Tektronix

TDS 520B Mod CM Digitizing Oscilloscope Component Service Manual

070-9710-03

First Edition: May 30, 1996
Revised: February 26, 1998

Serial Numbers: **B030000 and above**

Warning
The servicing instructions are for use by qualified personnel only. To avoid personal injury, do not perform any servicing unless you are qualified to do so. Refer to all safety summaries prior to performing service.

Printed in the U.S.A.

Tektronix, Inc., P.O. Box 1000, Wilsonville, OR 97070–1000

WARRANTY

Tektronix warrants that this product will be free from defects in materials and workmanship for a period of three (3) years from the date of shipment. If any such product proves defective during this warranty period, Tektronix, at its option, either will repair the defective product without charge for parts and labor, or will provide a replacement in exchange for the defective product.

In order to obtain service under this warranty, Customer must notify Tektronix of the defect before the expiration of the warranty period and make suitable arrangements for the performance of service. Customer shall be responsible for packaging and shipping the defective product to the service center designated by Tektronix, with shipping charges prepaid. Tektronix shall pay for the return of the product to Customer if the shipment is to a location within the country in which the Tektronix service center is located. Customer shall be responsible for paying all shipping charges, duties, taxes, and any other charges for products returned to any other locations.

This warranty shall not apply to any defect, failure or damage caused by improper use or improper or inadequate maintenance and care. Tektronix shall not be obligated to furnish service under this warranty a) to repair damage resulting from attempts by personnel other than Tektronix representatives to install, repair or service the product; b) to repair damage resulting from improper use or connection to incompatible equipment; or c) to service a product that has been modified or integrated with other products when the effect of such modification or integration increases the time or difficulty of servicing the product.

THIS WARRANTY IS GIVEN BY TEKTRONIX WITH RESPECT TO THIS PRODUCT IN LIEU OF ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED. TEKTRONIX AND ITS VENDORS DISCLAIM ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. TEKTRONIX' RESPONSIBILITY TO REPAIR OR REPLACE DEFECTIVE PRODUCTS IS THE SOLE AND EXCLUSIVE REMEDY PROVIDED TO THE CUSTOMER FOR BREACH OF THIS WARRANTY. TEKTRONIX AND ITS VENDORS WILL NOT BE LIABLE FOR ANY INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES IRRESPECTIVE OF WHETHER TEKTRONIX OR THE VENDOR HAS ADVANCE NOTICE OF THE POSSIBILITY OF SUCH DAMAGES.

General Safety Summary

Review the following safety precautions to avoid injury and prevent damage to this product or any products connected to it. To avoid potential hazards, use the product only as specified.

Only qualified personnel should perform service procedures.

Injury Precautions

Use Proper Power Cord To avoid fire hazard, use only the power cord specified for this product.

Avoid Electric Overload To avoid electric shock or fire hazard, do not apply a voltage to a terminal that is outside the range specified for that terminal.

Ground the Product This product is grounded through the grounding conductor of the power cord. To avoid electric shock, the grounding conductor must be connected to earth ground. Before making connections to the input or output terminals of the product, ensure that the product is properly grounded.

Do Not Operate Without Covers To avoid electric shock or fire hazard, do not operate this product with covers or panels removed.

Use Proper Fuse To avoid fire hazard, use only the fuse type and rating specified for this product.

Do Not Operate in Wet/Damp Conditions To avoid electric shock, do not operate this product in wet or damp conditions.

Do Not Operate in Explosive Atmosphere To avoid injury or fire hazard, do not operate this product in an explosive atmosphere.

Keep Probe Surface Clean To avoid electric shock and erroneous readings, keep probe surface clean.

Product Damage Precautions

Use Proper Power Source Do not operate this product from a power source that applies more than the voltage specified.

Use Proper Voltage Setting

Before applying power, ensure that the line selector is in the proper position for the power source being used.

Provide Proper Ventilation

To prevent product overheating, provide proper ventilation.

Do Not Operate With Suspected Failures

If you suspect there is damage to this product, have it inspected by qualified service personnel.

Do Not Immerse in Liquids

Clean the probe using only a damp cloth. Refer to cleaning instructions.

Safety Terms and Symbols

Terms in This Manual

These terms may appear in this manual:

WARNING. *Warning statements identify conditions or practices that could result in injury or loss of life.*

CAUTION. *Caution statements identify conditions or practices that could result in damage to this product or other property.*

Terms on the Product

These terms may appear on the product:

DANGER indicates an injury hazard immediately accessible as you read the marking.

WARNING indicates an injury hazard not immediately accessible as you read the marking.

CAUTION indicates a hazard to property including the product.

Symbols on the Product

The following symbols may appear on the product:

DANGER
High Voltage

Protective Ground
(Earth) Terminal

ATTENTION
Refer to
Manual

Double
Insulated

Certifications and Compliances

CSA Certified Power Cords

CSA Certification includes the products and power cords appropriate for use in the North America power network. All other power cords supplied are approved for the country of use.

Service Safety Summary

Only qualified personnel should perform service procedures. Read this *Service Safety Summary* and the *General Safety Summary* before performing any service procedures.

Do Not Service Alone

Do not perform internal service or adjustments of this product unless another person capable of rendering first aid and resuscitation is present.

Disconnect Power

To avoid electric shock, disconnect the main power by means of the power cord or, if provided, the power switch.

Use Caution When Servicing the CRT

To avoid electric shock or injury, use extreme caution when handling the CRT. Only qualified personnel familiar with CRT servicing procedures and precautions should remove or install the CRT.

CRTs retain hazardous voltages for long periods of time after power is turned off. Before attempting any servicing, discharge the CRT by shorting the anode to chassis ground. When discharging the CRT, connect the discharge path to ground and then the anode. Rough handling may cause the CRT to implode. Do not nick or scratch the glass or subject it to undue pressure when removing or installing it. When handling the CRT, wear safety goggles and heavy gloves for protection.

Use Care When Servicing With Power On

Dangerous voltages or currents may exist in this product. Disconnect power, remove battery (if applicable), and disconnect test leads before removing protective panels, soldering, or replacing components.

To avoid electric shock, do not touch exposed connections.

X-Radiation

To avoid x-radiation exposure, do not modify or otherwise alter the high-voltage circuitry or the CRT enclosure. X-ray emissions generated within this product have been sufficiently shielded.

Preface

This preface contains information needed to properly use this manual to service the TDS 520B Digitizing Oscilloscope, as well as general information critical to safe and effective servicing of this oscilloscope.

Manual Structure

This manual is divided into sections, such as *Theory of Operation* and *Parts Lists*. Further, it is divided into subsections, such as *Product Description* and *Removal and Installation Procedures.*

Sections containing procedures also contain introductions to those procedures. Be sure to read these introductions because they provide information needed to do the service correctly and efficiently. The following is a brief description of each manual section.

- *Theory of Operation* contains circuit descriptions that support general service and fault isolation down to the module level.
- *Electrical Parts List* contains a statement referring you to *Mechanical Replaceable Parts*, where both electrical and mechanical modules are listed.
- *Mechanical Parts List* includes a table of all replaceable modules, their descriptions, and their Tektronix part numbers.
- *Schematics* contains schematic diagrams of the various circuit boards in the TDS 520B.
- Dollies contains diagrams of the various circuit boards in the TDS 520B.

Manual Conventions

This manual uses certain conventions which you should become familiar with before doing service.

Modules

Throughout this manual, any replaceable component, assembly, or part of these Digitizing Oscilloscope is referred to generically as a module. In general, a module is an assembly, like a circuit board, rather than a component, like a resistor or an integrated circuit. Sometimes a single component is a module; for example, each chassis part of the oscilloscope is a module.

Safety Symbols and terms related to safety appear in the Safety Summary found at the beginning of this manual.

Symbols Besides the symbols related to safety, this manual uses the following symbols:

STOP*. The stop labels information which must be read in order to correctly do service and to avoid incorrectly using or applying service procedures.*

The clock icon labels procedure steps which require a pause to wait for the oscilloscope to complete some operation before you can continue.

Various icons such as the example icon at the left are used in procedures to help identify certain readouts and menu functions on screen.

Related Manuals

The TDS 520B Digitizing Oscilloscope, Option CM comes with the following manuals:

TDS 520B, TDS 540B, TDS 620B, TDS 644B, TDS 680B, TDS 684B, TDS 724A, TDS 744A, & 784A User Manual (Tektronix part number 070-9383-XX) contains a tutorial to quickly show you how to operate the TDS 520B Digitizing Oscilloscope and an in depth discussion of how to more completely use their features. Applications are also discussed.

TDS 520B, TDS 540B, TDS 620B, TDS 644B, TDS 680B, TDS 684B, TDS 724A, TDS 744A, & TDS 784A Reference (Tektronix part number 070-9382-XX) contains a brief overview of oscilloscope operation.

TDS Family (400A, 500B, 600B, and 700A) Programmer Manual (Tektronix part number 070-9556-XX) contains information for programmed operation via the GPIB interface. Included are the complete command set, setup information, and programming examples.

TDS 520B, TDS 540B, TDS 620B, TDS 644B, TDS 680B, TDS 684B, TDS 724A, TDS 744A, & TDS 784A Technical Reference (Tektronix part number 070-9384-XX) contains performance verification procedures and specifications.

TDS 520B, TDS 540B, TDS 620B, TDS 644B, TDS 680B, TDS 684B, TDS 724A, TDS 744A, & TDS 784A Service (Tektronix part number 070-9386-XX) contains repair procedures to the modular level.

Theory of Operation

Theory of Operation

This section describes the electrical operation of the TDS 520B Digitizing Oscilloscope. First, an overview discussion, based on the block diagram, gives an overall view of the module design. Next, a detailed circuit description, based on the schematic diagrams in Section 5, gives a more detailed view. These descriptions, together with the troubleshooting information in the TDS 500B, 600B, and 700A Service Manual, Tektronix part number 070-9386-01, should enable a qualified technician with the appropriate test equipment to isolate a problem to the appropriate level.

This section has three main parts:

- *Logic Conventions* describes how logic functions are discussed and represented in this manual.
- *Module Overview* describes circuit operation from a functional-circuit block perspective.
- *Detailed Circuit Description* provides detailed information about TDS 520B Digitizing Oscilloscope hardware with reference to the numbered schematics in Section 3.

Logic Conventions

The Digitizing Oscilloscope contain many digital logic circuits. This manual refers to these circuits with standard logic symbols and terms. Unless otherwise stated, all logic functions are described using the positive-logic convention: the more positive of the two logic levels is the high (1) state, and the more negative level is the low (0) state. Signal states may also be described as “true” meaning their active state or “false” meaning their nonactive state. The specific voltages that constitute a high or low state vary among the electronic devices.

Active-low signals are indicated by a tilde prefixed to the signal name (~RESET). Signal names are considered to be either active-high, active-low, or to have both active-high and active-low states.

Module Overview

This module overview describes the basic operation of each functional circuit block as shown in Diagram ◇0◇. Figure 5-2.

General

The TDS 520B Digitizing Oscilloscope is a portable two-channel instrument. Each channel provides a calibrated vertical scale factor.

Input Signal Path

A signal enters the oscilloscope through a probe connected to a BNC on the A10 Attenuator/Acquisition board.

Attenuators. Circuitry in the attenuator selects the input coupling, termination, and the attenuation factor. The processor system, by way of the acquisition system, controls the attenuators. For example, if 50 Ω input termination is selected and the input is overloaded, the processor system switches the input to the 1 MΩ position.

Probe Coding Interface. Probe coding interface signals pass through the attenuator portion of the A10 Attenuator/Acquisition to the acquisition system, where they are sensed and controlled.

Acquisition System. The acquisition system amplifies the input signals, samples them, converts them to digital signals, and controls the acquisition process under direction of the processor system. The acquisition system includes the trigger, acquisition timing, and acquisition mode generation and control circuitry.

D1 Bus. The acquisition system passes the digital values representing the acquired waveform through the A14 D1 Bus to the A11 DRAM Processor/Display board. This happens after a waveform acquisition is complete if the digital signal processor in the processor system requests the waveform.

Processor System. The processor system contains a 68020 microprocessor that controls the entire instrument. This system also includes the firmware and a GPIB interface. You can reprogram the firmware from a remote controller using the GPIB and an external software package.

The processor also includes a digital signal processor. This signal processor processes each waveform as directed by the system processor. Waveforms and any text to be displayed are passed on to the display system. The A11 DRAM Processor/Display board contains both the processor and display systems.

Display System. Text and waveforms are processed by different parts of the display circuitry. The display system sends the text and waveform information to the tube assembly as a video signal. The display system also generates and sends vertical (VSYNC) and horizontal (HSYNC) sync signals to the tube assembly. A VGA-compatible video output is at the rear of the TDS 520B.

Tube Assembly

All information (waveforms, text, graticules, and pictographs) is displayed by the A20 Display system. The A20 generates the high voltages necessary to drive the display tube. It also contains the video amplifier, horizontal oscillator, and the vertical and horizontal yoke driver circuitry.

Front Panel

The processor system sends instructions to and receives information from the Front Panel Processor on the A12 Front Panel board. The Front Panel Processor reads the front-panel switches and potentiometers. Any changes in their settings are reported to the processor system. The Front Panel Processor also turns the LEDs on and off and generates the bell signal.

Front-panel menu switches are also read by the Front Panel Processor. The processor sends any changes in menu selections to the processor system. The **ON/STBY** switch is one of the menu switches. However, it is not read by the Front Panel Processor, but passes through the A12 Front Panel board and the A11 DRAM Processor/Display board to the low voltage power supply.

The front panel also generates the probe compensation signals **SIGNAL** and **GND**.

Rear Panel

The **GPIB** connector provides access to stored waveforms, and allows external control of the oscilloscope. Other rear panel connectors are the **AUX TRIGGER INPUT**, **MAIN** and **DELAYED TRIGGER OUTPUT**, and a **CHANNEL 3 SIGNAL OUTPUT**.

You can make hardcopies on the GPIB port. If your TDS 520B has the optional RS-232 and Centronics ports, you can also use those.

Low Voltage Power Supply

The low voltage power supply is a switching power converter with active power factor control. It supplies power to all of the circuitry in the oscilloscope.

The principal **POWER** switch, located on the rear panel, controls all power to the oscilloscope including the Low Voltage Power Supply. The **ON/STBY** switch, located on the front panel, also controls all of the power to the oscilloscope except for part of the circuitry in the Low Voltage Power Supply.

The power supply sends a power fail (~PF) warning to the processor system if the power is going down.

Fan

The fan provides forced air cooling for the oscilloscope. It connects to +25 V from the Low Voltage Power Supply by way of the A11 DRAM Processor/Display module.

Detailed Circuit Description

This detailed circuit description describes the operation of the oscilloscope circuitry shown in schematic diagrams in the *Diagrams* section. While reading this description, refer to the block diagrams and the schematic diagrams in the *Diagrams* section.

Acquisition System A10 ◇1

The A10 Acquisition board amplifies, via the attenuator assembly, and acquires the analog signal. The acquisition system converts the signal to digital and stores it in acquisition memory. Acquisition and trigger control circuitry controls the acquisition process. DSP and the 68020 monitor and control the overall system, and transfer the acquired waveform to the display system.

Attenuators A10 ◇3 ◇4 ◇5 ◇6

The attenuator assembly contains four attenuator hybrids, see Figure 1–1, and four probe connectors. Each attenuator hybrid contains resistive dividers, an AC coupling capacitor, relays, a 50 Ω terminator, a buffer amplifier, and a preamp. The outputs of the attenuator assembly (the preamp output) drive the track and hold.

