Table of Contents

Section 1. General Description

1.1	Contents	21
1.2	Introduction	22
1.3	Features	22
1.4	MCU Block Diagram	24
1.5	Pin Assignments	26
1.5.1	Power Supply Pins (V_{DDREG} , V_{SSREG} , V_{DD1} , V_{SS1} , V_{DD2} , and V_{SS2})	27
1.5.2	Voltage Regulator Out (REGOUT)	28
1.5.3	Oscillator Pins (OSC1 and OSC2)	28
1.5.4	External Reset Pin (\overline{RST})	28
1.5.5	External Interrupt Pin ($\overline{IRQ1}/V_{PP}$)	29
1.5.6	USB Data Pins (D+ and D-)	29
1.5.7	Port A Input/Output (I/O) Pins (PTA7–PTA0)	29
1.5.8	Port B (I/O) Pins (PTB7–PTB0)	29
1.5.9	Port C I/O Pins (PTC7–PTC0)	29
1.5.10	Port D I/O Pins (PTD7/ $\overline{KBD7}$ –PTD0/ $\overline{KBD0}$)	30
1.5.11	Port E I/O Pins (PTE6–PTE3 and PTE2/TCH1, PTE1/TCH0, PTE0/TCLK)	30

Section 2. Memory Map

2.1	Contents	31
2.2	Introduction	31
2.3	Input/Output (I/O) Section	33
2.4	Monitor ROM	42

Section 3. Random-Access Memory (RAM)

3.1 Contents 43
 3.2 Introduction 43
 3.3 Functional Description 43

Section 4. EPROM/OTPROM

4.1 Contents 45
 4.2 Introduction 45
 4.3 Functional Description 45
 4.4 EPROM/OTPROM Control Register 46
 4.5 EPROM/OTPROM Programming Sequence 47

Section 5. Configuration Register (CONFIG)

5.1 Contents 49
 5.2 Introduction 49
 5.3 Functional Description 49

Section 6. Central Processor Unit (CPU)

6.1 Contents 53
 6.2 Introduction 53
 6.3 Features 54
 6.4 CPU Registers 55
 6.4.1 Accumulator 55
 6.4.2 Index Register 56
 6.4.3 Stack Pointer 57
 6.4.4 Program Counter 58
 6.4.5 Condition Code Register 59
 6.5 Arithmetic/Logic Unit (ALU) 61
 6.6 Instruction Set Summary 61
 6.7 Opcode Map 67

Section 7. Oscillator

7.1	Contents	69
7.2	Introduction	69
7.3	Oscillator External Connections	70
7.4	I/O Signals	71
7.4.1	Crystal Amplifier Input Pin (OSC1)	71
7.4.2	Crystal Amplifier Output Pin (OSC2)	71
7.4.3	Oscillator Enable Signal (SIMOSCEN)	71
7.4.4	External Clock Source (CGMXCLK)	71
7.4.5	Oscillator Out (CGMOUT)	72
7.5	Low-Power Modes	72
7.5.1	Wait Mode	72
7.5.2	Stop Mode	72
7.6	Oscillator During Break Mode	72

Section 8. System Integration Module (SIM)

8.1	Contents	73
8.2	Introduction	74
8.3	SIM Bus Clock Control and Generation	77
8.3.1	Bus Timing	78
8.3.2	Clock Startup from POR	78
8.3.3	Clocks in Stop Mode and Wait Mode	78
8.4	Reset and System Initialization	78
8.4.1	External Pin Reset	79
8.4.2	Active Resets from Internal Sources	80
8.4.2.1	Power-On Reset	81
8.4.2.2	Computer Operating Properly (COP) Reset	82
8.4.2.3	Illegal Opcode Reset	82
8.4.2.4	Illegal Address Reset	82
8.4.2.5	Universal Serial Bus Reset	83
8.5	SIM Counter	83
8.5.1	SIM Counter During Power-On Reset	83
8.5.2	SIM Counter During Stop Mode Recovery	84
8.5.3	SIM Counter and Reset States	84

8.6	Exception Control	84
8.6.1	Interrupts	84
8.6.1.1	Hardware Interrupts	87
8.6.1.2	SWI Instruction	88
8.6.2	Interrupt Status Registers	88
8.6.2.1	Interrupt Status Register 1	89
8.6.2.2	Interrupt Status Register 2	89
8.6.3	Reset	90
8.6.4	Break Interrupts	90
8.6.5	Status Flag Protection in Break Mode	90
8.7	Low-Power Modes	91
8.7.1	Wait Mode	91
8.7.2	Stop Mode	92
8.8	SIM Registers	94
8.8.1	Break Status Register	94
8.8.2	Reset Status Register	96
8.8.3	Break Flag Control Register	97

Section 9. Universal Serial Bus Module (USB)

9.1	Contents	99
9.2	Features	101
9.3	Overview	102
9.3.1	USB Protocol	103
9.3.1.1	Sync Pattern	105
9.3.1.2	Packet Identifier Field	106
9.3.1.3	Address Field (ADDR)	106
9.3.1.4	Endpoint Field (ENDP)	106
9.3.1.5	Cyclic Redundancy Check (CRC)	107
9.3.1.6	End-of-Packet (EOP)	109
9.3.2	Reset Signaling	110
9.3.3	Suspend	111
9.3.4	Resume After Suspend	111
9.3.4.1	Host Initiated Resume	111
9.3.4.2	USB Reset Signalling	112
9.3.4.3	Remote Wakeup	112
9.3.5	Low-Speed Device	113

9.4	Clock Requirements	113
9.5	Hardware Description	114
9.5.1	Voltage Regulator	114
9.5.2	Regulator Bypass Option	115
9.5.3	USB Transceiver	116
9.5.3.1	Output Driver Characteristics	116
9.5.3.2	Low Speed (1.5 Mbs) Driver Characteristics	116
9.5.3.3	Receiver Data Jitter	118
9.5.3.4	Data Source Jitter	118
9.5.3.5	Data Signal Rise and Fall Time	119
9.5.4	USB Control Logic	120
9.5.4.1	Data Encoding/Decoding	121
9.5.4.2	Bit Stuffing	122
9.6	I/O Register Description	124
9.6.1	USB Address Register	126
9.6.2	USB Interrupt Register 0	127
9.6.3	USB Interrupt Register 1	129
9.6.4	USB Control Register 0	131
9.6.5	USB Control Register 1	132
9.6.6	USB Control Register 2	134
9.6.7	USB Status Register	136
9.6.8	USB Endpoint 0 Data Registers	137
9.6.9	USB Endpoint 1/Endpoint 2 Data Registers	138
9.7	USB Interrupts	139
9.7.1	USB End-of-Transaction Interrupt	139
9.7.1.1	Receive Control Endpoint 0	139
9.7.1.2	Transmit Control Endpoint 0	142
9.7.1.3	Transmit Endpoint 1 and Transmit Endpoint 2	143
9.7.2	Resume Interrupt	144
9.7.3	End-of-Packet Interrupt	144

Section 10. Monitor ROM (MON)

10.1	Contents	145
10.2	Introduction	145
10.3	Features	146
10.4	Functional Description	146

10.4.1	Entering Monitor Mode	148
10.4.2	Data Format	150
10.4.3	Break Signal	150
10.4.4	Baud Rate	151
10.4.5	Commands	151
10.5	Security	157

Section 11. Timer Interface Module (TIM)

11.1	Contents	159
11.2	Introduction	160
11.3	Features	160
11.4	Functional Description	160
11.4.1	TIM Counter Prescaler	164
11.4.2	Input Capture	164
11.4.3	Output Compare	164
11.4.3.1	Unbuffered Output Compare	164
11.4.3.2	Buffered Output Compare	165
11.4.4	Pulse Width Modulation (PWM)	166
11.4.4.1	Unbuffered PWM Signal Generation	167
11.4.4.2	Buffered PWM Signal Generation	168
11.4.4.3	PWM Initialization	168
11.5	Interrupts	170
11.6	Wait Mode	170
11.7	TIM During Break Interrupts	170
11.8	I/O Signals	171
11.8.1	TIM Clock Pin (PTE0/TCLK)	171
11.8.2	TIM Channel I/O Pins (PTE1/TCH0:PTE2/TCH1)	172
11.9	I/O Registers	172
11.9.1	TIM Status and Control Register	172
11.9.2	TIM Counter Registers	175
11.9.3	TIM Counter Modulo Registers	176
11.9.4	TIM Channel Status and Control Registers	177
11.9.5	TIM Channel Registers	181

Section 12. Input/Output Ports (I/O)

12.1	Contents	183
12.2	Introduction	183
12.3	Port A	185
12.3.1	Port A Data Register	185
12.3.2	Data Direction Register A	186
12.4	Port B	188
12.4.1	Port B Data Register	188
12.4.2	Data Direction Register B	189
12.5	Port C	191
12.5.1	Port C Data Register	191
12.5.2	Data Direction Register C	192
12.6	Port D	194
12.6.1	Port D Data Register	194
12.6.2	Data Direction Register D	195
12.7	Port E	197
12.7.1	Port E Data Register	197
12.7.2	Data Direction Register E	199
12.8	Port Options	201
12.8.1	Port Option Control Register	201

Section 13. Computer Operating Properly (COP)

13.1	Contents	203
13.2	Introduction	203
13.3	Functional Description	204
13.4	I/O Signals	205
13.4.1	CGMXCLK.	205
13.4.2	STOP Instruction	205
13.4.3	COPCTL Write	206
13.4.4	Power-On Reset	206
13.4.5	Internal Reset	206
13.4.6	Reset Vector Fetch	206
13.4.7	COPD (COP Disable)	206
13.4.8	COPRS (COP Rate Select).	206

13.5	COP Control Register	207
13.6	Interrupts	207
13.7	Monitor Mode	207
13.8	Low-Power Modes	207
13.8.1	Wait Mode	207
13.8.2	Stop Mode	208
13.9	COP Module During Break Mode	208

Section 14. External Interrupt (IRQ)

14.1	Contents	209
14.2	Introduction	209
14.3	Features	210
14.4	Functional Description	210
14.5	$\overline{\text{IRQ1}}/V_{\text{pp}}$ Pin	213
14.6	IRQ Module During Break Interrupts	214
14.7	IRQ Status and Control Register	215

Section 15. Keyboard Interrupt Module (KBI)

15.1	Contents	217
15.2	Introduction	217
15.3	Features	217
15.4	Functional Description	219
15.5	Keyboard Initialization	220
15.6	Low-Power Modes	221
15.6.1	Wait Mode	221
15.6.2	Stop Mode	221
15.7	Keyboard Module During Break Interrupts	222
15.8	I/O Registers	222
15.8.1	Keyboard Status and Control Register	222
15.8.2	Keyboard Interrupt Enable Register	224

Section 16. Break Module (BREAK)

16.1	Contents	225
16.2	Introduction	225
16.3	Features	226
16.4	Functional Description	226
16.4.1	Flag Protection During Break Interrupts	228
16.4.2	CPU During Break Interrupts	228
16.4.3	TIM During Break Interrupts	228
16.4.4	COP During Break Interrupts	228
16.5	Break Module Registers	229
16.5.1	Break Status and Control Register	229
16.5.2	Break Address Registers	230
16.6	Low-Power Modes	230
16.6.1	Wait Mode	230
16.6.2	Stop Mode	230

Section 17. Electrical Specifications

17.1	Contents	231
17.2	Introduction	231
17.3	Absolute Maximum Ratings	232
17.4	Functional Operating Range	233
17.5	Thermal Characteristics	233
17.6	DC Electrical Characteristics	234
17.7	Control Timing	235
17.8	Oscillator Characteristics	235
17.9	USB DC Electrical Characteristics	236
17.10	USB Low-Speed Source Electrical Characteristics	237
17.11	USB Signaling Levels	238
17.12	Timer Interface Module Characteristics	239
17.13	Memory Characteristics	239

Section 18. Mechanical Specifications

18.1 Contents241
18.2 Introduction241
18.3 Quad Flat Pack (Case 848B-04).242

Section 19. Ordering Information

19.1 Contents243
19.2 Introduction243
19.3 MC Order Numbers243

1.2 Introduction

The MC68HC708KL8 is a member of the low-cost, high-performance M68HC08 Family of 8-bit microcontroller units (MCUs). The M68HC08 Family is based on the customer-specified integrated circuit (CSIC) design strategy. All MCUs in the family use the enhanced M68HC08 central processor unit (CPU08) and are available with a variety of modules, memory sizes and types, and package types.

1.3 Features

Features of the MC68HC708KL8 include:

- High-performance M68HC08 architecture
- Fully upward-compatible object code with M6805, M146805, and M68HC05 Families
- 1.5-MHz internal bus operation
- Eight Kbytes of on-chip erasable programmable read-only memory (EPROM) or one-time programmable read-only memory (OTPROM)
- On-chip programming firmware for use with host personal computer
- EPROM/OTPROM data security¹
- 368 bytes of on-chip random access memory (RAM)
- 8-bit keyboard interrupt port
- 39 general-purpose input/output (I/O), 24 with software configurable pullups
- 16-bit, 2-channel timer interface module (TIM)
- Eight light-emitting diode (LED) direct drive port pins
- Full compatibility with *Universal Serial Bus (USB) Specification* Rev. 1.0

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the EPROM/OTPROM difficult for unauthorized users.

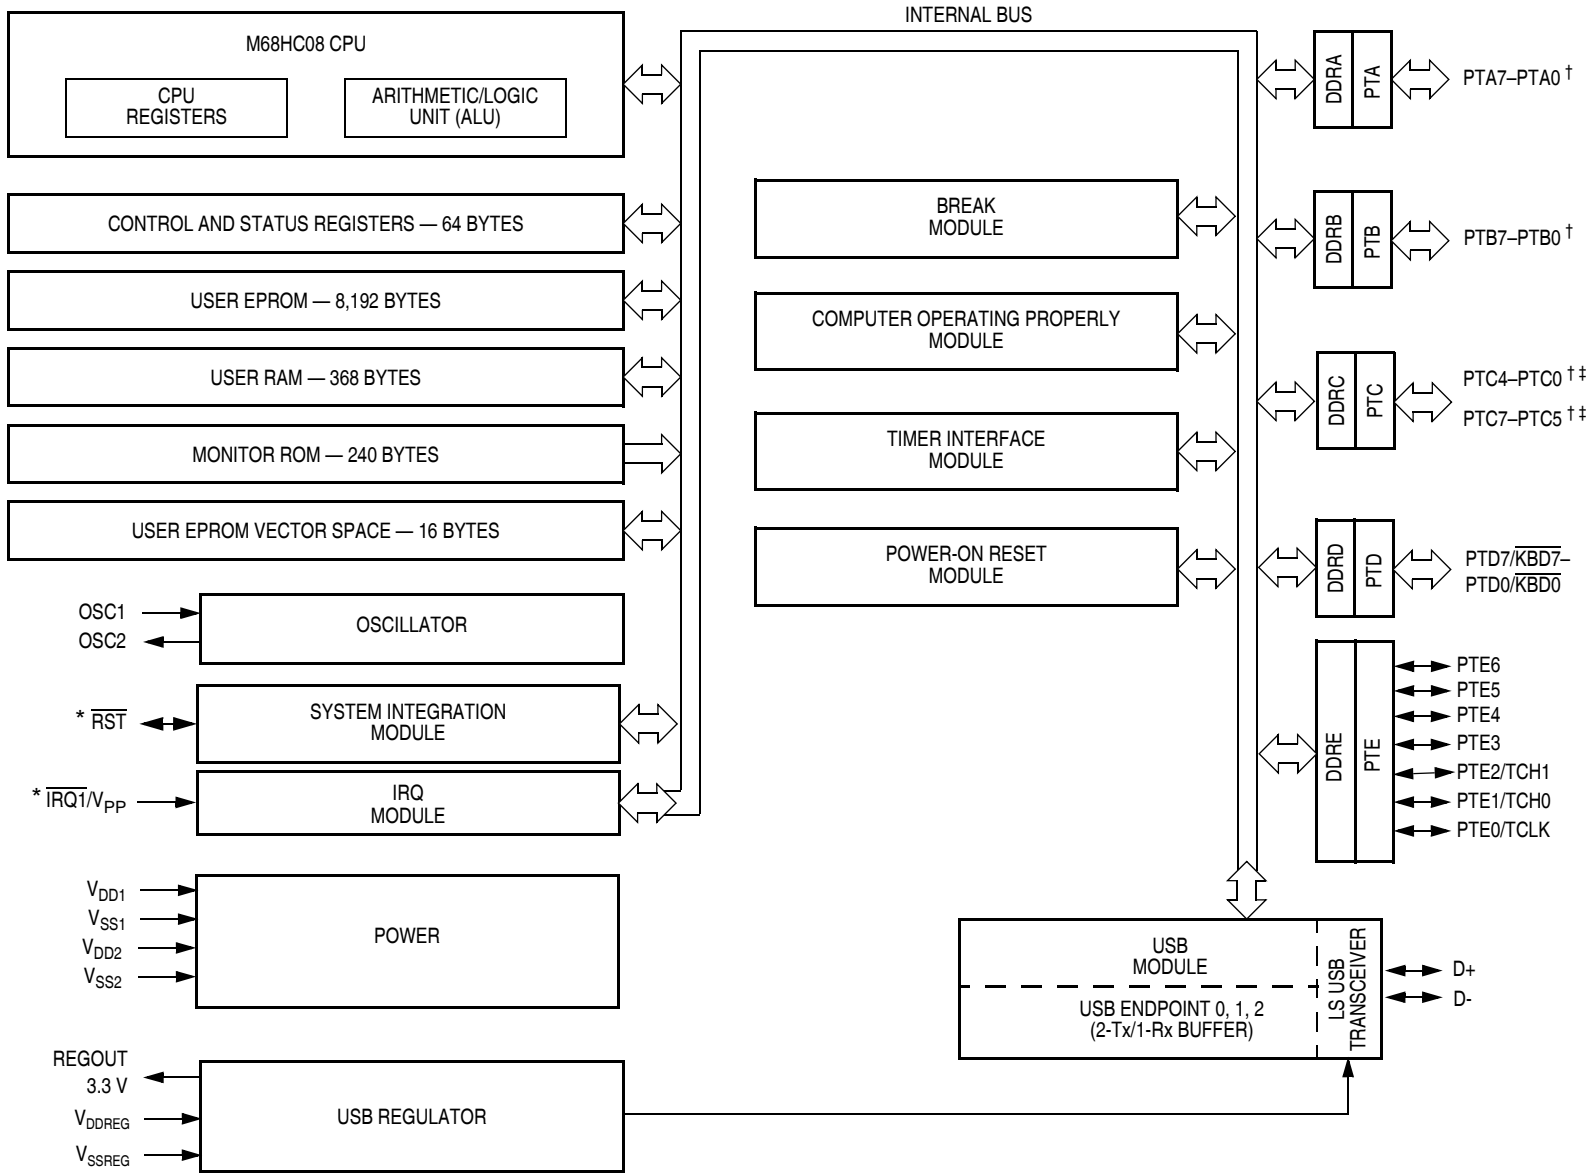

- Supports non-isochronous data
- Bidirectional half-duplex link
- 1.5 Mbps data rate (low speed)
- On-chip USB transceiver
- On-chip 3.3-V regulator for USB transceiver
- USB data control logic
 - Packet decoding/generation
 - CRC generation and checking
 - Non-return-to-zero inverted (NRZI) encoding/decoding and bit-stuffing
- Two 8-Byte transmit buffers
 - One dedicated for endpoint 0
 - One shared by endpoint 1 and endpoint 2
- One 8-byte receive buffer
 - Dedicated for control endpoint 0
- USB suspend/resume operation
- System protection features:
 - Optional computer operating properly (COP) reset
 - Illegal opcode detection with optional reset
 - Illegal address detection with optional reset
- 52-lead plastic quad flat pack (QFP) package
- Low-power design, fully static with stop and wait modes
- Master reset pin with internal pullup and power-on reset
- External asynchronous interrupt pin with internal pullup ($\overline{\text{IRQ1}}$)

Features of the CPU08 include:

- Enhanced HC05 programming model
- Extensive loop control functions
- 16 addressing modes (eight more than the HC05)
- 16-bit index register and stack pointer
- Memory-to-memory data transfers
- Fast 8×8 multiply instruction
- Fast 16/8 divide instruction
- Binary-coded decimal (BCD) instructions
- Optimization for controller applications
- Third party C language support

1.4 MCU Block Diagram

Figure 1-1 shows the structure of the MC68HC708KL8.

† Ports are software configurable with pullup device if input port.

 * Pin contains integrated pullup device

Figure 1-1. MCU Block Diagram

1.5 Pin Assignments

Figure 1-2 shows the 52-pin QFP assignments.

Figure 1-2. 52-Pin QFP Assignments (Top View)

1.5.1 Power Supply Pins (V_{DDREG} , V_{SSREG} , V_{DD1} , V_{SS1} , V_{DD2} , and V_{SS2})

V_{DDREG} and V_{SSREG} are the power supply and ground pins used by the on-board regulator. In regulator bypass, these become the supply pins for the USB transceiver.

V_{DD1} , V_{SS1} , V_{DD2} , and V_{SS2} are the power supply and ground pins. The MCU operates from a single power supply.

Fast signal transitions on MCU pins place high, short-duration current demands on the power supply. To prevent noise problems, take special care to provide power supply bypassing at the MCU as [Figure 1-3](#) shows. Place the bypass capacitors as close to the MCU power pins as possible. Use high-frequency-response ceramic capacitors for C_{BYPASS} . C_{BULK} are optional bulk current bypass capacitors for use in applications that require the port pins to source high current levels.

NOTE: Component values shown represent typical applications.

Figure 1-3. Power Supply Bypassing

1.5.2 Voltage Regulator Out (REGOUT)

REGOUT is the 3.3-V output of the on-chip voltage regulator. It is used to supply the voltage for the external pullup resistor required on the USB's D- line. REGOUT also is used internally for the USB data driver. The REGOUT pin requires an external bulk capacitor 1 μF or larger and a 0.1- μF ceramic bypass capacitor as [Figure 1-4](#) shows. Place the bypass capacitors as close to the REGOUT pin as possible. (See [Section 9. Universal Serial Bus Module \(USB\)](#).)

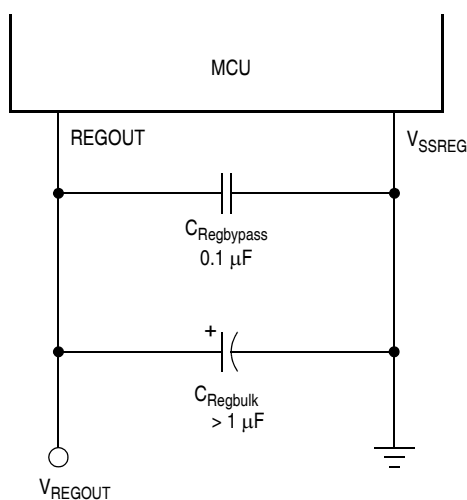

Figure 1-4. Regulator Supply Capacitor Configuration

1.5.3 Oscillator Pins (OSC1 and OSC2)

The OSC1 and OSC2 pins are the connections for the on-chip oscillator circuit. (See [Section 7. Oscillator](#).)

1.5.4 External Reset Pin ($\overline{\text{RST}}$)

A logic 0 on the $\overline{\text{RST}}$ pin forces the MCU to a known startup state. $\overline{\text{RST}}$ is bidirectional, allowing a reset of the entire system. It is driven low when any internal reset source is asserted. The $\overline{\text{RST}}$ pin contains an internal pullup device. (See [Section 8. System Integration Module \(SIM\)](#).)

1.5.5 External Interrupt Pin ($\overline{\text{IRQ1}}/V_{\text{PP}}$)

$\overline{\text{IRQ1}}/V_{\text{PP}}$ is an asynchronous external interrupt pin. $\overline{\text{IRQ1}}/V_{\text{PP}}$ is also the EPROM/OTPROM programming power pin. The $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin contains an internal pullup device. (See [Section 14. External Interrupt \(IRQ\)](#).)

1.5.6 USB Data Pins (D+ and D-)

D+ and D- are the differential data lines used by the USB module. (See [Section 9. Universal Serial Bus Module \(USB\)](#).)

1.5.7 Port A Input/Output (I/O) Pins (PTA7–PTA0)

PTA7–PTA0 are general-purpose bidirectional I/O port pins. (See [Section 12. Input/Output Ports \(I/O\)](#).) Each pin contains a software configurable pull-up device when the pin is configured as an input. (See [12.8 Port Options](#).)

1.5.8 Port B (I/O) Pins (PTB7–PTB0)

PTB7–PTB0 are general-purpose bidirectional I/O port pins. (See [Section 12. Input/Output Ports \(I/O\)](#).) Each pin contains a software configurable pull-up device when the pin is configured as an input. (See [12.8 Port Options](#).)

1.5.9 Port C I/O Pins (PTC7–PTC0)

PTC7–PTC0 are general-purpose bidirectional I/O port pins. (See [Section 12. Input/Output Ports \(I/O\)](#).) Port C pins are software configurable to be LED direct drive ports. Each pin contains a software configurable pullup device when the pin is configured as an input. (See [12.8 Port Options](#).)

1.5.10 Port D I/O Pins (PTD7/ $\overline{\text{KBD7}}$ –PTD0/ $\overline{\text{KBD0}}$)

PTD7/ $\overline{\text{KBD7}}$ –PTD0/ $\overline{\text{KBD0}}$ are general-purpose bidirectional I/O port pins. (See [Section 12. Input/Output Ports \(I/O\)](#).) Any or all of the port D pins can be programmed to serve as external interrupt pins. (See [Section 15. Keyboard Interrupt Module \(KBI\)](#).)

1.5.11 Port E I/O Pins (PTE6–PTE3 and PTE2/TCH1, PTE1/TCH0, PTE0/TCLK)

Port E is a 7-bit special function port that shares three of its pins with the timer interface module. (See [Section 12. Input/Output Ports \(I/O\)](#).) and [Section 11. Timer Interface Module \(TIM\)](#).)

Section 2. Memory Map

2.1 Contents

2.2	Introduction	31
2.3	Input/Output (I/O) Section	33
2.4	Monitor ROM	42

2.2 Introduction

The CPU08 can address 64 Kbytes of memory space. The memory map, shown in **Figure 2-1**, includes:

- Eight Kbytes of EPROM or OTPROM
- 368 bytes of RAM
- 16 bytes of user-defined vectors
- 240 bytes of monitor ROM

Memory Map

\$0000 ↓ \$003F	I/O REGISTERS (64 BYTES)
\$0040 ↓ \$01AF	RAM (368 BYTES)
\$01B0 ↓ \$DDFF	UNIMPLEMENTED (56,400 BYTES)
\$DE00 ↓ \$FDFF	EPROM (8,192 BYTES)
\$FE00	BREAK STATUS REGISTER (BSR)
\$FE01	RESET STATUS REGISTER (RSR)
\$FE02	RESERVED
\$FE03	BREAK FLAG CONTROL REGISTER (BFCR)

\$FF00 ↓ \$FFEF	UNIMPLEMENTED (240 BYTES)
\$FFF0 ↓ \$FFFF	VECTORS (16 BYTES)

Figure 2-1. Memory Map

2.3 Input/Output (I/O) Section

Addresses \$0000–\$003F, shown in [Figure 2-2](#), contain most of the control, status, and data registers. Additional I/O registers have these addresses:

- \$FE00 (break status register, BSR)
- \$FE01 (reset status register, RSR)
- \$FE03 (break flag control register, BFCR)
- \$FE04 (interrupt status register 1, INT1)
- \$FE05 (interrupt status register 2, INT2)
- \$FE07 (EPROM control register, EPMCR)
- \$FE0C and \$FE0D (break address registers, BRKH and BRKL)
- \$FE0E (break status and control register, BSCR)
- \$FFFF (COP control register, COPCTL)

2.4 Monitor ROM

The 240 bytes at addresses \$FE10–\$FEFF are reserved ROM addresses that contain the instructions for the monitor functions. (See [Section 10. Monitor ROM \(MON\)](#).)

Section 3. Random-Access Memory (RAM)

3.1 Contents

3.2	Introduction	43
3.3	Functional Description	43

3.2 Introduction

This section describes the 368 bytes of RAM.

3.3 Functional Description

Addresses \$0040–\$01AF are RAM locations. The location of the stack RAM is programmable. The 16-bit stack pointer allows the stack to be anywhere in the 64-Kbyte memory space.

NOTE: *For correct operation, the stack pointer must point only to RAM locations.*

Within page zero are 192 bytes of RAM. Because the location of the stack RAM is programmable, all page zero RAM locations can be used for I/O control and user data or code. When the stack pointer is moved from its reset location at \$00FF, direct addressing mode instructions can access efficiently all page zero RAM locations. Page zero RAM, therefore, provides ideal locations for frequently accessed global variables.

Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the CPU registers.

NOTE: *For M6805 Family compatibility, the H register is not stacked.*

Random-Access Memory (RAM)

During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements during pushes and increments during pulls.

NOTE: *Be careful when using nested subroutines. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.*

Section 4. EPROM/OTPROM

4.1 Contents

4.2	Introduction	45
4.3	Functional Description	45
4.4	EPROM/OTPROM Control Register	46
4.5	EPROM/OTPROM Programming Sequence	47

4.2 Introduction

This section describes the non-volatile memory (EPROM/OTPROM).

4.3 Functional Description

An MC68HC708KL8 MCU with a quartz window has 8 Kbytes of erasable, programmable ROM (EPROM). The quartz window allows EPROM erasure by using ultraviolet light. In an MC68HC708KL8 MCU without the quartz window, the EPROM cannot be erased and serves as 8 Kbytes of one-time programmable ROM (OTPROM). An unprogrammed or erased location reads as \$00. These addresses are user EPROM/OTPROM locations:

- \$DE00–\$FDFF
- \$FFF0–\$FFFF (These locations are reserved for user-defined interrupt and reset vectors.)

Programming tools are available from Freescale. Contact your local Freescale representative for more information.

NOTE: *A security feature prevents viewing of the EPROM/OTPROM contents.¹*

4.4 EPROM/OTPROM Control Register

The EPROM control register controls EPROM/OTPROM programming.

Address: \$FE07

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	ELAT	0	EPGM
Write:						ELAT		EPGM
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 4-1. EPROM/OTPROM Control Register (EPMCR)

ELAT — EPROM/OTPROM Latch Control Bit

This read/write bit latches the address and data buses for programming the EPROM/OTPROM. Clearing ELAT also clears the EPGM bit. EPROM/OTPROM data cannot be read when ELAT is set.

- 1 = Buses configured for EPROM/OTPROM programming
- 0 = Buses configured for normal operation

EPGM — EPROM/OTPROM Program Control Bit

This read/write bit applies the programming voltage from the $\overline{\text{IRQ1}}/V_{PP}$ pin to the EPROM/OTPROM. To write to the EPGM bit, the ELAT bit must be set already. Reset clears the EPGM bit.

- 1 = EPROM/OTPROM programming power switched on
- 0 = EPROM/OTPROM programming power switched off

1. No security feature is absolutely secure. However, Freescale’s strategy is to make reading or copying the EPROM/OTPROM difficult for unauthorized users.

4.5 EPROM/OTPROM Programming Sequence

The unprogrammed state is a 0. Programming changes the state to a 1.

Use the following procedure to program a byte of EPROM/OTPROM:

1. Apply V_{PP} to the $\overline{IRQ1}/V_{PP}$ pin.
2. Set the ELAT bit.

NOTE: *Writing logic 1s to both the ELAT and EPGM bits with a single instruction sets only the ELAT bit. EPGM must be set by a separate instruction in the programming sequence.*

3. Write to any user EPROM/OTPROM address.

NOTE: *Writing to an invalid address prevents the programming voltage from being applied.*

4. Set the EPGM bit.
5. Wait for a time, t_{EPGM} .
6. Clear the ELAT and EPGM bits.

Setting the ELAT bit configures the address and data buses to latch data for programming the array. Only data written to a valid EPROM address will be latched. Attempts to read any other valid EPROM address after step 2 will read the latched data written in step 3. Further writes to valid EPROM addresses after the first write (step 3) are ignored.

