Table 6-334. INTVECTOR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-346. INTVECTOR_12 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Table 6-361. INTVECTOR_27 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-361. INTVECTOR_27 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.360 INTVECTOR_28 Register (Offset = 2070h) [Reset = 0h]

INTVECTOR_28 is shown in Figure 6-362 and described in Table 6-362.

Return to the Table 6-2.

Table 6-375. INTVECTOR_41 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.374 INTVECTOR_42 Register (Offset = 20A8h) [Reset = 0h]

INTVECTOR_42 is shown in Figure 6-376 and described in Table 6-376.

Return to the Table 6-2.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Table 6-418. INTVECTOR_84 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.417 INTVECTOR_85 Register (Offset = 2154h) [Reset = 0h]

INTVECTOR_85 is shown in Figure 6-419 and described in Table 6-419.

Return to the Table 6-2.

Table 6-432. INTVECTOR_98 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.431 INTVECTOR_99 Register (Offset = 218Ch) [Reset = 0h]

INTVECTOR_99 is shown in Figure 6-433 and described in Table 6-433.

Return to the Table 6-2.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-446. INTVECTOR_112 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Table 6-503. INTVECTOR_169 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.502 INTVECTOR_170 Register (Offset = 22A8h) [Reset = 0h]

INTVECTOR_170 is shown in Figure 6-504 and described in Table 6-504.

Return to the Table 6-2.

Table 6-517. INTVECTOR_183 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.516 INTVECTOR_184 Register (Offset = 22E0h) [Reset = 0h]

INTVECTOR_184 is shown in Figure 6-518 and described in Table 6-518.

Return to the Table 6-2.

Table 6-531. INTVECTOR_197 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 6-531. INTVECTOR_197 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.530 INTVECTOR_198 Register (Offset = 2318h) [Reset = 0h]

INTVECTOR_198 is shown in Figure 6-532 and described in Table 6-532.

Return to the Table 6-2.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.544 INTVECTOR_212 Register (Offset = 2350h) [Reset = 0h]

INTVECTOR_212 is shown in Figure 6-546 and described in Table 6-546.

Return to the Table 6-2.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.558 INTVECTOR_226 Register (Offset = 2388h) [Reset = 0h]

INTVECTOR_226 is shown in Figure 6-560 and described in Table 6-560.

Return to the Table 6-2.

The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.586 INTVECTOR_254 Register (Offset = 23F8h) [Reset = 0h]

INTVECTOR_254 is shown in Figure 6-588 and described in Table 6-588.

Return to the Table 6-2.

Interrupt Q Vector Register (Q is 0 to 255 , Q= M+1 x 32) h2000 + Q x h258

Table 6-588. INTVECTOR_254 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.4.10.587 INTVECTOR_255 Register (Offset = 23FCh) [Reset = 0h]

INTVECTOR_255 is shown in Figure 6-589 and described in Table 6-589.

Return to the Table 6-2.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

6.1.5 Resets

AWR294x supports the following resets:

- CR5SS_POR_RST: This is the full MCU R5F subsystem reset. It is also the Power On Reset.
- CR5ASS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreA. None of the other logics are reset.
- CR5A_RST: This only reset the cortex of the R5F of the CoreA.

- CR5BSS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreB. None of the other logics are reset.
- CR5B_RST: This only reset the cortex of the R5F of the CoreB.
- VIMA_RST: This only reset the vectored interrupt manager of the CoreA.
- VIMB_RST: This only reset the vectored interrupt manager of the CoreB.

6.1.5.1 R5F Subsystem Reset Trigger

For the safe reset of the R5F subsystem, follow this reset sequence:

1. Write 3'b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER starts the sequencer.
2. The sequencer is waiting for WFI from only CR5A if WFI_CHECKEN for corresponding resets is programmed. The sequencer isolates CR5SS when it receives WFI from CR5A.
3. The sequencer triggers CR5SS_POR_RST, which triggers resets to all resets mentioned in resets-table.
4. The intent is to reset CR5SS when it is in isolation. Thus, before Step 1, ensure MSS_RCM:RST2ASSERTDLY is programmed to 0;.
5. Reset is asserted for RST_ASSERDLY: RST_ASSERDLY_COMMON number of clock cycles, and released.

6.2 TI C66x DSP Subsystem Overview

6.2.1 C66x DSP Subsystem

The purpose of this section is to provide an overview of the DSP subsystem (C66x CorePac) along with some integration details.

6.2.1.1 DSP Subsystem Overview

The DSP subsystem (C66x CorePac) supports the following key features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program Memory Controller (PMC):
  - 32KB Level 1 Program (L1P) Cache/SRAM
- Data Memory Controller (DMC):
  - 32KB L1 Data (L1D) Cache/SRAM
- L2 Memory Controller:
  - 384KB L2 RAM with up to 256KB of configurable into cache
- External Memory Controller (EMC):
  - Internal DMA (IDMA) engine
  - One 128-bit VBUSM slave port from DMA access at Div-by-2 clock
  - One 32-bit VBUSP master port to CFG access at Div-by-2 clock
- XMC (Extended Memory Controller):
  - One 256-bit port to L3 memory at Div-by-2 clock
- Multistream prefetch buffer
- Address extension/translation (32-bit to 36-bit)
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D
- Error Detection and Correction for all L2
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with Chip-level Interrupt Controller (CIC) for distribution of system interrupts to the C66x core. Interrupts can be routed directly to the C66x core or through the CIC module in a flexible manner
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
  - Support for halt mode, real time and monitor mode debug capabilities
  - Support for processor instruction trace and system trace (**printf**-style debug)
- Error Detection for L1P Data and Tag RAMs
- Error Detection and Correction for L1D Data and Tag RAMs
- Error Detection and Correction for all L2 Data and Tag RAMs

Figure 6-590 shows an overview of the C66x CorePac.

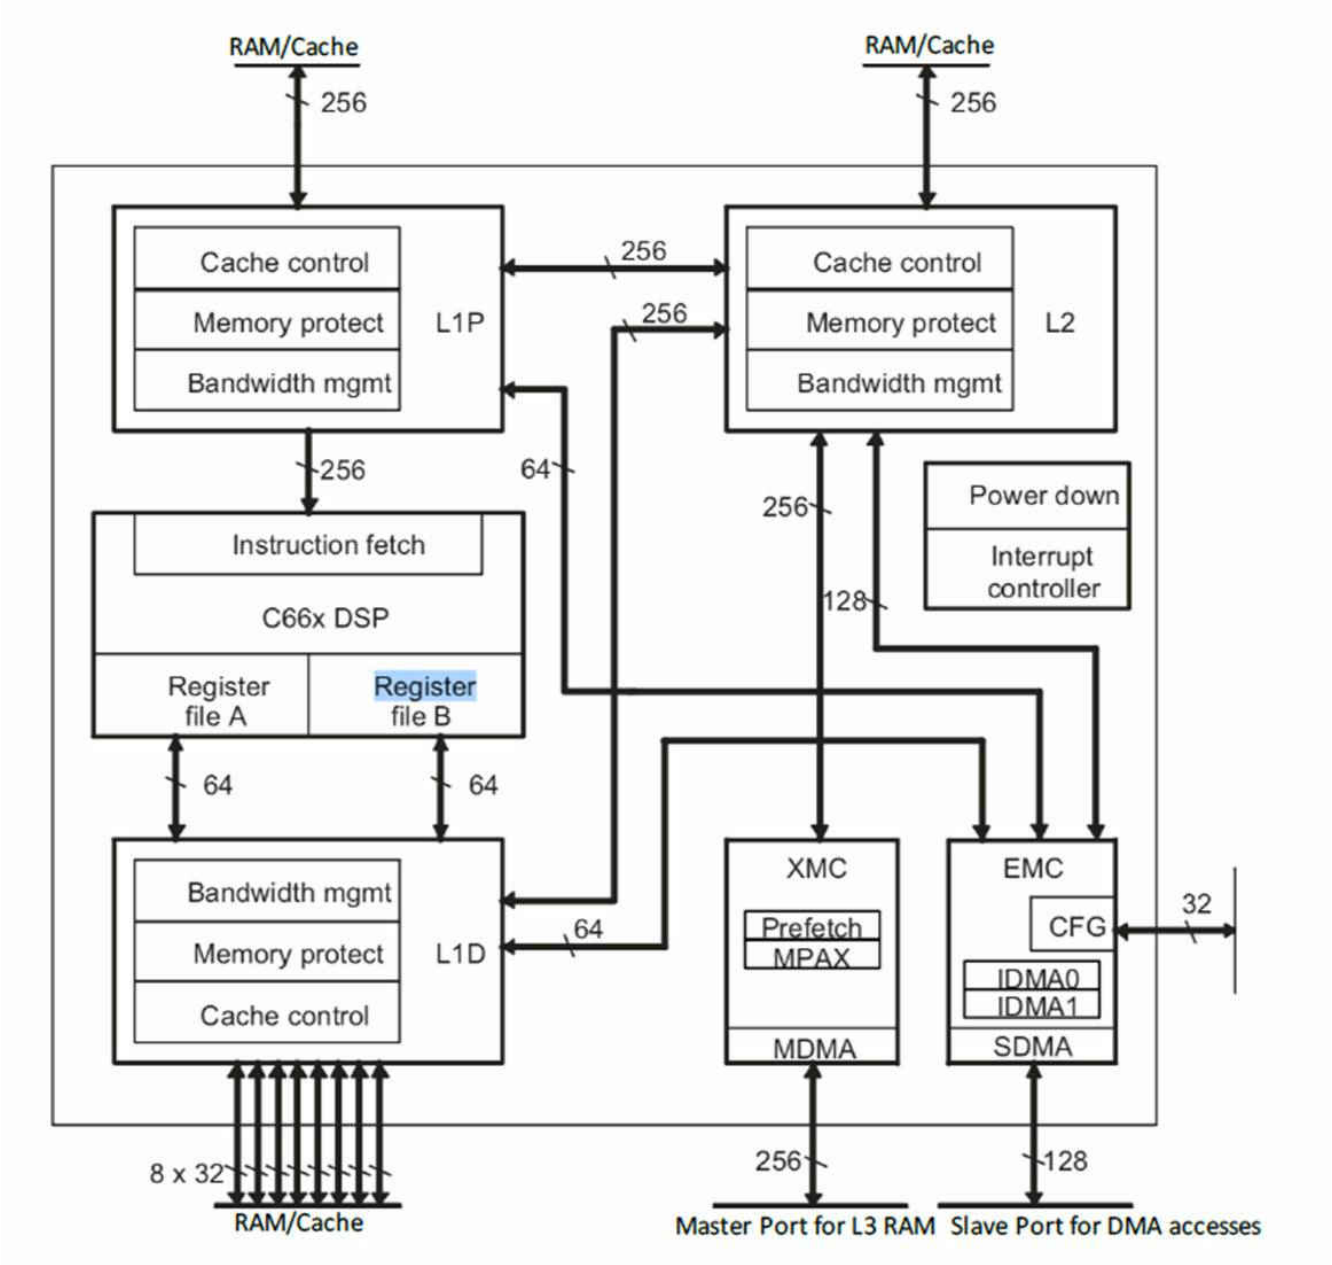

Figure 6-590. C66x CorePac Overview

For more information about:

- C66x CorePac, see the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).
- C66x CPU core, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide* (SPRUGH7).
- C66x cache memory system, see the *TMS320C66x DSP Cache User Guide* (SPRUGY8).
- C66x debug/trace support, see Section 20.1.

6.2.1.2 DSP Subsystem Integration

To turn on DSP power, please follow section 1.5.4.1 DSP power domain for details. To configure the DSP clock, please refer to section 1.5.3.3, DSS_DSP_CLK for clock source, divider, and gating selections details.

6.2.1.3 DSP Interrupt Sources

Refer to section 1.8.2.

6.2.1.4 DSP Subsystem Functional Description

For detailed DSP subsystem functional description, see the documents referenced in Section 6.2.1.1 .

6.2.1.5 DSP Subsystem Registers

Table 6-590 lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in Table 6-590 should be considered as reserved locations and the register contents should not be modified. For base addresses of the DSP subsystem internal modules, see Chapter .

The C66x CorePac registers are described in detail in the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).

Table 6-590. C66x CorePac Registers

Address	Acronym	Register Name
01800000h to 0180000Ch	EVTFLAG_0 to EVTFLAG_3	Event Flag Registers
01800020h to 0180002Ch	EVTSET_0 to EVTSET_3	Event Set Registers

6.2.2 DSP Subsystem Integration

The DSP C66x Corepac integrates the following IPs :

- Improved C66x Core and CGEM Megamodule with ECC
- 32-kB L1P Cache/SRAM
- 32-kB L1D Cache/SRAM
- 384-kB L2 Cache/SRAM
- ECC and EDC wherever supported
- L1P - 4-bit parity per 256-b location (1-b parity per 64-b line quadrant)
- L1D – no protection
- L2 – Distance-3 “detect 2, correct 1” Hamming code based error correction/detection

6.2.2.1 DSP Memory Overview

The L1P 32kB memory and L1D 32kB memory can be independently configured as part cache and part mapped to SRAM. The cache size can be 0KB, 4KB, 8KB, 16KB, or 32KB (where the mapped SRAM size is 32KB minus the cache size).

The L2 memory 384 kB memory can also be configured as part SRAM and part Cache. 128kB is always mapped as SRAM. The remaining 256kB can be configured to cache sizes of 0, 32k, 64k, 128k, or 256kB. The additional mapped SRAM available is 256-kB minus the cache size.

6.2.2.2 C66x Cache Subsystem

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* (SPRUGY8).

The device contains a 384KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see Chapter).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a two-way set-associative cache, while L1P is a direct-mapped cache.

6.2.2.2.1 L1P Memory

The L1P memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states

Figure 6-591 shows the available SRAM/cache configurations for L1P.

Note

L1P can only be configured as cache.

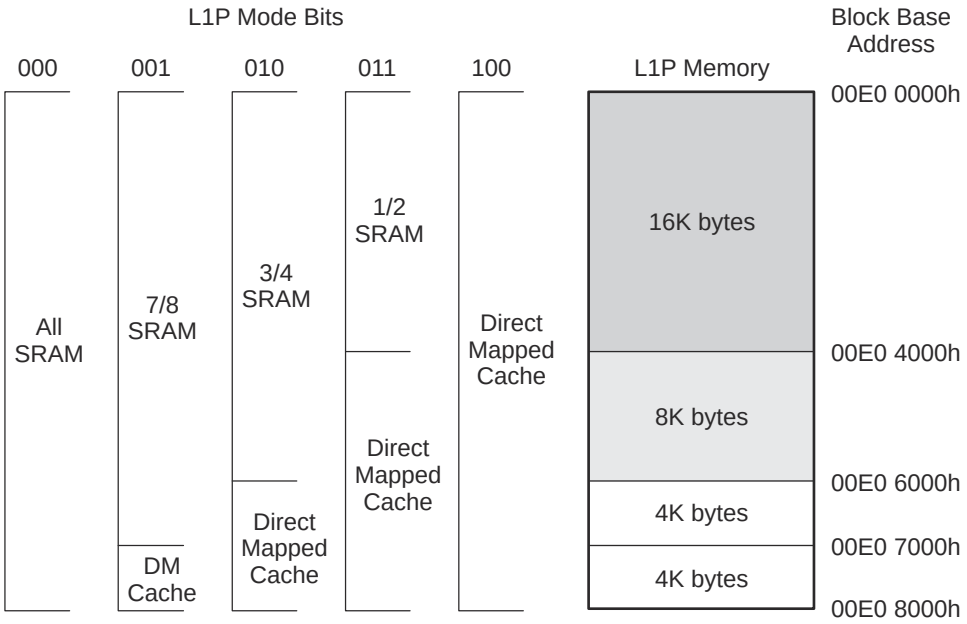

Figure 6-591. L1P Memory Configurations

6.2.2.2.2 L1D Memory

The L1D memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states.

Figure 6-592 shows the available SRAM/cache configurations for L1D.

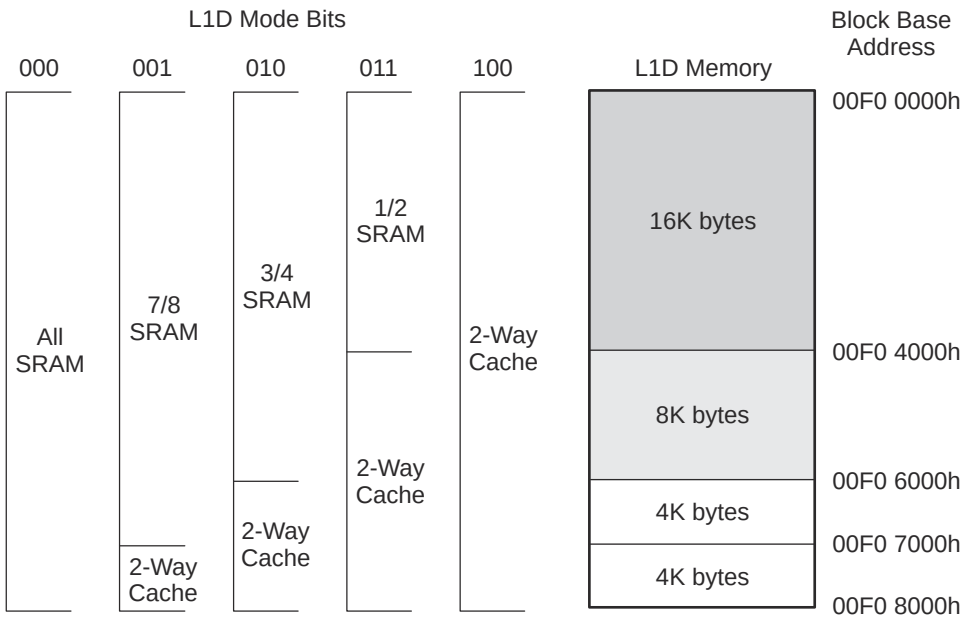

Figure 6-592. L1D Memory Configurations

6.2.2.2.3 L2 Memory

The L2 memory configuration for this device is as follows:

- 384KB of memory
- Local starting address is 0080 0000h.

L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac. Figure 6-593 shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

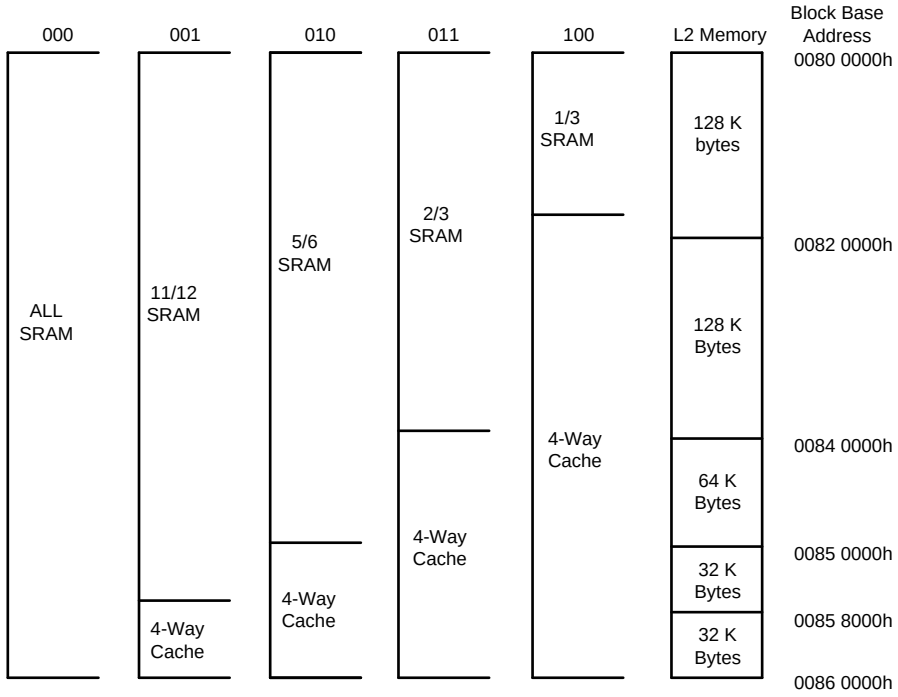

Figure 6-593. L2 Memory Configurations

6.2.2.2.4 DSP ECC Configuration

The device supports ECC/parity on all DSP internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 6-591 summarizes the ECC/parity support in DSP.

Table 6-591. DSP ECC/Parity Support

DSP Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag	Parity
L1D Data RAM	ECC-SECDED (Single Error Correction, Double Error Detection)
L1D Tag	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag	ECC-SECDED

6.3 Radar Processing Hardware Accelerator

In addition to the DSP cores, the AWR294x device incorporates Radar Hardware Accelerators HWA2.0 to offload the DSP from pre-processing computations.

6.3.1 Radar Accelerator Features Overview

- Flexible enough to offload almost all the operations from the initial compensation (DC estimation-correction, interference mitigation, and so forth) on raw ADC data before first dimension FFT until point cloud detection, with the least possible intervention from the DSP.
- Operating clock frequency is 300 MHz
- Data path bit-width of 24-bits (24-bit I)
- Input and output data formatter: scaling, truncation, head/tail sample skipping, zero padding/insertion of data, sample access pattern for DDMA use case.
- Capability to do all these operations in a single iteration: DC correction, interference zeroing out, complex multiplication, windowing, FFT, log, magnitude, stats computation with a capability of selecting/enabling or disabling/bypassing each of these computation blocks individually.
- 128KB local buffer/RAM split into eight 16KB banks, with each bank configurable as input or output for any compute/data transfer functionality.
- Flexible data flow and data sample arrangement to support efficient multi-dimensional operations and transpose accesses as required.
- Processing for inline (range FFT) and inter-frame (Doppler FFT, angle FFT, detection) threads simultaneously
- Support for CSI2 data input either in Rx interleaved or in serial manner
- Support for DC estimation and correction
- Support for interference mitigation
  - Estimation and zeroing out of the interference samples by estimating the average of the magniture of sudden spikes of vector elements, and applying scaled values as a threshold.
- Support for complex vector/scalar multiplications
- Support for a synthesizer channel combining and MIMO demodulation for DDMA
- Complex windowing – 2K samples window RAM with a capability to split 1KB ping- 1KB pong to allow programming new coefficients while older ones are used.
- Up to 2K point FFT with efficiency of 1 sample output per cycle and possibility to go higher in size until 4K/8K, with stitching (reduced efficiency).
- Doppler de-rotation of the FFT output
- Support for magnitude (absolute value) and Log-Magnitude computation.
- Nested loop support in PARAM sets
- Compression/decompression engine with block floating and exponential Golomb modes with performance of 1 complex sample processing per cycle
- Detection algorithm-specific accelerators (for example: CFAR CA/OS and other variants)
- 2D Local Maxima/Peak search algorithm with efficiency of 1 cell processing per cycle

- Lock-step state machine
- ECC on the PARAM RAMs and parity on local buffers

6.3.2 Radar Accelerator Architecture

The Radar accelerator details are covered in Chapter , which consists of 2 parts.

The first part covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. The (optional) second part covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

6.4 Radar Subsystem

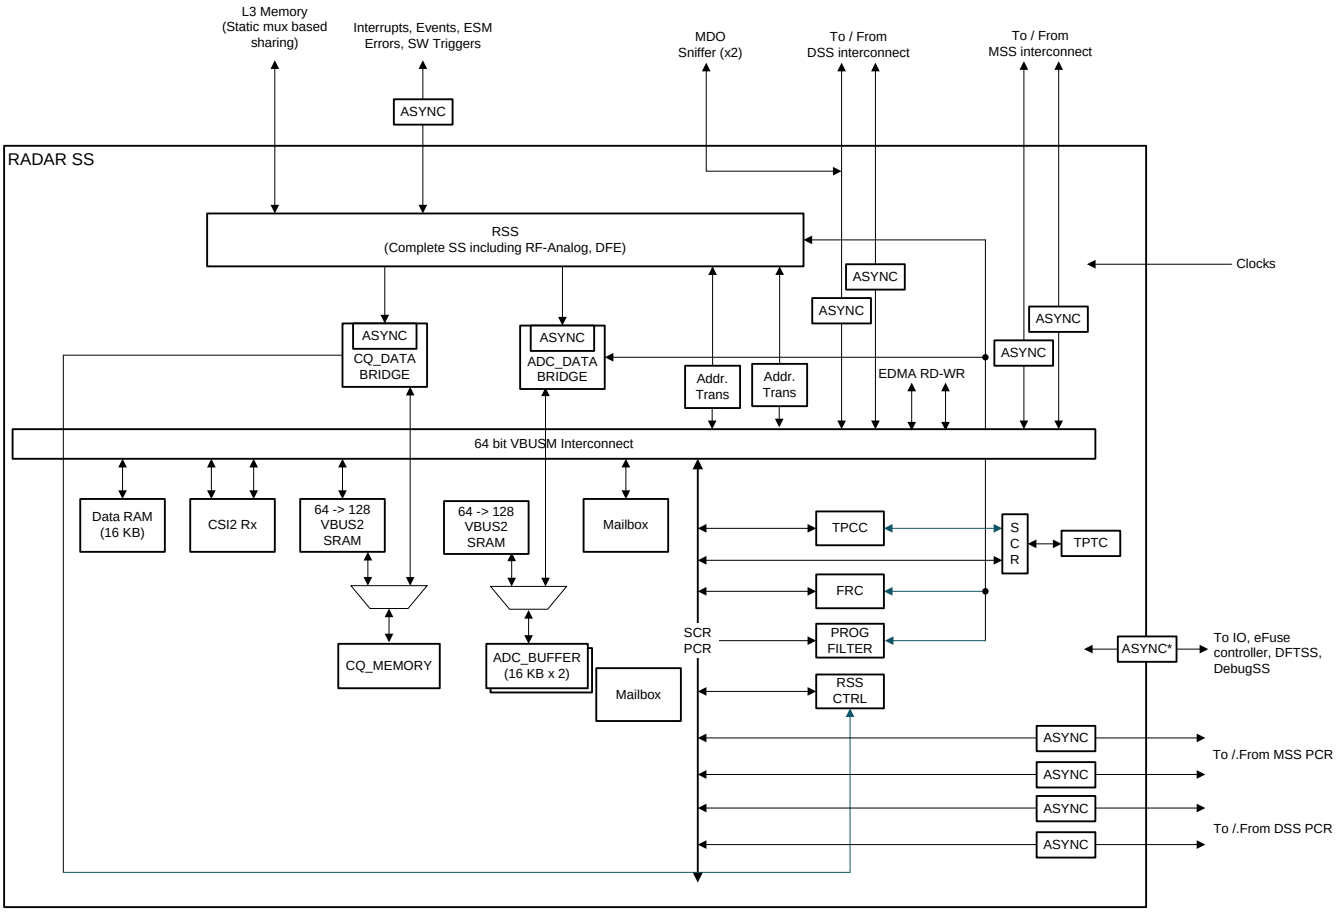

Figure 6-594. Block Diagram

6.4.1 BIST Subsystem

Figure 6-595 shows the BIST subsystem (BSS) block diagram.

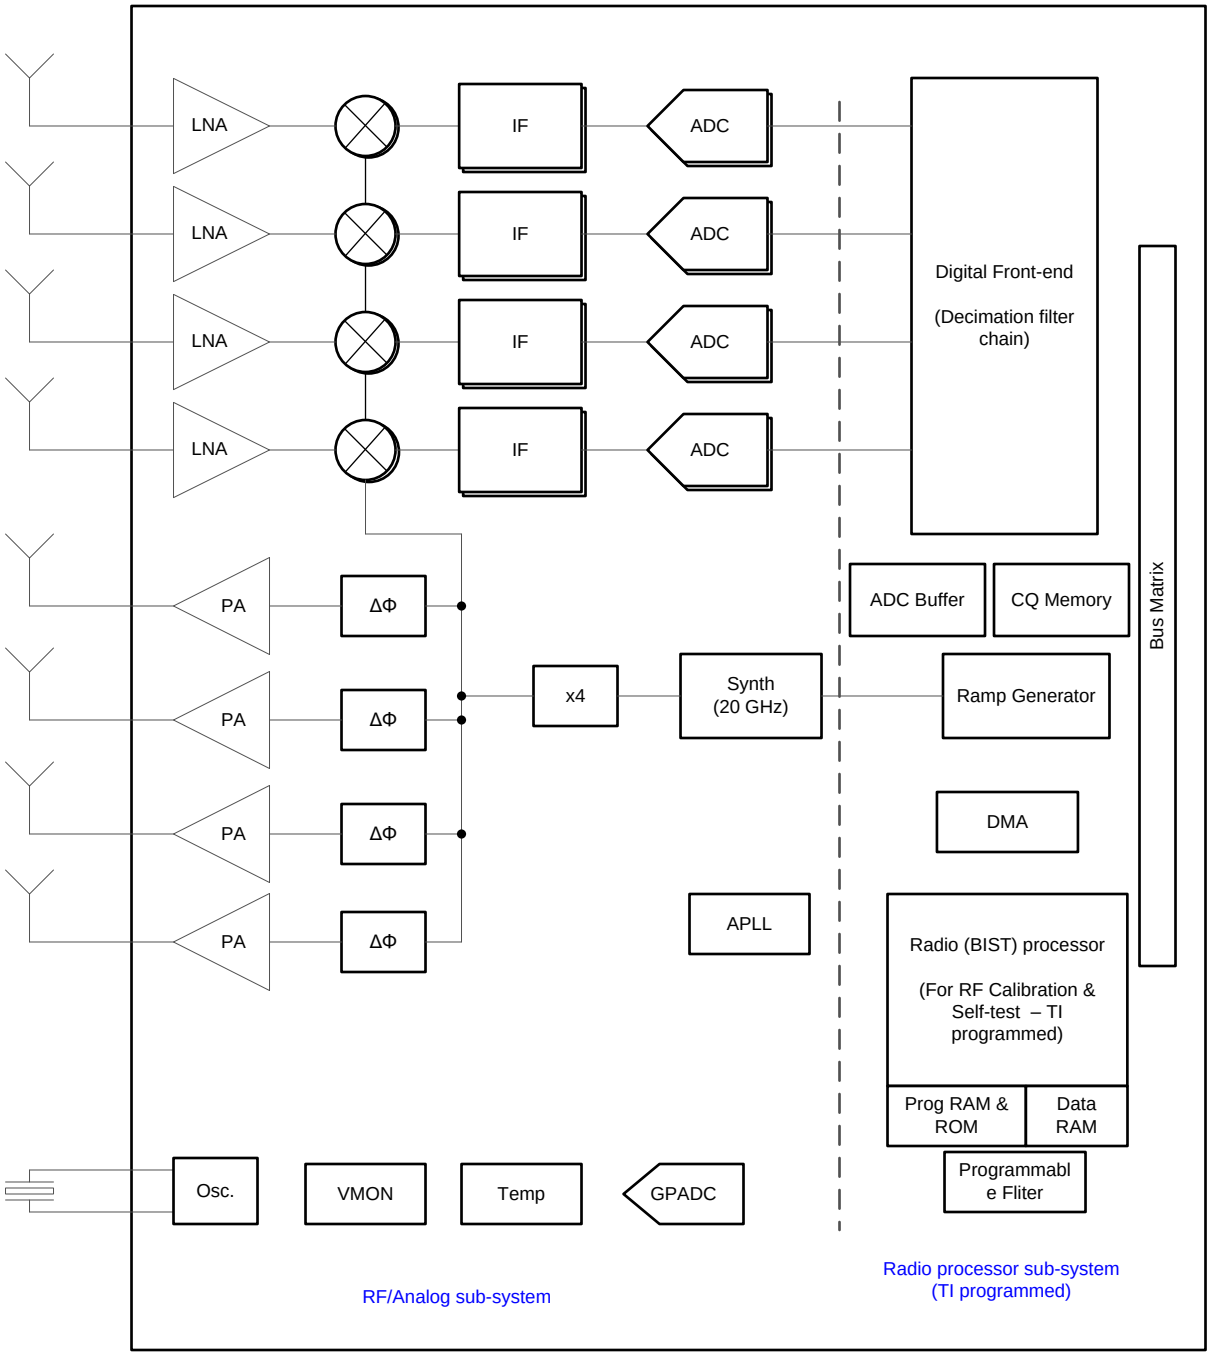

Figure 6-595. BIST Subsystem (BSS) Block Diagram

The BSS consists of the RF/Analog subsystem and the radio processor subsystem.

The RF/analog subsystem implements the frequency-modulated continuous-wave transceiver system with RF and analog circuitry – namely, the synthesizer, PA, LNA, mixer, IF, and ADC. This subsystem also includes the crystal oscillator and temperature sensors. The four transmit channels can be operated up to a maximum of two at a time simultaneously. The four receive channels can all be operated simultaneously.

The radio processor subsystem includes the digital front-end, the ramp generator, and an internal processor for controlling and configuring the low-level RF/analog and ramp generator registers, based on well-defined API messages from the main subsystem. This radio processor is programmed by TI, and addresses both RF calibration needs and some basic self-test and monitoring functions (BIST); this processor is not available

directly for customer use. The digital front-end filters and decimates the raw sigma-delta ADC output, and provides the final ADC data samples at a programmable sampling rate.

The programming of this BSS is abstracted at a TI-defined API interface. Figure 6-596 explains the high-level architecture and programming model.

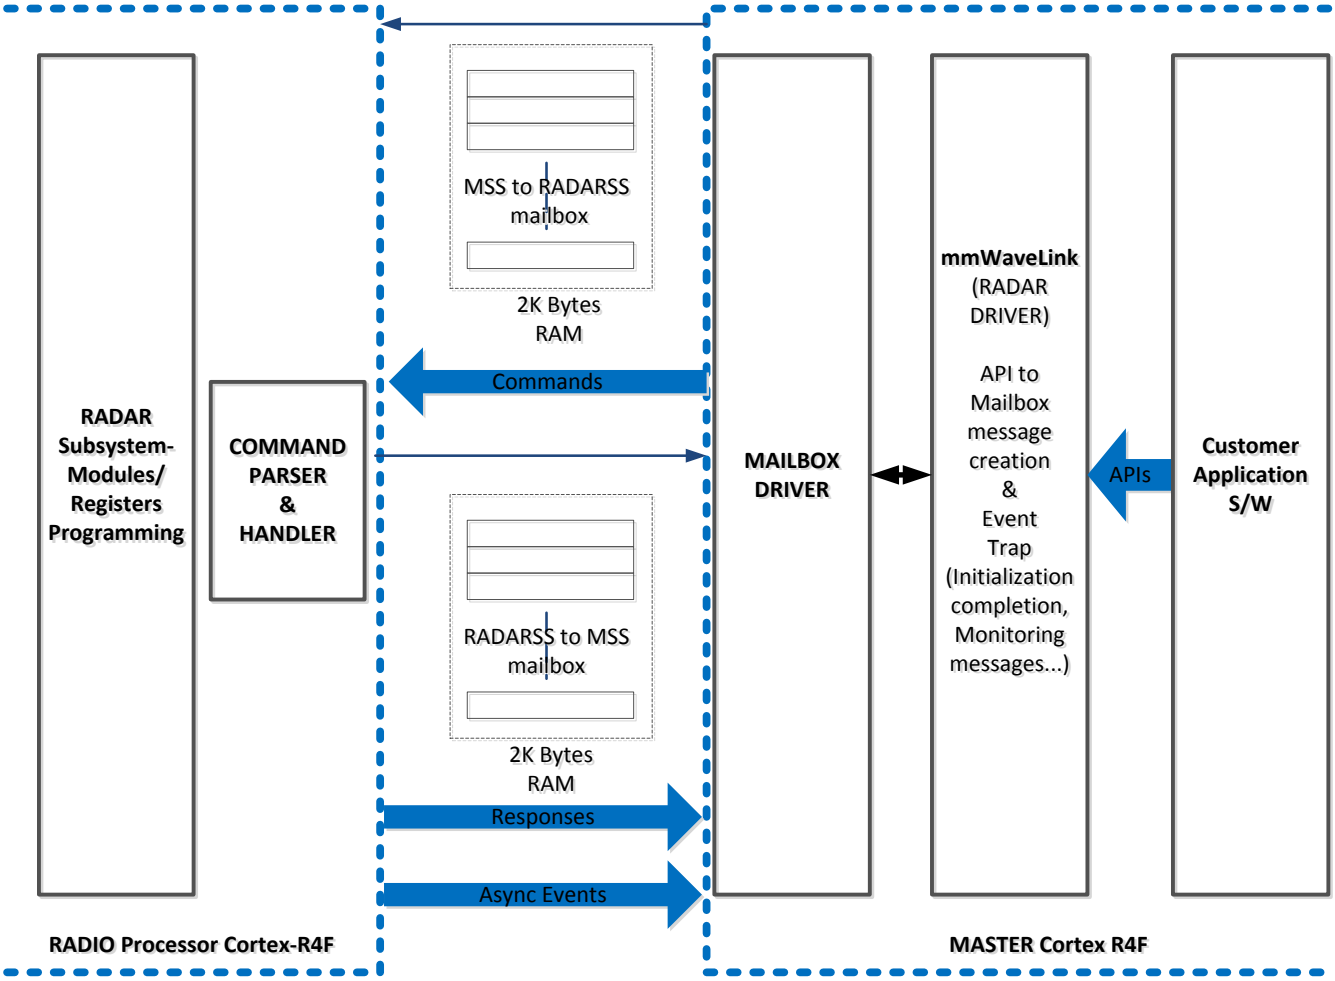

Figure 6-596. Programming Model

The radar subsystem is accessed through a well-defined set of APIs. The application software running on the main Cortex-R5F processor, through the API call, invokes the mmWaveLink-Radar driver, which then converts these APIs into mailbox-based messages. When a message is written into the mailbox memory, an interrupt is raised to the radio processor, which then passes the message and executes the command conveyed through the mailbox message. A mailbox message read event is raised to the main R5F to indicate the radio processor has read the message.

For more details, refer to the API interface control document (ICD).

Communication to BSS can also be done by C66x as well where user needs to implement communication protocol over mailbox to BSS using mmWaveLink library.

Note

On device bootup, RadarSS will be in the reset state. It is responsibility of SBL (secondary bootloader) or main-application (R5F), to bring RadarSS core (R4F) out of reset, load BSS firmware/patch and then un-halts (execute) it. Please refer SBL source code in MCU-PLUS-SDK-AWR294X for the right seqeunce.

6.4.2 Clock Subsystem

The AWR294x clock subsystem generates 76-81 GHz from an input reference of a 40-MHz crystal. The subsystem has a built-in oscillator circuit, followed by a clean-up PLL and an RF synthesizer circuit, as shown in Figure 6-597. The output of the RF synthesizer is then processed by an X4 multiplier to create the required frequency in the 76-81 GHz spectrum. The RF synthesizer output is modulated by the timing engine block to create the required waveforms for effective sensor operation. The timing engine is highly flexible and is programmed through the R4F-based radio controller subsystem. For details on waveforms and programming models, refer to the Radio Control API application note.

The clean-up PLL provides a reference clock for the host processor after system wakeup.

The clock subsystem has built-in mechanisms for detecting the presence of a crystal and monitoring the quality of the generated clock.

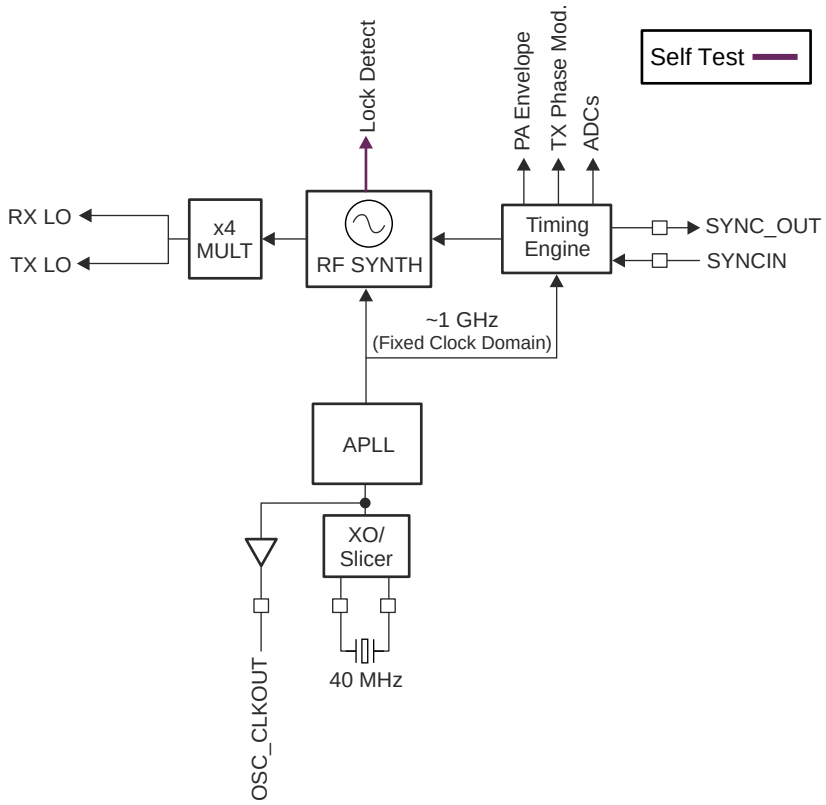

Figure 6-597. Clocking Subsystem

6.4.3 Transmit Subsystem

The transmit subsystem consists of four parallel transmit chains, each with independent phase and amplitude control, as shown in Figure 6-598. All transmit chains can be operational at the same time. The device supports binary phase modulation for MIMO radar and interference mitigation.

Each transmit chain is capable of delivering optimal power at the antenna port on the PCB, and supports programmable back-off for system optimization.

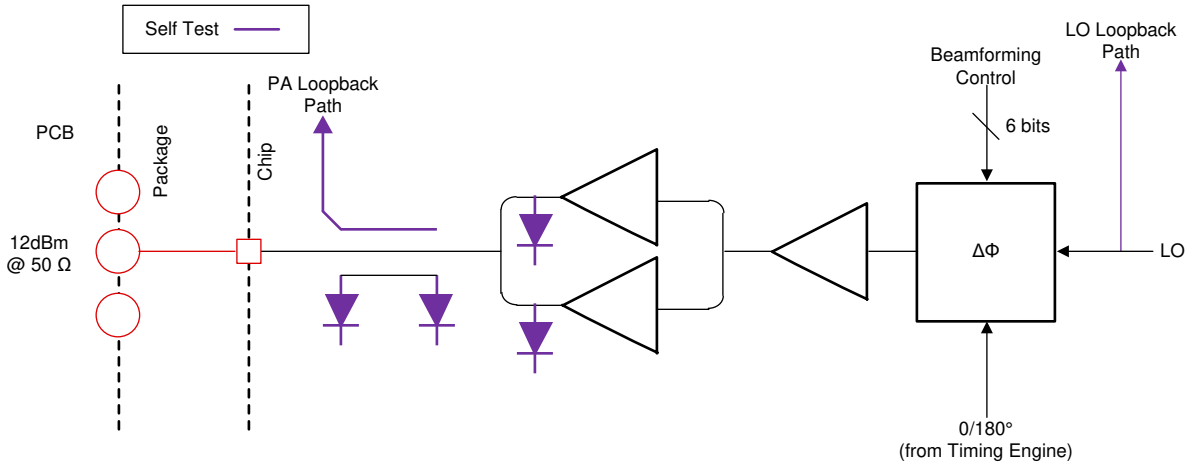

Figure 6-598. Transmit Subsystem

6.4.4 Receive Subsystem

The AWR294x receive subsystem consists of four parallel channels, as shown in Figure 6-599. A single receive channel consists of an LNA, mixer, IF filtering, A2D conversion, and decimation. All four receive channels can be operational at the same time. An individual power down option is also available for system optimization.

The AWR294x device supports an I-Only baseband architecture for each receiver channel. The AWR294x is targeted for fast chirp systems. The bandpass IF chain has configurable lower cutoff frequencies above 350 kHz, and can support bandwidths up to 15 MHz.

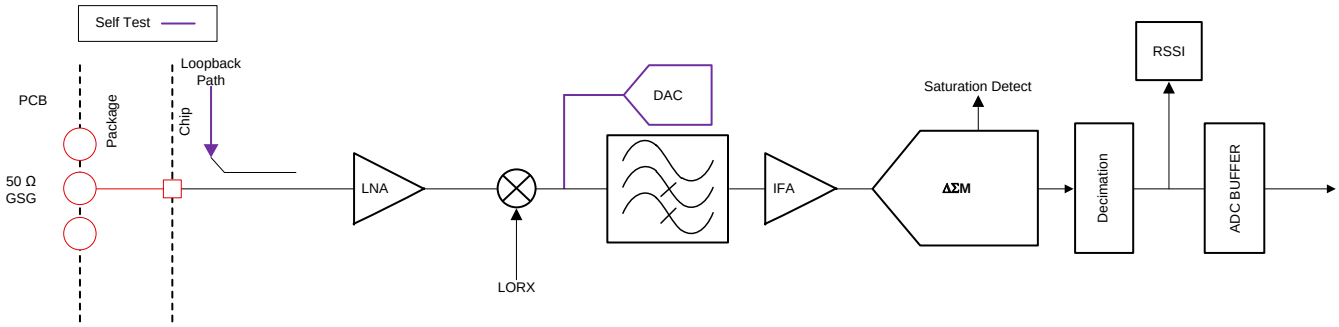

Figure 6-599. Receive Subsystem (Per Channel)

This section lists the various interrupts sources supported in the different subsystem of AWR294x device

7.1 Main Subsystem Cortex R5F Interrupt Map

Table 7-1. Main Subsystem Cortex R5F Interrupt Map

Interrupt Number	Define Name	Level/Pulse	Description
0	MSS_ESM_HI	Level	ESM High Priority Interrupt

39	RESERVED	RESERVED	RESERVED
40	RSS_ADC_CAPTURE_COMPLETE	Pulse	Raw ADC capture complete interrupt from DFE-DSP bridge
41	DSS_CBUFF_INT	Pulse	DSS CBUFF Interrupt
42	DSS_CBUFF_INT_ERR	Pulse	DSS CBUFF Error Interrupt
43	DSS_HWA_LOOP_INTR1	Pulse	DSS_HWA Loop complete interrupt1
44	DSS_HWA_PARAM_DONE_INTR1	Pulse	DSS_HWA Param done interrupt1
45	RESERVED	RESERVED	RESERVED
46	RESERVED	RESERVED	RESERVED
47	RESERVED	RESERVED	RESERVED
48	DFE_FRAME_START_TO_DSS	Pulse	Frame start interrupt from BSS
49	RCSS_TPCC_A_INTAGG	Level	RCSS_TPCC_A Aggregated Functional Interrupt
50	RCSS_TPCC_A_ERRAGG	Level	Interrupt is trigger during Falling edge of ADC valid
51	ADC_VALID_FALL_EDGE	Pulse	End of frame interrupt from RSS
52	DFE_FRAME_START_TO_MSS	Pulse	Frame start interrupt from BSS
53	DFE_CHIRP_CYCLE_START	Pulse	Chirp cycle start interrupt from DFE
54	DFE_CHIRP_CYCLE_END	Pulse	Chirp cycle end interrupt from DFE
55	DFE_END_OF_FRAME	Pulse	End of Frame interrupt from Dfe
56	RSS_FRC_FRAME_START	Pulse	Frame start interrupt from FRC
57	RSS_ADC_CAPTURE_COMPLETE_DITH	Pulse	ADC capture complete interrupt from DFE-DSP bridge after dithering
58	DSS_HWA_LOOP_INTR2	Pulse	DSS_HWA Loop complete interrupt2
59	DSS_HWA_PARAM_DONE_INTR2	Pulse	DSS_HWA Param done interrupt2
60	DSS_WDT_TB_INT	Level	DSS WDT Time Base Interrupt
61	DSS_HWA_LOCAL_RAM_ERR	Level	DSS_HWA Local RAM access error
62	DSS_DCCA_INT	Level	DSS DCCA Interrupt
63	DSS_DCCB_INT	Level	DSS DCCB Interrupt
64	DSS_RTIA_OVERFLOW_0	Level	DSS_RTIA Overflow 0
65	DSS_RTIA_OVERFLOW_1	Level	DSS_RTIA Overflow 1
66	DSS_RTIA_0	Level	DSS_RTIA Interrupt 0

Table 7-2. DSP Subsystem C66x Interrupt Map (continued)

Interrupt Number	Define Name	Level/Pulse	Description
67	DSS_RTIA_1	Level	DSS_RTIA Interrupt 1
68	DSS_RTIA_2	Level	DSS_RTIA Interrupt 2
69	DSS_RTIA_3	Level	DSS_RTIA Interrupt 3

Chapter 8

ADC Buffer

The ADC buffer is on-chip memory arranged as a ping-pong buffer, with ECC support for each ping and pong memory. The raw ADC output data from RADAR-SS is stored on this memory, to be consumed by the DSP, or by the hardware FFT accelerator for the post processing.

For the application software, the ADC buffer (either ping or pong) is seen as a single memory at the base address.

RadarSS generates Chirp Parameter (CP) and Chirp Quality (CQ) data along with ADC data. Interface Control Document (ICD) explains CP/CQ data format and steps to enable this feature. Refer ICD for the latest supported features towards CP/CQ/ADC of the device.

8.1 Functional Description

Figure 8-1 shows the block diagram of the ADC buffer scheme. The three data input sources to the ADC buffer are:

- Raw ADC output data from the digital front end (DFE)
- Ramp pattern data from the test pattern generator
- HIL data from the DMM interface

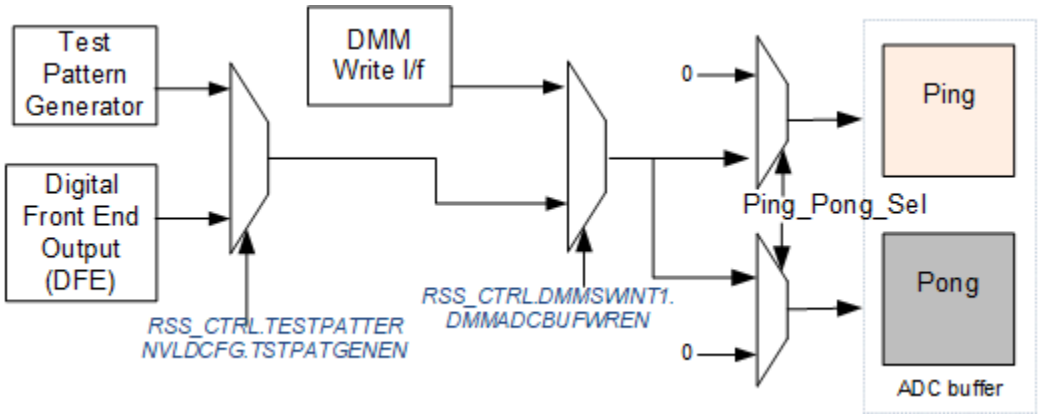

Figure 8-1. ADC Buffer Block Diagram

8.1.1 DFE Data Write Operation

The ADC buffer can be written from DFE in any of the three modes by configuring the control registers ADCBUFCFG1, ADCBUFCFG2, ADCBUFCFG3, and ADCBUFCFG4 in RSS_CTRL address space:

1. Single-chirp mode
2. Multi-chirp mode
3. Continuous mode

The DFE data from the four Rx channels can be independently enabled by programming the register ADCBUFCFG1.

In single-chirp mode, the FMCW chirp data from the DFE is written to the ADC buffer on a per chirp basis, and a chirp available interrupt is generated on the completion of the write data operation at the end of the chirp, as shown in Figure 8-2. ADC buffer control logic generates the Ping_Pong_Sel signal, as shown in Figure 8-2, which controls whether the data is written into either ping or pong buffer. Data write can start from either the ping or pong buffer.

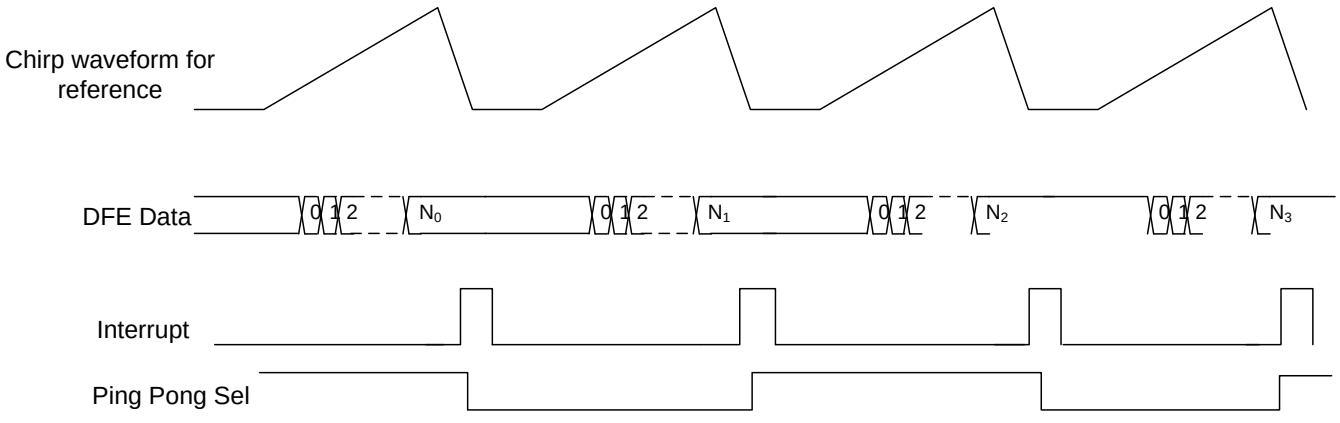

Figure 8-2. Single-Chirp Mode

In multi-chirp mode, ADC samples for N chirps are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The number of chirps stored in the ping buffer is

configured in the register field ADCBUFNUMCHRPPING, and the number of chirps to be stored in the pong buffer is configured in the register field ADCBUFNUMCHRPPONG.

Table 8-1 shows the programming sequence for the ADC buffer single-chirp and multi-chirp modes.

Note

Registers for ping and pong must be programmed with the same value for correct functionality.

Table 8-1. ADC Buffer Single-Chirp and Multi-Chirp Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
	ADCBUFCFG1.RX3EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE
Configure whether real or complex samples are to be stored in the ADC buffer. (only real mode is supported in AWR294x)	ADCBUFCFG1.ADCBUFREALONLYMODE
Configure the number of samples to be stored in each ping/pong buffer as N	ADCBUFCFG4.ADCBUFNUMCHRPPONG
	ADCBUFCFG4.ADCBUFNUMCHRPP1NG

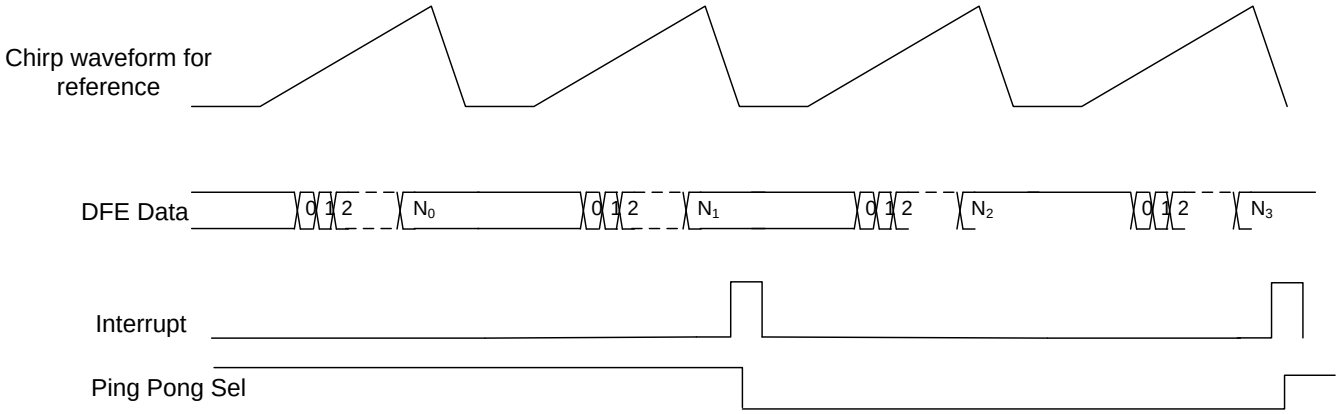

Figure 8-3. Multi-Chirp Mode

In continuous mode, where the FMCW transceiver is configured to output a single frequency tone in the range of X-Y GHz (where X is start and Y is end frequency supported by the device), 'N' ADC samples are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The value N is configured in the field RSS_CTRL.ADCBUFCFG4.ADCBUFSAMPCNT. In real mode, this value N refers to the number of real samples per channel, and in complex mode, this refers to the number of complex samples per channel. This counter increments once for every new sample (as long as 1 or more Rx channels are enabled). Continous mode is expected to be only used for CZ and ADC buffer testpattern mode.

Table 8-2 shows the programming sequence for ADC buffer continuous mode.

Table 8-2. ADC Buffer Continuous Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
	ADCBUFCFG1.RX3EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE

Table 8-2. ADC Buffer Continuous Mode Programming Sequence (continued)

Steps	Register/Bit Field/Programming
Configure whether real or complex samples are to be stored in the ADC buffer (only real mode is supported in AWR294x)	ADCBUFCFG1.ADCBUFREALONLYMODE
Configure the number of samples to be store in each ping/pong buffer	ADCBUFCFG4.ADCBUFSAMPCNT
Enable the ADC buffer in continuous mode	ADCBUFCFG1.ADCBUFCONTMODEEN
To start the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTRTPL
To stop the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTOPPL

8.1.2 Support for Hardware in Loop (HIL)

In hardware in loop mode, the ADC data write from DFE can be bypassed by writing the data from the DMM module. Enable this path by writing to the field RSS_CTRL.DMMSWINT1.DMMADCBUFWREN. The DMM can now access the ADCBUF memory through the ADCBUF_WRITE address space. To toggle the ping/pong buffer, toggle RSS_CTRL.DMMSWINT1.DMMADCBUFPINPONSEL.

8.1.3 Test Pattern Generator Support

An internal test pattern generator which outputs a ramp pattern helps during the initial software development and debug. The output of this module is muxed with the DFE data before sending it to the ADC buffers, as shown in Figure 8-1. Because this is meant for testing the path from the ADC buffer until the final output through LVDS, the ADC buffer configurations must be set to continuous streaming mode, in which the ping-pong switch is based on the number of samples. The test pattern generator can be configured by programming the register TESTPATTERNVLDCFG in the RSS_CTRL address space. Additional configurable registers are provided for configuring the ramp pattern output from the test pattern generator, such as offset at the start of ramp, step size, and so forth. Refer to the RSS_CTRL address space and test pattern generator-related registers for further information.

8.1.4 ADC Buffer Data Formats

The data is written in the following formats to the ADC buffer:

- Interleaved data format
- Non-interleaved data format

8.1.4.1 Interleaved Data Format

In interleaved format of data storage, Sample 0 of all the enabled channels, followed by Sample1 of all the enabled channels, and so forth, are written to the buffer as illustrated below for real/complex data, with different configurations of RX channels enabled.

For 4-channels-Rx channels 0,1, 2, and 3 enabled, complex:

RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 4-channels Rx channels 0,1, 2, and 3 enabled, Real Only:

RX3_I(1)	RX2_I(1)	RX1_I(1)	RX0_I(1)	RX3_I(0)	RX2_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0,1, and 2 enabled, Complex:

NA	NA	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 0,1, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 0, 2, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 1, 2, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)

For 3-channels-Rx channels 0, 1, and 2 enabled, Real only:

NA	NA	RX2_I(1)	RX1_I(1)	RX0_I(1)	RX2_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0, 1, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX1_I(1)	RX0_I(1)	RX3_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0, 2, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX2_I(1)	RX0_I(1)	RX3_I(0)	RX2_I(0)	RX0_I(0)

For 3-channels Rx channels 1, 2, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX2_I(1)	RX1_I(1)	RX3_I(0)	RX2_I(0)	RX1_I(0)

For 2-channels Rx channels 0, 1 enabled, Complex:

RX1_Q(1)	RX1_I(1)	RX0_Q(1)	RX0_I(1)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 2-channels Rx channels 0, 1 enabled, Real only:

RX1_I(3)	RX0_I(3)	RX1_I(2)	RX0_I(2)	RX1_I(1)	RX0_I(1)	RX1_I(0)	RX0_I(0)

For 1-channels Rx channels 0 enabled, Complex:

RX0_Q(3)	RX0_I(3)	RX0_Q(2)	RX0_I(2)	RX0_Q(1)	RX0_I(1)	RX0_Q(0)	RX0_I(0)

For 1-channels Rx channels 0 enabled, Real:

RX0_I(7)	RX0_I(6)	RX0_I(5)	RX0_I(4)	RX0_I(3)	RX0_I(2)	RX0_I(1)	RX0_I(0)

Where RXn_I/Q(m) stands for the ‘m’th sample I/Q of ‘n’th RX channel.

