

AMC1336 Small, High-Precision, Reinforced Isolated Delta-Sigma Modulator for Voltage Sensing Applications

1 Features

- Input structure optimized for voltage measurements:
 - Input voltage range: ± 1 V
 - Input resistance: 1.5 G Ω (typ)
- Excellent DC performance:
 - Offset error: ± 0.5 mV (max)
 - Offset drift: ± 4 μ V/ $^{\circ}$ C (max)
 - Gain error: $\pm 0.25\%$ (max)
 - Gain drift: ± 40 ppm/ $^{\circ}$ C (max)
- Transient immunity: 115 kV/ μ s (typ)
- Missing high-side supply detection
- Safety-related certifications:
 - 8000- V_{PEAK} reinforced isolation per DIN VDE V 0884-11: 2017-01
 - 5700- V_{RMS} isolation for 1 minute per UL1577
 - IEC 62368-1 end equipment standard

2 Applications

- Isolated AC and DC voltage measurement in:
 - [Uninterruptible power supplies](#)
 - [Photovoltaic inverters](#)
 - [Motor drives](#)

3 Description

The AMC1336 is a precision, delta-sigma ($\Delta\Sigma$) modulator with the output separated from the input circuitry by a capacitive double isolation barrier that is highly resistant to magnetic interference. This barrier is certified to provide reinforced isolation of up to 8000 V_{PEAK} according to the DIN VDE V 0884-11 and UL1577 standards. Used in conjunction with isolated power supplies, this isolated modulator separates parts of the system that operate on different common-mode voltage levels and protects lower-voltage parts from damage.

The unique wide, bipolar, ± 1 -V input voltage range of the AMC1336 and its high input resistance support direct connection of the device to resistive dividers in high-voltage applications. When used with a digital filter (for instance, as integrated in the [TMS320F28004x](#), [TMS320F2807x](#) or [TMS320F2837x](#) microcontroller families) to decimate the output bitstream, the device can achieve 16 bits of resolution with a dynamic range of 87 dB at a data rate of 82 kSPS.

On the high-side, the AMC1336 is supplied by a 3.3-V or 5-V power supply. The isolated digital interface operates from a 3.0-V, 3.3-V or 5-V power supply.

The AMC1336 performance is specified over the extended industrial temperature range of -40° C to $+125^{\circ}$ C.

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision A (December 2019) to Revision B	Page
• Changed P_D (AVDD = DVDD = 5.5 V) from 88 mW to 90.75 mW	5
• Changed P_{D1} (AVDD = 5.5 V) from 55 mW to 57.75 mW	5
• Added UL certification file number	7

Changes from Original (August 2019) to Revision A	Page
• Changed document status from advance information to production data	1

5 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NO.	NAME		
1	AVDD	—	Analog (high-side) power supply, 3.0 V to 5.5 V. See the Power Supply Recommendations section for decoupling recommendations.
2	AINP	I	Noninverting analog input
3	AINN	I	Inverting analog input
4	AGND	—	Analog (high-side) ground reference
5	DGND	—	Digital (controller-side) ground reference
6	DOUT	O	Modulator bitstream output, updated with the rising edge of the clock signal present on CLKIN. Use the rising edge of the clock to latch the modulator bitstream at the input of the digital filter device.
7	CLKIN	I	Modulator clock input with internal pulldown resistor (typical value: 1 MΩ). The clock signal must be applied continuously for proper device operation; see the Clock Input section for additional details.
8	DVDD	—	Digital (controller-side) power supply, 2.7 V to 5.5 V. See the Power Supply Recommendations section for decoupling recommendations.

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

- (1) Apply creepage and clearance requirements according to the specific equipment isolation standards of an application. Care must be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed circuit board (PCB) do not reduce this distance. Creepage and clearance on a PCB become equal in certain cases. Techniques such as inserting grooves, ribs, or both on a PCB are used to help increase these specifications.
- (2) This coupler is suitable for *safe electrical insulation* only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- (3) Testing is carried out in air or oil to determine the intrinsic surge immunity of the isolation barrier.
- (4) Apparent charge is electrical discharge caused by a partial discharge (pd).
- (5) All pins on each side of the barrier are tied together, creating a two-pin device.