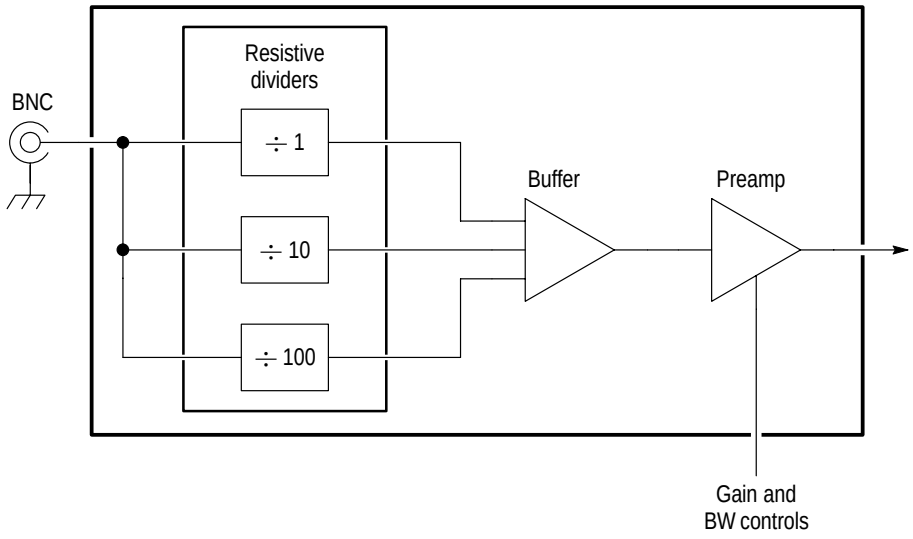

Figure 1–1: Attenuator hybrid

From here on the theory refers only to Ch4. The other channels work in similar ways.

The 68020 interprets user commands and initiates changes to the settings. The Acquisition Processor monitors the input overload sense (OVLS1–OVLS4) and the probe data (PRDATA1–PRDATA4) communication lines.

Each attenuator hybrid has five relays. One or more of the relays must be turned on if a signal is to pass from the BNC to the output of the attenuator.

The AC/DC coupling relay couples the output of the BNC to the other relays in the attenuator hybrid. For AC signals, the AC/DC coupling relay inserts a coupling capacitor into the input signal path.

When active, the 1 M/50 Ω relay terminates the input in 50 Ω.

A relay driver (U1102, sheet 6) selects an attenuator's attenuation factor by connecting one of its relays to the input BNC, and connecting all of its other relays to the ATTNCAL adjustment signal.

When ATTENSTB goes high, all attenuators enter their inactive state. Attenuator clock CCATTN clocks control data (DIN, U1102, pin 3) from the processor system into the attenuator Relay Driver. With a new pattern in the Relay Driver, the processor system sets ATTENSTB low, enabling the attenuators.

The serial data line (DIN, U1102, pin 3) comes from sheet 21, U1050, pin 27. The strobe (ATTENSTB, U1102, pin 8) comes from sheet 21, U1050 pin 11 (SCLK2). The DOUT line (U1102, pin 6) feeds the shifted data to the Ch3 relay driver, where it becomes DIN for Ch3 (U1202, pin 3). This continues until Ch1. After Ch1, the DOUT pin (sheet 3, U1402, pin 6) is sent back to sheet 21, U1050, pin 6. By feeding the serial data back to the control IC (U1050), the system can perform diagnostics on the serial data path.

Preamps A10

3 4 5 6 7

Since the preamp circuitry for each preamp is similar, only the circuitry for Preamp 4 is described. Preamp 4 provides gain switching, bandwidth limit filters, and outputs for the display, trigger, and other signal paths.

The system processor controls the Preamp 4 functions. It sends commands over serial data line.

The Analog DAC Control system provides DC voltage signals that set the Preamp offset. The Acquisition Processor (U600) stores the digital values of each of the voltage levels in digital-to-analog converter (DAC) U900. The Acquisition Processor transfers each voltage through DAC Multiplexer U934 to Preamp 4. Preamp variable gain, HF adjust, fine offset and balance controls are controlled by the daculator (U904) which is controlled by the GTL (U1050) via the serial data bus (SDOUT U1050).

Preamp 4 Control Buffers. (sheet 6) The Preamp 4 Control Buffers provide offset, balance, variable gain, and high frequency compensation voltages for the preamp.

The offset control voltage is sampled by U934 (sheet 26) and held on capacitor C1101. U1405 buffers the hold voltage so it can be fed into the attenuator hybrid and then to the preamp. Fine offset and balance controls do not need a hold cap because they come from the daculator (U904) which internally holds the voltages. Fine offset and balance are buffered by U1101 and then summed together with offset. HF adjust and var gain are fed directly to the preamp from the daculator (U904).

Preamp Control 4. U1403 and U1404 (sheet 7) are the serial in, parallel out shift registers that load the preamp control bits. Serial data flows into U1403 pin 1 (from sheet 21, U1050, pin 27). The data is shifted into the registers by SCLK3 (U1403 and U1404, pin 8). SCLK3 comes from sheet 21, U1050, pin 12. Data flows from the last bit of U1043 to the serial input pin of U1404 and then from the last bit of U1404 back to sheet 21, U1050, pin 7 for diagnostic purposes. There are three steps in the process of programming the preamps. First, 16 bits are shifted into the two registers (U1403 and U1404) – only QA, QB, QC, QD, and QE of each register will be used. The Ch1/Ch3 preamp strobe (sheet 3,

JP1400, pin 112 and sheet 5, JP1200, pin 112) is strobed to latch the gain and bandwidth bits into Ch1 and Ch3. This strobe pin comes from sheet 21, U1050, pin 17. Next, 16 more bits are shifted in and again only the 10 bits mentioned above are used. However, this time, the Ch2/Ch4 preamp strobe (sheet 4, JP1400, pin 212 and sheet 6, JP1200, pin 212) is strobed to latch the gain and bandwidth bits into Ch2 and Ch4. Finally, 16 more data bits are shifted in. These are left there to set the output controls of all four channels.

Preamp 4. The preamps amplify the input voltage. Input signals come from the attenuator. The nominal gain of each preamp is 1.05 (at 50 mV per division); the gain of the attenuator is 0.95 (in 1X attenuation). The combined gain from BNC connector to A/D Converter D is 1.00.

Preamp 4 is an integrated circuit containing:

- Two four-pole bandwidth-limit filters: 20 MHz and 250 MHz. Inputs B0–B1 control the bandwidth of Preamp 4. See Table 1–2.
- Six gain settings of 1 mV, 2 mV, 5 mV, 10 mV, 20 mV, and 50 mV per division (see Table 1–3). Inputs G0–G2 control the gain of Preamp 4.
- High-frequency adjust inputs.
- A variable gain control input which linearly adjusts the overall gain. The gain is zero at –1 V and maximum at +1 V.
- Three separate differential outputs that can be turned on or off using the output enable control signals (out1en, out2en, out3en). The inv controls are left at 0.

Table 1–2: Bandwidth Limit Selection Bits(Cont.)

Bandwidth	B1	B0
20 MHz	0	0
250 MHz	0	1
Maximum	1	X

Table 1–3: Gain Set Bits

Gain Setting	G2	G1	G0
20 mV	1	0	X
50 mV	1	1	X

Track/Hold A10 ◇8

The track/hold IC (U1250) samples the differential analog signals coming from the preamps before sending them to the A/D converters. The A/D clocks are also provided by the track/hold. The track/hold IC also provides all channel switching necessary to facilitate 2–way and 4–way interleaving. There are 8 control bits that are serially shifted into U1251 and parallel fed to the track/hold. The data line (SDATA, U1251 pin 1) comes from sheet 21, U1050, pin 27. The data is fed back (SDIAG1, U1251, pin 13) to U1050, pin 5 for diagnostic purposes). The data is clocked in by U1251, pin 8 (which comes from sheet 21, U1050 pin 10.) The differential analog signals coming from the preamps are labelled DISP1+/DISP1– thru DISP4+/DISP4–. The differential clocks going to the A/D converters are labelled CLKAH/CLKAL thru CLKDH/CLKDI. The differential analog sampled signals going to the A/D converters are labelled AP+/AP– through DP+/DP–. Note, from the top level block diagram, that the signals going from the preamps to the A/D converters get crossed (see Tables 1–4, 1–5, and 1–6 to verify this).

Table 1–4: Preamps to Track/Hold Input

Preamps	Track/Hold Input	Comments
Ch1	DISP1	
Ch2	DISP2	
Ch3	DISP4	Ch3 and Ch4 cross here

Table 1–5: Track/Hold Outputs to A/D Input

Track/Hold Outputs	A/D Input	Comments
AP	SIGB	AP and BP cross here
BP	SIGA	
CP	SIGC	CP and DP are inactive on the TDS 520B and TDS 724A
DP	SIGD	

Table 1–6: Preamps to Track/Hold Input

Track/Hold Clock Outputs	A/D Clock Input	Comments
CLKA	CLKB	
CLKB	CLKA	
CLKC	CLKC	CLKC and CLKD are inactive on the TDS 520B and TDS 724A
CLKD	CLKD	

In order to provide interleave capability, the Track/Hold must independently adjust the delays of each of the sample clocks going to the A/D converters. These are controlled by PHSA, PHSB, PHSC, and PHSD (pins 10, 111, 31, and 90 respectively of U1250) analog control voltages from the daculator (sheet 24, U906). A three phase version of the 1GHz timebase clock is fed in through the PHS1, PHS2, and PHS3 signals.

A/D Converters A10

9 10 11 12

***NOTE**. The TDS 520B and 724A only have A/D converts A and B. C and D are not placed.*

Since each A/D converter is similar, only the circuitry for A/D Converter D is described. A/D Converter D (U700) converts the selected differential analog input voltage to an 8-bit binary number. The analog input sensitivity is 2 mV per digitizing level. Conversions occur at the 1 GHz clock rate (CLKD U700, pins 53 and 55). Even though conversions occur at this rate, data is output as two differential 8-bit words (D0H/D0L–D7H/D7L and A0H/A0L–A7H/A7L) at a 500 MHz rate.

Pipes C and D (sheets 11 and 12) are not placed in the TDS 520B and TDS 724A.

Inputs. The A/D converter has one differential input (pins 60 and 62) fed from the track/hold. Tables 1–4, 1–5, and 1–6 show which track/hold output connects to which A/D converter. The 1 GHz differential input clocks from the track/hold are fed into pins 53 and 55. Each side of the differential clock is 250 mV p–p swing with the high level at 0 V.

Outputs. Outputs from the A/D Converter are differential, 500 mV digital swings (peak to peak on each side.) The output resistance is 65 ohms. The two 8–bit 500

MS/s streams become valid on alternate edges of the clock cycle (D is valid on the rising edge, A is valid on the falling edge.)

Control. The A/D converter has two DC analog controls: OFFSET, which sets the A/D offset, and VREF, which adjusts the gain. These controls come from a daculator IC (U906, sheet 24). The VREF control voltage is preconditioned by U701 so that it ranges from 1.56 V to 3.44 V.

Sampling of the analog input voltage occurs on the positive going transition of convert clock (CLK0, pins 53 and 55). Digitized value is available after the 11th subsequent clock cycle.

DMUX & Acquisition Memory A10

13 14 15 16

***NOTE**. The TDS 520B and 724A only have pipes A and B placed. They do not use C and D.*

Since the circuitry for each demultiplexer and acquisition memory is similar, only the circuitry for pipe D Acquisition Memory is described. The demultiplexer is the time base and memory control system for the output of an A/D converter. Each demultiplexer has an A/D data input (Ch4D and Ch4A), acquisition memory output, DSP bus interface, and a trigger interface (see Figure 1–2).

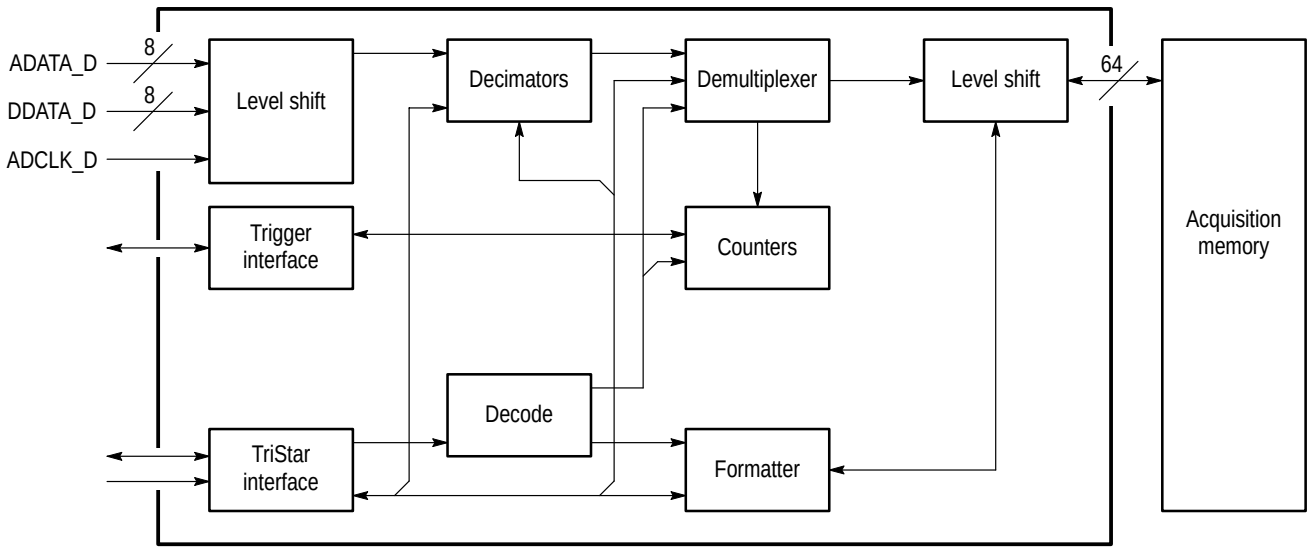

Figure 1–2: Demultiplexer Block Diagram

Demultiplexer D. Demultiplexer D has two operating modes. In acquire mode, Demultiplexer D (U100) collects data from an A/D converter and writes the data into Acquisition Memory D. In save mode, the DSP reads the acquired data from Acquisition Memory D. The display system then processes and displays the data.

In acquire mode, Demultiplexer D (U100) gets its data (ADATA_DH0/ADATA_DL0 – ADATA_DH7/ADATA_DL7 and DDATA_DH0/DDATA_DL0 – DDATA_DH7/DDATA_DL7) from A/D Converter D (U700) at a rate of two new 8-bit samples every 2 ns. The input data sample is a 500 mV swing with Von ≈ 4.2V. It latches the data on the falling edge of clock ADCLK_D and converts it to CMOS levels. Data then passes to a demultiplexer at full speed, or is decimated under program control.

The decimation mode determines the sample-rate. When the digital trigger is the source of the trigger, the state of the decimators is latched at the trigger to assist in point placement.

There are three decimation modes: normal, min/max, *and* hires*:*

- Normal (sub-sample) mode throws away samples between saved sample points.
- Min/max mode saves the maximum and minimum samples over the decimation interval.
- Hires mode gives extra resolution by averaging the samples, on a single-shot basis, over the decimation interval.

An internal demultiplexer splits the two 8-bit data streams coming out of the decimators into 16 8-bit data streams. The data streams are 2–way interleaved resulting in a 64–bit data bus, with two memory chips on each byte. This results in a 64-bit wide data word.

Demultiplexer D has three programmable counters that keep track of the number of samples before the trigger, the number of samples after the trigger, and the location in Acquisition Memory D where the trigger occurred. Before a trigger occurs, the RUNM signal is asserted by the trigger logic (U1001, pin 146, sheet 20). After the trigger when the proper number of post–trigger samples have been taken, RUNM is deasserted which stops the DMUX and causes it to interrupt the processor.

During save mode, the DSP can access Acquisition Memory D. Memory mapped I/O select MMIO accesses pin 74, the internal programming and status registers. To further decode the MMIO select, the middle address bits are used as sub-system selects.

Input MMIOA (U100, pin 73) acts as the sub-system selector for the memory mapped I/O in the demultiplexers. To address the internal registers, DSP asserts both MMIO and MMIOA.

During DSP writes to Acquisition Memory D, circuitry in Demultiplexer D aligns the byte-wide data for byte writes into Acquisition Memory D.

