26	PARITYERR	0	Parity error. The calculated parity differs from the received parity bit. If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set. Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		1	No parity error is detected. A parity error occurred.
25	TIMEOUT	0	Time-out because of non-activation of $\overline{\text{SPIEN}}_A$ pin. The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set. Note: This bit is valid only in master mode. Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		1	No $\overline{\text{SPIEN}}_A$ pin time-out occurred. An $\overline{\text{SPIEN}}_A$ signal time-out occurred.
24	DLENERR	0	Data length error flag. Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read. No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.

Table 10-181. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

10.1.4.9.18 SPI Emulation Register (SPIEMU)
Figure 10-203. SPI Emulation Register (SPIEMU) [offset = 44h]

LEGEND: R = Read only; -n = value after reset

Table 10-182. SPI Emulation Register (SPIEMU) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	8000h	Reads return 0. Writes have no effect.
15-0	EMU_RXDATA	0-FFFFh	SPI receive data. The SPI emulation register is a mirror of the SPIBUF register. The only difference between SPIEMU and SPIBUF is that a read from SPIEMU does not clear any of the status flags.

10.1.4.9.19 SPI Delay Register (SPIDELAY)
Figure 10-204. SPI Delay Register (SPIDELAY) [offset = 48h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-183. SPI Delay Register (SPIDELAY) Field Descriptions

Bit	Field	Value	Description
31-24	C2TDELAY	0-FFh	Chip-select-active to transmit-start delay. See Figure 10-205 for an example. C2TDELAY is used only in master mode. It defines a setup time (for the slave device) that delays the data transmission from the chip select active edge by a multiple of VCLK cycles. The setup time value is calculated as follows. $t_{C2TDELAY} = (C2TDELAY + 2) \times VCLK \text{ Period}$ Example: VCLK = 25 MHz -> VCLK Period = 40ns; C2TDELAY = 07h; $> t_{C2TDELAY} = 360 \text{ ns}$ When the chip select signal becomes active, the slave has to prepare data transfer within 360 ns. Note: If phase = 1, the delay between SPICS falling edge to the first edge of SPICLK will have an additional 0.5 SPICLK period delay. This delay is as per the SPI protocol.

Table 10-183. SPI Delay Register (SPIDELAY) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	T2CDELAY	0-FFh	<p>Transmit-end-to-chip-select-inactive-delay. See Figure 10-206 for an example. T2CDELAY is used only in master mode. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred.</p> <p>The hold time value is calculated as follows: $t_{T2CDELAY} = (T2CDELAY + 1) \times VCLK \text{ Period}$</p> <p>Example: VCLK = 25 MHz -> VCLK Period = 40ns; T2CDELAY = 03h; $> t_{T2CDELAY} = 160 \text{ ns}$</p> <p>After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns.</p> <p>Note: If phase = 0, then between the last edge of SPICLK and rise-edge of SPICS there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol.</p> <p>Both C2TDELAY and T2CDELAY counters do not have any dependency on the $\overline{\text{SPIEN}}_A$ pin value. Even if the $\overline{\text{SPIEN}}_A$ pin is asserted by the slave, the master will continue to delay the start of SPICLK until the C2TDELAY counter overflows.</p> <p>Similarly, even if the $\overline{\text{SPIEN}}_A$ pin is deasserted by the slave, the master will continue to hold the SPICS pins active until the T2CDELAY counter overflows. In this way, it is assured that the setup and hold times of the $\overline{\text{SPICS}}$ pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.</p>
15-8	T2EDELAY	0-FFh	<p>Transmit-data-finished to ENA-pin-inactive time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before $\overline{\text{SPIEN}}_A$ signal has to become inactive and after $\overline{\text{SPICS}}$ becomes inactive. SPICLK depends on which data format is selected. If the slave device is missing one or more clock edges, it becomes de-synchronized. In this case, although the master has finished the data transfer, the slave is still waiting for the missed clock pulses and the ENA signal is not disabled.</p> <p>The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the $\overline{\text{SPIEN}}_A$ signal is not deactivated in time. The DESYNC flag is set to indicate that the slave device did not de-assert its $\overline{\text{SPIEN}}_A$ pin in time to acknowledge that it received all bits of the sent word. See Figure 10-207 for an example of this condition.</p> <p>Note: DESYNC is also set if the SPI detects a de-assertion of $\overline{\text{SPIEN}}_A$ before the end of the transmission.</p> <p>The time-out value is calculated as follows: $t_{T2EDELAY} = T2EDELAY / \text{SPIClock}$</p> <p>Example: SPIClock = 8 Mbit/s; T2EDELAY = 10h; $> t_{T2EDELAY} = 2 \mu\text{s}$</p> <p>The slave device has to disable the ENA signal within 2 μs, otherwise DESYNC is set and an interrupt is asserted (if enabled).</p>
7-0	C2EDELAY	0-FFh	<p>Chip-select-active to ENA-signal-active time-out. C2EDELAY is used only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between when the SPI activates the chip-select signal and the addressed slave has to respond by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. See Figure 10-208 for an example of this condition.</p> <p>Note: If the slave device does not respond with the ENA signal before the time-out value is reached, the TIMEOUT flag in the SPIFLG register is set and a interrupt is asserted (if enabled).</p> <p>If a time-out occurs, the SPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer, and continues with the transfer of the next buffer in the sequence that is enabled.</p> <p>The timeout value is calculated as follows: $t_{C2EDELAY} = C2EDELAY / \text{SPIClock}$</p> <p>Example: SPIClock = 8 Mbit/s; C2EDELAY = 30h; $> t_{C2EDELAY} = 6 \text{ ms}$</p> <p>The slave device has to activate the ENA signal within 6 ms after the SPI has activated the chip select signal ($\overline{\text{SPICS}}$), otherwise the TIMEOUT flag is set and an interrupt is asserted (if enabled).</p>

10.1.4.9.20 SPI Default Chip Select Register (SPIDEF)

Figure 10-209. SPI Default Chip Select Register (SPIDEF) [offset = 4Ch]

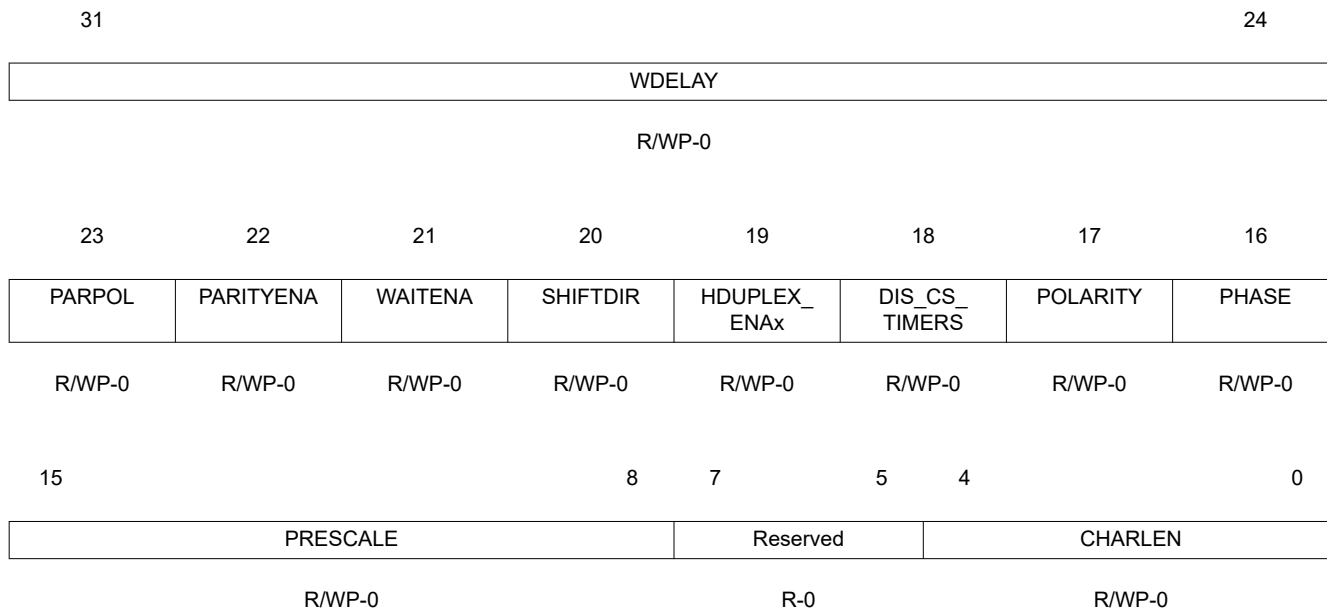

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-184. SPI Default Chip Select Register (SPIDEF) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	CDEF	0-FFh	Chip select default pattern. Master-mode only. The CSDEF bits are output to the \overline{SPICS} pins when no transmission is being performed. It allows the user to set a programmable chip-select pattern that deselects all of the SPI slaves.
		0	\overline{SPICS} is cleared to 0 when no transfer is active.
		1	\overline{SPICS} is set to 1 when no transfer is active.

10.1.4.9.21 SPI Data Format Registers (SPIFMT)

Figure 10-210. SPI Data Format Registers (SPIFMT[3:0]) [offset = 5Ch-50h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-185. SPI Data Format Registers (SPIFMT) Field Descriptions

Bit	Field	Value	Description
31-24	WDELAY	0-FFh	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: $WDELAY \times P_{VCLK} + 2 \times P_{VCLK}$ $P_{VCLK} \rightarrow$ Period of VCLK.
23	PARPOL	0 1	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 0 An even parity flag is added at the end of the transmit data stream. 1 An odd parity flag is added at the end of the transmit data stream.
22	PARITYENA	0 1	Parity enable for data format x. No parity generation/ verification is performed for this data format. 0 A parity bit is transmitted at the end of each transmitted word. At the end of a transfer the parity generator compares the received parity bit with the locally-calculated parity flag. If the parity bits do not match, the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 1 Note: If an uncorrectable error flag is set in a slave-mode SPI, then the wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SPISOMI pins will be forced to transmit all 0s, and the parity bit will be transmitted as 1 if even parity is selected and as 0 if odd parity is selected (using the PARPOLx bit of this register). This behavior occurs regardless of an uncorrectable parity error on either TXRAM or RXRAM.
21	WAITENA	0 1	The master waits for the ENA signal from slave for data format x. WAITENA is valid in master mode only. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines, for each transferred word, whether the addressed slave generates the ENA signal or not. 0 The SPI does not wait for the ENA signal from the slave and directly starts the transfer. 1 Before the SPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag.

Table 10-185. SPI Data Format Registers (SPIFMT) Field Descriptions (continued)

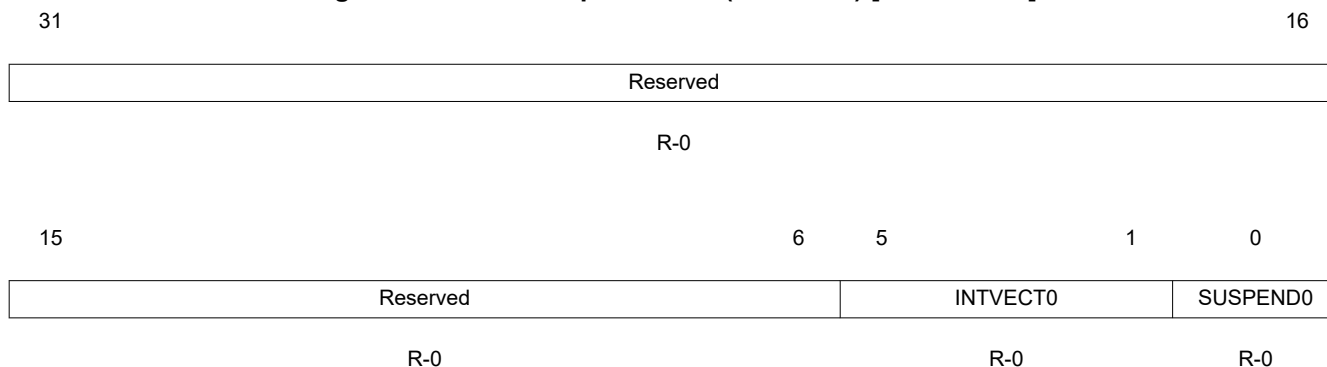

Bit	Field	Value	Description
20	SHIFTDIR	0 1	Shift direction for data format x. With bit SHIFTDIRx, the shift direction for data format x (x=0,1,2,3) can be selected. MSB is shifted out first. LSB is shifted out first.
19	HDUPLEX_ENAx	0 1	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. Normal Full Duplex transfer. If MASTER = 1, SPISIMO pin will act as an RX pin (No TX possible) If MASTER = 0, SPISIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain 0. It is intended for the usage when the SPISIMO pin is used for both TX and RX operations at different times.
18	DIS CS TIMERS	0 1	Disable chip-select timers for this format. The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format, if they are not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip-select delay timers for any slaves. Both C2TDELAY and T2CDELAY counts are inserted for the chip selects. No C2TDELAY or T2CDELAY is inserted in the chip select timings.
17	POLARITY	0 1	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. The following restrictions apply when switching clock phase and/or polarity: <ul style="list-style-type: none"> In 3-pin/4-pin with $\overline{\text{SPIEN}}_A$ pin configuration of a slave SPI, the clock phase and polarity cannot be changed on-the-fly between two transfers. The slave should be reset and reconfigured if clock phase/polarity needs to be switched. In summary, SPI format switching is not fully supported in slave mode. Even while using chip select pins, the polarity of SPICLK can be switched only while the slave is not selected by a valid chip select. The master SPI should ensure that while switching SPICLK polarity, it has deselected all of its slaves. Otherwise, the switching of SPICLK polarity may be incorrectly treated as a clock edge by some slaves. If POLARITYx is cleared to 0, the SPI clock signal is low-inactive, that is, before and after data transfer the clock signal is low. If POLARITYx is set to 1, the SPI clock signal is high-inactive, that is, before and after data transfer the clock signal is high.
16	PHASE	0 1	SPI data format x clock delay. PHASEx defines the clock delay of data format x. If PHASEx is cleared to 0, the SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge. If PHASEx is set to 1, the SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.
15-8	PRESCALE		SPI data format x prescaler. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is use to derive SPICLK from VCLK. If the SPI is configured as slave, PRESCALEx does not need to be configured. The clock rate for data format x can be calculated as: $BR_{\text{Formatx}} = VCLK / (\text{PRESCALEx} + 1)$ Note: When PRESCALEx is cleared to 0, the SPI clock rate defaults to VCLK/2.
7-5	Reserved	0	Reads return 0. Writes have no effect.
4-0	CHARLEN	0-1Fh	SPI data format x data-word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 00 or 1Fh are not allowed; their effect is indeterminate.

10.1.4.9.22 Interrupt Vector 0 (INTVECT0)

Note

The TG interrupt is not available in MibSPI in compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 10-211. Interrupt Vector 0 (NTVECT0) [offset = 60h]

LEGEND: R = Read only; -n = value after reset

Table 10-186. Transfer Group Interrupt Vector 0 (INTVECT0)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5-1	INTVECT0	0	INTVECT0. Interrupt vector for interrupt line INT0. Returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupt is pending, INTVECT0 always references the highest prior interrupt source first. Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.
		1h + x	There is no pending interrupt.
		11h	Transfer group x (x = 0 to 15) has a pending interrupt. SUSPEND0 reflects the type of interrupt (<i>suspend</i> or <i>finished</i>).
		13h	Error Interrupt pending. The lower half of SPIFLG contains more details about the type of error.
		12h	The pending interrupt is a Receive Buffer Overrun interrupt.
		14h	SPI mode: The pending interrupt is a Receive Buffer Full interrupt. Mib mode: Reserved. This bit combination should not occur.
		All Other Combinations	SPI mode: The pending interrupt is a Transmit Buffer Empty interrupt. Mib mode: Reserved. This bit combination should not occur.
		All Other Combinations	SPI mode: Reserved. These bit combinations should not occur.
0	SUSPEND0	0	Transfer suspended / Transfer finished interrupt flag. Every time INTVECT0 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT0 is updated with the vector coming next in the priority chain.
		0	The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT0 has asserted an interrupt because all of data from the transfer group has been transferred.
		1	The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT0 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.

Note

Reading from the INTVECT0 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

Note

In multi-buffer mode, INTVECT0 contains the interrupt for the highest priority transfer group. A read from INTVECT0 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT0 and its corresponding SUSPEND flag to get loaded into SUSPEND0. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT0 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR).

10.1.4.9.23

10.1.4.9.24 Interrupt Vector 1 (INTVECT1)

Note

The TG interrupt is not available in SPI in compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 10-212. Interrupt Vector 1 (INTVECT1) [offset = 64h]

LEGEND: R = Read only; -n = value after reset

Table 10-187. Transfer Group Interrupt Vector 1 (INTVECT1)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.

Table 10-187. Transfer Group Interrupt Vector 1 (INTVECT1) (continued)

Bit	Field	Value	Description
5-1	INTVECT1		<p>INTVECT1. Interrupt vector for interrupt line INT1.</p> <p>Returns the vector of the pending interrupt at interrupt line INT1. If more than one interrupt is pending, INTVECT1 always references the highest prior interrupt source first.</p> <p>Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.</p> <p>0 There is no pending interrupt. SPI mode only.</p> <p>11h Error Interrupt pending. The lower half of SPIINT1 contains more details about the type of error. SPI mode only.</p> <p>13h The pending interrupt is a Receive Buffer Overrun interrupt. SPI mode only.</p> <p>12h The pending interrupt is a Receive Buffer Full interrupt. SPI mode only.</p> <p>14h The pending interrupt is a Transmit Buffer Empty interrupt. SPI mode only.</p> <p>All Other Combinations Reserved. These bit combinations should not occur. SPI mode only.</p>
0	SUSPEND1		<p>Transfer suspended / Transfer finished interrupt flag.</p> <p>Every time INTVECT1 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT1 is updated with the vector coming next in the priority chain.</p> <p>0 The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT1 has asserted an interrupt because all of data from the transfer group has been transferred.</p> <p>1 The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT1 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.</p>

Note

Reading from the INTVECT1 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

Note

In multi-buffer mode, INTVECT1 contains the interrupt for the highest priority transfer group. A read from INTVECT1 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT1 and its corresponding SUSPEND flag to get loaded into SUSPEND1. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT1 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXOVRN_BUF_ADDR register.

10.1.4.9.25 SPI Pin Control Register 9 (SPIPC9)

SPIPC9 only applies to SPI2.

Figure 10-213. SPI Pin Control Register 9 (SPIPC9) [offset = 68h]

31	25	24	23	17	16	
Reserved		SOMISRS0	Reserved		SIMOSRS0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-188. SPI Pin Control Register 9 (SPIPC9) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return the value that was last written. Writes have no effect.
24	SOMISRS0	0 1	SPI2 SOMI[0] slew control. This bit controls between the fast or slow slew mode. Note: Duplicate Control Bits for SPI2 SOMI[0]. Bit 24 is not physically implemented. It is a mirror of bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPI2 SOMI[0] pin. The read value of bit 24 always reflects the value of bit 11. 0 Fast mode is enabled; the normal output buffer is used for this pin. 1 Slow mode is enabled; slew rate control is used for this pin.
23-17	Reserved	0	Reads return the value that was last written. Writes have no effect.
16	SIMOSRS0	0 1	SPI2 SIMO[0] slew control. This bit controls between the fast or slow slew mode. Note: Duplicate Control Bits for SPI2 SIMO[0]. Bit 16 is not physically implemented. It is a mirror of bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPI2 SIMO[0] pin. The read value of bit 16 always reflects the value of bit 10. 0 Fast mode is enabled; the normal output buffer is used for this pin. 1 Slow mode is enabled; slew rate control is used for this pin.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMISRS0	0 1	SPI2 SOMI[0] slew control. This bit controls between the fast or slow slew mode. 0 Fast mode is enabled; the normal output buffer is used for this pin. 1 Slow mode is enabled; slew rate control is used for this pin.
10	SIMOSRS0	0 1	SPI2 SIMO[0] slew control. This bit controls between the fast or slow slew mode. 0 Fast mode is enabled; the normal output buffer is used for this pin. 1 Slow mode is enabled; slew rate control is used for this pin.
9	CLKSRS	0 1	SPI2 CLK slew control. This bit controls between the fast or slow slew mode. 0 Fast mode is enabled; the normal output buffer is used for this pin. 1 Slow mode is enabled; slew rate control is used for this pin.
8-0	Reserved	0	Reads return the value that was last written. Writes have no effect.

10.1.4.9.26 Parallel/Modulo Mode Control Register (SPIPMCTRL)

Note

Do not configure MODCLKPOLx and MMODEx bits since this device does not support modulo mode.

Note

The bits of this register are used in conjunction with the SPIFMTx registers. Each byte of this register corresponds to one of the SPIFMTx registers.

1. Byte0 (Bits 7:0) are used when SPIFMT0 register is selected by DFSEL[1:0] = 00 in the control field of a buffer.
2. Byte1 (Bits 15:8) are used when SPIFMT1 register is selected by DFSEL[1:0] = 01 in the control field of a buffer.
3. Byte2 (Bits 23:16) are used when SPIFMT2 register is selected by DFSEL[1:0] = 10 in the control field of a buffer.
4. Byte3 (Bits 31:24) are used when SPIFMT3 register is selected by DFSEL[1:0] = 11 in the control field of a buffer.

10.1.4.9.27 Multi-buffer Mode Enable Register (MIBSPIE)

Note

Accessibility of Multi-Buffer RAM

The multi-buffer RAM is not accessible unless the MSPIENA bit set to 1. The only exception to this is in test mode, where, by setting RXRAMACCESS to 1, the multi-buffer RAM can be fully accessed for both read and write.

Figure 10-215. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h]

31	17	16
Reserved		RXRAM_ACCESS
R-0		R/WP-0
15	1	0
Reserved		MSPIENA
R-0		R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-190. Multi-buffer Mode Enable Register (MIBSPIE) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	RXRAM ACCESS	0 1	Receive-RAM access control. During normal operating mode of SPI, the receive data/status portion of multi-buffer RAM is read-only. To enable testing of receive RAM, direct read/write access is enabled by setting this bit. 0 The RX portion of multi-buffer RAM is not writable by the CPU. 1 The whole of multi-buffer RAM is fully accessible for read/write by the CPU. Note: The RX RAM ACCESS bit remains 0 after reset and it should remain cleared to 0 at all times, except when testing the RAM. SPI should be given a local reset by using the nRESET (SPIGCR0[0]) bit after RAM testing is performed so that the multi-buffer RAM gets re-initialized.
15-1	Reserved	0	Reads return 0. Writes have no effect.
0	MSPIENA	0 1	Multi-buffer mode enable. After power-up or reset, MSPIENA remains cleared, which means that the SPI runs in compatibility mode by default. If multi-buffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. If MSPIENA is not set to 1, the multi-buffer mode registers are not writable. 0 The SPI runs in compatibility mode, that is, in this mode the MibSPI is fully code-compliant to the standard device SPI. No multi-buffered-mode features are supported. 1 The SPI is configured to run in multi-buffer mode.

Note

Accessibility of Registers

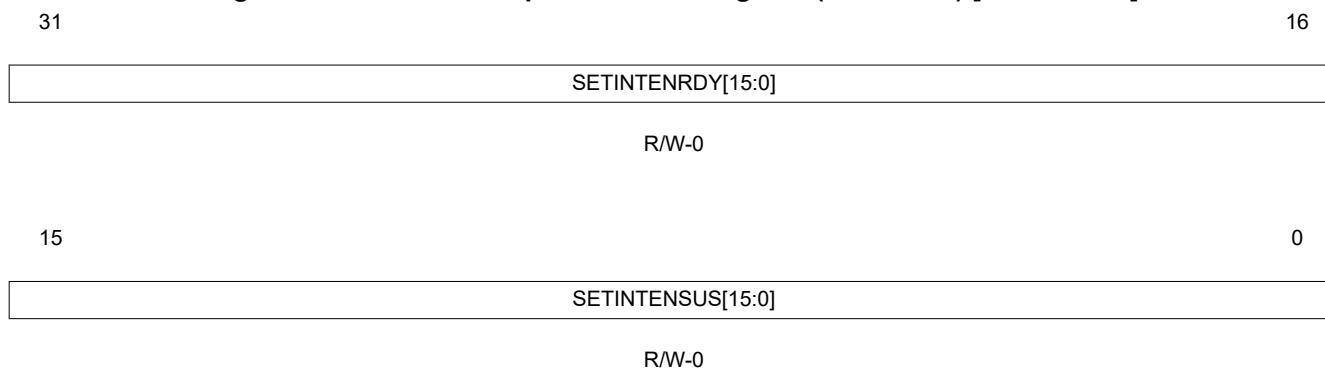

Registers from this offset address onwards are not accessible in SPI compatibility mode. They are accessible only in the multi-buffer mode.

10.1.4.9.28 TG Interrupt Enable Set Register (TGITENST)

The register TGITENST contains the TG interrupt enable flags for transfer-finished and for transfer-suspended events. Each of the enable bits in the higher half-word and the lower half-word of TGITENST belongs to one TG.

The register map shown in [Figure 10-216](#) and [Table 10-191](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 10-216. TG Interrupt Enable Set Register (TGITENST) [offset = 74h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-191. TG Interrupt Enable Set Register (TGITENST) Field Descriptions

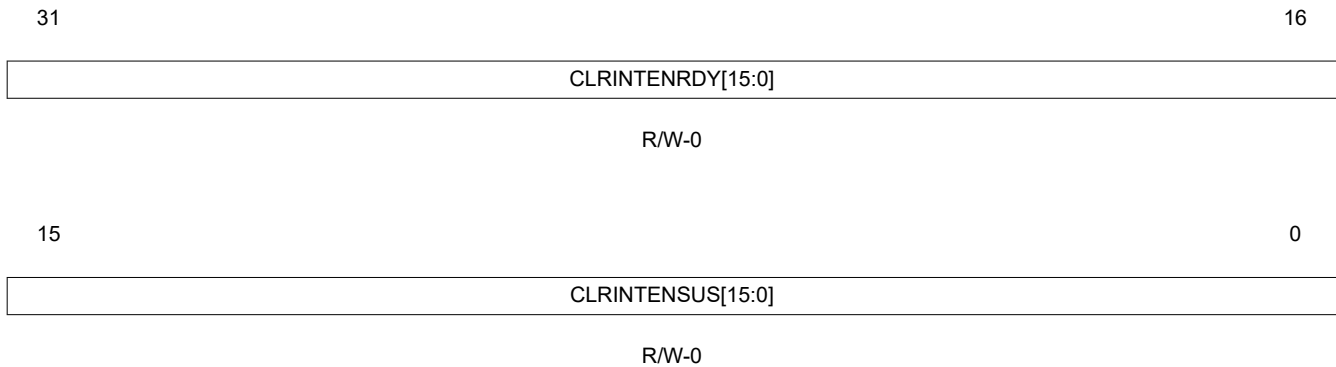

Bit	Field	Value	Description
31-16	SETINTENRDY[n]	0	TG interrupt set (enable) when transfer finished. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx completes. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx completes. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx completes.
15-0	SETINTENSUS[n]	0	TG interrupt set (enabled) when transfer suspended. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx is suspended. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx is suspended. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx is suspended.

10.1.4.9.29 TG Interrupt Enable Clear Register (TGITENCR)

The register TGITENCR is used to clear the interrupt enables for the TG-completed interrupt and the TG-suspended interrupts.

The register map shown in [Figure 10-217](#) and [Table 10-192](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 10-217. TG Interrupt Enable Clear Register (TGITENCR) [offset = 78h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-192. TG Interrupt Enable Clear Register (TGITENCR) Field Descriptions

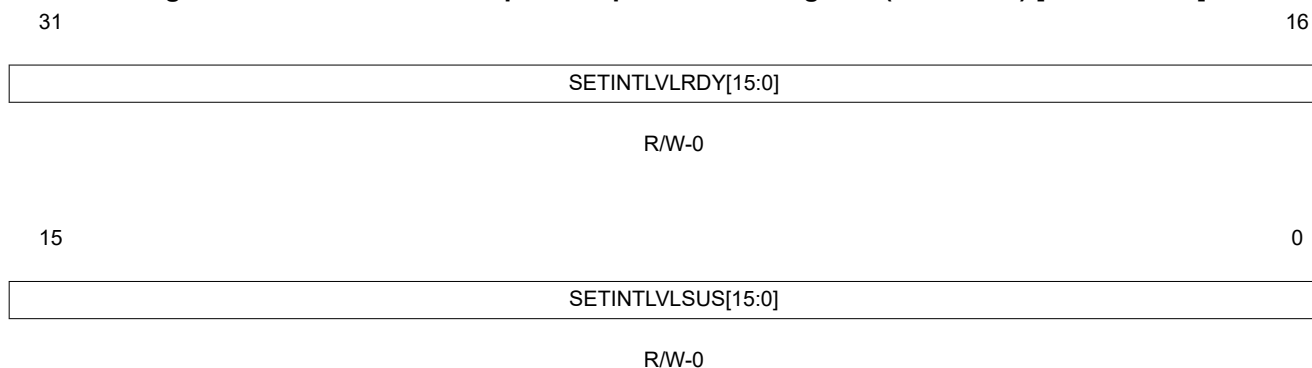

Bit	Field	Value	Description
31-16	CLRINTENRDY[n]	0	TG interrupt clear (disabled) when transfer finished. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx completes. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx completes. Write: Disable the TGx-completed interrupt. The interrupt does not get generated when TGx completes.
15-0	CLRINTENSUS[n]	0	TG interrupt clear (disabled) when transfer suspended. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx is suspended. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx is suspended. Write: Disable the TGx-completed interrupt. The interrupt does not get generated when TGx is suspended.

10.1.4.9.30 Transfer Group Interrupt Level Set Register (TGITLVST)

The register TGITLVST sets the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 1.

The register map shown in [Figure 10-218](#) and [Table 10-193](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 10-218. Transfer Group Interrupt Level Set Register (TGITLVST) [offset = 7Ch]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-193. Transfer Group Interrupt Level Set Register (TGITLVST) Field Descriptions

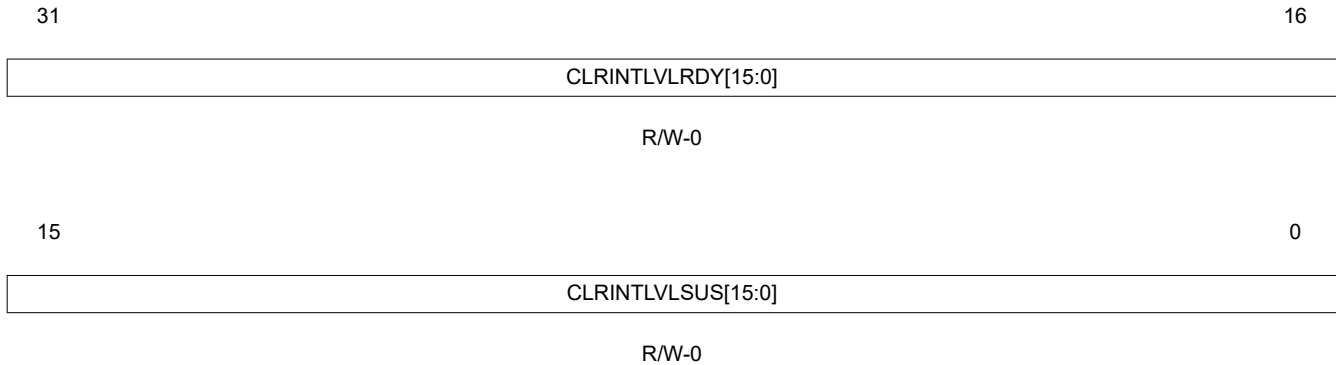

Bit	Field	Value	Description
31-16	SETINTLVLRDY[n]	0	Transfer-group completed interrupt level set. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. Read: The TGx-completed interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is set to INT1. Write: Set the TGx-completed interrupt to INT1.
15-0	SETINTLVLSUS[n]	0	Transfer-group suspended interrupt level set. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. Read: The TGx-suspended interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-suspended interrupt is set to INT1. Write: Set the TGx-suspended interrupt to INT1.

10.1.4.9.31 Transfer Group Interrupt Level Clear Register (TGITLVCR)

The register TGITLVCR clears the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 0.

The register map shown in [Figure 10-219](#) and [Table 10-194](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 10-219. Transfer Group Interrupt Level Clear Register (TGITLVCR) [offset = 80h]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-194. Transfer Group Interrupt Level Clear Register (TGITLVCR) Field Descriptions

Bit	Field	Value	Description
31-16	CLRINTLVLRDY[n]	0	Transfer-group completed interrupt level clear. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. Read: The TGx-completed interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is set to INT1. Write: Clear the TGx-completed interrupt to INT0.
15-0	CLRINTLVLSUS[n]	0	Transfer group suspended interrupt level clear. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. Read: The TGx-suspended interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-suspended interrupt is set to INT1. Write: Clear the TGx-suspended interrupt to INT0.

10.1.4.9.32 Transfer Group Interrupt Flag Register (TGINTFLG)

The TGINTFLG register comprises the transfer group interrupt flags for transfer-completed interrupts (INTFLGRDYx) and for transfer-suspended interrupts (INTFLGSUSx). Each of the interrupt flags in the higher half-word and the lower half-word of TGINTFLG belongs to one TG.

The register map shown in [Figure 10-220](#) and [Table 10-195](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 10-220. Transfer Group Interrupt Flag Register (TGINTFLG) [offset = 84h]

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -n = value after reset

Table 10-195. Transfer Group Interrupt Flag Register (TGINTFLG) Field Descriptions

Bit	Field	Value	Description
31-16	INTFLGRDY[n]	0	Transfer-group interrupt flag for a transfer-completed interrupt. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the vector registers is 0. Read: No transfer-completed interrupt occurred since last clearing of the INTFLGRDYx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer finished interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don't care) or whether the interrupt is mapped to INTO or INT1, INTFLGRDYx is set right after the transfer from TGx is finished. Write: The corresponding bit flag is cleared.
15-0	INTFLGSUS[n]	0	Transfer-group interrupt flag for a transfer-suspend interrupt. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGSUSx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the corresponding vector registers is 1. Read: No transfer-suspended interrupt occurred since the last clearing of the INTFLGSUSx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer-suspended interrupt from TGx occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don't care) or whether the interrupt is mapped to INTO or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended. Write: The corresponding bit flag is cleared.

10.1.4.9.33 Tick Count Register (TICKCNT)

One of the trigger sources for TGs is an internal periodic time trigger. This time trigger is called a tick counter and is basically a down-counter with a preload/reload value. Every time the tick counter detects an underflow it reloads the initial value and toggles the trigger signal provided to the TGs.

The trigger signal, shown in Figure 10-221 as a square wave, illustrates the different trigger event types for the TGs (for example, rising edge, falling edge, and both edges).

Figure 10-221. Tick Counter Operation

This register is shown in Figure 10-222 and described in Table 10-196.

Figure 10-222. Tick Count Register (TICKCNT) [offset = 90h]

31	30	29	28	27	16
TICKENA		RELOAD	CLKCTRL		Reserved
R/W-0		R/S-0	R/W-0		R-0
15					0
TICKVALUE					
R/W-0					

LEGEND: R/W = Read/Write; R = Read only; S = Set; -n = value after reset

Table 10-196. Tick Count Register (TICKCNT) Field Descriptions

Bit	Field	Value	Description
31	TICKENA	0 1	Tick counter enable. The internal tick counter is disabled. The counter value remains unchanged. Note: When the tick counter is disabled, the trigger signal is forced low. The internal tick counter is enabled and is clocked by the clock source selected by CLKCTRL. When TICKENA goes from 0 to 1, the tick counter is automatically loaded with the contents of TICKVALUE.
30	RELOAD		Pre-load the tick counter. RELOAD is a set-only bit; writing a 1 to it reloads the tick counter with the value stored in TICKVALUE. Reading RELOAD always returns a 0. Note: When the tick counter is reloaded by the RELOAD bit, the trigger signal is not toggled.
29-28	CLKCTRL	0 1h 2h 3h	Tick counter clock source control. CLKCTRL defines the clock source that is used to clock the internal tick counter. SPICLK of data word format 0 is selected as the clock source of the tick counter. SPICLK of data word format 1 is selected as the clock source of the tick counter. SPICLK of data word format 2 is selected as the clock source of the tick counter. SPICLK of data word format 3 is selected as the clock source of the tick counter.
27-16	Reserved	0	Reads return 0. Writes have no effect.

Table 10-196. Tick Count Register (TICKCNT) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	TICKVALUE	0-FFFFh	Initial value for the tick counter. TICKVALUE stores the initial value for the tick counter. The tick counter is loaded with the contents of TICKVALUE every time an underflow condition occurs and every time the RELOAD flag is set by the host.

10.1.4.9.34 Last TG End Pointer (LTGPEND)

Figure 10-223. Last TG End Pointer (LTGPEND) [offset = 94h]

31	29	28	24	23	16
Reserved		TG_IN_SERVICE		Reserved	
R-0		R-0		R-0	
15	14	8	7		
Rsvd	LPEND		Reserved		
R-0	R/W-0		R-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-197. Last TG End Pointer (LTGPEND) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28-24	TG_IN_SERVICE	0 1h : 10h 11h-1Fh	The TG number currently being serviced by the sequencer. These bits indicate the current TG that is being serviced. This field can generally be used for code debugging. No TG is being serviced by the sequencer. TG0 is being serviced by the sequencer. : TG15 is being serviced by the sequencer. Note: The number of transfer groups varies by device. Invalid values.
23-15	Reserved	0	Reads return 0. Writes have no effect.
14-8	LPEND	0-7Fh	Last TG end pointer. Usually the TG end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent TG (PSTART). The TG ends one word before the next TG starts (PEND[x] = PSTART[x+1] - 1). For a full configuration of MibSPI, the last TG has no subsequent TG, that is, no end address is defined. Therefore, LPEND has to be programmed to specify explicitly the end address of the last TG. Note: When using all 8 transfer groups, program the LPEND bits to define the end of the last transfer group. When using less than 8 transfer groups, leave the LPEND bits programmed to point to the end of the buffer and create a dummy transfer group that defines the end of your last intentional transfer group and occupies all the remaining buffer space.
7-0	Reserved	0	Reads return 0. Writes have no effect.

10.1.4.9.35 TGx Control Registers (TGxCTRL)

Each TG can be configured via one dedicated control register. The register description shows one control register (x) that is identical for all TGs. For example, the control register for TG2 is named TG2CTRL and is located at *base address + 98h + 4 × 2*. The actual number of available control registers varies by device.

Figure 10-224. MibSPI TG Control Registers (TGxCTRL) [offsets = 98h-D4h]

31	30	29	28	27	24

Rsvd	PSTART			Rsvd	PCURRENT			
R-0	R/W-0			R-0	R-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-198. TG Control Registers (TGxCTRL) Field Descriptions

Bit	Field	Value	Description
31	TGENA	0 1	TGx enable. If the correct event (TRIG EVTx) occurs at the selected source (TRIG SRCx), a group transfer is initiated if no higher-priority TG is in active-transfer mode or if one or more higher-priority TGs are in transfer-suspend mode. Disabling a TG while a transfer is ongoing will finish the ongoing word transfer but not the whole group transfer. 0 TGx is disabled. 1 TGx is enabled.
30	ONESHOTx	0 1	Single transfer for TGx. 0 TGx initiates a transfer every time a trigger event occurs and TGENAx is set. 1 A transfer from TGx will be performed only once (one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared and therefore no additional transfer can be triggered before the host enables the TG again. This one shot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data.

Table 10-198. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
29	PRSTx		<p>TGx pointer reset mode. Configures the way to resolve trigger events during an ongoing transfer. This bit is meaningful only for level-triggered TGs. Edge-triggered TGs cannot be restarted before their completion by another edge. The PRST bit will have no effect on this behavior.</p> <p>Note: When the PRST bit is set, if the buffer being transferred at the time of a new trigger event is a LOCK, CSHOLD or NOBRK buffer, then only after finishing those transfers, the TG will be restarted. This means that even if the TG is retriggered, the TG will only be restarted after finishing the transfer of the first non-LOCK or non-CSHOLD buffer. In the case of the NOBRK buffer, after completing the ICOUNT number of transfers, the TG will be restarted from its PSTART.</p> <p>This means that TX control fields such as LOCK and CSHOLD, and DMA control fields such as NOBRK have higher priority over anything else. They have the capability to delay the restart of the TG even if it is retriggered when PRST is 1.</p> <p>0 If a trigger event occurs during a transfer from TGx, the event is ignored and is not stored internally. The TGx transfer has priority over additional trigger events.</p> <p>1 The TGx pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same TG is ongoing. Every trigger event resets PCURRENTx no matter whether the concerned TG is in transfer mode or not. The trigger events have priority over the ongoing transfer.</p>
28	TGTDx		<p>TG triggered.</p> <p>0 TGx has not been triggered or is no longer waiting for service.</p> <p>1 TGx has been triggered and is either currently being serviced or waiting for servicing.</p>
27-24	Reserved	0	Reads return 0. Writes have no effect.

Table 10-198. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
23-20	TRIGEVTx		<p>Type of trigger event. A level-triggered TG can be stopped by de-activating the level trigger. However, the following restrictions apply.</p> <ul style="list-style-type: none"> Deactivating the level trigger for a TG during a NOBRK transfer does not stop the transfers until all of the ICOUNT number of buffers are transferred for the NOBRK buffer. Once a NOBRK buffer is prefetched, the trigger event loses control over the TG until the NOBRK buffer transfer is completed. Once the transfer of a buffer with CSHOLD or LOCK bit set starts, deactivating the trigger level does not stop the transfer until the sequencer completes the transfer of the next non-CSHOLD or non-LOCK buffer in the same TG. Once the last buffer in a TG is pre-fetched, de-activating the trigger level does not stop the transfer group until the last buffer transfer is completed. This means even if the trigger level is deactivated at the beginning of the penultimate (one-before-last) buffer transfer, the sequencer continues with the same TG until it is completed.
		0	never Never trigger TGx. This is the default value after reset.
		1h	rising edge A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		2h	falling edge A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		3h	both edges Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		4h	Rsvd Reserved
		5h	high-active While the selected trigger source (TRIGSRCx) is at a logic-high level (1), the group transfer is continued and at the end of one group, transfer is restarted at the beginning. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. Note: If ONESHOTx is set, the transfer is performed only once.
		6h	low-active While the selected trigger source (TRIGSRCx) is at a logic-low level (0), the group transfer is continued and at the end of one group, transfer is restarted at the beginning. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. Note: If ONESHOTx is set, the transfer is performed only once.
		7h	always A repetitive group transfer will be performed. Note: By setting the TRIGSRC to 0, the TRIGEVT to 7h (ALWAYS), and the ONESHOTx bit to 1, software can trigger this TG. Upon setting the TGENA bit, the TG is immediately triggered. Note: If ONESHOTx is set, the transfer is performed only once.
		8h-Fh	Rsvd Reserved

Table 10-198. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	TRIGSRCx	0 1h 2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh	Trigger source. After reset, the trigger sources of all TGs are disabled. Disabled External trigger source 0. The actual source varies per device (for example, HET I/O channel, event pin). External trigger source 10. The actual source varies per device (for example, HET I/O channel, event pin). External trigger source 11. The actual source varies per device (for example, HET I/O channel, event pin). External trigger source 12. The actual source varies per device (for example, HET I/O channel, event pin). External trigger source 13. The actual source varies per device (for example, HET I/O channel, event pin). TICK Internal periodic event trigger. The tick counter can initiate periodic group transfers.
15	Reserved	0	Reads return 0. Writes have no effect.
14-8	PSTARTx	0-7Fh	TG start address. PSTARTx stores the start address of the corresponding TG. The corresponding end address is inherently defined by the subsequent TG start address minus 1 ($PENDx[TGx] = PSTARTx[TGx+1]-1$). PSTARTx is copied into PCURRENTx when: <ul style="list-style-type: none"> • The TG is enabled • The end of the TG is reached during a transfer • A trigger event occurs while PRST is set to 1
7	Reserved	0	Reads return 0. Writes have no effect.
6-0	PCURRENTx	0-7Fh	Pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127) of the buffer that corresponds to this TG. If the TG switches from active-transfer mode to suspend-to-wait mode, PCURRENTx contains the address of the currently suspended word. After the TG resumes from suspend-to-wait mode, the next buffer will be transferred; that is, no buffer data is transferred because of suspend-to-wait mode.

Note**Register bits vary by device**

TG0 has the highest priority and TG15 has the lowest priority. Under the following conditions, a lower-priority TG cannot be interrupted by a higher-priority TG:

1. When there is a CSHOLD or LOCK buffer, until the completion of the next buffer transfer that is a non-CSHOLD or non-LOCK buffer.
 2. An entire sequence of words transferred for a NOBRK DMA buffer.
 3. Once the last word in a TG is pre-fetched.
-

10.1.4.9.36 DMA Channel Control Register (DMAxCTRL)

Each DMA channel can be configured via one dedicated control register. The register description below shows one exemplary control register that is identical for all DMA channels; for example, the control register for DMA channel 0 is named DMA0CTRL. The MibSPI supports up to 8 bidirectional DMA channels.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA channel control registers may vary.

Figure 10-225. DMA Channel Control Register (DMAxCTRL) [offset = D8h-F4h]

R-0	R-0	R-0					

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-199. DMA Channel Control Register (DMAxCTRL) Field Descriptions

Bit	Field	Value	Description
31	ONESHOT	0 1	Auto-disable of DMA channel after ICOUNT + 1 transfers. Note: This ONESHOT applies to the DMA channel identified by x and will autotisable based on ICOUNTx. 0 The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI. 1 ONESHOT allows a block transfer of defined length (ICOUNTx + 1), mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx + 1 transfers, the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer.
30-24	BUFIDx	0-7Fh	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the "suspend to wait until..." modes must be used.
23-20	RXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to 1, then RXDMA_MAPx shall differ from TXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.

Table 10-199. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	TXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. TXDMA_MAPx defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to 1, then TXDMA_MAPx shall differ from RXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.
15	RXDMAENAx	0 1	Receive data DMA channel enable. 0 No DMA request upon new receive data. 1 The physical DMA channel for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The buffer should be configured in as "skip until RXEMPTY is set" or "suspend to wait until RXEMPTY is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.
14	TXDMAENAx	0 1	Transmit data DMA channel enable. 0 No DMA request upon new transmit data. 1 The physical DMA channel for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The buffer should be configured in the as "skip until TXFULL is set" or "suspend to wait until TXFULL is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.
13	NOBRKx	0 1	Non-interleaved DMA block transfer. This bit is available in master mode only. Note: Special Conditions during a NOBRK Buffer Transfer. If a NOBRK DMA buffer is currently being serviced by the sequencer, then it is not allowed to be disabled prematurely. During a NOBRK transfer, the following operations are not allowed: <ul style="list-style-type: none"> • Clearing the NOBRKx bit to 0 • Clearing the RXDMAENAx to 0 (if it is already 1) • Clearing the TXDMAENAx to 0 (if it is already 1) • Clearing the BUFMODE[2:0] bits in TXRAM to 000 Note: Any attempts to perform these actions during a NOBRK transfer will produce unpredictable results. 0 DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or TGs. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer. 1 NOBRKx ensures that ICOUNTx + 1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx + 1 transfers have been processed. For example, this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD = 1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. Note: Triggering of higher priority TGs or enabling of higher priority DMA channels will not interrupt a NOBRK block transfer.
12-8	ICOUNTx	0-1Fh	Initial count of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfers equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer. If ONESHOTx and NOBRKx are not set, ICOUNTx should be 0. Note: See Section 10.1.4.9.37 (ICOUNT) and Section 10.1.4.9.38 (DMACNTLEN) about how to increase the ICOUNT to a 16-bit value. With this extended capability, MibSPI can transfer a block of up to 65535 (65K) words without interleaving (if NOBRK is used) or without deasserting the chip select between the buffers (if CSHOLD is used).
7	Reserved	0	Reads return 0. Writes have no effect.
6	COUNT_BIT17x		The 17th bit of the COUNT field of DMAxCOUNT register.

Table 10-199. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
5-0	COUNTx	0-3Fh	Actual number of remaining DMA transfers. This field contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Note: If the TX and RX DMA requests are enabled, the COUNT register will be decremented when the RX has been serviced.

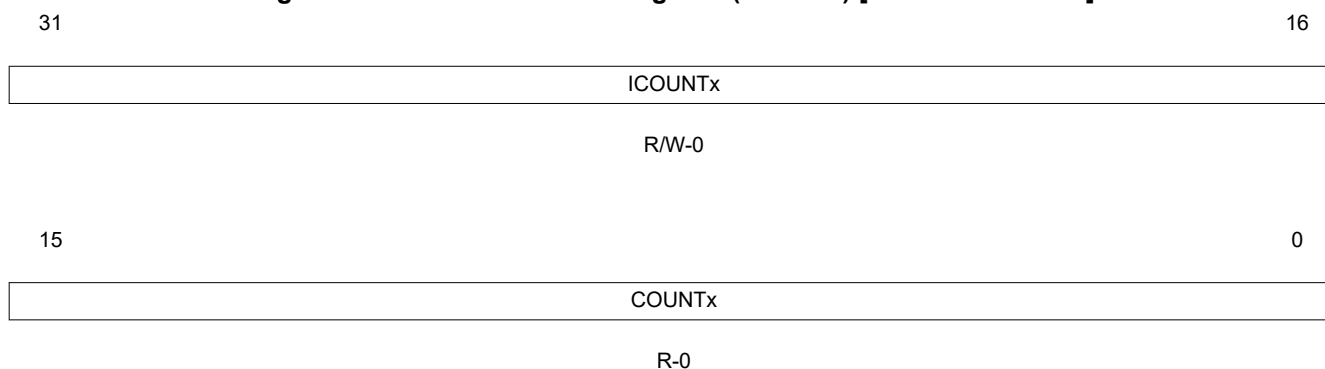

10.1.4.9.37 DMAxCOUNT Register (ICOUNT)

Note

These registers are used only if the LARGE COUNT bit in the DMACNTLEN register is set.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA registers varies by device.

Figure 10-226. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h]

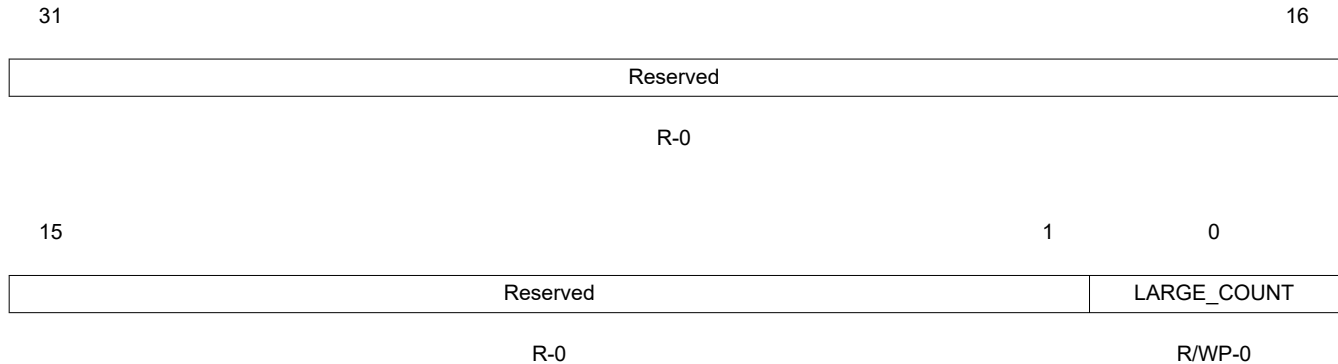

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-200. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions

Bit	Field	Value	Description
31-16	ICOUNTx	0-FFFFh	Initial number of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the corresponding DMA channel. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer.
15-0	COUNTx	0-FFFFh	Actual number of remaining DMA transfers. COUNTx Contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Since the real counter value is always ICOUNTx +1, the 17th bit of COUNTx is available on DMAXCTRLx[6] bit. Note: Usage Tip for Block Transfer Using a Single DMA Request. It is possible to use the multi-buffer RAM to transfer chunks of data to/from an external SPI. A DMA Controller can be used to handle the data in bursts. Suppose a chunk of 64 bytes of data needs to be transferred and a single DMA request needs to be generated at the end of transferring the 64 bytes. This can be easily achieved by configuring a TG register for the 64 buffer locations and using the DMAXCTRL/DMAXCOUNT registers to configure the last buffer (64th) of the TG as the BUFID and enable RXDMA (NOBRK = 0). At the end of the transfer of the 64th buffer, a DMA request will be generated on the selected DMA request channel. The DMA controller can do a burst read of all 64 bytes from RXRAM and/or then do a burst write to all 64 bytes to the TXRAM for the next chunk.

10.1.4.9.38 DMA Large Count (DMACNTLEN)

Figure 10-227. DMA Large Count Register (DMACNTLEN) [offset = 118h]

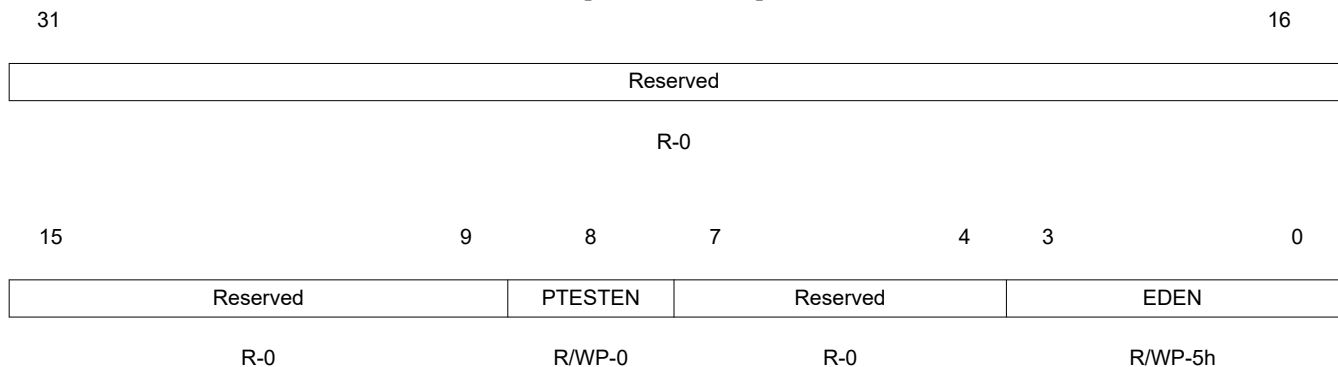

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-201. MibSPI DMA Large Count Register (DMACNTLEN) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	LARGE_COUNT	0	Select either the 16-bit DMAxCOUNT counters or the smaller counters in DMAxCTRL. Select the DMAxCTRL counters. Writes to the DMAxCTRL register will modify the ICOUNT value. Reading ICOUNT and COUNT can be done from the DMAxCTRL register. The DMAxCOUNT register should not be used since any write to this register will be overwritten by a subsequent write to the DMAxCTRL register to set the TXDMAENA or RXDMAENA bits.
		1	Select the DMAxCOUNT counters. Writes to the DMAxCTRL register will not modify the ICOUNT value. The ICOUNT value must be written to in the DMAxCOUNT register before the RXDMAENA or TXDMAENA bits are set in the DMAxCTRL register. The DMAxCOUNT register should be used for reading COUNT or ICOUNT.

10.1.4.9.39 Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL)

Figure 10-228. Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL) [offset = 120h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-202. Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL) Field Descriptions

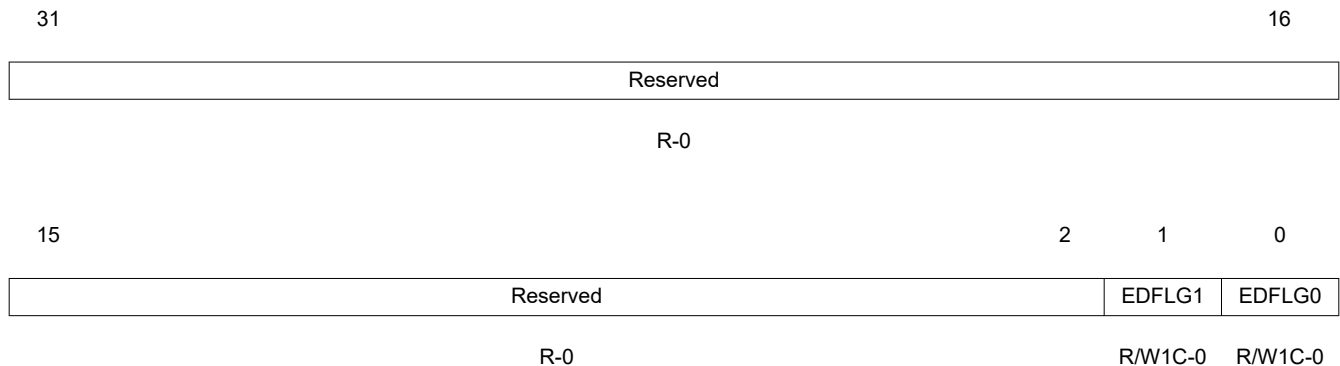

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.

**Table 10-202. Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL)
Field Descriptions (continued)**

Bit	Field	Value	Description
8	PTESTEN	0 1	Parity memory test enable. This bit maps the parity bits corresponding to multi-buffer RAM locations into the peripheral RAM frame to make them accessible by the CPU. See Section 10.1.4.11 for further details about parity memory testing. Parity bits are not memory-mapped. Parity bits are memory-mapped.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	EDEN	5h All Other Values	Error detection enable. These bits enable parity error detection. Parity error detection logic (default) is disabled. Parity error detection logic is enabled. Note: It is recommended to write a 1010 to enable error detection, to guard against a soft error from disabling parity error detect

10.1.4.9.40 Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT)

**Figure 10-229. Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT)
[offset = 124h]**

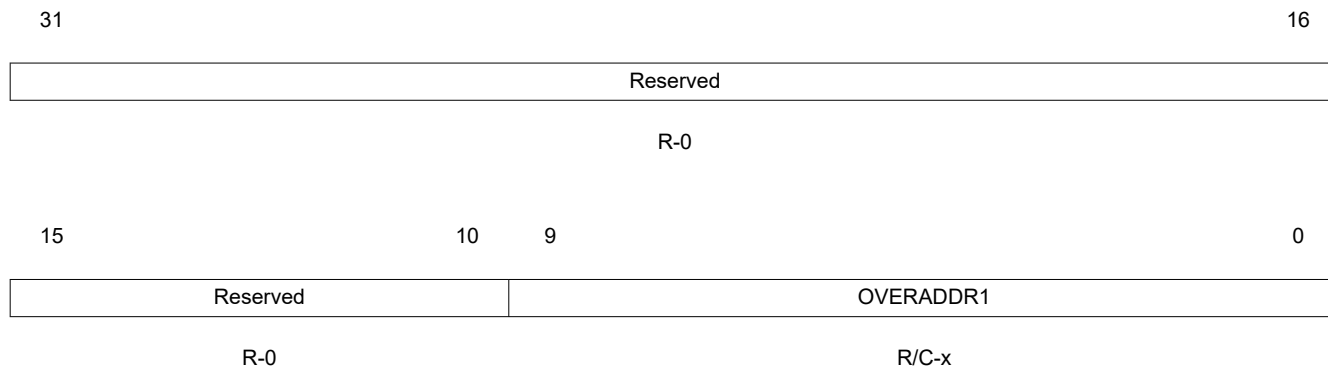

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

**Table 10-203. Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT)
Field Descriptions**

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	EDFLG1	0	Uncorrectable parity error detection flag. This flag indicates if a parity error occurred in the RXRAM. Note: Reading the UERRADDR1 register clears the EDFLG1 bit. Read: No error has occurred. Write: Writing a 0 to this bit has no effect.
		1	Read: An error was detected and the address is captured in the UERRADDR1 register. Write: The bit is cleared to 0.
0	EDFLG0	0	Uncorrectable parity error detection flag. This flag indicates if a parity error occurred in the TXRAM. Note: Reading the UERRADDR0 register clears the EDFLG0 bit. Read: No error has occurred. Write: Writing a 0 to this bit has no effect.
		1	Read: An error was detected and the address is captured in the UERRADDR0 register. Write: The bit is cleared to 0.

10.1.4.9.41 RXRAM Uncorrectable Parity Error Address Register (UERRADDR1)

Figure 10-230. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) [offset = 128h]

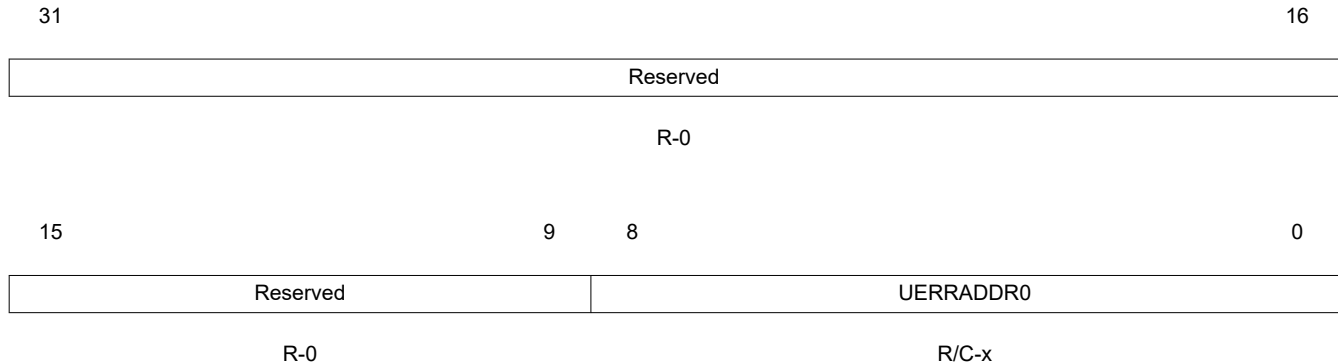

LEGEND: R = Read only; C = Clear; -n = value after reset

Table 10-204. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	OVERADDR1	200h-3FFh	<p>Uncorrectable parity error address for RXRAM. This register holds the address where a parity error is generated while reading RXRAM. Only the CPU or DMA can read from RXRAM locations. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of RXRAM varies from 200h-3FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset or even power-on reset.</p> <p>A read operation to this register clears its contents to the default value 200h. After a power-on reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value, if required. However, the contents of this register are meaningful only when EDFLG1 is set to 1.</p> <p>Note: A read of the UERRADDR1 register will clear EDFLG1 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR1 register does not clear EDFLG1.</p>

10.1.4.9.42 TXRAM Uncorrectable Parity Error Address Register (UERRADDR0)

Figure 10-231. TXRAM Uncorrectable Parity Error Address Register (UERRADDR0) [offset = 12Ch]

LEGEND: R = Read only; C = Clear; -n = value after reset

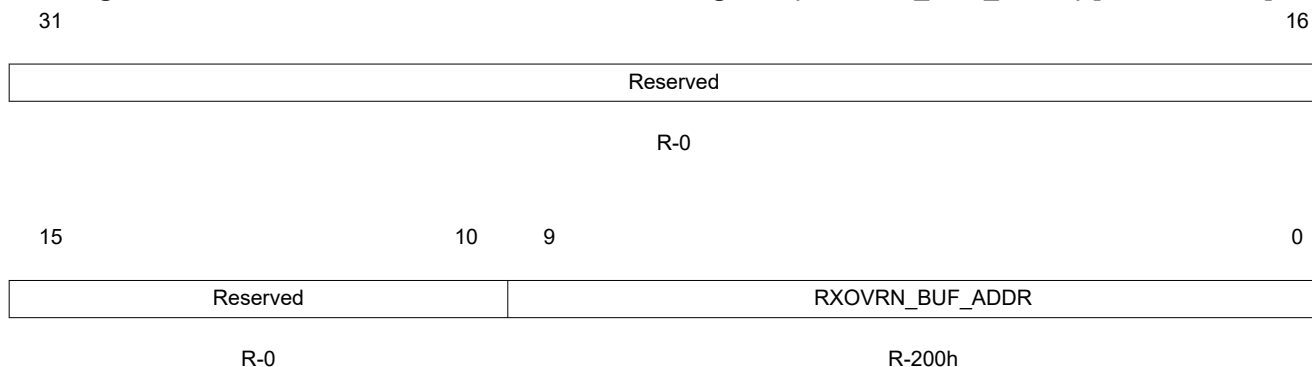

Table 10-205. TXRAM Uncorrectable Parity Error Address Register (UERRADDR0) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.
8-0	UERRADDR0	0-1FFh	<p>Uncorrectable parity error address for TXRAM. This register holds the address where a parity error is generated while reading from TXRAM. The TXRAM can be read either by CPU or by the MibSPI sequencer logic for transmission. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of TXRAM varies from 0-1FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset, or even power-on reset.</p> <p>A read operation to this register clears its contents to all 0s. After a power-on reset, the contents of this register will be unpredictable. A read operation can be performed after power-up to clear the this register's contents, if required. However, the contents of this register are meaningful only when EDFLG0 is set to 1.</p> <p>Note: A read from the UERRADDR0 register will clear EDFLG0 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR0 register does not clear EDFLG0.</p>

10.1.4.9.43 RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR)

In multi-buffer mode, if a particular RXRAM location is written by the MibSPI sequencer logic after the completion of a new transfer when that location already contains valid data, the RX_OVR bit will be set to 1 while the data is being written. The RXOVRN_BUF_ADDR register captures the address of the RXRAM location for which a receiver overrun condition occurred.

Figure 10-232. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) [offset = 130h]

LEGEND: R = Read only; -n = value after reset

Table 10-206. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	RXOVRN_BUF_ADDR	200h-3FCh	Address in RXRAM at which an overwrite occurred. This address value will show only the offset address of the RAM location in the multi-buffer RAM address space. Refer to the device-specific data sheet for the actual absolute address of RXRAM. This word-aligned address can vary from 200h-3FCh. Contents of this register are valid only when any of the INTVECT0 or INTVECT1 and SPIFLG registers show an RXOVRN error vector while in multi-buffer mode. If there are multiple overrun errors, then this register holds the address of first overrun address until it is read. Note: Reading this register clears the RXOVRN interrupt flag in the SPIFLG register and the TGINTVECTx. Note: Receiver overrun errors in multi-buffer mode can be completely avoided by using the SUSPEND until RXEMPTY feature, which can be programmed into each buffer of any TG. However, using the SUSPEND until RXEMPTY feature will make the sequencer wait until the current RXRAM location is read by the VBUS master before it can start the transfer for the same buffer location again. This may affect the overall throughput of the SPI transfer. By enabling the interrupt on RXOVRN in multi-buffer mode, the user can rely on interrupts to know if a receiver overrun has occurred. The address of the overrun in RXRAM is indicated in this RXOVRN_BUF_ADDR register.

10.1.4.9.44 I/O-Loopback Test Control Register (IOLPBKTSTCR)

This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog. In addition, it contains control bits to induce error conditions into the module. These are to be used only for module testing.

All of the control/status bits in this register are valid only when the IOLPBKTSTENA field is set to Ah.

Figure 10-233. I/O-Loopback Test Control Register (IOLPBKTSTCR) [offset = 134h]

Table 10-207. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SCS FAIL FLG	0	Bit indicating a failure on $\overline{\text{SPICS}}$ pin compare during analog loopback. Read: No mismatches occurred on any of the eight chip select pins (vs. the internal chip select number CSNR during transfers). Write: Writing a 0 to this bit has no effect.
		1	Read: A comparison between the internal CSNR field and the analog looped-back value of one or more of the $\overline{\text{SPICS}}$ pins failed. A stuck-at fault is detected on one of the $\overline{\text{SPICS}}$ pins. Comparison is done only on the pins that are configured as functional and during transfer operation. Write: This flag bit is cleared.
23-21	Reserved	0	Reads return 0. Writes have no effect.
20	CTRL BITERR	0	Controls inducing of BITERR during I/O loopback test mode. Do not interfere with looped-back data.
		1	Induces bit errors by inverting the value of the incoming data during loopback.

Table 10-207. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions (continued)

Bit	Field	Value	Description
19	CTRL DESYNC	0	Controls inducing of the desync error during I/O loopback test mode. Do not cause a desync error.
		1	Induce a desync error by forcing the incoming $\overline{\text{SPIEN}}\overline{\text{A}}$ pin (if functional) to remain 0 even after the transfer is complete. This forcing will be retained until the kernel reaches the idle state.
18	CTRL PARERR	0	Controls inducing of the parity errors during I/O loopback test mode. Do not cause a parity error.
		1	Induce a parity error by inverting the polarity of the parity bit.
17	CTRL TIMEOUT	0	Controls inducing of the timeout error during I/O loopback test mode. Do not cause a timeout error.
		1	Induce a timeout error by forcing the incoming $\overline{\text{SPIEN}}\overline{\text{A}}$ pin (if functional) to remain 1 when transmission is initiated. The forcing will be retained until the kernel reaches the idle state.
16	CTRL DLENERR	0	Controls inducing of the data length error during I/O loopback test mode. Do not cause a data-length error.
		1	Induce a data-length error. <i>Master mode:</i> The $\overline{\text{SPIEN}}\overline{\text{A}}$ pin (if functional) is forced to 1 when the module starts shifting data. <i>Slave mode:</i> The incoming $\overline{\text{SPICS}}$ pin (if functional) is forced to 1 when the module starts shifting data.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IOLPBKSTENA	Ah	Module I/O loopback test enable key. Enable I/O loopback test mode.
		All Other Values	Disable I/O loopback test mode.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5-3	ERR SCS PIN	0	Inject error on chip-select pin number x. The value in this field is decoded as the number of the chip select pin on which to inject an error. During analog loopback, if CTRL SCS PIN ERR bit is set to 1, then the chip select pin selected by this field is forced to the opposite of its value in the CSNR. Select $\overline{\text{SPICS}}[0]$ for injecting error.
		1h	Select $\overline{\text{SPICS}}[1]$ for injecting error.
		:	:
		7h	Select $\overline{\text{SPICS}}[7]$ for injecting error.
2	CTRL SCS PIN ERR	0	Enable/disable the injection of an error on the $\overline{\text{SPICS}}$ pins. The individual $\overline{\text{SPICS}}$ pins can be chosen using the ERR SCS PIN field. Disable the $\overline{\text{SPICS}}$ error-inducing logic.
		1	Enable the $\overline{\text{SPICS}}$ error-inducing logic.
1	LPBK TYPE	0	Module I/O loopback type (analog/digital). See Figure 10-182 for the different types of loopback modes. Enable Digital loopback when IOLPBKTSTENA = 1010.
		1	Enable Analog loopback when IOLPBKTSTENA = 1010.
0	RXPENA	0	Enable analog loopback through the receive pin. Note: This bit is valid only when LPBK TYPE = 1, which chooses analog loopback mode. Analog loopback is through the transmit pin.
		1	Analog loopback is through the receive pin.

10.1.4.9.45 SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1[7:0] of EXTENDED_PRESCALE1 and PRESCALE1 of SPIFMT1 register will always reflect the same contents. Similarly, EPRESCALE_FMT0[7:0] and PRESCALE0 of SPIFMT0 reflect the same contents.

Figure 10-234. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) [offset = 138h]

31		27	26		16
Reserved			EPRESCALE_FMT1		
R-0			R/WP-0		
15		11	10		0
Reserved			EPRESCALE_FMT0		
R-0			R/WP-0		

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 10-208. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	EPRESCALE_FMT1	0-7FFh	<p>EPRESCALE_FMT1. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 determines the bit transfer rate of data format 1 if the SPI/MibSPI is the network master. EPRESCALE_FMT1 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT1 does not need to be configured. These EPRESCALE_FMT1[7:0] bits and PRESCALE1 bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format1} = VCLK / (EPRESCALE_FMT1 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE1 bits of SPIFMT1 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE1[26:16] or SPIFMT1[15:8] register.</p> <p>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE1 field of SPIFMT1 will automatically clear EPRESCALE_FMT1[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</p>
15-11	Reserved	0	Reads return 0. Writes have no effect.

**Table 10-208. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions
(continued)**

Bit	Field	Value	Description
10-0	EPRESCALE_FMT0	0-7FFh	<p>EPRESCALE_FMT0. Extended Prescale value for SPIFMT0. EPRESCALE_FMT0 determines the bit transfer rate of data format 0 if the SPI/MibSPI is the network master. EPRESCALE_FMT0 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT0 does not need to be configured. These EPRESCALE_FMT0[7:0] bits and PRESCALE0 bits of SPIFMT0 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{\text{Format0}} = VCLK / (EPRESCALE_FMT0 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE0 bits of SPIFMT0 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE0[10:0] or SPIFMT0[15:8] register.</p> <p>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE0 field of SPIFMT0 will automatically clear EPRESCALE_FMT0[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</p>

10.1.4.9.46 SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT3[7:0] of EXTENDED_PRESCALE2 and PRESCALE3 of SPIFMT3 register will always reflect the same contents. Similarly, EPRESCALE_FMT2[7:0] and PRESCALE2 of SPIFMT2 reflect the same contents.

Table 10-209. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	EPRESCALE_FMT3	0-7FFh	<p>EPRESCALE_FMT3. Extended Prescale value for SPIFMT3. EPRESCALE_FMT3 determines the bit transfer rate of data format 3 if the SPI/MibSPI is the network master. EPRESCALE_FMT3 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT3 does not need to be configured. These EPRESCALE_FMT3[7:0] bits and PRESCALE3 bits of SPIFMT3 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format3} = VCLK / (EPRESCALE_FMT3 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE3 bits of SPIFMT3 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE3[26:16] or SPIFMT3[15:8] register.</p> <p>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE3 field of SPIFMT3 will automatically clear EPRESCALE_FMT3[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</p>
15-11	Reserved	0	Reads return 0. Writes have no effect.

**Table 10-209. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2) Field Descriptions
(continued)**

Bit	Field	Value	Description
10-0	EPRESCALE_FMT2	0-7FFh	<p>EPRESCALE_FMT2. Extended Prescale value for SPIFMT2. EPRESCALE_FMT2 determines the bit transfer rate of data format 2 if the SPI/MibSPI is the network master. EPRESCALE_FMT2 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT2 does not need to be configured. These EPRESCALE_FMT2[7:0] bits and PRESCALE2 bits of SPIFMT2 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{\text{Format2}} = VCLK / (EPRESCALE_FMT2 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE2 bits of SPIFMT2 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE2[10:0] or SPIFMT2[15:8] register.</p> <p>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE2 field of SPIFMT2 will automatically clear EPRESCALE_FMT2[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</p>

10.1.4.10 Multi-Buffer RAM

The multi-buffer RAM is used for holding transmit and received data, control and status information. The multi-buffer RAM contains two banks of up to 128 32-bit words for a maximum configuration. One bank (TXRAM) contains entries for transmit data (replicating the SPIDAT1 register). The other bank (RXRAM) contains received data (replicating the SPIBUF register). The buffers can be partitioned into multiple TGs, each containing a programmable number of buffers. Each of the buffers can be subdivided into 16-bit transmit field, 16-bit receive field, 16-bit control field, and 16-bit status field, as displayed in Figure 10-236. A 4-bit parity field per word is also included in each bank of RAM.

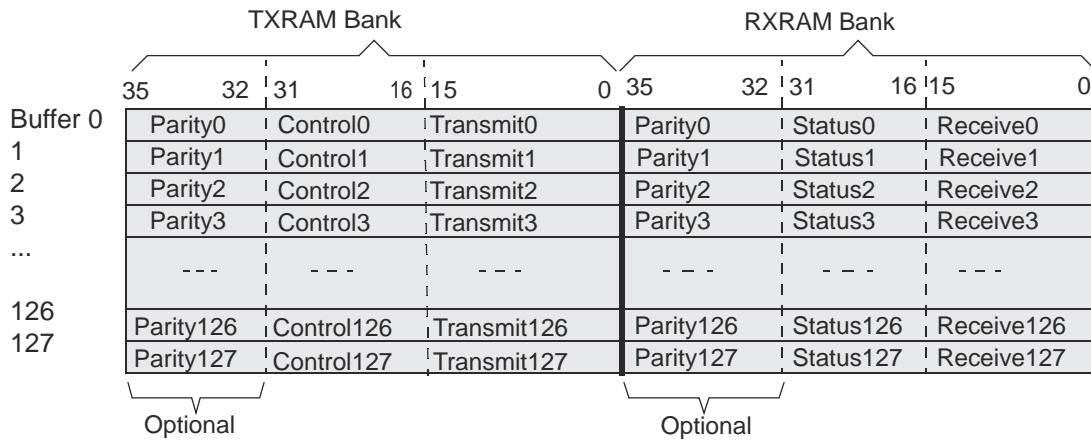

Figure 10-236. Multi-Buffer RAM Configuration

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number (CSNR) bit field of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

Note

Please refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2st buffer and so on.