6.8 Safety Limiting Values

Safety limiting intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I _S	Safety input, output, or supply current	R _{θJA} = 94°C/W, T _J = 150°C, T _A = 25°C, AVDD = DVDD = 5.5 V, see Figure 3			241	mA
		R _{θJA} = 94°C/W, T _J = 150°C, T _A = 25°C, AVDD = DVDD = 3.6 V, see Figure 3			369	
P _S	Safety input, output, or total power ⁽¹⁾	R _{θJA} = 94°C/W, T _J = 150°C, T _A = 25°C, see Figure 4			1329	mW
T _S	Maximum safety temperature				150	°C

- (1) The maximum safety temperature, T_S, has the same value as the maximum junction temperature, T_J, specified for the device. The I_S and P_S parameters represent the safety current and safety power, respectively. Do not exceed the maximum limits of I_S and P_S. These limits vary with the ambient temperature, T_A.

The junction-to-air thermal resistance, R_{θJA}, in the [Thermal Information](#) table is that of a device installed on a high-K test board for leaded surface-mount packages. Use these equations to calculate the value for each parameter:

T_J = T_A + R_{θJA} × P, where P is the power dissipated in the device.

T_{J(max)} = T_S = T_A + R_{θJA} × P_S, where T_{J(max)} is the maximum junction temperature.

P_S = I_S × AVDD_{max} + I_S × DVDD_{max}, where AVDD_{max} is the maximum high-side voltage and DVDD_{max} is the maximum controller-side supply voltage.

6.9 Electrical Characteristics

minimum and maximum specifications apply from T_A = –40°C to +125°C, AVDD = 3.0 V to 5.5 V, DVDD = 2.7 V to 5.5 V, AINP = –1 V to +1 V, and AINN = AGND = 0 V; typical specifications are at T_A = 25°C, AVDD = 5 V, DVDD = 3.3 V, and f_{CLKIN} = 20 MHz (unless otherwise noted)

- (1) Integral nonlinearity is defined as the maximum deviation from a straight line passing through the end-points of the ideal ADC transfer function expressed as number of LSBs or as a percent of the specified linear full-scale range FSR.
- (2) Offset error drift is calculated using the box method, as described by the following equation:

$$\text{TCE}_O = (\text{value}_{\text{MAX}} - \text{value}_{\text{MIN}}) / \text{TempRange}$$
- (3) The typical value includes one sigma statistical variation.
- (4) Gain error drift is calculated using the box method, as described by the following equation:

$$\text{TCE}_G (\text{ppm}) = ((\text{value}_{\text{MAX}} - \text{value}_{\text{MIN}}) / (\text{value} \times \text{TempRange})) \times 10^6$$

7 Detailed Description

7.1 Overview

The differential analog input (comprised of input signals AINP and AINN) of the AMC1336 is a chopper-stabilized instrumentation amplifier, followed by the switched-capacitor input of a second-order, delta-sigma ($\Delta\Sigma$) modulator stage that digitizes the input signal into a 1-bit output stream. The data output DOUT of the converter provides a stream of digital ones and zeros that is synchronous to the externally provided clock source at the CLKIN pin with a frequency in the range of 5 MHz to 21 MHz. The time average of this serial bitstream output is proportional to the analog input voltage. The [Functional Block Diagram](#) section shows a detailed block diagram of the AMC1336. The 1.6-G Ω differential input resistance of the analog input stage supports low gain-error signal sensing in high-voltage applications using resistive dividers. The external clock input simplifies the synchronization of multiple current-sensing channels on the system level.

The silicon-dioxide (SiO₂)-based capacitive isolation barrier supports a high level of magnetic field immunity, as described in the [ISO72x Digital Isolator Magnetic-Field Immunity](#) application report, available for download at www.ti.com.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Analog Input

The AMC1336 incorporates front-end circuitry that contains an instrumentation amplifier, followed by a $\Delta\Sigma$ modulator. To support a bipolar input range with a unipolar high-side supply AVDD, the device uses a charge pump to simplify the overall system design and minimize circuit cost. For reduced offset and offset drift, the input buffer is chopper-stabilized with the switching frequency set at $f_{CLKIN} / 32$. [Figure 39](#) illustrates the spur created by the switching frequency.