DSP can clock Demultiplexer D for test purposes. Diagnostics can switch in a counter instead of A/D Converter D so that Demultiplexer D acquires a predictable pseudorandom sequence.

Acquisition Memory D. During acquire mode, Demultiplexer D writes to Acquisition Memory D when eight samples accumulate. The full 64 bits are always written in parallel. Two address buses allow two sets of memory to share the 64-bit data bus on alternate 8ns cycles.

Phase lock loop/clock generator A10 17

The 1 GHz system timebase is generated from a VCO (centered around Q531) that is phase locked to a 25 ppm, 25 MHz reference crystal oscillator. U510 is the phase/frequency detector. The integrator is made from U502 and surrounding components. The single–ended 1 GHz VCO output is converted to differential (via delay lines) and fed to the trigger logic (U1001, sheet 20, pins 140 and 142). The trigger logic divides the clock down to 25 MHz and feeds it back to the PLL (from U1001, pins 12 and 13).

Analog Triggers A10 18

The analog triggers are free-running analog comparators with channel switching.

The following is described in terms of the Ch1 and Ch2 analog triggers:

The analog trigger comparator (U1551, sheet 18) is a channel switch and analog comparator combination. Ch1 is differentially fed into IN1(H/L) (pin 5,4), CH2 is fed into IN2(H/L) (pin 41,41). The main trigger output is OUT11(H/L) (pins 20, 21) and the delay trigger output is OUT21(H/L) (pins 26, 25). The channel switch allows either Ch1 or Ch2 to be the main or delay trigger event or both. The comparators are after the channel switch, so the trigger level and hysteresis controls are associated with the main delay trigger rather than Ch1 or Ch2 trigger. Trigger coupling is generated with U1560/U1561 filter circuits. Referring to Ch1, AC coupled trigger occurs when C1556 is connected to ground via U1556 and the analog trigger (U1551) is programmed to subtract this filter output from the Ch1 trigger input signal. LF reject is achieved similarly except C1556 is disconnected from ground. HF reject is like LF reject except that rather than subtracting the CP1 input signal (pin 7) from the Ch1 trigger signal, the CP1 input signal itself is used as the input. Noise reject is done by increasing the trigger hysteresis via those analog control voltages (pins 11 and 35 for main and delay hysteresis respectively).

U1552 does the same thing for Ch3 and Ch4. The EVNT1–4 outputs from U1551 and U1552 are fed to the trigger logic IC (U1001, sheet 20), The trigger logic chooses between Ch1/2 and Ch3/4 for main and delay trigger events.

U1551 and U1552 contain built–in shift registers for programming of the channel switch and coupling modes. The serial data SDATA comes from U1050,

sheet 21, pin 27. The data is fed serially into U1551, then U1552, and then back to U1050, pin 91. The data is clocked into the shift registers with SCLK0 (U1551/U1552, pin 13) from sheet 21, U1050, pin 92. Once the shift registers are loaded, the data is latched in by strobing DSTR0 (U1551/1552, pin 33). DSTRB0 comes from sheet 21, U1050, pin 93.

Trigger Logic A10 

Trigger Logic is the digital part of the trigger system. It is composed of two IC's referred to as U1001 and U1050. The circuitry has many clock generation and triggering functions:

- Divides the 1 GHz VCOH/VCOL by 4 to get 250 MHz. The 250 MHz is used to drive the time interpolators. It is further divided to operate the trigger logic. It is also divided by 10 to generate the 25 MHz used by the scope's timebase PLL.
- Provides proper timing on the two resets (ACQRST1 and ACQRST2).
- Selects the trigger event.
- Puts the oscilloscope into posttrigger mode when the trigger is detected.
- Places the trigger point with respect to the data in memory.
- Provides trigger measurement functions.
- Provides part of the trigger holdoff and time interpolator functions.

Extended Trigger A10 

The Extended Trigger (EXTL) is primarily used to trigger on the end of an event pulse, qualified by the width of that pulse in time. Extended Trigger also allows the trigger system to act as a flip-flop, as in state trigger.

The Extended Trigger responds to digital signals or "events" provided by the Analog Triggers and the Trigger Logic. When a trigger condition is satisfied, the Extended Trigger, (U1703, sheet 22) generates EEVNT.

A combination of analog ramps and the Trigger Logic define the reference pulse widths. The analog ramps cover fast timing settings, while the Trigger Logic counts pulse widths greater than 1 microsecond. For time references less than or equal to this (where only the ramp is used), the Trigger Logic counter is disabled and the outputs are set high.

Daculator-derived ramp currents at pins 10,11,12, 34, 35, and 36 define the analog ramp times. The pins should always be within 25 mV of ground.

Each pulse width timer has two DAC/resistor networks. The slow range uses a 150 kΩ resistor for 30 ns to 1 μs. The fast range uses 4.75 kΩ for 2 ns to 28 ns.

Time Interpolators A10 ◇23◇

There are two time interpolators. One is for the main trigger, and the other is for the delay trigger. The time interpolator allows the trigger system to determine the time of occurence of a trigger event to the sub clock cycle resolution needed at fast time/div settings.

A triple ramp technique is employed to perform the interpolation. When the trigger event occurs, a large current is injected onto a capacitor generating what is called the fast ramp. When the second subsequent clock occurs, the fast current stops and the capacitor has a voltage that is proportional to the amount of time from the trigger event to the next clock cycle plus a fixed offset. After the fast current shuts off, a medium current starts to discharge the capacitor generating what is called the medium ramp. This drains off most of the fixed offset. At the end of the medium ramp, the medium current shuts off and is replaced by a small current which slowly discharges the capacitor generating the slow ramp. The time taken by the slow ramp to finish discharging the capacitor is proportional to the initial time interval between the trigger event and following clock edge. This system measures this much slower slow ramp time to obtain the measurement.

For the main time interpolator (U1600, sheet 23), the fast ramp is set by R1640 and R1641. The slow and medium ramp currents are set by the control voltages ISMAIN and IMMAIN respectively during SPC. The control voltages are buffered by U1601 before being applied to the current setting resistors (R1639 and R1638).

The trigger event is fed differentially into pins 10 and 11 of U1600 (MAUTH/L). The differential clock is fed into pins 4 and 3 (TICLKMH/L). The timing ramps are all internal to U1600 – an internal clock is generated that clocks a five-bit counter for the duration of the slow timing ramp. The MSB of this counter (CNTENMP/N, pins 44, 43 of U1600) is fed to U1050, sheet 21 where it clocks a larger counter in that chip thus effectively concatenating the two counters to make one counter. When the clock in U1600 stops, the counter is left with a number proportional to the time from the trigger event to the next clock edge. Once the system stores the trigger measurement, the trigger event line MAUT/L is set low which resets the time interpolator.

The time interpolator also synchronizes the trigger event (U1600, pins 28, 27) and returns it to U1001, sheet 20, pins 18 and 19. Operation for the delay time interpolator is identical except it is in U1650, sheet 23 and operates on delay trigger events.

Daculators A10 ◇24◇

Most of the analog control voltages are generated from the daculator ICs (U904, U905, and U906). The daculators contain an internal 12–bit DAC, 1:16 analog multiplexing circuit, and buffers. Serial data SDATA is shifted into the three daculators (starting with U904) which are strung together daisy chain style. The data serially shifts out of U906 (SDIAG4) back to U1050, sheet 21, pin 8. SCLK4 clocks the serial shift registers (it comes from U1050, sheet 21, pin 14).

DSTRB6 (from U1050, sheet 21, pin 25) causes the shifted data to take effect. The data contains information on which daculator voltage to change and what voltage to change it to. This is a total of 16 bits per daculator or 48 bits total.

Calibrator A10 25

U962, U963, and U950 along with the supporting circuitry on that sheet form the circuitry that generates the calibration voltages for Signal path Compensation (SPC). U962 samples VDAC10 and stores that voltage on C956. VDAC10 comes from the DAC on sheet 26 (U900, pin 9). U963 selects an attenuated version of this stored voltage for 1x, 10x, or 100x calibration. It can also select ground for offset calibration. U962 and U963 are controlled from the trigger logic (sheet 21, U1050, CVR0–6). The percent error of VDAC10 is characterized at factory cal and stored along with all other calibration constants in NVRAM (U1052 and U1055, sheet 21).

Acq Processor A10 26

The system processor communicates commands to the Acquisition Processor (U600) via the D1 Bus. The Acquisition Processor in turn controls the acquisition process. It controls the DAC and analog multiplexers that send control voltages to the preamps. The Acquisition Processor also controls the probe interface and senses internal temperature and timebase PLL lock.

DAC and analog MUXs A10 26

U900 is a 12-bit DAC that is controlled by the acquisition processor. The analog MUX (U934) stores the DAC output on hold capacitors. As the acquisition processor changes the DAC output through a sequence of output voltages, the analog multiplexor switches in sync with the DAC to store each voltage on a different hold cap. There are 8 hold caps connected to U934 – four of them (C939 C942) control probe offset, the other four (C1401, C1301, C1201, C1101 on sheets 3, 4, 5, and 6 respectively) control offset to the preamps. The output of the DAC is reduced by a factor of four to ±2.5 V before being fed to U934. The full ±10 V output of the DAC is also fed to U962 in the calibrator system on sheet 25 where its held value is used for calibration voltage generation. The acquisition processor controls the cycling of both the DAC and the analog MUX.

Processor System A11 ◇1

The processor system includes two processors: the 68020 (U1155) and U1097 the Digital Signal Processor (TriStar). The 68020 processor coordinates all oscilloscope activities. It also directs the activities of the Acquisition Processor and the Front Panel Processor via a parallel to serial interface using DUART U1317. The Digital Signal Processor (DSP) manipulates acquisitions. It performs tasks as directed by the 68020 processor and reports results back either through interrupts or by using the FIFO (U1074). The 68020 has access to everything on the DSP bus, allowing it to run diagnostics, retrieve waveforms, pass data, and load DSP instruction memory.

Processor/Display Board Connectors A11 ◇2 ◇3

All connectors for the A11 DRAM Processor/Display board are grouped together on these schematics. Regulator U12 supplies power for the NVRAM write enable circuitry. Connector J20 connects power to the fan.

Decode A11 ◇4 ◇5

The Decode circuitry decodes the 68020 memory space (U1055, U1056), generates wait states, data transfer and size acknowledge signals U2001, byte enables U2001, and the system ON/STBY signal.

Main Decode. The Main Decode. circuitry decodes the 68020 address space into 16 blocks of 16 Megabytes each. Table 1–7 shows the memory map for the Processor System.

Wait State ◇5. Dynamic bus sizing allows the 68020 to automatically determine the size of a port on each access by using DSACK signals.

Wait states are generated either from the device or port being accessed.

Data transfer and size acknowledge signals ~DSACK0 and ~DSACK1 control bus speed (by adding wait states) and dynamic bus sizing for circuitry that does not generate its own data transfer and size acknowledge signals.

Byte Enable Decode ◇5. Byte Enable Decoder prevents the 68020 from overwriting data during writes to word and long-word ports.

68020 Interrupts, Kernel Registers, and Decode A11 ◇5

The 68020 supports seven levels of auto-vectored interrupts. Level seven auto-vector (non-maskable) interrupts are reserved for ~PF, an interrupt indicating that power failure is imminent, and ~50OHMOVERLOAD, an interrupt indicating an overload in the A15 Attenuator. Interrupts from other modules are shared on the other 6 interrupt levels. Table 1–21 lists the device assigned to each interrupt level, and the name of the interrupt signals.

Interrupt Decode. Interrupt circuitry in U2000 decodes interrupts into the three signals that notify the 68020 of an interrupt. The ENABLEINT from the Bus Control Register in U2000 determines if only level seven and Kernel interrupts are enabled, or if all interrupts are enabled. Because the Interrupt Read Registers are outside the Kernel, in Kernel operation the 68020 must read from the interrupting device itself to determine the source of the interrupt.

Interrupt Mask and Miscellaneous Registers. All interrupts other than level 7 are maskable. By asserting the appropriate mask bit in the Interrupt Mask register (see Table 1–22) for an interrupt, the 68020 can ignore that interrupt. The 68020 can still read the status of the interrupt using Interrupt Read Registers.

The 68020 processor writes to Miscellaneous Register to control system circuitry and one interrupt mask (see Table 1–22). By reading Miscellaneous Registers, the 68020 processor determines the status of the interrupt masks.

Clock Logic. Clock logic uses a 25 MHz clock to generate clocks for buss error logic, GPIB, DUART.

DRAM Logic. DRAM logic generate address and control signals for DRAM.

Interrupt Read Registers. Since there is usually more than one interrupt per priority level, the 68020 processor reads the Interrupt Read Registers to determine which device caused the interrupt (see Tables 1–24 and 1–25).

Kernel CPU and Control A11 ◇5◇ ◇6◇

At the start of power-up, the 68020 (U1155) disables as many subsystem buffers as possible. This allows the 68020 processor to start execution with as small a system as possible (the Kernel). As diagnostics progress, subsystems are turned on and diagnosed one at a time.

CPU and Control. After the Kernel passes its power-up diagnostics, the firmware enables the control bus buffer U1135. Gates U1001C, U1082B, and U1082D generate the DSP read and write control signals ~ERDS and ~EWRS.

U2001 ◇5◇ combine all data transfer and size acknowledge signals (DSACKs) from circuitry throughout the system, and generate the actual data transfer and size acknowledge signals.

Kernel Address Decode and Kernel Wait States ◇5◇. To isolate the Kernel from the rest of the system, the Kernel decodes its own address space using decoders inside U2000. The DSACKS control bus speed and allow for dynamic bus sizing (byte, word, or long word).

Bus Control Register ◇5◇**.** The Bus Control Register contains system control bits. They include interrupt mask and enable bits, main bus enables, power down initiation, and other control bits.

Bus Error Logic ◇5◇**.** A “watchdog timer” inside U2001 of approximately 2 milliseconds monitors 68020 cycle times. If any cycle exceeds 2 milliseconds, then it generates a bus error (~BERR). Bus error can also be asserted when the 68020 tries to write to the Boot ROM. .

Reset. The 68020 processor resets both at power-up and power-down using the reset signal into U1155 pin C1. Reset controller U1175 controls system reset. Power-on reset asserts for a minimum of 400 milliseconds after the +5 V supply stabilizes. Power-off reset asserts when the supply falls below a usable threshold or when the 68020 asserts PWRDWN.

Kernel Memory, IO and Buffers A11 ◇7◇

Kernel resident memory, IO, and buffers allow diagnostics to run while isolated from the rest of the oscilloscope.

Kernel RAM. Kernel RAM. (U1336) runs internal diagnostics and flash EPROM burn routines. It can also run down-loaded diagnostics.

Boot ROM. The Boot ROM. contains the 68020 power-up instructions. The instructions begin with diagnostics. In addition, the Boot ROM. has the software for operating the GPIB and programming the system flash EPROMS.

Address Buffers and Data Buffers. These buffers isolate the kernel address and data lines from the rest of the system. The Bus Control Register enables or disables these buffers.

7 Segment LED. Power-up diagnostics use this seven segment LED to communicate the pass or fail status of kernel diagnostics.

DIP Switch ◇5◇**.** The 68020 reads this switch at power-up to determine which diagnostic or firmware routines to run.

GPIB. The circuitry is made up of GPIB controller U1305, with transceivers U1302 and U1311 buffering signals to and from the GPIB.

ID Register ◇5◇**.** Two ID Registers inside U2000 determines the A11 DRAM Processor/Display board type and revision number.

Memory A11 ◇8◇

The Memory subsystem includes NVRAM for power-off storage and Dynamic RAM for the main system RAM.

NVRAM. The NVRAM. consists of non-volatile memory IC. This RAM provides long-term power-off storage of calibration constants, front-panel settings, waveforms, and hardware write-protected calibration constants.

NVRAM Write Protect. NVRAM Write Protect. circuitry can prevent a write to portions of the NVRAM. that are reserved for calibration constants.

