Table 6-335. INTVECTOR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.333 INTVECTOR_1 Register (Offset = 2004h) [Reset = 0h]

Table 6-348. INTVECTOR_13 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.346 INTVECTOR_14 Register (Offset = 2038h) [Reset = 0h]

INTVECTOR_14 is shown in [Figure 6-348](#) and described in [Table 6-349](#).

Return to the [Table 6-3](#).

Table 6-362. INTVECTOR_27 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-362. INTVECTOR_27 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Table 6-376. INTVECTOR_41 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.374 INTVECTOR_42 Register (Offset = 20A8h) [Reset = 0h]

INTVECTOR_42 is shown in [Figure 6-376](#) and described in [Table 6-377](#).

Return to the [Table 6-3](#).

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.388 INTVECTOR_56 Register (Offset = 20E0h) [Reset = 0h]

INTVECTOR_56 is shown in [Figure 6-390](#) and described in [Table 6-391](#).

Return to the [Table 6-3](#).

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-502. INTVECTOR_167 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.528 INTVECTOR_196 Register (Offset = 2310h) [Reset = 0h]

INTVECTOR_196 is shown in [Figure 6-530](#) and described in [Table 6-531](#).

Return to the [Table 6-3](#).

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.542 INTVECTOR_210 Register (Offset = 2348h) [Reset = 0h]

INTVECTOR_210 is shown in [Figure 6-544](#) and described in [Table 6-545](#).

Return to the [Table 6-3](#).

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.556 INTVECTOR_224 Register (Offset = 2380h) [Reset = 0h]

INTVECTOR_224 is shown in [Figure 6-558](#) and described in [Table 6-559](#).

Return to the [Table 6-3](#).

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-572. INTVECTOR_237 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5.10.584 INTVECTOR_252 Register (Offset = 23F0h) [Reset = 0h]

INTVECTOR_252 is shown in [Figure 6-586](#) and described in [Table 6-587](#).

6.1.6 Resets

AM273x supports the following resets:

- CR5SS_POR_RST: This is the full MCU R5F subsystem reset. It is also the Power On Reset.
- CR5ASS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreA. None of the other logics are reset.
- CR5A_RST: This only reset the cortex of the R5F of the CoreA.

- CR5BSS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreB. None of the other logics are reset.
- CR5B_RST: This only reset the cortex of the R5F of the CoreB.
- VIMA_RST: This only reset the vectored interrupt manager of the CoreA.
- VIMB_RST: This only reset the vectored interrupt manager of the CoreB.

6.1.6.1 R5F Subsystem Reset Trigger

For the safe reset of the R5F subsystem, follow this reset sequence:

1. Write 3'b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER starts the sequencer.
2. The sequencer is waiting for WFI from only CR5A if WFI_CHECKEN for corresponding resets is programmed. The sequencer isolates CR5SS when it receives WFI from CR5A.
3. The sequencer triggers CR5SS_POR_RST, which triggers resets to all resets mentioned in resets-table.
4. The intent is to reset CR5SS when it is in isolation. Thus, before Step 1, ensure MSS_RCM:RST2ASSERTDLY is programmed to 0;.
5. Reset is asserted for RST_ASSERTDLY: RST_ASSERTDLY_COMMON number of clock cycles, and released.

6.2 TI C66x DSP Subsystem (DSS) Overview

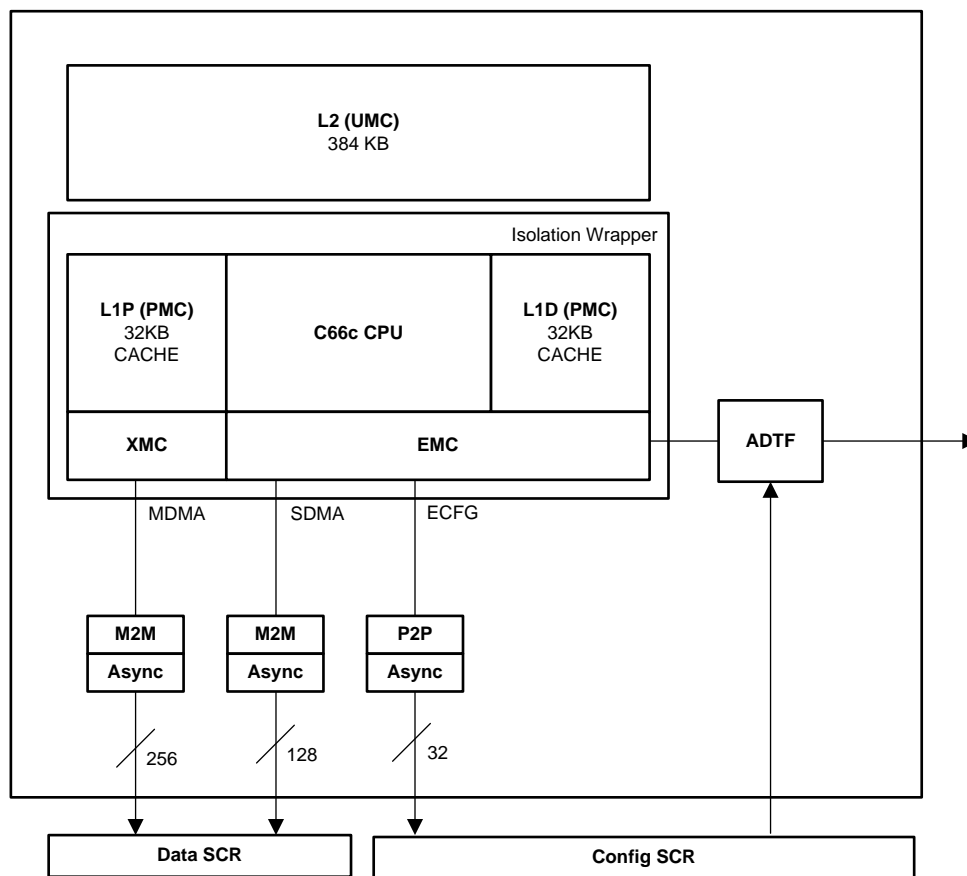

Figure 6-590. DSP C66x Subsystem

6.2.1 C66x DSP Subsystem

The purpose of this section is to provide an overview of the DSP subsystem (C66x CorePac) along with some integration details.

6.2.1.1 DSP Subsystem Overview

The DSP subsystem (C66x CorePac) supports the following key features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program Memory Controller (PMC):
 - 32KB Level 1 Program (L1P) Cache/SRAM
- Data Memory Controller (DMC):
 - 32KB L1 Data (L1D) Cache/SRAM
- L2 Memory Controller:
 - 384KB L2 RAM with up to 256KB of configurable into cache
- External Memory Controller (EMC):
 - Internal DMA (IDMA) engine
 - One 128-bit VBUSM slave port from DMA access at Div-by-2 clock
 - One 32-bit VBUSP master port to CFG access at Div-by-2 clock
- XMC (Extended Memory Controller):
 - One 256-bit port to L3 memory at Div-by-2 clock
- Multistream prefetch buffer
- Address extension/translation (32-bit to 36-bit)
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D
- Error Detection and Correction for all L2
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with Chip-level Interrupt Controller (CIC) for distribution of system interrupts to the C66x core. Interrupts can be routed directly to the C66x core or through the CIC module in a flexible manner
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
 - Support for halt mode, real time and monitor mode debug capabilities
 - Support for processor instruction trace and system trace (**printf**-style debug)
- Error Detection for L1P Data and Tag RAMs
- Error Detection and Correction for L1D Data and Tag RAMs
- Error Detection and Correction for all L2 Data and Tag RAMs

Figure 6-591 shows an overview of the C66x CorePac.

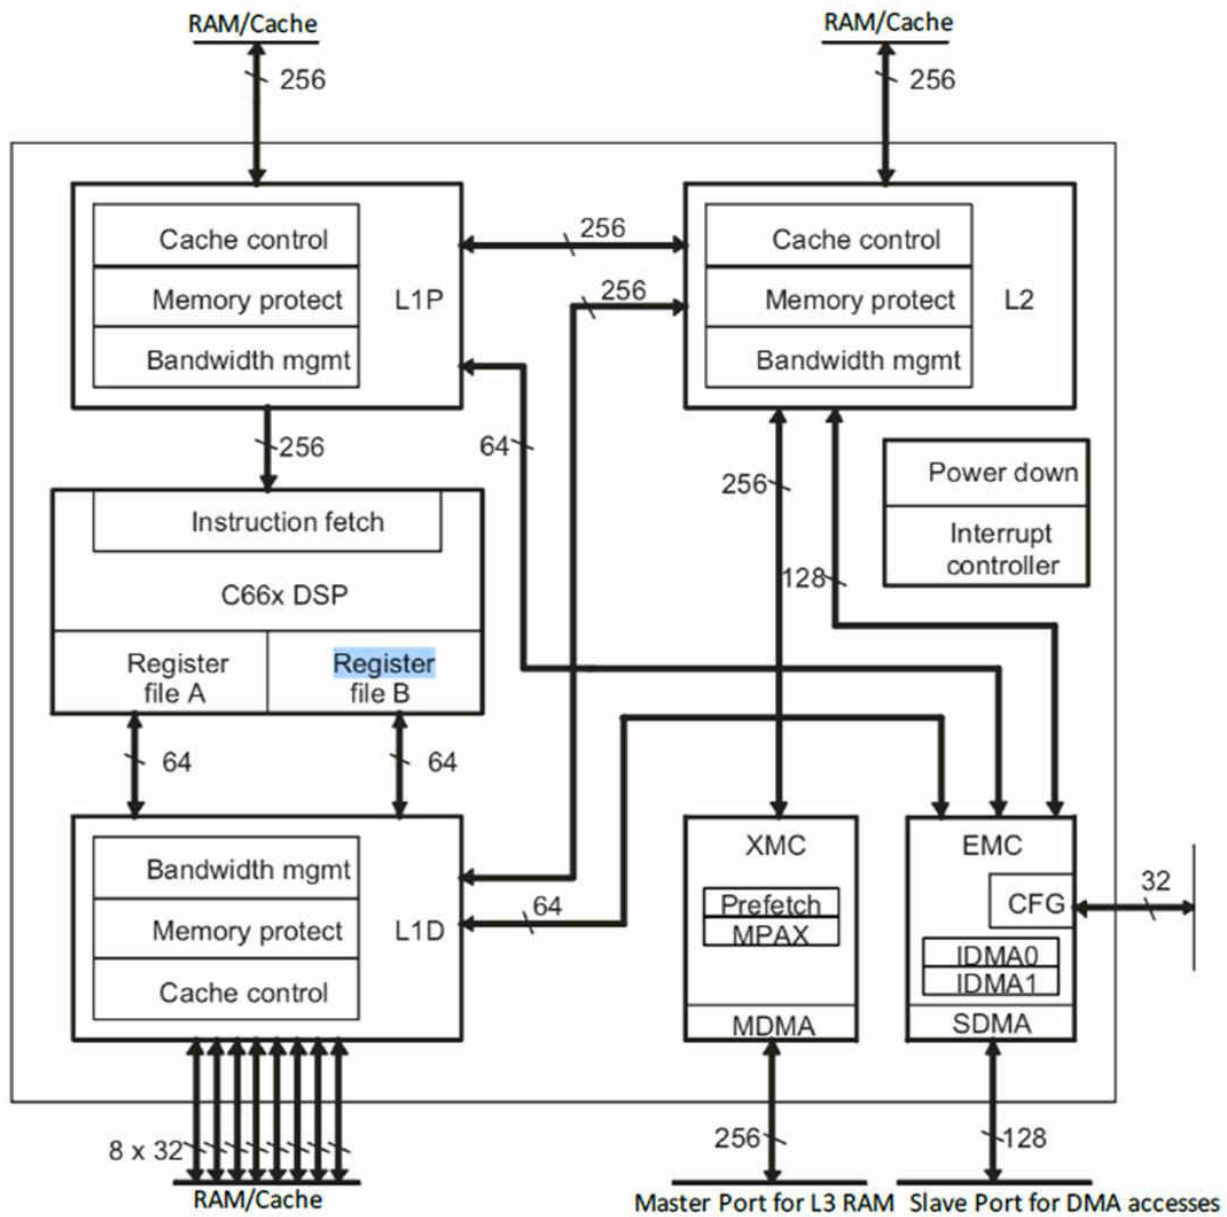

Figure 6-591. C66x CorePac Overview

For more information about:

- C66x CorePac, see the *TMS320C66x DSP CorePac User Guide* ([SPRUGW0](#)).
- C66x CPU core, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide* ([SPRUGH7](#)).
- C66x cache memory system, see the *TMS320C66x DSP Cache User Guide* ([SPRUGY8](#)).
- C66x debug/trace support, see [Section 11.1](#).

6.2.1.2 DSP Subsystem Integration

To turn on DSP power, please follow section 1.5.4.1 DSP power domain for details. To configure the DSP clock, please refer to section 1.5.3.3, DSS_DSP_CLK for clock source, divider, and gating selections details.

6.2.1.3 DSP Interrupt Sources

Refer to section 1.8.2.

6.2.1.4 DSP Subsystem Functional Description

For detailed DSP subsystem functional description, see the documents referenced in [Section 6.2.1.1](#) .

6.2.1.5 DSP Subsystem Registers

Table 6-591 lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in Table 6-591 should be considered as reserved locations and the register contents should not be modified. For base addresses of the DSP subsystem internal modules, see Chapter 2.

The C66x CorePac registers are described in detail in the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).

Table 6-591. C66x CorePac Registers

Address	Acronym	Register Name

6.2.2 DSP Subsystem Integration

The DSP C66x Corepac integrates the following IPs :

- Improved C66x Core and CGEM Megamodule with ECC
- 32-kB L1P Cache/SRAM
- 32-kB L1D Cache/SRAM
- 384-kB L2 Cache/SRAM
- ECC and EDC wherever supported
- L1P - 4-bit parity per 256-b location (1-b parity per 64-b line quadrant)
- L1D – no protection
- L2 – Distance-3 “detect 2, correct 1” Hamming code based error correction/detection

6.2.2.1 DSP Memory Overview

The L1P 32kB memory and L1D 32kB memory can be independently configured as part cache and part mapped to SRAM. The cache size can be 0KB, 4KB, 8KB, 16KB, or 32KB (where the mapped SRAM size is 32KB minus the cache size).

The L2 memory 384 kB memory can also be configured as part SRAM and part Cache. 128kB is always mapped as SRAM. The remaining 256kB can be configured to cache sizes of 0, 32k, 64k, 128k, or 256kB. The additional mapped SRAM available is 256-kB minus the cache size.

6.2.2.2 C66x Cache Subsystem

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* ([SPRUGY8](#)).

The device contains a 384KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see [Chapter 2](#)).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a two-way set-associative cache, while L1P is a direct-mapped cache.

6.2.2.2.1 L1P Memory

The L1P memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states

[Figure 6-592](#) shows the available SRAM/cache configurations for L1P.

Note

L1P can only be configured as cache.

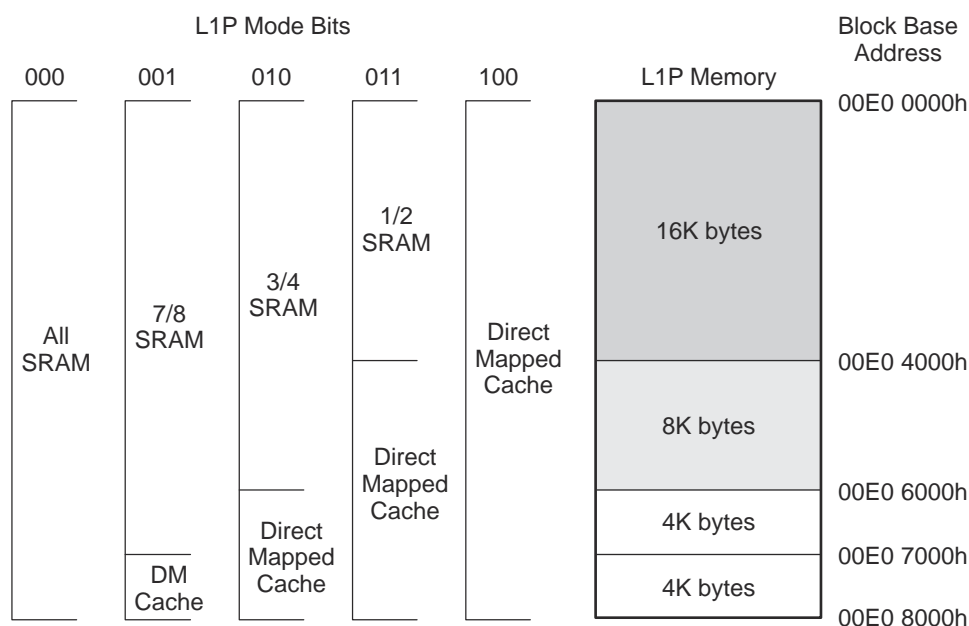

Figure 6-592. L1P Memory Configurations

6.2.2.2.2 L1D Memory

The L1D memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states.

[Figure 6-593](#) shows the available SRAM/cache configurations for L1D.

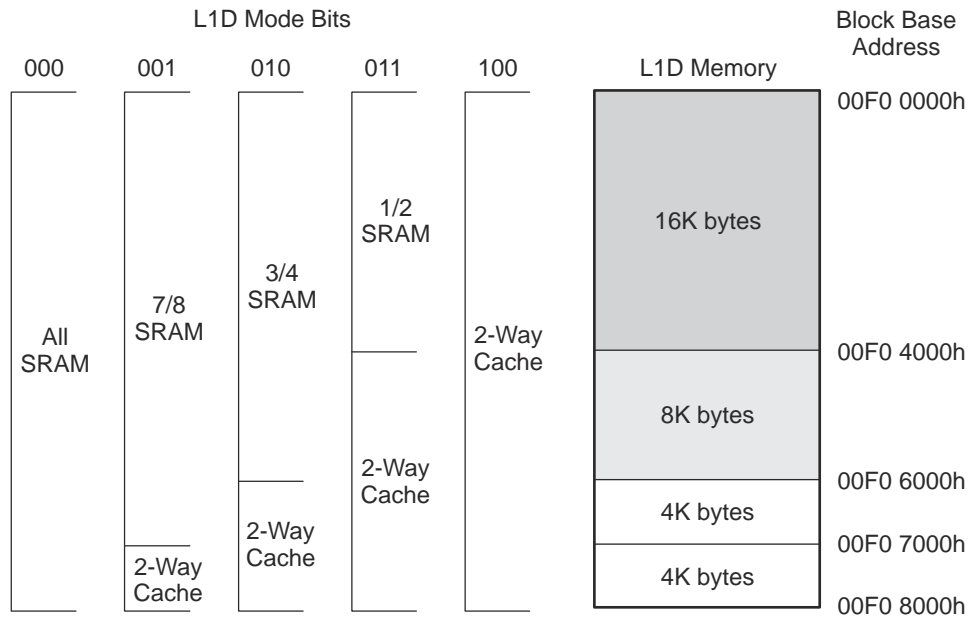

Figure 6-593. L1D Memory Configurations

6.2.2.2.3 L2 Memory

The L2 memory configuration for this device is as follows:

- 384KB of memory
- Local starting address is 0080 0000h.

L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac. [Figure 6-594](#) shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

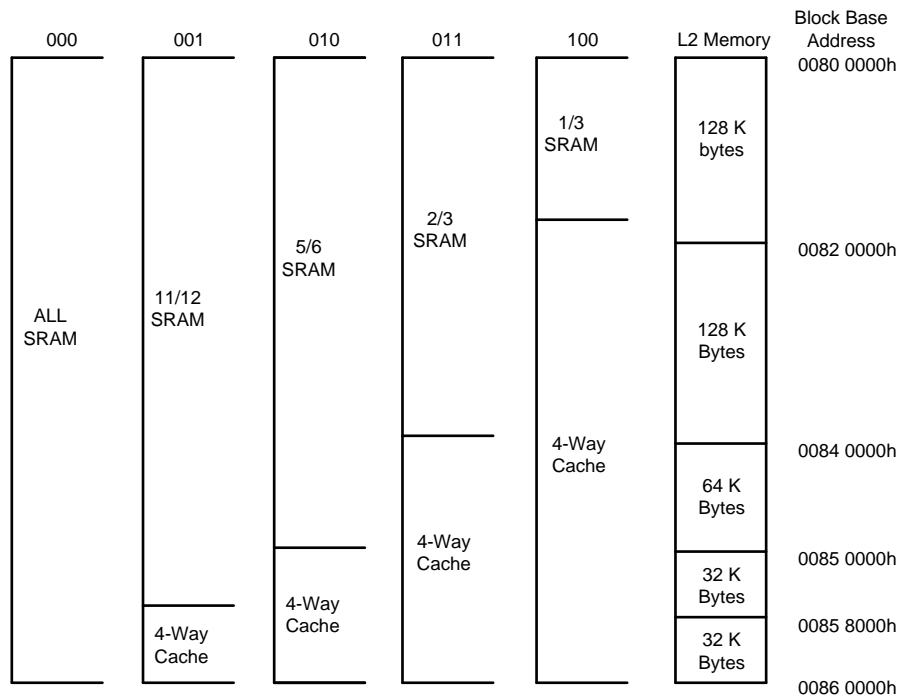

Figure 6-594. L2 Memory Configurations

6.2.2.2.4 DSP ECC Configuration

The device supports ECC/parity on all DSP internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 6-592 summarizes the ECC/parity support in DSP.

Table 6-592. DSP ECC/Parity Support

DSP Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag	Parity
L1D Data RAM	ECC-SECDED (Single Error Correction, Double Error Detection)
L1D Tag	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag	ECC-SECDED

6.3 Radar Processing Hardware Accelerator

In addition to the DSP cores, the AM273x device incorporates Radar Hardware Accelerators HWA2.0 to offload the DSP from pre-processing computations.

6.3.1 Radar Accelerator Features Overview

- Flexible enough to offload almost all the operations from the initial compensation (DC estimation-correction, interference mitigation, and so forth) on raw ADC data before first dimension FFT until point cloud detection, with the least possible intervention from the DSP.
- Operating clock frequency is 400 MHz
- Data path bit-width of 24-bits (24-bit I, 24-bit Q)
- Input and output data formatter: scaling, truncation, head/tail sample skipping, zero padding/insertion of data, sample access pattern for DDMA use case.
- Capability to do all these operations in a single iteration: DC correction, interference zeroing out, complex multiplication, windowing, FFT, log, magnitude, stats computation with a capability of selecting/enabling or disabling/bypassing each of these computation blocks individually.
- 128KB local buffer/RAM split into eight 16KB banks, with each bank configurable as input or output for any compute/data transfer functionality.
- Flexible data flow and data sample arrangement to support efficient multi-dimensional operations and transpose accesses as required.
- Processing for inline (range FFT) and inter-frame (Doppler FFT, angle FFT, detection) threads simultaneously
- Support for CSI2 data input either in Rx interleaved or in serial manner
- Support for DC estimation and correction
- Support for interference mitigation
 - Estimation and zeroing out of the interference samples by estimating the average of the magnitude of sudden spikes of vector elements, and applying scaled values as a threshold.
- Support for complex vector/scalar multiplications
- Support for a synthesizer channel combining and MIMO demodulation for DDMA
- Complex windowing – 2K samples window RAM with a capability to split 1KB ping- 1KB pong to allow programming new coefficients while older ones are used.
- Up to 2K point FFT with efficiency of 1 sample output per cycle and possibility to go higher in size until 4K/8K, with stitching (reduced efficiency).
- Doppler de-rotation of the FFT output
- Support for magnitude (absolute value) and Log-Magnitude computation.
- Nested loop support in PARAM sets
- Compression/decompression engine with block floating and exponential Golomb modes with performance of 1 complex sample processing per cycle
- Detection algorithm-specific accelerators (for example: CFAR CA/OS and other variants)
- 2D Local Maxima/Peak search algorithm with efficiency of 1 cell processing per cycle

- Lock-step state machine
- ECC on the PARAM RAMs and parity on local buffers

6.3.2 Radar Accelerator Architecture

The Radar accelerator details are covered in [Section 6.4](#), which consists of 2 parts.

The first part covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. The (optional) second part covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

6.4 Radar Hardware Accelerator 2.0

This chapter describes the Radar Hardware Accelerator architecture, features, and operation of various blocks and their register descriptions. The purpose is to enable the user to understand the capabilities offered by the Radar Hardware Accelerator and to program it appropriately to achieve the desired functionality.

This chapter provides an overview of the overall architecture and features available in the Radar Hardware Accelerator. The main features, such as, windowing, FFT, and log-magnitude are covered in this chapter.

The chapter also covers additional features like CFAR and other advanced usage possibilities, which can be skipped if the user is interested only in the FFT computation capability.

This chapter covers the introduction and high-level architecture, the state machine, trigger mechanisms, input/output formatting, and general framework for using the accelerator. Later sections describe the primary computational unit features, namely, windowing, FFT, and log-magnitude.

6.4.1 Radar Hardware Accelerator – Overview

This section provides an overview of the Radar Hardware Accelerator 2.0. The section covers the key features of the accelerator and overall architecture.

6.4.1.1 Introduction

The Radar Hardware Accelerator 2.0 is a hardware IP that enables off-loading the burden of certain frequently used computations in FMCW radar signal processing from the main processor. It is well known that FMCW radar signal processing involves the use of FFT and log-magnitude computations to obtain a radar image across the range, velocity, and angle dimensions. Some of the frequently used functions in FMCW radar signal processing can be done within the Radar Hardware Accelerator, while still retaining the flexibility of implementing other proprietary algorithms in the main processor.

6.4.1.2 Key Features

The main features of the Radar Hardware Accelerator 2.0 are as follows.

- Fast FFT computation, with programmable FFT sizes (2, 4, 8..., 2048-pt, and 3, 6, 12, ..., 1536-pt) complex FFT.
- Internal FFT bit width of 24 bits (for each I and Q) for good SQNR performance, with fully programmable butterfly scaling at every stage for user flexibility.
- Built-in capabilities for pre-FFT processing – specifically DC estimation and removal, interference localization and mitigation, channel equalization, channel combination, zero insertion, and programmable windowing.
- Magnitude (absolute value) and log-magnitude computation capability.
- Flexible data flow and data sample arrangement to support efficient multidimensional FFT operations and transpose accesses as required.
- Chaining, looping and context switching mechanisms to sequence a set of accelerator operations one-after-another with minimal intervention from the main processor
- CFAR-CA and CFAR-OS detector support (linear and logarithmic), Local Maxima engine
- Statistics including 2D maxima, Histogram and CDF
- Radar data compression / decompression capability
- Miscellaneous other capabilities of the accelerator:
 - Stitching two or four 2K-point FFTs to get the equivalent of 4096-point or 8192-point FFT for industrial level sensing applications where large FFT sizes are required
 - Slow DFT mode, with resolution equivalent to 16K size FFT, for FFT peak interpolation purposes (for example, range interpolation)
 - Complex vector multiplication and Dot product capability for vectors up to 1024 in size

This chapter covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. It also covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

6.4.1.3 High Level Architecture

The Radar Hardware Accelerator module is loosely coupled to the main processor (eg. C6x DSP). The accelerator is connected to a 128-bit bus that is present in the main processor system, as shown in [Figure 6-595](#).

The Radar Hardware Accelerator module comprises an accelerator engine and four memories, each of 16KB size, which are used to send input data to and pull output data from the accelerator engine. These memories are referred to as *local memories* of the Radar Accelerator (ACCEL_MEM). For convenience, these four local memories are referred to as ACCEL_MEM0, ACCEL_MEM1, ACCEL_MEM2, and ACCEL_MEM3.

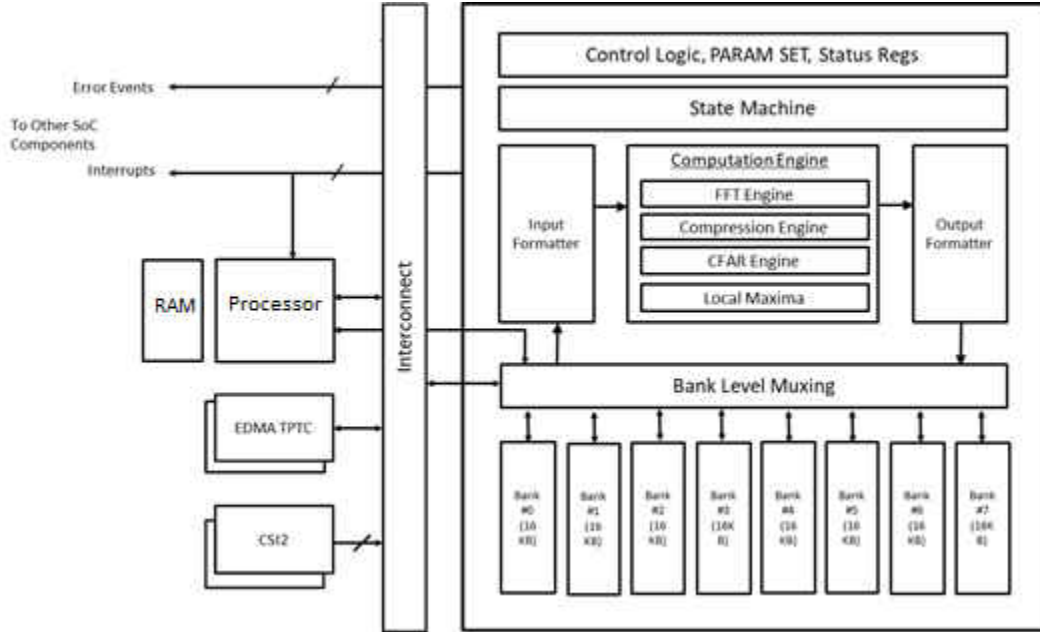

Figure 6-595. Radar Hardware Accelerator

6.4.1.3.1 High-Level Data Flow

The typical data flow is that the DMA module is used to bring samples (for example, FFT input samples) into the local memories of the Radar Hardware Accelerator, so that the main accelerator engine can access and process these samples. Once the accelerator processing is done, the DMA module reads the output samples from the local memories of the Radar Hardware Accelerator and stores them back in the Radar data memory for further processing by the main processor.

The purpose behind the eight separate local memories (16KB each) inside the Radar Hardware Accelerator is to enable the *ping-pong* mechanism, for both the input and output, such that the DMA write (and read) operations can happen in parallel to the main computational processing of the accelerator. The presence of four memories enables such parallelism. For example, the DMA can be configured to write FFT input samples (ping) into ACCEL_MEM0 and read FFT output samples (pong) from ACCEL_MEM2. At the same time, the accelerator engine can be working on FFT input samples (pong) from ACCEL_MEM1 and writing FFT output samples (pong) into ACCEL_MEM3. However, both the DMA and the accelerator cannot access the same 16KB memory at the same time. This would lead to an error (refer to the MEM_ACCESS_ERR_STATUS register description in TBD-Table 3). As will be explained in later sections, the accelerator engine can perform multiple computational steps one after another autonomously. In each step, the input samples are read from one of the eight local memories and the output samples are written into another one of the eight local memories.

The Radar Hardware Accelerator operates on a single clock domain and the operating clock frequency is 400MHz.

The accelerator local memories are 128-bits wide, for example, each of the 16KB banks is implemented as 1024 words of 128 bits each. This allows the DMA to bring data into the accelerator local memories efficiently (up to a maximum throughput of 128 bits per clock cycle, depending upon the DMA configuration). Two ports for accessing the HWA local memories are available and these map the same 128KB into two different address spaces.

It is important to note that any of the eight local memories can be the *source* of the input samples to the accelerator engine and any of the eight local memories can be the *destination* for the output samples from the accelerator engine – with the important restriction that the source and destination memories cannot be the same 16KB bank. Note also that the accelerator local memories do not necessarily need to be used in ping-pong mode and can instead be used as larger 32KB input and output memories, if the use case requires. The address space for the four 16KB memories is contiguous (including a wrap-around from the end of ACCEL_MEM7 to the start of ACCEL_MEM0). Therefore the source as well as destination memory addresses can span beyond 16KB.

6.4.1.3.2 Configuration

The operations of the Radar Hardware Accelerator are configured using registers, which are of two types – *parameter sets* and *common* (common for all parameter sets) registers. The purpose of the parameter sets is to enable a complete sequence of various accelerator operations to be preprogrammed (with appropriate source and destination memory addresses and other configurations specified for each operation in that sequence), such that the accelerator can perform them one after the other, with minimal intervention from the main processor.

The parameter-set register configurations are programmed into a separate 4KB *parameter-set configuration memory*. A state machine built into the accelerator handles the loading of one parameter-set configuration at a time and sequences the preprogrammed operations one after another. This process is further explained in later sections of this user's guide.

6.4.1.4 Accelerator Engine Block Diagram

As previously mentioned, the Radar Hardware Accelerator module consists of eight local memories of 16KB each (ACCEL_MEM) and the main accelerator engine. The accelerator engine has the following five components (as shown in [Figure 6-596](#)) – a state machine, input formatter block, output formatter block, core computational unit, and the 4KB parameter-set configuration memory.

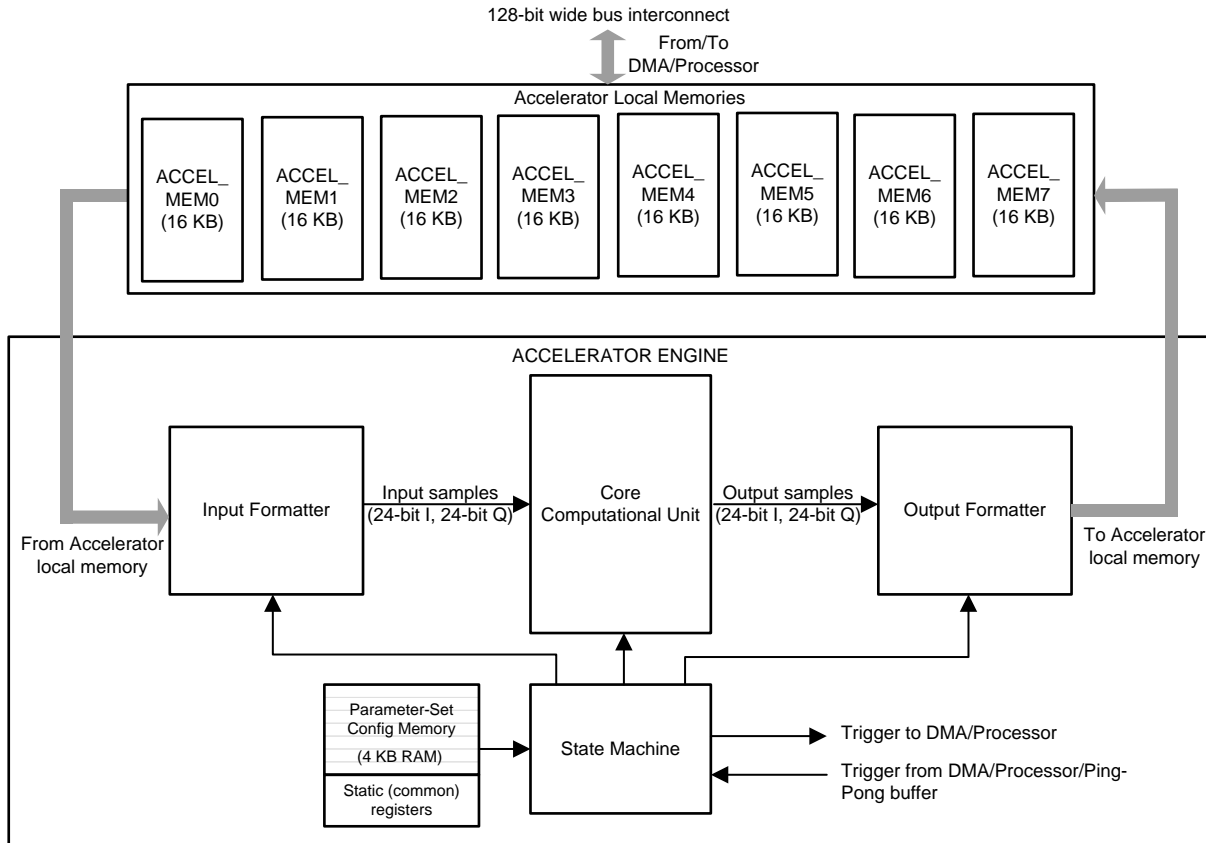

Figure 6-596. Accelerator Engine Block Diagram

The purpose of these components is as follows.

- **State machine:** the state machine is responsible for controlling the overall operation of the accelerator – specifically, the starting, looping, stopping, as well as triggering and handshake mechanisms between the accelerator, DMA, and main processor. The state machine is also closely connected to the parameter-set configuration memory and takes care of sequencing and chaining a sequence of multiple accelerator operations as programmed in the parameter-set configuration memory.
- **Input formatter:** the input formatter block is responsible for reading the input samples from any one of the local memories and feeding them into the core computational unit. In this process, this block provides flexible ways of accessing the input samples, in terms of 16-bit versus 32-bit aligned input samples, transpose read-out, flexible scaling, and sign extension to generate internal bit-width of 24 bits, and so on. Lastly the input formatter block provides 24-bit complex samples as input to the core computational unit. The local memory (memories) from which the input formatter reads the input samples is called the *source* memory.
- **Output formatter:** the output formatter block is responsible for writing the output samples from the core computational unit into the local memories. This block also provides flexible ways of formatting the output samples, in terms of 16-bit versus 32-bit aligned output samples, transpose write, flexible scaling from internal bit-width of 24 bits, to 16-bit or 32-bit aligned output samples, sign-extension, and so on. The local memory (memories) to which the output formatter writes the output samples is called the *destination* memory.
- **Core computational unit:** the core computational unit contains the main computational logic for various operations, such as windowing, FFT, magnitude, log2, and CFAR calculations. The unit accepts a streaming input from the input formatter block (at the rate of one input sample per clock cycle), performs computations, and produces a streaming output to the output formatter block (typically at the rate of one output sample per clock cycle), with some initial latency depending on the nature of the computations involved.
- **Parameter-set configuration memory:** this is a 4096-byte RAM that is used to preconfigure the sets of parameters (register settings) for a chained sequence of accelerator operations, which can then be executed

by the state machine in a loop. This allows the accelerator to perform a preprogrammed sequence of operations in a loop without frequent intervention from the main processor.

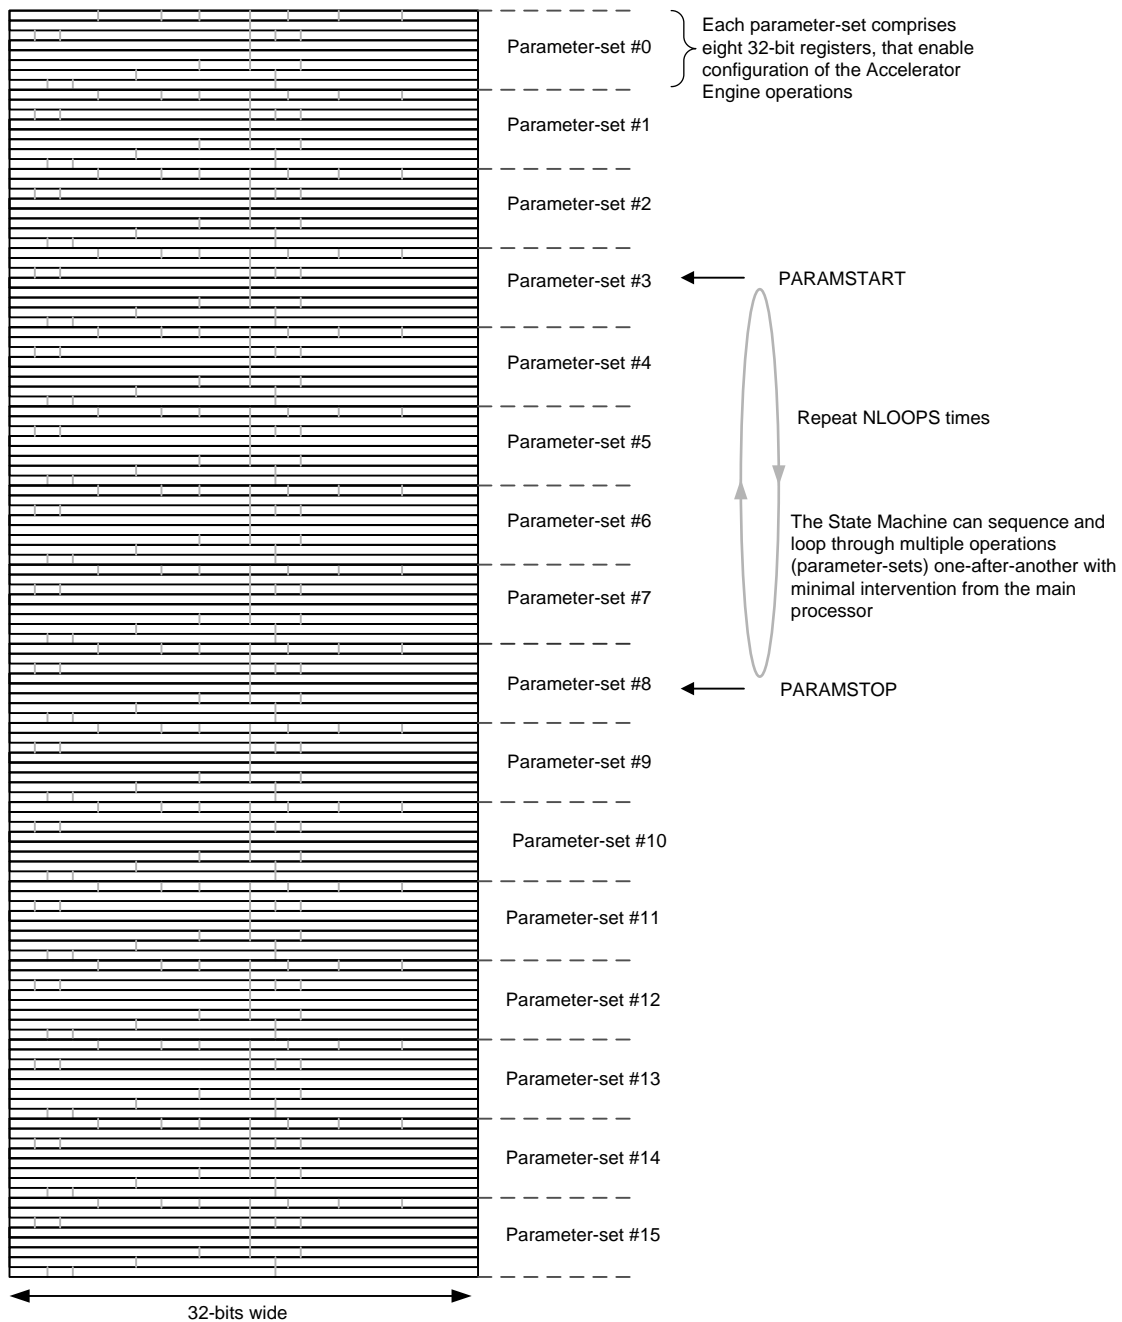

Figure 6-597. Parameter-Set Configuration Memory (4KB)

The number of parameter sets that can be preconfigured and sequenced (chained) is 64. This means that up to 64 accelerator operations can be chained together and these can then be looped as well, with minimal intervention from the main processor. For example, operations like FFT, log-magnitude, and CFAR detection can be preconfigured in the parameter-set configuration memory and the state machine can be made to sequence them one after another and run them in a loop for specified number of times. There is a provision available to interrupt the main processor and/or trigger a DMA channel at the end of each parameter set if required. This allows various ways by which the accelerator, DMA, and the main processor can work together to establish a data and processing flow. As shown in [Figure 6-597](#), each parameter set contains the equivalent of sixteen 32-

bit registers, which corresponds to total RAM size of $64 \times 16 \times 32$ bits = 4KB for the parameter-set configuration memory.

The layout of the parameter-set register map is provided in [Section 6.4.6](#). Note that the parameter-set RAM must be programmed using 32-bit word writes only (i.e., byte-writes and half-word writes are not supported). The detailed descriptions of the registers is provided in the various sections, as and when the functionality of each component is presented.

Typically, all necessary parameter sets can be pre-configured before triggering execution by the accelerator. If needed, the parameter sets can be modified on-the-fly but without modifying the parameter set being executed at that time.

6.4.1.5 Accelerator Engine Operation

The accelerator engine and the local memories run on a single clock domain. The overall operation of the accelerator can be summarized as follows. The accelerator engine is configured by the main processor through common configuration registers (common for all parameter sets), as well as the parameter-set configuration memory. As explained earlier, the former comprises common register settings for overall control of the accelerator engine, and the latter comprises the 64 parameter-set specific settings which control the functioning of the accelerator for each of its *chained* sequence of operations.

When the accelerator engine is enabled, the state machine kicks off and controls the overall operation of the accelerator, which involves loading the parameter sets one at a time from the parameter-set configuration memory into various internal registers of the accelerator engine and running the accelerator as per the programmed configuration for each parameter set one after another. The entire procedure then repeats in a loop for a programmed number of times (NUMLOOPS described later).

Each parameter set includes various configuration details such as the accelerator mode of operation (FFT, Log2, and so on), the source memory address, number of samples, the destination memory address, input formatting, output formatting, trigger mode for controlling the start of computations to ensure proper handshake with the DMA, and so on.

6.4.1.5.1 Data Throughput

Once the state machine has loaded the registers corresponding to the current parameter set to be executed, the data flow happens as follows: at each clock cycle, one sample from the source memory is read by the input formatter and fed into the core computational unit with appropriate scaling and formatting as configured. The data interface between the input formatter and the core computational unit is a 24-bit complex bus (24-bit for each I and Q) which streams one input sample every clock cycle. The core computational unit processes this streaming sequence of input samples and in general, produces a streaming output also at one sample every clock cycle, after an initial latency period. Thus for most operations (FFT, log-magnitude, CFAR, and so on), in steady state the core computational unit maintains a streaming data rate of one sample per clock cycle. The data interface between the core computational unit and the output formatter is also a 24-bit complex bus (24-bit for each I and Q) and the output formatter is responsible for writing into the destination memory, with appropriate scaling and formatting as configured.

The next section provides more details regarding the state machine, including its detailed operation, registers, trigger mechanisms, and so on.

6.4.2 Accelerator Engine – State Machine

This section describes the state machine block present in the accelerator engine (see [Figure 6-598](#)). This block, together with the input formatter and output formatter blocks described in the next two sections, provides the overall framework for establishing the data flow and using the accelerator for various computations.

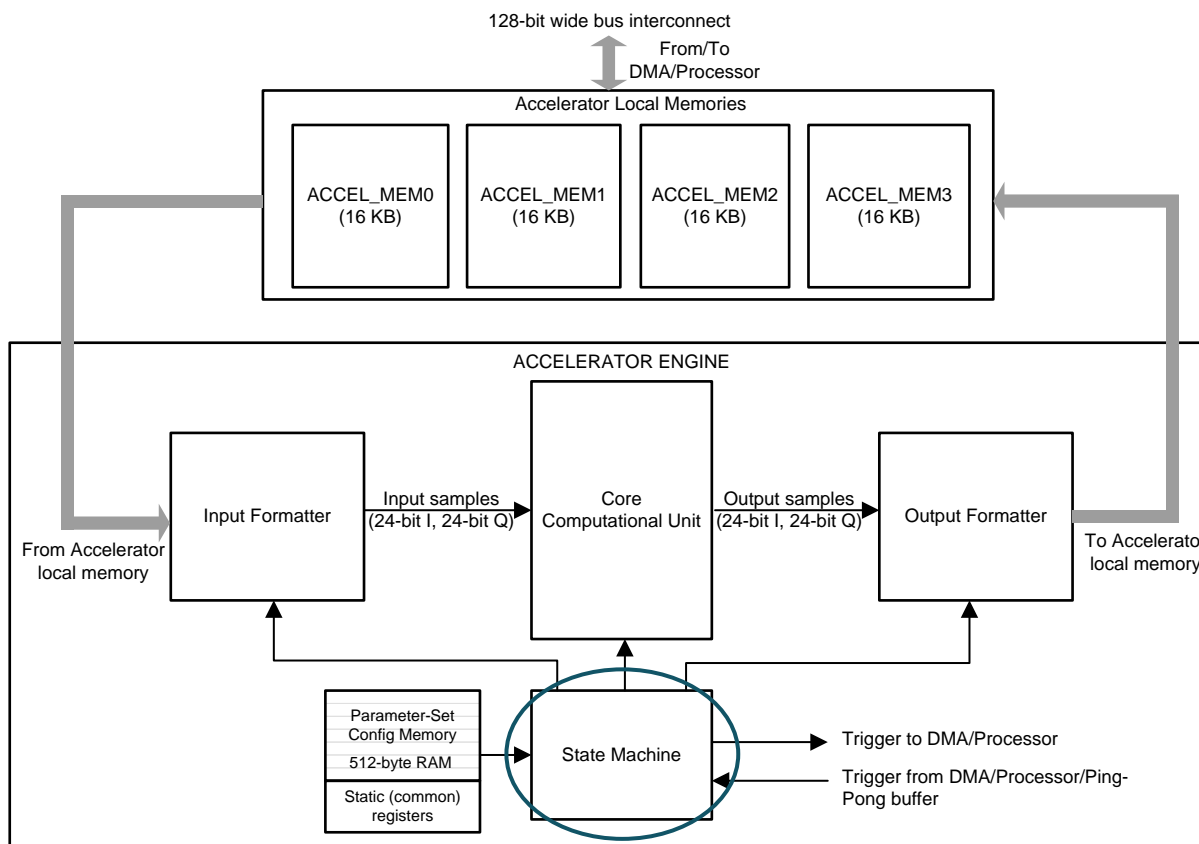

Figure 6-598. State Machine

6.4.2.1 State Machine

The state machine controls the overall functioning of the Radar Hardware Accelerator. The state machine controls the enabling and disabling of the accelerator, as well as supports sequencing an entire set of operations (configured using parameter-set configuration memory), and looping through those operations one after another without needing frequent intervention from the main processor.

6.4.2.1.1 State Machine – Operation

The state machine block and the entire accelerator remain in reset and disabled state by default. The state machine (and hence the accelerator in general) is enabled by setting the HWA_CLK_EN register bit, followed by writing 111b into the HWA_EN register.

Note that a complete list of registers pertaining to the state machine is provided in [Section 6.4.2.1.4](#). Some of the registers are common (common for all parameter sets) registers, whereas some other registers are parameter-set registers, which as explained in the previous section means that they can be uniquely programmed for each of the 64 parameter sets. For each register, [Table 6-593](#) lists whether it is part of the parameter set or not. [Table 6-593](#) also provides a brief description of each register.

When enabled, the state machine steps through (one after another) the parameter sets programmed in the parameter-set configuration memory and executes the computations as per the configuration of each parameter set. The registers PARAM_START_IDX and PARAM_END_IDX define the starting index and ending index within the 64 parameter sets, so that only those parameter sets between the start and end indices are executed by

the accelerator, as shown in TBD. The state machine also loops through these parameter sets for a total of NUMLOOPS times (unless NUMLOOPS is programmed as 0 or 4095, in which case the loop does not run or runs infinite times respectively). As an example, if the state machine needs to be configured to run the first four parameter sets in a loop 64 times, then the registers should be programmed as follows: PARAM_START_IDX = 0, PARAM_END_IDX = 3, and NUMLOOPS = 64.

For each parameter set, there is a TRIGMODE register, which is used to control when the state machine starts executing the computations for that parameter set. This control is useful, for example, to ensure that the input data is ready in the accelerator local memory (source memory) before the computations are started. Specifically, it is possible to trigger the start of computations after completion of a DMA transfer, or after a CSI2 line is received, and so on. The TRIGMODE register setting thus controls when the accelerator operation is triggered for the current parameter set and there are four trigger mechanisms supported as listed in the next subsection. Once triggered, the state machine loads all the registers from the parameter-set configuration memory for the current parameter set into corresponding internal registers of the accelerator and starts the actual computations for that parameter set. After completion of computations of the current parameter set, it moves to the next parameter set.

After a sequence of operations as programmed in the parameter set(s) for the specified number of loops is complete, the accelerator provides a completion interrupt (DSS_HWA_THREAD1_LOOP_INT) to the processor. The accelerator can be reconfigured as desired. For reconfiguration, the following procedure must be followed. The accelerator must be disabled by writing 000b to the HWA_EN register. Then, a reset must be asserted by writing 111b followed by 000b to the HWA_RESET register. The new configurations can now be written in to the accelerator, and then the accelerator can be enabled again by writing 111b to HWA_EN.

6.4.2.1.2 State Machine – Trigger Mechanisms (Incoming)

As mentioned in the previous subsection, for each parameter set, the start of the computations can be triggered based on specific events. Four trigger mechanisms are supported as follows.

- Immediate trigger (TRIGMODE = 000b): In this case, the state machine does not wait for any trigger and starts the accelerator computations immediately for the current parameter set. This mode is applicable when chaining (sequencing) a set of operations one after another in the accelerator without any need for control handshake or data exchange outside the accelerator (for example, when chaining FFT and log-magnitude operations) with no need to wait for a trigger in between.
- Wait for processor-based software trigger (TRIGMODE = 001b, TRIGMODE = 111b): This is a software-triggered mode that is useful when the main processor must directly control the data flow and start or stop of accelerator computations. In this trigger mode, the state machine waits for a software-based trigger, which involves the main processor setting a separate self-clearing bit in a FW2HWA_TRIGGER_0 or FW2HWA_TRIGGER_1 register (single-bit register). The state machine keeps monitoring that register bit and waits as long as the value is zero. When the value becomes 1 (set), the state machine gets triggered to start the accelerator operations for the current parameter set. FW2HWA_TRIGGER_0 register bit corresponds to TRIGMODE = 001b and FW2HWA_TRG_1 corresponds to TRIGMODE = 111b.
- TRIGMODE = 010b : mode is reserved.
- Wait for the DMA-based trigger (TRIGMODE = 011b): This trigger mode is useful when a DMA transfer completion must be used to trigger the start of the accelerator computations for the current parameter set. The primary purpose of this trigger mode is as follows; when performing second dimension FFT, the DMA is used to bring the FFT input samples from the Radar data memory to the local memory of the accelerator. Upon completion of each DMA transfer, it is useful to automatically trigger the accelerator to perform the FFT.

To achieve this, the state machine of the accelerator has a 32-bit register called the DMA2HWA_TRIGGER register, where each register bit maps to one of 32 DMA channels that are associated with the accelerator. To use the DMA-based trigger mode, the HWA_TRIGSRC register in the current parameter set must be programmed to the DMA channel whose completion we wish to monitor. The state machine then monitors the corresponding register bit in the DMA2HWA_TRIGGER register, and triggers the execution of the current parameter set only when that register bit gets set. For e.g. if HWA_TRIGSRC is programmed to 5, then the current parameter set will execute only once the register bit #5 gets set in DMA2HWA_TRIGGER.

The user may utilize the EDMA's linking capability to set the appropriate register bit in DMA2HWA_TRIGGER. Linking is a programmable feature of the EDMA, where the completion of a DMA transfer can automatically trigger a second DMA transfer. In the present context, the DMA transfer that moves data to the local memory of the accelerator can be linked to a second DMA whose purpose is to write a one-hot signature into DMA2HWA_TRIGGER to set a specific register bit and trigger the accelerator. Note that there are 32 read-only, one-hot, signature registers (SIG_DMACH1_DONE, SIG_DMACH2_DONE, and more) that are available. These registers are simply read-only registers which contain hard-coded values (each register is a one-hot signature – 0x0001, 0x0002, 0x0004, 0x0008, and so on). For convenience, these hard-coded 32 read-only signatures can be used, so that the second DMA can simply copy from one of these SIG_DMACHx_DONE registers into the DMA2HWA_TRIGGER register to set the appropriate register bit.

- Wait for hardware trigger (TRIGMODE = 0b100): These trigger modes are useful when a hardware signal such as CSI interrupt needs to be used to trigger the start of the accelerator computations for the current parameter set. The hardware trigger sources can be either CSI #1 frame start, CSI #1 lineend, or CSI #2 frame start, or CSI #2 line end. The HWA_TRIG_SRC register in the parameter-set decides which of these trigger sources is selected. . The valid range for HWA_TRIG_SRC register is 0 to 19, and these values correspond to different trigger sources – specifically, a value of 0 selects the right most trigger and 19 selects left most trigger in the following trigger sources: RCSS_CSI2A_SOF_INT[0,1], RCSS_CSI2A_EOL_CNTX[0..7]_INT, RCSS_CSI2B_SOF_INT[0,1], RCSS_CSI2B_EOL_CNTX[0..7]_INT. Please refer to the device TRM for more details.

6.4.2.1.3 State Machine – Trigger Mechanisms (Outgoing)

After the accelerator computations for the current parameter set are triggered (using one of the four incoming trigger mechanisms mentioned in the previous subsection), it performs the actual computation operations for that parameter set. These computations typically take several tens or hundreds of clock cycles, depending on the nature of the configuration programmed. Once the accelerator completes its computation operations for the current parameter set, the state machine advances to the next parameter set and repeats the same process. But before advancing to the next parameter set, it can interrupt the main processor and/or trigger a DMA channel. This provision is useful if the main processor is required to read or write registers or memory locations at the end of the current parameter set. Also, this provision is useful for triggering a DMA channel, so that the output of the accelerator can be copied out of the accelerator local memories.

There are two trigger mechanisms provided as follows:

- Interrupt(s) to main processor (CPU_INTR1_EN = 1, CPU_INTR2_EN = 1): The accelerator interrupts the main processor(s) at the end of completion of computations for the current parameter set, if the register bit CPU_INTR1_EN or CPU_INTR2_EN is set. Two interrupt signals are available and they are enabled or disabled for each parameter-set by these two register bits. Setting CPU_INTR1_EN in a parameter-set enables DSS_HWA_PARAM_DONE_INTR1 interrupt to be generated at the end of that parameter-set. Setting CPU_INTR2_EN in a parameter-set enables DSS_HWA_PARAM_DONE_INTR2 interrupt to be generated at the end of that parameter-set.

- Trigger to DMA (DMATRIG_DMATRIG_ENEN = 1): The accelerator gives a trigger to a DMA channel at the end of completion of computations for the current parameter set, if the register bit DMATRIG_EN is set. If DMATRIG_EN is set, then the particular DMA channel as specified in a separate HWA2DMA_TRIGDST register (valid values are 0 to 31, for the 32 DMA channels dedicated for the accelerator) is triggered. Thus, it is possible to preconfigure up to 32 DMA channels and trigger the appropriate one at the end of the computations of the current parameter set. The trigger from accelerator to the DMA channels can also be emulated by the processor, by writing to a FW2DMA_TRIGGER register. This can be used by the processor to kick-start a full/repetitive chain of operations, that are then subsequently managed between the DMA and the accelerator without further processor involvement – for example, the processor writes to the FW2DMA_TRIGGER register to trigger a DMA channel for the first time, and this kicks off a series of back-to-back data transfers and accelerator computations, with the DMA and accelerator hand-shaking with each other.

6.4.2.1.4 State Machine – Register Descriptions

Table 6-593 lists all the registers of the state machine block. As explained previously, some of the registers are common (common for all parameter sets) registers, whereas some others are *part of each parameter set*. For each register, this distinction is captured as part of the register description in Table 6-593.

Table 6-593. State Machine Registers

Register.Field	Width	Parameter Set	Description
HWA_ENABLE.hwa_en	3	No	Enable and Disable Control: This register enables or disables the entire Radar Hardware Accelerator. The reason for a 3-bit register (instead of 1-bit) is to avoid an accidental bit-flip (for example, transient error caused by a neutron strike) from unintentionally turning on the accelerator engine. A value of HWA_EN = 111b enables the Radar Hardware Accelerator and any other value of the register keeps the accelerator engine in disabled state.
HWA_ENABLE.hwa_clk_en	1	No	Clock-gating Control: This register bit controls the enable/disable for the clock of the Radar Accelerator. This register bit can be set to 0 to clock-gate the accelerator when not using the accelerator. Before enabling the accelerator or before configuring the accelerator's registers, this register bit should be set first, so that the clock is available.
HWA_ENABLE.hwa_reset	3	No	Software Reset Control: This register provides software reset control for the Radar Hardware Accelerator. The assertion of these register bits by the main processor will bring the accelerator engine to a known reset state. This is mostly applicable for resetting the accelerator in case of unexpected behavior. Under normal circumstances, it is expected that whenever the accelerator is enabled (from disabled state), it always comes up in a known reset state automatically. The recommended sequence to be followed in case software reset is desired is to write 111b to this register and then a 000b, before the clock is enabled to the accelerator.
PARAM_RAM_LOOP.numloops	12	No	Number of loops: This register controls the number of times the state machine will loop through the parameter sets (from a programmed start index till a programmed end index) and run them. The maximum number of times the loop can be made is run is 4094. A value of 4095 (0xFFFF) programmed in this register should be considered as a special case and it should be interpreted as an infinite loop mode, for example, keep looping and never stop the accelerator engine unless reset by the main processor. A value of zero programmed in this register means that the looping mechanism is disabled. In this case, the accelerator engine can still be used under direct control of the main processor (without the state machine looping provision coming into the picture).

Table 6-593. State Machine Registers (continued)

PARAM_RAM_IDX.param_start_idx	4	No	Parameter-set Start Index: These registers are used to control the start and stop index of the parameter set through which the state machine loops through. The state machine starts at the parameter set specified by PARAM_START_IDX and loads each parameter set one after another and runs the accelerator as per that configuration. When the state machine reaches the parameter set specified by PARAM_END_IDX, it loops back to the start index as specified by PARAM_START_IDX.
PARAM_RAM_IDX.param_end_idx	4	No	Parameter-set Stop Index: Refer register description for PARAM_START_IDX
HWA_ENABLE. hwa_dyn_clk_en	1	No	Dynamic Clock-gating Control: Setting this register bit to '1' enables the capability to clock gate the unused computation engines (i.e., from the four computation engines, namely FFT, CFAR, Memory compression, Local Maxima) to save power consumption, based on the specific parameter-set being executed.
TRIGMODE	4	Yes	Trigger mode select: 0000b – Immediate trigger 0001b – Software trigger 0010b – Reserved 0011b – DMA-based trigger 0100b – Hardware based trigger 0101b – Reserved 0110b – Reserved 0111b – M4 Micro-controller based trigger (equivalent to software trigger, differentiating trigger source between external and HWA CPU.
FW2HWA_TRIG_0.fw2hwa_trigger_0	1	No	Software trigger bit: This register bit is relevant whenever software triggered mode is used (TRIGMODE = 001b). Whenever this software triggered mode is configured for a parameter set, the state machine keeps monitoring this register bit and waits as long as the value is zero. The main processor software can set this register bit, so that the state machine gets triggered and starts the accelerator operations for that parameter set.
FW2HWA_TRIG_1.fw2hwa_trigger_1	1	No	Software trigger bit: This register bit is similar to FW2HWA_TRIGGER_0, except that this register bit corresponds to TRIGMODE = 111b.
DMA2HWA_TRIG.dma2hwa_trigger	32	No	DMA trigger register: This register is relevant whenever DMA triggered mode is used (for example, TRIGMODE = 011b). Whenever a DMA channel has finished copying input samples into the local memory of the accelerator and wants to trigger the accelerator, the procedure to follow is to use a second linked DMA channel to write a 32-bit one-hot signature into this register to trigger the accelerator. In DMA triggered mode, the state machine keeps monitoring this 32-bit register and waits as long as a specific bit (see DMA2HWA_TRIGSRC) in this register is zero. The second linked DMA channel writes a one-hot signature that sets the specific bit, so that the state machine gets triggered and starts the accelerator operations for that parameter set.
DMA2HWA_TRIGSRC	5	Yes	DMA channel select for DMA completion trigger: This parameter-set register is relevant whenever DMA triggered mode is used (for example, TRIGMODE = 011b). This register selects the bit number in DMA2HWA_TRIGGER for the state machine to monitor to trigger the operation for that parameter set.

Table 6-593. State Machine Registers (continued)

CPU_INTR1_EN	1	Yes	Completion interrupt to main processor: This parameter-set register is used to enable/disable interrupt to the main processor upon completion of the accelerator operation for that parameter set. If enabled, the main processor receives an interrupt from the Radar Hardware Accelerator at the end of operations for that parameter set, so that the main processor can take any necessary action. Two interrupts are available, and this register bit enables or disables the first interrupt.
CPU_INTR2_EN	1	Yes	Completion interrupt to main processor: Similar to CPU_INTR1_EN. This register bit enables or disables the second interrupt to the main processor.
PARAM_DONE_SET_STATUS_0 . param_done_set_status_0 PARAM_DONE_SET_STATUS_1. param_done_set_status_1	32	No	Parameter-set done status: These read-only status registers can be used by the main processor to see which parameter sets are complete that led to the interrupt to the main processor. The individual bits in these 32-bit status register indicate which of the 64 parameter sets have completed. These status bits are not automatically cleared, but they can be individually cleared by writing to another set of 32-bit registers (PARAM_DONE_STATUS_CLR)
PARAM_DONE_STATUS_CLR_0 PARAM_DONE_STATUS_CLR_1	32	No	Refer register description for PARAM_DONE_SET_STATUS
DMATRIG_EN	1	Yes	Completion trigger to DMA: This parameter-set register is used to enable DMA channel trigger upon completion of the accelerator operation for that parameter set. This trigger mechanism enables the accelerator to hand-shake with the DMA so that output data samples are copied out of the accelerator local memory. If enabled, the accelerator triggers a specified DMA channel, so that the output samples can be shipped from the local memory to Radar data memory.
HWA2DMA_TRIGDST	5	Yes	DMA channel select for accelerator completion trigger: This parameter-set register is used to select which of the 32 DMA channels allocated to the accelerator should be triggered upon completion of the accelerator operation for that parameter set. This register is to be used in conjunction with DMATRIG_EN.
FW2DMA_TRIGGER. fw2dma_trigger	32	No	Trigger from processor to DMA: This register can be used by the processor to trigger a DMA channel for the first time, so that a full sequence of repeated operations between the DMA and the accelerator gets kick-started.
PARAMADDR.paramaddr	6	No	Debug register for current parameter-set index: This read-only status register indicates the index of the current parameter set that is under execution. This is useful for debug, where parameter sets can be executed in single-step manner (one-by-one) using SW trigger mode for each of them. In such a debug, this register indicates which parameter set is currently waiting for the SW trigger.
LOOP_CNT.loop_cnt	12	No	Debug register for current loop count: This read-only status register indicates what is the loop count that is presently running. When the state machine is programmed for NUMLOOPS loops, this register shows the current loop count that is running.
TRIGGER_SET_STATUS_0. Trigger_set_status_0	32	No	Debug register for trigger status: This is a read-only status register, which indicates the trigger status of the accelerator, for example, whether a DMA trigger was ever received (refer TRIGMODE). The 32 bits in this register correspond to the 32 DMA trigger bits (refer DMA2HWA_TRIGGER).
TRIGGER_SET_STATUS_1. Trigger_set_status_1	32	No	Debug register for trigger status: This is a read-only status register, which indicates the trigger status of the accelerator, for example, whether a specific hardware trigger or software trigger or context switch trigger has even been received. <TO_BE_UPDATED_IN_FUTURE_DOC_VERSION>

Table 6-593. State Machine Registers (continued)

TRIGGER_SET_IN_CLR_0. Trigger_set_in_clr_0	1	No	Clear trigger status read-only register: This register-bit when set clears the trigger status register TRIGGER_SET_STATUS_0 described above.
TRIGGER_SET_IN_CLR_1 Trigger_set_in_clr_1	1	No	Clear trigger status read-only register: This register-bit when set clears the trigger status register TRIGGER_SET_STATUS_1 described above.
FORCED_CONTEXTSW_EN	1	Yes	Force context switch: This register bit is useful in Context Switching. If this bit is set, the state machine switches the context to other thread after the completion of the current parameter-set. Refer the Context Switching section in Part 2 of the user guide for details.
CONTEXTSW_EN	1	Yes	Enable context switch: This register bit is useful in Context Switching. If this bit is set, the state machine is allowed to switch context at the end of execution of this parameter-set. Refer the Context Switching section in Part 2 of the user guide for details
PARAM_RAM_IDX_ALT.param_start_idx	10	No	Refer Context Switching section in Part 2 of user guide.
PARAM_RAM_IDX_ALT.param_end_idx	10	No	Refer Context Switching section in Part 2 of user guide.
PARAM_RAM_IDX_ALT.numloops	12	No	Refer Context Switching section in Part 2 of user guide.

The next two sections cover the Input Formatter and Output Formatter blocks, including their detailed operation, registers and usage procedure.

6.4.3 Accelerator Engine – Input Formatter

This section describes the input formatter block present in the accelerator engine (see Figure 6-599).

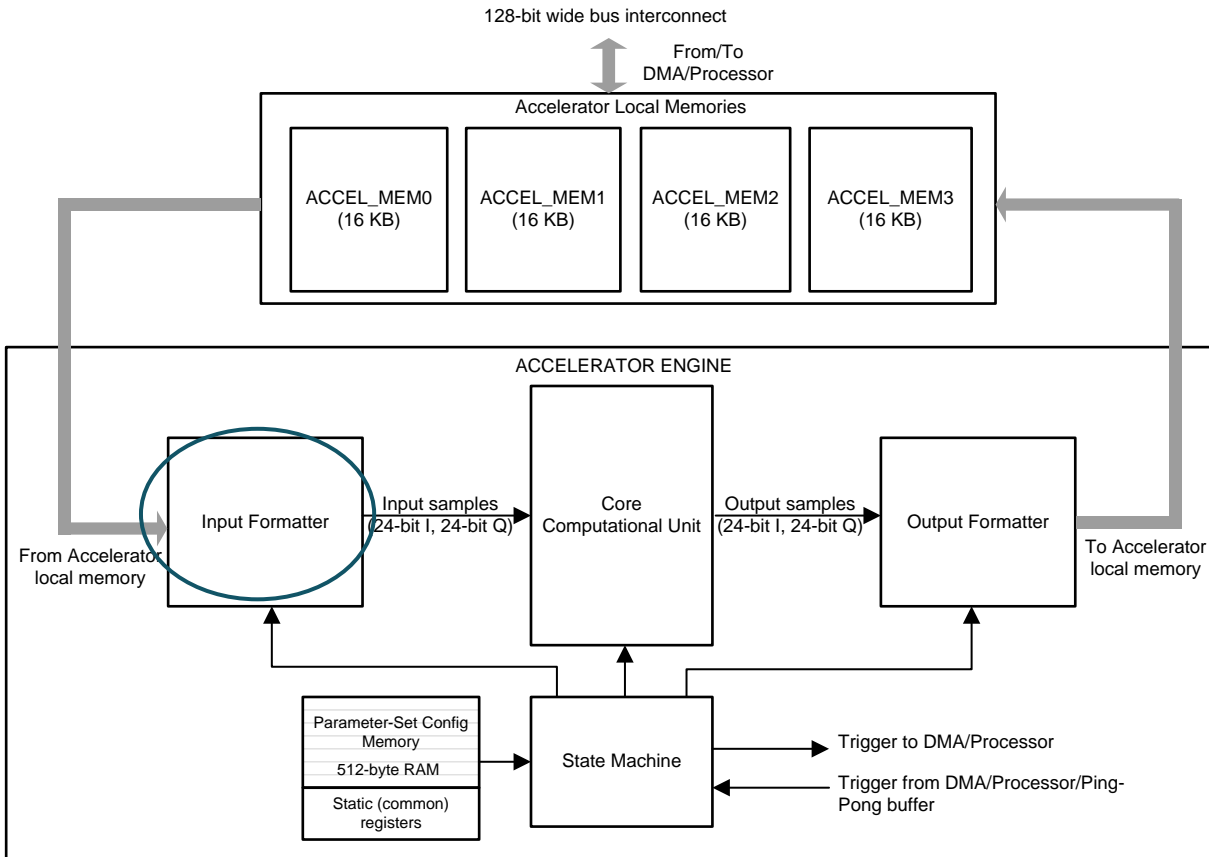

Figure 6-599. Input Formatter

6.4.3.1 Input Formatter

The input formatter is used to access, format, and feed the data from the local memories of the accelerator as 24-bit I and 24-bit Q samples into the core computational unit. The input formatter provides various capabilities to access and format the samples from the local memories – especially, various multidimensional access patterns (for example transpose access), 16-bit or 32-bit aligned word access, scaling using bit-shifts to generate 24-bit wide samples from 16-bit or 32-bit words, real versus complex input, sign extension, conjugation, and more.

6.4.3.1.1 Input Formatter – Operation

The input formatter block is responsible for reading the input samples from the accelerator local memory and feeding them into the core computational unit (see Figure 6-599). The data flow from the input formatter, through the core computational unit, to the output formatter is designed to sustain a steady-state throughput of one complex sample per clock cycle. The input formatter thus feeds one sample (24-bit I and 24-bit Q) into the core computational unit every clock cycle.

To make the best use of the capabilities of the core computational unit and to allow meaningful chaining of radar signal processing operations with minimal intervention from the R4F processor, the input formatter supports flexibility in how the input samples are accessed from the memory and how they are formatted and fed into the core computational unit.

The memory from which the input formatter picks up the data is referred to as *source memory*. Note that any of the four accelerator local memories can be the source memory. However, as will be described in a subsequent

section, there is an important restriction which explains that the source memory cannot be the same as the destination memory (which is the memory to which the output formatter writes the output data).

6.4.3.1.2 Input Formatter – 2D Indexed Addressing for Source Memory Access

The parameter-set register SRCADDR specifies the start address at which the input samples must be accessed. This register is a byte-address, and a value of 0x00000 corresponds to the first memory location of ACCEL_MEM0 memory. The SRCADDR register maps to the entire 128 KB address space of the eight accelerator local memories (8x16KB). Note that even though SRCADDR register is a 20-bit register, only the 17 LSB bits are used. The 3 MSB bits are reserved for future extension purpose.

The input data can be read from the memory as either 16-bit wide samples or 32-bit wide samples. Also, they can be read as real samples or complex samples. These two aspects are configured using register bits SRC16b32b and SRCREAL. See [Section 6.4.3.1.5](#) for a description of these and other registers pertaining to the input formatter block. As an example, if SRC16b32b = 0 and SRCREAL = 0, then the input samples are read from the memory as 16-bit complex samples (16-bit I and 16-bit Q), shown in [Figure 6-600](#).

An important feature of the input formatter block is that it supports flexible access pattern to fetch data from the source memory, which makes it convenient when the data corresponding to multiple RX channels are interleaved or when performing multi-dimensional (FFT) processing. This feature is facilitated through the SRCAINDX, SRCACNT, SRCBINDX, and BCNT registers, which are part of each parameter-set configuration.

The register SRCAINDX specifies how many bytes separate successive samples to be fetched from the source memory and the register SRCACNT specifies how many samples need to be fetched per iteration. An iteration is typically one computational routine, such as one FFT operation. It is possible to perform multiple iterations back-to-back – for example, four FFT operations corresponding to four RX channels. The register SRCBINDX specifies how many bytes separate the start of input samples for successive iterations and BCNT specifies how many iterations to perform back-to-back. These registers can be better understood using the example given in [Figure 6-600](#).

Figure 6-600. Input Formatter Source Memory Access Pattern (Example)

In [Figure 6-600](#), the input data consists of complex data (16-bit I and 16-bit Q) that is contiguously present in ACCEL_MEM0. The data in memory consists of four sets of 128 samples each (say, corresponding to four RX antennas) and these are shown in four different colors. Because each sample occupies 4 bytes and the samples are contiguously placed in the memory starting at the beginning of ACCEL_MEM0, values of SRCADDR = 0x0000 and SRCBNDX = 4 are used to fetch these samples.

In each clock cycle, the input formatter fetches one complex sample from the memory and feeds it into the core computational unit (with appropriate scaling, as described later). Because there are 128 samples to be fed for the first iteration (computational routine), a value of SRCACNT = 127 is used. For the second iteration, the samples are fetched starting from a memory location that is SRCBNDX (=128 × 4 = 512) bytes away from SRCADDR.

This process repeats for the programmed number of iterations as per the BCNT register. For example, the value of BCNT = 3 used in this example corresponds to four iterations. Note that the registers shown here are part of parameter-set configuration registers and the four iterations described here can be performed using a single parameter set. Thus, A-dimension is used to run through samples of a given vector, and B-dimension is used to repeat (iterate) the same operation for multiple vectors.

In addition to A and B dimensions, the Input Formatter also includes a provision for C-dimension. The C-dimension is only available in a certain restricted mode of operation called the Local Maxima Engine and its usage is explained in the part 2 of the user guide.

An important restriction in programming the registers related to source memory access pattern is that the input formatter can only read data from one memory row (128-bit memory location) in a clock cycle. Therefore, if a sample is placed in memory such that the real-part (I value) is at the end of one memory location and the imaginary part (Q value) is at the beginning of the next memory location, then that would be an invalid configuration (see [Figure 6-601](#)). Further, although the accelerator supports byte-addresses, only even values are allowed for SRCADDR, SRCAINDX, SRCBINDX and SRCCINDX.

Figure 6-601. Invalid Configuration Example

6.4.3.1.3 Input Formatter – Circular and Shuffled Addressing

The input formatter additionally supports circular addressing in each of the A, B and C dimensions. For the A dimension, the register, SRCA_CIRCSHIFT controls the initial offset, while the registers, SRCA_CIRCSHIFTWRAP and SRC_CIRCSHIFTWRAP3X (bit 0) indicate the circular modulus at which the wrap-around happens.

For example, if SRCA_CIRCSHIFT is programmed as 7, then the input formatter skips sample indices 0 to 6 and reads samples from the source memory starting directly from index 7 (i.e., the 8th sample). Then, for wrap-around, if SRCA_CIRCSHIFTWRAP is programmed with a non-zero value and the LSB bit (bit 0) of SRC_CIRCSHIFTWRAP3X is 0, then the sample index wraps around (i.e., resets to 0) at $2^{\wedge}SRCA_CIRCSHIFTWRAP$. Continuing the previous example, if SRCA_CIRCSHIFT = 7, SRCA_CIRCSHIFTWRAP = 9, and the LSB bit of SRC_CIRCSHIFTWRAP3X = 0, then the sample indices will be in the following order: 7, 8, 9, 10, 11, ..., 510, 511, 0, 1, 2, 3, 4, 5, 6. On the other hand, in the same example, if the LSB bit (bit 0) of SRC_CIRCSHIFTWRAP3X is set equal to 1, then the sample index wraps around at $3^{\wedge}2^{\wedge}SRCA_CIRCSHIFTWRAP$, and then the sample indices will be in the following order: 7, 8, 9, 10, 11, ..., 1534, 1535, 0, 1, 2, 3, 4, 5, 6. Circular shifting is generally useful in CFAR and Local Maxima engines. Its usage is explained in more detail in the CFAR engine section in the part 2 of the user guide.

Circular shifting is also supported in B-dimension with registers SRCB_CIRCSHIFT, SRC_CIRCSHIFTWRAP and SRC_CIRCSHIFTWRAP3X (bit 1).

In addition to linear and circular addressing, the input formatter allows a shuffled access, in either the A-dimension or the B-dimension (selectable through the register SHUFFLE_AB). When engaged in A-dimension, the A-dimension's sample index is remapped (or shuffled) through a programmable look up table, Shuffle LUT. The Shuffle LUT is a 256 element vector (RAM) storing 12-bit numbers and this LUT can be programmed by the user with the shuffled index pattern that is desired. This feature is useful in rearranging angle dimension input samples for FFT. Note that the Shuffle LUT can hold only 256 elements at most, and therefore the shuffled access is only supported for a maximum count of 256 (eg. SRCACNT of 255). Since Angle dimension FFT is usually small in size, this limitation is acceptable.

The start index within the Shuffle LUT (RAM) is also configurable in the parameter-set using the 4-bit register SHUFFLE_INDX_START_OFFSET. This 4-bit register value along with 4 LSBs padded as zeros becomes the 8-bit start index for the 256-element look-up table RAM. This feature allows multiple small shuffle patterns to be pre-stored in the Shuffle LUT, so that any of those patterns can be selected by appropriately setting this start index register in the parameter-set. For example, if SHUFFLE_INDX_START_OFFSET = 0010b, then the shuffled indices are picked up starting from index 32 (i.e., 00100000b) of the Shuffle LUT, and these shuffled indices in turn are used to pick up appropriate input samples from the source memory.

While A- and B-dimension have independent circular wrap around capabilities through the registers explained above, some use cases may need a combined (A, B) wrap around capability. A limited wrap around capability in the combined (A, B) dimension is provided through the register WRAP_COMB (see [Figure 6-602](#)). If shuffling

is enabled, it is possible that after combining (A, B) dimension, the combined value attempts to access an address outside the valid range. The register WRAP_COMB can be programmed to overcome this, and the input formatter wraps back any access outside the range [0, WRAP_COMB) to fall within this range.

Figure 6-602 shows how the sample count value (A-dimension sample index) and the iteration count value (B-dimension count) are used to calculate the address of the input sample to be fetched from the source memory. The exact addressing calculation is indicated in the schematic of the below figure. The bottom section of the figure showing C-dimension is only applicable in the case of a Local Max Engine mode of operation, which will be introduced later.

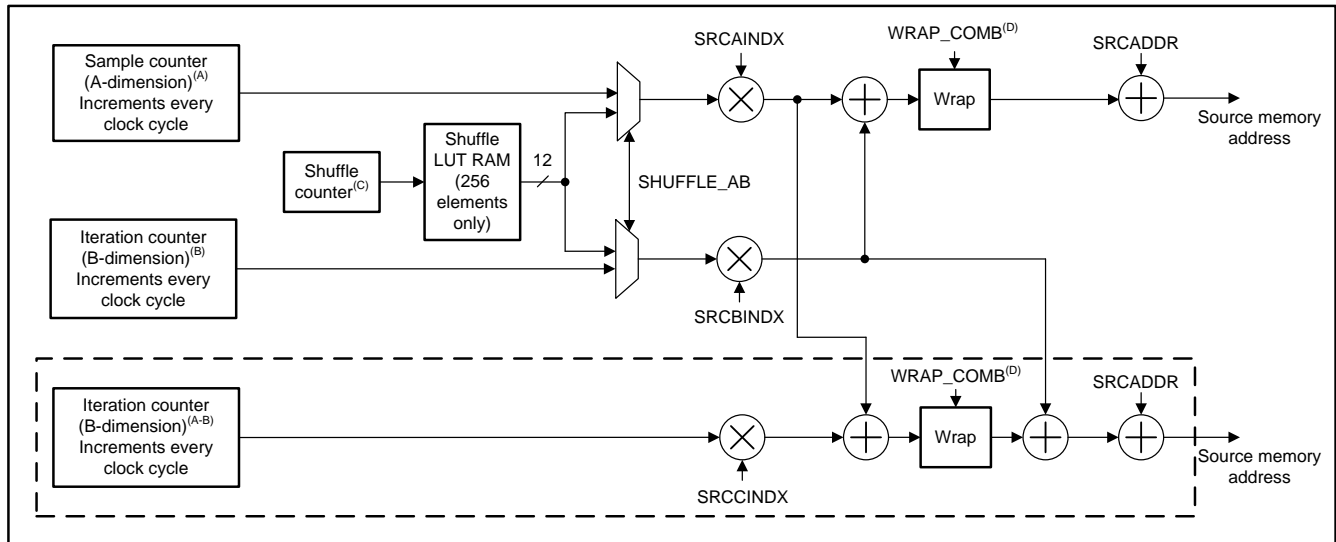

Figure 6-602. Input Formatter's Source Memory Address Generation

6.4.3.1.4 Input Formatter – Scaling and Formatting

The input formatter allows the input samples read from the source memory to be scaled and formatted before feeding them as 24-bit complex samples into the core computational unit.

