CAUTION

The ANT Connector is used for "over the air" testing only. Do not connect a transmitter to this input.

Maximum ON time for measurement of transmitter output using the TRANS/RCVR connector is:

10 sec at 100W, 15% duty cycle.
20 sec at 50W, 30% duty cycle.
2 min at 30W, 50% duty cycle.

Do not connect transmitter to the 10 MHz REF OUTPUT Jack. Damage to the 10 MHz Ref. Oscillator will result.

If the test set is connected to a vehicle's d.c. supply, unplug the test set while starting the engine. If this is not done a blown fuse or other problems may result.

Do not exceed 200V into the SCOPE Input connector. Voltages over 200V will damage the scope circuitry.

Remove any possible static charge from an unterminated antenna before connecting to unit. To do this short the center conductor to the shield briefly.

Do not attempt to force the attenuator dial past the stops. Internal damage to the attenuator will result.

FM/AM-1000A

SPECIFICATIONS

SIGNAL GENERATOR

GENERAL SPECIFICATIONS

Frequency Range:	Frequency synthesized type - 100Hz to 999.9999 MHz in 100Hz phase-locked increments. Ovened-crystal master oscillator provides an accuracy of .00005% of selected output frequency after 20 minutes warm-up from oven off condition. Oven operates continuously with ac line connected; optionally on battery power with the set turned off. Aging stability is 2 to 3 PPM per year during the first year and 1 PPM per year thereafter.
Internal Modulation:	Frequency synthesized tone generator; 5Hz to 9999.9Hz in 0.1Hz increments. Accuracy is controlled by the master oscillator. Front panel connector provides convenient modulation tones output. AM variable 0-90% 10Hz to 5 kHz with 70% maximum from 5 kHz to 10 kHz. Low frequency FM response facilitates swept receiver I.F. alignments when used in conjunction with internal scope.
External Modulation:	Front Panel connector allows external modulation input to the generators. 6.0V (± 2V) P-P produces ± 15kHz deviation through the modulating frequency range 2Hz to 15 kHz. 3.0V (± 1V) P-P produces 100% AM.
Simultaneous Modulation:	Generator may be modulated simultaneously from internal and external sources and internal tone generator may be externally keyed for sequential tone coding.
Quieting:	42dB below 3.3 kHz deviation at 1 kHz.
Output Power:	Continuously variable from -133 dBm to -33 dBm (0.05µV to 5000µV) subject to attenuator accuracy.
Attenuator Accuracy:	±2.5 dB up to 400 MHz ±3.0 dB 400 MHz to 999.9999 MHz

RECEIVER

Frequency Range:	1 to 999.9999 MHz.
Sensitivity:	Better than 2μV, (typically 1μV) for "off-the-air" transmitter frequency checks. Sensitivity is reduced below 800 kHz.
Internal Cross-Feed Signal:	With the last four digits of the Frequency Select Switch set to zero e.g. 111.0000 MHz, Internal Cross-Feed Signal is less than 2.0μV as measured on 111.0000 MHz. This cross-feed signal is used to calibrate the frequency of the FM/AM-1000A by zero beating with NBS station WWV.
Quieting:	Deviation measurements can be made down to 0.1 kHz.
Bandwidth:	Narrow; RCVR ± 7 kHz, Detector Audio bandwidth is 8 kHz. Mid; RCVR ±100 kHz, Detector Audio bandwidth is 8 kHz. Wide; RCVR±±100 kHz. Detector Audio bandwidth is 80 kHz.
Monitoring:	Frequency error and deviation simultaneously displayed on the scope and meters. AM modulation percentage information displayed using scope 250 kHz I.F. envelope.
Auto Zeroing:	Frequency error meter is automatically zeroed every 1.5 seconds during a 3ms time period. AUTO Zeroing may deleted with AUTO- ZERO/BATT switch.
Beat Frequency Oscillator:	Variable injection level for calibrated signal strength measurements from 2 microvolts to 5,000 microvolts; frequency variable ±1.5 kHz. Also enables single-sideband and C.W. monitoring.
Antenna Input Protection:	Built in static discharge protector for antenna jack.
Certification:	The receiver model number FM/AM-1000A is capable of complying with the requirements of Part 15, subpart C of the FCC Rules and Regulations under normal operation.

POWER MEASUREMENTS

Range:	0 to 10 and 0 to 100 Watts read directly on a front panel meter to an accuracy of ±10% full scale to 225 MHz. See operation instructions for duty cycle and on-time limitations.

TONE FREQUENCY MONITORING

Measurement Techniques:	Precision internal tone generator is selectable with the scope timebase switch to produce a Lissajou scope pattern from a received tone, enabling accuract "off-the-air" tone frequency measurements.

OSCILLOSCOPE

3dB Bandwidth:	Ac or dc inputs. 1 MHz with external vertical dc input at one half full deflection

PHYSICAL CHARACTERISTICS

Power:	Conveniently portable with self contained battery that automatically recharges when ac line is connected. Battery operation typically is 1 hour with the scope off and 40 minutes with the scope on before recharge is required. Operates on 110/230V ac 50-400Hz, 80 Watts, and 11 to 28V dc. Typical dc currents 4.3 A at 12V and 1.85A at 28V.
Size:	8" (20.32 cm) high, 13.5" (34.29 cm) wide, 18.5" (46.99 cm) deep. Weight 40 lbs (18.2 kg). Rugged all metal construction, designed for field and bench use.
Fan:	Thermostatically controlled fan, switches on when reaching 95°F. (35°C).

Functional Description of Front Panel Controls, Indicators, and Connectors

Refer to Figure 1-1

1. Power Switch. When depressed on the left side (PWR), the Test Set is powered by external dc or ac power and the ON lamp lights. When returned to the center position (OFF), power is removed from all systems except the master oscillator oven and battery charger (see paragraph 4). When momentarily depressed on the right side (BATT), the Test Set is powered by the internal rechargable batteries and the ON lamp lights. Press again to turn off.

   In the BATT mode, the Test Set will automatically turn off after approximately eight minutes as battery-saving feature. Depress the switch to the right momentarily to recycle the timer. The batteries are charged whenever the line cord is plugged in whether or not the Test Set is on.

2. TRANS/RCVR Connector. A 50 ohm input/output connection for the transceiver under test. Maximum transmitter input is 30W at 50% duty cycle and 100W at 15% duty cycle or 15W cw (uninterrupted) CAUTION! Maximum ON time is 10 seconds at 100W, 20 seconds at 50W, and 2 minutes at 30W.

3. AUTO ZERO/BATT switch. This is a dual purpose switch. In the AUTO position, the Auto zeroing circuit is operational and not operational in the OFF (center) position. The switch should be in the OFF position if the Auto-Zeroing reference pulse is objectionable in the audio system or visual displays. When the FM/AM-1000A is used as a demodulator to feed decoding equipment, the AUTO-ZERO/BATT switch must be OFF (center position) or data will be lost during the 3ms reference pulse time period. Frequency error measurements should not be relied upon for more than a few seconds after AUTO ZERO/BATT switch is positioned to OFF. Before making frequency measurements, return switch to AUTO position for correct meter reference. The switch may be held in the spring-loaded BATT position for a voltage check. The battery charge is adequate when the right-hand meter indicates in the green band.

4. BATT OVEN Switch. When ON, powers the master oscillator oven from the batteries so the oven temperature can be stabilized when the Test Set is in transit.

5. OVEN Lamp Indicates whether the master oscillator oven is approaching temperature (lamp bright), or stabilized at final temperature (lamp dim), or oven power off (lamp off).

6. RF LEVEL/BFO INJECTION - μV Control. When Test Set is in signal generator (GEN) mode (see paragraph 10), controls the RF level into a 50 ohm load in either μV into 50 ohm, or dBm. When in receiver mode (RCVR), controls beat frequency oscillator (BFO) injection level into receiver for making signal strength measurements of a remote transmitter (see paragraphs 20 and 36).

7. ANT Connector. Connection for external antenna for "over-the-air" testing. DO NOT connect a transmitter to this input.

   NOTE! No antenna may be required if a transmitter is radiating at a small distance from the Service Monitor. Verify that the "SIG" Meter does not go past full scale, indicating too high a signal level, because erroneous data may be obtained with an input signal overload.

8. INPUT LEVEL Lamp. When lighted, indicates that the squelch is open. An internal static discharge protection circuit provides protection for most antenna transients.

9. DEV/PWR Meter Function Switch. In 2, 6, or 20 kHz full scale positions, right-hand meter indicates peak FM deviation of the received signal when the Test Set is in FM RCVR (receiver) or peak FM deviation of the Test Set's signal generator in FM GEN (generator) mode. In X1 or X10 watts positions, meter indicates power of the transmitter under test connected to TRANS/RCVR jack. In SIG (received signal strength) position, the meter indicates the relative signal strength of the received signal at the ANT connector.