DRAM. Dynamic RAM is organized as 512K long words of memory for a total of 2 Megabyte. The circuitry includes the DRAM ICs, a dynamic RAM controller/driver U2001.

DRAM Controller ◇5◇. DRAM Controller automatically refreshes the DRAM..

During a normal 68020 access the dynamic RAM controller multiplexes the address (on A2 to A21) onto the UMA0 to UMA8 address lines.

Clocks, FPP, ACQP, and Display Interface A11 ◇9◇

Clocks for the Processor System and the Display System are shared and are derived from 25 MHz and 32 MHz oscillators Y1, Y2. The clock circuitry divides the 25MHz_OSC signal by varying amounts to produce the clocks needed by oscilloscope circuitry.

The Bus Control Register buffers and enables the Clocks, FPP, ACQP, and Display Interface subsystem prior to 68020 access. Devices on the Clocks, FPP, ACQP, and Display Interface subsystem (SP bus) are the DUART and the 68020 port into the Display system.

SP Data Buffers. The SP Data Buffers. buffer the main system data bus (D16 to D31) to the SP data bus (SPD16 to SPD31).

Clocks. Y1 (25 MHz), and Y2 (32 MHz) crystal oscillators generate required clocks for processor and display circuits.

DUART (Front Panel and Acquisition Processor Interface). The DUART (U1317) is the 68020's parallel-to-serial interface for both the Front Panel Processor and the Acquisition Processor.

Table 1–19 lists the serial port interface signals to both the Front Panel Processor and the Acquisition Processor.

68020 to DSP Buffers and Latches A11 ◇10

The 68020 to DSP Buffers and Latches buffer the 68020 address and data buses to the DSP address and data buses.

DSP and Instruction Memory A11 ◇11

Digital Signal Processor U1097 (DSP) provides fast waveform processing. The processor uses prefetched instructions, from DSP Instruction Memory, and two data memories. DSP Instruction Memory is loaded at power-on by the 68020. The memory is 24 bits wide, fetched twice per DSP cycle, for an effective 48-bit instruction word.

Buffers U1084 and U1083B buffer the DSP's read and write signals to its three buses. When BUSGRANT goes high, the outputs enter their high impedance state, so that the 68020 can use the DSP's buses. Table 1–13 lists the memory map for the DSP Memory.

DSP D1 Buffers, Latches and Memory A11 ◇12

In general, the acquisition system uses the D1 Memory. The buffers and latches buffer and demultiplex the X bus from the DSP to create the D1 bus. When the bus is granted to the 68020 (BUSGRANT is high), the outputs of the buffers and latches enter their high impedance state.

DSP D2 Buffers, Latches and Memory A11 ◇13

In general, the display system uses the D2 Memory. The buffers and latches buffer and demultiplex the Y bus from the DSP to create the D2 bus. When the bus is granted to the 68020 (BUSGRANT is high), the outputs of the buffers and latches enter their high-impedance state.

DSP Bus Arbitration Interrupts D2MMIO and FIFO A11 ◇14

D2MMIO Decoding decodes the address space and generates chip selects for all registers on the A11 DRAM Processor/Display board accessible by the DSP.

The DSP D2MMIO Misc Register inside U2111 controls 68020 interrupts and tells both the DSP and the 68020 whether or not the FIFO is full. Table 1–14 describes the contents the D2MMIO Misc Register.

The DSP performs tasks as directed by the 68020 processor and reports results back either through interrupts or by using the FIFO (U1074). The DSP can pass data back to the 68020 through the FIFO without having to halt DSP processing. Interrupt ~FIFOINT, to the 68020, is generated when any data is in the FIFO, and ~FIFOFULL internal to U2111 tells the DSP not to write to it or data will be lost.

DSP Bus Arbitration and Interrupts A11 ◇14

Many buses in the oscilloscope are accessed by more than one processor. The bus arbitration circuitry inside U2111 ensures that only one processor at one time may access a bus.

Bus Arbitration. The 68020 has access to all of the DSP's address space on the D1 Memory, the D2 Memory, and the DSP Instruction Memory buses (see Table 1–7, 68020 Memory Map).

DSP Interrupts. The DSP has only one interrupt level. The interrupt circuitry is similar to the 68020 interrupt circuitry. Interrupt mask (see Table 1–11) and status (see Table 1–12) registers allow the interrupt routine to determine which device(s) have interrupts pending and allow the masking of each interrupt. Table 1–12 lists the interrupt signals.

Display System A11

The Display System drives a 60 Hz non-interlaced, raster-scan CRT.

The display circuit's primary function is writing waveforms into a waveform plane. The circuitry provides several different display modes. These modes include the Vector (Raster), Dot, XY, and YT modes.

There are four main blocks in the display circuit: the Pixel Processor, the Vector Lists, the Address Counter, and the Rasterizer. These blocks are connected together in different ways for different display modes.

The Display System is a graphics system with two bit maps: the text plane and the waveform plane. All information displayed is first written to one of these two planes. The information is sent at regular intervals to the RAMDAC, which converts it into an analog video signal. The contents of the bit maps are modified through two different paths. The waveform display circuit, which is on the DSP D2 bus, normally modifies the waveform plane, and the 68020 modifies the text plane. The Video System Controller. and Video Timing blocks inside U2100 generate signals which affect the display system.

To maximize the waveform update rate, only waveforms are written to the waveform plane. All other displayable information such as the graticule, readout, cursors, and menus is written to the text plane. Both planes may be updated at the same time.

The waveform display circuit takes a list of sample points, translates them into bit pattern, writes those bit pattern in the proper location, and interrupts the DSP when it is done.

D2 Interface and Display Control Register A11 ◇14

The DSP D2 Interface connects the Rasterizer, Pixel Processor, Vector Lists, RAMDAC, Display Control Register, and part of the Video Timing to the DSP. It also generates two interrupts and a wait signal to the DSP system.

Display Control Register inside U2111 is an 8-bit register whose data lines are connected to D2D8–D2D15.

Vector List 0 and Vlist Address Counter A11 ◇16

A vector list stores waveform sample data. Before starting a normal display mode, the DSP writes data to a vector list. After the DSP starts the Pixel Processor, the Pixel Processor reads the waveform sample data from the vector list.

The Pixel Processor controls the Vector List Address Counter which addresses the vector lists during waveform display modes. It is an 11-bit counter (U28, U29, U30) with three control lines: *PIPEN*, *CLKOUT*, and *~LINEND*.

Vector List 1 A11 ◇17

This circuitry performs the same function as Vector List 0.

Rasterizer A11 ◇18

The primary function of the Rasterizer is to "draw" vectors between sample points. It also generates waveform display control signals.

To rasterize waveforms, the Rasterizer generates an intensity for every point in the waveform plane. It generates points from left-to-right top-to-bottom, in the same way a raster scan CRT scans the phosphor. The Rasterizer outputs the intensities to the Pixel Processor on LV3–LV6.

Rasterizer U59 has internal registers and lookup tables that the DSP can access. During internal accesses the Rasterizer uses address inputs *D2A0-D2A8* to determine which register or memory is being accessed. Signal ~VFVIEN is low during an internal access.

Pixel Processor and 020/WFM Data Buffers A11 ◇19

The PP Data Buffers and the 020/WFM Data Buffers buffer and multiplex the Pixel Processor data bus onto both the 68020 data bus and the SP data bus. The PP Address Mux's multiplex the DSP D2 address bus and the vector lists data outputs onto the Pixel Processor address bus.

Like the Rasterizer, Pixel Processor U60 has both internal registers and lookup tables that can be accessed from the DSP.

The DSP D2 Interface asserts ~MEMACC or ~INTACCP during accesses to internal registers. The Pixel Processor asserts WAITP whenever it is in a display cycle. A DSP access to Pixel Processor address space with WAITP asserted causes a XWAIT (U2111 pin 37) signal to the DSP.

Pixel Processor U60 contains the display circuit state machine, the control interface to the waveform planes, and hardware for implementing many of the display modes. The display modes are selected from a register inside the Pixel Processor.

A memory refresh or display update cycle forces the current display mode to be temporarily suspended.

For each display mode, except system processor access mode, the following steps are taken to start the Pixel Processor state machine:

1. Select the desired mode.
2. Write to the X register.
3. Write to the Y register.

The Pixel Processor then asserts WAITP and starts the desired mode. When finished, the Pixel Processor deasserts WAITP and asserts ~DISPINTTS, which interrupts the DSP. (Random dot mode does not generate a ~DISPINTTS interrupt.)

Waveform plane refresh cycles and 68020 access occur through the Pixel Processor.

The Pixel Processor also performs the top and bottom clip display functions on waveforms.

- Top Clip will not display points whose vertical coordinate is above the value stored in the Pixel Processor's top register. A vertical coordinate of 0 is considered the top of the screen.
- Bottom Clip will not display points whose vertical coordinate is below the value stored in the Pixel Processor's bottom register.

Waveform Plane 0 and 1 A11 

The waveform planes are 512 by 512 bit maps. Only the upper 480 lines are displayed.

The Pixel Processor has exclusive control of all waveform plane control lines with two exceptions:

- The Video System Controller. can access the waveform planes during control cycles such as DRAM. refresh cycles.
- The 68020 can access the plane in diagnostic mode.

Either the Pixel Processor or the 68020 can supply the data for the waveform plane.

In system processor access mode, VRAM control signals from the Video System Controller. (U2100) control the waveform plane control lines through the Pixel Processor.

WFM Address Multiplexers. The WFM Address Multiplexers. multiplex the VSC's VRAM address lines, VA0–VA7, to the waveform planes address inputs when ~VADEN is low. ~VADEN goes low only if the *SPACC* bit in the Rasterizer mode register is high.

The 020/WFM Data Buffers allow 68020 data onto the waveform plane data bus.

Waveform 0, 1 Memory. Waveform 0, 1 Memory. stores the actual waveform data that will be displayed.

Text Planes and Display A11 ◇21◇

The Video System Controller. refreshes the text and waveform planes and generates video control signals. The 020/VSC Interface. controls communication with the Video System Controller..

020/VSC Interface. The major functions of the 020/VSC Interface. inside U2100 are to communicate with the Video System Controller. and the 68020 (during 68020 accesses to the display). This interface circuitry also generates control signals ~VADEN and ~WBFEN for 68020 access to the waveform plane.

020/VSC interface determines whether the Video System Controller. can execute a 68020 requested cycle. If not, it waits until the Video System Controller. is ready and then tells it to start.

Video System Controller. Both the text plane and the waveform plane are made up of dynamic VRAMs. Video System Controller. inside U2100 refreshes both of these memory planes in one refresh cycle. The Video System Controller. executes one DRAM refresh cycle for every scan line (every 31.25 μs).

The Video System Controller. also generates 3 video control signals, vertical sync (~VSYNC), horizontal sync (~HSYNC), and blank (~BLANK). Horizontal and vertical sync are sent to the A20 CRT Driver along with VIDEO_OUT. Blank signal ~BLANK blanks the VIDEO_OUT signal during vertical and horizontal retrace periods.

A display update cycle runs once for every horizontal blanking interval. During the cycle, the Video System Controller. transfers one row from both the text and the waveform plane memories (VRAMs) to shift registers located inside the VRAMs. Once the data is in the shift registers it is shifted out of the VRAMs serially, thereby leaving the VRAMs' random access port free.

Video System Controller. internal registers control how often, on what rows, and at what points the Video System Controller. executes display update cycles.

Text Planes. Text Planes 0, 1, 2, 3 store all non-waveform data. Circuit operation resembles that of waveform plane 0. The text planes do not need an address multiplexer because, with the exception of the Video System Controller., the 68020 has exclusive access to the text planes. The Video System Controller. accesses the text plane only on control cycles such as DRAM refresh cycles.

Each text plane is a 1024 × 512 bit map with one bit per pixel. The upper left-hand corner of the bit map, a 640 × 480 section, is sent to the RAMDAC.

VGA RAMDAC

22

The VGA RAMDAC (U199) converts the VGA signals from U2011 into 3 analog video signals, red, green, and blue. The RAMDAC and its internal registers and memory are addressed from Dsp D2 memory space.

Video data and ~Blankout are latched into the RAMDAC on the rising edge of 25 MHz. The RAMDAC sets the VIDEO_OUT signal levels to 0 Volts upon receiving ~Blankout.

Color RAM DAC and Frame Buffers A11

23

The Color RAMDAC (U193) receives digital video signals from frame buffers and convert them into an analog video signal. The Color RAMDAC and its internal registers and memory are addressed from DSP D2 memory space.

Video data, (FS0–FS19) presented at the inputs are latched at the rising edge of SCLK (20 MHz). VCLK is used to clock and synchronize ~LCS_BLANK. The RAMDAC sets the VIDEO_OUT signal level to 0 volts upon receiving ~BLANKOUT.

Video Timing, Save on Delta and Color Interface A11

24

Video Timing. The Video Timing circuitry inside U2011 generates control and timing signals used throughout the display system.

Save On Delta. Save On Delta. and the Pixel Processor recognize that a trigger has occurred. When it occurs, the DSP reads WFM_SAVE in the D2MMIO Misc Register. Once WFM_SAVE has been activated, it remains active until cleared by ~MEMACC.

Color Interface. 16 bits of waveform data and 8 bits of text data are multiplexed inside U2101 to generate 5 bits of VGA data. U2011 converts these data to 24 bits of information for frame buffers.

Firmface A11

Firmface section holds the Flash ROM, and allows 4 Meg of space for software code.

Flash ROM Buffers, Decoding, and Version ID

This circuitry contains address and data buffers, address decoding, and Flash ROM version identification circuitry.

Flash ROM A11

27

The oscilloscope makes use of flash memories for its Flash ROM. This allows the Flash ROM to be programmed while it is in the oscilloscope. With +12 V supplied to the Firmface, the Flash ROM can be programmed via programs running in Kernel RAM. , programs which are downloaded via the GPIB.

Flash Fundamentals. Programming Flash ROM involves three steps. In step one, if the Flash ROM is not fully erased (erased byte = $FF), then it is programmed to the zero-state. In step two, if step one was necessary, every cell is erased to the one-state. Step three sequentially programs each long word with the desired data. Only those cells that are zero bits are programmed. Bits that are ones are simply left alone, in the erase state.

Writes to the Flash ROM are possible only when +12 V is supplied. The A11 DRAM Processor/Display board has a switch (S1002) that turns this programming voltage on and off. Switch forward = programming voltage on. *This switch should only be toggled forward or back as directed by the firmware update program.*

The program queries the A11 DRAM Processor/Display board and the Firmface board for their ID numbers, so it can determine how to configure registers on the A11 DRAM Processor/Display board and how to program the DRAM Controller to enable the DRAM..

Front Panel A12

The front panel is the operator's interface for controlling the user-selectable scope functions. All front panel controls are "soft" controls in that they are not connected directly into the signal path.

Pots and FPP A12

1

The Front Panel Processor monitors the front-panel controls. It consists of a single-chip microprocessor with built-in RAM, ROM, A-to-D converter (for digitizing the potentiometer wiper voltages), a programmable timer (for generating the outputs for the bell and probe compensator signal), and a serial communications interface (for data transfer to and from the 68020).

The knob scanning circuitry, working with the A-to-D converter internal to the Front Panel Processor, produces digital values for the wiper voltages of the front panel knobs. Analog multiplexers U8 and U9 select one of 12 possible pot inputs to read. Although there are only six knobs on the front panel, each is a continuous-rotation potentiometer made up of two wipers, separated by 180 degrees, which contact a single resistive arc.

Three control lines to multiplexers U8 and U9 select the pot input or wiper voltage to be read. The analog voltage at the wiper of the pot selected is applied to the Front Panel Processor. This voltage is digitized, and the amount and direction of change from the previously stored value is calculated. The change information is sent to the 68020.

Switches A12 ◇2

The Front Panel Switches and Menu Switches are arranged in an array of eight rows and columns. When a switch is closed, one row line is connected to one column line through an isolation diode. A complete scan of the Front Panel Switches consists of setting all eight row lines low, in sequence, and performing an eight-column scan to check for a change from the state stored in the Front Panel Processor. Low bits in the column-line data tell the Front Panel Processor that a switch is closed.