Even though the data read from the source memory is initially 16-bits or 32-bits wide (for each I and Q), the samples expected by the core computational unit are 24-bit complex samples (24-bits each for I and Q). There is a SRCSCAL register which provides scaling options using bit-shift to generate 24-bit samples from the original 16- or 32-bit data (see Figure 6-603).

For the 16-bit case, the 24-bit sample is generated by padding (8-SRCSCAL) zeros at the LSB and SRCSCAL redundant MSBs. For the 32-bit case, the 24-bit sample is generated by dropping SRCSCAL bits at the LSB and clipping (8-SRCSCAL) bits at the MSB. Note that the register bit SRCIGNED is used to indicate whether the input samples are signed or unsigned. When this register bit is set, the input samples are treated as signed numbers and hence any extra MSB bits are sign-extended and any clipping of MSB bits takes care of signed saturation. In most cases of interest in part one of this user guide (for example, when performing FFT operation), the input samples would be signed and hence SRCIGNED should be set (i.e., equal to 1).

For 16-bit case, if REG_SRCSCAL = 5, then 5 zeros are padded at the LSB, and 3 redundant (extension) bits are padded at the MSB

For the 32-bit case, the 24-bit sample is generated by dropping REG_SRCSCAL bits at the LSB and clipping (8-REG_SRCSCAL) bits at the MSB

A. 16- or 32-bit words to 24-bit samples

Figure 6-603. Input Formatter Data Scaling

When the input samples are complex (for example, SRCREAL = 0), there is a provision to conjugate the input samples. Setting the register bit SRCCONJ conjugates the input samples before feeding them to the core computational unit. This feature (together with a corresponding DSTCONJ register bit in the output formatter block) enables an IFFT mode from the FFT engine. Note that conjugating the input and output of an FFT block is equivalent to an IFFT function.

There is also provision for swapping I and Q samples read from memory. This can be controlled using SRCIQSWAP register bit. If SRCIQSWAP = 0, then the I sample is located at the LSB bits, and the Q sample is located at the MSB bits.

There are other registers in the input formatter, such as BPM_EN, BPMPATTERNLSB and BPMPATTERNMSB, BPMRATE, and so on, which are beyond the scope of part one of this user's guide and these registers are described in part two. For the immediate purpose of the first part of the user's guide, it is important to note that BPM_EN and unused dimension (C) registers must be kept 0.

6.4.3.1.5 Input Formatter – Register Descriptions

Table 6-594 lists all the registers of the input formatter block.

Table 6-594. Input Formatter Registers

Register	Width	Parameter Set	Description
SRCADDR	20	Yes	Source start address: This register specifies the starting address of the input samples, for example, it specifies the source memory start address from which input samples have to be fetched by the input formatter. This is a byte-address but only even values are valid. This register covers the entire address space of the eight local memories (8 × 16KB = 128 KB). Only the 17 LSB bits of this register are relevant for this device, and the 3 MSB bits are reserved for future use. The eight accelerator local memories are contiguous in the memory address space and any of them can act as the source memory (as long as the same memory bank is not configured to be used as destination memory at the same time).
SRCACNT	12	Yes	Source sample count: This register specifies the number of samples (minus 1) from the source memory to process for every iteration. The sample count is in number of samples, not number of bytes. For example, the sample count can be specified as 255 (SRCACNT = 0x0FF) in a case where a 256-point FFT is required to be performed. Note however that the sample count register does not always match the FFT size. This can happen when zero-padding of input samples is required. For example, a sample count of 192 could be used with an FFT size of 256, in which case, the input formatter will automatically append 64 zeros.
SRCAINDX	20	Yes	Source sample index increment: This register specifies the number of bytes separating successive samples in the source memory. For example, a value of SRCAINDX = 16 means that successive samples are separated by 16 bytes in memory. Only even values are allowed for this register. The maximum value allowed for this register is 65534.

Table 6-594. Input Formatter Registers (continued)

BCNT	12	Yes	Number of iterations: This register specifies the number of times (minus 1) the processing should be repeated. This register can be used to process the four RX chains back-to-back – for example, a value of BCNT = 3 means that the processing (say first dimension FFT processing) is repeated four times. Note the distinction between the NUMLOOPS register of the state machine block and the BCNT register of the input formatter block. The NUMLOOPS register specifies how many times the state machine loops through all the configured parameter sets (with each time possibly awaiting a trigger), whereas the register BCNT specifies how many times the input formatter and the computational processing of the accelerator is iterated back-to-back for the current parameter set (without any intermediate triggers). Non-zero BCNT should be used only with non-zero ACNT.
SRCBINDX	20	Yes	Source offset per iteration: This register specifies the number of bytes separating the starting address of input samples for successive iterations. For example, when using four iterations to process the four RX chains, this register can be used to specify the offset in the starting address between the successive RX chains. Note the distinction that SRCAINDX specifies the number of bytes separating successive samples for a particular iteration, whereas SRCBINDX specifies the number of bytes separating the starting address of the first sample for successive iterations. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
CCNT	12	Yes	C-dimension count – i.e., Number of times (minus 1) that the B dimension iterations are performed. This register specifies the C-dimension count. C-dimension is applicable only to Local Maxima Engine. Non-zero CCNT should be used only with non-zero BCNT.
SRCCINDX	20	Yes	Source offset in C-dimension: This register specifies the number of bytes separating the starting address of input samples for successive sets of B-dimension iterations. Only even values are allowed for this register. Refer to the description section for details on the address generation logic.
SRCREAL	1	Yes	Complex or Real Input: This register-bit specifies whether the input samples are real or complex. A value of SRCREAL = 0 implies complex input and a value of SRCREAL = 1 implies real input. When real input is selected, the input formatter block automatically feeds zero for the imaginary part into the core computational unit.
SRCA_CIRCSHIFT	12	Yes	Start index for circular shift in A-dimension. Input Formatter reads samples from the source memory with this start offset to the sample index.
SRCB_CIRCSHIFT	12	Yes	Start index for circular shift in B-dimension (similar to A-dimension circular shift).
SRCA_CIRCSHIFTWRAP	4	Yes	Circular shift wrap-around point for A-dimension: This register, when set to a non-zero value, specifies the wrap-around point for A-dimension sample counter. If SRC_CIRCSHIFTWRAP3X (A-dimension bit) is set to 0, the A-dimension sample index counter wraps around (i.e., resets to 0) when the counter exceeds $(2^{\text{SRCA_CIRCSHIFTWRAP}}-1)$. When that bit is 1, the A-dimension sample index counter wraps around when the counter exceeds $(3 \cdot 2^{\text{SRCA_CIRCSHIFTWRAP}}-1)$.

Table 6-594. Input Formatter Registers (continued)

SRCB_CIRCSHIFTWRAP	4	Yes	Circular shift wrap-around point for B-dimension: This register, when set to a non-zero value, specifies the wrap-around point for B-dimension iteration counter. Functionality is similar to SRCA_CIRCSHIFTWRAP.
SRC_CIRCSHIFTWRAP3X	2	Yes	3X enable for circular shift wrap-around: This register is used in conjunction with SRCA_CIRCSHIFTWRAP and SRCB_CIRCSHIFTWRAP to specify the wrap-around point when circular shift is used. Bit 0 of this register corresponds to A-dimension, and bit 1 corresponds to B-dimension. Refer description of SRCA_CIRCSHIFTWRAP for details.
SHUFFLE_AB	2	Yes	Shuffled addressing: If this register is set to 0b01, the Shuffle LUT is used for sample index re-ordering in A-dimension. If it is set to 0b10, it is used in B-dimension. If this register is set to 0b00, the Shuffle LUT is bypassed / ignored.
SHUFFLE LUT RAM[256] DSS_HWA_SHUFFLE_RAM	12	No	This RAM stores the Shuffle LUT contents
SHUFFLE_INDX_START_OFFSET	4	Yes	Start index for the Shuffle LUT: This register together with 4 zeros padded at the LSB becomes the 8-bit starting index for the 256-element Shuffle LUT (RAM).
WRAP_COMB	20	Yes	Combined wrap around for A and B dimension: This is applicable in Shuffled addressing mode. The combined A & B dimension based address offset is wrapped around this number.
SRC16b32b	1	Yes	16-bit or 32-bit input word alignment: This register-bit specifies whether the input samples fetched from source memory are to be read as 16-bits or 32-bits wide. A value of SRC16b32b = 0 implies that the input samples are 16-bits wide each (in case of complex input, real and imaginary parts are each 16 bits wide). A value of SRC16b32b = 1 implies that the input samples are 32-bits wide each.
SRCIGNED	1	Yes	Input sign-extension mode: This register-bit, when set, specifies that the input samples are signed numbers and hence, sign-extension or signed-saturation at the MSB is required when converting 16-bit or 32-bit input words to the 24-bit wide samples to be fed into the core computational unit.
SRCCONJ	1	Yes	Input conjugation: This register-bit specifies whether the input samples should be conjugated before feeding them into the core computational unit. If SRCCONJ is set, then the input samples are conjugated. Setting this register-bit only makes sense if the samples are complex numbers (for example, SRCREAL = 0). This register, together with its counterpart in the output formatter block, enable an IFFT mode for the FFT engine. Note that conjugating the input and output of an FFT block is equivalent to an IFFT function.
SRCSCAL	8	Yes	Input scaling: This register specifies a programmable scaling using bit-shift, when converting the 16-bit or 32-bit wide input data to 24-bit wide samples before feeding into the core computational unit. See Figure 8 and its description for more details regarding this register.
SRCIQSWAP	1	Yes	Swap the I & Q samples drawn from memory. LSB bits drawn from memory is used as I, and the MSB bits are used a Q of input
IP_OP_FORMATTER_CLIP_STATUS. ip_formatter_clip_status	1	No	Read-only register that indicates clip status for input formatter (during scaling).

Table 6-594. Input Formatter Registers (continued)

CLR_CLIP_MISC.clr_clip_status	1	No	Below clip status read-registers will be cleared upon writing to this self-clearing register bit: channel_comb_clip_status, dc_acc_clip_status, dc_est_clip_status, intf_stats_mag_accumulator_clip_status, intf_stats_magdiff_accumulator_clip_status, intf_stats_thresh_mag_clip_status, intf_stats_thresh_magdiff_clip_status, twid_incr_delta_frac_clip_status, ip_formatter_clip_status, op_formatter_clip_status
BPM_PATTERN_0, BPMPATTERN_1, ... BPMPATTERN_7	–	–	Described in part two of this user's guide. For the immediate purposes relevant to part one of this user's guide, all of these registers must be kept as 0.
BPMRATE	–	–	Described in part two of this user's guide.
BPMPHASE	–	–	Described in part two of this user's guide.

6.4.4 Accelerator Engine – Output Formatter

This section describes the output formatter block present in the accelerator engine (see [Figure 6-604](#)).

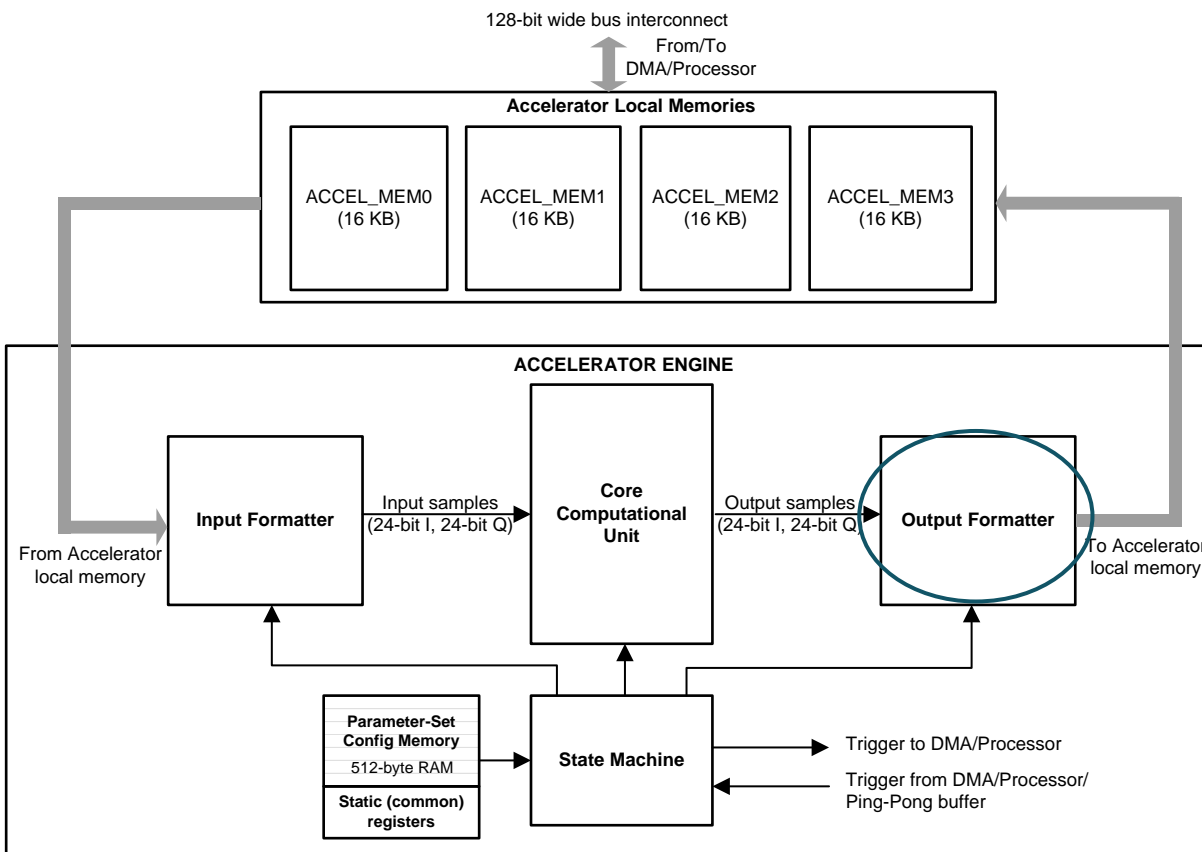

Figure 6-604. Output Formatter

6.4.4.1 Output Formatter

The output formatter is used to format and write the data coming out of the core computational unit into the accelerator local memory. Similar to the input formatter block discussed in the previous section, the output formatter block also provides various capabilities to format and write the samples written to the local memory – especially, various multidimensional access patterns (for example, transpose writes), 16-bit or 32-bit aligned word writes, scaling using bit-shifts to generate 16-bit or 32-bit words from 24-bit wide samples, real versus complex output write, and more.

6.4.4.1.1 Output Formatter – Operation

The output formatter block is responsible for storing the samples coming out of the core computation unit into the accelerator local memory (see [Figure 6-604](#)). As mentioned in the previous section, the data flow from the input formatter, through the core computational unit, to the output formatter, is designed to sustain a steady-state throughput of one complex sample per clock cycle. Thus, typically, the output formatter accepts one sample (24-bit I and 24-bit Q) from the core computational unit every clock cycle and writes it to the accelerator local memory. Just like the input formatter, the output formatter also supports lot of flexibility in how the samples are formatted and written into the memory.

The memory into which the output formatter writes the data is referred to as *destination memory*. Note that any of the four accelerator local memories can be the destination memory, with the important restriction that the source memory cannot be same as the destination memory. In other words, each of the eight 16KB memory banks can either function as source memory, or as destination memory at any time (for example, in any given parameter set).

6.4.4.1.2 Output Formatter – 2-D Indexed Addressing for Destination Memory Access

The parameter-set register DSTADDR specifies the start address at which the output samples must be written into the accelerator local memory. Similar to the SRCADDR register of the input formatter, the DSTADDR register of the output formatter is a byte-address and a value of 0x0 corresponds to the first memory location of ACCEL_MEM0 memory. The DSTADDR register maps to the entire 128KB address space of the eight accelerator local memories (each 16KB). As mentioned in the previous paragraph, in a given parameter set, SRCADDR and DSTADDR cannot be configured such that the input samples being fetched and the output samples being written out are accessing the same memory bank.

Even though the core computational unit produces a 24-bit complex output stream, this output data can be written to the memory as either 16-bit wide samples or 32-bit wide samples. Also, they can be written out as complex samples or real samples (for example, drop imaginary part – applicable when performing log-magnitude computation). These two aspects are configured using register bits DST16b32b and DSTREAL. See [Section 6.4.4.1.4](#) for a description of these and other registers pertaining to the output formatter block. As an example, if DST16b32b = 0 and DSTREAL = 0, then the output samples are written to the memory as 16-bit complex samples (16-bit I and 16-bit Q), shown in [Figure 6-605](#).

Similar to the input formatter block, the output formatter block also supports flexible patterns to write multidimensional data to the destination memory and this makes it convenient when the data corresponding to multiple RX channels must be interleaved, or when performing multidimensional (FFT) processing. This feature is facilitated through the DSTAINDX, DSTACNT, DSTBINDX, and BCNT registers, which are part of each parameter-set configuration.

The register DSTAINDX specifies how many bytes separate successive samples to be written to the destination memory and the register DSTACNT specifies how many samples must be written per iteration. Note that DSTACNT can be different from SRCACNT – this is useful when only a subset of the output samples need to be stored in the output memory (for example, if some FFT output bins must be discarded). The register DSTBINDX specifies how many bytes separate the start of output samples for successive iterations and BCNT specifies the number of iterations. The BCNT register is common for input formatter and output formatter. These registers can be better understood using the example given in [Figure 6-605](#).

Figure 6-605. Output Formatter Destination Memory Access Pattern (Example)

In the example shown in [Figure 6-605](#), the output data consists of complex data (16-bit I and 16-bit Q) that is written to ACCEL_MEM3. The output data consists of four sets of 128 samples each (say, corresponding to FFT output of four RX antennas) and these are shown in four different colors. Each sample occupies 4 bytes and the samples are written to the output memory at a specific start address inside ACCEL_MEM3, as shown in [Figure 6-605](#). The samples for the four RX antennas are written to the memory in an interleaved manner. Thus, for this example, a value of DSTADDR = 0xC040, DSTAINDX = 16, DSTACNT = 127, and DSTBINDX = 4 are used. The register BCNT (common for input formatter and output formatter) is configured with a value of 3, corresponding to the four iterations required (for the four RX antennas). In steady state, for each clock cycle, the output formatter accepts one complex sample from the core computational unit and writes it into the memory as per the 2-D indexed addressing pattern programmed.

The register DSTACNT, which corresponds to the number of samples written to the destination memory for each iteration does not need to be equal to SRCACNT. This is useful in cases where some of the output samples (for example, some FFT bins at the end) can be dropped and do not need to be written into the destination memory. Another register, DST_SKIP_INIT is also available, which can be used to skip some samples in the beginning as well. The number of samples written to the destination memory for each iteration is equal to (DSTACNT + 1) – DST_SKIP_INIT.

Note that when performing FFT operations, internally the core computational unit sends out FFT output data in bit-reversed addressing order, but this is automatically handled in the output formatter, such that when the FFT output samples are written into the destination memory, they are written out in the correct normal order. Therefore, no special procedure is required on the part of the main processor to read the FFT output samples in the right sequence.

Similar to the input formatter, the output formatter can write data into only one memory row (128-bit memory location) in a clock cycle. Therefore DSTADDR, DSTAINDX, and DSTBINDX should be programmed such that

no sample needs to be partially written in one memory row and the next (e.g. if $DST16b32b=1$). Also, these address parameters should be restricted to even values.

6.4.4.1.3 Output Formatter – Scaling and Formatting

The output formatter allows the 24-bit output samples from the core computational unit to be scaled and formatted before writing them to the destination memory as 16-bit or 32-bit words. There is a `DSTSCAL` register which provides scaling options using bit-shift, to take the 24-bit samples and convert them to 16-bit or 32-bit data.

For the 16-bit case (see [Figure 6-606](#)), the 24-bit sample (24-bits for each I and Q) is converted to 16-bit word by dropping `DSTSCAL` bits at the LSB and by clipping with saturation (8-`DSTSCAL`) bits at the MSB. For the 32-bit case, the 24-bit sample is padded with `DSTSCAL` extra bits at the MSB and with (8-`DSTSCAL`) extra zeros at the LSB. Note that the register bit `DSTSIGNED` is used to indicate whether the output samples are signed or unsigned. When this register bit is set, the output samples are treated as signed numbers and therefore any extra MSB bits are sign-extended and any clipping of MSB bits handles signed saturation. In most cases of interest in part one of this user's guide (for example, when performing FFT operation), the output samples would be signed and therefore `DSTSIGNED` should be set (for example, equal to 1). However, if the log-magnitude operation in the core computational unit is enabled, then the output samples are unsigned and therefore `DSTSIGNED` is cleared (for example, equal to zero).

For 16-bit case, if `REG_DSTCAL = 3`, then 3 bits are dropped at the LSB, and 5 bits are clipped (saturated) at the MSB

For 32-bit case, if `REG_DSTCAL = 3`, then 5 zeros are padded at the LSB, and 3 bits are extended at the MSB

Figure 6-606. Output Formatter Data Scaling

When the output samples are complex (for example, `DSTREAL = 0`), there is a provision to conjugate the output samples. Setting the register bit `DSTCONJ` conjugates the output samples before writing them to the destination memory. This feature (together with a corresponding `SRCCONJ` register bit in the input formatter block) enables an IFFT mode from the FFT engine.

In addition, there is provision for swapping I and Q samples written into the destination memory. This is controlled using `DSTIQSWAP` register bit.

6.4.4.1.4 Output Formatter – Register Descriptions

[Table 6-595](#) lists all the registers of the output formatter block.

Table 6-595. Output Formatter Registers

Register	Width	Parameter Set	Description
DSTADDR	20	Yes	Destination start address: This register specifies the starting address of the output samples, for example, it specifies the destination memory start address at which the output samples have to be written by the output formatter. This is a byte-address but only even values are valid. This register covers the entire address space of the eight local memories ($8 \times 16\text{KB} = 128\text{KB}$). Only the 17 LSB bits of this register are relevant for this device, and the 3 MSB bits are reserved for future use. The eight accelerator local memories are contiguous in the memory address space and any of them can act as the destination memory (as long as the same memory bank is not configured to be used as source memory at the same time).

Table 6-595. Output Formatter Registers (continued)

DSTACNT	12	Yes	Destination sample count: This register specifies the number of samples (minus 1) to be written to the destination memory for every iteration. The sample count is in number of samples, not number of bytes. For example, the sample count can be specified as 191 (DSTACNT = 0x0BF) in a case where 192 samples must be written. Note that the DSTACNT register can be different from SRCACNT or even the FFT size. This is useful when only a part of the FFT bins must be written to memory and the remaining (far-end FFT bins) can be discarded. This register description is true when the DST_SKIP_INIT register value is zero (see further for more information related to DST_SKIP_INIT).
DSTAINDX	20	Yes	Destination sample index increment: This register specifies the number of bytes separating successive samples to be written to the destination memory. For example, a value of DSTAINDX = 16 means that successive samples written to the destination memory should be separated by 16 bytes. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
DSTBINDX	20	Yes	Destination offset per iteration: This register specifies the number of bytes separating the starting address of output samples for successive iterations. For example, when using four iterations to process four RX chains, this register can be used to specify the offset in the starting address between the successive RX chains. Note the distinction that DSTAINDX specifies the number of bytes separating successive samples for a particular iteration, whereas SRCBINDX specifies the number of bytes separating the starting address of the first sample for successive iterations. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
DST_SKIP_INIT	10	Yes	Destination skip sample count: This register specifies how many output samples should be skipped in the beginning, before starting to write to the destination memory. This is useful if only a certain part of the FFT output (skipping the first several bins) need to be stored in memory. The total number of samples written to destination memory is equal to DSTACNT+1-DST_SKIP_INIT.
DSTREAL	1	Yes	Complex or real output: This register-bit specifies whether the output samples are real or complex. A value of DSTREAL = 0 implies complex output and a value of DSTREAL = 1 implies real output. When real output is selected, the output formatter block automatically stores only the real part into the destination memory. This is useful when the core computational unit is configured to output magnitude or log-magnitude values.

Table 6-595. Output Formatter Registers (continued)

DST16b32b	1	Yes	16-bit or 32-bit output word alignment: This register-bit specifies whether the output samples are to be written as 16-bits or 32- bits wide in the destination memory. A value of DST16b32b = 0 implies that the output samples are to be written as 16-bit words (in case of complex output, real and imaginary parts are each 16 bits wide). A value of DST16b32b = 1 implies that the output samples are 32-bits wide each.
DSTSIGNED	1	Yes	Output sign-extension mode: This register-bit, when set, specifies that the output samples are signed numbers and therefore, sign-extension or signed-saturation at the MSB is required when converting the 24-bit wide samples coming from the core computational unit into 16-bit or 32-bit output words to be written to the destination memory.
DSTCONJ	1	Yes	Output conjugation: This register-bit specifies whether the output samples must be conjugated before writing them into the destination memory. If DSTCONJ is set, then the output samples are conjugated. Setting this register-bit only makes sense if the samples are complex numbers (for example, DSTREAL = 0). This register, together with its counterpart in the output formatter block, enables an IFFT mode for the FFT engine.
DSTSCAL	8	Yes	Output scaling: This register specifies a programmable scaling using bit-shift, when converting the 24-bit samples coming from the core computational unit into 16-bit or 32-bit wide words to be written to the destination memory. See Figure 11 and its description for more details regarding this register.
DSTIQSWAP	1	Yes	IQ Swapping : Swap the I & Q samples written out to memory.
IP_OP_FORMATTER_CLIP_STATUS. op_formatter_clip_status	1	No	Read-only register that indicates clip status for output formatter (during scaling).
DMEM0, DMEM1... DMEM7 (MEM_ACCESS_ERR_STATUS) MEM_ACCESS_ERR_STATUS.dmem0..7	1	No	Memory access error: This set of 8 1-bit read-only registers indicates if there is a memory access error caused by incorrect configuration or usage of the accelerator, where both the DMA and the accelerator are attempting to access the same 16KB memory at the same time. The composite 8- bit register indicates the error status for the 8 16KB memories (DMEM0 bit corresponds to ACCEL_MEM0).

6.4.5 Accelerator Engine – Core Computational Unit

This section describes the core computational unit present in the accelerator engine (see Figure 6-607).

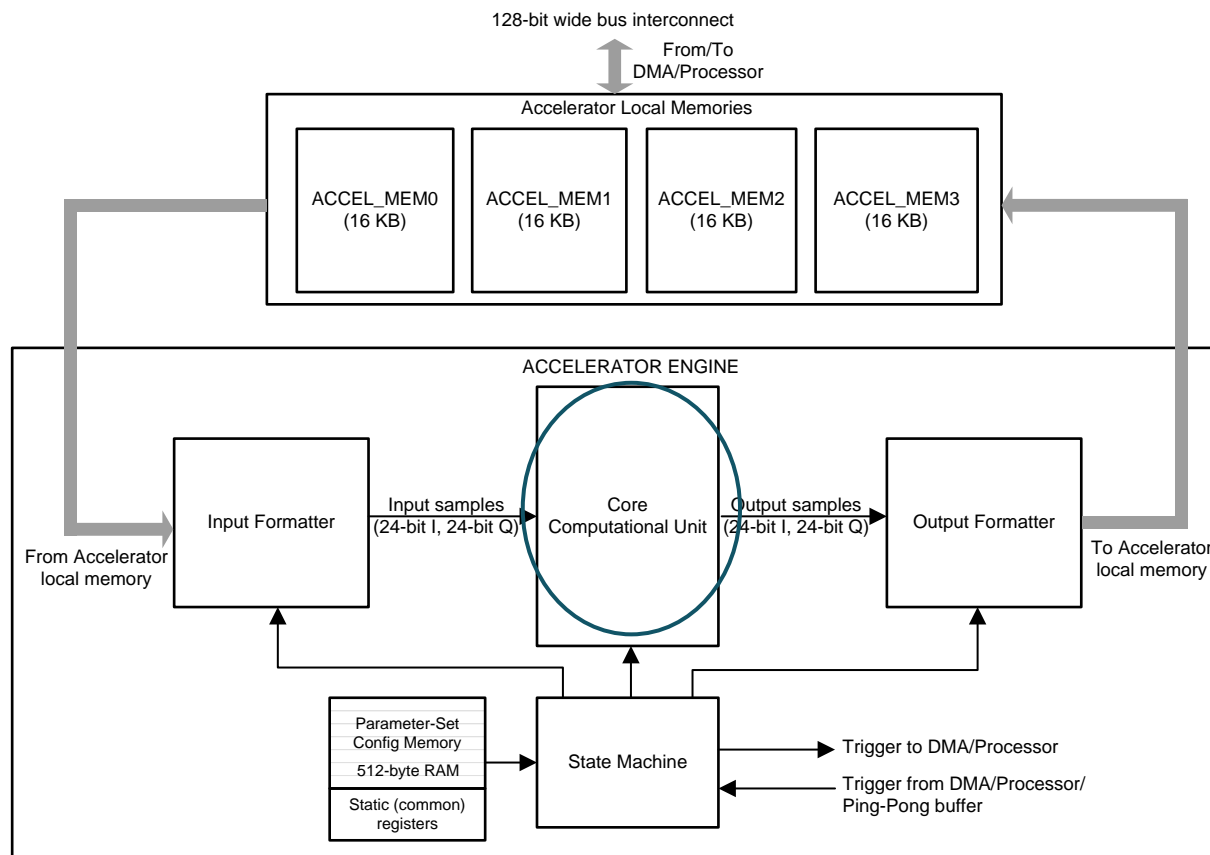

Figure 6-607. Core Computational Unit

6.4.5.1 Core Computational Unit

The core computational unit performs the mathematical operations required for the key functions, such as FFT, log-magnitude, CFAR detection, and so on. The core computational unit accepts a streaming 24-bit complex input (24 bits for each I and Q) from the input formatter block and it outputs a streaming 24-bit complex output (24 bits for each I and Q) to the output formatter block.

Figure 6-608 shows the block diagram of the core computational unit. The core computational unit has four main computation engines, namely:

- FFT Engine: Performs Pre-processing, Windowing, FFT and Log-magnitude.
- CFAR Engine: Performs CFAR detection using CFAR-CA or CFAR-OS method.
- Local Maxima Engine: Performs threshold and local maxima based peak identification.
- Compression Engine: Used for compression and decompression of radar data.

Only one of these four engines can be operational at any given instant. However, in separate parameter sets, different engines can be configured and used, so that multiple parameter sets executing one after another can accomplish a sequence of computational operations as desired. The register ACCEL_MODE controls which engine gets used in a given parameter set.

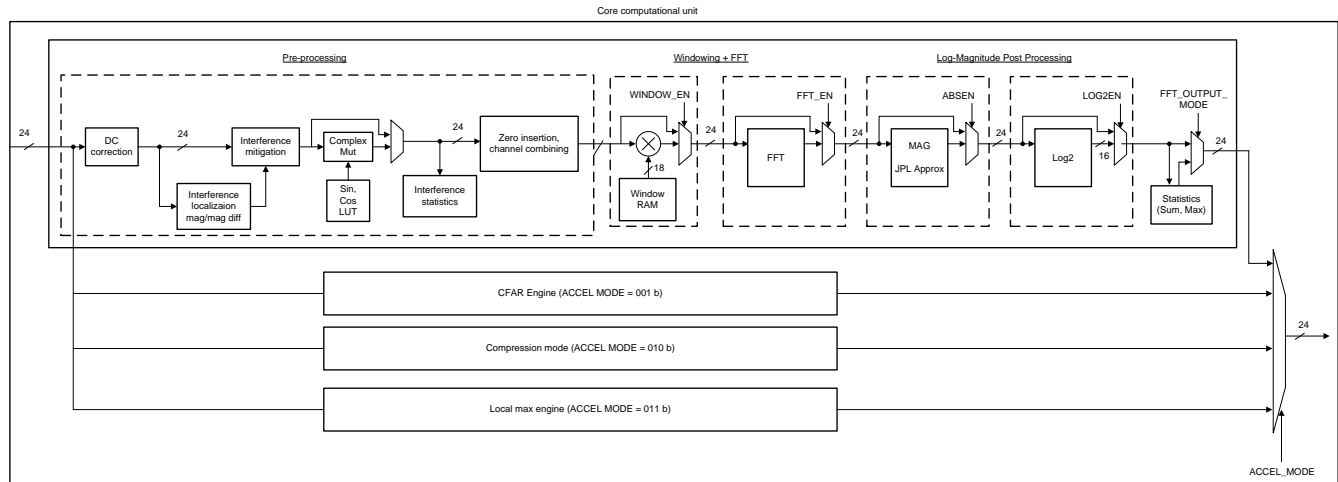

Figure 6-608. Core Computational Unit Block Diagram

For the purpose of part one of the user's guide, only the FFT Engine path is described. Specifically, the windowing, FFT, and log-magnitude operations are covered in this document. The greyed-out blocks in Figure 6-608, namely the Pre-processing, Statistics, and CFAR Engine, are covered in part two of the user's guide and can be ignored for the present purpose.

6.4.5.1.1 Core Computational Unit – FFT Engine – Operation

The core computational unit operates on the streaming input of samples coming from the input formatter block, and in general outputs a stream of samples (after an initial latency in some cases) to the output formatter block. In general, at steady-state, one input sample is processed and one output sample is produced every clock.

The FFT Engine in the core computational unit has the ability to perform pre-processing, windowing, FFT, and log-magnitude computations. Each of these computational subblocks operate on a streaming input and produce a streaming output at the throughput of one sample per clock. These computational subblocks are stitched together one after the other in a series, as shown in Figure 14. This architecture allows multiple operations to be done in a streaming manner (for example, windowing and FFT can be done together), while at the same time, providing the user flexibility to choose one operation at a time.

The parameter-set registers WINDOW_EN, FFT_EN, ABS_EN, and LOG2_EN control the multiplexers (see Figure 14), which decide what operations are performed on the input samples for that parameter set.

Notethat for the purpose of part one of the user's guide, the registers ACCEL_MODE and FFTOUT_MODE must be kept at zero. The purpose of these registers is covered in part two.

6.4.5.1.2 Core Computational Unit – FFT Engine – Windowing

The incoming samples from the input formatter to the core computational unit are passed through the (optional) windowing operation (see Figure 6-609). Windowing operation is often required prior to performing FFT, to mitigate the sinc roll-off leakage from one strong FFT bin to the adjacent bins.

As the incoming samples from the input formatter stream in, each sample is multiplied by the appropriate window coefficient read from a Window RAM. Because the incoming samples are complex 24-bits wide (24-bits for each I and Q), the windowing operation involves multiplying the 24-bit I and 24-bit Q of the incoming sample with the window coefficient (see Figure 6-609). The output of this multiplication is rounded back to 24-bit I and 24-bit Q by dropping excess LSBs. Note that windowing can be enabled by setting the register bit WINDOW_EN to 1.

The window RAM can hold up to 2048 32-bit words. The window coefficients can be stored in these words in one of the following three formats:

1. 18-bit real coefficients: If WINDOW_MODE = 0b00, the window coefficients are assumed to be 18-bit signed real values. Up to 2048 real coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores one 18-bit coefficient).
2. 16-bit real coefficients: If WINDOW_MODE = 0b01, the window coefficients are assumed to be 16-bit signed real values. Up to 4096 real coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores two successive 16-bit coefficients: the 16LSBs store coefficients 0, 2, 4, etc. and 16MSBs store coefficients 1, 3, 5, etc.).
3. 16-bit complex coefficients: If WINDOW_MODE = 0b10, the window coefficients are assumed to be 16-bit I and 16-bit Q complex values. Up to 2048 complex coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores the real part of the coefficient in the 16 LSBs of the word and the imaginary part in the 16 MSBs of the word).

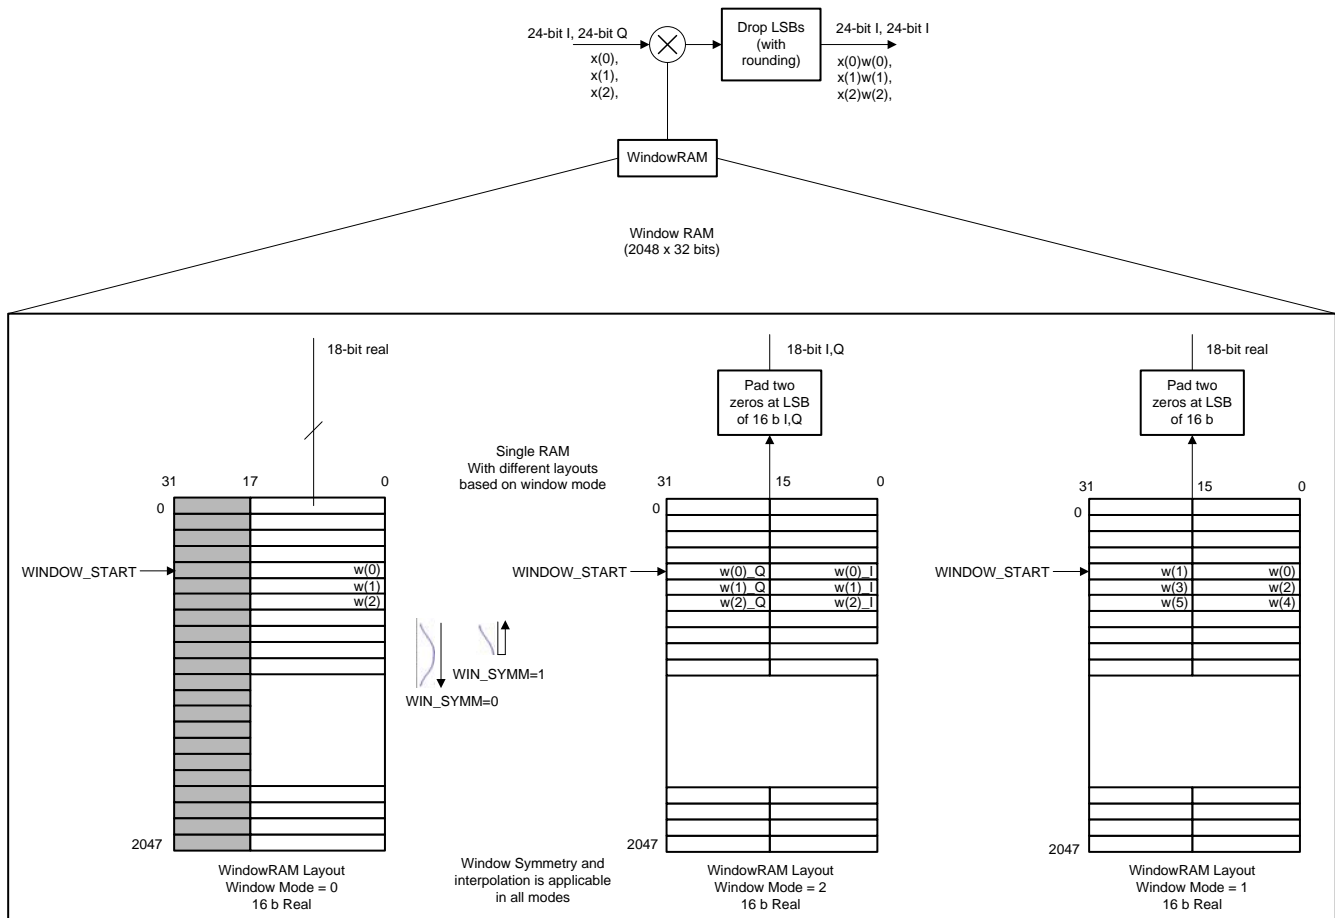

Figure 6-609. Window RAM Layout for 18b Real, 16b Complex and 16b Real Modes

The start location (32-bit word index) in the window RAM is programmed in a 11-bit register WINDOW_START as part of the parameter set, so that the windowing computation can pick the appropriate window coefficients starting from that index. For each incoming sample, the index keeps incrementing, so that each successive sample is multiplied by the successive window coefficient. At the end of each iteration (for example, when

SRCACNT number of samples have been processed), the index resets back to the starting coefficient index programmed for the parameter set, so that the next iteration can be performed. At the end of all the iterations of the current parameter set, the next parameter set can use a different window if desired. For example, when performing second- and third-dimension FFTs one after another (in two parameter sets), the window functions for both these FFTs can be pre-stored in the Window RAM and appropriate start index can be provided for each of the FFT operation dimensions.

If the window function is symmetric, the user may store only one half of the window coefficients in the Window RAM. The register bit WINSYMM, when set, indicates that after $\text{SRCACNT} / 2$ samples (or, if SRCACNT is odd, $(\text{SRCACNT} + 1) / 2$ samples) are processed, the window coefficients read-indexing must be reversed, so that the same set of coefficients used for the first $\text{SRCACNT} / 2$ samples are reused in the reverse order for the next $\text{SRCACNT} / 2$ samples. (See [Figure 6-609](#)). If SRCACNT is odd, then the last window coefficient is read only once, when the direction is reversed. If SRCACNT is even, then the last window coefficients is read twice, when the direction is reversed. In the dynamic window mode, the coefficients are read from the corresponding bank only.

The output of the windowing computation is 24-bit I and 24-bit Q, which is streamed into the FFT subblock.

6.4.5.1.3 Core Computational Unit – FFT Engine – FFT

The FFT subblock performs FFT on the incoming 24-bit I and 24-bit Q data stream. The FFT size is programmable, in the range, 2 to 2048. FFTs of length $2N$ for $N = 0$ to 11, and $3 \times 2N$ for $N = 0$ to 9 are supported. Advanced features such as direct computation of two-dimensional FFTs, as well as an FFT *stitching* feature that realizes FFTs of larger lengths using a two-step process, are also supported. But their description is deferred to the part two of the user's guide.

The lowest FFT size of 2 is mostly useful as a *complexadd-subtract* feature or while using the *FFTstitching* feature. FFT sizes of 4, 8, 16, and 32 can be used for third dimension (angle estimation) FFT.

The FFT operation can be enabled or disabled by using the register bit FFT_EN. When enabled, the FFT subblock computes the FFT of the input data stream and produces a 24-bit I and 24-bit Q output stream. This output stream is initially in bit-reversed order, but the output formatter handles appropriately writing the output to the destination memory in the correct order.

The FFT implementation comprises a series of butterfly stages. Depending on the FFT size needed, an appropriate number of butterfly stages are employed. The FFT size is programmed using the registers, FFTSIZE and FFTSIZE_3X_EN.

For power-of-2 FFT sizes, the register bit FFTSIZE_3X_EN should be kept 0. The FFT size is configured using the register FFTSIZE and the actual FFT size in this case is 2^{FFTSIZE} . When an FFT size of the form $(3 * \text{power-of-2})$ is needed, then the register bit FFTSIZE_3X_EN should be set to 1. In this case, the actual FFT size is $3 * 2^{\text{FFTSIZE}}$.

For example, if FFTSIZE_3X_EN is 0, then FFTSIZE = 5 means 32-point FFT, FFTSIZE = 7 means 128-point FFT, and so on. In this case, the FFT is realized using a series of FFTSIZE number of radix-2 butterfly stages. On the other hand, if FFTSIZE_3X_EN is set to 1, then FFTSIZE = 5 means a 96-point FFT, FFTSIZE = 7 means 384-point FFT. In these cases, an additional radix 3 butterfly stage is engaged before feeding to the original series of radix-2 butterfly stages.

Note that the FFT size must be equal to or larger than SRCACNT, and the input formatter block automatically zero-pads extra samples to account for the difference between FFT size and SRCACNT.

6.4.5.1.4 Core Computational Unit – FFT Engine – FFT – Zero Padding

The FFT engine has provision for *zeropadding*, which is important when performing FFT of a set of samples whose length doesn't match a supported FFT size. The FFT engine automatically feeds the required number of zeros into the core computational unit, whenever the FFT size (as programmed using the FFTSIZE register, which is described in a later section) does not match the SRCACNT setting.

For example, if the number of input samples read by the input formatter is 56 (for example, SRCACNT = 55) and the FFT size is programmed to be 64 (FFTSIZE = 6, FFTSIZE_3X_EN = 0), then the FFT engine feeds

8 zeros at the end of each iteration, before starting to read the input samples for the next iteration from the source memory. This zero-padding provision enables the core computational unit to perform 64-point FFT with the correct set of zero-padded input samples.

The zero padding is effective only when performing FFT operation in the core computational unit (i.e., when `FFT_EN = 1`) and not otherwise. Advanced features such as zero insertion (at programmable locations) and channel combining are described in part 2 of this user guide.

6.4.5.1.5 Core Computational Unit – FFT Quantization and Speed Performance

As is well known, a butterfly stage typically consists of add-subtract and twiddle multiplication operations. At the output of each add-subtract structure, the bit-width would increase by 1 bit (for example, 24-bit input would grow to 25-bit output). To handle this one-bit growth due to add-subtract operation, there is a provision at the output of each butterfly add-subtract stage to scale the result back to 24 bits, by either dividing the output by 2 (round off one LSB) or by saturating one MSB, shown in [Figure 6-610](#).

The multi-bit register `BFLY_SCALING` is used to control this divide-by-2 scaling operation at each stage, so that the user has full flexibility to control the signal level through the different butterfly stages. If `BFLY_SCALING = 0` for a particular stage, then the 25-bit output is saturated at the MSB to get back to 24 bits. Otherwise, it is convergent-rounded at the LSB to get back to 24 bits. The user can thus control the scaling at each of the butterfly stages. The LSB of this multi-bit register corresponds to the last stage and the MSB of this register corresponds to the first stage. For an FFT size of 64, only the LSB 6 bits are relevant. Similarly, for an FFT size of 3^*64 , the LSB 6 bits are relevant. Additionally the register, `BFLY_SCALING_FFT3X` indicates the scaling option for the single radix-3 stage (i.e., it supports removing 0 or 1 or 2 LSBs).

There is a multi-bit read-only register `FFTCLIP` which indicates whether there was any clipping in any of the butterfly stages. This register is a sticky register that gets set when a clipping event occurs and remains set until it is cleared using the `CLR_FFTCLIP` register bit. See the register description of `FFTCLIP` in [Section 6.4.5.1.9](#).

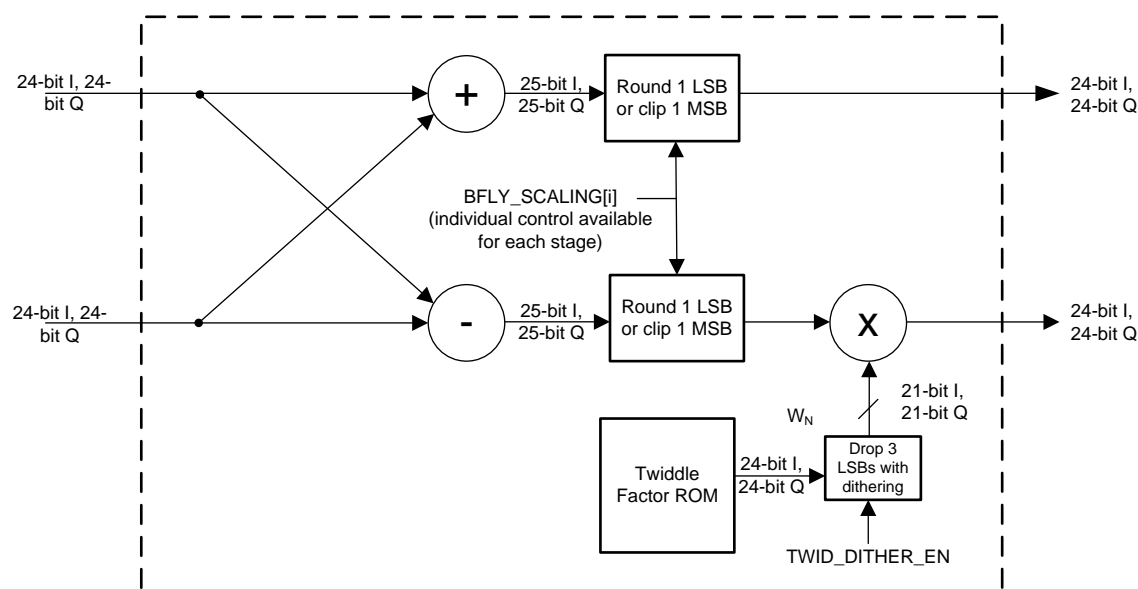

Figure 6-610. Butterfly Stage Fixed-Point

The twiddle factors are stored as 24-bit I and 24-bit Q coefficients. Prior to twiddle factor multiplication, the coefficients are reduced to 21-bit I and 21-bit Q by dropping three LSBs (with optional dithering). The purpose of dithering is to eliminate any repetitive quantization noise patterns from degrading the SFDR of the FFT. TI recommends that dithering be enabled (`DITHER_TWIDEN` should be set). For dithering, an LFSR is used to generate a random pattern, for which the LFSR seed must be loaded with a non-zero value (see `LFSRSEED` in the register descriptions).

The SFDR performance of the FFT, with dithering enabled, is better than -140 dBc, as shown in [Figure 6-611](#).

Figure 6-611. FFT SFDR Performance With and Without Dithering

The architecture of the FFT is such that it can take a streaming input (one sample per clock) and produce a streaming FFT output (one sample per clock), in steady-state. There is an initial latency of approximately *FFT size* number of clocks. This latency only comes into picture once for a given parameter set. Within a parameter set, multiple FFT iterations can be performed back-to-back (for example, for four RX) with no additional latency between iterations.

Because the implementation uses 400MHz clock in the device, a 256-point complex FFT for four RX chains would take $256 + 256 \times 4$ clock cycles to complete, which corresponds to $3.2 \mu\text{s}$ (plus a few clocks of implementation latencies, which are not accounted here since it is negligible). Table 6-596 lists the approximate computation time needed for various FFT sizes.

Table 6-596. FFT Computation Time

Example	FFT Size	Number of Back-to-Back Iterations	Number of Clock Cycles (Initial latency + Computation)	Total Duration
1	256	4	$256 + (256 \times 4)$	$3.2 \mu\text{s}$
2	128	4	$128 + (128 \times 4)$	$1.6 \mu\text{s}$
3	8	64	$8 + (64 \times 8)$	$1.3 \mu\text{s}$

The output of the FFT can be fed to the output formatter or it can be sent to the magnitude/log-magnitude computation subblock.

Note

The FFT is a complex FFT implementation. If the input samples are real-only, then the SRCREAL register bit can be set, such that the imaginary part (Q-part) will be forced to zero by the input formatter block.

6.4.5.1.6 Advanced FFT Features – FFT Stitching

FFT Engine additionally allows the computation of 4096 & 8192-point FFTs by using FFT stitching. This is done in two-passes. In the first pass, 2 or 4 sets of 2048-point FFT are computed. In the next pass, 2048 sets of 2-point or 4-point FFTs are computed with appropriate twiddle pre-multiplications using the complex multiplier in mode 3 (described in part 2 of user guide) yielding the final 4096 or 8192-point FFT. The relevant register (CMULT_MODE, TWIDINCR, WINDOW_INTERP) settings are indicated in table below. A detailed example of FFT stitching along with window interpolation is provided in HWA 2.0 Examples document.

Table 6-597. FFT Stitching Registers

FFT Size	CMULT_MODE	TWIDINCR	WINDOW_INTERP
4096	3	1	2
8192	3	2	1

6.4.5.1.7 Advanced FFT Features – 2D FFT

The traditional approach for realizing an $M \times N$ point 2-D FFT involves two passes: first pass computing M number of N -point FFTs on the input arrays, and then a second pass computing N number of M -point FFTs on the result of the first pass. HWA2.0 instead supports a direct and faster computation of $M \times N$ 2-D FFT, for small $M \times N$ sizes ($M \times N \leq 2048$, N being a power of 2).

The following illustrates the necessary programming for an example with $M=16$ and $N=4$. The register `FFT_SIZE` should be set to , and the register `FFT_SIZE_DIM2` should be set to . Further the $M \times N$ samples of input data should be placed in the memory and fed sequentially to the FFT engine in an interleaved manner as follows. If A is the 2-D 16×4 size input array for the 2-D FFT, then the data placement should ensure that the FFT engine's input order is $A_{0,0}, A_{0,1}, A_{0,2}, A_{0,3}, A_{1,0}, A_{1,1}, A_{1,2}, A_{1,3}, A_{2,0}, A_{2,1}, \dots, A_{15,0}, A_{15,1}, A_{15,2}, A_{15,3}$. The FFT engine computes the 2-D FFT results, and automatically stores them in the destination memory in the right order. The output memory contents would be linear order: $B_{0,0}, B_{0,1}, B_{0,2}, B_{0,3}, B_{1,0}, B_{1,1}, B_{1,2}, B_{1,3}, B_{2,0}, B_{2,1}, \dots, B_{15,0}, B_{15,1}, B_{15,2}, B_{15,3}$, where B represents $\text{FFT2D}(A)$.

If zero padding is required in one or both dimensions, it can be achieved through the accelerator's zero insertion feature. It can be done by adding zeros at right locations in the $M \times N$ long linear array streaming into the FFT engine (subject to the 256 element limit in zero insertion feature). If 2-D windowing is required before the 2-D FFT, then the 2-D $M \times N$ window coefficients can be unrolled into one long linear array and placed in the window RAM. This is illustrated in the below figure for a 32×16 2-D FFT case. If 2-D FFT feature is enabled in any parameter set, it is recommended that the advanced 2D statistics feature be disabled in that parameter set.

This 2-D FFT feature can be used in performing small sized 2-D FFTs, repeatedly over several iterations (e.g. Azimuth \times Elevation 2-D FFTs using A dimension, performed for multiple Doppler or Range bins using B dimension). The computation time for B iterations of $M \times N$ 2-D FFTs would be $(B+1) \times (MN) = BMN + MN$. In comparison, the traditional two pass approach mentioned earlier, uses $(BM+1) \times N$ cycles for first pass (if first passes of all B iterations are performed together) and $(BN+1) \times M$ cycles for second pass, in total $2BMN + M + N$.

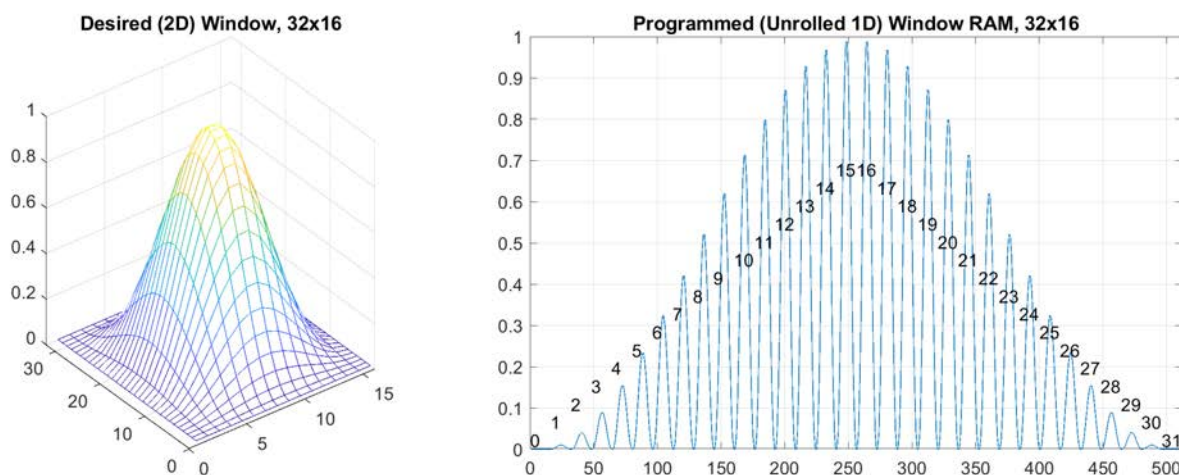

Figure 6-612. Unrolling 32x16 2D Array Window Coefficients to a 512 1D Vector for Placement in Window RAM

6.4.5.1.8 Core Computational Unit – FFT Engine – Magnitude and Log-Magnitude Post-Processing

The magnitude and log-magnitude post-processing block computes absolute value or log₂ of the absolute value of its input. Because this block is connected to the output of the FFT engine, the computation of absolute value (and log₂) can be directly performed on the streaming FFT output. Alternately, the FFT block can be bypassed and only the magnitude and log-magnitude block can be employed.

The processing in this block first involves computation of magnitude (absolute value) of the input samples in the magnitude subblock (using JPL approximation). The result of the magnitude computation is fed into a Log₂ computation subblock, which uses a look-up table-based approximation to compute logarithm- base-2 of the magnitude.

As shown in Figure 14, if the register-bit ABS_EN is set, the magnitude computation subblock is enabled. In addition, if the register-bit LOG2_EN is set, then the Log₂ computation subblock is also enabled. Note that setting LOG2_EN makes sense only when ABS_EN is also set.

The magnitude computation uses JPL (Levitt and Morris) approximation. This approximation for magnitude of a complex number (I + jQ) is defined as follows, let U = max(|I|, |Q|) and V = min(|I|, |Q|).

Then, the magnitude can be approximated as follows in Equation 1.

$$\text{Magnitude} \approx \max(U + V / 8, 7U / 8 + V / 2) \tag{1}$$

The magnitude output is 24-bits wide (real number).

Next, the log₂ computation of the magnitude value is achieved as follows. Any unsigned input number N can be written as N = 2^k(1 + f) and the log₂(N) can then be written as follows in Equation 2.

$$\log_2(N) = k + \log_2(1+f) \tag{2}$$

The implementation of log₂ computation uses the previous formula, where a look-up table approximation is used to generate the second term, for example, log₂(1 + f). The accuracy of the log₂ computation is shown in Figure 18. The log₂ output is 16-bits wide. The 16-bit logarithm output consists of 5 bits of integer part and 11 bits of fractional part.

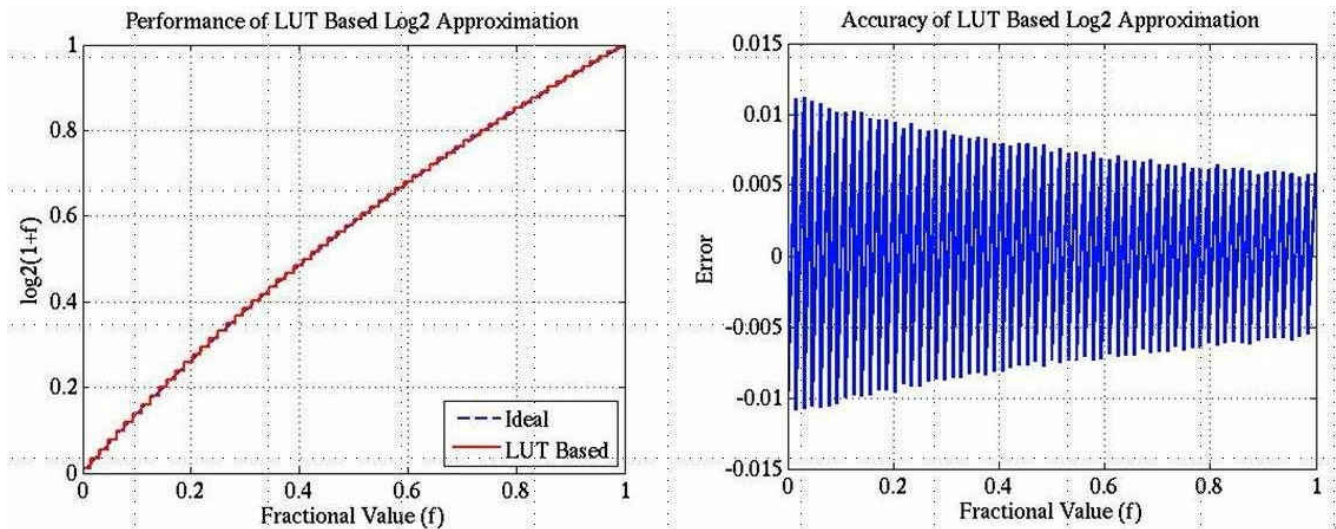

Figure 6-613. Accuracy of Log₂ Computation

Depending on the settings of ABS_EN and LOG2_EN, either the magnitude or the log-magnitude is sent as the final output of the core computational unit. The final output of the core computational unit going to the output formatter is 24-bits I and 24-bits Q. Thus, if either magnitude or log-magnitude is enabled, the Q-values are just made zeros. Similarly, when log₂ is enabled, because the output is 16-bits, 8 MSBs are filled as zero.

The outputformatter handles writing the samples to the destination memory as per the configured destination memory access pattern described in a previous section.

6.4.5.1.9 Core Computational Unit – FFT Engine – Register Descriptions

Table 6-598 lists all the registers of the FFT Engine within the core computational unit.

Table 6-598. FFT Engine Registers

Register	Width	Parameter Set	Description
WINDOW_EN	1	Yes	Windowing Enable: This register-bit enables or disables the pre-FFT windowing operation. If this register is set to 1, then the windowing is enabled, otherwise, it is disabled. The exact window function (coefficients) to be applied is specified in a dedicated Window RAM, which is 2048 × 32 bits in size.
FFT_EN	1	Yes	FFT Enable: This register-bit is used to enable the FFT computation. If FFT_EN = 1, then the FFT computation is enabled. Otherwise, it is disabled (bypassed).
ABS_EN	1	Yes	Magnitude Enable: This register-bit is used to enable the magnitude calculation. If this register bit is set, then the magnitude calculation is enabled, else it is bypassed. When enabled, the magnitude (absolute value) of the input complex samples are calculated using JPL approximation and the resulting magnitude value is sent on the I-arm of the output. The Q-arm is made zeros.
LOG2_EN	1	Yes	Log2 Enable: This register-bit is used to enable the Log2 computation. If this register bit is set, then the Log2 computation is enabled, else it is bypassed. Note that setting this register bit only makes sense if the inputs to the Log2 computation are unsigned real numbers, such as when the Magnitude Enable bit (ABS_EN) is also set. When enabled, the Log2 of the magnitude of the input samples is calculated and sent out on the I-arm of the output. The Q-arm is made zeros.
WINDOW_START	11	Yes	Windowing coefficients start location in Window RAM: This register specifies the starting location (32-bit word index) of the window coefficients within the Window RAM. The purpose of this register is to allow multiple windows (for example, one window of 512 coefficients and another window of 256 coefficients) to be stored in the Window RAM and one of these windows can be used by programming this start location register appropriately in the current parameter set.
WINSYMM	1	Yes	Window symmetry: This register-bit indicates whether the complete set of window coefficients are stored in the Window RAM or whether one half of the coefficients are stored. If this register bit is set, it means that the window function is symmetric and therefore, only one half of the window function coefficients are stored in the Window RAM. See the description section related to Windowing computation for more details.
WINDOW_MODE	2	Yes	Window Mode: 00b : 18-bit signed real coefficients, 01b: 16-bit signed real coefficients, 10b: 16-bit I, 16-bit Q complex coefficients
FFTSIZE	4	Yes	FFT size: This register indicates the number of FFT radix-2 butterfly stages employed. Refer detailed description section for more details on this register.
FFTSIZE3X_EN	1	Yes	FFT size 3X enable: This register indicates whether to engage the additional FFT radix-3 butterfly stage. Together with FFTSIZE, this register specifies the FFT size. This can be used to realize FFTs of length 3x2N point FFTs..
FFTSIZE_DIM2	4	Yes	2D FFT dimension specification: This register can be used to realize 2 dimensional FFTs. If this register is set to 0 (default), the FFT engine computes the usual one dimensional FFT. Otherwise, it computes a two dimensional FFT of size $2^{(FFTSIZE-FFTSIZE_DIM2)} \times 2^{FFTSIZE_DIM2}$. <TO_BE_UPDATED_IN_A_FUTURE_DOC_VERSION>

Table 6-598. FFT Engine Registers (continued)

Register	Width	Parameter Set	Description
BFLY_SCALING	12	Yes	Butterfly scaling for radix-2 stages: This register is used to control the butterfly scaling at each of the radix-2 butterfly stages. If the Nth bit in this register is set to 0, then the 25-bit output of the Nth radix-2 stage from the last is saturated to 24-bit. Otherwise it is scaled down by 2 and rounded to produce a 24-bit output.
BFLY_SCALING_FFT3X	2	Yes	Butterfly scaling for radix-3 stage: This register is applicable only if FFTSIZE3X_EN is set to 1. This register is used to control the butterfly scaling in the 3-point FFT structure that precedes the powers-of-2 FFT structure. If this register is set to 0, then that 26-bit output after radix-3 stage is saturated at the MSB to get back to 24 bits. If it is 2, it is rounded to remove 2 LSBs to get back to 24 bits. A middle option exists by setting this to 1. In this case, the 26 bit temporary output is convergent-rounded to remove 1 LSB and the 25-bit output thus obtained is saturated to 24 bits.
DITHER_TWID_EN. dither_twid_en	1	No	Twiddle factor dithering enable: This register-bit is used to enable and disable dithering of twiddle factors in the FFT. The twiddle factors are 24-bits wide (24-bits for each I and Q), but they are quantized to 21-bits before twiddle factor multiplication. This quantization is implemented with dithering on the LSB, to avoid periodic quantization pattern affecting SFDR performance of the FFT. It is recommended to keep this register bit set to 1 (dithering enabled), with appropriate LFSR seed loaded.
LFSR_SEED.lfsr_seed	29	No	Seed for LFSR (random pattern): For twiddle factor dithering, there is an LFSR that is used, whose seed value is loaded by writing to this 29-bit LFSRSEED register. The LFSRSEED register should be set to any non-zero value, say 0x1234567. To load the LFSR seed, a pulse signal needs to be provided, by writing a 1 followed by a 0 (i.e., by setting and clearing) the LFSRLOAD register-bit.
LFSR_LOAD.lfsr_load	1	No	For twiddle factor dithering, there is an LFSR that is used, whose seed value is loaded by writing to this 29-bit LFSRSEED register. The LFSRSEED register should be set to any non-zero value, say 0x1234567. To load the LFSR seed, a pulse signal needs to be provided, by writing a 1 followed by a 0 (i.e., by setting and clearing) the LFSRLOAD register-bit.
FFT_CLIP.fft_clip	13	No	FFT Clip Status (read-only): This is a read-only status register, which indicates any saturation/clipping events that have happened in the FFT butterfly stages. Note that each of the individual butterfly stages in the FFT can be programmed to either saturate the MSB or round the LSB. Whenever saturation of MSB is used in any stage, there is a possibility that that stage can saturate or clip samples. In that case, this saturation event is indicated in the corresponding bit in this status register, so that the processor can read it. If multiple FFTs are performed, this status register includes any saturation events happening in any of them. This status register can only be cleared by the R4F, by setting another single-bit register CLR_FFTCLIP, so that the saturation status indication gets cleared back to 0 and any subsequent saturation events can be freshly monitored. The MSB of this register indicates clip status corresponding to the radix 3 butterfly (note: it is the MSB, independent of the number of radix-2 stages engaged).
CLR_FFTCLIP.clr_fftclip	1	No	Clear FFT Clip Status register: This register bit, when set, clears the FFTCLIP register.
WINDOW_RAM[2048] DSS_HWA_WINDOW_RA M	32b each	No	This RAM stores the window co-efficients. Note that there is only one RAM and based on Window_mode, the samples are accordingly chosen as illustrated in Fig. 15

Table 6-598. FFT Engine Registers (continued)

Register	Width	Parameter Set	Description
ACCEL_MODE	3	Yes	<p>Select Core Computational Unit Data Path: This register selects the data-path of the accelerator's core computational unit – for example, it selects which of the paths: the FFT engine path, or the CFAR engine path, or the compression/decompression path, or the local maxima engine path, or none is active. Value = 0b000: FFT engine path Value = 0b001: CFAR engine path Value = 0b010: Compression / decompression engine path Value = 0b011: Local Maxima engine path Value = 0b111: No Operation.</p> <p>The No Operation setting can be used together with an appropriate trigger mode to cause the state machine to wait for an event before moving to the next parameter-set.</p>
WINDOW_INTERP_FRACTION CMULT_MODE TWIDINCR FFT_OUTPUT_MODE FFTSUMDIV MAX<n>_VALUE ISUM<n>, QSUM<n>	–	–	<p>Described in part two of this user's guide. For the immediate purposes relevant to part one of this user's guide, all of these registers should be kept as 0.</p>

6.4.7 FFT Engine – Pre-Processing

As explained in Part 1 of this chapter, the FFT Engine comprises pre-processing, windowing, FFT and Log-magnitude subblocks and these are stitched together one after the other in series (refer to Figure 6-618). This architecture allows multiple operations to be done in a streaming manner (for example, windowing and FFT can be done together), while at the same time, providing the user flexibility to choose one operation at a time. This section provides an overview of the pre-processing subblock inside the FFT engine of the core computational unit.

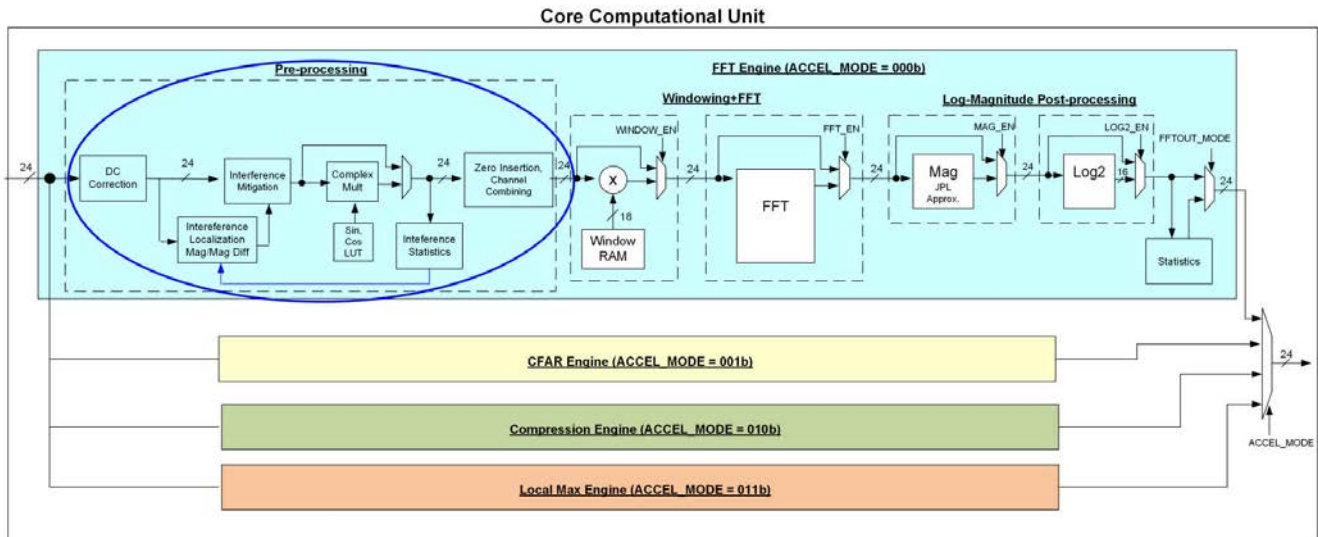

Figure 6-618. Core Computational Unit

The pre-processing subblock provides capability for DC estimation and correction, Interference localization and mitigation, complex multiplication, channel combining and zero-insertion.

6.4.7.1 DC Estimation

The DC estimation block estimates the time-domain average of the stream of samples along the A dimension. The stream can be one chirp, or set of chirps, i.e., frame. The DC is estimated on a per-iteration basis (i.e., along A dimension for each B iteration) for I & Q samples. Up-to 12 estimates corresponding to up to 12 iterations are available.

DC estimation is based on accumulation followed by a fine scaling and a programmable right shift. The fine scaling is configured as 1.8 value, via the 9-bit DCEST_SCALE register. The subsequent programmable right shift is configurable from 6 to 20 bits. Therefore, the DC estimation is well suited for cases where the number of samples per iteration is between 2^6 and 2^{20} . The fixed point details are captured in Figure 6-619. The internal accumulator reset supports several modes as shown in Table 6-599. For example, when DCEST_RESET_MODE = 2, the internal DC accumulators are reset at the beginning of the current parameter-set execution. Therefore, this mode estimates DC value for each set of SRCACNT samples along the A-dimension for up to 12 iterations along B-dimension within the current parameter-set. This mode is useful for per-chirp DC estimation. In this mode, the estimated DC values per iteration are latched at the end of current param-set and the accumulators are reset at the start. On the other hand, when DCEST_RESET_MODE = 3, the internal DC accumulators are reset only when the state machine executes the first loop of the parameter-set. As the state machine loops through various parameter-sets multiple times as programmed via NLOOPS register, the DC accumulators are not reset in between these loops. This mode is useful for per-frame DC estimation, where each loop corresponds to one chirp and the NLOOPS loops (chirps) correspond to a complete frame. The estimated DC values per iteration are latched at the end of last execution of the param-set.

The processor can read the DC estimates through the read-only registers – DCESTI_0VAL, ..., DCESTI_11VAL & DCESTQ_0VAL, ..., DCESTQ_11VAL. The DC estimates can also be used for DC subtraction described next.

Table 6-599. DC Estimation – Reset Modes

DCEST_RESET_MODE	Comments
0	Hold the DC internal accumulators without updating (bypass DC estimation).
1	DC estimation enabled, but free-running without automatic reset (i.e., not reset at the start of this parameter-set). In this mode, the software can reset the DC accumulators by writing to DC_EST_RESET_SW register bit.
2	Reset the DC internal accumulators at the start of this parameter-set. This mode is applicable for per-chirp DC estimation.
3	Reset the DC internal accumulators at the start of this parameter-set only if the loop-counter is 0. This mode is applicable for per-frame DC estimation.

**Figure 6-619. DC Estimation**

6.4.7.2 DC Subtraction

The DC subtraction feature is enabled if the register `DCSUB_EN` is set to 1.

DC subtraction (see [Figure 6-620](#)) can use the output from the built-in DC estimation accumulators, or a user-programmed value, based on the register bit, `DCSUB_SELECT`. If `DCSUB_SELECT` is 1, the DC estimation based on the internal accumulators is used. If `DCSUB_SELECT` is 0, the software override values are used (they are given by `DC_SW_I<n>` and `DC_SW_Q<n>` for the *n*th iteration).

When using the built-in DC estimation accumulators, DC subtraction is performed on 12 individual streams corresponding to 12 RX on a per-iteration basis. Note that in a typical usage, for performing per-chirp DC estimation and DC subtraction, a two-pass approach is needed, where the first pass is configured for DC estimation via one parameter-set, and the second pass is configured for DC subtraction in the next parameter-set. Alternately, if a previous DC estimate (eg. From the previous chirp) is desired to be used for DC subtraction for the current chirp, then DC subtraction can be directly accomplished in one pass.

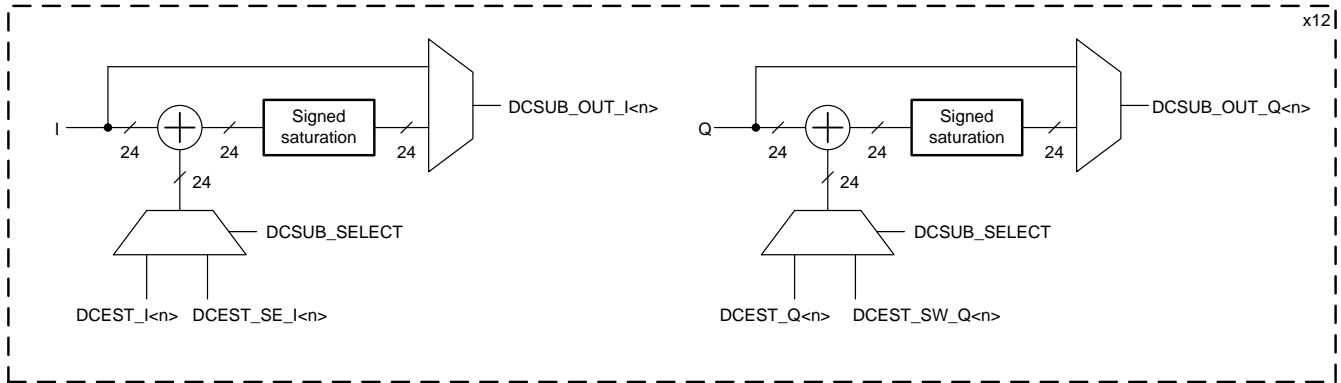

Figure 6-620. DC Subtraction

6.4.7.3 Interference Localization

In an FMCW radar transceiver, interference from another radar typically manifests itself as a time-domain spike in a few samples. This spike corresponds to the time duration when the chirping frequency of both radars overlap with each other. Such a time-domain spike caused by interference can lead to degradation in the noise floor at the FFT output, causing degradation in detection performance.

In order to mitigate the impact of interference, the pre-processing block provides capability to perform interference localization to identify samples corrupted by interference, followed by interference mitigation to repair those samples.

The INTF_LOC_THRESH_EN register is provided as part of the parameter-set to control when the interference localization should be enabled. When enabled, the input samples are fed through a magnitude calculation (based on JPL approximation), which computes a 24-bit magnitude of the 24-bit input complex sample. For definition of this approximation, see Part 1 of this user guide. Similarly, magnitude of the backward difference between adjacent samples is also computed, which is another useful metric for interference (glitch) detection.

Any sample whose magnitude and/or magnitude of backward difference exceeds thresholds THRESH_MAG<n> and THRESH_MAGDIFF<n> is considered as affected by interference and is marked by a corresponding Interference indicator Bit (IIB). This is supported individually for up to 12 iterations. The register, INTF_LOC_THRESH_MODE determines the logic to set the IIB bit using the magnitude and/or magnitude of difference estimates. Based on this register, samples are marked with IIB if they exceed the THRESH_MAG<n>, or THRESH_MAGDIFF<n>, a logical AND of both, a logical OR of both as shown in Figure 6-621.

This applies across all iterations.

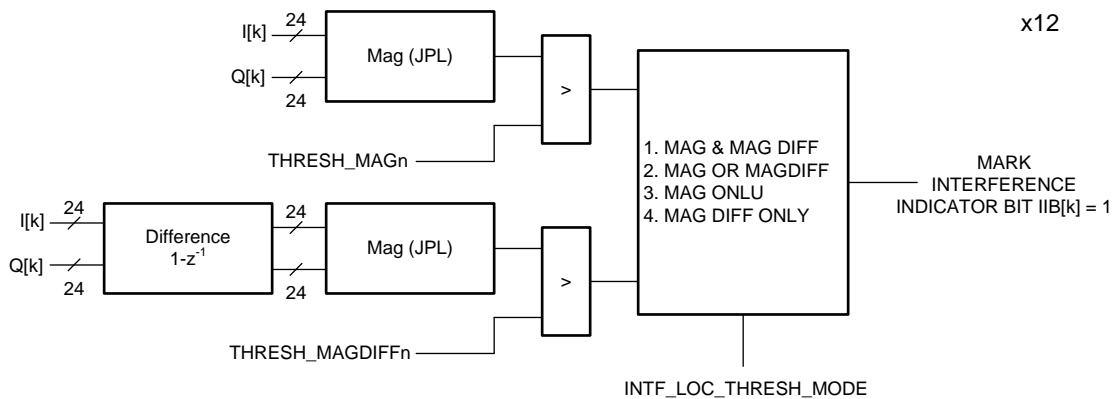

Figure 6-621. Interference Localization

The threshold values of THRESH_MAG<n> and THRESH_MAGDIFF<n> applied on a per-channel basis can be derived from SW – INTF_LOC_THRESH_MAG<n>_SW, INTF_LOC_THRESH_MAGDIFF<n>_SW or from a built-in Interference statistics block – INTF_LOC_THRESH_MAG<n>, INTF_LOC_THRESH_MAGDIFF<n> as

described in the next section. The user can also choose to sum the built-in interference statistics estimates across all channels to derive a common interference threshold across all iterations— INTF_STATS_SUM_MAG, INTF_STATS_SUM_MAGDIFF. The register, INTF_LOC_THRESH_SELECT is used to select these threshold options.

The number of samples marked with IIB across the iterations is recorded in the read-only registers, INTF_LOC_COUNT_ALL_CHIRP and INTF_LOC_COUNT_ALL_FRAME. This can be read after every chirp or after the completion of a frame (when the state machine completes all the programmed parameter-set loops and enters idle state).

6.4.7.4 Interference Statistics

This block (see [Figure 6-622](#)) provides the thresholds for interference localization. In order to obtain the interference statistics and derive the thresholds, the magnitude and magnitude of backward difference of the incoming samples are accumulated per iteration and up to 12 such independent accumulations are supported. These registers can be reset on a per-chirp or per-frame basis, and the behavior can be controlled using the register INTF_STATS_RESET_MODE. These reset modes are similar to DCEST_RESET_MODE previously explained (refer to [Table 6-599](#)). The interference statistics accumulators can be reset by software via writing the INTF_STATS_RESET_SW register bit. This reset also clears the INTF_LOC_COUNTS.

The determination of interference threshold for interference localization is based on taking the above accumulator values and applying a programmable fine scaling, followed by a programmable right shift. The fine scaling is configured via 8-bit registers, INTF_STATS_MAG_SCALE and INTF_STATS_MAGDIFF_SCALE in 5.3 format. The fine scaling value is interpreted as an unsigned 8-bit number with 5 integer bits and 3 fractional bits giving a scale in range [0 to 31.875]. The default value of this register is 8, applying a scaling of 1.0. The programmable right-shift in the range of 6 to 12 is applied via the registers, INTF_STATS_MAG_SHIFT and INTF_STATS_MAGDIFF_SHIFT respectively. Note that if the sum mode of threshold selection is made, then the shift values have to include the extra division based on number of iterations being summed.

The resulting values INTF_LOC_THRESH_MAG_n and INTF_LOC_THRESH_MAGDIFF_n are used as thresholds in the interference localization block as described in the previous section.