8.1.4.2 Non-Interleaved Data Format

In non-interleaved mode storage, each channel data is stored in different memory locations, as shown in Table 8-3.

Table 8-3. Non-Interleaved Data Format

RX0(3)	RX0(2)	RX0(1)	RX0(0)
RX0(7)	RX0(6)	RX0(5)	RX0(4)
RX1(3)	RX1(2)	RX1(1)	RX1(0)
RX1(7)	RX1(6)	RX1(5)	RX1(4)
RX2(3)	RX2(2)	RX2(1)	RX2(0)
RX2(7)	RX2(6)	RX2(5)	RX2(4)

Table 8-3. Non-Interleaved Data Format (continued)

RX3(3)	RX3(2)	RX3(1)	RX3(0)
RX3(7)	RX3(6)	RX3(5)	RX3(4)

Chapter 9

Ethernet SubSystem (MCU_CPSW0)

This chapter describes the Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

9.1 MCU_CPSW0 Overview

The two-port Ethernet MAC (MCU_CPSW0) subsystem provides Ethernet packet communication for the device and is configured in a similar manner as a two-port Ethernet switch. MCU_CPSW0 features the Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

The device has integrated two-port Ethernet Switch subsystem into device MCU domain named MCU_CPSW0.

Figure 9-1 shows the MCU_CPSW0 module overview.

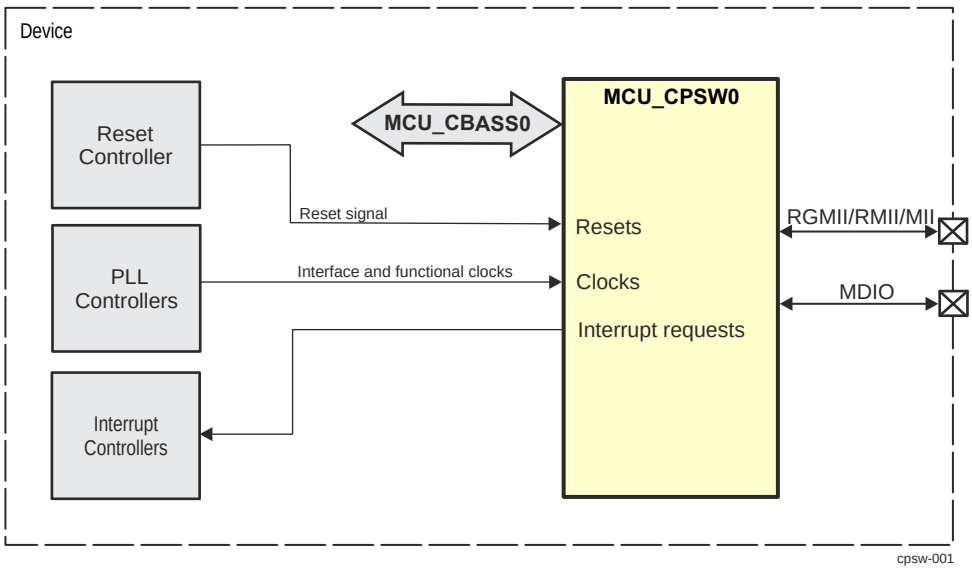

Figure 9-1. MCU_CPSW0 Overview

9.1.1 MCU_CPSW0 Features

The MCU_CPSW0 subsystem provides the following features:

- One Ethernet port with selectable MII, RMII and RGMII interfaces (port 1).
- One CPDMA CPPI DMA Host Interface (Port 0)
- Synchronous 10/100 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
  - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
  - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control (802.3x) Support
- Non Blocking switch fabric
- Time Sensitive Network Support
  - IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
  - Configurable number of addresses plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging and/or auto-aging
  - Spanning tree support

  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based Multicast and Broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Configurable number of classifier/policers
  - VLAN support
    - 802.1Q compliant
      - Auto add port VLAN for untagged frames on ingress
      - Auto VLAN removal on egress and with pad to minimum frame size
- EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (per port)
- Ethernet or Castignoli CRC selectable on Ethernet egress
- Digital Loopback supported (Ethernet egress to Ethernet ingress)
- OAM Loopback supported (FIFO Loopback - port ingress to egress including host port)
- CPSGMII Loopback Modes (Ethernet egress to Ethernet ingress)
- Maximum frame size of 2024 bytes (including VLAN)
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Full duplex mode supported in 10/100 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECDED)
- InterVLAN Routing is supported - 4 routes per egress port.
- Automotive Security Features
  - VLANs can be configured to not allow fragmented IPv4 frames (that is, fragmented IPv4 traffic)
  - VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6 Next Header values
  - Drop invalid source addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
  - Drop frames that the IEEE802.3 length is not contained within the frame. (Ether Types 0-1500)
  - Any source address can be secured to a port dropping any attempts from other ports to masquerade as a service
  - Any source or destination address can be blocked
  - Per port or per VLAN ingress checking, dropping traffic from non-member ports
  - Classification, policing on L2 and L3 information

9.1.2 MCU_CPSW0 Not Supported Features

The following MCU_CPSW0 features are not supported:

- Gigabit operation (1000 Mbps) is not supported
- Frames greater than 2024 bytes with VLAN
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet
- Software reset
- Rate-limiting is not supported in half-duplex mode
- Dual VLAN switch operations are not supported
- RGMII Internal Delay Mode disabled.
- Priority based flow control is not supported.
- InterVLAN routed packets will be dropped if the FIFO room is insufficient regardless of receive 803.3x flow control.

9.1.3 Terminology

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Trasport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
OUI	Organizationally Unique Identifier
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network
CPSW_2G	CPSW two port

9.2 MCU_CPSW0 Environment

9.2.1 MCU_CPSW0 RMII Interface

Figure 9-2 shows a device with integrated RMII and MDIO interface connection in a typical system. The individual MCU_CPSW0 and MDIO signals for the RMII interface are summarized in Table 9-1.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

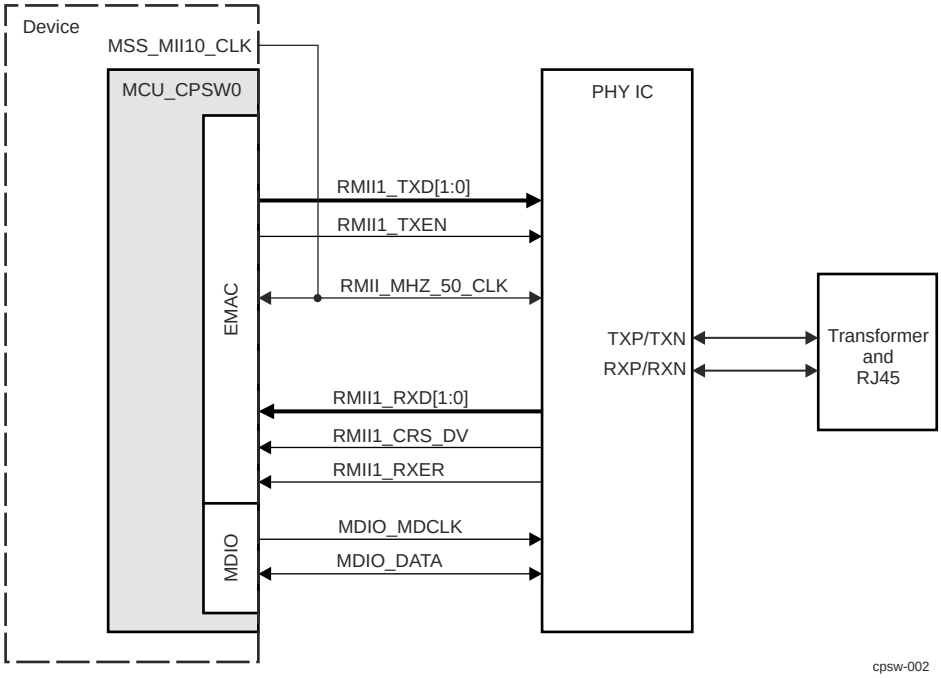

Figure 9-2. RMII Interface Typical Application

Table 9-1. RMII I/O Description

Signal	Device Pin	I/O[1]	Description
RMII_TXD[1:0]	MCU_RMII_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	MCU_RMII_TX_EN	O	RMII transmit enable. The transmit enable signal indicates that the MCU_RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	MCU_RMII_REF_CLK	I	RMII 50MHz reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz. This bit controls the clock source MSS_CTRL::CPSW_CONTROL:: CPSW_CONTROL_RMII_REF_CLK_OE_N
RMII_RXD[1:0]	MCU_RMII_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is de-asserted.
RMII_CRS_DV	MCU_RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	MCU_RMII_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	MCU_MDIO_CLK	O	Management data clock (MDIO_MDCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_DATA pin.

Table 9-1. RMII I/O Description (continued)

Signal	Device Pin	I/O(1)	Description
MDIO_DATA	MCU_MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

9.2.2 MCU_CPSW0 RGMII Interface

Figure 9-3 shows a device with integrated RGMII and MDIO interface connection in a typical system. The individual MCU_CPSW0 and MDIO signals for the RGMII interface are summarized in Table 9-2.

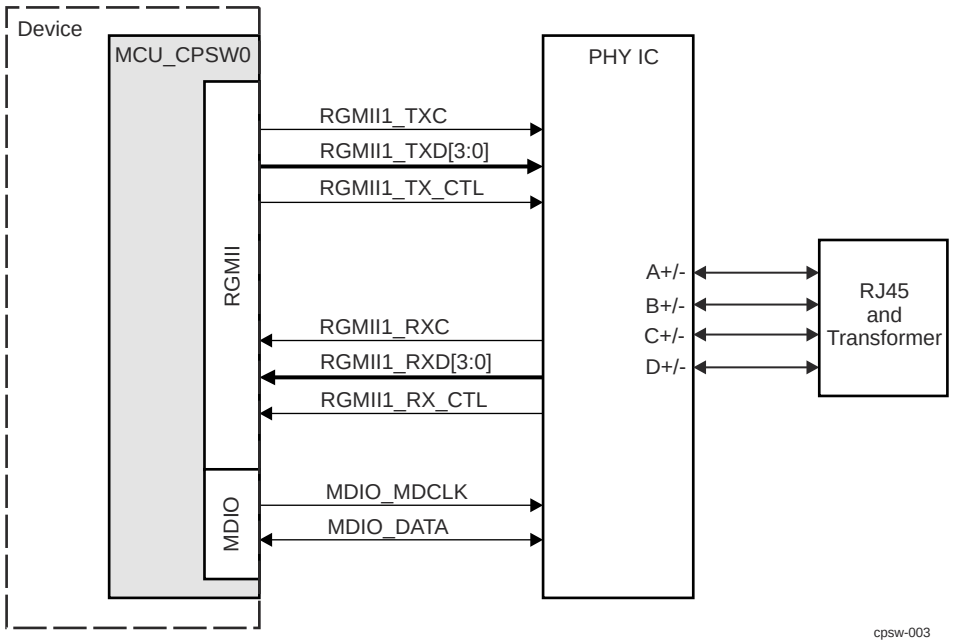

Figure 9-3. RGMII Interface Typical Application

Table 9-2. RGMII I/O Description

Signal	Device Pin(s)	I/O(1)	Description
RGMII_TXD[3:0]	MCU_RGMII_TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TX_CTL is asserted.
RGMII_TX_CTL	MCU_RGMII_TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII_TXC	MCU_RGMII_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps* of operation.
RGMII_RXD[3:0]	MCU_RGMII_RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_RX_CTL is asserted
RGMII_RX_CTL	MCU_RGMII_RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII_RXC	MCU_RGMII_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps* of operation.

Table 9-2. RGMII I/O Description (continued)

Signal	Device Pin(s)	I/O(1)	Description
MDIO_MDCLK	MCU_MDIO_CLK	O	Management data clock (MDIO_MDCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_DATA pin.
MDIO_DATA	MCU_MDIO_DATA	I/O	The MCU_MDIO0_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

Note

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see , Pad Configuration Registers in *Control Module (CTRL_MMR)* and the device-specific Datasheet.

1000 Mbps is not supported with AWR294x device.

9.3 MCU_CPSW0 Integration

Figure 9-4 shows the integration of the MCU_CPSW0 module in the device.

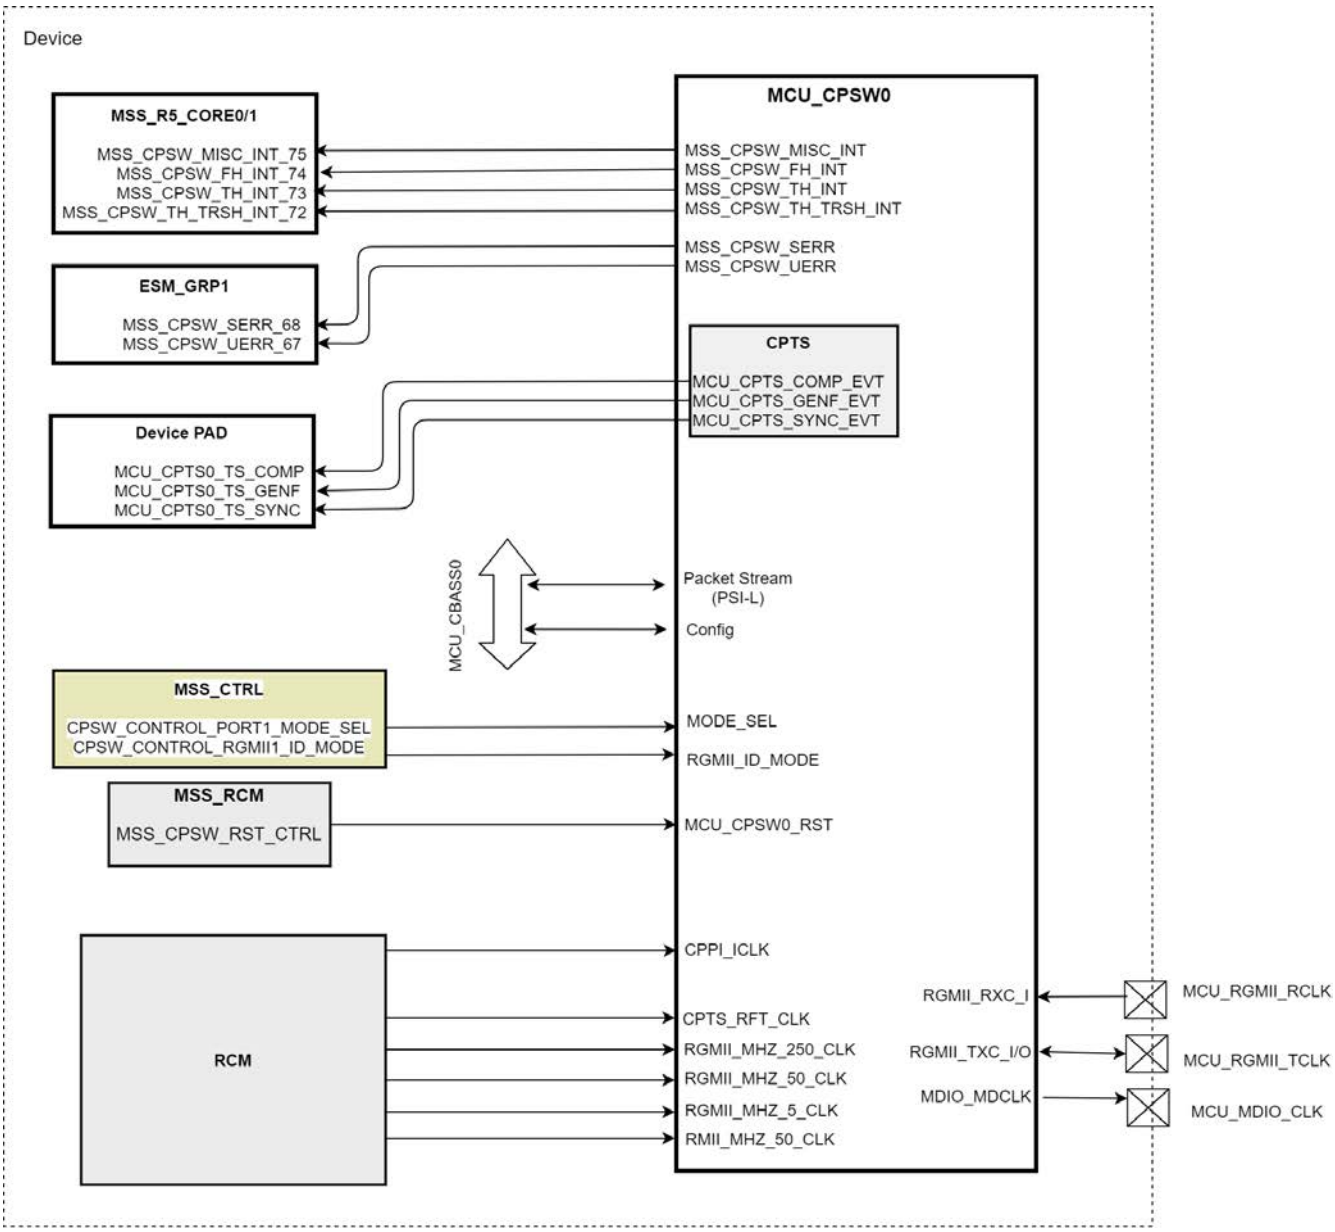

Figure 9-4. MCU_CPSW0 Integration

Below Tables summarize the integration of the MCU_CPSW0 module in the device.

Table 9-3. MCU_CPSW0 Clocks and Resets

Clocks			
Module Instance	**Module Clock Input**	**Reference/Source**	**Description**
MCU_CPSW0	CPPI_CLK	MSS_RCM::CPSW_CLK	CPPI packet streaming interface clock. Main clock for MCU_CPSW0.
	CPTS_RFT_CLK	MSS_RCM::MSS_CPTS_CLK	Time sync Reference Clock 400/250/divided
	RGMII_MHZ_5_CLK	MSS_RCM::MSS_MII10_CLK	5-MHz RGMII reference clock.
	RGMII_MHZ_50_CLK	MSS_RCM::MSS_MII100_CLK	50-MHz RGMII reference clock.

Table 9-3. MCU_CPSW0 Clocks and Resets (continued)

RGMII_MHZ_250_CLK	MSS_RCM::MSS_RGMII_CLK	250-MHz RGMII reference clock.
RMII_MHZ_50_CLK	MSS_RCM::MSS_MII100_CLK	50-MHz RMII reference clock.

Resets			
Module Instance	**Module Reset Input**	**Reference/Source**	**Description**
MCU_CPSW0	MCU_CPSW0_RST	MCSS_RCM::MSS_CPSW_RST_CTRL	IP Reset

Table 9-4. MCU_CPSW0 Hardware Requests

Interrupt Requests				
Module Instance	**Module Interrupt Signal**	**Destination Interrupt Input**	**Description**	**Type**
MCU_CPSW0	MCU_CPSW_STAT_PEND	MSS_CPSW_MISC_INT_75	MCU_CPSW0 statistic pending interrupt 0	Pulse
	MCU_CPSW_EVNT_PEND	MSS_CPSW_MISC_INT_75	MCU_CPSW0 event pending interrupt	Pulse
	MCU_CPSW_MDIO_INTR	MSS_CPSW_MISC_INT_75	MCU_CPSW0 MDIO interrupt	Pulse
	MCU_CPSW_THost_INT	MSS_CPSW_TH_INT_73	MCU_CPSW0 T-host interrupt	Pulse
	MCU_CPSW_FHost_INT	MSS_CPSW_FH_INT_74	MCU_CPSW0 F-host interrupt	Pulse
	MCU_CPSW_TH_TRSH_INT	MSS_CPSW_TH_TRSH_INT_72	MCU_CPSW0 TH-threshold interrupt	Pulse
	MCU_CPSW_ECC_SEC_INT	MCU_ESM_EVT_68	MCU_CPSW0 SEC ECC error interrupt	Pulse
	MCU_CPSW_ECC_DED_INT	MCU_ESM_EVT_67	MCU_CPSW0 SEC DED error interrupt	Pulse
Time Sync and Compare Events				
Module Instance	**Module Event**	**Device Pin**	**Description**	**Type**
MCU_CPSW0	MCU_CPSW_COMP_EVT	MCU_CPTS0_TS_COMP	MCU_CPSW0 compare event interrupt	Edge
	MCU_CPSW_GENF_EVT	MCU_CPTS0_TS_GENF	MCU_CPSW0 CPTS generator function event interrupt	Edge
	MCU_CPSW_SYNC_EVT	MCU_CPTS0_TS_SYNC	MCU_CPSW0 CPTS sync event interrupt	Edge

Note

For more information about interrupts, see *Local Interrupt Controller*.

For more information on the interconnects, see Chapter .

For more information on the power, reset and clock management, see the corresponding sections within Chapter .

For more information on the device interrupt controllers, see *Interrupt Controllers*.

9.4 MCU_CPSW0 Functional Description

The two-port switch Ethernet subsystem modules (CPSW) are compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in Figure 9-5.

9.4.1 Functional Block Diagram

The two-port Ethernet subsystem consists of:

- CPSW_2G
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

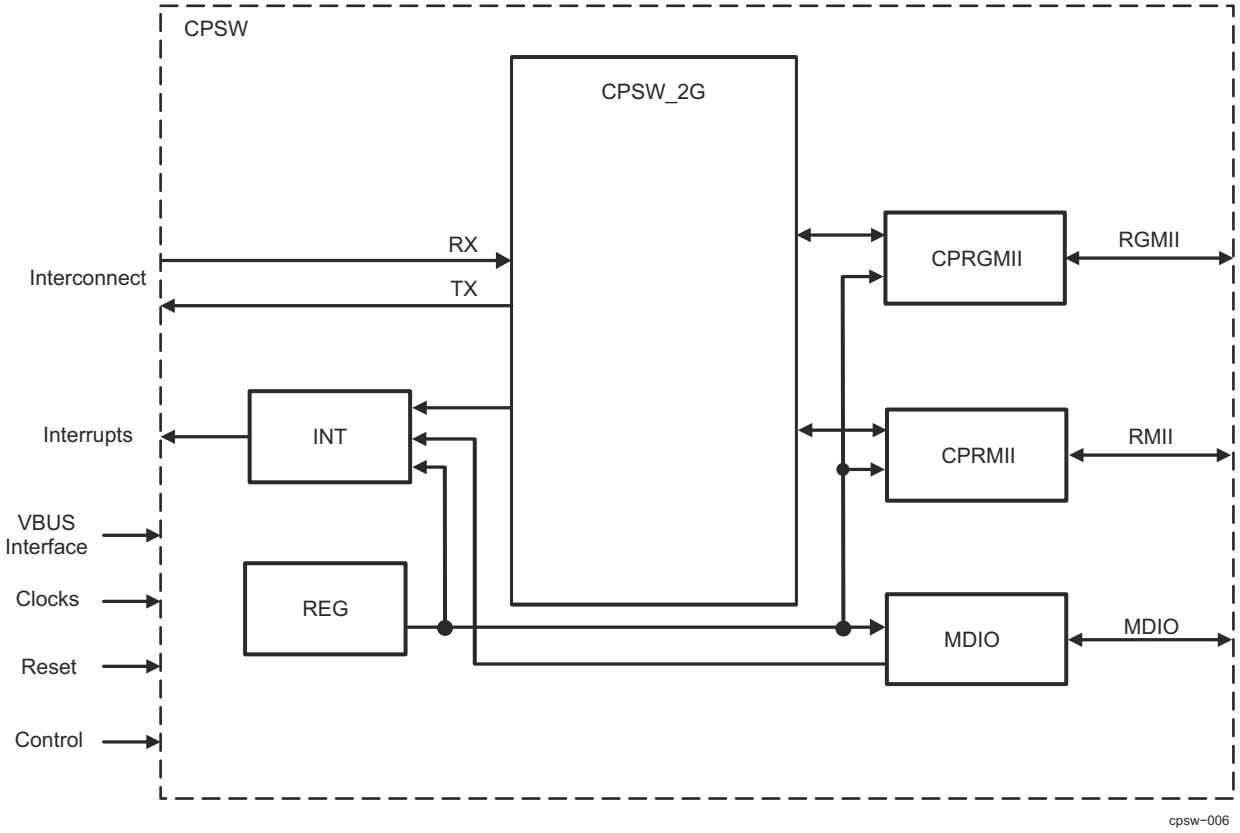

Figure 9-5. CPSW Top Level Block Diagram

9.4.2 CPSW Ports

The Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external port connected to RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI CPDMA Host Port
- Port1 is referred to the interfaces RGMII/RMII

9.4.2.1 Ethernet Port Operation

9.4.2.1.1 Interface Mode Selection

The two-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable MII, RMII, and RGMII interfaces. These interfaces can be enabled by **MSS_CTRL:CPSW_CONTROL:CPSW_CONTROL_PORT1_MODE_SEL**

For specific interface mode further features is selected by configuring the Ethernet bits (EXT_EN, GIG, FULLDUPLEX, IFCTL_A) in the **PN_MAC_CONTROL** register.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

CPSW_CONTROL_PORT1_MODE_SEL	Link Type
00	GMII/MII
01	RMII
10	RGMII

9.4.2.1.2 RMII Operation

The **IFCTL_A** bit determines the RMII link speed (0=10mbps, 1=100mbps). The **FULLDUPLEX** bit controls RMII duplexity. The **IFCTL_B** is not used.

9.4.2.1.3 RGMII Operation

Each port RGMII interface can operate in a forced mode or an in-band mode as determined by the **EXT_EN** bit. Forced mode is with **EXT_EN** cleared. In-band mode is with **EXT_EN** set.

9.4.2.1.3.1 RGMII In-Band Operation

A port CPRGMII is operating in the in-band mode of operation when the **EXT_EN** is set. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification and can be read in the **SS_RGMII1_STATUS** register. The link speed is indicated as shown in Table 9-5.

Table 9-5. RGMII Link Speed

SPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

Note

1000 Mbs mode is not supported for AWR294x

9.4.2.1.3.2 RGMII Forced Mode Operation

A RGMII is operating in the forced mode of operation when **EXT_EN** is cleared. In the forced mode of operation, the in-band data is ignored if present. The link status is forced set, the duplexity is set by the **FULLDUPLEX** bit, and the speed is set by the **GIG** bit. If the **GIG** bit is cleared, then operation is 100mbps mode (**SPEED(1:0)** = 01). 10mbps is not supported when operating in the forced mode.

Note

For AWR294x gigabit mode (**GIG** bit set) is not supported.

9.4.3 Clocking

9.4.3.1 Subsystem Clocking

CPSW clocking summary is shown in Section 9.3, *CPSW Integration*.

9.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

9.4.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

9.4.3.2.2 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

MCU_RMII1_REFCLK pin or internal RGMII_MHZ_50_CLK clock (default clock) can be selected through CTRLMMR_MCU_ENET_CLKSEL[0]RMII_CLK_SEL and one of these clocks can be used as the clock source for RMII interface. For more details on RMII clocking, please see Section 9.3, *CPSW Integration*.

CTRLMMR_MCU_CLKOUT0_CTRL[4]CLK_EN and CTRLMMR_MCU_CLKOUT0_CTRL[0]CLK_SEL bits are used to enable and select the clock source for MCU_CLKOUT pin.

9.4.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW_MDIO_CONTROL_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

9.4.4 Interrupt Functionality

Table 9-6. Interrupt Functionality

Interrupt	Description
MSS_CPSW_FH_INT	FHost (from host to Ethernet) interrupt
MSS_CPSW_TH_INT	THost (from Ethernet to host) interrupt
MSS_CPSW_TH_TRSH_INT	THost (from Ethernet to host) Threshold interrupt
MSS_CPSW_MISC_INT	Miscellaneous interrupt
MSS_CPSW_SERR	ECC SEC interrupt – output from CPSW ECC module. This interrupt is also included in the **MSS_CPSW_MISC_INT** if enabled or this interrupt can be used separately.
MSS_CPSW_UERR	ECC DED interrupt – output from CPSW ECC module. This interrupt is also included in the **MSS_CPSW_MISC_INT** if enabled or this interrupt can be used separately.

9.4.4.1 MSS_CPSW_TH_TRSH_INT Interrupt Description

The **MSS_CPSW_TH_TRSH_INT** interrupts are each an immediate (non-paced) pulse interrupt selected from the CPSW_2G **TH_THRESH_PEND[7:0]** interrupts. The THost threshold pending interrupt(s) is selected by setting one or more bits in the **SS_TH_THRESH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_TH_THRESH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_THRESH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x0 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.2 MSS_CPSW_TH_INT Interrupt Description

The **MSS_CPSW_TH_INT**interrupts are each a paced pulse interrupt selected from the CPSW_2G **TH_PEND[7:0]** interrupts. The THost pending interrupt(s) is selected by setting one or more bits in the **SS_TH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_TH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s) to acknowledge the CPDMA interrupt.
- Write the CPSW_2G completion pointer(s).
- Write 0x1 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.3 MSS_CPSW_FH_INT Interrupt Description

The **MSS_CPSW_FH_INT** interrupts are each a pulse interrupt selected from the CPSW_2G **FH_PEND[7:0]** interrupts. The transmit pending interrupt(s) is selected by setting one or more bits in the **SS_FH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_FH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_FH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s).
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x2 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.4 MSS_CPSW_MISC_INT Interrupt Description

The **MSS_CPSW_MISC_INT** interrupts are each an immediate (non-paced) pulse interrupt selected from the miscellaneous interrupts (**DED_PEND, SEC_PEND, EVNT_PEND, STAT_PEND,HOST_PEND, MDIO_LINKINT,MDIO_USERINT**). The miscellaneous interrupt bits are enabled by setting one or more bits in the **SS_MISC_EN_REG** register. The masked interrupt status can be read in the **SS_MISC_STATUS_REG** register. Upon reception of an interrupt, software should perform the following:

- Read the **SS_MISC_STATUS_REG** register to determine the cause of the interrupt.
  - MDIO_USERINT is the logical “OR” of the CPSW_2G MDIO MDIO_USERINT[1:0].
  - MDIO_LINKINT is the logical “OR” of the CPSW_2G MDIO MDIO_LINKINT[1:0]
  - HOST_PEND is the CPSW_2G CPDMA host error interrupt.
  - STAT_PEND is the logical “OR” of the CPSW_2G statistics interrupt STAT_PEND[2:0].
  - EVNT_PEND is the CPSW_2G CPTS event interrupt.
  - SEC_PEND is the ECC Single bit error interrupt.
  - DED_PEND is the ECC double bit error interrupt.
- Process the interrupt.
- Write 0x3 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.5 ECC SEC ESM Interrupt (MSS_CPSW_SERR)

ESM interrupt indicating a CPSW_2G ECC single error has been detected and corrected. Although the **MSS_CPSW_SERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[5]** and read status from **SS_TH_PULSE_STATUS_REG[5]**

9.4.4.6 ECC DED ESM Interrupt (MSS_CPSW_UERR)

ESM interrupt indicating a CPSW_2G ECC double error has been detected. Although the **MSS_CPSW_UERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[6]** and read status from **SS_MISC_STATUS_REG[6]**.

9.4.4.7 THost Threshold Interrupts for CPDMA

Each of the eight THost channels has a corresponding THost threshold interrupt (**TH_THRESH_PEND[7:0]**). The THost threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt receive interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. A **TH_THRESH_PEND[7:0]** interrupt bit is asserted when enabled and when the channel's associated freebuffer count (**CPDMA_TH(0/7)_FREEBUFFER**) is less than or equal to the channel's associated flow control threshold register (**CPDMA_TH(0/7)_PENDTHRESH**. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

9.4.4.8 Thost Packet Completion Interrupts for CPDMA

The THost DMA controller has eight channels with each channel having a corresponding interrupt (**TH_PEND[7:0]**). The THost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. When a packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel queue's **CPDMA_TH(0..7)_CP** completion pointer. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated **CPDMA_TH(0..7)_CP** Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA. If the two values are equal then the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

9.4.4.9 Fhost Packet Completion Interrupts for CPDMA

The FHost DMA controller has eight channels with each channel having a corresponding interrupt (**FH_PEND[7:0]**). The FHost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_CLR** register. The raw and masked interrupt status may be read by reading the **CPDMA_FH_INTSTAT_RAW** and **CPDMA_FH_INTSTAT_MASKED** registers respectively. When each packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel **CPDMA_FH(0..7)_CP** completion pointer register. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated Fhost Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA and if the two values are equal then the interrupt is removed, otherwise the interrupt

remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

9.4.5 Media Independent Interfaces (XGMII/GMII)

For the purposes of this document, Ethernet transmit is egress and Ethernet receive is ingress.

9.4.5.1 Receive Control

Data received from the PHY is interpreted and forwarded by the MAC into the switch. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

9.4.5.1.1 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):
1. An Inter-Packet Gap (IPG).
2. A seven octet preamble (all octets 0x55).
3. A one octet start frame delimiter (0x5d).

9.4.5.1.2 Received Frame Classification

Received frames are proper (good) frames if they are between 64 and **PN_RX_MAXLEN** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **PN_RX_MAXLEN** register. The **PN_RX_MAXLEN** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are runt frames. Short frames with CRC, code, or alignment errors are fragment frames. If **RX_CSF_EN** in **PN_MAC_CONTROL** is set, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If **RX_CSF_EN** and **RX_CEF_EN** in **PN_MAC_CONTROL** are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain **PN_RX_MAXLEN** number of bytes transferred to memory (if **RX_CEF_EN** = 1). Examples with **PN_RX_MAXLEN** = 1518 is below:
- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.
- If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

9.4.5.2 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet in half-duplex mode. If the collision was late (after the first 64 bytes have been transmitted) then the collision is ignored. If the collision is not late, then

the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

9.4.5.2.1 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **TX_PACE** bit in the **PN_MAC_CONTROL** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non-zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

9.4.5.2.2 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **MCRS** is de-asserted within approximately 48 bit times of **MTXEN** being de-asserted, then 96 bit times is measured from **MTXEN**. If the frame suffered a collision, or if **MCRS** is not de-asserted until more than approximately 48 bit times after **MTXEN** is de-asserted, then 96 bit times (approximately, but not less) is measured from **MCRS**.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the **TX_SHORT_GAP_ENABLE** bit each **PN_MAC_CONTROL** register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The **GAP_THRESH** register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the **GAP_THRESH** value then short gap is triggered.

9.4.5.2.3 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **PN_MAC_TX_GAP** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

9.4.5.2.4 Back Off

The Ethernet Mac implements the 802.3 binary exponential back-off algorithm for half-duplex based collisions.

9.4.5.3 Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**SOFT** and **FREE** in the **PN_MAC_EMCONTROL** register)allow Mac operation to be suspended. When the emulation suspend state is entered, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals. Table 9-7 shows the operations of emulation control input and register bits.

Table 9-7. Emulation Control Input and Register Bits

TBEMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

9.4.5.4 Command IDLE

The **CMD_IDLE** bit in the **PN_MAC_CONTROL** register allows MAC operation to be suspended by software. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored (dropped without any processing or statistics). Commanded idle is similar in operation to emulation control and hardware clock stop.

9.4.6 CPSW_2G

The CPSW_2G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_2G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_2G is shown in Figure 9-6.

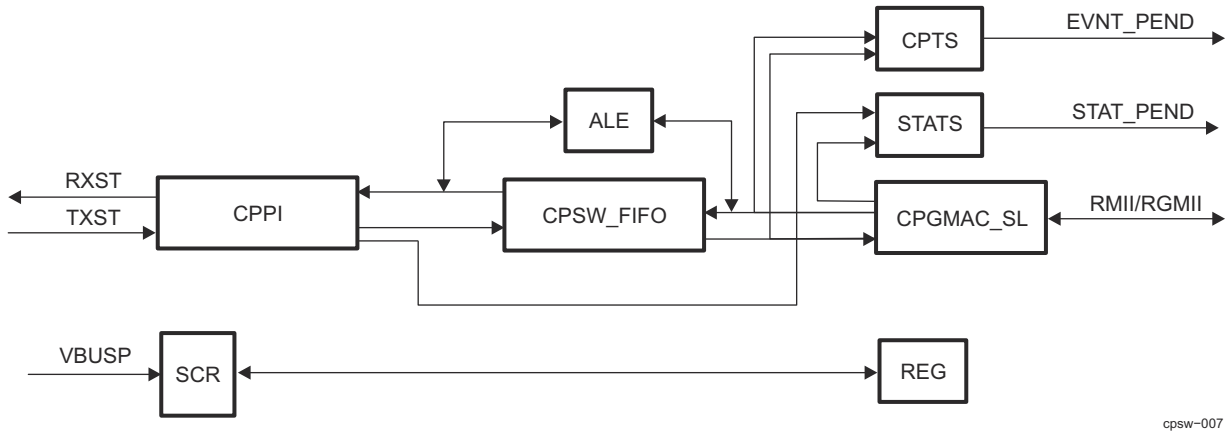

Figure 9-6. CPSW_2G Block Diagram

9.4.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE bit in the ALE_CONTROL_REG register is set. All packets are dropped when the ENABLE bit is cleared to 0.

9.4.6.1.1 Error Handling

In normal operation, the Ethernet port is configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the PN_MAC_CONTROL_REG configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

9.4.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the BYPASS bit in the ALE_CONTROL_REG register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

9.4.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the enable_oui_deny bit in the ALE_CONTROL register. When in OUI deny mode, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches with a supervisory table entry. (Non-matching OUI source address broadcast/multicast packets will be dropped to the host unless the packet destination address is entered into the table with the super bit set. Non-matching OUI source address unicast packets will be dropped to the host unless the unicast destination address is in the table with block and Secure both set). When enable_oui_deny is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. (Broadcast packets matching the OUI source address will be dropped to the host unless the broadcast destination address is entered into the table with the super bit set. Unicast packets matching the OUI source address will be dropped to the host unless the unicast destination address is in the table with block and Secure both set)

9.4.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. The events specified through the CPSW_ALE_STAT_DIAG[3-0] STAT_DIAG field are individually counted in CPSW per port statistics counters.

9.4.6.1.5 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwaded for special purposes.

9.4.6.1.6 ALE Lookup Table Entry Definitions

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 9-8. Learned Address Control Bits

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40.** (1:Multicast, 0:Unicast)

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**(1:Multicast, 0:Unicast)

9.4.6.1.6.1 Free Table Entry

Table 9-9. Free (Unused) Address Table Entry Bit Values

70:62	61:60	59:0
Reserved	ENTRY_TYPE (00)	Reserved

9.4.6.1.6.2 Multicast Address Table Entry (Bit 40==1)

Table 9-10. Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	IgnoreMbits	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

IgnoreMbits

Ignore Multicast Bits - Indication that the Multicast Address has ignored bits.

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

9.4.6.1.6.3 VLAN/Multicast Address Table Entry (Bit 40==1)

Table 9-11. VLAN/Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0

Table 9-11. VLAN/Multicast Address Table Entry Bit Values (continued)

Reseved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

9.4.6.1.6.4 Unicast Address Table Entry (Bit 40==0)

Table 9-12. Unicast Address Table Entry Bit Values

70:68	67	66	65	64	63:62	61:60	59:48	47:0
Reseved	TRUNK	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_ADDRESS

Trunk

Trunk Indicator -

0 - the port bits in the entry are the port number

1 - the port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

9.4.6.1.6.5 OUI Unicast Address Table Entry

Table 9-13. OUI Unicast Address Table Entry Bit Values

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

9.4.6.1.6.6 VLAN/Unicast Address Table Entry (Bit 40==0)

Table 9-14. Unicast Address Table Entry Bit Values

70:68	67	66	65	64	63:62	61:60	59:48	47:0
Reseved	TRUNK	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Trunk

Trunk Indicator -

0 - the port bits in the entry are the port number

1 - the port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

9.4.6.1.6.7 VLAN Table Entry

Table 9-15. Inner VLAN Table Entry

70:68	67:66	65	64:62	61:60	59:48	47	46:44	43	42:26	25:24	23	22:20	19	18:2	1:0
Resvd	NoLrnMsk	Ingress Chk	000	10	iVLANID	Resvd	RegIdx	NoFrag	Reserved	fwdutag	Reserved	UregIdx	LmtNxtHdr	Reserved	Member

Table 9-16. Outer VLAN Table Entry

70:68	67:66	65	64:62	61:60	59:48	47	46:44	43	42:26	25:24	23	22:20	19	18:2	1:0
Resvd	NoLrn Msk	Ingress Chk	010	10	oVLAN ID	Resvd	RegIdx	NoFrag	Reserved	fwdutag	Reserved	UregIdx	LmtNxt Hdr	Reserved	Member

Member

VLAN Member list - This field indicates which port(s) are a member of the associated VLAN.

LmtNxtHdr

VLAN Limit Next Header Control - Causes frames to be dropped if the Protocol/Nxt Header does not match the ALE_NXT_HDR register values

UregIdx

VLAN Unregister Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the unregistered multicast flood mask.

fwdutag

VLAN Forward Untagged Egress - Causes the packet VLAN tag to be removed on egress for the specified port(s).

NoFrag

LAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

RegIdx

VLAN Registered Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the registered multicast flood mask.

iVLANID

Inner VLAN ID - This is the 12-bit Inner VLAN ID, normally referred to as C-VLANID

oVLANID

Outer VLAN ID - This is the 12-bit Outer VLAN ID, normally referred to as S-VLANID

IngressChk

VLAN Ingress Check - When set, if the receive port is not a member of this VLAN then the packet is dropped. This is similar to the vid_ingress_check bit in the ale_port_control register except this check is for this VLAN only (not all VLANs).

NoLrnMsk

VLAN No Learn Mask - When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

Table 9-17. IPv4 Table Entry

70	69:65	64:62	61:60	59:32	31:0
Resvd	IgnBits	110	10	Reserved	IPv4Adr

Table 9-18. IPv6 Table Entry High

70:64	63	62	61:60	59:0
IgnBits	Resvd	1	10	IPv6Adr[127:68]

Table 9-19. IPv6 Table Entry Low

70:63	62	61:60	59:0
IPv6Adr[67:60]	1	10	IPv6Adr[59:0]

IgnBits

Inore Bits - Indicates the number of lower address bits (IPv4 or IPv6) to be ignored starting at bit zero. Ignored bits must be zero value in the table entry

9.4.6.1.7 ALE Policing and Classification

The ALE has a number of configurable policer engines. Each policer engine can be used for classification and or policing. Policing is an extension of the classifier function that allows for color marking and rate limiting due to classifier bandwidth measurement thresholds. Any policer engine can be used for classification alone by not using the bandwidth limiting thresholds. The policers_div_8 field in the ALE_Status register indicates the number of policers available to be used for classification or policing.

Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

ALE Policing

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the committed information rate (CIR) counter and the second counter is the peak information rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

CIR policing rate in Mbit/s = ((ALE frequency in Mhz) * cir_idle_inc_val) / 32768

PIR policing rate in Mbit/s = ((ALE frequency in Mhz) * pir_idle_inc_val) / 32768

Each policer has 10 different match operations (see below Classification). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

9.4.6.1.7.1 ALE Classification

Each policer can be enabled to classify on one or more of any of the below packet fields for classification or policing. All but Port and Priority are index references to the ALE table entries.

- Port or Trunk Group Number

- Priority extracted from VLAN, mapped from DSCP if enabled or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID - S-VLANID
- Inner VLANID - C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6

Multiple classifiers can match on a single packet. For example a classifier can be enabled to match on priority while another classifier could match on IP address. The ALE will return to the switch the highest classifier entries thread ID that matched with an enabled thread ID number. This could be used to further host routing of the packet.

9.4.6.1.7.1.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW_ALE_THREAD_DEF_REG, CPSW_ALE_THREAD_CTL_REG and CPSW_ALE_THREAD_VAL_REG). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREAD_CTL_REG register allows the CPSW_ALE_THREAD_VAL_REG register contents to be written to the selected classifier. There is a single CPSW_ALE_THREAD_DEF_REG that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

9.4.6.1.8 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

Destination port mirroring allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR_DP=A, MIRROR_DEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Source port mirroring allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port.(MIRROR_SP=1h in the ALE_PORTn_CONTROL register, MIRROR_SEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Table entry mirroring allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR_MIDX=C, MIRROR_MEN=1h, MIRROR_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The

packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in ALE_CONTROL, ALE_CONTROL2 and the port control registers.

- MIRROR_DP - The destination port that will have its traffic mirrored (ALE_CONTROL_REG register).
- MIRROR_TOP - The port to which mirrored traffic is sent (ALE_CONTROL_REG register).
- MIRROR_MEN - The enable for mirroring traffic that matches a supported lookup table entry (ALE_CONTROL_REG register).
- MIRROR_DEN - The Enable for destination port mirroring (ALE_CONTROL_REG register).
- MIRROR_SEN - The Enable for source port mirroring (ALE_CONTROL_REG register).
- MIRROR_MIDX - The index of a lookup table entry that will be mirrored ALE_CONTROL2_REG register).
- Px_MIRROR_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (ALE_PORTn_CONTROL register).

9.4.6.1.9 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the ALE_CONTROL2_REG register and in each ALE ALE_PORTn_CONTROL_REG register:

- TRK_EN_DST - Enable destination address hashing for trunk port calculation.
- TRK_EN_SRC - Enable source address hashing for trunk port calculation.
- TRK_EN_PRI - Enable priority hashing for trunk port calculation.
- TRK_EN_VLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK_EN_SIP - Enable source IP address hashing for trunk port calculation.
- TRK_EN_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK_BASE - Hashing formula starting value and test port offset.
- TRUNK_EN - Enable this port as a trunk group
- TRUNK_NUMBER - Trunk group number defines this port as a member of a particular trunk group.

9.4.6.1.10 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See P0_RX_DSCP_MAP_REG and PN_RX_DSCP_MAP_REG registers in the Register Manual section for DSCP mapping.

9.4.6.1.11 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, *VLAN_Unaware Lookup*, and *Egress.*

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST_FWD_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set in the CPSW_PN_MAC_CONTROL_REG register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW PN_MAC_CONTROL_REG register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

9.4.6.1.11.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx PORT_STATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet
if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not RATE_LIMIT_TX) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements • Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet

if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode)) then discard the packet

If (VLAN_Unaware)
CPSW_ALE_FORCE_UNTAGGED_EGRESS_REG = “000000”

if (Broadcast packet) then use found VLAN_MEMMBER_LIST and goto Egress process

9.4.6.1.11.4 Egress Process

Condition and action
Clear Rx port from portmask (don’t send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask

if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (RATE_LIMIT_TX)) then if (not SUPER) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

9.4.6.1.11.5 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

9.4.6.1.11.5.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (DROP_UNTAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown VLAN_MEMMBER_LIST = “000”)) then do not learn address
if ((VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VID))) then learn address without VLAN

9.4.6.1.11.5.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (DROP_UNTAGGED)) then do not update address

if ((VLAN_AWARE) and (VLAN not found) and (unknown VLAN_MEMMBER_LIST = “000”)) then do not update address
if ((VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

9.4.6.1.11.5.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched

9.4.6.2 CPPI CPDMA Host Interface

9.4.6.2.1 Functional Operation

For legacy reasons this document uses FHost (“cpsw ingress **F**rom **Host**”) interchangeably with host receive and THost (“cpsw egress **T**o **Host**”) interchangeably with host transmit.

Host Software sends and receives network frames via the CPDMA CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data from the host to Ethernet and free buffer queues available for packet data from Ethernet to the host.

After reset, initialization, and configuration the host may initiate CPDMA host interface operations. FHost DMA operations (from host to Ethernet) are initiated by host writes to the appropriate FHost channel head descriptor pointer. The FHost DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol and proceeds with packet operations. The DMA controller fetches the packet data in 64-byte (maximum) bursts.

Host CPDMA THost operations are initiated by host writes to the appropriate THost channel head descriptor pointer after host initialization and configuration. The THost DMA controller writes Ethernet received packet data to external host memory in accordance with CPPI 3.0 protocol.

9.4.6.2.2 THost CPDMA Interface

The THost DMA (Ethernet to host) is an eight channel CPPI 3.0 compliant interface. Each priority/channel (priority and channel are used interchangeably) has a single queue for frame reception.

9.4.6.2.2.1 THost CPDMA Host Configuration

To configure the CPDMA for THost operations the host must perform the following:

- Initialize the CPDMA_TH(0..7)_HDP Registers to zero.
- Enable the desired THost interrupts in the CPDMA_TH_INTSTAT_SET register.
- Write the CPDMA_TH_BUFFER_OFFSET register value.
- Setup the channel(s) buffer descriptors in host memory as required by CPPI.
- Enable the CPDMA controller by setting the TH_EN bit in the CPDMA_TH_CONTROL register.

9.4.6.2.2.2 THost CPDMA Buffer Descriptors

A THost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 9-20. THost Buffer Descriptor format

Word Offset	Bit fields																													
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	next descriptor pointer																															
	buffer pointer																															
	reserved					buffer offset											reserved					buffer length									
	sop	eop	ownership	eoq	teardown_complete	passed_crc	long	short	mac_ctl	overrun	pkt_err	vlan_encap	from_port				ts_encap	memory_protect_err	crc_type	checksum_encap	reserved	packet length									

Field	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next_descriptor_pointer**.
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**.
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. The buffer offset is reduced to 12-bits. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the **buffer_offset** with the value from the **CPDMA_TH_BUFFER_OFFSET** register value. The host initializes the **buffer_offset** to zero for free buffers. The **buffer_length** must be greater than the **CPDMA_TH_BUFFER_OFFSET** register value. The buffer offset is valid only on **sop**.
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. The buffer length is reduced to 12-bits. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the **buffer_length**, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The **buffer_length** must be greater than zero.
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. The port sets the **sop** bit. 0 - Not start of packet buffer 1 - Start of packet buffer

Field	Description
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. The port sets the **eop** bit. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on **sop**. This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port
eoq	End Of Queue - Set by the port to indicate that the RX queue empty condition exists. This bit is valid only on **eop**. The port determines the end of queue condition by a zero **next_descriptor_pointer**. 0 – The RX queue has more buffers available for reception. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.
teardown_complete	Teardown Complete – Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on **sop**. 0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.
passed_crc	Passed CRC – Set by the port to indicate that the CRC was passed with the data. The **Packet_Length** includes the CRC bytes. The **passed_crc** bit is valid only on SOP. The **p0_tx_crc_remove** bit in the **CPDMA_Control** register determines if CPPI THost packets have a CRC included or not.
long	Jabber Frame – Indicates that the frame is a jabber frame and was not discarded because **rx_cef_en** was set in the ingress port **Pn_MAC_Control** register. Valid only on SOP.
short	Fragment Frame – Indicates that the frame is a fragment and was not discarded because **rx_cef_en** was set in the ingress port **Pn_MAC_Control** register. Valid only on SOP.
mac_ctl	Control Frame – Indicates that the frame is a MAC control frame and was not discarded because the **rx_cmf_en** bit was set inthe ingress port **Pn_Mac_Control** register. Valid only on SOP.
overrun	Overrun – Set by the port to indicate that the frame reception was aborted due to THost buffer overrun. This bit is valid only on SOP. 0 – no overrun occurred on the packet 1 – The packet was aborted due to overrun
pkt_error	Packet Contained Error on Ethernet Ingress. This field is valid on SOP. – 00 – no error 01 – CRC error on ingress 10 – Code error on ingress 11 – align error on ingress
vlan_encap	VLAN Encapsulated Packet – Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the **CPDMA_Control** register **th_vlan_encap** bit. If both **th_vlan_encap** and **th_ts_encap** are set then the VLAN is first. This encapsulated word also contains the ALE classification FLOW (threadval). This bit is valid on SOP.
ts_encap	Timestamp Encapsulated Packet – Indicates when set that the packet data contains a 64-bit timestamp (two 32-bit words with the lower 32-bit word first) that is included in the packet byte count. This field is set by the port to be the value of the **CPDMA_Control** register **th_ts_encap** bit. If both **th_vlan_encap** and **thost_ts_encap** are set then the VLAN is first. This bit is valid on SOP.
chksum_encap	Checksum Encapsulated Packet – Indicates when set that the packet data contains 4-bytes of THost checksum information at the end of the packet (last 4 bytes). The packet length includes the checksum bytes.
memory_protect_error	Memory Protect Error – An error was detected in the packet Castignoli protect CRC. The Packet should be dropped by the host.

Field	Description
from_port	From Port – Indicates the Ethernet ingress port number. This field is valid only on SOP.
packet_length	Packet Length – Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP.

9.4.6.2.2.3 THost CPDMA Channel Teardown

The host commands a THost channel teardown by writing the channel number to the **CPDMA_TH_TEARDOWN** register. When a teardown command is issued to an enabled THost channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next THost buffer descriptor in the chain if there is one.
- The channel head descriptor pointer will be cleared to zero
- A THost interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

9.4.6.2.3 FHost CPDMA Interface

The FHost DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by **FH_PTYPE** in the **CPDMA_Control** register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the TX_VBUSP interface in 64-byte maximum burst transfers. Any packet can be designated by the host to generate a host timesync event on Ethernet egress by setting the **host_event** bit in the packet buffer descriptor.

9.4.6.2.3.1 FHost CPDMA Host Configuration

To configure the CPDMA for FHost operations the host must do the following:

- Initialize the CPDMA_FH(0..7)_HDP registers to a zero value.
- Enable the desired ingress interrupts in the CPDMA_FH_INTSTAT_MASKED_SET register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the ingress operation as desired in the CPDMA_FH_Control register.
- Write the appropriate CPDMA_FH(0..7)_HDP registers with the appropriate values to start packet operations.

9.4.6.2.3.2 FHost CPDMA Buffer Descriptors

An FHost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 9-21. FHost Buffer Descriptor format

Word Offset	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	next descriptor pointer																															
1	buffer pointer																															
2	buffer offset																buffer length															

Table 9-21. FHost Buffer Descriptor format (continued)

3	sop	eop	ownership	eoq	teardown_complete	pass_crc	crc_type	reserved	to_port_en	to_port	host_event	chksum_encap	reserved	packet_length

Name	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the FHost queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next_descriptor_pointer**.
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**.
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the **buffer_offset** value (which may be zero to the buffer length minus 1). Valid only on **sop**.
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the **buffer_length.** The **buffer_length** must be greater than zero.
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. 0 - Not start of packet buffer 1 - Start of packet buffer
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on **sop**. This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port
eoq	End Of Queue - Set by the port to indicate that all packets in the queue have been transferred and the FHost queue is empty. End of queue is determined by the port when the **next_descriptor_pointer** is zero on an **eop** buffer. This bit is valid only on **eop**. 0 - The FHost queue has more packets to transfer. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Name	Description
teardown_complete	Teardown Complete – Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on **sop**. 0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.
crc_type	CRC Type – 0 – Ethernet CRC 1 – Castignoli CRC (if **$CPPI_Cast** = 1)
pass_crc	Pass CRC – Valid only on SOP 0 – A CRC is not included with the packet data. The Ethernet port(s) will generate the CRC on Ethernet egress. A CRC (or placeholder) at the end of the data is allowed, but not required, and the **buffer_count** and **packet_length** fields should not include the CRC bytes if they are present. 1 – A CRC is included with the host packet data. The **packet_length** and **buffer_count** fields should include the four CRC bytes. The host supplied CRC should be in the last four bytes of the data.
to_port	To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode. 1 – Send the packet to port 1 if **to_port_en** is asserted. 2 – Send the packet to port 2 if **to_port_en** is asserted.
to_port_en	To Port Enable – Indicates when set that the packet is a directed packet to be sent to the **to_port** field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP. 0 – not a directed packet 1 – directed packet
host_event	Host Timesync Event – Generate a host timesync event on Ethernet egress. The upper 28-bits of the packet SOP buffer descriptor address are the domain[7:0], message_type[3:0], and sequence_id[15:0] in that order. 0 – The packet will not generate a host event on Ethernet egress 1 – The packet will generate a host event on Ethernet egress
chksum_encap	Checksum Encapsulated Packet – Indicates when set that the packet data contains 4-bytes of FHost checksum information at the start of the packet (first 4 bytes). The packet length includes the checksum bytes.
packet_length	Packet Length – Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

9.4.6.2.3.3 FHost CPDMA Channel Teardown

The host commands a FHost channel teardown by writing the channel number to the **CPDMA_FH_Teardown** register. When a teardown command is issued to an enabled FHost channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due

to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

9.4.6.2.4 VLAN Aware Mode

The CPSW is in VLAN aware mode when the CPSW Control register **vlan_aware** bit is set. In VLAN aware mode port 0 THost packets may or may not be VLAN encapsulated depending on the CPDMA_Control register **th_vlan_encap** bit. The header packet VLAN is generated as described in later sections of this specification. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set **vlan_encap** bit in the packet buffer descriptor. The VLAN encapsulation header is included in the packet length and has the below format:

32-bit VLAN Header Encapsulation Word																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
hdr_pkt_priority			hdr_pkt_cfi	hdr_pkt_vid												flow						pkt_type		reserved							

Field	Description
hdr_pkt_priority	Header Packet VLAN priority (7 is highest priority)
hrd_pkt_cfi	Header Packet VLAN CFI bit. The
hdr_pkt_vid	Header Packet VLAN ID.
flow	FLOW – A nonzero value indicates that the ALE matched a classifier with the **flow** (threadval).
pkt_type	Packet Type – Indicates whether the packet is a VLAN tagged, priority tagged or non-tagged packet. 00 – VLAN tagged packet 01 – reserved 10 – priority tagged packet 11 – non-tagged packet

9.4.6.2.5 VLAN Unaware Mode

The CPSW is in VLAN unaware mode when the CPSW Control register **vlan_aware** bit is cleared. Port 0 THost packets (egress) may or may not be VLAN encapsulated depending on the CPSW Control register **th_vlan_encap** bit.

9.4.6.2.6 CPDMA Command IDLE

The **cmd_idle** bit in the **CPDMA_Control** register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing THost and FHost frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For FHost, any

frame in process will be completed. For THost, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

9.4.6.2.7 CPDMA CPPI 3.0 Interface Bandwidth

The HOST CPPI 3.0 FHost and THost interfaces are capable of supporting linerate on the Ethernet ports provided that the clock frequency is sufficient, and provided that the Host master VBUSP read/write latency is low.

9.4.7 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP and TCP over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the **s_cn_switch** bit must be set for the **vlan_ltype_outer** to be supported. Because it's not now a dual vlan switch, A C-switch cannot have an outer VLAN. An S-switch can have an inner, an outer, or both (outer then inner).

9.4.7.1 CPPI THost Checksum Offload

When **p0_tx_chksum_en** is set in **P0_Control**, IPV4 and IPV6 UDP and TCP packets received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The EOP Thost buffer descriptor bit **chksum_encap** indicates whether or not the THost checksum information is included with the THost egress packet or not. If the checksum information is included in the packet the **packet_length** includes the four checksum information bytes. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLANs. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host (no checksum information with the error packet).

9.4.7.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

9.4.7.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

9.4.7.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.

- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

9.4.7.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

9.4.7.1.5 THost Checksum Encapsulation Word

The 4-byte checksum encapsulation word is included as the last 4-bytes of the THost packet data when EOP buffer descriptor **chksum_encap** is set. The **packet_length** includes the four encapsulation bytes.

THost Checksum Encapsulation Word																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved											ipv4_valid	ipv6_valid	tcp_udp_n	fragment	checksum_error	checksum_add																

Field	Name	Description
31:21	reserved	
20	ipv4_valid	IPV4 Valid – An IPV4 TCP or UDP packet was detected
19	**ipv6_valid**	IPV6 Valid – An IPV6 TCP or UDP Packet was detected
18	tcp_udp_n	TCP or UDP packet – Valid only when either the **ipv4_valid** or **ipv6_valid** bits are set. 0 – Indicates UDP packet was detected. 1 – Indicates TCP packet was detected.
17	fragment	Fragment – Indicates that an IP fragment was detected. Valid only when when either the **ipv4_valid** or **ipv6_valid** bits are set.
16	checksum_error	Checksum Error detected. Valid only when either the **ipv4_valid** or **ipv6_valid** bits are set.

