to be used.
3. Check that the Line Fuse (A3F1) is the correct value and type.

NOTE

Remove the HP-IB Connector Plug, if connected.

4. Check that the LINE switch is in STANDBY and insert the Power Cable into the Line Module.
5. Set the rear panel controls and cables as follows:
 - a. FREQ STANDARD INT/EXT switch to INT.
 - b. Jumper (A3W3) connecting A3J9 to A3J10.
6. Set the front panel controls and switches as follows:
 - a. METER MODE to LEVEL
 - b. RF selector to ON.
 - c. OUTPUT LEVEL RANGE control to one step from fully clockwise (0 dBm).
 - d. OUTPUT LEVEL VERNIER control to fully clockwise (+3 dB).
 - e. ALC selector to INT.
 - f. AM selector to OFF.
 - g. FM selector to OFF.

Test	Results	If Faulty Go To
1. Set LINE switch to STANDBY position.	OVEN and STANDBY annunciators light.	Continue to step 2
2. Set line switch to ON position.	00 dBm Range displayed. Meter indicates full scale. ALC annunciator INT lights. RF annunciator ON lights. NOT PHASE LOCKED annunciator may light momentarily and then extinguish. Frequency within specified range ¹ .	SS4 SS4 SS4 SS4
3. Press PRESET pushbutton.	Frequency goes to 3000.000 MHz.	SS3
4. Press FREQUENCY RESOLUTION pushbutton on the left to produce 100 MHz resolution.	Light Bar for 100 MHz resolution lights.	SS3
5. Turn TUNING control first clockwise then counterclockwise.	Frequency increases and then decreases in 100 MHz steps.	SS3
6. Press FREQUENCY RESOLUTION pushbutton next to the left to produce 1 MHz resolution and turn the TUNING control clockwise and then counterclockwise.	Light Bars for 100 and 1 MHz resolution light and frequency increases and decreases in 1 MHz steps.	SS3
7. Press the next FREQUENCY RESOLUTION pushbutton to produce 10 kHz resolution and turn the TUNING control clockwise and then counterclockwise.	Light Bars for 100 and 1 MHz and 10 kHz resolution light; the frequency increases and decreases in 10 kHz steps.	SS3

¹The Synthesizer will produce the last frequency entered. If the Synthesizer was remotely programmed to an out-of-range frequency, when power is applied and the Synthesizer is in local, it will count up or down until a legal frequency is reached. This action can be terminated by pressing the PRESET pushbutton. A dead battery can produce similar results when first applying power.

Table 8-3. Overall Troubleshooting (2 of 3)

Test	Results	If Faulty Go To																					
8. Press the last FREQUENCY RESOLUTION pushbutton to produce 1 kHz resolution ¹ and turn the TUNING control cw, then ccw.	Light Bars for 100 and 1 MHz, 10 and 1 kHz light and frequency increases and decreases in 1 kHz steps. ¹	SS3																					
9. Press the HOLD pushbutton.	All Light Bars extinguish.	SS3																					
10. Turn the TUNING control cw and then ccw.	Frequency does not change.	SS3																					
11. Press the PRESET pushbutton.	Frequency goes to 3000.000 MHz.	SS3																					
<p>SETUP Connect spectrum analyzer to RF OUTPUT connector and adjust to observe a 3 GHz signal. Use 50 dB input attenuation, 2 kHz scan width, 0.3 kHz bandwidth, 50 milliseconds scan time, and +10 dBm log reference level.</p>																							
12. Set OUTPUT LEVEL RANGE control to +10 dBm and VERNIER control to approximately 0 dB.	Signal displayed on Spectrum Analyzer approaches top graticule line. LEV UNCAL annunciator may light.	Continue to step 13																					
13. Turn OUTPUT LEVEL RANGE control counterclockwise to -100 dBm.	Signal drops in 10 dB steps.	SS4																					
14. Set OUTPUT LEVEL RANGE to -20 dBm. Then set the RF switch to OFF position.	Power level drops to zero.	SS4																					
15. Set RF switch to ON and apply a 1 kHz signal at 600 ohms impedance to AM INPUT connector. Set METER MODE selector to AM and AM selector to 30% position. Adjust modulation signal level for full scale Meter indication.	Spectrum Analyzer displays sidebands approximately 16.5 dB below carrier.	SS4																					
16. Set AM selector to 100% position and adjust modulation signal level for half scale indication on Meter.	Sidebands approximately 12 dB below carrier.	SS4																					
17. Set AM selector to OFF and METER MODE selector to FM position. Apply modulating signal at 50 ohms impedance to FM INPUT connector. Adjust modulation level to null the carrier for the following deviation ranges.																							
<table border="1"> <thead> <tr> <th data-bbox="240 1622 503 1691">FM Deviation Selector</th> <th data-bbox="508 1622 790 1691">Modulation Frequency</th> <th data-bbox="795 1622 1089 1691">Meter Indication</th> </tr> </thead> <tbody> <tr> <td data-bbox="240 1698 503 1733">0.03 MHz</td> <td data-bbox="508 1698 790 1733">10 kHz</td> <td data-bbox="795 1698 1089 1733">24 ± 1.5 kHz</td> </tr> <tr> <td data-bbox="240 1740 503 1775">0.1 MHz</td> <td data-bbox="508 1740 790 1775">37.5 kHz</td> <td data-bbox="795 1740 1089 1775">90 ± 5 kHz</td> </tr> <tr> <td data-bbox="240 1782 503 1817">0.3 MHz</td> <td data-bbox="508 1782 790 1817">125 kHz</td> <td data-bbox="795 1782 1089 1817">300 ± 15 kHz</td> </tr> <tr> <td data-bbox="240 1824 503 1859">1 MHz</td> <td data-bbox="508 1824 790 1859">125 kHz</td> <td data-bbox="795 1824 1089 1859">300 ± 50 kHz</td> </tr> <tr> <td data-bbox="240 1866 503 1901">3 MHz</td> <td data-bbox="508 1866 790 1901">1 MHz</td> <td data-bbox="795 1866 1089 1901">2.4 MHz ± 150 kHz</td> </tr> <tr> <td data-bbox="240 1908 503 1942">10 MHz</td> <td data-bbox="508 1908 790 1942">3 MHz</td> <td data-bbox="795 1908 1089 1942">7.2 MHz ± 500 kHz</td> </tr> </tbody> </table>			FM Deviation Selector	Modulation Frequency	Meter Indication	0.03 MHz	10 kHz	24 ± 1.5 kHz	0.1 MHz	37.5 kHz	90 ± 5 kHz	0.3 MHz	125 kHz	300 ± 15 kHz	1 MHz	125 kHz	300 ± 50 kHz	3 MHz	1 MHz	2.4 MHz ± 150 kHz	10 MHz	3 MHz	7.2 MHz ± 500 kHz

Table 8-3. Overall Troubleshooting (3 of 3)

SETUP Set the FM selector to the OFF position. Connect the frequency counter to the RF OUTPUT connector. Set the OUTPUT LEVEL RANGE to 0 dBm. Use the Synthesizer's rear panel 10 MHz OUT as the counter timebase.		
Test	Results	If Faulty Go To
18. Press PRESET key.	Counter indicates 3000.000 MHz.	Continue with step 19.
19. Set frequency to 7000.000 MHz.	Counter indicates 7000.000 MHz	If frequency is half that desired, go to SS4.
20. Set frequency to 13 000.000 MHz.	Counter indicates 13 000.000 MHz.	If frequency is a 3rd or 2/3rds that desired, go to SS4.
21. Connect Power Meter to RF OUTPUT connector and connect EXT ALC INPUT connector to Power Meter's Recorder output connector. Set OUTPUT LEVEL RANGE to 0 dBm and ALC selector to PWR MTR position.	Power Meter indicates approximately -10 dBm.	SS4
22. Set OUTPUT LEVEL RANGE control to -10 dBm.	Power Meter indicates same level as in step 21.	SS4
23. Set OUTPUT LEVEL RANGE control to -20 dBm.	Power Meter indicates same level as in step 21.	SS4
24. Set ALC selector to INT position.		
25. Set FREQ STANDARD INT/EXT switch to EXT position.	INTERNAL REF OFF and NOT PHASE LOCKED annunciators light.	SS2
26. Disconnect Jumper (A3W3) from A3J9 and A3J10. Connect a 10 MHz signal at 0 dBm to (A3J10) FREQ STANDARD External Input connector.	INTERNAL REF OFF annunciator remains lighted and NOT PHASE LOCKED annunciator extinguishes. Synthesizer is phase locked.	SS2
27. To thoroughly check remote operation, load and run the HP-IB Diagnostic Program (Section VIII). For a quicker but less complete check, load and run the Remote Operator's Checks (Section VIII).

SERVICE SHEET 2

A3 RF Source Assembly

TROUBLESHOOTING HELP: In addition to this service sheet refer to:

- Block diagram Page 8-33
- Motherboard wiring Last 3 foldout sheets
- Parts list Page 6-1
- Performance tests Page 4-1
- Adjustment procedures Page 5-1

PRINCIPLES OF OPERATION

General

The Synthesizer's fundamental RF output signal is generated by the YTO (YIG Tuned Oscillator). This signal is phase-locked through the other loops to the Synthesizer's time base—an internal crystal oscillator. The YTO Loop pretunes and locks the YTO signal to the output of the M/N Loop and the 20/30 MHz (LFS) Loop (part of the A2 assembly). The M/N and 20/30 MHz Loops serve two basic functions. First, they are phase-locked to the reference crystal oscillator through the Reference Loop. They also provide the stepped tuning of the YTO output signal. The M/N Loop provides the larger steps (2000 to 6199 MHz in 10 MHz steps) while the 20/30 loop provides the smaller (1 MHz, 100, 10 and 1 kHz) steps.

Power is supplied to the Synthesizer by the power supply circuits, the Rectifier Assembly and the Positive and Negative Regulator Assemblies. Some functions are controlled by switching power supply outputs on and off.

Reference Loop

The Reference Loop is phase-locked to the A3A8 10 MHz Reference Oscillator Assembly. The Reference Loop's phase-locked outputs (10, 20 and 400 MHz) are used as references for the 20/30 MHz (LFS) Loop (part of A2 assembly) and the M/N Loop. The 10 MHz signal is also used as the master clock for digital circuits in the Synthesizer. The loop also can be locked to an external 5 or 10 MHz reference.

The 100 MHz VCXO (Voltage Controlled Crystal Oscillator) is the heart of this loop. The 100 MHz output signal is 1) multiplied by four to generate the 400 MHz reference for the M/N Loop and 2) divided by five to generate a 20 MHz reference signal that is also used in the M/N Loop. The 20 MHz signal is divided by two to produce a 10 MHz that is used as a reference and the master clock for the Synthesizer's digital circuits. The 10 MHz signal also is phase compared to the 10 MHz Reference Oscillator output. The resulting error signal is passed through the integrating amplifier and tunes the VCXO to phase lock the Reference Loop.

M/N Loop

The frequency output of the M/N loop 1) is dependent on the front panel frequency and 2) in part, controls the YTO output frequency. An encoded equivalent of the front panel frequency's most significant digits (10 MHz to 10 GHz) are input to the M/N Loop as M and N numbers. The ratio of the M and N numbers determine the M/N OUT frequency. The M/N OUT frequency's Nth harmonic (based on the N number and selected by the YTO pretuning) tunes the YTO frequency in 10 MHz steps. There is a 10 MHz step for each valid M/N OUT frequency (M/N ratio) and Nth harmonic (N number). This 10 MHz step complements the 20/30 MHz loop because its tuning range

SERVICE SHEET 2 (Cont'd)

is 10 MHz and step size is 1 kHz. Together, the M/N Loop, YTO pretuning and 20/30 MHz Loop are able to tune the YTO from 2000.000 to 6199.999 MHz in 1 kHz steps.

The M/N Loop VCO generates an output signal ($f_{M/N VCO}$) that varies between 355 and 395 MHz. The VCO signal is 1) divided by two ($f_{M/N}$) and is output to the YTO Loop and 2) mixed with the 400 MHz reference to produce an IF signal (f_{IF}) that varies between 5 and 45 MHz. The IF signal is divided by the M number and is phase compared to the quotient of the 20 MHz reference signal divided by the N number. The error voltage from the detector is integrated and tunes the M/N VCO to achieve phase lock.

The frequency output from the M/N Loop is dependent on the ratio of the M and N numbers. These numbers are input in the form of digital tuning information to the M/N Loop Phase Detector. The following equation shows the relationship between the output frequency and the M and N numbers.

$$f_{M/N} = \left[200 - 10 \left(\frac{M}{N} \right) \right] \text{ MHz}$$

where $f_{M/N}$ = M/N out frequency

M = M number

N = N number

For a listing of the M and N numbers, M/N output frequencies ($f_{M/N}$) and the YTO frequencies (f_o), refer to Table 8-4, M and N Numbers and Resulting Frequencies.

The M and N numbers and $f_{M/N}$ may also be calculated by the following formulas:

$$M = 27 - \left(\frac{1}{10} \right) [f_{o(A)} - f_{o(B)}]$$

$$N = \text{INT} \left[\frac{(f_o + 300)}{200} \right]$$

$$\text{and } f_{M/N} = \frac{1}{N} [(f_{o(A)} + 30)]$$

where $f_{M/N}$ = M/N Out frequency

f_o = YTO frequency

$f_{o(A)}$ = YTO frequency rounded off to lower 10 MHz.

$f_{o(B)}$ = YTO frequency rounded off to lower odd 100 MHz.

M = M number

N = N number

SERVICE SHEET 2 (Cont'd)

YTO Loop

Phase Lock System. When a frequency change occurs, the YTO is pretuned near the new desired frequency. This places the YTO frequency 20 to 30 MHz below the Nth harmonic of the M/N Loop output. (The Nth harmonic is the same as the M/N Loop's N number.) The YTO frequency and M/N Loop harmonic are mixed in the Sampler (Harmonic Mixer). The YTO IF (20-30 MHz) is phase compared with the 20/30 Loop output. (Note that the YTO IF and 20/30 Loop output are equal if the YTO Loop is locked.) The YTO Phase Detector's error voltage is integrated and ultimately is used to tune the YTO to achieve phase lock. The following formula expresses the relationship between the frequencies found in the YTO Loop:

$$f_{20/30} = f_{\text{YTO IF}} = N(f_{\text{M/N}} - f_o)$$

where $f_{20/30}$ = 20/30 Loop frequency

$f_{\text{YTO IF}}$ = YTO IF frequency

$f_{\text{M/N}}$ = M/N Loop frequency

f_o = YTO frequency

N = N number (same as in the M/N Loop)

The various frequencies in the YTO Loop can also be determined by using the front panel frequency reading as long as it is from 2000.000 to 6199.999 MHz. In this case

$$f_{20/30} = (30.000 - D_4 \cdot D_3 D_2 D_1) \text{ MHz}$$

$$\text{and } f_o = (D_7 D_6 D_5 D_4 D_3 D_2 D_1) \text{ MHz}$$

where D_1 to D_7 is the front panel frequency reading with D_1 being the least significant digit (1 kHz).

FM System. During the CW mode, the YTO Phase Detector output voltage may be expressed as follows:

$$V_e = \int f_o$$

where V_e = the error voltage

f_o = the YTO frequency

The error voltage is fully dependent on the YTO carrier frequency. During the FM mode, however, the error voltage is also dependent on the instantaneous frequency deviation. Because the frequency deviation is dependent on the modulation drive voltage, then:

$$V_e = \int f_o + \int V_{\text{FM}}(t) dt$$

where $V_{\text{FM}}(t)$ = the instantaneous drive voltage.

8-34c

SERVICE SHEET 2 (Cont'd)

The effect of the phase detector reacting in this way to FM is a cancellation of FM within the loop bandwidth (<20 kHz). Outside the bandwidth (>20 kHz), the cancellation effect is reduced as the FM drive rate is increased.

To compensate for the FM cancellation, the FM drive input is integrated and summed with (subtracted from) the phase detector's error output. Note that the FM drive is input to the YTO's FM coil just after the Loop Integrator and the integrated FM drive signal is summed with the phase detector's error signal output just before the Loop Integrator. The result is that only the phase lock voltage is integrated and passed on to phase lock the YTO Loop; therefore the YTO Loop does not affect the frequency response of the FM system.

Power Supplies

The Synthesizer's power supply section is made up of three assemblies and their associated assemblies and components. These are the Positive and Negative Regulators, and the Rectifier Assembly.

The Mains (line) voltage is input to the Synthesizer through the Line Power Module. The primary ac voltage is always connected to the Fan Relay and, with the LINE SWITCH in the ON position, to the Fan. Also, the Transformer, Rectifier Assembly, and Positive and Negative Regulators all receive power inputs if the Mains voltage is connected. The +22V output is regulated and is independent of the LINE switch. Its primary purpose is to supply the heater voltage for the 10 MHz Reference Oscillator and to supply power to the A2 Assembly frequency retention circuit.

The Positive Regulator, in conjunction with the LINE switch, controls the power supply voltage to the Synthesizer (with the exception of +22V). The front panel LINE switch, through the Front Panel Shutdown (PWR ON), turns the +20V supply on or off. The +20V supply is the reference for all other supplies that come from the Positive and Negative Regulators. The +11V switch (that turns the 10 MHz Reference Oscillator ON or OFF) is controlled by the rear panel FREQ STND INT/EXT switch. The Thermal Shutdown circuit turns off the +20V supply (thus turning the Synthesizer off) if the internal temperature exceeds +85°C. The fan will continue to run (if the LINE switch is ON) and will cool the instrument. At +55°C the Synthesizer will return to normal operation.

The Negative Regulator is controlled by the +20V supply. The -5.2 and -10V supplies are both taken from the -10V regulated input. The -10V switch is controlled by the front panel RF switch.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheet 1 was used to isolate an A3 Assembly malfunction. The following troubleshooting information may be used to further isolate the problem to one of the four RF Source Assembly sections.

- a. The Power Supply Section

8-34d

SERVICE SHEET 2 (Cont'd)

- b. The YTO Phase-Locked Loop section
- c. The M/N Phase-Locked Loop section
- d. The Reference Phase-Locked Loop section

Test Equipment

Frequency Counter	HP 5340A
Spectrum Analyzer	HP 8565A
Test Oscillator	HP 651A
Digital Voltmeter	HP 3455A

Procedure

1. Remove the Synthesizer's top cover. Connect the Synthesizer to the Mains (line) power. Set the RF switch to ON. Be sure the rear panel FREQ STANDARD switch is set to INT and the reference jumper is in place.
2. Observe the phase lock Status indicator's on A2A7. If the instrument has been disconnected from the Mains for more than a few minutes, the REF indicator may be off and the front panel OVEN light will be on. If that is the case, allow 10 minutes warm-up before continuing (or until the OVEN light goes off).
3. The phase lock Status indicators can help to quickly isolate a malfunction. In normal operation they all should be on. If the Reference Loop indicator is off go to Step 8. If the LFS Loop indicator is off, go to Service Sheet 3. If the M/N Loop indicator is off, go to Step 9. If the YTO Loop indicator is off, make sure the RF switch is ON. If the switch is ON, go to Step 11.
4. Connect the frequency counter to A3W9, the semirigid coaxial cable that connects A3 to A1. Tune to 2 GHz; then tune each frequency digit from zero to 9. The counter readout should be the same as the front panel frequency from 2 to 6.199 GHz, half the frequency from 6.2 to 12.399 GHz and one-third the frequency above 12.4 GHz. If the frequency is incorrect but the lock indicators are all on, one of the loops is probably locked at the wrong frequency due to incorrect data from the A2 Controller or a loop divider malfunction. Use the following table to determine which loop is probably the cause of a malfunction of a particular digit.

Loop Name	Digits Controlled	If Wrong
LFS loop	1 kHz to 1 MHz	Go to Service Sheet 3
M/N loop	10 MHz to 1 GHz	Go to Step 10
YTO loop	Controls all digits and pretunes 1 MHz — 1 GHz	Go to Step 12

SERVICE SHEET 2 (Cont'd)

5. The FM function is checked next. Connect the spectrum analyzer to A3W9 in place of the frequency counter. Set the front panel FM Deviation switch to the 300 kHz range. Apply a modulation signal of 100 kHz at 0.5668 Vrms to the FM input connector. This should yield a modulation index of 2.404 (first carrier null). Adjust the voltage slightly to obtain the deepest carrier null; it should occur between 0.5271 Vrms and 0.6065 Vrms. If the voltage is incorrect, go to Step 7.

NOTE

If this test is done at any frequency other than 100 kHz, the FM flatness specification must be added to the input accuracy specification to obtain an overall accuracy number ($\pm 32.89\%$ at $+15$ to $+35^\circ\text{C}$).

6. Set the Meter Mode switch to FM. Set the FM Deviation switch to 100 kHz and input 100 kHz at 0.707 Vrms. The first sidebands should average 4.8 ± 0.8 dB below the carrier and the meter should indicate full scale $\pm 10\%$. If the results of both steps 5 and 6 are correct, the FM circuits are operating properly. If only step 6 results are incorrect, go to Service Sheet 10-A3 to troubleshoot the A3A7 FM Driver Assembly. Do not overlook the possibility that only an adjustment may be required.
7. In this step an FM malfunction is isolated to either the A1 or A3 Assemblies. Tune to 3000 MHz. Locate A3A7TP5 and attach the digital voltmeter. Apply 100 kHz at 0.707 Vrms to FM input connector. The voltage at TP5 should be 1 Vrms. If the voltage is correct, measure the voltage at A3A7TP1; it should be 3.4 Vrms. If the voltage at TP5 is incorrect go to Service Sheet 8-A1. Otherwise, go to Service Sheet 10-A3.
8. The following steps check the Reference Loop. Connect the frequency counter to the 100 MHz output on the rear panel. For this measurement, the time base of the counter *must not be* connected to the Synthesizer. The signal should be stable and within ± 100 Hz of 100 MHz. If the frequency is correct and the lock indicator indicates the loop is unlocked, go to Service Sheet 1-A3 to troubleshoot the lock indicator. If the frequency is incorrect, go to Service Sheet 1-A3 and begin troubleshooting.
9. The following steps check the M/N Loop. Use a common time base between the frequency counter and Synthesizer. Connect the frequency counter to M/N output connector on A3A1A5. Tune the Synthesizer's frequency to 2100 MHz. The counter should indicate 177.500 000 MHz. If the frequency is correct go to Service Sheet 3-A3 to troubleshoot the phase lock comparator.
10. Connect the digital voltmeter to A3A1A4 TUNE test point. Disconnect the IF OUT (red/white) coax. The voltage should go to about -0.5 Vdc. Connect the IF cable previously disconnected to the 20 MHz reference in place of the gray/white coax. The phase detector should swing the tune voltage to the opposite limit, about -38 Vdc. If the voltages are correct, go to Service Sheet 4-A3 to troubleshoot the M/N VCO. If the voltages are incorrect, go to Service Sheet 3-A3 to troubleshoot the dividers or phase detector.
11. The following steps check the YTO loop. Make sure the front panel RF switch is on. Connect the frequency counter to the semirigid coaxial cable A3W9 (the YTO loop output). Ground A3A6TP1 to open the loop. The YTO should be pretuned within ± 20 MHz of the selected frequency from 2 to 6.199 GHz. Tune the 1 MHz and 10 MHz digits from zero to 9 and tune the 1 GHz and 100 MHz digits from 20 to 61 while observing the pretune frequency to assure it stays within ± 20 MHz of the selected frequency. If the frequency does not tune properly, continue with the next step. Otherwise go to Service Sheet 10-A3 to troubleshoot the YTO Loop.
12. Connect the digital voltmeter to A3A5TP3. The voltage should be -3.000 V/GHz at this point at any frequency from 2 to 6.199 GHz. The voltage should remain within ± 0.005 V of the correct voltage over the entire range. Slowly tune the frequency and observe the voltage. If the voltage is incorrect perform the DAC adjustment procedure. If necessary, go to Service Sheet 6-A3 to troubleshoot the DAC Assembly. If the voltage is correct go to Service Sheet 7-A3 to troubleshoot the main coil driver.

Table 8-4. Listing of All M and N Numbers and Resulting Frequencies (1 of 4)

Freq. MHz	M	N	M/N MHz	Freq. MHz	M	N	M/N MHz
2000	17	11	184.545455	2530	24	14	182.857143
2010	16	11	185.454545	2540	23	14	183.571429
2020	15	11	186.363636	2550	22	14	184.285714

PRINCIPLES OF OPERATION

General

The Synthesizer's fundamental RF output signal is generated by the YTO (YIG Tuned Oscillator). This signal is phase-locked through other loops to the Synthesizer's reference oscillator. The Controller Assembly consists of the LFS (Low Frequency Synthesizer) or 20/30 MHz loop, a Digital controller, which generates tuning information, and a Remote Control section.

LFS Loop (A2A3, A2A4 and A2A5). The low frequency phase lock loop translates tuning data for the four least significant digits into frequencies from 30 MHz to 20.001 MHz. This translation is straightforward. The loop output frequency is calculated by the following equation:

$$f = 30 - x.xxx \text{ MHz}$$

where x.xxx signifies the four least significant digits of the YTO frequency.

The VCO in the low frequency section of this loop operates from 160 to 240 MHz. The output from this VCO is divided into two paths; one path is filtered and the other path is divided by eight and then filtered. In the output loop path, the signal is divided by eight and filtered to obtain a relatively clean sine wave between 20.001 MHz and 30.000 MHz. In the feedback path the signal is filtered and prescaled by a divider which can divide by either 10 or 11. The output of the prescaler is applied to the programmable divider which produces an 80 kHz output if the loop is locked. This signal is phase compared to an 80 kHz reference signal (10 MHz divided by 125) to generate a pulse whose width is determined by the phase difference between the two 80 kHz signals. The pulse is integrated to obtain a dc tuning voltage which can be either negative or positive. When the loop is properly locked, the phase detector's output pulse is approximately 30 nanoseconds wide. If the loop becomes unlocked, a one-shot is triggered to generate a 140 μ s wide out-of-lock signal. If the loop remains unlocked, the one-shot is retriggered and the NOT PHASE-LOCKED annunciator will light.

Digital Controller (A2A1, A2A2, A2A8, A2A10, and A2A11). The digital controller generates frequency data for use by the phase lock loops. The frequency stored in the digital controller can be changed

SERVICE SHEET 3 (Cont'd)

in various resolutions by the FREQUENCY RESOLUTION push-buttons and the TUNING control on the front panel or by remote programming. A battery supply provides a protected supply to allow the digital controller to retain the stored frequency data in the event of a power failure.

The Register 1 Assembly (A2A10) is a CMOS register that can be powered by either the Synthesizer's power supply or a rechargeable NICAD battery (A2BT1) if the line power is interrupted. This register stores the center frequency data in a BCD format. When the front panel TUNING control is turned, pulses are generated on two lines RPG 1 and RPG 2 from the Rotary Pulse Generator (A2A2). When the control is turned clockwise, RPG1 occurs before RPG2 and when turned counterclockwise, RPG2 occurs before RPG1. The Sign Decode circuit (A2A11) determines which pulse occurred first. When RPG1 occurs first, the ± 1 Adder circuit (A2A11) is set to add one to the appropriate frequency digit as the data from Register 1 is clocked through the ± 1 Adder by CLK1 (a train of 9 pulses). The three clock lines in the digital controller are triggered when the TUNING control is turned. As the data leaves the ± 1 Adder it is routed to the Front Panel Display (A2A1), to Register 2 (A2A8), and back into Register 1 (A2A10).

In the standard Synthesizer, the Offset Adder circuit (A2A11) passes data without change. The data is clocked into Register 2 by the first nine pulses of CLK2. The LEFT line then goes high and sets Register 2 into the left shift mode. The next nine pulses of CLK2 shifts the data through a divider circuit that can divide by 1, 2, or 3. At the end of the division, the remainder must be zero. If the remainder is not zero, a one will be added or subtracted from the least significant digit of the data in Register 1, and the result will be clocked into Register 2 where the division will again occur. This process will continue until the remainder is reduced to zero. When the remainder is zero, a single clock pulse, CLK3, causes the data in Register 2 to be dumped in parallel into Register 3. The outputs of Register 3 are decoded to generate tuning data for the phase lock loops.

Remote Control Section (A2A7 and A2A9). Remote programming of the Synthesizer is accomplished via the Hewlett-Packard Interface Bus (HP-IB). The Synthesizer accepts most bus commands as well as data to set frequency, power output, modulation, and leveling. When addressed to talk, the Synthesizer transmits an 8-bit byte which indicates the status of certain portions of the Synthesizer. (Section III of this manual contain programming information under Remote Programming.) The remote interface circuits are contained on two boards. The HP-IB Address Assembly (A2A9), handles the actual communications while the Interface Assembly (A2A7) distributes data to the appropriate locations within the Synthesizer. Data is received from the bus by the transceivers on A2A9. The transceivers convert the low true bus signals to high true signals for use within the Synthesizer. The same transceivers convert the high true signals from the Synthesizer into low true signals for the bus.

