5	MON	Bus Monitoring Mode The MCAN_CCCR[5] MON bit can only be set by the Host CPU when both MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set to 1. The bit can be reset by the Host CPU at any time. 0x0: Bus Monitoring Mode is disabled 0x1: Bus Monitoring Mode is enabled	RW	0x0
4	CSR	Clock Stop Request 0x0: No clock stop is requested 0x1: Clock stop requested. When clock stop is requested, first the MCAN_CCCR[0] INIT bit and then the MCAN_CCCR[3] CSA bit will be set after all pending transfer requests have been completed and the CAN bus reached idle.	RW	0x0
3	CSA	Clock Stop Acknowledge 0x0: No clock stop acknowledged 0x1: The MCAN module may be set in power down by stopping MCAN_ICLK and MCAN_FCLK	R	0x0

Bits	Field Name	Description	Type	Reset
2	ASM	<p>Restricted Operation Mode</p> <p>The MCAN_CCCR[2] ASM bit can only be set by the Host CPU when both MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set to 1. The bit can be reset by the Host CPU at any time. For a description of the Restricted Operation Mode, see Section 10.4.3.4.4.5.</p> <p>0x0: Normal CAN operation 0x1: Restricted Operation Mode active</p>	RW	0x0
1	CCE	<p>Configuration Change Enable</p> <p>0x0: The Host CPU has no write access to the protected configuration registers 0x1: The Host CPU has write access to the protected configuration registers (while the MCAN_CCCR[0] INIT = 1)</p>	RW	0x0
0	INIT	<p>Initialization</p> <p>0x0: Normal Operation 0x1: Initialization is started</p> <p>Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to the MCAN_CCCR[0] INIT bit can be read back. Therefore the software has to assure that the previous value written to the MCAN_CCCR[0] INIT bit has been accepted by reading the MCAN_CCCR[0] INIT bit before setting the MCAN_CCCR[0] INIT bit to a new value.</p>	RW	0x1

Table 10-1728. MCAN_NBTP

Address Offset	0x0000 1A1C
Description	<p>Nominal Bit Timing & Prescaler Register Configuration of arbitration phase bit timing.</p> <p>This register is only writable if the MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 MCAN_FCLK periods. $t_q = (\text{MCAN_NBTP}[24:16] \text{ NBRP} + 1) \text{ mtq}$. The MCAN_NBTP[15:8] NTSEG1 field is the sum of Prop_Seg and Phase_Seg1. The MCAN_NBTP[6:0] NTSEG2 field is Phase_Seg2.</p> <p>Therefore the length of the bit time is (programmed values) [MCAN_NBTP[15:8] NTSEG1 + MCAN_NBTP[6:0] NTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.</p> <p>The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.</p>
Type	RW

22:16	TDCV	Transmitter Delay Compensation Value Position of the secondary sample point, defined by the sum of the measured delay from the MCAN_TX to MCAN_RX pins and the MCAN_TDCR[14:8] TDCO field. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq (0x00-0x7F).	R	0x0
15	RESERVED	Reserved	R	0x0
14	PXE	Protocol Exception Event 0x0: No protocol exception event occurred since last read access 0x1: Protocol exception event occurred	R	0x0
13	RFDF	Received a CAN FD Message This bit is set independent of acceptance filtering. 0x0: Since this bit was reset by the Host CPU, no CAN FD message has been received 0x1: Message in CAN FD format with FDF flag set has been received	R	0x0
12	RBRS	BRS flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its BRS flag set 0x1: Last received CAN FD message had its BRS flag set	R	0x0

Bits	Field Name	Description	Type	Reset
11	RESI	ESI flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its ESI flag set 0x1: Last received CAN FD message had its ESI flag set	R	0x0
10:8	DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for the MCAN_PSR[2:0] LEC field. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.	R	0x7
7	BO	Bus_Off Status 0x0: The MCAN module is not Bus_Off 0x1: The MCAN module is in Bus_Off state	R	0x0
6	EW	Warning Status 0x0: Both error counters are below the Error_Warning limit of 96 0x1: At least one of error counter has reached the Error_Warning limit of 96	R	0x0
5	EP	Error Passive 0x0: The MCAN module is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 0x1: The MCAN module is in the Error_Passive state	R	0x0
4:3	ACT	Activity Monitors the module's CAN communication state. 0x0: Synchronizing - node is synchronizing on CAN communication 0x1: Idle - node is neither receiver nor transmitter 0x2: Receiver - node is operating as receiver 0x3: Transmitter - node is operating as transmitter Note: ACT is set to 00 by a Protocol Exception Event.	R	0x0

Bits	Field Name	Description	Type	Reset
2:0	LEC	<p>Last Error Code</p> <p>The MCAN_PSR[2:0] LEC field indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error.</p> <p>0x0: No Error: No error occurred since the MCAN_PSR[2:0] LEC field has been reset by successful reception or transmission.</p> <p>0x1: Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.</p> <p>0x2: Form Error: A fixed format part of a received frame has the wrong format.</p> <p>0x3: AckError: The message transmitted by the MCAN module was not acknowledged by another node.</p> <p>0x4: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.</p> <p>0x5: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the Host CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>0x6: CRCErrror: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.</p> <p>0x7: NoChange: Any read access to the Protocol Status Register re-initializes the MCAN_PSR[2:0] LEC field to '0x7'. When the MCAN_PSR[2:0] LEC field shows the value '0x7', no CAN bus event was detected since the last Host CPU read access to the Protocol Status Register.</p> <p>Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in the MCAN_PSR[10:8] DLEC field instead of the MCAN_PSR[2:0] LEC field. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.</p> <p>Note: The Bus_Off recovery sequence (see ISO11898-1:2015) cannot be shortened by setting or resetting the MCAN_CCCR[0] INIT bit. If the device goes Bus_Off, it will set the MCAN_CCCR[0] INIT bit of its own accord, stopping all bus activities. Once the MCAN_CCCR[0] INIT bit has been cleared by the Host CPU, the device will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before</p>	R	0x7

Bits	Field Name	Description	Type	Reset
		resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of the MCAN_CCCR[0] INIT bit, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the MCAN_PSR[2:0] LEC field, enabling the Host CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. The MCAN_ECR[14:8] REC field is used to count these sequences.

Address Offset 0x0000 1A58

Table 10-1738. MCAN_ILS (continued)**Description**

Interrupt Line Select

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via the MCAN_ILE[0] EINT0 and MCAN_ILE[1] EINT1 bits.

15:2	TBSA	Tx Buffers Start Address Start address of Tx Buffers section in Message RAM (32-bit word address, see Figure 10-1665). Note: Be aware that the sum of the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.	RW	0x0
1:0	RESERVED	Reserved	R	0x0

Table 10-1756. MCAN_TXFQS

Address Offset 0x0000 1AC4

Description Tx FIFO/Queue Status
Tx FIFO/Queue full indication and put index, Tx FIFO get index and fill level.
The Tx FIFO/Queue status is related to the pending Tx requests listed in the MCAN_TXBRP register. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (the MCAN_TXBRP register not yet updated).

Type R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 10-1759. MCAN_TXBAR

Address Offset	0x0000 1AD0
Description	<p>Tx Buffer Add Request Add transmission requests. Each Tx Buffer has its own Add Request bit. Writing a '1' will set the corresponding Add Request bit; writing a '0' has no impact. This enables the Host CPU to set transmission requests for multiple Tx Buffers with one write to the MCAN_TXBAR register. The MCAN_TXBAR bits are set only for those Tx Buffers configured via the MCAN_TXBC register. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.</p> <p>Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding MCAN_TXBRP bit already set), this add request is ignored.</p>

Table 10-1761. MCAN_TXBTO

Address Offset	0x0000 1AD8
Description	Tx Buffer Transmission Occurred Signals successful transmissions, set when corresponding MCAN_TXBRP flag is cleared. Each Tx Buffer has its own Transmission Occurred bit. The bits are set when the corresponding MCAN_TXBRP bit is cleared after a successful transmission. The bits are reset when a new transmission is requested by writing a '1' to the corresponding bit of register the MCAN_TXBAR register.

10.5 Timer Modules

10.5.1 Real-Time Interrupt (RTI) and Watchdog Module

This chapter describes the functionality of the real-time interrupt (RTI) module. The RTI is designed as an operating system timer to support a real time operating system (RTOS).

Note

This chapter describes a superset implementation of the RTI module that includes features and functionality related to DMA and Timebase control. These features are dependent on the device-specific feature content. Consult your device-specific datasheet to determine the applicability of these features to your device being used.

10.5.1.1 Overview	4180
10.5.1.2 Module Operation	4181
10.5.1.3 RTI Control Registers	4190

10.5.1.1 Overview

The real-time interrupt (RTI) module provides timer functionality for operating systems and for benchmarking code. The RTI module can incorporate several counters that define the timebases needed for scheduling in the operating system.

The timers also allow you to benchmark certain areas of code by reading the values of the counters at the beginning and the end of the desired code range and calculating the difference between the values.

10.5.1.1.1 Features

The RTI module has the following features:

- Two independent 64 bit counter blocks
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- Fast enabling/disabling of events
- Two time stamp (capture) functions for system or peripheral interrupts, one for each counter block
- Digital windowed watchdog

10.5.1.1.2 Industry Standard Compliance Statement

This module is specifically designed to fulfill the requirements for OSEK (**O**ffene **S**ysteme und deren **S**chnittstellen für die **E**lektronik im **K**raftfahrzeug, or Open Systems and the Corresponding Interfaces for Automotive Electronics) as well as OSEK/time-compliant operating systems, but is not limited to it.

10.5.1.2 Module Operation

Figure 10-1671 illustrates the high level block diagram of the RTI module.

The RTI module has two independent counter blocks for generating different timebases: counter block 0 and counter block 1. The two counter blocks provide the same basic functionality.

A compare unit compares the counters with programmable values and generates four independent interrupt or DMA requests on compare matches. Each of the compare registers can be programmed to be compared to either counter block 0 or counter block 1.

The following sections describe the individual functions in more detail.

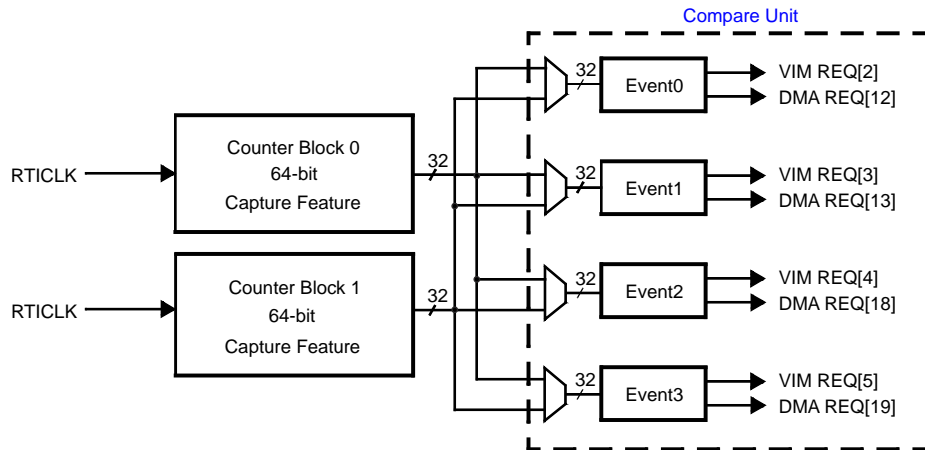

Figure 10-1671. RTI Block Diagram

10.5.1.2.1 Counter Operation

Each counter block consists of the following (see Figure 10-1672):

- One 32-bit prescale counter (RTIUC0 or RTIUC1)
- One 32-bit free running counter (RTIFRC0 or RTIFRC1)

The RTIUC0/1 is driven by the RTICK and counts up until the compare value in the compare up counter register (RTICPUC0 or RTICPUC1) is reached. When the compare matches, RTIFRC0/1 is incremented and RTIUC0/1 is reset to 0. If RTIFRC0/1 overflows, an interrupt is generated to the vectored interrupt manager (VIM). The overflow interrupt is not intended to generate the timebase for the operating system. See Section 10.5.1.2.2 for the timebase generation. The up counter together with the compare up counter value prescale the RTI clock. The resulting formula for the frequency of the free running counter (RTIFRC0/1) is:

$$f_{RTIFRCx} = \begin{cases} \frac{f_{RTICK}}{RTICPUCx + 1} & \text{when } RTICPUCx \neq 0 \\ \frac{f_{RTICK}}{2^{32} + 1} & \text{when } RTICPUCx = 0 \end{cases} \quad (14)$$

Note

Setting RTICPUCx equal to zero is not recommended. Doing so will hold the Up Counter at zero for two RTICK cycles after it overflows from 0xFFFFFFFF to zero.

The counter values can be determined by reading the respective counter registers or by generating a hardware event which captures the counter value into the respective capture register. Both functions are described in the following sections.

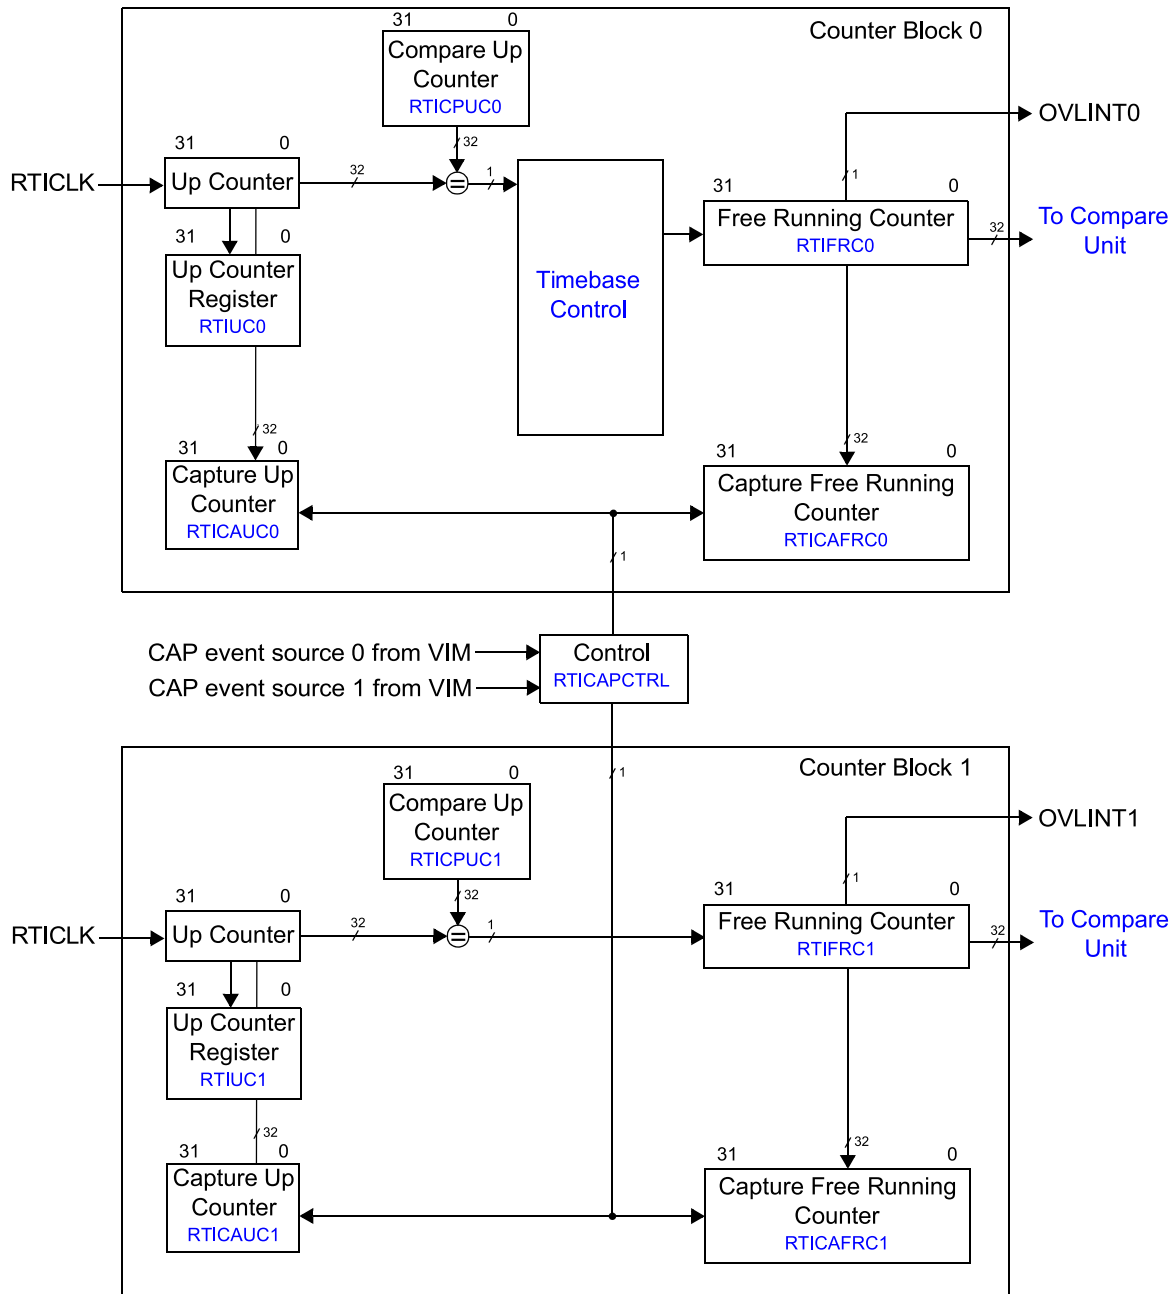

Figure 10-1672. Counter Block Diagram

10.5.1.2.1.1 Counter and Capture Read Consistency

Portions of the device internal databus are 32-bits wide. If the application wants to read the 64-bit counters or the 64-bit capture values, a certain order of 32-bit read operations needs to be followed. This is to prevent one counter incrementing in between the two separate read operations to both counters.

Reading the Counters

The free running counter (RTIFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTIFRCx, the up counter value is stored in its counter register (RTIUCx). The second read has to access the up counter register (RTIUCx), which then holds the value which corresponds to the number of RTICLK cycles that have elapsed at the time reading the free running counter register (RTIFRCx).

Note

The up counters are implemented as shadow registers. Reading RTIUCx without having read RTIFRCx first will return always the same value. RTIUCx will only be updated when RTIFRCx is read.

Reading the Capture Values

The free running counter capture register (RTICAFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTICAFRCx, the up counter value is stored in its counter register (RTICAUCx). The second read has to access the up counter register (RTICAUCx), which then holds the value captured at the time when reading the capture free running counter register (RTICAFRCx).

Note

The capture up counter registers are implemented as shadow registers. Reading RTICAUCx without having read RTICAFRCx first will return always the same value. RTICAUCx will only be updated when RTICAFRCx is read.

10.5.1.2.1.2 Capture Feature

Both counter blocks also provide a capture feature on external events. Two capture sources can trigger the capture event. The source triggering the block is configurable (RTICAPCTRL). The sources originate from the Vectored Interrupt Manager (VIM) and allow the generation of capture events when a peripheral module has generated an interrupt. Any of the peripheral interrupts can be selected as the capture event in the VIM.

When an event is detected, RTIUCx and RTIFRCx are stored in the capture up counter (RTICAUCx) and capture free running counter (RTICAFRCx) registers. The read order of the captured values must be the same as the read order of the actual counters (see [Section 10.5.1.2.1.1](#)).

10.5.1.2.2 Interrupt/DMA Requests

There are four compare registers (RTICOMPy) to generate interrupt requests to the VIM or DMA requests to the DMA controller. The interrupts can be used to generate different timebases for the operating system. Each of the compare registers can be configured to be compared to either RTIFRC0 or RTIFRC1. When the counter value matches the compare value, an interrupt is generated. To allow periodic interrupts, a certain value can be added to the compare value in RTICOMPy automatically. This value is stored in the update compare register (RTIUDCPy) and will be added after a compare is matched. The period of the generated interrupt/DMA request can be calculated with:

$$t_{COMPx} = t_{RTICK} \times (RTICPUCy + 1) \times RTIUDCPy$$

if $RTICPUCy \neq 0$,

$$t_{COMPx} = t_{RTICK} \times (2^{32} + 1) \times RTIUDCPy$$

if $RTIUDCPy = 0$,

$$t_{COMPx} = t_{RTICK} \times (RTICPUCy + 1) \times 2^{32} \tag{15}$$

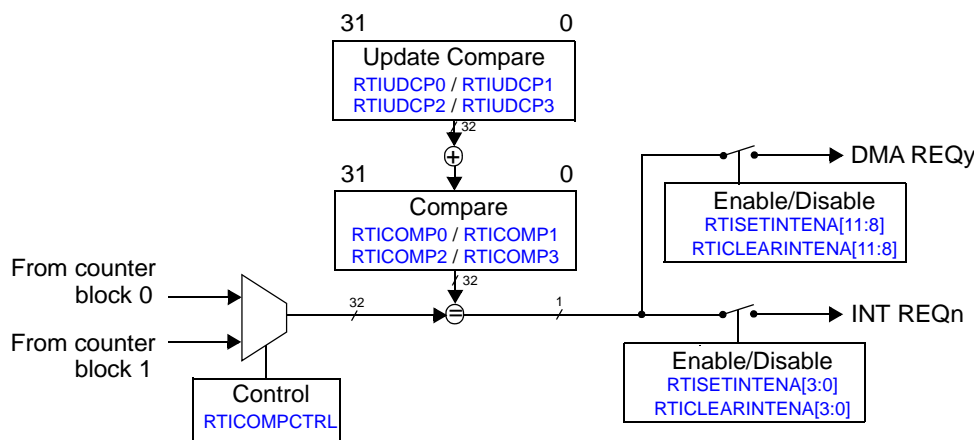

Figure 10-1673. Compare Unit Block Diagram (shows only 1 of 4 blocks for simplification)

Another interrupt that can be generated is the overflow interrupt (OVLINTx) in case the RTIFRCx counter overflows.

The interrupts/DMA requests can be enabled in the RTISETINTENA register and disabled in the RTICLEARINTENA register. The RTIINTFLAG register shows the pending interrupts.

10.5.1.2.3 RTI Clocking

The counter blocks are clocked with RTICK.

A clock supervision for the NTUX clocking scheme is implemented to avoid missing operating system ticks.

10.5.1.2.4 Digital Watchdog (DWD)

The digital watchdog (DWD) is an optional safety diagnostic which can detect a runaway CPU and generate either a reset or NMI (non-maskable interrupt) response. It generates resets or NMIs after a programmable period, or if no correct key sequence was written to the RTIWDKEY register. [Figure 10-1674](#) illustrates the DWD.

Figure 10-1674. Digital Watchdog

10.5.1.2.4.1 Digital Watchdog (DWD)

The DWD is disabled by default. If it should be used, it must be enabled by writing a 32-bit value to the RTIDWDCTRL register.

Note

Once the DWD is enabled, it cannot be disabled except by system reset or power on reset.

If the correct key sequence is written to the RTIWDKEY register (0xE51A followed by 0xA35C), the 25-bit DWD down counter is reloaded with the left justified 12-bit preload value stored in RTIDWDPRLD. If an incorrect value is written, a watchdog reset or NMI will occur immediately. A reset or NMI will also be generated when the DWD down counter is decremented to 0.

While the device is in suspend mode (halting debug mode), the DWD down counter keeps the value it had when entering suspend mode.

The DWD down counter will be decremented with the RTICLK frequency.

Figure 10-1675. DWD Operation

The expiration time of the DWD down counter can be determined with the following equation:

$$t_{exp} = (DWDPRLD + 1) \times 2^{13}/RTICLK$$

where

$$DWDPRLD = 0 \dots 4095$$

Note

Care should be taken to ensure that the CPU write to the watchdog register is made allowing time for the write to propagate to the RTI.

10.5.1.2.4.2 Digital Windowed Watchdog (DWWD)

In addition to the time-out boundary configurable via the digital watchdog discussed in [Section 10.5.1.2.4.1](#), for enhanced safety metrics it is desirable to check for a watchdog "pet" within a time window rather than using a single time threshold. This is enabled by the digital windowed watchdog (DWWD) feature.

- Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a NMI to the CPU. This is controlled by configuring the

RTIWDRXNCTRL register. As with the DWD, the DWWD is disabled after power on reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The NMI handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the NMI handler does not service the watchdog in time, it could count down all the way to zero and wrap around. If the NMI Handler does not service the watchdog in time, the NMI gets generated continuously, each time the counter counts to '0'.

The DWWD uses the Digital Watchdog (DWD) preload register (RTIDWDPRLD) setting to define the end-time of the window. The start-time of the window is defined by a window size configuration register(RTIWWDSECTRL).

The default window size is set to 100%, which corresponds to the DWD functionality of a time-out-only watchdog. The window size can be selected (through register RTIWWDSECTRL) from among 100%, 50%, 25%, 12.5%, 6.25% and 3.125% as shown in Figure 10-1676. The window with the respective size will be opened before the end of the DWD expiration. The user has to serve the watchdog in the window. Otherwise, a reset or NMI will generate. Figure 10-1677 shows an DWWD operation example (25% window).

- Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD. This feature can be utilized to dynamically set windows of different sizes based on task execution time, adding a program sequence element to the diagnostic which can improve fault coverage.

Figure 10-1676. Digital Windowed Watchdog Timing Example

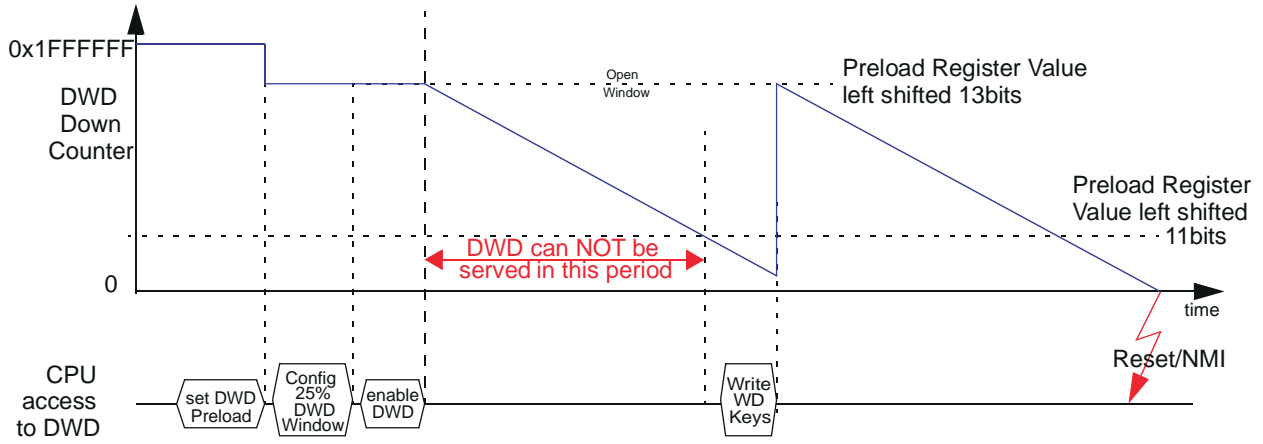

Figure 10-1677. Digital Windowed Watchdog Operation Example (25% Window)

10.5.1.2.5 Low Power Modes

Low power modes allow the trade off of the current used during low power versus functionality and fast wakeup response. All low power modes have the following characteristics:

- CPU and system clocks are disabled.
- Flash banks and pump are in sleep mode.
- All peripheral modules are in low power modes and the clocks are disabled (exceptions to this may occur and would be documented in the specific device data sheet).

Flexibility in enabling and disabling clocks allows for many different low-power modes.

The operation of the RTI Module is guaranteed in Run, Doze and Snooze modes. In Sleep mode, all clocks will be switched off and the RTI will not work.

In Doze and Snooze modes, the RTI is active and is able to wake up the device with compare, timebase and overflow interrupts. The compare interrupts can be used to periodically wake up the device. The overflow interrupt can be used to notify the operating system that a counter overflow has occurred. Capturing events generated by the Vectored Interrupt Module (VIM) is also possible since, in both of these low power modes, the peripheral modules are able to generate interrupts that can trigger capture events. Capturing events while in Sleep mode is not supported as the clock to the RTI is not active.

When the device is put into low power mode, the peripheral which is generating the external clock NTU is no longer active, and the timebase control circuitry has to switch to an internal clocking scheme when it detects a missing clock on NTU. The timebase interrupt will wake up the device and the application software has to adapt the periodic interrupt generation to the internal clock source.

DMA transfers will be disabled, and DMA requests will not be generated after device wakeup since the DMA controller will be powered down.

Note

RTICLK in Doze Mode

In the special case of Doze Mode with PLL off, RTICLK might have a different period than with PLL enabled since RTICLK will be derived from the oscillator output. It has to be ensured that the VCLK to RTICLK ratio is at least 3:1.

10.5.1.2.6 Halting Debug Mode Behaviour

Once the system enters halting debug mode, the behavior of the RTI depends on the COS (continue on suspend) bit. If the bit is cleared and halting debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode. However, if the external timebase (NTU) is used and the system is in halting debug mode, the timebase control circuit will switch to internal timebase once it detects the missing NTU signal of the suspended communication controller. This will be signaled with an TBINT interrupt so that software can resynchronize after the device exits halting debug mode.

10.5.1.3 RTI Control Registers

Table 10-1785 provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers.

Table 10-1785. RTI Registers

Writes to Reserved registers may clear the pending RTI interrupt.

RTI Global Control Register (RTIGCTRL)

The global control register starts/stops the counters and selects the signal compared with the timebase control circuit. This register is shown in [Figure 10-1677](#) and described in [Table 10-1786](#).

Figure 10-1677. RTI Global Control Register (RTIGCTRL) [offset = 00]

31	20	19	16
Reserved		NTUSEL	
R-0		R/WP-0	
15	14	2	1 0
COS	Reserved		CNT1EN CNT0EN
R/WP-0	R-0		R/WP-0 R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1786. RTI Global Control Register (RTIGCTRL) Field Descriptions

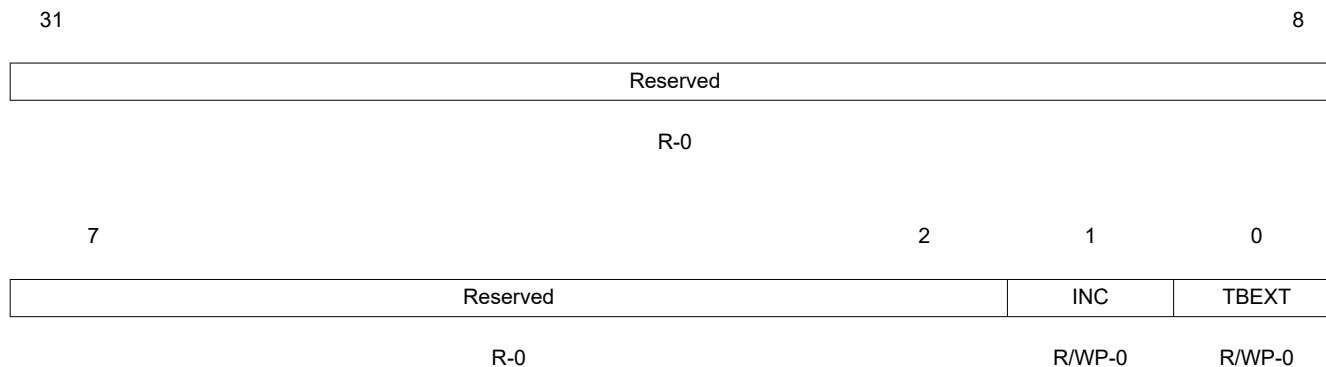

Bit	Field	Value	Description
31-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	NTUSEL	0h 5h Ah Fh All other values	Select NTU signal. These bits determine which NTU input signal is used as external timebase NTU0 NTU1 NTU2 NTU3 Tied to 0
15	COS	0 1	Continue on suspend. This bit determines if both counters are stopped when the device goes into halting debug mode or if they continue counting. Counters are stopped while in halting debug mode. Counters are running while in halting debug mode.
14-2	Reserved	0	Reads return 0. Writes have no effect.
1	CNT1EN	0 1	Counter 1 enable. This bit starts and stops counter block 1 (RTIUC1 and RTIFRC1). Counter block 1 is stopped. Counter block 1 is running.
0	CNT0EN	0 1	Counter 0 enable. This bit starts and stops counter block 0 (RTIUC0 and RTIFRC0). Counter block 0 is stopped. Counter block 0 is running.

Note

If the application uses the timebase circuit for synchronization between the communications controller and the operating system and the device enters halting debug mode, the synchronization may be lost depending on the COS setting in the RTI module and the halting debug mode behavior of the communications controller.

RTI Timebase Control Register (RTITBCTRL)

The timebase control register selects if the free running counter 0 is incremented by RTICLK or NTU. This register is shown in [Figure 10-1678](#) and described in [Table 10-1787](#).

Figure 10-1678. RTI Timebase Control Register (RTITBCTRL) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

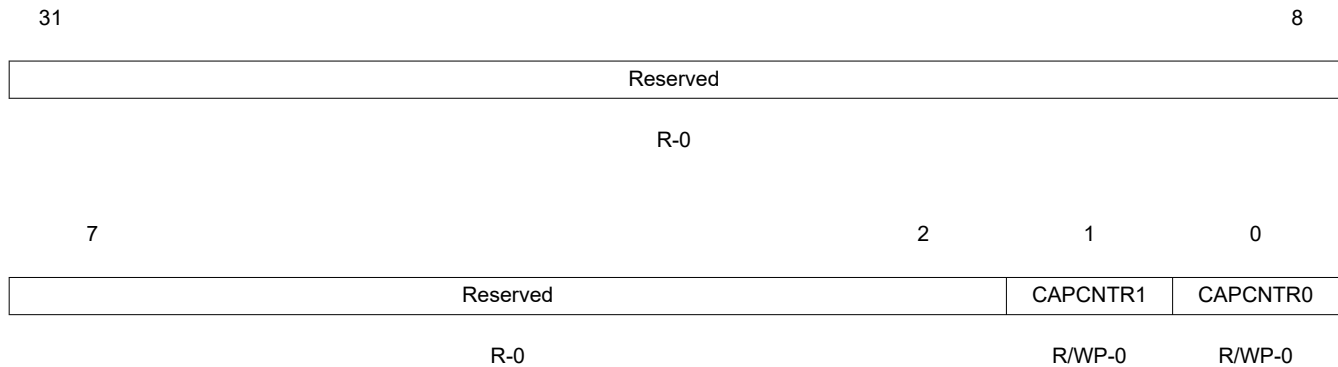

Table 10-1787. RTI Timebase Control Register (RTITBCTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	INC	0 1	Increment free running counter 0. This bit determines whether the free running counter 0 (RTIFRC0) is automatically incremented if a failing clock on the NTU signal is detected. 0 RTIFRC0 will not be incremented on a failing external clock. 1 RTIFRC0 will be incremented on a failing external clock.
0	TBEXT	0 1	Timebase external. This bit selects whether the free running counter 0 (RTIFRC0) is clocked by the internal up counter 0 (RTIUC0) or from the external signal NTU. Setting the TBEXT bit from 0 to 1 will not increment RTIFRC0, since RTIUC0 is reset. When the timebase supervisor circuit detects a missing clock edge, then the TBEXT bit is reset. Only the software can select whether the external signal should be used. 0 RTIUC0 clocks RTIFRC0. 1 NTU clocks RTIFRC0.

RTI Capture Control Register (RTICAPCTRL)

The capture control register controls the capture source for the counters. This register is shown in [Figure 10-1679](#) and described in [Table 10-1788](#).

Figure 10-1679. RTI Capture Control Register (RTICAPCTRL) [offset = 08h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

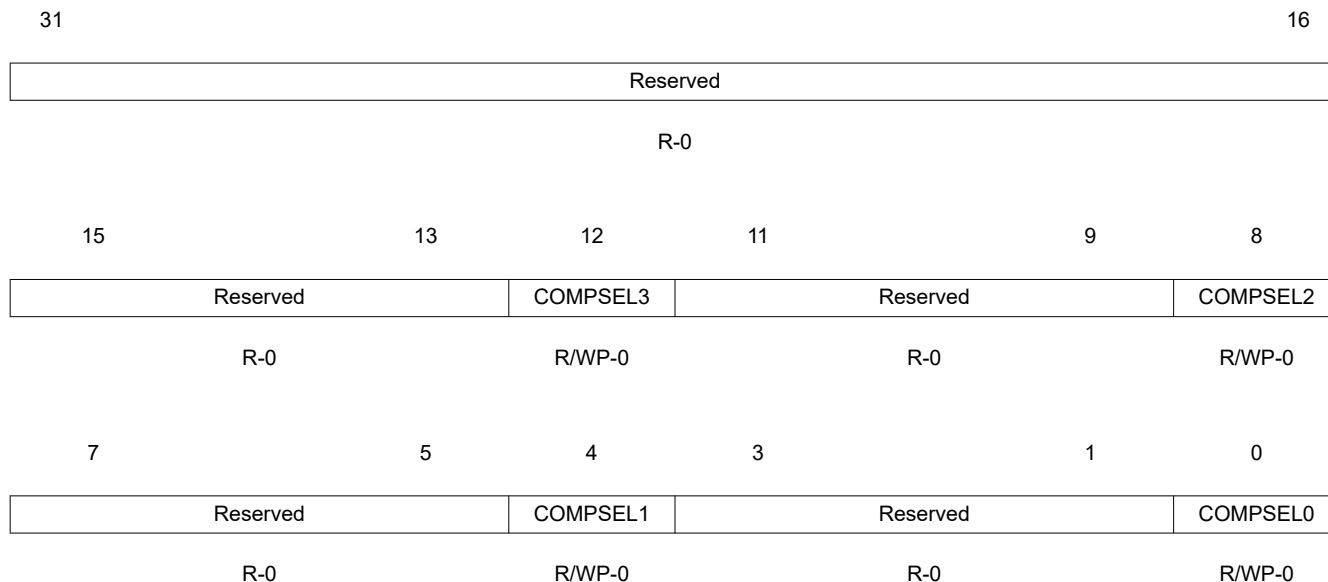

Table 10-1788. RTI Capture Control Register (RTICAPCTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	CAPCNTR1	0	Capture counter 1. This bit determines which external interrupt source triggers a capture event of RTIUC1 and RTIFRC1.
		0	Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 0.
		1	Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 1.
0	CAPCNTR0	0	Capture counter 0. This bit determines which external interrupt source triggers a capture event of RTIUC0 and RTIFRC0.
		0	Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 0.
		1	Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 1.

RTI Compare Control Register (RTICOMPCTRL)

The compare control register controls the source for the compare registers. This register is shown in [Figure 10-1680](#) and described in [Table 10-1789](#).

Figure 10-1680. RTI Compare Control Register (RTICOMPCTRL) [offset = 0Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1789. RTI Compare Control Register (RTICOMPCTRL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12	COMPSEL3	0	Compare select 3. This bit determines the counter with which the compare value held in compare register 3 (RTICOMP3) is compared. Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
11-9	Reserved	0	Reads return 0. Writes have no effect.
8	COMPSEL2	0	Compare select 2. This bit determines the counter with which the compare value held in compare register 2 (RTICOMP2) is compared. Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
7-5	Reserved	0	Reads return 0. Writes have no effect.
4	COMPSEL1	0	Compare select 1. This bit determines the counter with which the compare value held in compare register 1 (RTICOMP1) is compared. Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
3-1	Reserved	0	Reads return 0. Writes have no effect.
0	COMPSEL0	0	Compare select 0. This bit determines the counter with which the compare value held in compare register 0 (RTICOMP0) is compared. Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.

RTI Free Running Counter 0 Register (RTIFRC0)

The free running counter 0 register holds the current value of free running counter 0. This register is shown in [Figure 10-1681](#) and described in [Table 10-1790](#).

Figure 10-1681. RTI Free Running Counter 0 Register (RTIFRC0) [offset = 10h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

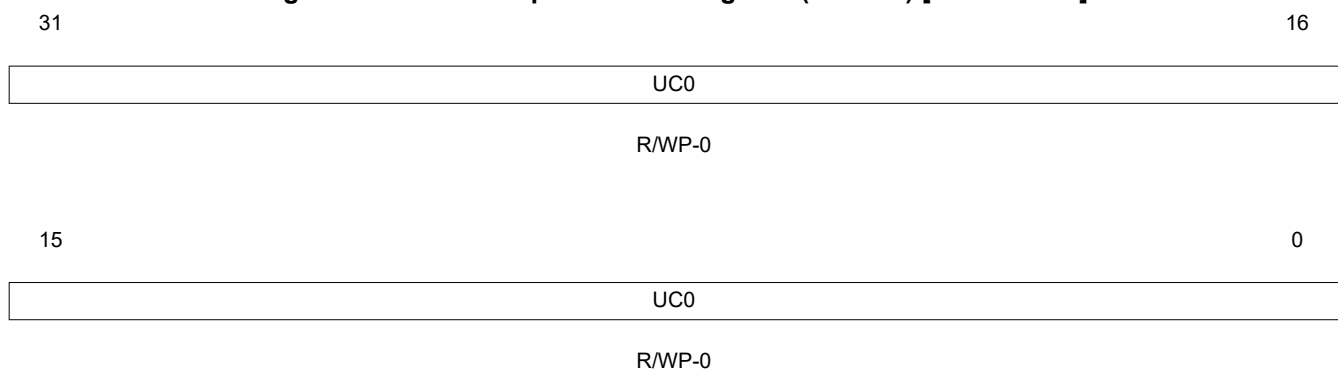

Table 10-1790. RTI Free Running Counter 0 Register (RTIFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	FRC0	0-FFFF FFFFh	Free running counter 0. This registers holds the current value of the free running counter 0. A read of this counter returns the current value of the counter. The counter can be preset by writing (in privileged mode only) to this register. The counter increments then from this written value upwards. Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0.

RTI Up Counter 0 Register (RTIUC0)

The up counter 0 register holds the current value of prescale counter. This register is shown in [Figure 10-1682](#) and described in [Table 10-1791](#).

Figure 10-1682. RTI Up Counter 0 Register (RTIUC0) [offset = 14h]

LLEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

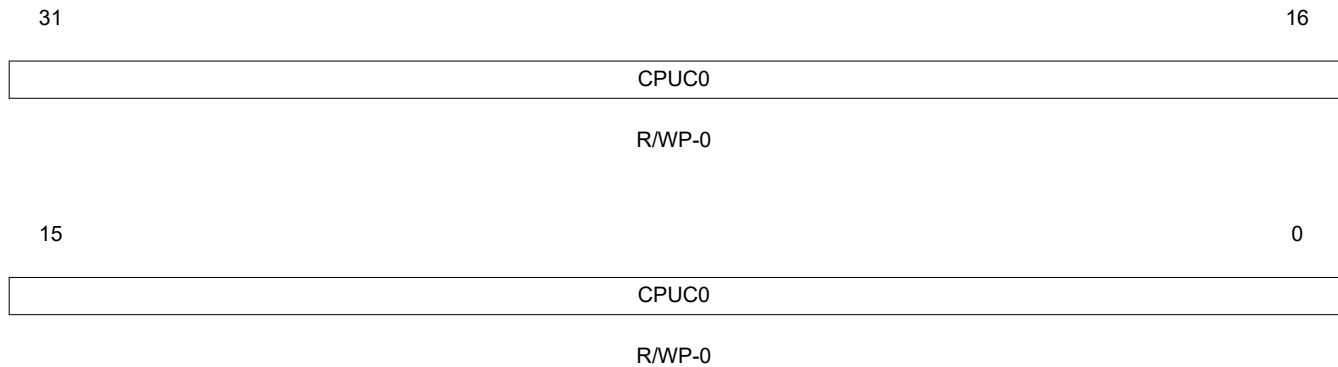

Table 10-1791. RTI Up Counter 0 Register (RTIUC0) Field Descriptions

Bit	Field	Value	Description
31-0	UC0	0-FFFF FFFFh	<p>Up counter 0. This register holds the current value of the up counter 0 and prescales the RTI clock. It will be only updated by a previous read of free running counter 0 (RTIFRC0). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on up counter 0 (RTIUC0) and free running counter 0 (RTIFRC0).</p> <p>A read of this counter returns the value of the counter at the time RTIFRC0 was read.</p> <p>A write to this counter presets it with a value. The counter then increments from this written value upwards.</p> <p>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0.</p> <p>Note: If the preset value is bigger than the compare value stored in register RTICPUC0, then it can take a long time until a compare matches, since RTIUC0 has to count up until it overflows.</p>

RTI Compare Up Counter 0 Register (RTICPUC0)

The compare up counter 0 register holds the value to be compared with prescale counter 0 (RTIUC0). This register is shown in [Figure 10-1683](#) and described in [Table 10-1792](#).

Figure 10-1683. RTI Compare Up Counter 0 Register (RTICPUC0) [offset = 18h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

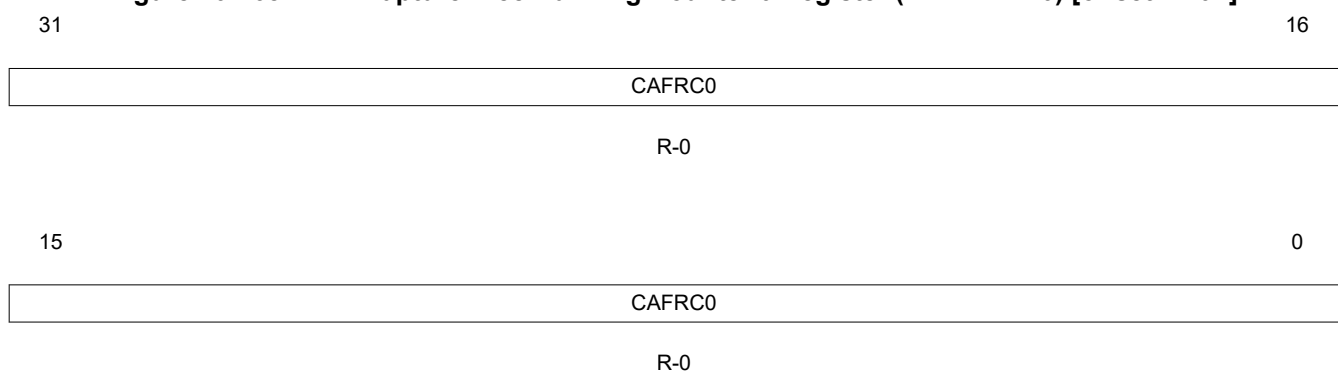

Table 10-1792. RTI Compare Up Counter 0 Register (RTICPUC0) Field Descriptions

Bit	Field	Value	Description
31-0	CPUC0	0-FFFF FFFFh	<p>Compare up counter 0. This register holds the value that is compared with the up counter 0. When the compare shows a match, the free running counter 0 (RTIFRC0) is incremented. RTIUC0 is set to 0 when the counter value matches the RTICPUC0 value. The value set in this register prescales the RTI clock.</p> <p>If CPUC0 = 0, then $f_{FRC0} = RTICLK / (2^{32} + 1)$ (Setting CPUC0 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)</p> <p>If CPUC0 ≠ 0, then $f_{FRC0} = RTICLK / (RTICPUC0 + 1)$</p> <p>A read of this register returns the current compare value.</p> <p>A write to this register:</p> <ul style="list-style-type: none"> • If TBEXT = 0, the compare value is updated. • If TBEXT = 1, the compare value is unchanged.

RTI Capture Free Running Counter 0 Register (RTICAFRC0)

The capture free running counter 0 register holds the free running counter 0 on external events. This register is shown in [Figure 10-1684](#) and described in [Table 10-1793](#).

Figure 10-1684. RTI Capture Free Running Counter 0 Register (RTICAFRC0) [offset = 20h]

LEGEND: R = Read only; -n = value after reset

Table 10-1793. RTI Capture Free Running Counter 0 Register (RTICAFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAFRC0	0-FFFF FFFFh	Capture free running counter 0. This register captures the current value of the free running counter 0 (RTIFRC0) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC0 on a capture event.

RTI Capture Up Counter 0 Register (RTICAUC0)

The capture up counter 0 register holds the current value of prescale counter 0 on external events. This register is shown in [Figure 10-1685](#) and described in [Table 10-1794](#).

Figure 10-1685. RTI Capture Up Counter 0 Register (RTICAUC0) [offset = 24h]

LEGEND: R = Read only; -n = value after reset

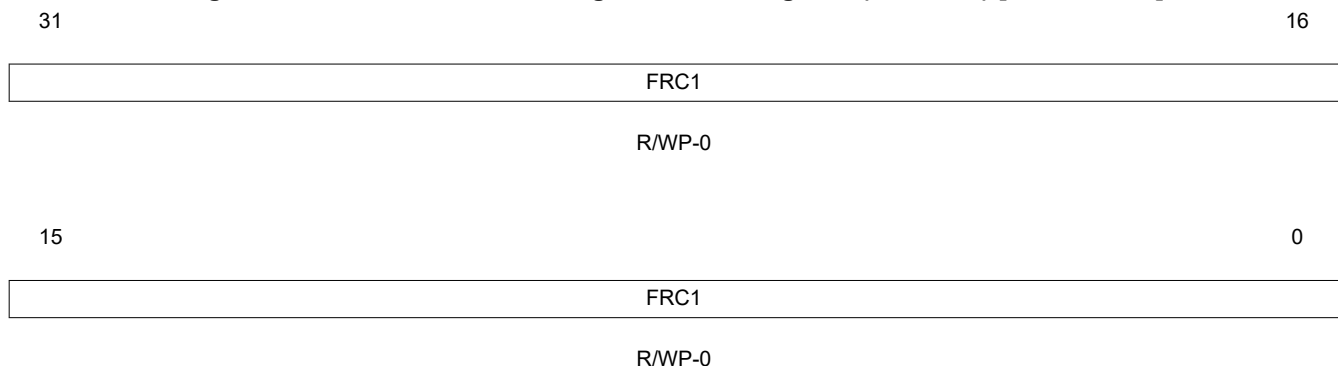

Table 10-1794. RTI Capture Up Counter 0 Register (RTICAUC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAUC0	0-FFFF FFFFh	Capture up counter 0. This register captures the current value of the up counter 0 (RTIUC0) when an event occurs, controlled by the external capture control block. Note: The read sequence must be the same as with RTIUC0 and RTIFRC0. Therefore, the RTICAFRC0 register must be read before the RTICAUC0 register is read. This sequence ensures that the value of the RTICAUC0 register is the corresponding value to the RTICAFRC0 register, even if another capture event happens in between the two reads. A read of this register returns the value of RTIUC0 on a capture event.

RTI Free Running Counter 1 Register (RTIFRC1)

The free running counter 1 register holds the current value of the free running counter 1. This register is shown in [Figure 10-1686](#) and described in [Table 10-1795](#).

Figure 10-1686. RTI Free Running Counter 1 Register (RTIFRC1) [offset = 30h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

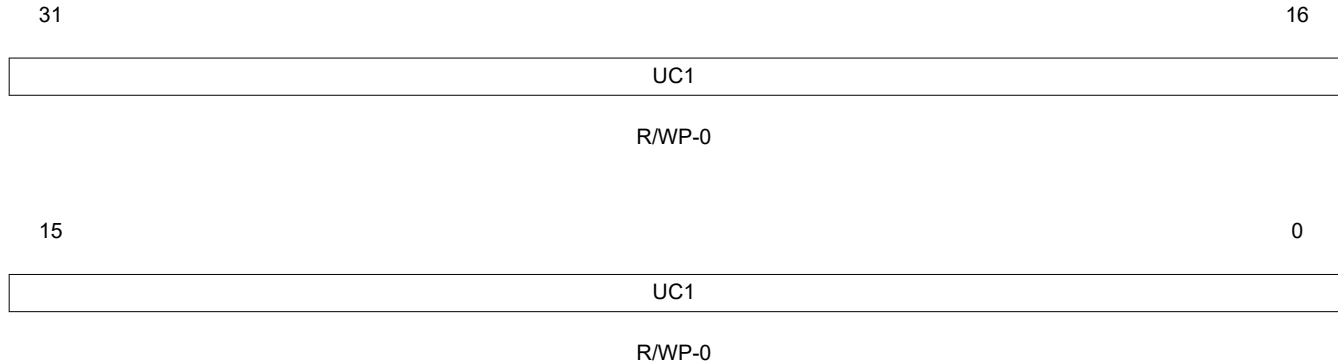

Table 10-1795. RTI Free Running Counter 1 Register (RTIFRC1) Field Descriptions

Bit	Field	Value	Description
31-0	FRC1	0-FFFF FFFFh	<p>Free running counter 1. This register holds the current value of the free running counter 1 and will be updated continuously.</p> <p>A read of this register returns the current value of the counter.</p> <p>A write to this register presets the counter. The counter increments then from this written value upwards.</p> <p>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.</p>

RTI Up Counter 1 Register (RTIUC1)

The up counter 1 register holds the current value of the prescale counter 1. This register is shown in [Figure 10-1687](#) and described in [Table 10-1796](#).

Figure 10-1687. RTI Up Counter 1 Register (RTIUC1) [offset = 34h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

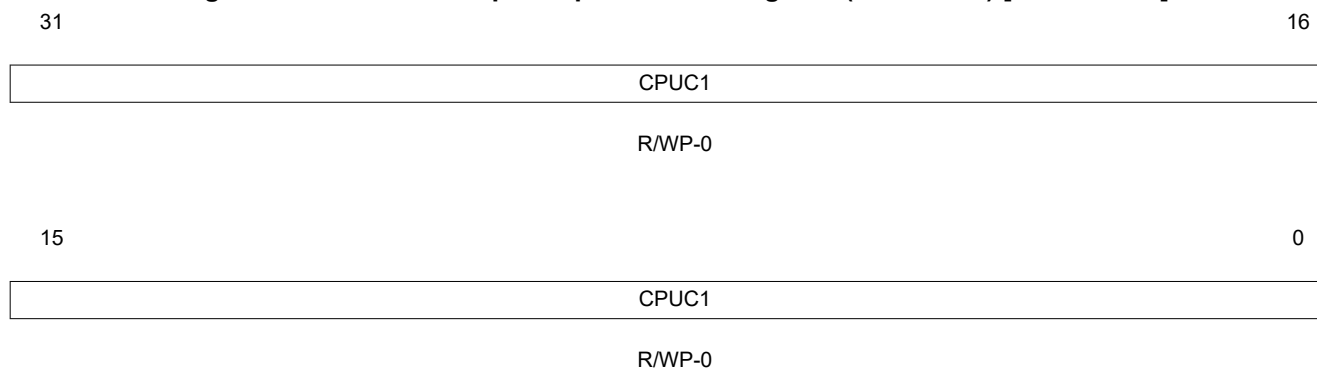

Table 10-1796. RTI Up Counter 1 Register (RTIUC1) Field Descriptions

Bit	Field	Value	Description
31-0	UC1	0-FFFF FFFFh	<p>Up counter 1. This register holds the current value of the up counter 1 and prescales the RTI clock. It will be only updated by a previous read of free running counter 1 (RTIFRC1). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on RTIUC1 and RTIFRC1.</p> <p>A read of this register will return the value of the counter when the RTIFRC1 was read.</p> <p>A write to this register presets the counter. The counter then increments from this written value upwards.</p> <p>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.</p> <p>Note: If the preset value is bigger than the compare value stored in register RTICPUC1, then it can take a long time until a compare matches, since RTIUC1 has to count up until it overflows.</p>

RTI Compare Up Counter 1 Register (RTICPUC1)

The compare up counter 1 register holds the value compared with prescale counter 1. This register is shown in [Figure 10-1688](#) and described in [Table 10-1797](#).

Figure 10-1688. RTI Compare Up Counter 1 Register (RTICPUC1) [offset = 38h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1797. RTI Compare Up Counter 1 Register (RTICPUC1) Field Descriptions

Bit	Field	Value	Description
31-0	CPUC1	0-FFFF FFFFh	<p>Compare up counter 1. This register holds the compare value, which is compared with the up counter 1. When the compare matches, the free running counter 1 (RTIFRC1) is incremented. The up counter is cleared to 0 when the counter value matches the CPUC1 value. The value set in this prescales the RTI clock according to the following formula:</p> <p>If CPUC1 = 0, then $f_{FRC1} = RTICLK / (2^{32} + 1)$ (Setting CPUC1 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)</p> <p>If CPUC1 \neq 0, then $f_{FRC1} = RTICLK / (RTICPUC1 + 1)$</p> <p>A read of this register returns the current compare value. A write to this register updates the compare value.</p>

RTI Capture Free Running Counter 1 Register (RTICAFRC1)

The capture free running counter 1 register holds the current value of free running counter 1 on external events. This register is shown in [Figure 10-1689](#) and described in [Table 10-1798](#).

Figure 10-1689. RTI Capture Free Running Counter 1 Register (RTICAFRC1) [offset = 40h]

LEGEND: R = Read only; -n = value after reset

Table 10-1798. RTI Capture Free Running Counter 1 Register (RTICAFRC1) Field Descriptions

Bit	Field	Value	Description
31-0	CAFRC1	0-FFFF FFFFh	Capture free running counter 1. This register captures the current value of the free running counter 1 (RTIFRC1) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC1 on a capture event.

RTI Capture Up Counter 1 Register (RTICAUC1)

The capture up counter 1 register holds the current value of prescale counter 1 on external events. This register is shown in [Figure 10-1690](#) and described in [Table 10-1799](#).

Figure 10-1690. RTI Capture Up Counter 1 Register (RTICAUC1) [offset = 44h]

LEGEND: R = Read only; -n = value after reset

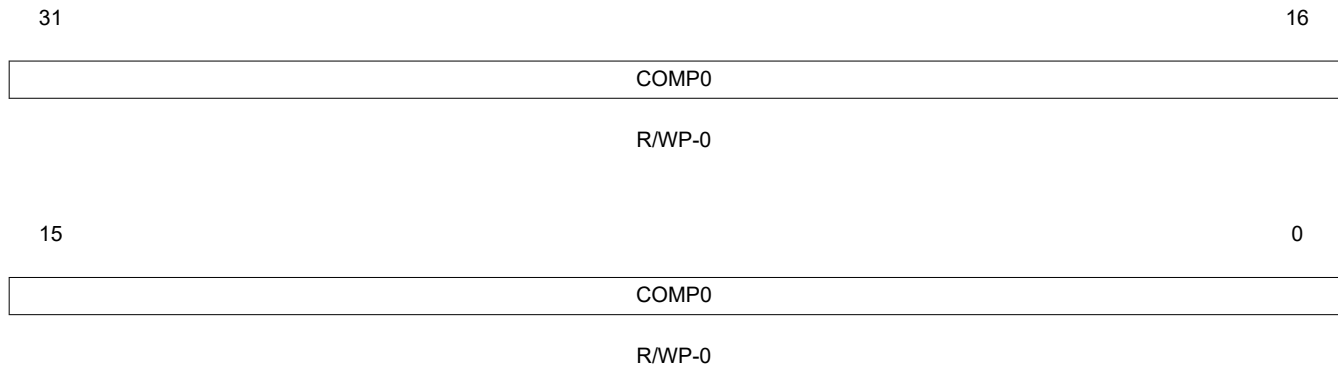

Table 10-1799. RTI Capture Up Counter 1 Register (RTICAUC1) Field Descriptions

Bit	Field	Value	Description
31-0	CAUC1	0-FFFF FFFFh	<p>Capture up counter 1. This register captures the current value of the up counter 1 (RTIUC1) when an event occurs, controlled by the external capture control block.</p> <p>Note: The RTICAFRC1 register must be read before the RTICAUC1 register is read. This sequence ensures that the value of the RTICAUC1 register is the corresponding value to the RTICAFRC1 register, even if another capture event happens in between the two reads.</p> <p>A read of this register returns the value of RTIUC1 on a capture event.</p>

RTI Compare 0 Register (RTICOMP0)

The compare 0 register holds the value to be compared with the counters. This register is shown in [Figure 10-1691](#) and described in [Table 10-1800](#).

Figure 10-1691. RTI Compare 0 Register (RTICOMP0) [offset = 50h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

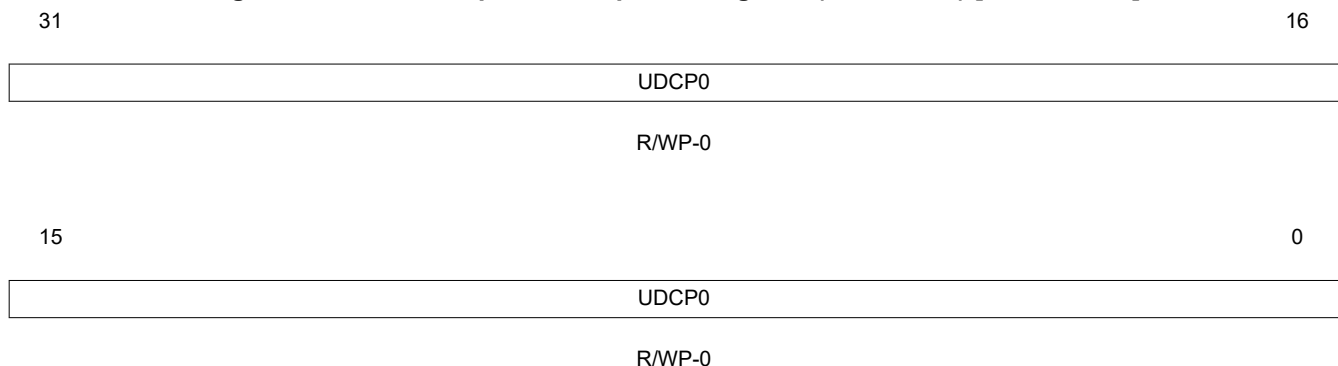

Table 10-1800. RTI Compare 0 Register (RTICOMP0) Field Descriptions

Bit	Field	Value	Description
31-0	COMP0	0-FFFF FFFFh	Compare 0. This registers holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches the compare value, an interrupt is flagged. With this register it is also possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register (in privileged mode only) will update the compare register with a new compare value.

RTI Update Compare 0 Register (RTIUDCP0)

The update compare 0 register holds the value to be added to the compare register 0 value on a compare match. This register is shown in [Figure 10-1692](#) and described in [Table 10-1801](#).

Figure 10-1692. RTI Update Compare 0 Register (RTIUDCP0) [offset = 54h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1801. RTI Update Compare 0 Register (RTIUDCP0) Field Descriptions

Bit	Field	Value	Description
31-0	UDCP0	0-FFFF FFFFh	<p>Update compare 0. This register holds a value that is added to the value in the compare 0 (RTICOMP0) register each time a compare matches. This function allows periodic interrupts to be generated without software intervention.</p> <p>A read of this register will return the value to be added to the RTICOMP0 register on the next compare match.</p> <p>A write to this register will provide a new update value.</p>

RTI Compare 1 Register (RTICOMP1)

The compare 1 register holds the value to be compared to the counters. This register is shown in [Figure 10-1693](#) and described in [Table 10-1802](#).

Figure 10-1693. RTI Compare 1 Register (RTICOMP1) [offset = 58h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

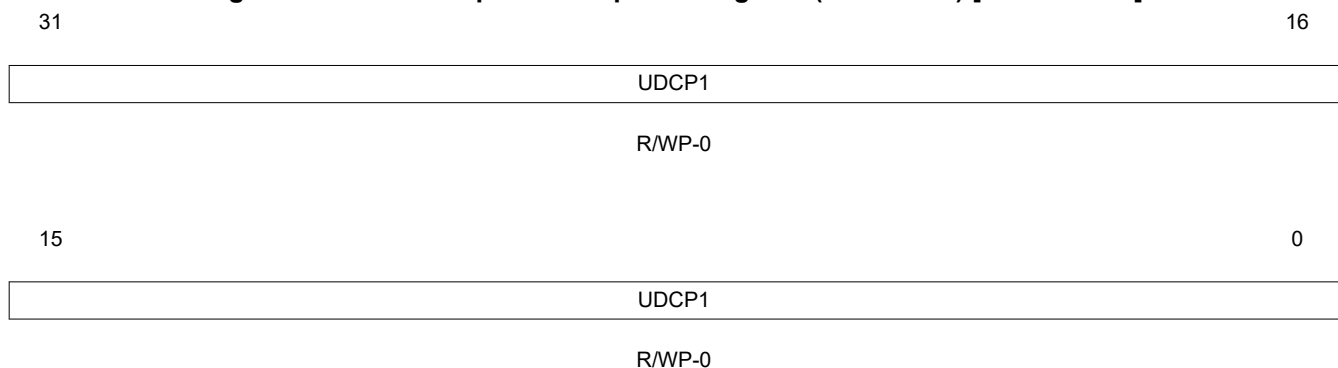

Table 10-1802. RTI Compare 1 Register (RTICOMP1) Field Descriptions

Bit	Field	Value	Description
31-0	COMP1	0-FFFF FFFFh	Compare 1. This register holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches this compare value, an interrupt is flagged. With this register, it is possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register will update the compare register with a new compare value.