Field	Name	Description
15:0	checksum_add	Checksum Add Value – This is the value that was summed during the checksum computation. This value is 0xffff for IPV4/6 UDP/TCP packets with no checksum error.

9.4.7.2 CPPI FHost Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The **rx_chksum_en** bit in the **P0_CONTROL** register must be set for receive checksum operation to be enabled. When enabled and when the **chksum_encap** SOP FHost buffer descriptor is set, the first four packet bytes contain the checksum information which determines how the checksum is calculated. The **checksum_result** field determines where the checksum is inserted in the egress packet. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

9.4.7.2.1 FHost Checksum Encapsulation Word

The 4-byte FHost checksum encapsulation word is included as the first four bytes of the packet data when **chksum_encap** is set in the FHost SOP buffer descriptor. The **packet_length** includes the four checksum encapsulation bytes.

FHost Checksum Encapsulation Word																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
checksum_result								checksum_start_byte								chksum_inv	reserved	checksum_bytecount													

Field	Name	Description
31:24	**checksum_result**	Checksum Result Byte Location – This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is byte 1 (not byte zero).
23:16	**checksum_start_byte**	Checksum Start Byte – This is the packet byte number to start the checksum calculation on. The first packet byte is byte 1.
15	**chksum_inv**	Checksum Invert Zero – When set, a zero checksum value will be inverted and sent as 0xffff.
14	reserved	
13:0	checksum_bytecount	Checksum Byte Count – This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

9.4.8 Egress Packet Operations

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations. **Intra**VLAN processing either adds, removes, or replaces VLAN information or does nothing. **Inter**VLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, OAM loopback allows the loopback packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

9.4.8.1 IntraVLAN Processing

All ports (Ethernet and CPPI) process packet VLAN's identically on cpsw egress. CPSW ingress packet VLAN's are not modified on ingress regardless of the port type or VLAN mode.

9.4.8.1.1 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is cleared to zero. In VLAN unaware mode, transmit (egress) packets are not modified on egress (no IntraVLAN processing).

9.4.8.1.2 VLAN Aware Mode

An egress port is operating in the VLAN aware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is set. In VLAN aware mode, transmitted packet data is changed depending on the packet type, the packet priority (**pkt_pri**), and the VLAN information as shown in the below tables. The **vlan_ltype_sel** value is selected by the **s_cn_switch** bit in the **CPSW_Control** register and is either the **vlan_ltype_inner** (0x8100 default)or **vlan_ltype_outer** (0x88a8 default) value. The **force_untagged_egress** bit comes from the Address Lookup Engine (ALE) lookup:

VLAN Aware Mode Non Tagged Transmit Packet Processing	
Insert VLAN Case	Non-tagged input packets have the header packet VLAN inserted when the **force_untagged_egress** bit in the transmit packet header (from the ALE) is de-asserted. **The vlan_ltype_sel** length/type is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the **hdr_pkt_pri**, the **hdr_pkt_cfi**,and the **hdr_pkt_vid**. The packet length/type field is output four bytes later than it is input and is not removed or replaced.
No Change Case	Non tagged input packets are output unchanged when the **force_untagged_egress** transmit packet header bit is asserted.

VLAN Aware Mode Priority Tagged Transmit Packet Processing	
Replace PRI/VID Case	Priority tagged input packets have the packet VLAN ID (VID) and the packet priority replaced with the **hdr_pkt_vid** and the **hdr_pkt_pri** when the transmit packet header **force_untagged_egress** bit (from the ALE) is de-asserted.
Remove VLAN Case	Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header **force_untagged_egress** bit (from the ALE) is asserted. **The vlan_ltype_sel** length/type is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on.

VLAN Aware Mode VLAN Tagged Transmit Packet Processing	
Replace PRI Case	VLAN tagged input packets are output with the packet priority replaced with the **hdr_pkt_pri** when the transmit packet header **force_untagged_egress** bit is de-asserted.
Remove VLAN Case	VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header **force_untagged_egress** bit is asserted. **The vlan_ltype_sel** length/type is removed as is the two byte packet VLAN. Input 64-67 byte VLAN tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte VLAN tagged packets use all four input CRC bytes as pad, input 65-byte VLAN tagged packets use three of the input CRC bytes as pad, and so on. The output CRC is generated when the VLAN is removed.

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (Ethernet and CPPI port egress) if the VLAN is to be removed on egress.

9.4.8.2 ALE Egress Opcode Operations

The Address Lookup Engine (ALE) can be setup to pass an 8-bit opcode to the destination port(s) egress packet processing logic. InterVLAN routing and OAM Source/Destination address swap are supported operation codes as shown in the below table.

ALE Egress OP Code	Egress Operation
0x00	No egress opcode (NOP)
0x01	InterVLAN (route) opcode 1
0x02	InterVLAN (route) opcode 2
0x03	InterVLAN (route) opcode 3
0x04	InterVLAN (route) opcode 4
0x05-0xFE	reserved
0xFF	DA/SA Swap opcode

9.4.8.2.1 InterVLAN Routing

The CPSW is capable of InterVLAN routing with a limited number of routes (InterVLAN opcode 1 to 4). The Address Lookup Engine (ALE) determines an InterVLAN egress opcode for each packet to be VLAN routed via a classifier/policer configured for the route. Non VLAN routed packets do not have an InterVLAN (egress) opcode. The ALE classifier/policer can use the ingress packet destination address, source address, VLAN, IPDA, and/or IPSA to determine if a packet is to be VLAN routed or not. If a packet is to be routed, then the InterVLAN opcode is used on Ethernet packet egress with a total of 4 available VLAN routes (opcodes) per egress port. Each InterVLAN routing opcode contains the below fields in the opcode's associated **Pn_InterVLAN_OPX_x** registers (where **x** = A to D):

Field	Description
da[47:0]	Destination Address
sa[47:0]	Source Address
vid[11:0]	VLAN ID
replace_da_sa	When set, the routed packet Destination Address is replaced with **da[47:0]** and the packet Source Address is replaced with **sa[47:0]** from InterVLAN opcode x (the selected egress opcode).
replace_vid	When set, Replace the packet VLAN ID with **vid[11:0]** from InterVLAN opcode x (the selected egress opcode).
dest_force_untagged_egress	Remove the VLAN on the egress routed packet when set (associated with the destination VLAN). **Note** The ALE **force_untagged_egress** bit from the ALE is for the source VLAN and is ignored for an InterVLAN routed packet. On InterVLAN routed packets this bit is used because it is associated with the destination vlan. This **dest_force_untagged_egress** bit would not be set by software if the destination VLAN is different from the port VLAN since that might cause leaky VLANs.
decrement_ttl	When set, the Time To Live (TTL) field in the header is decremented: • IPV4 – Decrement the TTL byte and update the Header Checksum • IPV6 – Decrement the Hop Limit. note: The ALE will send any IPv4/6 packet with a zero or one TTL field to the host. When this bit is cleared the TTL/Hop Limit fields are not checked or modified.

9.4.8.2.2 OAM Source and Destination Address Swap

To facilitate OAM or generic testing, the ALE can be configured to loopback packets from Ethernet receive to Ethernet Transmit. Packets destined for OAM loopback have only the source address and destination addresses swapped. No other egress processing is performed. The ALE does not perform lookups for a port in OAM loopback mode, but directed packets are transferred as normal.

9.4.9 IEEE 1588 Clock Synchronization Support

The CPSW supports 1588 clock synchronization (annex D, annex E, and annex F). Ethernet GMII Transmit and receive time sync operation are supported. Time sync is double-step on egress but may be single-step on ingress.

9.4.9.1 1588 Receive (Ingress) Packet Operation

There are two CPSW egress time sync interfaces for each Ethernet port. The first is the TS_RX_MII interface and the second is the TS_RX_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW that control time sync operations in addition to the registers in the CPTS module. The TS_RX_MII interface issues a record signal along with a handle to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS_RX_MII to the TS_RX_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received. The TS_RX_MII logic is in the receive wireside clock domain. There is no decode logic in the TS_RX_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS_RX_DEC block along with the packet. The packet decode is performed in the TS_RX_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS_RX_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_RX_DEC interface. If the packet is determined to be a time sync event packet and if the ALE did not drop the packet (the packet was to be sent to at least one port), then the ALE lookup is overridden and the packet is forced only to the host. The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). A packet is determined to be a receive event packet under the following conditions.

Note

TS_RX_DEC and TS_RX_MII are internal interfaces that have no registers. They are included here for description purposes only.

9.4.9.1.1 Annex D (IPv4)

1. Receive annex D time sync is enabled (pn_ts_rx_annex_d_en is set in the Pn_TS_Ctl register).
2. One of the sequences below is true.
   - The first packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.
4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)

5. Byte 22 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_CTL_LTYPE2 register is zero, or byte 22 contains any value if ts_ttl_nonzero is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 30 through 33 contain:
   - Decimal 224.0.1.129 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.130 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.131 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.132 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.0.107 and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set

   Or:

   The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.
11. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.9.1.2 Annex E (IPv6)

1. Receive annex E time sync is enabled (pn_ts_rx_annex_e_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
   - The first packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype2 andts_rx_vlan_ltype2_en is set and the second packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 21 contains any value if ts_ttl_nonzero is set. Byte 21 is the TTL/HOP field.
6. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 38 through 53 contain:
   - FF0M:0:0:0:0:0:0:0181 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0182 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0183 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0184 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:006B and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set (all values above are 16-bit hex numbers with M is enabled in the ts_mcast_type_en field in the Pn_TS_Ctl2 register.

   Or:

   The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.
10. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.9.1.3 Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (ts_rx_annex_f_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.

- The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
- The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
- The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
- The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
- The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
- The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
- The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1
- The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set

3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
5. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.9.2 1588 Transmit Packet Operation

There are two CPSW transmit time sync interfaces for each Ethernet port. The first is the TS_TX_DEC interface and the second is the TS_TX_MII interface. Both interfaces are internal to the cpsw and are input to the CPTS module.

The TS_TX_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_TX_DEC interface (**pn_ts_tx_dec_evnt**, **pn_ts_tx_dec_hndl[3:0]**, **pn_ts_tx_dec_msg_type[3:0], pn_ts_tx_dec_seq_id[15:0]** and **pn_ts_rx_dec_domain[7:0]**). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS_TX_MII with an indication that the packet is a time sync event packet. Unlike receive; only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encrypt the packet. The encryption is after the decode function on transmit (egress). A packet is determined to be a transmit event packet under the following conditions.

9.4.9.2.1 Annex D (IPv4)

1. Transmit time sync is enabled (ts_tx_annex_d_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
   - The first packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set (PN_TS_VLAN_LTYPE register) and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en (PN_TS_CTL_REG) is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present then the byte numbers push down.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 22 contains any value if ts_ttl_nonzero bit is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The pn_ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and bytes 30 through 33 contain:
   - Decimal 224.0.1.129 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.130 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.131 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.132 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.0.107 and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set

   Or:

   The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_CTL_Ltype2 register is set, or
   - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_CTL_Ltype2 register is set.
9. The PTP message begins in byte 42 (this is offset 0).
10. The packet message type is enabled in ts_msg_type_en field in the Pn_TS_Ctl register.
11. The packet was sent by the host (port 0).

9.4.9.2.2 Annex E (IPv6)

1. Transmit annex E time sync is enabled (ts_tx_annex_e_en is set in the Pn_TS_Ctl register).
2. One of the sequences below is true.
   - The first packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches 0x86dd.
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 21 contains any value if ts_ttl_nonzero is set. Byte 21 is the TTL/HOP field.
6. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 38 through 53 contain:
   - FF0M:0:0:0:0:0:0:0181 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0182 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0183 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:0184 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - FF0M:0:0:0:0:0:0:006B and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set (all values above are 16-bit hex numbers with M is enabled in the ts_mcast_type_en field in the Pn_TS_Ctl2 register.

   Or:

   The pn_ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.
10. The packet was sent by the host (port 0).

9.4.9.2.3 Annex F (IEEE 802.3)

1. Transmit time sync is enabled (ts_tx_annex_f_en is set in the switch Pn_TS_Ctl register).

2. One of the sequences below is true.
   - The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
   - The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
3. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
4. The packet was sent by the host (port 0).

The TS_TX_MII interface issues a single clock record signal at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal along with a handle will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS_TX_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS_TX_DEC to the TS_TX_MII block at any given time. The handle value increments only on time sync event packets. The TS_TX_MII logic is in the transmit wireside clock domain.

Note

TS_TX_DEC and TS_TX_MII are internal interfaces that have no registers. They are included for description purposes only.

9.4.10 Rate Limiting (Traffic Shaping)

Rate-limit mode is intended to allow some CPPI ingress channels and some Ethernet transmit (switch egress) priorities to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on lower priority non rate-limited channels and FIFO priorities. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited Etherent ingress traffic can be dropped. For rate limited priorities, the configured transfer rate includes the committed information rate and the excess information rate. The excess information rate will only be attempted to be sent when there is no packet backlog on every priority that does not have the excess information rate enabled. The committed information rate will be sent regardless of network traffic as long as the configuration is not oversubscribed. The excess information rate will be sent only when network conditions allow.

9.4.10.1 CPPI Port Ingress Rate Limiting

Port 0 FHost operations can be configured to rate limit the packet data for each channel (priority). FHost has 8 priorities for QOS. There is a committed information rate (**P0_Pri_CIR**) and an excess information rate for each priority (**P0_Pri_EIR**). Rate limiting is enabled for a priority when the committed information rate for the

priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. No bulk priority will be enabled to send unless there are **tx_host_blks_rem** number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The “blocks remaining check” ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the ingress priority type must be fixed. Round-robin priority type is not allowed when rate-limiting is configured for any priority. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second for each priority is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate in Mbit/s = ((((Frequency in MHZ) * **P0_Pri_CIR**) / 32768) +

(((Frequency in MHZ) * **P0_PriX_EIR**) / 32768))

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 10Mbps on priority 7 would give the below:

10Mbps = ~ ((350 * 936) / 32768), at 350Mhz and **p0_pri7_cir** value = 936 (no excess information rate)

9.4.10.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (**Pn_PriX_CIR**) and an excess information rate for each priority (**Pn_PriX_EIR**). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

Priority Transfer rate in Mbit/s = ((((Frequency in MHZ) * **Pn_PriX_CIR**) / 32768) +

(((Frequency in MHZ) * **Pn_PriX_EIR**) / 32768))

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 100Mbps on priority 7 would give the below:

100Mbps = ~ ((350 * 9360) / 32768), at 350Mhz and **pn_pri7_cir** value = 9360, with no excess information rate.

9.4.11 Transmit Priority Escalation

Bulk (non rate limited) traffic can be escalated in order to preclude starvation of lower bulk traffic priorities from higher bulk traffic priorities. Escalation is configured and enabled in the **PTYPE** register with the **pn_ptype_esc** and **esc_pri_ld_val** fields. Escalation can be enabled with rate limited priorities. The rate limited priorities are on the upper priorities starting with priority 7 and going down(consecutively), and therefore, the escalated priorities are on the lower bulk priorities.

9.4.12 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

9.4.12.1 EST Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 msb's) and an 8-bit priority fetch allow (8 lsb's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and prempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (wire clear is performed with zero allow).
- EST can be used with or without premption. The pn_mac_prempt[7:0] value determines whether the priority is enabled on the express or prempt queue. Whether a priority is on the express or prempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the prempt queue unless preemption is configured, enabled, and verified - allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

9.4.12.2 EST Fetch RAM

- The EST fetch RAM is read/write in the CPSW configuration address space.
- Each Ethernet transmit port has 128 locations in the global EST fetch RAM.
  - Ethernet port 1 has EST fetch RAM addresses 0x000-0x1ff.
  - Ethernet port 2 has EST fetch RAM addresses 0x200-0x3ff, and so on.
- One buffer operation – When est_onebuf is set, the 128 port locations operate as one buffer. The est_bufact bit in Pn_FIFO_Status is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- Two buffer operation - When est_onebuf of PN_EST_CONTROL register is cleared there are two 64-location buffers with est_bufsel selecting the buffer to be used. When the buffer is switched by changing the est_bufsel value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the est_bufact bit in Pn_FIFO_Status. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port's address zero location is then read again at the beginning of the next cycle repeating the time interval packet operations.

9.4.12.3 EST Time Interval

- Each Ethernet port has an EST function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS_RCLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allow (8 lsb's of the fetch command from the EST fetch RAM) value is at the port's base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock delay allows the first fetch value to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when est_onebuf=0, and 128 maximum fetch values when est_onebuf=1.
- The next cycle start then causes the fetch to once again start at the port's address zero location.

9.4.12.4 EST Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in gigabit mode (pn_gig=1) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. There is no requirement that the packet end in the time interval. The actual packet transmission on the wire may carry over into the next fetch count - which is the reason for the wire clear time in a fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time. However, if a packet were enabled in a previous fetch allow there the packet could finish in the current time interval.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks (minimum of 16 fetch count).
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. However, packets that were started in the previous interval could still be on the wire. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch.
- EST Ram Configuration – The simplest EST configuration is for a single express packet on a single priority in the EST time interval. Ram Address 0 will be read at the start of each interval, the timed packet goes out in Ram Address 1 interval, and Ram Address 2 priorities are held for the duration of the cycle in this simple configuration.
  - Ram Address 0 – 0xD0000 (10/100 with 1518 max pkt length in previous allow)
    - This is a zero allow at the beginning of each cycle which clears the wire for the timed express packet in the next fetch. The zero allow time (0xD00 in this case) allows the wire to be cleared for the express packet. Setting this value lower might push out the timed express packet into the next interval. For a 2020 max packet size in the previous allow, this value should be 0x10F400. The number of clocks required for the zero allow is determined by the below equation.
      - Clocks in zero allow = Maximum ***Express*** packet length in previous allow (times 2 for 10/100) + decimal 292. (If preemption is configured and enabled then this minimum time is 0x100 if only prempt priorites are in the previous allow – which is not a normal case).
  - Ram Address 1 – 0x01080
    - This is a decimal 16 clock allow for the timed express packet on priority 7. The 16 clock allow value permits only a single packet to start in the time interval.
  - Ram Address 2 – 0x0007F
    - This is a zero fetch count that allows priorities 6 downto 0 for the duration of the EST time interval. This is the previous allow for the zero allow in Address 0 above.

9.4.12.5 EST Packet Fill

- Packet fill can (should) be configured and enabled to occur in the fetch count time associated with a fetched zero allow that preceeds a timed express packet. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch. Incorrect configuration might push out in time any express timed packet which indicates that the fill margin needs to be increased.
- Fill Configuration
  - The est_fill_margin value in Pn_EST_Control should be written with a 0x100 value.

- The est_prempt_comp value in Pn_EST_Control should be written with a 0x12 value (if IET is to be configured and enabled). This value times eight is the number of wireside clocks required to clear prempt packets off the wire at the end of a zero allow.
- The est_fill_en bit in Pn_EST_Control should be set.

9.4.12.6 EST Time Stamp

- EST can be configured to generate CPTS timestamp events for selected express traffic.
- EST timestamp events use the CPTS host event type (event_type=7). EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.
- EST Events (host events EVENT_n_REG) contain the below information:
  - Time Stamp of the selected express packet.
  - The event port_number indicates the transmit port number.
  - The event event_type is decimal 7 (host event).
  - The event message_type indicates the packet transmit hardware switch priority.
  - The event sequence_id upper nibble indicates the packet receive port number.
  - The event sequence_id lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence id rolls over to zero after 0xff (8-bits).
  - The event domain is the value from the est_ts_domain[8:0] register.
- When est_ts_en is set, timestamp events will be generated on selected express traffic.
- When est_ts_first is also set, events will be generated only on the first express packet in each time interval. If est_ts_onepri is also set then the event will only be on the first est_ts_pri express packet in the time interval. If est_ts_onepri is clear then the event will be generated on the first express packet in the time interval on any priority.
- When est_ts_first is clear, events will be generated on every express packet. If est_ts_onepri is set then the event will be generated on every est_ts_pri express packet. If est_ts_onepri is clear then event will be generated on every express packet on any priority.

9.4.12.7 EST Packets Per Priority – (N = 2 only)

With a MAC configuration (**N** = 2), the number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to **p0_rx_pkts_pri[7-0]**. The port 0 receive gap should then be enabled by setting the corresponding priority **rx_gap_en[7:0]**. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority than the **p0_rx_pkt_pri[7:0]** value has selected.

9.4.13 DSCP

The ALE can map DSCP field to priority prior to port trunking hashing and policing/classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See the Switch Port configuration for the registers describing DSCP mapping.

9.4.14 Packet Priority Handling

There are three priorities used inside the CPSW - the packet priority, the header packet priority, and the switch priority. The packet priority is the determined priority of the ingress packet. The header packet priorityis used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The switch prioritydetermines which of the eight FIFO priority queues the packet uses during egress.

The **vlan_ltype_sel** value below is selected by the **s_cn_switch** bit in the **CPSW_Control** register and is either the **vlan_ltype_inner** (0x8100 default) or **vlan_ltype_outer** (0x88a8 default) value.

9.4.14.1 Ethernet Port Ingress

Ethernet ingress packets have an ingress packet priority of 0 to 7 (with 7 being the highest priority). The packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the ingress packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and dscp_ipv4_en is set in Pn_Control, then the ingress packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in Pn_Control, then the ingress packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the ingress packet priority is the source (ingress) port priority taken from the port's Pn_Port_VLAN register.

The packet priority is mapped through the ingress port's associated "packet priority to header packet priority mapping register" (**pn_rx_pri_map**) to obtain the header packet priority (**hdr_pkt_pri**). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress. The header packet priority is mapped at each destination FIFO through the **pn_tx_pri_map** register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

9.4.14.2 CPPI Port FHost (Ingress)

FHost packets have a packet priority (0 to 7 with 7 being the highest priority). The FHost packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the FHost packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and p0_dscp_ipv4_en is set in P0_Control, then the FHost packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in P0_Control, then the FHost packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the FHost packet priority is the source port priority taken from P0_Port_VLAN.

The ingress packet priority is mapped through the port's associated "packet priority to header packet priority mapping register" (**p0_rx_pri_map**) to obtain the header packet priority. The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

For CPPI FHost packets, the destination port hardware switch priority is the below selected value remapped through **p0_rx_pri_map**:

1. If the FHost packet is priority tagged or vlan tagged:
   - If rx_remap_vlan is clear then the the destination hardware switch priority is the CPPI FHost channel number.
   - If rx_remap_vlan is set then the the destination hardware switch priority is the packet priority value. Port transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 FHost. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and **dscp_ipv4_en** is set in **P0_Control**:
   - If rx_remap_dscp_v4 is clear then the destination hardware switch priority is the CPPI ingress priority.
   - If rx_remap_dscp_v4 is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet). Port 1 transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
3. Else if the ingress packet has the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and **dscp_ipv6_en** is set in **CPPI_P0_Control**:

- If rx_remap_dscp_v6 is clear then the destination hardware switch priority is the CPPI ingress priority.
- If rx_remap_dscp_v6 is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet). Port 1 transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.

4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI ingress channel number.

9.4.14.3 CPPI Port THost (Egress)

If the **thost_ch_override** bit in **CPDMA_Control** is clear then the CPDMA packet THost channel number is the port 0 hardware switch priority. If **thost_ch_overide** is set, then for packets with a classification match the THost channel number is the lower three bits of the 6-bit address lookup engine classification match value (**threadval[2:0]** in ALE register **THREADMAPVAL**). The **flow** value in the VLAN encapsulation word is all 6 bits of the **threadval** for classifier matches regardless of the setting of **thost_ch_override** if the encapsulation word is transferred.

9.4.15 Packet CRC Handling

Every cpsw ingress packet on all ports is checked for CRC correctness. Each packet is then given an internally generated Castignoli CRC for transport through the cpsw to egress port(s). The internally generated Castignoli CRC protects the packet from end to end through the cpsw. Ingress Packets with CRC errors are handled as indicated below.

9.4.15.1 Ethernet Port Ingress

Ethernet ports check each ingress packet CRC for correctness in all modes/speeds. The port can check for either Ethernet CRC for correctness as determined by the **crc_type** bit in the **Mac_Control** register. Ethernet packets received with a CRC error are dropped at the receive port unless the receive port **rx_cef_en** bit is set. Error packets are sent only to the host port. For packets with Ethernet ingress errors sent to the host, the error is indicated in the host egress buffer descriptor and the original packet CRC bytes are kept for CPDMA THost.

9.4.15.2 Ethernet Port Egress

Ethernet ports transmit egress packets with the CRC type selected by the **crc_type** bit in the **Pn_Mac_Control** register regardless of the packet's ingress CRC type. On Ethernet egress, after passing through the switch, the internally generated Castignoli CRC is checked for correctness and if correct the packet is output with the generated selected output CRC type. If the internally generated CRC is incorrect, due either to a bit flip in a memory (or logic) or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the internally generated Castignoli CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

9.4.15.3 CPPI Port FHost

CPPI host port FHost packets can be passed in with or without a CRC. The FHost packet CRC type is indicated in the buffer descriptor word **crc_type** bit and can be Ethernet. The **p0_rx_pass_crc_err** bit in the **CPSW_Control** register determines if FHost packets with CRC errors are passed or dropped. Passed packets with CRC errors will be transmitted on Ethernet egress with a CRC error.

9.4.15.4 CPPI Port Egress (THost)

The **p0_tx_crc_remove** bit in the **CPSW_Control** register determines if all CPPI THost packets have a CRC included or not. THost packets not filtered on Ethernet ingress due to **pn_rx_cef_en** have the packet error CRC included (not replaced by the egress CRC type) if the CRC is not removed on egress. The error is indicated in the buffer descriptor. CPPI THost packets that detected a CRC error on the internally generated Castignoli CRC, due to a bit flip in logic or memory, will indicate the error with the **drop** bit set in the buffer descriptor.

9.4.16 Ethernet FIFO

Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority) regardless of the memory configuration. The receive logical FIFO is combined with the transmit logical FIFO into the same RAM instance. The receive FIFO is used for single packet reception and error detection and flow control runout. Packets are queued on transmit. Ethernet FIFO size is 20 KBytes.

9.4.17 Ethernet Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the Mac from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X or Priority Based Flow Control (PFC) pause frames. In all cases, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx_flow_en** bit in the **Pn_Mac_Control** register, and **rx_flow_pri[7:0]** in **Pn_Pri_Ctl**. For 10/100 modes of operation, collision or IEEE 802.3X flow control is determined via the **fullduplex** bit in the **Pn_Mac_Control** register. The **fullduplex** bit must be set for Priority Based Flow Control.

9.4.17.1 MII (10/100) Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex**is cleared in **Pn_Mac_Control)**. When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

9.4.17.2 IEEE 802.3X (10/100/1G/10G) Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex**is set in **Pn_Mac_Control)**. When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Mac will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 down to zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full at which time the receive FIFO will overrun and **Rx_Top_Of_FIFO_Drop** will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Mac will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address – Pn_SA(47:0) (PN_SA_L, PN_SA_H registers).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte packet length (The MAC will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx_flow_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

9.4.17.2.1 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to **rx_flow_thresh**. The flow control packet runout is then contained in the remainder of the receive FIFO.

9.4.17.3 Ethernet Transmit Flow Control

9.4.17.3.1 IEEE 802.3X (10/100/1G/10G) Based Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Mac from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx_flow_en** bits in the **Pn_Mac_Control** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the **rx_cmf_en** (Copy MAC Frames) bit in the **Pn_Mac_Control** register is set. The **tx_flow_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- tx_flow_en is set in Pn_Mac_Control, and
- the frame's length is 64 to rx_maxlen bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx_flow_en** in **Pn_Mac_Control** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**MRXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01, or
  - The Enet_Pn_SA[47:0] input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte packet length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The MAC will recognize any pause frame between 64 bytes and **rx_maxlen** bytes in length.

9.4.18 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the external clock controller to turn off (in a glitch-less manner) the module input clock (**CLK**) during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE is supported in MII/GMII/RGMII but not RMII, The chosen PHY must also support EEE. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the switch EEE_Prescale register. The pre-scaler is used to clock all EEE related counters.
2. The port Idle to LPI count values (Pn_Idle2LPI) are written with the desired values.
3. The port LPI to Wake count values (Pn_LPI2Wake) are written with the desired values.
4. The eee_en bit is set in the switch CPSW_Control register.

Energy Efficient Ethernet operation can begin after configuration. The host allows the module to enter a low power state by asserting the **CLKSTOP_REQ** signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert **CLKSTOP_REQ**.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the MII/RGMII interface. The PHY indicates LPI by asserting **GMII_MRXER_SEL** with a **GMII_MRXD[7:0]** value of 0x01 while **GMII_MRXDV** is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the **PX_Idle2LPI** value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted **GMII_MTXER** with a **GMII_MTXD[7:0]** value of 0x01. while **GMII_MTXEN** is deasserted (inter-packet gap). The CPPI LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive interfaces have both been idle for the Idle to LPI time (**P0_Idle2LPI**). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the **CLKSTOP_ACK** signal is asserted, and the external clock controller is allowed to stop the input module clock (**CLK**). The clock must be stopped (and re-started) in a glitch-less manner. When **CLKSTOP_ACK** is asserted, the clockmay be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the module memory address space, and then turn off the clock again while **CLKSTOP_ACK** is asserted. The clock must be restarted for two clock periods before the assertion of **SLV_VBUSP_REQ** and must remain asserted for five clock periods after the de-assertion of **SLV_VBUSP_REQ**.

The host can remove and disable from re-entering the CPSW LPI state by restarting the module clock (in a glitch-less manner) and then de-asserting **CLKSTOP_REQ**. There must be at least one rising edge of the clockbefore **CLKSTOP_REQ** is de-asserted. The module **CLKSTOP_ACK** output signal will be deasserted on the clock after the de-assertion of **CLKSTOP_REQ**. The host may queue CPPI receive packets at any time without regard to the module LPI state. The Host must deassert **CLKSTOP_REQ** on wakeup for a minimum of two clock periods. If **CLKSTOP_REQ** is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet ports to awaken.

The external Ethernet PHY's can also wakeup the external clock controller by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with **CLKSTOP_ACK** asserted and the receive LPI indication is removed, the **CLKSTOP_WAKEUP** signal will be asynchronously asserted. On wakeup, the external clock controller must restart the clock and de-assert the **CLKSTOP_REQ** signal. The **CLKSTOP_WAKEUP** signal will be synchronously deasserted with **CLKSTOP_ACK**. There must be at least one positive edge of the clock

before the **CLKSTOP_REQ** signal is deasserted. Upon the de-assertion of **CLKSTOP_REQ**, the Ethernet ports will count the **Pn_LPI2Wake** time for each port at which time the port is available for transmit.

9.4.19 Switch Latency

When the CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit. The store and forward latency is shown in the below table:

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

9.4.20 Emulation Control

The emulation control input (**EMUSUSP**), emulation control register, and the submodule emulation control registers allow CPSW operation to be completely or partially suspended. The CPDMA Host port and each Ethernet port has associated emulation control registers. The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if the switch level emulation control register and all submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or more submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals. The following table shows the operation of the emulation control input and register bits:

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

Note

Enable Suspend control (EMUSUSP) by MSS_CTRL: MSS_DBG_ACK_CTL0[26:24]

9.4.21 Software IDLE

The software idle register bits enable switch operation to be completely or partially suspended by software control. Each Ethernet port may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled port until the idle command is removed. The CPSW software idle inhibits packets from starting to be unloaded from each port switch FIFO, but packets already in process are unaffected.

9.4.22 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of up to 32 external clock sources.
- Software control of time sync events via interrupt or polling.
- Supports 8 hardware timestamp push inputs.
- Supports timestamp counter compare output (TS_COMP).
- Supports timestamp counter bit output (TS_SYNC).
- Supports a configurable number of timestamp Generator bit outputs (TS_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (TS_ESTFn).
- 64-bit timestamp mode with PPM and nudge adjustment.

9.4.22.1 CPTS Integration

This section describes CPTS module integration in the device, including information about clocks, resets, and hardware requests.

Figure 9-7 shows CPTS integration in the device.

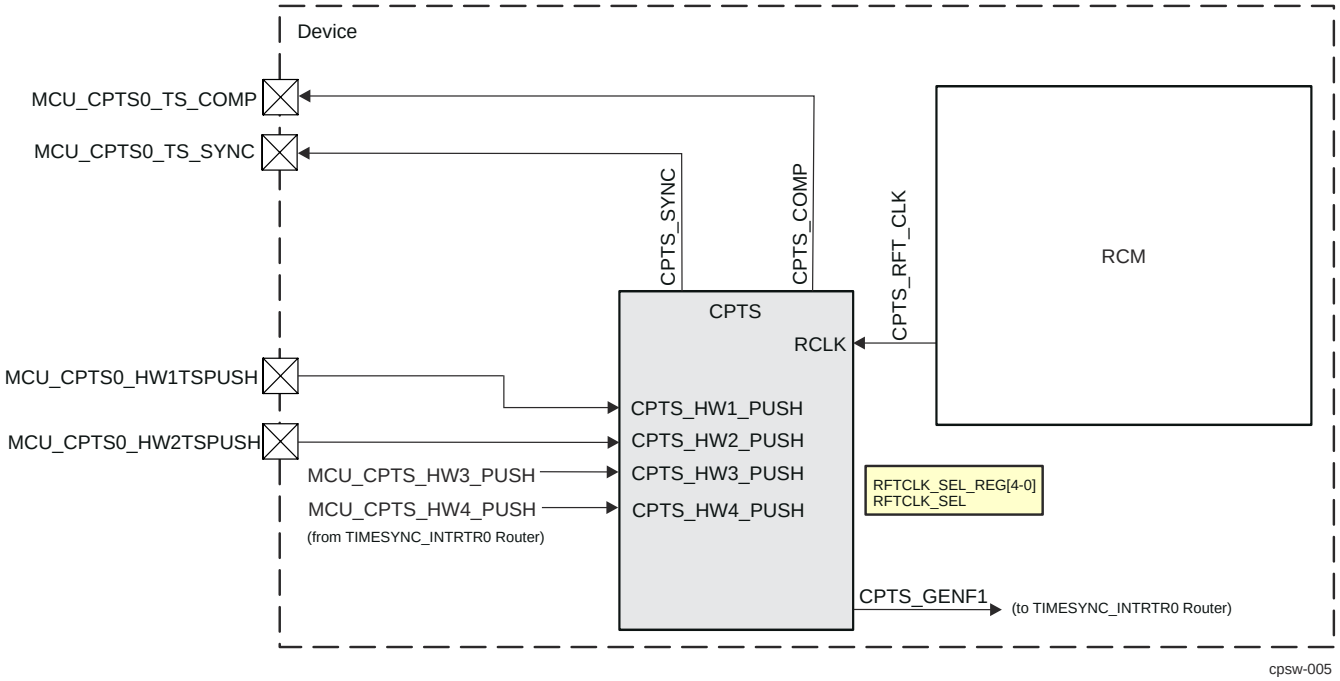

Figure 9-7. CPTS Integration

CPTS IEEE 1588 clock (RCLK) is selected through the CPSW_CPTS_RFTCLK_SEL_REG register.

Note

For more information about CPTS clocks and resets, see Table 9-3 in Section 9.3 *CPSW Integration*.

9.4.22.2 CPTS Architecture

Figure 9-8 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO. The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources.

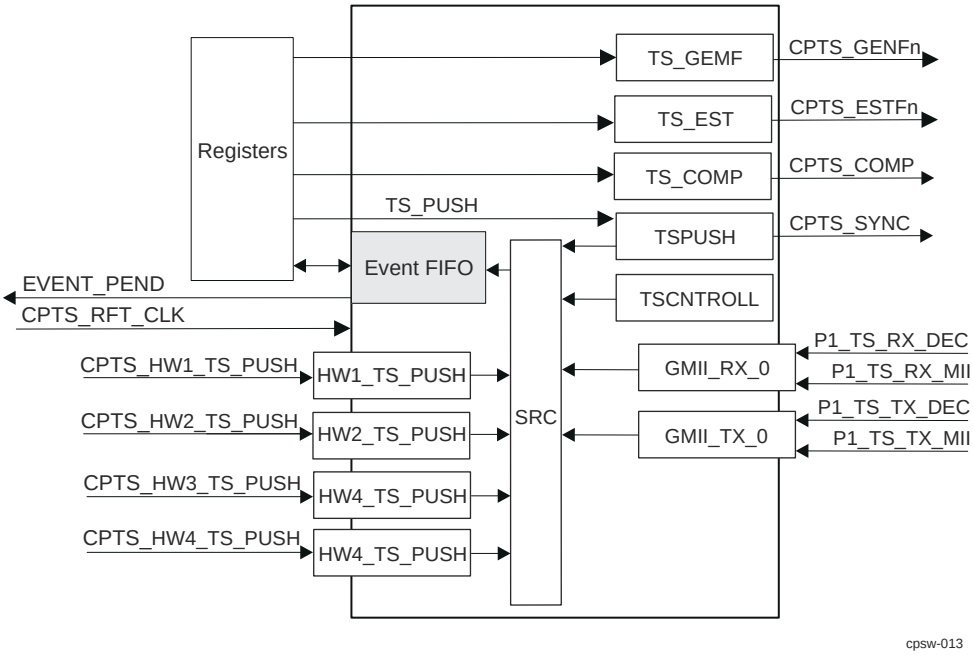

Figure 9-8. CPTS Block Diagram

Note

See Section 9.4.22.1, *CPTS Integration* for CPTS integration in the device.

9.4.22.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the **rftclk_sel[4:0]** value in the **RFTCLK_Sel** register with the desired reference clock multiplexor value. This value is allowed to be written only when the **cpts_en** bit in CPTS control register is cleared to zero.
3. Write a one to the **cpts_en** bit in the **TS_Control** register. The **RCLK** domain is in reset while this bit is low.
4. Enable the interrupt by writing a one to the **ts_pend** bit in the **Int_Enable** register (if using interrupts and not polling)..

9.4.22.4 32-bit Time Stamp Value

The **time_stamp** value is a 32-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments on each **RCLK** rising edge when **cpts_en** is set to one. The time stamp value can be written via the time stamp load function (**TS_Load_En** and **TS_Load_Low_val** registers). Host software maintains the required number of upper bits of the time stamp value. The upper time stamp value is incremented by the host when the rollover event is detected. The **add_val[2:0]** of **TS_ADD_VAL** value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

9.4.22.5 64-bit Time Stamp Value

The **time_stamp** value is a 64-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments by the increment value (1 to 8) on each **RCLK** rising edge when **cpts_en** is set to one. The increment value is from 1 to 8 (1 + **ts_add_val[2:0]**). The default increment value is one. The time stamp value can be written via the time stamp load function (**TS_Load_En**, **TS_Load_Low_val**, and **TS_Load_High_val** registers). The **add_val** feature (TS_ADD_VAL_Reg) is included to allow 1ns timestamp operations with an **RCLK** rate less than 1Ghz.The below table shows the **RCLK** and **add_val** values for 1ns operations. The highest **RCLK** frequency possible should be used as allowed by the technology. Table 9-22 shows the RFTCLK_SEL and TS_ADD_VAL_REG values for 1ns operations.

Table 9-22. ADD_VAL feature

RFTCLK_SEL (MHz)	TS_ADD_VAL_REG[2-0]
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

9.4.22.6 64-Bit Timestamp Nudge

The 64-bit **time_stamp** value can be adjusted by writing the **ts_nudge_val[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 **RCLK** from the next incremented **time_stamp[63:0]** value. A nudge value of 0x01 will add 1 **RCLK** to the next incremented **time_stamp[63:0]** value. For example, if the current **time_stamp** value is 0x0f06, and **add_val[2:0]**=3, the next incremented timestamp value would be 0x0f0a without a nudge and 0x0f0a +/- **tx_nudge_val[7:0]** with a nudge. The **ts_nudge** value is cleared to zero when the nudge has occurred.

9.4.22.7 64-bit Timestamp PPM

The 64-bit **time_stamp** can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the **ts_ppm[41:0]** (PPM_High & PPM_High)value enables PPM operations. The adjustment is up or down depending on the **ppm_dir** bit (TS_control_Reg). The **time_stamp** value is increased by the PPM value when **ppm_dir** is cleared and decreased by the PPM value when **ppm_dir** is set.

Parts Per Million example:
To adjust for 100 parts per million the configured value for **ts_ppm[41:0]** is:

1,000,000/100 = decimal 10,000

Parts Per Hour example:
To adjust for 1 part per hour at 1 Ghz **RCLK** the configured value for **ts_ppm[41:0]** is: (1,000,0000,000hz/1pph) * (3600 seconds/hour) = hex 34630B8A000

9.4.22.8 Event FIFO

The event FIFO contains at least as many locations as two times the number of ports plus 6 locations. Software must service the event FIFO in a timely manner which prevents event FIFO overrun. No overrun indication will be given.

9.4.22.9 Timestamp Compare Output

The **TS_COMP** function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. **TS_COMP** is not compatible with timestamp PPM or a non-zero **TS_ADD_VAL** value.

9.4.22.9.1 Non-Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_length[31:0] RCLK** periods when the **time_stamp[31:0]** (EVENT_0_REG) value compares with the **ts_comp_val[31:0]** and the length value is non-zero. The **TS_COMP** rising edge occurs three **RCLK** periods after the values compare. A timestamp compare event is pushed into the event FIFO when **TS_COMP** is asserted. The polarity of the **TS_COMP** output is determined by the **ts_comp_polarity** bit. The output is asserted low when the polarity bit is low.

9.4.22.9.2 Non-Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **timestamp[63:0]** are used (Event_0_reg and Event_3_reg) instead of only the lower 32-bits. The 64-bit timestamp cannot be allowed to rollover.

9.4.22.9.3 Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_len[31:0] RCLK** periods when the **time_stamp[31:0]** value compares with the **ts_comp_low_val[31:0]** and the length value is non-zero. The **TS_COMP** toggles thereafter on **ts_comp_low_len[31:0] RCLK** periods. The length high or low can be adjusted by writing the **TS_COMP_NUDGE[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 **RCLK** from the **ts_comp_length[31:0]** value. A value of 0x01 will add 1 **RCLK** to the **ts_comp_length[31:0]** value. Only a single high or low time is adjusted (nudged) and the **ts_comp_nudge** value is cleared to zero when the nudge has occurred. The **TS_COMP** output is asserted low when the **TS_Comp_Polarity** bit is low. No compare events and no **CPTS_EVNT** interrupts are generated in toggle mode. The **ts_comp_tog** bit must be set for toggle mode, and must be set before writing a non-zero value to **ts_comp_length[31:0]**.

9.4.22.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIMESTAMP are used (EVENT_0_REG and EVENT_3_REG). In 32-bit mode only the lower 32-bits (EVENT_0_REG) are used.

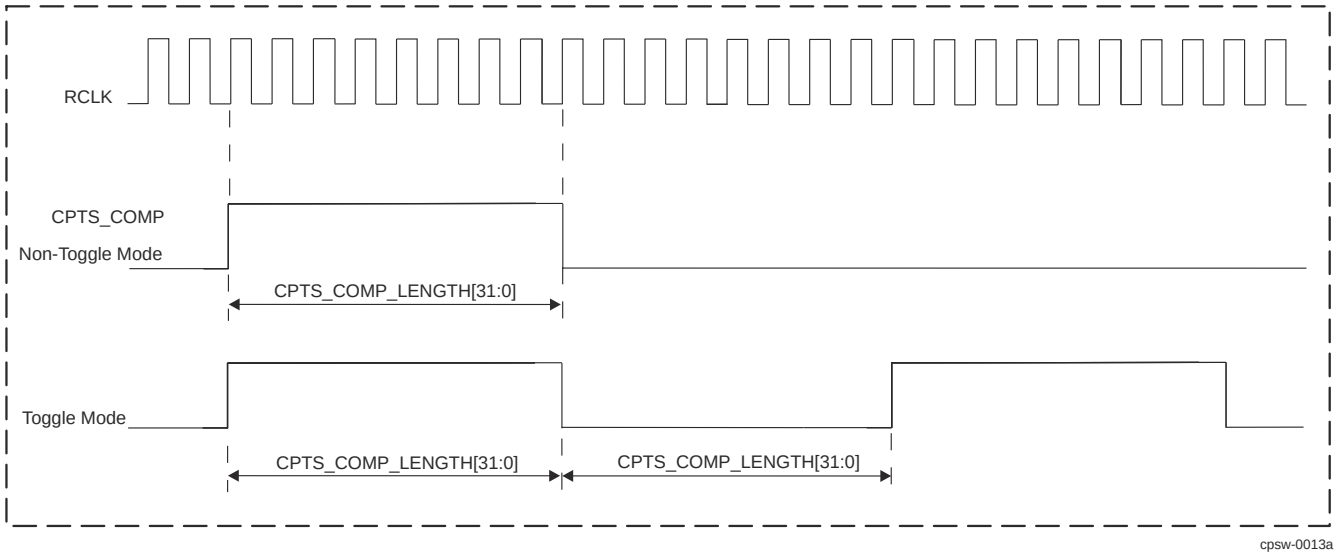

Figure 9-9. CPTS_COMP Output in Toggle and Non-Toggle Mode

9.4.22.10 Timestamp Sync Output

The CPTS_SYNC output is a selected bit of the [31-0]TIME_STAMP counter value. One of bits 17-31 can be selected in CPTS_CONTROL_REG[31-28] TS_SYNC_SEL. The CPTS_SYNC output is disabled when CPTS_CONTROL_REG[31-28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the CPTS_SYNC output. A rising edge will occur on the CPTS_SYNC output upon the next transition to 1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the CPTS_SYNC operation. The CPTS_SYNC output is two CPTS_RFT_CLK periods after the actual count value.

9.4.22.11 Timestamp GENFn Output

The CPTS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_I[31-0] CPTS_RFT_CLK periods (which is different than CPTS_COMP operation). Figure 9-10 represents the CPTS_GENFn output signal.

The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_I[31-0] CPTS_RFT_CLK periods beginning when the 64-bit TIME_STAMP value compares with the 64-bit GENFn_COMP value (CPSW_GENF0_COMP_LOW_REG_I and CPSW_GENF0_COMP_HIGH_REG_I registers) and the length value is non-zero. The CPTS_GENFn output cycle repeats thereafter every CPSW_GENF0_LENGTH_REG_I[31-0] CPTS_RFT_CLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is low. No compare events and no CPTS_EVNT interrupts are generated.

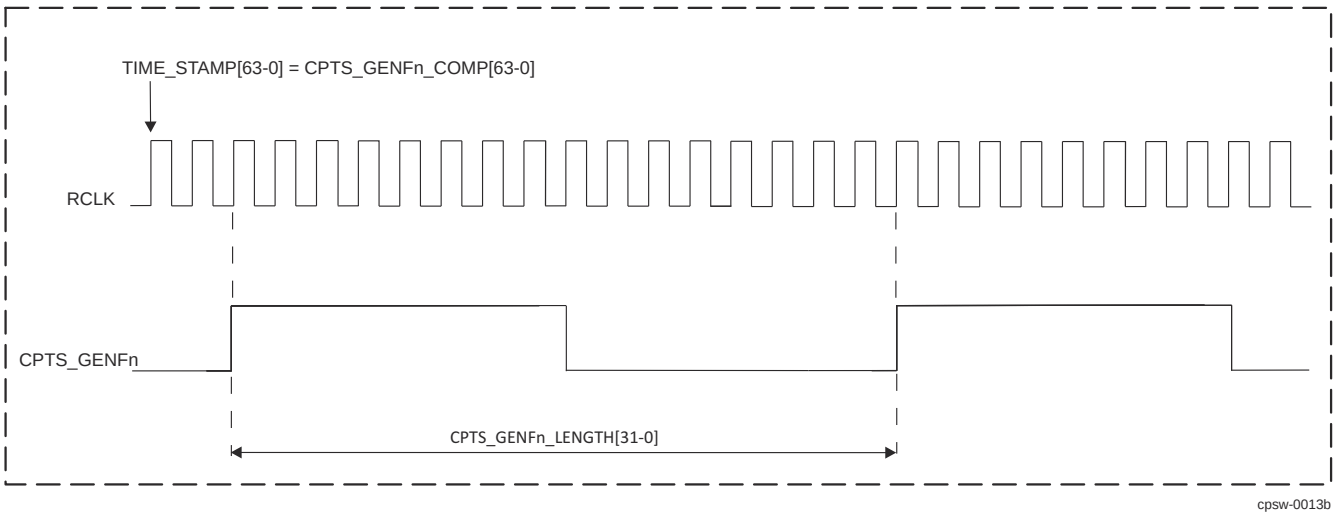

Figure 9-10. CPTS_GENFn Output Signal Diagram

9.4.22.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS_RFT_CLK from the CPSW_GENF0_LENGTH_REG_I[31-0] value. A value of 1h will add 1 CPTS_RFT_CLK to the CPSW0_ESTF1_LENGTH_REG_I[23-0] value. The CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

9.4.22.11.2 GENFn PPM

The CPTS_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW_GENF0_PPM_LOW_REG_I/ CPSW_GENF0_PPM_HIGH_REG_I enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS_RFT_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW_ESTF1_CONTROL_REG[0] PPM_DIR bit. When PPM_DIR bit is set a single CPTS_RFT_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR bit is cleared a single CPTS_RFT_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

Parts Per Million example:
To adjust for 100 parts per million the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_I and CPSW_GENF0_PPM_HIGH_REG_I) is:
1,000,000/100 = 10,000(decimal)

Parts Per Hour example:
To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_I and CPSW_GENF0_PPM_HIGH_REG_I) is:
(1,000,0000,000Hz/1pph) * (3600 seconds/hour) = 34630B8A000 (hex)

9.4.22.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

9.4.22.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

Word	Bit fields																													
	31	**30**	**29**	**28**	**27**	**26**	**25**	**24**	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

event_2	reserved																								**domain**							
event_3	**time_stamp[63:0]**																															

Name	Description
time_stamp	Time Stamp – The timestamp is valid for transmit, receive, and time stamp push event types. The timestamp value is not valid for counter roll event types.
port_number	Port Number – indicates the port number of an Ethernet event (1 to 4 encoded) or the hardware push number (1 to 8 encoded).

Name	Description
event_type	Time Sync Event Type 0000 – Time Stamp Push Event 0001 – Time Stamp Rollover Event (32-bit mode only) 0010 – Time Stamp Half Rollover Event (32-bit mode only) 0011 – Hardware Time Stamp Push Event 0100 – Ethernet Receive Event 0101 – Ethernet Transmit Event 0110 – Time Stamp Compare Event 0111 – Host Event 1000 --- - reserved 1111
message_type	Message type – The message type value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
sequence_id	Sequence ID – The 16-bit sequence id is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
domain	Domain – The 8-bit domain is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
prempt_queue	Prempt Queue – 0 – The packet was received/transmitted on the express queue. 1 – The packet was received/transmitted on the prempt queue.

9.4.22.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPSW_CPTS_TS_PUSH_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW_CPTS_EVENT_3_REG register) of the timestamp are zero in 32-bit mode.

9.4.22.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

9.4.22.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 9-11 shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the

time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

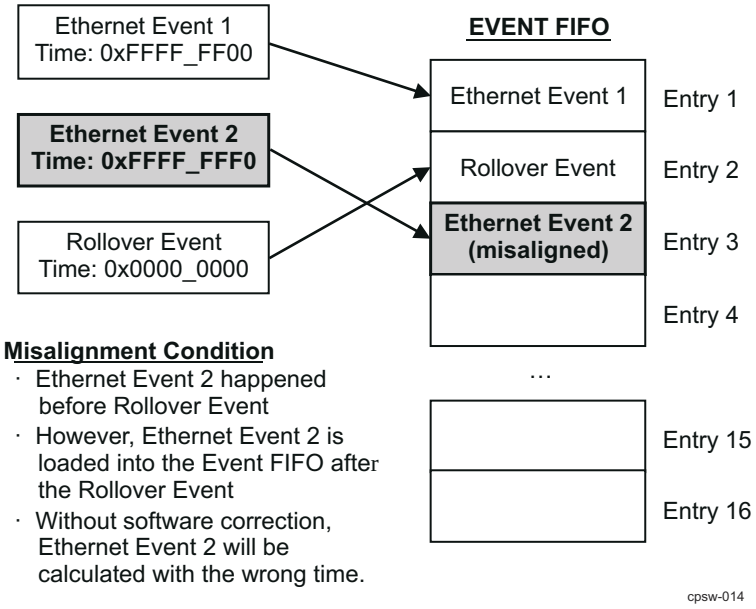

Figure 9-11. Event FIFO Misalignment Condition

9.4.22.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (CPTS_HW[1:4]_TS_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in Figure 9-7. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPSW_CPTS_EVENT_1_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS_RFT_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW_CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

9.4.22.13.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 9-12. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field in the CPSW_PN_TS_SEQ_LTYPE_REG register or the TS_LTYPE2 field in CPSW_PN_TS_CTL_LTYPE2_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-12. To indicate to the CPTS hardware that a virtual LAN is in use, the TS_TX_VLAN_LTYPE1_EN (or TS_TX_VLAN_LTYPE2_EN) enable bit must be set in the CPSW_PN_TS_CTL_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS_VLAN_LTYPE1 (or TS_VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_PN_TS_VLAN_LTYPE_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-12. In this case, both TS_VLAN_LTYPE1 and TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the TS_VLAN_LTYPE1 field, and the inner tag must match the value of the TS_VLAN_LTYPE2 field.

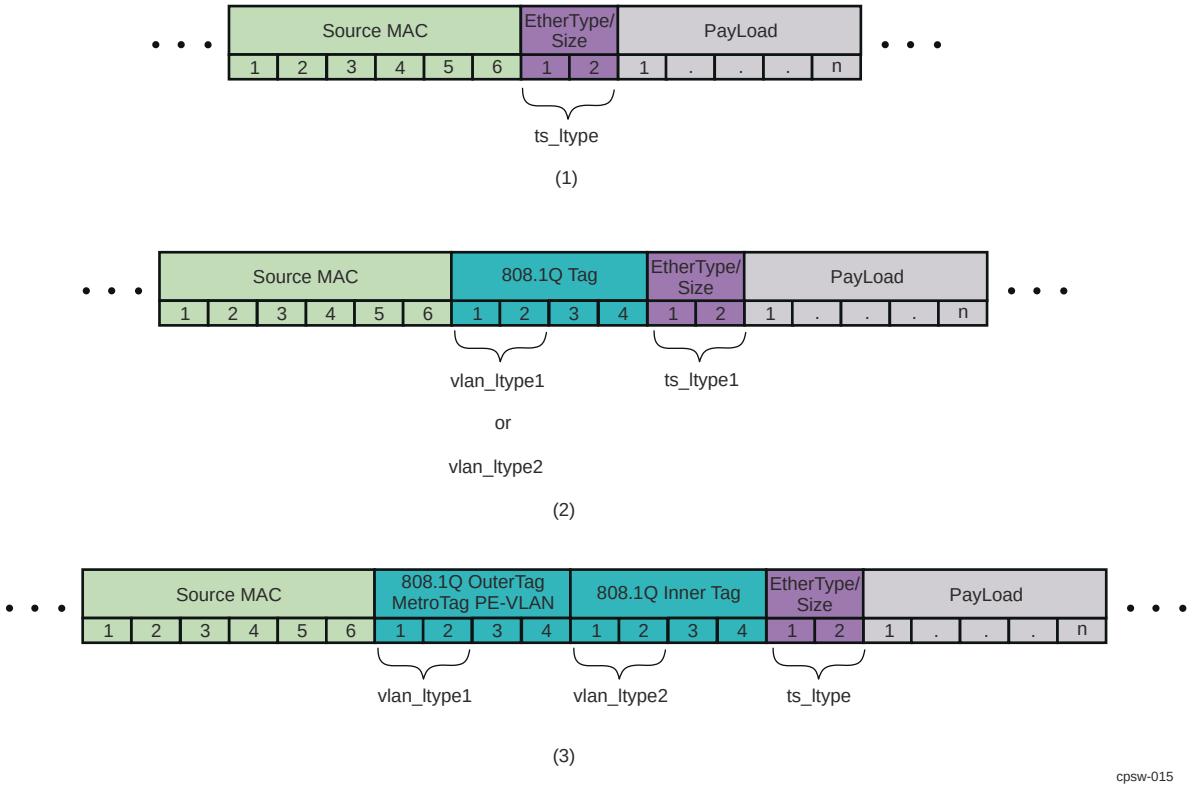

Figure 9-12. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

9.4.22.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured

by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RFT_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (IPv4)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x0800
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if CPSW_PN_TS_CTL_LTYPE2_REG is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
   a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

   -OR-

   The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set -OR-
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
9. The PTP message begins in byte 42.

10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (IPv6)

1. Receive annex E time sync is enabled (TS_RX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
   a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

   Note

   All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

   -OR-

   The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1 and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL2_REG register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.
10. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (TS_RX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).

2. One of the sequences below is true:
   a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
   b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
   c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
   e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
   f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
   g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
   h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

9.4.22.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use to the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (IPv4)

1. Transmit time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x0800
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800

c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800

3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if TS_TTL_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
   a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   f. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was sent by host port 0.

Annex E (IPv6)

1. Transmit annex E time sync is enabled (TS_TX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).

4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
   a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

   Note

   All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

   -OR-

   The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1h and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
10. The packet was sent by host port 0.

Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
   a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
   b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
   c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
   d. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
   e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
   f. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
   g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and

TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.

h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register

3. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RFT_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

9.4.22.13.5.3

Table 9-23. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPTS_EVENT_1 register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_0 (and CPTS_EVENT_3) register contains the time stamp value when the packet arrived at the corresponding port.

9.4.22.14 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

9.4.22.14.1 32-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (EVENT_0_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG register and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value

should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

9.4.22.14.2 64-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG) compares with the CPWS0_TS_COMP_VAL_REG and CPWS0_TS_COMP_HIGH_VAL_REG registers and the CPWS0_TS_COMP_LEN_REG value is non-zero. The CPWS0_TS_COMP_LEN_REG value should be written by software after the CPWS0_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

9.4.22.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP_EN bit and sends the DOMAIN, MESSAGE_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW_2G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

9.4.22.16 CPTS Interrupt Handling

The **TS_PEND** interrupt is enabled by writing a logic high to the **ts_int_enable** bit in the interrupt enable register. The raw interrupt value (before the enable) can be read by reading the **TS_Instat_raw** register. The enabled interrupt value can be read by reading the **TS_Instat_masked** register.

Software can process time sync events via interrupts in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt, read the **Event_0-4** register values.
3. Write logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
4. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt enter the CPTS service routine.
3. Read the **Event_0-4** register values.
4. Write a logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four **RCLK** periods plus four **VBUSP_CLK** periods.
6. Read bit 0 (**ts_pend_raw**) in the **TS_Intstat_raw** register to determine if another valid event is in the event FIFO. If bit zero is asserted then go to step 3. If bit 0 is not asserted then go to step 7.
7. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software also has the option of disabling the interrupt and polling the **ts_intstat_raw** bit to determine if a valid event is on the event FIFO.

9.4.23 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

Features Supported

- Clause 22 and CLuse 45 support
- Supports up to 32 PHY addresses.
- Two user access registers to control and monitor up to two PHYs simultaneously.
- VBUS 3.0 compliant slave interface for configuration and control.
- Each PHY can be individually enabled to be polled.
- The inter-poll gap between PHY polls can be changed.
- State Change Mode of operation to monitor up to 32 PHYs simultaneously.
- The MDIO interface can be manually controlled by software for GPIO operations.

9.4.23.1 MDIO Frame Formats

Clause 22

Table 9-24. MDIO Clause 22 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 9-25. MDIO Clause 22 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a "01" pattern. The pattern assures transitions from the default logic one state to zero and back to one.

Operation Code

The operation code for a read is "10", while the operation code for a write is a "01".

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16-bits. The first bit transmitted and received is the MSbit of the data word.

Clause 45

Table 9-26 shows the address, Table 9-27 shows the read format and Table 9-28 shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

Table 9-26. MDIO Clause 45 Address Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

Table 9-27. MDIO Clause 45 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 9-28. MDIO Clause 45 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction. The **MDIO User_Addr** registers must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a "00" pattern.

Operation Code

The operation code for an address transaction is "00", The operation code for a read is "11", while the operation code for a write is a "01".