The EPGM bit cannot be set if ELAT bit is cleared. This is to ensure proper programming sequence. If EPGM is set and a valid EPROM write occurred, V_{PP} will be applied to the user EPROM array. When the EPGM bit is cleared, the program voltage is removed from the array.

Section 5. Configuration Register (CONFIG)

5.1 Contents

5.2	Introduction	49
5.3	Functional Description	49

5.2 Introduction

This section describes the configuration register (CONFIG). The configuration register controls the following options:

- USB regulator bypass
- Stop mode recovery time (32 or 4096 CGMXCLK cycles)
- COP timeout period ($2^{18} - 2^4$ or $2^{13} - 2^4$ CGMXCLK cycles)
- STOP instruction
- Operation of the computer operating properly module (COP)

5.3 Functional Description

The configuration register is used in the initialization of various options. The configuration register can be written once after each reset. All of the configuration register bits are cleared during reset. Since the various options affect the operation of the MCU, it is recommended that this register be written immediately after reset. The configuration register is located at \$001F. For compatibility, a write to a ROM version of the MCU at this location will have no effect. The configuration register may be read at any time.

Configuration Register (CONFIG)

NOTE: The CONFIG module is known as an MOR (mask option register) on a ROM device. For references in the documentation which refer to the MOR (mask option register), the CONFIG would be applicable for the EPROM/OTPROM version of the device.

Address: \$001F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	R	REGBP	R	0	SSREC	COPRS	STOP	COPD
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented
 R = Reserved

Figure 5-1. Configuration Register (CONFIG)

REGBP — Regulator Bypass Bit

The REGBP causes the on-chip regulator to pass V_{DDREG} to the REGOUT pin.

1 = V_{DDREG} voltage applied to the REGOUT pin.

0 = Regulator output drives 3.3 volts on REGOUT pin.

NOTE: The bypass mode is reserved for transceiver testing and should not be used in normal operation.

SSREC — Short Stop Recovery Bit

SSREC enables the CPU to exit stop mode with a delay of 32 CGMXCLK cycles instead of a 4096-CGMXCLK cycle delay.

1 = Stop mode recovery after 32 CGMXCLK cycles

0 = Stop mode recovery after 4096 CGMXCLK cycles

NOTE: Exiting stop mode by pulling reset will result in the long stop recovery. If using an external crystal oscillator, do not set the SSREC bit.

COPRS — COP Rate Select Bit

COPD selects the COP timeout period. Reset clears COPRS. (See [Section 13. Computer Operating Properly \(COP\)](#).)

1 = COP timeout period = $2^{13} - 2^4$ CGMXCLK cycles

0 = COP timeout period = $2^{18} - 2^4$ CGMXCLK cycles

STOP — STOP Instruction Enable Bit

STOP enables the STOP instruction.

1 = STOP instruction enabled

0 = STOP instruction treated as illegal opcode

COPD — COP Disable Bit

COPD disables the COP module. (See [Section 13. Computer Operating Properly \(COP\)](#).)

1 = COP module disabled

0 = COP module enabled

Configuration Register (CONFIG)

Section 6. Central Processor Unit (CPU)

6.1 Contents

6.2	Introduction	53
6.3	Features	54
6.4	CPU Registers	55
6.4.1	Accumulator	55
6.4.2	Index Register	56
6.4.3	Stack Pointer	57
6.4.4	Program Counter	58
6.4.5	Condition Code Register	59
6.5	Arithmetic/Logic Unit (ALU)	61
6.6	Instruction Set Summary	61
6.7	Opcode Map	67

6.2 Introduction

This section describes the central processor unit. The M68HC08 CPU is an enhanced and fully object-code-compatible version of the M68HC05 CPU. The *CPU08 Reference Manual* (Freescale document number CPU08RM/AD) contains a description of the CPU instruction set, addressing modes, and architecture.

6.3 Features

Features of the CPU include:

- Fully Upward, Object-Code Compatibility with M68HC05 Family
- 16-Bit Stack Pointer with Stack Manipulation Instructions
- 16-Bit Index Register with X-Register Manipulation Instructions
- 8-MHz CPU Internal Bus Frequency
- 64-Kbyte Program/Data Memory Space
- 16 Addressing Modes
- Memory-to-Memory Data Moves Without Using Accumulator
- Fast 8-Bit by 8-Bit Multiply and 16-Bit by 8-Bit Divide Instructions
- Enhanced Binary-Coded Decimal (BCD) Data Handling
- Modular Architecture with Expandable Internal Bus Definition for Extension of Addressing Range Beyond 64 Kbytes
- Low-Power Stop and Wait Modes

6.4 CPU Registers

Figure 6-1 shows the five CPU registers. CPU registers are not part of the memory map.

Figure 6-1. CPU Registers

6.4.1 Accumulator

The accumulator is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and the results of arithmetic/logic operations.

Figure 6-2. Accumulator (A)

6.4.2 Index Register

The 16-bit index register allows indexed addressing of a 64-Kbyte memory space. H is the upper byte of the index register, and X is the lower byte. H:X is the concatenated 16-bit index register.

In the indexed addressing modes, the CPU uses the contents of the index register to determine the conditional address of the operand.

Figure 6-3. Index Register (H:X)

The index register can serve also as a temporary data storage location.

6.4.3 Stack Pointer

The stack pointer is a 16-bit register that contains the address of the next location on the stack. During a reset, the stack pointer is preset to \$00FF. The reset stack pointer (RSP) instruction also sets the least significant byte (LSB) to \$FF but does not affect the most significant byte (MSB). The stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack.

In the stack pointer 8-bit offset and 16-bit offset addressing modes, the stack pointer can function as an index register to access data on the stack. The CPU uses the contents of the stack pointer to determine the conditional address of the operand.

Figure 6-4. Stack Pointer (SP)

NOTE: *The location of the stack is arbitrary and may be relocated anywhere in RAM. Moving the SP out of page zero (\$0000 to \$00FF) frees direct address (page zero) space. For correct operation, the stack pointer must point only to RAM locations.*

6.4.4 Program Counter

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched.

Normally, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

During reset, the program counter is loaded with the reset vector address located at \$FFFE and \$FFFF. The vector address is the address of the first instruction to be executed after exiting the reset state.

Figure 6-5. Program Counter (PC)

6.4.5 Condition Code Register

The 8-bit condition code register contains the interrupt mask and five flags that indicate the results of the instruction just executed. Bits 6 and 5 are set permanently to logic 1. The following paragraphs describe the functions of the condition code register.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	V	1	1	H	I	N	Z	C
Write:								
Reset:	X	1	1	X	1	X	X	X

X = Indeterminate

Figure 6-6. Condition Code Register (CCR)

V — Overflow Flag

The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.

1 = Overflow

0 = No overflow

H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an ADD or ADC operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C flags to determine the appropriate correction factor.

1 = Carry between bits 3 and 4

0 = No carry between bits 3 and 4

I — Interrupt Mask

When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the interrupt vector is fetched.

1 = Interrupts disabled

0 = Interrupts enabled

NOTE: *To maintain M6805 Family compatibility, the upper byte of the index register (H) is not stacked automatically. If the interrupt service routine modifies H, then the user must stack and unstack H using the PSHH and PULH instructions.*

After the I bit is cleared, the highest-priority interrupt request is serviced first.

A return-from-interrupt (RTI) instruction pulls the CPU registers from the stack and restores the interrupt mask from the stack. After any reset, the interrupt mask is set and can only be cleared by the clear interrupt mask software instruction (CLI).

N — Negative flag

The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result.

- 1 = Negative result
- 0 = Non-negative result

Z — Zero flag

The CPU sets the zero flag when an arithmetic operation, logic operation, or data manipulation produces a result of \$00.

- 1 = Zero result
- 0 = Non-zero result

C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.

- 1 = Carry out of bit 7
- 0 = No carry out of bit 7

6.5 Arithmetic/Logic Unit (ALU)

The ALU performs the arithmetic and logic operations defined by the instruction set.

Refer to the *CPU08 Reference Manual* (Freescale document number CPU08RM/AD) for a description of the instructions and addressing modes and more details about the CPU's architecture.

6.6 Instruction Set Summary

Table 6-1 provides a summary of the M68HC08 instruction set.

7.2 Introduction

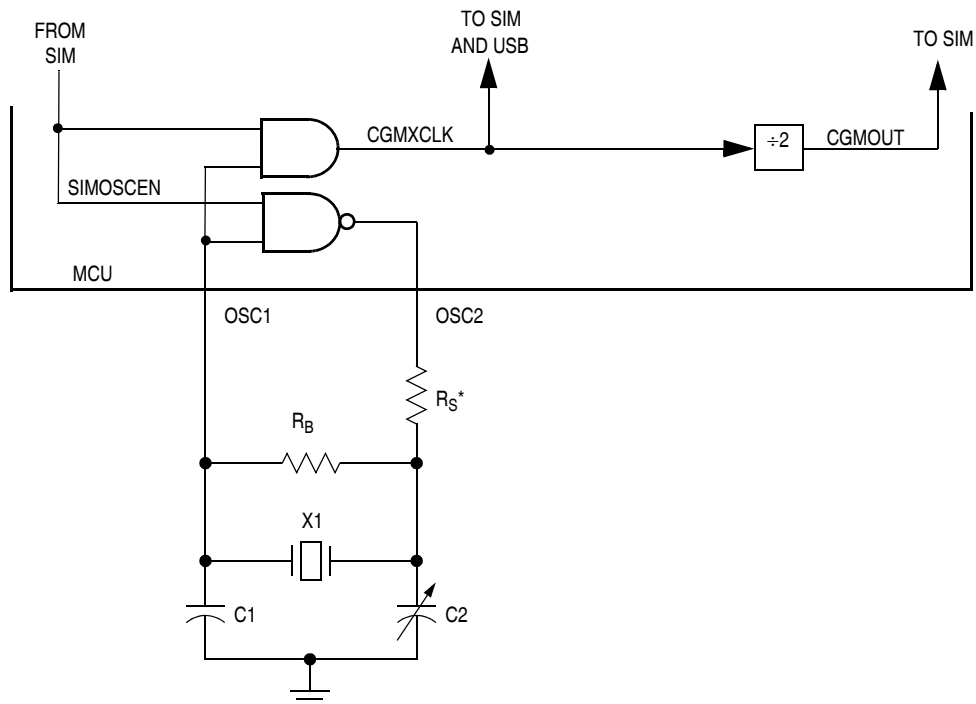

The oscillator circuit is designed for use with crystals or ceramic resonators. The oscillator circuit generates the crystal clock signal, CGMXCLK, at the frequency of the crystal. This signal is divided by two before being passed on to the system integration module (SIM) for bus clock generation.

Figure 7-1 shows the structure of the oscillator. The oscillator requires various external components.

7.3 Oscillator External Connections

In its typical configuration, the oscillator requires five external components. The crystal oscillator is normally connected in a Pierce oscillator configuration, as shown in **Figure 7-1**. This figure shows only the logical representation of the internal components and may not represent actual circuitry. The oscillator configuration uses five components:

- Crystal, X_1
- Fixed capacitor, C_1
- Tuning capacitor, C_2 (can also be a fixed capacitor)
- Feedback resistor, R_B
- Series resistor, R_S (optional)

* R_S can be 0 (shorted) when used with higher-frequency crystals. Refer to manufacturer's data.

Figure 7-1. Oscillator External Connections

The series resistor (R_S) is included in the diagram to follow strict Pierce oscillator guidelines and may not be required for all ranges of operation, especially with high-frequency crystals. Refer to the crystal manufacturer's data for more information.

7.4 I/O Signals

The following paragraphs describe the oscillator input/output (I/O) signals.

7.4.1 Crystal Amplifier Input Pin (OSC1)

The OSC1 pin is an input to the crystal oscillator amplifier.

7.4.2 Crystal Amplifier Output Pin (OSC2)

The OSC2 pin is the output of the crystal oscillator inverting amplifier.

7.4.3 Oscillator Enable Signal (SIMOSCEN)

The SIMOSCEN signal comes from the system integration module (SIM) and enables the oscillator.

7.4.4 External Clock Source (CGMXCLK)

CGMXCLK is the crystal oscillator output signal. It runs at the full speed of the crystal (f_{XCLK}) and comes directly from the crystal oscillator circuit. **Figure 7-1** shows only the logical relation of CGMXCLK to OSC1 and OSC2 and may not represent the actual circuitry. The duty cycle of CGMXCLK is unknown and may depend on the crystal and other external factors. Also, the frequency and amplitude of CGMXCLK can be unstable at startup.

7.4.5 Oscillator Out (CGMOUT)

The clock driven to the SIM is the crystal frequency divided by two. This signal is driven to the SIM for generation of the bus clocks used by the CPU and other modules on the MCU. CGMOUT will be divided again in the SIM and results in the internal bus frequency being one fourth of the CGMXCLK frequency.

7.5 Low-Power Modes

The WAIT and STOP instructions put the MCU in low-power-consumption standby modes.

7.5.1 Wait Mode

The WAIT instruction has no effect on the oscillator logic. CGMXCLK continues to drive to the SIM module.

7.5.2 Stop Mode

The STOP instruction disables the CGMXCLK output.

7.6 Oscillator During Break Mode

The oscillator continues to drive CGMXCLK when the chip enters the break state.

8.2 Introduction

This section describes the system integration module (SIM), which supports up to 16 external and/or internal interrupts. Together with the CPU, the SIM controls all MCU activities. The SIM is a system state controller that coordinates CPU and exception timing. A block diagram of the SIM is shown in [Figure 8-1](#). [Table 8-1](#) is a summary of the SIM I/O registers.

The SIM is responsible for:

- Bus clock generation and control for CPU and peripherals
 - Stop/wait/reset/break entry and recovery
 - Internal clock control
- Master reset control, including power-on reset (POR) and COP timeout
- Interrupt control:
 - Acknowledge timing
 - Arbitration control timing
 - Vector address generation
- CPU enable/disable timing
- Modular architecture expandable to 128 interrupt sources

Figure 8-2. SIM Register Summary

Table 8-1 shows the internal signal names used in this section.

Table 8-1. Signal Name Conventions

Signal Name	Description
CGMXCLK	Buffered OSC1 from the oscillator
CGMOUT	The CGMXCLK frequency divided by two. This signal is again divided by two in the SIM to generate the internal bus clocks. (Bus clock = CGMXCLK divided by four)
IAB	Internal address bus
IDB	Internal data bus
PORRST	Signal from the power-on reset module to the SIM
IRST	Internal reset signal
R/ \overline{W}	Read/write signal

8.3 SIM Bus Clock Control and Generation

The bus clock generator provides system clock signals for the CPU and peripherals on the MCU. The system clocks are generated from an incoming clock, CGMOUT, as shown in **Figure 8-3**.

Figure 8-3. SIM Clock Signals

8.3.1 Bus Timing

In user mode, the internal bus frequency is the oscillator frequency (CGMXCLK) divided by four.

8.3.2 Clock Startup from POR

When the power-on reset (POR) module generates a reset, the clocks to the CPU and peripherals are inactive and held in an inactive phase until after the 4096 CGMXCLK cycle POR timeout has completed. The $\overline{\text{RST}}$ pin is driven low by the SIM during this entire period. The IBUS clocks start upon completion of the timeout.

8.3.3 Clocks in Stop Mode and Wait Mode

Upon exit from stop mode by an interrupt, break, or reset, the SIM allows CGMXCLK to clock the SIM counter. The CPU and peripheral clocks do not become active until after the stop delay timeout. This timeout is selectable as 4096 or 32 CGMXCLK cycles. (See [8.7.2 Stop Mode](#).)

In wait mode, the CPU clocks are inactive. The SIM also produces two sets of clocks for other modules. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

8.4 Reset and System Initialization

The MCU has these reset sources:

- Power-on reset module (POR)
- External reset pin ($\overline{\text{RST}}$)
- Computer operating properly module (COP)
- Illegal opcode
- Illegal address
- Universal serial bus module (USB)

All of these resets produce the vector \$FFFE–FFFF (\$FEFE–FEFF in monitor mode) and assert the internal reset signal (IRST). IRST causes all registers to be returned to their default values and all modules to be returned to their reset states.

An internal reset clears the SIM counter (see [8.5 SIM Counter](#)), but an external reset does not. Each of the resets sets a corresponding bit in the reset status register (RSR). (See [8.8 SIM Registers](#).)

8.4.1 External Pin Reset

The $\overline{\text{RST}}$ pin circuits include an internal pullup device. Pulling the asynchronous $\overline{\text{RST}}$ pin low halts all processing. The PIN bit of the reset status register (RSR) is set as long as $\overline{\text{RST}}$ is held low for a minimum of 67 CGMXCLK cycles, assuming that the POR was not the source of the reset. See [Table 8-2](#) for details. [Figure 8-4](#) shows the relative timing.

Table 8-2. PIN Bit Set Timing

Reset Type	Number of Cycles Required to Set PIN
POR	4163 (4096 + 64 + 3)
All others	67 (64 + 3)

Figure 8-4. External Reset Timing

8.4.2 Active Resets from Internal Sources

All internal reset sources actively pull the $\overline{\text{RST}}$ pin low for 32 CGMXCLK cycles to allow resetting of external peripherals. The internal reset signal IRST continues to be asserted for an additional 32 cycles. (See [Figure 8-5](#).) An internal reset can be caused by an illegal address, illegal opcode, COP timeout, the USB module or POR. (See [Figure 8-6](#).) Note that for POR resets, the SIM cycles through 4096 CGMXCLK cycles during which the SIM forces the $\overline{\text{RST}}$ pin low. The internal reset signal then follows the sequence from the falling edge of $\overline{\text{RST}}$ shown in [Figure 8-5](#).

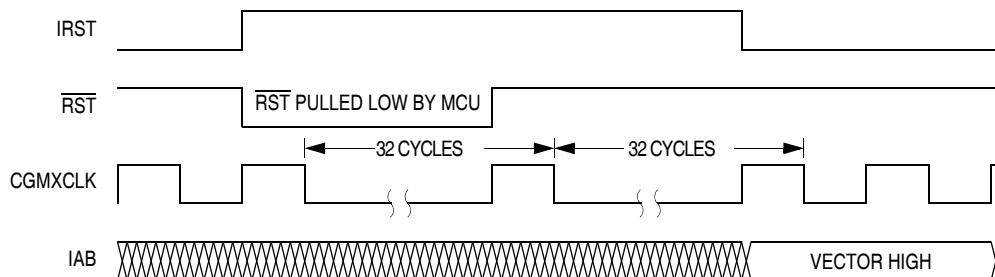

Figure 8-5. Internal Reset Timing

The COP reset is asynchronous to the bus clock.

Figure 8-6. Sources of Internal Reset

The active reset feature allows the part to issue a reset to peripherals and other chips within a system built around the MCU.

8.4.2.1 Power-On Reset

When power is first applied to the MCU, the power-on reset module (POR) generates a pulse to indicate that power-on has occurred. The external reset pin ($\overline{\text{RST}}$) is held low while the SIM counter counts out 4096 CGMXCLK cycles. Sixty-four CGMXCLK cycles later, the CPU and memories are released from reset to allow the reset vector sequence to occur.

At power-on, the following events occur:

- A POR pulse is generated.
- The internal reset signal is asserted.
- The SIM enables the oscillator to drive CGMXCLK.
- Internal clocks to the CPU and modules are held inactive for 4096 CGMXCLK cycles to allow stabilization of the oscillator.
- The $\overline{\text{RST}}$ pin is driven low during the oscillator stabilization time.
- The POR bit of the reset status register (RSR) is set and all other bits in the register are cleared.

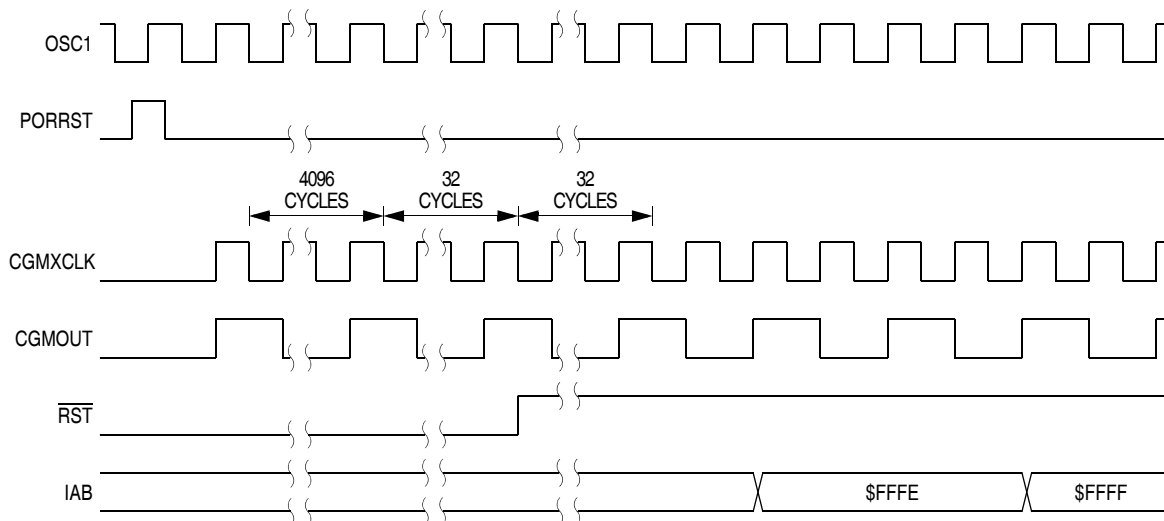

Figure 8-7. POR Recovery

8.4.2.2 Computer Operating Properly (COP) Reset

An input to the SIM is reserved for the COP reset signal. The overflow of the COP counter causes an internal reset and sets the COP bit in the reset status register (RSR). The SIM actively pulls down the $\overline{\text{RST}}$ pin for all internal reset sources.

To prevent a COP module timeout, write any value to location \$FFFF. Writing to location \$FFFF clears the COP counter and stages 12 through 5 of the SIM counter. The SIM counter output, which occurs at least every $2^{12} - 2^4$ CGMXCLK cycles, drives the COP counter. The COP should be serviced as soon as possible out of reset to guarantee the maximum amount of time before the first timeout.

The COP module is disabled if the $\overline{\text{RST}}$ pin or the $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin is held at V_{TST} while the MCU is in monitor mode. The COP module can be disabled only through combinational logic conditioned with the high voltage signal on the $\overline{\text{RST}}$ or the $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin. This prevents the COP from becoming disabled as a result of external noise. During a break state, V_{TST} on the $\overline{\text{RST}}$ pin disables the COP module.

8.4.2.3 Illegal Opcode Reset

The SIM decodes signals from the CPU to detect illegal instructions. An illegal instruction sets the ILOP bit in the reset status register (RSR) and causes a reset.

If the stop enable bit, STOP, in the mask option register is logic 0, the SIM treats the STOP instruction as an illegal opcode and causes an illegal opcode reset. The SIM actively pulls down the $\overline{\text{RST}}$ pin for all internal reset sources.

8.4.2.4 Illegal Address Reset

An access from an unmapped address generates an illegal address reset. The SIM verifies that the CPU is fetching an opcode prior to asserting the ILAD bit in the reset status register (RSR) and resetting the MCU. A data fetch from an unmapped address does not generate a reset. The SIM actively pulls down the $\overline{\text{RST}}$ pin for all internal reset sources.

8.4.2.5 Universal Serial Bus Reset

The USB module will detect a reset signaled on the bus by the presence of an extended SE0 at the USB data pins of a device. The reset signaling is specified to be present for a minimum of 10 ms. An active device (powered and not in the suspend state) seeing a single-ended 0 on its USB data inputs for more than 2.5 μ s may treat that signal as a reset, but must have interpreted the signaling as a reset within 5.5 μ s. For a low-speed device, an SE0 condition between 4 and 8 low-speed bit times represents a valid USB reset. After the reset is removed, the device will be in the attached, but not yet addressed or configured, state (refer to Section 9.1 USB Devices of the *Universal Serial Bus Specification* Rev. 1.0). The device must be able to accept the device address via a SET_ADDRESS command (refer to Section 9.4 of the *Universal Serial Bus Specification* Rev. 1.0) no later than 10 ms after the reset is removed.

Reset can wake a device from the suspended mode. A device may take up to 10 ms to wake up from the suspended state.

8.5 SIM Counter

The SIM counter is used by the power-on reset module (POR) and in stop mode recovery to allow the oscillator time to stabilize before enabling the internal bus (IBUS) clocks. The SIM counter also serves as a prescaler for the computer operating properly module (COP). The SIM counter uses 12 stages for counting, followed by a 13th stage that triggers a reset of SIM counters and supplies the clock for the COP module. The SIM counter is clocked by the falling edge of CGMXCLK.

8.5.1 SIM Counter During Power-On Reset

The power-on reset module (POR) detects power applied to the MCU. At power-on, the POR circuit asserts the signal PORRST. Once the SIM is initialized, it enables the oscillator to drive the bus clock state machine.

8.5.2 SIM Counter During Stop Mode Recovery

The SIM counter also is used for stop mode recovery. The STOP instruction clears the SIM counter. After an interrupt, break, or reset, the SIM senses the state of the short stop recovery bit, SSREC, in the configuration register. If the SSREC bit is a logic 1, then the stop recovery is reduced from the normal delay of 4096 CGMXCLK cycles down to 32 CGMXCLK cycles. This is ideal for applications using canned oscillators that do not require long startup times from stop mode. External crystal applications should use the full stop recovery time, that is, with SSREC cleared in the configuration register (CONFIG).

8.5.3 SIM Counter and Reset States

External reset has no effect on the SIM counter. (See [8.7.2 Stop Mode](#) for details.) The SIM counter is free-running after all reset states. (See [8.4.2 Active Resets from Internal Sources](#) for counter control and internal reset recovery sequences.)

8.6 Exception Control

Normal, sequential program execution can be changed in three different ways:

- Interrupts
 - Maskable hardware CPU interrupts
 - Non-maskable software interrupt instruction (SWI)
- Reset
- Break interrupts

8.6.1 Interrupts

An interrupt temporarily changes the sequence of program execution to respond to a particular event. [Figure 8-8](#) flow charts the handling of system interrupts.

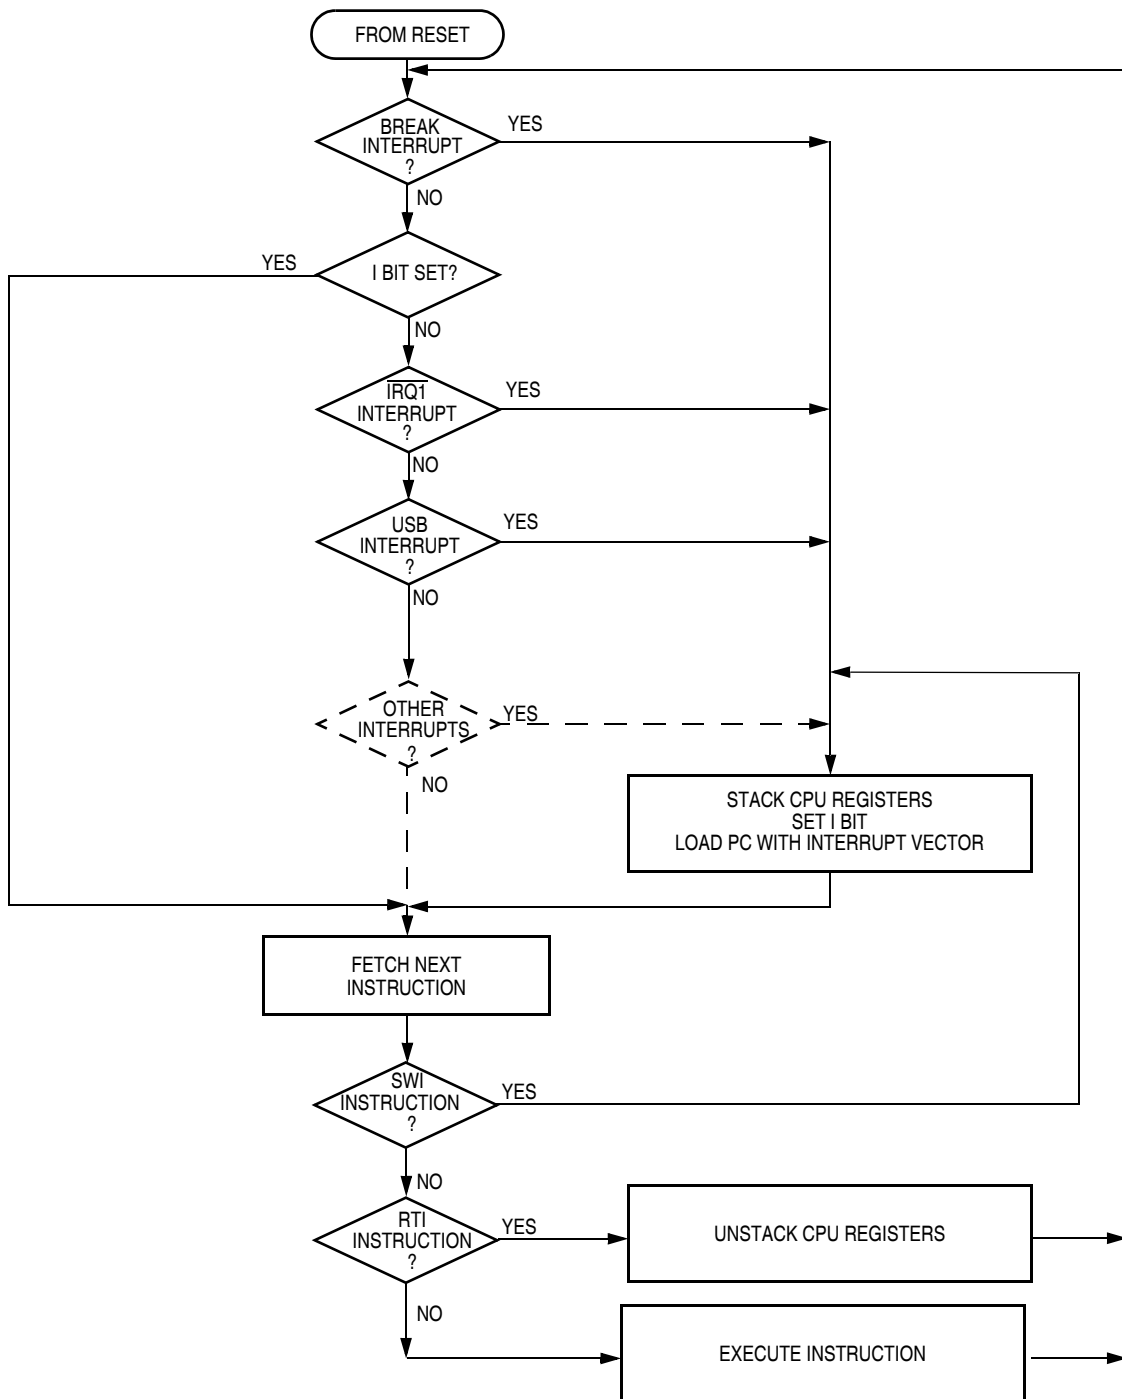

Figure 8-8. Interrupt Processing

Interrupts are latched and arbitration is performed in the SIM at the start of interrupt processing. The arbitration result is a constant that the CPU uses to determine which vector to fetch. Once an interrupt is latched by the SIM, no other interrupt can take precedence, regardless of priority, until the latched interrupt is serviced or the I bit is cleared.

At the beginning of an interrupt, the CPU saves the CPU register contents on the stack and sets the interrupt mask (I bit) to prevent additional interrupts. At the end of an interrupt, the RTI instruction recovers the CPU register contents from the stack so that normal processing can resume. **Figure 8-9** shows interrupt entry timing. **Figure 8-10** shows interrupt recovery timing.

