The ON key activates the RS flipflop (D1). The LED (G11) is turned on by the driver (D1) and the clock oscillator (D2) is then operative.

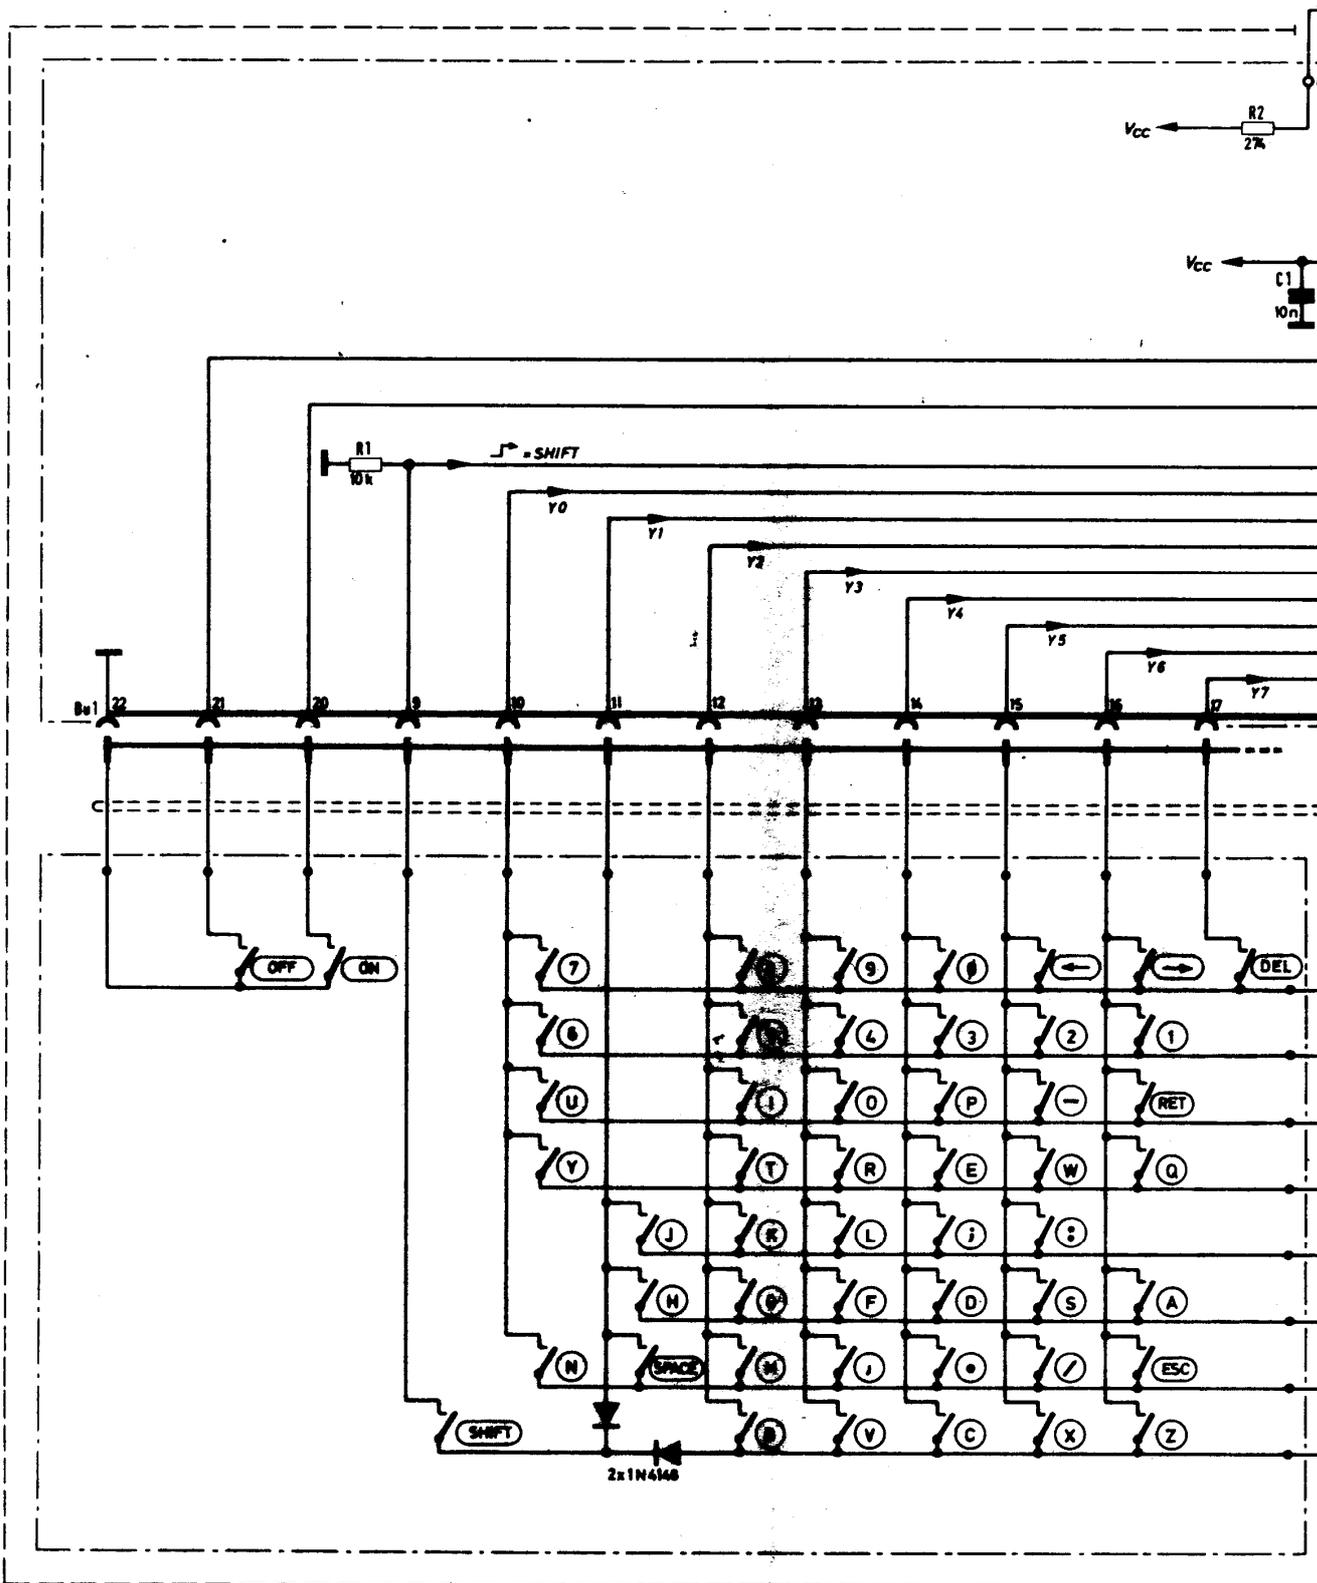

Because of the enabled gate (D2) the 6-stage binary counter (D5) constantly alters its count with the positive edge of the clock. The three (least significant) bits drive the decoder (D3), whose outputs go active Low one after the other (1-out-of-8). The inputs of the data selector (D4) are read out one after the other (1-out-of-8) by the three (most significant) bits.

An activated key closes the associated matrix point of decoder output and data-selector input. The count continues to alter until this matrix point conducts current. With the negative edge of the clock the Z output of the data selector goes Low and the retrigger/bare monoflop (D7) starts up. If the key remains activated, the following edges of the clock prevent the monoflop from dropping out. If the key is released, the monoflop remains active because of the timing network (R8/C11) (key debouncing). The output signals of the active monoflop close the gate and the frozen count is read into the latch (D6). The "Key active" signal is High. The 7-bit-wide output signal of the latch calls up an address in the character generator (P0). With this address a bit pattern appears on the data outputs of the character generator. The bit pattern is allocated to the key and is ASCII standard (positive logic).

Diese Zeichnung ist unser Eigentum. Vervielfältigung, unbefugte Verwertung, Mitteilung an andere ist strafbar und schadenersatzpflichtig.