RTI Update Compare 1 Register (RTIUDCP1)

The update compare 1 register holds the value to be added to the compare register 1 value on a compare match. This register is shown in [Figure 10-1694](#) and described in [Table 10-1803](#).

Figure 10-1694. RTI Update Compare 1 Register (RTIUDCP1) [offset = 5Ch]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1803. RTI Update Compare 1 Register (RTIUDCP1) Field Descriptions

Bit	Field	Value	Description
31-0	UDCP1	0-FFFF FFFFh	<p>Update compare 1. This register holds a value that is added to the value in the RTICOMP1 register each time a compare matches. This process allows periodic interrupts to be generated without software intervention.</p> <p>A read of this register will return the value to be added to the RTICOMP1 register on the next compare match.</p> <p>A write to this register will provide a new update value.</p>

RTI Compare 2 Register (RTICOMP2)

The compare 2 register holds the value to be compared to the counters. This register is shown in [Figure 10-1695](#) and described in [Table 10-1804](#).

Figure 10-1695. RTI Compare 2 Register (RTICOMP2) [offset = 60h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1804. RTI Compare 2 Register (RTICOMP2) Field Descriptions

Bit	Field	Value	Description
31-0	COMP2	0-FFFF FFFFh	Compare 2. This register holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches this compare value, an interrupt is flagged. With this register, it is possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register (in privileged mode only) will provide a new compare value.

RTI Update Compare 2 Register (RTIUDCP2)

The update compare 2 register holds the value to be added to the compare register 2 value on a compare match. This register is shown in [Figure 10-1696](#) and described in [Table 10-1805](#).

Figure 10-1696. RTI Update Compare 2 Register (RTIUDCP2) [offset = 64h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1805. RTI Update Compare 2 Register (RTIUDCP2) Field Descriptions

Bit	Field	Value	Description
31-0	UDCP2	0-FFFF FFFFh	<p>Update compare 2. This register holds a value that is added to the value in the RTICOMP2 register each time a compare matches. This process makes it possible to generate periodic interrupts without software intervention.</p> <p>A read of this register will return the value to be added to the RTICOMP2 register on the next compare match.</p> <p>A write to this register will provide a new update value.</p>

RTI Compare 3 Register (RTICOMP3)

The compare 3 register holds the value to be compared to the counters. This register is shown in [Figure 10-1697](#) and described in [Table 10-1806](#).

Figure 10-1697. RTI Compare 3 Register (RTICOMP3) [offset = 68h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

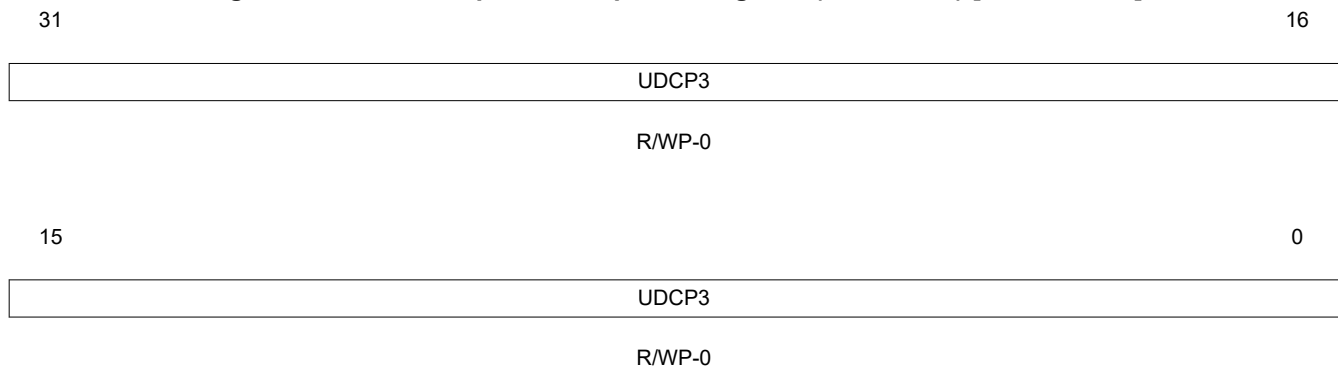

Table 10-1806. RTI Compare 3 Register (RTICOMP3) Field Descriptions

Bit	Field	Value	Description
31-0	COMP3	0-FFFF FFFFh	Compare 3. This register holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches this compare value, an interrupt is flagged. With this register, it is possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register will provide a new compare value.

RTI Update Compare 3 Register (RTIUDCP3)

The update compare 3 register holds the value to be added to the compare register 3 value on a compare match. This register is shown in [Figure 10-1698](#) and described in [Table 10-1807](#).

Figure 10-1698. RTI Update Compare 3 Register (RTIUDCP3) [offset = 6Ch]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

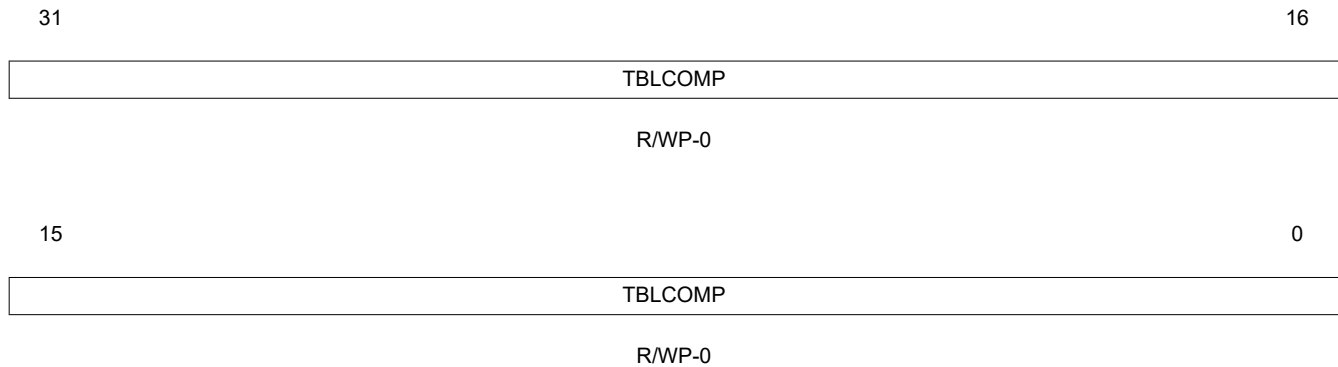

Table 10-1807. RTI Update Compare 3 Register (RTIUDCP3) Field Descriptions

Bit	Field	Value	Description
31-0	UDCP3	0-FFFF FFFFh	<p>Update compare 3. This register holds a value that is added to the value in the RTICOMP3 register each time a compare matches. This process makes it possible to generate periodic interrupts without software intervention.</p> <p>A read of this register will return the value to be added to the RTICOMP3 register on the next compare match.</p> <p>A write to this register will provide a new update value.</p>

RTI Timebase Low Compare Register (RTITBLCOMP)

The timebase low compare register holds the value to activate the edge detection circuit. This register is shown in [Figure 10-1699](#) and described in [Table 10-1808](#).

Figure 10-1699. RTI Timebase Low Compare Register (RTITBLCOMP) [offset = 70h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

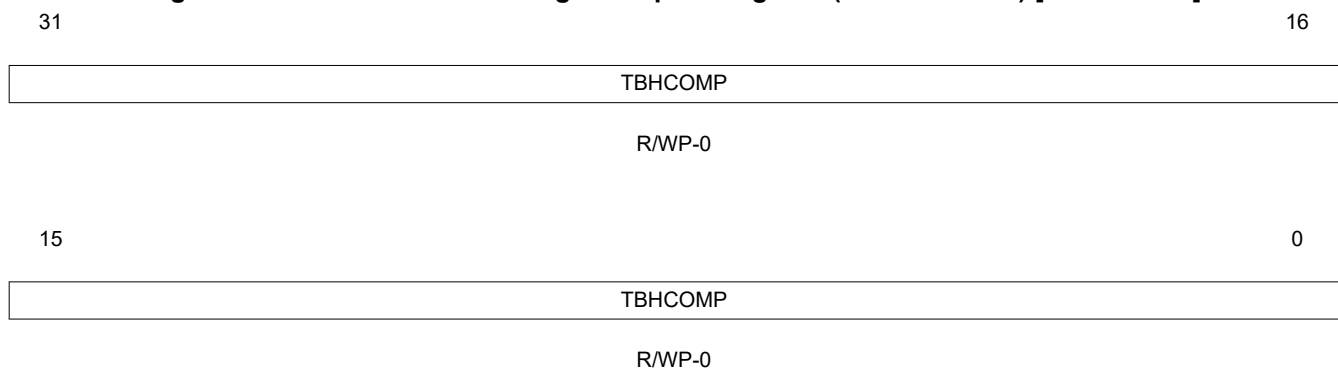

Table 10-1808. RTI Timebase Low Compare Register (RTITBLCOMP) Field Descriptions

Bit	Field	Value	Description
31-0	TBLCOMP	0-FFFF FFFFh	Timebase low compare value. This value determines when the edge detection circuit starts monitoring the NTU signal. It will be compared with RTIUC0. A read of this register will return the current compare value. A write to this register has the following effects: If TBEXT = 0: The compare value is updated. If TBEXT = 1: The compare value is not changed.

RTI Timebase High Compare Register (RTITBHCMP)

The timebase high compare register holds the value to deactivate the edge detection circuit. This register is shown in [Figure 10-1700](#) and described in [Table 10-1809](#).

Figure 10-1700. RTI Timebase High Compare Register (RTITBHCMP) [offset = 74h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 10-1809. RTI Timebase High Compare Register (RTITBHCMP) Field Descriptions

Bit	Field	Value	Description
31-0	TBHCMP	0-FFFF FFFFh	<p>Timebase high compare value. This value determines when the edge detection circuit will stop monitoring the NTU signal. It will be compared with RTIUC0.</p> <p>RTITBHCMP must be less than RTICPUC0 because RTIUC0 will be reset when RTICPUC0 is reached.</p> <p>Example: The NTU edge detection circuit should be active ± 10 RTICLK cycles around RTICPUC0.</p> <ul style="list-style-type: none"> • RTICPUC0 = 0050h • RTITBLCMP = 0046h • RTITBHCMP = 0009h <p>A read of this register will return the current compare value.</p> <p>A write to this register has the following effects:</p> <p>If TBEXT = 0: The compare value is updated.</p> <p>If TBEXT = 1: The compare value is not changed.</p>

RTI Set Interrupt Enable Register (RTISETINTENA)

This register prevents the necessity of a read-modify-write operation if a particular interrupt should be enabled. This register is shown in [Figure 10-1701](#) and described in [Table 10-1810](#).

Figure 10-1701. RTI Set Interrupt Control Register (RTISETINTENA) [offset = 80h]

Table 10-1812. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	OVL1INT	0	Free running counter 1 overflow interrupt flag. This bit determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.
17	OVL0INT	0	Free running counter 0 overflow interrupt flag. This bit determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.
16	TBINT	0	Timebase interrupt flag. This flag is set when the TBEXT bit is cleared by detection of a missing external clock edge. It will not be set by clearing TBEXT by software. It determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.
15-4	Reserved	0	Reads return 0. Writes have no effect.
3	INT3	0	Interrupt flag 3. These bits determine if an interrupt due to a Compare 3 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.

Table 10-1812. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions (continued)

Bit	Field	Value	Description
2	INT2	0	Interrupt flag 2. These bits determine if an interrupt due to a Compare 2 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.
1	INT1	0	Interrupt flag 1. These bits determine if an interrupt due to a Compare 1 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.
0	INT0	0	Interrupt flag 0. These bits determine if an interrupt due to a Compare 0 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0.

Digital Watchdog Control Register (RTIDWDCTRL)

The software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. This register is shown in [Figure 10-1703](#) and described in [Table 10-1812](#).

Bit	Field	Value	Description
31-0	DWDCTRL	5312 ACEDh	Digital Watchdog Control. <i>Read:</i> DWD counter is disabled. <i>Write:</i> State of DWD counter is unchanged (stays enabled or disabled).
		A985 59DAh	<i>Read:</i> DWD counter is enabled. <i>Write:</i> DWD counter is enabled.
		All other values	<i>Read:</i> DWD counter state is unchanged (enabled or disabled). <i>Write:</i> State of DWD counter is unchanged (stays enabled or disabled). Note: Once the enable value is written, all other future writes are blocked. In other words, once DWD is enabled, it can only be disabled by system reset or power on reset. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog.

Digital Watchdog Preload Register (RTIDWDPRLD)

This register sets the expiration time of the DWD. This register is shown in [Figure 10-1703](#) and described in [Table 10-1812](#).

Figure 10-1705. Digital Watchdog Preload Register (RTIDWDPRLD) [offset = 94h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

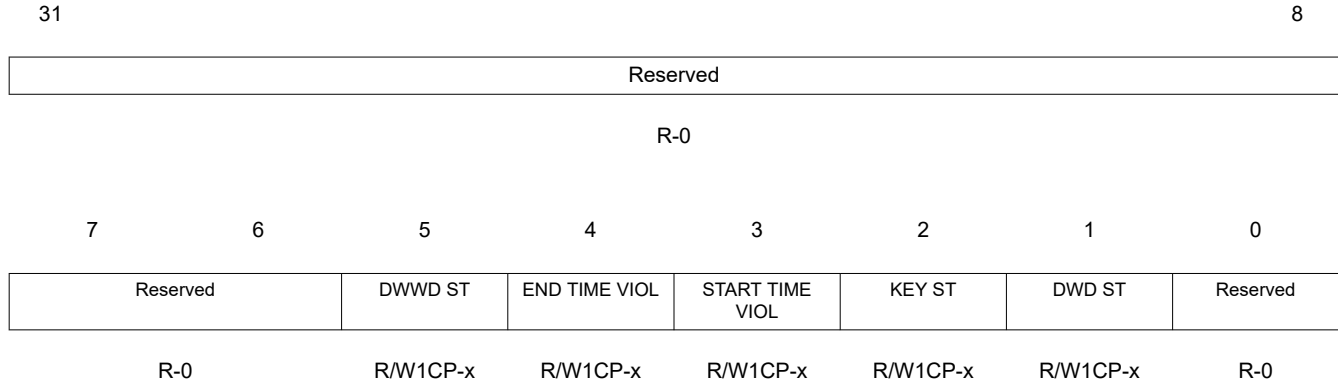

Table 10-1814. Digital Watchdog Preload Register (RTIDWDPRLD) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads return 0 and writes have no effect.
11-0	DWDPRLD	0-FFFh	Digital Watchdog Preload Value. <i>Read:</i> The current preload value <i>Write:</i> Set the preload value. The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter. The expiration time of the DWD Down Counter can be determined with following equation: $t_{exp} = (DWDPRLD + 1) \times 2^{13} / RTICK1$ where: DWDPRLD = 0...4095

Watchdog Status Register (RTIWDSTATUS)

This register records the status of the DWD. The values of the following status bits will not be affected by a soft reset. These bits are cleared by a power-on reset, or by a write of 1. These bits can be used for debug purposes. This register is shown in [Figure 10-1703](#) and described in [Table 10-1812](#).

Figure 10-1706. Watchdog Status Register (RTIWDSTATUS) [offset = 98h]

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 10-1815. Watchdog Status Register (RTIWDSTATUS) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5	DWWWD ST	0	Windowed Watchdog Status <i>Read:</i> No time-window violation has occurred. <i>Write:</i> Leaves the current value unchanged.
		1	<i>Read:</i> Time-window violation has occurred. The watchdog has generated either a system reset or a non-maskable interrupt to the CPU in this case. <i>Write:</i> Bit is cleared to 0. This will also clear all other status flags in the RTIWDSTATUS register. Clearing of the status flags will deassert the non-maskable interrupt generated due to violation of the DWWWD.
4	END TIME VIOL	0	Windowed Watchdog End Time Violation Status. This bit indicates whether the Watchdog counter expired. <i>Read:</i> No end-time window violation has occurred. <i>Write:</i> Leaves the current value unchanged.
		1	<i>Read:</i> End-time defined by the windowed watchdog configuration has been violated. <i>Write:</i> Bit is cleared to 0.
3	START TIME VIOL	0	Windowed Watchdog Start Time Violation Status. This bit indicates whether the key is written before the watchdog window opened up. <i>Read:</i> No start-time window violation has occurred. <i>Write:</i> Leaves the current value unchanged.
		1	<i>Read:</i> Start-time defined by the windowed watchdog configuration has been violated. <i>Write:</i> Bit is cleared to 0.
2	KEY ST	0	Watchdog key status. This bit indicates a reset or NMI generated by a wrong key or key sequence written to the RTIWDKEY register. <i>Read:</i> No wrong key or key-sequence written. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Wrong key or key-sequence written to RTIWDKEY register. <i>Write:</i> Bit is cleared to 0.

Table 10-1815. Watchdog Status Register (RTIWDSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
1	DWD ST	0	DWD status. This bit is equivalent to bit END TIME VIOL. <i>Read:</i> No reset or NMI was generated. <i>Write:</i> Bit is unchanged.
		1	<i>Read:</i> Reset or NMI was generated. <i>Write:</i> Bit is cleared to 0.
0	Reserved	0	Reads return 0. Writes have no effect.

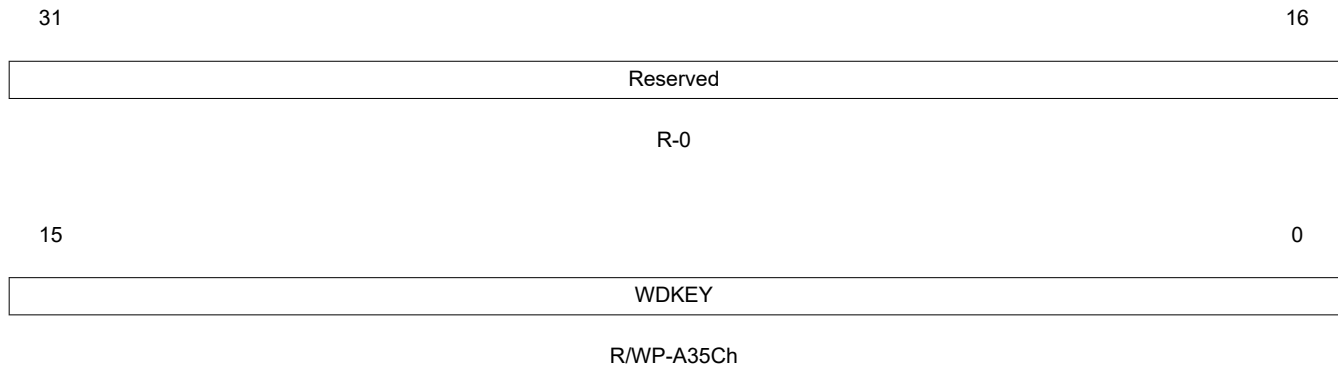

RTI Watchdog Key Register (RTIWDKEY)

This register must be written with the correct written key values to serve the watchdog. This register is shown in [Figure 10-1707](#) and described in [Table 10-1816](#).

Note

It has to be taken into account that the write to the RTIWDKEY register takes 3 VCLK cycles.

Figure 10-1707. RTI Watchdog Key Register (RTIDWDKEY) [offset = 9Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1816. RTI Watchdog Key Register (RTIDWDKEY) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0 and writes have no effect.
15-0	WDKEY	0-FFFFh	Watchdog key. These bits provide the key sequence location. Reads returns the current WDKEY value. A write of E51Ah followed by A35Ch in two separate write operations defines the key sequence and reloads the DWD. Writing any other value causes a reset or NMI, as shown in Table 10-1817 . Writing any other value will cause the WDKEY to reset to A35Ch.

Table 10-1817. Example of a WDKEY Sequence

Step	Value Written to WDKEY	Result
1	A35Ch	No action
2	A35Ch	No action
3	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
4	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
5	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
6	A35Ch	Watchdog is reset.
7	A35Ch	No action
8	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
9	A35Ch	Watchdog is reset.
10	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
11	2345h	System reset or NMI; incorrect value written to WDKEY.

RTI Digital Watchdog Down Counter (RTIDWDCNTR)

This register provides the current value of the DWD down counter. This register is shown in [Figure 10-1708](#) and described in [Table 10-1818](#).

Figure 10-1708. RTI Watchdog Down Counter Register (RTIDWDCNTR) [offset = A0h]

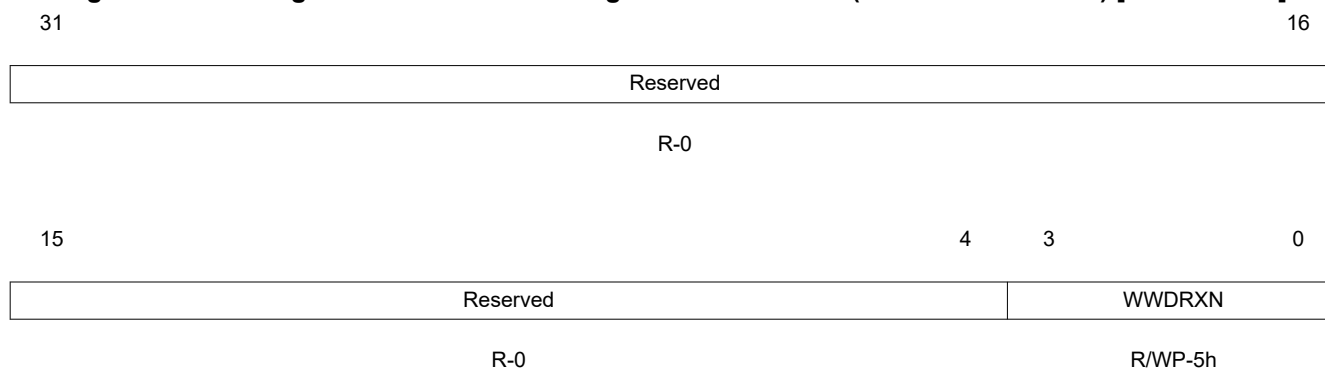

LEGEND: R = Read only; -n = value after reset

Table 10-1818. RTI Watchdog Down Counter Register (RTIDWDCNTR) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0 and writes have no effect.
24-0	DWD CNTR	0-1FF FFFFh	DWD down counter. Reads return the current counter value.

Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL)

This register selects the DWWD reaction if the watchdog is serviced outside the time window. This register is shown in [Figure 10-1709](#) and described in [Table 10-1819](#).

Figure 10-1709. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) [offset = A4h]

Table 10-1819. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0 and writes have no effect.

Table 10-1819. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
3-0	WWDRXN	5h	The DWWD reaction The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		Ah	The windowed watchdog will generate a non-maskable interrupt to the CPU if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		All other values	The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all. Note: The DWWD reaction can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDRXN is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDRXN is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)

This register selects the DWWD window size. This register is shown in [Figure 10-1710](#) and described in [Table 10-1820](#).

If a change to the WWDSIZE is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDSIZE is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE)

When the RTI compare event is configured to generate a DMA request or triggers (all triggered by RTI compare interrupt request flag) to other peripherals, it is often desirable to clear the RTI compare flag automatically so that the requests can be generated repeatedly without any CPU intervention. This register works with the RTI compare clear registers to enable an "auto-clear" of the compare interrupt enable bit after a compare equal event. This register is shown in [Figure 10-1711](#) and described in [Table 10-1821](#).

Bit	Field	Value	Description
31-28	Reserved	0	Reads return 0. Writes have no effect.
27-24	INTCLRENABLE3	5h	Enables the auto-clear functionality on the compare 3 interrupt. <i>Read:</i> Auto-clear for compare 3 interrupt is disabled. <i>Privileged Write:</i> Auto-clear for compare 3 interrupt becomes disabled.
		All other values	<i>Read:</i> Auto-clear for compare 3 interrupt is enabled. <i>Privileged Write:</i> Auto-clear for compare 3 interrupt becomes enabled.
23-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	INTCLRENABLE2	5h	Enables the auto-clear functionality on the compare 2 interrupt. <i>Read:</i> Auto-clear for compare 2 interrupt is disabled. <i>Privileged Write:</i> Auto-clear for compare 2 interrupt becomes disabled.
		All other values	<i>Read:</i> Auto-clear for compare 2 interrupt is enabled. <i>Privileged Write:</i> Auto-clear for compare 2 interrupt becomes enabled.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	INTCLRENABLE1	5h	Enables the auto-clear functionality on the compare 1 interrupt. <i>Read:</i> Auto-clear for compare 1 interrupt is disabled. <i>Privileged Write:</i> Auto-clear for compare 1 interrupt becomes disabled.
		All other values	<i>Read:</i> Auto-clear for compare 1 interrupt is enabled. <i>Privileged Write:</i> Auto-clear for compare 1 interrupt becomes enabled.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INTCLRENABLE0	5h	Enables the auto-clear functionality on the compare 0 interrupt. <i>Read:</i> Auto-clear for compare 0 interrupt is disabled. <i>Privileged Write:</i> Auto-clear for compare 0 interrupt becomes disabled.
		All other values	<i>Read:</i> Auto-clear for compare 0 interrupt is enabled. <i>Privileged Write:</i> Auto-clear for compare 0 interrupt becomes enabled.

RTI Compare 0 Clear Register (RTICMP0CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 0 register [Section RTI Compare Control Register \(RTICOMPCTRL\)](#). The user needs to choose the value such that the compare clear 0 event occurs before next compare 0 event. If the Free Running Counter matches the compare value, the compare 0 interrupt request flag is cleared and the value in the RTIUDCP0 register [Section RTI Update Compare 0 Register \(RTIUDCP0\)](#) is added to this register. This register is shown in [Figure 10-1712](#) and described in [Table 10-1822](#).

Figure 10-1712. RTI Compare 0 Clear Register (RTICMP0CLR) [offset = B0h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

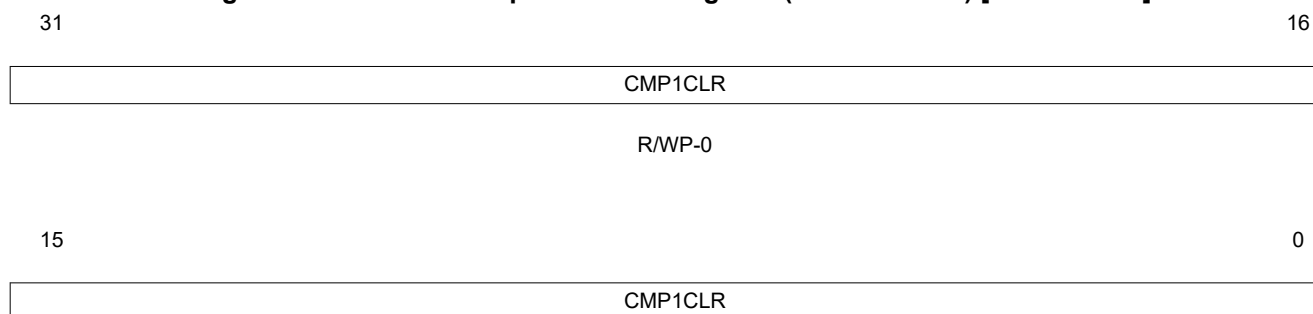

Table 10-1822. RTI Compare 0 Clear Register (RTICMP0CLR) Field Descriptions

10.6 Internal Diagnostics Modules

10.6.1 Data Modification Module (DMM)

A Data Modification Module (DMM) gives the ability to write external data into the device memory.

This chapter describes the functionality of the Data Modification Module (DMM), which provides the capability to modify data in the entire 4 GB address space of the device from an external peripheral, with minimal interruption of the application. A DMM gives the ability to write external data into the device memory. For HIL (playback), DMM can be used in I/O Mode and CSI mode (trace only mode).

10.6.1.1 Overview	4236
10.6.1.2 Module Operation	4237
10.6.1.3 DMM Control Registers	4242

10.6.1.1 Overview

10.6.1.1.1 Features

The DMM module has the following features:

- Acts as a bus master, thus enabling direct writes to the 4GB address space without CPU intervention
- Writes to memory locations specified in the received packet (leverages packets defined by trace mode of the RAM trace port (RTP) module)
- Writes received data to consecutive addresses, which are specified by the DMM module (leverages packets defined by direct data mode of RTP module)
- Configurable port width (1, 2, 4, 8, 16 pins)
- Up to 65 Mbit/s pin data rate
- Unused pins configurable as GPIO pins

10.6.1.1.2 Block Diagram

Figure 10-1717 shows the block diagram for the DMM.

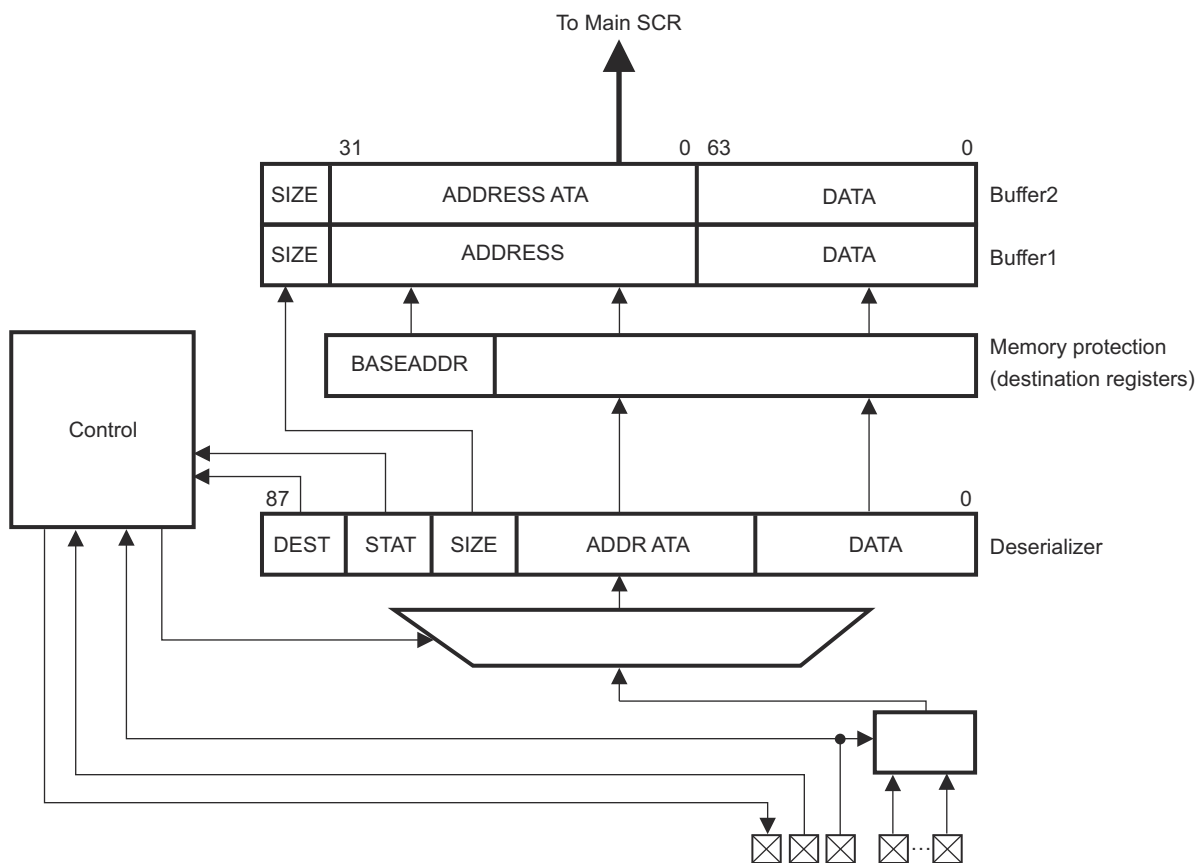

Figure 10-1717. DMM Block Diagram

10.6.1.2 Module Operation

The DMM receives data over the DMM pins from external systems and writes the received data directly to the base address programmed in the module plus offset address given in the packet or into a buffer specified by start address and length. It leverages the protocol defined by the RAM Trace Port (RTP) module to have a common interface definition for external systems. It can also be used to connect an RTP and DMM module together for fast processor intercommunication.

The DMM module provides two modes of operation:

- **Trace Mode:** In this mode, the DMM writes the received data directly to an address that is calculated from the base address programmed into the destination register ([Section 10.6.1.3.12](#); [Section 10.6.1.3.14](#)) plus the offset address contained in the received packet. An interrupt can be generated when data is written the lowest address of a programmed region. This capability enables the sender to raise an interrupt at the receiver while sending specific information.
- **Direct Data Mode:** In this mode, the DMM writes the received data into an address range of the 4GB address space. The buffer start address ([Section 10.6.1.3.8](#)) and blocksize ([Section 10.6.1.3.9](#)) is programmable in the DMM module. When the buffer reaches its end address, the buffer pointer wraps around and points to the beginning of the buffer again. The EO_BUFF flag ([Section 10.6.1.3.5](#)) will be set and if enabled, an interrupt will be generated to indicate a buffer-full condition. Another interrupt, can be configured to indicate different buffer fill levels. This can be accomplished by programming a certain fill level into the DMMINTPT register ([Section 10.6.1.3.11](#)). The PROG_BUFF flag ([Section 10.6.1.3.5](#)) indicates that this level has been reached.

Data will be captured by the input buffer and moved to the appropriate bit field in the deserializer. When the deserializer is completely full, the data will be moved to the output buffer register. A two-level buffer is implemented to avoid overflow conditions if the internal bus is occupied by other transactions. In addition the $\overline{\text{DMMENA}}$ signal can be used to signal the external hardware that an overflow might occur if more data is sent. The automatic generation of the $\overline{\text{DMMENA}}$ signal can be configured by setting the ENAFUNC bit ([Section 10.6.1.3.16](#)). While the $\overline{\text{DMMENA}}$ signal is active, the DMM module will not receive any new data.

The DMM is a bus master and forwards the received data to the bus system. The write operation will be minimally intrusive to the program flow, because the CPU/DMA access will only be blocked if the CPU/DMA accesses the same resource as the DMM.

To prevent an external system from overwriting critical data in the memory while configured in Trace Mode, a memory protection mechanism is implemented via a programmable start address and block size of a region. A maximum of four destinations with two regions each are supported.

For proper operation, at least DMMCLK, DMMSYNC and DMMDATA[0] need to be programmed in functional mode ([Section 10.6.1.3.16](#)). If a large amount of data should be transmitted in a short time, more data pins should be used in functional mode. The module supports 1, 2, 4, 8, or 16-pin configurations.

The module can be configured to handle a free running clock provided on DMMCLK ([Section 10.6.1.3.1](#)). Clock pulses between two DMMSYNC pulses that exceed the number of valid clock pulses for a packet will be ignored.

10.6.1.2.1 Data Format

Below is a description of the packet and frame format.

10.6.1.2.1.1 Clocking Scheme

The DMM supports both continuous and noncontinuous clocking. The clock received on DMMCLK in the continuous clocking scheme is a free-running clock. In noncontinuous clocking scheme, the clock will stop after each packet and will start with the reception of a DMMSYNC signal.

10.6.1.2.1.2 Trace Mode Packet

[Figure 10-1718](#) illustrates the trace mode packet format. One packet consists of 2 bits (DEST) denoting the destination in which the data is stored, 2 status bits (STAT), the 2-bit SIZE of the data, the 18-bit address of where the data should be written to, and a variable data field.

The DEST bits (Table 10-1826) will be used to determine which destination register applies to the transmitted data and the received address determines if the packet falls into a valid region of the destination area. If the address is valid, the base address, programmed in one of the destination registers (Section 10.6.1.3.12; Section 10.6.1.3.14) of this particular region will be applied to create the complete 32-bit address for the destination. The DMM module only takes action on a "11" setting of the STAT bits (Table 10-1827). This signals that an overflow in the transmitting hardware module has occurred. If this is the case the SRC_OVF flag (Section 10.6.1.3.5) will be set and the received data will be written to the address specified in the packet. The size information of the data transmitted in the packet is denoted in the SIZE bits (Table 10-1828) of the packet. Depending on the SIZE information, the module expects to receive only this amount of data.

Figure 10-1718. Trace Mode Packet Format

Table 10-1826 through Table 10-1828 illustrate the encoding of packet format in trace mode.

Table 10-1826. Encoding of Destination Bits in Trace Mode Packet Format

DEST[1:0]	Destination
00	Dest 0
01	Dest 1
10	Dest 2
11	Dest 3

Table 10-1827. Encoding of Status Bits in Trace Mode Packet Format

STAT[1:0]	Status
00	don't care
01	don't care
10	don't care
11	overflow

Table 10-1828. Encoding of Write Size in Packet Format

SIZE[1:0]	Write Size
00	8 bit
01	16 bit
10	32 bit
11	64 bit

10.6.1.2.1.3 Direct Data Mode Packet

Figure 10-1719 illustrates the direct data mode packet format.

Figure 10-1719. Direct Data Mode Packet Format

The packet consists only of data bits and no header information. It can be 8-, 16- or 32-bit wide. A variable packet width is not supported because the DMM module will check the number of incoming bits (DMMCLK cycles) for error detection. The DMM will write the received data to the destination once the programmed number of bits has been received.

If the programmed word width does not correspond to the received data, the following actions will be taken:

- If the received data is greater than the programmed width, only the configured number of bits are transferred into the RAM buffer, the additional bits are discarded.
- If the received number of bits is smaller than the programmed width, no data will be written to the buffer, because a new DMMSYNC signal has been received before the expected number of bits.

10.6.1.2.2 Data Port

The packet will be received in several subpackets, depending on the width of the external data bus (DMMDATA[y:0]) and the amount of data to be transmitted. [Table 10-1829](#) illustrates the number of clock cycles required for a complete packet.

Table 10-1829. Number of Clock Cycles per Packet

Port Width/ Pins	Write Size in Bits			
	8	16	32	64
1	32	40	56	88
2	16	20	28	44
4	8	10	14	22
8	4	5	7	11
16	2	3	4	6

The user can program the port width in the DMMPC0 register ([Section 10.6.1.3.16](#)). This feature allows pins that are not used for DMM functionality to be used as GIO pins. Only the pins shown in [Table 10-1830](#) can be used for a desired port width.

Table 10-1830. Pins Used for Data Communication

Port Width	Pins Used
1	DMMDATA[0]
2	DMMDATA[1:0]
4	DMMDATA[3:0]
8	DMMDATA[7:0]
16	DMMDATA[15:0]

Note

If pins other than the ones specified in [Table 10-1830](#) are programmed as functional pins for a desired port width, the received data will be corrupted and will not be transferred to the deserializer.

Note

If DMMCLK or DMMSYNC are programmed as nonfunctional pins, functional operation will not occur.

10.6.1.2.2.1 Signal Description

DMMSYNC	This signal has to be provided by external hardware. It signals the start of a new packet. It has to be active (high) for one full DMMCLK cycle, starting with the rising edge of DMMCLK. If the DMMSYNC pulse is longer than a single DMMCLK cycle and two falling edges of DMMCLK see a high pulse on DMMSYNC, the module will treat the second DMMSYNC pulse as the start of a packet and will flag a PACKET_ERR_INT (Section 10.6.1.3.5).
DMMCLK	The clock is externally generated and can be suspended between two packets. For this feature, CONTCLK must be set to 0 (Section 10.6.1.3.1). If the clock is not stopped between two packets, CONTCLK must be set to 1. Data will be latched on the falling edge of the DMMCLK signal.
DMMENA	This signal is pulled high if no new data should be received via the data pins, because of a potential overflow situation.
DMMDATA[15:0]	These pins receive the packet information transmitted by the external hardware. Data is latched on the falling edge of DMMCLK.

Figure 10-1720 shows an example of multiple packets received during trace mode, in noncontinuous clock configuration.

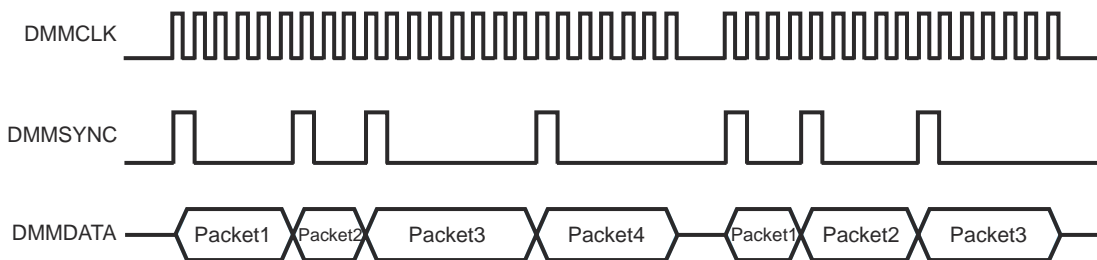

Figure 10-1720. Packet Sync Signal Example

Figure 10-1721 shows an example of a 4-bit data port with 8-bit receive data (A5h) to be written into DEST1 (address 0001 2345h) on a trace mode packet.

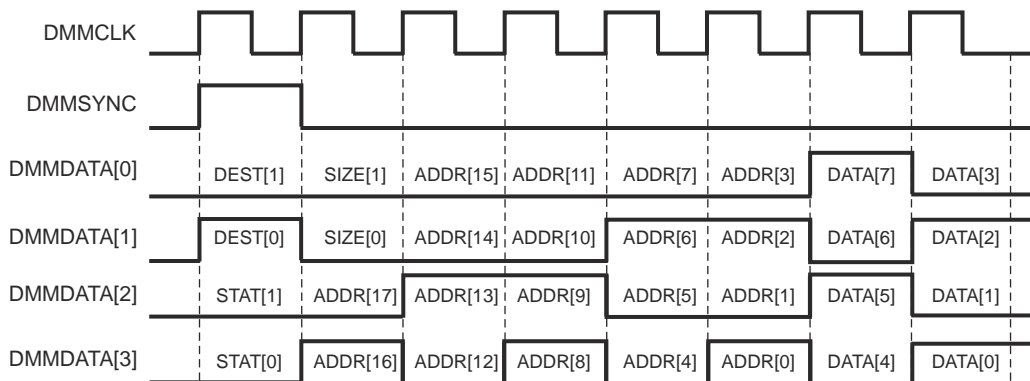

Figure 10-1721. Example Single Packet Transmission

10.6.1.2.3 Error Handling

The module will generate two different kind of errors. Once an error condition is recognized, an interrupt will be generated if enabled.

10.6.1.2.3.1 Overflow Error

This error is signaled when the module has received new data before the previous data was written to the destination address. If the internal buffers are full, the DMMENA signal will go high. If the sending module does not evaluate the DMMENA signal and keeps on sending new frames, the data that was previously received might be overwritten, thus resulting in setting the BUFF_OVF flag (Section 10.6.1.3.5).

10.6.1.2.3.2 Packet Error

Noncontinuous Clock Mode

The size of the incoming packet is defined by the SIZE information of a trace mode packet or the programmed size of a direct data mode packet. If too many or less than the number of bits are received before the next sync signal, the PACKET_ERR_INT flag will be set (Section 10.6.1.3.5). In case of receiving a DMMCLK signal without a corresponding DMMSYNC signal, a packet error will also be generated.

Continuous Clock Mode

If less than the expected number of bits are received, the PACKET_ERR_INT flag will be set (Section 10.6.1.3.5) when the next DMMSYNC signal is received. Packets with more than the expected number of bits cannot be detected.

The check for packet error is done only after the detection of the first DMMSYNC signal after the DMM is turned on or comes out of suspend mode (with COS = 0; Section 10.6.1.3.1), that is, before the reception of first DMMSYNC, the toggling of DMMCLK would be ignored.

10.6.1.2.3.3 Bus Error

If an error occurs on the microcontroller internal bus system while transferring the data from the DMM to the destination, the BUSERROR flag will be set.

10.6.1.2.4 Interrupts

The module provides different interrupts. These can be programmed to different interrupt levels independently using DMMINTLVL (Section 10.6.1.3.4).

Figure 10-1722. Interrupt Structure

Interrupts can be divided into error interrupts and functional interrupts. The error handling is described in Section 10.6.1.2.3. Functional interrupts depend on the mode (Trace Mode, Direct Data Mode) the DMM module is used in.

Trace Mode: An interrupt can be enabled whenever an access to the lowest address of a defined region is performed. This address is the starting address programmed in the DMMDESTxREGy register. An interrupt for each of the region can be generated by setting the individual interrupt enable bits.

Direct Data Mode: There are two interrupts that can be individually controlled. One is generated when the buffer pointer reaches the end of the defined buffer and wraps around (EO_BUFF; Section 10.6.1.3.2). The other one is generated when the buffer pointer matches the programmed interrupt threshold (PROG_BUFF; Section 10.6.1.3.2). The buffer pointer points to the next address to be written, therefore there are (interrupt threshold - 1) values stored in the buffer. The interrupt threshold can be programmed in the DMMINTPT register (Section 10.6.1.3.11).

10.6.1.3 DMM Control Registers

This section describes the DMM registers. The registers support 8, 16, and 32-bit writes. The offset is relative to the associated peripheral select. [Table 10-1831](#) provides a summary of the registers and their bits. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 10-1831. DMM Registers

Offset	Acronym	Register Description	Section
0h	DMMGLBCTRL	DMM Global Control Register	Section 10.6.1.3.1
4h	DMMINTSET	DMM Interrupt Set Register	Section 10.6.1.3.2

8Ch	DMMPC8	DMM Pin Control 8	Section 10.6.1.3.24

10.6.1.3.1 DMM Global Control Register (DMMGLBCTRL)

With this register the basic operation of the module is selected.

Figure 10-1722. DMM Global Control Register (DMMGLBCTRL) [offset = 00h]

31				25	24
Reserved				BUSY	
R-0				R-0	
23				19	18
Reserved			CONTCLK	COS	RESET
R-0			R/WP-0	R/WP-0	R/WP-0
15				11	10
Reserved			DDM_WIDTH		TM_DDM
R-0			R/WP-0		R/WP-0
7				4	3
Reserved			ON/OFF		
R-0			R/WP-5h		

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1832. DMM Global Control Register (DMMGLBCTRL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads returns 0. Writes have no effect.
24	BUSY	0	Busy indicator. The DMM does not currently receive data and has no data in its internal buffers, which needs to be transferred.
		1	The module is currently receiving data, or has data in its internal buffers
23-19	Reserved	0	Reads returns 0. Writes have no effect.
18	CONTCLK		Continuous DMMCLK input. User and privilege mode read, privilege mode write:
		0	DMMCLK is expected to be suspended between two packets.
17	COS	1	DMMCLK is expected to be free running between packets.
			Continue on suspend. Influences behavior of module while in debug mode. In all cases the corresponding interrupt will be set. User and privilege mode (read):
		0	Packets will not be received during debug mode. Before entering debug mode, the ongoing reception of a packet will be finished and the value will be written to the destination.
		1	Continue receiving packets and update destination, while in debug mode
			Privilege mode (write):
		0	Disable data reception while in debug mode
		1	Enable data reception while in debug mode

Table 10-1832. DMM Global Control Register (DMMGLBCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
16	RESET		Reset. This bit resets the state machine and the registers to its reset value, except the RESET bit itself. It must be cleared by writing to it.
		0	User and privilege mode (read): No reset of DMM module
		1	Reset of DMM module
		0	Privilege mode (write): No reset of DMM module
		1	Reset DMM module to its reset state
15-11	Reserved	0	Reads returns 0. Writes have no effect.
10-9	DDM_WIDTH		Packet Width in direct data mode.
		Bit Encoding	User and privilege mode read and privilege mode write operation: Transfer Size
		0	8 bit
		1h	16 bit
		2h	32 bit
3h	Reserved		
8	TM_DMM		Packet Format.
		0	User and privilege mode (read): The DMM module assumes packets in trace mode definition
		1	The DMM module assumes packets in direct data mode definition
		0	Privilege mode (write): Enable trace mode
		1	Enable direct data mode
7-4	Reserved	0	Reads returns 0. Writes have no effect.
3-0	ON/OFF		Switch module on or off
		All other	User and privilege mode (read): The DMM module does not receive data
		Ah	The DMM module receives data and writes it to the buffer
		All other	Privilege mode (write): Disable receive/write operations. Packets in reception, will still be finished
		Ah	Enable receive/write operations. Packets will be received 1 HCLK cycle after enabling the module

Note

It is recommended to write 5h to ON/OFF to avoid having a soft error inadvertently enabling the module when a single bit flips.

Note

Registers that affect the operation of the module, should be only programmed when the BUSY bit is 0 and the ON/OFF bits are not Ah.

Note

If the module was in operation, turned off (ON/OFF = all other than Ah) and then turned on (ON/OFF = Ah) again, it is recommended to perform a reset (RESET = 1) of the module before switching it on. This avoids that the state machine is held in an unrecoverable state.

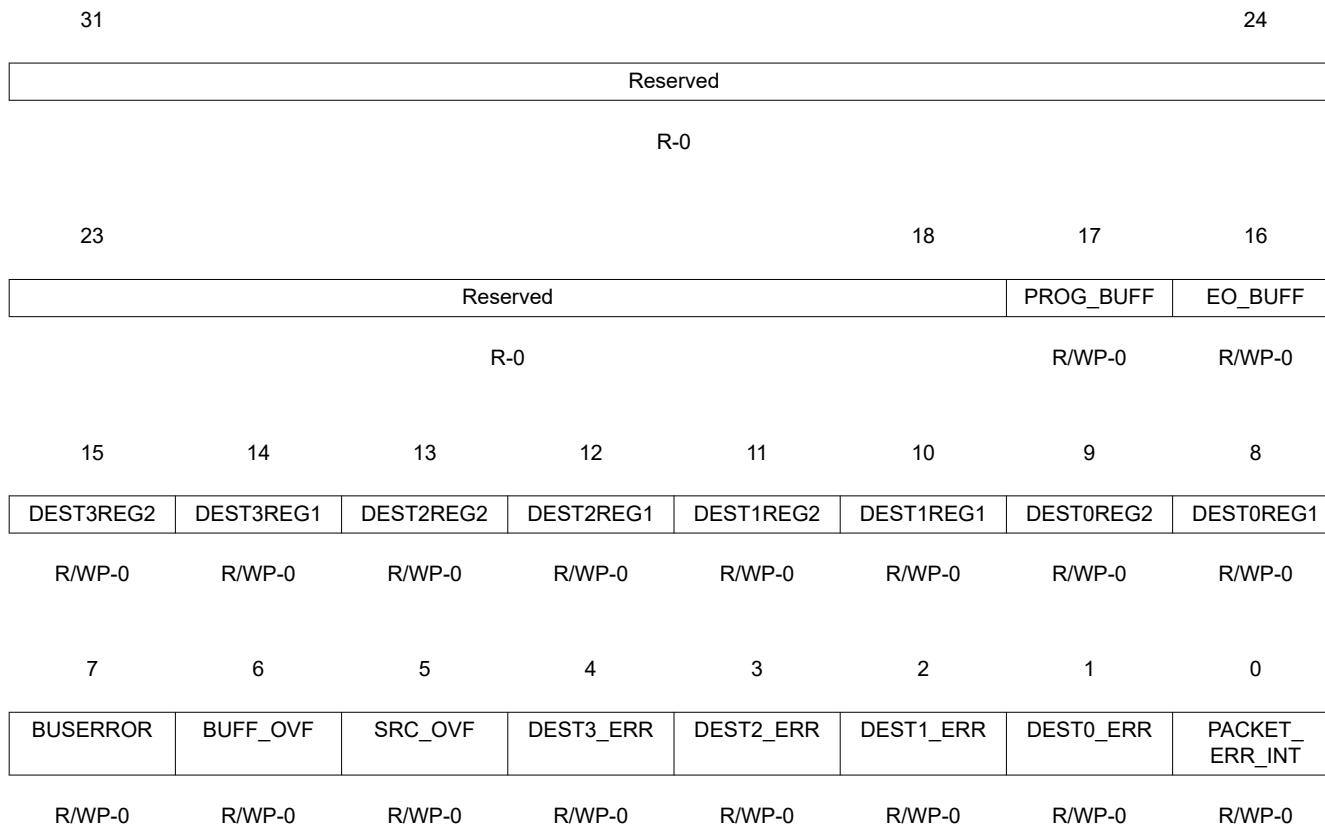

Note

A write to these register bits while receiving a packet will not have any effect on the received packet. The mode change will be performed after the packet is received

10.6.1.3.2 DMM Interrupt Set Register (DMMINTSET)

This register contains the interrupt set bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation.

Figure 10-1723. DMM Interrupt Set Register (DMMINTSET) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1833. DMM Interrupt Set Register (DMMINTSET) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0. Writes have no effect.
17	PROG_BUFF	0 1	<p>Programmable Buffer Interrupt Set. This enables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register (Section 10.6.1.3.11). This bit is only relevant in Direct Data Mode.</p> <p>User and privilege mode (read):</p> <ul style="list-style-type: none"> 0 No interrupt will be generated 1 An interrupt will be generated on pointer match.
		0 1	<p>Privilege mode (write):</p> <ul style="list-style-type: none"> 0 No influence on bit 1 Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 10-1833. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
16	EO_BUFF		End of Buffer Interrupt Set. This enables the interrupt generation in case data was written to the last entry in the buffer and the pointer wrapped around to the beginning of the buffer. This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on writing to the last entry.
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
15	DEST3REG2		Destination 3 Region 2 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
14	DEST3REG1		Destination 3 Region 1 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
13	DEST2REG2		Destination 2 Region 2 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
12	DEST2REG1		Destination 2 Region 1 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 10-1833. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
11	DEST1REG2	0	Destination 1 Region 2 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 1 Region 2. This bit is only relevant in Trace Mode. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
10	DEST1REG1	0	Destination 1 Region 1 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 1 Region 1. This bit is only relevant in Trace Mode. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
9	DEST0REG2	0	Destination 0 Region 2 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 0 Region 2. This bit is only relevant in Trace Mode. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
8	DEST0REG1	0	Destination 0 Region 1 Interrupt Set. This enables the interrupt generation in case data was accessed at the startaddress of Destination 0 Region 1. This bit is only relevant in Trace Mode. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
7	BUSERROR	0	Bus Error Response for errors generated when doing internal bus transfers. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
6	BUFF_OVF	0	Buffer Overflow. This enables the interrupt generation in case new data is received, while the previous data still has not been transmitted. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 10-1833. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
5	SRC_OVF	0	Source Overflow. This enables an interrupt if the external system experienced an overflow which was signalled in the Trace Mode packet. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
4	DEST3_ERR	0	Destination 3 Error. This enables the interrupt generation in case data should be written into an address not specified by DMMDEST3REG1/DMMDEST3BL1 or DMMDEST3REG2/DMMDEST3BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
3	DEST2_ERR	0	Destination 2 Error Interrupt Set. This enables the interrupt generation in case data should be written into an address not specified by DMMDEST2REG1/DMMDEST2BL1 or DMMDEST2REG2/DMMDEST2BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
2	DEST1_ERR	0	Destination 1 Error Interrupt Set. This enables the interrupt generation in case data should be written into an address not specified by DMMDEST1REG1/DMMDEST1BL1 or DMMDEST1REG2/DMMDEST1BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
1	DEST0_ERR	0	Destination 0 Error Interrupt Set. This enables the interrupt generation in case data should be written into an address not specified by DMMDEST0REG1/DMMDEST0BL1 or DMMDEST0REG2/DMMDEST0BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

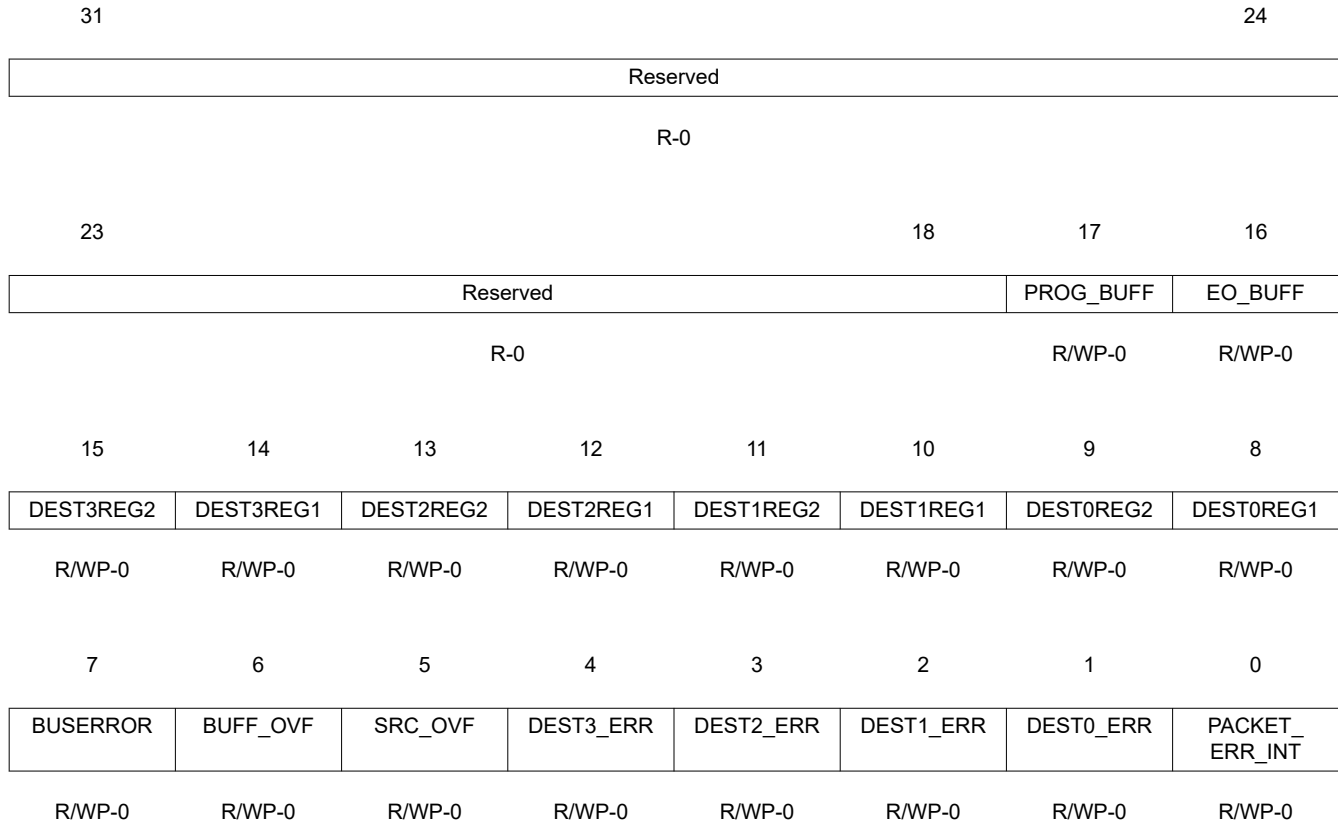

Table 10-1833. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
0	PACKET_ERR_INT		Packet Error. This enables the interrupt generation in case of an error condition in the packet reception. Refer to #unique_1258referenceTitle for the error conditions.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

10.6.1.3.3 DMM Interrupt Clear Register (DMMINTCLR)

This register contains the interrupt clear bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation

Figure 10-1724. DMM Interrupt Clear Register (DMMINTCLR) [offset = 08h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 10-1834. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0. Writes have no effect.
17	PROG_BUFF		Programmable Buffer Interrupt Set. This disables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register (Section 10.6.1.3.11). This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on pointer match.
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))

Table 10-1834. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)

		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
3	DEST2_ERR	0	Destination 2 Error Interrupt Set. This disables the interrupt generation in case data should be written into an address not specified by DMMDEST2REG1/DMMDEST2BL1 or DMMDEST2REG2/DMMDEST2BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. User and privilege mode (read): No interrupt will be generated
		1	An interrupt will be generated
		0	Privilege mode (write): No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))

Table 10-1834. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)

Bit	Field	Value	Description
2	DEST1_ERR		Destination 1 Error Interrupt Set. This disables the interrupt generation in case data should be written into a address not specified by DMMDEST1REG1/DMMDEST1BL1 or DMMDEST1REG2/DMMDEST1BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
1	DEST0_ERR		Destination 0 Error Interrupt Set. This disables the interrupt generation in case data should be written into a address not specified by DMMDEST0REG1/DMMDEST0BL1 or DMMDEST0REG2/DMMDEST0BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
0	PACKET_ERR_INT		Packet Error. This disables the interrupt generation in case of an error condition in the packet reception. Refer to #unique_1258referenceTitle for the error conditions.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))

10.6.1.3.4 DMM Interrupt Level Register (DMMINTLVL)

This register contains the interrupt level bits for error interrupts and normal interrupts.

10.6.1.3.6 DMM Interrupt Offset 1 Register (DMMOFF1)

This register holds the offset indicating which interrupt occurred on interrupt level 0. The CPU can read this register to determine the source of the interrupt without having to test individual interrupt flags.

Figure 10-1727. DMM Interrupt Offset 1 Register (DMMOFF1) [offset = 14h]

LEGEND: R = Read only; -n = value after reset

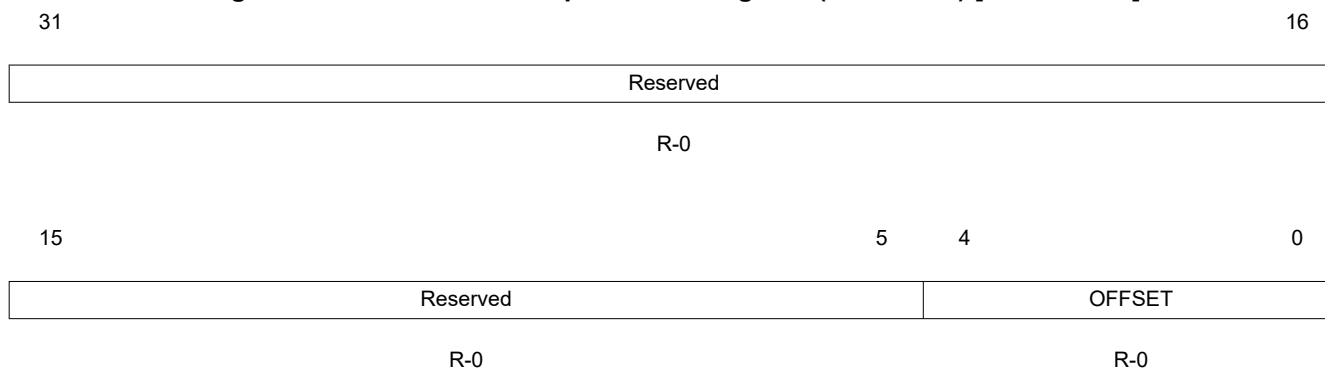

Table 10-1837. DMM Interrupt Offset 1 Register (DMMOFF1) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Read returns 0. Writes have no effect.
4-0	OFFSET	Bit Encoding	User and privilege mode (read): Interrupt
		0	Phantom. All interrupt flags have been cleared before the offset register has been read.
		1h	Packet Error
		2h	Destination 0 Error
		3h	Destination 1 Error
		4h	Destination 2 Error
		5h	Destination 3 Error
		6h	Source Overflow
		7h	Buffer Overflow
		8h	Bus Error
		9h	Destination 0 Region 1
		Ah	Destination 0 Region 2
		Bh	Destination 1 Region 1
		Ch	Destination 1 Region 2
		Dh	Destination 2 Region 1
		Eh	Destination 2 Region 2
		Fh	Destination 3 Region 1
		10h	Destination 3 Region 2
		11h	End of Buffer
		12h	Programmable Buffer
		13h-1Fh	Reserved
			Reading the offset will clear the corresponding flag in DMMINTFLG (Section 10.6.1.3.5).
			Privilege and user mode writes have no effect

10.6.1.3.7 DMM Interrupt Offset 2 Register (DMMOFF2)

This register holds the offset indicating which interrupt occurred on interrupt level 1. The CPU can read this register to determine the source of the interrupt without having to test individual interrupt flags.