10. GEN/RCVR Mode Switch. In GEN (signal generator) position, a RF signal is produced at the TRANS/RCVR jack. Its level is set by the RF LEVEL μV control, frequency by the FREQUENCY MHz thumbwheel, modulation type by the AM/FM switch, internal modulation frequency by the MODULATION FREQ Hz thumbwheel, and modulation level by the INT MOD (internal modulation) level control. The modulation depth or deviation is set up using the peak deviation (DEV/PWR) meter or the oscilloscope in FM mode or the oscilloscope and DEMOD OUT jack in AM mode (see paragraph 25).

    In RCVR (receiver) position, the Test Set acts as a receiver measuring the power, frequency, peak FM deviation, and sub-audible tone frequencies of the transmitter under test connected to the TRANS/RCVR jack. The above measurements excluding power and including received signal strength can also be made for remote transmitters monitored at an antenna connected to the ANT jack. The AM modulation depth of the transmitter under test can be displayed on the scope. Note: the Test Set will automatically be placed in the RCVR mode upon application of greater than 3W of RF power at the TRANS/RCVR connector.

11. ZERO RCVR Control. Zeroes the Frequency Error meter when GEN/RCVR switch is in GEN position. (Not a normal operating control).

12. 10 MHz REF OUT Connector. Output for measuring the frequency of the master oscillator.

13. 10 MHz CAL Screwdriver Adjustment. A fine adjustment of the frequency of the master oscillator.

14. NARROW/MID/WIDE Bandwidth Switch.
Detector Audio bandwidth is 8 kHz. Narrow - RCVR ± 7 kHz.
Detector Audio bandwidth is 8 kHz. Mid - RCVR ± 100 kHz.
Detector Audio bandwidth is 80 kHz. Wide - RCVR ±100 kHz.

15. EXT SPKR Connector. Connector for external speaker. Internal speaker is disconnected when a plug is inserted in this jack.

16. SQUELCH Control. Squelch control for internal RCVR except in GEN mode.

17. INT MOD/RCVR Switch. In RCVR (receiver), connects the speaker to the receiver output; in INT MOD (internal modulation), connects speaker to the internal modulation synthesizer.

18. VOL (Volume) Control. Controls level to internal or external speaker.

19. FREQUENCY MHz Thumbwheel. Selects the signal generator or receiver frequency.

20. BFO/OFF Control. When out of the detent (OFF) position, controls the frequency of an internal Beat-Frequency Oscillator (BFO) used in reception of CW, SSB, or DSB/SC modulation. When the BFO is on, the RF LEVEL/BFO INJECTION control can be used to measure the received signal strength at the ANT jack by adjusting this control until the peak of the beat between the BFO and the signal to be measured just goes to zero amplitude on the oscilloscope I.F. display. Place AM/FM switch to AM and RCVR/GEN to RCVR for this measurement.

21. AM/FM Switch. For this switch in AM and RCVR/GEN in RCVR position, the receiver's AM detector output is heard through the speaker and the 250 kHz I.F. signal is connected to the oscilloscope when its vertical sensitivity switch is in any of the kHz positions. For GEN mode, the INT (or EXT) MOD signal is connected to signal generator's AM modulator.

    For FM position, the receiver's FM demodulation output is heard through the speaker and is connected to the vertical input of the oscilloscope with full scale sensitivities of 1.5, 6, 15 kHz.

    For the FM mode, the peak deviation meter measures the FM deviation of the received signal or signal generator.

22. EXT MOD Connector. External modulation input connector. The input connection is made using a standard 3 conductor ¼" phone plug.

    The "Ring" connection is for external modulation, and the "tip" is for External Keying. For typical External Modulation levels, consult the SPECIFICATIONS sheet. In the External Keying mode, the Internal Tone Generator is ON when the connection is open and OFF when the Connection is grounded.

23. DEMOD OUT Connector. AM detector or FM demodulator output.

24. INT MOD OUT Connector. Internal modulation oscillator output. Level is controlled by INT MOD control.

25. INT MOD Control. Controls the AM depth of modulation or FM peak deviation. The AM depth can be set by connecting an ac voltmeter to the DEMOD OUT jack and noting the voltmeter reading (reference level) when the 250 kHz I.F. display on the oscilloscope is adjusted for 100% AM. The desired modulation is then set by adjusting the modulation level control until the DEMOD OUT is the desired percent times the reference voltage level measured above. Example: if 100% modulation corresponds to 3.0 volts at DEMOD jack, then 30% would correspond to 1.0V.

26. MODULATION FREQ Hz Thumbwheel. Selects the frequency of the internal modulation synthesizer.

27. SCOPE IN Connector. External vertical input for oscilloscope.

28. SWEEP Control. Controls oscilloscope horizontal sweep speed in 10, 1, .1ms/div or 10us/div rates. Since sweep is synchronized (as opposed to triggered) to the vertical signal, the small vernier control may have to be taken out of CAL to obtain a stable display.

    The extreme ccw position of the switch connects the internal modulation oscillator to the oscilloscope horizontal input to display the Lissajou pattern between a received signaling tone and the internal oscillator for tone frequency measurements.

29. AC/DC/OFF Switch. In OFF, disconnects power from the oscilloscope to conserve the batteries when so powered. In ac or dc applies internal power to the scope and ac or dc couples the scope inputs. It is necessary to pause in the off position to insure scope power supply inverter will start.

30. Oscilloscope Vertical Sensitivity Switch. On the kHz ranges, selects the sensitivity for the display of the output of the FM demodulator for measuring peak deviation of a received signal or setting up the signal generator's FM modulation. On EXT V/DIV ranges selects the sensitivity of the external input.

31. Frequency Error Range Switch. Selects the full scale sensitivity of the frequency error meter.

32. HORIZ Control. Adjusts the oscilloscope trace horizontal position.

33. VERT Control. Adjusts the oscilloscope trace vertical position.

34. FOCUS Control. Adjusts the oscilloscope trace focus.

35. INTENSITY Control. Adjusts the oscilloscope trace intensity.

36. RF Level BFO Injection-uV Control Dual Range Switch. The FM/AM-1000A, RF level control system has provisions for two output ranges. One range provides the output level indicated by the RF Level/BFO injection/uV control dial; the other range adds 40dB to the dial reading when selected. The outer (μV) dial on the RF Level/BFO injection/uV control reads from .05 to 50, the inner (-dBm) dial reads 80 to 130. The range selector switch is labeled "μv x 100", "+40dB" and "NORM".

    The dual range RF level control system has a fixed attenuator and solid state switch module mounted on the second mixer assembly. This attenuator switch is connected to the output port of the RF level control to provide the two output ranges.

    Because the selectable fixed attenuator is connected to the output port of the RF level control, the output level is either that shown on the dial or increased by 40dB depending upon the position of the range selector switch. If the +40dB range is selected, the operator must algebraically add 40dB to the -dBm setting on the dial. For example, if -80dBm is shown on the attenuator dial and the +40dB range is selected, the actual output level becomes -80dBm +40dB = -40dBm.

    The microvolt scale is simplier to use. In the +40dB range, multiply the microvolt dial reading times 100 for the output level in microvolts. In the NORM position the output level corresponds to the microvolt dial reading.

37. High Frequency Phase LOCK Lamp. This lamp to the left of LOCK indicates proper operation of the High Frequency Phase Lock Board and should be lit at all times when the FM/AM-1000A is ON.

38. Low Frequency Phase LOCK Lamp. This lamp to the right of LOCK indicates proper operation of the 79-80 MHz Phase Lock Board and should be lit at all times after the initial five minutes the FM/AM-1000A Power Switch is ON.

39. Frequency Error Meter Mechanical Zero Adjustment. Used in calibration of the Frequency Error Meter.

40. Deviation/Power Meter Mechanical Zero Adjustment. Used in calibration of the Deviation Power Meter.

TESTING PROCEDURES

PRELIMINARY:

Connect transceiver under test (T.U.T.) to TRANS/RCVR jack.

Apply power to Test Set. Allow approximately 15 minutes for master crystal oscillator to stabilize (OVEN lamp will dim) for most accurate frequency measurements.

A. TRANSMITTER TESTS:

Set Controls:

RCVR/GEN . . . . . .RCVR

Oscilloscope Power . . . . .dc

Oscilloscope Vertical. . . .1.5, 6, 15 kHz sensitivity

AM/FM. . . . . .As required

SQUELCH/OFF. . . . . .SQUELCH

FREQUENCY MHz. . . . . .As required

I. Carrier Power Output. Place DEV/PWR to X1 to X10 watts range as required. Key transmitter and read carrier power on meter.