Feature Description (continued)

sinc^3 filter, $\text{OSR} = 1$, $f_{\text{CLKIN}} = 20 \text{ MHz}$, $f_{\text{IN}} = 1 \text{ kHz}$

Figure 39. Quantization Noise Shaping

The linearity and noise performance of the device are ensured only when the differential analog input voltage remains within the specified linear full-scale range (FSR), that is $\pm 1 \text{ V}$, and within the specified input common-mode range.

Figure 40 shows the specified common-mode input voltage that applies for the full-scale input voltage range as specified in this document.

If smaller input signals are used, the operational common-mode input voltage range widens. Figure 41 shows the common-mode input voltage that applies with no differential input signal; that is, when the voltage applied on AINP is equal to the voltage applied on AINN. The common-mode input voltage range scales with the actual differential input voltage between this range and the range in Figure 40.

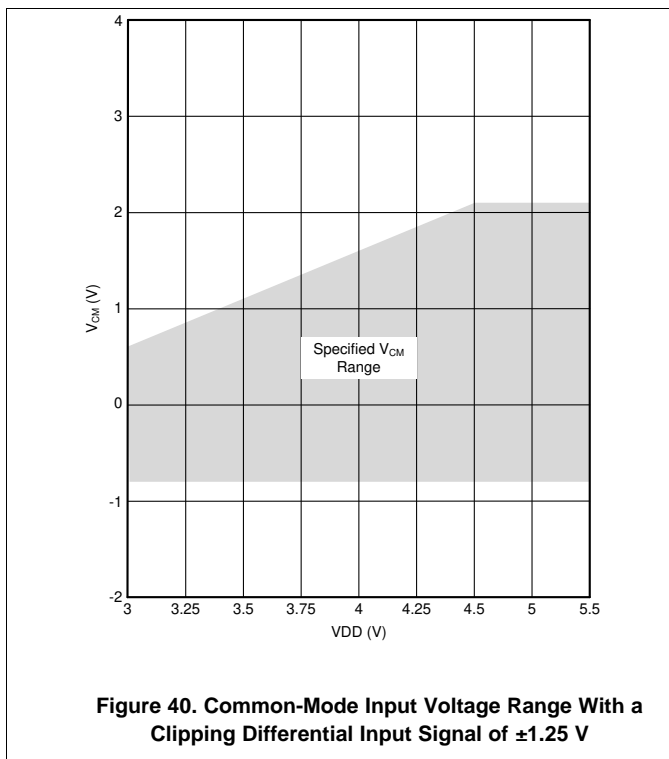

Figure 40. Common-Mode Input Voltage Range With a Clipping Differential Input Signal of $\pm 1.25 \text{ V}$

Figure 41. Common-Mode Input Voltage Range With a Zero Differential Input Signal

Feature Description (continued)

There are two restrictions on the analog input signals (AINP and AINN). First, if the input voltage exceeds the range $AGND - 5\text{ V}$ to $AVDD + 0.5\text{ V}$, the input current must be limited to 10 mA because the device input electrostatic discharge (ESD) diodes turn on. In addition, the linearity and noise performance of the device are ensured only when the differential analog input voltage remains within the specified linear full-scale range (FSR) and within the specified input common-mode range.

7.3.2 Modulator

The modulator implemented in the AMC1336, as conceptualized in Figure 42, is a second-order, switched-capacitor, feed-forward $\Delta\Sigma$ modulator. The analog input voltage V_{IN} and the output V_5 of the 1-bit digital-to-analog converter (DAC) are subtracted, providing an analog voltage V_1 at the input of the first integrator stage. The output of the first integrator feeds the input of the second integrator stage, resulting in an output voltage V_3 that is differentiated with the input signal V_{IN} and the output of the first integrator V_2 . Depending on the polarity of the resulting voltage V_4 , the output of the comparator is changed. In this case, the 1-bit DAC responds on the next clock pulse by changing the associated analog output voltage V_5 , causing the integrators to progress in the opposite direction and forcing the value of the integrator output to track the average value of the input.