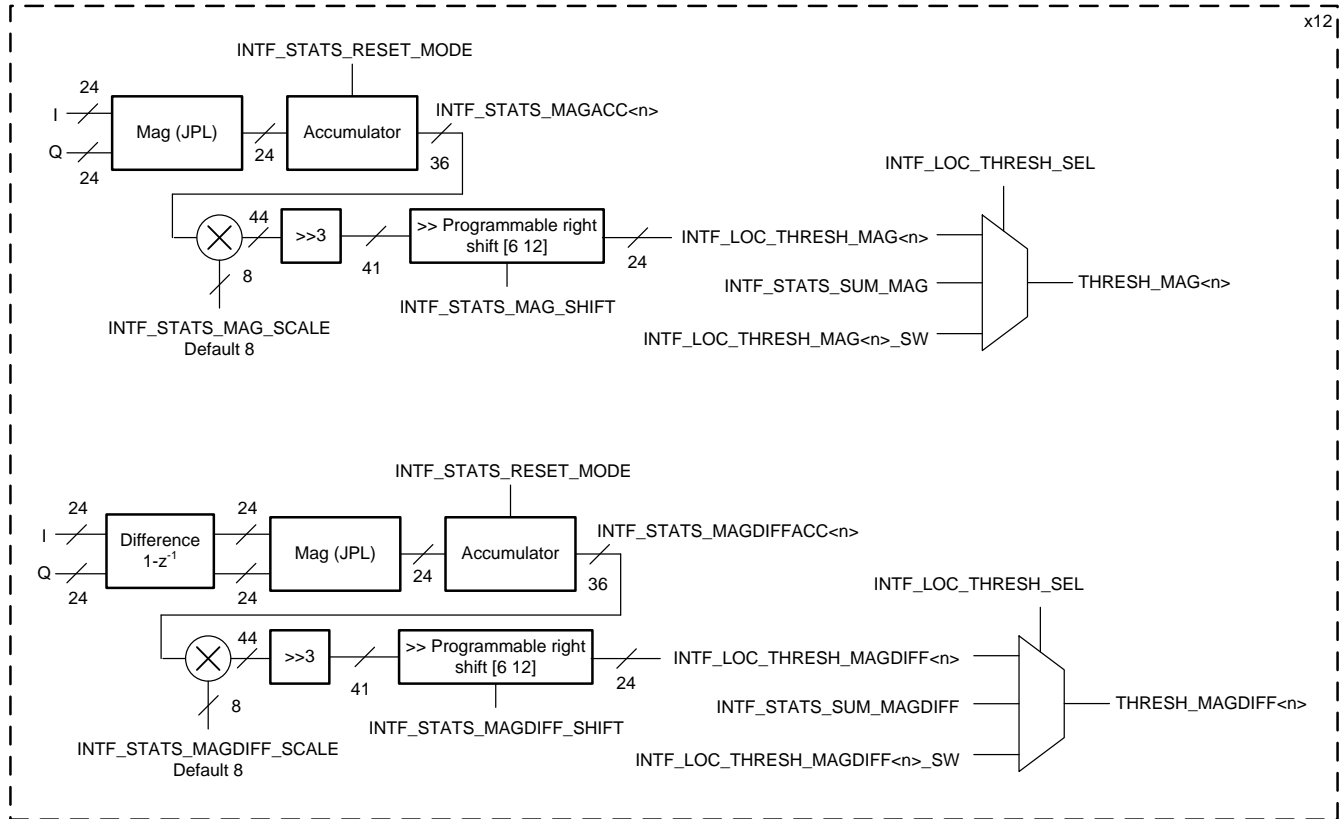

Figure 6-622. Interference Statistics

6.4.7.5 Interference Mitigation

Interference mitigation block (Figure 6-623) uses the results of Interference Localization block and mitigates the interference affecting the input samples which are marked as interference-corrupted through the Interference Indicator Bit. Interference mitigation is applicable for max. 12 iterations

The interference mitigation feature can be enabled by setting the INTF_MITG_EN bit in the parameter-set.

The first sub-module of the Interference Mitigation Block is a hysteresis module, which provides de-bouncing logic. For each incoming sample, its own IIB bit, as well as INTF_MITG_RIGHT_HYST_ORD number of right IIB bits and INTF_MITG_LEFT_HYST_ORD number of left IIB bits are considered in order to decide whether that particular sample is actually affected by interference. If the number of IIB bits in that interval is greater than or equal to INTF_MITG_CNTTHRESH, then that sample is assumed to be affected by interference. Thus, the hysteresis module outputs a filtered version of the IIB bit stream, which is then used for interference mitigation.

There are three different options (Figure 6-624) for interference mitigation and one of these can be selected using the INTF_MITG_PATH_SEL register. If INTF_MITG_PATH_SEL = 0, then the interference mitigation block simply zeros out samples that are marked with the IIB bit. This is a simple form of interference mitigation.

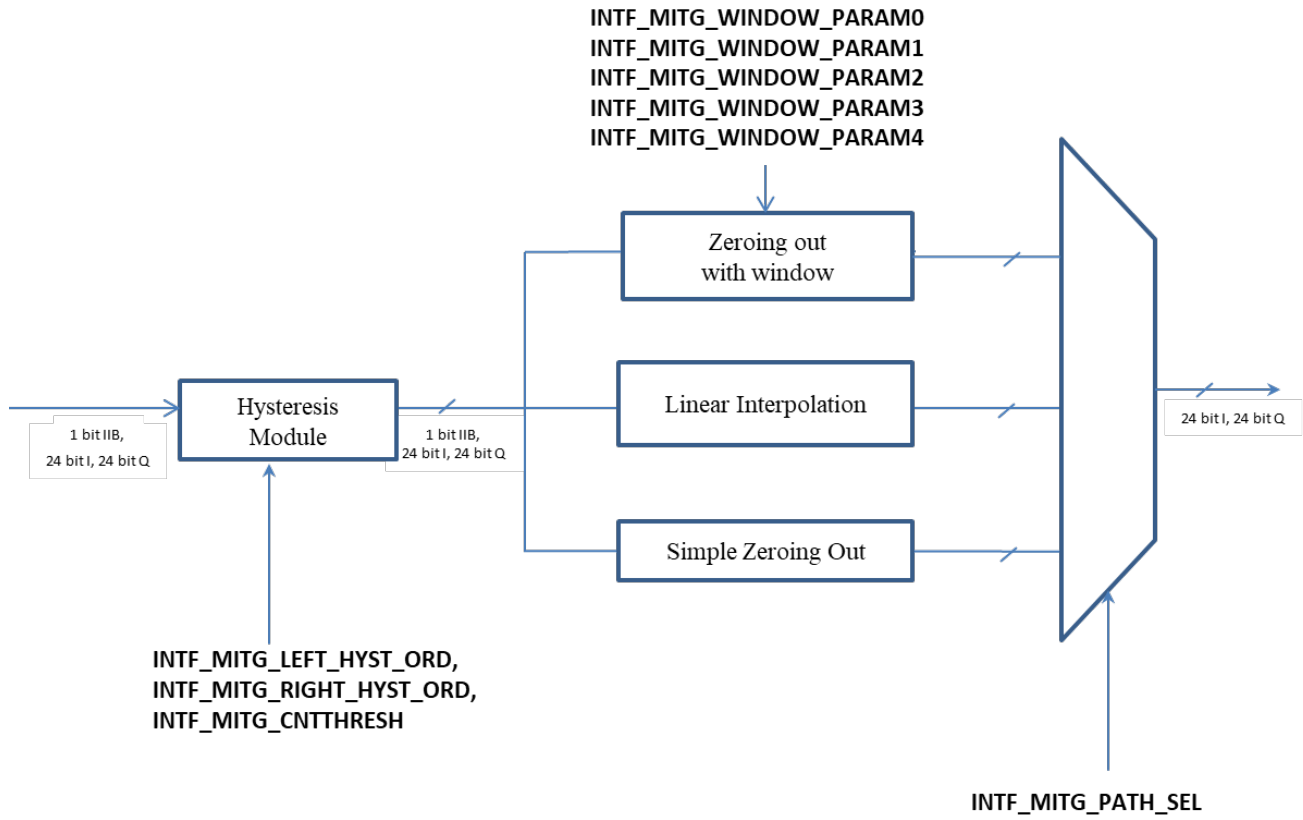

Figure 6-623. Interference Mitigation Block

Figure 6-624. Interference Mitigation Methods

If `INTF_MITG_PATH_SEL = 1`, then the interference mitigation block performs a windowed zero-out, where a smoothing window is applied to the edge samples of the interference-affected set of samples, in order to reduce the side-lobe increase that can happen with abrupt windowing. The windowing function that is applied is programmable via the `INTF_MITG_WINDOW_PARAM <n>` registers. The manner in which this smoothing window is applied is as follows.

Assume that the input sample array is: $[x[0], x[1], x[2], x[3], x[4], x[5], x[6], x[7], x[8], x[9], x[10]]$. Assume that the IIB array input is of the form $[0, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0]$. (In other words, the 6th and 7th samples are corrupted by interference.) Then, the output of the windowed zero-out module would be:

$$[x[0]w[4], x[1]w[3], x[2]w[2], x[3]w[1], x[4]w[0], 0, 0, x[7]w[0], x[8]w[1], x[9]w[2], x[10]w[3]].$$

Where $w[n] = \text{INTF_MITG_WINDOW_PARAM}<n>$.

Note that the samples that are affected by interference are always zeroed out. The window is applied on the neighbours of these samples, so as to smoothen the transition to zero.

If `INTF_MITG_PATH_SEL = 2`, then the interference mitigation block performs a linear interpolation between the two good (i.e., non-interference-affected) samples at the start and end of the interference affected set of samples and this linear interpolation procedure is used to replace the interference affected samples themselves. The number of interference affected samples between these good samples can be any number. However, if it exceeds 32, then the 'last good sample' is pushed out in the place of affected samples until a new good sample arrives. Then linear interpolation will be performed across the 32 remaining affected samples.

6.4.7.6 Complex Multiplication

In addition to interference zero-out, the pre-processing block contains a complex multiplication sub-block. The purpose of this sub-block (Figure 6-625) is to enable several assorted capabilities that require complex multiplication of the input samples. The `CMULT_MODE` register is used to enable and configure the complex

multiplication functionality. The complex multiplication sub-block can be disabled (bypassed) by the setting CMULT_MODE to 0b0000. Any other value of this register will enable the complex multiplication sub-block and configure it to perform specific operation as described in the next few paragraphs.

There are nine modes of the complex multiplier supported as follows. They are frequency shifter mode, frequency shifter with auto-increment mode (a slow DFT mode), FFT stitching mode, magnitude squared mode, scalar multiplication mode, vector multiplication modes-1 & 2, recursive windowing and LUT based frequency shifter modes.

In all the nine modes of the complex multiplier, one complex multiplication is performed every clock cycle.

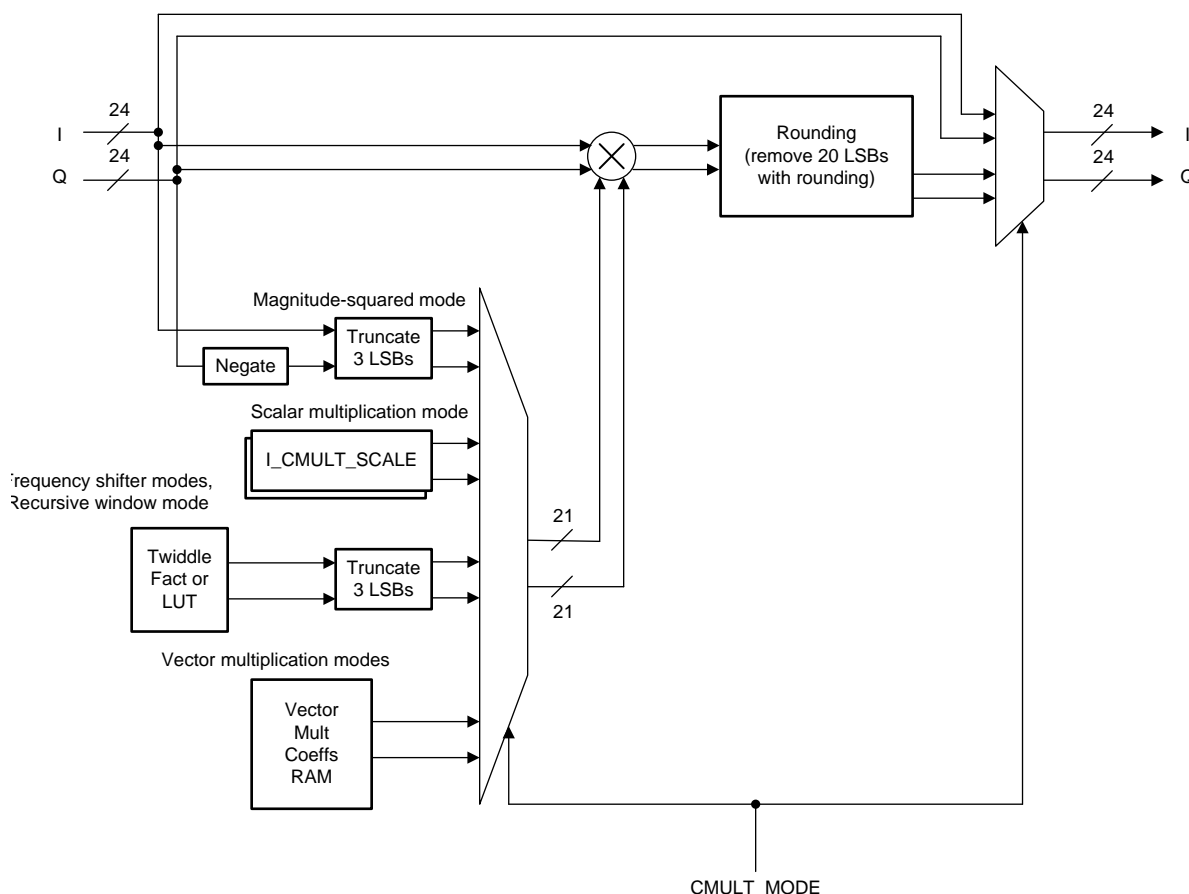

Figure 6-625. Complex Multiplication Capability in Pre-Processing Block

- Frequency shifter mode: If the register value is CMULT_MODE = 0001b, then the complex multiplier functions as a frequency shifter, which can be used to de-rotate the input samples by a certain frequency. This de-rotation is accomplished using cos, sin values from a twiddle factor look-up table (LUT). This LUT contains the (compressed) equivalent of the cos, sin values corresponding to the 16384 long sequence $\exp(-j \cdot 2 \cdot \pi \cdot (0:16383)/16384)$. TWIDINCR is used to specify the de-rotation frequency, by specifying how much the phase should change for each successive input sample (that register controls how much the LUT read index increments every sample) as shown in (Figure 9). The starting phase in this mode is always zero, since the 20-bit accumulator always starts at zero for each iteration.

Note that although the figure shows another TWIDINCR_DELTA_FRAC register (portions shown in the red dotted box), that functionality is only applicable for CMULT_MODE = 1010b described later and it is not applicable in the present complex multiplier mode (0001b).

Figure 6-626. Frequency Shifter Mode

- Frequency shifter with auto-increment mode (a slow DFT mode): If the register value is CMULT_MODE = 0010b, then the complex multiplier functions in a mode which enables Discrete Fourier Transform (DFT) computation. In this case, the complex multiplier performs a function that is very similar to frequency shifter mode, except that, at the end of each iteration, the de-rotation frequency is automatically incremented for the next iteration. Note that DFT computation for a given set of input samples involves de-rotating the samples by one frequency at a time, and computing a sum of the de-rotated samples for each such frequency. To achieve DFT computation, the Input Formatter should be configured to send the same set of input samples to the complex multiplier for multiple iterations (as many as the number of DFT bins required) and the complex multiplier de-rotates the samples by one frequency at a time and auto-increments to the next frequency for the next iteration. Also, the statistics block (explained in a later section) is used to compute the sum of the de-rotated samples corresponding to each iteration, which then becomes the final DFT value.

The DFT computation is ‘slow’ in the sense that in each clock cycle, only one complex multiplication is performed. For example, for a 512-point input sample set, it would take 512 clock cycles per DFT bin. However, since the DFT mode is typically only used for FFT peak interpolation (very few bins), it is acceptable. The starting frequency for the DFT computation is specified in the TWIDINCR register (similar to the frequency shifter mode). The increment value by which the frequency increments every iteration is obtained from FFTSIZE register – Note that the DFT mode cannot be used simultaneously with FFT enabled, hence the FFTSIZE register has been over-loaded for providing the increment value in this mode. The increment value is calculated as $2^{(14 - \text{FFTSIZE})}$ and hence the DFT resolution is $16384/2^{(14 - \text{FFTSIZE})} = 2^{\text{FFTSIZE}}$. As an example, if FFTSIZE = 1011b, then the DFT resolution is 2048. This is equivalent to computing DFT points corresponding to 2K size FFT grid. The highest resolution for the DFT would be obtained when FFTSIZE = 1110b (max allowed value), in which case the DFT resolution is 16384 (corresponding to 16K size FFT grid). In effect, for the kth iteration (with k starting from 0), the input samples $x(n)$ for $n = 0$ to $\text{SRCACNT}-1$ are multiplied by the sequence, $\exp(-j*2*\pi*(\text{TWIDINCR}+2^{(14 - \text{FFTSIZE})*k})*(0:\text{SRCACNT}-1)/16384)$.

- FFT Stitching mode: If the register value is CMULT_MODE = 0011b, then the complex multiplier functions in FFT stitching mode. This mode is useful when large size FFTs (4K and 8K) are required. Since the FFT block natively supports only up to 2048 size, for 4096 and 8192 point FFT, an FFT Stitching procedure using two steps (two parameter-sets) can be used. As an example, when an 8K size FFT is needed, it is achieved in two steps as follows. In the first step, every 4th input sample is passed through a 2K size FFT (four 2K point FFTs are performed on decimated input samples). Then, in the next step, the resulting 4x2048 FFT outputs are sent through four-point “stitching” FFTs (2048 four-point FFTs), with an additional pre-multiplication by the complex multiplier block to achieve FFT stitching. This pre-multiplication uses the twiddle factor LUT in a specific pattern, for which additional configuration information is available in 2 LSBs of TWID_INCR register. Value ‘01’ is for 4K (2x2048) size FFT stitching. If ‘10’, then the twiddle factor pattern will correspond to what is required for 8K (4x2048) size FFT stitching. In the FFT stitching mode of operation, the 12 MSBs of TWID_INCR must be kept as 0.

The last section includes a more detailed explanation and configuration information for the FFT stitching example for 4K and 8K FFT, including the use of WINDOW_INTERP_FRACTION register for extending the window RAM using linear interpolation to more than 2048 coefficients. Note that Window Symmetry and Interpolation modes can’t be used simultaneously.

- Magnitude squared mode: If the register value is CULT_MODE = 0100b, then the complex multiplier functions in magnitude squared mode. In this case, the complex multiplier takes a complex input and produces the magnitude squared as the output. This can be used together with the statistics block (explained in Section 3) to compute the mean squared sum of the input samples.

- Scalar multiplication mode: This mode is selected by setting `CMULT_MODE = 0101b`. It supports two options – multiplication by a complex scalar that remains constant across all iterations or by a complex scalar that changes per iteration.

If the register bit `CMULT_SCALE_EN = 0`, then the complex multiplier functions in constant scalar multiplication mode. This feature is useful if the input samples need to be scaled by some constant factor. In this case, the complex multiplier will multiply each input sample with a 21-bit scalar complex number that is programmed in `ICMULT_SCALE0` and `QCMULT_SCALE0` registers (for I and Q value, each having 21 bits). The `ICMULT_SCALE0` and `QCMULT_SCALE0` registers are common registers and not part of parameter-set.

To multiply the input samples for different iterations (channels) with different complex scalars, set `CMULT_SCALE_EN = 1`. In this mode, upto 12 different complex scalars are supported, viz. from `ICMULT_SCALE0`, `QMULT_SCALE0` to `ICMULT_SCALE11`, `QMULT_SCALE11` that are used for multiplication per iteration. `TWID_INCR` Register has no implication in this mode.

- Vector multiplication mode 1: If the register value is `CMULT_MODE = 0110b`, then the complex multiplier functions in vector multiplication mode 1. The purpose of this mode is to enable element-wise multiplication of two complex vectors, as well as dot-product capability (using statistics block to sum the element-wise multiplication output). The samples from the Input Formatter block constitute one of the two vectors, whereas the other vector is taken from a pre-loaded 'Vector Multiplication Coefficient RAM' inside the core computational unit. This Vector Multiplication Coefficient RAM can store 1024-complex samples and hence the vector multiplication can support a maximum of 1024 elements of multiplication. The Vector multiplication is not a highly parallelized operation, in the sense that only one complex multiplication is done per clock cycle.

The operation of the vector multiplication mode 1 is as follows. The streaming set of samples from the Input Formatter block is element-wise multiplied with successive samples from the Vector Multiplication Coefficient RAM. The statistics block (described in a later section) can be used to compute the sum for every iteration, which enables a dot-product implementation if desired. At the end of every iteration, the addressing from the Vector Multiplication Coefficient RAM is reset, so that for the next iteration, the samples are picked up from the start index of the Vector Multiplication Coefficient RAM. It is possible to choose a non-zero start address for the Vector Multiplication Coefficient RAM, by programming the `TWID_INCR` register. The top 12 MSBs of the `TWID_INCR` register functions as a sample address offset for the RAM. The 2 LSBs must be kept zero. For example, if `TWID_INCR = 20`, then the vector multiplication happens starting from the 5th coefficient in the RAM (zero-based count).

When the size of vectors is small (≤ 12 coefficients), this mode can also be realized by setting the bit `CMULT_SCALE_EN = 1` and programming `ICMULT_SCALE0`, `QCMULT_SCALE0` to `ICMULT_SCALE11`, `QCMULT_SCALE11` registers to store the successive coefficients. This mode can be used for example in RX channel gain and phase mismatch equalization. Because these `ICMULT_SCALE<n>` and `QCMULT_SCALE<n>` registers are independent of the Vector Multiplication Coefficients RAM, the user can use the RAM approach for some parameter-set which may need vector multiplication coefficients up to 1024, while another parameter-set of the processing chain uses the registers approach.

- Vector multiplication mode 2: If the register value is `CMULT_MODE = 0111b`, then the complex multiplier functions in vector multiplication mode 2, which is slightly different from the earlier Vector multiplication mode 1. The only difference in this case is that at the end of every iteration, the addressing of the Vector Multiplication Coefficient RAM is not reset, so that for the next iteration, the samples from the Vector Multiplication Coefficient RAM are picked up with an address that continues from where it left off at the end of the previous iteration. This mode can be used when a given set of input samples needs to be element-wise multiplied with multiple vectors. In this case, the input formatter block can be configured to repeat the same set of samples for multiple iterations, and the Vector Multiplication Coefficient RAM can be loaded with all the vectors, such that for successive iterations, the input samples are multiplied with successive vectors. As in previous mode, `TWID_INCR` functions as an address offset for the RAM.
- Recursive windowing mode (Figure 10) is supported using `CMULT_MODE = 1000b`. In this mode, a set of possibly random phase values $\theta(n)$ is stored in an internal RAM. This internal RAM is shared with the Vector Multiplication Coefficient RAM, in the sense that each of the $\theta(n)$ values takes up one coefficient location in the Vector Multiplication Coefficients RAM, and therefore use of Recursive Windowing mode comes at the expense of reduced number of coefficients storage for the other vector multiplication modes. For the purpose

of recursive windowing the vector multiplication RAM must be programmed with appropriate values and it is as shown below:

- If θ is in degrees, the corresponding code to be programmed in the RAM is $(\theta/360) * 2^{16}$
- If θ is in radians, the corresponding code to be programmed in the RAM is $(\theta / (2*\pi)) * 2^{16}$

The operation of Recursive Windowing mode is explained as follows.

Assuming that the Window RAM (which is separate) contains the window coefficients $w0(n)$, the final window function is computed as: $wK(n) = w0(n) * \exp(-j*K*q(n))$. This computed window function $wK(n)$ is used for the windowing prior to FFT operation. Here K is either the iteration count (zero-based count corresponding to B -dimension iterations) within the parameter-set, or the current execution count of the parameter-set where $CMULT_MODE = 0b1000$. This selection can be made using the register bit, $RECWIN_MODE_SEL$. A value of $RECWIN_MODE_SEL = 0$ indicates K is based on iteration count, and $RECWIN_MODE_SEL = 1$ indicates it is based on the said execution count. When $REC_WIN_MODE_SEL = 0$, the value of K resets to zero at the end of all iterations of the current parameter-set. On the other hand, when $REC_WIN_MODE_SEL = 1$, the value of K persists (and increments) across multiple loops of the parameter-set and it can be reset via software by writing to the register bit $RECWIN_RESET_SW$.

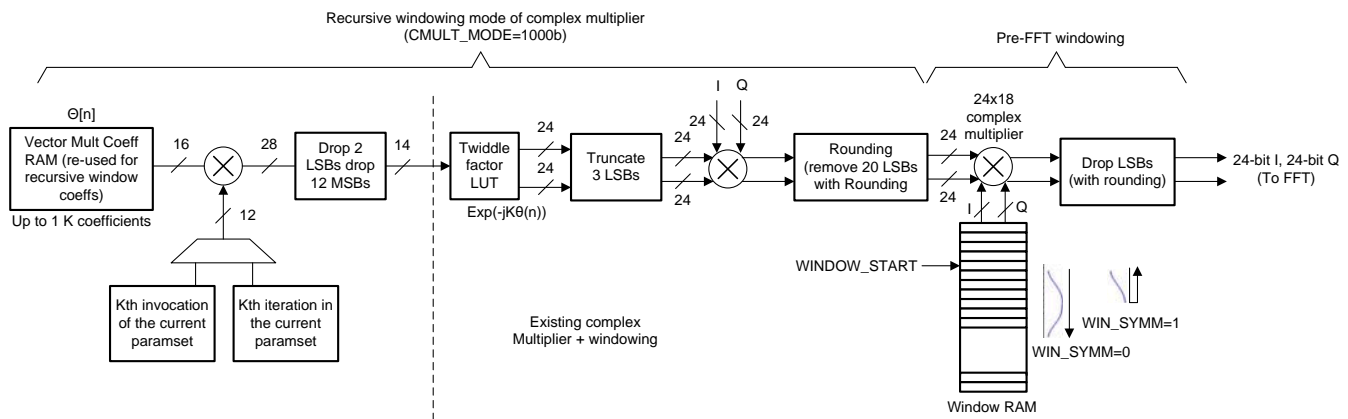

Figure 6-627. Recursive Windowing using the Complex Multiplier

- LUT based frequency and phase de-rotation mode: This mode is enabled using $CMULT_MODE = 1001b$. This mode is similar to Frequency shifter mode (previously explained, where $CMULT_MODE = 0001b$), except that it supports both frequency de-rotation and phase de-rotation based on a programmable RAM, $TWID_ANGLE_RAM$. Up to store 64 different frequency de-rotation and starting phase values can be programmed. Each entry in the RAM is 32 bits wide. The 16 MSBs contain starting phase word – $TWID_PHA$ and in remaining 16 LSB, the top-most two bits are don't cares, the next 14 LSBs contain the de-rotation frequency word. The 6 LSBs of $TWIDINCR$ register are used as a start address index to the $TWID_ANGLE_RAM$.

There are two sub-modes of this feature, selectable by bit 13 of $TWIDINCR$ register. If this bit set to 1 (Auto-increment mode), then the RAM index is incremented automatically after each iteration (i.e., B dimension), else (Non-increment mode), the RAM index is constant for all iterations, based on the 6 LSBs of $TWIDINCR$ register. Further, bit 12 of $TWIDINCR$ controls whether the RAM index saturates at 63 (behavior when the bit is set to 1) or wraps around (behavior when the bit is 0) in the Auto-increment mode.

- Frequency shifter mode with fine frequency increment: This mode is enabled using $CMULT_MODE = 1010b$. This mode is an extension of the Frequency shifter mode (previously explained, where $CMULT_MODE = 0001b$). In this mode, in addition to the previously explained frequency shifter functionality, there is another signed 10-bit offset $TWIDINCR_DELTA_FRAC$ that can be added to the de-rotation frequency, such that the de-rotation frequency changes incrementally after every “execution count”. The $TWIDINCR_DELTA_FRAC$ value is automatically accumulated to the de-rotation frequency at the end of the current execution of the current parameter-set with $CMULT_MODE = 1010b$. The fixed-point design of this datapath is illustrated in Figure 9). In effect, the input samples $x(n)$ for $n = 0$ to $SRCACNT-1$ are multiplied by the sequence: $\exp(-j * 2*\pi * ((TWIDINCR + 2^{(-6)} * TWIDINCR_DELTA_FRAC * execution_count) * (0:SRCACNT-1) / 16384))$. The $execution_count$ here refers to the current execution count of the parameter-set with

CMULT_MODE = 1010b. The TWIDINCR_DELTA_FRAC accumulator is reset only via software by writing to the TWID_INCR_DELTA_FRAC_RESET_SW register bit. Note that the TWIDINCR_DELTA_FRAC register is applicable only in this mode of the complex multiplier and is ignored in all other modes.

The memory layouts for different modes are illustrated in Figure 6-628.

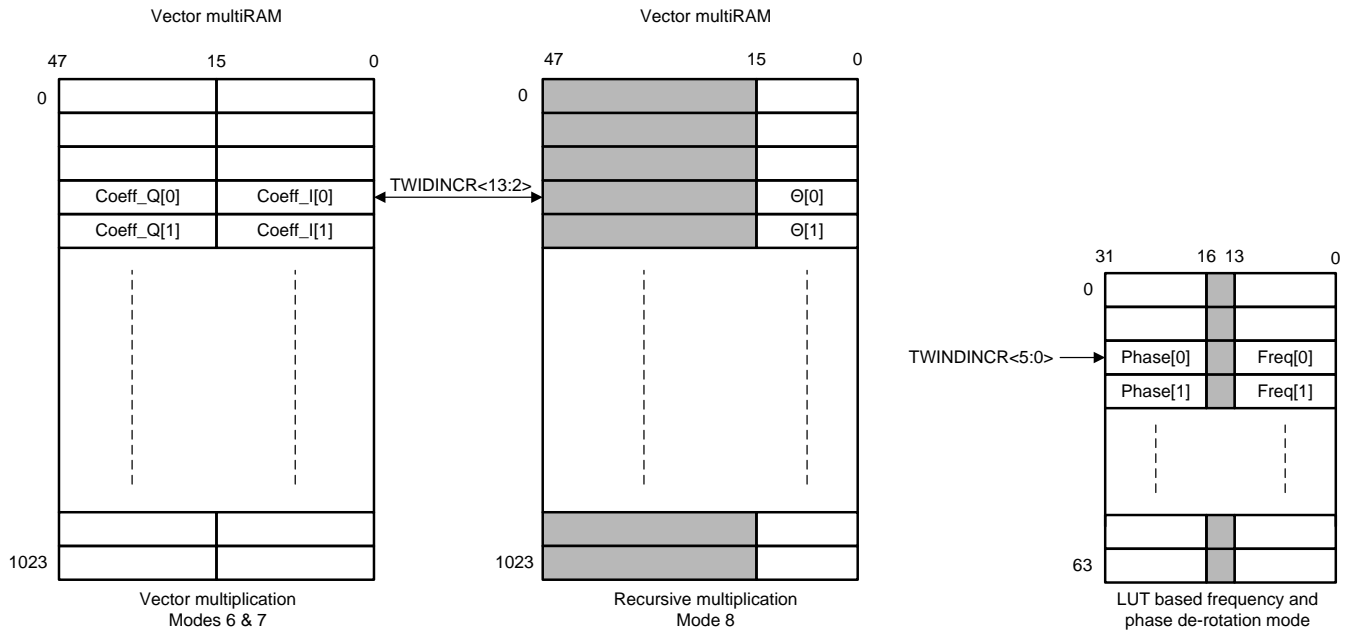

Figure 6-628. Memory Layout for Different Multiplication Modes

6.4.7.7 BPM Removal

Although not explicitly shown in Figure 1, it is possible to multiply the input samples going from the input formatter into the core computational unit with a +1/-1 programmable binary sequence (of length up to 256). This feature is enabled by setting the register bit BPM_EN in the parameter-set.

This feature may be useful when Binary Phase Modulation (BPM) is used during transmission of chirps. The BPM pattern is generally a pseudo-random sequence (chipping sequence) of 1's and -1's, which have already been applied to the radar transmit signal. Therefore, the radar signal processing of the resultant analog-to-digital converter (ADC) samples prior to FFT needs to undo the modulation. For instance, if each chirp is transmitted with a +1 or -1 polarity, then it is necessary to undo this sequence prior to the second dimension FFT processing across chirps. The BPM removal feature can be used to achieve this.

Note that an alternate way to achieve this is to pre-multiply the window coefficients, which are signed numbers, in the window RAM, so that the process of windowing prior to FFT takes care of undoing the BPM sequence.

When BPM removal is enabled, each input sample is multiplied by a +1 or -1, based on the bit sequence present in the eight 32-bit registers, BPMPATTERN0, BPMPATTERN1, ... BPMPATTERN7. A bit value of 0 (1) multiplies the input sample with 1 (-1). The register BPMRATE is used to control for how many consecutive samples the same BPM bit is applied. For example, if BPMRATE = 4, then the same BPM bit is applied for 4 consecutive samples. Similarly, if BPMRATE = 1, then the BPM bit is changed for every sample.

Figure 6-629. BPM Removal Capability

There is another register `BPMPHASE` that specifies the number of consecutive samples for which the first BPM bit is applied. Note that this is applicable only for the first BPM bit. If `BPMPHASE = 0`, then the first BPM bit is applied for `BPMRATE` number of samples. Otherwise, the first BPM bit is applied for `BPMRATE - BPMPHASE` number of samples. For example, if `BPMPHASE = 1` and `BPMRATE = 4`, then the first BPM bit is applied for $4 - 1 = 3$ samples, and then subsequent BPM bits are applied with periodicity of 4 samples for each bit. This is shown in Figure 6-629. If multiple iterations (for example, four back-to-back FFTs in a single parameter-set using `BCNT=3`) are done, then the same BPM pattern gets applied to the input samples in each iteration.

Note the limitation that the BPM pattern register is 256 bits long, hence, the maximum BPM sequence length that is supported is 256. For higher BPM sequence length, the alternate approach of pre-multiplying the window coefficients stored in the window RAM may be considered.

6.4.7.8 Channel Combining

The accelerator allows combining of data samples from multiple channels into one effective channel. This is done via an accumulator that sums a set of successive samples along the A dimension. The samples to combine are indicated by a 256-length bit-vector, `CHAN_COMB_VEC`. A string of '1' or a string of '0' sums the samples corresponding to the indices. A '10' or '01' transition demarcates the groups. This results in a variable rate output based on the length of 1s-string & 0s-string. The down-stream processing stalls during the grouping. The LSB of this bit-vector corresponds to the first input sample. An additional register, `CHAN_COMB_SIZE` needs to be programmed to indicate the number of samples after this combination in A dimension. The combination pattern is the same across all iterations. The channel combining is feature is enabled only if `CHAN_COMB_EN` is set to 1. The bit-vector `CHAN_COMB_VEC` is specified through eight 32-bit registers, `CHAN_COMB_VEC0`, `CHAN_COMB_VEC1`, ... `CHAN_COMB_VEC7`.

Channel combination is illustrated with an example here: if `CHAN_COMB_VEC0 = 0x008C` (and `CHAN_COMB_VEC1-7` are 0s), `SRCACNT = 11` (i.e. 12 samples), and `CHAN_COMB_SIZE = 5`, then the first 2 samples are combined into one output sample, the next 2 samples are combined into one output sample, and the next 3 samples are combined into one output sample, the next sample is output as another output sample, and the last 4 samples are combined into one output sample. Note that the 1s and 0s in `CHAN_COMB_VEC` can be flipped to achieve the same effect.

6.4.7.9 Zero Insertion

In addition to traditional zero padding before FFT, the accelerator includes a Zero Insertion feature. This feature allows filling of zeros at arbitrary locations in the A dimension, prior to windowing and FFT. Zero insertion is typically meant for angle-dimension FFT to account for missing antenna positions. The Zero Insertion capability is applicable to FFT sizes up to 256.

`ZERO_INSERT_MASK` is a 256-bit vector (split in eight 32-bit registers) that holds the positions of zero-insertion. A bit value of '0' inserts a zero and a value of '1' means the input is passed through. Input streaming is stalled during the zero insertion. The register `ZERO_INSERT_NUM` is used indicate the number of zeros to be inserted. The register `ZERO_INSERT_EN`, if set to 1, enables this feature.

Zeros insert locations directly refer to FFT's input sample indices. For example, if FFT size is 16, `SRCACNT` is 11, `ZERO_INSERT_MASK0 = 0xFF0F` means that the first 4 samples are passed through, 4 zeros are inserted, and the next 8 samples are passed through. As with channel combination, the zero insertion pattern remains same across iterations.

This mode is not to be confused with zero padding mode where zeros are appended to an input stream. The number of zeros padded at the end depends on FFTsize, zero insertion and channel combination. It is recommended to avoid zero insertion for the last sample in the iteration (the last sample should come through input formatter).

6.4.7.10 Pre-Processing Block – Register Descriptions

Table 6-600 lists all the registers of the pre-processing block. As explained in the first part of this chapter, some of the registers are common (common for all parameter-sets) registers, whereas, some others are “part of each parameter-set”. For each register, this distinction is captured as part of the register description in Table 6-600.

Table 6-600. Pre-Processing Registers

Register.field	Width	Parameter-Set? (Y/N)	Description
DCEST_RESET_MODE	2	Y	2-bit field that controls the reset behavior for all 12 DC accumulators 00 : Hold Accumulator state without updating 01 : Reserved 10 : Reset at start of param-set (i.e., per-chirp DC estimation). 11 : Reset at start of param-set only if loop counter is 0 (i.e., per-frame DC estimation)
DC_EST_CTRL.dc_est_scale	9	N	Programmable fine scaling for DC estimation: 9-bit scale applied to all 12 DC accumulators. This is followed by right shift and truncation. Multiplies the accumulator output by DC_EST_SCALE/256. Default value is 256 giving a scale of 1.0. Setting it to 128, gives a scale of 0.5.
DC_EST_CTRL.dc_est_shift	4	N	Programmable right shift for DC estimation: Right bit-shift applied to all 12 DC accumulator outputs. Cannot be bypassed. Accumulator outputs are scaled by $2^{(8 + 6 + DC_EST_SHIFT)}$. Valid range for this register is 0 to 14 (i.e., scaling of 2^{14} to 2^{28}). Note that DC_EST_SHIFT = 15 is not supported.
DC_ACC_I_<n>_VAL_LSB. Dc_acc_i_<n>_val_lsb n=0,1,..11	32	N	These read-only registers provide the lower 32 bits of 36b DC estimation accumulator values –I&Q for 12 streams for processor read-out.
DC_ACC_I_<n>_VAL_MSB. Dc_acc_i_<n>_val_msb n=0,1,..11	4	N	These read-only registers provide the upper 4 bits of 36b DC estimation accumulator values –I&Q for 12 streams for processor read-out.
DC_EST_RESET_SW.dc_est_reset_sw	1	N	Software reset for DC accumulators: Setting this register bit to 1 resets all 12 DC estimation accumulators. This is a self-clearing reset bit.
DC_EST_I_<n>_VAL.dc_est_i_<n>_val DC_EST_Q_<n>_VAL.dc_est_q_<n>_val n=0,1,..11	24	N	These read-only registers provide the DC estimates – I&Q for 12 streams – for the processor to read.
DC_ACC_CLIP_STATUS.dc_acc_clip_status	12	N	Clip status indication (read-register) for the 12 DC accumulators (both I and Q combined). Value of 1 indicates a clipping event occurred.
DC_EST_CLIP_STATUS.dc_est_clip_status	12	N	Clip status indication (read-register) for the 12 DC estimates (both I and Q combined). Value of 1 indicates a clipping event occurred.
DCSUB_EN	1	Y	Enable or Disable DC subtraction. If this register bit is set to 1, DC subtraction is enabled. Else, it is disabled.

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
DCSUB_SELECT	1	Y	Source select for DC subtraction: 0 : Value comes from processor via DC_SW_I<n> & DC_SW_Q<n> 1: Value comes from built-in DC estimation hardware, i.e., DCEST_I<n> & DCEST_Q<n>
DC_I<n>_SW.dc_i<n>_sw DC_Q<n>_SW.dc_q<n>_sw n=0,1,..11	24	N	User-programmed DC values used for DC subtraction. These registers are relevant only when DCSUB_SELECT is 0.
DC_SUB_CLIP.dc_sub_clip	1	N	Clip status indication (read-register) for DC subtraction node (both I and Q combined). Value of 1 indicates a clipping event occurred.
INTF_LOC_THRESH_EN	1	Y	Enable/Disable for Interference localization (marking out): This register bit controls the enable/disable for the interference marking (setting Interference Indicator Bit) feature. The feature is enabled if this register bit is set to 1.
INTF_LOC_THRESH_MAG<n> _SW.intf_loc_thresh_mag<n> _sw n=0..11	24	N	Software Interference threshold for Magnitude These registers are used to specify the user-programmed threshold for marking out samples affected by interference in the Interference localization block. The magnitude of each incoming samples is compared with this threshold to decide whether it is corrupted by interference or not.
INTF_LOC_THRESH_MAGD IFF<n>_SW.intf_loc_thresh_magdiff<n> _sw n=0...11	24	N	Software Interference threshold for Magnitude of backward difference These registers are used to specify the user-programmed threshold for marking out samples affected by interference in the Interference localization block. The magnitude of backward difference of incoming samples is compared with this threshold to decide whether it is corrupted by interference or not.
INTF_LOC_THRESH_MODE	2	Y	Interference detection mode selection: This register is used to control the mode for interference detection in the Interference localization block. 00 : Magnitude OR Magnitude difference 01: Only Magnitude difference 10: Only Magnitude 11 : Magnitude AND Magnitude difference
INTF_LOC_THRESH_SEL	2	Y	Select the source of interference threshold 0 : User-defined threshold via INTERFTHRESH_MAG_SW and INTERFTHRESH_MAGDIFF_SW 1 : Single threshold based on built-in interference statistics outputs using sum value across collected interference statistics 2 : Threshold based on built-in interference statistics outputs, with each statistic being used for corresponding iteration (RX channel)
INTF_STATS_RESET_MODE	2	Y	Reset mode control for Interference statistics accumulators: Controls the reset behavior for all 12 magnitude and magdiff accumulators. 00 : Hold Accumulator state without updating 01 : Free-running accumulator mode 10 : Reset at start of parameter-set (i.e., per-chirp accumulation). 11 : Reset at start of parameter-set only if loop counter is 0 (i.e., per-frame)

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
INTF_STATS_CTRL.intf_stats_mag_scale	8	N	Programmable fine scaling for Interference statistics Magnitude: Scaling applied to INTF_STATS_MAGACC<n> from interference statistics block.
INTF_STATS_CTRL.intf_stats_mag_shift	3	N	Programmable right shift for Interference statistics Magnitude: Right bit-shift applied to the interference magnitude accumulator. Total right shift of the accumulator is $2^{(3+6+INTF_STATS_MAG_SHIFT)}$. Valid range for this register is 0 to 6 (i.e., the total right shift can't be more than 2^{15}).
INTF_STATS_CTRL.intf_stats_magdiff_scale	8	N	Programmable fine scaling for Interference statistics MagDiff: Scaling applied to INTF_STATS_MAGDIFFACC<n> from interference statistics block.
INTF_STATS_CTRL.intf_stats_magdiff_shift	3	N	Programmable right shift for Interference statistics MagDiff: Right bit-shift applied to the interference magdiff accumulator. Total right shift of the accumulator is $2^{(3+6+INTF_STATS_MAGDIFF_SHIFT)}$. Valid range for this register is 0 to 6 (i.e., the right shift can't be more than 2^{15}).
INTF_STATS_MAG_ACC_<n>_LSB.intf_stats_mag_acc_<n>_lsb	32	N	These read-only registers provide the lower 32 bits of 36b magnitude accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAG_ACC_<n>_MSB.intf_stats_mag_acc_<n>_msb	4	N	These read-only registers provide the upper 4 bits of 36b magnitude accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAGDIFF_ACC_<n>_LSB.intf_stats_magdiff_acc_<n>_lsb	32	N	These read-only registers provide the lower 32 bits of 36b magnitude difference accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAGDIFF_ACC_<n>_MSB.intf_stats_magdiff_acc_<n>_msb	4	N	These read-only registers provide the upper 4 bits of 36b magnitude difference accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_RESET_SW.intf_stats_reset_sw	1	N	Software reset bit for all the interference statistics accumulators. This is a self-clearing reset bit.
INTF_LOC_THRESH_MAG_<n>_VAL.intf_loc_thresh_mag_<n>_val	24	N	Read-only thresholds – scaled and shifted INTF_STATS_MAGACC<n> of interference statistics block
INTF_STATS_SUM_MAG_VAL.intf_stats_sum_mag_val	24	N	Sum of INTF_LOC_THRESH_MAG_<n>_VAL, based on number of iterations. Useful as single magnitude threshold value across all iterations
INTF_LOC_THRESH_MAGDIFF_<n>_VAL.intf_loc_thresh_magdiff_<n>_val	24	N	Read-only thresholds – scaled and shifted INTF_STATS_MAGACCDIFF<n> of interference statistics block
INTF_STATS_SUM_MAGDIFF_VAL.intf_stats_sum_magdiff_val	24	N	Sum of INTF_LOC_THRESH_MAGDIFF_<n>_VAL, based on number of iterations. Useful as single magnitude difference threshold value across all iterations
INTF_STATS_SUM_MAG_VAL_CLIP_STATUS.intf_stats_sum_mag_val_clip_status	12	N	Read-only clip status indication register for 12 interference statistics magnitude accumulators INTF_STATS_MAGACC<n>. Value of 1 indicates a clipping event occurred in atleast one accumulator
INTF_STATS_SUM_MAGDIFF_VAL_CLIP_STATUS.intf_stats_sum_magdiff_val_clip_status	12	N	Read-only clip status indication register for 12 interference statistics magnitude-difference accumulators INTF_STATS_MAGACCDIFF<n>. Value of 1 indicates a clipping event occurred in atleast one accumulator
INTF_STATS_ACC_CLIP_STATUS.intf_stats_mag_accumulator_clip_status	12	N	Read-only clip status indication register for 12 magnitude based interference threshold. INTF_LOC_THRESH_MAG_<n>_VAL. Value of 1 indicates a clipping event occurred in atleast one estimate

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
INTF_STATS_ACC_CLIP_S TATUS.intf_stats_magdiff_ac cumulator_clip_status	12	N	Read-only clip status indication register for magnitude-difference based interference threshold. INTF_LOC_THRESH_MAGDIFF<n>_VAL. Value of 1 indicates a clipping event occurred in atleast one estimate
INTF_STATS_THRESH_CLI P_STATUS.intf_stats_thresh _mag_clip_status	1	N	Read-only clip status for sum of all magnitude thresholds computed by the statistics block. Value of 1 indicates that the sum clipped.
INTF_STATS_THRESH_CLI P_STATUS.intf_stats_thresh _magdiff_clip_status	1	N	Read-only clip status for sum of all magnitude difference thresholds computed by statistics block. Value of 1 indicates that the sum clipped.
INTF_LOC_COUNT_ALL_C HIRP.intf_loc_count_all_chirp	12	N	Read-only register indicating the number of samples that exceeded the threshold in a given param-set. The count is saturated to $2^{12} - 1$.
INTF_LOC_COUNT_ALL_F RAME.intf_loc_count_all_fra me	20	N	Read-only register indicating the number of samples that exceeded the threshold across multiple executions of same param-set. The count is saturated to $2^{20} - 1$.
INTF_MITG_EN	1	Y	If this bit is set, the interference mitigation path is activated, else it is bypassed.
INTF_MITG_PATH_SEL	2	Y	Based on the value of this register, one of the three paths is activated. 00b: Simple Zeroing out 01b: Windowed Zeroing out 10b: Linear Interpolation 11b: Reserved
INTF_MITG_WINDOW_PAR AM_<n>.intf_mitg_window_p aram_<n> n=0..4	5 (each)	N	This is a programmable array of window parameters. Each window parameter is an unsigned 5 bit integer. The length of the array is 5. The parameters of the window are assumed to be monotonically ascending. For example : val = floor(hanning(14)*32) INTF_MITG_WINDOW_PARAM = val(2:6); If a shorter window (of length less than 5) is desired, some of the earlier window parameters can be set to 31. This sets the window parameter to 31/32 (or ~1).
INTF_MITG_CNTTHRESH	5	Y	The (total) number of non-zero IIB within the 'Hysteresis window' should exceed this threshold for the sample-under-test to be considered to be affected by interference. Range : 0 to 31.
INTF_MITG_RIGHT_HYST_ ORD	4	Y	The length of the IIB array considered on the right side of (i.e. after) the sample under test. Range : 0 to 15.
INTF_MITG_LEFT_HYST_O RD	4	Y	The length of the IIB array considered on the left side of (i.e. before) the sample under test. Range : 0 to 15.
CMULT_MODE	4	Y	Complex multiplication mode selection: This register is used to configure the mode of the complex multiplication sub-block. A value of 0000b disables/bypasses the complex multiplication. Any other value chooses one of nine available modes of operation . Detailed description of the nine modes in the main description section.

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CMULT_SCALE_EN	1	Y	<p>Complex multiplier iteration enable :</p> <p>This register bit is applicable in certain modes of the complex multiplication pre-processing to enable per-iteration change of the complex scalar coefficient.</p> <p>When using scalar multiplication mode of the complex multiplier (CMULT_MODE = 0101b), if CMULT_SCALE_EN is set to 1, then the input samples are multiplied by a different complex scalar (i.e., ICMULTSCALE0, QMULTSCALE0 to ICMULTSCALE11, QMULTSCALE11) for each iteration. Else, a constant complex scalar ICMULTSCALE0 and QCMULTSCALE0 is applied to all samples across all iterations.</p> <p>When using vector multiplication mode (CMULT_MODE = 0110b), if CMULT_SCALE_EN is set to 1, then instead of pulling the coefficients for vector multiplication from the Vector Multiplication Coefficients RAM, the input samples are multiplied successively by ICMULTSCALE0, QMULTSCALE0 to ICMULTSCALE11, QMULTSCALE11 registers.</p>
ICMULT_SCALE<n>.icmult_scale<n> QCMULT_SCALE<n>.qcmult_scale<n> n = 0 ..11	21	N	<p>Coefficients for Complex multiplication:</p> <p>Refer the description for CMULT_SCALE_EN register.</p>
VEC_MULT_RAM[1024] DSS_HWA_MULT_RAM	48	N	<p>Vector multiplication RAM : Stores the complex vector multiplication coefficients used in modes 6, 7 and 8. Layout shown in Fig. 11</p>
TWIDINCR	14	Y	<p>Frequency shifter configuration:</p> <p>When the complex multiplication sub-block is programmed in one of the frequency shifter modes (CMULT_MODE = 0001b or 0010b), this register is used to indicate the amount of frequency shift.</p> <p>When the complex multiplication sub-block is programmed in FFT stitching mode (CMULT_MODE = 0011b), the last two bits of this register specify whether it is 4K or 8K FFT stitching. Specifically, if the last two bits are 01b, then it is 4K FFT stitching and if the last two bits are 10b, then it is 8K FFT stitching. Values of 00b and 11b are reserved. Also, the 12 MSB bits of this register must be kept zero in the FFT stitching mode.</p> <p>In all other modes of the complex multiplication sub-block, this 14-bit register must be kept as 0.</p> <p>When the complex multiplication sub-block is programmed with CMULT_MODE = 0110b, 0111b or 1000b, then the 12 MSBs of this register are used as an address offset for the Vector Multiplication Coefficients RAM (the 2 LSBs must be kept 0).</p> <p>When the complex multiplication sub-block is programmed with CMULT_MODE = 1001b, then the 6 LSBs of this register are used as an address offset for TWID_ANGLE_RAM, with bit 13 enabling auto-address increment over iterations and bit 12 enabling address saturation or address roll-over after 63.</p>
TWID_INCR_DELTA_FRAC.twid_incr_delta_frac	10	N	<p>Fractional frequency increment per execution of the parameter-set:</p> <p>Frequency shift value to be accumulated at the end of current parameter-set. Refer main description for more details.</p>

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
DSS_HWA_DEROT_RAM	32	N	Frequency and Phase values for generic frequency shifter mode: This is only applicable when CMULT_MODE = 1001b. In this mode, these 64 registers represent the starting phase and frequency values used. Layout is shown in Fig. 11
RECWIN_MODE	1	Y	Recursive window mode select bit.(0) –the K value increments with iteration. (1) –the K value increments with paramset execution count. K always starts from 0
RECWIN_RESET_SW.recwin_reset_sw	1	N	Software reset bit for recursive window K value. This is a self-clearing reset bit.
RECWIN_INIT_KVAL.recwin_init_kval	12	N	RESERVED. This is a reserved register and should be always kept 0.
TWID_INCR_DELTA_FRAC_RESET_SW.twid_incr_delta_frac_reset_sw	1	N	Software reset bit for fine frequency increment accumulator (in CMULT_MODE = 1010b). This is a self-clearing reset bit.
TWID_INCR_DELTA_FRAC_CLIP_STATUS.twid_incr_delta_frac_clip_status	1	N	Read-only register bit that indicates clip status for the fine-frequency increment accumulator (in CMULT_MODE = 1010b).
BPM_EN	1	Y	Enable/Disable BPM removal: This register bit specifies whether the BPM removal needs to be enabled or not. If this register is set, then BPM removal is enabled prior to feeding samples from the input formatter into the core computational unit.
BPM_PATTERN<n>.bpm_pattern_<n>n=0..7	256	N	BPM pattern: Specifies the BPM pattern to be used to multiply the input samples if BPM removal is enabled. The 256-bit word is split into 8 32-bit words as [BPM_PATTERN_7, BPM_PATTERN_6, BPM_PATTERN_5, BPM_PATTERN_4, BPM_PATTERN_3, BPM_PATTERN_2, BPM_PATTERN_1, BPM_PATTERN_0]
BPM_RATE.bpm_rate	10	N	BPM rate: Specifies the number of input samples corresponding to each BPM bit. Minimum valid value for this register is 1.
BPM PHASE	4	Y	BPM starting phase: Specifies the starting phase of the BPM pattern periodicity. For more information, see the detailed description.
CHAN_COMB_EN	1	Y	Enable/Disable channel combining: If this register bit is set to 1, then the channel combining feature is enabled.
CHAN_COMB_VEC_<n>.chan_comb_vec_<n>n=0..7	256	N	Sample index indicator for Channel combining : This register indicates the sample indices that need to be combined in the Channel combiner block. A '01' or '10' transition demarcates the groups. The 256-bit word is split into 8 32-bit words as [CHAN_COMB_VEC_7, CHAN_COMB_VEC_6, CHAN_COMB_VEC_5, CHAN_COMB_VEC_4, CHAN_COMB_VEC_3, CHAN_COMB_VEC_2, CHAN_COMB_VEC_1, CHAN_COMB_VEC_0]
CHAN_COMB_SIZE.chan_comb_size	8	N	This register indicates the number of samples after channel combination in each iteration.

Table 6-600. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CHANNEL_COMB_CLIP_STATUS.channel_comb_clip_status	1	N	Clip status indication (read-register) during channel combining. Value of 1 indicates a clipping event occurred.
ZERO_INSERT_EN	1	Y	Enable/Disable zero-insertion: If this register bit is set to 1, then the zero-insertion feature is enabled.
ZERO_INSERT_NUM.zero_insert_num	8	N	This register indicates the number of zeros to be inserted in each iteration.
ZERO_INSERT_MASK_<n>.zero_insert_mask_<n>n=0..7	256	N	Sample index indicator for Zero Insertion: This is a 256-bit register that holds the positions of zero-insertion. A bit value of '0' inserts a zero at the corresponding index location. A bit value of '1' means the input is passed through. The input sample stream from Input formatter is stalled during the zero insertion. The 256-bit word is split into 8 32-bit words as [ZERO_INSERT_MASK_7, ZERO_INSERT_MASK_6 ZERO_INSERT_MASK_5, ZERO_INSERT_MASK_4 ZERO_INSERT_MASK_3, ZERO_INSERT_MASK_2 ZERO_INSERT_MASK_1, ZERO_INSERT_MASK_0]

6.4.8 Core Computational Unit - CFAR Engine

This section describes the CFAR engine block present in the core computational unit.

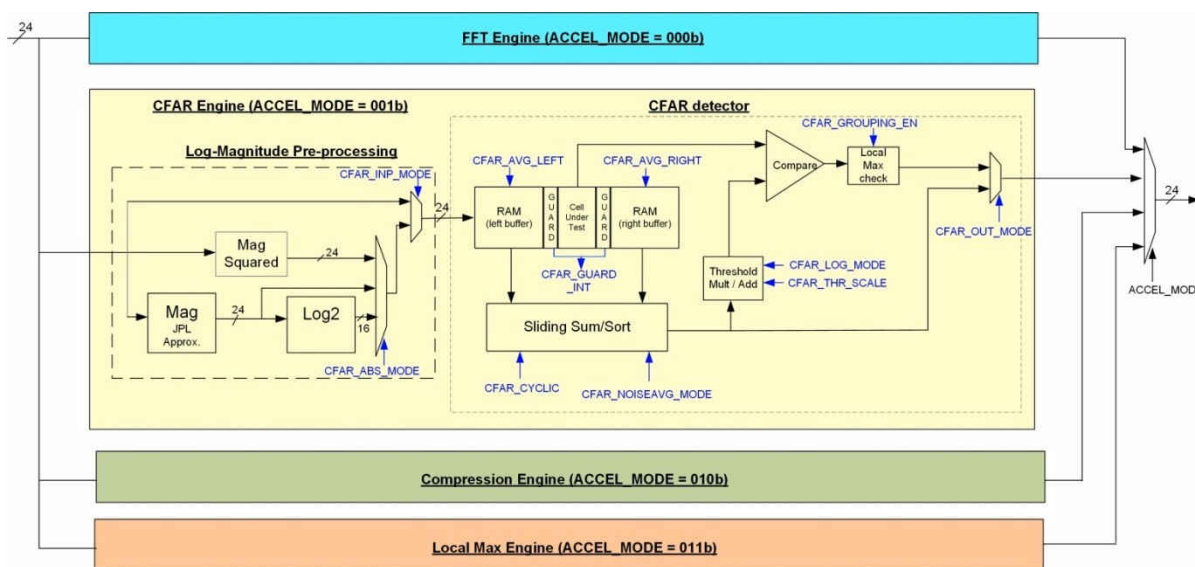

Figure 6-630. CFAR Engine

6.4.8.1 CFAR Engine

The CFAR engine (Figure 6-630) is a module that enables detection of objects, by identifying peaks in the FFT output. Although there are several detection algorithms, the accelerator supports CFAR-CA and CFAR-OS algorithms. CFAR-CA stands for constant false alarm rate – Cell Averaging. CFAR-OS stands for constant false alarm rate – Ordered Statistic.

As shown in figure, the CFAR engine path is selected by setting the accelerator mode ACCEL_MODE = 001b. In this mode, the FFT path is not usable simultaneously and the input 24-bit samples from the input formatter block will be routed into the CFAR engine. The CFAR engine has capability to perform CFAR- detection processing (both linear and logarithmic CFAR modes are available) and generate a peak list.

In CFAR, the processing steps involve computing a threshold for each sample under test (cell under test) and deciding whether a peak is detected or not based on whether the cell under test crosses that threshold. Additionally, peak grouping may be done, where a peak is declared only if the cell under test is greater than or equal to its most immediate neighboring cells to its left and right. One thing to note here is that for peak grouping, the left and right neighboring cells themselves are not required to be CFAR qualified.

In CFAR-CA case, for each cell under test, the computation of threshold is done by averaging the magnitude (or magnitude-squared or log-magnitude) of a specified number of noise samples to the left and right of the cell under test to determine a ‘surrounding noise level’ and then applying a scale factor (or addition factor in case log-magnitude is used) on that surrounding noise average to determine the threshold. Thus, the CFAR-CA detector takes one cell at a time, computes the threshold and decides whether a valid peak is present at that cell. In the case of CFAR-OS, for each cell under test, the computation of threshold is done by sorting the magnitude (or magnitude-squared or log-magnitude) of a specified number of noise samples to the left and right of the cell under test and selecting a specific “K-th” lowest value from the sorted list as representative of the surrounding noise level, and then applying a scale factor on that value to determine the threshold.

6.4.8.1.1 CFAR Engine – Operation

The CFAR engine receives 24-bit input samples from the Input Formatter block. Typically, these are real samples, representing the magnitude or magnitude-squared or log-magnitude of the FFT output. However, the input to CFAR engine can instead be complex samples, in which case, either magnitude or magnitude-squared or log-magnitude of the complex samples can be computed inside the CFAR engine itself. This is done by the log-magnitude pre-processing sub-block inside the CFAR engine (see Figure 6-630). The real unsigned result from this pre-processing operation is sent to CFAR detection processing. The registers CFAR_INP_MODE and CFAR_ABS_MODE are used to configure real vs. complex input, as well as the nature of pre-processing required. The log-magnitude computation uses the same JPL approximation for magnitude calculation and the same look-up table (LUT) approximation for log2 computation as described in Part 1 of the user guide for FFT engine post-processing. Note that for the case of real input (i.e., CFAR_INP_MODE = 1), the input samples must be unsigned. In this case, CFAR_ABS_MODE register has no effect.

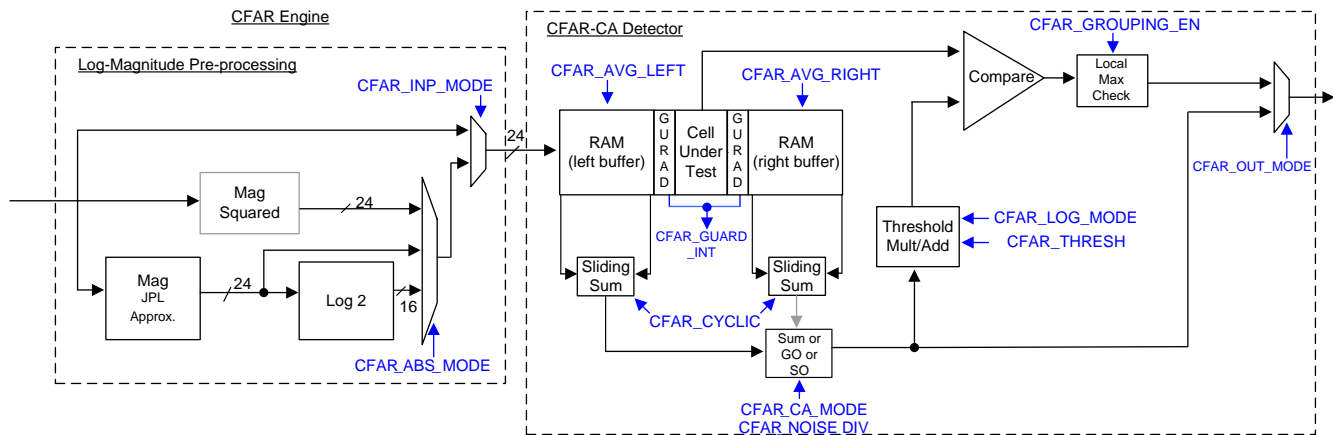

Figure 6-631. CFAR Engine Block Diagram

As described earlier, the CFAR detection processing involves finding a “surrounding noise average” for each cell under test and then determining a threshold that is a function of the surrounding noise average. The cell under test is compared against this threshold to decide whether a peak is present or not in that cell. To calculate the threshold, the surrounding noise average is multiplied with (or added to) a threshold scaling factor specified in CFAR_THRESH register.

There are two modes in which the CFAR detector can be used – in non-logarithmic mode (a.k.a linear CFAR), the threshold scale factor is multiplied, and in logarithmic mode (a.k.a logarithmic CFAR), the threshold scale factor is added. This is decided based on CFAR_LOG_MODE register.

Note: The linear and logarithmic modes are available for CFAR-CA and its variants. Their detection cores are built with 24-bit datapath width. Only the logarithmic mode is available for CFAR-OS. The CFAR-OS detection core is built with 16-bit datapath width, which is sufficient in logarithmic mode.

The final detection threshold that is so obtained is used to compare against the cell under test to determine whether a peak is detected in that cell.

Table 6-601 summarizes the register settings for the different CFAR modes of operation.

Table 6-601. CFAR Modes and Register Settings

Desired CFAR Mode	Input Real or Complex	Desired Pre-Processing	Register Values to Use		
			CFAR_INP_MODE	CFAR_ABS_MODE	CFAR_LOG_MODE
Linear CFAR	Real	N/A	1	00	0
	Complex	Magnitude	0	10	0
		Mag-squared	0	00	0
		Log2-Mag	0	11	0
Log CFAR	Real	N/A	1	00	1
	Complex	Log2-Mag	0	11	1

Desired CFAR-CA Algorithm	CFAR_CA_MODE Register Setting
CFAR-CA	00
CFAR-CAGO	01
CFAR-CASO	10
CFAR-OS	11

The surrounding noise level computation has multiple options – cell averaging (CFAR-CA), cell averaging with greater-of selection (CFAR-CAGO), cell averaging with smaller-of selection (CFAR-CASO) and ordered statistic (CFAR-OS). The register CFAR_CA_MODE is used to select one among CFAR-CA, CFAR-CAGO, CFAR-CASO and CFAR-OS modes. In CFAR-CA, the noise samples on the left side and right side of the cell under test (after ignoring some guard cells on either side) are simply averaged to determine the surrounding noise level. In CFAR-CAGO, the noise samples on the left side and right side are averaged independently and the greater of the two is used to determine the threshold. In CFAR-CASO, the lesser of the two is used. In CFAR-OS, the noise samples on the left side and right side of the cell under test (after ignoring some guard cells on either side) are sorted and the “K-th” lowest value from the sorted list is selected as the surrounding noise level. The selection of “K-th value” from the sorted list is based on the register CFAR_OS_KVALUE (see table of registers for more details on this register).

The number of samples on the left side and right side used for computing the noise average is configured using CFAR_AVG_LEFT and CFAR_AVG_RIGHT registers and the number of guard cells is configured using CFAR_GUARD_INT register (Figure 6-631). The number of samples used for left side noise averaging is given by $2 \times \text{CFAR_AVG_LEFT}$. The number of samples used for right side noise averaging is given by $2 \times \text{CFAR_AVG_RIGHT}$. The number of guard cells that are ignored on each side of the cell under test is given by CFAR_GUARD_INT. For example as shown in Figure 6-632, if CFAR_AVG_LEFT = CFAR_AVG_RIGHT = 16, and CFAR_GUARD_INT = 3, then it means that the most immediate three samples each to the left and right of the cell under test are skipped and then, 32 samples on the left and 32 samples on the right side are used for noise averaging. Note that even though the term noise averaging is used here, the actual implementation simply adds the noise samples first and the “averaging” is done as a divide by a power-of- 2 as specified in a separate register, CFAR_NOISE_DIV. These registers are described in Table 7.

Note: The CFAR engine also supports a special “constant threshold mode” of CFAR detection. In this special mode, the detection threshold value to compare with each cell-under-test is based on a user configurable constant – CFAR_DET_THR. This detection threshold value is independent of “surrounding noise level”, and the detection comparison depends only CFAR_DET_THR, CFAR_THR_SCALE, and CFAR_LOG_MODE. This mode of operation can be achieved by setting the engine in CFAR-CA mode and additionally setting

CFAR_AVG_LEFT = CFAR_AVG_RIGHT = 0. In this constant threshold mode, CFAR_THRESH scalefactor is multiplied with CFAR_DET_THR in the linear mode, and in the logarithmic mode the threshold scale factor is added.

In case of CFAR-CA, the valid values for CFAR_AVG_LEFT and CFAR_AVG_RIGHT is any number between 0 and 63 (except 1), which means that the number of samples each on the left side and right side used for noise averaging can be one of 0, 4, 6, 8, 10, 12, 14, ... 124, 126. The values of CFAR_AVG_LEFT and CFAR_AVG_RIGHT can be different in cyclic mode of CFAR and need to be equal in non-cyclic mode (both are described in a later section).

However, in the case of CFAR-OS, the valid values for CFAR_AVG_LEFT and CFAR_AVG_RIGHT are highly restricted. They need to be equal (i.e., same window size on left and right sides) and further, the only values supported for these registers in CFAR-OS mode are: 0, 4, 6, 8, 12, 16, 24 and 32 (which corresponds to number of samples being 0, 8, 12, 16, 24, 32, 48 and 64 on either side). Note that the register CFAR_NOISE_DIV, which is used in CFAR-CA for noise “averaging”, is not applicable in case of CFAR-OS.

Figure 6-632. CFAR-CA: Cells Used for Surrounding Noise Average

As mentioned earlier, the CFAR_THRESH register specifies the threshold scaling factor. This is an 18-bit register whose value is used to either multiply or add to the ‘surrounding noise average’ to determine the threshold used for detection of the present cell under test. If logarithmic mode is disabled (in magnitude or magnitude-squared mode), then the register value is multiplied with the surrounding noise average to determine the threshold, else it is added to the surrounding noise average. In the former case, this 18-bit register is interpreted as a 14.4 value and supports a range of values from 1/16 to 2¹⁴-1. In the latter case (logarithmic mode), the 18-bit register is interpreted as a 7.11 value.

The CFAR engine supports a few output formats that are described next.

6.4.8.1.2 CFAR Engine – Output Formats

As part of CFAR detection, the cells that exceed the threshold are noted and this ‘Detected Peaks list’ is sent to the destination memory. Since the output format of the core computational unit is 24-bits I and 24-bits Q, the detected peaks list is formatted into ‘I’ and ‘Q’ channels as shown in [Figure 6-633](#) below. The 24-bit I channel contains the index at which the peak is detected, with the MSB 12 bits containing the iteration number (corresponding to BCNT counter value) and the LSB 12 bits containing the sample index number (corresponding to SRCACNT counter value). The 24-bit Q channel contains the surrounding noise level value or the cell under test value of that detected peak. This is chosen based on CFAR_OUT_MODE register setting. Instead of ‘Detected Peaks list’, it is also possible for the CFAR engine to send out the raw ‘surrounding noise level’ value for each cell. This is called ‘Raw output mode’.

Figure 6-633 and Table 6-602 show the different output formats available.

Output format of CFAR Engine in 'Detected Peaks list' mode

Output format of CFAR Engine in 'Raw output' mode

Figure 6-633. CFAR Engine Output Format

In detected peaks list mode, only the detected peaks are output to the destination memory. In this case, the read-only register CFARPEAKCNT indicates how many peaks have been totally detected, so that the main processor can read that many locations from the destination memory. In this mode, the number of peaks stored in the destination memory is limited to a maximum of 4095, or DSTACNT, whichever is smaller. If more peaks are detected beyond this number, they wrap around and circularly overwrite the same locations in the destination memory. Also, in this mode, the register DSTBINDX is not applicable and is ignored.

While detecting peaks, if 'peak grouping' is required, then it can be enabled using CFAR_GROUPING_EN register. In this case, a peak is declared as detected only if the cell under test exceeds the threshold, as well as, if the cell under test exceeds the two neighboring cells to its immediate left and right (the peak is a local maximum).

Further, there is a special mode of the CFAR Engine called "Dominant peaks mode". This mode can be used to create a modified copy of the range FFT output, where the range FFT bins corresponding to large objects are kept as is, and the range FFT bins which do not correspond to large objects are masked (zeroed out). In this special mode of the CFAR engine, the CFAR engine takes complex (I & Q) input samples and the CFAR engine outputs values that are simply equal to its input values at the sample indices corresponding to the detected peaks, and outputs zeros at all other sample indices. This thereby gives an output array which is the same as the input array AND'ed with the binary CFAR peak detection flags. Note that this special mode is only meaningful when the CFAR input is complex, i.e., when CFAR_INP_MODE = 0. The purpose of this "Dominant Peaks mode" is to re-construct interference affected samples, where this mode can be used to extract the FFT output bins corresponding to large peaks and later, doing an IFFT on this output to re-construct the time domain signal corresponding only to dominant peaks.

Output format of CFAR Engine in the special 'Dominant peaks' mode

Figure 6-634. CFAR Engine Output Format in Dominant Peaks Mode

Table 6-602. CFAR Output Modes and Register Settings

CFAR Output Mode	I Channel Output	Q Channel Output	Register Settings (CFAR_ADV_OUT_MODE, CFAR_OUT_MODE)
Raw output mode (all cells are output)	Surrounding noise level	Cell under test value	(0,00)
	Surrounding noise level	Binary detection result flag (0 or 1)	(0,01)
Detected peaks list mode (only detected peaks are output)	Peak index	Surrounding noise level value	(0,10)
	Peak index	Cell under test value	(0,11)
Dominant peaks mode	Reserved	Reserved	(1,00)
	Input array (I channel) AND'ed with binary detection result flag	Input array (Q channel) AND'ed with binary detection result flag	(1,01)

6.4.8.1.3 CFAR Engine – Cyclic vs. Non-Cyclic

The register CFAR_CYCLIC specifies whether the CFAR detector needs to work in cyclic mode or in non-cyclic mode. In general, the programmed number of samples for noise level computation (specified by CFAR_AVG_RIGHT and CFAR_AVG_LEFT) are available fully only for the cells under test which are in the middle of the input array (Figure 6-635). For first several cells under test, the available number of samples to the left is lesser than the programmed number. Similarly, for the last several cells under test, the available number of samples to the right is lesser than programmed.

In cyclic mode (Figure 6-636), this is handled by wrapping around the edges in a circular manner. For a cell under test near the left edge, some samples from the right edge (circular wrap around the edge) are fetched to collect the programmed CFAR_AVG_LEFT number of left side samples for noise level computation. Similarly, for a cell under test near the right edge, an appropriate number of samples from the left edge are used (again, circular wrap around the edge).

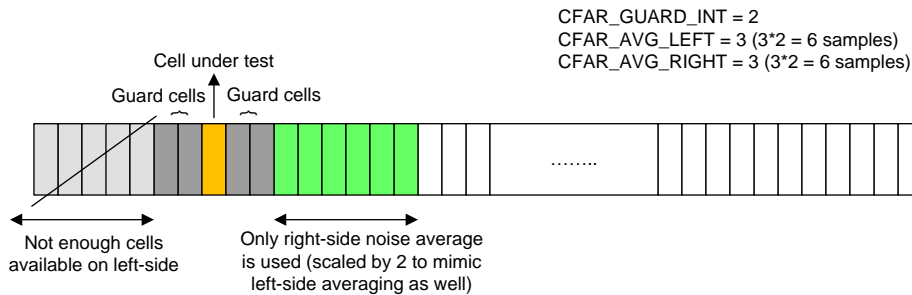

Figure 6-635. Handling of Samples Near the Edge in Non-Cyclic Mode

Figure 6-636. Handling of Samples Near the Edge in Cyclic Mode

This cyclic CFAR implementation is accomplished through a combination of a few register settings within the CFAR engine, as well as in the input and output formatter blocks. Specifically, the input formatter is configured to send additional samples (repeat samples) in a circular manner wrapping around the left and right edges. This is achieved by using the A-dimension circular shift (SRCA_CIRCSHIFT) and wrap-around (SRCA_CIRCSHIFTWRAP) registers in the input formatter, such that the required number of extra samples at both edges are streamed into the CFAR engine. The cyclic CFAR mode only works when the number of cells under test is a power of 2.

For example, if the number of cells under test is 256, the average number of left and right noise samples is 32 each and the number of guard cells is 3 on either side. Then, the registers need to be programmed as shown in Table 6-603.

Table 6-603. Configuration Example for CFAR Cyclic Mode

Module	RegisterSetting	Comments
CFAREngine	CFAR_GUARD_INT= 3	3guard cells on either side
	CFAR_AVG_LEFT= 16 CFAR_AVG_RIGHT= 16	32samples on left side and 32 samples on right side for noise averaging
Input Formatter	SRCACNT =325	255+ (32+3) + (32+3), where 255 is the usually configured value of SRCACNT for a 256 sample vector, plus 32+3 additional samples for circular repeat at either end
	SRCA_CIRCSHIFT= 221	256– (32+3), which is the starting offset for the circular shift, so that samples are streamed into CFAR engine start from this point
	SRCA_CIRCSHIFTWRAP= 8 SRC_CIRCSHIFTWRAP3X = 0	The circularwrap-around happens when SRCACNT counter value reaches $2^{\wedge}SRCA_CIRCSHIFTWRAP = 256$
Output Formatter	REG_DST_SKIP_INIT= 0	Noneed to skip any samples at Output Formatter even though extra samples are fed into CFAR engine, because CFAR engine automatically strips out the extra samples
	DSTACNT= 255	256outputs corresponding to 256 cells

Figure 6-637. Input Formatter Sample Streaming for the Cyclic CFAR Example

However, the handling of edge samples in non-cyclic mode of CFAR is different. It is explained below – first for CFAR-CA and then for CFAR-OS versions.

In non-cyclic mode of CFAR-CA, if the number of available samples on the left for any cell under test is lesser than CFAR_AVG_LEFT, then the noise average is computed solely from the right side. This is done by calculating the noise sum as twice the right side noise sum. Similarly, if the number of available samples on the right is lesser than CFAR_AVG_RIGHT, then the noise average is computed solely from the left side. This is done by calculating the noise sum as twice the left side noise sum. It is required that the CFAR_AVG_LEFT and CFAR_AVG_RIGHT be programmed equally in non-cyclic mode – otherwise, the noise computation for the edge samples is not ideal.

In non-cyclic mode of CFAR-OS, the edge samples are handled as follows. For the cells under test that are near the edges, the number of available surrounding samples for sorting is lesser than programmed (CFAR_AVG_LEFT or CFAR_AVG_RIGHT). These available samples are first sorted and the Kth lowest value is selected as the noise level. It should be noted that this Kth lowest sample in the available samples may result in a sub-optimal noise level for edge samples than non-edge samples because the number of available samples is lesser for edge samples than for non-edge samples. A minor variant for better handling this edge sample case can be enabled by setting the register CFAR_OS_NONCYC_VARIANT_EN to 1. In that case, available samples are first sorted. But instead of using the programmed K value directly for noise sample selection from the sorted array, a proportionally scaled down value is used based on the number of available surrounding samples for each cell under test. This is illustrated in Table 6-604 below, where, L represents the programmed

CFAR_AVG_LEFT (same as CFAR_AVG_RIGHT) and K represents the programmed CFAR_OS_KVAL. It is required that the CFAR_AVG_LEFT and CFAR_AVG_RIGHT be programmed equally in non-cyclic mode.

Table 6-604. Internal K Value used in CFAR-OS Non-Cyclic Mode

No. of available samples on one side (excluding guard)	No. of available samples on the other side (excluding guard)	Internal K value used for noise sample selection (CFAR_OS_NON_CYC_VARIANT_EN = 0)	Internal K value used for noise sample selection (CFAR_OS_NON_CYC_VARIANT_EN = 1)
L	0 to floor(L/4)-1	K	floor (4K/8)
L	floor(L/4) to floor(2L/4)-1	K	floor (5K/8)
L	floor(2L/4) to floor(3L/4)-1	K	floor (6K/8)
L	floor(3L/4) to floor(4L/4)-1	K	floor (7K/8)
L	L	K	K

In general, it is expected that CFAR Engine will be used for arrays much larger than the configured left and right window and guard lengths. Specifically, the ACNT should exceed the sum of configured left and right window and guard lengths.

6.4.8.2 CFAR Engine – Register Descriptions

Table 6-605 lists all the registers of the CFAR engine block.

Table 6-605. CFAR Engine Registers

Register field	Width	Parameter-Set? (Y/N)	Description
CFAR_AVG_LEFT	6	Y	<p>Number of left-side samples for noise level computation: This register is used to specify the number of samples used for noise level computation to the left of the cell under test. The number of samples used for noise level computation is equal to the value of this register multiplied by 2. For example, if this register value is 15, then the number of left-side samples used for averaging is 30. The maximum number that is possible is 126. A value of zero in this register means that the noise samples on the left side are not used for noise level computation.</p> <p>The valid values for this register are different for CFAR-CA and CFAR-OS modes: In CFAR-CA (and its variants CFAR-CAGO and CFAR-CASO), valid values for this register are 0, 2, 3, 4, ...63 (Note that a value of 1 is not supported). This corresponds to number of samples equal to 0, 4, 6, 8, 10, 12, 14, ... 124, or 126. In CFAR-OS mode, valid values for this register are restricted to 0, 4, 6, 8, 12, 16, 24, 32 only (which corresponds to number of samples equal to 0, 8, 12, 16, 24, 32, 48 or 64).</p>
CFAR_AVG_RIGHT	6	Y	<p>Number of right-side samples for noise level computation: This register is very similar to the above, except that this register specifies the averaging to the right of the cell under test. In most cases, it is expected that CFAR_AVG_RIGHT has the same value as CFAR_AVG_LEFT. In non-cyclic modes of CFAR, CFAR_AVG_RIGHT must be programmed equal to CFAR_AVG_LEFT.</p>

Table 6-605. CFAR Engine Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CFAR_GUARD_INT	3	Y	Number of guard cells: This register specifies the number of guard cells to ignore on either side of the cell under test. If this register value is 3, then three guard cells on the left side and three guard cells on the right side are ignored. Only the noise samples beyond this guard region are used for calculating the surrounding noise level.
CFAR_OS_KVALUE	7	Y	K-th value for ordered statistic: This register is useful only in CFAR-OS mode, where it indicates the parameter K. From the sorted list of left and right noise samples, the K'th lowest value is used as the noise sample. This is a zero-based count – for instance, if this register value is 27, then the 28th lowest element in the sorted array is selected. Note that since CFAR-OS supports a maximum of 64 samples each on left and right side, the maximum size of the vector to sort is 128, and hence the maximum valid value of CFAR_OS_KVALUE register is 127.
CFAR_OS_NON_CYC_VARIANT_EN	1	Y	Enable scaling of K value for edge samples in non-cyclic CFAR-OS: This is useful only in CFAR-OS in non-cyclic mode. Setting this to 1 enables a variant where the K value used for noise sample selection for edge samples is scaled down proportional to the number of available neighboring samples at edges.
CFAR_THRESH .cfar_thresh	18	N	Threshold scale factor: This register is used to specify the threshold scale factor. This value is used to either multiply or add to the 'surrounding noise level' to determine the threshold used for detection of the present cell under test. If logarithmic CFAR mode is disabled (in magnitude or magnitude-squared mode), then the register value is multiplied with the surrounding noise level to determine the threshold, else it is added to the surrounding noise level. In the former case, this 18-bit register is interpreted as a 14.4 value. In the latter case (logarithmic mode), the 18-bit register is interpreted as a 7.11 value.
CFAR_DET_THRESH.cfar_det_thresh	24	N	Constant detection threshold value in constant threshold mode: This register is applicable only in constant threshold mode of CFAR (i.e. only in CFAR-CA mode and only if CFAR_AVG_LEFT = CFAR_AVG_RIGHT = 0). In this special mode, this register specifies the detection threshold value used to compare with cell under test. The detection threshold value is held constant, and scaled by CFAR_THRESH linearly or logarithmically

Table 6-605. CFAR Engine Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CFAR_LOG_MODE	1	Y	<p>CFARlinear or logarithmic mode:</p> <p>This registeris one of the registers used to specify whether the CFAR detector operates in linear or logarithmic mode. If this register bit is set, then the CFAR detector operates in logarithmic mode, which means that the threshold scale factor is added to (instead of multiplied with) the surrounding noise level value to determine the threshold. Note that this mode is meaningful only when the input samples to the CFAR detector are log- magnitude samples (see CFAR_INP_MODE as well). If this register bit is 0, then the logarithmic mode is disabled, in which case, the threshold scale factor is multiplied with (instead of added to) the surrounding noise level to determine the threshold. This mode is meaningful when magnitude or magnitude-squared samples are fed to the CFAR detector.</p>
CFAR_INP_MODE	1	Y	<p>CFAREngine input mode:</p> <p>This registerbit specifies whether the inputs to the CFAR engine are complex samples or real values (the real values are already magnitude, magnitude-squared or log-magnitude numbers that can be directly sent to CFAR detection process). If this register bit is 1, then the input samples are real values and are directly sent to CFAR detection. If this register bit is 0, then the inputs are complex samples and hence either magnitude or magnitude- squared or log-magnitude computation is required prior to CFAR detection. Which of the three, viz., magnitude or magnitude-squared or log-magnitude is done, is selected by CFAR_ABS_MODE register described below.</p>
CFAR_ABS_MODE	2	Y	<p>CFARmagnitude, mag-squared or log-mag mode:</p> <p>This registeris used to specify which of the three computations, namely Magnitude, Mag- squared or Log-Magnitude, is enabled inside the CFAR engine prior to CFAR detection. This register is only relevant when CFAR_INP_MODE is 0 (complex samples are fed to CFAR engine).</p> <p>00b– Magnitude-squared 01b – Not valid 10b– Magnitude (using JPL approximation) 11b– Log2-Magnitude (using LUT approximation)</p>

Table 6-605. CFAR Engine Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CFAR_OUT_MODE	2	Y	CFARengine output mode: The MSBbit of this register selects whether the CFAR Engine outputs all the noise average values for all the cells ('Raw output' mode), or whether the CFAR Engine outputs only the detected peaks ('Detected Peaks List' mode). The LSB bit specifies the content of the 24-bit 'I' and 'Q' channel outputs logged in destination memory. If CFAR_ADV_OUT_MODE is set to 1 (special mode called "Dominant peaks"), this register should be set to 1. Refermain description section for details.
CFAR_ADV_OUT_MODE	1	Y	CFARengine special output mode (Dominant peaks mode): This register bit enables the special "Dominant peaks" mode of the CFAR engine. In this mode, the CFAR engine outputs the input array (I and Q) samples corresponding detected peak locations as is and suppresses the non-detected peak locations (sends zeros).
CFAR_GROUPING_EN	1	Y	CFARpeak grouping enable: This registerbit specifies whether peak grouping should be enabled. When this register bit is 0, peak grouping is disabled, which means that a peak is declared as detected as long as the cell under test exceeds the threshold. On the other hand, if this register bit is 1, then a peak is declared as detected only if it the cell under test exceeds the threshold, as well as, if the cell under test exceeds the two neighboring cells to its immediate left and right (local maximum).
CFAR_NOISE_DIV	4	Y	CFARnoise average division factor: This parameter is applicable only in CFAR-CA modes and it is not applicable in CFAR-OS mode. This registerspecifies the division factor with which the noise sum calculated from the left and right noise windows are divided, in order to get the final surrounding noise average value. The division factor is equal to $2^{\text{CFAR_NOISE_DIV}}$. Therefore, only powers-of-2 division are possible, even though the number of samples specified in CFAR_AVG_LEFT and CFAR_AVG_RIGHT are not restricted to powers of 2. The surrounding noise average value obtained after the division is multiplied or added with CFAR_THRESH to determine the final threshold used to compare the cell under test for detection. The maximum allowed value for this register is 8, which gives a division factor of 256.