10.1.4.10.1 Multi-Buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be 0 (Multi-buffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialization after reset, the auto-initialization sequence can also be done by:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the *Architecture* chapter for more details on the memory auto-initialization process.

Note

During Auto Initialization process, all the Multi-buffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the Multi-buffer mode registers.

10.1.4.10.2 Multi-Buffer RAM Register Summary

This section describes the multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. The base address for multi-buffer RAM is FF0E 0000h for MibSPI1 RAM, FF0C 000h for MibSPI3 RAM, and FF0A 0000h for MibSPI5 RAM.

Table 10-210. Multi-Buffer RAM Register Summary

Offset	Acronym	Register Description	Section
Base + 0h-1FFh	TXRAM	Multi-Buffer RAM Transmit Data Register	Section 10.1.4.10.3
Base + 200h-3FFh	RXRAM	Multi-Buffer RAM Receive Buffer Register	Section 10.1.4.10.4

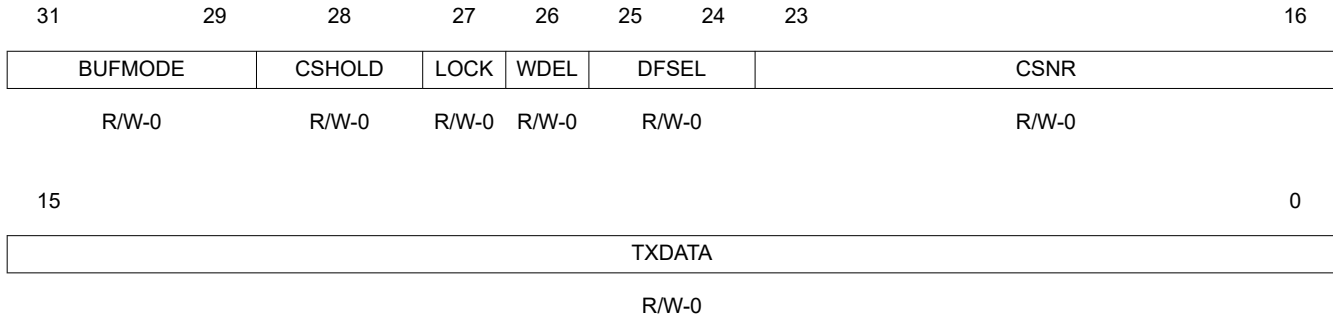

10.1.4.10.3 Multi-Buffer RAM Transmit Data Register (TXRAM)

Each word of TXRAM is a transmit-buffer register.

Note

Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Figure 10-237. Multi-Buffer RAM Transmit Data Register (TXRAM)
[offset = RAM Base + 0h-1FFh]

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-211. Multi-Buffer RAM Transmit Data Register (TXRAM) Field Descriptions

Bit	Field	Value	Description
31-29	BUFMODE		Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word. When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer. When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TXFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes.
		0	disabled. The buffer is disabled.
		1h	skip single-transfer mode. Skip this buffer until the corresponding TXFULL flag is set (new transmit data is available).
		2h	skip overwrite-protect mode. Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).
		3h	skip single-transfer overwrite-protect mode. Skip this buffer until both of the corresponding TXFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).
		4h	continuous mode. Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.
		5h	suspend single-transfer mode. Suspend-to-wait until the corresponding TXFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).
		6h	suspend overwrite-protect mode. Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host).
		7h	suspend single-transfer overwrite-protect mode. Suspend-to-wait until the corresponding TXFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).

Table 10-211. Multi-Buffer RAM Transmit Data Register (TXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
28	CSHOLD	0 1	<p>Chip select hold mode. The CSHOLD bit is supported in master mode only, it is ignored in slave mode. CSHOLD defines the behavior of the chip select line at the end of a data transfer.</p> <p>0 The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.</p> <p>1 The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.</p>
27	LOCK	0 1	<p>Lock two consecutive buffer words. Do not allow interruption by TGs with higher priority.</p> <p>0 Any higher-priority TG can begin at the end of the current transaction.</p> <p>1 A higher-priority TG cannot occur until after the next unlocked buffer word is transferred.</p>
26	WDEL	0 1	<p>Enable the delay counter at the end of the current transaction.</p> <p>Note: The WDEL bit is supported in master mode only. In slave mode, this bit is ignored.</p> <p>0 No delay will be inserted. However, $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.</p> <p>Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated also depends upon the time taken to supply a new word after completing the shift operation (in compatibility mode). If TXBUF is already full, then the $\overline{\text{SPICS}}$ pin will be deasserted for at least two VCLK cycles (if WDEL = 0).</p> <p>1 After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPICS pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.</p>
25-24	DFSEL	0 1h 2h 3h	<p>Data word format select.</p> <p>0 Data word format 0 is selected.</p> <p>1h Data word format 1 is selected.</p> <p>2h Data word format 2 is selected.</p> <p>3h Data word format 3 is selected.</p>
23-16	CSNR	0-FFh	<p>Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 10-212.</p> <p>Note: If your MiBSPi has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPi3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.</p>
15-0	TXDATA	0-7FFFh	<p>Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.</p> <p>SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of TXDATA to 0.</p> <p>A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the SPICS pins, if the pins are configured as functional pins (automatic chip select, see Section 10.1.4.2).</p> <p>When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.</p> <p>Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.</p>

Table 10-212. Chip Select Number Active

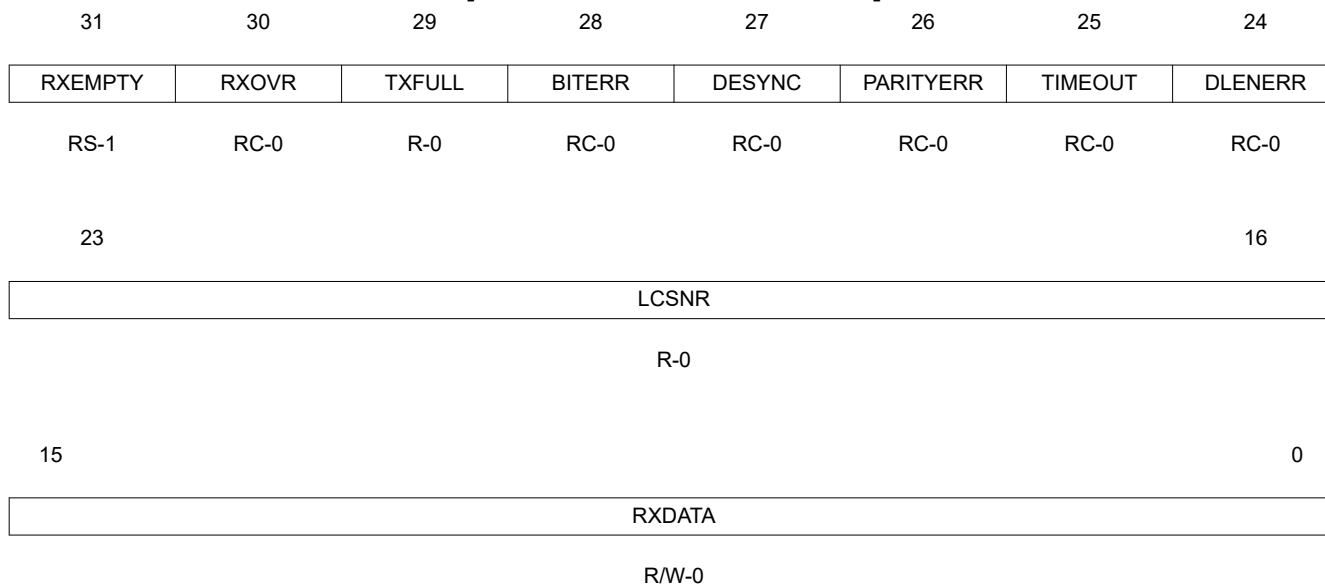

CSNR Value	Chip Select Active:						CSNR Value	Chip Select Active:					
	CS[5] ⁽¹⁾	CS[4] ⁽¹⁾	CS[3] ⁽¹⁾	CS[2] ⁽¹⁾	CS[1] ⁽¹⁾	CS[0]		CS[5] ⁽¹⁾	CS[4] ⁽¹⁾	CS[3] ⁽¹⁾	CS[2] ⁽¹⁾	CS[1] ⁽¹⁾	CS[0]

1Fh		x	x	x	x	x	3Fh	x	x	x	x	x	x

(1) If your MibSPI does not have this chip select pin, this bit is 0.

10.1.4.10.4 Multi-Buffer RAM Receive Buffer Register (RXRAM)

Each word of RXRAM is a receive-buffer register.

Figure 10-238. Multi-Buffer RAM Receive Buffer Register (RXRAM)
[offset = RAM Base + 200h-3FFh]

LEGEND: R/W = Read/Write; R = Read only; C = Clear; S = Set; -n = value after reset

Table 10-213. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY	0 1	<p>Receive data buffer empty. When the host reads the RXDATA field or the entire RXRAM register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA, and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into RXDATA.</p> <p>No data has been received since the last read of RXDATA.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> Reading the RXDATA field of the RXRAM register Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG) <p>Write-clearing the RXINTFLG bit before reading RXDATA indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of RXRAM (or the entire register).</p>
30	RXOVR	0 1	<p>Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to RXRAM; the contents of RXRAM are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVEXTx shows the RXOVRN condition. Two read operations from the RXRAM register are required to reach the overwritten buffer word (one to read RXRAM, which then transfers RXDATA into RXRAM for the second read).</p> <p>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</p> <p>Note: A special condition under which RXOVR flag gets set. If both RXRAM and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</p> <p>0 No receive data overrun condition occurred since last read of the data field.</p> <p>1 A receive data overrun condition occurred since last read of the data field.</p>

Table 10-213. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
29	TXFULL	0	Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag. The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.
28	BITERR	0	Bit error. There was a mismatch of internal transmit data and transmitted data. Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read. No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC	0	Desynchronization of slave device. This bit is valid in master mode only. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{2\text{DELAY}}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master. Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer. Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		1	No slave desynchronization is detected. A slave device is desynchronized.
26	PARITYERR	0	Parity error. The calculated parity differs from the received parity bit. If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set. Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		1	No parity error is detected. A parity error occurred.
25	TIMEOUT	0	Time-out because of non-activation of $\overline{\text{SPIEN}}\text{A}$ pin. The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set. Note: This bit is valid only in master mode. Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		1	No $\overline{\text{SPIEN}}\text{A}$ pin time-out occurred. An $\overline{\text{SPIEN}}\text{A}$ signal time-out occurred.
24	DLENERR	0	Data length error flag. Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read. No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.

Table 10-213. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

10.1.4.11 Parity Memory

The parity portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However, each read or write operation to the control/data/status portion of the multi-buffer RAM causes reads/writes to the parity portion as well.

- Each write to the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a write operation to the parity portion of RAM simultaneously to update the equivalent parity bits.
- Each read operation from the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a read operation from the parity portion of the RAM for parity comparison purpose.
- Reads/Writes to multi-buffer RAM can either be caused by any CPU/DMA accesses or by the sequencer logic of MibSPI itself.
- In case of Parity error ESM module is notified to generate MIBSPI Parity ESM interrupt. User can check the error status and address location captured in the UERRSTAT and UERRADDRx registers respectively.

For testing the parity portion of the multi-buffer RAM, which is a 4-bit field per word address (1 bit per byte), a separate parity memory test mode is available. Parity memory test mode can be enabled and disabled by the PTESTEN bit in the UERRCTRL register.

During the parity test mode, the parity locations are addressable at the address between RAM_BASE_ADDR + 0x400h and RAM_BASE_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See [Figure 10-239](#) for a diagram of the memory map of parity memory during normal operating mode and during parity test mode.

During parity test mode, after writing the data/control portion of the RAM, the parity locations can be written with incorrect parity bits to intentionally cause parity errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

Note

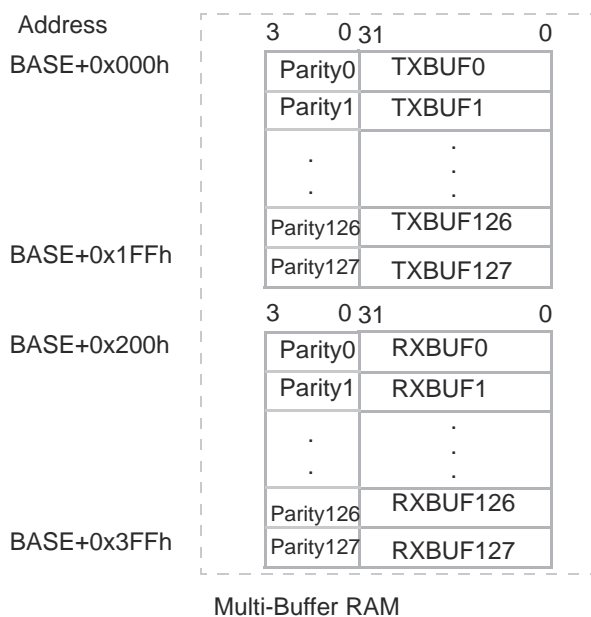

The RX_RAM_ACCESS bit can also be set to 1 during the parity test mode to be enable writes to RXRAM locations. Both parity RAM testing and RXRAM testing can be done together.

There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in [Figure 10-240](#) for further details.

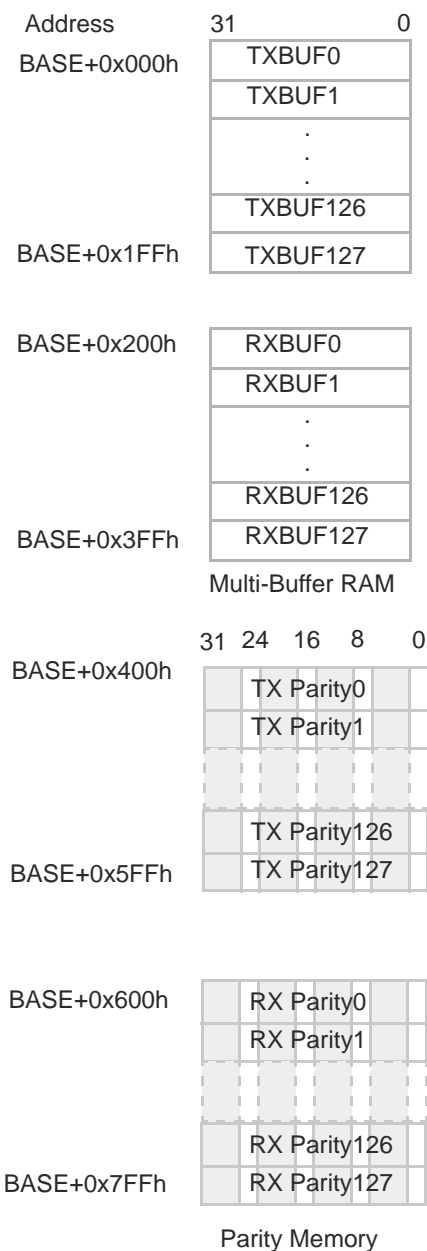

Note

Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

Memory Map During Normal Operation
(Parity locations are not accessible by CPU)

Memory Map During Parity Test Mode
(Parity locations are accessible by CPU)

* BASE - Base Address of Multi-Buffer RAM
Refer to specific Device Data sheet for the actual value of BASE.

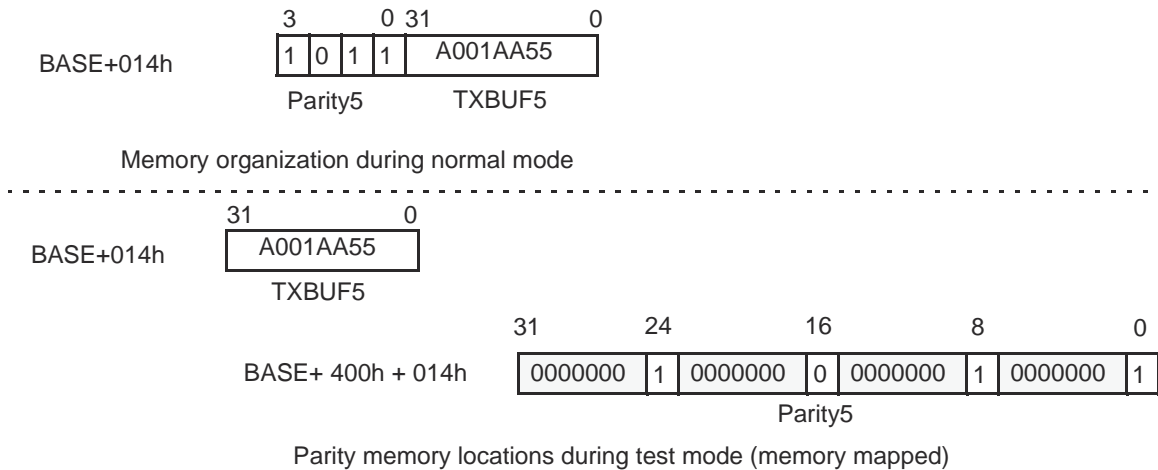

* Shaded areas indicate they are physically not present.

Figure 10-239. Memory Map for Parity Locations During Normal and Test Mode

10.1.4.11.1 Example of Parity Memory Organization

Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See [Figure 10-240](#) for a diagram.

1 Shaded areas indicate reads return 0, writes have no effect. These registers are not physically present.

Figure 10-240. Example of Memory-Mapped Parity Locations During Test Mode

Note

Read Access to Parity Memory Locations

Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.

10.1.4.12 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase and Polarity affect the pin timings.

The pin directions are based on the mode of operation.

Master mode SPI:

- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPICS}}$ (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIENA}}$ (SPI slave ready Enable) - Input

Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPICS}}$ - Input
- SPISOMI - Output
- $\overline{\text{SPIENA}}$ - Output

Note

All the timing diagrams given below are with Phase = 0 and Polarity = 0, unless explicitly stated otherwise.

10.1.4.12.1 Master Mode Timings for SPI/MibSPI

Figure 10-247. SPI/MibSPI Pins During Slave Mode in 5-pin Configuration - (Single Slave)

Figure 10-248. SPI/MibSPI Pins During Slave Mode in 5-pin Configuration - (Single/Multi Slave)

10.1.4.12.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO with respect to its internal SPICLK. In case of Master mode, the RX data on the SPISOMI pin is registered with respect to SPICLK received through the input buffer from the I/O pad.

If the chip select pin is functional, then the Master will drive out the $\overline{\text{SPICS}}$ pins before starting the SPICLK. If the $\overline{\text{SPIEN A}}$ pin is functional, then the Master will wait for an active low from the Slave on the input pin to start the SPICLK.

10.1.4.12.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only the SPISOMI and $\overline{\text{SPIEN A}}$ pins. All other pins are inputs to it. The RX data on the SPISIMO pin will be registered with respect to the SPICLK pin. The Slave will use the $\overline{\text{SPICS}}$ pin to drive out the $\overline{\text{SPIEN A}}$ pin if both are functional. If 4-pin with $\overline{\text{SPIEN A}}$ is configured, then the Slave will drive out an active-low signal on the $\overline{\text{SPIEN A}}$ pin when new data is written to the TX Shift Register. Irrespective of 4-pin with $\overline{\text{SPIEN A}}$ or 5-pin configuration, the Slave will deassert the $\overline{\text{SPIEN A}}$ pin after the last bit is received. If ENABLE_HIGHZ (SPIINT0.24) bit is 0, the de-asserted value of the $\overline{\text{SPIEN A}}$ pin will be 1. Otherwise, it will depend upon the internal pull up or pull down resistor (if implemented) depending upon the Specification of the Chip.

10.1.5 GPADC

10.1.5.1 GPADC Overview

The TPR1x device implements a GPADC module on MasterSS for safety monitoring the inputs, such as the temp sensor, voltage regulators, and so forth; both external and internal to the device. Features supported by the ADC module include:

- 10-bit ENOB 625Ksps ADC
- Full-scale range of GPADC input between 0 V and 1.8 V
- 8 external I/Os and internal components -temperature sensor, supplies, bias reference, LDO output mapped to GPADC input
- Total capacitance, including parasitic and sampling cap, for each of GPADC pins be less than 14pf
- Single or continuous conversion modes
- Event pin and software command mechanism to trigger the conversion
 - Event signal from either of the GPIO (provides options with pinmuxing) as well as from RTI timer module
- Data RAM to store the conversion results (1K results)
- Storage of min, max, and sum of the samples captured per channel
- Mechanism to skip initial M samples and program the number of samples N to be collected every channel
- Instruction PARAMs RAM to program the channels is monitored
- Mechanism to execute the instruction PARAMs in a circular manner without any CPU intervention
- DMA trigger when conversion is completed or data RAM threshold is achieved
- Self-test logic support for input channel failure detection (open / short to power / short to ground)
- Calibration logic using BGAP, for offset error correction
- Separate operating supply and ground pins on package
- Capability to have an external reference voltage for GPADC

10.1.5.2 Functional Description Modes of Operation

10.1.5.2.1 IFM Mode (Inter Frame Monitoring Mode)

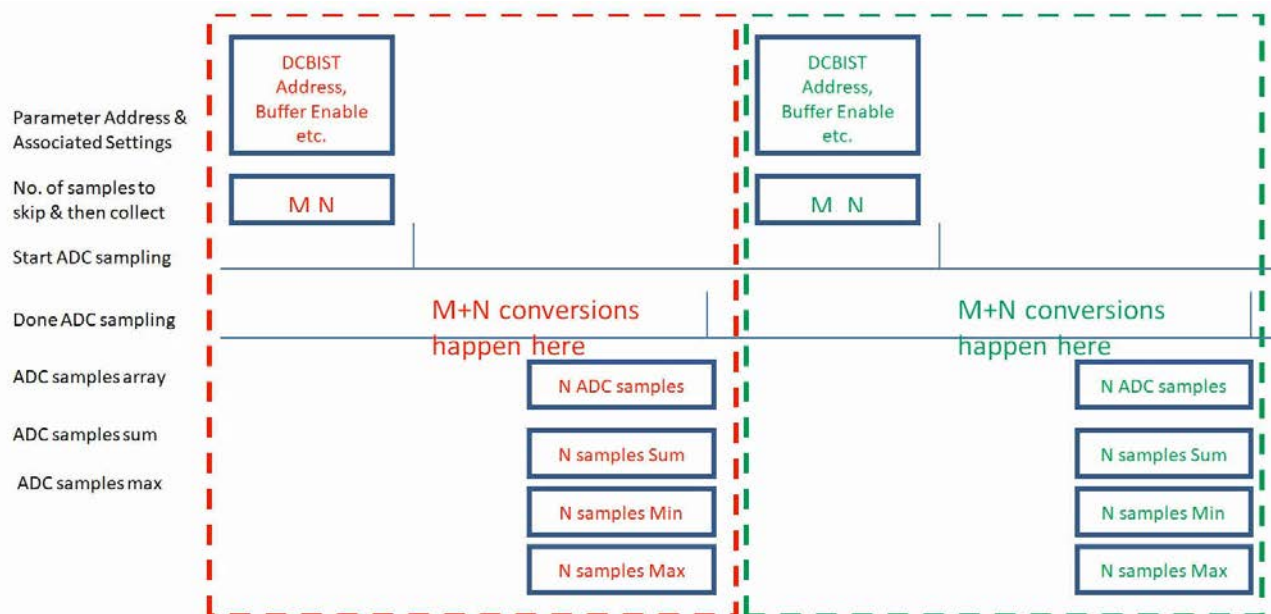

Figure 10-249. IFM Mode

Firmware writes the following register bit fields:

- Param_val_ifm
- Config_value_ifm
- Skip_samples_ifm(M)
- Collect_samples_ifm(N)
- Config settings in Analog
- ADC Reset =0
- ADC Enable =1
- ADC Start =1
- Firmware issues GPADC Trigger (self clearing bit)

Hardware skips M samples, collects N samples. Hardware outputs the sum, min, max of those samples in a register. Hardware outputs the actual array of samples in Data RAM (debug, if enabled). Each entry in the data RAM (256 deep) contains 4 ADC data samples, i.e. 1K ADC samples can be stored in the data RAM. Hardware issues a done interrupt.

10.1.5.2.2 CTM Mode (Continuous Time Monitoring Mode)

Before frame, the firmware programs parameters to be measured for all data-profiles in the instruction packet RAM. Firmware writes "Gpadc_init_mem" =1 (self-clearing) to initialize the data RAM to all '0's.

Configure settings in Analog

ADC Reset =0

ADC Enable =1

ADC Start =1

Program the instructions to be performed in instruction packet RAM.

GPADC_CTM_Trigger starts the CTM mode operation and finishes after completing the programmed instructions. At end of the operation, the firmware can read or process min-max-average.

10.1.5.3 Interrupts

The following interrupt is generated by GPADC:

- MSS_GPADC_IFM_DONE

10.1.5.4 GPADC Trigger Sources

10.1.5.4.1 IFM Mode

Writing 1'b1 to MSS_GPADC_REG::REG1:: GPADC_TRIGGER generates a trigger for IFM Mode to start.

10.1.5.4.2 CTM Mode

[Table 10-214](#) shows the 16 trigger sources for CTM Mode.

Table 10-214. CTM Mode Trigger Sources

No.	Trigger Source
0	GPIO_0
1	GPIO_1
2	GPIO_2
3	GPIO_3
4	RSS_CSI2A_EOL_INT
5	RSS_CSI2A_SOF_INT0
6	RSS_CSI2A_SOF_INT1
7	RSS_CSI2A_SOF_INT
8	RSS_CSI2B_SOF_INT
9	HW_Sync_FE1
10	HW_Sync_FE2
11	DSS_RTIA_1
12	DSS_RTIB_1
13	MSS_RTIA_INT1
14	MSS_RTIB_INT1
15	MMR based SW trigger

MSS_CTRL::GPADC_CTRL::GPADC_CTRL_GPADC_TRIGIN_SEL is used for selecting the trigger source for CTM mode.

Writing 1'b1 to MSS_CTRL::GPADC_CTRL::GPADC_CTRL_GPADC_SW_TRIG triggers the 15th trigger in [Table 10-214](#).

10.1.5.5 MSS GPADC Register Specification

10.1.5.5.1 MSS_GPADC_PKT_RAM Registers

Table 10-215 lists the MSS_GPADC_PKT_RAM registers. All register offset addresses not listed in Table 10-215 should be considered as reserved locations and the register contents should not be modified.

10.2 High-speed Serial Interfaces

10.2.1 Ethernet SubSystem (MCU_CPSW0)

This chapter describes the Gigabit Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

10.2.1.1 MCU_CPSW0 Overview.....	3363
10.2.1.2 MCU_CPSW0 Environment.....	3366
10.2.1.3 MCU_CPSW0 Integration.....	3369
10.2.1.4 MCU_CPSW0 Functional Description.....	3371
10.2.1.5 MSS_CPSW Registers.....	3455

10.2.1.1 MCU_CPSW0 Overview

The two-port Gigabit Ethernet MAC (MCU_CPSW0) subsystem provides Ethernet packet communication for the device and is configured in a similar manner as a two-port Ethernet switch. MCU_CPSW0 features the Reduced Gigabit Media Independent Interface (RGMI), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

The device has integrated two-port Gigabit Ethernet Switch subsystem into device MCU domain named MCU_CPSW0.

Figure 10-785 shows the MCU_CPSW0 module overview.

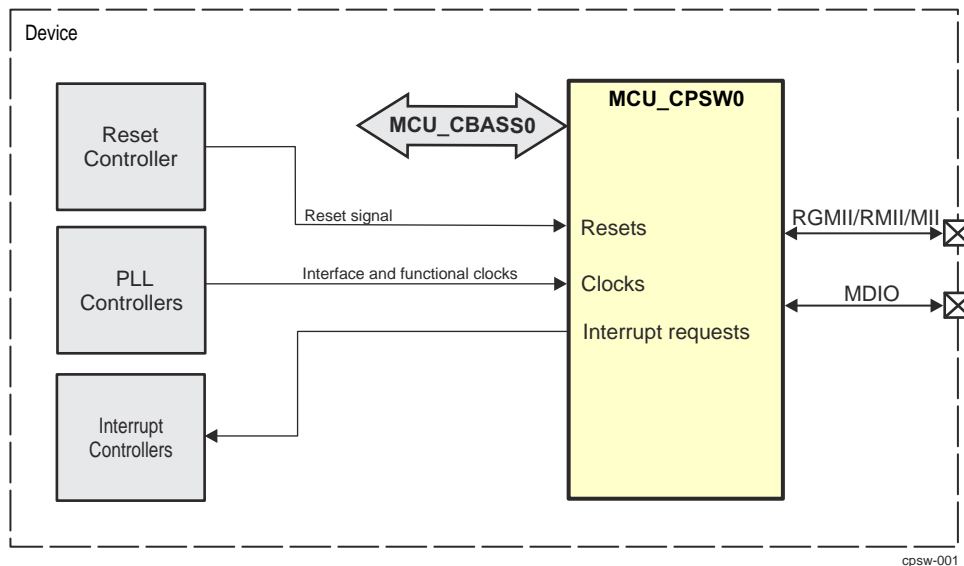

Figure 10-785. MCU_CPSW0 Overview

10.2.1.1.1 MCU_CPSW0 Features

The MCU_CPSW0 subsystem provides the following features:

- One Ethernet port with selectable MII, RMII and RGMII interfaces (port 1).
- One CPDMA CPPI DMA Host Interface (Port 0)
- Synchronous 10/100 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
 - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
 - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control (802.3x) Support
- Non Blocking switch fabric
- Time Sensitive Network Support
 - IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
 - Configurable number of addresses plus VLANs
 - Wire rate lookup
 - Host controlled time-based aging and/or auto-aging

- Spanning tree support
- L2 address lock and L2 filtering support
- MAC authentication (802.1x)
- Receive-based or destination-based Multicast and Broadcast rate limits
- MAC address blocking
- Source port locking
- OUI (Vendor ID) host accept/deny feature
- Configurable number of classifier/policers
- VLAN support
 - 802.1Q compliant
 - Auto add port VLAN for untagged frames on ingress
 - Auto VLAN removal on egress and with pad to minimum frame size
- EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (per port)
- Ethernet or Castagnoli CRC selectable on Ethernet egress
- Digital Loopback supported (Ethernet egress to Ethernet ingress)
- OAM Loopback supported (FIFO Loopback - port ingress to egress including host port)
- CPSGMII Loopback Modes (Ethernet egress to Ethernet ingress)
- Maximum frame size of 2024 bytes (including VLAN)
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Full duplex mode supported in 10/100 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCED)
- InterVLAN Routing is supported - 4 routes per egress port.
- Automotive Security Features
 - VLANs can be configured to not allow fragmented IPv4 frames (that is, fragmented IPv4 traffic)
 - VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6 Next Header values
 - Drop invalid source addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
 - Drop frames that the IEEE802.3 length is not contained within the frame. (Ether Types 0-1500)
 - Any source address can be secured to a port dropping any attempts from other ports to masquerade as a service
 - Any source or destination address can be blocked
 - Per port or per VLAN ingress checking, dropping traffic from non-member ports
 - Classification, policing on L2 and L3 information

10.2.1.1.2 MCU_CPSW0 Not Supported Features

The following MCU_CPSW0 features are not supported:

- Gigabit operation (1000 Mbps) is not supported
- Frames greater than 2024 bytes with VLAN
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet
- Software reset
- Rate-limiting is not supported in half-duplex mode
- Dual VLAN switch operations are not supported
- RGMII Internal Delay Mode disabled.
- Priority based flow control is not supported.
- InterVLAN routed packets will be dropped if the FIFO room is insufficient regardless of receive 803.3x flow control.

10.2.1.1.3 Terminology

Terminology:

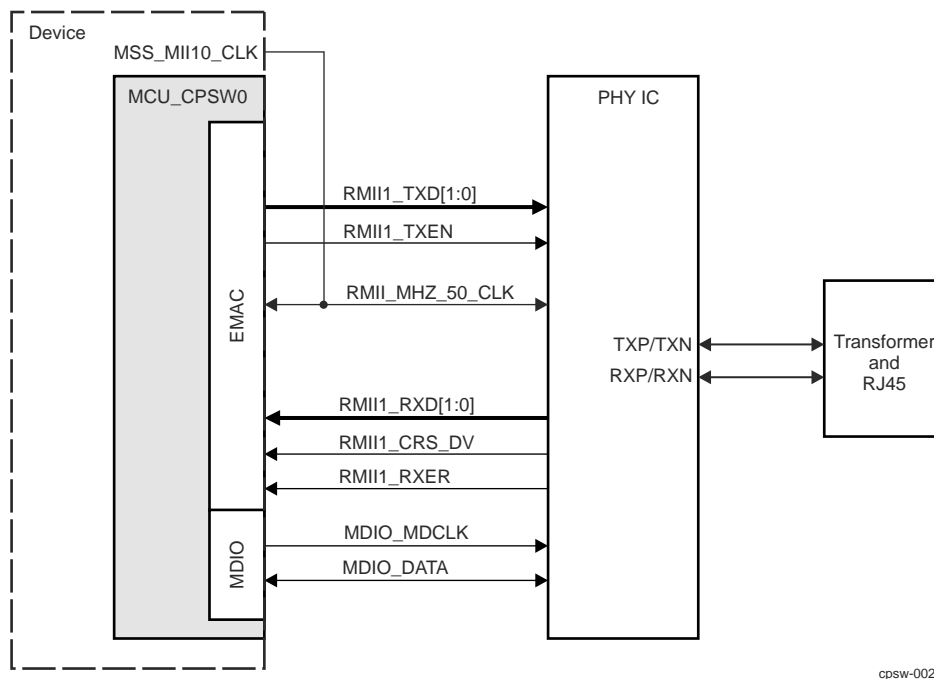

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Transport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
OUI	Organizationally Unique Identifier
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network
CPSW_2G	CPSW two port

10.2.1.2 MCU_CPSW0 Environment

10.2.1.2.1 MCU_CPSW0 RMI Interface

Figure 10-786 shows a device with integrated RMI and MDIO interface connection in a typical system. The individual MCU_CPSW0 and MDIO signals for the RMI interface are summarized in Table 10-752.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

cpsw-002

Figure 10-786. RMI Interface Typical Application

Table 10-752. RMI I/O Description

Signal	Device Pin	I/O ⁽¹⁾	Description
RMI1_TXD[1:0]	MCU_RMI1_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when RMI1_TXEN is asserted.
RMI1_TXEN	MCU_RMI1_TX_EN	O	RMI1 transmit enable. The transmit enable signal indicates that the MCU_RMI1_TXD pins are generating data for use by the PHY. RMI1_TXEN is synchronous to RMI1_MHZ_50_CLK.
RMI1_MHZ_50_CLK	MCU_RMI1_REF_CLK	I	RMI1 50MHz reference clock. The reference clock is used to synchronize all RMI1 signals. RMI1_MHZ_50_CLK must be continuous and fixed at 50 MHz. This bit controls the clock source MSS_CTRL::CPSW_CONTROL::CPSW_CONTROL_RMI1_REF_CLK_OE_N
RMI1_RXD[1:0]	MCU_RMI1_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when RMI1_CRS_DV is asserted and RMI1_RXER is de-asserted.
RMI1_CRS_DV	MCU_RMI1_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMI1_RXER	MCU_RMI1_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	MCU_MDIO_CLK	O	Management data clock (MDIO_MDCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_DATA pin.

Table 10-752. RMII I/O Description (continued)

Signal	Device Pin	I/O ⁽¹⁾	Description
MDIO_DATA	MCU_MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

10.2.1.2.2 MCU_CPSW0 RGMII Interface

Figure 10-787 shows a device with integrated RGMII and MDIO interface connection in a typical system. The individual MCU_CPSW0 and MDIO signals for the RGMII interface are summarized in Table 10-753.

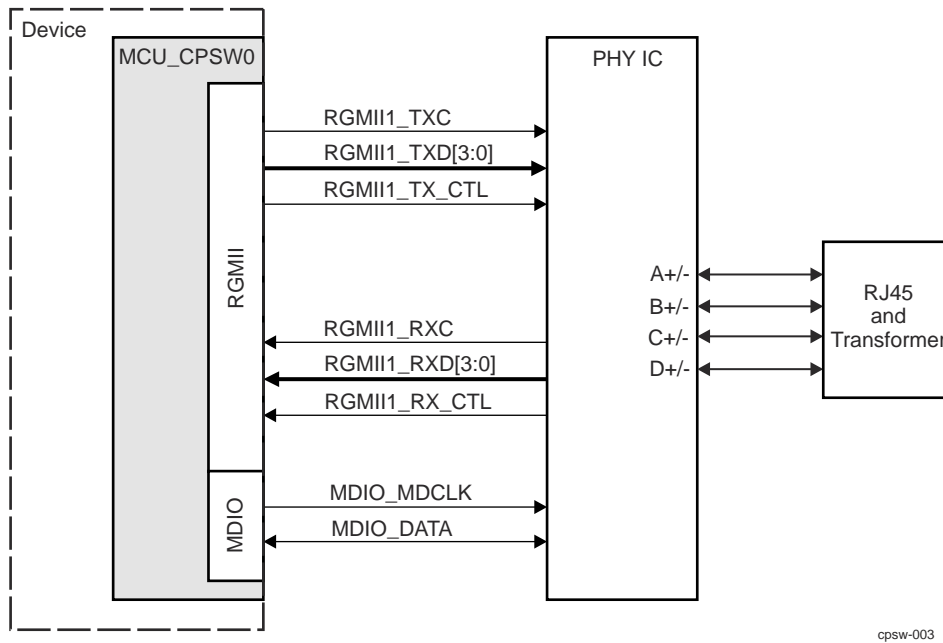

Figure 10-787. RGMII Interface Typical Application

Table 10-753. RGMII I/O Description

Signal	Device Pin(s)	I/O ⁽¹⁾	Description
RGMII_TXD[3:0]	MCU_RGMII_TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TX_CTL is asserted.
RGMII_TX_CTL	MCU_RGMII_TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII_TXC	MCU_RGMII_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RGMII_RXD[3:0]	MCU_RGMII_RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_RX_CTL is asserted
RGMII_RX_CTL	MCU_RGMII_RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII_RXC	MCU_RGMII_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.

Table 10-753. RGMII I/O Description (continued)

Signal	Device Pin(s)	I/O ⁽¹⁾	Description
MDIO_MDCLK	MCU_MDIO_CLK	O	Management data clock (MDIO_MDCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_DATA pin.
MDIO_DATA	MCU_MDIO_DATA	I/O	The MCU_MDIO0_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

Note

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see , Pad Configuration Registers in *Control Module (CTRL_MMR)* and the device-specific Datasheet.

10.2.1.3 MCU_CPSW0 Integration

Figure 10-788 shows the integration of the MCU_CPSW0 module in the device.

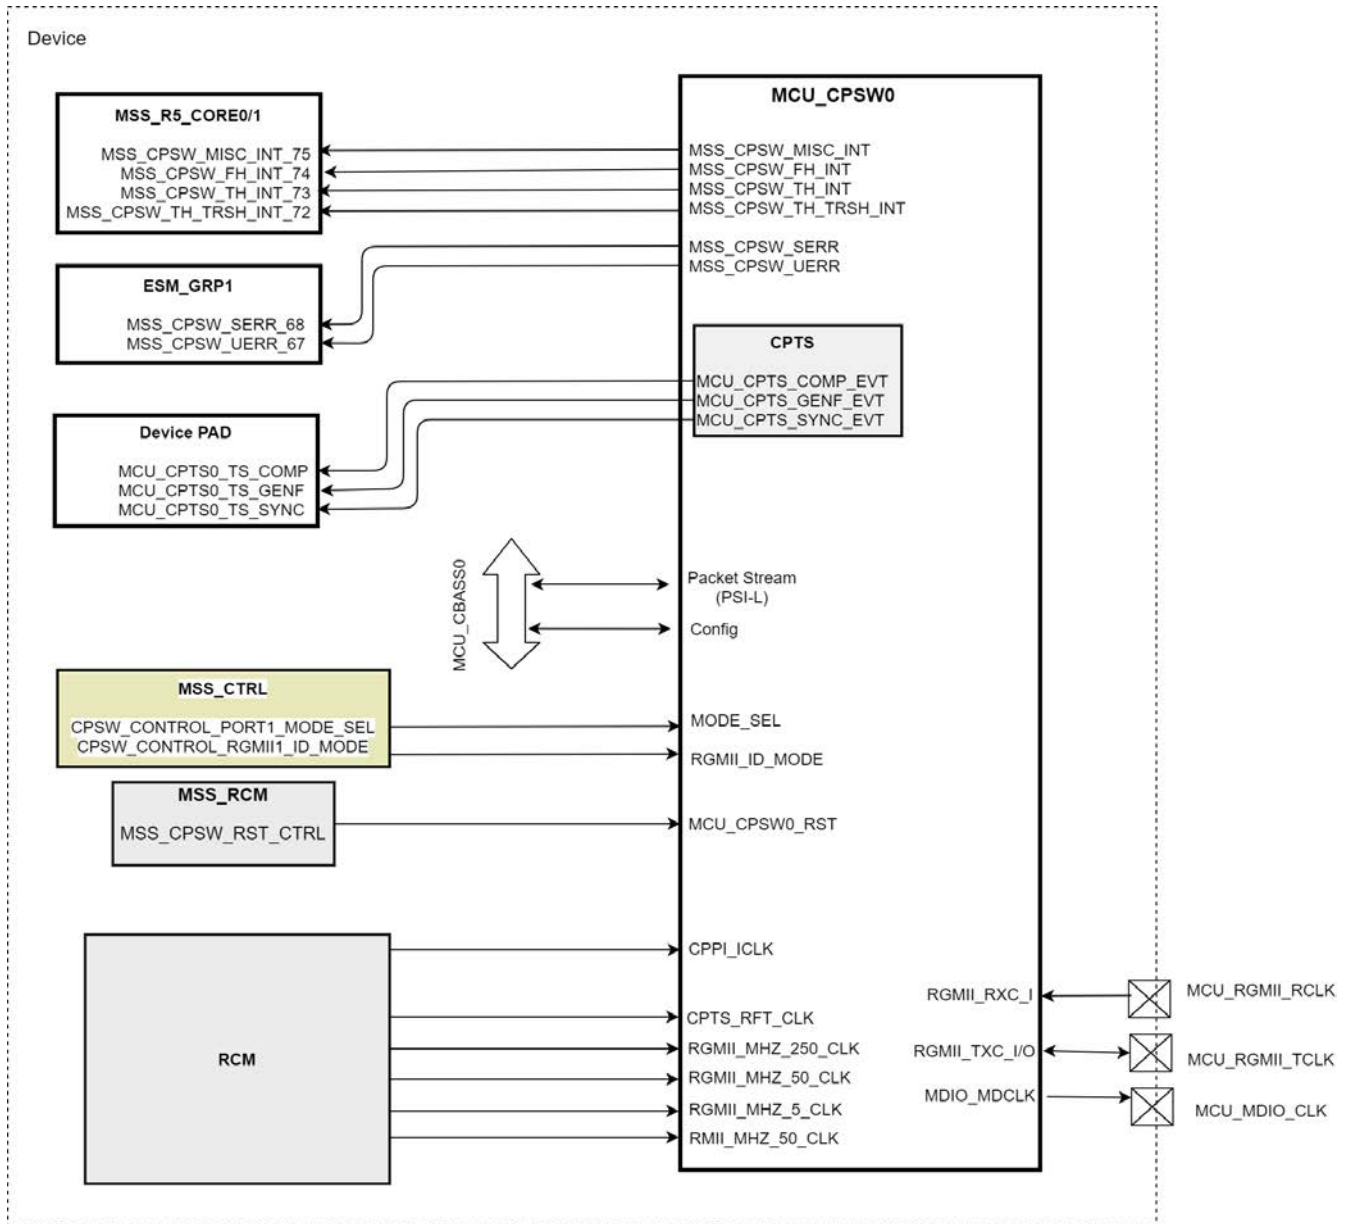

Figure 10-788. MCU_CPSW0 Integration

Below Tables summarize the integration of the MCU_CPSW0 module in the device.

Table 10-754. MCU_CPSW0 Clocks and Resets

Clocks			
Module Instance	Module Clock Input	Reference/Source	Description
MCU_CPSW0	CPPI_CLK	MSS_RCM::CPSW_CLK	CPPI packet streaming interface clock. Main clock for MCU_CPSW0.
	CPTS_RFT_CLK	MSS_RCM::MSS_CPTS_CLK	Time sync Reference Clock 400/250/divided
	RGMII_MHZ_5_CLK	MSS_RCM::MSS_MII10_CLK	5-MHz RGMII reference clock.
	RGMII_MHZ_50_CLK	MSS_RCM::MSS_MII100_CLK	50-MHz RGMII reference clock.

Table 10-754. MCU_CPSW0 Clocks and Resets (continued)

RGMII_MHZ_250_CLK	MSS_RCM::MSS_RGMII_CLK	250-MHz RGMII reference clock.
RMII_MHZ_50_CLK	MSS_RCM::MSS_MII100_CLK	50-MHz RMI reference clock.

Resets			
Module Instance	Module Reset Input	Reference/Source	Description
MCU_CPSW0	MCU_CPSW0_RST	MCSS_RCM::MSS_CPSW_RST_CTRL	IP Reset

Table 10-755. MCU_CPSW0 Hardware Requests

Interrupt Requests				
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Description	Type
MCU_CPSW0	MCU_CPSW_STAT_PEND	MSS_CPSW_MISC_INT_75	MCU_CPSW0 statistic pending interrupt 0	Pulse
	MCU_CPSW_EVNT_PEND	MSS_CPSW_MISC_INT_75	MCU_CPSW0 event pending interrupt	Pulse
	MCU_CPSW_MDIO_INTR	MSS_CPSW_MISC_INT_75	MCU_CPSW0 MDIO interrupt	Pulse
	MCU_CPSW_THost_INT	MSS_CPSW_TH_INT_73	MCU_CPSW0 T-host interrupt	Pulse
	MCU_CPSW_FHost_INT	MSS_CPSW_FH_INT_74	MCU_CPSW0 F-host interrupt	Pulse
	MCU_CPSW_TH_TRSH_INT	MSS_CPSW_TH_TRSH_INT_72	MCU_CPSW0 TH-threshold interrupt	Pulse
	MCU_CPSW_ECC_SEC_INT	MCU_ESM_EVT_68	MCU_CPSW0 SEC ECC error interrupt	Pulse
	MCU_CPSW_ECC_DED_INT	MCU_ESM_EVT_67	MCU_CPSW0 SEC DED error interrupt	Pulse

Time Sync and Compare Events				
Module Instance	Module Event	Device Pin	Description	Type
MCU_CPSW0	MCU_CPSW_COMP_EVT	MCU_CPTS0_TS_COMP	MCU_CPSW0 compare event interrupt	Edge
	MCU_CPSW_GENF_EVT	MCU_CPTS0_TS_GENF	MCU_CPSW0 CPTS generator function event interrupt	Edge
	MCU_CPSW_SYNC_EVT	MCU_CPTS0_TS_SYNC	MCU_CPSW0 CPTS sync event interrupt	Edge

Note

For more information about interrupts, see *Local Interrupt Controller*.

For more information on the interconnects, see [Chapter 3](#).

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5](#).

For more information on the device interrupt controllers, see *Interrupt Controllers*.

10.2.1.4 MCU_CPSW0 Functional Description

The two-port switch Ethernet subsystem modules (CPSW) are compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in [Figure 10-789](#).

10.2.1.4.1 Functional Block Diagram

The two-port Ethernet subsystem consists of:

- CPSW_2G
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

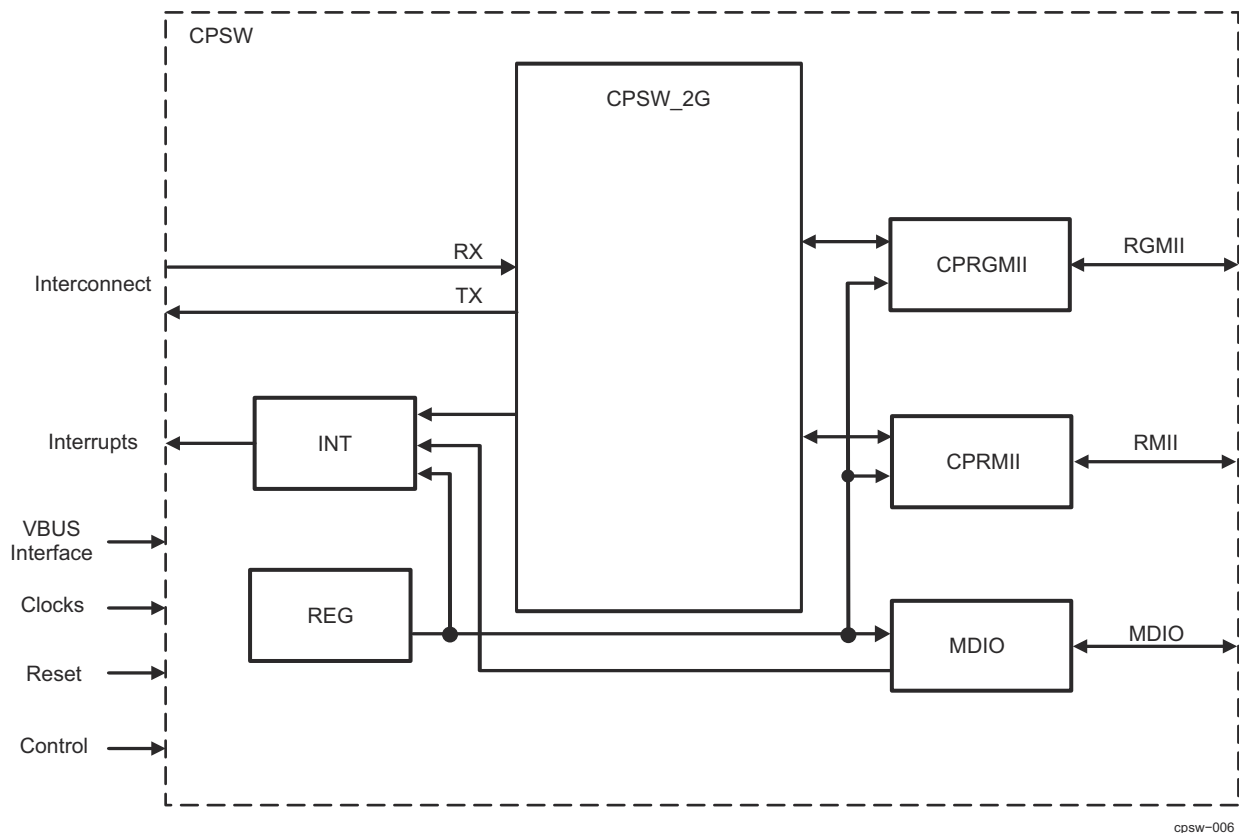

Figure 10-789. CPSW Top Level Block Diagram

10.2.1.4.2 CPSW Ports

The Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external port connected to RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI CPDMA Host Port
- Port1 is referred to the interfaces RGMII/RMII

10.2.1.4.2.1 Ethernet Port Operation

10.2.1.4.2.1.1 Interface Mode Selection

The two-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable MII, RMII, and RGMII interfaces. These interfaces can be enabled by

MSS_CTRL:CPSW_CONTROL:CPSW_CONTROL_PORT1_MODE_SEL

For specific interface mode further features is selected by configuring the Ethernet bits (EXT_EN, GIG, FULLDUPLEX, IFCTL_A) in the **PN_MAC_CONTROL** register.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

CPSW_CONTROL_PORT1_MODE_SEL	Link Type
00	GMII/MII
01	RMII
10	RGMII

10.2.1.4.2.1.2 RMII Operation

The **IFCTL_A** bit determines the RMII link speed (0=10mbps, 1=100mbps). The **FULLDUPLEX** bit controls RMII duplexity. The **IFCTL_B** is not used.

10.2.1.4.2.1.3 RGMII Operation

Each port RGMII interface can operate in a forced mode or an in-band mode as determined by the **EXT_EN** bit. Forced mode is with **EXT_EN** cleared. In-band mode is with **EXT_EN** set.

10.2.1.4.2.1.3.1 RGMII In-Band Operation

A port CPRGMII is operating in the in-band mode of operation when the **EXT_EN** is set. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification and can be read in the **SS_RGMII1_STATUS** register. The link speed is indicated as shown in [Table 10-756](#).

Table 10-756. RGMII Link Speed

SPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

10.2.1.4.2.1.3.2 RGMII Forced Mode Operation

A RGMII is operating in the forced mode of operation when **EXT_EN** is cleared. In the forced mode of operation, the in-band data is ignored if present. The link status is forced set, the duplexity is set by the **FULLDUPLEX** bit, and the speed is set by the **GIG** bit. If the **GIG** bit is set, then operation is gigabit mode (**SS_RGMII1_STATUS: SPEED(1:0) = 10**). If the **GIG** bit is cleared, then operation is 100mbps mode (**SPEED(1:0) = 01**). 10mbps is not supported when operating in the forced mode.

10.2.1.4.3 Clocking

10.2.1.4.3.1 Subsystem Clocking

CPSW clocking summary is shown in [Section 10.2.1.3, CPSW Integration](#).

10.2.1.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

10.2.1.4.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

- 125 MHz at 1000 Mbps

10.2.1.4.3.2.2 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

MCU_RMII1_REFCLK pin or internal RGMII_MHZ_50_CLK clock (default clock) can be selected through CTRLMMR_MCU_ENET_CLKSEL[0]RMII_CLK_SEL and one of these clocks can be used as the clock source for RMII interface. For more details on RMII clocking, please see [Section 10.2.1.3, CPSW Integration](#).

CTRLMMR_MCU_CLKOUT0_CTRL[4]CLK_EN and CTRLMMR_MCU_CLKOUT0_CTRL[0]CLK_SEL bits are used to enable and select the clock source for MCU_CLKOUT pin.

10.2.1.4.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW_MDIO_CONTROL_REG register for configuring the Clock Divider ([15:0]CLKDIV) value.

10.2.1.4.4 Interrupt Functionality

Table 10-757. Interrupt Functionality

Interrupt	Description
MSS_CPSW_FH_INT	FHost (from host to Ethernet) interrupt
MSS_CPSW_TH_INT	THost (from Ethernet to host) interrupt
MSS_CPSW_TH_TRSH_INT	THost (from Ethernet to host) Threshold interrupt
MSS_CPSW_MISC_INT	Miscellaneous interrupt
MSS_CPSW_SERR	ECC SEC interrupt – output from CPSW ECC module. This interrupt is also included in the MSS_CPSW_MISC_INT if enabled or this interrupt can be used separately.
MSS_CPSW_UERR	ECC DED interrupt – output from CPSW ECC module. This interrupt is also included in the MSS_CPSW_MISC_INT if enabled or this interrupt can be used separately.

10.2.1.4.4.1 MSS_CPSW_TH_TRSH_INT Interrupt Description

The MSS_CPSW_TH_TRSH_INT interrupts are each an immediate (non-paced) pulse interrupt selected from the CPSW_2G TH_THRESH_PEND[7:0] interrupts. The THost threshold pending interrupt(s) is selected by setting one or more bits in the SS_TH_THRESH_PULSE_EN_REG[7:0] register. The masked interrupt status can be read in the SS_TH_THRESH_PULSE_STATUS_REG[7:0] register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_THRESH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x0 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

10.2.1.4.4.2 MSS_CPSW_TH_INT Interrupt Description

The MSS_CPSW_TH_INT interrupts are each a paced pulse interrupt selected from the CPSW_2G TH_PEND[7:0] interrupts. The THost pending interrupt(s) is selected by setting one or more bits in the SS_TH_PULSE_EN_REG[7:0] register. The masked interrupt status can be read in the SS_TH_PULSE_STATUS_REG[7:0] register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s) to acknowledge the CPDMA interrupt.

- Write the CPSW_2G completion pointer(s).
- Write 0x1 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

10.2.1.4.4.3 MSS_CPSW_FH_INT Interrupt Description

The **MSS_CPSW_FH_INT** interrupts are each a pulse interrupt selected from the CPSW_2G **FH_PEND[7:0]** interrupts. The transmit pending interrupt(s) is selected by setting one or more bits in the **SS_FH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_FH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the **SS_FH_PULSE_STATUS_REG[7:0]** register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s).
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x2 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

10.2.1.4.4.4 MSS_CPSW_MISC_INT Interrupt Description

The **MSS_CPSW_MISC_INT** interrupts are each an immediate (non-paced) pulse interrupt selected from the miscellaneous interrupts (**DED_PEND, SEC_PEND, EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT**). The miscellaneous interrupt bits are enabled by setting one or more bits in the **SS_MISC_EN_REG** register. The masked interrupt status can be read in the **SS_MISC_STATUS_REG** register. Upon reception of an interrupt, software should perform the following:

- Read the **SS_MISC_STATUS_REG** register to determine the cause of the interrupt.
 - MDIO_USERINT is the logical “OR” of the CPSW_2G MDIO MDIO_USERINT[1:0].
 - MDIO_LINKINT is the logical “OR” of the CPSW_2G MDIO MDIO_LINKINT[1:0].
 - HOST_PEND is the CPSW_2G CPDMA host error interrupt.
 - STAT_PEND is the logical “OR” of the CPSW_2G statistics interrupt STAT_PEND[2:0].
 - EVNT_PEND is the CPSW_2G CPTS event interrupt.
 - SEC_PEND is the ECC Single bit error interrupt.
 - DED_PEND is the ECC double bit error interrupt.
- Process the interrupt.
- Write 0x3 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

10.2.1.4.4.5 ECC SEC ESM Interrupt (MSS_CPSW_SERR)

ESM interrupt indicating a CPSW_2G ECC single error has been detected and corrected. Although the **MSS_CPSW_SERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[5]** and read status from **SS_TH_PULSE_STATUS_REG[5]**

10.2.1.4.4.6 ECC DED ESM Interrupt (MSS_CPSW_UERR)

ESM interrupt indicating a CPSW_2G ECC double error has been detected. Although the **MSS_CPSW_UERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[6]** and read status from **SS_MISC_STATUS_REG[6]**.

10.2.1.4.4.7 THost Threshold Interrupts for CPDMA

Each of the eight THost channels has a corresponding THost threshold interrupt (**TH_THRESH_PEND[7:0]**). The THost threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt receive interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. A **TH_THRESH_PEND[7:0]** interrupt bit is asserted when enabled and when the channel’s associated freebuffer count (**CPDMA_TH(0/7)_FREEBUFFER**) is less

than or equal to the channel's associated flow control threshold register (**CPDMA_TH(0/7)_PENDTHRESH**). The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

10.2.1.4.4.8 Thost Packet Completion Interrupts for CPDMA

The THost DMA controller has eight channels with each channel having a corresponding interrupt (**TH_PEND[7:0]**). The THost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. When a packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel queue's **CPDMA_TH(0..7)_CP** completion pointer. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated **CPDMA_TH(0..7)_CP** Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA. If the two values are equal then the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

10.2.1.4.4.9 Fhost Packet Completion Interrupts for CPDMA

The FHost DMA controller has eight channels with each channel having a corresponding interrupt (**FH_PEND[7:0]**). The FHost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_CLR** register. The raw and masked interrupt status may be read by reading the **CPDMA_FH_INTSTAT_RAW** and **CPDMA_FH_INTSTAT_MASKED** registers respectively. When each packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel **CPDMA_FH(0..7)_CP** completion pointer register. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated Fhost Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA and if the two values are equal then the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

10.2.1.4.5 Media Independent Interfaces (XGMII/GMII)

For the purposes of this document, Ethernet transmit is egress and Ethernet receive is ingress.

10.2.1.4.5.1 Receive Control

Data received from the PHY is interpreted and forwarded by the MAC into the switch. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length,

data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

10.2.1.4.5.1.1 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

1. An Inter-Packet Gap (IPG).
2. A seven octet preamble (all octets 0x55).
3. A one octet start frame delimiter (0x5d).

10.2.1.4.5.1.2 Received Frame Classification

Received frames are proper (good) frames if they are between 64 and **PN_RX_MAXLEN** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **PN_RX_MAXLEN** register. The **PN_RX_MAXLEN** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are runt frames. Short frames with CRC, code, or alignment errors are fragment frames. If **RX_CSF_EN** in **PN_MAC_CONTROL** is set, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If **RX_CSF_EN** and **RX_CEF_EN** in **PN_MAC_CONTROL** are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain **PN_RX_MAXLEN** number of bytes transferred to memory (if **RX_CEF_EN** = 1). Examples with **PN_RX_MAXLEN** = 1518 is below:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.
- If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

10.2.1.4.5.2 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet in half-duplex mode. If the collision was late (after the first 64 bytes have been transmitted) then the collision is ignored. If the collision is not late, then the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

10.2.1.4.5.2.1 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **TX_PACE** bit in the **PN_MAC_CONTROL** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non-zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

10.2.1.4.5.2.2 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **MCRS** is de-asserted within approximately 48 bit times of **MTXEN** being de-asserted, then 96 bit times is measured from **MTXEN**. If the frame suffered a collision, or if **MCRS** is not de-asserted until more than approximately 48 bit times after **MTXEN** is de-asserted, then 96 bit times (approximately, but not less) is measured from **MCRS**.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the **TX_SHORT_GAP_ENABLE** bit each **PN_MAC_CONTROL** register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The **GAP_THRESH** register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the **GAP_THRESH** value then short gap is triggered.

10.2.1.4.5.2.3 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **PN_MAC_TX_GAP** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

10.2.1.4.5.2.4 Back Off

The Ethernet Mac implements the 802.3 binary exponential back-off algorithm for half-duplex based collisions.

10.2.1.4.5.3 Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**SOFT** and **FREE** in the **PN_MAC_EMCONTROL** register) allow Mac operation to be suspended. When the emulation suspend state is entered, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals. [Table 10-758](#) shows the operations of emulation control input and register bits.

Table 10-758. Emulation Control Input and Register Bits

TBEMUSUP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

10.2.1.4.5.4 Command IDLE

The **CMD_IDLE** bit in the **PN_MAC_CONTROL** register allows MAC operation to be suspended by software. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored (dropped without any processing or statistics). Commanded idle is similar in operation to emulation control and hardware clock stop.

10.2.1.4.6 CPSW_2G

The CPSW_2G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_2G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_2G is shown in Figure 10-790.

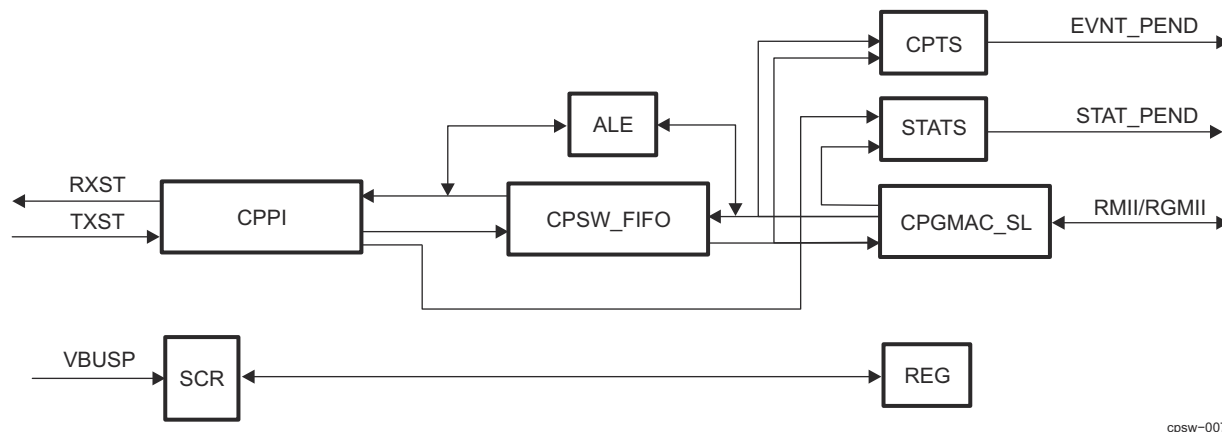

Figure 10-790. CPSW_2G Block Diagram

10.2.1.4.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE bit in the ALE_CONTROL_REG register is set. All packets are dropped when the ENABLE bit is cleared to 0.

10.2.1.4.6.1.1 Error Handling

In normal operation, the Ethernet port is configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the PN_MAC_CONTROL_REG configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

10.2.1.4.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the BYPASS bit in the ALE_CONTROL_REG register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

10.2.1.4.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the enable_oui_deny bit in the ALE_CONTROL register. When in OUI deny mode, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches with a supervisory table entry. (Non-matching OUI source address broadcast/multicast packets will be dropped to the host unless the packet destination address is entered into the table with the super bit set. Non-matching OUI source address unicast packets will be dropped to the host unless the unicast destination address is in the table with block and Secure both set). When enable_oui_deny is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table

entry. (Broadcast packets matching the OUI source address will be dropped to the host unless the broadcast destination address is entered into the table with the super bit set. Unicast packets matching the OUI source address will be dropped to the host unless the unicast destination address is in the table with block and Secure both set)

10.2.1.4.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. The events specified through the CPSW_ALE_STAT_DIAG[3-0] STAT_DIAG field are individually counted in CPSW per port statistics counters.

10.2.1.4.6.1.5 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes.

10.2.1.4.6.1.6 ALE Lookup Table Entry Definitions

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 10-759. Learned Address Control Bits

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**. (1:Multicast, 0:Unicast)

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.(1:Multicast, 0:Unicast)

10.2.1.4.6.1.6.1 Free Table Entry

Table 10-760. Free (Unused) Address Table Entry Bit Values

70:62	61:60	59:0
Reserved	ENTRY_TYPE (00)	Reserved

10.2.1.4.6.1.6.2 Multicast Address Table Entry (Bit 40==1)

Table 10-761. Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	IgnoreMbits	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

IgnoreMbits

Ignore Multicast Bits - Indication that the Multicast Address has ignored bits.

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

10.2.1.4.6.1.6.3 VLAN/Multicast Address Table Entry (Bit 40==1)

Table 10-762. VLAN/Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

10.2.1.4.6.1.6.4 Unicast Address Table Entry (Bit 40==0)

Table 10-763. Unicast Address Table Entry Bit Values

70:68	67	66	65	64	63:62	61:60	59:48	47:0
Reserved	TRUNK	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYP E (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_AD DRESS

Trunk

Trunk Indicator -

0 - the port bits in the entry are the port number

1 - the port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

10.2.1.4.6.1.6.5 OUI Unicast Address Table Entry

Table 10-764. OUI Unicast Address Table Entry Bit Values

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

10.2.1.4.6.1.6.6 VLAN/Unicast Address Table Entry (Bit 40==0)

Table 10-765. Unicast Address Table Entry Bit Values

70:68	67	66	65	64	63:62	61:60	59:48	47:0
Reserved	TRUNK	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Trunk

Trunk Indicator -

0 - the port bits in the entry are the port number

1 - the port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

10.2.1.4.6.1.6.7 VLAN Table Entry

Table 10-766. Inner VLAN Table Entry

70:68	67:66	65	64:62	61:60	59:48	47	46:44	43	42:26	25:24	23	22:20	19	18:2	1:0

Table 10-767. Outer VLAN Table Entry

70:68	67:66	65	64:62	61:60	59:48	47	46:44	43	42:26	25:24	23	22:20	19	18:2	1:0
Resvd	NoLrnMsk	IngressChk	010	10	oVLANI ID	Resvd	RegIdx	NoFra g	Reserv ed	fwdutag g	Reserve d	UregIdx x	LmtNxt Hdr	Reserv ed	Member

Member

VLAN Member list - This field indicates which port(s) are a member of the associated VLAN.

LmtNxtHdr

VLAN Limit Next Header Control - Causes frames to be dropped if the Protocol/Next Header does not match the ALE_NXT_HDR register values

UregIdx

VLAN Unregister Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the unregistered multicast flood mask.

fwdutag

VLAN Forward Untagged Egress - Causes the packet VLAN tag to be removed on egress for the specified port(s).

NoFrag

LAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

RegIdx

VLAN Registered Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the registered multicast flood mask.

iVLANI

Inner VLAN ID - This is the 12-bit Inner VLAN ID, normally referred to as C-VLANID

oVLANI

Outer VLAN ID - This is the 12-bit Outer VLAN ID, normally referred to as S-VLANID

IngressChk

VLAN Ingress Check - When set, if the receive port is not a member of this VLAN then the packet is dropped. This is similar to the vid_ingress_check bit in the ale_port_control register except this check is for this VLAN only (not all VLANs).

NoLrnMsk

VLAN No Learn Mask - When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

Table 10-768. IPv4 Table Entry

70	69:65	64:62	61:60	59:32	31:0
Resvd	IgnBits	110	10	Reserved	IPv4Adr

Table 10-769. IPv6 Table Entry High

70:64	63	62	61:60	59:0
IgnBits	Resvd	1	10	IPv6Adr[127:68]

Table 10-770. IPv6 Table Entry Low

70:63	62	61:60	59:0
IPv6Adr[67:60]	1	10	IPv6Adr[59:0]

IgnBits

Inore Bits - Indicates the number of lower address bits (IPv4 or IPv6) to be ignored starting at bit zero. Ignored bits must be zero value in the table entry

10.2.1.4.6.1.7 ALE Policing and Classification

The ALE has a number of configurable policer engines. Each policer engine can be used for classification and or policing. Policing is an extension of the classifier function that allows for color marking and rate limiting due to classifier bandwidth measurement thresholds. Any policer engine can be used for classification alone by not using the bandwidth limiting thresholds. The `policers_div_8` field in the `ALE_Status` register indicates the number of policers available to be used for classification or policing.

Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

ALE Policing

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the committed information rate (CIR) counter and the second counter is the peak information rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

$$\text{CIR policing rate in Mbit/s} = ((\text{ALE frequency in Mhz}) * \text{cir_idle_inc_val}) / 32768$$

$$\text{PIR policing rate in Mbit/s} = ((\text{ALE frequency in Mhz}) * \text{pir_idle_inc_val}) / 32768$$

Each policer has 10 different match operations (see below Classification). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

10.2.1.4.6.1.7.1 ALE Classification

Each policer can be enabled to classify on one or more of any of the below packet fields for classification or policing. All but Port and Priority are index references to the ALE table entries.

- Port or Trunk Group Number
- Priority extracted from VLAN, mapped from DSCP if enabled or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID - S-VLANID
- Inner VLANID - C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6

Multiple classifiers can match on a single packet. For example a classifier can be enabled to match on priority while another classifier could match on IP address. The ALE will return to the switch the highest classifier entries thread ID that matched with an enabled thread ID number. This could be used to further host routing of the packet.

2.1.4.6.1.7.1.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW_ALE_THREAD_DEF_REG, CPSW_ALE_THREAD_CTL_REG and CPSW_ALE_THREAD_VAL_REG). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREAD_CTL_REG register allows the CPSW_ALE_THREAD_VAL_REG register contents to be written to the selected classifier. There is a single CPSW_ALE_THREAD_DEF_REG that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

10.2.1.4.6.1.8 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

Destination port mirroring allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR_DP=A, MIRROR_DEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Source port mirroring allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port.(MIRROR_SP=1h in the ALE_PORTn_CONTROL register, MIRROR_SEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Table entry mirroring allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR_MIDX=C, MIRROR_MEN=1h, MIRROR_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in ALE_CONTROL, ALE_CONTROL2 and the port control registers.

- MIRROR_DP - The destination port that will have its traffic mirrored (ALE_CONTROL_REG register).
- MIRROR_TOP - The port to which mirrored traffic is sent (ALE_CONTROL_REG register).

- MIRROR_MEN - The enable for mirroring traffic that matches a supported lookup table entry (ALE_CONTROL_REG register).
- MIRROR_DEN - The Enable for destination port mirroring (ALE_CONTROL_REG register).
- MIRROR_SEN - The Enable for source port mirroring (ALE_CONTROL_REG register).
- MIRROR_MIDX - The index of a lookup table entry that will be mirrored ALE_CONTROL2_REG register).
- Px_MIRROR_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (ALE_PORTn_CONTROL register).

10.2.1.4.6.1.9 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the ALE_CONTROL2_REG register and in each ALE_PORTn_CONTROL_REG register:

- TRK_EN_DST - Enable destination address hashing for trunk port calculation.
- TRK_EN_SRC - Enable source address hashing for trunk port calculation.
- TRK_EN_PRI - Enable priority hashing for trunk port calculation.
- TRK_EN_VLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK_EN_SIP - Enable source IP address hashing for trunk port calculation.
- TRK_EN_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK_BASE - Hashing formula starting value and test port offset.
- TRUNK_EN - Enable this port as a trunk group
- TRUNK_NUMBER - Trunk group number defines this port as a member of a particular trunk group.

10.2.1.4.6.1.10 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See P0_RX_DSCP_MAP_REG and PN_RX_DSCP_MAP_REG registers in the Register Manual section for DSCP mapping.