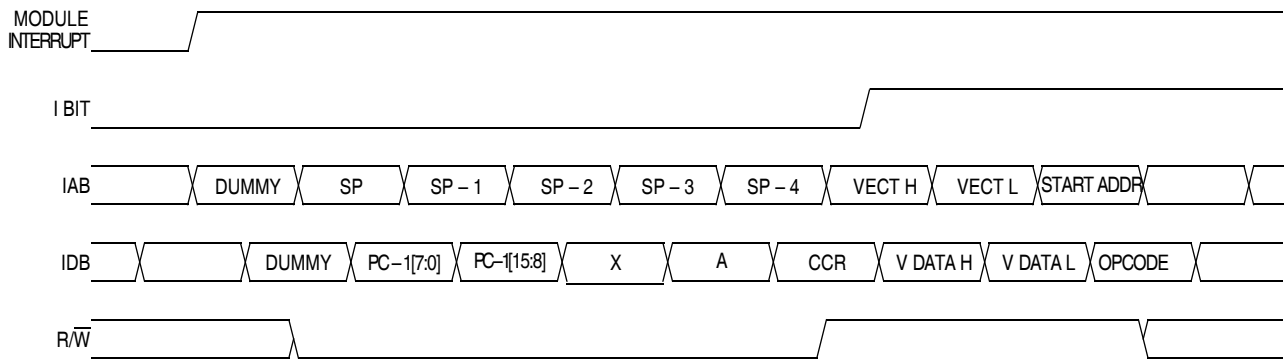

Figure 8-9. Interrupt Entry

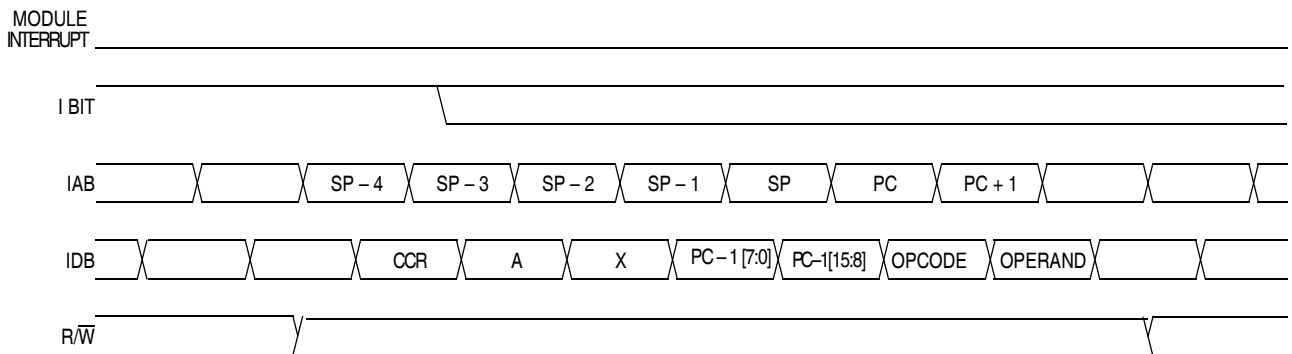

Figure 8-10. Interrupt Recovery

8.6.1.1 Hardware Interrupts

A hardware interrupt does not stop the current instruction. Processing of a hardware interrupt begins after completion of the current instruction. When the current instruction is complete, the SIM checks all pending hardware interrupts. If interrupts are not masked (I bit clear in the condition code register) and if the corresponding interrupt enable bit is set, the SIM proceeds with interrupt processing; otherwise, the next instruction is fetched and executed.

If more than one interrupt is pending at the end of an instruction execution, the highest priority interrupt is serviced first. **Figure 8-11** demonstrates what happens when two interrupts are pending. If an interrupt is pending upon exit from the original interrupt service routine, the pending interrupt is serviced before the LDA instruction is executed.

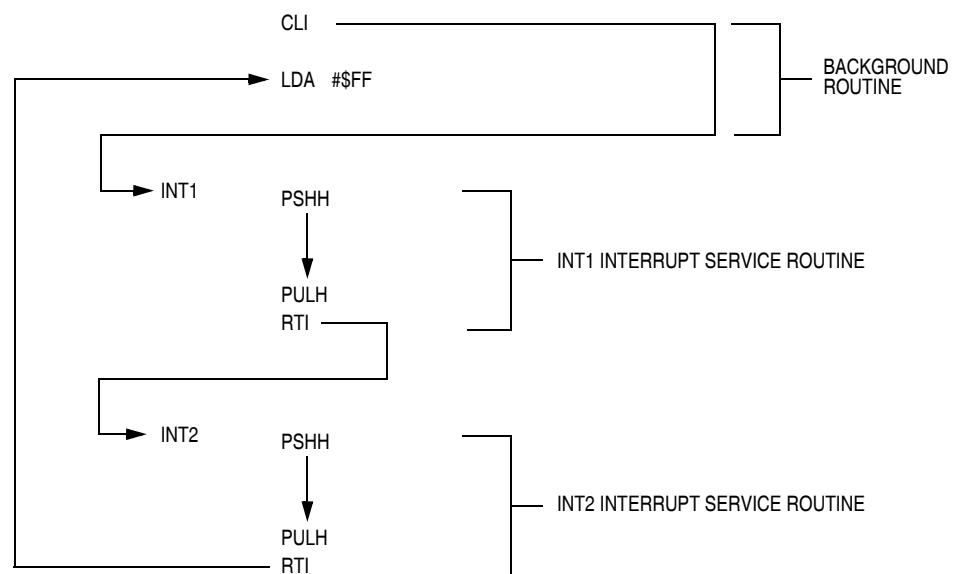

Figure 8-11. Interrupt Recognition Example

The LDA opcode is prefetched by both the INT1 and INT2 RTI instructions. However, in the case of the INT1 RTI prefetch, this is a redundant operation.

NOTE: *To maintain compatibility with the M6805 Family, the H register is not pushed on the stack during interrupt entry. If the interrupt service routine modifies the H register or uses the indexed addressing mode, software should save the H register and then restore it prior to exiting the routine.*

8.6.1.2 SWI Instruction

The SWI instruction is a non-maskable instruction that causes an interrupt regardless of the state of the interrupt mask (I bit) in the condition code register.

NOTE: *A software interrupt pushes PC onto the stack. A software interrupt does not push PC-1, as a hardware interrupt does.*

8.6.2 Interrupt Status Registers

The flags in the interrupt status registers identify maskable interrupt sources. [Table 8-3](#) summarizes the interrupt sources and the interrupt status register flags that they set. The interrupt status registers can be useful for debugging.

Table 8-3. Interrupt Sources

Source	Flags	Mask ⁽¹⁾	INT Register Flag	Priority ⁽²⁾	Vector Address
SWI Instruction			—	0	\$FFFC-\$FFFD
$\overline{\text{IRQ1}}$ Pin	IRQF1	IMASK1	IF1	1	\$FFFA-\$FFFB
USB Endpoint 0 Transmit	TXD0F	TXD0IE	IF2	2	\$FFF8-\$FFF9
USB Endpoint 0 Receive	RXD0F	RXD0IE			
USB Endpoint 1/ Endpoint 2 Transmit	TXD1F	TXD1IE			
USB End of Packet	EOPF	EOPIE			
USB Resume Interrupt	RESUMF	—			
TIM Channel 0	CH0F	CH0IE			
TIM Channel 1	CH1F	CH1IE	IF4	4	\$FFF4-\$FFF5
TIM Overflow	TOF	TOIE	IF5	5	\$FFF2-\$FFF3
Keyboard Pins	KEYF	IMASKK	IF6	6	\$FFF0-\$FFF1

1. The I bit in the condition code register is a global mask for all interrupt sources except the SWI instruction.
2. 0 = highest priority

8.6.2.1 Interrupt Status Register 1

Address: \$FE04

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IF6	IF5	IF4	IF3	IF2	IF1	0	0
Write:	R	R	R	R	R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 8-12. Interrupt Status Register 1 (INT1)

IF6–IF1 — Interrupt Flags 1–6

These flags indicate the presence of interrupt requests from the sources shown in [Table 8-3](#).

1 = Interrupt request present

0 = No interrupt request present

Bit 0 and Bit 1 — Always read 0

8.6.2.2 Interrupt Status Register 2

Address: \$FE05

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IF14	IF13	IF12	IF11	IF10	IF9	IF8	IF7
Write:	R	R	R	R	R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 8-13. Interrupt Status Register 2 (INT2)

IF14–IF7 — Interrupt Flags 14–7

Since the MC68HC708KL8 does not use these interrupt flags, these bits will always read 0.

8.6.3 Reset

All reset sources always have equal and highest priority and cannot be arbitrated.

8.6.4 Break Interrupts

The break module can stop normal program flow at a software-programmable break point by asserting its break interrupt output. (See [Section 16. Break Module \(BREAK\)](#).) The SIM puts the CPU into the break state by forcing it to the SWI vector location. Refer to the break interrupt subsection of each module to see how each module is affected by the break state.

8.6.5 Status Flag Protection in Break Mode

The SIM controls whether status flags contained in other modules can be cleared during break mode. The user can select whether flags are protected from being cleared by properly initializing the break clear flag enable bit (BCFE) in the break flag control register (BFCR).

Protecting flags in break mode ensures that set flags will not be cleared while in break mode. This protection allows registers to be freely read and written during break mode without losing status flag information.

Setting the BCFE bit enables the clearing mechanisms. Once cleared in break mode, a flag remains cleared even when break mode is exited. Status flags with a 2-step clearing mechanism — for example, a read of one register followed by the read or write of another — are protected, even when the first step is accomplished prior to entering break mode. Upon leaving break mode, execution of the second step will clear the flag as normal.

8.7 Low-Power Modes

Executing the WAIT or STOP instruction puts the MCU in a low-power-consumption mode for standby situations. The SIM holds the CPU in a non-clocked state. The operation of each of these modes is described here. Both STOP and WAIT clear the interrupt mask (I) in the condition code register, allowing interrupts to occur.

8.7.1 Wait Mode

In wait mode, the CPU clocks are inactive while the peripheral clocks continue to run. **Figure 8-14** shows the timing for wait mode entry.

A module that is active during wait mode can wake up the CPU with an interrupt if the interrupt is enabled. Stacking for the interrupt begins one cycle after the WAIT instruction during which the interrupt occurred. In wait mode, the CPU clocks are inactive. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

Wait mode can also be exited by a reset or break. A break interrupt during wait mode sets the SIM break stop/wait bit, SBSW, in the break status register (BSR). If the COP disable bit, COPD, in the configuration register is logic 0, then the computer operating properly module (COP) is enabled and remains active in wait mode.

NOTE: Previous data can be operand data or the WAIT opcode, depending on the last instruction.

Figure 8-14. Wait Mode Entry Timing

Figure 8-15 and Figure 8-16 show the timing for WAIT recovery.

Figure 8-15. Wait Recovery from Interrupt or Break

Figure 8-16. Wait Recovery from Internal Reset

8.7.2 Stop Mode

In stop mode, the SIM counter is reset and the system clocks are disabled. An interrupt request from a module can cause an exit from stop mode. Stacking for interrupts begins after the selected stop recovery time has elapsed. Reset or break also causes an exit from stop mode.

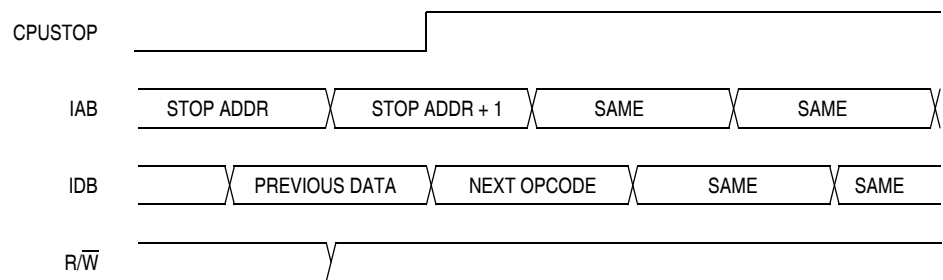

The SIM disables the oscillator signals (CGMOUT and CGMXCLK) in stop mode, stopping the CPU and peripherals. Stop recovery time is selectable using the SSREC bit in the configuration register (CONFIG). If SSREC is set, stop recovery is reduced from the normal delay of 4096 CGMXCLK cycles down to 32. This is ideal for applications using canned oscillators that do not require long startup times from stop mode.

NOTE: External crystal applications should use the full stop recovery time by clearing the SSREC bit.

A break interrupt during stop mode sets the SIM break stop/wait bit (SBSW) in the break status register (BSR).

The SIM counter is held in reset from the execution of the STOP instruction until the beginning of stop recovery. It is then used to time the recovery period. **Figure 8-17** shows stop mode entry timing.

NOTE: To minimize stop current, all pins configured as inputs should be driven to a logic 1 or logic 0.

NOTE: Previous data can be operand data or the STOP opcode, depending on the last instruction.

Figure 8-17. Stop Mode Entry Timing

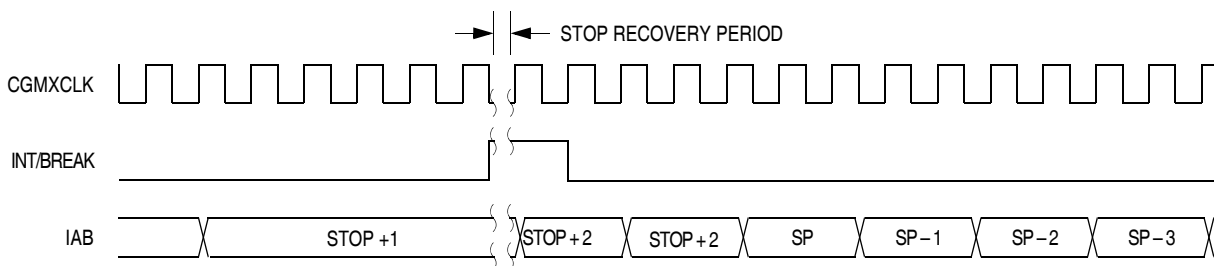

Figure 8-18. Stop Mode Recovery from Interrupt or Break

8.8 SIM Registers

The SIM has two break registers and one reset register.

8.8.1 Break Status Register

The break status register contains a flag to indicate that a break caused an exit from stop or wait mode.

Figure 8-19. Break Status Register (BSR)

SBSW — SIM Break Stop/Wait

This status bit is useful in applications requiring a return to wait or stop mode after exiting from a break interrupt. Clear SBSW by writing a logic 0 to it. Reset clears SBSW.

1 = Stop mode or wait mode was exited by break interrupt

0 = Stop mode or wait mode was not exited by break interrupt

SBSW can be read within the break state SWI routine. The user can modify the return address on the stack by subtracting one from it. The following code is an example of this. Writing 0 to the SBSW bit clears it.

This code works if the H register has been pushed onto the stack in the break service routine software. This code should be executed at the end of the break service routine software.

```

HIBYTE EQU 5
LOBYTE EQU 6
;      If not SBSW, do RTI
      BRCLR  SBSW,BSR, RETURN ; See if wait mode or stop mode was exited
                                ; by break.
      TST   LOBYTE,SP         ; If RETURNLO is not zero,
      BNE   DOLO              ; then just decrement low byte.
      DEC   HIBYTE,SP        ; Else deal with high byte, too.
DOLO   DEC   LOBYTE,SP      ; Point to WAIT/STOP opcode.
RETURN PULH                  ; Restore H register.
      RTI
    
```

8.8.2 Reset Status Register

This register contains six flags that show the source of the last reset. All flag bits are cleared automatically following a read of the register. The register is initialized on power-up as shown with the POR bit set and all other bits cleared. However, during a POR or any other internal reset, the $\overline{\text{RST}}$ pin is pulled low. After the pin is released, it will be sampled 32 CGMXCLK cycles later. If the pin is not above a V_{IH} at that time, then the PIN bit in the RSR may be set in addition to whatever other bits are set.

Address: \$FE01

	Bit 7	6	5	4	3	2	1	Bit 0

Figure 8-20. Reset Status Register (RSR)

POR — Power-On Reset Bit
 1 = A POR has occurred.
 0 = Read of RSR

PIN — External Reset Bit
 1 = An external reset has occurred since the last read of the RSR.
 0 = Read of RSR

COP — Computer Operating Properly Reset Bit
 1 = A COP reset has occurred since the last read of the RSR.
 0 = POR or read of RSR

ILOP — Illegal Opcode Reset Bit
 1 = An illegal opcode reset has occurred since the last read of the RSR.
 0 = POR or read of RSR

ILAD — Illegal Address Reset Bit (opcode fetches only)
 1 = An illegal address reset has occurred since the last read of the RSR.
 0 = POR or read of RSR

USB — Universal Serial Bus Reset Bit
 1 = Last reset caused by an USB module
 0 = POR or read of RSR

8.8.3 Break Flag Control Register

The break control register contains a bit that enables software to clear status bits while the MCU is in a break state.

Figure 8-21. Break Flag Control Register (BFCR)

BCFE — Break Clear Flag Enable Bit

This read/write bit enables software to clear status bits by accessing status registers while the MCU is in a break state. To clear status bits during the break state, the BCFE bit must be set.

1 = Status bits clearable during break
 0 = Status bits not clearable during break

9.2 Features

Features of the USB (universal serial bus) module include:

- Integrated 3.3-Volt Regulator with 3.3-Volt Output Pin
- Integrated USB Transceiver Supporting Low-Speed Functions
- USB Data Control Logic
 - Packet Decoding/Generation
 - CRC Generation and Checking
 - NRZI (Non-Return-to Zero Inserted) Encoding/Decoding
 - Bit-Stuffing
- USB Reset Support
- Control Endpoint 0 and Interrupt Endpoints 1 and 2
- Two 8-Byte Transmit Buffers
- One 8-Byte Receive Buffer
- Suspend and Resume Operations
 - Remote Wakeup Support
- USB-Generated Interrupts
 - Transaction Interrupt Driven
 - Resume Interrupt
 - End-of-Packet Interrupt
- Stall, Nak, and Ack Handshake Generation

9.3 Overview

This section provides an overview of the universal serial bus (USB) module developed for the MC68HC708KL8. This USB module is designed to serve as a low-speed (LS) USB device per the *Universal Serial Bus Specification Rev 1.0*. Three types of USB data transfers are supported: control, interrupt, and bulk (transmit only). Endpoint 0 functions as a receive/transmit control endpoint. Endpoints 1 and 2 can function as interrupt or bulk, but only in the transmit direction.

A block diagram of the USB module is shown in **Figure 9-1**. The USB module manages communications between the host and the USB function. The module is partitioned into four functional blocks. These blocks consist of a 3.3-volt regulator, a dual-function transceiver, the USB control logic, and the endpoint registers. The blocks are further detailed later in this section (see **9.5 Hardware Description**).

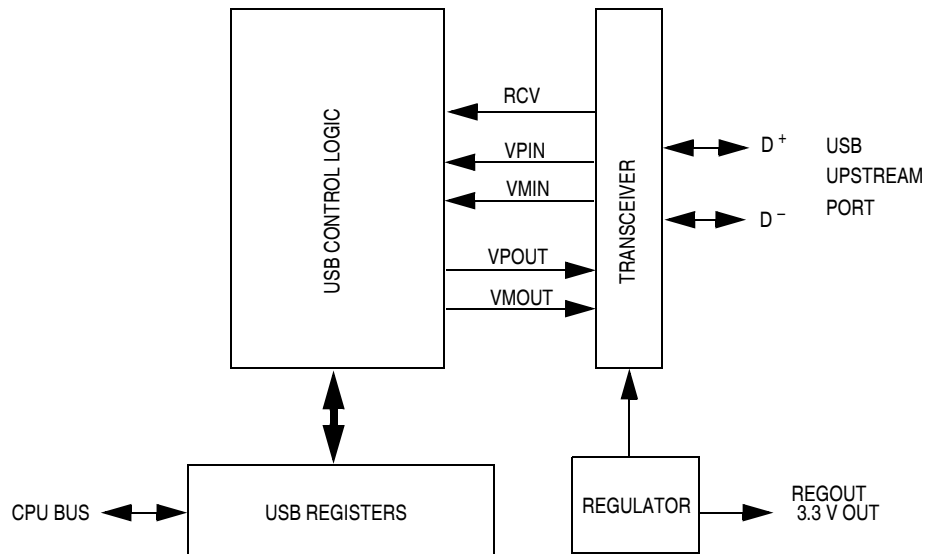

Figure 9-1. USB Block Diagram

9.3.1 USB Protocol

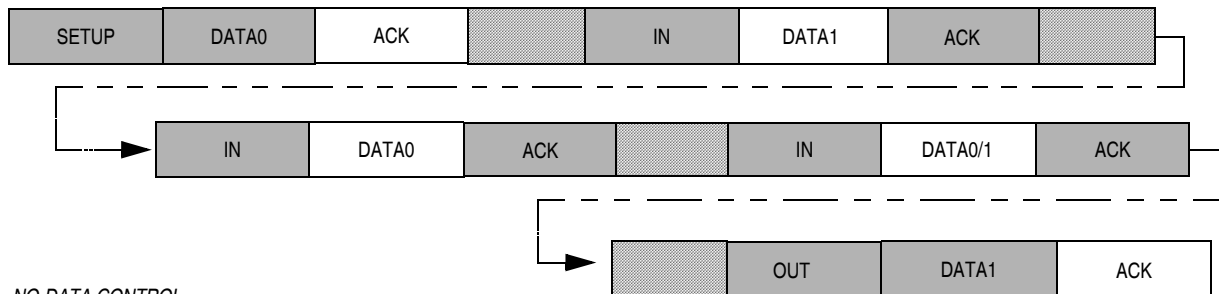

Figure 9-2 shows the various transaction types supported by the MC68HC708KL8 USB module. The transactions are portrayed as error free. The effect of errors in the data flow are discussed later.

ENDPOINT 0 TRANSACTIONS:

CONTROL WRITE

CONTROL READ

NO-DATA CONTROL

ENDPOINTS 1 AND 2 TRANSACTIONS:

INTERRUPT

BULK TRANSMIT

Figure 9-2. Supported Transaction Types Per Endpoint

Each USB transaction is comprised of a series of packets. The MC68HC708KL8 USB module supports the packet types shown in **Figure 9-3**. Token packets are generated by the USB host and decoded by the USB device. Data and handshake packets are both decoded and generated by the USB device, depending on the type of transaction.

Token Packet:

IN

OUT

SETUP

Data Packet:

DATA0

DATA1

0 – 8 Bytes

Handshake Packet:

ACK

NAK

STALL

Figure 9-3. Supported USB Packet Types

The following sections detail each segment used to form a complete USB transaction.

9.3.1.1 Sync Pattern

The NRZI (see [9.5.4.1 Data Encoding/Decoding](#)) bit pattern shown in [Figure 9-4](#) is used as a synchronization pattern and is prefixed to each packet. This pattern is equivalent to a data pattern of seven 0s followed by a 1 (0x80).

Figure 9-4. Sync Pattern

The start of a packet (SOP) is signaled by the originating port by driving the D+ and D– lines from the idle state (also referred to as the J state) to the opposite logic level (also referred to as the K state). This switch in levels represents the first bit of the sync field. [Figure 9-5](#) shows the data signaling and voltage levels for the start of packet and the sync pattern.

Figure 9-5. SOP, Sync Signaling, and Voltage Levels

9.3.1.2 Packet Identifier Field

The packet identifier field is an 8-bit number comprised of the 4-bit packet identification and its complement. The field follows the sync pattern and determines the direction and type of transaction on the bus. **Table 9-1** shows the packet identifier values for the supported packet types.

Table 9-1. Supported Packet Identifiers

Packet Identifier Value	Packet Identifier Type
%1001	IN Token
%0001	OUT Token
%1101	SETUP Token
%0011	DATA0 Packet
%1011	DATA1 Packet
%0010	ACK Handshake
%1010	NAK Handshake
%1110	STALL Handshake

9.3.1.3 Address Field (ADDR)

The address field is a 7-bit number that is used to select a particular USB device. This field is compared to the lower seven bits of the UADDR register to determine if a given transaction is targeting the MC68HC708KL8 USB device.

9.3.1.4 Endpoint Field (ENDP)

The endpoint field is a 4-bit number that is used to select a particular endpoint within a USB device. For the MC68HC708KL8, this will be a binary number between 0 and 2 inclusive. Any other value will cause the transaction to be ignored.

9.3.1.5 Cyclic Redundancy Check (CRC)

Cyclic redundancy checks are used to verify the address and data stream of a USB transaction. This field is five bits wide for token packets and 16 bits wide for data packets. CRCs are generated in the transmitter and sent on the USB data lines after both the endpoint field and the data field. **Figure 9-6** shows how the 5-bit CRC value is calculated from the data stream and verified for the address and endpoint fields of a token packet. **Figure 9-7** shows how the 16-bit CRC value is calculated and either transmitted or verified for the data packet of a given transaction.

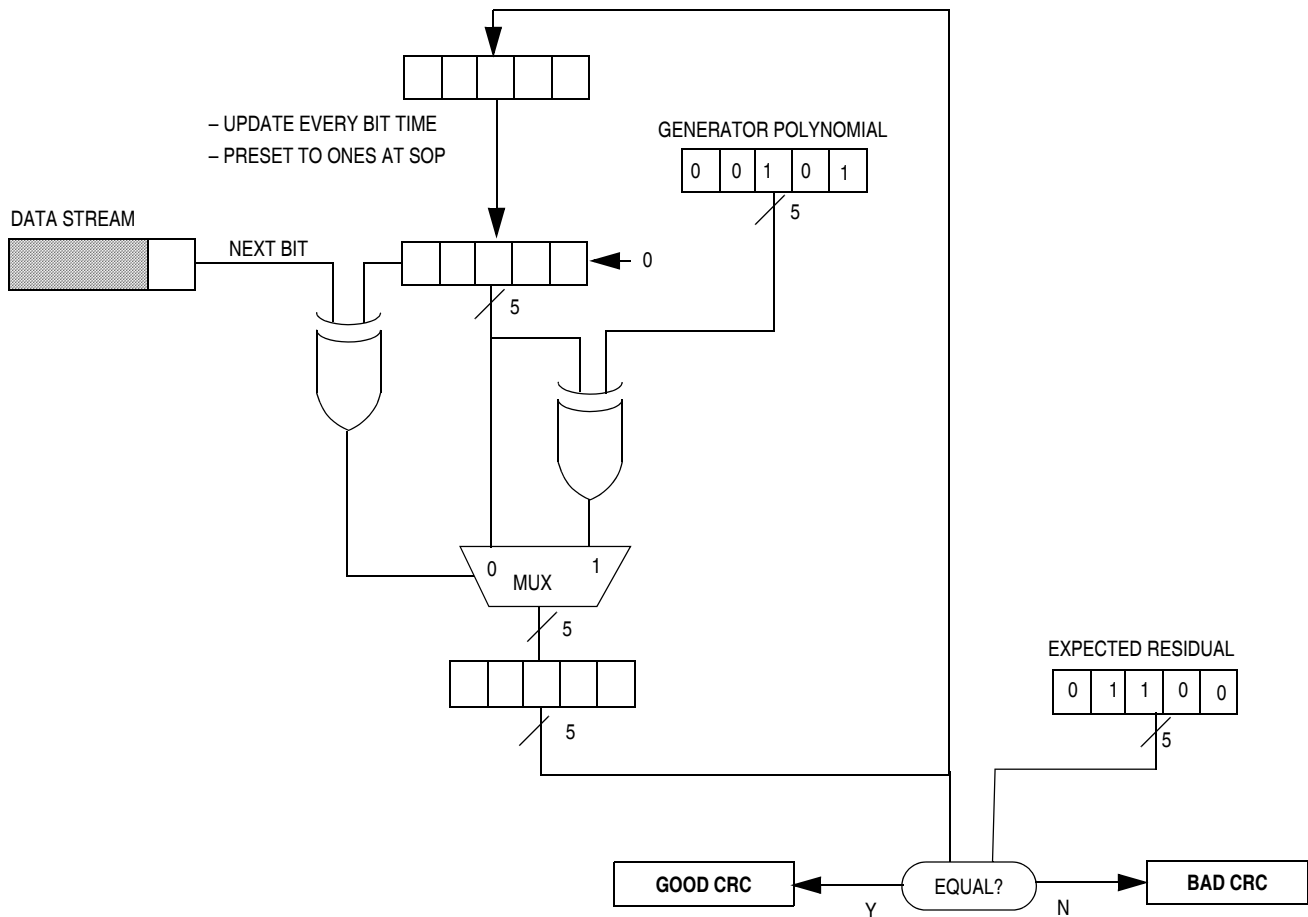

Figure 9-6. CRC Block Diagram for Token Packets

Universal Serial Bus Module (USB)

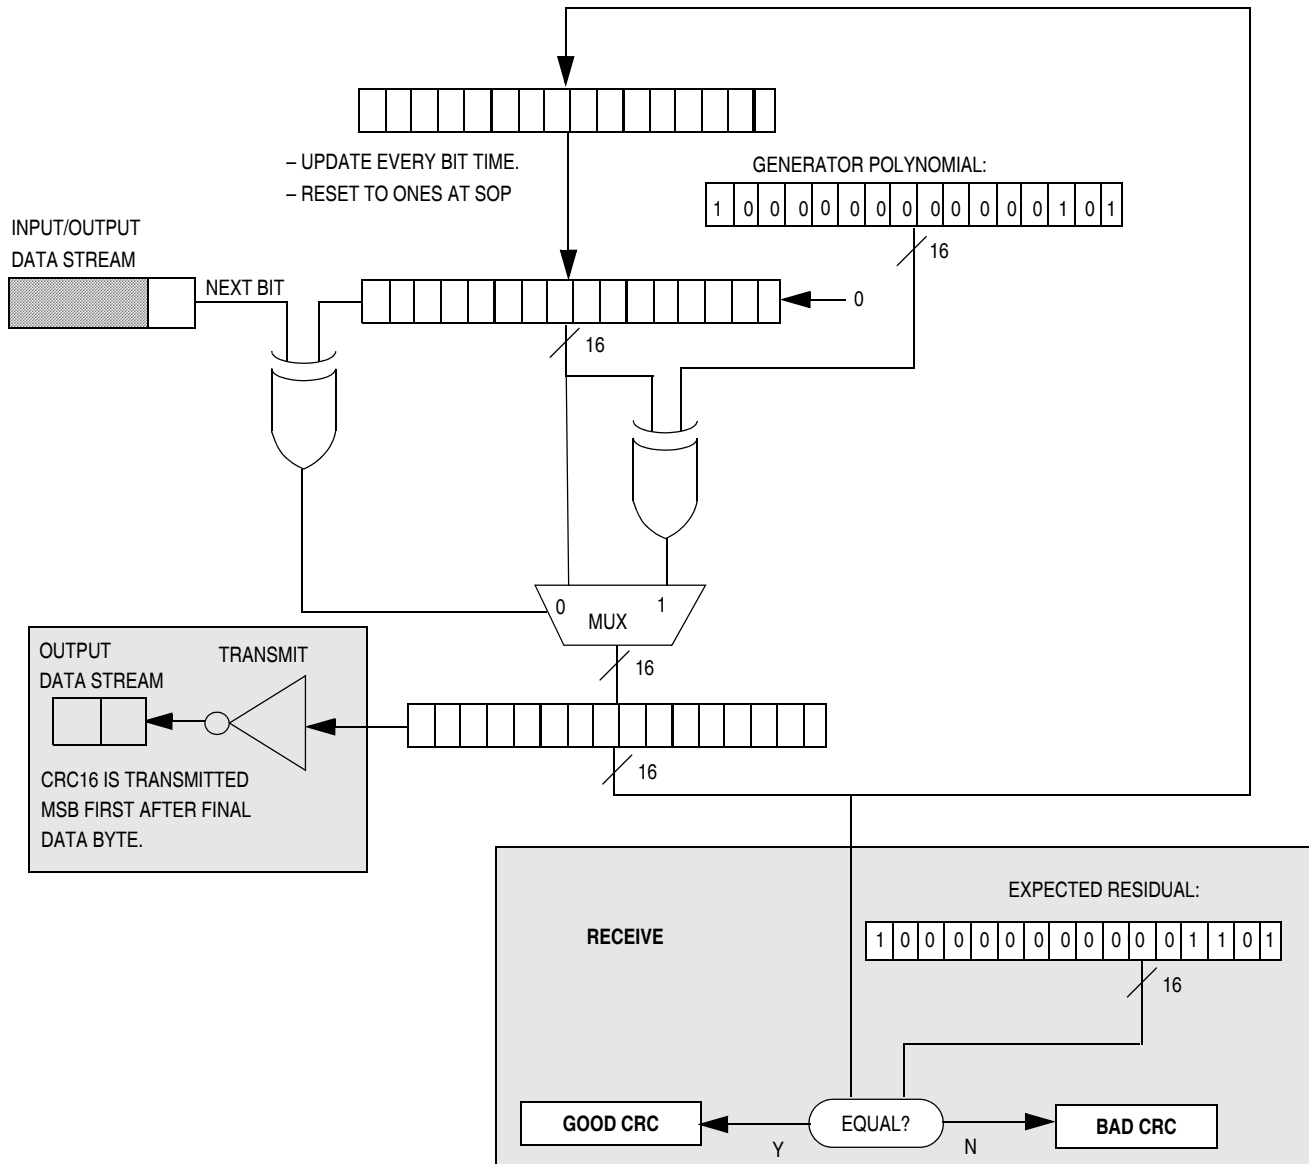

Figure 9-7. CRC Block Diagram for Data Packets

9.3.1.6 End-of-Packet (EOP)

The single-ended 0 (SE0) state is used to signal an end-of-packet (EOP). The single-ended 0 state is indicated by both D+ and D– being below 0.8 V. EOP will be signaled by driving D+ and D– to the single-ended 0 state for two bit times followed by driving the lines to the idle state for one bit time. The transition from the single-ended 0 to the idle state defines the end of the packet. The idle state is asserted for one bit time and then both the D+ and D– output drivers are placed in their high-impedance state. The bus termination resistors hold the bus in the idle state. **Figure 9-8** shows the data signaling and voltage levels for an end-of-packet transaction.