LEDS A12 ◇3

The LEDs (light-emitting diodes) are arranged in groups of eight. They are connected between the emitters of PNP transistors and a pull-up resistor to VCC. The base inputs of the PNPs are connected to the outputs of 8-bit LED latches U5, U6, and U7. The PNPs provide adequate electrical current, so that the LEDs are bright enough. When the 68020 needs to turn a particular LED on or off, it sends a command to the FPP indicating what to do to the LED, and which one to change. The FPP converts the LED identification number to the LED address within one of the three latches (U5, U6, or U7).

Bell, Calibrator, and Power Supply A12 ◇4

The Bell circuit gates an oscillating signal through output speaker LS1. As long as Q of U3A (U3 pin 6) is low, transistors Q2, Q4, Q5, and Q6 are off, and current is cut off to speaker LS1. When the Q output of U3A is high, LS1 produces a tone.

Flip-flop U3B of the Probe Compensator divides the 2 kHz signal from TCMP1 (U1 pin 2) by 2. Therefore, CALCLK is a 1 kHz square wave. When Q1 is on, CALSIG is a positive voltage (approximately 500 mV). When Q1 is off, CALSIG is at ground.

D1 Bus D14

The A14 D1 Bus board connects the DSP D1 Bus from the A11 DRAM Processor/Display board to other boards in the instrument.

Low Voltage Power Supply A16

The low voltage power supply generates voltages used throughout the oscilloscope. It is a switching power converter with active power factor control.

Primay Power Stages, Load Channel Regulators, Mains Trigger Filter A17

The AC Input includes an EMI filter (C5–C7, C11, L2, L3, and L7) and bleeder resistor. Also, thermistors and varistors protect against excessive current (RT1), voltage (RV1), and temperature (RT7).

The Standby Supply is a flyback converter. When an integral transistor in U12 is on, the voltage on C12 is applied to T7. This voltage (at C22) is monitored to provide the power fail warning signal ~PF (W4 pin 1).

The Boost Converter provides a pre-regulated bulk supply for the Main Converter. Two parallel FETs (Q5 and 6) form the boost converter switch. When pulsed on, energy is stored in boost inductor L1. When the FETs turn off, the inductor energy is delivered to bulk cap C12. The U10 Power Factor Control controls the on-time of the FETs to regulate the bulk voltage. The control circuit also provides for near unity power factor at the mains input.

The PWM Control (A18 ) references the secondary of T6 (+5.1 V FEED BACK). It turns Main Converter switching FETs Q7 and Q8 (A17 ) on and off by way of gate drive transformer T4. With Q7 and Q8 on, the bulk cap voltage is applied to the primary winding of transformer T6.

The Pulse Width Modulator (A18 ) width-regulates the GATE DRIVE pulse (Q10/Q11 base) regulating the main output voltage (+5.1 V).

The +24 output voltage is regulated from +5.1 through T6 turns ratio. The other four outputs are series pass regulated by VR10, VR11, Q14, and Q15. An output voltage summing comparator (U5) starts hiccup mode if one of these four outputs go outside of the 50% voltage window.

PWM Control , Fault Signal Conditioning A18

Pulse Width Modulator U5 is the heart of the PWM Control . Resistor R20 and capacitor C4 set the switching frequency. R41, VR3, and C15 provide a 1% reference. Capacitor C5 is a soft-start capacitor that slowly starts up the Boost Converter.

Pin 10 of U5 is a shutdown input, and it is also a pulse-by-pulse current limit. Pulling pin 10 high stops the output pulse within 200 ns. If pulled high for a

short time, the soft-start cap (pin 8) will not be discharged. If the soft-start cap discharges, it causes a normal soft-start when the voltage at pin 10 is removed.

Six signals are ORed together into the ONE-SHOT TRIG signal. They are the 24 V current limit, 24 V over voltage, the main 5.1 V over voltage, main 5.1 V current limit, and the output voltage summing comparator. Any of these faults will start hiccup mode. In hiccup mode the power supply cycles on and off at a low repetition rate until the fault is removed.

The On/Standby Control debounces the switch. Relay K1 ensures that the power supply powers up in the same state (On or Standby) it was in when the oscilloscope powered down.

The low bulk fault circuit monitors the bulk voltage by way of the peak detector on the Standby Supply. It warns the processor system and shuts down the Main Converter when the bulk voltage drops to about 300 V.

Display Driver Board A20

The TDS 520B uses a 640 × 480 pixel raster scan display. Scan rates are 60 Hz frame rate × 32 kHz line rate.

Display Block Diagram A20

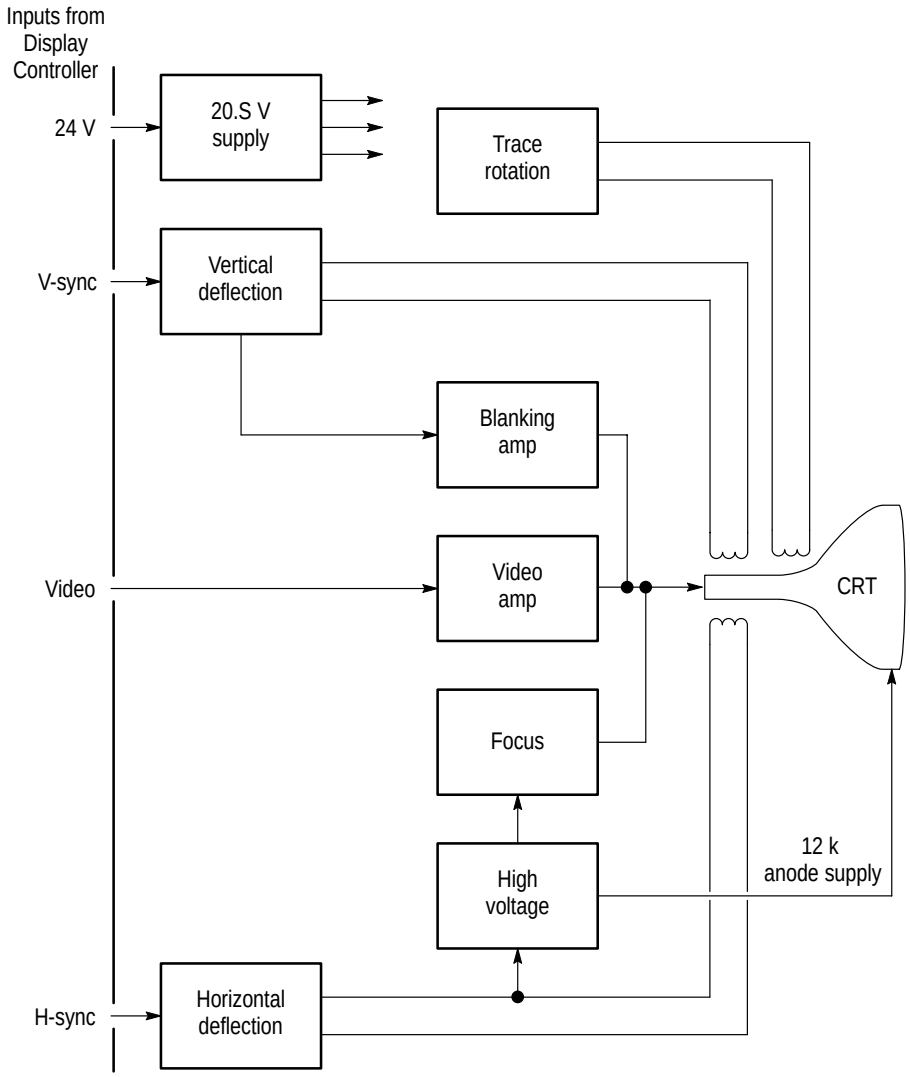

Figure 1–3: Display block diagram

The display circuit board, CRT, and deflection yoke all form a basic raster scanned picture monitor. Operating theory of this unit is very similar to most such displays and the display portions of television receivers.

All inputs are made to the display through a 2 × 16 pin connector. The inputs required are a video signal which produces the picture detail and horizontal and

vertical sync signals. The power for the display is provided by a single 24 volt DC source at an operating current of about one amp. The video amplifier is DC coupled and the signal must include a blanking pedestal to allow total extinction of the CRT beam during retrace and to provide for good “black” level. Sync signals are TTL compatible levels with the negative edge active.

The individual major sections are shown in the block diagram drawing. The CRT beam is scanned in the X and Y axis by the Horizontal and Vertical deflection circuits, which provide the scan currents for the deflection yoke. The “yoke” is made up of the two sets of deflection coils and several fixed and adjustable permanent magnets which allow for geometry correction and vertical and horizontal positioning. This assembly is mounted on the CRT neck at the transition to the funnel portion of the tube.

Several other calibration adjustments are provided to match the electronics to the individual yoke and CRT characteristics. The Horizontal deflection circuit also provides a large voltage pulse which is further increased by the high voltage circuit to supply the 12 kV for the CRT anode and also to provide the other internal supplies for the various circuits. CRT bias voltages for the CRT gun elements and dynamic focus correction signals are developed in the block marked “CRT Circuitry.” The Video Amplifier amplifies the video signal to some 25–30 volts peak which them drives the CRT cathode to produce the Z axis picture detail.

The three-terminal regulator provides a stable supply for the scan circuits to minimize changes in picture size due to any variations in the power input voltage.

Display Block Diagram Vertical Deflection Circuit A20 ◇1

This circuit provides the scan current for the vertical (field) deflection coil. The ramp of current moves the CRT beam from top to bottom of the CRT screen during each field and returns to the top for the next field at approximately a 60 Hz rate. All of the active components are included in a single monolithic IC, which is heat sunk to dissipate substantial power. Peak-to-peak currents of between one and one half and two amps are needed to deflect the beam over the required area. The output of the circuit is a current ramp, modified in shape to correct for geometric error in the CRT and for deflection coil anomalities.

A negative pulse at the deflection rate is introduced to the sync input of the circuit. This input may be either negative or positive; the sync circuit will recognize either, and causes the ramp to “retrace” to the top of the screen. The negative edge is the “active” edge in this application.

The retrace portion of the ramp signal occurs in relatively short time (less than 400 μsec) and to overcome a rather large inductance of the deflection coil, a “boost” voltage is applied to the output amplifier power supply rail. This larger voltage allows the current in the yoke winding to change rapidly. Once the retrace is complete, the supply rail returns to the normal voltage (21 V) to conserve power in the output amplifier. At the same time, the Ramp generator

portion of the IC has returned to the starting point of the ramp and will produce a voltage ramp at the rate set by the R?C timing components until another sync signal occurs. (in the absence of sync, the generator will reset itself at a predetermined level and the scan will “free-run” at a slightly lower frequency). An external component network modifies the ramp shape, resulting in a scan waveform which will produce a “linear” movement of the CRT beam across the face of the CRT. This correction causes the resulting ramp of voltage to acquire a slight “S” shape, hence the majority of the correction is called “S” correction. The center of the “S” may be moved about by the linearity adjustment to accommodate non-uniformity of the deflection coil and other coil losses.

The modified ramp is fed to the input of the output amplifier. This voltage is applied against a negative feedback signal which results from the deflection coil current flowing in a small “current sampling” resistor. The output amplifier signal is A–C coupled to the coil so that no D–C current will flow in the windings. Such current would cause an undesirable “position” effect that would vary with changes in the current. Some D–C voltage feedback is provided directly from the amplifier output to stabilize the amplifier operating conditions. An external compensation network insures the amplifier’s operating stability in the presence of a highly reactive load and large amounts of negative feedback.

The vertical size adjustment controls the amplitude of the ramp generator signal and allows for precise vertical display size adjustment. Vertical positioning of the rastered area is adjusted by movable permanent ring magnets mounted on the back of the deflection yoke assembly.

Horizontal Deflection Circuit A20

The horizontal deflection signal is produced by applying a voltage across the inductance of the deflection coil and allowing the current to build with time. At a point in time the voltage is switched off and the retrace current is produced by a resonant circuit which produces a large voltage across the inductance in the opposite direction, allowing rapid return of the current to the starting point.

If we start with the CRT beam at the center of the screen, applying a voltage across the coil will cause current to build in the coil at a rate linear with time. As this current builds, the beam will be deflected across the screen. By convention, it will be deflected to the righthand side. Suddenly opening the switch which provides this current would cause the voltage at the coil terminals to increase towards infinity in an effort to maintain the current flow (basic inductor theory). Attaching a capacitor across the coil would allow this voltage to charge the capacitor, resulting in a resonant circuit. Now, instead of the coil current trying to remain steady, it reverses as the stored energy flows to charge the capacitor, and this reversal of current direction move the beam back to the left extreme of the scanned area. If the resonant circuit were allowed to “ring”, the current would alternate in direction at the resonant frequency until losses in the circuit dissipate the stored energy. The voltage will reverse in polarity across the capacitor and when it does, a diode (:damper” diode) conducts the current back into the coil in the same direction it was flowing when the switch was first turned on, though the

current starts from a more negative point. It flows towards the zero point. Before it reaches zero, the switch is turned back on, and the current continues to flow past the zero point in the positive direction until the switch once again is turned off, repeating the cycle.

This switching of voltages and the resonant action during retrace will produce the linear change in current necessary to move the beam across the screen rapidly to cause the beam to return to the starting position.

Horizontal Control and Base Drive A20 ◇1

This circuitry generates the "switch" controlling signal and synchronizes the scan action to the horizontal sync signal. The horizontal control block is a monolithic IC which include a horizontal oscillator that is voltage controlled, a phase detector, and an output shaper. The output provides the square voltage waveform to ultimately drive the switch transistor which provides the deflection coil currents

Two signals are compared in phase to provide an error signal which will control the oscillator frequency, in and a "phased locked loop" configuration. The differentiated sync pulse is the reference signal, and a ramp of voltage derived from the retrace or "flyback" pulse is the feedback signal to be "locked" to the sync signal.

The phase detector output controls the frequency of the horizontal oscillator, maintaining close phase relationship between the scanning current and the sync signal. The oscillator output is shaped to provide a square wave output to the switch base drive transistor. This transistor is a saturated switch coupled to the yoke driver switch transistor by the base drive transformer. Substantial drive current is required by the yoke driver to provide fast switching action.

The center of the oscillator operating frequency range is adjustable by the Horizontal "hold" adjustment. The horizontal phase adjustment slightly alters the phase relationship of the sync to the scan currents. This allows optimization of the timing of the horizontal scan to the sync pulse, and allows centering of the video information within the rastered area.

Horizontal Deflection Driver and Coil Circuit A20 ◇1

The base of the deflection driver (Q203) is driven by the base drive transformer. This transistor operates as a saturated switch, providing the current for the deflection coil. The initial voltage is provided by the high voltage transformer primary. The R/C network in the base of Q203 aids in fast turn-off of the transistor. When Q203 is turned off and all the stored charge in the transistor junctions is depleted, the energy stored in the deflection coil inductance flows into the "retrace capacitor" C208. This resonant circuit "rings" positive to form a large positive pulse (flyback pulse). As the voltage swings negative, CR205 (damper diode) conducts and clamps the voltage at ground. The energy stored causes current to flow into the coil which deflects the beam from the left edge towards center of the screen. before the current crosses over the zero point, Q203 is once again turned on, starting the cycle over.

Additional inductors are series with the deflection coil. The horizontal size adjust coil limits the maximum current that will flow in the deflection coil and thus the scan size. The linearity coil is a non-linear inductor whose inductance changes with current amplitude and polarity. This introduces nonlinearity with complements that caused by losses in the deflection coil. In addition, "S" correction is required (similar to the need in the vertical scan). This is provided by the series capacitor, C320. A parabola of voltage appears across this capacitor due to the deflection current flow, and the result is an "S" shaped error in the linear current which complements the error caused by the CRT change as the beam length changes from center to edge.