10.2.1.4.6.1.11 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, *VLAN_Unaware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST_FWD_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet

is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set in the CPSW_PN_MAC_CONTROL_REG register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW PN_MAC_CONTROL_REG register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

10.2.1.4.6.1.11.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx PORT_STATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet
if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not RATE_LIMIT_TX)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> • Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (not block) and (receive port number != port_number) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet

<p>If (VLAN_Unaware)</p> <p>CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG = "000000"</p> <p>CPSW_ALE_UNKNOWN_MCAST_FLOOD_REG = "111111"</p> <p>CPSW_ALE_UNKNOWN_REG_MCAST_FLOOD_REG = "111111"</p> <p>VLAN_MEMBER_LIST = "111111"</p> <p>else if (VLAN not found)</p> <p>CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG = CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG</p> <p>CPSW_ALE_UNKNOWN_MCAST_FLOOD_REG = CPSW_ALE_UNKNOWN_REG_MCAST_FLOOD_REG</p> <p>CPSW_ALE_UNKNOWN_REG_MCAST_FLOOD_REG = CPSW_ALE_UNKNOWN_MCAST_FLOOD_REG</p> <p>VLAN_MEMBER_LIST = CPSW_ALE_UNKNOWN_VLAN_REG</p> <p>else</p> <p>CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG = found CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG</p> <p>CPSW_ALE_UNKNOWN_MCAST_FLOOD_REG = found CPSW_ALE_UNKNOWN_MCAST_FLOOD_REG</p> <p>CPSW_ALE_UNKNOWN_REG_MCAST_FLOOD_REG = found CPSW_ALE_UNKNOWN_REG_MCAST_FLOOD_REG</p> <p>VLAN_MEMBER_LIST = found VLAN_MEMBER_LIST</p>
<p>if ((not SUPER) and (VID_INGRESS_CHECK) and (Rx port is not VLAN member))</p> <p>then discard the packet</p>

if (Broadcast packet) then use found VLAN_MEMBER_LIST and goto Egress process

10.2.1.4.6.1.11.4 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask
if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask

if ((ENABLE_RATE_LIMIT) and (RATE_LIMIT_TX)) then if (not SUPER) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

10.2.1.4.6.1.11.5 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

2.1.4.6.1.11.5.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (DROP_UNTAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown VLAN_MEMBER_LIST = "000")) then do not learn address
if ((VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VID))) then learn address without VLAN

2.1.4.6.1.11.5.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (DROP_UNTAGGED)) then do not update address
if ((VLAN_AWARE) and (VLAN not found) and (unknown VLAN_MEMBER_LIST = "000")) then do not update address
if ((VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address

```
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK))
then do not update address