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

MMD Number

The MMD number is the 5-bits allowing 32 unique values. The first bit transmitted is the MSbit.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Address

The address field is 16-bits on address operations. The first bit transmitted is the MSbit of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the **MDIO User_Addr0/1** register values as the 16-bit address.

Data

The Data field is 16-bits on read and write operations. The first bit transmitted and received is the MSbit of the data word.

9.4.23.2 MDIO Functional Description

The MDIO Management I/F will remain idle until enabled by setting the **enable** bit in the **MDIO Control** register. The module will then continuously poll the linkstatus bits from within the GenericStatusRegister of all enabled 32 PHY addresses. Individual PHY's can be enabled or disabled for polling thru the associated bit in the **Poll_En** register. The **MDIO Link** and **MDIO alive** register bit values are updated on the poll of each PHY. In Normal Mode, The link status of two of the 32 possible PHY addresses can also be determined using the **MLINK** pin inputs. The **linksel** bit in the **MDIO USER_PHY_SEL** register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the **MDIO LinkIntRaw** register and the **MDIO LinkIntMasked** register, if enabled by the **linkint_enable** bit in the **MDIO User_Phy_Sel** register. In State Change Mode, a change in any PHY status will be indicated on the **MDIO LINKINT[0]** interrupt if enabled.

The **MDIO Alive** register is updated if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also update the **MDIO Alive** register bit associated with the PHY.

At any time, the host can initiate a transaction for the MDO module to undertake using the **data, phyadr, regadd/MMD,** and **write** fields in an **MDIO User_Access** register. When the host sets the **go** bit in this register, the MDIO module will begin the transaction without any further intervention from the host. Upon completion, the MDIO will clear the **go** bit and set the **userintraw** bit in the **MDIO User_Int_Raw** register corresponding to the **MDIO User_Access** register being used. The corresponding bit in the **MDIO User_Int_Masked** register may also be set depending on the mask setting in the **MDIO User_Int_Mask_Set** and **MDIO User_Int_Mask_Clear** registers. A round-robin arbitration scheme is used to schedule transactions which may queued by the host in different **MDIO User_Access** registers. The host should check the status of the **go** bit in the **MDIO User_Access** register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the **ack** bit in the **MDIO User_Access** register to determine the status of a read transaction.

Software may use the MDIO module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the **MAC Control** register in the corresponding MAC.

9.4.24 Reset Isolation

The CPSW supports reset isolation of the Ethernet switch ports. When the **ISOLATE** input is asserted the below occur simultaneously:

- The Host Port 0 is removed from ALE processing (packets received on ports 1 through N-1 will be dropped to port 0).
- FHost packets are dropped. Any packet currently in progress when ISOLATE is asserted is dropped due to a FHost packet code error (and possible a CRC or FRAG error).
- THost packets in queue are dropped.

The intent of reset isolation is to allow packets to switch between the Ethernet ports while the remainder of the system is undergoing a reset. Isolation assumes that the external host and logic connected to the port 0 host interface is reset and will not be in the middle of a packet when **ISOLATE** is de-asserted.

9.4.25 CPSW Initialization and Configuration

To configure the CPSW for operation the host must perform the following:

- Ensure that at least 2000 VBUSP_CLK periods are run after reset is de-asserted.
- Configure the CPSW Control register.
- Configure the Ethernet Port Source Address registers
- Configure the Statistics Port Enable registers
- Configure the ALE.
- Configure the Ethernet Ports.

9.4.26 Enet Mac Reset or XGMII/GMII Mode Change Configuration

- Set pn_cmd_idle in the Ethernet port Pn_Mac_Control registers.

- Wait for pn_Idle to be indicated in the Ethernet port Pn_Mac_Status registers.
- Set pn_soft_reset in the Ethernet port Pn_Soft_Reset registers.
- Wait for pn_soft_reset in the Pn_Soft_Reset registers to be cleared to confirm reset completion.
- Configure the Ethernet ports.

9.4.27 Memory Error Detection and Correction

The cpsw error detection and correction logic uses the IP ECC Aggregator Module. The ECC Aggregator allows the control of the cpsw RAMs as shown in the below table. ECC is always enabled. The cpsw FIFO RAMS implement ECC only on packet headers. The packet data is protected by Castignoli CRC (regardless of the input packet CRC type or output CRC type). The ALE and EST RAMs have complete ECC as normal.

9.4.27.1 Packet Header ECC

Only packet headers bits are protected by ECC in the cpsw RAMs. The **ECC_Error_Control1** register **ecc_row** is not implemented – **ecc_bit1** is implemented to determine which bit of the header is flipped for an SEC error when the **ecc_crc_mode** bit is cleared in the **CPSW_Control** register. The ECC status registers return the RAM address that was flipped (**ecc_row**) along with the **ecc_bit1** value. Forcing double bit errors in testing can cause indeterminate switch operation if multiple used packet header bits are flipped given that only single bit errors are fixed by the ECC logic. Header bits 207 downto 200 are not currently used in the switch and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when **ecc_crc_mode** is set to one. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test ecc header errors.

The header ECC code is stored in bits 255 downto 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on 'bit 0', it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse on **ECC_PULSE_INTR** as does an ale ram ECC error.

9.4.27.2 Packet Protect CRC

Each ingress packet without error is passed through the cpsw with an internally generated Castignoli protect CRC. The protect CRC is checked on port egress for correctness and is replaced. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on THost then the **memory_protect_error** buffer descriptor bit will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the **ECC_PULSE_INTR** signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on **STAT_PEND_INTR** if any CRC memory protect error occurs (and the statistics for that port are enabled). When the **ecc_crc_mode** bit in the **CPSW_Control** register is set, the **ecc_bit1** aggregator register will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when **ecc_crc_mode** is set. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test packet CRC errors.

RAM 0	ALE Ram
RAM 1	Port 0 FIFO Rx Ram
RAM 2	Port 0 FIFO Tx Ram
RAM 3	Port 1 FIFO Rx Ram
RAM 4	Port 1 FIFO Tx Ram
RAM 5	Port 2 FIFO Rx Ram
RAM 6	Port 2 FIFO Tx Ram
…	…
RAM (N*2) - 1	Port N FIFO Rx Ram
RAM (N*2)	Port N FIFO Tx Ram

RAM 19	EST Ram

9.4.27.3 Aggregator Ram Control

The ECC logic for each FIFO ram (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the ram in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in the below table. The **ecc_bit1[15:0]** value returned on error is a 16-bit value that is the concatenation of 5-bits of zero, 3-bits of the encoder/decoder number (0 to 7), 3-bits of zero, and 5-bits of index into the indicated 26-bit encoder/decoder. For example, an **ecc_bit1** value of 0x0308 is bit-8 of encoder/decoder 3, which is header bit 86 (((26*3) + 8).

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:78	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 Code
219:214	Encoder/Decoder 1 Code
225:220	Encoder/Decoder 2 Code
231:226	Encoder/Decoder 3 Code
237:232	Encoder/Decoder 4 Code
243:238	Encoder/Decoder 5 Code
249:244	Encoder/Decoder 6 Code
255:250	Encoder/Decoder 7 Code

9.4.28 CPSW Network Statistics

The CPSW has statistics that record events associated with frame traffic on each port. STAT0 keeps statistics for PORT0, STAT1 for PORT1 and so on. All statistics are 32-bit registers. By convention the statistics registers are receive for ingress and transmit for egress for all ports.

If any bit in **stat_port_en** is set for a specific STAT module, the value written to a statistics register will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xffffffff will clear a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x00000000 will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, “the port” refers to any enabled port (with a corresponding set **stat_port_en** bit).

9.4.28.1 Rx (only) Statistics Descriptions

9.4.28.1.1 Good Rx Frames

The total number of good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.2 Broadcast Rx Frames

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:
- any data or MAC control frame which was destined for address 0xFFFFFFFFFFFF only, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.3 Multicast Rx Frames

The total number of good multicast frames received on the port. A good multicast frame is defined to be:
- any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.4 Pause Rx Frames

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:
- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error, and
- pause frames are enabled on the port (pn_tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic

or

The total number of priority based flow control (802.1Qbb) pause frames received by the port (whether acted upon or not). Such a frame:
- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, and
- priority based flow control pause frames are enabled on the port.

See the **Rx CRC errors** statistic descriptions for definitions of CRC errors. Overruns have no effect upon this statistic

9.4.28.1.5 Rx CRC Errors

The total number of frames received on the port that experienced a CRC error. Such a frame:
- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no code/align error, and
- had a CRC error.

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- a frame containing an even number of nibbles, and
- fails the Frame Check Sequence test.

9.4.28.1.6 Rx Align/Code Errors

The total number of frames received (ingress) on the port that experienced an alignment error or code error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had either an alignment error or a code error.

Over-runs have no effect upon this statistic.

An alignment error is defined to be:

- a frame containing an odd number of nibbles, and
- also fails the Frame Check Sequence test if the final nibble is ignored.

A code error is defined to be:

- A frame which has been discarded because the port's **MRXER** pindriven with a one for at least one bit-time's duration at any point during the frame's reception.

Note

RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing **Rx Align/Code Errors** and **Rx CRC errors** (see below).

10G: For XGMII, packets are ended at the code error and only that number of bytes are kept when rx_cef is set (includes the code error bytes).

9.4.28.1.7 Oversize Rx Frames

The total number of oversized frames received on the port. An oversized frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen in bytes, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.8 Rx Jabbers

The total number of jabber frames received on the port. A jabber frame is:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen bytes long, and
- had a CRC error, an alignment error, or a code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.9 Undersize (Short) Rx Frames

The total number of undersized frames received on the port. An undersized frame is defined to be:

- any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was less than 64 bytes long, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.10 Rx Fragments

The total number of frame fragments received on the port. A frame fragment is defined to be:

- any data frame (address matching does not matter), and
- was less than 64 bytes long, and
- had a CRC error, an alignment error, or a code error, and
- was not the result of a collision caused by half duplex, collision based flow control.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.1.11 Rx IPG Error

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

9.4.28.1.12 Rx Bottom Of FIFO Drop

Ethernet Ports

The total number of ingress frames on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI transmit port) should not drop packets on ingress because port 0 ingress flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. The overrun frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- Was dropped on port 0 due to a lack of memory space in the receive FIFO

Note

This stat should be zero

Host Port 0

This statistic also counts frames dropped on port 0 that were 17 to 33 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet with 33 bytes was dropped. No other statistics are counted for frames shorter than 33 bytes.

9.4.28.1.13 Portmask Drop

All Ports

The total number of ingress frames on a port that were dropped by the ALE (the ALE did not forward the packet to any port). The frame was defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

Note

This stat does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero **port_mask**.

9.4.28.1.14 Rx Top Of FIFO Drop

All Ports

The total number of frames received on a port that had a **START** of frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

9.4.28.1.15 ALE Drop

All Ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the **port_mask** was zero).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the destination address was not equal to the source address, and
- The packet was not destined for the port it was receive on, and
- had a zero port_mask

9.4.28.1.16 ALE Overrun Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with **pn_rx_csf_en** at a rate that exceeded the maximum lookup rate.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

9.4.28.1.17 ALE Rate Limit Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were pruned due to rate limiting).

9.4.28.1.18 ALE VLAN Ingress Check Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to VLAN ingress check failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and

- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the VLAN ID ingress check failed (the receive port was not in the group), and
- The address lookup did not return a match with the super bit set

9.4.28.1.19 ALE DA=SA Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to destination address equal to source address.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- The destination address was equal to the source address
- The source address was not an entry in the table.

9.4.28.1.20 Block Address Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source or destination address matched a table entry with the block bit set.

9.4.28.1.21 ALE Secure Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source address is an entry in the table with the secure bit set and a port number for a different receive port.

9.4.28.1.22 ALE Authentication Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- enable_auth_mode is set, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the super bit set.

9.4.28.1.23 ALE Unknown Unicast

The total number of frames received on a port that had a unicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

Note

The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

9.4.28.1.24 ALE Unknown Multicast

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a multicast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

Note

The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

9.4.28.1.25 ALE Unknown Broadcast

The total number of frames received on a port that had a Broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a broadcast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

Note

The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

9.4.28.1.26 ALE Policer Match

The total number of frames received on a port that had a matched a policer. The frame is defined to be:

- any data frame, and
- matched a condition on a policer, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

9.4.28.1.27 ALE Policer Match Red

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- any data frame, and
- matched a policer with the condition red, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

9.4.28.1.28 ALE Policer Match Yellow

The total number of frames received on a port that had matched a policer and the condition was yellow. The frame is defined to be:

- any data frame, and
- matched a policer with the condition yellow, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

9.4.28.1.29 IET Receive Assembly OK

The total number of correctly received and re-assembled premptable frames.

- any premptable frame received
- was any size, and
- was correctly received and re-assembled without error.

9.4.28.1.30 IET Receive Assembly Error

The total number of premptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine).

9.4.28.1.31 IET Receive SMD Error

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note

If **iet_en** is not set, this statistic counts any received frame with any non express SMD.

9.4.28.1.32 IET Receive Merge Fragment Count

The total number of received non-initial fragments that did not have an assembly error. The IET stat aMACMergeFragCountRx is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error.

9.4.28.1.33 Rx Octets

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.28.2 Tx (only) Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

Thost overruns (**P0_Tx_SOF_OVERRUN** and **P0_Tx_MOF_OVERRUN**) have no effect on Tx statistics. They are counted separately.

9.4.28.2.1 Good Tx Frames

The total number of good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.28.2.2 Broadcast Tx Frames

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- any data or MAC control frame destined for address 0xFFFFFFFFFFFF only, and
- was of any length, and

- had no late or excessive collisions, no carrier loss and no underrun

9.4.28.2.3 Multicast Tx Frames

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:
- any data or MAC control frame destined for any multicast address other than 0xFFFFFFFFFFFF, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.28.2.4 Pause Tx Frames

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the **Tx Multicast Frames** and **64octect Frames** statistics.

9.4.28.2.5 Collisions

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
   - was destined for any unicast, broadcast or multicast address, and
   - was any size, and
   - had no carrier loss and no underrun, and
   - experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions).

   CRC errors have no effect upon this statistic.
2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

9.4.28.2.6 Single Collision Tx Frames

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:
- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

9.4.28.2.7 Multiple Collision Tx Frames

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:
- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.28.2.8 Excessive Collisions

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:
- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and

- experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.28.2.9 Late Collisions

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect upon this statistic.

9.4.28.2.10 Deferred Tx Frames

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced no collisions before being successfully transmitted, and
- found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic

See RFC1623 Ref. 2.6 dot3StatsDefferredTransmissions.

9.4.28.2.11 Carrier Sense Errors

The total number of frames on the port that experienced carrier loss. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- the carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don’t care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.
- CRC errors and underrun have no effect upon this statistic.

9.4.28.2.12 Tx Octets

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no late or excessive collisions and no carrier loss.

9.4.28.2.13 Transmit Priority 0-7

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- any frame transmitted from priority 0-7, and
- was less than or equal to cpsw_tx_pri(0-7)_maxlen.
- Collision retries are not counted in this statistic
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note

The Transmit Priority 0-7 Bytecount statististic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

9.4.28.2.14 Transmit Priority 0-7 Drop

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to **cpsw_tx_pri(0-7)_maxlen**.

- any frame destined to be transmitted from priority 0-7, and
- was any size, and
- was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than cpsw_tx_pri(0-7)_maxlen.

Note

The Transmit Priority 0-7 Drop Bytecount statististic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

9.4.28.2.15 Transmit Memory Protect Errors

The total number of transmit frames on the port that had a memory protect CRC error on egress.

- any frame destined to be transmitted, and
- was any size, and
- Had a memory protect CRC error on egress.

Frames to the host with memory protect errors are indicated to be dropped with a set receive buffer descriptor **drop** bit. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.

This statistic is 8-bits wide only and will not rollover but will limit at 0xff.

A non-zero value in this statistic will issue a **STAT_PEND_INTR** interrupt for the associated port.

9.4.28.2.16 IET Transmit Merge Fragment Count

The total number of non-initial premptable transmit fragments on premptable transmit.

- any frame destined to be transmitted on the premptable port, and
- was any size, and
- was a non-initial fragment.

9.4.28.2.17 IET Transmit Merge Hold Count

The total number of premptable frames that were prempted and reassembled by the assertion of **pn_mac_hold** in the **Enet_Pn_IET_Control** register or were prempted by EST. The IET statistic aMACMergeHoldCount can be derived and maintained by software.

- any frame destined to be transmitted on the premptable port, and
- was any size, and
- was prempted by the assertion of pn_mac_hold, or
- was prempted by Enhanced Scheduled Traffic (EST).

9.4.28.3 Rx and Tx (shared) Statistics Descriptions

9.4.28.3.1 Net Octets

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter), and
- was of any size (including <64 byte and > pn_rx_maxlen byte frames).

Also counted in this statistic are:

- every byte transmitted before a carrier-loss was experienced,
- every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time),
- every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

9.4.28.3.2 Rx + Tx 64 Octet Frames

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.28.3.3 Rx + Tx 65-127 Octet Frames

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 65 to 127 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

9.4.28.3.4 Rx + Tx 128-255 Octet Frames

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 128 to 255 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

For Rx reference only, see RFC1757 Ref. 1.13 etherStatsPkts128to255Octets.

9.4.28.3.5 Rx + Tx 256-511 Octet Frames

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 256 to 511 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.Rx + Tx 512-1023 Octet Frames

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 512 to 1023 bytes long.

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.28.3.6 Rx + Tx 1024_Up Octet Frames

The total number of frames of size 1024 to **pn_rx_maxlen** bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 1024 to pn_rx_maxlen bytes long on receive, or any size on transmit.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

Table 9-29. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data			< 64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	> rx_maxlen	flow coll.	CRC error	align / code	over-run	addr disc.
			Pausefrme	Non-pause	Multicast	Broadcast	Unicast													
Good Rx Frames	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Broadcast Rx Frames	F	Rx	(%|	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	Rx	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/ Code Errors	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n

Table 9-29. Rx Statistics Summary (continued)

Rx Fragments	F	Rx	n	n	(y|	y|	y)	y^	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns	F	Rx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	Rx+Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames)
6. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

7. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
8. “y^” Frame fragments are not counted if less than 8 bytes.
9. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the ‘-‘s in this column might in reality be ‘n’s.
10. The rx_overruns stat show above is for rx_mof_overruns and rx_sof_overruns added together.

Table 9-30. Tx Statistics Summary

Tx Statistic	Frame/ Oct	Tx/ Rx+ Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC error	Collision type					No carrier	Queued	Deferred	Underrun
			Pause (MAC)	Any (CPU)	Multicast	Broadcast	Unicast									flow	1	2-15	16	late				
Good Tx Frames	F	Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	Tx	n	(%|	n	y)	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	Tx	(y|	%|	y)	n	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n

Table 9-30. Tx Statistics Summary (continued)

512-1023octect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctect Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octects	O	Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Net Octects	O	Rx+Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	$	$	$	$	$	-	-	-

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause(MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so cannot collide
5. “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. “+” indicates collisions which are “summed” (i.e. every collision is counted in the Collisions statistic). Jam sequences used for half-duplex flow control are also counted.
7. “$” Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the ‘-‘s in this column might in reality be ‘n’s. To prevent double-counting, Net Octects are unaffected by the jam sequence – the ‘received’ bytes, however, are counted. (see Rx Statistics table).
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

9.5 MSS_CPSW Registers

Table 9-31 lists the MSS_CPSW registers. All register offset addresses not listed in Table 9-31 should be considered as reserved locations and the register contents should not be modified.

Table 9-31. MSS_CPSW Registers

Offset	Acronym	Register Name	Section
0h	SS_IDVER_REG	ID Version Register	Section 9.5.1
4h	SS_SYNCE_COUNT_REG	Sync E Count Value - This value determines the toggle rate of the TS_SYNCE output. When this value is zero the TS_SYNCE output is disabled (low). When this value is non-zero, the TS_SYNCE output toggles each time the synce count value is reached. If this value is to be changed to another non-zero value then it should be written with a zero value before writing the new non-zero value.	Section 9.5.2

CLKDIV							
R/W-FFh							

Table 9-50. MDIO_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine idle. Set to 1 when the state machine is in the idle state.
30	ENABLE	R/W	0h	Enable control. Writing a 1 to this bit enables the MDIO state machine, writing a 0 disables it. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register.
29	RESERVED	R/W	X	
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest useraccess channel that is available in the module and is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.
23-21	RESERVED	R/W	X	

Table 9-50. MDIO_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	PREAMBLE	R/W	0h	Preamble disable. Writing a 1 to this bit disables this device from sending MDIO frame preambles in clause 22 mode of operation. This bit has no effect in clause 45 mode of operation.
19	FAULT	R/W	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit.
18	FAULT_DETECT_ENABLE	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection
17	INT_TEST_ENABLE	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the userint and linkint bits for test purposes.
16	RESERVED	R/W	X	
15-0	CLKDIV	R/W	FFh	Clock divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when clkdiv is set to 0. MDCLK frequency = clk frequency/(clkdiv+1).

9.5.20 MDIO_ALIVE_REG Register (Offset = F08h) [Reset = 0h]

MDIO_ALIVE_REG is shown in Figure 9-32 and described in Table 9-51.

Return to the Table 9-31.

MDIO Alive Register

ALIVE																															
R/W-0h																															

Table 9-51. MDIO_ALIVE_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ALIVE	R/W	0h	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are intended to be used to give an indication of the presence or not of the PHY with the corresponding address. Writing a '1' to any bit will clear it, writing a '0' has no effect.

9.5.21 MDIO_LINK_REG Register (Offset = F0Ch) [Reset = 0h]

MDIO_LINK_REG is shown in Figure 9-33 and described in Table 9-52.

Return to the Table 9-31.

MDIO Link Register

Figure 9-33. MDIO_LINK_REG Register

R/W-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 9-139. PN_EST_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R/W	X	
25-16	est_fill_margin	R/W	0h	Transmit FIFO EST Fill Margin. Sets the fill margin (in bytes) required to ensure that the Ethernet wire is clear so that the timed EST express packet can egress at the correct required time. Setting this value too high will put an unnecessary gap on the wire. Setting this value too low will cause the express packet to egress at a time later than intended (pushed out by non express traffic).
15-9	est_prempt_comp	R/W	0h	Transmit FIFO EST Prempt Comparision Value. When the count in a zero allow is less than or equal to this value in bytes (times 8), prempt packets are cleared from the wire. This is the prempt clear margin value.
8	est_fill_en	R/W	0h	Transmit FIFO EST Fill Enable
7-5	est_ts_pri	R/W	0h	Transmit FIFO EST TimeStamp Priority. Selects the express priority that timestamp(s) will be generated on when pn_est_ts_onepri is set.
4	est_ts_onepri	R/W	0h	Transmit FIFO EST TimeStamp One Priority. When set, timestamp only enabled packets on the express priority selected by pn_est_ts_pri. When cleared to zero, express packet selection for timestamp is independent of priority.
3	est_ts_first	R/W	0h	Transmit FIFO EST TimeStamp First Express Packet. Generate a timestamp only on the first selected express packet in each EST time interval when express timestamps are enabled. (If pn_est_ts_onepri is also set then the timestamp is generated only on the first packet on pn_est_ts_pri).
2	est_ts_en	R/W	0h	Transmit FIFO EST TimeStamp Enable. Enable express timestamps (when est_en and pn_est_port_en are set).
1	est_bufsel	R/W	0h	Transmit FIFO EST Buffer Select. If pn_est_onebuf is cleared, this bit selects the upper (when set) or the lower (when cleared) 64-word fetch buffer. The actual fetch buffer used changes only at the start of the EST time interval and can be read in the Pn_FIFO_Status register pn_est_bufact bit.
0	est_onebuf	R/W	0h	Transmit FIFO EST One Buffer. When set indicates that all 128 fetch words are used in one buffer. When cleared, indicates that the 128 fetch words are split into two 64-word fetch buffers. The pn_est_bufsel selects the buffer to be used when pn_est_onebuf is cleared to zero.

9.5.109 PN_RX_DSCP_MAP_REG_y Register (Offset = 00022120h + formula) [Reset = X]

Table 9-160. PN_MAC_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R/W	X	

Table 9-160. PN_MAC_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of pn_rx_cmf_en. Frames transferred to memory due to pn_rx_cmf_en will have the control bit set in their EOP buffer descriptor. 0 – MAC control frames are filtered (but acted upon if enabled). 1 – MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to host memory due to pn_rx_csf_en will have the fragment or undersized bit set in their buffer descriptor. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 – Short frames are filtered 1 – Short frames are transferred to host memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when this bit is not set. 0 – Frames containing errors are filtered. 1 – Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	R/W	0h	Transmit Short Gap Limit Enable. When set this bit limits the number of short gap packets transmitted to 100ppm. The pn_tx_short_gap_en bit must also be set. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed. This bit is used only with GMII (not XGMII).
20	EXT_TX_FLOW_EN	R/W	0h	External Transmit Flow Control Enable
19	EXT_RX_FLOW_EN	R/W	0h	External Receive Flow Control Enable
18	EXT_EN	R/W	0h	External Enable. Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the pn_fullduplex and pn_gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected
17	GIG_FORCE	R/W	0h	Gigabit Mode Force
16	IFCTL_B	R/W	0h	Interface Control B
15	IFCTL_A	R/W	0h	Interface Control A
14-13	RESERVED	R/W	X	
12	CRC_TYPE	R/W	0h	Port CRC Type. 0 – Ethernet CRC
11	CMD_IDLE	R/W	0h	Command Idle. 0 – Idle not commanded, 1 – Idle Commanded (read pn_idle in Pn_Mac_Status)
10	TX_SHORT_GAP_ENABLE	R/W	0h	Transmit Short Gap Enable
9-8	RESERVED	R/W	X	
7	GIG	R/W	0h	Gigabit Mode. 0 – 10/100 mode, 1 – Gigabit mode (full duplex only).
6	TX_PACE	R/W	0h	Transmit Pacing Enable
5	GMII_EN	R/W	0h	GMII Enable
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. 0 – Transmit Flow Control Disabled. Full-duplex mode – Incoming pause frames are not acted upon. 1 – Transmit Flow Control Enabled . Full-duplex mode – Incoming pause frames are acted upon.

Table 9-160. PN_MAC_CONTROL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable. 0 – Receive Flow Control Disabled Half-duplex mode – No flow control generated collisions are sent. Full-duplex mode – No outgoing pause frames are sent. 1 – Receive Flow Control Enabled Half-duplex mode – Collisions are initiated when receive flow control is triggered. Full-duplex mode – Outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	R/W	0h	Manufacturing Test Mode
1	LOOPBACK	R/W	0h	Loop Back Mode. Loopback mode forces internal fullduplex mode regardless of whether the pn_fullduplex bit is set or not. The pn_loopback bit should be changed only when pn_gmii_en is de-asserted. Loopback is used only with GMII (not XGMII). Loopback is not compatible with timestamp operations (CPTS). 0 – Not looped back 1 – Loop Back Mode enabled
0	FULLDUPLEX	R/W	0h	Full Duplex mode. Gigabit mode forces fullduplex mode regardless of whether the pn_fullduplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 – half duplex mode 1 – full duplex mode

9.5.130 PN_MAC_STATUS_REG Register (Offset = 00022334h) [Reset = X]

PN_MAC_STATUS_REG is shown in Figure 9-142 and described in Table 9-161.

Table 9-182. CPDMA_SOFT_RESET_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R/W	X	
0	SOFT_RESET	R/W	0h	CPDMA and CPSW Soft Reset Enable. Writing a one to this bit causes the entire CPSW logic to be reset. Software reset occurs when the DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

9.5.152 CPDMA_CONTROL_REG Register (Offset = 00034020h) [Reset = X]

CPDMA_CONTROL_REG is shown in Figure 9-164 and described in Table 9-183.

Table 9-183. CPDMA_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R/W	X	
6	TH_TS_ENCAP	R/W	0h	CPDMA Receive TimeStamp Encapsulated. 0 – THost packets do not contain a 64-bit timestamp 1 – THost packets contain a 64-bit timestamp prepended to the packet data (32-bit lsword first).
5	TH_VLAN_ENCAP	R/W	0h	CPDMA Receive VLAN Encapsulated. 0 – THost packets are not VLAN encapsulated 1 – THost packets are VLAN encapsulated
4	TH_CEF	R/W	0h	CPDMA Receive Copy Error Frames. Enables THost DMA overrun frames to be transferred to memory (up to the point of buffer overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when thost_cef is not set. THost frames with other error bits set are not affected by this bit. This is related only to frames that overrun on the THost DMA due to buffer limitations. 0 – Frames containing overrun errors are filtered. 1 – Frames containing overrun errors are transferred to memory.
3	CMD_IDLE	R/W	0h	CPDMA Command Idle. 0 – Idle not commanded 1 – Idle Commanded (read idle in CPDMA_Status register)
2	TH_OFFLEN_BLOCK	R/W	0h	CPDMA Receive Offset/Length Word Write Block. 0 – Do not block the DMA writes to the THost buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI. 1 – Block all CPDMA DMA controller writes to the THost buffer descriptor offset/buffer length words during CPPI packet processing. When this bit is set, the CPDMA will never write the third word to any THost buffer descriptor.
1	TH_OWNERSHIP	R/W	0h	CPDMA Receive Ownership Write Bit Value. 0 – The CPDMA writes the THost buffer descriptor ownership bit to zero at the end of packet processing as specified in CPPI. 1 – The CPDMA writes the THost buffer descriptor ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
0	FH_PTYPE	R/W	0h	CPDMA Transmit Queue Priority Type. 0 – The queue uses a round robin scheme to select the next channel. 1 – The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel.

9.5.153 CPDMA_STATUS_REG Register (Offset = 00034024h) [Reset = X]

CPDMA_STATUS_REG is shown in Figure 9-165 and described in Table 9-184.

Return to the Table 9-31.

Bit	Field	Type	Reset	Description
31-11	RESERVED	R/W	X	
10-0	TH_BUFFER_OFFSET	R/W	0h	CPDMA Receive Buffer Offset Register. The fhost_buffer_offset will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the fhost_buffer_offset value of bytes. A value of 0x0 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0xF (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

9.5.155 CPDMA_EMULATION_CONTROL_REG Register (Offset = 0003402Ch) [Reset = X]

Table 9-209. CPDMA_TH0_FREEBUFFER_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R/W	X	
14-0	TH0_FREEBUFFER	R/W	0h	CPDMA THost Free Buffer Count Register. This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.

9.5.179 CPDMA_TH1_FREEBUFFER_REG Register (Offset = 000340E4h) [Reset = X]

CPDMA_TH1_FREEBUFFER_REG is shown in Figure 9-191 and described in Table 9-210.

W-X							
7	6	5	4	3	2	1	0
RESERVED							TS_PUSH
W-X							W-0h

Table 9-392. TS_PUSH_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	W	X	
0	TS_PUSH	W	0h	Time stamp event push. When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

9.5.362 TS_LOAD_VAL_REG Register (Offset = 0003D010h) [Reset = 0h]

TS_LOAD_VAL_REG is shown in Figure 9-374 and described in Table 9-393.

Return to the Table 9-31.

Time Stamp Load Low Value Register

Figure 9-374. TS_LOAD_VAL_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS_LOAD_VAL																															
R/W-0h																															

Table 9-393. TS_LOAD_VAL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TS_LOAD_VAL	R/W	0h	Time stamp load low value. Writing the ts_load_en bit causes ts_load[63:0] to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.

9.5.363 TS_LOAD_EN_REG Register (Offset = 0003D014h) [Reset = X]

TS_LOAD_EN_REG is shown in Figure 9-375 and described in Table 9-394.

Return to the Table 9-31.

Bit	Field	Type	Reset	Description
31-1	RESERVED	W	X	
0	EVENT_POP	W	0h	Event pop. When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read from the Event_0-3 registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt.

9.5.371 EVENT_0_REG Register (Offset = 0003D034h) [Reset = 0h]

EVENT_0_REG is shown in Figure 9-383 and described in Table 9-402.

Return to the Table 9-31.

9.5.396 ALE_STATUS Register (Offset = 0003E004h) [Reset = X]

ALE_STATUS is shown in Figure 9-408 and described in Table 9-427.

Return to the Table 9-31.

The ALE status provides information on the ALE configuration and state. The ~iramdepth is used to determine how IPv6 entries are stored in the table. IPv6 entries are stored in two entries where IPv6 Entry hi is designated by the odd slice index and lo is designated by the even slice index. The slice index is above the ram depth like {SlixeIndex,RamIndex}. So for a 64 deep RAM index of 0x005, the Hi portion of the IPv6 entry is located at 0x005|0x040 and the Lo portion is located at 0x005&(~0x040).

Table 9-428. ALE_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE_ALE	R/W	0h	Enable ALE 0 - Drop all packets 1 - Enable ALE packet processing
30	CLEAR_TABLE	R/W	0h	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W	0h	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes four times the number of table entries clock cycles (4096 cycles for 1K addresses) best case (no ale packet processing during ageout) and sixty five times the number of table entries clock cycles (66560 cycles for 1K addresses) absolute worst case.

Table 9-428. ALE_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28-25	RESERVED	R/W	X	
24	MIRROR_DP	R/W	0h	Mirror Destination Port - This field defines the port to which destination traffic destined will be duplicated. That is all traffic that is forwarded to this port will also be mirrored to the ~imirror_top port.
23-21	UPD_BW_CTRL	R/W	0h	The ~iupd_bw_ctrl field allows for up to 8 times the rate in which adds, updates, touches, writes, and aging updates can occur. At frequencies of 350Mhz, the table update rate should be at it lowest or 5 Million updates per second. When operating the switch core at frequencies or above, the ~iupd_bw_ctrl can be programmed more aggressive. If the ~iupd_bw_ctrl is set but the frequency of the switch subsystem is below the associated value, ALE will drop packets due to insufficient time to complete lookup under high traffic loads. 0 - 350Mhz, 5M 1 - 359Mhz, 11M 2 - 367Mhz, 16M 3 - 375Mhz, 22M 4 - 384Mhz, 28M 5 - 392Mhz, 34M 6 - 400Mhz, 39M 7 - 409Mhz, 45M
20-17	RESERVED	R/W	X	
16	MIRROR_TOP	R/W	0h	Mirror To Port - This field defines the destination port for the mirror traffic. If the traffic is received or transmitted on the mirror destination port it will not be duplicated. Traffic defined as mirror traffic only may be dropped by the switch due to congestion.
15	UPD_STATIC	R/W	0h	Update Static Entries - A static Entry is an entry that is not agable. When clear this bit will prevent any static entry (agable bit clear) from being updated due to port change. When set it allows static entries (agable bit clear) to update the source port if required. This bit should normally be '0' for most switch configurations.
14	RESERVED	R/W	X	
13	UVLAN_NO_LEARN	R/W	0h	Unknown VLAN No Learn - This field when set will prevent source addresses of unknown VLAN IDs from being automatically added into the look up table if learning is enabled.
12	MIRROR_MEN	R/W	0h	Mirror Match Entry Enable - This field enables the match mirror option. When this bit is set any traffic whose destination, source, VLAN or OUI matches the ~imirror_midx entry index will have that traffic also sent to the ~imirror_top port.
11	MIRROR_DEN	R/W	0h	Mirror Destination Port Enable - This field enables the destination port mirror option. When this bit is set any traffic destined for the ~imirror_dp port will have its transmit traffic also sent to the ~imirror_top port.
10	MIRROR_SEN	R/W	0h	Mirror Source Port Enable - This field enables the source port mirror option. When this bit is set any port with the ~ipX_mirror_sp set in the ALE Port Control registers set will have its received traffic also sent to the ~imirror_top port.
9	RESERVED	R/W	X	
8	EN_HOST_UNI_FLOOD	R/W	0h	Unknown unicast packets flood to host 0 - unknown unicast packets are not sent to the host 1 - unknown unicast packets flood to host port as well as other ports
7	LEARN_NO_VLANID	R/W	0h	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID). Determines the entry type.
6	ENABLE_VID0_MODE	R/W	0h	Enable VLAN ID = 0 Mode 0 - Process the priority tagged packet with VID = PORT_VLAN[11:0]. 1 - Process the priority tagged packet with VID = 0.

Table 9-428. ALE_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	ENABLE_OUI_DENY	R/W	0h	Enable OUI Deny Mode - When set, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches a supervisory destination address table entry. When cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory destination address table entry.
4	ENABLE_BYPASS	R/W	0h	ALE Bypass - When set, packets received on non-host ports are sent to the host. It is expected that packets from the host are directed to the particular port. 0 - no bypass 1 - bypass the ALE
3	BCAST_MCAST_CTL	R/W	0h	Rate Limit Transmit mode 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based
2	ALE_VLAN_AWARE	R/W	0h	ALE VLAN Aware - Determines how traffic is forwarded using VLAN rules. 0 - Simple switch rules, packets forwarded to all ports for unknown destinations. 1 - VLAN Aware rules, packets forwarded based on VLAN members
1	ENABLE_AUTH_MODE	R/W	0h	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There is no auto learning of addresses in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode
0	ENABLE_RATE_LIMIT	R/W	0h	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.

9.5.398 ALE_CTRL2 Register (Offset = 0003E00Ch) [Reset = X]

ALE_CTRL2 is shown in Figure 9-410 and described in Table 9-429.

Return to the Table 9-31.

The ALE Control 2 Register is used to set the extended features used for all ports.

R/W-X	R/W-0h

Table 9-429. ALE_CTRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TRK_EN_DST	R/W	0h	Trunk Enable Destination Address - This field enables the destination MAC address to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination.
30	TRK_EN_SRC	R/W	0h	Trunk Enable Source Address - This field enables the source MAC address to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination.
29	TRK_EN_PRI	R/W	0h	Trunk Enable Priority - This field enables the VLAN Priority bits to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination. In the event that DSCP mapping is enabled and there is no VLAN the DSCP priority will be used. For all other non IP frames without VLAN the port default priority is used.
28	RESERVED	R/W	X	
27	TRK_EN_IVLAN	R/W	0h	Trunk Enable Inner VLAN - This field enables the inner VLAN ID value (C-VLANID) to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination.
26	RESERVED	R/W	X	
25	TRK_EN_SIP	R/W	0h	Trunk Enable Source IP Address - This field enables the source IP address to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.
24	TRK_EN_DIP	R/W	0h	Trunk Enable Destination IP Address - This field enables the destination IP address to be used with the hash function G(X) = 1 + X + X^3 and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.
23	DROP_BADLEN	R/W	0h	Drop Bad Length will drop any packet that the 802.3 length field is larger than the packet. Ethertypes 0-1500 are 802.3 lengths, all others are Ether types.
22	NODROP_SRCMCST	R/W	0h	No Drop Source Multicast will disable the dropping of any source address with the multicast bit set.
21	DEFNOFRAG	R/W	0h	Default No Frag field will cause an IPv4 fragmented packet to be dropped if a VLAN entry is not found.
20	DEFLMTNXTHDR	R/W	0h	Default limit next header field will cause an IPv4 protocol or IPv6 next header packet to be dropped if a VLAN entry is not found and the protocol or next header does not match the ~iALE_NXT_HDR register values.
19	RESERVED	R/W	X	
18-16	TRK_BASE	R/W	0h	Trunk Base - This field is the hash formula starting value. Changing this value will cause the packet distribution on trunk ports to be changed. If all the ~itrk_en_dst, ~itrk_en_src, ~itrk_en_pri and ~itrk_en_vlan are '0', this value is used as the distribution index. That is a '0' will select the 1st bit of an 'N' link trunk, a '1' will select the second, etc. Below is the distribution across the trunk links. The first number in the ~iitalic sequence indicates the traffic is sent to the lowest numbered port of a trunk group. For example if you have a 3 port trunk, the hash result 0 will go to the base port (0), hash result 1 will go to the highest port of the trunk group (2), hash result 2 will go to the middle port (1), etc. 1 - ~i00000000 2 - ~i01010101 3 - ~i02102102 4 - ~i03210321
15-5	RESERVED	R/W	X	

Table 9-429. ALE_CTRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	MIRROR_MIDX	R/W	0h	Mirror Index - This field is the ALE lookup table entry index that when a match occurs will cause this traffic to be mirrored to the ~imirror_top port. That is any VLAN, ONU or address with or withou VLAN can be selected for traffic mirroring.

9.5.399 ALE_PRESCALE Register (Offset = 0003E010h) [Reset = X]

ALE_PRESCALE is shown in Figure 9-411 and described in Table 9-430.

Return to the Table 9-31.

The ALE Prescale Register is used to set the Broadcast and Multicast rate limiting prescaler value.

Figure 9-411. ALE_PRESCALE Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

9.5.406 I0_ALE_PORTCTL0_y Register (Offset = 0003E040h + formula) [Reset = X]

I0_ALE_PORTCTL0_y is shown in Figure 9-418 and described in Table 9-437.

Return to the Table 9-31.

The ALE Port Control Register sets the port specific modes of operation.

Offset = 0003E040h + (y * 4h); where y = 0h to 1h

Table 9-437. I0_ALE_PORTCTL0_y Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	I0_REG_P0_BCAST_LIMIT	R/W	0h	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field.
23-16	I0_REG_P0_MCAST_LIMIT	R/W	0h	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.The ~imcast_limit is the number of Multicast packets that will be forwaded per ~iale_prescale time.
15	I0_REG_P0_DROP_DOUBLE_VLAN	R/W	0h	Drop Double VLAN - When set cause any received packet with double VLANs to be dropped. That is if there are two ctag or two stag fields in the packet it will be dropped.
14	I0_REG_P0_DROP_DUAL_VLAN	R/W	0h	Drop Dual VLAN - When set will cause any received packet with dual VLAN stag followed by ctag to be dropped.
13	I0_REG_P0_MACONLY_CAF	R/W	0h	Mac Only Copy All Frames - When set a Mac Only port will transfer all received good frames to the host. When clear a Mac Only port will transfer packets to the host based on ALE destination address lookup operation (which operates more like an Ethernet Mac). A Mac Only port is a port with ~imaconly set.
12	I0_REG_P0_DIS_PAUTHMOD	R/W	0h	Disable Port authorization - When set will allow unknown addresses to arrive on a switch in authorization mode. It is intended for device to device network connection on ports which do not require MACSEC encryption.
11	I0_REG_P0_MACONLY	R/W	0h	MAC Only - When set enables this port be treated like a MAC port for the host. All traffic received is only sent to the host. The host must direct traffic to this port as the lookup engine will not send traffic to the ports with the ~ip0_maconly bit set and the ~ip0_no_learn also set. If ~ip0_maconly bit is set and the ~ip0_no_learn is not set, the host can send non-directed packets that can be sent to the destination of a MacOnly port. It is also possible that The host can broadcast to all ports including MacOnly ports in this mode.
10	I0_REG_P0_TRUNKEN	R/W	0h	Trunk Enable - This field is used to enable a port into a trunk. Any port can be used as a trunk port, any two or more ports with the ~ip0_trunken its set and having the same ~ip0_trunknum will be placed in the same trunk. There is no requirement for trunk ports to be adjacent. If all ports are enabled in the same trunk, no traffic can flow as traffic received within a trunk is never trasnmitted out the same trunk. If only a single port is a member of a trunk, it looks like a normal port with exception of entries in the look up table will be noted as a trunk entry.
9-8	I0_REG_P0_TRUNKNUM	R/W	0h	Trunk Number - This field is used as the trunk number when the ~ip0_trunken is also set. Ports with the same trunk number that have the ~ip0_trunken also set will have traffic distributed within the trunk based on the result of the hash function descrived above.
7	I0_REG_P0_MIRROR_SP	R/W	0h	Mirror Source Port - This field enables the source port mirror option. When this bit is set any traffic received on the port with the reg_p0_mirror_sp bit set will have its received traffic also sent to the ~imirror_top port.
6	RESERVED	R/W	X	

Table 9-437. I0_ALE_PORTCTL0_y Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	I0_REG_P0_NO_SA_UPDATE	R/W	0h	No Source Address Update - When set will not update the source addresses for this port.
4	I0_REG_P0_NO_LEARN	R/W	0h	No Learn - When set will not learn the source addresses for this port.
3	I0_REG_P0_VID_INGRESS_CHECK	R/W	0h	VLAN Ingress Check - When set if a packet received is not a member of the VLAN, the packet will be dropped.
2	I0_REG_P0_DROP_UN_TAGGED	R/W	0h	If Drop Untagged - When set will drop packets without a VLAN tag.
1-0	I0_REG_P0_PORTSTATE	R/W	0h	Port State - Defins the current port state used for lookup operations. 0 - Disabled 1 - Blocked 2 - Learning 3 - Forwarding

9.5.407 ALE_UVLAN_MEMBER Register (Offset = 0003E090h) [Reset = X]

ALE_UVLAN_MEMBER is shown in Figure 9-419 and described in Table 9-438.

Return to the Table 9-31.

The ALE Unknown VLAN Member Mask Register is used to specify the member list for unknown VLAN ID.

1-0	I1_REG_VLAN_MASK_MUX_1	R/W	0h	VLAN Mask Mux x - When selected by the VLAN lookup table entry FwdUnRegIdx or FwdAllRegIdx is used as the FwdUnRegMask or FwdUnRegMask values anded with the member list to determine the forwarding of packets. The Value of vlan_mask_mux_0 is read only and set to all ones for all ports.

9.5.415 EGRESSOP Register (Offset = 0003E0FCh) [Reset = X]

EGRESSOP is shown in Figure 9-427 and described in Table 9-446.

Return to the Table 9-31.

The Egress Operation register allows enabled classifiers with IPSA or IPDA match to use the CPSW Egress Packet Operations Inter VLAN Routing sub functions. If the packet was destined for the host, but matches a clasifier that has a programmed egress opcode, it will be forwarded to the destination ports where the destination ports will use the thier egress opcode entry to modify the packet. InterVLAN Routing and mirroring need to be understood, they are orthogonal functions.

Table 9-446. EGRESSOP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	EGRESS_OP	R/W	0h	The Egress Operation defines the operation performed by the CPSW Egress Packet Operations 0: NOP : 1-n: Defines which egress Operation will be performed. This allows Inter VLAN routing to be configured for high bandwidth traffic, reducing CPU load. 0xff: Swap SA and DA of packet, this is intended to allow OAM diagnostics for a link.
23-21	EGRESS_TRK	R/W	0h	The Egress Trunk Index is the calculated trunk index from the SA, DA or VLAN if modified to that InterVLAN routing will work on trunks as well. The DA, SA and VLAN are ignored for trunk generation on InterVLAN Routing so that this field is the index generated from the Egress Op replacements elclusive or'd together into a three bit index.
20	TTL_CHECK	R/W	0h	The TTL Check will cause any packet that fails TTL checks to not be routed to the Inter VLAN Routing sub functions. The packet will be routed to the host it was destined to.
19-2	RESERVED	R/W	X	
1-0	DEST_PORTS	R/W	0h	The Destination Ports is a list of the ports the classified packet will be set to. If a destination is a Trunk, all the port bits for that trunck must be set.

9.5.416 POLICECFG0 Register (Offset = 0003E100h) [Reset = X]

POLICECFG0 is shown in Figure 9-428 and described in Table 9-447.

Return to the Table 9-31.

The Policing Config 0 holds the port, frame priority and ONU address index as well as match enables for port, frame priority and ONU address matching.

Table 9-455. POLICECONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	POLICING_EN	R/W	0h	Policing Enable - Enables the policing to color the packets, this also enables red or yellow drop capabilities.
30	RESERVED	R/W	X	
29	RED_DROP_EN	R/W	0h	RED Drop Enable - Enables the ALE to drop the red colored packets.
28	YELLOW_DROP_EN	R/W	0h	WELLOW Drop Enable - Enables the ALE to drop yellow packets based on the ~iyellowthresh value. This field would normally not be used as to let the switch drop packets at a buffer threshold instead. In the event that the switch does not enable buffer threshold dropping, YELLOW packets can be dropped based on this feature.
27	RESERVED	R/W	X	
26-24	YELLOWTHRESH	R/W	0h	Yellow Threshold - When set enables a portion of the yellow packets to be dropped based on the ~iyellow_drop_en enable. 0-100% 1=50% 2-33% 3-25% 4=20% 5-17% 6-14% 7-13%
23-22	POLMCHMODE	R/W	0h	Policing Match Mode - This field determines what happens to packets that fail to hit any policing/classifier entry. 0 - No Hit packets are marked GREEN 1 - No Hit packets are marked YELLOW 2 - No Hit packets are marked RED 3 - No Hit packets are marked based on policing/classifier entry=0 state.
21	PRIORITY_THREAD_EN	R/W	0h	Priority Thread Enable - This field determines if priority is OR'd to the default thread when no classifiers hit and the default thread is enabled.
20	MAC_ONLY_DEF_DIS	R/W	0h	MAC Only Default Disable - This field when set disables the default thread on MAC Only Ports. That is the default thread will be {port,priority}. If the traffic matches a classifier with a thread mapping, the classifier thread mapping still occurs.
19-0	RESERVED	R/W	X	

9.5.425 POLICETESTCTL Register (Offset = 0003E128h) [Reset = X]

POLICETESTCTL is shown in Figure 9-437 and described in Table 9-456.

Return to the Table 9-31.

The Policing Test Control enables the ability to determine which policing entry has been hit and whether they reported a red or yellow rate condition.

Chapter 10

Quad Serial Peripheral Interface (QSPI)

10.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a controller only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 10-1 shows the QSPI module overview.

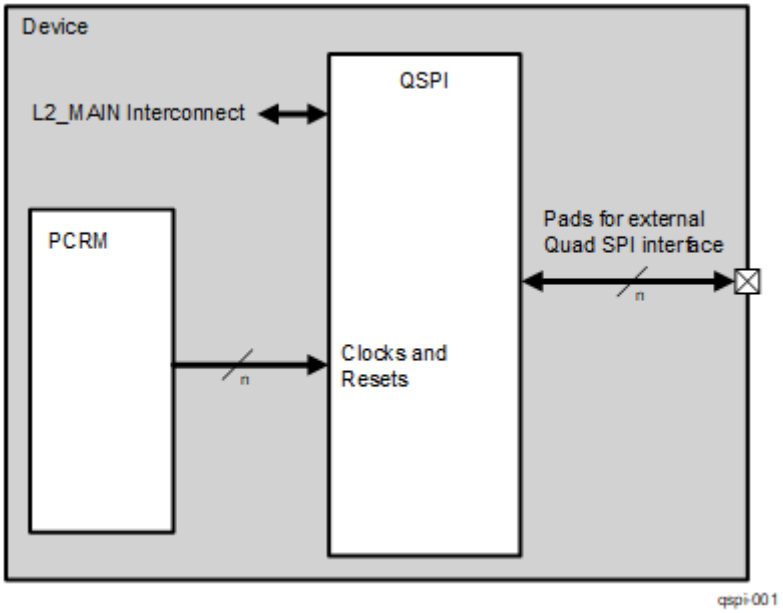

Figure 10-1. QSPI Overview

The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 2 external chip-select signal
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L2_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support
  - Quad read support

- Little-endian support (only for memory mapped reegisters used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

Note

The QSPI module does not support cache line wrap mode.

10.2 QSPI Environment

Figure 10-2 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

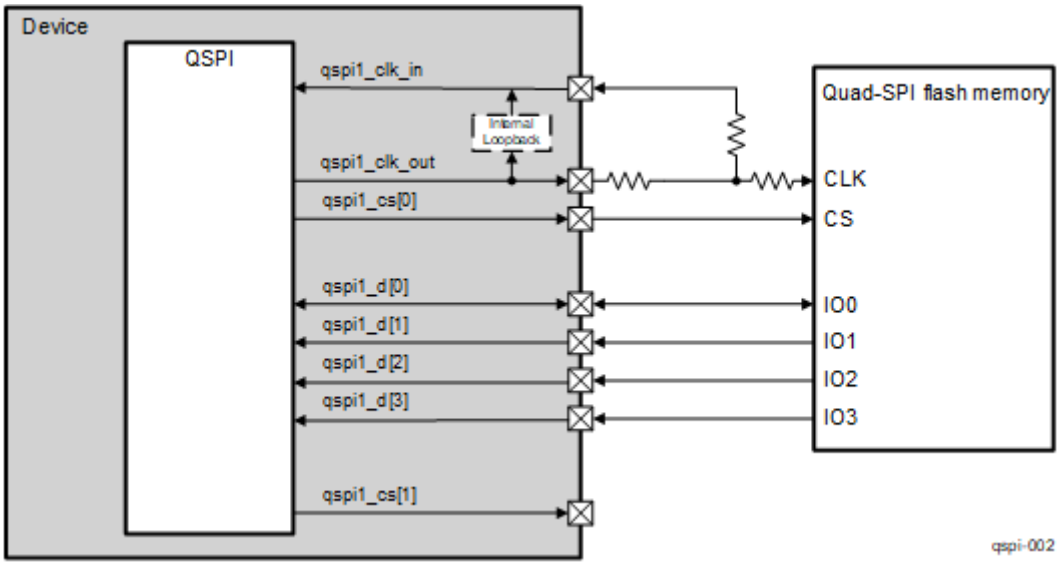

Figure 10-2. QSPI Connected to an External Quad-SPI Flash Memory

Table 10-1 lists and describes the QSPI I/O signals.

Table 10-1. QSPI I/O Signals

QSPI Signal/Pad name	I/O(1)	Description					
		3-pin(2) SPI Read (Single Read)	3-pin(2) SPI Write (Single Write)	4-pin(2) SPI Read (Single Read)	4-pin(2) SPI Write (Single Write)	4-pin(2) SPI Read (Dual Read)	6-pin(2) SPI Read (Quad Read)
qspi1_d[0]	IO	Used as SPI data input	Used as SPI data output	Not used	Used as SPI data output	Used as SPI data input 0	Used as SPI data input 0
qspi1_d[1]	I	Not used	Not used	Used as SPI data input	Not used	Used as SPI data input 1	Used as SPI data input 1
qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

(1) I = Input; O = Output
(2) This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

Note

In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

10.3 QSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

10.4 QSPI Functional Description

10.4.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 10-3 shows the QSPI block diagram.

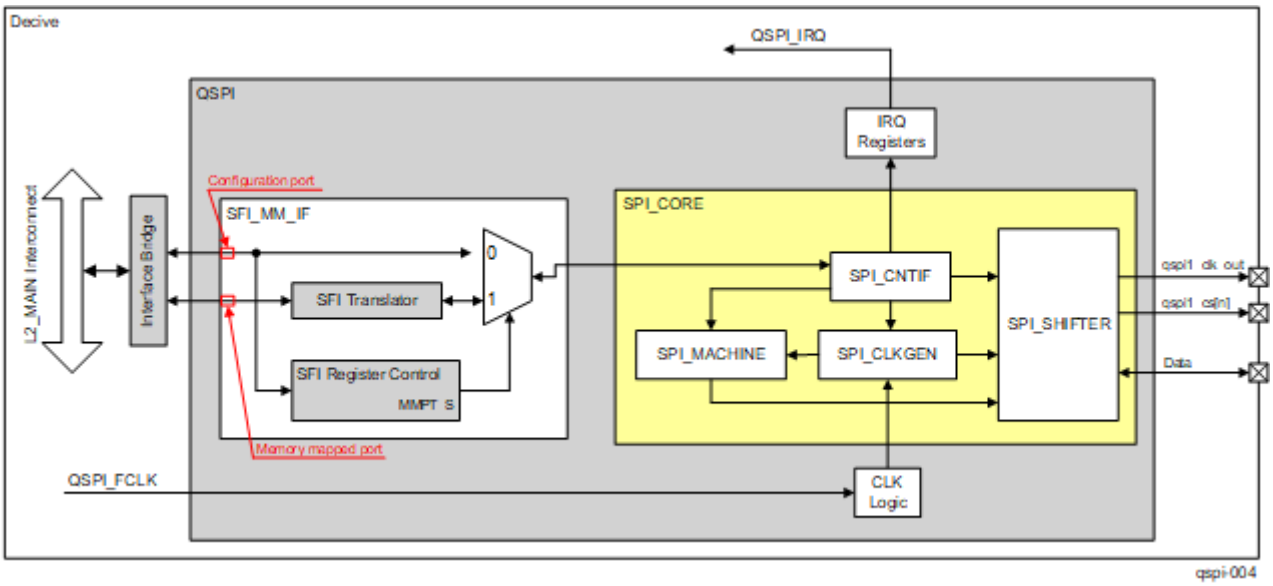

Figure 10-3. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L2_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

Note

The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

10.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUPi_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUPi_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SPI_SETUPi_REG[9:8] NUM_A_BYTES bit field
- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUPi_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUPi_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUPi_REG[13:12] READ_TYPE bit field. (i is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUPi_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 10-3) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 10-3) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

10.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

10.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - QSPI_SPI_DATA_REG
  - QSPI_SPI_DATA_REG_1
  - QSPI_SPI_DATA_REG_2
  - QSPI_SPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previosly described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

Note

The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

10.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 10-4 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

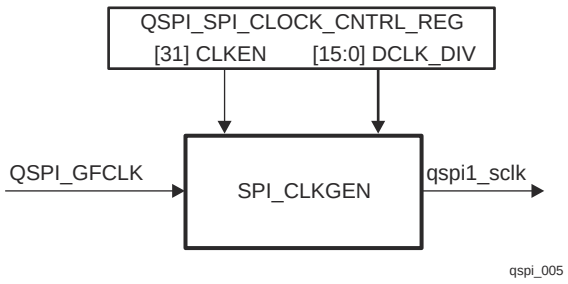

Figure 10-4. SPI_CLKGEN Block

10.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG®[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length (QSPI_SPI_CMD_REG[11:0] FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

10.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 10-2 lists the four defined clock modes of operation for the QSPI.

Table 10-2. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

Note

Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

Figure 10-5 shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

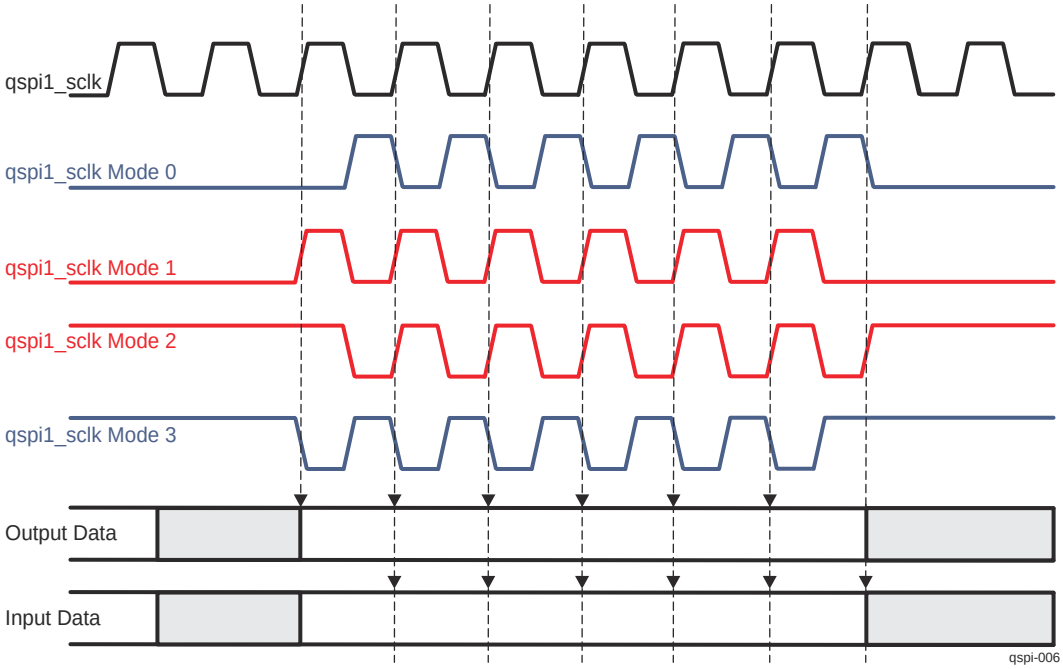

Figure 10-5. SPI Clock Modes

10.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

10.4.3 QSPI Interrupt Requests

Figure 10-6 shows a logical representation of the QSPI interrupt generation scheme.