The HP-IB handshake sequence is handled by two circuits, one for talking (source handshake) and one for listening (acceptor hand-

SERVICE SHEET 3 (Cont'd)

shake). The handshake sequence monitors the DCU BZY (Busy) line and will not allow the handshake to continue until the digital controller has finished processing the previous data.

Circuits on A2A9 determine if the information on the eight bus data lines (DI01-8) is to be interpreted as data, addresses, or totally ignored. Service requests are generated on A2A9 by examining the status signals generated by the rest of the Synthesizer. For instance, if the Synthesizer is unlocked or if the FM is overmodulated and the RF is on, then a service request (SRQ) will be generated. If there is a frequency error, an SRQ will be generated whether or not the RF is on or off. A short delay is included at the clock input to the service request flip-flop to avoid generating a service request every time the frequency is changed. The delay is approximately 50 ms, long enough to allow the Synthesizer to settle at any new frequency except when FM is on.

After the Synthesizer is addressed to listen and with the bus in the data mode, data is routed to the A2A7 board where it is first interpreted as either an internal address (alpha) or as data (numeric) to be stored. Internal address data, also called program codes, causes the address counter flip-flops to be preset. This counter controls the distribution of data to the output registers. When data is received without internal address information, the address counter will be incremented one count for each character received. When the "Frequency Execute" command is received, A2A7 generates two clock signals to trigger the digital controller to process the remote frequency data.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheet 1 was used to isolate an A2 Assembly malfunction. The following troubleshooting information may be used to further isolate the problem to one of the three controller sections.

- a. The LFS Loop
- b. The Digital Controller
- c. The Remote Control Section

Test Equipment:

Digital Voltmeter HP 3455A
or
Logic Probe HP 545A
Oscilloscope HP 180C/1801A/1821A

NOTE

If there is an obvious front panel fault (i.e., dead annunciator) go directly to troubleshoot A2A1.

1. Set RF switch ON.

8-38C

SERVICE SHEET 3 (Cont'd)

2. Observe LED lock indicators on A2A7. All indicators should be on.

REF — Fixed Reference Loop (A3A1A1, A3A1A2, A3A8)

M/N — M/N Loop (A3A1A3, A3A1A4, A3A1A5)

YTO — YIG Tuned Upper Loop (A3A5, A3A6, A3A7, A3A9)

LFS — Low Frequency Loop (A2A3, A2A4, A2A5)

If the REF, M/N or YTO Loops are unlocked go to Service Sheet 2. If the LFS Loop is unlocked, go to Service Sheet 1-A2.

3. If the malfunction involves incorrect frequency output continue with this procedure. Otherwise go to step 9.

4. Install A2A8 (Register board) on extender.

5. Set center frequency to 6169.696 MHz. If you cannot tune to this frequency skip to step 9. Measure logic state at the edge connector pins indicated by arrows pointing to them. All such pins on the front of connector A should be "0", all on the rear of A should be "1". All such pins on the front of B should be "1" and on the rear of B should be "0".

6. Set frequency to 3,696.969 MHz.

Front of A should be "1".

Back of A should be "0".

Front of B should be "0".

Back of B should be "1".

7. Set frequency to 5,990.000 MHz.

Front of C should be "1".

Rear of C should be "0".

8. Set frequency to 3640 MHz.

Front of C should be "0".

Rear of C should be "1".

If there is a frequency data malfunction in A2, it should show up as a pattern of incorrect logic states on the output pins. Check the logic states at all 4 frequency settings as this will help to isolate the defect. If steps 5 through 8 all measure OK, determine which phase lock loop is mistuning by measuring their output frequencies with a counter. The equation needed to determine the *correct* frequencies are shown on the Service Sheet 2 block diagram.

9. If the frequency cannot be changed (but is a legal frequency), continue with this step. Otherwise, go to step 11. Check RPG1 and RPG2 signals at pins 3B and 16B of A2A11 with a dual channel oscilloscope. The normal output is two pulses of about 2.5V in phase quadrature as the TUNING knob is turned. The leading pulse is determined by the direction the knob is turned. If the RPG signals are bad, troubleshoot RPG and interconnections.

10. If the RPG signals are normal, check the ± 1 bit line at pin 22A. This signal is a string of pulses as the TUNING knob is turned. Check the ± 1 bit line at all tuning resolution settings. If ± 1 bit is OK, troubleshoot A2A11, otherwise troubleshoot A2A1.

11. If the instrument does not turn on properly, check the following items.

(a) Battery charge

(b) Clock signal from mainframe

(c) CLK1, CLK2 and CLK3 signals on A2A11

(d) PWRUP line to A2A11

12. If frequency limits are improper, check frequency decoder circuit on A2A10.

- Parts list Page 6-1
- Performance tests Page 4-1
- Adjustment procedures Page 5-1

PRINCIPLES OF OPERATION

General

The characteristics of the RF signal from the A3 Assembly are changed by the circuits that it passes through in the A1 Assembly. The YTO frequency (2 to 6.2 GHz) is multiplied by 2 or 3 to extend the frequency range to 18 GHz. The amplitude is leveled so that the output is held relatively constant across the frequency range. The RF output level is set to the desired amplitude by the level control circuits. RF output level is indicated by the RANGE display and the front panel meter.

Control of amplitude modulation and the modulation process both occur in the A1 Assembly. The frequency modulation drive signal is controlled in the A1 Assembly but modulation actually occurs in the A3 Assembly. Mode of operation is selected by the front panel switch settings (local) or by the programmed commands (remote) that are input to the digital control circuits. Digital signals are output to the controlled circuits. The mode of operation is indicated by the front panel annunciators.

YIG Tuned Multiplier

The YTM (YIG Tuned Multiplier) consists of an SRD (Step Recovery Diode) multiplier and a YIG tuned filter. The YTM passes the harmonic signal that corresponds to the desired frequency and attenuates the unwanted signals.

The SRD BIAS level causes the maximum power output from the SRD at the desired frequency. For example, in the X1 mode (2 to 6.2 GHz), the SRD is back biased (off) and the RF signal is passed directly to the YTM. In band 2 (6.2 to 12.4 GHz), the SRD is biased to produce the maximum power output at the second harmonic. In band 3 (12.4 to 18 GHz), the maximum power output occurs on the third harmonic. Note that the RF signal input to the SRD is 3.1 to 6.2 GHz on band 2 and 4.133 to 6.0 GHz on band 3.

The TUNE current tunes the tracking filter (YTM) to pass the desired frequency. The current is proportional to YTO TUNE 1, the voltage which tunes the YTO (the primary signal source). An offset is added to the TUNE current when output frequencies in bands 2 or 3 are selected. This makes possible the tuning of the frequencies above 6.2 GHz.

ALC Loop

An ALC Loop always includes three basic components, a detector, an error amplifier and a modulator. The detector measures (or detects) the RF output amplitude. The error amplifier sums the detector output voltage and a reference voltage and outputs a control voltage. The modulator receives a current input that controls the level of attenuation of an RF signal as it passes from input

8-40a

SERVICE SHEET 4 (Cont'd)

to output. Because of the non-linear characteristics of the detector and modulator and because the modulator must be current driven, extra circuits are required in the Synthesizer's ALC Loop.

Refer to the ALC Loop Simplified Block Diagram. The detector's output V_{DET1} is linear with respect to the level of the RF output power it represents. Therefore, V_{DET1} is input to the Logging Amplifier which outputs V_{DET2} and has a linear voltage-to-dBm power characteristic. As the YTO frequency is changed, the change in YTO power output is evident in a voltage change in V_{DET1} and V_{DET2} . V_{DET2} is summed with V_{REF} and causes the voltage change at the error amplifier's output. This voltage is linear with respect to power in dBm.

The modulator's control of the RF signal attenuation level (in dB) is logarithmic with respect to the input current. Because the current driver is a transistor with the collector connected to the modulator's PIN diodes, the collector current and diode current are the same. The net result is the attenuation-to-drive voltage relationship and indicates that control of RF attenuation by the error amplifier's output and by V_{DET2} is linear. Note that a linear change in the reference voltage V_{REF} will also effect a linear dBm power change.

As long as the ALC Loop is operating properly and the output is leveled, the ERROR voltage will be very close to 0 Vdc.

The basic operation of the ALC Loop is not affected by the inclusion of the YIG Tuned Multiplier between the modulator and detector. The amplitude of the RF signal input to the detector is always directly proportional to the amplitude of the RF signal output from the modulator.

The external leveling mode allows the leveling to occur at a remote location such as the input of a device under test. An external detector or power meter is used to generate the signal equivalent to the RF power level. The signal is input at the front panel EXT ALC INPUT.

RF Output Level Control

The RF output level is selected by the front panel OUTPUT LEVEL RANGE switch and VERNIER control (local) or by programmed inputs (remote). The OUTPUT LEVEL switch or the equivalent programmed input selects ranges of attenuation from 0 to 120 dB. This is equivalent to the front panel range indication of +10 (overrange) to -110 dBm. The VERNIER has continuously variable control of the RF signal level from +3 to -10 dB during local operation. In the remote mode, four lines of digital data (Remote Vernier Data) select the level from +3 to -10 dB in 1 dB steps. The VERNIER or programmed 1 dB steps of attenuation effectively control the dc voltage V_{REF} shown on the ALC Loop Simplified Block Diagram.

Modulation

Modulation drive signals are input at the front panel. The AM drive modulates the RF signal amplitude through the ALC circuits. The FM drive modulates the RF frequency through the A3 Assembly's YTO Loop circuits.

8-406

SERVICE SHEET 4 (Cont'd)

Modulation levels may be monitored by the front panel meter. The AM drive signal is summed with the V_{REF} and V_{DET2} signals by the error amplifier on the A1A5 Assembly. Therefore, the AM rate is determined by the drive signal rate while the AM level (%AM) is determined by the drive signal amplitude.

The FM drive signal is processed by circuits within the A1A9 Assembly. The drive signal is attenuated in differing amounts due to the selection of FM ranges. Also, attenuation is introduced to keep the peak deviation constant when the RF output frequency is doubled or tripled the band 2 or band 3 ranges. This is to compensate for FM deviation which is multiplied along with the RF frequency in the YTM.

MODE OF OPERATION

The A1 Assembly's operating mode is selected by the front panel switches or by programmed inputs received from the A2 Controller. The REMOTE line selects programmed inputs (REMOTE DATA) or front panel inputs (LOCAL DATA) to the Digital Processor Assembly. Digital outputs to the various assemblies control the mode of operation. Equivalent outputs go to the front panel annunciators. The annunciators visually indicate the mode of operation.

In the event the ALC Loop is not leveling properly, a digital UNLVL signal is sent by the Digital Processor Assembly. A LEV UNCAL output is generated and is sent to a front panel annunciator and to the A2 Controller. There a service request and an unlevelled output status signal is sent to a computing controller.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a RF Output problem to the circuits shown on this schematic.

Test Equipment

Power Meter	HP 436A
Test Oscillator	HP 651B
Oscilloscope	HP 180C/1801A/1821A
Digital Voltmeter	HP 3455A

Procedure

1. Set OUTPUT LEVEL RANGE switch fully clockwise. The RANGE display should indicate +10 dBm. If the units digit is not zero, make sure the LED is properly seated in its socket. If the display other than the units digit is not correct, go to Service Sheet 6-A1 to continue troubleshooting.
2. Make sure the OUTPUT LEVEL VERNIER control is set fully clockwise, the METER mode switch is set to LEVEL and the ALC switch

8-40C

SERVICE SHEET 4 (Cont'd)

is set to INT. Also set the RANGE switch to 0 dBm. Press the PRESET key. The meter should indicate full scale. If the meter indicates full scale, the ALC Loop is probably working properly. If the RF and ALC annunciators do not indicate ON and INT, go to Service Sheet 7-A1 to troubleshoot the lamps, display drivers and incoming data.

3. Connect the power meter to the RF OUTPUT connector. The Synthesizer's output should be $+3.00 \pm 0.75$ dBm. If the power is correct but the meter does not read properly, go to Service Sheet 1-A1 to check operation of the RF Level Meter driver. If the meter error is slight, perform the ALC Adjustments in Section V. Continue to the next step.
4. Set the ALC switch to XTAL or PWR MTR. The LEV UNCAL lamp should light and the front panel meter should go to zero, but the power meter should indicate the maximum power available from the Synthesizer. Tune from 1 to 18 GHz in 100 MHz steps and observe the power output. The power must remain above +3 dBm over the entire range. The figure shows the typical maximum power output from the 8672A. If the maximum available power is too low, perform the YTM and ALC adjustments in Section V. However, if there is no power output across portions of the band (or across the entire band), go to step 13 and continue troubleshooting.
5. Set the output voltage of a low voltage dc power supply to 0 Vdc. Connect the supply

to the external ALC connector (polarity is not critical). At zero volts, the power output should be the maximum available. Slowly increase the voltage to 1 Vdc. The power output should drop smoothly to less than -30 dBm. If performance is correct, the ALC Detector Assembly (A1A6), ALC Assembly (A1A5) and PIN modulator (A1AT3) are all working properly for external inputs. If the power does not decrease properly with increased voltage, go to Service Sheet 1-A1 and continue troubleshooting. Begin with the ERROR line.

6. With the RANGE switch, lower the output power in 10 dB steps to the limit of the power meter. Then use a spectrum analyzer to continue down as far as possible to assure that each 10 dB step of attenuation switches properly and that the front panel RANGE display indicates correctly from +10 to -110 dBm. If the power drops properly but the RANGE display is incorrect, go to Service Sheet 6-A1 to troubleshoot the LED 10 to LED 100 plus the HB and VB lines. If the display is correct but the power does not drop correctly, go to Service Sheet 5-A1 to troubleshoot the attenuator and control circuits. If both the attenuator and the display are malfunctioning, go to Service Sheet 6-A1.
7. Set the OUTPUT LEVEL RANGE to -20 dBm and the RF switch OFF. The power level should drop to zero on the spectrum analyzer. The RF OFF, LEV UNCAL and NOT PHASE LOCKED lamps should light and the level meter should drop to zero or below. If the power does not drop to zero, go to Service Sheet 6-A1 to see if the RF PWR CON line is functioning properly (a low should produce RF off). If the power drops to zero but some of the lamps don't light, check the lamp and driver circuits on Service Sheet 7-A1 or on Service Sheet 12-A2 for the NOT PHASE LOCKED lamp.
8. Connect 10 kHz at 0.707 Vrms to the EXT AM INPUT. Set the METER mode switch to AM and the AM range switch to 30%. The meter should indicate $30\% \pm 3\%$ and the first sidebands displayed on the spectrum analyzer should be about 16.5 dB below the carrier. If both are correct, continue with the next step. If the meter reads correctly but the sidebands are incorrect, go to Service Sheet 1-A1. If the meter reads incorrectly but the sidebands are correct, go to Service Sheet 8-A1. If

SERVICE SHEET 4 (Cont'd)

both are incorrect, check the AM input cable A1W17 and blocking capacitors A1A14C3 and C4 (on the mother board).

9. Set the AM switch to 100% and adjust the input voltage to obtain sidebands 12 dB below the carrier level. The input voltage should be $0.354 \text{ Vrms} \pm 0.018\text{V}$. If the voltage is at the wrong level, go to Service Sheet 1-A1 to check operation of the AM 30% network. If the meter indication is incorrect, ($50\% \pm 10\%$) go to Service Sheet 8-A1.
10. Set the AM switch OFF and the FM switch to the 300 kHz deviation range. Set the METER Mode switch to FM. Connect the test oscillator to the EXT INPUT connector. Apply 100 kHz and adjust output level to obtain the first carrier null ($\beta=2.404$). The voltage applied should be $0.567 \pm 0.049 \text{ Vrms}$ and the meter should indicate $240 \text{ kHz} \pm 30 \text{ kHz}$ deviation. If the desired deviation cannot be obtained, go to Service Sheet 8-A1.
11. If the voltage is correct, but the meter reading is wrong, go to Service sheet 8-A1 to troubleshoot the FM meter driver. If the meter is only slightly out of calibration, perform the

FM Adjustment procedure in Section 5. If everything is OK to this step, FM circuits in the A1 Assembly are probably operating properly.

12. Install A1A9 on an extender board. Apply 1Vpk (0.707 Vrms) to the EXT FM INPUT connector. Measure the voltage at the edge connector (pin 11) with the FM switch set to the ranges listed in the table.

FM DEVIATION RANGE	PIN 11 VOLTAGE
10 MHz	1 Vrms
3 MHz	0.3 Vrms
1 MHz	0.1 Vrms
0.3 MHz	0.03 Vrms

If all the voltages are correct, go to Service Sheet 10-A3 to troubleshoot the FM Driver. If any of the voltages are incorrect, go to Service Sheet 8-A1.

13. Measure the RF output from the YTO Loop. It should deliver $>+11 \text{ dBm}$ from 2 to 6.2 GHz. If the output is correct, go to Service Sheet 2-A1. If the output is incorrect, go to Service Sheet 2.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the preamplifier and PIN Modulator in the RF path and the ALC Assembly which is part of the ALC Loop.

RF Path

The A1A13A1 Preamplifier Assembly includes a frequency selective attenuator which pre-levels the signal before application to the ALC Loop. PIN modulator, A1AT3, controls the RF power for leveling, level setting, and amplitude modulation.

ALC Assembly A1A5

This assembly processes the ALC ERROR voltage and the AM signal, and sums them to produce the ALC MOD voltage and signals for the Unleveled Detector and Level Meter. The ERROR voltage from the ALC detector is applied to an amplifier, U3, which has three possible gains depending on the band of the Synthesizer's output frequency. This is to compensate for the YTM's different transfer characteristic on each band. The output of U3 drives Q2, which along with associated circuitry, is a current source for the PIN modulator. Q4 and C12 control the ALC Loop's bandwidth. When the Synthesizer is being amplitude modulated, Q4 isolates C12 from ground, thereby widening the bandwidth.

The AM signal is applied to amplifier U7, the gain of which is switched by Q12 and Q13 to select 30% or 100% modulation ranges. This amplifier has a transistor in its feedback path so that the output voltage will be proportional to the log of the input voltage. This is necessary because the AM signal is summed with the ERROR voltage which is proportional to the log of the ALC detector output. Q6 and associated circuitry form an emitter follower that compensates for high frequency rolloff in the PIN modulator caused by shunt capacitance. It does this by increasing the level of the modulating signal as modulation frequency increases.

The Meter Driver circuit converts the ERROR voltage into a meter current proportional to the RF output in dB. The REF VOLTAGE is summed with the ERROR voltage to prevent the meter from indicating incorrectly when the loop is unleveled.

8-42a

SERVICE SHEET 1-A1 (Cont'd)

The unlevelled detector tells the front panel and the Controller (A2) when the ALC Loop is not able to level the RF signal.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a modulation or ALC problem to the circuits shown on this schematic.

Test Equipment

Power Meter HP 436A
Test Oscillator HP 651B
Oscilloscope HP 180C/1801A/1821A
Digital Voltmeter HP 3455A

Procedure

1. Remove Synthesizer top cover and A1 cover. Connect power meter to RF OUTPUT connector. Disconnect blue bias cable from A1AT3 PIN modulator. The Synthesizer power output should rise to the maximum available. At 3 GHz this will normally be $>+8$ dBm and will vary by several dB across the band. If the power is proper, the RF chain is working properly. Note that the available power must be at least $+3$ dBm at any frequency from 2 GHz to 18 GHz. If the power is incorrect or unmeasurable, continue with this procedure. Otherwise, skip to step 4.
2. Connect power meter to output of A1AT3. The power should be $>+10$ dBm. If power is correct, go to Service Sheet 2-A1 to continue troubleshooting the RF chain.
3. Measure output power from A3A9 YTO Loop. It should be $>+11$ dBm from 2 GHz to 6.199 GHz. If the power is incorrect, go to Service Sheet 10-A3. Otherwise troubleshoot A1A13 and A2AT3.
4. Reconnect the PIN modulator bias cable using a tee and connect one arm of the tee to an oscilloscope.
5. Attach a test oscillator to the AM input. Set AM switch to 100% range and set test oscillator to 10 kHz at 0.5 Vrms. The modulation signal on the oscilloscope should be about .06 Vpk. If the signal is incorrect, troubleshoot the Log Amplifier on/off selector and buffer amplifier.
6. Set AM switch to 30%. The signal on the oscilloscope should decrease to 0.02 Vpk. If the signal is incorrect, troubleshoot the 30% NETWORK (Q9 to Q13).
7. Disconnect test oscillator and set AM switch off. Set VERNIER fully clockwise and RANGE to 0 dBm. The oscilloscope should indicate about 0.75 Vdc. Set METER switch to LEVEL. If the voltage is correct but the meter is not indicating full scale,

8-42b

SERVICE SHEET 1-A1 (Cont'd)

troubleshoot the meter driver U8 and Q14 (or perform the ALC Adjustments in Section V).

8. Tune the frequency above 6.2 GHz. The voltage at the Tee will normally drop to about 0.65 Vdc.
9. Tune the frequency above 12.4 GHz. The voltage will normally remain about 0.65 Vdc. If the voltages in steps 8 and 9 do not behave properly, troubleshoot U1, U3, and Q3.
10. Set the RF switch OFF. The LEV UNCAL lamp should light and the voltage at the Tee should be near zero. If the LEV UNCAL lamp does not light, troubleshoot U4, U5, and the lamp. If everything is correct to this point, the A1A5 ALC board is working properly.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also, the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the Power Amplifier, Isolator, High Pass Filter, and YIG Tuned Multiplier in the RF path and the YTM Driver Assembly.

RF Path

The Power Amplifier (A1A2) operates close to saturation and provides a high drive level to the YTM. Isolator (A1AT2) protects the amplifier from reflections from the multiplier. The isolator's output goes to a 1.5 GHz High Pass Filter (A1FL1) and then to a step recovery diode (SRD) multiplier. The diode is biased to provide maximum output power at frequencies in the selected harmonic band. The YIG Filter selects the correct harmonic and is tuned over the Synthesizer's frequency range by a current ramp generated by the YTM Driver Assembly.

YTM Driver Assembly

This assembly converts the 2-6.2 GHz voltage ramp, YTM TUNE, into a 2-18 GHz current ramp. The main coil shaping circuit multiplies the YTM TUNE voltage by factors determined by the decoded band information (I1, I2, I3, G2, and G3). This results in a linear ramp voltage which U5 and associated transistors convert into a current ramp that can tune the YIG Filter. The YIG Filter has some non-linearities so the positive and negative current sources and the Band 3 breakpoint circuit generate compensating currents that are summed with the main current at the emitter of Q1 so the YTM will accurately track the YTO frequency.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a YTM problem to the circuits shown on this schematic.

Test Equipment

Power Meter	HP 436A
Test Oscillator	HP 651B
Oscilloscope	HP 180C/1801A/1821A
Digital Voltmeter	HP 3455A

8-44a

SERVICE SHEET 2-A1 (Cont'd)

Procedure

1. Connect power meter to YTM output using an SMA-to-N adapter. Tune frequency from 2 to 18.0 GHz in 100 MHz steps; the power should remain above +8.5 dBm over the entire range. If the power remains up over the range, the YTM and all driving circuits are working properly. At band edges, 6.2 GHz and 12.4 GHz, it is normal to have an abrupt change in power level; if a power change does not occur, be suspicious that the YTM may not be changing bands.
2. If the power is not correct, measure output of A1A12 power amplifier. It should deliver about +20 dBm from 2 to 6.2 GHz. If the output power is not correct, measure the input power, which should be >+10 dBm. If the input is incorrect, go to Service Sheet 1-A1.
3. Connect dc voltmeter to A1A8 SENSE test point. Set frequency to 2 GHz. The voltage should be about -1 Vdc.
4. Set frequency to 18 GHz. The voltage should be about -9.9 Vdc. (The change with frequency is about -0.55 V/GHz.)
5. If the output voltage is significantly wrong, measure the tuning voltage at edge connector pin 6. That voltage should be -3.000V/GHz from 2 to 6.199 GHz. If the tuning voltage is incorrect, go to Service Sheet 6-A3 to check DAC operation or perform DAC Adjustment procedure.
6. If the output voltage is correct, but the YTM output is wrong, troubleshoot to isolate the malfunction between the YTM, Isolator or high pass filter.
7. If the input tuning voltage is correct, but the output voltage is wrong, perform the YTM and ALC adjustments. A malfunction on the YTM Driver will generally be seen as a failure to adjust correctly. Use the voltages on the schematic to locate the malfunction. Also use table of voltages on Service Sheet 3-A1 to be sure all band related inputs to the YTM Driver are functioning correctly.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also, the signal is amplified, leveled, amplitude modulated (if selected), and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the SRD Bias Assembly which decodes band information and generates an F CORRECT voltage for the ALC Loop.

SRD Bias Assembly

The coupler correct circuit converts the COUPLER CORRECT voltage, which is derived from the YTM tuning ramp, into a voltage ramp with the proper slope to correct for rolloff of the directional coupler. This ramp, F CORRECT, is then summed with the ERROR voltage in the ALC Loop. The Band Decode and Logic Level Converters translate the Synthesizer's band information, HN1 and HN2, to control signals for the YTM Driver Assembly.

The Bias Correct circuit generates a bias signal for the Step Recovery Diode (SRD) so that the SRD output power will be optimum in the band of the Synthesizer's output frequency.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate an SRD bias problem to the circuits shown on this schematic.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the Directional Coupler in the RF path and the Leveling Detector and ALC Detector Assembly which are part of the ALC Loop.

RF Path

Directional Coupler A1DC1 samples the RF output power and applies it to the Leveling Detector A1CR1. The sampled signal level is low enough that the detector operates in its square law region. As a result, the detected voltage linearly represents the RF power in watts. A logarithmic amplifier in the ALC Detector Assembly is used to obtain a voltage that is linearly proportional to the RF power in dB.

The output level of the directional coupler rolls off with increasing frequency but the detector doesn't detect this. Therefore, an F CORRECT voltage is applied to the ALC Loop (see Service Sheet 3-A1) to provide a flat output level.

ALC Detector Assembly

The Int ALC Log Amplifier converts the output of the Leveling Detector into a dc voltage that is proportional to the RF output in dB. This allows for linear voltage control of the output level and for the output level meter scale to read linearly in dB. U6 sums the REF VOLTAGE from the RF Output Level Control Assembly with the logged detector voltage. The resulting ERROR voltage is summed with the AM signal in the ALC Assembly and applied to the PIN modulator.

The Ext ALC Amplifier allows the ALC Loop to be calibrated for use with an external detector. U5 acts as an absolute value converter so that positive or negative detectors can be used.

SERVICE SHEET 4-A1 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a ALC Detector problem to the circuits shown on this schematic.

Test Equipment

Power Meter	HP 436A
Test Oscillator	HP 651B
Oscilloscope	HP 180C/1801A/1821A
Digital Voltmeter	HP 3455A

Procedure

1. Make sure the green output cable from A1CR1 is securely attached. If it is loose, there may be unleveling problems at low vernier levels.
2. Set ALC switch to INT, RF switch to ON, AM and FM off. Disconnect the Leveling Detector (A1CR1) from the Directional Coupler (A1DC1). Measure the power available at the coupled arm of A1DC1. It should be >-8.5 dBm, unlevelled, from 2 to 18 GHz. If sufficient power is not available, perform the YTM and ALC adjustments.
3. With the detector still disconnected, measure the voltage at A1A6TP3. With no leveling input, the voltage should be about -0.6 Vdc. Change the OUTPUT RANGE switch to +10 dBm. The voltage at TP3 should not change significantly. If these voltages are not correct, troubleshoot the internal ALC Log Amplifier log network and buffer amplifier using voltages on the schematic.
4. Set ALC switch to XTAL. Make sure nothing is connected to the ALC input. The voltage should not change much. Switch to PWR MTR; the voltage should not change. If the voltages are incorrect in external leveling, troubleshoot the external ALC Amplifier and Log Amplifier.
5. Connect a low voltage power supply to the EXT ALC INPUT connector. Slowly increase the power supply output from zero to 1 Vdc. The signal at A1A6TP3 should increase smoothly from about -0.4 Vdc to $+0.13$ Vdc. If the voltage swing is correct, the external ALC amplifiers and the output buffer amplifier are working properly. To isolate buffer amplifier problems, the signal at TP4 should vary from about -0.08 Vdc to $+0.04$ Vdc.
6. Set the ALC switch to INT and reconnect the leveling detector. The voltage at TP3 should be about 0.17 Vdc and vary as the VERNIER is varied from about -0.21 Vdc to $+0.17$ Vdc. If the voltage is present but does not vary, go to Service Sheet 5-A1 to continue troubleshooting.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the Programmable Attenuator in the RF path and the Level Control Assembly, which controls the ALC Loop and the Programmable Attenuator (A1AT1).