```
if ((source address found) and (ageable) and (not touched))
then set touched
```

10.2.1.4.6.2 CPPI CPDMA Host Interface

10.2.1.4.6.2.1 Functional Operation

For legacy reasons this document uses FHost (“cpsw ingress **From Host**”) interchangeably with host receive and THost (“cpsw egress **To Host**”) interchangeably with host transmit.

Host Software sends and receives network frames via the CPDMA CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data from the host to Ethernet and free buffer queues available for packet data from Ethernet to the host.

After reset, initialization, and configuration the host may initiate CPDMA host interface operations. FHost DMA operations (from host to Ethernet) are initiated by host writes to the appropriate FHost channel head descriptor pointer. The FHost DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol and proceeds with packet operations. The DMA controller fetches the packet data in 64-byte (maximum) bursts.

Host CPDMA THost operations are initiated by host writes to the appropriate THost channel head descriptor pointer after host initialization and configuration. The THost DMA controller writes Ethernet received packet data to external host memory in accordance with CPPI 3.0 protocol.

10.2.1.4.6.2.2 THost CPDMA Interface

The THost DMA (Ethernet to host) is an eight channel CPPI 3.0 compliant interface. Each priority/channel (priority and channel are used interchangeably) has a single queue for frame reception.

10.2.1.4.6.2.2.1 THost CPDMA Host Configuration

To configure the CPDMA for THost operations the host must perform the following:

- Initialize the CPDMA_TH(0..7)_HDP Registers to zero.
- Enable the desired THost interrupts in the CPDMA_TH_INTSTAT_SET register.
- Write the CPDMA_TH_BUFFER_OFFSET register value.
- Setup the channel(s) buffer descriptors in host memory as required by CPPI.
- Enable the CPDMA controller by setting the TH_EN bit in the CPDMA_TH_CONTROL register.

10.2.1.4.6.2.2.2 THost CPDMA Buffer Descriptors

A THost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 10-771. THost Buffer Descriptor format

Word Order Offset	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	next descriptor pointer																															
	buffer pointer																															
	reserved								buffer offset								reserved								buffer length							

Table 10-771. THost Buffer Descriptor format (continued)

sop	eop	ownership	packet length
-----	-----	-----------	---------------

Field	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the next_descriptor_pointer .
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer .
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. The buffer offset is reduced to 12-bits. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the buffer_offset with the value from the CPDMA_TH_BUFFER_OFFSET register value. The host initializes the buffer_offset to zero for free buffers. The buffer_length must be greater than the CPDMA_TH_BUFFER_OFFSET register value. The buffer offset is valid only on sop .
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. The buffer length is reduced to 12-bits. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the buffer_length , but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The buffer_length must be greater than zero.
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. The port sets the sop bit. 0 - Not start of packet buffer 1 - Start of packet buffer
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. The port sets the eop bit. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on sop . This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port

Field	Description
eoq	End Of Queue - Set by the port to indicate that the RX queue empty condition exists. This bit is valid only on eop . The port determines the end of queue condition by a zero next_descriptor_pointer . 0 - The RX queue has more buffers available for reception. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.
teardown_complete	Teardown Complete - Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on sop . 0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.
passed_crc	Passed CRC - Set by the port to indicate that the CRC was passed with the data. The Packet_Length includes the CRC bytes. The passed_crc bit is valid only on SOP. The p0_tx_crc_remove bit in the CPDMA_Control register determines if CPPI THost packets have a CRC included or not.
long	Jabber Frame - Indicates that the frame is a jabber frame and was not discarded because rx_cef_en was set in the ingress port Pn_MAC_Control register. Valid only on SOP.
short	Fragment Frame - Indicates that the frame is a fragment and was not discarded because rx_cef_en was set in the ingress port Pn_MAC_Control register. Valid only on SOP.
mac_ctl	Control Frame - Indicates that the frame is a MAC control frame and was not discarded because the rx_cmf_en bit was set in the ingress port Pn_Mac_Control register. Valid only on SOP.
overrun	Overrun - Set by the port to indicate that the frame reception was aborted due to THost buffer overrun. This bit is valid only on SOP. 0 - no overrun occurred on the packet 1 - The packet was aborted due to overrun
pkt_error	Packet Contained Error on Ethernet Ingress. This field is valid on SOP. - 00 - no error 01 - CRC error on ingress 10 - Code error on ingress 11 - align error on ingress
vlan_encap	VLAN Encapsulated Packet - Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPDMA_Control register th_vlan_encap bit. If both th_vlan_encap and th_ts_encap are set then the VLAN is first. This encapsulated word also contains the ALE classification FLOW (threadval). This bit is valid on SOP.
ts_encap	Timestamp Encapsulated Packet - Indicates when set that the packet data contains a 64-bit timestamp (two 32-bit words with the lower 32-bit word first) that is included in the packet byte count. This field is set by the port to be the value of the CPDMA_Control register th_ts_encap bit. If both th_vlan_encap and thost_ts_encap are set then the VLAN is first. This bit is valid on SOP.
chksum_encap	Checksum Encapsulated Packet - Indicates when set that the packet data contains 4-bytes of THost checksum information at the end of the packet (last 4 bytes). The packet length includes the checksum bytes.
memory_protect_error	Memory Protect Error - An error was detected in the packet Castagnoli protect CRC. The Packet should be dropped by the host.
from_port	From Port - Indicates the Ethernet ingress port number. This field is valid only on SOP.
packet_length	Packet Length - Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length . Valid only on SOP.

10.2.1.4.6.2.2.3 THost CPDMA Channel Teardown

The host commands a THost channel teardown by writing the channel number to the **CPDMA_TH_TEARDOWN** register. When a teardown command is issued to an enabled THost channel the following will occur:

- Any current frame in reception will complete normally.

- The `teardown_complete` bit will be set in the next THost buffer descriptor in the chain if there is one.
- The channel head descriptor pointer will be cleared to zero
- A THost interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a `0xffffffff` acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a `0xffffffff` acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be `0xffffffff` if the interrupt was due to a teardown command.

10.2.1.4.6.2.3 FHost CPDMA Interface

The FHost DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by `FH_PTYPE` in the `CPDMA_Control` register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the `TX_VBUSP` interface in 64-byte maximum burst transfers. Any packet can be designated by the host to generate a host timesync event on Ethernet egress by setting the `host_event` bit in the packet buffer descriptor.

10.2.1.4.6.2.3.1 FHost CPDMA Host Configuration

To configure the CPDMA for FHost operations the host must do the following:

- Initialize the `CPDMA_FH(0..7)_HDP` registers to a zero value.
- Enable the desired ingress interrupts in the `CPDMA_FH_INTSTAT_MASKED_SET` register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the ingress operation as desired in the `CPDMA_FH_Control` register.
- Write the appropriate `CPDMA_FH(0..7)_HDP` registers with the appropriate values to start packet operations.

10.2.1.4.6.2.3.2 FHost CPDMA Buffer Descriptors

An FHost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 10-772. FHost Buffer Descriptor format

Word or Offset	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Name	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the FHost queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the next_descriptor_pointer .
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer .
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the buffer_offset value (which may be zero to the buffer length minus 1). Valid only on sop .
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the buffer_length . The buffer_length must be greater than zero.
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. 0 - Not start of packet buffer 1 - Start of packet buffer
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on sop . This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port
eq	End Of Queue - Set by the port to indicate that all packets in the queue have been transferred and the FHost queue is empty. End of queue is determined by the port when the next_descriptor_pointer is zero on an eop buffer. This bit is valid only on eop . 0 - The FHost queue has more packets to transfer. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Name	Description
teardown_complete	<p>Teardown Complete – Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on sop.</p> <p>0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.</p>
crc_type	<p>CRC Type –</p> <p>0 – Ethernet CRC 1 – Castagnoli CRC (if \$CPPI_Cast = 1)</p>
pass_crc	<p>Pass CRC – Valid only on SOP</p> <p>0 – A CRC is not included with the packet data. The Ethernet port(s) will generate the CRC on Ethernet egress. A CRC (or placeholder) at the end of the data is allowed, but not required, and the buffer_count and packet_length fields should not include the CRC bytes if they are present. 1 – A CRC is included with the host packet data. The packet_length and buffer_count fields should include the four CRC bytes. The host supplied CRC should be in the last four bytes of the data.</p>
to_port	<p>To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.</p> <p>1 – Send the packet to port 1 if to_port_en is asserted. 2 – Send the packet to port 2 if to_port_en is asserted.</p>
to_port_en	<p>To Port Enable – Indicates when set that the packet is a directed packet to be sent to the to_port field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.</p> <p>0 – not a directed packet 1 – directed packet</p>
host_event	<p>Host Timesync Event – Generate a host timesync event on Ethernet egress. The upper 28-bits of the packet SOP buffer descriptor address are the domain[7:0], message_type[3:0], and sequence_id[15:0] in that order.</p> <p>0 – The packet will not generate a host event on Ethernet egress 1 – The packet will generate a host event on Ethernet egress</p>
chksum_encap	<p>Checksum Encapsulated Packet – Indicates when set that the packet data contains 4-bytes of FHost checksum information at the start of the packet (first 4 bytes). The packet length includes the checksum bytes.</p>
packet_length	<p>Packet Length – Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.</p>

10.2.1.4.6.2.3.3 FHost CPDMA Channel Teardown

The host commands a FHost channel teardown by writing the channel number to the **CPDMA_FH_Teardown** register. When a teardown command is issued to an enabled FHost channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xfffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due

to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xffffffff acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xffffffff if the interrupt was due to a teardown command.

10.2.1.4.6.2.4 VLAN Aware Mode

The CPSW is in VLAN aware mode when the CPSW Control register **vlan_aware** bit is set. In VLAN aware mode port 0 THost packets may or may not be VLAN encapsulated depending on the CPDMA_Control register **th_vlan_encap** bit. The header packet VLAN is generated as described in later sections of this specification. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set **vlan_encap** bit in the packet buffer descriptor. The VLAN encapsulation header is included in the packet length and has the below format:

32-bit VLAN Header Encapsulation Word																																								
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0									
h			h	hdr_pkt_vid												f											p	reserved												
d			d													l														k										
r			r													o														t										
—			—													w													—											
p			p																											t										
k			k																											y										
t			t																											e										
—			—																																					
p			p																																					
r			r																																					
l			l																																					
o																																								
r																																								
l																																								
t																																								
y																																								

Field	Description
hdr_pkt_priority	Header Packet VLAN priority (7 is highest priority)
hdr_pkt_cfi	Header Packet VLAN CFI bit. The
hdr_pkt_vid	Header Packet VLAN ID.
flow	FLOW – A nonzero value indicates that the ALE matched a classifier with the flow (threadval).
pkt_type	Packet Type – Indicates whether the packet is a VLAN tagged, priority tagged or non-tagged packet. 00 – VLAN tagged packet 01 – reserved 10 – priority tagged packet 11 – non-tagged packet

10.2.1.4.6.2.5 VLAN Unaware Mode

The CPSW is in VLAN unaware mode when the CPSW Control register **vlan_aware** bit is cleared. Port 0 THost packets (egress) may or may not be VLAN encapsulated depending on the CPSW Control register **th_vlan_encap** bit.

10.2.1.4.6.2.6 CPDMA Command IDLE

The **cmd_idle** bit in the **CPDMA_Control** register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing THost and FHost frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For FHost, any

frame in process will be completed. For THost, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

10.2.1.4.6.2.7 CPDMA CPPI 3.0 Interface Bandwidth

The HOST CPPI 3.0 FHost and THost interfaces are capable of supporting linerate on the Ethernet ports provided that the clock frequency is sufficient, and provided that the Host master VBUSP read/write latency is low.

10.2.1.4.7 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP and TCP over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the **s_cn_switch** bit must be set for the **vlan_ltype_outer** to be supported. Because it's not now a dual vlan switch, A C-switch cannot have an outer VLAN. An S-switch can have an inner, an outer, or both (outer then inner).

10.2.1.4.7.1 CPPI THost Checksum Offload

When **p0_tx_chksum_en** is set in **P0_Control**, IPV4 and IPV6 UDP and TCP packets received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The EOP THost buffer descriptor bit **chksum_encap** indicates whether or not the THost checksum information is included with the THost egress packet or not. If the checksum information is included in the packet the **packet_length** includes the four checksum information bytes. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLANs. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host (no checksum information with the error packet).

10.2.1.4.7.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

10.2.1.4.7.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

10.2.1.4.7.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.

- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

10.2.1.4.7.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

10.2.1.4.7.1.5 THost Checksum Encapsulation Word

The 4-byte checksum encapsulation word is included as the last 4-bytes of the THost packet data when EOP buffer descriptor **chksum_encap** is set. The **packet_length** includes the four encapsulation bytes.

THost Checksum Encapsulation Word																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Name	Description
31:21	reserved	
20	ipv4_valid	IPV4 Valid – An IPV4 TCP or UDP packet was detected
19	ipv6_valid	IPV6 Valid – An IPV6 TCP or UDP Packet was detected
18	tcp_udp_n	TCP or UDP packet – Valid only when either the ipv4_valid or ipv6_valid bits are set. 0 – Indicates UDP packet was detected. 1 – Indicates TCP packet was detected.
17	fragment	Fragment – Indicates that an IP fragment was detected. Valid only when when either the ipv4_valid or ipv6_valid bits are set.
16	checksum_error	Checksum Error detected. Valid only when either the ipv4_valid or ipv6_valid bits are set.

Field	Name	Description
15:0	checksum_add	Checksum Add Value – This is the value that was summed during the checksum computation. This value is 0xffff for IPV4/6 UDP/TCP packets with no checksum error.

10.2.1.4.7.2 CPPI FHost Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The **rx_chksum_en** bit in the **P0_CONTROL** register must be set for receive checksum operation to be enabled. When enabled and when the **chksum_encap** SOP FHost buffer descriptor is set, the first four packet bytes contain the checksum information which determines how the checksum is calculated. The **checksum_result** field determines where the checksum is inserted in the egress packet. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

10.2.1.4.7.2.1 FHost Checksum Encapsulation Word

The 4-byte FHost checksum encapsulation word is included as the first four bytes of the packet data when **chksum_encap** is set in the FHost SOP buffer descriptor. The **packet_length** includes the four checksum encapsulation bytes.

FHost Checksum Encapsulation Word																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

																h		e															
																k		s															
																s		e															
																u		r															
																m		v															
																-		e															
																i		d															
																n																	
																v																	

Field	Name	Description
31:24	checksum_result	Checksum Result Byte Location – This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is byte 1 (not byte zero).
23:16	checksum_start_byte	Checksum Start Byte – This is the packet byte number to start the checksum calculation on. The first packet byte is byte 1.
15	chksum_inv	Checksum Invert Zero – When set, a zero checksum value will be inverted and sent as 0xffff.
14	reserved	
13:0	checksum_bytecount	Checksum Byte Count – This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

10.2.1.4.8 Egress Packet Operations

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations. **Intra**VLAN processing either adds, removes, or replaces VLAN information or does nothing. **Inter**VLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, OAM loopback allows the loopback packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

10.2.1.4.8.1 IntraVLAN Processing

All ports (Ethernet and CPPI) process packet VLAN's identically on cpsw egress. CPSW ingress packet VLAN's are not modified on ingress regardless of the port type or VLAN mode.

10.2.1.4.8.1.1 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is cleared to zero. In VLAN unaware mode, transmit (egress) packets are not modified on egress (no IntraVLAN processing).

10.2.1.4.8.1.2 VLAN Aware Mode

An egress port is operating in the VLAN aware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is set. In VLAN aware mode, transmitted packet data is changed depending on the packet type, the packet priority (**pkt_pri**), and the VLAN information as shown in the below tables. The **vlan_ltype_sel** value is selected by the **s_cn_switch** bit in the **CPSW_Control** register and is either the **vlan_ltype_inner** (0x8100 default) or **vlan_ltype_outer** (0x88a8 default) value. The **force_untagged_egress** bit comes from the Address Lookup Engine (ALE) lookup:

VLAN Aware Mode Non Tagged Transmit Packet Processing	
Insert VLAN Case	Non-tagged input packets have the header packet VLAN inserted when the force_untagged_egress bit in the transmit packet header (from the ALE) is de-asserted. The vlan_ltype_sel length/type is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the hdr_pkt_pri , the hdr_pkt_cfi , and the hdr_pkt_vid . The packet length/type field is output four bytes later than it is input and is not removed or replaced.
No Change Case	Non tagged input packets are output unchanged when the force_untagged_egress transmit packet header bit is asserted.

VLAN Aware Mode Priority Tagged Transmit Packet Processing	
Replace PRI/VID Case	Priority tagged input packets have the packet VLAN ID (VID) and the packet priority replaced with the hdr_pkt_vid and the hdr_pkt_pri when the transmit packet header force_untagged_egress bit (from the ALE) is de-asserted.
Remove VLAN Case	Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header force_untagged_egress bit (from the ALE) is asserted. The vlan_ltype_sel length/type is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on.

VLAN Aware Mode VLAN Tagged Transmit Packet Processing	
Replace PRI Case	VLAN tagged input packets are output with the packet priority replaced with the hdr_pkt_pri when the transmit packet header force_untagged_egress bit is de-asserted.
Remove VLAN Case	VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header force_untagged_egress bit is asserted. The vlan_ltype_sel length/type is removed as is the two byte packet VLAN. Input 64-67 byte VLAN tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte VLAN tagged packets use all four input CRC bytes as pad, input 65-byte VLAN tagged packets use three of the input CRC bytes as pad, and so on. The output CRC is generated when the VLAN is removed.

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (Ethernet and CPPI port egress) if the VLAN is to be removed on egress.

10.2.1.4.8.2 ALE Egress Opcode Operations

The Address Lookup Engine (ALE) can be setup to pass an 8-bit opcode to the destination port(s) egress packet processing logic. InterVLAN routing and OAM Source/Destination address swap are supported operation codes as shown in the below table.

ALE Egress OP Code	Egress Operation
0x00	No egress opcode (NOP)
0x01	InterVLAN (route) opcode 1
0x02	InterVLAN (route) opcode 2
0x03	InterVLAN (route) opcode 3
0x04	InterVLAN (route) opcode 4
0x05-0xFE	reserved
0xFF	DA/SA Swap opcode

10.2.1.4.8.2.1 InterVLAN Routing

The CPSW is capable of InterVLAN routing with a limited number of routes (InterVLAN opcode 1 to 4). The Address Lookup Engine (ALE) determines an InterVLAN egress opcode for each packet to be VLAN routed via a classifier/policer configured for the route. Non VLAN routed packets do not have an InterVLAN (egress) opcode. The ALE classifier/policer can use the ingress packet destination address, source address, VLAN, IPDA, and/or IPSA to determine if a packet is to be VLAN routed or not. If a packet is to be routed, then the InterVLAN opcode is used on Ethernet packet egress with a total of 4 available VLAN routes (opcodes) per egress port. Each InterVLAN routing opcode contains the below fields in the opcode's associated **Pn_InterVLAN_OPX_x** registers (where **x** = A to D):

Field	Description
da[47:0]	Destination Address
sa[47:0]	Source Address
vid[11:0]	VLAN ID
replace_da_sa	When set, the routed packet Destination Address is replaced with da[47:0] and the packet Source Address is replaced with sa[47:0] from InterVLAN opcode x (the selected egress opcode).
replace_vid	When set, Replace the packet VLAN ID with vid[11:0] from InterVLAN opcode x (the selected egress opcode).
dest_force_untagged_egress	Remove the VLAN on the egress routed packet when set (associated with the destination VLAN). <div style="text-align: center;"> Note </div> <p>The ALE force_untagged_egress bit from the ALE is for the source VLAN and is ignored for an InterVLAN routed packet. On InterVLAN routed packets this bit is used because it is associated with the destination vlan. This dest_force_untagged_egress bit would not be set by software if the destination VLAN is different from the port VLAN since that might cause leaky VLANs.</p>
decrement_ttl	When set, the Time To Live (TTL) field in the header is decremented: <ul style="list-style-type: none"> IPV4 – Decrement the TTL byte and update the Header Checksum IPV6 – Decrement the Hop Limit. <p>note: The ALE will send any IPv4/6 packet with a zero or one TTL field to the host. When this bit is cleared the TTL/Hop Limit fields are not checked or modified.</p>

10.2.1.4.8.2.2 OAM Source and Destination Address Swap

To facilitate OAM or generic testing, the ALE can be configured to loopback packets from Ethernet receive to Ethernet Transmit. Packets destined for OAM loopback have only the source address and destination addresses swapped. No other egress processing is performed. The ALE does not perform lookups for a port in OAM loopback mode, but directed packets are transferred as normal.

10.2.1.4.9 IEEE 1588 Clock Synchronization Support

The CPSW supports 1588 clock synchronization (annex D, annex E, and annex F). Ethernet GMII Transmit and receive time sync operation are supported. Time sync is double-step on egress but may be single-step on ingress.

10.2.1.4.9.1 1588 Receive (Ingress) Packet Operation

There are two CPSW egress time sync interfaces for each Ethernet port. The first is the TS_RX_MII interface and the second is the TS_RX_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW that control time sync operations in addition to the registers in the CPTS module. The TS_RX_MII interface issues a record signal along with a handle to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets "in flight" from the TS_RX_MII to the TS_RX_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received. The TS_RX_MII logic is in the receive wireside clock domain. There is no decode logic in the TS_RX_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS_RX_DEC block along with the packet. The packet decode is performed in the TS_RX_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS_RX_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_RX_DEC interface. If the packet is determined to be a time sync event packet and if the ALE did not drop the packet (the packet was to be sent to at least one port), then the ALE lookup is overridden and the packet is forced only to the host. The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). A packet is determined to be a receive event packet under the following conditions.

Note

TS_RX_DEC and TS_RX_MII are internal interfaces that have no registers. They are included here for description purposes only.

10.2.1.4.9.1.1 Annex D (IPv4)

1. Receive annex D time sync is enabled (**pn_ts_rx_annex_d_en** is set in the **Pn_TS_Ctl** register).
2. One of the sequences below is true.
 - The first packet LTYPE matches 0x0800
 - The first packet LTYPE matches **ts_vlan_ltype1** and **ts_rx_vlan_ltype1_en** is set and the second packet LTYPE matches 0x0800
 - The first packet LTYPE matches **ts_vlan_ltype2** and **ts_rx_vlan_ltype2_en** is set and the second packet LTYPE matches 0x0800
 - The first packet LTYPE matches **ts_vlan_ltype1** and **ts_rx_vlan_ltype1_en** is set and the second packet LTYPE matches **ts_vlan_ltype2** and **ts_rx_vlan_ltype2_en** is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.
4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)

5. Byte 22 contains 0x01 (HOP Limit = 1) if the `ts_ttl_nonzero` bit in the switch `Pn_TS_CTL_LTYPE2` register is zero, or byte 22 contains any value if `ts_ttl_nonzero` is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is zero and Bytes 30 through 33 contain:
 - Decimal 224.0.1.129 and the `ts_129` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.130 and the `ts_130` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.131 and the `ts_131` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.132 and the `ts_132` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.0.107 and the `ts_107` bit in the `Pn_TS_Ctl_Ltype2` register is set

Or:

The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is set and Bytes 30 through 33 contain any values.

8. Bytes 36 and 37 contain:
 - Decimal 0x01 and 0x3f respectively and the `ts_319` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 0x01 and 0x40 respectively and the `ts_320` bit in the `Pn_TS_Ctl_Ltype2` register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the `ts_msg_type_en` field in `Pn_TS_Ctl`.
11. The packet was received without error (not long/short/mac_ctl/crc/code/align).

10.2.1.4.9.1.2 Annex E (IPv6)

1. Receive annex E time sync is enabled (`pn_ts_rx_annex_e_en` is set in the switch `Pn_TS_Ctl` register).
2. One of the sequences below is true.
 - The first packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype1` and `ts_rx_vlan_ltype1_en` is set and the second packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype2` and `ts_rx_vlan_ltype2_en` is set and the second packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype1` and `ts_rx_vlan_ltype1_en` is set and the second packet LTYPE matches `ts_vlan_ltype2` and `ts_rx_vlan_ltype2_en` is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the `ts_ttl_nonzero` bit in the switch `Pn_TS_Ctl_LTYPE2` register is zero, or byte 21 contains any value if `ts_ttl_nonzero` is set. Byte 21 is the TTL/HOP field.
6. The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is zero and Bytes 38 through 53 contain:
 - FF0M:0:0:0:0:0:0181 and the `ts_129` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0182 and the `ts_130` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0183 and the `ts_131` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0184 and the `ts_132` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:006B and the `ts_107` bit in the `Pn_TS_Ctl_Ltype2` register is set (all values above are 16-bit hex numbers with M is enabled in the `ts_mcast_type_en` field in the `Pn_TS_Ctl2` register).

Or:

The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is set and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - Decimal 0x01 and 0x3f respectively and the `ts_319` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 0x01 and 0x40 respectively and the `ts_320` bit in the `Pn_TS_Ctl_Ltype2` register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the `ts_msg_type_en` field in `Pn_TS_Ctl`.
10. The packet was received without error (not long/short/mac_ctl/crc/code/align).

10.2.1.4.9.1.3 Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (`ts_rx_annex_f_en` is set in the switch `Pn_TS_Ctl` register).
2. One of the sequences below is true.

- The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
3. The PTP message begins in the byte after the LTYPE.
 4. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
 5. The packet was received without error (not long/short/mac_ctl/crc/code/align).

10.2.1.4.9.2 1588 Transmit Packet Operation

There are two CPSW transmit time sync interfaces for each Ethernet port. The first is the TS_TX_DEC interface and the second is the TS_TX_MII interface. Both interfaces are internal to the cpsw and are input to the CPTS module.

The TS_TX_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_TX_DEC interface (**pn_ts_tx_dec_evtnt**, **pn_ts_tx_dec_hdl[3:0]**, **pn_ts_tx_dec_msg_type[3:0]**, **pn_ts_tx_dec_seq_id[15:0]** and **pn_ts_rx_dec_domain[7:0]**). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS_TX_MII with an indication that the packet is a time sync event packet. Unlike receive; only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encrypt the packet. The encryption is after the decode function on transmit (egress). A packet is determined to be a transmit event packet under the following conditions.

10.2.1.4.9.2.1 Annex D (IPv4)

1. Transmit time sync is enabled (ts_tx_annex_d_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
 - The first packet LTYPE matches 0x0800
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set (PN_TS_VLAN_LTYPE register) and the second packet LTYPE matches 0x0800
 - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches 0x0800
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en (PN_TS_CTL_REG) is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present then the byte numbers push down.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the `ts_ttl_nonzero` bit in the switch `Pn_TS_Ctl_LType2` register is zero, or byte 22 contains any value if `ts_ttl_nonzero` bit is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The `pn_ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is zero and bytes 30 through 33 contain:
 - Decimal 224.0.1.129 and the `ts_129` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.130 and the `ts_130` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.131 and the `ts_131` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.1.132 and the `ts_132` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 224.0.0.107 and the `ts_107` bit in the `Pn_TS_Ctl_Ltype2` register is set

Or:

The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - Decimal 0x01 and 0x3f respectively and the `ts_319` bit in the `Pn_TS_CTL_Ltype2` register is set, or
 - Decimal 0x01 and 0x40 respectively and the `ts_320` bit in the `Pn_TS_CTL_Ltype2` register is set.
9. The PTP message begins in byte 42 (this is offset 0).
10. The packet message type is enabled in `ts_msg_type_en` field in the `Pn_TS_Ctl` register.
11. The packet was sent by the host (port 0).

10.2.1.4.9.2.2 Annex E (IPv6)

1. Transmit annex E time sync is enabled (`ts_tx_annex_e_en` is set in the `Pn_TS_Ctl` register).
2. One of the sequences below is true.
 - The first packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype1` and `ts_tx_vlan_ltype1_en` is set and the second packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype2` and `ts_tx_vlan_ltype2_en` is set and the second packet LTYPE matches 0x86dd.
 - The first packet LTYPE matches `ts_vlan_ltype1` and `ts_tx_vlan_ltype1_en` is set and the second packet LTYPE matches `ts_vlan_ltype2` and `ts_tx_vlan_ltype2_en` is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the `ts_ttl_nonzero` bit in the switch `Pn_TS_Ctl_LType2` register is zero, or byte 21 contains any value if `ts_ttl_nonzero` is set. Byte 21 is the TTL/HOP field.
6. The `ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is zero and Bytes 38 through 53 contain:
 - FF0M:0:0:0:0:0:0:0:181 and the `ts_129` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0:0:182 and the `ts_130` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0:0:183 and the `ts_131` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0:0:184 and the `ts_132` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - FF0M:0:0:0:0:0:0:0:006B and the `ts_107` bit in the `Pn_TS_Ctl_Ltype2` register is set (all values above are 16-bit hex numbers with M is enabled in the `ts_mcast_type_en` field in the `Pn_TS_Ctl2` register.

Or:

The `pn_ts_uni_en` bit in the `Pn_TS_Ctl_Ltype2` register is set and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - Decimal 0x01 and 0x3f respectively and the `ts_319` bit in the `Pn_TS_Ctl_Ltype2` register is set, or
 - Decimal 0x01 and 0x40 respectively and the `ts_320` bit in the `Pn_TS_Ctl_Ltype2` register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the `ts_msg_type_en` field in `Pn_TS_Ctl`.
10. The packet was sent by the host (port 0).

10.2.1.4.9.2.3 Annex F (IEEE 802.3)

1. Transmit time sync is enabled (`ts_tx_annex_f_en` is set in the switch `Pn_TS_Ctl` register).

2. One of the sequences below is true.
 - The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1
 - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
3. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
4. The packet was sent by the host (port 0).

The TS_TX_MII interface issues a single clock record signal at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal along with a handle will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS_TX_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS_TX_DEC to the TS_TX_MII block at any given time. The handle value increments only on time sync event packets. The TS_TX_MII logic is in the transmit wireside clock domain.

Note

TS_TX_DEC and TS_TX_MII are internal interfaces that have no registers. They are included for description purposes only.

10.2.1.4.10 Rate Limiting (Traffic Shaping)

Rate-limit mode is intended to allow some CPPI ingress channels and some Ethernet transmit (switch egress) priorities to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on lower priority non rate-limited channels and FIFO priorities. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited Ethernet ingress traffic can be dropped. For rate limited priorities, the configured transfer rate includes the committed information rate and the excess information rate. The excess information rate will only be attempted to be sent when there is no packet backlog on every priority that does not have the excess information rate enabled. The committed information rate will be sent regardless of network traffic as long as the configuration is not oversubscribed. The excess information rate will be sent only when network conditions allow.

10.2.1.4.10.1 CPPI Port Ingress Rate Limiting

Port 0 FHost operations can be configured to rate limit the packet data for each channel (priority). FHost has 8 priorities for QOS. There is a committed information rate (**P0_Pri_CIR**) and an excess information rate for each priority (**P0_Pri_EIR**). Rate limiting is enabled for a priority when the committed information rate for the

priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. No bulk priority will be enabled to send unless there are **tx_host_blks_rem** number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The “blocks remaining check” ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the ingress priority type must be fixed. Round-robin priority type is not allowed when rate-limiting is configured for any priority. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second for each priority is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

$$\text{Priority Transfer rate in Mbit/s} = \left(\left(\left(\text{Frequency in MHZ} \right) * \text{P0_Pri_CIR} \right) / 32768 \right) + \left(\left(\left(\text{Frequency in MHZ} \right) * \text{P0_PriX_EIR} \right) / 32768 \right)$$

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 10Mbps on priority 7 would give the below:

$$10\text{Mbps} = \sim \left(\left(\left(350 * 936 \right) / 32768 \right) \right), \text{ at } 350\text{Mhz} \text{ and } \text{p0_pri7_cir} \text{ value} = 936 \text{ (no excess information rate)}$$

10.2.1.4.10.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (**Pn_PriX_CIR**) and an excess information rate for each priority (**Pn_PriX_EIR**). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

$$\text{Priority Transfer rate in Mbit/s} = \left(\left(\left(\text{Frequency in MHZ} \right) * \text{Pn_PriX_CIR} \right) / 32768 \right) + \left(\left(\left(\text{Frequency in MHZ} \right) * \text{Pn_PriX_EIR} \right) / 32768 \right)$$

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 100Mbps on priority 7 would give the below:

$$100\text{Mbps} = \sim \left(\left(\left(350 * 9360 \right) / 32768 \right) \right), \text{ at } 350\text{Mhz} \text{ and } \text{pn_pri7_cir} \text{ value} = 9360, \text{ with no excess information rate.}$$

10.2.1.4.11 Transmit Priority Escalation

Bulk (non rate limited) traffic can be escalated in order to preclude starvation of lower bulk traffic priorities from higher bulk traffic priorities. Escalation is configured and enabled in the **PTYPE** register with the **pn_ptype_esc** and **esc_pri_id_val** fields. Escalation can be enabled with rate limited priorities. The rate limited priorities are on the upper priorities starting with priority 7 and going down (consecutively), and therefore, the escalated priorities are on the lower bulk priorities.

10.2.1.4.12 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

10.2.1.4.12.1 EST Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 msb's) and an 8-bit priority fetch allow (8 lsb's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (wire clear is performed with zero allow).
- EST can be used with or without preemption. The `pn_mac_preempt[7:0]` value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified - allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

10.2.1.4.12.2 EST Fetch RAM

- The EST fetch RAM is read/write in the CPSW configuration address space.
- Each Ethernet transmit port has 128 locations in the global EST fetch RAM.
 - Ethernet port 1 has EST fetch RAM addresses 0x000-0x1ff.
 - Ethernet port 2 has EST fetch RAM addresses 0x200-0x3ff, and so on.
- One buffer operation – When `est_onebuf` is set, the 128 port locations operate as one buffer. The `est_bufact` bit in `Pn_FIFO_Status` is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- Two buffer operation - When `est_onebuf` of `PN_EST_CONTROL` register is cleared there are two 64-location buffers with `est_bufsel` selecting the buffer to be used. When the buffer is switched by changing the `est_bufsel` value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the `est_bufact` bit in `Pn_FIFO_Status`. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port's address zero location is then read again at the beginning of the next cycle repeating the time interval packet operations.

10.2.1.4.12.3 EST Time Interval

- Each Ethernet port has an EST function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (`CPTS_RCLK`).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allow (8 lsb's of the fetch command from the EST fetch RAM) value is at the port's base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock delay allows the first fetch value to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when `est_onebuf=0`, and 128 maximum fetch values when `est_onebuf=1`.
- The next cycle start then causes the fetch to once again start at the port's address zero location.

10.2.1.4.12.4 EST Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in gigabit mode (pn_gig=1) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. There is no requirement that the packet end in the time interval. The actual packet transmission on the wire may carry over into the next fetch count - which is the reason for the wire clear time in a fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time. However, if a packet were enabled in a previous fetch allow there the packet could finish in the current time interval.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks (minimum of 16 fetch count).
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. However, packets that were started in the previous interval could still be on the wire. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch.
- EST Ram Configuration – The simplest EST configuration is for a single express packet on a single priority in the EST time interval. Ram Address 0 will be read at the start of each interval, the timed packet goes out in Ram Address 1 interval, and Ram Address 2 priorities are held for the duration of the cycle in this simple configuration.
 - Ram Address 0 – 0xD0000 (10/100 with 1518 max pkt length in previous allow)
 - This is a zero allow at the beginning of each cycle which clears the wire for the timed express packet in the next fetch. The zero allow time (0xD00 in this case) allows the wire to be cleared for the express packet. Setting this value lower might push out the timed express packet into the next interval. For a 2020 max packet size in the previous allow, this value should be 0x10F400. The number of clocks required for the zero allow is determined by the below equation.
 - Clocks in zero allow = Maximum **Express** packet length in previous allow (times 2 for 10/100) + decimal 292. (If preemption is configured and enabled then this minimum time is 0x100 if only preempt priorities are in the previous allow – which is not a normal case).
 - Ram Address 1 – 0x01080
 - This is a decimal 16 clock allow for the timed express packet on priority 7. The 16 clock allow value permits only a single packet to start in the time interval.
 - Ram Address 2 – 0x0007F
 - This is a zero fetch count that allows priorities 6 down to 0 for the duration of the EST time interval. This is the previous allow for the zero allow in Address 0 above.

10.2.1.4.12.5 EST Packet Fill

- Packet fill can (should) be configured and enabled to occur in the fetch count time associated with a fetched zero allow that precedes a timed express packet. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch. Incorrect configuration might push out in time any express timed packet which indicates that the fill margin needs to be increased.
- Fill Configuration
 - The est_fill_margin value in Pn_EST_Control should be written with a 0x100 value.

- The `est_prempt_comp` value in `Pn_EST_Control` should be written with a 0x12 value (if IET is to be configured and enabled). This value times eight is the number of wireside clocks required to clear preempt packets off the wire at the end of a zero allow.
- The `est_fill_en` bit in `Pn_EST_Control` should be set.

10.2.1.4.12.6 EST Time Stamp

- EST can be configured to generate CPTS timestamp events for selected express traffic.
- EST timestamp events use the CPTS host event type (`event_type=7`). EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.
- EST Events (host events `EVENT_n_REG`) contain the below information:
 - Time Stamp of the selected express packet.
 - The event `port_number` indicates the transmit port number.
 - The event `event_type` is decimal 7 (host event).
 - The event `message_type` indicates the packet transmit hardware switch priority.
 - The event `sequence_id` upper nibble indicates the packet receive port number.
 - The event `sequence_id` lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence id rolls over to zero after 0xff (8-bits).
 - The event domain is the value from the `est_ts_domain[8:0]` register.
- When `est_ts_en` is set, timestamp events will be generated on selected express traffic.
- When `est_ts_first` is also set, events will be generated only on the first express packet in each time interval. If `est_ts_onepri` is also set then the event will only be on the first `est_ts_pri` express packet in the time interval. If `est_ts_onepri` is clear then the event will be generated on the first express packet in the time interval on any priority.
- When `est_ts_first` is clear, events will be generated on every express packet. If `est_ts_onepri` is set then the event will be generated on every `est_ts_pri` express packet. If `est_ts_onepri` is clear then event will be generated on every express packet on any priority.

10.2.1.4.12.7 EST Packets Per Priority – (N = 2 only)

With a MAC configuration ($N = 2$), the number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to `p0_rx_pkts_pri[7:0]`. The port 0 receive gap should then be enabled by setting the corresponding priority `rx_gap_en[7:0]`. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority than the `p0_rx_pkt_pri[7:0]` value has selected.

10.2.1.4.13 DSCP

The ALE can map DSCP field to priority prior to port trunking hashing and policing/classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See the Switch Port configuration for the registers describing DSCP mapping.

10.2.1.4.14 Packet Priority Handling

There are three priorities used inside the CPSW - the packet priority, the header packet priority, and the switch priority. The packet priority is the determined priority of the ingress packet. The header packet priority is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The switch priority determines which of the eight FIFO priority queues the packet uses during egress.

The `vlan_ltype_sel` value below is selected by the `s_cn_switch` bit in the `CPSW_Control` register and is either the `vlan_ltype_inner` (0x8100 default) or `vlan_ltype_outer` (0x88a8 default) value.

10.2.1.4.14.1 Ethernet Port Ingress

Ethernet ingress packets have an ingress packet priority of 0 to 7 (with 7 being the highest priority). The packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the ingress packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and dscp_ipv4_en is set in Pn_Control, then the ingress packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in Pn_Control, then the ingress packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the ingress packet priority is the source (ingress) port priority taken from the port's Pn_Port_VLAN register.

The packet priority is mapped through the ingress port's associated "packet priority to header packet priority mapping register" (**pn_rx_pri_map**) to obtain the header packet priority (**hdr_pkt_pri**). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress. The header packet priority is mapped at each destination FIFO through the **pn_tx_pri_map** register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

10.2.1.4.14.2 CPPI Port FHost (Ingress)

FHost packets have a packet priority (0 to 7 with 7 being the highest priority). The FHost packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the FHost packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and p0_dscp_ipv4_en is set in P0_Control, then the FHost packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in P0_Control, then the FHost packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the FHost packet priority is the source port priority taken from P0_Port_VLAN.

The ingress packet priority is mapped through the port's associated "packet priority to header packet priority mapping register" (**p0_rx_pri_map**) to obtain the header packet priority. The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

For CPPI FHost packets, the destination port hardware switch priority is the below selected value remapped through **p0_rx_pri_map**:

1. If the FHost packet is priority tagged or vlan tagged:
 - If rx_remap_vlan is clear then the destination hardware switch priority is the CPPI FHost channel number.
 - If rx_remap_vlan is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 FHost. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and **dscp_ipv4_en** is set in **P0_Control**:
 - If rx_remap_dscp_v4 is clear then the destination hardware switch priority is the CPPI ingress priority.
 - If rx_remap_dscp_v4 is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet). Port 1 transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
3. Else if the ingress packet has the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and **dscp_ipv6_en** is set in **CPPI_P0_Control**:

- If `rx_remap_dscp_v6` is clear then the destination hardware switch priority is the CPPI ingress priority.
 - If `rx_remap_dscp_v6` is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (`Pn_Tx_Pri_Map` should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI ingress channel number.

10.2.1.4.14.3 CPPI Port THost (Egress)

If the `thost_ch_override` bit in `CPDMA_Control` is clear then the CPDMA packet THost channel number is the port 0 hardware switch priority. If `thost_ch_override` is set, then for packets with a classification match the THost channel number is the lower three bits of the 6-bit address lookup engine classification match value (`threadval[2:0]` in ALE register `THREADMAPVAL`). The `flow` value in the VLAN encapsulation word is all 6 bits of the `threadval` for classifier matches regardless of the setting of `thost_ch_override` if the encapsulation word is transferred.

10.2.1.4.15 Packet CRC Handling

Every cpsw ingress packet on all ports is checked for CRC correctness. Each packet is then given an internally generated Castignoli CRC for transport through the cpsw to egress port(s). The internally generated Castignoli CRC protects the packet from end to end through the cpsw. Ingress Packets with CRC errors are handled as indicated below.

10.2.1.4.15.1 Ethernet Port Ingress

Ethernet ports check each ingress packet CRC for correctness in all modes/speeds. The port can check for either Ethernet CRC for correctness as determined by the `crc_type` bit in the `Mac_Control` register. Ethernet packets received with a CRC error are dropped at the receive port unless the receive port `rx_cef_en` bit is set. Error packets are sent only to the host port. For packets with Ethernet ingress errors sent to the host, the error is indicated in the host egress buffer descriptor and the original packet CRC bytes are kept for CPDMA THost.

10.2.1.4.15.2 Ethernet Port Egress

Ethernet ports transmit egress packets with the CRC type selected by the `crc_type` bit in the `Pn_Mac_Control` register regardless of the packet's ingress CRC type. On Ethernet egress, after passing through the switch, the internally generated Castignoli CRC is checked for correctness and if correct the packet is output with the generated selected output CRC type. If the internally generated CRC is incorrect, due either to a bit flip in a memory (or logic) or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the internally generated Castignoli CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

10.2.1.4.15.3 CPPI Port FHost

CPPI host port FHost packets can be passed in with or without a CRC. The FHost packet CRC type is indicated in the buffer descriptor word `crc_type` bit and can be Ethernet. The `p0_rx_pass_crc_err` bit in the `CPSW_Control` register determines if FHost packets with CRC errors are passed or dropped. Passed packets with CRC errors will be transmitted on Ethernet egress with a CRC error.

10.2.1.4.15.4 CPPI Port Egress (THost)

The `p0_tx_crc_remove` bit in the `CPSW_Control` register determines if all CPPI THost packets have a CRC included or not. THost packets not filtered on Ethernet ingress due to `pn_rx_cef_en` have the packet error CRC included (not replaced by the egress CRC type) if the CRC is not removed on egress. The error is indicated in the buffer descriptor. CPPI THost packets that detected a CRC error on the internally generated Castignoli CRC, due to a bit flip in logic or memory, will indicate the error with the `drop` bit set in the buffer descriptor.

10.2.1.4.16 Ethernet FIFO

Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority) regardless of the memory configuration. The receive logical FIFO is combined with the transmit logical FIFO into the same RAM instance. The receive FIFO is used for single packet reception and error detection and flow control runout. Packets are queued on transmit. Ethernet FIFO size is 20 KBytes.

10.2.1.4.17 Ethernet Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the Mac from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X or Priority Based Flow Control (PFC) pause frames. In all cases, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx_flow_en** bit in the **Pn_Mac_Control** register, and **rx_flow_pri[7:0]** in **Pn_Pri_Ctl**. For 10/100 modes of operation, collision or IEEE 802.3X flow control is determined via the **fullduplex** bit in the **Pn_Mac_Control** register. The **fullduplex** bit must be set for Priority Based Flow Control.

10.2.1.4.17.1 MII (10/100) Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex** is cleared in **Pn_Mac_Control**). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

10.2.1.4.17.2 IEEE 802.3X (10/100/1G/10G) Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex** is set in **Pn_Mac_Control**). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Mac will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 down to zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full at which time the receive FIFO will overrun and **Rx_Top_Of_FIFO_Drop** will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Mac will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address – Pn_SA(47:0) (PN_SA_L, PN_SA_H registers).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte packet length (The MAC will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx_flow_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

10.2.1.4.17.2.1 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to **rx_flow_thresh**. The flow control packet runout is then contained in the remainder of the receive FIFO.

10.2.1.4.17.3 Ethernet Transmit Flow Control

10.2.1.4.17.3.1 IEEE 802.3X (10/100/1G/10G) Based Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Mac from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx_flow_en** bits in the **Pn_Mac_Control** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the **rx_cmf_en** (Copy MAC Frames) bit in the **Pn_Mac_Control** register is set. The **tx_flow_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- **tx_flow_en** is set in **Pn_Mac_Control**, and
- the frame's length is 64 to **rx_maxlen** bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx_flow_en** in **Pn_Mac_Control** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**MRXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
 - The reserved multicast destination address 01.80.C2.00.00.01, or
 - The **Enet_Pn_SA[47:0]** input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte packet length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The MAC will recognize any pause frame between 64 bytes and **rx_maxlen** bytes in length.

10.2.1.4.18 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the external clock controller to turn off (in a glitch-less manner) the module input clock (**CLK**) during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE is supported in MII/GMII/RGMII but not RMII, The chosen PHY must also support EEE. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the switch **EEE_Prescale** register. The pre-scaler is used to clock all EEE related counters.
2. The port Idle to LPI count values (**Pn_Idle2LPI**) are written with the desired values.
3. The port LPI to Wake count values (**Pn_LPI2Wake**) are written with the desired values.
4. The **eee_en** bit is set in the switch **CPSW_Control** register.

Energy Efficient Ethernet operation can begin after configuration. The host allows the module to enter a low power state by asserting the **CLKSTOP_REQ** signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert **CLKSTOP_REQ**.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the MII/RGMII interface. The PHY indicates LPI by asserting **GMII_MRXER_SEL** with a **GMII_MRXD[7:0]** value of 0x01 while **GMII_MRXDV** is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the **PX_Idle2LPI** value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted **GMII_MTXER** with a **GMII_MTXD[7:0]** value of 0x01. while **GMII_MTXEN** is deasserted (inter-packet gap). The CPPI LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive interfaces have both been idle for the Idle to LPI time (**P0_Idle2LPI**). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the **CLKSTOP_ACK** signal is asserted, and the external clock controller is allowed to stop the input module clock (**CLK**). The clock must be stopped (and re-started) in a glitch-less manner. When **CLKSTOP_ACK** is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the module memory address space, and then turn off the clock again while **CLKSTOP_ACK** is asserted. The clock must be restarted for two clock periods before the assertion of **SLV_VBUSP_REQ** and must remain asserted for five clock periods after the de-assertion of **SLV_VBUSP_REQ**.

The host can remove and disable from re-entering the CPSW LPI state by restarting the module clock (in a glitch-less manner) and then de-asserting **CLKSTOP_REQ**. There must be at least one rising edge of the clock before **CLKSTOP_REQ** is de-asserted. The module **CLKSTOP_ACK** output signal will be deasserted on the clock after the de-assertion of **CLKSTOP_REQ**. The host may queue CPPI receive packets at any time without regard to the module LPI state. The Host must deassert **CLKSTOP_REQ** on wakeup for a minimum of two clock periods. If **CLKSTOP_REQ** is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet ports to awaken.

The external Ethernet PHY's can also wakeup the external clock controller by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with **CLKSTOP_ACK** asserted and the receive LPI indication is removed, the **CLKSTOP_WAKEUP** signal will be asynchronously asserted. On wakeup, the external clock controller must restart the clock and de-assert the **CLKSTOP_REQ** signal. The **CLKSTOP_WAKEUP** signal will be synchronously deasserted with **CLKSTOP_ACK**. There must be at least one positive edge of the clock

before the **CLKSTOP_REQ** signal is deasserted. Upon the de-assertion of **CLKSTOP_REQ**, the Ethernet ports will count the **Pn_LPI2Wake** time for each port at which time the port is available for transmit.

10.2.1.4.19 Switch Latency

When the CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit. The store and forward latency is shown in the below table:

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

10.2.1.4.20 Emulation Control

The emulation control input (**EMUSUSP**), emulation control register, and the submodule emulation control registers allow CPSW operation to be completely or partially suspended. The CPDMA Host port and each Ethernet port has associated emulation control registers. The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if the switch level emulation control register and all submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or more submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals. The following table shows the operation of the emulation control input and register bits:

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

Note

Enable Suspend control (EMUSUSP) by MSS_CTRL: MSS_DBG_ACK_CTL0[26:24]

10.2.1.4.21 Software IDLE

The software idle register bits enable switch operation to be completely or partially suspended by software control. Each Ethernet port may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled port until the idle command is removed. The CPSW software idle inhibits packets from starting to be unloaded from each port switch FIFO, but packets already in process are unaffected.

10.2.1.4.22 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of up to 32 external clock sources.
- Software control of time sync events via interrupt or polling.
- Supports 8 hardware timestamp push inputs.
- Supports timestamp counter compare output (TS_COMP).
- Supports timestamp counter bit output (TS_SYNC).
- Supports a configurable number of timestamp Generator bit outputs (TS_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (TS_ESTFn).
- 64-bit timestamp mode with PPM and nudge adjustment.

10.2.1.4.22.1 CPTS Integration

This section describes CPTS module integration in the device, including information about clocks, resets, and hardware requests.

Figure 10-791 shows CPTS integration in the device.

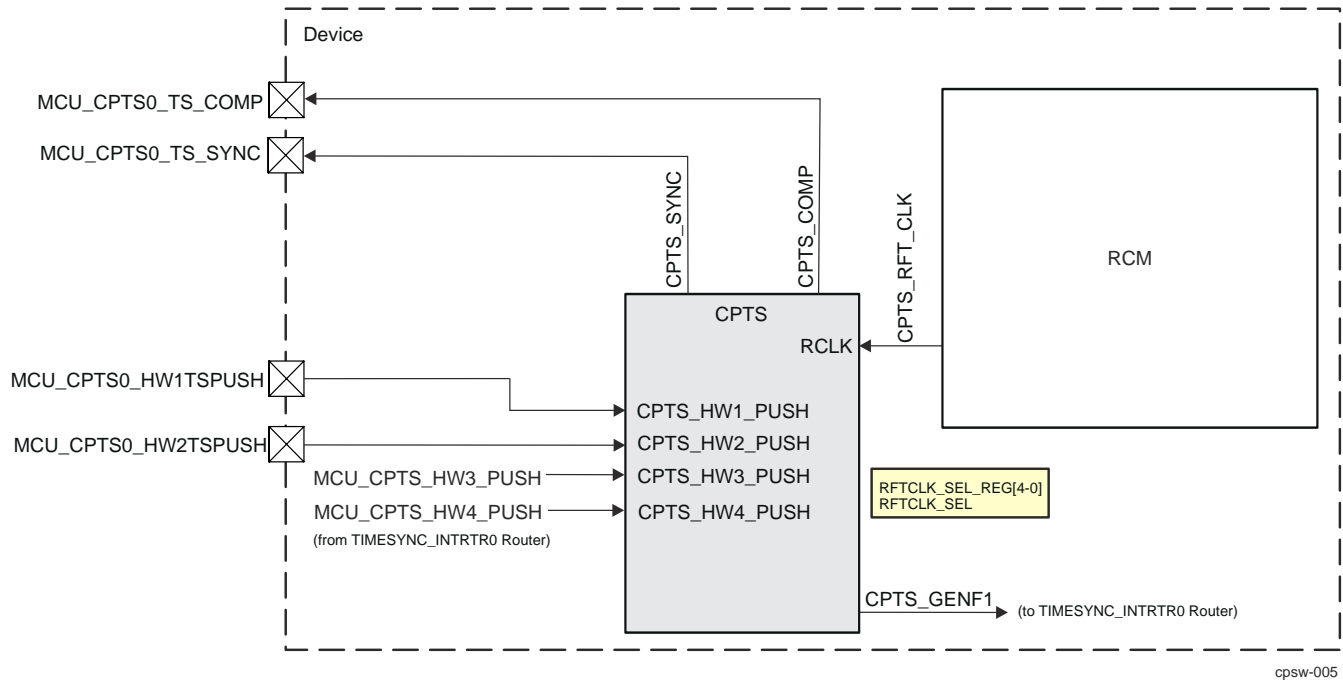

Figure 10-791. CPTS Integration

CPTS IEEE 1588 clock (RCLK) is selected through the CPSW_CPTS_RFTCLK_SEL_REG register.

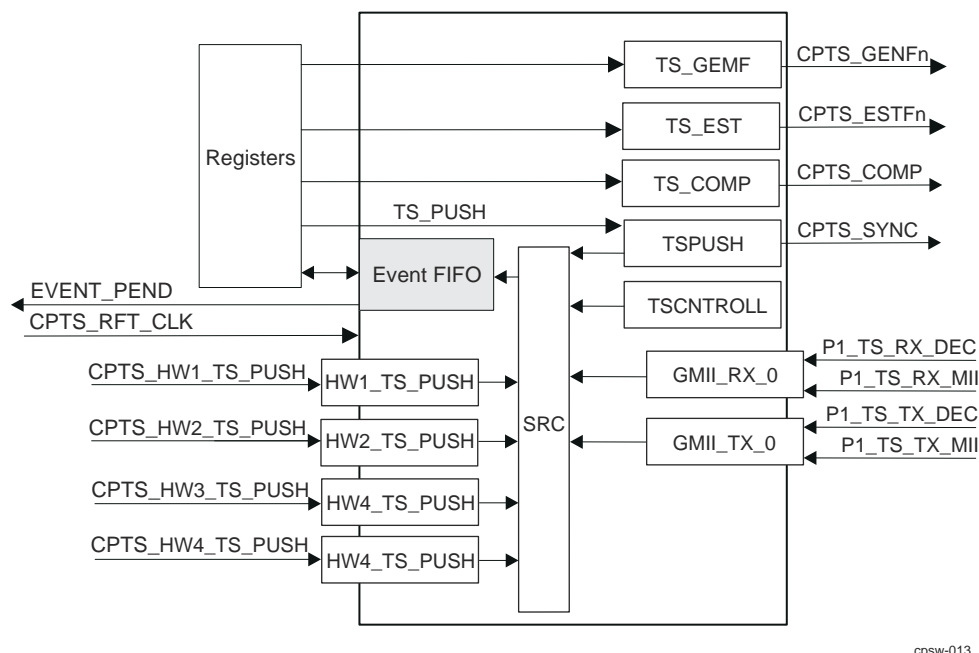

Note

For more information about CPTS clocks and resets, see [Table 10-754](#) in [Section 10.2.1.3 CPSW Integration](#).

10.2.1.4.22.2 CPTS Architecture

Figure 10-792 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources.

cpsw-013

Figure 10-792. CPTS Block Diagram

Note

See [Section 10.2.1.4.22.1](#), *CPTS Integration* for CPTS integration in the device.

10.2.1.4.22.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the **rftclk_sel[4:0]** value in the **RFTCLK_Sel** register with the desired reference clock multiplexor value. This value is allowed to be written only when the **cpts_en** bit in CPTS control register is cleared to zero.
3. Write a one to the **cpts_en** bit in the **TS_Control** register. The **RCLK** domain is in reset while this bit is low.
4. Enable the interrupt by writing a one to the **ts_pend** bit in the **Int_Enable** register (if using interrupts and not polling)..

10.2.1.4.22.4 32-bit Time Stamp Value

The **time_stamp** value is a 32-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments on each **RCLK** rising edge when **cpts_en** is set to one. The time stamp value can be written via the time stamp load function (**TS_Load_En** and **TS_Load_Low_val** registers). Host software maintains the required number of upper bits of the time stamp value. The upper time stamp value is incremented by the host when the rollover event is detected. The **add_val[2:0]** of **TS_ADD_VAL** value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

10.2.1.4.22.5 64-bit Time Stamp Value

The **time_stamp** value is a 64-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments by the increment value (1 to 8) on each **RCLK** rising edge when **cpts_en** is set to one. The increment value is from 1 to 8 (1 + **ts_add_val[2:0]**). The default increment value is one. The time stamp value can be written via the time stamp load function (**TS_Load_En**, **TS_Load_Low_val**, and **TS_Load_High_val** registers). The **add_val** feature (**TS_ADD_VAL_Reg**) is included to allow 1ns timestamp operations with an **RCLK** rate less than 1Ghz. The below table shows the **RCLK** and **add_val** values for 1ns operations. The highest **RCLK** frequency possible should be used as allowed by the technology. [Table 10-773](#) shows the **RFTCLK_SEL** and **TS_ADD_VAL_REG** values for 1ns operations.

Table 10-773. ADD_VAL feature

RFTCLK_SEL (MHz)	TS_ADD_VAL_REG[2:0]
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

10.2.1.4.22.6 64-Bit Timestamp Nudge

The 64-bit **time_stamp** value can be adjusted by writing the **ts_nudge_val[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 **RCLK** from the next incremented **time_stamp[63:0]** value. A nudge value of 0x01 will add 1 **RCLK** to the next incremented **time_stamp[63:0]** value. For example, if the current **time_stamp** value is 0x0f06, and **add_val[2:0]=3**, the next incremented timestamp value would be 0x0f0a without a nudge and 0x0f0a +/- **tx_nudge_val[7:0]** with a nudge. The **ts_nudge** value is cleared to zero when the nudge has occurred.

10.2.1.4.22.7 64-bit Timestamp PPM

The 64-bit **time_stamp** can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the **ts_ppm[41:0]** (**PPM_High** & **PPM_Low**) value enables PPM operations. The adjustment is up or down depending on the **ppm_dir** bit (**TS_control_Reg**). The **time_stamp** value is increased by the PPM value when **ppm_dir** is cleared and decreased by the PPM value when **ppm_dir** is set.

Parts Per Million example:

To adjust for 100 parts per million the configured value for **ts_ppm[41:0]** is:

$$1,000,000/100 = \text{decimal } 10,000$$

Parts Per Hour example:

To adjust for 1 part per hour at 1 Ghz **RCLK** the configured value for **ts_ppm[41:0]** is: (1,000,000,000hz/1pph) * (3600 seconds/hour) = hex 34630B8A000

10.2.1.4.22.8 Event FIFO

The event FIFO contains at least as many locations as two times the number of ports plus 6 locations. Software must service the event FIFO in a timely manner which prevents event FIFO overrun. No overrun indication will be given.

10.2.1.4.22.9 Timestamp Compare Output

The **TS_COMP** function is a software oriented feature that is intended to be replaced going forward by the hardware oriented **GENF** function. **TS_COMP** is not compatible with timestamp PPM or a non-zero **TS_ADD_VAL** value.

10.2.1.4.22.9.1 Non-Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_length[31:0]** **RCLK** periods when the **time_stamp[31:0]** (**EVENT_0_REG**) value compares with the **ts_comp_val[31:0]** and the length value is non-zero. The **TS_COMP** rising edge occurs three **RCLK** periods after the values compare. A timestamp compare event is pushed into the event FIFO when **TS_COMP** is asserted. The polarity of the **TS_COMP** output is determined by the **ts_comp_polarity** bit. The output is asserted low when the polarity bit is low.

10.2.1.4.22.9.2 Non-Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **timestamp[63:0]** are used (**Event_0_reg** and **Event_3_reg**) instead of only the lower 32-bits. The 64-bit timestamp cannot be allowed to rollover.

10.2.1.4.22.9.3 Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_len[31:0]** RCLK periods when the **time_stamp[31:0]** value compares with the **ts_comp_low_val[31:0]** and the length value is non-zero. The **TS_COMP** toggles thereafter on **ts_comp_low_len[31:0]** RCLK periods. The length high or low can be adjusted by writing the **TS_COMP_NUDGE[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 RCLK from the **ts_comp_length[31:0]** value. A value of 0x01 will add 1 RCLK to the **ts_comp_length[31:0]** value. Only a single high or low time is adjusted (nudged) and the **ts_comp_nudge** value is cleared to zero when the nudge has occurred. The **TS_COMP** output is asserted low when the **TS_Comp_Polarity** bit is low. No compare events and no **CPTS_EVNT** interrupts are generated in toggle mode. The **ts_comp_tog** bit must be set for toggle mode, and must be set before writing a non-zero value to **ts_comp_length[31:0]**.

10.2.1.4.22.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **TIMESTAMP** are used (**EVENT_0_REG** and **EVENT_3_REG**). In 32-bit mode only the lower 32-bits (**EVENT_0_REG**) are used.

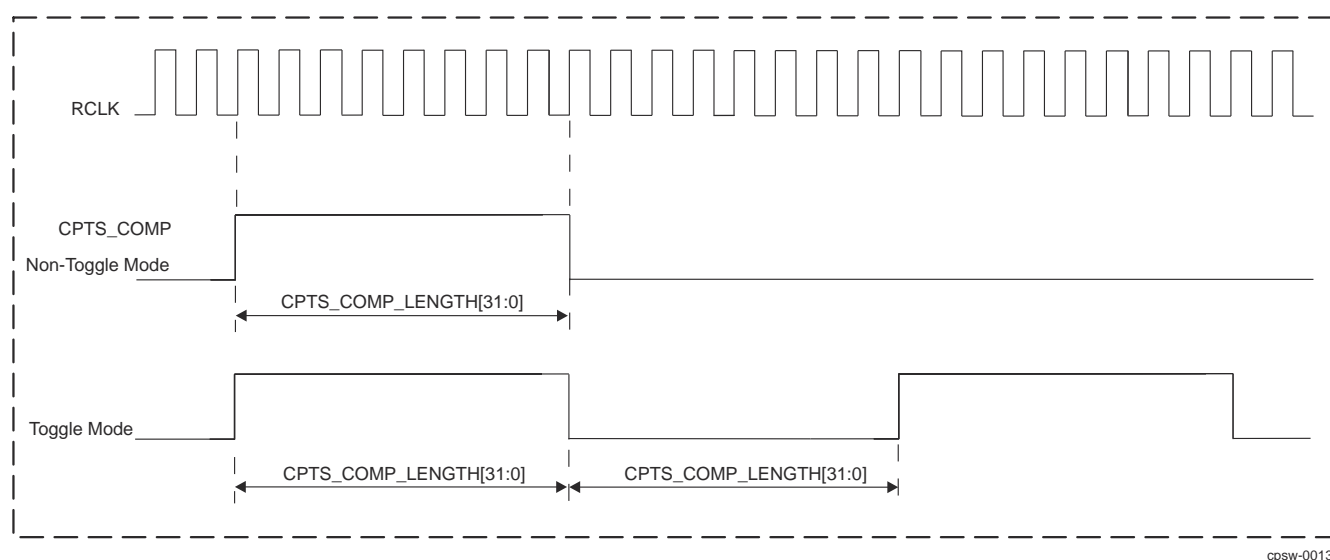

Figure 10-793. CPTS_COMP Output in Toggle and Non-Toggle Mode

10.2.1.4.22.10 Timestamp Sync Output

The **CPTS_SYNC** output is a selected bit of the [31:0]**TIME_STAMP** counter value. One of bits 17-31 can be selected in **CPTS_CONTROL_REG[31-28]** **TS_SYNC_SEL**. The **CPTS_SYNC** output is disabled when **CPTS_CONTROL_REG[31-28]** **TS_SYNC_SEL** is zero.

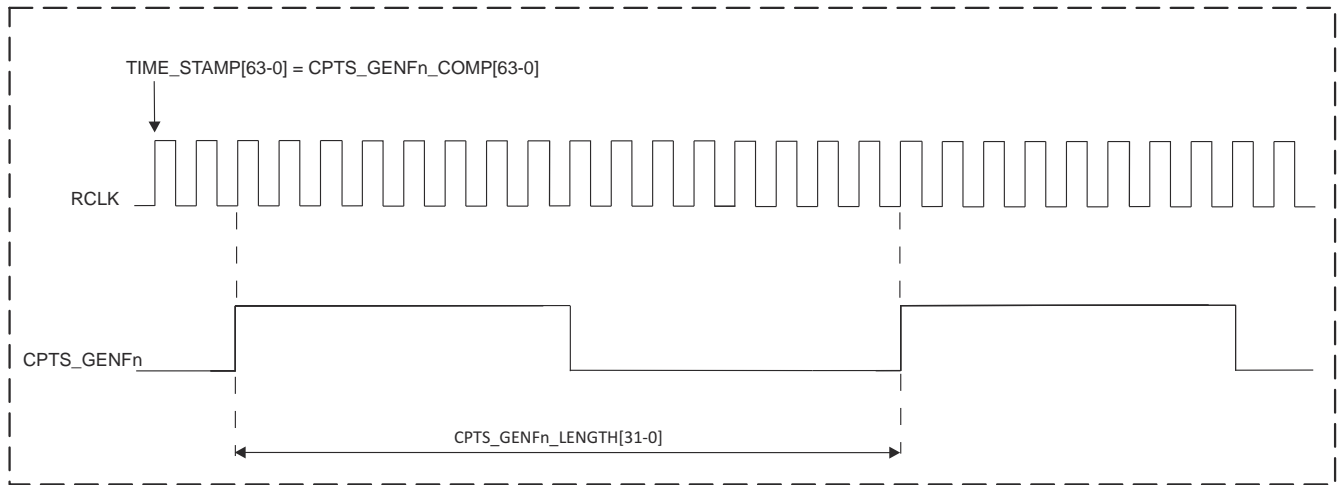

If the selected counter bit is 1 at the time when **TS_SYNC_SEL** value is written then a rising edge will not occur on the **CPTS_SYNC** output. A rising edge will occur on the **CPTS_SYNC** output upon the next transition to 1 of the selected counter bit. The **TS_SYNC_SEL** value must be written to zero before changing to a different non-zero value. No events are generated due to the **CPTS_SYNC** operation. The **CPTS_SYNC** output is two **CPTS_RFT_CLK** periods after the actual count value.

10.2.1.4.22.11 Timestamp GENFn Output

The **CPTS_GENFn** outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The **CPTS_GENFn** output cycle is **CPSW_GENF0_LENGTH_REG_I[31-0]** **CPTS_RFT_CLK** periods (which is different than **CPTS_COMP** operation). [Figure 10-794](#) represents the **CPTS_GENFn** output signal.

The **CPTS_GENFn** output cycle is **CPSW_GENF0_LENGTH_REG_I[31-0]** **CPTS_RFT_CLK** periods beginning when the 64-bit **TIME_STAMP** value compares with the 64-bit **GENFn_COMP** value (**CPSW_GENF0_COMP_LOW_REG_I** and **CPSW_GENF0_COMP_HIGH_REG_I** registers) and the length value is non-zero. The **CPTS_GENFn** output cycle repeats thereafter every **CPSW_GENF0_LENGTH_REG_I[31-0]** **CPTS_RFT_CLK** periods. The upper 32-bit word should be written first

for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is low. No compare events and no CPTS_EVTN interrupts are generated.

cpsw-0013b

Figure 10-794. CPTS_GENFn Output Signal Diagram

10.2.1.4.22.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS_RFT_CLK from the CPSW_GENF0_LENGTH_REG_I[31-0] value. A value of 1h will add 1 CPTS_RFT_CLK to the CPSW0_ESTF1_LENGTH_REG_I[23-0] value. The CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

10.2.1.4.22.11.2 GENFn PPM

The CPTS_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW_GENF0_PPM_LOW_REG_I/ CPSW_GENF0_PPM_HIGH_REG_I enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS_RFT_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW_ESTF1_CONTROL_REG[0] PPM_DIR bit. When PPM_DIR bit is set a single CPTS_RFT_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR bit is cleared a single CPTS_RFT_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_I and CPSW_GENF0_PPM_HIGH_REG_I) is:
 $1,000,000/100 = 10,000$ (decimal)

Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_I and CPSW_GENF0_PPM_HIGH_REG_I) is:
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600\text{ seconds}/\text{hour}) = 34630\text{B8A000}$ (hex)

10.2.1.4.22.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

10.2.1.4.22.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

Word	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
event_0	time_stamp[31:0]																															
event_1	reserved	port_number	port_number	event_type	message_type	sequence_id																										
event_2	reserved																								domain							
event_3	time_stamp[63:0]																															

Name	Description
time_stamp	Time Stamp – The timestamp is valid for transmit, receive, and time stamp push event types. The timestamp value is not valid for counter roll event types.
port_number	Port Number – indicates the port number of an Ethernet event (1 to 4 encoded) or the hardware push number (1 to 8 encoded).

Name	Description
event_type	Time Sync Event Type 0000 – Time Stamp Push Event 0001 – Time Stamp Rollover Event (32-bit mode only) 0010 – Time Stamp Half Rollover Event (32-bit mode only) 0011 – Hardware Time Stamp Push Event 0100 – Ethernet Receive Event 0101 – Ethernet Transmit Event 0110 – Time Stamp Compare Event 0111 – Host Event 1000 --- - reserved 1111
message_type	Message type – The message type value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
sequence_id	Sequence ID – The 16-bit sequence id is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
domain	Domain – The 8-bit domain is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
preempt_queue	Preempt Queue – 0 – The packet was received/transmitted on the express queue. 1 – The packet was received/transmitted on the preempt queue.

10.2.1.4.22.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPSW_CPTS_TS_PUSH_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW_CPTS_EVENT_3_REG register) of the timestamp are zero in 32-bit mode.

10.2.1.4.22.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

10.2.1.4.22.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW_CPTS_EVENT_0_REG[31:0] TIME_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 10-795](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the

time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

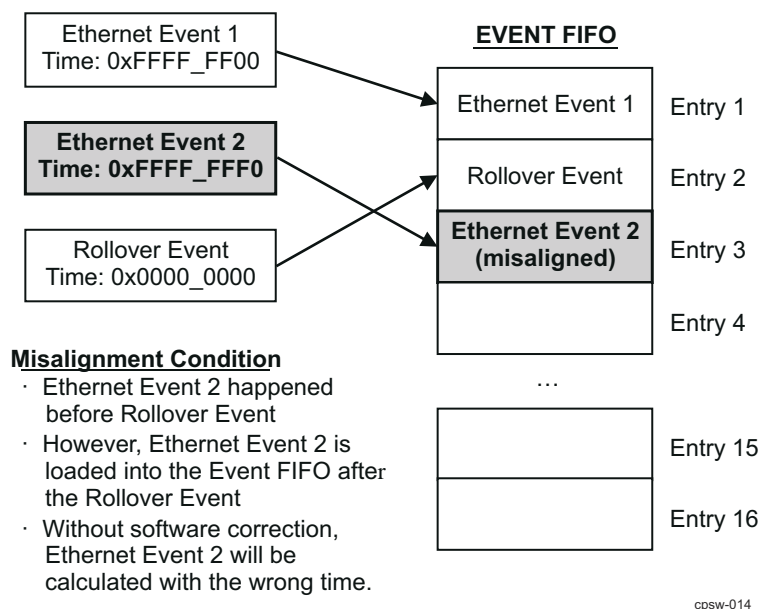

Figure 10-795. Event FIFO Misalignment Condition

10.2.1.4.22.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (CPTS_HW[1:4]_TS_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in Figure 10-791. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPSW_CPTS_EVENT_1_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS_RFT_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW_CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

10.2.1.4.22.13.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 10-796. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field in the CPSW_PN_TS_SEQ_LTYPE_REG register or the TS_LTYPE2 field in CPSW_PN_TS_CTL_LTYPE2_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 10-796. To indicate to the CPTS hardware that a virtual LAN is in use, the TS_TX_VLAN_LTYPE1_EN (or TS_TX_VLAN_LTYPE2_EN) enable bit must be set in the CPSW_PN_TS_CTL_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS_VLAN_LTYPE1 (or TS_VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_PN_TS_VLAN_LTYPE_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 10-796. In this case, both TS_VLAN_LTYPE1 and TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the TS_VLAN_LTYPE1 field, and the inner tag must match the value of the TS_VLAN_LTYPE2 field.

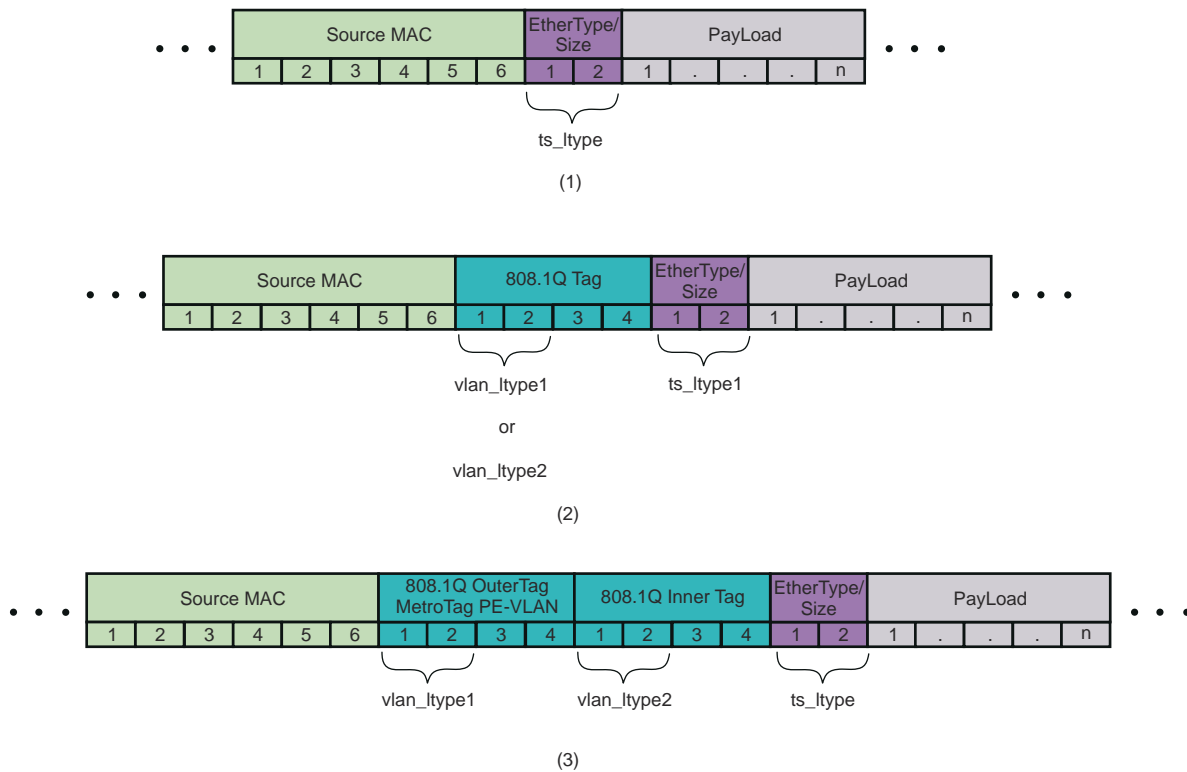

Figure 10-796. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

10.2.1.4.22.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured

by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RFT_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (IPv4)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
 5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if CPSW_PN_TS_CTL_LTYPE2_REG is set to 1h. Byte 22 is the TTL/HOP field.
 6. Byte 23 contains 0x11 (Next Header UDP Fixed).
 7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
 - a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set
- OR-
- The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set -OR-
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
 9. The PTP message begins in byte 42.

10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (IPv6)

1. Receive annex E time sync is enabled (TS_RX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x86dd.
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
 - a. FF0M:0:0:0:0:0:0:0:0:181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. FF0M:0:0:0:0:0:0:0:0:182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. FF0M:0:0:0:0:0:0:0:0:183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. FF0M:0:0:0:0:0:0:0:0:184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. FF0M:0:0:0:0:0:0:0:0:06B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

Note

All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

-OR-

The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1 and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL2_REG register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.
10. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (TS_RX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).

2. One of the sequences below is true:
 - a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

10.2.1.4.22.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (IPv4)

1. Transmit time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800

- c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if TS_TTL_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
 - a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - f. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was sent by host port 0.

Annex E (IPv6)

1. Transmit annex E time sync is enabled (TS_TX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x86dd.
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).

4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
 - a. FF0M:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. FF0M:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. FF0M:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. FF0M:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. FF0M:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

Note

All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

-OR-

The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
10. The packet was sent by host port 0.

Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
 - a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
 - d. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
 - f. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and

- TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
- h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register
 3. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
 4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RFT_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

10.2.1.4.22.13.5.3

Table 10-774. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPTS_EVENT_1 register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_0 (and CPTS_EVENT_3) register contains the time stamp value when the packet arrived at the corresponding port.

10.2.1.4.22.14 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

10.2.1.4.22.14.1 32-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (EVENT_0_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG register and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

10.2.1.4.22.14.2 64-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG) compares with the CPWS0_TS_COMP_VAL_REG and CPWS0_TS_COMP_HIGH_VAL_REG registers and the CPWS0_TS_COMP_LEN_REG value is non-zero. The CPWS0_TS_COMP_LEN_REG value should be written by software after the CPWS0_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

10.2.1.4.22.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP_EN bit and sends the DOMAIN, MESSAGE_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW_2G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

10.2.1.4.22.16 CPTS Interrupt Handling

The **TS_PEND** interrupt is enabled by writing a logic high to the **ts_int_enable** bit in the interrupt enable register. The raw interrupt value (before the enable) can be read by reading the **TS_Instat_raw** register. The enabled interrupt value can be read by reading the **TS_Instat_masked** register.

Software can process time sync events via interrupts in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt, read the **Event_0-4** register values.
3. Write logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
4. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt enter the CPTS service routine.
3. Read the **Event_0-4** register values.
4. Write a logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four **RCLK** periods plus four **VBUSP_CLK** periods.
6. Read bit 0 (**ts_pend_raw**) in the **TS_Intstat_raw** register to determine if another valid event is in the event FIFO. If bit zero is asserted then go to step 3. If bit 0 is not asserted then go to step 7.
7. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software also has the option of disabling the interrupt and polling the **ts_intstat_raw** bit to determine if a valid event is on the event FIFO.

10.2.1.4.23 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

Features Supported

- Clause 22 and CLuse 45 support
- Supports up to 32 PHY addresses.
- Two user access registers to control and monitor up to two PHYs simultaneously.
- VBUS 3.0 compliant slave interface for configuration and control.
- Each PHY can be individually enabled to be polled.
- The inter-poll gap between PHY polls can be changed.
- State Change Mode of operation to monitor up to 32 PHYs simultaneously.
- The MDIO interface can be manually controlled by software for GPIO operations.

10.2.1.4.23.1 MDIO Frame Formats

Clause 22

Table 10-775. MDIO Clause 22 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 10-776. MDIO Clause 22 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a "01" pattern. The pattern assures transitions from the default logic one state to zero and back to one.

Operation Code

The operation code for a read is "10", while the operation code for a write is a "01".

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16-bits. The first bit transmitted and received is the MSbit of the data word.

Clause 45

[Table 10-777](#) shows the address, [Table 10-778](#) shows the read format and [Table 10-779](#) shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

Table 10-777. MDIO Clause 45 Address Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

Table 10-778. MDIO Clause 45 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 10-779. MDIO Clause 45 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction. The **MDIO User_Addr** registers must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceding address frame.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a "00" pattern.

Operation Code

The operation code for an address transaction is "00", The operation code for a read is "11", while the operation code for a write is a "01".

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

MMD Number

The MMD number is the 5-bits allowing 32 unique values. The first bit transmitted is the MSbit.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Address

The address field is 16-bits on address operations. The first bit transmitted is the MSbit of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the **MDIO User_Addr0/1** register values as the 16-bit address.

Data

The Data field is 16-bits on read and write operations. The first bit transmitted and received is the MSbit of the data word.

10.2.1.4.23.2 MDIO Functional Description

The MDIO Management I/F will remain idle until enabled by setting the **enable** bit in the **MDIO Control** register. The module will then continuously poll the linkstatus bits from within the GenericStatusRegister of all enabled 32 PHY addresses. Individual PHY's can be enabled or disabled for polling thru the associated bit in the **Poll_En** register. The **MDIO Link** and **MDIO alive** register bit values are updated on the poll of each PHY. In Normal Mode, The link status of two of the 32 possible PHY addresses can also be determined using the **MLINK** pin inputs. The **linksel** bit in the **MDIO USER_PHY_SEL** register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the **MDIO LinkIntRaw** register and the **MDIO LinkIntMasked** register, if enabled by the **linkint_enable** bit in the **MDIO User_Phy_Sel** register. In State Change Mode, a change in any PHY status will be indicated on the **MDIO LINKINT[0]** interrupt if enabled.

The **MDIO Alive** register is updated if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also update the **MDIO Alive** register bit associated with the PHY.

At any time, the host can initiate a transaction for the MDO module to undertake using the **data**, **phyadr**, **regadd/MMD**, and **write** fields in an **MDIO User_Access** register. When the host sets the **go** bit in this register, the MDIO module will begin the transaction without any further intervention from the host. Upon completion, the MDIO will clear the **go** bit and set the **userintraw** bit in the **MDIO User_Int_Raw** register corresponding to the **MDIO User_Access** register being used. The corresponding bit in the **MDIO User_Int_Masked** register may also be set depending on the mask setting in the **MDIO User_Int_Mask_Set** and **MDIO User_Int_Mask_Clear** registers. A round-robin arbitration scheme is used to schedule transactions which may queued by the host in different **MDIO User_Access** registers. The host should check the status of the **go** bit in the **MDIO User_Access** register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the **ack** bit in the **MDIO User_Access** register to determine the status of a read transaction.

Software may use the MDIO module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the **MAC Control** register in the corresponding MAC.

10.2.1.4.24 Reset Isolation

The CPSW supports reset isolation of the Ethernet switch ports. When the **ISOLATE** input is asserted the below occur simultaneously:

- The Host Port 0 is removed from ALE processing (packets received on ports 1 through N-1 will be dropped to port 0).
- FHost packets are dropped. Any packet currently in progress when ISOLATE is asserted is dropped due to a FHost packet code error (and possible a CRC or FRAG error).
- THost packets in queue are dropped.

The intent of reset isolation is to allow packets to switch between the Ethernet ports while the remainder of the system is undergoing a reset. Isolation assumes that the external host and logic connected to the port 0 host interface is reset and will not be in the middle of a packet when **ISOLATE** is de-asserted.

10.2.1.4.25 CPSW Initialization and Configuration

To configure the CPSW for operation the host must perform the following:

- Ensure that at least 2000 VBUSP_CLK periods are run after reset is de-asserted.
- Configure the CPSW Control register.
- Configure the Ethernet Port Source Address registers
- Configure the Statistics Port Enable registers
- Configure the ALE.
- Configure the Ethernet Ports.

10.2.1.4.26 Enet Mac Reset or XGMII/GMII Mode Change Configuration

- Set **pn_cmd_idle** in the Ethernet port **Pn_Mac_Control** registers.

- Wait for pn_Idle to be indicated in the Ethernet port Pn_Mac_Status registers.
- Set pn_soft_reset in the Ethernet port Pn_Soft_Reset registers.
- Wait for pn_soft_reset in the Pn_Soft_Reset registers to be cleared to confirm reset completion.
- Configure the Ethernet ports.

10.2.1.4.27 Memory Error Detection and Correction

The cpsw error detection and correction logic uses the IP ECC Aggregator Module. The ECC Aggregator allows the control of the cpsw RAMs as shown in the below table. ECC is always enabled. The cpsw FIFO RAMS implement ECC only on packet headers. The packet data is protected by Castignoli CRC (regardless of the input packet CRC type or output CRC type). The ALE and EST RAMs have complete ECC as normal.

10.2.1.4.27.1 Packet Header ECC

Only packet headers bits are protected by ECC in the cpsw RAMs. The **ECC_Error_Control1** register **ecc_row** is not implemented – **ecc_bit1** is implemented to determine which bit of the header is flipped for an SEC error when the **ecc_crc_mode** bit is cleared in the **CPSW_Control** register. The ECC status registers return the RAM address that was flipped (**ecc_row**) along with the **ecc_bit1** value. Forcing double bit errors in testing can cause indeterminate switch operation if multiple used packet header bits are flipped given that only single bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the switch and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when **ecc_crc_mode** is set to one. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test ecc header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on 'bit 0', it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse on **ECC_PULSE_INTR** as does an ale ram ECC error.

10.2.1.4.27.2 Packet Protect CRC

Each ingress packet without error is passed through the cpsw with an internally generated Castignoli protect CRC. The protect CRC is checked on port egress for correctness and is replaced. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on THost then the **memory_protect_error** buffer descriptor bit will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the **ECC_PULSE_INTR** signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on **STAT_PEND_INTR** if any CRC memory protect error occurs (and the statistics for that port are enabled). When the **ecc_crc_mode** bit in the **CPSW_Control** register is set, the **ecc_bit1** aggregator register will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when **ecc_crc_mode** is set. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test packet CRC errors.

RAM 0	ALE Ram
RAM 1	Port 0 FIFO Rx Ram
RAM 2	Port 0 FIFO Tx Ram
RAM 3	Port 1 FIFO Rx Ram
RAM 4	Port 1 FIFO Tx Ram
RAM 5	Port 2 FIFO Rx Ram
RAM 6	Port 2 FIFO Tx Ram
...	...
RAM (N*2) - 1	Port N FIFO Rx Ram
RAM (N*2)	Port N FIFO Tx Ram
RAM 19	EST Ram

10.2.1.4.27.3 Aggregator Ram Control

The ECC logic for each FIFO ram (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the ram in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in the below table. The **ecc_bit1[15:0]** value returned on error is a 16-bit value that is the concatenation of 5-bits of zero, 3-bits of the encoder/decoder number (0 to 7), 3-bits of zero, and 5-bits of index into the indicated 26-bit encoder/decoder. For example, an **ecc_bit1** value of 0x0308 is bit-8 of encoder/decoder 3, which is header bit 86 ($((26*3) + 8)$).

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:78	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 Code
219:214	Encoder/Decoder 1 Code
225:220	Encoder/Decoder 2 Code
231:226	Encoder/Decoder 3 Code
237:232	Encoder/Decoder 4 Code
243:238	Encoder/Decoder 5 Code
249:244	Encoder/Decoder 6 Code
255:250	Encoder/Decoder 7 Code

10.2.1.4.28 CPSW Network Statistics

The CPSW has statistics that record events associated with frame traffic on each port. STAT0 keeps statistics for PORT0, STAT1 for PORT1 and so on. All statistics are 32-bit registers. By convention the statistics registers are receive for ingress and transmit for egress for all ports.

If any bit in **stat_port_en** is set for a specific STAT module, the value written to a statistics register will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xffffffff will clear a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x00000000 will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, “the port” refers to any enabled port (with a corresponding set **stat_port_en** bit).

10.2.1.4.28.1 Rx (only) Statistics Descriptions

10.2.1.4.28.1.1 Good Rx Frames

The total number of good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.2 Broadcast Rx Frames

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- any data or MAC control frame which was destined for address 0xFFFFFFFF only, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.3 Multicast Rx Frames

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFF, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.4 Pause Rx Frames

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error, and
- pause frames are enabled on the port (pn_tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic

or

The total number of priority based flow control (802.1Qbb) pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, and
- priority based flow control pause frames are enabled on the port.

See the **Rx CRC errors** statistic descriptions for definitions of CRC errors. Overruns have no effect upon this statistic

10.2.1.4.28.1.5 Rx CRC Errors

The total number of frames received on the port that experienced a CRC error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no code/align error, and
- had a CRC error.

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- a frame containing an even number of nibbles, and
- fails the Frame Check Sequence test.

10.2.1.4.28.1.6 Rx Align/Code Errors

The total number of frames received (ingress) on the port that experienced an alignment error or code error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had either an alignment error or a code error.

Over-runs have no effect upon this statistic.

An alignment error is defined to be:

- a frame containing an odd number of nibbles, and
- also fails the Frame Check Sequence test if the final nibble is ignored.

A code error is defined to be:

- A frame which has been discarded because the port's **MRXER** pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note

RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing **Rx Align/Code Errors** and **Rx CRC errors** (see below).

10G: For XGMII, packets are ended at the code error and only that number of bytes are kept when rx_cef is set (includes the code error bytes).

10.2.1.4.28.1.7 Oversize Rx Frames

The total number of oversized frames received on the port. An oversized frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen in bytes, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.8 Rx Jabbers

The total number of jabber frames received on the port. A jabber frame is:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen bytes long, and
- had a CRC error, an alignment error, or a code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.9 Undersize (Short) Rx Frames

The total number of undersized frames received on the port. An undersized frame is defined to be:

- any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was less than 64 bytes long, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.10 Rx Fragments

The total number of frame fragments received on the port. A frame fragment is defined to be:

- any data frame (address matching does not matter), and
- was less than 64 bytes long, and
- had a CRC error, an alignment error, or a code error, and
- was not the result of a collision caused by half duplex, collision based flow control.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.1.11 Rx IPG Error

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

10.2.1.4.28.1.12 Rx Bottom Of FIFO Drop

Ethernet Ports

The total number of ingress frames on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI transmit port) should not drop packets on ingress because port 0 ingress flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. The overrun frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- Was dropped on port 0 due to a lack of memory space in the receive FIFO

Note

This stat should be zero

Host Port 0

This statistic also counts frames dropped on port 0 that were 17 to 33 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet with 33 bytes was dropped. No other statistics are counted for frames shorter than 33 bytes.

10.2.1.4.28.1.13 Portmask Drop

All Ports

The total number of ingress frames on a port that were dropped by the ALE (the ALE did not forward the packet to any port). The frame was defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

Note

This stat does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero **port_mask**.

10.2.1.4.28.1.14 Rx Top Of FIFO Drop

All Ports

The total number of frames received on a port that had a **START** of frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

10.2.1.4.28.1.15 ALE Drop

All Ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the **port_mask** was zero).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the destination address was not equal to the source address, and
- The packet was not destined for the port it was receive on, and
- had a zero port_mask

10.2.1.4.28.1.16 ALE Overrun Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with **pn_rx_csf_en** at a rate that exceeded the maximum lookup rate.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

10.2.1.4.28.1.17 ALE Rate Limit Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were pruned due to rate limiting).

10.2.1.4.28.1.18 ALE VLAN Ingress Check Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to VLAN ingress check failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and

- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the VLAN ID ingress check failed (the receive port was not in the group), and
- The address lookup did not return a match with the super bit set

10.2.1.4.28.1.19 ALE DA=SA Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to destination address equal to source address.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- The destination address was equal to the source address
- The source address was not an entry in the table.

10.2.1.4.28.1.20 Block Address Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source or destination address matched a table entry with the block bit set.

10.2.1.4.28.1.21 ALE Secure Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source address is an entry in the table with the secure bit set and a port number for a different receive port.

10.2.1.4.28.1.22 ALE Authentication Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- enable_auth_mode is set, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the super bit set.

10.2.1.4.28.1.23 ALE Unknown Unicast

The total number of frames received on a port that had a unicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

Note

The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

10.2.1.4.28.1.24 ALE Unknown Multicast

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a multicast destination address, and
 - the source address was not a table entry, and
 - was of length 64 to pn_rx_maxlen bytes inclusive, and
 - had no CRC error, alignment error or code error.
-

Note

The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

10.2.1.4.28.1.25 ALE Unknown Broadcast

The total number of frames received on a port that had a Broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a broadcast destination address, and
 - the source address was not a table entry, and
 - was of length 64 to pn_rx_maxlen bytes inclusive, and
 - had no CRC error, alignment error or code error.
-

Note

The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

10.2.1.4.28.1.26 ALE Policer Match

The total number of frames received on a port that had a matched a policer. The frame is defined to be:

- any data frame, and
- matched a condition on a policer, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

10.2.1.4.28.1.27 ALE Policer Match Red

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- any data frame, and
- matched a policer with the condition red, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

10.2.1.4.28.1.28 ALE Policer Match Yellow

The total number of frames received on a port that had matched a policer and the condition was yellow. The frame is defined to be:

- any data frame, and
- matched a policer with the condition yellow, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

10.2.1.4.28.1.29 IET Receive Assembly OK

The total number of correctly received and re-assembled preemptable frames.

- any preemptable frame received
- was any size, and
- was correctly received and re-assembled without error.

10.2.1.4.28.1.30 IET Receive Assembly Error

The total number of preemptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine).

10.2.1.4.28.1.31 IET Receive SMD Error

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note

If **iet_en** is not set, this statistic counts any received frame with any non express SMD.

10.2.1.4.28.1.32 IET Receive Merge Fragment Count

The total number of received non-initial fragments that did not have an assembly error. The IET stat aMACMergeFragCountRx is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error.

10.2.1.4.28.1.33 Rx Octets

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

10.2.1.4.28.2 Tx (only) Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

Those overruns (**P0_Tx_SOF_OVERRUN** and **P0_Tx_MOF_OVERRUN**) have no effect on Tx statistics. They are counted separately.

10.2.1.4.28.2.1 Good Tx Frames

The total number of good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

10.2.1.4.28.2.2 Broadcast Tx Frames

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- any data or MAC control frame destined for address 0xFFFFFFFF only, and
- was of any length, and

- had no late or excessive collisions, no carrier loss and no underrun

10.2.1.4.28.2.3 Multicast Tx Frames

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- any data or MAC control frame destined for any multicast address other than 0xFFFFFFFF, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