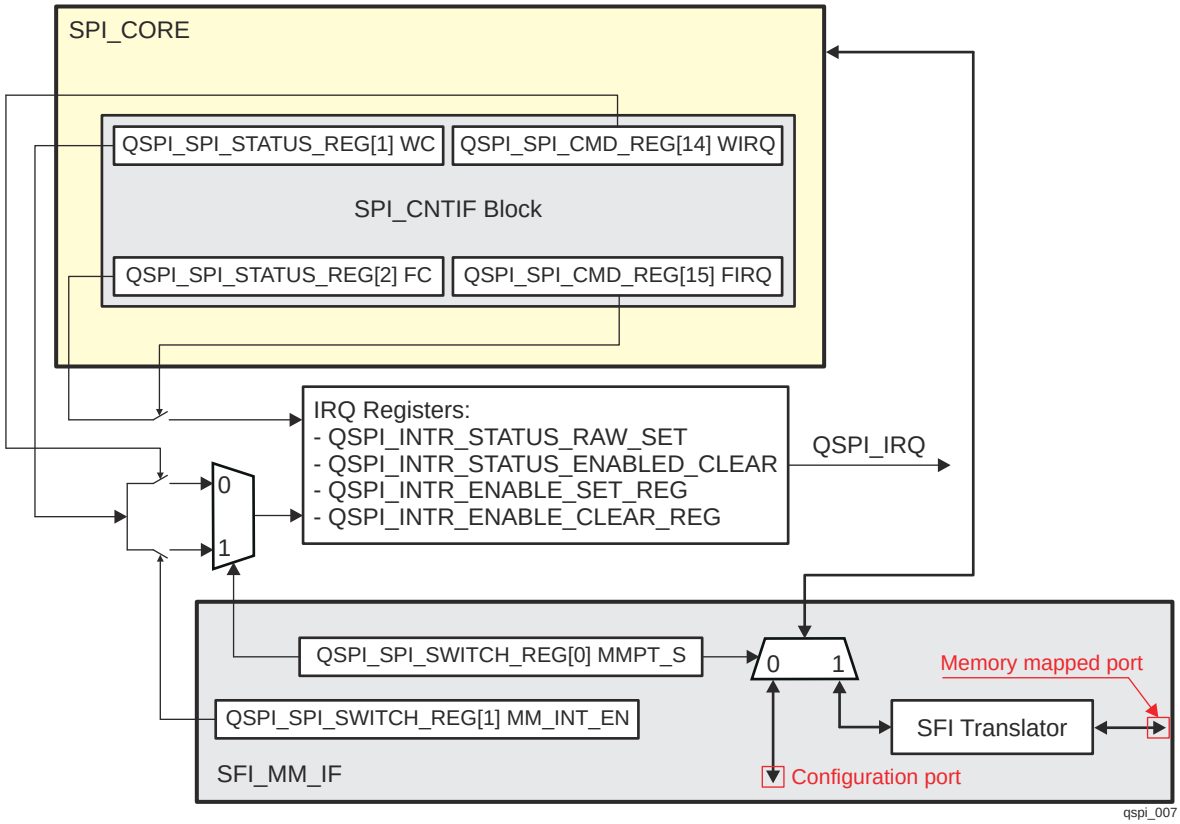

Figure 10-6. Logical Representation of the QSPI Interrupt Generation Scheme

QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

Note

The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 10-3 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 10-3. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA QSPI_SPI_STATUS_REG[1] WC	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR QSPI_SPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA QSPI_SPI_STATUS_REG[2] FC	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR QSPI_SPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

Note

QSPI_IRQ can also be used to trigger DMA events

10.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the supported external SPI devices. The L2_MAIN start address at which the configuration port is available is 0xC800 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x6000 0000 and ends at 0x6200 0000 L2_MAIN address.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 10-4. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available thorough these four data registers, which can be accessed only through the configuration port.

10.5 QSPI Registers

10.5.1 QSPI Register Summary

Table 10-4. QSPI Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset
QSPI_PID	R	32	0x0000 0000
QSPI_SYSCONFIG	RW	32	0x0000 0010
QSPI_INTR_STATUS_RAW_SET	RW	32	0x0000 0020
QSPI_INTR_STATUS_ENABLED_CLEAR	RW	32	0x0000 0024

Table 10-24. QSPI_SPI_DATA_REG_3

Address Offset	0x0000 0070
Description	The data received in this register is shifted to the LSB position and the content of the register is shifted to the left. This register acts as the fourth 32-bit register of the 128-bit shift in/out register. This register is cleared between reads or writes and can only be written when the QSPI module is not busy, as identified by the QSPI_SPI_STATUS_REG[0] BUSY bit.

Chapter 11

Enhanced Direct Memory Access (EDMA)

This section describes the Enhanced Direct Memory Access (EDMA) controller. This chapter covers features of EDMA module. For features applicable to the EDMA instances in the device, see the device-specific Integration section. The primary purpose of the EDMA controller is to service data transfers programmed between two memory-mapped slave endpoints on the device. The EDMA controller consists of two principle blocks:

- EDMA channel controllers: EDMA_TPCC
- EDMA transfer controllers: EDMA_TPTC

Devices can have multiple instances of EDMA channel controllers, each associated with multiple EDMA transfer controllers.

The EDMA channel controller serves as the user interface for the EDMA controller. The EDMA_TPCC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TR) to the EDMA3 transfer controller.

The EDMA transfer controllers are responsible for data movement. The transfer request packets (TRP) submitted by the EDMA_TPCC contain the transfer context, based on which the transfer controller issues read/write commands to the source and destination addresses programmed for a given transfer.

11.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

Figure 11-1 shows an overview of the EDMA module.

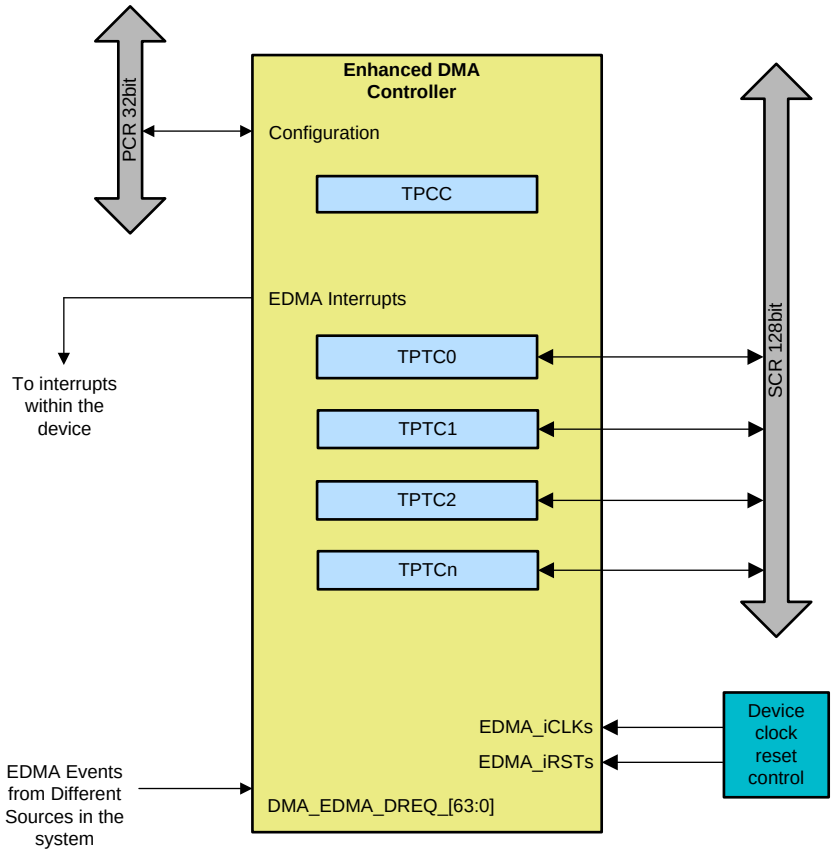

Figure 11-1. EDMA Module Overview

Note

When connecting to DSS, the SCR is 128 bit. When connecting to MSS and RCSS, the SCR is 64 bit.

For EDMA instances available on the device, see the device-specific integration section.

The **TPCC** is a high flexible channel controller that serves as both a user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals, as programmed in the Active and Pending set of the registers. The transfer controllers are responsible for data movement, and issue read/write commands to the source and destination addresses programmed for a given transfer in the EDMA_TPCC.

11.1.1 EDMA Features

This section shows generic EDMA features. For features applicable to the EDMA instances in the device, see the device-specific Integration section.

The EDMA_TPCC channel controller has the following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions
  - A-synchronized transfers: one dimension serviced per event
  - AB-synchronized transfers: two dimensions serviced per event
  - Independent indexes on source and destination
  - Chaining feature allowing a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes
  - Linking mechanism allows automatic PaRAM set update
  - Chaining allows multiple transfers to execute with one event
- Interrupt generation for the following:
  - Transfer completion
  - Error conditions
- Debug visibility:
  - Queue water marking/threshold
  - Error and status recording to facilitate debug
- 64 DMA request channels:
  - Event synchronization
  - Manual synchronization (CPUs write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Multiple transfer controllers/event queues.
- 16 event entries per event queue.

The **EDMA_TPTC** transfer controller has the following features:

- 128-bit wide read and write ports per TC
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the third dimension)
- Support for increment or constant addressing mode transfers
- Interrupt and error support
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness

11.2 EDMA Integration

This section describes modules integration in the device, including information about clocks, resets, and hardware requests.

11.2.1 EDMA Integration (AM263x)

There are TBD modules integrated in the device. The diagram below provides a visual representation of the device integration details.

Figure 11-2. MODULE Integration Diagram (Placeholder)

The tables below summarize the device integration details of MODULE# (where # = INSERT INSTANCE COUNT).

Table 11-1. *MODULE* Device Integration

This table describes the module device integration details.

Module Instance	Device Allocation	SoC Interconnect
MODULE0	✓	TBD

Table 11-2. *MODULE* Clocks

This table describes the module clocking signals.

Module Instance	Module Clock Input	Source Clock Signal	Source	Default Freq	Description
MODULE0	TBD	TBD	TBD	TBD	TBD

Table 11-3. *MODULE* Resets

This table describes the module reset signals.

Module Instance	Module Reset Input	Source Reset Signal	Source	Description

MODULE0	TBD	TBD	TBD	TBD	TBD

Table 11-6. *MODULE* Capture Event Inputs

This table describes the module capture event inputs.

Module Instance	Module Capture Event Input	Capture Event Source Signal	Source	Type	Description
MODULE0	TBD	TBD	TBD	TBD	TBD

Note

For more information on the interconnects, see the *System Interconnect* chapter.

For more information on power, reset, and clock management, see the corresponding sections within the *Device Configuration* chapter.

For more information on the device interrupt controllers, see the *Interrupt Controllers* chapter.

11.2.2 EDMA Interrupt Aggregator

The following EDMA interrupts are aggregated and sent to the processor:

- TPCC Completion Interrupt
- TPCC Completion Region Interrupts
- TPTCs Completion Interrupt

shows the associated interrupt and registers for each TPCC instance.

Table 11-7. TPCC Interrupts

TPCC	Interrupt	Registers Space
TPCC0	TPCC0_INTAGG	*_INTAGG_MASK *_INTAGG_STATUS *_INTAGG_STATUS_RAW

For an event to generate an interrupt to the processor, the corresponding bit field must be unmasked in TPCC_x_INTAGG_MASK.

Only an interrupt processor can read the TPCC_x_INTAGG_STATUS register to detect which event triggered the interrupt.

The interrupt can be cleared by writing 0x1 to the corresponding bit in TPCC_x_INTAGG_STATUS.

The software must ensure that all the aggregated interrupts are cleared so that the level interrupt is de-asserted before exiting the ISR. Only then is it ensured that a new pulse interrupt is generated to the processor. Thus, after clearing the software should read the register to confirm a value of 0x0.

The register TPCC_x_INTAGG_STATUS_RAW is set on an event irrespective of the value in TPCC_x_INTAGG_MASK. This field can be cleared by writing 0x1 to the corresponding bit in TPCC_x_INTAGG_STATUS_RAW.

11.2.3 EDMA Error Interrupt Aggregator

The following interrupts are aggregated and sent to the processor:

- TPCC Error
- TPCC MPU Error
- TPTCs Error
- TPCC Read and Write Config Space Access error
- TPTCs Read and Write Config Space Access error

Table 11-8. TPCC Error Interrupt Aggregators

TPCC	Interrupt	Registers Space
TPCC0	TPCC0_ERRAGG	*_ERRAGG_MASK *_ERRAGG_STATUS *_ERRAGG_STATUS_RAW

For an event to generate an interrupt to the processor, the corresponding bit field must be unmasked in TPCC_x_ERRAGG_MASK.

Only an interrupt processor can read the TPCC_x_ERRAGG_STATUS register to detect which event triggered the interrupt.

The interrupt can be cleared by writing 0x1 to the corresponding bit in TPCC_x_ERRAGG_STATUS.

The software must ensure that all the aggregated interrupts are cleared so that the level interrupt is de-asserted before exiting the ISR. Only then is it ensured that a new pulse interrupt is generated to the processor. Thus, after clearing the software should read the register to confirm a value of 0x0

The register TPCC_x_ERRAGG_STATUS_RAW is set on an event irrespective of the value in TPCC_x_ERRAGG_MASK. This field can be cleared by writing 0x1 to the corresponding bit in TPCC_x_ERRAGG_STATUS_RAW.

11.2.4 EDMA Configuration

- The device has 1 channel controller: TPCC0 and two transfer controllers: TPTC0 and TPTC1.

Table 11-9. EDMA Channel Controller Configuration

Parameters	TPCC0
DMA Channel	64

Table 11-9. EDMA Channel Controller Configuration (continued)

Parameters	TPCC0
Param Entires	256
QDMA Channel	8
Event queues	2
Mem Protection	Yes
Channel Mapping	Yes
Num TCs	2
Num Interrupt Channel	64
Num Regions	8

Table 11-10. EDMA Transfer Controller Configuration

Parameters	TPTC<0/1>
FIFO Size	512
TR Pipe Depth	4
Bus Width	8
Read Cmd Num	8
Write Cmd Num	8
RAM ECC	Yes

Default Burst Size configuration (DBS)

All TPTCs in the device support four different configurable default-burst-sizes. shows the config-value to DBS mapping.

Table 11-11. Config Value to DBS Mapping

Config value	Burst size
2'b00	16 bytes
2'b01	32 bytes
2'b10	64 bytes
2'b11	128 bytes

Table 11-12. TPTC DBS Configuration Registers

TPTC instance	Corresponding Register
TPTC<0/1>	TPTC_DBS_CONFIG::TPTC_DBS_CONFIG_TPTC<0/1>

11.3 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller. The description contained in this section is generic to the EDMA module, and not all features mentioned here are supported by the device. See the EDMA integration section of the device to determine the applicability of these features.

11.3.1 Block Diagram

Figure 11-3 shows the functional block diagram of the EDMA controller.

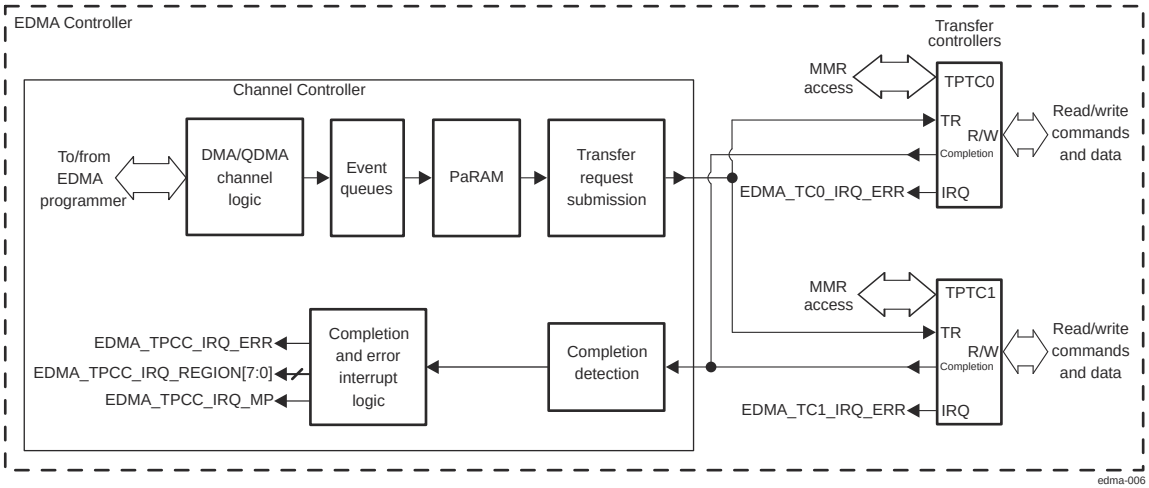

Figure 11-3. EDMA Controller Block Diagram

11.3.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 11-4 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- EDMA event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 11-4 is a block diagram of the EDMA_TPCC.

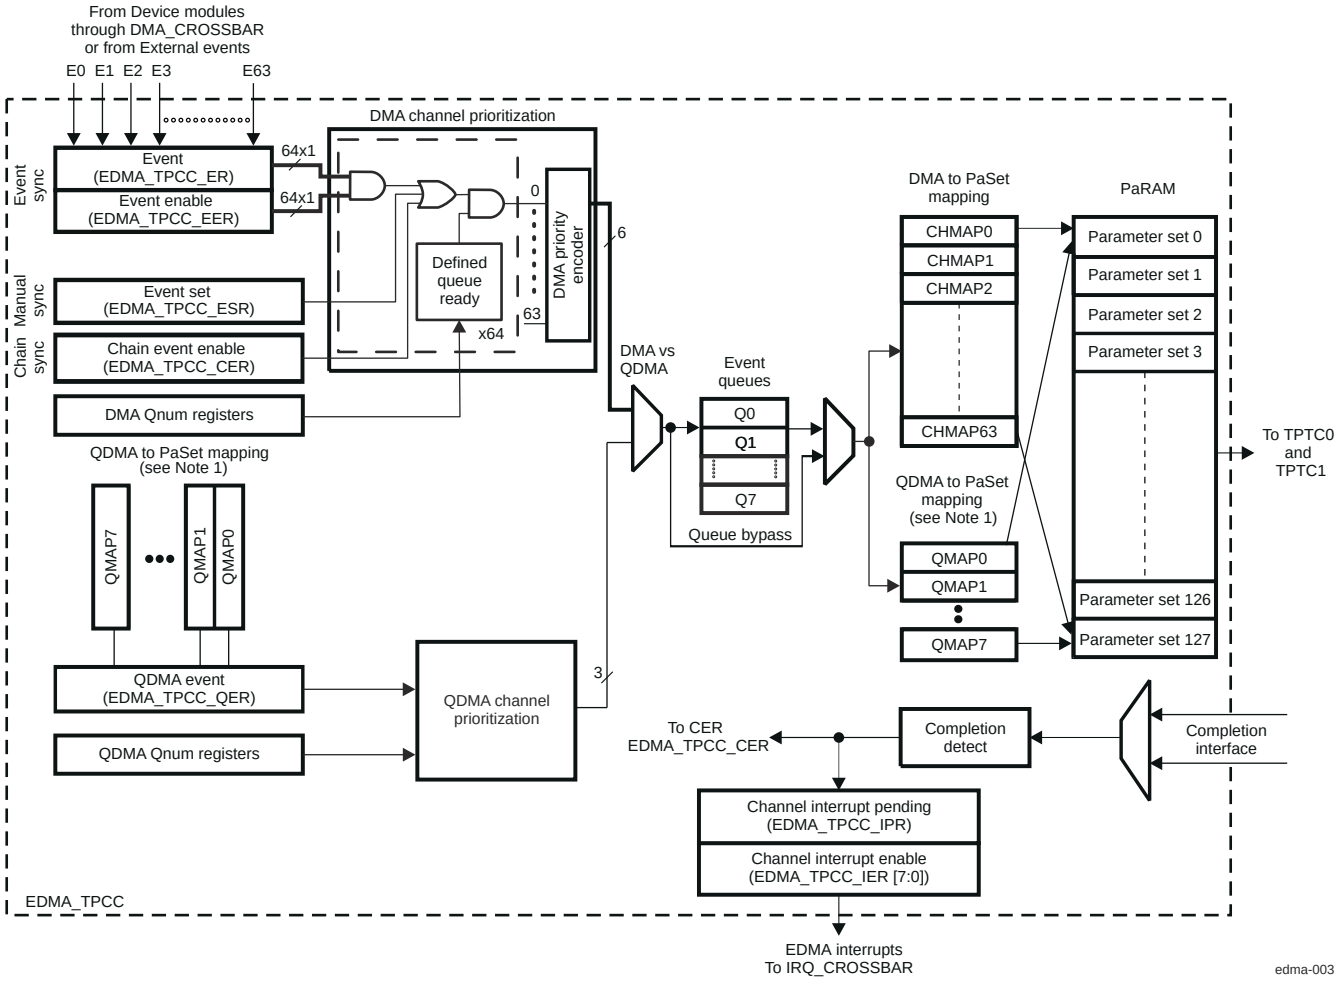

Figure 11-4. EDMA Channel Controller Block Diagram

A. Although it is depicted twice in Figure 11-4, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry.

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

11.3.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated controller ports: a read-only port and a write-only port.

Figure 11-5 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

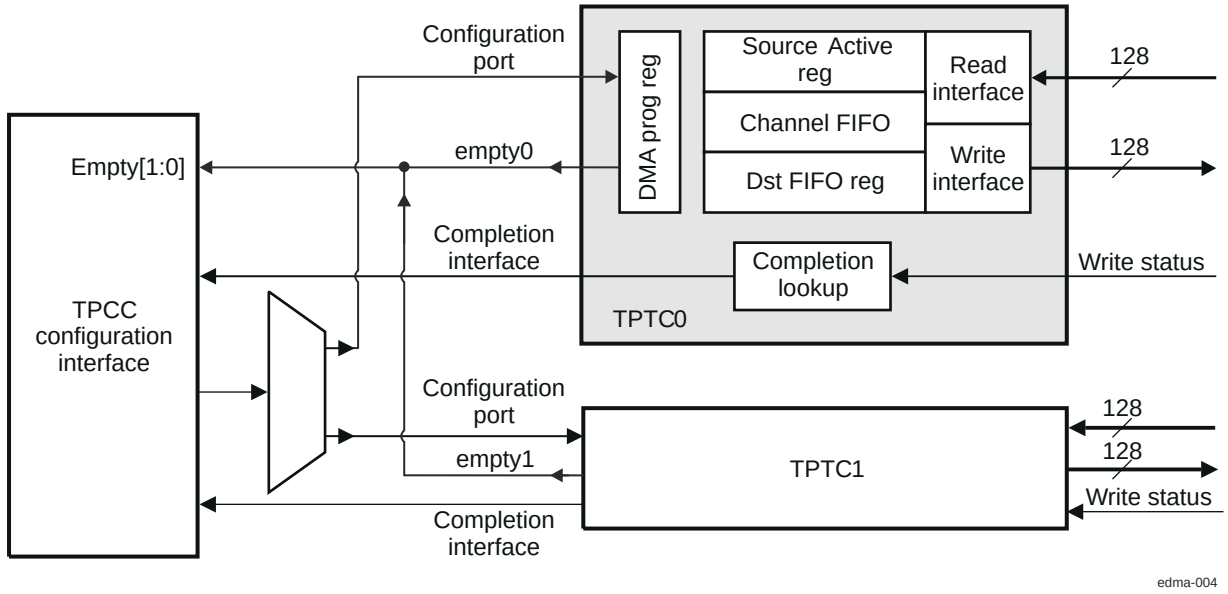

Figure 11-5. TPTC Block Diagram

Note

The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- DMA Program Register Set: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- Source Active Register Set : Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.
- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.

- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Target interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

11.3.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 11-6 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

Note

The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

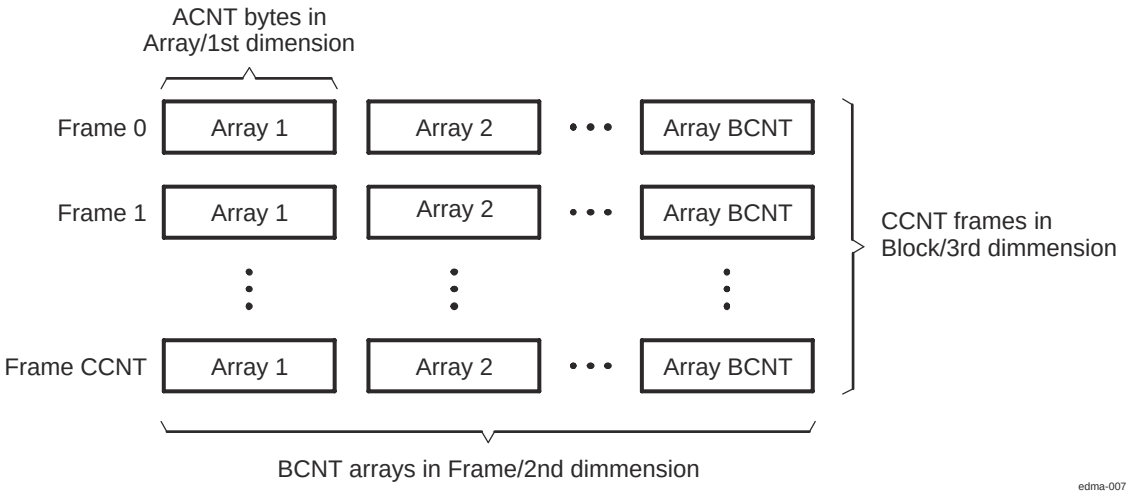

Figure 11-6. Definition of ACNT, BCNT, and CCNT

11.3.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0]SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 11-7, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 11-7, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 11-7 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 11-7 for details on parameter set updates.

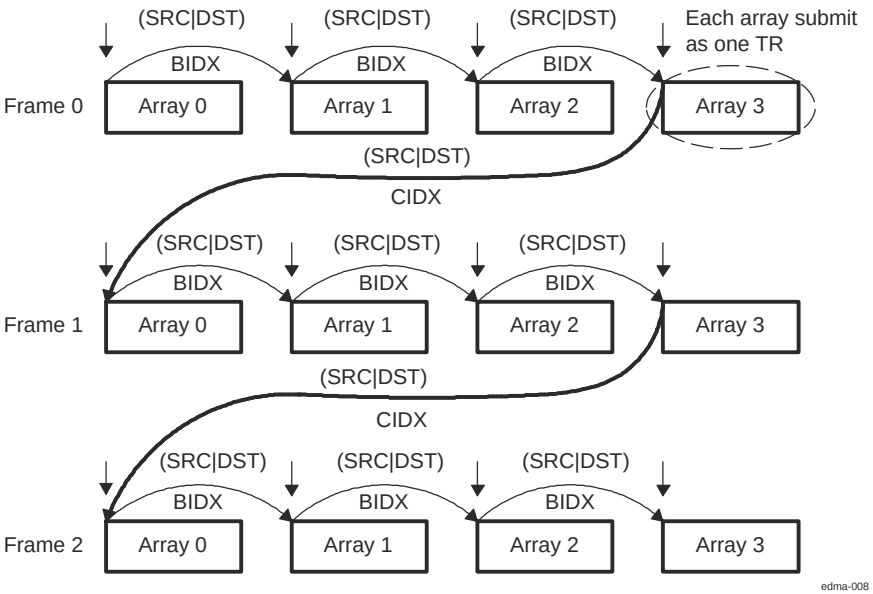

Figure 11-7. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

11.3.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 11-8. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 11.3.3.6 *Parameter Set Updates* for details on parameter set updates.

Figure 11-8 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

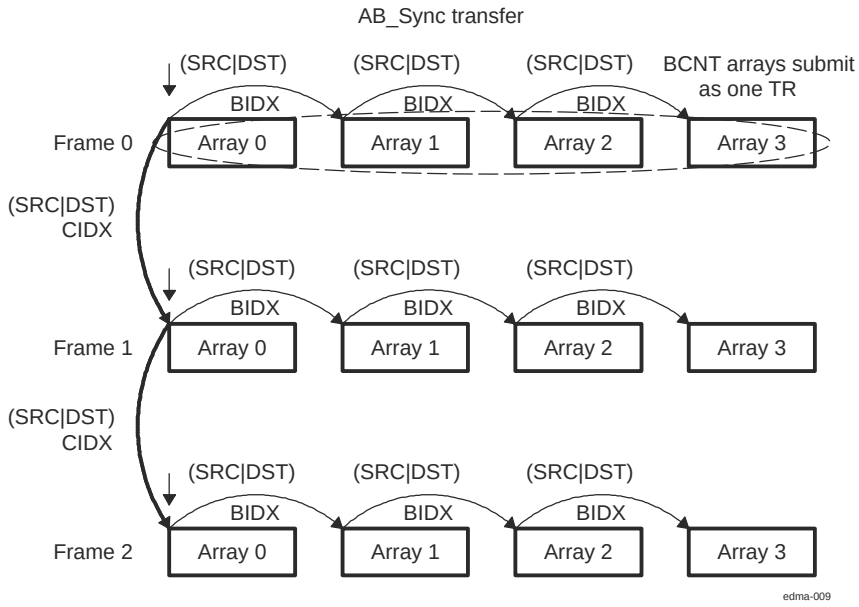

Figure 11-8. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

Note

ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

11.3.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 128 PaRAM sets

- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 8 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 11-13. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
127	EDMA Base Address + 5000h to EDMA Base Address + 501Fh	PaRAM set 127

11.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in and described in . Each PaRAM set consists of 16-bit and 32-bit parameters.

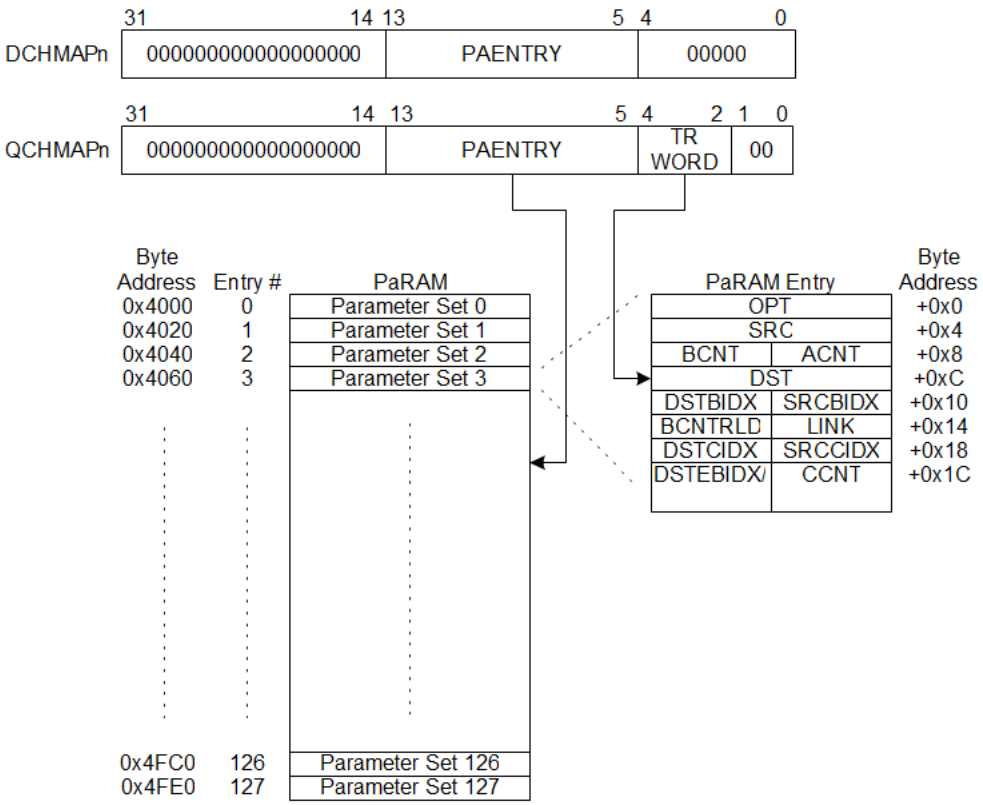

Figure 11-9. PaRAM Set

Note

Figure above is a representation of 128 bit entries. For device specific details please refer to EDMA configuration chapter.

Table 11-14. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

11.3.3.2 EDMA Channel PaRAM Set Entry Fields

11.3.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in Section 11.6.

11.3.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 11.3.12.3 *Error Generation* for additional details.

11.3.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 11.3.12.3 *Error Generation* for additional details.

11.3.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 11.3.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.3.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.3.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 11.3.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.3.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.3.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to Section 11.3.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.3.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.3.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on

each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

11.3.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

11.3.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to Section 11.3.3.2.8 *Source B Index (SBIDX)* for examples.

11.3.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 11-7), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 11-8).

11.3.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 11-7), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 11-8).

11.3.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see Section 11.3.5 *Completion of a DMA Transfer* for details on terminating a transfer.

11.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).
This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

11.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

11.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EDMA_TPCC_EMR to get set and the E*n* bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 11-15 summarizes the conditions and effects of null and dummy transfer requests.

Table 11-15. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No

Table 11-15. Dummy and Null Transfer Request (continued)

Feature	Null TR	Dummy TR
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

11.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to Table 11-16 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 11.3.3.7 *Linking Transfers*.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.

Note

PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 11.3.12 *EDMA Transfer Controller (EDMA_TPTC)*. For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

Table 11-16 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 11-16. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_CCNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TPTC	+= SCIDX	= Link.EDMA_TPCC_SRC_n

OPT(1)	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

Note

The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

11.3.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

Note

It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to Section 11.3.3.3 *Null PaRAM Set*.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set.
Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 11-10 shows an example of a linked transfer.

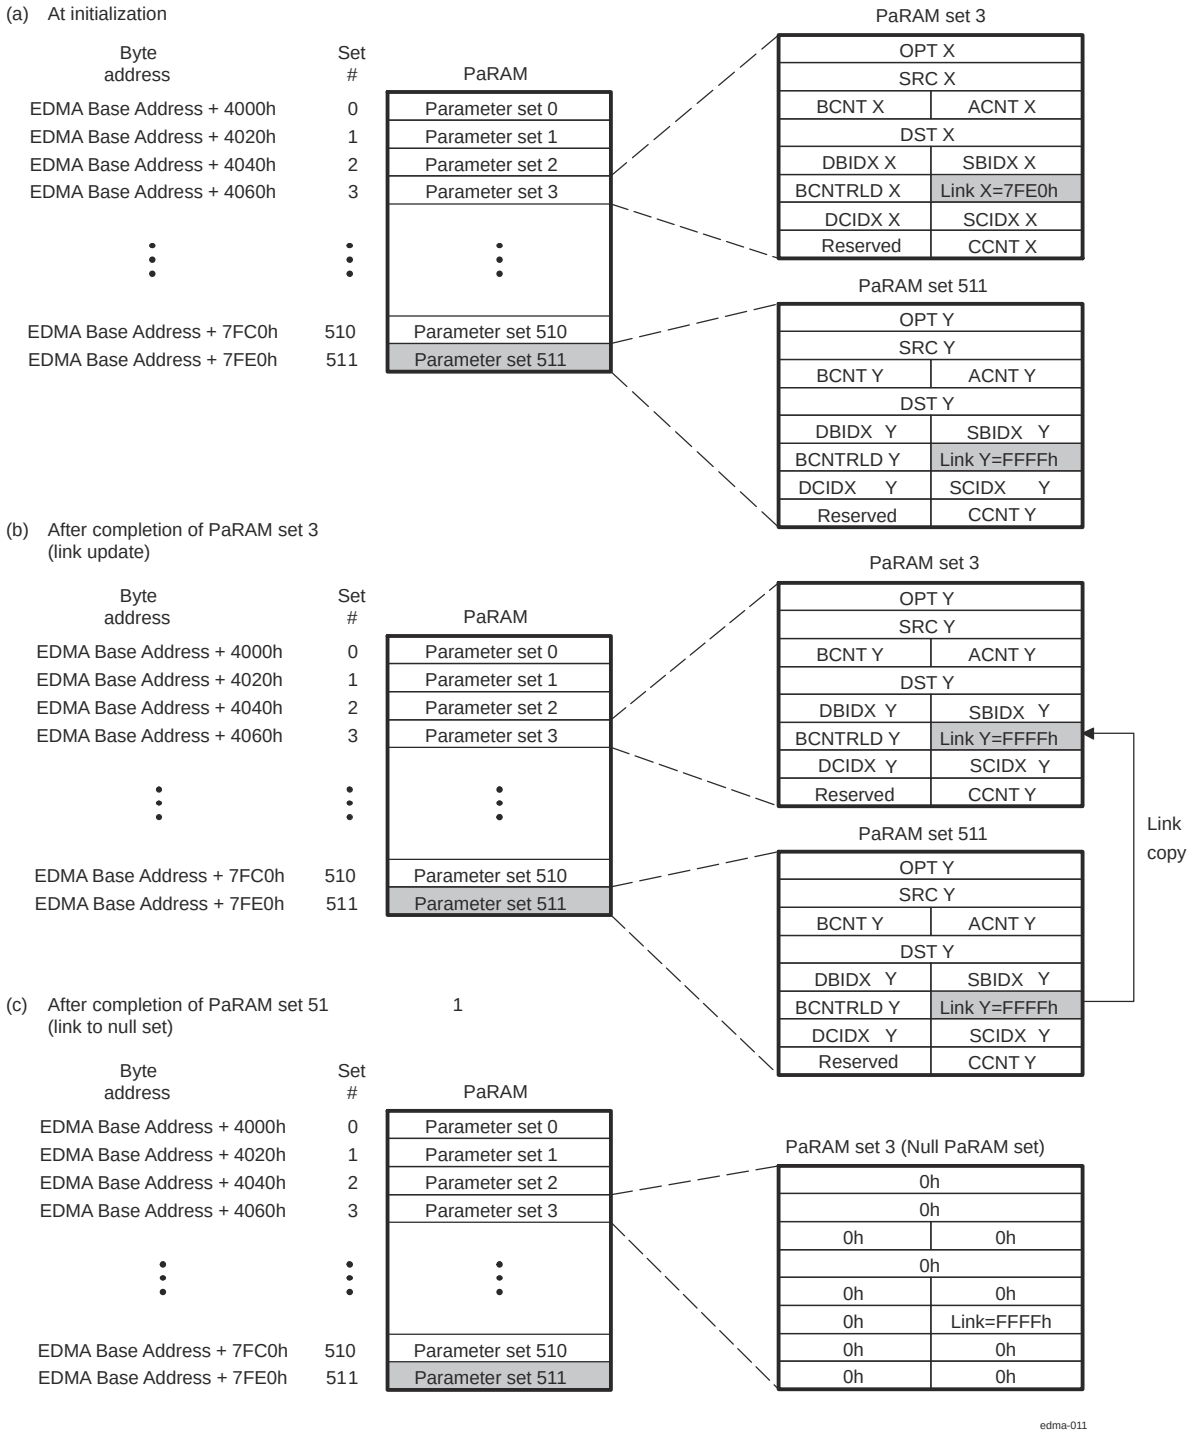

Figure 11-10. Linked Transfer

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 11.3.6 *Event, Channel, and PaRAM Mapping*) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used to

create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to Section 11.3.4.2 *QDMA Channels*.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 11-11 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

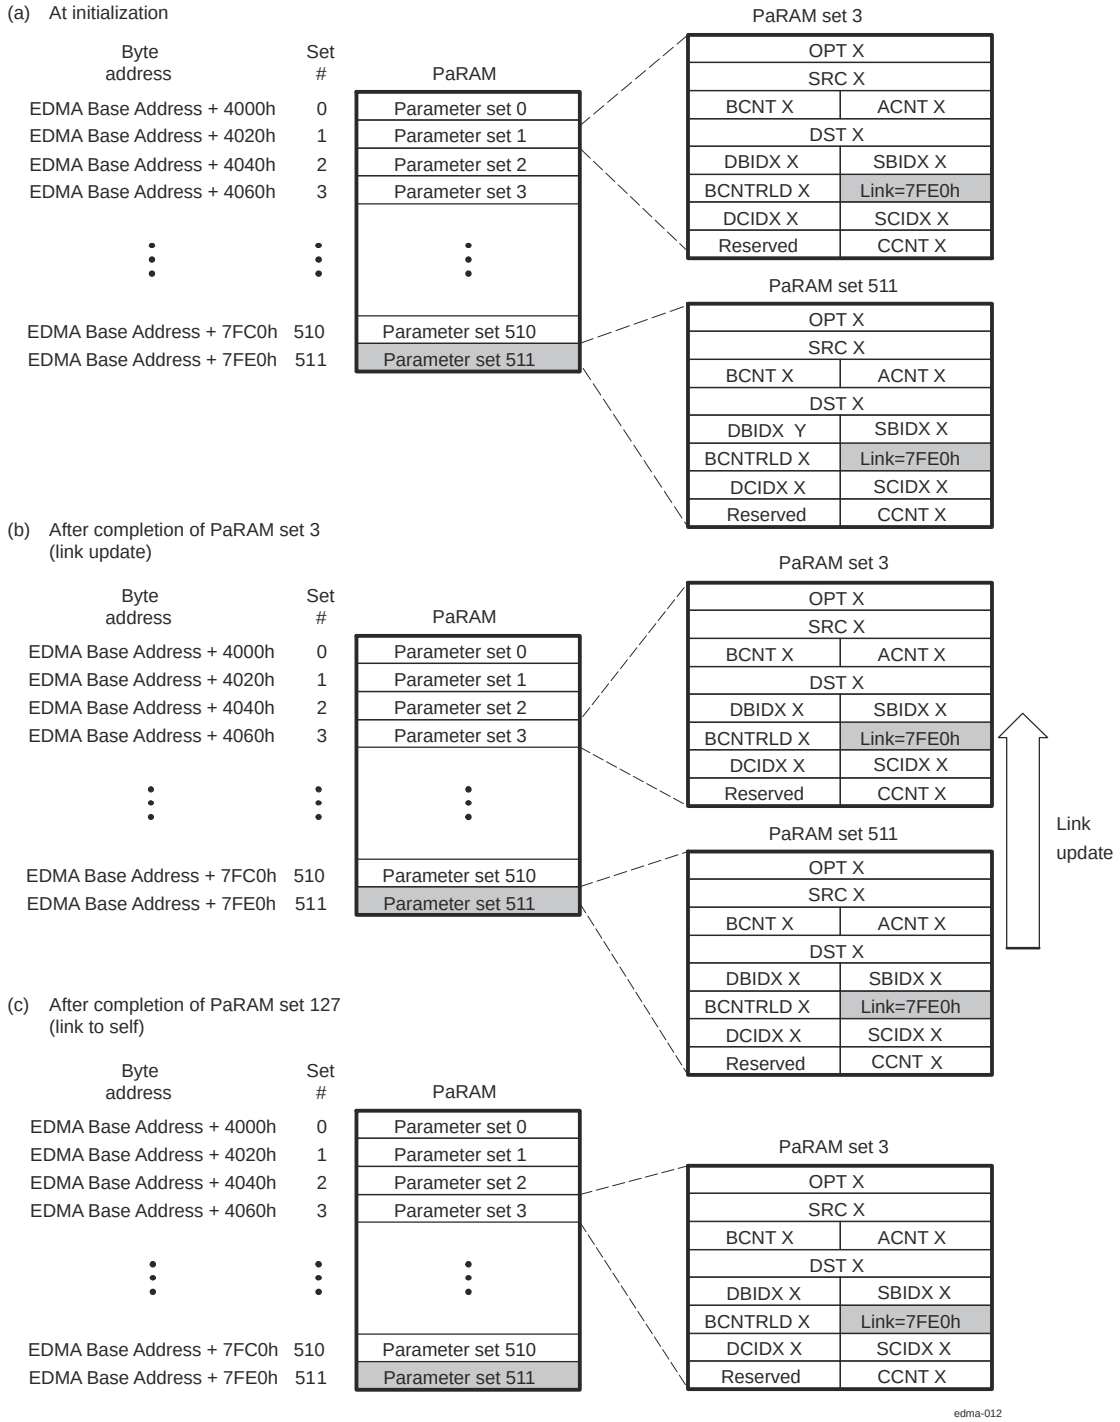

Figure 11-11. Link-to-Self Transfer

Note

If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

11.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to Section 11.3.12.3 *Error Generation*.

Note

The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM =0) by appropriately programming the count and indices values.

11.3.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

11.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

11.3.4.1 DMA Channels

11.3.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] E*n* = 1). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.
If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] E*n* bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see Section 11.3.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] E*n* = 1), regardless of the state of EDMA_TPCC_EER[31:0] E*n*. If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] E*n* = 1 and EDMA_TPCC_EER[31:0] E*n* = 0), the EDMA_TPCC_ER[31:0] E*n* bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] E*n* = 1).

11.3.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 11.3.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] E*n* = 1 prior to the original being cleared EDMA_TPCC_ESR[31:0] E*n* = 0, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

11.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] E[TCC] = 1).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 11.3.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] E*n* bit is cleared and

simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

Note

Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E*n* can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

11.3.4.2 QDMA Channels

11.3.4.2.1 Auto-Triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] E*n* = 1. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] E*n* = 1 and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] E*n* = 1.

11.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

Note

The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to

re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT =1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

11.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/ non-dummy transfer is shown in Table 11-17 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 11-17. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to Section 11.3.8 *Chaining EDMA Channels* for details on chaining (intermediate/final chaining) and Section 11.3.9 *EDMA Interrupts* for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to Section 11.3.3.7 *Linking Transfers* for more details.

Note

Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to Section 11.3.3.5 *Dummy Versus Null Transfer Comparison*.

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

11.3.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

11.3.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

11.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set Section 11.3.3.4 or null set Section 11.3.3.3. In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

11.3.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[3:0] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

11.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 11-12 illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

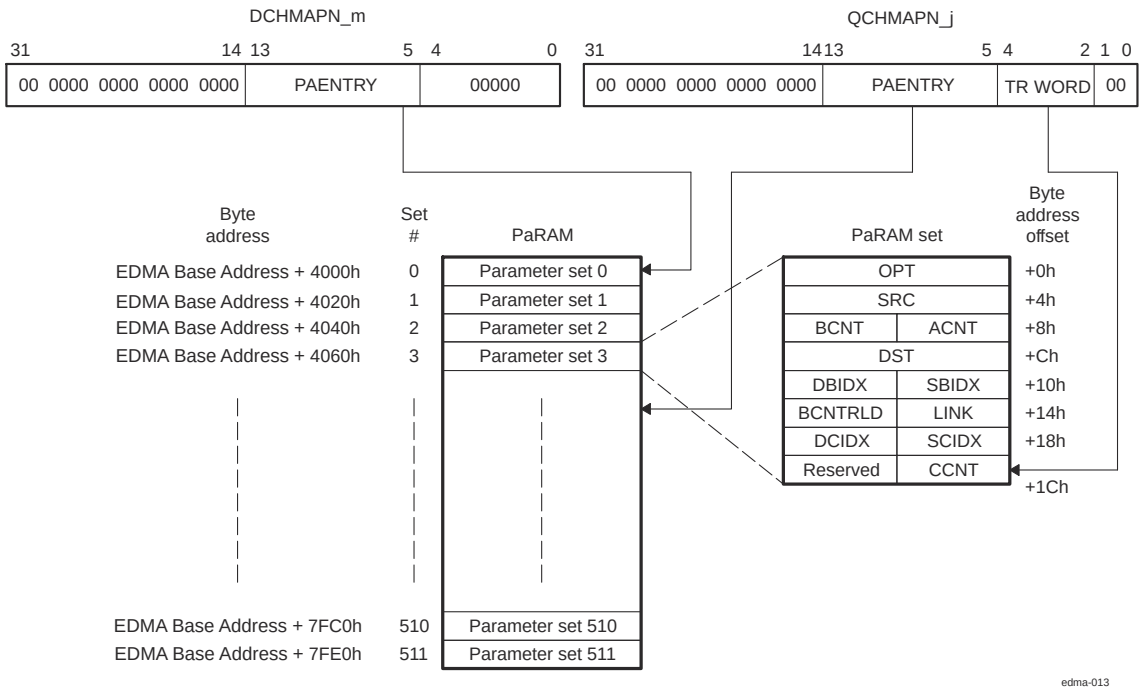

Figure 11-12. DMA Channel and QDMA Channel to PaRAM Mapping

11.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register EDMA_TPCC_QCHMAPN_j in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 11-13 illustrates the use of EDMA_TPCC_QCHMAPN_j.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by EDMA_TPCC_QCHMAPN_j for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

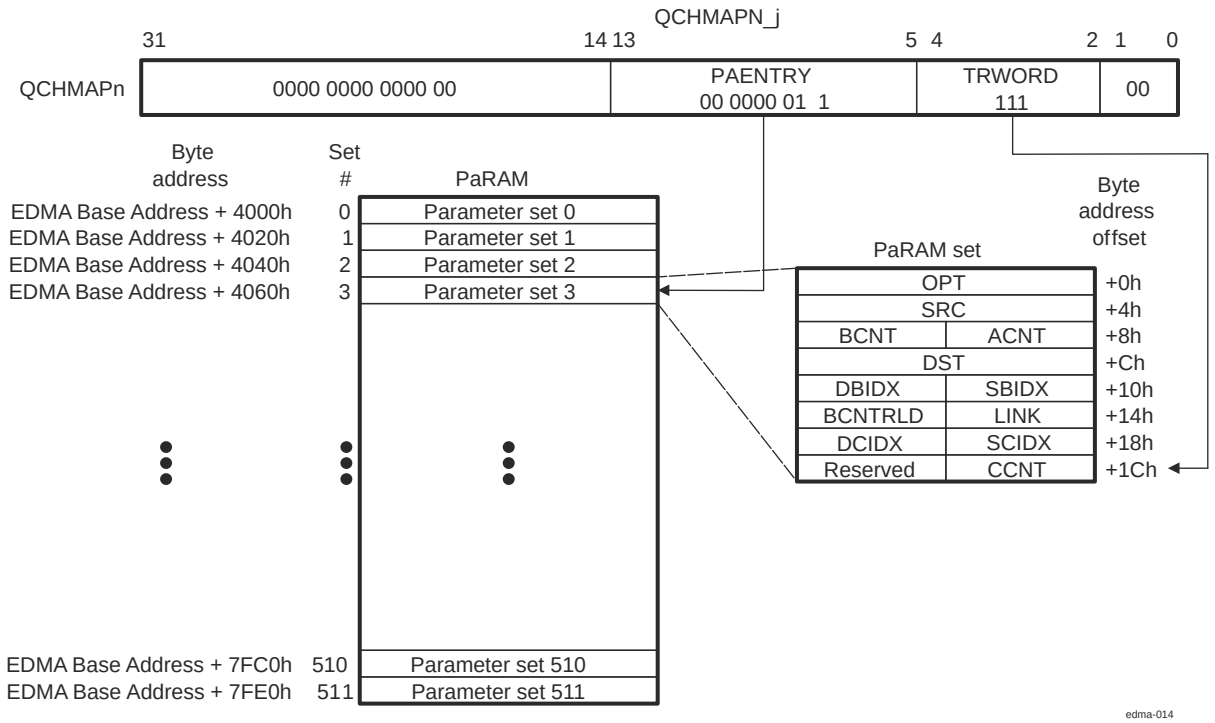

Figure 11-13. QDMA Channel to PaRAM Mapping

11.3.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in Section 11.3.10 *Memory Protection*.

11.3.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). Table 11-18

lists the registers in the shadow region memory map. Refer to *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Table 11-18. Shadow Region Registers

EDMA_TPCC_DRAEM_k	EDMA_TPCC_DRAEHM_k	EDMA_TPCC_QRAEN_k

Figure 11-14 illustrates the conceptual view of the regions.

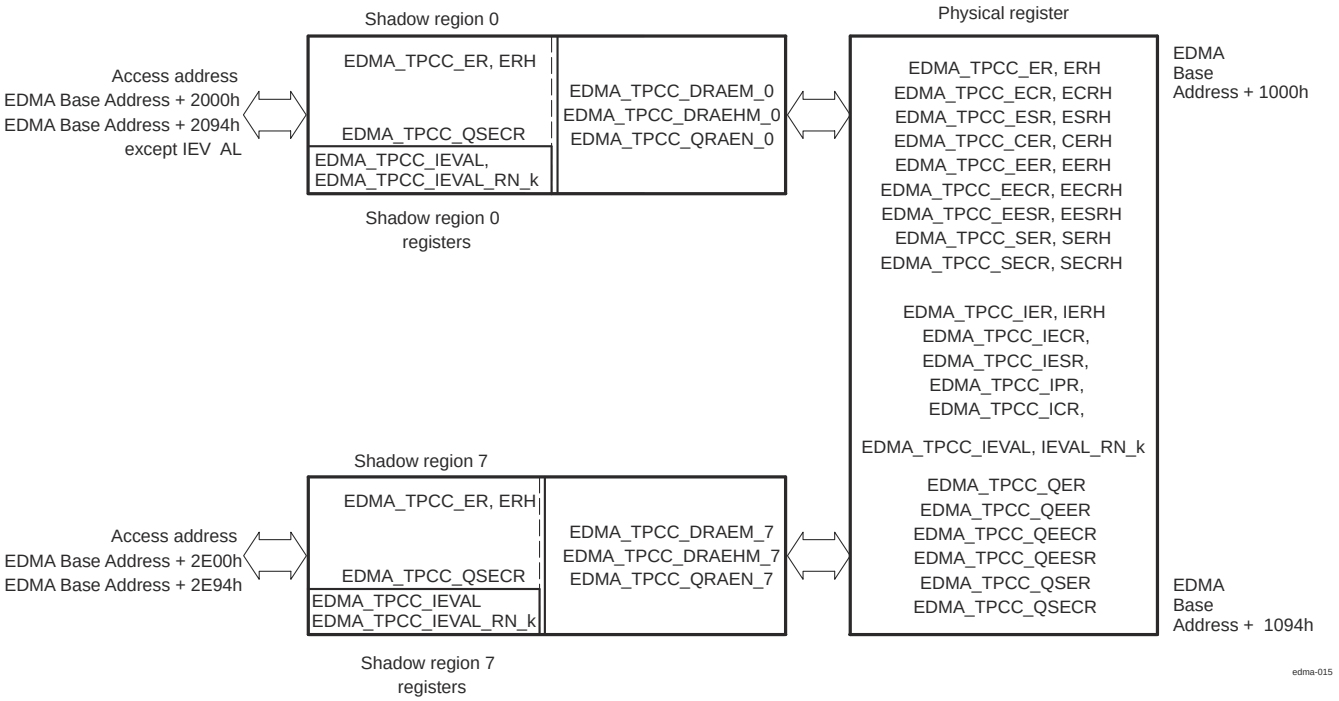

Figure 11-14. Shadow Region Registers

11.3.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMA_TPCC_DRAEM_k and EDMA_TPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMA_TPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMA_TPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMA_TPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMA_TPCC_QEESR there will be no the desired effect.
- EDMA_TPCC_MPPAN_k and EDMA_TPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k have the associated bit set.

Example 11-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

11.3.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to *Hardware Request* for more information about EDMA Interrupts.

11.3.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 11.3.3.7 *Linking Transfers*). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see Section 11.3.4.1.3 *Chain-Triggered Transfer Request*).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 11-19 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 11-19. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

11.3.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 11-20. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 11-20. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
EDMA_TPCC_INT3	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 11-21. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

11.3.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA controllers). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 11.3.9.1.1 *Enabling Transfer Completion Interrupts* for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 11-22. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set(1)
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	...	...	...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 11-23 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 11-23. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

11.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see Figure 11-15

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

Figure 11-15 shows the Interrupt diagram of the EDMA controller.

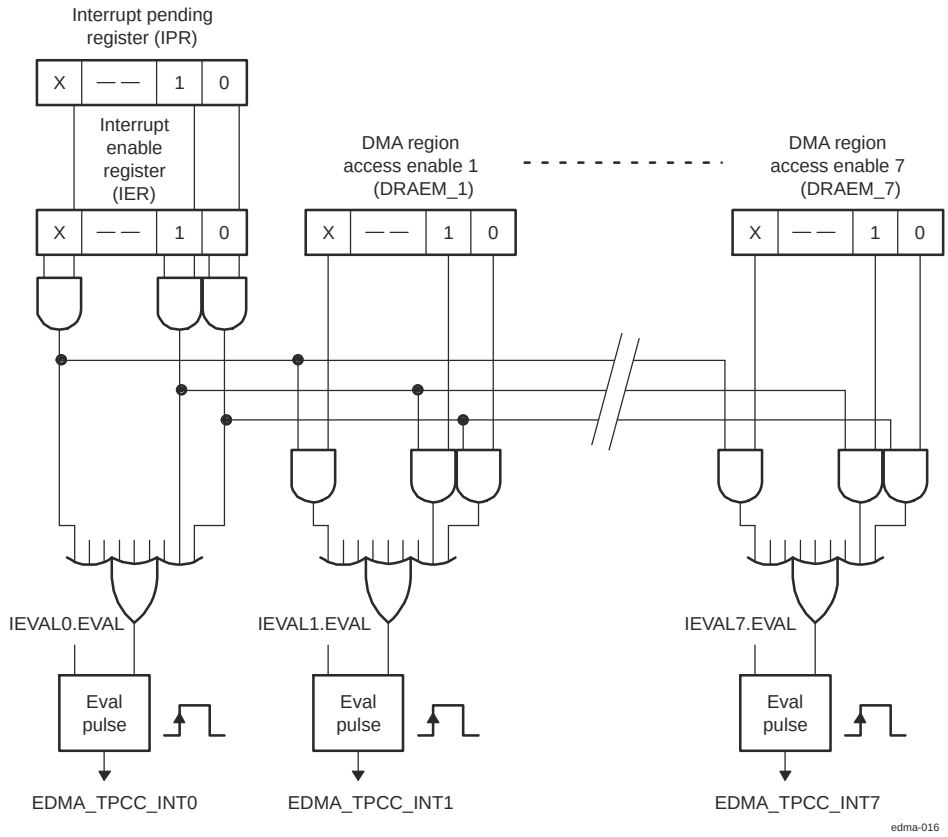

Figure 11-15. Interrupt Diagram

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | …| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

Note

The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

11.3.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

11.3.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/ EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in Example 11-2 and Example 11-3.

The ISR routine in Example 11-2 is more exhaustive and incurs a higher latency.

Example 11-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:

a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, assure that all of the enabled interrupts are inactive.

Note

An event may occur during step 4 while the EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

11.3.9.3

Example 11-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 11-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the EDMA_TPCC_IEVAL[0] EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
3. For the condition that is set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA_TPCC after step 2).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH prior to exiting the ISR:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, then exit the ISR.
   b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, then set EDMA_TPCC_IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

11.3.9.4 Interrupt Evaluation Operations

The EDMA_TPCC has interrupt evaluate registers EDMA_TPCC_IEVAL that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k. Writing a 1 to the EDMA_TPCC_IEVAL[0] EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMA_TPCC_IER / EDMA_TPCC_IERH) is still pending EDMA_TPCC_IPR / EDMA_TPCC_IPRH. This register assures that the CPU does not miss the interrupts (or the EDMA controller associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to Example 11-3 about the use of EDMA_TPCC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register EDMA_TPCC_EEVAL exists in the global region. Writing a 1 to the EDMA_TPCC_EEVAL[0] EVAL bit causes the pulsing of the error interrupt if any pending errors are in EDMA_TPCC_EMR / EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR. See Section 11.3.9.5 *Error Interrupts* for additional information regarding error interrupts.

Note

While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

11.3.9.5 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

Figure 11-16 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with ‘1’ after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

Note

It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

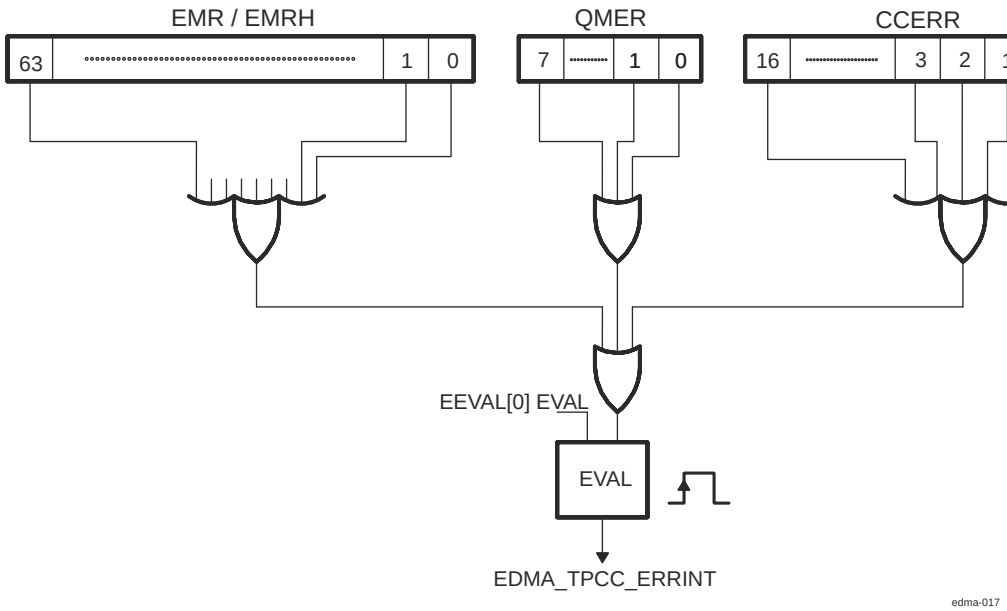

Figure 11-16. Error Interrupt Operation

11.3.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

11.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to Section 11.8.1.