Figure 10-1728. DMM Interrupt Offset 2 Register (DMMOFF2) [offset = 18h]

LEGEND: R = Read only; -n = value after reset

Table 10-1838. DMM Interrupt Offset 2 Register (DMMOFF1) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Read returns 0. Writes have no effect.
4-0	OFFSET	Bit Encoding 0 1h 2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh 10h 11h 12h 13h-1Fh	User and privilege mode (read): Interrupt Phantom. All interrupt flags have been cleared before the offset register has been read. Packet Error Destination 0 Error Destination 1 Error Destination 2 Error Destination 3 Error Source Overflow Buffer Overflow Bus Error Destination 0 Region 1 Destination 0 Region 2 Destination 1 Region 1 Destination 1 Region 2 Destination 2 Region 1 Destination 2 Region 2 Destination 3 Region 1 Destination 3 Region 2 End of Buffer Programmable Buffer Reserved Reading the offset will clear the corresponding flag in DMMINTFLG (Section 10.6.1.3.5). Privilege and user mode writes have no effect

10.6.1.3.8 DMM Direct Data Mode Destination Register (DMMDDMDEST)

This register defines the starting address of the buffer used to store the received data in Direct Data Mode. By writing to this register, the DMMDDMPT register (Section 10.6.1.3.10) will be set to 0x0000.

Figure 10-1729. DMM Direct Data Mode Destination Register (DMMDDMDEST) [offset = 1Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

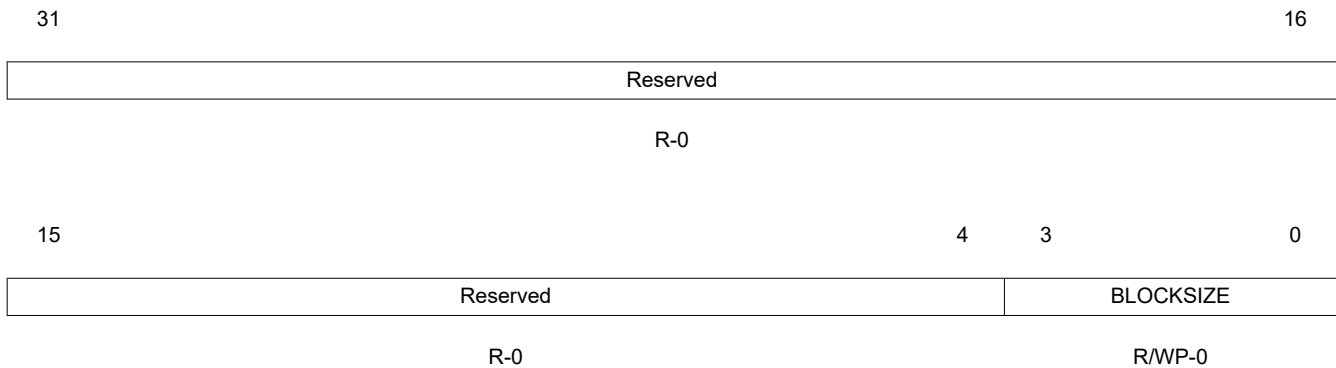

Table 10-1839. DMM Direct Data Mode Destination Register (DMMDDMDEST) Field Descriptions

Bit	Field	Description
31-0	STARTADDR	These bits define the starting address of the buffer. The starting address has to be a multiple of the blocksize chosen in DMMDDMBL (Section 10.6.1.3.9). User and privilege mode (read): current start address Privilege mode (write): sets start address to value written

10.6.1.3.9 DMM Direct Data Mode Blocksize Register (DMMDDMBL)

This register defines the blocksize of the buffer used to store the received data in Direct Data Mode.

Figure 10-1730. DMM Direct Data Mode Blocksize Register (DMMDDMBL) [offset = 20h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-1840. DMM Direct Data Mode Blocksize Register (DMMDDMBL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Read returns 0. Writes have no effect.

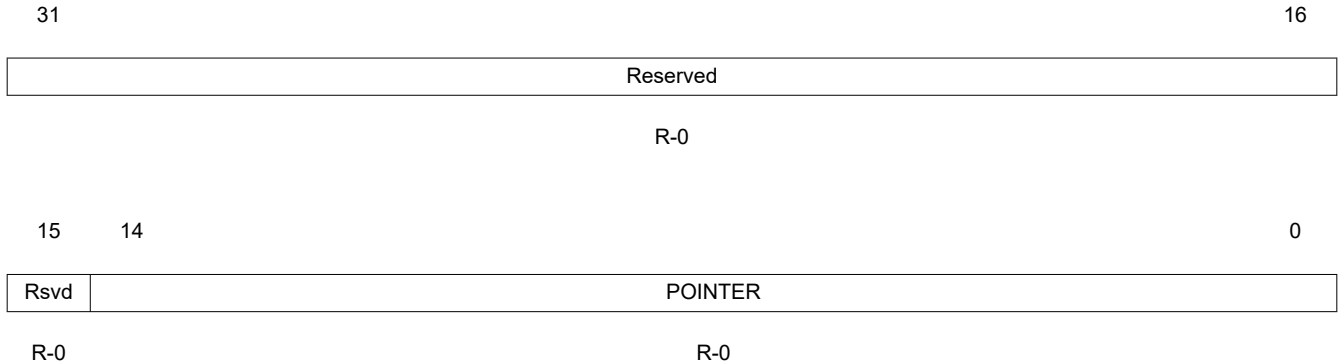

Table 10-1840. DMM Direct Data Mode Blocksize Register (DMMDDMBL) Field Descriptions (continued)

Bit	Field	Value	Description
3-0	BLOCKSIZE		These bits define the size of the buffer region
			User and privilege mode (read): current block size
			Privilege mode (write):
		0	Buffer disabled. No data will be stored.
		1h	32 Byte
		2h	64 Byte
		3h	128 Byte
		4h	256 Byte
		5h	512 Byte
		6h	1 KByte
		7h	2 KByte
		8h	4 KByte
		9h	8 KByte
		Ah	16 KByte
		Bh	32 KByte
		Ch-Fh	Reserved

10.6.1.3.10 DMM Direct Data Mode Pointer Register (DMMDDMPT)

This register shows the pointer into the buffer programmed by DMMDDMDEST (Section 10.6.1.3.8) and DMMDDMBL (Section 10.6.1.3.9).

Figure 10-1731. DMM Direct Data Mode Pointer Register (DMMDDMPT) [offset = 24h]

LEGEND: R = Read only; -n = value after reset

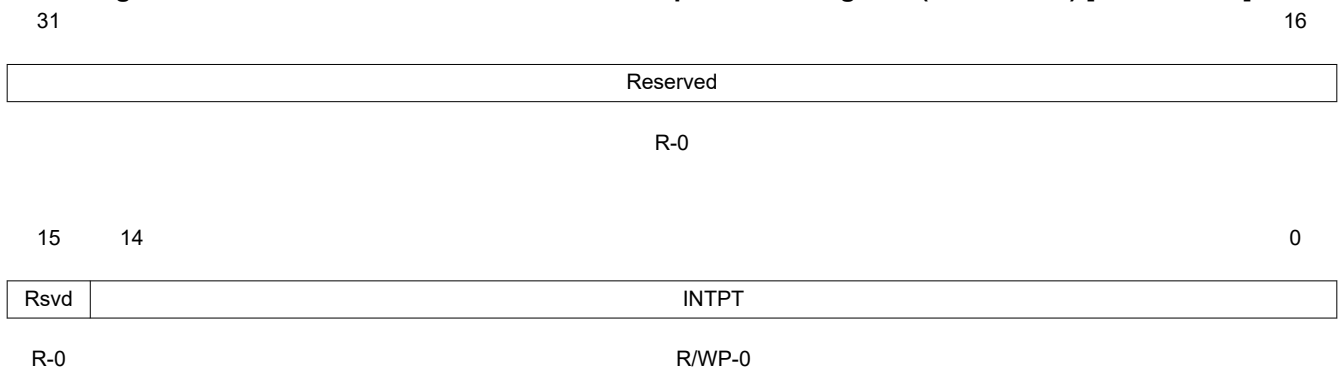

Table 10-1841. DMM Direct Data Mode Pointer Register (DMMDDMPT) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Read returns 0. Writes have no effect.
14-0	POINTER		These bits hold the pointer to the next entry to be written in the buffer. The pointer points to the byte aligned address. If in 16-bit DDM mode, bit 0 will be 0. If in 32-bit DDM mode, bit 0 and 1 will be 0. User and privilege mode (read): next data entry Privilege mode (write): writes have no effect

10.6.1.3.11 DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT)

This register can be programmed to hold a threshold to which the DMMDDMPT register (Section 10.6.1.3.10) is compared. An interrupt can be generated when both match.

Figure 10-1732. DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT) [offset = 28h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-1842. DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Read returns 0. Writes have no effect.

**Table 10-1842. DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT) Field Descriptions
(continued)**

Bit	Field	Value	Description
14-0	INTPT		Interrupt Pointer. When the buffer pointer (Section 10.6.1.3.10) matches the programmed value in DMMINTPT and the PROG_BUF interrupt (Section 10.6.1.3.2) is set, an interrupt is generated. User and privilege mode (read): current interrupt threshold Privilege mode (write): new interrupt threshold

10.6.1.3.12 DMM Destination x Region 1 (DMMDESTxREG1)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG1 and DMMDESTxBL1, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG1, DMMDEST1REG1, DMMDEST2REG1, DMMDEST3REG1.

Figure 10-1733. DMM Destination x Region 1 (DMMDESTxREG1) [offset = 2Ch, 3Ch, 4Ch, 5Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

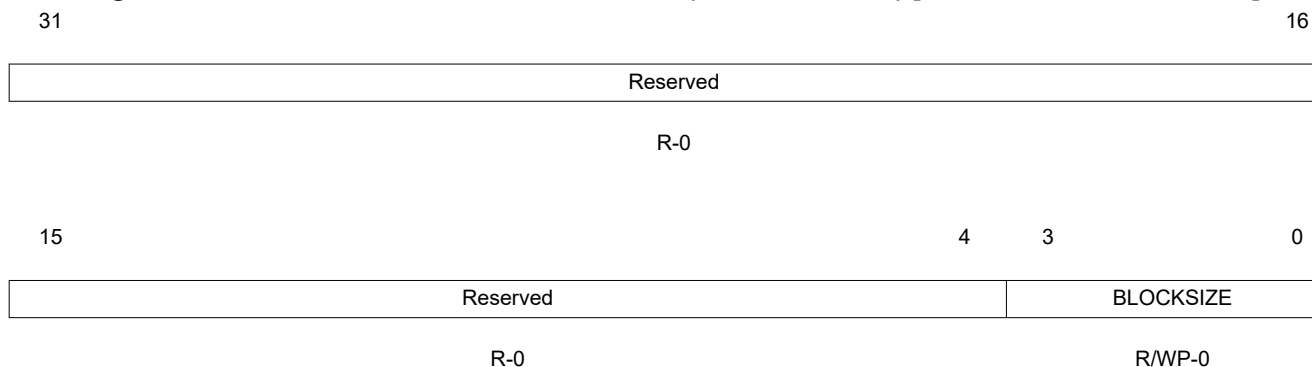

Table 10-1843. DMM Destination x Region 1 (DMMDESTxREG1) Field Descriptions

Bit	Field	Description
31-18	BASEADDR	These bits define the base address of the 256kB region where the buffer is located. User and privilege mode (read): current start address Privilege mode (write): sets base address to value written
17-0	BLOCKADDR	These bits define the starting address of the buffer in the 256kB page. The starting address has to be a multiple of the blocksize chosen in DMMDESTxBL1 (Section 10.6.1.3.13). User and privilege mode (read): current start address Privilege mode (write): sets start address to value written

10.6.1.3.13 DMM Destination x Blocksize 1 (DMMDESTxBL1)

This register defines the blocksize of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG1 and DMMDESTxBL1, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0BL1, DMMDEST1BL1, DMMDEST2BL1, DMMDEST3BL1.

Figure 10-1734. DMM Destination x Blocksize 1 (DMMDESTxBL1) [offset = 30h, 40h, 50h, 60h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

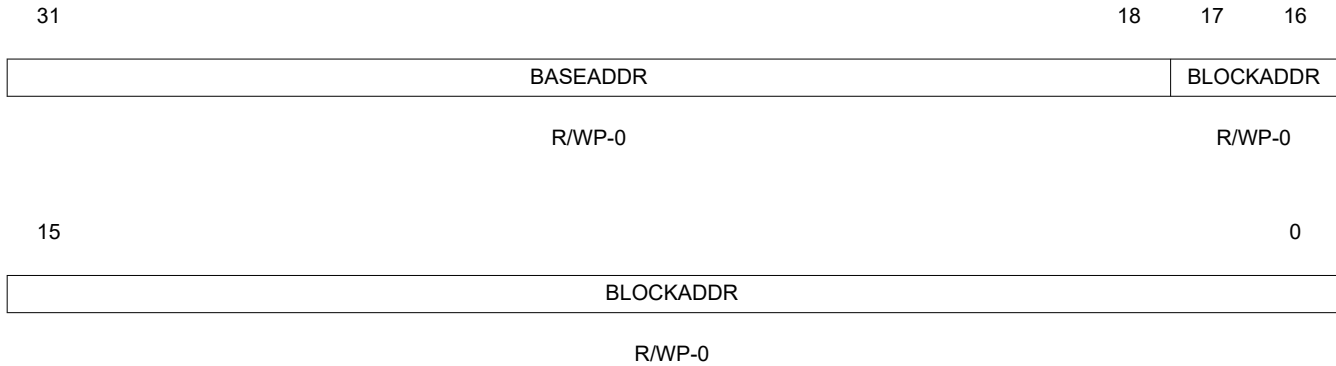

Table 10-1844. DMM Destination x Blocksize 1 (DMMDESTxBL1) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Read returns 0. Writes have no effect.
3-0	BLOCKSIZE		These bits define the length of the buffer region. If all bits are 0, the region is disabled and no data will be stored. User and privilege mode (read): current block size Privilege mode (write):
		0	Region disabled
		1h	1 KByte
		2h	2 KByte
		3h	4 KByte
		4h	8 KByte
		5h	16 KByte
		6h	32 KByte
		7h	64 KByte
		8h	128 KByte
		9h	256 KByte
		Ah-Fh	Reserved

10.6.1.3.14 DMM Destination x Region 2 (DMMDESTxREG2)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG2 and DMMDESTxBL2, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG2, DMMDEST1REG2, DMMDEST2REG2, DMMDEST3REG2.

Figure 10-1735. DMM Destination x Region 2 (DMMDESTxREG2) [offset = 34h, 44h, 54h, 64h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-1845. DMM Destination x Region 2 (DMMDESTxREG2) Field Descriptions

Bit	Field	Description
31-18	BASEADDR	These bits define the base address of the 256kB region where the buffer is located. User and privilege mode (read): current start address Privilege mode (write): sets base address to value written
17-0	BLOCKADDR	These bits define the starting address of the buffer in the 256kB page. The starting address has to be a multiple of the blocksize chosen in DMMDESTxBL1 (Section 10.6.1.3.15). User and privilege mode (read): current start address Privilege mode (write): sets start address to value written

10.6.1.3.15 DMM Destination x Blocksize 2 (DMMDESTxBL2)

This register defines the blocksize of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG2 and DMMDESTxBL2, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0BL2, DMMDEST1BL2, DMMDEST2BL2, DMMDEST3BL2.

Figure 10-1736. DMM Destination x Blocksize 2 (DMMDESTxBL2) [offset = 38h, 48h, 58h, 68h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-1846. DMM Destination x Blocksize 2 (DMMDESTxBL2) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Read returns 0. Writes have no effect.
3-0	BLOCKSIZE		These bits define the length of the buffer region. If all bits are 0, the region is disabled and no data will be stored. User and privilege mode (read): current block size Privilege mode (write):
		0	Region disabled
		1h	1 KByte
		2h	2 KByte
		3h	4 KByte
		4h	8 KByte
		5h	16 KByte
		6h	32 KByte
		7h	64 KByte
		8h	128 KByte
		9h	256 KByte
		Ah-Fh	Reserved

10.6.1.3.16 DMM Pin Control 0 (DMMP0)

This register defines if the DMM pins are used in functional or GIO mode. It should only be written when ON/OFF = 0101 and the BUSY bit = 0 (Section 10.6.1.3.1). If pins other than the pins specified in are configured, or DMMCLK and DMMSYNC are programmed as non-functional pins, no operation in trace mode or direct data mode is possible.

Bit	Field	Value	Description
31-19	Reserved	0	Reads returns 0. Writes have no effect.
18	ENAFUNC		Functional mode of DMMENA pin. This bit defines whether the pin is used in functional mode or in GIO mode.
			User and privilege mode (read):
		0	Pin is used in GIO mode
		1	Pin is used in Functional mode
			Privilege mode (write):
		0	Pin is used in GIO mode
		1	Pin is used in Functional mode

Table 10-1847. DMM Pin Control 0 (DMMP0) Field Descriptions (continued)

Bit	Field	Value	Description
17-2	DATAxFUNC		Functional mode of DMMDATA[x] pin. This bit defines whether the pin is used in functional mode or in GIO mode. If pins are configured in functional mode, only pins defined in have to be used for proper operation.
		0	User and privilege mode (read): Pin is used in GIO mode
		1	Pin is used in Functional mode
		0	Privilege mode (write): Pin is used in GIO mode
		1	Pin is used in Functional mode
1	CLKFUNC		Functional mode of DMCLK pin. This bit defines whether the pin is used in functional mode or in GIO mode.
		0	User and privilege mode (read): Pin is used in GIO mode
		1	Pin is used in Functional mode
		0	Privilege mode (write): Pin is used in GIO mode
		1	Pin is used in Functional mode
0	SYNCFUNC		Functional mode of DMMSYNC pin. This bit defines whether the pin is used in functional mode or in GIO mode.
		0	User and privilege mode (read): Pin is used in GIO mode
		1	Pin is used in Functional mode
		0	Privilege mode (write): Pin is used in GIO mode
		1	Pin is used in Functional mode

10.6.1.3.17 DMM Pin Control 1 (DMMP1)

The bits in this register define the direction of the individual module pins when in GIO mode.

Table 10-1848. DMM Pin Control 1 (DMMPC1) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads returns 0. Writes have no effect.
18	ENADIR		Direction of DMMENA pin. User and privilege mode (read):
		0	Pin is used as input
		1	Pin is used as output
			Privilege mode (write):
		0	Pin is set to input
		1	Pin is set to output
17-2	DATAxDIR		Direction of DMMDATA[x] pin. This bit defines whether the pin is used as input or output in GIO mode. User and privilege mode (read):
		0	Pin is used as input
		1	Pin is used as output
			Privilege mode (write):
		0	Pin is set to input
		1	Pin is set to output
1	CLKDIR		Direction of DMCLK pin. This bit defines whether the pin is used as input or output in GIO mode. User and privilege mode (read):
		0	Pin is used as input
		1	Pin is used as output
			Privilege mode (write):
		0	Pin is set to input
		1	Pin is set to output
0	SYNCDIR		Direction of DMMSYNC pin. This bit defines whether the pin is used as input or output in GIO mode. User and privilege mode (read):
		0	Pin is used as input
		1	Pin is used as output
			Privilege mode (write):
		0	Pin is set to input
		1	Pin is set to output

10.6.1.3.18 DMM Pin Control 2 (DMMPC2)

The bits in this register reflect the digital representation of the voltage level at the module pins. Even if a pin is configured to be an output pin, the level can be read back via this register.

Figure 10-1739. DMM Pin Control 2 (DMMPC2) [offset = 74h]

Table 10-1851. DMM Pin Control 4 (DMMP4) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads returns 0. Writes have no effect.
18	ENASET		Sets output state of DMMENA pin to logic high. Value in the ENASET bit sets the data output control register bit to 1 regardless of the current value in the ENAOUT bit.
			User and privilege mode (read):
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Logic high (output voltage is set to V_{OH} or higher)
17-2	DATAxSET		Sets output state of DMMDATA[x] pin to logic high. Value in the DATAxSET bit sets the data output control register bit to 1 regardless of the current value in the DATAxOUT bit.
			User and privilege mode (read):
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Logic high (output voltage is set to V_{OH} or higher)
1	CLKSET		Sets output state of DMCLK pin to logic high. Value in the CLKSET bit sets the data output control register bit to 1 regardless of the current value in the CLKOUT bit.
			User and privilege mode (read):
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Logic high (output voltage is set to V_{OH} or higher)
0	SYNCSET		Sets output state of DMMSYNC pin logic high. Value in the SYNCSET bit sets the data output control register bit to 1 regardless of the current value in the SYNCOUT bit.
			User and privilege mode (read):
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Logic high (output voltage is set to V_{OH} or higher)

10.6.1.3.21 DMM Pin Control 5 (DMMPC5)

This register allows to set individual pins to a logic low level without having to do a read-modify-write operation as would be the case with the DMMPC3 register (Section 10.6.1.3.19). Writing a one to a bit will change the output to a logic low level, writing a zero will not change the state of the pin.

1	CLKCLR		Sets output state of DMMCLK pin to logic low. Value in the CLKCLR bit clears the data output control register CLKOUT bit to 0, regardless of the current value in the CLKOUT bit.
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Clears the pin to logic low (output voltage is set to V_{OL} or lower)
0	SYNCLR		Sets output state of DMMSYNC pin to logic low. Value in the SYNCLR bit clears the data output control register SYNCOUT bit to 0, regardless of the current value in the SYNCOUT bit.
		0	Logic low (output voltage is V_{OL} or lower)
		1	Logic high (output voltage is V_{OH} or higher)
			Privilege mode (write):
		0	State of the pin is unchanged
		1	Clears the pin to logic low (output voltage is set to V_{OL} or lower)

10.6.1.3.22 DMM Pin Control 6 (DMMP6)

These bits configure the pins in push-pull or open-drain functionality. If configured to be open-drain, the module only drives a logic-low level on the pin. An external pull-up resistor needs to be connected to the pin to pull it high, when the pin is in high-impedance mode.

10.6.2 Safety Modules

10.6.2.1 Dual Clock Comparator (DCC)	4287
10.6.2.2 ECC_AGGREGATOR	4306
10.6.2.3 ECC Registers	4313
10.6.2.4 Error Signaling Module (ESM)	4423
10.6.2.5 Cyclic Redundancy Check (CRC)	4473
10.6.2.6 Self-Test Controller (STC)	4556
10.6.2.7 Programmable Built-In Self-Test (PBIST)	4642

10.6.2.1 Dual Clock Comparator (DCC)

This section describes the dual-clock comparator (DCC) module.

10.6.2.1.1 Introduction

The primary purpose of a DCC module is to measure the frequency of a clock signal using a second known clock signal as a reference. Specifically, DCC is designed to detect drifts from the expected clock frequency. This capability can be used to ensure the correct frequency range for several different device clock sources, thereby enhancing the system safety metrics.

10.6.2.1.1.1 Main Features

The main features of each of the DCC modules are:

- Allows application to ensure that a fixed ratio is maintained between frequencies of two clock signals
- Supports the definition of a programmable tolerance window in terms of number of reference clock cycles
- Supports continuous monitoring without requiring application intervention
- Also supports a single-sequence mode for spot measurements
- Allows selection of clock source for each of the counters resulting in several specific use cases

10.6.2.1.1.2 Block Diagram

Figure 10-1747 illustrates the main concept of the DCC module.

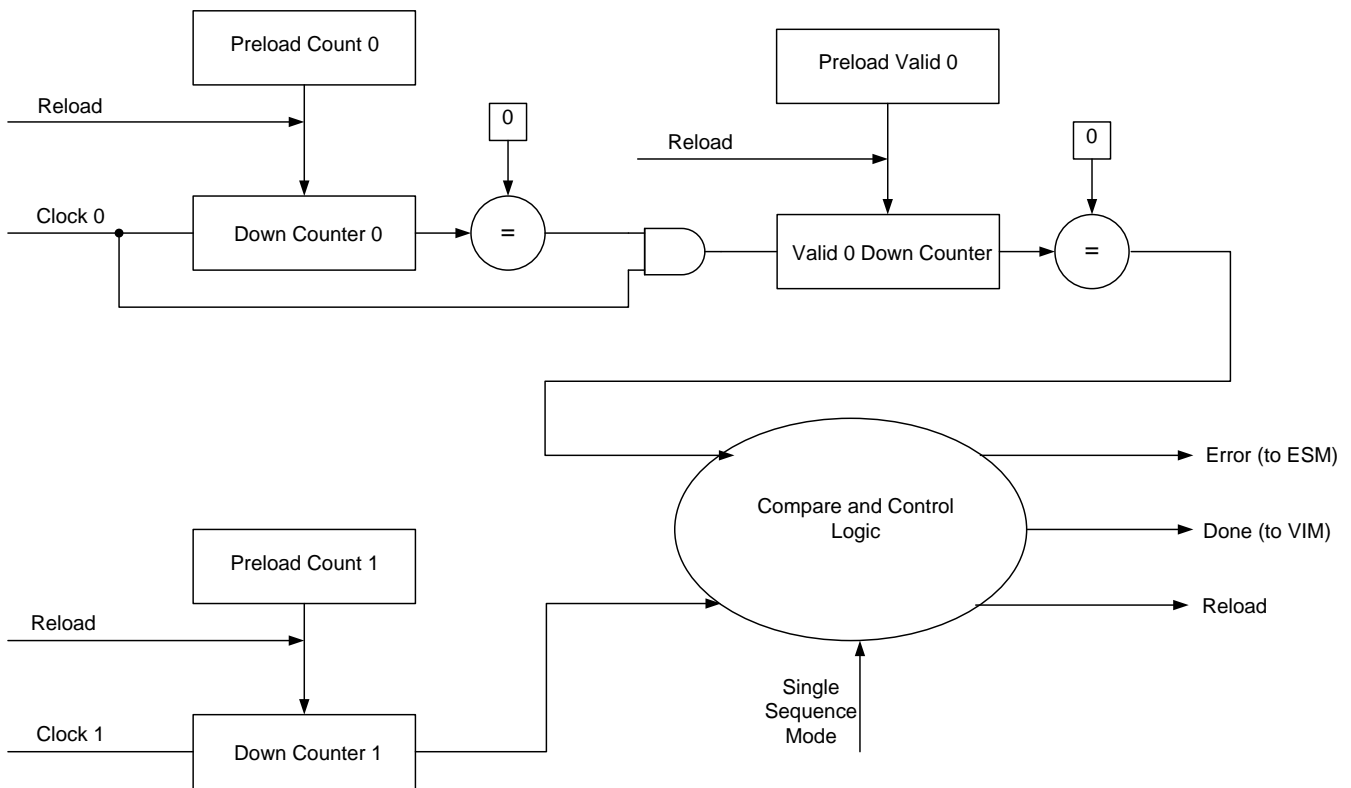

Figure 10-1747. Block Diagram

10.6.2.1.2 Module Operation

As shown in [Figure 10-1747](#), the DCC contains two counters – counter0 and counter1, which are driven by two signals – clock0 and clock1. The application programs the seed values for both these counters. The application also configures the tolerance window time by configuring the valid counter for clock0.

Counter0 and counter1 both start counting simultaneously once the DCC is enabled. When counter0 counts down to zero, this automatically triggers the count down of the tolerance window counter (valid0).

The DCC module can be used in two different operating modes:

10.6.2.1.2.1 Continuous Monitoring Mode

In this mode, the DCC is used by the application to ensure that two clock signals maintain the correct frequency ratio. Suppose the application wants to ensure that the PLL output signal (clock source # 1) always maintains a fixed frequency relationship with the main oscillator (clock source # 0).

- In this case, the application can use the main oscillator as the clock0 signal (for counter0 and valid0) and the PLL output as the clock1 (for counter1).
- The seed values of counter0, valid0 and counter1 are selected such that if the actual frequencies of clock0 and clock1 are equal to their expected frequencies, then the counter1 will reach zero either at the same time as counter0 or during the count down of the valid0 counter.
- If the counter1 reaches zero during the count down of the valid0 counter, then all the counters (counter0, valid0, counter1) are reloaded with their initial seed values once valid0 has also counted down to zero.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters also all get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

10.6.2.1.2.1.1 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0 and Counter1 all reach 0 without any error

Figure 10-1752. Clock0 Not Present - Results in an Error and Stops Counting

10.6.2.1.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0. Alternatively, the DCC can be programmed to stop counting when the down counter1 reaches 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot measurements of the frequency of a signal. This frequency could be an unknown for the application before the measurement.

Example Usage of Single-Shot Measurement Mode: Trimming the High-Frequency Low-Power Oscillator

A practical example of the usage of the spot measurement mode is in trimming the HF LPO (clock source # 5) using the main oscillator as a reference. This measurement sequence would proceed as follows:

- The application sets up the seed values for counter0 and valid0 for the duration of the measurement. Suppose the main oscillator frequency is 10 MHz and the intended duration of the measurement is 500 μ s. The application needs to configure a seed value of 5000.
- These 5000 counts need to be divided between the counter0 and the valid0 counters. The minimum value for the valid0 seed is 4, so the application can configure counter0 seed value as 4996 and the valid0 seed value as 4.
- Suppose the HF LPO frequency is truly unknown. In this case the application can choose the maximum allowed seed value for counter1. This increases the probability of counter0 and valid0 counting down while the counter1 has still not fully counted down to zero. The maximum allowed seed value for counter1 is 1048575.
- Once the DCC is enabled, the counters counter0 and counter1 both start counting down from their seed values.
- When counter0 reaches zero, it automatically triggers the valid0 counter.
- When valid0 reaches zero, if counter1 is not zero as well, an ERROR status flag is set and a "DCC error" is sent to the ESM. Counter1 is also frozen so that it stops counting down any further. The application can enable an interrupt to be generated from the ESM whenever this DCC error is indicated. Refer the device datasheet to identify the ESM group and channel where the DCC error is connected.
- The DCC error interrupt service routine can then check the value of counter1 when the error was generated. Suppose that the counter1 now reads 1044575. This means that counter1 has counted 1048575 - 1044575,

or 4000 cycles within the 500- μ s measurement period. This means that the average frequency of the HF LPO over this 500- μ s period was 4000 cycles / 500 μ s, or 8 MHz.

- The application then needs to clear the ERROR status flag and restart the DCC module so that it is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

The conditions that cause a DCC error are identical between the continuous monitoring mode and the single-shot measurement mode.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

Freezing Counters when Counter1 Reaches Zero:

The DCC module also allows the counters to be frozen when the counter1 reaches zero. This allows one of the clock sources for counter1 to be used as a reference for measuring one of the clock sources for counter0. The error conditions are the same as those where (counter0=0 and valid0=0) define the condition when the DCC counters are frozen. That is, an error is indicated if counter0 and valid0 become zero while counter1 is still non-zero. In this case, however, the application would typically set up the seed values such that the counter1 will become zero before counter0. Essentially the measurement period is defined by the seed value of the counter1. Note that this is also an error condition, and the interrupt service routine can use the measurement period and the actual cycles counted by counter1 to determine the frequency of the clock0 signal.

10.6.2.1.3 MSS DCC Integration

4-DCC modules have been instantiated in the SOC as part of MSS. Clocks to the module are mentioned in the following sections.

10.6.2.1.3.1 Input Clock sources

DSS_CLKSRC6_CLK	Counter 1 Clock Source	RCSS_SPIA_CLK
DSS_CLKSRC7_CLK	Counter 1 Clock Source	PLL_PER_HSDIV0_CLKOUT1

Refer to the interrupt and DMA tables for mapping of the IPs interrupts and DMA requests.

10.6.2.1.5 Clock Source Selection for Counter0 and Counter1

Refer the device datasheet to identify the available options for selecting the clock sources for both counters of the DCC module. Some microcontrollers may include multiple instances of the DCC module. This will also be identified in the device datasheet.

The selection of the clock sources for counter0 and counter1 is done by a combination of the KEY, CNT0 CLKSRC and CNT1 CLKSRC control fields of the CNT0CLKSRC and CNT1CLKSRC registers.

10.6.2.1.6 DCC Registers

Table 10-1862 lists the DCC memory-mapped registers. All register offset addresses not listed in Table 10-1862 should be considered as reserved locations and the register contents should not be modified.

Table 10-1862. DCC Registers

Offset	Acronym	Register Name	Section
0h	DCCGCTRL	DCCGCTRL	Section 10.6.2.1.6.1

Complex bit access types are encoded to fit into small table cells. Table 10-1863 shows the codes that are used for access types in this section.

Table 10-1863. DCC Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.6.2.1.6.1 DCCGCTRL Register (Offset = 0h) [reset = 5555h]

DCCGCTRL is shown in [Figure 10-1752](#) and described in [Table 10-1864](#).

Return to [Table 10-1862](#).

Starts / stops the counters clears the error signal

10.6.2.2 ECC_AGGREGATOR

This section describes the common ECC aggregator functionality.

10.6.2.2.1 ECC Aggregator Overview

To increase functional safety and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface

10.6.2.2.2 Integration Details

In TPR1x design, there are five ECC aggregators.

- MSS_ECC_AGG_R5A
- MSS_ECC_AGG_R5B
- MSS_ECC_AGG_MSS
- DSS_ECC_AGG
- HSM_ECC_AGGR (details will be available in HSM document)

This aggregator is used to fault inject all memory ecc_controllers and aggregate the errors to generate a single error to ESM.

10.6.2.2.3 ECC Aggregator Features

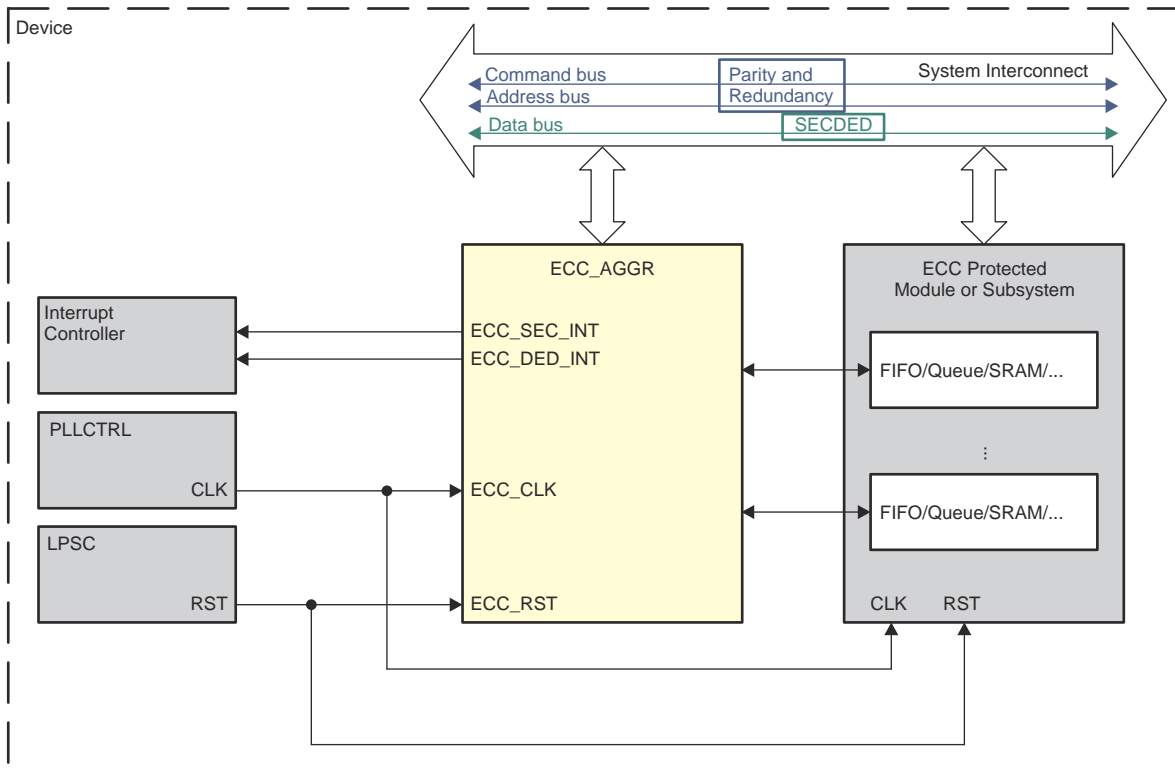

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error

- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- An ECC endpoint can be ECC RAM component.
- Detects single bit error via parity checking on:
 1. Memory mapped configuration interface FIFO
 2. Serial interface FIFO
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

10.6.2.2.4 ECC Aggregator Integration

This section describes ECC aggregator integration in the device, including information about clocks, resets, and hardware requests.

ecc-001

Note

For more information on the interrupts, see [Section 10.6.2.2.9](#).

For more information on the interconnects, see [Chapter 3](#).

For more information on the power, reset and clock management, see the corresponding sections in [Chapter 5](#).

For more information on the device interrupt controllers, see *Interrupt Controllers*.

10.6.2.2.5 ECC Aggregator Function Description

This section describes the architecture and functional details of the ECC aggregator.

10.6.2.2.5.1 ECC Aggregator Block Diagram

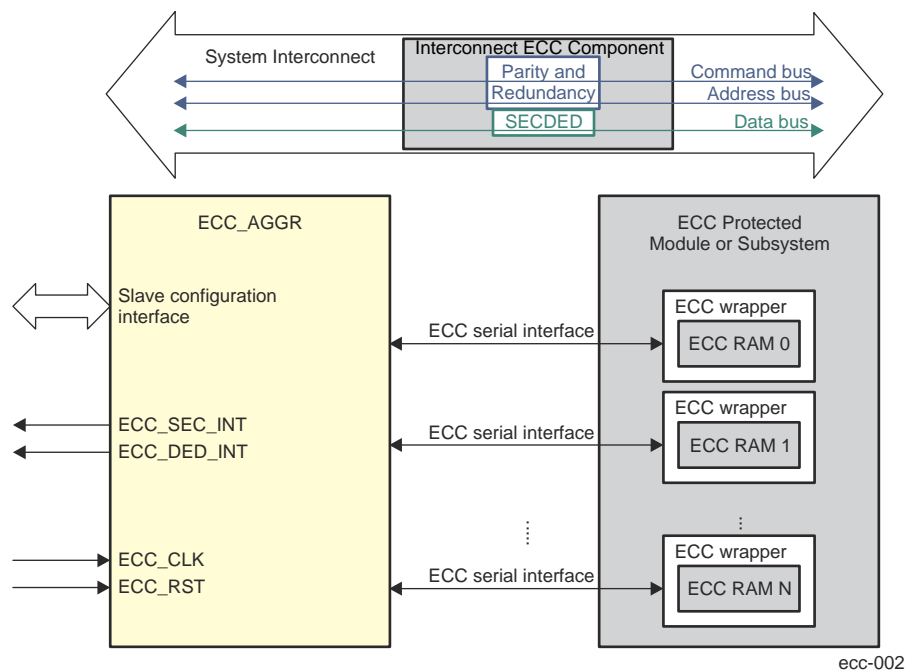

Figure 10-1765. ECC Aggregator Block Diagram

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software

access to all ECC related registers through its memory mapped slave configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

10.6.2.2.6 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC_VECTOR and ECC_REV registers. Each ECC endpoint has assigned a unique ID.

When this ID is written to the ECC_VECTOR[10-0] ECC_VECTOR field the corresponding endpoint is selected either for control or for status reading.

- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC_VECTOR[10-0] ECC_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in Section 12.9.4.3.3. These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers.

10.6.2.2.7 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

1. Software writes the following in the ECC_VECTOR register:
 - The ECC endpoint ID in the ECC_VECTOR[10-0] ECC_VECTOR field to select particular ECC endpoint.
 - The register read address in the ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field to select which register has to be read through the ECC serial interface.
 - A value of 0x1 in the ECC_VECTOR[15] RD_SVBUS bit to trigger read operation through the ECC serial interface.
2. Software polls the ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
3. Software reads the data from the register previously selected by the ECC_VECTOR[23-16]RD_SVBUS_ADDRESS field.

10.6.2.2.8 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

1. Software specifies the ECC endpoint ID in the ECC_VECTOR[10-0] ECC_VECTOR field. The ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field is a don't care but the ECC_VECTOR[15] RD_SVBUS bit must be set to 0x0.
2. Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

1. Write 0x0000 0008 to the ECC_VECTOR register.
2. Write 0x0000 000F to the ECC_CTRL register. This sends write request with data 0x0000 000F to the ECC_CTRL register associated with ECC RAM with ID = 8.

10.6.2.2.9 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC_SEC_INT) where hardware can correct the error but notifies the system in case of SEC.

- Non-correctable interrupt (ECC_DED_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
 - ECC_SEC_ENABLE_SET_REG0 for the correctable interrupt
 - ECC_DED_ENABLE_SET_REG0 for the noncorrectable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:
 - ECC_SEC_STATUS_REG0 for the correctable interrupt ECC_DED_STATUS_REG0 for the non-correctable interrupt
- Software performs serial read operations as described in Section 12.9.4.3.3 to read the following status registers that contain details about the error:
 - If the endpoint is ECC RAM:
 - ECC_ERR_STAT1
 - ECC_ERR_STAT2
 - ECC_ERR_STAT3
 - If the endpoint is interconnect ECC component:
 - ECC_CBASS_ERR_STAT1
 - ECC_CBASS_ERR_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC_ERR_STAT1 and ECC_ERR_STAT3 registers or in the ECC_CBASS_ERR_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.

The value of the *_PEND_CLR fields in the ECC_CBASS_ERR_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC_CBASS_ERR_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC_CBASS_ERR_STAT1 register should not be modified, write a value of 0x0 to that field.

- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
 - ECC_SEC_EOI_REG for the correctable interrupt
 - ECC_DED_EOI_REG for the non-correctable interrupt

10.6.2.2.10 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC_CBASS_CTRL[11-8] ECC_PATTERN). The ECC_CBASS_ERR_CTRL1 and ECC_CBASS_ERR_CTRL2 registers should be written first to setup the injection. Then, either the ECC_CBASS_CTRL[3] FORCE_SE or the ECC_CBASS_CTRL[4] FORCE_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC_CBASS_CTRL[5] FORCE_N_BIT bit should be set to 0x1. Once the FORCE_N_BIT is set, then each successive injection can simply write the ECC_CBASS_CTRL register to set the FORCE_SE or FORCE_DE again. Reading 0x0 from either the FORCE_SE or the FORCE_DE bit

indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

10.6.2.2.11 Errors

Each aggregator generates two errors which drive the ESM.

- <modulename>_SERR module names are mentioned in the below section
- <modulename>_SERR module names are mentioned in the below section

Group1 and Group2 mappings are found the ESM interrupt sections.

10.6.2.4 Error Signaling Module (ESM)

This section provides the details of the error signaling module (ESM) that aggregates device errors and provides internal and external error response based on error severity.

10.6.2.4.1 Overview

The Error Signaling Module (ESM) collects and reports the various error conditions on the microcontroller. The error condition is categorized based on a severity level. Error response is then generated based on the category of the error. Possible error responses include a low priority interrupt, high priority interrupt, and an external pin action.

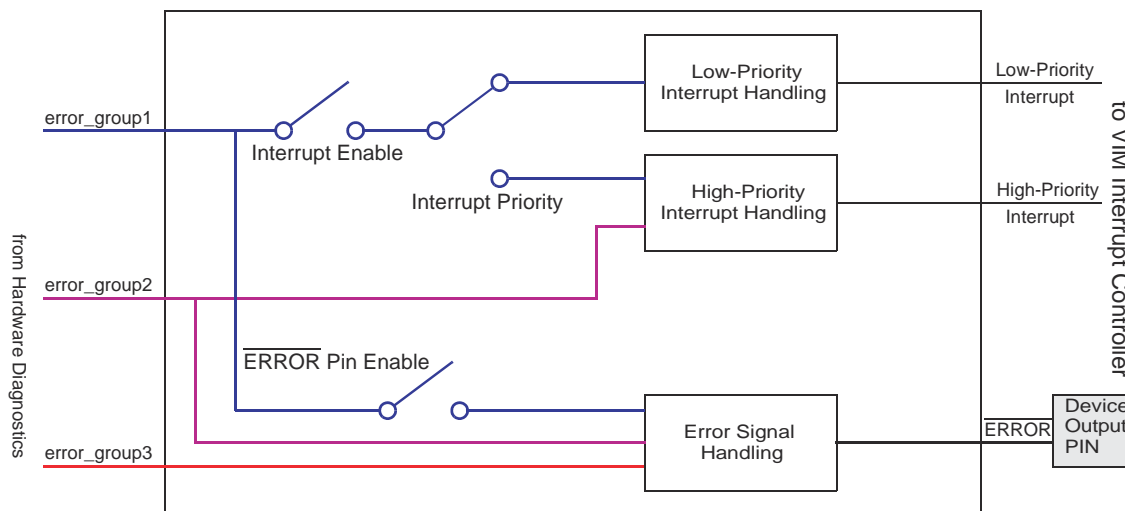

10.6.2.4.2 Feature List

- Up to 192 error channels (MSS/DSS) are supported, divided into 3 different groups:
 - 128 Group1 (low severity) channels with configurable interrupt generation and configurable $\overline{\text{ERROR}}$ pin behavior
 - 32 Group2 (high severity) channels with predefined interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior
 - 32 Group3 (high severity) channels with no interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior. These channels have no interrupt response as they are reserved for CPU based diagnostics that generate aborts directly to the CPU.
- Dedicated device $\overline{\text{ERROR}}$ pin to signal an external observer
- Configurable timebase for $\overline{\text{ERROR}}$ pin output
- Error forcing capability for latent fault testing

10.6.2.4.3 Block Diagram

As shown in [Figure 10-1854](#), the ESM channels are divided into three groups. Group1 channels are considered to be low severity. Group1 errors have a configurable interrupt response and configurable $\overline{\text{ERROR}}$ pin behavior. Note that the ESM Status Register 1 (ESMSR1) for error group 1 gets updated, regardless if the interrupt enable is active or not. Group2 channels are $\overline{\text{ERROR}}$ high severity. Group2 errors always generate a high priority interrupt and an output on the $\overline{\text{ERROR}}$ pin. Group3 errors are reserved for high severity errors generated by diagnostics which have already generated a CPU abort response. Because an abort response is generated, there is no need to generate an interrupt response. Group3 errors always generate an $\overline{\text{ERROR}}$ pin output.

The ESM interrupt and $\overline{\text{ERROR}}$ pin behavior are also summarized in [Table 10-1973](#).

Note that the ESM Status Register 1 (ESMSR1) for error_group1 gets updated, regardless if the interrupt enable is active or not.

Figure 10-1854. Block Diagram

Table 10-1973. ESM Interrupt and ERROR Pin Behavior

Error Group	Interrupt Generated	Interrupt Priority	ERROR Pin Response Generated
1	configurable interrupt	configurable priority	configurable output generation
2	interrupt generated	high priority	output generated
3	no interrupt	NA	output generated

Figure 10-1855 and Figure 10-1856 show the interrupt response handling and ERROR pin response handling with register configuration. The total active time of the ERROR pin is controlled by the Low-Time Counter Preload register (LTCP) and the key register (ESMEPSR) as shown in Figure 10-1856. See for details.

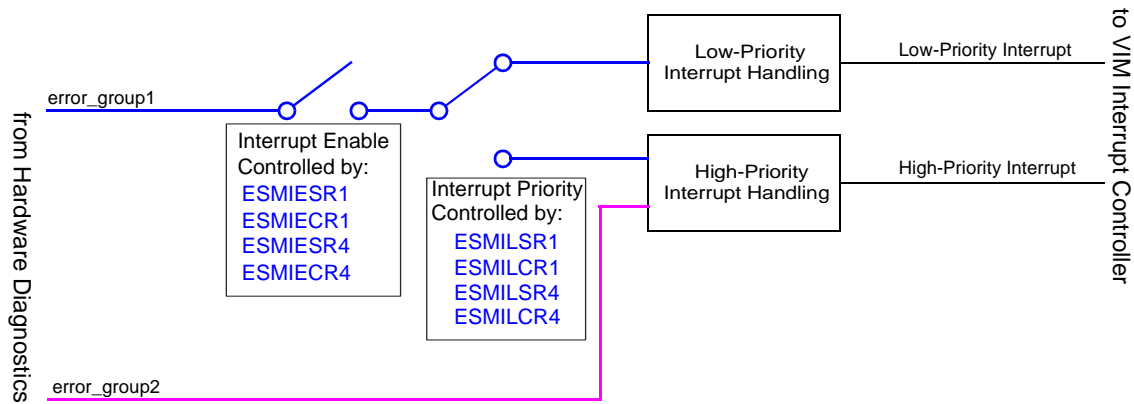

Figure 10-1855. Interrupt Response Handling

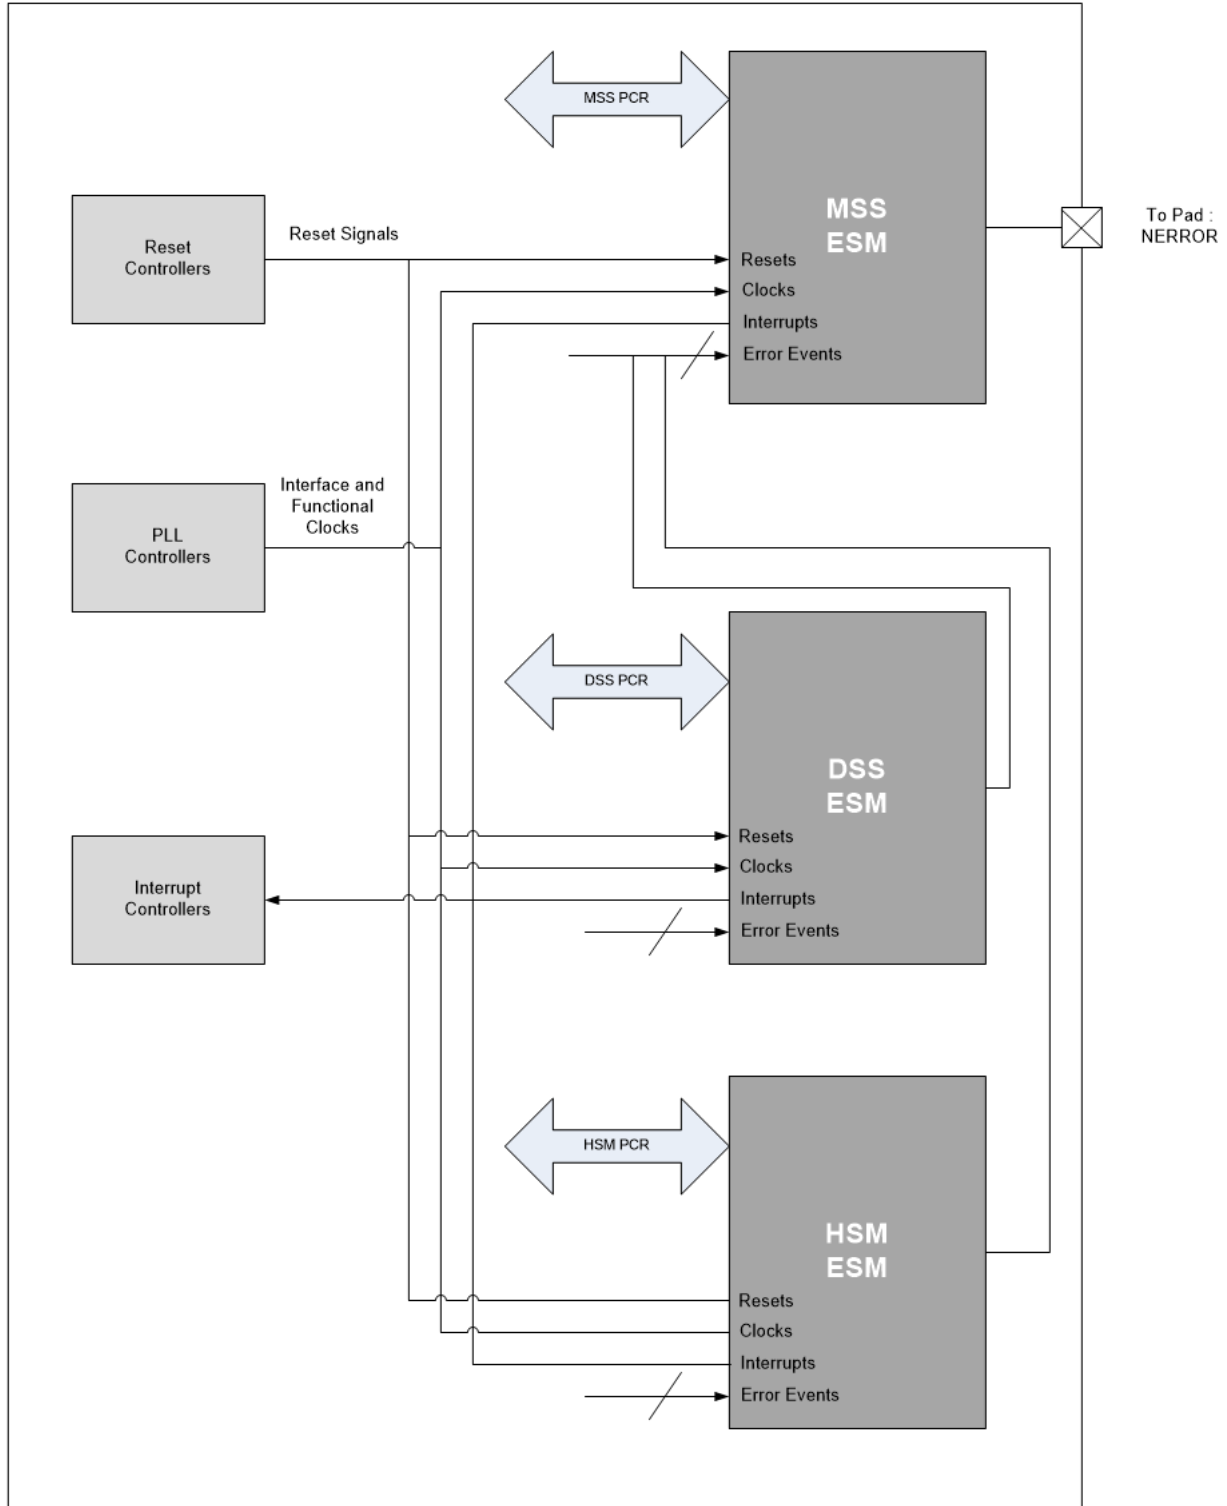

Figure 10-1857. ESM Block Diagram

10.6.2.4.5 Module Operation

This device has 192 error channels (MSS & DSS), divided into 3 different error groups. Please refer to the device datasheet for ESM channel assignment details.

The ESM module has error flags for each error channel. The error status registers ESMSR1, ESMSR4, ESMSR2, ESMSR3 provide status information on a pending error of Group1 (Channel 0-31), Group1 (Channel 32-63), Group1 (Channel 64-95), Group2, and Group3, respectively. The ESMEPSR register provides the current $\overline{\text{ERROR}}$ status. The module also provides a status shadow register, ESMSSR2, which maintains the error flags of Group2 until power-on reset ($\overline{\text{PORRST}}$) is asserted. See for details of their behavior during power on reset and warm reset.

Once an error occurs, the ESM module will set the corresponding error flags. In addition, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM error pin back to normal state. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR7, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

You can also test the functionality of the $\overline{\text{ERROR}}$ pin by forcing an error.

10.6.2.4.5.1 Reset Behavior

Power on reset:

- $\overline{\text{ERROR}}$ pin behavior

When nPORRST is active, the $\overline{\text{ERROR}}$ pin is in a high impedance state (output drivers disabled).

- Register behavior

After $\overline{\text{PORRST}}$, all registers in ESM module will be re-initialized to the default value. All the error status registers are cleared to zero.

Warm reset ($\overline{\text{RST}}$):

- $\overline{\text{ERROR}}$ pin behavior

During $\overline{\text{RST}}$, the $\overline{\text{ERROR}}$ pin is in “output active” state with pull-down disabled. The $\overline{\text{ERROR}}$ pin remains unchanged after $\overline{\text{RST}}$.

- Register behavior

After $\overline{\text{RST}}$, ESMSR1, ESMSR4, ESMSR7, ESMSSR2, ESMSR3 and ESMEPSR register values remains un-changed. Since $\overline{\text{RST}}$ does not clear the critical failure registers, the user can read those registers to debug the failures after $\overline{\text{RST}}$ pin goes back to high.

After $\overline{\text{RST}}$, if one of the flags in ESMSR1, ESMSR4 and ESMSR7 is set, the interrupt service routine will be called once the corresponding interrupt is enabled.

-

Note

ESMSR2 is cleared after $\overline{\text{RST}}$. The flag in ESMSR2 gets cleared when reading the appropriate vector in the ESMIOFFHR offset register. Reading ESMIOFFHR will not clear the ESMSR1, ESMSR4, ESMSR7 and the shadow register ESMSSR2. Reading ESMIOFFLR will also not clear the ESMSR1, ESMSR4 and ESMSR7.

10.6.2.4.5.2 $\overline{\text{ERROR}}$ Pin Timing

The $\overline{\text{ERROR}}$ pin is an active low function. The state of the pin is also readable from $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). A warm reset ($\overline{\text{RST}}$) does not affect the state of the pin. The pin is in a high-impedance state during power-on reset. Once the ESM module drives the $\overline{\text{ERROR}}$ pin low, it remains in this state for the time specified by the Low-Time Counter Preload register (LTCP). Based on the time period of the peripheral clock (VCLK), the total active time of the $\overline{\text{ERROR}}$ pin can be calculated as:

$$t_{\overline{\text{ERROR}}_low} = t_{VCLK} \times (LTCP + 1) \tag{16}$$

Once this period expires, the $\overline{\text{ERROR}}$ pin is set to high in case the reset of the $\overline{\text{ERROR}}$ pin was requested. This request is done by writing an appropriate key (0x5) to the key register (ESMEKR) during the $\overline{\text{ERROR}}$ pin low time. Here are a few examples:

Example 1: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. No $\overline{\text{ERROR}}$ pin reset is requested. The $\overline{\text{ERROR}}$ pin continues outputting low until power on reset occurs.

Figure 10-1858. $\overline{\text{ERROR}}$ Pin Timing - Example 1

Example 2: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received before $t_{\overline{\text{ERROR}}_low}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{\text{ERROR}}_low}$ expires.

Figure 10-1859. $\overline{\text{ERROR}}$ Pin Timing - Example 2

Example 3: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received after $t_{\overline{\text{ERROR}}_low}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $\overline{\text{ERROR}}$ pin reset request is received.

Figure 10-1860. $\overline{\text{ERROR}}$ Pin Timing - Example 3

Example 4: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. Another failure occurs within the time the pin stays low. In this case, the low time counter will be reset when the other failure occurs. In other words, $t_{\overline{\text{ERROR}}_low}$ should be counted from whenever the most recent failure occurs.

Figure 10-1861. $\overline{\text{ERROR}}$ Pin Timing - Example 4

Example 5: The reset of the $\overline{\text{ERROR}}$ pin was requested by the software even before the failure occurs. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{\text{ERROR}}_low}$ expires. This case is not recommended and should be avoided by the application.

Figure 10-1862. $\overline{\text{ERROR}}$ Pin Timing - Example 5

10.6.2.4.5.3 Forcing an Error Condition

The error response generation mechanism is testable by software by forcing an error condition. This allows testing the $\overline{\text{ERROR}}$ pin functionality. By writing a dedicated key to the error forcing key register (ESMEKR), the $\overline{\text{ERROR}}$ pin is set to low for the specified time. The following steps describe how to force an error condition:

1. Check $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). This register must be 1 to switch into the error forcing mode. Check $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). This register must be 1 to switch into the error forcing mode. The ESM module cannot be switched into the error forcing mode if a failure has already been detected in functional mode. The application command to switch to error forcing mode is ignored.
2. Write "1010b" to the error forcing key register (ESMEKR). After that, the $\overline{\text{ERROR}}$ pin should output low (error force mode). Once the application puts the ESM module in the error forcing mode, the $\overline{\text{ERROR}}$ pin cannot indicate the normal error functionality. If a failure occurs during this time, it gets still latched and the LTC is reset and stopped. The error output pin is already driven low on account of the error forcing mode. When the ESM is forced back to normal functional mode, the LTC becomes active and forces the $\overline{\text{ERROR}}$ pin low until the expiration of the LTC.
3. Write "0000" to the error forcing key register (ESMEKR) back to the active normal mode. If there are no errors detected while the ESM module is in the error forcing mode, the $\overline{\text{ERROR}}$ pin goes high immediately after exiting the error forcing mode.

10.6.2.4.6 Recommended Programming Procedure

During the initialization stage, the application code should follow the recommendations in [Figure 10-1863](#) to initialize the ESM.

Once an error occurs, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM back to normal state. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR7, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

10.6.2.5 Cyclic Redundancy Check (CRC)

This section describes the cyclic redundancy check (CRC) controller module. Presently two CRC modules have been instantiated in the TRP1x one for MSS and another for DSS.

10.6.2.5.1 Overview

The CRC controller is a module that is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into CRC controller. The responsibility of CRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. CRC controller supports two channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

10.6.2.5.2 Features

The CRC controller offers:

- Two channels to perform background signature verification on any memory sub-system.
- Data compression on 8, 16, 32, and 64-bit data size.
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial.
- Each channel has a CRC Value Register that contains the pre-determined CRC value.
- Use timed base event trigger from timer to initiate DMA data transfer.
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression.
- Three modes of operation. Auto, Semi-CPU and Full-CPU.
- For each channel, CRC can be performed either by CRC Controller or by CPU.
- Automatically perform signature verification without CPU intervention in AUTO mode.
- Generate interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself.
- Generate CRC fail interrupt in AUTO mode if signature verification fails.
- Generate Timeout interrupt if CRC is not performed within the time limit.
- Generate DMA request per channel to initiate CRC value transfer.

10.6.2.5.3 Block Diagram

[Figure 10-1894](#) shows a block diagram of the CRC controller.

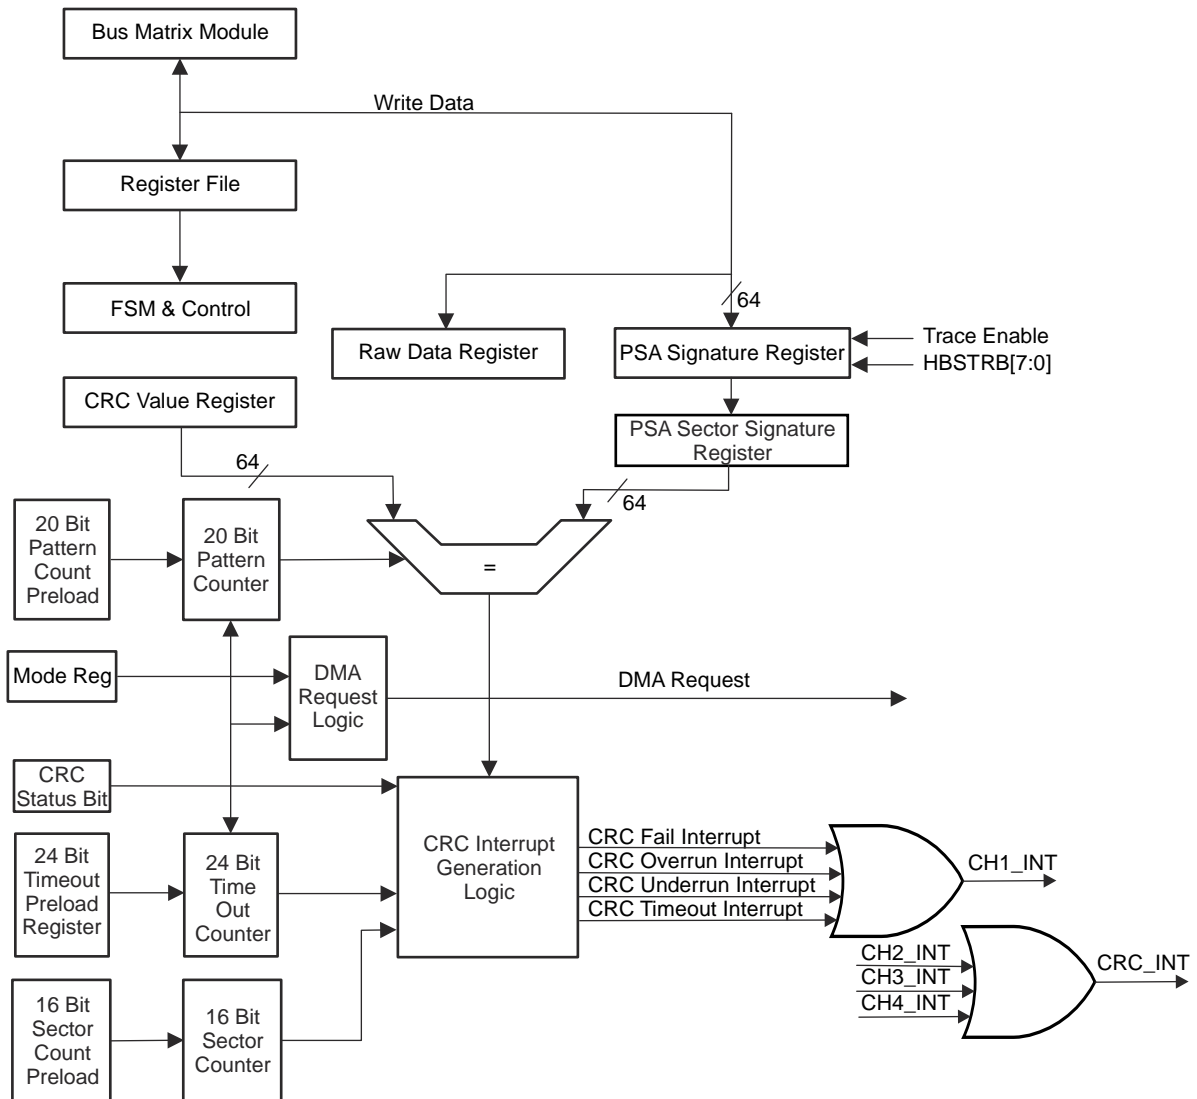

Figure 10-1894. CRC Controller Block Diagram For One Channel

10.6.2.5.4 Module Operation

10.6.2.5.4.1 General Operation

There are two channels in CRC controller, and for each channel there is a memory-mapped PSA (Parallel Signature Analysis) Signature Register and a memory-mapped CRC (Cyclic Redundancy Check) Value Register. A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be 8-, 16-, 32-, or 64-bit data. CRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory from which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated. A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by CRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self sustained CRC signature calculation can be achieved without any CPU intervention.