10.2.1.4.28.2.4 Pause Tx Frames

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the **Tx Multicast Frames** and **64octet Frames** statistics.

10.2.1.4.28.2.5 Collisions

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
 - was destined for any unicast, broadcast or multicast address, and
 - was any size, and
 - had no carrier loss and no underrun, and
 - experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions).

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

10.2.1.4.28.2.6 Single Collision Tx Frames

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

10.2.1.4.28.2.7 Multiple Collision Tx Frames

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

10.2.1.4.28.2.8 Excessive Collisions

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and

- experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

10.2.1.4.28.2.9 Late Collisions

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect upon this statistic.

10.2.1.4.28.2.10 Deferred Tx Frames

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced no collisions before being successfully transmitted, and
- found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic

See RFC1623 Ref. 2.6 dot3StatsDeferredTransmissions.

10.2.1.4.28.2.11 Carrier Sense Errors

The total number of frames on the port that experienced carrier loss. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- the carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.
- CRC errors and underrun have no effect upon this statistic.

10.2.1.4.28.2.12 Tx Octets

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no late or excessive collisions and no carrier loss.

10.2.1.4.28.2.13 Transmit Priority 0-7

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- any frame transmitted from priority 0-7, and
- was less than or equal to `cpsw_tx_pri(0-7)_maxlen`.
- Collision retries are not counted in this statistic
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note

The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

10.2.1.4.28.2.14 Transmit Priority 0-7 Drop

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to **cpsw_tx_pri(0-7)_maxlen**.

- any frame destined to be transmitted from priority 0-7, and
 - was any size, and
 - was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
 - Was dropped due to frame size larger than **cpsw_tx_pri(0-7)_maxlen**.
-

Note

The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

10.2.1.4.28.2.15 Transmit Memory Protect Errors

The total number of transmit frames on the port that had a memory protect CRC error on egress.

- any frame destined to be transmitted, and
- was any size, and
- Had a memory protect CRC error on egress.

Frames to the host with memory protect errors are indicated to be dropped with a set receive buffer descriptor **drop** bit. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.

This statistic is 8-bits wide only and will not rollover but will limit at 0xff.

A non-zero value in this statistic will issue a **STAT_PEND_INTR** interrupt for the associated port.

10.2.1.4.28.2.16 IET Transmit Merge Fragment Count

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was a non-initial fragment.

10.2.1.4.28.2.17 IET Transmit Merge Hold Count

The total number of preemptable frames that were preempted and reassembled by the assertion of **pn_mac_hold** in the **Enet_Pn_IET_Control** register or were preempted by EST. The IET statistic **aMACMergeHoldCount** can be derived and maintained by software.

- any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was preempted by the assertion of **pn_mac_hold**, or
- was preempted by Enhanced Scheduled Traffic (EST).

10.2.1.4.28.3 Rx and Tx (shared) Statistics Descriptions
10.2.1.4.28.3.1 Net Octets

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter), and
- was of any size (including <64 byte and > **pn_rx_maxlen** byte frames).

Also counted in this statistic are:

- every byte transmitted before a carrier-loss was experienced,

- every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time),
- every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

10.2.1.4.28.3.2 Rx + Tx 64 Octet Frames

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

10.2.1.4.28.3.3 Rx + Tx 65-127 Octet Frames

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 65 to 127 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

10.2.1.4.28.3.4 Rx + Tx 128-255 Octet Frames

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 128 to 255 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

For Rx reference only, see RFC1757 Ref. 1.13 etherStatsPkts128to255Octets.

10.2.1.4.28.3.5 Rx + Tx 256-511 Octet Frames

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 256 to 511 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.
Rx + Tx 512-1023 Octet Frames

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 512 to 1023 bytes long.

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

10.2.1.4.28.3.6 Rx + Tx 1024_Up Octet Frames

The total number of frames of size 1024 to **pn_rx_maxlen** bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 1024 to pn_rx_maxlen bytes long on receive, or any size on transmit.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

Table 10-780. Rx Statistics Summary

Rx Statistic	Frame/Oct	Rx/Rx+Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data			< 64	64	65-127	128-255	256-511	512-1023	1024 - rx_maxlen	> rx_maxlen	flow coll.	CRC error	align / code	over-run	addr disc.
			Pause frame	Non-pause	Multi-cast	Broad-cast	Unicast													
Good Rx Frames	F	Rx	(y	y	y	y	y	n	(y	y	y	y	y	y	n	-	n	n	-	n
Broadcast Rx Frames	F	Rx	(%	%	n	y	n	n	(y	y	y	y	y	y	n	-	n	n	-	n

Table 10-780. Rx Statistics Summary (continued)

Rx Fragments	F	Rx	n	n	(y	y	y)	y^	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	y	n	
64octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	y	n	n	n	n	n	-	-	-	-	n	
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	-	-	-	-	n	
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	-	-	-	-	n	
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	-	-	-	-	n	
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	-	-	-	-	n	
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	-	-	

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-” indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames)
6. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

7. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
8. “y^” Frame fragments are not counted if less than 8 bytes.
9. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the ‘-’s in this column might in reality be ‘n’s.
10. The rx_overruns stat show above is for rx_mof_overruns and rx_sof_overruns added together.

Table 10-781. Tx Statistics Summary

Tx Statistic	Frame/Oct	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC error	Collision type					No carrier	Queued	Deferred	Underrun

256-511 octet Frames	F	Rx+ Tx	(y	y	y	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-	

Table 10-781. Tx Statistics Summary (continued)

512-1023 octet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-	
1024-UP octet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-	
Tx Octets	O	Tx	(y	y	y	y	y	(y	y	y	y	y	y	y	-	-	-	-	n	n	n	-	-	n	
Net Octets	O	Rx+Tx	(y	y	y	y	y	(y	y	y	y	y	y	y	-	-	\$	\$	\$	\$	\$	\$	-	-	-

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause(MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so cannot collide
5. “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. “+” indicates collisions which are “summed” (i.e. every collision is counted in the Collisions statistic). Jam sequences used for half-duplex flow control are also counted.
7. “\$” Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the ‘-’s in this column might in reality be ‘n’s. To prevent double-counting, Net Octets are unaffected by the jam sequence – the ‘received’ bytes, however, are counted. (see Rx Statistics table).
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

10.2.1.5 MSS_CPSW Registers

Table 10-782 lists the MSS_CPSW registers. All register offset addresses not listed in Table 10-782 should be considered as reserved locations and the register contents should not be modified.

Table 10-782. MSS_CPSW Registers

Offset	Acronym	Register Name	Section
0h	SS_IDVER_REG	ID Version Register	Section 10.2.1.5.1
4h	SS_SYNCE_COUNT_REG	Sync E Count Value - This value determines the toggle rate of the TS_SYNCE output. When this value is zero the TS_SYNCE output is disabled (low). When this value is non-zero, the TS_SYNCE output toggles each time the synce count value is reached. If this value is to be changed to another non-zero value then it should be written with a zero value before writing the new non-zero value.	Section 10.2.1.5.2

Table 10-782. MSS_CPSW Registers (continued)

Table 10-801. MDIO_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine idle. Set to 1 when the state machine is in the idle state.
30	ENABLE	R/W	0h	Enable control. Writing a 1 to this bit enables the MDIO state machine, writing a 0 disables it. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register.
29	RESERVED	R/W	X	
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.
23-21	RESERVED	R/W	X	

Table 10-801. MDIO_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	PREAMBLE	R/W	0h	Preamble disable. Writing a 1 to this bit disables this device from sending MDIO frame preambles in clause 22 mode of operation. This bit has no effect in clause 45 mode of operation.
19	FAULT	R/W	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit.
18	FAULT_DETECT_ENABLE	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection
17	INT_TEST_ENABLE	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the userint and linkint bits for test purposes.
16	RESERVED	R/W	X	
15-0	CLKDIV	R/W	FFh	Clock divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when clkdiv is set to 0. MDCLK frequency = clk frequency/(clkdiv+1).

10.2.1.5.20 MDIO_ALIVE_REG Register (Offset = F08h) [Reset = 0h]

ALIVE																															
R/W-0h																															

Table 10-802. MDIO_ALIVE_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ALIVE	R/W	0h	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are intended to be used to give an indication of the presence or not of the PHY with the corresponding address. Writing a '1' to any bit will clear it, writing a '0' has no effect.

10.2.1.5.21 MDIO_LINK_REG Register (Offset = F0Ch) [Reset = 0h]

MDIO_LINK_REG is shown in [Figure 10-817](#) and described in [Table 10-803](#).

Return to the [Table 10-782](#).

R/W-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 10-890. PN_EST_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R/W	X	
25-16	est_fill_margin	R/W	0h	Transmit FIFO EST Fill Margin. Sets the fill margin (in bytes) required to ensure that the Ethernet wire is clear so that the timed EST express packet can egress at the correct required time. Setting this value too high will put an unnecessary gap on the wire. Setting this value too low will cause the express packet to egress at a time later than intended (pushed out by non express traffic).
15-9	est_preempt_comp	R/W	0h	Transmit FIFO EST Preempt Comparison Value. When the count in a zero allow is less than or equal to this value in bytes (times 8), preempt packets are cleared from the wire. This is the preempt clear margin value.
8	est_fill_en	R/W	0h	Transmit FIFO EST Fill Enable
7-5	est_ts_pri	R/W	0h	Transmit FIFO EST TimeStamp Priority. Selects the express priority that timestamp(s) will be generated on when pn_est_ts_onepri is set.
4	est_ts_onepri	R/W	0h	Transmit FIFO EST TimeStamp One Priority. When set, timestamp only enabled packets on the express priority selected by pn_est_ts_pri. When cleared to zero, express packet selection for timestamp is independent of priority.
3	est_ts_first	R/W	0h	Transmit FIFO EST TimeStamp First Express Packet. Generate a timestamp only on the first selected express packet in each EST time interval when express timestamps are enabled. (If pn_est_ts_onepri is also set then the timestamp is generated only on the first packet on pn_est_ts_pri).
2	est_ts_en	R/W	0h	Transmit FIFO EST TimeStamp Enable. Enable express timestamps (when est_en and pn_est_port_en are set).
1	est_bufsel	R/W	0h	Transmit FIFO EST Buffer Select. If pn_est_onebuf is cleared, this bit selects the upper (when set) or the lower (when cleared) 64-word fetch buffer. The actual fetch buffer used changes only at the start of the EST time interval and can be read in the Pn_FIFO_Status register pn_est_bufact bit.
0	est_onebuf	R/W	0h	Transmit FIFO EST One Buffer. When set indicates that all 128 fetch words are used in one buffer. When cleared, indicates that the 128 fetch words are split into two 64-word fetch buffers. The pn_est_bufsel selects the buffer to be used when pn_est_onebuf is cleared to zero.

Bit	Field	Type	Reset	Description
31-25	RESERVED	R/W	X	

Table 10-911. PN_MAC_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of pn_rx_cmf_en. Frames transferred to memory due to pn_rx_cmf_en will have the control bit set in their EOP buffer descriptor. 0 – MAC control frames are filtered (but acted upon if enabled). 1 – MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to host memory due to pn_rx_csf_en will have the fragment or undersized bit set in their buffer descriptor. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 – Short frames are filtered 1 – Short frames are transferred to host memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when this bit is not set. 0 – Frames containing errors are filtered. 1 – Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	R/W	0h	Transmit Short Gap Limit Enable. When set this bit limits the number of short gap packets transmitted to 100ppm. The pn_tx_short_gap_en bit must also be set. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed. This bit is used only with GMII (not XGMII).
20	EXT_TX_FLOW_EN	R/W	0h	External Transmit Flow Control Enable
19	EXT_RX_FLOW_EN	R/W	0h	External Receive Flow Control Enable
18	EXT_EN	R/W	0h	External Enable. Enables the full duplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the pn_full duplex and pn_gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual full duplex mode selected
17	GIG_FORCE	R/W	0h	Gigabit Mode Force
16	IFCTL_B	R/W	0h	Interface Control B
15	IFCTL_A	R/W	0h	Interface Control A
14-13	RESERVED	R/W	X	
12	CRC_TYPE	R/W	0h	Port CRC Type. 0 – Ethernet CRC
11	CMD_IDLE	R/W	0h	Command Idle. 0 – Idle not commanded, 1 – Idle Commanded (read pn_idle in Pn_Mac_Status)
10	TX_SHORT_GAP_ENABLER	R/W	0h	Transmit Short Gap Enable
9-8	RESERVED	R/W	X	
7	GIG	R/W	0h	Gigabit Mode. 0 – 10/100 mode, 1 – Gigabit mode (full duplex only).
6	TX_PACE	R/W	0h	Transmit Pacing Enable
5	GMII_EN	R/W	0h	GMII Enable
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. 0 – Transmit Flow Control Disabled. Full-duplex mode – Incoming pause frames are not acted upon. 1 – Transmit Flow Control Enabled . Full-duplex mode – Incoming pause frames are acted upon.

Table 10-911. PN_MAC_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable. 0 – Receive Flow Control Disabled Half-duplex mode – No flow control generated collisions are sent. Full-duplex mode – No outgoing pause frames are sent. 1 – Receive Flow Control Enabled Half-duplex mode – Collisions are initiated when receive flow control is triggered. Full-duplex mode – Outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	R/W	0h	Manufacturing Test Mode
1	LOOPBACK	R/W	0h	Loop Back Mode. Loopback mode forces internal full duplex mode regardless of whether the pn_full duplex bit is set or not. The pn_loopback bit should be changed only when pn_gmii_en is de-asserted. Loopback is used only with GMII (not XGMII). Loopback is not compatible with timestamp operations (CPTS). 0 – Not looped back 1 – Loop Back Mode enabled
0	FULLDUPLEX	R/W	0h	Full Duplex mode. Gigabit mode forces full duplex mode regardless of whether the pn_full duplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 – half duplex mode 1 – full duplex mode

Table 10-933. CPDMA_SOFT_RESET_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R/W	X	
0	SOFT_RESET	R/W	0h	CPDMA and CPSW Soft Reset Enable. Writing a one to this bit causes the entire CPSW logic to be reset. Software reset occurs when the DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

10.2.1.5.152 CPDMA_CONTROL_REG Register (Offset = 00034020h) [Reset = X]

CPDMA_CONTROL_REG is shown in [Figure 10-948](#) and described in [Table 10-934](#).

Return to the [Table 10-782](#).

R/W-X	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 10-934. CPDMA_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R/W	X	
6	TH_TS_ENCAP	R/W	0h	CPDMA Receive TimeStamp Encapsulated. 0 – THost packets do not contain a 64-bit timestamp 1 – THost packets contain a 64-bit timestamp prepended to the packet data (32-bit lsword first).
5	TH_VLAN_ENCAP	R/W	0h	CPDMA Receive VLAN Encapsulated. 0 – THost packets are not VLAN encapsulated 1 – THost packets are VLAN encapsulated
4	TH_CEF	R/W	0h	CPDMA Receive Copy Error Frames. Enables THost DMA overrun frames to be transferred to memory (up to the point of buffer overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when thost_cef is not set. THost frames with other error bits set are not affected by this bit. This is related only to frames that overrun on the THost DMA due to buffer limitations. 0 – Frames containing overrun errors are filtered. 1 – Frames containing overrun errors are transferred to memory.
3	CMD_IDLE	R/W	0h	CPDMA Command Idle. 0 – Idle not commanded 1 – Idle Commanded (read idle in CPDMA_Status register)
2	TH_OFFLEN_BLOCK	R/W	0h	CPDMA Receive Offset/Length Word Write Block. 0 – Do not block the DMA writes to the THost buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI. 1 – Block all CPDMA DMA controller writes to the THost buffer descriptor offset/buffer length words during CPPI packet processing. When this bit is set, the CPDMA will never write the third word to any THost buffer descriptor.
1	TH_OWNERSHIP	R/W	0h	CPDMA Receive Ownership Write Bit Value. 0 – The CPDMA writes the THost buffer descriptor ownership bit to zero at the end of packet processing as specified in CPPI. 1 – The CPDMA writes the THost buffer descriptor ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
0	FH_PTYPE	R/W	0h	CPDMA Transmit Queue Priority Type. 0 – The queue uses a round robin scheme to select the next channel. 1 – The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel.

10.2.1.5.153 CPDMA_STATUS_REG Register (Offset = 00034024h) [Reset = X]

CPDMA_STATUS_REG is shown in [Figure 10-949](#) and described in [Table 10-935](#).

Return to the [Table 10-782](#).

Bit	Field	Type	Reset	Description
31-11	RESERVED	R/W	X	
10-0	TH_BUFFER_OFFSET	R/W	0h	CPDMA Receive Buffer Offset Register. The <code>fhost_buffer_offset</code> will be written by the port into each frame SOP buffer descriptor <code>buffer_offset</code> field. The frame data will begin after the <code>fhost_buffer_offset</code> value of bytes. A value of 0x0 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0xF (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

Table 10-960. CPDMA_TH0_FREEBUFFER_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R/W	X	
14-0	TH0_FREEBUFFER	R/W	0h	CPDMA THost Free Buffer Count Register. This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.

7	6	5	4	3	2	1	0
RESERVED							TS_PUSH
W-X							W-0h

Table 10-1143. TS_PUSH_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	W	X	
0	TS_PUSH	W	0h	Time stamp event push. When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

10.2.1.5.362 TS_LOAD_VAL_REG Register (Offset = 0003D010h) [Reset = 0h]

TS_LOAD_VAL_REG is shown in Figure 10-1158 and described in Table 10-1144.

Return to the Table 10-782.

Time Stamp Load Low Value Register

Figure 10-1158. TS_LOAD_VAL_REG Register

Table 10-1152. EVENT_POP_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	W	X	
0	EVENT_POP	W	0h	Event pop. When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read from the Event_0-3 registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt.

10.2.1.5.371 EVENT_0_REG Register (Offset = 0003D034h) [Reset = 0h]

EVENT_0_REG is shown in [Figure 10-1167](#) and described in [Table 10-1153](#).

Return to the [Table 10-782](#).

10.2.1.5.396 ALE_STATUS Register (Offset = 0003E004h) [Reset = X]

ALE_STATUS is shown in [Figure 10-1192](#) and described in [Table 10-1178](#).

Return to the [Table 10-782](#).

The ALE status provides information on the ALE configuration and state. The ~iramdepth is used to determine how IPv6 entries are stored in the table. IPv6 entries are stored in two entries where IPv6 Entry hi is designated by the odd slice index and lo is designated by the even slice index. The slice index is above the ram depth like {SlixelIndex,RamIndex}. So for a 64 deep RAM index of 0x005, the Hi portion of the IPv6 entry is located at 0x005|0x040 and the Lo portion is located at 0x005&(~0x040).

Table 10-1179. ALE_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE_ALE	R/W	0h	Enable ALE 0 - Drop all packets 1 - Enable ALE packet processing
30	CLEAR_TABLE	R/W	0h	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W	0h	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes four times the number of table entries clock cycles (4096 cycles for 1K addresses) best case (no ale packet processing during ageout) and sixty five times the number of table entries clock cycles (66560 cycles for 1K addresses) absolute worst case.

Table 10-1179. ALE_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28-25	RESERVED	R/W	X	
24	MIRROR_DP	R/W	0h	Mirror Destination Port - This field defines the port to which destination traffic destined will be duplicated. That is all traffic that is forwarded to this port will also be mirrored to the ~imirror_top port.
23-21	UPD_BW_CTRL	R/W	0h	The ~iupd_bw_ctrl field allows for up to 8 times the rate in which adds, updates, touches, writes, and aging updates can occur. At frequencies of 350Mhz, the table update rate should be at it lowest or 5 Million updates per second. When operating the switch core at frequencies or above, the ~iupd_bw_ctrl can be programmed more aggressive. If the ~iupd_bw_ctrl is set but the frequency of the switch subsystem is below the associated value, ALE will drop packets due to insufficient time to complete lookup under high traffic loads. 0 - 350Mhz, 5M 1 - 359Mhz, 11M 2 - 367Mhz, 16M 3 - 375Mhz, 22M 4 - 384Mhz, 28M 5 - 392Mhz, 34M 6 - 400Mhz, 39M 7 - 409Mhz, 45M
20-17	RESERVED	R/W	X	
16	MIRROR_TOP	R/W	0h	Mirror To Port - This field defines the destination port for the mirror traffic. If the traffic is received or transmitted on the mirror destination port it will not be duplicated. Traffic defined as mirror traffic only may be dropped by the switch due to congestion.
15	UPD_STATIC	R/W	0h	Update Static Entries - A static Entry is an entry that is not agable. When clear this bit will prevent any static entry (agable bit clear) from being updated due to port change. When set it allows static entries (agable bit clear) to update the source port if required. This bit should normally be '0' for most switch configurations.
14	RESERVED	R/W	X	
13	UVLAN_NO_LEARN	R/W	0h	Unknown VLAN No Learn - This field when set will prevent source addresses of unknown VLAN IDs from being automatically added into the look up table if learning is enabled.
12	MIRROR_MEN	R/W	0h	Mirror Match Entry Enable - This field enables the match mirror option. When this bit is set any traffic whose destination, source, VLAN or OUI matches the ~imirror_midx entry index will have that traffic also sent to the ~imirror_top port.
11	MIRROR_DEN	R/W	0h	Mirror Destination Port Enable - This field enables the destination port mirror option. When this bit is set any traffic destined for the ~imirror_dp port will have its transmit traffic also sent to the ~imirror_top port.
10	MIRROR_SEN	R/W	0h	Mirror Source Port Enable - This field enables the source port mirror option. When this bit is set any port with the ~ipX_mirror_sp set in the ALE Port Control registers set will have its received traffic also sent to the ~imirror_top port.
9	RESERVED	R/W	X	
8	EN_HOST_UNI_FLOOD	R/W	0h	Unknown unicast packets flood to host 0 - unknown unicast packets are not sent to the host 1 - unknown unicast packets flood to host port as well as other ports
7	LEARN_NO_VLANID	R/W	0h	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID). Determines the entry type.
6	ENABLE_VID0_MODE	R/W	0h	Enable VLAN ID = 0 Mode 0 - Process the priority tagged packet with VID = PORT_VLAN[11:0]. 1 - Process the priority tagged packet with VID = 0.

Table 10-1179. ALE_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	ENABLE_OUI_DENY	R/W	0h	Enable OUI Deny Mode - When set, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches a supervisory destination address table entry. When cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory destination address table entry.
4	ENABLE_BYPASS	R/W	0h	ALE Bypass - When set, packets received on non-host ports are sent to the host. It is expected that packets from the host are directed to the particular port. 0 - no bypass 1 - bypass the ALE
3	BCAST_MCAST_CTL	R/W	0h	Rate Limit Transmit mode 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based
2	ALE_VLAN_AWARE	R/W	0h	ALE VLAN Aware - Determines how traffic is forwarded using VLAN rules. 0 - Simple switch rules, packets forwarded to all ports for unknown destinations. 1 - VLAN Aware rules, packets forwarded based on VLAN members
1	ENABLE_AUTH_MODE	R/W	0h	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There is no auto learning of addresses in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode
0	ENABLE_RATE_LIMIT	R/W	0h	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.

10.2.1.5.398 ALE_CTRL2 Register (Offset = 0003E00Ch) [Reset = X]

ALE_CTRL2 is shown in [Figure 10-1194](#) and described in [Table 10-1180](#).

Return to the [Table 10-782](#).

The ALE Control 2 Register is used to set the extended features used for all ports.

R/W-0h

Table 10-1180. ALE_CTRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TRK_EN_DST	R/W	0h	Trunk Enable Destination Address - This field enables the destination MAC address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.
30	TRK_EN_SRC	R/W	0h	Trunk Enable Source Address - This field enables the source MAC address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.
29	TRK_EN_PRI	R/W	0h	Trunk Enable Priority - This field enables the VLAN Priority bits to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. In the event that DSCP mapping is enabled and there is no VLAN the DSCP priority will be used. For all other non IP frames without VLAN the port default priority is used.
28	RESERVED	R/W	X	
27	TRK_EN_IVLAN	R/W	0h	Trunk Enable Inner VLAN - This field enables the inner VLAN ID value (C-VLANID) to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.
26	RESERVED	R/W	X	
25	TRK_EN_SIP	R/W	0h	Trunk Enable Source IP Address - This field enables the source IP address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.
24	TRK_EN_DIP	R/W	0h	Trunk Enable Destination IP Address - This field enables the destination IP address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.
23	DROP_BADLEN	R/W	0h	Drop Bad Length will drop any packet that the 802.3 length field is larger than the packet. Ethertypes 0-1500 are 802.3 lengths, all others are Ether types.
22	NODROP_SRCMCST	R/W	0h	No Drop Source Multicast will disable the dropping of any source address with the multicast bit set.
21	DEFNOFRAG	R/W	0h	Default No Frag field will cause an IPv4 fragmented packet to be dropped if a VLAN entry is not found.
20	DEFLMTNXTHDR	R/W	0h	Default limit next header field will cause an IPv4 protocol or IPv6 next header packet to be dropped if a VLAN entry is not found and the protocol or next header does not match the \sim iALE_NXT_HDR register values.
19	RESERVED	R/W	X	
18-16	TRK_BASE	R/W	0h	Trunk Base - This field is the hash formula starting value. Changing this value will cause the packet distribution on trunk ports to be changed. If all the \sim itrk_en_dst, \sim itrk_en_src, \sim itrk_en_pri and \sim itrk_en_vlan are '0', this value is used as the distribution index. That is a '0' will select the 1st bit of an 'N' link trunk, a '1' will select the second, etc. Below is the distribution across the trunk links. The first number in the \sim italic sequence indicates the traffic is sent to the lowest numbered port of a trunk group. For example if you have a 3 port trunk, the hash result 0 will go to the base port (0), hash result 1 will go to the highest port of the trunk group (2), hash result 2 will go to the middle port (1), etc. 1 - \sim i00000000 2 - \sim i01010101 3 - \sim i02102102 4 - \sim i03210321
15-5	RESERVED	R/W	X	

Table 10-1180. ALE_CTRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	MIRROR_MIDX	R/W	0h	Mirror Index - This field is the ALE lookup table entry index that when a match occurs will cause this traffic to be mirrored to the ~imirror_top port. That is any VLAN, ONU or address with or without VLAN can be selected for traffic mirroring.

10.2.1.5.399 ALE_PRESCALE Register (Offset = 0003E010h) [Reset = X]

ALE_PRESCALE is shown in [Figure 10-1195](#) and described in [Table 10-1181](#).

Return to the [Table 10-782](#).

The ALE Prescale Register is used to set the Broadcast and Multicast rate limiting prescaler value.

Figure 10-1195. ALE_PRESCALE Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31	TABLEWR	R/W	0h	Table Write - This bit is used to write the table words to the lookup table. 0 - Table Read Operation is performed. The contents of the ~b TABLEIDX entry will be read into the ~b ALE_TBLWx registers 1 - Table write operation is performed. This will take the current contents from the ~b ALE_TBLWx registers and write them to the table at the specified ~b TABLEIDX.
30-5	RESERVED	R/W	X	
4-0	TABLEIDX	R/W	0h	The table index is used to determine which lookup table entry is read or written.

10.2.1.5.403 ALE_TBLW2 Register (Offset = 0003E034h) [Reset = X]

ALE_TBLW2 is shown in [Figure 10-1199](#) and described in [Table 10-1185](#).

Return to the [Table 10-782](#).

The ALE Table Word 2 is the most significant word of an ALE table entry.

--------	-------	--------	--------	--------	--------	--------

Table 10-1188. I0_ALE_PORTCTL0_y Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	I0_REG_P0_BCAST_LIMIT	R/W	0h	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field.
23-16	I0_REG_P0_MCAST_LIMIT	R/W	0h	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field. The ~imcast_limit is the number of Multicast packets that will be forwarded per ~iale_prescale time.
15	I0_REG_P0_DROP_DOUBLE_VLAN	R/W	0h	Drop Double VLAN - When set cause any received packet with double VLANs to be dropped. That is if there are two ctag or two stag fields in the packet it will be dropped.
14	I0_REG_P0_DROP_DUAL_VLAN	R/W	0h	Drop Dual VLAN - When set will cause any received packet with dual VLAN stag followed by ctag to be dropped.
13	I0_REG_P0_MACONLY_CAF	R/W	0h	Mac Only Copy All Frames - When set a Mac Only port will transfer all received good frames to the host. When clear a Mac Only port will transfer packets to the host based on ALE destination address lookup operation (which operates more like an Ethernet Mac). A Mac Only port is a port with ~imaconly set.
12	I0_REG_P0_DISABLE_PAUTHMOD	R/W	0h	Disable Port authorization - When set will allow unknown addresses to arrive on a switch in authorization mode. It is intended for device to device network connection on ports which do not require MACSEC encryption.
11	I0_REG_P0_MACONLY	R/W	0h	MAC Only - When set enables this port be treated like a MAC port for the host. All traffic received is only sent to the host. The host must direct traffic to this port as the lookup engine will not send traffic to the ports with the ~ip0_maconly bit set and the ~ip0_no_learn also set. If ~ip0_maconly bit is set and the ~ip0_no_learn is not set, the host can send non-directed packets that can be sent to the destination of a MacOnly port. It is also possible that The host can broadcast to all ports including MacOnly ports in this mode.
10	I0_REG_P0_TRUNKEN	R/W	0h	Trunk Enable - This field is used to enable a port into a trunk. Any port can be used as a trunk port, any two or more ports with the ~ip0_trunken its set and having the same ~ip0_trunknum will be placed in the same trunk. There is no requirement for trunk ports to be adjacent. If all ports are enabled in the same trunk, no traffic can flow as traffic received within a trunk is never transmitted out the same trunk. If only a single port is a member of a trunk, it looks like a normal port with exception of entries in the look up table will be noted as a trunk entry.
9-8	I0_REG_P0_TRUNKNUM	R/W	0h	Trunk Number - This field is used as the trunk number when the ~ip0_trunken is also set. Ports with the same trunk number that have the ~ip0_trunken also set will have traffic distributed within the trunk based on the result of the hash function described above.
7	I0_REG_P0_MIRROR_SP	R/W	0h	Mirror Source Port - This field enables the source port mirror option. When this bit is set any traffic received on the port with the reg_p0_mirror_sp bit set will have its received traffic also sent to the ~imirror_top port.
6	RESERVED	R/W	X	

Table 10-1188. IO_ALE_PORTCTL0_y Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	IO_REG_P0_NO_SA_UPDATE	R/W	0h	No Source Address Update - When set will not update the source addresses for this port.
4	IO_REG_P0_NO_LEARN	R/W	0h	No Learn - When set will not learn the source addresses for this port.
3	IO_REG_P0_VID_INGRESS_CHECK	R/W	0h	VLAN Ingress Check - When set if a packet received is not a member of the VLAN, the packet will be dropped.
2	IO_REG_P0_DROP_UNTAGGED	R/W	0h	If Drop Untagged - When set will drop packets without a VLAN tag.
1-0	IO_REG_P0_PORTSTATE	R/W	0h	Port State - Defines the current port state used for lookup operations. 0 - Disabled 1 - Blocked 2 - Learning 3 - Forwarding

10.2.1.5.407 ALE_UVLAN_MEMBER Register (Offset = 0003E090h) [Reset = X]

ALE_UVLAN_MEMBER is shown in [Figure 10-1203](#) and described in [Table 10-1189](#).

Return to the [Table 10-782](#).

The ALE Unknown VLAN Member Mask Register is used to specify the member list for unknown VLAN ID.

The Value of vlan_mask_mux_0 is read only and set to all ones for all ports.

10.2.1.5.415 EGRESSOP Register (Offset = 0003E0FCh) [Reset = X]

EGRESSOP is shown in [Figure 10-1211](#) and described in [Table 10-1197](#).

Return to the [Table 10-782](#).

The Egress Operation register allows enabled classifiers with IPSA or IPDA match to use the CPSW Egress Packet Operations Inter VLAN Routing sub functions. If the packet was destined for the host, but matches a classifier that has a programmed egress opcode, it will be forwarded to the destination ports where the destination ports will use the thier egress opcode entry to modify the packet. InterVLAN Routing and mirroring need to be understood, they are orthogonal functions.

Table 10-1206. POLICECONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	POLICING_EN	R/W	0h	Policing Enable - Enables the policing to color the packets, this also enables red or yellow drop capabilities.
30	RESERVED	R/W	X	
29	RED_DROP_EN	R/W	0h	RED Drop Enable - Enables the ALE to drop the red colored packets.
28	YELLOW_DROP_EN	R/W	0h	YELLOW Drop Enable - Enables the ALE to drop yellow packets based on the ~iyellowthresh value. This field would normally not be used as to let the switch drop packets at a buffer threshold instead. In the event that the switch does not enable buffer threshold dropping, YELLOW packets can be dropped based on this feature.
27	RESERVED	R/W	X	
26-24	YELLOWTHRESH	R/W	0h	Yellow Threshold - When set enables a portion of the yellow packets to be dropped based on the ~iyellow_drop_en enable. 0-100% 1=50% 2=33% 3=25% 4=20% 5=17% 6=14% 7=13%
23-22	POLMCHMODE	R/W	0h	Policing Match Mode - This field determines what happens to packets that fail to hit any policing/classifier entry. 0 - No Hit packets are marked GREEN 1 - No Hit packets are marked YELLOW 2 - No Hit packets are marked RED 3 - No Hit packets are marked based on policing/classifier entry=0 state.
21	PRIORITY_THREAD_EN	R/W	0h	Priority Thread Enable - This field determines if priority is OR'd to the default thread when no classifiers hit and the default thread is enabled.
20	MAC_ONLY_DEF_DIS	R/W	0h	MAC Only Default Disable - This field when set disables the default thread on MAC Only Ports. That is the default thread will be {port,priority}. If the traffic matches a classifier with a thread mapping, the classifier thread mapping still occurs.
19-0	RESERVED	R/W	X	

10.2.1.5.425 POLICETESTCTL Register (Offset = 0003E128h) [Reset = X]

POLICETESTCTL is shown in [Figure 10-1221](#) and described in [Table 10-1207](#).

Return to the [Table 10-782](#).

The Policing Test Control enables the ability to determine which policing entry has been hit and whether they reported a red or yellow rate condition.

Figure 10-1221. POLICETESTCTL Register

10.2.2 LVDS

10.2.2.1 LVDS Overview.....	3676
10.2.2.2 LVDS Programming Sequence.....	3676
10.2.2.3 CBUFF and LVDS Registers.....	3678

10.2.2.1 LVDS Overview

The LVDS interface includes the following signals:

- LVDS bit clock
- LVDS data lanes (the HSI integration chapter specific to the device lists the number of available lanes specific to the device)
- LVDS frame clock
- LVDS data_valid signal

Figure 10-1242. LVDS Interface Timings

The LVDS interface supports the following data rates:

- 900 Mbps (450-MHz DDR Clock)
- 600 Mbps (300-MHz DDR Clock)
- 450 Mbps (225-MHz DDR Clock)
- 400 Mbps (200-MHz DDR Clock)
- 300 Mbps (150-MHz DDR Clock)
- 225 Mbps (112.5-MHz DDR Clock)
- 150 Mbps (75-MHz DDR Clock)

Refer to the device data sheet for more details.

10.2.2.2 LVDS Programming Sequence

The following sections show the programming sequence needed before the hardware triggers are generated to initiate the high-speed LVDS data transmission.

10.2.2.2.1 LVDS Global Initialization

Table 10-1228. Main Sequence – PRCM and Global Configuration

Steps	Register/Bit Field/Programming	Value
Power on the LVDS I/Os	MSS_TOP_RCM.LVDS_PAD_CTRL0 MSS_TOP_RCM.LVDS_PAD_CTRL1	0x0 0x0
Power off the LVDS I/Os	MSS_TOP_RCM.LVDS_PAD_CTRL0 MSS_TOP_RCM.LVDS_PAD_CTRL1	0x01010101 0x010101
Power on the LVDS I/Os	MSS_TOP_RCM.LVDS_PAD_CTRL0 MSS_TOP_RCM.LVDS_PAD_CTRL1	0x0 0x0
Source IP Selection for LVDS	TOP_CTRL.MDO_CTRL.MDO_CTRL_SRC_SELECT	0: Aurora on LVDS 1: CBUFF on LVDS

10.2.2.2.2 CBUFF Configuration

Table 10-1229. Main Sequence – CBUFF LVDS Static Configuration

Steps	Register/Bit Field/Programming	Value
Assert the CBUFF soft reset	CONFIG_REG_0.CSWCRST	0x1
Configure CBUFF for LVDS data transfer	CONFIG_REG_0.CFG_1LVDS_0CSI	0x1

Table 10-1229. Main Sequence – CBUFF LVDS Static Configuration (continued)

Steps	Register/Bit Field/Programming	Value
Configure static values for LVDS	CONFIG_REG_0.CVC0EN	
	CFG_SPHDR_ADDRESS	0x55555555
	CFG_CMD_VSVAL	0x55555555
	CFG_CMD_VEVAL	0xAAAAAAAA
	CFG_LPHDR_ADDRESS	0xAAAAAAAA
	CFG_LVDS_GEN_0.CCSMEN	0x1
Configure the number of chirps in a frame	CFG_CHIRPS_PER_FRAME	X
Configure static values for LVDS based on LVDS CRC enabled or disabled	CFG_LVDS_GEN_0.CBCRCEN CFG_CMD_HEVAL CFG_CMD_HSVAl	X
Enable the LVDS lanes	CFG_LVDS_GEN_0.CFG_LVDS_LANE[X]_EN	0x1
Set the SDR or DDR mode	CFG_LVDS_GEN_0.CFG_BIT_CLK_MODE	0x-
Set the SDR or DDR mode clock mux	CFG_LVDS_GEN_0.CCLKSEL1	0x-
Configure the alignment for start of samples	CFG_LVDS_GEN_0.CPOSSEL	0x-
Configure the LVDS FIFO initial threshold	CFG_LVDS_GEN_0.CFDLY	0x8
Set the 3C3L mode if the system configuration is interleaved 3 channel – 3 lane	CFG_LVDS_GEN_1.C3C3L	0x-
Configure the lane-mapping format registers	CFG_LVDS_MAPPING_LANE[X]_FMT_0 CFG_LVDS_MAPPING_LANE[X]_FMT_1	X
Release the CBUFF from soft reset	CONFIG_REG_0.CSWCRST	0x0

The configuration in [Table 10-1230](#) should be performed for each linklist entry required to transmit the LVDS packet.

Table 10-1230. Main Sequence – CBUFF Linklist

Steps	Register/Bit Field/Programming	Value
Set the valid for the linklist	CFG_DATA_LL[X].LL[X]_VALID	0x1
If the linklist is the start of a new LVDS packet	CFG_DATA_LL[X].LL[X]_LPHDR_EN CFG_DATA_LL[X].LL[X]_HS	0x-
Configure the long packet header to static value for LVDS	CFG_DATA_LL[X]_LPHDR_VAL	0xBBBBBBBB
If the linklist is the end of a LVDS packet	CFG_DATA_LL[X].LL[X]_HE	0x-
Configure the size in CBUFF units	CFG_DATA_LL[X].LL[X]_SIZE	X
Configure the format of the CSI2 packet to which the linklist belongs	CFG_DATA_LL[X].LL[X]_FMT	X
Select the LVDS format-mapping register for the LVDS packet	CFG_DATA_LL[X].LL[X]_FMT_MAP	0x-
Set the input format	CFG_DATA_LL[X].LL[X]_FMT_IN	X
Set the Linklist write threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_WR_THRESHOLD	X
Set the Linklist read threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_RR_THRESHOLD	X

10.2.2.3 CBUFF and LVDS Registers

10.2.2.3.1 DSS_CBUFF Registers

Table 10-1231 lists the DSS_CBUFF registers. All register offset addresses not listed in Table 10-1231 should be considered as reserved locations and the register contents should not be modified.

Table 10-1231. DSS_CBUFF Registers

Table 10-1232. CONFIG_REG_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	dbussel	R/W	0h	TI Internal feature. 1 : This selects the debug bus mode transmission on LVDS
27	cswcrst	R/W	0h	CBUFF controller SW Reset 1 => RESET the CBUFF Controller 0 => RELEASE RESET for CBUFF Controller
26	cswlrst	R/W	0h	TI Internal Feature. LVDS logic SW Reset. Debug feature. 1 => RESET the FSM 0 => RELEASE RESET
25	CFG_FRAME_START_TRIG		0h	SW Trigger generation : Write 1 to this bit to generate a Frame Start SW Trigger
24	CFG_CHIRP_AVAIL_TRIG		0h	SW Trigger generation : Write 1 to this bit to generate a Chirp Available SW Trigger
23-20	CFG_VBUSP_BURST_EN	R/W	0h	TI Internal Feature. Only required for 900 Mbps 4 lane trasmission CSI2 only Programming : 0xA : Burst Enable. Set this only for transmission at 900 Mbps Others : Burst disable.

Table 10-1232. CONFIG_REG_0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	dbusen	R/W	0h	TC2 Mode selection. TI Internal feature. 0 : Normal 1 : When in TC2 mode, setting this bit will enable debug bus to sent via LVDS
18	ccfwpen	R/W	0h	TI Internal Feature. Debug only. CSI2 only Programming : CFG_CSI2_FIFO_WORDS_PROCESSING_EN 0 : Use the fifo_free_words directly from CSI2 by vbusp_mstr to decide how many more words to send. 1 : Process the fifo_free_words and use it by vbusp_mstr to decide how many more words to send.
17-16	cvc3en	R/W	0h	CSI2 only Programming : 0 : No Vsync packet is sent at Frame boundary 1 : A VSYNC Start packet on Virtual Channel 3 is generated at beginning of Frame 2 : A VSYNC End packet on Virtual Channel 3 is generated at end of Frame 3 : A VSYNC Start packet on Virtual Channel 3 is generated at beginning of Frame and a VSYNC End packet on Virtual Channel 3 is generated at end of Frame
15-14	cvc2en	R/W	0h	CSI2 only Programming : 0 : No Vsync packet is sent at Frame boundary 1 : A VSYNC Start packet on Virtual Channel 2 is generated at beginning of Frame 2 : A VSYNC End packet on Virtual Channel 2 is generated at end of Frame 3 : A VSYNC Start packet on Virtual Channel 2 is generated at beginning of Frame and a VSYNC End packet on Virtual Channel 2 is generated at end of Frame
13-12	cvc1en	R/W	0h	CSI2 only Programming : 0 : No Vsync packet is sent at Frame boundary 1 : A VSYNC Start packet on Virtual Channel 1 is generated at beginning of Frame 2 : A VSYNC End packet on Virtual Channel 1 is generated at end of Frame 3 : A VSYNC Start packet on Virtual Channel 1 is generated at beginning of Frame and a VSYNC End packet on Virtual Channel 1 is generated at end of Frame
11-10	cvc0en	R/W	0h	CSI2 only Programming : 0 : No Vsync packet is sent at Frame boundary 1 : A VSYNC Start packet on Virtual Channel 0 is generated at beginning of Frame 2 : A VSYNC End packet on Virtual Channel 0 is generated at end of Frame 3 : A VSYNC Start packet on Virtual Channel 0 is generated at beginning of Frame and a VSYNC End packet on Virtual Channel 0 is generated at end of Frame
9	crdthsel	R/W	0h	TI Internal Feature. Debug only. CSI2 only Programming : CFG_RDTHRESHOLD_SEL . This is a Debug feature. Not required in Programming model 0 : The read threshold is selected based on the Write Side parsing engine 1 : The read threshold is selected based on the Read Side parsing engine.
8	ccfwlen	R/W	0h	TI Internal Feature. Debug only. CSI2 only Programming : CFG_CSI2_FIFO_WORDS_LOAD_SW_EN. This is a Debug feature. Not required in Programming model When CFG_CSI2_FIFO_WORDS_PROCESSING_EN==1 and CFG_CSI2_FIFO_WORDS_LOAD_SW_EN==1, then a fixed fifo_free_words from CSI2 is not used. Program the CFG_FIFO_FREE_THRESHOLD0 to 0x4
7-4	NU1	R	0h	
3	CFG_SW_TRIG_EN	R/W	0h	Select Chirp Available Trigger Source 0 : Chirp Available trigger will be generated by HW 1 : Chirp Available trigger will be generated by SW
2	cftrigen	R/W	0h	Select Frame Start Trigger Source 0 : Frame trigger will be generated by HW 1 : Frame trigger will be generated by SW
1	CFG_ECC_EN	R/W	0h	0 : Disable ECC on the CBUF FIFO 1 : Enable ECC on the CBUF FIFO
0	CFG_1LVDS_0CSI	R/W	0h	0 : Send data over CSI-2 1 : Send data over LVDS

10.2.2.3.1.2 CFG_SPHDR_ADDRESS Register (Offset = 4h) [Reset = 0h]

CFG_SPHDR_ADDRESS is shown in [Figure 10-1244](#) and described in [Table 10-1233](#).

Return to the [Table 10-1231](#).

Table 10-1243. CFG_DATA_LL0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	LL0_DATA_WR_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
30	LL0_LONG_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
29	LL0_SHORT_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
28	LL0_CRC_EN	R/W	0h	0 : CRC is disabled 1 : This linklist corresponds to ADC Buffer data. Enable the CRC check from ADC Buffer to CBUFF
27	LL0_LPHDR_EN	R/W	0h	CSI2 Programming : 1 : Entry is start of a new CSI-2 packet. Send the LP Payload Header before sending data correspond to this Linklist 0 : Link list is not the start of a Long packet but part of previous packet and hence directly send data LVDS Programming : 1 : Entry is start of a new LVDS Frame 0 : Entry is not the start of the new LVDS Frame
26	LL0_WAITFOR_PKTSENT	R/W	0h	TI Internal Feature Reserved for future debug enhancement 1 : Wait for packet sent signal ack from CSI2 to move forward 0 : Do not wait for packet sent

Table 10-1243. CFG_DATA_LL0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-23	LL0_BITPOS_SEL	R/W	0h	TI Internal Feature. Reserved for future use to select which of the 12-bits or 14-bits to be picked up from 16-bit CBUFF unit
22-9	LL0_SIZE	R/W	0h	Configure the Size of the data in terms of the number of samples (not in terms of number of bytes). Sample refers to a 16 bit CBUFF Unit
8	LL0_FMT_IN	R/W	0h	0 : The incoming data sources for this Linklist is aligned to 128-bit 1 : The incoming data sources for this Linklist is aligned to 96-bit
7	LL0_FMT_MAP	R/W	0h	LVDS only : 0 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_0_y 1 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_1_y
6-5	LL0_FMT	R/W	0h	Specify the LVDS/CSI2 output format. 00 - 16bit 01 - 14-bit 10 - 12-bit
4-3	LL0_VCNUM	R/W	0h	CSI-2 : Configure the Virtual Channel Number for the Long Packet over which this data is sent
2	LL0_HS	R/W	0h	CSI-2 : 0 : Do not send an Hsync Start packet before sending this data 1 : Send an Hsync Start Packet before sending this data LVDS : 0 : Entry is not the first data of LVDS Frame 1 : Entry is the first data in the LVDS Frame
1	LL0_HE	R/W	0h	CSI-2 : 0 : Do not send an Hsync End packet after sending this data 1 : Send an Hsync End Packet after sending this data LVDS : 0 : Entry is not the last data of LVDS Frame 1 : Entry is the last data in the LVDS Frame
0	LL0_VALID	R/W	0h	0 : Linklist entry is invalid 1 : Linklist entry is valid

10.2.2.3.1.13 CFG_DATA_LL0_LPHDR_VAL Register (Offset = 34h) [Reset = 0h]

CFG_DATA_LL0_LPHDR_VAL is shown in [Figure 10-1255](#) and described in [Table 10-1244](#).

Return to the [Table 10-1231](#).

Payload Description : Linked list entry 0

Table 10-1264. CFG_DATA_LL7 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	LL7_DATA_WR_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
30	LL7_LONG_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
29	LL7_SHORT_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
28	LL7_CRC_EN	R/W	0h	0 : CRC is disabled 1 : This linklist corresponds to ADC Buffer data. Enable the CRC check from ADC Buffer to CBUFF
27	LL7_LPHDR_EN	R/W	0h	CSI2 Programming : 1 : Entry is start of a new CSI-2 packet. Send the LP Payload Header before sending data correspond to this Linklist 0 : Link list is not the start of a Long packet but part of previous packet and hence directly send data LVDS Programming : 1 : Entry is start of a new LVDS Frame 0 : Entry is not the start of the new LVDS Frame
26	LL7_WAITFOR_PKTSENT	R/W	0h	TI Internal Feature Reserved for future debug enhancement 1 : Wait for packet sent signal ack from CSI2 to move forward 0 : Do not wait for packet sent
25-23	LL7_BITPOS_SEL	R/W	0h	TI Internal Feature. Reserved for future use to select which of the 12-bits or 14-bits to be picked up from 16-bit CBUFF unit
22-9	LL7_SIZE	R/W	0h	Configure the Size of the data in terms of the number of samples (not in terms of number of bytes). Sample refers to a 16 bit CBUFF Unit
8	LL7_FMT_IN	R/W	0h	0 : The incoming data sources for this Linklist is aligned to 128-bit 1 : The incoming data sources for this Linklist is aligned to 96-bit
7	LL7_FMT_MAP	R/W	0h	LVDS only : 0 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_0 _y 1 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_1 _y
6-5	LL7_FMT	R/W	0h	Specify the LVDS/CSI2 output format. 00 - 16bit 01 - 14-bit 10 - 12-bit
4-3	LL7_VCNUM	R/W	0h	CSI-2 : Configure the Virtual Channel Number for the Long Packet over which this data is sent
2	LL7_HS	R/W	0h	CSI-2 : 0 : Do not send an Hsync Start packet before sending this data 1 : Send an Hsync Start Packet before sending this data LVDS : 0 : Entry is not the first data of LVDS Frame 1 : Entry is the first data in the LVDS Frame
1	LL7_HE	R/W	0h	CSI-2 : 0 : Do not send an Hsync End packet after sending this data 1 : Send an Hsync End Packet after sending this data LVDS : 0 : Entry is not the last data of LVDS Frame 1 : Entry is the last data in the LVDS Frame
0	LL7_VALID	R/W	0h	0 : Linklist entry is invalid 1 : Linklist entry is valid

10.2.2.3.1.34 CFG_DATA_LL7_LPHDR_VAL Register (Offset = 88h) [Reset = 0h]

CFG_DATA_LL7_LPHDR_VAL is shown in [Figure 10-1276](#) and described in [Table 10-1265](#).

Table 10-1273. CFG_DATA_LL10 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	LL10_DATA_WR_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
30	LL10_LONG_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
29	LL10_SHORT_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
28	LL10_CRC_EN	R/W	0h	0 : CRC is disabled 1 : This linklist corresponds to ADC Buffer data. Enable the CRC check from ADC Buffer to CBUFF
27	LL10_LPHDR_EN	R/W	0h	CSI2 Programming : 1 : Entry is start of a new CSI-2 packet. Send the LP Payload Header before sending data correspond to this Linklist 0 : Link list is not the start of a Long packet but part of previous packet and hence directly send data LVDS Programming : 1 : Entry is start of a new LVDS Frame 0 : Entry is not the start of the new LVDS Frame

Table 10-1273. CFG_DATA_LL10 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	LL10_WAITFOR_PKTSENT	R/W	0h	TI Internal Feature Reserved for future debug enhancement 1 : Wait for packet sent signal ack from CSI2 to move forward 0 : Do not wait for packet sent
25-23	LL10_BITPOS_SEL	R/W	0h	TI Internal Feature. Reserved for future use to select which of the 12-bits or 14-bits to be picked up from 16-bit CBUFF unit
22-9	LL10_SIZE	R/W	0h	Configure the Size of the data in terms of the number of samples (not in terms of number of bytes). Sample refers to a 16 bit CBUFF Unit
8	LL10_FMT_IN	R/W	0h	0 : The incoming data sources for this Linklist is aligned to 128-bit 1 : The incoming data sources for this Linklist is aligned to 96-bit
7	LL10_FMT_MAP	R/W	0h	LVDS only : 0 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_0_y 1 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_1_y
6-5	LL10_FMT	R/W	0h	Specify the LVDS/CSI2 output format. 00 - 16bit 01 - 14-bit 10 - 12-bit
4-3	LL10_VCNUM	R/W	0h	CSI-2 : Configure the Virtual Channel Number for the Long Packet over which this data is sent
2	LL10_HS	R/W	0h	CSI-2 : 0 : Do not send an Hsync Start packet before sending this data 1 : Send an Hsync Start Packet before sending this data LVDS : 0 : Entry is not the first data of LVDS Frame 1 : Entry is the first data in the LVDS Frame
1	LL10_HE	R/W	0h	CSI-2 : 0 : Do not send an Hsync End packet after sending this data 1 : Send an Hsync End Packet after sending this data LVDS : 0 : Entry is not the last data of LVDS Frame 1 : Entry is the last data in the LVDS Frame
0	LL10_VALID	R/W	0h	0 : Linklist entry is invalid 1 : Linklist entry is valid

10.2.2.3.1.43 CFG_DATA_LL10_LPHDR_VAL Register (Offset = ACh) [Reset = 0h]

CFG_DATA_LL10_LPHDR_VAL is shown in [Figure 10-1285](#) and described in [Table 10-1274](#).

Bit	Field	Type	Reset	Description
30	LL23_LONG_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
29	LL23_SHORT_PKT_DELAY_EN	R/W	0h	TI Internal Feature CSI2 only Programming : Use the Packet Delay configured in CFG_DELAY_CONFIG. This is a Debug feature. Not required in Programming model
28	LL23_CRC_EN	R/W	0h	0 : CRC is disabled 1 : This linklist corresponds to ADC Buffer data. Enable the CRC check from ADC Buffer to CBUFF
27	LL23_LPHDR_EN	R/W	0h	CSI2 Programming : 1 : Entry is start of a new CSI-2 packet. Send the LP Payload Header before sending data corresponind to this Linklist 0 : Link list is not the start of a Long packet but part of previous packet and hence directly send data LVDS Programming : 1 : Entry is start of a new LVDS Frame 0 : Entry is not the start of the new LVDS Frame
26	LL23_WAITFOR_PKTSENT	R/W	0h	TI Internal Feature Reserved for furture debug enhancement 1 : Wait for packet sent signal ack from CSI2 to move forward 0 : Do not wait for packet sent
25-23	LL23_BITPOS_SEL	R/W	0h	TI Internal Feature. Reserved for future use to select which of the 12-bits or 14-bits to be picked up from 16-bit CBUFF unit
22-9	LL23_SIZE	R/W	0h	Configure the Size of the data in terms of the numer of samples (not in terms of number of bytes). Sample refers to a 16 bit CBUFF Unit
8	LL23_FMT_IN	R/W	0h	0 : The incoming data sources for this Linklist is aligned to 128-bit 1 : The incoming data sources for this Linklist is aligned to 96-bit
7	LL23_FMT_MAP	R/W	0h	LVDS only : 0 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_0 _y 1 : Choose CFG_LVDS_MAPPING_LANE _x _FMT_1 _y
6-5	LL23_FMT	R/W	0h	Specify the LVDS/CSI2 output format. 00 - 16bit 01 - 14-bit 10 - 12-bit
4-3	LL23_VCNUM	R/W	0h	CSI-2 : Configure the Virtual Channel Number for the Long Packet over which this data is sent
2	LL23_HS	R/W	0h	CSI-2 : 0 : Do not send an Hsync Start packet before sending this data 1 : Send an Hsync Start Packet before sending this data LVDS : 0 : Entry is not the first data of LVDS Frame 1 : Entry is the first data in the LVDS Frame
1	LL23_HE	R/W	0h	CSI-2 : 0 : Do not send an Hsync End packet after sending this data 1 : Send an Hsync End Packet after sending this data LVDS : 0 : Entry is not the last data of LVDS Frame 1 : Entry is the last data in the LVDS Frame
0	LL23_VALID	R/W	0h	0 : Linklist entry is invalid 1 : Linklist entry is valid

10.2.2.3.1.82 CFG_DATA_LL23_LPHDR_VAL Register (Offset = 148h) [Reset = 0h]

CFG_DATA_LL23_LPHDR_VAL is shown in [Figure 10-1324](#) and described in [Table 10-1313](#).

Return to the [Table 10-1231](#).

Table 10-1349. CFG_LVDS_GEN_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CFG_LVDS_GEN_2	R/W	0h	CFG_LVDS_GEN_2[0]: Configure LSB/MSB first for CRC. This feature is supported only when the field CFG_LVDS_GEN_0[28] is set to 1 0 -> The calculated value of 32-bit Ethernet polynomial CRC is swapped and sent out, clear this bit if data is set to LSB first (CFG_LVDS_GEN_0[23]=0) but CRC should be MSB first or vice-versa 1 -> The calculated value of 32-bit Ethernet polynomial CRC is sent out without swapping, set this bit if both data and CRC should have same format (LSB/MSB first) CFG_LVDS_GEN_2[1]: Configure value of frame clock during inter frame period 0 -> Frame clock is held low 1 -> Frame clock is held high CFG_LVDS_GEN_2[2]: Configure frame clock period. This feature is supported only when the field CFG_LVDS_GEN_0[28] is set to 1 0 -> 32-bit CRC is transmitted as single packet with frame clock set to 16h16l (16 high 16 low) configuration 1 -> 32-bit CRC is transmitted as two packets with frame clock set to 8h8l (8 high 8 low) configuration for each packet CFG_LVDS_GEN_2[3]: Configure bit clock during inter frame period 0 -> Bit clock toggles during inter frame period 1 -> Bit clock does not toggle during inter frame period, the value of bit clock is held low This feature is supported when DDR clock is selected (CFG_LVDS_GEN_0[10]=1) and first data sample is driven on posedge of DDR clock (CFG_LVDS_GEN_0[22]=1) CFG_LVDS_GEN_2[4]: Configure CRC inversion. This feature is supported only when the field CFG_LVDS_GEN_0[28] is set to 1 0 -> The calculated value of 32-bit Ethernet polynomial CRC is inverted and sent out 1 -> The calculated value of 32-bit Ethernet polynomial CRC is sent out without inversion CFG_LVDS_GEN_2[5]: Enable/disable the calibration mode, in this mode frame clock will follow data lane[0] 0 -> Calibration mode is disabled 1 -> Calibration mode is enabled

10.2.2.3.1.119 CFG_MASK_REG0 Register (Offset = 1DCh) [Reset = FFFFFFFFh]

CFG_MASK_REG0 is shown in [Figure 10-1361](#) and described in [Table 10-1350](#).

10.2.3 MDO/Aurora

10.2.3.1 Measurement Data Output Infrastructure

10.2.3.1.1 MDO Infra Design Overview

MDO is used to capture the transactions on the bus connected from different interfaces of the TPR1x device and transmitted outside over LVDS (4-data lanes). MDO is comprised of a sniffer, FIFO, and aggregator, which are explained in following sections.

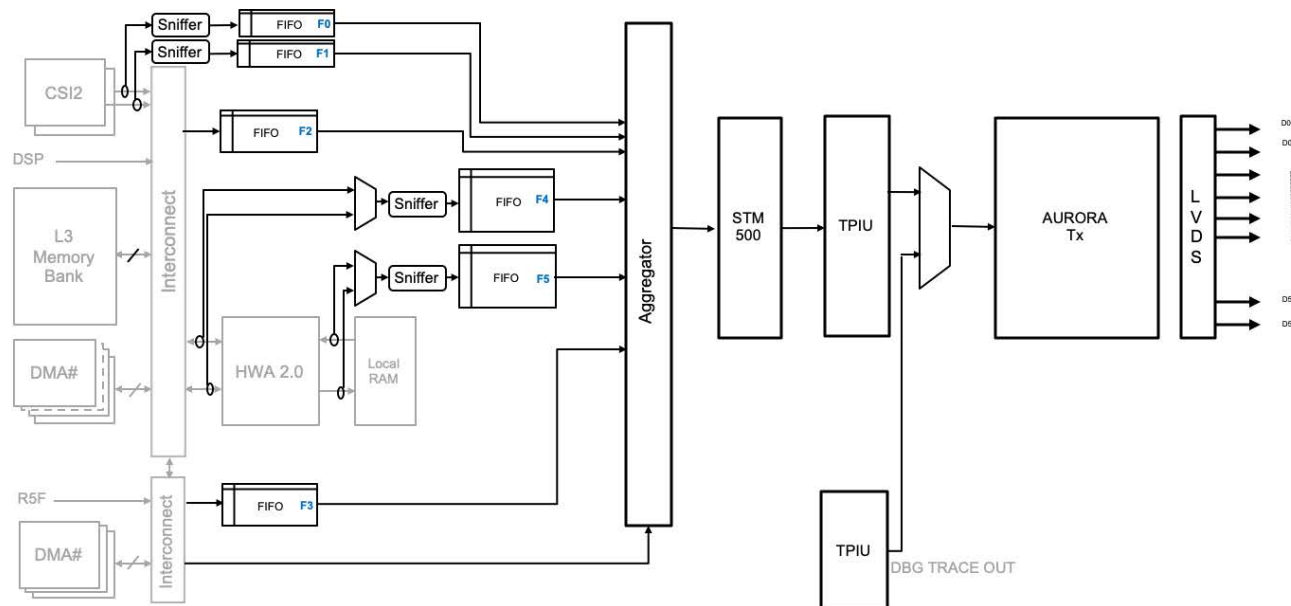

Figure 10-1383. MDO Diagram

As depicted in above figure, the sniffer can access the data from the the CSI2 receiver, L3 memory, DMA, HWA, and from local RAM, which are then sent to the aggregator.

10.2.3.1.2 MDO Sniffer

10.2.3.1.2.1 Overview

The MDO sniffer module is responsible for monitoring the hardware interfaces in the SoC and capturing the transactions on the bus which are within the configured addressing region of interest, and writing the transaction details into a FIFO.

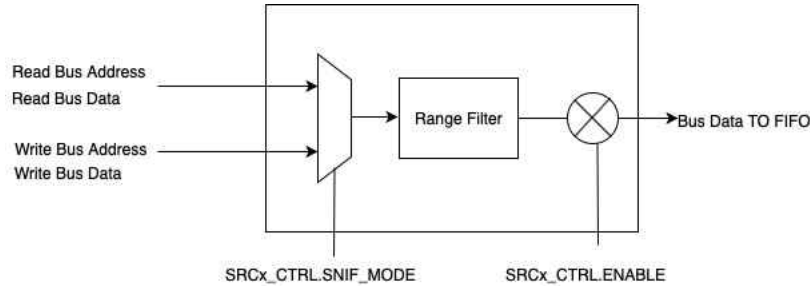

Figure 10-1384. MDO Sniffer

The sniffer module can sniff a bus interface and filter transfers to be sent to the MDO FIFO.

Read OR Write interface can be selected based on the configuration TOP_MDO_INFRA.SRCx_CTRL.SNIF_MODE.

Table 10-1372. MDO Source Address Range Selection

Start Address	End Address	Range Enable
		.RANGE_EN[0]
		.RANGE_EN[1]
		.RANGE_EN[2]
		.RANGE_EN[3]

- The address/paramset is used to filter transactions.
- Only the data bus is captured. Range is not sent to the FIFO.
- On completion of configuration, the sniffer can be enabled by writing 0x1 to .ENABLE.
- If .CROP_EN is set to 0x1, then for every 32 bits of DATA[31:0], DATA[27:16], and DATA[11:0] is written to the FIFO (24 bits).

10.2.3.1.3 MDO FIFO Master

10.2.3.1.3.1 Overview

The data from MDO sniffer accumulates in the FIFO. When a threshold is reached, the data is sent out to the aggregator as a burst transfer.

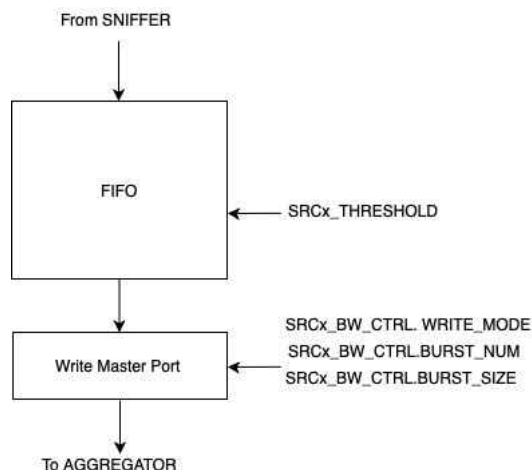

Figure 10-1385. MDO FIFO Master

- When `.WRITE_MODE` is 0x0, then the data is sent out as a burst where the burst size is the `THRESHOLD`.
- When `.WRITE_MODE` is 0x1, then the data is sent out as a series of bursts of count `BURST_NUM` each of size `BURST_SIZE`.

10.2.3.1.3.2 Sniffer Marker Generation

An MDO source can inject a marker indicator along with its data. A marker indicator is sent to the STM module to generate a `FLAG` or `FLAG_TS`.

A marker indicator can be injected into the source stream by:

- A hardware event when register field `:HW_MARKER_EN` is 0x1
- Software writing to the register field `:MARKER`

If `SRCx_CHANNEL_CFG_NONDATA_TIMESTAMPED` is set, then the STM is written to generate a `FLAG_TS` packet; else, a `FLAG` packet is generated.

An MDO source can inject a flush indicator in its data stream. A flush causes all the previous data in the FIFO to be sent to the STM irrespective of the threshold.

A flush indicator can be injected into the source stream by:

- A hardware event when register field `:HW_FLUSH_EN` is 0x1
- Software writing to the register field `:FLUSH`

10.2.3.1.3.3 Sniffer Flush Operation

On a flush request, the MDO FIFO Master empties the FIFO, irrespective of the threshold. Any new data in the FIFO is not drained and is sent out only when the threshold is reached or a new flush request is received.

Figure 10-1386. Sniffer Flush Operation

10.2.3.1.4 MDO Aggregator

10.2.3.1.4.1 Overview

The aggregator module merges the streams of data from the various MDO sources (SRCx) and sends it to the CS-STM Block.

- If there are multiple active SRC streams, it uses round robin arbitration to arbitrate which SRC should be sent.
- When an SRC wins arbitration, it has access for the entire duration of its burst transfer.
- The aggregator module also provides the correct address for the STM channel.

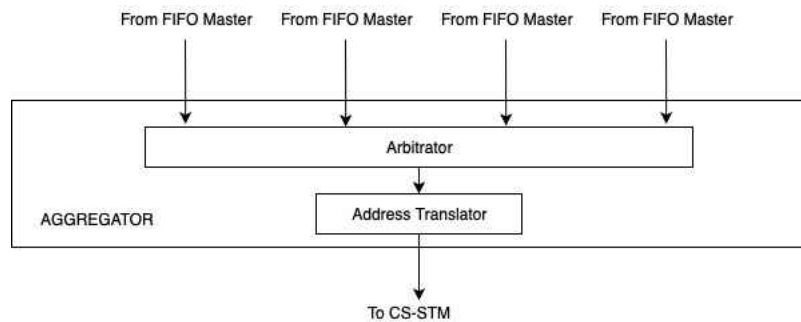

Figure 10-1387. MDO Aggregator

10.2.3.1.4.2 Address Translator - CS_STM Mapping

The address provided to the CS-STM for each of the sources is derived as shown in [Table 10-1373](#) and [Table 10-1374](#).

Table 10-1373. Address Mapping for Data Access

CS-STM Address	Mapping
[31:8]	SRCx_CHANNEL_ADDR[31:8]
[7]	!SRCx_CHANNEL_CFG_DATA_GUARANTEED
[6:5]	Tie Low
[4]	!SRCx_CHANNEL_CFG_DATA_MARKED

Table 10-1373. Address Mapping for Data Access (continued)

CS-STM Address	Mapping
[3]	!SRCx_CHANNEL_CFG_DATA_TIMESTAMPED
[2:0]	Tie Low

Table 10-1374. Address Mapping for Non Data Access

CS-STM Address	Mapping
[31:8]	SRCx_CHANNEL_ADDR[31:8]
[7]	!SRCx_CHANNEL_CFG_NONDATA_GUARANTEED
[6:5]	Tie High
[4]	Tie Low
[3]	!SRCx_CHANNEL_CFG_NONDATA_TIMESTAMPED
[2:0]	Tie Low

10.2.3.1.5 MDO Transmission Example

Table 10-1375. MDO Transmission Example

SRC	Data	Size	Threshold
SRC2	DSP Processor Variables	2 KB	256 Bytes
SRC3	MSS SPI Data	2 KB	256 Bytes
SRC4	HWA 1D FFT Output 256 16 bit complex samples for 4 channels	4 KB	512 Bytes

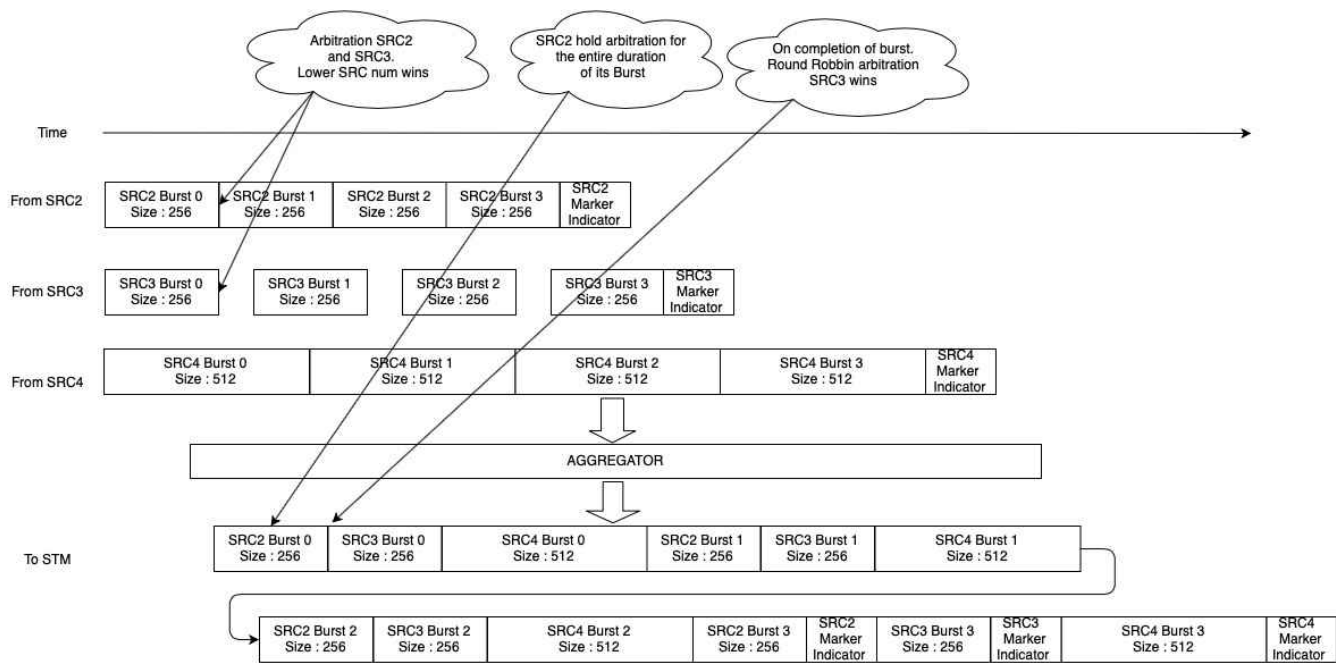

Figure 10-1388. MDO Transmission

10.2.3.1.6 MDO Source Attributes

Table 10-1376. MDO Source Attributes

SRC Num	SRC Name	Read/Write	Bus Matrix Stall Capability	HW Marker Event	Range Selection Parameter
0	RCSS_CSI2A_MDMA	Write	No	0 : RCSS_CSI2A_SOF_INT0 1 : RCSS_CSI2A_SOF_INT1 2 : RCSS_CSI2A_EOF_INT0 3 : RCSS_CSI2A_EOF_INT1	Address
1	RCSS_CSI2B_MDMA	Write	No	0 : RCSS_CSI2B_SOF_INT0 1 : RCSS_CSI2B_SOF_INT1 2 : RCSS_CSI2B_EOF_INT0 3 : RCSS_CSI2B_EOF_INT1	Address
2	DSS_MDO_FIFO	Write	Yes		Address
3	MSS_MDO_FIFO	Write	Yes		Address
4	DSS_HWA_DMA0 OR DSS_HWA_DMA1	Read OR Write	No	No	HWA Param Set Num
5	DSS_HWA_ENGINE	Read OR Write	No		HWA Param Set Num

Note

Because the DSS_MDO_FIFO (Address 0x83400000:0x83403FFC) and MSS_MDO_FIFO (Address 0xCA000000:0xCA00FFFC) have stall capability as they are hooked up to the bus matrix, these sources do not overflow.

10.2.3.1.7 References

Table 10-1377 shows the ARM Coresight components that are part of the MDO Datapath.

10.2.3.2 Aurora TX IP

10.2.3.2.1 Features Supported

The Aurora Tx IP has the following features:

- Configurable 4/2/1 lane of operation
- Transmit data compliant to Aurora 8B/10B Serial Simplex Operation
- Transmit data compliant to Aurora 64B/66B Serial Simplex Operation
- Only Tx support. No Rx support
- Supports input format for TWP from ARM Coresight CS-TPIU IP
- Support for packing TWP packets as an Aurora User PDU
- Configurable option to append CRC for TWP data
- Configurable option to drop TWP padding packets
- Support for transmission of user-defined flow control packet for overflow condition

10.2.3.2.2 Block Diagram

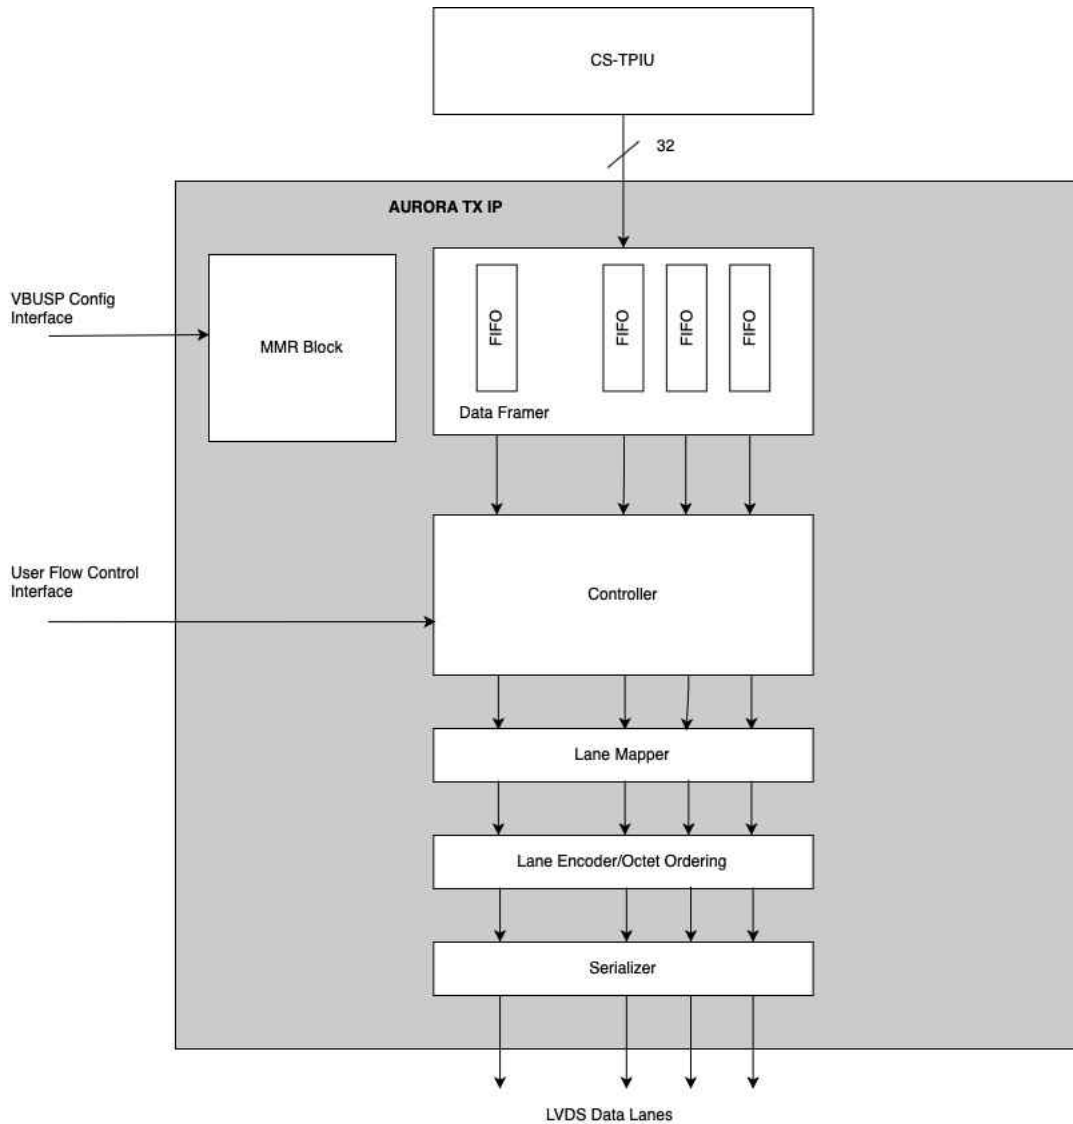

Figure 10-1506. Block Diagram

10.2.3.2.2.1 Aurora UDP Packet Format

The following is the structure of a user data packet.

Figure 10-1507. UDP Packet for 8b10b

Figure 10-1508. UDP Packet for 64b66b

10.2.3.2.2.1.1 Header Data (Optional)

An optional 64-byte frame header is inserted at the start of every aurora packet. The header data should be written to the AURORA_TX_UDP_FRAME_HEADER_n registers. AURORA_TX_UDP_FRAME_HEADER_n is an array of 32-bit registers numbered from 0 to 15.

The AURORA_TX_UDP_CONFIG_FRAME_HEADER_EN of AURORA_TX_UDP_CONFIG register specifies the amount of header data to be sent with the aurora packets in multiples of 4 bytes.

For example, if AURORA_TX_UDP_CONFIG_FRAME_HEADER_EN = 4, a 128-bit header is sent.

10.2.3.2.2.1.2 Packet Completion

The incoming TWP data is packetized to an aurora packet based on the AURORA_TX_UDP_CONFIG:AURORA_TX_UDP_CONFIG_PACK_MODE_SEL register. The available options are:

- Number of bytes transferred. This enables the delineation of aurora packets based on the number of received bytes through the TPIU interface. Configuring the AURORA_TX_UDP_SIZE register specifies the number of bytes. This register value should be a multiple of 4 bytes, as the input TPIU data-width is 32 bits. A write to the AURORA_TX_EOP_REQ_TRIGGER ends the packet abruptly without waiting for the AURORA_TX_UDP_SIZE to be completed. AURORA_TX_UDP_SIZE should be programmed to a value greater than 4.
- Number of TWP packets. This enables the delineation of aurora packets based on the number of TWP packets. Configuring the AURORA_TX_UDP_SIZE register specifies the number of packets. A write to the AURORA_TX_EOP_REQ_TRIGGER ends the packet abruptly without waiting for the AURORA_TX_UDP_SIZE to be completed.
- Software End of Packet signal. The third option enables only the AURORA_TX_EOP_REQ_TRIGGER to end the packet. An aurora packet without an ECP or SEP block is possible if this value is not asserted.

10.2.3.2.2.1.3 Idle Filtering

The idle filter removes all the padding packets from the input TWP stream for transmission through the aurora interface.

The TWP idle filter can be enabled by writing a value of 1 to the AURORA_TX_UDP_CONFIG:TWP_IDLE_FILTER_EN register.

10.2.3.2.2.1.4 Frame Sync Compression

The frame sync compression transmits N consecutive frame syncs and ignores all subsequent consecutive frame syncs. It can be used to avoid sending long frame sync packets when data is not available.

10.2.3.2.2.1.5 CRC

A CRC is computed on 32 bits of input data in a single clock cycle. The computed CRC is inserted at the end of an aurora packet. The CRC insertion is an optional feature which can be enabled by writing a value of 1 to the register AURORA_TX_UDP_CONFIG:CRC_EN.

- A 16-bit CRC is appended in 8b10b mode: $X^{16} + X^{15} + X^2 + 1$
- A 32-bit CRC is appended in 64b66b mode: $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$

10.2.3.2.2.1.6 TEST PATTERN ENABLE

When test mode is enabled, a linear feedback shift register (LSFR) is used to generate a test pattern which is transmitted as user data. Only CRC and pattern data is transmitted in a frame. The polynomial used for the LSFR is $x^{65} + x^{47} + 1$ with initial seed 0x1_6B61A3B5_EF91F65A.

A Ramp pattern is also possible. This generates data in increments of 0x1. To enable this pattern, set the AURORA_TX_TESTPATTERN_CTRL:RAMP_EN bit to 0x1.

10.2.3.2.2.1.7 BYPASS AURORA

Aurora protocol can be disabled by writing a value of 1 to the register AURORA_TX_UDP_CONFIG.BYPASS_EN.

In this mode, the unencoded 8b/10b User Data Packets are transmitted.

The LVDS Pad : LVDS Bit Clk is available.

An additional LVDS Pad is available : LVDS Frame Clock signal to indicate that atleast 1 lane has a Start of Packet/End of Packet.

No Initialization/Clock Compensation/UFC etc is sent. Only UDP.

When the receiver sees Frame Clock high, it indicates one of the following:

- Lane 0 is transmitting an SCP pair (unencoded). This is the “Start of a new packet”.
- One of the lanes is transmitting an ECP pair (unencoded) and subsequent higher lanes are transmitting an Idle packet. This is “End of packet”.

Because the user has the qualifier of Frame Clock for SCP/ECP, there is no mistaking data as control.

LVDS Clock, Frame Clock, and data timing relationship are the same in CBUFF LVDS transmission as in AM273x and mmWave Gen1 Devices. The protocol relationship is as mentioned above.

10.2.3.2.3 Flow Control

10.2.3.2.3.1 Stall and Overflow Mechanism

Data loss due to overflow can occur only at the sniffer. There is no data loss at any other point in the chain. Overflow information is sent as an interrupt to the CPU and the Aurora Tx IP.

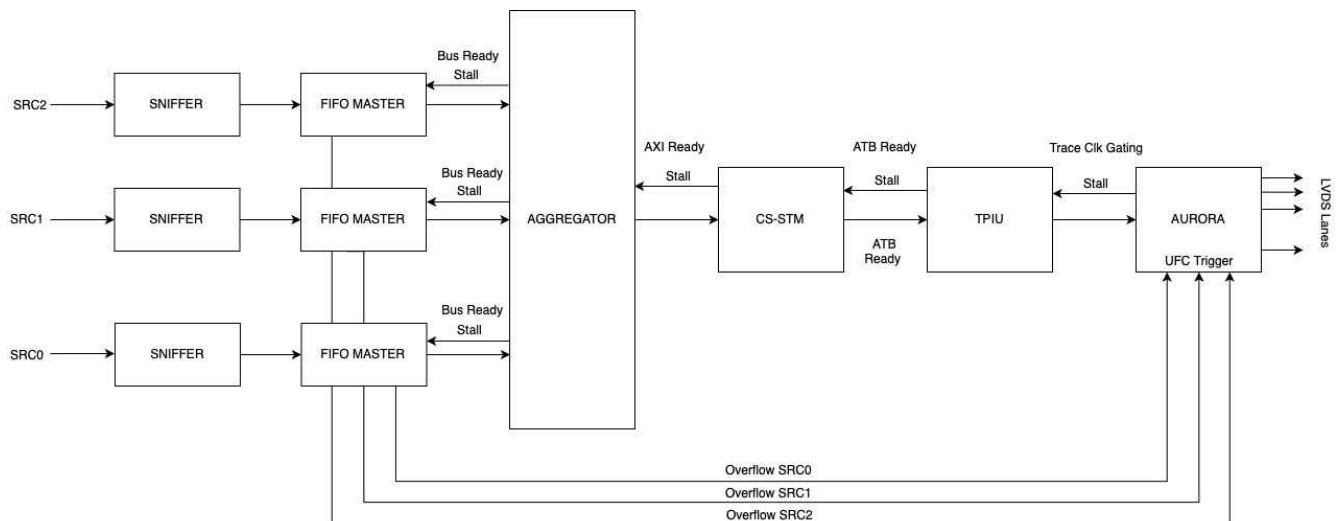

Figure 10-1509. Stall and Overflow Mechanism

10.2.3.2.3.2 Aurora User Flow Control Packet

The Aurora Tx IP on receiving an overflow from a source can generate as User Flow Control Packet.

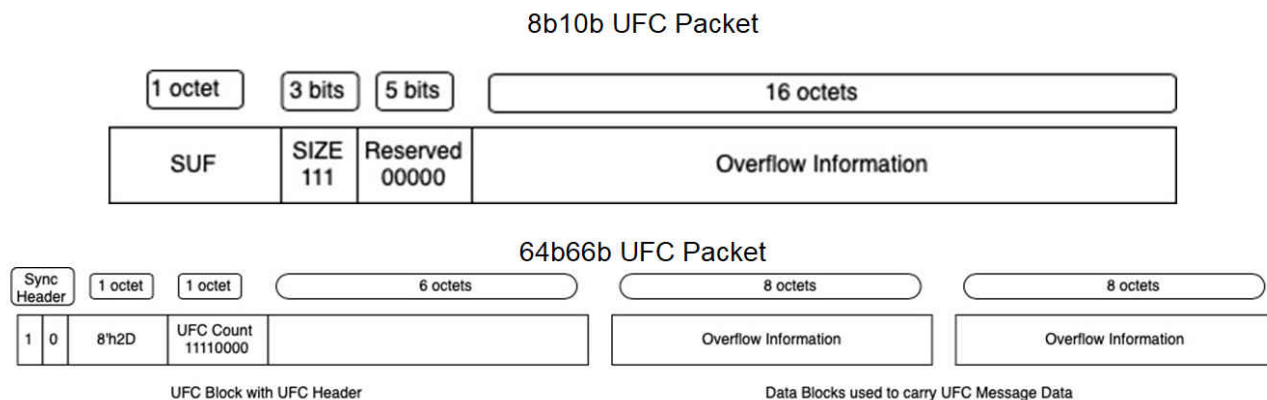

Figure 10-1510. Aurora User Flow Control Packet

10.2.3.2.3.3 Aurora User Flow Control Packet Overflow Information Mapping

The following is the contents of the UFC packet.

SW_MSG0 is the data in register AURORA_TX_UFC_MESSAGE0

SW_MSG1 is the data in register AURORA_TX_UFC_MESSAGE1

Table 10-1496 shows the mapping for the hardware message.

10.2.3.2.5 Global Flush

10.2.3.2.5.1 Architecture

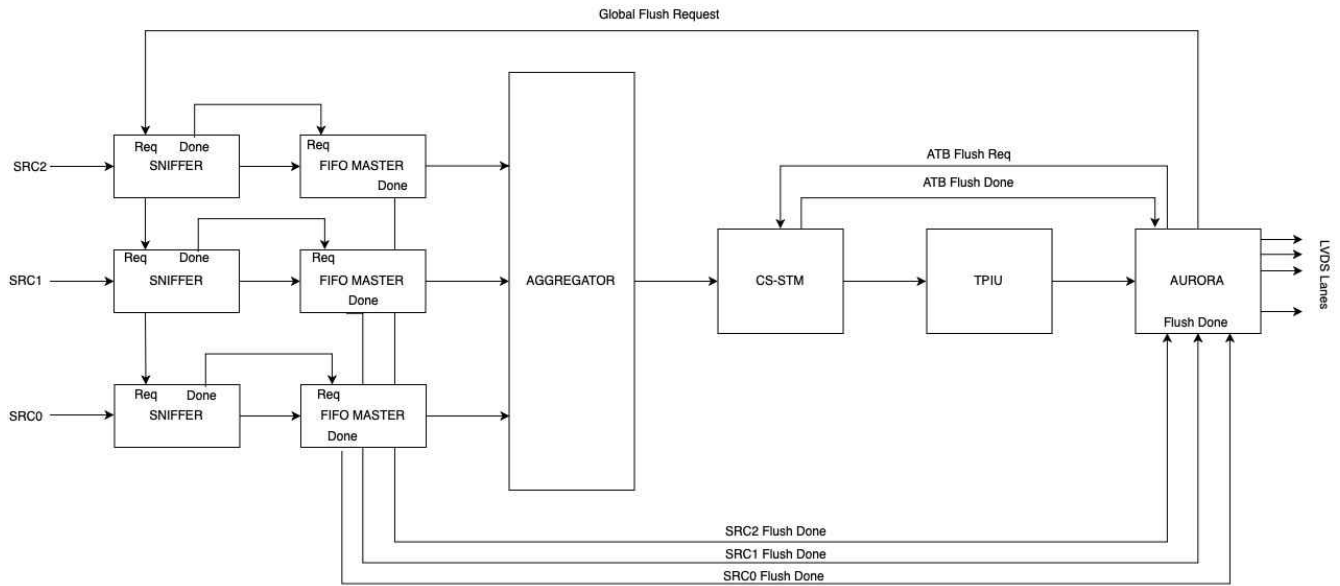

Figure 10-1517. Global Flush Architecture

10.2.3.2.5.2 Sequence

Refer to [Section 10.2.3.2.7](#) for more details on the software sequence.

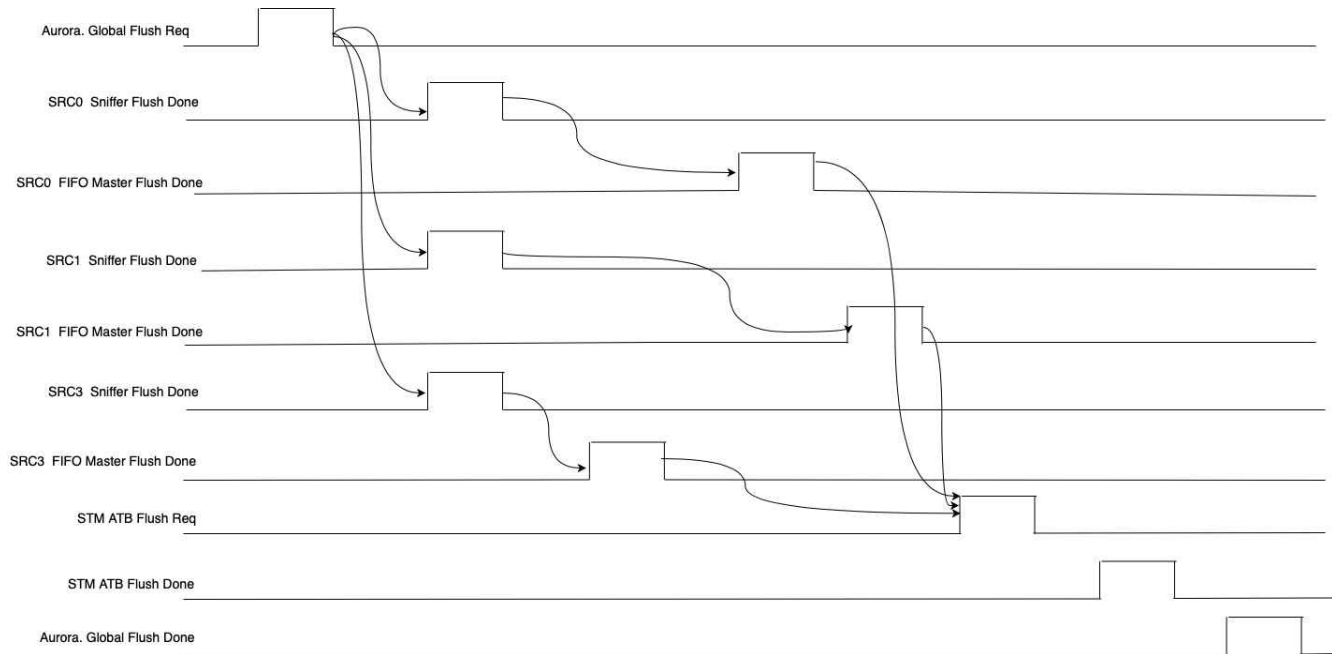

Figure 10-1518. Global Flush Sequence

10.2.3.2.6 Interrupts

The IP generates two interrupt output lines. Each line has the following aggregated interrupts.

10.2.3.2.6.1 AURORA_TX_INTAGG

Table 10-1497 shows the bit aggregation to generate the interrupt. The register AURORA_TX_INTAGG_MASK is used to mask some of the aggregated events from generating an interrupt. On receiving an interrupt, the processor must read the AURORA_TX_INTAGG_STATUS register to analyze the event that caused the interrupt. Writing 0x1 to the corresponding bit set clears the interrupt. Only unmasked events generate an interrupt and their status latched in the AURORA_TX_INTAGG_STATUS register. AURORA_TX_INTAGG_STATUS_RAW latches any event assertion irrespective of the mask register.

Table 10-1497. AURORA_TX_INTAGG Bit Aggregation

Interrupt Number	Interrupt	Description
0	AURORA_TX_INIT_DONE	Indicates completion of Aurora Initialization sequence
1	AURORA_TX_FLUSH_DONE	Indicates that the Aurora IP has completed flush operation on its Data FIFO
2	AURORA_TX_EXT_FLUSH_DONE	Indicates that the MDO infrastructure has completed flushing its components
3	AURORA_TX_UFC_SENT	Indicates that a UFC packet has been generated as sent
4	AURORA_TX_CC_DONE	Indicate completion of Clock compensation sequence transmission
5	DATA_STOP_DONE	
6	AURORA_TX_EOP_DONE	Indicates completion of UDP packets
7	AURORA_TX_HEADER_DONE	Indicates completion of Frame Header transmission

10.2.3.2.6.2 AURORA_TX_ERRAGG

Table 10-1498 shows the bit aggregation to generate the interrupt. The register AURORA_TX_ERRAGG_MASK is used to mask some of the aggregated events from generating an interrupt. On receiving an interrupt, the processor must read the AURORA_TX_ERRAGG_STATUS register to analyze the event that caused the interrupt. Writing 0x1 to the corresponding bit set clears the interrupt. Only unmasked events generate an interrupt and their status latched in the AURORA_TX_ERRAGG_STATUS register. AURORA_TX_ERRAGG_STATUS_RAW latches any event assertion irrespective of the mask register.

Table 10-1498. AURORA_TX_ERRAGG Bit Aggregation

Interrupt Number	Interrupt	Description
0	AURORA_TX_UFC_ERR	Indicates that another UFC generation request was received with the IP was in the progress of transmitting the previous request

10.2.3.2.7 Programming Sequence

10.2.3.2.7.1 Programming Sequence for Typical Data Flow

- Enable lvds PADS from TOP_RCM:
 - LVDS_PAD_CTRL0.LVDS_PAD_CTRL0 = 0
 - LVDS_PAD_CTRL1.LVDS_PAD_CTRL1 = 0
- Program Aurora config registers:
 - AURORA_TX_CONFIG.AURORA_TX_CONFIG_ENABLE = 1
 - AURORA_TX_CONFIG.AURORA_TX_CONFIG_NUM_LANES = 1 (2 lanes active)
 - AURORA_TX_CONFIG.AURORA_TX_CONFIG_PROTOCOL_SEL = 1 (For Aurora 64b/66b)
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_PACK_MODE_SEL = 1 (TWP packets)
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_CRC_EN = 1
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_TWP_SYNC_COMPRESSION_EN = 1
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_TEST_PATTERN_EN = 0
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_BYPASS_EN = 0
 - Configuring for an 8-byte Frame Header:
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_FRAME_HEADER_EN = 2 (Optional)
 - If FRAME_HEADER_EN > 0: AURORA_TX_UDP_FRAME_HEADER0 = 0x900
 - If FRAME_HEADER_EN > 1: AURORA_TX_UDP_FRAME_HEADER1 = 0xA00
 - AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_TWP_IDLE_FILTER_EN = 1

- Mapping Logical Lane 0 and 1 to physical lanes 0 and 1, respectively: `AURORA_TX_LANE_MAP= 0x98`
 - `AURORA_TX_TWP_SYNC_CNT.AURORA_TX_TWP_SYNC_CNT_SYNC_CNT = 2`
 - `AURORA_TX_UDP_SIZE.AURORA_TX_UDP_SIZE = 0x18`
 - `AURORA_TX_CC_CNT.AURORA_TX_CC_CNT_SYNC_COUNT = 0x199C`
3. For Aurora 64b66b only:
 - `AURORA_TX_CB_CNT.AURORA_TX_CB_CNT_CB_COUNT = 0x199C`
 4. Lane initialization sequence count:
 - `AURORA_TX_INIT_CNT_LRC.AURORA_TX_INIT_CNT_LRC = 0x3E8`
 - `AURORA_TX_INIT_CNT_ALIGN.AURORA_TX_INIT_CNT_ALIGN_ALIGN_LEN = 0x10`
 - `AURORA_TX_INIT_CNT_ALIGN.AURORA_TX_INIT_CNT_ALIGN_ALIGN_MUL = 0x7`
 5. Channel bonding sequence count:
 - `AURORA_TX_INIT_CNT_BONDING.AURORA_TX_INIT_CNT_BONDING_BOND_LEN = 0x11`
 - `AURORA_TX_INIT_CNT_BONDING.AURORA_TX_INIT_CNT_BONDING_BOND_MUL = 0x5`
 - `AURORA_TX_INIT_CNT_BONDING.AURORA_TX_INIT_CNT_BONDING_NO_OF_IDLES = 0x4`
 6. For Aurora 8b10b only: Channel verification sequence count:
 - `AURORA_TX_INIT_CNT_VERIFY.AURORA_TX_INIT_CNT_VERIFY_VERIFY_LEN = 0x6`
 - `AURORA_TX_INIT_CNT_VERIFY.AURORA_TX_INIT_CNT_VERIFY_VERIFY_MUL = 0x4`
 7. Assert init req:
 - `AURORA_TX_INITIALIZE_REQ.AURORA_TX_INITIALIZE_REQ_TX_INIT = 1`
 8. Poll for init to get over:
 - `AURORA_TX_INIT_STATUS.AURORA_TX_INIT_STATUS_TX_CH_RDY (to 1).`
 9. For a test pattern, follow this step. Else, skip to Step 11. At this stage, the test pattern can also be enabled so that Aurora starts sending test data generated internally within the Aurora module. This part is optional, and the user can skip this step to directly jump to next step:
 - `AURORA_TX_TESTPATTERN_START_REQ = 1`
 - Wait as long as needed to receive test pattern
 - `AURORA_TX_TESTPATTERN_STOP_REQ = 1`
 10. Clock source selection
 - `TOP_AURORA_TX.AURORA_TX_RESET_REQ.AURORA_TX_RESET_REQ_TX_RESET = 1`
 11. For MDO Data, follow these steps. Programming MDO registers; example scenario: Sniffer 2 , STM channel 3, threshold of 1024 bytes, write mode=0
 -
 -
 -
 -
 -
 - = 0x300 (For STM channel=3, set bits[31:8]=3)
 - Ensure guaranteed access:
 - Enable the sniffer: `TOP_MDO_INFRA.SRC2_CTRL_UN.SRC2_CTRL_ENABLE = 0x1`
 12. Programming STM regs; scenario: sniffer 2 , STM schannel 3, threshold of 1024 bytes, write mode=0 ()
 - `TOP_DEBUGSS.STMTCSR = 0x0` (Initializing to 0)
 - `TOP_DEBUGSS.STMTCSR.EN = 0x1` (Global STM enable)
 - `TOP_DEBUGSS.STMTCSR.TRACEID = 0x1` (Set trace ID to a nonzero value)
 - `TOP_DEBUGSS.STMSPER.STMSPER = 0x8` (Enabling stimulus port:STM channel 3 - bit[3])
 13. Assert data start:
 - `AURORA_TX_DATA_START_REQ. DATA_START = 1`
 14. Trigger the transfer on the subsystem which the user wants to sniff.

10.2.3.2.7.2 To Stop Data Transmission with Flush of Data

1. Disable the sniffer when the user must stop sniffing:
 -
2. Flush MDO-Aurora modules:
 - `AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_PACK_MODE_SEL = 0x3`

- [AURORA_TX_FLUSH_REQ.AURORA_TX_FLUSH_REQ_TRIGGER = 1](#)
3. Poll for flush done:
- [AURORA_TX_INTAGG_STATUS_RAW.AURORA_TX_INTAGG_STATUS_RAW_INT1](#)

10.2.3.2.7.3 To Stop Data Transmission Without Flush of Data

1. Stop Data:
 - [AURORA_TX_UDP_CONFIG.AURORA_TX_UDP_CONFIG_PACK_MODE_SEL = 0x3](#)
 - [AURORA_TX_DATA_STOP_REQ.AURORA_TX_DATA_STOP_REQ_DATA_STOP = 1](#)
2. Poll for Data Stop:
 - [AURORA_TX_INTAGG_STATUS_RAW.AURORA_TX_INTAGG_STATUS_RAW_INT5](#)

10.2.3.2.7.4 Aurora Programming Care-about

- Test patterns support a minimum transfer size of 16 bytes.
- Header-only transmission is not supported.
- Synch compression supports minimum 2 sync packets; less than this cannot be programmed in the [AURORA_TX_TWP_SYNC_CNT](#) register.
- To ensure that the header has been sent out before updating for next header, ensure the header done interrupt has occurred.

LVDS Aurora Muxing

Below table specifies all muxing modes for different functionality:

Register Details: TOP_CTRL:: MDO_CTRL_SRC:: MDO_CTRL_SRC_SELECT

4-Lane LVDS Packaging:

PAD NAME	Legacy Mode (Select = 2'b01)	Aurora Full data (Select = 2'b00)	Aurora bypass (Select = 2'b10)	Aurora (LOP) (Select = 2'b11)
LVDS_TXM1_CLKM LVDS_TXP1_CLKP	Bit clock from cbuff	Data[2] from aurora	Bit clk from aurora	This mode is specific for 3-Lane LVDS packaging
LVDS_TXM2_FRCLKM LVDS_TXP2_FRCLKP	Frame clk from cbuff	Data[3] from aurora	Frame clk from aurora	
LVDS_TXM0_ARCLKM LVDS_TXM0_ARCLKP	Data[0] from cbuff	Data[0] from aurora	Data[0] from aurora	
LVDS_TXM3_ARFRCLKM LVDS_TXP3_ARFRCLKP	Data[1] from cbuff	Data[1] from aurora	Data[1] from aurora	

3-Lane LVDS Packaging:

PAD NAME	Legacy Mode (Select = 2'b01)	Aurora Full data (Select = 2'b00)	Aurora bypass (Select = 2'b10)	Aurora (LOP) (Select = 2'b11)
LVDS_TXM1_CLKM LVDS_TXP1_CLKP	Bit clock from cbuff	Data[2] from aurora	Bit clk from aurora	Bit clk from aurora
LVDS_TXM2_FRCLKM LVDS_TXP2_FRCLKP	Frame clk from cbuff	Data[3] from aurora	Frame clk from aurora	Data[3] from aurora
LVDS_TXM0_ARCLKM LVDS_TXM0_ARCLKP	Data[0] from cbuff	Data[0] from aurora	Data[0] from aurora	Data[0] from aurora
LVDS_TXM3_ARFRCLKM LVDS_TXP3_ARFRCLKP	Not used	Not used	Not used	Not used

2-Lane LVDS Packaging

PAD NAME	Legacy Mode (Select = 2'b01)	Aurora Full data (Select = 2'b00)	Aurora bypass (Select = 2'b10)	Aurora (LOP) (Select = 2'b11)
LVDS_TXM1_CLKM LVDS_TXP1_CLKP	This mode cannot be supported in 2-Lane LVDS	Data[2] from aurora	Bit clk from aurora	Bit clk from aurora
LVDS_TXM2_FRCLKM LVDS_TXP2_FRCLKP		Not used	Not used	Not used
LVDS_TXM0_ARCLKM LVDS_TXM0_ARCLKP		Data[0] from aurora	Data[0] from aurora	Data[0] from aurora
LVDS_TXM3_ARFRCLK LVDS_TXP3_ARFRCLKP		Not used	Not used	Not used

10.2.3.3 TOP_AURORA_TX Registers

This section provides information on the TOP_AURORA_TX Module Instance within this product. Each of the registers within the Module Instance is described separately below.

10.2.3.3.1 TOP_AURORA_TX Registers Mapping Summary

5:00	PID_MINOR	RO	0x13	

10.2.3.3.2.2 TOP_AURORA_TX:AURORA_TX_CONFIG

Address offset: 0x0000 0014

Physical address: 0x0306 0014

Instance: TOP_AURORA_TX

Type: RW

Table 10-1501. TOP_AURORA_TX:AURORA_TX_CONFIG

Bits	Field Name	Type	Reset	Description
18:16	AURORA_TX_CONFIG_NUM_LANES	RW	0x0	Selects the number of lanes for transmission 0 : 1 Lane 1 : 2 Lanes 2 : 3 Lanes 3 : 4 Lanes
2	AURORA_TX_CONFIG_STRICT_ALIGN	RW	1	Reserved for HW RnD. Do not modify
1	AURORA_TX_CONFIG_PROTOCOL_SELECT	RW	0	Selects if the IP is in 8b/10b OR 64b/66b mode. 0 : 8b/10b 1 : 64b/66b
0	AURORA_TX_CONFIG_ENABLE	RW	0	Select to Enable or Disable IP. 0 : Disable 1 : Enable

10.2.3.3.2.3 TOP_AURORA_TX:AURORA_TX_LANE_MAP

Address offset: 0x0000 0018

Physical address: 0x0306 0018

Instance: TOP_AURORA_TX

Type: RO

Table 10-1502. TOP_AURORA_TX:AURORA_TX_LANE_MAP

Bits	Field Name	Type	Reset	Description
31:28:00	AURORA_TX_LANE_MAP_LANE7_MAP	RW	0x0	Reserved for HW RnD. Do not modify
27:24:00	AURORA_TX_LANE_MAP_LANE6_MAP	RW	0x0	Reserved for HW RnD. Do not modify
23:20	AURORA_TX_LANE_MAP_LANE5_MAP	RW	0x0	Reserved for HW RnD. Do not modify
19:16	AURORA_TX_LANE_MAP_LANE4_MAP	RW	0x0	Reserved for HW RnD. Do not modify
15:12	AURORA_TX_LANE_MAP_LANE3_MAP	RW	0x0	Bits [2:0] bits determine the logical lane that is transported over the physical lane 3. 000 : Logical lane 0 is transported over physical lane 3 001 : Logical lane 1 is transported over physical lane 3. ... 111 : Logical lane 7 is transported over physical lane 3. Bit 3 determines if the entry is valid

Table 10-1502. TOP_AURORA_TX:AURORA_TX_LANE_MAP (continued)

Bits	Field Name	Type	Reset	Description
11:08	AURORA_TX_LANE_MAP_LANE2_M AP	RW	0x0	Bits [2:0] determine the logical lane that is transported over the physical lane 2. 000 : Logical lane 0 is transported over physical lane 2 001 : Logical lane 1 is transported over physical lane 2. ... 111 : Logical lane 7 is transported over physical lane 2. Bit 3 determines if the entry is valid
7:04	AURORA_TX_LANE_MAP_LANE1_M AP	RW	0x0	Bits [2:0] determine the logical lane that is transported over the physical lane 1. 000 : Logical lane 0 is transported over physical lane 1 001 : Logical lane 1 is transported over physical lane 1. ... 111 : Logical lane 7 is transported over physical lane 1. Bit 3 determines if the entry is valid
3:00	AURORA_TX_LANE_MAP_LANE0_M AP	RW	0x0	Bits [2:0] determine the logical lane that is transported over the physical lane 0. 000 : Logical lane 0 is transported over physical lane 0 001 : Logical lane 1 is transported over physical lane 0. ... 111 : Logical lane 7 is transported over physical lane 0. Bit 3 determines if the entry is valid

10.2.3.3.2.4 TOP_AURORA_TX:AURORA_TX_UDP_CONFIG

Address offset: 0x0000 001C

Physical address: 0x0306 001C

Instance: TOP_AURORA_TX

Type: RW

Table 10-1503. TOP_AURORA_TX:AURORA_TX_UDP_CONFIG

Bits	Field Name	Type	Reset	Description
20:16	AURORA_TX_UDP_CONFIG_FRAME_ HEADER_EN	RW	0x00	Header Enable configuration 0x0 : Disable Header transmission 0x1 - 0x10 : Number of 32 bit Header to be transmitted
8	AURORA_TX_UDP_CONFIG_BYPASS_ _EN	RW	0	Writing a value of 1'b1 : Bypass the aurora protocol. - No aurora framing is done 1'b0 : Normal Mode - Framing is done as per aurora protocol
7	AURORA_TX_UDP_CONFIG_TEST_P ATTEN_EN	RW	0	Writing a value of 1'b1: Enable the test pattern generation when the aurora transmitter is in IDLE state.

Table 10-1503. TOP_AURORA_TX:AURORA_TX_UDP_CONFIG (continued)

Bits	Field Name	Type	Reset	Description
6	AURORA_TX_UDP_CONFIG_TWP_SYNC_COMPRESSION_EN	RW	0	Writing a value of 1'b1 : Enables the compression of incoming synchronisation packets. This allows only a configurable number of TWP synchronization packets define by AURORA_TX_TWP_SYNC_CNT::AURORA_TX_TWP_SYNC_CNT_SYNC_CNT to be send through aurora interface. 1'b0 : Disable the TWP padding packet filter.
5	AURORA_TX_UDP_CONFIG_CRC_EN	RW	0	Writing a value of 1'b1 : Enable the UDP CRC calculation 1'b0 : Disable UDP CRC calculation
4	AURORA_TX_UDP_CONFIG_TWP_IDLE_FILTER_EN	RW	0	Writing a value of 1'b1 : Filters out the incoming TWP Padding Packet from being send via aurora interface. 1'b0 : Disable the TWP padding packet filter.
1:00	AURORA_TX_UDP_CONFIG_PACK_MODE_SEL	RW	0x0	Configure to select AURORATX_UDP_SIZE format 0: Number of TWP Packets 1 : Number of Bytes 3: SW only

10.2.3.3.2.5 TOP_AURORA_TX:AURORA_TX_UDP_SIZE

Address offset: 0x0000 0020

Physical address: 0x0306 0020

Instance: TOP_AURORA_TX

Type: RW

Table 10-1504. TOP_AURORA_TX:AURORA_TX_UDP_SIZE

Bits	Field Name	Type	Reset	Description
31:00:00	AURORA_TX_UDP_SIZE_SIZE	RW	0x0000 0000	Configure the number of TWP packets or data bytes to be sent as one packet based on AURORATX_CTRL::PACK_MODE. If PACK_MODE=1 Value configure should be multiple of 4 Bytes.

10.2.3.3.2.6 TOP_AURORA_TX:AURORA_TX_UDP_FRAME_HEADER0

Bits	Field Name	Type	Reset	Description
15:00	AURORA_TX_CC_CNT_SYNC_COUNT	RW	0x26FC	The 16-bit count value used to indicate the number of code group octets after which the CC sequence should be transmitted. Default is 0x26FC (decimal 9980) and increasing the period beyond this value is not advised as corruption of data can occur.

10.2.3.3.2.51 TOP_AURORA_TX:AURORA_TX_CB_STATUS

Address offset: 0x0000 0148

Physical address: 0x0306 0148

Instance: TOP_AURORA_TX

Type: RW

Table 10-1550. TOP_AURORA_TX:AURORA_TX_CB_STATUS

Bits	Field Name	Type	Reset	Description
0	AURORA_TX_CB_STATUS_CB_COMP	RW	0	This bit reflects the state of the Channel Bonding FSM. Read 0 : CB Block is not complete. Read 1 : CB Block is complete. Write 0 : No effect. Write 1 : Clears the bit. Setting the SEND_CB bit also clears this bit. This bit is applicable only in the 64B/66B protocol mode after the Channel Ready state has been reached.

10.2.3.3.2.52 TOP_AURORA_TX:AURORA_TX_CB_REQ

Address offset: 0x0000 014C

Physical address: 0x0306 014C

Instance: TOP_AURORA_TX

Type: RW

Table 10-1551. TOP_AURORA_TX:AURORA_TX_CB_REQ

Bits	Field Name	Type	Reset	Description
1	AURORA_TX_CB_REQ_SEND_CB	RW	0	Write pulse bit field: The single bit input that can trigger a Channel Bonding Block. The internal FSM will insert a Channel Bonding sequence at the earliest possible opportunity. This bit is applicable only in the 64B/66B protocol mode after the Channel Ready state has been reached.

10.2.3.3.2.53 TOP_AURORA_TX:AURORA_TX_CB_CNT

Address offset: 0x0000 0150

Physical address: 0x0306 0150

Instance: TOP_AURORA_TX

Type: RW

Table 10-1552. TOP_AURORA_TX:AURORA_TX_CB_CNT

Bits	Field Name	Type	Reset	Description
15:00	AURORA_TX_CB_CNT_CB_COUNT	RW	0x4E20	The 16-bit count value used to indicate the number of data blocks after which the Channel Bonding sequence should be transmitted. The default value is 0x4E20 (decimal 20000). A value of zero will ensure that the Channel Bonding sequence is not sent periodically. In this case, the Channel Bonding sequence can only be sent by setting the SEND_CB bit in the AURORA_TX_CB_REQ register. This bit is applicable only in the 64B/66B protocol mode after the Channel Ready state has been reached.

10.2.3.3.2.54 TOP_AURORA_TX:AURORA_TX_RESET_REQ

Table 10-1563. TOP_AURORA_TX:AURORA_TX_STATUS (continued)

Bits	Field Name	Type	Reset	Description
3:00	AURORA_TX_STATUS_TX_STATE	RO	0x0	<p>These read only bits indicate the state of the transmitter in 8B/10B and 64B/66B.</p> <p>0000 : Reset, no transmission. 0001 : Initialization 0010 : Clock Compensation 0011 : Idle 0100 : UFC 0101 : Run (data) 0110 : Test (data) 0111 : Reserved 1111 : Reserved</p> <p>The user must note that these bits reflect the controller state and that the actual octets on the PHY lines may differ due to internal data path latencies.</p>

10.2.3.3.2.65 TOP_AURORA_TX:AURORA_TX_INIT_STATUS

Address offset: 0x0000 0204

Physical address: 0x0306 0204

Instance: TOP_AURORA_TX

Type: RO

Table 10-1564. TOP_AURORA_TX:AURORA_TX_INIT_STATUS

Bits	Field Name	Type	Reset	Description
4	AURORA_TX_INIT_STATUS_TX_CH_RDY	RO	0	The status bit that indicates that the channel ready state has been reached. This bit is reset with the device reset and when the TX_RESET bit is set.
3	AURORA_TX_INIT_STATUS_TX_TXCB0	RO	0	The status bit that indicates that the TX_TXCB0 state has been completed. This bit is reset with the device reset and when the TX_RESET bit is set.
2	AURORA_TX_INIT_STATUS_TX_INIT0	RO	0	The status bit that indicates that the TX_INIT0 state has been completed. This bit is reset with the device reset and when the TX_RESET bit is set.
1	AURORA_TX_INIT_STATUS_TX_RESET1	RO	0	The status bit that indicates that the TX_RESET1 state has been completed. This bit is reset with the device reset and when the TX_RESET bit is set.
0	AURORA_TX_INIT_STATUS_TX_RESET0	RO	0	The status bit that indicates that the TX_RESET0 state has been completed. This bit is reset with the device reset and when the TX_RESET bit is set.

10.2.3.3.2.66 TOP_AURORA_TX:AURORA_TX_CC_STATUS

Address offset: 0x0000 0208

Physical address: 0x0306 0208

Instance: TOP_AURORA_TX

Type: RW

Table 10-1565. TOP_AURORA_TX:AURORA_TX_CC_STATUS

Bits	Field Name	Type	Reset	Description
0	AURORA_TX_CC_STATUS_CC_COMP	RW	0	This bit reflects the state of the CC FSM. Read 0 : CC sequence is not complete. Read 1 : CC sequence is complete. Write 0 : No effect. Write 1 : Clears the bit. Setting the SEND_CC bit also clears this bit.

10.2.3.3.2.67 TOP_AURORA_TX:AURORA_TX_IDLE_STATUS

Address offset: 0x0000 020C

Physical address: 0x0306 020C

Instance: TOP_AURORA_TX

Type: RW

Table 10-1566. TOP_AURORA_TX:AURORA_TX_IDLE_STATUS

Bits	Field Name	Type	Reset	Description
0	AURORA_TX_IDLE_STATUS_IDLE_COMP	RW	0	This bit reflects the state of the IDLE FSM. Read 0 : IDLE sequence is not complete. Read 1 : IDLE sequence is complete. Write 0 : No effect. Write 1 : Clears the bit. Setting the SEND_IDLE bit also clears this bit.

10.2.3.3.2.68 TOP_AURORA_TX:AURORA_TX_INTAGG_MASK

Address offset: 0x0000 0210

Physical address: 0x0306 0210

Instance: TOP_AURORA_TX

8	AURORA_TX_INTAGG_STATUS_INT8	RW	0	Reserved for HW RnD. Do not modify
7	AURORA_TX_INTAGG_STATUS_INT7	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_HEADER_DONE.
6	AURORA_TX_INTAGG_STATUS_INT6	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_EOP_DONE.
5	AURORA_TX_INTAGG_STATUS_INT5	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of DATA_STOP_DONE.
4	AURORA_TX_INTAGG_STATUS_INT4	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_CC_DONE
3	AURORA_TX_INTAGG_STATUS_INT3	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_UFC_SENT.
2	AURORA_TX_INTAGG_STATUS_INT2	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_EXT_FLUSH_DONE

Table 10-1568. TOP_AURORA_TX:AURORA_TX_INTAGG_STATUS (continued)

Bits	Field Name	Type	Reset	Description
1	AURORA_TX_INTAGG_STATUS_INT1	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_FLUSH_DONE
0	AURORA_TX_INTAGG_STATUS_INT0	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This field indicates assertion of AURORA_TX_INIT_DONE

10.2.3.3.2.70 TOP_AURORA_TX:AURORA_TX_INTAGG_STATUS_RAW

Address offset: 0x0000 0218

Physical address: 0x0306 0218

Instance: TOP_AURORA_TX

Type: RW

Table 10-1569. TOP_AURORA_TX:AURORA_TX_INTAGG_STATUS_RAW

Bits	Field Name	Type	Reset	Description
15	AURORA_TX_INTAGG_STATUS_RAW_INT15	RW	0	Reserved for HW RnD. Do not modify
14	AURORA_TX_INTAGG_STATUS_RAW_INT14	RW	0	Reserved for HW RnD. Do not modify
13	AURORA_TX_INTAGG_STATUS_RAW_INT13	RW	0	Reserved for HW RnD. Do not modify
12	AURORA_TX_INTAGG_STATUS_RAW_INT12	RW	0	Reserved for HW RnD. Do not modify
11	AURORA_TX_INTAGG_STATUS_RAW_INT11	RW	0	Reserved for HW RnD. Do not modify
10	AURORA_TX_INTAGG_STATUS_RAW_INT10	RW	0	Reserved for HW RnD. Do not modify
9	AURORA_TX_INTAGG_STATUS_RAW_INT9	RW	0	Reserved for HW RnD. Do not modify
8	AURORA_TX_INTAGG_STATUS_RAW_INT8	RW	0	Reserved for HW RnD. Do not modify
7	AURORA_TX_INTAGG_STATUS_RAW_INT7	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_HEADER_DONE- Indicates completion of Frame Header transmission.
6	AURORA_TX_INTAGG_STATUS_RAW_INT6	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_EOP_DONE- Indicates completion of UDP packets.
5	AURORA_TX_INTAGG_STATUS_RAW_INT5	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of DATA_STOP_DONE.

Table 10-1569. TOP_AURORA_TX:AURORA_TX_INTAGG_STATUS_RAW (continued)

Bits	Field Name	Type	Reset	Description
4	AURORA_TX_INTAGG_STATUS_RAW_IN_T4	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_CC_DONE- Indicate completion of Clock compensation sequence transmission.
3	AURORA_TX_INTAGG_STATUS_RAW_IN_T3	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_UFC_SENT- Indicates that a UFC packet has been generated as sent.
2	AURORA_TX_INTAGG_STATUS_RAW_IN_T2	RW	1	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_EXT_FLUSH_DONE-Indicates that the MDO infrastructure has completed flushing is components
1	AURORA_TX_INTAGG_STATUS_RAW_IN_T1	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_FLUSH_DONE -Indicates that the Aurora IP has completed flush operation on its Data FIFO
0	AURORA_TX_INTAGG_STATUS_RAW_IN_T0	RW	0	Read of 0x1 indicates a rising edge was detected on the corresponding event line . This is the raw status that will be asserted even if the event has been masked in AURORA_TX_INTAGG_MASK. This field indicates assertion of AURORA_TX_INIT_DONE - Indicates completion of Aurora Initialization sequence

10.3 Memory Interfaces

10.3.1 Quad Serial Peripheral Interface (QSPI)

10.3.1.1 Quad Serial Peripheral Interface Overview	3888
10.3.1.2 QSPI Environment	3889
10.3.1.3 QSPI Integration	3890
10.3.1.4 QSPI Functional Description	3890
10.3.1.5 QSPI Registers	3898

10.3.1.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. [Figure 10-1519](#) shows the QSPI module overview.

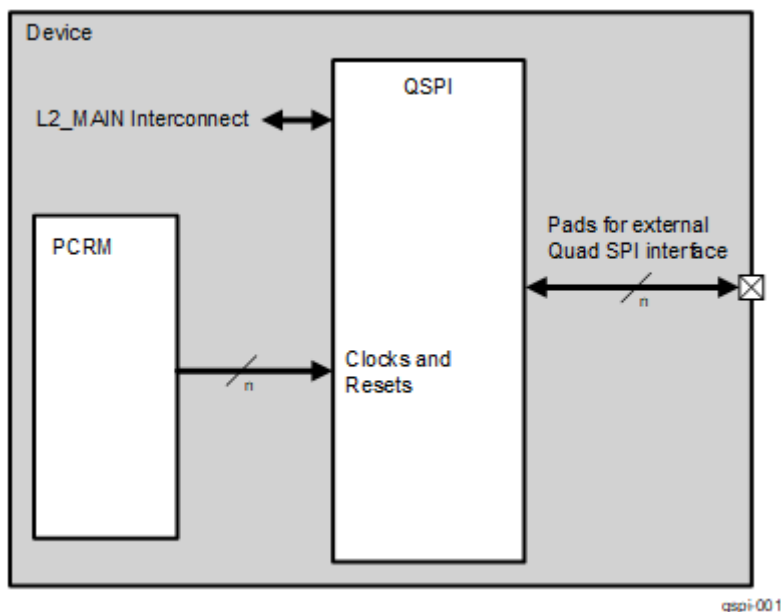

Figure 10-1519. QSPI Overview

The QSPI supports the following features:

- General SPI features:
 - Programmable clock divider
 - Six pin interface
 - Programmable length (from 1 to 128 bits) of the words transferred
 - Programmable number (from 1 to 4096) of the words transferred
 - 2 external chip-select signal
 - Support for 3-, 4-, or 6-pin SPI interface
 - Optional interrupt generation on word or frame (number of words) completion
 - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
 - Programmable signal polarities
 - Programmable active clock edge
 - Software-controllable interface allowing for any type of SPI transfer
 - Control through L2_MAIN configuration port
- Serial flash interface (SFI) features:
 - Serial flash read/write interface
 - Additional registers for defining read and write commands to the external serial flash device
 - 1 to 4 address bytes
 - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
 - Dual read support
 - Quad read support

- Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

Note

The QSPI module does not support cache line wrap mode.

10.3.1.2 QSPI Environment

Figure 10-1520 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

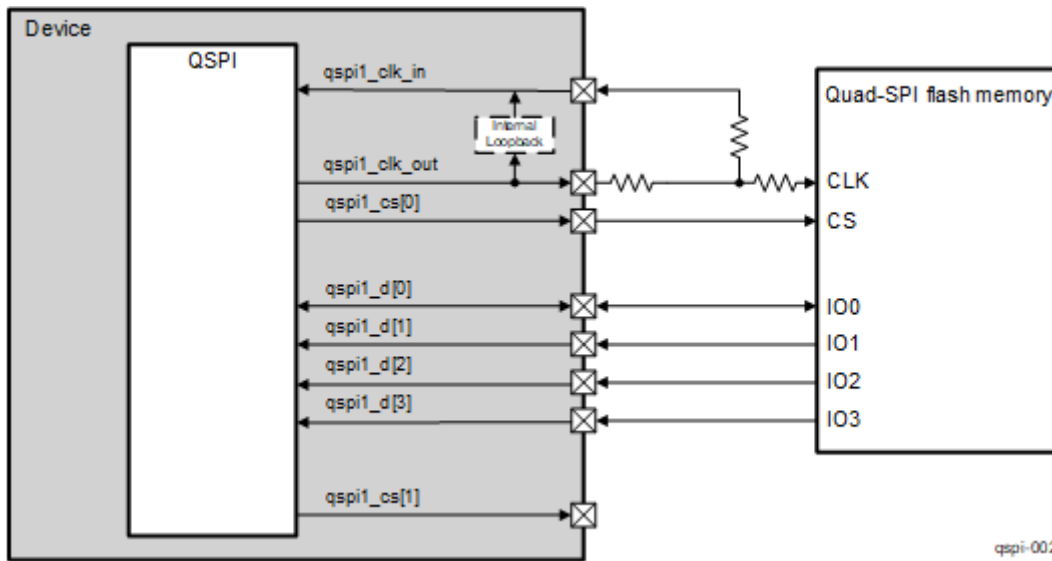

Figure 10-1520. QSPI Connected to an External Quad-SPI Flash Memory

Table 10-1597 lists and describes the QSPI I/O signals.

Table 10-1597. QSPI I/O Signals

QSPI Signal/Pad name	I/O ⁽¹⁾	Description					
		3-pin ⁽²⁾ SPI Read (Single Read)	3-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Single Read)	4-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Dual Read)	6-pin ⁽²⁾ SPI Read (Quad Read)
qspi1_d[0]	IO	Used as SPI data input	Used as SPI data output	Not used	Used as SPI data output	Used as SPI data input 0	Used as SPI data input 0
qspi1_d[1]	I	Not used	Not used	Used as SPI data input	Not used	Used as SPI data input 1	Used as SPI data input 1
qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

(1) I = Input; O = Output

(2) This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

Note

In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

10.3.1.3 QSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

10.3.1.4 QSPI Functional Description

10.3.1.4.1 QSPI Block Diagram

Initial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the `qspi1_d[0]` signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. [Figure 10-1521](#) shows the QSPI block diagram.

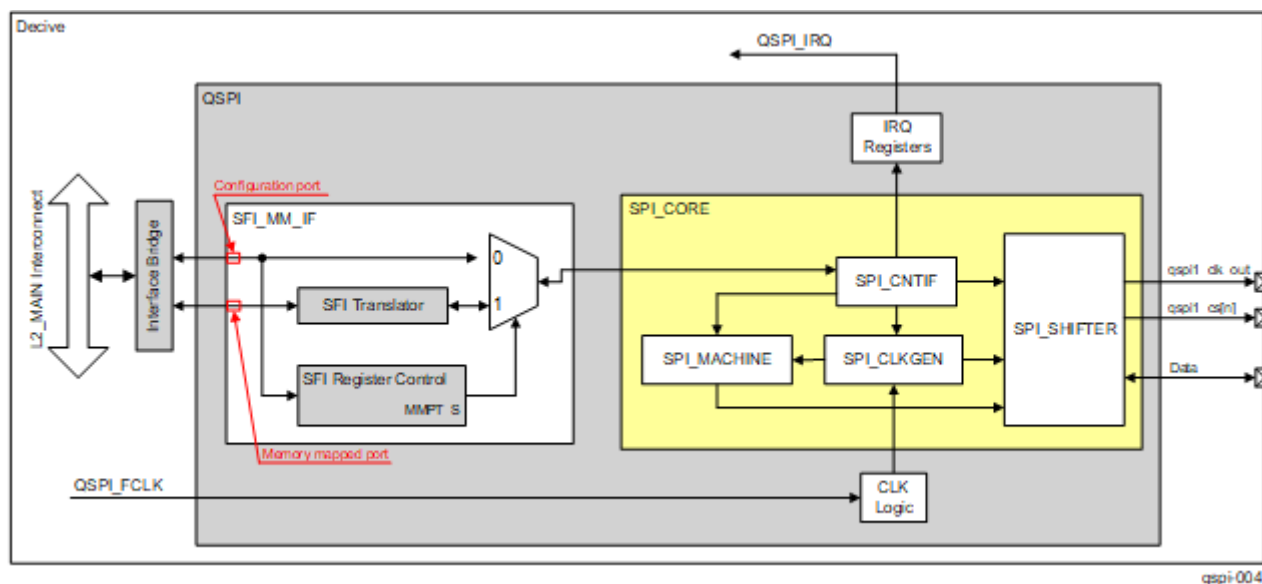

Figure 10-1521. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L2_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

Note

The SFI_MM_IF block only allows reading and writing to an externally connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

10.3.1.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUP_i_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUP_i_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SPI_SETUP_i_REG[9:8] NUM_A_BYTES bit field
- Number of "dummy bytes" that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUP_i_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUP_i_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUP_i_REG[13:12] READ_TYPE bit field. (*i* is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUP_i_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in [Figure 10-1521](#)) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in [Figure 10-1521](#)) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

10.3.1.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

10.3.1.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
 - QSPI_SPI_DATA_REG
 - QSPI_SPI_DATA_REG_1
 - QSPI_SPI_DATA_REG_2
 - QSPI_SPI_DATA_REG_3
- These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits. This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previously described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

Note

The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

10.3.1.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 10-1522 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

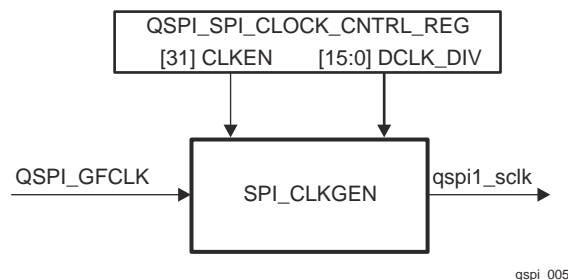

Figure 10-1522. SPI_CLKGEN Block

10.3.1.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG@[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length (QSPI_SPI_CMD_REG[11:0] FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

10.3.1.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. [Table 10-1598](#) lists the four defined clock modes of operation for the QSPI.

Table 10-1598. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

Note

Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

[Figure 10-1523](#) shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

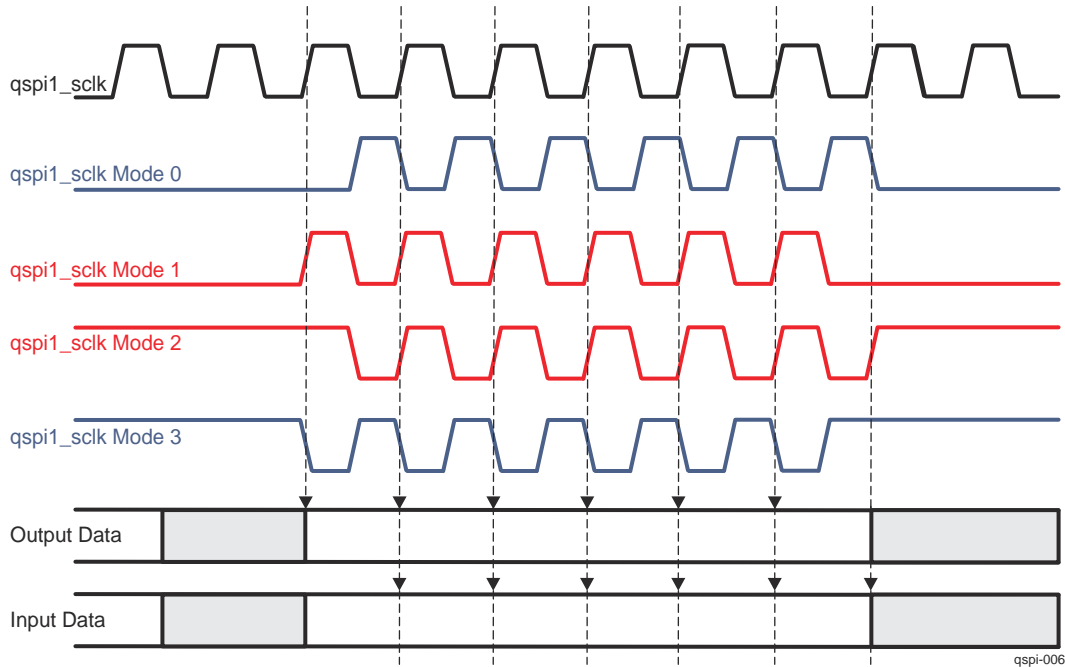

Figure 10-1523. SPI Clock Modes

10.3.1.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

10.3.1.4.3 QSPI Interrupt Requests

Figure 10-1524 shows a logical representation of the QSPI interrupt generation scheme.

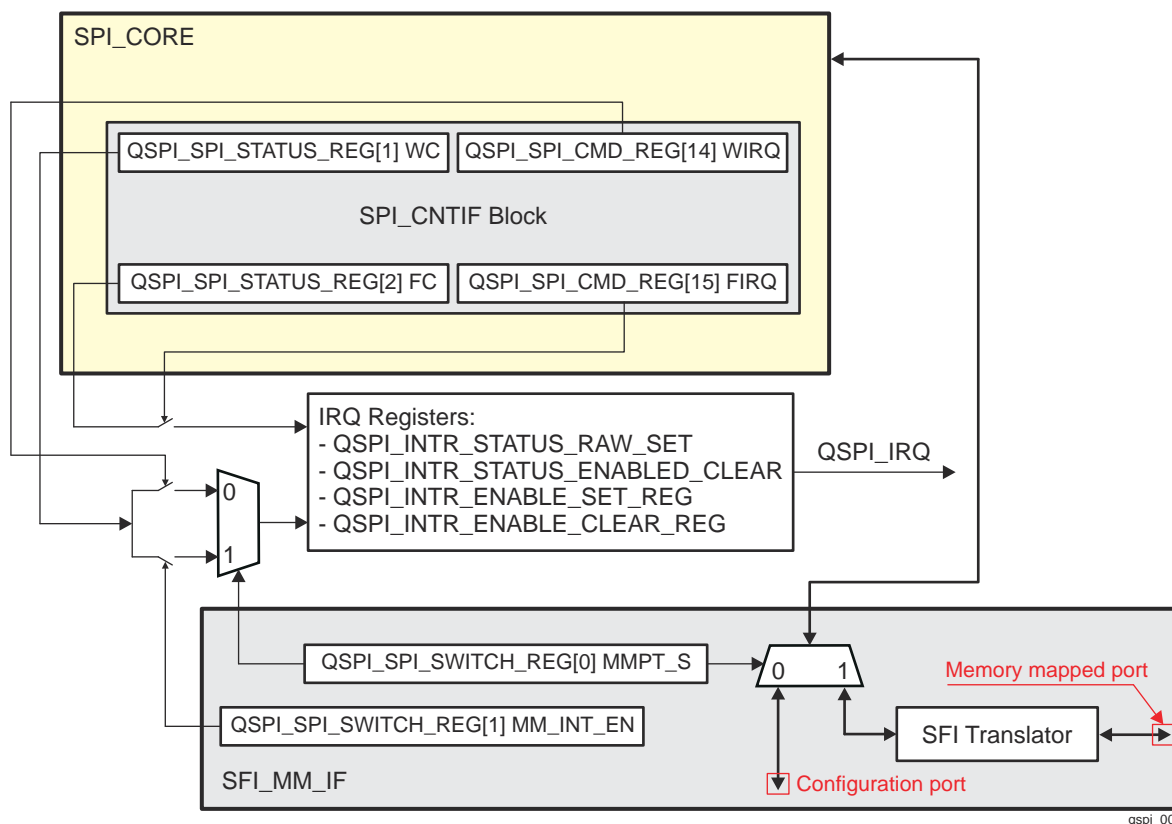

Figure 10-1524. Logical Representation of the QSPI Interrupt Generation Scheme

QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

Note

The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
 - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
 - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 10-1599 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 10-1599. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA QSPI_SPI_STATUS_REG[1] WC	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR QSPI_SPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA QSPI_SPI_STATUS_REG[2] FC	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR QSPI_SPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

Note

QSPI_IRQ can also be used to trigger DMA events

10.3.1.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the supported external SPI devices. The L2_MAIN start address at which the configuration port is available is 0xC800 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x6000 0000 and ends at 0x6200 0000 L2_MAIN address.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 10-1600. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available through these four data registers, which can be accessed only through the configuration port.

10.4 Industrial and Control Interfaces

10.4.1 Enhanced Capture (eCAP) Module

The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important. This microcontroller implements 6 instances of the eCAP module.

10.4.1.1 Introduction	3910
10.4.1.2 Description	3910
10.4.1.3 Capture and APWM Operating Mode	3911
10.4.1.4 Capture Mode Description	3912
10.4.1.5 ECAP Registers	3919
10.4.1.6 Application of the ECAP Module	3934
10.4.1.7 Application of the APWM Mode	3943

10.4.1.1 Introduction

Uses for eCAP include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module described in this guide includes the following features:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

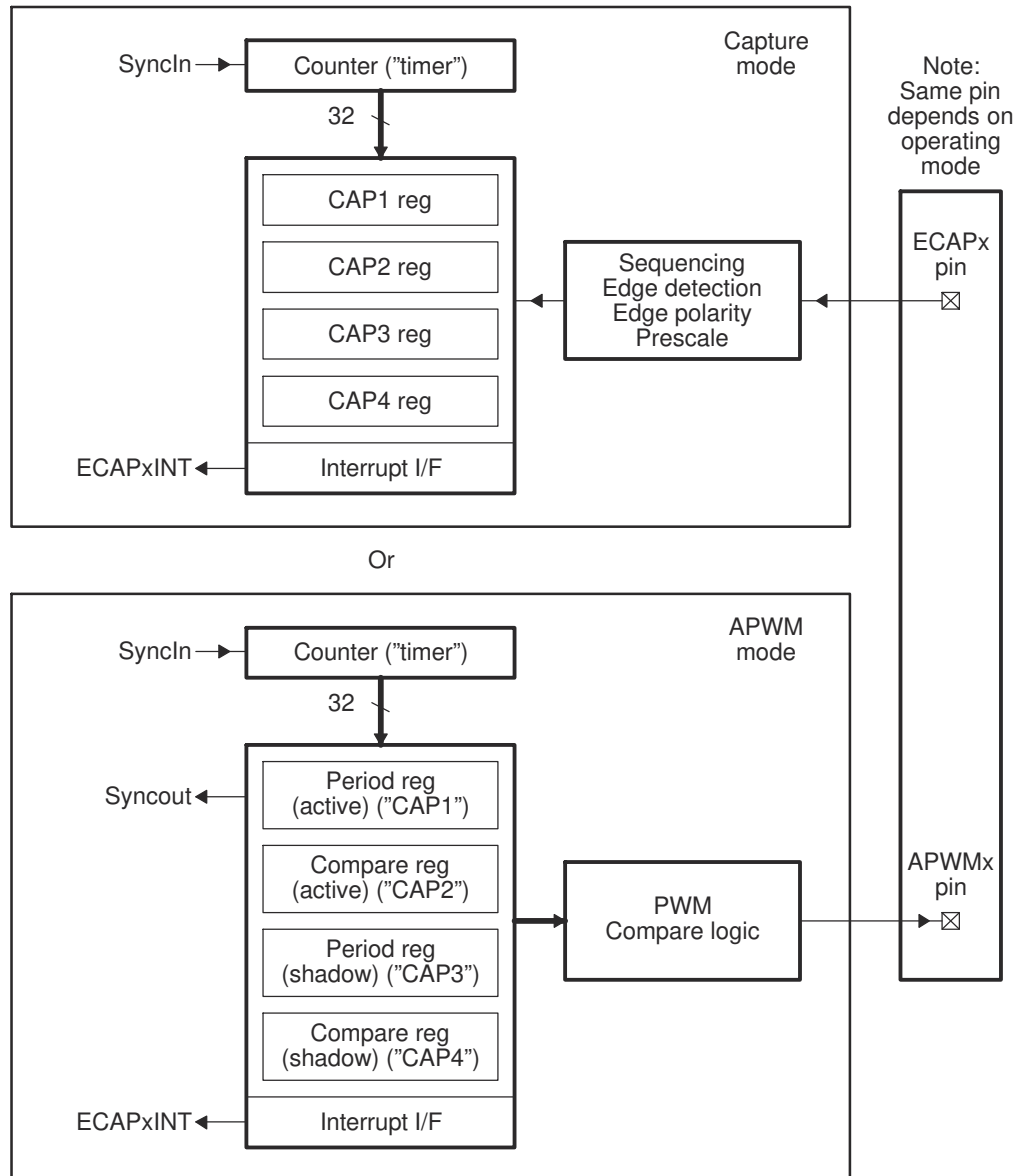

10.4.1.2 Description

In the context of this chapter, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base (counter)
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2 to 62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

10.4.1.3 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 10-1525 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

- A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 10-1525. Capture and APWM Modes of Operation

10.4.1.4 Capture Mode Description

Figure 10-1526 shows the various components that implement the capture function.

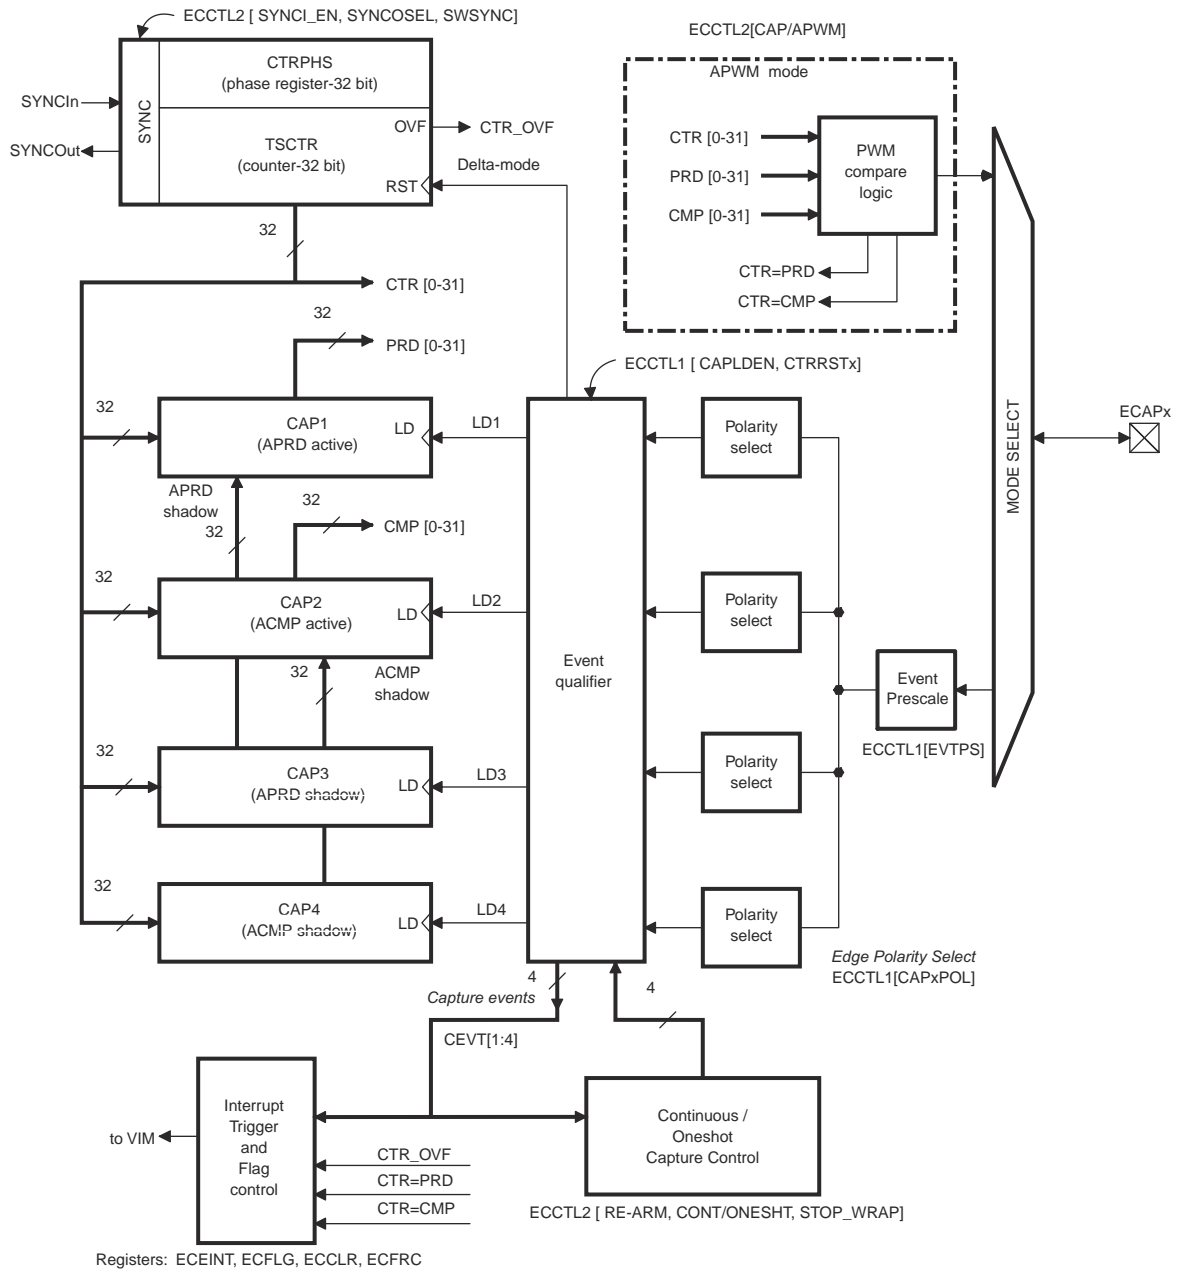

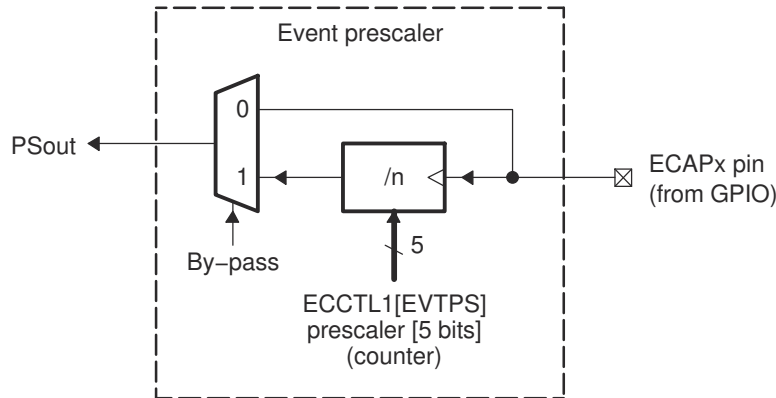

Figure 10-1526. Capture Function Diagram

10.4.1.4.1 Event Prescaler

- An input capture signal (pulse train) can be prescaled by $N = 2-62$ (in multiples of 2) or can bypass the prescaler.

This is useful when very high frequency signals are used as inputs. Figure 10-1527 shows a functional diagram and Figure 10-1528 shows the operation of the prescale function.

- A. When a prescale value of 1 is chosen (that is, $ECCTL1[13:9] = 0,0,0,0,0$) the input capture signal by-passes the prescale logic completely.

Figure 10-1527. Event Prescale Control

Figure 10-1528. Prescale Function Waveforms

10.4.1.4.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection MUXes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

10.4.1.4.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (that is, time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

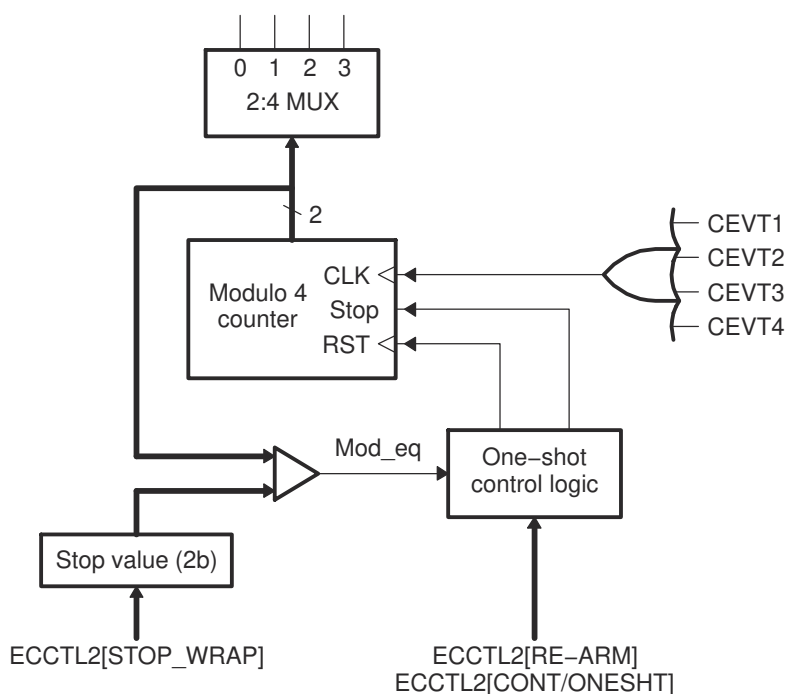

Figure 10-1529. Details of the Continuous/One-shot Block

10.4.1.4.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

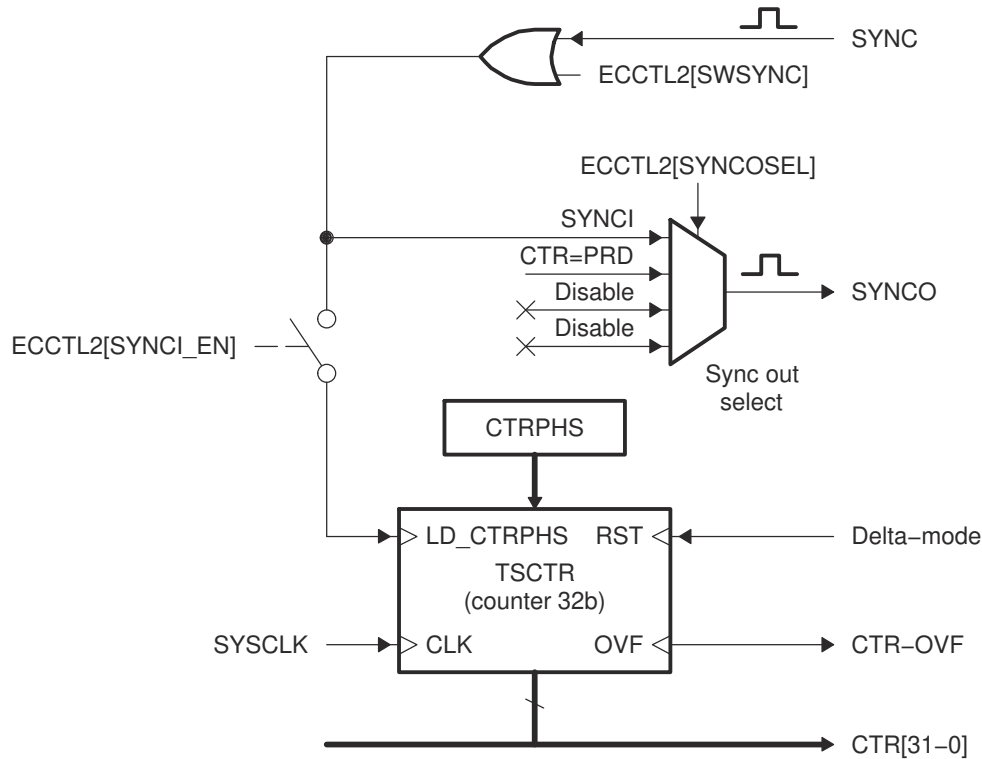

Figure 10-1530. Details of the Counter and Synchronization Block

10.4.1.4.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (that is, capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, that is, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

10.4.1.4.6 Interrupt Control

An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).

A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

Note: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP_APWM == 0]). The CTR_PRD, CTR_CMP flags are only valid in APWM mode (ECCTL2[CAP_APWM == 1]). CNTOVF flag is valid in both modes.

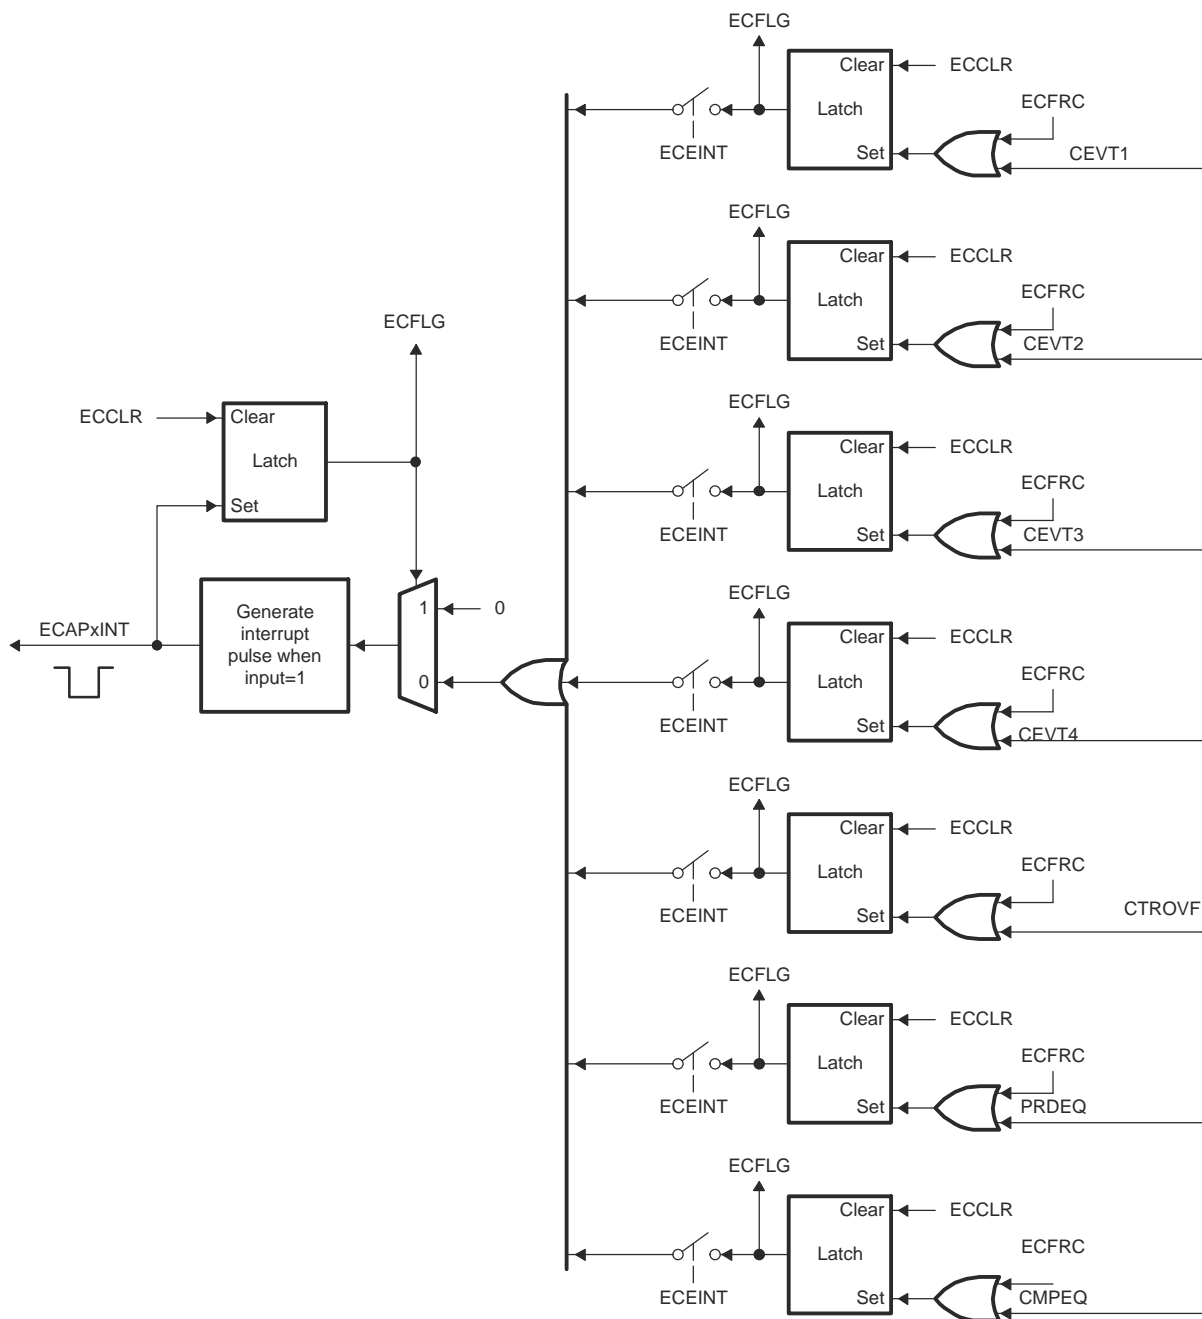

Figure 10-1531. Interrupts in eCAP Module

10.4.1.4.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, that is, CTR[31:0] = PRD[31:0]

10.4.1.4.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, that is, during run-time, you only need to use the shadow registers.

Figure 10-1532. PWM Waveform Details Of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