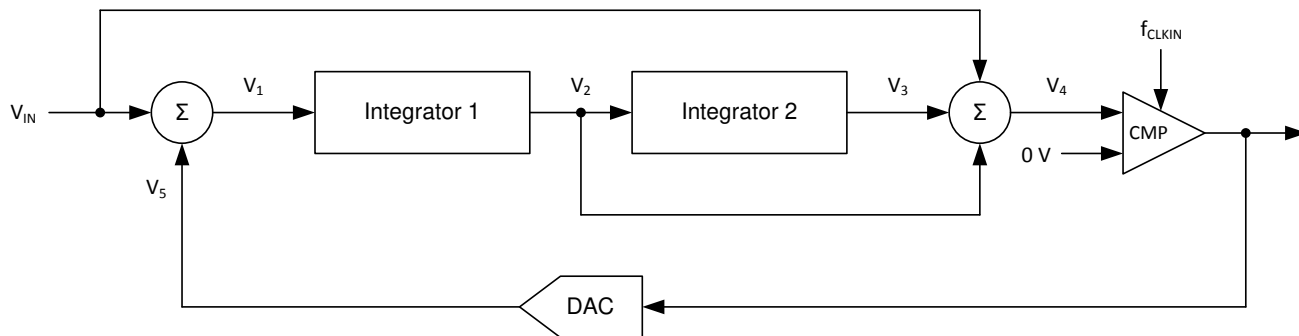

Figure 42. Block Diagram of a Second-Order Modulator

As depicted in Figure 39, the modulator shifts the quantization noise to high frequencies. Therefore, use a low-pass digital filter at the output of the device to increase the overall performance. This filter is also used to convert from the 1-bit data stream at a high sampling rate into a higher-bit data word at a lower rate (decimation). TI's microcontroller families TMS320F2807x and TMS320F2837x offer a suitable programmable, hardwired filter structure termed a *sigma-delta filter module* (SDFM) optimized for usage with the AMC1336. Furthermore, the SD24_B converters on the MSP430F677x microcontrollers offer a path to directly access the integrated sinc filters for a simple system-level solution for multichannel, isolated current sensing. An additional option is to use a suitable application-specific device, such as the AMC1210 (a four-channel digital sinc-filter). Alternatively, a field-programmable gate array (FPGA) can be used to implement the filter.

Feature Description (continued)

7.3.3 Isolation Channel Signal Transmission

The AMC1336 uses an on-off keying (OOK) modulation scheme to transmit the modulator output bitstream across the capacitive SiO₂-based isolation barrier. The transmitter modulates the bitstream at TX IN in [Figure 43](#) with an internally-generated, 480-MHz carrier across the isolation barrier to represent a digital *one* and sends a *no signal* to represent the digital *zero*. The receiver demodulates the signal after advanced signal conditioning and produces the output. The symmetrical design of each isolation channel improves the common-mode transient immunity (CMTI) performance and reduces the radiated emissions caused by the high-frequency carrier. [Figure 43](#) shows the block diagram of an isolation channel integrated in the AMC1336.

Figure 43. Block Diagram of an Isolation Channel

[Figure 44](#) shows the concept of the on-off keying scheme.

Figure 44. OOK-Based Modulation Scheme

Feature Description (continued)

7.3.4 Clock Input

The AMC1336 system clock is provided externally at the CLKIN pin. The clock signal must be applied continuously for proper device operation.

To support the bipolar input voltage range with a unipolar high-side supply AVDD, the AMC1336 includes a charge pump. This charge pump stops operating if the clock signal is below the specified frequency range or if the signal is paused or missing. In that case, the input bias current increases beyond the specified range and significantly reduces the input resistance of the device. When the clock signal is paused or missing, the modulator stops the analog signal conversion and the digital output signal remains frozen in the last logic state. When the clock signal is applied again after a pause, the internal analog circuitry biasing must settle for proper device performance. In this case, consider the t_{ASTART} specification in the [Switching Characteristics](#) table.