Table 6-605. CFAR Engine Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
CFAR_CA_MODE	2	Y	CFARnoise averaging mode: This registerconfigures the noise averaging mode in the CFAR detector from one of these options – CFAR-CA, CFAR-CAGO, CFAR-CASO, CFAR-OS. 00b– CFAR-CA 01b– CFAR-CAGO 10b– CFAR-CASO 11b– CFAR-OS
CFAR_CYCLIC	1	Y	CFARcyclic vs. non-cyclic mode: This registerbit specifies whether the CFAR detector needs to work in cyclic mode or in non-cyclic mode. When this register bit is 0, the CFAR detector works in non-cyclic mode and when it is 1, it works in cyclic mode. Refer main description section for details on how to configure and use cyclic mode.
CFAR_PEA KCNT.cfar_peakcnt	12	N	CFARdetected peak count: This isa read-only register that contains the number of detected peaks that are logged in the destination memory, when CFAR Engine is configured in 'Detected Peaks List' mode. In the Detected Peaks List mode, since only the detected peaks are logged in the destination memory, this read-only register provides the number of detected peaks that are logged to the main processor, so that the main processor can determine how many entries to read from the destination memory.

6.4.9 Core Computational Unit – Statistics

This section describes the statistics block present in the core computational unit.

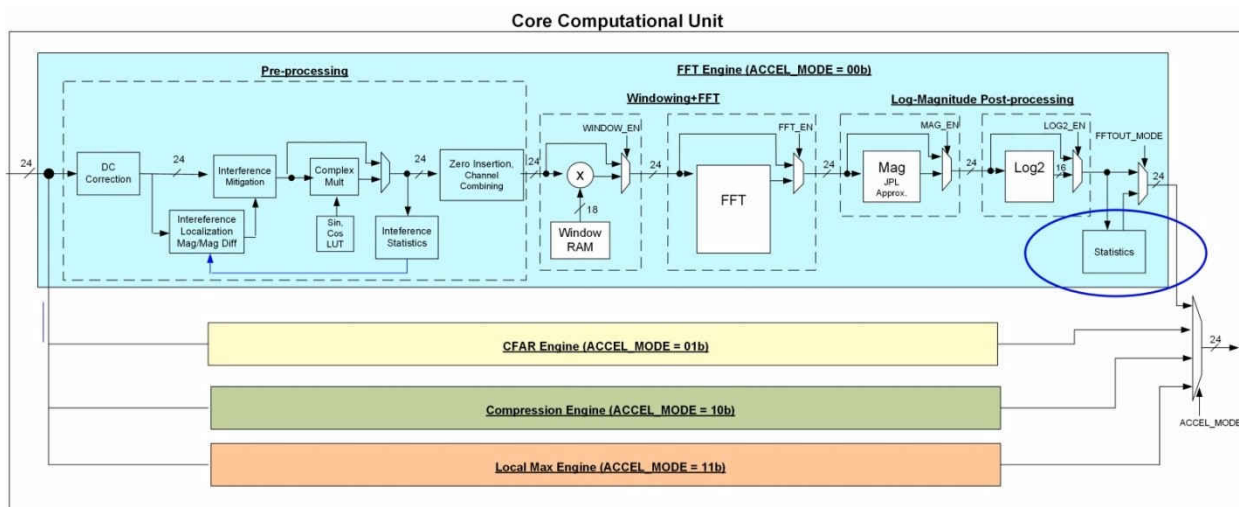

Figure 6-638. Statistics Block

6.4.9.1 Statistics Block

The corecomputational unit has a statistics computation block at the end of the FFT Engine path as shown in [Figure 6-638](#). It can be used to compute a few simple statistics of the samples output by the core computational unit. It supports computing statistics on 1- and 2-dimensional array inputs.

With 1-dimensional array input, it can compute sum and maximum of samples. It also supports a few advanced features, with 2-dimensional array inputs. It can compute 2 arrays of maxima (one in each dimension) and multiple histograms or cumulative distribution functions (CDFs) of the input samples (one histogram for each sample index).

The simple basic mode of operation is described first. The advanced features are described in separate later sub-sections.

6.4.9.1.1 Basic Statistics Block – Operation

The 24-bit I and 24-bit Q output of the core computational unit goes to a statistics computation block. The purpose of this block is to find the maximum and sum (average) of the output samples

The sum and max statistics are computed on a ‘per-iteration’ basis (the sum and max values are logged at the end of each iteration) and the computation is reset for the next iteration. The sum and max values are logged in register-sets (see MAXn_VALUE, MAXn_INDEX, ISUMn, QSUMn register-sets), which can be read by the main processor. However, only four such registers are provided for each statistic and therefore, the sum and max values can be logged in these registers only for up to a maximum of four iterations.

The max statistics register-set comprises four read-only registers of 24 bits each, named MAXn_VALUE, for recording max values, and four read-only registers each 12 bits unsigned, named MAXn_INDEX, for recording the max indices. The sum statistics register-set contains four registers of 36 bits each, named ISUMn, for I-sum statistics, and 4 registers of 36 bits each, named QSUMn, for Q-sum statistics.

For larger number (>4) of iterations, either the sum or the max value can be sent to the destination memory for each iteration, which allows the statistic to be available even for cases with more than four iterations. The logging of the statistic into the destination memory is enabled using FFT_OUTPUT_MODE register described below.

The MSB bit of the FFT_OUTPUT_MODE (Table 8) register selects whether the default (main) output of the core computational unit goes to the destination memory, or the statistics block output. If the MSB of this 2-bit register is 0, then it selects the default mode of operation, where the main output (FFT or Log-Mag result) is sent to the destination memory. If the MSB is 1, then it selects the statistics output mode, where either the sum or max statistic is sent to the destination memory (one value per iteration). Whether the sum or max is sent to memory is dependent on the LSB bit. If the LSB bit is 0, then the statistic value that is sent is the max value (useful in conjunction with Log-Mag enabled to find the biggest peak and peak index per iteration). Here, the I output is the maximum value itself and the Q output is the index (location) of the maximum value. If the LSB bit is 1, then the statistic value that is sent is the sum value (useful for DFT mode, as well as for mean squared or mean of absolute values computation).

Table 6-606. Statistics Output Modes

FFT_OUTPUT_MODE Register	IChannel Output	QChannel Output
00b– Default output mode	Main output of core computational unit	
10b– Max statistics output (One output per iteration)	MaxValue	MaxIndex
11b– Sum statistics output (One output per iteration)	Sum of I values	Sum of Q values

The max statistic records the maximum value (and its index) of the magnitude or log-magnitude samples corresponding to every iteration. The sum statistic records the sum of the magnitude or log-magnitude or the complex output samples corresponding to each iteration. If the main output of the core computational unit is the complex FFT output (ABS EN=0 and LOG2EN=0), then the sum statistics is the complex sum.

The complex sum statistics mode is useful when used in conjunction with the complex multiplier block in DFT mode or vector multiplication mode. For example, the sum statistic computed here, together with the DFT mode of the complex multiplier block, enable DFT computation for the desired number of bins (iterations). When the desired number of bins is more than 4, the sum statistic can be sent to destination memory (instead of the main data output that is normally sent to the destination memory).

Note that when the sum statistics is logged into the destination memory, it goes through the Output Formatter block as only 24-bits each for I and Q (same bit-width as the primary FFT outputs). Hence, the computed sum statistics value of 36-bits width, needs to be scaled down by right-shifting the appropriate number of LSBs (using FFTSUMDIV register) before sending to output formatter. Thus, when logging the statistics in destination memory, the sum statistics is to be used as an “average” value, rather than a “sum” value itself.

The FFTSUMDIV register specifies the number of bits to right-shift the sum statistic before it is written to destination memory. The internal sum statistic register is 36-bits wide (allowing 12 bits of MSB growth of the 24-bit data path), but this statistics value needs to be scaled down to 24 bits to match the data path width going to the Output Formatter. This register specifies how many LSBs to drop to convert the sum statistics to 24-bit value. Note that only signed saturation is implemented (irrespective of whether magnitude values are being summed or complex FFT output values are being summed). Therefore, it is recommended that this register is configured to drop an appropriate number of LSBs such that incorrect saturation in case of magnitude sum is avoided.

Note that in statistics output mode, the registers DSTACNT, DSTAINDX, DSTBINDX, DST16b32b and DSTREAL are not meant to be used, since it is known that there is only one value to be written to destination memory for every iteration in a specific format. It is recommended that in this mode, DSTACNT be programmed to a value of 0, DSTAINDX and DSTBINDX are both programmed to a value of 8 bytes, DST16b32b is set to 1 and DSTREAL is reset to 0. The statistics is then always logged in the destination memory as consecutive 32-bit I and Q samples, irrespective of whether sum statistic or max statistic is being logged.

6.4.9.1.2 Statistics Block – Register Descriptions

Table 6-607 lists all the registers of the statistics block.

Table 6-607. Statistics Block Registers

Register.field	Width	Parameter-Set? (Y/N)	Description
MAX<n>_VALUE.max<n>_value n=1..4	24	N	Max value: These registers contain the max value on a per-iteration basis. These registers are meaningful only when Magnitude or Log-Magnitude is enabled. Only the max values for up to four iterations are recorded in these registers. For larger number of iterations, use statistics output mode (FFT_OUTPUT_MODE below).
MAX<n>_INDEX.max<n>_index n=1..4	12	N	Max index: These registers contain the max index on a per-iteration basis, corresponding to each max value in the MAXn_VALUE registers.

Table 6-607. Statistics Block Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
I_SUM<n>_LSB. I_sum<n>_lsb I_SUM<n>_MSB.i_sum<n>_msb Q_SUM<n>_LSB. Q_sum<n>_lsb Q_SUM<n>_MSB. Q_sum<n>_msb			Sum statistics: These registers contain the sum of the I outputs and Q outputs on a per-iteration basis. Only the statistics for up to four iterations are recorded in these registers. For larger number of iterations, use statistics output mode (FFT_OUTPUT_MODE below).
FFT_OUTPUT_MODE	2	Y	FFT Path output mode: This register specifies the output mode of the FFT path. Instead of the default mode where the main output of the core computational unit is sent to the destination memory, this register can be configured such that either the max or sum statistics can be sent to the destination memory. 00b – Default mode (main output) 10b – Max statistics output mode 11b – Sum statistics output mode
FFTSUMDIV.fftsumdiv	5	N	Right-shifting for Sum statistic: This register specifies the number of bits to right-shift the sum statistic before it is written to destination memory. The internal sum statistic register is 36-bits wide (allowing 12 bits of MSB growth of the 24-bit data path), but this statistics value needs to be scaled down to 24 bits to match the data path width going to the Output Formatter. This register specifies how many LSBs to drop to convert the sum statistics to 24-bit value.

6.4.9.1.3 Advanced Statistics – 2-Dimensional Maxima

The Statistics block can be used to compute 2 arrays (one in each dimension) of maxima on the input samples. This feature can be enabled by setting the register, MAX2D_EN to 1.

For each iteration, the maximum value observed and the corresponding sample index are stored in per-iteration RAMs. Similarly, for each sample index, the maximum value observed over all the iterations and the corresponding iteration index are stored in per-sample RAMs. Thus, as shown in [Figure 6-639](#) the results include (value, location) pairs stored on a per-iteration basis and per-sample index basis. These RAMs are a part of the Advanced Statistics Memories. This feature supports SRCACNT (samples) in the range of 1 to 255 and BCNT (iteration) in the range of 0 to 1023.

The processor as well as the local maxima computation engine can access the Advanced Statistics Memories. This allows the 2D maxima to be used as thresholds in the local maxima computation steps.

Local Maxima peak detector can be configured to use the max value RAMs as arrays of thresholds. The max value and max index RAMs can also be read and modified by the CPU/DSP. This allows flexible and application specific control on the peak detection thresholds. The data read/write format for the 2Dmax output RAMs are described in the table of Advanced Statistics Memories ([Table 13](#)).

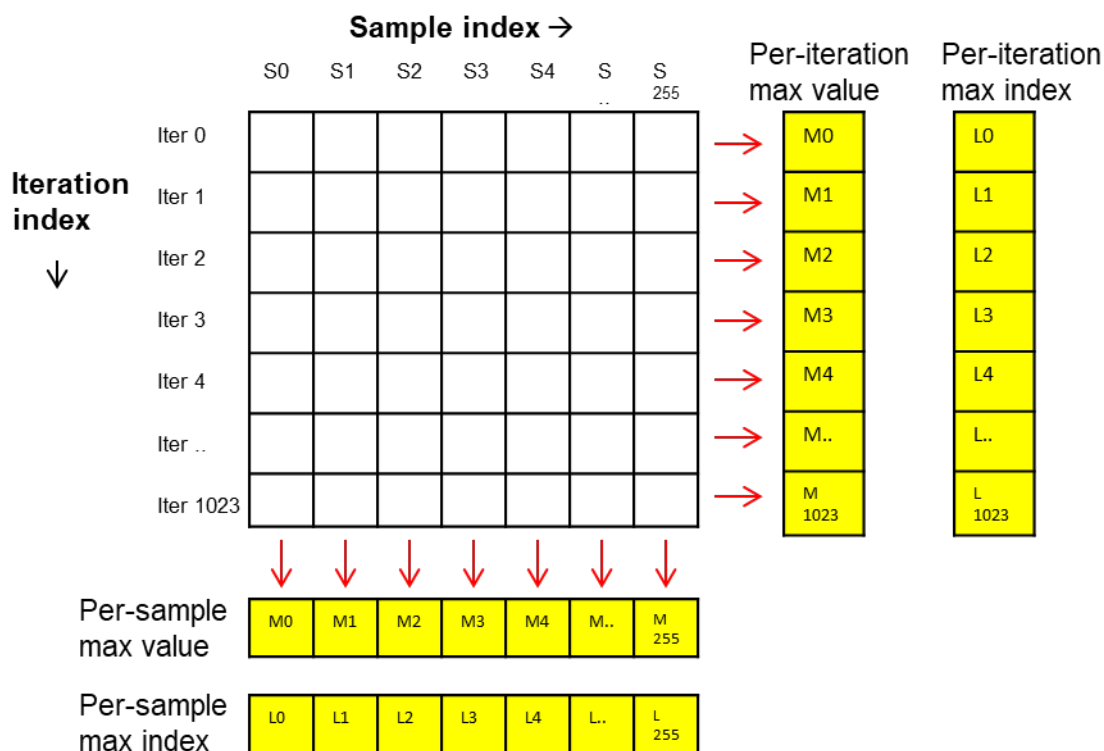

Figure 6-639. 2D Max Advanced Statistics Computation

6.4.9.1.4 Advanced Statistics – Histograms, CDF, and CDF Count Threshold

The Statistics block can compute the histograms or CDFs of the input samples. The statistics block can also be used to calculate a detection threshold based on the CDF.

The histogram function operates on a 2-D matrix of input samples. The ACNT (or $2^{\text{FFT_SIZE}}$) number of samples received in a single iteration constitute the “sample” dimension. BCNT+1 iterations of the sample dimension data are received, which constitutes the “iteration” dimension. One histogram is computed for each sample index using values received across all iterations corresponding to that sample index as shown in figure below.

Figure 6-640. Advanced Statistics Histogram Computation

The results are stored in corresponding RAMs which are part of the Advanced Statistics Memories. The register HIST_MODE can be used to enable this feature and select the exact operation mode as mentioned in the table below. MEM_INIT_START bit 13 & 14 should be set to start the Histogram Memory initialization. MEM_INIT_DONE bit 13 & 14 indicates the histogram Memory initialization completion.

Table 6-608. Histogram Operating Modes

HIST_MODE	Histogram Statistics Computation
00	Disabled: In this mode, the histogram computation is totally bypassed and the Histogram RAM is retained in its existing state.
01	Histogram computation mode: In this mode, histograms are computed, one histogram per sample index. The histograms are stored in the Histogram RAM.
10	CDF count computation mode: In this mode, CDF counts are computed, one CDF per sample index. The CDF count range (0, number of iterations programmed) maps to the CDF range (0, 1). The CDFs are stored in the Histogram RAM. The CDF count computation needs additional computation time over and above the histogram computation mode. The number of histogram bins times the number of histograms is the number of additional cycles..
11	CDF threshold computation mode: In this mode, histograms are computed similar to the histogram computation mode. Additionally, for the purpose of computing a detection threshold, information about the histogram bin at which the corresponding CDF would just exceed the programmed register, CDF_CNT_THRESH, is calculated and reported through CDF_CNT_BINNUM. The corresponding CDF and histogram values at that bin are reported through CDF_CNT_CDFVAL and CDF_CNT_HISTVAL.

The histograms are computed on a per-sample-index basis. Up to 64 histograms can be computed. The valid range of SRCACNT for this feature is 1 to 63. The histogram size (number of bins) is programmable (from 8 to 64, in powers of 2) using the register HIST_SIZE_SEL. The bins are uniformly spaced. It should be noted that histogram resolution is optimal if input is in log-magnitude mode rather than linear-magnitude. Since the log-magnitude mode gives outputs with high precision (in 5.11u format, i.e. 5 integer bits, 11 fractional bits, unsigned), they can be scaled down through a programmable right shift before histogram computation, using the register HIST_SCALE_SEL. Valid values for HIST_SCALE_SEL are 7, 8, 9, 10, 11, 12 and 13. The HIST_SIZE_SEL and the HIST_SCALE_SEL registers are explained in [Figure 6-641](#).

Figure 6-641. HIST_SCALE_SEL and HIST_SCALE_VAL Configuration

It should be noted that the input samples that exceed the highest bin are counted in the histogram's highest bin index. Also, if any bin's count (i.e. the number of occurrences) exceeds the bit-width allocated in the histogram output memory, then the count is clipped to the maximum level.

As an illustration, if SRCACNT = 31, BCNT = 767, HIST_SIZE_SEL = 4, HIST_SCALE_SEL = 10, and HIST_MODE = 0b01, then 32 histograms, each with 16 bins are computed and stored in the Histogram RAM. The bins correspond to the input ranges, [0 to 1023], [1024 to 2047], ..., [14*1024 to 15*1024 - 1], [\geq 15*1024]. In each of the 32 histograms, the sum of all bin values will match 768. This example assumes that the pre-processing block's channel combining and zero insertion features are not enabled. If they are enabled, then the number of histograms will match the resultant number of samples in A-dimension after the channel combining and zero insertion operations.

The contents of the Histogram RAM can be read by the CPU/DSP and may be utilized to update the threshold arrays for Local Maxima peak detection. The Histogram RAM can be read with the format explained in table of the Advanced Statistics Memories ([Table 13](#)).

In HIST_MODE = 0b11, the CDF_CNT_BINNUM (bin number where CDF just exceeds the programmed CDF_CNT_THRESH) for each sample is stored along with the corresponding CDF_CNT_CDFVAL and CDF_CNT_HISTVAL. These values are stored in the CDF Threshold RAM which can be read with the format as explained in the Advanced Statistics Memories ([Table 13](#)).

6.4.9.1.5 Advanced Statistics Block – Register Descriptions

[Table 6-609](#) lists all the registers of the statistics block.

Table 6-609. Advanced Statistics – Control Registers

Register	Width	Parameter Set	Description
MAX2D_EN	1	Yes	2-Dimensional Maxima Computation Enable: If this bit is set to 1, one maxima (and corresponding index) array for A dimension and another for B dimension are computed and stored in the per-sample and per-iteration RAMs.

Table 6-609. Advanced Statistics – Control Registers (continued)

Register	Width	Parameter Set	Description
HIST_MODE	2	Yes	<p>Histogram Computation Mode:</p> <p>00: Disable</p> <p>01: Histogram computation mode</p> <p>10: CDF computation mode</p> <p>11: CDF threshold computation mode</p> <p>Refer to the earlier section for details.</p>
HIST_SCALE_SEL	4	Yes	<p>Histogram Input Scale Select:</p> <p>This register is used to select the input scaling before histogram computation. It provides a way to control the resolution of the histogram bins by right-shifting the input sample values before histogram computation. If this register is set to X (and $Y=2^X$), then the histogram bin ranges are [0, Y-1], [Y, 2Y-1] and so on. Valid values for this register are X=7, 8, 9, 10, 11, 12, and 13.</p>
HIST_SIZE_SEL	4	Yes	<p>Histogram Size Select:</p> <p>This register is used to select the histogram size (number of bins). The size is configurable in powers of 2. The number of histogram bins is $2^{\text{HIST_SIZE_SEL}}$. Valid values of this register are 3, 4, 5, and 6. They correspond to histogram sizes of 8, 16, 32, and 64.</p>
CDF_CNT_THRESH.cdf_cnt_thresh	12	No	<p>This register is applicable in CDF count threshold mode of operation.</p> <p>CDF is computed over the histogram till the value of the CDF just exceeds the CDF_CNT_THRESH specified by the user. This register can take values from 0 to BCNT. CDF count threshold value is same for all samples indices (histograms).</p>

Table 6-609. Advanced Statistics – Control Registers (continued)

Register	Width	Parameter Set	Description
MEM_INIT_START	32	No	Writing 1'b1 to bit locations – 13 & 14 would start the memory initialization for the Histogram Memory. These are self-clearing bits Bit 13 : MEM_INIT_START_HIST_ODD_RAM Bit 14 : MEM_INIT_START_HIST_EVEN_RAM
MEM_INIT_DONE	32	No	When the memory initialization is complete, then bit locations 13 & 14 shall be 1b'1 Bit 13 : MEM_INIT_DONE_HIST_ODD_RAM Bit 14 : MEM_INIT_DONE_HIST_EVEN_RAM

Table 6-610 lists the contents of the Advanced Statistics Memory.

Table 6-610. Contents of Advanced Statistics Memory Output

RAM content	Width	Description
MAXVAL_ARRAY_DIM1 [1024] DSS_HWA_2DSTAT_ITER_VAL_RAM	24 bits each	2-D Maxima Array – maximum values of each iteration: The maximum value across samples in each iteration is recorded here (one value per iteration, first address corresponding to first iteration).
MAXLOC_ARRAY_DIM1 [256] DSS_HWA_2DSTAT_SMPL_VAL_RAM	10 bits each	2-D Maxima Array – maximum locations corresponding to each iteration: The sample index at which the maximum value occurred in each iteration is recorded here (one value per iteration, first address corresponding to first iteration).
MAXVAL_ARRAY_DIM2 [1024] DSS_HWA_2DSTAT_ITER_IDX_RAM	24 bits each	2-D Maxima Array – maximum values corresponding to each sample index: The maximum value across the iterations for each sample index is recorded here (one value per sample index, first address corresponding to first sample index).
MAXLOC_ARRAY_DIM2[256] DSS_HWA_2DSTAT_SMPL_VAL_RAM	10 bits each	2-D Maxima Array – maximum locations corresponding to each sample:: The iteration count at which the maximum value occurred corresponding to each sample is recorded here (one value per sample index, first address corresponding to first sample index).

Table 6-610. Contents of Advanced Statistics Memory Output (continued)

RAM content	Width	Description
DSS_HWA_HIST_RAM HIST_OUT_ARRAY[64][64]	12 bits each	Histogram Output Corresponding to each Sample Index: The number of occurrences in each histogram bin is recorded here for different sample indices.
DSS_HWA_HIST_THRESH_RAM CDF_CNT_BINNUM [64]	6 bits each	If CDF count threshold mode is enabled: the bin number at which the specified count (CDF_CNT_THRESH) is just exceeded is stored in this register for all the sample indices.
DSS_HWA_HIST_THRESH_RAM CDF_CNT_CDFVAL [64]	12 bits each	Valid when CDF count threshold mode is enabled. This stores the CDF count at CDF_CNT_BINNUM bin for all the sample indices.
CDF_CNT_HISTVAL [64] DSS_HWA_HIST_THRESH_RAM	12 bits each	Valid when CDF count threshold mode is enabled. This stores the Histogram count at CDF_CNT_BINNUM bin for all the sample indices.

Table 6-611 lists the read/write format for Advanced Statistics Memories.

6.4.10 Core Computational Unit – Local Maxima Engine

The Core Computation Unit includes a Local Maxima Engine, which can be enabled by setting ACCEL_MODE = 011b.

In context of Radar signal processing, Local Maxima Engine is useful in a peak detection step where each sample/bin (Cell Under Test (CUT)) is compared against detection threshold(s), and also compared against the neighboring samples and the CUT is declared as a valid local peak if the sample amplitude exceeds the detection threshold and is “more than or equal to” the neighboring cells. Local maxima computations are done on a 2D matrix. Typically, local maxima are computed after the Angle FFT, on the Doppler-Beam/angle “2D” plane (2D Local Maxima).

The output of the local maxima computations is stored into the destination memory as a bit pattern, where each bit indicates whether the specific sample/CUT was detected as a valid local peak or not. More details on this are given in the later section of the document. The detection thresholds can either be configured into the configuration registers or in the Advanced Statistics Memory (borrowed from the Statistics module), in case there are individual thresholds for the different rows and columns of the 2D matrix.

6.4.10.1 Local Maxima Engine – Operation

Figure 6-642 shows an example of 2D plane (eg. Dopplers-Beams plane) used for Local maxima computations. A 3x3 matrix (CUT and all its neighboring samples) is needed to compute the local maxima. To keep the scheme simple and efficient from memory access perspective (as the input samples for local maxima computations are fetched from the memory), a 3x4 matrix (shown as red box in Figure) is fetched.

Every cycle, four consecutive samples (16-bit x 4 = 64bits) are picked from the memory and this is repeated three times across three row vectors (doppler bins) to fetch the 3x4 matrix data. This box keeps on moving to the right (computation wise) till the last group of four samples are fetched. By the end of this process, we get a bit-pattern of size (bits) equivalent to the number of columns (i.e., beams), with each bit indicating whether the specific bin was a local peak or not. This scheme is repeated for each doppler vector to get the bit-pattern output for the complete 2D plane.

Samples are fetched using the three-dimension addressing scheme built-in to the Input Formatter (the dimensions denoted by A, B and C) by configuring the configuration registers accordingly. For Local Maxima

operation, there are restrictions on the maximum sizes of these dimensions. The number of columns (achieved through dimension B) has to be one of these supported values: 8, 12, 16, 24, 32, 48, 64, 96, 128, 192, 256. The number of rows (achieved through dimension C) can be any value between 3 and 1024.

Typically, for CUT processing at the edges, wrap-around around these dimensions would be required (cyclic mode of operation). This is achieved using the configuration registers SRCB_CIRCSHIFTWRAP, SRC_CIRCSHIFTWRAP3X and WRAP_COMB. If non-cyclic mode of operation is desired (i.e., for the edge samples, the neighboring cells should not be wrapped around), then LM_DIMB_NONCYCLIC and LM_DIMC_NONCYCLIC register bits can be set. In this case, the unavailable neighbouring samples will be considered as masked out.

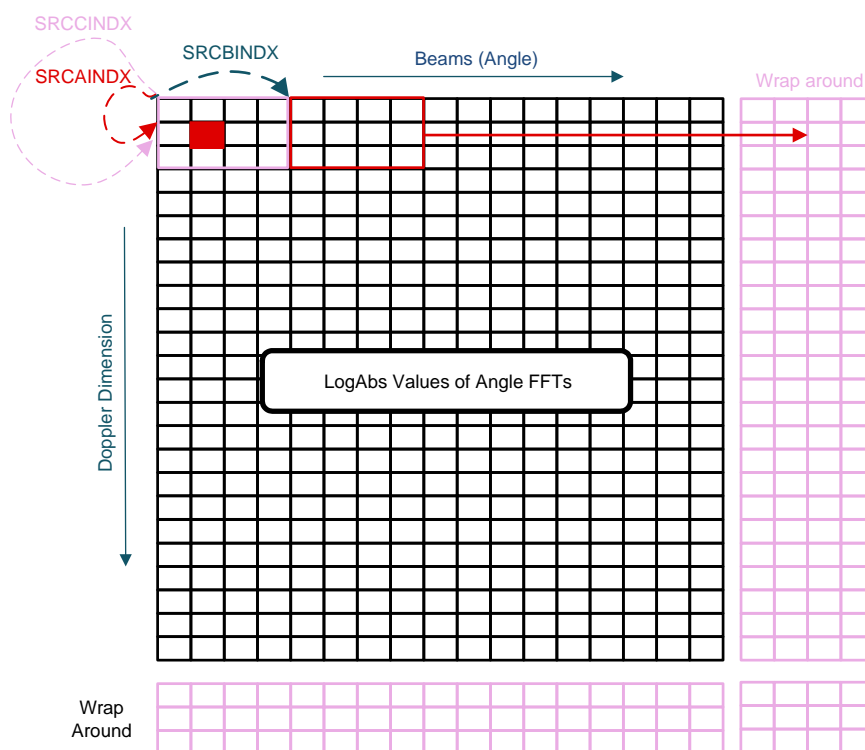

Figure 6-642. Local Maxima Engine A, B and C-Dimension Usage

Below is the example of the configuration values of each of these registers accessing the samples from the source memory for Local maxima computations for a 256x12 matrix. Note that though SRCACNT and SRCBINDEX values are part of configuration registers, for the local maxima functionality, the values shall always be fixed to the values of 2 and 8 respectively, as shown below in Figure 6-643. The other registers are calculated easily as a function of the number of beams (number of columns) and number of Doppler (number of rows) as shown in the figure. Note that these configurations are irrespective of whether cyclic or non-cyclic mode of operation. It is important that in Local Maxima Engine mode of operation, the registers of Input Formatter and Output Formatter listed in figure below are programmed exactly as per the calculations shown.

Register	Value
SRCACNT	2
SRCAINDX	NumCols * 2
BCNT	NumCols / 4
SRCBINDX	8
CCNT	NumRows - 1
SRCOINDX	NumCols * 2
SRCREAL	0
SRC16b32b	1
WRAPCOMB	NumCols * NumRows * 2
CIRCSHIFTWRAP3X	10b, if NumCols is one of {12, 24, 48, 96, 192} 00b, if NumCols is one of {8, 16, 32, 64, 128, 256}
SRCBCIRCSHIFTWRAP	log2(NumCols / 12), if NumCols is one of {12, 24, 48, 96, 192} log2(NumCols / 4), if NumCols is one of {8, 16, 32, 64, 128, 256}
DSTREAL	1
DSTACNT	ceil(NumCols/32) - 1
DSTAINDX	4
DSTBINDX	4 * ceil(NumCols/32)
DST16b32b	1

Figure 6-643. Local Maxima Engine Configuration

6.4.10.2 Local Maxima Engine – Operating Mode Configurations

Local maxima computations involve comparing each CUT with several values. The values that can be compared with are the 8 neighboring (adjacent right/left/top/bottom/diagonal) samples in the 2D matrix, row-threshold and a column-threshold. Each of these comparisons can be enabled or disabled through the configuration registers LM_NEIGH_BITMASK (8-bit) and LM_THRESH_BITMASK (2-bit).

The row- and column-thresholds can be selected from software configurable registers DIMB_THRESH_VALUE and DIMC_THRESH_VALUE or Maxima Arrays from Advanced Statistics RAM. This selection can be made through the register LM_THRESH_MODE. Further, if the Maxima Arrays from Advanced Statistics RAM are selected for determining thresholds, then the Local Maxima engine has provision for adding 24-bit signed offsets (one in each dimension). This can be useful in log-mode of operation, to convert the maxima arrays to row- and column-thresholds for peak detection. The offsets are programmable through the registers, MAX2D_OFFSET_DIM1 and MAX2D_OFFSET_DIM2. As these offsets are *added* to the Maxima Arrays from Advanced Statistics RAM to derive the detection thresholds, typically, these registers are expected to be set to negative values.

Figure 6-644 and Figure 6-645 illustrate the thresholding and comparisons in Local Maxima. The result of the Local Maxima comparisons is a 2D bit pattern. Each bit in it indicates whether the corresponding (row, column) CUT either exceeded *or equaled* each of the values it was compared against. A value of 0 in the result bit indicates that at least one of these values exceeded the CUT and 1 indicates otherwise.

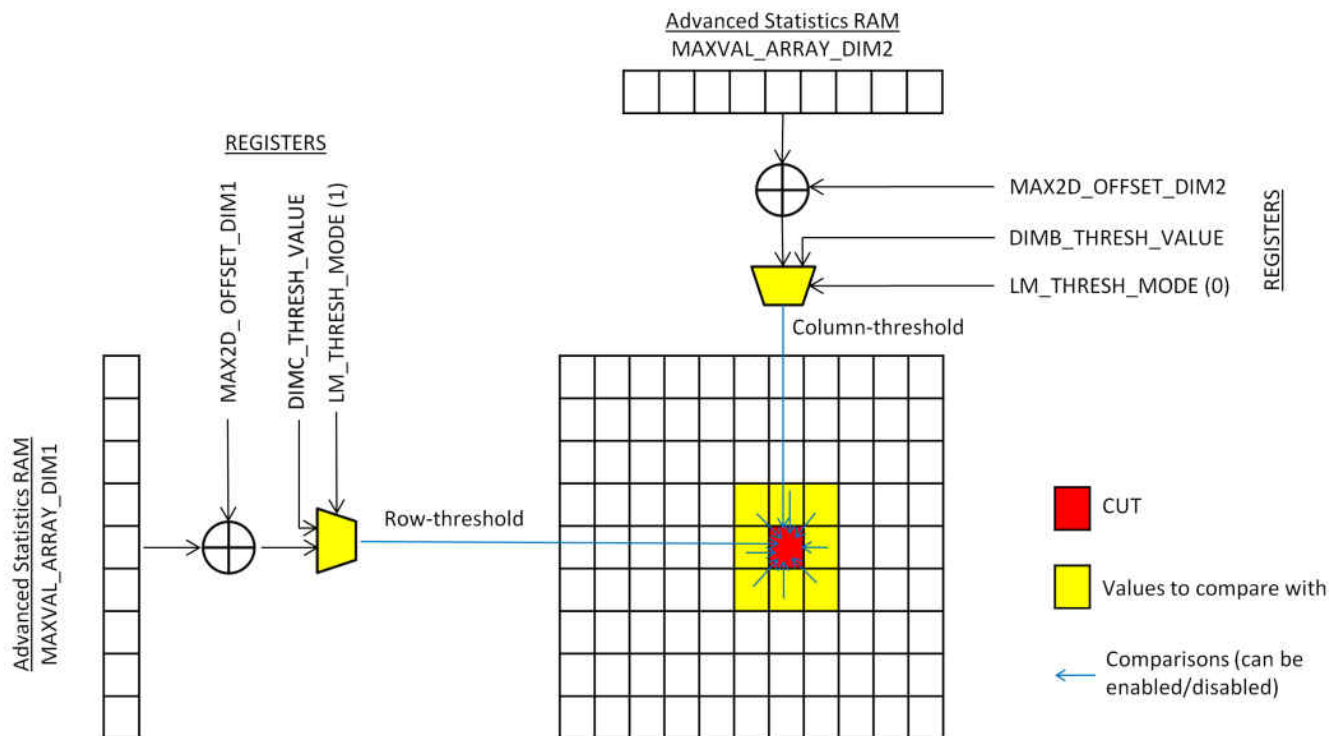

Figure 6-644. Local Maxima – Example Operating Mode Configurations

LM_NEIGH_BITMASK (0)	LM_NEIGH_BITMASK (1)	LM_NEIGH_BITMASK (2)

LM_NEIGH_BITMASK (6)	LM_NEIGH_BITMASK (5)	LM_NEIGH_BITMASK (4)

Figure 6-645. Local Maxima – Bitmask Configuration

6.4.10.3 Local Maxima Engine – Output Write Pattern

The output of the local maxima computations is first shifted to a local shift register of 256 bits. The output is pushed on to the local memory in HWA only once the computations worth one full row is completed. So, 256 puts a restriction on the maximum number of bins can be used in a particular row.

The output bit pattern is stored in the destination memory packed as 32-bit words, with the LSB bit corresponding to B-dimension (column) count of 0. In case when the output of a vector is not a multiple of 32 bits, the remaining bits in the last 32-bit word would be irrelevant bits and shall be ignored (set to '0'). If the number of bits per Doppler row is less than 32, for example 16, then 16 LSB of a 32b word are populated with bitmask and the remaining 16b are set to '0'.

This mechanism is described in the below diagrams [Figure 6-646](#) and [Figure 6-647](#).

6.4.10.4 Local Maxima Engine – Register Descriptions

Table 6-612. Local Maxima Engine – Registers

Register	Width	Parameter Set	Description
LM_NEIGH_BITMASK	8	Y	Neighbour bitmask for CUT comparison: Bit mask for the 8 neighbouring cells (adjacent left/right/top/left/diagonal) to enable or disable the comparison with cell under test. Starting from left top corner and moving in a clock-wise direction. If a bit is set to 1, then the corresponding comparison is disabled.

Table 6-612. Local Maxima Engine – Registers (continued)

Register	Width	Parameter Set	Description
LM_THRESH_BITMASK	2	Y	Enable/Disable for detection threshold comparison: 00b: Enable CUT comparison with detection threshold in both dimensions 01b: Enable CUT comparison with detection threshold in column dimension only (B-dimension threshold) 10b: Enable CUT comparison with detection threshold in row dimension only (C-dimension threshold) 11b: Disable CUT comparison with detection thresholds in both dimensions
LM_THRESH_MODE	2	Y	Threshold source selection: This 2-bit register is used to indicate whether the detection threshold is provided by a software register, or derived from the built-in Advanced Statistics RAM. The LSB of this register corresponds to column dimension (B-dimension), and the MSB corresponds to row dimension (C-dimension). If the register bit is 0, then the threshold is taken from software configured register (DIMB_THRESH_VALUE, DIMC_THRESH_VALUE), whereas if the register bit is 1, then the threshold is taken from the built-in Advanced Statistics RAM, with an offset addition (see registers MAX2D_OFFSET_DIM1, MAX2D_OFFSET_DIM2).
LM_THRESH_VAL.dimb_thresh_val	16	N	SW configurable column threshold register: Refer description of LM_THRESH_MODE for more details.
LM_THRESH_VAL.dimc_thresh_val	16	N	SW configurable row threshold register: Refer description of LM_THRESH_MODE for more details.

Table 6-612. Local Maxima Engine – Registers (continued)

Register	Width	Parameter Set	Description
MAX2D_OFFSET_DIM1.max2d_offset_dim1	24	N	Offset for row thresholds from Advanced Statistics RAM: Offset to be added to dimension 1 Maxima results (from Advanced Statistics) to derive row thresholds for Local Maxima computation.
MAX2D_OFFSET_DIM2.max2d_offset_dim2	24	N	Offset for column thresholds from Advanced Statistics RAM: Offset to be added to dimension 2 Maxima results (from Advanced Statistics) to derive column thresholds for Local Maxima computation.
LM_DIMB_NONCYCLIC	1	Y	Dimension B Non Cyclic: 1: Non-cyclic mode of Local Maxima detection (i.e., for the edge samples, the neighboring cells will not be wrapped around) 0: Cyclic mode of Local Maxima detection (i.e., for the edge samples, the neighboring cells will be wrapped around)
LM_DIMC_NONCYCLIC	1	Y	Dimension C Non Cyclic: 1: Non-cyclic mode of Local Maxima detection (i.e., for the edge samples, the neighboring cells will not be wrapped around) 0: Cyclic mode of Local Maxima detection (i.e., for the edge samples, the neighboring cells will be wrapped around)

6.4.11 Context Switching

The state machine supports an advanced feature called "Context Switching" that allows a sequence of operations running in the hardware accelerator to be interrupted, in order to run a different (higher priority) sequence of operations, before returning back to resume execution of the original sequence. This state machine feature is useful when Doppler FFT, detection and angle FFT processing of a radar frame is still running, while the chirps for the subsequent frame have already started. In such a case, it is possible for the hardware accelerator to perform the Doppler FFT, detection and angle FFT processing in one context (a.k.a the background context), while permitting "context switching" to an alternate context (a.k.a the high priority context) to perform inline range FFT processing as and when new chirp ADC data samples are received.

6.4.11.1 Context Switching – Operation

The context switching feature of the state machine can be enabled by setting the CS_ENABLE register bit. This register is a common (static) register that controls the overall enabling/disabling of the feature.

The background context execution is programmed and configured using PARAM_START_IDX, PARAM_END_IDX, and NUMLOOPS registers as before. The high priority context is programmed using additional parameter-sets that are configured using PARAM_START_IDX_ALT, PARAM_END_IDX_ALT and ALT_NUMLOOPS registers (refer [Table 16](#)). Normally, the state machine executes the parameter-sets in the

background (low-priority) context by looping through the parameter-sets between PARAM_START_IDX and PARAM_END_IDX, until a context switch is triggered. Whenever a context switch from background context to high priority context happens, the state machine jumps to PARAM_START_IDX_ALT and executes the parameter-sets from PARAM_START_IDX_ALT to PARAM_END_IDX_ALT for ALT_NUMLOOPS number of times and returns back to resume execution of the background context from where it left off.

The context switch from background context to high priority context is triggered based on the settings of CS_TRIGMODE and CS_TRIGSRC registers. Specifically, CS_TRIGMODE can be configured to trigger context switch based on a DMA completion, or based on a CSI2 line/frame end event. Refer the register description section for details of these registers.

It is important to note that the context switch only happens at the end of execution of a parameter-set and never in the middle of execution of a parameter-set. Also, the context switch is allowed to happen at the end of a parameter-set only if CONTEXTSW_EN register bit in the parameter-set is set. If this register is not set, then context switch will not happen at the end of that parameter-set. CONTEXTSW_EN should only be set in the parameter-sets corresponding to background context.

Context switch from the high priority context back to the background context typically occurs after the completion of all parameter-sets in the high priority context. But if an early exit is needed, i.e. after the execution of a certain high priority parameter-set, the register FORCED_CONTEXTSW_EN in that parameter-set can be set. This forces a context switch to the background context, without the need for any explicit context switch trigger. In such a case, when the next context switch trigger occurs, the high priority context execution resumes from where it left off. FORCED_CONTEXTSW_EN should be set only in the parameter-sets corresponding to the high priority context, and can be used for debug purposes. It can also be used when a large time gap is expected between execution of one high priority parameter-set and the next (e.g. due to the timing of the associated trigger sources), and it is desired that this time gap be used for some background context execution.[SK1]

Generally, for most computations, there is no 'state information' that carries forward across parameter-sets – i.e., each parameter-set is independent of the other. However, there are four specific items – namely, DC estimation accumulators, Interference statistics accumulators, TWID_INCR_DELTA_FRAC execution count and Recursive window execution count, which have state information in the form of accumulator value or execution count value that is applicable across parameter-sets. Therefore, while using the context switching feature, appropriate care has to be taken by the user to ensure that these features do not conflict when used in both the background context and high-priority context at the same time. The solution to this is to use these features only in one context at a time (eg. DC estimation and compensation can be used only in range FFT context), or to avoid jumping context between certain back-to-back parameter-sets (eg. Avoid jumping context between Interference statistics estimation and Interference mitigation steps), or to use the processor to save and restore state information (where possible). Also, care should be taken by the user to ensure that the usage of source and destination (ACCEL_MEMx) memories is mutually exclusive between the two contexts, so that there is no unintentional overwriting of the memory bank that is still under use by the background context by some computations of the high-priority context.

The operation of the state machine featuring the context switch capability is shown in [Figure 6-648](#). In the figure, Context1 and Thread1 indicate the background context (states shown in left side of the figure) and Context2 and Thread2 indicate the high-priority thread (states shown in right side of the figure).

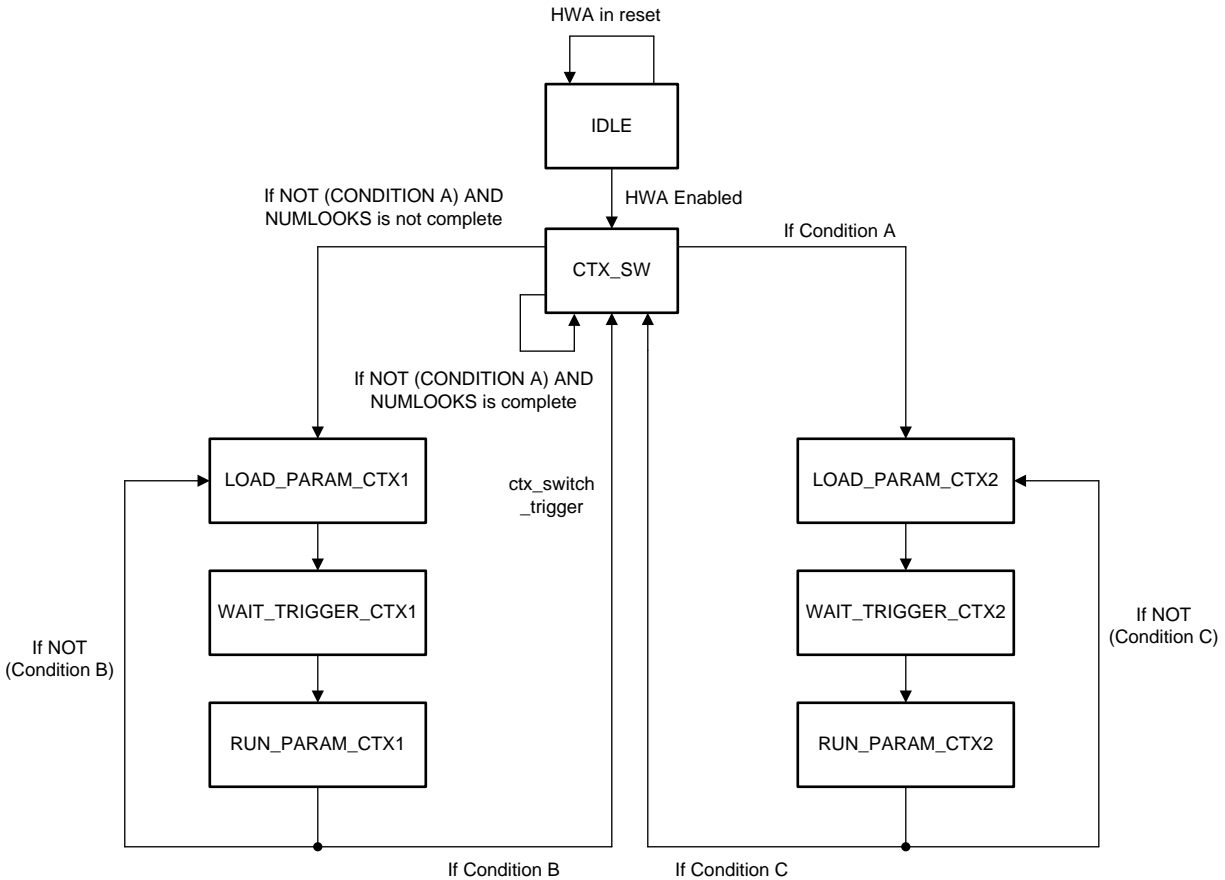

Figure 6-648. Context Switching State Machine

Whenever the NUMLOOPS of the background context completes, the state machine raises a loop complete interrupt (DSS_HWA_THREAD1_LOOP_INT). For every time the ALT_NUMLOOPS of the high-priority context completes, the state machine raises a different loop complete interrupt (DSS_HWA_THREAD2_LOOP_INT).

Note that when the background context completes (i.e., NUMLOOPS is done), the state machine does not automatically move to IDLE state and remains in the CTX_SW state. This state means that the high-priority context switch can still happen even after all the operations for the background context are complete. The only way to make the state machine go back to IDLE state is by disabling the hardware accelerator completely. In typical frame-by-frame processing applications, the host may disable the accelerator after the background context is completed and the necessary number of calls of the high priority context have been completed for one frame (counted by the host), and if necessary reconfigure the accelerator and trigger it again to restart the process.

Note that the accelerator’s execution always begins with the background thread and proceeds to the high priority context upon receiving context switch trigger. If the application needs the operations to begin directly with the high priority context, then the user can define a “No Operation” parameter set in the background context and set CONTEXT_SW_EN in it, to indirectly achieve this.

6.4.11.2 State Machine – Context Switching – Register Descriptions

Table 6-613. Context Switching – Registers

Register	Width	Parameter Set	Description
CS_CONFIG.cs_enable	1	N	Context Switching Enable: 0: Disable context switching feature. 1: Enable context switching feature.

Table 6-613. Context Switching – Registers (continued)

Register	Width	Parameter Set	Description
PARAM_RAM_IDX_ALT.param_start_idx	10	N	Parameter-set start index for high-priority context: When context switch from background context to high-priority context happens, the state machine starts execution of high-priority context at the parameter-set indicated by this register. Valid range: 0-63
PARAM_RAM_IDX_ALT.param_end_idx	10	N	Parameter-set stop index for high-priority context: When running the high-priority context, this register indicates the last parameter-set in the sequence, before looping back to PARAM_START_IDX_ALT. Valid range: 0-63
PARAM_RAM_LOOP_ALT.numloops	12	N	Number of loops for high-priority context: This register specifies how many times (loops) for which the parameter-sets corresponding to the high-priority context are executed before returning back to resume the background context.
CS_CONFIG.cs_trigmode	4	N	Trigger mode selection for context switch: 0000b: Reserved 0001b: Reserved 0010b: Reserved 0011b: DMA-based trigger (used in conjunction with CS_TRIGSRC) 0100b: Hardware trigger (used in conjunction with CS_TRIGSRC) 0101b: Software trigger (used in conjunction with CS_FW2ACC_TRIG) Other values : Reserved
CS_CONFIG.cs_trgsrc	4	N	Trigger source for context switch: When CS_TRIGMODE = 0011b (i.e., in case of DMA-based trigger mode), this register specifies which DMA channel (i.e., which bit in DMA2CS_TRIG register) to wait for being set in order to perform context switch to high-priority context. When CS_TRIGMODE = 0100b (i.e., in case of hardware trigger mode), this register specifies which CSI2 trigger signal (out of the 20 possible trigger signals) to wait for in order to switch to high-priority context. The 20 signals are listed below, with CS_TRIGSRC = 0 corresponding to the last signal in the list: {CSI2A_FRAME_START[1:0], CSI2A_LINE_END[7:0], CSI2B_FRAME_START[1:0], CSI2B_LINE_END[7:0]}

Table 6-613. Context Switching – Registers (continued)

Register	Width	Parameter Set	Description
CONTEXTSW_EN	1	Y	Context switch enable register: This register is used in the background context. If this register is set to 1 in a parameter-set, then the state machine checks for a context switch trigger at the end of that parameter-set execution. If a trigger is found, the higher priority parameter-sets start executing. On returning from the higher priority context the next background parameter-set is run.
FORCED_CONTEXTSW_EN	1	Y	Forced context switch enable register: This register can be used in the higher priority context. If this register is set to 1 in a parameter-set, then the higher priority execution is interrupted after this parameter-set. And the execution switches to the next background parameter-set. Later when a context switch trigger is received the higher priority thread resumes from the parameter-set after the parameter-set having FORCED_CONTEXTSW_EN set.
CS_FW2ACC_TRIG.fw2hwa_trigger_cs	1	N	Software context switch trigger: When CS_TRIGMODE = 0101b, this register bit can be set by software to trigger a context switch.

6.4.12 Compression Engine

The accelerator includes a Compression Engine, which can compress or uncompress data in order to reduce storage RAM size requirements. For example, after range dimension FFT of the received RX data, the FFT results can be input to the Compression Engine and its output can be stored in a relatively smaller RAM in the device (e.g. L3 RAM). And before performing any Doppler FFT processing, the data can be retrieved from the RAM, input to the Compression Engine for uncompression, and then fed to any further Doppler FFT processing steps.

The features and configurability of the Compression Engine are described in a separate document.

6.4.13 Radar Hardware Accelerator Registers

6.4.13.1 DSS_HWA_CFG Registers

Table 6-614 lists the memory-mapped registers for the DSS_HWA_CFG registers. All register offset addresses not listed in Table 6-614 should be considered as reserved locations and the register contents should not be modified.

Complex bit access types are encoded to fit into small table cells. [Table 6-615](#) shows the codes that are used for access types in this section.

Table 6-615. DSS_HWA_CFG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.4.13.1.1 PID Register (Offset = 0h) [Reset = 61800214h]

PID is shown in [Figure 6-649](#) and described in [Table 6-616](#).

Return to the [Table 6-614](#).

7	6	5	4	3	2	1	0
RESERVED					hwa_en		
R/W-X					R/W-0h		

Table 6-621. HW_REG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R/W	X	
24	hwa_dyn_clk_en	R/W	0h	Dynamic Clock-gating Control: Setting this register bit to '1' enables the capability to clock gate the 4 Radar Accelerator core IPs (FFT datapath, CFAR, Memory compression, Local Maxima) based on the ParamSet being executed.
23-19	RESERVED	R/W	X	
18-16	hwa_reset	R/W	0h	Software Reset Control: This register provides software reset control for the Radar Hardware Accelerator. The assertion of these register bits by the main processor will bring the Accelerator Engine to a known reset state. This is mostly applicable for resetting the accelerator in case of unexpected behavior. The sequence to be followed in case software reset is to write 111b to this register and then a 000b
15-11	RESERVED	R/W	X	
10-8	hwa_clk_en	R/W	0h	Clock-gating Control: This register controls the enable/disable for the clock of the Radar Accelerator. This register bit can be set to 0 to clock-gate the accelerator when not using the accelerator. Before enabling the accelerator or before configuring the accelerator's registers, this register bit should be set first to 111b, so that the clock is available
7-3	RESERVED	R/W	X	
2-0	hwa_en	R/W	0h	Enable/Disable Control: A value of ACC_ENABLE = 111b enables the Radar Hardware Accelerator and any other value of the register keeps the Accelerator Engine in disabled state. A 000b to 111b transition is expected to trigger a new Paramset execution

6.4.13.1.7 CS_CONFIG Register (Offset = 18h) [Reset = X]

CS_CONFIG is shown in [Figure 6-655](#) and described in [Table 6-622](#).

dma2hwa_trigger																															
R/W-0h																															

Table 6-624. DMA2HWA_TRIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	dma2hwa_trigger	R/W	0h	DMA trigger register: This register is relevant whenever DMA triggered mode is used (i.e., TRIGMODE = 011b). Whenever a DMA channel has finished copying input samples into the local memory of the accelerator and wants to trigger the accelerator, the procedure to follow is to use a second linked DMA channel to write a 16-bit one-hot signature into this register to trigger the accelerator. In DMA triggered mode, the State Machine keeps monitoring this 32-bit register and waits as long as a specific bit (see DMA2ACC_CHANNEL_TRIGSRC) in this register is zero. The second linked DMA channel writes a one-hot signature that sets the specific bit, so that the State Machine gets triggered and starts the accelerator operations for that parameter-set. It is a Self clearing bit

6.4.13.1.10 SIGDMACH0DONE Register (Offset = 24h) [Reset = 1h]

SIGDMACH0DONE is shown in [Figure 6-658](#) and described in [Table 6-625](#).

RESERVED									dc_est_scale						
R/W-X									R/W-100h						

Table 6-678. DC_EST_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R/W	X	
19-16	dc_est_shift	R/W	0h	Programmable shift applied to all 12 accumulator outputs. Cannot be bypassed. Output shifted by $2^{8 + 6 + \text{DCEST_SHIFT}}$. For DCEST_SHIFT = 15 also gives 2^{28} and not 29 (saturate at 28)
15-9	RESERVED	R/W	X	
8-0	dc_est_scale	R/W	100h	9-bit scale applied to all 12 accumulators. Multiplies the accumulator output by DCEST_SCALE/256. This is followed by right shift and truncation. Default value is 256 giving a scale of 1.0. Setting it to 128, gives a scale of 0.5

6.4.13.1.64 DC_EST_I_0_VAL Register (Offset = FCh) [Reset = X]

Table 6-949. DITHER_TWID_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R/W	X	
0	dither_twid_en	R/W	0h	Twiddle factor dithering enable: This register-bit is used to enable and disable dithering of twiddle factors in the FFT. The twiddle factors are 24-bits wide (24-bits for each I and Q), but they are quantized to 21-bits before twiddle factor multiplication. This quantization is implemented with dithering on the LSB, to avoid periodic quantization pattern affecting SFDR performance of the FFT. TI recommends keeping this register bit set to 1 (for example, dithering enabled), with appropriate LSFR seed loaded (see the following).

6.4.13.1.335 FFT_CLIP Register (Offset = 538h) [Reset = X]

Table 6-950. FFT_CLIP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	X	
12-0	fft_clip	R	0h	FFT Clip Status (read-only): This is a read-only status register, which indicates any saturation/clipping events that have happened in the FFT butterfly stages. Note that each of the individual butterfly stages in the FFT can be programmed to either saturate the MSB or round the LSB. Whenever saturation of MSB is used in any stage, there is a possibility that that stage can saturate or clip samples. In that case, this saturation event is indicated in the corresponding bit in this status register, so that the Cortex-R4F processor can read it. If multiple FFTs are performed, this status register includes any saturation events happening in any of them. This status register can only be cleared by the R4F, by setting another single-bit register CLR_FFTCLIP, so that the saturation status indication gets cleared back to 0 and any subsequent saturation events can be freshly monitored. The MSB of this register indicates clip status corresponding to the radix 3 butterfly.

7.1 Mailbox

The device provides a mailbox mechanism to asynchronously exchange the messages between any two processors.

Each processor has a mailbox memory space, and registers designated to be used by other processor that wishes to communicate with it.

Each processor has two sets of mailbox memory space and registers, and each set is designated per other processor to communicate with it.

Note

There is an MPU at every Mailbox that may be used to partition the mailbox memory between the Masters/cores. So instead of a fixed allocation, this gives some flexibility.

7.1.1 Maibox Message Scheme.....	2160
----------------------------------	------

7.1.1 Mailbox Message Scheme

The processor which wishes to send a message to another processor writes the message to the mailbox memory space, then interrupts the receiver processor. The receiver processor acknowledges the interrupt, then reads the message from the mailbox memory space. The receiver informs the sender that the message is read by an interrupt, which is acknowledged back by the sender. The sender must not initiate another message to the same receiver until the previously initiated mailbox interaction with the same receiver is complete.

1. SENDER writes the message in the RECEIVER mailbox.
2. SENDER triggers an interrupt to RECEIVER by writing 1 to <SENDER_SS>_CTRL: <SENDER>_MBOX_WRITE_DONE [RECEIVER]. Note: It is writing to its own CTRL space.
3. RECEIVER gets a single interrupt for all interprocessor communication, which is an aggregated interrupt. RECEIVER reads the register <RECEIVER_SS>_CTRL::<RECEIVER>_MBOX_READ_REQ and sees bit [SENDER] is 0x1.
4. RECEIVER writes to 0x1 to <RECEIVER_SS>_CTRL::<RECEIVER>_MBOX_READ_REQ [SENDER] to clear the interrupt.
5. RECEIVER reads the message.
6. RECEIVER writes to 0x1 to <RECEIVER_SS>_CTRL::<RECEIVER>_MBOX_READ_DONE_ACK[SENDER] to generate an acknowledgment interrupt to SENDER. SENDER gets a single interrupt for all interprocessor communication, which is an aggregated ACK interrupt.
7. SENDER reads the register <SENDER_SS>_CTRL:<SENDER>_MBOX_READ_DONE and sees bit [RECEIVER] is 0x1.
8. SENDER writes 0x1 to <SENDER_SS>_CTRL:<SENDER>_MBOX_READ_DONE [RECEIVER] to clear the interrupt.

Mailbox message example (message from MSS CR5 C0 to DSS DSP):

1. MSS CR5_C0 writes the message in the DSS DSP mailbox.
2. MSS triggers an interrupt to DSS by writing 1 to MSS_CTRL: MSS_CR5A_MBOX_WRITE_DONE [4]. Note: It is writing to its own CTRL space.
3. DSS DSP gets a single interrupt for all interprocessor communication, which is an aggregated interrupt. DSP reads the register DSS_CTRL::DSS_DSP_MBOX_READ_REQ and sees bit [0] is 0x1.
4. DSP writes to 0x1 to DSS_CTRL::DSS_DSP_MBOX_READ_REQ [0] to clear the interrupt.
5. DSP reads the message.
6. DSP writes to 0x1 to DSS_CTRL::DSS_DSP_MBOX_READ_DONE_ACK [0] to generate an acknowledgment interrupt to MSS CR5 C0.
7. MSS CR5 C0 gets a single interrupt for all interprocessor communication, which is an aggregated ACK interrupt. MSS CR5 C0 reads the register MSS_CTRL: MSS_CR5A_MBOX_READ_DONE and sees bit [3] is 0x1.
8. MSS CR5 C0 writes 0x1 to MSS_CTRL: MSS_CR5A_MBOX_READ_DONE [3] to clear the interrupt.

Every processor is always writing to its own control space.

Each processor has only 2 interrupts (aggregated): <PROC>MBOX_READ_REQ and <PROC>MBOX_READ_ACK to its interrupt controller.

Scheme ensures the number of mailbox interrupts to a processor is always only 2, regardless of the number of procs in the SoC.

Refer to [Section 5.2.6](#), [Section 5.2.7](#), and [Section 5.2.8](#) for details on the relevant RECEIVER/SENDER processors.

This section lists the various interrupts sources supported in the different subsystem of AM273x device

8.1 Master Subsystem Cortex R5F Interrupt Map

Table 8-1. Master Subsystem Cortex R5F Interrupt Map

Interrupt Number	Define Name	Description
0	MSS_ESM_LO	ESM Low Priority Interrupt
1	MSS_ESM_HI	ESM High Priority Interrupt
2	CR5SS_STC_DONE	Cortexr5ss subsystem STC complete interrupt
3	MSS_RTIA_INT0	RTIA compare interrupt
4	MSS_RTIA_INT1	RTIA compare interrupt
5	MSS_RTIA_INT2	RTIA compare interrupt
6	MSS_RTIA_INT3	RTIA compare interrupt
7	MSS_RTIA_OVERFLOW_INT0	RTIA overflow interrupt
8	MSS_RTIA_OVERFLOW_INT1	RTIA overflow interrupt
9	MSS_RTIB_INT0	RTIB compare interrupt
10	MSS_RTIB_INT1	RTIB compare interrupt
11	MSS_RTIB_OVERFLOW_INT0	RTIB overflow interrupt
12	MSS_RTIB_OVERFLOW_INT1	RTIB overflow interrupt
13	MSS_RTIC_INT0	RTIC compare interrupt
14	MSS_RTIC_INT1	RTIC compare interrupt
15	MSS_RTIC_OVERFLOW_INT0	RTIC overflow interrupt
16	MSS_RTIC_OVERFLOW_INT1	RTIC overflow interrupt
17	MSS_WDT_INT0	WDT compare interrupt
18	MSS_WDT_INT1	WDT compare interrupt
19	MSS_WDT_INT2	WDT compare interrupt
20	MSS_WDT_INT3	WDT compare interrupt
21	MSS_WDT_OVERFLOW_INT0	WDT over flow interrupt
22	MSS_WDT_OVERFLOW_INT1	WDT over flow interrupt
23	MSS_WDT_TB_INT	WDT time base interrupt
24	MSS_MCRC_INT	Interrupt from MCRC
25	MSS_DCCA_INT	MSS_DCCA Clock compare done interrupt
26	MSS_DCCB_INT	MSS_DCCB Clock compare done interrupt
27	MSS_DCCC_INT	MSS_DCCC Clock compare done interrupt
28	MSS_DCCD_INT	MSS_DCCD Clock compare done interrupt
29	MSS_CCCA_INT	MSS_CCCA dual clock compare done interrupt
30	MSS_CCCB_INT	MSS_CCCB dual clock compare done interrupt
31	MSS_SPIA_INT0	MSS_SPIA level 0 interrupt
32	MSS_SPIA_INT1	MSS_SPIA level 1 interrupt

Table 8-1. Master Subsystem Cortex R5F Interrupt Map (continued)

Interrupt Number	Define Name	Description
33	MSS_SPIB_INT0	MSS_SPIB level 0 interrupt
34	MSS_SPIB_INT1	MSS_SPIB level 1 interrupt
35	MSS_QSPI_INT	MSS_QSPI interrupt
36	MSS_GIO_INT0	MSS_GIO high-level Interrupt
37	MSS_GIO_INT1	MSS_GIO low-level interrupt
38	MSS_ETPWMA_INT0	MSS_ETPWMA Interrupt 0 which is a output to pad
39	MSS_ETPWMA_INT1	MSS_ETPWMA Interrupt 1 which is a output to pad
40	MSS_ETPWMB_INT0	MSS_ETPWMB Interrupt 0 which is a output to pad
41	MSS_ETPWMB_INT1	MSS_ETPWMB Interrupt 1 which is a output to pad
42	MSS_ETPWMC_INT0	MSS_ETPWMC Interrupt 0 which is a output to pad
43	MSS_ETPWMC_INT1	MSS_ETPWMC Interrupt 1 which is a output to pad
44	MSS_MCANA_INT0	MSS_MCANA first interrupt
45	MSS_MCANA_INT1	MSS_MCANA second interrupt
46	MSS_MCANA_FE_INT1	MSS_MCANA message filter interrupt1
47	MSS_MCANA_FE_INT2	MSS_MCANA message filter interrupt2
48	MSS_MCANB_INT0	MSS_MCANB first interrupt
49	MSS_MCANB_INT1	MSS_MCANB second interrupt
50	MSS_MCANB_FE_INT1	MSS_MCANB message filter interrupt1
51	MSS_MCANB_FE_INT2	MSS_MCANB message filter interrupt2
52	MSS_I2C_INT	MSS_I2C interrupt
53	MSS_SCIA_INT0	MSS_SCIA level0 input
54	MSS_SCIA_INT1	MSS_SCIA level1 input
55	MSS_SCIB_INT0	MSS_SCIB level0 input
56	MSS_SCIB_INT1	MSS_SCIB level1 input
57	TOP_PBIST_DONE_INT	TOP_PBIST done interrupt
58	MSS_GIO_PAD_INT0	Interrupt Triger from GIO[0][0]
59	MSS_GIO_PAD_INT1	Interrupt Triger from GIO[0][1]
60	MSS_GIO_PAD_INT2	Interrupt Triger from GIO[0][2]
61	MSS_GIO_PAD_INT3	Interrupt Triger from GIO[0][3]
62	MSS_MCANA_FE_INT3	MSS_MCANA message filter interrupt3
63	MSS_MCANA_FE_INT4	MSS_MCANA message filter interrupt4
64	MSS_MCANA_FE_INT5	MSS_MCANB message filter interrupt5
65	MSS_MCANA_FE_INT6	MSS_MCANA message filter interrupt6
66	MSS_MCANA_FE_INT7	MSS_MCANB message filter interrupt7
67	MSS_TPCC_A_INTAGG	MSS_TPCC_A Aggregated Functional Interrupt
68	MSS_TPCC_B_INTAGG	MSS_TPCC_B Aggregated Functional Interrupt
69	MSS_TPCC_A_ERRAGG	MSS_TPCC_A Agregated Error Interrupt
70	MSS_TPCC_B_ERRAGG	MSS_TPCC_B Agregated Error Interrupt
71	MSS_GPADC_IFM_DONE	MSS_GPADC ifm done interrupt
72	MSS_CPSW_TH_TRSH_INT	MSS CPSW T-host threshold interrupt
73	MSS_CPSW_TH_INT	MSS CPSW T-host interrupt
74	MSS_CPSW_FH_INT	MSS CPSW F-host interrupt
75	MSS_CPSW_MISC_INT	MSS CPSW interrupt
76	RESERVED	RESERVED
77	MSS_CR5A_MBOX_READ_REQ	Aggregated interrupt to MSS CR5A from other processor asking it to read

Table 8-1. Master Subsystem Cortex R5F Interrupt Map (continued)

Interrupt Number	Define Name	Description
78	MSS_CR5A_MBOX_READ_ACK	Aggregated interrupt to MSS CR5A from other processor saying the reading from their mailbox is done.
79	MSS_CR5B_MBOX_READ_REQ	Aggregated interrupt to MSS CR5B from other processor asking it to read
80	MSS_CR5B_MBOX_READ_ACK	Aggregated interrupt to MSS CR5B from other processor saying the reading from their mailbox is done.
81	RESERVED	RESERVED
82	TOP_DEBUGSS_TXDATA_AVAIL	Interrupt from TOP_DEBUGSS
83	MSS_CR5A_PMU_INT	Pmu Interrupt from MSS_CR5A
84	MSS_CR5B_PMU_INT	Pmu Interrupt from MSS_CR5B
85	MSS_CR5A_FPU_INT	Floating point exception from MSS_CR5A
86	MSS_CR5B_FPU_INT	Floating point exception from MSS_CR5B
87	RESERVED	RESERVED
88	CR5A_CTI_IRQ	IRQ request from CTI module from CR5A
89	CR5B_CTI_IRQ	IRQ request from CTI module from CR5B
90	RESERVED	RESERVED
91	MSS_SW_INT0	Software Interrupt from MSS_CTRL
92	MSS_SW_INT1	Software Interrupt from MSS_CTRL
93	MSS_SW_INT2	Software Interrupt from MSS_CTRL
94	MSS_SW_INT3	Software Interrupt from MSS_CTRL
95	MSS_SW_INT4	Software Interrupt from MSS_CTRL
96	RESERVED	RESERVED
97	MSS_PERIPH_ACCESS_ERRAGG	Aggregation of all access-errors from mpu and control spaces
98	RESERVED	RESERVED
99	RESERVED	RESERVED
100	RESERVED	RESERVED
101	RESERVED	RESERVED
102	RESERVED	RESERVED

110	MSS_RTIC_INT3	RTIC compare interrupt
111	RESERVED	RESERVED
112	RESERVED	RESERVED
113	MSS_MCANB_FE_INT3	MSS_MCANB message filter interrupt3
114	MSS_MCANB_FE_INT4	MSS_MCANB message filter interrupt4
115	MSS_MCANB_FE_INT5	MSS_MCANB message filter interrupt5
116	MSS_MCANB_FE_INT6	MSS_MCANB message filter interrupt6
117	MSS_MCANB_FE_INT7	MSS_MCANB message filter interrupt7
118	RESERVED	RESERVED
119	RESERVED	RESERVED
120	DSS_TPCC_A_INTAGG	DSS_TPCC_A Aggregated Functional Interrupt
121	DSS_TPCC_A_ERRAGG	DSS_TPCC_A Aggregated Error Interrupt

Table 8-1. Master Subsystem Cortex R5F Interrupt Map (continued)

Interrupt Number	Define Name	Description
122	DSS_TPCC_B_INTAGG	DSS_TPCC_B Aggregated Functional Interrupt
123	DSS_TPCC_B_ERRAGG	DSS_TPCC_B Aggregated Error Interrupt
124	DSS_TPCC_C_INTAGG	DSS_TPCC_C Aggregated Functional Interrupt
125	DSS_TPCC_C_ERRAGG	DSS_TPCC_C Aggregated Error Interrupt
126	Reserved	
127	Reserved	
128	Reserved	
129	DSS_DSP_PBIST_CTRL_DONE	DSS DSP PBIST Controller Done Interrupt
130	DSS_SW_INT0	SW interrupt generated by writing 0x1 to register DSS_CTRL.DSS_SW_INT[0]
131	DSS_SW_INT1	SW interrupt generated by writing 0x1 to register DSS_CTRL.DSS_SW_INT[1]
132	DSS_SW_INT2	SW interrupt generated by writing 0x1 to register DSS_CTRL.DSS_SW_INT[2]
133	DSS_SW_INT3	SW interrupt generated by writing 0x1 to register DSS_CTRL.DSS_SW_INT[3]
134	Reserved	ESM Low Priority Interrupt
135	Reserved	ESM High Priority Interrupt
136	DSS_MCRC_INT	DSS MCRC Interrupt
137	DSS_DSP_STC_DONE	DSS DSP STC Done Interrupt
138	DSS_DSP_PBIST_DONE	DSS DSP PBIST Done Interrupt
139	DSS_SCIA_INT0	DSS SCIA Interrupt 0
140	DSS_SCIA_INT1	DSS SCIA Interrupt 1
141	RCSS_SCIA_INT	RCSS_SCIA Cominbed Interrupt from IP
142	RCSS_SCIA_ERR	RCSS_SCIA Error Interrupt
143	DSS_CBUFF_INT	DSS CBUFF Interrupt
144	DSS_CBUFF_INT_ERR	DSS CBUFF Error Interrupt
145	DSS_HWA_THREAD1_LOOP_INT	DSS_HWA Thread1 Loop complete interrupt
146	DSS_HWA_THREAD1_PARAM_DONE	DSS_HWA Thread1 Param done interrupt
147	RCSS_SPIA_INT0	RCSS SPI A Interrupt 0
148	RCSS_SPIA_INT1	RCSS SPI A Interrupt 1
149	RCSS_SPIB_INT0	RCSS SPI B Interrupt 0
150	RCSS_SPIB_INT1	RCSS SPI B Interrupt 1
151	RCSS_TPCC_A_INTAGG	RCSS_TPCC_A Aggregated Functional Interrupt
152	RCSS_TPCC_A_ERRAGG	RCSS_TPCC_A Aggregated Error Interrupt
153	RCSS_ECAP_INT	RCSS ECAP Interrupt
154	RCSS_MCASPA_TX_INT	RCSS McASP A Tx Interrupt
155	RCSS_MCASPB_TX_INT	RCSS McASP B Tx Interrupt
156	RCSS_MCASPB_TX_INT	RCSS McASP C Tx Interrupt
157	RCSS_MCASPA_RX_INT	RCSS McASP A Rx Interrupt
158	RCSS_MCASPB_RX_INT	RCSS McASP B Rx Interrupt
159	RCSS_MCASPC_RX_INT	RCSS McASP C Rx Interrupt
160	DSS_HWA_THREAD2_LOOP_INT	DSS_HWA Thread2 Loop complete interrupt
161	DSS_HWA_THREAD2_PARAM_DONE	DSS_HWA Thread2 Param done interrupt
162	DSS_WDT_TB_INT	DSS WDT Time Base Interrupt

Table 8-1. Master Subsystem Cortex R5F Interrupt Map (continued)

Interrupt Number	Define Name	Description
163	DSS_HWA_LOCAL_RAM_ERR	DSS_HWA Local RAM access error
164	DSS_DCCA_INT	DSS DCCA Interrupt
165	DSS_DCCB_INT	DSS DCCB Interrupt
166	DSS_RTIA_OVERFLOW_0	DSS_RTIA Overflow 0
167	DSS_RTIA_OVERFLOW_1	DSS_RTIA Overflow 1
168	DSS_RTIA_0	DSS_RTIA Interrupt 0
169	DSS_RTIA_1	DSS_RTIA Interrupt 1
170	DSS_RTIA_2	DSS_RTIA Interrupt 2

71	MSS_MPU_CR5A_SLV_PROT_ERR	MPU Protection Error for MSS_MPU_(X)_ADDR_ERR
70	MSS_MPU_CR5B_SLV_PROT_ERR	MPU Protection Error for MSS_MPU_(X)_ADDR_ERR
69	MSS_MPU_HSM_SLV_PROT_ERR	MPU Protection Error for MSS_MPU_(X)_ADDR_ERR
68	MSS_CPSW_SERR	Cpsw memories Single bit error pulse
67	MSS_CPSW_UERR	Cpsw memories Double bit error pulse
66	MSS_BUS_SAFETY_SEC_AGG_ERR	Aggregated error for SEC from all Nodes in MSS_SCR
64 to 65	RESERVED	RESERVED
63	ANA_LIMP_MODE	Error signal from analog if the CLK monitor finds the REF CLK to be outside the permissible range of frequency
62	MSS_MCRC_ERR	MCRC Comparison Error
61	MSS_DCCA_ERR	DCCA frequency comparison error
60	MSS_DCCB_ERR	DCCB frequency comparison error
59	MSS_DCCC_ERR	DCCC frequency comparison error
58	MSS_DCCD_ERR	DCCD frequency comparison error
57	MSS_CCCA_ERR	CCCA frequency comparison error
56	MSS_CCCB_ERR	CCCB frequency comparison error
55	MSS_SPIA_SERR	Single Bit correctable error indication for MIBSPI-A multi-buffer
54	MSS_SPIB_SERR	Single Bit correctable error indication for MIBSPI-B multi-buffer
53	MSS_SPIA_UERR	Multi Bit uncorrectable error indication for MIBSPI-A multi-buffer
52	MSS_SPIB_UERR	Multi Bit uncorrectable error indication for MIBSPI-B multi-buffer

Table 8-4. Master Subsystem ESM Interrupt Map Group 1 (continued)

ESM GROUP1	Define Name	Description
51	MSS_MCANA_SERR	Single Bit correctable error indication for MCANA Message Memory
50	MSS_MCANA_UERR	Multi Bit uncorrectable error indication for MCANA Message Memory
49	MSS_MCANA_TS_ERR	MCANA Timestamping Error
48	MSS_MCANB_SERR	Single Bit correctable error indication for MCANB Message Memory
47	MSS_MCANB_UERR	Multi Bit uncorrectable error indication for MCANB Message Memory
46	MSS_MCANB_TS_ERR	MCANB Timestamping Error
45	PAD_NERROR_IN	Nerror from PAD
44	MSS_TCMA_CR5A_SERR	Single Bit correctable error indication for ATCM of CR5A
43	MSS_TCMB1_CR5A_SERR	Single Bit correctable error indication for B1TCM of CR5A
42	MSS_TCMB0_CR5A_SERR	Single Bit correctable error indication for B0TCM of CR5A
41	MSS_TCMA_CR5B_SERR	Single Bit correctable error indication for ATCM of CR5B
40	MSS_TCMB1_CR5B_SERR	Single Bit correctable error indication for B1TCM of CR5B
39	MSS_TCMB0_CR5B_SERR	Single Bit correctable error indication for B0TCM of CR5B
38	MSS_CR5A_ITAG_SERR	Single Bit correctable error indication for Cache ITAG of CR5A
37	MSS_CR5A_IDATA_SERR	Single Bit correctable error indication for Cache IDATA of CR5A
36	MSS_CR5A_DTAG_SERR	Single Bit correctable error indication for Cache DTAG of CR5A
35	MSS_CR5A_DDATA_SERR	Single Bit correctable error indication for Cache DDATA of CR5A
34	MSS_CR5B_ITAG_SERR	Single Bit correctable error indication for Cache ITAG of CR5B
33	MSS_CR5B_IDATA_SERR	Single Bit correctable error indication for Cache IDATA of CR5B
32	MSS_CR5B_DTAG_SERR	Single Bit correctable error indication for Cache DTAG of CR5B
31	MSS_CR5B_DDATA_SERR	Single Bit correctable error indication for Cache DDATA of CR5B
30	MSS_TPCC_A_AGG_ERR	MSS_TPCC_A Aggregated Error Interrupt
		- TPCC Error
		- TPCC MPU Error
		- TPTC Error for all TPTCs connected to TPCC
		- Read and Write Config Space Access error to TPCC
		- Read and Write Config Space Access error or all TPTCs connected to TPCC

9.1 Enhanced Direct Memory Access (EDMA)

This section describes the Enhanced Direct Memory Access (EDMA) controller. This chapter covers features of EDMA module. For features applicable to the EDMA instances in the device, see the device-specific Integration section. The primary purpose of the EDMA controller is to service data transfers programmed between two memory-mapped slave endpoints on the device. The EDMA controller consists of two principle blocks:

- EDMA channel controllers: EDMA_TPCC
- EDMA transfer controllers: EDMA_TPTC

Devices can have multiple instances of EDMA channel controllers, each associated with multiple EDMA transfer controllers.

The EDMA channel controller serves as the user interface for the EDMA controller. The EDMA_TPCC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TR) to the EDMA3 transfer controller.

The EDMA transfer controllers are responsible for data movement. The transfer request packets (TRP) submitted by the EDMA_TPCC contain the transfer context, based on which the transfer controller issues read/write commands to the source and destination addresses programmed for a given transfer.

9.1.1 EDMA Module Overview	2189
9.1.2 EDMA Integration	2190
9.1.3 EDMA Controller Functional Description	2194
9.1.4 EDMA Transfer Examples	2242
9.1.5 EDMA Debug Checklist and Programming Tips	2249
9.1.6 EDMA Event Map	2251
9.1.7 EDMA Registers	2251

9.1.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

Figure 9-1 shows an overview of the EDMA module.