RF Path

The programmable attenuator provides 0 to 110 dB of attenuation in 10 dB steps. From the attenuator the RF is applied to the front panel RF OUTPUT connector.

Level Control Assembly

This assembly controls the 10 dB step attenuator, and converts the 1 dB remote level data or the OUTPUT LEVEL VERNIER position into the REF VOLTAGE for the ALC Loop.

The Encode Logic, Signal Buffers, and Solenoid Drivers condition the ATTEN 10 to 80 CONT signals so they can drive the programmable attenuator. In Remote, the D/A converter translates the 1 dB steps coded on the ALC 1 to 8 CONT lines into an analog reference voltage for the ALC Loop. In local, U7 acts as a follower for the voltage from the wiper of the OUTPUT LEVEL VERNIER control.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a level control problem to the circuits shown on this schematic.

Test Equipment

Power Meter	HP 436A
Test Oscillator	HP 651B
Oscilloscope	HP 180C/1801A/1821A
Digital Voltmeter	HP 3455A

If the malfunction involves the VERNIER or 1 dB steps, start at step 1. If the problem involves 10 dB steps, start at step 4.

8-50a

SERVICE SHEET 5-A1 (Cont'd)

Procedure

1. Connect voltmeter to DAC test point. Set ALC switch to INT; make sure the instrument is not in REMOTE. Set the VERNIER fully counterclockwise. The voltmeter should indicate about -6.5 Vdc. Turn the VERNIER control clockwise while observing the voltage. The amplitude should drop at 0.5 V/dB and should be about 0.0 Vdc when the VERNIER is fully clockwise. If the voltages are correct, the local reference voltage circuitry is working properly. Skip to step 3 to check remote reference voltages. If the voltages are incorrect, continue with this procedure.
2. Measure voltages at -6.2 Vdc test point and $+6.2$ Vdc test point. If the negative voltage is incorrect, the local reference voltage will be incorrect. If the positive voltage is incorrect, the remote reference voltage will be incorrect. If both voltages are correct, troubleshoot U7 and Q10-Q15.
3. Execute the following program to check the remote reference voltage at the DAC test point. Observe voltmeter while running the program.

```
10 CMD "7U3"  
20 FOR V=61 TO 48 STEP - 1  
30 OUTPUT (13, 40) V;  
40 FORMAT "L", B  
50 DISP -(V-48)/2 "VDC"  
60 WAIT 2000  
70 NEXT V  
80 OUTPUT (13, 90) 256, 1, 512;  
90 FORMAT 3B  
100 END
```

If the voltages are not correct, troubleshoot the +V Reference and the D/A Converter.

4. Set OUTPUT LEVEL RANGE switch to 0 dBm and connect spectrum analyzer or power meter to RF OUTPUT connector. Set VERNIER fully clockwise and RF switch ON. The power meter should indicate about $+3$ dBm.
5. Switch the RANGE switch to -10 dBm. The power meter should indicate -7 dBm.
6. Continue lowering the output range to the limit of the spectrum analyzer or power meter. If the power drops in 10 dB steps each time, the A1A10 board and the output attenuator are working properly. If the results are incorrect, continue with this procedure.
7. Locate the test points labeled 10, 20, 40, and 80 on A1A10. The signals here are TTL levels. Check them according to the truth table.

8-506

SERVICE SHEET 5-A1 (Cont'd)

Note that the test point labeled "80" actually controls a second 40 dB attenuator section which is used only at power levels -80 dBm and below.

If the test points do not agree with the truth table, check U6 and if it is working properly, go to Service Sheet 6-A1 to continue troubleshooting. Otherwise troubleshoot the appropriate solenoid driver.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the Digital Processor Assembly which selects between remote and local Synthesizer configuration information and converts the information into a form useable by the level and modulation control circuits and displayable by the front panel.

Digital Processor Assembly

The Local/Remote selectors have feedback resistors between the outputs and remote inputs so they will act as latches when first switched from local to remote. This ensures that the Synthesizer's functions assume known configurations.

The Range Encoder converts the RANGE switch position into a binary coded decimal value. Priority encoder U7 acts as an octal to binary converter.

Display Decoder, U8, is a ROM with a table that converts the BCD range value into sign and value information for the front panel display.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a digital processor problem to the circuits shown on this schematic.

Test Equipment

Digital Voltmeter HP 3455A
Spectrum Analyzer HP 8553B/8555A/141T

Procedure

1. Make sure the Synthesizer is in local at 3 GHz.
2. Attach spectrum analyzer to RF output. Rotate RANGE switch from fully clockwise to fully counterclockwise. The LED display should indicate from +10 to -110 in 10 dB steps. In the

8-52a

SERVICE SHEET 6-A1 (Cont'd)

- +10 dBm position, the OVERRANGE lamps should light. If operation is incorrect, measure OVRNG, LED 10, LED 20, LED 40, LED 80, LED 100, HB and VB plus ATN 10-80 lines to isolate the malfunction. The lines labeled HB and VB control the horizontal and vertical bars of the + and - signs.
3. Switch AM and FM controls through their ranges. The front panel annunciator lamps should correspond to the switch settings. If results are incorrect, measure the AM and FM attenuation and control lines from A1A11 to isolate the malfunction.
 4. Switch ALC control through its range and observe the annunciator lamps. The lamps should correspond to the switch positions and the LEV UNCAL lamp should come on in the XTAL and PWR MTR positions.
 5. Switch RF switch OFF. The RF annunciator should correspond, the LEV UNCAL and NOT PHASE LOCKED lamps should come on. If everything is correct so far, the local portions of A1A11 are working properly.
 6. The remaining steps in this procedure require an HP-IB controller. Program "K03701" to set initial conditions. Program output power from 0 to -130 dBm using "K0", "K1", "K2", "K3", "K4", "K5", "K6", "K7", "K8", "K9", "K:", "K;", "K<", and "K=". The LED display should go from 0 dB to -130 dBm. In the -120 and -130 dBm positions, the LEV UNCAL lamp should light. If the results are incorrect, measure REM ATTN 10-80 inputs to A1A11 to isolate the malfunction.
 7. Set the METER switch to LEV. Program vernier function through its range with "L0" through "L=". The meter should move in 1 dB steps from +3 to -10 dB. If the results are incorrect, measure REM ALC 1-8 lines to A1A11 to isolate the malfunction.
 8. Program "K003". The output level range should be +10 dBm and the OVERRANGE annunciator should be on. (The LEV UNCAL indicator may also be on.)
 9. Program "00". The RF should be OFF and the range should be 0 dBm. The LEV UNCAL and NOT PHASE LOCKED annunciators should be on.
 10. Program "05". The instrument should indicate external XTAL leveling and LEV UNCAL should be on.
 11. Program "0="". The instrument should indicate external PWR MTR leveling and LEV UNCAL should be on.
 12. Program AM functions through their range. M0 and M1 should set AM off. M2 sets AM 100% range and M3 sets 30% range. If the results are incorrect, check REM AM ON/OFF and REM AM ATTN 10 lines.

8-52b

SERVICE SHEET 6-A1 (Cont'd)

13. Program FM functions through their range. With "N0" to "N7". N6 and N7 should both set FM off. If the ranges do not switch properly, check the REM FM ATTN 10 through 40 lines. If everything has functioned properly through this step, the A1A11 Digital Processor is working properly.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Also the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the front panel assembly.

Front Panel Assembly

The front panel assembly has two major functions. It buffers status information and drives display lamps, and it applies switch position information to the Digital Processor.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a front panel problem to the circuits shown on this schematic.

Test Equipment

Test Oscillator HP 651B
Digital Voltmeter HP 3455A

Procedure

1. Rotate the OUTPUT RANGE switch from fully clockwise to fully counterclockwise. The LED display should indicate from +10 dBm to -110 dBm in 10 dB steps. (The last digit should always be zero). In the +10 dBm position, the OVERRANGE annunciator should light. If incorrect, go to service sheet 6-A1 unless the problem is in the last digit (in which case the problem must be on A1A1).
2. Switch the AM switch through its range to check the annunciators.
3. Switch the FM switch through its range to check the annunciators.
4. Switch RF off. The RF OFF and LEV UNCAL annunciators should light.
5. Switch ALC switch through its range to check the annunciators.

8-54a

SERVICE SHEET 7-A1 (Cont'd)

6. Apply 1 Vrms at 1 kHz to the FM input connector. Set FM switch to 10 MHz. The OVERMOD annunciator should light.
7. Set RF switch on and VERNIER clockwise and RANGE to 0 dBm. Set METER switch to LEV. The meter should be at full scale.
8. Set METER switch to AM. The meter should indicate zero. Apply 0.707 Vrms at 1 kHz to the AM input connector. Set AM switch to 30%. The meter should indicate full scale on the 0-30 range.
9. Lower input to 0.35 Vrms and set AM switch to 100%. The meter should indicate half scale.
10. Set METER switch to FM. The meter should indicate zero. Set FM switch to 10 MHz and apply 0.707 Vrms at 2 MHz to the FM input connector. The meter should indicate full scale.

PRINCIPLES OF OPERATION

General

As shown on Service Sheet 4, the RF Output Assembly multiplies the YTO signal by 1, 2, or 3 to produce the desired frequency range. Then the signal is amplified, leveled, amplitude modulated (if selected) and applied to a 10 dB step attenuator for final level selection.

This service sheet describes the metering assembly which conditions the FM signal and applies it to the YTO Loop (on the A3 Assembly), and provides a calibrated current that represents AM percentage and FM deviation to the front panel meter.

Metering Assembly

The band switched attenuator varies the FM signal level according to the band of the Synthesizer output frequency so that FM deviation will not be effected by frequency multiplication in the YIG Tuned Multiplier.

The Range Attenuator and FM Amplifier set the proper signal level for the selected modulation depth.

The AM and FM Meter Drivers are peak detectors and voltage to current converters that provide the front panel meter with a current proportional to the modulating signal amplitude.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 4 was used to isolate a metering or FM problem to the circuits shown on this schematic.

Test Equipment

Power Meter HP 436A
Test Oscillator..... HP 651B
Oscilloscope HP 180C/1801A/1821A
Digital Voltmeter HP 3455A

Procedure

1. Set the meter switch to AM and AM switch to 30%. Apply 0.707 Vrms at 1 kHz to AM input connector. The meter should indicate full scale on the 0-30 range. If OK, continue. Otherwise troubleshoot the AM meter driver circuit.

8-56a

SERVICE SHEET 8-A1 (Cont'd)

2. Set the center frequency to 3 GHz. Set METER switch to FM and FM switch to 10 MHz. Apply 0.707 Vrms at 2 MHz to FM input connector. The meter should indicate full scale on the 0-100 scale. If correct, continue. Otherwise troubleshoot the FM meter driver circuit.
3. Attach oscilloscope to edge connector pin 11. It should indicate 2.12 Vrms \pm 5%. If not correct, troubleshoot the FM amplifier chain.
4. Change the center frequency to 7 GHz. The signal at pin 11 should drop to half that measured in step 3.
5. Change the center frequency to 15 GHz. The signal should drop to one third that in step 3.
6. If the signals in steps 4 and 5 are incorrect, troubleshoot the band switched attenuator, U7.
7. Set the center frequency to 3 GHz. The signal measured in step 3 should return to its original value. Set FM switch to 3 MHz. The signal should drop to 30% of its original value.
8. Set FM switch to 1 MHz. The signal should drop to 30% of its original value.
9. Set FM switch to 0.3 MHz. The signal should drop to 3% of its original value.
10. If the signals in steps 7, 8, and 9 are correct, continue. Otherwise troubleshoot the range attenuator, U3, and FM control decoder, U5.
11. Attach dc voltmeter to edge connector pin 16. Apply 0.84 Vrms to FM input. Pin 16 should be at TTL high. Lower the input voltage to 0.707 Vrms. Pin 16 should go low. If not correct, troubleshoot the over mod comparator, U2. Otherwise the board is working properly.

PRINCIPLES OF OPERATION

LFS Loop

The 20/30 MHz Loop (LFS Loop) converts tuning information of the four least significant digits (1 MHz through 1 kHz) into a frequency between 20 MHz and 30 MHz. This frequency is obtained by dividing the 160–240 MHz VCO output by 8. The 160–240 MHz is fed back to a programmable divider where it is divided by a number, N_1 , to produce 80 kHz. The 10 MHz reference is divided (by 125) to obtain 80 kHz and the two are compared in the phase detector. Phase difference is converted into a VCO TUNE voltage and applied to the VCO.

The 20/30 MHz divider (A2A5 board) consists of a programmable divider and a fixed divider. The programmable divider consists of a divide by 10 or 11 prescaler and a low frequency divider. It divides by N_1 which varies between 2000.1 and 3000.0 depending on the last four digits of the YTO frequency. The relationship is as follows:

$$N_1 = 8 (30 \text{ MHz} - D_4 \cdot D_3 \cdot D_2 \cdot D_1 \text{ MHz}) / 80 \text{ kHz}$$

where:

D_4 = 1 MHz digit

D_3 = 100 kHz digit

D_2 = 10 kHz digit

D_1 = 1 kHz digit

If D_1 and D_2 are zero the prescaler divides by 11 for 10 of its output cycles and by 10 for the rest, and the low frequency divider counts the programmed number of prescaler output pulses. When D_2 is not zero, unit division takes place. This is done by the prescaler, which divides by 11 one less time for each increment of D_2 . For example if D_2 is 4, the prescaler will divide by 11 four less times. If D_1 is not zero, fractional division is done by changing the unit division number over ten 80 kHz cycles. For example, if N_1 is 2100.5, the 20/30 divider will divide by 2100 five times and by 2101 five times. This results in an average N_1 of 2100.5 and an average frequency (over ten output cycles) of 80 kHz.

20/30 Divider

The prescaler (U8) divides the 160–240 MHz VCO output by 10 if pin 2 is high and by 11 if it is low. The resulting pulses are counted by the low frequency divider. The count starts with the number pre-set by the 1 MHz and 100 kHz digits and ends at 299. This results in

8-8a

SERVICE SHEET 1-A2

a pulse at the beginning of each 80 kHz cycle. It stays that way until the first time U16A goes low. This clocks a low through U7B which causes the prescaler to divide by 11. When U14 reaches a count of 9, the J input of U7A goes high and is clocked through U7A by the next low going prescaler output. This causes a high to be clocked through U7B which tells the prescaler to divide by 10 until the end of the 80 kHz cycle.

Fractional division depends on the 1 kHz digit. Rate multiplier U12 outputs a number of negative transitions per ten 80 kHz cycles. This number is the value of the 1 kHz digit. Each of these negative transitions causes the prescaler to divide by 11 one less time than programmed by the D_2 information.

TROUBLESHOOTING

It is assumed that the troubleshooting information, Service Sheets 1, 2, and 3-A2 was used to isolate a 20/30 MHz divider problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Frequency Counter HP 5340A
Oscilloscope HP 180C/1801A/1821A

1. Install A2A5 on an extender board .
2. Observe the signal at A2A5TP2. You should see 2.5 ns wide pulses at an 80 kHz rate (12.5 μ s period), TTL levels. If so, continue with this procedure; otherwise, troubleshoot the \pm 125 counter.
3. Remove A2A3 and set the test switch to the TEST HIGH FREQ position. Reinstall A2A3. The output frequency should be greater than 240 MHz. This signal will be used to test the divider assembly.
4. Set the Synthesizer frequency to 3000.000 MHz. Attach a counter or oscilloscope to A2A5TP5. The frequency should be about 25 MHz at TTL levels. This signal is rich in harmonics (i.e., the sine wave is distorted). If the signal is near 22.7 MHz the 10/11 prescaler is dividing incorrectly (or its input control at pin 2 is wrong).
5. Ground A2A5TP4 (LSB). The frequency should drop to about 22.7 MHz as the prescaler is switched to divide by 11. If this does not happen troubleshoot U8 and associated components.
6. Disconnect the ground on TP4 and observe the signal at TP4 on an oscilloscope. Set the frequency to 2999.900 MHz. There should be low true pulses about 0.65 μ s wide with 8 μ s spacing, TTL levels.

8-586

SERVICE SHEET 1-A2

7. Increase the frequency in 1 kHz steps to 2999.999 MHz. The pulses should become narrower and finally disappear. This pattern is repeated every 100 kHz. The pulse spacing varies with frequency from 12 μ s for frequencies ending in 0.000 to 8 μ s for frequencies ending in 9.9xx. If the pulse does not behave properly, troubleshoot the \div 10/11 controller and associated circuits.
8. Connect the oscilloscope or frequency counter to TP3. At 3000.000 MHz the frequency should be about 83.3 kHz (250 MHz divided by 3000). Change frequency to 2999.999 MHz and TP3 should go to about 125 kHz (250 MHz divided by 2000.1). If both of these frequencies are correct the A2A5 divider assembly is probably OK. Otherwise, troubleshoot the LOW FREQUENCY DIVIDER (U14, U13, U11, U3 and U6).
9. As a final check of the dividers, tune in 1 kHz and 10 kHz steps from 3000 000 MHz to 2009 999 MHz to assure that the divider output frequency increases as the frequency is turned higher. If this happens, the divider is OK. Be sure to reset the TEST switch to the NORMAL position.
10. After any repairs to this board refer to Table 5-3 and perform the 20/30 Loop Divider Bias Adjustment and Signal-to-Phase Noise Ratio Test.

- Motherboard wiring Last 3 foldout pages
- Parts list Page 6-24
- Performance tests Refer to Table 5-2, page 5-3
- Adjustment procedures Page 5-22

PRINCIPLES OF OPERATION

LFS Loop

The 20/30 MHz Loop (LFS Loop) converts tuning information of the four least significant digits (1 MHz through 1 kHz) into a frequency between 20 MHz and 30 MHz. This frequency is obtained by dividing the 160–240 MHz VCO output by 8. The 160–240 MHz is fed back to a programmable divider where it is divided by a number, N1, to produce 80 kHz. The 10 MHz reference is divided (by 125) to obtain 80 kHz and the two are compared in the phase detector. Phase difference is converted into a VCO TUNE voltage and applied to the VCO.

The Digital Phase Detector compares the REF 80 kHz and $\pm N1$ 80 kHz and uses the phase difference to produce a dc voltage, VCO tune, which corrects the VCO frequency. Large frequency errors, especially those associated with a frequency change, result in an error voltage that may move the VCO out of the loop's locking bandwidth. When the loop is unlocked, the Gain Control Logic and Pulse Width Detector (pulse width varies directly with frequency or phase error) circuitry increases the integrating amplifier's gain (and thus increases bandwidth) during unlocked conditions, speeding up the re-lock process. When the loop is unlocked, the Unlock Detector will pulse the LFS UNLOCKED line high. If the loop remains unlocked, the signal on the LFS UNLOCKED line will be a string of 140 μ s pulses.

20/30 Phase Detector

Flip-Flops U3A,B and nand gate U2C phase compare the two 80 kHz inputs by generating a pulse that represents, by its width, the phase error. Starting in the reset state, the flip-flops non-inverting output will go high on the trailing edge of the first input pulse. When both U3A and U3B are high, the nand gate, U2C, goes low and resets the flip-flops, restarting the process. If the two 80 kHz inputs are in phase, the pulses at TP1 and TP2 will occur at the same time which, to the integrating amplifier's differential input, means no change in the TUNE voltage. The timing relationship looks like the following drawing. But, if a phase difference exists, one of the flip-flops will output a longer pulse which the Integrating Amplifier will translate to a positive or negative DC voltage. Normally, the REF pulse will begin to rise about 20 ns before the $\pm N1$ pulse.

8-60a

SERVICE SHEET 2-A2 (Cont'd)

Phase Detector Timing

Q1 and U5 form an operational amplifier which amplifies and integrates differences between the inputs to produce the VCO TUNE voltage. R8, R12, R16 and C9 and R11, R13, R20 and C12 determine the gain and integrating time constant, while CR1 and CR2 speed up the integration during fast input changes. VR1 and the voltage divider, R27 and R29 act as a clamp to keep VCO TUNE under 14 volts. A linearizing network, CR3, CR4 and associated resistors, modifies the VCO TUNE voltage so that loop bandwidth will be nearly constant for all frequencies, thus yielding a constant phase noise characteristic.

When the loop is out of lock, switches U4C and U4D close which shunts R8, R12 and R11, R13 with R10 and R14. This increases the Integrating Amplifier's gain allowing the loop to relock faster.

The 8 kHz notch filter removes the 8 kHz and 16 kHz sidebands produced during fractional division. Higher sidebands are attenuated by the low pass filter in the next stage.

One shot U7, Flip-Flop U8 and Nand gate U2D activates the switches, U4C and D, if the phase detector pulse width exceeds 1.5 μ s. When the output of U2D goes high, the one shot will trigger, but normally the input will stay high for only about 20 ns, so by the time U7 pin 6 goes high the D input to U8 is low and a low is clocked through to the switches. If a large phase error exists for more than 150 μ s U8 pin 12 will still be high when the one shot's output pulse goes positive and a high will be clocked through U8.

One shot U6 and nand gate U2A signal the front panel indicator and the HP-IB status byte circuitry when the LFS loop is unlocked. During lock periods and brief unlock periods both inputs to U2A are high. When the loop is unlocked U2A outputs negative pulses which are very short when the loop is unlocked for short periods but increases to 140 μ s for long unlock periods.

Short pulses are attenuated by R21 and C15 but longer ones will trigger U6, the output of which will cause the LFS UNLOCKED line to pulse high. As long as the loop remains unlocked, U6 will be triggered and output a string of 140 μ s pulses to the LFS UNLOCKED line via U2A.

8-60b

SERVICE SHEET 2-A2 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 3-A2 was used to isolate a 20/30 MHz phase detector problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
Oscilloscope HP180C/1801A/1821A

1. Set the Synthesizer to standby and install A2A4 on a 2x18 extender board. Be sure all loop cables remain connected.
2. Turn the Synthesizer on and set 3000.000 MHz center frequency. Measure the TUNE OUT voltage at TP4. It should be about +14 Vdc.
3. Set the frequency to 2999.999 MHz. The TUNE OUT voltage should drop to about +4V. If both voltages are correct, A2A4 is probably OK. Continue to be sure. If a voltage is wrong, skip to step 7.
4. Measure the voltage at pin 11 of the edge connector. If the loop is locked this voltage should be a TTL low. (Less than 0.7 Vdc).
5. Disconnect the red coax. The voltage at pin 11 should be a TTL high, the LFS indicator on A2A7 should go out, and the NOT PHASE-LOCKED indicator on the front panel should light. Reconnect the coax and the loop should relock. If all measurements are correct A2A4 is OK.
6. If the lock indicator is not working properly per steps 4 and 5, measure the pulse widths at pin 6, U7 and U6, when the red coax is disconnected. Both one shots should be generating pulses when the loop is unlocked. U7 and U8 are intended to help the loop lock by causing loop gain to increase for 1.5 μ s once an unlock condition has been detected. U6 generates a string of 140 μ s pulses to control the LFS UNLOCKED line.
7. With an oscilloscope, observe the pulses at TP1 (20 ns) and TP2 (40 ns). These should be TTL levels with an 80 kHz repetition rate. The falling edge of the pulses should be coincident as shown in the principles of operation. If these pulses exist, the phase detector is probably OK. If the pulses are not present, check the input signals to the phase detector. A missing input will generally reveal itself by causing the corresponding output of the phase detector to remain low. If the input is missing, turn to service sheet 1-A2 to continue troubleshooting.

8-60c

SERVICE SHEET 2-A2 (Cont'd)

8. Measure the inputs to U5 at pins 2 and 3. Both should be virtually the same at +12.1 Vdc. If these voltages are correct, troubleshoot U5 and associated components. Otherwise troubleshoot Q1 and associated components.

After any repairs to this board, refer to Table 5-3 and perform the A2A4 Assembly Notch Filter Adjustment, and the Non-Harmonically Related Spurious Test.

PRINCIPLES OF OPERATION

LFS Loop

The 20/30 MHz Loop (LFS Loop) converts tuning information of the four least significant digits (1 MHz through 1 kHz) into a frequency between 20 MHz and 30 MHz. This frequency is obtained by dividing the 160–240 MHz VCO output by 8. The 160–240 MHz is fed back to a programmable divider where it is divided by a number, N1, to produce 80 kHz. The 10 MHz reference is divided (by 125) to obtain 80 kHz and the two are compared in the phase detector. Phase difference is converted into a VCO TUNE voltage and applied to the VCO.

The VCO (A2A3) Assembly uses a varactor tuned oscillator and dividers to produce a 20–30 MHz signal, which is used in the YTO Loop, and a 160–240 MHz signal which is fed back to the N1 divider. The VCO TUNE voltage, after passing through a low pass filter, tunes the VCO over its 160–240 MHz range. A power splitter and drivers buffer the VCO output and drive a divider for the 20–30 MHz output and a low pass filter for the 160–240 MHz output.

160–240 MHz VCO

The oscillator consists of Q1 with the primary of T1 and CR1 through CR4 for the tuned circuit, and C6 providing feedback. Varactor bias, the VCO TUNE voltage, is applied through the low pass filter and switch S1. In the NORM position S1 connects the VCO TUNE voltage to the diodes, but in TEST HIGH FREQ or TEST LOW FREQ the loop is opened and dc voltage sets the VCO frequency to greater than 240 MHz or less than 160 MHz. Q1 is biased by the –40V supply through ripple filter Q6. RF energy is coupled to the Power Splitter by the one turn secondary of T1.

Amplifier Q4 buffers the VCO from the two common base drivers, Q2 and Q3. Q5 acts as a ripple filter for the Q2, Q3 and Q4 bias supply. Q2's output is filtered and applied to J2 as the 160–240 MHz OUTPUT. The signal at Q3's collector is divided by 8 by U2, U1A and U1B, filtered and applied to J1 as the 20/30 MHz output.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 3 was used to isolate a 160–240 MHz VCO problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

8-62a

SERVICE SHEET 3-A2 (Cont'd)

Test Equipment

Frequency Counter	HP 5340A
Spectrum Analyzer	HP 8553B/141T/8555A
High Impedance Probe	HP 1121A
Digital Voltmeter	HP 3455A

1. Set the Synthesizer to standby and install A2A3 on a 2 x 18 extender board.
2. Connect the frequency counter input to the A2A3 160-240 MHz OUTPUT. Common time base is not necessary for this measurement.
3. Set the test switch A2A3S1 to the TEST HIGH FREQ position. Turn on the synthesizer. The counter should indicate a frequency greater than 240 MHz.
4. Set the test switch to the TEST LOW FREQ position. The counter should indicate less than 160 MHz. If the results of either step 3 or 4 are incorrect, skip to step 8. Otherwise continue.
5. Connect the counter to the 20/30 MHz OUTPUT. The counter should indicate a frequency less than 20 MHz.
6. Set the test switch to the TEST HIGH FREQUENCY position. The counter should indicate a frequency greater than 30 MHz. If both steps 5 and 6 are correct, this board is functioning correctly. Return the test switch to the NORM position and reinstall the board.
7. Does loop appear to lock, but at the wrong frequency? If so, go to Service Sheet 1-A2 to troubleshoot the dividers.
8. If the loop fails to lock but the VCO checks out OK, go to Service Sheet 1-A2 to troubleshoot the phase detector or the inputs from the dividers.
9. Measure with a high impedance probe and spectrum analyzer the signal at A2A3U2 pin 7. The signal should be about -10 dBm at frequencies greater than 240 MHz. If this signal is OK, troubleshoot the ÷8 circuit, otherwise troubleshoot the power splitter and driver.
10. Measure the signal at the collector of Q4 with a high impedance probe and a spectrum analyzer. It should be about -10 dBm at less than 160 MHz. If this signal is correct, troubleshoot Q2 and associated components.
11. Measure these test voltages at R10:
 - +15.4V at TEST HIGH FREQ
 - +3.3V at TEST LOW FREQIf these voltages are correct, continue.
12. Measure Q1 dc bias voltages. They should be as shown on the schematic. If correct, continue; otherwise troubleshoot Q1, Q6 and associated components.

8-62b

SERVICE SHEET 3-A2 (Cont'd)

13. Set the Test switch to the HIGH FREQ position. Measure the signal at the base of Q4 with a high impedance probe and spectrum analyzer. It should be 0 dBm at greater than 240 MHz. If this signal is correct, troubleshoot Q4. Otherwise troubleshoot Q1 (pay special attention to T1 and CR1-4).