II. Carrier Frequency Error. Key transmitter and read carrier frequency error on meter at 1.5, 5, or 15 kHz scale range as required. This measurement can also be performed on a remote station from the ANT jack when the SIGNAL LEVEL lamp is on..

III. AM modulation depth is most easily observed by watching the oscilloscope display of the 250 kHz I.F. pattern, which is automatically fed to the scope with the generator AM/FM switch in the AM position.

NOTE! Amplitude of the 250 kHz I.F. display may be varied only with the scope vernier sensitivity control. This procedure is very convenient for observing speech modulation patterns.

IV. FM Deviation. Connect a microphone to the transmitter's audio input. Place the DEV/PWR to 2, 6, or 20 kHz Deviation position as required. Place WIDE/NARROW to MID or WIDE if measuring deviation above 5 kHz. Key the transmitter and speak into the microphone; or place the INT MOD/RCVR switch to INT MOD, adjust VOL and place the microphone next to the speaker opening.

The INT MOD OUT signal can also be used to modulate the T.U.T. (Note: use a dc blocking capacitor if the audio input is biased for a carbon microphone). Adjust the INT MOD control for the required modulation voltage. The fast attack, slow decay meter and the oscilloscope measure peak deviation. This measurement can also be performed on a remote station from the ANT jack.

V. Sub-Audible Tone Frequency. Place the oscilloscope SWEEP switch to MODULATOR FREQ (fully ccw). Key the transmitter and the sub-audible tone. Adjust the oscilloscope vertical sensitivity vernier control and the INT MOD control until the display has approximately equal vertical and horizontal sizes. Vary the MODULATION FREQ thumbwheel until the Lissajou pattern slows or stops, forming an ellipse. The thumbwheel setting is the sub-audible tone frequency. This measurement can also be performed on a remote station from the ANT.

NOTE: Due to receiver noise, the deviation as indicated by the meter will be higher than the actual value if the input signal strength is less than 40μV (measured at the ANT jack of the FM/AM-1000A). When this is the case, use the oscilloscope to determine the actual tone deviation.

VI. Received Signal Strength of a Remote Station (AM or FM). Connect an external antenna to the ANT jack. Tune in the station to be measured with the FREQUENCY thumbwheel. Place AM/FM to AM, oscilloscope vertical sensitivity to 6 kHz, sweep to 1.0ms/div, and adjust BFO frequency and INJECTION controls until a beat note is heard in the speaker. Adjust the INJECTION control until the peak of the beat between the BFO and the signal to be measured just goes to zero on the oscilloscope I.F. display. The μV reading on the INJECTION control is the station signal strength at the ANT jack.

B. RECEIVER TESTS

Set Controls:

RCVR/GEN. . . . . .GEN

Oscilloscope Power. . . . .dc

Oscilloscope Vertical . . .1.5, 6, 15 kHz as required
Sensitivity

AM/FM . . . . . .As required

FREQUENCY MHz . . . . . .As required

I. 20dB Receiver Quieting. Place INT MOD to OFF. Turn off the FM/AM-1000A and measure the audio output of the T.U.T. with an external ac voltmeter (reference level). Turn on the FM/AM-1000A and adjust the RF LEVEL until voltmeter reading is one-tenth the reference level and read RF LEVEL setting.

II. Carrier Type Squelch Sensitivity. With RF LEVEL at its minimum adjust squelch on T.U.T. until receiver quiets. Increase RF LEVEL until squelch opens and read RF LEVEL setting.

III. Receiver Squelch Point with Sub-Audible Tone.

Set Controls:

RCVR/GEN. . . . .GEN

Adjust INT MOD control for desired FM deviation as indicated by the oscilloscope. Reduce the RF LEVEL until the squelch on the receiver under test closes, and then advance the RF LEVEL to the point where the squelch just opens. Observe the RF LEVEL at this point.

C. SIGNAL GENERATOR CALIBRATION (Frequency).

Set Controls:

RCVR/GEN. . . . .RCVR
AM/FM . . . . . .AM

I. (WWV) Weak. Tune to any WWV frequency (2.5, 5, 10, 15 MHz). If no beat between WWV and the master oscillator (or its sub-harmonics or harmonics) is heard go to step II. If a beat is heard, adjust the 10 MHz - CAL screwdriver pot until the beat frequency is 1 Hz or less. NOTE! A one Hz beat results in a short term accuracy of:

.00004% when beating with WWV at 2.5 MHz
.00002% when beating with WWV at 5.0 MHz
.00001% when beating with WWV at 10.0 MHz

II. (WWV) Strong). Tune in WWV on 10 MHz. Insert a small whip antenna (or wire) in the 10 MHz REF OUT connector. Adjust the whip length (or wire proximity to ANT jack) until a beat is heard and adjust 10 MHz CAL Screwdriver pot for a beat frequency of 1 Hz or less. NOTE! It may be necessary to decrease the amplitude of the input RF signal by using a shorter antenna or a pad in series with the antenna jack. Input signal strength should give a meter indication in the lower quarter of the meter scale. Best adjustment results with the input WWV signal approximately equal to the internal crossfeed signal.

SECTION III

SELF CHECK OF FREQUENCY ERROR INDICATIONS

For all frequency error self checks, the AUTO ZERO/BATT switch must be in the AUTO (up) position.

3.1 Frequency Error Meter Self Checks.

3.1.1 FM/AM-1000A Control Settings:

GEN/RCVR Mode Switch	RCVR
NARROW/MID/WIDE Bandwidth Switch	NARROW
FREQUENCY MHz Thumbwheel	000.0000
AC/DC/OFF Switch	DC
VERT Control	15 kHz
Oscilloscope Vert. Sens. Sw. (Vernier)	CAL

3.1.2 Center the scope trace using the HORIZ and VERT. Controls.

3.1.3 Select 15 kHz on the Frequency Error Range Switch.

3.1.4 Change the setting of the FREQUENCY MHz Thumbwheel to 000.0100.

3.1.5 Verify that both the scope and the Frequency Error Meter read negative 10.0 kHz.

3.1.6 Other scope and meter ranges maybe checked in a similar manner.

3.2 Self Check Deviation/Power Meter.

Checking the Zero of the Meter.

- FM/AM-1000A Control Settings:

GEN/RCVR Mode Switch	RCVR
NARROW/MID/WIDE Bandwidth Switch	NARROW
FREQUENCY MHz Thumbwheel	000.0000
DEV/PWR Meter Function Switch	2.0 kHz

- Deviation/Power Meter should indicate zero.

3.2.2 Deviation/Power Meter Calibration Check.

- FM/AM-1000A Control Settings:

GEN/RCVR Mode Switch	GEN
NARROW/MID/WIDE Bandwidth Switch	MID
FREQUENCY MHZ Thumbwheel	000.0500
DEV/PWR Meter Function Switch	20.0 kHz
INT MOD Control	OFF (full ccw detent)

- Set the MODULATION FREQ Hz Thumbwheel at 1 kHz.
- Adjust the INT MOD Control level to ±10 kHz, observing the scope.
- NOTE: The vernier gain of the Oscilloscope Vertical Sensitivity Switch must be at max. cw.
- Select 20 kHz on the DEV/PWR Meter Function Switch.
- Meter should indicate 10 kHz.
- Move the Oscilloscope Vertical Sensitivity outer knob from 15 to 6 kHz.
- Reduce the INT MOD Control to ±6 kHz, observing the scope.
- Select the 6 kHz setting on the DEV/PWR Meter Function Switch.
- The Deviation/Power Meter should indicate 6 kHz.
- Reduce the INT MOD Control to a presentation of ±2.0 kHz on the scope.
- Set the DEV/PWR Meter Function Switch to 2.0 kHz.
- The Deviation/Power Meter should indicate 2.0 kHz.

3.3 Self Check Output Level.

3.3.1 FM/AM-1000A Control Settings:

GEN/RCVR Mode Switch	GEN
RF Level/BFO Injection/µV Control Dual Range Switch	+40 dB
RF LEVEL/BFO INJECTION/µV Control	1K µV
FREQUENCY MHz Thumbwheel	000.0500
Vertical Sensitivity Switch	.01 V/Div
(Outer Knob)	external on scope
(Vernier)	CAL (max cw)

3.3.2 Connect a short BNC-BNC coax from the TRANS/RCVR Connector to the SCOPE IN Connector.

3.3.3. Scope display should be 0.7 (±0.25) division high.

SECTION IV

THEORY OF OPERATION

4.1 Introduction.

4.1.1 This section contains the circuit theory of operation of the FM/AM-1000A. Included are general description and a main individual circuit description.

4.2 General Description.

4.2.1 The FM/AM-1000A is a digitally synthesized AM, FM, and SSB receiver and low power signal source. The unit is solid state except for the CRT display. It contains a quadruple conversion super heterodyne receiver and a low power signal generator designed to generate communications signals from 1.0 kHz to 999.9999 MHz.