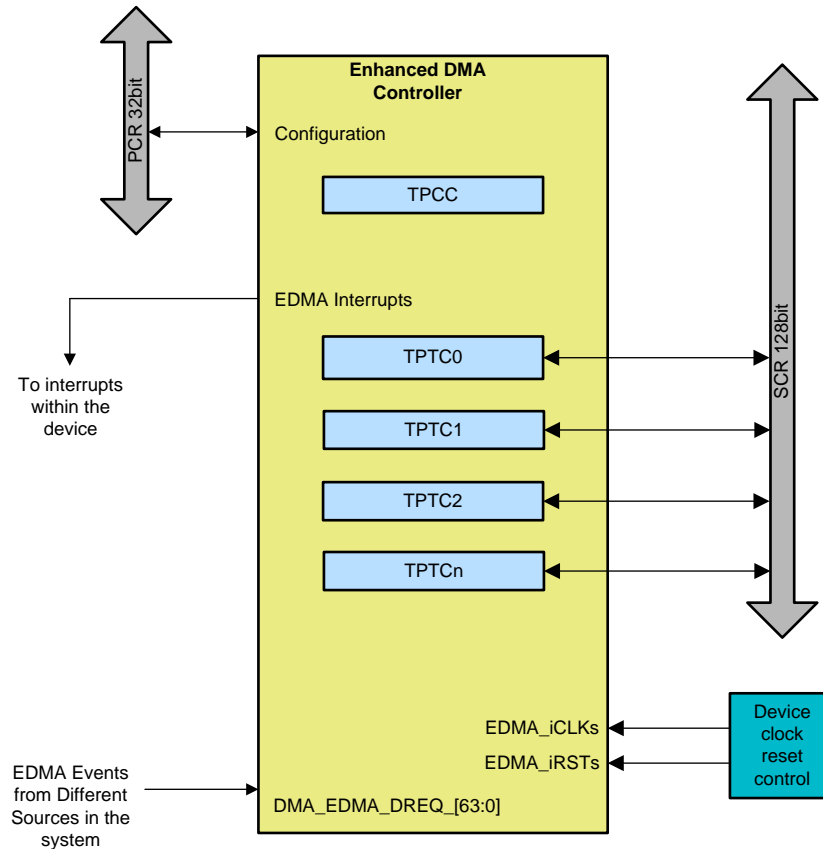

Figure 9-1. EDMA Module Overview

Note

When connecting to DSS, the SCR is 128 bit. When connecting to MSS and RCSS, the SCR is 64 bit.

For EDMA instances available on the device, see the device-specific integration section.

The **TPCC** is a high flexible channel controller that serves as both a user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals, as programmed in the Active and Pending set of the registers. The transfer controllers are responsible for data movement, and issue read/write commands to the source and destination addresses programmed for a given transfer in the EDMA_TPCC.

9.1.1.1 EDMA Features

This section shows generic EDMA features. For features applicable to the EDMA instances in the device, see the device-specific Integration section.

The EDMA_TPCC channel controller has the following features:

- Fully orthogonal transfer description:
 - Three transfer dimensions
 - A-synchronized transfers: one dimension serviced per event
 - AB-synchronized transfers: two dimensions serviced per event
 - Independent indexes on source and destination
 - Chaining feature allowing a 3-D transfer based on a single event.
- Flexible transfer definition:
 - Increment or FIFO transfer addressing modes
 - Linking mechanism allows automatic PaRAM set update
 - Chaining allows multiple transfers to execute with one event
- Interrupt generation for the following:
 - Transfer completion
 - Error conditions
- Debug visibility:
 - Queue water marking/threshold
 - Error and status recording to facilitate debug
- 64 DMA request channels:
 - Event synchronization
 - Manual synchronization (CPUs write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
 - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
 - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
 - Support for programmable QDMA channel to PaRAM mapping.
- Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Multiple transfer controllers/event queues.
- 16 event entries per event queue.

The EDMA_TPTC transfer controller has the following features:

- 128-bit wide read and write ports per TC
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the third dimension)
- Support for increment or constant addressing mode transfers
- Interrupt and error support
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness

9.1.2 EDMA Integration

This section describes modules integration in the device, including information about clocks, resets, and hardware requests.

9.1.2.1 EDMA Integration (AM263x)

There are TBD modules integrated in the device. The diagram below provides a visual representation of the device integration details.

Figure 9-2. MODULE Integration Diagram (Placeholder)

The tables below summarize the device integration details of MODULE# (where # = INSERT INSTANCE COUNT).

Table 9-1. MODULE Device Integration

This table describes the module device integration details.

Module Instance	Device Allocation	SoC Interconnect
MODULE0	✓	TBD

Table 9-2. MODULE Clocks

This table describes the module clocking signals.

Module Instance	Module Clock Input	Source Clock Signal	Source	Default Freq	Description

Table 9-6. MODULE Capture Event Inputs

This table describes the module capture event inputs.

Module Instance	Module Capture Event Input	Capture Event Source Signal	Source	Type	Description
MODULE0	TBD	TBD	TBD	TBD	TBD

Note

For more information on the interconnects, see the *System Interconnect* chapter.

For more information on power, reset, and clock management, see the corresponding sections within the *Device Configuration* chapter.

For more information on the device interrupt controllers, see the *Interrupt Controllers* chapter.

9.1.2.2 EDMA Interrupt Aggregator

The following EDMA interrupts are aggregated and sent to the processor:

- TPCC Completion Interrupt
- TPCC Completion Region Interrupts
- TPTCs Completion Interrupt

shows the associated interrupt and registers for each TPCC instance.

Table 9-7. TPCC Interrupts

TPCC	Interrupt	Registers Space
TPCC0	TPCC0_INTAGG	*_INTAGG_MASK *_INTAGG_STATUS *_INTAGG_STATUS_RAW

For an event to generate an interrupt to the processor, the corresponding bit field must be unmasked in TPCC_x_INTAGG_MASK.

Only an interrupt processor can read the TPCC_x_INTAGG_STATUS register to detect which event triggered the interrupt.

The interrupt can be cleared by writing 0x1 to the corresponding bit in TPCC_x_INTAGG_STATUS.

The software must ensure that all the aggregated interrupts are cleared so that the level interrupt is de-asserted before exiting the ISR. Only then is it ensured that a new pulse interrupt is generated to the processor. Thus, after clearing the software should read the register to confirm a value of 0x0.

The register TPCC_x_INTAGG_STATUS_RAW is set on an event irrespective of the value in TPCC_x_INTAGG_MASK. This field can be cleared by writing 0x1 to the corresponding bit in TPCC_x_INTAGG_STATUS_RAW.

9.1.2.3 EDMA Error Interrupt Aggregator

The following interrupts are aggregated and sent to the processor:

- TPCC Error
- TPCC MPU Error
- TPTCs Error
- TPCC Read and Write Config Space Access error
- TPTCs Read and Write Config Space Access error

Table 9-8. TPCC Error Interrupt Aggregators

TPCC	Interrupt	Registers Space
TPCC0	TPCC0_ERRAGG	*_ERRAGG_MASK *_ERRAGG_STATUS *_ERRAGG_STATUS_RAW

For an event to generate an interrupt to the processor, the corresponding bit field must be unmasked in TPCC_x_ERRAGG_MASK.

Only an interrupt processor can read the TPCC_x_ERRAGG_STATUS register to detect which event triggered the interrupt.

The interrupt can be cleared by writing 0x1 to the corresponding bit in TPCC_x_ERRAGG_STATUS.

The software must ensure that all the aggregated interrupts are cleared so that the level interrupt is de-asserted before exiting the ISR. Only then is it ensured that a new pulse interrupt is generated to the processor. Thus, after clearing the software should read the register to confirm a value of 0x0

The register TPCC_x_ERRAGG_STATUS_RAW is set on an event irrespective of the value in TPCC_x_ERRAGG_MASK. This field can be cleared by writing 0x1 to the corresponding bit in TPCC_x_ERRAGG_STATUS_RAW.

9.1.2.4 EDMA Configuration

- The device has 1 channel controller: TPCC0 and two transfer controllers: TPTC0 and TPTC1.

Table 9-9. EDMA Channel Controller Configuration

Parameters	TPCC0
DMA Channel	64

Table 9-9. EDMA Channel Controller Configuration (continued)

Parameters	TPCC0
Param Entires	256
QDMA Channel	8
Event queues	2
Mem Protection	Yes
Channel Mapping	Yes
Num TCs	2
Num Interrupt Channel	64
Num Regions	8

Table 9-10. EDMA Transfer Controller Configuration

Parameters	TPTC<0/1>
FIFO Size	512
TR Pipe Depth	4
Bus Width	8
Read Cmd Num	8
Write Cmd Num	8
RAM ECC	Yes

Default Burst Size configuration (DBS)

All TPTCs in the device support four different configurable default-burst-sizes. shows the config-value to DBS mapping.

Table 9-11. Config Value to DBS Mapping

Config value	Burst size
2'b00	16 bytes
2'b01	32 bytes
2'b10	64 bytes
2'b11	128 bytes

Table 9-12. TPTC DBS Configuration Registers

TPTC instance	Corresponding Register
TPTC<0/1>	TPTC_DBS_CONFIG::TPTC_DBS_CONFIG_TPTC<0/1>

9.1.3 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller. The description contained in this section is generic to the EDMA module, and not all features mentioned here are supported by the device. See the EDMA integration section of the device to determine the applicability of these features.

9.1.3.1 Block Diagram

Figure 9-3 shows the functional block diagram of the EDMA controller.

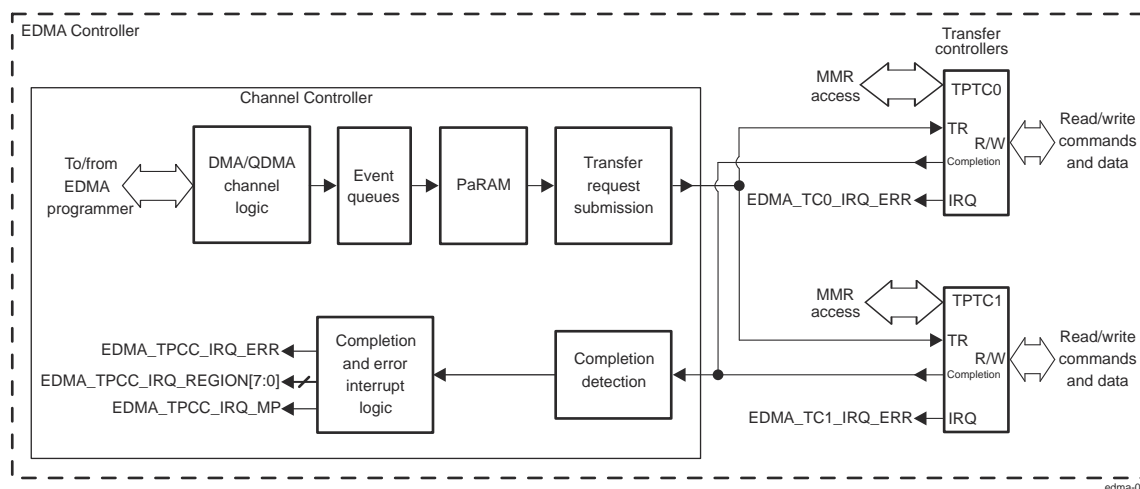

Figure 9-3. EDMA Controller Block Diagram

9.1.3.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 9-4 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- **EDMA event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 9-4 is a block diagram of the EDMA_TPCC.

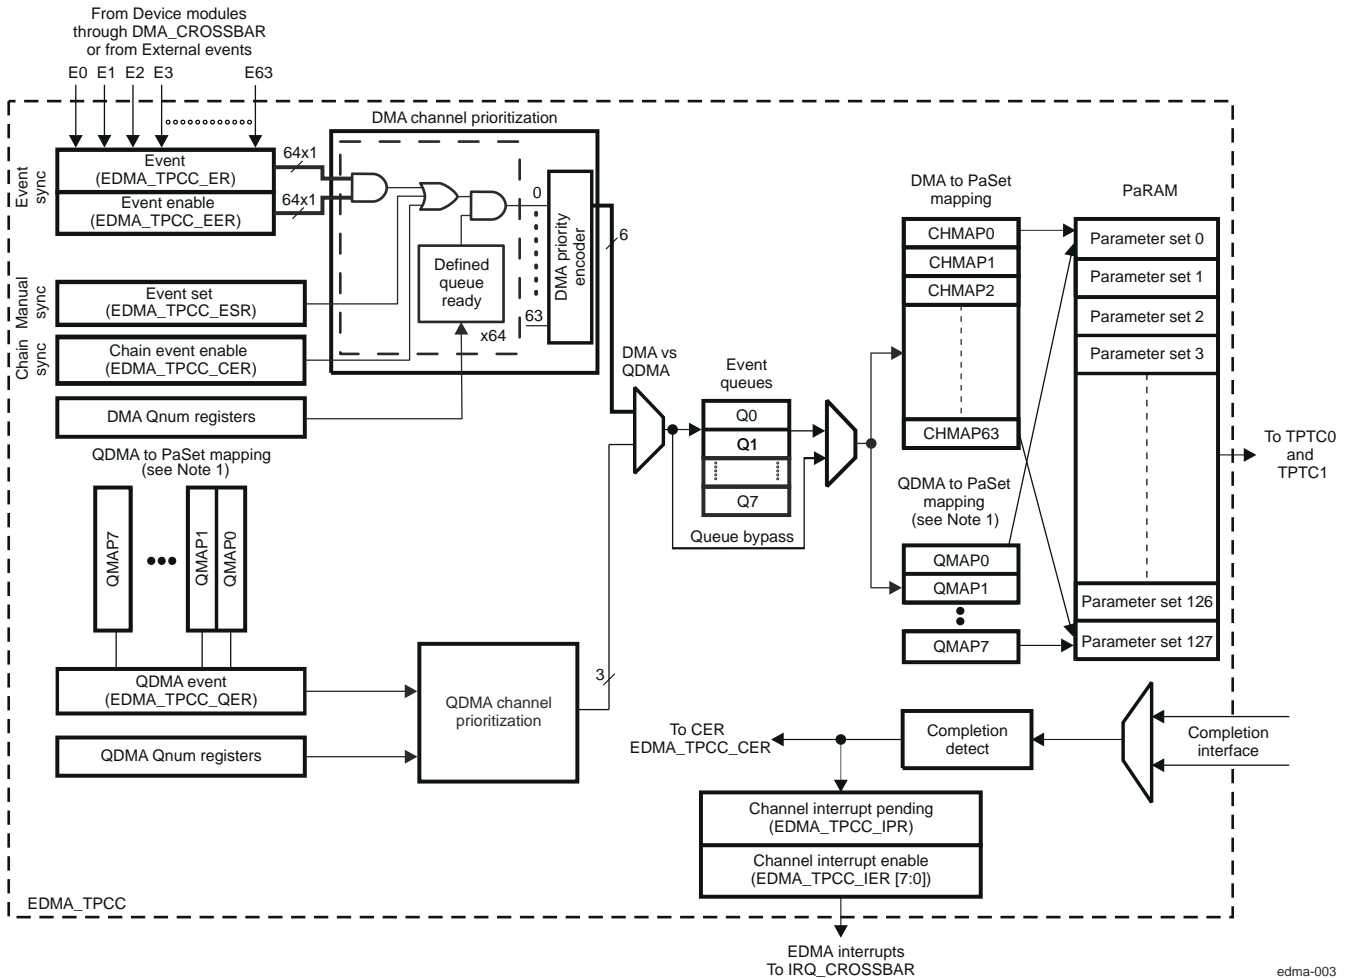

Figure 9-4. EDMA Channel Controller Block Diagram

A. Although it is depicted twice in Figure 9-4, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaPARAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaPARAM entry in anticipation of the next trigger event for that PaPARAM entry.

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

9.1.3.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 9-5 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

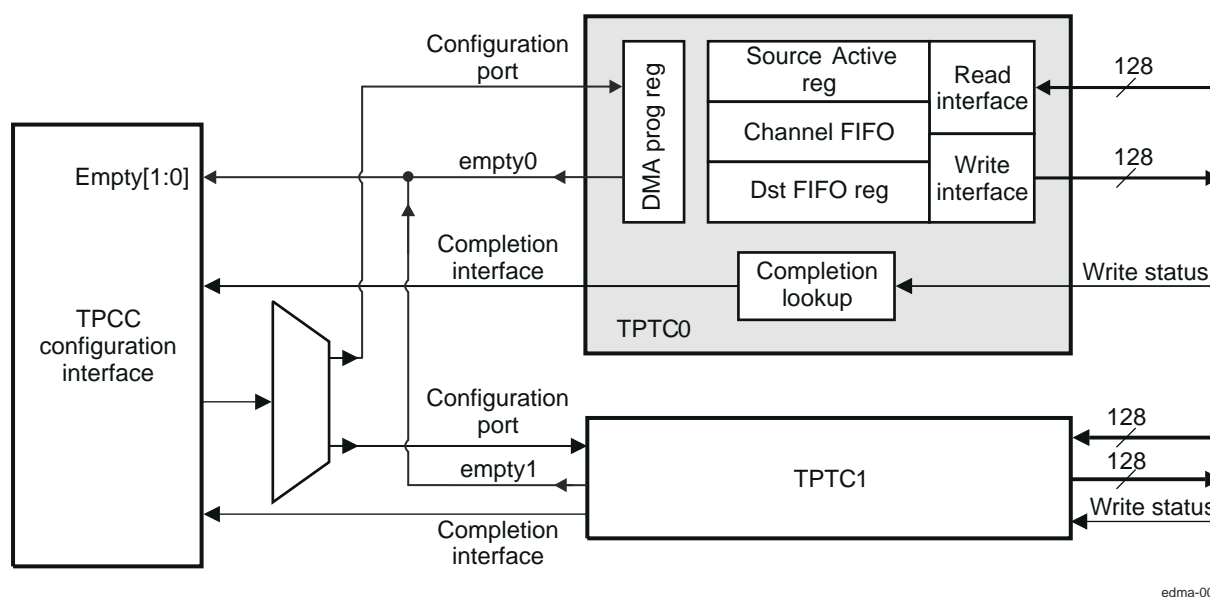

Figure 9-5. TPTC Block Diagram

Note

The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- **DMA Program Register Set:** Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- **Source Active Register Set :** Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.
- **Destination FIFO Register Set:** Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.

- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

9.1.3.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. [Figure 9-6](#) shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

Note

The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

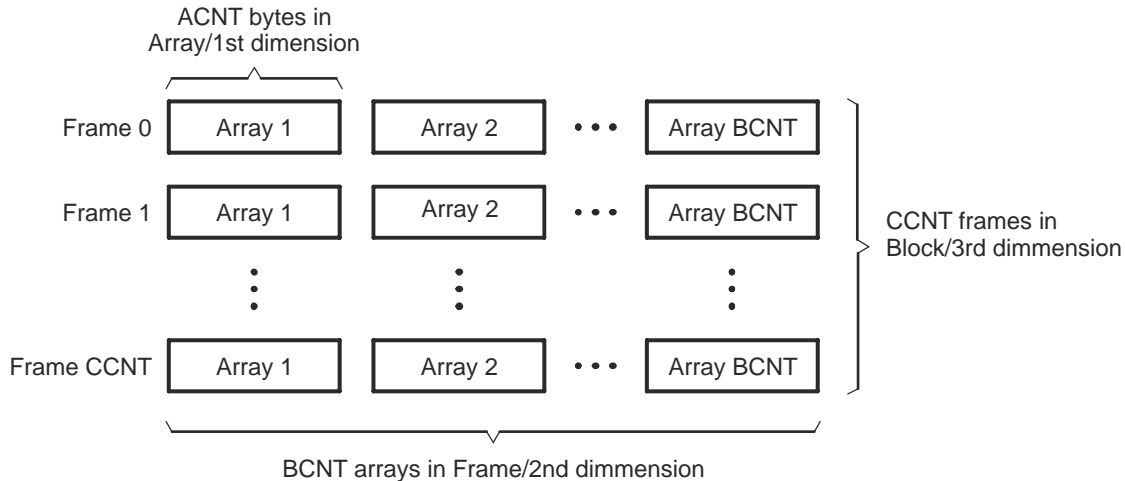

Figure 9-6. Definition of ACNT, BCNT, and CCNT

edma-007

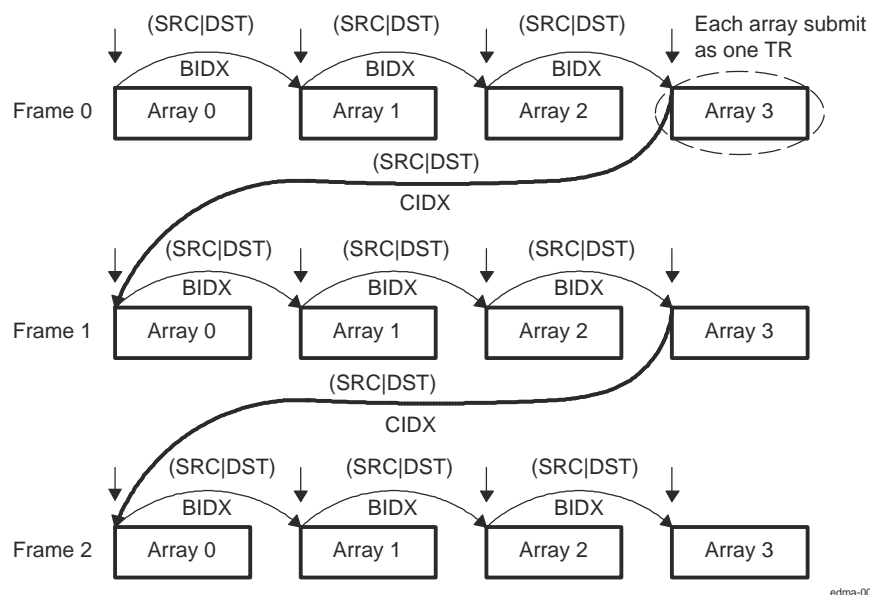

9.1.3.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 9-7, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/ DSTCIDX to the beginning address of the last array in the frame. As in Figure 9-7, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 9-7 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 9-7 for details on parameter set updates.

edma-008

Figure 9-7. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

9.1.3.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 9-8. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 9.1.3.3.6 Parameter Set Updates for details on parameter set updates.

Figure 9-8 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

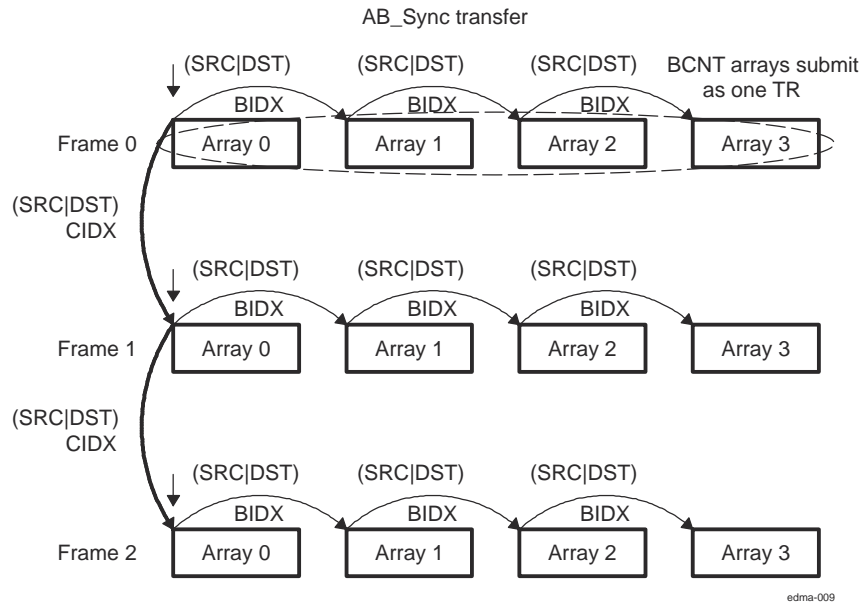

Figure 9-8. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

Note

ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

9.1.3.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 128 PaRAM sets

- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 8 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 9-13. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...
127	EDMA Base Address + 5000h to EDMA Base Address + 501Fh	PaRAM set 127

9.1.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in and described in . Each PaRAM set consists of 16-bit and 32-bit parameters.

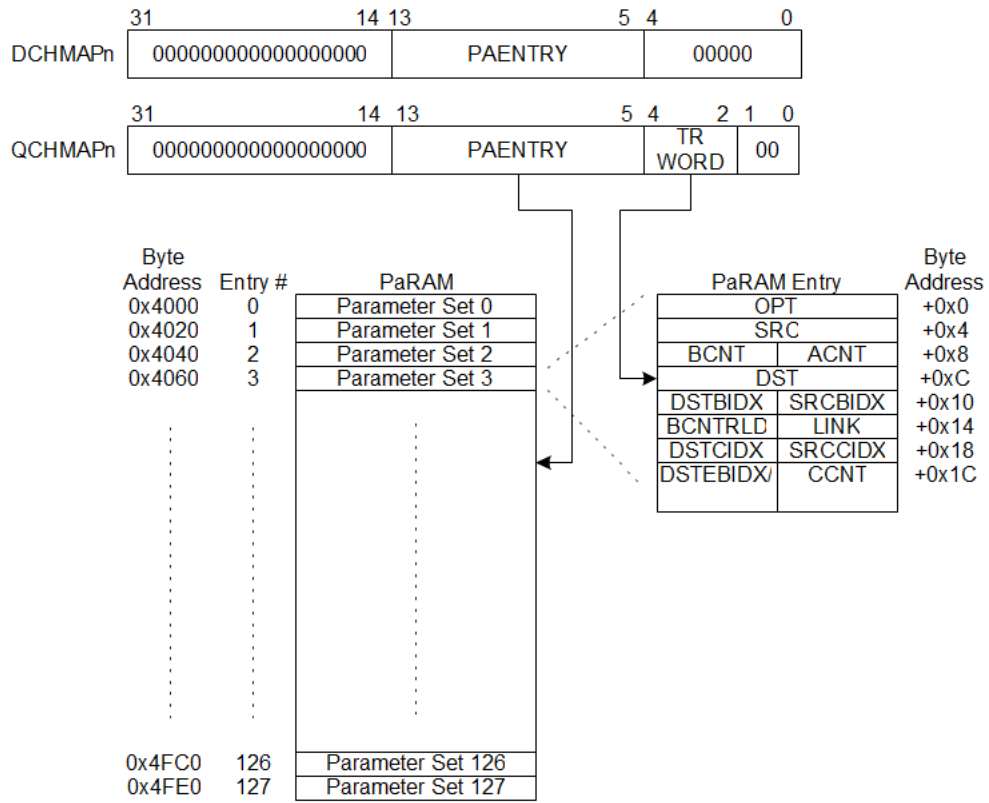

Figure 9-9. PaRAM Set

Note

Figure above is a representation of 128 bit entries. For device specific details please refer to [EDMA configuration](#) chapter.

Table 9-14. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from -32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from -32 768 and 32 767.
14h	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from -32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from -32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

9.1.3.3.2 EDMA Channel PaRAM Set Entry Fields

9.1.3.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in [Section 9.1.6](#).

9.1.3.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 9.1.3.12.3 Error Generation](#) for additional details.

9.1.3.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 9.1.3.12.3 Error Generation](#) for additional details.

9.1.3.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to [Section 9.1.3.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 9.1.3.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

9.1.3.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to [Section 9.1.3.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 9.1.3.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

9.1.3.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to [Section 9.1.3.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 9.1.3.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

9.1.3.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on

each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

9.1.3.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (−1): the address offset from the beginning of an array to the beginning of the next array in a frame is -1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

9.1.3.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to [Section 9.1.3.3.2.8 Source B Index \(SBIDX\)](#) for examples.

9.1.3.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 9-7](#)), while the current array in an AB-synchronized transfer is the first array in the frame ([Figure 9-8](#)).

9.1.3.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 9-7](#)), while the current array in a AB-synchronized transfer is the first array in the frame ([Figure 9-8](#)).

9.1.3.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programmed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see [Section 9.1.3.5 Completion of a DMA Transfer](#) for details on terminating a transfer.

9.1.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).

This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

9.1.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

9.1.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (En) in EDMA_TPCC_EMR to get set and the En bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

[Table 9-15](#) summarizes the conditions and effects of null and dummy transfer requests.

Table 9-15. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No

Table 9-15. Dummy and Null Transfer Request (continued)

Feature	Null TR	Dummy TR
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes

9.1.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to [Table 9-16](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 9.1.3.3.7 Linking Transfers](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0] LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0] LINK.

Note

PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 9.1.3.12 EDMA Transfer Controller \(EDMA_TPTC\)](#). For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

[Table 9-16](#) shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 9-16. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_CCNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

OPT ⁽¹⁾	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

Note

The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

9.1.3.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field of the current parameter set. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

Note

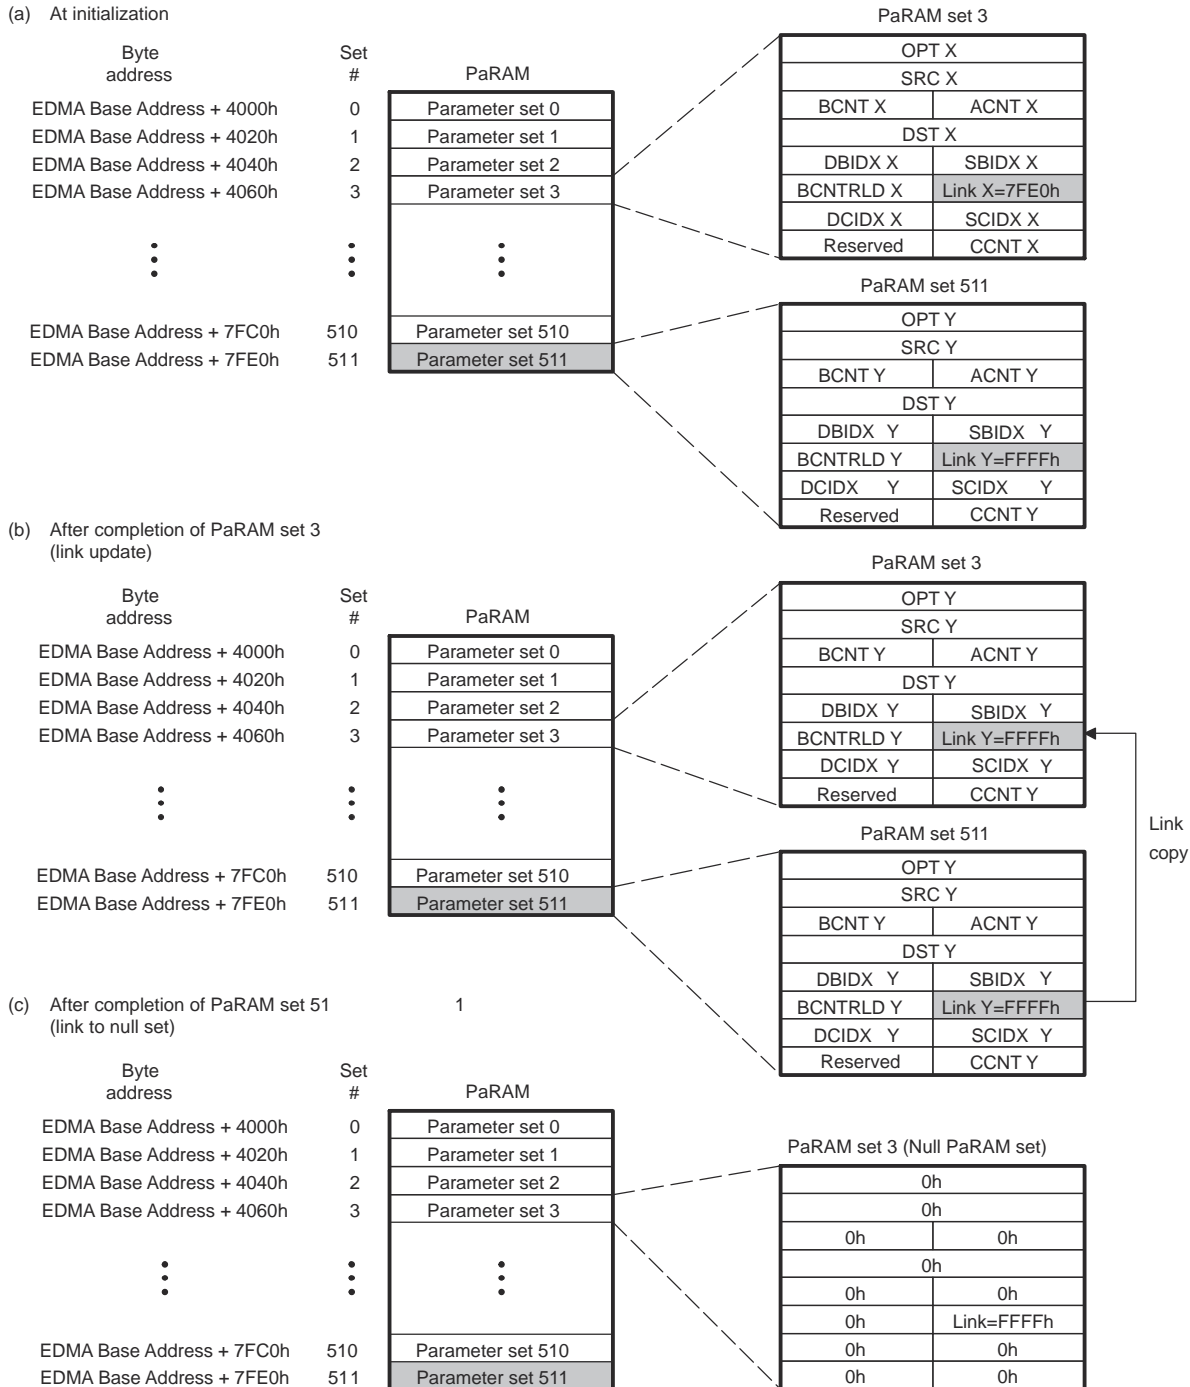

It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to [Section 9.1.3.3.3 Null PaRAM Set](#).

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set.

Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 9-10](#) shows an example of a linked transfer.

edma-011

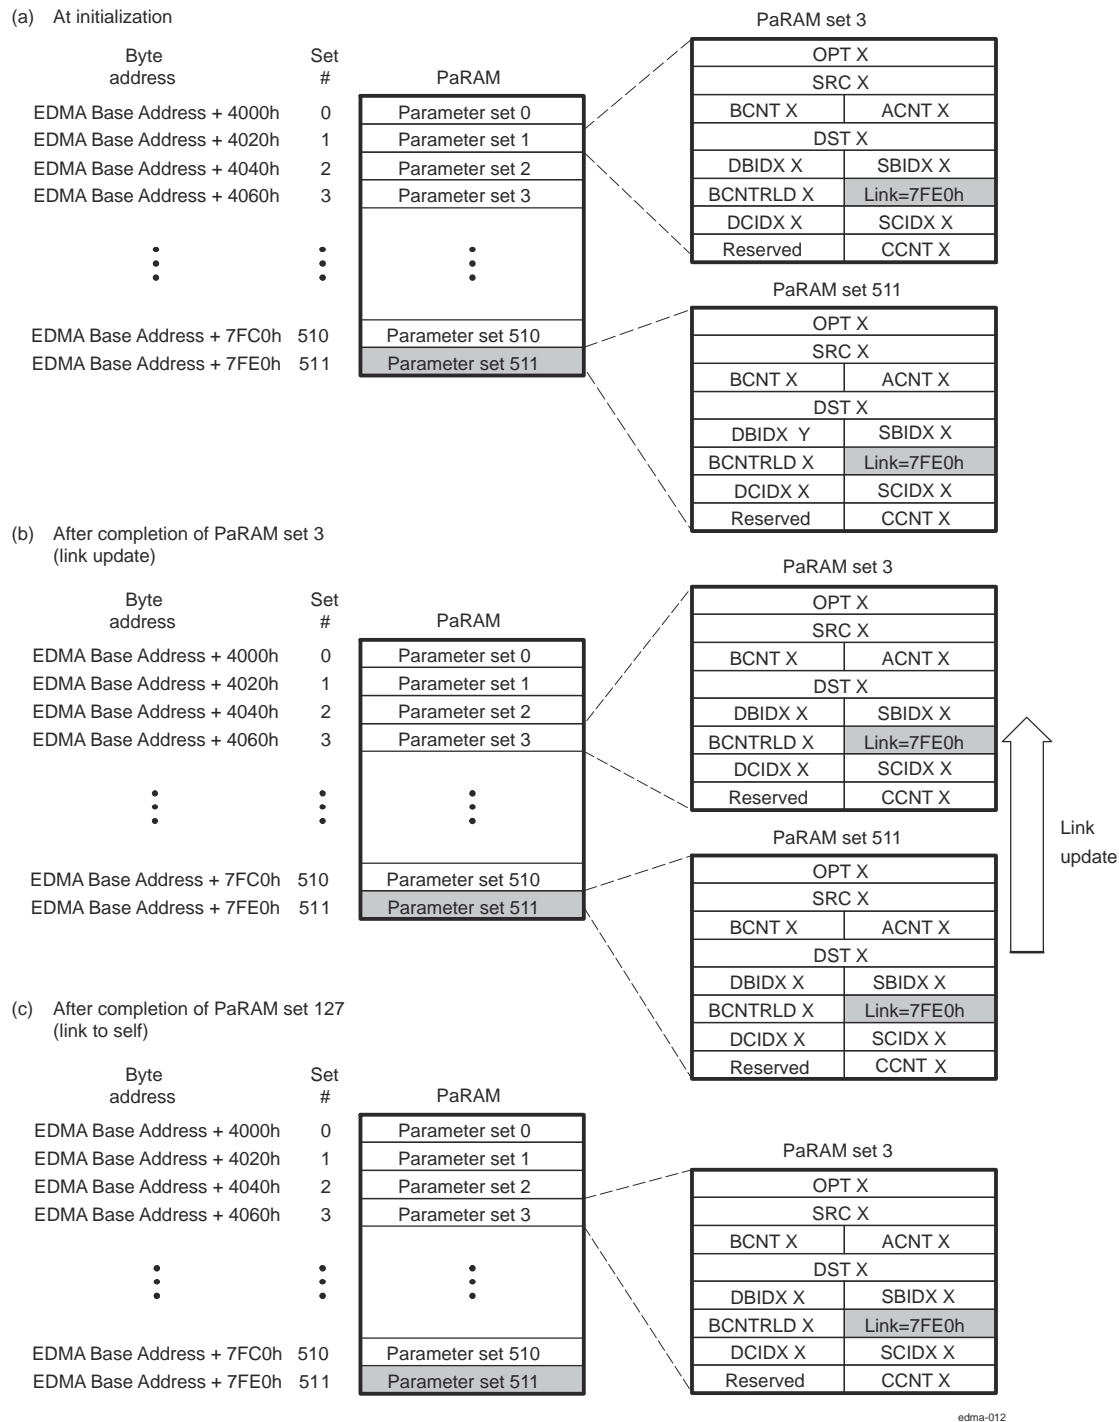

Figure 9-10. Linked Transfer

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 9.1.3.6 Event, Channel, and PaRAM Mapping) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used

to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to [Section 9.1.3.4.2 QDMA Channels](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. [Figure 9-11](#) shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

edma-012

Figure 9-11. Link-to-Self Transfer

Note

If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

9.1.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to [Section 9.1.3.12.3 Error Generation](#).

Note

The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 0) by appropriately programming the count and indices values.

9.1.3.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

9.1.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

9.1.3.4.1 DMA Channels

9.1.3.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] $E_n = 1$). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.

If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] $E_n = 1$), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] En bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see [Section 9.1.3.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] En bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] $En = 1$) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] $En = 1$), regardless of the state of EDMA_TPCC_EER[31:0] En . If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] $En = 1$ and EDMA_TPCC_EER[31:0] $En = 0$), the EDMA_TPCC_ER[31:0] En bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] $En = 1$), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] En bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] $En \neq 0$), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] $En = 1$).

9.1.3.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] En bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 9.1.3.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] En bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] $En = 1$ to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] $En = 1$ prior to the original being cleared EDMA_TPCC_ESR[31:0] $En = 0$, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] $En = 1$.

9.1.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] $E[TCC] = 1$).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 9.1.3.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] En bit is cleared and

simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] $E_n = 1$ to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] $E_n \neq 0$), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] $E_n = 1$.

Note

Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E_n can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

9.1.3.4.2 QDMA Channels

9.1.3.4.2.1 Auto-Triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] $E_n = 1$. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] $E_n = 1$).
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] $E_n = 1$.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] $E_n = 1$ and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] $E_n = 1$.

9.1.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

Note

The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to

re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

9.1.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 9-17](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 9-17. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to [Section 9.1.3.8 Chaining EDMA Channels](#) for details on chaining (intermediate/final chaining) and [Section 9.1.3.9 EDMA Interrupts](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to [Section 9.1.3.3.7 Linking Transfers](#) for more details.

Note

Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to [Section 9.1.3.3.5 Dummy Versus Null Transfer Comparison](#).

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

9.1.3.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

9.1.3.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

9.1.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set [Section 9.1.3.3.4](#) or null set [Section 9.1.3.3.3](#). In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

9.1.3.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[3:0] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

9.1.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. [Figure 9-12](#) illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

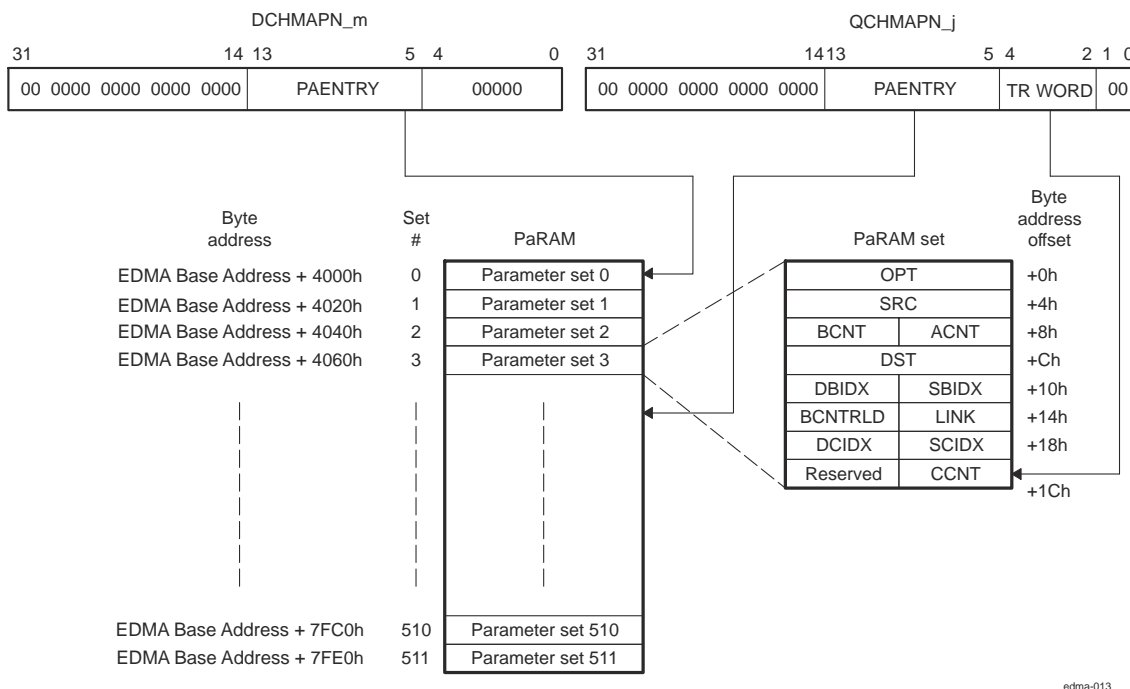

Figure 9-12. DMA Channel and QDMA Channel to PaRAM Mapping

9.1.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register **EDMA_TPCC_QCHMAPN_j** in the **EDMA_TPCC** allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 9-13 illustrates the use of **EDMA_TPCC_QCHMAPN_j**.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for **EDMA_TPCC** is a write to the trigger word in the PaRAM set pointed to by **EDMA_TPCC_QCHMAPN_j** for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

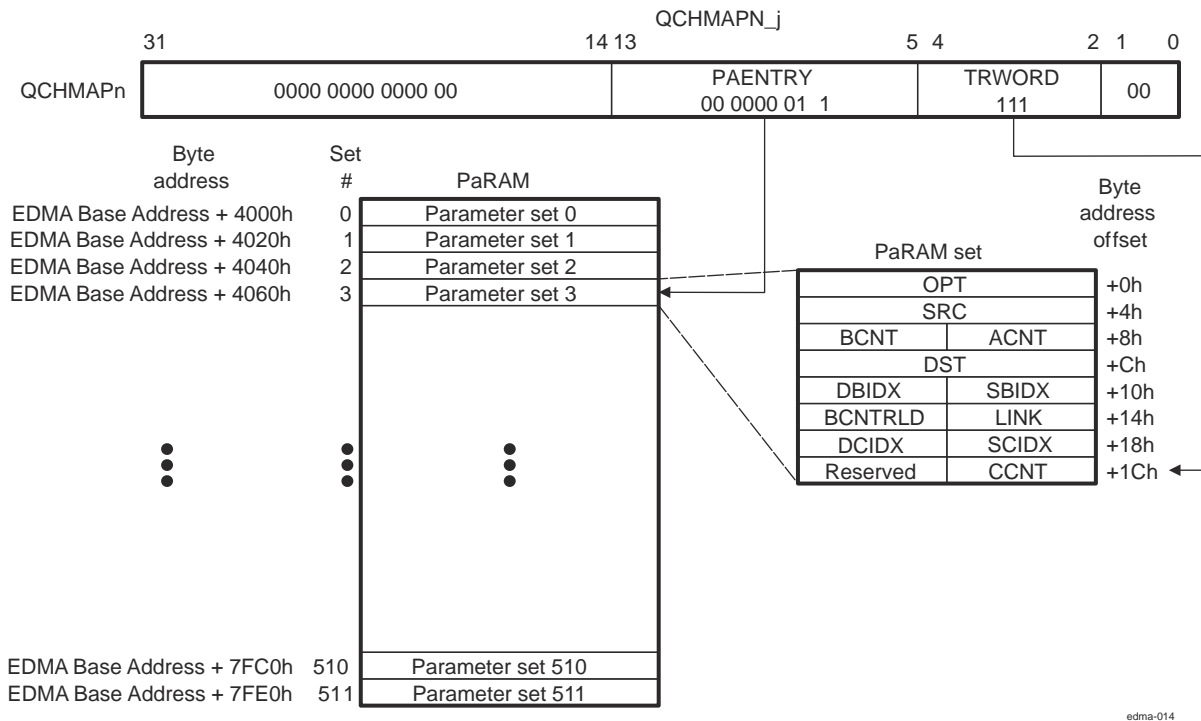

Figure 9-13. QDMA Channel to PaRAM Mapping

edma-014

9.1.3.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in [Section 9.1.3.10 Memory Protection](#).

9.1.3.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow n channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). [Table 9-18](#)

lists the registers in the shadow region memory map. Refer to *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Figure 9-14 illustrates the conceptual view of the regions.

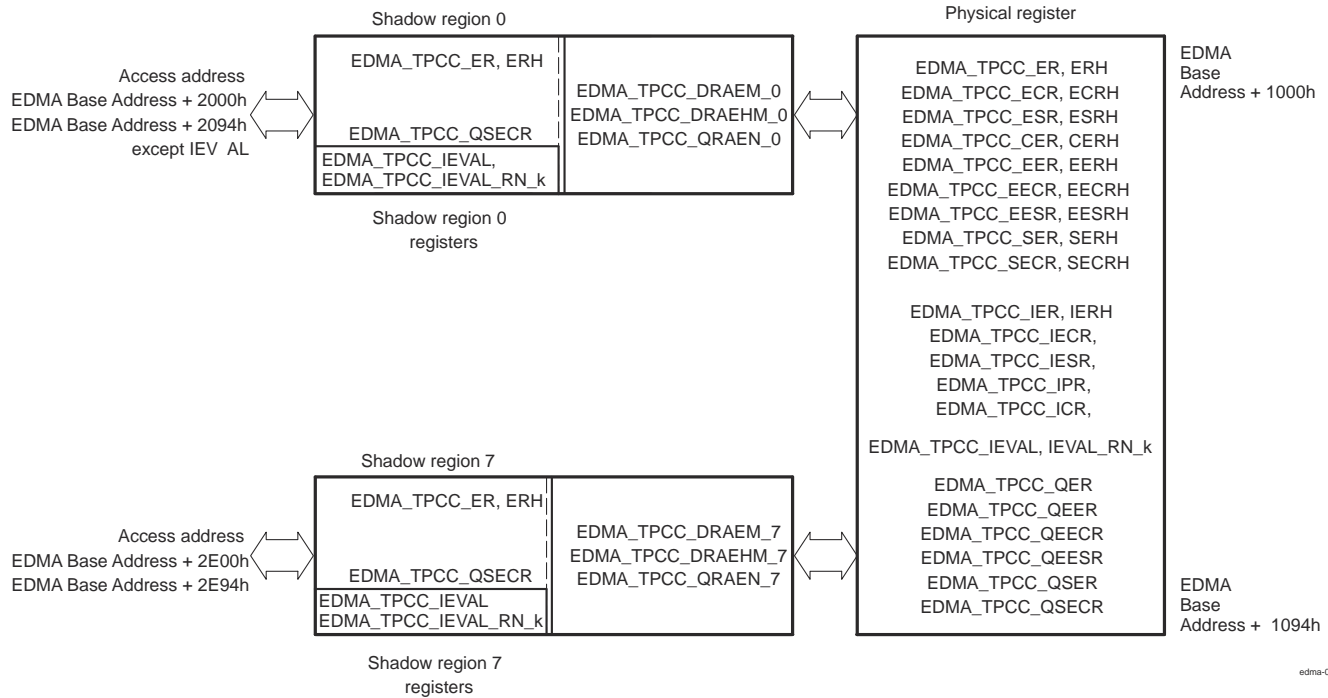

Figure 9-14. Shadow Region Registers

9.1.3.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMATPCC_DRAEM_k and EDMATPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMATPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMATPCC_DRAEM_k[31:0] / EDMATPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMATPCC_DRAEM_k[31:0] / EDMATPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMATPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMATPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMATPCC_QEESR there will be no the desired effect.
- EDMATPCC_MPPAN_k and EDMATPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMATPCC_DRAEM_k / EDMATPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMATPCC_DRAEM_k / EDMATPCC_QRAEN_k have the associated bit set.

Example 9-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

9.1.3.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to *Hardware Request* for more information about EDMA Interrupts.

9.1.3.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 9.1.3.3.7 Linking Transfers](#)). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see [Section 9.1.3.4.1.3 Chain-Triggered Transfer Request](#)).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel m (DMA/QDMA) required to chain to channel n . Channel number n (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel m channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel m is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 9-19 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 9-19. Chain Event Triggers

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

9.1.3.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 9-20. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 9-20. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2

EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 9-21. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

9.1.3.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See [Section 9.1.3.9.1.1 Enabling Transfer Completion Interrupts](#) for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 9-22. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set ⁽¹⁾
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 9-23 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 9-23. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

9.1.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

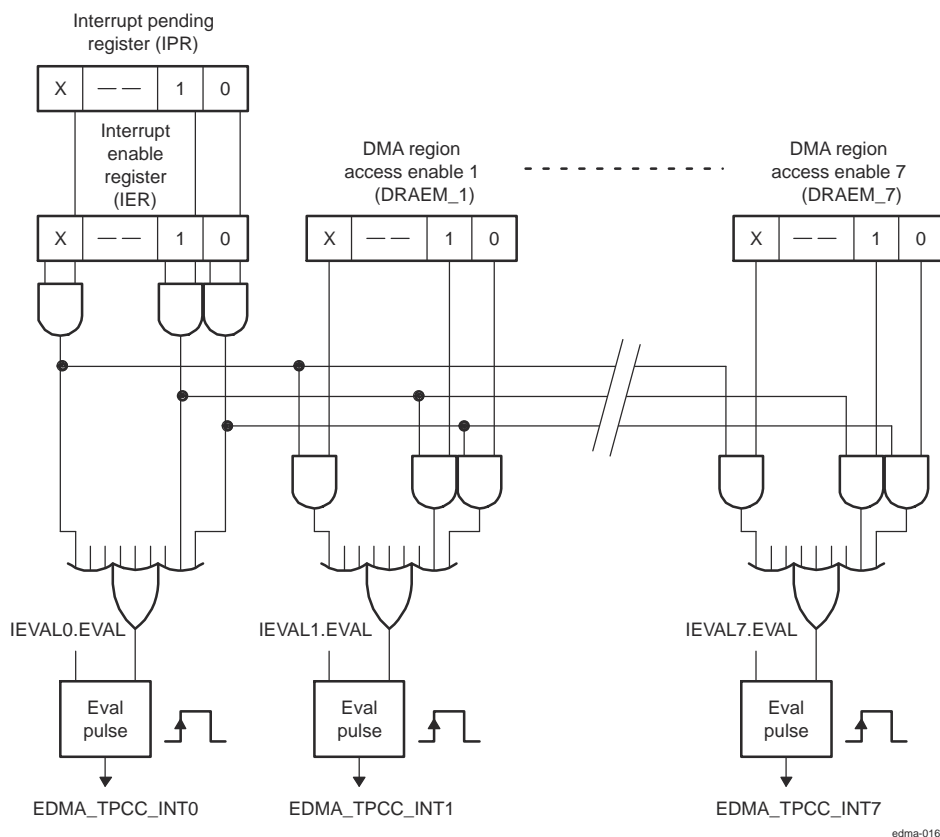

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see [Figure 9-15](#)

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

[Figure 9-15](#) shows the Interrupt diagram of the EDMA controller.

Figure 9-15. Interrupt Diagram

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | ...| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

Note

The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This means that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

9.1.3.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

9.1.3.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/ EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in [Example 9-2](#) and [Example 9-3](#).

The ISR routine in [Example 9-2](#) is more exhaustive and incurs a higher latency.

Example 9-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:

- a. If `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
- b. If `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` is equal to 0, assure that all of the enabled interrupts are inactive.

Note

An event may occur during step 4 while the `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

9.1.3.9.3

[Example 9-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 9-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the `EDMA_TPCC_IEVAL[0]` EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads `EDMA_TPCC_IPR / EDMA_TPCC_IPRH`.
3. For the condition that is set in `EDMA_TPCC_IPR / EDMA_TPCC_IPRH`:
 - a. Service interrupt as the application requires.
 - b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to `EDMA_TPCC` after step 2).
4. Reads `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` prior to exiting the ISR:
 - a. If `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` is equal to 0, then exit the ISR.
 - b. If `EDMA_TPCC_IPR / EDMA_TPCC_IPRH` is not equal to 0, then set `EDMA_TPCC_IEVAL` so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

9.1.3.9.4 Interrupt Evaluation Operations

The `EDMA_TPCC` has interrupt evaluate registers `EDMA_TPCC_IEVAL` that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers `EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k`. Writing a 1 to the `EDMA_TPCC_IEVAL[0]` EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via `EDMA_TPCC_IER / EDMA_TPCC_IERH`) is still pending `EDMA_TPCC_IPR / EDMA_TPCC_IPRH`. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to [Example 9-3](#) about the use of `EDMA_TPCC_IEVAL` in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register `EDMA_TPCC_EEVAL` exists in the global region. Writing a 1 to the `EDMA_TPCC_EEVAL[0]` EVAL bit causes the pulsing of the error interrupt if any pending errors are in `EDMA_TPCC_EMR / EDMA_TPCC_EMRH`, `EDMA_TPCC_QEMR`, or `EDMA_TPCC_CCERR`. See [Section 9.1.3.9.5 Error Interrupts](#) for additional information regarding error interrupts.

Note

While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

9.1.3.9.5 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

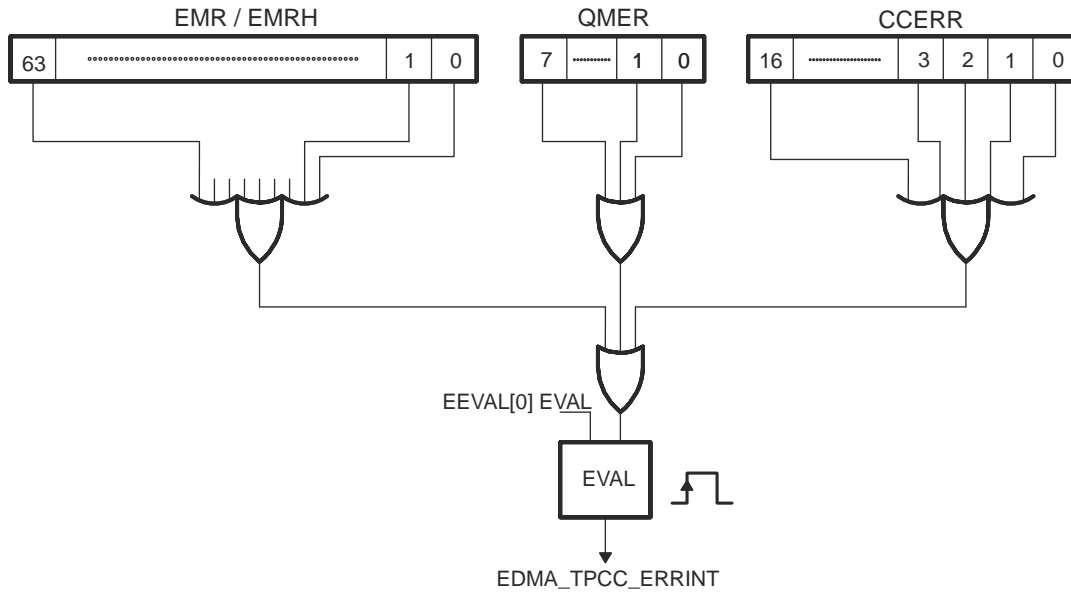

Figure 9-16 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with '1' after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

Note

It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

Figure 9-16. Error Interrupt Operation

9.1.3.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

9.1.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to [Section 9.1.7](#).

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

[Table 9-24](#) shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 9-24. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 9-25](#) describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 9-25. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect ⁽¹⁾	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k. MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 9-26. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k N_k (offset 0x082C)	0x0000 04B0 X	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1. Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example Access Allowed

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesses to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.
6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 9-27. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√	Access allowed.
	↓	
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2	DMA Region Access Enable Filter
	↓	
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
	↓	
EDMA_TPCC_EER (offset 0x1020)	0xBC0 0102	Final value of EER.

9.1.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in [Figure 9-17](#).

Figure 9-17. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT_n) Content

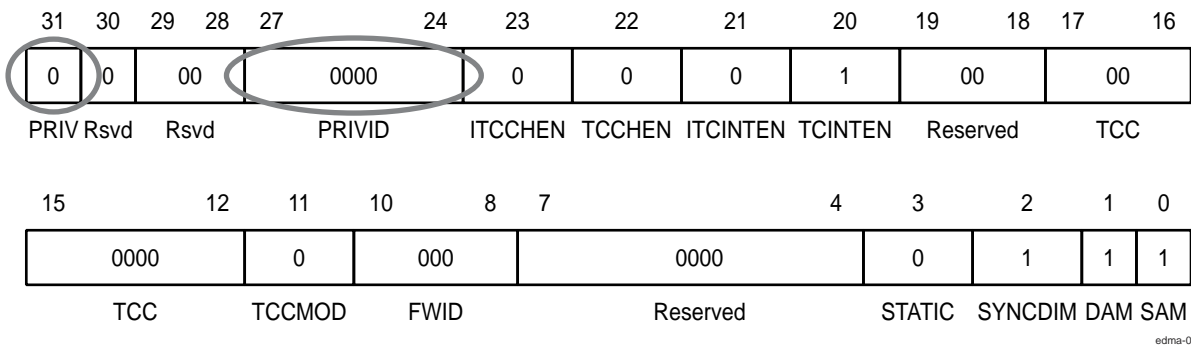

Figure 9-18. Channel Options Parameter (OPT) Example

The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 9-19 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

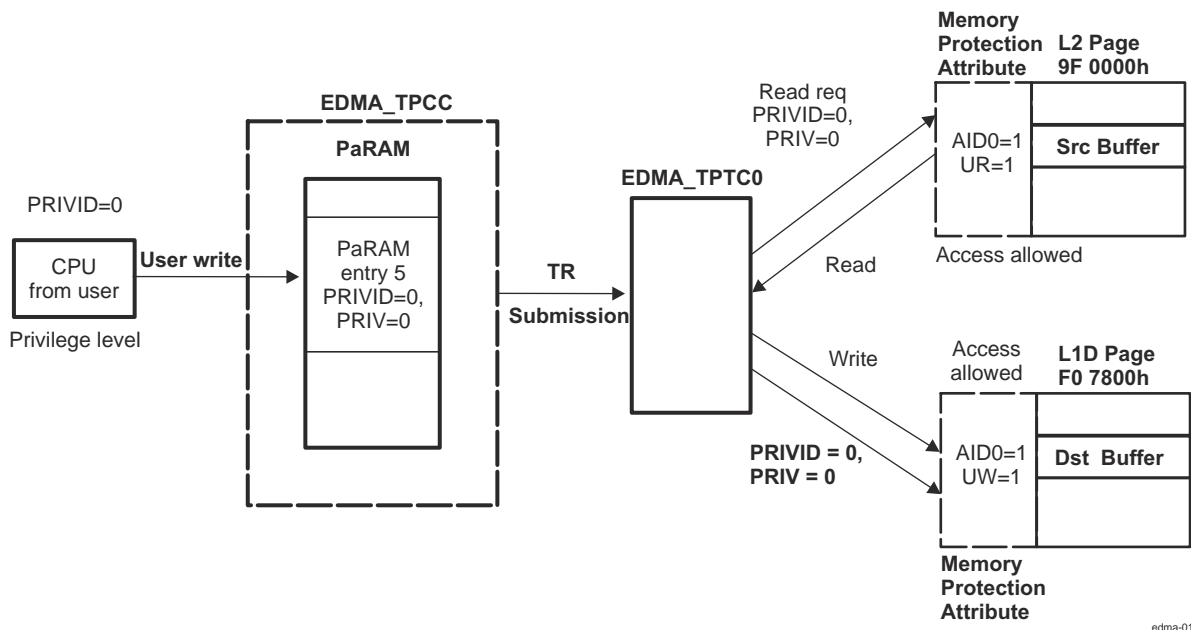

Figure 9-19. Proxy Memory Protection Example

9.1.3.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to [Section 9.1.3.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to [Section 9.1.7](#) for EDMA_TPCC_Q0E_p / EDMA_TPCC_Q1E_p descriptions of the bit fields.

9.1.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to [Section 9.1.3.11.4 System-level Performance Considerations](#).

Note

If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

9.1.3.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (QxEy Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT n EDMA_TPCC_QSTATN $_i$) includes fields for the start pointer EDMA_TPCC_QSTATN $_i$ [3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN $_i$ [12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN $_i$ [3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN $_i$ [12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

9.1.3.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programmed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN $_i$ [20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN $_i$ [12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRCD n bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN $_i$ [24] THRCD bit, where n stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

9.1.3.11.4 Performance Considerations

The device system bus infrastructure arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to *Control Module Register Manual* in the *Control Module* chapter).

9.1.3.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

9.1.3.12.1 Architecture Details

9.1.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in the *TPTC DBS Configuration registers*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT $_n$ [15:0] ACNT and EDMA_TPCC_ABCNT $_n$ [31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 9-28](#) lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT $_n$ [15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the

EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

[Table 9-28](#) lists conditions in which the optimizations are performed.

Table 9-28. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

9.1.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 9-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8,
EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10,
EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1,
EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

9.1.3.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

9.1.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

9.1.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

9.1.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

Note

If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

9.1.3.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

9.1.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]En / EDMA_TPCC_ERH[31:0] En (or EDMA_TPCC_CER[31:0] En / EDMA_TPCC_CERH[31:0] En, EDMA_TPCC_ESR[31:0] En / EDMA_TPCC_ESRH[31:0] En, EDMA_TPCC_QER[7:0] En) bit.

2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] *En* \ EDMA_TPCC_SERH[31:0] *En* (or EDMA_TPCC_QSER[7:0] *En*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] *En*/ EDMA_TPCC_ERH[31:0] *En* (or EDMA_TPCC_CER[31:0] *En* / EDMA_TPCC_CERH[31:0] *En*, EDMA_TPCC_ESR[31:0] *En* / EDMA_TPCC_ESRH[31:0] *En*, EDMA_TPCC_QER[31:0] *En*) bit and the EDMA_TPCC_SER[31:0] *En*/ EDMA_TPCC_SERH[31:0] *En* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] *En*/ EDMA_TPCC_SERH[31:0] *En* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC_n.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC_n then signals completion status to the EDMA_TPCC.

9.1.3.14 EDMA Controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 9-20](#) shows the different places EDMA priorities come into play.

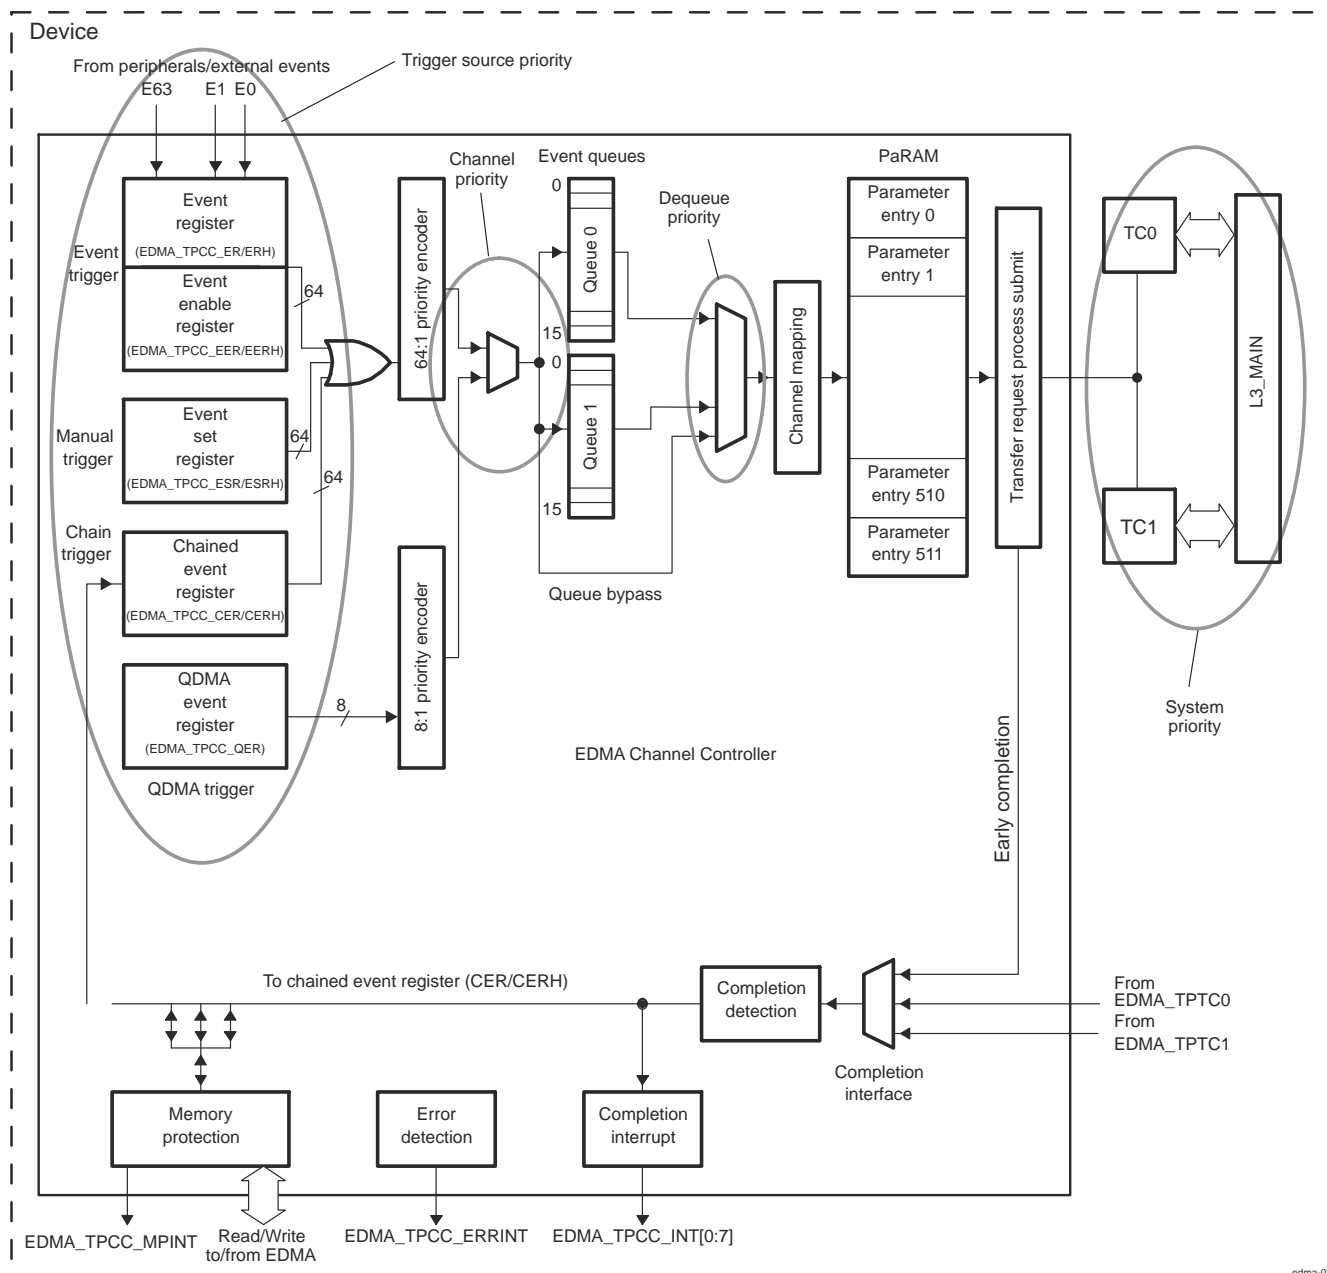

Figure 9-20. EDMA Prioritization

9.1.3.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

9.1.3.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] $E_n = 1$, EDMA_TPCC_ESR[31:0] $E_n = 1$, EDMA_TPCC_CER[31:0] $E_n = 1$), then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] $E_0 = 1$ and EDMA_TPCC_CER[0] $E_0 = 1$ at the same time, then the EDMA_TPCC_ER[0] E_0 event is always queued before the EDMA_TPCC_CER[0] E_0 event.

9.1.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

9.1.3.15 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

9.1.4 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

9.1.4.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in [Figure 9-21](#).

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in [Figure 9-22](#) holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programmed to be the highest numbered offset in the PaRAM set that undergoes change.

[Figure 9-22](#) shows the parameters Block Move transfer.

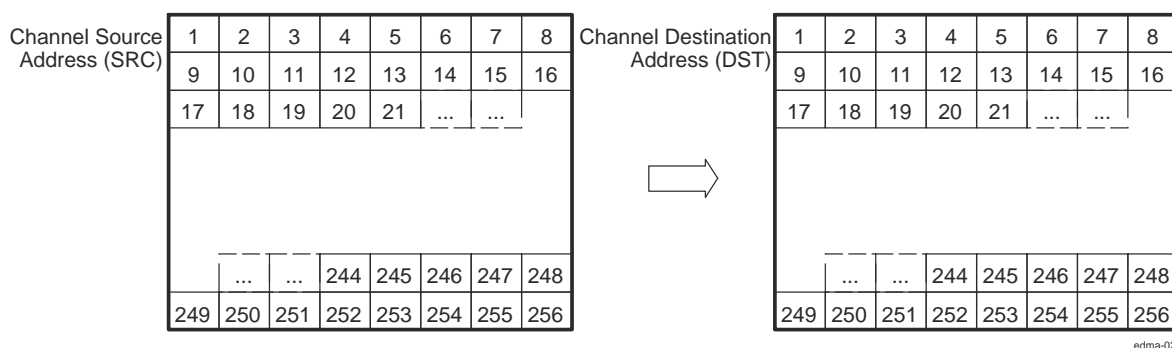

Figure 9-21. Block Move Example

Figure 9-22. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0008h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0001h	0100h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0000h	0000h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

9.1.4.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 9-23 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 9-24 shows the parameters for Subframe Extraction transfer.

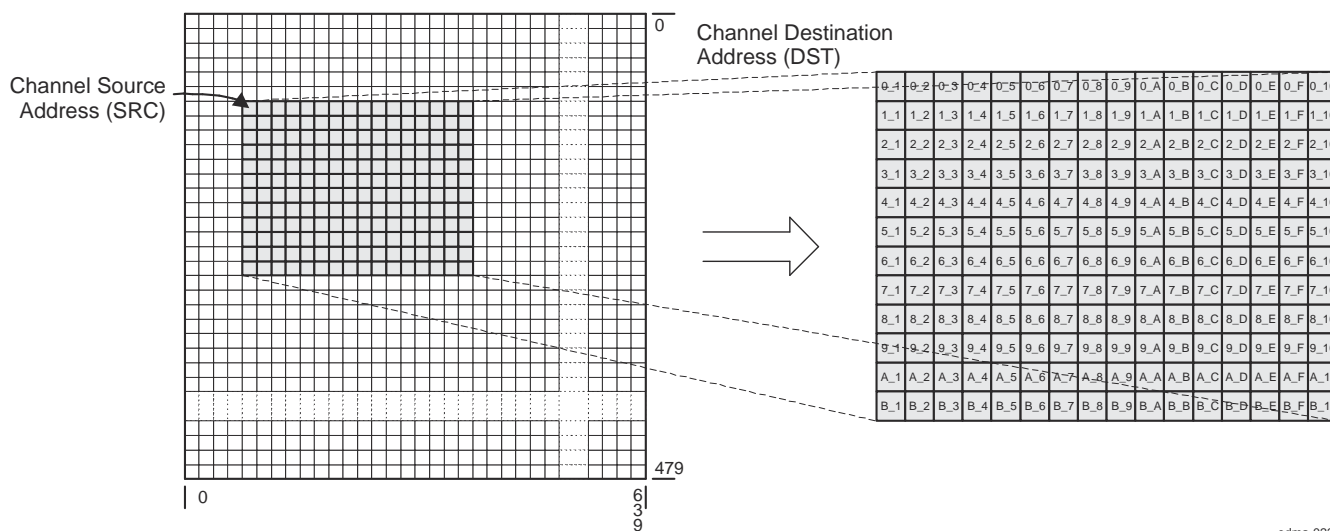

Figure 9-23. Subframe Extraction Transfer

Figure 9-24. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 000Ch		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
000Ch	0020h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0020h	0500h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

9.1.4.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 9-26 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 9-25 shows the Data Sorting transfer

Figure 9-25. Data Sorting Example

Figure 9-26. Data Sorting Example PaRAM Configuration
(a) EDMA Parameters

Parameter Contents		Parameter	
0090 0004h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0400h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0010h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0004h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1
- EDMA_TPCC_OPT_n[23] ITCCHEN = 0x1

9.1.4.4 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel
 - a. Determine the type of channel (QDMA or DMA) to be used.
 - b. Channel mapping
 - i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
 - ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
 - c. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 9.1.3.7.1.](#))
 - d. Determine the type of triggering used.
 - i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
 - ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
 - e. Queue setup
 - i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
 - ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.
2. Parameter set setup
 - a. Program the PaRAM set number associated with the channel. Note that

Note

If it is a QDMA channel, the PaPARAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

3. Interrupt setup
 - a. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
 - b. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
 - c. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
 - d. Set up the interrupt controller properly to receive the expected EDMA interrupt.
4. Initiate transfer
 - a. This step is highly dependent on the event trigger source:
 - i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
 - ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
 - iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
 - iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.
5. Wait for completion
 - a. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits

- in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.
- b. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

9.1.5 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

9.1.5.1 EDMA Debug Checklist

Table 9-29 provides some common issues and their probable causes and resolutions.

Table 9-29. Debug Checklist

Issue	Description/Solution
<p>The transfer associated with the channel does not happen. The channel does not get serviced.</p>	<p>The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
<p>The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.</p>	<p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] En and EDMA_TPCC_EMER[31:0] En set, preventing further event prioritization. <p>Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMER / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.</p>

Table 9-29. Debug Checklist (continued)

Issue	Description/Solution
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	<p>Check the following:</p> <ol style="list-style-type: none"> 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 9.1.3.9.1.2 Clearing Transfer Completion Interrupts for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).</p>

9.1.5.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAE / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

9.1.6 EDMA Event Map

9.1.7 EDMA Registers

9.1.7.1 TPCC Registers

Table 9-30 lists the TPCC registers. All register offset addresses not listed in Table 9-30 should be considered as reserved locations and the register contents should not be modified.

Table 9-30. TPCC Registers

Offset	Acronym	Register Name	Section
0h	PID	PID	Section 9.1.7.1.1
4h	CCCFG	CCCFG	Section 9.1.7.1.2
200h	QCHMAPN	QCHMAPN	Section 9.1.7.1.3
240h	DMAQNUMN	DMAQNUMN	Section 9.1.7.1.4
260h	QDMAQNUM	QDMAQNUM	Section 9.1.7.1.5
280h	QUETCMAP	QUETCMAP	Section 9.1.7.1.6
284h	QUEPRI	QUEPRI	Section 9.1.7.1.7
300h	EMR	EMR	Section 9.1.7.1.8
304h	EMRH	EMRH	Section 9.1.7.1.9
308h	EMCR	EMCR	Section 9.1.7.1.10
30Ch	EMCRH	EMCRH	Section 9.1.7.1.11
310h	QEMR	QEMR	Section 9.1.7.1.12
314h	QEMCR	QEMCR	Section 9.1.7.1.13
318h	CCERR	CCERR	Section 9.1.7.1.14
31Ch	CCERRCLR	CCERRCLR	Section 9.1.7.1.15
320h	EEVAL	EEVAL	Section 9.1.7.1.16
340h	DRAEM	DRAEM	Section 9.1.7.1.17
344h	DRAEHM	DRAEHM	Section 9.1.7.1.18
380h	QRAEN	QRAEN	Section 9.1.7.1.19
400h	QNE0	QNE0	Section 9.1.7.1.20
404h	QNE1	QNE1	Section 9.1.7.1.21
408h	QNE2	QNE2	Section 9.1.7.1.22
40Ch	QNE3	QNE3	Section 9.1.7.1.23
410h	QNE4	QNE4	Section 9.1.7.1.24
414h	QNE5	QNE5	Section 9.1.7.1.25
418h	QNE6	QNE6	Section 9.1.7.1.26
41Ch	QNE7	QNE7	Section 9.1.7.1.27
420h	QNE8	QNE8	Section 9.1.7.1.28
424h	QNE9	QNE9	Section 9.1.7.1.29
428h	QNE10	QNE10	Section 9.1.7.1.30
42Ch	QNE11	QNE11	Section 9.1.7.1.31
430h	QNE12	QNE12	Section 9.1.7.1.32
434h	QNE13	QNE13	Section 9.1.7.1.33
438h	QNE14	QNE14	Section 9.1.7.1.34
43Ch	QNE15	QNE15	Section 9.1.7.1.35
600h	QSTATN	QSTATN	Section 9.1.7.1.36
620h	QWMTHRA	QWMTHRA	Section 9.1.7.1.37
640h	CCSTAT	CCSTAT	Section 9.1.7.1.38
700h	AETCTL	AETCTL	Section 9.1.7.1.39
704h	AETSTAT	AETSTAT	Section 9.1.7.1.40
708h	AETCMD	AETCMD	Section 9.1.7.1.41
1000h	ER	ER	Section 9.1.7.1.42

Table 9-30. TPCC Registers (continued)

Offset	Acronym	Register Name	Section
1004h	ERH	ERH	Section 9.1.7.1.43
1008h	ECR	ECR	Section 9.1.7.1.44
100Ch	ECRH	ECRH	Section 9.1.7.1.45
1010h	ESR	ESR	Section 9.1.7.1.46

9.1.7.1.1 PID Register (Offset = 0h) [reset = 4001AB00h]

PID is shown in [Figure 9-27](#) and described in [Table 9-31](#).

Return to the [Table 9-30](#).

Peripheral ID Register

Figure 9-27. PID Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCHEME		RES1		FUNC											
R-1h		R-0h		R-1h											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTL				MAJOR			CUSTOM			MINOR					
R-15h				R-3h			R-0h			R-0h					

Table 9-31. PID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	PID Scheme: Used to distinguish between old ID scheme and current. Spare bit to encode future schemes EDMA uses 'new scheme' indicated with value of 0x1.
29-28	RES1	R	0h	RESERVE FIELD
27-16	FUNC	R	1h	Function indicates a software compatible module family.
15-11	RTL	R	15h	RTL Version
10-8	MAJOR	R	3h	Major Revision
7-6	CUSTOM	R	0h	Custom revision field: Not used on this version of EDMA.
5-0	MINOR	R	0h	Minor Revision

9.1.7.1.2 CCCFG Register (Offset = 4h) [reset = 00213445h]

CCCFG is shown in [Figure 9-28](#) and described in [Table 9-32](#).

Return to the [Table 9-30](#).

CC Configuration Register

Figure 9-28. CCCFG Register

31	30	29	28	27	26	25	24
RES2						MPEXIST	CHMAPEXIST
R-0h						R-0h	R-0h
23	22	21	20	19	18	17	16
RES3		NUMREGN		RES4	NUMTC		
R-0h		R-2h		R-0h	R-1h		
15	14	13	12	11	10	9	8
RES5	NUMPAENTRY			RES6	NUMINTCH		
R-0h		R-3h		R-0h	R-4h		
7	6	5	4	3	2	1	0
RES7	NUMQDMACH			RES8	NUMDMACH		
R-0h		R-4h		R-0h	R-5h		

Table 9-32. CCCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RES2	R	0h	RESERVE FIELD
25	MPEXIST	R	0h	Memory Protection Existence MPEXIST = 0 : No memory protection. MPEXIST = 1 : Memory Protection logic included.
24	CHMAPEXIST	R	0h	Channel Mapping Existence CHMAPEXIST = 0 : No Channel mapping. CHMAPEXIST = 1 : Channel mapping logic included.
23-22	RES3	R	0h	RESERVE FIELD
21-20	NUMREGN	R	2h	Number of MP and Shadow regions
19	RES4	R	0h	RESERVE FIELD
18-16	NUMTC	R	1h	Number of Queues/Number of TCs
15	RES5	R	0h	RESERVE FIELD
14-12	NUMPAENTRY	R	3h	Number of PaRAM entries
11	RES6	R	0h	RESERVE FIELD
10-8	NUMINTCH	R	4h	Number of Interrupt Channels
7	RES7	R	0h	RESERVE FIELD
6-4	NUMQDMACH	R	4h	Number of QDMA Channels
3	RES8	R	0h	RESERVE FIELD
2-0	NUMDMACH	R	5h	Number of DMA Channels

9.1.7.1.3 QCHMAPN Register (Offset = 200h) [reset = 0h]

QCHMAPN is shown in [Figure 9-29](#) and described in [Table 9-33](#).

Return to the [Table 9-30](#).