7.3.5 Digital Output

A differential input signal of 0 V ideally produces a stream of ones and zeros that are high 50% of the time. A differential input of 1 V produces a stream of ones and zeros that are high 90% of the time. With 16 bits of resolution, that percentage ideally corresponds to code 58982 (an unsigned code). A differential input of –1 V produces a stream of ones and zeros that are high 10% of the time and ideally results in code 6553 with 16-bit resolution. These input voltages are also the specified linear range of the AMC1336 with performance as specified in this document. If the input voltage value exceeds this range, the output of the modulator shows nonlinear behavior when the quantization noise increases. The output of the modulator clips with a stream of only zeros with an input less than or equal to –1.25 V or with a stream of only ones with an input greater than or equal to 1.25 V. In this case, however, the AMC1336 generates a single 1 (if the input is at negative full-scale) or 0 every 128 clock cycles to indicate proper device function (see the [AVDD Diagnostics and Fail-Safe Output](#) section for more details). [Figure 45](#) shows the input voltage versus the output modulator signal.

Figure 45. Analog Input versus the AMC1336 Modulator Output

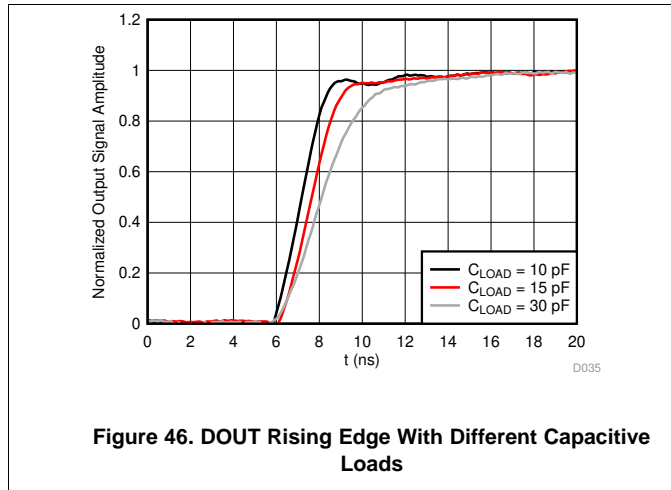

[Equation 1](#) calculates the density of ones in the output bitstream for any input voltage value (with the exception of a full-scale input signal, as described in the [Output Behavior in Case of a Full-Scale Input](#) section):

$$\frac{V_{IN} + V_{Clipping}}{2 \times V_{Clipping}} \quad (1)$$

The modulator bitstream on the DOUT pin changes with the rising edge of the clock signal applied on the CLKIN pin. Use the rising edge of the clock to latch the modulator bitstream at the input of the digital filter device.

Feature Description (continued)

The AMC1336 features a slew-rate-controlled output stage that reduces the over- and undershoots of the output amplitude and radiated emissions of the DOUT line in the system. [Figure 46](#) and [Figure 47](#) show examples of rising and falling edges of DOUT with different capacitive loads.

7.4 Device Functional Modes

The AMC1336 is operational when the power supplies AVDD and DVDD, and the clock signal CLKIN are applied, as specified in the [Recommended Operating Conditions](#) and [Switching Characteristics](#) tables.

7.4.1 Output Behavior in Case of a Full-Scale Input

Figure 48 shows that if a full-scale input signal is applied to the AMC1336 (that is, $V_{IN} \geq V_{Clipping}$), the device generates a single one or zero every 128 bits at DOUT, depending on the actual polarity of the signal being sensed. This feature can be used for advanced system-level diagnostics to differentiate between system failures caused by missing high-side supply AVDD or input overvoltage events.

Figure 48. Out-of-Range Output of the AMC1336

7.4.2 AVDD Diagnostics and Fail-Safe Output

In the case of a missing high-side supply voltage AVDD, the output of a $\Delta\Sigma$ modulator is not defined and can cause a system malfunction. In systems with high safety requirements, this behavior is not acceptable. As shown in Figure 49, the AMC1336 implements an AVDD diagnostics and fail-safe output function that ensures that the output DOUT of the device offers a steady-state bitstream of logic 0's in case of a missing AVDD. Sample at least 128 CLKIN cycles in order to distinguish a missing AVDD condition from an input underrange condition.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Digital Filter Usage

The modulator generates a bitstream that is processed by a digital filter to obtain a digital word similar to a conversion result of a conventional analog-to-digital converter (ADC). Equation 2 shows a sinc³-type filter, which is a very simple filter that is built with minimal effort and hardware:

$$H(z) = \left(\frac{1 - z^{-OSR}}{1 - z^{-1}} \right)^3 \quad (2)$$

This filter provides the best output performance at the lowest hardware size (count of digital gates) for a second-order modulator. All the characterization in this document is also done with a sinc³ filter with an oversampling ratio (OSR) of 256 and an output word width of 16 bits.