Figure 9-8. EOP Transaction Voltage Levels

The width of the SE0 in the EOP is about two bit times. The EOP width is measured with the same capacitive load used for maximum rise and fall times and is measured at the same level as the differential signal crossover points of the data lines.

Figure 9-9. EOP Width Timing

9.3.2 Reset Signaling

A reset is signaled on the bus by the presence of an extended SE0 at the USB data pins of a device. The reset signaling is specified to be present for a minimum of 10 ms. An active device (powered and not in the suspend state) seeing a single-ended 0 on its USB data inputs for more than 2.5 μ s may treat that signal as a reset, but must have interpreted the signaling as a reset within 5.5 μ s. For a low-speed device, an SE0 condition between four and eight low-speed bit times represents a valid USB reset.

A USB sourced reset will hold the 68HC68708KL8 in reset for the duration of the reset on the USB bus. The USB bit in the reset status register (RSR) will be set after the internal reset is removed. Refer to [8.8.2 Reset Status Register](#) for more detail. The MCU's reset recovery sequence is detailed in [Section 8. System Integration Module \(SIM\)](#).

The reset flag bit (RSTF) in the USB interrupt register 0 (UIR0) also will be set after the internal reset is removed. Refer to [9.6.2 USB Interrupt Register 0](#) for more detail.

After a reset is removed, the device will be in the attached, but not yet addressed or configured state (refer to Section 9.1 USB Device States of the *Universal Serial Bus Specification* Rev. 1.0). The device must be able to accept a device address via a SET_ADDRESS command (refer to Section 9.4 Standard Device Request in the *Universal Serial Bus Specification* Rev. 1.0) no later than 10 ms after the reset is removed.

Reset can wake a device from the suspended mode. A device may take up to 10 ms to wake up from the suspended state.

9.3.3 Suspend

The MC68HC708KL8 supports suspend mode for low power. Suspend mode should be entered when the USB data lines are in the idle state for more than 3.0 ms. Entry into suspend mode is controlled by the SUSPND bit in the USB interrupt register. Any low-speed bus activity should keep the device out of the suspend state. Low-speed devices are kept awake by periodic low-speed EOP signals from the host. This is referred to as low speed keep alive (refer to Section 11.2.5.1 of the *Universal Serial Bus Specification Rev. 1.0*).

Firmware should monitor the EOPF flag and enter suspend mode by setting the SUSPND bit if an EOP is not detected for 3 ms.

Per the USB specification, the MC68HC708KL8 is required to draw less than 500 μA from the V_{DD} supply when in the suspend state. This includes the current supplied by the voltage regulator to the 15 $\text{k}\Omega$ to ground termination resistors placed at the host end of the USB bus. This low-current requirement means that firmware is responsible for entering stop mode once the USB module has been placed in the suspend state.

9.3.4 Resume After Suspend

The MC68HC708KL8 can be activated from the suspend state by normal bus activity, a USB reset signal, or by a forced resume driven from the MC68HC708KL8.

9.3.4.1 Host Initiated Resume

The host signals resume by initiating resume signalling (K state) for at least 20 ms followed by a standard low-speed EOP signal. This 20 ms ensures that all devices in the USB network are awakened.

After resuming the bus, the host must begin sending bus traffic within 3 ms to prevent the device from re-entering suspend mode.

9.3.4.2 USB Reset Signalling

Reset can wake a device from the suspended mode. A device may take up to 10 ms to wake up from the suspended state.

9.3.4.3 Remote Wakeup

The MC68HC708KL8 also supports the remote wakeup feature. The firmware has the ability to exit suspend mode by signaling a resume state to the upstream host or hub. A non-idle state (K state) on the USB data lines is accomplished by asserting the FRESUM bit in the UCR1 register.

When using the remote wakeup capability, the firmware must wait for at least 5 ms after the bus is in the idle state before sending the remote wakeup resume signaling. This allows the upstream devices to get into their suspend state and prepare for propagating resume signaling. The FRESUM bit should be asserted to cause the resume state on the USB data lines for at least 10 ms, but not more than 15 ms. Note that the resume signalling is controlled by the FRESUM bit and meeting the timing specifications is dependent on the firmware. When FRESUM is cleared by firmware, the data lines will return to their high-impedance state. Refer to the register definitions (see [9.6.5 USB Control Register 1](#)) for more information about how the force resume (FRESUM) bit can be used to initiate the remote wakeup feature.

9.3.5 Low-Speed Device

Externally, low-speed devices are configured by the position of a pullup resistor on the USB D– pin of the MC68HC708KL8. Low-speed devices are terminated as shown in [Figure 9-10](#) with the pullup on the D– line.

Figure 9-10. External Low-Speed Device Configuration

For low-speed transmissions, the transmitter's EOP width must be between 1.25 μs and 1.50 μs . These ranges include timing variations due to differential buffer delay and rise/fall time mismatches and to noise and other random effects. A low-speed receiver must accept a 670 ns SE0 followed by a J transition as a valid EOP. An SE0 shorter than 330 ns or an SE0 not followed by a J transition must be rejected as an EOP. An EOP between 330 ns and 670 ns may be rejected or accepted as discussed. Any SE0 that is 2.5 μs or longer is automatically a reset.

9.4 Clock Requirements

The low-speed data rate is nominally 1.5 Mbps. The CGMXCLK signal driven by the oscillator circuits is the clock source for the USB module and requires that a 6-MHz oscillator circuit be connected to the OSC1 and OSC2 pins. The permitted frequency tolerance for low-speed functions is approximately $\pm 1.5\%$ (15,000 ppm). This tolerance includes inaccuracies from all sources: initial frequency accuracy, crystal capacitive loading, supply voltage on the oscillator, temperature, and aging. The jitter in the low-speed data rate must be less than 10 ns. This tolerance allows the use of resonators in low-cost, low-speed devices.

9.5 Hardware Description

The USB module as previously shown in [Figure 9-1](#) contains four functional blocks: a 3.3-volt regulator, a low-speed USB transceiver, the USB control logic, and the USB registers. The following details the function of the regulator, transceiver, and control logic. See [9.6 I/O Register Description](#) for the register discussion.

9.5.1 Voltage Regulator

The USB data lines are required by the USB specification to have a maximum output voltage between 2.8 V and 3.6 V. The data lines also are required to have an external 1.5-k Ω pullup resistor connected between a data line and a voltage source between 3.0 V and 3.6 V. Since the power provided by the USB cable is specified to be between 4.4 V and 5.0 V, an on-chip regulator is used to drop the voltage to the appropriate level for sourcing the USB transceiver and external pullup resistor. An output pin driven by the regulator voltage is provided to source the 1.5- k Ω external resistor. The REGOUT pin requires an external bulk capacitor 1 μ F or larger and a 0.1- μ F ceramic bypass capacitor. [Figure 9-11](#) shows the worst case electrical connection for the voltage regulator.

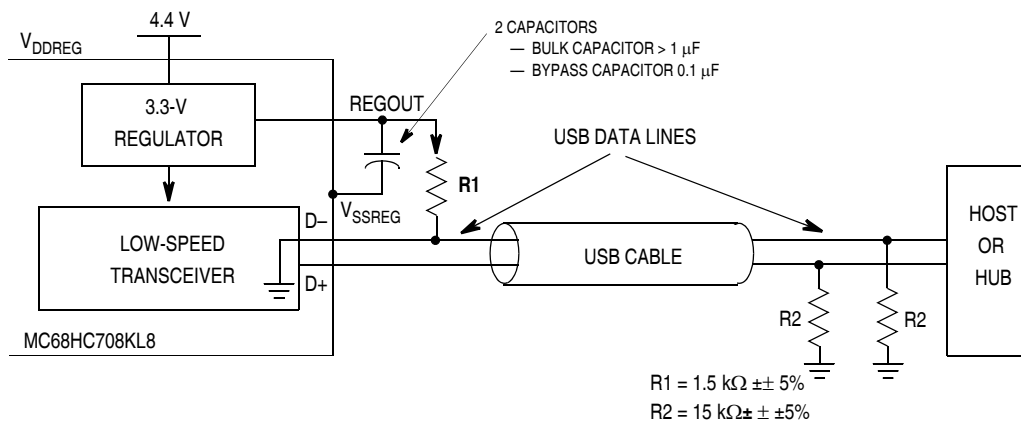

Figure 9-11. Regulator Electrical Connections

9.5.2 Regulator Bypass Option

Under normal user operation, the REGOUT voltage is sourced from the 3.3-volt regulator. The transceiver is powered by the regulator and the V_{DDREG} input. For testability of the transceiver, the 3.3-volt regulator has a bypass option that allows the REGOUT and USB transceiver power to be sourced from the V_{DDREG} input.

NOTE: *The bypass mode is to be used for transceiver testing and should not be used in normal operation.*

See [Section 5. Configuration Register \(CONFIG\)](#) for setting the bypass option. [Figure 9-12](#) illustrates operation of the REGBP bit in the configuration register.

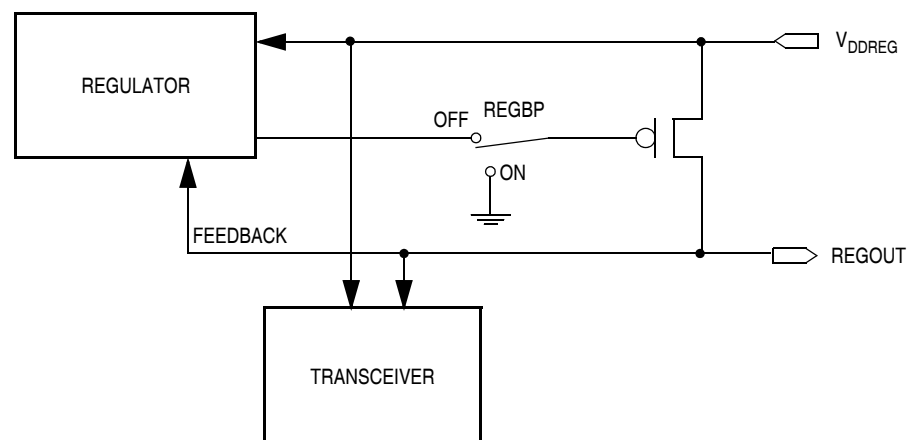

Figure 9-12. Regulator Bypass Option

9.5.3 USB Transceiver

The USB transceiver provides the physical interface to the USB D+ and D– data lines. The transceiver is composed of two parts: an output drive circuit and a receiver.

9.5.3.1 Output Driver Characteristics

The USB transceiver uses a differential output driver to drive the USB data signal onto the USB cable. The static output swing of the driver in its low state is below the V_{OL} of 0.3 V with a 1.5-k Ω load to 3.6 V and in its high state is above the V_{OH} of 2.8 V with a 15-k Ω load to ground. The output swings between the differential high and low state are well balanced to minimize signal skew. Slew rate control on the driver is used to minimize the radiated noise and cross talk. The driver's outputs support 3-state operation to achieve bidirectional half duplex operation. The driver can tolerate a voltage on the signal pins of –0.5 V to 3.8 V with respect to local ground reference without damage.

9.5.3.2 Low Speed (1.5 Mbs) Driver Characteristics

The rise and fall time of the signals on this cable are greater than 75 ns to keep RFI (radio frequency interference) emissions under FCC (Federal Communications Commission) class B limits and less than 300 ns to limit timing delays, signaling skews, and distortions. The driver reaches the specified static signal levels with smooth rise and fall times, and minimal reflections and ringing when driving the cable. This driver is used only on network segments between low-speed devices and the ports to which they are connected.

USB data transmission is done with differential signals. A differential input receiver is used to accept the USB data signal. A differential 1 on the bus is represented by D+ being at least 200 mV more positive than D– as seen at the receiver, and a differential 0 is represented by D– being at least 200 mV more positive than D+ as seen at the receiver. The signal cross over point must be between 1.3 V and 2.0 V.

Figure 9-13. Receiver Characteristics

The receiver features an input sensitivity of 200 mV when both differential data inputs are in the range of 0.8 V to 2.5 V with respect to the local ground reference. This is called the common mode input voltage range. Proper data reception also is achieved when the differential data lines are outside the common mode range, as shown in [Figure 9-14](#). The receiver can tolerate static input voltages between -0.5 V to 3.8 V with respect to its local ground reference without damage. In addition to the differential receiver, there is a single-ended receiver (Schmitt trigger) for each of the two data lines.

Figure 9-14. Differential Input Sensitivity Over Entire Common Mode Range

9.5.3.3 Receiver Data Jitter

The data receivers for all types of devices must be able to properly decode the differential data in the presence of jitter. The more of the bit time that any data edge can occupy and still be decoded, the more reliable the data transfer will be. Data receivers are required to decode differential data transitions that occur in a window plus and minus a nominal quarter bit time from the nominal (centered) data edge position.

Jitter will be caused by the delay mismatches and by mismatches in the source and destination data rates (frequencies). The receive data jitter budget for low speed is given in [Section 17. Electrical Specifications](#). The specification includes the consecutive (next) and paired transition values for each source of jitter.

9.5.3.4 Data Source Jitter

The source of data can have some variation (jitter) in the timing of edges of the data transmitted. The time between any set of data transitions is $N * T_{Period} \pm \text{jitter time}$, where N is the number of bits between the transitions and T_{Period} is defined as the actual period of the data rate. The data jitter is measured with the same capacitive load used for maximum rise and fall times and is measured at the crossover points of the data lines as shown in [Figure 9-15](#).

Figure 9-15. Data Jitter

For low-speed transmissions, the jitter time for any consecutive differential data transitions must be within ± 25 ns and within ± 10 ns for any set of paired differential data transitions. These jitter numbers include timing variations due to differential buffer delay, rise/fall time mismatches, internal clock source jitter, noise and other random effects.

9.5.3.5 Data Signal Rise and Fall Time

The output rise time and fall time are measured between 10% and 90% of the signal. Edge transition time for the rising and falling edges of low-speed signals is 75 ns (minimum) into a capacitive load (C_L) of 50 pF and 300 ns (maximum) into a capacitive load of 350 pF. The rising and falling edges should be transitioning (monotonic) smoothly when driving the cable to avoid excessive EMI.

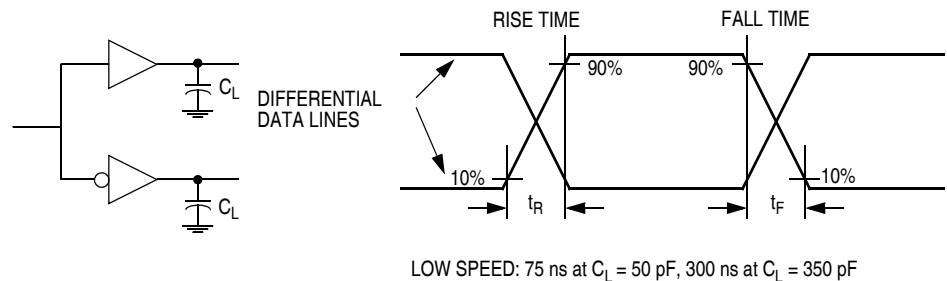

Figure 9-16. Data Signal Rise and Fall Time

9.5.4 USB Control Logic

The USB control logic manages data movement between the CPU and the transceiver. The control logic handles both transmit and receive operations on the USB. It contains the logic used to manipulate the transceiver and the endpoint registers.

The byte count buffer is loaded with the active transmit endpoints byte count value during transmit operations. This same buffer is used for receive transactions to count the number of bytes received and, upon the end of the transaction, transfer that number to the receive endpoints byte count register.

When transmitting, the control logic handles parallel-to-serial conversion, CRC generation, NRZI encoding, and bit stuffing.

When receiving, the control logic handles sync detection, packet identification, end-of-packet detection, bit (un)stuffing, NRZI decoding, CRC validation, and serial-to-parallel conversion. Errors detected by the control logic include bad CRC, timeout while waiting for EOP, and bit stuffing violations.

9.5.4.1 Data Encoding/Decoding

The USB employs NRZI data encoding when transmitting packets. In NRZI encoding, a 1 is represented by no change in level and a 0 is represented by a change in level. **Figure 9-17** shows a data stream and the NRZI equivalent and **Figure 9-18** is a flow diagram for NRZI. The high level represents the J state on the data lines in this and subsequent figures showing NRZI encoding. A string of 0s causes the NRZI data to toggle each bit time. A string of 1s causes long periods with no transitions in the data.

Figure 9-17. NRZI Data Encoding

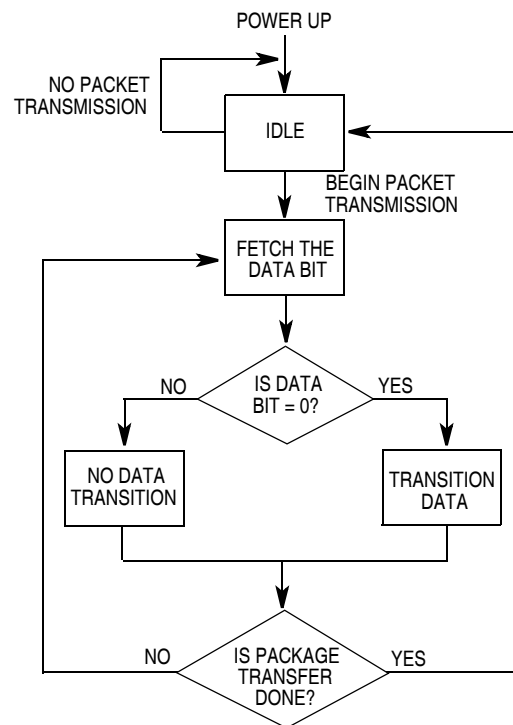

Figure 9-18. Flow Diagram for NRZI

9.5.4.2 Bit Stuffing

To ensure adequate signal transitions, bit stuffing is employed by the transmitting device when sending a packet on the USB (see [Figure 9-19](#) and [Figure 9-20](#)). A 0 is inserted after every six consecutive 1s in the data stream before the data is NRZI encoded to force a transition in the NRZI data stream. This gives the receiver logic a data transition at least once every seven bit times to guarantee the data and clock lock. The receiver must decode the NRZI data, recognize the stuffed bits, and discard them. Bit stuffing is enabled beginning with the sync pattern and throughout the entire transmission. The data 1 that ends the sync pattern is counted as the first 1 in a sequence. Bit stuffing is always enforced, without exception. If required by the bit stuffing rules, a 0 bit will be inserted even if it is the last bit before the end-of-packet (EOP) signal.

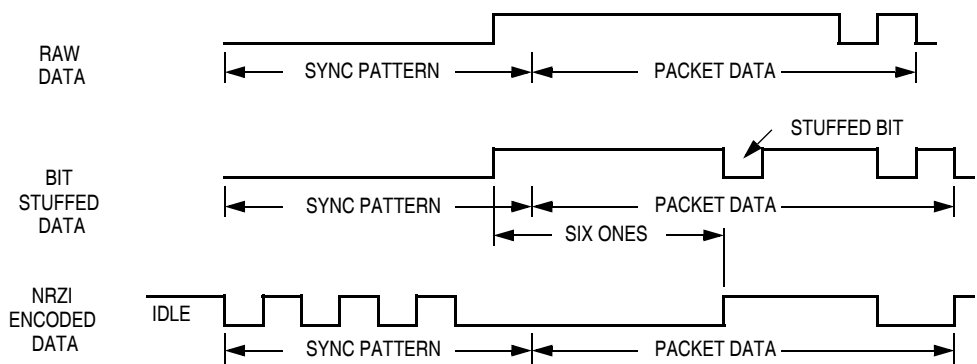

Figure 9-19. Bit Stuffing

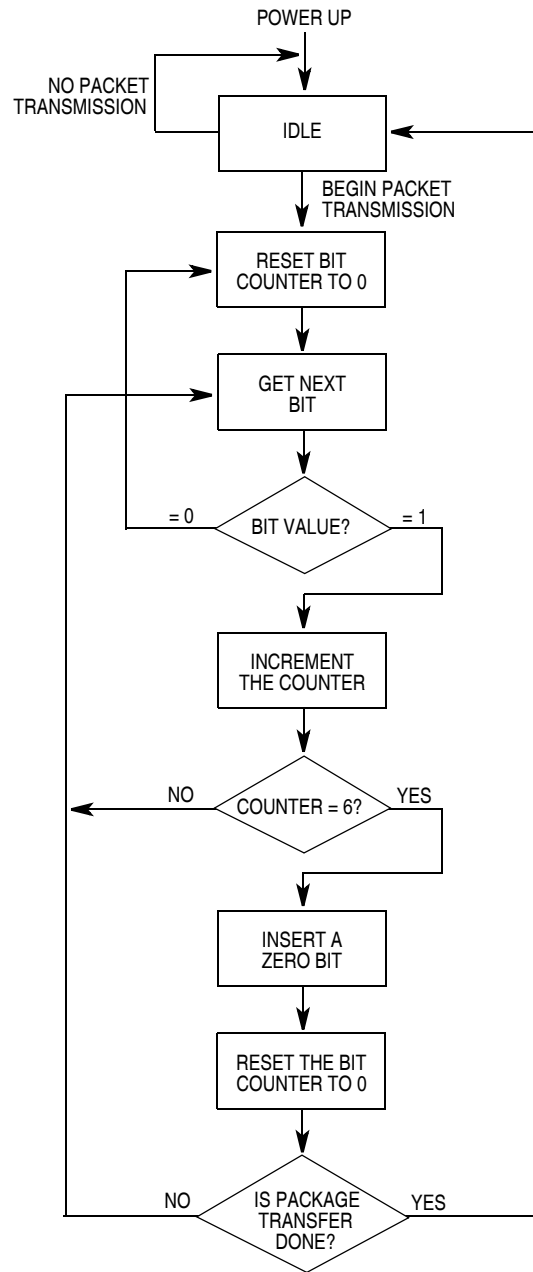

Figure 9-20. Flow Diagram for Bit Stuffing

9.6 I/O Register Description

The USB endpoint registers are comprised of a set of control/status registers and 24 data registers that provide storage for the buffering of data between USB and the CPU. See [Figure 9-21](#).

Figure 9-21. USB Register Summary (Sheet 2 of 2)

9.6.1 USB Address Register

Address: \$0038

	Bit 7	6	5	4	3	2	1	Bit 0
Read:								
Write:	USBEN	UADD6	UADD5	UADD4	UADD3	UADD2	UADD1	UADD0
Reset:	0	0	0	0	0	0	0	0

Figure 9-22. USB Address Register (UADDR)

USBEN — USB Module Enable

This read/write bit enables and disables the USB module and the USB pins. When USBEN is clear, the USB module will not respond to any traffic. Reset clears this bit.

1 = USB function enabled

0 = USB function disabled

NOTE: *The user must set this bit before the USB module will recognize USB reset signalling.*

UADD6–UADD0 — USB Function Address

These bits specify the USB address of the device. Reset clears these bits.

9.6.2 USB Interrupt Register 0

Address: \$0039

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TXD0F	RXD0F	RSTF	SUSPND	TXD0IE	RXD0IE	0	0
Write:							TXD0FR	RXD0FR
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 9-23. USB Interrupt Register 0 (UIR0)

TXD0F — Endpoint 0 Data Transmit Flag

This read-only bit is set after the data stored in endpoint 0 transmit buffers has been sent and an ACK handshake packet from the host is received. Once the next set of data is ready in the transmit buffers, software must clear this flag by writing a logic 1 to the TXD0FR bit. To enable the next data packet transmission, TX0E also must be set. If the TXD0F bit is not cleared, a NAK handshake will be returned in the next IN transaction.

Reset clears this bit. Writing to TXD0F has no effect.

1 = Transmit on endpoint 0 has occurred.

0 = Transmit on endpoint 0 has not occurred.

RXD0F — Endpoint 0 Data Receive Flag

This read-only bit is set after the USB module has received a data packet and responded with an ACK handshake packet. Software must clear this flag by writing a logic 1 to the RXD0FR bit after all of the received data has been read. Software also must set the RX0E bit to 1 to enable the next data packet reception. If the RXD0F bit is not cleared, a NAK handshake will be returned in the next OUT transaction.

Reset clears this bit. Writing to RXD0F has no effect.

1 = Receive on endpoint 0 has occurred.

0 = Receive on endpoint 0 has not occurred.

RSTF — USB Reset Flag

This read-only bit is set when a valid reset signal state is detected on the D+ and D– lines. This reset detection will also generate an internal reset signal to reset the CPU and other peripherals including the USB module. This bit is cleared by writing a logic 1 to the RSTFR bit in the UCR2 register. This bit also is cleared by a POR reset.

NOTE: *The RSTF bit is included to maintain backward compatibility with the 68HC705JB2 USB implementation. The USB bit in the RSR register (see [8.8.2 Reset Status Register](#)) is also a USB reset indicator.*

SUSPND — USB Suspend Flag

To save power, this read/write bit should be set by the software if a 3-ms constant idle state is detected on the USB bus. Setting this bit puts the transceiver and regulator into a power-saving mode. This bit is automatically cleared by hardware when the resume flag (RESUMF) is set.

TXD0IE — Endpoint 0 Transmit Interrupt Enable

This read/write bit enables the transmit endpoint 0 to generate CPU interrupt requests when the TXD0F bit becomes set. Reset clears the TXD0IE bit.

- 1 = Transmit endpoint 0 can generate a CPU interrupt request.
- 0 = Transmit endpoint 0 cannot generate a CPU interrupt request.

RXD0IE — Endpoint 0 Receive Interrupt Enable

This read/write bit enables the receive endpoint 0 to generate CPU interrupt requests when the RXD0F bit becomes set. Reset clears the RXD0IE bit.

- 1 = Receive endpoint 0 can generate a CPU interrupt request.
- 0 = Receive endpoint 0 cannot generate a CPU interrupt request.

TXD0FR — Endpoint 0 Transmit Flag Reset

Writing a logic 1 to this write-only bit will clear the TXD0F bit if it is set. Writing a logic 0 to TXD0FR has no effect. Reset clears this bit.

RXD0FR — Endpoint 0 Receive Flag Reset

Writing a logic 1 to this write-only bit will clear the RXD0F bit if it is set. Writing a logic 0 to RXD0FR has no effect. Reset clears this bit.

9.6.3 USB Interrupt Register 1

Address: \$003A

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TXD1F	EOPF	RESUMF	0	TXD1IE	EOPIE	0	0
Write:				RESUMFR				
Reset:	0	0	0	0	0	0	—	—

 = Unimplemented

Figure 9-24. USB Interrupt Register 1(UIR1)

TXD1F — Endpoint 1/Endpoint 2 Data Transmit Flag

This read-only bit is shared by endpoint 1 and endpoint 2. It is set after the data stored in the shared endpoint 1/endpoint 2 transmit buffer has been sent and an ACK handshake packet from the host is received. Once the next set of data is ready in the transmit buffers, software must clear this flag by writing a logic 1 to the TXD1FR bit. To enable the next data packet transmission, TX1E also must be set. If the TXD1F bit is not cleared, a NAK handshake will be returned in the next IN transaction.

Reset clears this bit. Writing to TXD1F has no effect.

1 = Transmit on endpoint 1 or endpoint 2 has occurred.

0 = Transmit on endpoint 1 or endpoint 2 has not occurred.

EOPF — End-of-Packet Detect Flag

This read-only bit is set when a valid end-of-packet sequence is detected on the D+ and D– lines. Software must clear this flag by writing a logic 1 to the EOPFR bit.

Reset clears this bit. Writing to EOPF has no effect.

1 = End-of-packet sequence has been detected.

0 = End-of-packet sequence has not been detected.

RESUMF — Resume Flag

This read-only bit is set when USB bus activity is detected while the SUSPND bit is set. Software must clear this flag by writing a logic 1 to the RESUMFR bit.

Reset clears this bit. Writing a logic 0 to RESUMF has no effect.

1 = USB bus activity has been detected.

0 = No USB bus activity has been detected.

RESUMFR — Resume Flag Reset

Writing a logic 1 to this write-only bit will clear the RESUMF bit if it is set. Writing to RESUMFR has no effect. Reset clears this bit.

TXD1IE — Endpoint 1/Endpoint 2 Transmit Interrupt Enable

This read/write bit enables the USB to generate CPU interrupt requests when the shared transmit endpoint 1/endpoint 2 interrupt flag (TXD1F) bit becomes set. Reset clears the TXD1IE bit.

1 = Transmit endpoints 1 and 2 can generate a CPU interrupt request.

0 = Transmit endpoints 1 and 2 cannot generate a CPU interrupt request.

EOPIE — End-of-Packet Detect Interrupt Enable

This read/write bit enables the USB to generate CPU interrupt requests when the EOPF bit becomes set. Reset clears the EOPIE bit.

1 = End-of-packet sequence detection can generate a CPU interrupt request.

0 = End-of-packet sequence detection cannot generate a CPU interrupt request.

TXD1FR — Endpoint 1/Endpoint 2 Transmit Flag Reset

Writing a logic 1 to this write-only bit will clear the TXD1F bit if it is set. Writing a logic 0 to TXD1FR has no effect. Reset clears this bit.

EOPFR — End-of-Packet Flag Reset

Writing a logic 1 to this write-only bit will clear the EOPF bit if it is set. Writing a logic 0 to the EOPFR has no effect. Reset clears this bit.

9.6.4 USB Control Register 0

Address: \$003B

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	T0SEQ	STALL0	TX0E	RX0E	TP0SIZ3	TP0SIZ2	TP0SIZ1	TP0SIZ0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 9-25. USB Control Register 0 (UCR0)

T0SEQ — Endpoint 0 Transmit Sequence Bit

This read/write bit determines which type of data packet (DATA0 or DATA1) will be sent during the next IN transaction directed at endpoint 0. Toggling of this bit must be controlled by software. Reset clears this bit.

1 = DATA1 token active for next endpoint 0 transmit.

0 = DATA0 token active for next endpoint 0 transmit.

STALL0 — Endpoint 0 Force Stall Bit

This read/write bit causes endpoint 0 to return a STALL handshake when polled by either an IN or OUT token by the USB host controller. The USB hardware clears this bit when a SETUP token is received. Reset clears this bit.

1 = Send STALL handshake.

0 = Default

TX0E — Endpoint 0 Transmit Enable

This read/write bit enables a transmit to occur when the USB host controller sends an IN token to endpoint 0. Software should set this bit when data is ready to be transmitted. It must be cleared by software when no more endpoint 0 data needs to be transmitted.

If this bit is 0 or the TXD0F is set, the USB will respond with a NAK handshake to any endpoint 0 IN tokens. Reset clears this bit.

1 = Data is ready to be sent.

0 = Data is not ready. Respond with NAK.