After any repairs to this board, refer to Table 5-3 and perform the 20/30 Loop VCO Adjustment, and the Signal-to-Phase Noise Ratio Test.

- Address selection Page 2-3

PRINCIPLES OF OPERATION

General

The HP-IB Interface converts ASCII characters on the bus' data lines into RF section program information and frequency digits. Also, it converts status information from other parts of the Synthesizer into a status byte which it sends on the 8 data lines. This section of the Synthesizer consists of two boards: HP-IB Address Assembly (A2A9), and the HP-IB Interface Assembly (A2A7).

The HP-IB Address Assembly (A2A9) receives a character from the data lines under the control of the 3 handshake lines. Then it decodes the 5 control lines to determine if the character is an address, a command, or a data character. If the character is an address, and it matches the Synthesizer's talk or listen address switch setting (see address selection in Section II), the Synthesizer will talk or listen. If the character is a command, the Synthesizer will respond to it if it has the capability (see Table 3-5). If the character is data and the Synthesizer has already been addressed to listen, the Address Assembly tells the Interface Assembly to decode it.

The HP-IB Interface Assembly (A2A7) determines whether character is a program code or an argument. If the character is a program code, it selects the correct route for the next character which will usually be an argument.

HP-IB Address Assembly

The Remote Bus Transceivers do three things. They allow the Synthesizer to send or receive over the same bus line. They invert logic levels; the bus uses low true logic and the Synthesizer uses high true logic. Also, they buffer the Synthesizer from the bus. Received characters (DI 1-7) go to the address selectors, command decoders, RF program selectors, and Interface storage register. If the Attention (ATN) line is true, the address selectors decode the DI 1-7 lines as an address or command. Switches S2 and S3 select the Synthesizer's Talk and Listen address. If the selected address appears at the same time as a STOR pulse from U20B, the TALK, LISTEN or REMOTE flip-flops will set. The schematic illustrates the logic for setting and resetting the three flip-flops. When the Synthesizer is in remote, addressed to listen, and the attention line (ATN) is false, an NRSTOR pulse tells the Interface Assembly to treat the DI 1-7 lines as an internal address (instruction) or as an argument to be stored at the previously determined address. All characters are transferred asynchronously over the bus DIO 1-8 lines in a bit parallel byte serial format. The handshake circuitry controls the transfer. Beginning with receive, the Acceptor Handshake circuit lets the not ready for data line (NRFD) go high when the Synthesizer is ready to receive a character. Then, when the controller pulls the data valid (DAV) line low, nand gate U13B waits about 2.5 μ s and triggers one shot U20B. The resulting STOR and NSTOR pulses do

8-64a

SERVICE SHEET 4-A2 (Cont'd)

several things. The leading edge of STOR clocks the serial poll flip-flop, enables the NRSTOR gate (U9B), and clocks the TALK, LISTEN and REMOTE flip-flops. The trailing edge of NSTOR clocks U5B, which after another 2.5 μ s delay allows the not data accepted line (NDAC) to go high. This signals the talker that the character transfer is complete.

For sending characters, the source handshake circuit monitors the not ready for data line (NRFD). When this line goes high, and the other conditions shown on the schematic are met, U20A is triggered. The resulting System Delay State pulse (SDYS and NSDYS) clocks the character onto the bus and after a 2 μ s settling delay sets the data valid line (DAV) low (true). When the not data accepted line (NDAC) goes high, U5A resets and the circuit is ready to send another character.

The parallel poll circuitry outputs a status bit on a switch selected data line (DIO 1-8) when the controller sets the end or identify line (EOI) true. Logic polarity of the status bit is switch selected and the bit will be true when any of the conditions monitored by the status encoder are true.

The service request flip-flop (U23B) stores the states of the RSV bit (bit 7) of the status byte and the bus service request line (SRQ).

The state of the status encoder is clocked through U23A when the Synthesizer is addressed to talk. U23B will set the service request line (SRQ) true if the output of the status encoder is true for more than 50 μ s. This time delay is set by R23 and C9. The SRQ line is cleared when the output of the status encoder goes false or when the Synthesizer is addressed to talk with the SPMS line (serial poll mode state) true.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 3 was used to isolate an HP-IB Address problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter or Logic Probe HP 3455A
Oscilloscope or Bus System Analyzer HP 180C/1801A/1821A

NOTE

This procedure requires the use of a remote programming device such as the 9830 or 9825 controllers or the 59401A Bus System Analyzer.

1. Determine the address to which the synthesizer is set.
2. Program the Synthesizer 12345.678 MHz at 0 dBm AM, FM and RF on. The data string to do this is "P12345678Z1K0322". Make sure the remote enable line is set true. If the Synthesizer accepts this data, most of the remote circuits are working

8-64b

SERVICE SHEET 4-A2 (Cont'd)

- properly. If this data is not accepted, go to step 12 to troubleshoot. Make sure front panel controls are disabled.
3. Program the Synthesizer to an out-of-range frequency "P8Z1" (80 GHz) and check for a service request on the bus (SRQ true). If the Synthesizer is not requesting service, go to step 16.
 4. Set the Synthesizer to talk and then check the status byte. It should be a decimal 96. (Binary 01100000).
 5. Program an in-range frequency "A4Z1" and check to see if the service request (SRQ) has cleared. If SRQ has not cleared, troubleshoot the service request flip-flop, U23.
 6. Program a device clear command. The synthesizer should go to 3000.000 MHz with RF, AM, and FM off. If the response is incorrect, skip to step 18.
 7. Program an ABORT command if your controller has the capability. After the abort has been set, transmit data "Q5Z0" without addressing the Synthesizer to listen. If the abort was properly executed, the Synthesizer should not accept the data. If the data is accepted, troubleshoot U19B, the listen flip-flop, with particular attention to the REF line. However, be sure the controller did not automatically readdress the Synthesizer before sending the data.
 8. Program a LOCAL command. The REMOTE lamp should go out and the front panel controls should be operational.
 9. Program a remote enable command and program the Synthesizer to an out-of-range frequency — "P8Z1".
 10. Program a parallel poll (if your controller has the capability) to see if the Synthesizer is sending a require service message on its assigned line. The line assignment and logic sense are set by rotary switches on A2A9. With a 9825 controller use the line shown below to avoid setting REN false during the parallel poll. If the results are incorrect, troubleshoot the status encoder circuit and the parallel poll response circuit. Parallel poll line for 9825:
mact; wti 0,7; wti 7,226; rdi 7→A; rdi 6→B; wti 7,202
 11. If everything has worked properly so far, the A2A9 board is working properly. Return the Synthesizer to local.
 12. This step should be done if a problem was noted in step 2 of this procedure. Install A2A9 on an extender board. Program a remote enable command followed by the Synthesizer's listen address. Measure edge connector pin 24, the REMOTE line, with a logic probe or voltmeter. It should be a CMOS high. If the line is not high troubleshoot the remote flip-flop (U17B) and the address select circuit.
 13. Attach a voltmeter or logic probe to edge connector pin 25 (ATN line). In the command mode this line should be TTL high and in the data mode it should be TTL low. If this line is not

8-64c

SERVICE SHEET 4-A2 (Cont'd)

performing correctly, troubleshoot the remote flip-flop U17B or the circuit (U20B and associated gates). If the line is operating properly, continue with this procedure.

14. Monitor the handshake operation with an oscilloscope or Bus System Analyzer. The handshake should proceed approximately as shown below. The pulse widths probably will not be as shown but the rise-fall relationships should be approximately correct. If the handshake is working correctly, proceed with this procedure. Otherwise troubleshoot the handshake circuits.

HP-IB Handshake

15. Check data lines DI1 to DI7. If the data accurately reflects the data being transmitted, but the Synthesizer does not respond properly, troubleshoot A2A7. Otherwise troubleshoot the Remote Bus Transceivers or the bus itself.
16. This step should be done if a problem was noted in step 3 of this procedure. Observe the front panel frequency display; it should indicate 80005.678 MHz and the OUT OF RANGE lamp should be on. If the frequency is correct, measure the ERRS line at edge connector pin 11. The line should be high. If the line is correct, troubleshoot the status encoder circuit and service request flip-flop. If the line is incorrect, troubleshoot A2A11.
17. If the frequency is incorrect, resend it to be sure there has been no error in the remote command. Be sure the letters transmitted by the controller are upper case. The Synthesizer does not respond to lower case letters. If the frequency is still wrong, check the data on line DI1 to DI7. If correct, troubleshoot A2A7; otherwise troubleshoot the Remote bus Transceivers.
18. Install A2A9 on extender board and measure the DC (device clear) line, edge connector pin 23, while sending a device clear command. The line should go high during the command. If the line responds correctly troubleshoot A2A7 (Service Sheet 5-A2) otherwise troubleshoot U1B, U1C, U15A and the bus command decoder circuit.

PRINCIPLES OF OPERATION

General

The HP-IB Interface converts ASCII characters on the bus' 8 data lines into RF section program information and frequency digits. Also, it converts status information from other parts of the Synthesizer into a status byte which it sends on the 8 data lines. This section of the Synthesizer consists of two boards: HP-IB Address Assembly (A2A9), and the HP-IB Interface Assembly (A2A7).

P/O HP-IB Interface Assembly

This board decodes program codes and routes the argument to the appropriate assembly. Any character on the bus will appear on the seven data lines (DI 1-7) but the HP-IB Interface assembly will only respond when the ATN line is false and an NRSTOR (low going) pulse is received. When these conditions are met, a program string is being sequenced into the Synthesizer. During this sequence, ATN will always be low and a NRSTOR pulse will occur for each character. The characters will be coded as shown in the table on this sheet and the string format is as follows (see Section III for complete programming information):

WHERE: C REPRESENTS A PROGRAM CODE
X REPRESENTS AN ARGUMENT

The transfer order is left to right. When the first character appears on the data lines, the program code/argument decoder will look at bits DI5 to DI7 to determine if it is a program code. Then, it will make pin 1 of the internal address counter (U4) high which will parallel load the DI 1-4 bits. During this time the NRSTOR pulse is disabling the instruction decoders, but when NRSTOR goes high U5 and U3 decode the program code. The next character could be another program code in which case the address counter would be reloaded, but normally it will be an argument as shown above. This character

8-66a

SERVICE SHEET 5-A2 (Cont'd)

appears on the bus about 2 μ s before the next NRSTOR pulse so it has time to be routed to the frequency register or RF program selector and latched. Then when NRSTOR goes low, the address counter is clocked to serial shift (count up), and the instruction decoders are disabled. This sets the address counter to the next program code in the sequence shown in the table. The new program code will be decoded when NRSTOR goes high. If the next character in the string is an argument rather than a program code, the data will be routed to the next internal address due to the serial shift that occurred in the address counter.

Switching delays are timed by U15 and U16 to allow the Synthesizer to finish processing a character before receiving another one, and to signal the controller via a service request that ALC and output level have not settled.

TROUBLESHOOTING

It is assumed that the troubleshooting information Service Sheets 1, 3, and 4-A2 was used to isolate an HP-IB Interface problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Oscilloscope HP 180C/1801A/1821A
or
Logic Probe

1. Load and run the operator's check program. If the program runs properly, A2A7 is OK. If a specific portion did not function properly, retest that section for proper operation in local.
2. If local operation is correct but remote operation is incorrect, continue with this procedure; otherwise go to the service sheet involved with the malfunctioning circuit.
 - If the problem involves frequency, start with step 3.
 - If the problem involves modulation or RF output, start with step 6.
3. Attach a logic probe or oscilloscope to A2A7TP1. Program the Synthesizer's center frequency "P12345678Z1". When the frequency execute command "Z0" is received by the Synthesizer, TP1 should pulse high for a few microseconds. A program loop is useful to generate a string of pulses for this and most of the remaining tests.
4. Observe pulses at pins 14 (INTF CLK1) and 15 (INTF CLK2) of U5. There should be one INTF CLK1 pulse for each of the left four frequency digit positions (10 GHz to 10 MHz) which are sent. There can be from zero to four pulses. There should also be one INTF CLK2 pulse for each of the right four frequency digits (1 MHz to 1 kHz) which are sent. For example if the data string "A2345Z1" is sent, there will be three INTF CLK1 pulses (due to the 2, 3 and 4) and one INTF CLK2 pulse (due to the 5). Troubleshoot U5 and U4 after checking the input data DI 1-8 if the pulses are not correct.

8-666

SERVICE SHEET 5-A2 (Cont'd)

5. Program frequency "P12345678Z1". Check the outputs of U3 REM 1000 CLK to REM 1 CLK. The REM 1000 CLK line should pulse once for the 10 GHz digit and once for the 1 MHz digit. The other three lines should perform similarly for their digits. If these pulses are correct go to Service Sheet 6-A2 to troubleshoot the Interface Storage Register. If the pulses are incorrect, troubleshoot U3, U4 and associated gates.
6. The following troubleshooting should be performed if there is a remote RF level programming problem. Program KØLØ01". The outputs of U10 and U11 should all be low and the RF output level should be +3 dBm. If the outputs of U10 and U11 are correct but the indicated power is incorrect, go to Service Sheet 6-A1 to continue troubleshooting.
7. Measure U25A pin 3 REM ATTN CNTL and U3 pin 3 REM VERNIER CNTL. The appropriate line should pulse high when remote level data is received. If the lines do not pulse properly, troubleshoot U3, U4 and the associated gates.
8. The following troubleshooting steps should be performed if the remote problem involves AM, FM or ALC. Program "MØØØ". The outputs of U2, U1 and U9 should all be low; AM and RF should be off; FM deviation range should be 10 MHz. If the outputs of U2, U1 and U9 are correct but the front panel indications are incorrect, go to Service Sheet 6-A1 to continue troubleshooting.
9. Measure the pulses at U3 pin 2 (REM FM CNTL), pin 14 (REM AM CNTL), and pin 15 (REM ALC CNTL). A single pulse should occur at the appropriate pin when remote data for the function is received. If the pulse occurs properly but the output data is incorrect, troubleshoot the appropriate RF Program Selector IC, U2, U1, or U9. If the pulse does not occur, troubleshoot the message decoder, address counter (U4) and the instruction decoder (U3).

PRINCIPLES OF OPERATION

General

The HP-IB Interface converts ASCII characters on the 8 bus data lines into RF output section program information and frequency digits. Also, it converts status information from other parts of the Synthesizer into a status byte, which it sends on the 8 data lines. This part of the HP-IB Interface Assembly stores programmed frequency information, and consolidates loop unlock information.

P/O HP-IB Interface Assembly

Frequency digits on the DI 1-4 lines are clocked into the interface frequency register by the remote clocks (REM 1-1000 clk). This register is loaded in blocks of four digits. Digits in the 10 GHz to 10 MHz block are clocked in first, then when enough time has elapsed for data register 1 to load the information, the interface register reset line (INTF REG RST) goes high and clears the register. Then the 1 MHz through 1 kHz digits are loaded.

The schematic illustrates how the unlock signals from the Synthesizer's phase lock loops drive unlock indicators and are OR'd to make the UNLOCK bit of the status byte.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3 and 4-A2 was used to isolate an HP-IB Interface problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
Logic Probe HP 545A

1. Set the Synthesizer to 3 GHz with RF switch ON and rear panel reference switch set to INT with jumper cable in place. Observe the lock indicator LED's on A2A7. All four indicators should

8-68a

SERVICE SHEET 6-A2 (Cont'd)

be on and the front panel NOT PHASE LOCKED indicator should be off. If any of the LED indicators are not on, measure the unlocked signal from the appropriate phase lock loop. The UNLOCKED lines should all be low as they enter A2A7 for a locked loop. If the line is low, troubleshoot the lock indicator, otherwise troubleshoot the malfunctioning phase-locked loop.

2. This step checks the switching of the phase lock indicators.
 - a. Set rear panel REF switch to EXT. The REF Loop indicator should go out. Return the switch to INT and the indicator should relight.
 - b. Set front panel RF switch OFF. The YTO Loop indicator should go out. Return the switch to ON.
 - c. Unplug the blue coax from A3A1A1. The LFS Loop indicator should go out. (This also disables the A2 controller). Reconnect the cable. The YTO indicator may also extinguish at this step.
 - d. Unplug the white/red coax at A3A1A5. The M/N Loop indicator should go out. The YTO indicator may also extinguish at this step. Reinstall the cable. All the lock indicators should be on.
3. Quickly tune the frequency in 100 MHz steps. Measure the voltage at A2A7 edge connector A pin 9. This voltage should go low when the YTO is unlocked.
4. The following steps should only be followed if troubleshooting a frequency related programming problem. Program the following code: "P0000". Do not program a frequency execute command at this time. The outputs of U19-U22 should all be low. If all are OK, continue with this procedure. If the outputs of only one register is wrong, troubleshoot it. If the outputs of all registers are the same but incorrect, troubleshoot input lines DI 1-4.
5. Program "P1" through "P9" to assure that the outputs of U21 remain correct for all inputs. The data format is BCD.
6. Program "Q1" through "Q9" to assure that the outputs of U20 remain correct for all inputs.
7. Program "R1" through "R9" to assure that the outputs of U22 remain correct for all inputs.
8. Program "S1" through "S9" to assure that the outputs of U19 remain correct for all inputs.
9. Program "P12345678Z1". The front panel frequency display should indicate 12345.678 MHz. The outputs of U19 through U22 should be reset to zero. If all is OK through this step, the circuits on this service sheet are working properly.

PRINCIPLES OF OPERATION

General

The Register 1 Assembly (A2A10) consists of a protected CMOS shift register (DATA REGISTER 1) and circuits for band and error decoding. Data Register 1 stores the Synthesizer's frequency. A battery keeps the register active when Mains power is off. The band and error decoding circuit examines the Synthesizer frequency for errors and tells the divider on the Output Register Assembly (A2A8) whether to divide by 1, 2, or 3, and tells the Yig Tuned Multiplier (YTM) whether to multiply by 1, 2, or 3.

Register 1 Assembly

Shift registers U7—U9 and U19—U23 store the Synthesizer's frequency in a BCD format. The 10 GHz digit is on top and the 1 kHz digit is on the bottom. An extra digit which duplicates the 1 kHz digit is stored in the serial output latch. Nine clock 1 (CLK1) pulses serial shift the frequency out of the register, through the Timing and Control Assembly, into the front panel display and back to Data Register 1. This happens when NGO (Not Go) is true (low). Remote programmed frequencies are parallel shifted into Data Register 1 four digits at a time by INTF CLK1 and 2.

The adder, U15, converts the register's parallel BCD output into a binary address for the first ROM, U14. This ROM and U3 store tables of Harmonic numbers (HN2, HN1) and incorrect frequencies (NERR). Signals from the RF section effect the frequency limits of the instrument. Circuit operation is summarized as follows:

f = frequency	HN1	HN2	NERR	BAND
<2000.000 MHz	—	—	Low	Out of range
2000.000 MHz — 6199.999 MHz	0	0	High	1
6200.000 — 12399.998	1	0	High	2
12400.002—18599.997	0	1	High	3
>18600.000 MHz	—	—	Low	Out of range

8-70a

SERVICE SHEET 7-A2 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 10-A2 was used to isolate a Register 1 problem to the circuits shown on this schematic. The following information will aid in isolating the defective component:

Test Equipment

Logic Analyzer HP 1601A
Digital Voltmeter HP 3455A

1. Tune the synthesizer frequency to 12345.678 MHz. If the frequency tunes properly, Register 1 is properly storing and clocking data. If the frequency does not tune properly, skip to step 3.
2. Unplug the Synthesizer for at least one minute. Reapply Mains power. The frequency should be the same as shown before power was removed. If not correct, troubleshoot battery A2BT1 and the charging circuit plus the clock protect circuitry on A2A11 (see Service Sheet 9-A2). If everything is OK so far, skip to step 5.
3. Press the PRESET (3 GHz) pushbutton. Attach a logic analyzer to DR101-8. Use CLK1 to clock the logic analyzer. Set the analyzer to END DISPLAY and trigger on a BCD 3. Rotate the TUNING knob. BCD data for 3 GHz with the three at the bottom of the display should be displayed on the logic analyzer.
4. If the data does not appear to clock out properly, check CLK1 with an oscilloscope. It should be a string of 9 TTL pulses when the TUNING knob is turned or when test point pair A2A11TP1 is shorted together with an alligator clip. If CLK1 is not correct, go to Service Sheet 8-A2.
5. Observe the HN1 and HN2 lines with a voltmeter. Below 6.2 GHz both lines should be TTL low. Between 6.2 GHz and 12.399998 GHz HN1 should be high. Above 12.4 GHz HN2 should be high.
6. Tune to the highest possible frequency. It should be 18599.997 MHz. Then tune to the lowest possible frequency. It should be 2000.000 MHz. If either one is incorrect, troubleshoot the frequency limit detection circuitry, U14, U3 and other associated gates. If everything has worked properly to this step, A2A10 is working correctly.

8-706

SERVICE SHEET 7-A2

MNEMONICS

Mnemonics	Definition	Explanation
GO (NGO)	Do a data cycle	Puts the shift registers in the serial shift mode.
CLK1	Clock 1	Nine pulses occurring during the first half of a data cycle.
DINTF	Data Interface	Frequency information from the HP-IB interface.
INTF CLK1	Interface Clock 1	Shifts the 10 GHz to 10 MHz digits into the top half of Data Register 1.
INTF CLK2	Interface Clock 2	Shifts the 1 MHz to 1 kHz digits into the bottom half of Data Register 1.
DR1I 1-8	Data Register 1 In	Serial input to the register.
DR1O 1-8	Data Register 1 Out	Serial output of the register.
NERR	Not Error	Low means that an out of range frequency is stored.
LEFT	Data register 2 shift left	High during the second half of a data cycle.
HN1, 2	Harmonic Number	Tells the divider and YTM the band of the frequency stored in Data Register 1.

DEFINITION

Data Cycle -- The process of changing the Synthesizer's frequency by adding or subtracting 1 from one of the digits.

PRINCIPLES OF OPERATION

General

The timing and control assembly generates signals that initiate and control DATA CYCLES. A data cycle is the process of changing the Synthesizer's frequency by adding or subtracting one from one of the digits stored in data register 1. The timing and control signals include clocks, tuning direction indicators, and error flags. If at the end of a data cycle an error flag is set, the timing and control assembly will do more data cycles until the error is corrected.

Schematics are on Service Sheets 8-A2 and 9-A2 while a complete block diagram appears to the left of each schematic. The shaded area indicates the circuitry on the adjacent schematic. Notice that the main signal flow (the frequency data) is on Service Sheet 9 and most of the timing and control circuitry is covered by Service Sheet 8.

Relation to the Rest of the Instrument

The Digital Controller (see block diagram below) is static between frequency changes. The information is latched in Register 3 and applied, through output decoders, to the phase lock loops. Since this data is the basis for all future frequency changes, it is also stored in the Protected Register (Register 1) and displayed by the front panel.

Digital Controller Block Diagram

8-72a

SERVICE SHEET 8-A2 (Cont'd)

The frequency (2—18.5 GHz) is displayed and stored as 8 BCD digits (10 GHz to 1 kHz) but the phase lock loops tune from 2—6.2 GHz, which means the frequency must be divided by 1, 2, or 3 before being used to tune the loops. Frequency changes occur during a Data Cycle which is initiated by turning the TUNING control, pressing the PRESET button, or remotely programming a new frequency. During each data cycle the Controller operates on the frequency stored in Register 1 as follows:

In Local when the TUNING control is turned:

- Add ± 1 to the digit selected by the resolution button.
- Update the display.
- Divide the new frequency by 1, 2, or 3 (so the phase lock loops will tune from 2—6.2 GHz).
- If a remainder exists, do more data cycles, adding or subtracting one from the least significant digit until the remainder is zero.
- Shift the new frequency data into Register 3.
- Stop!

In Local when PRESET is pushed:

- Clear Register 1.
- Add 3 to the 1 GHz digit.
- Update the display.
- Divide by 1 in Register 2.
- Shift the new frequency data (3 GHz) into Register 3.
- Stop!

In remote when a new frequency is programmed:

- Shift the new frequency into Register 1.
- Update the display.
- Divide by 1, 2, or 3.
- If a remainder exists, do more DATA CYCLES, adding ± 1 to the 1 kHz digit until an evenly divisible frequency is obtained.

A data cycle begins when the GO line goes true. The clock generator produces timing signals as shown below:

Clock Generator Outputs

Starting with the 1 kHz digit, CLK1 shifts the frequency data serially out of Register 1 and into the ± 1 adder. The adder adds or subtracts 1 from the digit selected by the RESOLUTION buttons. The new frequency goes to three places: the front panel display, back into Register 1, and into Register 2. Then LEFT goes high, changing Register 2 to the left shift mode, and the second half of CLK2 serial shifts the data (starting with the 10 GHz digit), through the divider. The divided frequency is shifted back into Register 2. If a remainder exists another data cycle will commence and the 1 kHz digit of the frequency Register 1 will be changed and the division will again occur. This process continues until an evenly divisible frequency is obtained. When the remainder is zero CLK3 parallel shifts the data into Register 3 where it is decoded and applied to the phase lock loops.

8-72b

SERVICE SHEET 8-A2 (Cont'd)

P/O Timing and Control Assembly

Clock divider, U14, divides the 10 MHz reference by 16 which results in a stream of 625 kHz pulses. The clock counter counts nine of these pulses during which time they are gated through U5C (clock 1) and U5D (first half of clock 2). At the end of the count U5C is disabled and the clock divider is reset. It stays reset until the end of the time delay measured by C6, R12 and R9 is finished. This accounts for the interval between the two halves of clock 2. U14 starts dividing again and 9 more pulses go through U5D. Clock 3 (CLK3) signals the end of an error free data cycle by going high for a short period when triggered by the negative going edge of LEFT.

The RPG (Rotary Pulse Generator) converts the smooth rotation of the TUNING control into digital information. The controller interprets this information to determine if the frequency should be increased or decreased. RPG1 and RPG2 are pulses, the frequency of which depend on rotation speed, and the phase relationship depends on rotation direction. If the TUNING control is turned clockwise RPG1 will lead RPG2 and the Synthesizer's frequency will increase. The presence of the squarewaves tells the Controller to do data cycles. RPG1's negative edge triggers a one shot composed of C3, and Q6 and associated resistors. This results in a short duration low pulse at U29B pin 6, the trailing edge of which sets GO. The gate, U29B, must be enabled by the Pulse Swallower. This circuit controls the rate of frequency change by varying the number of pulses gated through U29B. If the RPG is turning slowly only every third pulse gets through to set GO, but if turned fast enough every pulse clocks U20B. C8 and C9 store the positive voltage which enables U29B. Q5 opens a discharge path every time GO becomes true. C8 requires three pulses to charge to the on threshold of U29B and is completely discharged every time Q5 conducts. This accounts for the every third pulse setting GO when the RPG is turned slowly. C9, however, charges relatively fast and discharges slowly so it works out that when the RPG is turning fast, a positive voltage will always be applied through CR7 to U29B thus allowing every pulse to gate U20B.

The Errs flip-flop gets set when the band and error decoding circuit on the Register 1 assembly detects an incorrect frequency. This will cause the controller to repeat data cycles, modifying the RESOLUTION selected digit (1 kHz by default), until the frequency is in range. This occurs when an attempt has been made to tune below 2.0 GHz or above 18.6 GHz. If, for example, the frequency is 2.0 GHz, the RESOLUTION is 1 MHz, and the RPG is turned counterclockwise; the ± 1 adder will subtract 1 MHz resulting in 1.999 GHz. The error circuitry will then cause the adder to add 1 MHz and thereby return to 2.0 GHz. Register 3 cannot be clocked when there is an error, so the frequency of the loops is unaffected. The process is so rapid that the operator will not be able to see 1.999 GHz on the front panel.

The First Cycle flip-flop tells the Controller whether or not the current data cycle is the first one or succeeding ones used to produce an evenly divisible frequency or correct an error. The XSCC (Excess Cycle Counter) and UPDATE SIGN flip-flop work together to determine whether a frequency to be modified should be increased or decreased.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 10-A2 was used to isolate a Timing and Control problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

8-72c

SERVICE SHEET 8-A2 (Cont'd)

Test Equipment

Oscilloscope HP 180C/1801A/1821A
Digital Voltmeter HP 3455A

This assembly contains several test point pairs which are designed to set certain lines to known conditions. By shorting the pair together with an alligator clip, the line will be connected high or low as appropriate.

- A2A11TP1 — causes controller to continually cycle data
- A2A11TP2 — suppresses frequency error limits
- A2A11TP3 — suppresses operation of the ± 1 adder
- A2A11TP4 — suppresses round off
- A2A11TP5 — aborts controller operation

This assembly also contains a manual clock switch. Use this switch by unplugging the blue coax on A3A1A1 to disconnect the controller clock. (Disconnecting this cable also causes the LFS loop to unlock but that is not important when troubleshooting the controller.)