4.3 General Circuit Theory.

4.3.1 The receiver is tuneable from the front panel from 300.0 kHz to 999.9999 MHz in 100 Hz increments. The first I.F. frequency is variable from 1199.0001 MHz to 1200.0000 MHz as the left hand three thumbswitches of the FREQUENCY MHz Thumbwheel are switched from 999 to 000.

4.3.2 The First Local Oscillator operates in 1 MHz increments from 1200 MHz to 2199 MHz as the left three thumbswitches are switched from 000 to 999.

4.3.3 The output of the Second Local Oscillator is variable from 1079.0001 to 1080.0000 MHz as the right hand four digits are thumbswitched from .9999 to .0000. The Second Local Oscillator (Approximately 1080 MHz) beats with the first I.F. (Approximately 1200 MHz) to produce the second I.F. of 120 MHz.

4.3.4 A beat frequency oscillator injection signal is injected into the "Second Mixer Diode Switch" for received signal level measurements and receiving of SSB and CW signals. A 10 MHz crystal is pulled approximately ±208 Hz from 10 MHz, and is multiplied by six and by two to produce 120 MHz ±2.5 kHz. This circuitry is in the GEN module. The injection level is selected by the front panel RF LEVEL/BFO INJECTION /µV Control.

4.3.5 The Third Local Oscillator is a crystal oscillator to 109.3 MHz which beats with the 120 MHz I.F. to produce the third I.F. of 10.7 MHz.

4.3.6 The Fourth Local Oscillator is a crystal oscillator that produces a 10.950 MHz signal which beats with the 10.7 MHz I.F. to produce a Fourth I.F. of 250 kHz.

4.3.7 The 250 kHz I.F output is demodulated for FM by a pulse counter operating at 250 kHz or diode detected for AM output.

4.4 Frequency Control System for the First Local Oscillator (1200-2199 MHz).

4.4.1 Control for the First Local Oscillator starts with a 10 MHz signal from the oven stabilized Master Oscillator operating at 10 MHz ±.00005%. This 10 MHz signal is multiplied ten times in the 100 MHz Multiplier and 108 MHz Mixer Module (see block diagram Fig. 6-30). The 100 MHz signal is fed through a filter amplifier and then into a 100 MHz amplifier which drives a snap diode. Harmonics of the snap diode are selected by five tuned filters: 1100 MHz, 1300 MHz, 1500 MHz, 1700 MHz, and 1900 MHz. Diode switches select which filter output drives the single diode mixer. The mixer is also driven with a signal from the First Local Oscillator (1200-2199 MHz). When the Local Oscillator is operating from 1200-1399 MHz, the output of the 1100 MHz filter is selected to mix with the Local Oscillator. The mixer produces an output of 100-299 MHz. As the First Local Oscillator is operating from 1400-1599 MHz, the 1300 MHz filter is selected. There are five bands in which the First Local Oscillator operates in this manner. In each of these bands, the mixer output is always 100-299 MHz. This 100-299 MHz signal is divided by two in the Heterodyne amplifier and Divide by Two Prescaler. The prescaler output (50-149.5 MHz) feeds the program divider and phase lock loop which controls the First Local Oscillator frequency. The left hand three digits of the front panel thumbswitches control this program divider.

4.5 Frequency Control System for Second Local Oscillator (1079.0001-1080.0000 MHz).

4.5.1 10 MHz from the oven stabilized Master Oscillator is multiplied to 100 MHz in the 100 MHz Multiplier and 108 MHz Mixer Module. A front panel controlled phase locked loop, operating from 79.0001-80.0000 MHz and then divided by 10, is mixed with 100 MHz in the 100 MHz Multiplier and 108 MHz Mixer Module to produce 107.90001-108.0000 MHz. This signal is filtered further by a passive 108 MHz filter and fed on to the 1080 MHz Multiplier Amp Module, which multiplies this signal ten times to produce 1079.0001-1080.0000 MHz at a typical level of +5 dBm.

4.6 Audio Modulation Generator (5 Hz to 9999.9 Hz).

4.6.1 A heterodyne system produces the audio tone output by mixing a 20 kHz reference signal with approximately 20-30 kHz. The result is approximately a 5 Hz-10 kHz output after passing through a low pass filter. A 2-3 MHz, (actually 2.0005-2.9999 MHz), oscillator output frequency is divided by one hundred to derive the 20-30 kHz signal. A phase locked loop controlled by the MODULATION FREQ Hz Switch controls this 2-3 MHz oscillator. A selected audio modulation frequency of 0000.0 Hz produces 2.0000 MHz and a selected audio frequency of 9999.9 Hz produces 2.9999 MHz.

4.7 Clock Divider Circuit.

4.7.1 10 MHz from the oven stabilized Master Oscillator is divided to lower frequencies by TTL dividers to be used for the following reference frequencies:

1. 20 kHz - Audio Modulation Generator
2. 10 kHz - 120 MHz FM/AM Generator Module
3. 100 Hz - Low Frequency Phase Lock Loop
   (79.0001-80.0000 MHz ÷ 10 = 7.90001-8.00000)
4. 10 Hz - Audio Modulation Generator

4.8 Oscilloscope.

4.8.1 The horizontal deflection plates of the CRT are controlled by a differential amplifier consisting of Q3414, Q3415, and Q3416. Q3415 provides a constant current source to the differential pair consisting of Q3414 and Q3416, which drives the left and right-hand deflection plates, respectively. A reference voltage from the HORIZ Control is applied to Q3416. Q3414 is driven by either the scope's internal Horizontal Sweep Generator or by the Audio Modulation Generator as selected by the SWEEP Control.

4.8.1.2 The sweep generator is a sawtooth generator consisting of a constant current source, a flip-flop, a buffer amplifier, a trigger, a clamp, and a horizontal retrace blanker. The flip-flop, consisting of Q3408 and Q3409, starts out with Q3408 in the "off" state and Q3409 in the "on" state. A Ground Path is provided for one of four timing capacitors by the front panel SWEEP Control. This capacitor is charged through the constant current source (Q3412) and as it charges, the base voltage of the buffer amplifier (Q3413) becomes more positive, allowing the emitter to become more positive. This turns the left-hand leg of the differential driver (Q3414) on in a linear fashion, causing the beam to sweep across the tube. At the same time, the emitter of the trigger (Q3407) is going positive to a level set by the voltage on the base through the trigger amp (X3402). When the timing capacitor charges to the trigger voltage Q3407 conducts. This supplies a trigger voltage to a flip-flop consisting of Q3408 and Q3409. This turns on Q3408, which in turn turns Q3409 off. The collector of Q3409 drives the clamp and the blanker. When Q3409 turns off, the blanker (Q3410) and clamp (Q3411) turn on. The clamp provides a ground path to discharge the timing capacitor. As the timing capacitor discharges to near zero volts, CR3405 turns off Q3408 which resets the flip-flop. Resetting the flip-flop turns off the clamp and blanking transistors and allows the timing capacitor to start charging.

4.8.2 Vertical Deflection Circuit and Vertical Pre-Amplifier.

4.8.2.1 The vertical deflection plates of the CRT are controlled by a differential amplifier consisting of Q3404, Q3405, and Q3406. Q3404 and Q3405 are the differential amplifier and Q3406 is a constant current source. Q3405 drives the bottom deflection plate and is the reference. Vertical centering is accomplished by a front panel control, VERT Control, which adjusts the reference voltage input to Q3405, the reference leg of the differential amplifier. Q3404 receives its signal from the vertical amplifier. When the inputs to Q3404 and Q3405 are at equal levels, the beam on the CRT will be centered.

4.8.2.2 The vertical amplifier is an operational amplifier (X3403) fed by a differential FET Amplifier (Q3402) to provide a high impedance input.

4.8.2.3 X3401 and Q3401 are a +11 V Regulator for the oscilloscope functions. CR3418 and CR3419 provide high voltage protection to the FET input.

4.9 Power Supply

4.9.1 Rear Panel (Fig. 6-4)

4.9.1.1 In the AC Mode of operation T18001 provides taps for 110 or 220 V ac and drops it down to approximately 15.0 V ac. It is then rectified by CR18001 and filtered by C18001 to provide 18.0 V dc at 4.5 Amps. This 18 V supply feeds the oscillator oven and the duty cycle regulator when the front panel Power Switch is in the PWR position.

4.9.1.2 External dc from 12-23 V dc can also be fed to the same point that the ac power supply feeds.

4.9.1.3 The battery can also be charged directly from an external source through CR18001 which prevents discharge of the battery through the external source.