RX0E — Endpoint 0 Receive Enable

This read/write bit enables a receive to occur when the USB host controller sends an OUT token to endpoint 0. Software should set this bit when data is ready to be received. It must be cleared by software when data cannot be received.

If this bit is 0 or the RXD0F is set, the USB will respond with a NAK handshake to any endpoint 0 OUT tokens. Reset clears this bit.

1 = Data is ready to be received.

0 = Not ready for data. Respond with NAK.

TP0SIZ3–TP0SIZ0 — Endpoint 0 Transmit Data Packet Size

These read/write bits store the number of transmit data bytes for the next IN token request for endpoint 0. These bits are cleared by reset.

9.6.5 USB Control Register 1

Address: \$003C

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	T1SEQ	ENDADD	TX1E	FRESUM	TP1SIZ3	TP1SIZ2	TP1SIZ1	TP1SIZ0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 9-26. USB Control Register 1 (UCR1)

T1SEQ — Endpoint1/Endpoint 2 Transmit Sequence Bit

This read/write bit determines which type of data packet (DATA0 or DATA1) will be sent during the next IN transaction directed to endpoint 1 or endpoint 2. Toggling of this bit must be controlled by software. Reset clears this bit.

1 = DATA1 token active for next endpoint 1/endpoint 2 transmit

0 = DATA0 token active for next endpoint 1/endpoint 2 transmit

ENDADD — Endpoint Address Select

This read/write bit specifies whether the data inside the registers UE1D0–UE1D7 are used for endpoint 1 or endpoint 2.

If all the conditions for a successful endpoint 2 USB response to a host IN token are satisfied (TXD1F = 0, TX1E = 1, STALL2 = 0, and ENABLE2 = 1) except that the ENDADD bit is configured for endpoint 1, the USB responds with a NAK handshake packet.

1 = The data buffers are used for endpoint 2.

0 = The data buffers are used for endpoint 1.

TX1E — Endpoint 1/Endpoint 2 Transmit Enable

This read/write bit enables a transmit to occur when the USB host controller sends an IN token to endpoint 1 or endpoint 2. The appropriate endpoint enable bit, ENABLE1 or ENABLE2 bit in the UCR2 register, also should be set. Software should set the TX1E bit when data is ready to be transmitted. It must be cleared by software when no more data needs to be transmitted.

If this bit is 0 or the TXD1F is set, the USB will respond with a NAK handshake to any endpoint 1 or endpoint 2 directed IN tokens. Reset clears this bit.

1 = Data is ready to be sent.

0 = Data is not ready. Respond with NAK.

FRESUM — Force Resume

This read/write bit forces a resume state (K or non-idle state) onto the USB data lines to initiate a remote wakeup. Software should control the timing of the forced resume to be between 10 and 15 ms. Setting this bit will not cause the RESUMF bit to be set.

1 = Force data lines to K state

0 = Default

TP1SIZ3–TP1SIZ0 — Endpoint 1/Endpoint 2 Transmit Data Packet Size

These read/write bits store the number of transmit data bytes for the next IN token request for endpoint 1 or endpoint 2. These bits are cleared by reset.

9.6.6 USB Control Register 2

Address: \$0037

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	TX1ST	0	ENABLE2	ENABLE1	STALL2	STALL1
Write:	RSTFR	TX1STR						
Reset:	—	—	0	—	0	0	0	0

 = Unimplemented

Figure 9-27. USB Control Register 2 (UCR2)

RSTFR — Clear Reset Indicator Bit

Writing a logic 1 to this write-only bit will clear the RSTF bit in the UIR0 register if it is set. Writing a logic 0 to the RSTFR has no effect. Reset clears this bit.

TX1STR — Clear Transmit First Flag

Writing a logic 1 to this write-only bit will clear the TX1ST bit if it is set. Writing a logic 0 to the TX1STR has no effect. Reset clears this bit.

TX1ST — Transmit First Flag

This read-only bit is set if the endpoint 0 data transmit flag (TXD0F) is set when the USB control logic is setting the endpoint 0 data receive flag (RXD0F). In other words, if an unserviced endpoint 0 transmit flag is still set at the end of an endpoint 0 reception, then this bit will be set. This bit lets the firmware know that the endpoint 0 transmission happened before the endpoint 0 reception.

Reset clears this bit.

1 = IN transaction occurred before SETUP/OUT.

0 = IN transaction occurred after SETUP/OUT.

ENABLE2 — Endpoint 2 Enable

This read/write bit enables endpoint 2 and allows the USB to respond to IN packets addressed to endpoint 2. Reset clears this bit.

1 = Endpoint 2 is enabled and can respond to an IN token.

0 = Endpoint 2 is disabled.

ENABLE1 — Endpoint 1 Enable

This read/write bit enables endpoint 1 and allows the USB to respond to IN packets addressed to endpoint 1. Reset clears this bit.

1 = Endpoint 1 is enabled and can respond to an IN token.

0 = Endpoint 1 is disabled.

STALL2 — Endpoint 2 Force Stall Bit

This read/write bit causes endpoint 2 to return a STALL handshake when polled by either an IN or OUT token by the USB host controller. Reset clears this bit.

1 = Send STALL handshake.

0 = Default

STALL1 — Endpoint 1 Force Stall Bit

This read/write bit causes endpoint 1 to return a STALL handshake when polled by either an IN or OUT token by the USB host controller. Reset clears this bit.

1 = Send STALL handshake.

0 = Default

9.6.7 USB Status Register

Address: \$003D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	RSEQ	SETUP	0	0	RPSIZ3	RPSIZ2	RPSIZ1	RPSIZ0
Write:								
Reset:	X	X	—	—	X	X	X	X

= Unimplemented
 X = Indeterminate

Figure 9-28. USB Status Register (USR)

RSEQ — Endpoint 0 Receive Sequence Bit

This read-only bit indicates the type of data packet last received for endpoint 0 (DATA0 or DATA1).

1 = DATA1 token received in last endpoint 0 receive.

0 = DATA0 token received in last endpoint 0 receive.

SETUP — SETUP Token Detect Bit

This read-only bit indicates that a valid SETUP token has been received.

1 = Last token received for endpoint 0 was a SETUP token.

0 = Last token received for endpoint 0 was not a SETUP token.

RPSIZ3–RPSIZ0 — Endpoint 0 Receive Data Packet Size

These read-only bits store the number of data bytes received for the last OUT or SETUP transaction for endpoint 0. These bits are not affected by reset.

9.6.8 USB Endpoint 0 Data Registers

UE0D0	Address: \$0020	Bit 7	6	5	4	3	2	1	Bit 0

Write:	UE0TD7	UE0TD6	UE0TD5	UE0TD4	UE0TD3	UE0TD2	UE0TD1	UE0TD0	
Reset:	X	X	X	X	X	X	X	X	X

X = Indeterminate

Figure 9-29. USB Endpoint 0 Data Register (UE0D0–UE0D7)

UE0RD7–UE0RD0 — Endpoint 0 Receive Data Buffer

These read-only bits are serially loaded with OUT token or SETUP token data directed at endpoint 0. The data is received over the USB's D+ and D– pins.

UE0TD7–UE0TD0 — Endpoint 0 Transmit Data Buffer

These write-only buffers are loaded by software with data to be sent on the USB bus on the next IN token directed at endpoint 0.

9.6.9 USB Endpoint 1/Endpoint 2 Data Registers

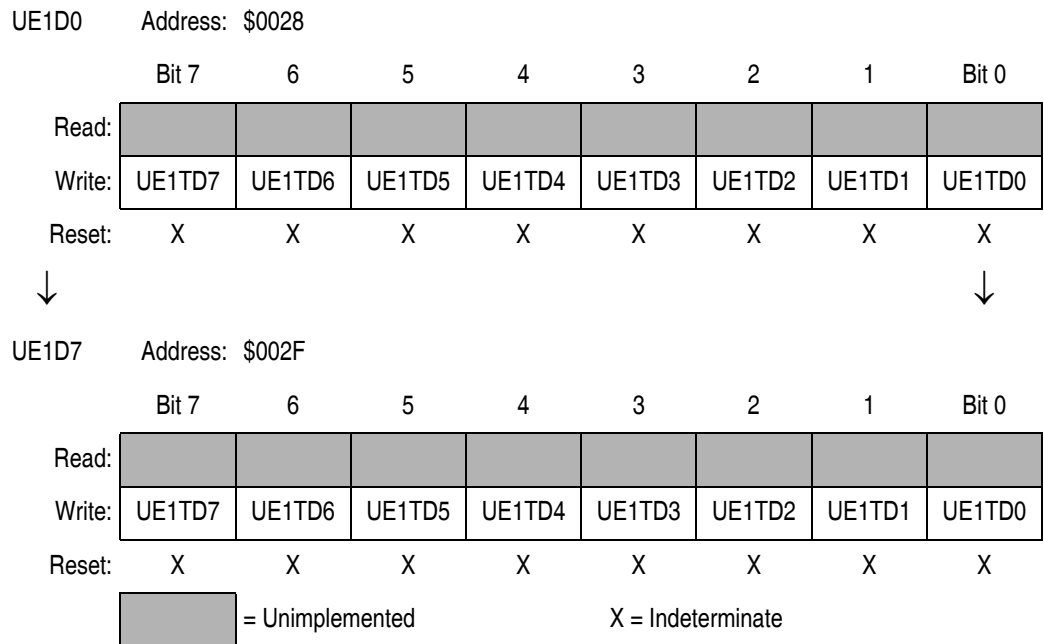

Figure 9-30. USB Endpoint 1/Endpoint 2 Data Register (UE1D0–UE1D7)

UE1TD7–UE1TD0 — Endpoint 1/ Endpoint 2 Transmit Data Buffer

These write-only buffers are loaded by software with data to be sent on the USB bus on the next IN token directed at endpoint 1 or endpoint 2. These buffers are shared by endpoints 1 and 2 and depend on proper configuration of the ENDADD bit.

9.7 USB Interrupts

The USB module is capable of generating interrupts and causing the CPU to execute the USB interrupt service routine. There are three types of USB interrupts:

- End-of-transaction interrupts signify either a completed transaction receive or transmit transaction.
- Resume interrupts signify that the USB bus is reactivated after having been suspended.
- End-of-packet interrupts signify that a low-speed end-of-packet signal was detected.

All USB interrupts share the same interrupt vector. Firmware is responsible for determining which interrupt is active.

9.7.1 USB End-of-Transaction Interrupt

There are three possible end-of-transaction interrupts:

- Endpoint 0 receive
- Endpoint 0 transmit
- Shared Endpoint 1 or Endpoint 2 transmit

End-of-transaction interrupts occur as detailed in the following sections.

9.7.1.1 Receive Control Endpoint 0

For a control OUT transaction directed at endpoint 0, the USB module will generate an interrupt by setting the RXD0F flag in the UIR0 register. The conditions necessary for the interrupt to occur are shown in the flowchart in [Figure 9-31](#).

SETUP transactions cannot be stalled by the USB function. A SETUP received by a control endpoint will clear the STALL0 bit if it is set. The conditions for receiving a SETUP interrupt are shown in [Figure 9-32](#).

Universal Serial Bus Module (USB)

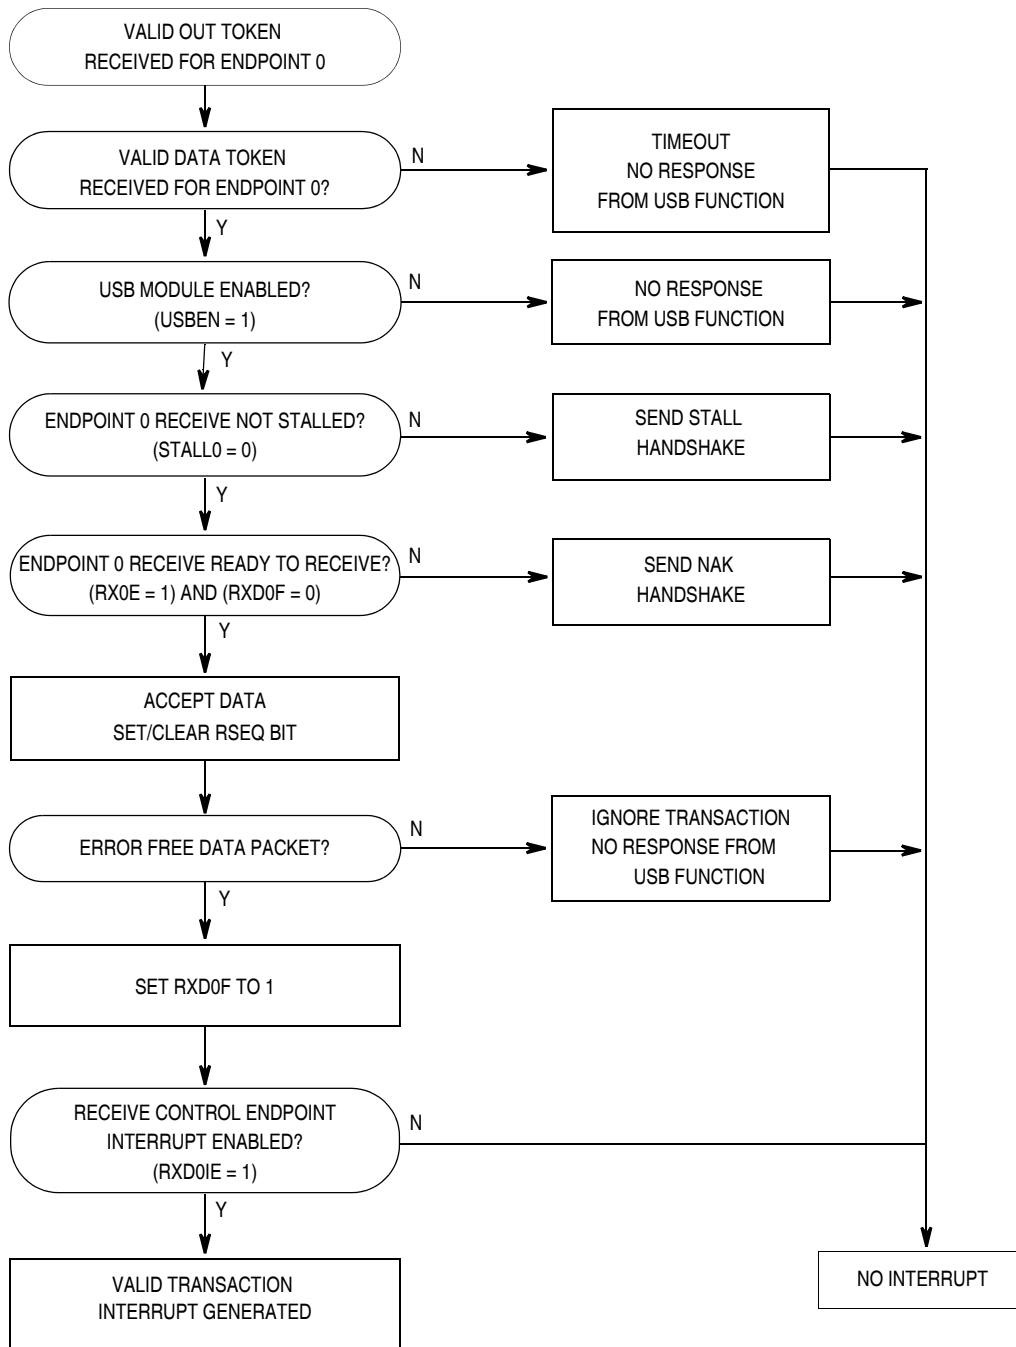

Figure 9-31. OUT Token Data Flow for Receive Endpoint 0

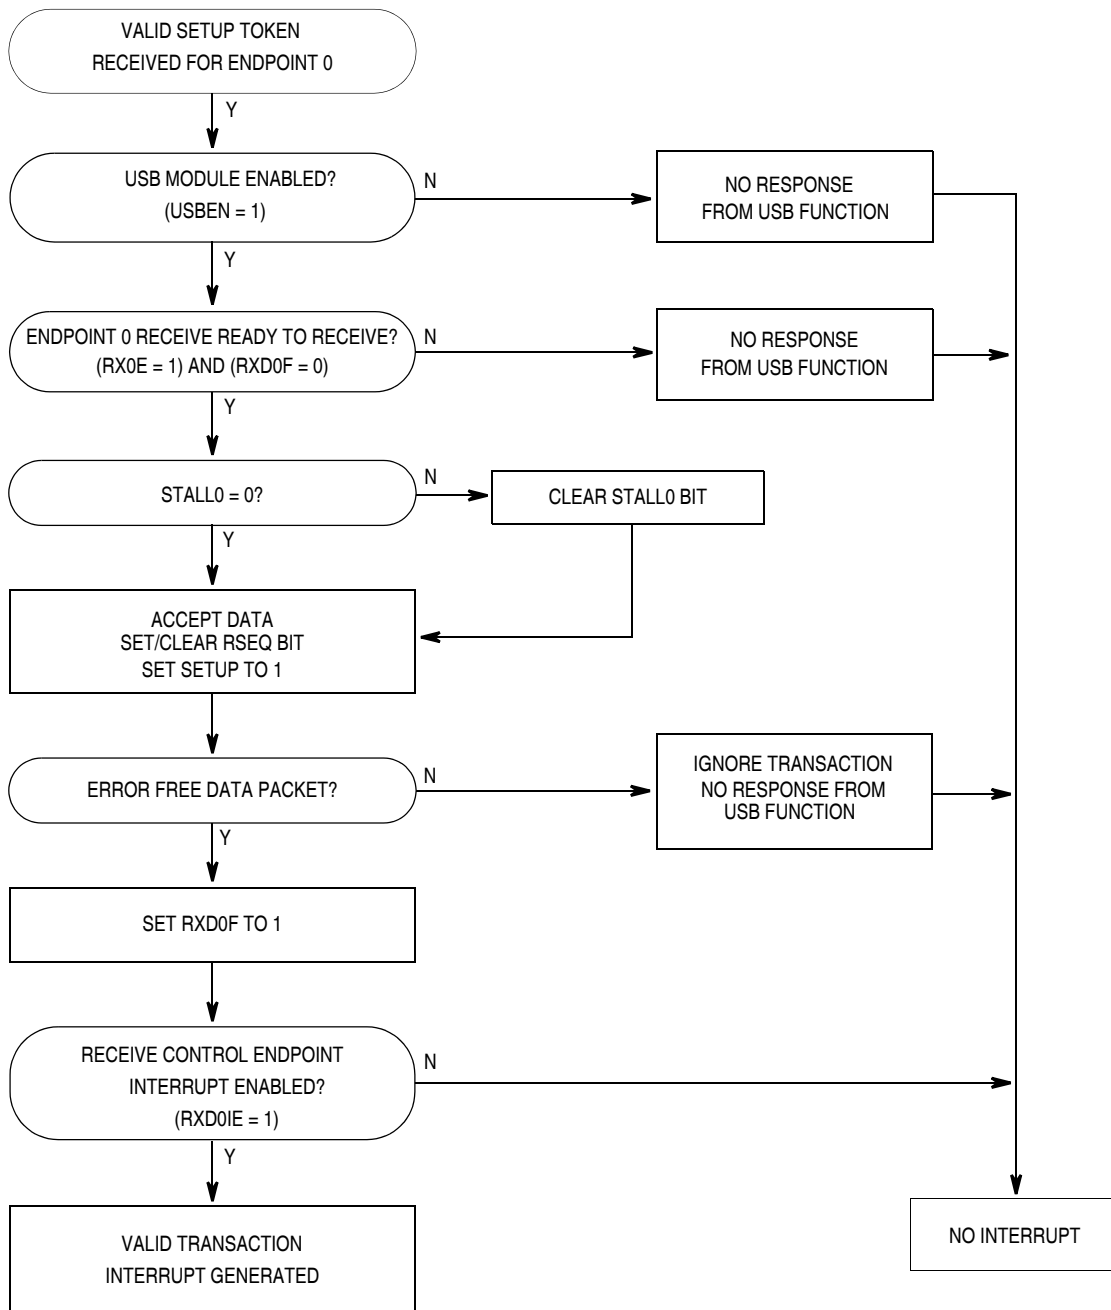

Figure 9-32. SETUP Token Data Flow for Receive Endpoint 0

9.7.1.2 Transmit Control Endpoint 0

For a control IN transaction directed at endpoint 0, the USB module will generate an interrupt by setting the TXD0F flag in the UIR0 register. The conditions necessary for the interrupt to occur are shown in the flowchart in **Figure 9-33**.

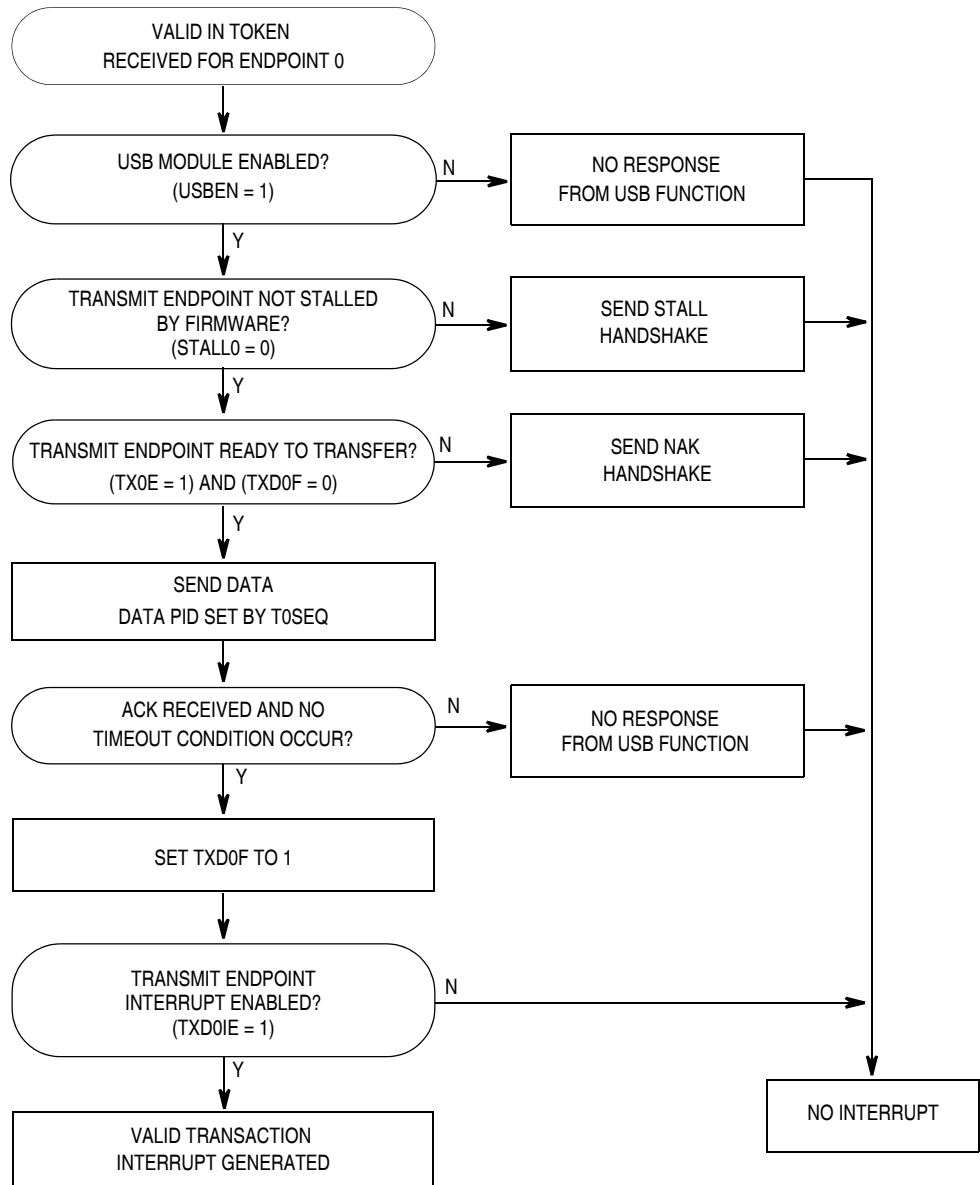

Figure 9-33. IN Token Data Flow for Transmit Endpoint 0

9.7.1.3 Transmit Endpoint 1 and Transmit Endpoint 2

Transmit endpoints 1 and 2 share their interrupt flag. For an IN transaction directed at endpoint 1 or 2, the USB module will generate an interrupt by setting the TXD1F flag in the UIR1 register. The conditions necessary for the interrupt to occur are shown in **Figure 9-34**.

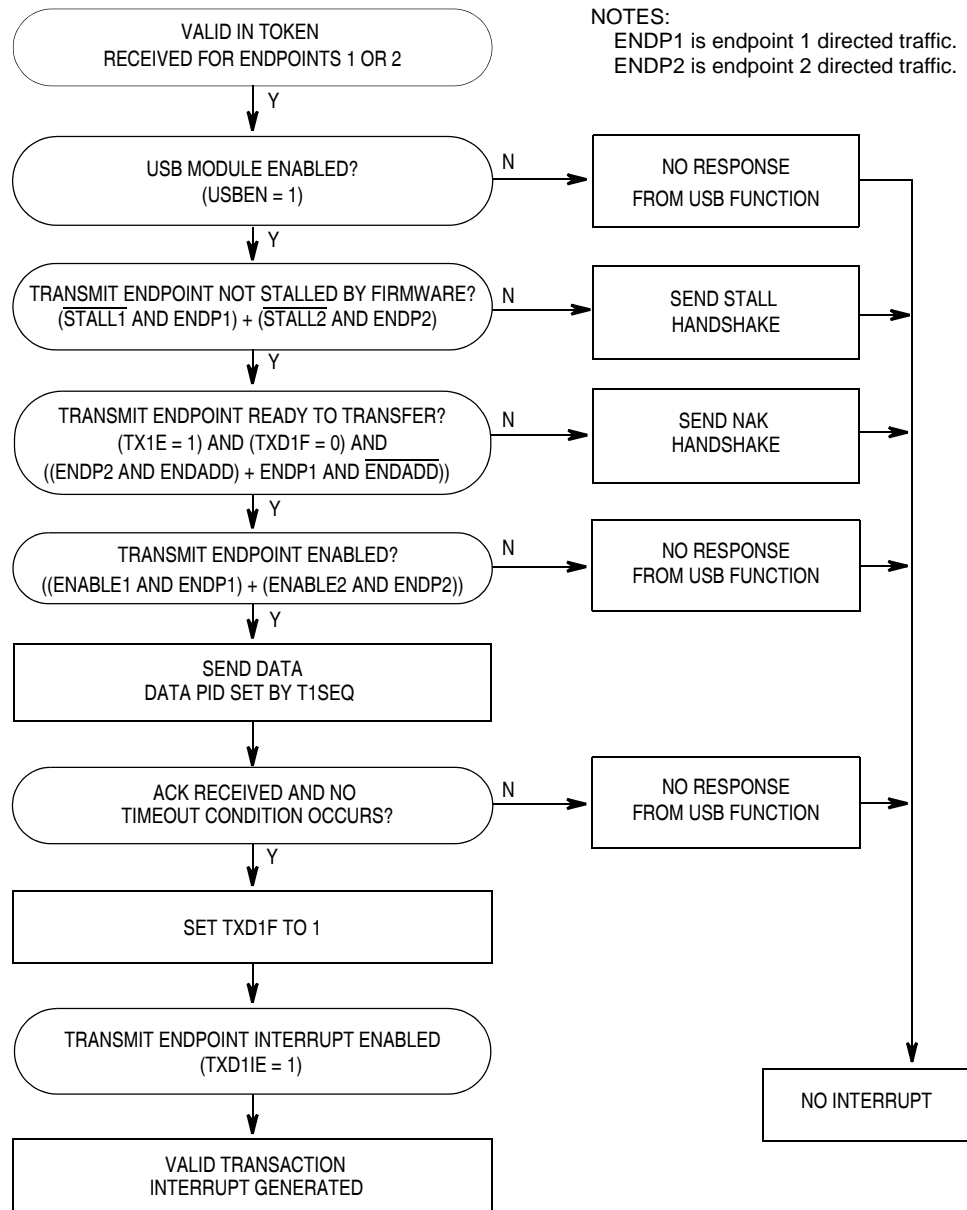

Figure 9-34. IN Token Data Flow for Transmit Endpoint 1/Endpoint 2

9.7.2 Resume Interrupt

The USB module will generate a CPU interrupt if low-speed bus activity is detected after entering the suspend state. A transition of the USB data lines to the non-idle state (K state) while in the suspend mode will set the RESUMF flag in the UIR1 register. There is no interrupt enable bit for this interrupt source and an interrupt will be executed if the I bit in the CCR is cleared. A resume interrupt can only occur while the MC68HC708KL8 is in the suspend mode.

9.7.3 End-of-Packet Interrupt

The USB module can generate a USB interrupt upon detection of an end-of-packet signal for low-speed devices. Upon detection of an end-of-packet signal, the USB module sets the EOPF bit and will generate a CPU interrupt if the EOPIE bit in the UIR1 register is set.

10.4.5	Commands	151
10.5	Security	157

10.2 Introduction

This section describes the monitor ROM. The monitor ROM allows complete testing of the MCU through a single-wire interface with a host computer.