An example code for implementing a sinc³ filter in an FPGA is discussed in the [Combining the ADS1202 with an FPGA Digital Filter for Current Measurement in Motor Control Applications](#) application note, available for download at www.ti.com.

8.2 Typical Application

Isolated $\Delta\Sigma$ modulators are widely used in frequency inverter designs because of their high AC and DC performance. Frequency inverters are critical parts of industrial motor drives, photovoltaic inverters (string and central inverters), uninterruptible power supplies (UPS), and other industrial applications.

Figure 50 shows a simplified schematic of a frequency inverter application with the AMC1336 used for the DC-link and output phase voltage sensing. In this example, the ground reference point for the microcontroller is not connected by any means to the power stage. This configuration is usually the case in systems with the microcontroller located on a dedicated control card or PCB.

Current feedback is performed with shunt resistors (R_{SHUNT}) and TI's AMC1306M25 isolated modulators. Depending on the system design, either all three or only two motor phase currents are sensed.

Depending on the overall digital processing power requirements and with a total of eight $\Delta\Sigma$ modulator bitstreams to be processed by the microcontroller (MCU), a derivate from either the low-cost single-core TMS320F2807x or the dual-core TMS320F2837x families can be used in this application.

Figure 50. The AMC1336 in a Frequency Inverter Application

Typical Application (continued)

Figure 51 shows an additional example of the AMC1336 used for input phase and DC-link voltage sensing. Also in this case, the microcontroller is located on a dedicated control card and the AMC1306M25 is used for shunt-based current sensing.

Figure 51. Input Phase Voltage Sensing Application with AMC1336

Typical Application (continued)

8.2.1 Design Requirements

Table 1 lists the parameters for this typical application.

Table 1. Design Requirements

PARAMETER	VALUE
Supply voltage	3.3 V
Voltage drop across the sensing resistor R_{DC1} for a linear response	1 V (maximum)
Voltage drop across the sensing resistors R_{ACx} for a linear response	± 1 V (maximum)
Current through the sensing resistors R_{ACx}	± 100 μ A (maximum)

8.2.2 Detailed Design Procedure

Use Ohm's Law to calculate the minimum total resistance of the resistive dividers to limit the cross current to the desired values:

- For the voltage sensing on the DC bus: $R_{DC1} + R_{DC2} + R_{DC3} = V_{BUS} / I_{DC}$
- For the voltage sensing on the output phases U, V, and W: $R_{AC1} + R_{AC2} + R_{AC3} = V_{PHASE (max)} / I_{AC}$

Consider the following two restrictions to choose the proper value of the resistors R_{DC3} and R_{AC3} :

- The voltage drop caused by the nominal voltage range of the system must not exceed the recommended input voltage range of the AMC1336: $V_{XC3} \leq V_{FSR}$
- The voltage drop caused by the maximum allowed system overvoltage must not exceed the input voltage that causes a clipping output: $V_{XC3} \leq V_{Clipping}$

Use similar approach for calculation of the shunt resistor values R_{SHUNT} and see the [AMC1306M25 data sheet](#) for further details.

Table 2 lists examples of nominal E96-series (1% accuracy) resistor values for systems using 600 V and 800 V on the DC bus.

Table 2. Resistor Value Examples for DC Bus Sensing

PARAMETER	600-V DC BUS	800-V DC BUS
Resistive divider resistor R_{DC1}	3.01 M Ω	4.22 M Ω

Resulting current through resistive divider I_{DC}	99.5 μ A	94.7 μ A
Resulting voltage drop on sense resistor V_{RDC3}	0.995 V	0.994 V

Table 3 lists examples of nominal E96-series (1% accuracy) resistor values for systems using 230 V and 690 V on the input or output phases.