4.9.2 Duty Cycle Regulator and Battery Charger (Fig. 6-11).

4.9.2.1 The battery charger circuit is a current regulator consisting of X5102, Q5110 and Q5111. The op-amp (X5102) senses battery voltage and provides a control voltage through Q5111 to Q5110. Q5111 provides a low impedance output to the op-amp. Q5110 is a series regulator controlling the current from the raw dc out of the power supply to the battery.

4.9.2.2 The Duty Cycle Regulator's driving oscillator is a 20 kHz multivibrator which has a square wave output that is changed into a modified sawtooth by C5113 and Q5105. Q5105 is a constant current source. The modified sawtooth is fed into the inverting input of the op-amp X5101. The noninverting input of X5101 sets the level at which X5101 switches. The output is a square wave with a duty cycle responsive to the dc voltage on the noninverting input of X5101. Q5101 provides a constant current source and CR5109 is a 6.2V regulator used for the multivibrator and for a reference transistor (Q5109). If the 12V secondary of the transformer is too high the collector of Q5109 goes higher increasing the reference voltage on the noninverting input on the op-amp. This sets the cutoff higher up the ramp shortening the duty cycle which shortens the charging time on the primary of T5101 which will lower the output voltage on the secondary and maintain 12V dc. If the 12V output is loaded so that the voltage is low, the reference will go low which will lower the switching point on the ramp lengthening the pulse which will increase charging on the transformer which will increase the current capacity of the secondary increasing the secondary to 12V. The drive circuit consists of Q5106, Q5107, Q5108, Q5102 and Q5112. Q5106 is a buffer driver which supplies the current necessary to switch on the parallel drivers. This current goes through a two turn winding so that the bases of the outputs can go below ground in order to turn on the power taansistors fully. R5115 adjusts the base level of Q5109 which sets the +12V output.

4.10 Operation as a Signal Generator (Fig. 6-16 and 6-59)

4.10.1 As a signal generator, the signal originates in the 10 MHz oven stabilized master oscillator and is divided down to 10 kHz in the "Clock Divider" module, then fed as a reference signal to the "120 MHz FM/AM Generator" module. In the "120 MHz FM/AM Generator" module, 120 MHz is produced by mixing a 54.78 MHz crystal oscillator with a 5.22 MHz FM oscillator to produce 60 MHz, then multiplying by two. FM modulation of ± 7.5 kHz is imposed on the 5.22 MHz VCO which then becomes ± 15 kHz at the 120 MHz output stage because of the frequency doubling stage. The 60 MHz signal is phase locked to the incoming 10 kHz reference from the clock divider.

4.10.2 Refer to figure 6-16. The Second Mixer is fed in reverse by the 120 MHz FM/AM Generator's output after being attenuated by the front panel RF Level Control. The 1199.0001-1200.0000 MHz I.F. system is also reversed by a diode switch so that the First Mixer is now a signal Generator from 100 Hz to 999.9999 MHz. This signal passes through the transfer relay, now in the generator mode, and passes through a 20 dB pad, and then to the front panel "TRANS/RCVR" jack. The level at this jack is from -33 dBm to -133 dBm into a 50 ohm load.

SECTION V

PERFORMANCE EVALUATION

5.1 Introduction.

5.1.1 This section contains procedures to verify the proper performance of the FM/AM-1000A. If the unit fails to meet the performance as outlined in this section refer to the appropriate calibration section of this manual.

5.1.2 This instrument has been tested and calibrated at the factory prior to shipping and should only require periodic inspection and calibration. DO NOT attempt any adjustment except as specified in the calibration section of this manual and then only with a thorough understanding of the theory of operation.

5.1.3 Case Disassembly. (Not required for general evaluation).

5.1.3.1 Remove the four Phillips screws that hold the support bars to the legs and remove the bars. Remove the eight Phillips screws around the outside perimeter of the rear of the case. Remove the top Phillips screw at the front center top of the case. Remove the Phillips screw at the front center bottom of the case. Set the unit on its legs and slide the case back. Lift the unit out of the case.

5.2 Signal Generator Calibration (Frequency).

5.2.1 Before applying power, ensure that both panel meters are mechanically zeroed. Set the RCVR/GEN switch to RCVR, and the AM/FM switch to AM. Connect external antenna to antenna input connector. Ensure that AUTO ZERO/BATT switch is in AUTO position.

5.2.2 Tune to any WWV frequency +1 kHz (2.5, 5, 10, or 15 MHz). If no beat between WWV and the Master Oscillator is heard because of strong WWV signal, go on to paragraph 5.2.3. If a beat is heard, adjust the 10 MHz-CAL screwdriver pot on front panel until the beat frequency is 1 Hz or less.

NOTE

A one Hz beat results in a short term accuracy of .0004% when beating with WWV at 2.5 MHz, .00002% when beating with WWV at 5.0 MHz, .00001% when beating with WWV at 10 MHz.

5.2.3 Tune in WWV on 10 MHz +1 kHz. Insert a small whip antenna or wire) in the 10 MHz REF OUT Connector. Adjust the wire length or whip proximity to antenna jack) until a beat is heard and adjust the 10 MHz CAL screwdriver pot for a beat frequency of 1 MHz or less.

NOTE

When not using the procedure in 5.2.3, it may be necessary to decrease the input of the RF signal when WWV is strong by using a shorter antenna or pad in series with the antenna jack. The input signal strength should give a meter indication in the lower quarter of the meter scale. Best adjustments result with the input WWV signal approximately equal to the internal crossfeed signal.

5.3 Self Check of Frequency Error Meter.

5.3.1 Set RCVR/GEN switch to RCVR position, set FM/AM switch in FM, set bandwidth switch in narrow band position and select 000.0000 frequency. Position AUTO ZERO/BATT switch to AUTO for remainder of the Evaluation Procedure. Center the scope trace, zero the frequency error meter, and select 15 kHz range. Select 000.0100 MHz and verify the frequency error meter indicates a negative 10.0 kHz ± 10%). The scope should indicate negative 10 kHz (± 5%). Select 1.5 kHz scale on Frequency Error Meter range selector switch. Select GEN position and re-zero Frequency Error Meter using front panel ZERO RCVR screwdriver control if necessary. Other scope and meter ranges can be checked in a similar manner.

NOTE

FREQ ERROR meter may be positioned off zero when the squelch isn't opened. This offset does not represent an error or malfunction. FREQ ERROR meter zeroing should be evaluated in the generate function.

5.4 Self check of Deviation Meter. Use actual scope reading obtained in 5.3.1 as reference for deviation meter checks. By doing this the Deviation Meter is referenced directly to the frequency synthesizer.

5.4.1 Select the RCVR position of the RCVR/GEN switch. Select narrow band operation with the bandwidth switch. Select 000.0000 MHz. Select the 2.0 position on the deviation meter switch. The deviation meter should indicate zero (± 100 Hz).

5.4.1.1 Switch to GEN Mode, set bandwidth switch to mid, turn Internal Modulation off, select 2 kHz scale on deviation meter and observe that meter indicates zero (± 50 Hz), and select 20 kHz on deviation meter. Select 1 kHz on Internal Modulation frequency

select thumbswitches and adjust INT MOD level for a scope indication of "+" and "-" 10 kHz. The DEV meter should indicate 10 kHz (±7%). Reduce INT MOD for a scope indication of "+" and "-" 5 kHz. Select 6 kHz scale on the DEV meter. The deviation meter should indicate 5 kHz (± 7%). Reduce INT MOD for a scope indication of "+" and "-" 2 kHz. The deviation meter should indicate 2.0 kHz (± 10%).

5.5 Self Check of Output Level.

5.5.1 Select GEN Mode, adjust output attenuator for 1K µV, select 000.0500 MHz on the frequency MHz thumbswitches. Select External Input at .01V/DIV on scope and ensure that the vertical vernier is in CAL position. Connect a short BNC to BNC coax from RF output to scope input. The scope display should be 0.7 divisions high (± 0.25 divisions).

5.6 Check of RF Power Meter.

5.6.1 Using short lengths of coaxial cable connect a 5-10 watt VHF transmitter with a 150 MHz range to the input of an in-line RF power meter with a verified accuracy of ± 5%. Connect the output of the RF power meter to the TRANS/RCVR input of the unit. Select X1 watts on "DEV/PWR" switch. Key transmitter and read power output on the in-line watt meter. Check that FM/AM-1000A indicates the same, ±10%.

5.6.2 Perform the same test on the X10 watts range with a 50-90 watt transmitter.

5.7 Check for holes in Synthesizer Operation.

5.7.1 Set frequency select MHz thumbswitches to 000.0000 MHz. Set RCVR/GEN switch on RCVR position, set FM/AM switch in FM position, and set bandwidth switch in NARROW position. Select the 1.5 kHz range on the kHz frequency error range switch. Center the scope trace and select the 1.5 kHz range. Step the 100 Hz frequency select switch through its range and check that the frequency error meter steps in approximately 100 Hz negative steps for each increment. Select the 15 kHz range on the scope and on the frequency error meter. Step the 1 kHz frequency select thumbswitch through its range and check that the FREQ ERROR meter and the scope indications move negative in approximately 1 kHz increments for each step. On the 15 kHz range, turn the scope vernier full counterclockwise and center trace, bandwidth on wide, and step the 10 kHz thumbswitch through its range and check that the scope trace moves in equal negative increments of the thumbswitch.