10.6.2.5.4.2 CRC Modes of Operation

CRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

10.6.2.5.4.2.1 AUTO Mode

In AUTO mode, CRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register and CRC Value Register are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to CPU. A 16-bit current sector ID register is provided to identify which sector causes a CRC failure.

10.6.2.5.4.2.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register. Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register, and compares it to a pre-determined CRC value.

10.6.2.5.4.2.3 Full CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register. After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

10.6.2.5.4.3 PSA Signature Register

The 64-bit PSA Signature Register is based on the primitive polynomial (as in the following equation) to produce the maximum length LFSR (Linear Feedback Shift Register), as shown in [Figure 10-1895](#).

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (17)$$

Figure 10-1895. Linear Feedback Shift Register (LFSR)

The serial implementation of LFSF has a limitation that, it requires 'n' clock cycles to calculate the CRC values for an 'n' bit data stream. The idea is to produce the same CRC value operating on a multi-bit data stream, as would occur if the CRC were computed one bit at a time over the whole data stream. The algorithm involves looping to simulate the shifting, and concatenating strings to build the equations after 'n' shift.

The parallel CRC calculation based on the polynomial can be illustrated in the following HDL code:

```

for i in 63 to 0 loop
  NEXT_CRC_VAL(0) := CRC_VAL(63) xor DATA(i);
  for j in 1 to 63 loop
    case j is
      when 1|3|4 =>
        NEXT_CRC_VAL(j) :=
          CRC_VAL(j - 1) xor CRC_VAL(63) xor DATA(i);
      when others =>
        NEXT_CRC_VAL(j) := CRC_VAL(j - 1);
    end case;
  end loop;
  CRC_VAL := NEXT_CRC_VAL;
end loop;
    
```

Note

- 1) The inner loop is to calculate the next value of each shift register bit after one cycle
- 2) The outer loop is to simulate 64 cycles of shifting. The equation for each shift register bit is thus built before it is compressed into the shift register.
- 3) MSB of the DATA is shifted in first

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHx_MODE bits. If CHx_MODE=Data Capture, a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

CRC Controller should be used in conjunction with the on chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA master. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After system reset and when AUTO mode is enabled, CRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register. After the comparison the CRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then CRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. The OS can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

CRC Controller supports doubleword, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zero's before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bit because a compressed value is always expressed in 64 bit.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

10.6.2.5.4.4 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the PSA Sector Signature Register. PSA Signature Register is a read only register. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will in the ISR read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enable to generate when overrun condition occurs. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

10.6.2.5.4.5 CRC Value Register

Associated with each channel there is a CRC Value Register. The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, CRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, CRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU should not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, CRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

CRC Controller supports doubleword, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bit.

10.6.2.5.4.6 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the Raw Data Register. This register is read only.

10.6.2.5.4.7 Example DMA Controller Setup

DMA controller needs to be setup properly in either either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

10.6.2.5.4.7.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register. The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register. The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 10-1896](#) a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, CRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the CRC_PCOUNT_REGx and the number of sectors in one block is programmed in the CRC_SCOUNT_REGx of the respective channel. CRC_PCOUNT_REGx multiplies CRC_SCOUNT_REGx and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that an HW DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 10-1896](#), an HW DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by CRC Controller.

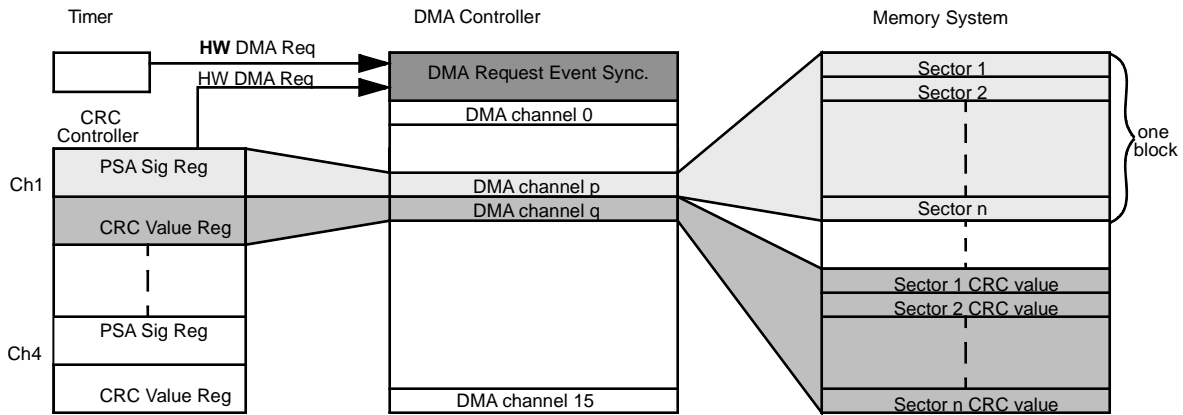

Figure 10-1896. AUTO Mode Using Hardware Timer Trigger

10.6.2.5.4.7.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. See Figure 10-1897 for an illustration.

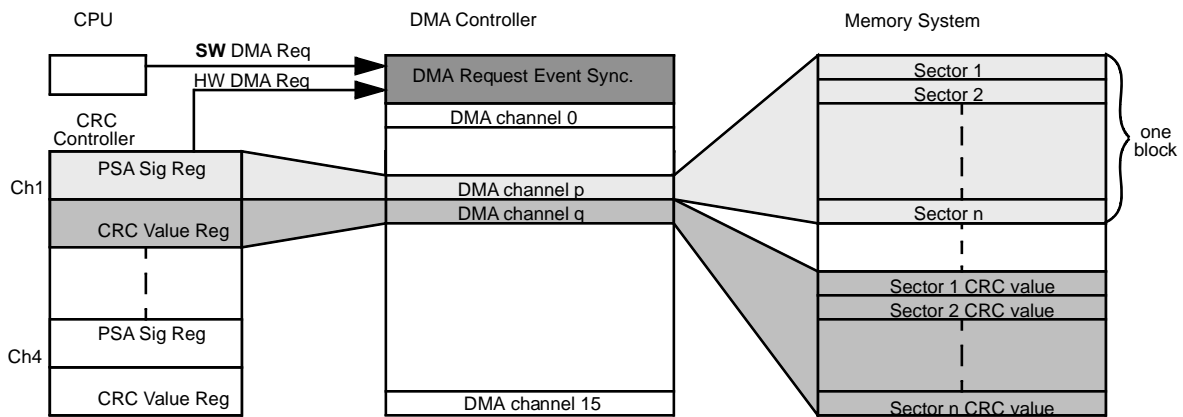

Figure 10-1897. AUTO Mode With Software CPU Trigger

10.6.2.5.4.7.3 Semi-CPU Mode Using Hardware Timer Trigger

During semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 10-1898](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

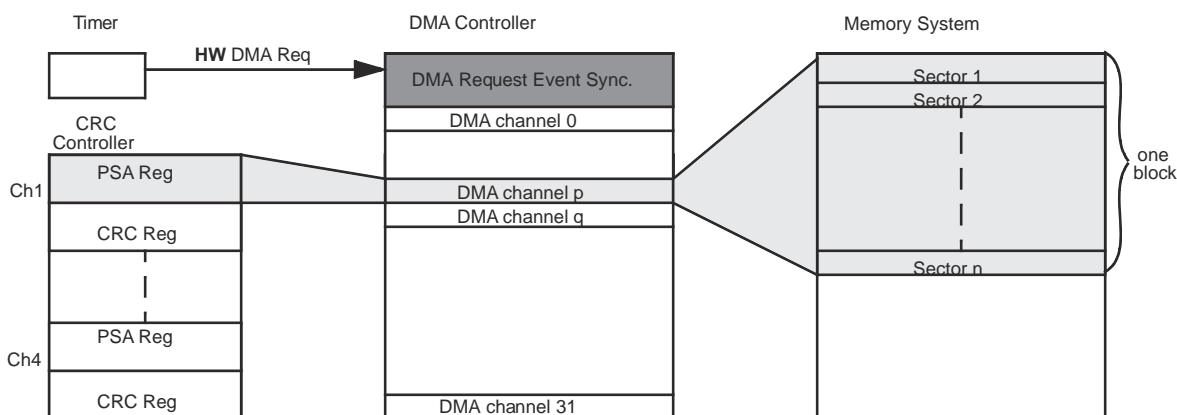

Figure 10-1898. Semi-CPU Mode With Hardware Timer Trigger

Table 10-2009. CRC Modes in Which DMA Request and Counter Logic are Active or Inactive

Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full-CPU	Inactive	Inactive	Inactive	Inactive

10.6.2.5.4.8 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register. When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

Note

The data pattern count should be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

10.6.2.5.4.9 Sector Count Register/Current Sector Register

Each channel contains a 16 bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register. If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure, it is advisable to use the following equation during CRC and DMA setup:

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count}$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

The current sector register is reset when the PSA software reset is enabled.

Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

10.6.2.5.4.10 Interrupt

The CRC controller generates several types of interrupts per channel. Associated with each interrupt, there is an interrupt enable bit. No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

Table 10-2010. Modes in Which Interrupt Condition Can Occur

	AUTO	Semi-CPU	Full-CPU
Compression Complete	no	yes	no
CRC Fail	yes	no	no
Overrun	yes	yes	no
Underrun	yes	no	no
Timeout	yes	yes	no

10.6.2.5.4.10.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated.

10.6.2.5.4.10.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set,. CPU should take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

10.6.2.5.4.10.3 Overrun Interrupt

Overrun interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register. If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register. If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

10.6.2.5.4.10.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, CRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

10.6.2.5.4.10.5 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24 bit timeout counter per CRC channel. The 24 bit timeout down counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (CRC_WDTPLDx) and block complete timeout pre-load value (CRC_BCTOPLDx). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of HCLK clock.

First pattern of data must be transferred by the DMA before the timeout counter expires, Watchdog timeout pre-load register (CRC_WDTPLDx) is used as timeout counter. Block complete timeout pre-load register (CRC_BCTOPLDx) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with CRC_WDTPLDx after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with CRC_BCTOPLDx the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with CRC_BCTOPLDx value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count x sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with CRC_WDTPLDx value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

In [Figure 10-1899](#), a timer generates DMA request every 10ms to trigger one block (pattern count x sector count) transfer. Since we want to make sure that DMA does start to transfer a block every 10 ms we would set the first pre-load value to 10ms in CRC_WDTPLDx. We also want to make sure that one block of data patterns are compressed within 4ms. With such a requirement, we would set the second pre-load value to 4ms in CRC_BCTOPLDx register.

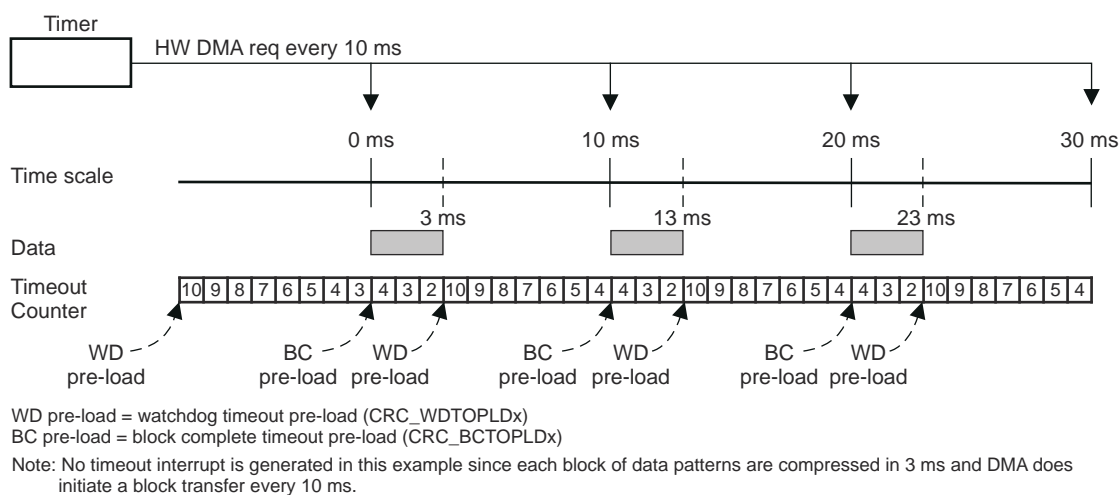

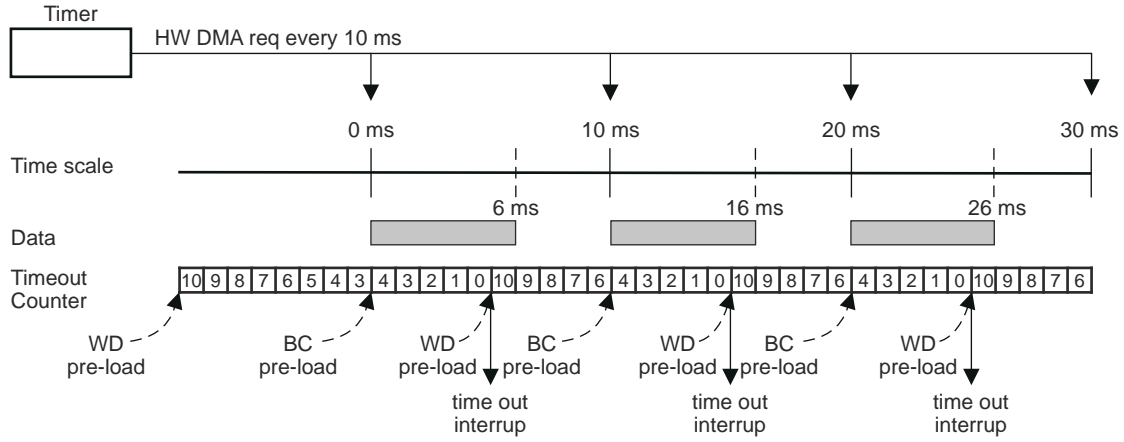

Figure 10-1899. Timeout Example 1

WD pre-load = watchdog timeout pre-load (CRC_WDTPLDx)
 BC pre-load = block complete timeout pre-load (CRC_BCTOPLDx)
 Note: Timeout interrupt is generated in this example since each block of data patterns are compressed in 6 ms and this is out of the 4ms time frame.

Figure 10-1900. Timeout Example 2

WD pre-load = watchdog timeout pre-load (CRC_WDTPLDx)
 BC pre-load = block complete timeout pre-load (CRC_BCTOPLDx)
 Note: Timeout interrupt is generated in this example since DMA can not transfer the second block of data within 10ms time limit and the reason may be that DMA is set up in fixed priority scheme and DMA is serving other higher priority channels at the time before it can service the timer request.

Figure 10-1901. Timeout Example 3

10.6.2.5.4.10.6 Interrupt Offset Register

CRC Controller only generates one interrupt request to interrupt manager. A interrupt offset register is provided to indicate the source of the pending interrupt with highest priority. [Table 10-2011](#) shows the offset interrupt vector address of each interrupt condition in an ascending order of priority.

Table 10-2011. Interrupt Offset Mapping

Offset Value	Interrupt Condition
0	Phantom
1h	Ch1 CRC Fail
2h	Ch2 CRC Fail
3h-8h	Reserved
9h	Ch1 Compression Complete
Ah	Ch2 Compression Complete
Bh-10h	Reserved
11h	Ch1 Overrun
12h	Ch2 Overrun
13h-18h	Reserved
19h	Ch1 Underrun
1Ah	Ch2 Underrun
1Bh-20h	Reserved
21h	Ch1 Timeout
22h	Ch2 Timeout
23h-24h	Reserved

10.6.2.5.4.10.7 Error Handling

When an interrupt is generated, host CPU should take appropriate actions to identify the source of error and restart the respective channel in DMA and CRC module. To restart a CRC channel, the user should perform the following steps in the ISR:

1. Write to software reset bit in CRC_CTRL register to reset the respective PSA Signature Register.
2. Reset the CHx_MODE bits to 00 in CRC_CTRL register as Data capture mode.
3. Set the CHx_MODE bits in CRC_CTRL register to desired new mode again.
4. Release software reset.

The host CPU should use byte write to restart each individual channel.

10.6.2.5.4.11 Power Down Mode

CRC module can be put into power down mode when the power down control bit PWDN is set. The module wakes up when the PWDN bit is cleared.

10.6.2.5.4.12 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading an interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No Peripheral Master bus error should be generated if reading from the unimplemented locations.

10.6.2.5.4.13 Peripheral Bus Interface

CRC is a Peripheral slave module. The register interface is similar to other peripheral modules. CRC supports following features:

- Different sizes of burst operation.
- Aligned and unaligned accesses.
- Abort is generated for any illegal address accesses.

10.6.2.5.5 Example

This section illustrates several of the ways in which the CRC Controller can be utilized to perform CRC.

10.6.2.5.5.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2Mbyte (256k doubleword) is to be checked in the background of CPU. CRC is to be performed every 1K byte (128 doubleword). Therefore there should be 2048 pre-recorded CRC values. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all DMA transfers are carried out in 64-bit transfer size.

10.6.2.5.5.1.1 DMA Setup

- Set up DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1 to trigger a **frame** transfer.
- Set up DMA channel 2 with the source address from which the contents of memory to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 2048. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use **hardware** DMA request for channel 2 to trigger an entire **block** transfer.

10.6.2.5.5.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Set up timer to generate DMA request associated with DMA channel 2. For example, an OS can set up the timer to generate a DMA request every 10ms.

10.6.2.5.5.1.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load (CRC_BCTOPLDx) value to 15625 (5 ms / (1 HCLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, CRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generate a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2Mbyte are consumed. If the timeout counter reached zero before the entire 2Mbytes are compressed a timeout interrupt is generated. After 2MBytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and CRC Controller. The CRC is performed totally without any CPU intervention.

10.6.2.5.5.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1kbytes is to be checked in the background of CPU. CRC is to be performed every 1Kbytes. Therefore there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all transfers carried out by DMA are in 64 bit transfer size.

10.6.2.5.5.2.1 DMA Setup

- Set up DMA channel 1 with the source address from which the pre-determined CRC value is stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1.
- Set up DMA channel 2 with the source address from which the memory area to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a **software** DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

10.6.2.5.5.2.2 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 1.
- Leaving the timeout count register with the reset value of zero means no timeout interrupt is generated.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, the CRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a **software** DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generates a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 again after one sector is compressed. After 1kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

10.6.2.5.5.3 Example: Semi-CPU Mode

If DMA controller is available in a system, the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controller generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2Mbyte is to be verified with the help of the CPU. CRC operation is to be performed every 1K byte. Since there are 2Mbyte (256k doublewords) of memory to be check and we want to perform a CRC every 1Kbyte (128 doublewords) and therefore there should be 2048 pre-recorded CRC values. In Semi-CPU mode, the CRC Value Register is not updated and contains indeterminate data.

10.6.2.5.5.3.1 DMA Setup

Set up DMA channel 1 with the source address from which the memory area to be verified are mapped. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

10.6.2.5.5.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

Set up timer to generate DMA request associated with DMA channel 1. For example, an OS can set up the timer to generate a DMA request every 10ms.

10.6.2.5.5.3.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load value to 15625 ($5 \text{ ms} / (1 \text{ HCLK period} \times 64)$) if CRC is operating at 200 MHz.
- Enable Semi-CPU mode and enable all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the PSA Signature Register, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the PSA Sector Signature Register. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2Mbyte are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from PSA Sector Signature Register before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

10.6.2.5.5.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2Mbyte is to be checked with the help of the CPU. CRC verification is to be performed every 1K byte. In CPU mode, the CRC Value Register is not updated and contains indeterminate data.

10.6.2.5.5.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the PSA Signature Register inside CRC Controller. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After **2MBytes** data patterns are compressed, CPU can read from the PSA Signature Register. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

10.6.2.5.6 MSS_MCRC Registers

Table 10-2012 lists the PCR_generated_memory_map registers. All register offset addresses not listed in Table 10-2012 should be considered as reserved locations and the register contents should not be modified.

Table 10-2023. CRC_CURSEC_REG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	CRC_CURSEC1	R/W	0h	Channel 1 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number.

10.6.2.5.6.12 CRC_WDTPD1 Register (Offset = 4Ch) [reset = 0h]

CRC_WDTPD1 is shown in [Figure 10-1911](#) and described in [Table 10-2024](#).

Table 10-2036. CRC_CURSEC_REG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	CRC_CURSEC2	R/W	0h	Channel 2 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number.

10.6.2.5.6.25 CRC_WDTPD2 Register (Offset = 8Ch) [reset = 0h]

CRC_WDTPD2 is shown in [Figure 10-1924](#) and described in [Table 10-2037](#).

- MSS_STC.STC_CLKDIV clock division features.

10.6.2.6.2 General Description

The enhanced Self-Test Controller (STC) is used to test logic cores based on the On-Product Multiple Input Signature Register (OPMISR) scan compression architecture.

Software-based self-test programs for the cores are available, but offer less test coverage. Due to the complexity of the soft cores, it is difficult to achieve the required coverage; also, the program size is larger.

For these complex cores, on-chip logic BIST support for the self-test is preferred.

The main features of this solution include:

- Implements the OPMISR controller, along with the on-chip self-test controller for the synthesizable module logic, which enables high test coverage.
- Can divide the complete test run into independent test sets (intervals).
- Capable of running the complete test, and running several intervals at a time.
- Can continue from the last executed interval (test set), and restart from the beginning (first interval in the ROM), or start from the first interval of each segment.

- A single self-test controller can support a test of up to 4 logical segments. A segment identifier corresponding to each interval is stored in the self-test ROM.
- The self-test controller facilitates complete isolation of the logical segment under the test from the rest of the system during the self-test run. Configure critical control signals in the master and slave ports of the logical segment under the test to a safe state.
- The self-tested CPU core master bus transaction signals are configured to be in idle mode during the self-test run.
- Can capture the failure interval number.
- Time-out counter for the self-test run as a fail-safe feature.
- Can read the MISR data (shifted from the OPMISR controller) of the last executed interval of the self-test run, for debugging purposes.
- Can capture power reduction using dead cycles before and after the capture pulse.
- Coverage improvements technique – ROM inverse access mode. In this, the patterns are read in a reverse order from ROM and applied to the UUT. Pattern randomization due to this approach results in coverage improvement, without an increase in the number of patterns. Corresponding INV_MISR is also stored in the ROM.

A self test segment corresponds to a portion of discreet safety-critical logic which can be tested in isolation from the rest of the system by the self test controller and OPMISR logic.

10.6.2.6.2.1 OPMISR Concept

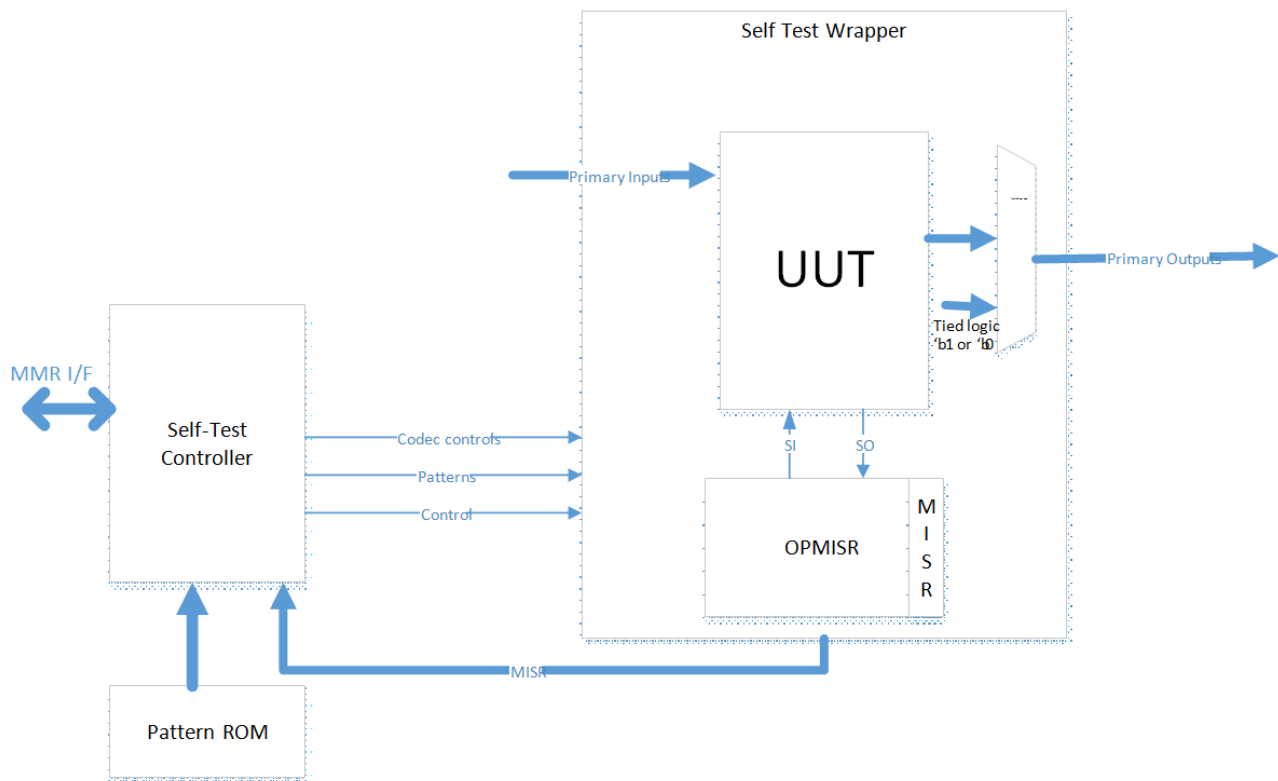

Figure 10-1964. OPMISR Conceptual Diagram

The On-Product Multiple-Input Signature Register (OPMISR) is a methodology which moves the test pattern generation on-chip. Logic BIST is implemented on functional partitions (BIST'ed COREs) that are speed-critical and have high gate count. A conceptual diagram of OPMISR implementation is shown in [Figure 10-1964](#).

The MISR test structure modifies the typical fullscan scan chain such that each scan data input internally drives many chains. These chains feed to the inserted MISR structure. The chain's values are captured into the MISR during shift, generating a resulting signature that can be shifted out.

A given Unit Under Test (UUT) is scan-inserted, and the scan chains are hooked to the OPMISR logic. The self-test wrapper created around the UUT and the OPMISR logic includes the isolation muxes for the output ports of the core, to ensure that the core and UUT are isolated from the rest of the system during the self-test.

10.6.2.6.3 Block Diagram

The STC module is composed of following blocks:

- ROM interface
- FSM and sequence control
- Register file
- STC bypass / ATE interface
- Peripheral bus interface (VBUSP interface)

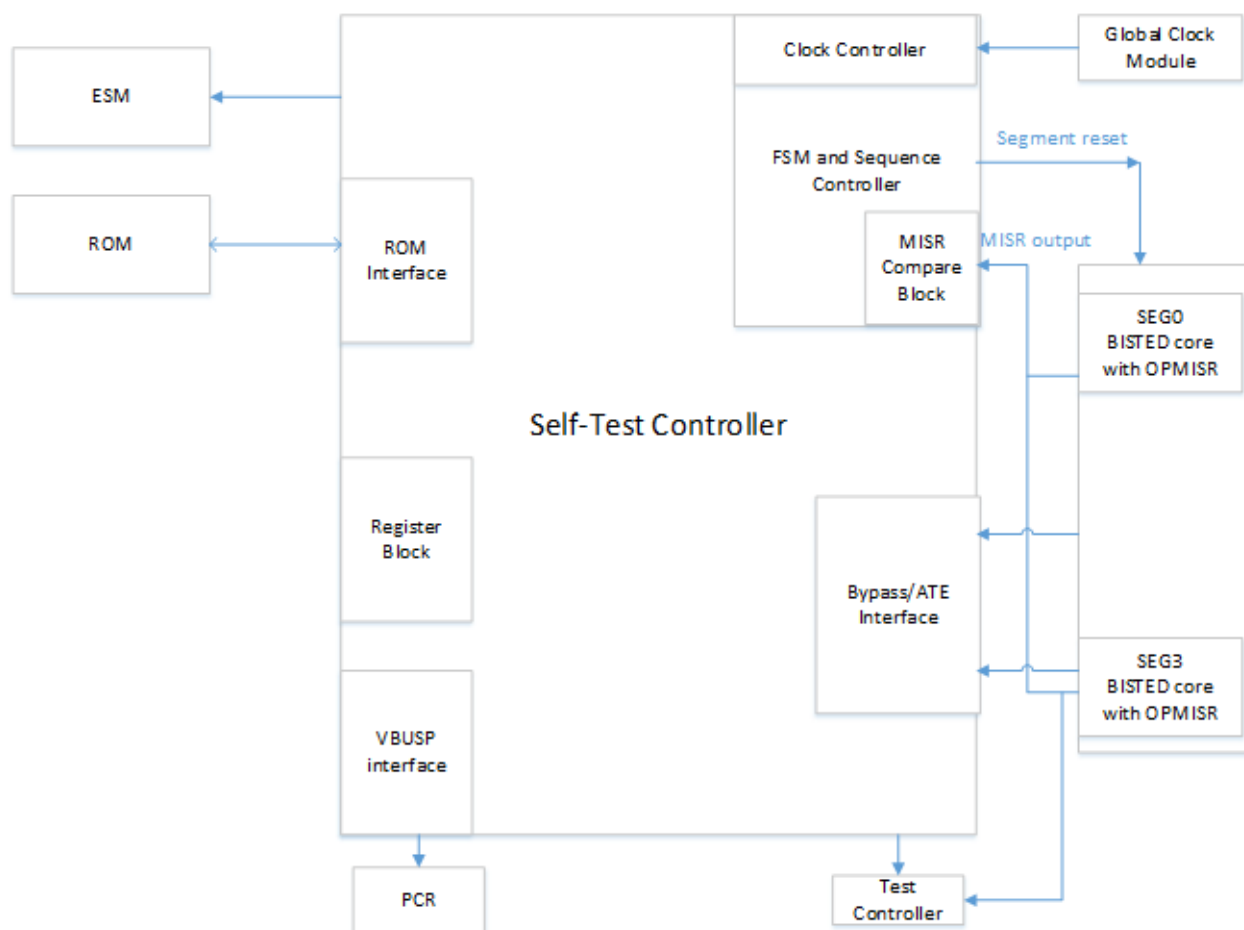

Figure 10-1965. Block Diagram for STC With Multiple Segments

10.6.2.6.4 Module Description

10.6.2.6.4.1 ROM Interface

This block handles the ROM address and control signal generation to read the self-test microcode from the ROM. The test microcode, patterns, and golden signature value for each interval is stored in ROM.

Detailed information of the ROM microcode is available at ROM.

10.6.2.6.4.2 FSM and Sequence Control

This block generates the signals and data to OPMISR controller based on the test type and scan chain depth. The sequence of operation per interval is defined in [Section 10.6.2.6.4.6](#).

10.6.2.6.4.2.1 Clock Control

The CLOCK CNTRL sub-block handles the clock selection and clock generation for ROM, OPMISR controller, and BIST'ed CORE clocks.

10.6.2.6.4.2.2 MISR Compare Block

At the end of the each self-test interval, an 896-bit MISR value from the OPMISR controller is shifted into NSTC. This is compared with the MISR_GOLDEN value, which is copied into a buffered register before the start of the interval. The result is updated into the status registers.

10.6.2.6.4.3 Register Block

This block implements the user-programmable control registers that determine when to start a self test, at what clock frequency the scan test should be performed, which segment to be selected for the test, how many pattern intervals to be completed before stopping, and so forth.

The register block also captures various status information of the self test for the user.

10.6.2.6.4.4 STC Bypass / ATE Interface

This is a production test interface. This section bypasses the self-test FSM. The OPMISR signal interface is brought out directly to the module ports, and these are accessible to the ATE (tester) at the device level using the test controller module. The intent of the block is to provide capability for fault isolation for parts failing the logic self test run.

This block receives two sets of signals; one from the device test controller, and another similar set from the self-test FSM (test sequencer). The bypass indicator signal is used to select one of the two sets of signals to be routed to the OPMISR controller.

10.6.2.6.4.5 VBUSP Interface

The control and the status registers of the STC module can be accessed through the VBUSP interface. During application programming, configuration registers are programmed through the peripheral interface, to enable and run the self-test controller.

CFG for interval 1, when rom_access_inversion =1 (same as when_rom_access_inversion =0)	Reserved	pattern_count[9:0]	Reserved	Reserved	Reserved	Seg_ID[1]	Seg_ID[0]	FT	TR_T

The ROM contains the data to be processed by STC for the self-test run. This includes the control fields such as Segment ID, Pattern Count, and Golden MISR value for the STC, and the pattern scan data for the OPMISR controller.

The ROM space is divided into chunks, with each chunk containing the data corresponding to one OPMISR interval. The size required for an interval varies depending on the number patterns packed into the interval and the length of internal scan chains required.

Because each interval requires 64 rows of ROM for storing control and Golden MISR values, minimizing the number of intervals by packing more patterns into each interval provides the best ROM size. This works best if the self-test must be run only as a part of the boot-up sequence. However, if the self-test is performed during

application IDLE time, the number of patterns that can be packed into each interval will be dictated by the IDLE time available for the self-test, because an interval is the smallest granularity of a self-test run.

Details of the ROM image micro-code fields are given in the following sections.

10.6.2.6.4.7.1 TR_T: Transition Delay Methodology Type

This specifies the transition delay methodology for the current transition delay interval.

0	Launch-on-System-Clock
1	Launch-on-Last-Shift

10.6.2.6.4.7.2 FT: Fault Model for the BIST Run

This specifies the fault model for the current interval of the test.

0	Stuck-at
1	Transition Delay

10.6.2.6.4.7.3 SEG_ID[1:0]

This indicates which logical segment is selected for the associated interval during the self-test run.

SEG_SEL[1:0]	Segment Under Test
00	Segment 0
01	Segment 1
10	Segment 2
11	Segment 3

10.6.2.6.4.7.4 Pattern Count (patt_count[9:0])

This specifies the number of scan data patterns within a self-test interval. The pattern counts can vary from a minimum of 2 to a maximum of 1024.

patt_count[9:0]	Patterns per Interval
00_000_0000	Not a valid interval [defaults to 2 patterns per interval]
00_000_0001	2 patterns per interval
00_000_0010	3 patterns per interval
...	...
11_111_1110	1023 patterns per interval
11_111_1111	1024 patterns per interval

10.6.2.6.4.7.5 MISR_GOLDEN[895:0]: Golden Signature Data Bits

This part of ROM contains the golden signature data of the current interval. This value is used to compare with the actual MISR value, when ST_GCR1.ROM_ACCESS_INV=0 and ST_GCR1.LP_SCAN_MODE=0, to generate the pass/fail information of the interval.

10.6.2.6.4.7.6 LP_MISR_GOLDEN[895:0]: Low Power Mode Golden Signature Data Bits

This part of ROM contains the LP golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=0 and STCGCR1.LP_SCAN_MODE=1, to generate the pass/fail information of the interval.

10.6.2.6.4.7.7 INV_MISR_GOLDEN[895:0]: Inverse Mode Golden Signature Data Bits

This part of ROM contains the inverse mode golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=1 and STCGCR1.LP_SCAN_MODE=0, to generate the pass/fail information of the interval.

10.6.2.6.4.7.8 LP_INV_MISR_GOLDEN[895:0]: Low Power Inverse Mode Golden Signature Data Bits

This part of ROM contains the low-power inverse mode golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=1 and STCGCR1.LP_SCAN_MODE=1, to generate the pass/fail information of the interval.

10.6.2.6.4.7.9 Pn_SDm[7:0] (n - no. of patterns, m - scan chain length): OP-MISR Scan Data

This part of the ROM contains the scan data corresponding to each pattern. Each interval can have n number of scan patterns, as defined in the patt_count field. The number of 7bits of scan data in a pattern is equal to the length of the scan chain formed inside the UUT.

10.6.2.6.5 STC Registers

Table 10-2077 lists the memory-mapped registers for the STC. All register offset addresses not listed in Table 10-2077 should be considered as reserved locations and the register contents should not be modified.

Table 10-2077. STC Registers

Table 10-2079. STCGCR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	INTCOUNT_B16	R/W	1h	Number of intervals of the self test run (RWP - Read, Privilege Mode Write only) Count of intervals that need to be covered for a specific selftest run. The selftest controller sends out "complete" indication once it runs all of the intervals programmed in this field. INTCOUNT_B16=0 is an invalid configuration for a selftest.
15-11	NU0	R	0h	Reserved bits
10-8	CAP_IDLE_CYCLE	R/W	1h	Idle cycles before and after capture clock (RWP - Read, Privilege Mode Write only) Idle Cycles before and after capture clock. This value is used to insert that many idle cycles in the Capture phase. Programmable idle cycles allow implementation flexibility on SCAN_EN signal at chip level based on the size of the UUT and timing requirements.
7-5	SCANEN_HIGH_CAP_IDLE_CYCLE	R/W	1h	Idle cycles before and after capture clock (RWP - Read, Privilege Mode Write only). *NOT BYTE ACCESSIBLE Idle Cycles between scan_en going high to func_clk_en generation and scan_en going high to misr_log_en generation. This value is used to insert that many idle cycles in the shift clock (scan_en going high to func_clk_en generation) and misr_log_clk (scan_en going high to misr_log_en generation) generation. Programmable idle cycles allow implementation flexibility on SCAN_EN signal at chip level based on the size of the UUT and timing requirements.
4-2	NU1	R	0h	Reserved bits

Table 10-2079. STCGCR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RS_CNT_B1	R/W	0h	Restart/Continue or preload (RWP - Read, Priviledge Mode Write only) This bit specifies the selftest controller whether to continue the run from next interval onwards, restart from ROM address 0 or preload from a prescribed interval. This bit gets reset after the completion of selftest run. 00 = Continue NSTC run from previous interval 01 = Restart NSTC run from ROM address 0 1X = Start from segment number specified in STC_SEGPLR register

10.6.2.6.5.2 STCGCR1 Register (Offset = 4h) [reset = 25h]

STCGCR1 is shown in [Figure 10-1967](#) and described in [Table 10-2080](#).

Return to [Table 10-2077](#).

TO_PRELOAD																															
R/W-FFFFFFFh																															

Table 10-2081. STCTPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TO_PRELOAD	R/W	FFFFFFFh	Self test time out preload (RWP - Read, Priviledge Mode Write only) This register contains the total number of STC clock cycles it will take before a self-test timeout error will be triggered after the initiation of the self-test run. This is a fail safe feature to avoid system hang-up situation on account of any run away self test issues. This register should be loaded with a meaningful count value for this feature to be effective. This register value (preload count value) gets loaded into the self test timeout down counter whenever a self test run is initiated (ST_ENA is enabled). and gets disabled on completion of a self test run.

10.6.2.6.5.4 STC_CADDR Register (Offset = Ch) [reset = 0h]

STC_CADDR is shown in [Figure 10-1969](#) and described in [Table 10-2082](#).

Return to [Table 10-2077](#).

10.6.2.7 Programmable Built-In Self-Test (PBIST)

This section describes the programmable built-in self-test (PBIST) controller module used for testing the on-chip memories.

10.6.2.7.1 Overview

The PBIST (Programmable Built-In Self-Test) controller architecture provides a run-time-programmable memory BIST engine for varying levels of coverage across many embedded memory instances.

Name	Frame Address (Hex) Start	Frame Address (Hex) End	Size	Description
TOP_PBIST	0x02F7_9500	0x02F7_95CC	204B	PBIST module configuration registers. This IP covers memory test for all memories excluding DSP L1P, L1D and associated TAG memories
DSS_DSP_PBIST	0x06F7_9100	0x06F7_91CC	204B	PBIST module configuration registers. This IP covers memory test for all memories excluding DSP L1P, L1D and associated TAG memories

10.6.2.7.1.1 PBIST vs. Application Software-Based Testing

The PBIST architecture consists of a small coprocessor with a dedicated instruction set targeted specifically toward testing memories. This coprocessor executes test routines stored in the PBIST ROM and runs them on multiple on-chip memory instances. The on-chip memory configuration information is also stored in the PBIST ROM.

The PBIST Controller architecture offers significant advantages over tests running on the main processor (application software-based testing):

- Embedded CPUs have a long access path to memories outside the tightly-couple memory sub-system, while the PBIST controller has a dedicated path to the memories specifically for the self-test

- Embedded CPUs are designed for their targeted use and are often not easily programmed for memory test algorithms.
- The memory test algorithm code on embedded CPUs is typically significantly larger than that needed for PBIST.
- The embedded CPU is significantly larger than the PBIST controller.

10.6.2.7.1.2 PBIST Block Diagram

Figure 10-2039 illustrates the basic PBIST blocks and its wrapper logic for the device.

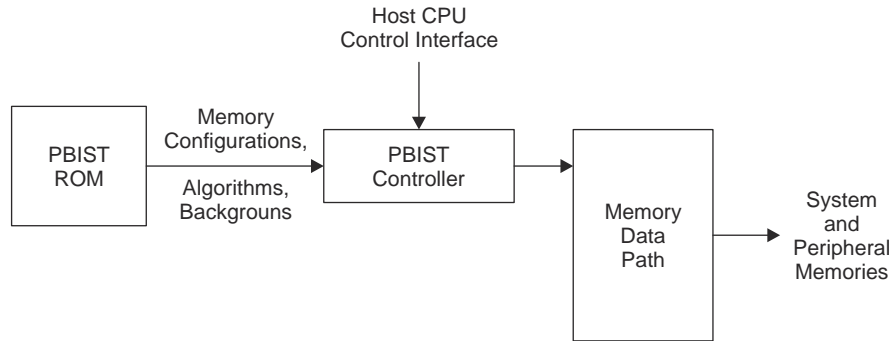

Figure 10-2039. PBIST Block Diagram

10.6.2.7.1.2.1 On-chip ROM

The on-chip ROM contains the information regarding the algorithms and memories to be tested.

10.6.2.7.1.2.2 Host Processor Interface to the PBIST Controller Registers

The CPU can select the algorithm and RAM groups for the memories' self-test from the onchip ROM based on the application requirements. Once the self-test has executed, the CPU can query the PBIST controller registers to identify any memories that failed the self-test and to then take appropriate next steps as required by the application's author.

10.6.2.7.1.2.3 Memory Data Path

This is the read and write data path logic between different system and peripheral memories tightly coupled to the PBIST memory interface. The PBIST controller executes each selected algorithm on each valid memory group sequentially until all the algorithms are executed.

Note

NOTE: Not all algorithms are designed to run on all RAM groups. If an algorithm is selected to run on an incompatible memory, this will result in a failure. Refer to and for RAM grouping and algorithm information.

10.6.2.7.2 RAM/ROM Grouping and Algorithm

10.6.2.7.2.1 RAM Algorithm: March13N

This section provides a brief description for some of the test algorithms used for memory self-test.

-

- **March13N:**

- March13N is the baseline test algorithm for SRAM testing. It provides the highest overall coverage.

The other algorithms provide additional coverage of otherwise missed boundary conditions of the SRAM operation.

- The concept behind the general march algorithm is to indicate:

- The bits around the bit cell do not affect the bit cell.
- The bit cell can be written and read as both a 1 and a 0.

- The basic operation of the march is to initialize the array to a know pattern, then march a different pattern through the memory.

- Type of faults detected by this algorithm:

- Address decoder faults
- Stuck-At faults
- Coupled faults
- State coupling faults
- Parametric faults
- Write recovery faults
- Read/write logic faults

10.6.2.7.2.2 Read/write logic faults

The triple read reads the array, all the way through, three times while summing the reads to compare the sums for all three read formats. The algorithm checks if there is enough margin in both the erasure and programming to operate at full speed with the CPU. This can be addressed with the XOR Read (Memory Contents XOR Memory Address). An error in the XOR Read indicates that the interaction between adjacent bit cells, being a different polarity, may be causing speed issues when the CPU exercises worstcase instruction sequencing. Each read can be performed on any memory block, and an associated checksum is calculated to determine PASS or FAIL.

Type of faults detected by this algorithm:

- Address decoder faults
- Stuck-At faults
- Coupled faults
- State coupling faults
- Parametric faults
- Read logic faults

10.6.2.7.2.3

Note

March13N is the most recommended algorithm for the memory self-test

10.6.2.7.3 PBIST Registers

Table 10-2150 lists the memory-mapped registers for the PBIST. All register offset addresses not listed in Table 10-2150 should be considered as reserved locations and the register contents should not be modified.

Table 10-2150. PBIST Registers

Offset	Acronym	Register Name	Section

10.7 Audio Interfaces

10.7.1 Multichannel Audio Serial Port (McASP)

This section describes the multichannel audio serial port (McASP).

10.7.1.1 McASP Overview	4659
10.7.1.2 McASP Environment	4662
10.7.1.3 McASP Integration	4673
10.7.1.4 McASP Functional Description	4677
10.7.1.5 McASP Low-Level Programming Model	4715
10.7.1.6 McASP Register Manual	4736

10.7.1.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

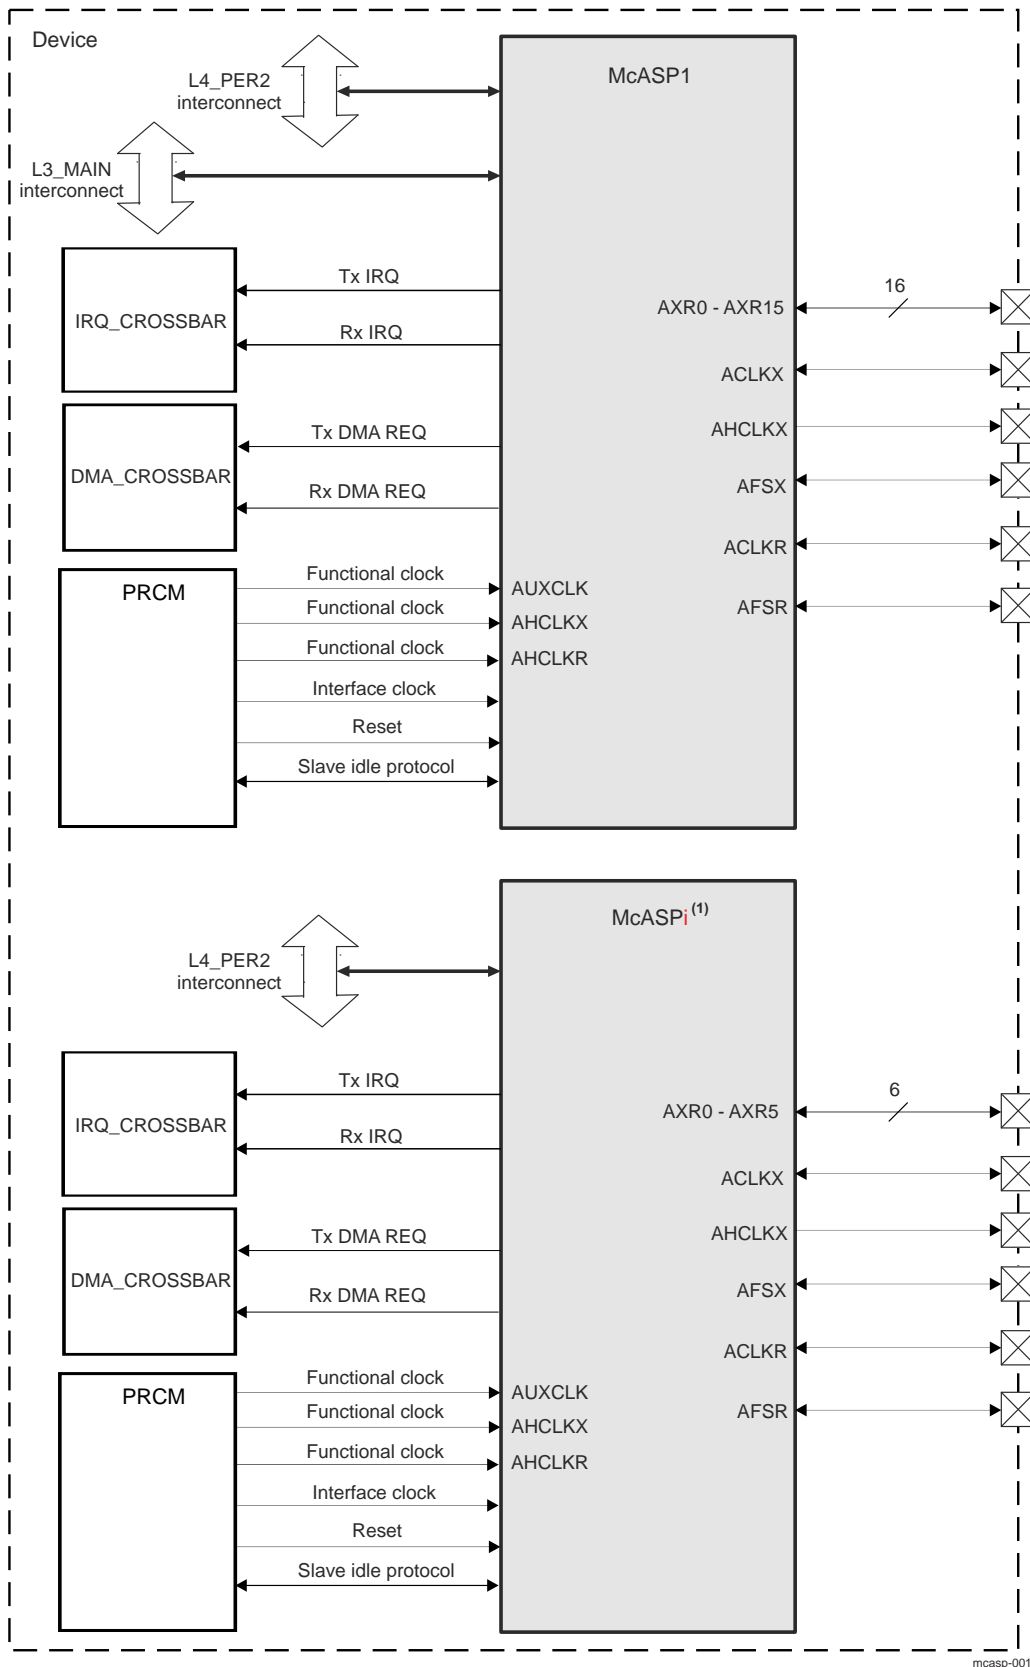

The device have integrated three McASP modules with:

- McASP1 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP2 and McASP3 support up to 6 channels with independent TX/RX clock/sync domain. McASP2 and McASP3 are introduced in silicon revision SR2.0.

Note

There is only one McASP module on SR1.0 devices called McASP. On SR2.0, there are three McASP modules called McASP1, McASP2 and McASP3. McASP1 in SR2.0 is the McASP module in SR1.0.

[Figure 10-2052](#) shows the McASP modules in the device.

A. $i = 2$ and 3 (SR2.0 Only)

Figure 10-2052. McASP Modules Overview

McASP module includes the following main features:

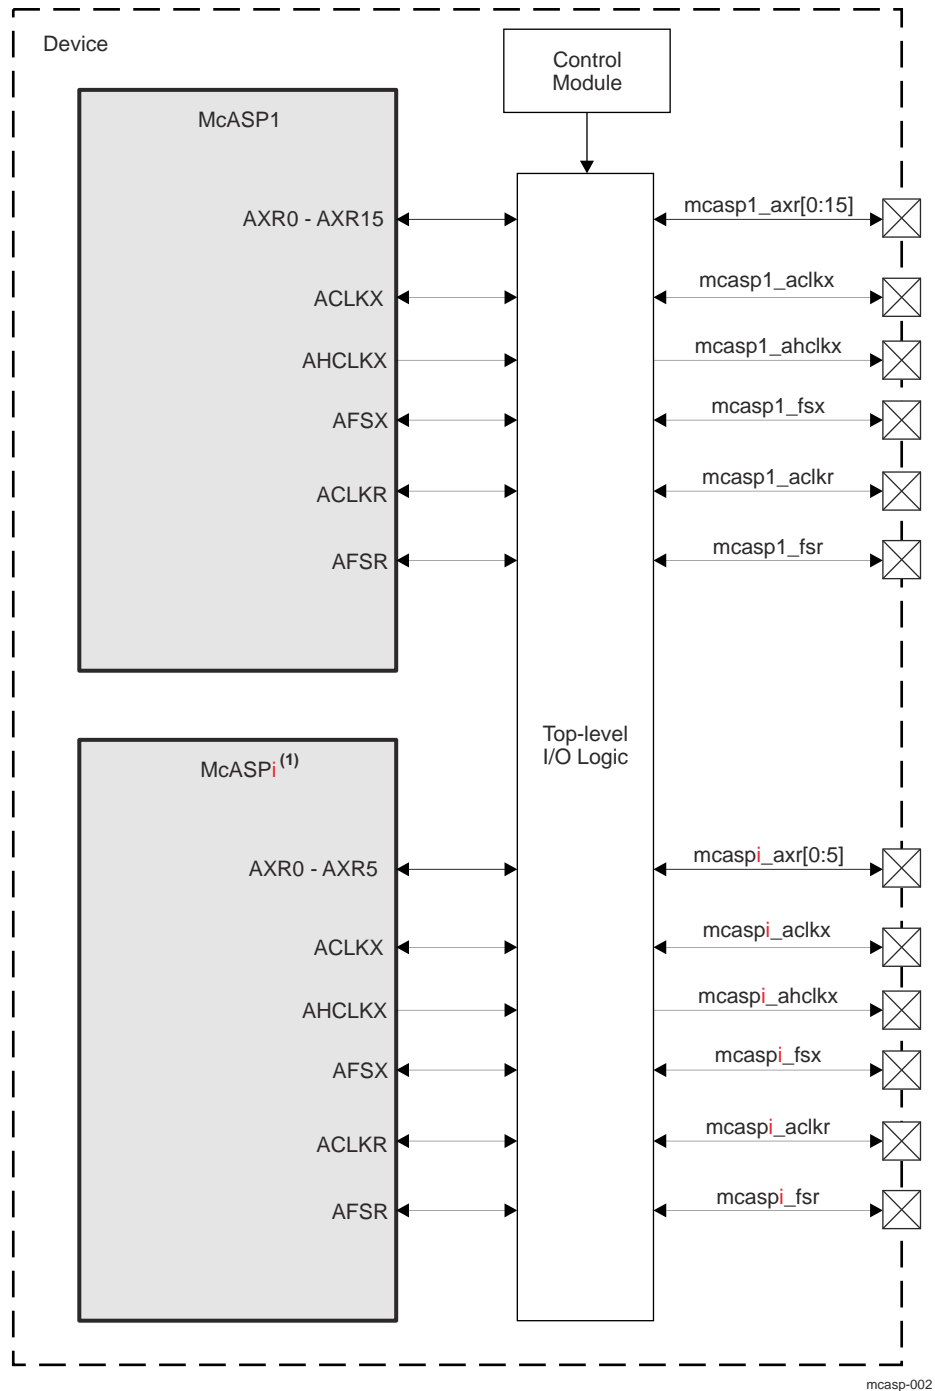

- McASP1 supports up to 16 channels and independent TX/RX clock/sync domains.
- Two modules (McASP2 and McASP3) supporting up to 6 channels each and independent TX/RX clock/sync domains. McASP2 and McASP3 are introduced with SR2.0.
- Independent serializer for each AXRx channel.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
 - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
 - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
 - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
 - internally (master mode)
 - supplied over McASP serial interface (slave mode)
 - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
 - Programmable clock and frame sync generator.
 - TDM streams from 2 to 32, and 384 time slots.
 - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
 - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
 - S/PDIF, IEC60958-1, AES-3 formats.
 - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
 - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
 - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
 - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
 - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

Note

Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

10.7.1.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 10-2053 shows the McASP modules in their environment in the device.

A. $i = 2$ and 3 (SR2.0 Only)

Figure 10-2053. McASP Environment

Note

There is only one McASP module in SR1.0 devices called McASP and equal to McASP1 in SR2.0.

10.7.1.2.1 McASP Signals

Table 10-2164 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 10-2164. McASP I/O Signals

Module Pin Name	Device Level Signal Name	I/O ⁽¹⁾	Description	Module Pin Reset Value

Table 10-2164. McASP I/O Signals (continued)

Module Pin Name	Device Level Signal Name	I/O ⁽¹⁾	Description	Module Pin Reset Value
AXR3	mcasp3_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp3_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp3_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
ACLKX	mcasp3_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	mcasp3_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp3_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp3_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp3_fsr	I/O	Receive frame synchronization	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

Note

For the mcasp_x_aclkx, mcasp_x_ahclkx and mcasp_x_aclkr signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the *Pad Configuration Registers and Control Module Register Manual* in *Control Module*.

Note

Except the pad configuration registers, additional Control Module registers have to be configured to map McASP2 and McASP3 signals to the device pads. The MUXMODE field of the corresponding pad configuration register has to be set to 0xF and the corresponding bit in CTRL_CORE_SMA_SW_14 and CTRL_CORE_SMA_SW_15 has to be set to 0x1.

Note

A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP_XRSRCTLn.

10.7.1.2.2 Protocols and Data Formats

10.7.1.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
 - Automatically aligns data internally in either Q31 or integer formats.
 - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

Note

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

Note

The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

Note

An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

10.7.1.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 10-2054](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. [Figure 10-2054](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

A word is a group of bits that make up the data being transferred between the McASP and the external device. [Figure 10-2054](#) shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In [Figure 10-2054](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. [Figure 10-2055](#) shows these options.

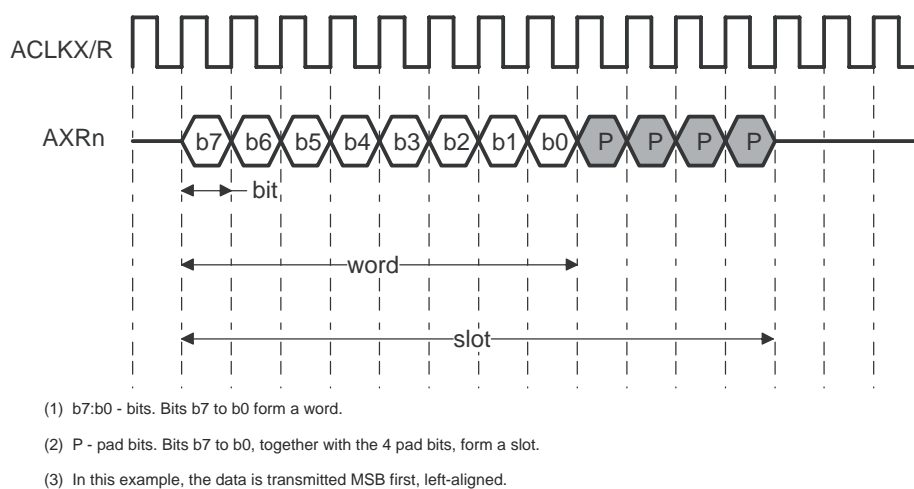

Figure 10-2054. Definition of Bit, Word, and Slot

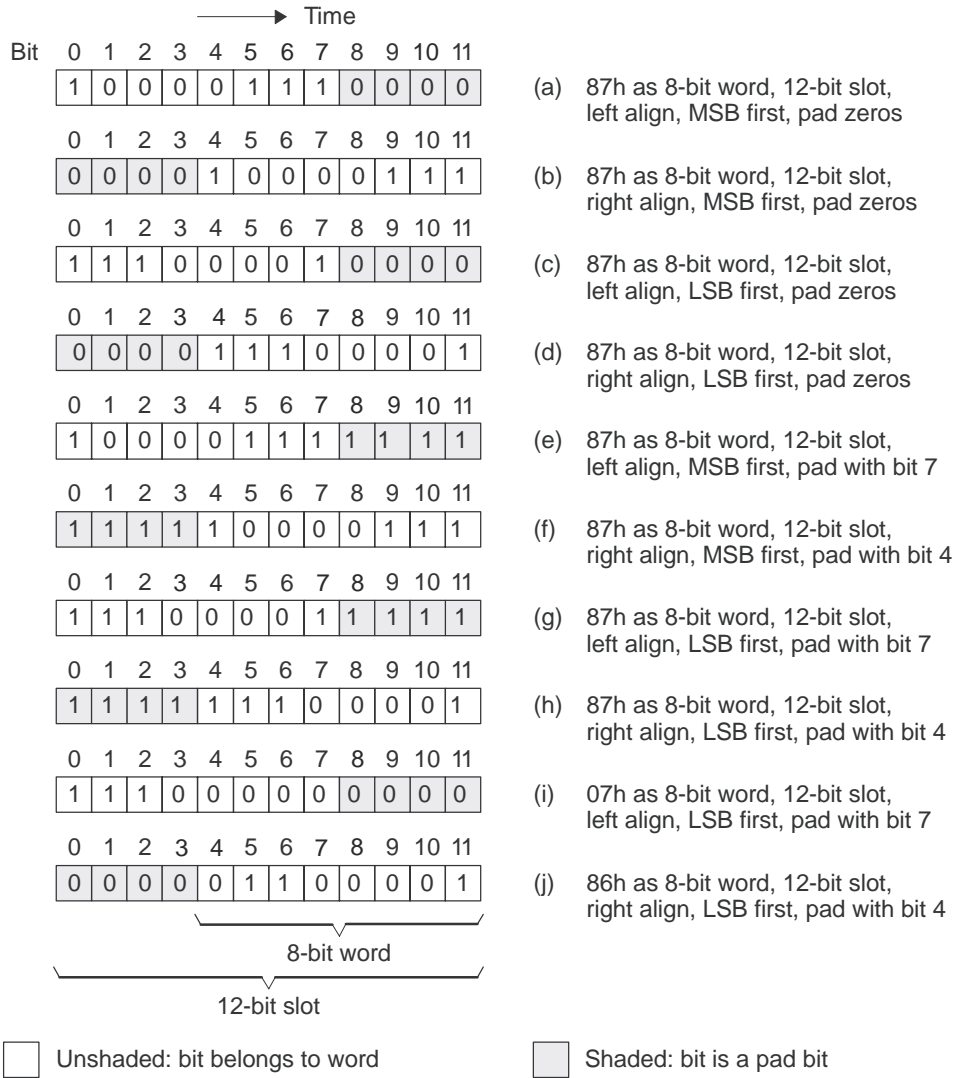

Figure 10-2055. Bit Order and Word Alignment Within a Slot Examples

• Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 10-2056](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. [Figure 10-2056](#) does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see [Section 10.7.1.2.2.3, TDM Format](#) and [Section 10.7.1.2.2.5, S/PDIF-Coding Format](#).