Table 3. Resistor Value Examples for Phase Voltage Sensing

PARAMETER	± 400 -V _{AC} PHASE	± 690 -V _{AC} PHASE
Resistive divider resistor R_{AC1}	2.0 M Ω	3.48 M Ω
Resistive divider resistor R_{AC2}	2.0 M Ω	3.48 M Ω
Sense resistor R_{AC3}	10.0 k Ω	10.0 k Ω
Resulting current through resistive divider I_{AC}	99.8 μ A	99.0 μ A
Resulting voltage drop on sense resistor V_{RAC3}	± 0.998 V	± 0.990 V

Use a power supply with a nominal voltage of 3.3 V for DVDD to directly connect all modulators to the microcontroller.

For modulator output bitstream filtering, a device from TI's [TMS320F2807x](#) family of low-cost microcontrollers (MCUs) or [TMS320F2837x](#) family of dual-core MCUs is recommended. These MCU families support up to eight channels of dedicated hardwired filter structures called sigma-delta filter modules (SDFMs) that significantly simplify system level design by offering two filtering paths per channel: one providing high accuracy results for the control loop and one that offers a fast response path for overcurrent detection. Use one of the pulse-width modulation (PWM) sources inside the MCU to generate the clock for the modulators and for easy synchronization of all feedback signals and the switching control of the gate drivers.

The application examples in [Figure 50](#) and [Figure 51](#) use a clock buffer to distribute the clock reference signal generated on one of the PWMx outputs of the MCU to all modulators used in the circuit and as a reference for the digital filters in the MCU. In this example, TI's [CDCLVC1106](#) is used for this purpose. Each CDCLVC1106 output can drive a load of 8 pF that is sufficient to drive up to two modulator and up to four SDFM clock inputs.

8.2.3 Application Curve

The effective number of bits (ENOB) is often used to compare the performance of ADCs and $\Delta\Sigma$ modulators. [Figure 52](#) shows the ENOB of the AMC1336 with different oversampling ratios. In this document, this number is calculated from the SINAD by using following equation: $SINAD = 1.76 \text{ dB} + 6.02 \times ENOB$.

Figure 52. Measured Effective Number of Bits versus Oversampling Ratio

8.2.4 What to Do and What Not to Do

Do not leave the inputs of the AMC1336 unconnected (floating) when the device is powered up. If either modulator input is left floating, the input bias current can drive this input beyond the specified common-mode input voltage range. If both inputs are beyond that range, the gain of the front-end diminishes and the output bitstream is not valid.

9 Power Supply Recommendations

In a typical frequency-inverter application, the high-side power supply (AVDD) for the AMC1336 is generated from the controller-side supply (DVDD) of the device by an isolated dc/dc converter circuit. Figure 53 shows a low-cost solution based on the push-pull driver SN6501 and a transformer that supports the desired isolation voltage ratings. TI recommends using a low-ESR decoupling capacitor of 0.1 μF and an additional capacitor of minimum 1 μF for both supplies of the AMC1336. Place these decoupling capacitors as close as possible to the device power-supply pins to minimize supply current loops and electromagnetic emissions.

The AMC1336 does not require any specific power up sequencing. Consider the analog settling time t_{ASTART} as specified in the *Switching Characteristics* table after ramp up of the AVDD high-side supply.

Connect the high-side ground pin AGND of the AMC1336 to one of the analog inputs AINx to avoid common-mode input voltage range violations.

Figure 53. Decoupling the AMC1336

10 Layout

10.1 Layout Guidelines

Figure 54 shows an example layout that is used on the AMC1336 evaluation module. For best performance, place the smaller 0.1- μF decoupling capacitors (C7 and C9) as close as possible to the AMC1336 power-supply pins, followed by the additional C1 and C11 capacitors with a minimum value of 1 μF . The resistors and capacitors used for the analog input filter (R1, R2, C4, C5, and C8) are placed next to the decoupling capacitors. Use 1206-size, SMD-type, ceramic decoupling capacitors and route the traces to the AINx pins underneath. Connect the supply voltage sources in a way that allows the supply current to flow through the pads of the decoupling capacitors before powering the device.

Consider use of RC filters on the digital clock and data lines to reduce reflections and slew rate that cause radiated emissions. The AMC1336 evaluation module offers placeholders for RC filters (termed R8 and C13 in Figure 54) for the CLKIN line, and R7 and C12 for the DOUT line.