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

Table 11-24 shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. TheEDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 11-24. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 11-25 describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 11-25. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect(1)	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k.MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example *Access denied.*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 11-26. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1.
	X	Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example *Access Allowed*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.
6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 11-27. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

11.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in Figure 11-17.

Figure 11-17. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 0007h			Channel Options Parameter (OPT)	
009F 0000h			Channel Source Address (SRC)	
0001h	0004h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h			Channel Destination Address (DST)	
0001h	0001h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h		Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT_n) Content

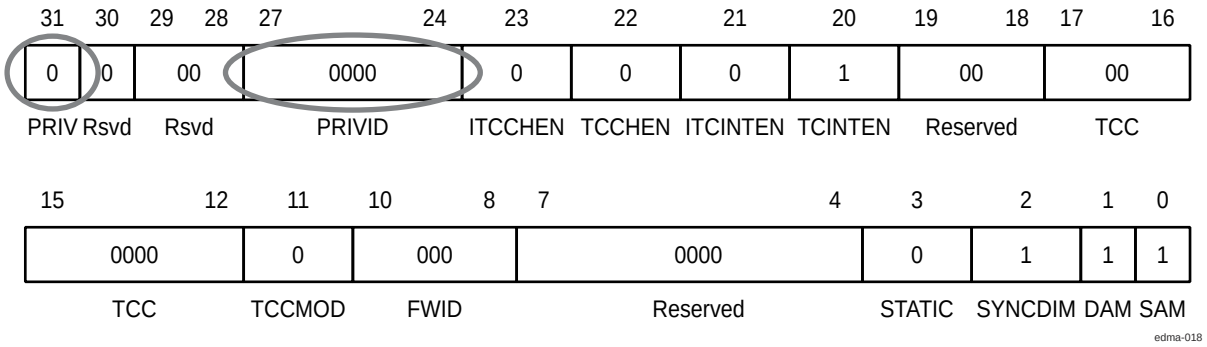

Figure 11-18. Channel Options Parameter (OPT) Example

The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 11-19 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

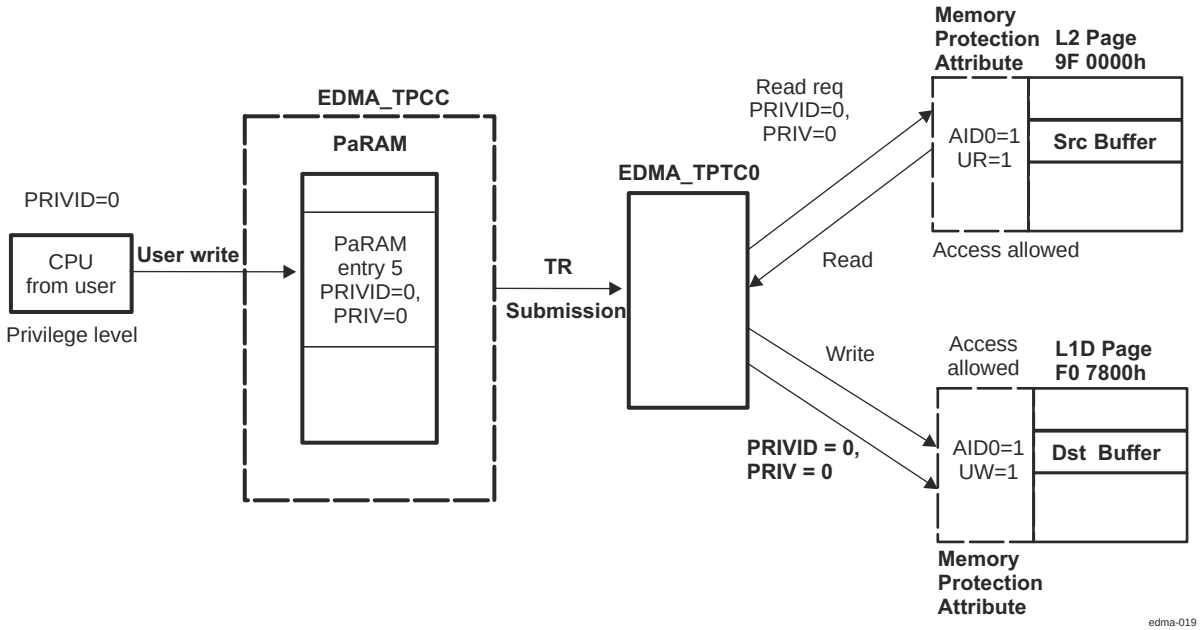

Figure 11-19. Proxy Memory Protection Example

11.3.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to Section 11.3.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to Section 11.8.1 for EDMA_TPCC_Q0E_p / EDMA_TPCC_Q1E_p descriptions of the bit fields.

11.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to Section 11.3.11.4 *System-level Performance Considerations*.

Note

If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

11.3.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (Q*x*E*y* Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n* EDMA_TPCC_QSTATN_i) includes fields for the start pointer EDMA_TPCC_QSTATN_i[3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN_i[12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN_i[3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN_i[12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

11.3.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN_i[20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN_i[12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRXCD*n* bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN_i[24] THRXCD bit, where *n* stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

11.3.11.4 Performance Considerations

The device system bus infrastructure arbitrates bus requests from all of the controllers (TCs, CPU(S), and other bus controllers) to the shared target resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other controllers within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to *Control Module Register Manual* in the *Control Module* chapter).

11.3.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

11.3.12.1 Architecture Details

11.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in the *TPTC DBS Configuration registers*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_ABCNT_n[31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 11-28 lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the

EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

Table 11-28 lists conditions in which the optimizations are performed.

Table 11-28. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

11.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 11-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8, EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10, EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.
2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1, EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

11.3.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a target, delaying other (potentially higher priority) controllers from successfully submitting commands to that target. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available target resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

11.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a controller) of the controller initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

11.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

11.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

Note

If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

11.3.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

11.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]E*n* / EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0] E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[7:0] E*n*) bit.

2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] E*n* \ EDMA_TPCC_SERH[31:0] E*n* (or EDMA_TPCC_QSER[7:0] E*n*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] E*n*/ EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0]E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[31:0] E*n*) bit and the EDMA_TPCC_SER[31:0] E*n*/ EDMA_TPCC_SERH[31:0] E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] E*n*/ EDMA_TPCC_SERH[31:0] E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC*n* then signals completion status to the EDMA_TPCC.

11.3.14 EDMA Controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 11-20 shows the different places EDMA priorities come into play.

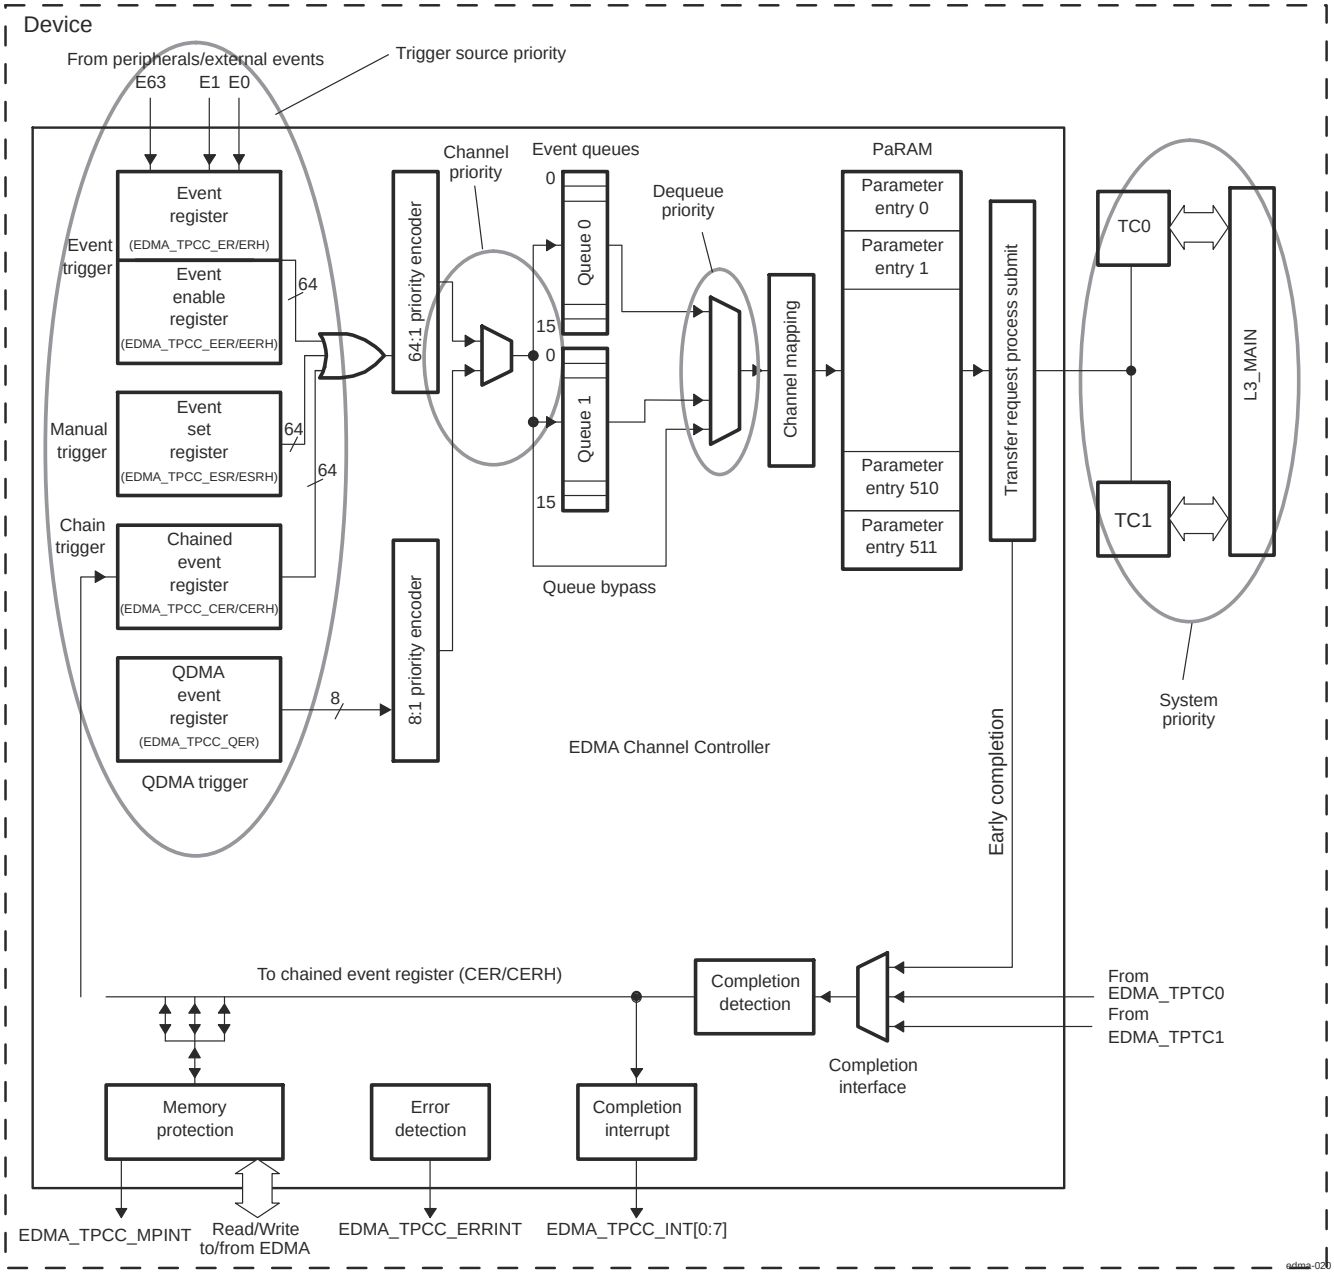

Figure 11-20. EDMA Prioritization

11.3.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

11.3.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] E*n* = 1, EDMA_TPCC_ESR[31:0] E*n* = 1 , EDMA_TPCC_CER[31:0] E*n* = 1) , then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] E0 = 1 and EDMA_TPCC_CER[0] E0 = 1 at the same time, then the EDMA_TPCC_ER[0] E0 event is always queued before the EDMA_TPCC_CER[0] E0 event.

11.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

11.3.15 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple controller and target peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

11.4 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

11.4.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 11-21.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 11-22 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 11-22 shows the parameters Block Move transfer.

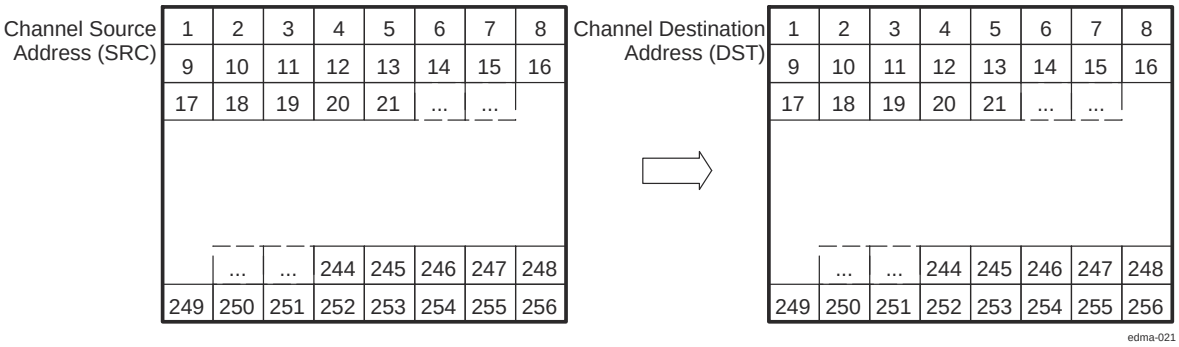

Figure 11-21. Block Move Example

Figure 11-22. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0008h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0001h	0100h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0000h	0000h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

11.4.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 11-23 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 11-24 shows the parameters for Subframe Extraction transfer.

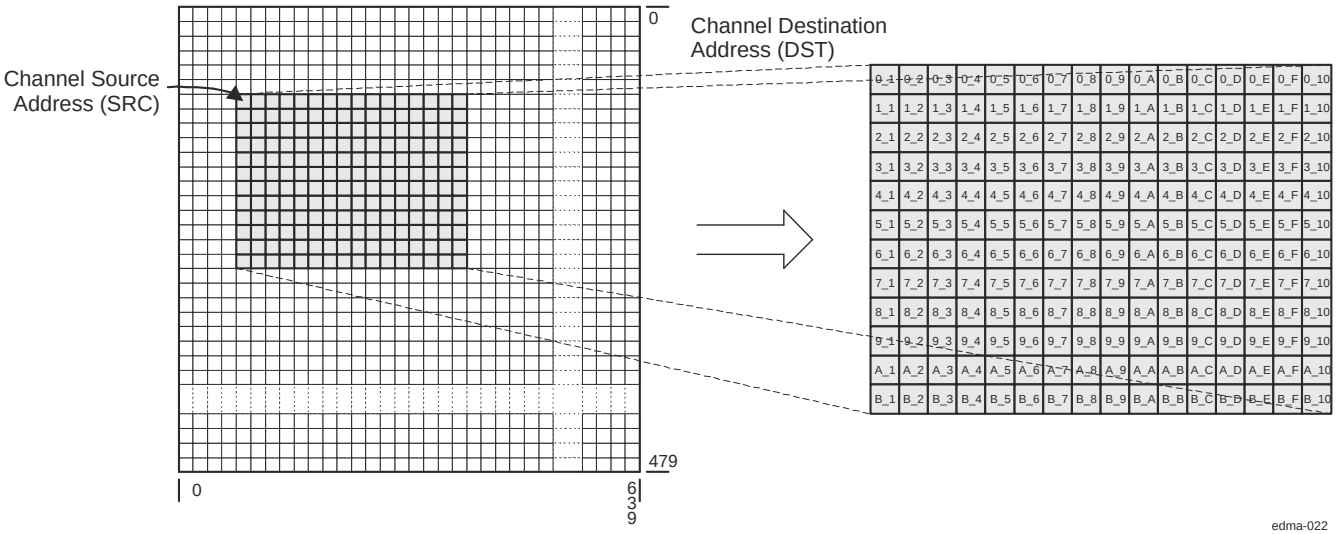

Figure 11-23. Subframe Extraction Transfer

Figure 11-24. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 000Ch			Channel Options Parameter (OPT)	
Channel Source Address (SRC)			Channel Source Address (SRC)	
000Ch	0020h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)			Channel Destination Address (DST)	
0020h	0500h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h		Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

11.4.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 11-26 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 11-25 shows the Data Sorting transfer

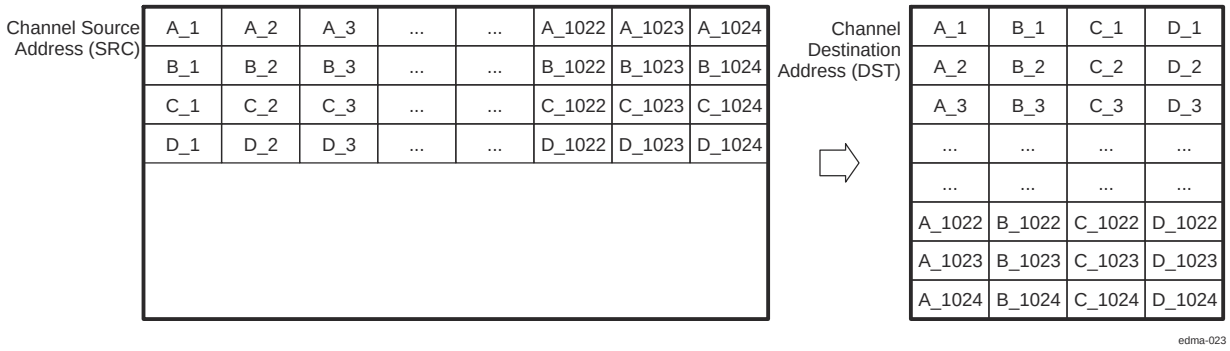

Figure 11-25. Data Sorting Example

Figure 11-26. Data Sorting Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0090 0004h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0400h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0010h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0004h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1
- EDMA_TPCC_OPT_n[23] ITCCHEN = 0x1

11.4.4 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel
   a. Determine the type of channel (QDMA or DMA) to be used.
   b. Channel mapping
      i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
      ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
   c. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 11.3.7.1.)
   d. Determine the type of triggering used.
      i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
      ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
   e. Queue setup
      i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
      ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.
2. Parameter set setup
   a. Program the PaRAM set number associated with the channel. Note that

Note

If it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

3. Interrupt setup
   a. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
   b. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
   c. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
   d. Set up the interrupt controller properly to receive the expected EDMA interrupt.
4. Initiate transfer
   a. This step is highly dependent on the event trigger source:
      i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
      ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
      iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
      iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.
5. Wait for completion
   a. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits

in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.

b. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

11.5 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

11.5.1 EDMA Debug Checklist

Table 11-29 provides some common issues and their probable causes and resolutions.

Table 11-29. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] E*n* and EDMA_TPCC_EMR[31:0] E*n* set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.

Table 11-29. Debug Checklist (continued)

Issue	Description/Solution
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 11.3.9.1.2 *Clearing Transfer Complerion Interrupts* for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

11.5.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAE / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
   For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
   However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

11.8.1.1.5 QDMAQNUM Register (Offset = 260h) [reset = 0h]

QDMAQNUM is shown in Figure 11-31 and described in Table 11-40.

Return to the Table 11-35.

QDMA Queue Number Register Contains the Event queue number to be used for the corresponding QDMA Channel.

Figure 11-31. QDMAQNUM Register

Bit	Field	Type	Reset	Description
31-7	RES29	R	0h	RESERVE FIELD
6-4	PRIQ1	R/W	0h	Priority Level for Queue 1 Dictates the priority level used for the OPTIONS field programmation for Qn TRs. Sets the priority used for TC read and write commands.
3	RES30	R	0h	RESERVE FIELD
2-0	PRIQ0	R/W	0h	Priority Level for Queue 0 Dictates the priority level used for the OPTIONS field programmation for Qn TRs. Sets the priority used for TC read and write commands.

11.8.1.1.8 EMR Register (Offset = 300h) [reset = 0h]

EMR is shown in Figure 11-34 and described in Table 11-43.

Return to the Table 11-35.

Event Missed Register: The Event Missed register is set if 2 events are received without the first event being cleared or if a Null TR is serviced. Chained events (CER) Set Events (ESR) and normal events (ER) are treated individually. If any bit in the EMR register is set (and all errors (including QEMR/CCERR) were previously clear) then an error will be signaled with TPCC error interrupt.

Bit	Field	Type	Reset	Description
31-17	RES33	R	0h	RESERVE FIELD
16	TCERR	R	0h	Transfer Completion Code Error: TCCERR = 0 : Total number of allowed TCCs outstanding has not been reached. TCCERR = 1 : Total number of allowed TCCs has been reached. TCCERR can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors were previously clear) then an error will be signaled with TPCC error interrupt.
15-8	RES34	R	0h	RESERVE FIELD
7	QTHRXCD7	R	0h	Queue Threshold Error for Q7: QTHRXCD7 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD7 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD7 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
6	QTHRXCD6	R	0h	Queue Threshold Error for Q6: QTHRXCD6 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD6 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD6 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

Table 11-49. CCERR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	QTHRXCD5	R	0h	Queue Threshold Error for Q5: QTHRXCD5 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD5 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD5 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
4	QTHRXCD4	R	0h	Queue Threshold Error for Q4: QTHRXCD4 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD4 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD4 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
3	QTHRXCD3	R	0h	Queue Threshold Error for Q3: QTHRXCD3 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD3 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD3 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
2	QTHRXCD2	R	0h	Queue Threshold Error for Q2: QTHRXCD2 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD2 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD2 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
1	QTHRXCD1	R	0h	Queue Threshold Error for Q1: QTHRXCD1 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD1 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD1 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
0	QTHRXCD0	R	0h	Queue Threshold Error for Q0: QTHRXCD0 = 0 : Watermark/ threshold has not been exceeded. QTHRXCD0 = 1 : Watermark/ threshold has been exceeded. CCERR.QTHRXCD0 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

11.8.1.1.15 CCERRCLR Register (Offset = 31Ch) [reset = 0h]

CCERRCLR is shown in Figure 11-41 and described in Table 11-50.

Return to the Table 11-35.

Bit	Field	Type	Reset	Description
31-2	RES37	R	0h	RESERVE FIELD
1	SET	W	0h	Error Interrupt Set: CPU write of '1' to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of EMR/EMRH QEMR or CCERR. CPU write of '0' has no effect.
0	EVAL	W	0h	Error Interrupt Evaluate: CPU write of '1' to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the EMR/EMRH QEMR or CCERR registers. CPU write of '0' has no effect.

11.8.1.1.17 DRAEM Register (Offset = 340h) [reset = 0h]

DRAEM is shown in Figure 11-43 and described in Table 11-52.

Return to the Table 11-35.

DMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt.

15-14	RES62	R	0h	RESERVE FIELD

Table 11-73. CCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-8	COMPACTV	R	0h	Completion Request Active: Counter that tracks the total number of completion requests submitted to the TC. The counter increments when a TR is submitted with TCINTEN or TCCHEN set to '1'. The counter decrements for every valid completion code received from any of the external TCs. The CC will not service new TRs if COMPACTV count is already at the limit. COMPACTV = 0 : No completion requests outstanding. COMPACTV = 1: Total of '1' completion request outstanding. ... COMPACTV = 63 : Total of 63 completion requests are outstanding. No additional TRs will be submitted until count is less than 63.
7-5	RES63	R	0h	RESERVE FIELD
4	ACTV	R	0h	Channel Controller Active: Channel Controller Active is a logical-OR of each of the ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0 : Channel is idle. ACTV = 1 : Channel is busy.
3	RES64	R	0h	RESERVE FIELD
2	TRACTV	R	0h	Transfer Request Active: TRACTV = 0 : Transfer Request processing/submission logic is inactive. TRACTV = 1 : Transfer Request processing/submission logic is active.
1	QEVTACTV	R	0h	QDMA Event Active: QEVTACTV = 0 : No enabled QDMA Events are active within the CC. QEVTACTV = 1 : At least one enabled DMA Event (ER & EER ESR CER) is active within the CC.
0	EVTACTV	R	0h	DMA Event Active: EVTACTV = 0 : No enabled DMA Events are active within the CC. EVTACTV = 1 : At least one enabled DMA Event (ER & EER ESR CER) is active within the CC.

11.8.1.1.39 AETCTL Register (Offset = 700h) [reset = 0h]

AETCTL is shown in Figure 11-65 and described in Table 11-74.

Return to the Table 11-35.

Table 11-76. AETCMD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RES68	R	0h	RESERVE FIELD
0	CLR	W	0h	AET Clear command: CPU write of '1' to the CLR bit causes the tpcc_aet output signal and AETSTAT.STAT register to be cleared. CPU write of '0' has no effect..

11.8.1.1.42 ER Register (Offset = 1000h) [reset = 0h]

ER is shown in Figure 11-68 and described in Table 11-77.

Return to the Table 11-35.

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

11.8.1.1.48 CER Register (Offset = 1018h) [reset = 0h]

CER is shown in Figure 11-74 and described in Table 11-83.

Return to the Table 11-35.

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

11.8.1.1.49 CERH Register (Offset = 101Ch) [reset = 0h]

CERH is shown in Figure 11-75 and described in Table 11-84.

Return to the Table 11-35.

Chained Event Register (High Part): If CERH.En bit is set (regardless of state of EERH.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared via software.

11.8.1.1.50 EER Register (Offset = 1020h) [reset = 0h]

EER is shown in Figure 11-76 and described in Table 11-85.

Return to the Table 11-35.

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

11.8.1.1.56 SER Register (Offset = 1038h) [reset = 0h]

SER is shown in Figure 11-82 and described in Table 11-91.

Return to the Table 11-35.

Secondary Event Register: The secondary event register is used along with the Event Register (ER) to provide information on the state of an Event. En = 0 : Event is not currently in the Event Queue. En = 1 : Event is currently stored in Event Queue. Event arbiter will not prioritize additional events.

Table 11-105. IEVAL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RES69	R	0h	RESERVE FIELD
1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

11.8.1.1.71 QER Register (Offset = 1080h) [reset = 0h]

QER is shown in Figure 11-97 and described in Table 11-106.

Return to the Table 11-35.

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

11.8.1.1.72 QEER Register (Offset = 1084h) [reset = 0h]

QEER is shown in Figure 11-98 and described in Table 11-107.

Return to the Table 11-35.

QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. QEER.En is not directly writeable. QDMA channels can be enabled via writes to QEESR and can be disabled via writes to QEECR register. QEER.En = 1 The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in QER.En. QEER.En = 0 The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in QER.En.

11.8.1.1.75 QSER Register (Offset = 1090h) [reset = 0h]

QSER is shown in Figure 11-101 and described in Table 11-110.

Return to the Table 11-35.

QDMA Secondary Event Register: The QDMA secondary event register is used along with the QDMA Event Register (QER) to provide information on the state of a QDMA Event. En = 0 : Event is not currently in the Event Queue. En = 1 : Event is currently stored in Event Queue. Event arbiter will not prioritize additional events.

Figure 11-101. QSER Register

11.8.1.1.76 QSECR Register (Offset = 1094h) [reset = 0h]

QSECR is shown in Figure 11-102 and described in Table 11-111.

Return to the Table 11-35.

QDMA Secondary Event Clear Register: The secondary event clear register is used to clear the status of the QSER and QER register (note that this is slightly different than the SER operation which does not clear the ER.En register). CPU write of '1' to the QSECR.En bit clears the QSER.En and QER.En register fields. CPU write of '0' has no effect..

Figure 11-102. QSECR Register

11.8.1.1.77 ER_RN Register (Offset = 2000h) [reset = 0h]

ER_RN is shown in Figure 11-103 and described in Table 11-112.

Return to the Table 11-35.

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

11.8.1.1.79 ECR_RN Register (Offset = 2008h) [reset = 0h]

ECR_RN is shown in Figure 11-105 and described in Table 11-114.

Return to the Table 11-35.

Event Clear Register: CPU write of '1' to the ECR.En bit causes the ER.En bit to be cleared. CPU write of '0' has no effect.

11.8.1.1.83 CER_RN Register (Offset = 2018h) [reset = 0h]

CER_RN is shown in Figure 11-109 and described in Table 11-118.

Return to the Table 11-35.

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

11.8.1.1.85 EER_RN Register (Offset = 2020h) [reset = 0h]

EER_RN is shown in Figure 11-111 and described in Table 11-120.

Return to the Table 11-35.

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

11.8.1.1.86 EERH_RN Register (Offset = 2024h) [reset = 0h]

EERH_RN is shown in Figure 11-112 and described in Table 11-121.

Return to the Table 11-35.

Event Enable Register (High Part): Enables DMA transfers for ERH.En pending events. ERH.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CERH) or Event Set Register (ESRH). Note that if a bit is set in ERH.En while EERH.En is disabled no action is taken. If EERH.En is enabled at a later point (and ERH.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EERH.En is not directly writeable. Events can be enabled via writes to EESRH and can be disabled via writes to EECRH register. EERH.En = 0: ER.En is not enabled to trigger DMA transfers. EERH.En = 1: ER.En is enabled to trigger DMA transfers.

11.8.1.1.93 SECR_RN Register (Offset = 2040h) [reset = 0h]

SECR_RN is shown in Figure 11-119 and described in Table 11-128.

Return to the Table 11-35.

Secondary Event Clear Register: The secondary event clear register is used to clear the status of the SER registers. CPU write of '1' to the SECR.En bit clears the SER register. CPU write of '0' has no effect.

7	I7	W	0h	Interrupt associated with TCC #7
6	I6	W	0h	Interrupt associated with TCC #6

Table 11-134. IESR_RN Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	I5	W	0h	Interrupt associated with TCC #5
4	I4	W	0h	Interrupt associated with TCC #4
3	I3	W	0h	Interrupt associated with TCC #3
2	I2	W	0h	Interrupt associated with TCC #2
1	I1	W	0h	Interrupt associated with TCC #1
0	I0	W	0h	Interrupt associated with TCC #0

11.8.1.1.100 IESRH_RN Register (Offset = 2064h) [reset = 0h]

IESRH_RN is shown in Figure 11-126 and described in Table 11-135.

Return to the Table 11-35.

Int Enable Set Register (High Part): CPU write of '1' to the IESRH.In bit causes the IESRH.In bit to be set. CPU write of '0' has no effect..

11.8.1.1.101 IPR_RN Register (Offset = 2068h) [reset = 0h]

IPR_RN is shown in Figure 11-127 and described in Table 11-136.

Return to the Table 11-35.

Interrupt Pending Register: IPR.In bit is set when a interrupt completion code with TCC of N is detected. IPR.In bit is cleared via software by writing a '1' to ICR.In bit.

Figure 11-127. IPR_RN Register

15	14	13	12	11	10	9	8
RES76							
R-0h							
7	6	5	4	3	2	1	0
RES76						SET	EVAL
R-0h						W-0h	W-0h

Table 11-140. IEVAL_RN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RES76	R	0h	RESERVE FIELD
1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

11.8.1.1.106 QER_RN Register (Offset = 2080h) [reset = 0h]

QER_RN is shown in Figure 11-132 and described in Table 11-141.

Return to the Table 11-35.

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

Figure 11-132. QER_RN Register

11.8.1.1.107 QEER_RN Register (Offset = 2084h) [reset = 0h]

QEER_RN is shown in Figure 11-133 and described in Table 11-142.

Return to the Table 11-35.

QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. QEER.En is not directly writeable. QDMA channels can be enabled via writes to QEESR and can be disabled via writes to QEECR register. QEER.En = 1 The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in QER.En. QEER.En = 0 The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in QER.En.

Table 11-147. OPT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PRIV	R	0h	Privilege level: privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus. PRIV = 0 : User level privilege PRIV = 1 : Supervisor level privilege
30-28	RES83	R	0h	RESERVE FIELD
27-24	PRIVID	R	0h	Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus.
23	ITCCHEN	R/W	0h	Intermediate transfer completion chaining enable: 0: Intermediate transfer complete chaining is disabled. 1: Intermediate transfer complete chaining is enabled.
22	TCCHEN	R/W	0h	Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.
21	ITCINTEN	R/W	0h	Intermediate transfer completion interrupt enable: 0: Intermediate transfer complete interrupt is disabled. 1: Intermediate transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
20	TCINTEN	R/W	0h	Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
19	WIMODE	R/W	0h	Backward compatibility mode: 0: Normal operation 1 : WI Backwards Compatibility mode forces BCNT to be adjusted by '1' upon TR submission (0 means 1 1 means 2 ...) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)

Table 11-147. OPT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	RES84	R	0h	RESERVE FIELD
17-12	TCC	R/W	0h	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER (bit CER[TCC]) for chaining or in IER (bit IER[TCC]) for interrupts.
11	TCCMODE	R/W	0h	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .
10-8	FWID	R/W	0h	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.
7-4	RES85	R	0h	RESERVE FIELD
3	STATIC	R/W	0h	Static Entry: 0: Entry is updated as normal 1: Entry is static Count and Address updates are not updated after TRP is submitted. Linking is not performed.
2	SYNCDIM	R/W	0h	Transfer Synchronization Dimension: 0: A-Sync Each event triggers the transfer of ACNT elements. 1: AB-Sync Each event triggers the transfer of BCNT arrays of ACNT elements
1	DAM	R/W	0h	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO Dst addressing within an array wraps around upon reaching FIFO width.
0	SAM	R/W	0h	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR Src addressing within an array increments. Source is not a FIFO. 1: FIFO Src addressing within an array wraps around upon reaching FIFO width.

11.8.1.1.113 SRC Register (Offset = 4004h) [reset = 0h]

SRC is shown in Figure 11-139 and described in Table 11-148.

Return to the Table 11-35.

Source Address

Figure 11-139. SRC Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC																															
R/W-0h																															

Table 11-148. SRC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SRC	R/W	0h	Source Address: The 32-bit source address parameters specify the starting byte address of the source . If SAM is set to FIFO mode then the user should program the Source address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.

11.8.1.1.114 ABCNT Register (Offset = 4008h) [reset = 0h]

ABCNT is shown in Figure 11-140 and described in Table 11-149.

Return to the Table 11-35.

A and B byte count

Figure 11-140. ABCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															
R/W-0h																R/W-0h															

Table 11-149. ABCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNT	R/W	0h	BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation valid values for BCNT can be anywhere between 1 and 65535. Therefore the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame and BCNT=0 means 0 arrays in the frame. In normal mode a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the programmed BCNT value will be incremented by '1' before submission to TC. I.e. 0 means 1 1 means 2 2 means 3 ...
15-0	ACNT	R/W	0h	ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0 it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition the ACNT definition will disregard the 2 msbits. I.e. a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer resulting in null or dummy operation dependent on the state of BCNT and CCNT.

11.8.1.1.115 DST Register (Offset = 400Ch) [reset = 0h]

DST is shown in Figure 11-141 and described in Table 11-150.

Return to the Table 11-35.

Destination Address

Figure 11-141. DST Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST																															
R/W-0h																															

Table 11-150. DST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DST	R/W	0h	Destination Address: The 32-bit destination address parameters specify the starting byte address of the destination. If DAM is set to FIFO mode then the user should program the Destination address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.

11.8.1.1.116 BIDX Register (Offset = 4010h) [reset = 0h]

BIDX is shown in Figure 11-142 and described in Table 11-151.

Return to the Table 11-35.

Register description is not available

Figure 11-142. BIDX Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBIDX																SBIDX															
R/W-0h																R/W-0h															

Table 11-151. BIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DBIDX	R/W	0h	Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2's complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.
15-0	SBIDX	R/W	0h	Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2's complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.

11.8.1.1.117 LNK Register (Offset = 4014h) [reset = 0h]

LNK is shown in Figure 11-143 and described in Table 11-152.

Return to the Table 11-35.

Link and Reload parameters

Figure 11-143. LNK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															
R/W-0h																R/W-0h															

Table 11-152. LNK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNTRLD	R/W	0h	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT not thus BCNTRLD is a don't care field.
15-0	LINK	R/W	0h	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e. after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore if the user uses the literal address with a range from 0x4000 to 0x7FFF it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000 thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs) behavior is undefined for the user (i.e. don't have to test it). In the former case (2 msbs) user should be able to take advantage of this feature (i.e. do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM then the Link will be treated as a Null Linkand all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid/Secure state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e. a value of 0x3FFE is a non-NULL PaRAM link field.

11.8.1.1.118 CIDX Register (Offset = 4018h) [reset = 0h]

CIDX is shown in Figure 11-144 and described in Table 11-153.

Return to the Table 11-35.

Register description is not available

Figure 11-144. CIDX Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCIDX																SCIDX															
R/W-0h																R/W-0h															

Table 11-153. CIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DCIDX	R/W	0h	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a ABsync transfer is the first array in the frame.
15-0	SCIDX	R/W	0h	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a AB-sync transfer is the first array in the frame.

11.8.1.1.119 CCNT Register (Offset = 401Ch) [reset = 0h]

CCNT is shown in Figure 11-145 and described in Table 11-154.

Return to the Table 11-35.

C byte count

Figure 11-145. CCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-16	RES86	R	0h	RESERVE FIELD
15-0	CCNT	R/W	0h	CCNT : Count for 3rd Dimension: CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT can be anywhere between 1 and 65535. Therefore the maximum number of frames in a block is 65535 (64K-1 frames). CCNT of '1' means '1' frame in the block and CCNT of '0' means '0' frames in the block. A CCNT value of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. WIMODE has no affect on CCNT operation.

11.8.1.2 TPTC Registers

Table 11-155 lists the TPTC registers. All register offset addresses not listed in Table 11-155 should be considered as reserved locations and the register contents should not be modified.

Table 11-155. TPTC Registers

Offset	Acronym	Register Name	Section
0h	PID	Peripheral ID Register	Section 11.8.1.2.1

Table 11-158. TCSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	X	
13-12	DFSTRTPTR	R	0h	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO in units of entries. Legal values = 0x0 to 0x3
11-9	RESERVED	R	X	
8	ACTV	R	1h	Channel Active Channel Active is a logical-OR of each of the BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0 : Channel is idle. ACTV = 1 : Channel is busy.
7	RESERVED	R	X	
6-4	DSTACTV	R	0h	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter.
3	RESERVED	R	X	
2	WSACTV	R	0h	Write Status Active WSACTV = 0 : Write status is not pending. Write status has been received for all previously issued write commands. WSACTV = 1 : Write Status is pending. Write status has not been received for all previously issued write commands.

Table 11-158. TCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SRCACTV	R	0h	Source Active State SRCACTV = 0 : Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full [DSTFULL == 1]. SRCACTV = 1 : Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.
0	PROGBUSY	R	0h	Program Register Set Busy PROGBUSY = 0 : Prog set idle and is available for programming. PROGBUSY = 1 : Prog set busy. User should poll for PROGBUSY equal to '0' prior to re-programming the Program Register set.

11.8.1.2.4 INTSTAT Register (Offset = 104h) [reset = X]

INTSTAT is shown in Figure 11-149 and described in Table 11-159.

Return to the Table 11-155.

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	X	
17	TCCHEN	R	0h	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.
16	TCINTEN	R	0h	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.
15-14	RESERVED	R	X	
13-8	TCC	R	0h	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.
7-4	RESERVED	R	X	
3-0	STAT	R	0h	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec.

11.8.1.2.12 ERRCMD Register (Offset = 130h) [reset = X]

ERRCMD is shown in Figure 11-157 and described in Table 11-167.

Chapter 12
CANFD

This chapter describes the Modular Controller Area Network (MCAN) module.

12.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 5 Mbit/s data rate and is compliant to ISO 11898-1:2015.

Note

The availabilty of CAN FD feature is device part number dependent. Refer to device Data Manual for more information.

Figure 12-1 shows the MCAN module overview.

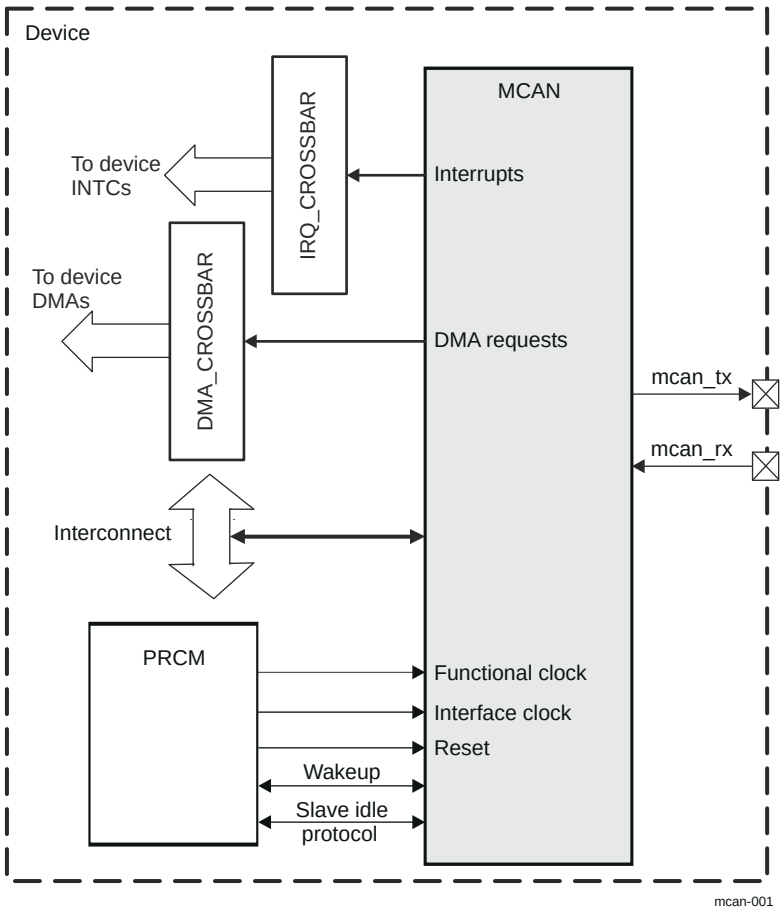

Figure 12-1. MCAN Module Overview

12.1.1 Features

The MCAN module implements the following features:

- Conforms with ISO 11898-1:2015

- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)
- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

12.2 MCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 12-2 shows an overview of a typical MCAN application.

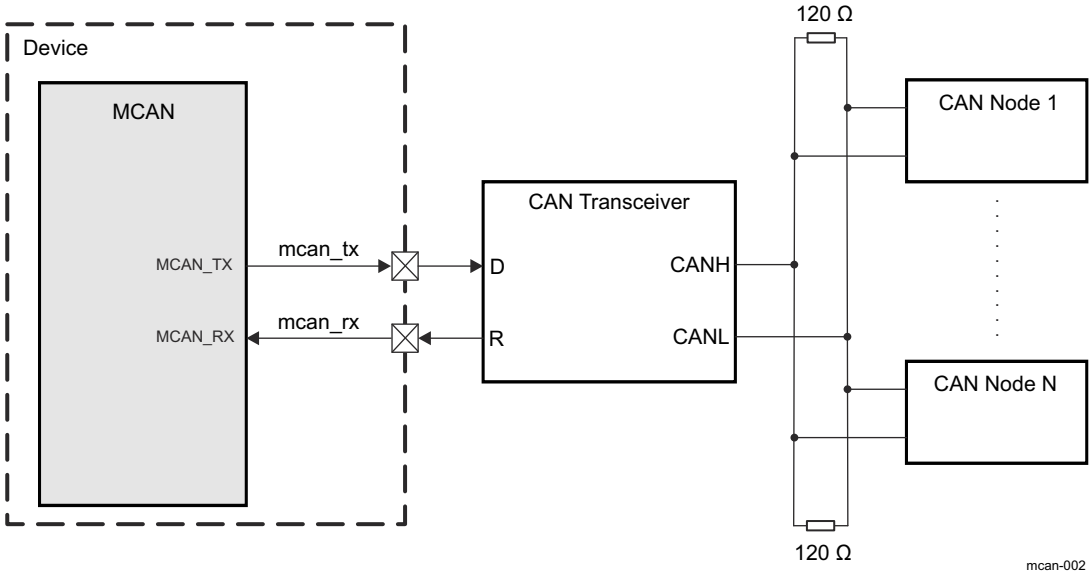

Figure 12-2. MCAN Typical Application

Table 12-1 describes the external signals of the MCAN module.

Table 12-1. MCAN I/O Description

Module Signal	Device Signal	I/O(1)	Description	Value at Reset
MCAN_RX	mcan_rx	I	Serial data input from external CAN tranceiver	HiZ
MCAN_TX	mcan_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* of *Control Module*.

12.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- The network is multicontroller. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored.

- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signalling*.

12.3 MCAN Integration

Figure 12-3 shows the integration of the MCAN module in the device.

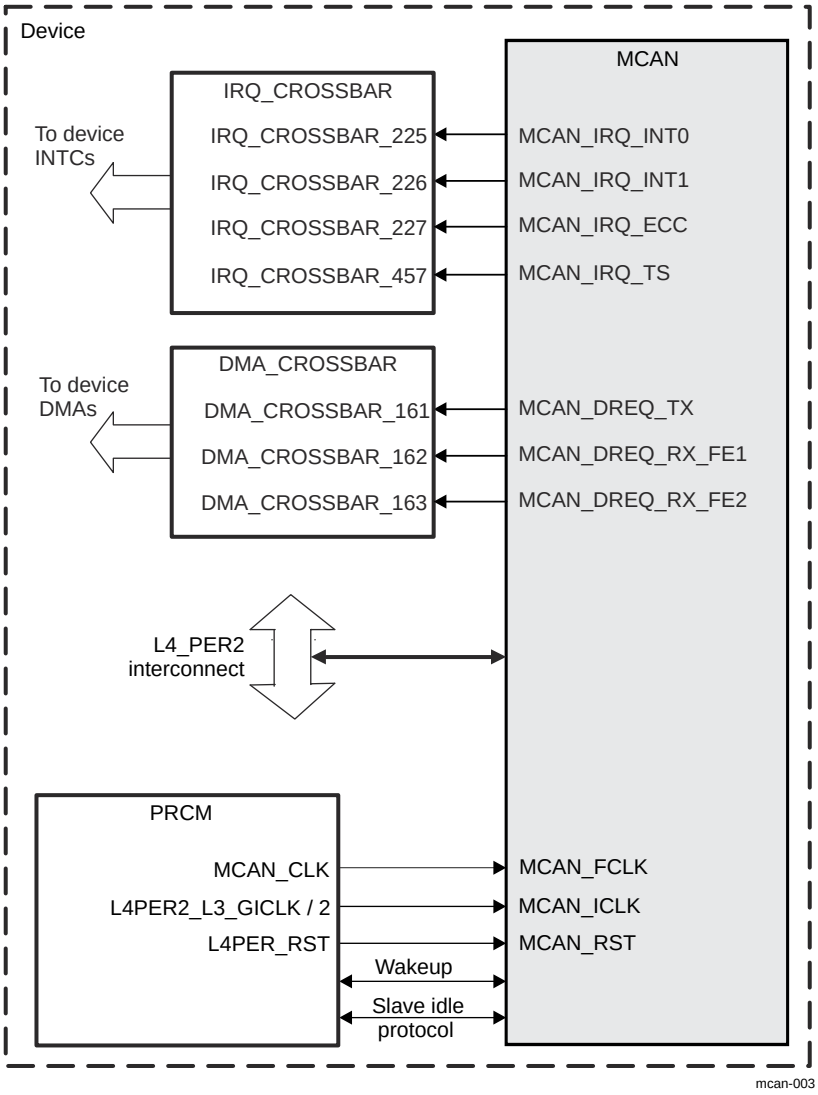

Figure 12-3. MCAN Integration

Table 12-2 through Table 12-4 summarize the integration of the MCAN module in the device.

Table 12-2. MCAN Integration Attributes

Module Instance	Attributes

	MCAN_IRQ_ECC	IRQ_CROSSBAR_227	-	MCAN ECC interrupt
	MCAN_IRQ_TS	IRQ_CROSSBAR_457	-	MCAN timestamp interrupt
DMA Requests				
Module Instance	**Source Signal Name**	**DMA_CROSSBAR Input**	**Default Mapping**	**Description**
MCAN	MCAN_DREQ_TX	DMA_CROSSBAR_161	-	MCAN TX DMA Event
	MCAN_DREQ_RX_FE1	DMA_CROSSBAR_162	-	MCAN RX Filter Event 1
	MCAN_DREQ_RX_FE2	DMA_CROSSBAR_163	-	MCAN RX Filter Event 2

Note

The MCAN module has no default IRQ mappings through the IRQ_CROSSBAR. For the MCAN module, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description* in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description* in *Control Module*.

Note

For the description of the interrupt source, see Section 12.4.2, *Interrupt and DMA Requests*.

12.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 5 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 12-4 shows the MCAN module block diagram.

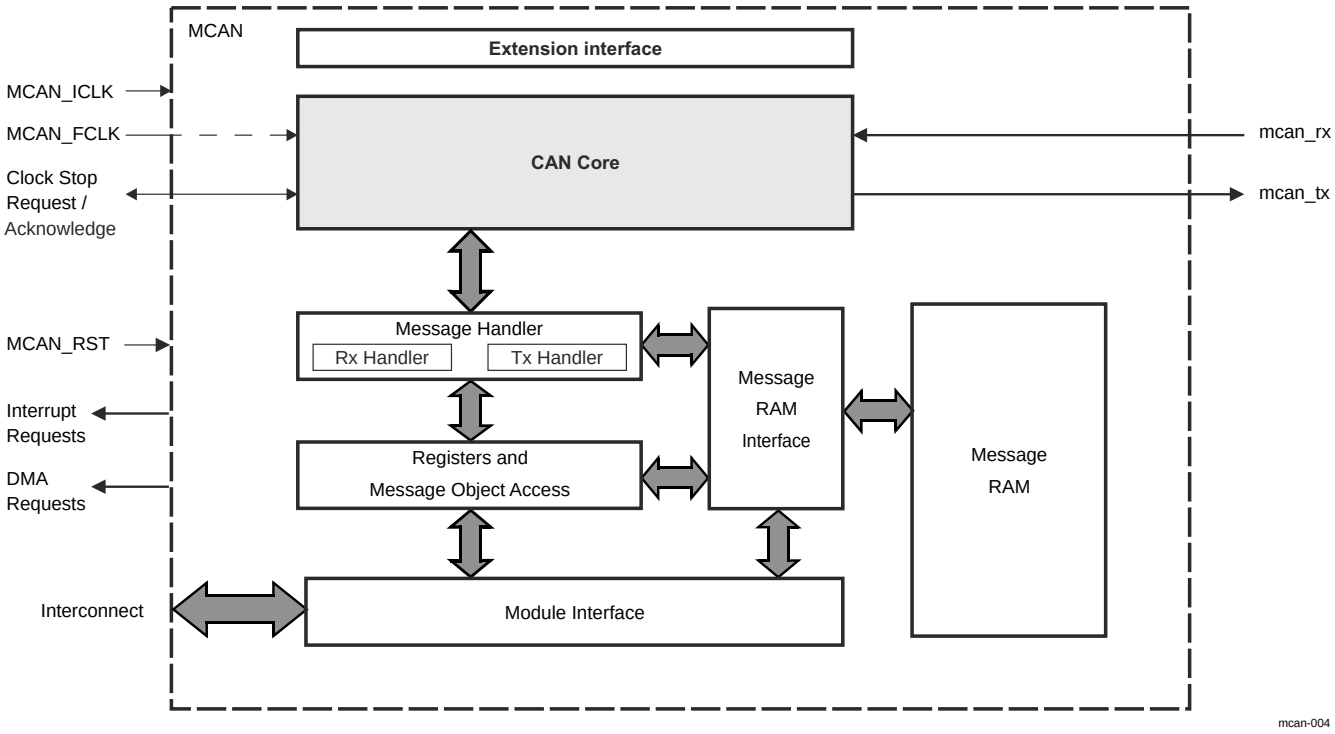

Figure 12-4. MCAN Block Diagram

The MCAN module blocks description:

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler**: the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 12.4.11, *Message RAM*).
- **Message RAM Interface**: enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access**: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface**: The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface**: All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

12.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

Note

MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$f_{0,ICLK}(OCP) \pm \Delta f_{FM,ICLK}(OCP) \geq f_{FCLK}$

CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than Classic CAN. For optimal performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK (GMAC_DSP_DPLL_CLK) for the system. Lower N-divider values increase the loop bandwidth of the PLL which in turn improves timing margins for CAN-FD.

For CAN-FD operations > 2 Mbps:
- For 20 MHz input clocks, N = 0 is the preferred configuration.

For CAN-FD operations < 2 Mbps:
- For 20 MHz input clocks, N = 0 is the preferred configuration.
- For 19.2 MHz input clocks, N = 11 is the preferred configuration.

For more information on how to configure the relevant clock source registers, see *PRCM* and the device data manual.

12.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see Section 12.4.4.8.2, *Suspend Mode*).

12.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write 1 to MCANSS_ECC_EOI[8] ECC_EOI bit (for more information, see Section 12.4.7.2, *ECC Aggregator*).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see Section 12.4.5.1, *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status (MCANSS_IES)
- End Of Interrupt (MCANSS_EOI)
- External Timestamp Prescaler (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

12.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extention Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

12.4.2.3

For more information about available Interrupt and DMA Requests, see Section 12.3, *MCAN Integration*.

12.4.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing 1 to MCAN_CCCR[8] FDOE bit. A value of 0 on the primary configuration port (mcanss_enable_fdoe) will force the MCAN_CCCR[8] FDOE bit during write to the MCAN_CCCR register which will prevent the device from enabling and using the CAN FD mode.

12.4.4 Operating Modes

12.4.4.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output MCAN_TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = 1. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15:0] TOC field is preset to the value configured by the MCAN_TOCC[31:16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN_CCCR[1] CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1.

12.4.4.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

Note

Automated transmission on reception of remote frames is not supported.

12.4.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR[4:3] ACT = 10) to Integrating (MCAN_PSR[4:3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 1, transmission of CAN FD frames

with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the DLC coding differs from the standard CAN format (see Table 12-5).

Table 12-5. DLC Coding

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames with bit rate switchingIn, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 12-5) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

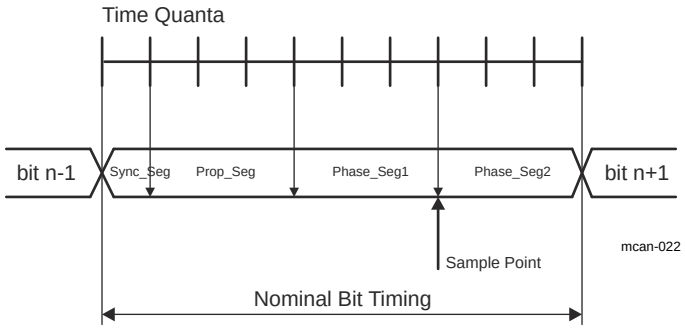

Figure 12-5. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

12.4.4.4 Transmitter Delay Compensation

12.4.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the MCAN_TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the MCAN_RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase

independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output MCAN_TX pin through the transceiver to the receive input MCAN_RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14:8] TDCO field (see Figure 12-6). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22:16] TDCV field. This filed is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

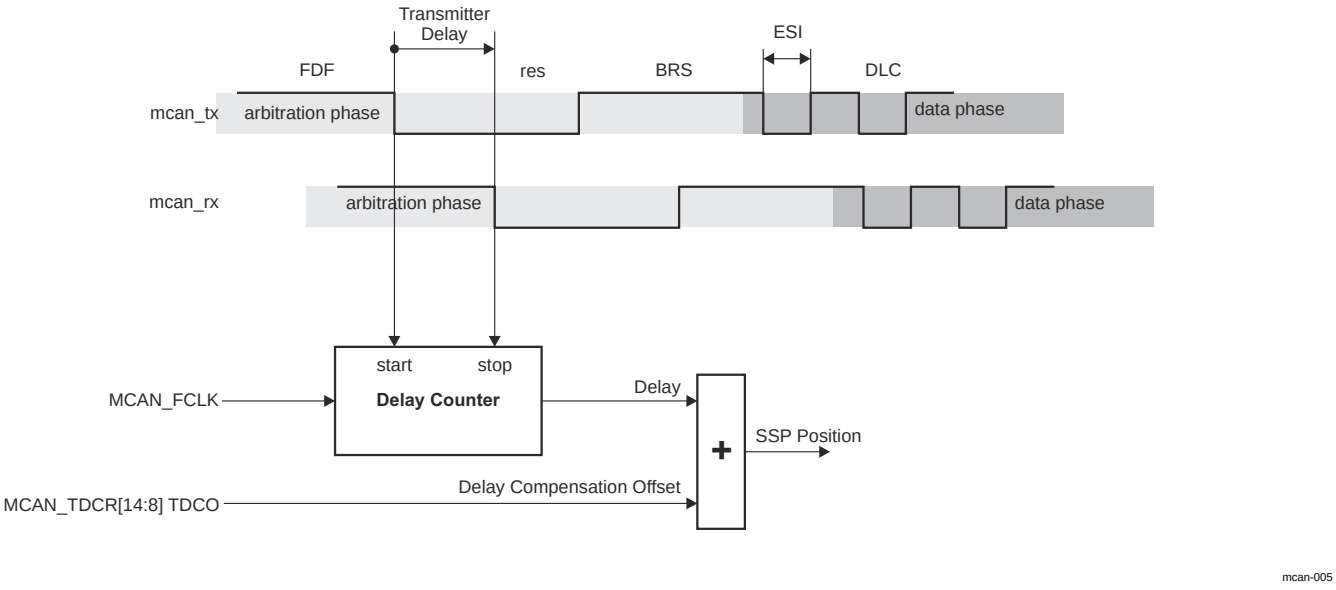

Figure 12-6. Transmitter Delay Measurement

12.4.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input MCAN_RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 12-6). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6:0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the MCAN_RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6:0] TDCF field and the MCAN_RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

12.4.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The recieve and transmit error counters (MCAN_ECR[14:8] REC and MCAN_ECR[7:0] TEC) are frozen while CAN error logging (MCAN_ECR[23:16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[1] INIT bits are set to 1.

The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

12.4.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN_CCCR[5] MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 12-7 shows the connection of the MCAN_TX and MCAN_RX signals to the MCAN module in Bus Monitoring Mode.

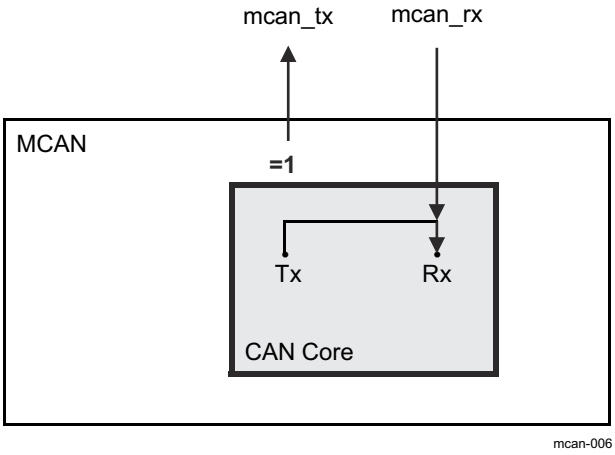

Figure 12-7. Connection of Signals in Bus Monitoring Mode

12.4.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR[6] DAR bit).