Note

All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

- AHCLKX, ACLKX, and AFSX for the transmitting section
- ACLKR and AFSR for the receiving section

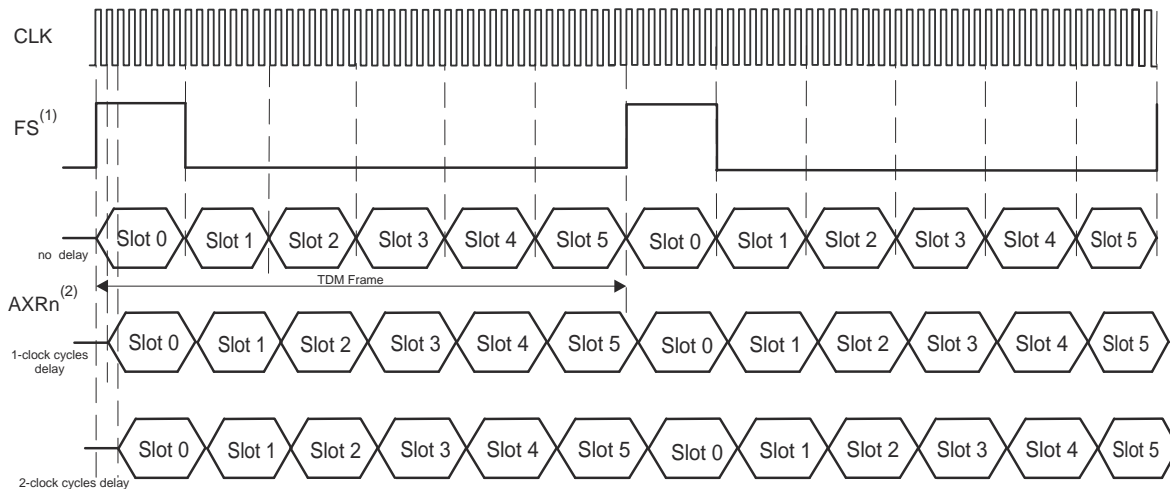

Figure 10-2056. Definition of Frame and Frame-Sync Width

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See [Section 10.7.1.2.2.3](#) for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

10.7.1.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on [Figure 10-2057](#).

(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported
 (2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

Figure 10-2057. TDM Format - 6 channel example

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 10.7.1.2.2.2), the latter being also referred to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-, 1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

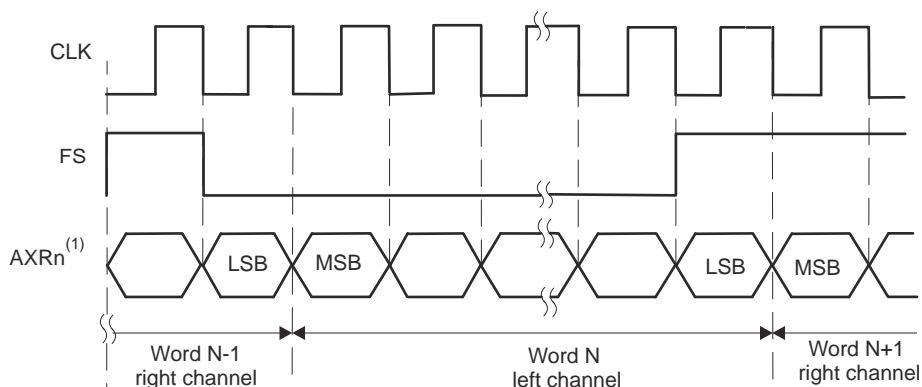

In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period T_s of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

10.7.1.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 10-2058.

(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasep-036

Figure 10-2058. I2S Format Overview

10.7.1.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphasemark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

Note

The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

10.7.1.2.2.5.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). For each serializer transmitter n , the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 10-2059](#) and [Table 10-2165](#) show how data is encoded to the BMC format.

As shown in [Figure 10-2059](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to $128 \times f_s$, where f_s is the sample rate (see [Section 10.7.1.2.2.5.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

10.7.1.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 10-2060 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 10-2166.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 10-2166, the preambles (time intervals 0–3) are also defined with even parity.

Figure 10-2060. S/PDIF Subframe Format

As listed in [Table 10-2166](#), the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 10-2166. Preamble Codes

Preamble Code ⁽¹⁾	Previous Logical State	Logical States on pin AXRn ⁽²⁾	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

- (1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.
- (2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

10.7.1.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 10-2061](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s . The S/PDIF format clock rate is therefore $128 \times f_s$ ($128 = 32$ cells per subframe $\times 2$ clocks per cell $\times 2$ subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128×192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 10-2061. S/PDIF Frame Format

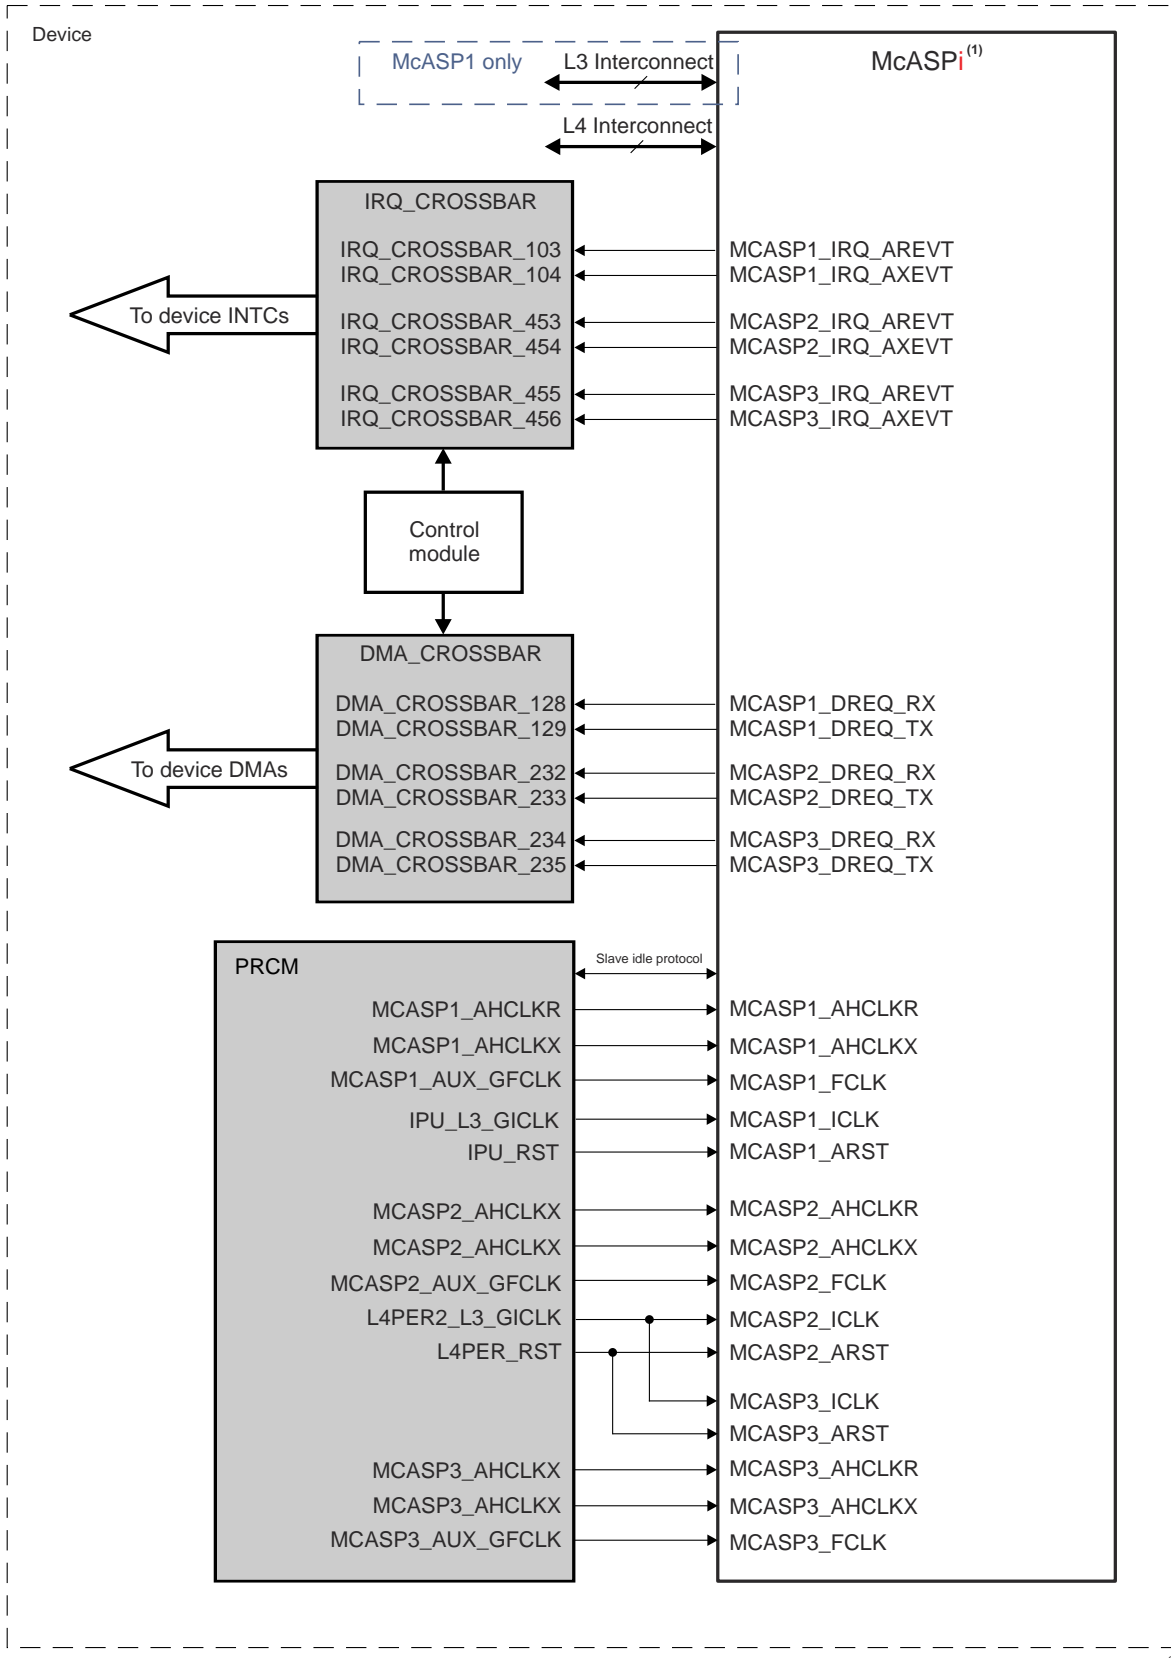

10.7.1.3 McASP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

[Figure 10-2062](#) shows McASP integration.

mcasp-011

A. $i = 1$ to 3 (2 and 3 only on SR2.0)

Figure 10-2062. McASP Integration

Note

There is only one McASP module on SR1.0 devices called McASP. On SR2.0 there are 3 McASP modules called McASP1, McASP2 and McASP3. McASP1 on SR2.0 is same as McASP on SR1.0.

Note

For more information about the slave idle protocol, see *Module Level Clock Management in Power, Reset, and Clock Management*.

Table 10-2167 through Table 10-2169 summarize McASP integration in the device.

Table 10-2167. McASP Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP1	PD_COREAON	No	L3_MAIN L4_PER2
McASP2 (SR2.0 Only)	PD_COREAON	No	L4_PER2
McASP3 (SR2.0 Only)	PD_COREAON	No	L4_PER2

Table 10-2168. McASP Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
McASP1	MCASP1_AHCLKR	MCASP1_AHCLKR	PRCM	McASP1 AHCLKR receive high-frequency master clock
	MCASP1_AHCLKX	MCASP1_AHCLKX		McASP1 AHCLKX transmit high-frequency master clock
	MCASP1_FCLK	MCASP1_AUX_GFCLK		McASP1 functional clock
	MCASP1_ICLK	IPU_L3_GICLK		McASP1 interface clock
McASP2 (SR2.0 Only)	MCASP2_AHCLKR	MCASP2_AHCLKX	PRCM	McASP2 AHCLKR receive high-frequency master clock
	MCASP2_AHCLKX	MCASP2_AHCLKX		McASP2 AHCLKX transmit high-frequency master clock
	MCASP2_FCLK	MCASP2_AUX_GFCLK		McASP2 functional clock
	MCASP2_ICLK	L4PER2_L3_GICLK		McASP2 interface clock
McASP3 (SR2.0 Only)	MCASP3_AHCLKR	MCASP3_AHCLKX	PRCM	McASP3 AHCLKR receive high-frequency master clock
	MCASP3_AHCLKX	MCASP3_AHCLKX		McASP3 AHCLKX transmit high-frequency master clock
	MCASP3_FCLK	MCASP3_AUX_GFCLK		McASP3 functional clock

Table 10-2169. McASP Hardware Requests

Interrupt Requests	
--------------------	--

Table 10-2169. McASP Hardware Requests (continued)

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
McASP1	MCASP1_IRQ_AREVT	IRQ_CROSSBAR_103	-	McASP1 module receive interrupt request
	MCASP1_IRQ_AXEVT	IRQ_CROSSBAR_104	-	McASP1 module transmit interrupt request
McASP2 (SR2.0 Only)	MCASP2_IRQ_AREVT	IRQ_CROSSBAR_453	-	McASP2 module receive interrupt request
	MCASP2_IRQ_AXEVT	IRQ_CROSSBAR_454	-	McASP2 module transmit interrupt request
McASP3 (SR2.0 Only)	MCASP3_IRQ_AREVT	IRQ_CROSSBAR_455	-	McASP3 module receive interrupt request
	MCASP3_IRQ_AXEVT	IRQ_CROSSBAR_456	-	McASP3 module transmit interrupt request
DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
McASP1	MCASP_DREQ_RX	DMA_CROSSBAR_128	DMA_DSP1_DREQ_0	McASP module receive event request
	MCASP_DREQ_TX	DMA_CROSSBAR_129	DMA_DSP1_DREQ_1	McASP module transmit event request
McASP2 (SR2.0 Only)	MCASP2_DREQ_RX	DMA_CROSSBAR_232	-	McASP2 module receive event request
	MCASP2_DREQ_TX	DMA_CROSSBAR_233	-	McASP2 module transmit event request
McASP3 (SR2.0 Only)	MCASP3_DREQ_RX	DMA_CROSSBAR_234	-	McASP3 module receive event request
	MCASP3_DREQ_TX	DMA_CROSSBAR_235	-	McASP3 module transmit event request

Note

The **Default Mapping** column in [Table 10-2169 McASP Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

For more information about the device DSP1_EDMA, see *DSP Integrated EDMA Subsystem*.

Note

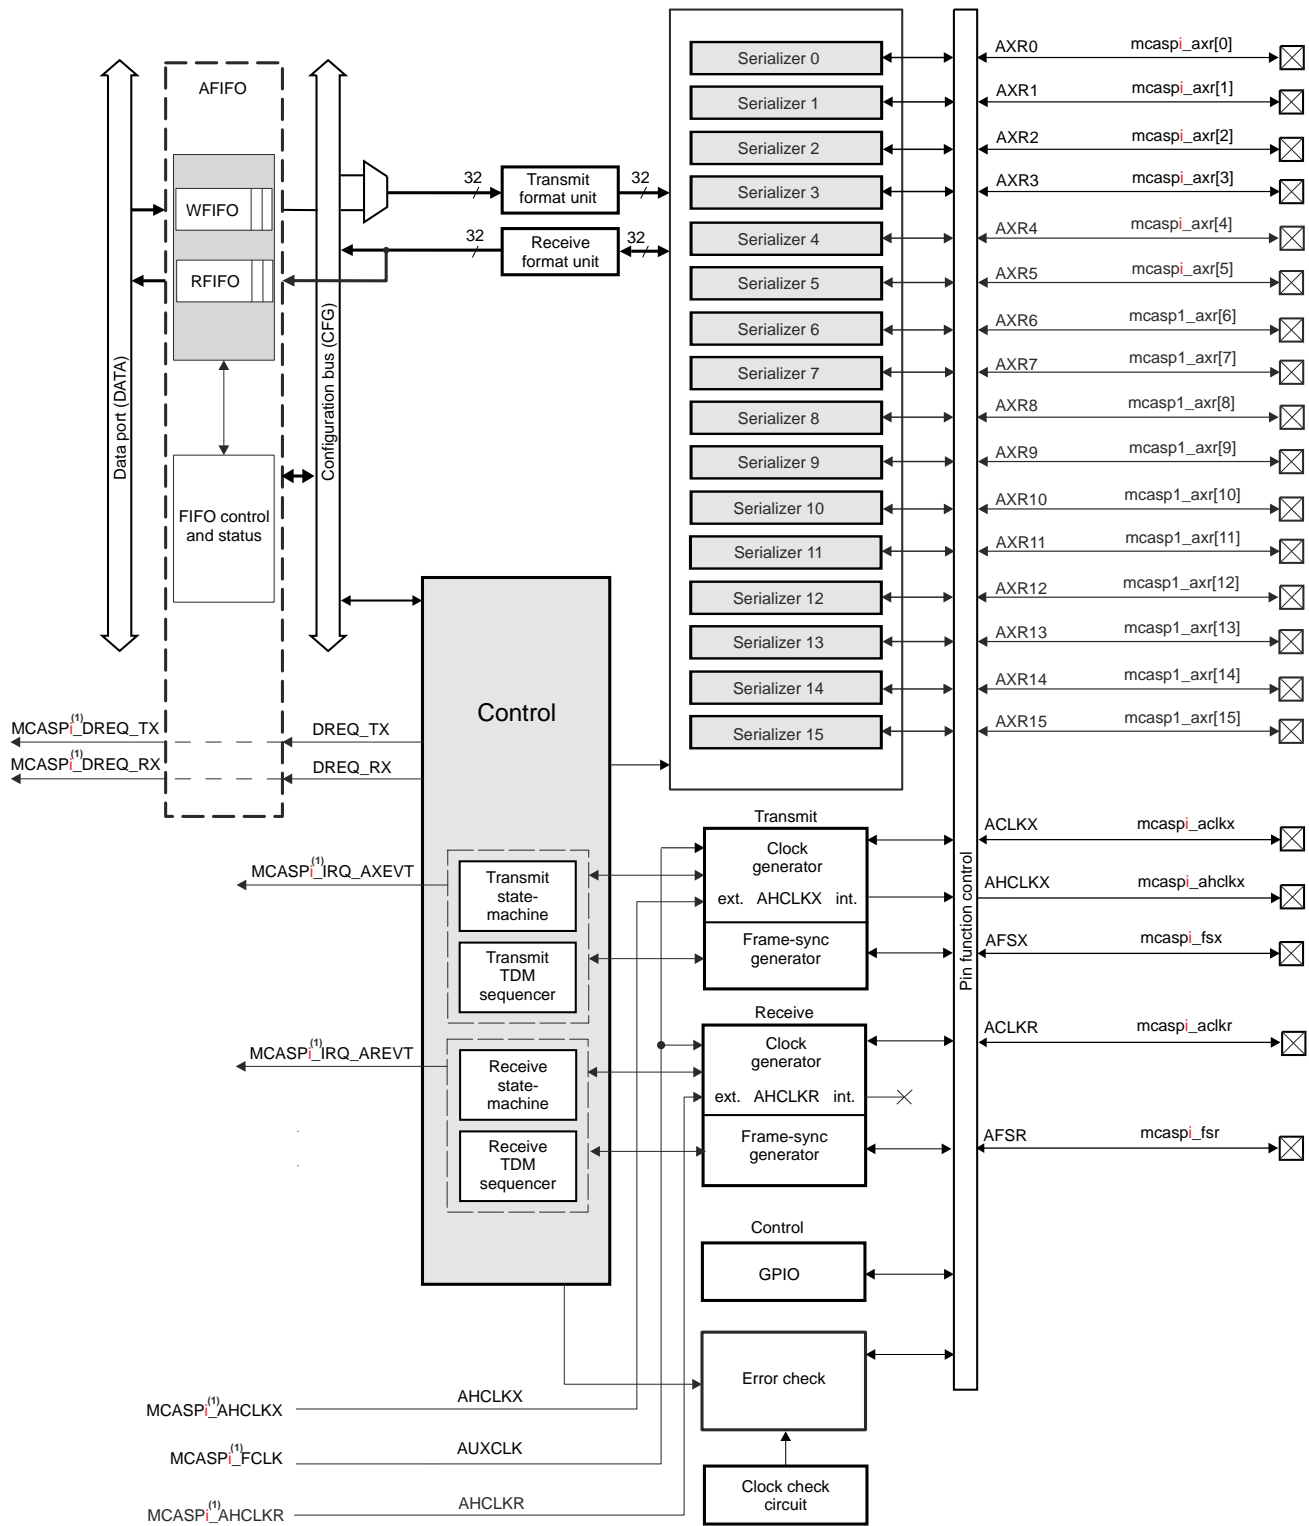

- For the description of the interrupt source, see [Section 10.7.1.4.12, McASP Events and Interrupt Requests](#).
- For the description of the DMA source, see [Section 10.7.1.4.13, DMA Requests](#).

10.7.1.4 McASP Functional Description

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see [Section 10.7.1.2, McASP Environment](#), and [Section 10.7.1.3, McASP Integration](#)

10.7.1.4.1 McASP Block Diagram

[Figure 10-2063](#) shows the major blocks of the McASP module. McASP1 has 16 serializers, and McASP2 and McASP3 have 6 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

mcasp-012

A. $i = 1$ to 3 (2 and 3 only on SR2.0)

Figure 10-2063. McASP Module Block Diagram

Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

10.7.1.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

10.7.1.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 10.7.1.4.2](#), the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_ACLKXCTL[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 10-2064](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 10-2064](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

Note

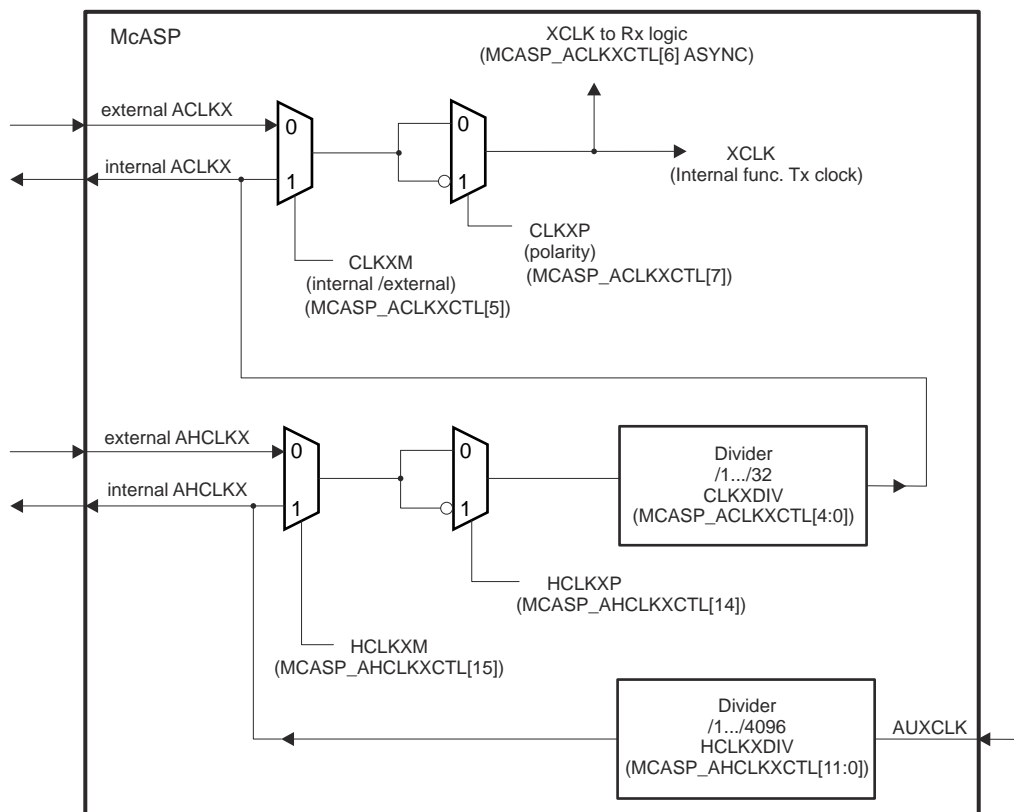

The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

Note

In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 10-2064](#) is the block diagram of the transmit clock generator.

mcasp-013

Figure 10-2064. Transmit Clock Generator Block Diagram

Note

In this device:

- ACLKX is mapped on the device ball mcaspi_aclkx, where i = 1 to 3
- internal AHCLKX is mapped on the device ball mcaspi_ahclkx
- external AHCLKX is mapped on MCASPi_AHCLKX clock from the PRCM

For more on McASP integration, see [Section 10.7.1.2, McASP Environment](#), and [Section 10.7.1.3, McASP Integration](#).

10.7.1.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 10.7.1.4.2](#)) and the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11:0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

Note

The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 10-2064](#) and [Figure 10-2065](#)) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 10.7.1.4.2.4](#).

[Figure 10-2065](#) is the block diagram of the receive clock generator.

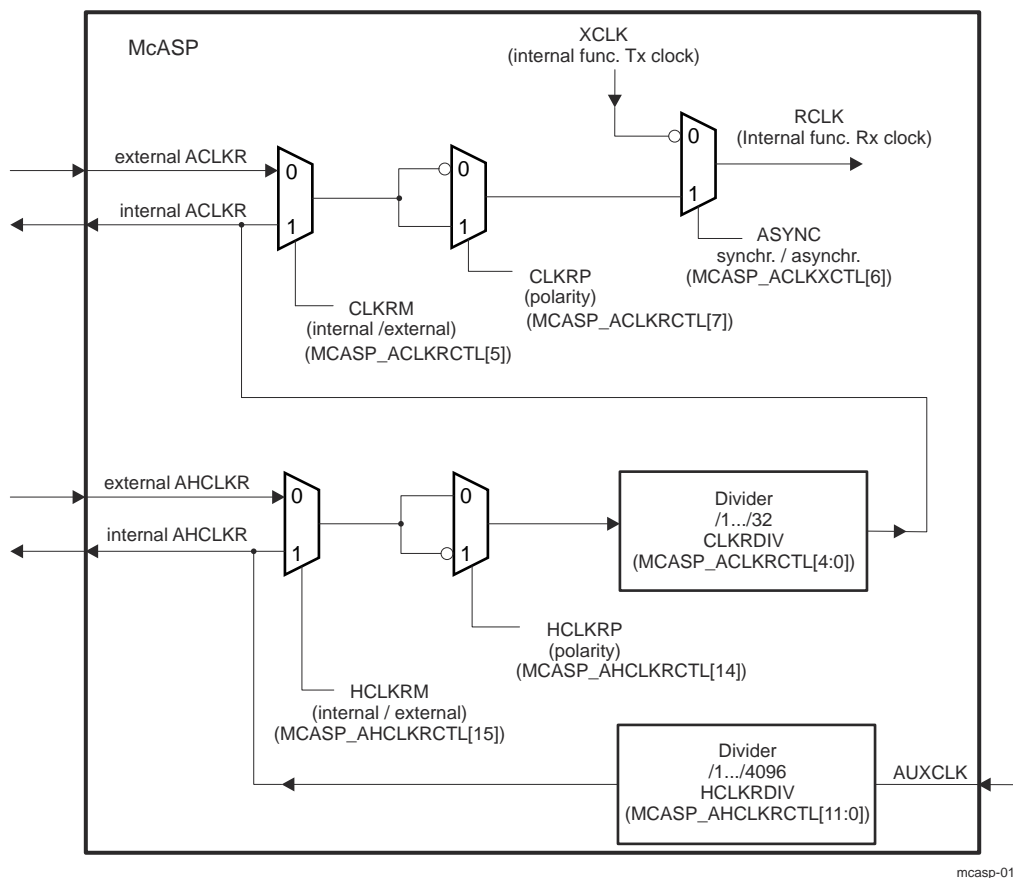

Figure 10-2065. Receive Clock Generator Block Diagram

Note

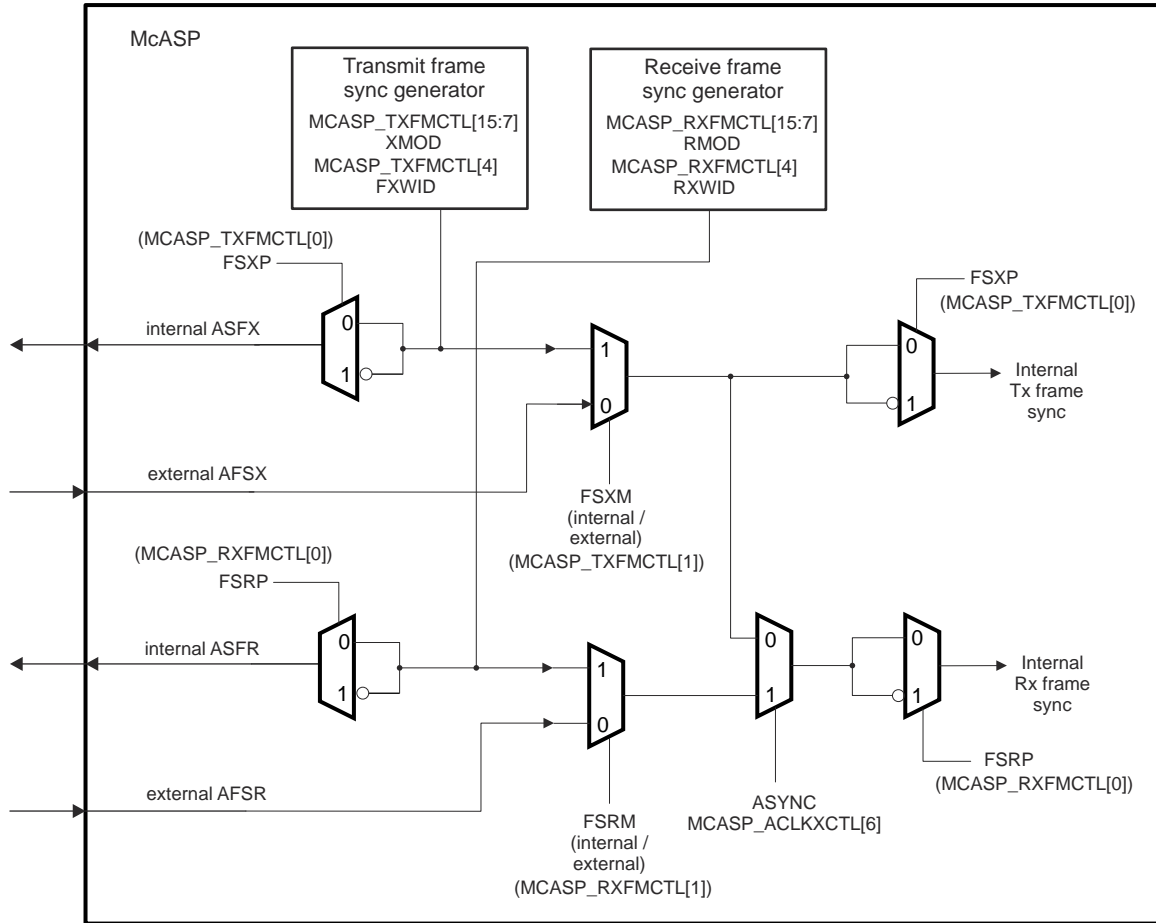

In this device:

- ACLKR is mapped on the device ball mcaspi_aclkr, where i = 1 to 3
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi_AHCLKR from PRCM

For more on McASP integration, see [Section 10.7.1.2, McASP Environment](#), and [Section 10.7.1.3, McASP Integration](#).

10.7.1.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in [Figure 10-2066](#). I/O buffers are not part of the McASP module, and are not shown in the figure.

mcasp-015

Figure 10-2066. Frame Sync Generator Block Diagram

Note

For more on McASP integration, see [Section 10.7.1.2, McASP Environment](#), and [Section 10.7.1.3, McASP Integration](#).

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_TXFMCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_TXFMCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_TXFMCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_TXFMCTL[15:7] XMOD, as follows:
 - For DIT mode (384 slots) - MCASP_TXFMCTL[15:7] XMOD = 0x180
 - For I2S mode (2 TDM slots) - MCASP_TXFMCTL[15:7] XMOD = 0x2
 - For TDM mode (from 3 to 32 TDM slots) - MCASP_TXFMCTL[15:7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_TXFMCTL[17:16] XDATDLY

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_RXFMCTL[1] FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_RXFMCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_RXFMCTL[4] FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_RXFMCTL[15:7] RMOD, as follows:

- For I2S mode (2 TDM slots) - MCASP_RXFMCTL[15:7] RMOD = 0x2
- For TDM mode (from 3 to 32 TDM slots) - MCASP_RXFMCTL[15:7] RMOD set in range 0x3 - 0x20
- For the special 384-slot TDM mode - MCASP_RXFMCTL[15:7] RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RXFMT[17:16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 10.7.1.4.2.4](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

Note

Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in [Section 10.7.1.4.2.4](#).

10.7.1.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 10-2065](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_TXDITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKRCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

Note

Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when MCASP_TXDITCTL[0] DITEN=0b0).

10.7.1.4.3 Serializers

The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUF_n used either for transmitting (write accessible in register MCASP_TXBUF_n) or for receiving (read accessible in register MCASP_RXBUF_n) data. In addition, each serializer has a dedicated control register (MCASP_XRSRCTL_n) and a serial bidirectional data pin - AXR_n. The register MCASP_XRSRCTL_n allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSR_n shifter configured as a receiver in MCASP_XRSRCTL_n, shifts in data through McASP corresponding device level bidirectional data pad AXR_n. A given serializer XRSR_n shifter configured as a

transmitter in MCASP_XRSRCTLn, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 10-2067 is the serializer block diagram.

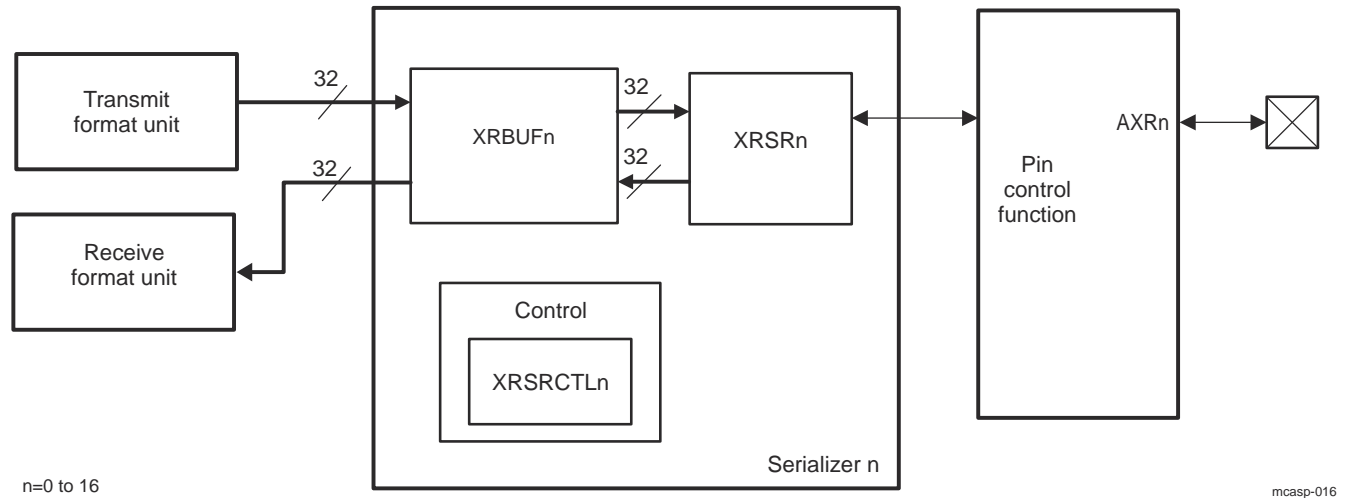

Figure 10-2067. Individual Serializer and Connections Within McASP

Transmission on the n-th serializer is performed as follows:

The McASP is serviced by writing data into the register MCASP_TXBUFn, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer is performed as follows:

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn, and can be accessed in the MCASP_RXBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_XRSRCTLn[3:2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see [Section 10.7.1.2.2.5](#)

10.7.1.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words

between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

Note

The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RXFMT/MCASP_TXFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP_RXFMT/MCASP_TXFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RXFMT/MCASP_TXFMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

10.7.1.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

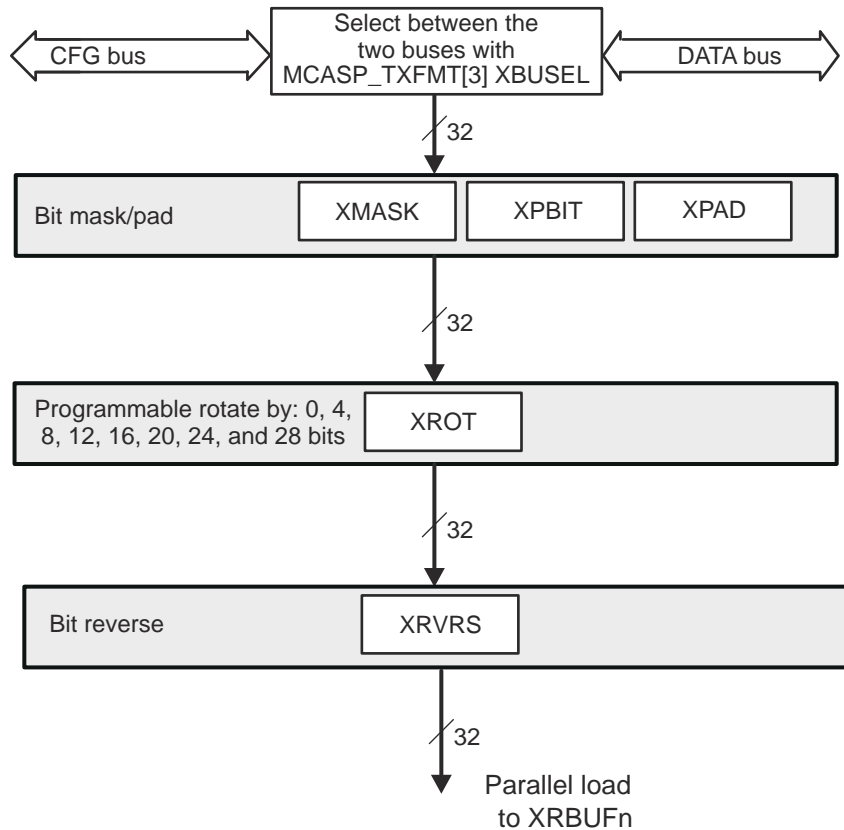

Figure 10-2068 shows the transmit formatting unit.

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP_TXFMT:

- XRVR: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

mcasp-017

Figure 10-2068. Transmit Format Unit

As shown in [Figure 10-2068](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_TXFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 10.7.1.4.10.1.3, Transfers Through the DATA Port](#), and [Section 10.7.1.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

10.7.1.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots. XSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 10-2170](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 10-2170](#) assumes that all slot size (SLOT in [Table 10-2170](#)) and word size (WORD in [Table 10-2170](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19

significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the MPU or DSP (typically Q31 or integer).

Table 10-2170. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT ⁽¹⁾	XRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first ⁽²⁾	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

10.7.1.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT =
 - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
 - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
 - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 10-2171](#) should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 10-2171. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 10-2171](#), the user must set XMASK=0xFFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVR = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

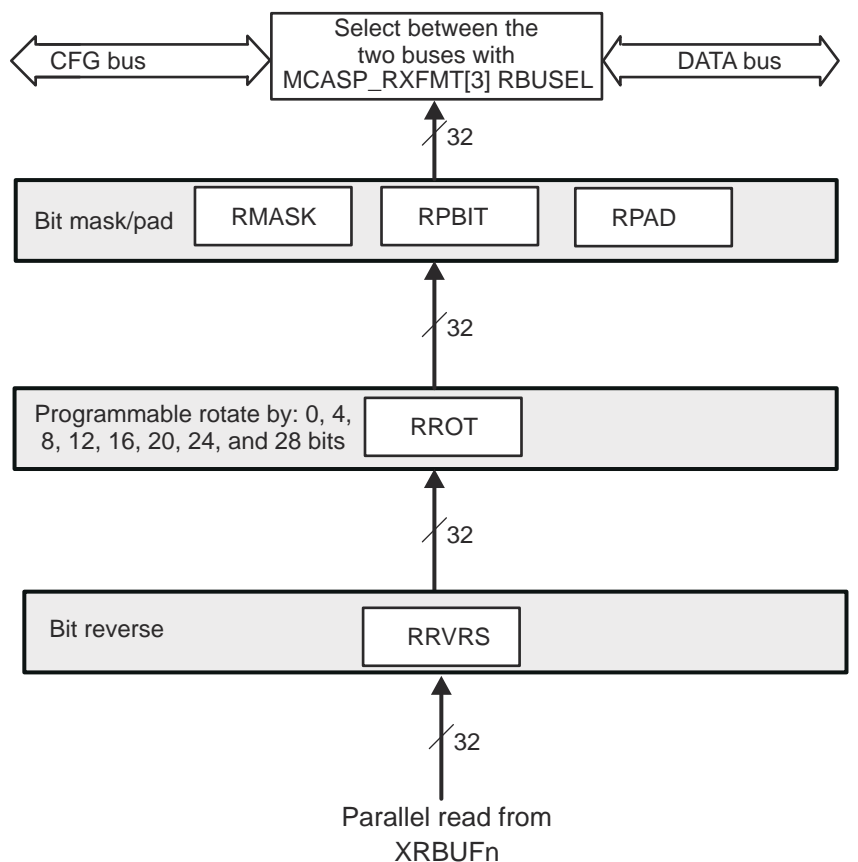

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

10.7.1.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 10-2069](#) shows the receive format unit (RFU).

mccasp-018

Figure 10-2069. Receive Format Unit

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size \leq Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RXFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 10-2069](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RXFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 10.7.1.4.10.1.3, Transfers Through the DATA Port](#), and [Section 10.7.1.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

10.7.1.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 10-2172 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 10-2172. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT ⁽¹⁾	RRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first ⁽²⁾	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 10-2172 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 10-2069), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer, for example).

10.7.1.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RXSTAT).

10.7.1.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM/MCASP_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_XRSRCTLn[3:2] DISMOD. Refer also to [Section 10.7.1.4.9.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_TXBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[9:0] XSLOT CNT bit field.

10.7.1.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

10.7.1.4.8 McASP Power Management

[Table 10-2173](#) describes power-management features available to the McASP.

Table 10-2173. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PWRIDLESYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x2.

10.7.1.4.9 Transfer Modes

10.7.1.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see [Figure 10-2070](#)), as specified for transmit (MCASP_TXFMCTL[15:7] = 0) and receive (MCASP_RXFMCTL[15:7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_RXFMCTL[4] FRWID = 0, MCASP_TXFMCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUFn (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF_n (for every serializer set to operate as a receiver) has been read.

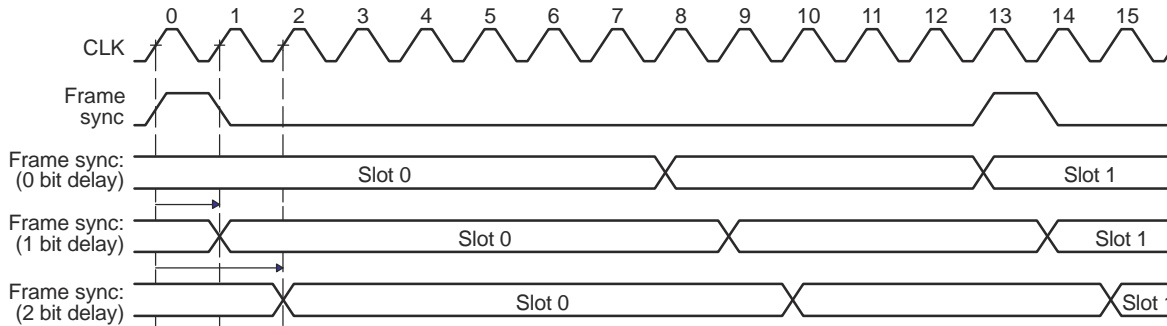

Figure 10-2070. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- **MCASP_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP_PDOUT**, **MCASP_PDIN**, **MCASP_PDSET**, **MCASP_PDCLR**: Not applicable. Leave at default.
- **MCASP_GBLCTL**: Follow the initialization sequence in [Section 10.7.1.5.1.2, McASP Global Initialization](#), to configure this register.
- **MCASP_AMUTE**: Not applicable. Leave at default.
- **MCASP_LBCTL**: If loopback mode is desired, configure this register according to [Section 24.6.4.14 Loopback Modes](#), otherwise leave this register at default.
- **MCASP_TXDITCTL**: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- **MCASP_RXMASK/MCASP_TXMASK**: Mask desired bits according to [Section 10.7.1.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Program all fields according to data format desired. See [Section 10.7.1.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- **MCASP_ACLKRCTL/MCASP_ACLKRCTL**: Program all fields according to bit clock desired. See [Section 10.7.1.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP_AHCLKRCTL/MCASP_AHCLKRCTL**: Program all fields according to high-frequency clock desired. See [Section 10.7.1.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP_RXTDM/MCASP_TXTDM**: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- **MCASP_EVTCTLR/MCASP_EVTCTLX**: Program all fields according to interrupts desired.
- **MCASP_RXCLKCHK/MCASP_TXCLKCHK**: Not applicable. Leave at default.
- **MCASP_XRSRCTLn**: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- **MCASP_DITCSRai**, **MCASP_DITCSRBi**, **MCASP_DITUDRAi**, **MCASP_DITUDRBi**: Not applicable. Leave at default.

10.7.1.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 10.7.1.2.2.3](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- **ACLKX** - transmit bit clock
- **AFSX** - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, **AXR_n**, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the [Section 10.7.1.4.2.1, Transmit Clock](#), and [Section 10.7.1.4.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to [Section 10.7.1.4.2.2, Receive Clock](#), and [Section 10.7.1.4.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- **MCASP_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP_PDOUT**, **MCASP_PDIN**, **MCASP_PDSET**, **MCASP_PDCLR**: Not applicable. Leave at default.
- **MCASP_GBLCTL**: Follow the initialization sequence is described in the [Section 10.7.1.5.2, Operational Modes Configuration](#).
- **MCASP_AMUTE**: Leave this register at default state.
- **MCASP_LBCTL**: If loopback mode is desired, configure this register according to [Section 10.7.1.4.14](#), otherwise leave this register at default.
- **MCASP_TXDITCTL**: DITEN must be left at default 0 to select TDM mode (transmitters only).
- **MCASP_RXMASK/MCASP_TXMASK**: Mask desired bits according to [Section 10.7.1.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Program all fields according to data format desired. See the [Section 10.7.1.4.4, Format Units](#).
- **MCASP_RXFMCTL/MCASP_TXFMCTL**: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- **MCASP_ACLKRCTL/MCASP_ACLKXCTL**: Program all fields according to bit clock desired. For more information, refer to [Section 10.7.1.4.2](#).
- **MCASP_AHCLKRCTL/MCASP_AHCLKXCTL**: Program all fields according to high-frequency clock desired. For more details, refer to [Section 10.7.1.4.2](#).
- **MCASP_RXTDM/MCASP_TXTDM**: Program all fields according to the time slot characteristics desired.
- **MCASP_EVTCTLX**: Program all fields according to transmit interrupts desired.
- **MCASP_RXCLKCHK/MCASP_TXCLKCHK**: Program all fields according to clock checking desired.
- **MCASP_XRSRCTLn**: Program all fields according to serializer operation desired.

Note

The **MCASP_DITCSRAi**, **MCASP_DITCSRBi**, **MCASP_DITUDRAi**, **MCASP_DITUDRBi** (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

10.7.1.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring **MCASP_TXTDM** and/or **MCASP_RXTDM** registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either **MCASP_TXTDM** or **MCASP_RXTDM** to determine if the McASP transmits/receives in that time slot.

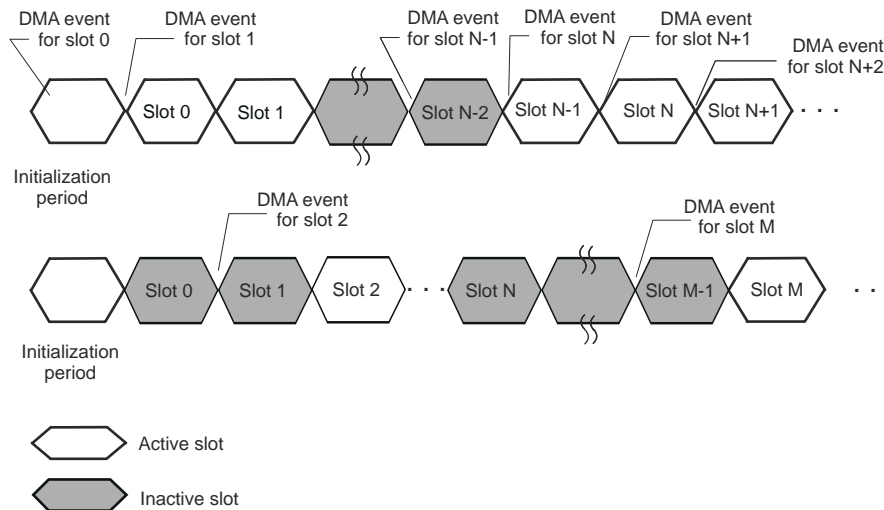

Note

If a MCASP_TXTDM/MCASP_RXTDM bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_XRSRCTLn[3:2] DISMOD.

Figure 10-2071 shows when the transmit DMA event - AXEVT is generated. See Section 10.7.1.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF_n to XRSR_n generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

mcasp-019

Figure 10-2071. Transmit DMA Event (AXEVT) Generation in TDM Time Slots

10.7.1.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RXTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXR_n, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in MCASP_RXFMCTL to 384 (0x180) to receive 384 time slots

10.7.1.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see [Section 10.7.1.2.2.5, S/PDIF Coding Format](#).

10.7.1.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

Note

The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 10.7.1.4.4.1.2](#).

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

10.7.1.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
 - Internally generated transmit frame sync, FSXM = 1
 - Rising-edge frame sync, FSXP = 0
 - Bit-width frame sync, FXWID = 0
 - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- **MCASP_PFUNC**: The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- **MCASP_PDIR**: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- **MCASP_GBLCTL**: Global initialization
- **MCASP_AMUTE**: Leave this register at default state.
- **MCASP_TXDITCTL**: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- **MCASP_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP_TXFMT**: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 10.7.1.4.4.1.2](#).

- MCASP_TXFMCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_TXTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_EVTCTLX: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.
- MCASP_XRSRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins.
- MCASP_DITCSRAi and MCASP_DITCSRBi: Program the channel status bits as desired.
- MCASP_DITUDRAi and MCASP_DITUDRBi: Program the user data bits as desired.

Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see [Section 10.7.1.2.2.5.1](#)).

10.7.1.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 10.7.1.2.2.5.2, S/PDIF Subframe Format](#). The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSR0 to MCASP_DITCSR5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 10-2061](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 10-2174](#).

10.7.1.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the MCASP_TXBUF_n registers for transmit operations, and by reading data from the MCASP_RXBUF_n registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 10.7.1.4.10.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details.

The McASP transmit/receive XRBUF_n buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 10.7.1.4.10.1.3](#), *Transfers Through the Data Port (DATA)*, and [Section 10.7.1.4.10.1.4](#), *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 10.7.1.4.10.1.5](#), *Using the device CPUs for McASP Servicing*, and [Section 10.7.1.4.10.1.6](#), *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3_MAIN-interconnect or L4_PER2 interconnect, using burst transfers. The physical addresses to access these registers are listed in [Section 10.7.1.6.2.5](#).

10.7.1.4.10.1 Data Ready Status and Event/Interrupt Generation

10.7.1.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_TXSTAT register reflects the data ready status of XRBUF_n buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF_n to its corresponding XRSR_n shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF_n is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTL_n[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_TXBUF_n is written to by the host, the MCASP_XRSRCTL_n[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_TXBUF_n register has to be currently written. Once all requested MCASP_TXBUF_n are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_TXSTAT[5] XDATA bit is written to 0b1, or once MCASP_TXBUF_n registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_DREQ_TX line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_TXBUF_n empty status. An interrupt - MCASPi_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see [Section 10.7.1.4.12.1](#), *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 10-2072](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the MCASP_TXBUF_n (service time). The CPU must write word C into the MCASP_TXBUF_n within the setup time required by the McASP (setup time).

The maximum service time (see [Figure 10-2072](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

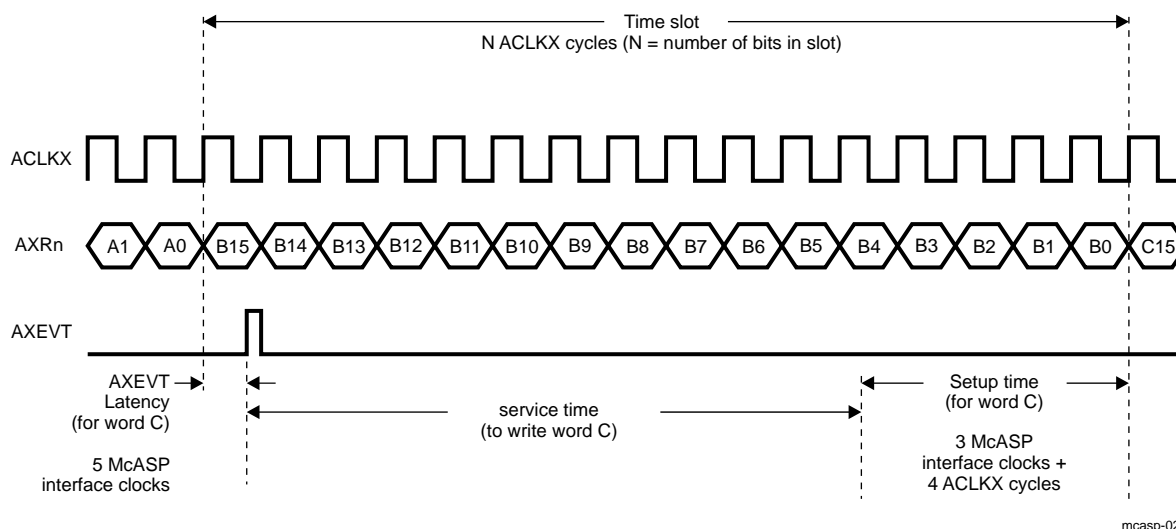

Figure 10-2072. Service Time Upon Transmit DMA Event (AXEVT)

10.7.1.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP_RXSTAT register reflects the data ready status of XRBUF_n buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR_n to its corresponding XRBUF_n data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUF_n already contains received data (i.e. a buffer is full) and is ready to transfer it to the host (MPU/DSP). The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTL_n [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RXBUF_n is read from the host, the MCASP_XRSRCTL_n [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RXBUF_n register has to be currently read. Once all requested MCASP_RXBUF_n are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP_RXSTAT[5] RDATA bit is written to 0b1, or once MCASP_RXBUF_n registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_DREQ_RX line (if enabled in the MCASP_REVTCTL register) to notify the DMA of the MCASP_RXBUF_n full status. An interrupt - MCASPi_IRQ_AREVT can be also generated if the RDATA interrupt is enabled in the MCASP_EVTCTLR register (for details, see [Section 10.7.1.4.12.1, Receive Data Ready Interrupt](#)).

[Figure 10-2073](#) shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the MCASP_RXBUF_n (service time). The CPU must read Word A from the MCASP_RXBUF_n register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see [Figure 10-2073](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AREVT Latency} - \text{Setup Time}$$

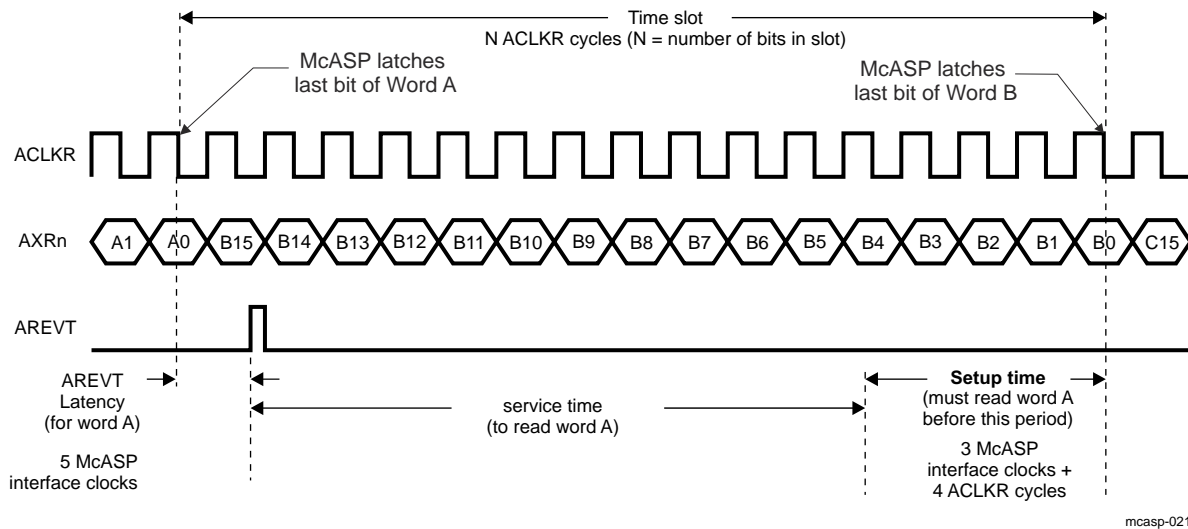

Figure 10-2073. CPU Service Time Upon Receive Event (AREVT)

mcasp-021

10.7.1.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_TXFMT/MCASP_RXFMT register, respectively. Failure to do so may result in software malfunction.

Note

McASP1, whose data port is accessible directly via L3_MAIN, does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUF_n transmit buffer through the McASP data port (DATA) on L3_MAIN Interconnect for McASP1 and on L4_PER2 Interconnect for McASP2/3. CPU hosts can access both XRBUF_n transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconnect DATA port location. Refer to [Section 10.7.1.6.2.5](#). Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 10.7.1.4.11](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in [Section 10.7.1.6.2.5](#), the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See [Section 10.7.1.6.2.5](#)).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Note

For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See [Section 10.7.1.6.2.5](#)).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

Note

To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to [Section 10.7.1.6.2.5](#)), respectively.

See [Section 10.7.1.6.2.5, McASP_DATA Register Summary](#), for more details about XRBUF_n buffer physical address corresponding to the McASP DATA port on:

- Main Interconnect (L3_MAIN or L4_PER2)

Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP_TXTDM) and *transmit* (Tx enabled in MCASP_XRSRCTL_n) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 10.7.1.4.15.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP_RXTDM) and *receive* (Rx enabled in MCASP_XRSRCTL_n) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 10.7.1.4.15.2, Buffer Overrun Error - Receiver](#)).

10.7.1.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_TXFMT/MCASP_RXFMT registers, respectively. Failure to do so may result in software malfunction.

Note

McASP1, whose data port is accessible directly via L3_MAIN does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the DMA/CPU accesses the XRBUF_n transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUF_n transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4_PER2 accesses. The XRBUF_n buffer of the n-th serializer configured as a transmitter is aliased - MCASP_TXBUF_n in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_TXBUF2 register. Similarly, the XRBUF_n buffer of the n-th serializer configured as a receiver is aliased - MCASP_RXBUF_n in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RXBUF3 register.

Accessing the XRBUF through the DATA port (see [Section 10.7.1.4.10.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact MCASP_TXBUF_n or MCASP_RXBUF_n address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_TXBUF_n and MCASP_RXBUF_n addresses corresponding to McASP CFG port, see [Section 10.7.1.6.2.1, MCASP_CFG Register Summary](#).

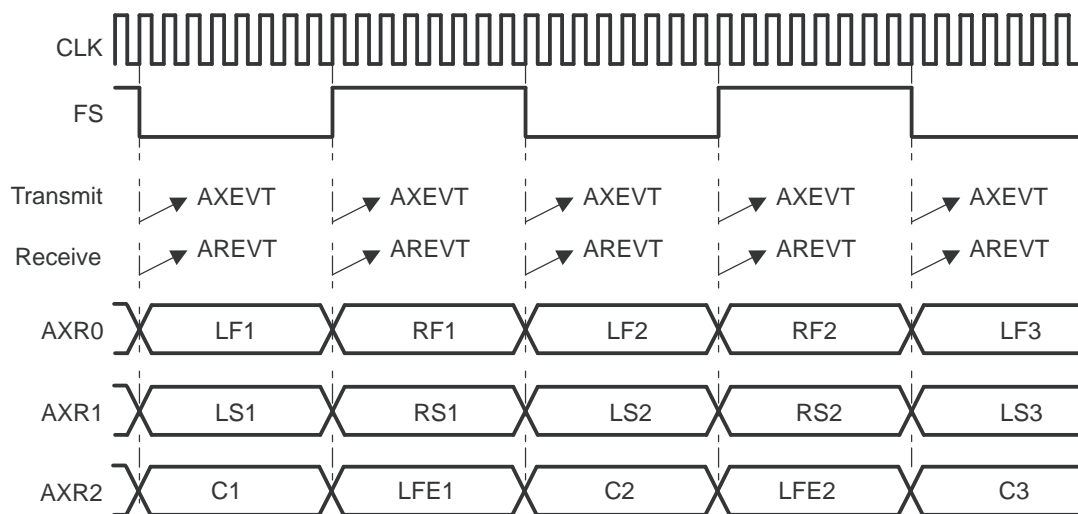

10.7.1.4.10.1.5 Using a Device CPU for McASP Servicing

The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_IRQ_AXEVT and MCASPi_IRQ_AREVT interrupts). Because these interrupt events are connected to device IRQ_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_TXSTAT register and RDATA bit in the MCASP_RXSTAT register can be performed by device CPUs, respectively. As discussed in [Section 10.7.1.4.10.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 10.7.1.4.10.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_EVTCTLX/MCASP_EVTCTLR registers, to generate interrupts MCASPi_IRQ_AXEVT/MCASPi_IRQ_AREVT to the device CPUs upon data ready

10.7.1.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 10-2063](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 10.7.1.4.11](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 10.7.1.4.11](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASPi_DREQ_TX and MCASPi_DREQ_RX outputs. If the AFIFO is disabled (default state) it is transparent for the McASP module and all request are directly sent to the DMA controller.

mcasp-022

Figure 10-2074. DMA Transmit and Receive Event in an Audio Example – One Event

In transmit mode, the DMA event - AXEVT (MCASPi_DREQ_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUF_n transmit buffers. In receive mode, the DMA event AREVT (MCASPi_DREQ_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUF_n receive buffers.