1. Summary

The host computer consists of four elements: IEEE interface, SD interface, MS interface and MCU configuration. The MS (master/slave) interface forms the link between the host computer and the slave computer; communication is on the serial MS bus (eight lines).

The SD (slave device) interface is the link between the host computer and the keyboard; communication is on the parallel SD bus (20 lines).

The IEEE interface permits computer-aided control of the host computer on the IEEE-488 bus.

2. MCU configuration

The nucleus of the MCU configuration is the CPU (D11), the program and data memory, a timer/counter (D21) and the control logic (D4, D5, D6, D7, D10, D13, D14, D15). For the program memory (HP0-HP3) EPROMs of the type MBM27C256-30DC or MBM27C512-25Z (or equivalents) can be used; jumper Br1 has to be wired accordingly (see table 2.1). For HP4 either a RAM or an EPROM of the type HM62256P or MBM27C256-30DC can be used (see table 2.1).

RAMs of the type MB84256-15P (or equivalents) are used for data memory (D1-D2). For each of the two program-memory configurations an appropriate PAL P2 is to be selected (see table 1). EEPROM D3 serves as a constant memory. Write protection is produced by the wiring of D6. A fast-mode algorithm is used to optimize the write time. The address area of the memory can be determined with reference to table 2.1 or the details in the circuit diagram.

The timer/counter D21 produces interrupts of highest priority at defined times. Device D10 serves for buffering the data lines D0-D7. A system clock of 8 MHz is obtained from the sinusoidal small signal 8 MHz by the digital PLL D15 and by division in D13.

Ref.No. 250 031 F Type 4031	Sub Host Computer Unit	Date <i>28.5.87</i>
		Sheet 1/4
Schlumberger		Functional Description

The signals VMA and E are implemented with the two flipflops of D14 for controlling the synchronous peripheral devices of the 6800 family. The handshake signals VPA and DTACK of the asynchronous CPU are derived with D6 and D7. Device D12 and the PAL P2 serve for address decoding and for generating the chip-select signals for memory and peripheral devices.

Device D4 is used for supervising the supply voltage and ensuring the required reset times. The RESET and HALT signals are buffered by tristate driver D5 for bidirectionality.

On the hardware side two interrupt levels are implemented, the timer/counter being the highest. All peripheral devices with the exception of IEC-bus controller D24 can trigger interrupts; at the moment they are suppressed by software however. The slave computer is at the lower interrupt level, while the interrupts of the CRT slave are scanned by the PIA D22 on a sensing line.

For further information, refer to the description of the slave computer (RF/AF-MCU, 250 032 F).

3. IEEE interface

The IEEE-488 interface is the link between the host computer and the IEEE bus. It consists of the two driver devices D25 and D26 and the device D24.

4. MS interface

Communication between the host computer and the slave computer is on ACIA D20. The serial transfer clock SCLK (0.5 MHz) is derived from the system timing of 8 MHz by frequency division in D13. The interrupt to the selected CPU is enabled by the RTS (Ready To Send) signal. RD (Read Data) is the line for reading the host, Write Data the line for writing the host. The address SA0-SA2 of the slave computer is generated by the PIA D22; A0-A2 corresponds to this of the MS interface on the slave computer. There is an input on the PIA D22 for reading an interrupt CRTIRQ from the CRT slave.

Ref.No. 250 031 F Type 4031	Sub Host Computer Unit	Date <i>25.5.87</i>
		Sheet 2/4
Schlumberger		Functional Description

5. SD interface

The reading and control of the keyboard by the MCU are by means of a PIA (D23) on the control interface I bus (SD bus). This consists of eight bidirectional data lines PB0-PB7, eight unidirectional address lines PA0-PA7 and a strobe signal CB2. The remaining three signals CB1, CA1 and CA2 are optionally available.