12.4.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

12.4.4.8 Power Down (Sleep) Mode

Entering Power Down mode is controlled via the input clock stop request signal (mcanss_clkstp_clkstop_req) or MCAN_CCCR[4] CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[1] INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal (mcanss_clkstop_clkstop_ack) to 1 and the MCAN_CCCR[3] CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR[1] INIT bit will have no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN_CCCR[1] INIT bit.

12.4.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see Section 12.4.4.8.3, *Wakeup request*). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

12.4.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] FREE and MCANSS_CTRL[2] SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see Section 12.4.4.8.3, *Wakeup request*). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23:16] CEL
- MCAN_PSR[2:0] LEC
- MCAN_PSR[10:8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

12.4.4.8.3 Wakeup Request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive MCAN_RX pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the MCANSS_CTRL[4] WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

12.4.4.9 Test Mode

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit MCAN_TX pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6:5] TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive MCAN_RX pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6:5] TX filed until the new configuration is visible at the output MCAN_TX pin. This applies also when reading input MCAN_RX pin via the MCAN_TEST[7] RX bit.

Note

Test modes should be used for self test only. The software control for MCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

12.4.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to 1. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the MCAN_TX and MCAN_RX pins. In this mode MCAN_RX pin is disconnected from the MCAN module and MCAN_TX pin is held recessive. Figure 12-8 shows the connection of the MCAN_TX and MCAN_RX pins to the MCAN module in case of Internal Loop Back Mode.

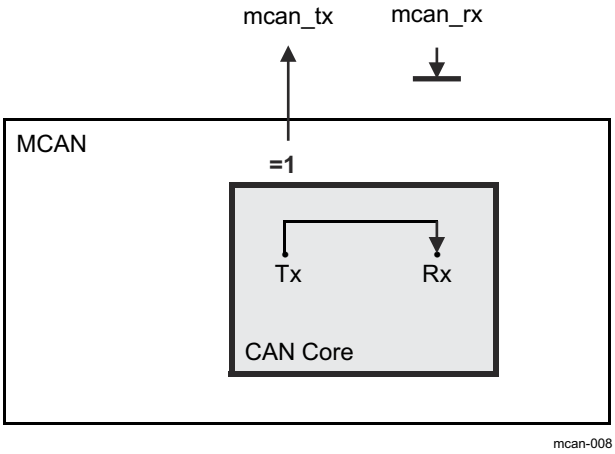

Figure 12-8. Internal Loop Back Mode

12.4.5 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19:16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15:0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 12.4.11, *Message RAM*.

12.4.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1:0] TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23:0] PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN_IRQ_TS interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the MCANSS_IRS register is set (see Figure 12-9). The MCANSS_IE register can be affected by writing to the MCAN_IESS register to set or to the MCANSS_IECS register to clear. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the

MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

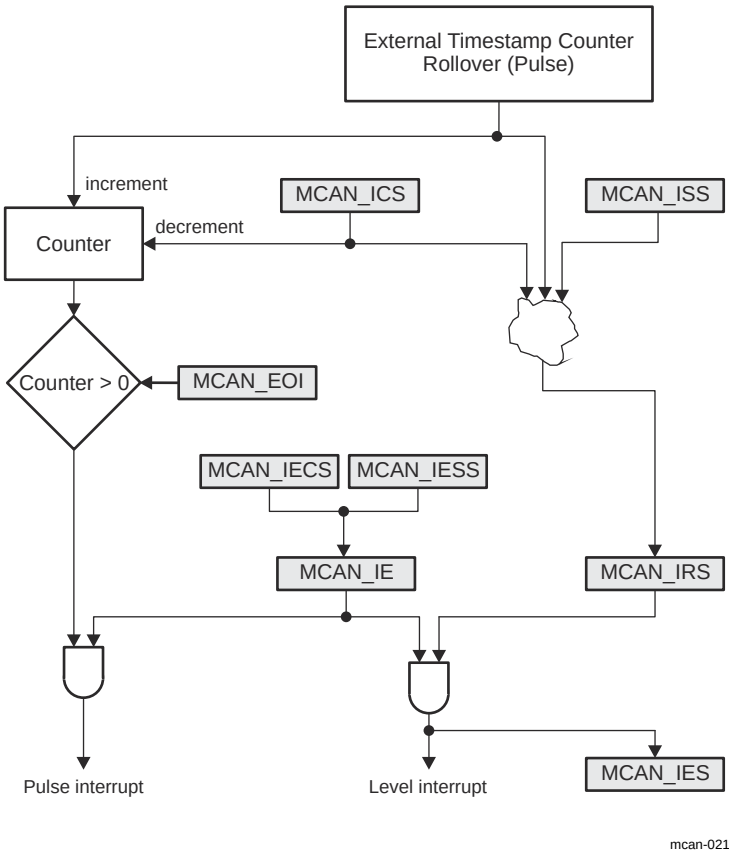

Figure 12-9. External Timestamp Counter Interrupt

12.4.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19:16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15:0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[1] INIT = 0 and stopped when MCAN_CCCR[1] INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2:1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_CCCR[1] INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31:16] TOP field.

12.4.7 Safety

The Message Memory is wrapped in an ECC wrapper provididing SECDED parity functionalilty. The ECC wrapper is controlled by an ECC Aggregator.

12.4.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

12.4.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

12.4.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

12.4.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register (MCANSS_ECC_AGGR_REVISION), ECC Vector Register (MCANSS_ECC_VECTOR), Misc Status Register (MCANSS_ECC_MISC_STATUS), ECC Control Register (MCANSS_ECC_CONTROL), and ECC Wrapper Revision Register (MCANSS_ECC_WRAP_REVISION).
- Control and status registers - ECC Error Control Registers (MCANSS_ECC_ERR_CTRL1 and MCANSS_ECC_ERR_CTRL2) and ECC Error Status Registers (MCANSS_ECC_ERR_STAT1 and MCANSS_ECC_ERR_STAT2).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANSS_ECC_SEC_EOI_REG
  - MCANSS_ECC_SEC_STATUS_REG0
  - MCANSS_ECC_SEC_ENABLE_SET_REG0
  - MCANSS_ECC_SEC_ENABLE_CLR_REG0
  - MCANSS_ECC_DED_EOI_REG
  - MCANSS_ECC_DED_STATUS_REG0
  - MCANSS_ECC_DED_ENABLE_SET_REG0
  - MCANSS_ECC_DED_ENABLE_CLR_REG0

12.4.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.
- Software then polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is 1. This bit indicates that the read operation has completed.

- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

12.4.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the MCANSS_ECC_SEC_ENABLE_SET_REG0/MCANSS_ECC_DED_ENABLE_SET_REG0 register.
- Software writes the ECC RAM ID in the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR.
- Software writes the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger the read.
- Software writes the MCANSS_ECC_ERR_STAT1 register address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the MCANSS_ECC_VECTOR register again if it needs to read the MCANSS_ECC_ERR_STAT2 register.
- Software polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit. When this bit is set, a read of the MCANSS_ECC_ERR_STAT1/MCANSS_ECC_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANSS_ECC_ERR_STAT1[8] CLR_ECC_SEC or MCANSS_ECC_ERR_STAT1[9] CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the MCANSS_ECC_ERR_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANSS_ECC_SEC_EOI_REG/MCANSS_ECC_DED_EOI_REG register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANSS_ECC_EOI[8] ECC_EOI bit.

12.4.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

12.4.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 12.4.11, *Message RAM*) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1

- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see Section 12.4.2.1, *DMA Requests*.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
  New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields).
- Rx FIFO:
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 12.4.8.2.2 have to be considered.

12.4.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 12.4.11.5, *Standard Message ID Filter Element* and Section 12.4.11.6, *Extended Message ID Filter Element*.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

12.4.8.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT =01/Extended Filter Type EFT =01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see Section 12.4.11.5, *Standard Message ID Filter Element* and Section 12.4.11.6, *Extended Message ID Filter Element*.

12.4.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

12.4.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in Figure 12-10. Section 12.4.11.5, *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

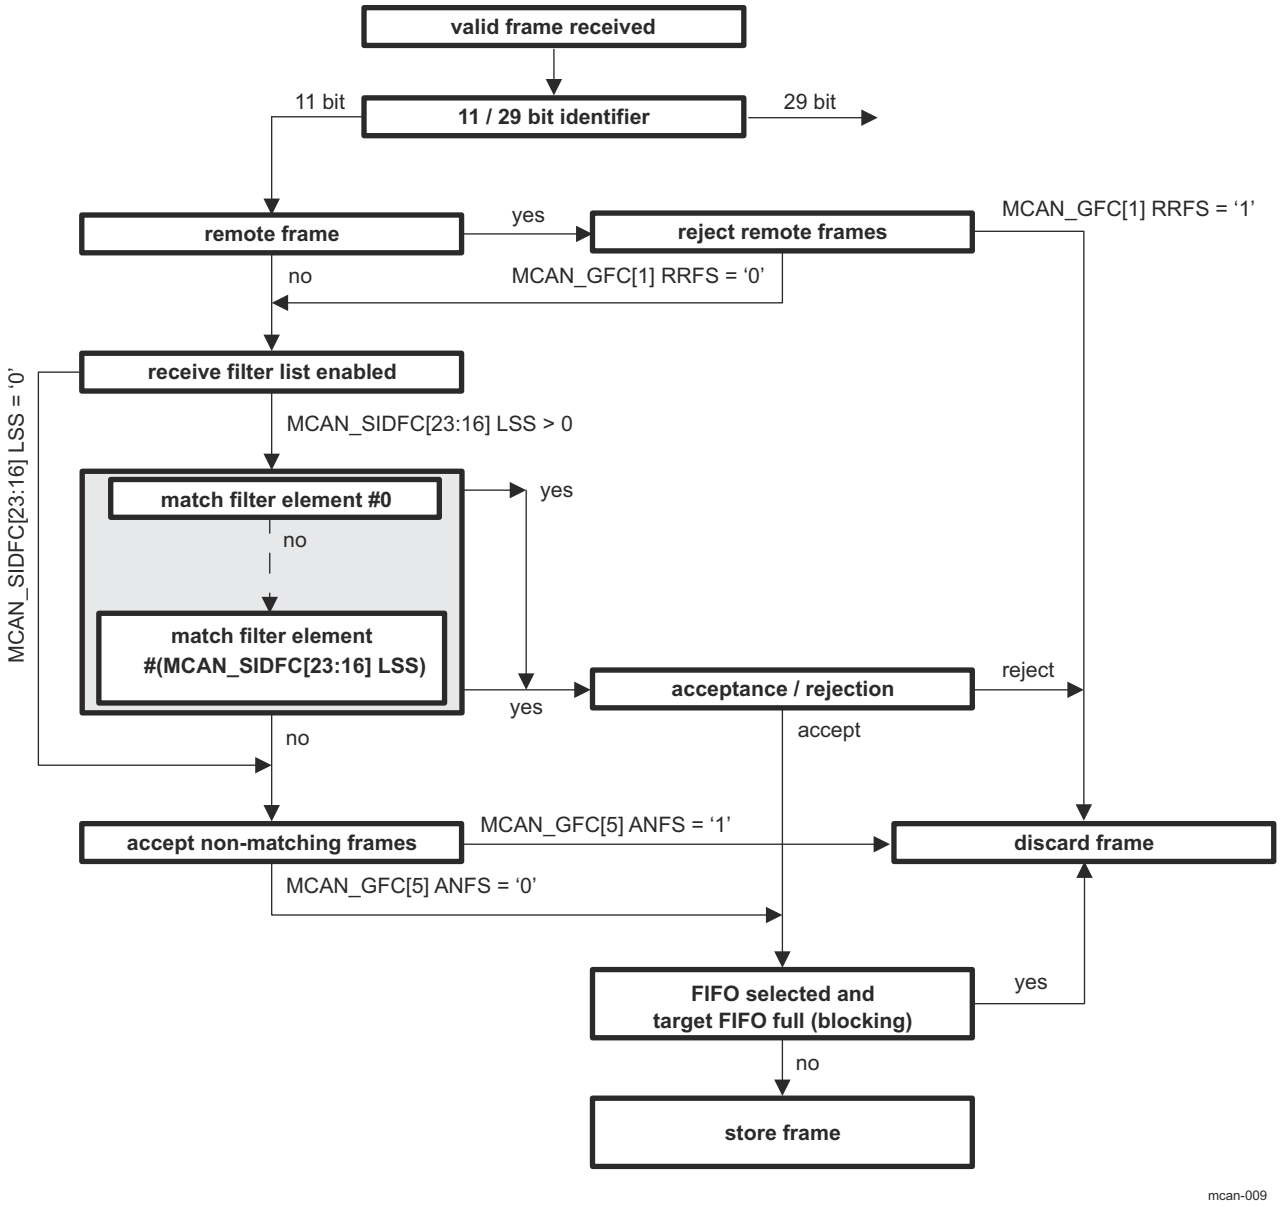

Figure 12-10. Standard Message ID Filter Path

12.4.8.1.5 Extended Message ID Filtering

The extended Message ID (29-bit ID) filtering flow is shown in Figure 12-11. Section 12.4.11.6, *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

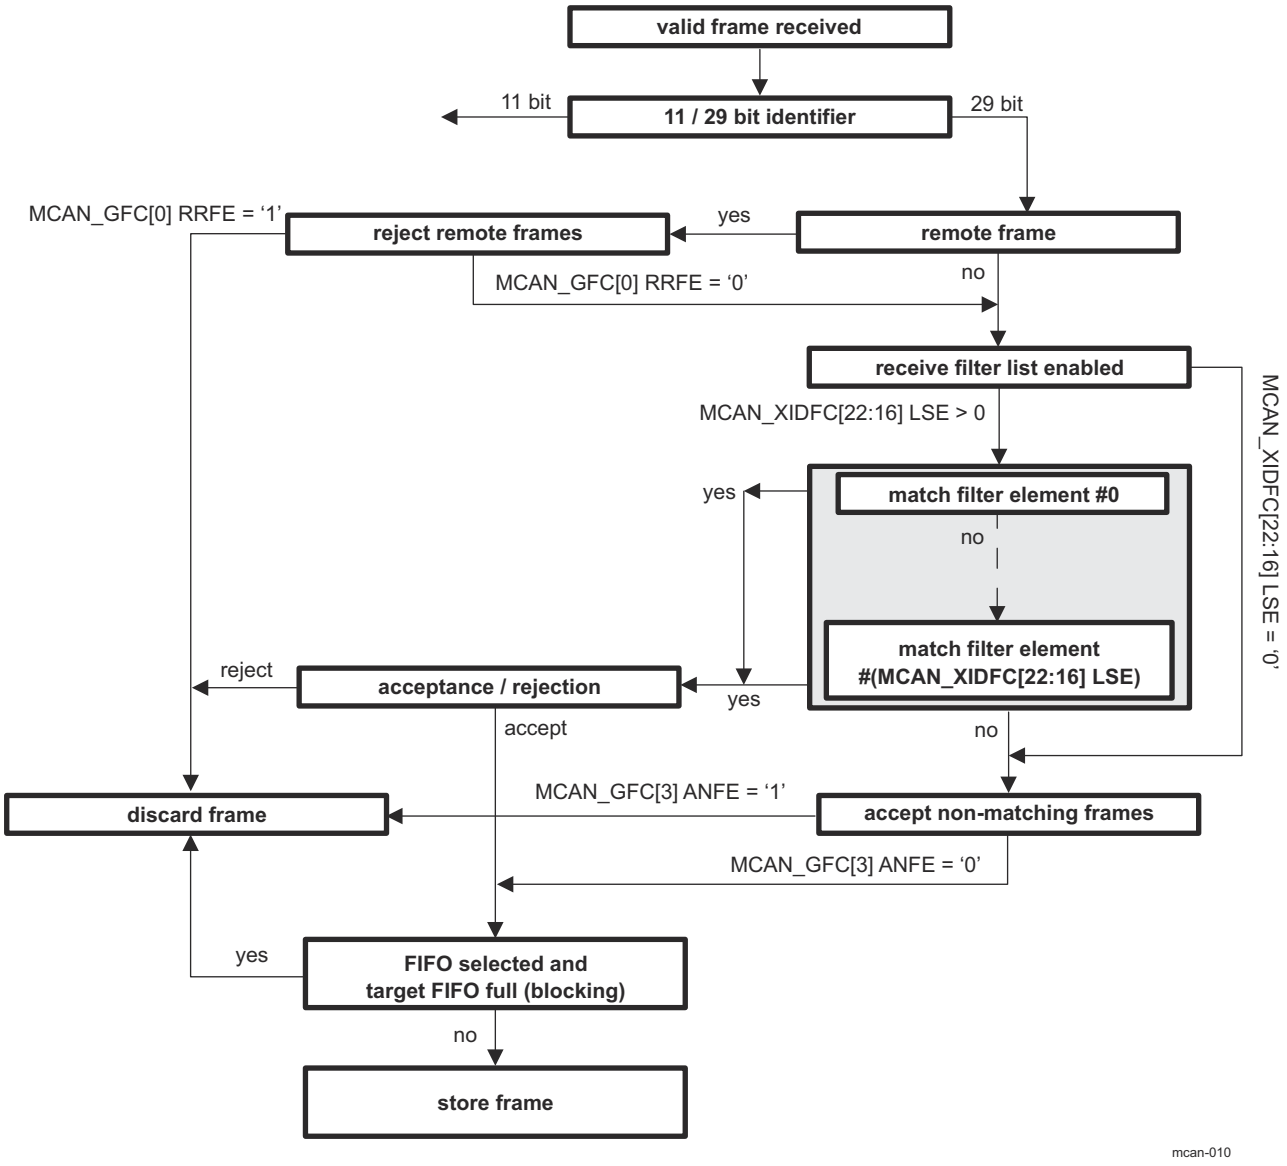

Figure 12-11. Extended Message ID Filter Path

12.4.8.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in Section 12.4.8.1, *Acceptance Filtering*. Section 12.4.11.2, *Rx Buffer and FIFO Element* describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W/MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set. Figure 12-12 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

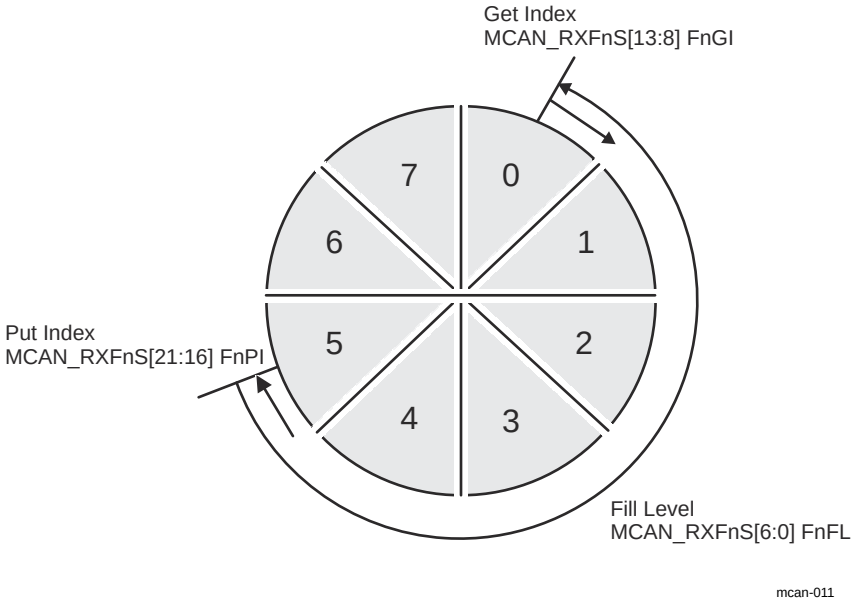

Figure 12-12. Rx FIFO Status

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 12-6 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 12-6. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS/ MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

12.4.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR[3] RFnL/ MCAN_IR[25] RFnL is set.

12.4.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 12-13 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

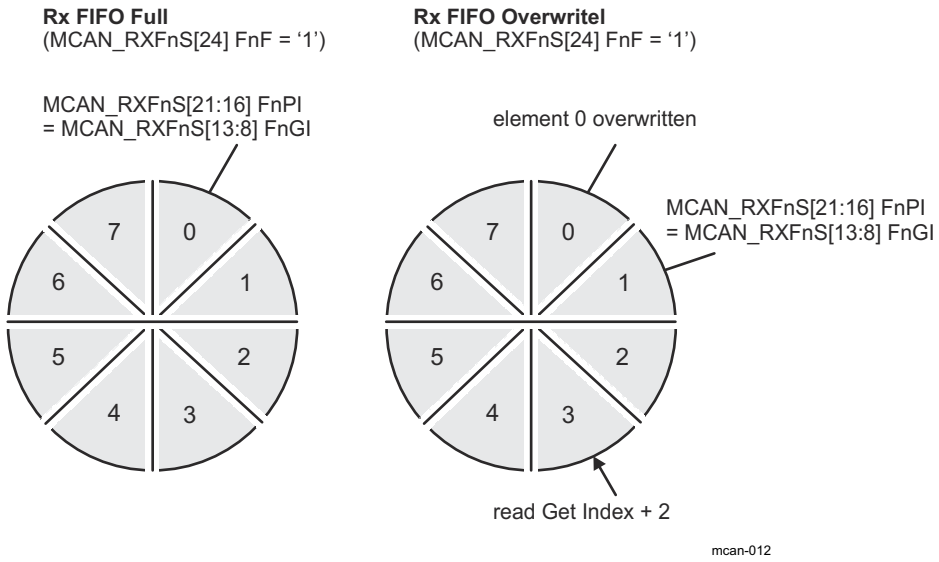

Figure 12-13. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

12.4.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 12.4.11.5, *Standard Message ID Filter Element* and Section 12.4.11.6, *Extended Message ID Filter Element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 12-7 shows Example Filter Configuration for Rx Buffers.

Table 12-7. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

12.4.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

12.4.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 12.4.11.3 describes the Tx Buffer Element. Table 12-8 shows the possible configurations for message transmission.

Table 12-8. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

12.4.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

12.4.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 12-9 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20:16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

Table 12-9. Tx Buffer/Tx FIFO/Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

12.4.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12:8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = 1) the Put Index is incemented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20:16] TFQPI = MCAN_TXFQS[12:8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 12-9). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

12.4.9.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 12-9). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

12.4.9.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29:24] TFQS field

If the MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12:8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-14 shows Mixed Dedicated Tx Buffers/Tx FIFO example.

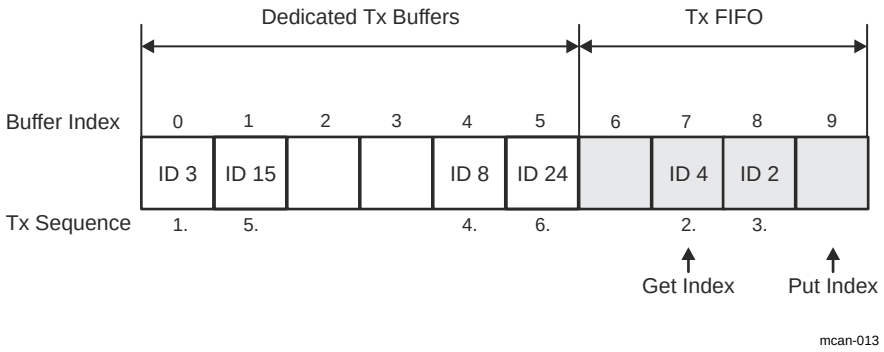

Figure 12-14. Mixed Dedicated Tx Buffers /Tx FIFO (example)

12.4.9.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29:24] TFQS field

If MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-15 shows Mixed Dedicated Tx Buffers/Tx Queue example.

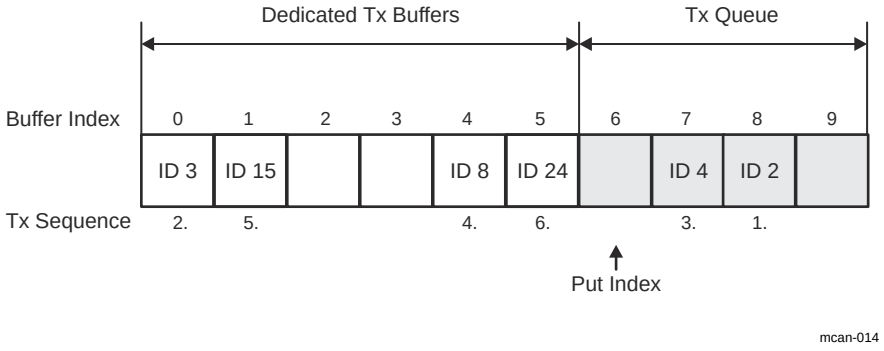

Figure 12-15. Mixed Dedicated Tx Buffers /Tx Queue (example)

12.4.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = 1.

Note

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

12.4.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 12.4.11.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12:8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29:24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS[12:8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15:2] EFSA field.

12.4.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

12.4.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

12.4.11.1 Message RAM Configuration

The MCAN module is configured to allocate 1600 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from 0x4848 0000 to 0x4848 18FC.

The Message RAM is capable to include each of the sections listed in Figure 12-16. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2:0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6:4] F1DS field
- Rx Buffers via the MCAN_RXESC[10:8] RBDS field
- Tx Buffers via the MCAN_TXESC[2:0] TBDS field

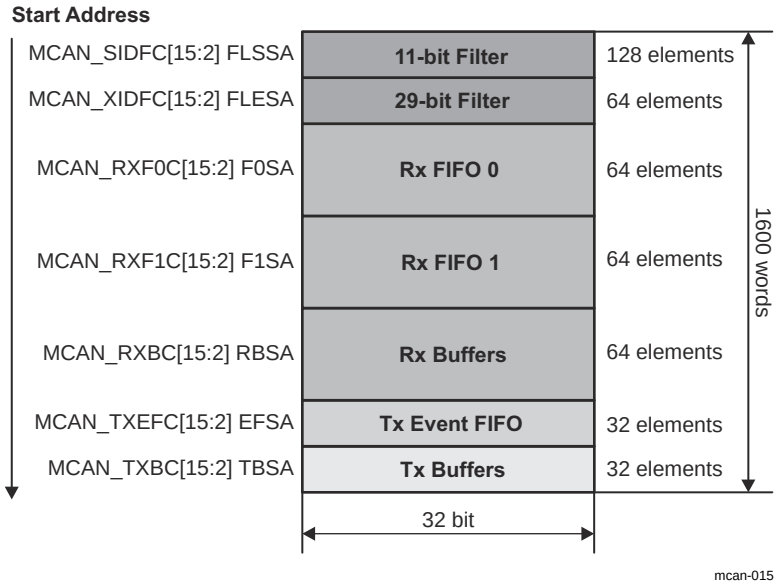

Figure 12-16. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

12.4.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 12-17 shows Rx Buffer/Rx FIFO element structure.

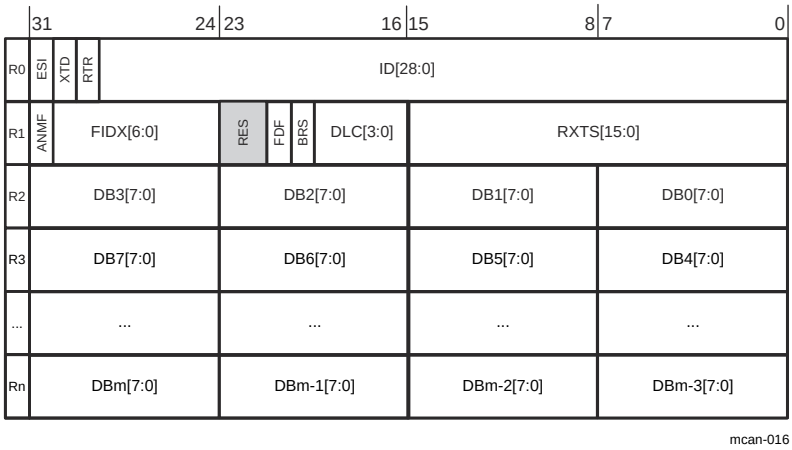

Figure 12-17. Rx Buffer/Rx FIFO Element Structure

Table 12-10 shows Rx Buffer/Rx FIFO element field descriptions.

Table 12-10. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].

Table 12-10. Rx Buffer/Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5:4] ANFS and MCAN_GFC[3:2] ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23:16] LSS - 1 respectively MCAN_XIDFC[22:16] LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP.
R2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

12.4.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 12-18 shows Tx Buffer element structure.

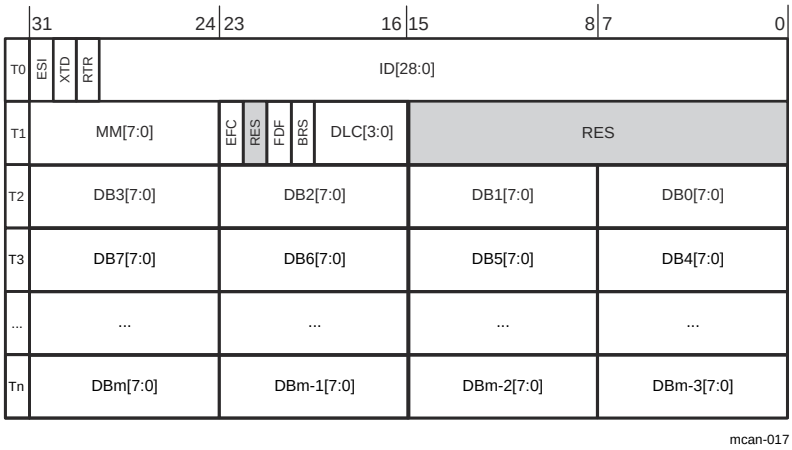

Figure 12-18. Tx Buffer Element Structure

Table 12-11 shows Tx Buffer element field descriptions.

Table 12-11. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR[8] FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 12-11. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 12-12).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled vie the MCAN_CCCR[8] FDOE bit. BRS bit is only evaluated when in addition the MCAN_CCCR[9] BRSE = 1.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

12.4.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 12-19 shows Tx Event FIFO element structure.

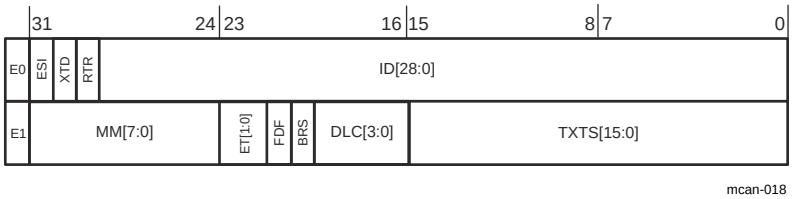

Figure 12-19. Tx Event FIFO Element Structure

Table 12-12 shows Tx Event FIFO element field descriptions.

Table 12-12. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 12-12. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 12-11).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP filed.

12.4.11.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN_SIDFC[15:2] FLSSA field plus the index of the filter element (0-127).

Figure 12-20 shows Standard Message ID Filter element structure.

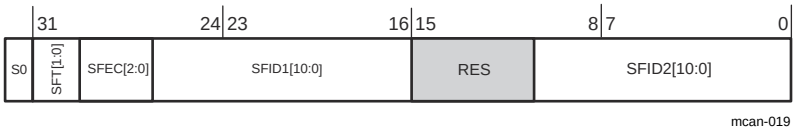

Figure 12-20. Standard Message ID Filter Element Structure

Table 12-13 shows Standard Message ID Filter element field descriptions.

Table 12-13. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer, configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • 1) SFEC = 001 - 110 Second ID of standard ID filter element • 2) SFEC = 111 Filter for Rx Buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2].RBSA field for storage of a matching message.

12.4.11.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN_XIDFC[15:2] FLESA field plus two times the index of the filter element (0-63).

Figure 12-21 shows Extended Message ID Filter element structure.

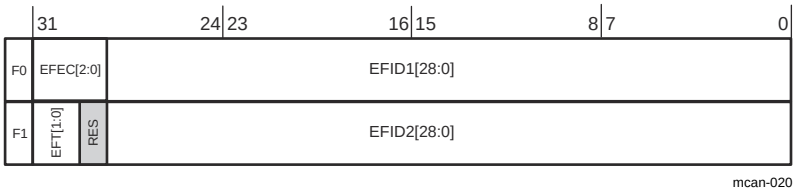

Figure 12-21. Extended Message ID Filter Element Structure

Table 12-14 shows Extended Message ID Filter element field descriptions.

Table 12-14. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 12.4.8.1.5, *Extended Message ID Filtering*) is used.

Table 12-14. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • 1) EFEC = 001 - 110 Second ID of extended ID filter element • 2) EFEC = 111 Filter for Rx Buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

12.5 MCAN Register Manual

Note

After hardware reset, the registers of the MCAN module hold the values shown in the register descriptions.

Additionally, the Bus_Off state is reset and the MCAN_TX pin is set to recessive (high). The MCAN_CCCR[0] INIT bit is set to enable the software initialization. The MCAN module will not influence the CAN bus until the software resets the MCAN_CCCR[0] INIT bit.

Table 12-30. MCAN_DBTP

Address Offset	0x0000 1A0C
Description	Data Bit Timing & Prescaler Register Configuration of data phase bit timing, transmitter delay compensation enable. This register is only writable if the MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 MCAN_FCLK periods. t_q = (MCAN_DBTP[20:16] DBRP + 1) mtq (minimum time quantum = CAN clock period (MCAN_FCLK)). The MCAN_DBTP[12:8] DTSEG1 field is the sum of Prop_Seg and Phase_Seg1. The MCAN_DBTP[7:4] DTSEG2 field is Phase_Seg2. Therefore the length of the bit time is (programmed values) [MCAN_DBTP[12:8] DTSEG1 + MCAN_DBTP[7:4] DTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q. The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point. **Note:** With a CAN clock (MCAN_FCLK) of 8 MHz, the reset value of 0x0000 0A33 configures the MCAN module for a data phase bit rate of 500 kBit/s. **Note:** The bit rate configured for the CAN FD data phase via the MCAN_DBTP register must be higher or equal to the bit rate configured for the arbitration phase via the MCAN_NBTP register.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED																TSC															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0
15:0	TSC	Timestamp Counter The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When the MCAN_TSCC[1:0] TSS = 01, the Timestamp Counter is incremented in multiples of CAN bit times [1-16] depending on the configuration of the MCAN_TSCC[19:16] TCP field. A wrap around sets interrupt flag MCAN_IR[16] TSW. Write access resets the counter to zero. When the MCAN_TSCC[1:0] TSS = 10, the MCAN_TSCV[15:0] TSC field reflects the external Timestamp Counter value. A write access has no impact. **Note:** A 'wrap around' is a change of the Timestamp Counter value from non-zero to zero not caused by write access to the MCAN_TSCV register.	RWTC	0x0

Table 12-37. MCAN_TOCC

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0
15:0	TOC	Timeout Counter The Timeout Counter is decremented in multiples of CAN bit times [1-16] depending on the configuration of the MCAN_TSCC[19:16] TCP field. When decremented to zero, interrupt flag MCAN_IR[18] TOO is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via the MCAN_TOCC[2:1] TOS field.	RWTC	0xFFFF

Table 12-39. MCAN_ECR

Address Offset	0x0000 1A40
Description	Error Counter Register State of Rx/Tx Error Counter, CAN Error Logging.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								CEL								RP	REC							TEC							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved	R	0x0
23:16	CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to the MCAN_ECR[23:16] CEL field. The counter stops at 0xFF; the next increment of the MCAN_ECR[7:0] TEC or MCAN_ECR[14:8] REC fields sets interrupt flag MCAN_IR[22] ELO.	R	0x0
15	RP	Receive Error Passive 0x0: The Receive Error Counter is below the error passive level of 128 0x1: The Receive Error Counter has reached the error passive level of 128	R	0x0
14:8	REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.	R	0x0

Bits	Field Name	Description	Type	Reset
7:0	TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255. **Note:** When the MCAN_CCCR[2] ASM bit is set, the CAN protocol controller does not increment the MCAN_ECR[7:0] TEC and MCAN_ECR[14:8] REC fields when a CAN protocol error is detected, but the MCAN_ECR[23:16] CEL field is still incremented.	R	0x0

Table 12-40. MCAN_PSR

Address Offset	0x0000 1A44
Description	Protocol Status Register CAN protocol controller status, transmitter delay compensation value.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								TDCV								RESERVED	PXE	RFDF	RBRS	RESI	DLEC			BO	EW	EP	ACT			LEC	

Bits	Field Name	Description	Type	Reset
31:23	RESERVED	Reserved	R	0x0
22:16	TDCV	Transmitter Delay Compensation Value Position of the secondary sample point, defined by the sum of the measured delay from the MCAN_TX to MCAN_RX pins and the MCAN_TDCR[14:8] TDCO field. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq (0x00-0x7F).	R	0x0
15	RESERVED	Reserved	R	0x0
14	PXE	Protocol Exception Event 0x0: No protocol exception event occurred since last read access 0x1: Protocol exception event occurred	R	0x0
13	RFDF	Received a CAN FD Message This bit is set independent of acceptance filtering. 0x0: Since this bit was reset by the Host CPU, no CAN FD message has been received 0x1: Message in CAN FD format with FDF flag set has been received	R	0x0
12	RBRS	BRS flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its BRS flag set 0x1: Last received CAN FD message had its BRS flag set	R	0x0

Bits	Field Name	Description	Type	Reset
11	RESI	ESI flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its ESI flag set 0x1: Last received CAN FD message had its ESI flag set	R	0x0
10:8	DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for the MCAN_PSR[2:0] LEC field. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.	R	0x7
7	BO	Bus_Off Status 0x0: The MCAN module is not Bus_Off 0x1: The MCAN module is in Bus_Off state	R	0x0
6	EW	Warning Status 0x0: Both error counters are below the Error_Warning limit of 96 0x1: At least one of error counter has reached the Error_Warning limit of 96	R	0x0
5	EP	Error Passive 0x0: The MCAN module is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 0x1: The MCAN module is in the Error_Passive state	R	0x0
4:3	ACT	Activity Monitors the module's CAN communication state. 0x0: Synchronizing - node is synchronizing on CAN communication 0x1: Idle - node is neither receiver nor transmitter 0x2: Receiver - node is operating as receiver 0x3: Transmitter - node is operating as transmitter **Note:** ACT is set to 00 by a Protocol Exception Event.	R	0x0

Bits	Field Name	Description	Type	Reset
2:0	LEC	Last Error Code The MCAN_PSR[2:0] LEC field indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error. 0x0: No Error: No error occurred since the MCAN_PSR[2:0] LEC field has been reset by successful reception or transmission. 0x1: Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 0x2: Form Error: A fixed format part of a received frame has the wrong format. 0x3: AckError: The message transmitted by the MCAN module was not acknowledged by another node. 0x4: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant. 0x5: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the Host CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incom-ing message does not match with the CRC calculated from the received data. 0x7: NoChange: Any read access to the Protocol Status Register re-initializes the MCAN_PSR[2:0] LEC field to '0x7'. When the MCAN_PSR[2:0] LEC field shows the value '0x7', no CAN bus event was detected since the last Host CPU read access to the Protocol Status Register. **Note:** When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in the MCAN_PSR[10:8] DLEC field instead of the MCAN_PSR[2:0] LEC field. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error. **Note:** The Bus_Off recovery sequence (see ISO11898-1:2015) cannot be shortened by setting or resetting the MCAN_CCCR[0] INIT bit. If the device goes Bus_Off, it will set the MCAN_CCCR[0] INIT bit of its own accord, stopping all bus activities. Once the MCAN_CCCR[0] INIT bit has been cleared by the Host CPU, the device will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before	R	0x7

Bits	Field Name	Description	Type	Reset
		resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of the MCAN_CCCR[0] INIT bit, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the MCAN_PSR[2:0] LEC field, enabling the Host CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. The MCAN_ECR[14:8] REC field is used to count these sequences.		

Table 12-41. MCAN_TDCR

Address Offset	0x0000 1A48

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x0
14:8	TDCO	Transmitter Delay Compensation Offset Offset value defining the distance between the measured delay from the MCAN_RX and MCAN_TX pins and the secondary sample point. Valid values are 0 to 127 mtq (0x00-0x7F).	RW	0x0
7	RESERVED	Reserved	R	0x0
6:0	TDCF	Transmitter Delay Compensation Filter Window Length Defines the minimum value for the SSP position, dominant edges on the MCAN_RX pin that would result in an earlier SSP position are ignored for transmitter delay measure-ment. The feature is enabled when the MCAN_TDCR[6:0] TDCF field is configured to a value greater than the MCAN_TDCR[14:8] TDCO filed. Valid values are 0 to 127 mtq (0x00-0x7F).	RW	0x0

Table 12-42. MCAN_IR

Address Offset	0x0000 1A50
Description	Interrupt Register The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host CPU clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset will clear the register. The configuration of the MCAN_IE register controls whether an interrupt is generated. The configuration of the MCAN_ILS register controls on which interrupt line an interrupt is signalled.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

22	ELO	Error Logging Overflow 0x0: CAN Error Logging Counter did not overflow 0x1: Overflow of CAN Error Logging Counter occurred	RW1TC	0x0
21	BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by input signal generated by parity/ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets the MCAN_CCCR[0] INIT bit to 1. This is done to avoid transmission of corrupted data. 0x0: No bit error detected when reading from Message RAM 0x1: Bit error detected, uncorrected (example: parity logic)	RW1TC	0x0
20	BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by input signal generated by parity/ECC logic attached to the Message RAM. 0x0: No bit error detected when reading from Message RAM 0x1: Bit error detected and corrected (example: ECC)	RW1TC	0x0

Bits	Field Name	Description	Type	Reset
19	DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0x0: No Rx Buffer updated 0x1: At least one received message stored into an Rx Buffer	RW1TC	0x0
18	TOO	Timeout Occurred 0x0: No timeout 0x1: Timeout reached	RW1TC	0x0
17	MRAF	Message RAM Access Failure The flag is set, when the Rx Handler: • has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. • was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated respectively the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the MCAN module is switched into Restricted Operation Mode (see Section 12.4.4.5). To leave Restricted Operation Mode, the Host CPU has to reset the MCAN_CCCR[2] ASM bit. 0x0: No Message RAM access failure occurred 0x1: Message RAM access failure occurred	RW1TC	0x0

Table 12-51. MCAN_NDAT1

Address Offset 0x0000 1A98

Description New Data 1
NewDat flags of dedicated Rx buffers 0-31.
The register holds the New Data flags of Rx Buffers 0 to 31. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host CPU clears them. Aflag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. Ahard reset will clear the register.

RW	0x0

Table 12-64. MCAN_TXBRP

Address Offset	0x0000 1ACC
Description	Tx Buffer Request Pending Tx buffers with pending transmission request. Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via the MCAN_TXBAR register. The bits are reset after a requested transmission has completed or has been cancelled via the MCAN_TXBCR register. The MCAN_TXBRP bits are set only for those Tx Buffers configured via the MCAN_TXBC register. After a MCAN_TXBRP bit has been set, a Tx scan (see Section 12.4.9, *Tx Handling*) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register the MCAN_TXBRP register. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding MCAN_TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signalled via the MCAN_TXBCF • after successful transmission together with the corresponding MCAN_TXBTO bit • when the transmission has not yet been started at the point of cancellation • when the transmission has been aborted due to lost arbitration • when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding MCAN_TXBCF bit is set for all unsuccessful transmissions. **Note:** The TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding MCAN_TXBRP bit is reset.

Table 12-66. MCAN_TXBCR

Address Offset 0x0000 1AD4

Description Tx Buffer Cancellation Request
Request cancellation of pending transmissions.
Each Tx Buffer has its own Cancellation Request bit. Writing a '1' will set the corresponding Cancellation Request bit; writing a '0' has no impact. This enables the Host CPU to set cancellation requests for multiple Tx Buffers with one write to the MCAN_TXBCR register. The MCAN_TXBCR bits are set only for those Tx Buffers configured via the MCAN_TXBC register. The bits remain set until the corresponding bit of the MCAN_TXBRP register is reset.

Table 12-68. MCAN_TXBCF

Address Offset	0x0000 1ADC
Description	Tx Buffer Cancellation Finished Signals successful transmit cancellation, set when corresponding TXBRP flag is cleared after cancellation request. Each Tx Buffer has its own Cancellation Finished bit. The bits are set when the corresponding MCAN_TXBRP bit is cleared after a cancellation was requested via the MCAN_TXBCR register. In case the corresponding MCAN_TXBRP bit was not set at the point of cancellation, MCAN_TXBCF[n] CF bit is set immediately. The bits are reset when a new transmission is requested by writing a '1' to the corresponding bit of the MCAN_TXBAR register.

Chapter 13

Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)

This chapter provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This chapter also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this chapter, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

Note

This chapter describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation ($\overline{\text{SPIENA}}$).

13.1 Overview

The MibSPI/MibSPIP is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted in and out of the device at a programmed bit-transfer rate. Typical applications for the SPI include interfacing to external peripherals, such as I/Os, memories, display drivers, and analog-to-digital converters.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 11-bit baud clock generator
- Serial clock (SPICLK) pin
- 1 SPIPOCI/SPIPICO pin for data transfer, with programmable pin direction
- SPI enable ($\overline{\text{SPIENA}}$) pin
- Up to 6 peripheral chip select ($\overline{\text{SPICS}}$) pins
- SPICLK can be internally-generated (and driven) or received from an external clock source
- Each word transferred can have a unique format
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

Note

PICO - Peripheral In Controller Out Pin
POCI - Peripheral Out Controller In Pin
SPICS - SPI Chip Select Pin
SPIENA - SPI Enable Pin

13.1.1 Word Format Options

Each word transferred can have a unique format. Several format characteristics are programmable for each word transferred:

- SPICLK frequency
- Character length (2 to 16 bits)
- Phase (with and without delay)
- Polarity (high or low)
- Parity enabled/disabled
- Chip Select(CS) timers for setup and hold
- Shift direction (Most-Significant Bit (MSB) first or Least-Significant Bit (LSB) first)
- Multi-pin parallel modes

13.1.2 Multi-buffering (Mib) Support

The MibSPI has a programmable buffer memory that enables programmed transmission to be completed without CPU intervention. The buffers are combined in different Transfer Groups (TGs) that can be triggered by external events (timers, Input/Output activity, and so on) or by the internal tick counter. The internal tick counter supports periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different TGs, allowing the user to move data between internal memory and an external controller with minimal CPU interaction.

13.1.2.1 Multi-buffer Mode

Multi-buffer Mode is an extension to the SPI. In multi-buffer mode, many extended features are configurable:

- Number of buffers for each peripheral (or data source/destination, up to 128 buffers supported) or group (up to 8 groupings)
- Triggers for each group, trigger types, trigger sources for individual groups (14 external trigger sources and 1 internal trigger source supported)
- Memory fault detection via an internal parity circuit
- Number of DMA-controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
- Number of DMA transfers for each buffer (up to 65536 words for up to 8 buffers)
- Uninterrupted DMA buffer transfer (NOBREAK buffer)

13.1.2.2 Compatibility Mode

Compatibility Mode of the MibSPI makes it behave exactly like a standard platform SPI module and ensures full compatibility with other SPIs. All features in compatibility mode of the MibSPI are directly applicable to a SPI. Multi-buffer Mode features are not available in Compatibility Mode.

Note

The SPIDAT0 register is not accessible in the multi-buffer mode of MibSPI. It is only accessible in compatibility mode.

13.1.3 Transmission Lock (Multi-Buffer Mode Controller Only)

Some peripheral devices require transmission of a command followed by data. In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows a consecutive transfer to happen without being interrupted by another higher-priority group transfer.

13.2 Operating Modes

The SPI can be configured via software to operate as either a controller or a peripheral. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPIPICO and SPIPOCI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The chip select ($\overline{\text{SPICS}}$) pins are used when communicating with multiple peripheral devices or, with a single peripheral device, to delimit messages containing a leading register address. When a write occurs to SPIDAT1 in controller mode, the $\overline{\text{SPICS}}$ pins are automatically driven to select the specified peripheral device.

Handshaking mechanism, provided by the $\overline{\text{SPIENA}}$ pin, enables a peripheral SPI to delay the generation of the clock signal supplied by the controller if it is not prepared for the next exchange of data.

Note

If in the peripheral mode of operation and configured in either 3-pin or 4-pin (without $\overline{\text{SPIENA}}$) modes, there must be a minimum of 8 VCLK cycles of delay between the last SPICLK and the start of the SPICLK for the next buffer transmit. In general, this equates to a VCLK/SPICLK ratio of ≤16 requiring a minimum of 1 SPICLK delay between transmissions.

13.2.1 Pin Configurations

The SPI supports data connections as shown in Table 13-1.

Note

1. When the SPICS signals are disabled, the chip select field in the transmit data is not used.
2. When the $\overline{\text{SPIENA}}$ signal is disabled, the $\overline{\text{SPIENA}}$ pin is ignored in controller mode, and not driven as part of the SPI transaction in peripheral mode.

Table 13-1. Pin Configurations

Pin	Controller Mode		Peripheral Mode	
SPICLK	Drives the clock to external devices		Receives the clock from the external controller	
SPIPSOCI	Receives data from the external peripheral		Sends data to the external controller	
SPIPICO	Transmits data to the external peripheral		Receives data from the external controller	
$\overline{\text{SPIENA}}$	**$\overline{\text{SPIENA}}$ disabled:** GIO	**$\overline{\text{SPIENA}}$ enabled:** Receives ENA signal from the external peripheral	**$\overline{\text{SPIENA}}$ disabled:** GIO	**$\overline{\text{SPIENA}}$ enabled:** Drives ENA signal from the external controller
$\overline{\text{SPICS}}$	**$\overline{\text{SPICS}}$ disabled:** GIO	**$\overline{\text{SPICS}}$ enabled:** Selects one or more peripheral devices	**$\overline{\text{SPICS}}$ disabled:** GIO	**$\overline{\text{SPICS}}$ enabled:** Receives the CS signal from the external controller

13.2.2 Data Handling

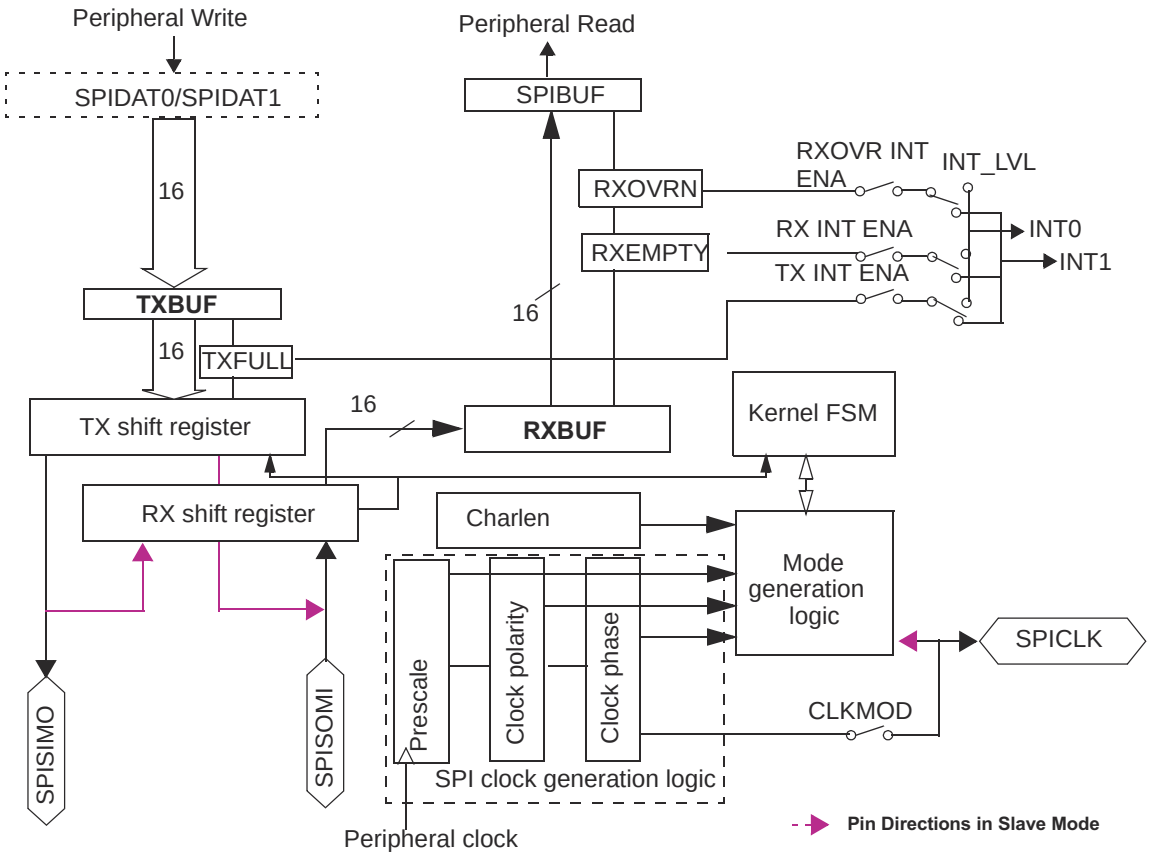
Figure 13-1 shows the SPI transaction hardware. TXBUF and RXBUF are internal buffers that are intended to improve the overall throughput of data transfer. TXBUF is a transmit buffer, while RXBUF is a receive buffer.

13.2.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX_DMA_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is empty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

13.2.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register

- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.



1 This is a representative diagram, which shows three-pin mode hardware.
2 TXBUF, RXBUF, and SHIFT_REGISTER are user-invisible registers.
3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

Figure 13-1. SPI Functional Logic Diagram

13.2.2.3 Three-Pin Mode

In controller mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see Figure 13-2).

Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See Section 13.2.2.1 and Section 13.2.2.2 for details about the data handling for transmit and receive operations.

In peripheral mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPIPOCI pin and in on the SPIPICO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network controller. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network controller. To receive data, the SPI waits for the network controller to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the peripheral simultaneously, it must be written to the SPIDAT0 or SPIDAT1 register before the beginning of the SPICLK signal.

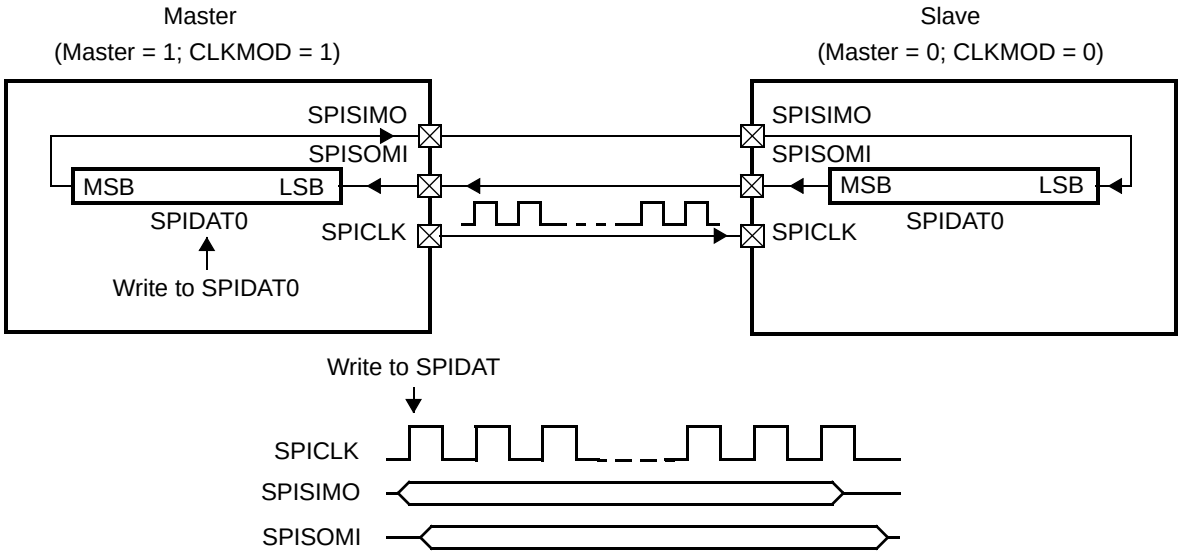


Figure 13-2. SPI Three-Pin Operation

13.2.3 Operation with $\overline{\text{SPICS}}$

In controller mode, each chip select signal is used to select a specific peripheral. In peripheral mode, the chip select signal is used to enable and disable the transfer. Chip-select functionality is enabled by setting one of the $\overline{\text{SPICS}}$ pins as a chip select. It is disabled by setting all $\overline{\text{SPICS}}$ pins as GIOs in SPIPC0.

13.2.3.1 Multiple Chip Selects

The $\overline{\text{SPICS}}$ pins that are used must be configured as functional pins in the SPIPC0 register. The default pattern to be put on the $\overline{\text{SPICS}}$ when all the peripherals are deactivated is set in the SPIDEF register. This pattern allows different peripherals with different chip-select polarity to be activated by the SPI.

The controller-mode SPI is capable of driving either 0 or 1 as the active value for any $\overline{\text{SPICS}}$ output pin. The drive state for the $\overline{\text{SPICS}}$ pins is controlled by the CSNR field of SPIDAT1. The pattern that is driven will select the peripheral to which the transmission is dedicated.

In peripheral mode, the SPI can only be selected by an active value of 0 on any of its selected $\overline{\text{SPICS}}$ input pins.

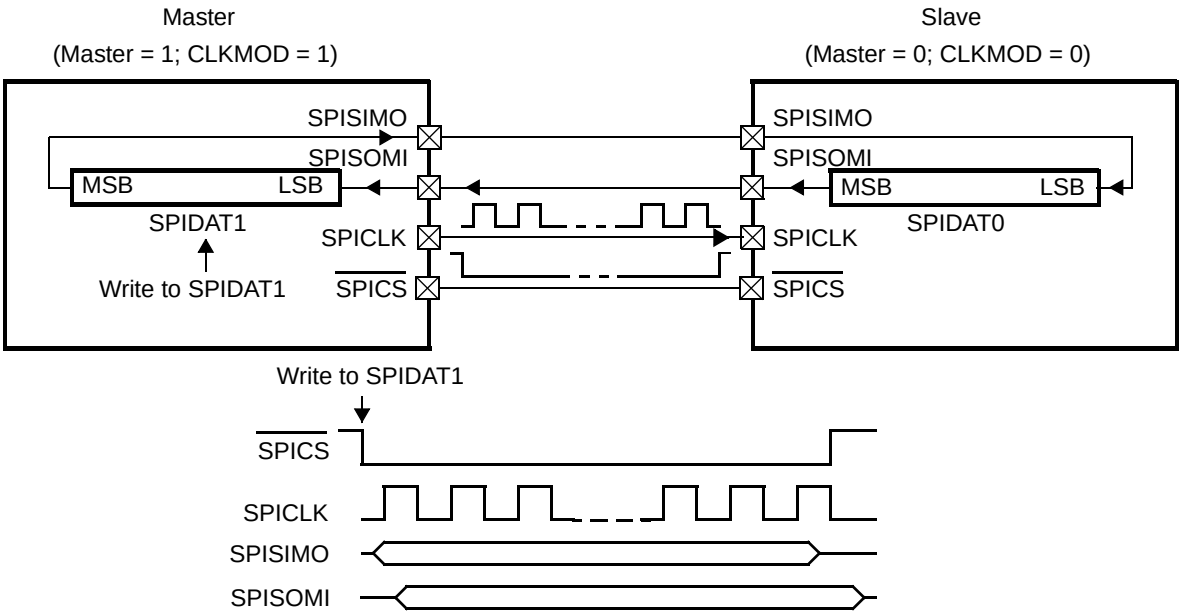

Figure 13-3. Operation with $\overline{\text{SPICS}}$

13.2.4 Operation with $\overline{\text{SPIENA}}$

The $\overline{\text{SPIENA}}$ operates as a WAIT signal pin. For both the peripheral and the controller, the $\overline{\text{SPIENA}}$ pin must be configured to be functional (SPIPC0[8] = 1). In this mode, an active-low signal from the peripheral on the $\overline{\text{SPIENA}}$ pin allows the controller SPI to drive the clock pulse stream. A high signal tells the controller to hold the clock signal (and delay SPI activity).

If the $\overline{\text{SPIENA}}$ pin is in high-impedance mode (ENABLE_HIGHZ = 1), the peripheral will put $\overline{\text{SPIENA}}$ into the high-impedance once it completes receiving a new character. If the $\overline{\text{SPIENA}}$ pin is in push-pull mode (ENABLE_HIGHZ = 0), the peripheral will drive $\overline{\text{SPIENA}}$ to 1 once it completes receiving a new character. The peripheral will drive $\overline{\text{SPIENA}}$ low again for the next word to transfer, after new data is written to the peripheral TX shift register.