Figure 10-2074 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 10-2074, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

10.7.1.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 10-2075 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFCTL and RFIFCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

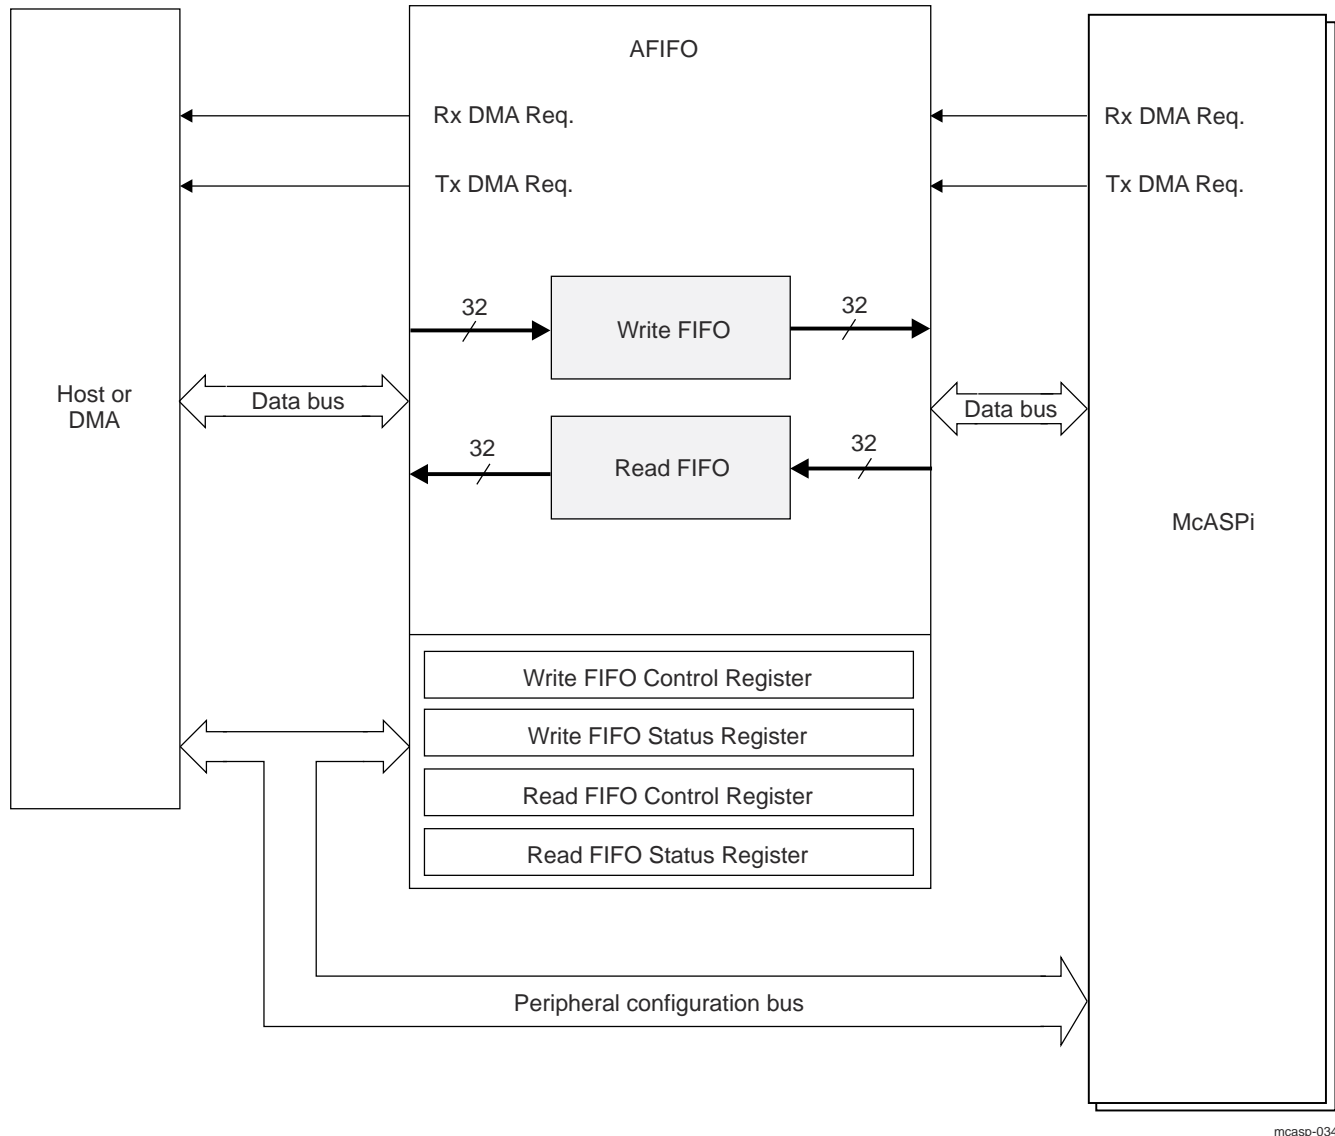

Figure 10-2075. McASP Audio FIFO (AFIFO) Block Diagram

10.7.1.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for WFIFOCTL[7:0] WNUMDMA.) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

10.7.1.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the

host or DMA controller is reduced. If the Write FIFO has space to accept WNUM EVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUM EVT words have been written to the FIFO, it checks again to see if there is space for WNUM EVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, WFIFOCTL[15:8] WNUM EVT should be set to a non-zero integer multiple of the value in WFIFOCTL[7:0] WNUM DMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL[15:8] WNUM EVT should be set equal to the value in WFIFOCTL[7:0] WNUM DMA.

10.7.1.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUM DMA 32-bit words from the McASP, if and when the RFIFO has space for RNUM DMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUM DMA words from the McASP. (See description for RFIFOCTL[7:0] RNUM DMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUM EVT words, those words will be read correctly, emptying the FIFO.

10.7.1.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUM EVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUM EVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUM EVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, RFIFOCTL[15:8] RNUM EVT should be set to a non-zero integer multiple of the value in RFIFOCTL[7:0] RNUM DMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL[15:8] RNUM EVT should be set equal to the value in RFIFOCTL[7:0] RNUM DMA.

10.7.1.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

10.7.1.4.12 McASP Events and Interrupt Requests

[Table 10-2175](#) lists all the transmit event flags. [Table 10-2176](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectively.

Table 10-2175. TX Events⁽²⁾

Event Mask	Event Flag	Map to ⁽¹⁾	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt

Table 10-2175. TX Events⁽²⁾ (continued)

Event Mask	Event Flag	Map to ⁽¹⁾	Description
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR XCKFAIL XUNDRN XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

- (1) Every McASPi module generates separate IRQ event.
(2) Global events for all transmitting serializers in a single McASPi module.

Table 10-2176. RX Events⁽²⁾

Event Mask	Event Flag	Map to ⁽¹⁾	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR RCKFAIL ROVRN RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

- (1) Every McASP module generates separate IRQ event.
(2) Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

Software has to read the MCASP_TXSTAT/MCASP_RXSTAT register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_XRSRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_IRQ_AXEVT) is asserted (active high) when one of the MCASP_TXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLX bit. Similarly, a Rx interrupt line (MCASPi_IRQ_AREVT) is asserted (active high) when one of MCASP_RXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLR bit. See also [Section 10.7.1.4.12.4, Multiple Interrupts](#) and the [Section 10.7.1.4.10.1, Data Ready Status and Event/Interrupt Generation](#).

10.7.1.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. The [Section 10.7.1.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

10.7.1.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the MCASP_RXSTAT register and RDATA is enabled in MCASP_EVTCTLR. The [Section 10.7.1.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when RDATA flag is set in the MCASP_RXSTAT register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

10.7.1.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_TXSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RXSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_EVTCTLR). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

10.7.1.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_TXSTAT is set and the interrupt is enabled in MCASP_EVTCTLX.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_TXSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_TXSTAT/MCASP_RXSTAT and the interrupt enabled in MCASP_EVTCTLX/MCASP_EVTCTLR generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_TXSTAT/MCASP_RXSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

10.7.1.4.13 DMA Requests

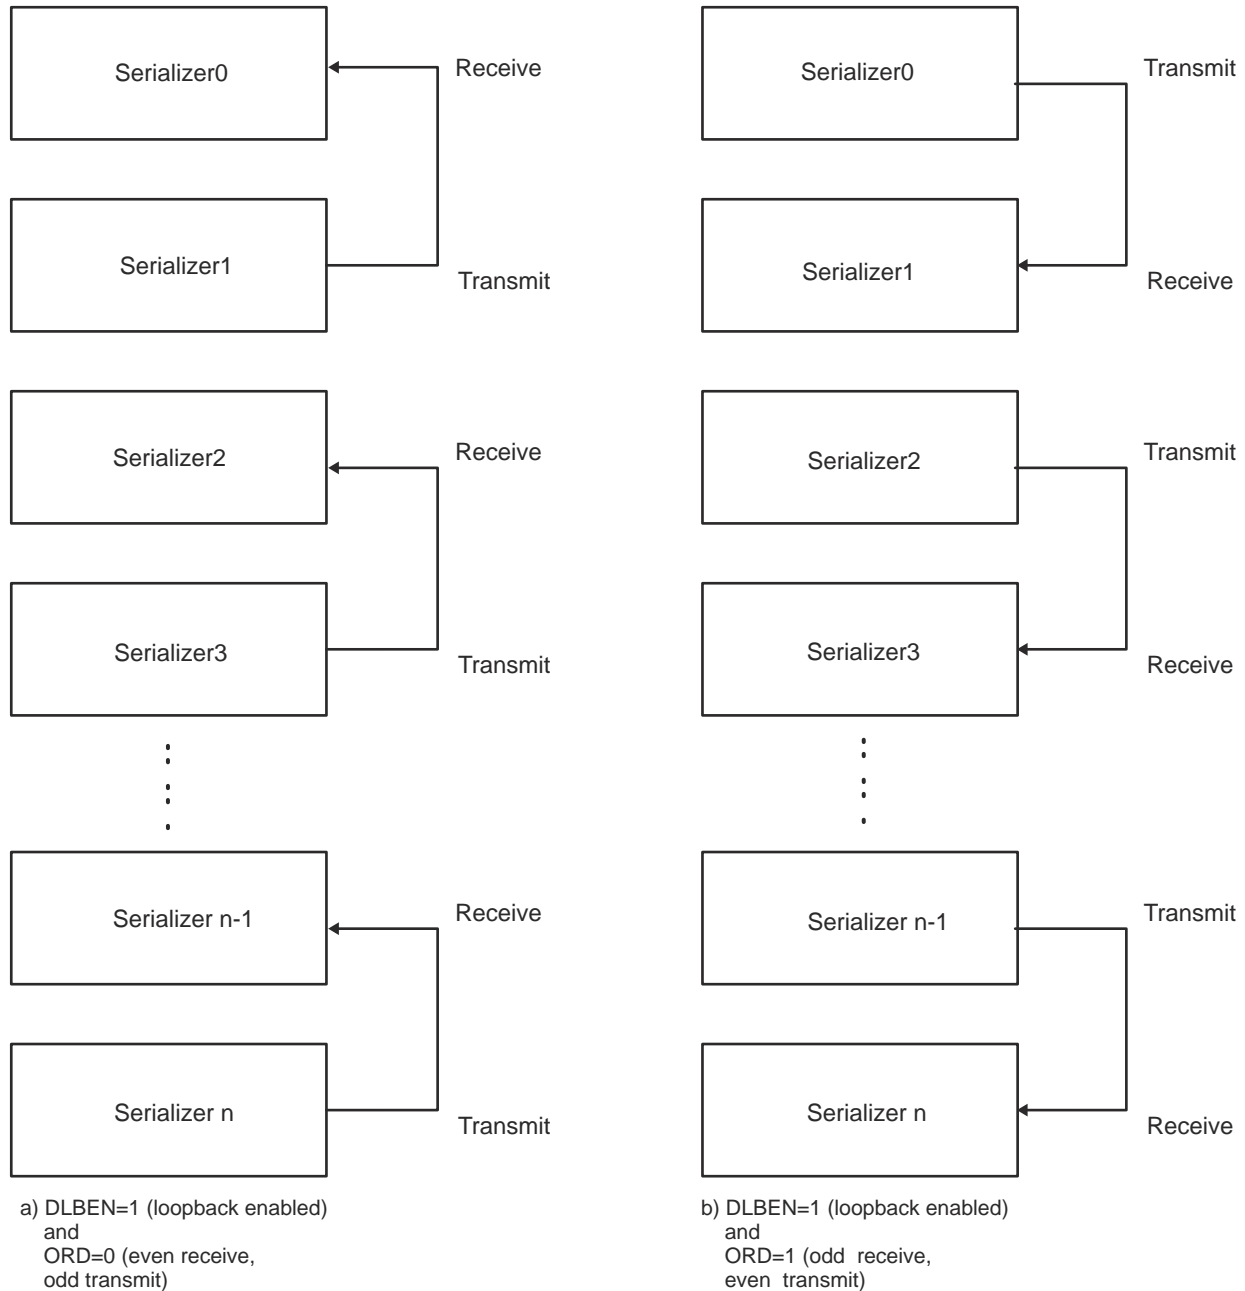

The McASP can generate one DMA request to the DMA_CROSSBAR to transmit (MCASPi_DREQ_TX) or receive (MCASPi_DREQ_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the

MCASP_XEVTCTL register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the MCASP_REVTCTL register is cleared.

10.7.1.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

Figure 10-2076 shows the basic logical connection of the serializers in loopback mode.

mcasp-023

Figure 10-2076. McASP Serializers Operation in Loopback Mode

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_LBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_LBCTL) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (i.e. to function as McASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see *Pad Configuration Rregisters in Control Module*.

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_LBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

10.7.1.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP_LBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The MCASP_LBCTL[4] IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The MCASP_LBCTL[3:2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_LBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - MCASP_ACLKXCTL[6] ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - MCASP_RXFMCTL[15:7] RMOD and MCASP_TXFMCTL[15:7] XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

Note

Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

10.7.1.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

10.7.1.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUF_n buffer to XRSR_n shift register, but the corresponding (MCASP_TXBUF_n) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

10.7.1.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSR_n shift register to XRBUF_n receiver buffer, but the corresponding MCASP_RXBUF_n register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUF_n buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RXSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

10.7.1.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The MCASP_TXSTAT[7] XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

10.7.1.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RXSTAT register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The MCASP_RXSTAT[7] RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RXSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

10.7.1.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
 - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
 - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

10.7.1.4.15.6 Clock Failure Detection

10.7.1.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
 - a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RXCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RXSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
 - a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_EVTCTLR)

10.7.1.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 10-2077](#)) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every

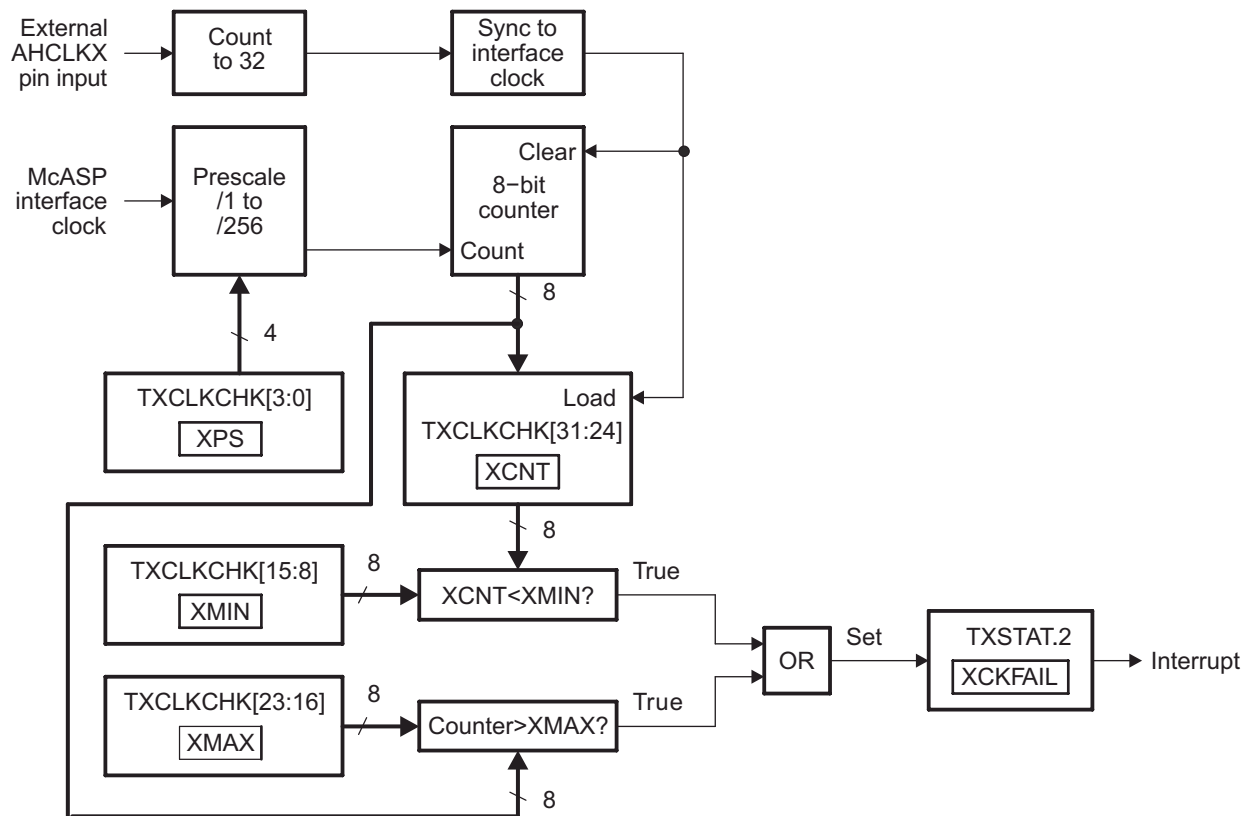

32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

mcasp-024

Figure 10-2077. Transmit Clock Failure Detection Circuit Block Diagram

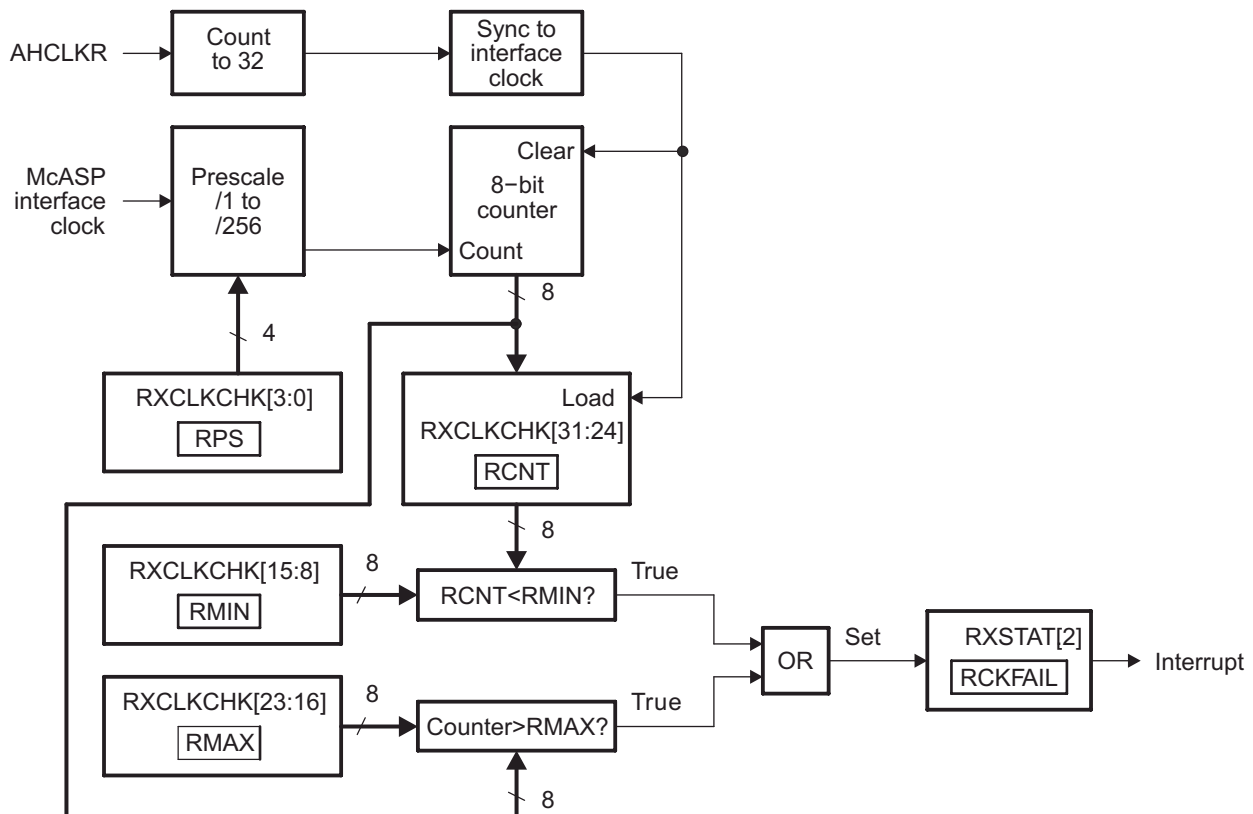

10.7.1.4.15.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see Figure 10-2078) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RXCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

mcasp-025

Figure 10-2078. Receive Clock Failure Detection Circuit Block Diagram

10.7.1.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

10.7.1.5.1 Global Initialization

10.7.1.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see [Section 10.7.1.3, McASP Integration](#), and [Section 10.7.1.2, McASP Environment](#)).

[Table 10-2177](#), describes the global initialization of surrounding modules.

Table 10-2177. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See <i>Clock Management Functional Description</i> , in <i>Power, Reset, and Clock Management</i> .)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See <i>Pad Configuration Registers</i> , in <i>Control Module</i>).
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see <i>IRQ_CROSSBAR Module Functional Description</i> , in <i>Control Module</i> .
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see <i>DMA_CROSSBAR Module Functional Description</i> , in <i>Control Module</i> .
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see <i>L3_MAIN Interconnect Overview</i> in <i>L3 Interconnect</i> .

Note

The IRQ_CROSSBAR and the DMA_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

10.7.1.5.1.2 McASP Global Initialization

10.7.1.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in [Table 10-2178](#) initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 10-2178. McASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 10.7.1.5.1.2.1.1 .	
5. Configure the transmit frame sync generator.	See Section 10.7.1.5.1.2.1.2 .	
6. Configure the transmit clock generator.	See Section 10.7.1.5.1.2.1.3 .	

Table 10-2178. McASP Transmitters Global Initialization for DIT-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMs	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. ⁽³⁾	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 10.7.1.5.1.2.1.4 .	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1 ⁽²⁾
11. Configure DIT-specific subframe fields.	See Table 10-2183 .	
12. Release from reset state the divider that outputs the AHCLKX clock. ⁽¹⁾	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. ⁽¹⁾	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

(2) This globally configures all active transmitters to operate in DIT-mode.

(3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

10.7.1.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in [Table 10-2179](#) configures the transmit frame format unit of the McASP module for a DIT-transmission.

Note

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 10-2179. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x- ⁽¹⁾
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- ⁽¹⁾
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x- ⁽¹⁾
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to [Section 10.7.1.4.4.1](#), *Transmit Format Unit* and [Section 10.7.1.4.4.1.2](#), *DIT-Mode Transmission Data Alignment Settings*.

10.7.1.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in [Table 10-2180](#) configures the transmit frame synchronization generator of the McASP module.

Note

The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 10-2180. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

10.7.1.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

Note

By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 10-2181](#) configures the transmit clock generator of the McASP module.

Table 10-2181. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 10.7.1.4.15.6.1, Clock Failure Check Startup.	

10.7.1.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in [Table 10-2182](#) configures the McASP pins for McASP functionality.

Table 10-2182. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs:	MCASP_PDIR[28] AFSX;	0x1
AFSX	MCASP_PDIR[27] AHCLKX;	0x1
AHCLKX	MCASP_PDIR[26] ACLKX;	0x1
ACLKX	MCASP_PDIR [i] AXRi	0x1
Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.		

10.7.1.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in [Table 10-2183](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 10-2183. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5	0x-
	MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5	0x-
	MCASP_DITCSRBi[31:0], where i = 0 to 5	0x-

10.7.1.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in [Table 10-2184](#) initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Note

The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

Table 10-2184. McASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 10.7.1.5.1.2.2.1 .	
5. Configure the receive frame sync generator.	See Section 10.7.1.5.1.2.2.2 .	
6. Configure the receive clock generator.	See Section 10.7.1.5.1.2.2.3 .	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. ⁽⁴⁾	MCASP_XRSRCTLn [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See Section 10.7.1.5.1.2.2.4 .	
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 10.7.1.4.14.1, Loopback Mode Configurations .	0x- ⁽⁵⁾
11. Release from reset state the divider that outputs the AHCLKR clock. ⁽¹⁾ See also ⁽²⁾ .	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also ⁽²⁾ .	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. ⁽¹⁾ See also ⁽³⁾ .	MCASP_GBLCTL[0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also ⁽³⁾ .	MCASP_GBLCTL[0] RCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKRCTL and MCASP_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.

(2) This step is necessary even if external high-frequency serial clocks are used.

(3) This step can be skipped if external serial clocks are used and they are running.

(4) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

- (5) In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so MCASP_ACLKXCTL[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

10.7.1.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in [Table 10-2185](#) configures the receive frame format unit of the McASP module for TDM slots reception.

Table 10-2185. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT[7:4] RSSZ	0x ⁽¹⁾
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK[31:0] RMASK	0x ⁽²⁾
Select a padding value for masked-out bits.	MCASP_RXFMT[14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUF _n which value to be used as a pad value in case MCASP_RXFMT[14:13] RPAD=0x2.	MCASP_RXFMT[12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT[2:0] RROT	0x- ⁽³⁾
Received stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RXFMT[15] RRVRS	0x- ⁽³⁾
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RXFMT[17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT[3] RBUSEL	0x-

- (1) Refer to [Section 10.7.1.4.4.2, Receive Format Unit](#), regarding options for received TDM-slot sizes.
 (2) For more details on Rx masking value, refer to [Section 10.7.1.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#)
 (3) For more details on rotation and received TDM stream bit order, refer to [Section 10.7.1.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#) and [Table 10-2172, McASP RFU Settings](#).

10.7.1.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 10-2186](#) configures the transmit frame synchronization generator of the McASP module.

Note

The same bit - MCASP_ACLKXCTL[6] ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either internally or externally sourced). Hence, the settings in below table [Table 10-2186](#) have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0.

Table 10-2186. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_RXFMCTL[15:7] RMOD	0x ⁽¹⁾
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_RXFMCTL[0] FSRP	0x-
I Receive frame sync - FS is internally generated	Software test condition	

Table 10-2186. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)

Step	Register/Bit Field/Programming Model	Value
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_RXFMCTL[1] FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the Table 10-2184 . This must not be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: mcaspi_fsr)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

- (1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to [Section 10.7.1.4.9.2](#).

10.7.1.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in [Table 10-2187](#) configures the receive clock generator of the McASP module.

Note

The settings in below table [Table 10-2187](#) have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

Table 10-2187. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IF receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-

Table 10-2187. Receive Clock Generator Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the Table 10-2184 . This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input direction for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 10.7.1.4.15.6.1 , <i>Clock Failure Check Startup</i> .	

10.7.1.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in [Table 10-2188](#) configures the McASP pins for McASP functionality.

Table 10-2188. McASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x- ⁽¹⁾ 0x- ⁽²⁾ 0x0

(1) See [Table 10-2186](#).

(2) For more details on McASP clock configurations, refer to [Table 10-2187](#).

10.7.1.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in [Table 10-2189](#) initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 10-2189. McASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 10.7.1.5.1.2.3.1 .	
5. Configure the transmit frame sync generator.	See Section 10.7.1.5.1.2.3.2 .	
6. Configure the transmit clock generator.	See Section 10.7.1.5.1.2.3.3 .	

Table 10-2189. McASP Transmitters Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31 ⁽⁴⁾	0x-
8. Configure the desired n-th serializer for transmit mode operation. ⁽³⁾	MCASP_XRSRCTLn[1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL[0] DITEN	0x0 ⁽²⁾
10. Configure the McASP pins functionality.	See Section 10.7.1.5.1.2.3.4 .	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 10.7.1.4.14.1 , <i>Loopback Mode Configurations</i> .	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See ⁽¹⁾	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See ⁽¹⁾	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

- (1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
- (2) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.
- (3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.
- (4) Appropriately program in bitfield MCASP_XRSRCTLn [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

10.7.1.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in [Table 10-2190](#) configures the transmit frame format unit of the McASP module for TDM slots transmission.

Table 10-2190. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x- ⁽¹⁾
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x- ⁽²⁾
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUFn which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- ⁽³⁾
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVR	0x- ⁽³⁾
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

- (1) Refer to [Section 10.7.1.4.4.1](#), *Transmit Format Unit*, regarding options for transmitted TDM-slot sizes.
- (2) For more details on Tx masking value, refer to [Section 10.7.1.4.4.1.1](#), *TDM - Mode Transmission Data Alignment Settings*

- (3) For more details on rotation and transmit TDM stream bit order, refer to [Section 10.7.1.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#) and [Table 10-2170, McASP TFU TDM Mode Settings](#).

10.7.1.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 10-2191](#) configures the transmit frame synchronization generator of the McASP module.

Table 10-2191. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_TXFMCTL[0] FSXP	0x-
IF transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the Table 10-2189 . This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 10.7.1.4.2.3 .	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

10.7.1.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in [Table 10-2192](#) configures the transmit clock generator of the McASP module.

Table 10-2192. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IF transmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the Table 10-2189 . This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1

Table 10-2192. Transmit Clock Generator Configuration for TDM Cases (continued)

Step	Register/Bit Field/Programming Model	Value
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input direction for the AHCLKX pin	MCASP_PDIR[27] AHCLKX	0b0
ENDIF		
Select an internally-generated transmit clock.	MCASP_ACLKXCTL[5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the Table 10-2189 . This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL[5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Setup an input direction for the ACLKX pin	MCASP_PDIR[26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 10.7.1.4.15.6.1, Clock Failure Check Startup .	

10.7.1.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in [Table 10-2193](#) configures the McASP pins for McASP functionality.

Table 10-2193. McASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an output for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x-(1) 0x-(2) 0x- (2) 0x1

10.7.1.5.2 Operational Modes Configuration

10.7.1.5.2.1 McASP Transmission Modes

10.7.1.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

[Figure 10-2079](#) shows the McASP DIT-/TDM- polling method.

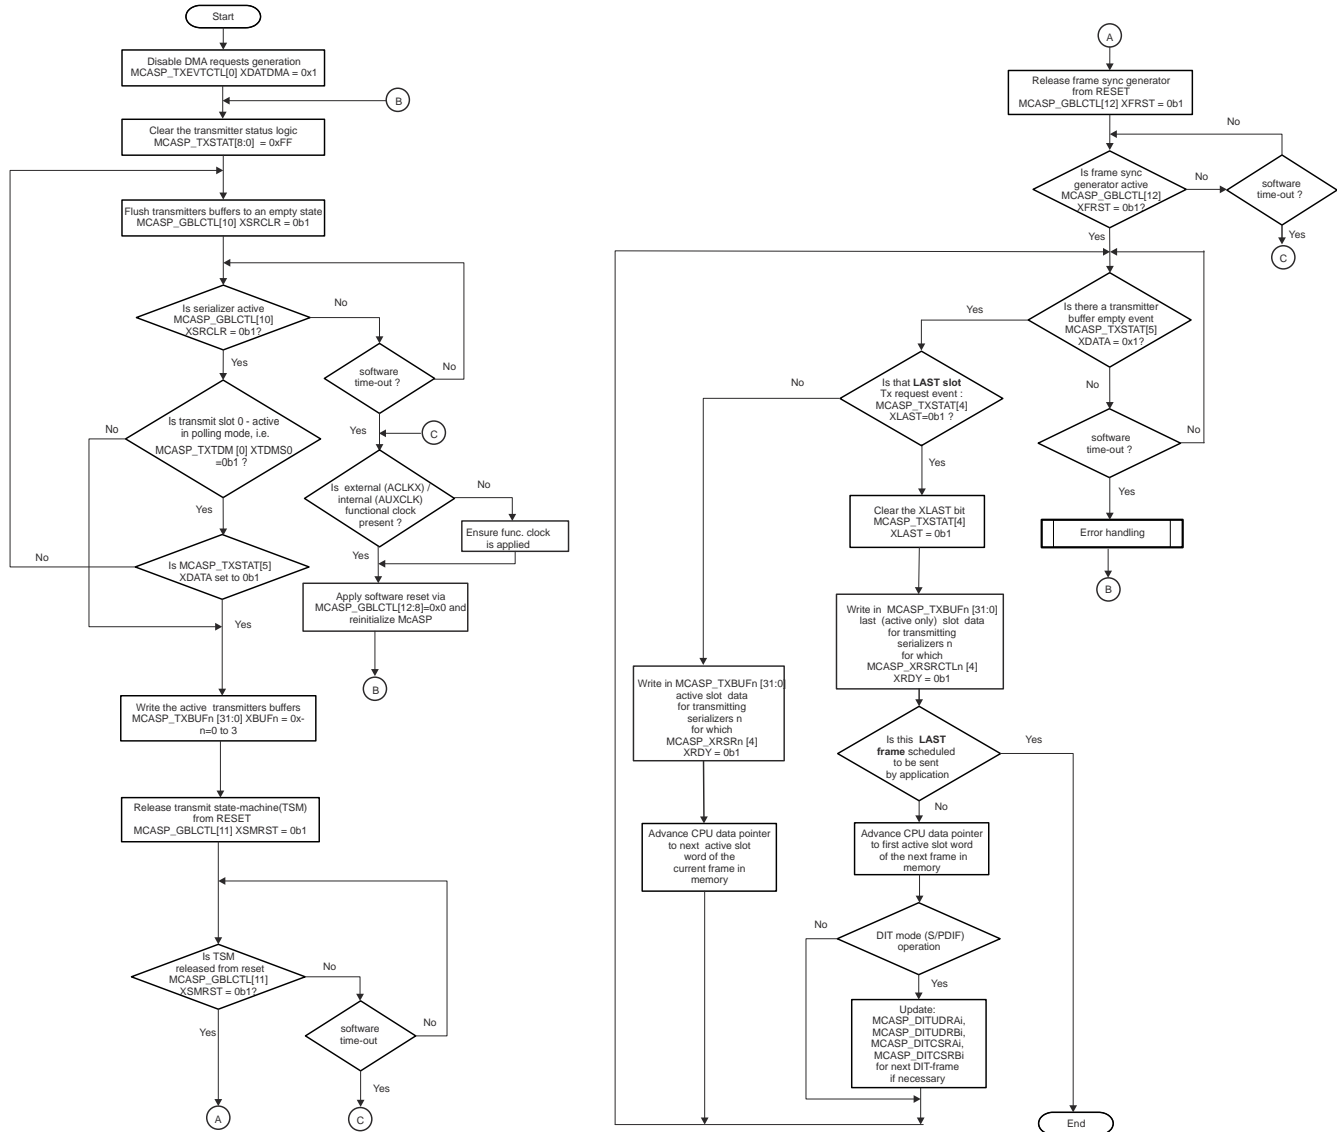

Figure 10-2079. McASP DIT- /TDM- Transmission Polling Method

summarizes the register call for the transmission DIT-/TDM- polling mode.

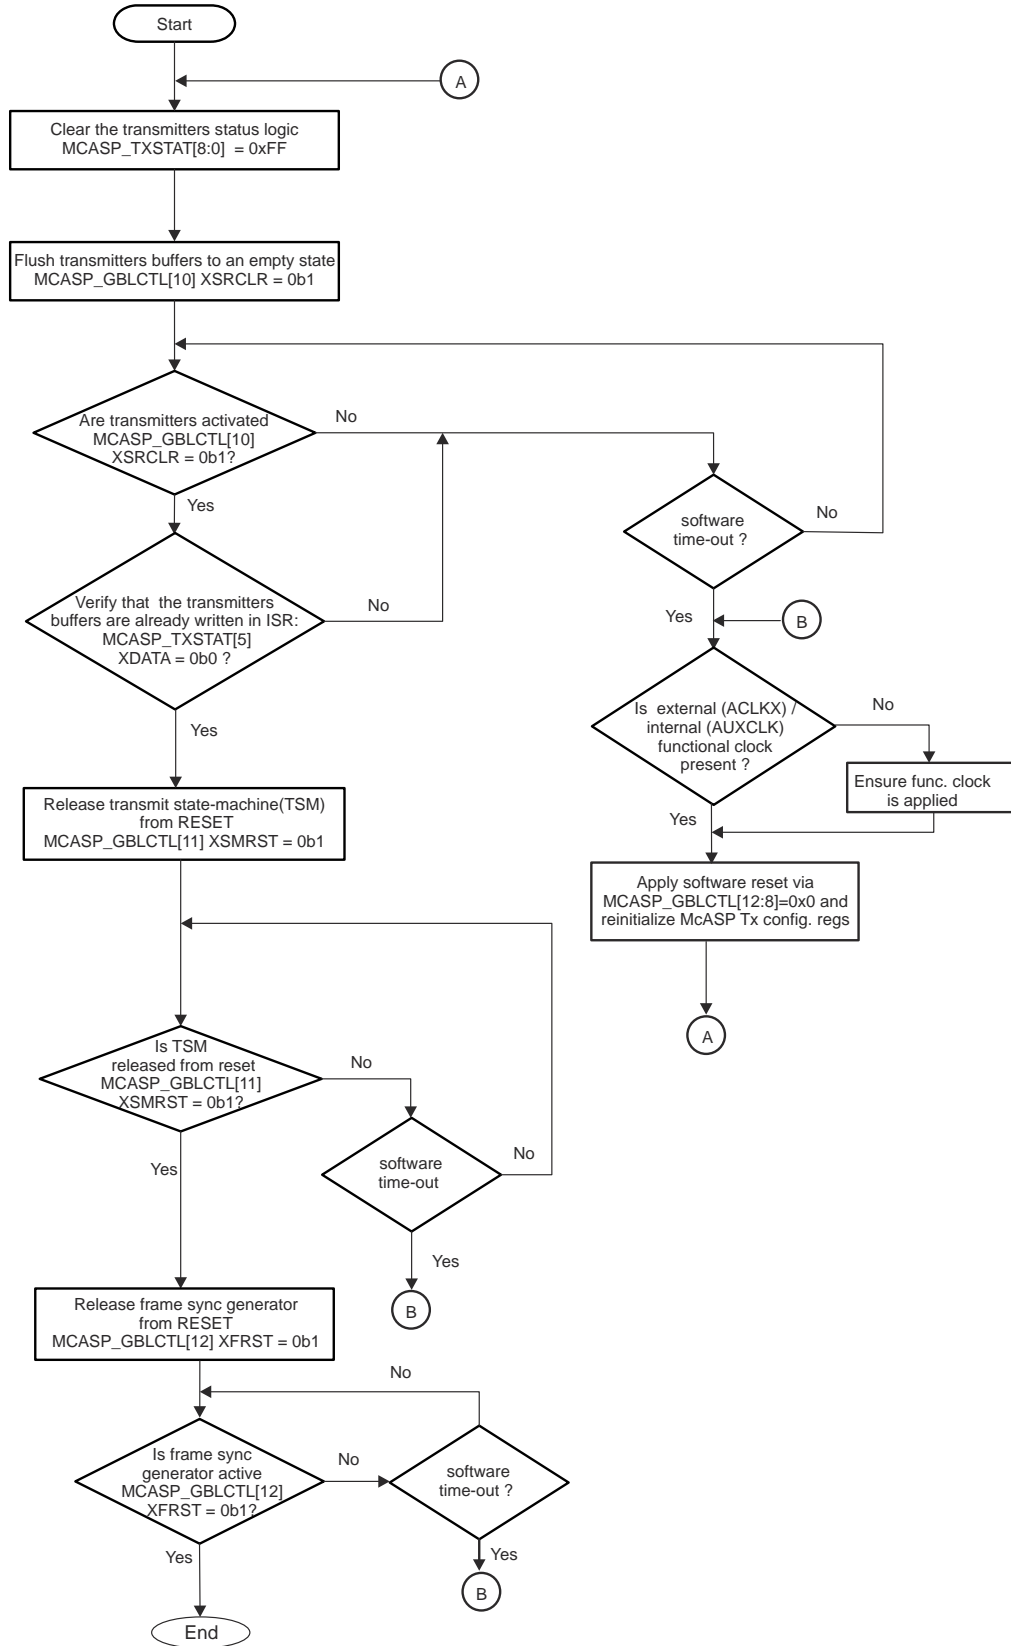

Table 10-2194 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

Table 10-2194. Subprocess Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 10-2085

10.7.1.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method

Figure 10-2080 shows the initial setup for interrupt-based transmission.

mcasp-027

Figure 10-2080. Subsequence – DIT-/TDM- Transmission Startup Procedure

Table 10-2195 shows the configuration of the McASP using an interrupt method for DIT-/TDM- transmission.

Table 10-2195. McASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTLX[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IF write transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the <i>McASP Transmitters Global Initialization</i> - see Table 10-2178)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 10-2080 .	

10.7.1.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 10-2196 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 10-2196. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTLX[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 10-2080 . The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 10-2083 .	See Figure 10-2080 .	

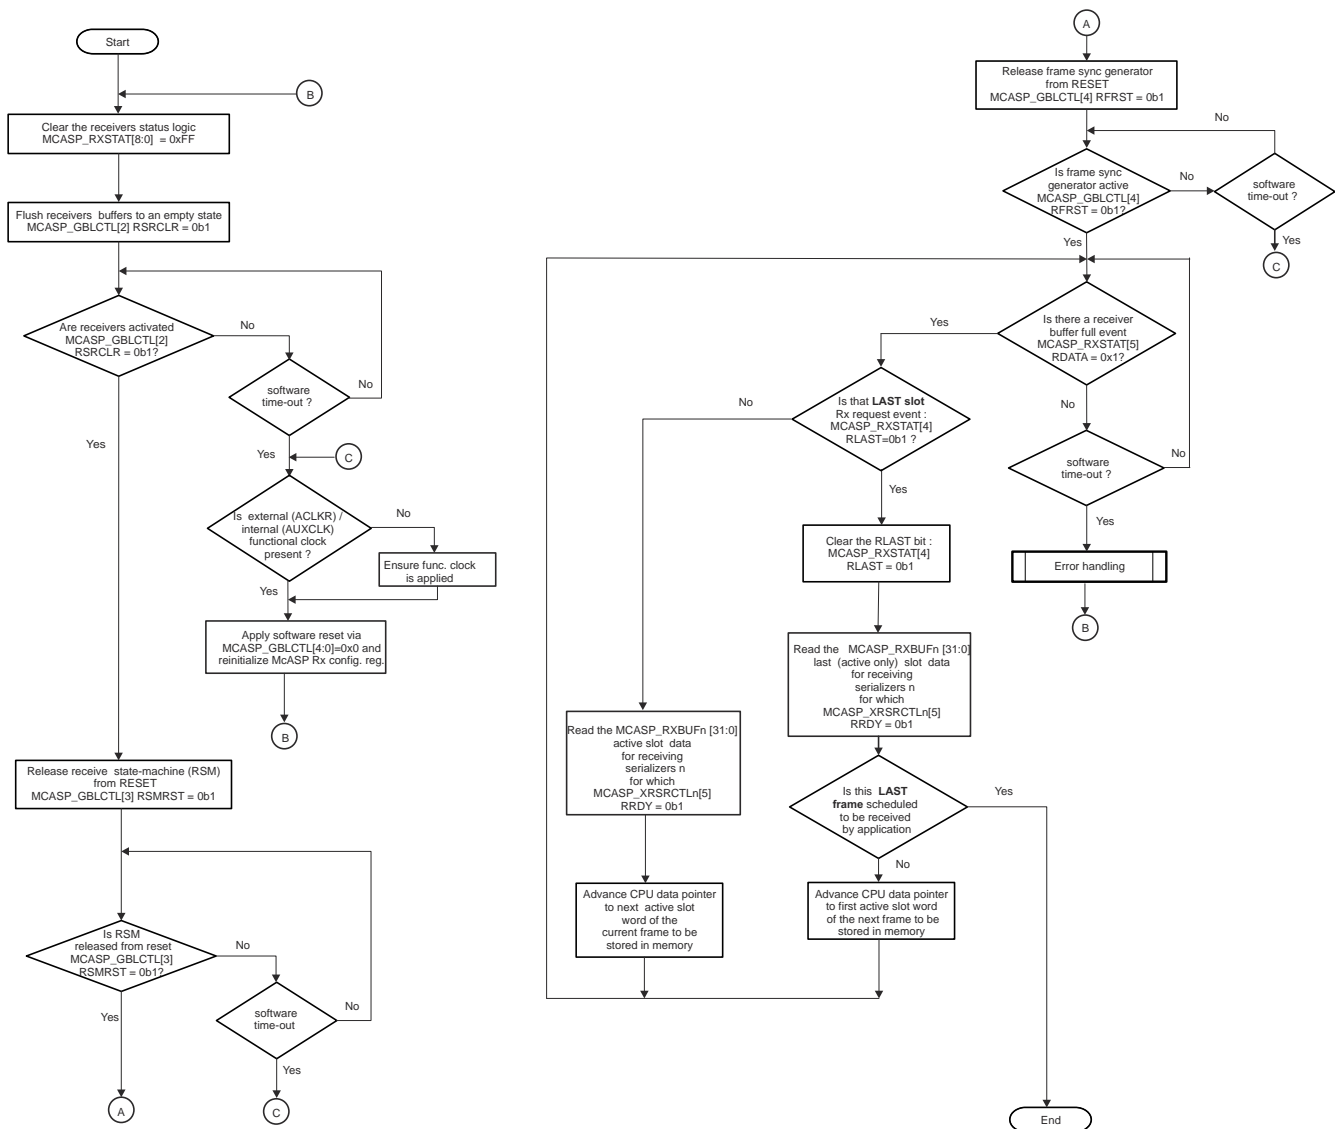

10.7.1.5.2.2 McASP Reception Modes

10.7.1.5.2.2.1 Main Sequence – McASP Polling Reception Method

Figure 10-2081 shows the McASP polling reception method.

Note

The McASP polling reception model considers the device CPUs as the accessor of audio data from the McASP receive buffers.

mcasp-043

Figure 10-2081. McASP Polling Reception Method

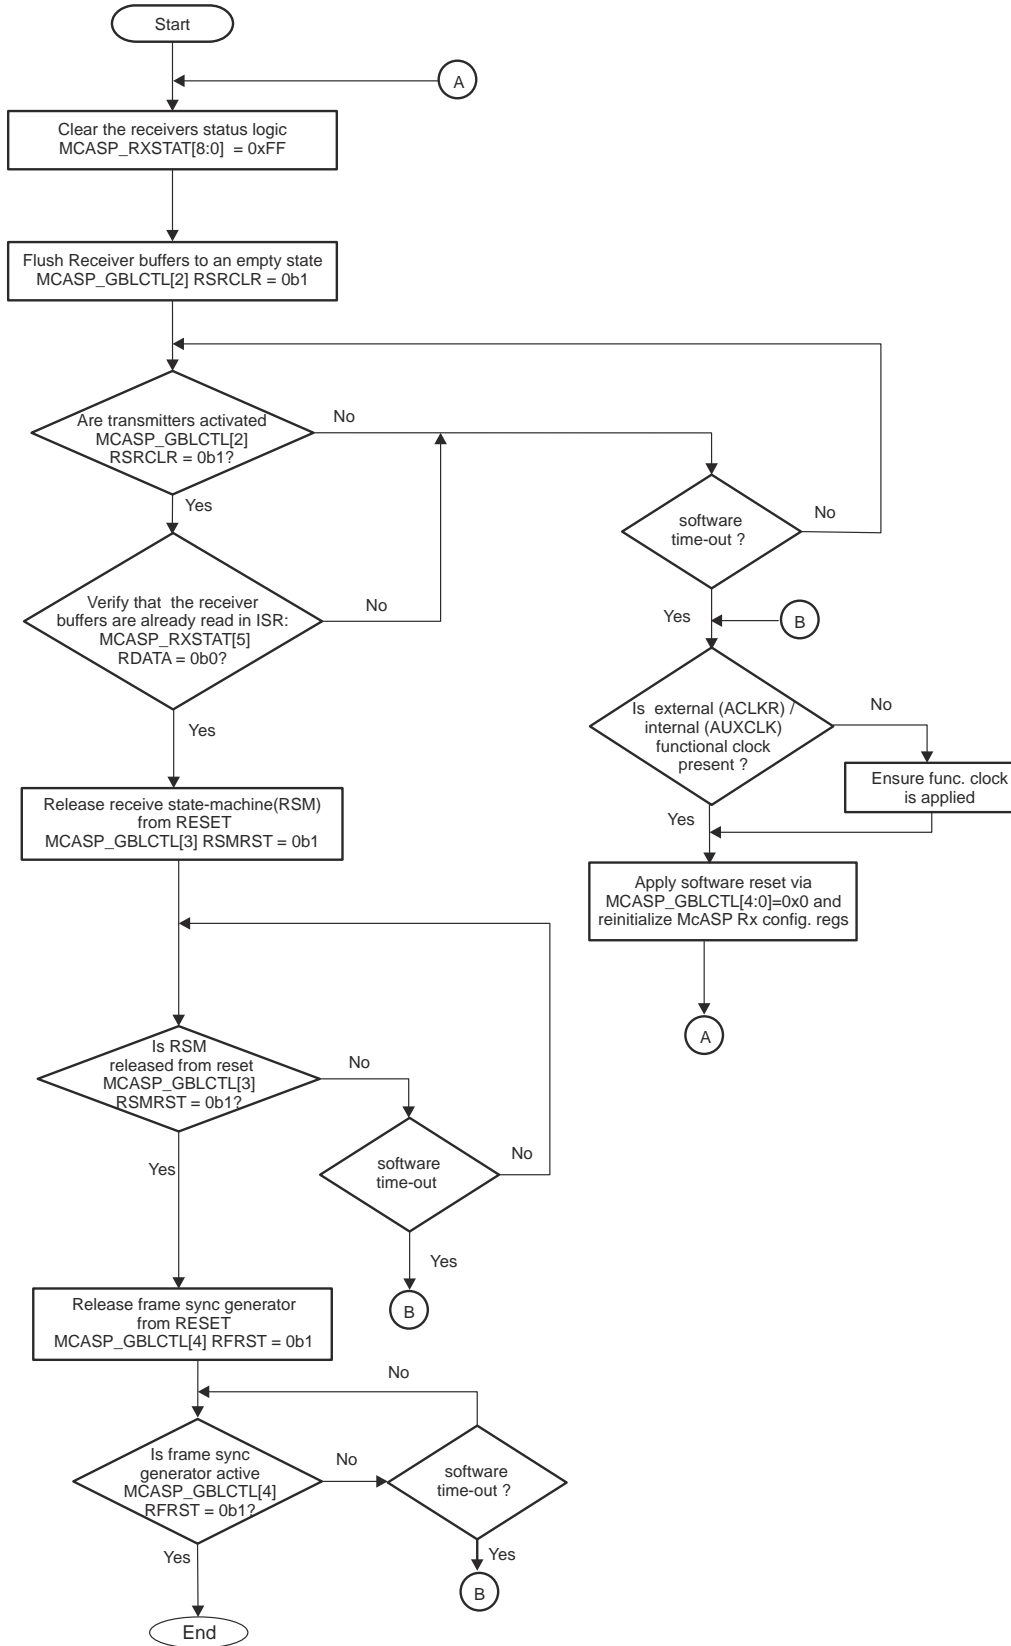

Table 10-2197 summarizes the subprocess call for the polling mode.

Table 10-2197. Subprocess Call Summary for Main Sequence – McASP Reception Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 10-2086

10.7.1.5.2.2.2 Main Sequence – McASP TDM - Interrupt Reception Method

[Figure 10-2082](#) shows the initial setup for interrupt-based reception.

mcasp-032

Figure 10-2082. Subsequence – TDM - Reception Startup Procedure

Table 10-2198 shows the configuration of the McASP using an interrupt method for TDM- reception.

Table 10-2198. McASP TDM- Interrupt Reception Model

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_REVTCTL[0] RDATA	0x1
Enable the data ready event receive interrupt.	MCASP_EVTCTLR[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt.	MCASP_EVTCTLR [7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt	MCASP_EVTCTLR[4] RLAST	0x1
IF read transfer is through the McASP DATA port (MCASP_RXFMT[3] RBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the <i>McASP Receivers Global Initialization for TDM-Mode Operation</i> - see Table 10-2184)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x0
ENDIF		
TDM - Transmission Startup Procedure	See Figure 10-2082.	

10.7.1.5.2.2.3 Main Sequence – McASP TDM - Mode DMA Reception Method

Table 10-2199 shows the configuration of the McASP using the DMA method for reception. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

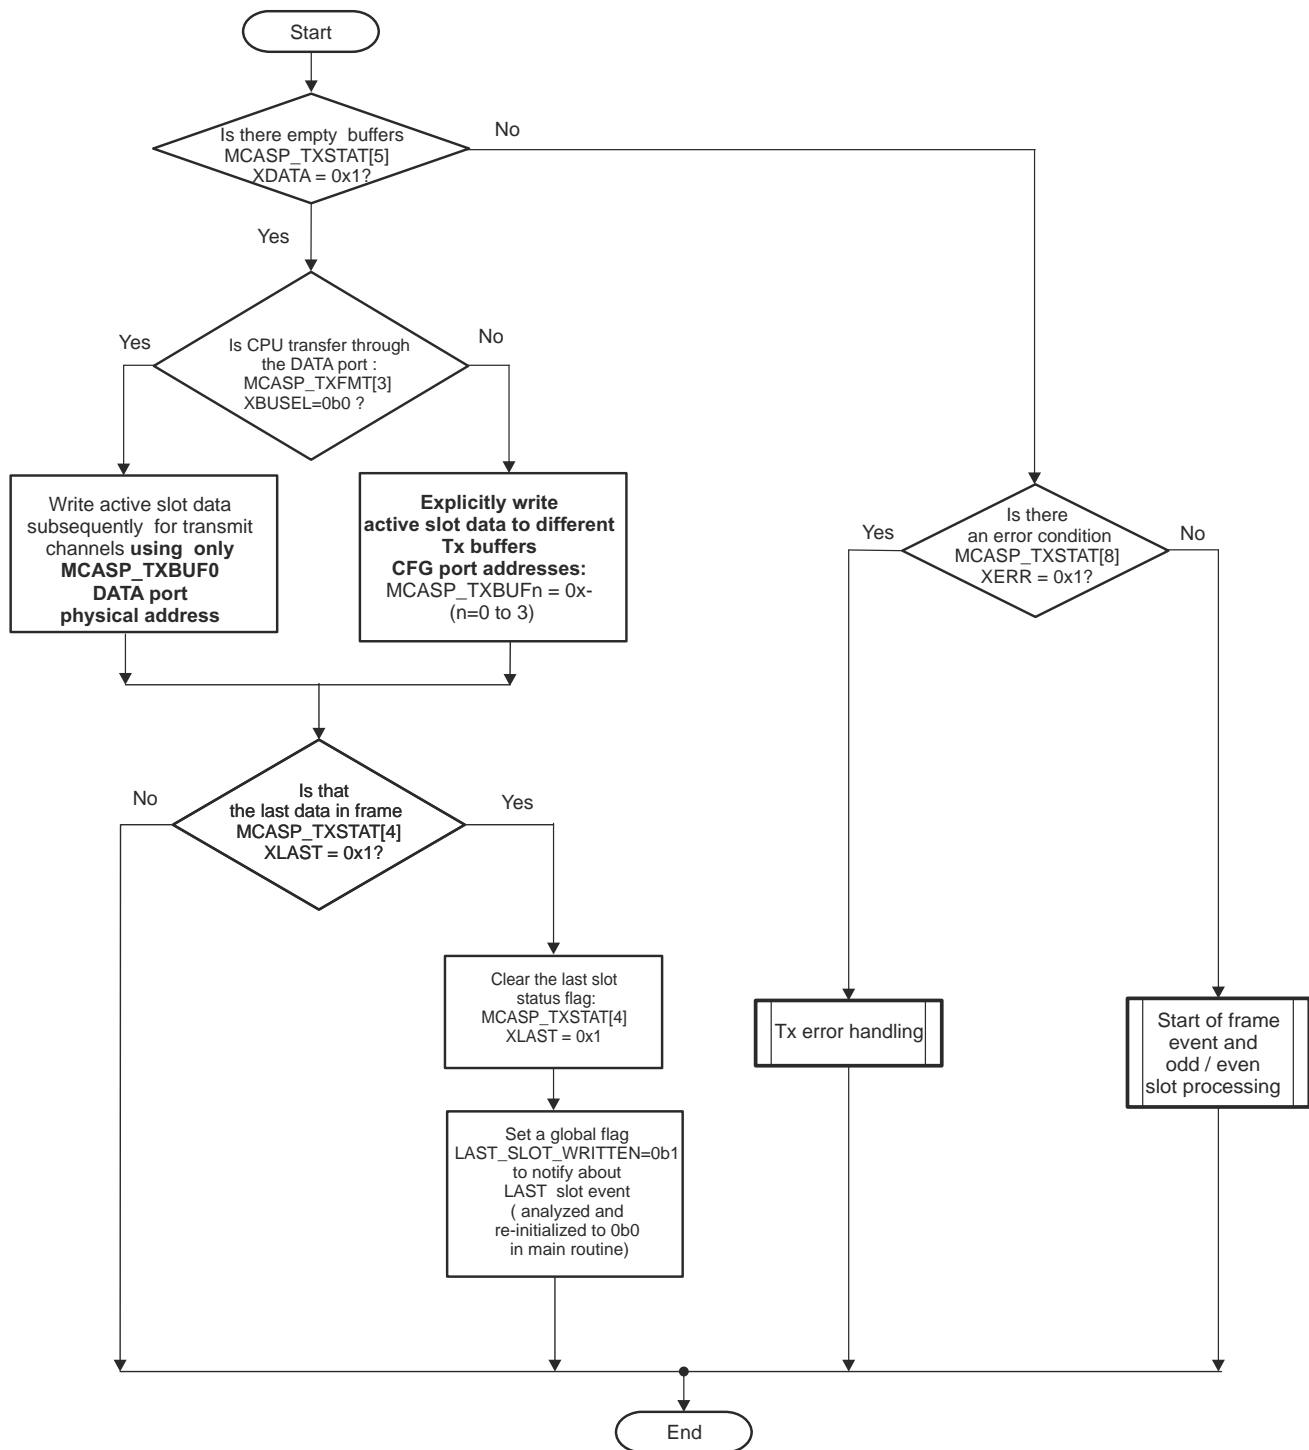

Table 10-2199. McASP DMA Reception Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_RXFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_REVTCTL[0] RDATA	0x0
Enable the Rx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLR[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt.	MCASP_EVTCTLR [7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_EVTCTLR[4] RLAST	0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_EVTCTLR[5] RDATA	0x0
DMA startup reception procedure. This procedure is identical than the one shown in Figure 10-2082. The only difference is that DMA automatically services all the AREVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 10-2084.	See Figure 10-2082.	

10.7.1.5.2.3 McASP Event Servicing

10.7.1.5.2.3.1 McASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 10-2083 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

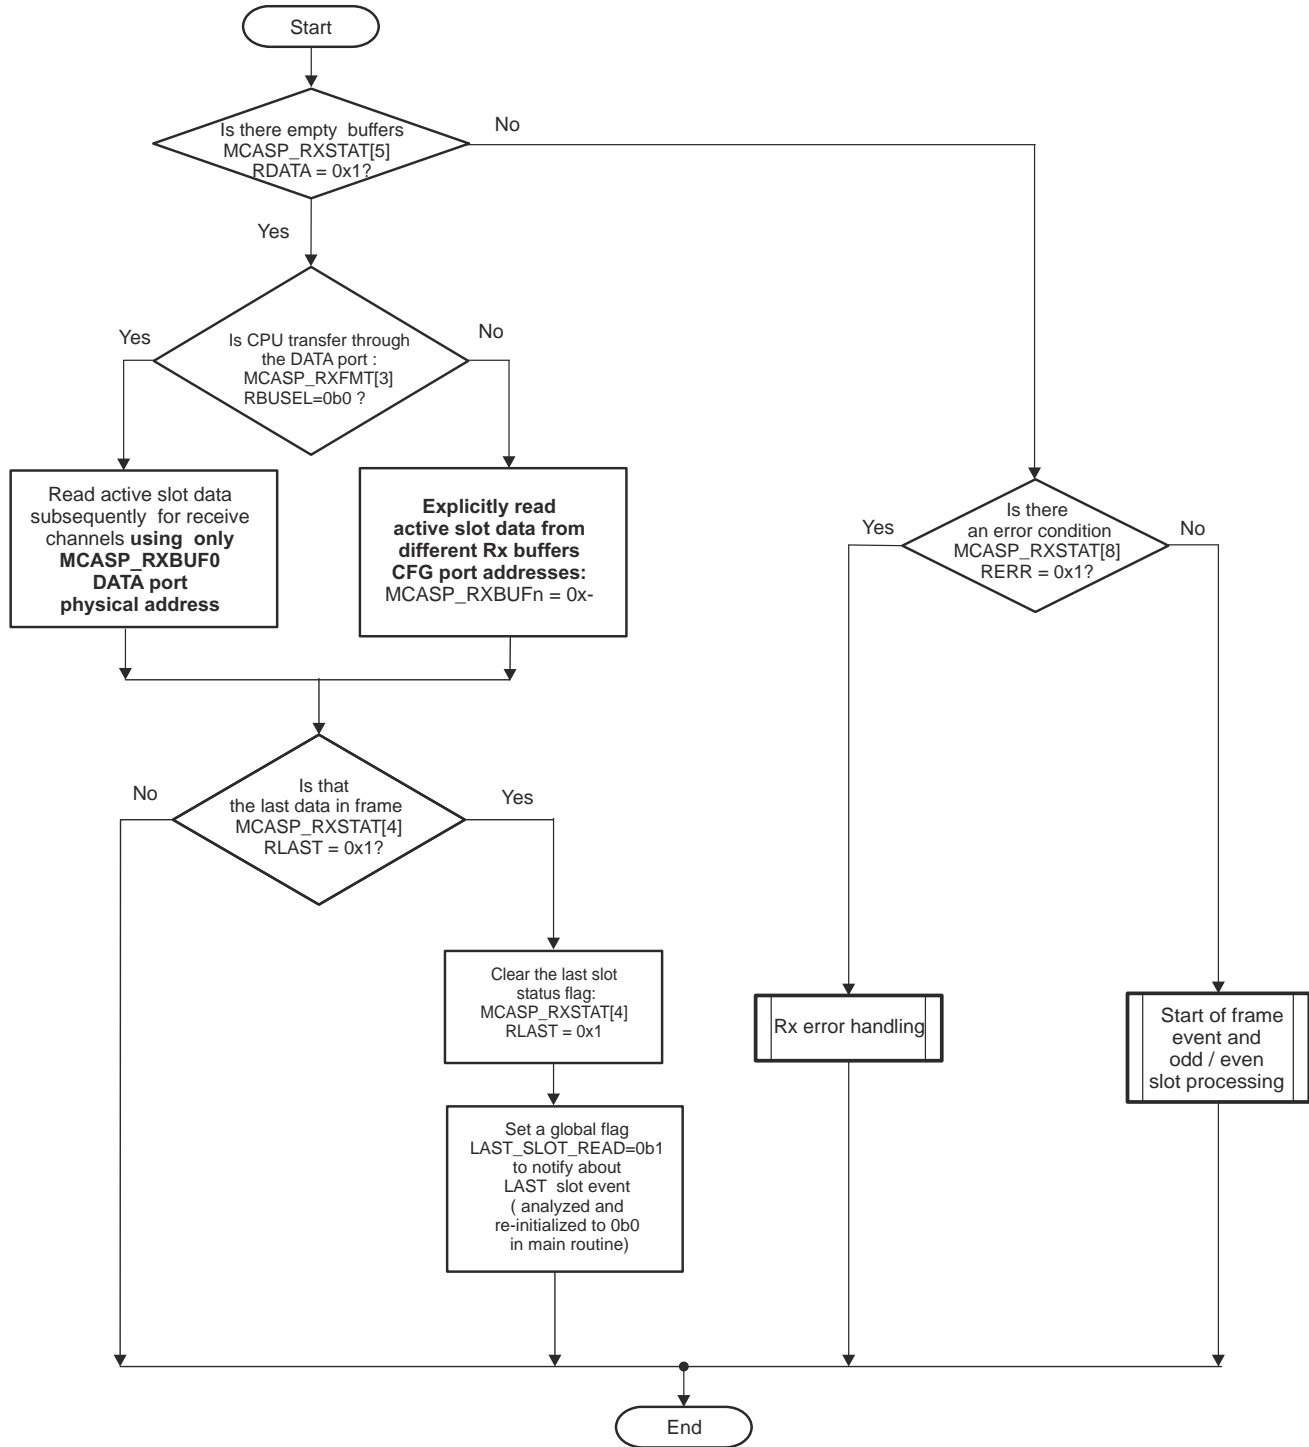

mcasp-029

Figure 10-2083. McASP Transmit Interrupt Events Servicing

10.7.1.5.2.3.2 McASP TDM- Receive Interrupt Events Servicing

Figure 10-2084 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

mcasp-033

Figure 10-2084. McASP Receive Interrupt Events Servicing

Table 10-2200 lists the subprocess call summary for receive interrupt events servicing.