High Voltage, Internal Power Supplies, and CRT Circuitry A20 ◇1

The CRT high voltage is generated from the large pulse of voltage which occurs during horizontal retrace (flyback pulse). This approximately 350 V pulse is stepped up to the 12 KV peak by the high voltage transformer and rectified by an internal diode. The conductive coatings on both sides of the CRT envelope act as a filter capacitor for the anode voltage which is connected to the CRT by the high voltage lead and connector. A large value internal resistor in the transformer bleeds off the high voltage charge when the power is turned off.

Other secondary voltages are derived from the flyback pulse and used internally by the display circuitry. They are rectified and filtered as shown in the block. Focus potential for the CRT gun is derived from an adjustable divider spread between the –170 V and the 500 V supply. Bias voltage for the CRT control grid (G1) is developed from a divider between –170 and 50 volts, and is made adjustable to set the black level or "brightness" level for the tube. This adjustment is normally set to just extinguish the CRT beam during "black" portions of the video signal.

Vertical Retrace Blanking A20 ◇1

In the event that the black or background level is visable, the horizontal scan lines may be visable during the rapid vertical retrace period. This produces slanted, bright interfering lines in the picture background. A signal which drives the display further into the black (further into CRT "cutoff") is provided to blank the beam during this period, even though the background is visable. This is called vertical retrace blanking, or internal blanking and is independent from the blanking portion of the video signal.

A large pulse is generated by the vertical deflection circuit during vertical retrace. A portion of this signal is fed to Q442 where it is inverted and A–C coupled to the CRT G1. This signal drives the grid some 50 V more negative than normal during the retrace period, preventing the scan lines from being unblanked, even when the background is visable.

Dynamic Focus A20 ◇1

There is normally some defocus of the CRT beam as it leaves the center area of the CRT screen because the path the beam must travel lengthens as it moves to the outer edges of the screen. By changing the focus voltage dynamically, this

effect can be reduced and overall focus improved somewhat. (There are other causes for edge defocus also; not all of the errors can be corrected).

In this display, a parabolic voltage waveform is developed which is synchronized to the horizontal scan. This waveform is added to the D–C focus voltage and is adjustable in amplitude to improve focus at the CRT edges. An LC network is fed the negative pulse from the –170 V winding of the high voltage transformer. By tuning the resonant circuit below the resonant frequency, a high voltage parabola is generated. its amplitude is typically set for about 250 volts peak by adjusting the inductor core.

Video Amplifier A20 ◇1

The video amplifier consists of two stages, the input emitter follower which provides current gain to drive the second voltage gain stage. The second stage is a “Cascade” configuration which provides a voltage gain of approximately 40X at a bandwidth in excess of 30 MHz. The amplifier is D–C coupled and depends on the input signal being referenced to ground (blank level). There is a “peaking” network in the collector of the output stage to optimize transient response of the amplifier. The amplified video is directly coupled to the CRT cathode. Spark gaps are built into the CRT socket assembly and a gas-filled gap is present in the output of the amplifier to absorb high energy pulses which will occur if there is an internal high voltage arc in the CRT.

The input signal amplitude is adjustable over a limited range by the “contrast” control, and is used to normalize the amplifier gain and set the display peak white intensity.

Trace Rotation A20 ◇1

Trace rotation is accomplished by applying DC voltage to a coil wound onto the front of the deflection yoke. This creates a magnetic field that offsets the deflection field and thereby “tilts” the display. The driving circuitry is a simple DC amplifier configured to reverse current in the rotator coil and provide about three degrees of tilt in each direction. The rotation adjustment is located so it can be accessed from the front left side of the instrument by slipping the cover back a few inches.

Memory Maps

Since the memory map is not fully decoded, unused addresses may actually map into real memory somewhere. Unfilled address space may cause a bus error when accessed or it may overlay some other address space.

Table 1–7: 68020 Memory Map

Base Address	Chip Select	Description	Port Size
0000 0000–00FF FFFF	~KERNEL	Kernel address space, see “Kernel Addr Decode”	Byte
0100 0000–01FF FFFF	~SYSROM	System ROM address space. The firmface buffer enable bit in the Bus Control Register must be set. The number of wait states for system ROM must be set in Miscellaneous Register inside U2000.	Long
0200 0000–02FF FFFF	~OPTION1CS	Reserved for options	B,W,L

F7000	075E E000	Write FIFO Data
80000–FFFFF	075C 0000–075F FFFF	Display
DSP Instruction Memory Address	**68020 Address**	**Description**
00000–0FFFF	0700 0000–0701 FFFF	DSP Instruction Memory

Table 1–14: D2MMIO Miscellaneous Register

DSP Data Bit	680020 Data Bit	Signal Name	Description
D15	D31	~TSINT020	Asserted when DSP wants to interrupt the 68020
D14	D30	Unused	
D13	D29	Unused	
D12	D28	Unused	
D11	D27	WFMSAVE (read only)	
D10	D26	Unused	
D9	D25	~FIFOFULL	Asserted when the FIFO is full. In this condition further writes to the FIFO result in lost data.
D8	D24	TMSKFIFOINT	Masks the interrupt from the FIFO to the 68020

Table 1–15: 68020 to DSP Instruction Memory Accesses

68020 Address	D31 – D24	D23 – D16
0700 0000	TSID23–TSID16	TSID15–TSID8
0700 0002	TSID7–TSID0	
0700 0004	TSID23–TSID16	TSID15–TSID8
0700 0006	TSID7–TSID0	
0700 0008	TSID23–TSID16	TSID15–TSID8
0700 000A	TSID7–TSID0	

Since the memory map is not fully decoded, unused addresses may map into real memory somewhere. Accessing unfilled address space can cause a bus error or over-write decoded address space.

TP50		31	Receiver Clock

Table 1–20: A10 Acquisition Demultiplexer DB Memory Map

Address	R/W	Initialized	Use
0	R/W	Zero at power-up	Acquisition Memory DB addressing control
1	R/W	Zero at power-up	Acquisition done and point available control
2	R/W	—	Data for programmable inverter
3	R/W	—	Data for clip detector inverter
4	R/W	—	Trigger control
5	R/W	—	Pre-trigger count
6	R/W	—	Post-trigger count
7	R/W	—	Start value for address counter
8	R/W	—	Stop value for address counter
9	R/W	—	Decimator control
A	R/W	—	Decimator divider count
B	R/W	—	Hi-res decimator shift count
C	R	—	Roll data register
D	R	—	Status register 1
E	R	—	Status register 2
F	R	—	Value of address counter at acquisition done
10	R	—	Value of address counter at trigger
11	R	—	Value of trigger time (least significant word) at trigger
12	R	—	Value of trigger time (middle word) at trigger
13	R	—	Value of trigger time (most significant word) at trigger
14	R	—	Value of trigger synchronizer counter at trigger
15	R	—	Current pre-trigger count
16	R	—	Current post-trigger count
17	R/W	Zero at power-up	Input control / diagnostic counter
18	R/W	—	Hi-res decimator 20-bit incrementer and diagnostic control register 1
19	R/W	—	Hi-res decimator 20-bit incrementer and diagnostic control register 2

Table 1–21: Device Interrupt Levels

Interrupt Level	Device	Interrupt Signal
Level 0	None	
Level 1	Floppy	Floppy
Level 2	Duart Interrupt (Acquisition and Front Panel Processor Communications)	DUART
Level 3	FIFO Interrupt and DSP Interrupt	FIFO and TRISTAR
Level 4	GPIB Interrupt	GPIB
Level 5	Option 1 Interrupt, Option 2 Interrupt, and I/O Option Bus Interrupt	OPTION1, OPTION2, and IOBUS
Level 6	Display Interrupt to System Processor, Console Interrupt, and Timer (6.5536 ms periodic interrupt)	DISPLAY, CONSOLE, and TIMER
Level 7	50 Ω overload interrupt, and PFBAR Interrupt (power is going away in ~10 ms)	50OHMINT, POWERFAIL

Table 1–22: Interrupt Mask Register 0900 0000 (R/W)

68020 Data Bit	Signal Name	Description
D31	MSKFLOPPYINT	Masks floppy interrupt
D30	MSKOPTION2INT	Masks option board 2 interrupt
D29	MSKFIFO	Masks FIFO interrupt
D28	MSKIOINT	Masks I/O bus interrupt
D27	MSKDUART	Masks Duart interrupt
D26	MSKOPTION1INT	Masks option board 1 interrupt
D25	MSKTIMER	Masks timer interrupt
D24	MSKDISP	Masks display interrupt

Table 1–23: Miscellaneous Register 0920 0000 (R/W)

680020 Data Bit	Signal Name	Description
D31	~RESETACQP	Resets acquisition processor (not an interrupt mask)
D30	~020INTTS	If asserted, interrupts Tristar (not an interrupt mask)
D29	~TSRESET	Resets the DSP. Can be asserted to forcibly take the DSP bus. Deasserting restarts the DSP
D28	SYSROMWTS1	Most significant bit of the number of system ROM wait states
D27	SYSROMWTS0	Least significant bit of the number of system ROM wait states
D26	MASKTSINT020	Masks the DSP interrupts to the CPU
D25	BUSREQ	Requests the DSP bus (the nice mode of operation)
D24	TSPP = Write TSFO = Read	Bits for the DSP diagnostic testing

Table 1–24: Interrupt Read Register 1 0940 0000 (Read Only)

680020 Data Bit	Signal Name	Description
D31	~FLOPPYINT	Application memory card interrupt
D30	~OPTION2INT	Interrupt from option compartment number 2
D29	~FIFOINT	FIFO interrupt (the DSP has placed something in FIFO)
D28	~IOINTERRUPT	I/O bus interrupt
D27	~DUARTINT	DUART interrupt
D26	~OPTION1INT	Interrupt from option compartment number 1
D25	~TIMERINT	6.5536 ms timer interrupt
D24	~DISPINT020	Display interrupt 68020

Table 1–25: Interrupt Read Register 2 0960 0000 (Read Only)

680020 Data Bit	Signal Name	Description
D31	LOW	
D30	BUSGRANT	The DSP has relinquished the D1, D2, and IM busses. Automatically asserted during ~TSRESET.
D29	~PF	First indication that power is going away, in 10 ms
D28	~50OHMINT	50 Ω attenuator overload interrupt
D27	~CONSOLEINT	Interrupt from cardedge console port
D26	~TSINT020	DSP interrupt to the CPU
D25	~GPIBINT	GPIB interrupt
D24	~LOW	

Table 1–26: Troubleshooting Procedure For LED Display

Test Name	LED Display (a failed test is preceded by a flashing decimal)	A11 DRAM Processor/Display Troubleshooting Procedure
Bus Control Read	1	Bus Control Register
Kernel RAM 1	2	Kernel RAM
Kernel RAM 2	3	Kernel RAM
Kernel RAM 3	4	Kernel RAM
BootROM Check Sum	5	BootROM Control
Bus Error Timeout	6	CPU Bus Error
Write Bus Control	7	Bus Control Register
CPU Interrupt Mask Register	8	CPU Interrupt
CPU Miscellaneous Register	9	CPU Interrupt
Timer Interrupt	a	Timer Interrupt
NV Ram Dsacks	b	Bdsack
FlashROM programming voltage is applied. NVRam is write protected.	c	On the A11 DRAM Processor/Display board press S1002 towards the back of the oscilloscope and cycle power.
FlashROM DSACKS	d	Bdsack
FlashROM Check Sum	e	FlashROM
ID Register The LED displays the A11 DRAM Processor/Display ID in hex: the most significant nibble (4 bits) first and then the least significant nibble.		ID Register

The Columbia primitive input is an eight bit dip switch (S1001) on the A11 DRAM Processor/Display board. When the system powers up the system processor honors any special requests made by the dip switch. The eight switches are active in the open position.

Table 1–27: DIP Switch Options

DIP Selection (8–1)	Action
0010 0000	Enter SDM Monitor via the GPIB
0011 0000	Enter SDM Monitor via Console RS-232
0110 0000	Expand error log and increase diag messages
0101 0000	Do not attach the ethernet
0100 1000	Do not add extra ram to pool
0100 0100	Do not execute diagnostics
0100 0010	Do not execute higher level code
0100 0001	Do not execute system ram test
1X00 0000	Loop or Skip ALL bootrom Tests
1X00 0001	Bus Control Read
1X00 0010	Kernel Ram Test 1
1X00 0011	Kernel Ram Test 2
1X00 0100	Kernel Ram Test 3
1X00 0101	Bootrom Check Sum
1X00 0110	Bus Error Timeout Test
1X00 0111	Write Bus Control (open)
1X00 1000	Interrupt Mask Register 1
1X00 1001	Miscellaneous Register
1X00 1010	Timer Interrupt (Auto-Vector)
1X00 1011	NV Ram DSACKS
1X00 1100	Flashrom prog. voltage applied. NV Ram is write protected.
1X00 1101	Flashrom DSACKS
1X00 1110	Flashrom Check Sum
1X10 0000	Loop or Skip ALL Kernel Ram Tests
1X10 0001	Loop or Skip ALL Kernel Tests
1X10 0010	*Walk 7 Segment LED
1X10 0011	*Display Processor Version Number

If X = 1 (open) – *skip* (do not execute) test(s).

If X = 0 (closed) – *loop* on test(s).

*** executes forever – power must be cycled to stop test**

The Columbia primitive output consists of a 7 segment LED (DS1) on the A11 DRAM Processor/Display board.

Table 1–28: A11 DRAM Processor/Display LED (DS1)

LED Display	Explanation
Decimal Point (DP)	When this precedes one of the hex numbers, the particular test the number represents has failed.
.E	This indicates an exception
.11	This indicates an interrupt
.P	This indicates a non maskable interrupt
.8	Displayed at power-up or reset
0	First displayed after power up
1	Bus Control Read diagnostic
2	Kernel RAM 1 diagnostic
3	Kernel RAM 2 diagnostic
4	Kernel RAM 3 diagnostic
5	BootROM Check Sum diagnostic
6	Bus Error Timeout diagnostic
7	Write Bus Control diagnostic
8	CPU Interrupt Mask Register diagnostic
9	CPU Miscellaneous Register diagnostic
a	Timer Interrupt diagnostic
b	NV RAM Dsacks diagnostic
c	FlashROM programming voltage is applied. The NV RAM is write protected.
d	FlashROM Dsacks
e	FlashROM Checksum

Maintenance

Firmware Reprogramming

Minimum Tool & Equipment List

- TDS 7U01 Upgrade Kit
- IBM Compatible PC
- GPIB card (such as the National Instruments PCII (Tek GURU), PCIIA (Tek GURU II), PCII/IIA (Tek S3FG210) cards)
- GPIB cable (such as Tektronix part number 012-0991-00)
- GPIB driver software appropriate to the GPIB card (such as NI-488.2 software)
- TDS 520B model oscilloscope

Instructions

Setting Up PC & TDS

The following instructions will guide you through setting up your PC and TDS oscilloscope

Attach an IEEE Std 488.1-1987 GPIB cable (available from Tektronix as part number 012-0991-00) to the 24-pin GPIB connector on the rear panel of the TDS, as shown in Figure 2–1.

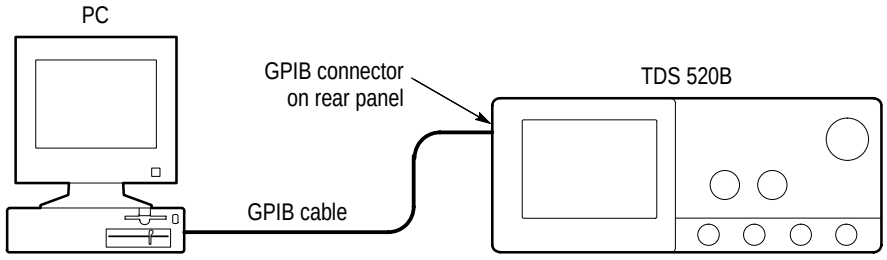

Figure 2–1: PC & TDS setup

Setting the GPIB Parameters

You need to set the GPIB parameters of the digitizing oscilloscope to match the configuration of the bus. Once you have set these parameters, you can control the digitizing oscilloscope through the GPIB interface.