10.3 Features

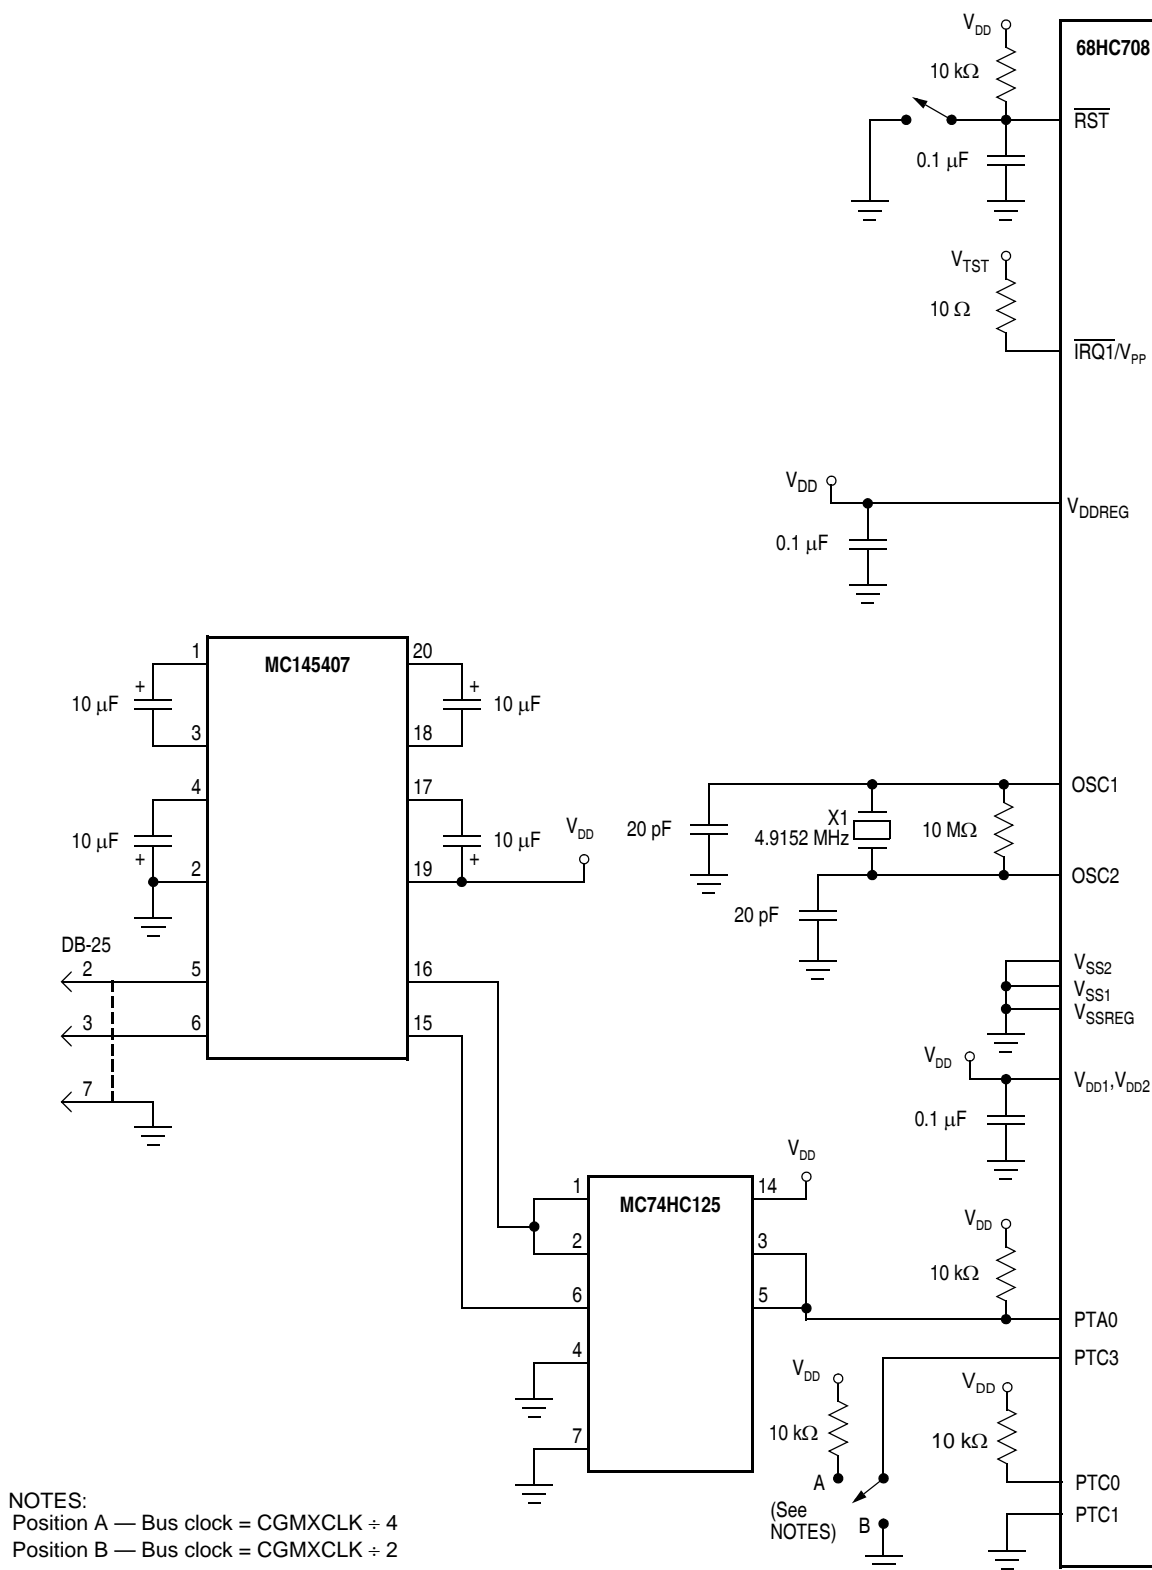

Features of the monitor ROM include:

- Normal User-Mode Pin Functionality
- One Pin Dedicated to Serial Communication between Monitor ROM and Host Computer
- Standard Mark/Space Non-Return-to-Zero (NRZ) Communication with Host Computer
- Execution of Code in RAM or EPROM
- EPROM Programming
- EPROM Security

10.4 Functional Description

The monitor ROM receives and executes commands from a host computer. [Figure 10-1](#) shows an example circuit used to enter monitor mode and communicate with a host computer via a standard RS-232 interface.

Simple monitor commands can access any memory address. In monitor mode, the MCU can execute host-computer code in RAM while all MCU pins retain normal operating mode functions. All communication between the host computer and the MCU is through the PTA0 pin. A level-shifting and multiplexing interface is required between PTA0 and the host computer. PTA0 is used in a wired-OR configuration and requires a pullup resistor.

Figure 10-1. Monitor Mode Circuit

10.4.1 Entering Monitor Mode

Table 10-1 shows the pin conditions for entering monitor mode.

Table 10-1. Monitor Mode Entry

$\overline{\text{IRQ1V}}_{\text{PP}}$ Pin	PTA7 Pin	PTC0 Pin	PTC1 Pin	PTA0 Pin	PTC3 Pin	CGMOUT	Bus Frequency
V_{TST}	0	1	0	1	1	$\frac{\text{CGMXCLK}}{2}$	$\frac{\text{CGMOUT}}{2}$
					0	CGMXCLK	

If PTC3 is low upon monitor mode entry, CGMOUT is equal to the crystal frequency. The bus frequency in this case is a divide-by-two of the input clock. If PTC3 is high upon monitor mode entry, the bus frequency will be a divide-by-four of the input clock.

NOTE: *Holding the PTC3 pin low when entering monitor mode causes a bypass of a divide-by-two stage at the oscillator. The CGMOUT frequency is equal to the CGMXCLK frequency, and the OSC1 input directly generates internal bus clocks. In this case, the OSC1 signal must have a 50% duty cycle at maximum bus frequency.*

Enter monitor mode with the pin configuration shown above by pulling $\overline{\text{RST}}$ low and then high. The rising edge of $\overline{\text{RST}}$ latches monitor mode. Once monitor mode is latched, the values on the specified pins can change.

NOTE: *The PA7 pin must remain at logic 0 for 24 bus cycles after the $\overline{\text{RST}}$ pin goes high.*

Once out of reset, the MCU waits for the host to send eight security bytes. (See **10.5 Security**.) After the security bytes, the MCU sends a break signal (10 consecutive logic 0s) to the host, indicating that it is ready to receive a command.

In monitor mode, the MCU uses different vectors for reset, SWI, and break interrupt than those for user mode. The alternate vectors are in the \$FE page instead of the \$FF page and allow code execution from the internal monitor firmware instead of user code.

The COP module is disabled in monitor mode as long as V_{TST} is applied to either the \overline{IRQ} pin or the \overline{RST} pin.

Table 10-2 summarizes the differences between user mode and monitor mode.

Table 10-2. Mode Differences

Modes	Functions						
	COP	Reset Vector High	Reset Vector Low	Break Vector High	Break Vector Low	SWI Vector High	SWI Vector Low
User	Enabled	\$FFFE	\$FFFF	\$FFFC	\$FFFD	\$FFFC	\$FFFD
Monitor	Disabled ⁽¹⁾	\$FEFE	\$FEFF	\$FEFC	\$FEFD	\$FEFC	\$FEFD

1. If the high voltage (V_{TST}) is removed from the \overline{IRQ}/V_{PP} pin or the \overline{RST} pin, the SIM asserts its COP enable output. The COP is a mask option enabled or disabled by the COPD bit in the configuration register.

10.4.2 Data Format

Communication with the monitor ROM is in standard non-return-to-zero (NRZ) mark/space data format. Transmit and receive baud rates must be identical.

Figure 10-2. Monitor Data Format

10.4.3 Break Signal

A start bit (logic 0) followed by nine logic 0 bits is a break signal. When the monitor receives a break signal, it drives the PTA0 pin high for the duration of two bits and then echoes back the break signal.

Figure 10-3. Break Transaction

10.4.4 Baud Rate

The communication baud rate is controlled by the crystal frequency and the state of the PTC3 pin upon entry into monitor mode. When PTC3 is high, the divide by ratio is 1024. If the PTC3 pin is at logic 0 upon entry into monitor mode, the divide by ratio is 512. [Table 10-3](#) lists crystal frequencies required to achieve standard baud rates. Other standard baud rates can be accomplished using higher crystal frequencies.

Table 10-3. Monitor Baud Rate Selection

Crystal Frequency (MHz)	PTC3 Pin	Baud Rate
4.9152	0	9600
4.9152	1	4800

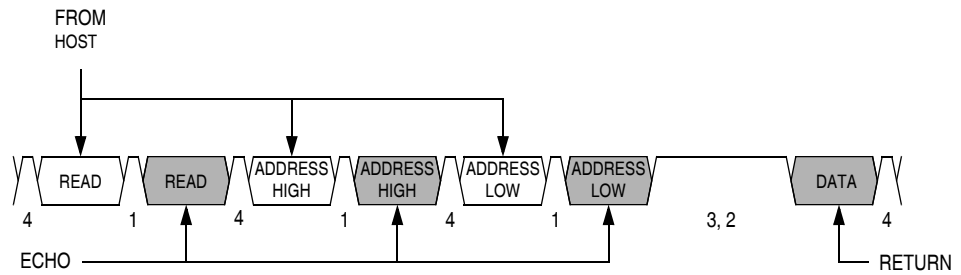

10.4.5 Commands

The monitor ROM firmware uses these commands:

- READ (read memory)
- WRITE (write memory)
- IREAD (indexed read)
- IWRITE (indexed write)
- READSP (read stack pointer)
- RUN (run user program)

The monitor ROM firmware echoes each received byte back to the PTA0 pin for error checking. An 11-bit delay at the end of each command allows the host to send a break character to cancel the command. A delay of two bit times occurs before each echo and before READ, IREAD, or READSP data is returned. The data returned by a read command appears after the echo of the last byte of the command.

NOTE: *Wait one bit time after each echo before sending the next byte.*

NOTES:

- 1 = Echo delay, 2 bit times
- 2 = Data return delay, 2 bit times
- 3 = Cancel command delay, 11 bit times
- 4 = Wait 1 bit time before sending next byte.

Figure 10-4. Read Transaction

NOTES:

- 1 = Echo delay, 2 bit times
- 3 = Cancel command delay, 11 bit times
- 4 = Wait 1 bit time before sending next byte.

Figure 10-5. Write Transaction

A brief description of each monitor mode command follows:

Table 10-4. READ (Read Memory) Command

Description	Read Byte from Memory
Operand	2-Byte Address in High Byte:Low Byte Order
Data Returned	Returns Contents of Specified Address
Opcode	\$4A
Command Sequence	
<p>The diagram illustrates the command sequence for the READ command. It shows a sequence of signals: READ, READ, ADDRESS HIGH, ADDRESS HIGH, ADDRESS LOW, ADDRESS LOW, and DATA. Arrows indicate that the first two READ signals are sent to the monitor. The ADDRESS HIGH and ADDRESS LOW signals are also sent to the monitor. The DATA signal is returned from the monitor. An ECHO signal is shown below the READ and ADDRESS signals, and a RETURN signal is shown below the DATA signal.</p>	

Table 10-5. WRITE (Write Memory) Command

Description	Write Byte to Memory
Operand	2-Byte Address in High Byte:Low Byte Order; Low Byte Followed by Data Byte
Data Returned	None
Opcode	\$49
Command Sequence	
<p>The diagram illustrates the command sequence for the WRITE command. It shows a sequence of signals: WRITE, WRITE, ADDRESS HIGH, ADDRESS HIGH, ADDRESS LOW, ADDRESS LOW, DATA, and DATA. Arrows indicate that the first two WRITE signals are sent from the host. The ADDRESS HIGH and ADDRESS LOW signals are also sent from the host. The two DATA signals are sent from the host. An ECHO signal is shown below the WRITE and ADDRESS signals.</p>	

Table 10-6. IREAD (Indexed Read) Command

Description	Read Next 2 Bytes in Memory from Last Address Accessed
Operand	2-Byte Address in High Byte:Low Byte Order
Data Returned	Returns Contents of Next Two Addresses
Opcode	\$1A
Command Sequence	

Table 10-7. IWRITE (Indexed Write) Command

Description	Write to Last Address Accessed + 1
Operand	Single Data Byte
Data Returned	None
Opcode	\$19
Command Sequence	

A sequence of IREAD or IWRITE commands can access a block of memory sequentially over the full 64-Kbyte memory map.

Table 10-8. READSP (Read Stack Pointer) Command

Description	Reads Stack Pointer
Operand	None
Data Returned	Returns Incremented Stack Pointer Value (SP + 1) in High Byte:Low Byte Order
Opcode	\$0C
Command Sequence	

Table 10-9. RUN (Run User Program) Command

Description	Executes PULH and RTI Instructions
Operand	None
Data Returned	None
Opcode	\$28
Command Sequence	

The MCU executes the SWI and PSHH instructions when it enters monitor mode. The RUN command tells the MCU to execute the PULH and RTI instructions. Before sending the RUN command, the host can modify the stacked CPU registers to prepare to run the host program. The READSP command returns the incremented stack pointer value, SP + 1. The high and low bytes of the program counter are at addresses SP + 5 and SP + 6.

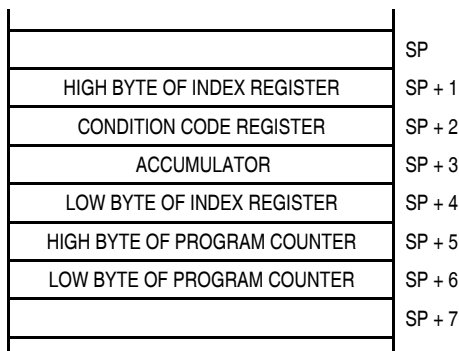

Figure 10-6. Stack Pointer at Monitor Mode Entry

10.5 Security

A security feature discourages unauthorized reading of ROM locations while in monitor mode. The host can bypass the security feature at monitor mode entry by sending eight security bytes that match the bytes at locations \$FFF6–\$FFFD. Locations \$FFF6–\$FFFD contain user-defined data.

NOTE: Do not leave locations \$FFF6–\$FFFD blank. For security reasons, program locations \$FFF6–\$FFFD even if they are not used for vectors.

During monitor mode entry, the MCU waits after the power-on reset for the host to send the eight security bytes on pin PA0.

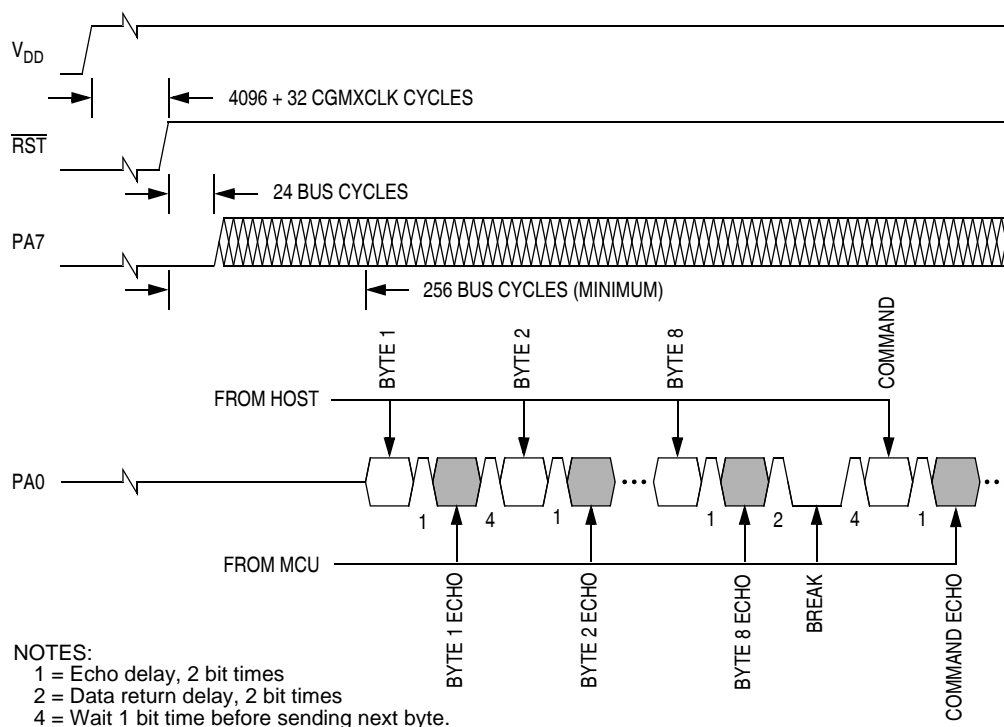

Figure 10-7. Monitor Mode Entry Timing

If the received bytes match those at locations \$FFF6–\$FFFD, the host bypasses the security feature and can read all ROM locations and execute code from ROM. Security remains bypassed until a power-on reset occurs. After the host bypasses security, any reset other than a power-on reset requires the host to send another eight bytes. If the reset was not a power-on reset, security remains bypassed regardless of the data that the host sends.

If the received bytes do not match the data at locations \$FFF6–\$FFFD, the host fails to bypass the security feature. The MCU remains in monitor mode, but reading ROM locations returns undefined data, and trying to execute code from ROM causes an illegal address reset.

After receiving the eight security bytes from the host, the MCU transmits a break character signalling that it is ready to receive a command.

NOTE: *The MCU does not transmit a break character until after the host sends the eight security bytes.*

11.2 Introduction

This section describes the timer interface module (TIM2, Version B). The TIM is a 2-channel timer that provides a timing reference with input capture, output compare, and pulse-width-modulation functions. [Figure 11-1](#) is a block diagram of the TIM.

11.3 Features

Features of the TIM include:

- Two Input Capture/Output Compare Channels
 - Rising-Edge, Falling-Edge, or Any-Edge Input Capture Trigger
 - Set, Clear, or Toggle Output Compare Action
- Buffered and Unbuffered Pulse Width Modulation (PWM) Signal Generation
- Programmable TIM Clock Input
 - 7-Frequency Internal Bus Clock Prescaler Selection
 - External TIM Clock Input (Bus Frequency $\div 2$ Maximum)
- Free-Running or Modulo Up-Count Operation
- Toggle Any Channel Pin on Overflow
- TIM Counter Stop and Reset Bits
- Modular Architecture Expandable to Eight Channels

11.4 Functional Description

[Figure 11-1](#) shows the structure of the TIM. The central component of the TIM is the 16-bit TIM counter that can operate as a free-running counter or a modulo up-counter. The TIM counter provides the timing reference for the input capture and output compare functions. The TIM counter modulo registers, TMODH:TMODL, control the modulo value of the TIM counter. Software can read the TIM counter value at any time without affecting the counting sequence.

The two TIM channels are programmable independently as input capture or output compare channels.

Figure 11-2. TIM I/O Register Summary

11.4.1 TIM Counter Prescaler

The TIM clock source can be one of the seven prescaler outputs or the TIM clock pin, PTE0/TCLK. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS[2:0], in the TIM status and control register (TSC) select the TIM clock source.

11.4.2 Input Capture

With the input capture function, the TIM can capture the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the TIM latches the contents of the TIM counter into the TIM channel registers, TCHxH:TCHxL. The polarity of the active edge is programmable. Input captures can generate TIM CPU interrupt requests.

11.4.3 Output Compare

With the output compare function, the TIM can generate a periodic pulse with a programmable polarity, duration, and frequency. When the counter reaches the value in the registers of an output compare channel, the TIM can set, clear, or toggle the channel pin. Output compares can generate TIM CPU interrupt requests.

11.4.3.1 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in [11.4.3 Output Compare](#). The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIM channel registers.

An unsynchronized write to the TIM channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIM overflow interrupt routine to write a new, smaller output

compare value may cause the compare to be missed. The TIM may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable channel x TIM overflow interrupts and write the new value in the TIM overflow interrupt routine. The TIM overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

11.4.3.2 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the PTE1/TCH0 pin. The TIM channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIM channel 0 status and control register (TSC0) links channel 0 and channel 1. The output compare value in the TIM channel 0 registers initially controls the output on the PTE1/TCH0 pin. Writing to the TIM channel 1 registers enables the TIM channel 1 registers to synchronously control the output after the TIM overflows. At each subsequent overflow, the TIM channel registers (0 or 1) that control the output are the ones written to last. TSC0 controls and monitors the buffered output compare function, and TIM channel 1 status and control register (TSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE2/TCH1, is available as a general-purpose I/O pin.

NOTE: *In buffered output compare operation, do not write new output compare values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered output compares.*

11.4.4 Pulse Width Modulation (PWM)

By using the toggle-on-overflow feature with an output compare channel, the TIM can generate a PWM signal. The value in the TIM counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIM counter modulo registers. The time between overflows is the period of the PWM signal.

As **Figure 11-3** shows, the output compare value in the TIM channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIM to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIM to set the pin if the state of the PWM pulse is logic 0.

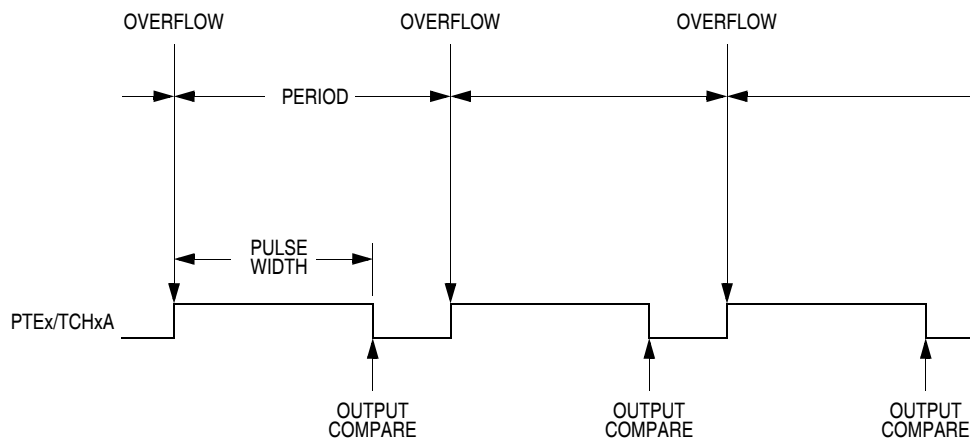

Figure 11-3. PWM Period and Pulse Width

The value in the TIM counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIM counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is 000 (see **11.9.1 TIM Status and Control Register**).

The value in the TIM channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256

increments. Writing \$0080 (128) to the TIM channel registers produces a duty cycle of 128/256 or 50%.

11.4.4.1 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in [11.4.4 Pulse Width Modulation \(PWM\)](#). The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the old value currently in the TIM channel registers.

An unsynchronized write to the TIM channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIM overflow interrupt routine to write a new, smaller pulse width value may cause the compare to be missed. The TIM may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable channel x TIM overflow interrupts and write the new value in the TIM overflow interrupt routine. The TIM overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output*

compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.

11.4.4.2 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the PTE1/TCH0 pin. The TIM channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIM channel 0 status and control register (TSC0) links channel 0 and channel 1. The TIM channel 0 registers initially control the pulse width on the PTE1/TCH0 pin. Writing to the TIM channel 1 registers enables the TIM channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIM channel registers (0 or 1) that control the pulse width are the ones written to last. TSC0 controls and monitors the buffered PWM function, and TIM channel 1 status and control register (TSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE2/TCH1, is available as a general-purpose I/O pin.

NOTE: *In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered PWM signals.*

11.4.4.3 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use this initialization procedure:

1. In the TIM status and control register (TSC):
 - a. Stop the TIM counter by setting the TIM stop bit, TSTOP.
 - b. Reset the TIM counter by setting the TIM reset bit, TRST.
2. In the TIM counter modulo registers (TMODH:TMODL), write the value for the required PWM period.
3. In the TIM channel x registers (TCHxH:TCHxL), write the value for the required pulse width.

4. In TIM channel x status and control register (TSCx):
 - a. Write 0:1 (for unbuffered output compare or PWM signals) or 1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB:MSxA. (See [Table 11-2.](#))
 - b. Write 1 to the toggle-on-overflow bit, TOVx.
 - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB:ELSxA. The output action on compare must force the output to the complement of the pulse width level. (See [Table 11-2.](#))

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

5. In the TIM status control register (TSC), clear the TIM stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIM channel 0 registers (TCH0H:TCH0L) initially control the buffered PWM output. TIM status control register 0 (TSCR0) controls and monitors the PWM signal from the linked channels. MS0B takes priority over MS0A.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIM overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0% duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and clearing the TOVx bit generates a 100% duty cycle output. (See [11.9.4 TIM Channel Status and Control Registers.](#))

11.5 Interrupts

The following TIM sources can generate interrupt requests:

- TIM overflow flag (TOF) — The TOF bit is set when the TIM counter value rolls over to \$0000 after matching the value in the TIM counter modulo registers. The TIM overflow interrupt enable bit, TOIE, enables TIM overflow CPU interrupt requests. TOF and TOIE are in the TIM status and control register.
- TIM channel flags (CH1F:CH0F) — The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIM CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE. Channel x TIM CPU interrupt requests are enabled when CHxIE = 1. CHxF and CHxIE are in the TIM channel x status and control register.

11.6 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

The TIM remains active after the execution of a WAIT instruction. In wait mode the TIM registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIM can bring the MCU out of wait mode.

If TIM functions are not required during wait mode, reduce power consumption by stopping the TIM before executing the WAIT instruction.

11.7 TIM During Break Interrupts

A break interrupt stops the TIM counter.

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the break flag control register (BFCR) enables software to clear status bits during the break state. (See [8.8.3 Break Flag Control Register](#).)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a 2-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

11.8 I/O Signals

Port E shares three of its pins with the TIM. PTE0/TCLK is an external clock input to the TIM prescaler. The two TIM channel I/O pins are PTE1/TCH0 and PTE2/TCH1.

11.8.1 TIM Clock Pin (PTE0/TCLK)

PTE0/TCLK is an external clock input that can be the clock source for the TIM counter instead of the prescaled internal bus clock. Select the PTE0/TCLK input by writing logic 1s to the three prescaler select bits, PS[2:0]. (See [11.9.1 TIM Status and Control Register](#).) The minimum TCLK pulse width, $TCLK_{L\text{MIN}}$ or $TCLK_{H\text{MIN}}$, is:

$$\frac{1}{\text{bus frequency}} + t_{\text{SU}}$$

The maximum TCLK frequency is:

$$\text{bus frequency} \div 2$$

PTE0/TCLK is available as a general-purpose I/O pin when not used as the TIM clock input. When the PTE0/TCLK pin is the TIM clock input, it is an input regardless of the state of the DDRE0 bit in data direction register E.

11.8.2 TIM Channel I/O Pins (PTE1/TCH0:PTE2/TCH1)

Each channel I/O pin is programmable independently as an input capture pin or an output compare pin. **PTE1/TCH0** can be configured as buffered output compare or buffered PWM pins.

11.9 I/O Registers

The following I/O registers control and monitor operation of the TIM:

- TIM status and control register (TSC)
- TIM control registers (TCNTH:TCNTL)
- TIM counter modulo registers (TMODH:TMODL)
- TIM channel status and control registers (TSC0 and TSC1)
- TIM channel registers (TCH0H:TCH0L and TCH1H:TCH1L)

11.9.1 TIM Status and Control Register

The TIM status and control register:

- Enables TIM overflow interrupts
- Flags TIM overflows
- Stops the TIM counter
- Resets the TIM counter
- Prescales the TIM counter clock

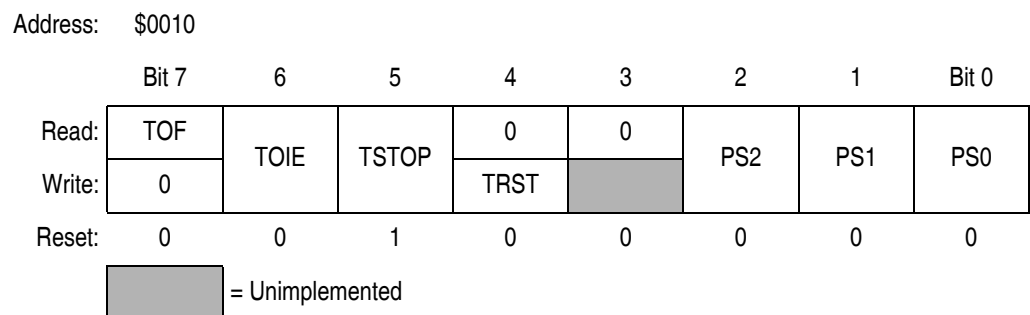

Figure 11-4. TIM Status and Control Register (TSC)

TOF — TIM Overflow Flag Bit

This read/write flag is set when the TIM counter resets to \$0000 after reaching the modulo value programmed in the TIM counter modulo registers. Clear TOF by reading the TIM status and control register when TOF is set and then writing a logic 0 to TOF. If another TIM overflow occurs before the clearing sequence is complete, then writing logic 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a logic 1 to TOF has no effect.

1 = TIM counter has reached modulo value.

0 = TIM counter has not reached modulo value.

TOIE — TIM Overflow Interrupt Enable Bit

This read/write bit enables TIM overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

1 = TIM overflow interrupts enabled.

0 = TIM overflow interrupts disabled.

TSTOP — TIM Stop Bit

This read/write bit stops the TIM counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIM counter until software clears the TSTOP bit.

1 = TIM counter stopped

0 = TIM counter active

NOTE: *Do not set the TSTOP bit before entering wait mode if the TIM is required to exit wait mode.*

TRST — TIM Reset Bit

Setting this write-only bit resets the TIM counter and the TIM prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIM counter is reset and always reads as logic 0. Reset clears the TRST bit.

1 = Prescaler and TIM counter cleared

0 = No effect

NOTE: *Setting the TSTOP and TRST bits simultaneously stops the TIM counter at a value of \$0000.*

PS[2:0] — Prescaler Select Bits

These read/write bits select either the PTE0/TCLK pin or one of the seven prescaler outputs as the input to the TIM counter as [Table 11-1](#) shows. Reset clears the PS[2:0] bits.

Table 11-1. Prescaler Selection

PS[2:0]	TIM Clock Source
000	Internal Bus Clock ÷ 1
001	Internal Bus Clock ÷ 2
010	Internal Bus Clock ÷ 4
011	Internal Bus Clock ÷ 8
100	Internal Bus Clock ÷ 16
101	Internal Bus Clock ÷ 32
110	Internal Bus Clock ÷ 64
111	PTE0/TCLK

11.9.2 TIM Counter Registers

The two read-only TIM counter registers contain the high and low bytes of the value in the TIM counter. Reading the high byte (TCNTH) latches the contents of the low byte (TCNTL) into a buffer. Subsequent reads of TCNTH do not affect the latched TCNTL value until TCNTL is read. Reset clears the TIM counter registers. Setting the TIM reset bit (TRST) also clears the TIM counter registers.

NOTE: *If you read TCNTH during a break interrupt, be sure to unlatch TCNTL by reading TCNTL before exiting the break interrupt. Otherwise, TCNTL retains the value latched during the break.*

Figure 11-5. TIM Counter Registers (TCNTH:TCNTL)

11.9.3 TIM Counter Modulo Registers

The read/write TIM modulo registers contain the modulo value for the TIM counter. When the TIM counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIM counter resumes counting from \$0000 at the next clock. Writing to the high byte (TMODH) inhibits the TOF bit and overflow interrupts until the low byte (TMODL) is written. Reset sets the TIM counter modulo registers.

TMODH Address: \$0014

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8

Reset:	1	1	1	1	1	1	1	1

TMODL Address: \$0015

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Write:								
Reset:	1	1	1	1	1	1	1	1

Figure 11-6. TIM Counter Modulo Registers (TMODH:TMODL)

NOTE: Reset the TIM counter before writing to the TIM counter modulo registers.

11.9.4 TIM Channel Status and Control Registers

Each of the TIM channel status and control registers does the following:

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIM overflow
- Selects 100% PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

TSC0 Address: \$0016

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	CH0F	CH0IE	MS0B	MS0A	ELS0B	ELS0A	TOV0	CH0MAX
Write:	0							
Reset:	0	0	0	0	0	0	0	0

TSC1 Address: \$0019

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	CH1F	CH1IE	0	MS1A	ELS1B	ELS1A	TOV1	CH1MAX
Write:	0							
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 11-7. TIM Channel Status and Control Registers (TSC0:TSC1)

CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIM counter registers matches the value in the TIM channel x registers.

When TIM CPU interrupt requests are enabled (CHxIE = 1), clear CHxF by reading the TIM channel x status and control register with CHxF set and then writing a logic 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing logic 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a logic 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIM CPU interrupt service requests on channel x. Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests enabled
- 0 = Channel x CPU interrupt requests disabled

MSxB — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MSxB exists only in the TIM channel 0 status and control register.

Setting MS0B disables the channel 1 status and control register and reverts TCH1 to general-purpose I/O.

Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

MSxA — Mode Select Bit A

When ELSxB:A ≠ 00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation.

See [Table 11-2](#).

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHx pin. (See [Table 11-2](#).) Reset clears the MSxA bit.