Table 10-2200. Subprocess Call Summary for Receive Interrupt Events Servicing

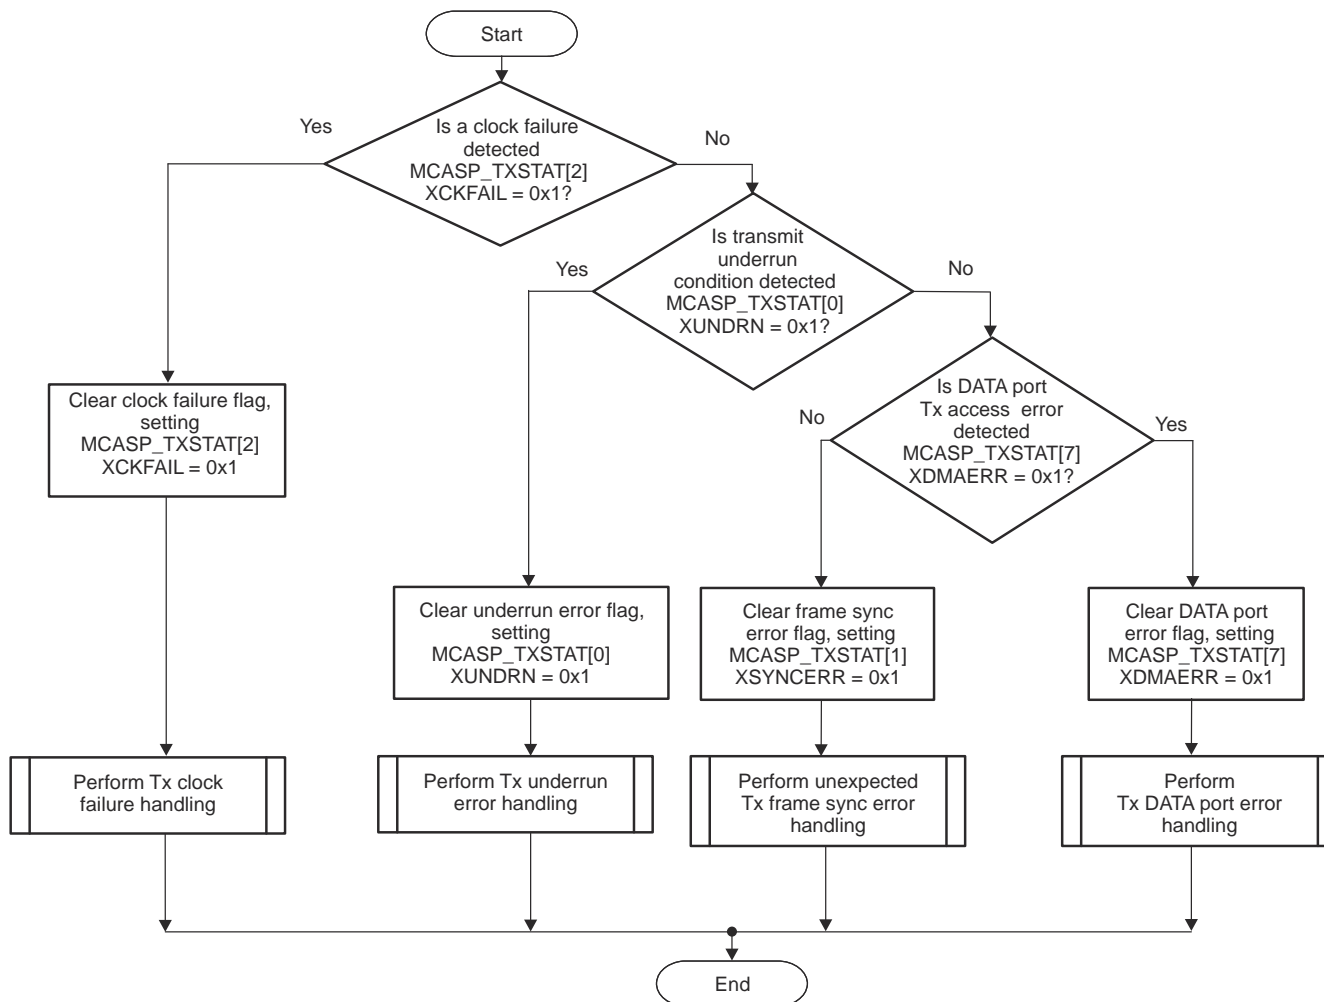

Subprocess Name	Cross-Reference
McASP receive error handling	Figure 10-2086

Table 10-2200. Subprocess Call Summary for Receive Interrupt Events Servicing (continued)

Subprocess Name	Cross-Reference
Start of frame handling	Section 10.7.1.4.12.2

10.7.1.5.2.3.3 Subsequence – McASP DIT-/TDM -Modes Transmit Error Handling

Figure 10-2085 shows the transmit error handling schema for the McASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

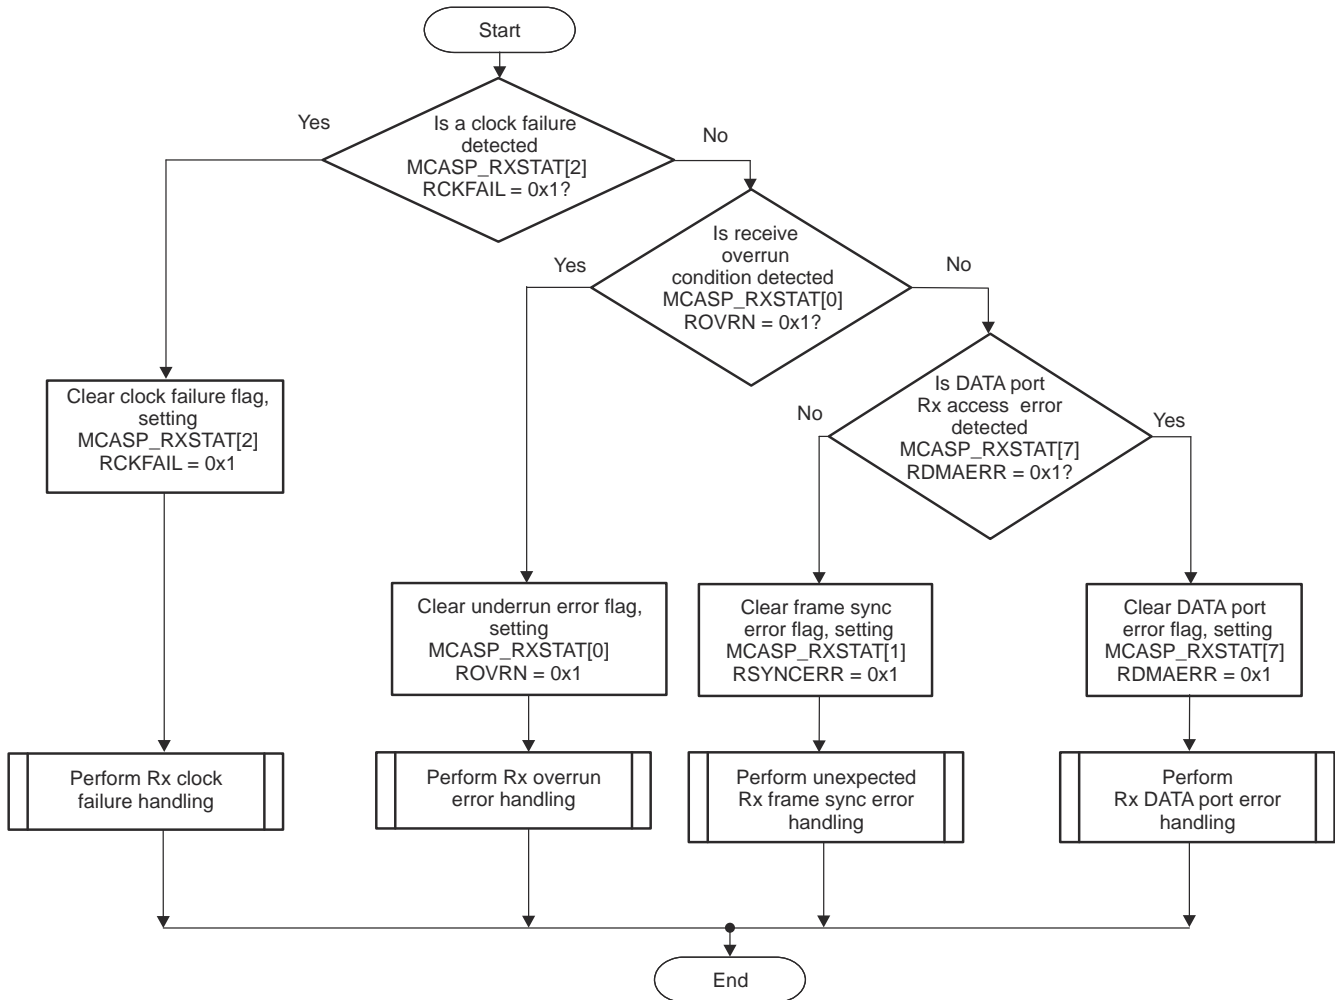

mcasp-030

Figure 10-2085. McASP Transmit Error Handling
Note

- For more information about transmit clock failure handling, see [Section 10.7.1.4.15.6.2, Transmit Clock Failure Check and Recovery](#).
- For more information about transmit buffer underrun handling, see [Section 10.7.1.4.15.1, Buffer Underrun Error - Transmitter](#).
- For more information about DATA port Tx error handling, see [Section 10.7.1.4.15.3, DATA Port Error - Transmitter](#).
- For more information about unexpected Tx frame sync error handling, see [Section 10.7.1.4.15.5, Unexpected Frame Sync Error](#).

10.7.1.5.2.3.4 Subsequence – McASP Receive Error Handling

Figure 10-2086 shows the receive error handling schema for the McASP, which can ONLY be implemented as part of the Rx polling sequence.

mcaspp-031

Figure 10-2086. McASP Receive Error Handling

Note

- For more information about receive clock failure handling, see [Section 10.7.1.4.15.6.3, Receive Clock Failure Check and Recovery](#).
- For more information about receive buffer overrun handling, see [Section 10.7.1.4.15.2, Buffer Overrun Error - Receiver](#).
- For more information about DATA port Rx error handling, see [Section 10.7.1.4.15.4, DATA Port Error - Receiver](#).
- For more information about unexpected Rx frame sync error handling, see [Section 10.7.1.4.15.5, Unexpected Frame Sync Error](#).

10.7.1.6 McASP Register Manual

10.7.1.6.1 McASP Instance Summary

Table 10-2201 summarizes the McASP instances.

Table 10-2201. McASP Instance Summary

Module Name	Base Address L3_MAIN Interconnect	Base Address L4_PER2 Interconnect	Size

(1) i = 0 to 5

(2) n = 0 to 5

Note

The address locations listed in [Table 10-2202](#) and [Table 10-2203](#), *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
- MCASP_TXBUFn registers
- MCASP_RXBUFn registers

through the McASP peripheral configuration (CFG) port.

The MCASP_TXFMT[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFn buffer. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFn buffer.

10.7.1.6.2.2 MCASP_CFG Register Description

The tables below describe the individual MCASP_CFG register bits.

Note

For all of the below described registers the indexes n and N are applying to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For the particular McASP instantiation, please refer to [Section 10.7.1.2, McASP Environment](#), and [Section 10.7.1.3, McASP Integration](#).

Table 10-2206. MCASP_PFUNC (continued)**Description**

Specifies the function of the pins as either a McASP pin or a GPIO pin.

Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 10-2208. MCASP_PDOUT

Address Offset	0x0000 0018	Instance	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Physical Address	0x4846 0018 0x4846 C018 0x4847 0018		
Description	<p>Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIDR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIDR is set to 1 (output).</p> <p>When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin.</p> <p>When writing data, writes to the corresponding MCASP_PDOUT[n] bit.</p> <p>PDOUT has these aliases or alternate addresses:</p> <ul style="list-style-type: none"> MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged. MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged <p>There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.</p> <p>Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.</p>

	0x4847 0020		MCASP3_CFG_PER2_L4																																
Description	<p>The pin data clear register is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDCLR bit clears the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic low on the pin.</p> <p>Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.</p>

	0x4847 0044		MCASP3_CFG_PER2_L4

Table 10-2212. MCASP_GBLCTL (continued)

Description Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. AXR[n] pin state: If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
4	RFRST	Receive frame sync generator reset enable bit. 0x0: Receive frame sync generator is reset. 0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit. 0x0: Receive state machine is held in reset. 0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0x0: Receive serializers are cleared. 0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit. 0x0: Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit. 0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: Receive clock divider is running.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN RSYNCERR RCKFAIL RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0

Bits	Field Name	Description	Type	Reset
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs or DMA. When RDATA is set, it always causes a DMA event (AREVT).	RW	0
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN XSYNCERR XCKFAIL XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0

Bits	Field Name	Description	Type	Reset
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect 0x0: XBUF[n] is written and is full 0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

Bits	Field Name	Description	Type	Reset																																																						
31:6	RESERVED	Reserved	RW	0x0000000																																																						
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn. Read 0x0: Receive buffer (MCASP_RXBUFn) is empty. Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0																																																						
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data. Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0																																																						
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0																																																						
1:0	SRMOD	Serializer mode bit 0x0: The serializer is inactive 0x1: The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

10.7.1.6.2.5 MCASP_DAT Register Summary

Table 10-2254 and Table 10-2255 summarize the MCASP_DAT register mapping.

Table 10-2254. MCASP_DAT Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000 ⁽¹⁾	0x4580 0000
MCASP_TXBUF	W	32	0x0000 0000 ⁽¹⁾	0x4580 0000

- (1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUF_n RX/TX buffers through the McASP DATA port.

Table 10-2255. MCASP_DAT Register Summary 2

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L4_PER2 Physical Address	MCASP3_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000 ⁽¹⁾	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000 ⁽¹⁾	0x4843 6000	0x4843 A000

- (1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUF_n RX/TX buffers through the McASP DATA port.

Note

For MCASP_RXBUF and MCASP_TXBUF buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_TXFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

Note

The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

Note

The McASP1, whose data port is accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

10.7.1.6.2.6 MCASP_DAT Register Description

Table 10-2256. MCASP_RXBUF

Address Offset	0x0000 0000
----------------	-------------

Table 10-2256. MCASP_RXBUF (continued)

Physical Address	0x4580 0000 0x4843 6000 0x4843 A000	Instance	MCASP1_DAT_MAIN_L3 MCASP2_DAT_PER2_L4 MCASP3_DAT_PER2_L4
Description	Through the DATA port, the Host can service all serializers through a single address and the McASP automatically cycles through the appropriate serializers. For receive operations through the DATA port, the Host should read from the same RBUF DATA port address to service all of the active receive serializers upon each receive data ready event. To enable accesses from the Host to the McASP XRBUF registers through the DATA port, one must clear the RBUSEL bits to 0 in the respective MCASP_RXFMT registers in the MCASP_CFG Memory Map.

10.8 Camera Subsystem

10.8.1 CSI2-RX

10.8.1.1 CSI2 Interface.....	4783
------------------------------	------

10.8.1.1 CSI2 Interface

10.8.1.1.1 CSI Overview

The AM273x integrates two four-lane CSI2 receiver interfaces (2 × DHPYv0.92 + CSI-RX) in the Radar processing subsystem. The prime functionality of these interfaces is to support the reception of radar front end raw data (raw ADC data or 1st D FFT data), Chirp Quality, and monitoring data from the Radar Frontend device.

10.8.1.1.1.1 CSI2 Interface Features

- The Two CSI2 camera interfaces: CSI2-A (primary) and CSI2-B (secondary)
- Transfer pixels and data received by the CSI2 digital physical layer receiver to the system memory.
- Use unidirectional data link
- Both CSI2-A and CSI2-B support four configurable data links in addition to the clock signaling.
- Maximum data rate of 1 Gbps per data lane
- Data merger for 2-, 3-, or 4-data lane configuration
- Maximum data rate of 1 Gbps per data lane, possible configurations are:
 - One data lane: 1000 Mbps (824 Mbps if lane 4 is used)
 - Two data lanes: 2 × 1000 Mbps (2 × 824 Mbps if lane 4 is used)
 - Three data lanes: 3 × 1000 Mbps (3 × 824 Mbps if lane 4 is used)
 - Four data lanes: 4 × 824 Mbps
- Error detection and correction by the protocol engine
- Direct memory access (DMA) engine integrated with dedicated first in first out (FIFO)
- One-dimensional (1D) and two-dimensional (2D) addressing mode
- Burst support
- Eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- All primary and secondary MIPI-defined formats are supported.
- Conversion of the RGB formats
- On-the-fly differential pulse code modulation (DPCM) decompression
- On-the-fly image cropping and A-law/DPCM compression
- Configuration of the complex input/output (I/O) physical layer (PHY) (MIPI D-PHY-compliant receiver PHY solution [D-PHY mode])
-
-
-

In addition to the above features, the CSI IP has been enhanced to support the following additional features.

- Support for 8/10/12/14/16-bits RAW data mode with capability of sign extension to align with 16-bit memory addressing for RAW10/12/14 modes
 - The CSI2 IP supports sign-extension in “EXP16” data modes. The below MMR bits are provided to enable sign extension instead of zero padding while writing into the CSI2 internal FIFO.
 - RCSS_CTRL: RCSS_CSI2A/B_CFG_SIGN_EXT_EN
- Interrupts for each of the DMA contexts (RCSS_CSI2A/B_EOL_CNTX0_INT...RCSS_CSI2A/B_EOL_CNTX7_INT)
 - 8 line end interrupts are generated corresponding to the 8 CSI2 contexts. These interrupts are generated after the last word of N line data (N= RCSS_CSI2A/B_CTX[0-7]_LINE_PING_PONG_NUM_LINES) for that particular context is written into the destination address by the CSI2 DMA.
 - These interrupts are connected to the following interrupt and DMA lines:
 - MSS CR5 A/B
 - DSS DSP
 - DSS CM4
 - DSS_TPCC_B (CSI2A interrupts)
 - DSS_TPCC_C (CSI2B interrupts)
 - RCSS_TPCC_A

- These context based interrupts are also connected to HWA and can be configured to be used as HWA triggers.
- Frame start interrupts (RCSS_CSI2A/B_SOF_INT0 , RCSS_CSI2A/B_SOF_INT1)
 - Can be independently configured to select any of the 8 CSI2 context based frame start interrupts using below MMR register
 - RCSS_CSI2A/B_CFG_SOF_INTR1_SEL / RCSS_CSI2A/B_CFG_SOF_INTR0_SEL
 - These interrupts are connected to the following interrupt and DMA lines
 - MSS CR5 A/B
 - DSS DSP
 - DSS CM4
 - DSS_TPCC_B(CSI2A interrupts)
 - DSS_TPCC_C(CSI2B interrupts)
 - RCSS_TPCC_A
 - These context based interrupts are also connected to HWA and can be configured to be used as HWA triggers.
- N Line wise Ping-pong mode
 - Legacy CSI2 IP supports only Frame based ping pong DMA trasfers. In AM273x, support is provided to support ping-pong switch at line level and also after “N”(N being programmable) number of lines. These can be enabled using below MMR registers
 - RCSS_CTRL: RCSS_CSI2A/B_CTX[0-7]_LINE_PING_PONG_ENABLE Enable line ping/pong feature instead of frame ping/pong
 - RCSS_CTRL: RCSS_CSI2A/B_CTX[0-7]_LINE_PING_PONG_NUM_LINES Number of lines after which the CSI2 DMA writes switch between ping and pong
 - At the start of a frame, the CSI2 DMA writes always starts from the PING start address for all contexts
- Parity for CSI2 memories
 - Byte-wise parity support is provided for FIFO RAM and CTX RAM
 - The parity enable for the RAMs are provided below
 - RCSS_CTRL:RCSS_CSI2A/B_PARITY_CTRL_FIFO_PARITY_EN
 - RCSS_CTRL: RCSS_CSI2A/B_PARITY_CTRL_CTX_PARITY_EN
 - The parity error status for the RAMs are available in below configuration registers
 - RCSS_CTRL: RCSS_CSI2A/B_PARITY_STATUS_FIFO_PARITY_ADDR
 - RCSS_CTRL: RCSS_CSI2A/B_PARITY_STATUS_FIFO_PARITY_ADDR

10.8.1.1.2 CSI2 PHY

10.8.1.1.2.1 CSI2 PHY Overview

Two MIPI D-PHY-compliant CSIRX PHY receivers act as a physical connection and configuration of clock/data lanes with external sensors. CSIRX PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receivers are compatible with the *MIPI D-PHY Specification v0.92*.

The PHY is controlled and must be configured first from the control module for pad configuration. The differential data/clock lanes coming into the CSI2-A and CSI2-B CSIRX are explained in the CSI2 PHY control registers CSI2_PHY_CFG.

As mentioned previously, two PHYs are integrated in the device. Both the CSI2-A and CSI2-B CSIRX contain four data lanes, as shown in [Figure 10-2087](#).

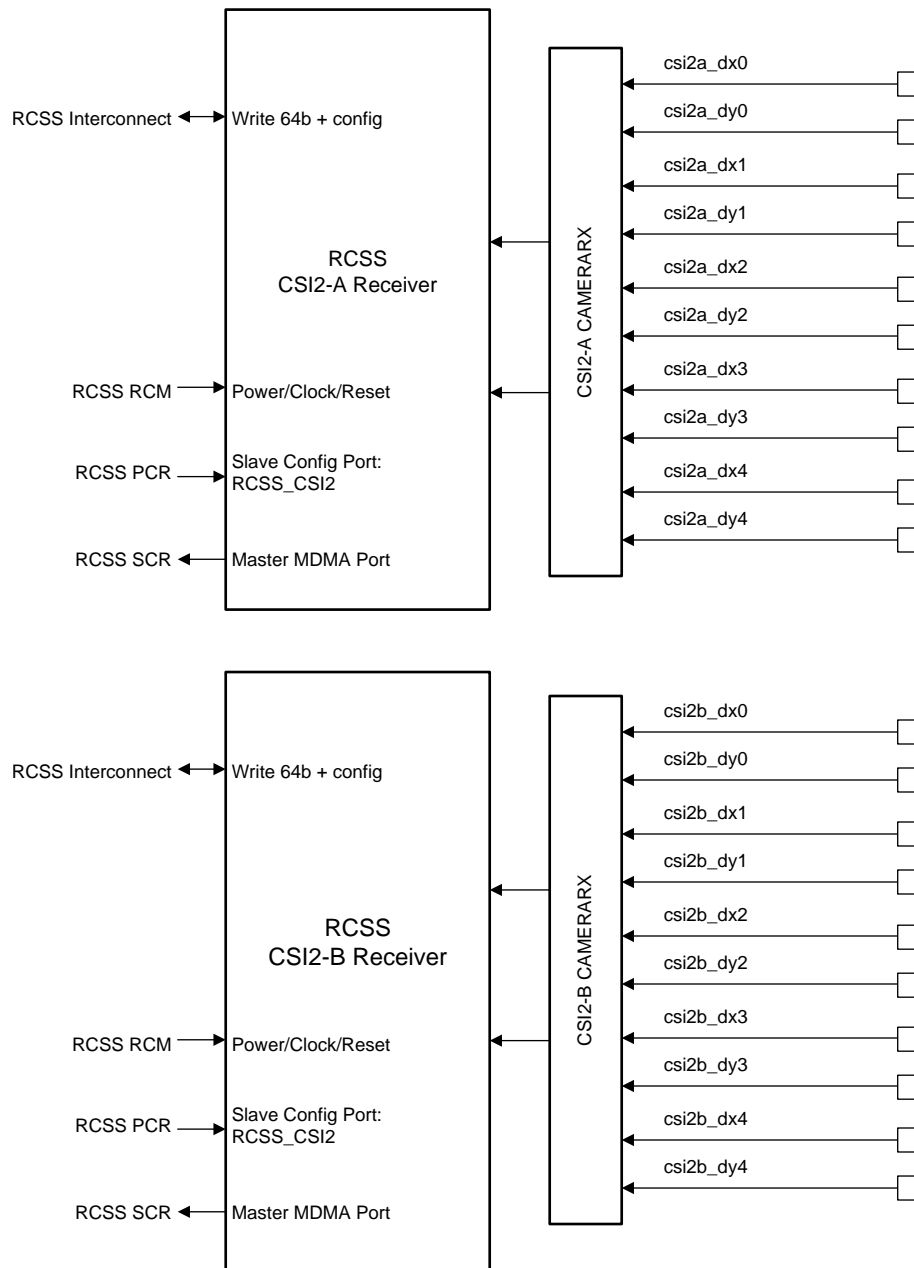

Figure 10-2087. Interfaces CSI2-A PHY Diagram Four D-PHY Data Lane Configuration

Note

LANE 4 can be used only as a data lane, never as a clock lane. All other configurations are possible. Also, a speed restriction is present when lane 4 is used; then all data lanes perform at up to 824 Mbps instead of 1000 Mbps.

CSI2-A and CSI2-B CSIRX represent the overall PHY solution for connecting external sensors to feed the CSI interface. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module, and the DX/DY data pad for each lane module can be configured as DP or DN pins defined.

10.8.1.1.2.2 CSI2 PHY Functional Description

10.8.1.1.2.2.1 CSI2 PHY Functional Configuration

The CSI2 PHY converts the bitstream, divided into 1 to 4 serial data lanes, into a bitstream compatible with the CSI2 receiver and one clock lane.

The [CSI2_COMPLEXIO_IRQSTATUS](#) register logs complex I/O events of the following types:

- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

The CSI2 receiver embeds two registers to configure/read some complex I/O parameters:

- The [CSI2_PHY_CFG_REG0](#) register detects clock miss with respect to the *MIPI D-PHY Specification v0.92* and control timing.
- The [CSI2_PHY_CFG_REG1](#) register reports completion of reset on the different parts of the module and configures the timing parameters.
- The [CSI2_COMPLEXIO_CFG](#) registers contain the PWR_AUTO and PWR_CMD bit fields, which affect the power management of the two complex I/Os.

The complex I/O has three power modes: on, off, and ultralow power (ULP). These modes can reflect the ON or ULP states of the five differential lines if the [CSI2_COMPLEXIO_CFG\[24\]](#) PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the complex I/O power state is controlled by the [CSI2_COMPLEXIO_CFG\[28:27\]](#) PWR_CMD bit field, which directly defines the power state. [Figure 10-2088](#) shows the complex I/O power finite state-machine (FSM).

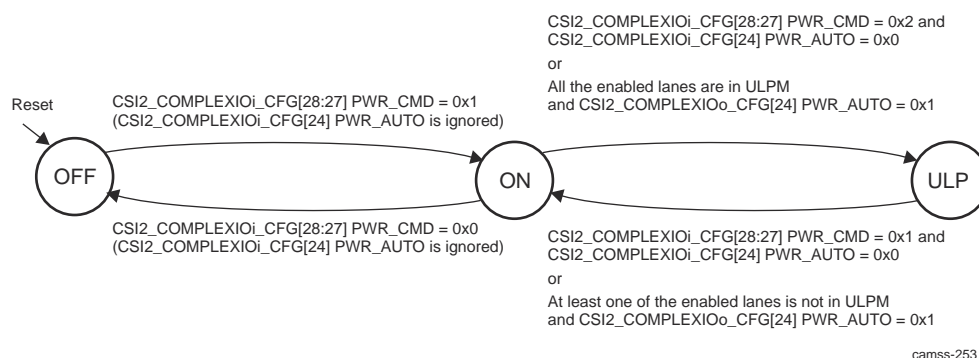

Figure 10-2088. CSI2 Complex I/O Power FSM

Another register, [CSI2_TIMING](#), is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the two complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The FORCE_RX_MODE_IO bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bits ([CSI2_TIMING\[14\]](#) STOP_STATE_X16_IO1, [CSI2_TIMING\[13\]](#) STOP_STATE_X4_IO1, and the [CSI2_TIMING\[12:0\]](#) STOP_STATE_COUNTER_IO1 bit field) configure the

delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock cycles and can be calculated as follows:

$$\text{Total delay in clock cycle} = \text{CSI2_TIMING.STOP_STATE_COUNTER_IO} \times (1 + \text{CSI2_TIMING.STOP_STATE_X16_IO} \times 15) \times (1 + \text{CSI2_TIMING.STOP_STATE_X4_IO} \times 3).$$

Table 10-2258 lists the possible values of the delay, in terms of the clock cycles, depending on the values of the STOP_STATE_X16_IO and STOP_STATE_X4_IO bits.

Table 10-2258. CSI2 Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO	STOP_STATE_X4_IO	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The FORCERXMODE signal is used at initialization time (complex I/O). Figure 10-2089 describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

Figure 10-2089. CSI2 RxMode and StopState FSM

10.8.1.1.2.2.2 CSI2 PHY and Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CSIRX. The CSI2 receiver is expected to coordinate the PHY initialization. The controller must ensure that the PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CSIRX for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state." One possible initialization sequence is:

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to be ready to receive signals/data from the CSIPHY:
 - a. Configure all needed CSI2 registers:
 - i. Set CSI2_COMPLEXIO_CFG[18:16] DATA4_POSITION.
 - ii. Set CSI2_COMPLEXIO_CFG[14:12] DATA3_POSITION.
 - iii. Set CSI2_COMPLEXIO_CFG[10:8] DATA2_POSITION.
 - iv. Set CSI2_COMPLEXIO_CFG[6:4] DATA1_POSITION.
 - v. Set CSI2_COMPLEXIO_CFG[2:0] CLOCK_POSITION.
 - vi.

CAUTION

This must be done before the CSIPHY is active.
2. CSIPHY and link initialization sequence:
 - a. Deassert the CSIPHY reset.
 - i. Set CSI2_COMPLEXIO_CFG[30] RESET_CTRL to 0x1.

CAUTION

For the [CSI2_COMPLEXIO_CFG](#)[29] RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSIPHY reset and before asserting the FORCERXMODE signal:

- [CSI2_PHY_CFG_REG0](#)
- [CSI2_PHY_CFG_REG1](#)
- [CSI2_PHY_CFG_REG2](#)

b. Assert the FORCERXMODE signal:

i. Set [CSI2_TIMING](#)[15] FORCE_RX_MODE_IO1 to 0x1.

c. Connect pulldown on link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):

For CSI2-A/B CSIRX pulldown on signals using the RCSS_CTRL: RCSS_CSI2A/B_LANE_CFG registers for each lane:

- [RCSS_CSI2A/B_LANE_n_CFG_DX/Y_n_IE](#) = 0x1
- [RCSS_CSI2A/B_LANE_n_CFG_DX/Y_n_ENBPD](#) = 0x1

d. Power up the CSIPHY:

i. Set [CSI2_COMPLEXIO_CFG](#)[28:27] PWR_CMD to 0x1.

e. Check whether the state status reaches the ON state:

- [CSI2_COMPLEXIO_CFG](#)[26:25] PWR_STATUS = 0x1

f. Wait for STOPSTATE = 1 (for all enabled lane modules):

- i. The timer is set through the [CSI2_TIMING](#)[14:0] bit field. The reset value can be kept.
- ii. Wait until [CSI2_TIMING](#)[15] FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.

g. Release PIPD* (= 1).

For CSI2-A/B CSIRX pullup on signals using the RCSS_CTRL: RCSS_CSI2A/B_LANE_CFG registers for each lane:

- [RCSS_CSI2A/B_LANE_n_CFG_DX/Y_n_ENBPU](#) = 0x1

3. The CSIPHY is initialized and ready/active in CSI2 mode.

10.8.1.1.2.3 CSI PHY Error Signals

In D-PHY mode, the CSIPHY supports the following error detection and signaling to the associated receiver:

- ERRSOTHS: Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSIPHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS: Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSIPHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL: Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC: Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.

10.8.1.1.3 CSI2

10.8.1.1.3.1 CSI2 Environment

10.8.1.1.3.1.1 CSI2 Protocol and Data Format

The CSI2 supports MIPI CSI2 multiple data type formats. This section describes MIPI CSI2 protocol and data formats. The CSI2 is compatible with the *MIPI CSI2 Specification v1.0-01-00 r0.03*. [Table 10-2259](#) lists the MIPI CSI2 supported by CSI2 formats in addition to JPEG8. Shading in the primary and secondary MIPI CSI2-defined formats indicates special format extensions of the CSI2 receiver.

[Table 10-2259](#) summarizes the pixel formats supported by the CSI2 receiver interface.

Table 10-2259. CSI2 Pixel Format Modes

CSI2_CTX_CTR L2_i[9:0] Format	CSI2 Data Format	Bits per Pixel (BPP)	Data Size Increases in Memory	2D Mode Availability	Comments

For more information about how the data formats are transmitted and how the data are stored in memory, see [Section 10.8.1.1.3.1.1.4, CSI2 Operating Modes](#).

10.8.1.1.3.1.1.1 CSI2 Physical Layer

The CSI2-A/CSI2-B receivers are tightly connected to a PHY layer (for more information about the PHY, see [Section 10.8.1.1.2, CSI2 PHY](#)). [#unique_1525/unique_1525_Connect_42_INT_SWPU220_ISS_INTERFACES_00281referenceTitle](#) lists the CSI2-A receiver I/O, and [Table 10-2261](#) lists the CSI2-B receiver I/O. The CSI2_RECEIVER provides access to the complex I/O configuration from the CSI2_COMPLEXIO_CFG register.

Table 10-2260. CSI2-A I/O Description

Signal Name		I/O ⁽¹⁾	Description
csi2a_dx0	lane 0 (position 1)	I	Serial data/clock input
csi2a_dy0			
csi2a_dx1	lane 1 (position 2)	I	Serial data/clock input
csi2a_dy1			
csi2a_dx2	lane 2 (position 3)	I	Serial data/clock input
csi2a_dy2			
csi2a_dx3	lane 3 (position 4)	I	Serial data/clock input
csi2a_dy3			
csi2a_dx4	lane 4 (position 5)	I	Serial data input only
csi2a_dy4			

(1) I = Input

Table 10-2261. CSI2-B I/O Description

Signal Name		I/O ⁽¹⁾	Description
csi2b_dx0	lane 0 (position 1)	I	Serial data/clock input
csi2b_dy0			
csi2b_dx1	lane 1 (position 2)	I	Serial data/clock input
csi2b_dy1			
csi2b_dx2	lane 2 (position 3)	I	Serial data/clock input
csi2b_dy2			
csi2b_dx3	lane 3 (position 4)	I	Serial data/clock input
csi2b_dy3			
csi2b_dx4	lane 4 (position 5)	I	Serial data input only
csi2b_dy4			

Note

The serial lane can be used as clock lane or data lane (excluding lane 4 on the CSI2-A I/O). The MIPI CSI2 protocol requires one clock lane (others are data lane or unused lane).

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

10.8.1.1.3.1.1.2 CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The lane merger can merge up to four lanes (CSI2-A) into a single byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2-A, CSI2-B receiver core depends on the lane configuration. The merger is not used for a single lane.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

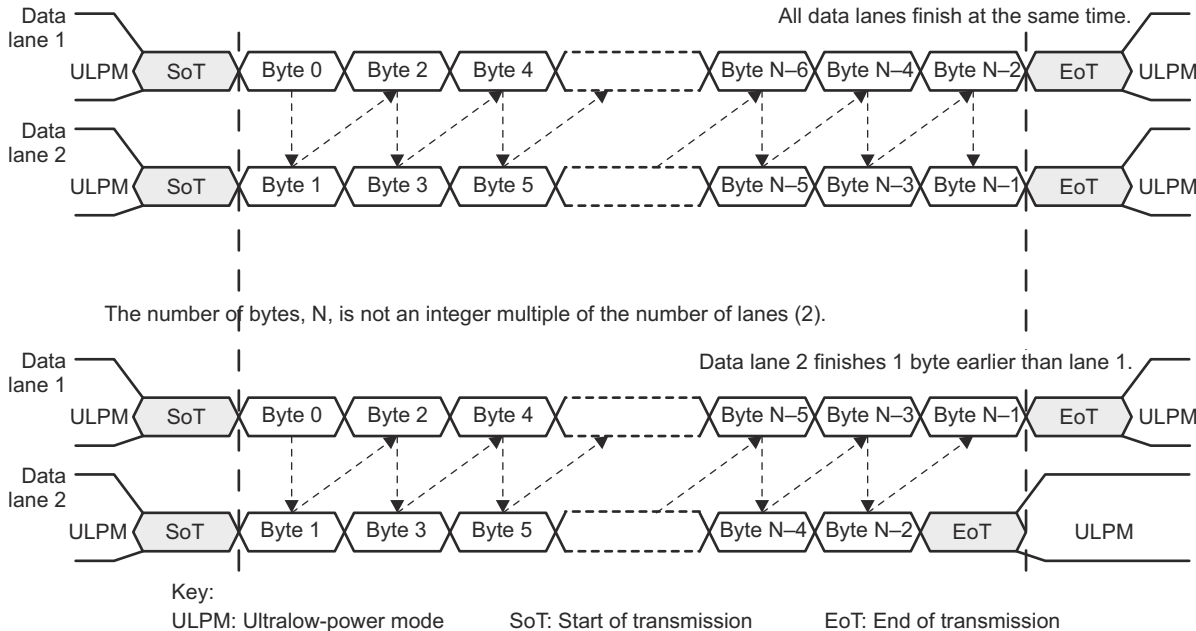

Figure 10-2090 to Figure 10-2093 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

camss-240

Figure 10-2090. CSI2 One Data-Lane Configuration

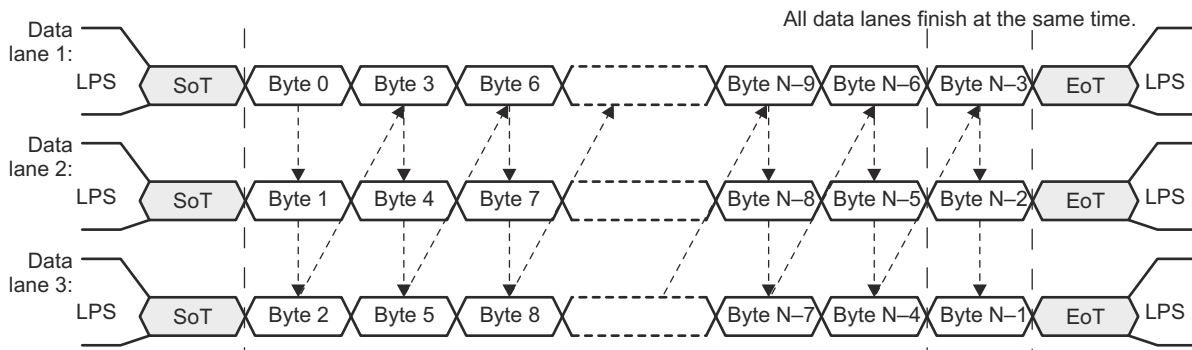

The number of bytes, N, is an integer multiple of the number of lanes (2).

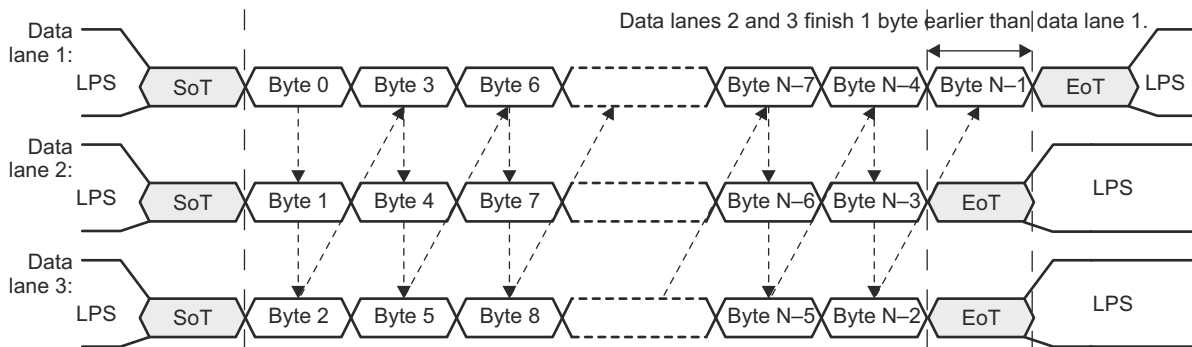

camss-239

Figure 10-2091. CSI2 Two Data-Lane Merger Configuration

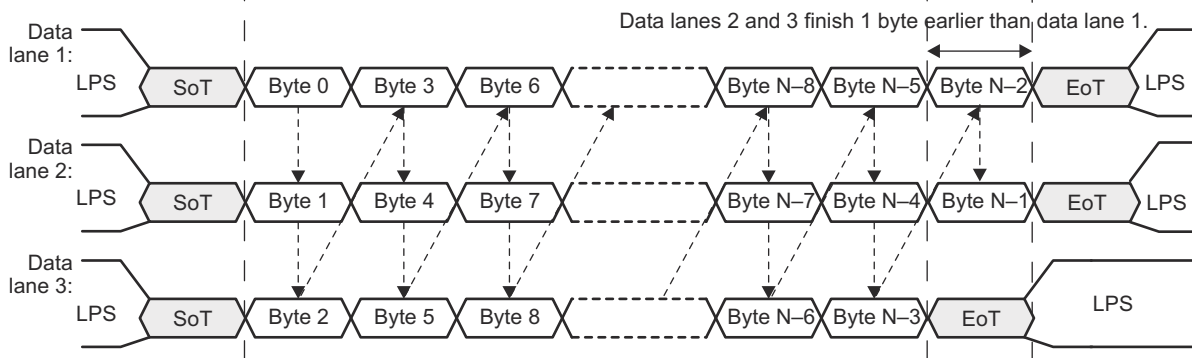

Number of bytes, N, transmitted is an integer multiple of the number of data lanes:

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 1):

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 2):

camss-258

Figure 10-2093. CSI2 Four Data-Lane Merger Configuration

10.8.1.1.3.1.1.3 CSI2 Protocol Layer

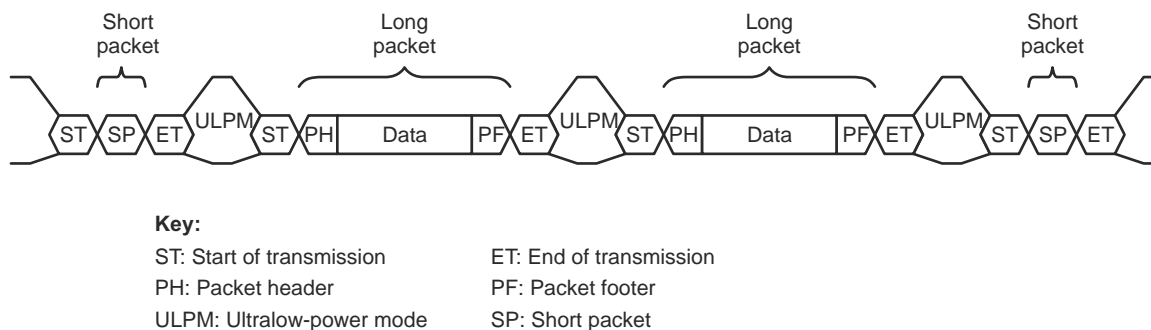

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 10-2094 shows the CSI2 protocol layer with short and long packets.

camss-241

Figure 10-2094. CSI2 Protocol Layer With Short and Long Packets

Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

8.1.1.3.1.3.1 CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 10-2095 shows the structure of a short packet.

camss-242

Figure 10-2095. CSI2 Short Packet Structure

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0 and is inoperative.
- The frame number increments by 1 for every FS packet within the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For LSC and LEC synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the use case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0 and is inoperative.
- The line number increments by 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended use is for progressive scan (noninterlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be different between successive frames. The intended use is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (up to eight contexts support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

8.1.1.3.1.1.3.2 CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

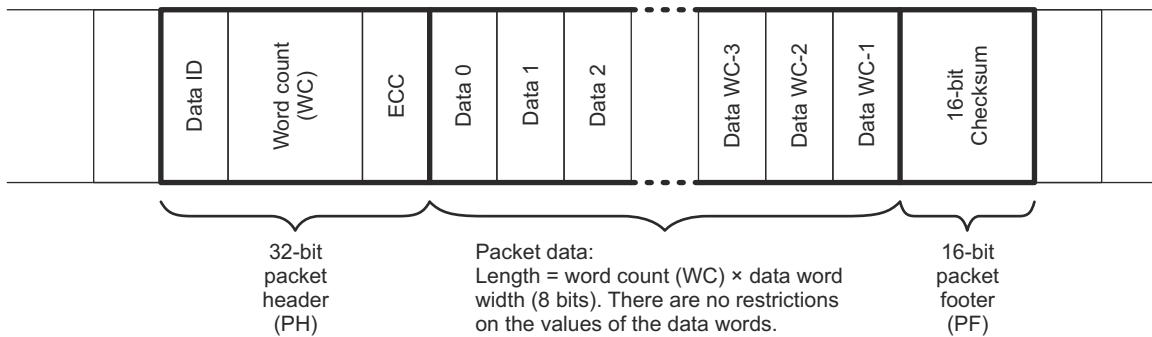

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

The packet header is composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 10-2096 and Table 10-2262 show the structure of a long packet.

camss-243

Figure 10-2096. CSI2 Long Packet Structure

Table 10-2262. CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bits)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC-8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit CRC for packet data

There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

8.1.1.3.1.1.3.3 CSI2 Data Identifier

The data identifier byte contains the virtual channel (VC) value and the data-type (DT) value, as shown in Figure 10-2097. The VC value is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 10-2097 shows the data identifier structure.

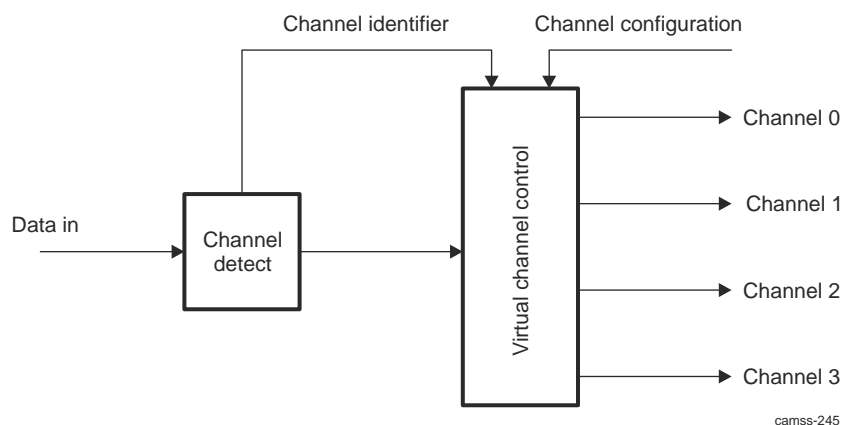

camss-244

Figure 10-2097. CSI2 Data Identifier Structure

Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. [Figure 10-2098](#) shows a virtual channel.

camss-245

Figure 10-2098. CSI2 Virtual Channel

Pixel Formats

8.1.1.3.1.1.3.4 CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

[Table 10-2263](#) summarizes the synchronization code values.

Table 10-2263. CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

8.1.1.3.1.1.3.5 CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

8.1.1.3.1.1.3.6 CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit nonimage data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

8.1.1.3.1.1.3.7 CSI2 Frame Structure

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as SOF and EOF information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

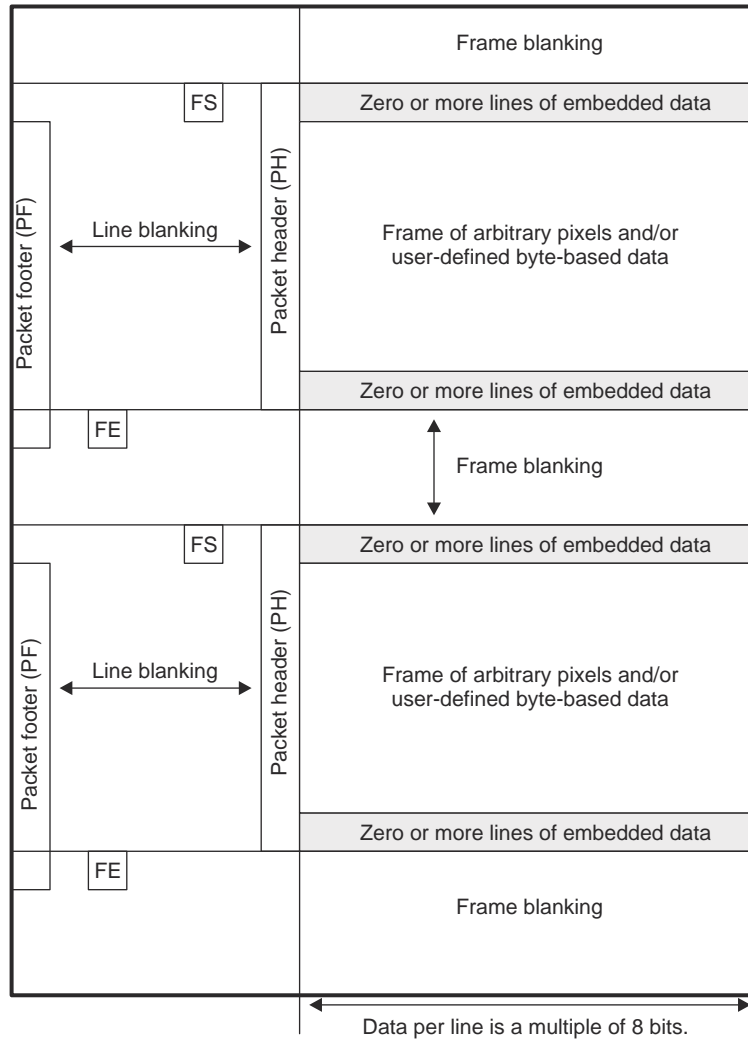

A frame contains embedded data and image-sensor data. [Figure 10-2099](#) shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in [Figure 10-2099](#) and [Figure 10-2100](#). The following definitions for a frame apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image embedded data is carried using separate data types and virtual channels (see [Section 10.8.1.1.3.3.2.4, CSI2 Virtual Channel and Context](#)).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See [Section 10.8.1.1.3.3.2.4, CSI2 Virtual Channel and Context](#).

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Key:
 PH: Packet header PF: Packet footer
 FS: Frame start FE: Frame end

Figure 10-2100 shows the frame structure of a YUV4:2:2 interlaced video frame without embedded data.

Figure 10-2100. CSI2 Digital Interlaced Video Frame (Informative)

The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0. The image data is stored in memory by selecting one of the various operating modes. [Section 10.8.1.1.3.1.1.4, CSI2 Operating Modes](#), explains storing image data frames into memory.

10.8.1.1.3.1.1.4 CSI2 Operating Modes

8.1.1.3.1.1.4.1 CSI2 YUV Operating Modes

1.1.3.1.1.4.1.1 CSI2 YUV4:2:0 8-Bit

YUV4:2:0 8-bit data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:0 use the CSI2_CTRL[4] ENDIANNESSESS bit. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 32 bits and the number of lines must be even. [Figure 10-2101](#) shows the storage format for YUV4:2:0 8-bit data. It is shown as little endian. If the data format is big endian, the figure changes accordingly. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x18

to select YUV4:2:0 8-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the CSI2_CTX_DAT_OFST_j[16:5] OFST bit field; for example, if the offset is 0, the data is written in a contiguous way (bit-to-bit of odd and even lines). If the data has an offset, set the destination offset between the first pixel of the previous line and the first pixel of the current line being written to memory.

YUV4:2:0 8-bit

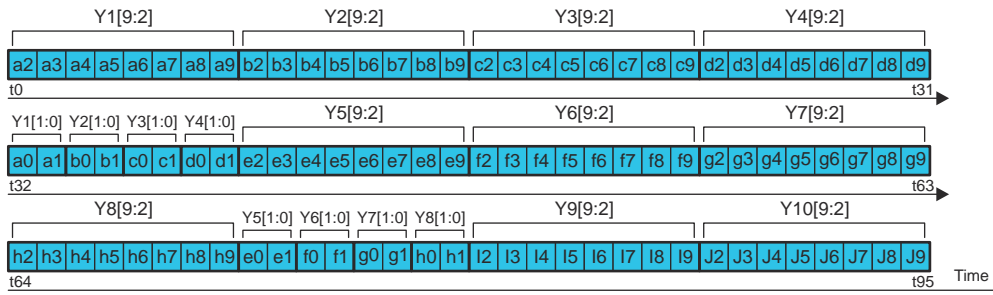

Figure 10-2101. CSI2 YUV4:2:0 8-Bit

1.1.3.1.1.4.1.2 CSI2 YUV4:2:0 10-Bit

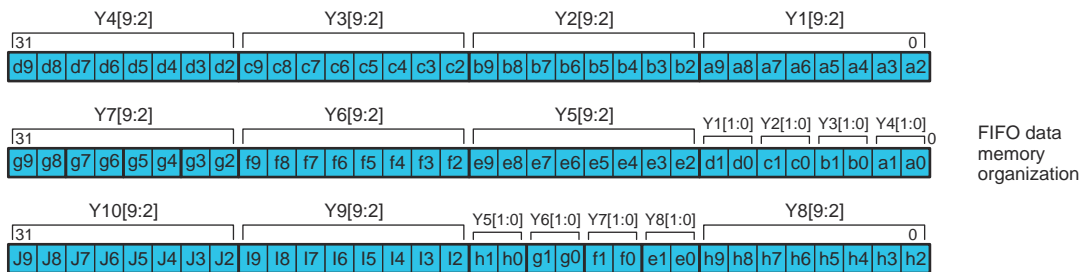

YUV4:2:0 10-bit data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. Figure 10-2102 shows the storage format for YUV4:2:0 10-bit data. Set the CSI2_CTX_CTRL2_j[9:0] FORMAT bit field to 0x19 to select YUV4:2:0 10-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the CSI2_CTX_DAT_OFST_j[16:5] OFST bit field.

1.1.3.1.4.1.5 CSI2 Byte Swap

The CSI2 receiver incorporates a byte-swapping function. Software can optionally enable byte-swapping of the payload data by setting the CSI2_CTx_CTRL1[31] BYTESWAP bit. This feature must be used only when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

RCSS CSI2 byte-swap

For example, CSI2_CTX_CTRL2[9:0] FORMAT = RAW8

8.1.1.3.1.1.4.2 CSI2 RGB Operating Modes

1.1.3.1.1.4.2.1 CSI2 RGB565

RGB565 data is output to memory without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 16 bits. Figure 10-2109 shows the storage format for RGB565 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x22 to select RGB565 mode.

Figure 10-2109. CSI2 RGB565

1.1.3.1.1.4.2.2 CSI2 RGB888

RGB888 data can be output to memory in two formats: with or without data expansion. If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). Figure 10-2110 shows the storage format for RGB888 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x24 to select RGB888 mode.

RGB888

camss-218

Figure 10-2110. CSI2 RGB888

1.1.3.1.1.4.2.3 CSI2 RGB666

RGB666 data is always output to memory with data expansion. The value of the 14 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). The line length sent through the CSI2 physical protocol is a multiple of 8 bits. Furthermore, the line length is a multiple of 9×8 bits to finish the pixel reconstruction correctly. Figure 10-2111 shows the storage format for RGB666 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x33 to select RGB666 mode.

RGB666

camss-219

Figure 10-2111. CSI2 RGB666

1.1.3.1.1.4.2.4 CSI2 RGB444

RGB444 data is output to memory with data expansion. When data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). Figure 10-2112 shows the storage format for RGB444 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0xA0 to select RGB444 mode.

RGB444

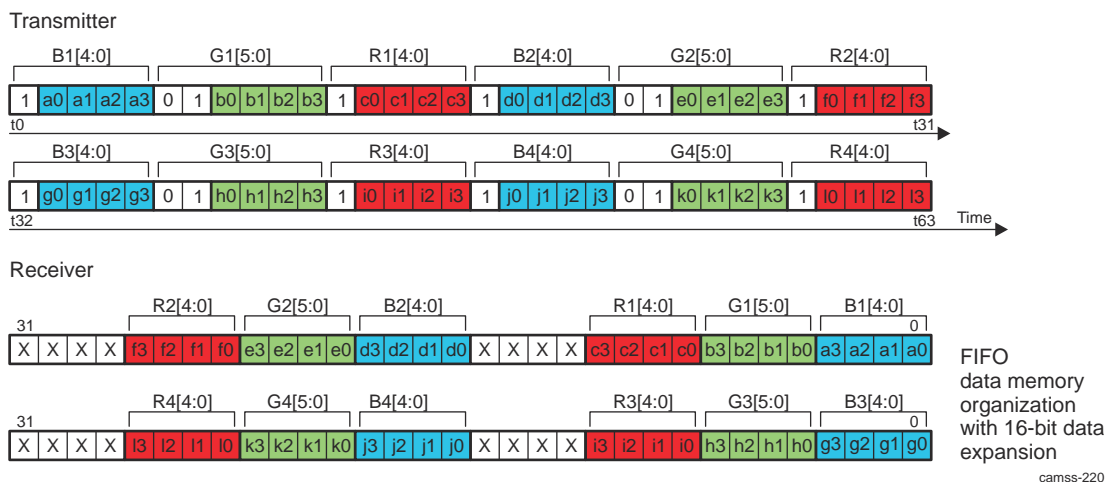

Figure 10-2112. CSI2 RGB444

1.1.3.1.1.4.2.5 CSI2 RGB555

RGB555 data is output to memory with data expansion. Figure 10-2113 shows the storage format for RGB555 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0xA1 to select RGB555 mode.

RGB555

8.1.3.1.1.4.3 CSI2 RAW Bayer RGB Operating Modes

1.1.3.1.1.4.3.1 CSI2 RAW6

RAW6 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits (6-bit image data + 2-bit expansion). Furthermore, the line length is a multiple of 3 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 6 is 24, so 3 × 8 bits). Figure 10-2114 shows the storage format for RAW6 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x28 to select RAW6 mode
- To 0x68 for RAW6 + 8-bit expansion

- To 0x2A8 for RAW6 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x3A8 for RAW6 + DPCM decompression to 12-bit expanded to 16-bit

Figure 10-2114. CSI2 RAW6

1.1.3.1.1.4.3.2 CSI2 RAW7

RAW7 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7×8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 7 is 56, so 7×8 bits). Figure 10-2115 shows the storage format for RAW7 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x29 to select RAW7 mode
- To 0x69 for RAW7 + 8-bit expansion
- To 0x229 for RAW7 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x369 for RAW7 + DPCM decompression to 12-bit expanded to 16-bit

RAW7

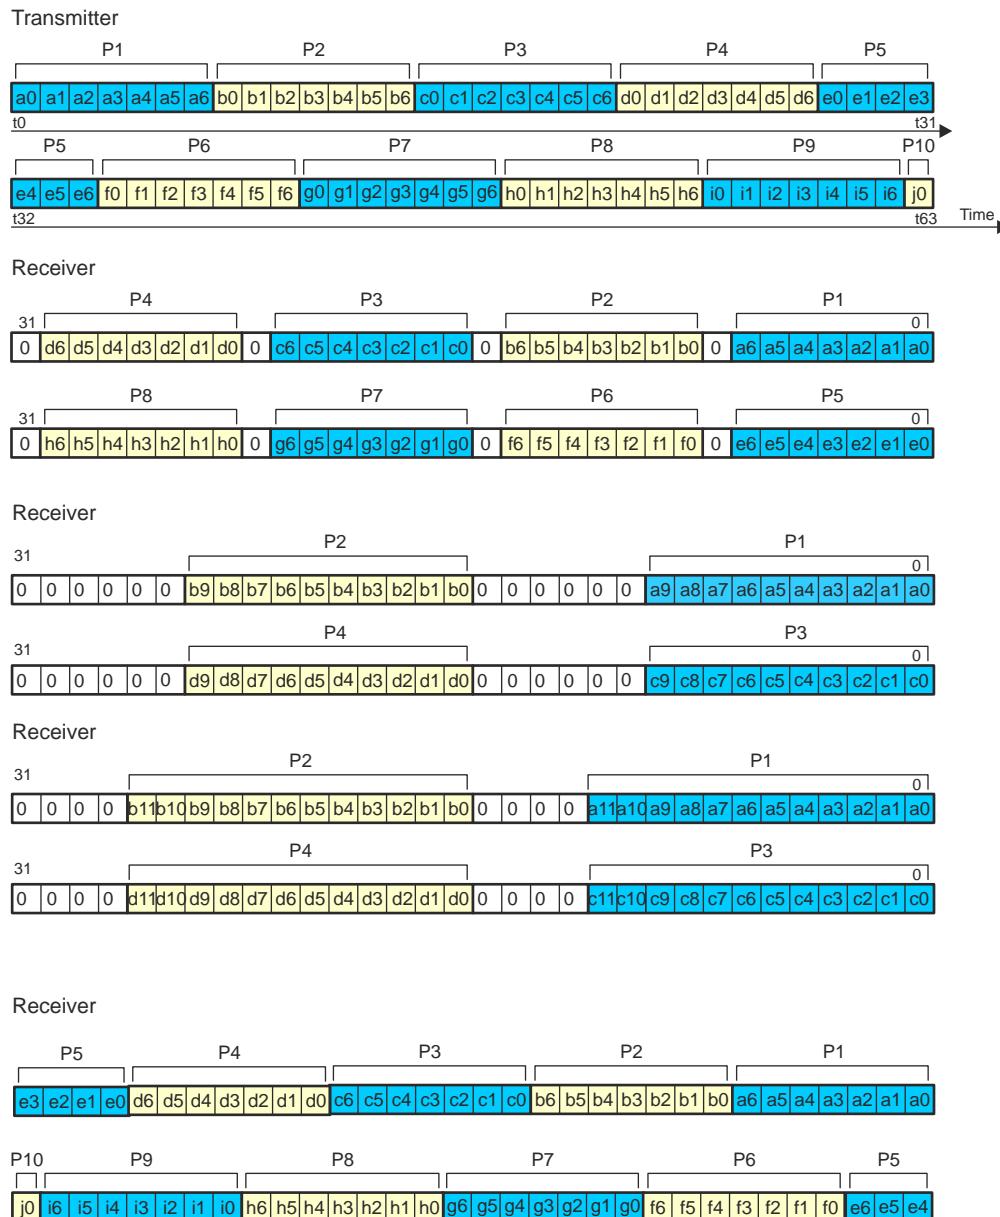

Figure 10-2115. CSI2 RAW7

1.1.3.1.1.4.3.3 CSI2 RAW8

RAW8 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 8 bits. Figure 10-2116 shows the storage format for RAW8 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x2A to select RAW8 mode
- To 0x2AA for RAW8 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x36A for RAW8 + DPCM decompression to 12-bit expanded to 16-bit

RAW8

Figure 10-2116. CSI2 RAW8

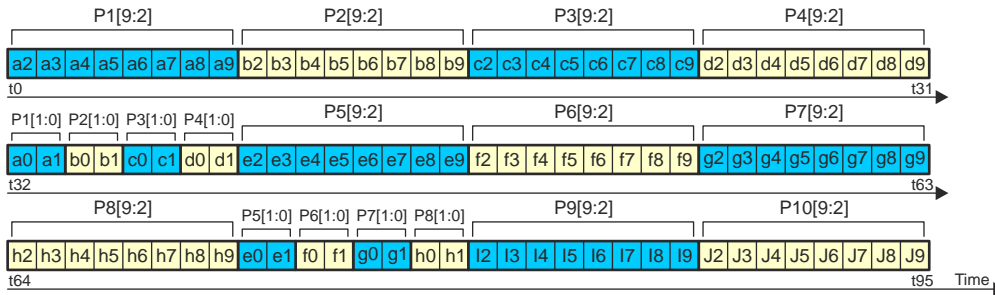

1.1.3.1.1.4.3.4 CSI2 RAW10

RAW10 data can be output memory in two formats: with or without data expansion. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 5×8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 10 is 40, so 5×8 bits). Figure 10-2117 shows the storage format for RAW10 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

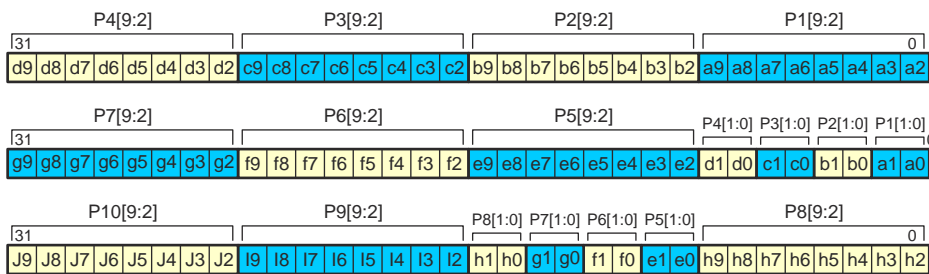

- To 0x2B to select RAW10 mode
- To 0xAB for RAW10 + 16-bit expansion

8.1.1.3.1.1.4.5 CSI2 Generic Format

The CSI2 receiver supports a generic format to send data to memory. The generic mode is entered by setting the CSI2_CTX_CTRL1_i[30] GENERIC bit. The CSI2_CTX_CTRL2_i[9:0] FORMAT bit field defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), the MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code.) When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If not matched, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is mapped only to a single context.

Figure 10-2121 shows the CSI2 generic format.

(2) To understand synchronization codes and long packets, see [Section 8.1.1.3.1.1.3.2, CSI2 Long Packet](#).

10.8.1.1.3.2 CSI2 Integration

Figure 10-2122 is an overview of the integration of the CSI2-A/CSI2-B interface in the device. The figure is the top-level block diagram of the CSI2-A/CSI2-B receiver. The CSI2-A/CSI2-B receiver receives the serial data coming from a CSI2 compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the RCSS interconnect interface.