1. Press the **UTILITY** (**SHIFT DISPLAY**) button to display the Utility menu.
2. Press the **System** button in the main menu until it highlights the **I/O** selection in the pop-up menu (See Figure 2–2).

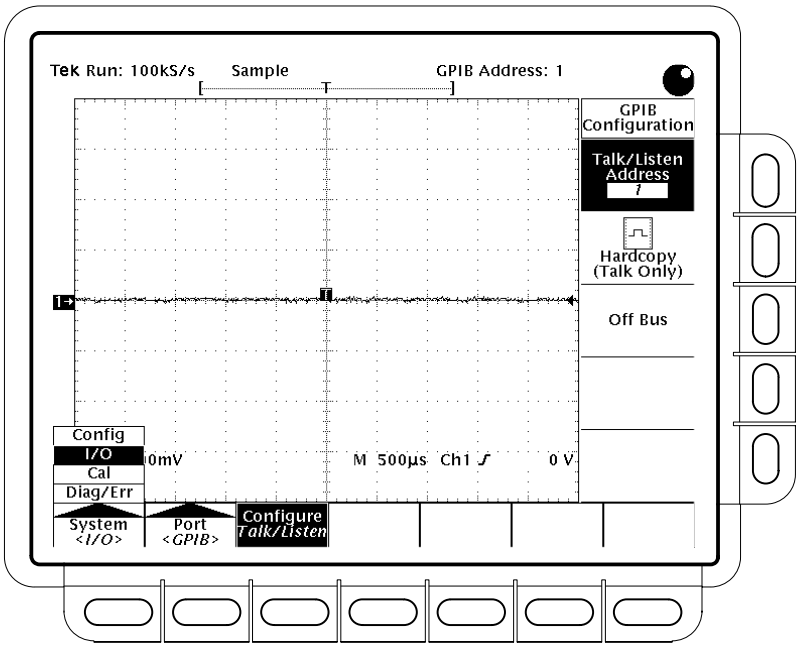

Figure 2–2: Selecting the I/O System in the Main Menu

3. Press the **Port** button in the main menu until it highlights the **GPIB** selection in the pop-up menu (See Figure 2–2).
4. Press the **Configure** button in the main menu to display the GPIB Configuration side menu (See Figure 2–2).
5. Press the **Talk/Listen Address** side menu button, and set the GPIB address using either the general purpose knob or, if available, the keypad.

Setting Up GPIB Card

The following instructions will guide you through setting up your PC with an approved GPIB card. The card works with the Firmware Upgrade disk (TDS500).

Instructions for installing an approved card (such as the National Instruments PCII (Tek GURU), PCIIA (Tek GURU II), PCII/IIA (Tek S3FG210) cards) and

accompanying driver software (such as NI-488.2 software) come with your card. The following hints will help you set up the card if your GPIB installation instructions are not readily available.

1. For National Instruments PCII (Tek GURU) card setup:
   - **a.** Remove PCII IRQ jumper.
   - **b.** Set PCII DMA jumpers to DRQ1 and Dack1.
   - **c.** Set DIP switch to: OFF = 1,2,3,5,6,7; ON = 4
   - **d.** Add to autoexec.bat file the command: SET GPIB0 = PC2 1 0 87
   - **e.** Add to autoexec.bat file the command: SET GPIB1 = PC2 1 0 87
2. For National Instruments PCIIA (Tek GURU II) card setup:
   - **a.** Remove PCIIA IRQ jumper.
   - **b.** Set PCIIA DMA jumpers to R1 and A1.
   - **c.** Set dip switch to: OFF = 1,2,3; ON = 4,5
   - **d.** Add to autoexec.bat file the command: SET GPIB0 = PC2A 1 0 0
   - **e.** Add to autoexec.bat file the command: SET GPIB1 = PC2A 1 0 0
3. For National Instruments PCII/IIA (Tek S3FG210) (8 Bit Bus) card setup:
   - **a.** Set DIP switch #9 to: OFF = PCII or ON = PCIIA.
   - **b.** Set the first 7 DIP switches (if emulating a PCII) or first 5 DIP switches (if emulating a PCIIA) according to the information outlined for those cards in step 1 and 2 above.
   - **c.** In either case, set DIP switch 8 to OFF. This uses 7210 handshake protocol.
   - **d.** Remove PCII/IIA IRQ jumper.
   - **e.** Set PCII/IIA DMA jumpers to DRQ1 and Dack1.
   - **f.** Add lines to the autoexec.bat file to mirror the ones used for the cards you wish to emulate — as documented above.

4. RIC 386 setup:

   The RIC 386 has a built-in GPIB board. It emulates the National Instruments PCII card. The default settings of this card are different from the stand-alone cards mentioned above. To use a RIC 386 with factory default configurations:

   a. Add to autoexec.bat file the command: SET GPIB0 = PC2 1 5 87

   b. Add to autoexec.bat file the command: SET GPIB1 = PC2 1 5 87

Installation on Hard Disk

The following instructions will guide you through installing the TDS firmware upgrade software on your PC.

1. Insert the new firmware disk into the PC's floppy disk drive.
2. Move to the floppy drive containing the disk (typically A drive).

   Type `A:`

   Press **RETURN**.

3. From the DOS prompt:

   Type `hdinstal` <space><drive>\<instrument type.firmware>

   Press return.

   Example: `hdinstal c:\loadfw`

Loading Firmware

The following instructions will guide you through installing the firmware on your oscilloscope.

1. Turn oscilloscope power OFF.
2. Insert a small, non-conductive object (adjustment tool) into the front access hole located on the right side of the oscilloscope near the front panel. Push the non-conductive object inward to position the NVRAM protection rocker switch in the Unprotected (write-enable position). See Figure 2–3.
3. Turn oscilloscope power ON.

***NOTE**. With the NVRAM protection rocker switch in the Unprotected (write-enable) position, the oscilloscope will NOT power up to normal operation.*

4. Move to the disk and directory containing the firmware. On the PC:

   Type `loadfw`

   Press **RETURN**

   This starts the program.

5. In the PC, highlight the **Load Firmware** window and press **RETURN**.

6. Highlight the **Load TDS<Model, Version>**window and press **RETURN**. The <Model, Version> stands for the actual TDS model and version that appears in your software. For example, if you were loading version 4.0 firmware on a TDS 520, the menu item might read:

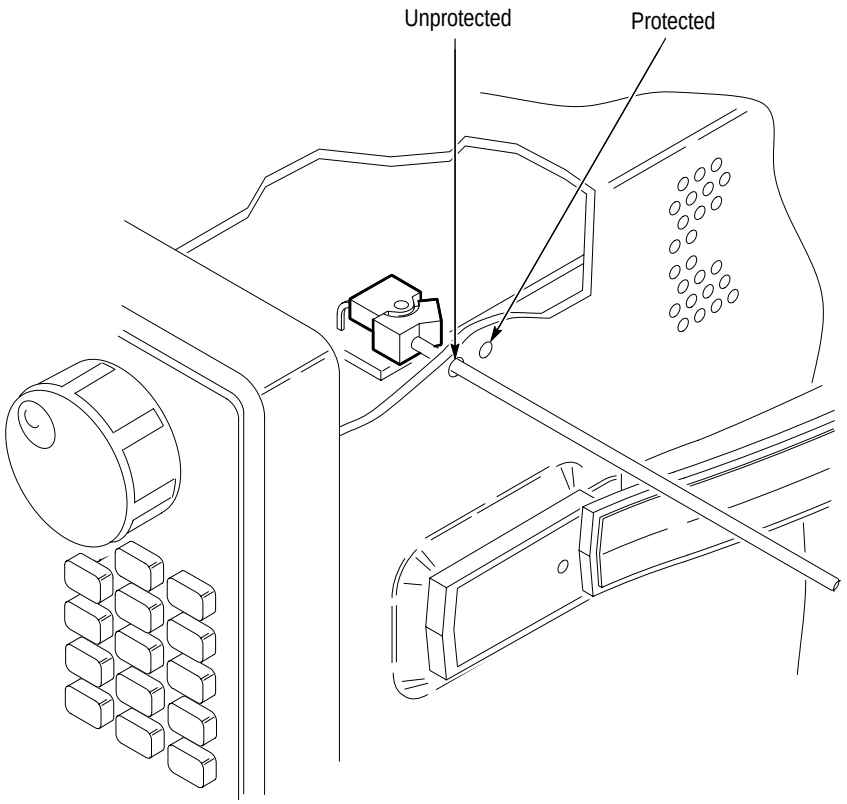

Figure 2–3: Accessing the Protection Switch

   Load TDS520B ver x.x.

7. To exit, highlight **Quit**, press **RETURN**, highlight **Exit**, press **RETURN**.

8. Turn the oscilloscope power OFF.

9. Insert a small, non-conductive object (adjustment tool) into the rear access hole located on the right side of the oscilloscope near the front panel. Push the non-conductive object inward to position the NVRAM protection rocker switch in the Protected (write-protect) position. See Figure 2–3.

10. Refer to Section 4 *Performance Verification* and Section 5 *Adjustment Procedures* in the TDS 520B Service Manual and calibrate as required.

Verify Installation

Press SHIFT and STATUS buttons. Verify that the version number shown of the screen is correct.

Storage and Shipment Instructions

Instructions

If you ship the oscilloscope, pack it in the original shipping carton and packing material. If the original packing material is not available, package the instrument as follows:

1. Obtain a corrugated cardboard shipping carton with inside dimensions at least 15 cm (6 inches) taller, wider, and deeper than the oscilloscope. The carton must be constructed of cardboard with 170 kg (375 pound test strength).
2. If you are shipping the oscilloscope to a Tektronix field office for repair, attach a tag to the oscilloscope showing the instrument owner and address, the name of the person to contact about the instrument, the instrument type, and the serial number.
3. Wrap the oscilloscope with polyethylene sheeting or equivalent material to protect the finish.
4. Cushion the oscilloscope in the carton by tightly packing dunnage or urethane foam on all sides between the carton and the oscilloscope. Allow 7.5 cm (3 inches) on all sides, top, and bottom.
5. Seal the carton with shipping tape or an industrial stapler.

Specifications

Table 2–1: Characteristics — Environmental

Name	Description
Atmospherics	Temperature (no diskette in floppy drive): TDS 520B: Operating: +4° C to +50° C Nonoperating: –22° C to +60° C Relative humidity (no diskette in floppy drive): Operating: 20% to 80%, at or below +32° C, upper limit derates to 30% relative humidity at +45° C Nonoperating: 5% to 90%, at or below +41° C, upper limit derates to 30% relative humidity at 60° C Altitude: To 4570 m (15,000 ft.), operating To 12190 m (40,000 ft.), nonoperating
Dynamics	Random vibration (optional floppy diskette not installed): 0.31 g rms, from 5 to 500 Hz, 10 minutes each axis, operating 3.07 g rms, from 5 to 500 Hz, 10 minutes each axis, nonoperating
Storage	Warehouse Stacking (uncontrolled warehouse climate): Up to 5 units high. Storage Shelf-Life: Performance can only be checked by actual field use. Component selection during design is made with the objective of meeting or exceeding the following Storage Shelf–life specification: $\geq$ 6 months if desiccant is included inside normal package, and normal package is placed inside a vacuum sealed bag and additional outer package.

Replaceable Electrical Parts

Replaceable Electrical Parts

Parts Ordering Information

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

When ordering parts, include the following information in your order: part number, instrument type or number, serial number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

List of Assemblies

A list of assemblies can be found at the beginning of the electrical parts list. The assemblies are listed in numerical order. When the complete component number of a part is known, this list will identify the assembly in which the part is located.

Cross Index-Mfr. Code Number to Manufacturer

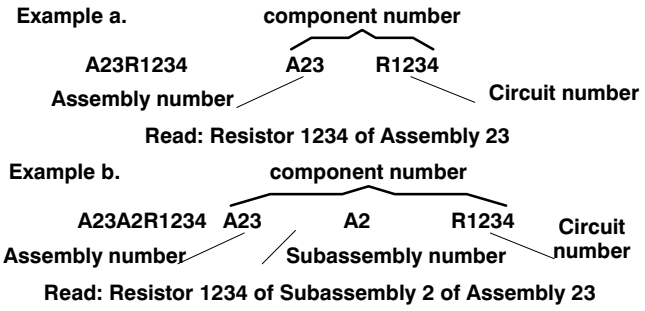
The Mfg. Code Number to Manufacturer Cross Index for the electrical parts list is located immediately after this page. The cross index provides codes, names, and addresses of manufacturers of components listed in the electrical parts list.

Abbreviations

Abbreviations conform to American National Standard Y1.1.

Component Number

(column 1 of the parts list)



The circuit component's number appears on the diagrams and circuit board illustrations. Each diagram and circuit board illustration is clearly marked with the assembly number. Assembly numbers are also marked on the mechanical exploded views located in the mechanical parts list. The component number is obtained by adding the assembly number prefix to the circuit number.

The electrical parts list is divided and arranged by assemblies in numerical sequence (e.g., assembly A1 with its subassemblies and parts, precedes assembly A2 with its subassemblies and parts).

Chassis-mounted parts have no assembly number prefix and are located at the end of the electrical parts list.

Tektronix Part No.

(column 2 of the parts list)

Indicates part number to be used when ordering replacement part from Tektronix.

Serial No.

(columns 3 & 4 of the parts list)

Column three (3) indicates the serial number at which the part was first used. Column four (4) indicates the serial number at which the part was removed. No serial number entered indicates part is good for all serial numbers.

Name & Description

(column five of the parts list)

In the parts list, an item name is separated from the description by a colon (:). Because of space limitations, an item name may sometimes appear as incomplete. For further item name identification, the U.S. Federal Catalog handbook H6-1 can be utilized where possible.

Mfr. Code

(column 6 of the parts list)

Indicates the code number of the actual manufacturer of the part. (Code to name and address cross reference can be found immediately after this page.)

Mfr. Part No.

(column 7 of the parts list)

Indicates actual manufacturer’s part number.

Replaceable Mechanical Parts

Replaceable Mechanical Parts

This section contains a list of compoents that are replaceable for the TDS 520B oscilloscope. Use this list to identify and order replacement parts.

Parts Ordering Information

Replacement parts are available through your local Tektronix field office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available and to give you the benefit of the latest circuit improvements. Therefore, when ordering parts, it is important to include the following information in your order.

- Part number
- Instrument type or model number
- Instrument serial number
- Instrument modification number, if applicable

If you order a part that has been replaced with a different or improved part, your local Tektronix field office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

Using the Replaceable Parts List

This section contains a list of the mechanical and/or electrical components that are replaceable for the oscilloscope. Use this list to identify and order replacement parts. The following table describes each column in the parts list.

Parts List Column Descriptions

Column	Column Name	Description
1	Figure & Index Number	Items in this section are referenced by component number.
2	Tektronix Part Number	Use this part number when ordering replacement parts from Tektronix.
3 and 4	Serial Number	Column three indicates the serial number at which the part was first effective. Column four indicates the serial number at which the part was discontinued. No entries indicates the part is good for all serial numbers.
5	Qty	This indicates the quantity of parts used.
6	Name & Description	An item name is separated from the description by a colon (:). Because of space limitations, an item name may sometimes appear as incomplete. Use the U.S. Federal Catalog handbook H6-1 for further item name identification.
7	Mfr. Code	This indicates the code of the actual manufacturer of the part. (Code to name and address cross reference is located after this page.)
8	Mfr. Part Number	This indicates the actual manufacturer's or vendor's part number.

Abbreviations Abbreviations conform to American National Standard ANSI Y1.1–1972.

Mfr. Code to Manufacturer Cross Index

The following table cross indexes codes, names, and addresses of manufacturers or vendors of components listed in the parts list.

Diagrams and Circuit Board Illustrations

Diagrams and Circuit Board Illustrations

This section contains block diagrams, circuit board illustrations, component locator tables and schematic diagrams.

Symbols

Graphic symbols and class designation letters are based on ANSI Standard Y32.2-1975. Abbreviations are based on ANSI Y1.1-1972.