1. Connect alligator clip to test point pair A2A11TP1. Observe CLK1 and CLK2 test points on oscilloscope. The strings of pulses should be as shown in the figure below ($5 \mu\text{s}/\text{div.}$, $2\text{V}/\text{div.}$). CLK1 consists of a string of 9 pulses. CLK2 consists of two strings of 9 pulses. If the front panel display is working properly, CLK1 must be OK.

Clock Pulse Waveforms

If these clock signals are OK, the clock divider, clock counter and clock drivers are OK. Also the RECYCLE flip-flop (U27B) is OK.

2. Attach one oscilloscope probe to A2A11 edge connector pin A30 (CLK3). Leave the other probe attached to CLK1. The timing relationship of CLK3 should be as shown in the text.
3. Observe LEFT and CYCLE lines in relationship to CLK1 and CLK2. They should be as shown in the following table.
4. Locate RPG SIGN test point. This point should go high when the TUNING control is tuned clockwise and low when turned counterclockwise.
5. Connect oscilloscope or voltmeter to A2A11 edge connector pin B1. This line should be a CMOS low for all in-range frequencies. If everything is correct so far, turn to Service Sheet 9-A2.

8-72d

SERVICE SHEET 8-A2 (Cont'd)

Clock, Cycle, and Left Timing Relationship

MNEMONICS

Mnemonic	Definition	Explanation
NRMDR	Not Remainder	Low means a remainder exists after dividing by 2 or 3.*
NLSDR	Not Least Significant Digit Resolution	Low means the 1 kHz digit RESOLUTION button has been pushed.
UPDATE	Correct band change error	Initiates more data cycles to correct the 1 kHz digit after a band change.
NERR	Not Error	Low means an out-of-range frequency is stored in Data Register 1.
CYCLE SET	Set first cycle flip-flop	High when either INTF CLK GO is true or there is a frequency error and the 1 kHz RESOLUTION button has been pushed.
UPDATE SIGN	Change state of SUBTRACT line	Indicates whether previous round off was an addition or subtraction.
LEFT	Shift left	High during the second half of a data cycle. Causes Data Register 2 to shift left.
CLK 1	Clock 1	Nine pulses during the first half of a data cycle. Each pulse corresponds to a frequency digit.
CLK 2	Clock 2	18 pulses: 9 during the first half of a data cycle and 9 during the second half.
CLK 3	Clock 3	1 pulse at the end of an error free data cycle.
GO	Do a data cycle	Leading (positive going) edge triggers a data cycle. Stays high until the data cycle is finished.
XSCC NXSCC	Excess Cycle Generator	XSCC and NXSCC are two bits used to tally the extra data cycles done to obtain an evenly divisible frequency.
RPG SIGN	Rotary Pulse Generator Sign	Indicates tuning direction. High is clockwise, low is counterclockwise.
SUBTRACT	Subtract 1 from the RESOLUTION selected digit	Tells the ± 1 ADDER whether to add or subtract. High = subtract, low = add.

*Should always be false (high) after the data cycle is completed.

DEFINITION

Data Cycle — The process of cycling frequency data through the various registers and the ± 1 adder, usually for the purpose of changing frequency.

PRINCIPLES OF OPERATION

General

The Timing and Control Assembly generates signals that initiate and control data cycles. A data cycle is the process of changing the Synthesizer's frequency by adding or subtracting one from one of the digits stored in Data Register 1. The timing and control signals include clocks, tuning direction indicators, and error flags. If at the end of a data cycle an error flag is set, the Timing and Control Assembly will do more data cycles until the error is corrected.

As shown by the shaded blocks of Figure 8-74, this part of the Timing and Control Assembly consists of the Band Change Detector, ± 1 Adder and the Offset Adder. The Band Change Detector translates harmonic number and excess cycle information into control signals for the Error and RPG Sign Logic. The ± 1 Adder modifies the appropriate frequency digit to set a new frequency or correct an error. The Offset Adder is not used in the standard Synthesizer but the frequency data passes through it. It may be used to add an IF offset in special instruments.

P/O Timing and Control Assembly

The ± 1 Adder, U33, performs the operation indicated by the SUBTRACT line when the ± 1 Bit line goes high. For example:

If SUBTRACT line is low:

Add 1	DR10	8	4	2	1	
Y input		0	1	0	1	= 5
Z input		0	0	0	1	= 1
Y + Z		0	1	1	0	= 5 + 1 = 6

If SUBTRACT is high:

Subtract 1						
Y input		0	1	0	1	= 5
Z input		1	1	1	1	= 15
Y + Z		0	1	0	0	= 5 - 1 = 4

8-74a

SERVICE SHEET 9-A2 (Cont'd)

If the sum is 10 an illegal BCD 1010 will result so it must be converted to binary 0000 with a carry of one. U17D pin 11 goes Low when this is necessary. This Low does two things. First, it is clocked through U9B by a delayed CLK1 from the Double Clock circuit — it keeps the Adder Enable flip-flop set. Second, it changes the number at the Adder's B input to 7. A new sum, 16 or binary 0000 with a carry, results. Note that this happens within the period of one CLK1 pulse. The carry is added to the next digit. A similar process performs subtraction with borrow.

The OR gates at the ± 1 Adder's output add 3 to the 1 GHz digit when the PRESET button is pushed. Pin 13 of U32D and pin 1 of 32A go high when the 1 GHz digit leaves the \pm Adder.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 10-A2 was used to isolate a Timing and Control problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Logic Analyzer HP 1601A

1. Observe the front panel frequency display and press the PRESET (3 GHz) pushbutton. If the frequency is displayed correctly (3000.000 MHz) the DR1I 1–8 lines from the ± 1 Adder (U33) are probably OK. If the frequency is not displayed properly, check the CLK1 line on Service Sheet 8-A2 or check the data entering the display.

NOTE

An open pin on the front panel display LED's will cause that pin to float high.

2. Attach a logic analyzer to DR1I 1–8 and DR2I 1–8 lines. Use CLK1 to clock the analyzer. Rotate the RPG to cause the data to circulate. The DR1 and DR2 data should be identical for standard instruments. If they are different, troubleshoot the Offset Adder. Otherwise continue.
3. Press the least significant digit (1 kHz) RESOLUTION pushbutton. Rotate the TUNING knob clockwise. Observe DR1I 1–8 on the logic analyzer. The data is displayed least significant digit first and should increase as the frequency is increased. Tune each digit from 0 to 9 to assure that none of the DR1 lines are stuck high or low. If the frequency does not change, troubleshoot the ± 1 Adder circuitry.
4. Note the center frequency and unplug Synthesizer from Mains. Wait at least one minute and reconnect Mains. The center frequency should not have changed. If the frequency has changed, troubleshoot the clock protect circuitry (U27A) and the battery or charger circuit on 7-A2.

8-746

SERVICE SHEET 9-A2 (Cont'd)

5. Tune the center frequency above 6.2 GHz and then tune the least significant digit. Between 6.2 and 12.4 GHz, the minimum step size should be 2 kHz; above 12.4 GHz, the minimum step should be 3 kHz. If the instrument turned on properly in step 4 and rounds off properly above 6.2 GHz, the recycle circuitry and the excess cycle counter circuitry on 8-A2 are working properly.

8-74C

SERVICE SHEET 9-A2 (Cont'd)

MNEMONICS

Mnemonics	Definition	Explanation
±1 BIT	Add or subtract 1 from the digit now at the Adders input.	High means operate on the digit at the Adders input.
FIRST CYCLE	First data cycle.	Distinguishes between a normal data cycle and extra data cycles done to eliminate round-off error.
NLSDR	Not Least Significant Digit Resolution	Low means the 1 kHz RESOLUTION button has been pushed.
NCYCLE	Not Cycle.	High during the first half of a data cycle.
NERRS	Not Error Stored	Low means that an out-of-range frequency is stored in Data Register 1.
NCLK 3	Not Clock 3	Low going pulse at the end of an error free data cycle.
RPG SIGN	Rotary Pulse Generator Sign	Indicates TUNING direction.
XSCC	Excess Cycle Counter	Two bits used to tally the extra data cycles done to obtain an evenly divisible frequency.*
HN1 HN2	Harmonic Number	Indicates band number of the frequency in Data Register 1: Band HN1 HN2 1 0 0 2 1 0 3 0 1
DR1O 1-8	Data Register 1 Out	Binary Coded Decimal digits from Data Register 1.
DR1I 1-8	Data Register 1 In	Binary Coded Decimal digits to the front panel, Data Register 2, and back to Data Register 1.
DR2I 1-8	Data Register 2 In	Binary Coded Decimal digits to Data Register 2.
UPDATE SIGN	Change state of SUBTRACT line	Indicates whether previous round-off was an addition or subtraction.
UPDATE	Correct band change	Initiates more data cycles to correct the 1 kHz digit after a band change.

DEFINITION

Data Cycle -- The process of cycling frequency data through the various registers and the ±1 adder, usually for the purpose of changing frequency.

PRINCIPLES OF OPERATION

General

The Output Register Assembly consists of Data Register 2, Data Register 3, a Digital Divider, and the DAC and M/N Decoder. Service Sheet 10-A2 covers the Digital Divider and Data Register 2 and Service Sheet 11-A2 covers the rest. Additionally, Service Sheet 10-A2 shows the Logic Test circuit which is used as a logic probe.

Data Register 2 accepts frequency data from the ± 1 Adder in a right shift mode during the first half of CLK2. Then LEFT goes true and the second half of CLK2 left shifts the data through the digital divider and back into Register 2.

The digital divider, controlled by HN1 and HN2, divides the frequency by 1, 2, or 3 so that the DAC, and M and N information will always tune the YTO Loop from 2 to 6.2 GHz.

P/O Output Register Assembly

Register 2 consists of shift registers U1, 2, 3, 6, 7, 11, 15, 16 and 23. U23 serves a dual purpose: it stores the GHz digit and steers the data. During right shift the LEFT Line is low to enable data to flow from the ± 1 Adder. When LEFT goes high during the second half of CLK2, data flows from the 100 MHz flip-flops, through the 2 inputs of U23 and to the digital divider.

The ROM's, U24 and U25, contain division tables. Each digit, starting with the most significant, enters both ROM's as a dividend (address). U24 feeds the quotient back to Register 2. U25 puts the remainder into U8 where it is clocked back to the ROM's as part of the next dividend. If a remainder exists after the last digit, the NRMDR line will be low (true) and cause the timing and control circuitry to start another data cycle.

SERVICE SHEET 10-A2 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 3 was used to isolate an Output Register problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
 Logic Analyzer HP 1601A

1. Install A2A8 on an extender board or on the Output Register Test Board. (HP Part Number 11712-60001.)
2. Set frequencies as shown in the following table. The edge connector pins with arrows should be measured with a logic probe or voltmeter or the data should be observed on the output register test board. By checking all four frequencies, each output line will be cycled high and low.

Frequency	A		B		C	
	Front	Rear	Front	Rear	Front	Rear
6169.696	L	H	H	L	X	X
3696.969	H	L	L	H	X	X
5990.000	X	X	X	X	H	L
3640.000	X	X	X	X	L	H

3. Check the input data by connecting a logic analyzer to DR2I 1-8 lines and to CLK1. Set the analyzer to END DISPLAY. Set the synthesizer frequency to 12345.678 MHz and set the logic analyzer to trigger on the "1". Connect an alligator clip to test point pair A2A11TP1. If the input data is correct, continue with this procedure. Otherwise go to Service Sheet 9-A2 to continue troubleshooting. The data is clocked in least significant digit first; the last nine characters on the logic analyzer display should be:

4. Check input lines CLK2, NCLK2 and LEFT with an oscilloscope. These lines should be as shown below. Trigger the oscilloscope on CLK1 for these measurements.

8-766

SERVICE SHEET 10-A 2 (Cont'd)

5. Check input lines HN1 and HN2. These lines set the divide number for the harmonic bands. If either line is malfunctioning, go to Service Sheet 7-A2 to continue troubleshooting.

Frequency (MHz)	HN1	HN2
2000-6199.999	L	L
6200-12399	H	L
12400-18599	L	H

6. If all the input lines are correct, trace back from the incorrect output(s) discovered in step 2 to isolate the malfunction to a particular part. Note that the output of Register 2 should not be over 6199.999 MHz after CLK2 has finished clocking the data through the divider.
7. To check the divider, connect a logic analyzer to the outputs of U24. Depending on the harmonic band selected (see step 5) the output of U24 should be the selected frequency divided by 1, 2, or 3.

MNEMONICS

Mnemonic	Definition	Explanation												
HN1 HN2	Harmonic Number	Tells the digital divider whether to divide by 1, 2, or 3. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>÷</th> <th>HN1</th> <th>HN2</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>0</td> <td>0</td> </tr> <tr> <td>2</td> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>0</td> <td>1</td> </tr> </tbody> </table>	÷	HN1	HN2	1	0	0	2	1	0	3	0	1
÷	HN1	HN2												
1	0	0												
2	1	0												
3	0	1												
CLK2	Clock 2	Two sets of nine pulses. Each pulse within a set corresponds to a frequency digit.												
LEFT	Shift Left	When low, Register 2 shifts right. When high, Register 2 shifts left.												
DR21 1-8	Data Register 2 In	Binary coded decimal digits to Data Register 2.												
NRMDR	Not Remainder	Low means that a remainder exists after division.												

DEFINITION

Data Cycle — The process of cycling frequency data through the various registers and the ± 1 adder, usually for the purpose of changing frequency.

PRINCIPLES OF OPERATION

P/O Output Register

This part of the output register assembly consists of Data Register 3 and the DAC and M/N Decoder circuits. CLK3, a single pulse at the end of the data cycle, parallel loads Register 3 with the frequency data. From here the 1 kHz through 8 MHz digit information goes directly to the LFS loop. The DAC and M/N Decoder translates the remaining digits into tuning information for the YTO loop. The outputs relate to the Yig Tuned Oscillator (YTO) frequency as follows:

DAC 1-3200 MHz: round down to nearest 10 MHz. Note that the DAC 100 MHz through DAC 3200 MHz bits are effectively in binary.

M and N: look up the frequency in Table 8-5 and convert M and N to binary.

TROUBLESHOOTING

Troubleshooting is covered on Service Sheet 10-A2.

PRINCIPLES OF OPERATION

General

The front panel (A2A1) consists of the power switch, frequency controls and indicators, and status indicators.

This portion of the A2A1 Assembly contains status indicators, tuning resolution indicators and the ± 1 bit control circuitry. The lamp drivers and status indicators show, by front panel lights, the following conditions: INT REF OFF, REMOTE, NOT PHASE LOCKED and frequency OUT OF RANGE. When the instrument is first turned on or the HOLD button is pressed, the tuning resolution circuits will disable Synthesizer tuning. If one of the RESOLUTION buttons is pressed, the frequency resolution indicators and lamp drivers will indicate which button was pressed and load that information into the resolution register. The ± 1 Bit output of this register tells the ± 1 Adder (located on A2A11) on which digit to operate.

P/O Front Panel Board Assembly

Pin 2 of the resolution register U9 goes high when the appropriate digit is clocked through the ± 1 Adder by CLK1. The desired resolution, selected by switches S3 through S6 and latched by U5, is clocked into U9 by the inverted GO line. When GO changes level, U9 goes low, U9 becomes a serial register and the selected resolution is shifted through by CLK1. Three supporting circuits are significant. Diode CR1 clocks U5 when the LOCAL line goes low (when the instrument switches to remote). This causes the lows at U5's D inputs to appear at U9 thus disabling the ± 1 Adder. U6A and associated capacitor and resistors debounce the RESOLUTION switches. OR gate Buffer, U1, drives the frequency resolution indicator circuitry, insuring that the selected resolution light and any higher significant digit lights are on.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 10-A2 was used to isolate a front panel problem to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Oscilloscope HP 180C/1801A/1821A

8-80a

SERVICE SHEET 12-A2 (Cont'd)

1. Set Synthesizer to ON. Press the PRESET (3 GHz) pushbutton. Push the right hand (least significant digit) tuning resolution pushbutton. All four tuning resolution indicators should light. Rotate the TUNING knob clockwise and counterclockwise. The frequency should change in 1 kHz steps. If not OK, skip to step 9.
2. Press the next tuning resolution pushbutton. The least significant indicator should unlight. The frequency should tune in 10 kHz steps.
3. Press the next tuning resolution pushbutton. The 10 kHz resolution indicator should unlight. The frequency should tune in 1 MHz steps.
4. Press the most significant tuning resolution pushbutton. Only the most significant resolution indicator should remain lit. The frequency should tune in 100 MHz steps.
5. Press the HOLD pushbutton. The remaining tuning resolution indicator should unlight and the frequency should not change when the TUNING knob is turned. If everything is OK so far, the tuning circuits on this service sheet are OK. Otherwise, skip to step 9.
6. Set the rear panel REF switch to EXT. The INT REFERENCE OFF and NOT PHASE LOCKED lamps should light. Return the switch to INT.
7. Remote program the synthesizer to 40 GHz (out of range). The REMOTE and OUT OF RANGE lamps should light.
9830 9825
CMD "?U3", "P4Z1" or wrt 719, "P4Z1"
If everything is OK thru this step, the circuits on 12-A2 are OK.
8. Return the Synthesizer to local operation and press PRESET (3 GHz).

NOTE

When the Synthesizer is returned to local with an out of range frequency displayed, it will begin to search in 1 kHz steps until a legal frequency is reached. If one of the tuning resolution pushbuttons is pressed, the instrument will search in the resolution selected.

9. If the frequency tunes but one or more of the resolution lamps do not light, troubleshoot U1, the lamps and their drivers.
10. If the frequency display does not tune, the problem may be in any of several places including
 - A2A11 Timing and Control Board (8-A3)
 - Reference phase lock loop (1-A3)
 - Rotary Pulse Generator (13-A2)
 - Register 1 (7-A2)
 - Resolution Register (this service sheet).

8-806

SERVICE SHEET 12-A2 (Cont'd)

To check the resolution register, connect test point pair A2A11TP1 together with an alligator clip to continuously generate clock signals. Compare the signal at A2A1U9 pin 2 with CLK1 (clock 1) as each resolution button is pushed. U9 Pin 2 should go high along with the clock 1 cycle corresponding to the digit selected by a resolution button.

If these pulses are OK, the circuits on 12-A2 are OK.

If the pulses are not correct or not present, check A2A1U9 pin 10 for the presence of CLK1 before troubleshooting U5 and U9 and U6.

MNEMONICS

Mnemonic	Definition	Explanation
GO	Start data cycle	True when the RPG is turned, PRESET is pushed, or a new frequency is remote programmed.
ERRS	Error Store	An out of range frequency is stored in Data Register 1.
NLSDR	Not Least Significant Digit Range	True (low) indicates the 1 kHz RESOLUTION button was pressed.
± 1 BIT	Add now	Tells the ± 1 adder that the digit now at its input is the one selected by a RESOLUTION button.
CLK1	Clock 1	Nine pulse occurring during the first half of a data cycle. Each pulse corresponds to a frequency digit.

DEFINITION

Data Cycle — The process of cycling frequency data through the various registers and the ± 1 adder, usually for the purpose of changing frequency.

PRINCIPLES OF OPERATION

General

The front panel (A2A1) consists of the power switch, frequency controls and indicators, and status indicators.

This part of the A2A1 assembly contains the Frequency display circuits, the oven temperature comparator, the LINE (on-standby) switch, and the TUNING Rotary Pulse Generator (RPG).

P/O Front Panel Board Assembly

Decoder/display chips DS1 through DS8 display the Synthesizer's output frequency. The display is updated during the first half of each data cycle. As each digit, starting with 1 kHz, appears on the DR11 1-8 lines the strobe latch, U4, sequentially latches the display chips. U4 is clocked by CLK1 which is delayed by R23, C5, U8C and U8E. The delay allows for the data lines to settle.

The four-digits on the left (DS1-DS4) have leading zeros blanked by U3 and associated components. Blanking is done sequentially starting with DS1 but a display blanks only when the blanking input stays high thus insuring that only leading zeros are blanked. NOR gate U6B indicates zeros by outputting a high. This high is clocked through U3 by CLK1 (undelayed) and applied to DS1. When a non-zero digit appears at U6B, the low at the output is clocked through U3. At the next CLK1 pulse, U3 is reset by U2C.

The OVEN light comes on when the 10 MHz crystal oven is below normal temperature. An analog voltage inversely proportional to the temperature is applied to the inverting input of U7 by the OVEN MON line. When the voltage goes above 17V, the output swings negative turning on DS4 and putting a low on the OVN OK line.

The RPG outputs pulses on lines RPG1 and RPG2 when the TUNING knob is turned. Tuning direction is indicated by the phase relationship of the pulses. When the TUNING knob is turned clockwise RPG1 leads RPG2.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 3, and 10-A2 was used to isolate a Front Panel problem to the circuits shown on this schematic. The following information will aid in isolating the defective component:

Test Equipment

Digital Voltmeter HP 3455A

8-82a

SERVICE SHEET 13-A2 (Cont'd)

1. Press the PRESET (3 GHz) pushbutton. The display should indicate exactly 3000.000 MHz. If the display is correct, CLK1 is correct and all the display LED's are properly receiving data.

NOTE

A floating data input on an LED display will be interpreted and displayed as a logic high.

2. Set the frequency to 2345.678 MHz. Disconnect the 10 MHz clock signal (blue coax) from A3A1A1. Set tuning the resolution to 1 kHz. If the frequency cannot be changed, go to step 7.
3. Turn the TUNING knob clockwise.
4. With the manual clock switch on A2A11 generate clock pulses. The display should progress in this manner:

Clock Pulse	Display
1	99999.999
2	77777.779
3	66666.679
4	55555.679
5	44445.679
6	33345.679
7	22345.679
8	02345.679
9	2345.679

Generate nine (9) more clock pulses to complete the controller cycle. The display should not change during the latter nine pulses. If the data does not clock in properly, check the input data (DR11 1-8) with a logic analyzer or probe to assure it is correct. If the data is OK, troubleshoot U4, U3, and A2DS 1-8. If the data is incorrect, go to Service Sheet 9-A2 to continue troubleshooting.

5. Set the instrument to STANDBY. The STANDBY lamp should light.
6. Unplug the instrument for 1-2 minutes. Reconnect Mains. The OVEN and STANDBY lamps should both come on. If neither of them come on, suspect a burned out lamp (with the OVEN light A2A1U7 or the A3A8 Reference Oscillator could be defective). If everything is OK to this step, the A2A1 and A2A3 assemblies are OK.
7. Swing open the controller front panel (requires removal of four screws) to gain access to the outputs of the A2A2 Rotary Pulse Generator (RPG). Observe the outputs (RPG2 and RPG1) on an oscilloscope. When tuning clockwise the TTL pulses of RPG1 should occur before RPG2 pulses and when tuning counterclockwise RPG2 should occur before RPG1. If the pulses occur properly, the RPG is OK and troubleshooting should proceed to Service Sheet 8-A2.

8-82b

SERVICE SHEET 13-A2 (Cont'd)

MNEMONICS

Mnemonic	Definition	Explanation
CLK1	Clock 1	Nine pulses during the first half of the data cycle. Each pulse coincides with a frequency digit.

PRINCIPLES OF OPERATION

General

The Reference Loop locks the M/N Loop and 20/30 MHz (LFS) Loop to the Synthesizer's time base. Two reference signals, 20 and 400 MHz, are provided for the M/N Loop. The 10 MHz signal is the reference for the 20/30 MHz Loop. It also is the master clock for the controller's digital circuits.

The output of the 100 MHz VCXO is used to generate the reference signals and to phase lock the Reference Loop. The signal is multiplied by 4, to 400 MHz. It is also buffered and output to the rear panel's 100 MHz OUT connector. A portion of the 100 MHz is divided by 5 to 20 MHz. The 20 MHz signal is divided by two to 10 MHz. A portion of this signal is phase compared to the 10 MHz time base signal. The resulting error voltage tunes the VCXO to achieve phase lock.

A3A8 10 MHz Reference Oscillator

The oscillator's oven temperature is held constant by an internal heater control unit. This unit is powered by the +22V supply and therefore receives power any time the Synthesizer is connected to the line power. The OVEN MONITOR signal controls a front panel OVEN annunciator which indicates that the oscillator has not reached operating temperature. The oscillator's RF operation is controlled by the rear panel FREQUENCY STANDARD INT/EXT switch through the +11V switched supply voltage.

A3A1A1 Reference Phase Detector Assembly

Phase Lock Sampler. This circuit outputs a dc level which is proportional to the phase difference between its two input frequencies. The sampling signal comes from the 10 MHz Reference Oscillator Assembly. The sampled signal is derived by passing the 100 MHz VCO output through a divide-by-ten circuit.

The Sampling signal passes through the Limiting Amplifier. Here the output level is converted to TTL logic levels before being input to the Pulse Generator. U2D squares up the output of the Limiting Amplifier. The signal to U2A pin 2 and 3 is inverted and delayed by R11 and C5. The delay causes a narrow pulse at TP1. The Buffer Amplifier supplies sufficient current to drive Phase Lock Sampler diodes CR3 and CR4.

The feedback (sampled) signal from the 100 MHz VCXO is divided-by-ten, amplified, phase shifted +45° and coupled to the Phase Lock Sampler. The Phase Lock Sampler output (the input to the integrating amplifier) is proportional to the phase difference between the reference and feedback signal. (This has been purposely set to -8 Vdc when the loop is locked). The small error voltage that is present when the loop is locked is integrated, amplified and output to the 100 MHz VCXO as a TUNE VOLTAGE.

8-84a

SERVICE SHEET 1-A3 (Cont'd)

Lock Indicator Sampler. The operation of the Lock Indicator Sampler is similar to the Phase Lock Sampler. The only difference is that the feedback signal's phase at the Lock Indicator Sampler lags by 45° . The total difference in phase between the sampler inputs is 90° . This causes a maximum negative output from the Lock Indicator Sampler when the reference loop is locked. The Phase Lock Detector indicates the locked condition with a low output (about -0.7 Vdc).

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 2 was used to isolate a reference loop malfunction. The following information will allow further isolation to circuits shown by one of the two reference loop schematics 1-A3 or 2-A3. If the malfunction is on 1-A3, this information will also aid in isolating the defective component.

Test Equipment

Oscilloscope	HP 180C/1801A/1821A

Frequency Counter	HP 5340A

NOTE

The power meter and frequency counter are to be used in place of the spectrum analyzer where precise power and frequency measurements are required.

1. Connect the A3A1A2 TUNE test point to a -8 Vdc power supply. The counter should measure 100 MHz ± 100 Hz. If the signal is incorrect, go to Service Sheet 2-A3 to troubleshoot the VCXO. (The VCXO may only need to be adjusted.) Otherwise, continue with step 2.
2. Connect the Synthesizer to the line voltage. Set the LINE switch to ON and allow 15 minutes for warm-up. When the Synthesizer is first plugged in, the OVEN and NOT PHASE LOCKED lights should be on. The NOT PHASE LOCKED light will generally go out after 15 minutes when the crystal reference is 10 MHz ± 50 Hz. Make sure the rear panel reference jumper is installed, the FREQUENCY STANDARD INT/EXT switch is set to INT and the front panel RF switch is ON.
3. To test phase lock of the reference loop, connect an oscilloscope's vertical amplifier to the rear panel 10 MHz OUTPUT (A3J8). Insert a BNC tee between the FREQUENCY STANDARD output (A3J9) and the cable. Connect the open port to the oscilloscope's horizontal input. Obtain a lissajous pattern on the oscilloscope. If the loop is locked, a steady 1:1 pattern should be seen. Use a 50 ohm load on each line to reduce harmonic content. If the loop is locked proceed to Step 7. Otherwise continue with Step 4.
4. Measure the FREQUENCY STANDARD output at A3J9 with power meter and frequency counter. The signal should be 10 MHz ± 10 Hz at

8-84b

SERVICE SHEET 1-A3 (Cont'd)

0 dBm. Harmonic content is not particularly important for this signal. If this signal is not correct, check the A3A8 10 MHz Reference Oscillator for proper operation and calibration. Check the heater voltage (+22 Vdc). Also, check the +11V switched input which supplies power to the oscillator. (See Service Sheet 12-A3.)