1 = Initial output level low

0 = Initial output level high

NOTE: Before changing a channel function by writing to the MSxB or MSxA bit, set the TSTOP and TRST bits in the TIM status and control register (TSC).

ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port E, and pin PTE_x/TCH_x is available as a general-purpose I/O pin. [Table 11-2](#) shows how ELSxB and ELSxA work. Reset clears the ELSxB and ELSxA bits.

Table 11-2. Mode, Edge, and Level Selection

MSxB:MSxA	ELSxB:ELSxA	Mode	Configuration
X0	00	Output Preset	Pin under Port Control; Initial Output Level High
X1	00		Pin under Port Control; Initial Output Level Low
00	01	Input Capture	Capture on Rising Edge Only
00	10		Capture on Falling Edge Only
00	11		Capture on Rising or Falling Edge
01	01	Output Compare or PWM	Toggle Output on Compare
01	10		Clear Output on Compare
01	11		Set Output on Compare
1X	01	Buffered Output Compare or Buffered PWM	Toggle Output on Compare
1X	10		Clear Output on Compare
1X	11		Set Output on Compare

NOTE: Before enabling a TIM channel register for input capture operation, make sure that the PTE_x/TCH_x pin is stable for at least two bus clocks.

TOV_x — Toggle-On-Overflow Bit

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIM counter overflows. When channel x is an input capture channel, TOV_x has no effect. Reset clears the TOV_x bit.

1 = Channel x pin toggles on TIM counter overflow.

0 = Channel x pin does not toggle on TIM counter overflow.

NOTE: When TOV_x is set, a TIM counter overflow takes precedence over a channel x output compare if both occur at the same time.

CH_xMAX — Channel x Maximum Duty Cycle Bit

When the TOV_x bit is at logic 0, setting the CH_xMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100%. As [Figure 11-8](#) shows, the CH_xMAX bit takes effect in the cycle after it is set or cleared. The output stays at the 100% duty cycle level until the cycle after CH_xMAX is cleared.

Figure 11-8. CH_xMAX Latency

11.9.5 TIM Channel Registers

These read/write registers contain the captured TIM counter value of the input capture function or the output compare value of the output compare function. The state of the TIM channel registers after reset is unknown.

In input capture mode ($MSxB:MSxA = 0:0$), reading the high byte of the TIM channel x registers (TCHxH) inhibits input captures until the low byte (TCHxL) is read.

In output compare mode ($MSxB:MSxA \neq 0:0$), writing to the high byte of the TIM channel x registers (TCHxH) inhibits output compares until the low byte (TCHxL) is written.

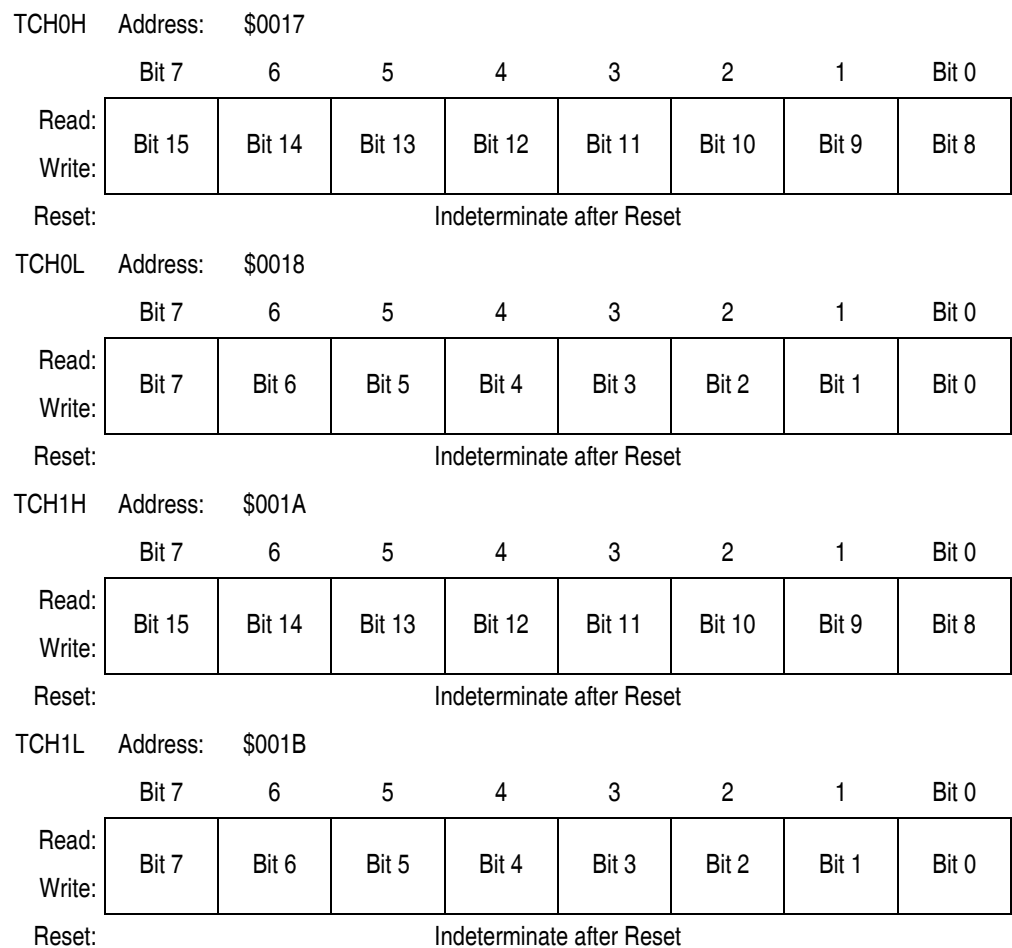

Figure 11-9. TIM Channel Registers (TCH0H/L:TCH1H/L)

12.2 Introduction

Thirty-nine bidirectional input-output (I/O) pins form five parallel ports. All I/O pins are programmable as inputs or outputs.

NOTE: *Connect any unused I/O pins to an appropriate logic level, either V_{DD} or V_{SS} . Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.*

Figure 12-1. I/O Port Register Summary (Continued)

12.3 Port A

Port A is an 8-bit general-purpose bidirectional I/O port with software configurable pullups.

12.3.1 Port A Data Register

The port A data register contains a data latch for each of the eight port A pins.

Address: \$0000

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PTA7	PTA6	PTA5	PTA4	PTA3	PTA2	PTA1	PTA0
Write:								
Reset:	Unaffected by Reset							

Figure 12-2. Port A Data Register (PTA)

PTA[7:0] — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

The port A pullup enable bit, PAP, in the port option control register (POC) enables pullups on port A pins if the respective pin is configured as an input. (See [12.8 Port Options](#).)

12.3.2 Data Direction Register A

Data direction register A determines whether each port A pin is an input or an output. Writing a logic 1 to a DDRA bit enables the output buffer for the corresponding port A pin; a logic 0 disables the output buffer.

Figure 12-3. Data Direction Register A (DDRA)

DDRA[7:0] — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA[7:0], configuring all port A pins as inputs.

1 = Corresponding port A pin configured as output

0 = Corresponding port A pin configured as input

NOTE: Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.

Figure 12-4 shows the port A I/O logic.

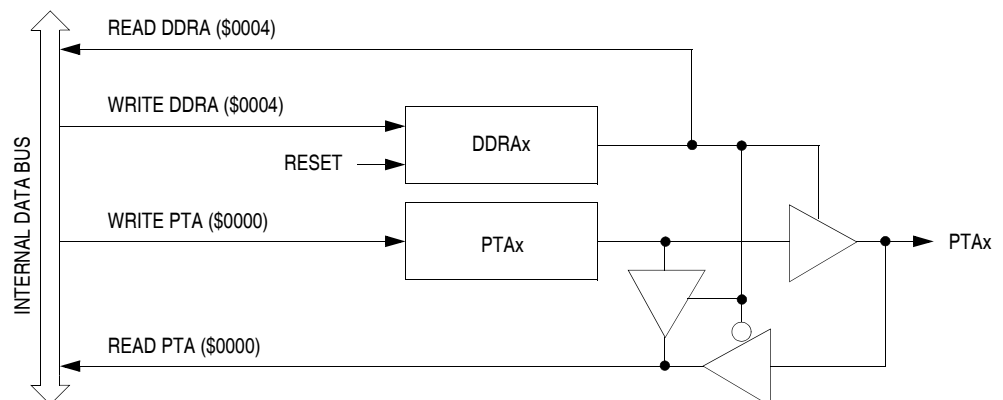

Figure 12-4. Port A I/O Circuit

When bit DDRAx is a logic 1, reading address \$0000 reads the PTAx data latch. When bit DDRAx is a logic 0, reading address \$0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 12-1** summarizes the operation of the port A pins.

Table 12-1. Port A Pin Functions

DDRA Bit	PTA Bit	I/O Pin Mode	Accesses to DDRA	Accesses to PTA	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRA[7:0]	Pin	PTA[7:0] ⁽³⁾
1	X	Output	DDRA[7:0]	PTA[7:0]	PTA[7:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

12.4 Port B

Port B is an 8-bit general-purpose bidirectional I/O port with software configurable pullups.

12.4.1 Port B Data Register

The port B data register contains a data latch for each of the eight port B pins.

Figure 12-5. Port B Data Register (PTB)

PTB[7:0] — Port B Data Bits

These read/write bits are software-programmable. Data direction of each port B pin is under the control of the corresponding bit in data direction register B. Reset has no effect on port B data.

The port B pullup enable bit, PBP, in the port option control register (POC) enables pullups on port B pins if the respective pin is configured as an input. (See [12.8 Port Options](#).)

12.4.2 Data Direction Register B

Data direction register B determines whether each port B pin is an input or an output. Writing a logic 1 to a DDRB bit enables the output buffer for the corresponding port B pin; a logic 0 disables the output buffer.

Figure 12-6. Data Direction Register B (DDRB)

DDRB[7:0] — Data Direction Register B Bits

These read/write bits control port B data direction. Reset clears DDRB[7:0], configuring all port B pins as inputs.

1 = Corresponding port B pin configured as output

0 = Corresponding port B pin configured as input

NOTE: Avoid glitches on port B pins by writing to the port B data register before changing data direction register B bits from 0 to 1.

Figure 12-7 shows the port B I/O logic.

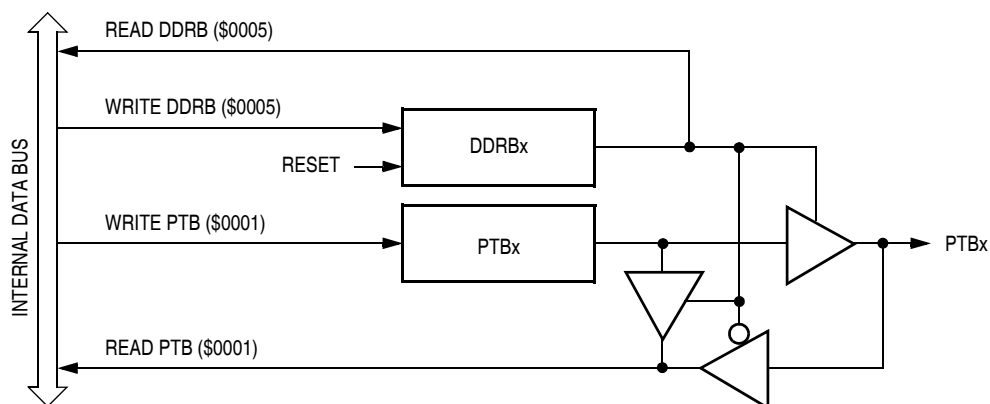

Figure 12-7. Port B I/O Circuit

When bit DDRBx is a logic 1, reading address \$0001 reads the PTBx data latch. When bit DDRBx is a logic 0, reading address \$0001 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 12-2](#) summarizes the operation of the port B pins. NOTES

Table 12-2. Port B Pin Functions

DDRB Bit	PTB Bit	I/O Pin Mode	Accesses to DDRB	Accesses to PTB	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRB[7:0]	Pin	PTB[7:0] ⁽³⁾
1	X	Output	DDRB[7:0]	PTB[7:0]	PTB[7:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

12.5 Port C

Port C is an 8-bit general-purpose bidirectional I/O port with software configurable pullups and current drive options.

12.5.1 Port C Data Register

The port C data register contains a data latch for each of the eight port C pins.

Figure 12-8. Port C Data Register (PTC)

PTC[7:0] — Port C Data Bits

These read/write bits are software-programmable. Data direction of each port C pin is under the control of the corresponding bit in data direction register C. Reset has no effect on port C data.

The LED direct drive bit, LDD, in the port option control register (POC) controls the drive options for port C.

The port C pullup enable bit, PCP, in the port option control register (POC) enables pullups on PTC[7:0] if the respective pin is configured as an input. (See [12.8 Port Options](#).)

12.5.2 Data Direction Register C

Data direction register C determines whether each port C pin is an input or an output. Writing a logic 1 to a DDRC bit enables the output buffer for the corresponding port C pin; a logic 0 disables the output buffer.

Figure 12-9. Data Direction Register C (DDRC)

DDRC[7:0] — Data Direction Register C Bits

These read/write bits control port C data direction. Reset clears DDRC[7:0], configuring all port C pins as inputs.

- 1 = Corresponding port C pin configured as output
- 0 = Corresponding port C pin configured as input

NOTE: *Avoid glitches on port C pins by writing to the port C data register before changing data direction register C bits from 0 to 1.*

Figure 12-10 shows the port C I/O logic.

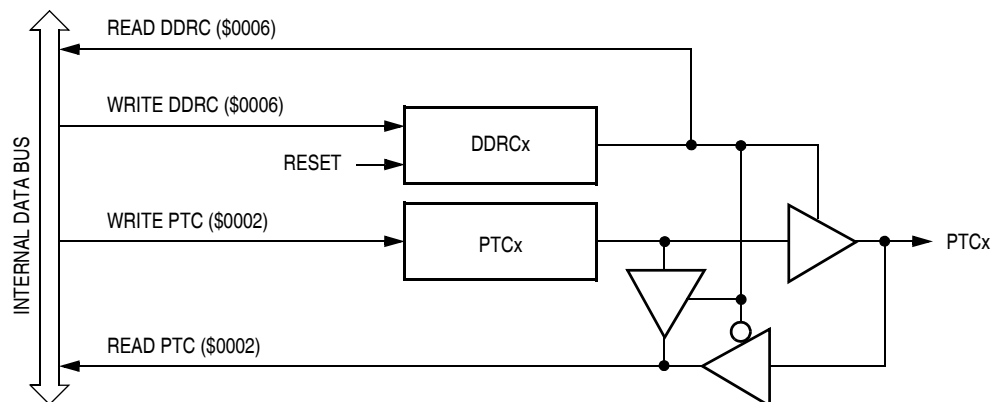

Figure 12-10. Port C I/O Circuit

When bit DDRCx is a logic 1, reading address \$0002 reads the PTCx data latch. When bit DDRCx is a logic 0, reading address \$0002 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 12-3](#) summarizes the operation of the port C pins.

Table 12-3. Port C Pin Functions

DDRC Bit	PTC Bit	I/O Pin Mode	Accesses to DDRC	Accesses to PTC	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRC[7:0]	Pin	PTC[7:0] ⁽³⁾
1	X	Output	DDRC[7:0]	PTC[7:0]	PTC[7:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

12.6 Port D

Port D is an 8-bit general-purpose bidirectional I/O port that shares its pins with the keyboard interrupt module (KBI).

12.6.1 Port D Data Register

The port D data register contains a data latch for each of the eight port D pins.

Figure 12-11. Port D Data Register (PTD)

PTD[7:0] — Port D Data Bits

These read/write bits are software programmable. Data direction of each port D pin is under control of the corresponding bit in data direction register D. Reset has no effect on port D data.

The keyboard interrupt enable bits, KBIE7–KBIE0, in the keyboard interrupt control register (KBICR), enable the port D pins as external interrupt pins. (See [Section 15. Keyboard Interrupt Module \(KBI\)](#).)

12.6.2 Data Direction Register D

Data direction register D determines whether each port D pin is an input or an output. Writing a logic 1 to a DDRD bit enables the output buffer for the corresponding port D pin; a logic 0 disables the output buffer.

Figure 12-12. Data Direction Register D (DDRD)

DDRD[7:0] — Data Direction Register D Bits

These read/write bits control port D data direction. Reset clears DDRD[7:0], configuring all port D pins as inputs.

1 = Corresponding port D pin configured as output

0 = Corresponding port D pin configured as input

NOTE: Avoid glitches on port D pins by writing to the port D data register before changing data direction register D bits from 0 to 1.

Figure 12-13 shows the port D I/O circuit logic.

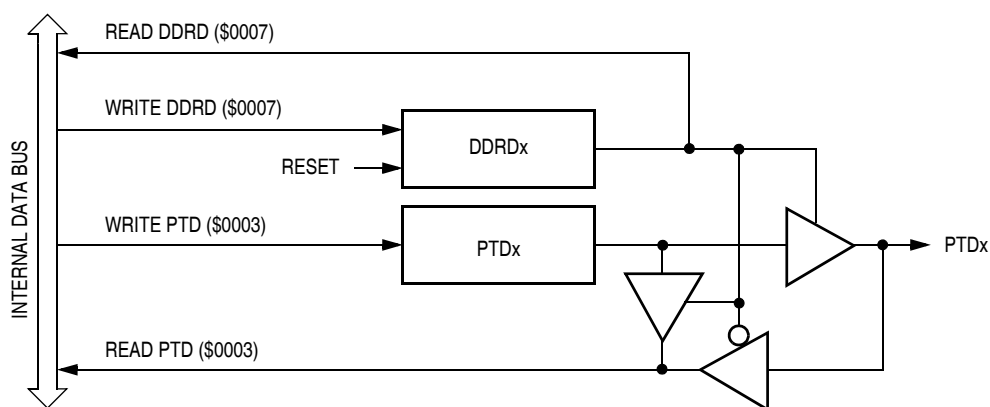

Figure 12-13. Port D I/O Circuit

When bit DDRDx is a logic 1, reading address \$0003 reads the PTDx data latch. When bit DDRDx is a logic 0, reading address \$0003 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 12-4](#) summarizes the operation of the port D pins.

Table 12-4. Port D Pin Functions

DDRD Bit	PTD Bit	I/O Pin Mode	Accesses to DDRD	Accesses to PTD	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRD[7:0]	Pin	PTD[7:0] ⁽³⁾
1	X	Output	DDRD[7:0]	PTD[7:0]	PTD[7:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

12.7 Port E

Port E is a 7-bit special function port that shares three of its pins with the timer interface module (TIM).

12.7.1 Port E Data Register

The port E data register contains a data latch for each of the seven port E pins.

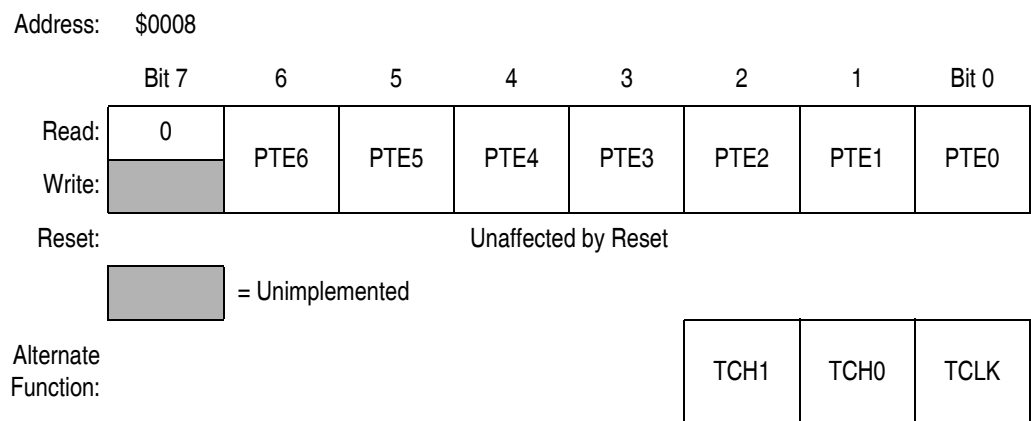

Figure 12-14. Port E Data Register (PTE)

PTE[6:0] — Port E Data Bits

PTE[6:0] are read/write, software-programmable bits. Data direction of each port E pin is under the control of the corresponding bit in data direction register E.

TCH1–TCH0 — Timer Channel I/O Bits

The PE2/TCH1–PE1/TCH0 pins are the TIM input capture/output compare pins. The edge/level select bits, ELSxB and ELSxA, determine whether the PE2/TCH1–PE1/TCH0 pins are timer channel I/O pins or general-purpose I/O pins. (See [Section 11. Timer Interface Module \(TIM\)](#).)

NOTE: *Data direction register E (DDRE) does not affect the data direction of port E pins that are being used by the TIM. However, the DDRE bits always determine whether reading port E returns the states of the latches or the states of the pins.*

TCLK — Timer Clock Input

The PE0/TCLK pin is the external clock input for the TIM. The prescaler select bits, PS2–PS0, selects PE0/TCLK as the TIM clock input. When not selected as the TIM clock, PE0/TCLK is available for general purpose I/O. (See [Section 11. Timer Interface Module \(TIM\)](#).)

12.7.2 Data Direction Register E

Data direction register E determines whether each port E pin is an input or an output. Writing a logic 1 to a DDRE bit enables the output buffer for the corresponding port E pin; a logic 0 disables the output buffer.

Figure 12-15. Data Direction Register E (DDRE)

DDRE[6:0] — Data Direction Register E Bits

These read/write bits control port E data direction. Reset clears DDRE[6:0], configuring all port E pins as inputs.

1 = Corresponding port E pin configured as output

0 = Corresponding port E pin configured as input

NOTE: Avoid glitches on port E pins by writing to the port E data register before changing data direction register E bits from 0 to 1.

Figure 12-16 shows the port E I/O circuit logic.

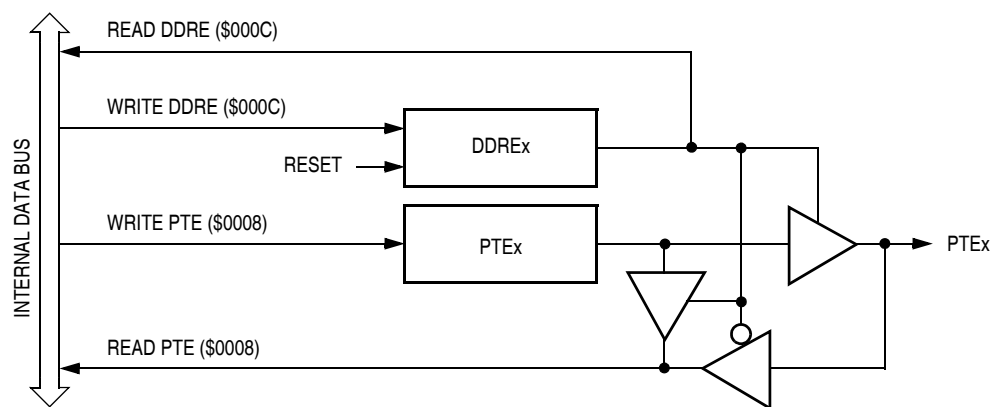

Figure 12-16. Port E I/O Circuit

When bit DDREx is a logic 1, reading address \$0008 reads the PTE_x data latch. When bit DDREx is a logic 0, reading address \$0008 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 12-3](#) summarizes the operation of the port E pins.

Table 12-5. Port E Pin Functions

DDRE Bit	PTE Bit	I/O Pin Mode	Accesses to DDRE	Accesses to PTE	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRE[6:0]	Pin	PTE[6:0] ⁽³⁾
1	X	Output	DDRE[6:0]	PTE[6:0]	PTE[6:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

12.8 Port Options

All pins of port A, port B, and port C have programmable pullup resistors. Port C also has LED drive capability.

12.8.1 Port Option Control Register

The pullup option for each port is controlled by one bit in the port option control register. One bit controls the LED drive configuration on port C.

Address: \$000F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	LDD	0	0	PCP	PBP	PAP
Write:								
Reset:	0	0	1	0	0	0	0	0

= Unimplemented

Figure 12-17. Port Option Control Register (POC)

LDD — LED Direct Drive Control

This read/write bit controls the output current capability of port C. When set, the port C pins have current limiting ability so that an LED can be connected directly between the port pin and V_{DD} or V_{SS} without the need of a series resistor.

- 1 = When respective port is configured as an output, make port C become current, limiting 3 mA source/10 mA sink port pins.
- 0 = Configure port C to become standard I/O port pins.

PCP — Port C Pullup Enable

This read/write bit controls the pullup option for port C[7:0] if its respective port pin is configured as an input.

- 1 = Configure port C to have internal pullups.
- 0 = Disconnect port C internal pullups.

PBP — Port B Pullup Enable

This read/write bit controls the pullup option for the eight bits of port B if its respective port pin is configured as an input.

1 = Configure port B to have internal pullups.

0 = Disconnect port B internal pullups.

PAP — Port A Pullup Enable

This read/write bit controls the pullup option for the eight bits of port A if its respective port pin is configured as an input.

1 = Configure port A to have internal pullups.

0 = Disconnect port A internal pullups.

13.8.2	Stop Mode.	208
13.9	COP Module During Break Mode	208

13.2 Introduction

This COP module contains a free-running counter that generates a reset if allowed to overflow. The COP module helps software recover from runaway code. Prevent a COP reset by clearing the COP counter periodically.

13.3 Functional Description

Figure 13-1 shows the structure of the COP module.

NOTE:

1. See [Section 8. System Integration Module \(SIM\)](#) for more details.

Figure 13-1. COP Block Diagram

Addr.	Register Name	Bit 7	6	5	4	3	2	1	Bit 0
\$FFFF	COP Control Register (COPCTL)	Read: Low Byte of Reset Vector							
		Write: Writing Clears COP Counter (Any Value)							
		Reset: Unaffected by Reset							

Figure 13-2. COP I/O Register Summary

The COP counter is a free-running 6-bit counter preceded by a 12-bit prescaler counter. If not cleared by software, the COP counter overflows and generates an asynchronous reset after $2^{18} - 2^4$ or $2^{13} - 2^4$ CGMXCLK cycles, depending on the state of the COP rate select bit, COPRS in the configuration register. When COPRS = 0, a 4.9152-MHz crystal gives a COP timeout period is 53.3 ms. Writing any value to location \$FFFF before an overflow occurs prevents a COP reset by clearing the COP counter and stages 12 through 5 of the SIM counter.

NOTE: *Service the COP immediately after reset and before entering or after exiting stop mode to guarantee the maximum time before the first COP counter overflow.*

A COP reset pulls the $\overline{\text{RST}}$ pin low for 32 CGMXCLK cycles and sets the COP bit in the reset status register (RSR).

In monitor mode, the COP is disabled if the $\overline{\text{RST}}$ pin or the $\overline{\text{IRQ1}}/V_{\text{PP}}$ is held at V_{TST} . During the break state, V_{TST} on the $\overline{\text{RST}}$ pin disables the COP.

NOTE: *Place COP clearing instructions in the main program and not in an interrupt subroutine. Such an interrupt subroutine could keep the COP from generating a reset even while the main program is not working properly.*

13.4 I/O Signals

The following paragraphs describe the signals shown in [Figure 13-1](#).

13.4.1 CGMXCLK

CGMXCLK is the crystal oscillator output signal. CGMXCLK frequency is equal to the crystal frequency.

13.4.2 STOP Instruction

The STOP instruction clears the COP prescaler.

13.4.3 COPCTL Write

Writing any value to the COP control register (COPCTL) (see [13.5 COP Control Register](#)) clears the COP counter and clears bits 12 through 4 of the SIM counter. Reading the COP control register returns the low byte of the reset vector.

13.4.4 Power-On Reset

The power-on reset (POR) circuit in the SIM clears the COP prescaler 4096 OSCXCLK cycles after power-up.

13.4.5 Internal Reset

An internal reset clears the SIM counter and the COP counter.

13.4.6 Reset Vector Fetch

A reset vector fetch occurs when the vector address appears on the data bus. A reset vector fetch clears the COP prescaler.

13.4.7 COPD (COP Disable)

The COPD signal reflects the state of the COP disable bit (COPD) in the configuration register (CONFIG). (See [Section 5. Configuration Register \(CONFIG\)](#).)

13.4.8 COPRS (COP Rate Select)

The COPRS signal reflects the state of the COP rate select bit (COPRS) in the configuration register (CONFIG).

13.5 COP Control Register

The COP control register is located at address \$FFFF and overlaps the reset vector. Writing any value to \$FFFF clears the COP counter and starts a new timeout period. Reading location \$FFFF returns the low byte of the reset vector.

\$FFFF	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Low Byte of Reset Vector							
Write:	Clear COP Counter							
Reset:	Unaffected by Reset							

Figure 13-3. COP Control Register (COPCTL)

13.6 Interrupts

The COP does not generate CPU interrupt requests.

13.7 Monitor Mode

The COP is disabled in monitor mode when V_{TST} is present on the $\overline{IRQ1}/V_{PP}$ pin or on the \overline{RST} pin.

13.8 Low-Power Modes

The WAIT and STOP instructions put the MCU in low-power consumption standby modes.

13.8.1 Wait Mode

The COP remains active during wait mode. To prevent a COP reset during wait mode, periodically clear the COP counter in a CPU interrupt routine.

13.8.2 Stop Mode

Stop mode turns off the CGMXCLK input to the COP and clears the COP prescaler. Service the COP immediately before entering or after exiting stop mode to ensure a full COP timeout period after entering or exiting stop mode.

The STOP bit in the configuration register (CONFIG) enables the STOP instruction. To prevent inadvertently turning off the COP with a STOP instruction, disable the STOP instruction by clearing the STOP bit.

13.9 COP Module During Break Mode

The COP is disabled during a break interrupt when V_{TST} is present on the \overline{RST} pin.

Section 14. External Interrupt (IRQ)

14.1 Contents

14.2	Introduction	209
14.3	Features	210
14.4	Functional Description	210
14.5	$\overline{\text{IRQ1}}/V_{PP}$ Pin	213
14.6	IRQ Module During Break Interrupts	214
14.7	IRQ Status and Control Register	215

14.2 Introduction

The IRQ module provides an external interrupt input.

14.3 Features

Features of the IRQ module include:

- A Dedicated External Interrupt Pin, $\overline{\text{IRQ1}}/V_{\text{PP}}$
- IRQ1 Interrupt Control Bits
- Hysteresis Buffer
- Programmable Edge-Only or Edge and Level Interrupt Sensitivity
- Automatic Interrupt Acknowledge
- $\overline{\text{IRQ1}}/V_{\text{PP}}$ Pin Includes Internal Pullup Resistor

14.4 Functional Description

A logic 0 applied to the external interrupt pin can latch a CPU interrupt request. [Figure 14-1](#) shows the structure of the IRQ module.

Interrupt signals on the $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin are latched into the IRQ1 latch. An interrupt latch remains set until one of the following actions occurs:

- Vector fetch — A vector fetch automatically generates an interrupt acknowledge signal that clears the IRQ latch.
- Software clear — Software can clear the interrupt latch by writing to the acknowledge bit in the interrupt status and control register (ISCR). Writing a logic 1 to the ACK1 bit clears the IRQ1 latch.
- Reset — A reset automatically clears the interrupt latch.

The external interrupt pin is falling-edge-triggered and is software-configurable to be either falling-edge or low-level-triggered. The MODE1 bit in the ISCR controls the triggering sensitivity of the $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin.

When the interrupt pin is edge-triggered only, the CPU interrupt request remains set until a vector fetch, software clear, or reset occurs.

When the interrupt pin is both falling-edge and low-level-triggered, the CPU interrupt request remains set until both of the following occur:

- Vector fetch or software clear
- Return of the interrupt pin to logic 1

The vector fetch or software clear may occur before or after the interrupt pin returns to logic 1. As long as the pin is low, the interrupt request remains pending. A reset will clear the latch and the MODE1 control bit, thereby clearing the interrupt even if the pin stays low.

When set, the IMASK1 bit in the ISCR mask all external interrupt requests. A latched interrupt request is not presented to the interrupt priority logic unless the IMASK1 bit is clear.