QDMA Channel N Mapping Register

Figure 9-29. QCHMAPN Register

31	30	29	28	27	26	25	24
RES10							
R-0h							
23	22	21	20	19	18	17	16
RES10							
R-0h

RES10		PAENTRY					
R-0h		R/W-0h					
7	6	5	4	3	2	1	0
PAENTRY			TRWORD			RESERVED	
R/W-0h			R/W-0h			R-	

Table 9-33. QCHMAPN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RES10	R	0h	RESERVE FIELD
13-5	PAENTRY	R/W	0h	PaRAM Entry number for QDMA Channel N.
4-2	TRWORD	R/W	0h	TRWORD points to the specific trigger word of the PaRAM Entry defined by PAENTRY. A write to the trigger word results in a QDMA Event being recognized.
1-0	RESERVED	R	0h	

9.1.7.1.4 DMAQNUMN Register (Offset = 240h) [reset = 0h]

DMAQNUMN is shown in [Figure 9-30](#) and described in [Table 9-34](#).

Return to the [Table 9-30](#).

DMA Queue Number Register n Contains the Event queue number to be used for the corresponding DMA Channel.

Figure 9-30. DMAQNUMN Register

R-0h		R/W-0h		R-0h		R/W-0h	

Table 9-34. DMAQNUMN Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RES11	R	0h	RESERVE FIELD
30-28	E7	R/W	0h	DMA Queue Number for event #7
27	RES12	R	0h	RESERVE FIELD
26-24	E6	R/W	0h	DMA Queue Number for event #6
23	RES13	R	0h	RESERVE FIELD
22-20	E5	R/W	0h	DMA Queue Number for event #5
19	RES14	R	0h	RESERVE FIELD
18-16	E4	R/W	0h	DMA Queue Number for event #4
15	RES15	R	0h	RESERVE FIELD
14-12	E3	R/W	0h	DMA Queue Number for event #3
11	RES16	R	0h	RESERVE FIELD
10-8	E2	R/W	0h	DMA Queue Number for event #2
7	RES17	R	0h	RESERVE FIELD
6-4	E1	R/W	0h	DMA Queue Number for event #1
3	RES18	R	0h	RESERVE FIELD
2-0	E0	R/W	0h	DMA Queue Number for event #0

9.1.7.1.5 QDMAQNUM Register (Offset = 260h) [reset = 0h]

QDMAQNUM is shown in [Figure 9-31](#) and described in [Table 9-35](#).

Return to the [Table 9-30](#).

QDMA Queue Number Register Contains the Event queue number to be used for the corresponding QDMA Channel.

Figure 9-31. QDMAQNUM Register

31	30	29	28	27	26	25	24
RES19	E7			RES20	E6

R-0h		R/W-0h		R-0h		R/W-0h	

Table 9-35. QDMAQNUM Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RES19	R	0h	RESERVE FIELD
30-28	E7	R/W	0h	QDMA Queue Number for event #7
27	RES20	R	0h	RESERVE FIELD
26-24	E6	R/W	0h	QDMA Queue Number for event #6
23	RES21	R	0h	RESERVE FIELD
22-20	E5	R/W	0h	QDMA Queue Number for event #5
19	RES22	R	0h	RESERVE FIELD
18-16	E4	R/W	0h	QDMA Queue Number for event #4
15	RES23	R	0h	RESERVE FIELD
14-12	E3	R/W	0h	QDMA Queue Number for event #3
11	RES24	R	0h	RESERVE FIELD
10-8	E2	R/W	0h	QDMA Queue Number for event #2
7	RES25	R	0h	RESERVE FIELD
6-4	E1	R/W	0h	QDMA Queue Number for event #1
3	RES26	R	0h	RESERVE FIELD
2-0	E0	R/W	0h	QDMA Queue Number for event #0

9.1.7.1.6 QUETCMAP Register (Offset = 280h) [reset = 10h]

QUETCMAP is shown in [Figure 9-32](#) and described in [Table 9-36](#).

Return to the [Table 9-30](#).

Queue to TC Mapping

7	6	5	4	3	2	1	0
RES29	PRIQ1			RES30	PRIQ0		
R-0h	R/W-0h			R-0h	R/W-0h		

Table 9-37. QUEPRI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RES29	R	0h	RESERVE FIELD
6-4	PRIQ1	R/W	0h	Priority Level for Queue 1 Dictates the priority level used for the OPTIONS field programming for Qn TRs. Sets the priority used for TC read and write commands.
3	RES30	R	0h	RESERVE FIELD
2-0	PRIQ0	R/W	0h	Priority Level for Queue 0 Dictates the priority level used for the OPTIONS field programming for Qn TRs. Sets the priority used for TC read and write commands.

9.1.7.1.8 EMR Register (Offset = 300h) [reset = 0h]

EMR is shown in [Figure 9-34](#) and described in [Table 9-38](#).

Return to the [Table 9-30](#).

Event Missed Register: The Event Missed register is set if 2 events are received without the first event being cleared or if a Null TR is serviced. Chained events (CER) Set Events (ESR) and normal events (ER) are treated individually. If any bit in the EMR register is set (and all errors (including QEMR/CCERR) were previously clear) then an error will be signaled with TPCC error interrupt.

Figure 9-34. EMR Register

9.1.7.1.9 EMRH Register (Offset = 304h) [reset = 0h]

EMRH is shown in [Figure 9-35](#) and described in [Table 9-39](#).

Return to the [Table 9-30](#).

Event Missed Register (High Part): The Event Missed register is set if 2 events are received without the first event being cleared or if a Null TR is serviced. Chained events (CER) Set Events (ESR) and normal events (ER) are treated individually. If any bit in the EMR register is set (and all errors (including QEMR/CCERR) were previously clear) then an error will be signaled with TPCC error interrupt.

Table 9-44. CCERR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	RES33	R	0h	RESERVE FIELD
16	TCERR	R	0h	Transfer Completion Code Error: TCCERR = 0 : Total number of allowed TCCs outstanding has not been reached. TCCERR = 1 : Total number of allowed TCCs has been reached. TCCERR can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors were previously clear) then an error will be signaled with TPCC error interrupt.
15-8	RES34	R	0h	RESERVE FIELD
7	QTHRXC7	R	0h	Queue Threshold Error for Q7: QTHRXC7 = 0 : Watermark/ threshold has not been exceeded. QTHRXC7 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXC7 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
6	QTHRXC6	R	0h	Queue Threshold Error for Q6: QTHRXC6 = 0 : Watermark/ threshold has not been exceeded. QTHRXC6 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXC6 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

Table 9-44. CCERR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	QTHRCD5	R	0h	Queue Threshold Error for Q5: QTHRCD5 = 0 : Watermark/ threshold has not been exceeded. QTHRCD5 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD5 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
4	QTHRCD4	R	0h	Queue Threshold Error for Q4: QTHRCD4 = 0 : Watermark/ threshold has not been exceeded. QTHRCD4 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD4 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
3	QTHRCD3	R	0h	Queue Threshold Error for Q3: QTHRCD3 = 0 : Watermark/ threshold has not been exceeded. QTHRCD3 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD3 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
2	QTHRCD2	R	0h	Queue Threshold Error for Q2: QTHRCD2 = 0 : Watermark/ threshold has not been exceeded. QTHRCD2 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD2 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
1	QTHRCD1	R	0h	Queue Threshold Error for Q1: QTHRCD1 = 0 : Watermark/ threshold has not been exceeded. QTHRCD1 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD1 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
0	QTHRCD0	R	0h	Queue Threshold Error for Q0: QTHRCD0 = 0 : Watermark/ threshold has not been exceeded. QTHRCD0 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRCD0 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

9.1.7.1.15 CCERRCLR Register (Offset = 31Ch) [reset = 0h]

CCERRCLR is shown in [Figure 9-41](#) and described in [Table 9-45](#).

Return to the [Table 9-30](#).

1	SET	W	0h	Error Interrupt Set: CPU write of '1' to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of EMR/EMRH QEMR or CCERR. CPU write of '0' has no effect.
0	EVAL	W	0h	Error Interrupt Evaluate: CPU write of '1' to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the EMR/EMRH QEMR or CCERR registers. CPU write of '0' has no effect.

9.1.7.1.17 DRAEM Register (Offset = 340h) [reset = 0h]

DRAEM is shown in [Figure 9-43](#) and described in [Table 9-47](#).

Return to the [Table 9-30](#).

DMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt.

15-14	RES62	R	0h	RESERVE FIELD

Table 9-68. CCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-8	COMPACTV	R	0h	Completion Request Active: Counter that tracks the total number of completion requests submitted to the TC. The counter increments when a TR is submitted with TCINTEN or TCCHEN set to '1'. The counter decrements for every valid completion code received from any of the external TCs. The CC will not service new TRs if COMPACTV count is already at the limit. COMPACTV = 0 : No completion requests outstanding. COMPACTV = 1 : Total of '1' completion request outstanding. ... COMPACTV = 63 : Total of 63 completion requests are outstanding. No additional TRs will be submitted until count is less than 63.
7-5	RES63	R	0h	RESERVE FIELD
4	ACTV	R	0h	Channel Controller Active: Channel Controller Active is a logical-OR of each of the ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0 : Channel is idle. ACTV = 1 : Channel is busy.
3	RES64	R	0h	RESERVE FIELD
2	TRACTV	R	0h	Transfer Request Active: TRACTV = 0 : Transfer Request processing/submission logic is inactive. TRACTV = 1 : Transfer Request processing/submission logic is active.
1	QEVACTV	R	0h	QDMA Event Active: QEVACTV = 0 : No enabled QDMA Events are active within the CC. QEVACTV = 1 : At least one enabled DMA Event (ER & EER ESR CER) is active within the CC.
0	EVTACTV	R	0h	DMA Event Active: EVTACTV = 0 : No enabled DMA Events are active within the CC. EVTACTV = 1 : At least one enabled DMA Event (ER & EER ESR CER) is active within the CC.

9.1.7.1.39 AETCTL Register (Offset = 700h) [reset = 0h]

AETCTL is shown in [Figure 9-65](#) and described in [Table 9-69](#).

Return to the [Table 9-30](#).

9.1.7.1.42 ER Register (Offset = 1000h) [reset = 0h]

ER is shown in [Figure 9-68](#) and described in [Table 9-72](#).

Return to the [Table 9-30](#).

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

9.1.7.1.48 CER Register (Offset = 1018h) [reset = 0h]

CER is shown in [Figure 9-74](#) and described in [Table 9-78](#).

Return to the [Table 9-30](#).

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

9.1.7.1.50 EER Register (Offset = 1020h) [reset = 0h]

EER is shown in [Figure 9-76](#) and described in [Table 9-80](#).

Return to the [Table 9-30](#).

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

9.1.7.1.51 EERH Register (Offset = 1024h) [reset = 0h]

EERH is shown in [Figure 9-77](#) and described in [Table 9-81](#).

Return to the [Table 9-30](#).

Event Enable Register (High Part): Enables DMA transfers for ERH.En pending events. ERH.En is set based on externally asserted events (via `tpcc_eventN_pi`). This register has no effect on Chained Event Register (CERH) or Event Set Register (ESRH). Note that if a bit is set in ERH.En while EERH.En is disabled no action is taken. If EERH.En is enabled at a later point (and ERH.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EERH.En is not directly writeable. Events can be enabled via writes to EESRH and can be disabled via writes to EECRH register. EERH.En = 0: ER.En is not enabled to trigger DMA transfers. EERH.En = 1: ER.En is enabled to trigger DMA transfers.

0	I32	W	0h	Interrupt associated with TCC #32

9.1.7.1.64 IESR Register (Offset = 1060h) [reset = 0h]

IESR is shown in [Figure 9-90](#) and described in [Table 9-94](#).

Return to the [Table 9-30](#).

Int Enable Set Register: CPU write of '1' to the IESR.In bit causes the IESR.In bit to be set. CPU write of '0' has no effect..

9.1.7.1.66 IPR Register (Offset = 1068h) [reset = 0h]

IPR is shown in [Figure 9-92](#) and described in [Table 9-96](#).

Return to the [Table 9-30](#).

Interrupt Pending Register: IPR.In bit is set when a interrupt completion code with TCC of N is detected. IPR.In bit is cleared via software by writing a '1' to ICR.In bit.

Figure 9-92. IPR Register

RES69						SET	EVAL
R-0h						W-0h	W-0h

Table 9-100. IEVAL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RES69	R	0h	RESERVE FIELD
1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

9.1.7.1.71 QER Register (Offset = 1080h) [reset = 0h]

QER is shown in [Figure 9-97](#) and described in [Table 9-101](#).

Return to the [Table 9-30](#).

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

Figure 9-97. QER Register

9.1.7.1.72 QEER Register (Offset = 1084h) [reset = 0h]

QEER is shown in [Figure 9-98](#) and described in [Table 9-102](#).

Return to the [Table 9-30](#).

QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. QEER.En is not directly writeable. QDMA channels can be enabled via writes to QEESR and can be disabled via writes to QEECR register. QEER.En = 1 The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in QER.En. QEER.En = 0 The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in QER.En.

9.1.7.1.77 ER_RN Register (Offset = 2000h) [reset = 0h]

ER_RN is shown in [Figure 9-103](#) and described in [Table 9-107](#).

Return to the [Table 9-30](#).

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

9.1.7.1.83 CER_RN Register (Offset = 2018h) [reset = 0h]

CER_RN is shown in [Figure 9-109](#) and described in [Table 9-113](#).

Return to the [Table 9-30](#).

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

9.1.7.1.85 EER_RN Register (Offset = 2020h) [reset = 0h]

EER_RN is shown in [Figure 9-111](#) and described in [Table 9-115](#).

Return to the [Table 9-30](#).

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

9.1.7.1.101 IPR_RN Register (Offset = 2068h) [reset = 0h]

IPR_RN is shown in [Figure 9-127](#) and described in [Table 9-131](#).

Return to the [Table 9-30](#).

Interrupt Pending Register: IPR.In bit is set when a interrupt completion code with TCC of N is detected. IPR.In bit is cleared via software by writing a '1' to ICR.In bit.

Table 9-135. IEVAL_RN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RES76	R	0h	RESERVE FIELD
1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

9.1.7.1.106 QER_RN Register (Offset = 2080h) [reset = 0h]

QER_RN is shown in [Figure 9-132](#) and described in [Table 9-136](#).

Return to the [Table 9-30](#).

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

9.1.7.1.107 QEER_RN Register (Offset = 2084h) [reset = 0h]

QEER_RN is shown in [Figure 9-133](#) and described in [Table 9-137](#).

Return to the [Table 9-30](#).

QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. QEER.En is not directly writeable. QDMA channels can be enabled via writes to QEESR and can be disabled via writes to QEECR register. QEER.En = 1 The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in QER.En. QEER.En = 0 The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in QER.En.

9.1.7.1.111 QSECR_RN Register (Offset = 2094h) [reset = 0h]

QSECR_RN is shown in [Figure 9-137](#) and described in [Table 9-141](#).

Return to the [Table 9-30](#).

QDMA Secondary Event Clear Register: The secondary event clear register is used to clear the status of the QSER and QER register (note that this is slightly different than the SER operation which does not clear the ER.En register). CPU write of '1' to the QSECR.En bit clears the QSER.En and QER.En register fields. CPU write of '0' has no effect..

Table 9-142. OPT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PRIV	R	0h	Privilege level: privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus. PRIV = 0 : User level privilege PRIV = 1 : Supervisor level privilege
30-28	RES83	R	0h	RESERVE FIELD
27-24	PRIVID	R	0h	Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus.
23	ITCCHEN	R/W	0h	Intermediate transfer completion chaining enable: 0: Intermediate transfer complete chaining is disabled. 1: Intermediate transfer complete chaining is enabled.
22	TCCHEN	R/W	0h	Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.
21	ITCINTEN	R/W	0h	Intermediate transfer completion interrupt enable: 0: Intermediate transfer complete interrupt is disabled. 1: Intermediate transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
20	TCINTEN	R/W	0h	Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
19	WIMODE	R/W	0h	Backward compatibility mode: 0: Normal operation 1 : WI Backwards Compatibility mode forces BCNT to be adjusted by '1' upon TR submission (0 means 1 1 means 2 ...) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)

Table 9-142. OPT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	RES84	R	0h	RESERVE FIELD
17-12	TCC	R/W	0h	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER (bit CER[TCC]) for chaining or in IER (bit IER[TCC]) for interrupts.
11	TCCMODE	R/W	0h	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .
10-8	FWID	R/W	0h	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.
7-4	RES85	R	0h	RESERVE FIELD
3	STATIC	R/W	0h	Static Entry: 0: Entry is updated as normal 1: Entry is static Count and Address updates are not updated after TRP is submitted. Linking is not performed.
2	SYNCDIM	R/W	0h	Transfer Synchronization Dimension: 0: A-Sync Each event triggers the transfer of ACNT elements. 1: AB-Sync Each event triggers the transfer of BCNT arrays of ACNT elements
1	DAM	R/W	0h	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO Dst addressing within an array wraps around upon reaching FIFO width.
0	SAM	R/W	0h	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR Src addressing within an array increments. Source is not a FIFO. 1: FIFO Src addressing within an array wraps around upon reaching FIFO width.

9.1.7.1.113 SRC Register (Offset = 4004h) [reset = 0h]

SRC is shown in [Figure 9-139](#) and described in [Table 9-143](#).

Return to the [Table 9-30](#).

Source Address

Figure 9-139. SRC Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC																															
R/W-0h																															

Table 9-143. SRC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SRC	R/W	0h	Source Address: The 32-bit source address parameters specify the starting byte address of the source . If SAM is set to FIFO mode then the user should program the Source address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.

9.1.7.1.114 ABCNT Register (Offset = 4008h) [reset = 0h]

ABCNT is shown in [Figure 9-140](#) and described in [Table 9-144](#).

Return to the [Table 9-30](#).

A and B byte count

Figure 9-140. ABCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															
R/W-0h																R/W-0h															

Table 9-144. ABCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNT	R/W	0h	BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation valid values for BCNT can be anywhere between 1 and 65535. Therefore the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame and BCNT=0 means 0 arrays in the frame. In normal mode a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the programmed BCNT value will be incremented by '1' before submission to TC. I.e. 0 means 1 1 means 2 2 means 3 ...
15-0	ACNT	R/W	0h	ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0 it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition the ACNT definition will disregard the 2 msbits. I.e. a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer resulting in null or dummy operation dependent on the state of BCNT and CCNT.

9.1.7.1.115 DST Register (Offset = 400Ch) [reset = 0h]

DST is shown in [Figure 9-141](#) and described in [Table 9-145](#).

Return to the [Table 9-30](#).

Table 9-145. DST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DST	R/W	0h	Destination Address: The 32-bit destination address parameters specify the starting byte address of the destination. If DAM is set to FIFO mode then the user should program the Destination address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.

9.1.7.1.116 BIDX Register (Offset = 4010h) [reset = 0h]

BIDX is shown in [Figure 9-142](#) and described in [Table 9-146](#).

Return to the [Table 9-30](#).

Register description is not available

Figure 9-142. BIDX Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBIDX																SBIDX															
R/W-0h																R/W-0h															

Table 9-146. BIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DBIDX	R/W	0h	Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2's complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.
15-0	SBIDX	R/W	0h	Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2's complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.

9.1.7.1.117 LNK Register (Offset = 4014h) [reset = 0h]

LNK is shown in [Figure 9-143](#) and described in [Table 9-147](#).

Return to the [Table 9-30](#).

Link and Reload parameters

Figure 9-143. LNK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															
R/W-0h																R/W-0h															

Table 9-147. LNK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNTRLD	R/W	0h	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT not thus BCNTRLD is a don't care field.
15-0	LINK	R/W	0h	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e. after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore if the user uses the literal address with a range from 0x4000 to 0x7FFF it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000 thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsb) behavior is undefined for the user (i.e. don't have to test it). In the former case (2 msbs) user should be able to take advantage of this feature (i.e. do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid/Secure state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e. a value of 0x3FFE is a non-NUL PaRAM link field.

9.1.7.1.118 CIDX Register (Offset = 4018h) [reset = 0h]

CIDX is shown in [Figure 9-144](#) and described in [Table 9-148](#).

Return to the [Table 9-30](#).

Register description is not available

Figure 9-144. CIDX Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCIDX																SCIDX															
R/W-0h																R/W-0h															

Table 9-148. CIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DCIDX	R/W	0h	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a ABsync transfer is the first array in the frame.
15-0	SCIDX	R/W	0h	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a AB-sync transfer is the first array in the frame.

9.1.7.1.119 CCNT Register (Offset = 401Ch) [reset = 0h]

CCNT is shown in [Figure 9-145](#) and described in [Table 9-149](#).

Return to the [Table 9-30](#).

C byte count

Figure 9-145. CCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES86																CCNT															
R-0h																R/W-0h															

Table 9-149. CCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RES86	R	0h	RESERVE FIELD
15-0	CCNT	R/W	0h	CCNT : Count for 3rd Dimension: CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT can be anywhere between 1 and 65535. Therefore the maximum number of frames in a block is 65535 (64K-1 frames). CCNT of '1' means '1' frame in the block and CCNT of '0' means '0' frames in the block. A CCNT value of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. WIMODE has no affect on CCNT operation.

9.1.7.2 TPTC Registers

Table 9-150 lists the TPTC registers. All register offset addresses not listed in Table 9-150 should be considered as reserved locations and the register contents should not be modified.

Table 9-153. TCSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	X	
13-12	DFSTRTPTR	R	0h	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO in units of entries. Legal values = 0x0 to 0x3
11-9	RESERVED	R	X	
8	ACTV	R	1h	Channel Active Channel Active is a logical-OR of each of the BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0 : Channel is idle. ACTV = 1 : Channel is busy.
7	RESERVED	R	X	
6-4	DSTACTV	R	0h	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter.
3	RESERVED	R	X	
2	WSACTV	R	0h	Write Status Active WSACTV = 0 : Write status is not pending. Write status has been received for all previously issued write commands. WSACTV = 1 : Write Status is pending. Write status has not been received for all previously issued write commands.

Table 9-153. TCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SRCACTV	R	0h	Source Active State SRCACTV = 0 : Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full [DSTFULL == 1]. SRCACTV = 1 : Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.
0	PROGBUSY	R	0h	Program Register Set Busy PROGBUSY = 0 : Prog set idle and is available for programming. PROGBUSY = 1 : Prog set busy. User should poll for PROGBUSY equal to '0' prior to re-programming the Program Register set.

9.1.7.2.4 INTSTAT Register (Offset = 104h) [reset = X]

INTSTAT is shown in [Figure 9-149](#) and described in [Table 9-154](#).

Return to the [Table 9-150](#).

10.1 General Connectivity Peripherals

10.1.1 General-Purpose Input/Output (GIO) Module

This chapter describes the general-purpose input/output (GIO) module. The GIO module provides the family of devices with input/output (I/O) capability. The I/O pins are bidirectional and bit-programmable. The GIO module also supports external interrupt capability.

Note

The "GIO" module is also known as the "GPIO" module in other TI MCU and MPU devices. The two terms are used interchangeably and represent the general use I/O module of the device.

10.1.1.1 Overview.....	2494
10.1.1.2 Quick Start Guide.....	2495
10.1.1.3 Functional Description of GIO Module.....	2497
10.1.1.4 Device Modes of Operation.....	2500
10.1.1.5 MSS_GIO Registers.....	2501
10.1.1.6 I/O Control Summary.....	2588

10.1.1.1 Overview

The GIO module offers general-purpose input and output capability. It supports up to eight 8-bit ports for a total of up to 64 GIO terminals. Each of these 64 terminals can be independently configured as input or output and configured as required by the application. The GIO module also supports generation of interrupts whenever a rising edge or falling edge or any toggle is detected on up to 32 of these GIO terminals. Refer to the device datasheet for identifying the number of GIO ports supported and the GIO terminals capable of generating an interrupt.

The main features of the GIO module are summarized as follows:

- Allows each GIO terminal to be configured for general-purpose input or output functions
- Supports programmable pull directions on each input GIO terminal
- Supports GIO output in push/pull or open-drain modes
- Allows up to 32 GIO terminals to be used for generating interrupt requests

10.1.1.2 Quick Start Guide

The GIO module comprises two separate components: an input/output (I/O) block and an interrupt generation block. Figure 10-1 and Figure 10-2 show what you should do after reset to configure the GIO module as I/O or for generating interrupts.

In GIO interrupt service routine, you shall read the GIO offset register (GIOFF1 or GIOFF2, depending on high-/low-level interrupt) to clear the flag and find the pending interrupt GIO channel.

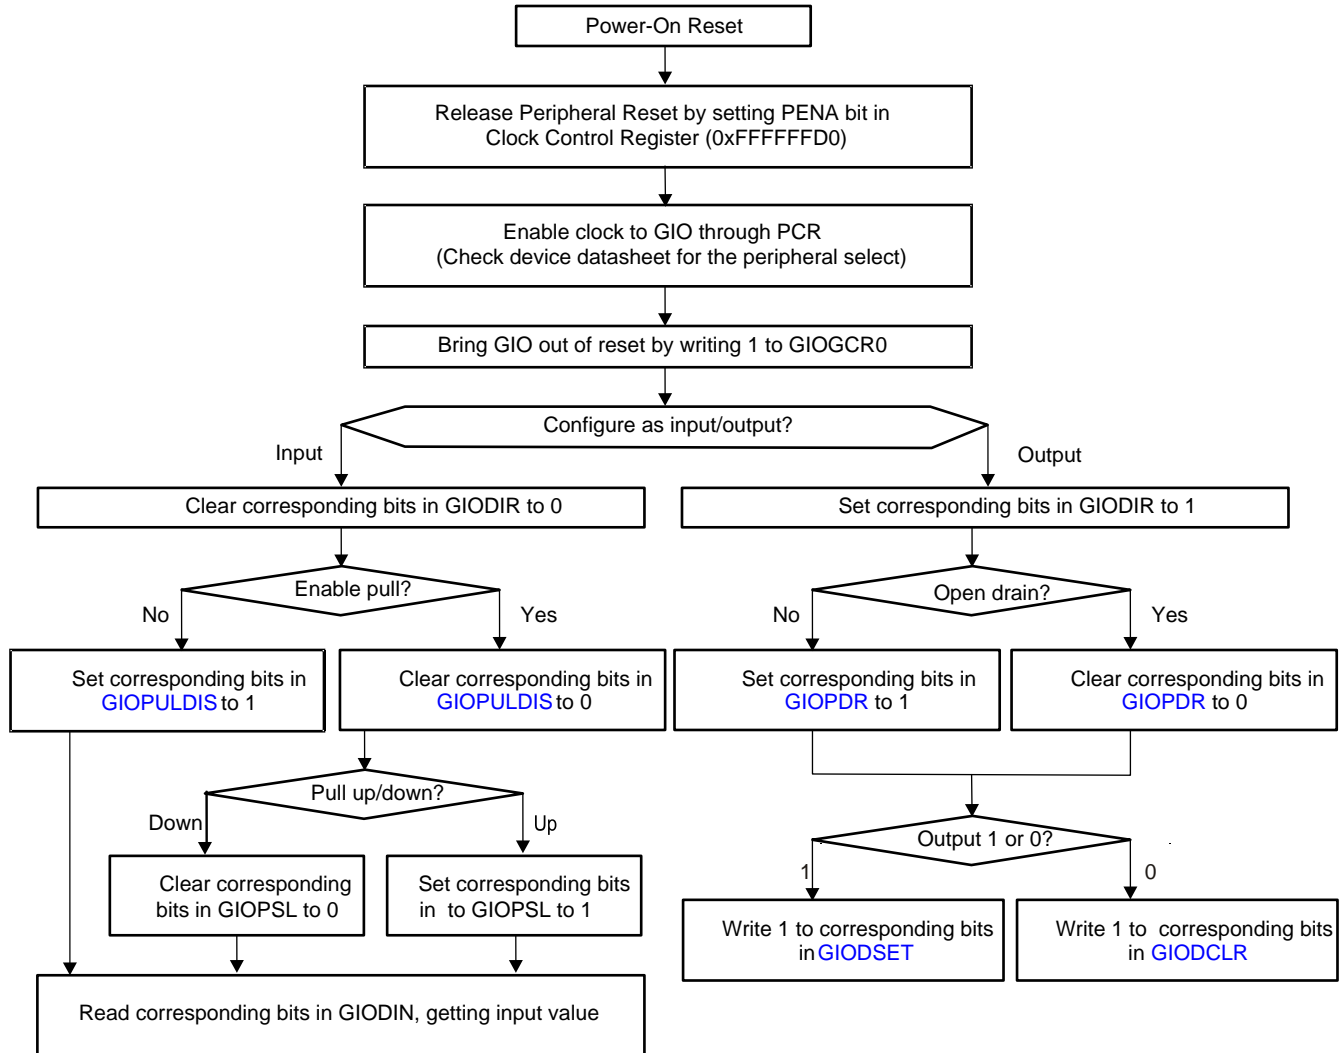

Figure 10-1. I/O Function Quick Start Flow Chart

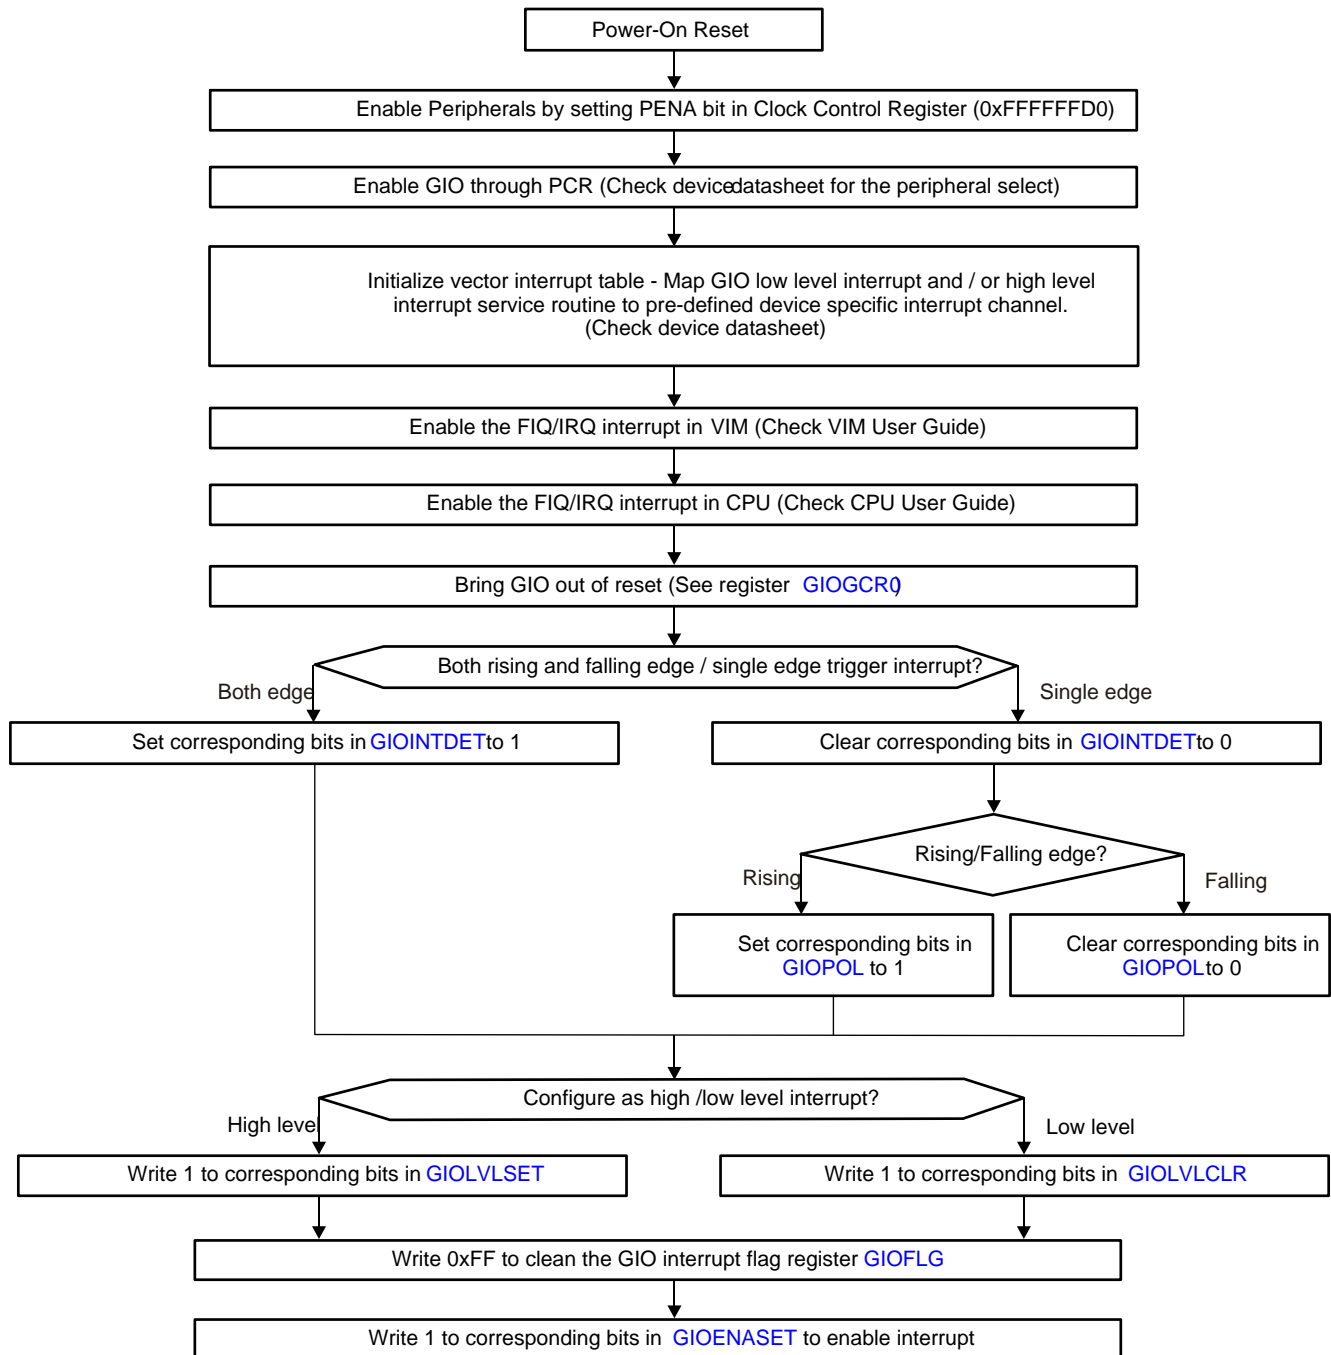

Figure 10-2. Interrupt Generation Function Quick Start Flow Chart

10.1.1.3 Functional Description of GIO Module

As shown in Figure 10-3, the GIO module comprises of two separate components: an input/output (I/O) block and an interrupt block.

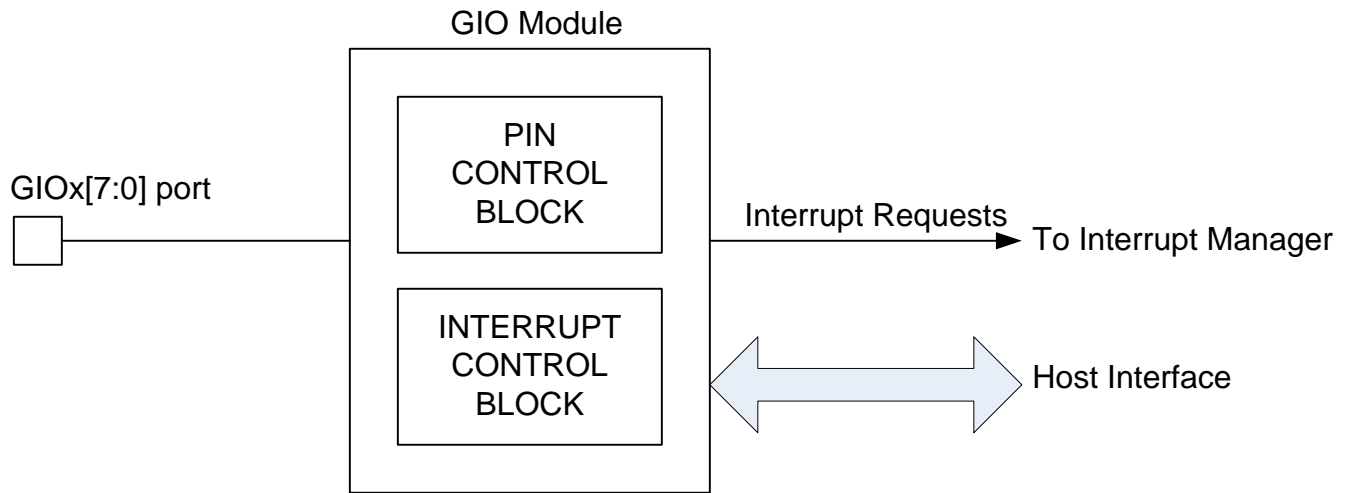

Figure 10-3. GIO Module Diagram

10.1.1.3.1 I/O Functions

The I/O block allows each GIO terminal to be configured for use as a general-purpose input or output in the application. The GIO module supports multiple registers to control the various aspects of the input and output functions. These are described as follows.

- Data direction (GIODIR)

Configures GIO terminal(s) as input (default) or output through the GIODIRx registers.

- Data input (GIODIN)

Reflects the logic level on GIO terminals in the GIODINx registers. A high voltage (V_{IH} or greater) applied to the pin causes a high value (1) in the data input register (GIODIN[7:0]). When a low voltage (V_{IL} or less) is applied to the pin, the data input register reads a low value (0). The V_{IH} and V_{IL} values are device specific and can be found in the device datasheet.

- Data output (GIODOUT)

Configures the logic level to be output on GIO terminal(s) configured as outputs. A low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower). A high value (1) written to the data output register (GIODOUTx) forces the pin to a high output voltage (V_{OH} or higher) if the open drain functionality is disabled (GIOPDRx[7:0]). If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z).

- Data set (GIODSET)

Allows logic HIGH to be output on GIO terminal(s) configured as outputs by writing 1's to the required bits in the GIODSETx registers. If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z). The GIODSETx registers eliminate the need for the application to perform a read-modify-write operation when it needs to set one or more GIO pin(s).

- Data clear (GIODCLR)

Allows logic LOW to be output on GIO terminal(s) configured as outputs by writing 1s to the required bits in the GIODCLR registers. The GIODCLR registers eliminate the need for the application to perform a read-modify-write operation when it needs to clear one or more GIO pin(s).

- Open drain (GIOPDR)

Open drain functionality is enabled or disabled (default) using the open drain register GIOPDR[7:0] register. If open-drain mode output is enabled on a pin, a high value (1) written to the data output register (GIODOUTx[7:0]) forces the pin to a high impedance state (Z).

- Pull disable (GIOPULDIS)

Disables the internal pull on GIO terminal(s) configured as inputs by writing to the GIOPULDISx registers.

- Pull select (GIOPSL)

Selects internal pull down (default) or pull up on GIO terminal(s) configured as inputs by writing to the GIOPULSELx registers.

Refer to the specific device's datasheet to identify the number of GIO ports as well as the input and output functions supported. Some devices may not support the programmable pull controls. In that case, the pull disable and the pull select register controls will not work.

10.1.1.3.2 Interrupt Function

The GIO module supports up to 32 terminals to be configured for generating an interrupt to the host processor through the Vectored Interrupt Manager (VIM). The main functions of the interrupt block are:

- Select the GIO pin(s) that is/are used to generate interrupt(s)

This is done via the interrupt enable set and clear registers, GIOENASET and GIOENACLR.

- Select the edge on the selected GIO pin(s) that is/are used to generate interrupt(s): rising/falling/both

Rising or falling edge can be selected via the GIOPOL register. If interrupt is required to be generated on both rising and falling edges, this can be configured via the GIOINTDET register.

- Select the interrupt priority

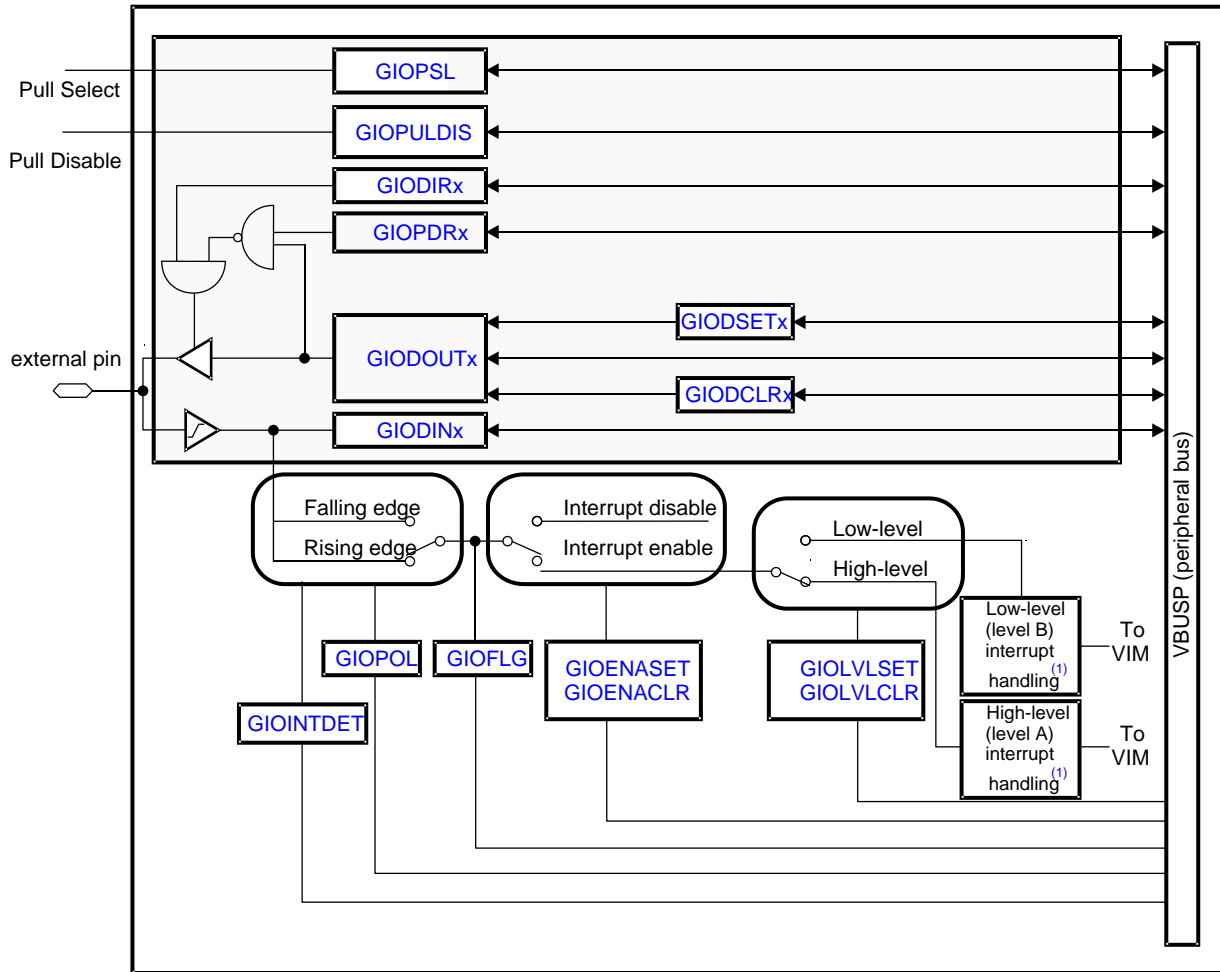

Low- or high-level interrupt can be selected through the GIOLVLSET and GIOLVLCLR registers.

- Individual interrupt flags are set in the GIOFLG register

The terminals on GIO ports A through D are all interrupt-capable and can be used to handle either general I/O functions or interrupt requests. Each interrupt request can be connected to the VIM at one of two different levels – High (or A) and Low (or B), depending on the VIM channel number. The VIM has an inherent priority scheme so that a request on a lower number channel has a higher priority than a request on a higher number channel. Refer the device datasheet to identify the VIM channel numbers for the GIO level A and level B interrupt requests. Also note that the interrupt priority of level A and level B interrupt handling blocks can be re-programmed in the VIM.

10.1.1.3.3 GIO Block Diagram

The GIO block diagram ([Figure 10-4](#)) represents the flow of information through a pin. The shaded area corresponds to the I/O block; the unshaded area corresponds to the interrupt block.

- A. A single low-level-interrupt-handling block and a single high-level-interrupt-handling block service all of the interrupt-capable external pins, but only one pin can be serviced by an interrupt block at a time.

Figure 10-4. GIO Block Diagram

10.1.1.4 Device Modes of Operation

The GIO module behaves differently in different modes of operation. There are two main modes:

- Emulation mode
- Power-down mode (low-power mode)

10.1.1.4.1 Emulation Mode

Emulation mode is used by debugger tools to stop the CPU at breakpoints to read registers.

Note

Emulation Mode and Emulation Registers

Emulation mode is a mode of operation of the device and is separate from the GIO emulation registers (GIOEMU1 and GIOEMU2). The contents of these emulation registers are identical to the contents of GIO offset registers (GIOOFF1 and GIOOFF2). Both emulation registers and GIO offset registers are NOT cleared when they are read in emulation mode. GIO offset registers are cleared when they are read in normal mode (other than emulation mode). The emulation registers are NOT cleared when they are read in normal mode. The intention for the emulation registers is that software can use them without clearing the flags.

During emulation mode:

- External interrupts are not captured because the VIM is unable to service interrupts.
- Any register can be read without affecting the state of the system.
- A write to a register still does affect the state of the system.

10.1.1.4.2 Power-Down Mode (Low-Power Mode)

In power-down mode, the clock signal to the GIO module is disabled. Thus, there is no switching and the only current draw comes from leakage current. In power-down mode, interrupt pins become level-sensitive rather than edge-sensitive. The polarity bit changes function from falling-edge-triggered to low-level-triggered and rising-edge-triggered to high-level-triggered. A corresponding level on an interrupt pin pulls the module out of low-power mode, if the interrupt is also enabled to wake up the device out of a low-power mode.

10.1.1.4.2.1 Module-Level Power Down

The GIO module can be placed into a power down state by disabling the GIO peripheral module via the appropriate bit in the peripheral power down register. Please refer to the Peripheral Central Resource Registers for details.

10.1.1.4.2.2 Device-Level Power Down

The entire device can be placed in one of the pre-defined low-power modes: doze, snooze, or sleep using the clock source and clock domain disable registers in the system module.

10.1.1.4.3 Interrupts

GIO generates aggregated interrupts for all inputs from PAD. Some of the interrupts to MSS_R5F are directly taken from GPIO-PAD.

MSS_GIO_INT0/1

MSS_GIO_PAD_INT0 from GPIO[0]

MSS_GIO_PAD_INT1 from GPIO[1]

MSS_GIO_PAD_INT2 from GPIO[2]

MSS_CTRL::MSS_GIO_CFG_GIO::MSS_GIO_CFG_GIO_CONFIG is used for selecting the edge that can give a trigger.

10.1.1.5 MSS_GIO Registers

Table 10-1 lists the MSS_GIO registers. All register offset addresses not listed in Table 10-1 should be considered as reserved locations and the register contents should not be modified.

10.1.1.6 I/O Control Summary

The behavior of the output buffer and the pull control is summarized in [Table 10-87](#).

Table 10-87. Output Buffer and Pull Control Behavior for GIO Pins

Module under Reset?	Pin Direction (GIODIR) ^{(1) (2)}	Open Drain Enable (GIOPDR) ⁽¹⁾	Pull Disable (GIOPULDIS) ^{(1) (3)}	Pull Select (GIOPSL) ^{(1) (4)}	Pull Control	Output Buffer ⁽⁵⁾
Yes	X	X	X	X	Enabled	Disabled
No	0	X	0	0	Pull down	Disabled
No	0	X	0	1	Pull up	Disabled
No	0	X	1	0	Disabled	Disabled
No	0	X	1	1	Disabled	Disabled
No	1	0	X	X	Disabled	Enabled
No	1	1	X	X	Disabled	Enabled

(1) X = Don't care

(2) GIODIR = 0 for input; = 1 for output

(3) GIOPULDIS = 0 for enabling pull control; = 1 for disabling pull control

(4) GIOPSL = 0 for pull-down functionality; = 1 for pull-up functionality

(5) If open drain is enabled, output buffer will be disabled if a high level (1) is being output.

10.1.2 Inter-Integrated Circuit (I2C) Module

This chapter describes the inter-integrated circuit (I2C or I²C) module. The I2C is a multi-master communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I²C-bus specification version 2.1 and connected by an I2C-bus. This module will support any slave or master I2C compatible device.

10.1.2.1 Overview	2589
10.1.2.2 I2C Module Operation	2593
10.1.2.3 I2C Operation Modes	2597
10.1.2.4 I2C Module Integrity	2599
10.1.2.5 Operational Information	2601
10.1.2.6 I2C Control Registers	2604
10.1.2.7 Sample Waveforms	2628

10.1.2.1 Overview

The I2C has the following features:

- Compliance to the Philips I²C bus specification, v2.1 (*The I²C Specification*, Philips document number 9398 393 40011)
 - Bit/Byte format transfer
 - 7-bit and 10-bit device addressing modes
 - General call
 - START byte
 - Multi-master transmitter/ slave receiver mode
 - Multi-master receiver/ slave transmitter mode
 - Combined master transmit/receive and receive/transmit mode
 - Transfer rates of 10 kbps up to 400 kbps (Phillips fast-mode rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Operates with VBUS frequency from 6.7 MHz up
- Operates with module frequency between 6.7 MHz to 13.3 MHz
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode

Note

This I2C module does **not** support:

- High-speed (HS) mode
 - C-bus compatibility mode
 - The combined format in 10-bit address mode (the I2C sends the slave address second byte every time it sends the slave address first byte)
-

10.1.2.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. [Figure 10-89](#) shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

Figure 10-89. Multiple I2C Modules Connection Diagram

10.1.2.1.2 Functional Overview

The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

Note

A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in [Figure 10-90](#). These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

The I2C module consists of the following primary blocks:

- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
 - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
 - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds.
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

In [Figure 10-90](#), the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:

- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

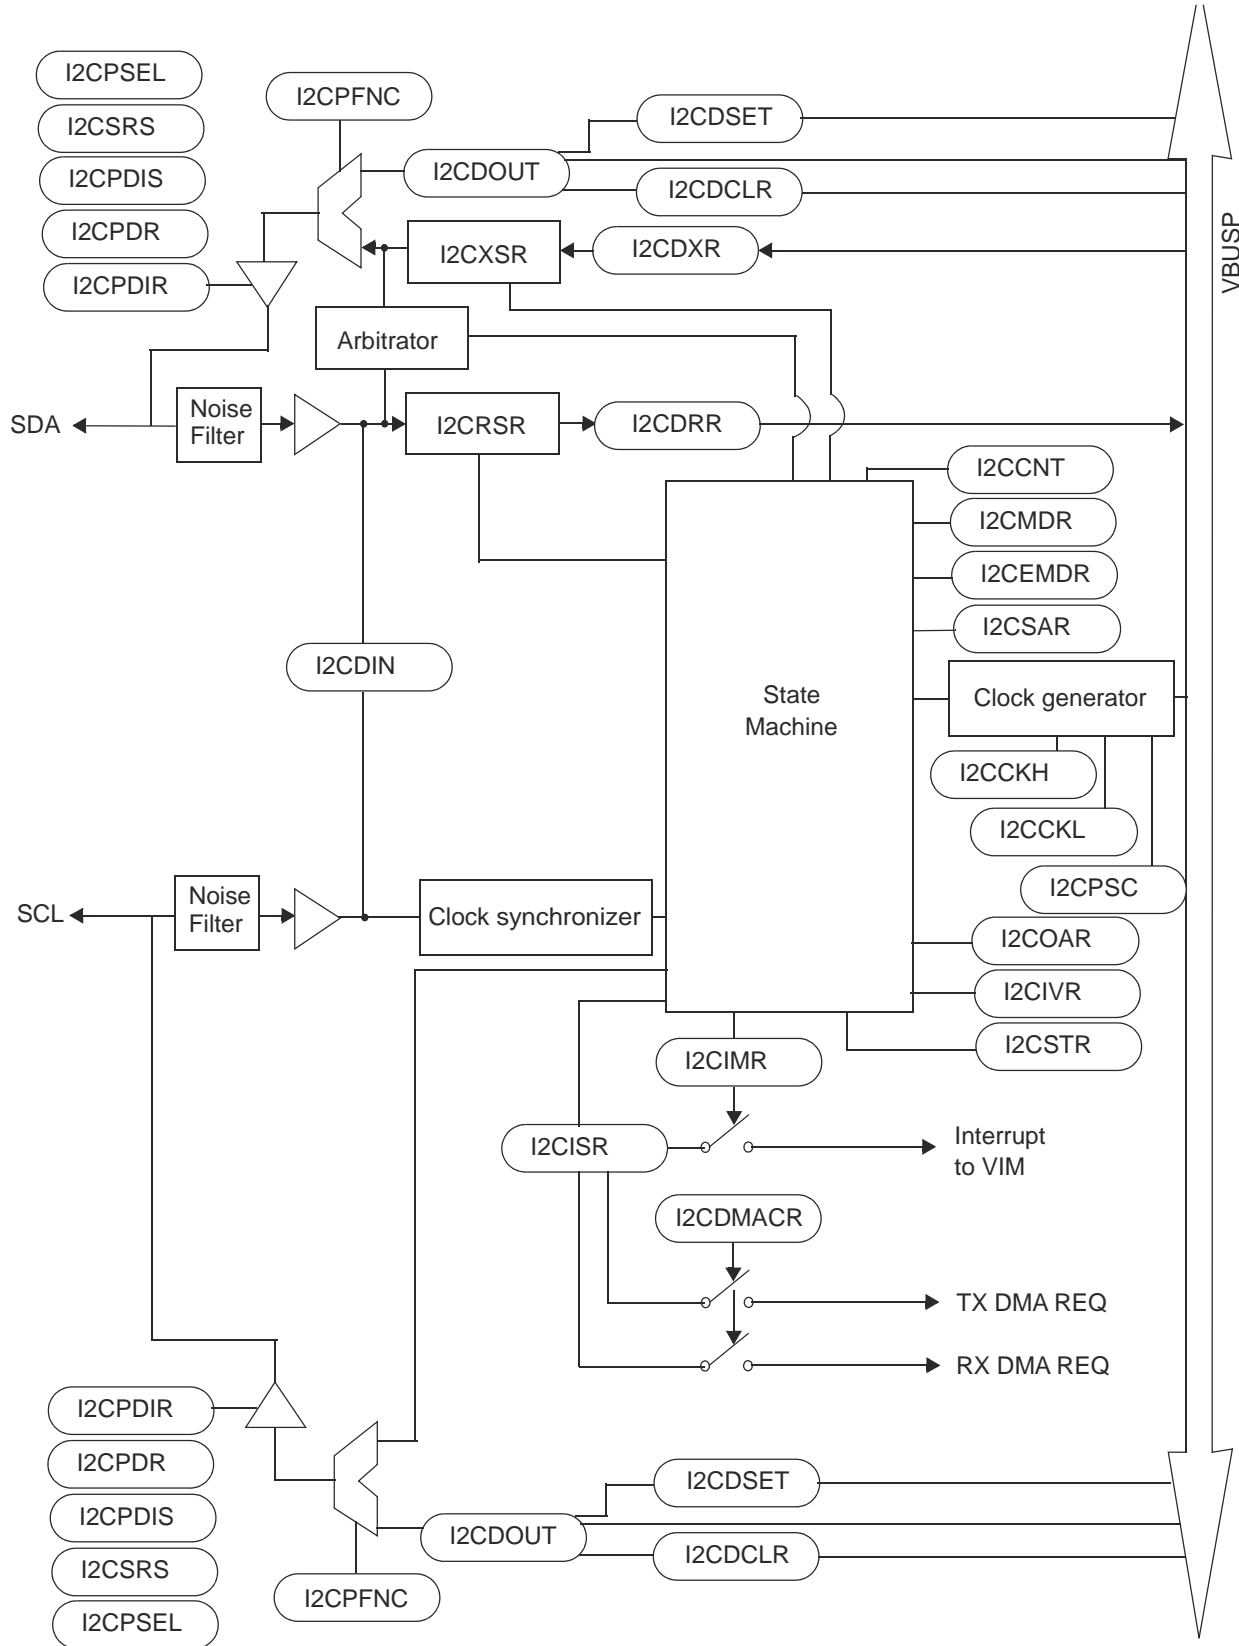

Figure 10-90. Simple I2C Block Diagram

10.1.2.1.3 Clock Generation

As shown in [Figure 10-91](#), the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

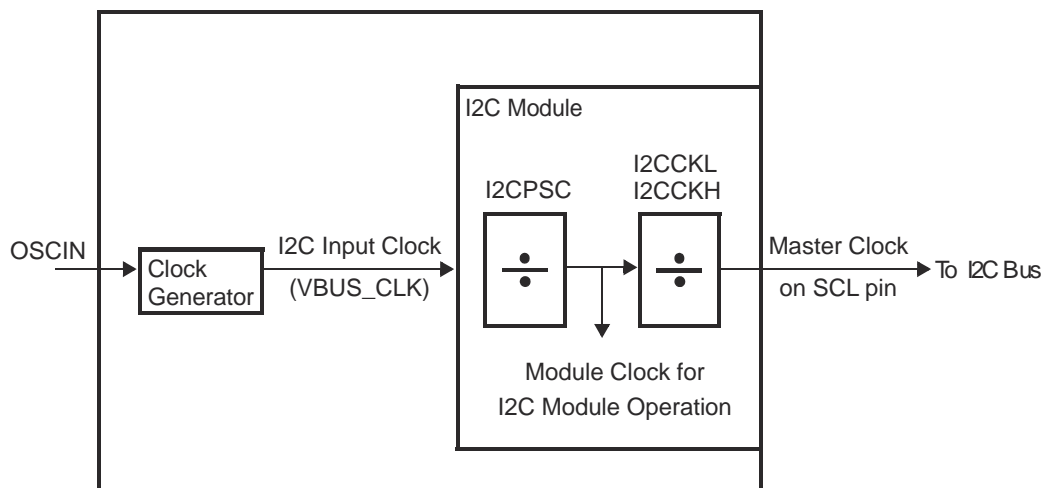

Figure 10-91. Clocking Diagram for the I2C Module

The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$ModuleClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)} \quad (3)$$

The module clock frequency must be between 6.7MHz and 13.3MHz. The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in [Figure 10-91](#), a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$MasterClockFrequency = \frac{ModuleClockFrequency}{(I2CCKL + d) + (I2CCKH + d)} \quad (4)$$

$$MasterClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)((I2CCKL + d) + (I2CCKH + d))} \quad (5)$$

where d depends on the value of I2CPSC:

I2CPSC	d
0	7

I2CPSC	d
1	6
Greater than 1	5

Note

The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

10.1.2.2 I2C Module Operation

The following section discusses how the I2C module operates.

10.1.2.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{CCIO} . For details, see the device specific data sheet.

10.1.2.2.2 I2C Module Reset Conditions

The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the \overline{IRS} bit in the I2C mode register (I2CMDR). When the global peripheral reset is removed, the \overline{IRS} bit is cleared to 0, keeping the I2C module in the reset state.

10.1.2.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See [Figure 10-92](#). The high and low state of the data line, the SDA, can only change when the clock signal is low.

Figure 10-92. Bit Transfer on the I2C Bus

10.1.2.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

Figure 10-93. I2C Module START and STOP Conditions

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

10.1.2.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 10-94). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

Figure 10-94. I2C Module Data Transfer

The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/ \bar{W} bit, or 8 data bits. The eighth bit, R/ \bar{W} , in the first byte determines the direction of the data. When the R/ \bar{W} bit is 0, the master writes (transmits) data to a selected slave device; when the R/ \bar{W} bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 10-95)
- 10-bit addressing format (Figure 10-96)
- 7-bit/10-bit addressing format with repeated START condition (Figure 10-97)
- Free-data format (Figure 10-98)

10.1.2.2.5.1 7-Bit Addressing Format

In the 7-bit addressing format (Figure 10-95), the first byte after the START condition consists of a 7-bit slave address followed by the R/ \bar{W} bit (in the LSB). The R/ \bar{W} bit determines the direction of the data transfer:

- R/ \bar{W} = 0: The master writes (transmits) data to the addressed slave.
- R/ \bar{W} = 1: The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/ \bar{W} bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMR and make sure the free data format mode is off (FDF = 0 in I2CMR).

Figure 10-95. I2C Module 7-Bit Addressing Format

10.1.2.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 10-96), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the R/ \bar{W} bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMR and make sure the free data format mode is off (FDF = 0 in I2CMR).

Figure 10-96. I2C Module 10-bit Addressing Format

10.1.2.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 10-97). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

Figure 10-97. I2C Module 7-Bit Addressing Format with Repeated START

10.1.2.2.5.4 Free Data Format

In this format (Figure 10-98), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

Figure 10-98. I2C Module in Free Data Format

10.1.2.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 10-88 summarizes the various ways a NACK can be generated.

Table 10-88. Ways to Generate a NACK Bit

I2C Module Condition	Basic NACK Bit Generation Options	Additional Option
Slave receiver mode	Disable data transfers (STT = 0) Allow an overrun condition (RSFULL = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode and repeat mode (RM = 1)	Generate a STOP condition (STP = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode with non-repeat mode (RM = 0)	If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition. If STP = 0, make STP = 1 to generate a STOP condition. Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

10.1.2.3 I2C Operation Modes

10.1.2.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in [Figure 10-95](#), [Figure 10-96](#), or [Figure 10-97](#) is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ($\overline{\text{XSMT}} = 0$) after a byte has been transmitted.

Note

If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

10.1.2.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in [Figure 10-95](#), [Figure 10-96](#), or [Figure 10-97](#), the master receiver mode is entered after the slave address byte and the R/ $\overline{\text{W}}$ bit have been transmitted (if the R/ $\overline{\text{W}}$ bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required ($\text{RSFULL} = 1$) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition ($\text{STP} = 1$) after reading the (message size - 1)th data.

10.1.2.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in [Figure 10-95](#), [Figure 10-96](#), or [Figure 10-97](#), the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/ $\overline{\text{W}}$ bit has been transmitted (if the R/ $\overline{\text{W}}$ bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ($\overline{\text{XSMT}} = 0$) after a byte has been transmitted.

10.1.2.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required ($\text{RSFULL} = 1$) after a byte has been received.

10.1.2.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module.

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

10.1.2.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

10.1.2.3.7 Ignore NACK Mode

The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

10.1.2.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

10.1.2.4.1 Arbitration

If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. [Figure 10-99](#) illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

Figure 10-99. Arbitration Procedure Between Two Master Transmitters

10.1.2.4.2 I2C Clock Generation and Synchronization

Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 10-100 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

Note

I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I²C bus specification, v2.1 (*The I²C Specification*, Philips document number 9398 393 40011), and will result in an I2C protocol fault: I2CCLKH = 2 I2CCLKL = 2I2CPSC = 2. This will cause the SDA data transition to occur while the SCL is high.

Figure 10-100. Synchronization of Two I2C Clock Generators During Arbitration

10.1.2.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

10.1.2.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

10.1.2.5 Operational Information

The following section provides specific information about how the I2C module operates.

10.1.2.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

10.1.2.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in [Table 10-89](#).

Table 10-89. Interrupt Requests Generated by I2C Module

Flag	Name	Generated
AL	Arbitration-lost interrupt	Generated when the I2C module has lost an arbitration contest with another master-transmitter
NACK	No-acknowledge interrupt	Generated when the master I2C does not receive an acknowledge from the receiver
ARDY	Register-access-ready interrupt	Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.
RXRDY	Receive-data-ready interrupt	Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.
TXRDY	Transmit-data-ready interrupt	Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXHR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR.
SCD	Stop-condition-detect interrupt	Generated when a STOP condition has been detected.
AAS	Address-as-slave interrupt	Generated when the I2C has recognized its own slave address or an address of all zeroes.

10.1.2.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXHR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into I2CSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

Note**Unexpected DMA transmit and receive event**

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

10.1.2.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the $\overline{\text{PORRST}}$ pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When $\overline{\text{PORRST}}$ is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

10.1.2.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

10.1.2.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is enabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

10.1.2.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower), whereas a high value (1) written to the data output register forces the pin to a high-impedance state. The open drain function is disabled when the pin is configured as an input pin.

10.1.2.6 I2C Control Registers

Table 10-90 provides a summary of the control registers. The upper word (upper 16 bits) of the registers all read as 0s. Writes have no effect on these bits.

Table 10-90. I2C Control Registers

Offset	Acronym	Register Description	Section
00h	I2COAR	I2C Own Address Manager	Section 10.1.2.6.1

10.1.2.6.1 I2C Own Address Manager (I2COAR)

The 16-bit memory-mapped I2C own address register is used to specify its own address. [Figure 10-101](#) and [Table 10-91](#) describe this register.

Figure 10-101. I2C Own Address Manager Register (I2COAR) [offset = 00]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-91. I2C Own Address Manager Register (I2COAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	OA	0-3FFh	Own address These bits reflect the bus address of the I2C module. When the expand address (XA) bit I2CMDR.8 is set to 1, the I2C is in expand address mode (10-bit addressing mode). In either 7 or 10-bit address mode, all 10-bits are both readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 10-92 provides the correct modes for these bits. Note that the user can program the I2C own address to any value as long as it does not conflict with other components in the system.

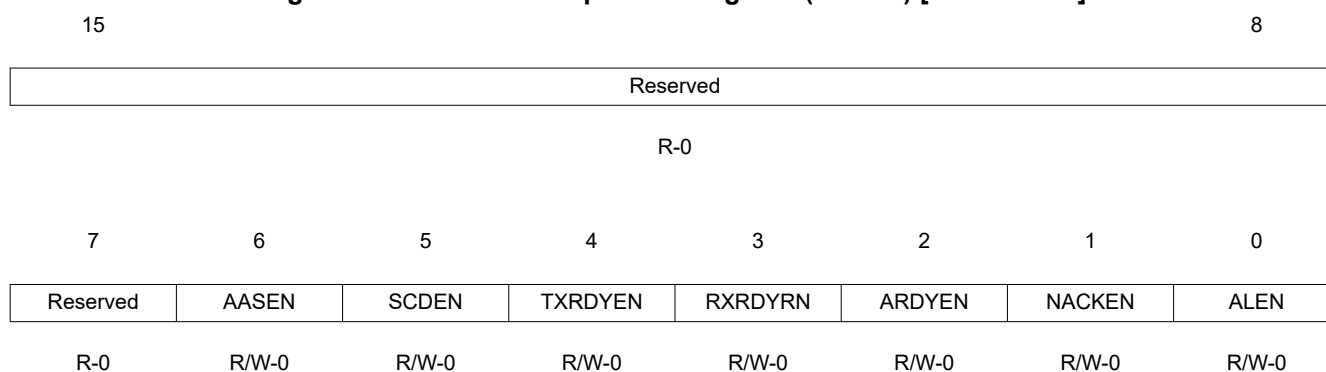

Table 10-92. Correct Mode for OA Bits

Bits Used	Mode	Value of XA
OA.6:0	7 Bit Addressing	0
OA.9:0	10 Bit Addressing	1

10.1.2.6.2 I2C Interrupt Mask Register (I2CIMR)

The 7-bit memory-mapped I2C interrupt mask register is used by the device to enable/disable the interrupts. Figure 10-102 and Table 10-93 describe this register.

Figure 10-102. I2C Interrupt Mask Register (I2CIMR) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-93. I2C Interrupt Mask Register (I2CIMR) Field Descriptions

Bit	Field	Value	Description
15-7	Reserved	0	Reads return 0. Writes have no effect.
6	AASEN	0 1	Address As Slave Interrupt Enable. AASEN interrupt is disabled. AASEN interrupt is enabled.
5	SCDEN	0 1	Stop Condition Interrupt Enable. SCDEN interrupt is disabled. SCDEN interrupt is enabled.
4	TXRDYEN	0 1	Transmit Data Ready Interrupt Enable. TXRDYEN interrupt is disabled. TXRDYEN interrupt is enabled.
3	RXRDYEN	0 1	Receive Data Ready Interrupt Enable. RXRDYEN interrupt is disabled. RXRDYEN interrupt is enabled.
2	ARDYEN	0 1	Register Access Ready Interrupt Enable. ARDYEN interrupt is disabled. ARDYEN interrupt is enabled.
1	NACKEN	0 1	No Acknowledgement Interrupt Enable. NACKEN interrupt is disabled. NACKEN interrupt is enabled.
0	ALEN	0 1	Arbitration Lost Interrupt Enable. ALEN interrupt is disabled. ALEN interrupt is enabled.

10.1.2.6.3 I2C Status Register (I2CSTR)

Figure 10-103 and Table 10-94 describe this register.

Figure 10-103. I2C Status Register (I2CSR) [offset = 08h]

15	14	13	12	11	10	9	8
Reserved	SDIR	NACKSNT	BB	RSFULL	XSMT	AAS	AD0
R-0	R/W1C-0	R/W1C-0	R-0	R-0	R/W-1	R-0	R-0
7	6	5	4	3	2	1	0
Reserved	SCD	TXRDY	RXRDY	ARDY	NACK	AL	
R-0	R/W1C-0	R/W-1	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

Table 10-94. I2C Status Register (I2CSTR) Field Descriptions

Bit	Field	Value	Description
15	Reserved	0	Reads return 0. Writes have no effect.
14	SDIR	0	Slave direction. Setting this bit to 1 indicates that the I2C slave is a transmitter. Clearing this bit to 0 indicates that the I2C is a master transmitter/receiver or a slave receiver. This bit is also cleared by the STOP or START conditions. In DLB mode (in which the configuration should be master-transmitter slave-receiver), this bit is cleared to 0. Writing a 1 to this bit will clear it.
		1	The I2C is a master transmitter/receiver or a slave receiver.
13	NACKSNT	0	No acknowledge sent. This bit is set to 1 to indicate that a no acknowledgement (NACK) has been sent because the NACKMOD bit was set to 1. Writing a 1 to this bit will clear it.
		1	A NACK has not been sent.
		1	A NACK was sent because the NACKMOD was set to 1.
12	BB	0	Bus busy. This bit indicates the state of the serial bus. On reception of a START condition or if the I2C detects a low state on I2CSCL, the device sets BB = 1. If the nIRS is set to 1 during transaction between other I2C devices, the BB bit is set at the first falling edge of SCL or START condition. BB is cleared to 0 after the reception of a STOP condition. BB is kept to 0 regardless of the SCL state when the I2C is in reset (nIRS = 0).
		1	The bus is free.
		1	The bus is busy.

Table 10-94. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
11	RSFULL	0 1	<p>Receiver shift full.</p> <p>This bit is set to 1 to indicate that the receiver has experienced overrun. Overrun occurs when the receive shift register is full and I2CDRR has not been read since the receive shift register to I2CDRR transfer. The contents of I2CDRR are not lost. The I2C core logic is holding for I2CDRR read access. This bit is also set when, in master-repeat-mode, the I2C receives a byte of data. There is no difference between RXRDY and RSFULL in this case. The I2C master will not continue the transfer as long as the received data is in the I2CDRR or receive shift register.</p> <p>RSFULL is cleared when reading the I2CDRR, resetting the I2C (nIRS = 0), or resetting the device.</p> <p>0 No overrun has occurred. 1 An overrun has occurred.</p>
10	XSMT	0 1	<p>Transmit shift empty.</p> <p>This bit is cleared to 0 to indicate that the transmitter has experienced underflow. Underflow occurs when the transmit shift register is empty and I2CDXR has not been loaded since the last I2CDXR to transmit shift register transfer. The I2C core logic is waiting for I2CDXR write access.</p> <p>XSMT is set to 1 as a result of writing to I2CDXR, by resetting the I2C block (nIRS = 0), or by resetting the device.</p> <p>In repeat mode, if the I2C in master transmitter mode is holding transfer with $\overline{XSMT} = 0$ (that is, waiting for further action) and the STT or STP bit is set, XSMT is set to 1 by hardware.</p> <p>0 An underflow has occurred. 1 No underflow has occurred.</p>
9	AAS	0 1	<p>Address as slave.</p> <p>This bit cannot be cleared by writing a 1 to the bit or by reading the I2CIVR register.</p> <p>0 This bit is cleared by a STOP condition or detection of any address byte that does not match I2COAR. 1 This bit is set to 1 by the device when it has recognized its own slave address or an address of all zeros (general call).</p>
8	AD0	0 1	<p>Address zero status.</p> <p>0 A START or STOP condition was detected. No general call was detected. 1 An address of all zeros (general call) was detected.</p>
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	SCD	0 1	<p>Stop condition detect interrupt flag.</p> <p>This bit is set to 1 when the I2C receives or sends a STOP condition.</p> <p>This bit is cleared to 0 by writing a 1 to this bit or reading the value 0x0006 from I2CIVR. Writing a 1 to this bit will clear the value 0x0006 from I2CIVR.</p> <p>0 No STOP condition has been sent or received. 1 A STOP condition has been sent or received.</p>
4	TXRDY	0 1	<p>Transmit data ready interrupt flag.</p> <p>This bit is set to 1 to indicate when data in the transmit data register, I2CDXR, has been copied into the transmit shift register. This bit can also be polled by the device to indicate when to write the next transmitted data into the I2CDXR. Writing a 1 to this bit will set it.</p> <p>This bit is cleared to 0 and code 0x0005 in I2CIVR is cleared when the I2CDXR is written. This bit cannot be cleared by reading the I2CIVR register.</p> <p>0 I2CDXR contains data to transmit. 1 I2CDXR is empty.</p>

Table 10-94. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
3	RXRDY		<p>Receive data ready interrupt flag.</p> <p>This bit is set to 1 to indicate when the data in the receive shift register has been copied into the data receive register (I2CDRR). This bit can also be polled by the device to indicate when to read the received data in the I2CDRR.</p> <p>Writing a 1 to this bit or reading from I2CDRR will clear this bit, and will also clear code 0x0004 from I2CIVR. This bit cannot be cleared by reading the I2CIVR register.</p>
		0	The I2CDRR has been read.
		1	The received data has been written into the I2CDRR.
2	ARDY		<p>Register access ready interrupt flag.</p> <p>This bit is set to 1 when the previously programmed address, data and command has been performed and the status bit has been updated. The flag is used by the device to indicate that the I2C registers are ready to be accessed again.</p> <p>This bit is automatically cleared by hardware when writing data to I2CDXR in transmit mode, reading data from I2CDRR in receive mode, or setting STT or STP bit. Writing a 1 to this bit will clear this bit. This bit cannot be cleared by reading the I2CIVR register.</p> <p>When RM = 0, ARDY is set when I2CCNT is passed 0 if STP register bit has not been set. When RM = 1, ARDY is set at each byte end.</p> <p>When FDF = 0, ARDY is asserted after the ACK for the slave address. When FDF = 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition.</p>
		0	<p><i>Nonrepeat mode, (RM = 0):</i> I2C registers are not ready to be accessed.</p> <p><i>Repeat mode (RM = 1):</i> I2C registers are not ready to be accessed.</p>
		1	<p><i>Nonrepeat mode, (RM = 0):</i> ICCNT passes 0 (if STP bit has not been set).</p> <p><i>Repeat mode (RM = 1):</i> The end of each byte was transmitted from I2CDXR.</p>
1	NACK		<p>No acknowledgement interrupt.</p> <p>This bit is set to 1 when the master I2C does not receive an acknowledgement from the receiver. This bit is set only when the I2C has received a no-acknowledge in master mode. This bit is NOT set by no-acknowledgement after Start byte. In master start byte mode, the first byte (address of all zeroes) receives a NACK but does not clear the stop bit.</p> <p>Writing a 1 to this bit or reading the value 0x0002 from I2CIVR will clear this bit.</p>
		0	An acknowledge was detected.
		1	No acknowledge was detected or the I2C is operating in the general call, even though an acknowledgement was received. This value clears the STP bit.
0	AL		<p>Arbitration lost interrupt flag.</p> <p>This bit is set to 1 when arbitration has been lost.</p> <p>Writing a 1 to this bit or reading the value 0x0001 from I2CIVR will clear this bit.</p>
		0	No loss of arbitration has been detected.
		1	The device in the master transmitter mode senses it has lost an arbitration. This occurs when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB=1. When this is set to 1 due to arbitration lost, the device becomes a slave receiver and the MST, STT and STP bits in I2CMDR are cleared to 0.

10.1.2.6.4 I2C Clock Divider Low Register (I2CCKL)

The I2C clock divider low register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock low time. [Figure 10-104](#) and [Table 10-95](#) describe this register.

Figure 10-104. I2C Clock Divider Low Register (I2CCKL) [offset = 0Ch]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-95. I2C Clock Divider Low Register (I2CCKL) Field Descriptions

Bit	Field	Description
15-0	CLKL	<p>Low time clock division factor.</p> <p>Used to divide down the module clock to create the low-time portion of the master clock signal that will appear on the SCL pin:</p> $LowTime = \left(\frac{I2CCKL + d}{ModuleClockFrequency} \right) \quad (6)$ <p>where <i>d</i> is the value that depends on the I2CPSC</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p>

10.1.2.6.5 I2C Clock Control High Register (I2CCKH)

The I2C clock divider high register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock high time. [Figure 10-105](#) and [Table 10-96](#) describe this register.

Figure 10-105. I2C Clock Control High Register (I2CCKH) [offset = 10h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-96. I2C Clock Control High Register (I2CCKH) Field Descriptions

Bit	Field	Description
15-0	CLKH	<p>High time clock division factor.</p> <p>Used to divide down the module clock to create the high-time portion of the master clock signal that will appear on the SCL pin:</p> $HighTime = \left(\frac{I2CCKH + d}{ModuleClockFrequency} \right) \quad (7)$ <p>where <i>d</i> is the value that depends on the I2CPSC</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p>

10.1.2.6.6 I2C Data Count Register (I2CCNT)

The I2C data count register is a 16-bit memory-mapped register used to count received or transmitted data bytes. This register is also used to generate the STOP condition that terminates the transfer after the counter reaches zero. [Figure 10-106](#) and [Table 10-97](#) describe this register.

Figure 10-106. I2C Data Count Register (I2CCNT) [offset = 14h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-97. I2C Data Count Register (I2CCNT) Field Descriptions

Bit	Field	Value	Description
15-0	CNT		Data counter. This down counter is used to generate a stop condition if a stop condition is specified (STP = 1). Note: ICCNT is a don't care when RM is set to 1.
		0	The data counter is 65536.
		1	The data counter is 1.

10.1.2.6.7 I2C Data Receive Register (I2CDRR)

The I2C data receive register is a 16-bit memory-mapped register used by the device to read the received data. [Figure 10-107](#) and [Table 10-98](#) describe this register.

Figure 10-107. I2C Data Receive Register (I2CDRR) [offset = 18h]

LEGEND: R = Read only; -n = value after reset

Table 10-98. I2C Data Receive Register (I2CDRR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	DATARX	0-FFh	Receive data. A read from this register clears the RXRDY bit and clears code 4h from the I2CIVR register.

10.1.2.6.8 I2C Slave Address Register (I2CSAR)

The I2C slave address register is a 16-bit memory-mapped register used to specify the address of the slave device to communicate to on the I2C bus. [Figure 10-108](#) and [Table 10-99](#) describe this register.

Figure 10-108. I2C Slave Address Register (I2CSAR) [offset = 1Ch]

15		10	9		0
Reserved			SA		
R-0			R/W-3FFh		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-99. I2C Slave Address Register (I2CSAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	SA		7- or 10-bit programmable slave address. In either mode, all 10-bits are readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 10-100 illustrates the correct mode for each bit.

Table 10-100. Correct Mode for SA Bits

Bits Used	Mode	Value of XA
SA(6–0)	7-bit addressing	0
SA(9–0)	10-bit addressing	1

10.1.2.6.9 I2C Data Transmit Register (I2CDXR)

[Figure 10-109](#) and [Table 10-101](#) describe this register.

Figure 10-109. I2C Data Transmit Register (I2CDXR) [offset = 20h]

15		8	7		0
Reserved			DATATX		
R-0			R/W-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-101. I2C Data Transmit Register (I2CDXR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	DATATX	0-FFh	Transmit data. Data written to this register will be transmitted on the I2C bus. A write to this register clears the TXRDY bit and clears code 0x05 from the I2CIVR register.

10.1.2.6.10 I2C Mode Register (I2CMDR)

Figure 10-110 and Table 10-102 describe this register.