5. Connect the 100 MHz TUNE test point A3A1A2TP1 to -8 Vdc from a low voltage power supply. This opens the loop and tunes the 100 MHz VCXO to approximately the correct frequency.
6. Measure the frequency of the 100 MHz OUT signal from A3A1A2. It should be 100 MHz about ± 100 Hz. If this signal is correct, continue with step 7. Otherwise go to Service Sheet 2-A3 and troubleshoot the A3A1A2 Assembly. Disconnect the clip lead from the 100 MHz TUNE and -8 Vdc.
7. Measure the voltage at the 100 MHz TUNE test point, A3A1A2TP1. It should be nominally -8 Vdc with a range between -5 Vdc and -20 Vdc. If the voltage is near nominal, continue with this procedure. Otherwise skip to step 11.
8. Measure the 10 MHz outputs of A3A1A1. The three outputs should deliver 0 dBm into a 50 ohm load at exactly 10 MHz.
9. Measure the 20 MHz output. It should deliver +3 dBm into a 50 ohm load at exactly 20 MHz.
10. Install A3A1A1 on an extender board and measure the voltage at edge connector pins 7 or 22. When the loop is locked the voltage should be -0.7 Vdc. Switch rear panel reference switch to external. The loop should unlock and the voltage should be +4.6 Vdc. If the voltages are correct then A3A1A1 is operating normally. Otherwise, troubleshoot the lock indicator circuitry.
11. Measure the signal at A3A1A1TP1 with an oscilloscope. It should be 3 volt pulses at a 10 MHz rate. If correct continue. Otherwise, troubleshoot the limiting amplifier pulse generator and reference oscillator.
12. Measure the signal at the junction of C27 and L3. It should be a 10 MHz sine wave at 3 Vp-p. If the loop is not phase locked, the frequency of this signal will be incorrect. If the signal is not present, troubleshoot the VCXO divider and the 45° Phase Lead and Buffer Amplifier. If the signal is present, continue.
13. Measure the signal at the base of Q4A. If the signals in steps 10 and 11 are at different frequencies, the difference between them (beat frequency) should be measureable here. If not present, troubleshoot the Phase Lock Sampler. If present, troubleshoot the Integrating Amplifier. If no problem is found continue troubleshooting on Service Sheet 2-A3.

NOTE

After repairing the A3A1A1 assembly, perform the Voltage Controlled Crystal Oscillator Adjustment in Section V. After replacing the A3A8 assembly, perform the 10 MHz Reference Oscillator Adjustment in Section V.

PRINCIPLES OF OPERATION

General

The Reference Loop locks the M/N Loop and 20/30 MHz (LFS) Loop to the Synthesizer's time base. Two reference signals, 20 and 400 MHz, are provided for the M/N Loop. The 10 MHz signal is the reference for the 20/30 MHz Loop. It also is the master clock for the controller's digital circuits.

The output of the 100 MHz VCXO is used to generate the reference signals and to phase lock the Reference Loop. The signal is multiplied by 4, to 400 MHz. It is also buffered and output to the rear panel's 100 MHz OUT connector. A portion of the 100 MHz is divided by 5 to 20 MHz. The 20 MHz signal is divided by two to 10 MHz. A portion of this signal is phase compared to the 10 MHz time base signal. The resulting error voltage tunes the VCXO to achieve phase lock.

A3A1A2 100 MHz VCXO Assembly

Oscillator. The heart of the Reference Phase Locked Loop is the 100 MHz voltage controlled crystal oscillator. The crystal which sets the frequency and the varactor diode which allows a small deviation are both found in the oscillator's feedback path. Diodes CR3 and CR4 are placed at the oscillator output and limit the output to ± 4 Vpk. The output is amplified and split by the tuned 100 MHz buffer. One output is connected back to the A3A1A1 Assembly where it is sampled by the phase detector circuits. The other output is coupled through a power splitter to the Quadrupler and another tuned 100 MHz amplifier.

Quadrupler. The Quadrupler is a Class C push-push amplifier. The output approximates a pulse and is rich in even harmonics. The amplifiers which follow are tuned to and therefore amplify the 400 MHz signal. The output level to the M/N loop is critical and is set by selecting the values of R67, R68 and R69 (50 Ω attenuator discrete resistors).

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 2 and 1-A3 was used to isolate a reference loop malfunction to the circuits shown on this schematic. The following information will aid in isolating the defective component.

8-86a

SERVICE SHEET 2-A3 (Cont'd)

Test Equipment

Digital Voltmeter	HP 3455A
Power Supply	HP 6202B
Spectrum Analyzer	HP 8555A/8552B/141T
Power Meter	HP 436A/8481A
Frequency Counter	HP 5340A

NOTE

The power meter and frequency counter may be used in place of the spectrum analyzer and vice versa.

1. Connect the TUNE test point A3A1A2TP1 to -8 Vdc from a low voltage power supply.
2. Measure the 400 MHz output with a spectrum analyzer or power meter and frequency counter. It should be -10 to -11 dBm at $400 \pm .004$ MHz (with the loop locked it should be exactly 400 MHz). If the frequency or level is incorrect, perform the Voltage Controlled Crystal Oscillator (VCXO) Adjustment in Section V.
3. Measure the rear panel 100 MHz output. It should be 0 dBm at precisely one fourth the frequency measured in step 2. If correct continue with step 4. Otherwise troubleshoot Q6 and its associated components.
4. Measure the remaining two 100 MHz outputs from A3A1A2. They should both deliver 0 dBm.
5. Ground the TUNE test point. Verify that the VCXO is oscillating at less than 100 MHz.
6. Connect the TUNE test point to -25 Vdc from a low voltage power supply. Verify that the VCXO frequency is greater than 100 MHz. If the results of steps 5 and 6 are not correct, a change in the value of A3A1A2L4 may be needed. See the VCXO adjustment procedure in Section V.
7. If the results of steps 2 through 6 are correct, A3A1A2 is working properly. If there are no outputs, check power supply inputs and troubleshoot the 100 MHz oscillator or buffer (Q5, Q8 and Q9 and associated components). If some outputs are correct, refer to the schematic and continue troubleshooting.

NOTE

After repairing the A3A1A2 assembly, perform the Voltage Controlled Crystal Oscillator Adjustment in Section V.

PRINCIPLES OF OPERATION

M/N Phase Lock Loop

The frequency output of the M/N loop 1) is dependent on the front panel frequency and 2) in part, controls the YTO output frequency. A digital equivalent (dependent on the front panel frequency's most significant digits 10 MHz to 10 GHz) is input to the M/N loop as M and N numbers. The ratio of the M and N numbers actually determine the M/N OUT frequency. The M/N OUT frequency's Nth harmonic (based on the N number and selected by the YTO pretuning) tunes the YTO frequency in 10 MHz steps. There is a 10 MHz step (or band) for each valid M/N OUT frequency (M/N ratio) and Nth harmonic (N number). This 10 MHz band complements the 20/30 MHz loop because its tuning range is 10 MHz and step size is 1 kHz. Together, the M/N Loop, YTO pretuning and 20/30 MHz Loop are able to tune the YTO from 2000.000 to 6199.999 MHz in 1 kHz steps.

The M/N loop provides a tunable phase locked reference signal for the YIG Tuned Oscillator (the Synthesizer's microwave signal source). The M/N Out frequency (177.5 to 197.5 MHz) is obtained by dividing the M/N VCO signal (355-395 MHz) by two. The M/N IF signal (5-45 MHz) is the lower mixing sideband of the VCO signal and the 400 MHz reference. The M/N loop is phase locked by comparing a fraction of 20 MHz (20 MHz divided by the N number) to a fraction of the IF signal (5 to 45 MHz divided by the M number) in the phase detector. The phase detector generates an error voltage that is integrated and coupled to the VCO as a tuning signal. The M and N numbers are determined by the A2 controller and vary with the 10 MHz steps of the YTO frequency. The M/N Out frequency is dependent on the ratio of the M and N numbers as expressed in the following formula:

$$f_{M/N} = [200 - 10 (M/N)] \text{ MHz}$$

where $f_{M/N}$ = M/N Out frequency

M = M number

N = N number

For example, if the ratio is 1-to-1 (M=N) then $f_{M/N} = 190.0000$ MHz. If the ratio is 1-to-2 (M=2N) then $f_{M/N} = 195.000$ MHz. Refer to Table 8-5, M and N Numbers and Resulting Frequencies for a complete list.

A3A1A3 M/N Phase Detector Assembly

M and N Dividers. The Phase Detector Assembly's M and N Dividers are essentially identical in operation. In each case the input frequency is divided by the divide number (a binary coded number input from the A2 Controller Assembly). The resulting output pulses are frequency and phase compared to produce an error voltage which ultimately tunes the M/N VCO. The following formulas show the frequency relationship of the inputs and outputs of the dividers:

$$f_N = \left(\frac{1}{N}\right) 20 \text{ MHz}$$

$$f_N = \left(\frac{1}{N}\right) f_{IF}$$

SERVICE SHEET 3-A3 (Cont'd)

where f_N = N Divider Output pulse repetition frequency (PRF)
(MHz).

f_M = M Divider Output PRF (MHz).

N = N Divide Number

M = M Divide Number

f_{IF} = M Divider Clock frequency (MHz)

20 MHz = N Divider Clock frequency

$f_N = f_M$ when the loop is phase locked

therefore $\left(\frac{4}{N}\right) 20 \text{ MHz} = \left(\frac{4}{M}\right) f_{IF}$

and $f_{IF} = \left[\left(\frac{M}{N}\right) 20\right]$ MHz for the phase locked condition.

Because of the similarities of the M and N Dividers, only the N Divider will be described in detail.

N Divider Operation. The divider circuit is clocked by a pulse train derived from the input frequency (in this case the 20 MHz reference signal). The divider outputs 4 pulses for each sequence of clock pulses which add up to the N number. In other words, a pulse is output for each N/4 or N/4 + 1 clock pulses. If dividing the N number by 4 leaves no remainder, the number of clock pulses between output pulses is determined solely by N/4. If there is a remainder, the number of clock pulses between outputs is determined by N/4 and N/4 + 1 where N/4 + 1 replaces N/4 once for each unit in the remainder. For example, if N = 16, then N/4 = 16/4 = 4 with a remainder R=0. An output pulse occurs for each 4 clock pulses. If N = 19, then N/4 = 19/4 = 4 with R=3. An output pulse occurs once with a spacing of 4 clock pulses and three times with a spacing of 5 clock pulses.

a. **Counting Operation and Control.** Refer to the schematic block diagram and the following figure and table entitled Divider Operation, and consider the example of N=16. At the beginning of a divide sequence (clock 1), the 4 most significant bits (MSB) of the N number (0100) are loaded into the programmable counter. Clock 2 subtracts 4 (0001) from the previous total leaving (0011) Clock 3 subtracts 4 more and the 0010 output enables the End of Count Decoder. At Clock 4, the Count Control and Output Flip-Flops are set. The Count Control outputs 1) inhibit the End of Count Decoder 2) cause the Programmable Counter to enter its load mode and 3) clocks the Divider Flip-Flops. The Output Flip-Flop outputs a high to the Phase/Frequency Detector. Clock 5 resets the flip-flops and loads the counter. This series of events repeats itself 3 more times for the N=16 sequence.

b. **Increment Decoder Operation.** The Increment Decoder and Divider (divide-by-four) circuits come into play if the N number cannot be divided by 4 evenly. The 2 least significant bits (LSB) of the N number (N2 and N1) control the output of the Increment Decoder. The divide-by-four circuit provides a sequence of four sequential states, that are input to the Increment Decoder. Each state coincides with one of the four count down sequences whose length is characterized by N/4 or N/4 + 1. Refer to the table entitled Increment Decoder Operation. Note that for the N=16 sequence, N2=N1=0. As explained in Counting Operation and Control, the Increment Decoder Output Sequence (TP6) never leaves the low state and the count down sequences are N/4. For N=19 (N2=N1=1) the first output is low with the remaining three high. This means that the first pulse occurs after N/4 clock pulses and the other three occur after N/4+1 pulses. During the final three count down sequences, the high at the Increment Decoder Output inhibits U11B allowing the counter to count down to 0001 (rather than 0010) before the End of Count Decoder is enabled through

8-886

SERVICE SHEET 3-A3 (Cont'd)

U11A. This allows the extra count to occur. The rest of the sequence occurs as indicated in the previous section. See also the table and figure entitled Divider Operation for N=19.

Divide-by-1 or 2 Operation. With the N input equal to or greater than 16, the N5 or N6 inputs are high and the Divide-by-1 or 2 Decoder is enabled. Thus the Output Flip-Flop follows the Count Control Flip-Flop and each End of Count pulse is passed directly to the output. If $N < 16$, then the Divide-by-1 or 2 Decoder is enabled and therefore passes only every other End of Count pulse to set the Output Flip-Flop. (Refer to the table entitled Divider Operation and the figure entitled Divider Clock Pulses versus Output Pulses). This circuit reduces the apparent gain of the Phase/Frequency Detector. This keeps the $\Delta F_{VCO} / \Delta V$ sensitivity of the VCO in a specific portion of its tuning curve thereby keeping the M/N loop bandwidth constant. Note that the N5 and N6 inputs are also connected to the M-Divider in the same manner as in the N Divider. Note also that the frequency of the M and N Divider Outputs is halved for $N < 16$.

Divider Clock Pulses Versus Output Pulses Frequency and Time Relationships

Divider Operation

8-88C

SERVICE SHEET 3-A3 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 2, and 5-A3 was used to isolate a M/N Loop malfunction to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Frequency Counter HP 5340A
Digital Voltmeter HP 3490A

1. Press the PRESET (3 GHz) pushbutton.
2. Observe the M/N loop lock indicator on A2A7. The lamp should be on. If the lamp is not on continue with this procedure. If the lamp is on, perform the next two steps to confirm correct loop operation.
3. Connect the frequency counter to the M/N loop output on A3A1A5. Use a common time base for this measurement. The frequency should be 189.375 000 MHz.
4. Check the following frequencies (the extremes of the M/N loop)

RF Output Frequency	M/N Loop Output
2100 MHz	177.500 000 MHz
6090 MHz	197.419 355 MHz

If the frequencies are correct, the loop has adequate tuning range and is probably operating correctly.

5. Measure the signal at A3A1A3TP1 with the Synthesizer set to 6100 MHz. The signal should be 20 MHz divided by 4/N (N=32 at 6100 MHz) or exactly 2.50 MHz at ECL levels. (Refer to Schematic Notes.)
6. Tune the Synthesizer to 2900 MHz. The signal at TP1 should be 5.0 MHz (N=16).
7. Tune to 2700 MHz. The signal at TP1 should be 2.666 666 MHz (2/N x 20 MHz; N=15). If steps 6, 7 and 8 were correct, The N-divider is working properly and the N-decoder in the controller is operating properly. Otherwise, check the input data and, if necessary, troubleshoot the divider.
8. Connect the IF IN white-red coax to the 20 MHz reference signal in place of the gray-white coax. This connects a known (20 MHz) signal to the M-divider. Tune to 3010 MHz and measure the frequency at TP4. It should be 5.0 MHz.
9. Tune to 2820 MHz (M=15). The frequency at TP4 should be 2.666 666 MHz. If steps 9 and 10 are correct the M-divider is working properly and the M-decoder in the controller is operating properly.
10. Reconnect the IF and 20 MHz inputs. Tune to 2800 MHz. Connect the voltmeter to A3A1A5 TUNE test point. The voltage should be about -4 Vdc. Tune to 3010 MHz. The voltage should change to about -26.2 Vdc. If these voltages are approximately correct, the Phase Detector Assembly is operating correctly.

NOTE

After repairing the A3A1A3 assembly, perform the M/N Loop Adjustments in Section V.

8-88d

PRINCIPLES OF OPERATION

M/N Phase Lock Loop

The frequency output of the M/N loop 1) is dependent on the front panel frequency and 2) in part, controls the YTO output frequency. A digital equivalent (dependent on the front panel frequency's most significant digits, 10 MHz to 10 GHz) is input to the M/N loop as M and N numbers. The ratio of the M and N numbers actually determine the M/N OUT frequency. The M/N OUT frequency's Nth harmonic (based on the N number and selected by the YTO pretuning) tunes the YTO frequency in 10 MHz steps. There is a 10 MHz step (or band) for each valid M/N OUT frequency (M/N ratio) and Nth harmonic (N number). This 10 MHz band complements the 20/30 MHz loop because its tuning range is 10 MHz and step size is 1 kHz. Together, the M/N Loop, YTO pretuning and 20/30 MHz Loop are able to tune the YTO from 2000.000 to 6199.999 MHz in 1 kHz steps.

The M/N loop provides a tunable phase locked reference signal for the YIG Tuned Oscillator (the Synthesizer's microwave signal source). The M/N Out frequency (177.5 to 197.5 MHz) is obtained by dividing the M/N VCO signal (355-395 MHz) by two. The M/N IF signal (5-45 MHz) is the lower mixing sideband of the VCO signal and the 400 MHz reference. The M/N loop is phase locked by comparing a subharmonic (fraction) of 20 MHz (20 MHz divided by the N number) to a subharmonic (fraction) of the IF signal (5 to 45 MHz divided by the M number) in the phase detector. The phase detector generates an error voltage that is integrated and coupled to the VCO as a tuning signal. The M and N numbers are determined by the A2 controller and vary with the 10 MHz steps of the YTO frequency. The M/N VCO frequency is dependent on the ratio of the M and N numbers as expressed in the following formula:

$$f_{M/N \text{ VCO}} = [400 - 20 (M/N)] \text{ MHz}$$

where $f_{M/N}$ = M/N OUT frequency

M = M number

N = N number

For example, if the ratio is 1-to-1 (M=N) then $f_{M/N \text{ VCO}} = 380.000$ MHz. If the ratio is 1-to-2 (M=2N) then $f_{M/N \text{ VCO}} = 390.000$ MHz.

8-90a

SERVICE SHEET 4-A3 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 2 and 5-A3 was used to isolate a M/N loop malfunction to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Power Supply HP 6202B
Spectrum Analyzer HP 8555A/8552B/141T
High Impedance Spectrum Analyzer Probe HP 1121A
Digital Voltmeter HP 3455A

1. Install A3A1A4/A5 on an extender board.

CAUTION

Do not apply a positive voltage to A3A1A4TP1. A positive voltage will forward bias the VCO tuning diodes and may destroy them.

2. Connect the positive output of a low voltage power supply to chassis ground. Connect the negative output to A3A1A4TP1 TUNE test point. Connect the white M/N VCO OUT cable to the spectrum analyzer.
3. Set power supply to -35.0 ± 0.5 Vdc. The M/N VCO output should be about 395 MHz at 0 ± 1 dBm.
4. Slowly reduce the voltage to -2 Vdc while monitoring the VCO power output and frequency. The power should remain greater than -1 dBm over the entire frequency span. At -2 Vdc the frequency should be about 355 MHz. See troubleshooting data in the table for some typical voltages and frequencies. If the frequency varies properly at the correct power level A3A1A4 is working properly.
5. If the output level and frequency are not correct, perform the M/N loop adjustment procedure in Section V, before troubleshooting. If adjustment doesn't solve the problem continue with this procedure.
6. Measure the -40 V power supply line as it enters A3A1A4. It should measure between -39 and -40.6 Vdc. If incorrect, turn to Service Sheet 13-A3 and continue troubleshooting.
7. Measure the bias voltages on Q2 as shown on the schematic. If correct, continue with this procedure. Otherwise troubleshoot Q2 and its associated components (Negative Resistance Oscillator). When measured with a high impedance probe, the power level at the emitter of Q2 should be approximately 0 dBm.
8. Measure the voltage at the pin labeled TUN. This should be the same voltage applied to A3A1A4TP1 TUNE test point.

8-90b

SERVICE SHEET 4-A3 (Cont'd)

9. Measure the RF voltage at Q1 base. Use the HP Model 1121A high impedance spectrum analyzer probe or high frequency oscilloscope to avoid disturbing signal level.
10. If the results of steps 7 and 8 are correct and the output from the oscillator is missing or too low, the A3A1A4A1 VCO Resonator assembly is probably defective and should be replaced with a new A3A1A4 assembly. Recheck the adjustment of A3A1A4A1C5 before ordering a new assembly.
11. If the RF voltage at the base of Q1 is correct, check the dc bias voltages on Q1 to determine why the output isn't correct.

VCO Tune Voltage and Frequency

TUNE Voltage (TP1)	Frequency
-35.0 Vdc	395.0 MHz
-10.0 Vdc	375.0 MHz
-5.2 Vdc	365.0 MHz
-2.2 Vdc	355.0 MHz

NOTE

After repairing the A3A1A4 Assembly, perform the M/N Loop Adjustments in Section V.

PRINCIPLES OF OPERATION

M/N Phase Lock Loop

The frequency output of the M/N loop 1) is dependent on the front panel frequency and 2) in part, controls the YTO output frequency. A digital equivalent (dependent on the front panel frequency's most significant digits; 10 MHz to 10 GHz) is input to the M/N loop as M and N numbers. The ratio of the M and N numbers actually determine the M/N OUT frequency. The M/N OUT frequency's Nth harmonic (based on the N number and selected by the YTO pretuning) tunes the YTO frequency in 10 MHz steps. There is a 10 MHz step (or band) for each valid M/N OUT frequency (M/N ratio) and Nth harmonic (N number). This 10 MHz band complements the 20/30 MHz loop because its tuning range is 10 MHz and step size is 1 kHz. Together, the M/N Loop, YTO pretuning and 20/30 MHz Loop are able to tune the YTO from 2000.000 to 6199.999 MHz in 1 kHz steps.

The M/N loop provides a tunable phase locked reference signal for the YIG Tuned Oscillator (the Synthesizer's microwave signal source). The M/N Out frequency (177.5–197.5 MHz) is obtained by dividing the M/N VCO signal (355–395 MHz) by two. The M/N IF signal (5–45 MHz) is the lower mixing sideband of the VCO signal and the 400 MHz reference. The M/N loop is phase locked by comparing a fraction of 20 MHz (20 MHz divided by the N number) to a fraction of the IF signal (5 to 45 MHz divided by the M number) in the phase detector. The phase detector generates an error voltage that is integrated and input to the VCO as the VCO TUNE signal. The M and N numbers are determined by the A2 controller and vary with the 10 MHz steps of the YTO frequency. The M/N Out frequency is dependent on the ratio of the M and N numbers as expressed in the following formula:

$$f_{M/N} = [200 - 10 (M/N)] \text{ MHz}$$

where $f_{M/N}$ = M/N OUT frequency

M = M number

N = N number

For example, if the ratio is 1-to-1 (M=N) then $f_{M/N} = 190.000$ MHz. If the ratio is 1-to-2 (M=2N) then $f_{M/N} = 195.000$ MHz. Refer to Table 8-5, M and N Numbers and Resulting Frequencies for a complete listing.

8-92a

SERVICE SHEET 5-A3 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information found on Service Sheets 1 and 2 was used to isolate a M/N loop malfunction. The following information will allow further isolation to circuits shown by one of the three M/N loop schematics 3-A3, 4-A3 or 5-A3. If the malfunction is on 5-A3, this information will also aid in isolating the defective component.

Test Equipment

Spectrum Analyzer HP 8555A/8552B/141T
Digital Voltmeter HP 3455A
Oscilloscope HP 180A/1801A/1821A

1. Turn the LINE switch OFF and install A3A1A5 on an extender board. Connect A3A4TP5 -5.2V to the A3A1A4TP1 TUNE test point. Measure the output of the M/N VCO to assure it is about 365 MHz at 0 dBm. If it is not correct turn to Service Sheet 4-A3 and continue troubleshooting. Otherwise continue with this procedure. (Be sure to reconnect the white coax).
2. Measure the IF OUT frequency and power. It should be 400 MHz minus the frequency measured in step 1 (about 35 MHz) at 0 dBm.
3. Measure M/N OUT frequency and power. It should be about 182.5 MHz at +3 dBm. If the results of both steps 2 and 3 are correct, proceed to step 8.
4. If step 2 results were correct but step 3 results were incorrect, troubleshoot the Divider Preamplifier, Divider and the Output Amplifier using the voltages on the schematic.
5. If the results of both steps 2 and 3 are incorrect, check the power supply voltages and input components on the M/N VCO IN line.
6. If the results of step 2 are incorrect and the step 3 results are correct, check the 400 MHz IN line. If correct, proceed with step 7. Otherwise turn to Service Sheet 2-A3 and continue troubleshooting.
7. Remove the .RFI shield top cover and measure the RF voltage at the output of mixer U1 (the junction of C8 and L4) with an oscilloscope. There should be 0.07 Vp-p. If this signal is correct, troubleshoot the IF Amplifier. Otherwise troubleshoot the Mixer Amplifier and the mixer. Note that the LO input should be 1 Vp-p and the RF input 200 mVp-p.
8. Measure the VCO Tune voltage at the edge connector pin 1 and at the yellow wire leading to A3A1A4. If the measured voltages are different, remove the circuit board. Measure the resistance from A3A1A4TP1 TUNE to the edge connector pin 1. It should be 4.16K ohms. If the resistance is correct the tune filter is probably not defective. Resistance to ground should be almost infinite after A3A1A4A2C11 is charged.

NOTE

After the A3A1A5 Assembly is repaired, perform the M/N Loop Adjustments in Section V.

PRINCIPLES OF OPERATION

YTO Phase Lock Loop

The Yig Tuned Oscillator's frequency output is phase locked 1) to the difference of the YTO frequency and a selected harmonic of the M/N loop and 2) to the 20/30 MHz loop. The YTO is tuned near the correct harmonic of the M/N Output frequency by the YTO pretune circuits which consist of the DAC (Digital-to-Analog Converter) and the Main Coil Driver. Once the pretuning is completed, the IF signal (20/30 MHz) from the YTO Loop Sampler is phase compared to the 20/30 MHz Loop signal and the resulting error signal tunes the YTO to achieve phase lock. The YTO frequency is related to the M/N Out frequency and the 20/30 loop frequency in the following manner:

$$f_o = (N) (f_{M/N} - f_{20/30})$$

where f_o = YTO output frequency (MHz)

N = N number input to M/N loop (also the M/N loop harmonic near to which the YTO loop is pretuned)

$f_{M/N}$ = M/N loop output frequency (MHz)

$f_{20/30}$ = 20/30 loop output frequency (MHz)

f_{YTO} , N and $f_{M/N}$ OUT may be looked up on Table 8-5, M and N numbers and Resulting Frequencies.

Also, $f_{20/30} = (30.000 - D_4 \cdot D_3 \cdot D_2 \cdot D_1) \text{ MHz}$

where D_4 = Front panel 1 MHz character

D_3 = front panel 100 kHz character

D_2 = front panel 10 kHz character

D_1 = front panel 1 kHz character

for YTO frequencies less than 6200 MHz. Refer to the Service Sheet 2 for a complete listing of pertinent formulas.

YTO Loop Pretune

The digital control inputs to the DAC from the A2 Controller Assembly select the pretuned frequency. These inputs are first

8-94a

SERVICE SHEET 6-A3 (Cont'd)

converted from a digital signal to an analog dc voltage (the YTO Pretune signal). This signal is amplified (in the Main Coil Driver) and output as a tuning current to the YTO. Notice that the input tuning resolution to the DAC is 1 MHz. If the YTO frequency is within ± 10 MHz of the desired frequency (for frequencies < 6.2 GHz) then the pretune circuits are operating properly. Pretuning, however, does normally bring to YTO frequency to within 1 or 2 MHz of the desired YTO frequency.

NOTE

In order to check the pretuning, the YTO loop must be opened. Refer to the YTO pretune troubleshooting information on Service Sheet 2.

A3A5 DAC (Digital-to-Analog Converter) Assembly

The digital inputs to the DAC are in a BCD and binary format. These inputs, (operating through the open-collector buffers) switch the diodes on-or-off. When on, current flows through the resistor, the diode and into the current summing node. The resistor value is selected so the current flow is proportional to binary or BCD weighting of the control input. The total current flow to the major summing node (at the input to the Summing and Buffer Amplifier) is proportional to the frequency as dictated by the digital inputs (0.5 mA/GHz). The amplifier with a gain of -6.000 V/ma converts this summed current to a voltage (-3.000 V/GHz). Note that the Summing and Output Buffer Amplifier also has components (R59 and C12) which speed up the action of the amplifier during a frequency change.

Current Summing. The least significant bits of the DAC inputs are summed in a node with 75 mA/GHz sensitivity. Upon dividing this current by 10, it is summed with those mid-range bits at 7.5 mA/GHz. This current is also divided (by 15) and summed with the most significant bits at 0.5 mA/GHz. Note that a 0.8 mA offset current equivalent to 1.6 GHz and used in adjusting the DAC is also summed at the major summing node.