5.7.2 Switch to GEN mode. Using a short length of coax connect scope input to TRANS/RCVR output. Set attenuator at maximum. Select 0.1V/DIV on vertical (ensure vernier is in CAL position). Select 10us/DIV horizontal. Step 100 kHz thumbswitch through its range and assure sinewave display changes 100 kHz each step.

5.7.3 If an external scope is available with a bandwidth of 50 MHz or greater, connect TRANS/RCVR output to vertical input of the scope. Use most sensitive range and adjust output attenuator for a usable amplitude. Select a sweep that produces a usable sine display, step the 1 MHz thumbswitch through its range and assure that the scope display changes each step. Depending on the bandwidth of the scope used, you may use this set up to check the 10 MHz decade in a similar manner.

NOTE

It may be necessary to put a BNC Tee connector on the input of the scope and terminate the open end of the Tee into a 50 ohm load in order to get a constant output from the generator.

5.8 Tone Generator Performance.

5.8.1 Using a short length of coax connect INT MOD OUT to SCOPE IN. Set Ext V/DIV to 1. Set SWEEP to 10ms. Set AC/OFF/DC switch to DC. Set MODULATION FREQ Hz switch to 1000.0 Hz. Set INT MOD control to give a scope indication of "+" and "-" 1.5V. Select 0010.0 on MODULATION FREQ Hz switch and adjust SWEEP vernier for a single sine wave on the scope. Select 0011.0 Hz through 0019.0 Hz on MODULATION FREQ Hz thumbswitches and observe that the frequency increases for each increment. Return MODULATION FREQ Hz thumbswitches to 0010.0 Hz. Step the 10 Hz thumbswitches through its range. The scope will indicate a new sine wave for each increment up to 0090.0. Select 0100 Hz, set the SWEEP to the 1ms range, and adjust the SWEEP vernier for a single sine wave as above. Step through the 100 Hz range. Each increment will add an additional sine wave up to 0900.0. Select 1000.0 Hz. Set SWEEP to .1ms range. Adjust vernier to display a single sine wave. Step through the 1 kHz range. Each increment will add an additional sine wave. The amplitude will vary through the range of the oscillator.

5.9 Power Supply Evaluation. (Remove case)

5.9.1 Back Panel. (Fig. 6-5)

A. With the set operating on line voltage, measure the +12 volt supply at pin E of the Regulator and Power Supply Board Connector J-17 (See Fig. 6-1-2 and 6-7 for connector pin layout) or at the red wire connection on J-3, located just to the right of J-17 (Fig. 6-1-2). The voltage should be +12.2 volts (typically +12.1 to +12.3 volts).

B. Measure the +5 supply at the orange wire connection on J-3. The voltage should be between +4.7 to +5.25 volts.

C. Measure the -39 volt supply with scope on and off at J-17 pin 7. The voltage should be between -37 to -45 volts while operating on line voltage or on battery power.

D. Using a scope, check the 20 kHz ripple on all dc supplies. Maximum allowable ripple voltage is 75mV P-P.

E. Disconnect rear panel battery and disconnect line cord. Connect external power supply to "+" terminal of battery connector and "-" side to test set chassis and set external power supply to 14 volts (± 0.3V). Press BATT TEST switch on front panel. Check panel meter for identical voltage (± 0.3V).

F. Turn on battery timer by momentarily depressing the POWER SWITCH to the BATT side. Battery timer "turn-on" should be indicated by test set operation. Slowly reduce external power supply voltage from 14 volts to approximately 11 volts. Battery timer and relay should shut off at external voltage of 11.15 volts to 10.8 volts. For this test, the external power supply must be capable of supplying 10 amps with a maximum ripple voltage of 0.2 volts P-P. Output impedance of the power supply should be quite low to prevent external power supply voltage instability as the input voltage is reduced and the test set duty cycle regulator compensates. For example, when the test set's input voltage decreases, the duty cycle regulator will increase the current drain from the external power supply to maintain constant power consumption. This will cause some external power supplies to become unstable. The start-up surge current of the duty cycle regulator is quite high and may cause some external power supply's current limiting to shut down.

G. Increase external power supply voltage to 14 volts. Turn on the BATT OVEN switch. Observe that the oven light comes on. Slowly reduce external power supply voltage toward 11 volts. Oven light should go out between 11.15 and 10.8 volts.

5.9.2 Power Supply and Regulator Board.

A. With the set operating on line voltage, measure the +11 volts supply at pin 5 of J-27, the Regulator and Power Supply Board Connector (see Fig. 6-1-2) (see Fig. 6-7 for connector pin layout). Voltage should be between 10.93 and 11.07 volts.

B. Measure -35 volt supply at the Regulator and Power Supply connector pin 11 (J-17). Voltage should between -34.5V and -35.5V.

C. Measure -12 volts supply at the Regulator and Power Supply Board connector pin 15 (J-17). Voltage should be between -10.5 and -13 volts.

SECTION VI

CALIBRATION

6.1 Introduction.

6.1.1 The purpose of this section is to give the technician a guide for correcting calibration errors discovered during performance checks (Section 5) of the FM/AM-1000A. A quality spectrum analyzer covering 10 MHz to 2.2 gHz, a well calibrated signal generator, and a 40 MHz oscilloscope are required for complete calibration and service of the FM/AM-1000A. Therefore, this section will be directed toward those portions of the unit that can be calibrated with the average communications shop's equipment.

6.2 Oscilloscope Calibration.

6.2.1 With power off, assure that both meters are mechanically zeroed. Select 000.0000 on FREQUENCY MHz thumbswitches. Select Receive. Select narrow band. Unless stated otherwise, set AUTO ZERO/BATT switch to AUTO for the entire calibration procedure. Zero Frequency Error meter with front panel screwdriver adjustment. Select 15 kHz range on scope Vertical Sensitivity switch. Select scope power to dc position. Center scope trace vertically. Select 000.0100 on FREQUENCY MHz thumbswitches. Scope should show "-" 10 kHz (± 0.5 kHz). If not adjust SCOPE DEVIATION pot (R44) (Fig. 6-76) for "-" 10 kHz indication on scope.

6.3 Receiver Narrow band/Wide band gain adjustment.

6.3.1 With no antenna connected, select AM. Select 155.5000 on FREQUENCY MHz thumbswitches. Select Narrow band. Select Receive. Adjust NARROW BAND ADJUST gain pot (R-8) (Fig. 6-76) upward until Signal Strength meter just moves. Note the RF noise level on the scope. Decrease NARROW BAND ADJUST gain pot (R-8) until RF noise level is reduced by 50%.

6.3.2 With no antenna connected, select AM. Select 155.5000 on FREQUENCY MHz thumbswitches. Select Wide band. Select Receive. Adjust WIDE BAND ADJUST gain pot (R-7) (Fig. 6-76) upward until Signal Strength meter just moves. Note the RF noise level on the scope. Decrease WIDE BAND ADJUST gain pot (R-7) until RF noise level is reduced by 50%.

6.4.3 AGC Adjustment. Select Narrow band. Select Receive. Select 155.5000 on FREQUENCY MHz thumbswitches. Assure that BFO is off. Select AM. Inject a signal of -6 dBm to the antenna input jack. Adjust AGC adjustment pot (R-80) (Fig. 6-76) until the RF level on the scope increases beyond AGC control. Adjust AGC adjustment pot (R-80) back to the point where AGC gains control of scope RF indication. (This is the point at which further downward adjustment of R-80 has no effect). Reduce input signal level to -25 dBm. If signal strength meter indication is above full scale, adjust R-80

to reduce meter indication to full scale. If meter indication is less than full scale, do not change R-80.