Table 1: PAL P2

HNK no.	Program desig.	EEPROM	RAM
834 764	P 32 R 32	32	32 Kbytes
834 765	P 64 R 32	64	32 Kbytes

Table 2.1: Memory options

Using jumper Br1 it is possible to choose between

a b c xxx = connection made

xxx		4 x 27C512 (= 256 Kbytes)
	xxx	4 x 27C256 (= 128 Kbytes)

In the same way jumper Br2 is used to specify whether an EPROM or a RAM is inserted at HP4

a b c xxx = connection made

xxx		1 x 27C256 (= 32-Kbyte EPROM)
	xxx	1 x 43256C (= 32-Kbyte RAM)

Jumpers Br3 and Br4 are then to be wired as follows:

Br2			Br3			Br4			
a	b	c	a	b	c	a	b	c	
xxx			xxx			xxx			1 x 27C256 (=32-Kbyte EPROM)
	xxx			xxx			xxx		1 x 43256C12L (=32-Kbyte RAM)

- 70 88. 1028

1. Summary

The slave computer consists of three elements: MS interface, SD interface and MPU configuration. The MS (master/slave) interface forms the link between the host computer and the slave computer; communication is on the serial MS bus (eight lines).

The SD (slave device) interface is the link between the slave computer and the board to be controlled; communication is on the parallel SD bus (20 lines).

2. MPU configuration

The nucleus of the MPU configuration is the CPU (D8), the program and data memory, a timer/counter (D15) with driving logic (D16), plus an ADU (D17) and two PIAs (D13, D14). For the program memory (SP0-SP1) EPROMs of the type MBM27C256-30DC (or equivalents) can be used. The linear address area is between 3000h and FFFFh. A RAM of the type HM6264P (or equivalent) with linear address area 1000h-2FFFh is used for data memory.

The timer/counter D15 can be driven by multiplexer D16 with signals P14-P17 so that the pulses AF COUNT and IF COUNT can be measured in the appropriate manner (see table 1).

The latches D9 and D10 serve for storing the addresses in multiplex mode and for noise-immune isolation. Multiplexer D3 impresses the operating mode of the CPU (mode 4 = multiplex) upon system reset (RESET). In the normal operating mode it produces the signals SCLK (serial transfer clock) for the CPU's internal ACIA, TCLK (timer clock) for the timer/counter and its TO (timeout).

Devices D2 and D4 serve for conditioning the externally applied sinusoidal clock (8 MHz) and converting it into the required squarewave clock of 4 MHz (testpoint 1).

		Sheet 1/4
Schlumberger		Functional Description

The addresses are decoded and the individual chip-select signals (IO, RAM, EP1, EP2) generated with the PAL P0 (HNK no. 834 763). The control signals E, R/W for the periphery, like the RESET signal, are adequately buffered.

If the slave computer is to be operated independently of the host computer (when testing for instance), a reset possibility must be provided on St67/18b (button).

The ADU D17 measures the analog voltage AF SUM and supervises the supply voltages of +5.5 V, +15.0 V and -15.0 V. As a reference D18 applies a voltage of 5.12 V (testpoint 2).

All peripheral devices can send interrupts to the CPU; in the present configuration they are suppressed by software however.

3. MS interface

Communication between the host computer and the slave computer is on D1, D5, D6 and D7. The digital comparator D1 selects the individual slave computer on address lines A0, A1 and A2. The interrupt to the selected CPU is enabled by the RTS (Ready To Send) signal. The logic of D7 can distinguish between the interrupts sent by the host computer and those generated by the devices on the slave computer. A flipflop in D4 can register a host interrupt that has taken effect on the MPU; if the interrupts of the MPU have been disabled, it is therefore possible to read whether the host computer has issued a request. Read Data is the line for reading the host, Write Data the line for writing the host. The slave computer can trigger an interrupt on the host computer by means of the SRQ (Service Request) line.

		Sheet 2/4

4. SD interface

Data are transferred to connected boards by the CPU using two PIAs (D13, D14) on the RF or AF bus (SN busses). Both consist of eight bidirectional data lines PB0-PB7, eight unidirectional address lines PA0-PA7 and a strobe signal CB2. The remaining three signals CB1, CA1 and CA2 are optionally available. CA1 of D13 is a sensor for the UP/DOWN signal.