Reference Amplifiers. The Reference Current Source generates a temperature stabilized constant current for VR1 via R6. The Reference Buffer U1B isolates VR1 and provides a stable but adjustable voltage reference for the rest of the circuits. This voltage is further buffered by Reference Buffers U3 and U4.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 2, and 7-A3 was used to isolate a power supply malfunction to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A

8-94b

SERVICE SHEET 6-A3 (Cont'd)

NOTE

An accurate digital voltmeter is essential for troubleshooting the Digital-to-Analog Converter (DAC). The voltmeter must be capable of measuring -18 Vdc with a minimum resolution of 1 mV (0.1 mV resolution is preferred).

1. Connect the DVM to A3A5TP4. The voltage should be -6.50 ± 0.06 Vdc. If it is not within tolerance, perform the complete DAC adjustment procedure in Section V before continuing. If the voltage can be adjusted within tolerance, proceed to step 4.
2. Measure the power supply inputs to the circuit board at pins 1, 2, 3, and 4. If correct, continue with step 3. Otherwise troubleshoot the power supply boards (A3A2, A3A3, and A3A4).
3. Measure the voltage at emitter Q1. It should be -20.9 Vdc. If correct, troubleshoot the Bias Buffer Amplifier. Otherwise, troubleshoot the Bias amplifier.
4. Measure the voltages at A3A5TP1 (+11 Vdc) and A3A5TP2 (+10 Vdc). If both are correct continue. Otherwise, troubleshoot the appropriate Reference Buffer amplifier (U3 or U4).
5. Tune the Synthesizer to 2000 MHz. Connect the DVM to A3A5TP3. The voltage should be -6.000 ± 0.001 Vdc. If voltage is not correct, perform the DAC adjustment procedure. If the voltage can be adjusted within the tolerance, skip to step 8. Otherwise, continue with step 6.
6. Measure the voltages at U7 pins 9 and 4. Both should be 0.6V (high). Pins 1, 8 and 12 should be 0 Vdc. If correct, proceed to step 7. Otherwise, troubleshoot U10, U7 and their associated components.
7. Measure the voltage at the base of Q5A. It should be very nearly 0 Vdc (a virtual ground). If correct, the Summing and Output Buffer Amplifier is properly balanced and is probably working correctly (proceed to step 8). Otherwise, tune to 3000 MHz and troubleshoot the amplifier by using the voltages on the schematic.
8. Tune to the frequencies as shown in the following table. As before, compare the DVM reading to the voltages in the table.

Frequency	Voltage at A3A5TP3
2200 MHz	-6.600 ± 0.001 Vdc
2800 MHz	-8.400 ± 0.001 Vdc
3200 MHz	-9.600 ± 0.001 Vdc
3600 MHz	-10.800 ± 0.001 Vdc
4800 MHz	-14.400 ± 0.001 Vdc

8-94c

SERVICE SHEET 6-A3 (Cont'd)

If all the voltages are correct, continue with this procedure. Otherwise, troubleshoot U10, U7, U4, Q4, and their associated components.

9. Tune the frequencies as shown in the following table. Compare the DVM reading to the voltages in the table.

Frequency	Voltage at A3A5TP3
2020 MHz	-6.060 \pm 0.001 Vdc
2040 MHz	-6.120 \pm 0.001 Vdc
2080 MHz	-6.240 \pm 0.001 Vdc
2100 MHz	-6.300 \pm 0.001 Vdc

If all voltages are correct continue with this procedure. Otherwise, perform the DAC adjustments. If the voltages cannot be adjusted within tolerance, troubleshoot U9, U6, Q3, and their associated components.

10. Tune the Synthesizer to the frequencies as shown in the following table and measure the voltages at A3A5TP3.

Frequency	Voltage at A3A5TP3
2001 MHz	-6.003 \pm 0.001 Vdc
2002 MHz	-6.006 \pm 0.001 Vdc
2004 MHz	-6.012 \pm 0.001 Vdc
2008 MHz	-6.024 \pm 0.001 Vdc
2010 MHz	-6.030 \pm 0.001 Vdc

If the voltages are correct, the DAC is working properly. If necessary, perform the DAC adjustment procedure. Otherwise, troubleshoot U5, U8, Q2, and their associated components.

NOTE

After the A3A5 assembly has been repaired, perform the Digital-to-Analog Converter Adjustments in Section V.

PRINCIPLES OF OPERATION

YTO Phase Lock Loop

The Yig Tuned Oscillator's frequency output is phase locked 1) to the difference of the YTO frequency and a selected harmonic of the M/N loop and 2) to the 20/30 MHz loop.

The YTO is tuned near the correct harmonic of the M/N Output frequency by the YTO pretune circuits which consist of the DAC (Digital-to-Analog Converter) and the Main Coil Driver. Once the pretuning is completed, the IF signal (20/30 MHz) from the YTO Loop Sampler is phase compared to the 20/30 MHz Loop signal and the resulting error signal tunes the YTO to achieve phase lock. The YTO frequency is related to the M/N Out frequency and the 20/30 loop frequency in the following manner:

$$f_o = (N) (f_{M/N} - f_{20/30})$$

where f_o = YTO output frequency (MHz)

N = N number input to M/N loop (also the M/N loop harmonic near to which the YTO loop is pretuned)

$f_{M/N}$ = M/N loop output frequency (MHz)

$f_{20/30}$ = 20/30 loop output frequency (MHz)

f_{YTO} , N and $f_{M/N}$ OUT may be looked up on Table 8-5, M and N Numbers and Resulting Frequencies.

Also, $f_{20/30} = (30.000 - D_4 \cdot D_3 \cdot D_2 \cdot D_1)$ MHz

where D_4 = front panel 1 MHz character

D_3 = front panel 100 kHz character

D_2 = front panel 10 kHz character

D_1 = front panel 1 kHz character

for YTO frequencies less than 6200 MHz. Refer to the Service Sheet 2 text for a complete listing of pertinent formulas.

8-96a

SERVICE SHEET 7-A3 (Cont'd)

YTO Loop Pretune

The digital control inputs to the DAC from the A2 Controller Assembly select the pretuned frequency. These inputs are first converted from a digital signal to an analog dc voltage (the YTO pretune signal). This signal is amplified (in the Main Coil Driver) and output as a tuning current to the YTO. Notice that the input tuning resolution to the DAC is 1 MHz. If the YTO frequency is within ± 10 MHz of the desired frequency (for frequencies < 6.2 GHz) then the pretune circuits are operating properly. Pretuning, however, does normally bring the YTO frequency to within 1 or 2 MHz of the desired YTO frequency.

NOTE

In order to check the pretuning, the YTO loop must be opened. Refer to the YTO pretune troubleshooting information on Service Sheet 2.

A3A6 YTO Driver Assembly

The YTO Driver Assembly produces a current in the YTO main coil that is proportional to the sum of the YTO Pretune (DAC output), the YTO TUNE 2 (the low frequency component of the YTO TUNE 1), and an offset voltage.

Coil Driver. The Coil Driver acts in two primary capacities. It provides a summing point for the input currents and it outputs a current to the YTO main coil. It is important to realize that the Coil Driver current flow is supplied through the Sense Resistor (This current is dependent upon the YTO Pretune voltage input) and from the Phase Lock Amplifier. The currents are summed at the Coil Driver's non-inverting output. The total current flows into the non-inverting input and out the inverting output as the YTO Main Coil Drive.

Input Amplifier. The YTO Pretune Voltage is amplified by the Input Amplifier (a discrete component operational amplifier). The output voltage appears at the Coil Driver's non-inverting output and therefore across the Sense Resistor. A portion of this voltage is returned to the Input Amplifier's inverting input. This return voltage is adjustable and allows for variation in the frequency-to-voltage sensitivity of Yig Tuned Oscillators. Refer to the following figure.

The Shaping Network (connected across the Sense Resistor) compensates for the non-linearity of the YTO frequency-to-voltage curve.

NOTE

The YTO Main Coil Drive current contributed by the Input Amplifier is equal to the YTO Pretune voltage divided by the sum of R16 (125Ω) and that portion of R24 (15Ω) that supplies the feedback voltage to the Input Amplifier through R25. The remaining summed current flows through R30.

SERVICE SHEET 7-A3 (Cont'd)

The dominant pole of this amplifier (at 0.8 Hz) is set by R11 and C7. They also provide noise filtering. Q8 and Q12 increase the slew rate of the amplifier by quickly charging or discharging C7 when large change occurs. The current limiter, Q13 protects its associated components by removing the drive voltage from Q12 if the current is excessive.

Phase Lock Amplifier. The YTO Tune 2 and Offset voltages are summed in the Phase Lock Amplifier. The YTO Tune 2 is the low frequency component of the YTO tuning voltage (YTO Tune 1). The 100 Hz low pass filter removes the high frequency components of the tuning voltage. The offset voltage is adjusted at 2 GHz (2 GHz Adj) so the YTO Frequency extrapolated to 0 GHz is 0 volts. (Refer to the following figure.)

YTO Frequency versus Coil Drive Current

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 2 was used to isolate a YTO pretune malfunction. The following information will allow further isolation to circuits shown by one of the two YTO pretune schematics 6-A3 or 7-A3. If the malfunction is on 7-A3, this information will also aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
Frequency Counter HP 5340A

1. Tune the Synthesizer to 2000 MHz. Measure the voltage at the edge connector XA3A6 pin 13. It should be -6.000 ± 0.001 Vdc. If correct, proceed to step 2. Otherwise, turn to Service Sheet 6-A3 and continue troubleshooting.

8-96c

SERVICE SHEET 7-A3 (Cont'd)

2. Ground A3A7TP2 to open the YTO loop.
3. Measure the voltage at A3A6TP2. It should be about -37.5 Vdc. Increase the frequency to 6199 MHz. The voltage at TP2 should drop to -32.5 Vdc. If the voltages are correct, proceed to step 6.
4. Set the frequency to 3000 MHz. Measure the voltage at the emitter of Q5. It should be -9.3 Vdc. If voltage is correct, use the voltages on schematic to troubleshoot the Coil Driver, Slewing Detector and the Coil Damping Network. Otherwise continue with step 5.
5. Measure the voltages at the inputs to the Input Amplifier. Compare them to the output voltage (measured at the emitter of Q8 and Q12. Since the Input Amplifier is a discrete operational amplifier, we can determine if the voltage change at the output follows the inputs. If the change does not follow the input, measure the voltages inside the amplifier to determine where the change occurs. If the output polarity follows the input polarity, measure voltages in the feedback path to find the defective component.
6. Remove the ground from A3A7TP2. Measure the voltage at A3A6TP1 and compare it to the voltage at A3A6TP4. $V_{TP4} = 2.9 + 0.64 (V_{TP1})$. If the voltage is correct, the phase lock amplifier is operating properly. Proceed to step 7. Otherwise, troubleshoot the Offset Reference and Phase Lock Amplifier.
7. Connect A3A7TP2 to ground. Connect the frequency counter to the RF OUTPUT connector. Tune to 2000 MHz. The counter should indicate 2000.0 ± 1.0 MHz. Tune to 6199 MHz. The counter should indicate 6199.0 ± 1.0 MHz. If the frequencies are correct, A3A6 is operating normally. Otherwise, perform the YTO Driver Adjustment in Section V.

NOTE

After the A3A6 assembly is repaired, perform the YTO Driver Adjustment in Section V.

PRINCIPLES OF OPERATION

YTO Phase Lock Loop

The Yig Tuned Oscillator's frequency output is phase locked 1) to the difference of the YTO frequency and a selected harmonic of the M/N loop and 2) to the 20/30 MHz loop. The YTO is tuned near the correct harmonic of the M/N Output frequency by the YTO pretune circuits. Once the pretuning is completed, the IF signal (20/30 MHz) from the YTO Loop Sampler is phase compared to the 20/30 MHz Loop signal and the resulting error signal tunes the YTO to achieve phase lock. The YTO frequency is related to the M/N Out frequency and the 20/30 loop frequency in the following manner:

$$f_o = (N) (f_{M/N} - f_{20/30})$$

where f_o = YTO output frequency (MHz)

N = N number input to M/N loop (also the M/N loop harmonic near to which the YTO loop is pretuned).

$f_{M/N}$ = M/N loop output frequency (MHz)

$f_{20/30}$ = 20/30 loop output frequency (MHz)

f_{YTO} , N and $f_{M/N}$ OUT may be looked up on Table 8-5, M and N Numbers and Resulting Frequencies.

Also, $f_{20/30} = (30.000 - D_4 \cdot D_3 \cdot D_2 \cdot D_1)$ MHz

where D_4 = front panel 1 MHz character

D_3 = front panel 100 kHz character

D_2 = front panel 10 kHz character

D_1 = front panel 1 kHz character

for YTO frequencies less than 6200 MHz. Refer to the Service Sheet 2 text for a complete listing of pertinent formulas.

NOTE

The RF INPUT is the same frequency as the YTO output f_o and the YTO IF signal is the same as $f_{20/30}$ if the YTO loop is locked. The M/N loop signal is the $f_{M/N}$ signal.

8-98a

SERVICE SHEET 8-A3 (Cont'd)

A3A9A5 Sampler Assembly

The YTO Output signal is mixed with the Nth harmonic of the M/N OUT signal. The difference signal (20/30 MHz) is output to the YTO Loop Phase Detector where it is phase compared to the 20/30 MHz (LFS) Loop output.

The M/N Loop Signal is matched to the input of the sampler drive amplifier by R40, L1 and C10. This signal is amplified and matched to the Sampler's Harmonic Generator input. The numerous harmonics are mixed with the RF Input signal in the Sampler's Harmonic Mixer. The outputs are summed and matched to the IF Preamplifier by L10 and R13. The impedance matching throws the IF amplifier's frequency response off. The de-emphasis network at the output provides compensation that brings the frequency response back to normal. After buffering, the signal passes through a 70 MHz low pass filter to remove the multitude of unimportant harmonics of the mixing process. The signal is then amplified and output to the YTO Phase Detector. The important signal is the 20 to 30 MHz signal which is to be phase compared with the 20/30 Loop signal in order to lock the YTO Loop.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 2 and 10-A3 was used to isolate a YTO loop malfunction to the circuits shown on this schematic. The following information will aid in isolating a defective component.

Test Equipment

Frequency Counter	HP 5340
Oscilloscope	HP 180C/1801A/1821A
Power Meter	HP 436A/8481A
Spectrum Analyzer	HP 8555A/8552B/141T
High Impedance Probe (Spectrum Analyzer).....	HP 1121A
Digital Voltmeter	HP 3455A

1. Connect the IF OUT to a frequency counter using a coaxial tee to keep the YTO loop closed. Tune the Synthesizer's frequency to 3000.000 MHz. The IF OUT should be exactly 30 MHz. Change the frequency to 2999.999 MHz. The IF should be 20.001 MHz.
2. Disconnect the frequency counter and connect an oscilloscope to the coaxial tee. The output should be between 1.2 and 3 Volts peak-to-peak. If the results of steps 1 and 2 are correct, the A3A9A5 Assembly is operating properly. Otherwise, continue with this procedure.
3. Measure the M/N Loop Signal frequency and power using a power meter and the frequency counter. At 3 GHz the frequency should be 189.375 MHz. See the table on Service Sheet 2 for the other M/N Loop frequencies. If they are correct, continue. Otherwise troubleshoot the M/N loop.
4. Measure the coupled output of the A3A9A1 Directional Coupler. It should be about -15 dBm. If correct, continue. Otherwise troubleshoot the YTO and the A3A6 YTO Driver Assembly.

8-98b

SERVICE SHEET 8-A3 (Cont'd)

5. Install the A3A9 assembly in the service position. (Refer to the Assembly and Disassembly procedure which precede the Service Sheets.) Remove the A3A9A5 cover. Use a high impedance probe with a spectrum analyzer to measure the signal at gate 1 of Q4. The signal should be about $300 \mu\text{V}_{\text{rms}}$ between 20 and 30 MHz. If the signal is correct, proceed to step 8. Otherwise, continue with step 6.
6. Check the Sampler Drive Amplifier at the junction of R9 and L9. It should deliver about +7 dBm into a 50 ohm load.
7. Measure the dc bias voltages to the Sampler at TP1. It should be +0.4 Vdc. If the drive signals are OK but the bias or output level is incorrect, the sampler A3A9U1 may be defective.

NOTE

The mixer (sampler) may be checked by measuring current flow and breakdown voltage of the diodes and internal resistance.

- a. Remove the mixer from the board.
- b. Make measurements across pin-1 (positive) and coaxial center pin (negative). $V_{BR} > 3V$ at $10 \mu\text{A}$.
- c. Measure across center pin (positive) and pin-2 negative. $V_{BR} > 3V$ at $10 \mu\text{A}$.
- d. Measure resistance from center pin to ground (about 50 ohms).
- e. Measure pin-3 (positive) to ground (negative). $V_{BR} > 30V$ at $10 \mu\text{A}$.

8. Measure the signal at base of Q6. The signal should be about the same level as measured in step 5. If correct, troubleshoot Q1, Q5, Q6 and their associated components. Otherwise, troubleshoot Q4, Q2, Q7 and their associated components.

NOTE

After the A3A9A5 Assembly has been repaired or when A3A9U1 is replaced, perform the YTO Loop Sampler Adjustments in Section V.

PRINCIPLES OF OPERATION

YTO Phase Lock Loop

The Yig Tuned Oscillator's frequency output is phase locked 1) to the difference of the YTO frequency and a selected harmonic of the M/N loop and 2) to the 20/30 MHz loop. The YTO is tuned near the correct harmonic of the M/N Output frequency by the YTO pretune circuits. Once the pretuning is completed, the IF signal (20/30 MHz) from the YTO Loop Sampler is phase compared to the 20/30 MHz Loop signal and the resulting error signal tunes the YTO to achieve phase lock. The YTO frequency is related to the M/N Out frequency and the 20/30 loop frequency in the following manner:

$$f_o = (N) (f_{M/N} - f_{20/30})$$

where f_o = YTO output frequency (MHz)

N = N number input to M/N loop (also the M/N loop harmonic near to which the YTO loop is pretuned)

$f_{M/N}$ = M/N Loop output frequency (MHz)

$f_{20/30}$ = 20/30 loop output frequency (MHz)

f_{YTO} , N and $f_{M/N}$ OUT may be looked up on Table 8-5, M and N Numbers and Resulting Frequencies.

Also, $f_{20/30} = (30.000 - D_4 \cdot D_3 \cdot D_2 \cdot D_1)$ MHz

where D_4 = front panel 1 MHz character

D_3 = front panel 100 kHz character

D_2 = front panel 10 kHz character

D_1 = front panel 1 kHz character

for YTO frequencies less than 6200 MHz. Refer to the Service Sheet 2 text for a complete listing of pertinent formulas.

YTO Loop FM Circuits

In the Synthesizer's CW mode of operation, the Phase Detector's error voltage is found to be proportional to the integral of the YTO frequency. In the FM mode, the error voltage is due to the sum of integrals of the YTO frequency and the frequency deviation. Since the deviation is directly proportional to the modulation drive voltage, the error voltage may be expressed as follows:

$$V_e = \int f_o(t) dt + \int V_{FM}(t) dt$$

where V_e = phase detector's error voltage

$f_o(t)$ = YTO frequency

$V_{FM}(t)$ = FM drive voltage.

8-100a

SERVICE SHEET 9-A3 (Cont'd)

The result is a cancellation of modulation for FM rates inside the YTO loop bandwidth (20 kHz) and a partial cancellation at rates greater than 20 kHz and decreasing as the rate increases. In order to make the YTO loop response to FM essentially flat, a portion of the FM drive signal is integrated and subtracted from the error voltage output by the Phase Detector. This voltage is adjusted to just cancel the error voltage caused by the FM signal. Now the YTO loop effectively passes all specified rates to the YTO with little or no effect. Note that the FM drive signal is input after the Loop Integrator and the integrated FM is subtracted from the error voltage just before the Loop Integrator.

A3A9A4 YTO Phase Detector Assembly

The Phase/Frequency Detector compares the frequency and phase of the Sampler IF signal to the output of the 20/30 MHz loop. The resultant error signal is integrated and amplified in the Loop Integrators. The output signal YTO tune 1 is applied to the YTO coils to achieve phase lock.

During frequency modulation, the integrated FM signal from the A3A7 FM Driver Assembly is subtracted from the error signal. The net result is that the loop does not respond to the modulating signal and the YTO can be modulated at rates within the loop bandwidth.

Phase/Frequency Detector. The IF IN (from the Sampler) and the 20/30 MHz Loop signal are divided by two and to the Phase/Frequency Detector. If the phase of the IF signal leads that of the 20/30 MHz signal, a negative going pulse appears at U1 pin 12 (TP4). Pin 3 (TP3) remains at a steady dc level (about -0.6V). If the 20/30 Loop signal leads, a negative pulse appears at pin 3 (TP3). In each case the pulse width is proportional to the phase difference between the signals. The outputs are filtered and coupled to the differential amplifier. The signal is then applied to the Loop Integrator. The output (YTO Tune 1) tunes the YTO frequency. When FM is applied to the YTO loop, the detector discriminates the FM signal. The following expression shows the relationship between modulation index (β), frequency deviation (f_{dev}) and rate of modulation (f_{mod}).

$$\beta = \frac{f_{dev}}{f_{mod}}$$

The detector's practical operating range is approximately 0.5 radians ($\beta = 3.0$). Because of the divider circuits which precede the detector, β is effectively doubled to 6.0. Note that the specified maximum modulation index is 5.

a. **Overmodulation Detector.** The active high outputs of the Phase/Frequency Detector are connected in a wired-or configuration to the Overmodulation Detector. When the present O-MOD limit (2.5 Vdc minimum at phase detector output) is exceeded, the Divide Selector and the FM Status/Enable retriggerable monostable multivibrators are set.

b. **FM Status/Enable.** In the FM mode the FM ON input (high) turns the FM Switch on (Q3 off) which ungrounds the IFM IN (integrated FM input). When overmodulation occurs, and the FM Status/Enable monostable multivibrator is set, then the FM ON input is grounded (through Q1). The FM Switch however, remains ON due to the high from the FM Status/Enable multivibrator (through CR14 on to the base of Q2 which keeps Q3 off).

c. **Divide Selector.** During overmodulation, the Divide Selector monostable multivibrator is also set. The active low output causes the Dividers to divide-by-three. In the divide-by-two mode, the signal that triggered the overmodulation is normally about $\beta = 6$ (or at the Phase/Frequency Detector output,

SERVICE SHEET 9-A3 (Cont'd)

$\beta - 3$). In the divide-by-three mode, the output beta is about 2. Therefore, the loop locks. Back in the normal divide-by-two mode, the Divide Selector will be set again if the loop has false locked on a transient or on an FM sideband, or it will simply remain as is if it has locked on the carrier.

NOTE

The YTO Loop can lock in either the divide-by-two or divide-by-three modes. In the divide-by-three mode, the loop bandwidth is reduced making it impossible to correctly adjust the YTO Phase Detector (refer to Section V).

Unlock Detector. The Unlock Detector compares the YTO TUNE 1 signal to a preset reference. If the voltage swing exceeds ± 5 Vdc, a YTO unlock signal is generated. Small ac transients provide unlock signal due to action of C12.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 2 was used to isolate a YTO loop malfunction. The following information will aid in isolating the defective component.

NOTE

*If the malfunction is FM related, skip directly to step 8.
Otherwise go to step 1.*

1. Connect an oscilloscope via a coaxial tee to the YTO TUNE 1 connector (gray cable). The loops should remain closed (feedback path should not be broken) for this measurement. When the loop is locked, YTO TUNE 1 should be 0 ± 2 Vdc. When the loop is unlocked the voltage will be greater than ± 6 Vdc depending on the direction of the phase error. Tune from 2000 to 6190 MHz in 100 MHz steps to check lock over the entire YTO range.
2. Make sure the YTO Unlock output tracks the YTO TUNE 1 output ($> \pm 2.6$ V should indicate unlocked). If both steps 1 and 2 are correct, the YTO phase detector is working properly.

CAUTION

Disconnect the line (mains) power before installing the A3A9 Assembly in service position.

3. Install A3A9 in service position and remove A3A9A4 cover. Refer to the Disassembly and Reassembly Procedures which precede the service sheets.
4. Reconnect the mains power and tune to 3000.000 MHz. Connect a dual channel oscilloscope to A3A9A4TP2 and TP5. The ECL pulses at these test points should be square waves of -1.0 to -1.5 V amplitude between 10 and 15 MHz (66 to 100 ns period). Refer to following figure. If those signals are correct, proceed to step 7.
5. If the signals at TP2 or TP5 are not correct, measure the IF IN (black cable) and the 20/30 loop signal (green cable). These signals should both be about 0 dBm. When measuring the IF signal, ground A3A7TP2 to open the loop. If the 20/30 MHz loop signal (30.000 MHz) is incorrect, go to Service Sheet 1-A2. If the IF signal is incorrect (30.000 MHz plus or minus the pretune error) go to Service Sheet 8-A3. Otherwise proceed to step 6.

8-100c

SERVICE SHEET 9-A3 (Cont'd)

Oscilloscope Display of Signal at A3A9A4TP2 and TP5 (CW/AM Modes)
0.95 Vp-p at 12.5 MHz

6. Observe the 20/30 MHz pulses at pins 2 and 14 of U6; they should be as shown in figures below. If these signals are correct, troubleshoot U6 and its associated components.
7. Check the phase detector operation by observing the signal at U3 pin 6. The width of the pulse is determined by the phase difference between the IF and 20/30 MHz loop signals. (If the loop is phase locked, the signal is an extremely narrow pulse). If this signal is not correct, troubleshoot U5, Q4 and their associated components. Otherwise troubleshoot U3, U1 and their associated components.

Oscilloscope Display of Signal at A3A9A4U6 Pin 2 (CW/AM) Modes)
1.0 Vp-p at 30.6 MHz

8-100d

SERVICE SHEET 9-A3 (Cont'd)

Oscilloscope Display of Signal at A3A9A4U6 Pin 4 (CW/AM Modes)
0.9 Vp-p at 30.6 MHz

8. Set the Synthesizer's FM DEVIATION switch to OFF and the METER MODE switch to FM.
9. Tune the test oscillator to 2 MHz and connect the 50 ohms output to the Synthesizer's FM INPUT connector.
10. Measure the FM ON input. It should be about +0.1 Vdc. While observing the voltage, switch the FM Deviation switch through its range. In all FM positions the FM ON line should be high (about +4.4 Vdc). Leave the switch in the 10 MHz DEVIATION range. If the FM ON line does not respond correctly, turn to Service Sheet 8-A1 and continue troubleshooting. If the line is held low, consider the possibility of a short on A3A9A4.
11. Set the test oscillator's frequency to 100 kHz and output voltage to achieve a full scale reading on the Synthesizer's front panel meter (10 MHz deviation). The FM OVERMOD display should now be on.
12. Connect an oscilloscope to U2 pin 7. The level should be high. Increase the test oscillator's output voltage. The signal should pulse low (period about 5 ms) and the FM OVERMOD display should be on. If the output does not pulse low, check U2, U4B, U7B and U9B, U5 and their associated components.
13. Tune the test oscillator to 10 kHz. Measure the IFM signal at the drain of Q3. If the signal is not present or if the FM OVERMOD display is not lit, check U4A, Q1 and their associated components.

NOTE

After repairing the A3A9A4 assembly, perform the YTO Loop Phase Detector Adjustments, the YTO Loop Offset and the FM Overmodulation Adjustments.

PRINCIPLES OF OPERATION

YTO Phase Lock Loop

The Yig Tuned Oscillator's frequency output is phase locked 1) to the difference of the YTO frequency and a selected harmonic of the M/N loop and 2) to the 20/30 MHz loop. The YTO is tuned near the correct harmonic of the M/N Output frequency by the YTO pretune circuits. Once the pretuning is completed, the IF signal (20/30 MHz) from the YTO Loop Sampler is phase compared to the 20/30 MHz Loop signal and the resulting error signal tunes the YTO to achieve phase lock. The YTO frequency is related to the M/N Out frequency and the 20/30 loop frequency in the following manner:

$$f_o = (N) (f_{M/N} - f_{20/30})$$

where f_o = YTO output frequency (MHz)

N = N number input to M/N loop (also the M/N loop harmonic near to which the YTO loop is pretuned)

$f_{M/N}$ = M/N loop output frequency (MHz)

$f_{20/30}$ = 20/30 Loop output frequency (MHz)

f_{YTO} , N and $f_{M/N}$ OUT may be looked up on Table 8-5, M and N Numbers and Resulting Frequencies.

Also, $f_{20/30} = (30.000 - D_4 \cdot D_3 \cdot D_2 \cdot D_1)$ MHz

where D_4 = front panel 1 MHz character

D_3 = front panel 100 kHz character

D_2 = front panel 10 kHz character

D_1 = front panel 1 kHz character

for YTO frequencies less than 6200 MHz. Refer to the Service Sheet 2 text for a complete listing of pertinent formulas.