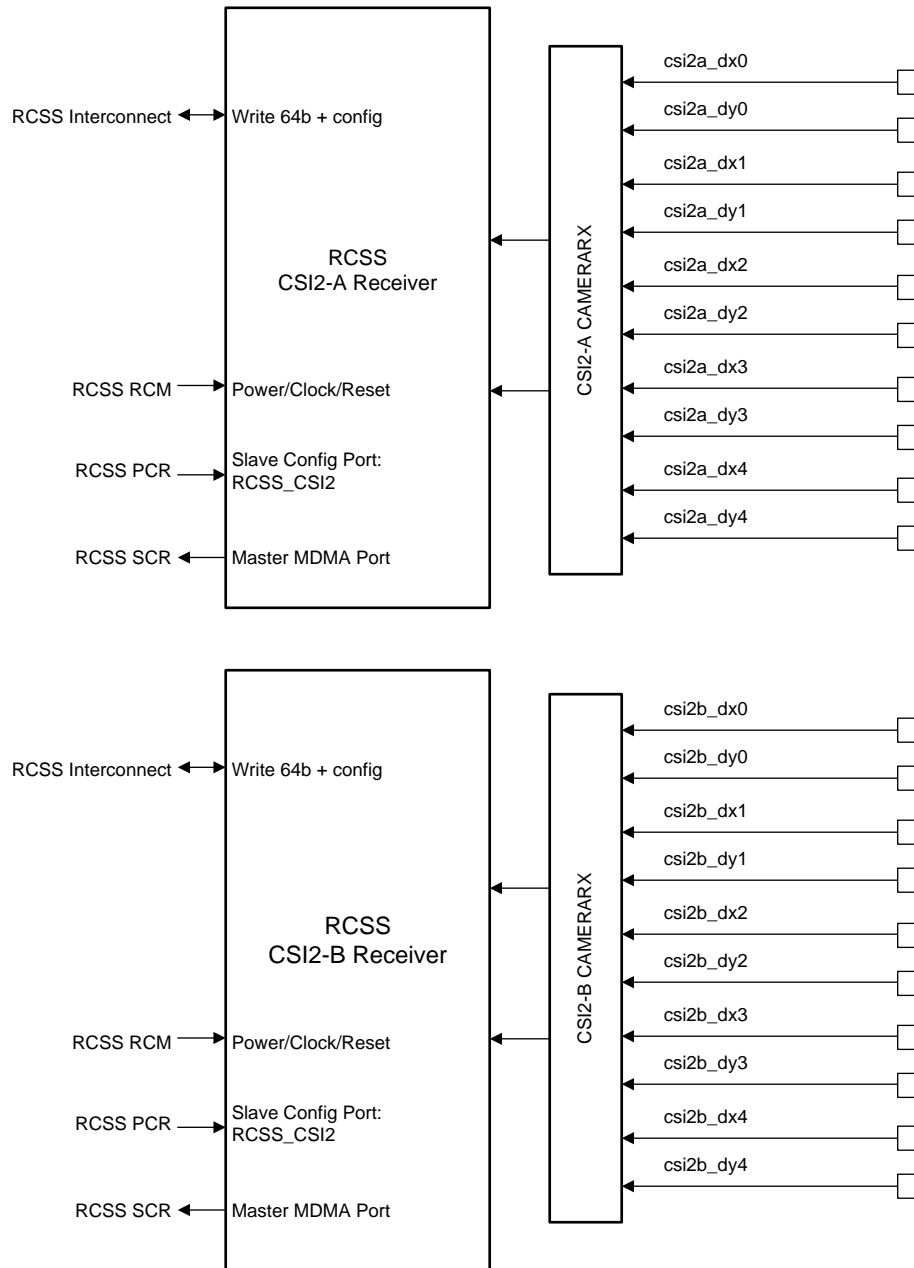

Figure 10-2122. CSI2-A /CSI2-B Integration

The CSI2-A/CSI2-B receiver can send data directly to system memory using the master port.

For power domain, clocks, reset, and hardware requests, see Section 5.4.

10.8.1.1.3.3 CSI2 Functional Description

10.8.1.1.3.3.1 CSI2 Overview

Figure 10-2123 is the CSI2-A/B receiver block diagram (it assumes there are four CSI2 image sensor data lines). The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver (up to four data pairs), converts it to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and outputs it through the RCSS interconnect interface.

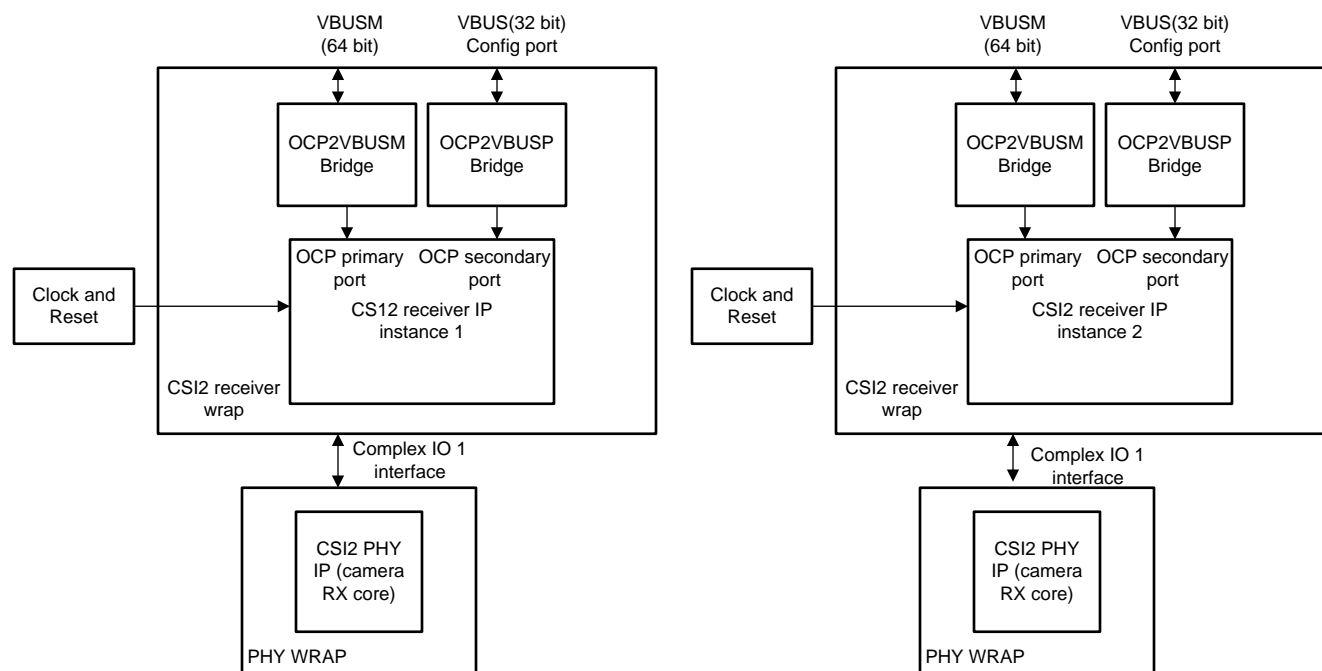

Figure 10-2123. CSI2-A Receiver Block Diagram

10.8.1.1.3.3.2 CSI2 Functional Description

10.8.1.1.3.3.2.1 CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or clock lane with a restriction to the fourth line, which can only be data (see Section 10.8.1.1.2.1, *CSI2 PHY Overview*). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the CSI2_COMPLEXIO_CFG registers for CSI2-A and CSI2-B PHY, respectively. The CSI2_COMPLEXIO_CFG[2:0] CLOCK_POSITION bit field and the CSI2_COMPLEXIO_CFG[3] CLOCK_POL bit configure which lane transmits the clock and define its polarity. DATAI_POSITION and DATAI_POL configure the data lanes and their polarity, where I is the number of the data lane (I = 1 to 4). When the DATAI_POSITION field is set to 0, data lane I is not used.

CAUTION

Lane 4 (position 5) supports only data. The CLOCK_POSITION must not be set at position 5.

10.8.1.1.3.3.2.2 CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

8.1.1.3.3.2.2.1 CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered to the host central processing unit (CPU).

For long and short packets, the correction is always done if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 10-2265](#) describes the field in which events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) and [CSI2_CTX_IRQENABLE_i](#) registers to prevent event generation at a higher level.

Table 10-2265. CSI2 ECC Event Logging

	Short Packet	Long Packet
With correction	Global CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	Context CSI2_CTX_IRQENABLE_i[8] ECC_CORRECTION_IRQ
Without correction	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by setting the [CSI2_CTRL\[2\] ECC_EN](#) bit to 0. Setting the bit to 1 enables the ECC check.

8.1.1.3.3.2.2.2 CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an interrupt is triggered to the host CPU.

CRC errors are logged in the CS_IRQ field of the corresponding context register, [CSI2_CTX_IRQSTATUS_i](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_CTX_IRQENABLE_i](#) register to prevent event generation at a higher level.

The CRC can be disabled for a specific context by setting the [CSI2_CTRL\[5\] CS_EN](#) bit to 0. Setting the bit to 1 enables the CRC.

10.8.1.1.3.3.2.3 CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled. Then, the short packet is written in the [CSI2_SHORT_PACKET\[23:0\] SHORT_PACKET](#) bit field. The ECC field is deleted from the short packet. [Figure 10-2124](#) shows the SHORT_PACKET bit field format.

Figure 10-2124. CSI2 SHORT_PACKET Bit Field Format

When a short packet is stored, an event is logged in the [CSI2_IRQSTATUS\[13\]](#) SHORT_PACKET_IRQ bit. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQSTATUS](#) register to prevent event generation at a higher level.

The application reads the [CSI2_SHORT_PACKET](#) register before the next short packet with a code from 0x8 to 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

10.8.1.1.3.3.2.4 CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts with their events to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following bit fields permit configuration of a context:

- [CSI2_CTX_CTRL2_i\[12:11\]](#) VIRTUAL_ID: Configures the virtual ID linked to the current context
- [CSI2_CTX_CTRL2_i\[9:0\]](#) FORMAT: Configures the data format linked to the current context

[Figure 10-2125](#) shows the relationships between virtual channels and contexts.

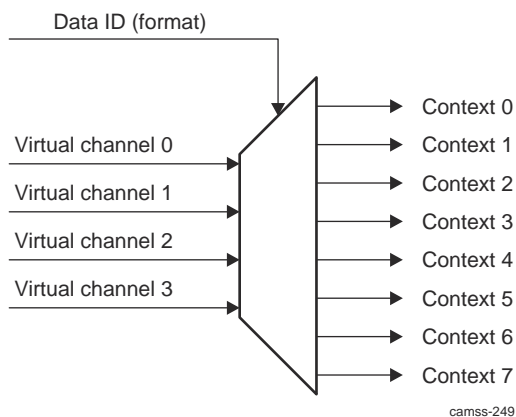

Figure 10-2125. CSI2 Virtual Channel to Context

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by setting the [CSI2_CTX_CTRL1_i\[0\]](#) CTX_EN bit to 1; setting this bit to 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2_CTX_CTRL1_i\[15:8\]](#) COUNT bit field. Acceptable values are 0 to 255; 0 stands for infinite capture (no count). After each frame is acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2_CTX_IRQSTATUS_i\[6\]](#) FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2_CTX_CTRL1_i\[4\]](#) COUNT_UNLOCK bit must be set to 1. If the value of the COUNT_UNLOCK bit is 0, a write in the COUNT bit field has no effect.

The `CSI2_CTX_CTRL3_i[15:0]` `LINE_NUMBER` bit field configures the generation of the `CSI2_CTX_IRQSTATUS_i[7]` `LINE_NUMBER_IRQ` event. The `CSI2_CTX_CTRL1_i[1]` `LINE_MODULO` bit configures how the `LINE_NUMBER` event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo `LINE_NUMBER` (the event can be generated more than once in a frame).

During a frame capture, the `CSI2_CTX_CTRL2_i[31:16]` `FRAME_NUMBER` bit field shows the number that identifies the frame received.

10.8.1.1.3.3.2.5 CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration is common to the eight channels and is defined in the `CSI2_CTRL` register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports:

- 1D addressing mode (no address line offset, `CSI2_CTX_DAT_OFST_i = 0`)
- 2D addressing mode (address line offset different than 0, `CSI2_CTX_DAT_OFST_i != 0`)

The burst size is defined in the `CSI2_CTRL[6:5]` `BURST_SIZE` bit field and the `CSI2_CTRL[16]` `BURST_SIZE_EXPAND` bit. The DMA uses the burst size or smaller sizes down to single open-core protocol (OCP) writes depending on the alignment at the end of lines. The DMA engine can handle burst requests. When the burst requests can be used, as soon as one burst of data is present in the FIFO, the DMA engine initiates a burst write.

Note

Unless there are specific requirements, CSI2 (also applies to all other initiators) must be configured to use only a burst size of 128 bytes and nonposted writes.

When single requests must be used, as soon as one element (the size depends on the data type and the post-processing: DPCM, EXT, etc.) is present in the FIFO, the DMA engine initiates a single write.

Interleave mode is dedicated by the CSI2 receiver only when the line numbers are received (short packets). The line number is used to calculate the start address of the line.

The DMA starts to write in memory using the `CSI2_CTX_DAT_PING_ADDR_i[31:5]` `ADDR` bit field for the first frame to be transferred, and then uses the `CSI2_CTX_DAT_PONG_ADDR_i[31:5]` `ADDR` bit field and the ping address alternately. Thus, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The `CSI2_CTX_CTRL1_i[3]` `PING_PONG` status bit indicates whether the ping address (`CSI2_CTX_DAT_PING_ADDR_i`) or the pong address (`CSI2_CTX_DAT_PONG_ADDR_i`) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the `CSI2_CTRL[0]` `IF_EN` bit, the pixel data is written in the ping buffer and the `CSI2_CTX_CTRL1_i[3]` `PING_PONG` bit = `PONG`. When the number of FECs received equals the value programmed in the `CSI2_CTX_CTRL1_i[23:16]` `FEC_NUMBER` bit field, the pixel data are written in the pong buffer and `CSI2_CTX_CTRL1_i[3]` `PING_PONG` = `PING`. `CSI2_CTX_CTRL1_i[3]` `PING_PONG` toggles after the `CSI2_CTX_CTRL1_i[23:16]` `FEC_NUMBER` `FEC` sync code with the virtual channel ID defined is received in the `CSI2_CTX_CTRL2_i[12:11]` `VIRTUAL_ID` bit field.

The `CSI2_CTX_CTRL1_i[23:16]` `FEC_NUMBER` bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the `PING_PONG` buffer.

8.1.1.3.3.2.5.1 CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the `CSI2_CTX_DAT_OFST_i`[31:5] OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the value of OFST sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

$$\text{@Line0} = \text{CSI2_CTX_DAT_PING_ADDR_i} \text{@Line1} = \text{@Line0} + \text{CSI2_CTX_DAT_OFST_i} \text{@Line2} = \text{@Line1} + \text{CSI2_CTX_DAT_OFST_i}$$

For the pong frame:

$$\text{@Line0} = \text{CSI2_CTX_DAT_PONG_ADDR_i} \text{@Line1} = \text{@Line0} + \text{CSI2_CTX_DAT_OFST_i} \text{@Line2} = \text{@Line1} + \text{CSI2_CTX_DAT_OFST_i}$$

8.1.1.3.3.2.5.2 CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

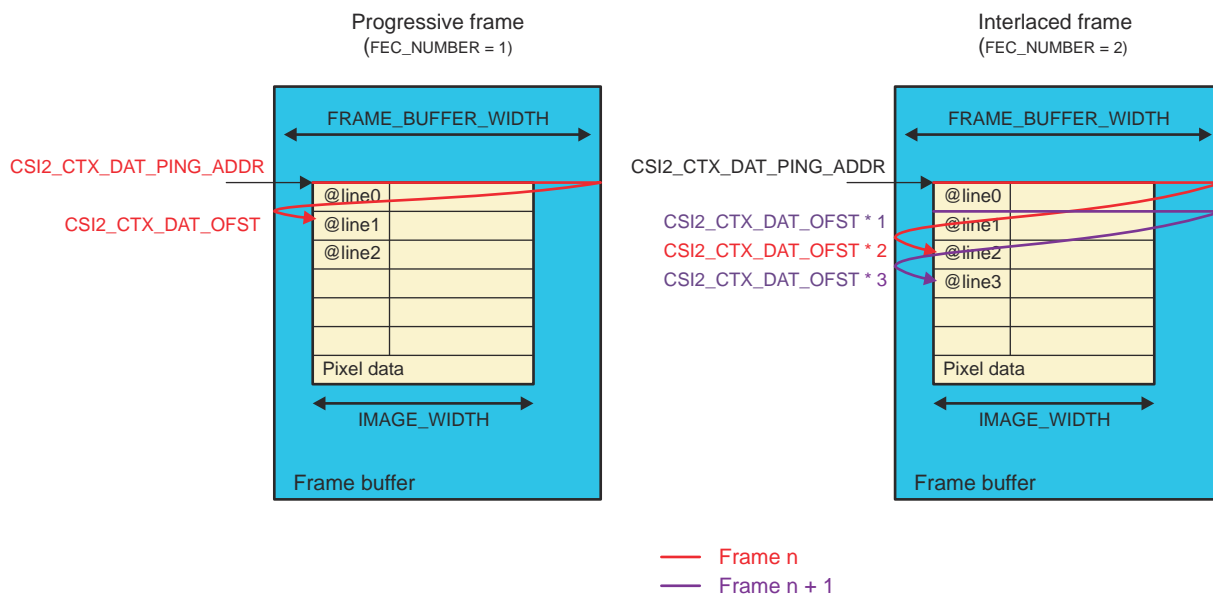

For the ping frame:

$$\text{@LineX} = \text{CSI2_CTX_DAT_PING_ADDR_i} + \text{CSI2_CTX_DAT_OFST_i} * \text{Line_Number}$$

For the pong frame:

$$\text{@LineX} = \text{CSI2_CTX_DAT_PONG_ADDR_i} + \text{CSI2_CTX_DAT_OFST_i} * \text{Line_Number}$$

Figure 10-2126 shows how data are stored in memory regarding the DMA configuration.

camss-250

Figure 10-2126. CSI2 Data Destination Setting in Progressive and Interlaced Mode

The burst size is defined in the `CSI2_CTRL`[6:5] `BURST_SIZE` bit field for bursts up to 16 × 64 bits or the `CSI2_CTRL`[16] `BURST_SIZE_EXPAND` bit for 16 × 128-bit bursts. It can be changed only while the `CSI2_CTRL`[0] `IF_EN` bit is reset to 0. The recommended value is the `CSI2_CTRL`[16] `BURST_SIZE_EXPAND` bit set to 1, which defines a burst of 16 × 64 bits (the maximum value); otherwise, by default it is set to 8 × 64 bits. When the `BURST_SIZE_EXPAND` bit is set, the `BURST_SIZE` setting has no effect. The DMA uses

nonposted writes by default. The CSI2_CTRL[13] NON_POSTED_WRITE bit must be set to 1 to match DMA default configuration. It can be changed only while the CSI2_CTRL[0] IF_EN bit is reset to 0.

10.8.1.1.3.3.2.6 CSI2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CSI2 real-time traffic, when required, based on the fullness of the CSI2 DMA read and write buffers. Programmable buffer thresholds indicate when the local MFLAG signal is generated. The MFLAG signal is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CSI2 MFLAG signal is asynchronous to any on-going OCP transaction. The threshold corresponds to the fullness of DMA buffer, and is defined by the following threshold parameters:

- High threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the CSI2_CTRL[22:20] MFLAG_LEVH register.
- Low threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the CSI2_CTRL[19:17] MFLAG_LEVEL register.

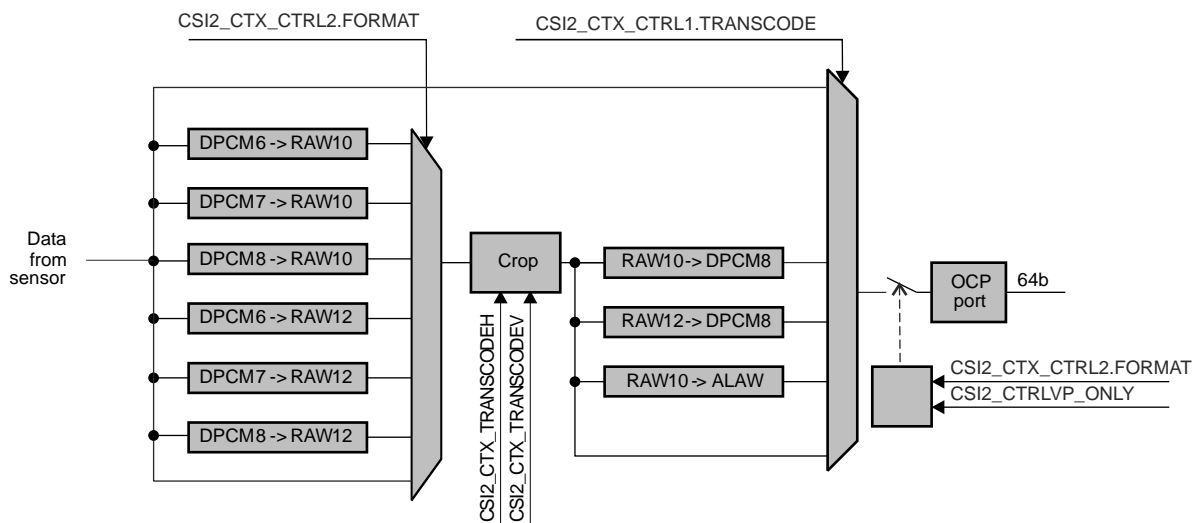

10.8.1.1.3.3.2.7 CSI2 Transcoding

Image transcoding is used mainly to reduce memory footprint and bandwidth when:

- The sensor does not support DPCM compression. In fact, A-Law and DPCM compressed pixels occupy only 6, 7, or 8 BPP of storage.
- Digital zoom is used
 - Data that is not going to be used by further processing does not need to be stored in system memory.
 - Pixels cannot be accessed from random locations in a DPCM-compressed frame. Transcoding avoids memory-to-memory processing of unused pixels.

Figure 10-2127 shows the logical representation of the image transcoding operation.

- Data is extracted from the CSI2 stream by the protocol engine.
- It is DPCM decompressed if necessary. That is the case when the received stream is DPCM-compressed and transcoding has been enabled using the CSI2_CTX_CTRL1_i[27:24] TRANSCODE bit field.
- Internal data are aligned on MSB when they enter the cropping stage. For example:
 - 4 LSBs are 0s when RAW10 data are handled.
 - 2 LSBs are 0s when RAW12 data are handled.

camss-255

Figure 10-2127. CSI2 Frame Processing

Table 10-2266 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the table are not supported for transcoding. The FORMAT and Corresponding Setting Value column corresponds to the value set in the CSI2_CTX_CTRL2_i[9:0] FORMAT register.

Table 10-2266. CSI2 Supported Transcoding Input Formats

CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value		Cropping Engine Input Format	DPCM Decomposition Enabled	Video Port Enabled
0x028	RAW6	RAW6		
0x068	RAW6 + EXP8			
0x029	RAW7	RAW7		
0x069	RAW7 + EXP8			
0x02A	RAW8	RAW8 RAW10		
0x02B	RAW10			
0x0AB	RAW10 + EXP16			
0x229	RAW7 + DPCM10 + EXP16		Yes	
0x2A8	RAW6 + DPCM10 + EXP16		Yes	
0x2AA	RAW8 + DPCM10 + EXP16		Yes	
0x2Cn	USER_DEFINED_BYTE_DATA + DPCM10 + EXP16		Yes	
0x02C	RAW12	RAW12		
0x0AC	RAW12 + EXP16			
0x35A	RAW8 DPCM12 + EXP16		Yes	
0x1Cn	USER_DEFINED_BYTE_DATA + DPCM12 + EXP16		Yes	
0x3A8	RAW6 + DPCM12 + EXP16		Yes	
0x369	RAW7 + DPCM12 + EXP16		Yes	
0x02D	RAW14	RAW14		
0x0AD	RAW14 + EXP16			

Image cropping parameters are controlled by software. [Figure 10-2128](#) shows the cropping operation.

Figure 10-2128. CSI2 Frame Cropping

CAUTION

- Hardware does not check for validity of the settings. The following rules must be respected:
- [CSI2_CTX_TRANSCODEH_i\[12:0\]](#) HSKIP + [CSI2_CTX_TRANSCODEH_i\[28:16\]](#) HCOUNT <= image width
 - [CSI2_CTX_TRANSCODEV_i\[12:0\]](#) VSKIP + [CSI2_CTX_TRANSCODEV_i\[28:16\]](#) VCOUNT <= image height

Furthermore, the [CSI2_CTX_TRANSCODEH_i\[28:16\]](#) HCOUNT bit field must comply with the following alignment constraints; otherwise, undefined behavior occurs. [Table 10-2267](#) shows the transcode alignment constraints

Table 10-2267. CSI2 Transcode Alignment Constraints

CSI2_CTX_CTRLi[27:24] TRANSCODE Value	Transcode	HCOUNT Must Be Multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

The [CSI2_CTX_CTRL1_i\[28\]](#) HSCALE configuration register enables horizontal downscaling of RAW data. It reduces the horizontal size and pixel clock by a factor of 2. The scaler uses a 2-tap horizontal filter operating on samples of the same color plane. The coefficients are: [1/2 ; 0 ; 1/2]

[Figure 10-2129](#) shows the scaler operation.

camss-710u

Figure 10-2129. CSI2 Horizontal Scaler

When data goes to the interface port, HCOUNT/2 must comply with the constraints from [Table 10-2267](#) (for example, for RAW10, HCOUNT must be a multiple of 8).

[Table 10-2268](#) lists possible combinations of input and output formats supported by the transcoding engine. The Transcode column corresponds to the [CSI2_CTX_CTRL1_i\[27:24\]](#) TRANSCODE bit field of a context.

Table 10-2268. CSI2-Supported Transcoding Output Formats

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
RAW6	0	Disabled	Yes	RAW10	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	Yes
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	Yes
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	Yes
	6	RAW10			6	RAW10	Yes
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14			9	RAW14	
RAW7	0	Disabled	Yes	RAW12	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	Yes
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	Yes
	8	RAW12			8	RAW12	Yes
	9	RAW14			9	RAW14	
RAW8	0	Disabled	Yes	RAW14	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8	Yes		4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14			9	RAW14	Yes

RAW pixels are packed into 64-bit words sent to the OCP master port, as defined in:

- [Section 1.1.3.1.1.4.3.3, CSI2 RAW8](#)
- [Section 1.1.3.1.1.4.3.4, CSI2 RAW10](#)
- [Section 1.1.3.1.1.4.3.5, CSI2 RAW12](#)
- [Section 1.1.3.1.1.4.3.6, CSI2 RAW14](#)

For RAW10 and RAW12, software can choose among packed and nonpacked storage. A-Law and DPCM-compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point.

Enabling of the OCP is controlled by the [CSI2_CTX_CTRL2_i\[9:0\]](#) FORMAT bit field and the [CSI2_CTRL\[11\]](#) VP_ONLY_EN and [CSI2_CTX_CTRL1_i\[2\]](#) VP_FORCE bits.

To enable transcoding, software configures the context normally and also configures the framing using the [CSI2_CTX_TRANSCODEV_i](#) and [CSI2_CTX_TRANSCODEH_i](#) registers. Software defines the after transcoding with the [CSI2_CTX_CTRL1_i\[27:24\]](#) TRANSCODE bit field.

10.8.1.1.3.3.2.8 CSI2 EndOfFrame and EndOfLine (EOF and EOL) Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line to the TCTRL. It is active during or after the adequate interface bridge transaction and becomes inactive before the first transaction of the next line. Software can enable/disable generation of those signals for each context using the [CSI2_CTX_CTRL1_i\[7\]](#) EOF_EN and [CSI2_CTX_CTRL1_i\[6\]](#) EOL_EN bits.

10.8.1.1.3.3.2.9 CSI2 Data Decompression

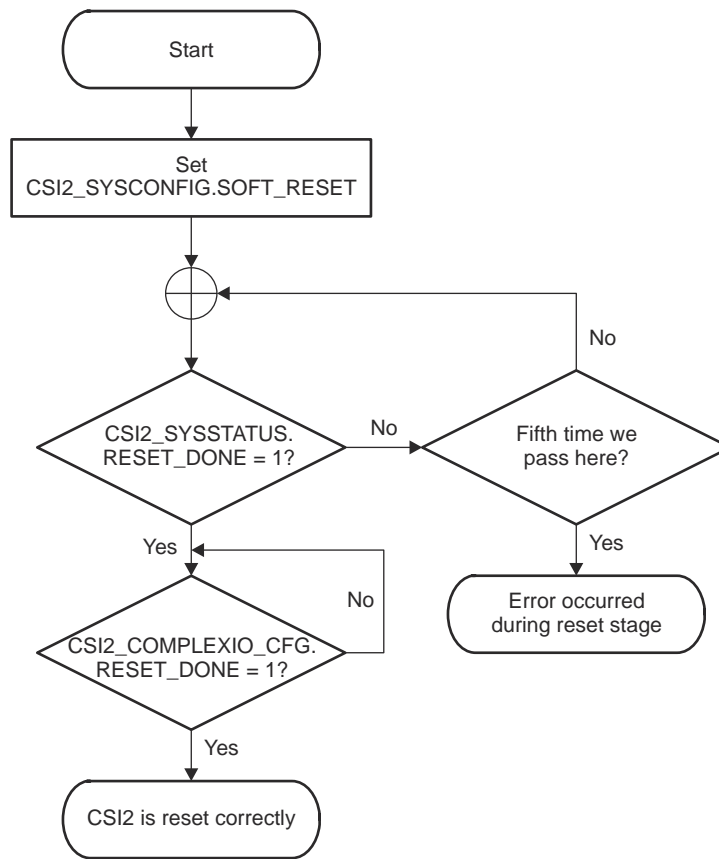

The data compression technique used is DPCM and PCM.

To select the DPCM decompression predictor for the CSI2 Interface, set the [CSI2_CTX_CTRL2_i\[10\]](#) DPCM_PRED bit to 1 for simple predictor or to 0 for advanced predictor.

10.8.1.1.3.4 CSI2 Programming Model

10.8.1.1.3.4.1 CSI2 Programming Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the complex I/O (A or B) and has the same effect as a hardware reset. [Figure 10-2130](#) shows how to reset CSI2 globally.

camss-252

Figure 10-2130. CSI2 Receiver Global Reset Flow Chart

Note

Before setting the software reset bit to 1 in the CSI2_SYSCONFIG register, the user must have access to a CSI2 receiver register.

Note

The CSI2_COMPLEXIO_CFG[29] RESET_DONE bit is set to 1 only after the initialization of the CSI2 receiver, CSI2 complex I/O, and external camera completes.

10.8.1.1.3.4.2 CSI2 Programming Enable Video/Picture Acquisition

Before using the receiver, a CSIPHY initialization in CSI2 mode must be made for CSI2-A CSIRX, which is associated with the CSI2 receiver. See [Section 10.8.1.1.2.2.2, CSI2 PHY and Link Initialization Sequence](#). To start a video/picture acquisition, perform the steps listed in [Table 10-2269](#).

Table 10-2269. CSI2 Global Initialization

Step	Register/Bit Field/Programming Model	Value
Reset the CSI2 receiver.	See Section 10.8.1.1.3.4.1, Reset Management .	
Configure the module power management. The module tries to enter smart-standby mode during the vertical blanking period. The CSI2_SYSCONFIG[0] AUTO_IDLE bit keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity.	CSI2_SYSCONFIG[13:12] M standby_MODE	0x2
Configure the interrupt generation as required. To enable context and/or complex I/O event reporting, enable the corresponding bit field in the CSI2_IRQENABLE register. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	CSI2_IRQENABLE and CSI2_IRQENABLE	
Configure the complex I/O interrupt generation as required. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	CSI2_COMPLEXIO_IRQSTATUS and CSI2_COMPLEXIO_IRQENABLE)	
Start complex I/O: Set the CSI2_COMPLEXIO_CFG[28:27] PWR_CMD bit field to 0x1 to pass the complex I/O to the ON state, and then check that the state status reaches the ON state (CSI2_COMPLEXIO_CFG[26:25] PWR_STATUS = 0x1) (for complex I/O A).	CSI2_COMPLEXIO_CFG[28:27] PWR_CMD	0x1
Configure the complex I/O: <ul style="list-style-type: none"> The complex I/O is fully functional with CSI2_COMPLEX_CFG set at its reset value. CSI2_COMPLEX_CFG must be changed according to the data rate being used. 	CSI2_COMPLEXIO_CFG	
Set RXMODE and STOPSTATE FSM to RXMODE state. Users can also configure the delay for the FSM to return from RXMODE to NORXMODE when all lines reach STOPSTATE.	CSI2_TIMING[15] FORCE_RX_MODE_IO1	0x1
Activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).	CSI2_CTRL[2] ECC_EN	0x1
Start the CSI2 receiver.	CSI2_CTRL[0] IF_EN	0x1
Configure the different contexts to be used.		
Link the context to a virtual channel and a data type.	See Section 10.8.1.1.3.4.6, Linking a Context to a Virtual Channel and a Data Type .	
Set the FEC_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see Section 10.8.1.1.3.3.2.5, DMA Engine .	CSI2_CTX_CTRL1_i[26:23] FEC_NUMBER	0x1 or 0x2
Capture an infinite number of frames (until the interface or the context is disabled).	CSI2_CTX_CTRL1_i[15:8] COUNT and CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x0

Table 10-2269. CSI2 Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the CSI2_CTX_IRQSTATUS_i[5] CS_IRQ bit).	CSI2_CTX_CTRL1_i[5] CS_EN	
Configure the DMA engine for the current channel: Configure the ping and pong addresses.	CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR and CSI2_CTX_DAT_PONG_ADDR_i[31:5] ADDR	
Set the CSI2_CTX_DAT_OFST_i[15:5] OFST bit field to 0x0 so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).	CSI2_CTX_DAT_OFST_i[15:5] OFST	
Keep the ALPHA setting at its reset value (0x0) for RGB padding.	CSI2_CTX_CTRL3_i[29:16] ALPHA	
Enable the contexts.	CSI2_CTX_CTRL1_i[0] CTX_EN	0x1

10.8.1.1.3.4.3 CSI2 Programming Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by setting the [CSI2_CTX_CTRL1_i\[0\] CTX_EN](#) bit to 0. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by setting the [CSI2_CTRL\[0\] IF_EN](#) bit to 0. This can have an immediate effect if the [CSI2_CTRL\[3\] FRAME](#) bit is set to 0, or it can be effective after all the enabled contexts receive the FEC if the [CSI2_CTRL\[3\] FRAME](#) bit is set to 1.

10.8.1.1.3.4.4 CSI2 Programming Capture a Finite Number of Frames

The CSI2 receiver can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the steps listed in [Table 10-2270](#).

Table 10-2270. CSI2 Capture a Finite Number of Frames

Step	Bit Field	Value
Enable a write to the COUNT bit field.	CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x1
Set the bit field to the number of frames the CSI2 receiver must capture.	CSI2_CTX_CTRL1_i[15:8] COUNT	Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
Disable a write to the COUNT bit field.	CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x0

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. Software reads the COUNT bit field to know how many frames must still be captured.

The COUNT bit can be updated during capture if the COUNT_UNLOCK bit is set to 1.

10.8.1.1.3.4.5 CSI2 Programming a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2_CTX_CTRL3_i\[15:0\] LINE_NUMBER](#) bit field. The event can be generated once or multiple times per frame, depending on the value of the [CSI2_CTX_CTRL1_i\[1\] LINE_MODULO](#) bit:

- If the LINE_MODULO bit = 0, the event is generated when the line number corresponding to the LINE_NUMBER bit field is received.
- If the LINE_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE_NUMBER value (LINE_NUMBER is used as a modulo).

10.8.1.1.3.4.6 CSI2 Programming a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in the [CSI2_CTX_CTRL2_i\[9:0\]](#) FORMAT bit field.

For each context, a [CSI2_CTX_CTRL2_i](#) register defines with which channel and data type the context is associated:

- The VIRTUAL_ID bit field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT bit field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT bit field also defines how DMA stores data in memory.
- **CSI2_CTXn_DAT_PING_ADDR** and **CSI2_CTX0_DAT_PONG_ADDR** need to be set in order to store the received data (ping or pong manner) from CSI2RX. Same set of registers would be used during HIL mode to write data to device's internal memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2_CTX_CTRL2_i](#) register.

10.8.1.1.3.4.7 CSI2 Programming Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2_CTX_CTRL1_i\[23:16\]](#) FEC_NUMBER bit field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC_NUMBER = 2: The current buffer is switched (ping to pong or pong to ping) after the FEC_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 10.8.1.1.3.3.2.5, DMA Engine](#).

Note

If FEC_NUMBER 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

10.8.1.1.3.4.8 CSI2 Programming Debug Mode

[Table 10-2271](#) lists the procedure to enable debug mode.

Table 10-2271. CSI2 Enable Debug Mode

Step	Bit	Value
Enable debug mode.	CSI2_CTRL[7] DBG_EN	0x1

- During debug mode the input does not come from the CSI2 receiver interface but from the CSI2_DBG_H and CSI2_DBG_P registers. The full CSI2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the CSI2_DBG_H register. The CSI2_CTRL[0] IF_EN bit has no affect during debug mode. To reset the FIFO in case of overflow, the CSI2_CTRL[7] DBG_EN bit must be reset to 0, and the interface must be enabled by setting the CSI2_CTRL[0] IF_EN bit to 0x1.
- The CSI2_DBG_H register is used to provide short packet and long packet headers.
- The CSI2_DBG_P register is used to provide long packet payload.

The following examples apply to the CSI2_DBG_H register:

- The sync codes for virtual channel 0 are written as CSI2_DBG_H = 0xFF00 0000 or 0xFF00 0001, or 0xFF00 0002 or 0xFF00 0003. To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, 0x547, write CSI2_DBG_H = 0x0123 4567, followed by CSI2_DBG_H = 0x89abcdef, and CSI2_DBG_H = 0x7654 3210.

10.8.1.1.3.5 CSI2 Register Manual

10.8.1.1.3.5.1 CSI2 Instance Summary

Table 10-2272 summarizes the CSI2 instance.

Table 10-2272. CSI2 Instance Summary

Module Name	Base Address	Size
RCSS_CSI2A	0x05080000	392 bytes
RCSS_CSI2B	0x050A0000	392 bytes

10.8.1.1.3.5.2 RCSS_CSI2 Registers

Table 10-2273 lists the memory-mapped registers for the RCSS_CSI2 registers. All register offset addresses not listed in Table 10-2273 should be considered as reserved locations and the register contents should not be modified.

Bit	Field	Type	Reset	Description
31-23	RES7	R	0h	RESERVE FIELD
22-20	MFLAG_LEVH	R/W	0h	RESERVE FIELD
19-17	MFLAG_LEVL	R/W	0h	RESERVE FIELD
16	BURST_SIZE_EXPAND	R/W	0h	Sets the DMA burst size on the L3 interconnect. 0: Use the burst size defined in the BURST_SIZE register 1: Allow generation of 16x64-bit bursts
15	VP_CLK_EN	R/W	0h	RESERVE FIELD
14	STREAMING	R/W	0h	Streaming mode 0: Disable 1: Enable
13	NON_POSTED_WRITE	R/W	0h	Not Posted Writes 0: Disable 1: Enable
12	RES8	R	0h	RESERVE FIELD
11	VP_ONLY_EN	R/W	0h	RESERVE FIELD
10	STREAMING_32_BIT	R/W	0h	Indicates if 64-bit or 32-bit streaming burst is used. Valid only if CS12_CTRL.STREAMING=1 0: 64-bit streaming burst is used; byte enable pattern is 0xFF 1: 32-bit streaming burst is used; byte enable pattern is 0x0F
9-8	VP_OUT_CTRL	R/W	0h	RESERVE FIELD
7	DBG_EN	R/W	0h	Enables the debug mode. 0: Disable 1: Enable
6-5	BURST_SIZE	R/W	0h	Sets the DMA burst size on the L3 interconnect. 0x0: 1x64 OCP writes 0x1: 2x64 OCP writes 0x2: 4x64 OCP writes 0x3: 8x64 OCP writes
4	ENDIANNESS	R/W	0h	Select endianness for YUV422 8 bit and YUV420 legacy formats. 0: Use native MIPI CSI2 endianness: Little endian for all formats except for YUV422 8b and YUV420 Legacy which a big endian. 1: Store all pixel formats little endian.
3	FRAME	R/W	0h	Set the modality in which IF_EN works. 0: If IF_EN = 0 the interface is disabled immediately. 1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.
2	ECC_EN	R/W	0h	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0: Disabled 1: Enabled
1	SECURE	R/W	0h	RESERVE FIELD

Table 10-2279. CSI2_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	IF_EN	R/W	0h	Enables the physical interface to the module. 0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code. 1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing '1' to this register when the current value is '0' has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, i.e., the CSI2_CTX_CTRL.PING_PONG bits are reset to '0' as well.

8.1.1.3.5.2.7 CSI2_DBG_H Register (Offset = 44h) [Reset = 0h]

CSI2_DBG_H is shown in [Figure 10-2135](#) and described in [Table 10-2280](#).

Return to the [Table 10-2273](#).

DEBUG REGISTER (Header) This register provides a way to debug the CSI2 RECEIVER module with no image sensor connected to the module. The debug mode is enabled by CSI2_CTRL.DBG_EN. Only full 32-bit values shall be written. The register is

Table 10-2291. CSI2_CTX0_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2291. CSI2_CTX0_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.19 CSI2_CTX0_CTRL2 Register (Offset = 74h) [Reset = 0h]

CSI2_CTX0_CTRL2 is shown in [Figure 10-2147](#) and described in [Table 10-2292](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2299. CSI2_CTX1_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')

Table 10-2299. CSI2_CTX1_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.27 CSI2_CTX1_CTRL2 Register (Offset = 94h) [Reset = 0h]

CSI2_CTX1_CTRL2 is shown in [Figure 10-2155](#) and described in [Table 10-2300](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2307. CSI2_CTX2_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2307. CSI2_CTX2_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.35 CSI2_CTX2_CTRL2 Register (Offset = B4h) [Reset = 0h]

CSI2_CTX2_CTRL2 is shown in [Figure 10-2163](#) and described in [Table 10-2308](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2315. CSI2_CTX3_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2315. CSI2_CTX3_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.43 CSI2_CTX3_CTRL2 Register (Offset = D4h) [Reset = 0h]

CSI2_CTX3_CTRL2 is shown in [Figure 10-2171](#) and described in [Table 10-2316](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2323. CSI2_CTX4_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2323. CSI2_CTX4_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.51 CSI2_CTX4_CTRL2 Register (Offset = F4h) [Reset = 0h]

CSI2_CTX4_CTRL2 is shown in [Figure 10-2179](#) and described in [Table 10-2324](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2331. CSI2_CTX5_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2331. CSI2_CTX5_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.59 CSI2_CTX5_CTRL2 Register (Offset = 114h) [Reset = 0h]

CSI2_CTX5_CTRL2 is shown in [Figure 10-2187](#) and described in [Table 10-2332](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2339. CSI2_CTX6_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2339. CSI2_CTX6_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.67 CSI2_CTX6_CTRL2 Register (Offset = 134h) [Reset = 0h]

CSI2_CTX6_CTRL2 is shown in [Figure 10-2195](#) and described in [Table 10-2340](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

Table 10-2347. CSI2_CTX7_CTRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BYTESWAP	R/W	0h	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0: Disabled 1: Enabled
30	GENERIC	R/W	0h	Enables the generic mode. 0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.
29	RES19	R	0h	RESERVE FIELD
28	HSCALE	R/W	0h	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0: Disable 1: Enable

Table 10-2347. CSI2_CTX7_CTRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-24	TRANSCODE	R/W	0h	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.
23-16	FEC_NUMBER	R/W	1h	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')
15-8	COUNT	R/W	0h	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.
7	EOF_EN	R/W	0h	Indicates if the end of frame signal shall be asserted at the end of the frame Read 0: The end of frame signal is not asserted at the end of each frame. Read 1: The end of frame signal is asserted at the end of each frame.
6	EOL_EN	R/W	0h	Indicates if the end of line signal shall be asserted at the end of the line. Read 0: The end of line signal is not asserted at the end of each frame. Read 1: The end of line signal is asserted at the end of each frame.
5	CS_EN	R/W	0h	Enables the checksum check for the received payload (long packet only). 0: Disabled 1: Enabled
4	COUNT_UNLOCK	W	0h	Unlock writes to the COUNT bit field. Write 0: COUNT bit field is locked. Writes have no effect Write 1: COUNT bit field is unlocked. Writes are possible.
3	PING_PONG	R	1h	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0: PING buffer Read 1: PONG buffer
2	VP_FORCE	R/W	0h	RESERVE FIELD
1	LINE_MODULO	R/W	0h	Line modulo configuration 0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)
0	CTX_EN	R/W	0h	Enables the Context 0: Disabled 1: Enabled

8.1.1.3.5.2.75 CSI2_CTX7_CTRL2 Register (Offset = 154h) [Reset = 0h]

CSI2_CTX7_CTRL2 is shown in [Figure 10-2203](#) and described in [Table 10-2348](#).

Return to the [Table 10-2273](#).

CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code (except for VIRTUAL_ID and FORMAT fields). The change of VIRTUAL_ID and FORMAT ha

This page intentionally left blank.

The debug subsystem contains one MCUDebugss at its core that allows the JTAG interface access to device components. The debug subsystem is designed to provide the following debug features:

- JTAG debug access to debug resources, mapped through an ARM SWJ-DP and TI ICEPickM scan module
- System memory access without halting the processor
- Trace for C66x DSP
- ETM-based trace for ARM R5F
- Cross trigger to halt and restart MSS and DSP, based on events such as watchdog, timers, DMA, and time-stamp events
- Capability to read the device ID

11.1 AM273x DebugSS Architecture	4934
---	-------------

11.1 AM273x DebugSS Architecture

11.1.1 DebugSS Overview

The OneMCU Debug Subsystem (OneMCUDebugSS) is used in the AM273x platform. An overview of the interconnectivity of the debug ports and trace ports are shown in [Figure 11-1](#).

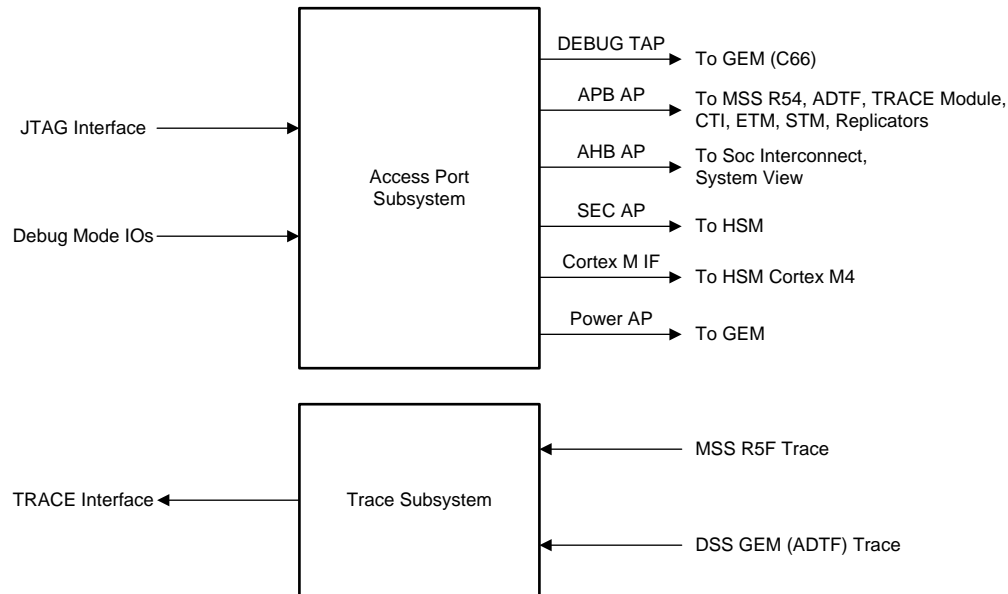

Figure 11-1. Debug SS Overview

11.1.2 DebugSS Architecture

The DebugSS architecture and the connectivity of the various debug components are shown in [Figure 11-2](#).

Figure 11-2. AM273x DebugSS Architecture

11.1.3 Debug Subsystem Address Map

The memory map view for RS232 and DAP AHB is the same as MSS CortexR5. [Table 11-1](#) shows the APB Port Address Map for the AM273x.

Table 11-1. Debug Subsystem Address Map

APB Port	Block Name	Start Address Offset	End Address Offset
APB EXTERNAL PORT 0	C66x ADTF	0x00010000	0x00010FFF
APB EXTERNAL PORT 0	C66x ATB REPLICATOR	0x00011000	0x00011FFF

APB EXTERNAL PORT 2	MSS CR5 C0 ETM	0x0003C000	0x0003CFFF

Table 11-1. Debug Subsystem Address Map (continued)

APB Port	Block Name	Start Address Offset	End Address Offset
APB EXTERNAL PORT 2	MSS CR5 C1 ETM	0x0003D000	0x0003DFFF

11.1.4 Trace Subsystem

11.1.4.1 Trace Infrastructure

The trace infrastructure is shown in [Figure 11-3](#). Trace data from the MSS CR5 cores, C66x DSP core, and HWA Cortex M4 cores may be routed to the external trace lines over the TPIU-Trace interface. Alternately, there is an 8KB trace memory to store the configured (filtered) trace data onto the memory.

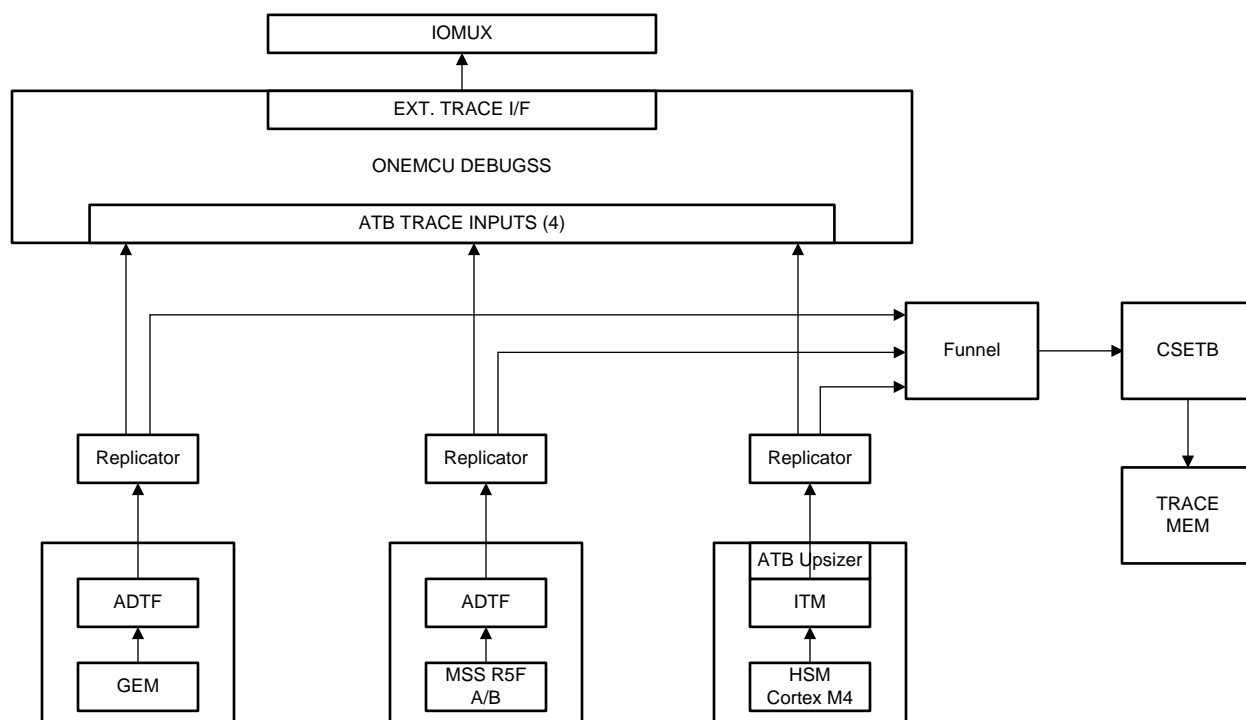

Figure 11-3. Trace Infrastructure

The CortexM4 ITM output requires an 8-bit to 32-bit ATB upsizer in the path to convert the signals to be compatible as input to the upstream layers/modules.

The maximum support frequency for the external interface trace clock is 125 MHz.

11.1.5 Cross Triggering

11.1.5.1 Cross Triggering Infrastructure

The cross triggering infrastructure is shown in [Figure 11-4](#). The host processors involved in the cross triggering sequence are:

- MSS Cortex R5F cores, ETB
- C66x DSP cores, ADF
- Host as suspend peripherals
 - HWA Accelerator

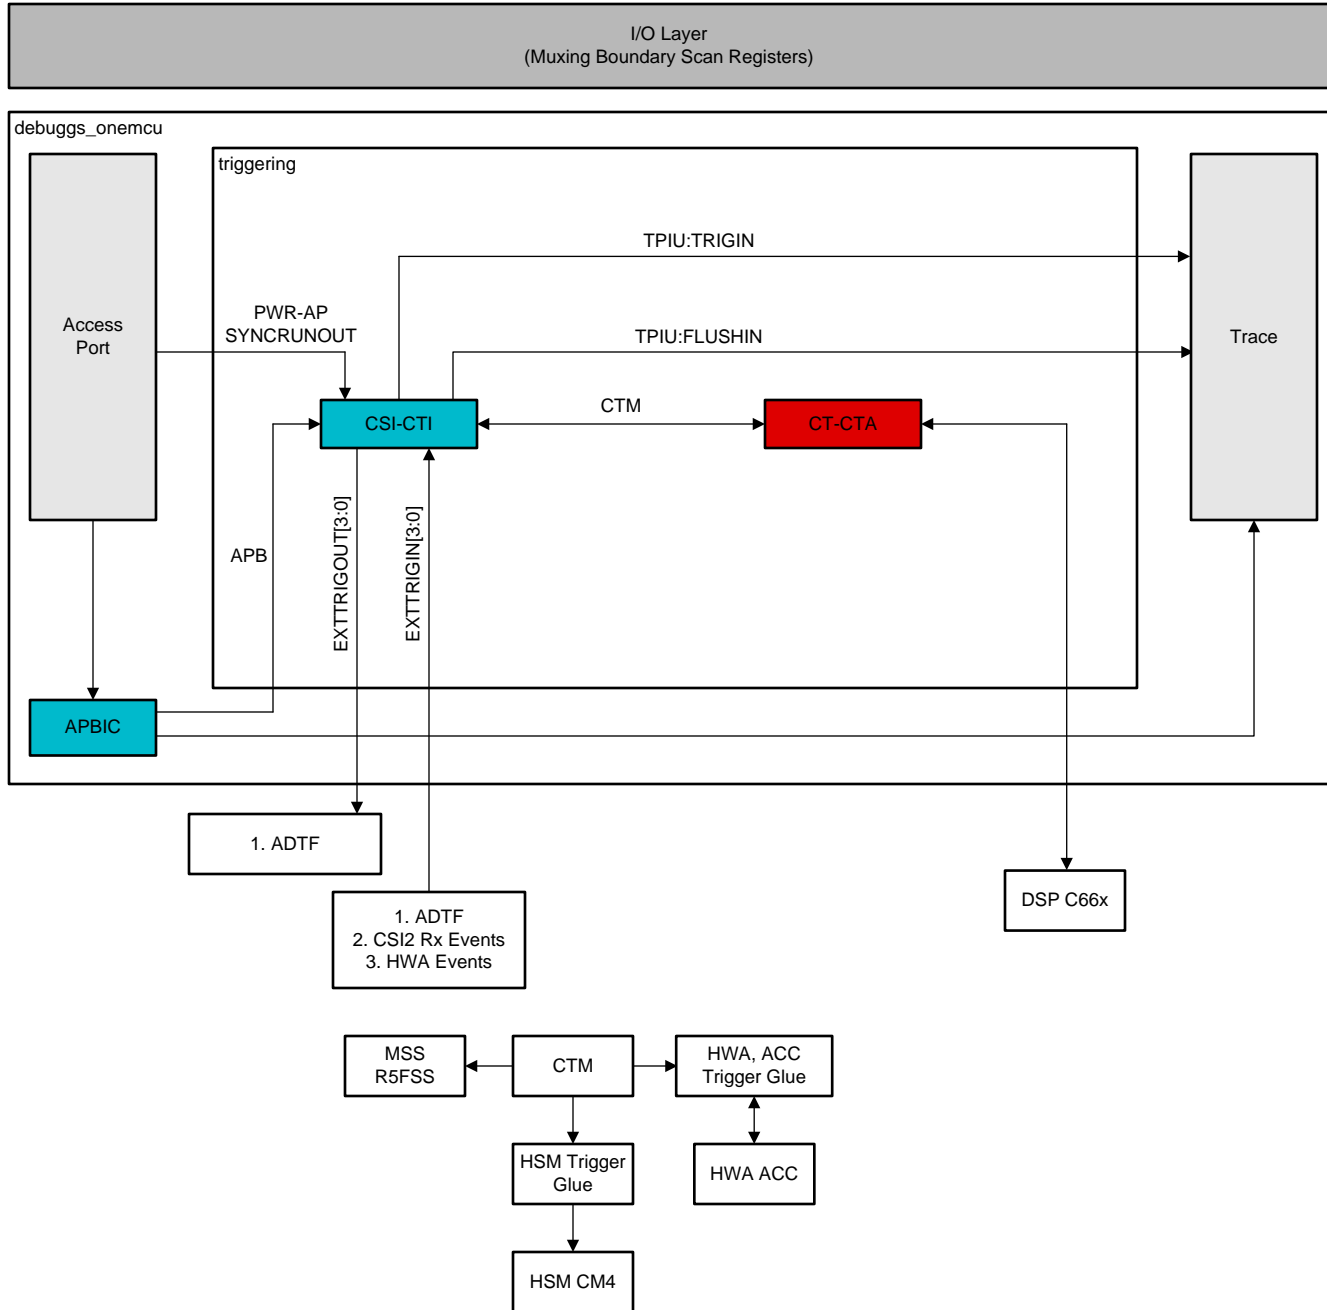

Figure 11-4. Cross Triggering Infrastructure

11.1.6 Suspend Peripherals

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters a debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

Table 11-8. Suspend Peripherals

Subsystems Peripherals	CPU Suspend	Peripherals	Peripheral Control Register
MSS Peripherals	MSS CR5 Cores	MSS_CPSW	MSS_CTRL:DBG_ACK_CTL0_CPSW
		MSS_MCANA	MSS_CTRL:DBG_ACK_CTL1_DCAN
		MSS_MCANB	MSS_CTRL:DBG_ACK_CTL1_DCAN
		MSS_WDT	MSS_CTRL:DBG_ACK_CTL1_WDT
		MSS_RTIA	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_RTIB	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_RTIC	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_MCRC	MSS_CTRL:DBG_ACK_CTL1_MCRC
		MSS_I2C	MSS_CTRL:DBG_ACK_CTL1_I2C

Complex bit access types are encoded to fit into small table cells. [MSS_DEBUGSS Access Type Codes](#) shows the codes that are used for access types in this section.

Table 11-10. MSS_DEBUGSS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

R-		R/W-0h	R-		R/W-0h	R/W-0h	R/W-0h

Table 11-281. STMTCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	
23	BUSY	R/W	0h	Indicates whether the STM is busy, for example the STM trace FIFO is not empty: 0b0 Not busy. 0b1 Busy.
22-16	TRACEID	R/W	0h	ATB trace ID. Setting this value to all zeroes or to a value greater than 0x6F might result in UNPREDICTABLE tracing. Reset value of this bit field is UNKNOWN.
15-6	RESERVED	R	0h	
5	COMPEN	R/W	0h	Compression enable for stimulus ports: 0b0 Disabled, the STM transmits data transfers based on the size of the transaction. 0b1 Enabled, the STM compresses data transfers to save bandwidth.
4-3	RESERVED	R	0h	
2	SYNCEN	R/W	0h	The STM implements the STMSYNCR, so this bit is Read As One. 0b1 The STM implements the STMSYNCR.
1	TSEN	R/W	0h	Determines whether to ignore timestamp requests: 0b0 Disable timestamping. The STM ignores requests for timestamp generation, and treats stimulus port writes that select timestamping as if timestamping were not selected. 0b1 Enable timestamping. If stimulus writes select timestamping, the STM outputs a timestamp according to STPv2.
0	EN	R/W	0h	Global STM enable: 0b0 Disabled 0b1 Enabled.

Table 11-285. STMAUXCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7	QHWEV OVERRIDE	R/W	0h	Low-power interface override when hardware event tracing is enabled: 0b0 The STM can accept a quiescence request on the STM low-power interface when the STMHEMCR.EN bit is set to 0b1. 0b1 If the STMHEMCR.EN bit is set to 0b1, all quiescence requests on the STM low-power interface are denied. Reset value is 0b0.
6-3	RESERVED	R	0h	
2	PRIORIN VDIS	R/W	0h	Controls arbitration between the AXI interface and the hardware event observation interface during flush: 0b0 Priority inversion. When the AXI flush completes, the hardware event observation interface gets priority until the hardware event observation interface flush completes. 0b1 Priority inversion disabled. The AXI always has priority over the hardware event observation interface. Reset value is 0b0.
1	ASYNCP E	R/W	0h	ASYNCP priority: 0b0 Always lower than trace. 0b1 Escalates on second synchronization request. Reset value is 0b0.
0	FIFOAF	R/W	0h	Auto-flush: 0b0 Disabled. 0b1 Enabled. The STM automatically drains all data even if the ATB interface is not fully utilized. Reset value is 0b0.

STMFEAT1R Register (Offset = 00016EA0h) [Reset = 006587D1h]

 STMFEAT1R is shown in [STMFEAT1R Register](#) and described in [STMFEAT1R Register Field Descriptions](#).

 Return to the [Summary Table](#).

Table 11-298. STMLSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	RESERVED	R	0h	
2	nTT	W	0h	Indicates whether the component implements the STMLAR as 8 bit or 32 bit. 0b0 32 bit.
1	SLK	W	0h	Returns the current status of the lock. 0b0 Enables write access to the STM. For read accesses to the STMLSR when the PADDRDBG31 signal is HIGH, this bit is always 0b0. 0b1 Blocks write access to the STM. The STM ignores all write accesses to the registers when the PADDRDBG31 signal is LOW. Reads are permitted
0	SLI	W	0h	Indicates that a lock control mechanism exists for the device. 0b0 No lock control mechanism exists. The STM ignores writes to the STMLAR. For read accesses to the STMLSR when the PADDRDBG31 signal is HIGH, this bit is always 0b0. 0b1 Lock control mechanism is present. For read accesses to the STMLSR when the PADDRDBG31 signal is LOW, this bit is always 0b1.

Table 11-303. STMPIDR4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-4	SIZE	R	0h	This 4-bit value indicates the total contiguous size of the memory window used by the component in powers of two from the standard 4KB. If a component only requires the standard 4KB, this bit field must read as 0x0, 4KB only. For 8KB set to 0x1, for 16KB set to 0x2, for 32KB set to 0x3, and so on. 0x0 The device only occupies 4KB of memory.
3-0	DES_2	R	4h	JEDEC continuation code indicating the designer of the component, together with the identity code. 0x4 ARM JEDEC identity code is on the fifth bank.

STMPIDR0 Register (Offset = 00016FE0h) [Reset = 63h]

STMPIDR0 is shown in [STMPIDR0 Register](#) and described in [STMPIDR0 Register Field Descriptions](#).

Return to the [Summary Table](#).

Peripheral ID0

Table 11-307. STMPIDR3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-4	REVAND	R	0h	Indicates minor errata fixes specific to the design, for example metal fixes after implementation. In most cases this field is zero. ARM recommends that the component designers ensure that the bit field can be changed by a metal fix if required, for example by driving the bit field from registers that reset to zero. 0x0 No metal fixes in the component.
3-0	CMOD	R	0h	Where the component is reusable IP, this value indicates whether the customer has modified the behavior of the component. In most cases this field is zero. 0x0 No modifications made.