NOTE: The interrupt mask (I) in the condition code register (CCR) masks all interrupt requests, including external interrupt requests. (See [8.6 Exception Control](#).)

Figure 14-2. IRQ I/O Register Summary

14.5 $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ Pin

A logic 0 on the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin can latch an interrupt request into the IRQ1 latch. A vector fetch, software clear, or reset clears the IRQ1 latch.

If the MODE1 bit is set, the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin is both falling-edge-sensitive and low-level-sensitive. With MODE1 set, both of the following actions must occur to clear IRQ1:

- Vector fetch or software clear — A vector fetch generates an interrupt acknowledge signal to clear the latch. Software may generate the interrupt acknowledge signal by writing a logic 1 to the ACK1 bit in the interrupt status and control register (ISCR). The ACK1 bit is useful in applications that poll the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin and require software to clear the IRQ1 latch. Writing to the ACK1 bit prior to leaving an interrupt service routine can also prevent spurious interrupts due to noise. Setting ACK1 does not affect subsequent transitions on the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin. A falling edge that occurs after writing to the ACK1 bit latches another interrupt request. If the IRQ1 mask bit, IMASK1, is clear, the CPU loads the program counter with the vector address at locations \$FFFA and \$FFFB.
- Return of the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin to logic 1 — As long as the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin is at logic 0, IRQ1 remains active.

The vector fetch or software clear and the return of the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin to logic 1 may occur in any order. The interrupt request remains pending as long as the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin is at logic 0. A reset will clear the latch and the MODE1 control bit, thereby clearing the interrupt even if the pin stays low.

If the MODE1 bit is clear, the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin is falling-edge-sensitive only. With MODE1 clear, a vector fetch or software clear immediately clears the IRQ1 latch.

The IRQF1 bit in the ISCR register can be used to check for pending interrupts. The IRQF1 bit is not affected by the IMASK1 bit, which makes it useful in applications where polling is preferred.

Use the BIH or BIL instruction to read the logic level on the $\overline{\text{IRQ1}}/\text{V}_{\text{PP}}$ pin.

NOTE: *When using the level-sensitive interrupt trigger, avoid false interrupts by masking interrupt requests in the interrupt routine.*

14.6 IRQ Module During Break Interrupts

The system integration module (SIM) controls whether the IRQ1 latch can be cleared during the break state. The BCFE bit in the break flag control register (BFGR) enables software to clear the latches during the break state. (See [Section 8. System Integration Module \(SIM\)](#).)

To allow software to clear the IRQ1 latch during a break interrupt, write a logic 1 to the BCFE bit. If a latch is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the latches during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), writing to the ACK1 bit in the IRQ status and control register during the break state has no effect on the IRQ latch.

14.7 IRQ Status and Control Register

The IRQ status and control register (ISCR) controls and monitors operation of the IRQ module. The ISCR has the following functions:

- Shows the state of the IRQ1 flag
- Clears the IRQ1 latch
- Masks IRQ1 and interrupt request
- Controls triggering sensitivity of the $\overline{\text{IRQ1}}/V_{\text{PP}}$ interrupt pin

Address: \$001E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	IRQF1	0	IMASK1	MODE1
Write:						ACK1		
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 14-3. IRQ Status and Control Register (ISCR)

IRQF1 — IRQ1 Flag

This read-only status bit is high when the IRQ1 interrupt is pending.

- 1 = $\overline{\text{IRQ1}}$ interrupt pending
- 0 = $\overline{\text{IRQ1}}$ interrupt not pending

ACK1 — IRQ1 Interrupt Request Acknowledge Bit

Writing a logic 1 to this write-only bit clears the IRQ1 latch. ACK1 always reads as logic 0. Reset clears ACK1.

IMASK1 — IRQ1 Interrupt Mask Bit

Writing a logic 1 to this read/write bit disables IRQ1 interrupt requests. Reset clears IMASK1.

- 1 = IRQ1 interrupt requests disabled
- 0 = IRQ1 interrupt requests enabled

MODE1 — IRQ1 Edge/Level Select Bit

This read/write bit controls the triggering sensitivity of the $\overline{\text{IRQ1}}/V_{\text{PP}}$ pin. Reset clears MODE1.

- 1 = $\overline{\text{IRQ1}}/V_{\text{PP}}$ interrupt requests on falling edges and low levels
- 0 = $\overline{\text{IRQ1}}/V_{\text{PP}}$ interrupt requests on falling edges only

15.2 Introduction

The keyboard module provides eight independently maskable external interrupts.

15.3 Features

Features of the keyboard interrupt module (KBI) include:

- Eight Keyboard Interrupt Pins with Separate Keyboard Interrupt Enable Bits and One Keyboard Interrupt Mask
- Hysteresis Buffers
- Programmable Edge-Only or Edge- and Level-Interrupt Sensitivity
- Exit from Low-Power Modes

Figure 15-2. I/O Register Summary

15.4 Functional Description

Writing to the KBIE7–KBIE0 bits in the keyboard interrupt enable register independently enables or disables each port D pin as a keyboard interrupt pin. Enabling a keyboard interrupt pin also enables its internal pullup device. A logic 0 applied to an enabled keyboard interrupt pin latches a keyboard interrupt request.

A keyboard interrupt is latched when one or more keyboard pins goes low after all were high. The MODEK bit in the keyboard status and control register controls the triggering mode of the keyboard interrupt.

- If the keyboard interrupt is edge-sensitive only, a falling edge on a keyboard pin does not latch an interrupt request if another keyboard pin is already low. To prevent losing an interrupt request on one pin because another pin is still low, software can disable the latter pin while it is low.
- If the keyboard interrupt is falling edge- and low level-sensitive, an interrupt request is present as long as any keyboard pin is low.

If the MODEK bit is set, the keyboard interrupt pins are both falling edge- and low level-sensitive, and both of the following actions must occur to clear a keyboard interrupt request:

- Vector fetch or software clear — A vector fetch generates an interrupt acknowledge signal to clear the interrupt request. Software may generate the interrupt acknowledge signal by writing a logic 1 to the ACKK bit in the keyboard status and control register (KBSCR). The ACKK bit is useful in applications that poll the keyboard interrupt pins and require software to clear the keyboard interrupt request. Writing to the ACKK bit prior to leaving an interrupt service routine also can prevent spurious interrupts due to noise. Setting ACKK does not affect subsequent transitions on the keyboard interrupt pins. A falling edge that occurs after writing to the ACKK bit latches another interrupt request. If the keyboard interrupt mask bit, IMASKK, is clear, the CPU loads the program counter with the vector address at locations \$FFF0 and \$FFF1.

- Return of all enabled keyboard interrupt pins to logic 1 — As long as any enabled keyboard interrupt pin is at logic 0, the keyboard interrupt remains set.

The vector fetch or software clear and the return of all enabled keyboard interrupt pins to logic 1 may occur in any order.

If the MODEK bit is clear, the keyboard interrupt pin is falling-edge-sensitive only. With MODEK clear, a vector fetch or software clear immediately clears the keyboard interrupt request.

Reset clears the keyboard interrupt request and the MODEK bit, clearing the interrupt request even if a keyboard interrupt pin stays at logic 0.

The keyboard flag bit (KEYF) in the keyboard status and control register can be used to see if a pending interrupt exists. The KEYF bit is not affected by the keyboard interrupt mask bit (IMASKK) which makes it useful in applications where polling is preferred.

To determine the logic level on a keyboard interrupt pin, use the data direction register to configure the pin as an input and read the data register.

NOTE: *Setting a keyboard interrupt enable bit (KBIE_x) forces the corresponding keyboard interrupt pin to be an input, overriding the data direction register. However, the data direction register bit must be a logic 0 for software to read the pin.*

15.5 Keyboard Initialization

When a keyboard interrupt pin is enabled, it takes time for the internal pullup to reach a logic 1. Therefore, a false interrupt can occur as soon as the pin is enabled.

To prevent a false interrupt on keyboard initialization:

1. Mask keyboard interrupts by setting the IMASKK bit in the keyboard status and control register.
2. Enable the KBI pins by setting the appropriate KBIE_x bits in the keyboard interrupt enable register.

3. Write to the ACKK bit in the keyboard status and control register to clear any false interrupts.
4. Clear the IMASKK bit.

An interrupt signal on an edge-triggered pin can be acknowledged immediately after enabling the pin. An interrupt signal on an edge- and level-triggered interrupt pin must be acknowledged after a delay that depends on the external load.

Another way to avoid a false interrupt:

1. Configure the keyboard pins as outputs by setting the appropriate DDRD bits in data direction register D.
2. Write logic 1s to the appropriate port D data register bits.
3. Enable the KBI pins by setting the appropriate KBIE_x bits in the keyboard interrupt enable register.

15.6 Low-Power Modes

The WAIT and STOP instructions put the MCU in low-power-consumption standby modes.

15.6.1 Wait Mode

The keyboard module remains active in wait mode. Clearing the IMASKK bit in the keyboard status and control register enables keyboard interrupt requests to bring the MCU out of wait mode.

15.6.2 Stop Mode

The keyboard module remains active in stop mode. Clearing the IMASKK bit in the keyboard status and control register enables keyboard interrupt requests to bring the MCU out of stop mode.

15.7 Keyboard Module During Break Interrupts

The system integration module (SIM) controls whether the keyboard interrupt latch can be cleared during the break state. The BCFE bit in the break flag control register (BF CR) enables software to clear status bits during the break state.

To allow software to clear the keyboard interrupt latch during a break interrupt, write a logic 1 to the BCFE bit. If a latch is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the latch during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), writing to the keyboard acknowledge bit (ACKK) in the keyboard status and control register during the break state has no effect. (See [15.8.1 Keyboard Status and Control Register](#).)

15.8 I/O Registers

These registers control and monitor operation of the keyboard module:

- Keyboard status and control register (KBSCR)
- Keyboard interrupt enable register (KBIER)

15.8.1 Keyboard Status and Control Register

The keyboard status and control register:

- Flags keyboard interrupt requests
- Acknowledges keyboard interrupt requests
- Masks keyboard interrupt requests
- Controls keyboard interrupt triggering sensitivity

Address: \$000D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	KEYF	0	IMASKK	MODEK
Write:						ACKK		
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 15-3. Keyboard Status and Control Register (KBSCR)

Bits 7–4 — Not used

These read-only bits always read as logic 0s.

KEYF — Keyboard Flag Bit

This read-only bit is set when a keyboard interrupt is pending. Reset clears the KEYF bit.

1 = Keyboard interrupt pending

0 = No keyboard interrupt pending

ACKK — Keyboard Acknowledge Bit

Writing a logic 1 to this write-only bit clears the keyboard interrupt request. ACKK always reads as logic 0. Reset clears ACKK.

IMASKK — Keyboard Interrupt Mask Bit

Writing a logic 1 to this read/write bit prevents the output of the keyboard interrupt mask from generating interrupt requests. Reset clears the IMASKK bit.

1 = Keyboard interrupt requests masked

0 = Keyboard interrupt requests not masked

MODEK — Keyboard Triggering Sensitivity Bit

This read/write bit controls the triggering sensitivity of the keyboard interrupt pins. Reset clears MODEK.

1 = Keyboard interrupt requests on falling edges and low levels

0 = Keyboard interrupt requests on falling edges only

15.8.2 Keyboard Interrupt Enable Register

The keyboard interrupt enable register enables or disables each port D pin to operate as a keyboard interrupt pin.

Address: \$000E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	KBIE7	KBIE6	KBIE5	KBIE4	KBIE3	KBIE2	KBIE1	KBIE0

16.6.2	Stop Mode.	230

16.2 Introduction

This section describes the break module. The break module can generate a break interrupt that stops normal program flow at a defined address to enter a background program.

16.3 Features

Features of the break module include the following:

- Accessible I/O Registers during the Break Interrupt
- CPU-Generated Break Interrupts
- Software-Generated Break Interrupts
- COP Disabling during Break Interrupts

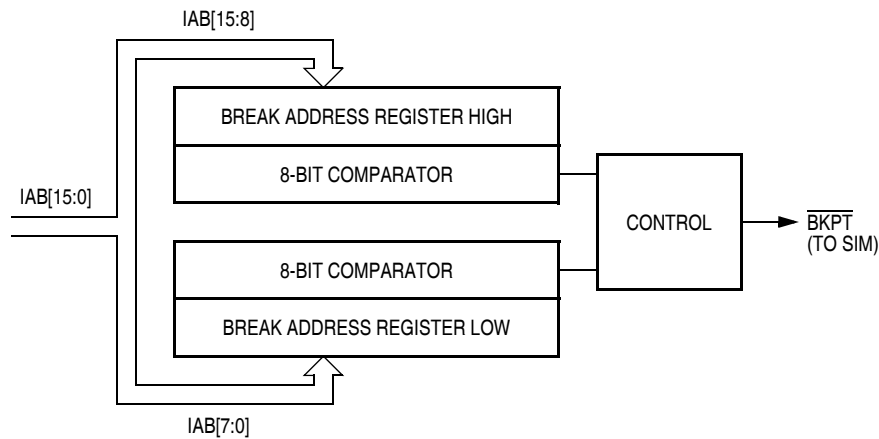

16.4 Functional Description

When the internal address bus matches the value written in the break address registers, the break module issues a breakpoint signal ($\overline{\text{BKPT}}$) to the SIM. The SIM then causes the CPU to load the instruction register with a software interrupt instruction (SWI) after completion of the current CPU instruction. The program counter vectors to \$FFFC and \$FFFD (\$FEFC and \$FEFD in monitor mode).

These events can cause a break interrupt to occur:

- A CPU-generated address (the address in the program counter) matches the contents of the break address registers.
- Software writes a logic 1 to the BRKA bit in the break status and control register.

When a CPU-generated address matches the contents of the break address registers, the break interrupt begins after the CPU completes its current instruction. A return-from-interrupt instruction (RTI) in the break routine ends the break interrupt and returns the MCU to normal operation. [Figure 16-1](#) shows the structure of the break module.

Figure 16-1. Break Module Block Diagram

Figure 16-2. Break I/O Register Summary

16.4.1 Flag Protection During Break Interrupts

The system integration module (SIM) controls whether or not module status bits can be cleared during the break state. The BCFE bit in the break flag control register (BFCR) enables software to clear status bits during the break state. (See [8.8.3 Break Flag Control Register](#) and see the break interrupts subsection for each module.)

16.4.2 CPU During Break Interrupts

The CPU starts a break interrupt by:

- Loading the instruction register with the SWI instruction
- Loading the program counter with \$FFFC:\$FFFD (\$FEFC:\$FEFD in monitor mode)

The break interrupt begins after completion of the CPU instruction in progress. If the break address register match occurs on the last cycle of a CPU instruction, the break interrupt begins immediately.

16.4.3 TIM During Break Interrupts

A break interrupt stops the timer counter.

16.4.4 COP During Break Interrupts

The COP is disabled during a break interrupt when V_{TST} is present on the \overline{RST} pin.

16.5 Break Module Registers

Three registers control and monitor operation of the break module:

- Break status and control register (BRKSCR)
- Break address register high (BRKH)
- Break address register low (BRKL)

16.5.1 Break Status and Control Register

The break status and control register contains break module enable and status bits.

Address: \$FE0E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	BRKE	BRKA	0	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 16-3. Break Status and Control Register (BRKSCR)

BRKE — Break Enable Bit

This read/write bit enables breaks on break address register matches. Clear BRKE by writing a logic 0 to bit 7. Reset clears the BRKE bit.

- 1 = Breaks enabled on 16-bit address match
- 0 = Breaks disabled

BRKA — Break Active Bit

This read/write status and control bit is set when a break address match occurs. Writing a logic 1 to BRKA generates a break interrupt. Clear BRKA by writing a logic 0 to it before exiting the break routine. Reset clears the BRKA bit.

- 1 = Break address match
- 0 = No break address match

16.5.2 Break Address Registers

The break address registers contain the high and low bytes of the desired breakpoint address. Reset clears the break address registers.

BRKH Address: \$FE0C

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 15	14	13	12	11	10	9	Bit 8
Write:								
Reset:	0	0	0	0	0	0	0	0

BRKL Address: \$FE0D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 7	6	5	4	3	2	1	Bit 0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 16-4. Break Address Registers (BRKH and BRKL)

16.6 Low-Power Modes

The WAIT and STOP instructions put the MCU in low-power-consumption standby modes.

16.6.1 Wait Mode

If enabled, the break module is active in wait mode. In the break routine, the user can subtract one from the return address on the stack if SBSW is set (see [8.7 Low-Power Modes](#)). Clear the SBSW bit by writing logic 0 to it.

16.6.2 Stop Mode

A break interrupt causes exit from stop mode and sets the SBSW bit in the break status register. See [8.8 SIM Registers](#).

17.2 Introduction

This section contains electrical and timing specifications. These values are design targets and have not yet been fully tested.

17.3 Absolute Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

The MCU contains circuitry to protect the inputs against damage from high static voltages; however, do not apply voltages higher than those shown in the table. Keep V_{IN} and V_{Out} within the range $V_{SS} \leq (V_{IN} \text{ or } V_{Out}) \leq V_{DD}$. Connect unused inputs to the appropriate voltage level, either V_{SS} or V_{DD} .

Characteristic ⁽¹⁾	Symbol	Value	Unit
Supply Voltage	V_{DD}, V_{DDREG}	-0.3 to +6.0	V
Regulator Supply Voltage	V_{DDREG}	-0.3 to +6.0	V
Input Voltage	V_{IN}	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
Programming Voltage	V_{PP}	$V_{SS} - 0.3$ to 14.0	V
Maximum Current Per Pin Excluding V_{DD} and V_{SS}	I	± 25	mA
Storage Temperature	T_{STG}	-55 to +150	°C
Maximum Current Out of V_{SS}	I_{MVSS}	100	mA
Maximum Current Into V_{DD}	I_{MVDD}	100	mA

1. Voltages referenced to V_{SS}

NOTE: *This device is not guaranteed to operate properly at the maximum ratings. Refer to [17.6 DC Electrical Characteristics](#) for guaranteed operating conditions.*

17.4 Functional Operating Range

Characteristic	Symbol	Value	Unit
Operating Temperature Range	T_A	0 to 85	°C
Operating Voltage Range	V_{DD}	4.4 to 5.5	V
Operating Regulator Voltage Range – Bypass Not Enabled – Bypass Enabled	V_{DDREG}	4.4 to 5.5 3.0 to 3.6	V

17.5 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal Resistance Quad Flat Pack, 52 Pins	θ_{JA}	70	°C/W
I/O Pin Power Dissipation	$P_{I/O}$	User Determined	W
Power Dissipation ⁽¹⁾	P_D	$P_D = (I_{DD} \times V_{DD}) + P_{I/O} =$ $K / (T_J + 273 \text{ }^\circ\text{C})$	W
Constant ⁽²⁾	K	$P_D \times (T_A + 273 \text{ }^\circ\text{C})$ $+ P_D^2 \times \theta_{JA}$	W/°C
Average Junction Temperature	T_J	$T_A + (P_D \times \theta_{JA})$	°C
Maximum Junction Temperature	T_{JM}	100	°C

1. Power dissipation is a function of temperature.
2. K is a constant unique to the device. K can be determined for a known T_A and measured P_D .
With this value of K, P_D and T_J can be determined for any value of T_A .

17.6 DC Electrical Characteristics

Characteristic ⁽¹⁾	Symbol	Min	Typ ⁽²⁾	Max	Unit	
Output High Voltage ($I_{Load} = -2.0$ mA) All I/O Pins	V_{OH}	$V_{DD} - 0.8$	—	—	V	
Output Low Voltage ($I_{Load} = 1.6$ mA) All I/O Pins	V_{OL}	—	—	0.4	V	
Input High Voltage All Ports, $\overline{IRQ1}/V_{PP}$, \overline{RST} , OSC1	V_{IH}	$0.7 \times V_{DD}$	—	V_{DD}	V	
Input Low Voltage All Ports, $\overline{IRQ1}/V_{PP}$, \overline{RST} , OSC1	V_{IL}	V_{SS}	—	$0.3 \times V_{DD}$	V	
Output High Current ($V_{OH} = 2.1$ V) Port C in LDD Mode	I_{OH}	2.5	4.6	7	mA	
Output Low Current ($V_{OL} = 2.3$ V) Port C in LDD Mode	I_{OL}	7	13.2	20	mA

Run, USB Suspended ⁽³⁾			3.75	5.0	mA	
Wait, Low Speed USB ⁽⁴⁾			2.25	3.5	mA	
Wait, USB Suspended ⁽⁴⁾			1.75	3.0	mA	
Stop ⁽⁵⁾			—	—	—	—
25 °C			180	225	μA	
0 °C to 85 °C	190	250	μA			
I/O Ports Hi-Z Leakage Current	I_{IL}	—	—	± 10	μA	
Input Current	I_{IN}	—	—	± 1	μA	
Capacitance Ports (as Input or Output)	C_{Out} C_{In}	— —	— —	12 8	pF	
POR ReArm Voltage ⁽⁶⁾	V_{POR}	0	—	100	mV	
POR Rise Time Ramp Rate ⁽⁷⁾	R_{POR}	0.035	—	—	V/ms	
Monitor Mode Entry Voltage	V_{TST}	$V_{DD} + 2.5$	—	13.5	V	
Pullup Resistor PA0–PA7, PB0–PB7, PC0–PC7, PD0–PD7, \overline{RST} , $\overline{IRQ1}/V_{PP}$	R_{PU}	20	35	50	kΩ	

- $V_{DD} = V_{DDREG} = 4.4$ to 5.5 Vdc, $V_{SS} = 0$ Vdc, $T_A = T_L$ to T_H , unless otherwise noted.
- Typical values reflect average measurements at midpoint of voltage range, 25 °C only.
- Run (operating) I_{DD} measured using external square wave clock source ($f_{XCLK} = 6$ MHz). All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. $C_L = 20$ pF on OSC2. All ports configured as inputs. OSC2 capacitance linearly affects run I_{DD} . Measured with all modules enabled.
- Wait I_{DD} measured using external square wave clock source ($f_{XCLK} = 6$ MHz); all inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. $C_L = 20$ pF on OSC2; 15 kΩ ± 5% termination resistors on D+ and D– pins; all ports configured as inputs; OSC2 capacitance linearly affects wait I_{DD}
- STOP I_{DD} measured with USB in suspend mode; OSC1 grounded; REGOUT, D+, and D– not connected; no port pins sourcing current.
- Maximum is highest voltage that POR is guaranteed.
- If minimum V_{DD} is not reached before the internal POR reset is released, \overline{RST} must be driven low externally until minimum V_{DD} is reached.

17.7 Control Timing

Characteristic ⁽¹⁾	Symbol	Min	Max	Unit
Internal Operating Frequency ⁽²⁾	f_{OP}	—	1.5	MHz
RST Input Pulse Width Low ⁽³⁾	t_{IRL}	50	—	ns

- $V_{DD} = V_{DDREG} = 4.4$ to 5.5 Vdc; $V_{SS} = 0$ Vdc; timing shown with respect to 20% V_{DD} and 70% V_{DD} , unless otherwise noted.
- Some modules may require a minimum frequency greater than dc for proper operation; see appropriate table for this information.
- Minimum pulse width reset is guaranteed to be recognized. It is possible for a smaller pulse width to cause a reset.

17.8 Oscillator Characteristics

Characteristic	Symbol	Min	Typ	Max	Unit
Crystal Frequency ⁽¹⁾	f_{XCLK}	1	—	8	MHz
External Clock Reference Frequency ^{(1), (2)}	f_{XCLK}	dc	—	32	MHz
Crystal Load Capacitance ⁽³⁾	C_L	—	—	—	
Crystal Fixed Capacitance ⁽³⁾	C_1	—	$2 \times C_L$	—	
Crystal Tuning Capacitance ⁽³⁾	C_2	—	$2 \times C_L$	—	
Feedback Bias Resistor	R_B	—	10 M Ω	—	
Series Resistor ^{(3), (4)}	R_S	—	—	—	

- The USB module is designed to function at $f_{XCLK} = 6$ MHz. The values given here are oscillator specifications.
- No more than 10% duty cycle deviation from 50%
- Consult crystal vendor data sheet
- Not required for high-frequency crystals

17.9 USB DC Electrical Characteristics

Characteristic ⁽¹⁾	Symbol	Conditions	Min	Typ	Max	Unit
Hi-Z State Data Line Leakage	I_{LO}	$0 V < V_{In} < 3.3 V$	-10		+10	μA
Differential Input Sensitivity	V_{DI}	$ (D+) - (D-) $	0.2			V
Differential Common Mode Range	V_{CM}	Includes V_{DI} Range	0.8		2.5	V
Single Ended Receiver Threshold	V_{SE}		0.8		2.0	V
Static Output Low	V_{OL}	R_L of 1.5 k to 3.6 V			0.3	V
Static Output High	V_{OH}	R_L of 15 k to GND	2.8		3.6	V
Regulator Supply Voltage ^{(2), (3)}	V_{REGOUT}	$I_L = 4 mA$	3.0	3.3	3.6	V
Regulator Bypass Capacitor	$C_{REGBYPASS}$			0.1		μF
Regulator Bulk Capacitor	$C_{REGBULK}$		1.0			μF

1. $V_{DD} = 4.4 - 5.5 V$, $V_{SS} = 0 V_{dc}$, $T_A = 0 \text{ }^\circ C$ to $+85 \text{ }^\circ C$, unless otherwise noted

2. Transceiver pullup resistor of $1.5 k\Omega \pm 5\%$ between REGOUT and D- and $15 k\Omega \pm 5\%$ to ground termination resistors on D+ and D-.

3. No external current draw besides the USB-required external resistors should be connected to the REGOUT pin.

17.10 USB Low-Speed Source Electrical Characteristics

Characteristic ⁽¹⁾	Symbol	Conditions	Min	Typ	Max	Unit
Internal Operating Frequency	f_{OP}	—	—	1.5	—	MHz
Transition Time ⁽²⁾						
Rise Time	t_R	$C_L = 50 \text{ pF}$	75	—	300	ns
Fall Time	t_F	$C_L = 350 \text{ pF}$ $C_L = 50 \text{ pF}$ $C_L = 350 \text{ pF}$	75	—	300	
Rise/Fall Time Matching	t_{RFM}	t_R/t_F	80	—	120	%
Output Signal Crossover Voltage	V_{CRS}		1.3	—	2.0	V
Low Speed Data Rate	t_{DRATE}	1.5 Mbs \pm 1.5%	1.4775 676.8	1.500 666.0	1.5225 656.8	Mbs ns
Source Differential Driver Jitter To Next Transition For Paired Transitions	t_{UDJ1} t_{UDJ2}	$C_L = 350 \text{ pF}$ Measured at crossover point	–25 –10	— —	25 10	ns
Receiver Data Jitter Tolerance To Next Transition For Paired Transitions	t_{DJR1} t_{DJR2}	$C_L = 350 \text{ pF}$ Measured at crossover point	–75 –45	— —	75 45	ns
Source EOP Width	t_{EOPT}	Measured at crossover point	1.25	—	1.50	μs
Differential to EOP Transition Skew	t_{DEOP}	Measured at crossover point	–40	—	100	ns
Receiver EOP Width Must Reject as EOP Must Accept	t_{EOPR1} t_{EOPR2}	Measured at crossover point	330 675	— —	— —	ns

1. All voltages are measured from local ground, unless otherwise specified. All timings use a capacitive load of 50 pF, unless otherwise specified. Low-speed timings have a 1.5-k Ω pullup to 2.8 V on the D– data line.
2. Transition times are measured from 10% to 90% of the data signal. The rising and falling edges should be smoothly transitioning (monotonic). Capacitive loading includes 50 pF of tester capacitance.

17.11 USB Signaling Levels

Bus State	Signaling Levels	
	From Originating Driver	At Receiver
Differential 1	$(D+) - (D-) > 200 \text{ mV}$ and $D+ \text{ or } D- > V_{SE} \text{ (min)}$	
Differential 0	$(D+) - (D-) < -200 \text{ mV}$ and $D+ \text{ or } D- > V_{SE} \text{ (min)}$	
Data J State Low Speed Full Speed	Differential 0 Differential 1	
Data K State Low Speed Full Speed	Differential 1 Differential 0	
Idle State Low Speed Full Speed	Differential 0 and $D- > V_{SE} \text{ (max)}$ and $D+ < V_{SE} \text{ (min)}$ Differential 1 and $D+ > V_{SE} \text{ (max)}$ and $D- < V_{SE} \text{ (min)}$	
Resume State Low Speed Full Speed	Differential 1 and $D+ > V_{SE} \text{ (max)}$ and $D- < V_{SE} \text{ (min)}$ Differential 0 and $D- > V_{SE} \text{ (max)}$ and $D+ < V_{SE} \text{ (min)}$	
Start of Packet (SOP)	Data lines switch from Idle to K State	
End of Packet (EOP)	$D+ \text{ and } D- < V_{SE} \text{ (min)}$ for 2 Bit Times ⁽¹⁾ Followed by an Idle for 1 Bit Time	$D+ \text{ and } D- < V_{SE} \text{ (min)}$ for $\checkmark 1$ Bit Time ⁽²⁾ Followed by a J State
Disconnect Upstream Only		$D+ \text{ and } D- < V_{SE} \text{ (max)}$ for $\checkmark 2.5 \mu\text{s}$
Connect Upstream Only		$D+ \text{ or } D- > V_{SE} \text{ (max)}$ for $\checkmark 2.5 \mu\text{s}$
Reset Downstream Only	$D+ \text{ and } D- < V_{SE}$ for $\checkmark 10 \text{ ms}$	$D+ \text{ and } D- < V_{SE} \text{ (min)}$ for $\checkmark 2.5 \mu\text{s}$; Must be Recognized within $5.5 \mu\text{s}$ ⁽³⁾

1. The width of EOP is defined in bit times relative to the speed of transmission.

2. The width of EOP is defined in bit times relative to the device type receiving the EOP.

3. These times apply to an active device that is not in the suspend state.

17.12 Timer Interface Module Characteristics

Characteristic	Symbol	Min	Max	Unit
Input Capture Pulse Width	t_{TIH}, t_{TIL}	125	—	ns
Input Clock Pulse Width	t_{TCH}, t_{TCL}	$(1/f_{OP}) + 5$	—	ns

17.13 Memory Characteristics

Characteristic	Symbol	Min	Typ	Max	Unit
EPROM Programming Voltage	V_{PP}	12.5	13.0	13.5	V
EPROM Data Retention	t_{DRET}	—	10.0	—	Years
EPROM Programming Time	t_{EPGM}	0.1		1	ms/Byte
RAM Data Retention Voltage	V_{RM}	1.3	—	—	V

Electrical Specifications

Section 18. Mechanical Specifications

18.1 Contents

18.2	Introduction	241
18.3	Quad Flat Pack (Case 848B-04)	242

18.2 Introduction

The MC68HC708KL8 is available in a 52-lead plastic quad flat pack (QFP) package. This section gives the dimensions for this package.

18.3 Quad Flat Pack (Case 848B-04)

- NOTES:
- DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
 - CONTROLLING DIMENSION: MILLIMETER.
 - DATUM PLANE -H- IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
 - DATUMS -A-, -B- AND -D- TO BE DETERMINED AT DATUM PLANE -H-.
 - DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE -C-.
 - DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 (0.010) PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE -H-.
 - DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.08 (0.003) TOTAL IN EXCESS OF THE D DIMENSION AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT.

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	9.90	10.10	0.390	0.398
B	9.90	10.10	0.390	0.398
C	2.10	2.45	0.083	0.096
D	0.22	0.38	0.009	0.015
E	2.00	2.10	0.079	0.083
F	0.22	0.33	0.009	0.013
G	0.65 BSC		0.026 BSC	
H	—	0.25	—	0.010
J	0.13	0.23	0.005	0.009
K	0.65	0.95	0.026	0.037
L	7.80 REF		0.307 REF	
M	5°	10°	5°	10°
N	0.13	0.17	0.005	0.007
Q	0°	7°	0°	7°
R	0.13	0.30	0.005	0.012
S	12.95	13.45	0.510	0.530
T	0.13	—	0.005	—
U	0°	—	0°	—
V	12.95	13.45	0.510	0.530
W	0.35	0.45	0.014	0.018
X	1.6 REF		0.063 REF