```
CMP = 0x00000000, output high for duration of period (0% duty)
```

```
CMP = 0x00000001, output low 1 cycle
```

```
CMP = 0x00000002, output low 2 cycles
```

```
CMP = PERIOD, output low except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output low for complete period (100% duty)
```

```
CMP > PERIOD+1, output low for complete period
```

10.4.1.5 ECAP Registers

Table 10-1621 lists the memory-mapped registers for the ECAP. All register offset addresses not listed in Table 10-1621 should be considered as reserved locations and the register contents should not be modified.

The base address for the control registers is FCF7 9300h for eCAP1, FCF7 9400h for eCAP2, FCF7 9500h for eCAP3, FCF7 9600h for eCAP4, FCF7 9700h for eCAP5, and FCF7 9800h for eCAP6.

Table 10-1621. ECAP Registers

CAP2 is shown in [Figure 10-1536](#) and described in [Table 10-1626](#).

Return to [Table 10-1621](#).

In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 10-1536. CAP2 Register

Table 10-1628. CAP4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CAP4	R/W	0h	In CMP mode, this is a time-stamp capture register. In APWM mode, this is the compare shadow (ACMP) register. Update the PWM compare value via this register. In this mode, CAP4 (ACMP) shadows CAP2.

10.4.1.5.7 ECCTL2 Register (Offset = 28h) [reset = 2h]

ECCTL2 is shown in [Figure 10-1539](#) and described in [Table 10-1629](#).

Return to [Table 10-1621](#).

Figure 10-1539. ECCTL2 Register

15	14	13	12	11	10	9	8
RESERVED					APWMPOL	CAP_APWM	SWSYNC
R-0h					R/W-0h	R/W-0h	R/W-0h
7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCI_EN	TSCTRSTOP	REARM	STOP_WRAP		CONT_ONESH T
R/W-0h		R/W-0h	R/W-0h	R/W-0h	R/W-1h		R/W-0h

Table 10-1629. ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode. 0h = Output is active high (that is, Compare value defines high time). 1h = Output is active low (that is, Compare value defines low time).
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select. 0h = ECAP module operates in capture mode. This mode forces the following configuration: inhibits TSCTR resets via CTR = PRD event, inhibits shadow loads on CAP1 and CAP2 registers, permits user to enable CAP1 to CAP4 register load, CAPx and APWMx pin operates as a capture input. 1h = ECAP module operates in APWM mode. This mode forces the following configuration: resets TSCTR on CTR = PRD event (period boundary, permits shadow loading on CAP1 and CAP2 registers, disables loading of time-stamps into CAP1 to CAP4 registers, CAPx and APWMx pin operates as a APWM output.
8	SWSYNC	R/W	0h	Software-forced Counter (TSCTR) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the CTR = PRD event. Note: Selection CTR = PRD is meaningful only in APWM mode, however, you can choose it in CAP mode if you find doing so is useful. 0h = Writing a 0 has no effect. Reading always returns 0. 1h = Writing a 1 forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to 0.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select. 0h = Select sync-in event to be the sync-out signal (pass through). 1h = Select CTR = PRD event to be the sync-out signal. 2h = Disable sync out signal. 3h = Disable sync out signal.
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode. 0h = Disable sync-in option. 1h = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a software force event.

Table 10-1629. ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control. 0h = TSCTR is stopped. 1h = TSCTR is free-running.
3	REARM	R/W	0h	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0h = Writing a 0 has no effect. Reading always returns 0. 1h = Arms the one-shot sequence as follows: resets the Mod4 counter to 0, unfreezes the Mod4 counter, enables capture register loads.
2-1	STOP_WRAP	R/W	1h	Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, two actions occur: 1) Mod4 counter is stopped (frozen). 2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again. 0h = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 1h = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 2h = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 3h = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control. This is applicable only in capture mode. 0h = Operate in continuous mode. 1h = Operate in one-shot mode.

10.4.1.5.8 ECCTL1 Register (Offset = 2Ah) [reset = 0h]

ECCTL1 is shown in [Figure 10-1540](#) and described in [Table 10-1630](#).

Return to [Table 10-1621](#).

0	INT	R	0h	Global Interrupt Status Flag. 0h = No interrupt is generated. 1h = An interrupt is generated.

10.4.1.5.10 ECEINT Register (Offset = 2Eh) [reset = 0h]

ECEINT is shown in [Figure 10-1542](#) and described in [Table 10-1632](#).

Return to [Table 10-1621](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events are still latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows: 1) Disable global interrupts. 2) Stop eCAP counter. 3) Disable eCAP interrupts. 4) Configure peripheral registers. 5) Clear spurious eCAP interrupt flags. 6) Enable eCAP interrupts. 7) Start eCAP counter. 8) Enable global interrupts.

10.4.1.6 Application of the ECAP Module

The following sections will provide applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, the examples use the eCAP “C” header files. Below are useful #defines that will help in the understanding of the examples.

```

// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING 0x0
#define EC_FALLING 0x1
// CTRRSTx bits
#define EC_ABS_MODE 0x0
#define EC_DELTA_MODE 0x1
// PRESCALE bits
#define EC_BYPASS 0x0
#define EC_DIV1 0x0
#define EC_DIV2 0x1
#define EC_DIV4 0x2
#define EC_DIV6 0x3
#define EC_DIV8 0x4
#define EC_DIV10 0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS 0x0
#define EC_ONESHOT 0x1
// STOPVALUE bit
#define EC_EVENT1 0x0
#define EC_EVENT2 0x1
#define EC_EVENT3 0x2
#define EC_EVENT4 0x3
// RE-ARM bit
#define EC_ARM 0x1
// TSCTRSTOP bit
#define EC_FREEZE 0x0
#define EC_RUN 0x1
// SYNCO_SEL bit
#define EC_SYNCIN 0x0
#define EC_CTR_PRD 0x1
#define EC_SYNCO_DIS 0x2
// CAP/APWM mode bit
#define EC_CAP_MODE 0x0

// APWMPOL bit
#define EC_ACTV_HI 0x0
#define EC_ACTV_LO 0x1
// Generic
#define EC_DISABLE 0x0
#define EC_ENABLE 0x1
#define EC_FORCE 0x1

```

10.4.1.6.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 10-1545 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (that is, time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (that is, maximum value), it wraps around to 0000 0000h (not shown in Figure 10-1545), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram, that is, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

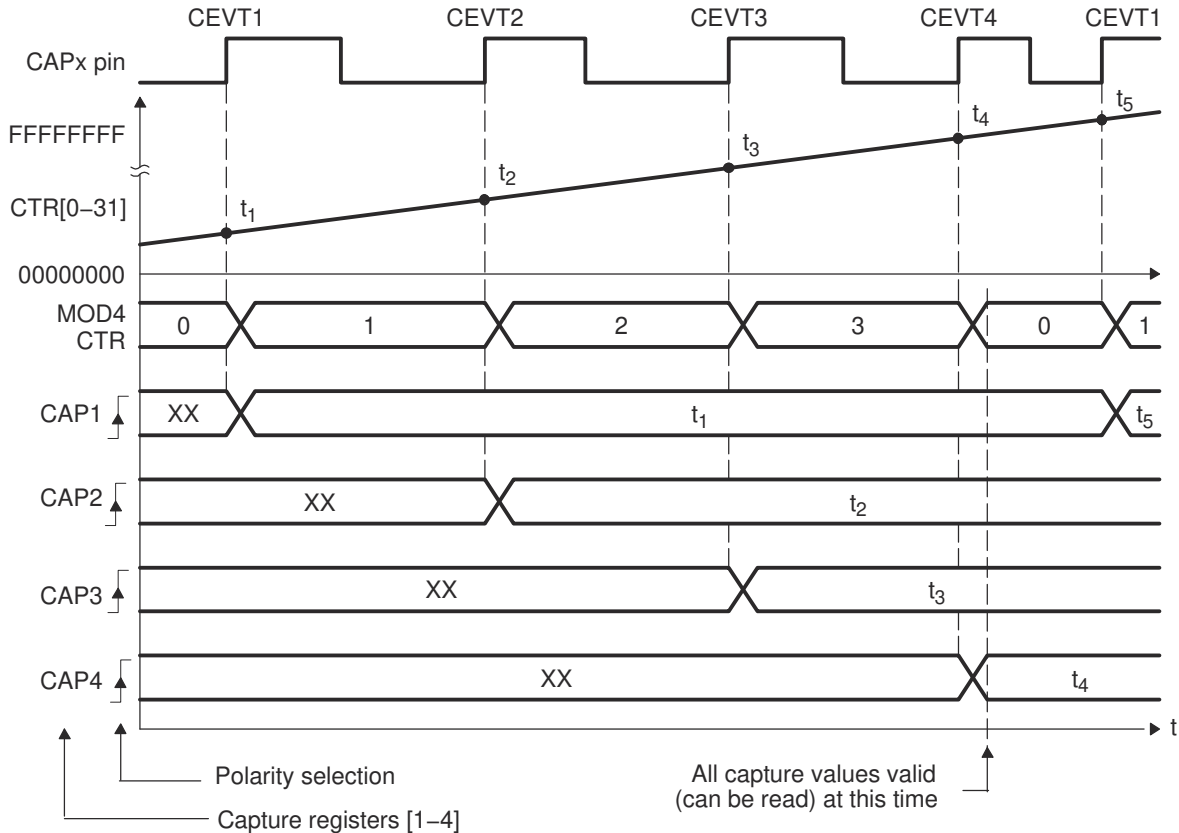

Figure 10-1545. Capture Sequence for Absolute Time-stamp and Rising Edge Detect

10.4.1.6.1 Code snippet for CAP mode Absolute Time, Rising Edge Trigger

```

// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;

// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at t1
TSt2 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at t2
TSt3 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at t3
TSt4 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1; // Calculate 1st period
Period2 = TSt3-TSt2; // Calculate 2nd period
Period3 = TSt4-TSt3; // Calculate 3rd period

```

10.4.1.6.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 10-1546 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is, $\text{Period1} = t_3 - t_1$, $\text{Period2} = t_5 - t_3$, and so on; $\text{Duty Cycle1 (on-time \%)} = (t_2 - t_1) / \text{Period1} \times 100\%$, and so on; $\text{Duty Cycle1 (off-time \%)} = (t_3 - t_2) / \text{Period1} \times 100\%$, and so on.

Figure 10-1546. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect

10.4.1.6.2.1 Code snippet for CAP mode Absolute Time, Rising & Falling Edge Triggers

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Initialization Time
//=====

```

10.4.1.6.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

This example Figure 10-1547 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (that is, time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (that is, maximum value), before the next event, it wraps around to 0000 0000h and continues, a CANTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = T_1 , Period2 = T_2 , and so on. As shown in the diagram, the CEVT1 event is a good trigger point to read the timing data, T_1 , T_2 , T_3 , T_4 are all valid here.

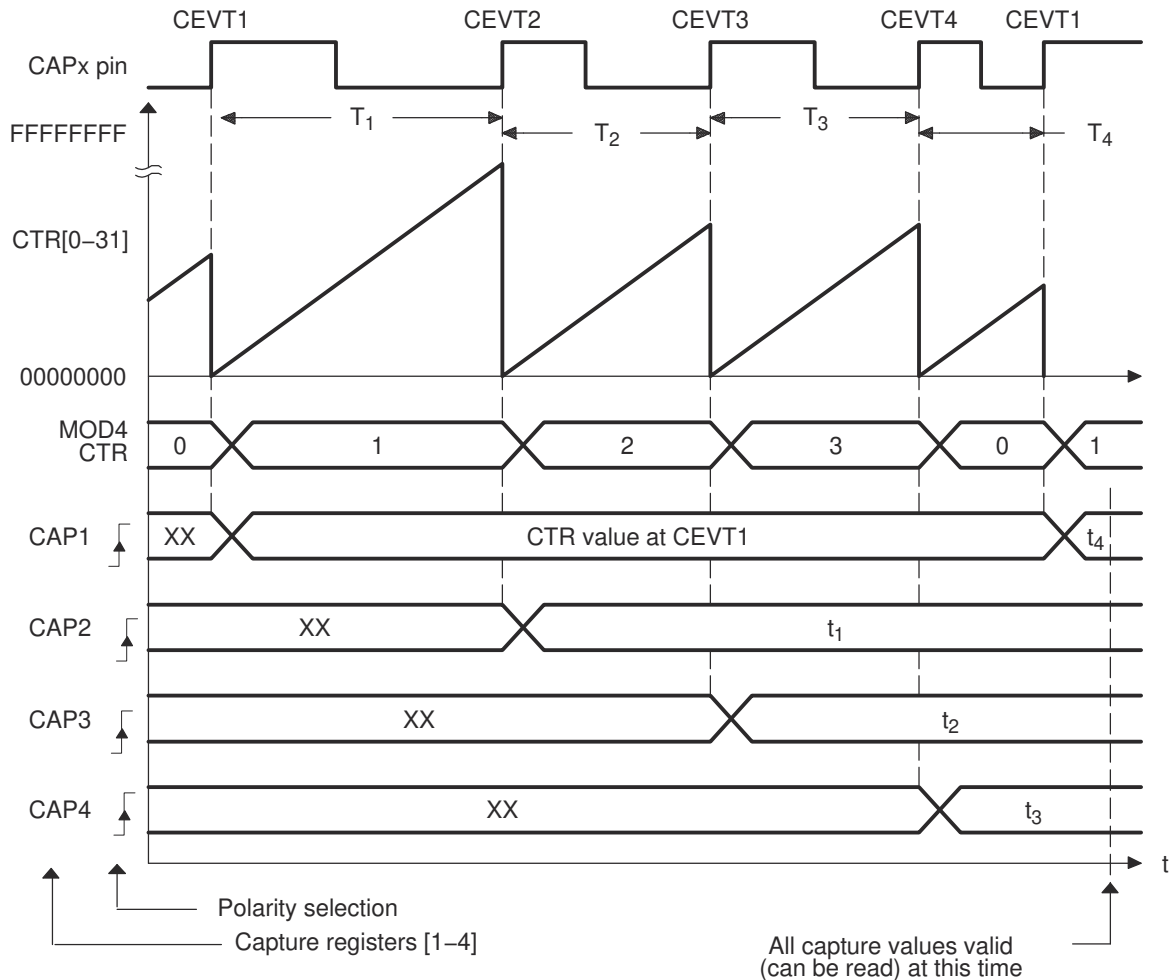

Figure 10-1547. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

10.4.1.6.3.1 Code snippet for CAP mode Delta Time, Rising Edge Trigger

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at T2
Period2 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at T3
Period3 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at T4
```

10.4.1.6.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 10-1548 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is, $Period1 = T_1 + T_2$, $Period2 = T_3 + T_4$, and so on; $Duty Cycle1 (on-time \%) = T_1 / Period1 \times 100\%$, and so on; $Duty Cycle1 (off-time \%) = T_2 / Period1 \times 100\%$, and so on.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, during run-time, only the shadow registers must be used.

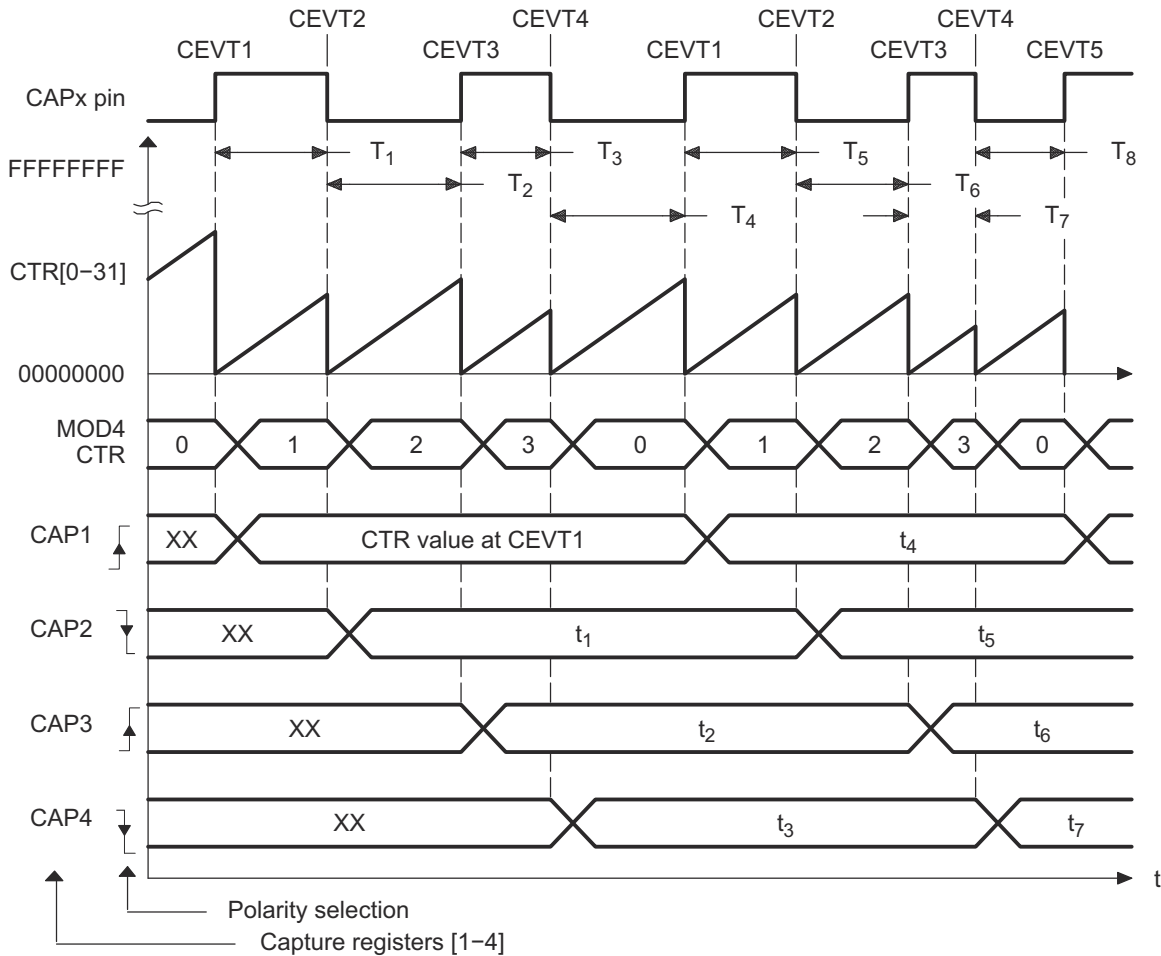

Figure 10-1548. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect

10.4.1.6.4.1 Code snippet for CAP mode Delta Time, Rising and Falling Edge Triggers

```

// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers

DutyOffTime2 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;

```

10.4.1.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWMx. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time. Note here values are in hexadecimal (h) notation.

10.4.1.7.1 Simple PWM Generation (Independent Channel/s)

Figure 10-1549. PWM Waveform Details of APWM Mode Operation

Example 10-1. Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.CAP1 = 0x1000; // Set period value
ECap1Regs.CTRPHS = 0x0; // make phase zero
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_APWM_MODE;
ECap1Regs.ECCTL2.bit.APWMPOL = EC_ACTV_HI; // Active high
ECap1Regs.ECCTL2.bit.SYNCR_EN = EC_DISABLE; // Synch not used
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS; // Synch not used
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time (Instant 1, e.g. ISR call)
//=====
ECap1Regs.CAP2 = 0x300; // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECap1Regs.CAP2 = 0x500; // Set Duty cycle i.e. compare value
```

10.4.2 Enhanced Pulse Width Modulator (ePWM) Module

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

10.4.2.2 ePWM Submodules	3949
10.4.2.3 Application Examples	4009
10.4.2.4 ePWM Module Control and Status Registers	4024

10.4.2.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

10.4.2.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 10-1550](#). Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
 - Two independent PWM outputs with single-edge operation
 - Two independent PWM outputs with dual-edge symmetric operation
 - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 10-1550](#). The signals are described in detail in subsequent sections.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 10-1551](#).

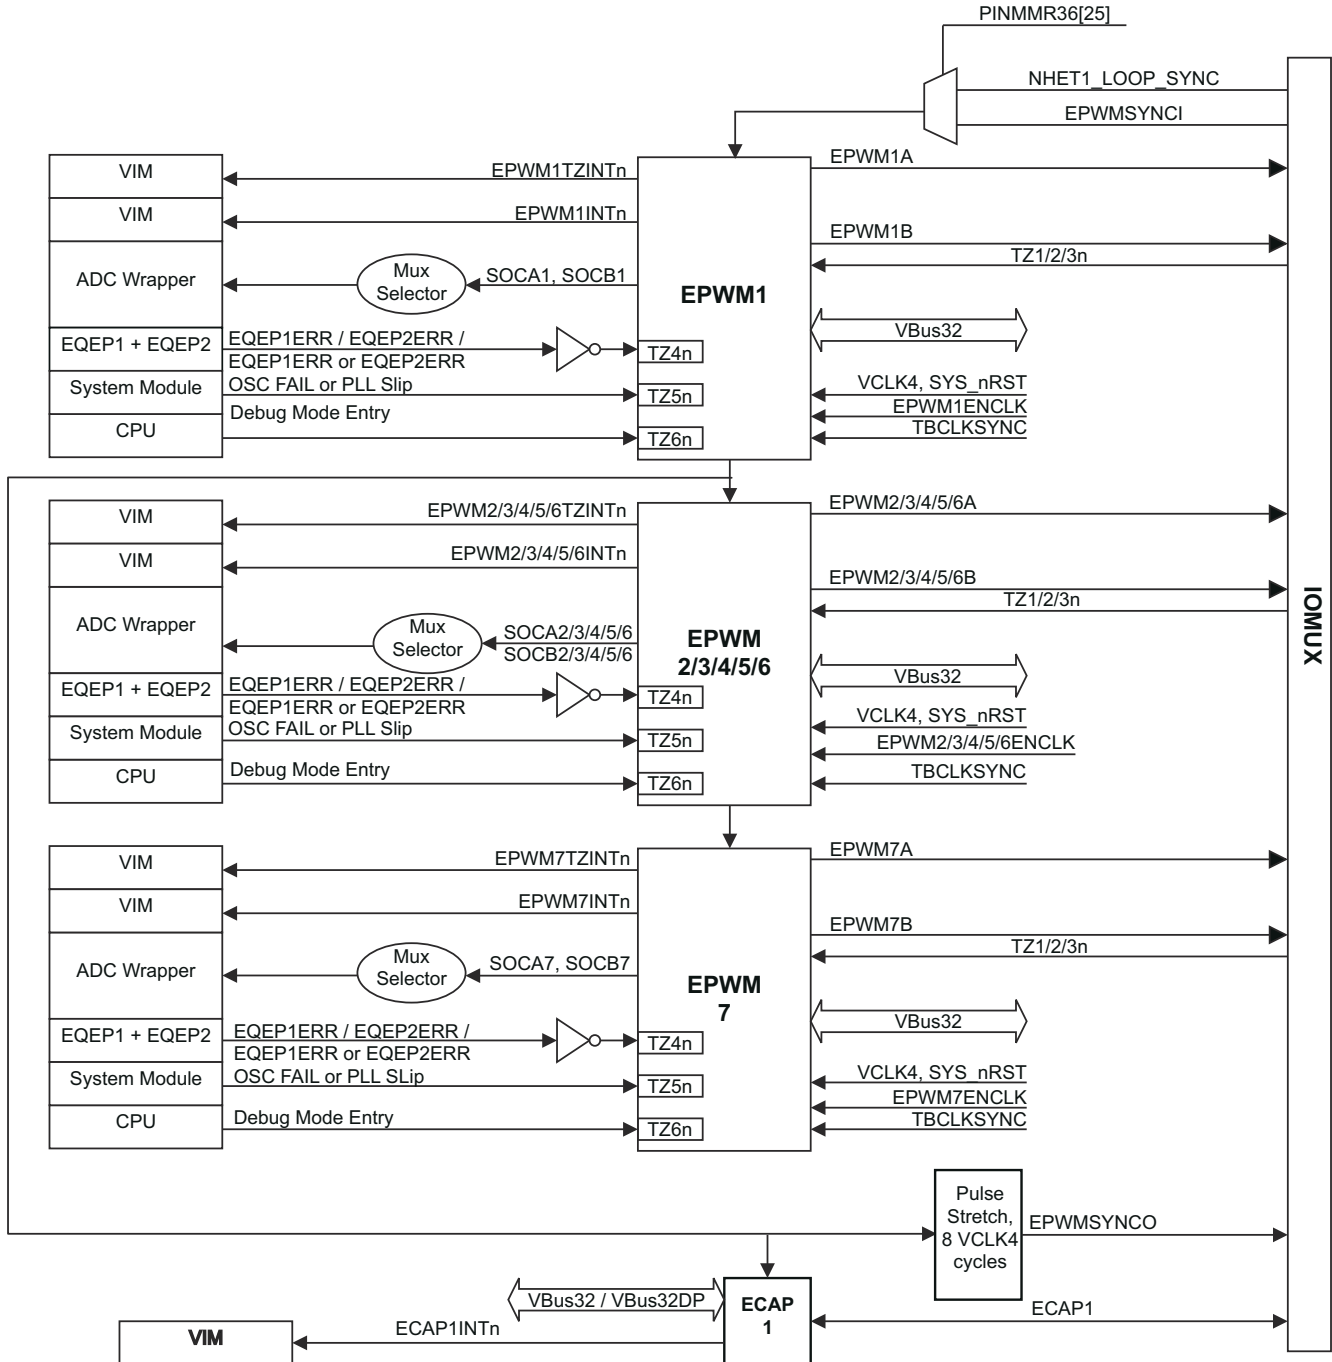

Figure 10-1550. Multiple ePWM Modules

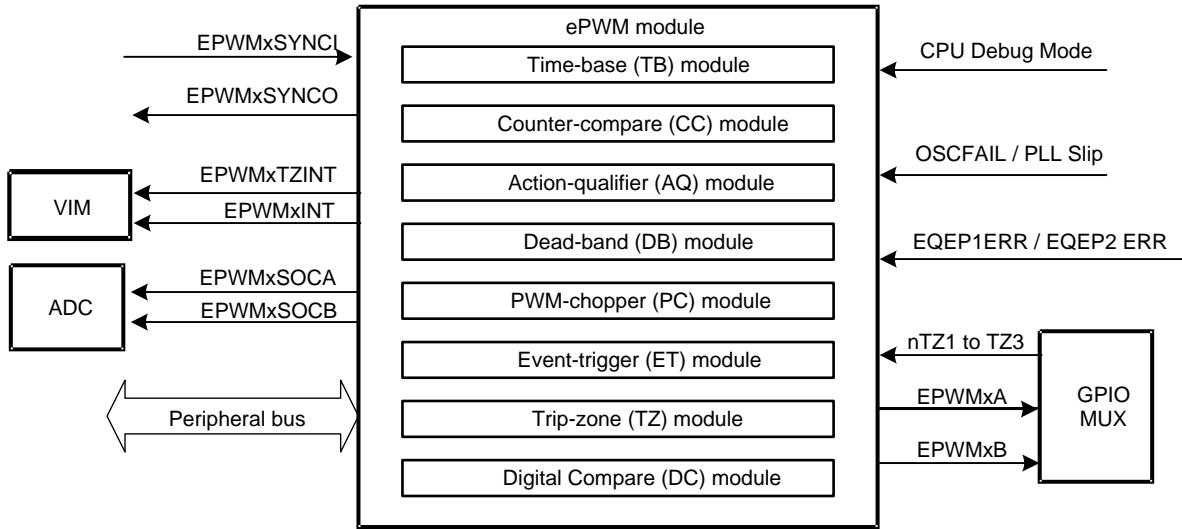

Figure 10-1551. Submodules and Signal Connections for an ePWM Module

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter of the device's technical reference manual.

- **Trip-zone signals (TZ1 to TZ6).**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The TZ1 to TZ3 trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK4, or double-synchronized and filtered through a 6-VCLK4-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM. TZ4 is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers. TZ5 is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected. TZ6 is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.**

The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCl of the first enhanced capture module (eCAP1).

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.

- **Peripheral Bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

10.4.2.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in [Table 10-1635](#). Each register set is duplicated for each instance of the ePWM module. The start address for each ePWM register file instance on a device is specified in the specific part's datasheet.

10.4.2.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

10.4.2.2.1 Overview

Table 10-1636 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 10.4.2.2.3 for relevant details.

Table 10-1636. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> • Scale the time-base clock (TBCLK) relative to the system clock (VCLK4). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: <ul style="list-style-type: none"> – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: <ul style="list-style-type: none"> – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	<ul style="list-style-type: none"> • Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output

Table 10-1636. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Action-qualifier (AQ)	<ul style="list-style-type: none"> • Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	<ul style="list-style-type: none"> • Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution.
PWM-chopper (PC)	<ul style="list-style-type: none"> • Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip-zone (TZ)	<ul style="list-style-type: none"> • Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to each trip-zone signal: <ul style="list-style-type: none"> – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	<ul style="list-style-type: none"> • Enable the ePWM events that will trigger an interrupt. • Enable ePWM events that will trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
Digital-compare (DC)	<ul style="list-style-type: none"> • Enables trip zone signals to create events and filtered events • Specify event-filtering options to capture TBCTR counter or generate blanking window

Code examples are provided in the remainder of this document that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm_defines.h* file in the device-specific header file and peripheral examples software package.

10.4.2.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 10-1552 illustrates the time-base module's place within the ePWM.

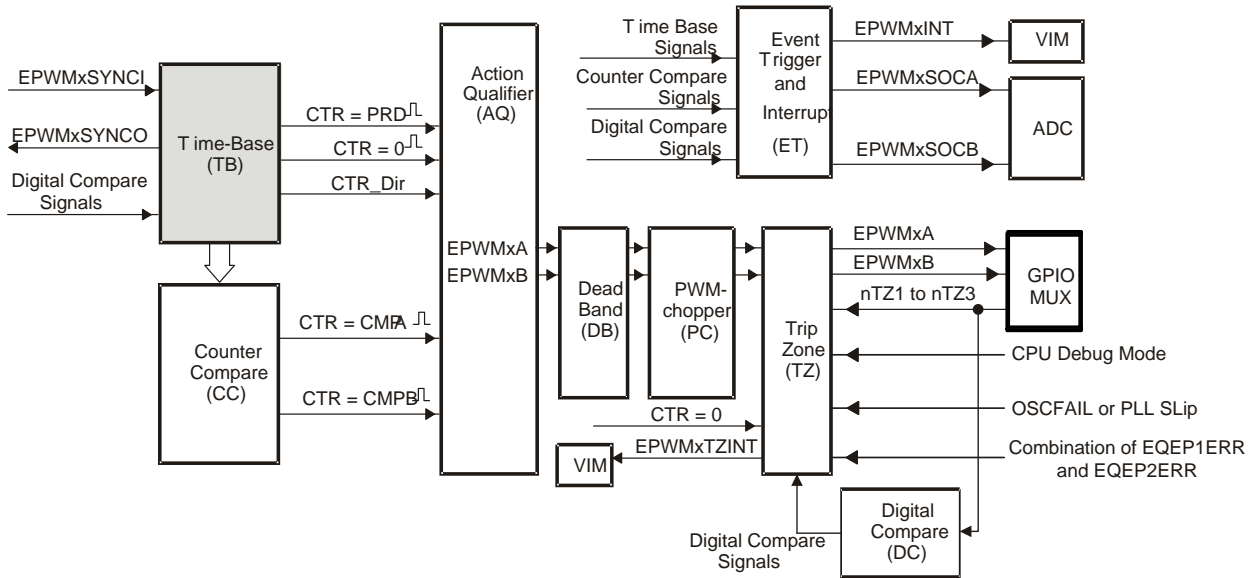

Figure 10-1552. Time-Base Submodule Block Diagram

10.4.2.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
 - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD) .
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK4). This allows the time-base counter to increment/decrement at a slower rate.

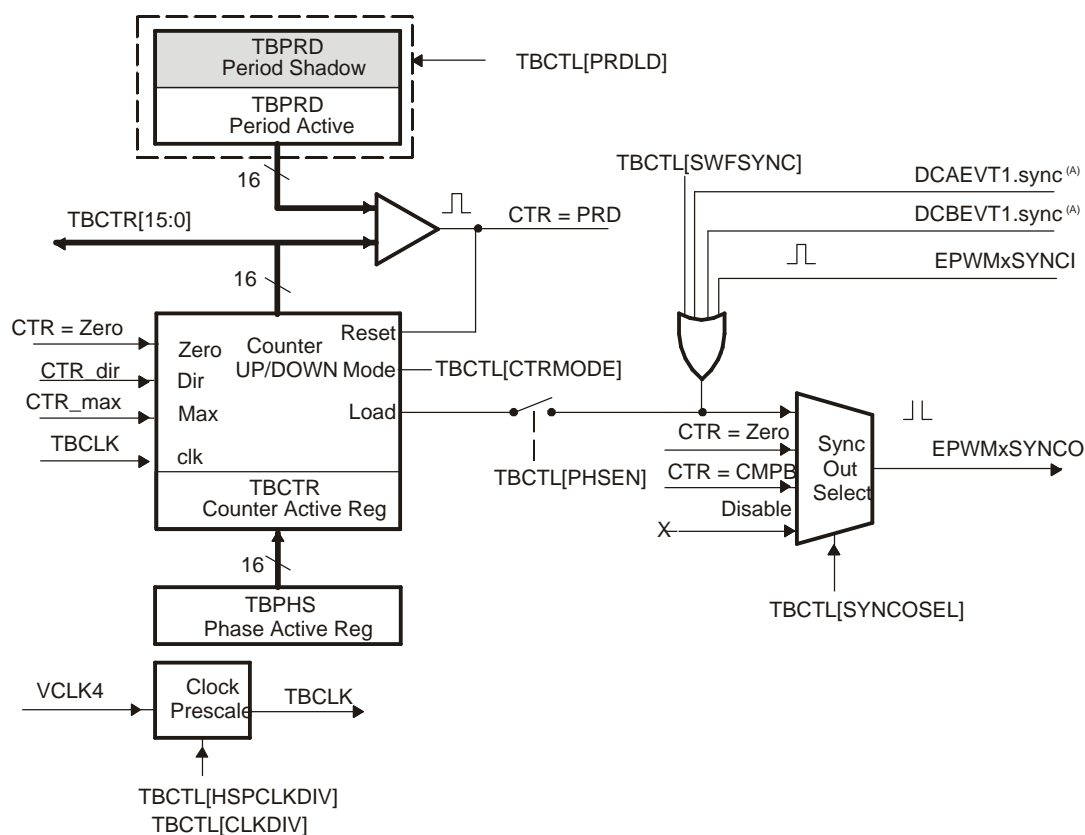

10.4.2.2.2 Controlling and Monitoring the Time-base Submodule

Table 10-1637 shows the registers used to control and monitor the time-base submodule.

Table 10-1637. Time-Base Submodule Registers

Register Name	Address Offset	Shadowed	Description
TBCTL	0x0002	No	Time-Base Control Register
TBSTS	0x0000	No	Time-Base Status Register
TBPHS	0x0004	No	Time-Base Phase Register
TBCTR	0x000A	No	Time-Base Counter Register
TBPRD	0x0008	Yes	Time-Base Period Register

The block diagram in Figure 10-1553 shows the critical signals and registers of the time-base submodule. Table 10-1638 provides descriptions of the key signals associated with the time-base submodule.

A. These signals are generated by the digital compare (DC) submodule.

Figure 10-1553. Time-Base Submodule Signals and Registers

Table 10-1638. Key Time-Base Signals

Signal	Description
EPWMxSYNCl	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1), this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules, this signal is passed from another ePWM peripheral. For example, EPWM2SYNCl is generated by the ePWM1 peripheral, EPWM3SYNCl is generated by ePWM2 and so forth. See Section 10.4.2.2.3.3 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: <ol style="list-style-type: none"> 1. EPWMxSYNCl (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock. This is a prescaled version of the system clock (VCLK4) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

10.4.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 10-1554 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK4).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

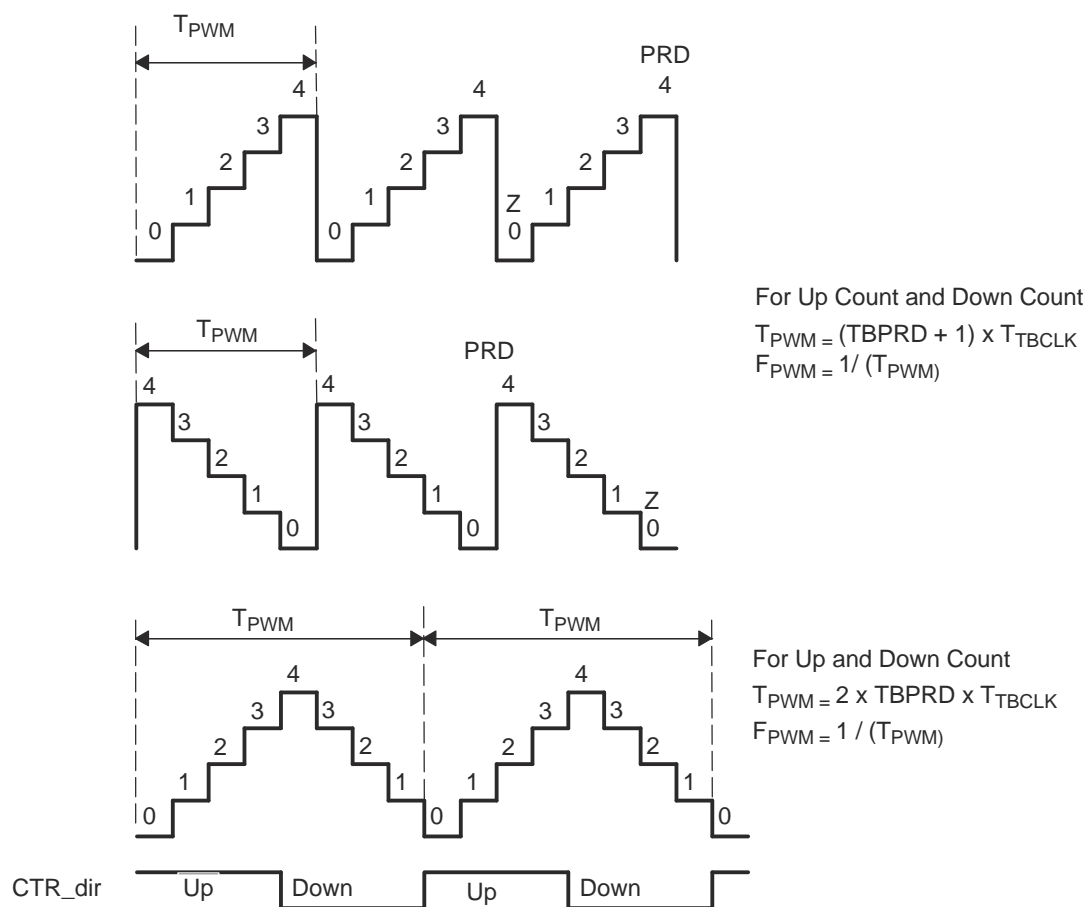

Figure 10-1554. Time-Base Frequency and Period

10.4.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

10.4.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR37 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

10.4.2.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in [Figure 10-1555](#).

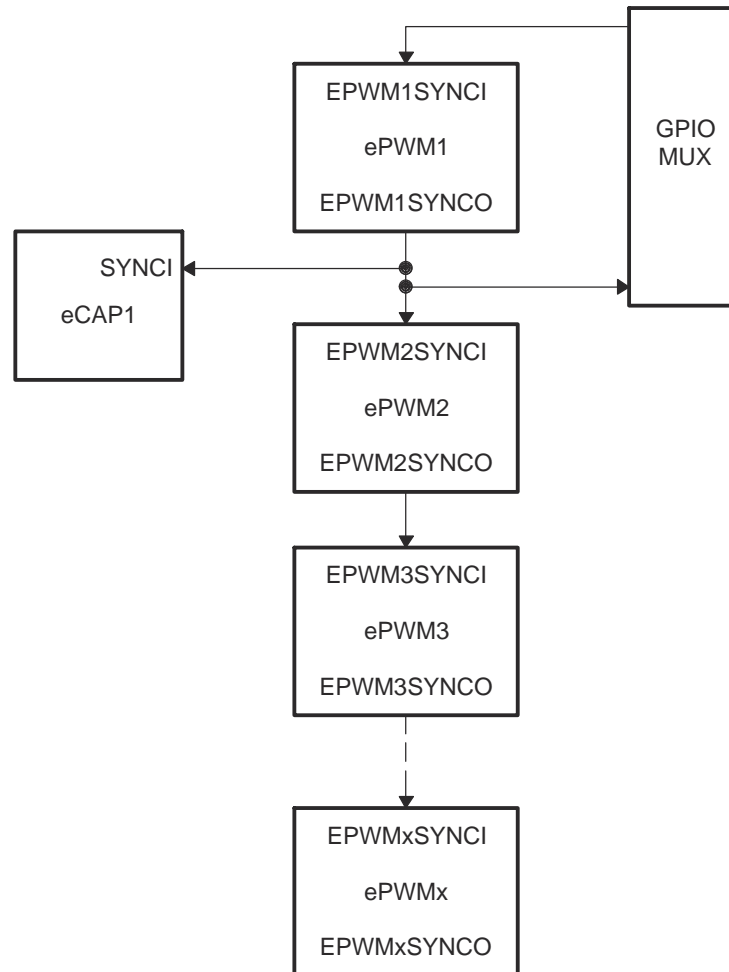

Figure 10-1555. Time-Base Counter Synchronization Scheme

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

The delay from internal master module to slave modules is given by:

- if (TBCLK = VCLK4): $2 \times VCLK4$
- if (TBCLK != VCLK4): 1 TBCLK

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 10-1556](#) through [Figure 10-1559](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

10.4.2.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

10.4.2.2.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

Figure 10-1556. Time-Base Up-Count Mode Waveforms

Figure 10-1557. Time-Base Down-Count Mode Waveforms

Figure 10-1558. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

Figure 10-1559. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

10.4.2.2.3 Counter-Compare (CC) Submodule

Figure 10-1560 illustrates the counter-compare submodule within the ePWM.

Figure 10-1561 shows the basic structure of the counter-compare submodule.

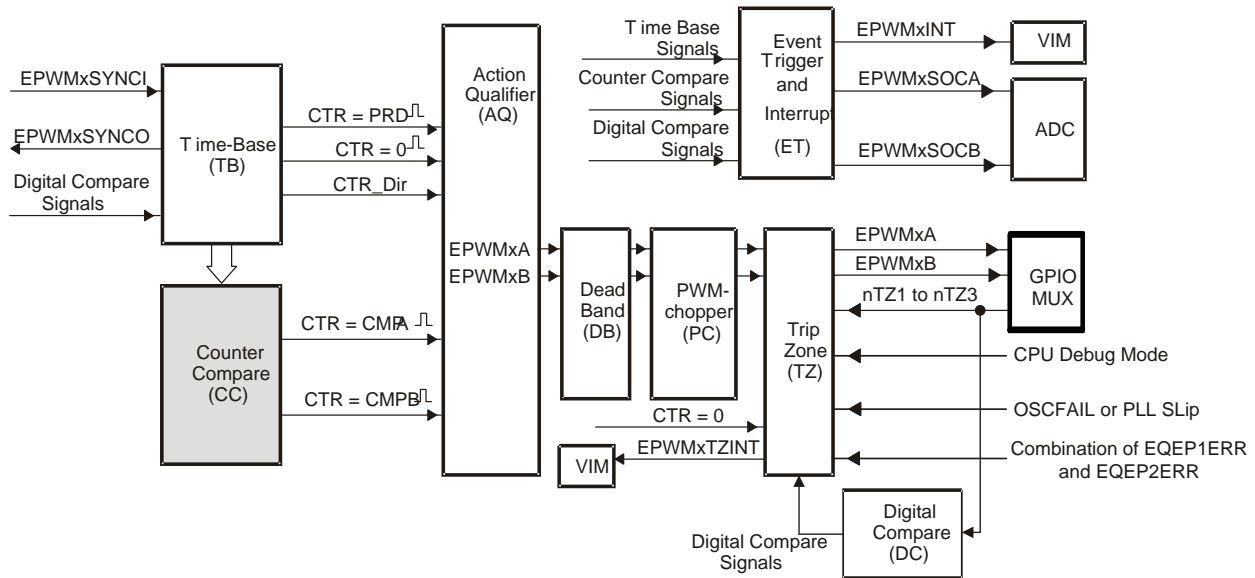

Figure 10-1560. Counter-Compare Submodule

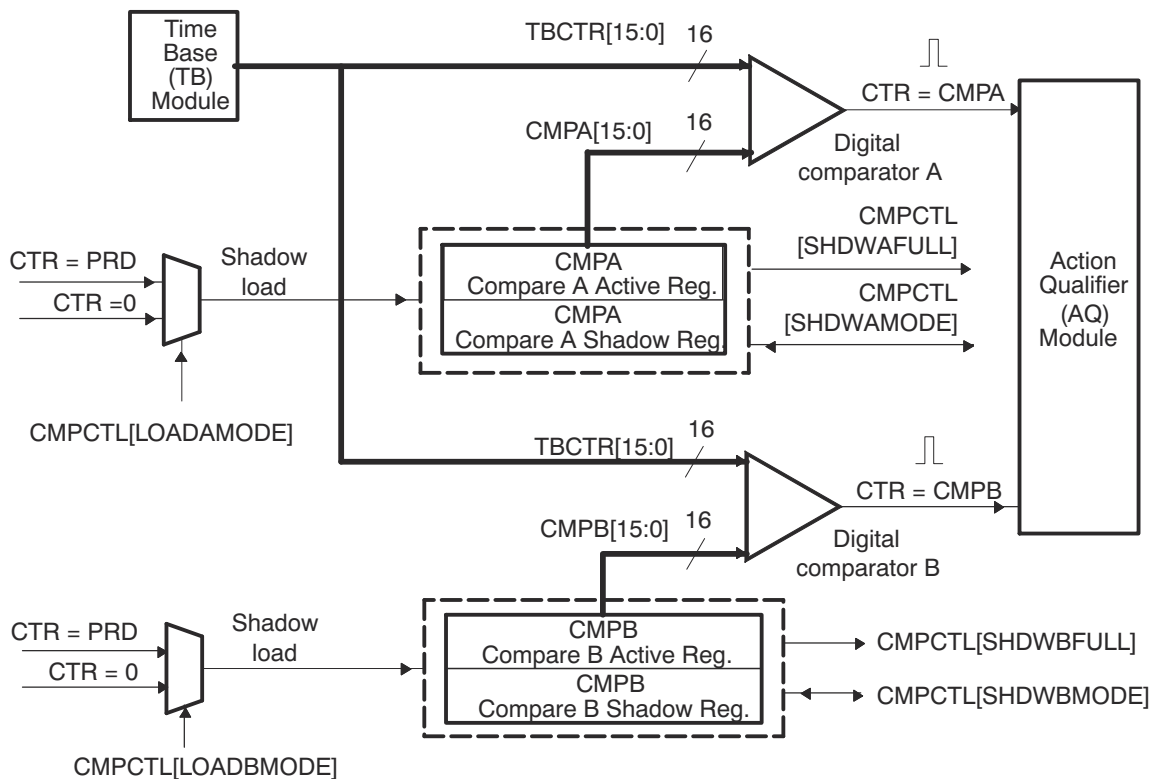

Figure 10-1561. Detailed View of the Counter-Compare Submodule

10.4.2.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
 - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA).
 - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

10.4.2.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers shown in [Table 10-1639](#):

Table 10-1639. Counter-Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
CMPCTL	0x000C	No	Counter-Compare Control Register.
CMPA	0x0010	Yes	Counter-Compare A Register
CMPB	0x0016	Yes	Counter-Compare B Register

The key signals associated with the counter-compare submodule are described in [Table 10-1640](#).

Table 10-1640. Counter-Compare Submodule Key Signals

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCTR = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCTR = TBPRD
CTR = ZERO	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCTR = 0x0000

10.4.2.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 10.4.2.2.4.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is as described:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If immediate load mode is selected (that is, TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

10.4.2.2.3.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 10-1562](#) through [Figure 10-1565](#) show when events are generated and how the EPWMxSYNCl signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 10-1562. Counter-Compare Event Waveforms in Up-Count Mode

Figure 10-1563. Counter-Compare Events in Down-Count Mode

Figure 10-1564. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

Figure 10-1565. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

10.4.2.2.4 Action-Qualifier (AQ) Submodule

Figure 10-1566 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

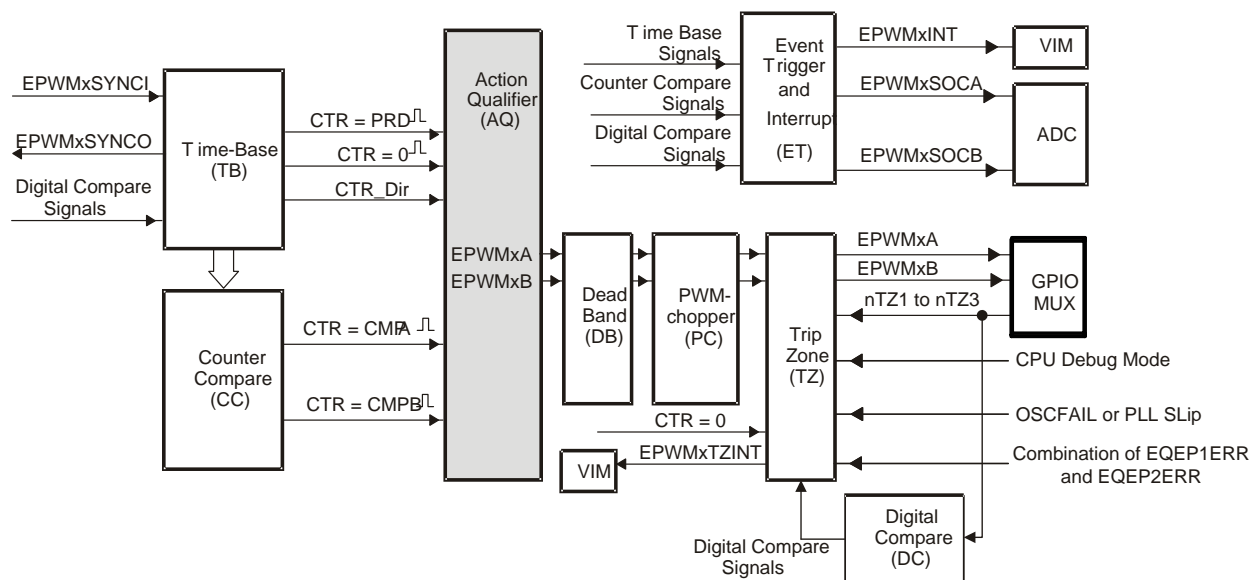

Figure 10-1566. Action-Qualifier Submodule

10.4.2.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
 - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
 - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
 - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

10.4.2.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is controlled and monitored via the registers in Table 10-1641.

Table 10-1641. Action-Qualifier Submodule Registers

Register Name	Address Offset	Shadowed	Description
AQCTLA	0x0014	No	Action-Qualifier Control Register For Output A (EPWMxA)
AQCTLB	0x001A	No	Action-Qualifier Control Register For Output B (EPWMxB)
AQSFRC	0x0018	No	Action-Qualifier Software Force Register
AQCSFRC	0x001E	Yes	Action-Qualifier Continuous Software Force

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Table 10-1641.

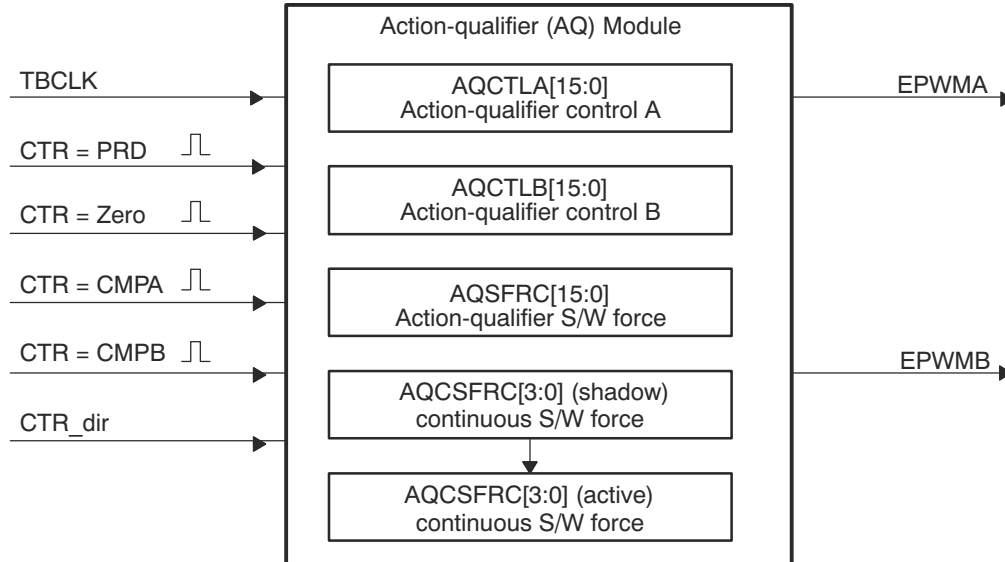

Figure 10-1567. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in [Table 10-1642](#).

Table 10-1642. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to zero	TBCTR = 0x0000
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFR and AQCSFR.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**

Set output EPWMxA or EPWMxB to a high level.

- **Clear Low:**

Set output EPWMxA or EPWMxB to a low level.

- **Toggle:**

If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.

- **Do Nothing:**

Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in [Section 10.4.2.2.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in [Figure 10-1568](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW X	Z X	CA X	CB X	P X	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

Figure 10-1568. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

10.4.2.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 10-1643](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 10-1643. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD)	Counter equals CMPB on up-count (CBU)
6 (Lowest)	Counter equals CMPA on down-count (CAD)	Counter equals CMPA on up-count (CBU)

[Table 10-1644](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 10-1644. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 10-1645](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 10-1645. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 10-1646](#).

Table 10-1646. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match ($TBCTR=CMPA$ or $CMPB$). If $CMPA/CMPB > TBPRD$, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If $CMPA/CMPB < TBPRD$, the event will occur on a compare match ($TBCTR=CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCTR=TBPRD$).
Up-Down-Count Mode	If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match ($TBCTR=CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCTR = TBPRD$).	If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match ($TBCTR=CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event occurs on a period match ($TBCTR=TBPRD$).