Logic symbology is based on ANSI/IEEE Standard 91-1984 in terms of positive logic. Logic symbols depict the logic function performed and can differ from the manufacturer's data.

The tilde (~) preceding a signal name indicates that the signal performs its intended function when in the low state.

Other standards used in the preparation of diagrams by Tektronix, Inc., include the following:

- ANSI Y14.159-1971 Interconnection Diagrams
- ANSI Y32.16-1975 Reference Designations for Electronic Equipment
- MIL-HDBK-63038-1A Military Standard Technical Manual Writing Handbook

Component Values

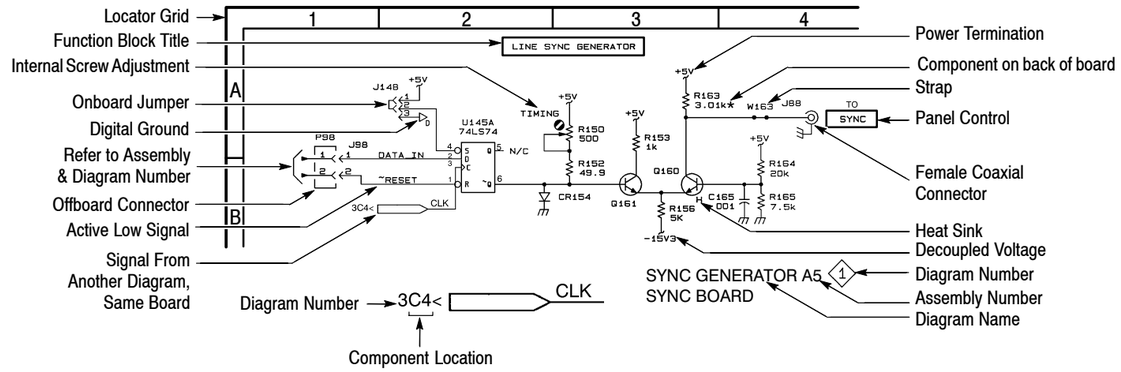
Electrical components shown on the diagrams are in the following units unless noted otherwise:

Capacitors: Values one or greater are in picofarads (pF).
Values less than one are in microfarads (μF).

Resistors: Values are in Ohms (Ω).

Graphic Items and Special Symbols Used in This Manual

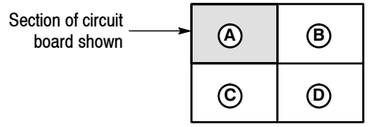
Each assembly in the instrument is assigned an assembly number (for example A5). The assembly number appears in the title on the diagram, in the lookup table for the schematic diagram, and corresponding component locator illustration. The Replaceable Electrical Parts list is arranged by assembly in numerical sequence; the components are listed by component number.

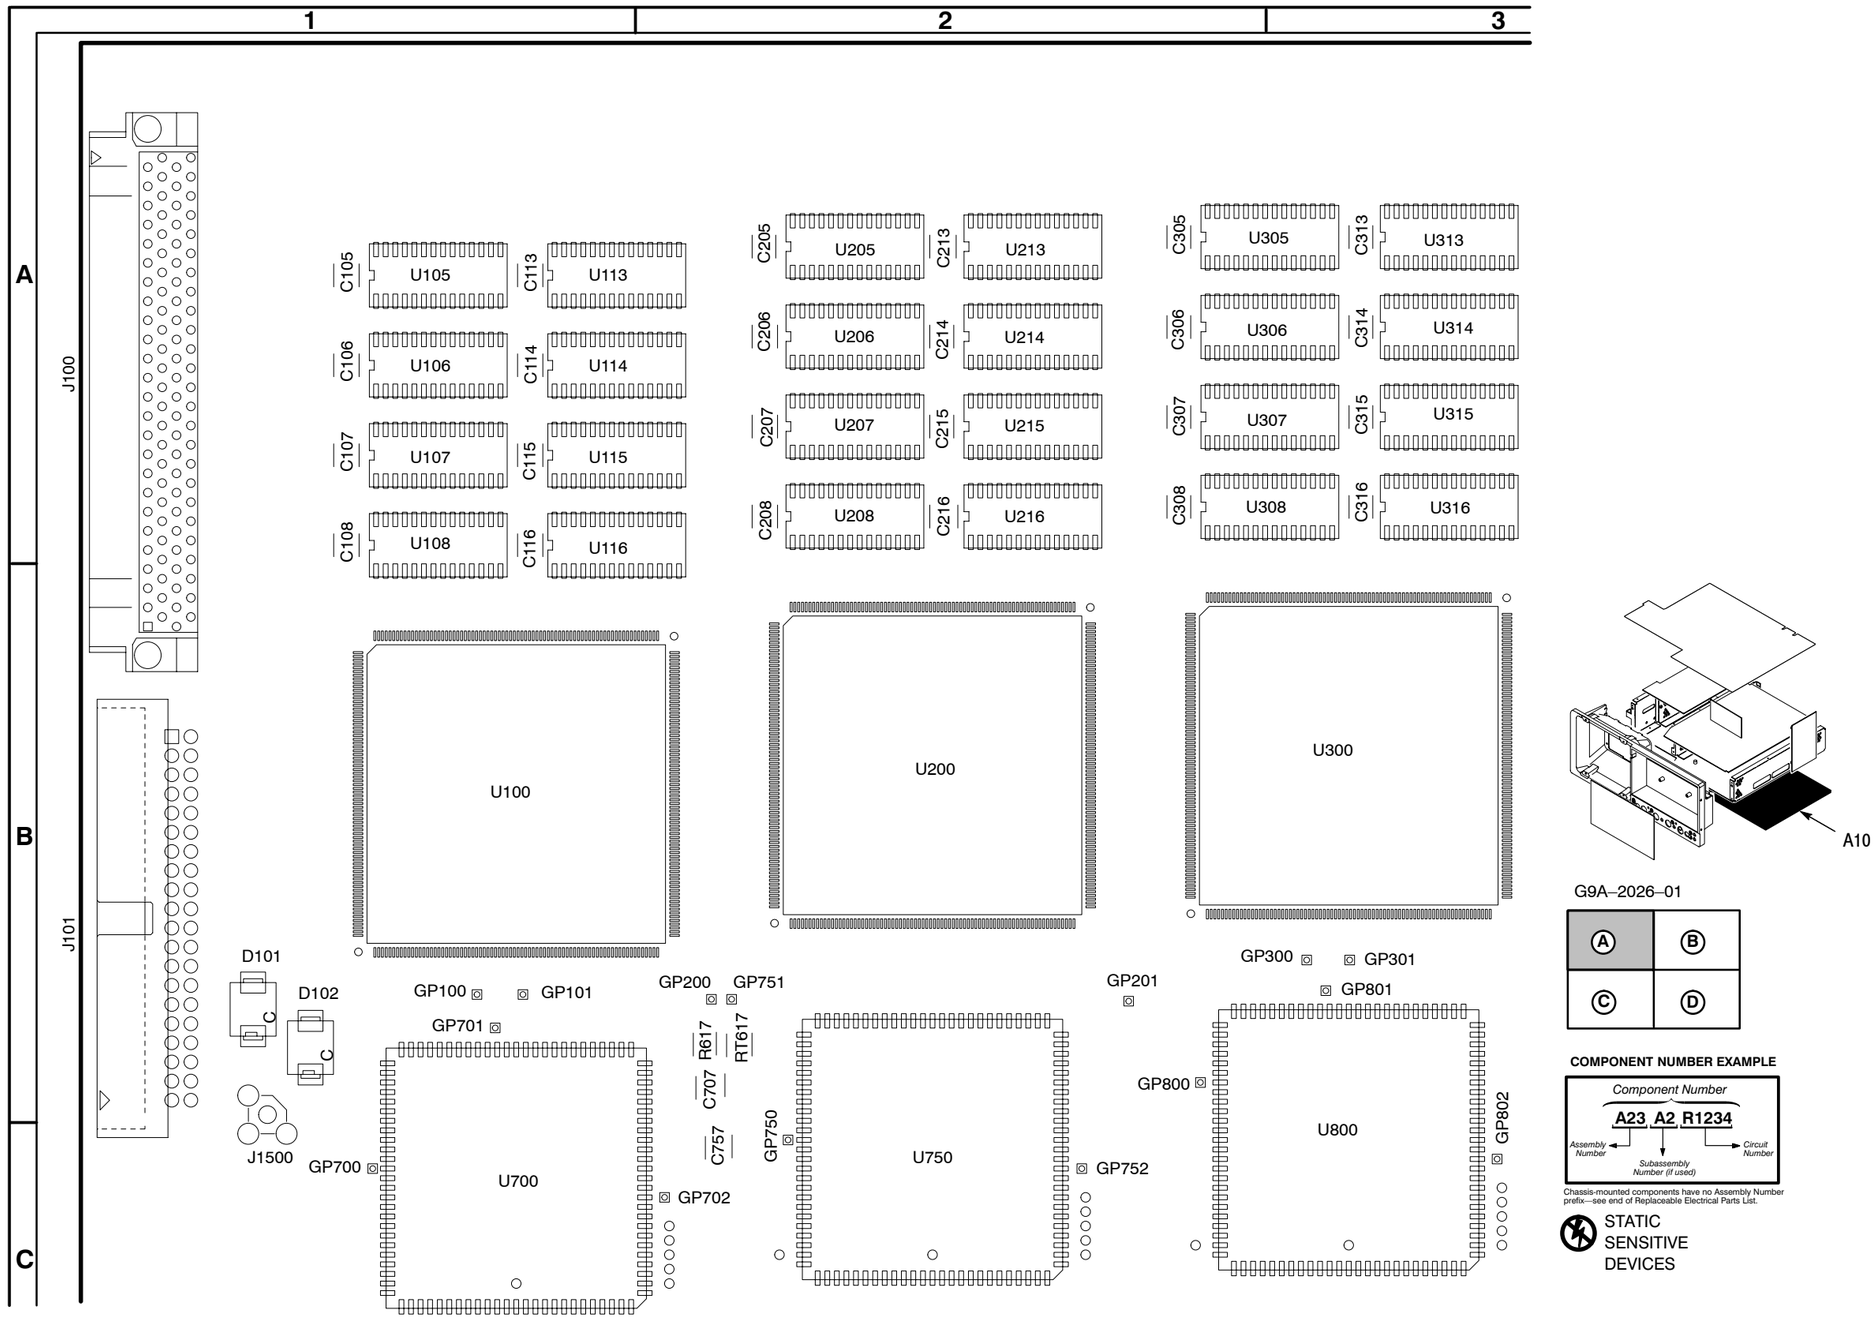


Component Locator Diagrams

The schematic diagram and circuit board component location illustrations have grids marked on them. The component lookup tables refer to these grids to help you locate a component. The circuit board illustration appears only once; its lookup table lists the diagram number of all diagrams on which the circuitry appears.

Some of the circuit board component location illustrations are expanded and divided into several parts to make it easier for you to locate small components. To determine which part of the whole locator diagram you are looking at, refer to the small locator key shown below. The gray block, within the larger circuit board outline, shows where that part fits in the whole locator diagram. Each part in the key is labeled with an identifying letter that appears in the figure titles under component locator diagrams.





G9A–2026–01

COMPONENT NUMBER EXAMPLE

Chassis-mounted components have no Assembly Number prefix—see end of Replaceable Electrical Parts List.

STATIC SENSITIVE DEVICES

The following parts are excluded from the TDS 520B:

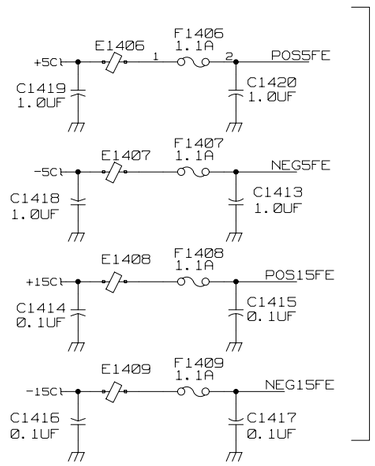
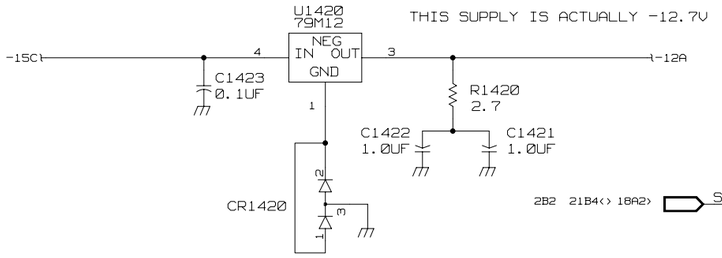
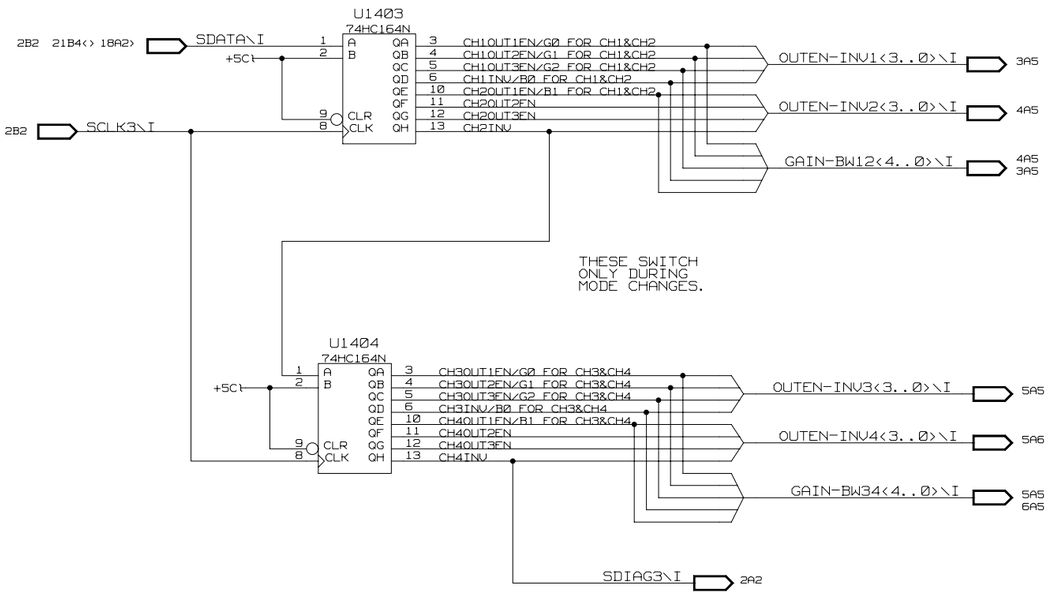
POWER	74HC164N
VDD	14
VSS	7

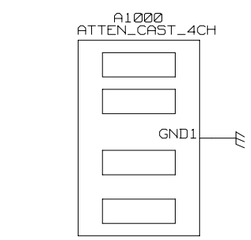


THESE SUPPLIES GO
TO J1153 7A1

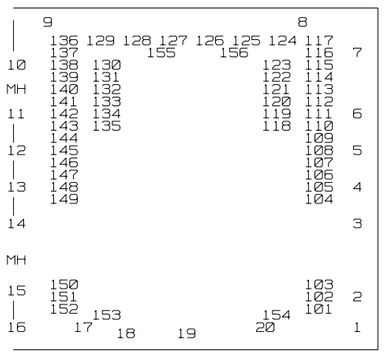




PCB INTERCONNECT TO CH1 OR 3 ATTENUATOR HYBRID
These are the pin numbers used on the
A1000 attenuator-amplifier modules.
Channels 2&4 add 100 to all 3-digit numbers.



(VIEWING GOLD CONTACTS)



All 1-digit and 2-digit numbers are grounds.

NOTE: JP1400 IS A CINCH CONNECTOR
USED FOR CHANNELS 1 & 2. JP1200
IS USED FOR CHANNELS 3 & 4.