6.4 Frequency Error Meter zeroing Adjustment (Setting automatic zeroing circuit to proper operating range).

6.4.1 Assure that both meters are mechanically zeroed with power off. Select Generate. Select Narrow band. Select 1.5 kHz range on Frequency Error meter range select switch. Adjust front panel zero adjustment (screwdriver adjustment) to zero Frequency Error meter. (Range of adjustment is approximately ± 600 Hz). If Frequency Error meter cannot be zeroed with front panel control because it is not out of range, return front panel zero adjustment control to Mid position. Monitor Test Point (TP) (Fig. 6-76) on 250 kHz IF Monitor and Audio Board with voltmeter or oscilloscope and observe voltage to be +1 volt (± 0.5V). If not, adjust FREQUENCY ERROR ZERO pot (R-27) slowly clockwise to increase voltage or counter-clockwise to decrease voltage. While adjusting R-27 for automatic zeroing pulse (every 1.5 seconds) until voltage indication is steady at +1V (± 0.5V). The automatic zeroing range voltage indication at the Test Point (TP, Fig. 6-76) is +6 volts to -7 volts. Outside of this range, automatic zeroing is inoperative. Select Wide band. Voltage at Test Point should be between +1 and -2.5 volts. (Typically, from +1 volt to -1 volt when switching from Narrow band to Wide band). The front panel Frequency Error meter should then be zeroed with front panel zero adjustment control. Switch to RCVR, turn SQUELCH full clockwise, and adjust R-109 to zero Frequency Error meter indication.

6.5 Frequency Error Meter Calibration.

6.5.1 1.5 kHz Adjustment. Select Receive. Select 000.0000 on FREQUENCY MHz thumbswitches. Zero Frequency Error meter using front panel screwdriver zeroing adjustment control. Select 1.5 kHz on Frequency Error Range switch. Select 000.0010 on FREQUENCY MHz thumbswitches. Frequency Error meter should indicate "-" 1 kHz (± 10%). If not, adjust 1.5 kHz FREQUENCY ERROR pot (R-42) (Fig. 6-76 for a "-" 1 kHz (± 10%) meter indication.

6.5.2 5 kHz Adjustment. Select 5 kHz on Frequency Error Range Switch. Select 000.0050 on FREQUENCY MHz thumbswitches. Frequency Error meter should indicate "-" 5 kHz. (± 10%). If not, adjust 5 kHz FREQUENCY ERROR pot (R-41) (Fig. 6-76) for a "-" 5 kHz (± 10%) meter indication.

6.5.3 15 kHz Adjustment. Select 15 kHz on Frequency Error Range Switch. Select 000.0100 on FREQUENCY MHz thumbswitches. Frequency Error meter should indicate "-" 10 kHz (± 10%). If not, adjust 15 kHz FREQUENCY ERROR pot (R-39) (Fig. 6-76) for a "-" 10 kHz (± 10%) meter indication. Select Generate. Select 1.5 kHz scale on Frequency Error Meter range select switch. Touch up meter zero with front panel screwdriver zero adjustment if necessary.

6.6. Frequency Deviation Meter Calibration. (Oscilloscope calibration must be completed prior to meter calibration).

6.6.1 Select Receive. Select Narrow band. Select 000.0000 on FREQUENCY MHz thumbswitches. Select 2 kHz on DEV/PWR Meter Function switch. Adjust RECEIVER DEVIATION ZERO pot (R-52) (Fig. 6-76) for zero Frequency Deviation meter indication. Select Generate. Select Mid band. Turn Tone generator off by rotating INT MOD Control fully counterclockwise. Ensure that 2 kHz is selected on DEV/PWR Meter Function Switch. Adjust GENERATOR DEVIATION ZERO pot (R-70) (Fig. 6-76) for zero Frequency Deviation meter indication (± ½ needle width). Select 15 kHz on scope Vertical Sensitivity Switch. Center scope trace. Select 20 kHz on DEV/PWR Meter Function switch. Select 1000.0 Hz on MODULATION FREQ Hz thumbswitches and set level with INT MOD control until scope shows + and - 10 kHz. Adjust 20 kHz DEVIATION ADJUST pot (R-68) (Fig. 6-76) until Frequency Deviation meter indicates 10 kHz (± 0.1 kHz). Select 6 kHz on scope Vertical Sensitivity switch. Reduce the 1000.0 Hz on scope to + and - 6 kHz deviation with INT MOD control. Select 6 kHz range on DEV/PWR Meter Function Switch. Adjust 6 kHz DEVIATION ADJUST pot (R-66) (Fig. 6-76) until Frequency Deviation meter indicates 6 kHz (± 0.1 kHz). Reduce 1000.0 Hz level on scope to + and - 2 kHz. Select 2 kHz on DEV/PWR Meter Function switch. Adjust 2 kHz DEVIATION ADJUST pot (R-64) (Fig. 6-76) until Frequency Deviation meter indicates 2 kHz (± 0.05 kHz).

6.6.2 If there are problems in obtaining desired results, contact IFR Customer Service Department.

6.7 RF Power Meter Calibration

6.7.1 0-10W Adjustment. Refer to Figure 6-9. Select 0-10W (X1) range on DEV/PWR Meter Function Switch. Adjust ZERO POWER ADJUSTMENT pot (R-4241) (Fig. 6-9) to zero the RF POWER METER indication. Using short lengths of coax cable, connect a 5 to 10 watt VHF transmitter to the input of an inline wattmeter with a known accuracy of 5%. Connect the output of the wattmeter to the TRANS/RCVR input of the FM/AM-1000A. Select Receive mode of operation. Key the transmitter and observe the forward power on the inline wattmeter. Adjust the 0-10W ADJUSTMENT pot on the Power Supply Regulator board (R-4244) (Fig. 6-9) until the front panel RF POWER METER indication agrees with the inline wattmeter.

6.7.2 0-100W Adjustment. Refer to Figure 6-9. Select 0-100W (X10) range on DEV/PWR Meter Function switch. Assure that RF POWER METER indication is zero. If not, adjust ZERO POWER ADJUSTMENT pot (R-4241) (Fig. 6-9) to zero the RF POWER METER indication. Using short lengths of coax cable connect a 50 to 60 watt VHF transmitter to the input of an inline wattmeter with a known accuracy 5%. Connect the output of the wattmeter to the TRANS/RCVR input of the FM/AM-1000A. Select Receive mode of operation. Key the transmitter and observe the forward power on the inline wattmeter. Adjust the 0-100W ADJUSTMENT pot (R-4242) on the Power Supply Regulator board (Fig. 6-9) until the front panel RF POWER METER indication agrees with the inline wattmeter.

6.7.3 If adjustment using normal shop equipment is not possible, contact IFR Customer Service Department.

6.8 Power Supply Calibration FM/AM-1000A. (Re: Power Supply Evaluation, Section 5).

6.8.1 Remove ac line cord and pull battery (or regulator) fuse to prevent damage from accidental shorts while removing duty cycle regulator cover. Remove back cover from Duty Cycle Regulator mounted on speaker side of back panel by removing four screws. The Duty Cycle Regulator board is attached to the cover.

A. Prior to the applying power, insert battery (or regulator) fuse, With the set operating on line voltage, measure the +12 voltage at pin E of the Regulator and Power Supply Board Connector, J-17 (Fig. 6-1-2) (see Figure 6-7 for connector pin layout). Voltage should be +12.2 volts (typically +12.1 to +12.3 volts). Adjust R-5115, the 1K pot, on the Duty Cycle Regulator board for +12.2 volts (Fig. 6-12).

B. +5 volt supply value is set by +12V adjustment and should be +4.7 to +5.25 volts on orange wires on J-3, located just to the right of J-17 (Fig. 6-1-2).

C. -39 volt supply value is set by +12V adjustment and should be between -37 to -45 volts at J17 pin 7 with scope on and off while operating on line or battery.

D. If more than a 75mV ripple is present on dc supply voltages, trouble in the filters is indicated.

E. Disconnect rear panel battery and disconnect line cord. Connect external power supply to "+" terminal of battery connector and "-" side to test set chassis and set external power supply to +14 volts (± 0.3V). Press BATT TEST switch on front panel. Panel meter should indicate 14V (± 0.3V). If not, adjust BATTERY METER ADJUSTMENT pot (R-4227) (Fig. 6-9) until panel meter indicates +14 volts (± 0.3 V).

F. Turn on battery timer by momentarily depressing the POWER SWITCH to the BATT side. Battery timer "turn-on" should be indicated by test set operation. Slowly reduce external power supply voltage from 14 volts to approximately 11 volts. Battery timer and relay should shut off at external voltage of 11.15 volts to 10.8 volts. If not, adjust LOW VOLTAGE CUTOFF pot (R-4214) (Fig. 6-9) so that battery timer and relay shut off between 11.15 and 10.8 volts. For this test, the external power supply must be capable of supplying 10 amps with a maximum ripple voltage of 0.2 volts P-P. Output impedance of the power supply should be quite low to prevent external power supply voltage instability as the input voltage is reduced and the test set's duty cycle regulator compensates. For example, when the test set's input voltage decreases, the duty cycle regulator will increase the current drain from the external power supply to maintain constant power consumpation. This will cause some external power

supplies to become unstable. The start-up surge current of the duty cycle regulator is quite high and may cause some external power supply's current limiting to shut down.