10.4.2.2.4.4 Waveforms for Common Configurations

Note

The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to $TBPRD - 1$.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to $TBPRD + 1$ to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report ([SPRAA11](#))

Figure 10-1569 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD - 1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

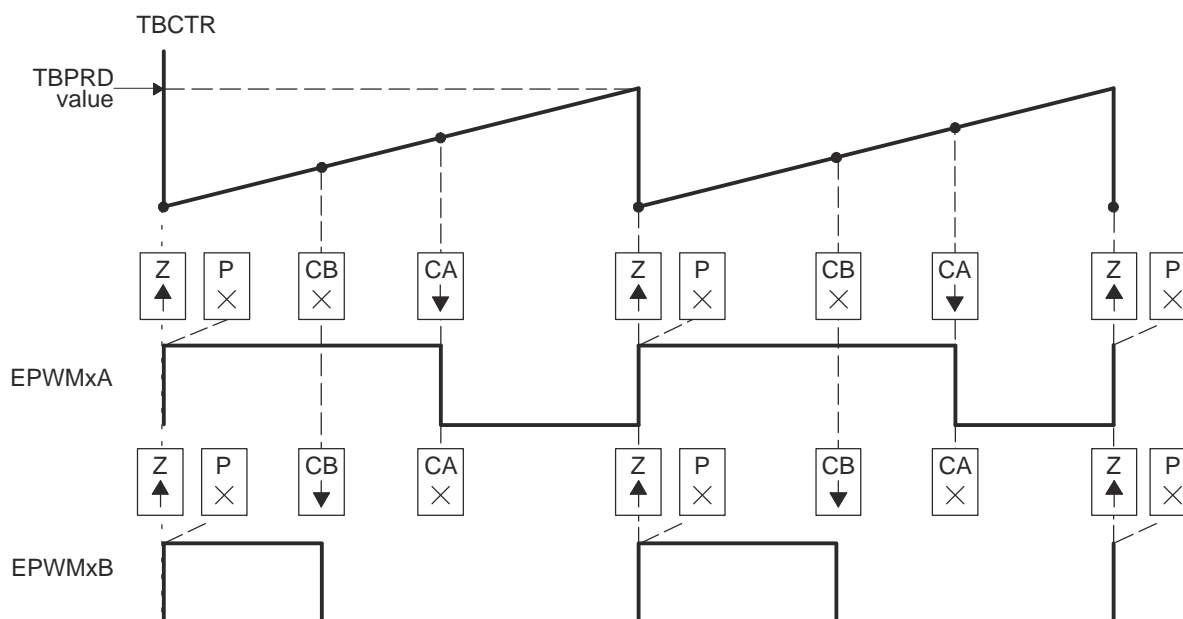

Figure 10-1569. Up-Down-Count Mode Symmetrical Waveform

The PWM waveforms in [Figure 10-1570](#) through [Figure 10-1575](#) show some common action-qualifier configurations. The C-code samples in [Example 10-2](#) through [Example 10-7](#) shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

- PWM period = $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

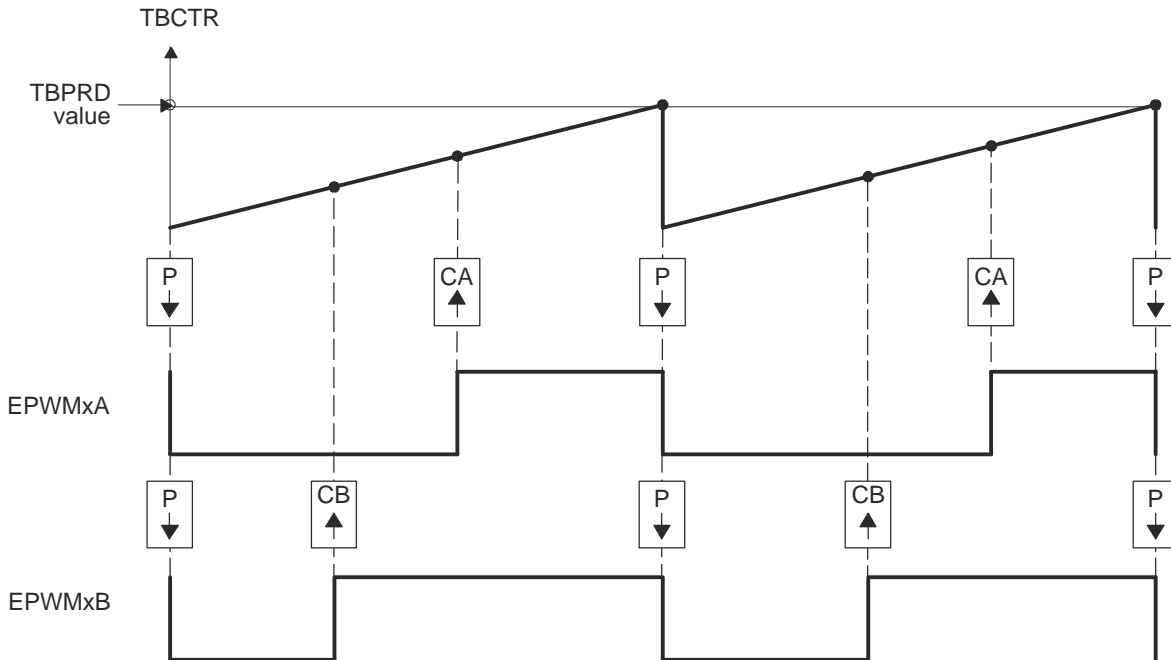

Figure 10-1570. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High

[Example 10-2](#) contains a code sample showing initialization and run time for the waveforms in [Figure 10-1570](#).

Example 10-2. Code Sample for Figure 10-1570

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600; // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350; // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200; // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTR = 0; // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = SYSCLK
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;

//
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = Duty1A; // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B; // adjust duty for output EPWM1B
    
```

10.4.2.2.4.6

- A. $PWM\ frequency = 1 / ((TBPRD + 1) \times T_{TBCLK})$
- B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C. High time duty proportional to (CMPB - CMPA)
- D. EPWMxB can be used to generate a 50% duty square wave with frequency = $1/2 \times ((TBPRD + 1) \times TBCLK)$

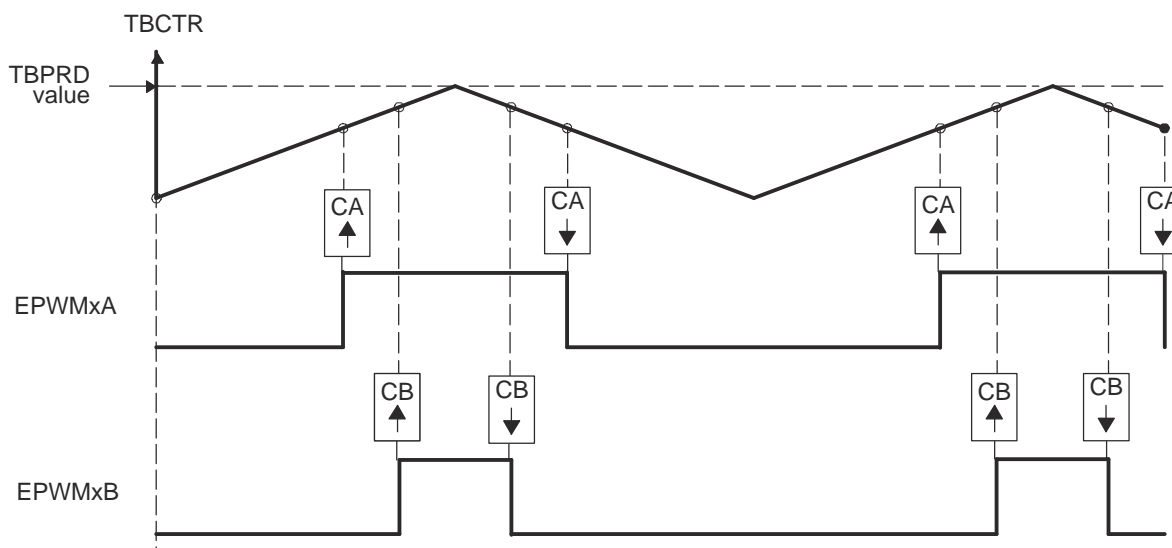

Figure 10-1572. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA

Example 10-4 contains a code sample showing initialization and run time for the waveforms in Figure 10-1572.

Example 10-4. Code Sample for Figure 10-1572

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600;           // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 200; // Compare A = 200 TBCLK counts
EPwm1Regs.CMPB = 400;           // Compare B = 400 TBCLK counts
EPwm1Regs.TBPHS = 0;            // Set Phase register to zero
EPwm1Regs.TBCTR = 0;            // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCOSSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CBU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_TOGGLE;
//
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = EdgePosA; // adjust duty for output EPWM1A only
EPwm1Regs.CMPB = EdgePosB;
```

10.4.2.2.4.7

- A. PWM period = $2 \times \text{TBPRD} \times T_{\text{TBCLK}}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Outputs EPWMxA and EPWMxB can drive independent power switches

Figure 10-1573. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low

Example 10-5 contains a code sample showing initialization and run time for the waveforms in Figure 10-1573.

Example 10-5. Code Sample for Figure 10-1573

```

// Initialization Time
// =====
EPwm1Regs.TBPRD = 600; // Period = 2*600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 400; // Compare A = 400 TBCLK counts
EPwm1Regs.CMPB = 500; // Compare B = 500 TBCLK counts
EPwm1Regs.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTR = 0; // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
xEPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
xEPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;
EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time
// =====

EPwm1Regs.CMPB = Duty1B; // adjust duty for output EPWM1B
    
```

10.4.2.2.4.9

- PWM period = $2 \times \text{TBPRD} \times \text{TBCLK}$
- Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- Duty modulation for EPWMxA is set by CMPA and CMPB.
- Low time duty for EPWMxA is proportional to $(\text{CMPA} + \text{CMPB})$.
- To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Set ! Clear and Clear Set).
- Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB)

Figure 10-1575. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low

Example 10-7 contains a code sample showing initialization and run time for the waveforms in Figure 10-1575.

10.4.2.2.5 Dead-Band Generator (DB) Submodule

Figure 10-1576 illustrates the dead-band submodule within the ePWM module.

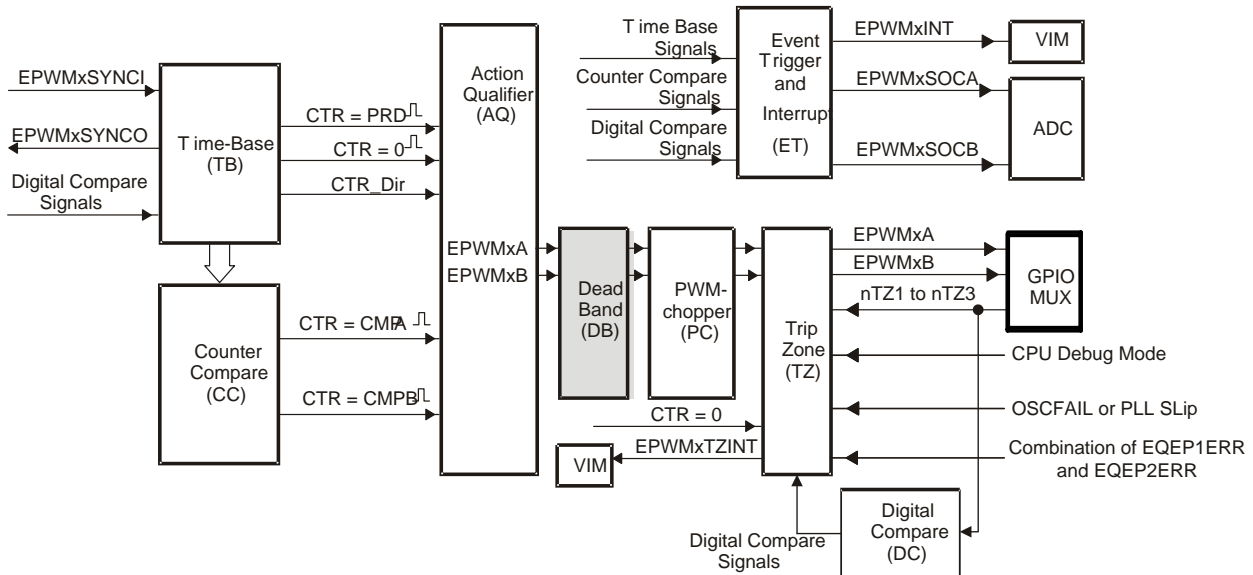

Figure 10-1576. Dead_Band Submodule

10.4.2.2.5.1 Purpose of the Dead-Band Submodule

Section 10.4.2.2.4 discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
 - Active high (AH)
 - Active low (AL)
 - Active high complementary (AHC)
 - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

10.4.2.2.5.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band submodule operation is controlled and monitored via the following registers:

Table 10-1647. Dead-Band Generator Submodule Registers

Register Name	Address Offset	Shadowed	Description
DBCTL	0x001C	No	Dead-Band Control Register
DBRED	0x0022	No	Dead-Band Rising Edge Delay Count Register
DBFED	0x0020	No	Dead-Band Falling Edge Delay Count Register

10.4.2.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in [Figure 10-1577](#).

- **Input Source Selection:**

The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:

- EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
- EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
- EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
- EPWMxB In is the source for both falling-edge and rising-edge delay.

- **Half Cycle Clocking:**

The dead-band submodule can be clocked using half cycle clocking to double the resolution (that is, counter clocked at 2× TBCLK)

- **Output Mode Control:**

The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.

- **Polarity Control:**

The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

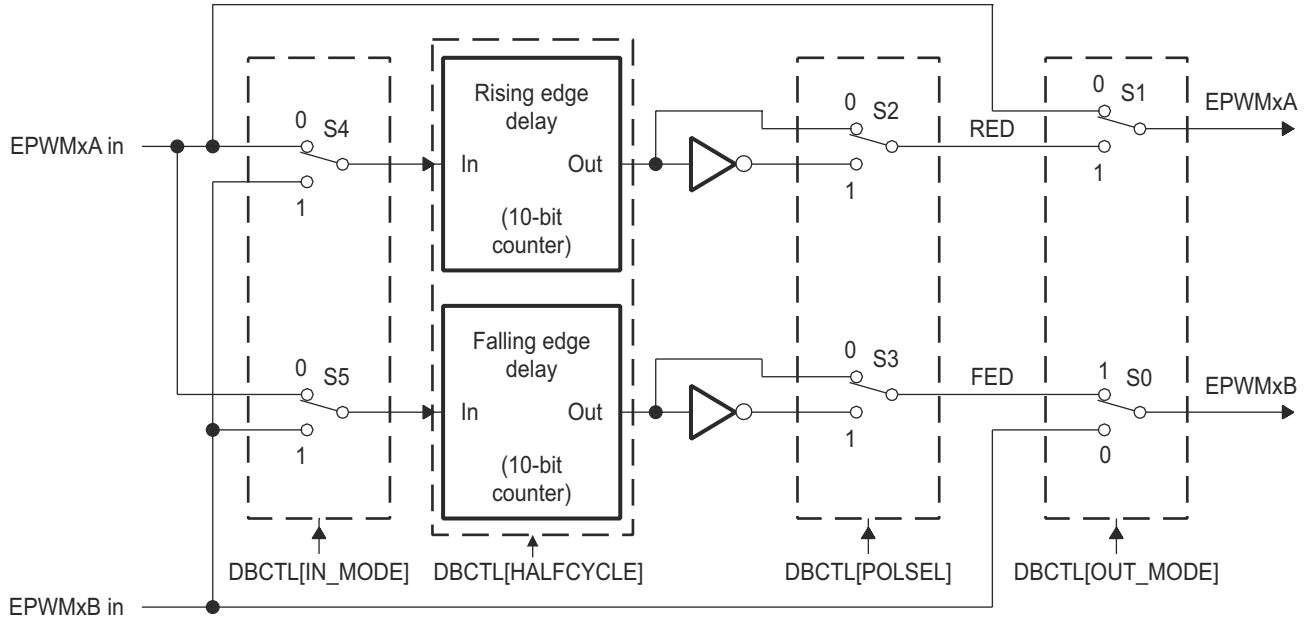

Figure 10-1577. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. [Table 10-1648](#) documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 10-1648](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

Allows you to fully disable the dead-band submodule from the PWM signal path.

- **Mode 2-5: Classical Dead-Band Polarity Settings:**

These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 10-1578](#). Note that to generate equivalent waveforms to [Figure 10-1578](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.

- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

Finally the last two entries in [Table 10-1648](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 10-1648. Classical Dead-Band Operating Modes

Mode	Mode Description	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

[Figure 10-1578](#) shows waveforms for typical cases where $0\% < \text{duty} < 100\%$.

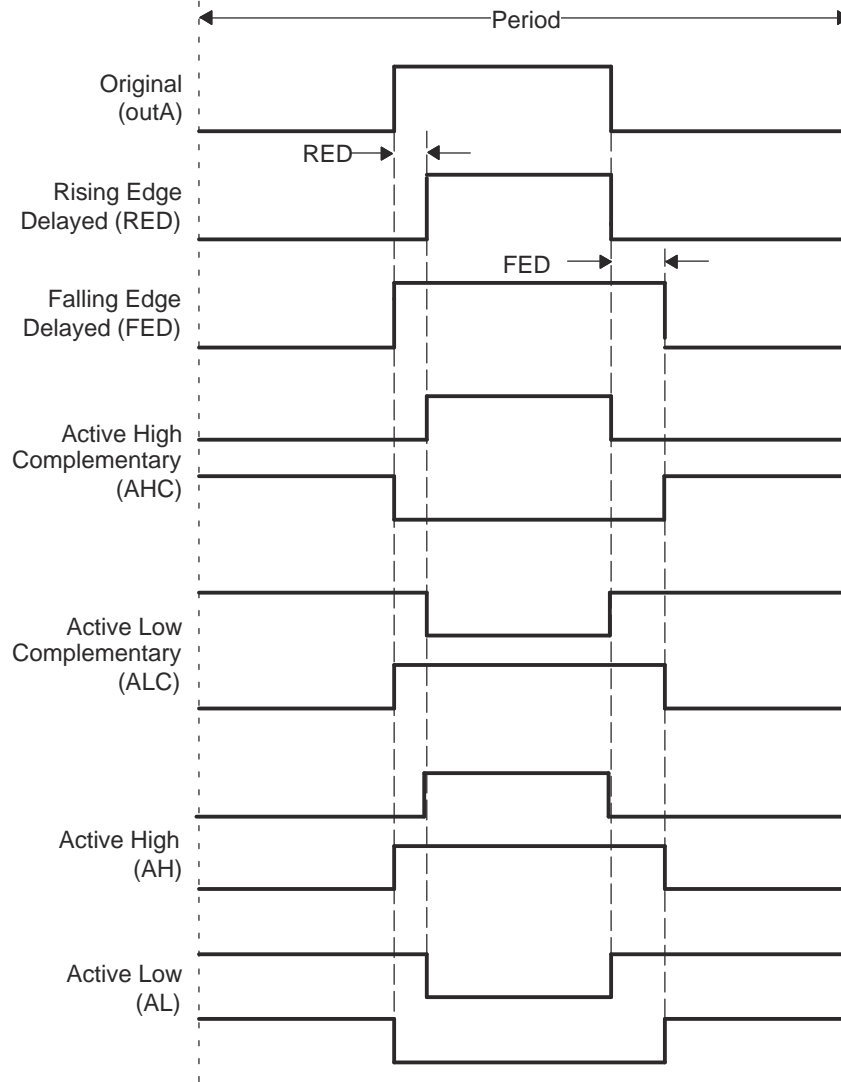

Figure 10-1578. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$FED = DBFED \times T_{TBCLK}$$

$$RED = DBRED \times T_{TBCLK}$$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VCLK4.

For convenience, delay values for various TBCLK options are shown in [Table 10-1649](#).

Table 10-1649. Dead-Band Delay Values in μ S as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay in μ S			
	DBFED, DBRED	TBCLK = VCLK4/1	TBCLK = VCLK4 /2	TBCLK = VCLK4/4
1		0.02 μ S	0.03 μ S	0.07 μ S
5		0.08 μ S	0.17 μ S	0.33 μ S
10		0.17 μ S	0.33 μ S	0.67 μ S
100		1.67 μ S	3.33 μ S	6.67 μ S
200		3.33 μ S	6.67 μ S	13.33 μ S
400		6.67 μ S	13.33 μ S	26.67 μ S
500		8.33 μ S	16.67 μ S	33.33 μ S
600		10.00 μ S	20.00 μ S	40.00 μ S
700		11.67 μ S	23.33 μ S	46.67 μ S
800		13.33 μ S	26.67 μ S	53.33 μ S
900		15.00 μ S	30.00 μ S	60.00 μ S
1000		16.67 μ S	33.33 μ S	66.67 μ S

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED \times T_{TBCLK}/2$$

$$RED = DBRED \times T_{TBCLK}/2$$

10.4.2.2.6 PWM-Chopper (PC) Submodule

Figure 10-1579 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

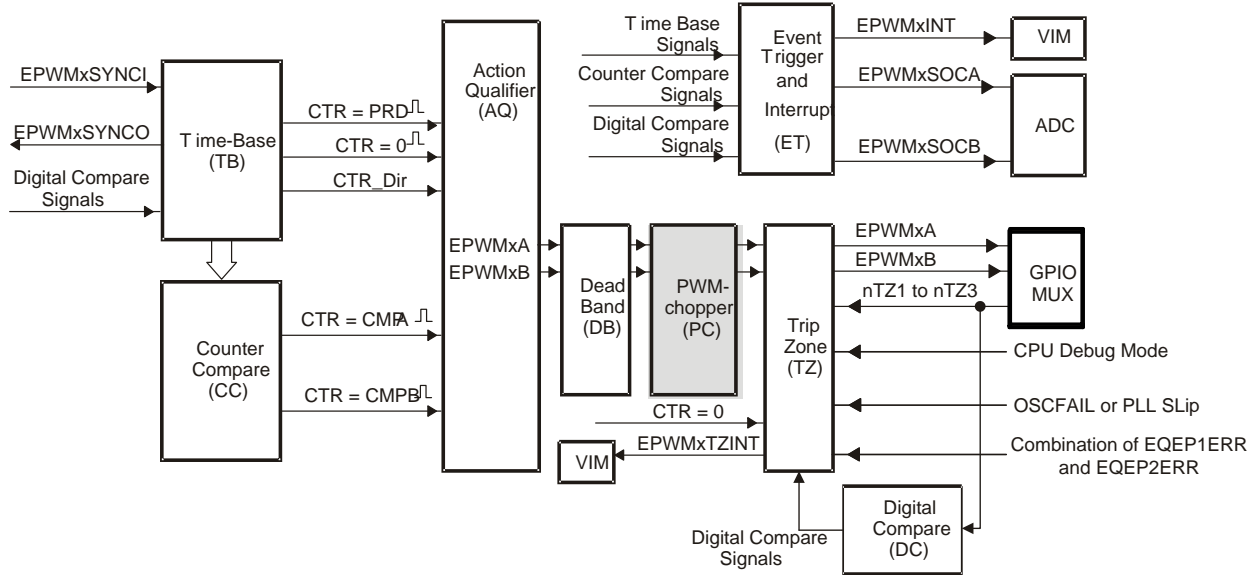

Figure 10-1579. PWM-Chopper Submodule

10.4.2.2.6.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

10.4.2.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 10-1650.

Table 10-1650. PWM-Chopper Submodule Registers

Register Name	Address Offset	Shadowed	Description
PCCTL	0x003E	No	PWM-chopper Control Register

10.4.2.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 10-1580 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK4. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

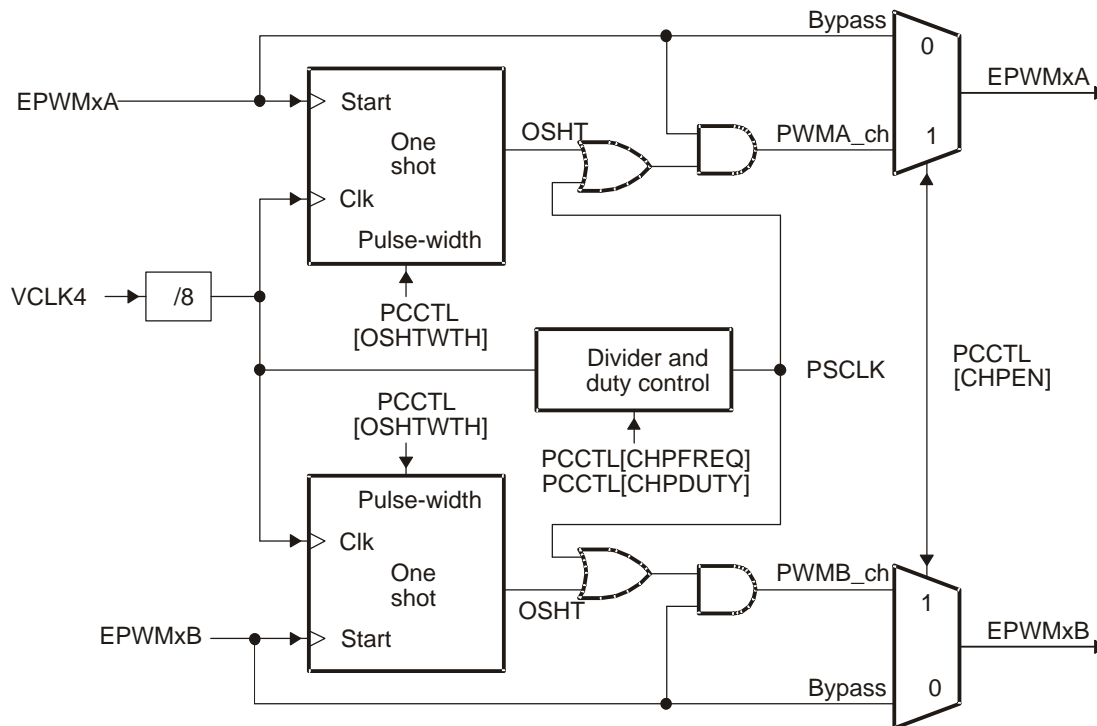

Figure 10-1580. PWM-Chopper Submodule Operational Details

10.4.2.2.6.4 Waveforms

Figure 10-1581 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 10-1581. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

10.4.2.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{VCLK4} \times 8 \times OSHTWTH$$

Where T_{VCLK4} is the period of the system clock (VCLK4) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 10-1582 shows the first and subsequent sustaining pulses and Table 10-1651 gives the possible pulse width values for a VCLK4 = 100 MHz.

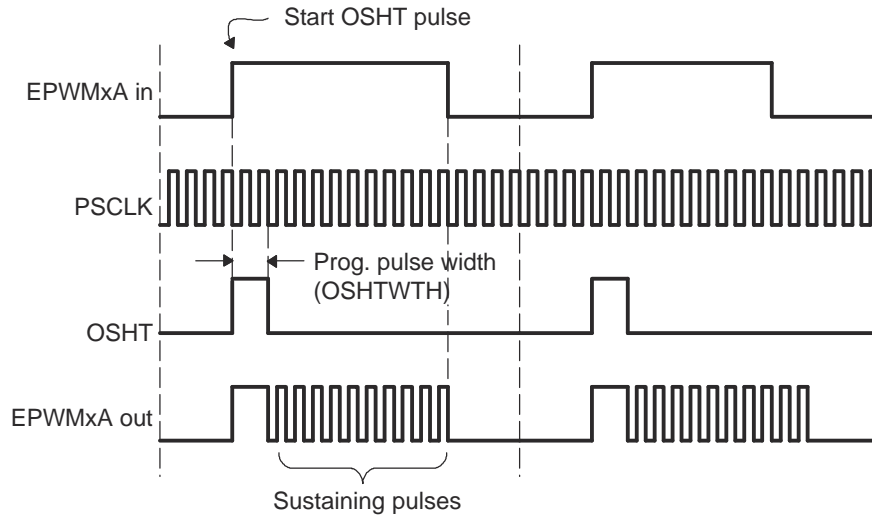

Figure 10-1582. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

Table 10-1651. Possible Pulse Width Values for VCLK4 = 100 MHz

OSHTWTHz (hex)	Pulse Width (nS)
0	100
1	200
2	300
3	400
4	500
5	600
6	700
7	800
8	900
9	1000
A	1100
B	1200
C	1300
D	1400
E	1500

**Table 10-1651. Possible Pulse Width Values for
VCLK4 = 100 MHz (continued)**

OSHTWTHz (hex)	Pulse Width (nS)
F	1600

10.4.2.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

[Figure 10-1583](#) shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

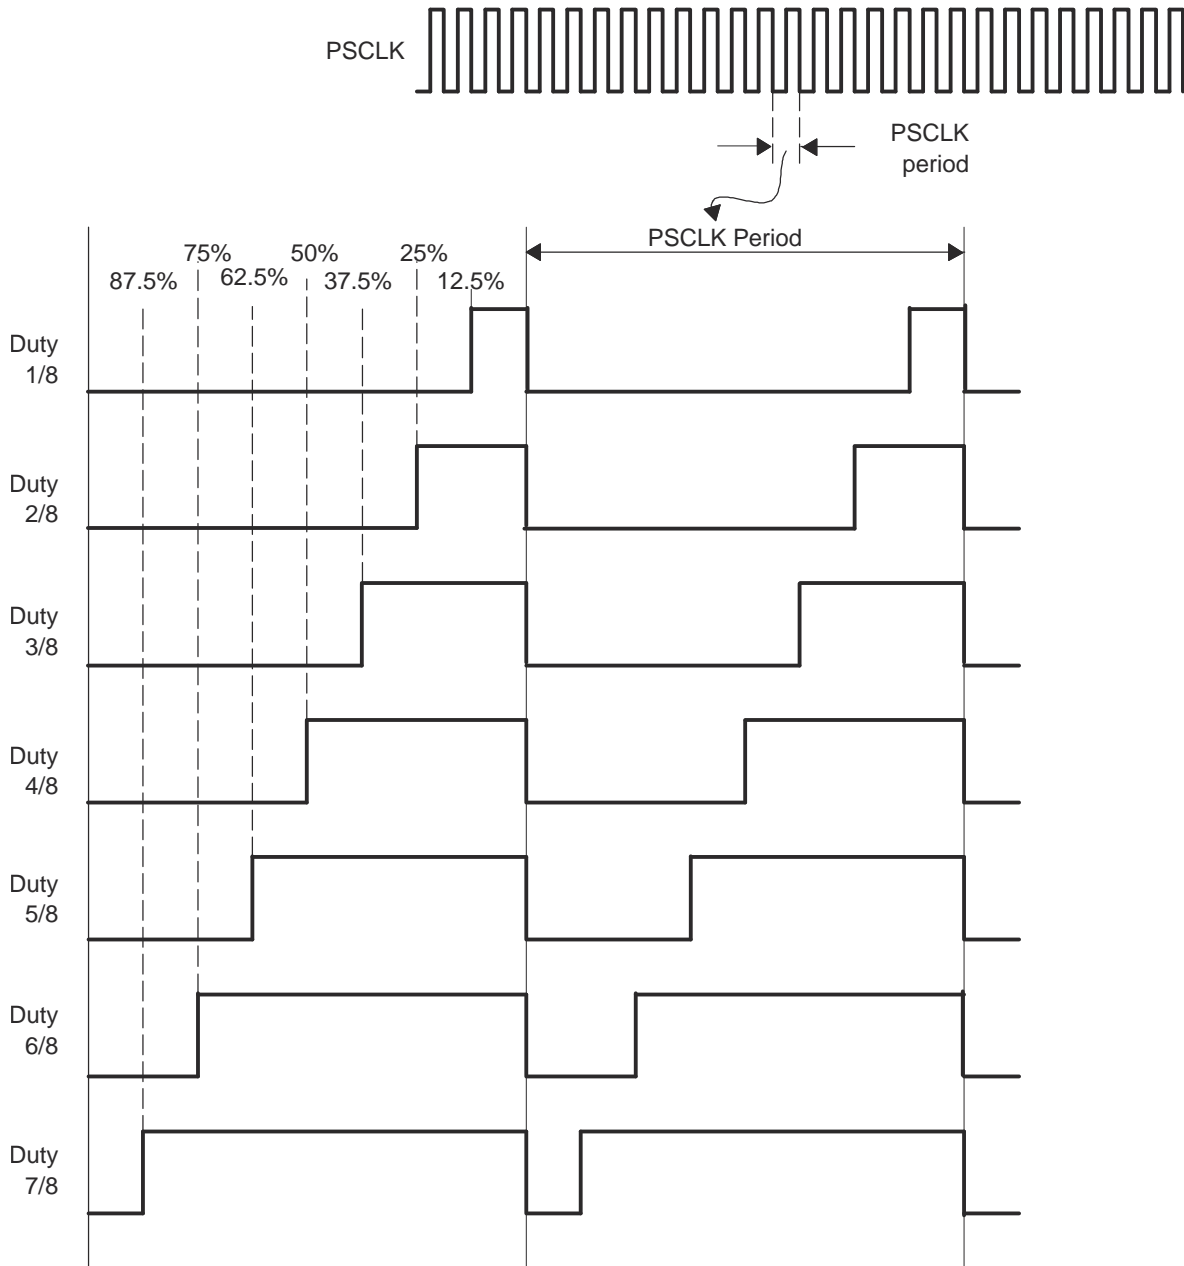

Figure 10-1583. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

10.4.2.2.7 Trip-Zone (TZ) Submodule

Figure 10-1584 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six \overline{TZn} signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from a combination of EQEP1ERR and EQEP2ERR signals. $\overline{TZ5}$ is connected to the system oscillator or PLL clock fail logic, and $\overline{TZ6}$ is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

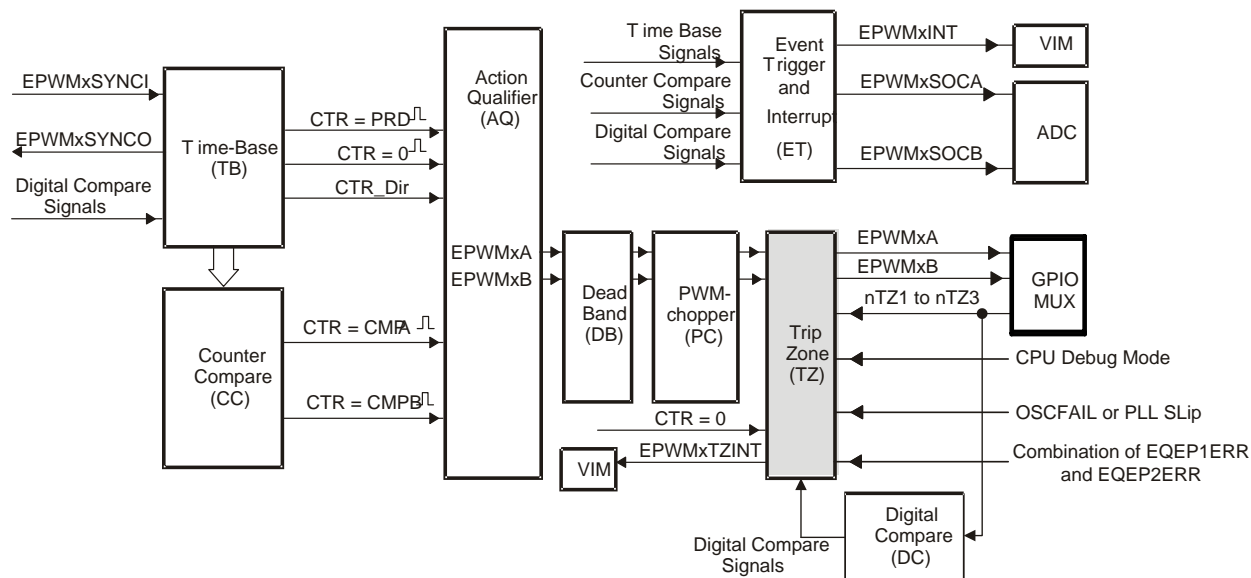

Figure 10-1584. Trip-Zone Submodule

10.4.2.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs EPWMxA and EPWMxB can be forced to one of the following:
 - High
 - Low
 - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

10.4.2.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 10-1652. Trip-Zone Submodule Registers

Register Name	Address Offset	Shadowed	Description ⁽²⁾
TZSEL	0x0026	No	Trip-Zone Select Register
TZDCSEL	0x0024	No	Trip-zone Digital Compare Select Register ⁽¹⁾
TZCTL	0x002A	No	Trip-Zone Control Register
TZEINT	0x0028	No	Trip-Zone Enable Interrupt Register
TZFLG	0x002E	No	Trip-Zone Flag Register
TZCLR	0x002C	No	Trip-Zone Clear Register
TZFRC	0x0032	No	Trip-Zone Force Register

(1) This register is discussed in more detail in [Section 10.4.2.2.9](#).

(2) All trip-zone registers are writable only in privileged mode.

10.4.2.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as \overline{TZn}) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK4) and digitally filtered within the GPIO MUX block. A minimum of $3 \cdot TBCLK$ low pulse width on \overline{TZn} inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on \overline{TZn} inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each \overline{TZn} input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 10-1653](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 10-1653](#) lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRISEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see [Section 10.4.2.9](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 10-1653](#) lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in [Table 10-1653](#), can be taken on a trip event.

Table 10-1653. Possible Actions On a Trip Event

TZCTL Register bit-field Settings	EPWMxA and/or EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

Example 10-8. Trip-Zone Configurations

Scenario A:

A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
 - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
 - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
 - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
 - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:

A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.

A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
 - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a one-shot event source for ePWM1
 - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
 - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
 - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
 - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
 - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

10.4.2.2.7.4 Generating Trip Event Interrupts

Figure 10-1585 and Figure 10-1586 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 10.4.2.2.9.

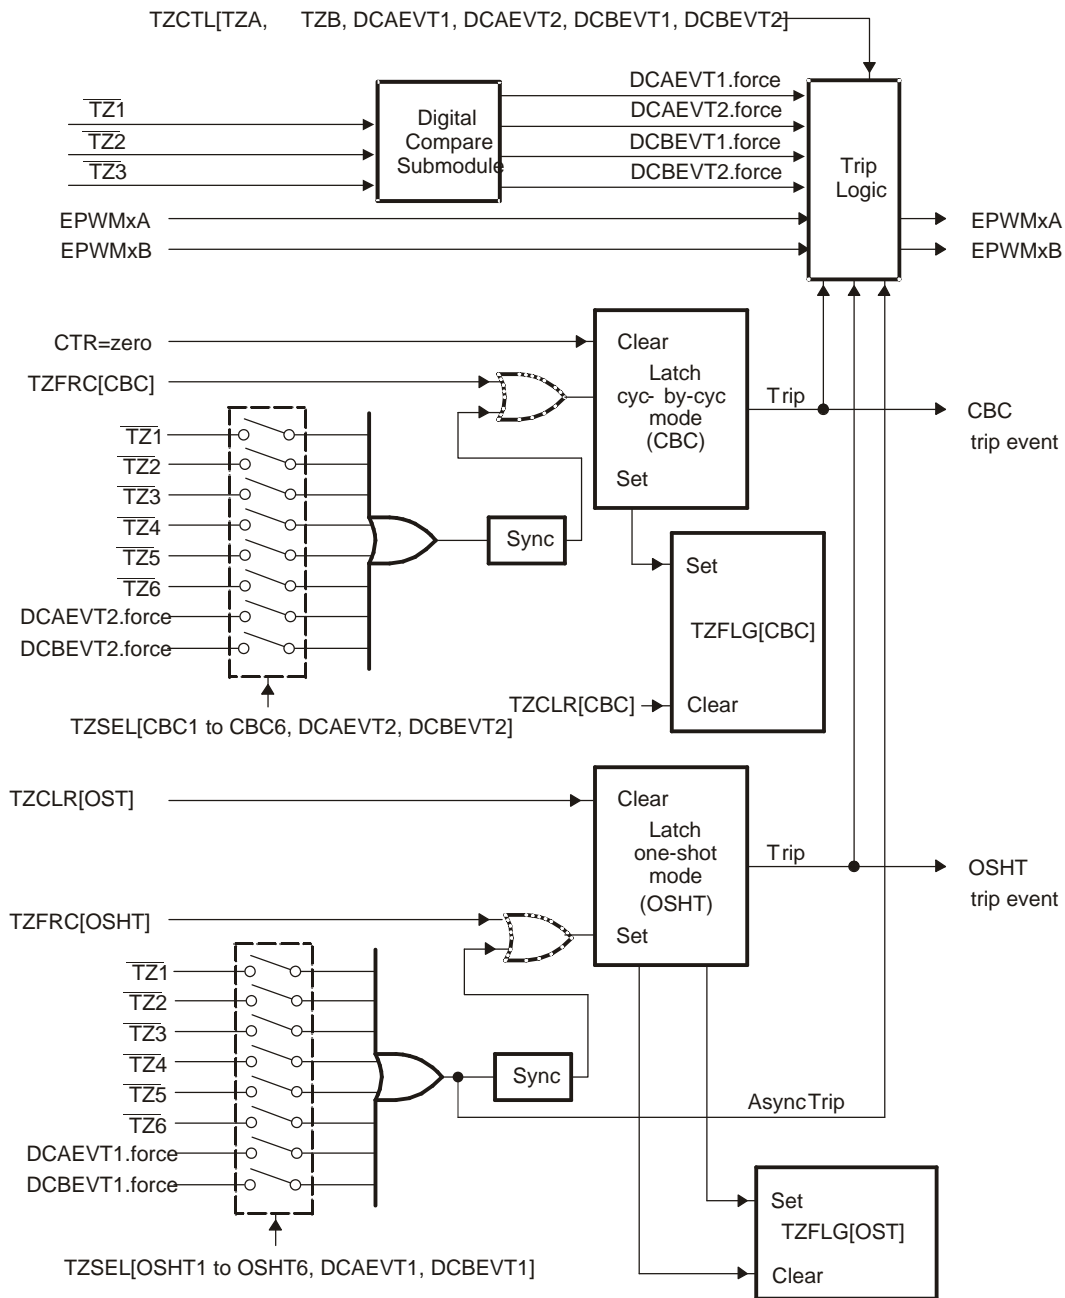

Figure 10-1585. Trip-Zone Submodule Mode Control Logic

Figure 10-1586. Trip-Zone Submodule Interrupt Logic

10.4.2.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
 - Every event
 - Every second event
 - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. Figure 10-1587 illustrates where the event-trigger submodule fits within the ePWM system.

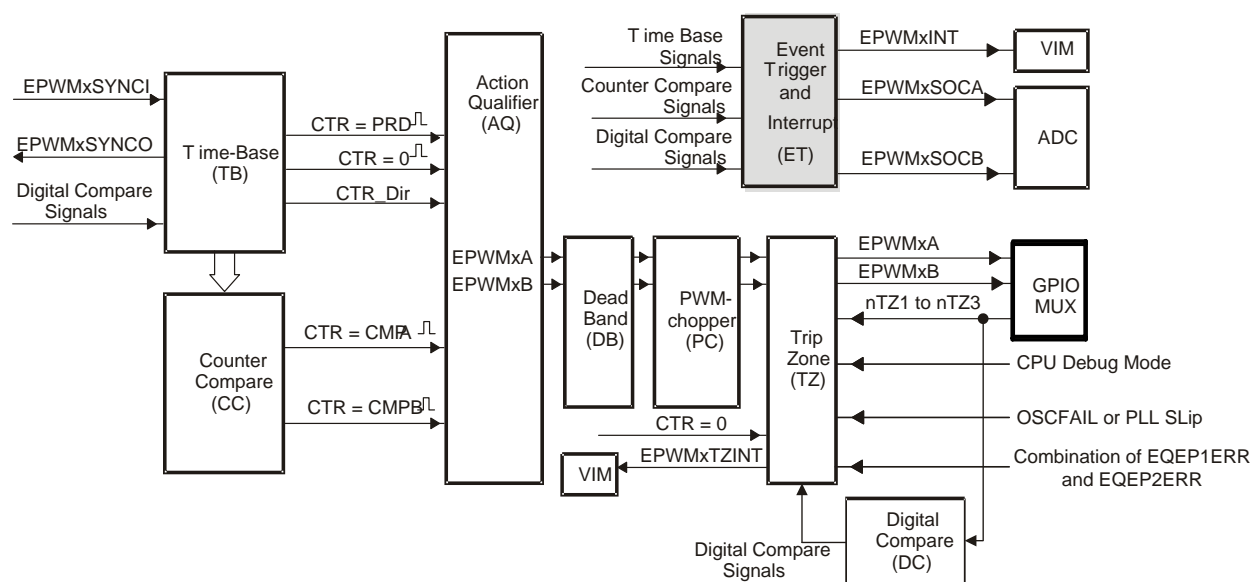

Figure 10-1587. Event-Trigger Submodule

10.4.2.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in Figure 10-1588, the ePWMxSOCA and ePWMxSOCB signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 10-1589) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

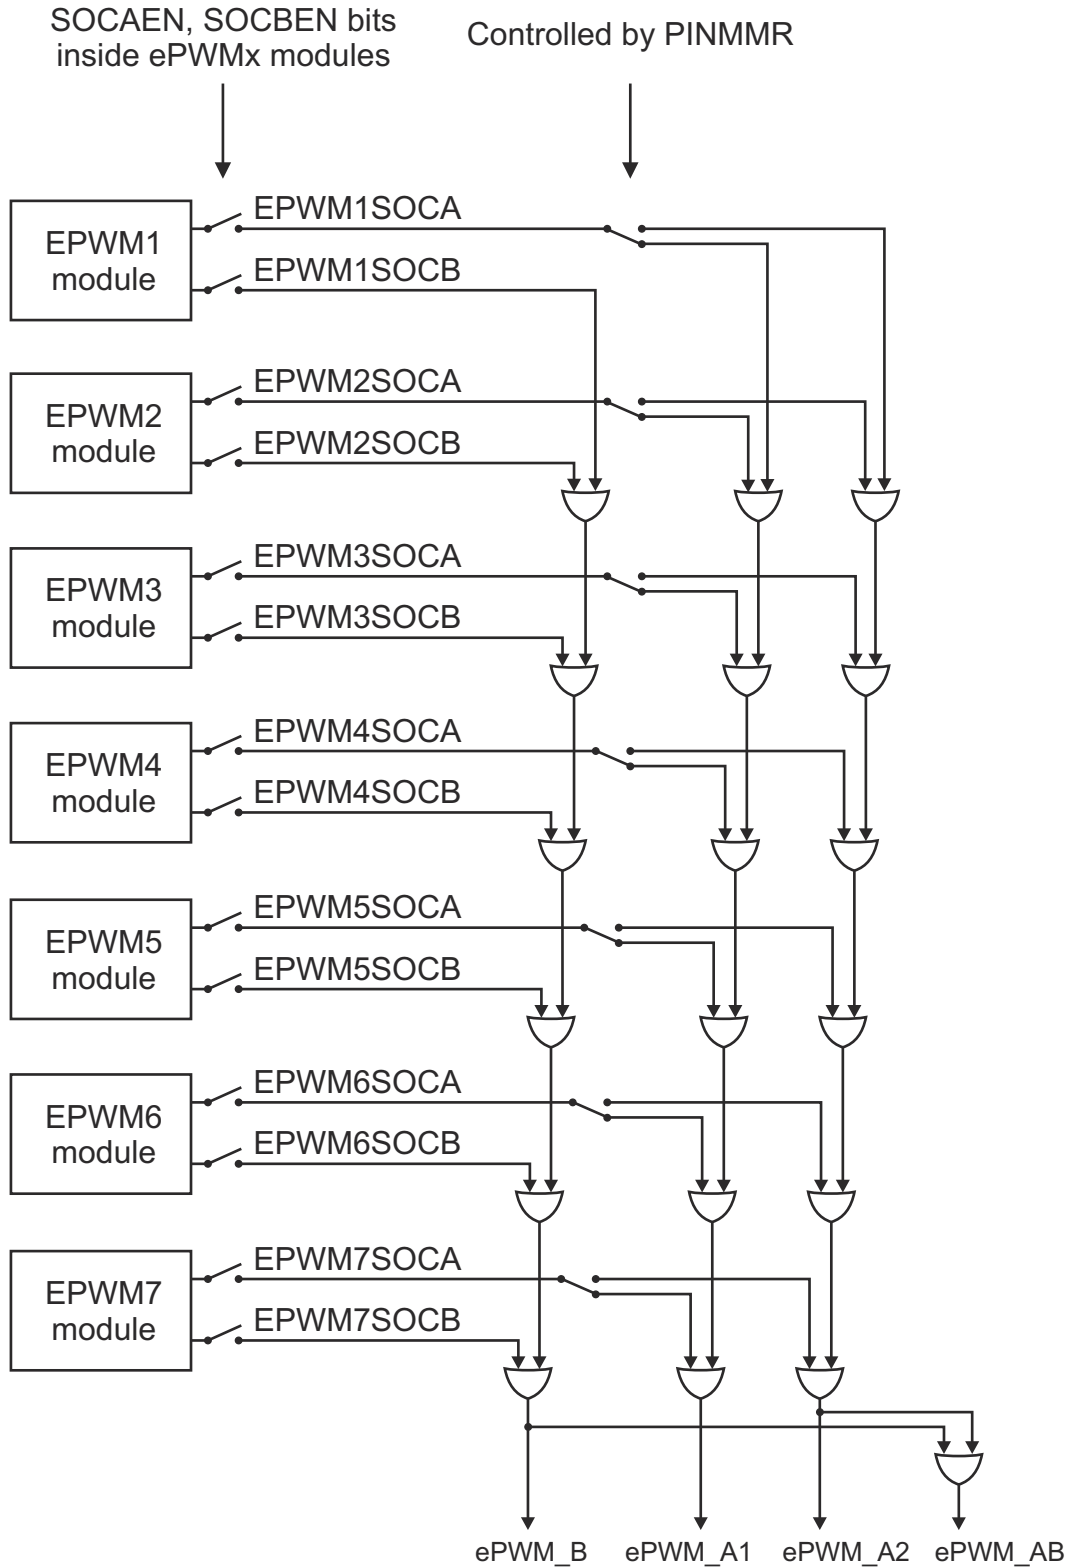

Figure 10-1588. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion

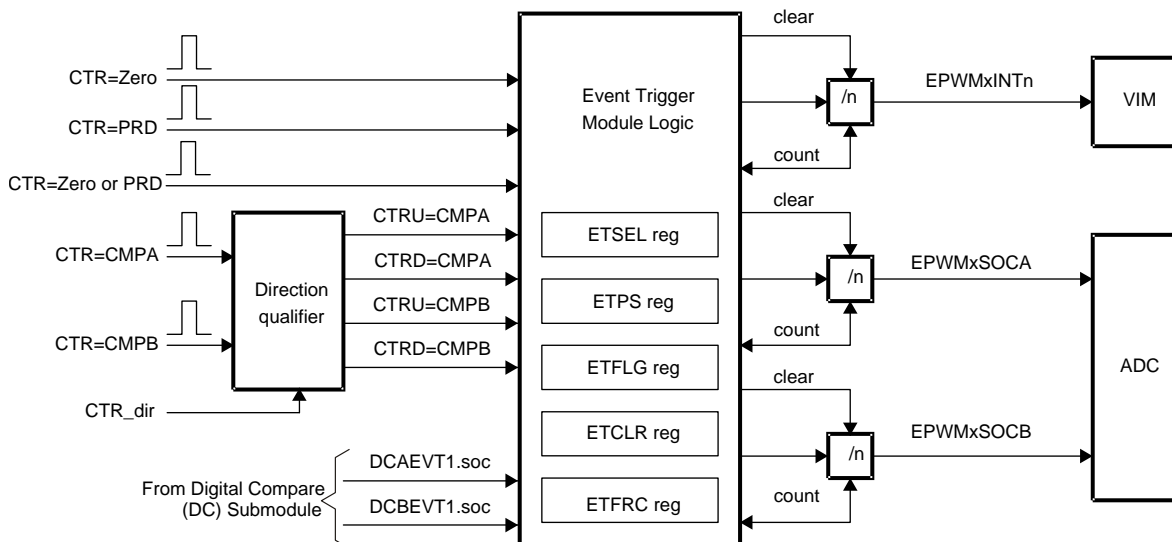

Figure 10-1589. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

The key registers used to configure the event-trigger submodule are shown in [Table 10-1654](#).

Table 10-1654. Event-Trigger Submodule Registers

Register Name	Address Offset	Shadowed	Description
ETSEL	0x0030	No	Event-trigger Selection Register
ETPS	0x0036	No	Event-trigger Prescale Register
ETFLG	0x0034	No	Event-trigger Flag Register
ETCLR	0x003A	No	Event-trigger Clear Register
ETFRC	0x0038	No	Event-trigger Force Register

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 10-1590](#), [Figure 10-1591](#), and [Figure 10-1592](#).

[Figure 10-1590](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.

- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

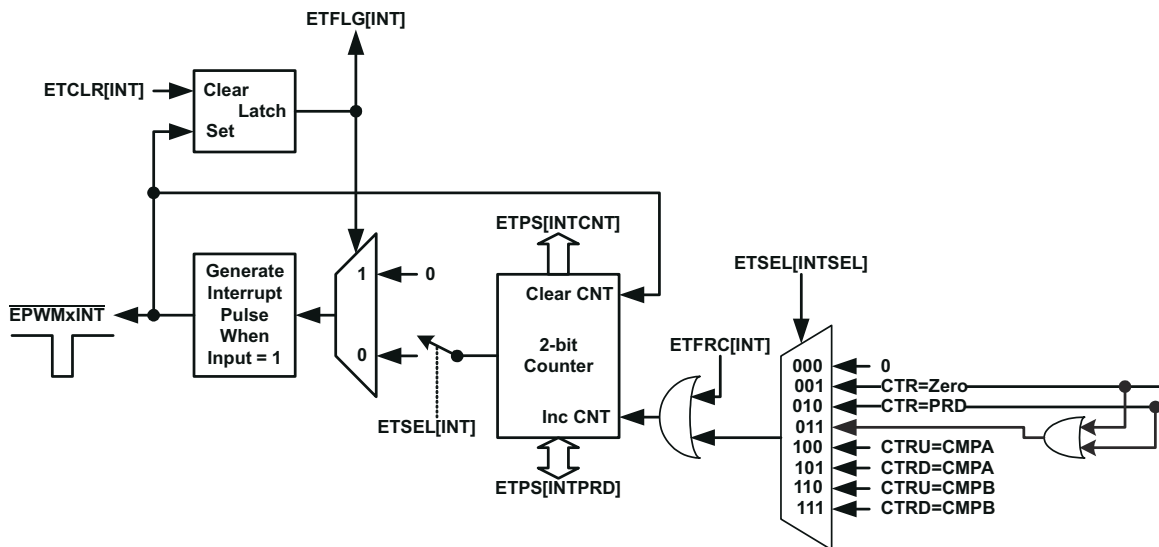

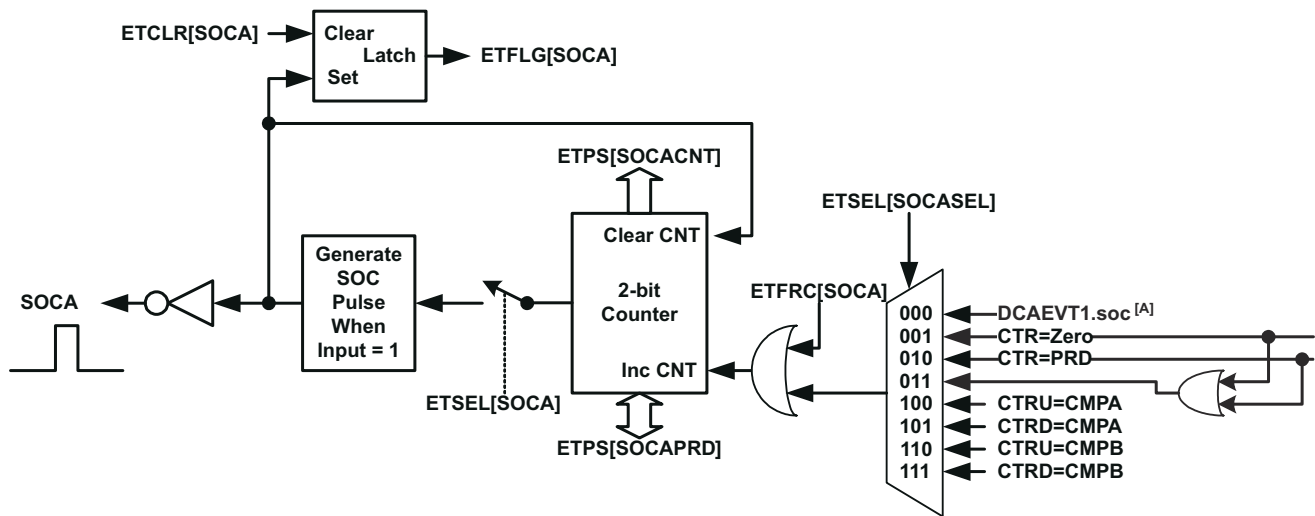

Figure 10-1590. Event-Trigger Interrupt Generator

Figure 10-1591 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.

A. The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 10.4.2.2.9.

Figure 10-1591. Event-Trigger SOCA Pulse Generator

Figure 10-1592 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

A. The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 10.4.2.2.9.

Figure 10-1592. Event-Trigger SOCB Pulse Generator

10.4.2.2.9 Digital Compare (DC) Submodule

Figure 10-1593 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions that then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

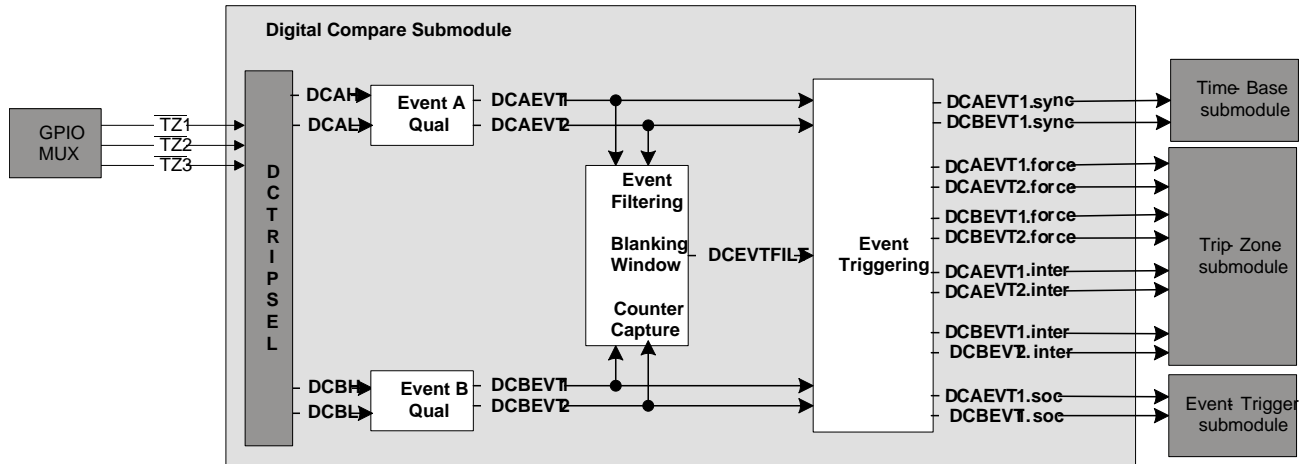

Figure 10-1593. Digital-Compare Submodule High-Level Block Diagram

10.4.2.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- $\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
 - generate a trip zone interrupt
 - generate an ADC start of conversion
 - force an event
 - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

10.4.2.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

Table 10-1655. Digital Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
TZDCSEL ⁽¹⁾ ⁽²⁾	0x0024	No	Trip Zone Digital Compare Select Register
DCTRISEL ⁽¹⁾	0x0062	No	Digital Compare Trip Select Register
DCACTL ⁽¹⁾	0x0060	No	Digital Compare A Control Register
DCBCTL ⁽¹⁾	0x0066	No	Digital Compare B Control Register
DCFCTL ⁽¹⁾	0x0064	No	Digital Compare Filter Control Register
DCCAPCTL ⁽¹⁾	0x006A	No	Digital Compare Capture Control Register
DCOFFSET	0x0068	Writes	Digital Compare Filter Offset Register
DCOFFSETCNT	0x006E	No	Digital Compare Filter Offset Counter Register
DCFWINDOW	0x006C	No	Digital Compare Filter Window Register
DCFWINDOWCNT	0x0072	No	Digital Compare Filter Window Counter Register
DCCAP	0x0070	Yes	Digital Compare Counter Capture Register

(1) These registers are writable only in privileged mode.

(2) The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

10.4.2.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

10.4.2.2.9.3.1 Digital Compare Events

As illustrated in [Figure 10-1593](#), trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) can be selected via the DCTRISEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

Note

The \overline{TZn} signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the \overline{TZn} , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of $3 \times TBCLK$ sync pulse width is required. If pulse width is $< 3 \times TBCLK$ sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 10.4.2.2.9.3.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)

- interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

[Figure 10-1594](#) and [Figure 10-1595](#) show how the DCAEVT1, DCAEVT2, or DCEVTFILT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

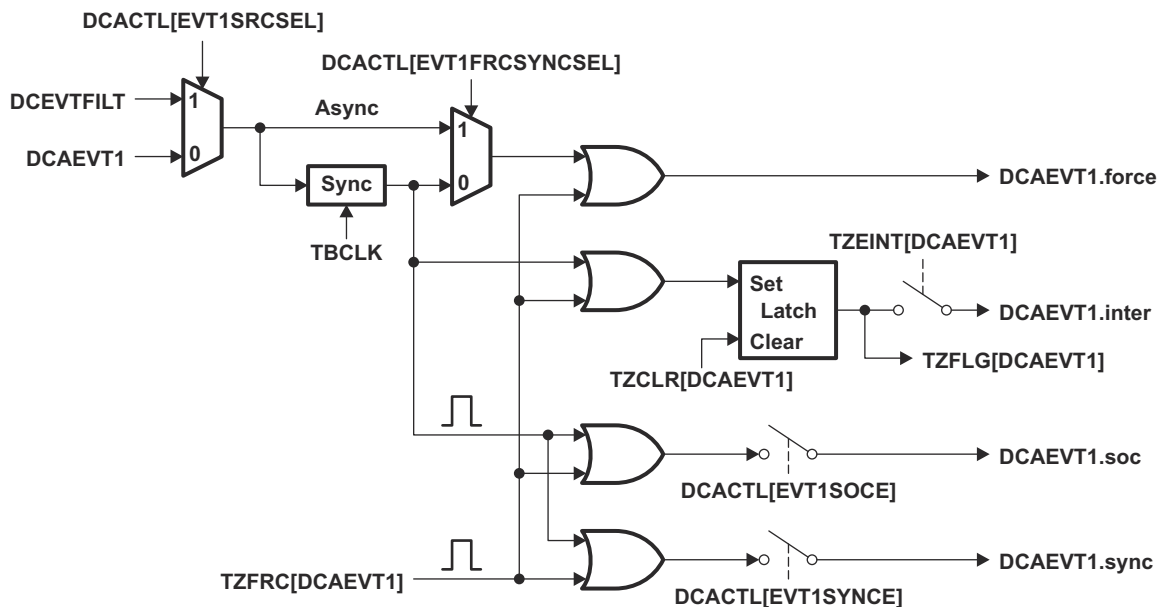

Figure 10-1594. DCAEVT1 Event Triggering

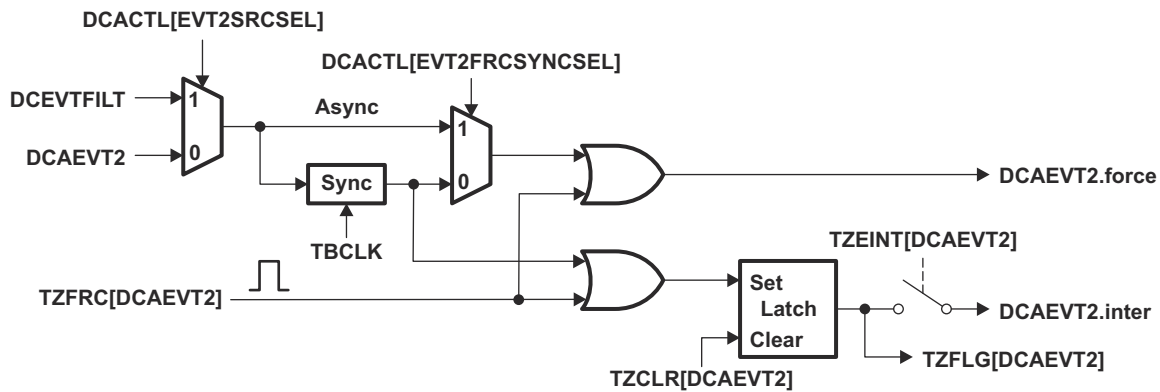

Figure 10-1595. DCAEVT2 Event Triggering

Figure 10-1596 and Figure 10-1597 show how the DCBEVT1, DCBEVT2, or DCEVTFLT signals are processed to generate the digital compare B event force, interrupt, soc, and sync signals.

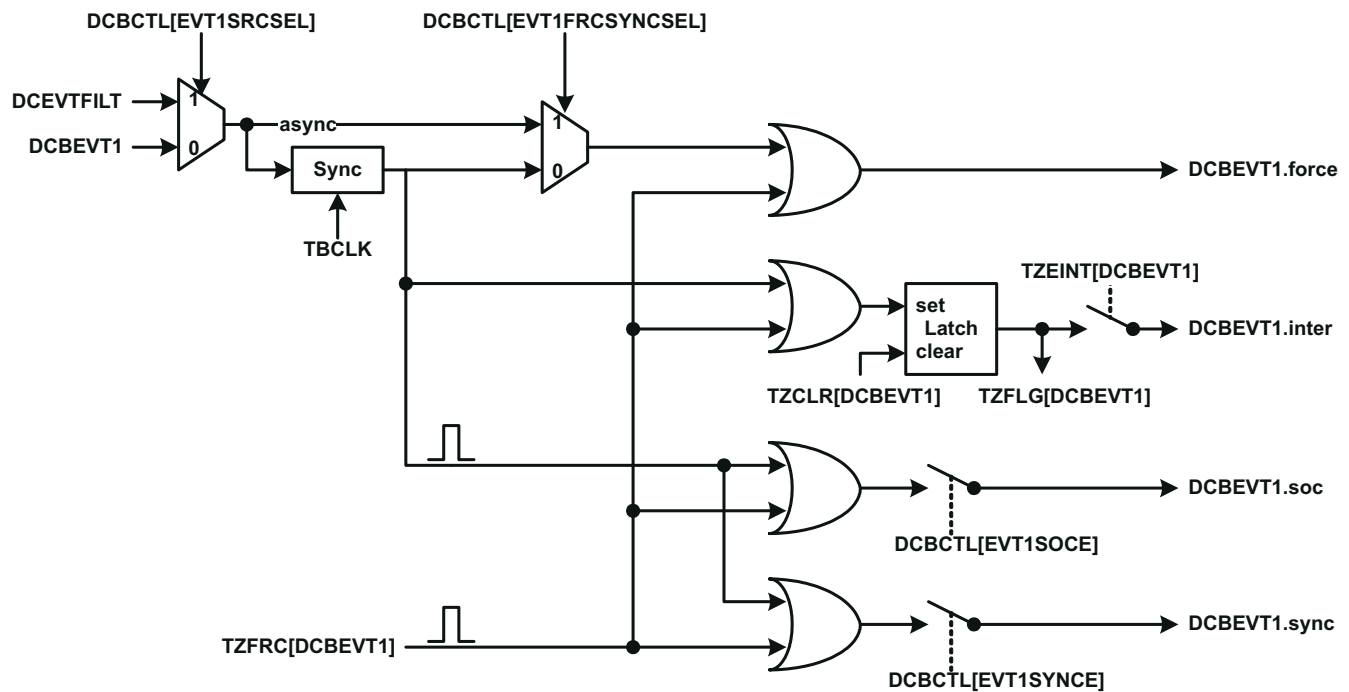

Figure 10-1596. DCBEVT1 Event Triggering

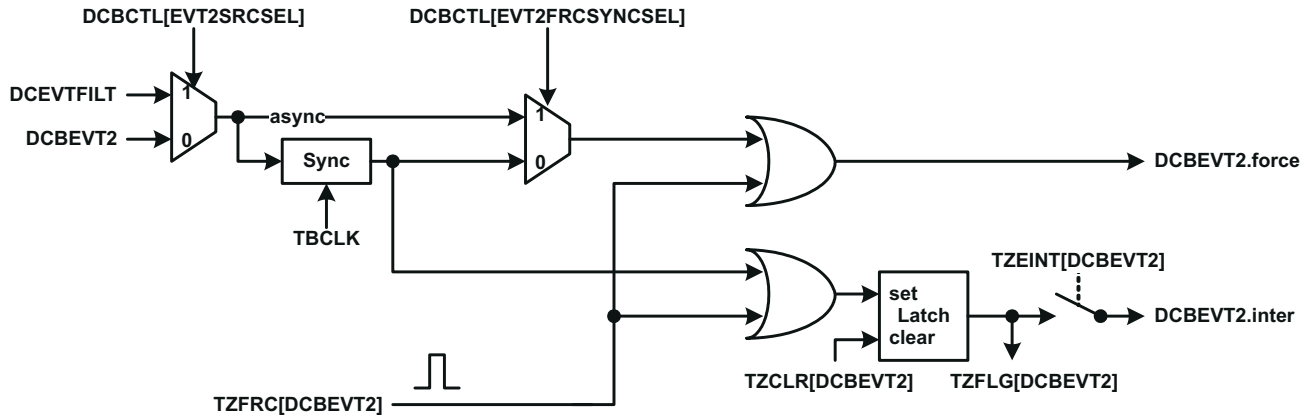

Figure 10-1597. DCBEVT2 Event Triggering

10.4.2.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. [Figure 10-1598](#) shows the details of the event filtering logic.

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

[Figure 10-1599](#) illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

Figure 10-1598. Event Filtering

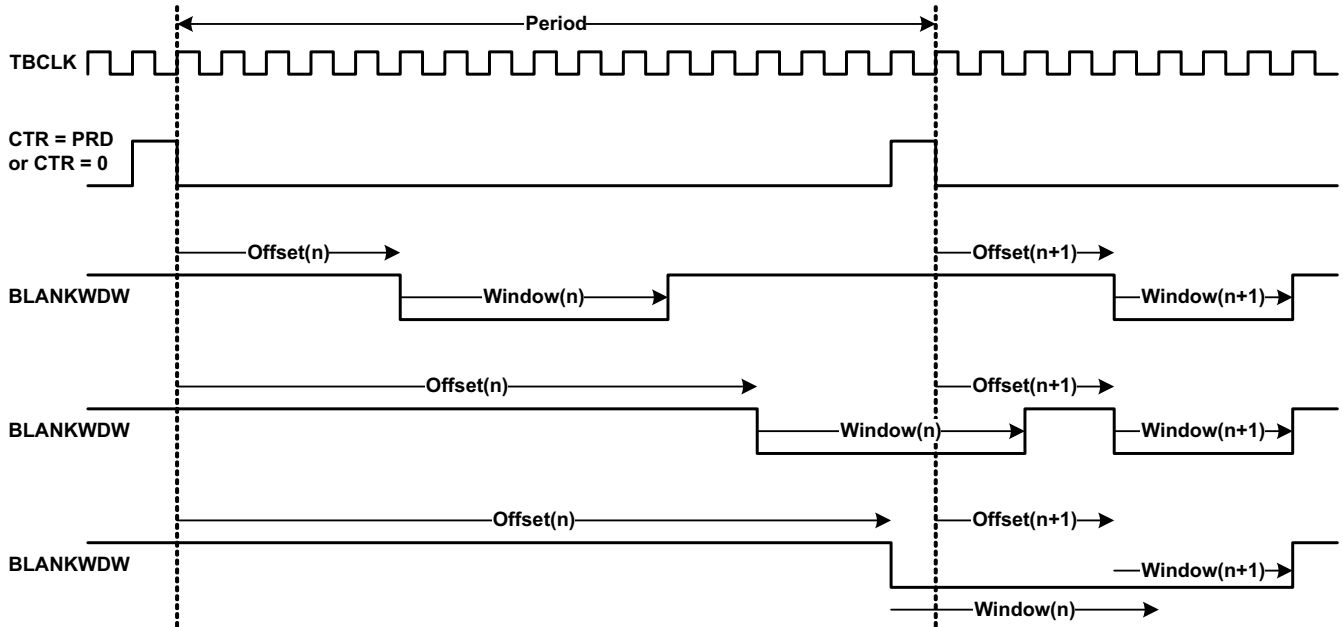

Figure 10-1599. Blanking Window Timing Diagram

10.4.2.2.10 Proper Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC = 0
4. Initialize peripheral registers
5. Set TBCLKSYNC = 1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

10.4.2.2.11

10.4.2.3 Application Examples

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

10.4.2.3.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 10-1600](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 10-1600. Simplified ePWM Module

10.4.2.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
 - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
 - Do nothing or ignore incoming sync strobe—enable switch open
 - Sync flow-through - SyncOut connected to SyncIn
 - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
 - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
 - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
 - Sync flow-through - SyncOut connected to SyncIn
 - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
 - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
 - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, that is, via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 10-1601](#).

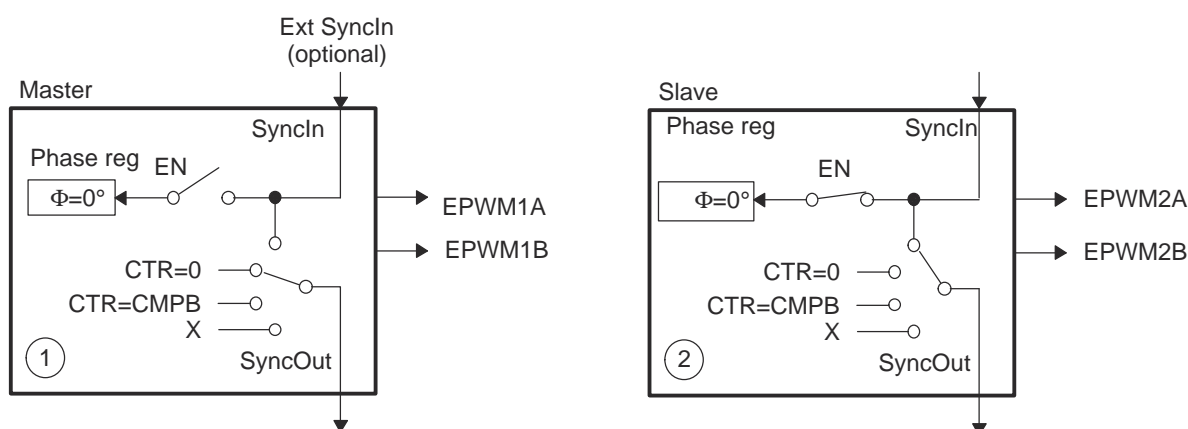

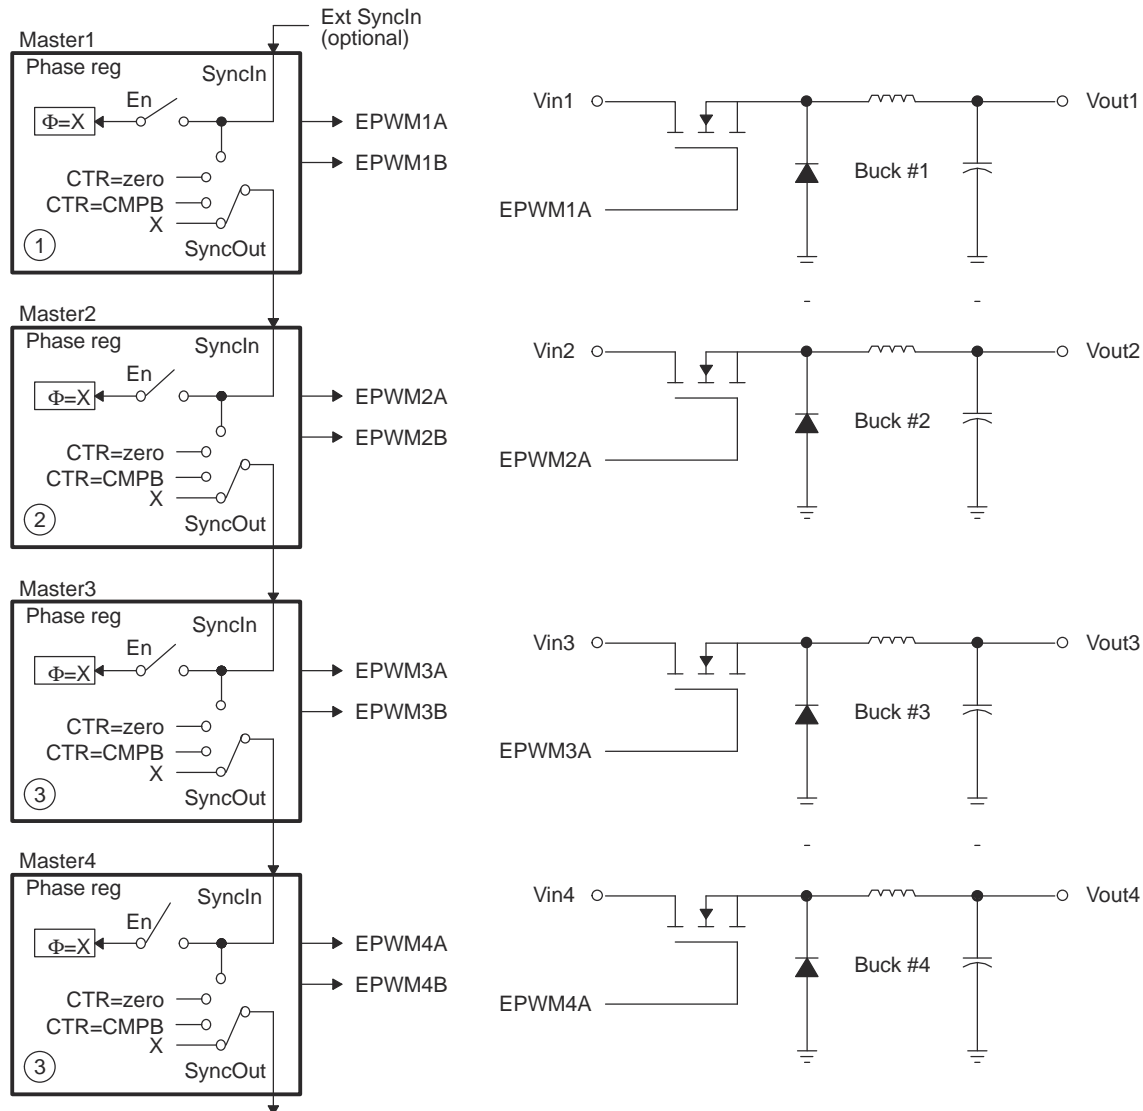

Figure 10-1601. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave

10.4.2.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 10-1602 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 10-1603 shows the waveforms generated by the setup shown in Figure 10-1602; note that only three waveforms are shown, although there are four stages.