YTO Loop FM Circuits

In the Synthesizer's CW mode of operation, the Phase Detector's error voltage is found to be proportional to the integral of the YTO frequency. In the FM mode, the error voltage is due to the sum of integrals of the YTO frequency and the frequency deviation. Since the deviation is directly proportional to the modulation drive voltage, the error voltage may be expressed as follows:

$$V_e = \int f_o(t) dt + \int V_{FM}(t) dt$$

where V_e = phase detector's error voltage

$f_o(t)$ = YTO frequency

$V_{FM}(t)$ = FM drive voltage

8-102a

SERVICE SHEET 10-A3 (Cont'd)

The result is a cancellation of modulation for FM rates inside the YTO loop bandwidth (20 kHz) and a partial cancellation at rates greater than 20 kHz and decreasing as the rate increases. In order to make the YTO loop response to FM essentially flat, a portion of the FM drive signal is integrated and subtracted from the error voltage output by the Phase Detector. This voltage is adjusted to just cancel the error voltage caused by the FM signal. Now the YTO loop effectively passes all specified rates to the YTO with little or no effect. Note that the FM drive signal is input after the Loop Integrator and the integrated FM is subtracted from the error voltage just before the Loop Integrator.

A3A7 FM Driver Assembly

The FM Driver Assembly performs three major functions. First, it combines and sums the FM drive signal with the high frequency component and the YTO Tune 1 signal. Then this combined signal is amplified, compensated (for frequency response) and converted to an FM coil drive current. The FM drive signal is integrated and coupled to the YTO Phase Detector Assembly, where it is summed with (subtracted from) the Phase Detector's error voltage output.

Two minor but extremely important functions are 1) shifting the YTO frequency to ensure it will pass through the loop capture range and achieve phase lock in the event the loop has become unlocked and 2) to divide YTO tuning voltage (YTO Tune 1) into its high and low frequency components.

Phase Lock and FM Drive Signals. The YTO TUNE 1's high frequency component and the FM drive signal are summed at the input to the FM Coil Driver. The combined signal is amplified and the drive current is applied to the FM coil through an impedance matching network. The Frequency Shaping Network, located in the coil driver's feedback loop and the main FM signal path, compensates for the gradual loss in sensitivity of the FM coil to higher frequencies. The 40 dB attenuator in the FM signal path allows switching between the most sensitive and least sensitive FM ranges. The other two attenuators (that allow switching between the six FM ranges) are located in the A1 Assembly.

Integrated FM Signal. The FM signal integrated by the FM integrator, U3A. R23 and C1 form the integrating network which operates at frequencies greater than 20 kHz while C3 operates below 20 kHz. Note the equivalent networks in the non-inverting input. These preserve the common mode rejection characteristics of the amplifier. U2A, the second FM integrator amplifier, includes an adjustable gain control. This allows adjustment of the IFM signal gain to exactly balance the FM signal discriminated by the YTO phase detector.

In the most sensitive FM ranges (1, 3 and 10 MHz/V), the gain of the first FM Integrator Amplifier (U3B) is 20 dB and the attenuation at the output of the second amplifier (U2A) is 0 dB. In the least sensitive ranges (0.03, 0.1 and 0.3 MHz/V), the gain of the first amplifier is reduced to Unity (0 dB) and the output of the second amplifier is attenuated by 20 dB. This, 40 dB change in level, in effect, keeps the gain constant with FM drive signal applied to the YTO's FM coil.

Attenuating the integrated FM signal at the output of the amplifiers improves the signal-to-noise ratio of the FM system in the least sensitive ranges.

YTO Loop Reset. The YTO Loop Reset ensures that the YTO loop acquires phase lock after a frequency transition. When a frequency change occurs in less than 15 ms the YTO achieves lock and the YTO RST does not effect the YTO TUNE 1 input. If the loop does not achieve lock in less than 15 ms, the YTO UNLOCK causes YTO RST to momentarily go low. The YTO TUNE 1 signal is

8-1026

SERVICE SHEET 10-A3 (Cont'd)

pulsed to 0V. The result is that the YTO frequency is shifted to another frequency and then tries to return to the pre-pulse frequency. During this transition, the YTO 20/30 MHz, IF signal passes through the capture range of the loop phase detector and the loop is locked. If a large frequency change occurs (on the order of 100 MHz), YTO SLEW causes the YTO RST to immediately go low. The YTO output is effectively frequency modulated and the IF signal passes through the loop capture range. If phase lock has not yet been achieved (after 15 ms), the YTO Tune 1 is pulsed to 0V sending the 20/30 MHz IF signal through the loops capture range to ensure locking.

Phase Lock Amplifiers. The YTO Tune 1 signal is amplified by Q10. The YTO Tune 2 signal is connected to the A3A6 Main Coil Driver Assembly where all frequencies above 100 Hz are filtered out. The high pass filter (C12, R7 and R53) pass only those components of the signal greater than 100 Hz to the Coil Driver.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 2 was used to isolate a YTO loop malfunction. The following information will allow further isolation to circuits shown by one of the three YTO loop schematics 8-A3, 9-A3 or 10-A3. If the malfunction is on 10-A3, this information will also aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
Test Oscillator HP 651B
Frequency Counter HP 5340A
Power Meter/Sensor HP 436A/8481A

1. Connect voltmeter to A3A7TP2. Set frequency to 3 GHz. Disconnect black IF jumper on A3A9. The phase detector should drive the test point to about -5.6 Vdc. Disconnect the green 20/30 MHz coax from its normal location and connect it to the IF IN connector. The voltage should go to about +5.9 Vdc. If either voltage is incorrect, go to Service Sheet 9-A3 to troubleshoot the dividers and phase detector.
2. Connect the voltmeter to A3A6TP1. The voltage should be +6.5 Vdc with the green coax connected to the IF IN connector or -5 Vdc with the green coax installed in its normal location and the IF jumper removed. If either voltage is incorrect, go to Step 5 to troubleshoot the FM Coil Driver on A3A7.
3. Reconnect the ground to A3A6TP1 and set the frequency to 3 GHz. Measure the IF OUT frequency and power. It should be 30 MHz \pm pretuning error at 0 dBm. (Ideally the frequency should be the same as the output of the LFS loop). If the frequency is correct troubleshoot the main coil driver (Service Sheet 7-A3), especially the buffer amplifier fed by YTO TUNE 2.
4. If the frequency is incorrect or unmeasurable, isolate the malfunction by measuring the M/N loop output and the YTO signal at the input to the A3A9U1 Sampler to isolate the malfunction.
5. Make sure the RF switch on front panel is ON. Measure the voltage at A3A7TP2 (YTO TUNE 1). This voltage should be less than +2.6 Vdc if the loop is locked. If the loop appears to be locked, continue with step 2. Otherwise, proceed to step 6.

8-102C

SERVICE SHEET 10-A3 (Cont'd)

6. Measure the voltage at A3A7TP1. It should be about 0 Vdc. If the voltage is not zero, troubleshoot the Phase Lock Amplifier, the Bias Stabilizer and the FM Coil Driver. Otherwise, continue.
7. Connect the test oscillator's 50 ohm output to the FM INPUT connector. Tune the oscillator to 5 MHz with an output signal of about 0.7 Vrms (full scale on the Synthesizer's front panel meter). Connect a dual channel oscilloscope to A3A7TP1 and TP4. Set the FM DEVIATION switch to 10 MHz. The signal at TP1 should be about 9.6 Vp-p. If this signal is correct, the FM Amplifier (Q4 and Q6) and the FM Coil Drivers are OK. If the signal is not correct, check the FM INPUT at TP5 before troubleshooting the FM Amplifier and Coil Driver. The signal at TP4 should be a sine wave.
8. Set FM DEVIATION switch to 0.1 MHz. The signals at TP1 and TP4 should decrease by 40 dB (1% of the original voltage). If the signals at TP1 and TP4 are correct, the FM portions of A3A7 are OK. If the malfunction is an FM problem, proceed to Service Sheet 9-A3.
9. Disconnect the test oscillator and set the FM DEVIATION switch to OFF. Tune the Synthesizer while measuring the dc voltage at A3A7TP2. The voltage at edge connector pins 8 and 23 should be 0.7V more positive than the voltage at TP2. If this voltage is correct, A3A7 is working properly. Otherwise, troubleshoot Q10. If the voltage is zero even when the frequency is tuned, troubleshoot the YTO LOOP RESET circuit. The YTO RST line should be a TTL high. It should pulse low when the loop is unlocked due to 1) excessive FM deviation, 2) a missing M/N loop signal, 3) RF OFF, or 4) the 20/30 MHz Loop Signal is missing.
10. Ground A3A7TP2 to open the loop and measure the pretune frequency at the A3A9A1 Directional coupler's main output with the Synthesizer tuned to 2 GHz. The frequency should be within ± 5 MHz at +14 dBm nominal. If the frequency is correct, continue. Otherwise, go to Service Sheet 7-A3 to troubleshoot or adjust the YTO Driver or DAC. If the frequency cannot be measured, troubleshoot the A3A9A3 YTO Assembly and the A3A9A1 Directional Coupler.
11. Tune to 6199 MHz. The measured frequency should be within ± 5 MHz. If the results of step 6 and 7 are correct, the DAC, YTO Driver and YTO main coil are OK. Otherwise troubleshoot the DAC, YTO Driver and YTO.

NOTE

After the A3A7 assembly is repaired, perform the FM Driver Adjustments in Section V. If A3A9A3 is replaced, perform the Power Supply, DAC, YTO Driver, YTO Loop, FM Driver, FM Modulation Meter and the YTO Loop Offset and Overmodulation Adjustments.

PRINCIPLES OF OPERATION

General

If power cable W1 is connected between the line (Mains) power outlet and the A3A11 Line Module, primary ac power is connected to transformer A3T1 and fan relay A3A10K1. Line Voltage Selector A3A11TB1 matches the line voltage to the transformer primary. When the front panel LINE switch is set to ON, 120 VAC is connected to the cooling fan A3B1.

A3A2 Rectifier Assembly

The secondary ac voltages from the transformer are always present on the rectifier circuit board if the line voltage is connected to the Synthesizer. The four inputs are rectified and filtered before being output to the regulator circuits.

+22 Volt Regulator. The primary purpose of the +22V Regulator is to supply power to the internal reference oscillator's heater circuit any time the instrument is connected to the line voltage. The oscillator is maintained at operating temperature. Therefore, the instrument is ready to operate immediately after the LINE switch is set to ON.

The unregulated +20V is also used to supply power to the +22V Regulator. A3A2U1 is a monolithic 18 volt regulator that has the common terminal raised +4 Vdc above ground. If the regulated output exceeds +25 Vdc, the overvoltage protection circuit shorts the output to ground which causes the regulator to current limit. This action effectively turns the Synthesizer off. If the primary power fuse A3F1 does not burn out, the instrument must be disconnected from line voltage to reset the overvoltage protection circuit.

Input Overvoltage Protection. If the input voltage on the unregulated -40V line exceeds 82.5 Vdc (measured from -40V Unreg to -40V Return), the overvoltage protection circuit will short circuit the -40V input causing primary power fuse A3F1 to burn out. The intent of this circuit is to protect the instrument if 220 or 240 VAC is input with Line Voltage Selector A3A11TP1 set for 100 or 120 VAC. If this occurs, change the fuse to the correct value and orient the Line Voltage Selector so the line voltage is correctly matched to the transformer.

8-104a

SERVICE SHEET 11-A3 (Cont'd)

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1, 2 and 12-A3 was used to isolate a power supply malfunction to the circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A
or
Oscilloscope HP 180C/1801A/1821A

1. Connect the Synthesizer to the line (Mains) power.
2. LED A3A2CR15 should be on.
3. Verify that the voltage at A3A2TP1 is $+22.0 \pm 0.1$ Vdc.
4. Disconnect the power cable from the line power.
5. Install the assembly on an extender board and reconnect the Synthesizer to the line power.

CAUTION

To prevent damage to the power supplies, measure the following voltages with a voltmeter that has a floating common.

6. Measure voltages between edge connector pins as shown below.

Positive Pin	Negative Pin	Voltage Range
6	5	27-35 Vdc
17	15	15-21 Vdc
3	1	48-60 Vdc
10	7	10-14 Vdc

7. If any of the voltages are incorrect, check the ac input voltages from the power transformer. The voltages should be as shown on the schematic.
8. The transformer output may be checked with no load by removing the A3A2 assembly.

NOTE

With A3A2 removed the fan will run continuously in both STANDBY and ON. After repairing the A3A2 assembly, perform the Power Supply Adjustments in Section V. Also, perform the performance tests (if any) that led to the power supply repair.

WARNING

SECONDARY ac VOLTAGES OF GREATER THAN 30VAC AND RECTIFIED dc VOLTAGES OF GREATER THAN 60VDC ARE ALWAYS PRESENT ON THIS ASSEMBLY WHEN THE INSTRUMENT IS CONNECTED TO THE LINE VOLTAGE. THESE VOLTAGES COULD CAUSE PERSONAL INJURY IF CONTACTED. BE CAREFUL WHILE WORKING ON THE CIRCUIT BOARDS WITH POWER SUPPLIED TO THE INSTRUMENT. IF THIS CIRCUIT BOARD IS PLACED ON AN EXTENDER BOARD, THE POSSIBILITY OF COMING IN CONTACT WITH THE SECONDARY ac VOLTAGES (>30VAC) OR RECTIFIED dc VOLTAGES (>60VDC) IS GREATLY INCREASED. THESE VOLTAGES COULD CAUSE PERSONAL INJURY IF CONTACTED. BE CAREFUL WHILE WORKING WITH THIS CIRCUIT BOARD WITH POWER SUPPLIED. WORK WITH ONE HAND, DO NOT TOUCH THE EXTENDER BOARD.

CAUTION

DO NOT REMOVE OR INSERT POWER SUPPLY BOARDS WITH THE POWER CABLE CONNECTED. DAMAGE TO THE INSTRUMENT MAY OCCUR.

NOTES

1. 3A 100/120 VAC
1.5A 220/240VAC.
 2. MEASURED WITH RESPECT TO CHASSIS GROUND.
 3. USE VOLTMEETER WITH FLOATING COMMON.
 4. CONNECTED IN 8672A ONLY; NO CONNECTION 8671A.

PRINCIPLES OF OPERATION

Power Supplies

The +20V Regulator provides a reference voltage for all regulated supplies other than the +22V supply. If, for any reason, the +20V supply is turned off, all the power supplies on the A3A3 and A3A4 Assemblies will also be off. This effectively turns off the instrument. Under normal circumstances the +20V Regulator is turned on or off with the front panel LINE switch.

A3A3 Positive Regulator Assembly

+20V Regulator. A3A3Q2 and Q3 form a current source for A3Q3. When the Synthesizer is turned on, the +20V output increases and supplies current to the non-inverting input of A3A3U3 through the voltage reference A3A3VR2. The output voltage is also divided by A3A3R9, R50 and R10 and coupled to the inverting input of A3A3U3. This divided voltage is adjustable and sets the output voltage level.

At some level of current flow through the +20V Regulator, the voltage drop across A3A3R3 will equal that across A3A3R4 and A3A3Q4 begins to conduct. The output of A3A3U3 goes more positive which turns the current limiter on harder. The +20V Regulator is completely turned off. The regulator will remain off until the cause of the excess current drain is removed.

If the output voltage of the +20V Regulator reaches +23 Vdc, the overvoltage protection circuit shorts the output to ground. This causes the current limiter to turn the regulator off.

Front Panel Shutdown. The front panel LINE switch in the STANDBY position causes the Power On input to A3A3U1A to be 0V. This causes A3A3Q3 to saturate which turns the +20V regulator off. In the LINE switch ON position, the input voltage is approximately +22 Vdc which turns A3A3Q8 off.

Thermal Shutdown. This circuit operates much like the Front Panel Shutdown. At normal operating temperatures (less than 55°C) the value of thermistor A3A3RT1 is much greater than the 107 ohms of A3A3R53. Therefore, the voltage at the inverting input of A3A3U1B is more positive than the non-inverting input. This causes A3A3Q1 to be turned off. At temperatures exceeding 85°C, the resistance of RT1 drops below 107 ohms which causes A3A3Q1 to turn on. Even though the instrument is effectively turned off, the fan will continue to run to cool the instrument. The instrument will not return to normal operation until the internal temperature drops to 55°C or less.

+5V Regulator. The operation of this circuit is much like that of the +20V regulator. The reference voltage is provided by the +20V supply and a separate fuse is provided for further protection.

8-106a

SERVICE SHEET 12-A3 (Cont'd)

Power Up/Down Detector. This circuit outputs a Power Up/Down voltage (+5 or 0 Vdc) when the instrument is turned on or off. This lets the last frequency displayed before turn-off to be restored at turnon.

Reference Oscillator Power Supply. A rear panel switch controls power supplied to the A3A8 Reference Oscillator Assembly. When the FREQUENCY STANDARD INT/EXT switch A3S1 is set to INT, the Reference Oscillator Power Supply circuit is turned on. The regulator reduces the +20 Vdc input to approximately +11 Vdc.

Troubleshooting

It is assumed that the troubleshooting information on Service Sheets 1 and 2 were used to isolate a power supply malfunction. The following procedure will allow further isolation onto circuits shown by one of the three power supply schematics 11-A3, 12-A3, or 13-A3. If the malfunction is on 12-A3, this information will also aid in isolating the defective components.

Test Equipment

Digital Voltmeter HP 3455A

1. Connect the line (Mains) power to the Synthesizer and set the LINE switch to ON. Set rear panel FREQUENCY STANDARD INT/EXT switch to INT.
2. Observe the LED's on the A3A3 Assembly. The two red LED's (+20V and +5.2V indicators) should be on and the yellow LED (Thermal Shutdown indicator) should be off.
3. Set line switch to STANDBY. The +20V and +5.2V indicators should turn off.
4. Set the LINE switch to ON and measure the following regulator output voltages.

Regulator	Test Point	LINE Switch Position	
		ON	STANDBY
+20V*	A3A3TP5	+20.000 ±0.001 Vdc	0V
+11V	A3A3TP6	+11.0 ±1.1 Vdc	0V
+5.2V	A3A3TP2	+5.2 ±0.1 Vdc	0V

*The +20V supply is the reference for all other except the +22V supply. If the +20V supply is incorrect, all other supplies except the +22V supply will also be incorrect.

5. While measuring the +11V supply, switch the FREQUENCY STANDARD INT/EXT switch to EXT. The supply should go to

8-1066

SERVICE SHEET 12-A3 (Cont'd)

0V. Set the FREQUENCY STANDARD INT/EXT switch to INT.

6. If the output voltages are incorrect, measure the input voltages.

Input Voltage	Test Point	LINE Switch Position	
		ON	STANDBY
+20V UNREG	A3A3TP4	~ 32 Vdc	~ 35.5 Vdc
+5.2 UNREG	A3A3TP1	~ 12.2 Vdc	~ 14.5 Vdc

Connect voltmeter common lead to chassis ground for these measurements.

If the input voltages are incorrect, go to Service Sheet 11-A3.

CAUTION

DO NOT remove or install power supply boards with the power cable connected. Instrument damage may occur.

7. If the output voltages are incorrect and input voltages are correct, check the fuses before continuing. Use the voltages noted on the schematic to continue troubleshooting.
8. To test the Thermal Shutdown circuit, ground A3A3U1B-pin 13. The yellow LED (Thermal Shutdown indicator) should light and the 5 red LED's on A3A3 and A3A4 assemblies should turn off. The front panel should turn off and the fan should continue to run. When the ground is removed the instrument should return to normal operation.
9. If the power supply problem is associated with the negative regulator circuits, refer to Service Sheet 13-A3.

Troubleshooting Line Related Spurious

NOTE

This procedure is not part of the normal troubleshooting information. This procedure normally follows failure of the Power Line Related Spurious Performance test.

High line related spurious can be caused by many different things; some ingenuity may be required to isolate the more subtle causes such as ground loops and externally inducted vibrations. The follow-

8-106c

SERVICE SHEET 12-A3 (Cont'd)

ing procedure suggests items to check when trying to isolate a line spurious problem.

1. With a sensitive oscilloscope, observe the power supply ripple on each of the positive and negative supplies. The +20V, +11V, -10V, and -40V supplies should have ripple less than $300 \mu\text{V}$ while the +20V, +5.2V, and -5.2V should have ripple less than 1 millivolt. Power supply induced ripple will generally be twice the line frequency plus harmonics (e.g., 120, 240, 360 Hz, etc., for a 60 Hz line). If one or more supplies has excessive ripple, check the filter capacitors.
2. If any circuit boards were removed and reinstalled, line related spurious can increase if the board position in the socket was changed or if ground contact resistance increased. Remove the board, clean the edge connector contacts and reinsert the board. When reinserting the board, push it as far as possible toward one end of the edge connector socket and thoroughly tighten any screws holding the board in place.
3. Fan induced spurious will generally be 3 to 5 Hz below line frequency. A loose circuit board (covers not properly tightened) can vibrate more than normal and may increase fan related spurious. The 100 MHz reference oscillator is also sensitive to vibration. Check the reference to make sure the rubber shock mounts are in good condition and the reference oscillator is properly mounted in them. An out of balance fan or one with defective bearings can generate much vibration. To isolate the origin, stop the fan with a pencil or other insulated tool to see if the spurious signals go away.
4. Apparent line related spurious can be caused by external instruments connected to the FM input when the FM deviation range is set to 10 MHz. A high level hum signal can cause significant FM sidebands even though the FM input is high pass filtered on the wide deviation ranges.
5. Bad ground connections and ground loops can occasionally cause spurious problems. Make sure the A1 and A2 assemblies are fully seated on their connectors and that all coax cables and circuit boards are properly seated on their connectors.

NOTE

After repairing the A3A3 assembly, perform the Power Supply Adjustments in Section V. Also, perform the performance tests (if any) that led to the power supply repair.

WARNING

VOLTAGES OF GREATER THAN 60Vdc DIFFERENTIAL ARE ALWAYS PRESENT ON THIS BOARD ASSEMBLY WHENEVER THE INSTRUMENT IS CONNECTED TO THE LINE VOLTAGE. THIS VOLTAGE COULD CAUSE PERSONAL INJURY IF CONTACTED. BE CAREFUL WHILE WORKING ON THIS BOARD WITH POWER SUPPLIED TO THE INSTRUMENT.

CAUTION

DON'T REMOVE OR INSERT POWER SUPPLY BOARDS WITH THE POWER CABLE CONNECTED. DAMAGE TO THE INSTRUMENT MAY OCCUR.

NOTES

1. A3A3 AND A3A4 ARE SEPARATE ASSEMBLIES MOUNTED ON THE REAR PANEL HEAT SINK AND A3A10 MOTHER BOARD ASSEMBLY.
 2. DURING NORMAL OPERATION THE VOLTAGE AT TP3 IS 4.2 Vdc (CR7 IS OFF). IN THE THERMAL SHUT DOWN MODE THE VOLTAGE AT TP3 IS < 6 Vdc (CR7 IS ON).
 3. RTI RESISTANCE IS ABOUT 1000 Ω AT 85°C; 107 Ω AT 25°C.
 4. CONNECTED IN 867A ONLY; NO CONNECTION IN 867A.

TROUBLESHOOTING HELP: In addition to this service sheet refer to:

- Block diagram Page 8-37
- Motherboard wiring Last 3 foldout pages
- Parts list Page 6-46
- Performance tests Refer to Table 5-2, page 5-3
- Adjustment procedures Page 5-6

PRINCIPLES OF OPERATION

Negative Power Supplies

The negative regulators are all controlled by the +20V Regulator output. The -10V Regulator and the -40V Regulator operate exactly like the positive regulators. The only difference in the -5.2V Regulator is that the regulation occurs in the negative leg of the supply. Each supply has current limiting and overvoltage protection, and each is fused. The fuse in the -10V Unreg line A3A4F3 is for the -10V and -5.2V Regulators. Note that there is a separate fuse for the -5.2V Regulator.

A3A4 Negative Regulator Assembly

-10V Regulator. When the Synthesizer is turned on, +20V is applied across the voltage divider. The -10V output goes more negative until the divided voltage (at the non-inverting input of U2) is 0 Vdc.

At some level of current flow through the -10V Regulator, the voltage drop across R1 and R23 equals that across R2 and CR1 and Q1 begins to conduct. The output of U2 goes more positive, which then turns the current limiter on harder. The -10V Regulator is completely turned off and will remain in this condition until the cause of excess current drain is removed.

-5.2V Regulator. The operation of this circuit is much like that of the -10V Regulator. The main difference is that the regulation is in the negative leg of the supply. Because it takes a feed-back voltage of the opposite sense to control regulation, the +20V to -5.2V voltage divider output is applied to the inverting input of U1.

-40V Regulator. The regulating action of this circuit is like that of the -10V Regulator. The differences in component values are due to the difference in voltage and current requirements.

RF Switch. The RF ON switch (on the front panel of the A1 RF Output Assembly) controls the -10V switch. This voltage is the supply voltage for the A3A9A3 YIG Tuned Oscillator Assembly.

TROUBLESHOOTING

It is assumed that the troubleshooting information on Service Sheets 1 and 12-A3 was used to isolate a power supply malfunction of the

8-108a

SERVICE SHEET 13-A3 (Cont'd)

circuits shown on this schematic. The following information will aid in isolating the defective component.

Test Equipment

Digital Voltmeter HP 3455A

CAUTION

DO NOT remove or install power supply boards with the power cable connected. Damage to the instrument's internal circuitry may occur.

1. Connect the line (Mains) power to the Synthesizer and set the LINE switch to ON.
2. Observe the three red LED's on the A3A4 Assembly. All should be on unless the Synthesizer is in thermal shutdown.

CAUTION

To avoid damage to the power supply circuits, disconnect the power cable from the line voltage before removing or replacing any power supply circuit board.

3. Measure the following regulator output voltages. If any of the voltages are incorrect, remove the A3A4 Assembly and place it on an extender board. If all the voltages are incorrect, measure the +20V input at pin 9 of the edge connector.

Regulator	Test Point	Output Voltage
-40V	A3A4TP1	-40.0 +0.6 - 1.0 Vdc
-10V	A3A4TP4	-10.0 ± 0.2 Vdc
-5.2V	A3A4TP5	-5.2 ± 0.1 Vdc

8-1086

SERVICE SHEET 13-A3 (Cont'd)

CAUTION

To avoid damage to the power supply circuits, measure the voltages of step 4 with a voltmeter that has a floating common.

4. Check the appropriate fuse and measure the input voltages.

Input Voltage	Positive Pin	Negative Pin	LINE Switch Position	
			ON	OFF
-10V UNREG	7 (A3A4TP3)	6	~ 18.8 Vdc	~ 21.9 Vdc
-40V UNREG	2 (A3A4TP2)	3	~ 57 Vdc	~ 63 Vdc

5. Measure the output voltage at edge connector pin 14. With the front panel RF switch ON the voltage should measure -10 Vdc; with the switch OFF it should be approximately +0.5 Vdc.
6. If the input voltages are correct but the output voltages are incorrect, use the voltages on the schematic to isolate the bad component.

NOTE

After the A3A4 assembly is repaired, perform the Power Supply Adjustments in Section V. Also, perform the performance tests (if any) that led to the power supply repair.

WARNING

DC VOLTAGES OF >60Vdc DIFFERENTIAL ALWAYS PRESENT ON THIS BOARD ASSEMBLY WHENEVER THE INSTRUMENT IS CONNECTED TO THE LINE VOLTAGE. THIS VOLTAGE COULD CAUSE PERSONAL INJURY IF CONTACTED. BE CAREFUL WHILE WORKING ON THIS CIRCUIT WITH THE LINE VOLTAGE CONNECTED. IF THIS CIRCUIT BOARD IS PLACED ON AN EXTENDER BOARD, THE POSSIBILITY OF COMING IN CONTACT WITH THE 60Vdc DIFFERENTIAL IS GREATLY INCREASED. THIS COULD CAUSE PERSONAL INJURY IF CONTACTED. BE CAREFUL WHILE WORKING WITH THIS CIRCUIT BOARD WITH POWER SUPPLIED. WORK WITH ONE HAND. DO NOT TOUCH THE EXTENDER BOARD.

CAUTION

DO NOT REMOVE OR INSERT POWER SUPPLY BOARDS WITH THE POWER CABLE CONNECTED. DAMAGE TO THE INSTRUMENT MAY OCCUR.

NOTES

1. R301 AND R302 ARE MOUNTED ON THE REAR PANEL HEAT SINK AND R3A10 MOTHER BOARD ASSEMBLY.
2. CONNECTED IN 8672A ONLY; NO CONNECTION IN 8671A.