In controller mode (CLKMOD = 1), if the $\overline{\text{SPIENA}}$ pin is configured as functional, then the pin acts as an input pin. If configured as a peripheral SPI and as functional, the $\overline{\text{SPIENA}}$ pin acts as an output pin.

Note

During a transfer, if a peripheral-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and $\overline{\text{SPIENA}}$ (if ENABLE_HIGHZ bit is set to 1) in high-impedance mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an DLENERR error flag and generates an interrupt (if enabled).

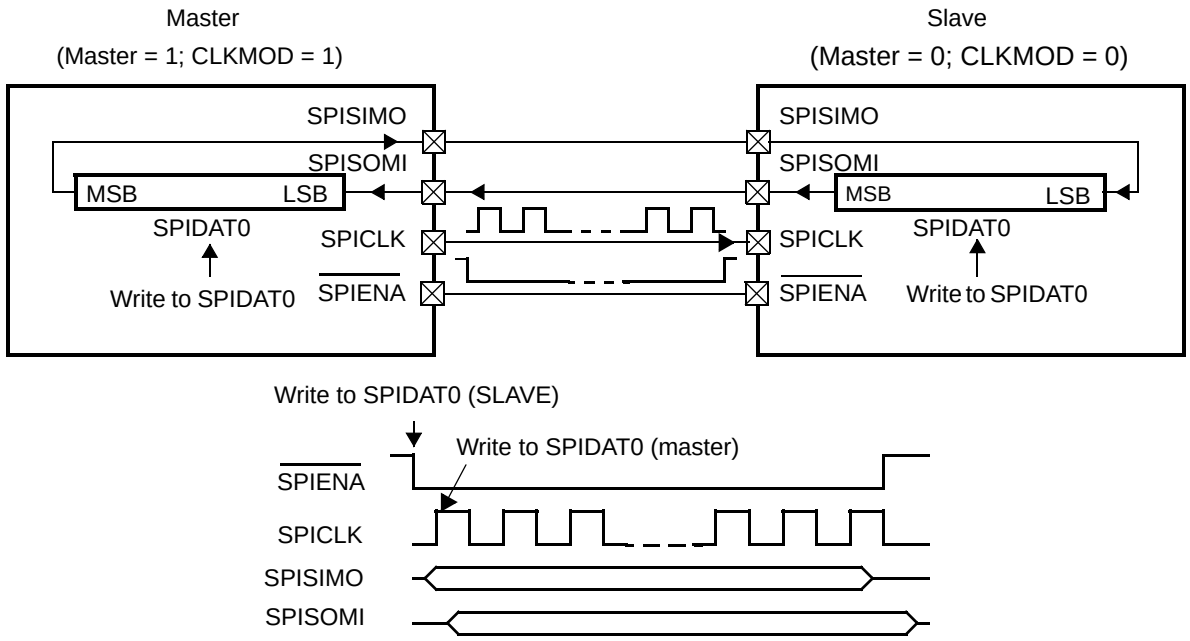

Figure 13-4. Operation with $\overline{\text{SPIENA}}$

13.2.5 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the SPIENA pin and the required number of SPICS pins must be configured as functional pins.

If the SPIENA pin is in high-impedance mode (ENABLE_HIGHZ = 1), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal SPIENA low when new data is written to the slave shift register and the slave has been selected by the master (SPICS is low).

If the SPIENA pin is in push-pull mode (ENABLE_HIGHZ = 0), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the SPIENA signal low when new data is written to the slave shift register (SPIDAT0/SPIDAT1) and the slave is selected by the master (SPICS is low). If the slave is deselected by the master (SPICS goes high), the slave SPIENA signal is driven high.

Note

Push-pull mode of the SPIENA pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common SPIENA pin, all of the slaves should configure their SPIENA pins in high-impedance mode.

In master mode, if the SPICS pins are configured as functional pins, then the pins will be in output mode. A write to the master's SPIDAT1/SPIDAT0 register will automatically drive the SPICS signals low. The master will drive the SPICS signals high again after completing the transfer of the bits of the data.

In slave mode (CLKMOD = 0), the SPICS pins act as SPI functional inputs.

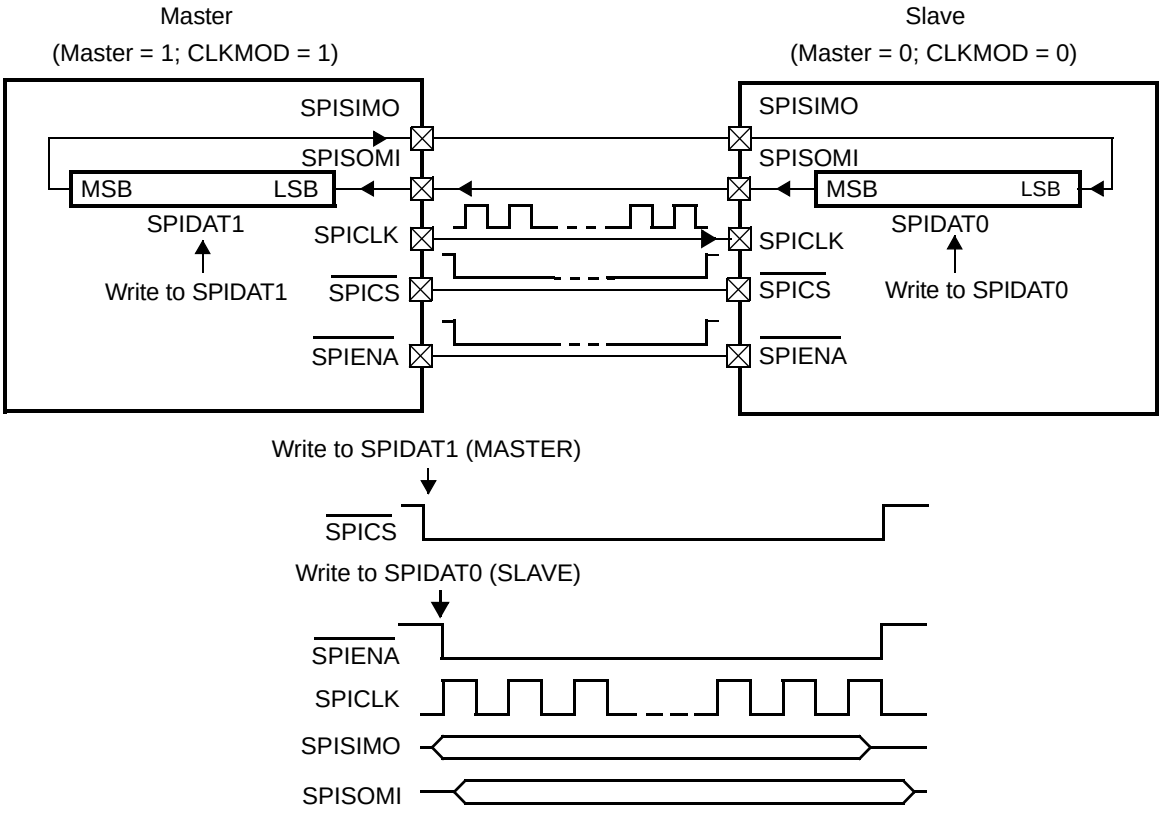

Figure 13-5. SPI Five-Pin Option with SPIENA and SPICS

13.2.6 Data Formats

To support multiple different types of peripherals in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the controller-mode SPI can drive two consecutive accesses to the same peripheral, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed peripheral. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **controller** and the **peripheral**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

Note

Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

Figure 13-6 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

Figure 13-6. Format for Transmitting an 12-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
x	x	x	x	1	1	1	0	1	1	0	0	1	0	0	1

Note

The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

Figure 13-7 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

Figure 13-7. Format for Receiving an 10-Bit Word

13.2.7 Clocking Modes

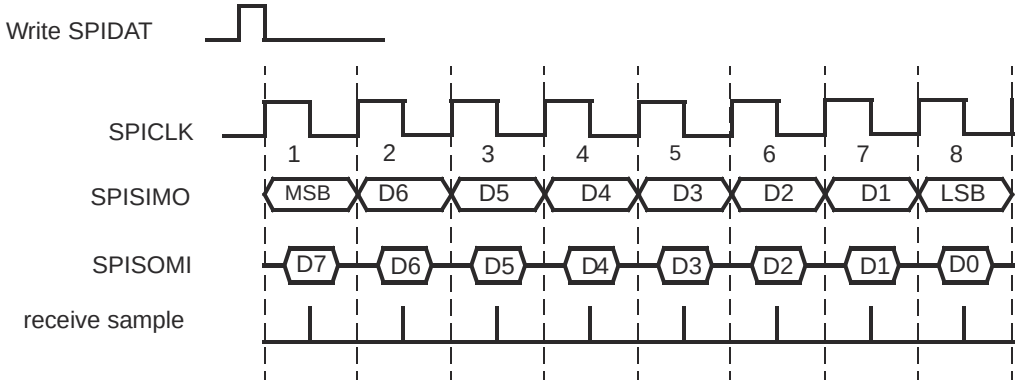
SPICLK may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.

The data input and output edges depend on the values of both POLARITY and PHASE as shown in Table 13-2.

Table 13-2. Clocking Modes

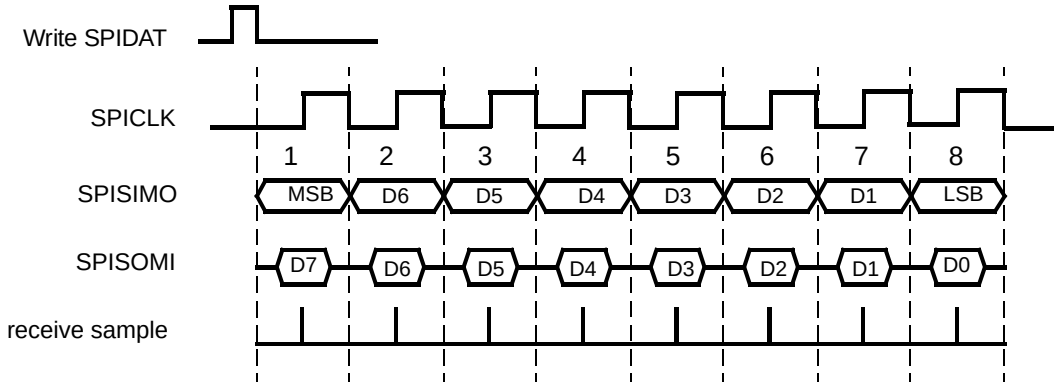
POLARITY	PHASE	Action
0	0	Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.
0	1	Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.
1	0	Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.
1	1	Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.

Figure 13-8 to Figure 13-11 illustrate the four possible configurations of **SPICLK** corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.



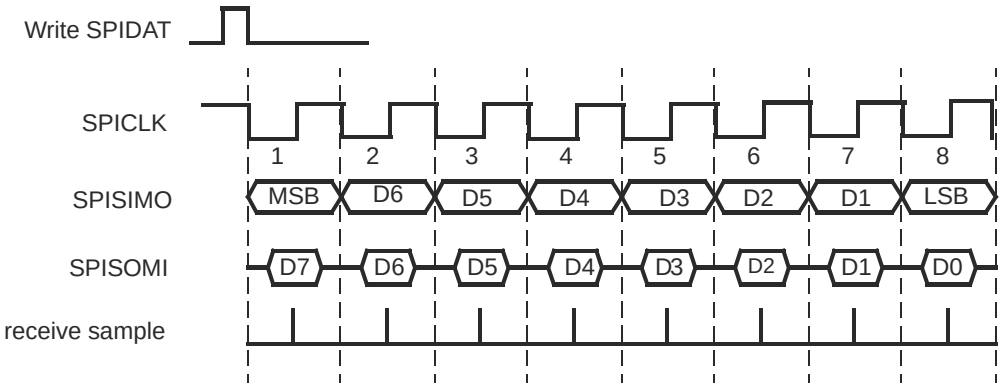
Data is output on the rising edge of SPICLK.
Input data is latched on the falling edge of SPICLK.

Figure 13-8. Clock Mode with Polarity = 0 and Phase = 0



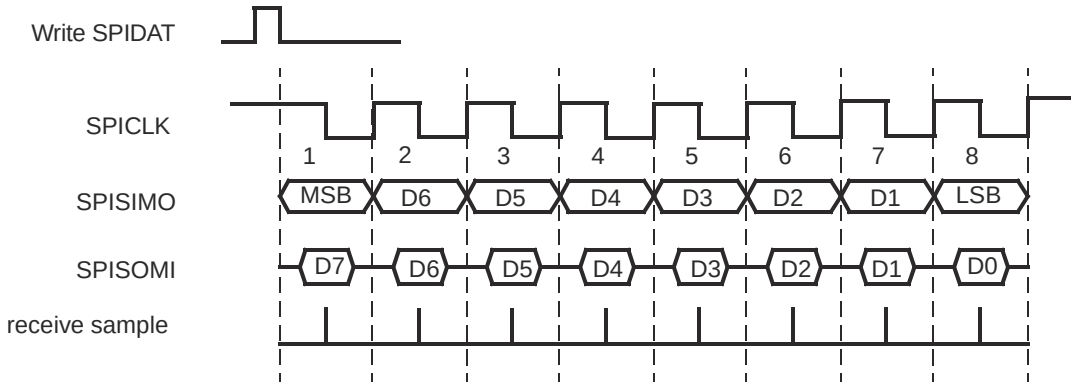
Data is output one-half cycle before the first rising edge of SPICLK and on subsequent falling edges of SPICLK
Input data is latched on the rising edge of SPICLK

Figure 13-9. Clock Mode with Polarity = 0 and Phase = 1



Data is output on the falling edge of SPICLK.
Input data is latched on the rising edge of SPICLK.

Figure 13-10. Clock Mode with Polarity = 1 and Phase = 0



Data is output one-half cycle before the first falling edge of SPICLK and on the subsequent rising edges of SPICLK.
Input data is latched on the falling edge of SPICLK.

Figure 13-11. Clock Mode with Polarity = 1 and Phase = 1

13.2.8 Data Transfer Example

Figure 13-12 illustrates a SPI data transfer between two devices using a character length of five bits.

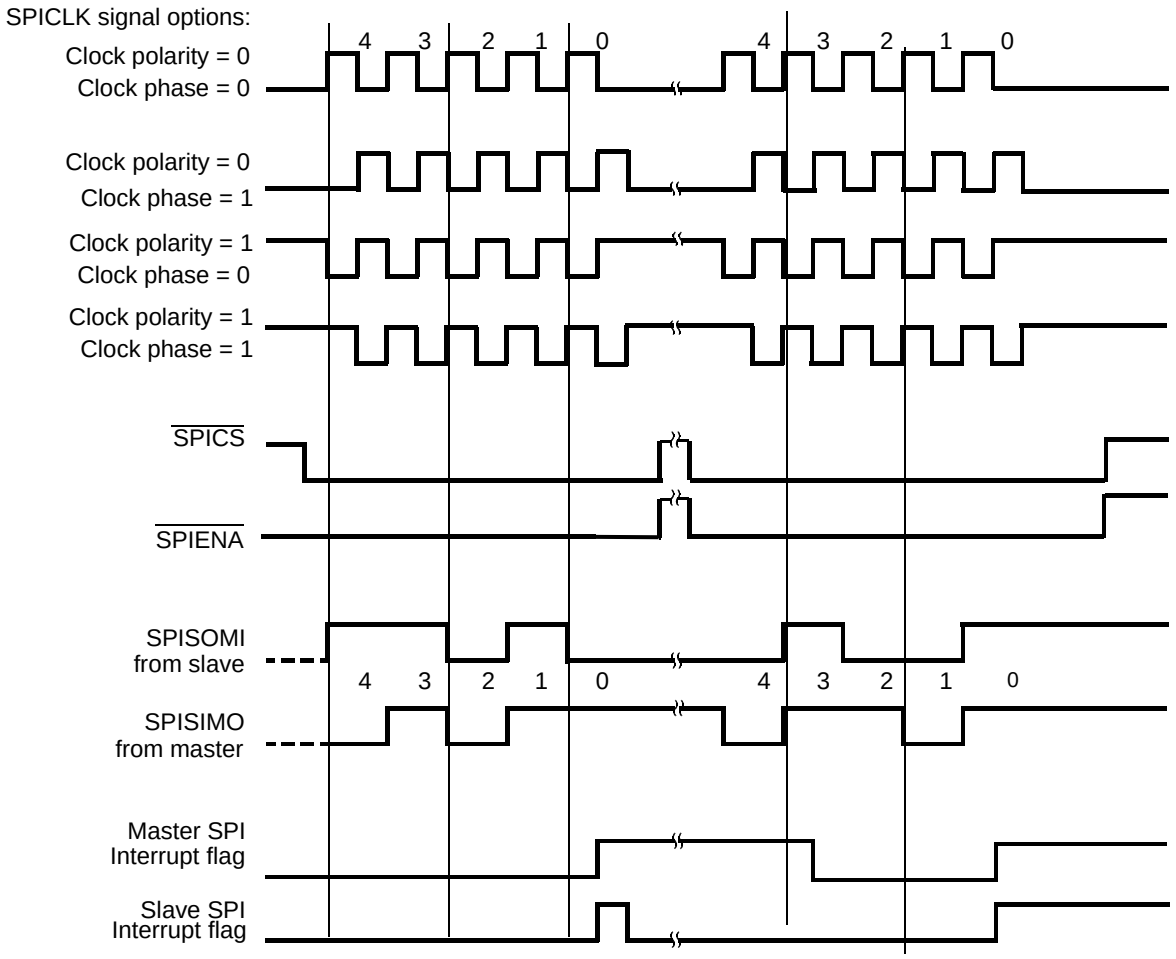


Figure 13-12. Five Bits per Character (5-Pin Option)

13.2.9 Decoded and Encoded Chip Select (Controller Only)

In this device, the SPI can connect to up to 6 individual peripheral devices using chip-selects by routing one wire to each peripheral. The 6 chip selects in the control field are directly connected to the 6 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR) of the SPIDAT1 register (SPIDAT1) is driven on the $\overline{\text{SPICS}}$ pins. When the transmission finishes, the default chip-select value (defined by the CSDEF register) is put on the $\overline{\text{SPICS}}$ pins.

The SPI can support more than 6 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active $\overline{\text{SPICS}}$ pins at the same time, which enables encoded chip selects from 0 to 16. To use encoded chip selects, all 6 chip select lines have to be connected to each peripheral device and each peripheral needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example, *n* $\overline{\text{SPICS}}$ pins can be used for encoding an *n*-bit address and the remaining pins can be connected to decoded-mode slaves.

13.2.10 Variable Chip Select Setup and Hold Timing (Controller Only)

In order to support slow peripheral devices, a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with the peripheral clock (VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pins, then they can be disabled in the corresponding SPIFMTx register.

13.2.11 Hold Chip-Select Active

Some peripheral devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other peripheral devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both controller and peripheral modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in controller mode and peripheral mode are different.

Note

If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

13.2.11.1 CSHOLD Bit in Controller Mode

Each word in a controller-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 13-13 shows the SPI pins when a controller-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

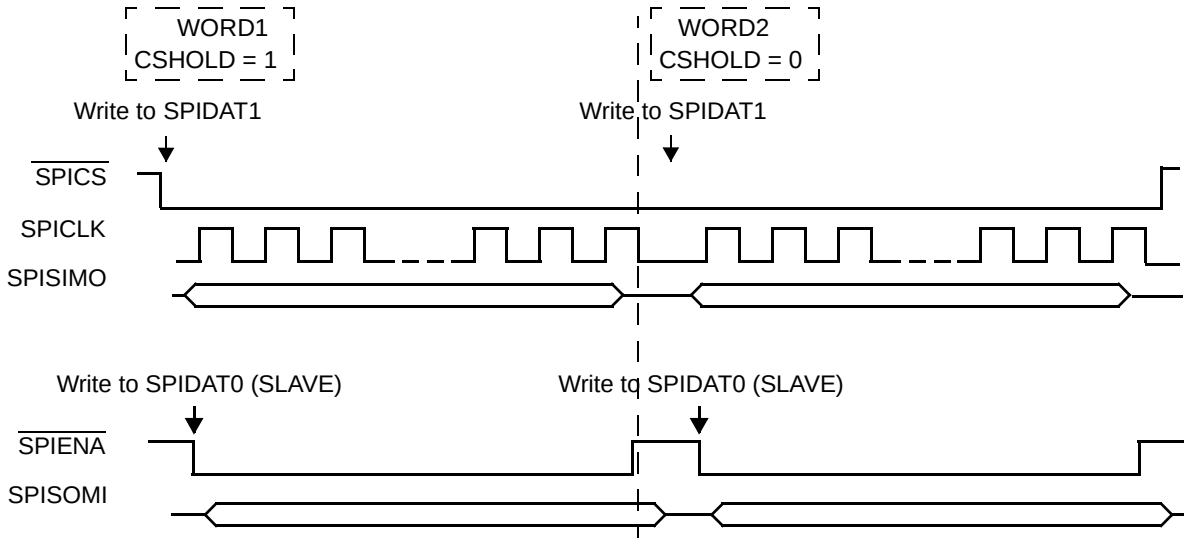

Figure 13-13. Typical Diagram when a Buffer in controller is in CSHOLD Mode (SPI-SPI)

13.2.11.2 CSHOLD Bit in Peripheral Mode (Multi-buffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the $\overline{\text{SPICS}}$ pins to be de-activated at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a peripheral in multi-buffer mode to do multiple data transfers without requiring the $\overline{\text{SPICS}}$ pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a peripheral MibSPI, even after the shift operation is done, the MibSPI waits until the $\overline{\text{SPICS}}$ pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the peripheral in multi-buffer mode requires its $\overline{\text{SPICS}}$ pins to be deasserted between any two buffer transfers; otherwise, the peripheral SPI will be unable to respond to the next data transfer.

Note

In compatibility mode, the peripheral does not require the $\overline{\text{SPICS}}$ pin to be deasserted between two buffer transfers. The CSHOLD bit of the peripheral will be ignored in compatibility mode.

13.2.12 Detection of Peripheral Desynchronization (Controller Only)

When a peripheral supports generation of an enable signal (ENA), desynchronization can be detected. With the enable signal a peripheral indicates to the controller that it is ready to exchange data. A desynchronization can occur if one or more clock edges are missed by the peripheral. In this case, the peripheral may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the desynchronized peripheral and the consecutive data word. A configurable 8-bit time-out counter (T2EDELAY), which is clocked with SPICLK, is implemented to detect this peripheral malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the peripheral does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

Note

Inconsistency of Desynchronization Flag in Compatibility Mode MibSPI

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS controller reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always assured to be for the current buffer.

13.2.13 ENA Signal Time-Out (Controller Only)

The SPI in controller mode waits for the hardware handshake signal (ENA) coming from the addressed peripheral before performing a data transfer. To avoid stalling the SPI by a non-responsive peripheral device, a time-out value can be configured using C2EDELAY. If the time-out counter overflows before an active ENA signal is sampled, the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

Note

When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

13.2.14 Data-Length Error

A SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

Data-Length Error in Controller Mode: During a data transfer, if the SPI detects a de-assertion of the $\overline{\text{SPIENA}}$ pin (by the peripheral) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a peripheral receiving extra clocks (for example, due to noise on the SPICLK line).

Note

In a controller mode SPI, the data length error will be generated only if the $\overline{\text{SPIENA}}$ pin is enabled as a functional pin.

Data-Length Error in peripheral Mode: During a transfer, if the SPI detects a de-assertion of the $\overline{\text{SPICS}}$ pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise If the peripheral SPI misses one or more SPICLK pulses from the controller. This error in peripheral mode implies that both the transmitted and received data were not complete.

Note

In a peripheral mode SPI, the data-length error flag will be generated only if at least one of the $\overline{\text{SPICS}}$ pins are configured as functional, and are being used for selecting the peripheral.

13.2.15 Parallel Mode (Multiple PICO/POCI Support, not available on all devices)

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (parallel 2, 4, or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (POCI and PICO lines)
- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the PICO/POCI lines. The receive parity is expected on bit0 of the POCI/PICO pins.

Parallel mode can be programmed using the PMODEx bits of SPIPMCTRL register. See Section 13.9.26 for details about this register.

After reset the parallel mode selection bits are cleared (single PICO/POCI lines).

13.2.15.1 Parallel Mode Block Diagram

Figure 13-14 and Figure 13-15 show the parallel connections to the SPI shift register.

13.2.15.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (controller mode) the shift register bits 15 and 7 will be connected to the pins PICO[1] and PICO[0], and the shift register bits 8 and 0 will be connected to the pins POCI[1] and POCI[0] or vice versa in peripheral mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on PICO[1] and PICO[0] on the rising edge if SPICLK. With the falling clock edge of the SPICLK, the received data on POCI[1] and POCI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. (PICO[1] will shift the data out from bit 15 to 8, PICO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 13-16 shows the clock/data diagram of the 2-data line mode. Figure 13-17 shows the timing of a two-pin parallel transfer.

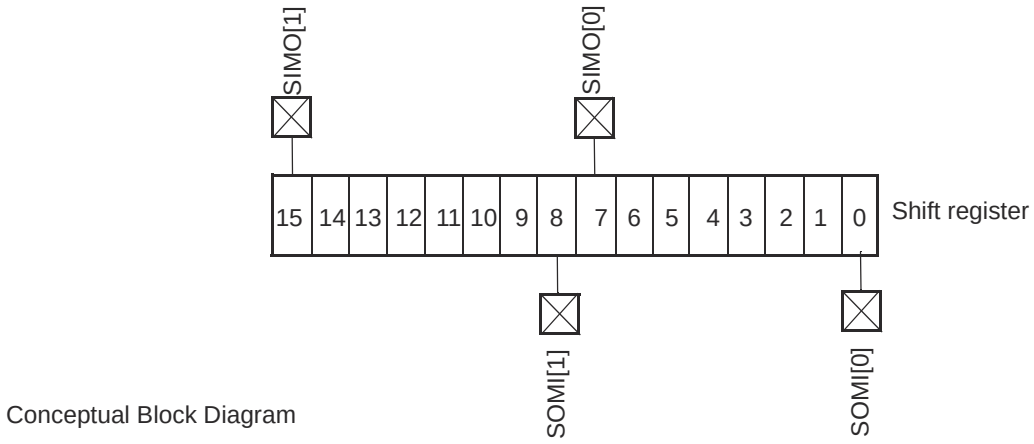

Figure 13-16. 2-data Line Mode (Phase 0, Polarity 0)

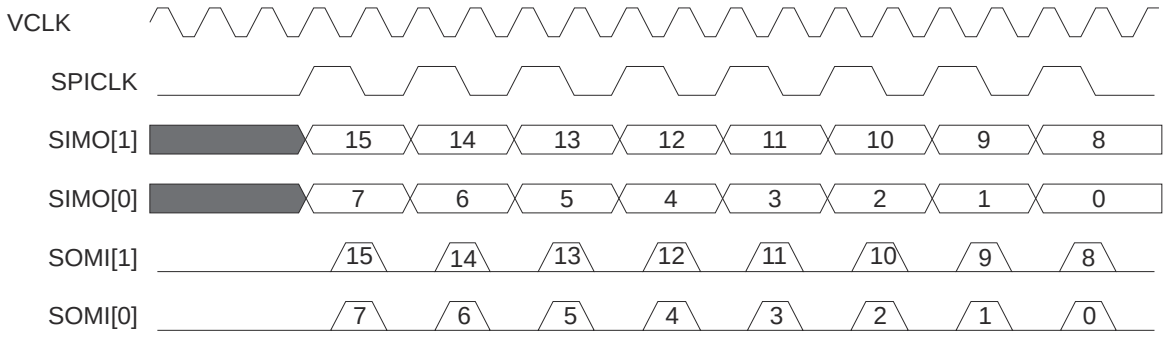

Figure 13-17. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)

13.2.15.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left (SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 13-18 shows the clock/data diagram of the four-data line mode. Figure 13-19, shows the timing diagram for four-data line mode.

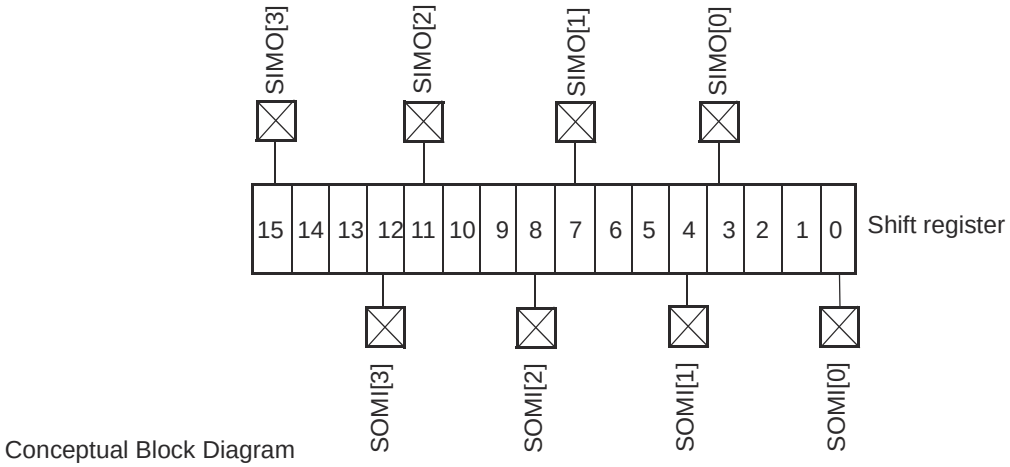

Figure 13-18. 4-Data Line Mode (Phase 0, Polarity 0)

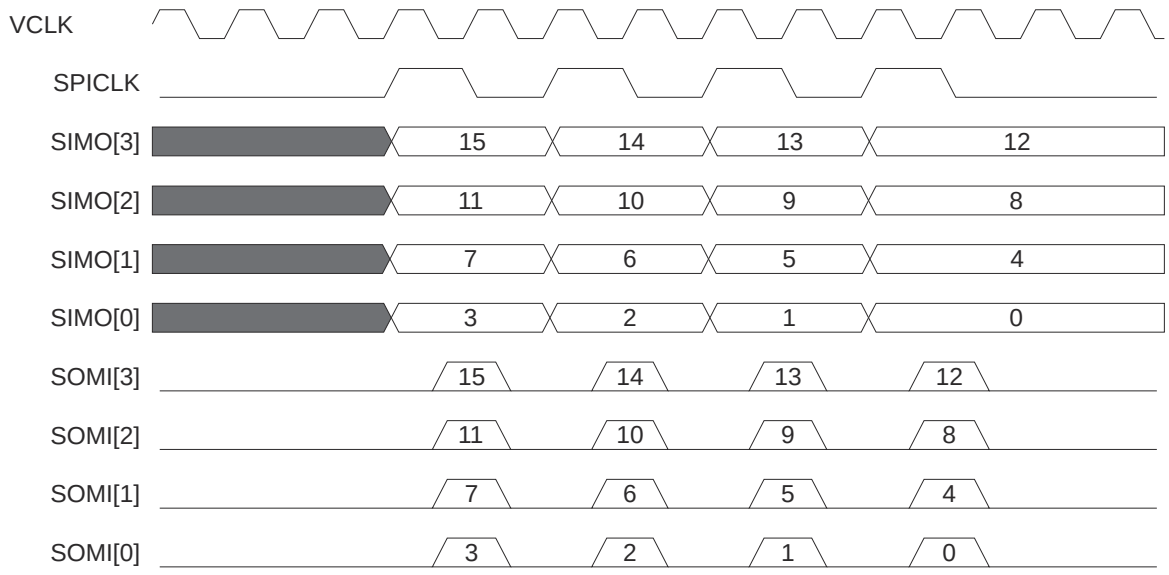

Figure 13-19. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

13.2.15.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (controller mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins PICO[7], PICO[6], PICO[5], PICO[4], PICO[3], PICO[2], PICO[1], and PICO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins POCI[7], POCI[6], POCI[5], POCI[4], POCI[3], POCI[2], POCI[1], and POCI[0] (or vice versa in peripheral mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on PICO[7], PICO[6], PICO[5], PICO[4], PICO[3], PICO[2], PICO[1], and PICO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on POCI[8], POCI[7], POCI[6],POCI[5], POCI[4], POCI[3], POCI[2], POCI[1], and POCI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 13-20 shows the clock/data diagram of the 8-data line mode. Figure 13-21 shows the pin timings for 8-data line mode.

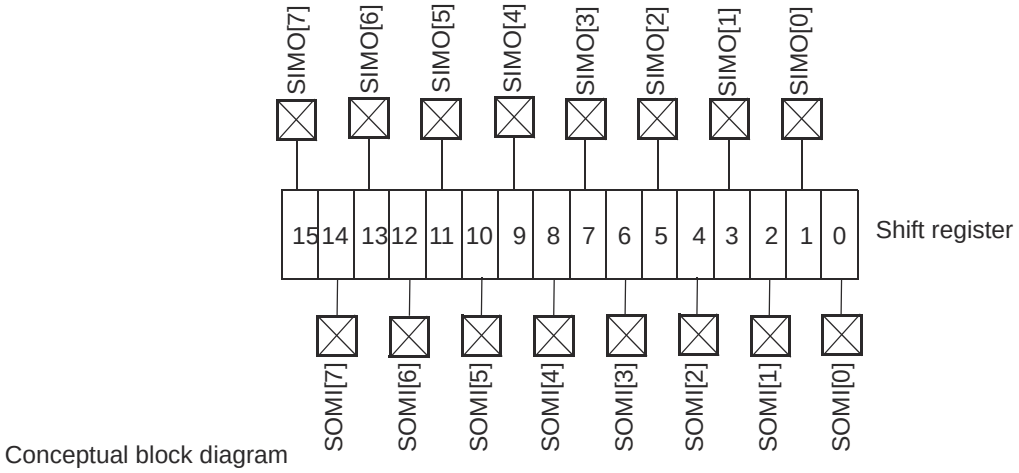

Figure 13-20. 8-data Line Mode (Phase 0, Polarity 0)

Note

Parity Support

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

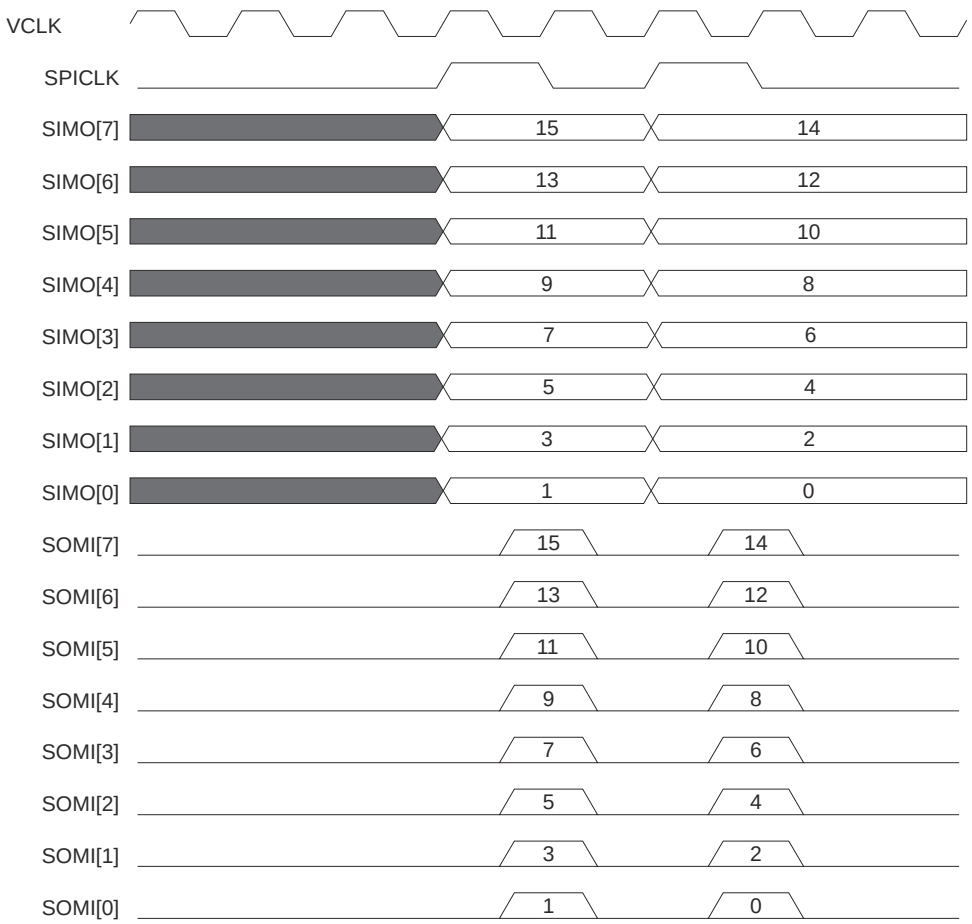

Figure 13-21. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

Note

Modulo Count Parallel Mode is not supported in this device.

13.2.16 Continuous Self-Test (Controller/Peripheral)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

Note

The compare is made from the output pin using its input buffer.

13.2.17 Half Duplex Mode

SPI by protocol is Full Duplex in nature, which means simultaneous TX and RX operations happen on two separate data pins, SIMO and SOMI. However, it is possible to use SPI/MibSPI to do the TX-only operation (ignoring the RX data) and the RX-only operation (using dummy TX data and ignoring the TX pin). But this requires that both SOMI and SIMO lines are bonded out in a chip to be able to support both TX-only or RX-only features.

13.2.17.1 Half Duplex Mode in Master

The Half Duplex Mode gives an additional flexibility to use the SIMO pin, which is normally used as a TX pin in Master mode, to work like an RX pin while the HDUPLEX_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Master mode, the SIMO pin acts as an RX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

13.2.17.2 Half Duplex Mode in Slave

In Half Duplex Slave mode, the SIMO pin, which is normally an RX pin, acts as a TX pin while the HDUPLEX_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Slave mode, the SIMO pin acts as a TX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

13.3 Test Features

13.3.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally feedback to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

Note

This mode cannot be changed during transmission.

13.3.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 13-22 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See Section 13.9.44 for details of the register field controlling these features.

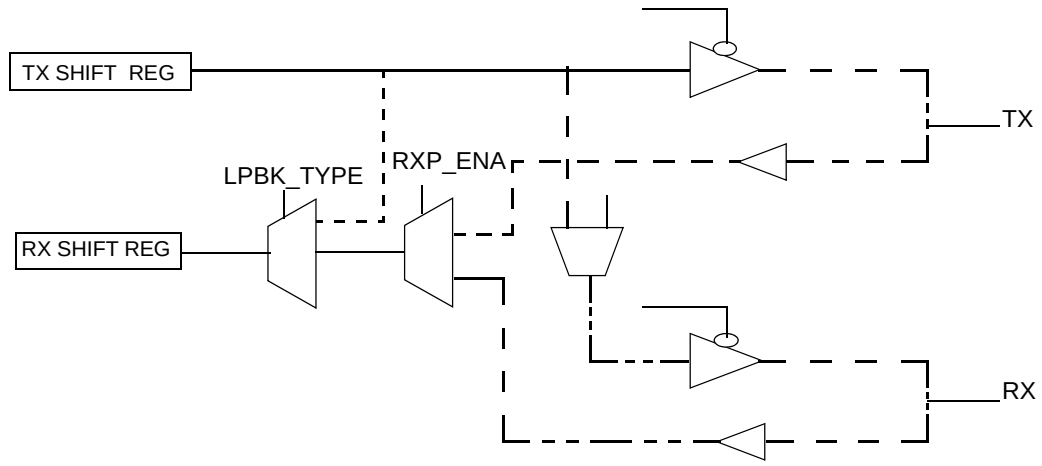
In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.

In Input/Output loopback test modes, if the module is in master mode, the $\overline{ENA}$ signal is also generated by internal logic so that an external interface is not required.

Note

Usage Guideline for Input/Output Loopback

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.



This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

Figure 13-22. I/O Paths during I/O Loopback Modes

13.3.2.1 Input/Output Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving $\overline{\text{SPICS}}$ to 0. The actual number of chip selects can be programmed to have any or all of the $\overline{\text{SPICS}}$ pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

13.4 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPCx control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode

13.5 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

Note

Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

13.6 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

Note

Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive. A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

13.6.1 Interrupts in Multi-Buffer Mode

In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

Figure 13-23 illustrates the TG interrupts.

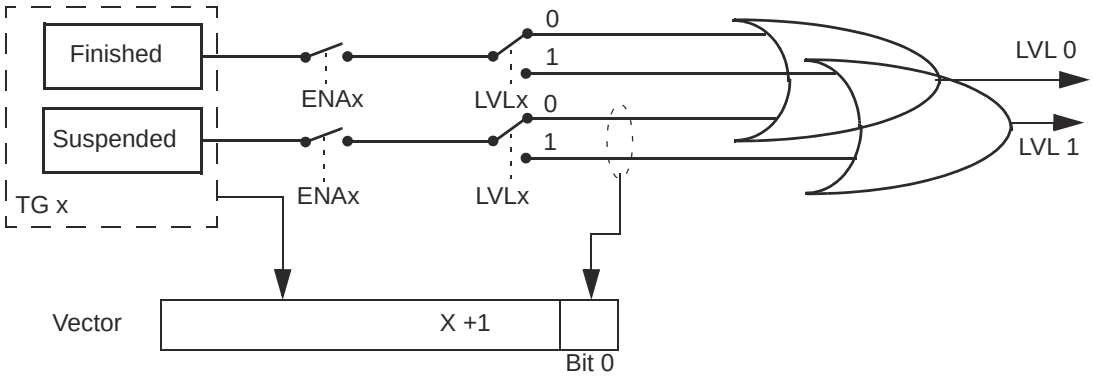


Figure 13-23. TG Interrupt Structure

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

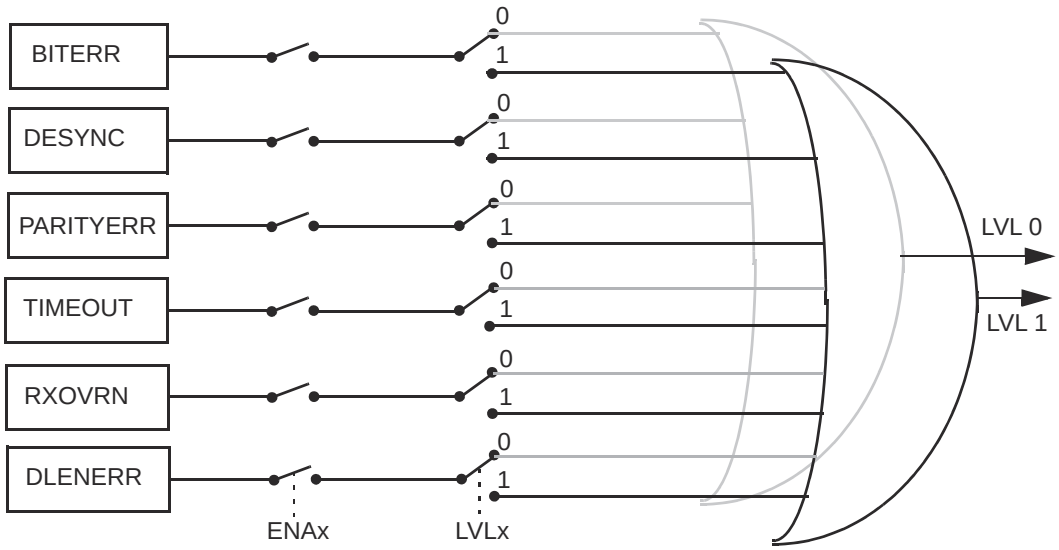

Figure 13-24. SPIFLG Interrupt Structure

Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

13.7 DMA Interface

In order to reduce CPU overhead in handling SPI message traffic on a character-by-character basis, SPI can use the DMA controller to transfer the data. The DMA request enable bit (DMA REQ EN) controls the assertion of requests to the DMA controller module. When a character is being transmitted or received, the SPI will signal the DMA via the DMA request signals, TX_DMA_REQ and RX_DMA_REQ. The DMA controller will then perform the required data transfer.

For efficient behavior during DMA operations, the transmitter empty and receive-buffer full interrupts can be disabled. For specific DMA features, see the DMA controller specification.

The SPI generates a request on the TX_DMA_REQ line each time the TX data is copied to the TX shift register either from the TXBUF or from peripheral data bus (when TXBUF is empty).

The first TX_DMA_REQ pulse is generated when either of the following is true:

- DMAREQEN (SPIINT0[16]) is set to 1 while SPIEN (SPIGCR1[24]) is already 1.
- SPIEN (SPIGCR1[24]) is set to 1 while DMAREQEN (SPIINT0[16]) is already 1.

The SPI generates a request on the RX_DMA_REQ line each time the received data is copied to the SPIBUF.

13.7.1 DMA in Multi-Buffer Mode

The MibSPI provides sophisticated programmable DMA control logic that completely eliminates the necessity of CPU intervention for data transfers, once programmed. When the multi-buffer mode is used, the DMA enable bit in the SPIINT0 register is ignored. DMA source or destination should be only the multi-buffer RAM and not SPIDAT0 / SPIDAT1 or SPIBUF register as in case of compatibility mode DMA.

The MibSPI offers up to eight DMA channels (for SEND and RECEIVE). All of the DMA channels are programmable individually and can be hooked to any buffer. The MibSPI provides up to 16 DMA request lines, and DMA requests from any channel can be programmed to be routed through any of these 16 lines. A DMA transfer can trigger both transmit and receive.

Each DMA channel has the capability to transfer a block of up to 32 data words without interruption using only one buffer of the array by configuring the DMAxCTRL register. Using the DMAxCOUNT and DMACTNTLEN register, up to 65535 (64K) words of data can be transferred without any interruption using just one buffer of the array. This enables the transfer of memory blocks from or into an external SPI memory.

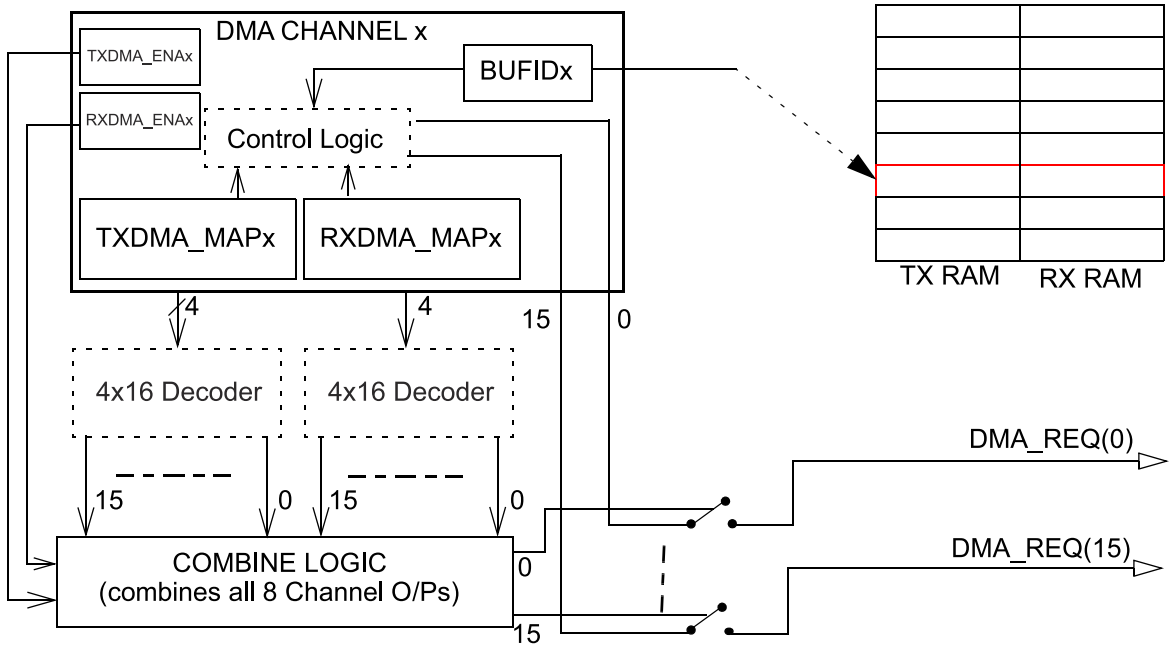

Figure 13-25. DMA Channel and Request Line (Logical) Structure in Multi-buffer Mode

13.8 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multi-buffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

13.8.1 Compatibility (SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, SPICLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIENA}}$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the chip select to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register (0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIEN bit to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- You must wait for TXFULL to reset or TXINT before writing next data to SPIDAT1 register.
- You must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

13.8.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA bit to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, SPICLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIENA}}$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers × Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIEN bit to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register, the 16 bit control fields in every TXRAM buffer in the TG have to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the data to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event, the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- You can poll Transfer Group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

13.9 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system.

Note

TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

Figure 13-26. SPI Global Control Register 0 (SPIGCR0) [offset = 00]

31	16
Reserved	
R-0	

15	1	0
Reserved		nRESET
R-0		R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 13-8. SPI Global Control Register 0 (SPIGCR0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	nRESET		This is the local reset control for the module. This bit needs to be set to 1 before any operation on SPI / MibSPI can be done. Only after setting this bit to 1, the Auto Initialization of Multi-buffer RAM starts. Clearing this bit to 0 will result in all of the control and status register values to return to their default values..
		0	SPI is in the reset state.
		1	SPI is out of the reset state.

13.9.2 SPI Global Control Register 1 (SPIGCR1)

Figure 13-27. SPI Global Control Register 1 (SPIGCR1) [offset = 04h]

Table 13-9. SPI Global Control Register 1 (SPIGCR1) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SPIEN		SPI enable. This bit enables SPI transfers. This bit must be set to 1 after all other SPI configuration bits have been written. When the SPIEN bit is 0 or cleared to 0, the following SPI registers get forced to their default states: • Both TX and RX shift registers • The TXDATA fields of the SPI Transmit Data Register 0 (SPIDAT0) and the SPI Transmit Data Register 1 (SPIDAT1) • All the fields of the SPI Flag Register (SPIFLG) • Contents of SPIBUF and the internal RXBUF registers
		0	The SPI is not activated for transfers.
		1	Activates SPI.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	LOOPBACK		Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO[7:0] pins are internally connected to the SPISOMI[7:0] pins (transmit data is looped back as receive data). GIO mode for these pins is not supported in loopback mode. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI[7:0] remains in the high-impedance state. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result. **Note: This loopback mode can only be used in master mode. Master mode must be selected before setting LOOPBACK. When this mode is selected, the CLKMOD bit should be set to 1, meaning that SPICLK is internally generated.**
		0	Internal loop-back test mode is disabled.
		1	Internal loop-back test mode is enabled.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	POWERDOWN		When active, the SPI state machine enters a power-down state.
		0	The SPI is in active mode.
		1	The SPI is in power-down mode.
7-2	Reserved	0	Reads return 0. Writes have no effect.

Table 13-9. SPI Global Control Register 1 (SPIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
1	CLKMOD		Clock mode. This bit selects either an internal or external clock source. This bit also determines the I/O direction of the $\overline{\text{SPIENA}}$ and $\overline{\text{SPICS}}$ pins in functional mode.
		0	Clock is external. • $\overline{\text{SPIENA}}$ is an output. • $\overline{\text{SPICS}}$ are inputs.
		1	Clock is internally-generated. • $\overline{\text{SPIENA}}$ is an input. • $\overline{\text{SPICS}}$ are outputs.
0	MASTER		SPISIMO/SPISOMI pin direction determination. Sets the direction of the SPISIMO and SPISOMI pins. **Note: For master-mode operation of the SPI, MASTER bit should be set to 1 and CLKMOD bit can be set either 1 or 0. The master-mode SPI can run on an external clock on SPICLK.** **For slave mode operation, both the MASTER and CLKMOD bits should be cleared to 0. Any other combinations may result in unpredictable behavior of the SPI. In slave mode. SPICLK will not be generated internally in slave mode.**
		0	SPISIMO[7:0] pins are inputs, SPISOMI[7:0] pins are outputs.
		1	SPISOMI[7:0] pins are inputs, SPISIMO[7:0] pins are outputs.

13.9.3 SPI Interrupt Register (SPIINT0)

Figure 13-28. SPI Interrupt Register (SPIINT0) [offset = 08h]

31							25	24

R-0	R/W-0	R-0	R/W-0	R/W-0	R/W-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-10. SPI Interrupt Register (SPIINT0) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	ENABLEHIGHZ		$\overline{\text{SPIENA}}$ pin high-impedance enable. When active, the $\overline{\text{SPIENA}}$ pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to high-impedance when not driving a low signal. If inactive, then the pin will output both a high and a low signal.
		0	$\overline{\text{SPIENA}}$ pin is pulled high when not active.
		1	$\overline{\text{SPIENA}}$ pin remains high-impedance when not active.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	DMAREQEN		DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to 1.
		0	DMA is not used.
		1	DMA requests will be generated.
			Note: A DMA request will be generated on the TX DMA REQ line each time a word is copied to the shift register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes.
			Note: A DMA request will be generated on the RX DMA REQ line each time a word is copied to the SPIBUF register either from RXBUF or directly from the shift register.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	TXINTENA		Causes an interrupt to be generated every time data is written to the shift register, so that the next word can be written to TXBUF. Setting this bit will generate an interrupt if the TXINTFLG bit (SPI Flag Register (SPIFLG)[9]) is set to 1.
		0	No interrupt will be generated upon TXINTFLG being set to 1.
		1	An interrupt will be generated upon TXINTFLG being set to 1.
			The transmitter empty interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.
			Note: An interrupt request will be generated as soon as this bit is set to 1. By default it will be generated on the INT0 line. The SPILVL register can be programmed to change the interrupt line.
8	RXINTENA		Causes an interrupt to be generated when the RXINTFLAG bit (SPI Flag Register (SPIFLG)[8]) is set by hardware.
		0	Interrupt will not be generated.
		1	Interrupt will be generated.
			The receiver full interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTENA		Overrun interrupt enable.
		0	Overrun interrupt will not be generated.
		1	Overrun interrupt will be generated.
5	Reserved	0	Reads return 0. Writes have no effect.
4	BITERRENA		Enables interrupt on bit error.
		0	No interrupt asserted upon bit error.
		1	Enables interrupt on bit error.
3	DESYNCENA		Enables interrupt on desynchronized slave. DESYNCENA is used in master mode only.
		0	No interrupt asserted upon desynchronization error.
		1	An interrupt is asserted on desynchronization of the slave (DESYNC = 1).
2	PARERRENA		Enables interrupt-on-parity-error.
		0	No interrupt asserted on parity error.
		1	An interrupt is asserted on a parity error.

Table 13-10. SPI Interrupt Register (SPIINT0) Field Descriptions (continued)

Bit	Field	Value	Description
1	TIMEOUTENA		Enables interrupt on ENA signal time-out.
		0	No interrupt asserted upon ENA signal time-out.
		1	An interrupt is asserted on a time-out of the ENA signal.
0	DLENERRENA		Data length error interrupt enable. A data length error occurs under the following conditions. **Master:** When $\overline{\text{SPIENA}}$ is used, if the $\overline{\text{SPIENA}}$ pin from the slave is deasserted before the master has completed its transfer, the data length error is set. That is, if the character length counter has not overflowed while $\overline{\text{SPIENA}}$ deassertion is detected, then it means that the slave has neither received full data from the master nor has it transmitted complete data. **Slave:** When $\overline{\text{SPICS}}$ pins are used, if the incoming valid $\overline{\text{SPICS}}$ pin is deactivated before the character length counter overflows, then the data length error is set.
		0	No interrupt is generated upon data length error.
		1	An interrupt is asserted when a data-length error occurs.

13.9.4 SPI Interrupt Level Register (SPILVL)

		1	Receive overrun interrupt is mapped to interrupt line INT1.
5	Reserved	0	Reads return 0. Writes have no effect.
4	BITERRLVL		Bit error interrupt level.
		0	Bit error interrupt is mapped to interrupt line INT0.
		1	Bit error interrupt is mapped to interrupt line INT1.
3	DESYNCLVL		Desynchronized slave interrupt level. (master mode only).
		0	An interrupt caused by desynchronization of the slave is mapped to interrupt line INT0.
		1	An interrupt caused by desynchronization of the slave is mapped to interrupt line INT1.
2	PARERRLVL		Parity error interrupt level.
		0	A parity error interrupt is mapped to interrupt line INT0.
		1	A parity error interrupt is mapped to interrupt line INT1.
1	TIMEOUTLVL		$\overline{\text{SPIENA}}$ pin time-out interrupt level.
		0	An interrupt on a time-out of the ENA signal (TIMEOUT = 1) is mapped to interrupt line INT0.
		1	An interrupt on a time-out of the ENA signal (TIMEOUT = 1) is mapped to interrupt line INT1.

Table 13-11. SPI Interrupt Level Register (SPILVL) Field Descriptions (continued)

Bit	Field	Value	Description
0	DLENERRLVL		Data length error interrupt level (line) select.
		0	An interrupt on data length error is mapped to interrupt line INT0.
		1	An interrupt on data length error is mapped to interrupt line INT1.

13.9.5 SPI Flag Register (SPIFLG)

Software must check all flag bits when reading this register.

Figure 13-30. SPI Flag Register (SPIFLG) [offset = 10h]

31	25	24	23	16
Reserved		BUFINIT ACTIVE	Reserved	
R-0		R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 13-12. SPI Flag Register (SPIFLG) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	BUFINITACTIVE		Indicates the status of multi-buffer initialization process. Software can poll for this bit to determine if it can proceed with the register configuration of multi-buffer mode registers or buffer handling. **Note: If the SPIFLG register is read while the multi-buffer RAM is being initialized, the BUFINITACTIVE bit will be read as 1. If SPIFLG is read after the internal automatic buffer initialization is complete, this bit will be read as 0. This bit will show a value of 1 as long as the nRESET bit is 0, but does not really indicate that buffer initialization is underway. Buffer initialization starts only when the nRESET bit is set to 1.**
		0	Multi-buffer RAM initialization is complete.
		1	Multi-buffer RAM is still being initialized. Do not attempt to write to either multi-buffer RAM or any multi-buffer mode registers.
23-10	Reserved	0	Reads return 0. Writes have no effect.
9	TXINTFLG		Transmitter-empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new word can be written to it. This flag is set when a word is copied to the shift register either directly from SPIDAT0/SPIDAT1 or from the TXBUF register. This bit is cleared by one of following methods: • Writing a new data to either SPIDAT0 or SPIDAT1 • Writing a 0 to SPIEN (SPIGCR1[24])
		0	Transmit buffer is now full. No interrupt pending for transmitter empty.
		1	Transmit buffer is empty. An interrupt is pending to fill the transmitter.

Table 13-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
8	RXINTFLG		Receiver-full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. This bit is cleared under the following methods: • Reading the SPIBUF register • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive buffer full interrupt • Writing a 1 to this bit • Writing a 0 to SPIEN (SPIGCR1[24]) • System reset During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.
		0	No new received data pending. Receive buffer is empty.
		1	A newly received data is ready to be read. Receive buffer is full.
			Note: Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. In this way, one can ignore a received word. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTFLG		Receiver overrun flag. The SPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI will generate an interrupt request if this bit is set and the RXOVRN INTEN bit (SPIINT0.6) is set high. This bit is cleared under the following conditions in compatibility mode of MibSPI: • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive-buffer-overrun interrupt • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself • Writing a 0 to SPIEN • Reading the data field of the SPIBUF register **Note: Reading the SPIBUF register does not clear this RXOVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.** **Note: There is a special condition under which the RXOVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another reception is underway, if any errors (TIMEOUT, BITERR, and DLEN_ERR) occur, then RXOVR in RXBUF and RXOVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a receive overrun.** In multi-buffer mode of MibSPI, this bit is cleared under the following conditions: • Reading the RXOVRN_BUF_ADDR register • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself In multi-buffer mode, if RXOVRNINTFLG is set, then the address of the buffer which experienced the overrun is available in RXOVRN_BUF_ADDR.
		0	Overrun condition did not occur.
		1	Overrun condition has occurred.
5	Reserved	0	Reads return 0. Writes have no effect.

Table 13-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
4	BITERRFLG		Mismatch of internal transmit data and transmitted data. This flag can be cleared by one of the following methods. • Write a 1 to this bit • Clear the SPIEN bit to 0
		0	No bit error occurred.