Figure 10-110. I2C Mode Register (I2CMDR) [offset = 24h]

15	14	13	12	11	10	9	8
NACKMOD	FREE	STT	Reserved	STP	MST	TRX	XA

RM	DLB	nIRS	STB	FDF	BC		
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-102. I2C Mode Register (I2CMDR) Field Descriptions

Bit	Field	Value	Description
15	NACKMOD	0 1	<p>No-acknowledge (NACK) mode.</p> <p>This bit is used to send an acknowledge (ACK) or a no-acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode, when the internal data counter decrements to 0, the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is 1. The NACKMOD bit should be set before the rising edge of the last data bit if a NACK must be sent, and this bit is cleared once a NACK has been sent.</p> <p>0 The I2C sends an ACK to the transmitter during the acknowledge cycle.</p> <p>1 The I2C sends a NACK to the transmitter during the acknowledge cycle.</p>
14	FREE	0 1	<p>Free running bit.</p> <p>This bit is used to determine the state of the I2C when a breakpoint is encountered in the high level language (HLL) debugger.</p> <p>0 The I2C stops immediately if SCL is low and keeps driving SCL low if the I2C master is a transmitter/receiver. If SCL is high, I2C waits until SCL becomes low and then stops. If the I2C is a slave, it will stop when the transmission/reception completes.</p> <p>1 The I2C runs free.</p>
13	STT	0 1	<p>Start condition.</p> <p>The start condition bit works with the STP bit (master only mode). The STT and STP bits are configured to generate different transfer formats (see Table 10-103). The STT and STP bits can be used to terminate the repeat mode. This bit takes one I2C module clock cycle to set.</p> <p>0 STT is reset to 0 by the hardware after the START condition has been generated.</p> <p>1 STT is set to 1 by the device to generate a START condition. In master mode, setting STT to 1 generates a START condition.</p>
12	Reserved	0	Reads return 0. Writes have no effect.
11	STP	0 1	<p>Stop condition (Master mode only).</p> <p>This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode (RM=0). In repeat mode (RM=1), the stop condition is generated if STP bit is 1. In transmitter mode, I2CTXRDY needs to be 1 (that is, you have to set STP bit unless you write data into I2CDXR).</p> <p>0 STP is reset to 0 by the hardware after the STOP condition has been generated.</p> <p>1 STP is set to 1 by the device to generate a STOP condition.</p>

Table 10-102. I2C Mode Register (I2CMDR) Field Descriptions (continued)

Bit	Field	Value	Description
10	MST	<p>0 The module is in the slave mode and the clock is received from the master device.</p> <p>1 The module is in the master mode and it generates the clock. This bit is cleared when the transfer has completed.</p>	<p>Master/slave mode bit.</p> <p>This bit determines whether the module will operate in master or slave mode; see Table 10-104. This bit is cleared after generating a STOP condition. The BB bit is cleared first, and MST bit is cleared second. Before starting the next transaction in master mode, this bit must be confirmed to be cleared.</p>
9	TRX	<p>0 The module is in the receive mode and data on the SDA line is shifted into the data register I2CDRR.</p> <p>1 The module is in the transmit mode and the data in the I2CDXR is shifted out on the SDA line.</p>	<p>Transmit/receive bit.</p> <p>This bit determines the direction of data transmission of the I2C module. See Table 10-104.</p>
8	XA	<p>0 The mode is set to 7-bit addressing mode (normal address mode).</p> <p>1 The mode is set to 10-bit addressing mode (expanded address mode).</p>	<p>Expand address enable bit.</p> <p>This bit controls the addressing mode. When XA is set to 1, the I2C does not support the combined format in master mode operations. However, the I2C will acknowledge and support the formats when configured as a slave. This bit needs to be configured even if the I2C is in slave mode.</p>
7	RM	<p>0 The mode is not in repeat mode.</p> <p>1 In repeat mode, data is continuously transmitted out of the ICDXR or received into the ICDRR until the STP bit is set to 1 regardless of ICCNT value. See Table 10-103 for module conditions.</p>	<p>Repeat mode enable bit (Master mode only).</p> <p>This bit is a 'don't care' if the module is configured in slave mode (MST = 0); see Table 10-103. Each time a byte of data is received, the user should decide whether or not to continue receiving more data. See Figure 10-111 for a diagram of this function.</p>
6	DLB	<p>0 Digital loop back mode is disabled.</p> <p>1 Digital loop back mode is enabled. In digital loop back mode, data transmitted out of the I2CDXR will be received in the I2CDRR. The address of the I2COAR is output on SDA.</p>	<p>Digital loop back enable bit.</p> <p>This bit enables the digital loopback mode of the I2C. This bit only applies in Master transmitter mode.</p>
5	nIRS	<p>0 I2C is in reset.</p> <p>1 I2C is out of reset.</p>	<p>I2C reset enable bit.</p> <p>When cleared to 0, this bit will place all status registers in this module to their default state. Resetting nIRS during a data transfer can hang the I2C bus.</p>
4	STB	<p>0 The module is not in START byte mode.</p> <p>1 The module is in START byte mode.</p>	<p>Start byte mode enable bit (Master mode only).</p> <p>The Start byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode. The I2C sends 00000001 regardless of the I2CSAR value. Refer to the Philips I2C specification for more details.</p>
3	FDF	<p>0 The module is not in free data format mode.</p> <p>1 The module is in free data format mode.</p>	<p>Free data format enable bit.</p> <p>This bit configures the module to operate in free data format mode (see Table 10-104) in both master and slave modes. When FDF is 0, ARDY is asserted after ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition. FDF mode is not supported in digital loop back mode.</p>

Table 10-102. I2C Mode Register (I2CMDR) Field Descriptions (continued)

Bit	Field	Value	Description
2-0	BC		<p>Bit count.</p> <p>This bit defines the number of bits starting from the LSB (excluding the acknowledge bit) that are sent on the bus when data is written to the data transmit register.</p> <p>If the bits BC0, BC1, and BC2 are all 0, then the number of bits sent on the bus is 8. If the bit count bits are a non-zero value, then the number of bits sent on the bus is that value. The value 001 is reserved. When performing a transfer using the bit count of, for example, n (where n is nonzero), only the n least significant bits in the data receive register are valid and correct. The rest of the bits should be disregarded. See Table 10-105 for more information.</p>

Figure 10-111. Typical Timing Diagram of Repeat Mode

Table 10-103. I2C Module Condition, Bus Activity, and Mode

RM	STT	STP	Condition	Bus Activities ⁽¹⁾	Mode
0	0	0	Idle	None	N/A
0	0	1	Stop	P	N/A
0	1	0	(Repeat) Start	S-A-D..(n)..D	Repeat n
0	1	1	(Repeat) Start-Stop	S-A-D..(n)..D-P	Repeat n

1	0	0	4	5
1	0	1	5	6
1	1	0	6	7
1	1	1	7	8

10.1.2.6.11 I2C Interrupt Vector Register (I2CIVR)

The I2C interrupt vector register is a 16-bit memory-mapped register used to indicate the occurrence of an interrupt. [Figure 10-112](#) and [Table 10-106](#) describe this register.

Figure 10-112. I2C Interrupt Vector Register (I2CIVR) [offset = 28h]

15	12	11	8	7	3	2	0
Reserved		TESTMD		Reserved		INTCODE	
R-0		R/W-0		R-0		R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

Table 10-106. I2C Interrupt Vector Register (I2CIVR) Field Descriptions

Bit	Field	Value	Description
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	TESTMD	0-3h	Reserved for internal testing.
7-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	INTCODE	0-3h	<p>Interrupt Code Bits.</p> <p>This binary coded interrupt vector indicates which interrupt has occurred. If there is more than one interrupt pending, reading I2CIVR provides the vector for the highest priority interrupt that is pending.</p> <p>Reading the I2CIVR will clear the corresponding flags in I2CSTR for AL, NACK and SCD as long as those interrupts are enabled. A new interrupt will be generated for each pending source.</p> <p>Reading I2CIVR will clear the INTCODE for AL, NACK, SCD, AAS, RXRDY and TXRDY. Reading I2CIVR will not clear the INTCODE for ARDY.</p> <p>The INTCODE for certain codes can also be cleared by either writing a 1 to the corresponding interrupt flag bits in I2CSTR, or by reading and writing to the receive or transmit registers. See Section 10.1.2.6.3 for more details.</p> <p>Users must read (clear) the I2CIVR before doing another start otherwise the I2CIVR could contain incorrect (old interrupt flag) value.</p>

Table 10-107. Interrupt Codes for INTCODE Bits

Code	INTCODE(2-0)	Interrupt Occurred
00h	000	None
01h	001 (highest priority)	Arbitration lost (AL)
02h	010	No acknowledgement (NACK)
03h	011	Receive access ready (ARDY)
04h	100	Receive data ready (RXRDY)
05h	101	Transmit data ready (TXRDY)
06h	110	Stop condition detection (SCD)

Table 10-107. Interrupt Codes for INTCODE Bits (continued)

Code	INTCODE(2-0)	Interrupt Occurred
07h	111 (lowest priority)	Address as slave (AAS)

10.1.2.6.12 I2C Extended Mode Register (I2CEMDR)

The I2C extended mode register is a 16-bit memory-mapped register that contains additional mode select bits. Figure 10-113 and Table 10-108 describe this register.

Figure 10-113. I2C Extended Mode Register (I2CEMDR) [offset = 2Ch]

15	2	1	0
Reserved		IGNACK	BCM
R-0		R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-108. I2C Extended Mode Register (I2CEMDR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	IGNACK	0	The master transmitter will operate normally, discontinue the data transfer, and set the ARDY and NACK status bits when a NACK signal is received from the slave.
		1	The master transmitter will ignore a NACK received from the slave.
0	BCM	0	The I2C is not in compatibility mode.
		1	The I2C is in compatibility mode.

10.1.2.6.13 I2C Prescale Register (I2CPSC)

The I2C prescaler register is a 16-bit memory-mapped register used for dividing down the VBUS_CLK to obtain a module clock frequency between 6.7 MHz and 13.3 MHz. Figure 10-114 and Table 10-109 describe this register.

Figure 10-114. I2C Prescale Register (I2CPSC) [offset = 30h]

15	8	7	0
Reserved		PSC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-109. I2C Prescale Register (I2CPSC) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	PSC	0-FFh	8-bit prescaler to divide down the VBUS clock to obtain the I2C module clock. This register must be initialized while the I2C is still in reset (nIRS = 0). The value takes effect on the rising edge of nIRS.

10.1.2.6.14 I2C Peripheral ID Register 1 (I2CPID1)

Figure 10-115 and Table 10-110 describe this register.

Figure 10-115. I2C Peripheral ID Register 1 (I2CPID1) [offset = 34h]

15		8	7	0
CLASS		REVISION		
R-1		R-46h		

LEGEND: R = Read only; -n = value after reset

Table 10-110. I2C Peripheral ID Register 1 (I2CPID1) Field Descriptions

Bit	Field	Value	Description
15-8	CLASS	0-FFh	Peripheral class. These bits identify the class of peripheral.
7-0	REVISION	0-FFh	Revision level of the I2C. These bits identify the revision level of the I2C.

10.1.2.6.15 I2C Peripheral ID Register 2 (I2CPID2)

Figure 10-116 and Table 10-111 describe this register.

Figure 10-116. I2C Peripheral ID Register 2 (I2CPID2) [offset = 38h]

15		8	7	0
Reserved		TYPE		
R-0		R-5h		

LEGEND: R = Read only; -n = value after reset

Table 10-111. I2C Peripheral ID Register 2 (I2CPID2) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TYPE	0-FFh	Peripheral type. These bits identify the type of peripheral.

10.1.2.6.16 I2C DMA Control Register (I2CDMACR)

This register contains the transmit and receive DMA enable bits. [Figure 10-117](#) and [Table 10-112](#) describe this register.

Figure 10-117. I2C DMA Control Register (I2CDMACR) [offset = 3Ch]

15		2	1	0
Reserved			TXDMAEN	RXDMAEN
R-0			R/W-1	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-112. I2C DMA Control Register (I2CDMACR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	TXDMAEN	0 1	<p>Transmitter DMA enable.</p> <p>This bit controls the transmit DMA event pin to the system. When this bit is a 1, the DMA transmit event is enabled and the DMA can occur. When this bit is a 0, the DMA transmit event is disabled.</p> <p>Writing a 1 to this bit will send a TXDMA request to the DMA module, if PINFUNC is also cleared to 0.</p> <p>The transmit DMA is disabled.</p> <p>The transmit DMA is enabled.</p>
0	RXDMAEN	0 1	<p>Receive DMA enable.</p> <p>This bit controls the receive DMA event pin to the system. When this bit is 1, the DMA receive event is enabled and the DMA can occur. When this bit is a 0, the DMA receive event is disabled.</p> <p>The receive DMA is disabled.</p> <p>The receive DMA is enabled.</p>

10.1.2.6.17 I2C Pin Function Register (I2CPFNC)

[Figure 10-118](#) and [Table 10-113](#) describe this register.

Figure 10-118. I2C Pin Function Register (I2CPFNC) [offset = 48h]

15		1	0
Reserved			PINFUNC
R-0			R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-113. I2C Pin Function Register (I2CPFNC) Field Descriptions

Bit	Field	Value	Description
15-1	Reserved	0	Reads return 0. Writes have no effect.
0	PINFUNC	0 1	<p>SDA and SCL pin function.</p> <p>This bit controls whether the SDA and SCL pins function as I2C pins or as I/O pins.</p> <p>SDA and SCL pins function as I2C pins.</p> <p>SDA and SCL pins function as I/O pins.</p>

10.1.2.6.18 I2C Pin Direction Register (I2CPDIR)

This register is used to independently configure each I2C pin, when configured as a general-purpose I/O, as either an input or output. [Figure 10-119](#) and [Table 10-114](#) describe this register.

Figure 10-119. I2C Pin Direction Register (I2CPDIR) [offset = 4Ch]

15		2	1	0
Reserved			SDADIR	SCLDIR
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-114. I2C Pin Direction Register (I2CPDIR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDADIR	0	SDA pin direction. This bit controls the direction of the I2C SDA pin when configured as a GPIO. SDA pin functions as an input.
		1	SDA pin functions as an output.
0	SCLDIR	0	SCL pin direction. This bit controls the direction of the I2C SCL pin when configured as a GPIO. SCL pin functions as an input.
		1	SCL pin functions as an output.

10.1.2.6.19 I2C Data Input Register (I2CDIN)

[Figure 10-120](#) and [Table 10-115](#) describe this register.

Figure 10-120. I2C Data Input Register (I2CDIN) [offset = 50h]

15		2	1	0
Reserved			SDAIN	SCLIN
R-0			R-X	R-X

LEGEND: R = Read only; -X = value is indeterminate; -n = value after reset

Table 10-115. I2C Data Input Register (I2CDIN) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAIN		Serial data in. The value of this bit reflects the value on the SDA pin.
0	SCLIN		Serial clock data in. The value of this bit reflects the value on the SCL pin.

10.1.2.6.20 I2C Data Output Register (I2CDOOUT)

This register contains the values sent to the I2C pins. [Figure 10-121](#) and [Table 10-116](#) describe this register.

Figure 10-121. I2C Data Output Register (I2CDOOUT) [offset 0x54]

15		2	1	0
Reserved			SDAOUT	SCLOUT
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-116. I2C Data Output Register (I2CDOOUT) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAOUT	0 1	SDA data output. This function is only active if the SDA pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SDA pin. 0 The pin is driven low. 1 The pin is driven high.
0	SCLOUT	0 1	SCL data output. This function is only active if the SCL pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SCL pin. 0 The pin is driven low. 1 The pin is driven high.

10.1.2.6.21 I2C Data Set Register (I2CDSET)

The I2CDSET register is an alias of the I2CDOOUT register. [Figure 10-122](#) and [Table 10-117](#) describe this register.

Figure 10-122. I2C Data Set Register (I2CDSET) [offset = 58h]

15		2	1	0
Reserved			SDASET	SCLSET
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-117. I2C Data Set Register (I2CDSET) Field Description

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDASET	0 1	Serial data set. This bit is used to set the SDA GPIO pin. 0 Read: Reads return value of SDAOUT. Write: No effect. 1 Read: Reads return value of SDAOUT. Write: SDAOUT is set to logic high (1).

Table 10-117. I2C Data Set Register (I2CDSET) Field Description (continued)

Bit	Field	Value	Description
0	SCLSET		Serial clock set. This bit is used to set the SCL GPIO pin.
		0	Read: Reads return value of SCLOUT. Write: No effect.
		1	Read: Reads return value of SCLOUT. Write: SCLOUT is set to logic high (1).

10.1.2.6.22 I2C Data Clear Register (I2CDCLR)

The I2CDCLR register is an alias of the I2CDOUT register. [Figure 10-123](#) and [Table 10-118](#) describe this register.

Figure 10-123. I2C Data Clear Register (I2CDCLR) [offset = 5Ch]

15		2	1	0
Reserved			SDACL	SCLCLR
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-118. I2C Data Clear Register (I2CDSET) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDACL	0	Serial data clear. This bit is used to clear the SDA GPIO pin. Read: Reads return value of SDAOUT. Write: No effect.
		1	Read: Reads return value of SDAOUT. Write: SDAOUT is cleared to logic low (0).
0	SCLCLR	0	Serial clock clear. This bit is used to clear the SCL GPIO pin. Read: Reads return value of SCLOUT. Write: No effect.
		1	Read: Reads return value of SCLOUT. Write: SCLOUT is cleared to logic low (0).

10.1.2.6.23 I2C Pin Open Drain Register (I2CPDR)

[Figure 10-124](#) and [Table 10-119](#) describe this register.

Figure 10-124. I2C Pin Open Drain Register (I2CPDR) [offset = 60h]

15		2	1	0
Reserved			SDAPDR	SCLPDR
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-119. I2C Pin Open Drain Register (I2CPDR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPDR	0	SDA pin open drain enable. The open drain function is enabled (the output voltage is V_{OL} or lower if SDAOUT = 0 and high-impedance if SDAOUT = 1).
		1	The open drain function is disabled (output voltage is V_{OL} or lower if SDAOUT = 0; V_{OH} or higher if SDAOUT = 1).

Table 10-119. I2C Pin Open Drain Register (I2CPDR) Field Descriptions (continued)

Bit	Field	Value	Description
0	SCLPDR		SCL pin open drain enable.
		0	The open drain function is enabled (the output voltage is V_{OL} or lower if SCLOUT = 0 and high-impedance if SCLOUT = 1).
		1	The open drain function is disabled (output voltage is V_{OL} or lower if SCLOUT = 0; V_{OH} or higher if SCLOUT = 1).

10.1.2.6.24 I2C Pull Disable Register (I2CPDIS)

Values in the I2CPDIS register enable or disable the pull control capability of the pins. [Figure 10-125](#) and [Table 10-120](#) describe this register.

Figure 10-125. I2C Pull Disable Register (I2CPDIS) [offset = 64h]

15		2	1	0
Reserved			SDAPDIS	SCLPDIS
R-0			R/W-1	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-120. I2C Pull Disable Register (I2CPDIS) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPDIS	0	The pull function is enabled.
		1	The pull function is disabled.
0	SCLPDIS	0	The pull function is enabled.
		1	The pull function is disabled.

10.1.2.6.25 I2C Pull Select Register (I2CPSEL)

Values in the I2CPSEL register select the pull up or pull down functions of the corresponding pins. [Figure 10-126](#) and [Table 10-121](#) describe this register.

Figure 10-126. I2C Pull Select Register (I2CPSEL) [offset = 68h]

15		2	1	0
Reserved			SDAPSEL	SCLPSEL
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-121. I2C Pull Select Register (I2CPSEL) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPSEL	0	The pull down function is enabled.
		1	The pull up function is enabled.
0	SCLPSEL	0	The pull down function is enabled.
		1	The pull up function is enabled.

10.1.2.6.25.1 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in [Table 10-122](#).

Table 10-122. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) ^{(1) (2)}	Pull Disable (PULDIS) ^{(1) (3)}	Pull Select (PULSEL) ^{(1) (4)}	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

- (1) X = Don't care
- (2) DIR = 0 for input, = 1 for output
- (3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
- (4) PULSEL = 0 for pull-down functionality
= 1 for pull-up functionality

10.1.2.6.26 I2C Pins Slew Rate Select Register (I2CSRS)

This register controls the slew rate of the signal on the I2C pins. [Figure 10-127](#) and [Table 10-123](#) describe this register.

Figure 10-127. I2C Pins Slew Rate Select Register (I2CSRS) [offset = 6Ch]

15	2	1	0
Reserved	SDASRS	SCLSRS	
R-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-123. I2C Pins Slew Rate Select Register (I2CSRS) Field Descriptions

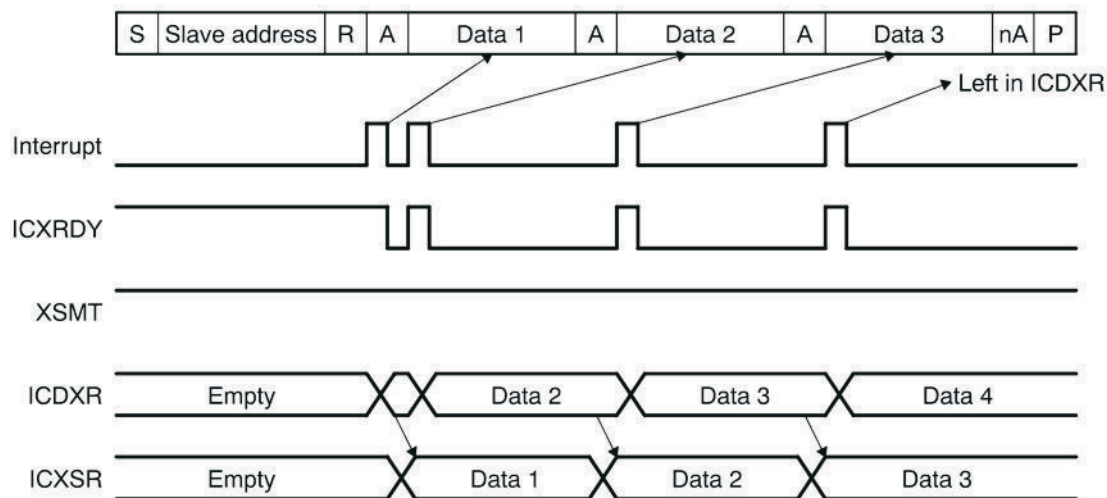

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDASRS	0	The slow buffer is selected.
		1	The normal buffer is selected.
0	SCLSRS	0	The slow buffer is selected.
		1	The normal buffer is selected.

10.1.2.7 Sample Waveforms

Figure 10-128 provides waveforms to illustrate the difference between normal operation and backward compatibility mode.

Slave transmitter

a) BCM=1

b) BCM=0

10.1.3 UART/SCI

This chapter contains the description of the serial communication interface (SCI) module.

10.1.3.1 Introduction.....	2630
10.1.3.2 SCI Communication Formats.....	2632
10.1.3.3 SCI Interrupts.....	2637
10.1.3.4 SCI DMA Interface.....	2640
10.1.3.5 SCI Configurations.....	2641
10.1.3.6 SCI Low-Power Mode.....	2642
10.1.3.7 SCI Control Registers.....	2644

10.1.3.8 GPIO Functionality	2679
--	-------------

10.1.3.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

10.1.3.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
 - Data word length programmable from one to eight bits
 - Additional address bit in address-bit mode
 - Parity programmable for zero or one parity bit, odd or even parity
 - Stop programmable for one or two stop bits
- Asynchronous communication mode with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

Note

SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

10.1.3.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

Transmitter (TX) contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VCLK.

Receiver (RX) contains two major registers to perform double buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 10-129 shows the detailed SCI block diagram.

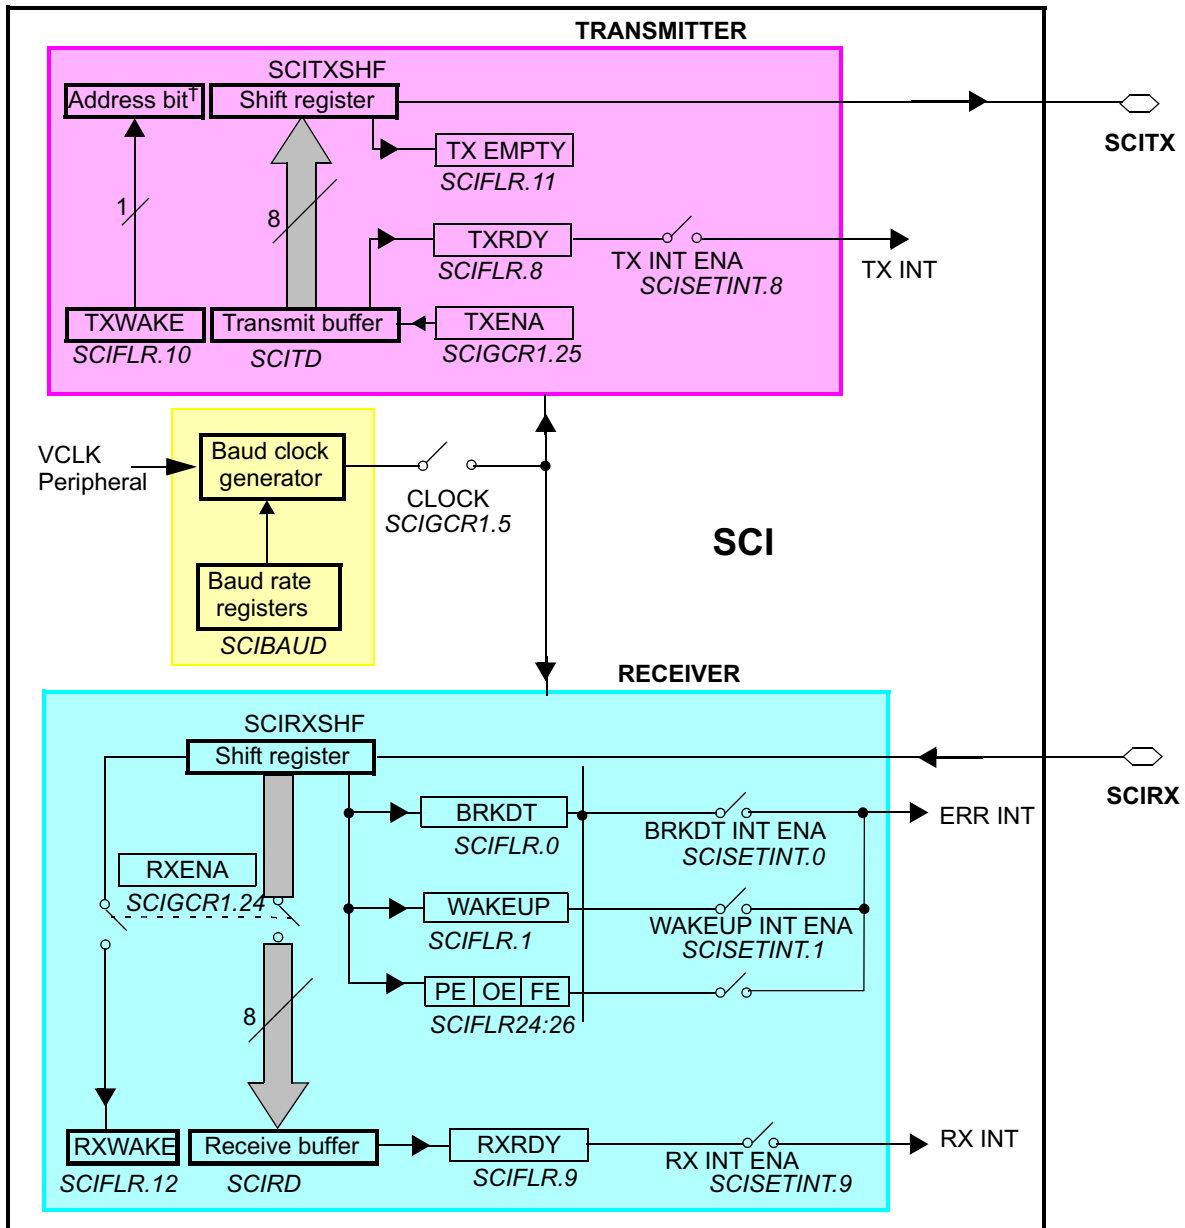

Figure 10-129. Detailed SCI Block Diagram

10.1.3.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

10.1.3.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 10-130](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 10-130](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 10-130](#) use one stop bit per frame.

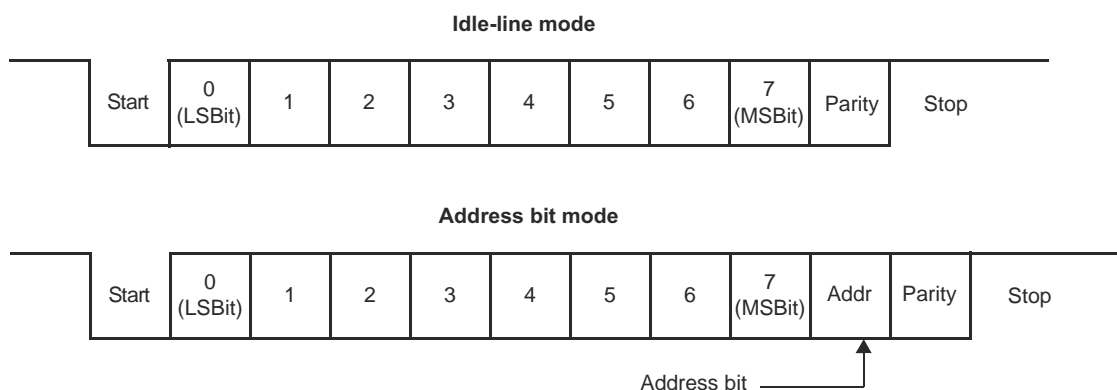

Figure 10-130. Typical SCI Data Frame Formats

10.1.3.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

10.1.3.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 10-131 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

Figure 10-131. Asynchronous Communication Bit Timing

10.1.3.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

10.1.3.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value of the BRS register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{16 * (\text{BAUD} + 1)}$$

For BAUD = 0,

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (8)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\text{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (9)$$

10.1.3.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

Note

Avoid Transmitting Simultaneously on the Same Serial Bus

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

10.1.3.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 10-132 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1 : Write a 1 to the TXWAKE bit.

Step 2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3 : Wait for the SCI to clear the TXWAKE flag.

Step 4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

Figure 10-132. Idle-Line Multiprocessor Communication Format

10.1.3.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. [Figure 10-133](#) illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

Figure 10-133. Address-Bit Multiprocessor Communication Format

10.1.3.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 10-134](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable and disable the interrupt in the SCISSETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

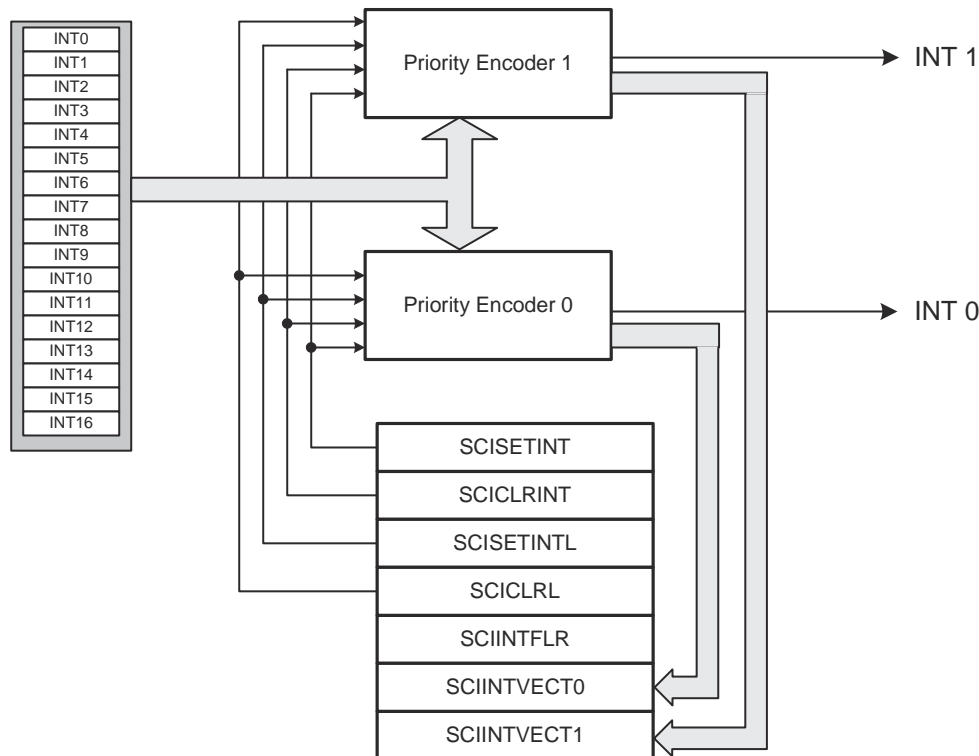

Figure 10-134. General Interrupt Scheme

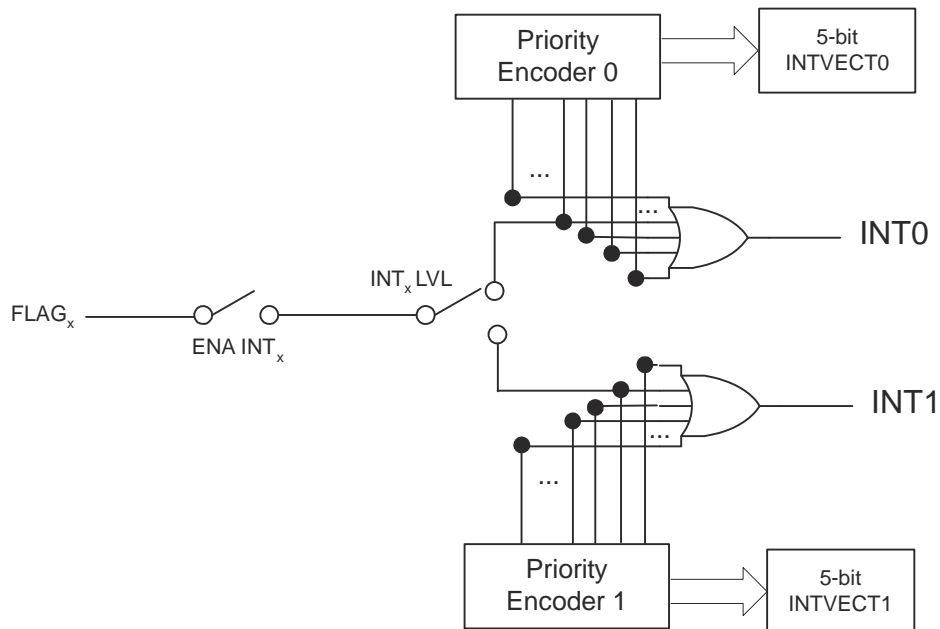

Figure 10-135. Interrupt Generation for Given Flags

10.1.3.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

10.1.3.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

10.1.3.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

10.1.3.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If any of these errors (PE, FE, BRKDT, OE) is flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports the following 7 interrupts as listed in [Table 10-124](#).

Table 10-124. SCI Interrupts

Offset ⁽¹⁾	Interrupt
0	Reserved
1	Wakeup
2	Reserved
3	Parity error
4	Reserved
5	Reserved
6	Frame error
7	Break detect error
8	Reserved
9	Overrun error
10	Reserved
11	Receive
12	Transmit
13-15	Reserved

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

10.1.3.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

10.1.3.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. [Table 10-125](#) specifies the bit values for DMA requests in multiprocessor modes.

Table 10-125. DMA and Interrupt Requests in Multiprocessor Modes

SET RX INT	SET RX DMA	SET RX DMA ALL	ADDR FRAME INT	ADDR FRAME DMA	DATA FRAME INT	DATA FRAME DMA
0	0	x	N	N	N	N
0	1	0	Y	N	N	Y
0	1	1	N	Y	N	Y
1	0	x	Y	N	Y	N
1	1	0	Y	N	Y	Y
1	1	1	Y	Y	Y	Y

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

10.1.3.4.2 Transmit DMA Requests

DMA functionality is enabled and disabled by the CPU with the SET TX DMA and CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits. If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set. The DMA will write the first byte to the transmit buffer.

10.1.3.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the SCIRX and SCITX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 10.1.3.5.1](#) and [Section 10.1.3.5.2](#)).

10.1.3.5.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general-purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from SCIRD register once RXRDY is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

10.1.3.5.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

10.1.3.6 SCI Low-Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the power-down bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

10.1.3.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 10-134](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

10.1.3.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in [Table 10-126](#). Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

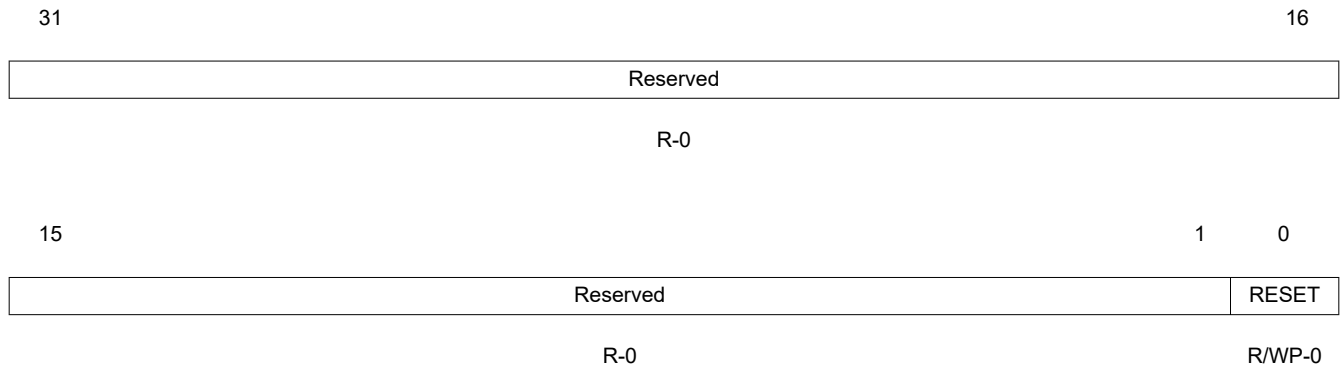

Table 10-126. SCI Control Registers Summary

Offset	Acronym	Register Description	Section
00h	SCIGCR0	SCI Global Control Register 0	Section 10.1.3.7.1
04h	SCIGCR1	SCI Global Control Register 1	Section 10.1.3.7.2
0Ch	SCISSETINT	SCI Set Interrupt Register	Section 10.1.3.7.3

10.1.3.7.1 SCI Global Control Register 0 (SCIGCR0)

The SCIGCR0 register defines the module reset. [Figure 10-136](#) and [Table 10-127](#) illustrate this register.

Figure 10-136. SCI Global Control Register 0 (SCIGCR0) [offset = 00]

LEGEND: R = Read only; R/WP = Read/Write in privileged mode only; -n = value after reset

Table 10-127. SCI Global Control Register 0 (SCIGCR0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	RESET	0	This bit resets the SCI module. SCI module is in reset.
		1	SCI module is out of reset.
			Note: Read/Write in privileged mode only.

10.1.3.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. [Figure 10-137](#) and [Table 10-128](#) illustrate this register.

Note

The SCIGCR1 Control Register Bits should not be changed during Frame Transmission or Reception.

Figure 10-137. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]

Table 10-128. SCI Global Control Register 1 (SCIGCR1) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reads return 0. Writes have no effect.
25	TXENA	0	Transmit enable. Data is transferred from SCITD to the SCITXSHF shift out register only when the TXENA bit is set. Disable transfers from SCITD to SCITXSHF.
		1	Enable SCI to transfer data from SCITD to SCITXSHF. Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent.

Table 10-128. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
24	RXENA	0 1	<p>Receive enable. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD.</p> <p>The receiver will not transfer data from the shift buffer to the receive buffer.</p> <p>The receiver will transfer data from the shift buffer to the receive buffer.</p> <p>Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 10-134) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.</p> <p>Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.</p> <p>Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not assured to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.</p>
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	CONT	0 1	<p>Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI operates when the program is suspended. The</p> <p>When debug mode is entered, the SCI state machine is frozen. Transmissions are halted and resume when debug mode is exited.</p> <p>When debug mode is entered, the SCI continues to operate until the current transmit and receive functions are complete.</p>
16	LOOP BACK	0 1	<p>Loopback bit. The self-checking option for the SCI can be selected with this bit. If the SCITX and SCIRX pins are configured with SCI functionality, then the SCITX pin is internally connected to the SCIRX pin. Externally, during loop back operation, the SCITX pin outputs a high value and the SCIRX pin is in a high-impedance state. If this bit value is changed while the SCI is transmitting or receiving data, errors may result.</p> <p>Loop back mode is disabled.</p> <p>Loop back mode is enabled.</p>
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	POWERDOWN	0 1	<p>Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.</p> <p>Normal operation.</p> <p>Low-power mode is enabled.</p>
8	SLEEP	0 1	<p>SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>Sleep mode is disabled.</p> <p>Sleep mode is enabled.</p> <p>Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 10-134) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.</p> <p>Note: The SLEEP bit is not automatically cleared when an address byte is detected.</p> <p>See for more information on using the SLEEP bit for multiprocessor communication.</p>
7	SWnRST	0 1	<p>Software reset (active low).</p> <p>The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 10-134 and Table 10-135. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.</p> <p>Note: The SCI should only be configured while SWnRESET = 0.</p>

Table 10-128. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
6	Reserved	0	Reads return 0. Writes have no effect.
5	CLOCK	0 1	<p>SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.</p> <p>0 The external SCICLK is the clock source. 1 The internal SCICLK is the clock source.</p> <p>Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.</p>
4	STOP	0 1	<p>SCI number of stop bits per frame.</p> <p>0 One stop bit is used. 1 Two stop bits are used.</p> <p>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</p>
3	PARITY	0 1	<p>SCI parity odd/even selection. If the PARITY ENA bit is set, PARITY designates odd or even parity.</p> <p>0 Odd parity is used. 1 Even parity is used.</p> <p>The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</p> <p>For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</p> <p>For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</p>
2	PARITY ENA	0 1	<p>Parity enable. This bit enables or disables the parity function.</p> <p>0 Parity is disabled; no parity bit is generated during transmission or is expected during reception. 1 Parity is enabled. A parity bit is generated during transmission and is expected during reception.</p>
1	TIMING MODE	0 1	<p>SCI timing mode bit.</p> <p>0 Synchronous timing is used. 1 Asynchronous timing is used.</p>
0	COMM MODE	0 1	<p>SCI communication mode bit.</p> <p>0 Idle-line mode is used. 1 Address-bit mode is used.</p>

10.1.3.7.3 SCI Set Interrupt Register (SCISSETINT)

Figure 10-138 and Table 10-129 illustrate this register. SCISSETINT register is used to enable the required interrupts supported by the module.

Figure 10-138. SCI Set Interrupt Register (SCISSETINT) [offset = 0Ch]

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; -n = value after reset

Table 10-129. SCI Set Interrupt Register (SCISSETINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	SET FE INT	0	Set framing-error interrupt. Setting this bit enables the SCI module to generate an interrupt when a framing error occurs. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.
25	SET OE INT	0	Set overrun-error interrupt. Setting this bit enables the SCI module to generate an interrupt when an overrun error occurs. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.
24	SET PE INT	0	Set parity interrupt. Setting this bit enables the SCI module to generate an interrupt when a parity error occurs. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.

Table 10-129. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)

Bit	Field	Value	Description
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	SET RX DMA ALL	0	Set receive DMA all. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames. <i>Read:</i> The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames). <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read and write:</i> The DMA request is enabled for address and data frames
17	SET RX DMA	0	Set receiver DMA. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on the SET RX INT bit (SCISSETINT[9]). <i>Read:</i> The DMA request is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read and write:</i> The DMA request is enabled for address and data frames
16	SET TX DMA	0	Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on the SET TX INT bit (SCISSETINT[8]). <i>Read:</i> Transmit DMA request is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read and write:</i> Transmit DMA request is enabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	SET RX INT	0	Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.
8	SET TX INT	0	Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	SET WAKEUP INT	0	Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local lowpower mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.
0	SET BRKDT INT	0	Set break detect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read or write:</i> The interrupt is enabled.

10.1.3.7.4 SCI Clear Interrupt Register (SCICLEARINT)

Figure 10-139 and Table 10-130 illustrate this register. SCICLEARINT register is used to clear the selected enabled interrupts with out accessing SCISSETINT register.

Figure 10-139. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]

31	27	26	25	24

R-0			R/W-0	R/WC-0

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; -n = value after reset

Table 10-130. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	CLR FE INT	0	Clear framing-error interrupt. This bit disables the framing-error interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.
25	CLR CE INT	0	Clear overrun-error interrupt. This bit disables the SCI overrun error interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.
24	CLR PE INT	0	Clear parity interrupt. This bit disables the parity error interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.

Table 10-130. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)

Bit	Field	Value	Description
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	CLR RX DMA ALL	0	Clear receive DMA all. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request. <i>Read:</i> Receive DMA request for address frames is disabled; Instead, RX interrupt requests are enabled for address frames. Receive DMA requests are still enabled for data frames. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The receive DMA request for address and data frames is enabled. <i>Write:</i> The receive DMA request for address and data frames is disabled.
17	CLR RX DMA	0	Clear receive DMA request. This bit disables the receive DMA request when set. <i>Read:</i> The DMA request is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The receive DMA request is enabled. <i>Write:</i> The receive DMA request for is disabled.
16	CLR TX DMA	0	Clear transmit DMA request. This bit disables the transmit DMA request when set. <i>Read:</i> Transmit DMA request is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The transmit DMA request is enabled. <i>Write:</i> The transmit DMA request for is disabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	CLR RX INT	0	Clear receiver interrupt. This bit disables the receiver interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.
8	CLR TX INT	0	Clear transmitter interrupt. This bit disables the transmitter interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	CLR WAKEUP INT	0	Clear wakeup interrupt. This bit disables the wakeup interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.
0	CLR BRKDT INT	0	Clear break detect interrupt. This bit disables the break-detect interrupt when set. <i>Read:</i> The interrupt is disabled. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> The interrupt is enabled. <i>Write:</i> The interrupt is disabled.

10.1.3.7.5 SCI Set Interrupt Level Register (SCISSETINTLVL)

Figure 10-140 and Table 10-131 illustrate this register. This register is used to set the interrupt level for the supported interrupts.

Figure 10-140. SCI Set Interrupt Level Register (SCISSETINTLVL) [offset = 14h]

R-0			R/W-0	R-0	R/WL-0	R/WC-0

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; -n = value after reset

Table 10-133. SCI Flags Register (SCIFLR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved		Reads return 0. Writes have no effect.
26	FE	0	<p>Framing error flag. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt, if the SET FE INT bit (SCISSETINT[26]) is set. The framing error flag is cleared by the following:</p> <ul style="list-style-type: none"> • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 • Reception of a new character <p>In multi-buffer mode, the frame is defined in the SCIFORMAT register.</p> <p><i>Read:</i> No framing error has been detected since the last clear. <i>Write:</i> Writing a 0 to this bit has no effect.</p>
		1	<p><i>Read:</i> A framing error has been detected since the last clear. <i>Write:</i> The bit is cleared to 0.</p>

Table 10-133. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
25	OE	0	<p>Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the SCI to generate an error interrupt if the SET OE INT bit (SCISSETINT[25]) is set. The OE flag is reset by the following:</p> <ul style="list-style-type: none"> Setting of the SW nRST bit Setting of the RESET bit A system reset Writing a 1 to this bit Reading the corresponding interrupt offset in SCIINTVECT0/1 <p><i>Read:</i> No overrun error has been detected since the last clear. <i>Write:</i> Writing a 0 to this bit has no effect.</p>
		1	<p><i>Read:</i> An overrun error has been detected since the last clear. <i>Write:</i> The bit is cleared to 0.</p>
24	PE	0	<p>Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the SCI to generate an error interrupt if the SET PE INT bit (SCISSETINT[24]) is set. The PE bit is reset by the following:</p> <ul style="list-style-type: none"> Setting of the SW nRST bit Setting of the RESET bit A system reset Writing a 1 to this bit Reception of a new character Reading the corresponding interrupt offset in SCIINTVECT0/1 <p><i>Read:</i> No parity error has been detected since the last clear. <i>Write:</i> Writing a 0 to this bit has no effect.</p>
		1	<p><i>Read:</i> A parity error has been detected since the last clear. <i>Write:</i> The bit is cleared to 0.</p>
23-13	Reserved	0	Reads return 0. Writes have no effect.
12	RXWAKE	0	<p>Receiver wakeup detect flag. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following:</p> <ul style="list-style-type: none"> Setting of the SW nRST bit Setting of the RESET bit A system reset Upon receipt of a data frame. <p>The data in SCIRD is not an address.</p>
		1	The data in SCIRD is an address.
11	TX EMPTY	0	<p>Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty.</p> <p>Note: The RESET bit, an active SW nRESET (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.</p> <p>Transmitter buffer or shift register (or both) are loaded with data.</p>
		1	Transmitter buffer and shift registers are both empty.

Table 10-133. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
10	TXWAKE		Transmitter wakeup method select. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. Note: TXWAKE is not cleared by the SW nRESET bit. <i>Address-bit mode</i>
		0	Frame to be transmitted will be data (address bit = 0).
		1	Frame to be transmitted will be an address (address bit = 1).
			<i>Idle-line mode</i>
		0	The frame to be transmitted will be data.
		1	The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).
9	RXRDY		Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit (SCISSETINT[9]) is set; RXRDY is cleared by the following: <ul style="list-style-type: none"> • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the SCIRD register in compatibility mode • Reading the last data byte RDY of the response in SCI mode Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
		0	<i>Read:</i> No new data is in SCIRD. <i>Write:</i> Writing a 0 to this bit has no effect.
		1	<i>Read:</i> New data is ready to be read from SCIRD. <i>Write:</i> The bit is cleared to 0.
8	TXRDY		Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write. Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the SET TX INT bit (SCISSETINT[8]) is set. Note: 1) TXRDY is also set to 1 by setting of the RESET bit, setting of the RESETE bit, or by a system reset. 2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register. 3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers SCITD0 and SCITD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1[25]).
		0	SCITD is full.
		1	SCITD is ready to receive the next character.
7-4	Reserved	0	Reads return 0. Writes have no effect.

Table 10-133. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
3	BUSY		<p>Bus busy flag. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If the SET WAKEUP INT bit (SCISSETINT[2]) is set and power down is requested while this bit is set, the SCI automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following:</p> <ul style="list-style-type: none"> Setting the SW nRST bit Setting of the RESET bit A system reset occurring
		0	The receiver is not currently receiving a frame.
		1	The receiver is currently receiving a frame.
2	IDLE		<p>SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs:</p> <ul style="list-style-type: none"> A system reset An SCI software reset A power down The RX pin is configured as a general I/O pin
		0	The idle period has been detected; the SCI is ready to receive.
		1	The idle period has not been detected; the SCI will not receive any data.
1	WAKEUP		<p>Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT[2]) is set. It is cleared by the following:</p> <ul style="list-style-type: none"> Setting of the SW nRST bit Setting of the RESET bit A system reset Writing a 1 to this bit Reading the corresponding interrupt offset in SCIINTVECT0/1 <p>For compatibility mode, see the SCI document for more information on low-power mode.</p>
		0	<p><i>Read:</i> The module will not wake up from power-down mode. <i>Write:</i> Writing a 0 to this bit has no effect.</p>
		1	<p><i>Read:</i> Wake up from power-down mode. <i>Write:</i> The bit is cleared to 0.</p>
0	BRKDT		<p>SCI break-detect flag. This bit is set when the SCI detects a break condition on the SCIRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit (SCISSETINT[0]) is set. The BRKDT bit is reset by the following:</p> <ul style="list-style-type: none"> Setting of the SW nRST bit Setting of the RESET bit A system reset Writing a 1 to this bit Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	<p><i>Read:</i> No break condition has been detected since the last clear. <i>Write:</i> Writing a 0 to this bit has no effect.</p>
		1	<p><i>Read:</i> A break condition has been detected. <i>Write:</i> The bit is cleared to 0.</p>

Table 10-134. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After SW nRESET ⁽¹⁾
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with their reset value while SW nRESET = 0.

Table 10-135. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After SW nRESET ⁽¹⁾
TX EMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with their reset value while SW nRESET = 0.

10.1.3.7.8 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 10-143 and Table 10-136 illustrate this register.

Figure 10-143. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]

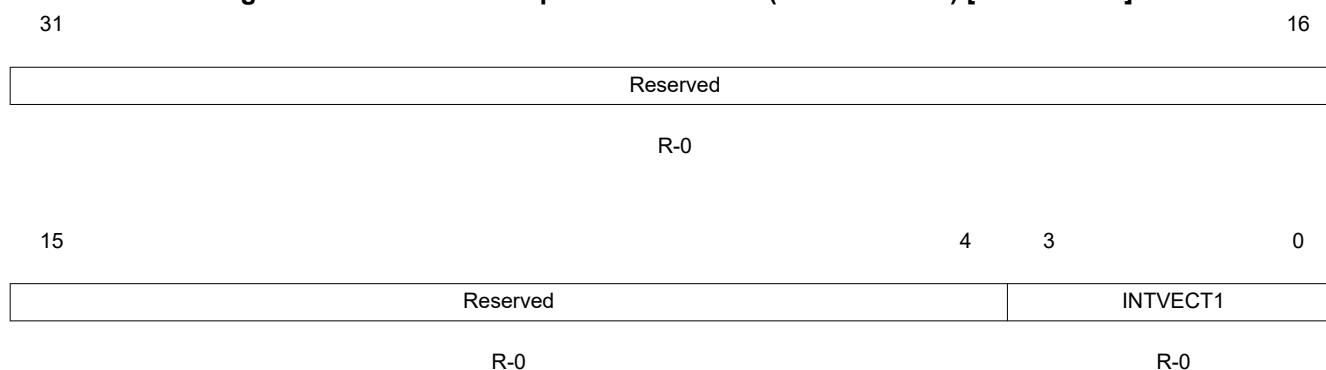

LEGEND: R = Read only; -n = value after reset

Table 10-136. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INVECT0	0-Fh	Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See for a list of the interrupts. Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).

10.1.3.7.9 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 10-144 and Table 10-137 illustrate this register.

Figure 10-144. SCI Interrupt Vector Offset 1 (SCIINTVECT1) [offset = 24h]

LEGEND: R = Read only; -n = value after reset

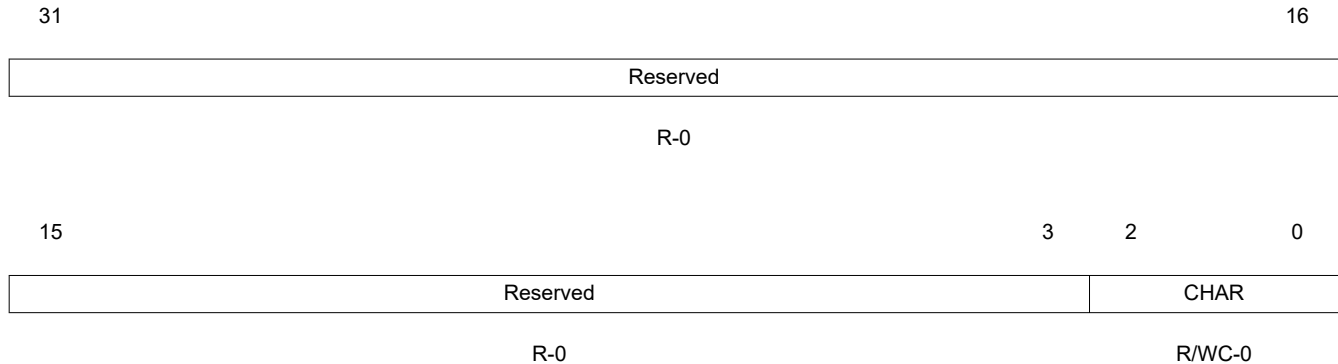

Table 10-137. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INVECT1	0-Fh	Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).

10.1.3.7.10 SCI Format Control Register (SCIFORMAT)

Figure 10-145 and Table 10-138 illustrate this register.

Figure 10-145. SCI Format Control Register (SCIFORMAT) [offset = 28h]

LEGEND: R/W = Read/Write; R = Read only; WC = Write in SCI-compatible mode only; -n = value after reset

Table 10-138. SCI Format Control Register (SCIFORMAT) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	CHAR		<p>Character length control bits. These bits set the SCI character length from 1 to 8 bits.</p> <p>When data of fewer than eight bits in length is received, it is left-justified in SCIRD and padded with trailing zeros.</p> <p>Data read from the SCIRD should be shifted by software to make the received data right-justified.</p> <p>Data written to the SCITD should be right-justified but does not need to be padded with leading zeros.</p> <p>0 The character is 1 bit long.</p> <p>1h The character is 2 bits long.</p> <p>2h The character is 3 bits long.</p> <p>3h The character is 4 bits long.</p> <p>4h The character is 5 bits long.</p> <p>5h The character is 6 bits long.</p> <p>6h The character is 7 bits long.</p> <p>7h The character is 8 bits long.</p>

10.1.3.7.11 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. [Figure 10-146](#) and [Table 10-139](#) illustrate this register.

Figure 10-146. Baud Rate Selection Register (BRS) [offset = 2Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-139. Baud Rate Selection Register (BRS) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-0	BAUD	0-FF FFFFh	<p>SCI 24-bit baud selection.</p> <p>The SCI has an internally-generated serial clock determined by the VCLK and the prescalers BAUD in this register. The SCI uses the 24-bit integer prescaler BAUD value of this register to select one of over 16,700,000.</p> <p>The baud rate can be calculated using the following formulas:</p> $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{16(\text{Baud} + 1)} \right) \quad (10)$ $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{\text{Baud} + 1} \right) \quad (11)$ <p>For BAUD = 0,</p> $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{32} \right) \quad (12)$ $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{2} \right) \quad (13)$ <p>Table 10-140 contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.</p>

Table 10-140. Comparative Baud Values (Asynchronous Mode) (1) (2)

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
26	00001A	115200	115740	0.47
53	000035	57600	57870	0.47
80	000050	38400	38580	0.47
162	0000A2	19200	19172	-0.15
299	00012B	10400	10417	0.16
325	000145	9600	9586	-0.15
399	00018F	7812.5	7812.5	0.00
650	00028A	4800	4800	0.00

Table 10-140. Comparative Baud Values (Asynchronous Mode) (1) (2) (continued)

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
15624	003BA0	200	200	0.00
624999	098967	5	5	0.00

(1) VCLK = 50 MHz

(2) Values are in decimal except for column 2.

10.1.3.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

10.1.3.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. [Figure 10-147](#) and [Table 10-141](#) illustrate this register.

Figure 10-147. Receiver Emulation Data Buffer (SCIED) [offset = 30h]

LEGEND: R = Read only; -n = value after reset

Table 10-141. Receiver Emulation Data Buffer (SCIED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	ED	0-FFh	Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.

10.1.3.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. [Figure 10-148](#) and [Table 10-142](#) illustrate this register.

Note

When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

Figure 10-148. Receiver Data Buffer (SCIRD) [offset = 34h]

15		8 7	0
Reserved		RD	
R-0		R-0	

LEGEND: R = Read only; -n = value after reset

Table 10-142. Receiver Data Buffer (SCIRD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	RD	0-FFh	Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set. Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.

10.1.3.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. [Figure 10-149](#) and [Table 10-143](#) illustrate this register.

Note

Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

Figure 10-149. Transmit Data Buffer Register (SCITD) [offset = 38h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

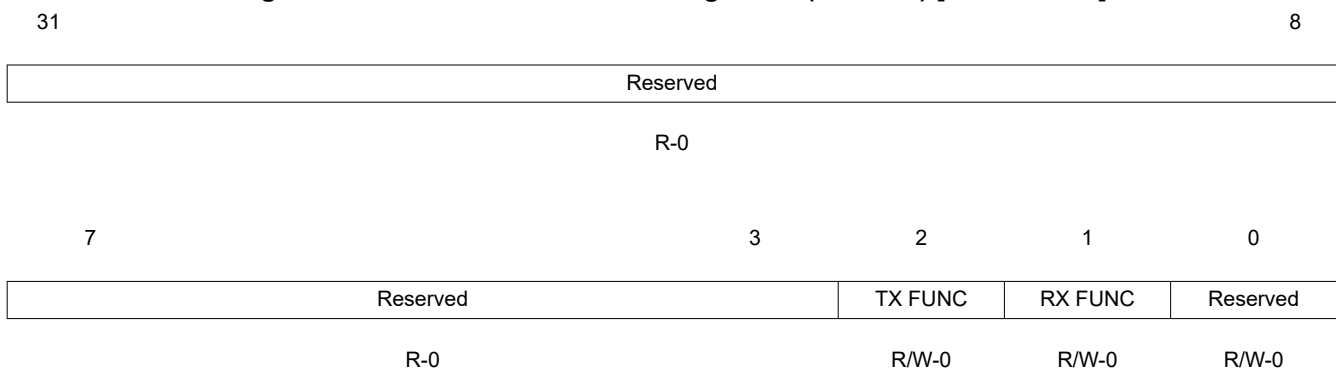

Table 10-143. Transmit Data Buffer Register (SCITD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TD	0-FFh	Transmit data. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data. Note: If TX INT ENA is set, this data transfer also causes an interrupt.

10.1.3.7.13 SCI Pin I/O Control Register 0 (SCIPIO0)

[Figure 10-150](#) and [Table 10-144](#) illustrate this register.

Figure 10-150. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-144. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.

Table 10-144. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions (continued)

Bit	Field	Value	Description
2	TX FUNC	0	Transfer function. This bit defines the function of pin SCITX. SCITX is a general-purpose digital I/O pin.
		1	SCITX is the SCI transmit pin.
1	RX FUNC	0	Receive function. This bit defines the function of pin SCIRX. SCIRX is a general-purpose digital I/O pin.
		1	SCIRX is the SCI receive pin.
0	Reserved	0	Reads return 0. Writes have no effect.

10.1.3.7.14 SCI Pin I/O Control Register 1 (SCIPIO1)

Figure 10-151 and Table 10-145 illustrate this register.

Figure 10-151. SCI Pin I/O Control Register 1 (SCIPIO1) [offset = 40h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-145. SCI Pin I/O Control Register 1 (SCIPIO1) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX DIR	0 1	Transmit pin direction. This bit determines the data direction on the SCITX pin if it is configured with general-purpose I/O functionality (TX FUNC = 0). See Table 10-146 for the SCITX pin control with this bit and others. 0 SCITX is a general-purpose input pin. 1 SCITX is a general-purpose output pin.
1	RX DIR	0 1	Receive pin direction. This bit determines the data direction on the SCIRX pin if it is configured with general-purpose I/O functionality (RX FUNC = 0). See Table 10-147 for the SCIRX pin control with this bit and others. 0 SCIRX is a general-purpose input pin. 1 SCIRX is a general-purpose output pin.
0	Reserved	0	Reads return 0. Writes have no effect.

Table 10-146. SCITX Pin Control

Function	TX IN ⁽¹⁾	TX OUT	TX FUNC	TX DIR
SCITX	X	X	1	X
General-purpose input	X	X	0	0
General-purpose output, high	X	1	0	1
General-purpose output, low	X	0	0	1

(1) TX IN is a read-only bit. Its value always reflects the level of the SCITX pin.

Table 10-147. SCIRX Pin Control

Function	RX IN ⁽¹⁾	RX OUT	RX FUNC	RX DIR
SCIRX	X	X	1	X
General-purpose input	X	X	0	0
General-purpose output, high	X	1	0	1

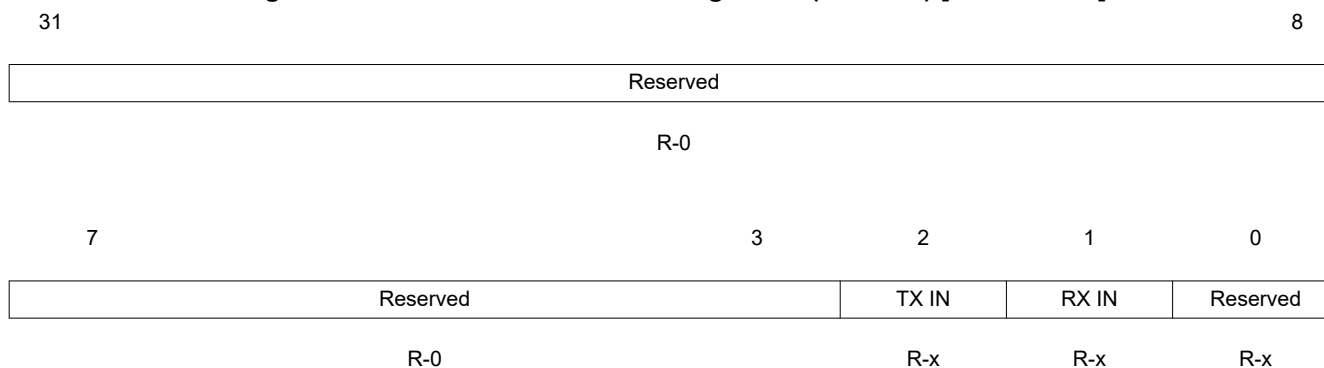

Table 10-147. SCIRX Pin Control (continued)

Function	RX IN ⁽¹⁾	RX OUT	RX FUNC	RX DIR
General-purpose output, low	X	0	0	1

(1) RX IN is a read-only bit. Its value always reflects the level of the SCIRX pin.

10.1.3.7.15 SCI Pin I/O Control Register 2 (SCIPIO2)

Figure 10-152 and Table 10-148 illustrate this register.

Figure 10-152. SCI Pin I/O Control Register 2 (SCIPIO2) [offset = 44h]

LEGEND: R = Read only; -n = value after reset; -x = Indeterminate

Table 10-148. SCI Pin I/O Control Register 2 (SCIPIO2) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX IN	0	The SCITX pin is at logic low (0).
		1	The SCITX pin is at logic high (1).
1	RX IN	0	The SCIRX pin is at logic low (0).
		1	The SCIRX pin is at logic high (1).
0	Reserved	0	Writes have no effect.

10.1.3.7.16 SCI Pin I/O Control Register 3 (SCIPIO3)

Figure 10-153 and Table 10-149 illustrate this register.

Figure 10-153. SCI Pin I/O Control Register 3 (SCIPIO3) [offset = 48h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-149. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX OUT	0 1	Transmit pin out. This pin specifies the logic to be output on pin SCITX if the following conditions are met: <ul style="list-style-type: none"> • TX FUNC = 0 (SCITX pin is a general-purpose I/O.) • TX DIR = 1 (SCITX pin is a general-purpose output.) See Table 10-146 for an explanation of this bit's effect in combination with other bits. The output on the SCITX is at logic low (0). The output on the SCITX pin is at logic high (1). (Output voltage is V_{OH} or higher if TXPDR = 0 and output is in high impedance state if TXPDR = 1)
1	RX OUT	0 1	Receive pin out. This bit specifies the logic to be output on pin SCIRX if the following conditions are met: <ul style="list-style-type: none"> • RX FUNC = 0 (SCIRX pin is a general-purpose I/O.) • RX DIR = 1 (SCIRX pin is a general-purpose output.) See Table 10-147 for an explanation of this bit's effect in combination with the other bits. The output on the SCIRX pin is at logic low (0). The output on the SCIRX pin is at logic high (1). (Output voltage is V_{OH} or higher if RXPDR = 0, and output is in high impedance state if RXPDR = 1)
0	Reserved	0	Reads return 0. Writes have no effect.

10.1.3.7.18 SCI Pin I/O Control Register 5 (SCIPIO5)

Figure 10-155 and Table 10-151 illustrate this register.

Figure 10-155. SCI Pin I/O Control Register 5 (SCIPIO5) [offset = 50h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

10.1.3.7.22 Input/Output Error Enable (IODFTCTRL) Register

Figure 10-159 and Table 10-155 illustrate this register. After the basic SCI module configuration, enable the required Error mode to be created followed by IODFT Key enable.

Note

1. All the bits are used in IODFT mode only.
2. Each IODFT are expected to be checked individually.

Figure 10-159. Input/Output Error Enable Register (IODFTCTRL) [offset = 90h]

31	27	26	25	24

Table 10-155. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	FEN	0	Frame error enable. This bit is used to create a frame error. No error is created.
		1	The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.
25	PEN	0	Parity error enable. This bit is used to create a parity error. No parity error occurs.
		1	The parity bit received is toggled so that a parity error occurs.
24	BRKD TENA	0	Break detect error enable. This bit is used to create a BRKDT error. No error is created.
		1	The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T _{BITS} so that a BRKDT error occurs.
32-21	Reserved	0	Reads return 0. Writes have no effect.

Table 10-155. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
20-19	PIN SAMPLE MASK	0 1h 2h 3h	Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry. No mask is used. Invert the TX Pin value at 7th.SCLK. Invert the TX Pin value at 8th.SCLK. Invert the TX Pin value at 9th.SCLK.
18-16	TX SHIFT	0 1h 2h 3h 4h 5h 6h 7h	Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit. No delay occurs. The value is delayed by 1 SCLK. The value is delayed by 2 SCLK. The value is delayed by 3 SCLK. The value is delayed by 4 SCLK. The value is delayed by 5 SCLK. The value is delayed by 6 SCLK. No delay occurs.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IODFTENA	Ah All Others	IODFT enable key. Write access permitted in Privilege mode only. IODFT is enabled. IODFT is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	LPBENA	0 1	Module loopback enable. Write access permitted in Privilege mode only. Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path. Digital loopback is enabled. Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.
0	RXPENA	0 1	Module analog loopback through receive pin enable. Write access permitted in Privilege mode only. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode). Analog loopback through the transmit pin is enabled. Analog loopback through the receive pin is enabled.

10.1.3.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

10.1.3.8.1 GPIO Functionality

Figure 10-160 illustrates the GPIO functionality.

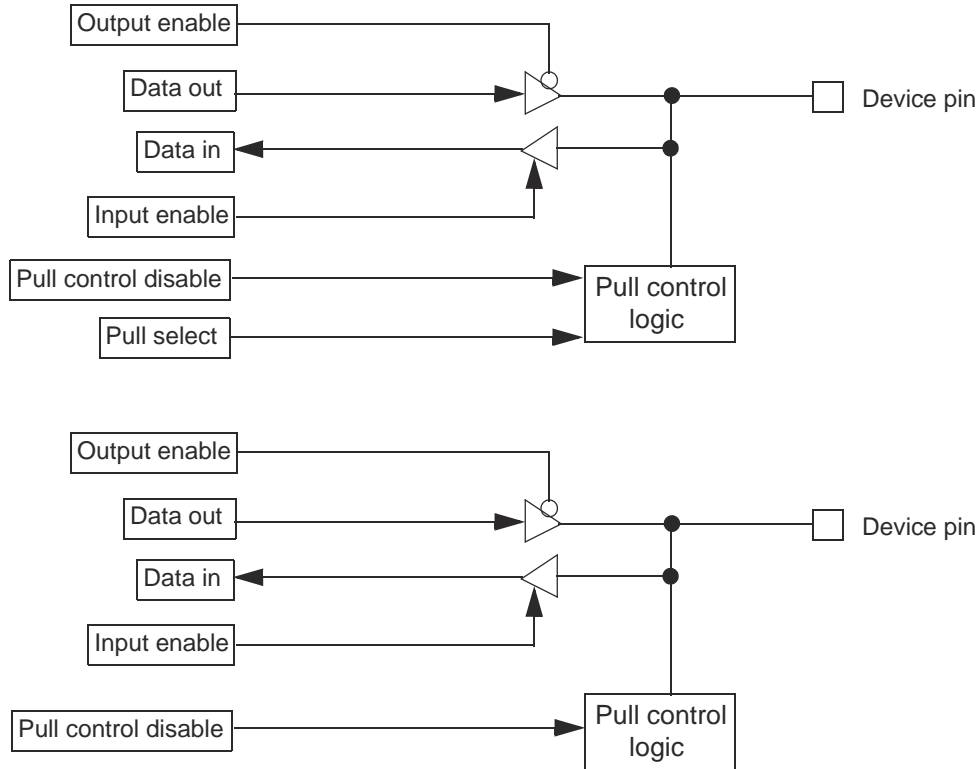

Figure 10-160. GPIO Functionality

10.1.3.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

10.1.3.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIO7 register (Section 10.1.3.7.20). In this case, if the PSL (pull select) bit in the SCIO8 register (Section 10.1.3.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

Note

The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIO7 (Section 10.1.3.7.20).

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIO1; Section 10.1.3.7.14) AND the open-drain feature is not enabled in the SCIO6 register (Section 10.1.3.7.19).

10.1.3.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled, if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low), if a high signal is being driven on to the pin.

Note

The open-drain feature is available only in I/O mode (SCIO0; Section 10.1.3.7.13).

10.1.3.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 10-156.

Table 10-156. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) ^{(1) (2)}	Pull Disable (PULDIS) ^{(1) (3)}	Pull Select (PULSEL) ^{(1) (4)}	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care

(2) DIR = 0 for input, = 1 for output

(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control

(4) PULSEL = 0 for pull-down functionality
= 1 for pull-up functionality

10.1.4 Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)

This chapter provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This chapter also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this chapter, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

Note

This chapter describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation (SPIENA).

10.1.4.1 Overview

The MibSPI/MibSPIP is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted in and out of the device at a programmed bit-transfer rate. Typical applications for the SPI include interfacing to external peripherals, such as I/Os, memories, display drivers, and analog-to-digital converters.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 11-bit baud clock generator
- Serial clock (SPICLK) pin
- 1 SPISOMI/SPISIMO pin for data transfer, with programmable pin direction
- SPI enable ($\overline{\text{SPIENA}}$) pin
- Up to 6 slave chip select ($\overline{\text{SPICS}}$) pins
- SPICLK can be internally-generated (and driven) or received from an external clock source
- Each word transferred can have a unique format
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

Note

SIMO - Slave In Master Out Pin
 SOMI - Slave Out Master In Pin
 SPICS - SPI Chip Select Pin
 SPIENA - SPI Enable Pin

10.1.4.1.1 Word Format Options

Each word transferred can have a unique format. Several format characteristics are programmable for each word transferred:

- SPICLK frequency
- Character length (2 to 16 bits)
- Phase (with and without delay)
- Polarity (high or low)
- Parity enabled/disabled
- Chip Select(CS) timers for setup and hold
- Shift direction (Most-Significant Bit (MSB) first or Least-Significant Bit (LSB) first)
- Multi-pin parallel modes

10.1.4.1.2 Multi-buffering (Mib) Support

The MibSPI has a programmable buffer memory that enables programmed transmission to be completed without CPU intervention. The buffers are combined in different Transfer Groups (TGs) that can be triggered by external events (timers, Input/Output activity, and so on) or by the internal tick counter. The internal tick counter supports periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different TGs, allowing the user to move data between internal memory and an external slave with minimal CPU interaction.

10.1.4.1.2.1 Multi-buffer Mode

Multi-buffer Mode is an extension to the SPI. In multi-buffer mode, many extended features are configurable:

- Number of buffers for each peripheral (or data source/destination, up to 128 buffers supported) or group (up to 8 groupings)
- Triggers for each group, trigger types, trigger sources for individual groups (14 external trigger sources and 1 internal trigger source supported)
- Memory fault detection via an internal parity circuit
- Number of DMA-controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
- Number of DMA transfers for each buffer (up to 65536 words for up to 8 buffers)
- Uninterrupted DMA buffer transfer (NOBREAK buffer)

10.1.4.1.2.2 Compatibility Mode

Compatibility Mode of the MibSPI makes it behave exactly like a standard platform SPI module and ensures full compatibility with other SPIs. All features in compatibility mode of the MibSPI are directly applicable to a SPI. Multi-buffer Mode features are not available in Compatibility Mode.

Note

The SPIDAT0 register is not accessible in the multi-buffer mode of MibSPI. It is only accessible in compatibility mode.

10.1.4.1.3 Transmission Lock (Multi-Buffer Mode Master Only)

Some slave devices require transmission of a command followed by data. In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows a consecutive transfer to happen without being interrupted by another higher-priority group transfer.

10.1.4.2 Operating Modes

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The slave chip select ($\overline{\text{SPIC}}\overline{\text{S}}$) pins are used when communicating with multiple slave devices or, with a single slave, to delimit messages containing a leading register address. When a write occurs to SPIDAT1 in master mode, the $\overline{\text{SPIC}}\overline{\text{S}}$ pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exchange of data.

Note

If in the slave mode of operation and configured in either 3-pin or 4-pin (without $\overline{\text{SPIEN}}\overline{\text{A}}$) modes, there must be a minimum of 8 VCLK cycles of delay between the last SPICLK and the start of the SPICLK for the next buffer transmit. In general, this equates to a VCLK/SPICLK ratio of ≤ 16 requiring a minimum of 1 SPICLK delay between transmissions.

10.1.4.2.1 Pin Configurations

The SPI supports data connections as shown in [Table 10-157](#).

Note

1. When the SPICS signals are disabled, the chip select field in the transmit data is not used.
2. When the SPIEN \bar{A} signal is disabled, the SPIEN \bar{A} pin is ignored in master mode, and not driven as part of the SPI transaction in slave mode.

Table 10-157. Pin Configurations

Pin	Master Mode		Slave Mode	
SPICLK	Drives the clock to external devices		Receives the clock from the external master	
SPISOMI	Receives data from the external slave		Sends data to the external master	
SPISIMO	Transmits data to the external slave		Receives data from the external master	
SPIEN \bar{A}	SPIEN\bar{A} disabled: GIO	SPIEN\bar{A} enabled: Receives ENA signal from the external slave	SPIEN\bar{A} disabled: GIO	SPIEN\bar{A} enabled: Drives ENA signal from the external master
SPICS	SPICS disabled: GIO	SPICS enabled: Selects one or more slave devices	SPICS disabled: GIO	SPICS enabled: Receives the CS signal from the external master

10.1.4.2.2 Data Handling

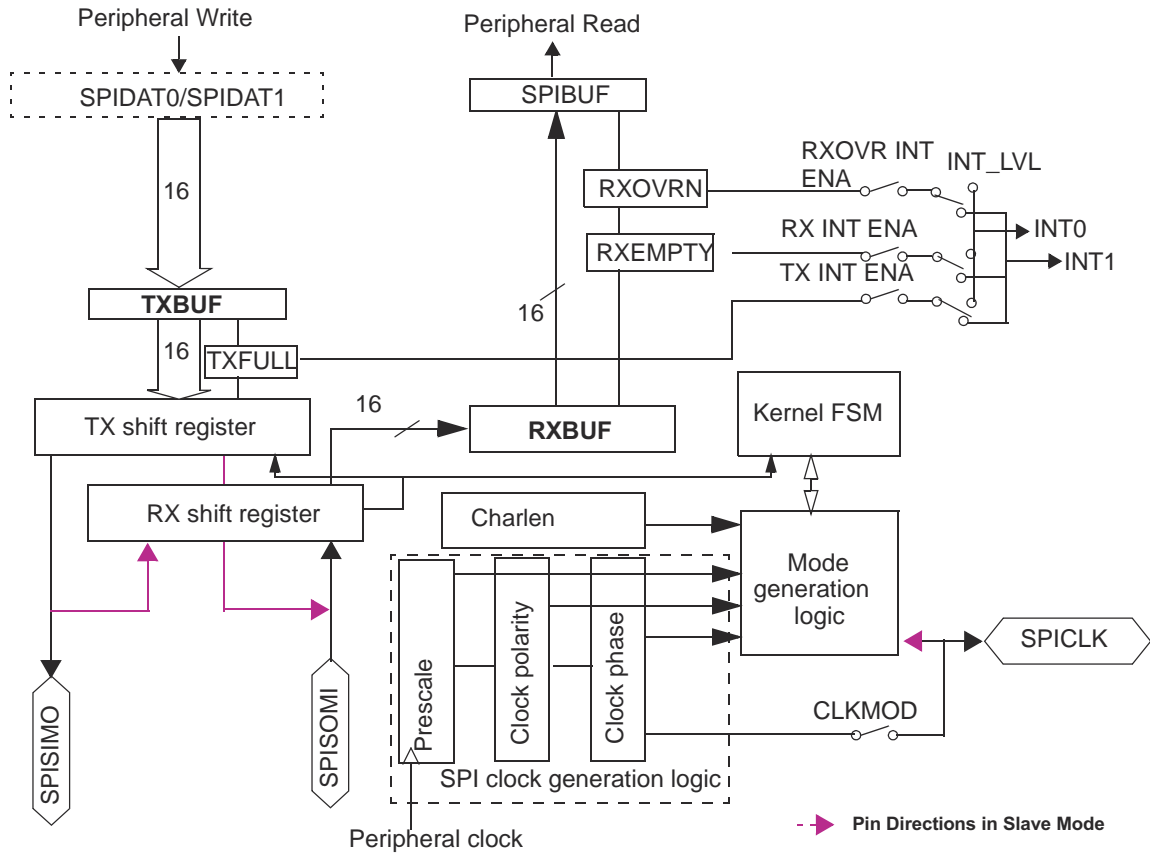

[Figure 10-161](#) shows the SPI transaction hardware. TXBUF and RXBUF are internal buffers that are intended to improve the overall throughput of data transfer. TXBUF is a transmit buffer, while RXBUF is a receive buffer.

10.1.4.2.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX_DMA_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is empty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

10.1.4.2.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register

- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.

- 1 This is a representative diagram, which shows three-pin mode hardware.
- 2 TXBUF, RXBUF, and SHIFT_REGISTER are user-invisible registers.
- 3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
- 4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

Figure 10-161. SPI Functional Logic Diagram

10.1.4.2.2.3 Three-Pin Mode

In master mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see Figure 10-162).

Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See Section 10.1.4.2.2.1 and Section 10.1.4.2.2.2 for details about the data handling for transmit and receive operations.

In slave mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network master. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the slave simultaneously, it must be written to the SPIDAT0 or SPIDAT1 register before the beginning of the SPICLK signal.

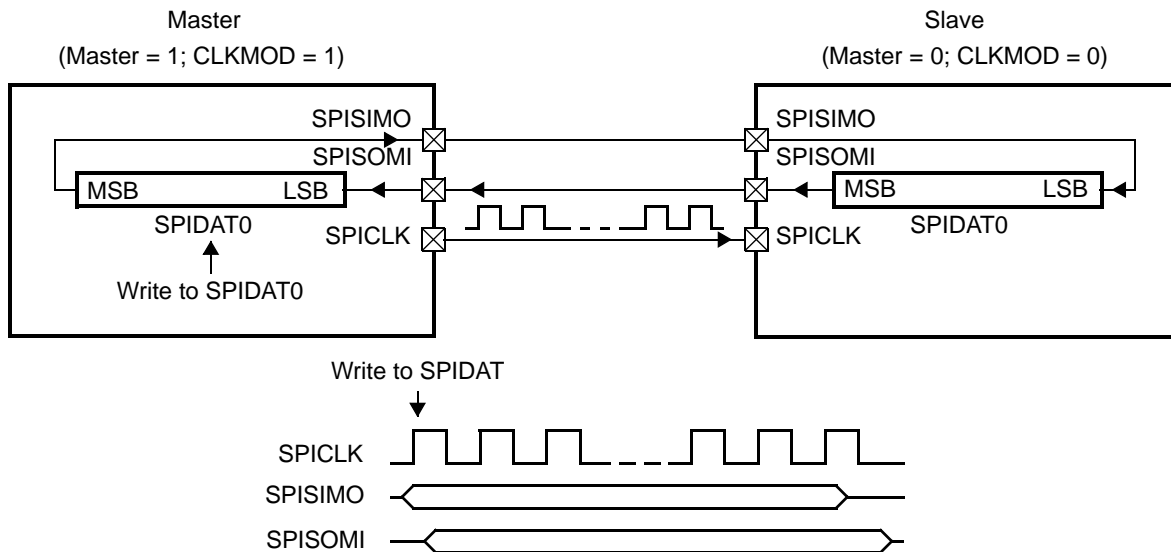

Figure 10-162. SPI Three-Pin Operation

10.1.4.2.3 Operation with $\overline{\text{SPICS}}$

In master mode, each chip select signal is used to select a specific slave. In slave mode, the chip select signal is used to enable and disable the transfer. Chip-select functionality is enabled by setting one of the $\overline{\text{SPICS}}$ pins as a chip select. It is disabled by setting all $\overline{\text{SPICS}}$ pins as GPIOs in SPIPC0.

10.1.4.2.3.1 Multiple Chip Selects

The $\overline{\text{SPICS}}$ pins that are used must be configured as functional pins in the SPIPC0 register. The default pattern to be put on the $\overline{\text{SPICS}}$ when all the slaves are deactivated is set in the SPIDEF register. This pattern allows different slaves with different chip-select polarity to be activated by the SPI.

The master-mode SPI is capable of driving either 0 or 1 as the active value for any $\overline{\text{SPICS}}$ output pin. The drive state for the $\overline{\text{SPICS}}$ pins is controlled by the CSNR field of SPIDAT1. The pattern that is driven will select the slave to which the transmission is dedicated.

In slave mode, the SPI can only be selected by an active value of 0 on any of its selected $\overline{\text{SPICS}}$ input pins.