A. $\Phi = X$ indicates value in phase register is a "don't care"

Figure 10-1602. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

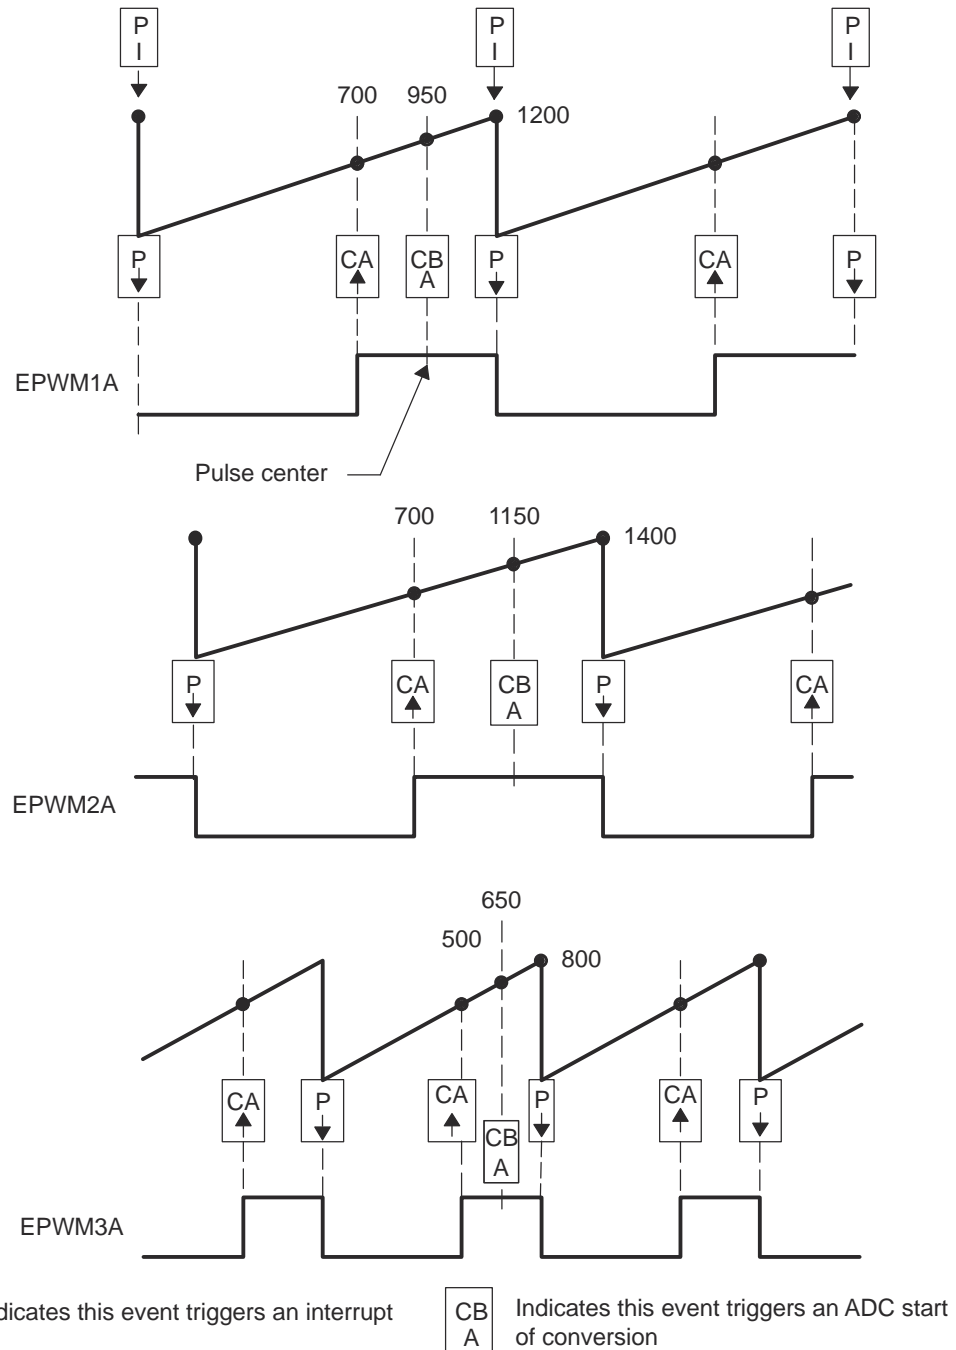

Figure 10-1603. Buck Waveforms for Figure 10-1602 (Note: Only three bucks shown here)

```

10.4.2.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 10-1604 shows such a configuration; Figure 10-1605 shows the waveforms generated by the configuration.

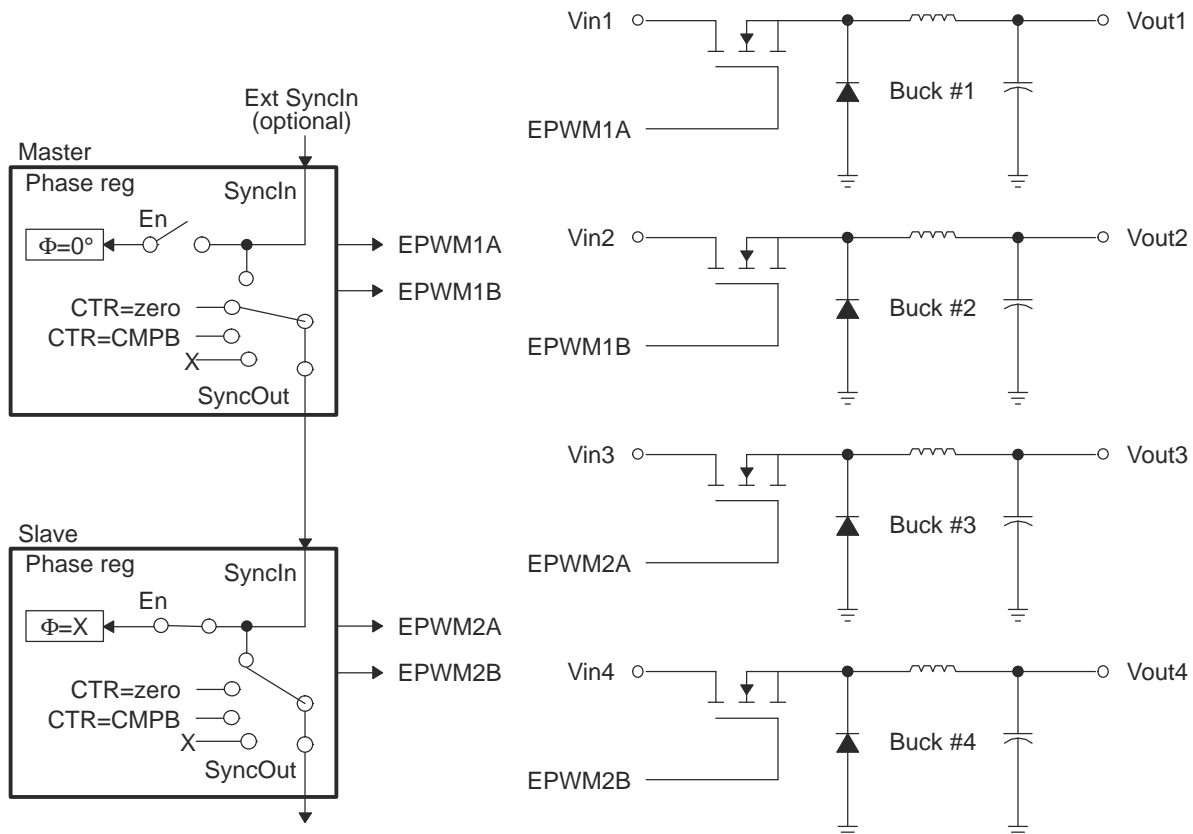

Figure 10-1604. Control of Four Buck Stages. (Note: $F_{PWM2} = N \times F_{PWM1}$)

Figure 10-1605. Buck Waveforms for Figure 10-1604 (Note: $F_{PWM2} = F_{PWM1}$)

Example 10-10. Code Snippet for Configuration in Figure 10-1604

```

//=====
// EPWM Module 1 config

EPwm2Regs.CMPB = 300; // adjust duty for output EPWM2B

```

10.4.2.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 10-1606 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 10-1607 shows the waveforms generated by the configuration shown in Figure 10-1606.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

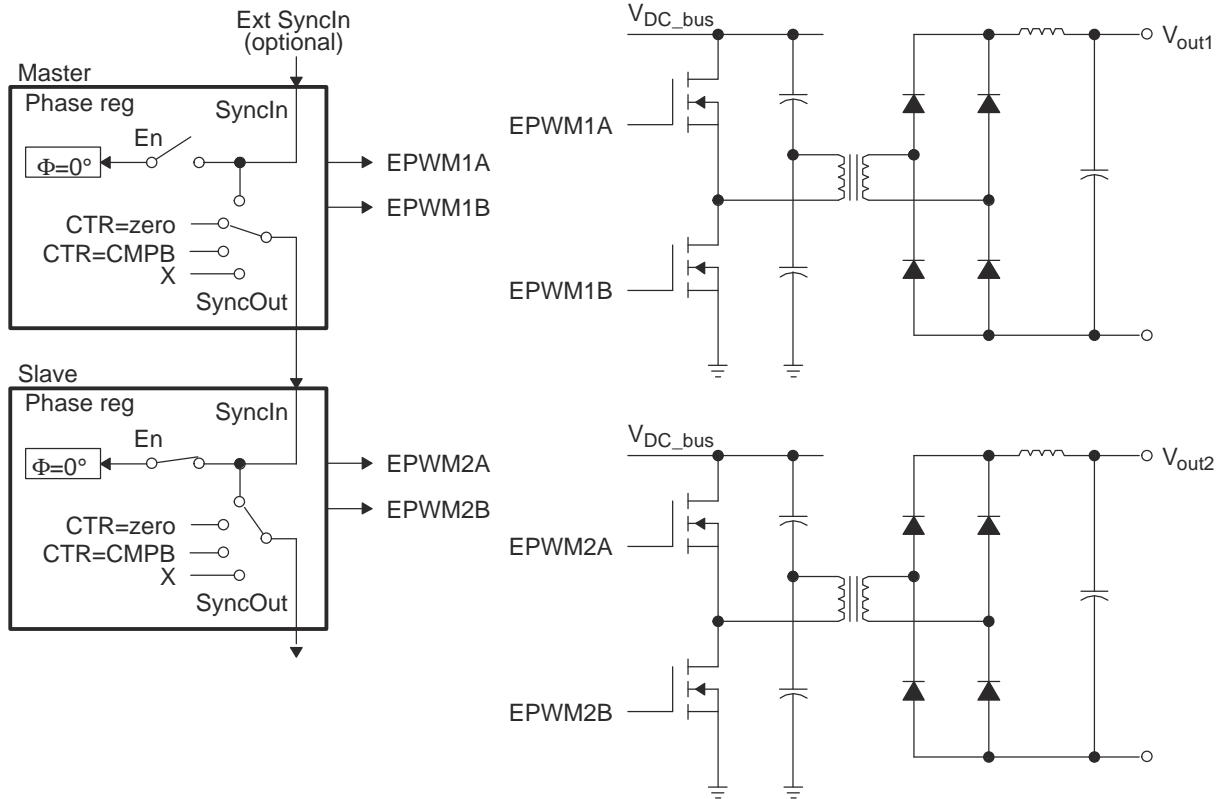

Figure 10-1606. Control of Two Half-H Bridge Stages ($F_{PWM2} = N \times F_{PWM1}$)

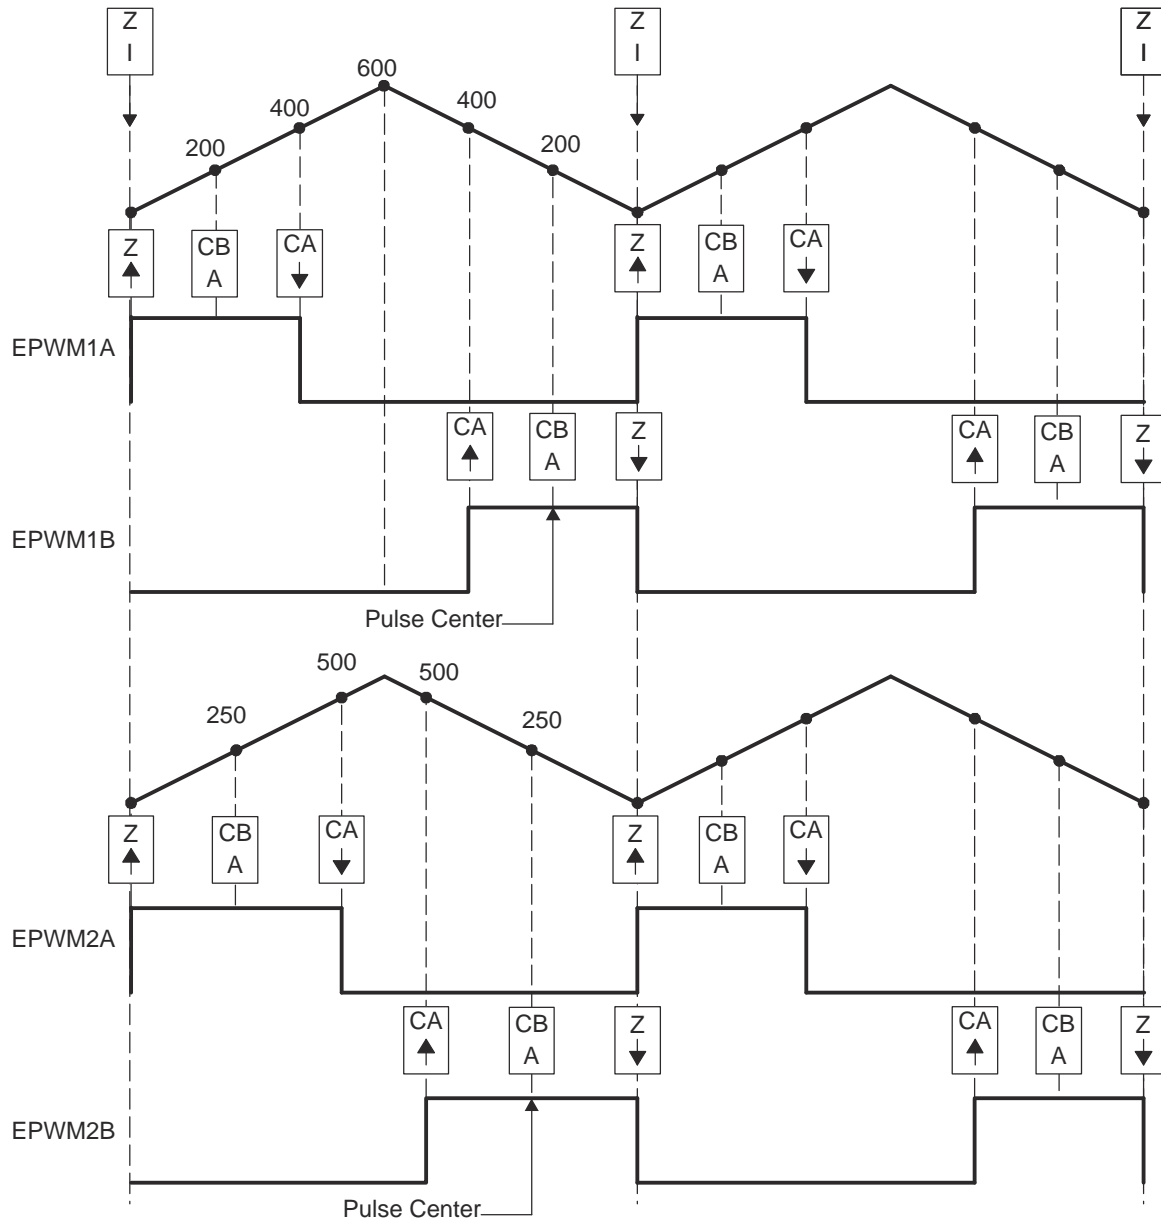

Figure 10-1607. Half-H Bridge Waveforms for Figure 10-1606 (Note: Here $F_{PWM2} = F_{PWM1}$)

Example 10-11. Code Snippet for Configuration in Figure 10-1606

```

//=====
// Config
//=====
// Initialization Time
//=====
// EPWM Module 1 config
EPwm1Regs.TBPRD = 600; // Period = 1200 TBCLK counts
EPwm1Regs.TBPHS.half.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode

```

10.4.2.3.5.1
10.4.2.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. [Figure 10-1608](#) shows how six PWM modules can control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in [Figure 10-1608](#)), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

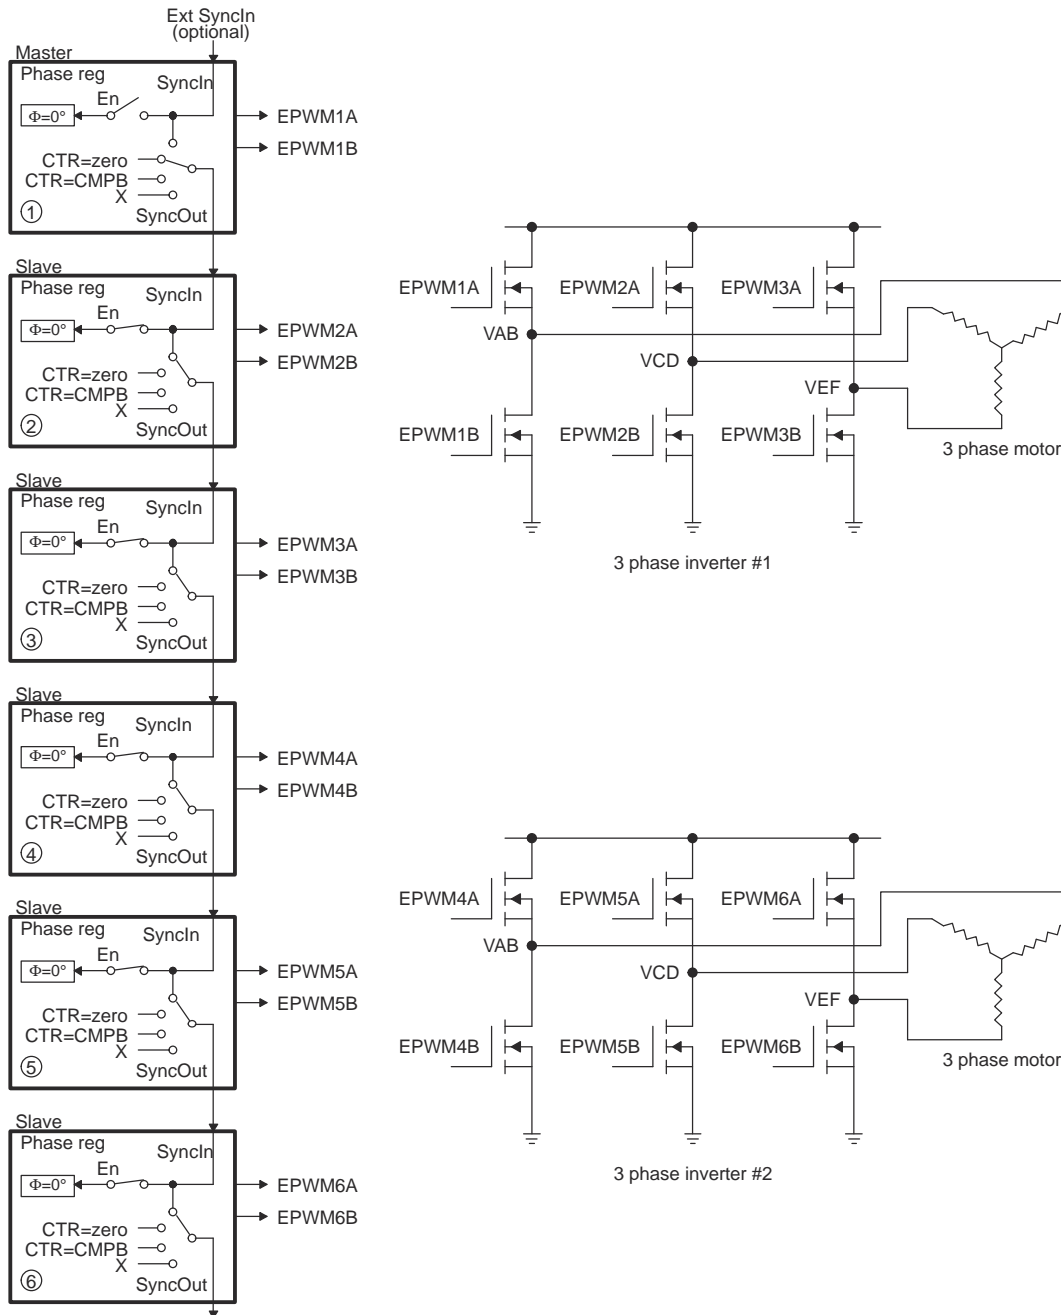

Figure 10-1608. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

Figure 10-1609. 3-Phase Inverter Waveforms for Figure 10-1608 (Only One Inverter Shown)

10.4.2.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, [Figure 10-1610](#) shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

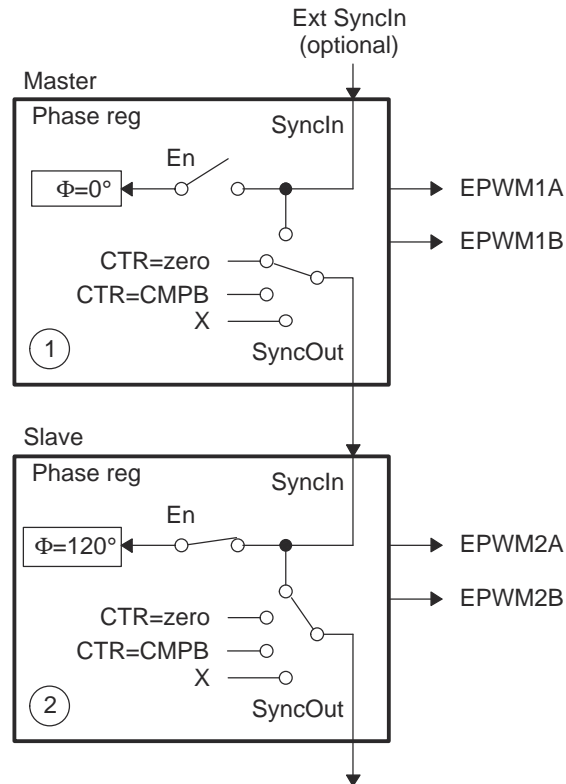

Figure 10-1610. Configuring Two PWM Modules for Phase Control

Figure 10-1611 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is, $200/600 \times 360^\circ = 120^\circ$). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120° .

Figure 10-1611. Timing Waveforms Associated With Phase Control Between 2 Modules

10.4.2.4 ePWM Module Control and Status Registers

Table 10-1656 lists the memory-mapped registers for the ePWM Module Control and Status Registers. All register offset addresses not listed in Table 10-1656 should be considered as reserved locations and the register contents should not be modified.

R-0h					R-0h	R/W-0h	R-1h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 10-1657. TBSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	CTRMAX	R	0h	Time-Base Counter Max Latched Status Bit 0h = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 1h = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.
1	SYNCI	R/W	0h	Input Synchronization Latched Status Bit 0h = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 1h = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.
0	CTRDIR	R	1h	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. 0h = Time-Base Counter is currently counting down. 1h = Time-Base Counter is currently counting up.

10.4.2.4.2 TBCTL Register (Offset = 2h) [reset = 83h]

TBCTL is shown in [Figure 10-1612](#) and described in [Table 10-1658](#).

Figure 10-1612. TBCTL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 10-1658. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0h = Stop after the next time-base counter increment or decrement. 1h = Stop when counter completes a whole cycle. In up-count mode, stop when the time-base counter = period (TBCTR = TBPRD). In down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). In up-down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). 2h = Free run 3h = Free run
13	PHSDIR	R/W	0h	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0h = Count down after the synchronization event. 1h = Count up after the synchronization event.
12-10	CLKDIV	R/W	0h	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = VCLK4 / (HSPCLKDIV \times CLKDIV)$ 0h = /1 (default on reset) 1h = /2 2h = /4 3h = /8 4h = /16 5h = /32 6h = /64 7h = /128

Table 10-1658. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = VCLK4 / (HSPCLKDIV \times CLKDIV)$ 0h = /1 1h = /2 (default on reset) 2h = /4 3h = /6 4h = /8 5h = /10 6h = /12 7h = /14
6	SWFSYNC	R/W	0h	Software Forced Synchronization Pulse. This event is ORed with the EPWMxSYNCl input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCl is selected by SYNCOSSEL = 0. 0h = Writing a 0 has no effect and reads always return a 0. 1h = Writing a 1 forces a one-time synchronization pulse to be generated.
5-4	SYNCOSSEL	R/W	0h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0h = EPWMxSYNCO 1h = CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000) 2h = CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB) 3h = Disable EPWMxSYNCO signal
3	PRDL	R/W	0h	Active Period Register Load From Shadow Register Select 0h = The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to 0. A write or read to the TBPRD register accesses the shadow register. 1h = Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.
2	PHSEN	R/W	0h	Counter Register Load From Phase Register Enable 0h = Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS) 1h = Load the time-base counter with the phase register when an EPWMxSYNCl input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs.
1-0	CTRM	R/W	3h	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0h = Up-count mode 1h = Down-count mode 2h = Up-down-count mode 3h = Stop-freeze counter operation (default on reset)

10.4.2.4.3 TBPHS Register (Offset = 4h) [reset = 0h]

TBPHS is shown in [Figure 10-1613](#) and described in [Table 10-1659](#).

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 10-1663. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	CMPA	R/W	0h	<p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> Do nothing, the event is ignored. Clear: Pull the EPWMxA and/or EPWMxB signal low Set: Pull the EPWMxA and/or EPWMxB signal high Toggle the EPWMxA and/or EPWMxB signal <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.</p>

Table 10-1665. CMPB Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	CMPB	R/W	0h	<p>The value in the active CMPB register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> Do nothing, event is ignored. Clear: Pull the EPWMxA and/or EPWMxB signal low Set: Pull the EPWMxA and/or EPWMxB signal high Toggle the EPWMxA and/or EPWMxB signal <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed. If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.</p>

10.4.2.4.10 AQSFR Register (Offset = 18h) [reset = 0h]

10.4.2.4.17 TZSEL Register (Offset = 26h) [reset = 0h]

TZSEL is shown in [Figure 10-1627](#) and described in [Table 10-1673](#).

One-Shot (OSHT) Trip-zone enable/disable (bits 15-8). When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until the user clears the condition via the TZCLR register. Cycle-by-Cycle (CBC) Trip-zone enable/disable (bits 7-0). When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.

Table 10-1689. DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	OFFSET	R	0h	Blanking Window Offset. Valid values: 0-FFFFh These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.

10.4.2.4.34 DCCAPCTL Register (Offset = 6Ah) [reset = 0h]

DCCAPCTL is shown in [Figure 10-1644](#) and described in [Table 10-1690](#).

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 10-1693. DCCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture. Valid values: 0-FFFFh To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address.

10.4.2.4.38 DCFWINDOWCNT Register (Offset = 72h) [reset = 0h]

DCFWINDOWCNT is shown in [Figure 10-1648](#) and described in [Table 10-1694](#).

15-8	RESERVED	R	0h	Any writes to these bit(s) must always have a value of 0.
7-0	WINDOWCNT	R	0h	Blanking Window Counter. Valid value: 0-FFh These 8 bits are read only and indicate the current value of the window counter. The counter counts down to zero and then stops until it is re-loaded when the offset counter reaches zero again.

10.4.3 CANFD

This chapter describes the Modular Controller Area Network (MCAN) module.

10.4.3.1 MCAN Overview	4074
10.4.3.2 MCAN Environment	4076
10.4.3.3 MCAN Integration	4078
10.4.3.4 MCAN Functional Description	4080
10.4.3.5 MCAN Register Manual	4114

10.4.3.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 5 Mbit/s data rate and is compliant to ISO 11898-1:2015.

Note

The availability of CAN FD feature is device part number dependent. Refer to device Data Manual for more information.

Figure 10-1650 shows the MCAN module overview.

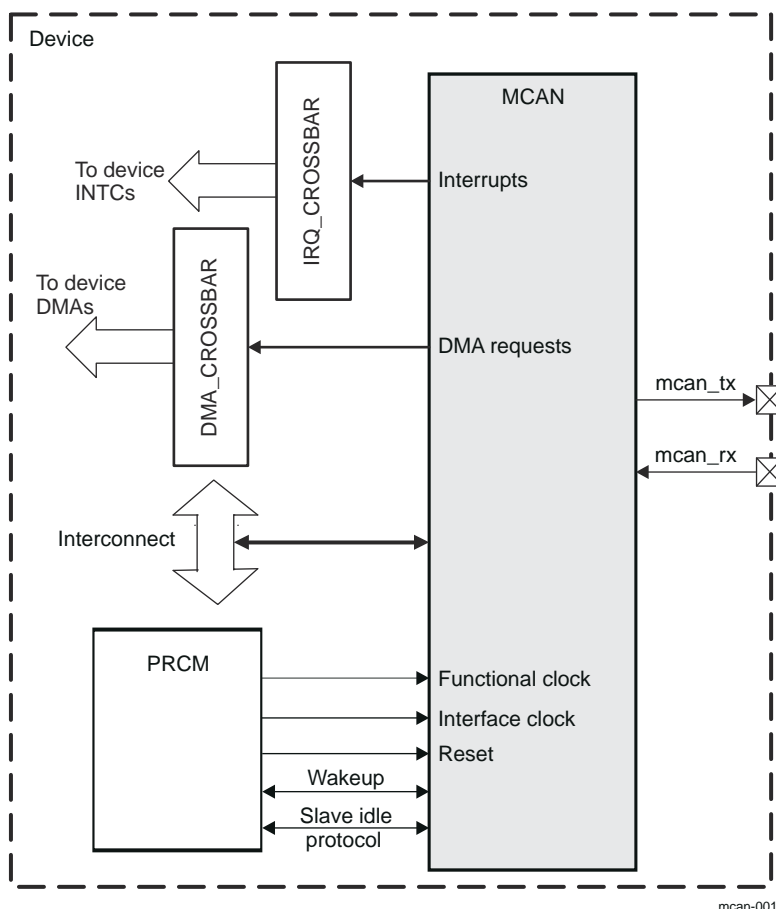

Figure 10-1650. MCAN Module Overview

10.4.3.1.1 Features

The MCAN module implements the following features:

- Conforms with ISO 11898-1:2015

- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECEDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)
- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

10.4.3.2 MCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 10-1651 shows an overview of a typical MCAN application.

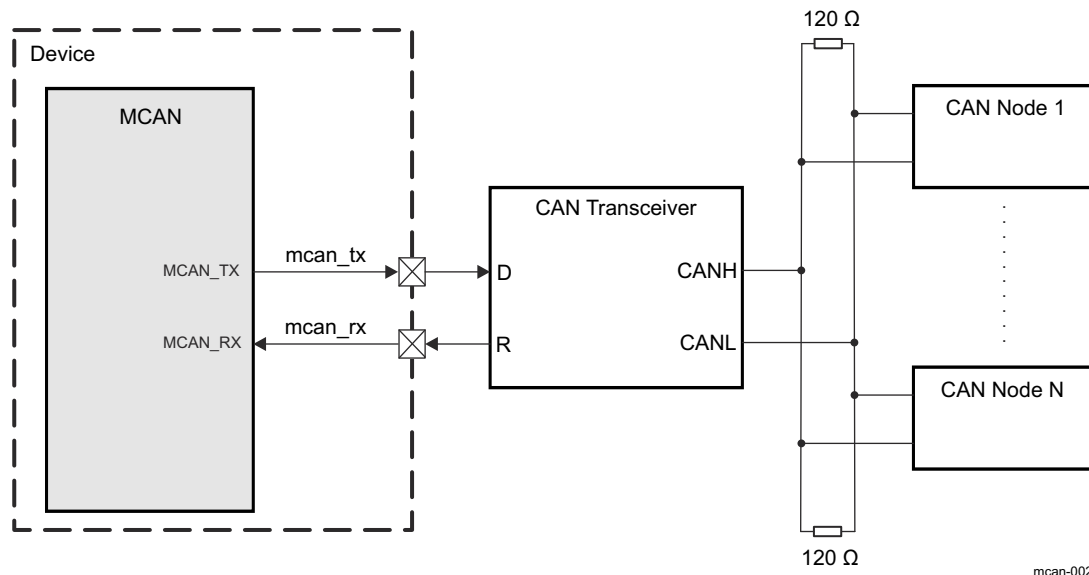

Figure 10-1651. MCAN Typical Application

Table 10-1695 describes the external signals of the MCAN module.

Table 10-1695. MCAN I/O Description

Module Signal	Device Signal	I/O ⁽¹⁾	Description	Value at Reset
MCAN_RX	mcan_rx	I	Serial data input from external CAN transceiver	HiZ
MCAN_TX	mcan_tx	O	Serial data output to external CAN transceiver	1

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers of Control Module*.

10.4.3.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
 - Recessive state (logical 1)
 - Dominant state (logical 0)
- The network is multimaster. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored.

- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
 - Arbitration field
 - Control field
 - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
 - CRC field
 - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signalling*.

10.4.3.3 MCAN Integration

Figure 10-1652 shows the integration of the MCAN module in the device.

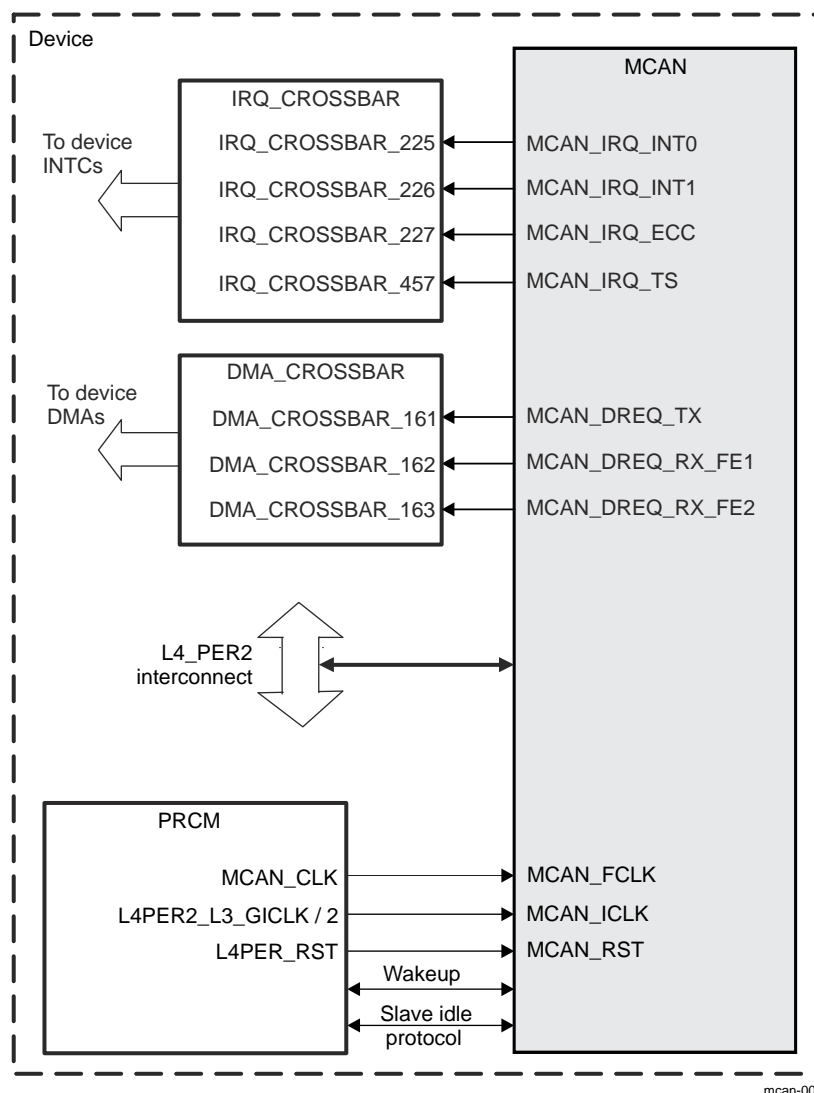

Figure 10-1652. MCAN Integration

Table 10-1696 through Table 10-1698 summarize the integration of the MCAN module in the device.

Table 10-1696. MCAN Integration Attributes

	MCAN_DREQ_RX_FE2	DMA_CROSSBAR_163	-	MCAN RX Filter Event 2

Note

The MCAN module has no default IRQ mappings through the IRQ_CROSSBAR. For the MCAN module, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description* in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description* in *Control Module*.

Note

For the description of the interrupt source, see [Section 10.4.3.4.2, Interrupt and DMA Requests](#).

10.4.3.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 5 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 10-1653 shows the MCAN module block diagram.

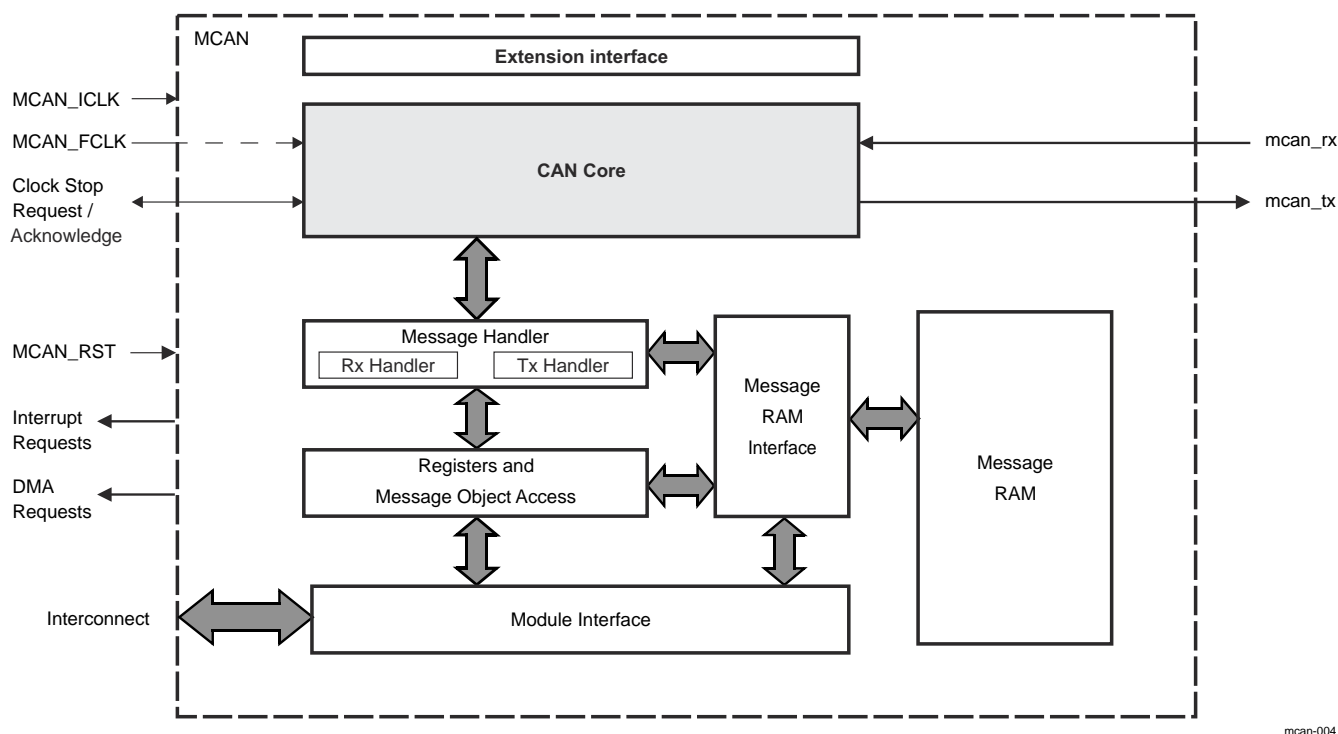

Figure 10-1653. MCAN Block Diagram

mcan-004

The MCAN module blocks description:

- **CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 10.4.3.4.11, Message RAM](#)).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

- **Clocking:** Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface:** All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

10.4.3.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

Note

MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$$f_{0,ICLK}(OCP) \pm \Delta f_{FM,ICLK}(OCP) \geq f_{FCLK}$$

CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than Classic CAN. For optimal performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK (GMAC_DSP_DPLL_CLK) for the system. Lower N-divider values increase the loop bandwidth of the PLL which in turn improves timing margins for CAN-FD.

For CAN-FD operations > 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.

For CAN-FD operations < 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.
- For 19.2 MHz input clocks, N = 11 is the preferred configuration.

For more information on how to configure the relevant clock source registers, see *PRCM* and the device data manual.

10.4.3.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 10.4.3.4.4.8.2, Suspend Mode](#)).

10.4.3.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write 1 to MCANSS_ECC_EOI[8] ECC_EOI bit (for more information, see [Section 10.4.3.4.7.2, ECC Aggregator](#)).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see [Section 10.4.3.4.5.1, External Timestamp Counter](#)).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status (MCANSS_IES)
- End Of Interrupt (MCANSS_EOI)
- External Timestamp Prescaler (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

10.4.3.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

10.4.3.4.2.3

For more information about available Interrupt and DMA Requests, see [Section 10.4.3.3, MCAN Integration](#).

10.4.3.4.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing 1 to MCAN_CCCR[8] FDOE bit. A value of 0 on the primary configuration port (mcanss_enable_fdoe) will force the MCAN_CCCR[8] FDOE bit during write to the MCAN_CCCR register which will prevent the device from enabling and using the CAN FD mode.

10.4.3.4.4 Operating Modes

10.4.3.4.4.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output MCAN_TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = 1. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15:0] TOC field is preset to the value configured by the MCAN_TOCC[31:16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN_CCCR[1] CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1.

10.4.3.4.4.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

Note

Automated transmission on reception of remote frames is not supported.

10.4.3.4.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR[4:3] ACT = 10) to Integrating (MCAN_PSR[4:3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as a form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 1, transmission of CAN FD frames

with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the DLC coding differs from the standard CAN format (see [Table 10-1699](#)).

Table 10-1699. DLC Coding

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames with bit rate switching, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 10-1654](#)) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

Figure 10-1654. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

10.4.3.4.4.4 Transmitter Delay Compensation

10.4.3.4.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the MCAN_TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the MCAN_RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase

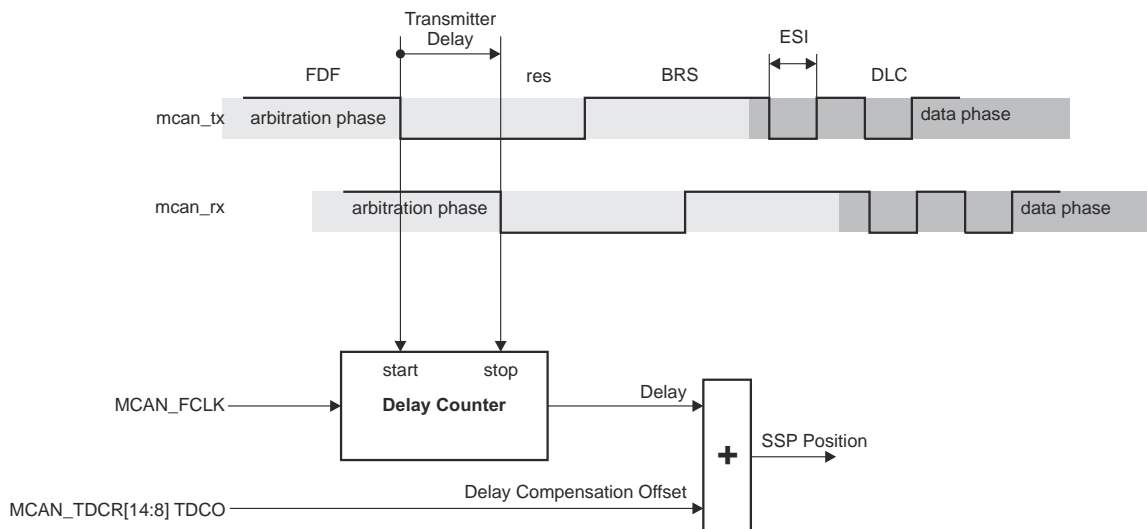

independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output MCAN_TX pin through the transceiver to the receive input MCAN_RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14:8] TDCO field (see Figure 10-1655). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22:16] TDCV field. This field is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

mcan-005

Figure 10-1655. Transmitter Delay Measurement

10.4.3.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input MCAN_RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 10-1655). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6:0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the MCAN_RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6:0] TDCF field and the MCAN_RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

10.4.3.4.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames.

In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (MCAN_ECR[14:8] REC and MCAN_ECR[7:0] TEC) are frozen while CAN error logging (MCAN_ECR[23:16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[1] INIT bits are set to 1.

The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

10.4.3.4.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN_CCCR[5] MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. [Figure 10-1656](#) shows the connection of the MCAN_TX and MCAN_RX signals to the MCAN module in Bus Monitoring Mode.

Figure 10-1656. Connection of Signals in Bus Monitoring Mode

10.4.3.4.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR[6] DAR bit).

10.4.3.4.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

10.4.3.4.4.8 Power Down (Sleep) Mode

Entering Power Down mode is controlled via the input clock stop request signal (mcanss_clkstp_clkstop_req) or MCAN_CCCR[4] CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[1] INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal (mcanss_clkstp_clkstop_ack) to 1 and the MCAN_CCCR[3] CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR[1] INIT bit will have no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN_CCCR[1] INIT bit.

10.4.3.4.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 10.4.3.4.4.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

10.4.3.4.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] FREE and MCANSS_CTRL[2] SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 10.4.3.4.4.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23:16] CEL
- MCAN_PSR[2:0] LEC
- MCAN_PSR[10:8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

10.4.3.4.4.8.3 Wakeup Request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive MCAN_RX pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the MCANSS_CTRL[4] WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

10.4.3.4.4.9 Test Mode

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit MCAN_TX pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6:5] TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive MCAN_RX pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6:5] TX filed until the new configuration is visible at the output MCAN_TX pin. This applies also when reading input MCAN_RX pin via the MCAN_TEST[7] RX bit.

Note

Test modes should be used for self test only. The software control for MCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

10.4.3.4.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to 1. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the MCAN_TX and MCAN_RX pins. In this mode MCAN_RX pin is disconnected from the MCAN module and MCAN_TX pin is held recessive. Figure 10-1657 shows the connection of the MCAN_TX and MCAN_RX pins to the MCAN module in case of Internal Loop Back Mode.

Figure 10-1657. Internal Loop Back Mode

10.4.3.4.5 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19:16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15:0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 10.4.3.4.11, Message RAM.

10.4.3.4.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1:0] TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23:0] PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN_IRQ_TS interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the MCANSS_IRS register is set (see Figure 10-1658). The MCANSS_IE register can be affected by writing to the MCAN_IESS register to set or to the MCANSS_IECS register to clear. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the

MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

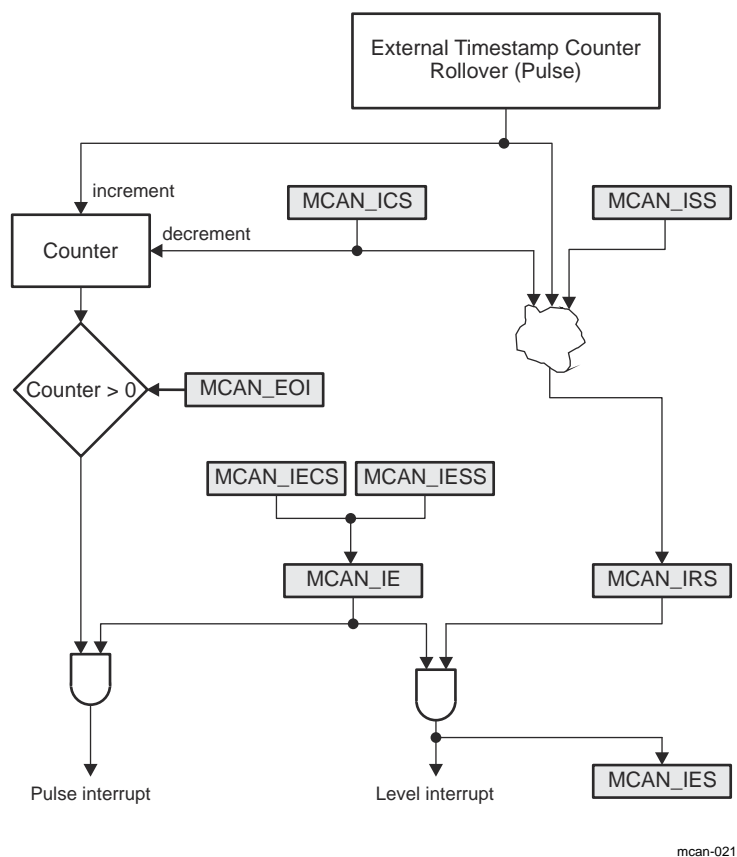

Figure 10-1658. External Timestamp Counter Interrupt

10.4.3.4.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19:16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15:0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[1] INIT = 0 and stopped when MCAN_CCCR[1] INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2:1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_CCCR[1] INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31:16] TOP field.

10.4.3.4.7 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

10.4.3.4.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

10.4.3.4.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

10.4.3.4.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

10.4.3.4.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register (MCANSS_ECC_AGGR_REVISION), ECC Vector Register (MCANSS_ECC_VECTOR), Misc Status Register (MCANSS_ECC_MISC_STATUS), ECC Control Register (MCANSS_ECC_CONTROL), and ECC Wrapper Revision Register (MCANSS_ECC_WRAP_REVISION).
- Control and status registers - ECC Error Control Registers (MCANSS_ECC_ERR_CTRL1 and MCANSS_ECC_ERR_CTRL2) and ECC Error Status Registers (MCANSS_ECC_ERR_STAT1 and MCANSS_ECC_ERR_STAT2).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
 - MCANSS_ECC_SEC_EOI_REG
 - MCANSS_ECC_SEC_STATUS_REG0
 - MCANSS_ECC_SEC_ENABLE_SET_REG0
 - MCANSS_ECC_SEC_ENABLE_CLR_REG0
 - MCANSS_ECC_DED_EOI_REG
 - MCANSS_ECC_DED_STATUS_REG0
 - MCANSS_ECC_DED_ENABLE_SET_REG0
 - MCANSS_ECC_DED_ENABLE_CLR_REG0

10.4.3.4.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.
- Software then polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is 1. This bit indicates that the read operation has completed.

- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

10.4.3.4.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the MCANSS_ECC_SEC_ENABLE_SET_REG0/MCANSS_ECC_DED_ENABLE_SET_REG0 register.
- Software writes the ECC RAM ID in the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR.
- Software writes the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger the read.
- Software writes the MCANSS_ECC_ERR_STAT1 register address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the MCANSS_ECC_VECTOR register again if it needs to read the MCANSS_ECC_ERR_STAT2 register.
- Software polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit. When this bit is set, a read of the MCANSS_ECC_ERR_STAT1/MCANSS_ECC_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANSS_ECC_ERR_STAT1[8] CLR_ECC_SEC or MCANSS_ECC_ERR_STAT1[9] CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the MCANSS_ECC_ERR_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANSS_ECC_SEC_EOI_REG/MCANSS_ECC_DED_EOI_REG register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANSS_ECC_EOI[8] ECC_EOI bit.

10.4.3.4.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

10.4.3.4.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
 - Range Filter (from - to)
 - Filter for specific IDs (for one or two dedicated IDs)
 - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 10.4.3.4.11, Message RAM](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1

- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see [Section 10.4.3.4.2.1, DMA Requests](#).
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields).
- Rx FIFO:
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 10.4.3.4.8.2.2](#) have to be considered.

10.4.3.4.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 10.4.3.4.11.5, Standard Message ID Filter Element](#) and [Section 10.4.3.4.11.6, Extended Message ID Filter Element](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

10.4.3.4.8.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 10.4.3.4.11.5, Standard Message ID Filter Element](#) and [Section 10.4.3.4.11.6, Extended Message ID Filter Element](#).

10.4.3.4.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

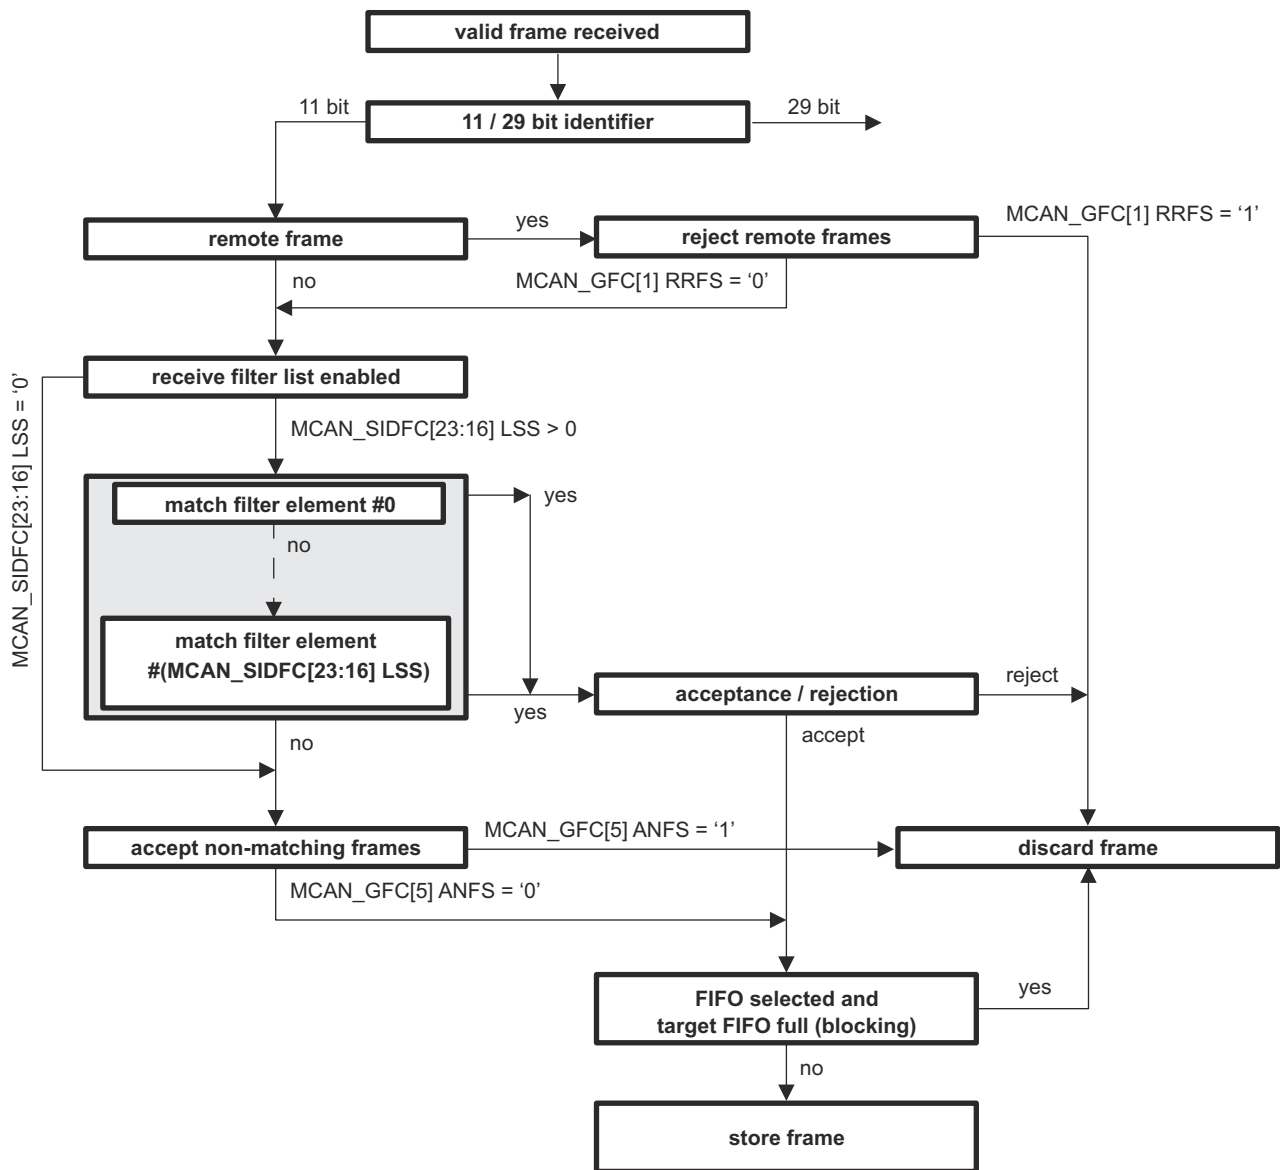

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

10.4.3.4.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 10-1659](#). [Section 10.4.3.4.11.5](#), *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

mcan-009

Figure 10-1659. Standard Message ID Filter Path

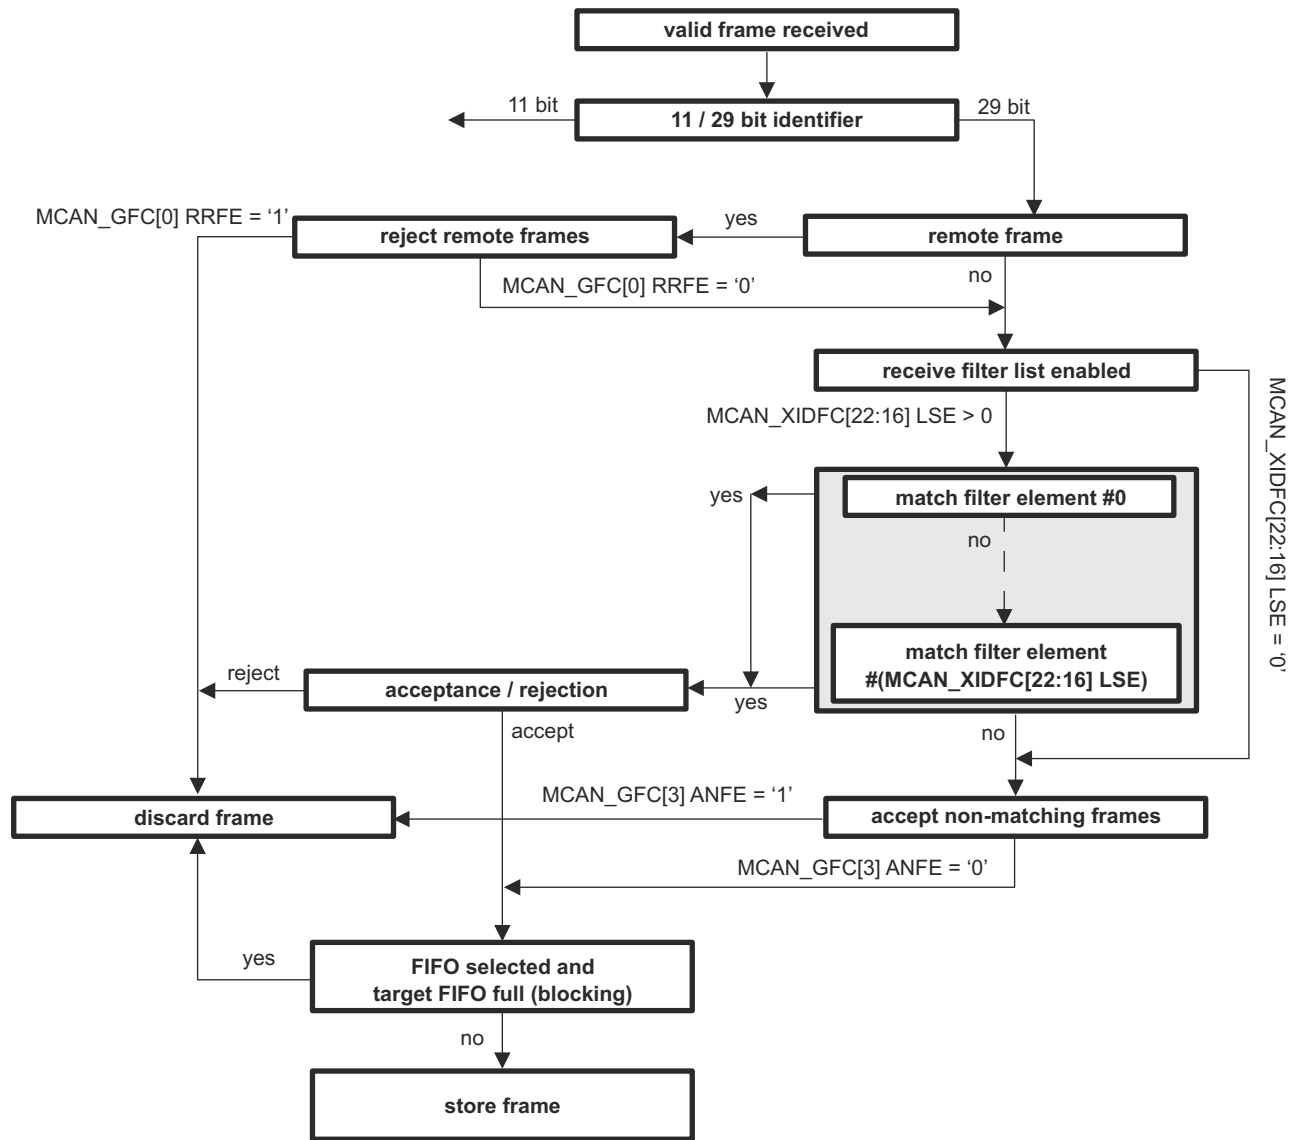

10.4.3.4.8.1.5 Extended Message ID Filtering

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 10-1660](#). [Section 10.4.3.4.11.6](#), *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

mcan-010

Figure 10-1660. Extended Message ID Filter Path

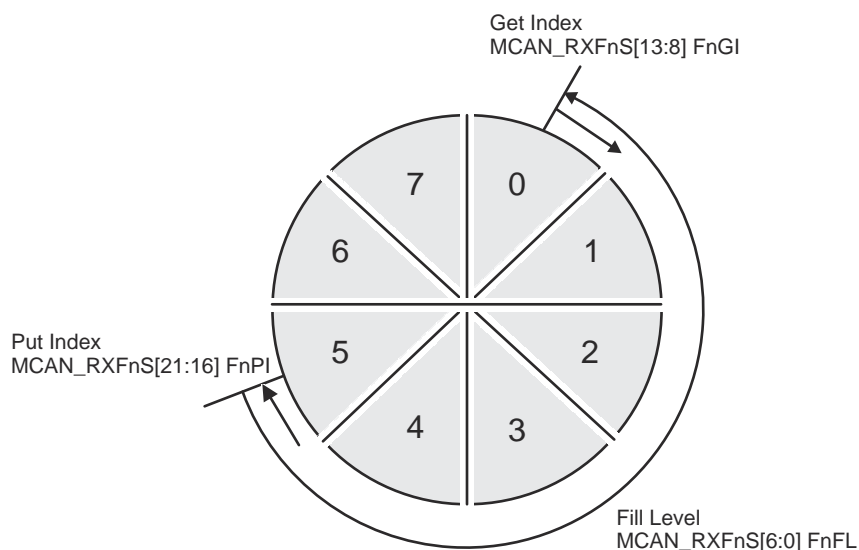

10.4.3.4.8.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 10.4.3.4.8.1, Acceptance Filtering](#). [Section 10.4.3.4.11.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W/MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set. Figure 10-1661 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

mcan-011

Figure 10-1661. Rx FIFO Status

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 10-1700 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 10-1700. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS/ MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

10.4.3.4.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR[3] RFnL/ MCAN_IR[25] RFnL is set.

10.4.3.4.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 10-1662 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

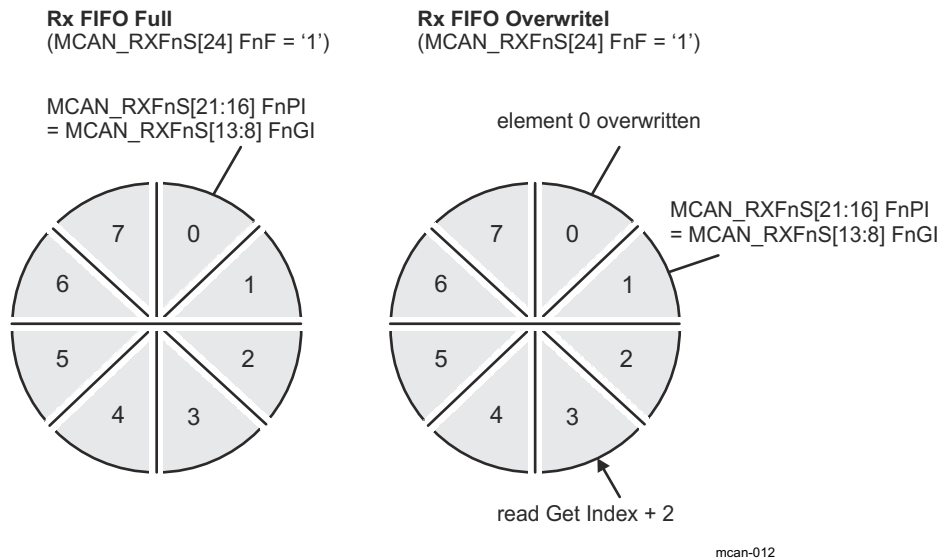

Figure 10-1662. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

10.4.3.4.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 10.4.3.4.11.5, Standard Message ID Filter Element and Section 10.4.3.4.11.6, Extended Message ID Filter Element).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 10-1701 shows Example Filter Configuration for Rx Buffers.

Table 10-1701. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

10.4.3.4.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

10.4.3.4.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 10.4.3.4.11.3](#) describes the Tx Buffer Element. [Table 10-1702](#) shows the possible configurations for message transmission.

Table 10-1702. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

10.4.3.4.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

10.4.3.4.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 10-1703 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20:16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

Table 10-1703. Tx Buffer/Tx FIFO/Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

10.4.3.4.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12:8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = 1) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20:16] TFQPI = MCAN_TXFQS[12:8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see [Table 10-1703](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

10.4.3.4.9.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 10-1703](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

10.4.3.4.9.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29:24] TFQS field

If the MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12:8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 10-1663](#) shows Mixed Dedicated Tx Buffers/Tx FIFO example.

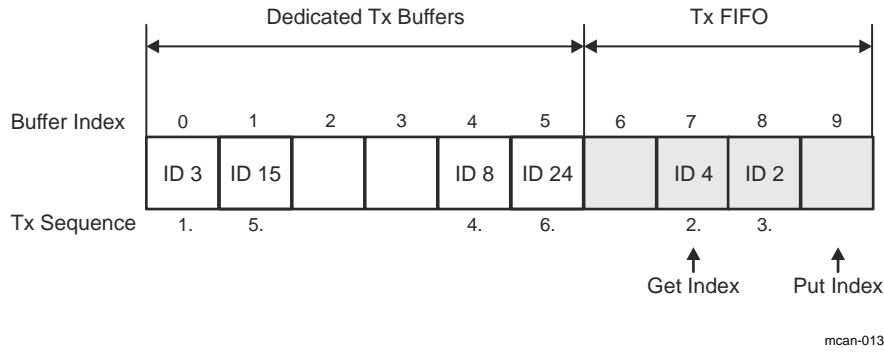

Figure 10-1663. Mixed Dedicated Tx Buffers /Tx FIFO (example)

10.4.3.4.9.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29:24] TFQS field

If MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 10-1664 shows Mixed Dedicated Tx Buffers/Tx Queue example.

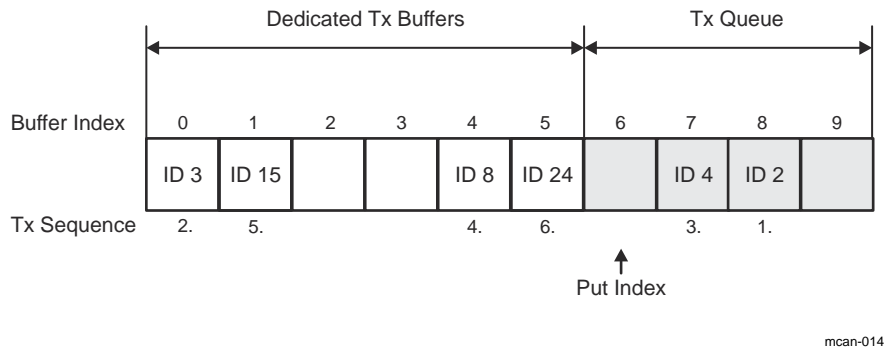

Figure 10-1664. Mixed Dedicated Tx Buffers /Tx Queue (example)

10.4.3.4.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = 1.

Note

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

10.4.3.4.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 10.4.3.4.11.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12:8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29:24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS[12:8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15:2] EFSA field.

10.4.3.4.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

10.4.3.4.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

10.4.3.4.11.1 Message RAM Configuration

The MCAN module is configured to allocate 1600 words in the Message RAM. The Message RAM has a width of 32 bits.

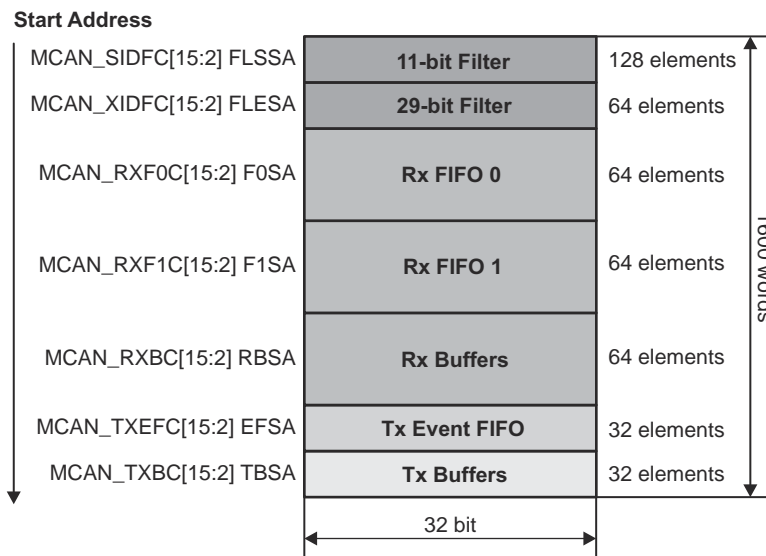

The address range of the Message RAM is from 0x4848 0000 to 0x4848 18FC.

The Message RAM is capable to include each of the sections listed in Figure 10-1665. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2:0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6:4] F1DS field
- Rx Buffers via the MCAN_RXESC[10:8] RBDS field
- Tx Buffers via the MCAN_TXESC[2:0] TBDS field

mcan-015

Figure 10-1665. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

10.4.3.4.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 10-1666 shows Rx Buffer/Rx FIFO element structure.

Figure 10-1666. Rx Buffer/Rx FIFO Element Structure

Table 10-1704 shows Rx Buffer/Rx FIFO element field descriptions.

Table 10-1704. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description

	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

10.4.3.4.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 10-1667 shows Tx Buffer element structure.

Figure 10-1667. Tx Buffer Element Structure

Table 10-1705 shows Tx Buffer element field descriptions.

Table 10-1705. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description

	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

10.4.3.4.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 10-1668 shows Tx Event FIFO element structure.

mcan-018

A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_I CKL period in case the filter matches.</p> <p>Note: Only two filter event pins are supported.</p>
		EFID2[5:0]	<p>This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.</p>

10.4.3.5 MCAN Register Manual

Note

After hardware reset, the registers of the MCAN module hold the values shown in the register descriptions.

Additionally, the Bus_Off state is reset and the MCAN_TX pin is set to recessive (high). The MCAN_CCCR[0] INIT bit is set to enable the software initialization. The MCAN module will not influence the CAN bus until the software resets the MCAN_CCCR[0] INIT bit.

Table 10-1724. MCAN_DBTP

Address Offset	0x0000 1A0C
Description	Data Bit Timing & Prescaler Register Configuration of data phase bit timing, transmitter delay compensation enable. This register is only writable if the MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 MCAN_FCLK periods. $t_q = (\text{MCAN_DBTP}[20:16] \text{ DBRP} + 1) \text{ mtq}$ (minimum time quantum = CAN clock period (MCAN_FCLK)). The MCAN_DBTP[12:8] DTSEG1 field is the sum of Prop_Seg and Phase_Seg1. The MCAN_DBTP[7:4] DTSEG2 field is Phase_Seg2. Therefore the length of the bit time is (programmed values) [MCAN_DBTP[12:8] DTSEG1 + MCAN_DBTP[7:4] DTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q . The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point. Note: With a CAN clock (MCAN_FCLK) of 8 MHz, the reset value of 0x0000 0A33 configures the MCAN module for a data phase bit rate of 500 kBit/s. Note: The bit rate configured for the CAN FD data phase via the MCAN_DBTP register must be higher or equal to the bit rate configured for the arbitration phase via the MCAN_NBTP register.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 10-1725. MCAN_TEST

Address Offset	0x0000 1A10
Description	Test Register Test mode selection. Write access to the Test Register has to be enabled by setting the MCAN_CCCR[7] TEST bit. All Test Register functions are set to their reset values when the MCAN_CCCR[7] TEST bit is reset. Loop Back Mode and software control of the MCAN_TX pin are hardware test modes. Programming of the MCAN_TEST[6:5] TX field ≠ 00 may disturb the message transfer on the CAN bus.

Table 10-1726. MCAN_RWD

Address Offset	0x0000 1A14
Description	RAM Watchdog Monitors the READY output of the Message RAM. The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access starts the Message RAM Watchdog Counter with the value configured by the MCAN_RWD[7:0] WDC field. The counter is reloaded with the MCAN_RWD[7:0] WDC field when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag MCAN_IR[26] WDI is set. The RAM Watchdog Counter is clocked by the Host clock (MCAN_ICLK).