G. Increase external power supply voltage to 14 volts. Turn on the BATT OVEN switch. Observe that oven light comes on. Slowly reduce external power supply voltage toward 11 volts. Oven light should go out between 11.15 and 10.8 volts. If not, adjust OVEN LOW VOLTAGE CUTOFF pot (R-4233) (Fig. 6-9) so that oven light goes out between 11.15 and 10.8 volts. Disconnect external power supply install duty cycle regulator and cover, install battery (or regulator) fuse, install battery and cover, and reconnect ac line cord.

6.8.2 Power Supply and Regulator Board

A. With the set operating on line voltage, measure the +11 volt supply at pin 5 of J17, the Regulator and Power Supply Board connector (see Fig. 6-1-2) (see Fig. 6-7 for connector pin layout). Voltage should be between 10.93 to 11.07 volts. If not, adjust 11V ADJUSTMENT (R-4224) (Fig. 6-9) for +11 volts (± 0.07V).

B. Measure -35 volt supply at the Regulator and Power Supply Board connector pin 11 (J-17). Voltage should be between -34.5V and -35.5V.

C. Measure -12 volt supply at the Regulator and Power Supply Board connector pin 15 (J-17). Voltage should be between -10.5V and -13V.

9 PC BOARD NO. 1-23-512
8 SCHEMATIC NO. 2-23-546
7 COMPONENT DESIGNATORS HAVE 46 PREFIX i.e. R4601, C4601. L4601 etc.

6 "*" DENOTES 1/8W, 10% RES.
5 R7 IS 51 OHM, 1/4W, 5% RES.
4 MAX. HEIGHT OF COMPONENTS TO BE .53 FROM COMPONENT SIDE OF BOARD.
3 COMPONENT LEADS MAY EXTEND .04 TO .06 BEYOND BOTTOM OF BOARD AFTER SOLDERING.
2 ALL CAPACITORS ARE IN µf EXCEPT AS NOTED.
1 ALL RESISTORS ARE 1/4W, 10% TOL. EXCEPT AS NOTED.

PC BD.: 1-23-0301
SCHEMATIC: 2-23-0300

1. ALL RESISTORS ARE 1/4 W., 10% TOLERANCE EXCEPT AS NOTED.
2. ALL CAPACITOR VALUES ARE IN µF EXCEPT AS NOTED, AND ARE NPO.
3. COMPONENT LEADS MAY EXTEND .04 TO .06 BEYOND BOTTOM OF BOARD AFTER SOLDERING.
4. MAXIMUM HEIGHT OF COMPONENTS TO BE .35 FROM COMPONENT SIDE OF BOARD.
5. PLACE CHIP CAPACITORS ON BACK SIDE OF BOARD.
6. ALL COMPONENT DESIGNATORS HAVE 300 PREFIX; i.e. R3001, Q3001, etc.

NOTES:

1. ALL RESISTORS ARE 1/4 W., 10% TOLERANCE EXCEPT AS NOTED.
2. ALL CAPACITOR VALUES ARE IN µF EXCEPT AS NOTED, AND ARE "NPO" TYPE.
3. COMPONENT LEADS MAY EXTEND .04 TO .06 BEYOND BOTTOM OF BOARD AFTER SOLDERING.
4. MAXIMUM HEIGHT OF COMPONENTS TO BE .84 FROM COMPONENT SIDE OF BOARD.
5. ASTERISK (✱), DENOTES "NPO" TYPE CAPACITORS.
6. ALL COMPONENT DESIGNATORS HAVE 262 PREFIX; i.e. R26201, Q26201, etc.
7. LOCATE RG-178 B/U FLEXIBLE COAX & APPLY "GE"/EQUIV. RTV IN LOCATION SHOWN TO SUITABLY SECURE CABLE ALONGEDGE OF P.C. BOARD.
8. COMPONENTS ON BACK OF BD. SHOULD BE LAID FLAT AGAINST THE BD.

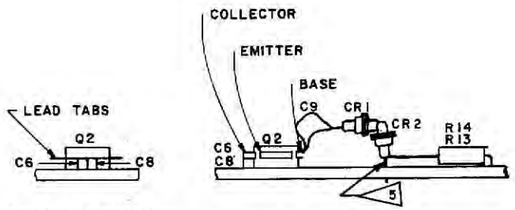
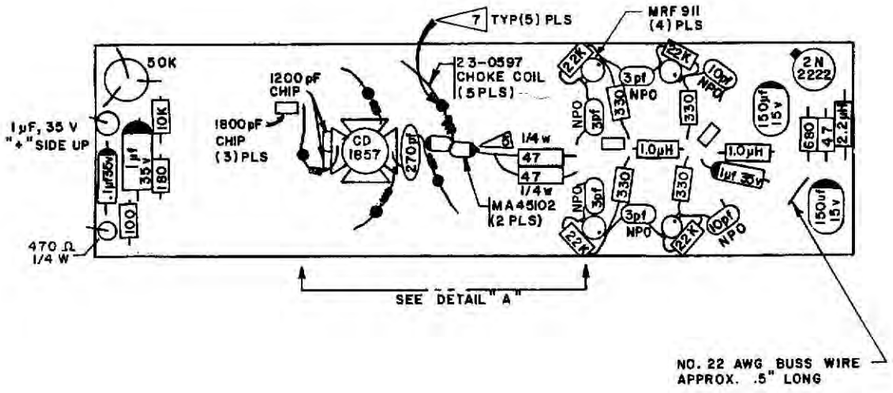
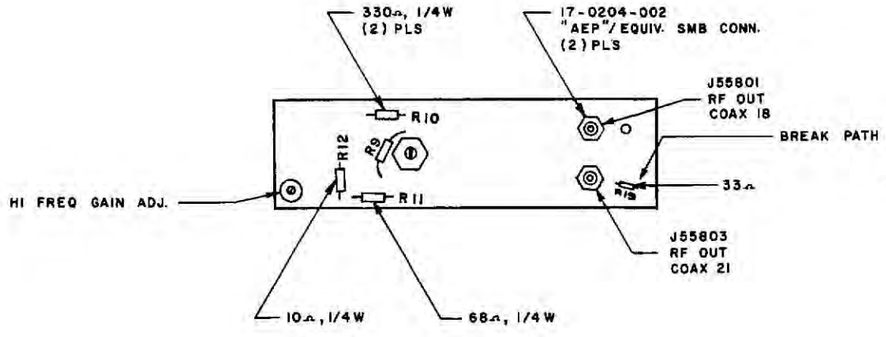
DETAIL "A"



ASSEMBLY NOTES:

1. THE CHIP CAPACITORS MUST BE HANDLED WITH THE AID OF NON-METALLIC TWEEZERS, OR BY USING LEAD TABS.
2. THE TWO CHIP CAPACITORS ARE MOUNTED AS CLOSE TO THE TRANSISTOR AS POSSIBLE AND BACK-TO-BACK, WITH THE LEAD TABS OF THE TWO CAPACITORS EXTENDING AWAY FROM EACH OTHER. TRIM LEAD TAB FLUSH WITH COLLECTOR AFTER CHIPS ARE MOUNTED.
3. C9 CAPACITOR IS MOUNTED IN A VERTICAL PLANE WITH ONE END ATTACHED AS CLOSE AS POSSIBLE TO THE TRANSISTOR (BASE LEAD TO BE AS SHORT AS POSSIBLE). THE OTHER LEAD OF C9 SHOULD BE APPROX. .25 SO THAT CR1 LEAD JOINT MAY BE VARIED DURING VCO ALIGNMENT.
4. CR2 DIODE SHOULD BE MOUNTED APPROX. VERTICAL AND ON THE BUSS WIRE JUST ABOVE THE JUNCTION OF R13 AND R14 RESISTORS. CR1 & CR2 LEADS TO BE AS SHORT AS POSSIBLE.
5. THE LEADS OF THE FIVE COILS (23-0597) THAT ARE ATTACHED TO THE TRANSISTOR OR DIODE SHOULD BE AS SHORT AS POSSIBLE. SEE FLAG # 7.





NOTES:

1. ALL RESISTORS ARE 1/8W., 10% TOLERANCE EXCEPT AS NOTED.
2. ALL CAPACITOR VALUES ARE IN µF EXCEPT AS NOTED.
3. COMPONENT LEADS MAY EXTEND .04 TO .06 BEYOND BOTTOM OF BOARD AFTER SOLDERING.
4. MAXIMUM HEIGHT OF COMPONENTS TO BE .35 FROM COMPONENT SIDE OF BOARD.
5. USE NO. 22 AWG BUSS WIRE TO CONNECT MA45102 DIODE & (2) 47Ω RESISTORS TO GROUND.
6. FM/AM 1000A
7. APPLY 1/16" DIA STRAND OF "G.E."/EQUIV. RTV FROM GROUND LEAD OF COIL TO SURFACE OF BOARD, APPROX. 1/8" FROM COIL.