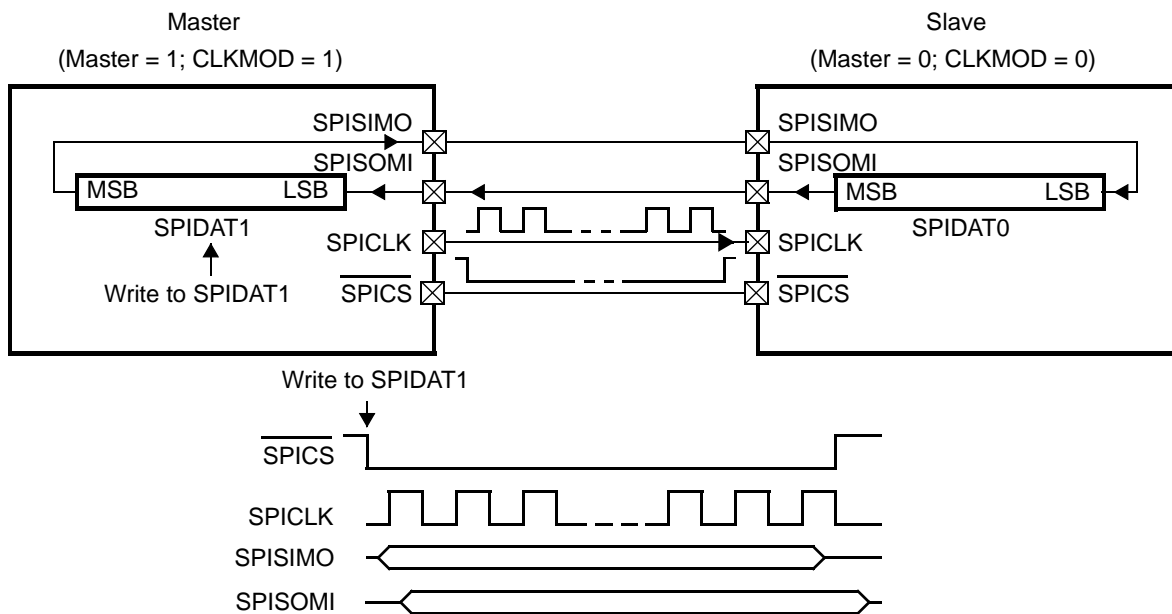

Figure 10-163. Operation with $\overline{\text{SPICS}}$

10.1.4.2.4 Operation with $\overline{\text{SPIENA}}$

The $\overline{\text{SPIENA}}$ operates as a WAIT signal pin. For both the slave and the master, the $\overline{\text{SPIENA}}$ pin must be configured to be functional ($\text{SPIPC0}[8] = 1$). In this mode, an active-low signal from the slave on the $\overline{\text{SPIENA}}$ pin allows the master SPI to drive the clock pulse stream. A high signal tells the master to hold the clock signal (and delay SPI activity).

If the $\overline{\text{SPIENA}}$ pin is in high-impedance mode ($\text{ENABLE_HIGHZ} = 1$), the slave will put $\overline{\text{SPIENA}}$ into the high-impedance once it completes receiving a new character. If the $\overline{\text{SPIENA}}$ pin is in push-pull mode ($\text{ENABLE_HIGHZ} = 0$), the slave will drive $\overline{\text{SPIENA}}$ to 1 once it completes receiving a new character. The slave will drive $\overline{\text{SPIENA}}$ low again for the next word to transfer, after new data is written to the slave TX shift register.

In master mode ($\text{CLKMOD} = 1$), if the $\overline{\text{SPIENA}}$ pin is configured as functional, then the pin acts as an input pin. If configured as a slave SPI and as functional, the $\overline{\text{SPIENA}}$ pin acts as an output pin.

Note

During a transfer, if a slave-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and $\overline{\text{SPIENA}}$ (if ENABLE_HIGHZ bit is set to 1) in high-impedance mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an DLENERR error flag and generates an interrupt (if enabled).

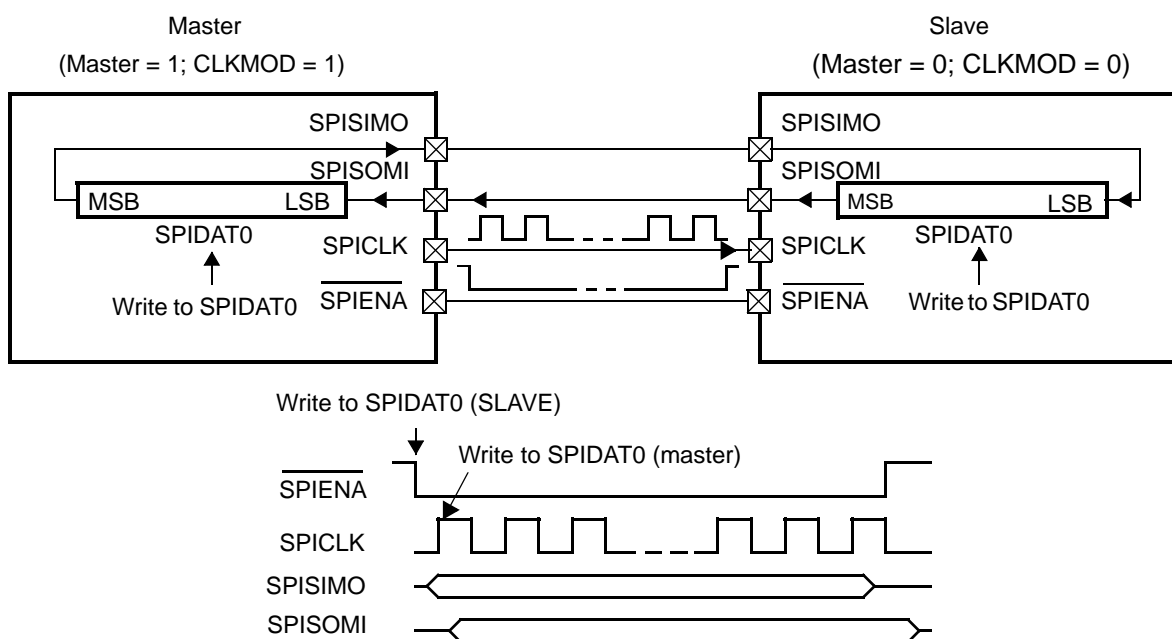

Figure 10-164. Operation with $\overline{\text{SPIENA}}$

10.1.4.2.5 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin and the required number of $\overline{\text{SPICS}}$ pins must be configured as functional pins.

If the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is in high-impedance mode ($\text{ENABLE_HIGHZ} = 1$), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal $\overline{\text{SPIEN}}\overline{\text{A}}$ low when new data is written to the slave shift register and the slave has been selected by the master ($\overline{\text{SPICS}}$ is low).

If the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is in push-pull mode ($\text{ENABLE_HIGHZ} = 0$), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the $\overline{\text{SPIEN}}\overline{\text{A}}$ signal low when new data is written to the slave shift register ($\text{SPIDAT0}/\text{SPIDAT1}$) and the slave is selected by the master ($\overline{\text{SPICS}}$ is low). If the slave is deselected by the master ($\overline{\text{SPICS}}$ goes high), the slave $\overline{\text{SPIEN}}\overline{\text{A}}$ signal is driven high.

Note

Push-pull mode of the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common $\overline{\text{SPIEN}}\overline{\text{A}}$ pin, all of the slaves should configure their $\overline{\text{SPIEN}}\overline{\text{A}}$ pins in high-impedance mode.

In master mode, if the $\overline{\text{SPICS}}$ pins are configured as functional pins, then the pins will be in output mode. A write to the master's $\text{SPIDAT1}/\text{SPIDAT0}$ register will automatically drive the $\overline{\text{SPICS}}$ signals low. The master will drive the $\overline{\text{SPICS}}$ signals high again after completing the transfer of the bits of the data.

In slave mode ($\text{CLKMOD} = 0$), the $\overline{\text{SPICS}}$ pins act as SPI functional inputs.

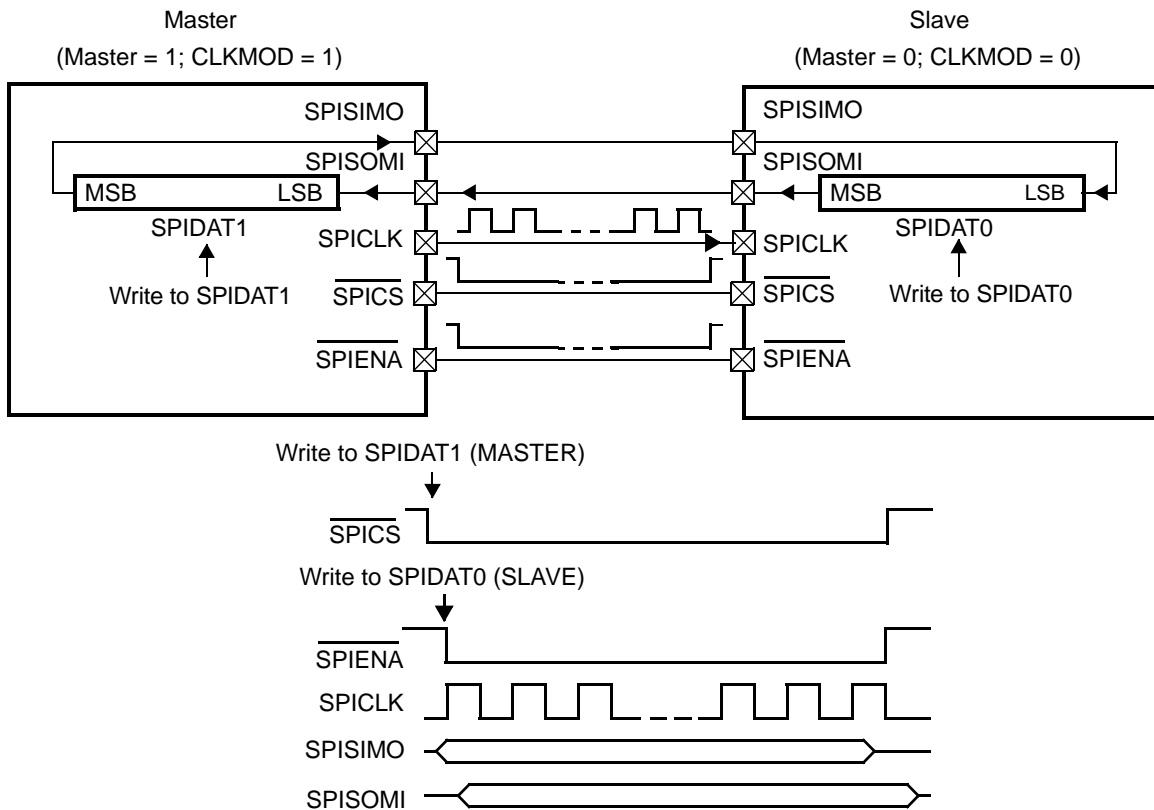

Figure 10-165. SPI Five-Pin Option with $\overline{\text{SPIEN}}\overline{\text{A}}$ and $\overline{\text{SPICS}}$

10.1.4.2.6 Data Formats

To support multiple different types of slaves in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the master-mode SPI can drive two consecutive accesses to the same slave, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed slave. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **master** and the **slave**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

Note

Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

Figure 10-166 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

Figure 10-166. Format for Transmitting an 12-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
x	x	x	x	1	1	1	0	1	1	0	0	1	0	0	1

Note

The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

Figure 10-167 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

Figure 10-167. Format for Receiving an 10-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	0	1	0	1	0	0	0	1	0

10.1.4.2.7 Clocking Modes

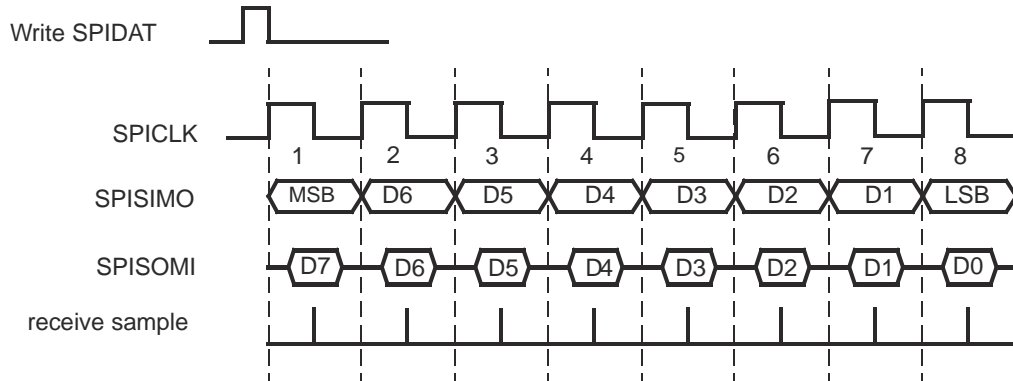

SPICLK may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.

The data input and output edges depend on the values of both POLARITY and PHASE as shown in Table 10-158.

Table 10-158. Clocking Modes

POLARITY	PHASE	Action
0	0	Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.
0	1	Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.
1	0	Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.
1	1	Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.

Figure 10-168 to Figure 10-171 illustrate the four possible configurations of SPICLK corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.

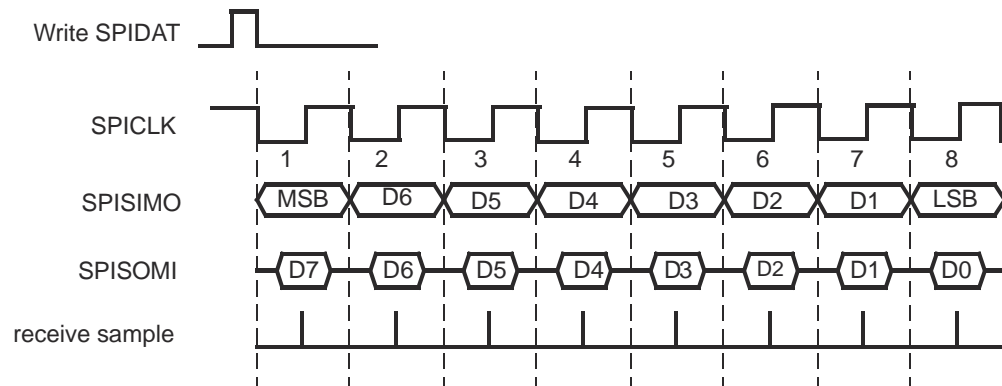

Data is output on the rising edge of SPICLK.
Input data is latched on the falling edge of SPICLK.

Figure 10-168. Clock Mode with Polarity = 0 and Phase = 0

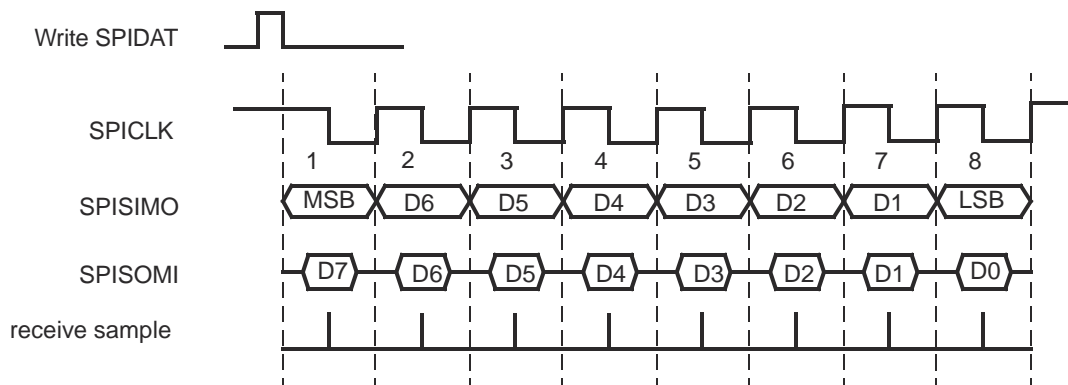

Data is output one-half cycle before the first rising edge of SPICLK and on subsequent falling edges of SPICLK
Input data is latched on the rising edge of SPICLK

Figure 10-169. Clock Mode with Polarity = 0 and Phase = 1

Data is output on the falling edge of SPICLK.
Input data is latched on the rising edge of SPICLK.

Figure 10-170. Clock Mode with Polarity = 1 and Phase = 0

Data is output one-half cycle before the first falling edge of SPICLK and on the subsequent rising edges of SPICLK.
Input data is latched on the falling edge of SPICLK.

Figure 10-171. Clock Mode with Polarity = 1 and Phase = 1

10.1.4.2.8 Data Transfer Example

Figure 10-172 illustrates a SPI data transfer between two devices using a character length of five bits.

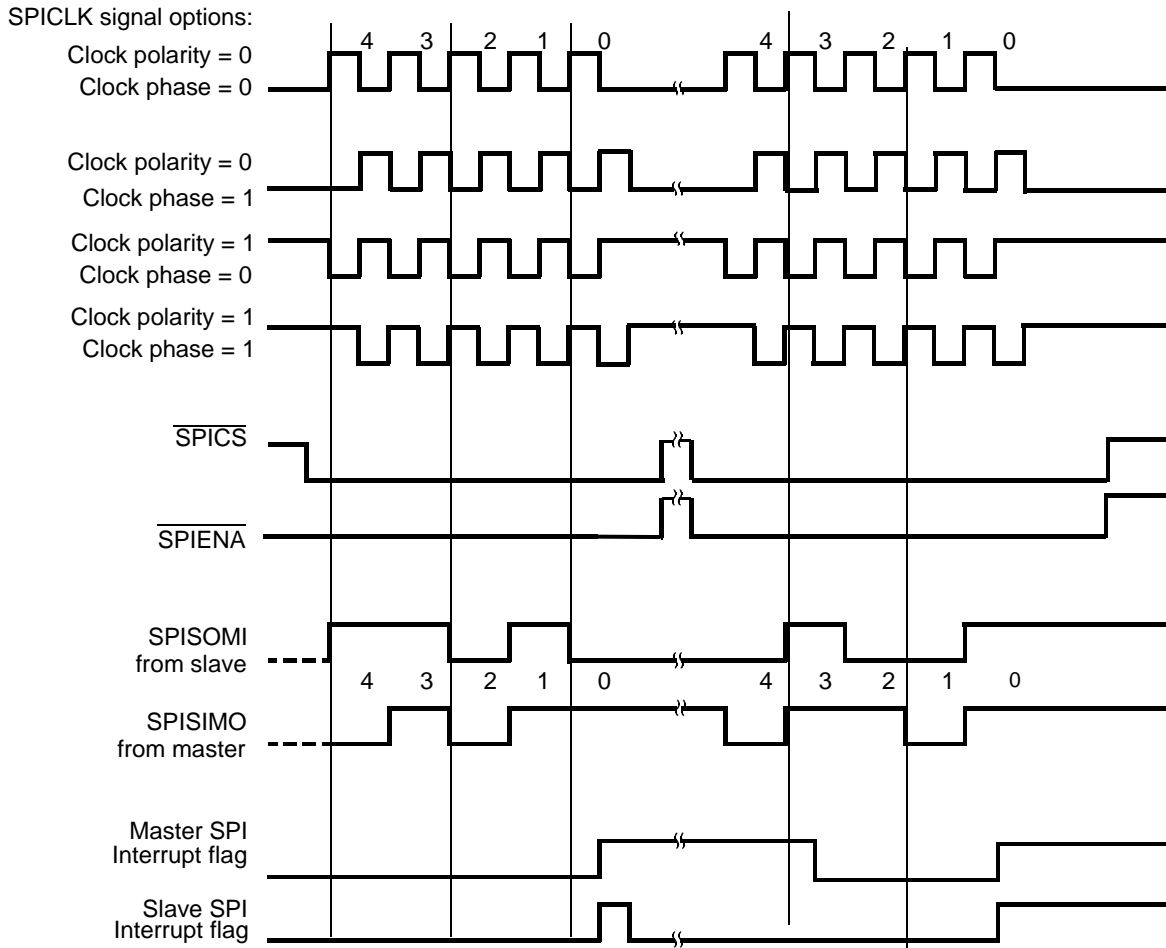

Figure 10-172. Five Bits per Character (5-Pin Option)

10.1.4.2.9 Decoded and Encoded Chip Select (Master Only)

In this device, the SPI can connect to up to 6 individual slave devices using chip-selects by routing one wire to each slave. The 6 chip selects in the control field are directly connected to the 6 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR) of the SPIDAT1 register (SPIDAT1) is driven on the $\overline{\text{SPICS}}$ pins. When the transmission finishes, the default chip-select value (defined by the CSDEF register) is put on the $\overline{\text{SPICS}}$ pins.

The SPI can support more than 6 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active $\overline{\text{SPICS}}$ pins at the same time, which enables encoded chip selects from 0 to 16. To use encoded chip selects, all 6 chip select lines have to be connected to each slave device and each slave needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example, n $\overline{\text{SPICS}}$ pins can be used for encoding an n -bit address and the remaining pins can be connected to decoded-mode slaves.

10.1.4.2.10 Variable Chip Select Setup and Hold Timing (Master Only)

In order to support slow slave devices, a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with the peripheral clock (VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pins, then they can be disabled in the corresponding SPIFMTx register.

10.1.4.2.11 Hold Chip-Select Active

Some slave devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both master and slave modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in master mode and slave mode are different.

Note

If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

10.1.4.2.11.1 CSHOLD Bit in Master Mode

Each word in a master-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 10-173 shows the SPI pins when a master-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

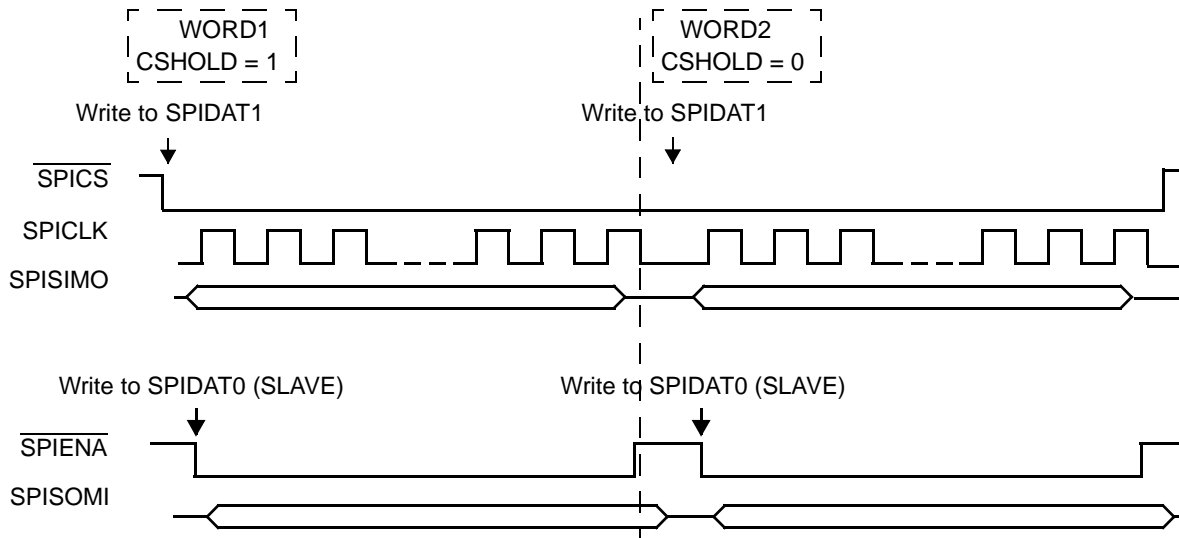

Figure 10-173. Typical Diagram when a Buffer in Master is in CSHOLD Mode (SPI-SPI)

10.1.4.2.11.2 CSHOLD Bit in Slave Mode (Multi-buffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the $\overline{\text{SPICS}}$ pins to be de-activated at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a slave in multi-buffer mode to do multiple data transfers without requiring the $\overline{\text{SPICS}}$ pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a slave MibSPI, even after the shift operation is done, the MibSPI waits until the $\overline{\text{SPICS}}$ pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the slave in multi-buffer mode requires its $\overline{\text{SPICS}}$ pins to be deasserted between any two buffer transfers; otherwise, the Slave SPI will be unable to respond to the next data transfer.

Note

In compatibility mode, the slave does not require the $\overline{\text{SPICS}}$ pin to be deasserted between two buffer transfers. The CSHOLD bit of the slave will be ignored in compatibility mode.

10.1.4.2.12 Detection of Slave Desynchronization (Master Only)

When a slave supports generation of an enable signal (ENA), desynchronization can be detected. With the enable signal a slave indicates to the master that it is ready to exchange data. A desynchronization can occur if one or more clock edges are missed by the slave. In this case, the slave may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the desynchronized slave and the consecutive data word. A configurable 8-bit time-out counter (T2EDELAY), which is clocked with SPICLK, is implemented to detect this slave malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the slave does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

Note
Inconsistency of Desynchronization Flag in Compatibility Mode MibSPI

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always assured to be for the current buffer.

10.1.4.2.13 ENA Signal Time-Out (Master Only)

The SPI in master mode waits for the hardware handshake signal (ENA) coming from the addressed slave before performing a data transfer. To avoid stalling the SPI by a non-responsive slave device, a time-out value can be configured using C2EDELAY. If the time-out counter overflows before an active ENA signal is sampled, the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

Note

When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

10.1.4.2.14 Data-Length Error

A SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

Data-Length Error in Master Mode: During a data transfer, if the SPI detects a de-assertion of the $\overline{\text{SPIEN}}_A$ pin (by the slave) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a slave receiving extra clocks (for example, due to noise on the SPICLK line).

Note

In a master mode SPI, the data length error will be generated only if the $\overline{\text{SPIEN}}_A$ pin is enabled as a functional pin.

Data-Length Error in Slave Mode: During a transfer, if the SPI detects a de-assertion of the $\overline{\text{SPICS}}$ pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise if the slave SPI misses one or more SPICLK pulses from the master. This error in slave mode implies that both the transmitted and received data were not complete.

Note

In a slave mode SPI, the data-length error flag will be generated only if at least one of the $\overline{\text{SPICS}}$ pins are configured as functional, and are being used for selecting the slave.

10.1.4.2.15 Parallel Mode (Multiple SIMO/SOMI Support, not available on all devices)

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (parallel 2, 4, or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (SOMI and SIMO lines)

- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the SIMO/SOMI lines. The receive parity is expected on bit0 of the SOMI/SIMO pins.

Parallel mode can be programmed using the PMODEx bits of SPIPMCTRL register. See [Section 10.1.4.9.26](#) for details about this register.

After reset the parallel mode selection bits are cleared (single SIMO/SOMI lines).

10.1.4.2.15.1 Parallel Mode Block Diagram

Figure 10-174 and Figure 10-175 show the parallel connections to the SPI shift register.

10.1.4.2.15.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (master mode) the shift register bits 15 and 7 will be connected to the pins SIMO[1] and SIMO[0], and the shift register bits 8 and 0 will be connected to the pins SOMI[1] and SOMI[0] or vice versa in slave mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on SIMO[1] and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[1] and SOMI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. (SIMO[1] will shift the data out from bit 15 to 8, SIMO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 10-176 shows the clock/data diagram of the 2-data line mode. Figure 10-177 shows the timing of a two-pin parallel transfer.

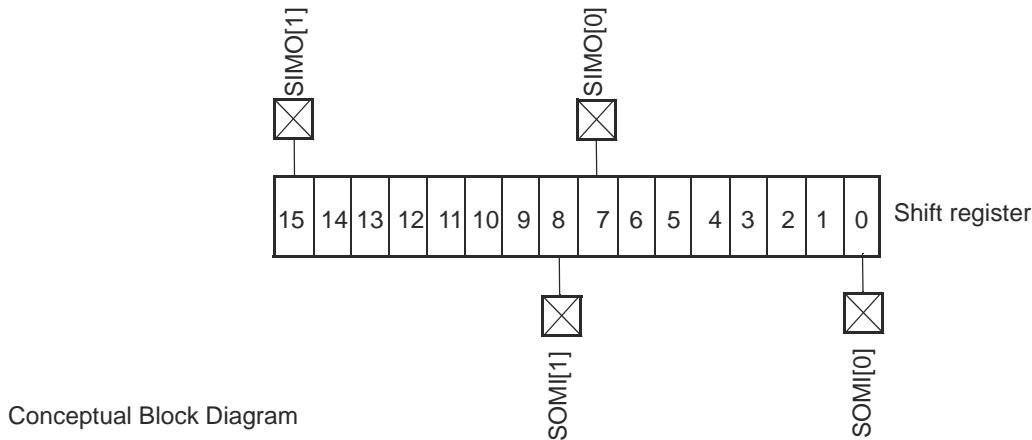

Figure 10-176. 2-data Line Mode (Phase 0, Polarity 0)

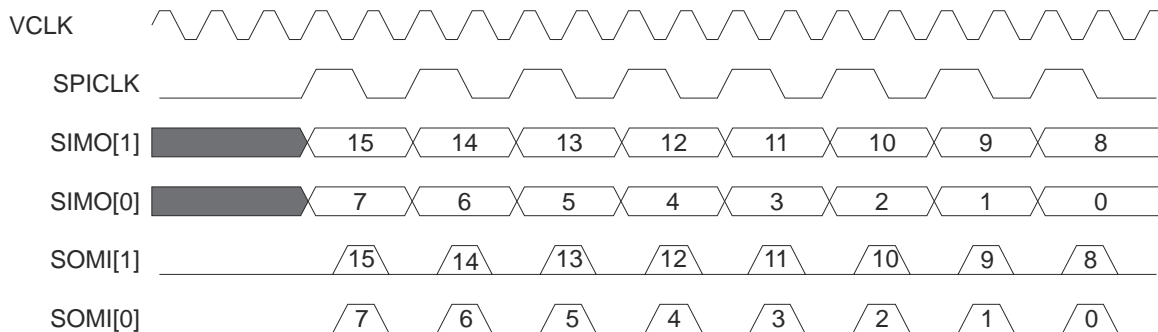

Figure 10-177. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)

10.1.4.2.15.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left (SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 10-178 shows the clock/data diagram of the four-data line mode. Figure 10-179, shows the timing diagram for four-data line mode.

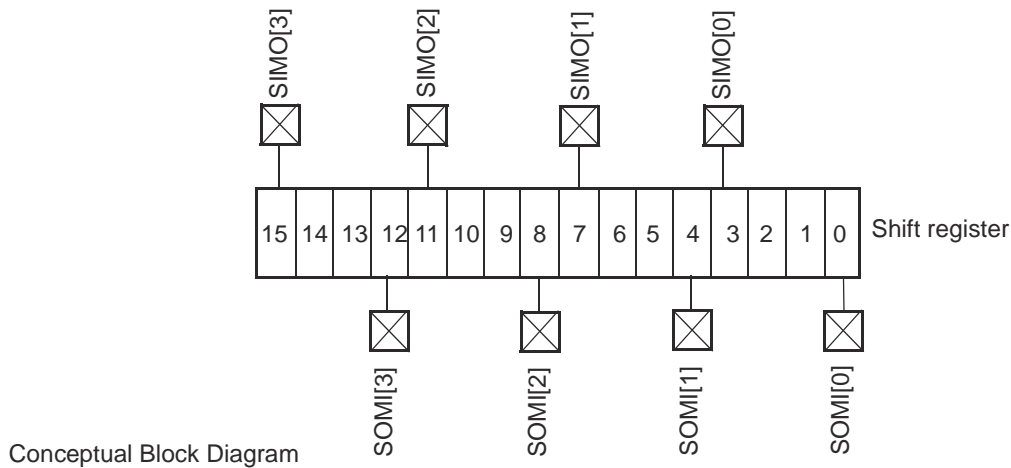

Figure 10-178. 4-Data Line Mode (Phase 0, Polarity 0)

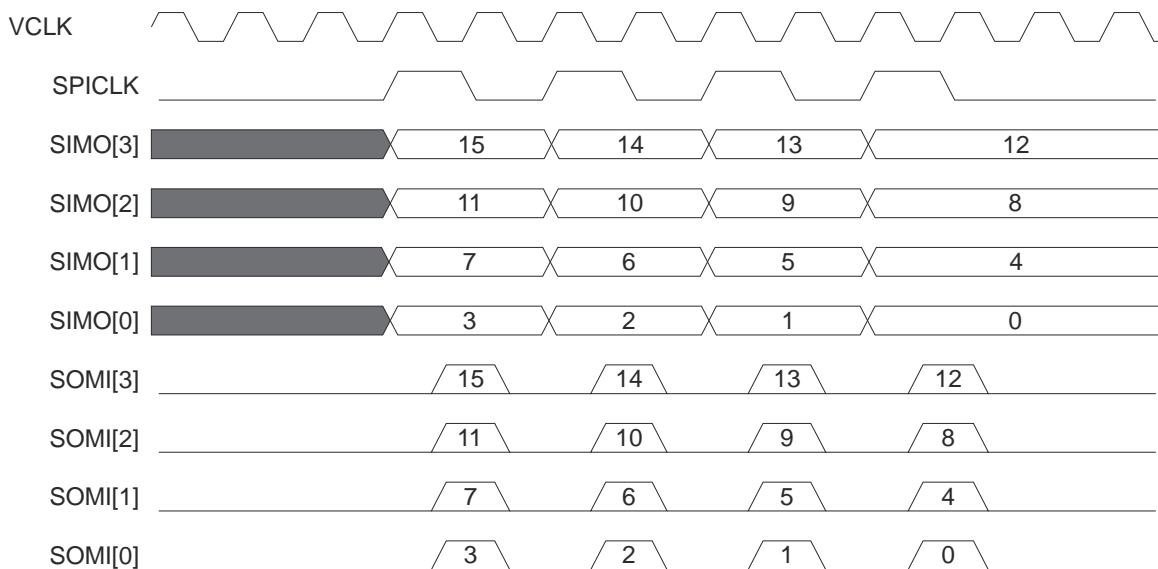

Figure 10-179. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

10.1.4.2.15.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (master mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on SOMI[8], SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. [Figure 10-180](#) shows the clock/data diagram of the 8-data line mode. [Figure 10-181](#) shows the pin timings for 8-data line mode.

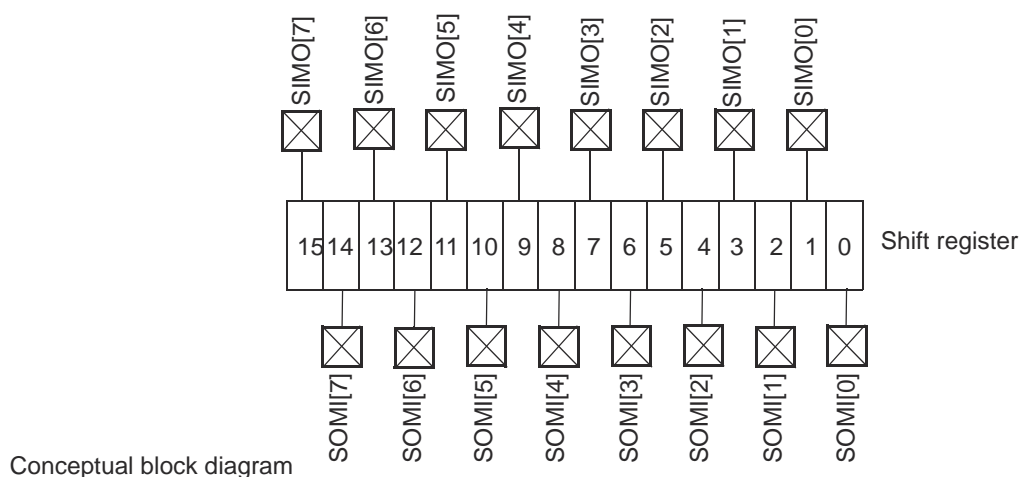

Figure 10-180. 8-data Line Mode (Phase 0, Polarity 0)

Note

Parity Support

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

Figure 10-181. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

Note

Modulo Count Parallel Mode is not supported in this device.

10.1.4.2.16 Continuous Self-Test (Master/Slave)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

Note

The compare is made from the output pin using its input buffer.

10.1.4.2.17 Half Duplex Mode

SPI by protocol is Full Duplex in nature, which means simultaneous TX and RX operations happen on two separate data pins, SIMO and SOMI. However, it is possible to use SPI/MibSPI to do the TX-only operation (ignoring the RX data) and the RX-only operation (using dummy TX data and ignoring the TX pin). But this requires that both SOMI and SIMO lines are bonded out in a chip to be able to support both TX-only or RX-only features.

10.1.4.2.17.1 Half Duplex Mode in Master

The Half Duplex Mode gives an additional flexibility to use the SIMO pin, which is normally used as a TX pin in Master mode, to work like an RX pin while the HDUPLEX_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Master mode, the SIMO pin acts as an RX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

10.1.4.2.17.2 Half Duplex Mode in Slave

In Half Duplex Slave mode, the SIMO pin, which is normally an RX pin, acts as a TX pin while the HDUPLEX_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Slave mode, the SIMO pin acts as a TX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

10.1.4.3 Test Features

10.1.4.3.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally feedback to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

Note

This mode cannot be changed during transmission.

10.1.4.3.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 10-182 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See Section 10.1.4.9.44 for details of the register field controlling these features.

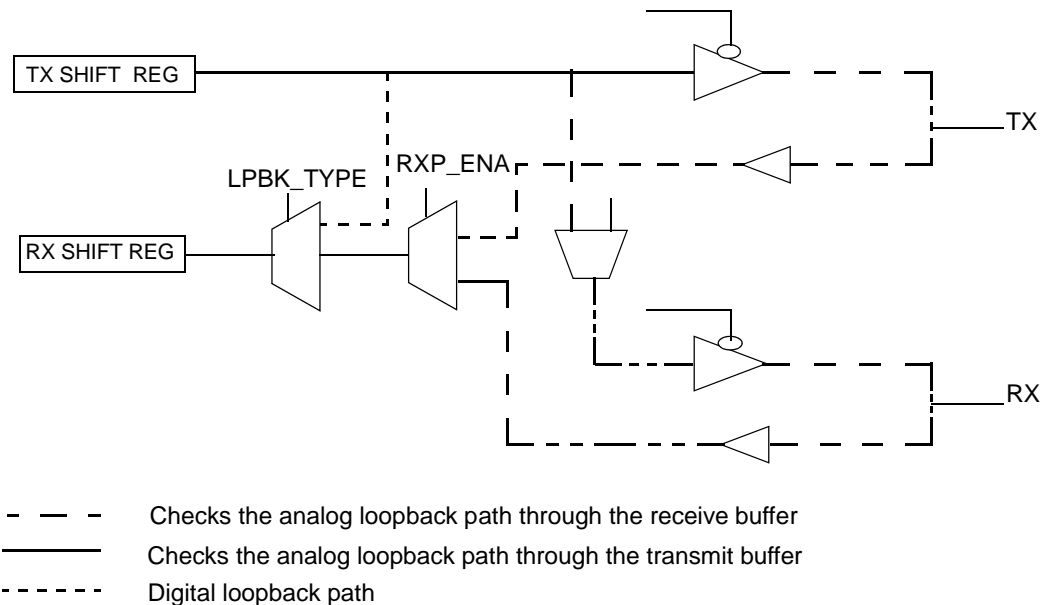

In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.

In Input/Output loopback test modes, if the module is in master mode, the $\overline{EN\bar{A}}$ signal is also generated by internal logic so that an external interface is not required.

Note

Usage Guideline for Input/Output Loopback

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.

This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

Figure 10-182. I/O Paths during I/O Loopback Modes

10.1.4.3.2.1 Input/Output Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving SPIC_S to 0. The actual number of chip selects can be programmed to have any or all of the SPIC_S pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

10.1.4.4 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPC_x control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode

10.1.4.5 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

Note

Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

10.1.4.6 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

Note

Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive. A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

10.1.4.6.1 Interrupts in Multi-Buffer Mode

In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

[Figure 10-183](#) illustrates the TG interrupts.

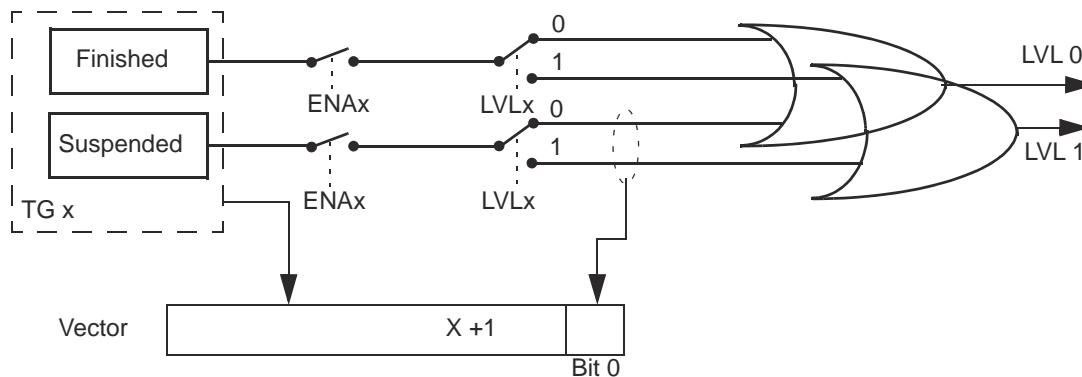

Figure 10-183. TG Interrupt Structure

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

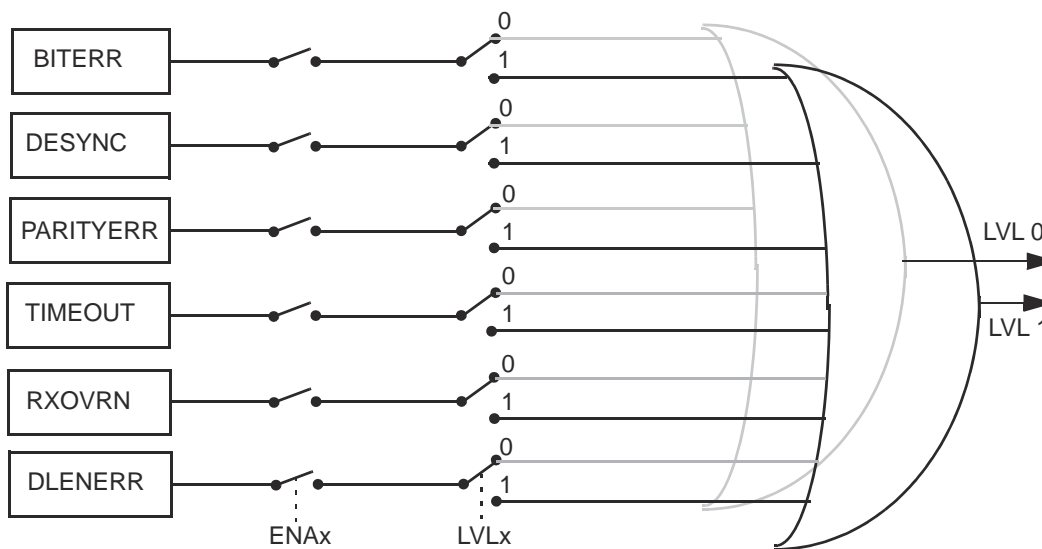

Figure 10-184. SPIFLG Interrupt Structure

Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

10.1.4.7 DMA Interface

In order to reduce CPU overhead in handling SPI message traffic on a character-by-character basis, SPI can use the DMA controller to transfer the data. The DMA request enable bit (DMA REQ EN) controls the assertion of requests to the DMA controller module. When a character is being transmitted or received, the SPI will signal the DMA via the DMA request signals, TX_DMA_REQ and RX_DMA_REQ. The DMA controller will then perform the required data transfer.

For efficient behavior during DMA operations, the transmitter empty and receive-buffer full interrupts can be disabled. For specific DMA features, see the DMA controller specification.

The SPI generates a request on the TX_DMA_REQ line each time the TX data is copied to the TX shift register either from the TXBUF or from peripheral data bus (when TXBUF is empty).

The first TX_DMA_REQ pulse is generated when either of the following is true:

- DMAREQEN (SPIINT0[16]) is set to 1 while SPIEN (SPIGCR1[24]) is already 1.
- SPIEN (SPIGCR1[24]) is set to 1 while DMAREQEN (SPIINT0[16]) is already 1.

The SPI generates a request on the RX_DMA_REQ line each time the received data is copied to the SPIBUF.

10.1.4.7.1 DMA in Multi-Buffer Mode

The MibSPI provides sophisticated programmable DMA control logic that completely eliminates the necessity of CPU intervention for data transfers, once programmed. When the multi-buffer mode is used, the DMA enable bit in the SPIINT0 register is ignored. DMA source or destination should be only the multi-buffer RAM and not SPIDAT0 / SPIDAT1 or SPIBUF register as in case of compatibility mode DMA.

The MibSPI offers up to eight DMA channels (for SEND and RECEIVE). All of the DMA channels are programmable individually and can be hooked to any buffer. The MibSPI provides up to 16 DMA request lines, and DMA requests from any channel can be programmed to be routed through any of these 16 lines. A DMA transfer can trigger both transmit and receive.

Each DMA channel has the capability to transfer a block of up to 32 data words without interruption using only one buffer of the array by configuring the DMAxCTRL register. Using the DMAxCOUNT and DMACTNTLEN register, up to 65535 (64K) words of data can be transferred without any interruption using just one buffer of the array. This enables the transfer of memory blocks from or into an external SPI memory.

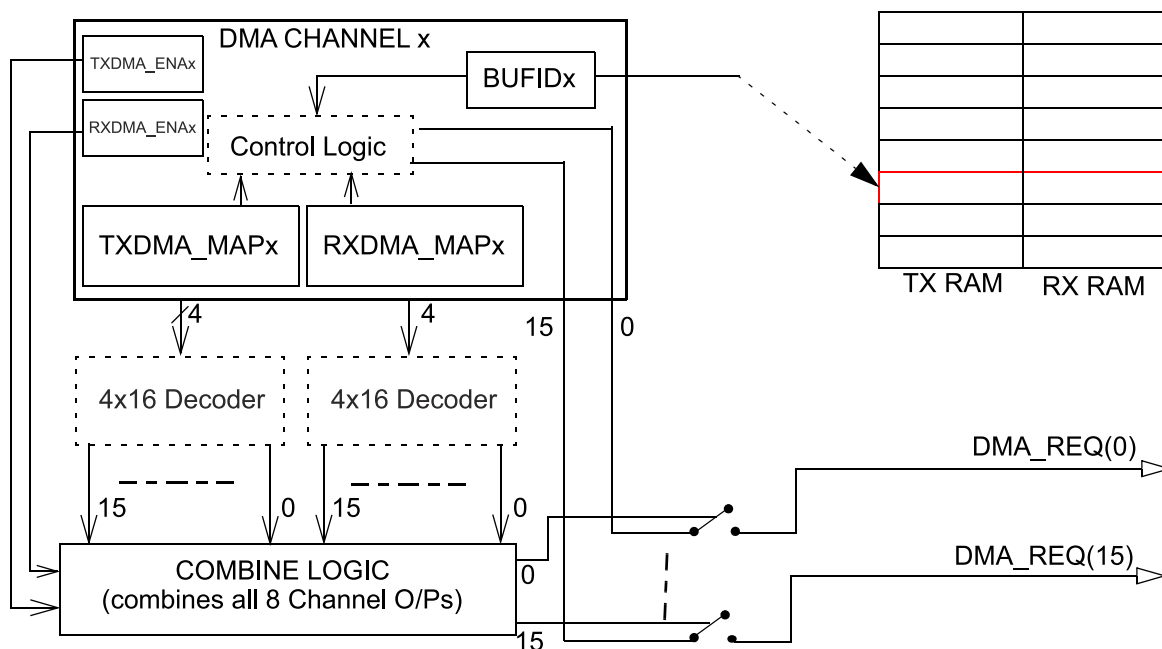

Figure 10-185. DMA Channel and Request Line (Logical) Structure in Multi-buffer Mode

10.1.4.8 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multi-buffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

10.1.4.8.1 Compatibility (SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, SPICLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIEN}}_A$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the chip select to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register (0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIEN bit to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- You must wait for TXFULL to reset or TXINT before writing next data to SPIDAT1 register.
- You must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

10.1.4.8.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA bit to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, SPICLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIENA}}$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers × Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIEN bit to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register, the 16 bit control fields in every TXRAM buffer in the TG have to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the data to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event, the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- You can poll Transfer Group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

10.1.4.9 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system.

Note

TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SPIEN	0 1	<p>SPI enable. This bit enables SPI transfers. This bit must be set to 1 after all other SPI configuration bits have been written. When the SPIEN bit is 0 or cleared to 0, the following SPI registers get forced to their default states:</p> <ul style="list-style-type: none"> • Both TX and RX shift registers • The TXDATA fields of the SPI Transmit Data Register 0 (SPIDAT0) and the SPI Transmit Data Register 1 (SPIDAT1) • All the fields of the SPI Flag Register (SPIFLG) • Contents of SPIBUF and the internal RXBUF registers <p>0 The SPI is not activated for transfers. 1 Activates SPI.</p>
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	LOOPBACK	0 1	<p>Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO[7:0] pins are internally connected to the SPISOMI[7:0] pins (transmit data is looped back as receive data). GIO mode for these pins is not supported in loopback mode. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI[7:0] remains in the high-impedance state. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result.</p> <p>Note: This loopback mode can only be used in master mode. Master mode must be selected before setting LOOPBACK. When this mode is selected, the CLKMOD bit should be set to 1, meaning that SPICLK is internally generated.</p> <p>0 Internal loop-back test mode is disabled. 1 Internal loop-back test mode is enabled.</p>
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	POWERDOWN	0 1	<p>When active, the SPI state machine enters a power-down state.</p> <p>0 The SPI is in active mode. 1 The SPI is in power-down mode.</p>
7-2	Reserved	0	Reads return 0. Writes have no effect.

Table 10-165. SPI Global Control Register 1 (SPIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
1	CLKMOD	0 1	<p>Clock mode. This bit selects either an internal or external clock source. This bit also determines the I/O direction of the $\overline{\text{SPIENA}}$ and $\overline{\text{SPICS}}$ pins in functional mode.</p> <p>0 Clock is external.</p> <ul style="list-style-type: none"> $\overline{\text{SPIENA}}$ is an output. $\overline{\text{SPICS}}$ are inputs. <p>1 Clock is internally-generated.</p> <ul style="list-style-type: none"> $\overline{\text{SPIENA}}$ is an input. $\overline{\text{SPICS}}$ are outputs.
0	MASTER	0 1	<p>SPISIMO/SPISOMI pin direction determination. Sets the direction of the SPISIMO and SPISOMI pins.</p> <p>Note: For master-mode operation of the SPI, MASTER bit should be set to 1 and CLKMOD bit can be set either 1 or 0. The master-mode SPI can run on an external clock on SPICLK.</p> <p>For slave mode operation, both the MASTER and CLKMOD bits should be cleared to 0. Any other combinations may result in unpredictable behavior of the SPI. In slave mode, SPICLK will not be generated internally in slave mode.</p> <p>0 SPISIMO[7:0] pins are inputs, SPISOMI[7:0] pins are outputs.</p> <p>1 SPISOMI[7:0] pins are inputs, SPISIMO[7:0] pins are outputs.</p>

Table 10-167. SPI Interrupt Level Register (SPILVL) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9	TXINTLVL	0	Transmit interrupt level. Transmit interrupt is mapped to interrupt line INT0.
		1	Transmit interrupt is mapped to interrupt line INT1.
8	RXINTLVL	0	Receive interrupt level. Receive interrupt is mapped to interrupt line INT0.
		1	Receive interrupt is mapped to interrupt line INT1.
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTLVL	0	Receive overrun interrupt level. Receive overrun interrupt is mapped to interrupt line INT0.
		1	Receive overrun interrupt is mapped to interrupt line INT1.
5	Reserved	0	Reads return 0. Writes have no effect.
4	BITERRLVL	0	Bit error interrupt level. Bit error interrupt is mapped to interrupt line INT0.
		1	Bit error interrupt is mapped to interrupt line INT1.
3	DESYNCLVL	0	Desynchronized slave interrupt level. (master mode only). An interrupt caused by desynchronization of the slave is mapped to interrupt line INT0.
		1	An interrupt caused by desynchronization of the slave is mapped to interrupt line INT1.
2	PARERRLVL	0	Parity error interrupt level. A parity error interrupt is mapped to interrupt line INT0.
		1	A parity error interrupt is mapped to interrupt line INT1.
1	TIMEOUTLVL	0	SPIEN \bar{A} pin time-out interrupt level. An interrupt on a time-out of the ENA signal (TIMEOUT = 1) is mapped to interrupt line INT0.
		1	An interrupt on a time-out of the ENA signal (TIMEOUT = 1) is mapped to interrupt line INT1.

Table 10-167. SPI Interrupt Level Register (SPILVL) Field Descriptions (continued)

Bit	Field	Value	Description
0	DLENERRLVL		Data length error interrupt level (line) select.
		0	An interrupt on data length error is mapped to interrupt line INT0.
		1	An interrupt on data length error is mapped to interrupt line INT1.

10.1.4.9.5 SPI Flag Register (SPIFLG)

Software must check all flag bits when reading this register.

Figure 10-190. SPI Flag Register (SPIFLG) [offset = 10h]

31				25	24	23			16

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

Table 10-168. SPI Flag Register (SPIFLG) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	BUFINITACTIVE	0 1	Indicates the status of multi-buffer initialization process. Software can poll for this bit to determine if it can proceed with the register configuration of multi-buffer mode registers or buffer handling. Note: If the SPIFLG register is read while the multi-buffer RAM is being initialized, the BUFINITACTIVE bit will be read as 1. If SPIFLG is read after the internal automatic buffer initialization is complete, this bit will be read as 0. This bit will show a value of 1 as long as the nRESET bit is 0, but does not really indicate that buffer initialization is underway. Buffer initialization starts only when the nRESET bit is set to 1. 0 Multi-buffer RAM initialization is complete. 1 Multi-buffer RAM is still being initialized. Do not attempt to write to either multi-buffer RAM or any multi-buffer mode registers.
23-10	Reserved	0	Reads return 0. Writes have no effect.
9	TXINTFLG	0 1	Transmitter-empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new word can be written to it. This flag is set when a word is copied to the shift register either directly from SPIDAT0/SPIDAT1 or from the TXBUF register. This bit is cleared by one of following methods: <ul style="list-style-type: none"> Writing a new data to either SPIDAT0 or SPIDAT1 Writing a 0 to SPIEN (SPIGCR1[24]) 0 Transmit buffer is now full. No interrupt pending for transmitter empty. 1 Transmit buffer is empty. An interrupt is pending to fill the transmitter.

Table 10-168. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
8	RXINTFLG	0 1	<p>Receiver-full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. This bit is cleared under the following methods:</p> <ul style="list-style-type: none"> • Reading the SPIBUF register • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive buffer full interrupt • Writing a 1 to this bit • Writing a 0 to SPIEN (SPIGCR1[24]) • System reset <p>During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.</p> <p>0 No new received data pending. Receive buffer is empty.</p> <p>1 A newly received data is ready to be read. Receive buffer is full.</p> <p>Note: Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. In this way, one can ignore a received word. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.</p>
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTFLG	0 1	<p>Receiver overrun flag. The SPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI will generate an interrupt request if this bit is set and the RXOVRN INTEN bit (SPIINT0.6) is set high. This bit is cleared under the following conditions in compatibility mode of MibSPI:</p> <ul style="list-style-type: none"> • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive-buffer-overrun interrupt • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself • Writing a 0 to SPIEN • Reading the data field of the SPIBUF register <p>Note: Reading the SPIBUF register does not clear this RXOVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.</p> <p>Note: There is a special condition under which the RXOVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another reception is underway, if any errors (TIMEOUT, BITERR, and DLEN_ERR) occur, then RXOVR in RXBUF and RXOVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a receive overrun.</p> <p>In multi-buffer mode of MibSPI, this bit is cleared under the following conditions:</p> <ul style="list-style-type: none"> • Reading the RXOVRN_BUF_ADDR register • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself <p>In multi-buffer mode, if RXOVRNINTFLG is set, then the address of the buffer which experienced the overrun is available in RXOVRN_BUF_ADDR.</p> <p>0 Overrun condition did not occur.</p> <p>1 Overrun condition has occurred.</p>
5	Reserved	0	Reads return 0. Writes have no effect.

Table 10-168. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
4	BITERRFLG	0 1	<p>Mismatch of internal transmit data and transmitted data. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> Write a 1 to this bit Clear the SPIEN bit to 0 <p>0 No bit error occurred.</p> <p>1 A bit error occurred. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERRFLG is set. If BITERRFLG is set an interrupt is asserted. Possible reasons for a bit error can be an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.</p>
3	DESYNCFLG	0 1	<p>Desynchronization of slave device. Desynchronization monitor is active in master mode only. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> Write a 1 to this bit Clear the SPIEN bit to 0 <p>0 No slave desynchronization is detected.</p> <p>1 A slave device is desynchronized. The master monitors the ENAble signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</p>
2	PARERRFLG	0 1	<p>Calculated parity differs from received parity bit. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRFLG is set. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> Write a 1 to this bit Clear the SPIEN bit to 0 <p>0 No parity error is detected.</p> <p>1 A parity error occurred.</p>
1	TIMEOUTFLG	0 1	<p>Time-out caused by nonactivation of ENA signal. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> Write a 1 to this bit Clear the SPIEN bit to 0 <p>0 No ENA-signal time-out occurred.</p> <p>1 An ENA signal time-out occurred. The SPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMEOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, that is, the SPI does not re-start a data transfer from this buffer.</p>
0	DLENERRFLG	0 1	<p>Data-length error flag. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> Write a 1 to this bit Clear the SPIEN bit to 0 <p>Note: Whenever any transmission errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected and the error flags are cleared by writing to the error bit in the SPIFLG register, the corresponding error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all of the old status bits in SPIBUF are cleared before starting the next transfer.</p> <p>0 No data length error has occurred.</p> <p>1 A data length error has occurred.</p>

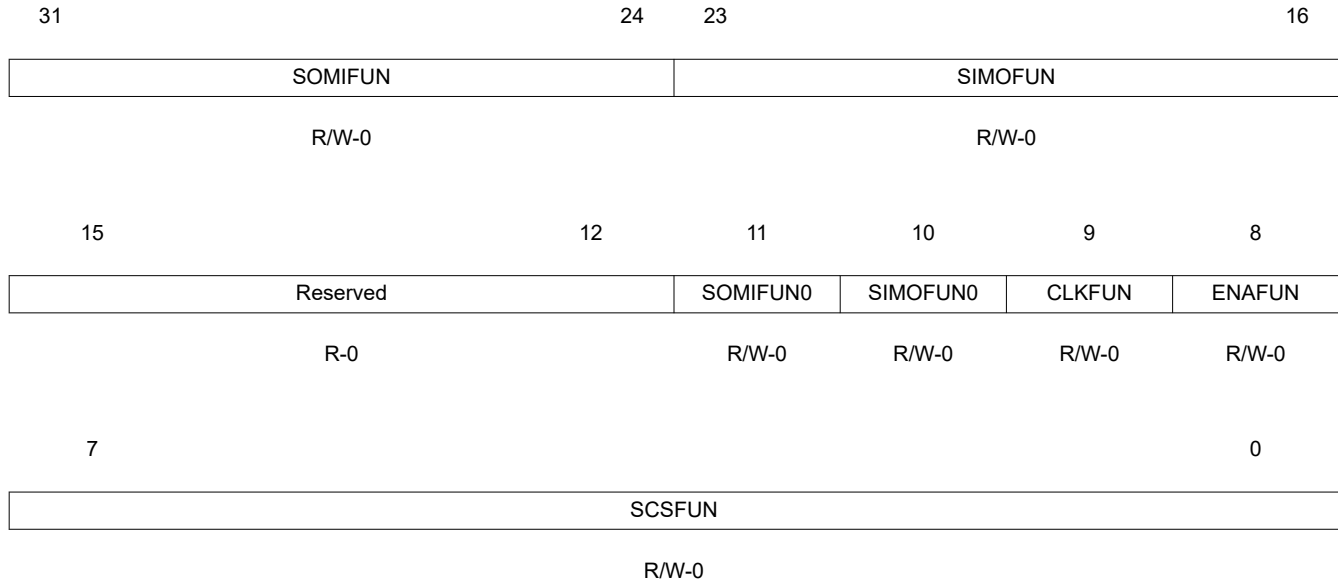

10.1.4.9.6 SPI Pin Control Register 0 (SPIPC0)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Figure 10-191. SPI Pin Control Register 0 (SPIPC0) [offset = 14h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-169. SPI Pin Control (SPIPC0) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIFUN	0 1	Slave out, master in function. Determines whether each SPISOMI[x] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. Note: Duplicate Control Bits for SPISOMI[0]. Bit 24 is not physically implemented. It is a mirror of Bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPISOMI[0] pin. The read value of bit 24 always reflects the value of bit 11. 0 The SPISOMI[x] pin is a GIO pin. 1 The SPISOMI[x] pin is a SPI functional pin.
23-16	SIMOFUN	0 1	Slave in, master out function. Determines whether each SPISIMO[x] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. Note: Duplicate Control Bits for SPISIMO[0]. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISIMO[0] pin. The read value of bit 16 always reflects the value of bit 10. 0 The SPISIMO[x] pin is a GIO pin. 1 The SPISIMO[x] pin is a SPI functional pin.
15-12	Reserved	0	Reads return 0. Writes have no effect.

Table 10-169. SPI Pin Control (SPIPC0) Field Descriptions (continued)

Bit	Field	Value	Description
11	SOMIFUN0	0 1	Slave out, master in function. This bit determines whether the SPISOMI[0] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. The SPISOMI[0] pin is a GIO pin. The SPISOMI[0] pin is a SPI functional pin. Note: Regardless of the number of parallel pins used, the SPISOMI[0] pin will always have to be programmed as functional pins for any SPI transfers.
10	SIMOFUN0	0 1	Slave in, master out function. This bits determine whether each SPISIMO[0] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. The SPISIMO[0] pin is a GIO pin. The SPISIMO[0] pin is a SPI functional pin. Note: Regardless of the number of parallel pins used, the SPISIMO[0] pin will always have to be programmed as functional pins for any SPI transfers.
9	CLKFUN	0 1	SPI clock function. This bit determines whether the SPICLK pin is to be used as a general-purpose I/O pin, or as a SPI functional pin. The SPICLK pin is a GIO pin. The SPICLK pin is a SPI functional pin.
8	ENAFUN	0 1	SPIEN \bar{A} function. This bit determines whether the SPIEN \bar{A} pin is to be used as a general-purpose I/O pin or as a SPI functional pin. The SPIEN \bar{A} pin is a GIO pin. The SPIEN \bar{A} pin is a SPI functional pin.
7-0	SCSFUN	0 1	SPICS function. Determines whether each SPICS pin is to be used as a general-purpose I/O pin or as a SPI functional pin. If the slave SPICS pins are in functional mode and receive an inactive high signal, the slave SPI will place its output in a high-impedance state and disable shifting. The SPICS pin is a GIO pin. The SPICS pin is a SPI functional pin.

10.1.4.9.7 SPI Pin Control Register 1 (SPIPC1)**Note****Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 10-170. SPI Pin Control Register (SPIPC1) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIDIR		SPISOMI[x] direction. Controls the direction of each SPISOMI[x] pin when used for general-purpose I/O. If SPISOMI[x] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register. Note: Duplicate Control Bits for SPISOMI[0]. Bit 24 is not physically implemented. It is a mirror of Bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPISOMI[0] pin. The read value of bit 24 always reflects the value of bit 11.
		0	The SPISOMI[x] pin is an input.
		1	The SPISOMI[x] pin is an output.
23-16	SIMODIR		SPISIMO[x] direction. Controls the direction of each SPISIMO[x] pin when used for general-purpose I/O. If SPISIMO[x] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register. Note: Duplicate Control Bits for SPISIMO[0]. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISIMO[0] pin. The read value of bit 16 always reflects the value of bit 10.
		0	The SPISIMO[x] pin is an input.
		1	The SPISIMO[x] pin is an output.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIDIR0		SPISOMI[0] direction. This bit controls the direction of the SPISOMI[0] pin when it is used as a general-purpose I/O pin. If the SPISOMI[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	The SPISOMI[0] pin is an input.
		1	The SPISOMI[0] pin is an output.
10	SIMODIR0		SPISIMO[0] direction. This bit controls the direction of the SPISIMO[0] pin when it is used as a general-purpose I/O pin. If the SPISIMO[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	The SPISIMO[0] pin is an input.
		1	The SPISIMO[0] pin is an output.
9	CLKDIR		SPICLK direction. This bit controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit.
		0	The SPICLK pin is an input.
		1	The SPICLK pin is an output.
8	ENADIR		$\overline{\text{SPIEN}}\overline{\text{A}}$ direction. This bit controls the direction of the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin when it is used as a general-purpose I/O. If the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	The $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is an input.
		1	The $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is an output.
7-0	SCSDIR		$\overline{\text{SPICS}}$ direction. These bits control the direction of each $\overline{\text{SPICS}}$ pin when it is used as a general-purpose I/O pin. Each pin could be configured independently from the others if the $\overline{\text{SPICS}}$ is used as a SPI functional pin. The I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	The $\overline{\text{SPICS}}$ pin is an input.
		1	The $\overline{\text{SPICS}}$ pin is an output.

10.1.4.9.8 SPI Pin Control Register 2 (SPIPC2)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

LEGEND: R/W = Read/Write; R = Read only; U = Undefined; -n = value after reset

Table 10-172. SPI Pin Control Register 3 (SPIPC3) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIDOUT	0 1	SPISOMI[x] data out write. This bit is only active when the SPISOMI[x] pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. Bit 11 or bit 24 can be used to set the direction for pin SPISOMI[0]. If a 32-bit write is performed, bit 11 will have priority over bit 24. 0 Current value on SPISOMI[x] pin is logic 0. 1 Current value on SPISOMI[x] pin is logic 1
23-16	SIMODOUT	0 1	SPISIMO[x] data out write. This bit is only active when the SPISIMO[x] pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. Bit 10 or bit 16 can be used to set the direction for pin SPISIMO[0]. If a 32-bit write is performed, bit 10 will have priority over bit 16. 0 Current value on SPISIMO[x] pin is logic 0. 1 Current value on SPISIMO[x] pin is logic 1.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIDOUT0	0 1	SPISOMI[0] data out write. This bit is only active when the SPISOMI[0] pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. 0 Current value on SPISOMI[0] pin is logic 0. 1 Current value on SPISOMI[0] pin is logic 1.

Table 10-172. SPI Pin Control Register 3 (SPIPC3) Field Descriptions (continued)

Bit	Field	Value	Description
10	SIMODOUT0	0 1	SPISIMO[0] data out write. This bit is only active when the SPISIMO[0] pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. Current value on SPISIMO[0] pin is logic 0. Current value on SPISIMO[0] pin is logic 1.
9	CLKDOUT	0 1	SPICLK data out write. This bit is only active when the SPICLK pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. The SPICLK pin is logic 0. The SPICLK pin is logic 1.
8	ENADOUT	0 1	SPIEN \bar{A} data out write. Only active when the SPIEN \bar{A} pin is configured as a general-purpose I/O pin and configured as an output pin. The value of this bit indicates the value sent to the pin. The SPIEN \bar{A} pin is logic 0. The SPIEN \bar{A} pin is logic 1.
7-0	SCSDOUT	0 1	SPIC \bar{S} data out write. Only active when the SPIC \bar{S} pins are configured as a general-purpose I/O pins and configured as output pins. The value of these bits indicates the value sent to the pins. The SPIC \bar{S} pin is logic 0. The SPIC \bar{S} pin is logic 1.

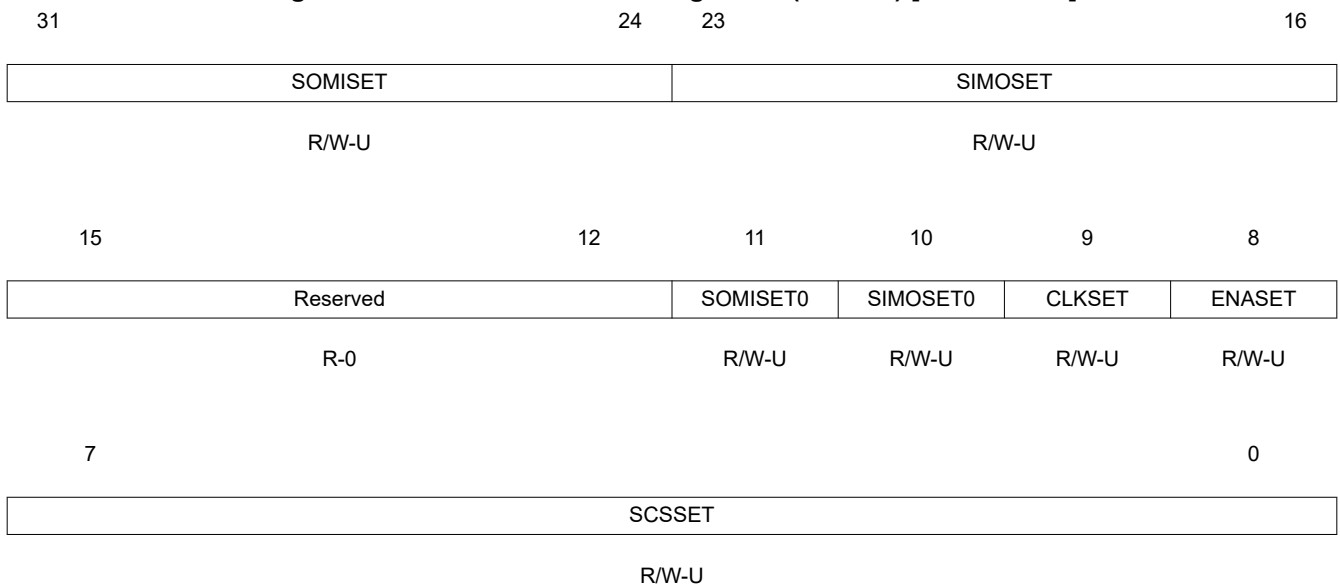

10.1.4.9.10 SPI Pin Control Register 4 (SPIPC4)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Figure 10-195. SPI Pin Control Register 4 (SPIPC4) [offset = 24h]

LEGEND: R/W = Read/Write; R = Read only; U = Undefined; -n = value after reset

Table 10-173. SPI Pin Control Register 4 (SPIPC4) Field Descriptions

Bit	Field	Value	Description
31-24	SOMISET	0	SPISOMI[x] data out set. This pin is only active when the SPISOMI[x] pin is configured as a general-purpose output pin. Bit 11 or bit 24 can be used to set the SPISOMI[0] pin. If a 32-bit write is performed, bit 11 will have priority over bit 24. Read: SPISOMI[x] is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: SPISOMI[x] is logic 1. Write: Logic 1 is placed on SPISOMI[x] pin, if it is in general-purpose output mode.
23-16	SIMOSET	0	SPISIMO[x] data out set. This bit is only active when the SPISIMO[x] pin is configured as a general-purpose output pin. Bit 10 or bit 16 can be used to set the SPISIMO[0] pin. If a 32-bit write is performed, bit 10 will have priority over bit 16. Read: SPISIMO[x] is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: SPISIMO[x] is logic 1. Write: Logic 1 is placed on SPISIMO[x] pin, if it is in general-purpose output mode.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMISET0	0	SPISOMI[0] data out set. This pin is only active when the SPISOMI[0] pin is configured as a general-purpose output pin. Read: SPISOMI[0] is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: SPISOMI[0] is logic 1. Write: Logic 1 is placed on SPISOMI[0] pin, if it is in general-purpose output mode.
10	SIMOSET0	0	SPISIMO[0] data out set. This pin is only active when the SPISIMO[0] pin is configured as a general-purpose output pin. Read: SPISIMO[0] is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: SPISIMO[0] is logic 1. Write: Logic 1 is placed on SPISIMO[0] pin, if it is in general-purpose output mode.
9	CLKSET	0	SPICLK data out set. This bit is only active when the SPICLK pin is configured as a general-purpose output pin. Read: SPICLK is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: SPICLK is logic 1. Write: Logic 1 is placed on SPICLK pin, if it is in general-purpose output mode.
8	ENASET	0	$\overline{\text{SPIEN}}_A$ data out set. This bit is only active when the $\overline{\text{SPIEN}}_A$ pin is configured as a general-purpose output pin. Read: $\overline{\text{SPIEN}}_A$ is logic 0. Write: Writing a 0 to this bit has no effect.
		1	Read: $\overline{\text{SPIEN}}_A$ is logic 1. Write: Logic 1 is placed on $\overline{\text{SPIEN}}_A$ pin, if it is in general-purpose output mode.

Table 10-173. SPI Pin Control Register 4 (SPIPC4) Field Descriptions (continued)

Bit	Field	Value	Description
7-0	SCSSET	0	<p>$\overline{\text{SPICS}}$ data out set. This bit is only active when the $\overline{\text{SPICS}}$ pin is configured as a general-purpose output pin. A value of 1 written to this bit sets the corresponding SCSDOUT bit to 1.</p> <p>Read: $\overline{\text{SPICS}}$ is logic 0.</p> <p>Write: Writing a 0 to this bit has no effect.</p>
		1	<p>Read: $\overline{\text{SPICS}}$ is logic 1.</p> <p>Write: Logic 1 is placed on $\overline{\text{SPICS}}$ pin, if it is in general-purpose output mode.</p>

10.1.4.9.11 SPI Pin Control Register 5 (SPIPC5)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Figure 10-196. SPI Pin Control Register 5 (SPIPC5) [offset = 28h]

LEGEND: R/W = Read/Write; R = Read only; U = Undefined; -n = value after reset

Table 10-174. SPI Pin Control Register 5 (SPIPC5) Field Descriptions

Bit	Field	Value	Description
31-24	SOMICLR	0	SPISOMI[x] data out clear. This pin is only active when the SPISOMI[x] pin is configured as a general-purpose output pin. Bit 11 or bit 24 can be used to set the SPISOMI[0] pin. If a 32-bit write is performed, bit 11 will have priority over bit 24. Read: The current value on SPISOMI[x] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISOMI[x] is 1. Write: Logic 0 is placed on SPISOMI[x] pin, if it is in general-purpose output mode.
23-16	SIMOCLR	0	SPISIMO[x] data out clear. This bit is only active when the SPISIMO[x] pin is configured as a general-purpose output pin. Bit 10 or bit 16 can be used to set the SPISIMO[0] pin. If a 32-bit write is performed, bit 10 will have priority over bit 16. Read: The current value on SPISIMO[x] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISIMO[x] is 1. Write: Logic 0 is placed on SPISIMO[x] pin, if it is in general-purpose output mode.
15-12	Reserved	0	Reads return 0. Writes have no effect.

Table 10-174. SPI Pin Control Register 5 (SPIPC5) Field Descriptions (continued)

Bit	Field	Value	Description
11	SOMICLR0	0	SPISOMI[0] data out clear. This pin is only active when the SPISOMI[0] pin is configured as a general-purpose output pin. Read: The current value on SPISOMI[0] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISOMI[0] is 1. Write: Logic 0 is placed on SPISOMI[0] pin, if it is in general-purpose output mode.
10	SIMOCLR0	0	SPISIMO[0] data out clear. This pin is only active when the SPISIMO[0] pin is configured as a general-purpose output pin. Read: The current value on SPISIMO[0] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISIMO[0] is 1. Write: Logic 0 is placed on SPISIMO[0] pin, if it is in general-purpose output mode.
9	CLKCLR	0	SPICLK data out clear. This bit is only active when the SPICLK pin is configured as a general-purpose output pin. Read: The current value on SPICLK is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPICLK is 1. Write: Logic 0 is placed on SPICLK pin, if it is in general-purpose output mode.
8	ENACLR	0	SPIENA data out clear. This bit is only active when the SPIENA pin is configured as a general-purpose output pin. A value of 1 written to this bit clears the corresponding ENABLEDOUT bit to 0. Read: The current value on SPIENA is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPIENA is 1. Write: Logic 0 is placed on SPIENA pin, if it is in general-purpose output mode.
7-0	SCSCLR	0	SPIC \overline{S} data out clear. This bit is only active when the SPIC \overline{S} pin is configured as a general-purpose output pin. Read: The current value on SCSDOUT is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SCSDOUT is 1. Write: Logic 0 is placed on SPIC \overline{S} pin, if it is in general-purpose output mode.

10.1.4.9.12 SPI Pin Control Register 6 (SPIPC6)**Note****Register bits vary by device**

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

10.1.4.9.13 SPI Pin Control Register 7 (SPIPC7)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Note

Default Register Value

The default values of these register bits vary by device. See your device datasheet for information about default pin states, which correspond to the register reset values (see the pin-list table).

Figure 10-198. SPI Pin Control Register 7 (SPIPC7) [offset = 30h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -x = value varies by device

Table 10-176. SPI Pin Control Register 7 (SPIPC7) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIDIS	0 1	SPISOMI[x] pull control disable. This bit disables pull control capability for each SPISOMI[x] pin if it is in input mode, regardless of whether it is in functional or GIO mode. Note: Bit 11 or bit 24 can be used to set pull-disable for SPISOMI[0]. If a 32-bit write is performed, bit 11 will have priority over bit 24. 0 Pull control on the SPISOMI[x] pin is enabled. 1 Pull control on the SPISOMI[x] pin is disabled.
23-16	SIMODIS	0 1	SPISIMO[x] pull control disable. This bit disables pull control capability for each SPISIMO[x] pin if it is in input mode, regardless of whether it is in functional or GIO mode. Note: Bit 10 or bit 16 can be used to set pull-disable for SPISIMO[0]. If a 32-bit write is performed, bit 10 will have priority over bit 16. 0 Pull control on the SPISIMO[x] pin is enabled. 1 Pull control on the SPISIMO[x] pin is disabled.
15-12	Reserved	0	Reads return 0. Writes have no effect.

Table 10-176. SPI Pin Control Register 7 (SPIPC7) Field Descriptions (continued)

Bit	Field	Value	Description
11	SOMIPDIS0	0 1	SPISOMI[0] pull control disable. This bit disables pull control capability for the SPISOMI[0] pin if it is in input mode, regardless of whether it is in functional or GIO mode. Pull control on the SPISOMI[0] pin is enabled. Pull control on the SPISOMI[0] pin is disabled.
10	SIMOPDIS0	0 1	SPISIMO[0] pull control disable. This bit disables pull control capability for the SPISIMO[0] pin if it is in input mode, regardless of whether it is in functional or GIO mode. Pull control on the SPISIMO[0] pin is enabled. Pull control on the SPISIMO[0] pin is disabled.
9	CLKPDIS	0 1	SPICLK pull control disable. This bit disables pull control capability for the SPICLK pin if it is in input mode, regardless of whether it is in functional or GIO mode. Pull control on the SPICLK pin is enabled. Pull control on the SPICLK pin is disabled.
8	ENAPDIS	0 1	$\overline{\text{SPIEN}}\overline{\text{A}}$ pull control disable. This bit disables pull control capability for the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin if it is in input mode, regardless of whether it is in functional or GIO mode. Pull control on the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is enabled. Pull control on the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is disabled.
7-0	SCSPDIS	0 1	$\overline{\text{SPICS}}$ pull control disable. This bit disables pull control capability for each $\overline{\text{SPICS}}$ pin if it is in input mode, regardless of whether it is in functional or GIO mode. Pull control on the $\overline{\text{SPICS}}$ pin is enabled. Pull control on the $\overline{\text{SPICS}}$ pin is disabled.

10.1.4.9.14 SPI Pin Control Register 8 (SPIPC8)**Note****Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Note**Default Register Value**

The default values of these register bits vary by device. See your device datasheet for information about default pin states, which correspond to the register reset values (see the pin-list table).

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-178. SPI Transmit Data Register 0 (SPIDAT0) Field Descriptions

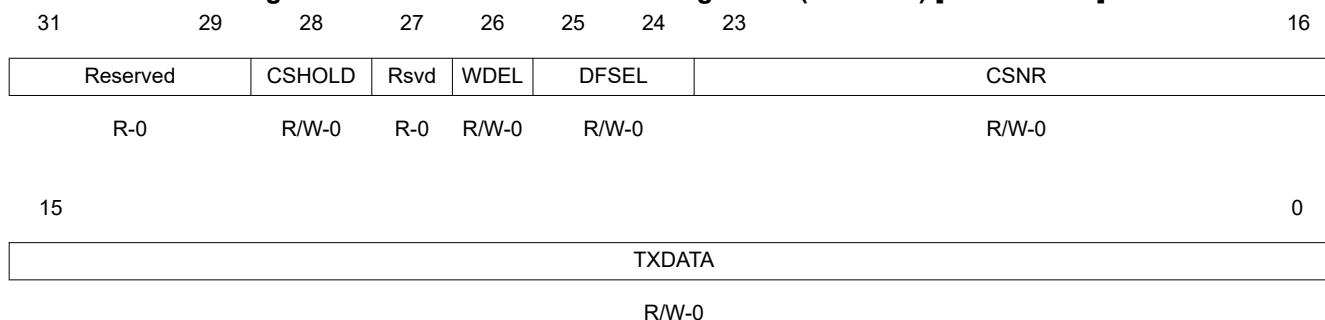

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	TXDATA	0-FFFFh	<p>SPI transmit data. When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, TXBUF holds the written data. SPIEN (SPICGR1[24]) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 to 0x00.</p> <p>Note: When this register is read, the contents TXBUF, which holds the latest written data, will be returned.</p> <p>Note: Regardless of character length, the transmit word should be right-justified before writing to the SPIDAT1 register.</p> <p>Note: The default data format control register for SPIDAT0 is SPIFMT0. However, it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 before using SPIDAT0, to select a different SPIFMTx register.</p> <p>Note: It is highly recommended to use SPIDAT1 register, SPIDAT0 is supported for compatibility reasons.</p>

10.1.4.9.16 SPI Transmit Data Register 1 (SPIDAT1)

Note

Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Figure 10-201. SPI Transmit Data Register 1 (SPIDAT1) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-179. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28	CSHOLD	0	Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of SPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer. The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.
27	Reserved	0	Reads return 0. Writes have no effect.
26	WDEL	0	Enable the delay counter at the end of the current transaction. Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored. No delay will be inserted. However, the $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0. Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated depends upon the time taken to supply a new word after completing the shift operation. If TXBUF is already full, then the SPICS pin will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The $\overline{\text{SPICS}}$ pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.
25-24	DFSEL	0	Data word format select. Data word format 0 is selected.
		1h	Data word format 1 is selected.
		2h	Data word format 2 is selected.
		3h	Data word format 3 is selected.

Table 10-179. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	CSNR	0-FFh	<p>Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 10-180.</p> <p>Note: If your MiBSPi has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPi3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.</p>
15-0	TXDATA	0-FFFFh	<p>Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.</p> <p>SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0x0000.</p> <p>A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the SPiCS pins, if the pins are configured as functional pins (automatic chip select, see Section 10.1.4.2).</p> <p>When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.</p> <p>Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.</p>

31	RXEMPTY	0 1	<p>Receive data buffer empty. When the host reads the RXDATA field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into RXDATA.</p> <p>No data has been received since the last read of RXDATA.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> Reading the RXDATA field of the SPIBUF register Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG) <p>Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of SPIBUF (or the entire register).</p>
30	RXOVR	0 1	<p>Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVEXTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read).</p> <p>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</p> <p>Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</p> <p>No receive data overrun condition occurred since last read of the data field.</p> <p>A receive data overrun condition occurred since last read of the data field.</p>

Table 10-181. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)

Bit	Field	Value	Description
29	TXFULL	0	Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag. The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.
28	BITERR	0	Bit error. There was a mismatch of internal transmit data and transmitted data. Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read. No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC	0	Desynchronization of slave device. This bit is valid in master mode only. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master. Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always assured to be for the current buffer. Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		1	No slave desynchronization is detected. A slave device is desynchronized.
